AppDynamics APM Platform Documentation 21.6

AppDynamics Essentials

Welcome to the AppDynamics Application Performance Management (APM) Platform. Our documentation set introduces you to the AppDynamics APM Platform. AppDynamics helps you understand and optimize your business performance, ranging from software to infrastructure to business journeys.

We detail common concepts and procedures across all product modules, including APM, Application Analytics, End User Monitoring, and more. We also cover the Controller UI, which is the browser-based console that you use to understand, configure, and troubleshoot your application environment.

To report issues with the documentation, email the AppDynamics Docs Team at docs@appdynamics.com.

This page describes the AppDynamics Application Performance Management (APM) Platform.

AppDynamics APM Platform Overview

The AppDynamics APM Platform enables management and monitoring of your application delivery ecosystem, ranging from mobile/browser client network requests to backend databases/servers and more.

AppDynamics APM offers a global view across your application landscape and allows you to quickly navigate through the distributed application into the call graphs/exception reports generated on individual hosts.

Application Performance Monitoring

At the tier level, AppDynamics provides a view of the runtime operation of your code via an AppDynamics App Server Agent. The agent detects calls to a service entry point at the tier and follows the execution path for the call through the call stack. It sends data about usage metrics, code exceptions, error conditions, and exit calls to backend systems to the Controller, either a SaaS or on-premises:

To get started with application monitoring, see Install App Server Agents.

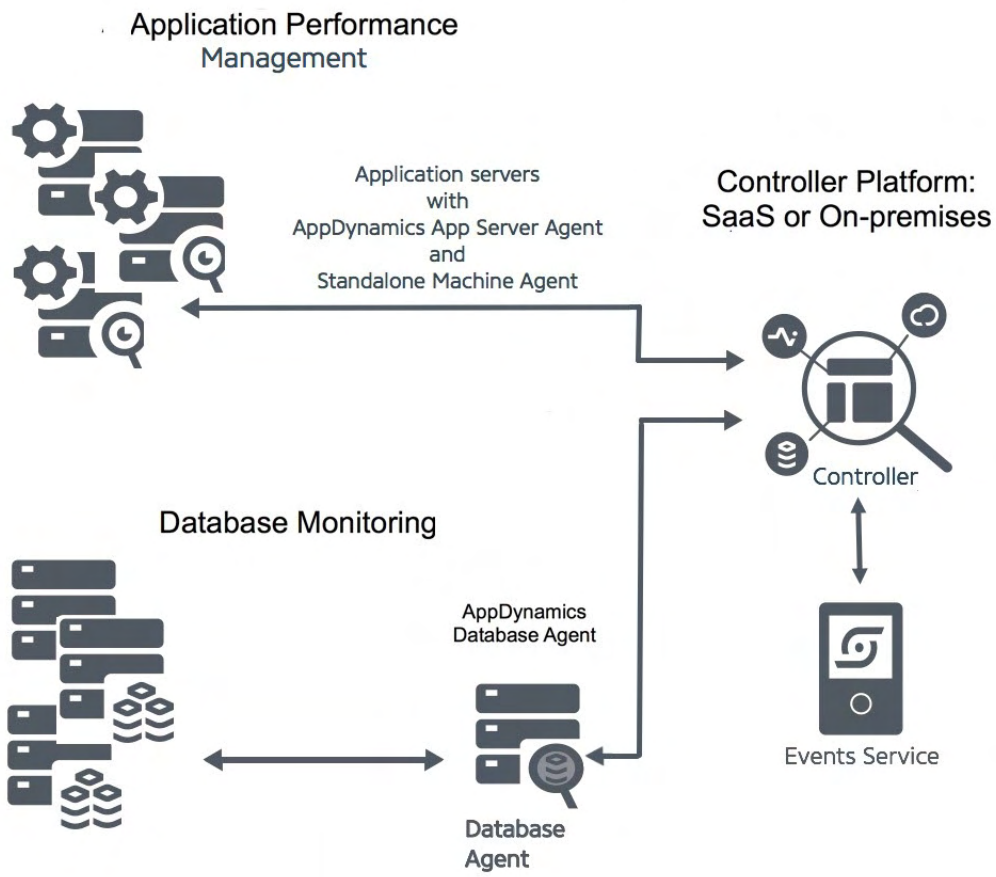
Most application environments contain more than one application server. They may contain distributed, interconnected servers and processes that participate in fulfilling a given user request. In this context, AppDynamics tracks transactions across distributed, heterogeneous services.

Infrastructure Visibility with Database Visibility

For greater visibility into your application delivery environment, you can add AppDynamics Database Visibility to the deployment.

App Agents provide information about calls to backend databases, including errors and call counts. The Database Visibility module extends your visibility into the workings of the database server itself by providing you with information about query execution and performance with an agent-less profile.

AppDynamics Server Visibility contributes to your view of the data center by adding valuable information on the performance of the machines and networks in your environment.



In this deployment, the Database Agent collects information from the database servers and sends it to the Controller, which persists some of that information in the Events Service. Database Analytics features may use the Events Service, the document storage component of the platform that AppDynamics has optimized for searching and storing high volumes of information.

End User Monitoring for Client Experience

While server-side monitoring provides insight into the end user's experience with application performance and suggests performance improvements to the server, end-user monitoring extends those insights from the initial client request to the client device response. AppDynamics End User Monitoring allows you to collect the information about where your requests are coming from, what devices/channels your users are using, and your code performance once deployed on your users' devices. Additionally, AppDynamics provides you with the visibility you need to investigate mobile crashes by displaying stack traces and other contextual data at the time of the crash and tying that to the Business Transaction data from the server.

Business iQ and Analytics for Business Impact

How does the overall performance of your application environment affect your business? Business iQ, powered by AppDynamics Analytics, helps you understand how the performance of your application environment and end-user applications ties to the business data of the transactions. It lets you sort, order, and understand the data that composes the Business Transactions. It also enables you to drill into the varieties of log data that your environment generates. See Using Analytics Data for information about how to install and use Analytics.

Using Metrics

A metric is a particular class of measurement, state, or event in the monitored environment. Many defaults relate to the overall performance of the application or business transaction, such as request load, average response time, or error rate. Others describe the state of the server infrastructure, such as percentage CPU busy or percentage of memory used.

Agents register the metrics they detect with the Controller. They then report measurements or occurrences of the metrics (depending on the nature of the metric) to the Controller at regular intervals. You can view metrics using the Metric Browser in the Controller UI.

Information points are a particular type of metric that enables you to report on how your business (as opposed to your application) is performing. For example, you could set up an information point to total the revenue from the purchase on your website of a specific product or set of products. You can also use information points to report on how your code is performing, for example, how many times a specific method is called and how long it is taking to execute.

You can create extensions that use the machine agent to report custom metrics that you define. These metrics are base-lined and reported in the Controller, just like the built-in AppDynamics metrics.

As an alternative to using the Controller UI, you can access metrics programmatically with the AppDynamics APIs.

Baselines and Thresholds

The AppDynamics Platform uses both self-learned baselines and configurable thresholds to help identify application issues. A complex distributed application has a large number of performance metrics, and each metric is important in one or more contexts. In such environments, it is difficult to:

- Determine the values or ranges that are normal for a particular metric
- Set meaningful thresholds on which to base and receive relevant alerts
- Determine what is a 'normal' metric when the application or infrastructure undergoes change

For these reasons, anomaly detection based on dynamic baselines or thresholds is one of the essential features of the AppDynamics platform.

The AppDynamics platform automatically calculates dynamic baselines for your metrics, defining what is 'normal' for each metric based on actual usage. Then the platform uses these baselines to identify subsequent metrics whose values fall out of this normal range. Static thresholds that are tedious to set up and, in rapidly changing application environments, error-prone, are no longer needed.

You can create health rules with conditions that use baselines, allowing you to trigger alerts or kick off other types of remedial actions when performance problems are occurring or may be about to happen. See Alert and Respond and Health Rules and Dynamic Baselines for more detail.

AppDynamics thresholds help you to maintain service level agreements (SLAs) and ensure optimum performance levels for your system by detecting slow, very slow and stalled transactions. Thresholds provide a flexible way to associate the right business context with a slow request to isolate the root cause. See Transaction Thresholds.

Health Rules, Policies, and Actions

AppDynamics uses dynamic baselining to establish what is considered normal behavior for your application automatically. Then you can set up health rules against those standard baselines (or use other health indicators) to track non-optimal conditions. A health rule might be, for example, to create a critical event when the average response time is four times slower than the baseline.

Policies that allow you to connect such problematic events (such as the health rule critical event) with actions that can trigger alerts/remedial behavior addresses the system's issues long before your users will be affected.

AppDynamics supplies default health rules. You can customize the default health rules and create new rules specific to your environment.

The out-of-the-box health rules test business transaction performance as follows:

- Business Transaction response time is much higher than normal
  Defines a critical condition as the combination of an average response time higher than the default baseline by three standard deviations and a load greater than 50 calls per minute. This rule defines a warning condition as the combination of an average response time higher than the default baseline by two standard deviations and a load greater than 100 calls per minute.
- Business Transaction error rate is much higher than normal
  Defines a critical condition as the combination of an error rate greater than the default baseline by three standard deviations and an error rate higher than ten errors per minute and a load greater than 50 calls per minute. This rule defines a warning condition as the combination of an error rate greater than the default baseline by two standard deviations and an error rate greater than five errors per minute and a load greater than 50 calls per minute.

For more information, see Alert and Respond.

Infrastructure Monitoring

While Business Transaction performance is typically the focus of a performance monitoring strategy, monitoring infrastructure performance can add insight into underlying factors about performance. AppDynamics can alert you of the problem at the Business Transaction and infrastructure level.

AppDynamics provides preconfigured application infrastructure metrics and default health rules to enable you to discover and correct infrastructure problems. You can also configure additional persistent metrics to implement a monitoring strategy specific to your business needs and application architecture.

In addition to health rules, you can view infrastructure metrics in the Metric Browser. In this context, the Correlation Analysis and Scalability Analysis graphs are useful to understand how infrastructure metrics can correlate or relate to Business Transaction performance.

Integrating and Extending AppDynamics

AppDynamics provides many ways for you to extend AppDynamics Pro and integrate metrics with other systems. The AppDynamics Exchange contains many extensions that you can download and if you cannot find what you need, you can develop your own.

AppDynamics Extensions are available in the following categories:

- Monitoring Extensions add metrics to the existing set of metrics that AppDynamics agents collect and report to the Controller. These can include metrics that you obtain from other monitoring systems. They can also include metrics that your system extracts from services that are not instrumented by AppDynamics, such as databases, LDAP servers, web servers, or C programs. To write specific monitoring extensions, see Extensions and Custom Metrics.
- Alerting Extensions let you integrate AppDynamics with external alerting or ticketing system and create custom notification actions. To learn how to write specialized custom notification see Build a Custom Action. Also, see Email Templates and HTTP Request Actions and Templates.
- Performance testing extensions consist of performance-testing extensions.
- Built-in integration extensions are bundled into the AppDynamics platform and only need to be enabled or configured. These include:
    - Integrate AppDynamics with Splunk
    - Integrate AppDynamics with DB CAM

To create custom extensions and integration components for AppDynamics, see AppDynamics APIs.

Deployment Planning Guide

This page describes best-practice deployment planning guidelines for the AppDynamics Application Performance Management (APM) Platform.

It is important to plan your AppDynamics deployment according to your environment. Taking time to outline your system strategy provides a smooth process flow. Use these guidelines to start working with AppDynamics.

Once you install the necessary agents, AppDynamics automatically builds an environment of your applications.

The Controller:

- Monitors your application workload.
- Uses machine learning to determine what is normal for your environment.
- Applies sensible defaults for detecting abnormal activity and application errors.

You can start using AppDynamics dashboards, flow maps, and monitoring tools in the Controller UI immediately without instrumentation and configuration. Later, you can customize the configuration for your specific environment and requirements.

> AppDynamics does not support user or agent requests that originate from any URL other than the Controller URL provided at registration or otherwise edited by AppDynamics. Due to system security improvements, requests from custom URLs will be rejected and may cause a service disruption.
>
> If a custom URL is required, we recommend that you create a forward proxy in your environment.

Network Port Requirements

To deploy AppDynamics, you may need to modify network components configuration to permit access to ports used in the AppDynamics deployment. These pages describe the specific ports used in the system:

- For SaaS: SaaS Domains and IP Ranges.
- For the on-premises platform: Port Settings.

Getting Started

Related pages:

- Release Upgrade Checklist
- Ask the AppDynamics Community
- Help and Support
- AppDynamics University

This page provides an overview of the options for creating an account and how to get started using your AppDynamics online Account Management Portal and Application Performance Monitoring (APM) Platform.

As part of your deployment, the AppDynamics APM provides:

- A Controller for data collection.
- A Controller UI for data analysis.
- An online Account Management Portal to manage your account, users, subscriptions, license usage, and role functionality.

As a best practice, we recommend that you follow the Deployment Planning Guide and create a deployment plan for your environment and needs.

Create an Account

Your first step to working with AppDynamics is to create an account. AppDynamics provides both SaaS and on-premises deployment options to fit your data security needs, application workflow, and business environment. Reviewing the Deployment Planning Guide will help you determine if the type of data you will be monitoring requires a SaaS, on-premises, or hybrid solution.

AppDynamics has implemented restrictions and will not enter into any negotiation with, or seek to solicit any interest from, any third party in relation to the sale or use of the AppDynamics products or software or any part thereof, whether directly or indirectly with any country or region subject to an embargo including but not limited to Cuba, Iran, North Korea, Sudan, Syria, and Crimea.

Choose an account type and deployment option.

Gain System Access

After you complete registration and create an account, you will have access to your Account Management Portal for online account administration and, if you opted for a SaaS deployment, access to your hosted Controller platform.

Online Account Administration

The Account Management Portal provides a secure online area where administrators can:

- Manage the company account and personal profile separately.
- See a company overview of account details, subscription information, open support tickets, and active resource projects.
- Launch available AppDynamics Controllers.
- Add, edit, and delete users, as well as administer user groups, subscriptions, and roles.
- Download agents, platforms, and product updates.

Your account type will determine the services available in the Account Management Portal. See Account Overview.

1. Access the Welcome email sent to the address you used to create your account.
2. Click **Get Started**.
3. Follow the instructions.

Controller UI

An AppDynamics Controller is fundamental to every deployment. Integrated agents collect data from a monitored environment and send it to the Controller. The Controller UI is where you can view, understand, and analyze that data.

How you access your controller depends on your deployment. Your account will include a subscription license for each product you purchased during registration. A subscription can have one or more modules and you can have multiple subscriptions, each one having a distinct lifecycle.

Choose your deployment configuration.

Install Application Agents

An AppDynamics deployment consists of multiple application agents to monitor different components in your environment. For installing most types of agents, you can use the **Getting Started Wizard** in the Controller UI.

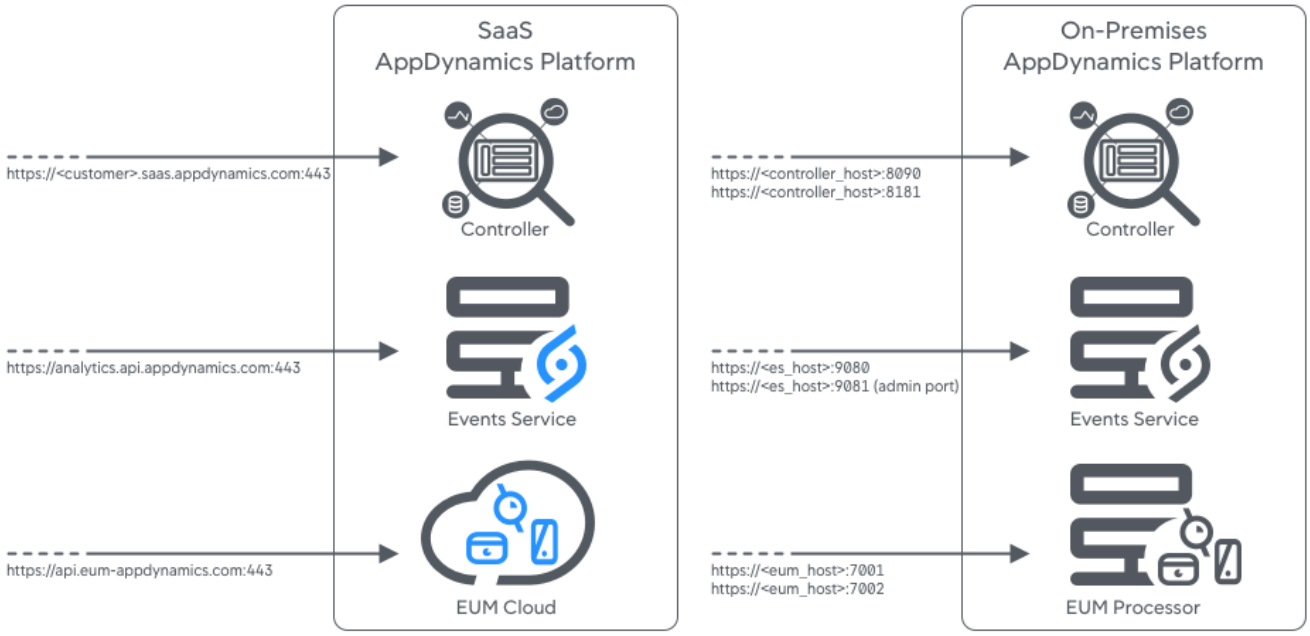
Log in to the Controller UI and navigate to **Applications** > **Create an Application** > **Create an Application using the Getting Started Wizard**. Follow the instructions in the Wizard to install agents in your application environment.

Review the Install App Server Agents documentation for instructions and guidance. AppDynamics provides an Agent Installer that simplifies the agent installation process and streamlines the deployment of the Java and Machine Agents.

Connect Agents to the Controller

The **Getting Started Wizard** automatically configures settings for connecting agents to the Controller. If you manually download agents, you must configure the Controller connections. You may need to adjust the configuration of network components, such as firewalls or proxies, to permit traffic from the agent to the Controller. The connection is unidirectional, meaning that agents always initiate the connections to the Controller.

The following graphic shows the connections agents use to reach the platform. The actual connections vary between on-premises and SaaS platforms.



Continue with Your AppDynamics Deployment

Best Practice

We recommend that you follow the Deployment Planning Guide and create a deployment plan for your environment and needs.

You can start using AppDynamics immediately without instrumentation and configuration. Then, at a later date, you can optimize the configuration to make the best use of AppDynamics for your environment and requirements. After you install agents and restart your applications, AppDynamics automatically builds an environment of your application. You can see the model in the dashboards and flow maps view of the Controller UI. The Controller monitors your application workload, uses machine learning to determine what is normal for your environment, and applies sensible defaults for detecting abnormal activity and application errors.

The timeline in the Deployment Planning Guide outlines a typical start to your AppDynamics journey.

Tutorials

Learn more about specific areas of the AppDynamics APM Platform by following one of these tutorials:

- Platform Installation Quick Start (on-premises installations only)
- Install the Java Agent
- Install the .NET Agent for Windows
- Manual Injection of the JavaScript Agent
- Instrument iOS Applications
- Instrument Android Applications
- Instrument Xamarin Applications
- Instrument Applications with the IoT C/C++ SDK

- Instrument Applications with the IoT Java SDK

Download AppDynamics Software

This page describes AppDynamics Download options and provides links to instructions for installing the appropriate AppDynamics software.

> ⚠ AppDynamics has implemented restrictions and will not enter into any negotiation with, or seek to solicit any interest from, any third party in relation to the sale or use of the AppDynamics products or software or any part thereof, whether directly or indirectly with any country or region subject to an embargo including but not limited to Cuba, Iran, North Korea, Sudan, Syria, and Crimea.

AppDynamics Download Options

You can download the AppDynamics software packages available for your account based on your subscription type from AppDynamics Downloads.

- If you purchased a SaaS subscription exclusively, you have access to Agents downloads.
- If you purchased an on-premises or dual subscription, you also have access to Platforms downloads.

Once you have an AppDynamics account:

1. Log in to accounts.appdynamics.com.
2. Select **Downloads.**
3. Follow the instructions on the Account Management Portal Downloads page to:
    - Download agents
    - Download the on-premises platform
    - Automate downloads with cURL
    - Validate package downloads

Deployment Options

This page describes the available AppDynamics deployment options.

> Before you select your AppDynamics deployment option, review the Deployment Planning Guide.

AppDynamics provides two deployment options:

- A cloud-based Software as a Service (SaaS) solution hosted and maintained by AppDynamics.
- An on-premises deployment where you install and manage all the platform components internally.

Every deployment includes:

- A Controller for data collection.
- A Controller UI to view, understand, and analyze the data.
- An online Account Management Portal to manage your account, users, subscriptions, license usage, and role functionality.

Every deployment requires:

- Installed agents to collect data from a monitored environment.
- Network port requirements.
- Health rules to monitor system parameters.
- Validated users.

> AppDynamics does not support user or agent requests that originate from any URL other than the Controller URL provided at registration or otherwise edited by AppDynamics. Due to system security improvements, requests from custom URLs will be rejected and may cause a service disruption.
>
> If a custom URL is required, we recommend that you create a forward proxy in your environment.

Controller UI Overview

This page describes the features of the AppDynamics Controller UI, which is the primary interface you use to monitor, troubleshoot, and analyze your entire application landscape from backend infrastructure/servers to the end user's application.

Supported Web Browsers

The AppDynamics Controller UI is an HTML5-based browser application that works best with the latest version of any modern browser.

The Controller UI has been tested with and supports the latest versions of these browsers:

- Firefox
- Google Chrome
- Internet Explorer
- Microsoft Edge
- Safari

Certain types of ad blockers can interfere with features in the Controller UI. We recommend disabling AdBlock when using the Controller UI to avoid issues loading particular screens.

General Navigation

As you start using the Controller UI to configure AppDynamics and monitor your environment, it is helpful to familiarize yourself with the most commonly-used elements of the Controller UI that are frequently referenced in this documentation.

The precise controls and features that appear in the UI depend on your user account permissions and product modules licenses. For example, you would have additional controls in application monitoring screens with an Analytics license. See Create and Manage Custom Roles.

The UI elements include:

- Top Navigation Bar: Use to navigate the major product areas and cross-product feature areas, such as **Alert & Respond** and **Dashboard & Reports**.
- Settings Menu: Access pages where you can customize the UI environment, view your account information, or, if permitted by your user role, configure administration settings such as adding user accounts, configuring authentication, and more.
- Time Range Menu: Controls what metric data AppDynamics represents in the UI in the selected time range. See the following section for more information on the time range menu.
- Left Navigation Menu: Use to access sections specific to the product area.

Administration Settings Overview

Create and administer users for a specific tenant in the Tenant UI. Use the Account Management Portal for global user account management and tenant license subscription assignments.

You must be logged in as a user with the Account Owner role to see Administration options.

The Administration UI allows you to set up several user options specific to the Tenant. If you have multiple SaaS accounts or a multi-tenant on-premises Controller, each account must be configured individually for each Tenant.

- **Users**—Create and administer users.
- **API Clients**—Create and use an API Client to provide secure access to the Tenant through REST API calls. See API Clients.
- **Groups**—Create and use groups to assign and manage roles for users collectively.
- **Roles**—Create and use roles to define user privileges in the Tenant UI.
- **Authentication Provider**—Configure external authentication settings for the tenant user. See LDAP Authentication or SAML Authentication.
- **Integrations**—Set up extension integrations to supplement AppDynamics capabilities. See Integration Modules.

Time Ranges and Settings

The Time Range menu is available throughout the UI. Your selection determines the range of data displayed in the UI, except in the case of pages such as the Scalability Analysis, where other time contexts apply. When you choose a new time range, it remains the active range as you navigate to other pages.

You can select a preconfigured **Standard** time range or enter a **Custom** one. Custom time ranges can be set to terminate in the past, making them useful for analyzing trends over time.

To create a custom time range:

1. Click **Custom** and select  .
2. Enter your start and end date and time selections in the dialogues.
3. Click  .
4. Enter a **Name** and optional **Description**.

5. Optionally, select **Share with Everyone** to share the range with all the other users of the Controller.

To manage a custom time range:

1. Click 
.
2. Select a time range.
3. Select to **Add**, **Edit**, **Delete**, or **Copy**.
4. Click **Apply** to save the changes and update the session.

To enable 5 and 15-minute auto-refresh for a flow map:

1. Select **Standard**.
2. Select 5 or 15 minutes to display the **Auto-refresh** checkbox at the bottom of the list.
3. Select the **Auto-refresh** checkbox to automatically refresh the data.

Share Views With Other Users

Troubleshooting an application issue is often a collaborative effort that may involve multiple users. You can share a particular view of the UI with a shareable URL that retains the time range currently active in the UI. Time ranges that are relative to the current time, such as "last 15 minutes," are represented as fixed time ranges in the URL.

To share a view:

1. Select **Settings** > **Copy a link to this screen to the clipboard**.
2. Paste and share the URL where desired.

AppDynamics Mobile App

The AppDynamics mobile application lets you monitor the health and performance of your applications on iOS and Android devices. Alerts on a device can notify you of application issues within minutes of their occurrence.

Supported Environments and Versions

Using the AppDynamics Mobile App requires:

- Controller >= 4.0
- For the device, these operating systems:
  - iPhone, iPad, or other iOS-based devices: iOS >= 8.0
  - Android: Android >= 4.0 (Ice Cream Sandwich)

You can view custom dashboards on the mobile app, but node- or tier-level custom dashboards are not available for viewing in the Mobile App.

Get the Mobile App

To get the AppDynamics Mobile App:

- For an iPhone, search for AppDynamics in the Apple App Store or directly from the AppDynamics Mobile App page.
- For an Android device, search for AppDynamics in Google Play.

After installation, set up your account from within the application using one of two methods:

- By scanning a QR code in the Controller UI with your mobile device.
- By configuring the Controller account settings manually.

Configure your Account by Scanning a QR Code

To set up your account by QR code:

1. In the Controller UI, click Settings and select **My Preferences**.
2. Click the **View Configuration Code** link.
3. Follow the instructions to set up your device with the QR code.

Configure your Account Manually

1. Launch the mobile app.
2. Click **Add New Account** if you have already set up an account and want to set up another.
3. Enter your Controller URL and click **Next**.
   If you are using SSL, make sure to check the **Use HTTPS** box.
4. Enter your account name based on your Controller type:
   - For a SaaS or multi-tenant Controller, enter the account name provided when you signed up for a SaaS Controller or the account name added by your administrator for a multi-tenant Controller.
   - For a single-tenant on-premises Controller, use the built-in default account, `Customer1`.
5. Click **Next**.
6. Enter your username and password and click **Next**.

Enable Notifications on the Device

You can set Mobile App to notify you when selected applications have an event or anomaly, which can help you to significantly reduce downtime. When notifications are enabled, you will receive them even when Mobile App is closed.

> An on-premises Controller is not configured to generate push notifications by default. To enable push notifications, follow the instructions to Enable Notifications from an On-Premises Controller.

If notifications fail, AppDynamics captures the error in the Controller log.

Enable Notifications from an On-Premises Controller

To generate notifications, the on-premises Controller must be able to reach this domain address: `https://mobile-push.api.appdynamics.com/`

You may need to configure your network or intervening firewalls to enable the Controller to access the domain address. Once you have ensured that the Controller can access the AppDynamics site:

1. Open the Administration Console.
2. From the **Controller Settings** page, locate and set the `push.notification.service.enabled` flag to `'true'.` The change takes effect immediately.

AppDynamics Support

Have a question about using AppDynamics or running into a problem? This page describes the necessary steps to help resolve your questions.

Search the Documentation

You can search for information from:

- The **Search** field on the right side of the top menu bar to initiate a search of the entire documentation set.
- The **Search** field in the left navigation pane to search within the current version only.

You can search across AppDynamics information resources, including the Community, Knowledge Base, Support, and more in the AppDynamics Support Center.

Ask the Community

If you have questions about using AppDynamics, ask the AppDynamics Community.

Contact Support

If you need further assistance, contact your Account Representative or Technical Support.

For Technical Support, click the Help tab while logged in with your AppDynamics account in the AppDynamics Support Center.

When requesting support, attach relevant logs for your issue(s):

- For log files from the Controller, see Platform Log Files.
- For the heap, histogram, and thread dumps, see Controller Dump Files.

AppDynamics has implemented restrictions and will not enter into any negotiation with, or seek to solicit any interest from, any third party in relation to the sale or use of the AppDynamics products or software or any part thereof, whether directly or indirectly with any country or region subject to an embargo including but not limited to Cuba, Iran, North Korea, Sudan, Syria, and Crimea.

Account Management

AppDynamics provides account administration through an Account Management Portal as well as the Tenant UI.

Use the Account Management Portal to:

- Manage user accounts globally.
- Assign Tenant license subscriptions to users.
- Inactivate or edit accounts for all AppDynamics components simultaneously.

Use the Tenant Administration UI to:

- Create and add users to the Tenant.
- Set role and group security specific to the Tenant.

User Account Management

- Account Management Portal
- User Management
- Tenant User Management
- Create and Manage Custom Roles

Permissions Management

- Application Permissions
- Transaction Analytics Permissions
- Custom Dashboard Permissions
- Database Permissions
- End-User Monitoring Permissions
- Server Visibility Permissions

Licensing and External Authentication

- License Management
- License Usage
- LDAP Authentication
- SAML Authentication

- Community

Account Management Portal

This page describes the secure online Account Management Portal for managing AppDynamics accounts.

The Account Management Portal is a secure online means for account administrators to manage users and account resources and for non-administrators to edit their profile, review account details, and access AppDynamics Downloads.

> ⚠ Use the Accounts Management Portal to fully inactivate or edit an account for all AppDynamics components and Tenants simultaneously. User account management through a Tenant UI affects permissions for that Tenant only.

Account Management Portal Overview

These secure administrative functions are available:

- Overview—This page displays selective account summary information and tools based on your user type and role permissions.
- License Usage—Illustrates product usage by subscription.
- User Management—Allows user account administrative functions.
- Resources—Displays a list of the services, support, and education resources available for your account.
- Downloads—Allows downloading AppDynamics software packages that are available for your account.

These non-administrative functions are available to all users from any active tab:

- Profile—Provides user profile options.
- University—Provides training information and learning tools.
- Community—Provides a discussion forum, knowledge base, and user community.

Upon login, the Account Management Portal opens to the Overview tab. Review the User Permissions Matrix for your user role options.

Edit Profile Settings

To edit different aspects of your profile, click your name and select **Profile**. Once finished with your edits, click your name and select **Account** to return to the Overview page.

To edit your user details:

1. Select the Personal Summary tab and click **Edit**.
2. Update your **User Details** accordingly.
3. Click **Submit**.

To update your password:

1. Select the Password tab and click **Edit**.
2. Enter your current password.
3. Create a new password according to the listed rules and click **Save**.

To customize your notifications:

1. Select the Notifications tab.
2. Select the **Notify me when a new version of AppDynamics is released** checkbox to receive emails of updates, hotfixes, and new releases.
3. Select the checkbox in the **License Notifications** column heading to receive emails whenever a license detail changes for all associated licenses.
4. Alternatively, you may select individual license names to reduce notifications.

   > ⓘ The primary contact must receive license notifications. Click **Email Us** in Account Details to contact your AppDynamics support representative to change the primary contact.

5. Select the checkbox in the **Maintenance Notifications** column to receive emails when planned maintenance or outages occur.
6. Alternatively, you may select individual license names to reduce notifications.
7. Click **Save**.

Access AppDynamics Downloads

You can download AppDynamics software packages available for your account based on your subscription type from AppDynamics Downloads. See Download AppDynamics Software.

Select **Downloads** and use the links at the top of the page for quick access to:

- Our **Getting Started** page for instructions to begin working with your subscription.
- License **Entitlements**.
- Our **Updates** page for product announcements.

- Instructions for the **Automation** of new version downloads.

Access AppDynamics University

AppDynamics University provides subscription-based educational tools to help you configure, manage, and monitor applications on your platform. Several subscription options and private training options are available.

The University offers self-paced and instructor-led courses, private training, and certification programs based on your subscription. Administrators have the option to delegate subscriptions to other users within their organization to bolster team competency.

Access AppDynamics Community

AppDynamics Community is an online customer platform where you can join discussion forums, access our knowledge base, and post questions to others in the user community.

1. Click your name and select **Community**.
2. Sign in using your AppDynamics credentials.

> Your profile menu on this site mirrors your Account Management Portal profile menu.

3. Review the **Latest Solutions** to current issues.
4. Review the **Latest Discussions** among users concerning current technologies.
5. Review the **Latest Posts from the Knowledge Base**.
6. Click **Start a Discussion** to ask questions of community users and experts.
7. Click **Access Knowledge Base** to search for answers to known issues.
8. Click a contributor's name to send them a message and view their profile.

Review Account Details

The Account Details section displays:

- The information provided when your company registered with AppDynamics.
- AppDynamics customer support contacts assigned to your account.
- An online tool for scheduling a 1:1 meeting with a technical consultant.
- An automated email link directed to your assigned customer success and/or sales representative.

Access a Controller

AppDynamics refers to a Controller license as a subscription. You can view your subscriptions and launch an available Controller in several ways.

Users must be assigned a license to a Controller for access. When a non-administrative user is assigned a Controller license, they become a Licens

To find a specific subscription, you can:

- Click a table heading to sort and include other Controllers in the summary view.
- Begin typing in the **Search subscription** field. The list will automatically display only those Controllers with the characters you enter.
- Click **View all subscriptions** to display the full list.

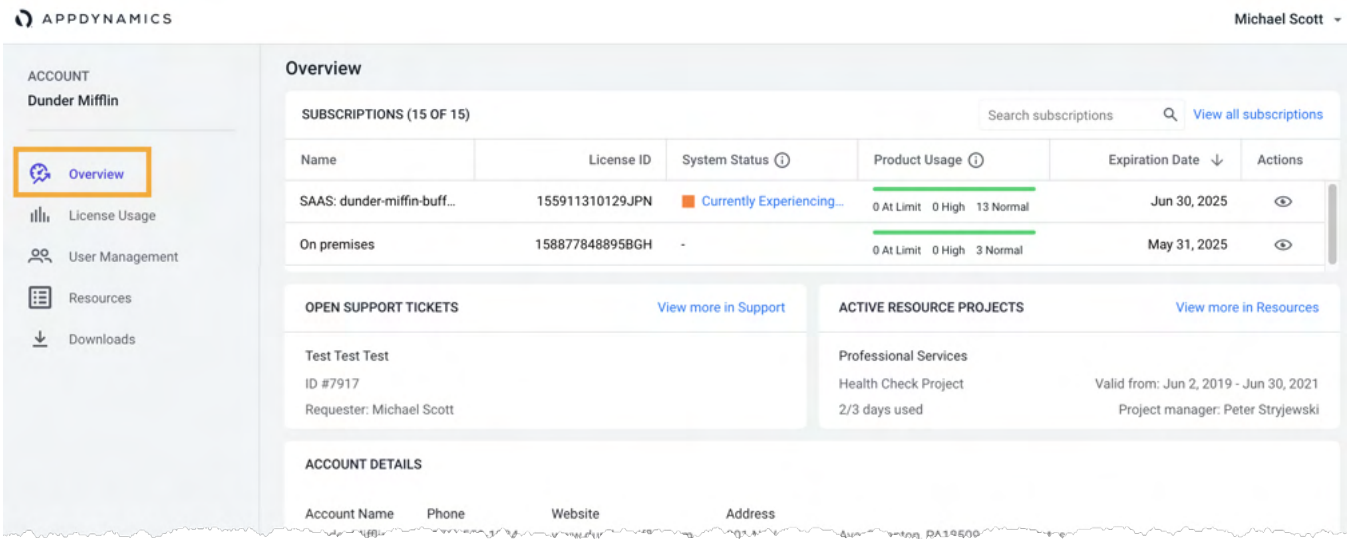
To launch a Controller, you can:

- Click a subscription name.
- Click your name and select a Controller from the list, or select **View All**.
- Click your name, select **Profile > Personal Summary**, and select a Controller URL from the **Assigned Subscriptions** list.

Overview

This page describes how to navigate the **Overview** page in the Account Management Portal.

The **Overview** page is role-based and presents a summary of account components according to the user's permissions. Components are presented in grouped panes, each with a link to access the full detail page.



Select a user type to see the options that display for that role.

License Usage

This page describes how to navigate the License Usage page in the Accounts Management Portal.

You must be a Company Administrator or License Administrator to access the License Usage page.

Navigation Overview

The License Usage page provides summary usage data for Tenant license subscriptions associated with your License Administrator account. The usage shown is based on the current or most recent usage period, including the data captured and aggregated from the previous day.

You can filter or arrange your subscription list in several ways:

- Click **View options** to select which Tenant type and subscription status to display.
- Begin typing in the autocomplete **Search** field to filter the list as you type.
- Click a column heading to sort the subscription list according to that column.
- Click (where available) to display information about the corresponding data.

Access Product Usage Detail

AppDynamics captures usage data in five-minute intervals and aggregates it into larger intervals.

There are several product families and each family has several products associated with it. Usage is measured differently for each product. See License Entitlements and Restrictions.

1. Select a **Subscription** to access usage detail for each product associated with the license, including:
   - Each **Product** associated with the selected license.
   - The **Product Family** category.
   - The current **Usage** of the product for a specified usage period.
   - The **Usage Period** in which the product can consume licenses before the usage limit is reset.
     The usage periods that display for each product in the detailed usage graphs are set as default time ranges for efficient page loading.
2. Select a **Product** to view:
   - License information
   - Maximum and average usage metrics
   - Total (cumulative) license usage for that product and product family.
     For the APM Any Language product, select or deselect the language to view or remove usage data in the graph.
3. Click one of the in the page navigation bread crumbs to select a different license or different product within that license.
   Only products associated with the chosen license display in the dropdown menu.
4. Click to adjust the time range, date, and time zone of data you want to view in the graph.
   You can select daily, hourly, weekly, or monthly data granularity.
   If you select a timeframe that is too long for the aggregation, certain granularity options are not visible.
   For example, if you choose a timeframe longer than one month, hourly granularity is disabled.
5. Click to toggle the data display as either a line graph or bar graph.
   For certain products under the Application Performance Management (APM) and End User Monitoring product families, there are two graph types. You can specify the data granularity and timeframe you want to view in both types.
   - A cumulative plot line graph for a given usage cycle.
   - A non-cumulative plot line graph for the same usage cycle.
6. Review the Max and Average usage metrics.
7. Hover over a data point on the graph to view granular metrics.
   If you set a timeframe to less than one month, hourly metrics are available. If you select a timeframe greater than or equal to one month, daily data is available.
8. When available, select **View usage as *<metered units>*** or **View usage as license units**.
   - Viewing usage by metered units displays consumption according to how many events you consumed due to license unit consumption. Each product has distinct meters on which licenses are consumed.
   - Viewing usage by license units displays how many licenses have been consumed.
     The usage data is the same; the x-axis displays the same usage on both graphs, while the y-axis reflects the view you select.

License units are always rounded up to the next highest integer because that is the minimum amount you would need for your monitoring.

Max and Average Usage Metrics

You can view these metrics reporting for the timeframe you chose in the date range selector UI:

- **Max**—The maximum usage of all agents aggregated over the chosen timeframe. It is the maximum of all the data points on the graph.
- **Monthly Average**—The average of all agents reporting usage during the chosen timeframe. It is the average of all the average values on the graph.

For certain products under the Application Performance Management (APM) and Infrastructure Visibility product families, the x-axis is the time frame and the y-axis is the number of license units used.

The APM Any Language product includes multiple agents. Click a corresponding checkbox in the filter bar to drill down into usage for a particular agent (such as Java). Agents that do not report data during the selected timeframe are grayed out in the filter.

You can interpret metrics according to the view:

- When you select all agent types, the maximums and the averages of all agents display reporting usage over the selected timeframe.
- When you select one agent type, the results are restricted to that agent's data.
- When you select a subset of agent types, the maximums and averages are calculated based only on the agents chosen.

Cumulative Plot Graph

This graph displays the total number of units used during either a usage cycle or a timeframe you choose.

- The y-axis represents the units used, either as the metered unit or as license units.
- The x-axis represents the time period.

For a given usage period, the **Usage Overview** will show usage as a percentage to display the quantity consumption against your total allocation.

Real User Monitoring, Synthetics Monitoring, and Transaction Analytics are a few examples of products that are metered on a cumulative basis.

Non-Cumulative Plot Graph

This graph plots the usage for a product's given usage cycle or timeframe and the granularity you select. You can use the non-cumulative graph to help you determine how much of the product is being used at a regular cadence and whether there are spikes in usage.

Hover over a data point on the graph to view granular metrics. You can also view an average data point for the set granularity.

APM Any Language, Server Visibility, and Databases Monitoring are a few examples of products that are metered on a non-cumulative basis.

User Management

This page provides details for managing users in the Account Management Portal.

Company Administrators and License Administrators can manage user access for AppDynamics accounts through the Account Management Portal. User accounts on a Tenant are managed based on the authentication options selected in the Tenant UI. See Tenant User Management.

> ⚠ Editing an account through the Accounts Management Portal affects the user for all AppDynamics components and some Tenant rights simultaneously. User account management through a Tenant UI affects permissions for that Tenant only.

Every AppDynamics user that has been registered in the User Management UI has subscription-based access to AppDynamics University and unlimited access to AppDynamics Community for FAQs and user forums.

User Management Overview

The Accounts Management Portal allows administrators to create and globally manage user accounts through the **User Management** UI. SaaS customers use the same login for both the Tenant and the Account Management Portal. However, on-premises users may have a different login credential for their Controller and the Account Management Portal.

User Status Options

A user account can have one of three possible statuses:

- Active—User has a valid email account that authenticates with the AppDynamics Identity Provider (IDP).
- Pending—User has been created in the system, but the email is not yet validated by the user.
- Inactive—User is restricted from accessing AppDynamics components.

When a user is created through the Account Management Portal, they receive a time-sensitive email prompting them to activate their account by creating a username and password. A user is in Pending status until they have completed the activation.

Once complete, the user can:

- Access to protected pages on appdynamics.com and accounts.appdynamics.com
- Submit Support tickets.
- Download AppDynamics Software with cURL
- Manage their own profile.

However, they do not have access to a Tenant until or unless an administrator adds the user account to a Tenant.

UI Options

The User Management UI displays users in a grid with sortable columns and an autocomplete search feature.

Editing functions become visible based on the selected user's status.

Option User Status	Add	View	Edit	Deactivate	Activate	Delete
Active	✓	✓	✓	✓	✗	✗
Pending	✓	✓	✓	✗	✗	✓
Inactive	✓	✓	✓	✗	✓	✓

User Security Role Options

There are four security roles available through **User Management** > **Edit**. This table explains the functionality and the User Permissions Matrix shows the specific permissions per role.

Role	Functionality
Company Admin	• Has the highest level of access. • Can view all licenses or Tenants the company owns.

License Admin	• Requires one user per Tenant to be designated as a Primary Contact with AppDynamics and is mandated to receive maintenance and licens • Can only view and administer licenses for a license to which they have been assigned. • Cannot administer a Tenant. • Can add or remove license admins on the same license (unless that admin is the Primary Contact).  To remove the Primary Contact from the role, you must open a Support request with AppDynamics and provide a new Primary Conta
Support	Provide managers with the ability to open and manage Support requests with AppDynamics.
Tenant User	• Is assigned to every user created on a Tenant. • Is the most basic user role. Specific permissions for this user are set at the Tenant level. See Tenant User Management and Create and Ma • Shows only once per user regardless of how many tenants they are associated with.

User Permissions Matrix

Roles / Permissions	Company Admin	License Admin	Support User	Tenant User (SaaS)	Company User
Add User	✓	✓	✗	✗	✗
Edit User Name	✓	✓	✗	✗	✗
Edit User Status	✓	✗	✗	✗	✗
Delete User	✓	✗	✗	✗	✗

Create and Manage a New User

Resources

This page describes how to navigate the Resources page in the Account Management Portal.

You must be a Company Administrator or License Administrator to access the License Usage page.

The Resources page provides a complete list of services and other components associated with your AppDynamics account. Resources can include:

- Professional Services
- Support
- Education
- Community

Click  (where available) for information about the corresponding resource.

Professional Services

You can use Professional Services to plan deployments, configurations, workstreams, and other technical projects.

The table automatically populates with these details when your AppDynamics account representative registers your account with the requested service:

- Resource name
- Number of days used/total number of days
- Entitlement effective dates
- Project manager

If you need additional services, click **Schedule a call with a consultant** or reach out to your AppDynamics account representatives provided on the Overview page in Account Details.

Support

You can use Support services to troubleshoot your account and technical issues. This section displays your current AppDynamics support agreements and their effective dates.

For additional support:

1. Click **Actions** .
2. Click **Visit Help and Support** for support options.
3. Click **View Support Requests** to review active and past support tickets.

Education

You can view your current Education benefits, including AppDynamics University subscription, Instructor Day(s), and exam vouchers. You can also assign users to Premium University subscription(s) if available. See AppDynamics University Registration and Subscriptions.

The Company Administrator or License Administrator must have access to the account that holds University subscriptions in order to view the vouchers associated with that account.

You may have to provide subscription details when you register for a course or class. These subscription details are available for your Education benefits:

- Standard, premium, enterprise, 12-user education, and exam voucher code(s)
- Number of seats purchased and consumed
- Number of exam attempts purchased and consumed
- Number of training units purchased and consumed
- Number of Instructor Days purchased and consumed
- Validity dates
- Expired vouchers and expired training units

To assign users to a University subscription:

1. Click **user seats activated**.
2. Click **Assign Users**.
3. Enter a valid email address.
   If the user email is not recognized, click **Go to User Management** to add the email address.
4. Click **Assign additional users** as necessary (up to the number of user seats available).
5. Click **Save**.

You can create an alias (friendly name) for your voucher code that relates to the course to make it easier to remember. To add or edit a voucher code or alias:

1. Click **Edit** .
2. Add the voucher code provided by AppDynamics or enter an alias.
3. Click **Submit**.

For additional support:

1. Click **Actions** .
2. Click **Visit University** for learning options.
3. Click **Contact University Team** to enter a message.
   An AppDynamics University Team member will contact you.
4. Click **Learn about subscriptions** for subscription options.

Community

You can use the AppDynamics Community to engage in user discussions and access Knowledge Base articles.

1. Click **Actions** .
2. Click **Visit Community** to view or browse the latest AppDynamics solutions and user discussions.
3. Click **Access Knowledge Base** to browse the latest How-To articles.

Downloads

This page describes AppDynamics Downloads.

AppDynamics Downloads is a central location to download Agents and the AppDynamics On-premises platform. The site provides download availability acc ording to your subscription type and permissions.

> ⚠ AppDynamics has implemented restrictions and will not enter into any negotiation with, or seek to solicit any interest from, any third party in relation to the sale or use of the AppDynamics products or software or any part thereof, whether directly or indirectly with any country or region subject to an embargo including but not limited to Cuba, Iran, North Korea, Sudan, Syria, and Crimea.

Navigation Overview

There are quick links provided to assist with management functions:

- **Getting Started**—provides instructions for creating an account, gaining system access, and so on.
- **Entitlements**—
- Our **Updates** page for product announcements
- Instructions for the **Automation** of new version downloads

Download Agents

AppDynamics agents monitor every line of code in your instrumented environment by using unique tags that are assigned to method calls and request headers. The agents capture performance activity and report to the Controller in real-time. Use the **Agents** download tab to access every available agent in each applicable version for three operating systems to match your environment.

Under Available Downloads, use the filter options or the **Search** field to find an agent.

Filters:

Each filter dropdown menu provides options that, when selected, automatically updates the list of available agents. If no agents display, edit your filter selections.

- **Type**—select one or more agents for download. The four most popular agents display at the top of the list with all additional agents listed alphabetically.
- **Version**—choose the latest agent version or one or more previous versions.
- **Operating System**—select one or more operating systems.
- **Compatible With Controller**—choose the latest Controller version or one or more previous versions.

Search Field:

1. Type the name and/or version of the desired agent in the **Search** field.
2. Press Enter on your keyboard to update the list of available agents for download.
3. If no agents display, there are none that match your search criteria. You may want to try the filter options.

Once you have a list of available agents:

1. Hover over **Checksums** in the **Description** column to view the MD5 and SHA256 hash functions for the component.
2. Click **View** for the agent to review the latest release notes.
3. Click **Download** to obtain the Agent.zip file.
4. Click **cURL** to generate code for cURL that includes a time-sensitive OAUTH access token.
5. Select **Copy to Clipboard** and paste the code in your server, VM, or docker container within an hour.

Download the On-Premises Platform

An on-premises AppDynamics Platform installation consists of several, separately installed, and configured components. These include the Enterprise Console, AppDynamics Cluster Manager, Synthetic Server, Events Service, and the optional EUM Server. Use the **Platforms** download tab to access each platform application in all available versions for three operating systems to build your environment.

Navigate to AppDynamics Downloads and select the **Platforms** tab. Use the filter options or the **Search** field to filter the list of available platform applications.

Filters:

Each filter dropdown menu provides options that, when selected, automatically updates the list of available agents. If no agents display, edit your filter selections.

- **Type**—select one or more agents for download. The four most popular agents display at the top of the list with all additional agents listed alphabetically.
- **Version**—choose the latest agent version or one or more previous versions.

- **Operating System**—select one or more operating systems.

Search Field:

1. Type the name and/or version of the desired component in the **Search** field.
2. Press Enter on your keyboard to update the list of available components for download.
3. If none display, there are none that match your search criteria. You may want to try the filter options.

Once you have a list of available agents:

1. Hover over **Checksums** in the **Description** column to view the MD5 and SHA256 hash functions for the agent.
2. Click **View** for the agent to review the latest release notes.
3. Click **Download** to obtain the software package file.
4. Click **cURL** to generate code for cURL that includes a time-sensitive OAUTH access token.
5. Select **Copy to Clipboard** and paste the code in your server, VM, or docker container within an hour.

Automate AppDynamics Software Downloads with cURL

When you download files, always copy or transfer the files in binary mode. If you want to transfer a file that you have downloaded on Windows to a Linux machine, use binary mode in your transfer program when you move the file to the destination Linux environment.

Where applicable, AppDynamics also publishes software for distribution on package manager repositories such as RPM, npm, pip, NuGet, and more. For products that are available via a package manager, you can find relevant instructions to retrieve and install the software in Install the Machine Agent.

The following steps demonstrate how to use cURL to get the latest version of an AppDynamics software download.

1. Retrieve an OAUTH token with the download scope:

   ```
   curl -X POST -d '{"username": "<username>","password": "<password>","scopes": ["download"]}' https://identity.msrv.saas.appdynamics.com/v2.0/oauth/token
   ```
2. View the latest version of each available product from https://download.appdynamics.com/download/downloadfilelatest. For example:

   ```
   curl https://download.appdynamics.com/download/downloadfilelatest/
   ```
3. Inspect the response (or parse via script) to find the `download_path` of the latest product version.
4. Download the binary by running the following command:

   Replace `access_token` with your OAUTH token from Step 1, and replace `url_to_file` with the `download_path` value from the response in Step 3.

   ```
   curl -L -O -H "Authorization: Bearer <access_token>" <url_to_file>
   ```

Validate Software Package Downloads

You can use checksum validation and a digital signature (for specific packages) to validate software downloaded from AppDynamics Downloads. This validation requires the machine on which you validate a package to include a TLS 1.2 implementation.

Checksum Validation

1. Navigate to AppDynamics Downloads.
2. Click **Checksums** beneath the software package description to display the MD5 and SHA256 checksums.
3. After your download completes, run a checksum tool and compare the results against the checksum information on the downloads page.

Digital Signatures

AppDynamics digitally signs the following packages using a certificate signed by a publicly known certificate authority:

- .NET Agent
- AppDynamics Controller for Windows MSI installer

AppDynamics digitally signs the following packages using a PGP key:

- Java Agent
- Standalone Machine Agent
- Standalone Machine Agent RPM package
- Python Agent pip package

The AppDynamics PGP public key is hosted on https://pgp.mit.edu under the User ID "help@appdynamics.com". For information about using a PGP signature to validate a software package, see Verify AppDynamics Software Downloads with PGP.

Tenant User Management

This page describes managing a user on a Tenant.

What is a Tenant?

An AppDynamics Controller can host one or more accounts, where each account represents one tenant on that Controller.

AppDynamics cloud-based Software as a Service (SaaS) deployment is a multi-tenant environment that allows you to access multiple tenants independently. On-premises deployments are single-tenancy by default, however, you can enable multi-tenancy if necessary. See Multi-Tenant On-Premises Accounts.

Whether you have a SaaS deployment or on-premises deployment, you can manage users through the Tenant UI. While both deployments provide an administrative UI, user functionality differs slightly. Once set up, you can add user accounts in the Tenant UI, allowing other users to access the UI and configure AppDynamics.

Role-Based Access Control (RBAC) Overview

AppDynamics uses Role-Based Access Control (RBAC) to set user permissions and privileges for only those functions necessary in defined job responsibilities. Each user account can have varying levels of access based on their role(s). See Create and Manage Custom Roles.

The tenant can authenticate users against local user accounts or external LDAP or SAML-based authentication providers. The user account for a SaaS Tenant user authenticates through the AppDynamics Identity Provider (IDP) in the Cloud rather than by an external authentication provider. See External Authentication Providers.

A group is a collection of users with a given set of assigned permissions that apply to the users in the group. Groups are used to manage roles for users collectively.

A role is a collection of permissions that define what actions a user can perform; RBAC. When a user is assigned a role, they inherit the specified permissions. A user's group membership and defined role remain constant for the duration of their login.

Permissions grant users the ability to perform an action on the platform. You can set permissions at a granular level to determine:

- Which business applications the user can monitor.
- What parts of the UI are visible.
- Types of configuration changes a user can make.

> AppDynamics University offers courses in Administrator functions.

Tenant User Management Overview

AppDynamics user credentials for both SaaS and on-premises deployments are managed according to the authentication options selected in **Settings** > **Administration** > **Authentication Provider**. There are three user authentication options:

Authentication Provider	User Type	Description
AppDynamics	Local User	⚠ Managing a Local User through the Tenant UI affects permissions for that tenant only. The user account retains Active status with existing permissions on other associated Tenants. Use the Account Management Portal to fully deactivate or edit an account for all AppDynamics components and Tenants simultaneously. • Users authenticate through AppDynamics IDP for SaaS deployment. • AppDynamics manages user account credentials. • User type can exist in parallel and access the system even when using SAML and LDAP authentication.
LDAP	LDAP User	• Users authenticate through your IDP. • You manage user account credentials through LDAP integration. • Non-LDAP users cannot access the system unless they have also been set up as a Local User.

SAML	SAML User	• Users authenticate through your IDP using the SAML 2.0 protocol. • You manage user account credentials through SAML integration. • Non SAML users cannot access the system unless they have also been set up as a Local User.

With a SaaS deployment, when you add a new local user through the Tenant UI, an email is sent to that user's valid address prompting them to create their own profile name and password. The user's email serves as their username. Only the account user can create their own password. Once completed, an account with the proper credentials is added to the tenant and authenticated through the AppDynamics IDP providing the user unified access to the Account Management Portal, University, Community, and role-specific functions on the Tenant UI.

With an on-premises deployment, when you add a new local user through the Tenant UI, an account with the proper credentials is created and stored on that tenant.

You can create and manage users, groups, roles, and permissions on the corresponding page through **Settings** > **Administration**.

- Create and Manage Tenant Users
- Create and Manage Groups
- Create and Manage Custom Roles

Create and Manage Tenant Users

This page explains how to create and administer users for a specific Tenant in the Tenant Administration UI.

Use the Account Management Portal for global user account management, Tenant license subscription assignments, and to fully inactivate or edit an account for all AppDynamics components simultaneously.

Use the Tenant Administration UI to create and manage user options specific to the Tenant. If you have multiple SaaS accounts or a multi-tenant on-premises Controller, you must configure each account individually for each Tenant. See Multi-Tenant On-Premises Accounts.

When creating a new user, AppDynamics recommends:

- Assigning at least one role for the new user. Although it is possible to assign a role after creation, the user has no functionality in the UI until you assign a role.
- For on-premises deployments, use only ASCII characters for usernames and passwords because of browser incompatibilities.

Create a New User

You must be logged in as a user with the Account Owner role to access Administration options and manage users. However, only the user has perm their password. Account owner roles and administrator roles cannot create or change user passwords for SaaS user accounts.

1. Navigate to **Settings** > **Administration** > **Users**.
2. Click **Create** and enter a unique **Name** and unique, valid **Email Address**.
3. **Add Roles** and **Groups** respectively and click **Save**.
   You can add or remove Roles and Groups any time after you save the new user account.

With a SaaS deployment, the new user instantly receives an email with a link to create their profile name and password. When finished, they are automatically redirected to their Tenant Home page with the permissions assigned at account creation. See Tenant User Management.

With an on-premises deployment, the new user is created and receives an email informing them that they have been added to the Tenant.

After creating a user, you can modify, delete, or duplicate the user account, or assign the user to a group or role. Use **View user details in Accounts** to view the new user in the Account Management Portal.

If the deleted user owns a custom dashboard, the dashboard and its associated shares and reports cease to function properly. See Dashboard Recovery.

Enforce Strong User Passwords (On-Premises Only)

Beginning with 21.2, AppDynamics requires new SaaS Local Users to comply with strong user password guidelines. Progressive use of this version will cause existing SaaS Local User accounts to require mandatory strong passwords. See Tenant User Management.

As an account administrator, you can require Local Users (those authenticated by AppDynamics) to use strong passwords.

Strong password requirements are not enforced by default, which allows a user to configure passwords of any length or complexity.

To require strong passwords:

1. Navigate to **Administration** > **Authentication Provider**.
2. Select **Password Requirements**.
3. Select **Require Strong Passwords**.

Enabling the requirement does not affect existing passwords. Existing weak passwords will continue to function after you enable strong passwords.

When enabled, passwords must:

1. Contain at least eight characters.
2. Contain both upper and lower case letters.
3. Contain at least one number.
4. Not be the username or user email.

Multi-Tenant On-Premises Accounts

This page describes how to create and manage accounts in a multi-tenant Controller. The tenant mode determines whether the Controller UI offers single or multiple environments. See Controller Deployment.

Switch from Single-Tenant to Multi-Tenant Mode

> ⚠ Switching from single-tenancy to multi-tenancy mode is supported. However, switching from multi-tenancy to single-tenancy is not. Take precautions to ensure multi-tenancy is the correct mode for your environment.

If multi-tenancy is enabled for an on-premises Controller, users must enter the account name in the **Account** field when logging in to the Controller UI.

1. Navigate to the Administration Console.
2. Locate the `multitenant.controller` setting.
3. Set the value to `true`.

Create Accounts in Multi-Tenant Mode

In multi-tenant mode, you can add accounts as follows:

1. Log in to the AppDynamics Administration Console as the AppDynamics root user.
2. Click **Account Settings** and then **Add**.
3. Define the licensing entitlements that apply to the account.
   Account-level license unit limits let you prevent a particular account from using more licensing units than it should. You can view the total license units available through **Settings** > **Admin** > **License**. See License Management.

   > ⓘ The overall license limits applicable at the Controller level are independent of any specific limits you apply at the account level.

   Agent-based Licensing: For example, if an account is set up with a Java Agent limit of 100, you can ensure that the new account never interferes with the license availability of another account by setting the **Java Units Provisioned** value for the account to a much smaller limit. However, if you set it to 100 and other accounts are also set to that amount, the first 100 agents that connect to the Controller would occupy those units, regardless of the accounts they report in to. Similarly, you can limit the lifespan of the account by setting an expiration date for the license.

   Infrastructure-based Licensing: For example, if an account is set up with an Infrastructure Monitoring limit of 100, you can ensure that the new account never interferes with the license availability of another account by setting the **Infrastructure Monitoring** value for the account to a much smaller limit. However, if you set it to 100 and other accounts are also set to that amount, the first servers with CPU cores totalling up to 100 would occupy those units, regardless of the accounts they report in to. Similarly, you can limit the lifespan of the account by setting an expiration date for the license.
4. When finished defining entitlements, click **Save**.

After enabling multi-tenant mode, users must specify the account they want to log into in the **Account** field in the Controller UI login screen. See:

- Java Agent Configuration Properties
- .NET Agent Configuration Properties
- Database Agent Configuration Properties
- Machine Agent Configuration Properties

Create and Manage Groups

This page explains how to create and manage user groups in AppDynamics.

A user can belong to one or more groups. Groups let you assign and manage roles for users collectively.

> If you use LDAP to authenticate all AppDynamics Tenant users, you do not need to create AppDynamics groups.

To create a new group:

1. Navigate to **Settings** > **Administration** > **Groups**.
2. Click **Create** and enter a unique **Name** and optional **Description**.
3. Add **Users** and **Roles** respectively and click **Save.**

After creating the group, you can assign users and roles by selecting the group and selecting the **Member** checkboxes for each user or role you want to associate.

Alternatively, navigate to **Roles** > (Select a Role) > **Users and Groups with this Role**.

Create and Manage Custom Roles

This page provides information and instructions for managing roles in AppDynamics.

A role is a collection of permissions that define what actions a user can perform within the AppDynamics-managed environment. You can use groups to manage roles collectively. A user or group can have more than one role but must have at least one defined role.

Administrators can grant user permissions at a granular level, including which business applications they can monitor, what parts of the UI are visible, and the types of configuration changes they can make.

Predefined Roles

The Tenant UI includes predefined roles for administrators and read-only users that you cannot change, however, you can create new custom roles.

Roles	Permissions
Account Owner	• Access to Administration, Agent, and Getting Started Wizard UIs. • Add or edit users, groups, roles, and the authentication provider. • Possesses most of the account-level permissions and is sometimes known as the account administrator. See Account Permissions. • Create War Rooms. • Configure alert, email, and HTTP request templates, emails, reports, Universal Agents, and licenses. • View licenses, business flows, reports, and Universal Agent.
Administrator	• View and modify components that change state, such as applications, business transactions, dashboards, and so on. • Create War Rooms, view business flows, and view and configure scheduled reports. • Cannot add or edit users, groups, or roles.
Analytics Administrator	• View and grant access to Analytics features, such as creating API keys, creating metrics, creating extracted fields, and granting access for viewing analytics data. • Controls which roles have access to specific applications or log source types. • The only role in charge of saved searches. Saved searches provide different data access levels to analytics users. See Analytics and Data Security and Transaction Analytics Permissions.
Applications and Dashboards Viewer	• View all applications and their dashboards. • Cannot edit dashboards (formerly known as the Read-Only User).
Dashboards Viewer	• View application dashboards. • Create custom dashboards.
DB Monitoring User	• Manage Events. • View the Database Monitoring UI. • Cannot add, edit, or delete database collectors.
DB Monitoring Administrator	• View the Database Monitoring UI. • Add, edit or delete database collectors.
Server Monitoring Administrator	• View the Server Monitoring UI. • Configure Service Monitoring features including Service Availability Monitoring.
Server Monitoring User	• View Server Monitoring UI. • Cannot configure Server Monitoring features.

Universal Agent Administrator	• Configure and view the Universal Agent. • Manage Events. • View the Universal Agent.
Universal Agent User	View the Universal Agent.
Workflow Executor	Execute Workflows.

Create Custom Roles

You must have the Account Owner role or the Administration, Agents, Getting Started Wizard permission to create new custom roles.

Roles can be managed collectively by using groups. A user or group must have at least one role but can have multiple. You have the option to add users and groups to predefined roles.

As a starting point for creating your own customized roles, you can copy predefined roles. If you are working under a custom role and copy a predefined role, some permissions may not be visible to you. You must adjust permissions for your customized role to ensure that you get the correct RBAC result.

To create a custom role:

1. Navigate to **Settings** > **Administration** > **Roles**.
2. Click **Create** and enter a unique **Name** and optional **Description**.
3. Configure permissions through the UI.
    a. **Account**—set role permissions
    b. **Applications**—set access and function permissions for applications and tiers
        i. **End User Monitoring**—enable end-user monitoring
        ii. **Server Visibility**—enable users to view and/or configure server components
    c. **Databases**—set access and function permissions for databases
    d. **Analytics**—set general, log, search, and event data view permissions
    e. **Dashboards**—set default and custom dashboard management permissions
    f. **User and Groups with this Role**—view existing or add new users and groups to the role
4. Click **Save**.

Account Permissions

Related pages:

- Create and Manage Custom Roles
- Create and Manage Groups
- Tenant User Management

This page provides the account-level permissions available in AppDynamics. You can set account permissions for custom roles from the Account tab in the Controller Administration UI. Most installations have one account per Controller. Usually, only very large installations or installations that have very distinct sets of users may require multiple accounts.

You can have multiple accounts when you select multi-tenant mode on your Controller. See Controller Deployment.

- In multi-tenant mode, the Controller UI context is divided into separate accounts. Each account has its own set of users, agents reporting to it, and application monitoring configuration.
- The account predefined role is the Account Owner. This role is also known as the account administrator and has all account-level permissions except Execute Workflows. This role can also create applications and dashboards and has all database visibility-related permissions.
- Most Account-level permissions can be considered administrative permissions and apply account-wide across business applications, products, and multiple application instances for the same account.

The following table lists the permissions that can be set at the account level.

Permission	Activities enabled	More Information
Administration, Agents, Getting Started Wizard	• Administer users, groups, roles, authentication, and so on. <table><tr><th>Users</th><th>Groups</th><th>Roles (non-default)</th><th>Authentication Provider</th></tr><tr><td>Add, edit, disable</td><td>Add, edit, delete</td><td>Add, edit, delete</td><td>Add, edit</td></tr></table>• View AppDynamics Agents. • Download agents using the Agent Download Wizard.	Create and Manage Custom Roles
Configure Alerting Templates	Create, edit, and delete alerting templates.	Configure and Manage Alerting Templates
Configure Cisco Secure Application	Configure and monitor the security of the APM-managed application using Cisco Secure Application. This grants permission to configure security settings, create or modify policies, add or edit notes, set status, and set severity.	Monitor Application Security Using Cisco Secure Application
Configure Email / SMS	Edit email and SMS settings used by AppDynamics to send alerts.	Enable an Email Server
Configure Email Templates	Configure email templates for use in notification alerts.	Email Templates
Configure HTTP Request Templates	Configure the HTTP request templates used by HTTP request actions, which are triggered by AppDynamics policies.	HTTP Request Actions and Templates
Configure Scheduled Reports	Create, delete, send, or update scheduled reports.	Reports
Configure Universal Agent	Use Universal Agent REST APIs that add or change Universal Agent configuration.	Universal Agent REST APIs
Create War Rooms	Create (start) a war room. War rooms are collaborative custom dashboards created in real-time.	Virtual War Rooms
View and Configure Licenses	View and create rules to specify the number of Application Performance Monitoring licenses to allocate to specified applications and machines.	License Management
View Business Flow	View all applications in a multi-business-application flow map, including those for which they are not granted explicit application permissions. Does not grant permission to drill down to applications that the user does not have permission to view. To see the downstream metrics and snapshots for the correlated application, the user must be a member of a role with view permissions to that business application.	Cross Application Flow
View Cisco Secure Application	View and monitor the security of the APM-managed application using the Cisco Secure Application dashboard.	Monitor Application Security Using Cisco Secure Application
View Scheduled Reports	View scheduled reports from the Dashboards and Reports section of the UI.	Reports
View Synthetic Credential Vault	Manage user permissions for the Synthetic Credential Vault.	Synthetic Credential Vault
Install Agent	Use the Agent Installer to deploy the Agent Installer Platform, Java Agent, and Machine Agent.	Agent Installer

Application Permissions

This page provides an overview of application permissions in AppDynamics. Application permissions follow an inheritance model with three levels listed in order from highest (default) to lowest (tier-specific):

- Default permissions
- Application-wide permissions
- Tier-specific permissions

By default, each level inherits from the one above it, unless you customize permissions at a lower level. This mechanism enables you to grant access to groups or users for specific business applications in the Tenant UI.

Customized permissions at a specific level override more general permissions at another level. That is, tier-specific permissions take precedence over application-specific permissions, and application-specific permissions override default permissions. Not all permissions can be customized at the tier-level.

You can set application permissions for custom roles from the Applications tab in the Tenant Administration UI. You can also assign the **Can Create Applications** permission to a custom role. See Create and Manage Custom Roles.

Create Default Permissions

All new applications inherit default permissions.

Configure Default Application Permissions

1. Log in to the Tenant Administration UI and select **Roles**.
2. Add a new role or select a custom role.
3. Click **Can Create Applications** to grant the role permission.
4. Under **Default Permissions**, select the default permissions for this role: **View**, **Edit**, or **Delete**.
    a. To give all permissions to all applications, click **Edit**.
    b. To specify permissions for specific application configurations for all applications, deselect **Edit**, and then click **Edit (None)**.
    c. In the **Edit Permissions** panel, select specific permissions.
    d. Click **Delete** to grant permissions to delete any application. To grant permission to delete a specific application, customize the permission at the application level. See Application and Tier Level Permissions.
5. Click **OK** then click **Save.**

Customize Application Permissions

To customize business application-level permissions:

1. Set the **Permissions** dropdown to **Custom**.
2. Select **View** and then **Edit (None)**.
   You can also grant permission to delete a specific application.

To customize permissions at the tier level,

1. Click **Add** to add tiers or select an existing tier.
2. Select **Edit**.
3. Select the individual permissions for the specific tier.
4. Click **OK** then click **Save**.

Overlapping Role Permissions Examples

Within specific and default permissions, granting a specific permission takes precedence over denying the same permission elsewhere. For example, if a user is assigned two roles and one grants a permission and the second role denies it, the user will have permissions for the activity.

These examples show how overlapping permissions of different roles interact. The examples enable view, edit, and delete permissions to applications for two Groups. The last column shows the resulting permissions for a specific user with roles that are assigned to each group.

Group 1			Group 2	
	Default Permissions (view, edit delete all applications)	**Explicit permissions (view, edit delete application-1)**	**Default Permissions (view, edit delete all applications)**	**Explicit permissions (view, edit delete application-1)**
A	None	Yes	Yes	None
B	Yes	None	Yes	Yes
C	Yes	None	None	Non

- Result for example A: User has view, edit, and delete permissions to all applications, including application-1.
- Result for example B: User has view, edit, and delete permissions to all applications, including application-1.
- Result for example C: User has view, edit, and delete permissions to all applications, excluding application-1.

General Permissions

Permission	Activities Enabled	More Information
Can Create Applications	Create business, browser, and mobile applications. Also controls the Archive Snapshot action.	Business Applications
View, Edit, and Delete permissions for new applications can be set as part of the default permissions for a custom role	View, edit, or delete business applications (and the tiers and nodes), browser, and mobile applications. Setting default delete permissions allows the user to delete all three artifacts from the application model.	Business Applications Tiers and Nodes

Application and Tier Permissions

You can grant the following permissions as specified. Permissions that you can customize at the tier level are indicated in the Description of Activities Enabled column. Asterisks (*) in the permissions table indicate permissions that are considered sensitive for security and data privacy purposes. Carefully consider the security and data privacy policies of your organization before granting these permissions.

Permission	Description of Activities Enabled	More Information
Configure Transaction Detection*	Create, edit, or delete transaction detection - can be at the tier level.	Transaction Detection Rules
Configure Backend Detection	Create, edit, or delete backends - can be at the tier level.	Backend Detection Rules
Configure Error Detection	Create, edit, or delete error detection.	Error Detection
Configure Diagnostic Data Collectors*	Create, edit, or delete diagnostic data collectors.	Data Collectors
Configure Call Graph Settings	• Edit call graph settings (no SQL) • Turn on or off capture raw SQL (call graph and SQL bind must both be on)	Call Graph Settings
Configure JMX	Create, edit, or delete JMX metrics.	Configure JMX Metrics from MBeans
Configure Memory Monitoring	Configure which custom classes are tracked by Object Instance Tracking. To enable or disable Object Instance Tracking, you need the Configure Agent Properties permission.	Object Instance Tracking for Java
Configure EUM (for Browser RUM)	See End User Monitoring Permissions.	Configure the Controller UI for Browser RUM
Configure EUM (for Mobile RUM)	See End User Monitoring Permissions.	Configure the Controller UI for Mobile RUM
Configure Information Points*	Create, edit, or delete information points.	Information Points
Configure Health Rules	Create, edit, or delete health rules.	Configure Health Rules
Configure Actions	Create, edit, or delete actions on agent properties UI. Create, edit, or delete email digests.	Alert and Respond Actions Email Digests
Configure Policies	Create, edit, or delete policies.	Configure Policies

Configure Business Transactions	Organize Business Transactions including: ▪ Group Business Transactions ▪ Exclude/un-exclude Business Transactions ▪ Delete Business Transactions ▪ Enable Business Transaction lockdown ▪ Rename Business Transactions Configure Business Transaction thresholds. Configure snapshot settings. Set as a background task. Configure data collectors. Enable End User Monitoring. Enable analytics for business transactions. Enable or disable GUID injection.	Organize Business Transactions Transaction Thresholds Transaction Snapshots Monitor Background Tasks Data Collectors Set Up and Access Browser RUM Collect Transaction Analytics Data Business Transaction and Log Correlation
Configure Baselines	Create, edit, or delete baselines.	Dynamic Baselines
Configure SQL Bind Variables*	Turn on or off capture raw SQL (also requires Configure Call Graph Settings).	Call Graph Settings
Configure Agent Properties	Create, edit, or delete agent configuration (can be at the tier level). Enable or disable automatic leak detection (can be at the tier level). Enable or disable object instance tracking (can be at the tier level). Enable or disable custom memory structure (can be at the tier level).	App Agent Node Properties Object Instance Tracking for Java Custom Memory Structures for Java
Agent Advanced Operation	Reset agent from the node dashboard. Request agent thread dumps. Request agent debug logs.	Manage App Agents Diagnostic Actions Request Agent Log Files
Set JMX MBean Attributes and Invoke Operations	Edit MBean attributes or invoke actions on operations.	Monitor JMX
Configure Service Endpoints	Create, edit, or delete service endpoints.	Service Endpoint Detection
Configure Monitoring Level (Production /Deployment)	Switch between production and development mode.	Development Level Monitoring
Configure 'My Dashboards' for Tiers and Nodes	Create, edit or delete custom dashboards (can be at the tier level).	Create and Manage Custom Dashboards and Templates Custom Dashboards
Create Events	Create, edit, or delete events.	Alert and Respond API
Start Diagnostic Sessions	Start a diagnostic session.	Diagnostic Sessions
View Sensitive Data*	In combination with the Configure Transaction Detection permission, enables the use of Live Preview and Business Transaction Discovery features to stream live data from your application.	Custom Match Rule Live Preview

Transaction Analytics Permissions

Related Pages:

- Create and Manage Custom Roles
- Analytics and Data Security

This page provides an overview of permissions in Analytics.

The predefined role for Analytics is the Analytics Administrator. You can set analytics permissions for custom roles from the Analytics tab in the Tenant UI. When creating a new role, select the permissions that you want to assign to the new role.

There are several analytics permissions categories:

- Transactions
- Logs
- Browser Requests
- Mobile Requests and Sessions
- Synthetic Sessions
- Connected Devices
- Custom Analytics Events

For a user to create metrics from Analytics searches, you must assign that user to a role with View access to the Analytics Application in the Applications tab.

Asterisks (*) in the permissions tables on this page indicate permissions that should be considered sensitive for security and data privacy purposes. Consider the security and data privacy policies of your organization before granting these permissions. For details on permissions related to Analytics data and functionality, see the More Information column.

Permission Name	Activities Enabled	More Information
General > Manage Centralized Log Config	Configure source rules for Centralized Log Management.	Configure Log Analytics Using Source Rules
General > Manage Fields*	Show and hide fields in analytics data so that you can restrict sensitive data to proper roles and users.	Manage Field Visibility
General > Manage APIs*	View the analytics API tab to create and manage API authentication keys. Users with this API permission have access to all analytics data since they can use cURL with the access key and access all data.	Manage API Keys
General > Manage Metrics	Create metrics from analytics searches. This permission controls which roles and users can create metrics from analytics searches. Once the metric exists, you can set up alerts in the usual way.	Create Analytics Metrics From Scheduled Queries
Search Permissions > Can Create a Search*	Create and save an analytics search. Configure view, edit, and delete permissions for each saved search.	Analytics and Data Security
Search Permissions > Saved Searches*	View, edit, or delete a specific saved analytics search.	Analytics and Data Security
Transaction Permissions*	View analytics transaction data from all applications or specific applications.	Analytics and Data Security
Log Permissions*	View analytics data for all Source Types or specific log sources.	Analytics and Data Security
Browser Requests and Sessions Permissions*	View analytics data from Browser requests.	Analytics and Data Security
Mobile Requests and Sessions Permissions*	View analytics data from mobile requests and crash reports.	Analytics and Data Security
Synthetic Sessions Permissions	View synthetic data from all or specific applications.	Analytics and Data Security
Connected Devices Permissions	View analytics data for connected devices.	IoT Monitoring
Custom Analytics Events Permissions*	Query custom analytics events data. Permissions can be granted to view data for all custom analytics events or on an event-by-event basis.	Analytics and Data Security

Custom Dashboard Permissions

Related pages:

- Create and Manage Custom Roles
- Custom Dashboards

This page provides an overview of permissions for custom dashboards in AppDynamics.

The predefined role is the Dashboards Viewer. The permissions of this role are limited to viewing custom dashboards in the Tenant UI. The permissions of this role apply if you do not set more specific permissions for an individual custom dashboard.

Each custom dashboard inherits the default custom dashboard permissions unless you override the defaults by configuring separate explicit permissions for individual dashboards.

For example, you could have a custom dashboard called SalesDashboard and a custom role SalesRole, and a second custom dashboard called FinanceDashboard, and a second custom role FinanceRole. The SalesRole could be configured to have permissions in the SalesDashboard but not in the FinanceDashboard and so on.

> Creating custom dashboard templates requires the **Configure 'My Dashboards' for Tiers and Nodes** permission, which you can set at the application level. See Application Permissions.

Default Permissions

Changes made to the default or custom permissions are automatically applied to existing and future dashboards. These permissions can be used to create special permissions for specific dashboards and override default permissions.

You can configure default permissions on the `Admin.jsp` page as follows:

1. Click **Settings** and select **Administration.**
2. Click **Roles**.
    a. Select **General** and click **Create** Unknown Attachment.
    b. Provide details (name and description) about the role.
    c. Click **Dashboards** and select the permissions that you want this role to acquire.
    d. Select **Can Create Dashboards** to grant role permission to create new dashboards.
    e. Select **Default Permissions** for this role: **View**, **Edit**, **Delete**, or **Share**.
    f. Click **Save**.

    > You cannot edit the permissions of the listed dashboard roles because they are set by default.
    >
    > If any of the dashboard permissions in the custom permissions list matches with the default permissions, that entry will be removed from the custom list.

3. Click **Users**.
    a. Create a new user or select an existing user.
    b. Select one or more options to assign the required role to the user.
    c. You can assign all the available roles to the user at once or disable them all at once.
4. Click **Save**.

Dashboard Permissions

Permission	Activities Enabled	More Information
View	View specific custom dashboards.	Custom Dashboards
Edit	Edit specific custom dashboards.	
Delete	Delete specific custom dashboards.	
Share	Share specific custom dashboards.	
Can Create Custom Dashboards	Create new custom dashboards.	

Share Permission

You can allow the users to share their dashboards publicly (without requiring a login) with the share permission. This permission allows you to control the permissions that a user or a role can acquire.

Enable the Share Permission

You can enable the **Share** icon on the dashboard after configuring the default share permissions:

1. Navigate to **Dashboards & Reports** and click **Dashboards**.
2. Right-click a dashboard.
3. Select **Share** > **Share Dashboard**.
   This table shows you how the **Share** icon appears on the dashboard menu based on the values assigned to share permission and the shared status:

Share Permission	Is shared	Share Icon
True	Yes	Active
True	No	Active
False	Yes	Inactive
False	No	Inactive

When the share permission is activated yet no role with share access exists, dashboard users cannot share the dashboard. You must update all default roles with `share=true` when appropriate.

Database Permissions

This page provides an overview of permissions for databases in AppDynamics.

You can set Database permissions for custom roles from the **Databases** page in the Controller Administration UI. See Create and Manage Custom Roles.

Navigate to **Administration** > **Roles** > **Applications** > **Databases** and ensure that the **Custom view** permission is set to active to view metrics associated with database collectors. You can also configure database collector permissions for custom roles.

For each custom role, you can select which databases the user is allowed to view, edit, or delete, and you can enable global permissions applying to database collectors.

Permission	Activities Enabled	More Information
Can Configure Collectors	Configure baselines, wait state filtering, and custom metrics, as well as enable or disable the masking of query literals.	Discover Normal Database and Server Activity Wait State Filtering Configure Custom Metrics Configuring Query Literals Security
Can Create Collectors	Create database collectors for any database.	Add Database Collectors
View	View all existing and new database collectors, and therefore the metrics for the databases associated with those collectors.	Database Dashboard
Edit	Edit database collector fields for any database.	Add Database Collectors
Delete	Delete database collectors for any database.	Add Database Collectors

End User Monitoring Permissions

Related pages:

- Configure the Controller UI for Browser RUM
- Configure the Controller UI for Mobile RUM

This page provides an overview of permissions for End User Monitoring.

You can set End User Monitoring permissions for custom roles from the Applications tab in the Controller Administration UI. You need the Configure EUM permission to configure Browser and Mobile RUM. You can add this permission as the default permission for all applications, or you can specify the permission at the application level.

Browser RUM

The Configure EUM permission permits the following actions for Browser RUM:

- Configure and download the JavaScript Agent.
- Add include/exclude rules for base pages, Ajax requests, and virtual pages.
- Enable JavaScript error capture and add rules to ignore specific JavaScript errors.
- Set thresholds for slow end-user experience.
- Enable the collection of slow, periodic, and error snapshots.

See Configure the Controller UI for Browser RUM for instructions and a list of the supported Browser RUM configurations.

Browser Synthetic Monitoring

The Configure EUM permission permits these actions for Browser Synthetic Monitoring: view, schedule, edit, and delete synthetic jobs.

Mobile RUM

The Configure EUM permission permits these actions for Mobile RUM:

- Upload dSYM files for iOS or ProGuard files for Android.
- Add include/exclude rules for network requests and the Events Service.
- Set thresholds for slow end-user experience.
- Configure mobile crash alerts.
- Configure mobile screenshots.

See Configure the Controller UI for Mobile RUM for instructions and a list of the supported Mobile RUM configurations.

Server Visibility Permissions

Related pages:

- Create and Manage Custom Roles
- Server Visibility

This page provides an overview of permissions for server visibility in AppDynamics.

When you create custom roles, you can assign the server visibility permissions to users as part of the default permissions for all applications or create customized applications permissions for new roles.

1. From the Controller Administration UI, navigate to **Roles > Applications**.
2. Select an existing role or create a new role.
3. From the Server Monitoring dropdown, select **Customized**.
4. Click **View** and **Edit** to see the available permissions.

Predefined Roles

- Server Visibility Administrator
- Server Visibility User

Permissions

Permission Name	Activities Enabled	More Information
Configure Server Visibility	View all Servers tabs and windows, and configure Service Availability Monitoring.	Service Availability Monitoring
View Server Visibility	View all Servers tabs and windows.	Server Visibility

External Authentication Providers

This page provides an overview of external authentication providers in AppDynamics.

User Authentication Types

AppDynamics manages user credentials according to your type of deployment. See Deployment Options.

- Local User—AppDynamics manages user account credentials (SaaS)
- SAML User—You manage user account credentials via SAML integration (SaaS and on-premises)
- LDAP User—You manage user account credentials via LDAP integration (on-premises)

You create and manage Local User accounts in the Tenant Administration UI. However, you can authenticate and authorize Tenant users with external LDAP or SAML-based authentication providers.

Authentication Options

Log in to the Tenant UI as an administrator and navigate to **Settings** > **Administration** > **Authentication Provider**.

By default, Tenant authentication is configured to the local authentication option, **AppDynamics**. With this configuration, AppDynamics manages the users and they authenticate through the AppDynamics Identity Provider (IDP)

Alternatively, you can have an external LDAP or SAML system perform user authentication and authorization.

- LDAP Authentication
- SAML Authentication

LDAP Authentication

This page provides instructions on how to integrate an AppDynamics Tenant with LDAP directory servers.

This page assumes a Controller and a Tenant are one and the same.

LDAP Support

You can delegate Tenant UI authentication and authorization to external directory servers that comply with LDAP (Lightweight Directory Access Protocol) version 3.

While a Tenant should be able to work with any LDAPv3-compliant server, these LDAP products have been verified:

- Microsoft Active Directory for Windows Server 2008 SP2 or later
- OpenLDAP 2.4 or later

To configure LDAP authentication on a Tenant, you must configure connection settings to the LDAP server and the queries that return user or group data. By mapping LDAP groups to roles, you can provision permissions in the AppDynamics Tenant based on LDAP groups.

- What happens if the LDAP server becomes unavailable?
  If the LDAP server configured for Tenant authentication becomes unavailable for any reason, the Tenant falls back to local user authentication. Given this possibility, you should provision local user accounts in AppDynamics for the administrative users who will need access if the LDAP server becomes unavailable.
- What happens if a user cannot be found in the LDAP directory?
  If a user cannot be found in the LDAP directory, the authentication failure event is logged as a warning. The user, whether a regular Tenant user or a REST client user, may still be authenticated through local authentication.

Prepare the LDAP Directory for AppDynamics Integration

To use an LDAP authentication provider, your AppDynamics Tenant must be able to connect to the external LDAP server. We recommend creating a user account in LDAP specifically for the Tenant to use to authenticate itself to the server and run the queries. The Tenant user only needs to have search privileges in LDAP.

You can map existing LDAP group definitions to roles in AppDynamics, however, your existing groups may not correspond directly to those roles. You can map LDAP groups to Tenant roles by creating a group in LDAP for each role you want to map in AppDynamics. LDAP groups for each role provide you with a manageable, one-to-one correspondence between your LDAP groups and AppDynamics roles.

This is a possible LDAP group scheme for mapping in AppDynamics:

- AppDynamics-AppA-ReadOnly
- AppDynamics-AppA-Admins
- AppDynamics-AppA-DashboardViewers
- AppDynamics-AppB-ReadOnly
- AppDynamics-AppB-Admins
- AppDynamics-AppB-DashboardViewers

The sample group names imply having custom roles in AppDynamics targeted to specific applications, AppA and AppB.

Naming the groups with a common prefix, as the `AppDynamics-` prefix in our sample, allows you to use an LDAP group filter. A group filter for the sample groups could be:

```
(&(objectClass=group)(cn=AppDynamics-*))
```

Use Paged Results for Large Result Sets

LDAP servers are sometimes configured to limit the number of entries they can return in a query response. If the results of your user or group query exceed that limit, AppDynamics reports a `max_results_exceeded` error.

To avoid this error, refine your query filter to produce a smaller result set. The results must include the users who will need to access the AppDynamics UI.

If your LDAP server supports it, you can enable paged results in the Tenant LDAP configuration. With paged results, the LDAP server divides the result set into separately transmitted blocks.

The paged results feature applies to the behind-the-scenes interaction between the AppDynamics Tenant and the backend LDAP server. It does not affect the UI view of the data.

LDAP Authentication with a SaaS AppDynamics Controller

Depending on your organization's security policies, it may not be possible to use LDAP authentication with the SaaS AppDynamics Tenant. Doing so requires opening your firewall to permit Tenant access to your corporate LDAP server.

To enable LDAP authentication with an AppDynamics SaaS Tenant, however, you must permit access through the firewall for the AppDynamics IP ranges listed in SaaS Domains and IP Ranges. The firewall rule should allow incoming LDAP requests from the Tenant at the LDAP port you configure.

Before You Start

To perform LDAP configuration, you must have:

- An LDAP server. There is a one-to-one correspondence between an AppDynamics account and an LDAP server.
- An account on an AppDynamics SaaS or on-premises Tenant
- Account administrator privileges on the AppDynamics Tenant, as described in Update the Root User and Glassfish Admin Passwords.
- Network connectivity between your LDAP server and the Controller. If using a SaaS Tenant, the LDAP server may not be accessible to the Tenant without enabling access through your network firewall. See LDAP Authentication with a SaaS AppDynamics Controller.

Configure LDAP Authentication

The high-level procedure to set up LDAP authentication includes:

- Configure the connection to the LDAP server.
- Configure and test the LDAP query that returns users to be provisioned in the AppDynamics Tenant.
- Configure the LDAP query that returns the LDAP groups to be mapped to AppDynamics roles.
- Map the users or groups to roles in AppDynamics.

Configure the Connection to the LDAP Server

As an Administrator or Account Owner in the Tenant UI, you can configure LDAP authentication by navigating to **Settings > Administration** and selecting **LDAP** in **Authentication Provider**.

Use the following paged results configuration if the user or group query you need to use returns more entries than the LDAP server permits:

- **Enable Paging**: Check this option to have the Controller request paged results from the server when submitting user or group queries.
- **Page Size**: Enter the number of entries per round-trip from the AppDynamics Controller to the LDAP server. The default is 500.

The page size should equal the total number of entries to be returned divided by the tolerable number of round trips between the LDAP server and the Tenant. For example, if you expect to receive 1200 results in a query and you can tolerate a maximum of two round trips, set the page size to 600 (1200 /2). See Using Paged Results for Large Result Sets.

Configure the LDAP connection settings:

- **Host:** Required address of the LDAP server.
- **Port:** Port on which the LDAP server listens. The default is 636 for an SSL connection and 389 if not using SSL. Required.
- **Use SSL:** Enabled by default to use a secure connection to the LDAP server. Clear if not using SSL.
- **Enable Referrals:** Enabled by default to support LDAP referrals. A referral is when an LDAP server forwards an LDAP client request to another LDAP server. Each referral event is referred to as a hop.
- **Maximum Referral Hops:** The maximum number of referrals that AppDynamics follows in a sequence of referrals. The default is five.
- **Bind DN:** Distinguished Name of the user on the LDAP Server on whose behalf the AppDynamics application searches. Required.
- **Password:** Password of the user on the LDAP server. Required.

Configure Users

In the **LDAP Configuration** page, configure information to find LDAP users:

- **Base DN:** Location in the LDAP tree to begin recursively searching for users. Required.
- **Filter:** Optional LDAP search string that filters the items matched from the base DN. See RFC2254 for information about LDAP search filters.
- **Login Attribute:** The LDAP field that corresponds to the username users will enter when logging in to the AppDynamics UI. The default is `uid`. For Active Directory, this would typically be `sAMAccountName`.
- **Display Name Attribute:** The LDAP field to use as the user's display name.
- **Group Membership Attribute:** Optional user group membership field. Recommended for faster retrieval.

- **Email Attribute:** Optional user email address.

Select **Test Query** to check the connection. If successful, a screen displays the first few users returned by the query. The test does not return the entire result set if the result set is large.

Configure Groups

Optionally, you can map LDAP groups to user roles in the AppDynamics Tenant. To do this, you must set up the LDAP query that returns the LDAP groups to map:

- **Base DN**: Location in the LDAP tree to begin recursively searching for groups. Required.
- **Enable Nested Groups:** Option to include nested LDAP groups to a depth of 10.
- **Filter:** Optional LDAP search string that filters the items matched from the base DN. See RFC2254 for information about LDAP search filters.
- **Name Attribute:** The LDAP field that contains the name of the group. Default is `cn`. Required.
- **Description Attribute:** The LDAP field that contains a description of the group. Optional.
- **User Membership Attribute:** Identifies members of the groups. Optional.
- **Referenced User Attribute:** Optional child attribute of the User Membership Attribute. Disabled if the parent is empty. Identifies the property of the user that the user membership attribute contains.

Select **Test Query** to check the connection. If successful, the first few groups returned by the query are shown.

You can now assign permissions in the AppDynamics Tenant to users or groups.

Assign AppDynamics Permissions to an LDAP User

1. In **Settings > Administration**, click **Users**. If LDAP is enabled and correctly configured, the AppDynamics Tenant fetches the user names from the LDAP server.
2. Select the name of the user to whom you want to assign permissions.
3. Add or delete the **Roles** that you want to assign to this user. You can assign multiple roles to a user.
4. Click **Save**.

Assign AppDynamics Permissions to an LDAP Group

LDAP Group configuration is optional.

1. In **Settings > Administration**, click **Groups**. If LDAP is enabled and correctly configured, AppDynamics fetches the group names in LDAP.
2. Select the name of the group to which you want to assign permissions.
3. Add or delete the **Roles** that you want to assign to this group. You can assign multiple roles to a group.
4. Click **Save**.

Configure the LDAP Cache Synchronization Frequency

The Tenant keeps information about LDAP users and groups in a local cache. It regularly connects to the LDAP server to synchronize its cache with the LDAP server.

The Tenant caches information about users and group membership. It does not cache user passwords. Accordingly, the Tenant authenticates the user credentials against the LDAP server at the start of every user session.

If you remove a user account from LDAP, the change reflects immediately and the user will not be able to log in to the Tenant UI. However, if the user has an existing session in the Tenant UI, that session continues until the user logs out or the session expires.

If the user's access to the Tenant is based on group membership and you remove the user from the group but maintain an account in the LDAP server, the user is able to log in to the Tenant until the next LDAP server synchronization. The default synchronization frequency setting would allow the ability to access the Tenant UI for up to an hour.

Configure the LDAP Synchronization Frequency

To modify the default synchronization frequency of one hour:

1. Stop the Tenant application server.

- From Linux, run:

```
platform-admin.sh stop-controller-appserver
```

- From Windows, run this command from an elevated command prompt (which you can open by right-clicking the **Command Prompt** in the Windows **Start** menu, and selecting **Run as administrator**):

```
platform-admin.exe cli stop-controller-appserver
```

2. Open the `<Controller-Installation-Directory>/appserver/glassfish/domains/domain1/config/domain.xml` file for editing.
3. In the `<jvm-options>` element, add a system property named `appdynamics.ldap.sync.frequency` with the desired synchronization frequency in milliseconds.
   For example, to have the Tenant synchronize to the LDAP server every 15 minutes (900000 milliseconds), add:

```
<jvm-options>-Dappdynamics.ldap.sync.frequency=900000</jvm-options>
```

   The default is 3600000 milliseconds (1 hour).
4. Save the file.
5. Restart the Tenant app server:
   - From Linux, run:

```
platform-admin.sh start-controller-appserver
```

   - From Windows, run this command from an elevated command prompt:

```
platform-admin.exe cli start-controller-appserver
```

SAML Authentication

This page provides an overview of Security Assertion Markup Language (SAML) authentication in AppDynamics.

This page assumes a Controller and a Tenant are one and the same.

The AppDynamics Tenant can use an external SAML identity provider (IDP) to authenticate and authorize users. See Configure Basic SAML Authentication Configuration.

Supported Identity Providers

AppDynamics certifies support for the following identity providers (IDPs):

- Okta
- Onelogin
- Ping Identity
- Azure AD
- IBM Cloud Identity
- Active Directory Federation Service (AD FS)

Other IDPs supporting HTTP POST binding should also be compatible with AppDynamics SAML authentication. If you are having issues setting up SAML with your IDP, contact your AppDynamics account representative for help.

Binding Support

AppDynamics supports identity federation with SAML 2.0, an open standard used by many IDPs. This identity federation enables single sign-on (SSO) with HTTP POST binding for the SAML request and HTTP POST binding for the IDP response.

The bindings have the following requirements:

- HTTP is the required transport. Optionally, you can also configure HTTPS transport.
- The AppDynamics Tenant uses HTTP GET or POST for the authentication request to the identity provider for the sign-out message to the identity provider. The IDP also uses HTTP GET and POST to return the response.

How SAML Authentication Works with AppDynamics

With SAML authentication enabled:

1. Navigate to your Tenant login page and enter your account name.
   The Tenant redirects you to the external SAML IDP.
2. From the IDP, enter your credentials.
3. The IDP redirects and logs you into the Tenant.

To log in to the Tenant UI, users require access to both the Tenant and the identity provider service through the network from their computer. You can configure the Tenant to assign roles to authenticated users based on group attributes in their SAML responses. See Map SAML-Authenticated Users to AppDynamics Roles.

Who Can Configure SAML

Only users assigned to the AppDynamics role Account Owner can configure SAML authentication in the Tenant and assign other users to the Account Owner role. Roles govern user privileges in the Tenant UI. See Create and Manage Custom Roles.

Configure Basic SAML Authentication

Related pages:

- Map SAML Group to AppDynamics Roles

This page provides guidelines for configuring basic SAML authentication.

Configure SAML Authentication for the Identity Provider

You can configure an identity provider to enable single sign-on access to the AppDynamics Controller using the SAML 2.0 protocol. Refer to the documentation of your identity provider for detailed configuration instructions.

SAML Settings for the Identity Provider

Your identity provider requires the following information about your AppDynamics Controller for the SAML settings. The `<controller_domain>` can be the domain of one of the AppDynamics SaaS Controllers or your on-premises Controller.

Setting	Description
Audience URI (Service Provider Entity ID)	The unique identifier intended for the SAML assertion. In most cases, it is the Service Provider Entity ID, unless the Service Provider decides to use a different identifier. • Syntax: `http://<controller_domain>/controller` • Example: `http://yourcompany.saas.appdynamics.com/controller`
Single Sign-On URL (Assertion Consumer URL)	The AppDynamics endpoint to service SAML Authentication. You need to specify your AppDynamics account name with the query string parameter `accountName` as shown below. • Syntax: `http://<controller_domain>/controller/saml-auth?accountName=<account_name>` • Example: `http://yourcompany.saas.appdynamics.com/controller/saml-auth?accountName=myaccount`

SAML Attributes for the Identity Provider (Recommended)

You set attributes with your identity provider that map to SAML users in your AppDynamics account. When the attributes are set, the Controller displays the user's information, such as the username and email. Changes to these attributes on the IDP will update the mapped SAML attributes on AppDynamics Controller when the user successfully logs in.

The table shows how IDP example attributes map to the **Username Attribute**, **Display Name Attribute**, and the **Email Attribute** settings of the Controller.

Example Attribute Name	Example Attribute Values	Description
Username Attribute	`User.loginName`	Unique identifier for the user in the SAML response. This value corresponds to the AppDynamics `username` field, so the value must be unique among all SAML users in the AppDynamics account. If no username is mapped, AppDynamics obtains the `username` from the `NameId` containing the `emailaddress` field.
Display Name Attribute	`User.fullName`	Informal name for the user corresponding to the AppDynamics `Name` field.
Email Attribute	`User.email`	User's email address, corresponding to AppDynamics `email` field.

Configure SAML Authentication from the Controller

To configure SAML authentication from the Controller:

Configure SAML Authentication

1. Navigate to your Controller.
2. Log in as the Account Owner. See Who Can Configure SAML.
3. As a user with AppDynamics account administrator privileges in the Controller UI, click **Settings**  **> Administration**.
4. Click the Authentication Provider tab and select **SAML**.
5. From **Authentication Provider** > **SAML**, enter the following SAML configuration settings:

- **Login URL:** The SAML Login URL where the Controller routes Service Provider (SP)-initiated login requests. This login URL is required.
- **Logout URL:** The URL where the Controller redirects users after they log out. If you do not specify a logout URL, users will get the AppDynamics login screen when they log out.
- **Certificate:** The X.509 certificate from your identity provider configuration. Paste the certificate between the `BEGIN CERTIFICATE` and `END CERTIFICATE` delimiters. Avoid duplicating `BEGIN CERTIFICATE` and `END CERTIFICATE` delimiters from the source certificate itself.

Configure SAML Attribute Mapping (Optional)

From **SAML Attribute Mappings**, you can specify how SAML-authenticated users are identified in the AppDynamics Controller with the following:

- **Username Attribute:** Unique identifier for the user in the SAML response. This value corresponds to the AppDynamics `username` field, so the value must be unique among all SAML users in the Controller account. Given the sample response below, the value for this setting would be `User.OpenIDName`.
- **Display Name Attribute:** The informal name for the user corresponding to the AppDynamics Name field. Given the sample response, this value would be `User.fullName`.
- **Email Attribute:** The user's email address, corresponding to AppDynamics email field. Given the sample response, this value would be `User.email`.

Map SAML-Authenticated Users to AppDynamics Roles

From **SAML Group Mappings,** you can map SAML-authenticated users to one of the Controller roles:

- **Default Role**: If a user's identity assertion has no SAML group attribute, the authenticated user is assigned the SAML default role upon the first login. The default role cannot be removed, and you are recommended to provide minimum permissions. An AppDynamics administrator can verify and adjust the roles for users manually in AppDynamics once those users have accounts.
- **SAML Group**: You can map SAML group membership attributes to roles in AppDynamics. Using this method, each time the user authenticates, the Controller checks the SAML assertion and updates the role assignment if needed.
- **Internal Group**: If a SAML-authenticated user has the same username as an AppDynamics internal user account and the SAML assertion does not contain mapped SAML group attributes, the Controller gives the user the roles for the internal AppDynamics account.

Configure Default Permissions

Instead of mapping SAML attributes to roles, you can also assign users to a default role with the permissions you specify:

1. To use default permissions, edit the **Default Permissions** settings in the **SAML Group Mappings** list.
2. In the **Default Group Mapping** dialog, choose the AppDynamics roles that all authenticated users get.

Verify the SAML Authentication Configuration

The best way to verify that you have configured SAML authentication correctly is to log in to your AppDynamics Controller.

This procedure shows the SAML flow from the service provider (your Controller) and describes the SAML requests and responses. You can also start the SAML flow from the IDP.

1. Navigate to your AppDynamics Controller.
2. You will see the **Login** dialog for the 3rd-party service, which is your IDP.
3. Click **Login**.
4. After you are redirected to your IDP, enter and submit your credentials.
5. The IDP redirects you to your AppDynamics Controller.

> ⚠ (On-premises only) If you are redirected, but the Controller fails to load, this could be because the request URL from the IDP is different from your internal Controller URL. The most common causes are your Controller is configured to use HTTPS but the redirect used HTTP, or you changed the default port of the Controller. See the suggested resolution in Support Advisory: SAML Authentication Fails after 4.3 Upgrade.

6. From the Controller, if you set SAML attributes to map to the user account, you can view the user info by clicking **Settings** **> My Preferences**.
7. If you set default permissions, the user is assigned to the default role, which can be viewed by clicking **Settings** **> Administration**.

Map SAML Group to AppDynamics Roles

This page describes how to configure SAML attributes to role mapping and the SAML group attribute value mapping options.

If the identity assertion from the SAML provider includes group names that correspond to AppDynamics roles, you can configure mappings between those group names and the roles. The **SAML Group Mappings** settings in **SAML Configuration > Authentication Provider** control the mappings.

Configure SAML Attribute to Role Mapping

To configure the SAML attribute to role mapping:

1. In the **SAML Group Attribute Name** field, enter the `Name` attribute value that identifies the SAML Attribute element with group affiliations for the user. For example, given the following response snippet, use `SAML groups-Membership` in the **SAML Group Attribute Name** field.

   ```
   <saml:Attribute NameFormat="urn:oasis:names:tc:SAML:2.0:attrname-format:basic" Name="Groups-Membership">
      <saml:AttributeValue xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="xs:string">
         {group1};{group2}
      </saml:AttributeValue>
   </saml:Attribute>
   ```

2. Use the **Group Attribute Value** and **Mapping of Group to Roles** settings to describe the structure of the SAML group attribute from which AppDynamics needs to extract the group value and the roles associated with those values. The Controller can extract Group Attribute values based on the following options:
   - Singular Group Values: The response contains an `AttributeValue` element with a single group-mapping value.
   - Multiple Nested Group Values: The response contains more than one `AttributeValue` element, each with a single group-mapping value.
   - Singular Delimited Group Value: The response contains one `AttributeValue` element with multiple, delimiter-separated group-mapping values.
   - Regex on Singular Group Value: The response contains a single `AttributeValue` element from which you want to extract the group-mapping value with a regular expression.

   The next sections provide examples for each option.
3. With any option selected, select the **Value is in LDAP Format** checkbox if the value or values returned by the group attribute value is in LDAP format. For example: `OU=AppDynamics-Users`. With this option enabled, only `AppDynamics-Users` is used to map to the SAML Group name.

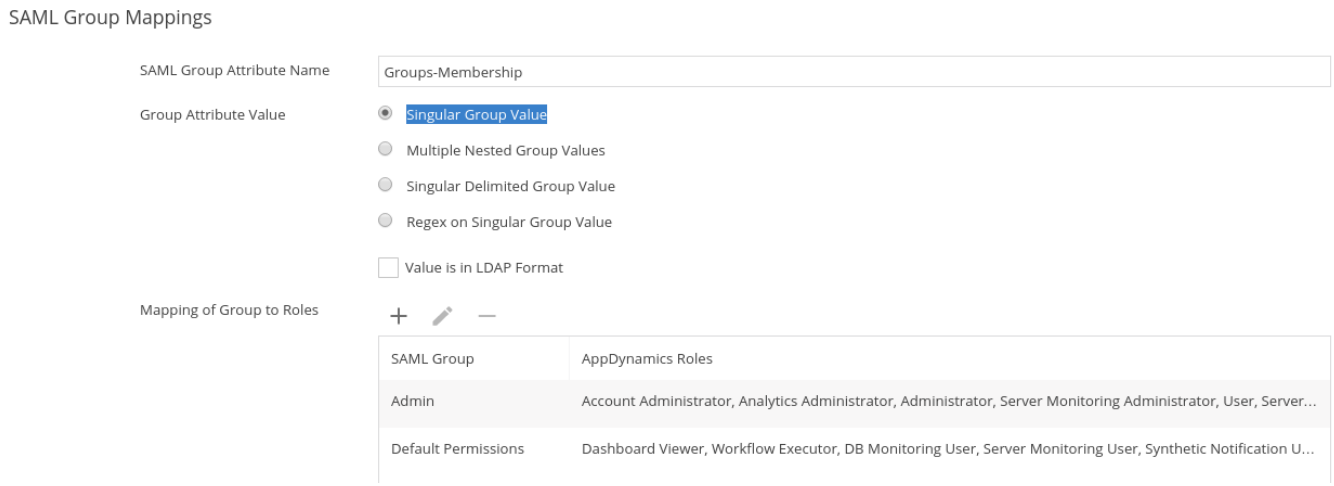
SAML Group Mappings

Singular Group Values

Select **Singular Group Value** if the SAML group attribute contains a single group, as in the following example.

```
<saml:AttributeStatement>
   <saml:Attribute Name="Groups-Membership" NameFormat="urn:oasis:names:tc:SAML:2.0:attrname-format:basic">
      <saml:AttributeValue xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="xs:string">Admin<
/saml:AttributeValue>
   </saml:Attribute>
</saml:AttributeStatement>
```

For this example, AppDynamics would extract the value `Admin` and associate the user with a SAML Group with the same name. In this sample configuration, the user would get the configured roles assigned to the Admin SAML group, such as Account Administrator and Analytics Administrator.

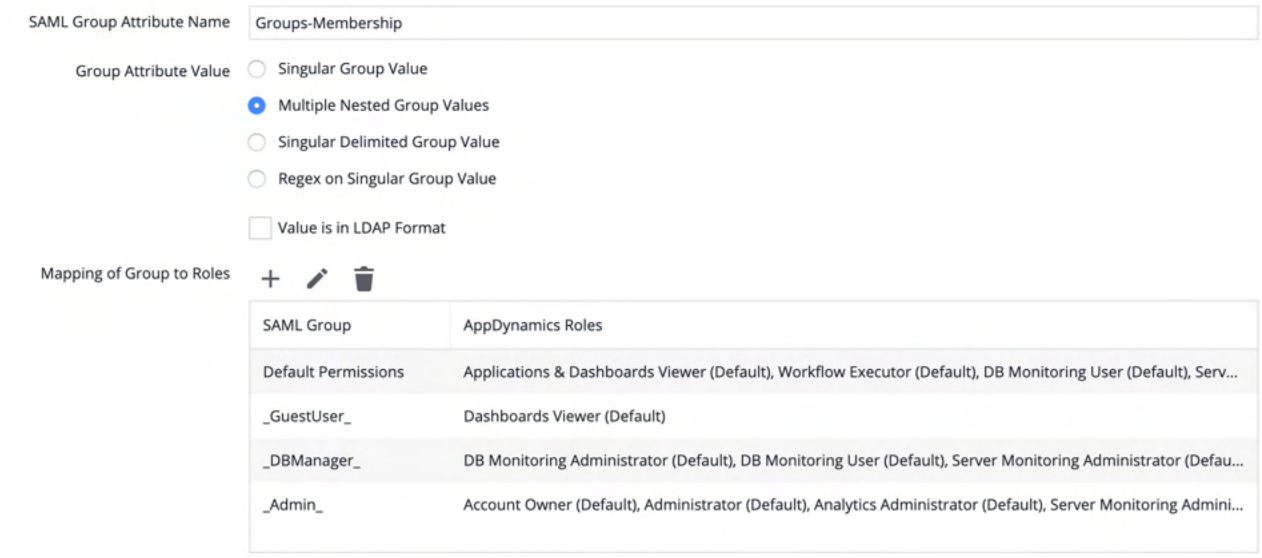


Multiple Nested Group Values

With **Multiple Nested Group Values** selected, AppDynamics expects multiple `AttributeValue` child elements under the SAML Attribute with the group information, as in the following example:

```
<saml:Attribute Name="Groups-Membership" NameFormat="urn:oasis:names:tc:SAML:2.0:attrname-format:basic">
   <saml:AttributeValue xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="xs:string">_Admin_<
/saml:AttributeValue>
   <saml:AttributeValue xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="xs:string">_DBManager_<
/saml:AttributeValue>
</saml:Attribute>
```

AppDynamics would extract `_Admin_` and `_DBManager_` from the example. In this sample configuration, the user with the previous response would receive the roles from the `_Admin_` and `_DBManager_` groups.



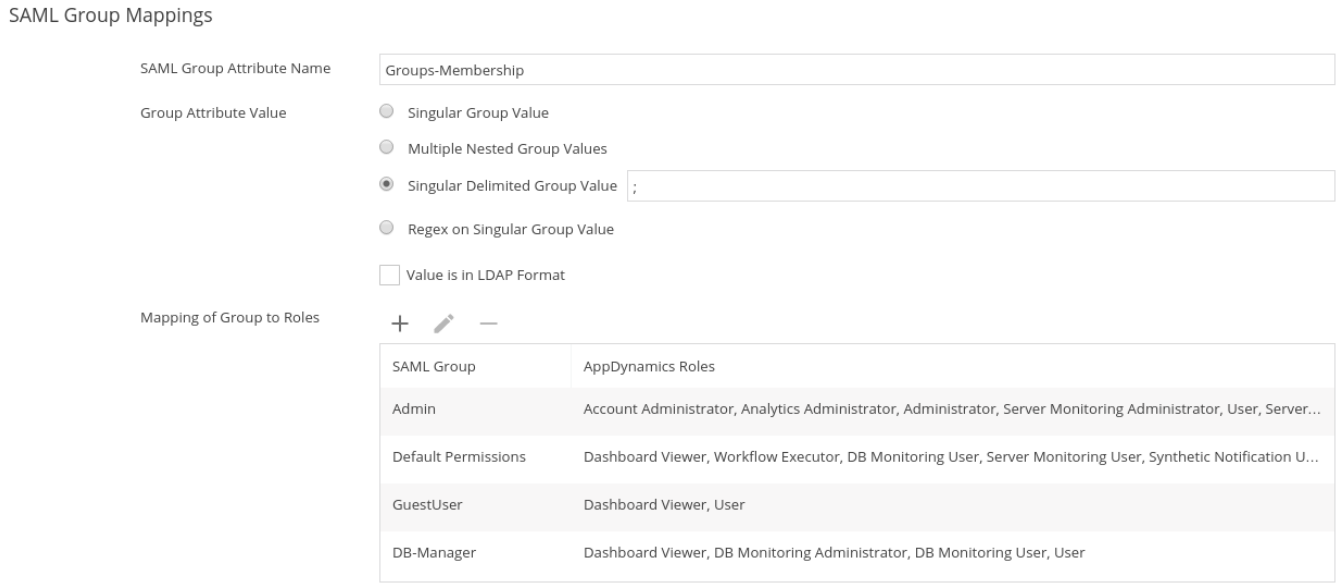
Singular Delimited Group Value

With this option selected, AppDynamics expects a single `AttributeValue` element with multiple, delimiter-separated values, as in the following example:

```
<saml:Attribute Name="Groups-Membership" NameFormat="urn:oasis:names:tc:SAML:2.0:attrname-format:basic">
   <saml:AttributeValue xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="xs:string">Admin;DB-
Manager</saml:AttributeValue>
</saml:Attribute>
```

Specify the delimiter that separates the values to extract, such as a semi-colon in the example.

In this sample configuration, the user would get the AppDynamics roles associated with both the Admin and DB-Manager groups, such as the Dashboard Viewer, User, and DB Monitoring Administrator.



Regex on Singular Group Value

Choose this option to have AppDynamics extract group mapping values using a regular expression. Regular expressions enable you to pull group values from unstructured contexts, such as from within a larger string, as in the following response example:

```
<saml:AttributeStatement>
   <saml:Attribute Name="Groups-Membership" NameFormat="urn:oasis:names:tc:SAML:2.0:attrname-format:basic">
   <saml:AttributeValue xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:type="xs:string">User
memberships in _Admin_ and _DBManager_ groups.</saml:AttributeValue>
   </saml:Attribute>
</saml:AttributeStatement>
```

In this example, the group names `_Admin_` and `_DBManager_` are embedded in the `AttributeValue` string. To extract those names, you can use a regular expression such as `_[a-zA-Z]_`. Like other types of group attribute sources, AppDynamics assigns all roles associated with both the `_Admin_` an d `_DBManager_` SAML Groups, as in this sample configuration:

SAML Group Mappings

SAML Group Attribute Name: Groups-Membership

Group Attribute Value:

- ○ Singular Group Value
- ○ Multiple Nested Group Values
- ○ Singular Delimited Group Value
- ◉ Regex on Singular Group Value: _[a-zA-Z]+_

☐ Value is in LDAP Format

Mapping of Group to Roles

SAML Group	AppDynamics Roles
GuestUser	User, Dashboard Viewer
DBManager	DB Monitoring Administrator, DB Monitoring User, User, Dashboard Viewer
Admin	Account Administrator, Analytics Administrator, Administrator, Server Monitoring Administrator, User, Server...
Default Permissions	Dashboard Viewer, Workflow Executor, DB Monitoring User, Server Monitoring User, Synthetic Notification U...

Encrypt SAML Responses

This page provides instructions on configuring encryption for SAML responses.

You can improve the security of the SAML authentication by encrypting the SAML response from the IDP to the service provider (your Controller). Your Controller shares a public key with the IDP and stores a private key to decrypt the public key.

You must be an Account Owner to configure the Controller to accept encrypted SAML responses.

Install OpenSSL

You will need to install the cryptography and SSL/TLS toolkit OpenSSL to generate the private key and certificate required for encrypting SAML responses.

Generate an x509 Certificate

1. Generate a private key:

```
openssl genrsa -out privatekey.pem 2048
```

2. Convert the private key into `pkcs8` format:

```
openssl pkcs8 -in privatekey.pem -topk8 -nocrypt -out privatekey.p8
```

3. Generate a certificate from the private key:

```
openssl req -new -x509 -key privatekey.pem -out ssocert.pem
```

Enable SAML Encryption

After you generate the private key in `pkcs8` format and the x509 certificate:

1. From your Controller, navigate to **AppDynamics > Administrator > Authentication Provider > SAML**.
2. Check **Enable** for **SAML Encryption**.

Add the Encrypted Certificate and the Private Key to the Controller

You must add the generated x509 certificate so that it can be shared with the IDP. You must also provide the private key so that the Controller can decrypt the SAML response from the IDP.

1. In the **SAML Encryption Certificate** text area, paste the content of your x509 certificate between the sections `-----BEGIN CERTIFICATE-----` and `-----END CERTIFICATE----:`

```
-----BEGIN CERTIFICATE-----
// Insert x509 certificate content here
-----END CERTIFICATE----
```

2. In the **SAML Encryption Key** text area, paste the content of your p8 key file between the sections `-----BEGIN PRIVATE KEY-----` and `-----END PRIVATE KEY-----`:

```
-----BEGIN PRIVATE KEY-----
// Insert p8 key content here
-----END PRIVATE KEY-----
```

3. Click **Save**.

Configure IDP to Encrypt Response

Each IDP requires a different configuration for encrypting responses. Follow this high-level procedure:

1. From your IDP, enable SAML encryption. In some IDPs, this is known as *assertion encryption*.
2. Select an encryption algorithm. You can select any encryption method, and some IDPs will choose one for you.
3. Upload the x509 certificate that you generated in Generate an x509 Certificate.

Verify SAML Responses Are Encrypted

If you have enabled encryption for SAML in your Controller and the SAML responses from your IDP are not encrypted, your Controller will reject the SAML authentication when using SAML authentication to log in to your Controller.

To verify that the SAML response is encrypted:

1. Sign in to your Controller using the SAML flow from the service provider (your Controller) described in Verify the SAML Authentication Configuration.
2. From the Networks tab of the developer console of your browser, find the network request similar to the following, where `<controller_domain_name>` is the domain name of the machine hosting your on-premises Controller, and `<account_name>` is your AppDynamics account name.

   ```
   http://<controller_domain_name>:8090/controller/saml-auth?accountName=<account_name>
   ```

3. Select this network request and locate the parameter `SAMLResponse` in the response. You should see a long hash representing the encrypted SAML response:

   ```
   SAMLResponse=PD94bWwgdmVyc2lvbj0iMS4wIiBlbmNvZGluZz0iVVRGLTgiPz48c2FtbDJwOlJlc3BvbnNlIERlc3RpbmF0aW9uPSJodHRwOi8vZWMyLTU0LTIxMi0wLTIxNi51cy13ZXN0LTIuY29tcHV0ZS5hbWF6b25hd3MuY29tOjgwODA]gRm9yb...
   ```

4. You can decode and inflate the encrypted SAML response with the `base64` command-line utility or an online tool:

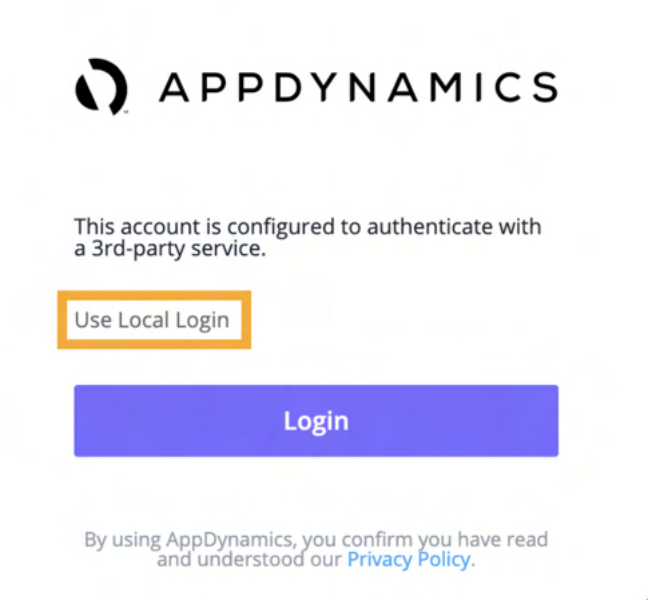
   ```
   base64 --decode
   SAMLResponse=PD94bWwgdmVyc2lvbj0iMS4wIiBlbmNvZGluZz0iVVRGLTgiPz48c2FtbDJwOlJlc3BvbnNlIERlc3RpbmF0aW9uPSJodHRwOi8vZWMyLTU0LTIxMi0wLTIxNi51cy13ZXN0LTIuY29tcHV0ZS5hbWF6b25hd3MuY29tOjgwODA]gRm9yb...
   ```

   If your SAML Response was encrypted, the decoded and inflated string should contain the SAML XML response.

Disable SAML Authentication

This page provides instructions on disabling SAML authentication.

1. Navigate to your Controller and click **Use Local Login**.



2. Enter your local credentials and click **Login**.
3. From the Controller UI, navigate to **Administration > Authentication Provider**.
4. Select **AppDynamics** as the Authentication Provider
5. Click **Save**.

User Preferences

This page provides an overview of user preferences in AppDynamics. Controller UI users can change their passwords, account settings, date and time format, and other preferences in the **My Preferences** page.

User Preferences

You can access the controls for changing your display name, contact email, or password from the **My Preferences** page by clicking the **Edit** link under your email. The controls require you to enter your password to complete the change.

The display name is the name that the Controller uses to identify you in specific screen text and messages. For example, it appears in notifications to other Controller users when you share a dashboard with them. You cannot change your username. To change your username, you need to have an administrator delete your account and create another one with the new name.

You can display non-English languages in the Controller UI. To do so, enable your font preference to use system fonts. Using system fonts directs the UI to display text in the font configured for the system running the browser.

Some user account settings are attributes of local users (that is, users validated against credentials stored in AppDynamics). If your Controller is configured to use an external authentication mechanism instead, such as SAML or LDAP, you need to change the equivalent settings in the external system instead.

Strong Passwords

Your Controller administrator may require strong passwords for local accounts. A secure password must meet these requirements:

- At least eight characters in length
- Contain both uppercase and lowercase letters
- Include at least one number
- Not the same as your username or email address

View Preferences

The Controller UI provides the following user preferences:

- **Date Format**: By default, the format is MM/DD/YY (for example, 09/25/14). Choose an alternate format from the dropdown.
- **Use 24-Hour Time Format**: Enable this option if you want the UI to represent time in 24-hour time format instead of 12-hour clock format.
- **Enable Help Pop-ups**: Help popups provide contextual help text in the Controller UI. By default, they are enabled. To prevent help popups from appearing in the UI, clear this checkbox. Alternatively, you can prevent individual popups by selecting the **Don't Show Again** checkbox when the popup appears. To clear the list of popups marked as *Don't Show Again*, click **Reset All**.

You may need to log out of the UI and log back in to see the effects of your changes.

Advanced User Preferences

The user preferences page presents advanced options that include debug mode.

Debug Mode

The debug mode in the Controller UI is primarily intended for internal use by the AppDynamics development team. In some cases, you may be asked to enable debug mode when consulting with AppDynamics Support, for example, when you are troubleshooting an issue. However, it is important to note that specific debug mode options can negatively impact Controller performance. For this reason, you should only enable debug mode when directly advised to do so by AppDynamics Support.

AppDynamics Licensing

On this page:

Related pages:

- License Entitlements and Restrictions
- License Management in the Controller

There are two licensing models for AppDynamics products:

- Infrastructure-based Licensing - new model launched February 23, 2021
- Agent-based Licensing - original model

Infrastructure-based Licensing Model

The Infrastructure-based Licensing model offers license packages for Application Performance Monitoring (APM), End User Monitoring (EUM), Application Analytics, and security. Each package includes a combination of AppDynamics Agents and is based on a single metering unit. Because each agent can pull from a single metering unit, Infrastructure-based Licensing can support diverse applications and provide better license usage estimates.

This table shows how licenses in the Infrastructure-based Licensing model bundle multiple AppDynamics products.

Monitoring Types	AppDynamics Product	Infrastructure-based Licensing Packages						
		Enterprise	Premium	Infrastructure Monitoring	Real User Monitoring Peak	Real User Monitoring Pro	Log Analytics Pro	Secure Application
Application Monitoring	Application Performance Monitoring	✓	✓					
	Server Visibility	✓	✓	✓				
	Network Visibility	✓	✓					
	Database Monitoring	✓	✓					
	Transaction Analytics	✓						
End User Monitoring	Real User Monitoring (Browser and Mobile RUM)*				✓	✓		
	Real User Monitoring Analytics*				✓			
Log Analytics	Log Analytics*						✓	
Security	Secure Application*							✓

Additional information:

- *Real User Monitoring (and RUM Analytics), Log Analytics, and Secure Application licenses are available outside the Infrastructure-based Licensing Model.
- For Infrastructure-based Licensing package entitlements, restrictions, and definitions, see License Entitlements and Restrictions.
- If you have an Infrastructure-based Licensing license and Controller >= 21.2.0, you have a new UI to manage licenses in the Controller. See the Infrastructure-based Licensing tab on License Management in the Controller.

Agent-based Licensing Model

If you purchased AppDynamics licenses before February 23, 2021, you most likely have licenses in the Agent-based Licensing model. Agent-based Licensing is the original model in which each AppDynamics agent is licensed and metered individually.

Additional information:

- For Agent-based Licensing license entitlements, restrictions, and definitions, see License Entitlements and Restrictions.
- If you have an Agent-based Licensing license, you have the original UI to manage licenses in the Controller. See the Agent-based Licensing tab on License Management in the Controller.

License Entitlements and Restrictions

This page describes AppDynamics license entitlements, restrictions, and definitions.

License Entitlements in the Infrastructure-based Licensing Model

The table below describes license packages and package editions within the Infrastructure-based Licensing model. For information on the Infrastructure-based Licensing model, see Licensing.

License	Entitlements
Application Performance Monitoring	
Enterprise	• Monitoring for servers, supported application languages, networks, and databases instrumented with AppDynamics for up to 1 CPU Core • Access to the AppDynamics Events Service • Event Service data retention is limited to 8 days • Transaction Analytics for Enterprise: Instrument up to 400,000 business transaction events per 24-hour period and access to the AppDynamics-hosted Events Service, with a data maximum of 50 GB per account per day for the following product types: AppDynamics for Java, .NET, and Node.js. Data retention limited to 8 days. Additional retention of 30, 60, or 90 days is available as an add-on. • See entitlements for Premium package

Premium	• Monitoring for servers, supported application languages, networks, and databases instrumented with AppDynamics for up to 1 CPU Core
	• See entitlements for:
	  • APM Any Language
	  • Network Visibility
	  • Database Visibility
	  • Infrastructure Monitoring package

Infrastructure Monitoring	• Monitoring for servers instrumented with AppDynamics for up to 1 CPU Core
	• See entitlements for:
	  • Server Visibility (SIM mode)
	  • Machine Agent (MA, MA+ mode)
	  • Cluster Agent
	  • .NET Machine Agent

Security	
AppDynamics with Cisco Secure Application	• Monitoring for supported applications languages instrumented with AppDynamics for up to 1 CPU Core • See entitlement for: • Java
End User Monitoring	
Real User Monitoring (SaaS) - Peak Edition	• One unit of Real User Monitoring (SaaS) • Access to Analytics functionality for Browser Real User Monitoring (SaaS) • Access to Analytics functionality for Mobile Real User Monitoring (SaaS)
Real User Monitoring (on-prem) - Peak Edition	• One unit of Real User Monitoring (on-prem) • Access to Analytics functionality for Browser Real User Monitoring (on-prem) • Access to Analytics functionality for Mobile Real User Monitoring (on-prem)

Real User Monitoring (SaaS) - Pro Edition	• 10,000,000 RUM Tokens • Access the AppDynamics-hosted EUM Cloud and AppDynamics-hosted Events Service. • See entitlement for Browser Real User Monitoring (SaaS) • See entitlement for Mobile Real User Monitoring (SaaS)
Real User Monitoring (on-prem) - Pro Edition	• 10,000,000 RUM Tokens • See entitlement for Browser Real User Monitoring (on-prem) • See entitlement for Mobile Real User Monitoring (on-prem)

License Entitlements in the Agent-based Licensing Model

The table below describes licenses and license editions within the Agent-based Licensing model. For information on the Agent-based Licensing model, see Licensing.

License	Entitlement
Application Performance Monitoring	
APM Any Language / AppDynamics for Java, .NET or Node.js (SaaS) - Peak Edition	• One unit of APM Any Language / AppDynamics for Java, .NET or Node.js (SaaS); and • One unit of Transaction Analytics (SaaS); and • One unit of Network Visibility; and • One unit of Server Visibility
APM Any Language / AppDynamics for Java, .NET or Node.js (on-prem) - Peak Edition	• One unit of APM Any Language / AppDynamics for Java, .NET or Node.js (on-prem); and • One unit of Transaction Analytics (on-prem); and • One unit of Network Visibility; and • One unit of Server Visibility
APM Any Language Microservices (SaaS) - Peak Edition	• The same entitlement as 5 APM Any Language (SaaS) units, restricted to use with the following: Docker Containers, all CloudFoundry-based providers, Redhat OpenShift, Heroku Dyno, Microsoft Azure App Services (including Azure WebApps, Azure WebJobs and Azure API Apps), Microsoft Azure Functions hosted on a Microsoft App Service plan, Microsoft Azure Service Fabric, Microsoft Azure Containers, Amazon Elastic Beanstalk, Oracle PaaS (Java and Node.js only) and Bluemix Containers; and • One unit of Transaction Analytics (SaaS); and • One unit of Network Visibility; and • One unit of Server Visibility
APM Any Language Microservices (on-prem) - Peak Edition	• The same entitlement as 5 APM Any Language (on-prem) units, restricted to use with the following: Docker Containers, all CloudFoundry-based providers, Redhat OpenShift, Heroku Dyno, Microsoft Azure App Services (including Azure WebApps, Azure WebJobs and Azure API Apps), Microsoft Azure Functions hosted on a Microsoft App Service plan, Microsoft Azure Service Fabric, Microsoft Azure Containers, Amazon Elastic Beanstalk, Oracle PaaS (Java and Node.js only) and Bluemix Containers; and • One unit of Transaction Analytics (on-prem); and • One unit of Network Visibility; and • One unit of Server Visibility
SAP Bundle (SaaS) - Peak Edition	• One unit of SAP - ABAP Agent; and • One unit of Datavard Insights; and • One unit of Transaction Analytics (SaaS); and • One unit of Network Visibility; and • One unit of Server Visibility

SAP Bundle (on-prem) - Peak Edition	• One unit of SAP - ABAP Agent; and • One unit of Datavard Insights; and • One unit of Transaction Analytics (on-prem); and • One unit of Network Visibility; and • One unit of Server Visibility
APM Any Language - Advanced Edition	• One unit of APM Any Language (on-prem or SaaS as applicable); and • One unit of Network Visibility; and • One unit of Server Visibility
APM Any Language Microservices - Advanced Edition	• The same entitlement as 5 APM Any Language (on-prem or SaaS as applicable) units, restricted to use with the following: Docker Containers, all CloudFoundry-based providers, Redhat OpenShift, Heroku Dyno, Microsoft Azure App Services (including Azure WebApps, Azure WebJobs and Azure API Apps), Microsoft Azure Functions hosted on a Microsoft App Service plan, Microsoft Azure Service Fabric, Microsoft Azure Containers, Amazon Elastic Beanstalk, Oracle PaaS (Java and Node.js only) and Bluemix Containers; and • One unit of Network Visibility; and • One unit of Server Visibility
APM Any Language - Pro Edition	One license unit from the following product types: Java, .NET, Node.js, PHP, Python, Web Server, C++, Go, IBM Integration Bus, or the rights to monitor 16 Value Units of IBM Mainframe capacity.
APM Any Language Microservices (5pack) - Pro Edition	The same entitlement as 5 APM Any Language units, restricted to use with the following: Docker Containers, all CloudFoundry-based providers, Redhat OpenShift, Heroku Dyno, Microsoft Azure App Services (including Azure WebApps, Azure WebJobs and Azure API Apps), Microsoft Azure Functions hosted on a Microsoft App Service plan, Microsoft Azure Service Fabric, Microsoft Azure Containers, Amazon Elastic Beanstalk, Oracle PaaS (Java and Node.js only) and Bluemix Containers.
Java Agent - Pro Edition	Instrument a single JVM instance; snapshots are retained for 14 days unless archived
Java Microservices - Pro Edition	Instrument a single JVM instance with a heap allocation less than or equal to 1 GB Note: This entitlement shall only apply to existing customers of AppDynamics for Java Microservices that have licensed a SKU for AppDynamics for Java Microservices. This entitlement is mutually exclusive with the entitlement to use AppDynamics for Any Language licenses.
.NET Agent - Pro Edition	• Instrument an unlimited number of CLRs, including .NET web applications, .NET Windows services, and .NET standalone apps, on a single Windows OS instance; snapshots are retained for 14 days unless archived • For APM Any Language Microservices, instrument an unlimited number of CLRs on a single instance of an application • For .NET on Microsoft Azure for Cloud Services, instrument an unlimited number of CLRs running in a single instance of a Microsoft Azure Web role or Worker role
PHP Agent - Pro Edition	Instrument a single PHP runtime instance; snapshots are retained for 14 days unless archived
Node.js Agent - Pro Edition	Instrument up to 10 Node.js processes per OS instance; snapshots are retained for 14 days unless archived
Python Agent - Pro Edition	Instrument an unlimited number of Python processes running on a single OS instance; snapshots are retained for 14 days unless archived
Web Server Agent - Pro Edition	Instrument an unlimited number of Apache Web Server instances on a single OS instance; snapshots are retained for 14 days unless archived
C++ Agent - Pro Edition	Instrument an unlimited number of C++ runtime applications on up to 3 OS instances using the software development kit; snapshots are retained for 14 days unless archived Instrument an unlimited number of Ruby runtime applications on up to 3 OS instances using the Ruby agent; snapshots are retained for 14 days unless archived
Go Agent - Pro Edition	Instrument up to 3 Go processes; snapshots are retained for 14 days unless archived. This is available as part of the APM Any Language license only.

SAP - ABAP Agent - Pro Edition	Instrument a single application server
IBM Integration Bus - Pro Edition	Instrument an unlimited number of IBM Integration Bus processes on 1 OS instance. This is available as part of the APM Any Language license only.
Universal Agent - Pro Edition	Deploy on a single instance of an OS
Datavard Insights - Pro Edition	Instrument a single application server
Debugging	
AppDynamics Deep Code Insights, powered by Rookout	Application debugging support for one license unit of AppDynamics APM Any Language, configured for the following product types only: AppDynamics for Java, .NET, Node.js, PHP, Python.
Infrastructure Visibility	
Machine Agent - Pro Edition	Instrument a single instance of an OS
Server Visibility - Pro Edition	Instrument a single instance of an OS Monitor a single Kubernetes cluster
Network Visibility - Pro Edition	Instrument an unlimited number of Java nodes on a single instance of an OS
Service Availability Monitoring - Pro Edition	Instrument 60 HTTP-based services
Database Visibility - Pro Edition	Monitor one Database Instance of the following*: Couchbase Server, IBM DB2, Microsoft SQL Server, MySQL, PostgreSQL, Sybase ASE, Sybase IQ, Oracle. Monitor one Microsoft Azure SQL database or one Microsoft Azure SQL Managed Instance. Monitor one MongoDB replica set (or, if no replica sets exist, one standalone MongoDB instance). *For clustered database products (e.g. Couchbase or Oracle RAC), monitor one Database Instance per node of the cluster. When multiple Database Instances are grouped together under a single Collector using the Collector/Sub-Collector configuration, licensing is per Database Instance as above. Event Data is retained for 10 days for each Database Instance monitored by AppDynamics for Database Visibility.
AppDynamics for NetApp (on-prem) - Pro Edition	Monitor one NetApp controller for the following NetApp controller types: FAS2nnn and FAS3nnn. Monitor ½ NetApp controller for the following NetApp controller types: FAS6nnn and FAS8nnn series; two license units are required to monitor a full NetApp controller of series FAS6nnn or FAS6nnn. Event Data is retained for 14 days by default for each NetApp controller monitored by a unit of AppDynamics for NetApp (on-prem).
Application Analytics	
Browser Analytics (SaaS)	Access to Analytics functionality for Browser Real User Monitoring (SaaS). Access to AppDynamics-hosted EUM Cloud and AppDynamics-hosted Events Service. For Browser Real User Monitoring data storage and retention entitlements, see details under “Browser Real User Monitoring (SaaS)”

Browser Analytics (on-prem)	Access to Analytics functionality for Browser Real User Monitoring (on-prem). Customer is not entitled to access the AppDynamics-hosted EUM Cloud or AppDynamics-hosted Events Service. For Browser Real User Monitoring data storage and retention entitlements, see details under “Browser Real User Monitoring (on-prem)”
Mobile Analytics (SaaS)	Access to Analytics functionality for Mobile Real User Monitoring (SaaS). Access to AppDynamics-hosted EUM Cloud and AppDynamics-hosted Events Service. For Mobile Real User Monitoring data storage and retention entitlements, see details under “Mobile Real User Monitoring (SaaS)”
Mobile Analytics (on-prem)	Access to Analytics functionality for Real User Monitoring (on-prem). Customer is not entitled to access the AppDynamics-hosted EUM Cloud or AppDynamics-hosted Events Service. For Mobile Real User Monitoring data storage and retention entitlements, see details under “Mobile Real User Monitoring (on-prem)”
Log Analytics (SaaS)	Publish/index 5 GB of log data per 24-hour period (limited to 8 days of data storage) and access the AppDynamics-hosted Events Service. Additional retention beyond 8 days can be purchased as an add-on.
Log Analytics (on-prem)	Publish/index 5 GB of log data per 24-hour period (default data storage is 8 days and available up to 90 days). Customer is not entitled to access the AppDynamics-hosted Events Service.
Transaction Analytics (SaaS)	Instrument up to 1,000,000 business transaction events per 24-hour period and access to the AppDynamics-hosted Events Service, with a data maximum of 50 GB per account per day for the following product types: AppDynamics for Java, .NET, and Node.js. Data retention limited to 8 days. Additional retention of 30, 60, or 90 days available as an add-on.
Transaction Analytics (on-prem)	Instrument up to 1,000,000 business transaction events per 24-hour period (limited to 90 days of data storage) per license unit. Customer is not entitled to access the AppDynamics-hosted Events Service.
End User Monitoring	
Browser Real User Monitoring (SaaS) - Peak Edition	One unit of Browser Real User Monitoring (SaaS) and one unit of Browser Analytics (SaaS)
Browser Real User Monitoring (on-prem) - Peak Edition	One unit of Browser Real User Monitoring (on-prem) and one unit of Browser Analytics (on-prem)
Mobile Real User Monitoring (SaaS) - Peak Edition	One unit of Mobile Real User Monitoring (SaaS) and one unit of Mobile Analytics (SaaS)
Mobile Real User Monitoring (on-prem) - Peak Edition	One unit of Mobile Real User Monitoring (on-prem) and one unit of Mobile Analytics (on-prem)
Browser RUM (SaaS) - Pro Edition	• Instrument 10 Million Pageviews per 12-month period following the license provision date • Access to the AppDynamics-hosted EUM Cloud and AppDynamics-hosted Events Service • Raw page requests, sessions, and resources are retained as Event Data with a default limit of 100 GB per account per day for each Event Data type. • AppDynamics reserves the right to drop customer traffic if the foregoing limitation is exceeded by the end user. • Customers may also choose to store raw Ajax or other events requests as Event Data if they also have access to Analytics, and every 5 requests stored consumes one Pageview. Event Data is retained for 8 days. • Additional retention of Event Data for 30, 60 or 90 days is available as an add-on at additional cost, and requires the purchase of AppDynamics Browser Analytics (SaaS). Resource Performance data is retained for 6 days.

Browser RUM (on-prem) - Pro Edition	Instrument 10 Million Pageviews per 12-month period; raw page requests and sessions are retained as Event Data. Customers may also choose to store raw Ajax or other events requests as Event Data, and every 5 requests stored consumes one Pageview. Event Data is retained for 8 days by default. Customer is not entitled to access the AppDynamics-hosted EUM Cloud or AppDynamics-hosted Events Service.
Mobile RUM (SaaS) - Pro Edition	Instrument 5,000 Active Agents per calendar month and access the AppDynamics-hosted EUM Cloud and AppDynamics-hosted Events Service. In addition, for each Active Agent unit, 500 events per day of the following types are stored on the event service as Event Data: network requests, sessions, breadcrumbs and custom data. Crash reports are retained for 365 days and all other Event Data is retained for 8 days. Additional retention of Event Data for 30, 60 or 90 days is available as an add-on at additional cost, and requires the purchase of AppDynamics Mobile Analytics (SaaS).
Mobile RUM (on-prem) - Pro Edition	Instrument 5,000 Active Agents per calendar month. In addition, for each Active Agent unit, 500 events per day of the following types are stored on the event service as Event Data: network requests, sessions, breadcrumbs and custom data. Crash reports are retained for 365 days and all other Event Data is retained for 8 days by default. Customer is not entitled to access the AppDynamics-hosted EUM Cloud or AppDynamics-hosted Events Service.
Browser Synthetic Monitoring - Hosted Agent (SaaS) - Pro Edition	40,000 units of 5-second Synthetic Time Blocks on AppDynamics' hosted synthetic network per calendar month, and use Business Performance Monitoring features on the synthetic Events Data, if applicable, which is retained for 13 months. Each run of a synthetic job is rounded up to the next 5 seconds. Unused time is not rolled over to the following month. Customer is entitled to access the AppDynamics-hosted EUM Cloud or AppDynamics-hosted Events Service, both of which are required to use this product.
Browser Synthetic Monitoring - Private Agent - Per Location (SaaS) - Pro Edition	Run a synthetic job that hits 1 page from 1 location (multiple units add together to run jobs that hit multiple pages from multiple locations), and use Business Performance Monitoring features on the synthetic Events Data, if applicable, which is retained for 13 months. A job that fails to hit any pages is counted as 1 page. Customer is entitled to access the AppDynamics-hosted EUM Cloud or AppDynamics-hosted Events Service, both of which are required to use this product.
Browser Synthetic Monitoring - Private Agent - Unlimited Locations (SaaS) - Pro Edition	Run a synthetic job that hits 1 page from any number of locations, and use Business Performance Monitoring features on the synthetic Events Data, if applicable, which are retained for 13 months. Customer is limited to 500,000 Pageviews per calendar month period. Unused Pageviews are not rolled over to the following month. A job that fails to hit any pages is counted as 1 page. Customer is entitled to access the AppDynamics-hosted EUM Cloud or AppDynamics-hosted Events Service, both of which are required to use this product.
Browser Synthetic Monitoring - Private Agent - Per Location (on-prem) - Pro Edition	Run a synthetic job that hits 1 page from 1 location (multiple units add together to run jobs that hit multiple pages from multiple locations), and use Business Performance Monitoring features on the synthetic Events Data, if applicable, which is retained for 13 months. A job that fails to hit any pages is counted as 1 page. Customer is not entitled to access the AppDynamics-hosted EUM Cloud or AppDynamics-hosted Events Service.
Browser Synthetic Monitoring - Private Agent - Unlimited Locations (on-prem) - Pro Edition	Run a synthetic job that hits 1 page from any number of locations, and use Business Performance Monitoring features on the synthetic Events Data, if applicable, which are retained for 13 months. Customer is limited to 500,000 Pageviews per calendar month period. Unused Pageviews are not rolled over to the following month. A job that fails to hit any pages is counted as 1 page. Customer is not entitled to access the AppDynamics-hosted EUM Cloud or AppDynamics-hosted Events Service.
IoT for Connected Devices (SaaS) - Pro Edition	Instrument 1,000 application instances that are embedded on a connected device (or multiple devices) per calendar month and access to the AppDynamics-hosted Events Service, with a data maximum of 50 GB per account per day. Only customers with at least 100,000 application instances that are (i) embedded on a connected device (or multiple devices), (ii) eligible to be instrumented AppDynamics for IoT and (iii) are actively in use by customer's end users shall be entitled to use AppDynamics for IoT. AppDynamics for IoT is only available to AppDynamics SaaS customers. An "eligible" application instance is an application that can be instrumented using AppDynamics' C/C++ SDK, Java SDK or AppDynamics Rest APIs (each for IoT). Event Data is retained for 8 days. Additional retention of Event Data for 30, 60 or 90 days is available as an add-on at additional cost.

License Restrictions

The table below describes license restrictions that are applicable to all products.

Category	Restriction

Third-party components	License restrictions with respect to any third party components included in the AppDynamics software, with which customers are required to comply, are located on the Legal Notices page.
Compatibility	Compatibility limitations with respect to any third party components are located on the Supported Environments page.
Use of MySQL database(s)	Customers are prohibited from using the MySQL database(s) included with the AppDynamics software with any other product or for any other purpose other than for the AppDynamics software as provided.
Machine and Universal Agents	Each unit of the products in the Application Performance Management includes one unit of Machine Agent and Universal Agent at no cost, but such Machine Agent and Universal Agent shall only be used on the instance of the OS being monitored by the purchased unit.
APM Peak Edition	AppDynamics for Java, .NET or Node.js : During the License Term of the Subscription Licenses (or, if applicable, during the Maintenance and Support Term of perpetual licenses) on the applicable Order Form, End User may, once per calendar quarter and upon 24 business hours' written notice, exchange licenses among the following types of Software units: AppDynamics Pro Edition for Java, .NET and Node. js on a one-for-one basis, and separately AppDynamics Test & Dev Edition (each an “Exchangeable Group”) for the same products on a one-for-one basis. For clarity, the list prices of all products within each Exchangeable Group (Pro Edition and Test & Dev Edition, respectively) are the same and through such exchanges, End User may not at any time use products with cumulative value exceeding the total list price of products on the applicable Order Form.
APM Any Language	APM Any Language customers are prohibited from instrumenting APM Any licenses on SAP application servers unless such customer has purchased the requisite AppDynamics for SAP - ABAP Agent(s).
EUM Peak Edition	Browser or Mobile RUM: During the License Term of the Subscription Licenses (or, if applicable, during the Maintenance and Support Term of perpetual licenses) on the applicable Order Form, End User may, once per calendar quarter and upon 24 business hours' written notice, exchange licenses among the following types of Software units: AppDynamics Pro Edition for Browser Real User Monitoring and Browser Analytics for units of Mobile Real User Monitoring and Mobile Analytics on a one-for-one basis (and vice versa), and separately AppDynamics Test & Dev Edition for the same products (and vice versa) on a one-for-one basis. End User may not exchange any AppDynamics for Browser Real User Monitoring licenses during any year in which End User has used any pageviews of such licenses. For clarity, the list prices of all products within each Exchangeable Group (Pro Edition and Test & Dev Edition, respectively) are the same and through such exchanges, End User may not at any time use products with cumulative value exceeding the total list price of products on the applicable Order Form.
Upgrades	Upgrade entitles the customer to the entitlement of the product to which the customer is upgrading.
Standard University Subscription	Customers that have purchased any of the software listed below under the heading "Application Performance Management" shall be entitled to access the AppDynamics University Self-Paced Library, subject to the conditions set forth in this paragraph. No greater than 20 unique users per month per AppDynamics account are entitled to this access. Access shall be limited to customers that have purchased this software either (i) on a subscription basis but remain current on payment of all subscription license fees, if any or (ii) on a perpetual basis but remain current on payment of all maintenance and support fees, if any. Customers may log in using AppDynamics account credentials.

Data Storage and Retention Entitlements

Deployment	Entitlement
SaaS	• Metric Data in one-minute increments are retained for 8 days • Metric Data in one-hour increments are retained for 365 days • Event Data is retained for 8 days ⓘ For the Enterprise package, additional retention of 30, 60, or 90 days is available as an add-on.
On-Premises	• Metric Data in one-minute increments are retained for 4 hours • Metric Data in ten-minute increments are retained for 48 hours • Metric Data in one-hour increments are retained for 365 days • Event Data is retained for 8 days, except that retention for on-premises deployments is configurable

License Entitlement Definitions

- **Active Agent**: A unique installation of an application instrumented with an AppDynamics Mobile Real User Monitoring Agent that was launched on a device in a given calendar month
- **Database Instance**: A complete running database environment, including the software, table structure and other functionality. Typically this corresponds to a host/port combination where the port is the listener port for the database software. Database administrators might create multiple database environments on the same physical hardware, with each such environment having its own unique listener port.
- **Dedicated Controller**: A version of the central repository and analytics engine component of the Software where End User’s data is logically separated from that of other customers
- **EUM Cloud**: The end user monitoring component that receives and processes data received from end user devices

- **Event Data**: The raw data generated by the Software and stored in the Events Service
- **Events Service**: The component that stores the Event Data
- **GB**: gigabyte
- **Instrument**: To collect data, monitor, troubleshoot and manage using the AppDynamics software
- **Metric Data**: The aggregate value of the data collected by the Software over a given period of time
- **Pageview**: A Pageview is an instance of a base page, virtual page, or iFrame loaded by a web browser. Each base page view, iframe view, and virtual page view is counted as a Pageview. Repeated views of one page are counted as separate Pageviews.
- **RUM Token**: The common unit of measure for consumption of Real User Monitoring products during each 12 calendar month period in a License Term, with the first such period beginning on the start date of the relevant License Term; one Pageview consumes one RUM Token, and deployment of one Active Agent consumes 160 RUM Tokens.
- **CPU Core**: Each logical thread core or processor reported by the operating system on a unique instance of a physical or virtual host machine and detected by AppDynamics. Where AppDynamics cannot detect CPU Core counts on a host, AppDynamics will calculate the licensed CPU Cores on a per-Agent basis as follows:

    - The quantity of APM Agents deployed multiplied by 4; and
    - The quantity of Database Agents deployed multiplied by 12 per unique database host

License Management in the Controller

Related pages:

- License Entitlements and Restrictions
- Licensing

This page describes how to manage licenses in the Controller.

In the Controller, you can view and manage license usage and create rules for APM licenses. The Controller UI differs based on what license you have. The instructions below are separated between two licensing models: Infrastructure-based Licensing and Agent-based Licensing. To find out what license you have, see License Entitlements.

License Best Practices and Troubleshooting

This page describes best practices and troubleshooting for AppDynamics licenses. The information is organized by licenses model: Infrastructure-based Licensing and Agent-based Licensing. To learn about the licensing models, see Licensing.

Apply or Update a License File

For AppDynamics Pro trial installations and SaaS Controllers, the license is applied and installed automatically.

If you are using AppDynamics on-premises, you must manually apply the license file after installing the Controller. Whenever you purchase additional units, you must update the license file. If you update Application Analytics licenses in an on-premises environment, you may have to do some manual updates when you update your Controller license. See License Entitlements and Restrictions.

Apply a License

1. Copy the license file to the Controller installation directory (typically found within {controller_home}/platform/product/controller/). After copying the file, allow up to five minutes for the license change to take effect.

   If the license has not been detected after five minutes, try the following:

   - Linux: Execute the following command:

     ```
     touch license.lic
     ```

   - Windows: Replace the license file again.

2. To verify that the license file is applied, check that the license you purchased appears in the **Peak Usage** tab of the **License** page.

Apply a License to a Multi-Tenant Controller

If you are updating the license file for a multi-tenant Controller, you must manually edit the accounts to affect the change. For example, if you purchase an additional 200 licenses to distribute across two accounts, you must manually allocate those other units by updating each account.

1. Copy the license file to the Controller installation directory. After copying the license file, allow up to five minutes for the license change to take effect.
2. Log in with root user at `http://<controller_host>:<port>/controller/admin.jsp`.
3. Click **Accounts** and select the account you want to apply the license to.
4. Update the license expiration date and license units based on license.lic.
5. Save the changes.

Update a License

1. Rename your old license file to something other than license.lic (so that the Controller ignores it). After copying the license file, allow up to five minutes for the license change to take effect.

   If the license has not been detected after five minutes, try the following:

   - Linux: Execute the following command:

     ```
     touch license.lic
     ```

   - Windows: Replace the license file again.

2. To verify that your license file is applied, check that the license you purchased appears in the **Account Usage** tab of the **License** page.

Update License Rules

If you are using license rules, you must update them to account for the additional units you purchased after updating your license. For example, if you buy another 200 licenses to distribute across two license rules, you must manually allocate those additional units by updating the rules.

Update MAC Address

AppDynamics licenses for on-premises Controllers are tied to the machine's MAC address on which you installed the Controller. The original MAC address set up must be done by AppDynamics Operations when a new on-premises license is first provisioned. Afterward, you can update your MAC address manually.

You can change the MAC address up to twelve times within a 12-month period using these steps. If you need to change it again, contact the AppDynamics Licensing Team by emailing licensing-help@appdynamics.com.

To update the MAC address on a permanent license:

All License Admins that have access privileges for a permanent on-premises license can update MAC addresses. To view a list of these users, navigate to the **Subscriptions** page under **Account**.

1. Navigate to www.appdynamics.com.
2. Log in with your AppDynamics user credentials.
3. Ensure that your account is set up with **License Admin** permissions.
4. On the main navigation bar, click **Account >Subscriptions**.
5. Click the [Controller] **Name** or **Actions**.
6. Click **Edit** next to the MAC address.
7. Enter the new hexadecimal MAC address.
8. Click **Save**.

Sensitive Data Collection and Security

AppDynamics collects data on application performance, health, and resources, in addition to the application components (transactions, code libraries) and related infrastructure (nodes, tiers). Before deploying AppDynamics, you should ensure that your application is secure and does not expose sensitive data. This page describes how to prevent sensitive data collection in your application environment.

Prevent Sensitive Data Collection

If your environment contains sensitive data that should not be processed by an AppDynamics product or sent to the AppDynamics SaaS environment, you should avoid:

- Applications that transmit sensitive data in URL query parameters
- Enabling HTTP request parameter capture
- Enabling bind variable capture
- Applications that send sensitive data in error logs and log files
- Allowing method invocation data collection
- Log captures

If you do capture logs, ensure that you mask values in those logs. The following sections cover additional measures that you can take to ensure you do not expose sensitive data.

SaaS Deployment

AppDynamics supports encryption at rest in its SaaS deployments on personally identifiable information and sensitive business data.

On-premises Deployment

AppDynamics offers an on-premises solution for customers who want to maintain full control over their deployment of the software. With this type of implementation, AppDynamics has no access to the software or the data it collects and processes. Customers subject to strict regulatory requirements for data security may want to consider an on-premises solution. On-premises customers are responsible for encrypting their data by either using self-encrypting drives or other non-product solutions.

Role-based Access Control

You can use role-based access controls (RBAC) to limit the number of users who can access data collection features. The controls let you restrict a user's access to specific functions, data, analytics queries, and APIs.

You can control user access to data by specifying permissions for each user role. To configure user access, navigate to **Settings** > **Administration**. See Analytics and Data Security and Create and Manage Custom Roles.

Suppress Raw SQL Capture

Application Monitoring collects raw SQL as prepared statements captured with dynamic parameters bound to runtime values.

You can disable the capture of raw SQL if it contains sensitive data. When you disable raw SQL capture, the SQL call appears in its original form, but with question mark parameters in place of sensitive data.

To disable the capture of raw SQL for an application, navigate to **Configuration** > **Instrumentation** > **Call Graph Settings** > **SQL Capture Settings**. Uncheck **Capture Raw SQL**.

You can also disable bind variable capture. Bind variables are placeholders for literal data in your SQL statements. When you disable bind variable capture, the values of bind variables are not displayed. For more information, see Call Graph Settings.

Hide Query Literals

Database Visibility hides query literals by default since queries can contain sensitive user data.

To verify that query literals are hidden for a database, navigate to **Configuration**. In the Security section, ensure that you have chosen **Remove literals from the queries**. See Configure Query Literals Security.

You may also want to use bind variables as placeholders for literal data in your SQL statements.

Exclude Error Logs

Application Monitoring logs exceptions and errors that match parameters you specify in your custom logger. You may want to exclude sensitive payload data so that it does not show up in error logs.

To exclude a class in your application:

1. Navigate to **Tiers & Nodes** > **Actions** > **Configure App Server Agent**.
2. Select **Use Custom Configuration**.
3. Click (**+**) to create a new agent property.
4. Set the agent property name to exceptions-to-ignore.
5. Set the agent property value to the name of the class you want to exclude.

See Error Detection.

Mask Log Analytics Values

When configured, Application Analytics collects performance data from your app server agents, data from your log files, and performance and sessions data from End User Monitoring. You can mask sensitive information in your log analytics data.

To mask log analytics data:

1. Navigate to **Analytics** > **Configuration** > **Log Analytics** > **Source Rules**.
2. Click the source rule that you want to specify masking for.
3. In the Field Management tab, next to ThreadName, you can specify the starting and ending position of the data you want to mask, and the character to use as the masking value.

See Configure Log Analytics Using Source Rules.

Disable the Data Collector

You can suppress data collection of HTTP request payloads, raw SQL, and other user data.

For the Java Agent, configure the `disabled-features` node property in the Controller UI.

For the .NET Agent, edit the `config.xml` file and set the `disabled-features` property to the names of features that you want to disable.

```
<property name="disabled-features" value="RAW_SQL,LOG_PAYLOAD,METHOD_INV_DATA_COLLECTOR,HTTP_DATA_COLLECTOR,
CUSTOM_EXIT_SNAP_DATA"/>
```

See App Agent Node Properties Reference and .NET Agent Configuration Properties.

Filter Sensitive Data in Environment Variables

You can mask sensitive data found in Java environment variables and system properties. To mask sensitive data, add the `sensitive-data-filter` property to app-agent-config.xml. The valid attributes are `applies-to`, `match-type`, and `match-pattern`. See Filter Sensitive Data.

Data Privacy Policy Dialog

Data collection has regulatory, legal, and customer-defined policies that you must follow. AppDynamics provides a data privacy policy reminder, in the form of a UI dialog, when you or your users configure parts of the AppDynamics products that could be used to collect regulated or other protected information.

This customizable statement is present in all areas of the AppDynamics UI where you can configure data collection. AppDynamics displays a default message if you have not made any customizations.

AppDynamics logs an event when it displays the data privacy policy dialog to you or another user.

Data Collection Dashboard

This page describes the Data Collection Dashboard, which displays all collected and processed data by AppDynamics.

About the Data Collection Dashboard

AppDynamics allows you to customize most data configurations. Due to the various AppDynamics agent types and products, you can change the configuration in many different places. This flexibility can make it challenging to keep track of all of your settings.

The Data Collection Dashboard addresses this challenge by providing a single, easy-to-access view of the current state of all of your configuration parameters that may affect your organization's security and privacy. The Data Collection Dashboard should help you understand what data AppDynamics is collecting for your configured application instance at any point in time.

The unified view is only available to admins.

To view the Data Collection Dashboard, click **Settings**  **> Data Collection Dashboard**.

The dashboard provides a read-only view. You can change the configuration values in the respective places of the platform.

You can find online help for a data collector type. To do so, navigate to **Applications**, choose an application, and then click **Configuration > Instrumentation > Data Collectors**. Click **Help**  in the data collector box of interest to view more information on that particular data collector and how to configure it.

You can click **Export** to save a raw JSON file of the selected data collection settings and share with non-admins, auditors, and sales.

Data Collector Types

This table lists all of the data collector types that you can view on the Data Collection Dashboard.

Data Collector Type	Description
Agents Logging Session	Agents Logging Sessions log information with a specific type of logging information, such as application configuration changes, metric data, and system agent registrations.
Agents Metadata Default Config	Agents Metadata Default Configs collect app agents transaction metadata.
Browser Settings Config	Browser Settings Configs collect Browser RUM and Synthetic metrics.
Custom Data Browser	Custom Data Browsers customize the agent to collect custom metrics for the browser.
Custom Data Mobile	Custom Data Mobiles customize the agent to collect custom data types such as information points, custom timers, and custom metrics.
DB Collector	Database Collectors run within the Database Agent to collect performance metrics about your database instances and servers.
DB Security Config	Database Security Configs collect literals, which can contain sensitive user data, retrieved from the database.
EUM Settings Config	EUM Settings Configs collect EUM metrics, custom data, and Analytics data.
GUID Injection	GUID Injections correlate logs and transaction analytics data to specific business transaction requests.
HTTP Request	HTTP Requests capture the URLs, parameter values, headers, and cookies of HTTP messages exchanged in a business transaction.
Information Points	Information Points reflect the data state across all invocations of a method, independently of business transactions.
Log Analytics Source Rule	Log Analytics Source Rules log data sources using job files to collect log analytics data.
Method Invocation	Method Invocations capture code data, such as method arguments, variables, and return values.
Mobile Settings Config	Mobile Settings Configs collect Mobile RUM metrics.
SIM HTTP User Service Config	SIM HTTP User Service Configs collect Standalone Machine Agent data using HTTP listeners.
SQL Data Collector	SQL Data Collectors collect the business data from SQL parameters for use in transaction analytics.

Metrics and Graphs

This page describes metrics and graphs in AppDynamics.

AppDynamics reports metrics for monitored systems over time. The Controller provides a variety of graphs and tools that visualize metric data so you can effectively analyze your application's performance.

Metric Visualization Tools

While metric data appears throughout the Controller, the Metric Browser is the main interface for you to inspect metrics. The Metric Browser displays all the metric values collected over the selected time period as an expandable tree.

In the browser, you can drag and drop metrics from the tree onto graphs to compare metrics and analyze patterns.

Metrics

AppDynamics includes a wealth of metrics that reflect your application's performance. It also lets you extend and adapt metrics in specific ways. Information points, for example, allow you to create metrics based on data collected from application values, such as method parameters or return values. Percentile metrics let you configure metrics at deviation points that are useful to you.

You can create a metric from any application parameter using custom metrics. See Extensions and Custom Metrics for information on custom metrics.

Metric Browser

This page describes how the Metric Browser provides a metrics-oriented view of the monitored environment for a selected time period.

In the Metric Browser, you can see metrics by nodes, business transactions, the overall application, and more. You can also compare two or more metrics and view metrics relative to a baseline. Use this tool when you want to drill into and analyze the details for a specific metric.

1. Click **Metric Browser**.
2. Expand a metric group and double-click an option for that metric to display in the graph. Add multiple metrics in the same manner to compare them.
3. Mark the checkbox for the type of data you want to see for each metric.
4. Select **Filters** ( ) and choose how you want to view data:
    - **Show Tiers / Nodes with performance data** to show entities and metrics for live entities over the specified time range.
    - **Show Tiers / Nodes with no performance data** to show metrics/entities of entities that are not alive over the specified time range.
    - Select both checkboxes to show metrics and entities without checking the liveness of entities.
5. Select **Plot Points** to enable the plot points on the graph line.
6. Select a **Scale** option to adapt the scale of the y-axis unit according to the values in the graph.

To remove a single metric from the graph, click **X** or click **Clear** at the top of the metric browser to remove all metrics.

Metric Data Point Details

For most types of metrics in the browser, you can click any of the points in the graph to view more information about the metric observed at that point in time. The information shown includes the metric identifier, date and time of the observation and any of the following values relevant to the metric:

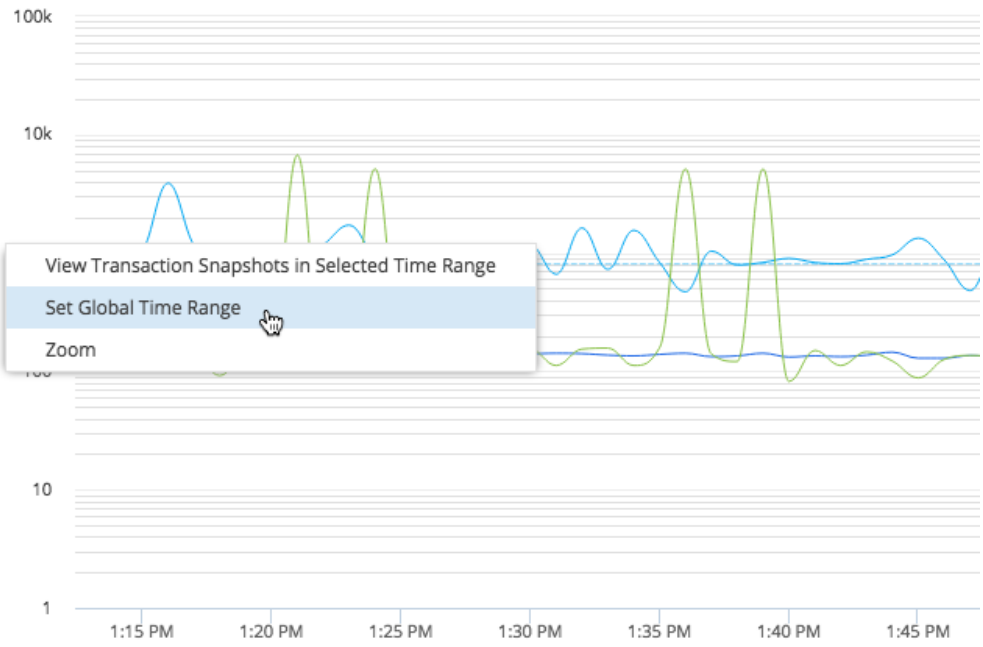
- **Obs**—The observed average of all data points seen for that interval. For the Percentile Metric for the App Agent for Java, this is the percentile value. For a cluster or a time rollup, this represents the weighted average across nodes or over time.
- **Min**—The minimum data point value for that interval.
- **Max**—The maximum data point value for that interval.
- **Sum**—The sum of all data point values for that interval. For the Percentile Metric for the App Agent for Java, this is the result of the percentile value multiplied by the Count.
- **Count**—The number of observations aggregated in that one point. For example, a count of five indicates that there were five one-minute data points aggregated into one point.
- **Base**—The baseline data for the metric. See Viewing Metrics Relative to Baselines.

By selecting the checkbox that corresponds to the metric information at the bottom of the graph, such as Min, Max, Count, or Sum, you can graph that information for the metric over the time range shown in the browser. Checkboxes for only the types of information relevant to the metric can be selected.

> For node-level metrics only, min and max values are available for any count- or sum-based metrics and for when the metric is rolled up to hourly or daily data points. Min and max values are not visible for tier- and application-level metrics. Count- and sum-based metrics include errors per minute, calls per minute, and so on.

Analyze Performance for a Time Range

Once you identify a time frame of interest in the metric browser, you may want to see snapshots in that time range. To analyze snapshots during a time range in the browser, click and hold the start of the time range in the graph and drag to the end of the time range. Release to view the **Time Range** pane.

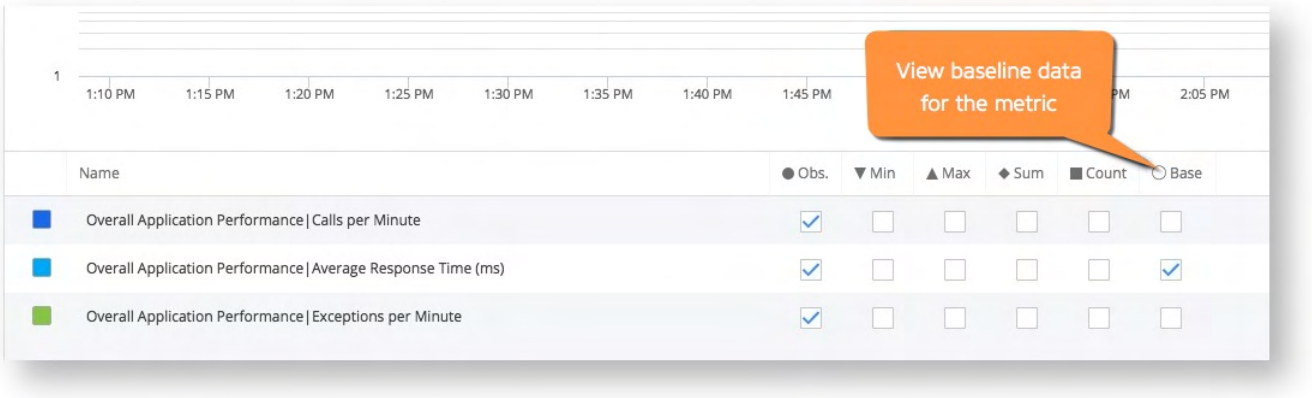


If you do not see a metric in the browser, you can add certain metrics by editing node properties. See App Agent Node Properties.

View Metrics Relative to Baselines

You can see how data in the Metric Browser compare to baseline values. Monitoring baseline deviation exposes performance metrics that might be violating your Service Level Agreements (SLAs). See Dynamic Baselines.

To display baseline patterns, select the baseline option for the metric in the view options for the metric.



Export Metric Data

You can export metric data that is currently displayed to a comma-separated values (CSV) file.

Exported data includes all the data displayed, even if there is a time range selected. To export data only for a specific time range, first set a global time range and then export.

To export all data:

1. Select **Actions** > **Export Data**.
2. In the popup, you can either copy the data to your clipboard or click **Export Data** to download the data as a CSV file.

To export data for an individual metric in the graph, click **Download** at the bottom of the graph.

Metric Data Resolution over Time

You can view metrics in the Controller for different time intervals or resolutions.

Metric Generation and Time Zone Differences

In a distributed system, the metrics that the Controller collects may come from different time zones.

Before sending metrics to the Controller, agents normalize the times associated with the metrics by applying a UTC (Coordinated Universal Time) offset appropriate to their region.

In the Controller UI, all times display in the Controller user's local time. To render local times, the UI applies the offset needed to render UTC time into the user's time zone as configured on the device on which the browser is running.

While the time zone used in the UI is taken from the local environment and cannot be modified apart from changing the computer's system time, each UI user can adjust the format of the time display, as described in User Preferences.

While the Controller UI displays times in the local system time, specific timestamps generated by AppDynamics reflect the Controller system time. These include, for example, event timestamps in notification messages, which indicate the Controller system time.

> SaaS Controllers use Pacific Time (PT) as their system time.

Metrics Data Resolution

Metrics Data Retention and Deletion

View Rolled Up Data in Graphs

Depending on your environment, AppDynamics measures hundreds, thousands, or even tens of thousands of metric values each minute. To display these results over time in a meaningful way, AppDynamics rolls up the data at regular intervals (for example, at one-minute, ten-minute, and one-hour intervals) based on how long ago the metric was measured.

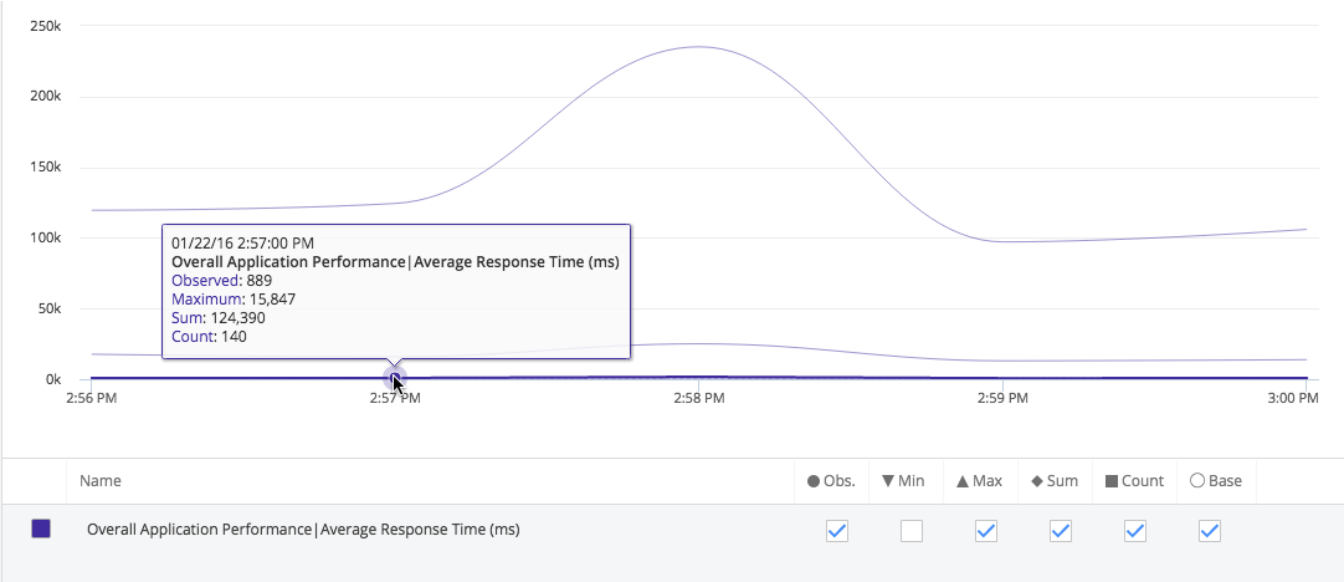
In graphs throughout the Controller UI, you can hover over a point on the chart to get the value of the metric data measured during the interval represented by the point. The point represents the beginning of the interval. The length of the interval depends on the selected time range. Admin-level users can adjust the amount of time data is retained at each resolution, although we do not generally recommend keeping data for longer than these default values. Default settings are listed below.

Rolled Up Data in Graphs

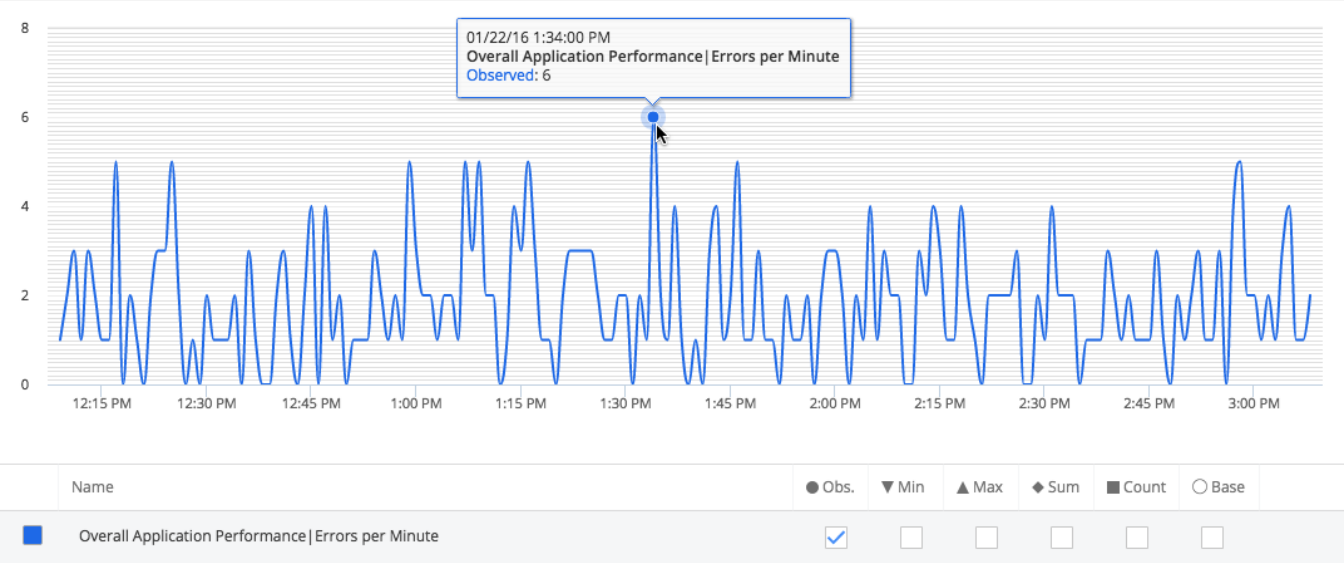
One-Minute Resolution

Each point on the graph represents a roll-up of all the values measured during one minute. For example, if AppDynamics measures the response time for an application for 300 calls in a minute, the response time values of those 300 calls are averaged to present the Average Response Time (ART) for that minute. When you hover over a point on the chart, the Count figure represents how many times the metric data was measured during that minute.

In this graph, response time was measured 140 times between 2:57 and 2:58 PM and the ART for that minute was 889 ms.



In this chart, the time range was set for the last three hours, so the interval is one minute. The errors per minute value displayed at the 1:34 PM point represents the number of errors recorded during the minute from 1:34 PM to the millisecond just before 1:35 PM.



Ten-Minute Resolution

Metric data is displayed at a 10-minute resolution, and each point on the graph represents a roll-up of the values measured during that 10-minute period.

The ART for the rolled-up time period represents the true average. The ART aggregates the sum and count of the total requests for the period; it does not average the ARTs calculated for the previous roll-up granularity.

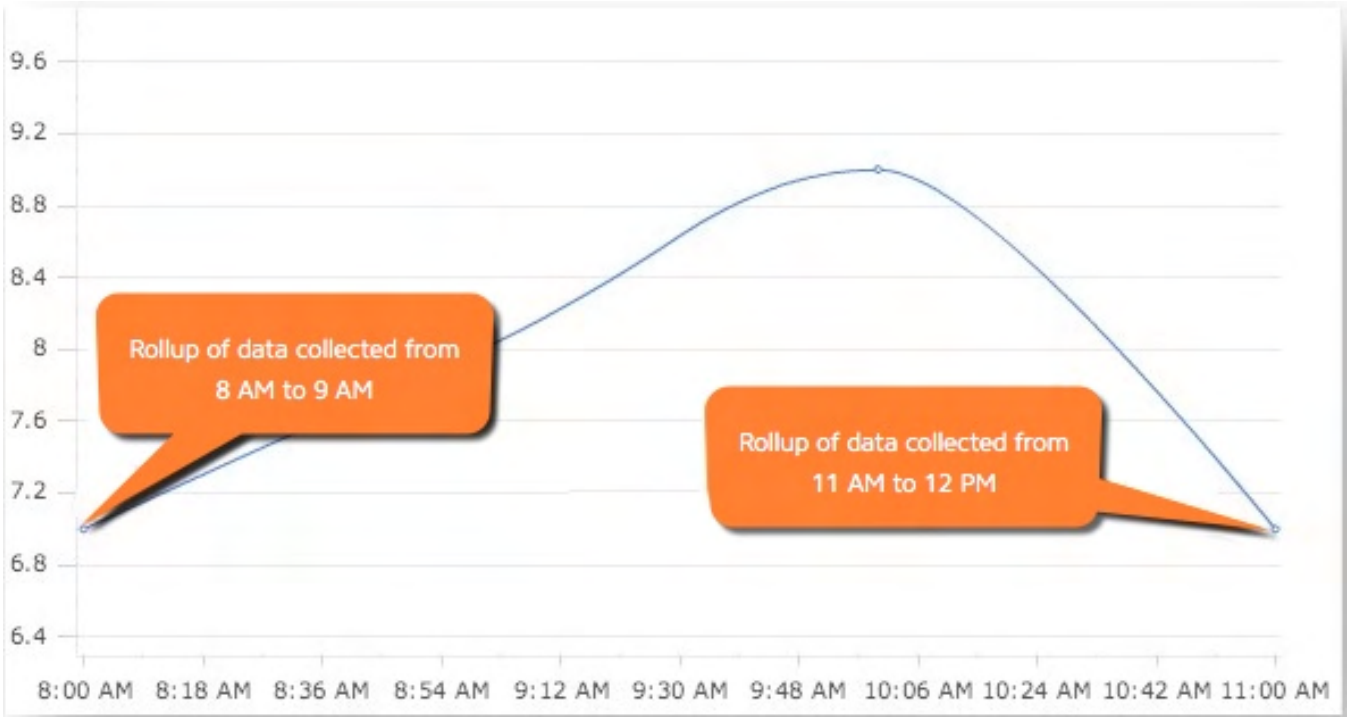
One-Hour Resolution

Metric data is displayed at a 1-hour resolution, and each point on the graph represents a roll-up of the values measured during that 60-minute period.

How the Last Interval Displays in a Chart

Because of the way rolled-up data displays, it may appear as if data is not included for the last increment in the time range. However, the last data point represents the last interval in the range.

For example, when you set a time range from 8 AM to 12 PM for a day that has been rolled up into 1-hour data points, you might expect to see five data points, one for 8 AM, 9 AM, 10 AM, 11 AM, and 12 PM. However, the returned data consists of four data points for the hours 8 AM, 9 AM, 10 AM, and 11 AM. The first data point, 8:00 AM, represents data collected from 8 AM to the millisecond just before 9 AM. The last data point, 11:00 AM, represents data collected from 11 AM to the millisecond just before 12 PM. So you are actually seeing data from 8 AM to 12 PM, even though the last data point in the graph is 11 AM.



View Charts for Long Time Ranges

For time ranges that are greater than three weeks, graphs in the UI such as the Slow Transaction graph show the 14th of each month as the time point on the x-axis. For a time range that is less than two full months, this means that the graph may only have a single point, the middle of the month encompassed by the time range.

View Details about Older Data

To review details for an issue that occurred during a period for which you have only 10-minute or 1-hour data, AppDynamics provides access to diagnostic data through Transaction Snapshots. For example, suppose you were seeing values for 2 AM and 3 AM three days ago, but you need to examine details about a problem you were alerted about that occurred at 2:15 AM that morning. You view Transaction Snapshots for the hour between 2 AM and 3 AM to see details about what happened during that time period. By default, snapshots are retained for two weeks, and individual snapshots can be archived. See Transaction Snapshots.

If you are viewing a graph in the Metric Browser, you can select a specific period in the chart and drill down to see Transaction Snapshots and other information. See Analyzing Performance for a Specific Time Range.

Percentile Metrics

This page describes percentile metrics and how to modify default percentile collection.

A percentile is a value below which a given percentage of measurements in a set falls. For example, a 95th percentile value of 150 ms means that 95% of all values are 150 ms or less. See Quick Tour of Percentile Metrics for Java.

Disable Percentile Metric Collection

The Java Agent and the .NET Agent capture percentile metrics by default. You can disable percentile metric collection in the Configure Percentile Metrics panel on the **Configuration > Slow Transaction Thresholds** page. Alternatively, manually setting the disable-percentile-metrics node property to `True` prevents the agent from collecting percentile metrics.

Specify Percentiles to Collect

By default, app agents capture the 95th percentile. You can indicate 5 whole numbers between 1 and 99 as Percentiles to Collect on the **Configuration > Slow Transaction Thresholds** page. You can apply the configuration changes to all existing business transactions or only to new transactions discovered after the configuration change.

Modify the Percentile Metric Algorithm

The agent uses one of the following methods to calculate percentile metrics:

- P Square algorithm (default): This option consumes the least amount of storage and incurs the least amount of CPU overhead. The accuracy of the percentile calculated varies depending on the nature of the distribution of the response times. You should use this option unless you doubt the accuracy of the percentiles presented.
- Quantile Digest algorithm: This option consumes slightly more storage and CPU overhead for the machine where the agent is running, but may offer better percentiles depending on how the response times are distributed.

To adjust the algorithm option, set the App Agent Node Property to percentile-method-option.

Monitor Events

Related Pages:

- Create a Custom Event
- Transaction Thresholds
- Virtual War Rooms

This page describes event monitoring in AppDynamics.

In the AppDynamics model, events represent a change in the state of a monitored application. An event can represent an error/exception generated by the application, the crossing of a performance threshold, or an operational change in the application (such as a JVM restart).

You can use events to investigate application issues underlying performance problems. You can define policies that generate notifications or perform actions when an event occurs. See Alert and Respond.

View and Monitor Events

You can view and analyze events in the Controller UI. From the Database Visibility, Server Visibility, or user experience application pages in the UI, you can view events by clicking **Events** from the left navigation tree.

> The Controller displays a subset of the types of events generated in AppDynamics. You can access additional event types through the REST API. See AppDynamics APIs.

To view events for application monitoring:

1. Navigate to **Events** on any business application, business transaction, tier or node dashboard to view events generated in the selected time frame.
2. Click **Filters** and select the type of event to display.
3. Review information about an event
   If the event is an application change, such as an application restart, the details contain a description of the event.
   If the event is a slow transaction or an error, the details are transaction snapshots from which you can drill down to the root cause of the problem.
4. From the **Event Details** dialog, right-click an event to start a war room, delete or archive the event, or test action execution.

Archive Events

An event is purged after two weeks, at which point it is no longer accessible. To save an event beyond the default snapshot lifespan for future analysis, you can archive the event.

Event Purging in Ephemeral Environments

Events associated with nodes that are deployed to machine instances in an ephemeral environment are subject to being purged. This occurs because the node associated with the events is identified by a label consisting of two discrete parts: a node name and a machine instance name. The node name is always fixed, but the machine instance name changes in ephemeral environments. Thus, when a node is redeployed to a new machine instance, the label identifying the node changes.

For example, the label for a node in an ephemeral environment might consist of the fixed node name `"Node1"` and the machine instance name `"INSTANCE-M-T1": NodeINSTANCE-M-T1`. When the node is redeployed to another machine instance, the label for the node could change because of the new machine instance to something such as "Node1INSTANCE-M-T2". If this occurs, the events associated with the first label `"NodeINSTANCE-M-T1"` could potentially be purged later.

Events Archived by Default

AppDynamics archives application configuration change events by default. In the Controller UI, these events display as **Application Configuration Change**. You can view the `APPLICATION_CONFIG_CHANGE` event type in the Controller UI or retrieve it with the AppDynamics REST APIs.

> Once `APPLICATION_CONFIG_CHANGE` events are archived or deleted, you can no longer retrieve them through the AppDynamics REST APIs.

Manually Archive Events

To manually archive events:

1. Select the event from the events list.
2. Click **Actions > Archive Event**.
3. Click **Archive** to confirm the action.

This indicates that an event has been archived. You can click the column heading to sort by archived events.

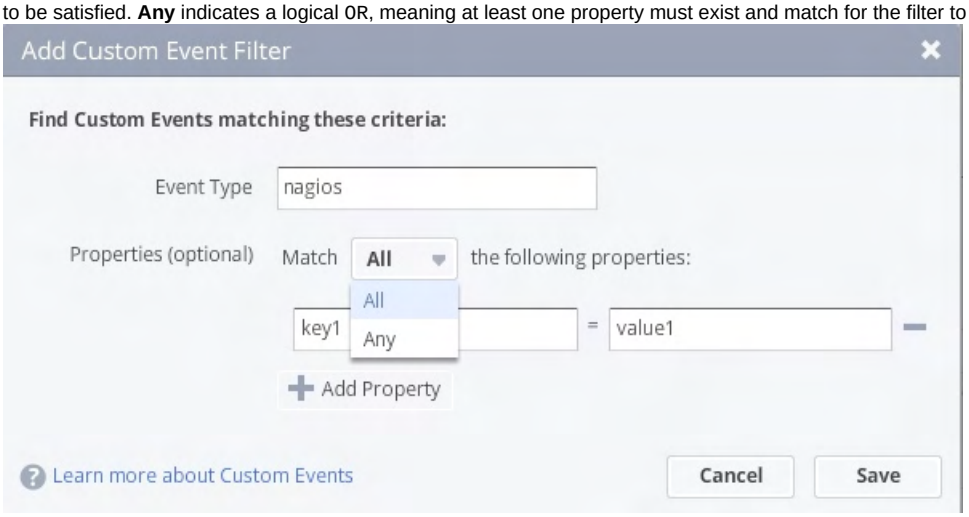
Modify Event Retention Period (On-Premises Controllers)

For on-premises Controllers, administrators can modify the default two-week period by configuring the events.retention.period property in **Administration > Controller Settings**.

Filter Custom Events

The AppDynamics REST API enables you to define custom events. You can then filter on those events by creating a custom filter:

1. Open the filter options on the **Events** page.
2. Navigate to **Filter by Custom Events** and click **Add Property** (**+**).
3. In the **Add Custom Event Filter** dialog, enter the name of the custom event type.
4. Optionally, specify filtering event properties as key/value pairs. The custom event needs to contain the property values you specify to satisfy the filter. If you add multiple properties, a matching value of **All** applies an `AND` operator to the list, meaning all properties need to match for the filter to be satisfied. **Any** indicates a logical `OR`, meaning at least one property must exist and match for the filter to be satisfied.



Monitor Application Change Events

Related Pages:

- Policies
- Monitor Events

This page describes monitoring application change events.

When investigating an application error or poor performance, you may want to see whether any application changes occurred at the same time as the error or issue. AppDynamics automatically detects and reports common application change events, such as app server restarts or changes to application environment variables. You can supplement automatically detected change events with custom application change events generated through the Controller or the REST API.

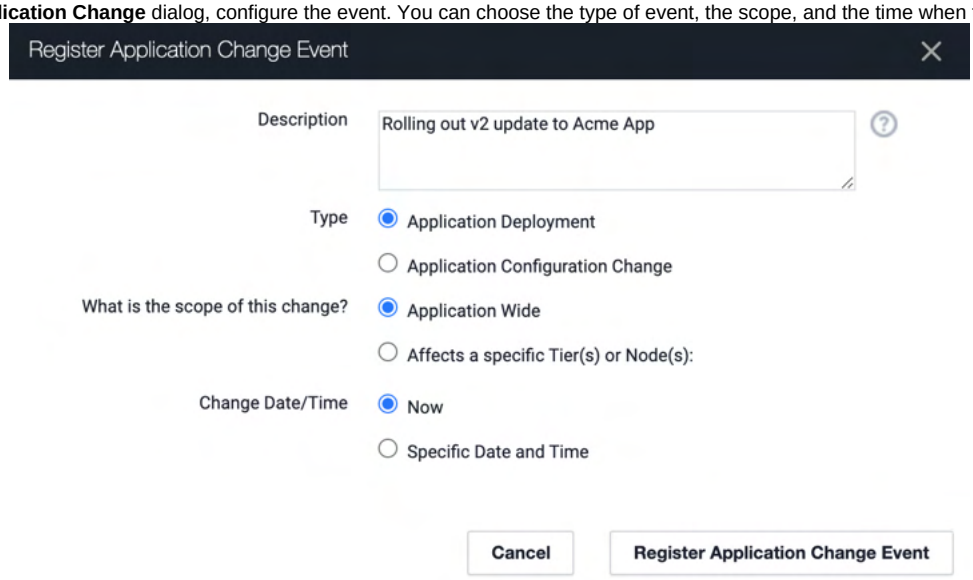
Application changes appear alongside other events in the Events List. Similar to other types of events, you can view details for the event by double-clicking the event or view the details in the context of other performance indicators. They can also serve as triggering conditions for policies.

Manually Register Application Changes

You can manually add an application change event to AppDynamics. This capability enables you to log a change event which might otherwise not be detected by AppDynamics. Controller users can then correlate the event to performance data. For example, you may want to create an event when you push an updated version of the application.

Create an Application Change Event Manually

1. From the **Events** page, expand the **Actions** menu and choose **Register Application Change Event**.
2. In the **Register Application Change** dialog, configure the event. You can choose the type of event, the scope, and the time when the event



should be registered.

3. Click **Register Application Change Event**. If **Now** is selected as the change time, the event appears in the events list immediately.
4. Double-click the event in the list to view more details about the event, including any actions triggered by the event as a result of a policy.

Automatically Register Application Changes

The AppDynamics REST API provides an alternative to creating application change events in the UI.

The API lets you automate event registration so that external systems can generate events based on their activities or conditions. For example, you can configure your release management system to generate an event in AppDynamics when it deploys an update to the application code, allowing you to correlate that event with application performance.

For information on creating a custom event through the REST API, see the Create a Custom Event method in AppDynamics APIs.

Correlate Application Changes with Other Events

You can view application changes in the context with other events and performance indicators in various Controller UI pages.

View Application Changes with Other Events in Transaction Score Histogram

1. In the Application Dashboard, click the Transaction Score tab.

2. Scroll down to the **Events** histogram.
3. Click **Add Criteria**.
4. From the dropdown, select **Event Types**.
5. Unselect all of the criteria except **Application Changes**.

Application change events appear in the **Events** histogram, where they appear in the context of other performance indicators.

Events Reference

Related pages:

- Monitor Events
- AppDynamics APIs

This page lists these types of events generated in AppDynamics:

- Event types that are common to the platform, such as UI, configuration, and licensing-related events
- Events generated by the alert and response system
- Application monitoring events

Information on event types that are specific to a platform module, if available, appears with the module-specific documentation. For example, Database Agent events are listed on Database Agent Events Reference.

Event types listed here that are not visible in the UI can be retrieved using the AppDynamics REST API.

ACTIVITY_TRACE

Description: The agent sent an internal event containing activity traces.
Activity traces enable the tracing of a code path that passes through a specified class/method. The App Agent for Java uses them to provide object instance tracking (OIT) and automatic leak detection (ALD)

Monitor Infrastructure

This page describes infrastructure monitoring in AppDynamics.

While business transaction performance is the main focus of a performance monitoring strategy, infrastructure performance provides additional insight into the underlying factors of business transaction performance. Infrastructure Visibility provides visibility into the underlying OS infrastructure and networks on which your applications run. These agents enable you to isolate, identify, and troubleshoot infrastructure problems that can affect application performance such as resource-hogging tiers.

AppDynamics provides preconfigured application infrastructure metrics and default health rules to enable you to discover and correct infrastructure problems. You can also configure additional persistent metrics to implement a monitoring strategy for your application architecture and business needs.

Additionally, you can view infrastructure metrics in the Metric Browser. **Correlation Analysis** and **Scalability Analysis** charts in the browser are useful for understanding how infrastructure metrics correlate to business transaction performance.

See Overview of Infrastructure Visibility.

Alert and Respond

Related Pages:

- Create and Manage Custom Roles
- Example Use Cases

This page describes the automated alert and response capabilities in AppDynamics.

Alert and Respond in AppDynamics

AppDynamics can generate notifications or invoke actions based on conditions or events you configure. Using the alert and respond feature, you can determine problems as they occur, or even before they occur.

Policies serve as central configuration artifacts for the alert and respond feature. A policy allows you to define the remedial actions that are invoked when one or more conditions are met or an event occurs. A health rule defines the performance condition or an event.

AppDynamics provides several pre-configured health rules that give you a head start to create your own health rules. You can also use built-in examples and customize them to match your application performance requirements. For example, the built-in health rules test for whether the *Business Transaction error rate is much higher than normal* or *CLR Garbage Collection Time is too high.* See Default Health Rules for more examples.

Actions automate the response to an event, such as, sending an alert, or performing diagnostic, or performing remediation actions. See Alert and Respond API to learn how to create custom URLs for notifications.

> Notification actions that use email or SMS and email digests require that the SMTP server be configured for the Controller. See Enable an Email Server.

Email digests generate email messages about the conditions and events in a system based on a pre-defined schedule.

Permissions

Different users with different roles typically set up and use the various alert and respond features. Some permissions can be granted at the account level and some can be granted at the application or even the tier level.

Account Level Permissions

Alerting templates, Email templates, HTTP request templates, and Email/SMS configuration are account-level features. The scope for these features is the entire AppDynamics account and all the applications in that account. Users who have account-level roles that include the necessary permissions can create and manage account-level templates and configuration. These permissions belong to the predefined Account Owner role. The Account Owner can also create custom roles that include some of these permissions. For example, an account owner can create an email template manager role and assign that role to users, who can then create and modify email templates.

To create, manage, and configure these account-level features, you need the following permissions respectively:

- Configure Alerting Templates
- Configure Email Templates
- Configure HTTP Request Templates
- Configure Email / SMS

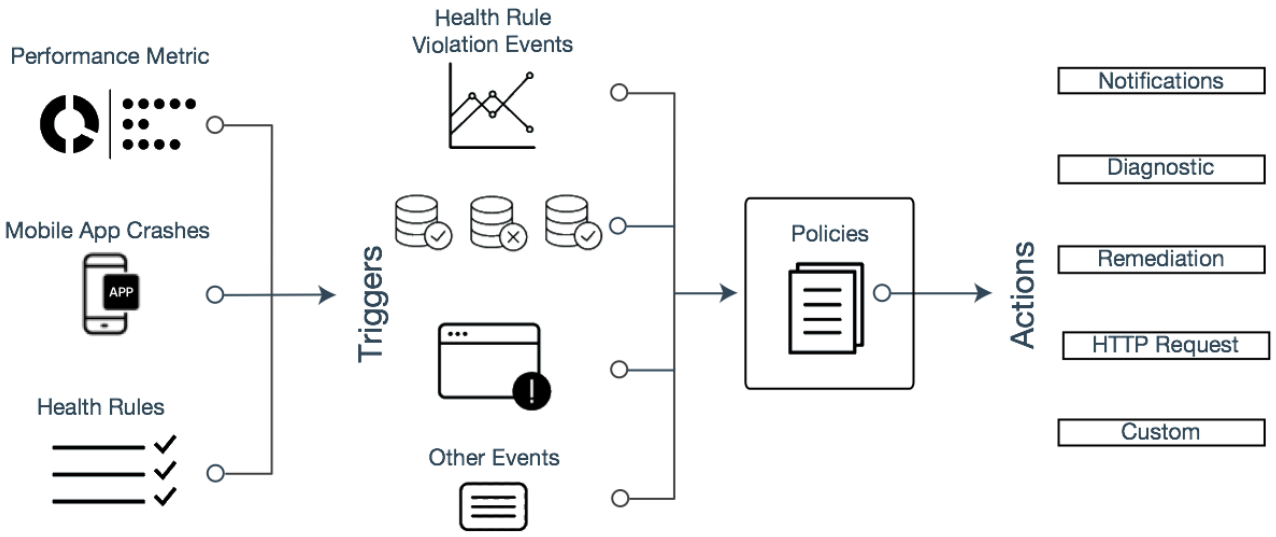
Application and Tier-Level Permissions

Policies, health rules, actions, and email digests are application-level or tier-level features. The scope of these features is the application or tier in which they were created. To create, manage, and configure these features, you need the following permissions respectively:

- Configure Policies: Create, edit or delete policies
- Configure Health Rules: Create, edit, or delete health rules
- Configure Actions: Create, edit, or delete actions on agent properties UI
- Configure Actions: Create, edit, or delete email digests

Alert and Respond Policy Structure

As shown in the following diagram, policies match event triggers with the action to be taken in response to those triggers.



Alert and Respond Across the Platform

The alert and respond features work across AppDynamics products, including Infrastructure Visibility, Analytics, EUM, and Application Monitoring. Unless otherwise noted, this section describes the features in the context of Application Monitoring, which, by its nature, offers the broadest range of configuration and use case options. Specific features as described may not apply to other AppDynamics products.

Additional usage notes include:

- Policy triggers for applications can be health rule violation events or other types of events. Policy triggers for databases and analytics must be health rule violation events.
- The types of actions that you can create for an application include notifications, diagnostics, remediation, HTTP requests, custom actions, and cloud auto-scaling. The types of actions that you can create for a database or analytics are limited to notifications, HTTP requests, and custom actions.
- The types of entities affected by a health rule are more limited for databases and analytics than for applications.
- For information on using policies triggered by browser synthetic events, see 'Alerting and Synthetics' in Browser Synthetic Monitoring.

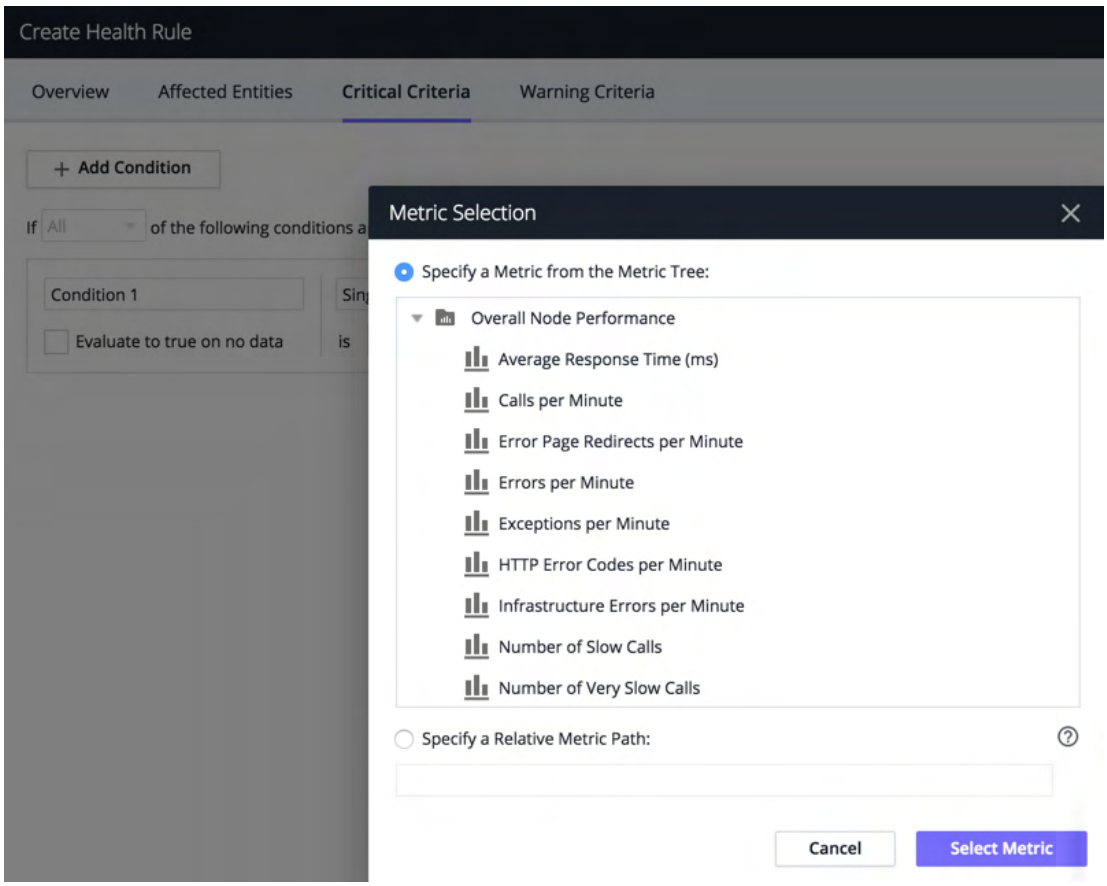
Example Use Cases

Related Pages:

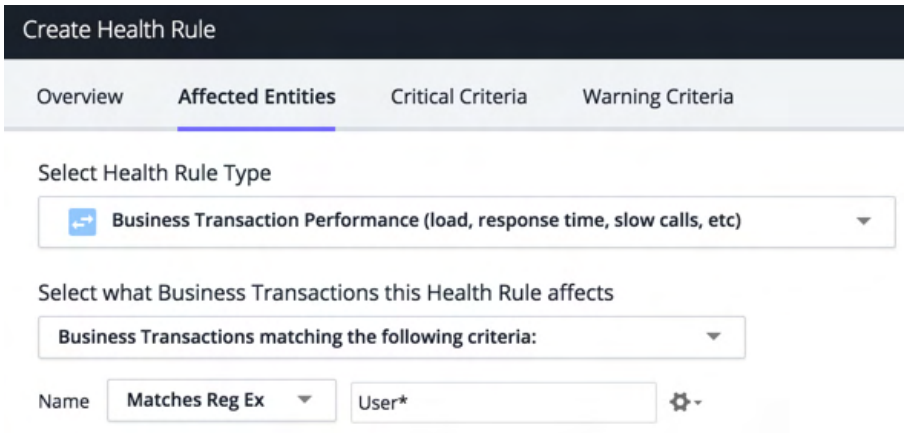
- Alert and Respond
- Policies
- Health Rules

This page provides use case examples for alert and response features:

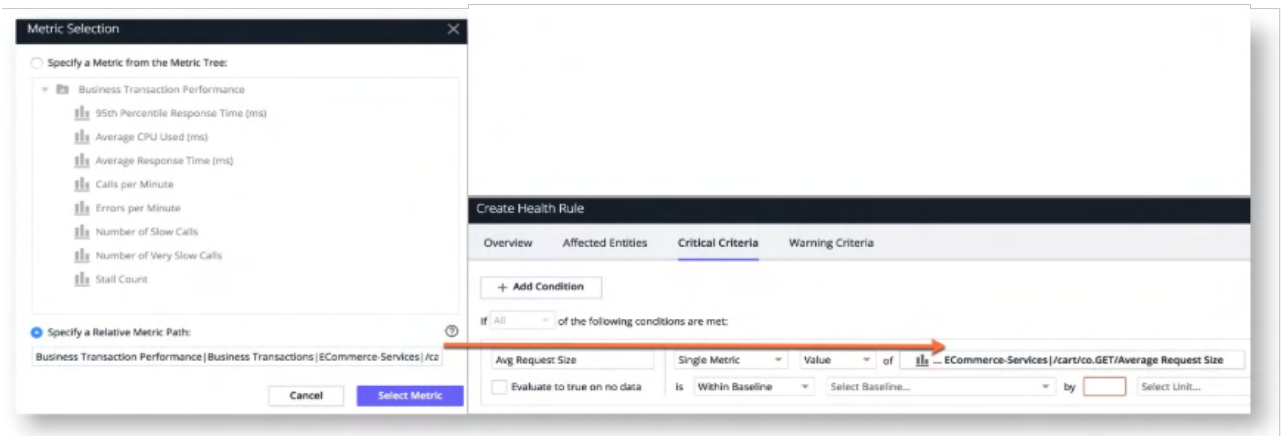
- Define health rules that apply to specific tiers or nodes. Instead of choosing specific nodes, you can trigger a rule when more than a certain percentage of nodes are unhealthy, say 20%.
- Start a diagnostic action for a business transaction.
- Alert when an app agent stops reporting to the Controller.
  Create a node health rule based on the value of the Availability metric reported by the agent. If Availability is less than one, the agent is not reporting.



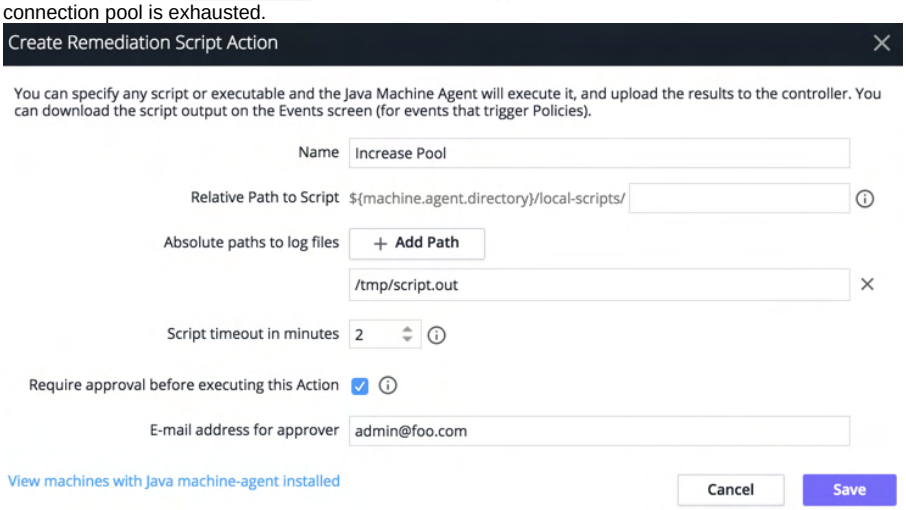
- Alert when the 95th percentile metrics for specific business transactions reach a certain value. You want to apply this rule only to business transactions with names beginning with *User*.



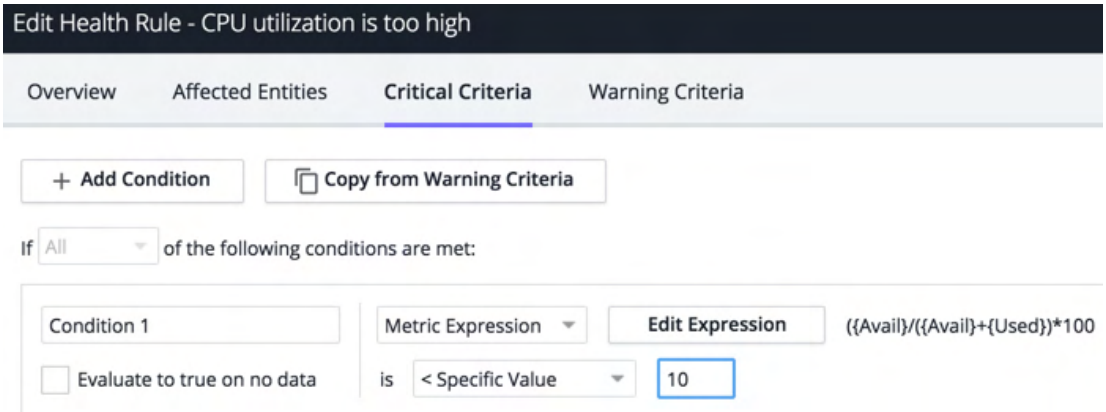
- You can generalize a health rule by specifying a relative metric path, rather than a specific metric. The health rule is evaluated for each of the affected business transactions. Use a relative metric path when you need to evaluate a single metric for multiple entities.



- You have a large operation with several development teams, each responsible for a different service. You create a health rule for one service and then copy it. Then create different policies in which you can pair each copy of the health rule to an alert addressed to the appropriate team.
- Start a script to change the size of the connection pool. You have an application that performs well for a normal load. However, peak loads can cause the application to slow. During peak load, the AppDynamics not only detects the connection pool contention but also allows you to create a remediation script that can automate increasing or decreasing the size of the connection pool. You can require human approval to run this script or just configure it to automatically execute when it is triggered. Create a runbook and associate it with a policy so that it will run when the connection pool is exhausted.

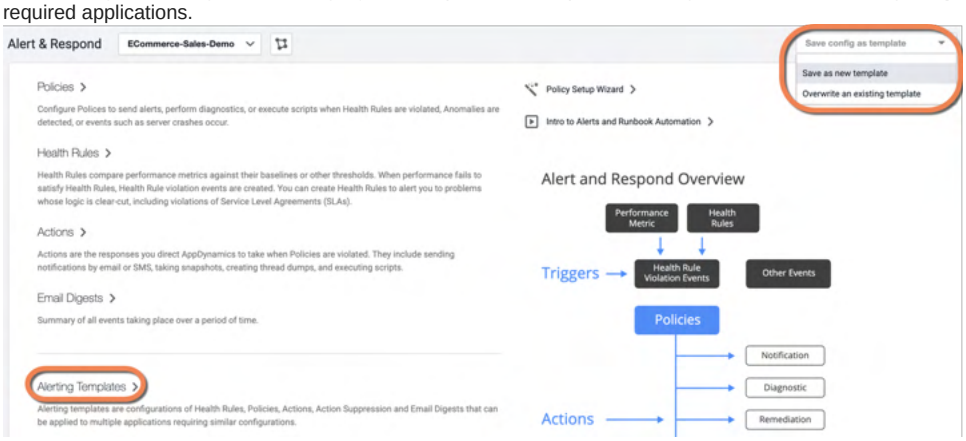


- Alert when the available disk volume is low. Use an expression including two metrics – available and used disk space – to be alerted when disk volume is low.



- When configuring **Alert and Respond** features for an application, you can select **Save Config as Template** to save the application configuration as a template. You can then apply this template to multiple applications to ensure consistency.

To make a global configuration change, you can update the template selecting **Overwrite an existing template** and then re-apply it to the required applications.



- To avoid receiving false alerts and to ensure that you calibrate the sensitivity of health rules appropriately, you can use Alert Sensitivity Tuning (AST). AST helps you visualize the impact of the alerting configuration as and when you configure. AST provides instant insights in a graphical format that helps you fine-tune the alerts.
  Depending on the baseline configuration you define, a graphical view of the metric data for the given baseline configuration displays. The graphical view is instantly updated when you update any configuration. You can also view granular details by modifying the graphical view. The metric data presented in the graph helps you calibrate the sensitivity of the metric evaluation and the health rule.

Policies

Related Pages:

- Health Rules
- Actions
- Configure Policies

This page provides an overview of policies in AppDynamics.

A policy consists of a trigger, which is based on one or more events, and an action, directly in response to the trigger. You can use policies to automate monitoring, alerting, and problem remediation.

View Policies

To view and create policies, access the Policies UI by selecting **Alert & Respond > Policies**.

The policy list displays all the policies created for your application, with its triggers and actions taken. You can modify a policy by double-clicking it in the policy list.

Policy Triggers

Policy triggers are events that cause the policy to fire. The events can be health-rule violation events or other types of events, such as hitting a slow transaction threshold or surpassing a resource pool limit. See Health Rules, Troubleshoot Health Rule Violations and Monitor Events.

The triggering events can be broad, affecting any object in the application, or very narrow, affecting a specific object. For example, you can have a broadly-defined policy that fires whenever a resource pool limit (such as >80% usage of EJB pools, connection pools and/or thread pools) is reached for any object in the application. Additionally, a narrowly-defined policy is one that would fire only when existing health rules on memory utilization or JVM garbage collection time are violated.

A policy is triggered when at least one of the specified triggering events occurs on at least one of the specified objects.

Policy Actions

You can assign the actions that are taken when a policy is triggered, such as an email or SMS notification. Other types of actions do more than just notify. For example, a resource pool violation can trigger a script that increases the pool size.

Other common actions include restarting an application server if it crashes, purging a message queue that is blocked, or triggering the collection of transaction snapshots. You can also trigger a custom action to invoke third-party systems.

Because the definition of health rules is separate from the definition of actions, you can specify different actions for an event in different contexts, such as a threshold crossing in either a tier or node context.

See Build a Custom Action for information about custom actions. See Actions for more information about the different types of actions.

Policy Actions in Batch

You can configure a policy to execute its actions either:

- Immediately for every triggering event.
  For example, if in a two-second period a policy matched 100 events, it would start its actions 100 times as soon as each event occurred.
- Once a minute for all the events that triggered over the last minute. This is the batch option. The **Execute actions in batch** checkbox is selected by default.
  For example, if in a two-second period, a policy matched 100 events and then no triggering events occurred for the next 58 seconds, the policy would start each action just once. The context for the actions would be all 100 events.

Which you choose depends primarily on the type of action. For a notification action, it probably doesn't make sense to send 100 emails or SMS messages in a few seconds. In this case, it makes sense to batch the actions with a summary of the events occurring during the last minute. This can be easily accomplished using an email template that iterates through the event list. See the example in Predefined Templating Variables.

However, if the actions are thread dumps, there is no reason to expect that all 100 events are on the same node. They might be on different nodes. For that kind of action, you probably want the thread dump to be taken for each event and also, not to wait another 58 seconds before taking the thread dump.

Configure Policies

Related Pages:

- Monitor Events
- Health Rules
- Troubleshoot Health Rule Violations
- Actions
- Enable an Email Server

This page provides instructions on configuring policies in AppDynamics. You can configure policies using these two methods:

- Use the Policy Setup Wizard for simple policies that send an email notification when a health rule is violated.
- Configure the policy manually for anything more complicated.

> To configure policies, you need the Configure Policies permission.

Policy Setup Wizard

For simple policies in the Controller, select **Alert & Respond > Policies > Policy Setup Wizard**.

To create a notification policy, you must set up an SMTP server and supply an email address. The policy is then created.

To modify the policy later, select the policy and click **Edit**.

Create Policy Manually

To create a policy manually in the Controller, select **Alert & Respond > Policies > Create Policy Manually**.

The **Create Policy** page contains the following panels:

- **Trigger**: Sets the events that trigger the policy, entities that are affected by the policy.
- **Health Rule Scope**: Defines the Health Rules that trigger the policy.
- **Object Scope**: Defines the objects that trigger the policy for application and user experience contexts.
- **Actions**: Set the actions to take when the policy is triggered.

In either panel, you can configure the policy name, enabled status, and whether to batch the actions executed by the policy.

Create Policies

1. Click **Alert & Respond**.
2. Click **Policies** either in the right panel or the left navigation pane.
3. Select the context for the policy (specific Application, User Experience, Databases, Servers, or Analytics) from the dropdown.
4. To create a new policy, click **Create Policy** (**+**).

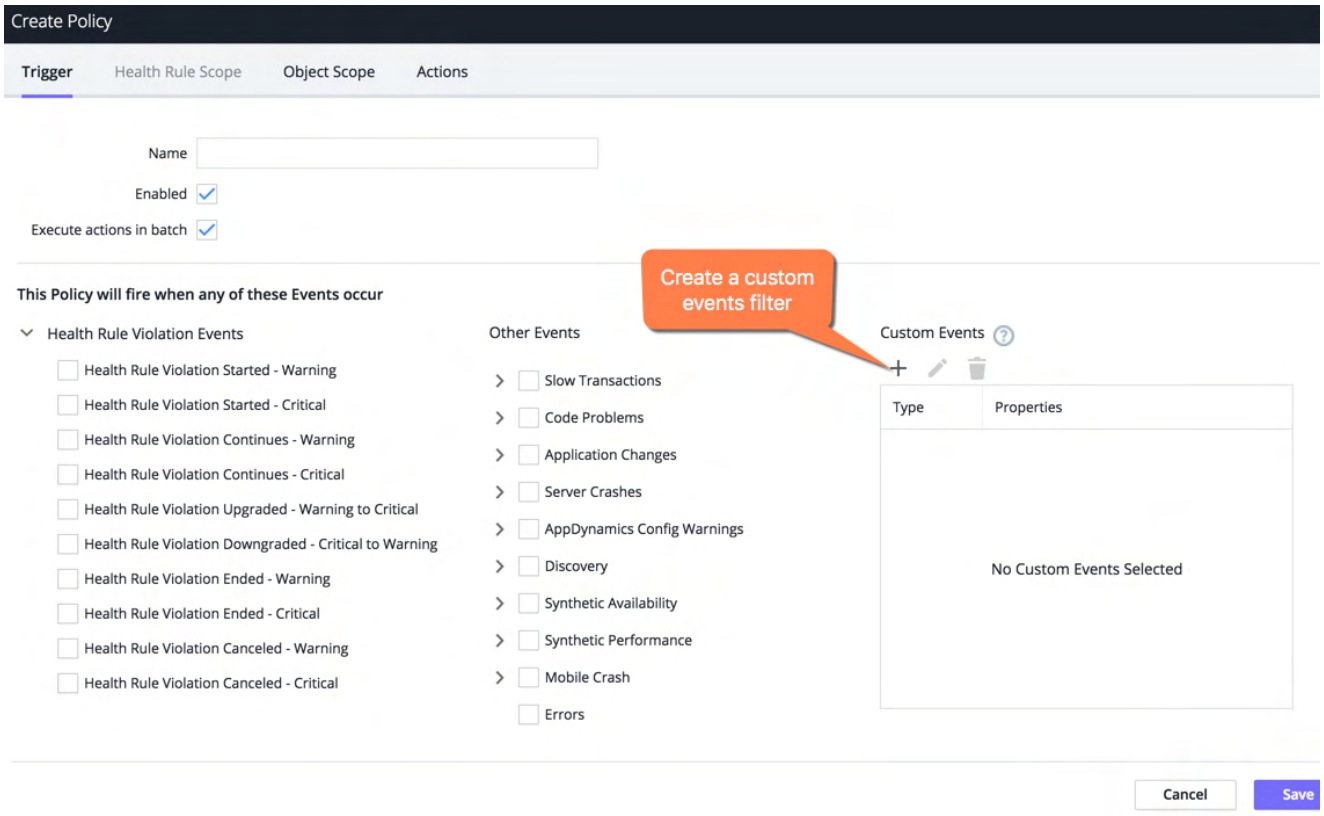
You can edit, copy, enable or disable, and delete a policy by clicking the appropriate button.

Configure Policy Triggers

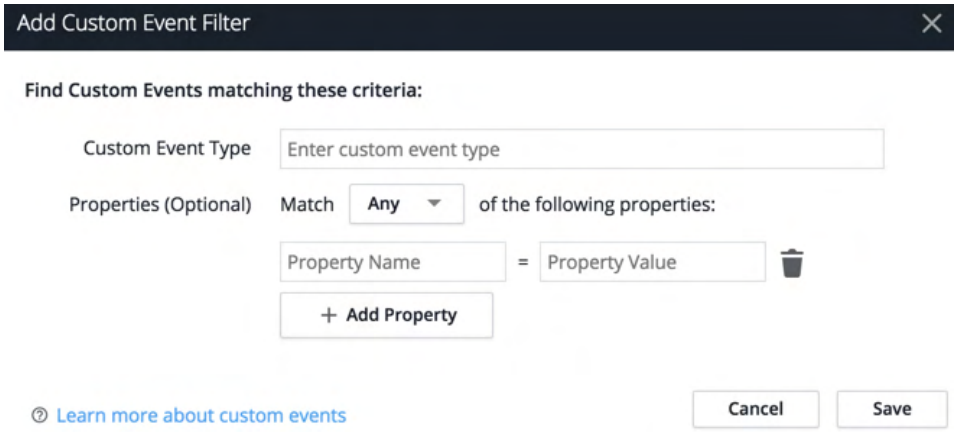
The policy trigger panel defines the events and objects that cause the policy to run and invoke its actions.

For policy triggers that depend on health violation events, you must create the health rules before you can create a policy that uses them. See Health Rules and Troubleshoot Health Rule Violations.

1. Click **Create Policy (+)** or select a policy and click **Edit** (pencil button).
2. Enter a name for the policy in the **Name** field.
3. To enable the policy, select the **Enabled** checkbox. To disable the policy, clear the **Enabled** checkbox.
   You can also enable or disable a policy by selecting it from the policy list and clicking **Enable** or **Disable**.
4. If you clear the **Execute actions in batch** checkbox, the policy starts its actions immediately for every triggering event. If you check this checkbox, the policy starts its actions once for all the triggering events that occurred in the last minute. See 'Policy Actions in Batch' in Policies.
5. Select the **Trigger** panel if it is not already selected.
6. Check one or more types of events that should trigger the policy. You may need to click the arrow to display specific events within an event category.
   If you check at least one health rule violation event, you can choose whether any or all health rule violations, or only specific health rule violations will trigger the policy.



If your AppDynamics environment includes browser synthetic monitoring, other additional events display for Synthetic Availability and Synthetic Performance. See 'Alerting and Synthetics' in Browser Synthetic Monitoring.
You can optionally designate specific custom events to trigger the policy, using the **Custom Events** panel in the lower right corner. Click **+**.



Specify the custom event type. Optionally, add particular properties on that event as key/value pairs.

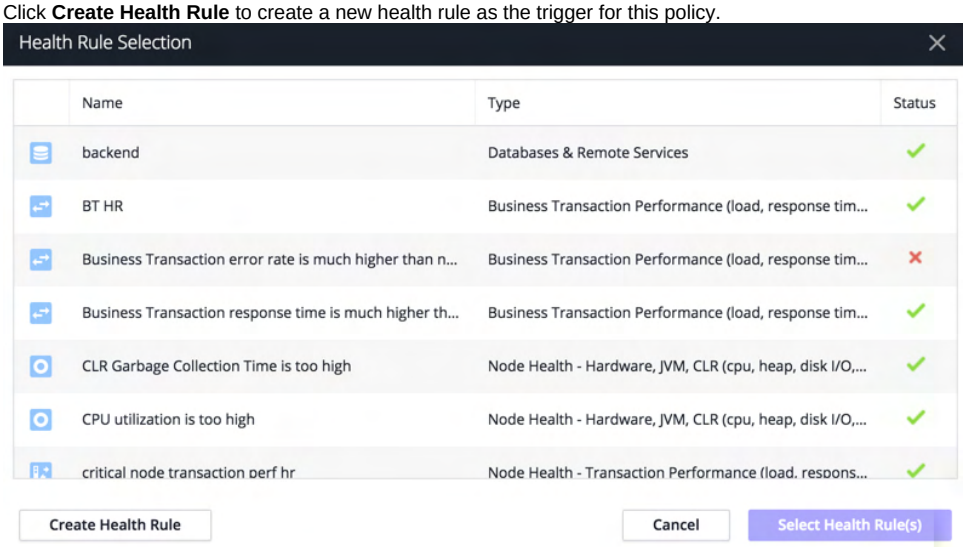
- For **Any**, at least one property must exist and match.
- For **All**, all properties must exist and match.

Configure Health Rule Violation Triggers

The **Health Rule Scope** panel determines the scope of the health rule violations that trigger the policy. If you have not created a health rule, you can create one by selecting **Create Health Rule** in this panel.

1. If you have not already done so, edit the policy to which you want to add Health Rule triggers.
2. Select the **Health Rule Scope** panel, then select **Any Health Rules** if you want the policy triggered by a violation of any health rule.

3. To designate specific health rule violations to trigger the policy, click **+**, and then select the health rules from the embedded health rule browser. Click **Create Health Rule** to create a new health rule as the trigger for this policy.



Configure Object Scope

The **Object Scope** panel defines the objects the policy is triggered on. The object scope applies only to business transaction performance type health rules and node health type health rules which comprise tiers and nodes.

1. When you have finished selecting the health rule violations that trigger the policy, click the **Object Scope** panel to select objects to be monitored in case of an event. If you select **Any Object**, the policy will be triggered by the configured events when they occur on any object in your application.
2. To restrict the policy to specific objects, select **These Specified Objects** and then choose the objects.
   For example, the following policy starts when selected events occur on the ECommerce Server tier. You can similarly restrict the objects to specific nodes, business transactions, Ajax Requests, and so forth.

   You can restrict the affected nodes on the node name, on the type of node (such as Java and .NET) on nodes in certain tiers, or on criteria such as meta-info, environment variables, and JVM system environment properties. Meta-info includes key-value pairs for:
   - key: `supportsDevMode`
   - key: `ProcessID`
   - key: appdynamics`.ip.addresses`
   - any key passed to the agent in the `appdynamics.agent.node.metainfo` system property

   To trigger by Health Rule Violation Events, leave the selection at **Any object**. Selecting **These specified objects** means that events occurring within the selected objects, for example, slow transactions, errors, and so forth, trigger the policy.
3. Click **Save**.

Configure Policy Actions

The policy actions panel binds an action to the trigger. It defines which actions the policy automatically initiates when the trigger causes the policy to start.

The actions must be created before you can create a policy that starts them. See Actions and the documentation for individual types of actions (for example, notification actions, remediation actions) for information on creating an action.

1. If you have not already done so, edit the policy to which you want to add actions. See To Access the Policy Wizard.
2. Select the **Actions** panel.
3. Click **+**. The list of existing actions displays. The available actions vary depending on the product area selected for the policy, such as Applications, Servers, Databases and so on.
   You can filter the list by selecting the checkboxes for the types of actions you want to see.
4. In the list of actions, select the action that you want this policy to execute and click **Select**.
   If you do not see an appropriate action for your needs, click **Create**. For information on creating actions, see Actions. After you have created the action, select it here to assign it to the policy that you are configuring.
5. Click **Save**.

You can optionally test whether your action will be fired using the Test Action Execution. Ensure that the policy you are testing is enabled.

Test Action Execution

Related Pages:

- Alert and Respond
- Monitor Events
- Configure Policies
- Actions

This page provides an overview of events actions in AppDynamics. An event represents an error or exception generated by the application, the crossing of a performance threshold, or an operational change in the application, such as a JVM restart.

You can view and analyze events in the Controller UI. From the **Database Visibility**, **Server Visibility**, or **User Experience** pages, you can view events by selecting **Events** from the left navigation panel. The events list also provides information on which policy actions are configured to start when a specific event occurs. It does not execute the actual actions configured for the policy.

This information provides answers to these questions:

- Why didn't my policy action execute? Perhaps policies are not actually configured to respond to an event as you thought they were.
- Why am I getting multiple actions, such as multiple emails, for the same event? Perhaps more than one policy is configured to perform the same action.

To see the actions that are triggered for an event:

1. In the events list, select the event for which you expect actions to start.
2. From the Actions menu, select **Test Action Execution**.

Anomaly Detection

Deployment Support

Related Pages:

- Enabling and Configuring Anomaly Detection
- Troubleshooting Anomalies

The AppDynamics Anomaly Detection and Automated Root Cause Analysis are two features designed to reduce Mean Time To Resolution (MTTR) for application performance problems.

Anomaly Detection automatically determines whether every Business Transaction in your application is performing normally. Automated Root Cause Analysis helps you quickly determine the root cause for problems revealed by Anomaly Detection.

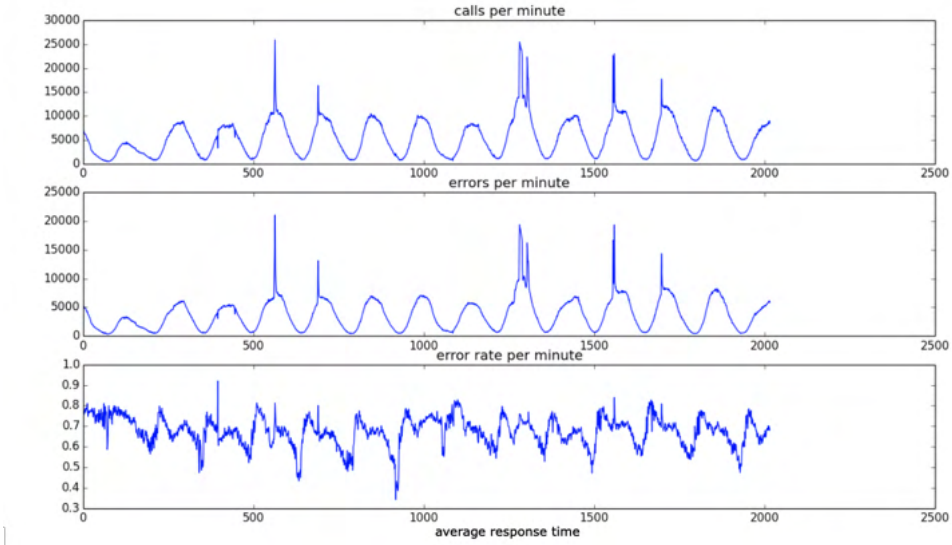
How Does Anomaly Detection Work?

Anomaly Detection uses machine learning capabilities to reduce the `Mean Time to Detect` (MTTD) when an anomaly occurs in a business transaction. It uses a specially designed algorithm that does not require you to configure anything. The Anomaly Detection algorithm works as follows:

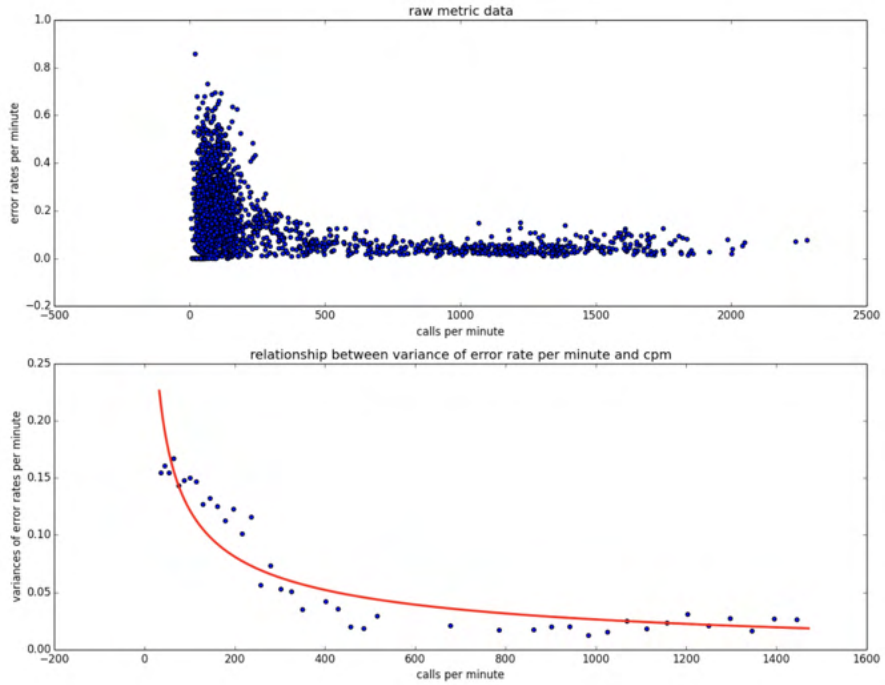
1. It detects if any abnormal reading is reported for the **Errors per minute** (EPM) metric.
2. It detects if any abnormal reading is reported for the **Average Response time** (ART) metric.
3. It then combines the data it learned from these metric readings using heuristics that are designed to reduce alert noise.

Anomaly Detection employs multiple techniques to ensure that the metric data it collects is accurate:

- It disregards any temporary spikes and periods of no data
- It normalizes the metric data. For example, when determining the EPM metric data, any spikes may not indicate a real problem unless there is a corresponding increase in **Calls per Minute** (CPM). EPM data may not be useful in itself, hence, Anomaly Detection uses Error Rate (EPM/CPM).



- It does not apply traditional seasonal baselines. Instead, it correlates the variance of EPM and ART to CPM to obtain reliable results.



What is Root Cause Analysis (RCA)?

When an entity in your application has an anomaly, you will want to know why. Anomaly Detection uses AI capabilities to enable Automated Root Cause Analysis to monitor the health of all the entities in your application, and show you the suspected causes for every anomaly. You can confirm or negate the suspected causes with a brief look, and drill down into deviating metrics and snapshots, as desired. Thus, you can quickly determine the root cause of any anomaly in the application.

How Does RCA Work?

RCA reduces the Mean Time to Identification (MTTI) by automatically pointing to the source of the problem. RCA considers metrics to identify the fault domain, and snapshots and events from the entire application, to find and surface suspected problems. This holistic approach is performed in two parts:

1. Fault domain isolation—Identification of the exact location of the problem in the system
2. Impacted component analysis—Analysis of logs, snapshots, trace, infrastructure, and so on to determine the affected components

How is Anomaly Detection Different from Health Rules?

While both Anomaly Detection and health rules alert you to performance problems in your application, Anomaly Detection provides powerful insights that would be difficult to obtain using health rules.

Anomaly Detection	Health Rules
Anomaly Detection uses machine learning to discover the normal ranges of key business transaction metrics and alerts you when these metrics deviate significantly from expected values. This enables Anomaly Detection to identify a wider range of problems than a person could capture in Health Rules.	Health rules are manually created to apply logical conditions that one or more metrics must satisfy. For example, you could monitor the **Average Response Time** (ART) to check if this metric deviates from the configured baseline.
Anomaly Detection requires no configuration except when you want to limit anomaly alerting.	AppDynamics provides a default set of health rules and you create additional health rules manually as required, configuring time periods, trends, and schedules.
Anomalies are associated with business transactions.	Health rules apply to any entity, for example, business transactions, service endpoints.

Enabling and Configuring Anomaly Detection

Related topics:

- Anomaly Detection
- Troubleshooting Anomalies

Anomaly Detection must be enabled, but requires no configuration except to limit anomaly alerting. Enabling Anomaly Detection also enables Automated Root Cause Analysis.

> Anomaly Detection and Automated Root Cause Analysis are available to SaaS customers only.

Enable Anomaly Detection

Enable Anomaly Detection separately for each application.

1. In **Alert & Respond > Anomaly Detection**, choose the desired application from the dropdown, and toggle Anomaly Detection **ON.**

   After you enable Anomaly Detection, it takes 48 hours for Anomaly Detection and Automated Root Cause Analysis to become available. During that time, the machine learning models train on the business transactions in your application.
2. Select **Alert & Respond > Anomaly Detection > Model Training** to view **Business Transaction** training status.

   This table explains the training statuses of a **Business Transaction**.

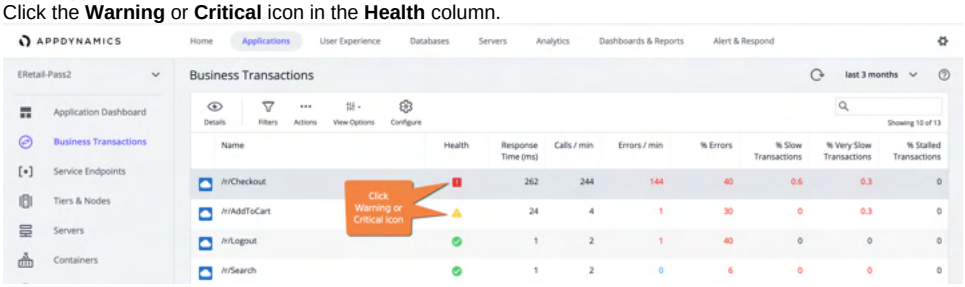
Status	Meaning
In Training	Model training is in progress for the Business Transaction.
Ready	Model training is complete, and the Business Transaction is healthy.
Warning	Model training is complete, but the Business Transaction has experienced one or more Warning level anomalies during the training period.
Critical	Model training is complete, but the Business Transaction has experienced one or more Critical level anomalies during the training period.
Not Available	Model training is incomplete, and the Business Transaction is not visible to Anomaly Detection.

   The models continue training as long as Anomaly Detection is enabled. If traffic to a **Business Transaction** is interrupted for long enough to prevent training that day, Anomaly Detection continues to function using the models from the previous seven days.

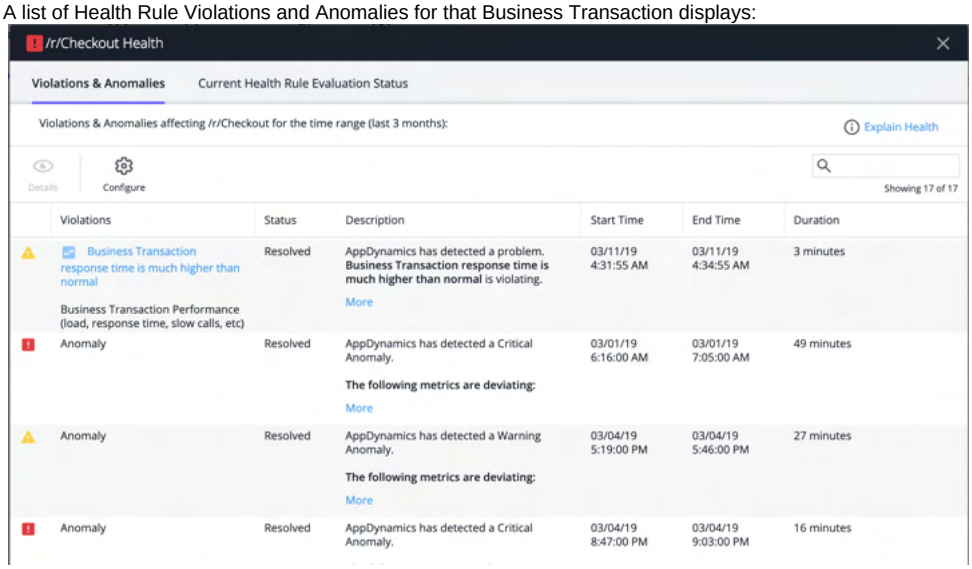
> No machine learning models are trained for **Business Transactions** which have very low CPM, because the sample size would be so small that the resulting model would be unreliable.

Monitor Anomalies

1. From **Applications > Business Transactions**, select any **Business Transaction** of interest.
2. Click the **Warning** or **Critical** icon in the **Health** column.



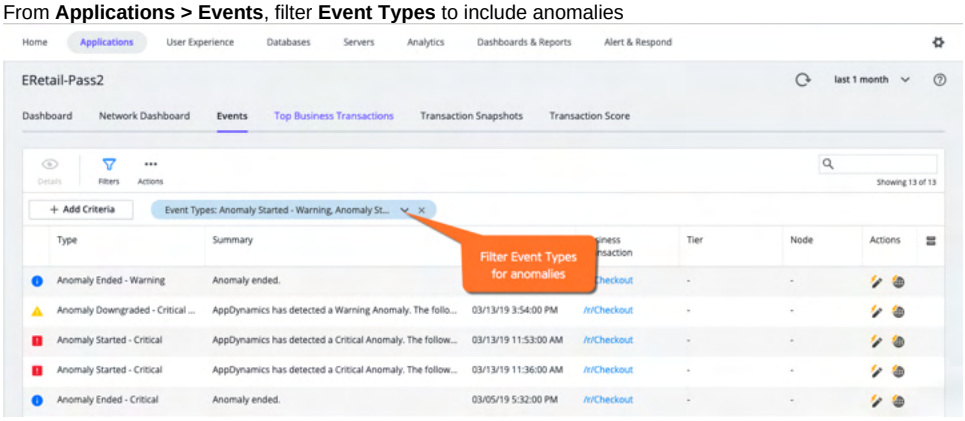
A list of Health Rule Violations and Anomalies for that Business Transaction displays:



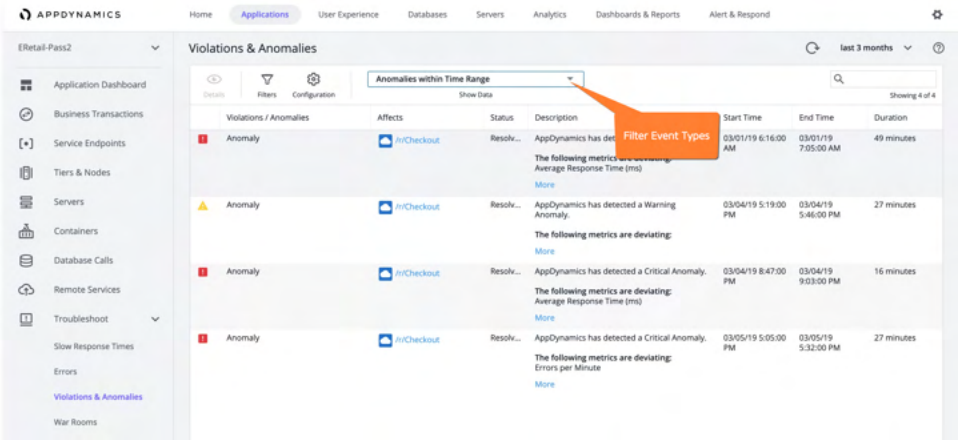
3. You can view lists of anomalies in multiple ways. Monitoring anomalies can reflect how you work with AppDynamics. Choose any of these options to open a detailed view that includes the results of Automated Root Cause Analysis.
    - If you set up and validate tools for a tools team:
      View the anomaly details from **Alert & Respond > Anomaly Detection > Anomalies**

    - If you monitor applications for an application ops team:

- From **Applications > Events**, filter **Event Types** to include anomalies



- From **Applications > Troubleshoot > Violations & Anomalies**, filter **Event Types** to include anomalies



You can configure policies to be triggered by anomalies, similar to the way you configure policies to be triggered by Health Rules.

Configure Anomaly Detection

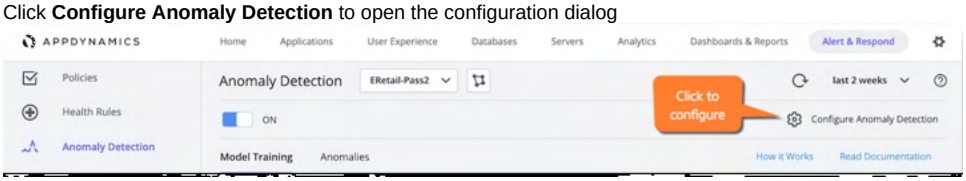
By default, Anomaly Detection alerts you about all Anomalies for all Business Transactions in your application.

You can configure Anomaly Detection to surface only those Anomalies within the combination of Business Transactions and severity levels that you specify. Do this if you prefer to see fewer, more narrowly focused alerts.

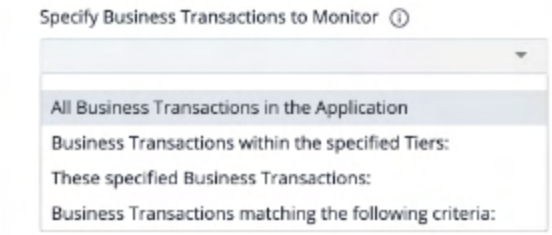
You do not need to configure or enable Automated Root Cause Analysis.

To configure Anomaly Detection:

1. Click **Configure Anomaly Detection** to open the configuration dialog



2. If desired, limit the **Business Transactions** on which you want Anomaly Detection to alert
    - Default (all Business Transactions) is shown



3. If desired, limit alerts to either **Warning** or **Critical** severity only

- Default (All Severities, meaning both Warning and Critical) is shown

Troubleshooting Anomalies

Related topics:

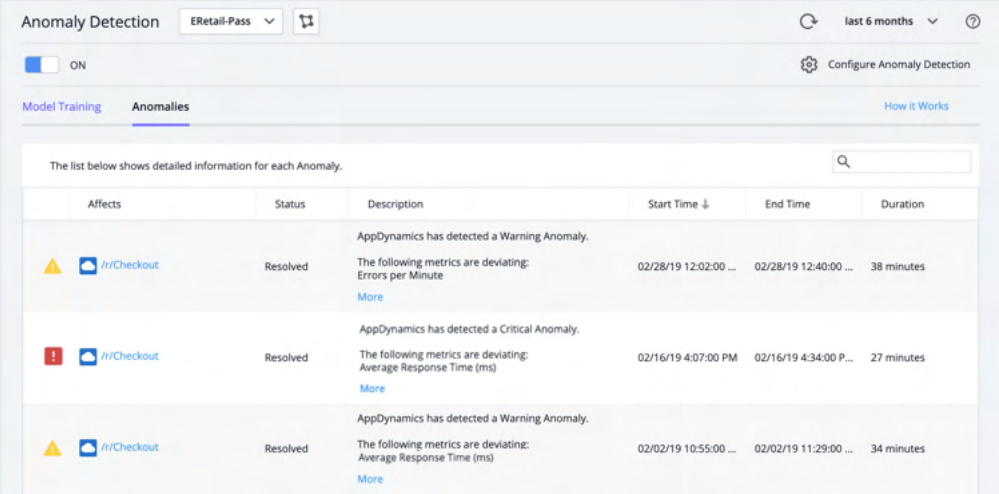
- Anomaly Detection
- Enabling and Configuring Anomaly Detection

To demonstrate techniques for using Anomaly Detection and Automated Root Cause Analysis effectively, this example follows an anomaly from the moment it surfaces until its root cause is confirmed. The troubleshooting process can begin with any of the multiple ways to view anomalies. This example assumes that you start with the **Alert & Respond > Anomaly Detection** page.

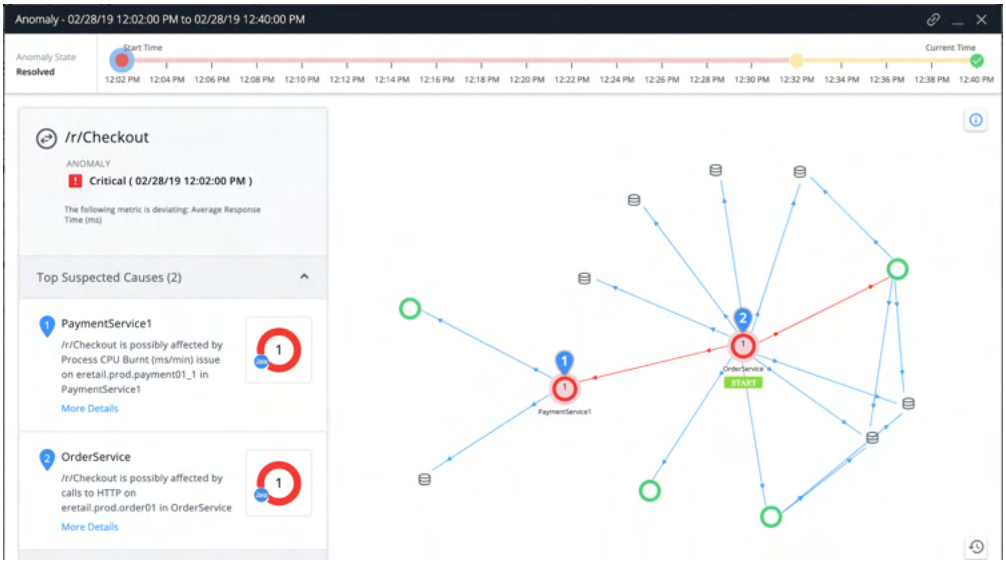
> Anomaly Detection and Automated Root Cause Analysis are available to SaaS customers only.

Drill Into an Anomaly

- **In Alert & Respond > Anomaly Detection**, view the Anomalies tab.



- Double-click an anomaly to open the detailed view.



Initially, the page describes everything that is occurring during the anomaly's Start Time. To review how things change later in the anomaly's lifecycle, click events further along its timeline.

Examine the Anomaly Description

The anomaly description describes the anomaly in relation to its named Business Transaction, the severity level of the selected state transition event, and the top deviating Business Transaction metrics.

In this example, these are:

- Business Transaction: `/r/Checkout`
- Severity Level: Critical
- Top Deviating Metrics: Average Response Time

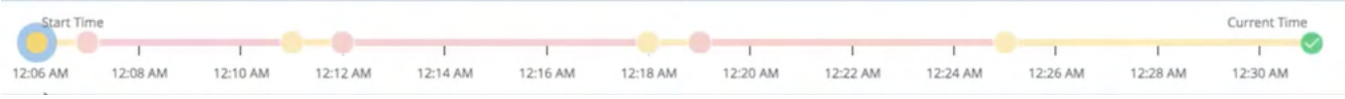
The deviating metric is Average Response Time indicating that checkout responding slowly is the problem.

Examine the Timeline

The state transition events mark the moments when the anomaly moves between **Warning** and **Critical** states.

- The timeline in this example begins in the **Critical** state, followed 30 minutes later by a transition to the **Warning** state, which lasts only eight minutes.
- Because this simple anomaly starts in the **Critical** state and remains there for most of its lifecycle, we can probably learn all we need to know from the initial event

By contrast, patterns that appear in more complicated timelines may help you to understand anomalies. For example, this timeline from a different anomaly repeatedly toggles from a brief **Warning** state to a longer **Critical** state:



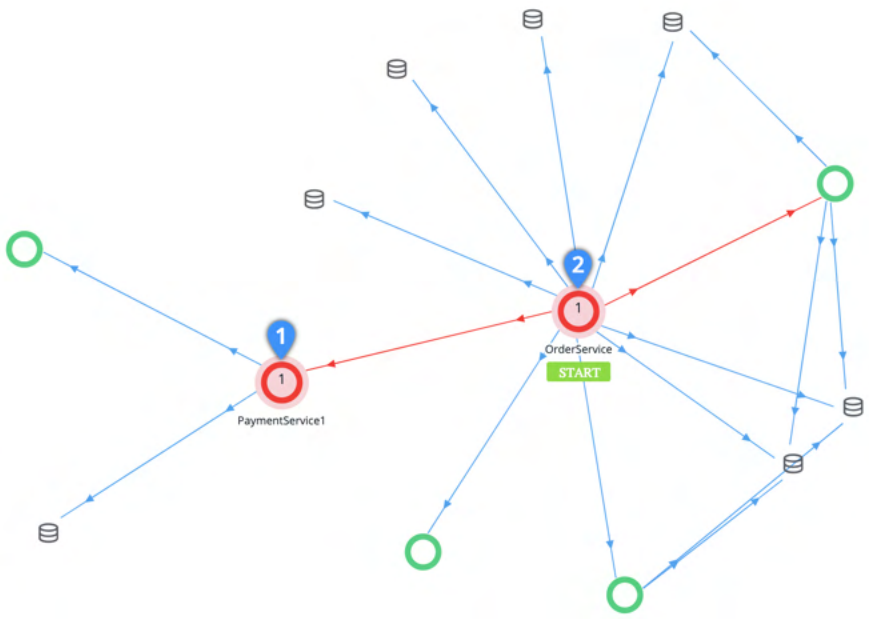
In this case, you should examine several state change events to determine what clues toggling between states offers about problems in your application.

Examine the Flow Map

The example flow map contains:

- The **START** label shows that the Business Transaction begins with the OrderService tier

- Between the OrderService tier and its numerous dependencies, two tiers are red—these are the tiers where the system has found Suspected Causes



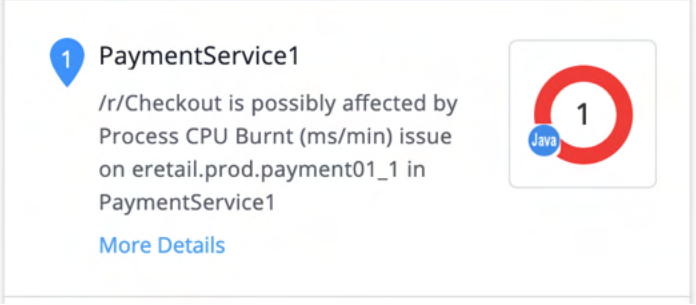
You can now focus on determining which of the red tiers contains the root cause of the anomaly.

> **Anomaly Detection flow maps are different**
>
> There are two types of flow maps in AppDynamics:
>
> - Anomaly Detection and Automated RCA flow map (described on this page)
> - Business Transaction flow map
>
> Each of these flow maps detects deviating or unhealthy entities in its own way. Therefore, you will see some differences:
>
> - The two flow maps may show a different health status (as represented by color) for the same entity because each one uses its own algorithm to determine health
> - User preferences for positioning or hiding entities saved for the Business Transaction flow map have no effect on the Anomaly Detection flow map
> - Some links between tiers might be shown in one type of flow map but hidden in the other
>   - For example, when no data is flowing through a tier or between tiers:
>   - Business Transaction flow map may hide them, as 'inactive' tiers or links
>   - Anomaly Detection flow map may show them in order to represent the application topology completely

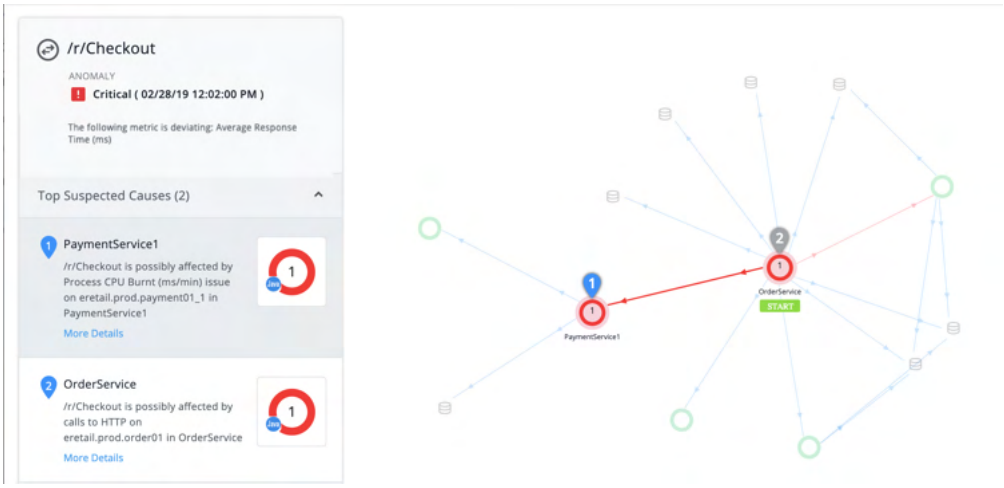
Examine the Top Suspected Causes

The Top Suspected Causes show likely root causes of a Business Transaction performance problem. In this case, we want to know why Checkout is responding slowly.

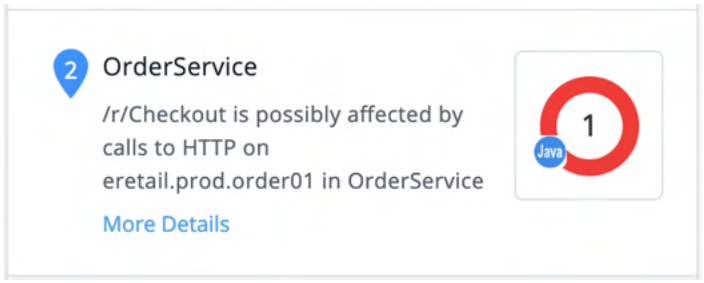
The first Suspected Cause is a Process CPU Burnt issue on the eretail.prod.payment01_1 node of the PaymentService1 tier:



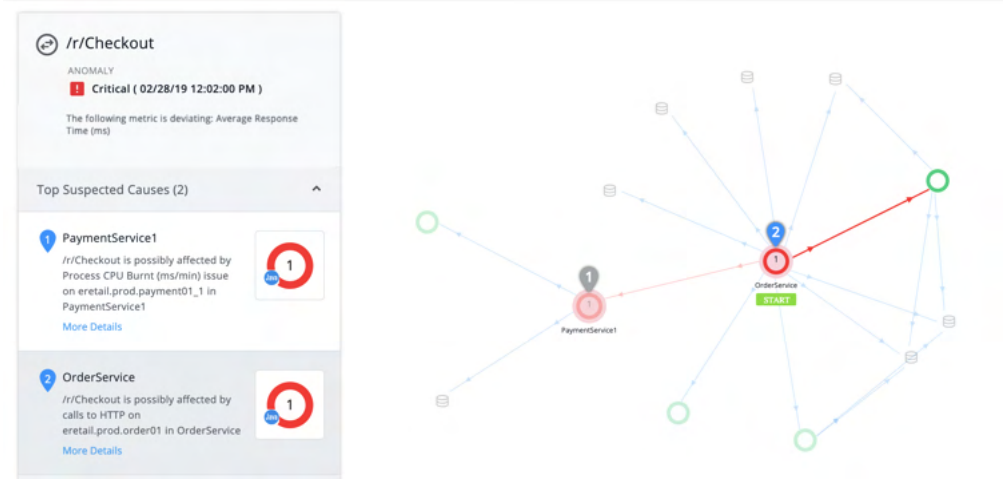
Hover over the Suspected Cause to highlight the relevant entities in the flow map. Everything but the critical path fades away, revealing that OrderService, where the Business Transaction starts, and which had a degraded response time, relies on PaymentService1:



The second Suspected Cause is an HTTP call on OrderService itself.



Hover to highlight the affected entities:



Which Suspected Cause is the root cause? Which is only a symptom of the overall problem?

- We have a plausible root cause in the Process CPU Burnt issue on PaymentService1 tier, which is ranked likeliest by the system.
- Meanwhile, the HTTP call on OrderService bears some analysis:
  - An HTTP call includes both a request and a response
  - We know that the tier on the other end, PaymentService1, has its own problem
  - Therefore, we can infer that the HTTP response from PaymentService1 is what makes the call slow

Now we see that both Suspected Causes originate with PaymentService1, and the HTTP call issue is really a side-effect of the Process CPU Burnt issue. The system's ranking makes sense.

As we continue to investigate, if we decide that the Process CPU Burn issue is not the root cause, we can reconsider the HTTP call.

There can be anywhere from zero to three Top Suspected Causes. For example, if ART is high but every entity connected with ART is behaving normally, there are zero suspected causes because no suspected cause can be identified.

Drill Into a Suspected Cause

Click **More Details** for the Suspected Cause to review:

- Simplified timeline
- Metrics graphed over time

Two types of graphed metrics display:

- **Top Deviating Metrics** for the Business Transaction
- **Suspected Cause Metrics**

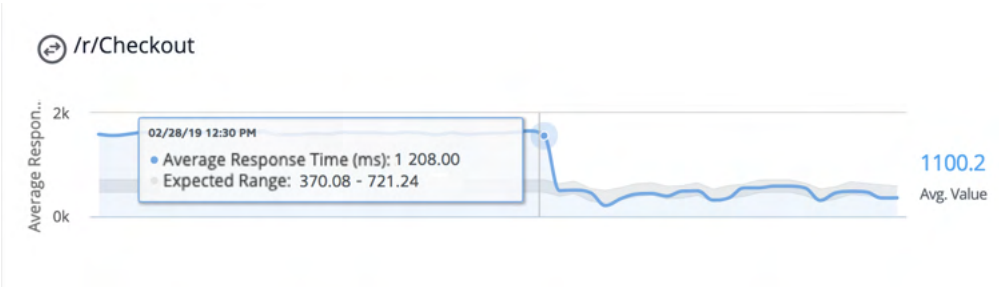
Examine Top Deviating Metrics for the Business Transaction

Deviating Business Transaction metrics can indicate why an anomaly was important enough to surface. (The system does not surface anomalies for every transitory or slight deviation in metrics. Such anomalies would be of dubious value, since their customer impact is minimal. For the same reason, anomalies are surfaced for Business Transactions which have a CPM of under 20.)

Each deviating metric is shown as a thin blue line (the metric's value) against a wide gray band (the metric's Expected Range).

You can:

- Scroll along the graph to compare a metric's value with its Expected Range at any time point
- Hover over a time point to view the metric's value and Expected Range in numerical form



> Hovering to view values in numerical form is essential when the Expected Range is so much smaller than the deviating metric values that the gray band "disappears" into the X axis.

In this example:

- The deviating metric spiked remained elevated for about 30 minutes, then subsided back into Expected Range
- Seven minutes after the metric returned to its Expected Range, the Severity Level changed from **Critical** to **Warning**, and eight minutes after that, to **Normal**

Hovering over time points tells us that for the period of deviation: the Average Response Time was around 1200 ms and above, while its Expected Range was from 370.08 to 721.24 ms

With a key metric elevated by this large amount, it made sense for the system to surface this anomaly.

> Because Top Deviating Metrics are at the Business Transaction level, they are the same for all Suspected Causes.

Examine Suspected Cause Metrics

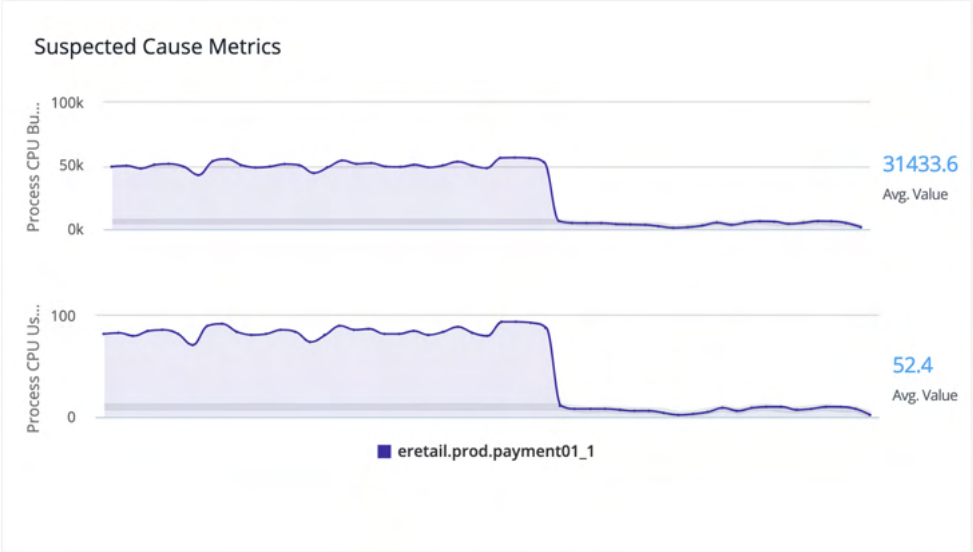
You view, scroll through, and hover over Suspected Cause Metrics similar to Top Deviating Metrics.

Top Deviating Metrics describe the Business Transaction, while Suspected Cause Metrics describe tiers or nodes further down in the entity tree. This means that if you have ART as a Top Deviating Metric and as a Suspected Cause Metric, *those are two different metrics*. Likewise, EPM as a Top Deviating Metric and as a Suspected Cause Metric are also two different metrics.

While the Suspected Cause Metric likely contributes to the way the Top Deviating Metric behaves, the values of the two metrics will differ.

In this example,

- Suspected Cause Metrics are shown for the eretail.prod.payment01_1 node within the ProcessPayment1 tier
- That is the *only* node the tier has—if the tier had multiple nodes, metrics could be viewed separately for each node
- The pattern of elevation in the Process CPU Burnt and Process CPU Used metrics perfectly matches the pattern we saw in the Business Transaction metrics



The hypothesis is now confirmed:

1. CPU usage spiked on ProcessPayment1, a tier that is downstream from the tier where the Business Transaction starts
2. This slowed down response time on ProcessPayment1, including its HTTP response to the HTTP request from OrderService
3. The slow HTTP call, in turn, slowed response time on OrderService
4. Since OrderService is where the Checkout Business Transaction starts, Checkout has a slow response time anomaly
5. Since the Process CPU Burn issue on ProcessPayment1 is the Suspected Cause that's deepest in the entity tree, that is the root cause of the anomaly

Results

We used Anomaly Detection and Automated Root Cause Analysis to quickly find the root cause of a Business Transaction performance problem. What kind of time and effort did Anomaly Detection and Automated Root Cause Analysis save us in this case?

Recall that the tier where the Business Transaction started, OrderService, has multiple dependencies including other services and datastores. Anomaly Detection and Automated Root Cause Analysis eliminated (1) all but two tiers as origins of the slow response time on OrderService, and (2) all but the most relevant of the many metrics on those tiers.

You were spared the tedious process of investigating multiple metrics on each dependency in turn. Instead, you confirmed or negated Suspected Causes with a quick glance at timelines, flow maps, and metrics. Anomaly Detection and Automated Root Cause Analysis performed the vast majority of the work in root cause analysis, presenting you with the information you needed to quickly form and verify a hypothesis.

(Optional) Inspect Snapshots and Execute Actions

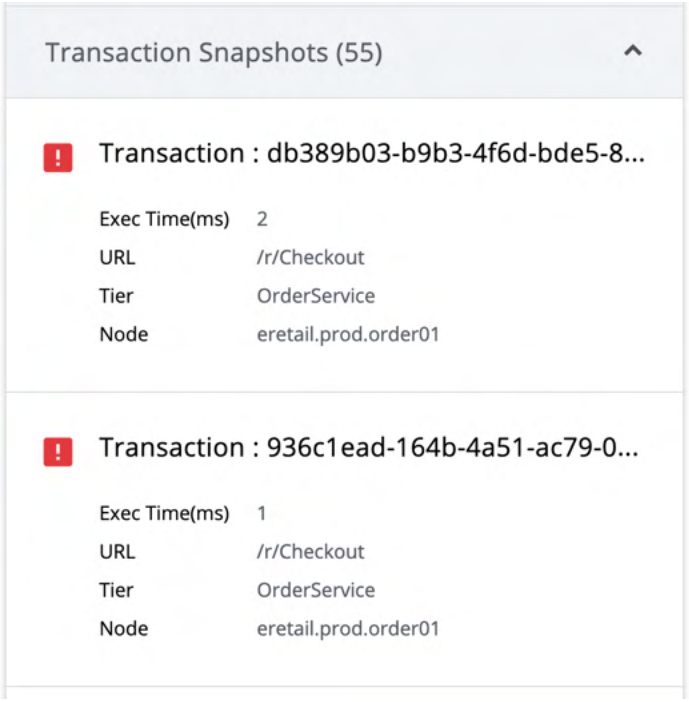
When you view an anomaly, you can inspect

- Business Transaction snapshots from the time period of the anomaly
- Actions executed as the result of policies you have configured for the Business Transaction

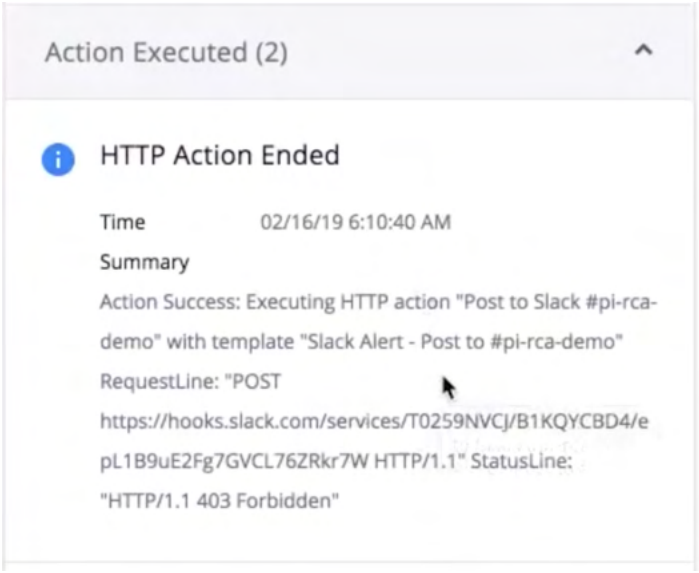
These are options of the standard troubleshooting flow. They are typically done as follow-up.

In this example:

- Suppose we want more context for the Process CPU Burnt issue on PaymentService1. We can view snapshots of transactions affected by that issue. Double-click a snapshot in the list to open it in its own pane, and if desired, drill down into details and call graphs.



- It is common to send messages to a ticketing system when an anomaly occurs. In this case, we posted to Slack, for our Ops team to see that on their phones.



Health Rules

Related pages:

- Configure Health Rules
- Troubleshoot Health Rule Violations
- Policies
- Actions

This page provides an overview of health rules, the policy statements that define triggers in AppDynamics policies.

What is a Health Rule?

Health rules let you specify the parameters that represent what you consider normal or expected operations for your environment. The parameters rely on metric values, for example, the average response time for a business transaction or CPU utilization for a node.

When the performance of an entity affected by the health rule violates the rule's conditions, a health rule violation occurs. The health statuses are represented as critical, warning, normal, and unknown.

When the health status of an entity changes, a health rule violation event occurs. Examples of a health rule violation:

- starting
- ending
- upgrading from warning to critical or
- downgrading from critical to warning

The health statuses of entities and health rule violations are surfaced in the controller user interface. A health rule violation event can also be used to trigger a policy, which can initiate automatic actions, such as, sending alerting emails or running remedial scripts.

You create health rules using the health rule wizard, described in Configure Health Rules. The wizard groups commonly-used system entities and related metrics to simplify setting up health rules. You can also use the default health rules provided by AppDynamics as-is, or modify them.

Default Health Rules

AppDynamics provides a default set of health rules for some products, such as applications and servers. These default health rules vary depending on the entity. To see the default rules, before any health rules have been added to your AppDynamics installation:

1. From the Alert & Respond tab, click **Health Rules**.
2. Select the entity.
   The default health rules for the selected entity are displayed.

If any of these predefined health rules are violated, the affected entities are marked in the UI as yellow-orange if it is a Warning violation and red if it is a Critical violation.

In many cases, the default health rules may be the only health rules that you need. You can edit and customize the health rules to suit your application. You can also disable the default health rules.

Health Rule Scopes

The health rule scope determines the set of default health rule types. You can choose the scope to get a set of default health rule types for applications, servers, or databases. For example, when you define a mobile application as the scope, the default health rules such as crash rates and HTTP/network error rates are displayed. Similarly, if you define the health rule scope for an application, the health rules would be for business transactions, CPU/memory utilization, and so on.

From **Alert & Respond > Health Rules**, you can select one of the following health rule scopes from the drop-down list:

- Applications
- User Experience: Browser Apps
- User Experience: Mobile Apps
- Databases
- Servers
- Analytics

You can also create new health rules to add to the default set for each scope. You may want to add the health rule *app starts* to your mobile application. This health rule is not part of the default set of health rules in the mobile app scope, so you would just need to add a new health rule.

Heath Rule Types

The health rule wizard groups health rules into types that are categorized by the entity that the health rule covers. This allows the wizard to display appropriate configuration items during the health rule creation.

The health rule types are:

- Transaction Performance
  - Overall Application Performance: Groups metrics related to load, response time, slow calls, stalls, with applications.
  - Business Transaction Performance: Groups metrics related to load, response time, slow calls, stalls, so on, with business transactions.
- Node Health
  - Node Health-Hardware, JVM, CLR: Groups metrics like CPU and heap usage, disk I/O, so on, with nodes.
  - Node Health-Transaction Performance: Groups metric related to load, response time, slow calls, stalls, so on, with nodes.
  - Node Health-JMX: Java only, groups metrics related to connection pools, thread pools, so on, with specific JMX instances and objects in specific nodes and tiers.
- User Experience-Browser Apps
  - Pages: Groups metrics like DOM building time, JavaScript errors, so on, with the performance of application pages for the end-user.
  - IFrames: Groups metrics like first-byte time, requests per minute, so on, with the performance of iFrames for the end-user.
  - AJAX Requests: Groups metrics like Ajax callback execution time, errors per minute, so on, with the performance of Ajax requests for the end-user.
  - Virtual Pages: Groups metrics like End User Response Time, Digest Cycles, HTML Download Time, DOM Building Time, etc. for virtual pages created with Angular. See AngularJS Support for information on what these metrics mean in the context of virtual pages.
- User Experience-Mobile Apps
  - Mobile Apps: Groups metrics related to mobile app crashes, starts, and server calls as well as network requests and errors.
  - Network Requests: Groups metrics like HTTP and network errors, request time, and requests per minute with network requests.
- Servers: Groups metrics related to hardware resources.
- Databases & Remote Services: Groups metrics related to response time, load, or errors with databases and other backends.
- Advanced Network: Groups metrics related to Network Visibility, such as PIE (performance impact events), zero window, data retransmission, and errors.
- Error Rates: Groups metrics related to exceptions, return codes, and other errors with applications or tiers.
- Information Points: Groups metrics like response time, load, or errors with information points.
- Service Endpoints: Java and .NET only; groups metrics like average response time, calls per minute, and errors per minute with service endpoints.
- Custom: Presents all the metrics collected by the agent that could affect a single business transaction, a single node or overall application performance. Use this type to create rules that evaluate custom metrics.

When you select one of these health rule types, the wizard offers you the metrics commonly associated with that type in an embedded browser.

How to Set Up Health Rules?

AppDynamics recommends the following process to set up health rules for your application:

1. Identify the key metrics (performance indicators) on the key entities that you need to monitor.
2. Click **Alert & Respond > Health Rules** to examine any default health rules that are provided by AppDynamics.
   - Compare your list of metrics with the metrics configured for the default rules.
   - You can view the list of affected entities for each of the default health rules and modify them. See Configure Affected Entities.
   - If the default health rules cover all the key metrics you need, determine if the pre-configured conditions are applicable to your environment. If required, modify the conditions.

     Define a metric expression to evaluate complex criteria for a condition.

     Define a boolean expression to evaluate multiple health rule conditions.
3. If default health rules do not cover all your requirements or if you need finely-applied health rules to cover specific use cases, create new health rules.
   a. Identify the type of health rule that you want to create. See Health Rule Types.
   b. Decide which entities are affected by the new rule. See Entities Affected by a Health Rule.
   c. Define the conditions to monitor. See Create and Configure Conditions.
4. If you want the health rules to be evaluated according to a pre-defined time schedule, create a health rule schedule. In some situations, a health rule is more useful if it is evaluated at a particular time. See Health Rule Schedules.

After you set up health rules you must configure policies and actions to be executed when health rules are violated. See Policies and Actions.

Additional Considerations

- Your application status is based on health rules for the current time range. If you disable old health rule policies or enable new ones, you might see errors in red in your application status, even if there are no current critical events based on the new policies. To verify that your new or disabled health rule policies have taken effect, change the time range in your dashboard to a smaller, more recent time frame.

- When you are configuring health rules for business transactions with baseline selected in the configured condition with a very fast average response time (ART) such as 25 ms, using standard deviation as a criterion can cause the health rule to be violated too frequently. The health rule may violate too frequently because a tiny increase in response time can represent multiple standard deviations. In this case, consider adding a second condition that sets a minimum ART as a threshold. For example, if you do not want to be notified unless ART is over 50 ms, you could set your threshold as ART > 2 Standard Deviations and ART > 50 ms.

- Similarly, when configuring health rules for calls-per-minute (CPM) metrics with baseline selected in the configured condition, the health rule may never be violated if the condition is using standard deviations, and the resulting value is below zero. In this case, consider adding a second condition that checks for a zero value, such as CPM < 2 Standard Deviations and CPM < 1.

Health Rule Schedules

Related Pages:

- Health Rules
- Configure Health Rules
- Troubleshoot Health Rule Violations
- Policies
- Actions

This page provides an overview of health rule schedules in AppDynamics.

The metrics associated with a health rule are evaluated according to a schedule that you control. You can configure:

- when a health rule is in effect
- which data set should be used, based on time
- what special rules should be in place during a violation event

Time evaluation for health rule schedules is based on the time zone you specify, regardless of the time zone of the Controller.

> For schedules created in AppDynamics controller version 4.5.15 or earlier, all schedules are executed based on the controller time zone. For schedules created in version 4.5.16 or later, schedules are executed based on the time zone you specify, irrespective of the controller time zone.

Health Rule Enabled Schedule

By default, health rules are always enabled. You can define schedules for evaluation of the health rules.

Built-in schedules exist for:

- End of business hours
- Weekday lunch
- Weekday mornings
- Weekdays
- Weekends
- Weeknights

You can also configure custom health rule schedules. The custom schedule allows you to define a time zone specific to your application, independent of the controller time zone. This eliminates the need to adjust the time zone manually if your application is in a separate time zone than that of the controller. For more details, see Create and Manage Health Rule Schedules.

Health Rule Evaluation Time Frame

The health rule evaluation time frame is the period of time over which the data used to evaluate the health rule is collected.

Different kinds of metrics provide better results using different sets of data. You can manage how much data AppDynamics uses when it evaluates a particular health rule by setting the data collection time period. You can define an evaluation time frame between 1 minute to 120 minutes. The default value is 30 minutes. You can select the following values in the **Use data from last** drop-down:

1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100, 110, 120

> You can define a persistence threshold for a condition only if you have defined the evaluation time frame of 30 mins or less.

Health Rule Wait Time After Violation

The health rule wait time setting lets you control how often an event is generated while the conditions found to violate a health rule continue. If the controller determines that a health rule has been violated, with a status of either Critical or Warning, an Open Critical or Open Warning event is generated. This event is used to trigger any policies that match the health rule and initiate any actions that the policies require.

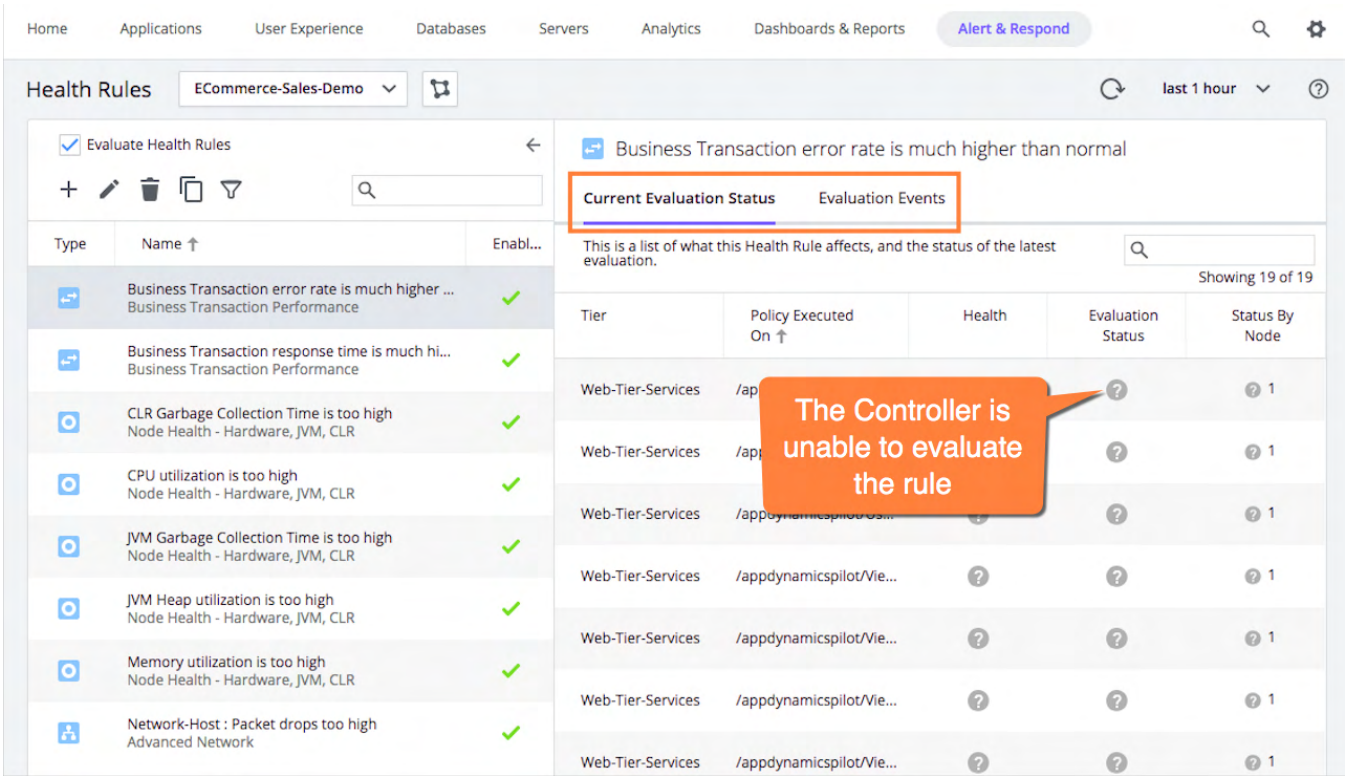
Once an Open event has occurred, the controller continues to evaluate the status of the health rule every minute. If the controller continues to detect the same violation, the violation remains open with the same status. A corresponding **Continues Critical** or **Continues Warning** event may be generated to link to any related policy.

A **Continues** event every minute might be too noisy for your health rule. The health rule's **Wait Time after Violation** setting is used to throttle how often these Continues events are generated for continuing health rule violations. The default is every 30 minutes.

To use Continues Critical and Continues Warning events, adjust the default **Wait Time after Violation** value to the desired frequency. Then configure a policy matching the health rule with the *Health Rule Violation Continues - Warning and/or Health Rule Violation Continues* - Critical events selected in the **H ealth Rule Violation Events** section of the policy settings.

The violations displayed in the **Health Rules Violations** page, under **Troubleshoot**, are updated only when a health rule violation event is triggered.

If the Controller is unable to evaluate the rule—for example, if a node stops reporting—the Evaluation Status of the health rule is marked as a grey question mark or Unknown in the **Current Evaluation Status** tab in the right panel of the health rules list. The current violation event remains open until the Wait Time after Violation period has elapsed, at which point the violation event is closed and a new event is triggered, causing the Health status itself of the rule to display as *Unknown*.



Health Rule Entities

Related Pages:

- Health Rules
- Configure Health Rules
- Troubleshoot Health Rule Violations
- Policies
- Actions

This page provides an overview of health rule entities in AppDynamics.

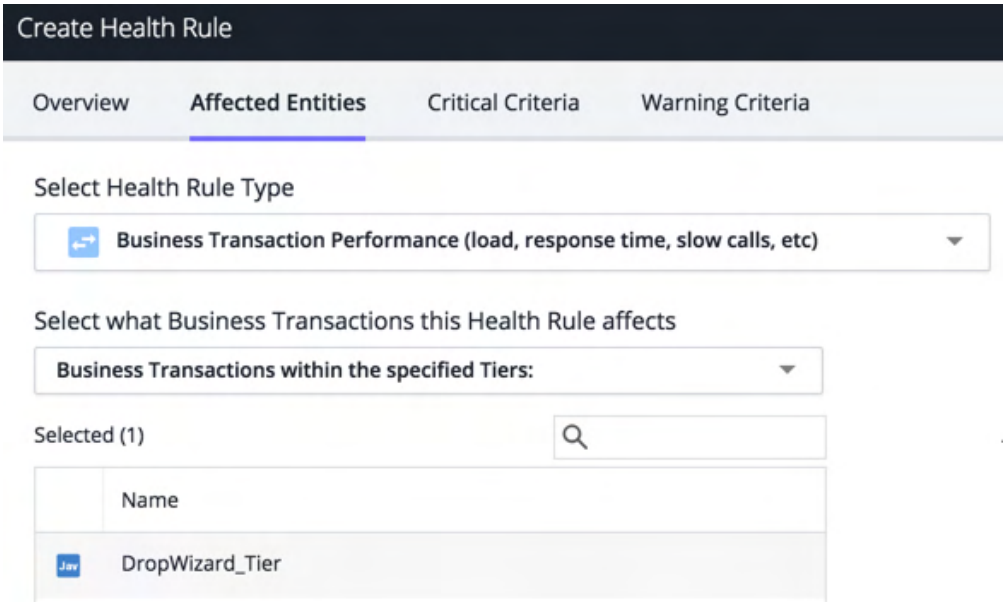
A health rule can evaluate metrics associated with an entire application or a limited set of entities. For example, you can create business transaction performance health rules that evaluate certain metrics for all Business Transactions in the application or node health rules that cover all the nodes in the application or all the nodes in specified tiers. The default health rules are in this category.

You can also create health rules that are applied to a limited set of entities in the application, or even a single entity such as a node or a JMX object or an error. For example, you can create a JMX health rule that evaluates the initial pool size and number of active connections for specific connection pools in nodes that share certain system properties.

Monitoring Serverless Entities

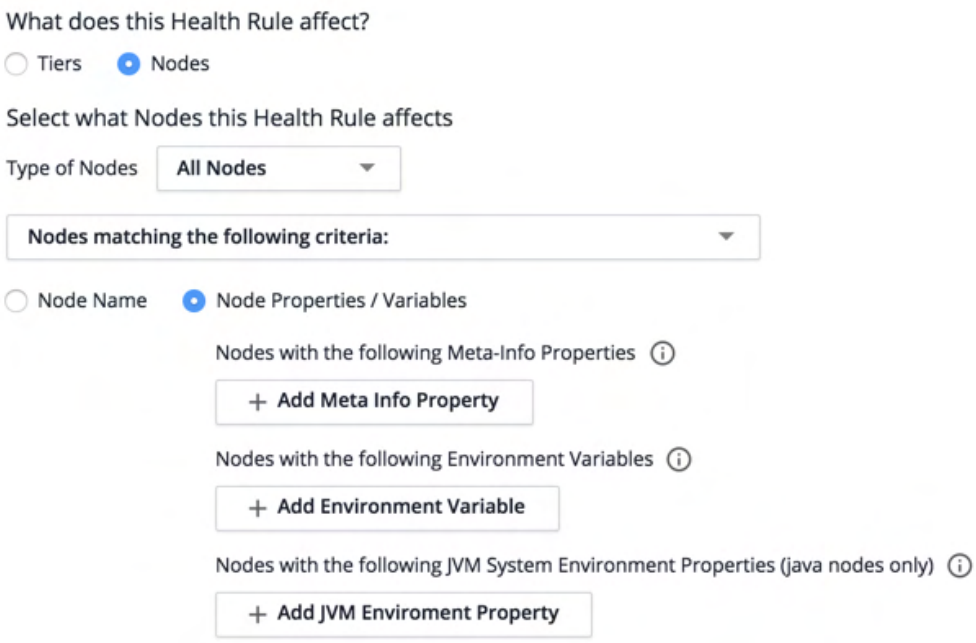
Serverless functions are tracked at the tier level. A serverless function is indicated by a lambda () icon inside each tier. When you configure a health rule for an application comprising serverless entities, you can choose to monitor the serverless tiers in the **Affected Entities** tab. For information on how various health rules are evaluated for serverless entities comprising tiers for AWS Lambda, see Evaluating Serverless Tiers.

The health rule wizard lets you specify which entities the health rule affects, enabling the creation of very specific health rules. For example, for a Business Transaction, you can limit the tiers that the health rule applies to, or limit the health rule application to specific business transactions by name or by names that match certain criteria.



For node health rules, you can specify the type of the node, such as Java, .NET, PHP, and so on.

You can specify that a health rule applies only to nodes that meet certain criteria.

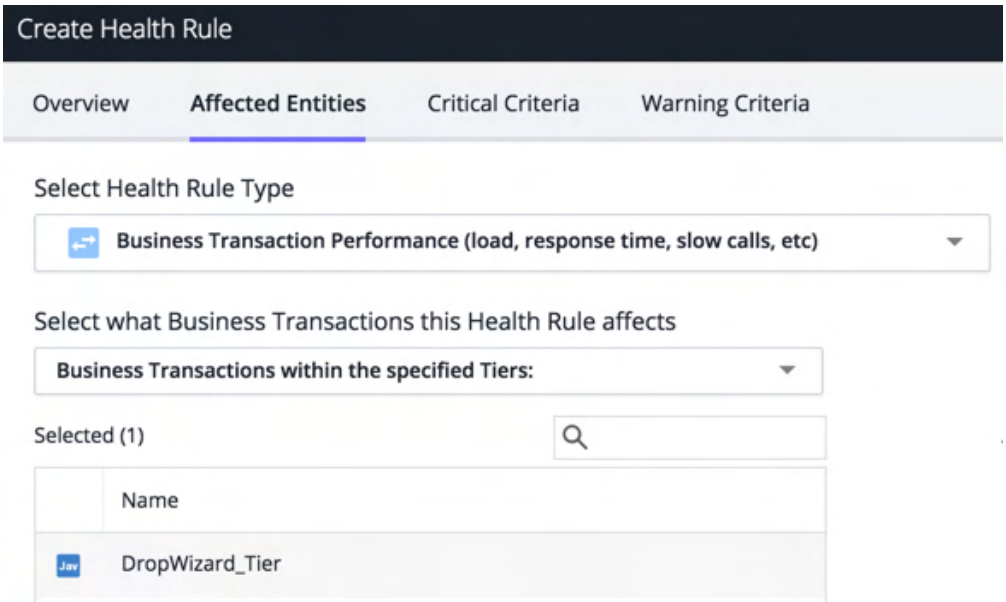


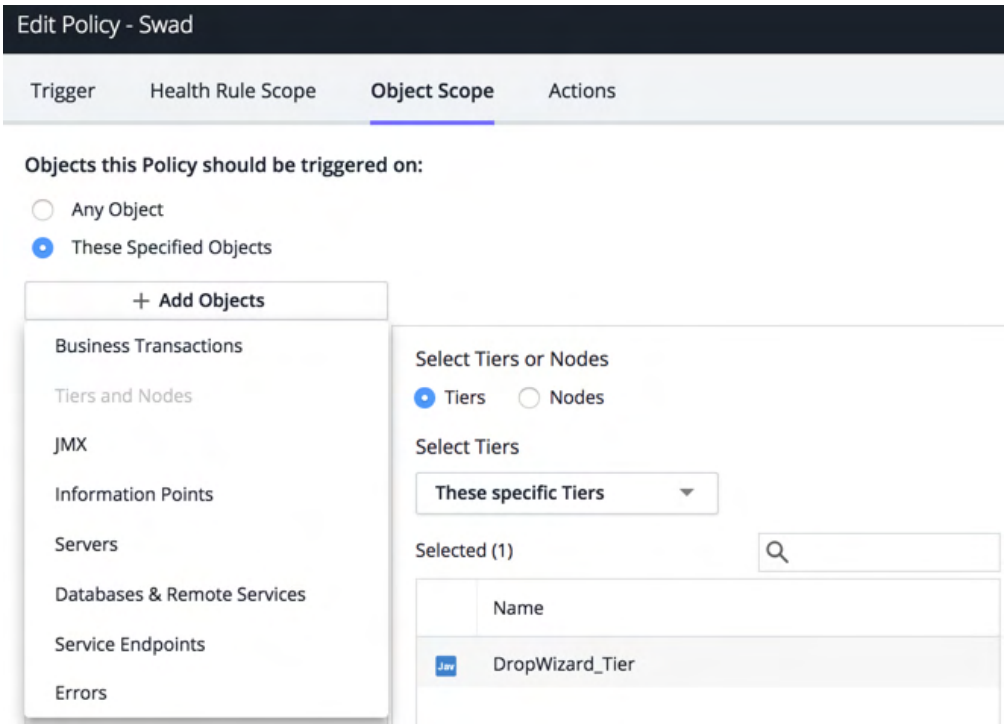
The **Type of Node** pulldown menu does not allow you to specify Node.js, Python, or Web Service nodes. To restrict a health rule to these types of nodes, you can specify the affected entity as a tier and then select only Node.js or Python or Web Service tiers as needed. Or to more finely-tune the affected nodes, use the **Nodes matching the following criteria** menu item to specify node names or matching environment variables or meta-info to restrict the health rule to the nodes you want.

Entities Affected by a Health Rule

For an **Overall Application Performance Health Rule** type, the health rule applies to the entire application, regardless of the business transaction, tier, or node.

If you configure your Health Rule to work with tiers, you must also configure the parallel policy to work with tiers. However, if you configure your Health Rule to work with tiers, but your policy is configured with nodes first, you will not trigger any actions or notifications. The inverse is also true. The following screenshots show examples of a health rule and a policy created in the correct order.





The following table lists the entities that you can apply health rules to.

Health Rule Type	Applicable Entities
Business Transaction Performance	• All Business Transactions in the application • All Business Transactions within tiers that you select • All Business Transactions within serverless tiers that you select for a serverless platform* • Individual Business Transactions that you select • Business Transactions with names that have patterns matching criteria that you specify (such as all Business Transactions with names that start with "INV")
Custom	• A business transaction that you specify • A node that you specify • Overall application performance
Databases & Remote Services health	• All databases and remote services in the application • Individual databases and remote services that you specify • Databases and remote services with name matching criteria that you specify
Error Rates	• All Errors in the application • Specific error types that you select • Errors with the specified tiers • Errors within the specified serverless tiers for serverless platform* • Errors with names that have patterns matching criteria that you specify
Information Points	• All servers in the application • Information points that you specify • Information points with names matching criteria that you specify

Node Health—JMX	• All JMX instance names (MBeans) in the application • Specific MBeans • MBeans on certain nodes • Specific JMX objects • All nodes in the application • Nodes within specified tiers • Individual nodes that you specify • Nodes with names, meta-data, environment variables or JVM system environment properties with matching criteria that you specify • Nodes with certain MBeans
Node Health—Transaction Performance or Node Health—Hardware, JVM, CLR	• All tiers in the application • Individual tiers that you specify • All serverless tiers in the application for a serverless platform* • Individual tiers that you specify for a serverless platform* • All nodes in the application • Nodes types, such as Java nodes, PHP nodes, and so on • Nodes within specified tiers • Individual nodes that you specify • Nodes with names, meta-data, environment variables or JVM system environment properties with matching criteria that you specify The performance of serverless tiers is not evaluated for **Tier/Node Health (Hardware)** health rules. AWS does not offer node-level dashboards or metrics because the serverless platform runtime instances spin up and down on demand.
Server health	• All servers in the application • Servers that you specify • Servers in specific tiers
Service Endpoint	• All service endpoints in the application • Service endpoints that you specify • Service endpoints with names matching criteria that you specify • Service endpoints within specified tiers • Service endpoints within specified serverless tiers for serverless platform*
User Experience - Mobile Apps	• All mobile apps with the specified app key • The specified mobile apps • Mobile apps matching the given criteria
User Experience - Mobile Network Requests	• All network requests in the application • Network requests that you specify • Network requests with names matching criteria that you specify • Network requests of the specified mobile apps
User Experience - Browser Apps—Pages, iframes, Ajax Requests, Virtual Pages, Synthetic jobs	• All such entities • Entities that you specify • Entities with names matching criteria that you specify

Health Rule Conditions

Related Pages:

- Health Rules
- Configure Health Rules
- Troubleshoot Health Rule Violations
- Policies
- Actions

You define the acceptable range for a metric by establishing health rule conditions. A health rule condition sets the metric levels that constitute a **Warning** s tatus or a **Critical** status.

A condition consists of a Boolean statement that compares the current value of a metric against one or more static or dynamic thresholds based on a selected baseline. If the condition is true, the health rule violates. The rules for evaluating a condition using multiple thresholds depend on configuration.

Static thresholds are straightforward. For example, is a business transaction's average response time greater than 200 ms? The condition is evaluated to 'true' if the average response time is greater than 200 ms and the health rule violates.

Dynamic thresholds are based on a percentage in relation to, or a standard deviation from, a baseline built on a rolled-up baseline trend pattern. A daily trend baseline rolls up values for a particular hour of the day during the last thirty days, whereas a weekly trend baseline rolls up values for a particular hour of the day, for a particular day of the week, for the last 90 days. For more information about baselines, see Dynamic Baselines.

You can define a threshold for a health rule based on a single metric value or on a mathematical expression built from multiple metric values.

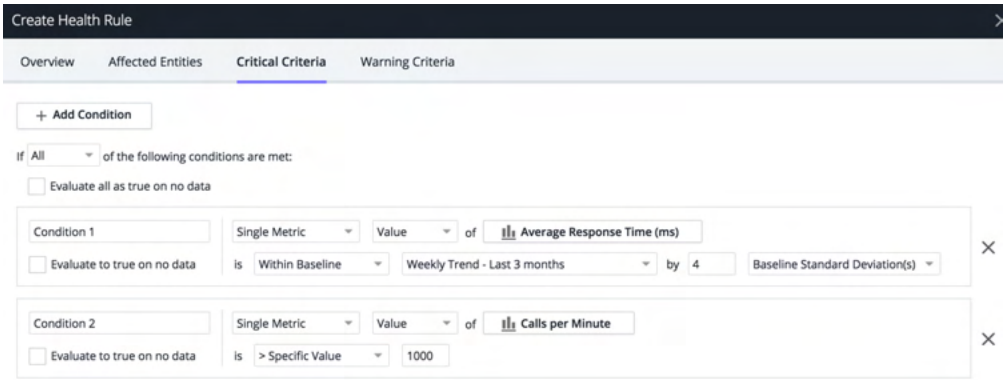
The following are typical health rule conditions:

- If the value of the Average Response Time is greater than the default baseline by 3 X the Baseline Standard Deviation . . .
- If the count of the Errors Per Minute is greater than 1000 . . .
- If the number of MB of Free Memory is less than 2 X the Default Baseline . . .
- If the value of **Errors per Minute/Calls per Minute** over the last 15 days > 0.2 . . .
  This example combines two metrics in a single condition. You can use the expression builder embedded in the health rules wizard to create conditions based on a complex expression comprising multiple interdependent metrics.
- If the (average response time > baseline OR errors per minute > baseline) **AND** (calls per minute > the defined threshold) . . .
  This example uses multiple conditions to evaluate the health rules. You can use the 'CUSTOM' option to define a boolean expression to evaluate the conditions.

Critical and Warning Conditions

Conditions are classified as either critical or warning conditions.

Critical conditions are evaluated before warning conditions. If you have defined a critical condition and a warning condition in the same health rule, the warning condition is evaluated only if the critical condition is not true.



The configuration procedures for critical and warning conditions are identical, but you configure these two types of conditions in separate panels. You can copy a critical condition configuration to a warning configuration and vice-versa and then adjust the metrics in the copy to differentiate them. For example, in the **Critical Condition** panel you can create a critical condition based on the rule:

- If the Average Response Time is greater than 1000

Then from the Warning Condition panel, copy that condition and edit it to be:

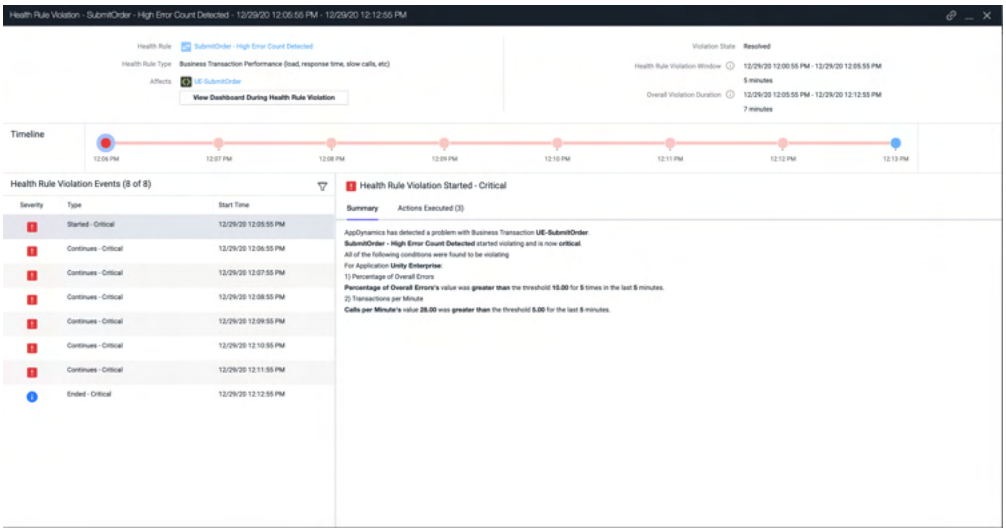
- If the Average Response Time is greater than 500

As performance changes, a health rule violation can be upgraded from warning to critical if performance deteriorates to the higher threshold or downgraded from critical to warning if performance improves to the warning threshold.

Health Rule Violation Event

When metric levels exceed the acceptable range, conditions violate, a health rule violation event occurs. The details of the violation event are displayed on the Health Rule Violation window. This window displays the following details:

- Number of violation events
- Summary of each violation event
- Details of actions initiated in response to the violation event
- Timeline of each violation event

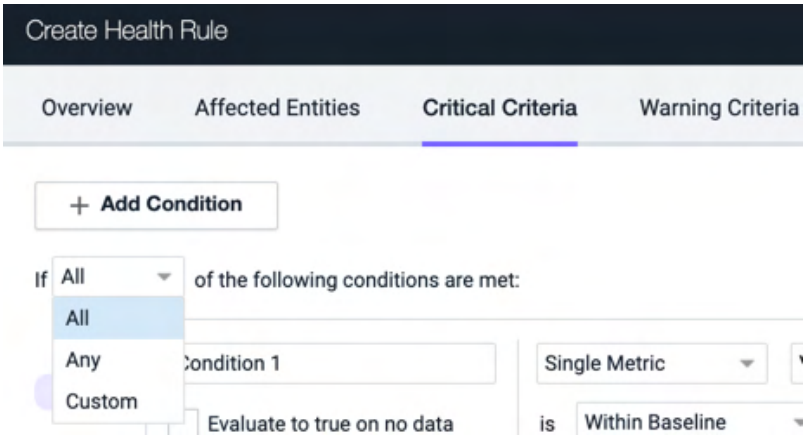


When you define a trigger for the condition, the health rule violation event summary does not display any metric value as there is no single value. However, when you do not define any trigger for the condition, the health rule violation event summary displays the metric value.

Evaluation Criteria

When you define multiple conditions for a health rule, they are evaluated based on the criteria you define. You can use the following options to define the evaluation criteria:

- All: the health rule violates if all the conditions defined in the criteria evaluate to 'true'.
- Any: the health rule violates if one of the conditions defined in the criteria evaluates to 'true'.
- Custom: the health rule violates if the boolean expression with multiple conditions evaluates to 'true'.



For information on how to configure evaluation criteria, see Configure Health Rule Evaluation Criteria.

The following table uses examples to illustrate how a health rule is evaluated based on the criteria and when is it considered to violate.

Health Rule Configuration	Evaluation	Example
Single condition	the condition evaluates to 'true'	A health rule that compares 'average response time' with a defined baseline.

Multiple conditions with 'ANY' evaluation criteria	one of the health rule conditions evaluates to 'true'	A health rule that monitors the health of business transaction may measure any of the following performance metrics: • average response time or • errors per min
Multiple conditions with 'ALL' evaluation criteria	all of the health rule conditions evaluate to 'true'	A health rule that monitors the health of business transaction measures all of the following metrics: • response time • average response time greater than a baseline value, correlated with the application load For example, 50 concurrent users on the system. A policy is defined such that a remedial action is initiated only if the load (calls per minute) is high although the response time threshold is reached. The first part of the condition evaluates the response time and the second part ensures that the health rule is violated only when there is sufficient load.
Multiple conditions with 'CUSTOM' evaluation criteria	the boolean expression with multiple conditions evaluates to 'true' ⓘ The condition is evaluated only if a valid combination of conditions using AND and OR operators is entered, else the evaluation fails.	A health rule that monitors the health of a Business Transaction, measures the performance based on the following conditions: • (average response time greater than baseline OR errors per min greater than baseline) AND • (calls per min greater than threshold)

Persistence Thresholds

Temporary spikes in metric performance data is a major cause of false alerts. Persistence thresholds allow you to define a 'sensitivity level' for a health rule and thereby reduce the number of false alerts. You can define the 'number of times metric performance data should exceed the defined threshold during the evaluation time frame' to constitute a violation and subsequently trigger an alert.

ⓘ You can define a persistence threshold for a condition only if you have defined an evaluation time frame of 30 minutes or less.

For example, when monitoring the CPU utilization, you would not want to be reported of a single violation (section A in the figure) of the threshold. However, if the violation of threshold continues to occur multiple times (section B in the figure) during the evaluation time period, you would want to be alerted.

Alert Sensitivity Tuning

> AST feature is enabled only if you create a health rule to monitor a business transaction, a service endpoint, or a remote service.

SaaS

It is important that you configure conditions appropriately to ensure that you do not miss any alerts or receive false alerts instead. With 'Alert Sensitivity Tuning' (AST), you can view historical data for metri and baselines when you configure conditions. This data helps visualize the impact of the configuration you define and assists in fine-tuning the configuration.

You can view a graphical representation of the metric data, threshold value, standard deviation, and the baseline. The graphical view is instantly updated when you update any configuration. You can also view granular details by modifying the graphical view. To view granular details, you can:

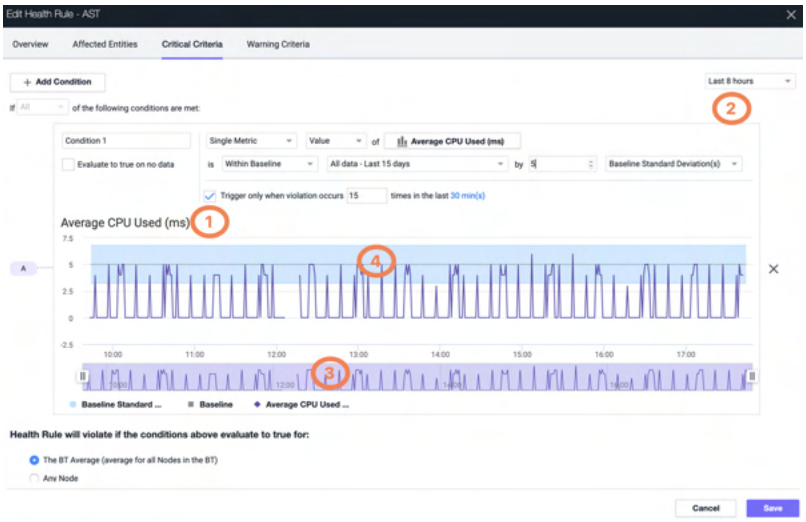
- increase the time period of the data capture to 1 day or 3 days.

  > If data is not available for the selected time period, only available data is presented.

- adjust the time range in the graph to view the metric data details.
- hover over the metric data to view metric and baseline values at any given time.

You can analyze the data presented and then make adjustments to your configuration accordingly. For more information on fine-tuning a condition, see Cre ate a BT Health Rule and Fine-tune Metric Evaluation.

For example, if you select **Average CPU Used (ms)** (1) as a metric to be monitored for a health rule condition, you can view the past metric data for a time period of 8 hours (2). The graphical representation of the metric data indicates the baseline (3) and the baseline standard deviation (4). Based on this data, you can fine-tune the evaluation of the condition so that you avoid false alerts and receive the alerts only when the health rule violates the conditions you define.



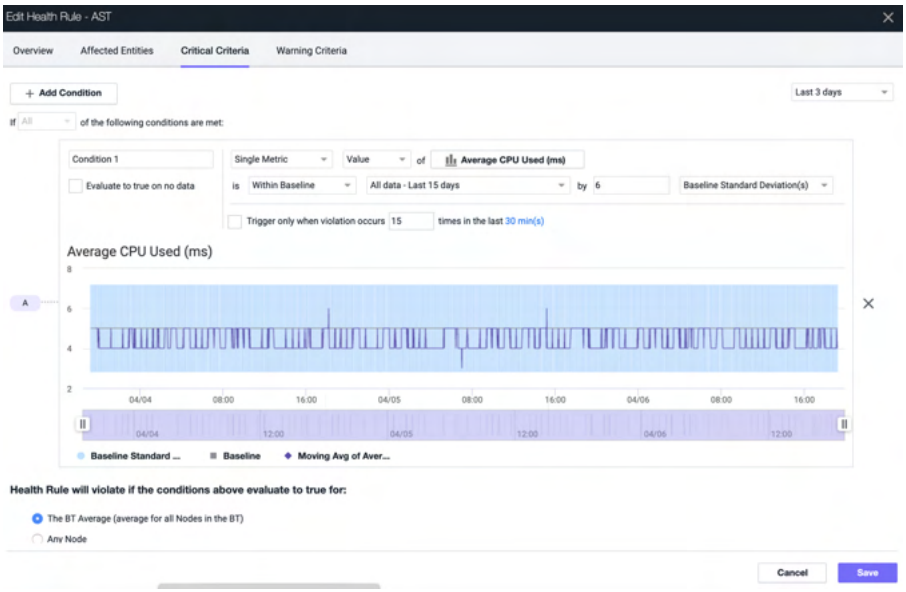
Moving Average

If you define a persistence threshold to evaluate a condition, the metric data for every minute is compared to the baseline and plotted on the AST graph. However, if you do not define the persistence threshold, a 'moving average' for the selected metric is plotted as follows:

1. Depending on the '**Use data from last**' value 'X', the metric data for 'X' minutes is considered.
2. On the 'X+1'th minute, the average of the past 'X' minutes is computed and denoted as the first point on the graph.
3. Similarly, the average for the following 'X' minutes is computed and points are denoted on the graph for the rest of the time range.

Why Use Moving Average?

Unless persistence thresholds are used, health rules compare the moving average of a metric to a threshold or a baseline. Thus, representing the moving average in the graph is appropriate. For more information, see Create a Health Rule and Fine-tune Metric Evaluation.



How are Conditions Evaluated if No Data is Reported?

The Evaluate to true on no data option controls the evaluation of the condition in cases where any metric on which the condition is based, does not return any data. The condition evaluates to 'unknown' (default) when no data is returned. If the health rule is based on all the conditions evaluating to true, having no data returned may affect whether the health rule triggers an action.

When you define a health rule evaluation time frame, reference data is collected for each data point. If the configured metric fails to report data during the time frame, the health rule condition is evaluated as follows:

Evaluate to true on no data	Trigger only when violation occurs x times in the last y min (s)	Condition Evaluation
Enabled	Enabled	The condition is evaluated for each data point in the evaluation time frame. The condition evaluates to 'true' when metric fails to report any data for a given data point. For example, when you set the persistence threshold, X = 3 for an evaluation time frame, Y = 5. This means that 5 data points are required to evaluate the condition. Data is reported for 4 data points, no data is reported for 1 data point and the metric exceeds the threshold twice. The condition evaluates to 'true' for the minute when no data is reported.
Enabled	Disabled	The condition does not evaluate to 'true' if a metric fails to report data for any data point during the evaluation time frame.
Disabled	Disabled	The condition does not evaluate to 'true' if the configured metric fails to report data for any data point during the evaluation time frame.

Custom Boolean Expression

A condition consists of single or multiple statements that evaluate different metrics. You can define a single condition or multiple conditions to evaluate the performance metrics of your application. When you define multiple conditions, you may want to define an evaluation criteria using a boolean expression.

Advantages of using a boolean expression are:

- eliminates the need to create multiple health rules to monitor various performance metrics. Using a boolean expression allows you to evaluate complex criteria for multiple conditions in one go.
- well-calibrated boolean expression ensures reduced false alerts.
- easy to create and maintain health rules with complex evaluation criteria using simple condition names. Conditions are named as **A**, **B**, **C** and so on.
- allows the use of `AND` and `OR` operators to define a highly complex boolean expression. You can use a maximum of 8 operators in your boolean expression.

Evaluation Scope

The health rule evaluation scope defines how many nodes in the affected entities must violate the condition before the health rule is considered violated.

Evaluation scope applies only to business transaction performance type health rules and node health type health rules in which the affected entities are defined at the tier level.

For example, you may have a critical condition in which the condition is unacceptable for any node, or you may want to consider the condition a violation only if the condition is true for 50% or more of the nodes in a tier.

Options for this evaluation scope are:

- The tier average: Evaluation is performed on the tier average instead of the individual nodes.
- Any node: If any node exceeds the thresholds, the rule is violated.
- Percentage of the nodes: If x% of the nodes exceed the thresholds, the rule is violated.
- Number of nodes: If x nodes exceed the thresholds, the rule is violated.

Health Rule Management

Related Pages:

- Health Rules
- Configure Health Rules
- Troubleshoot Health Rule Violations
- Policies
- Actions

This page provides an overview of health rule management in AppDynamics.

To view current health rules, including the default health rules, and to access the health rule wizard, click **Alert & Respond > Health Rules**. Then choose the type of entity for which you want health rules from the pulldown menu at the top.

Current health rules are listed in the left panel. If you click one of these rules, a list appears in the right panel showing which entities this selected health rule affects and what the status of the latest evaluation is. You can also select the **Evaluation Events** tab to see a detailed list of evaluation events.

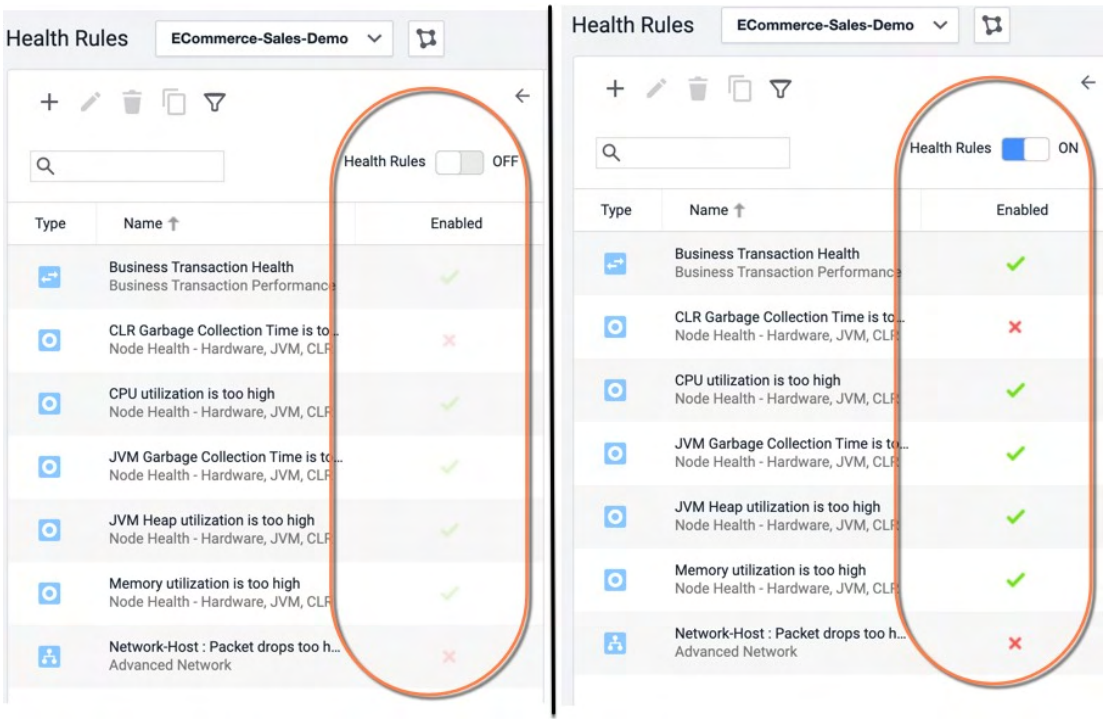
In the left panel, you can directly delete or duplicate a health rule. From here you can also access the health rule wizard to add a new rule or edit an existing one.

You can turn off the evaluation of all health rules in the selected entity by clearing the **Evaluate Health Rules** checkbox. Check it when you want health rule evaluation to start again.

See Configure Health Rules for details on using the health rule wizard.

Disable All Health Rules

You can disable the evaluation of all the health rules for a selected entity by setting the **Health Rules** toggle **OFF**. The **Health Rules** UI indicates the status of all the health rules.



To resume the health rule evaluation, set the toggle **ON**.

- You can disable the evaluation of an individual health rule in the **Create Health Rule** or **Edit Health Rule** dialog box by clearing the **Enabled** chec kbox.
- When you disable the evaluation of all health rules, individual health rules are not evaluated even if you select the **Enabled** checkbox in the **Creat e Health Rule** or **Edit Health Rule** dialog box.

See Configure Health Rules for details on using the health rule wizard.

View Health Rule Status

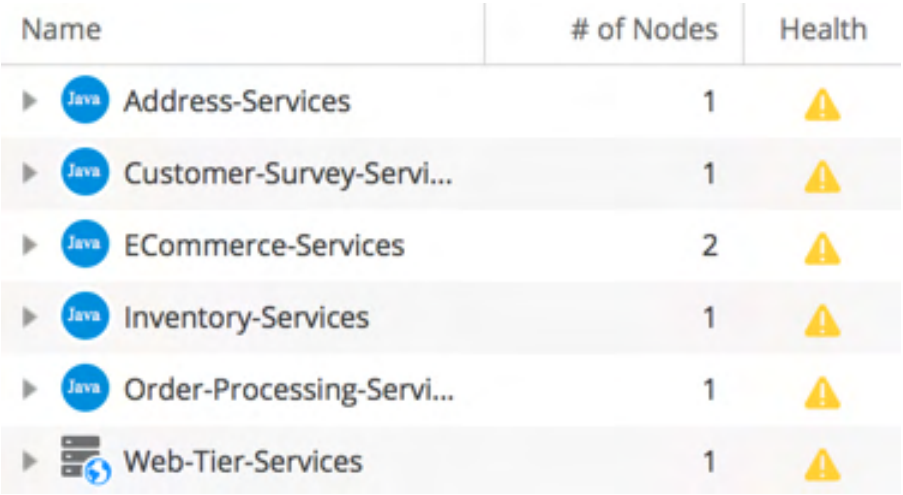
Across the UI, health rule status is color-coded:

- Green is healthy
- Yellow/orange is a warning condition
- Red is a critical condition
- Grey indicates that the status of the health rule is unknown (for example, if the Controller cannot gather the data necessary to evaluate the rule)

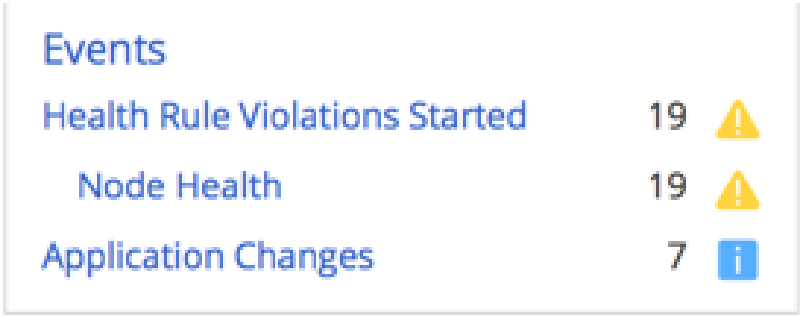
If you see a health rule violation reported in the UI, you can click it to get more information about the violation.

Here are the health summary bars on the built-in dashboards:

A health column is displayed in various lists, such as the tier list below:



In the dashboards, health rule violations are displayed in the Events panel.



Configure Health Rules

Related pages:

- Health Rules
- Configuration Import and Export API
- Metric Browser

This topic describes the detailed steps for configuring health rules using the health rule wizard. For more information on these settings, see Health Rules.

Permissions

To create, edit, or delete health rules, you need the Configure Health Rules permission. For more information, refer to Application Permissions.

Structure of the Health Rule Wizard

The health rule wizard contains four panels:

- Overview: Sets the health rule name, enabled status, the health rule schedule, evaluation period of the health rule data, and wait time post violation.
- Affected Entities: Sets the entities evaluated by the health rule. The options presented vary according to the health rule type you have defined.
- Critical Criteria: Sets the conditions, whether all or any of the conditions need to be true for a health rule violation to exist, and the evaluation scope—business transaction and node health policies defined at the tier level only—it also includes an expression builder to create complex expressions containing multiple metrics.
- Warning Criteria: Settings are identical to Critical Criteria, but configured separately.

You can navigate among these panels using the Back and Next buttons at the bottom of each panel or by clicking the panels in the wizard. You should configure the panels consecutively because the configuration of the health rule type determines the available affected entities in the Affected Entities panel as well as the available metrics in the Criteria panels.

> **Important**
>
> You must configure the panels consecutively because the configuration of the health rule type determines the available affected entities in the **Af fected Entities** panel as well as the available metrics in the **Criteria** panels.

Create and Configure a Health Rule

The following table outlines the steps required to create and configure a health rule:

1	Create a health rule.
2	Configure affected entities.
3	Configure health rule evaluation criteria.
4	Create and configure Conditions.

Create a Health Rule

Related Pages:

- Health Rules
- Configuration Import and Export API
- Metric Browser

You can use the default health rules provided by AppDynamic, modify them to map to your requirements, or define a custom health rule.

Access the Health Rule Wizard

1. Click **Alert & Respond** in the menu bar.
2. Click **Health Rules** either in the right panel or the left navigation pane.
3. Select the context for the health rule from the pulldown menu.
4. Do one of the following:
    - To create a new health rule, click the **+** icon.
    - To edit an existing health rule, select the health rule and click the **Edit** (pencil) icon.
    - To remove an existing health rule, select the health rule and click the **Delete** icon.

Configure Heath Rule Details

You configure health rule details in the **Overview** panel.

1. Enter a name. If a name already exists, you can change it.
2. Check **Enabled** to enable the rule, clear the checkbox to disable it.
3. The Always option is pre-selected in the **When is the rule enabled?** drop-down list. If the health rule is enabled only at certain times, select other predefined schedules from the **When is the rule enabled?** drop-down list.

    > To define a custom health rule schedule or modify the predefined time intervals, click **Manage Health Rule Schedules**. See Create and Manage Health Rule Schedules.

4. Click the drop-down list **Use data from last <> min(s)** and select a number between 1 and 120 minutes. The value you specify is the latest time interval during which data is collected to determine if there is a health rule violation. This value applies to both critical and warning criteria. See Health Rule Evaluation Time Frame.

    > If you have defined a persistence threshold for the health rule condition, ensure that you define an evaluation time frame of 30 mins or less.

5. In the **Wait Time after Violation** field, enter the number of minutes to wait before re-evaluating the rule for the same affected entity in which the violation occurred. See Health Rule Wait Time After Violation.

After you configure the Health Rule details in the **Overview** panel, proceed with the following steps.

1. Configure the entities affected for the health rule, see Configure Affected Entities.
2. Define the evaluation criteria for the health rule, see Configure Health Rule Evaluation Criteria.
3. Save your configuration.

Create and Manage Health Rule Schedules

1. In the Overview panel of the Create Health Rule wizard, click **Manage Health Rule Schedules**. The **Manage Health Rule Schedules** window lists all the predefined time intervals.
2. Select a predefined schedule in the **Manage Health Rule Schedules** window and click the **Edit** icon to see the details of the predefined schedule.
3. To edit a predefined schedule for health rule evaluation:
    a. In the **Edit Schedule** window, make necessary changes.
    b. Click **Save**.

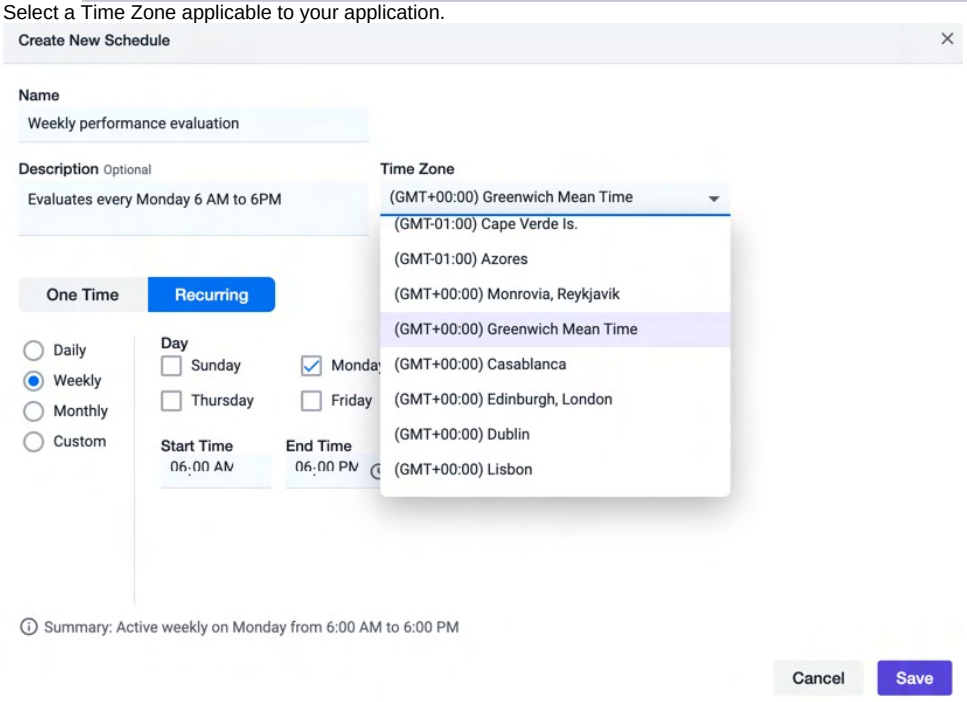
    > Schedules created in version 4.5.15 or earlier are set to 'Custom' type by default and the time zone is automatically set to the controller time zone.

4. To create a new health rule schedule:
    a. Click the **+** icon. The **Create New Schedule** window appears.
    b. Enter following details:
        i. a name for the schedule.
        ii. an optional description of the schedule.
    c. If you want to evaluate the health rule only once,
        i. Select One Time.
        ii. Enter the Start Date and Start Time.
        iii. Enter the End Date and End Time for the schedule.

d. If you want to define a recurring schedule to evaluate the health rules,
   - Select how often you want to evaluate the health rules:

Occurrence	Additional steps
Daily	i. Enter the Start Time and End Time.
Weekly	i. Select a specific day to execute the schedule. ii. Enter the Start Time and End Time.
Monthly	If you select a specific date of the month to execute the schedule: i. Enter the Start Date and Start Time. ii. Enter the End Date and End Time. For example, you might want to evaluate the health rules on the 1st of every month from 6.00 AM to the 5th until 6.00 PM. If you select a specific day of the month to execute the schedule: i. Select an occurrence and the Day. ii. Enter the Start Time and End Time. For example, you might want to evaluate the health rules on the first Monday of every month from 6.00 AM to 6.00 PM.
Custom	i. Enter a Start Date and Start Time for the schedule as a cron expression. ii. Enter an End Date and End Time for the schedule as a cron expression. For example, the following custom schedule specifies: a start time value of 0 0 13 ? * 2-6 and end time of 0 0 15 ? * 2-6 directing the health rule to be evaluated from 1 pm to 3 pm, Monday through Friday:

e. Select a Time Zone applicable to your application.



5. Save your configuration.

Delete Health Rule Schedule

To delete a health rule evaluation schedule, select the schedule in the **Manage Health Rule Schedules** window and click **Delete** – the bin icon at the top. Click **OK** to confirm the deletion.

Create a Health Rule and Fine-tune Metric Evaluation

To ensure that you do not miss alerts or receive false alerts, you must configure alerts appropriately. Alert Sensitivity Tuning (AST) helps configure alerts with appropriate sensitivity by providing historical data for the metric or the baseline being configured. AST also visualizes the impact of the alert configuration.

Create a Health Rule and Fine-tune Metric Evaluation

You can create a health rule to monitor the parameters of an application entity and fine-tune the sensitivity of a health rule using Alert Sensitivity Tuning (AST).

- You must be a SaaS customer.
- You must be monitoring a business transaction, a service endpoint, or a remote service (affected entity).

1. In the entity (BT, SEP, or remote services) UI, select an entity from the list.
2. Right-click the entity and click **Create new Health Rule**. The **Create Health Rule** UI is displayed.
3. Configure the health rule overview details. For more information, see Configure Heath Rule Details.
4. In the **Affected Entities** panel, select the entities to be monitored.
5. In the **Critical Criteria** panel, select **+Add Condition**.
6. Configure the health rule condition.
7. If required. select the **Warning Criteria** panel and define warning conditions as described in step 6.
8. Click **Save.** The health rule is saved.

Configure the Health Rule Condition

1. Enter a name for the condition in the first field of the condition row.
   This name is used in the generated notification text and in the AppDynamics console to identify the violation.
2. From the drop-down list next to the condition name field, select the single metric or metric expression to evaluate the condition.
   a. Single Metric:

Qualifier Type	Description
Minimum	The minimum value reported across the configured evaluation time length. Not all metrics have this type.
Maximum	The maximum value reported across the configured evaluation time length. Not all metrics have this type.
Value	The arithmetic average of all metric values reported across the configured evaluation time length. This value is based on the type of metric.
Sum	The sum of all the metric values reported across the configured evaluation time length.
Count	The number of times the metric value has been measured across the configured evaluation time length.
Group Count	The number of nodes contributing to a metric value, generally relevant for application or tier level metrics.
Current	The value for the current minute.

   i. From the **Value** drop-down list, select a qualifier for the metric from the following options:
   ii. Click **Select a Metric. Metric Selection** dialog box appears. The metric browser in the **Metric Selection** dialog box displays metrics appropriate to the health rule.
   iii. Select a metric from the list for the business transaction. Click **Select Metric**.
   A graphical view of the metric data for the last 8 hours appears.

   If you want to view the metric data for 1 day or 3 days, you can select the time period using the drop-down list.

   iv. From the drop-down list after the metric, select the type of comparison to evaluate the metric.

- To limit the effect of the health rule to conditions during which the metric is within a defined range—standard deviations or percentages—from the baseline, select **Within Baseline** from the drop-down list.
  To limit the effect of the health rule to when the metric is not within that defined range, select **Not Within Baseline**.
  Then select the following:
  -baseline to use
  -numeric qualifier of the unit of evaluation
  -unit of evaluation
  For example:

  ```
  Within Baseline of the Default Baseline by 3 Baseline Standard Deviations
  ```

- To compare the metric with a static literal value, select **< Specific value** or **> Specific Value** from the menu, then enter the specific value in the text field. For example:

  ```
  Value of Errors per Minute > 100
  ```

- To compare the metric with a baseline, **select < Baseline** or **> Baseline** from the drop-down list, and then select the following:
  - baseline to use
  - numeric qualifier of the unit of evaluation
  - unit of evaluation.
  You can use the Baseline Standard Deviation or Baseline Percentage as the unit of evaluation. For example:

  ```
  Maximum of Average Response Time is > Baseline of the Daily Trend by 3 Baseline
  Standard Deviations
  ```

  See Dynamic Baselines for information about the baseline options.

  > **Baseline Percentages**
  >
  > The *baseline percentage* is the percentage above or below the established baseline at which the condition will trigger. For example, if you have a baseline value of 850 and you have defined a baseline percentage of > 1%, the condition is true if the value is > `[850+(850x0.01)]` or `859`.

  To prevent health rule violations from being triggered when the sample sets are too small, these rules are not evaluated if the load—the number of times the value has been measured—is less than 1000. For example, if a very brief time slice is specified, the rule may not violate even if the conditions are met, because the load is not large enough.
  Depending on the baseline configuration you define, a graphical view of the metric data for the given baseline configuration is displayed. The graphical view is instantly updated when you update any configuration. You can also view granular details by zooming in on the graphical view. The metric data presented in the graph helps you calibrate the sensitivity of the metric evaluation.

b. Metric Expression:
   i. Select the **Metric Expression** option from the drop-down list and click **Add Expression**. The **Metric Expression** window appea rs that allows you to construct a mathematical expression to use as a metric. For example, the following expression is created to measure the number of calls per CPU: `Value of {calls} / {cpu} > 1`.
   ii. In the **Variable Declaration** panel of the Mathematical Expression builder, click **+ Add variable** to add a variable.
   iii. In the **Variable Name** field, enter a name for the variable.
   iv. From the drop-down list next to the **Variable Name** field, select the qualifier for the metric from the following options:

Qualifier Type	Description
Minimum	The minimum value reported across the configured evaluation time length. This qualifier is not available for all the metrics.
Maximum	The maximum value reported across the configured evaluation time length. This qualifier is not available for all the metrics.

Value	The arithmetic average of all metric values reported across the configured evaluation time length. This value is based on the type of the metric.
Sum	The sum of all the metric values reported across the configured evaluation time length.
Count	The number of times the metric value has been measured across the configured evaluation time length.
Group Count	The number of nodes contributing to a metric value, generally relevant for application or tier level metrics.
Current	The value for the current minute.

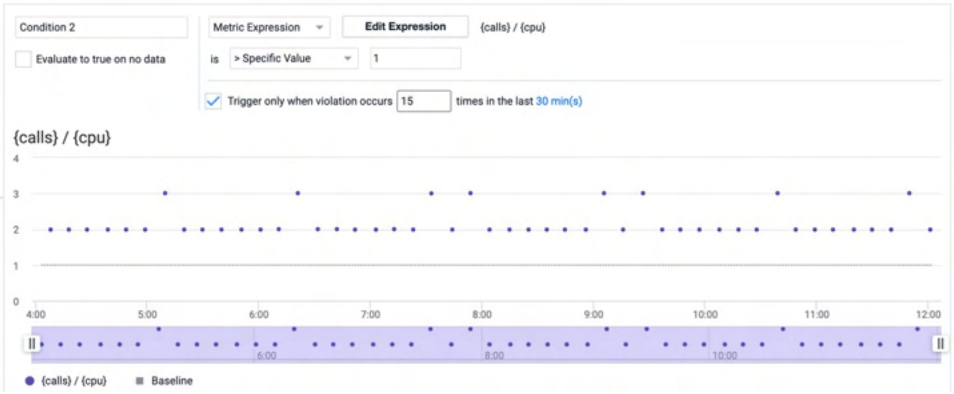
v. Click **Select a metric** to open an embedded metric browser. To avoid erroneous evaluations, if any metric in the expression has a null value, the health rule is not evaluated.

Expression	Null Value	Evaluation
a-b-c	a	entire expression is evaluated negative
a/b	b	the number 'a' is divided by zero, evaluates to an error
a*b	a or b	entire expression is evaluated as zero

vi. Repeat Steps I through V for every metric that you use in the expression. You can remove a variable by clicking the **Delete** icon.
vii. In the **Expression** pane, build the expression by clicking **Insert Variable** to insert variables created in the **Variable Declaration** pane along with appropriate mathematical signs.
viii. When the expression is built, click **Save**.
ix. Back on the **Critical Criteria** tab, select **< Specific value** or **> Specific Value** from the menu to compare the value of the metric evaluation with a static literal value, then enter the specific value in the text field. For example:

```
Value of {calls} / {cpu} > 1
```

A graphical view of the metric data for the last 8 hours appears.



You can view the metric data for 1 day or 3 days by selecting the time period using the drop-down menu.

3. If you want the condition to evaluate to true when a configured metric does not return any data during the evaluation time frame, select the **Evaluate to true on no data** option.
   This option does not affect the evaluation of the unknown in the case where there is no enough data for the rule to evaluate. For example, if the health rule is configured to evaluate the last 30 minutes of data and a new node is added, the condition evaluates to unknown for the first 30 minutes even if the **Evaluate to true on no data** option is selected.
4. If you want to define a 'Persistence Threshold' for the condition to reduce false alerts:

   a. Select **Trigger only when a violation occurs __ times in the last __ min(s).**
   b. Define the number of times metric performance data should exceed the defined threshold to constitute a violation.
   c. If required, adjust the evaluation time frame by setting an alternate evaluation time frame.

- You can define a persistence threshold for a condition only if you have defined an evaluation time frame of 30 minutes or less.
- If you define a persistence threshold for a condition, the metric data is plotted directly on the AST graph. If you do not define a persistence threshold, a 'moving average' for the selected metric is plotted. For more information, see Why Use Moving Average.

5. Specify the evaluation scope in the **Critical Criteria** and **Warning Criteria** panels, select the average of all nodes**.**

AST graphical view is displayed only when you set the health rule evaluation scope to the average for all nodes.

Configure Affected Entities

Related Pages:

- Health Rules
- Configuration Import and Export API
- Metric Browser

This page provides an overview of affected entities in AppDynamics.

The **Affected Entities** panel lets you define what entities your health rule affects. The health rule type you select determines the metrics that are offered for configuration in subsequent panels of the health rule wizard.

To define the affected entities:

1. Select a health rule type from the drop-down list. Depending on the type of the health rule, you can configure the corresponding entities that are affected. See Entities Affected by a Health Rule for information about the types of entities that can be affected by the various health rule types.
2. Use the drop-down list to select the entities affected by this health rule.
3. If you select entities based on matching criteria, specify the matching criteria.
   For example, if you select the Tier/Node Health - Transaction Performance as the health rule type, and if the health rule affects the nodes, you can restrict the health rule evaluation on the types of nodes or criteria such as meta-info, environment variables, and JVM system environment properties. Meta-info includes key-value pairs for:
   - `key: supportsDevMode`
   - `key: ProcessID`
   - `key: appdynamics.ip.addresses`
   - any key passed to the agent in the `appdynamics.agent.node.metainfo` system property

Configure Health Rule Evaluation Criteria

Related Pages:

- Health Rules
- Configuration Import and Export API
- Metric Browser

This page provides an overview of evaluation criteria for health rules in AppDynamics.

After configuring the entities affected by the health rule, you must define the evaluation criteria.

The high-level process for configuring the criteria is:

1. Determine which type of evaluation criteria for the health rule:
    - **Critical Criteria**
    - **Warning Criteria**

    Though the configuration processes for critical and warning conditions are identical, critical conditions are evaluated before warning conditions. If you have defined a critical condition and a warning condition in the same health rule, the warning condition is only evaluated if the critical condition is not true.

    You can copy the settings between Critical and Warning condition panels and edit the fields, if required. For example, if you have already defined a critical condition and you want to create a warning condition that is similar, in the **Warning Condition** window click **Copy from Critical Condition** to populate the fields with settings from the Critical condition.

2. Determine the number and kind of metrics the health rule should evaluate. For each performance metric you want to use, create a condition using one of the following methods:
    - Use a single metric
    - Use a complex metric expression

    For more information, see Configure a Condition.
3. If you have defined multiple conditions, check if the health rule violates by selecting one of the following options:
    - **All**: all conditions evaluate to true.
    - **Any**: one of the conditions evaluates to true.
    - **Custom**: if a boolean expression comprising all conditions evaluate to true.
4. For business transaction performance health rules and node health rule types that specify affected entities at the tier level, decide how many of the nodes must be violating the health rule to produce a violation event. See Health Rule Evaluation Scope.

Create and Configure Conditions

Related Pages:

- Health Rules
- Configuration Import and Export API
- Metric Browser

This page provides an overview of conditions in AppDynamics.

You can define a condition or a set of conditions to evaluate the performance metrics of your application.

Use the following options to evaluate the conditions:

- Expression builder embedded in the health rules wizard to create a condition based on a complex expression comprising multiple interdependent metrics.
- Custom boolean expression to evaluate multiple conditions within a health rule. You can use the `AND` and `OR` operators in a boolean expression.

Create a Condition

1. In the **Critical Condition** or **Warning Condition** window, click **+ Add Condition** to add a new condition component. A row defining the condition is displayed.
2. Configure the Condition as required.
3. Continue to add conditions as required. You can add a maximum of 8 conditions. Conditions are designated as A, B, C, and so on.
4. From the drop-down list above the conditions, select:
    - **All:** if all of the conditions must evaluate to true to constitute rule violation.
    - **Any:** if any of the conditions must evaluate to true to constitute rule violation.
    - **Custom:** if a combination of conditions defined in a boolean expression must evaluate to true to constitute rule violation. For more information on how to create a custom boolean expression, see Create a Custom Boolean expression.
5. For health rules based on the following health rule types, select:
    - Business Transaction
    - Node health-hardware
    - Node health-transaction performance

    You must specify the evaluation scope in the **Critical Criteria** and **Warning Criteria** panels:

    
    You can use Alert Sensitivity Tuning to configure health rule conditions for a business transaction, a service endpoint or a remote service only. You must set the health rule evaluation criteria to 'average of all nodes'. For more information, see Alert Sensitivity Tuning.

    If you select the percentage of nodes, enter the percentage. If you select the number of nodes, enter an absolute number.

Evaluating Serverless Tiers

When you monitor serverless entities comprising tiers for AWS Lambda, the health rules are evaluated as described below.

Health Rule Type	Affected Entities	Condition Evaluation Criteria	Evaluation
• Business transactions • Service endpoints • Error rates	serverless tier(s)	The BT Average	Metrics are aggregated at the tier level.
	serverless node(s)	• Any node • % of the Nodes • Number of the Nodes	Metrics for serverless tiers are aggregated at the tier level, while the metrics for other tiers are evaluated as per the defined criteria.

Tier/Node Health (Transaction Performance)	serverless tier(s)	• The Tier Average (average for all Nodes in the Tier) • Any node • % of the Nodes • Number of the Nodes	Metrics for serverless tiers are aggregated at the tier level, regardless of the evaluation criteria defined.
	serverless node(s)	• The Tier Average (average for all Nodes in the Tier) • Any node • % of the Nodes • Number of the Nodes	The performance of serverless tiers is not evaluated for **Tier/Node Health (Hardware)** health rules. AWS does not offer node-level dashboards or metrics because the serverless platform runtime instances spin up and down on-demand.
Tier/Node Health (Hardware)	• serverless tier(s) • serverless node(s)	-	The performance of serverless tiers is not evaluated for **Tier/Node Health (Hardware)** health rules. AWS does not offer node-level dashboards or metrics because the serverless platform runtime instances spin up and down on-demand.

Configure a Condition

1. In the first field of the condition row, enter a name for the condition.
   This name is used in the generated notification text and in the AppDynamics console to identify the violation.
2. From the drop-down list below the **Add Condition** button, define metrics to evaluate the condition, select:
   - a. From the Value drop-down list, select a qualifier for the metric from the following options:

Qualifier Type	Description
Minimum	The minimum value reported across the configured evaluation time length. Not all metrics have this type.
Maximum	The maximum value reported across the configured evaluation time length. Not all metrics have this type.
Value	The arithmetic average of all metric values reported across the configured evaluation time length. This value is based on the type of the metric.
Sum	The sum of all the metric values reported across the configured evaluation time length.
Count	The number of times the metric value has been measured across the configured evaluation time length.
Group Count	The number of nodes contributing to a metric value, generally relevant for application or tier level metrics.
Current	The value for the current minute.

   b. To specify a simple metric, click **Select a Metric.** Metric Selection window is displayed. The metric browser in the **Metric Selection** window displays metrics appropriate to the health rule type. Alternatively, you can define a relative metric path..

   c. Select a metric to monitor and click **Select Metric**.

   > You can use Alert Sensitivity Tuning to fine-tune metric evaluation for a health rule (that monitors BT, service endpoint or remote service). You must select a single metric to evaluate the condition. See Create a Health Rule and Fine-tune Metric Evaluation for more information.

   or
   - Metric Expression to build a metric expression.
3. From the drop-down list after the metric, select the type of comparison to evaluate the metric.

   - To limit the effect of the health rule to conditions during which the metric is within a defined range—standard deviations or percentages—from the baseline, select **Within Baseline** from the menu. To limit the effect of the health rule to when the metric is not within that defined range, select **Not Within Baseline**. Then select the baseline to use, the numeric qualifier of the unit of evaluation and the unit of evaluation. For example:

```
Within Baseline of the Default Baseline by 3 Baseline Standard Deviations
```

- To compare the metric with a static literal value, select **< Specific value** or **> Specific Value** from the menu, then enter the specific value in the text field. For example:

```
Value of Errors per Minute > 100
```

- To compare the metric with a baseline, **select < Baseline** or **> Baseline** from the drop-down list, and then select the baseline to use, the numeric qualifier of the unit of evaluation and the unit of evaluation. You can use the Baseline Standard Deviation or Baseline Percentage as the unit of evaluation. For example:

```
Maximum of Average Response Time is > Baseline of the Daily Trend by 3 Baseline Standard Deviations
```

See Dynamic Baselines for information about the baseline options.

> **Baseline Percentages**
>
> The *baseline percentage* is the percentage above or below the established baseline at which the condition will trigger. For example, if you have a baseline value of 850 and you have defined a baseline percentage of > 1%, the condition is true if the value is > `[850+(850x0.01)]` or `859`.
>
> To prevent health rule violations from being triggered when the sample sets are too small, these rules are not evaluated if the load—the number of times the value has been measured—is less than 1000. For example, if a very brief time slice is specified, the rule may not violate even if the conditions are met, because the load is not large enough.

4. If you want the condition to evaluate to true whenever a configured metric does not return any data during the evaluation time frame, check the **Evaluate to true on no data** option.
   This option does not affect the evaluation of unknown in the case where there is no enough data for the rule to evaluate. For example, if the health rule is configured to evaluate the last 30 minutes of data and a new node is added, the condition evaluates to unknown for the first 30 minutes even if the **Evaluate to true on no data** box is checked.
5. If you want to define a 'Persistence Threshold' for the condition to reduce false alerts:

   a. Select 'Trigger only when a violation occurs __ times in the last __ min(s)'.
   b. Define the number of times metric performance data should exceed the defined threshold to constitute a violation.
   c. If required, adjust the evaluation time frame by setting an alternate evaluation time frame.

> You can define a persistence threshold for a condition only if you have defined an evaluation time frame of 30 minutes or less.

6. Click **Save** when done.

Evaluation of Agent Availability Metrics

Using Health Rule Conditions to evaluate agent availability metrics can result in false positives. For example:

- Agents may not be connecting with controllers due to communication errors for a couple of minutes.
- Data may be delayed for a couple of minutes due to latency issues.

You can configure the health rules such that you get notified of any occasional one-to-two minute metric loss due to network issues, or when an agent fails to communicate to the controller. Configure your Health Rule as follows:

1. Select Nodes that the health rule affects. You can also set Tiers, however, it is recommended that you set Nodes.
2. Select Node Health - Hardware, JVM, CLR as the health rule **Type**.
3. Use the last five minutes, with a wait time of ten minutes.
4. Set your condition to be the Sum of < Specific value of three.

This configuration generates a violation when the agent is down for more than two minutes during the last five minutes.

Build an expression

To access the expression builder to create a complex expression as the basis of a condition, select the **Metric Expression** option from the drop-down list and click **Add Expression**. The **Metric Expression** window is displayed that allows you to construct a mathematical expression to use as a metric.

For example, the following expression is created to measure the percent of slow business transactions. See the screenshot that follows for the UI location where each step is performed.

1. In the **Variable Declaration** pane of the Mathematical Expression builder, click **+ Add variable** to add a variable.
2. In the **Variable Name** field enter a name for the variable.
3. From the drop-down list, select the qualifier for the metric from the following options:

Qualifier Type	Description

Minimum	The minimum value reported across the configured evaluation time length. This qualifier is not available for all the metrics.
Maximum	The maximum value reported across the configured evaluation time length. This qualifier is not available for all the metrics.
Value	The arithmetic average of all metric values reported across the configured evaluation time length. This value is based on the type of the metric.
Sum	The sum of all the metric values reported across the configured evaluation time length.
Count	The number of times the metric value has been measured across the configured evaluation time length.
Group Count	The number of nodes contributing to a metric value, generally relevant for application or tier level metrics.
Current	The value for the current minute.

4. Click **Select a metric** to open an embedded metric browser.

Health Rule Evaluation Condition

A health rule is not evaluated if any metric in the expression has a null value. This is to avoid erroneous evaluations as shown in the following examples:

Expression	Null Value	Evaluation
`a-b-c`	a	`entire expression is evaluated negative`
a/b	b	`the number 'a' is divided by zero, evaluates to an error`
`a*b`	a or b	`entire expression is evaluated as zero`

5. Repeat steps 1 through 4 for each metric that you use in the expression.
   You can remove a variable by clicking the delete icon.
6. In the **Expression** pane, build the expression by clicking **Insert Variable** to insert variables created in the **Variable Declaration** pane along with appropriate mathematical signs.
7. When the expression is built, click **Save**.

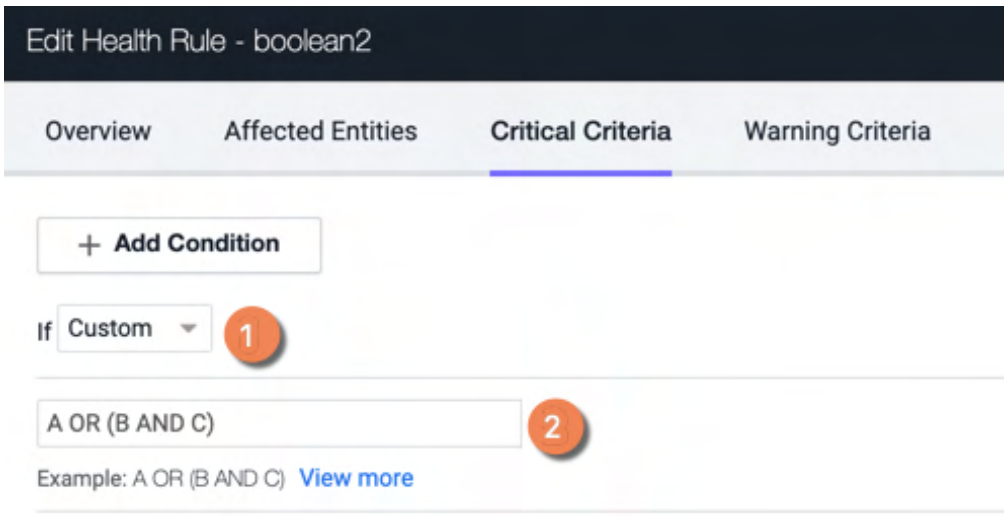
Create a Custom Boolean Expression

Once you define all the conditions required for the health rule, you can create a custom boolean expression to evaluate the health rule.

1. From the drop-down list above the conditions, select **Custom** option.
2. Enter a combination of conditions using `AND` and/or `OR` operators. For example, `(A OR B) AND C`.

Ensure that you enter a valid combination of conditions using `AND` and `OR` operators, else the evaluation fails.

3. Click **Save**.



Modify the Custom Boolean Expression

1. Select the expression in the **Condition Combination** field.
2. Edit the boolean expression as required.
3. Click **Save**.

Delete a condition

Delete a condition component by clicking the delete (**X**) icon.

> If you delete a condition, update the boolean expression accordingly.

Define Custom Metrics for Multiple Entities

Related Pages:

- Health Rules
- Configuration Import and Export API
- Metric Browser

To create a health rule on a custom metric in a single business transaction, node, or overall application performance, you specify the health rule type as *custom* and when you configure the condition component, in the **Select Metric** window, choose to **Specify a Metric from the Metric Tree** and select the metric from the embedded metric browser.

A different use case is to create a rule that evaluates a custom metric that exists across various entities, for example across several nodes. You want to do this with one health rule; you do not want to create a separate health rule for each node. In this case, you need to specify the custom metric using the relative metric path to the metric instead of selecting the metric from the embedded metric browser.

First, get the relative path to the metric and then configure the health rule using that relative path.

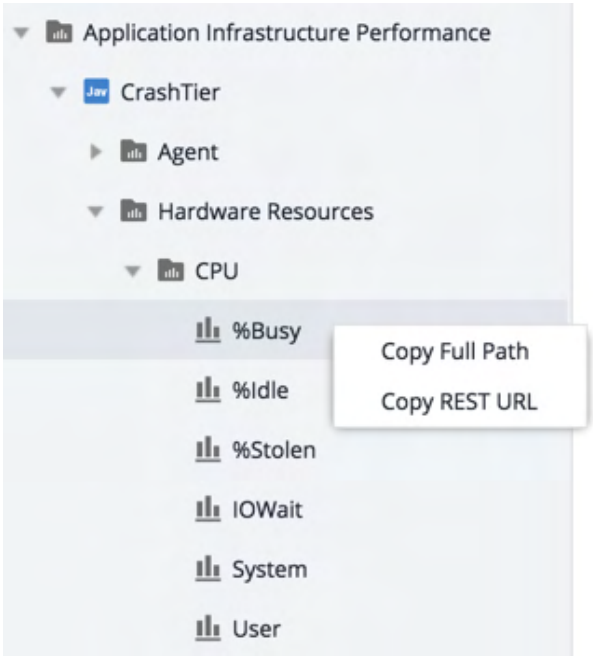
To specify Hardware Resources, JVM, and CLR metrics in multiple entities using a wildcard, you can use the procedure described in Use Wildcards in Metric Definitions.

> The wildcard feature is not supported for custom metrics.

To get the relative metric path for a multi-entity metric:

1. Navigate to the Metric Browser by selecting the **Metric Browser** in the left navigation pane.
2. Select the metric that you want to use for the condition.
3. Right-click and select **Copy Full Path**.
4. Save this value in a file from which you can copy it later.

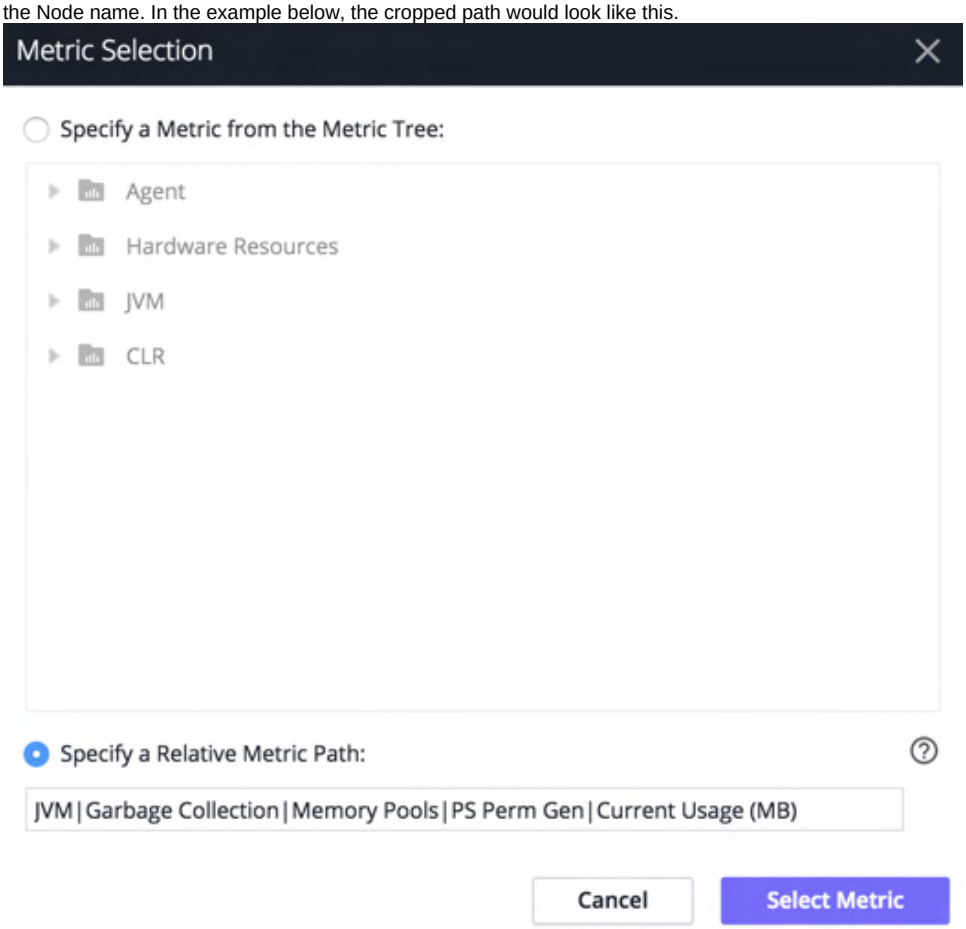
The following example gets the metric path for the CPU %Busy metric for the Inventory Server tier. The CPU %Busy metric would be appropriate to use in a health rule that affects all the nodes in that tier.



To configure a health rule that evaluates the custom metric over multiple entities

1. In the **Overview** panel of health rule wizard choose the health rule type for the kind of entity that you are monitoring.
2. In the **Affected Entities** panel select the affected entity.
3. When you create the condition component that uses the metric, in the Select Metric window choose **Specify a Relative Path Metric**.
4. Crop the relative metric path that you saved from the metric browser by doing one of the following:
    - For all health rule types except Node Health-Hardware, JVM, CLR or Custom, crop the path to use the metric name alone, for example, Average Wait Time (ms).

- For Node Heath-Hardware, JVM, CLR and Custom health rule types, crop the path to use everything after the entity, for example, after the Node name. In the example below, the cropped path would look like this.



5. Paste the cropped relative metric path in the relative metric path field of the **Metric Selection** window.
6. Click **Select Metric**.

JMX Health Rules

Related Pages:

- Monitor JMX
- Configure JMX Metrics from MBeans
- Configure Health Rules

This page provides an overview of JMX health rules, which establish the health status of entities in a monitored Java application based on JMX metrics.

JMX Instance Names

For health rules based on JMX metrics, you can create health rules on a node or on an entity called a JMX instance name. If you create the health rule on the JMX instance name, you have the option of restricting it to specific nodes. If you create the health rule on the node, you have the option of restricting it to specific JMX instance names.

A JMX metric is identified by its JMX metric path, its JMX instance name, and its metric name. These are determined by the **Metric Path**, **Object Name Match Pattern**, and **Metric Name** fields specified in the AppDynamics **JMX metric MBean Configuration** screens. The instance name is derived from the value returned by the object match pattern. Identical JMX instance name values are considered distinct when their metric paths differ.

JMX instance names appear in the Metric Browser under the appropriate JMX metric path. Specific JMX metrics are reported under each JMX instance name.

For details about how JMX metrics are configured, see Configure JMX Metrics from MBeans.

Creating JMX Health Rules

To create a health rule on one or more JMX metrics, in the **Affected Entities** panel of the health rule wizard, set the type of the rule to Node Health-JMX–connection pools, thread pools, and so on.

Determine what JMX objects the health rule will be evaluated on. In some IT organizations, different teams are responsible for different MBeans. In other organizations, different teams are responsible for different nodes or tiers.

The way your organization is set up determines how you think about JMX health, especially where it intersects with node health.

- As a team member responsible for a node, do you consider your node unhealthy because one or more of its MBeans is unhealthy? If so, which nodes or how many?
- As a team member responsible for your JMX infrastructure, are you primarily interested in the health of your JMX data regardless of the nodes that use it? Or are you interested in just specific JMX metrics in specific nodes? Which ones?

> It is recommended to have the JMX rule with instance identifier because it helps in selecting the metric under category in the metric select tree of the UI.

For the purpose of configuring JMX health rules and using them in policies, the ultimate question is: who will receive the alert when the agent reports unhealthy performance detected by JMX metrics? The flexibility of the AppDynamics health rules lets you fine-tune your JMX health rules so that the right people are alerted for the code for which they are responsible.

Select whether the affected entity should be the JMX instance name or the node. In either case, you can configure the rule to cover one of the following scopes:

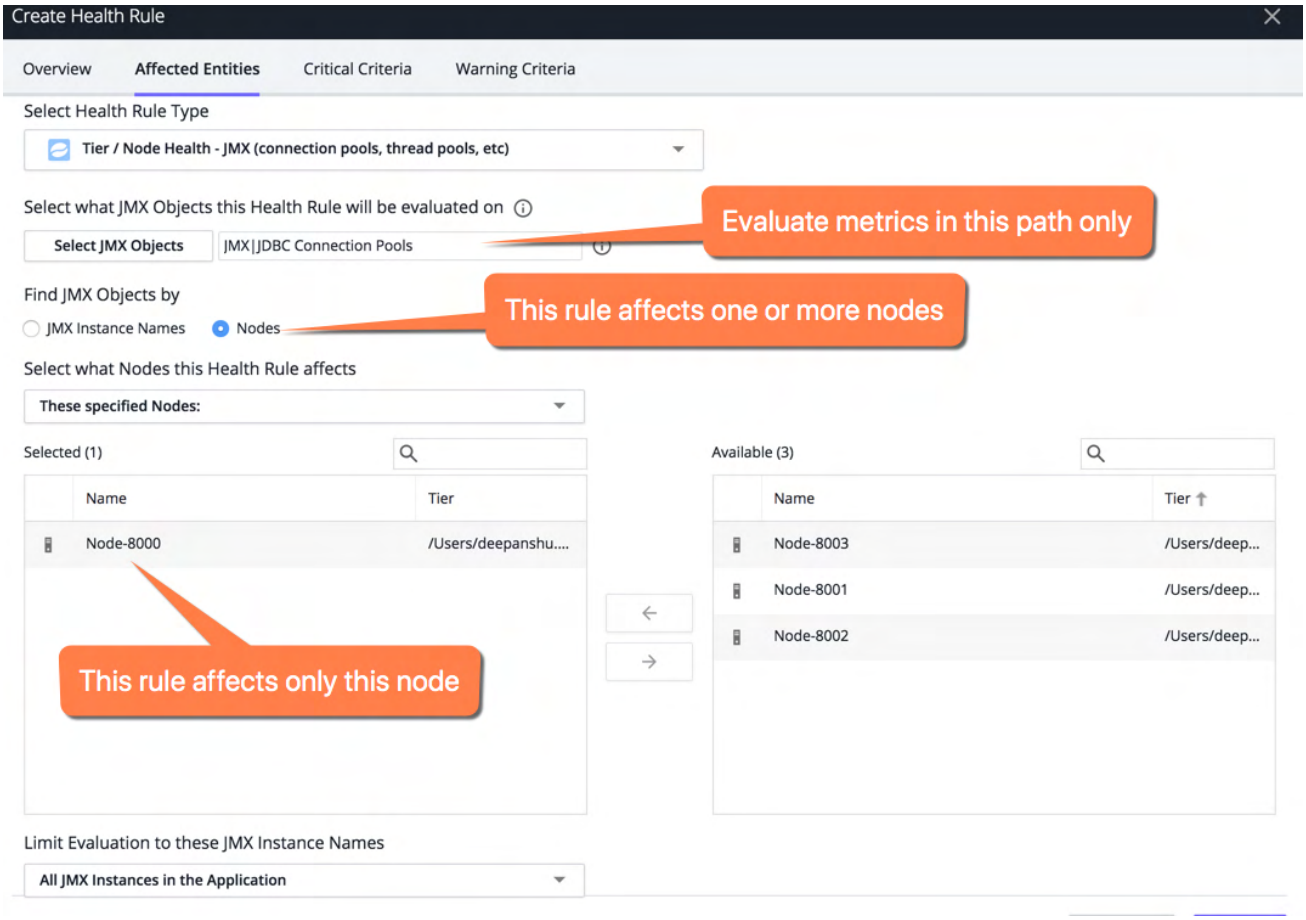
- All JMX instance names in the application
- Specific JMX instance names
- All nodes in the application
- Specific nodes in the application
- Nodes within the specified tiers
- Nodes matching a given criteria

You can limit the evaluation of the health rule to either the specified JMX instance names or nodes depending on the evaluation scope.

JMX Health Rules Affecting a Node

In one organization, teams are responsible for nodes. Mark is responsible for `WEB1_NODE`, Tao for `WEB2_NODE`, and so on.

If an MBean in `WEB1_NODE` generates JMX metrics that violate a critical condition, and a health rule is configured to evaluate a JMX object in that node, Mark or someone on Mark's team will get an alert. The configuration of the health rule would be:



If different people on Mark's team are responsible for different MBeans used in `WEB1_NODE`, they could refine the rule further by selecting specific JMX instance names for evaluation. For example, the last decision of this configuration can restrict the rule to evaluate only metrics in the `jdbc/ECommerceDB` JMX instance name.

Mark's team could create a similar rule for the remaining JMX instance names to use in a policy that alerts whoever on Mark's team is responsible for the `jdbc/OracleECommerceD` JMX instance names.

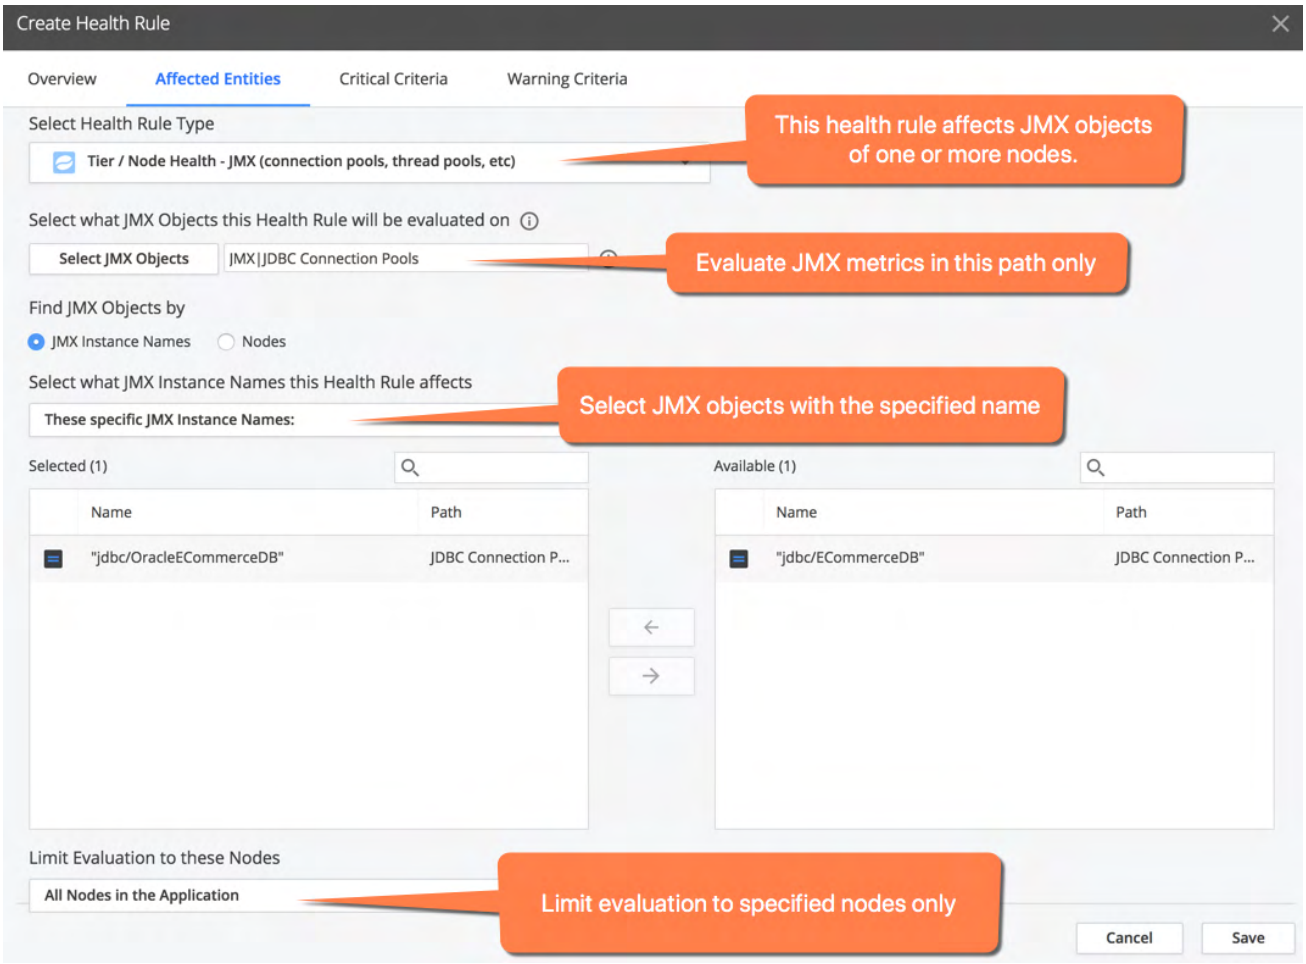
Mark's team could also create different rules that evaluate a different set of JMX metrics by choosing a different metric path in the Select JMX Objects field. For example, they could select **All Web Container Runtimes**.

For problems on `WEB2_NODE`, they would create a different health rule with `WEB2_NODE` as the affected node, so that the alerts for those problems go to Tao's team.

JMX Health Rules Affecting a JMX Instance Name

In another organization, teams are responsible for various parts of the JMX infrastructure. Mary is responsible for `jdbc/OracleECommerceDB`, Meera for `jdbc/ECommerceDB`, and so on, regardless of which nodes use these MBeans.

So if metrics in `jdbc/OracleECommerceDB` violate a critical condition, they want Mary to get the alert because her team is responsible. The configuration of the health rule would be:



The rule could be refined to evaluate the JMX metrics in the specified JMX instance names in all nodes in the application or only in specific nodes.

Troubleshoot Health Rule Violations

Related Pages:

- Health Rules
- Configure Health Rules
- Policies
- Alert and Respond
- Business Transactions

This page provides an overview of health rule violations in AppDynamics.

A health rule is violated when the health rule processor detects that the health rule's critical or warning condition is true. In this case, a health rule violation is created with a status of Open, and a Health Rule Violation Started - Critical event or a Health Rule Violation Started - Warning event is generated.

A health rule violation ends when it is either: resolved (the agent reports metrics that indicate that that the violated condition is no longer true) or canceled (t he health rule processor can no longer accurately assert that the health rule violation continues to violate or that it has ended).

When the violation status of a health rule becomes resolved, a *Health Rule Violation Canceled - Critical* event or a *Health Rule Violation Ended - Warning* event is generated.

The health rule violation status is canceled when:

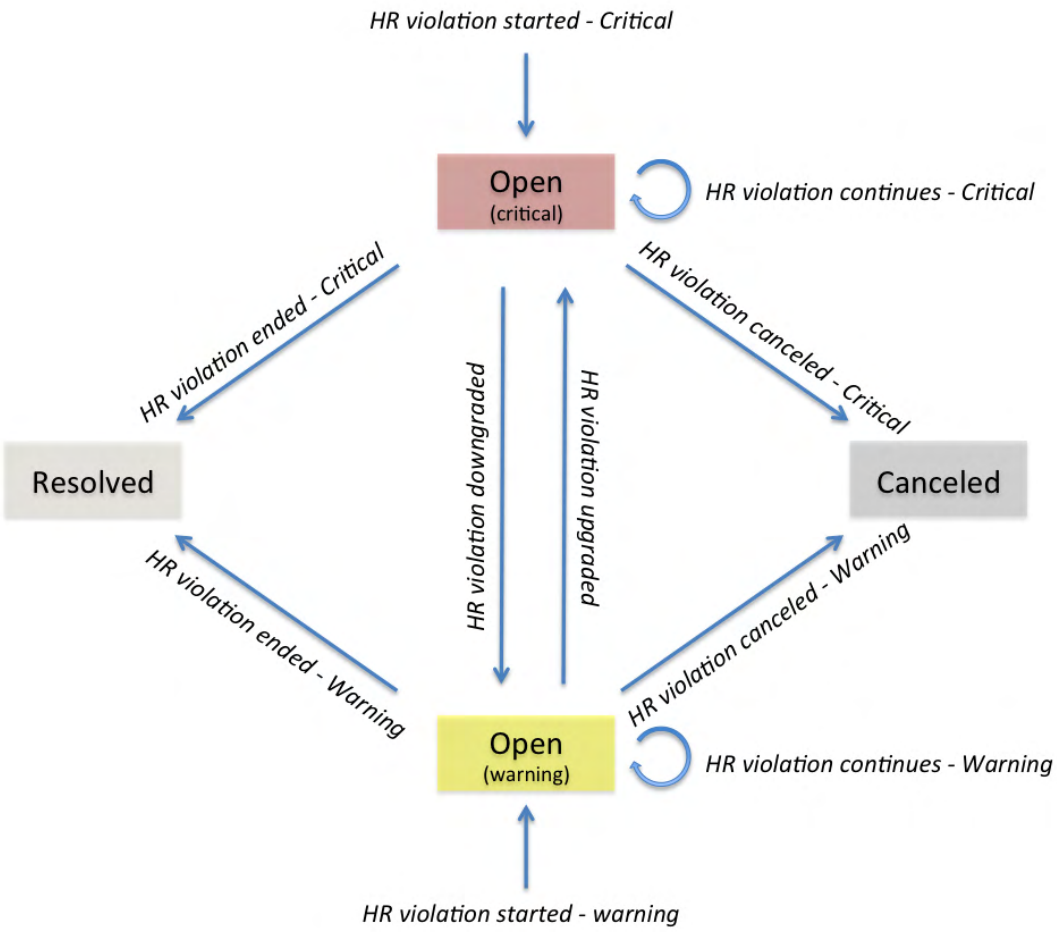
- The health rule is edited
- The health rule is disabled
- Affected entities or evaluation entities on which the health rule is based have been added or removed
- The metric values on which the health rule violation is based have become `UNKNOWN`

When the violation status of a health rule becomes *Canceled*, a *Health Rule Violation Ended - Canceled* event or a *Health Rule Violation Canceled - Warning* event is generated.

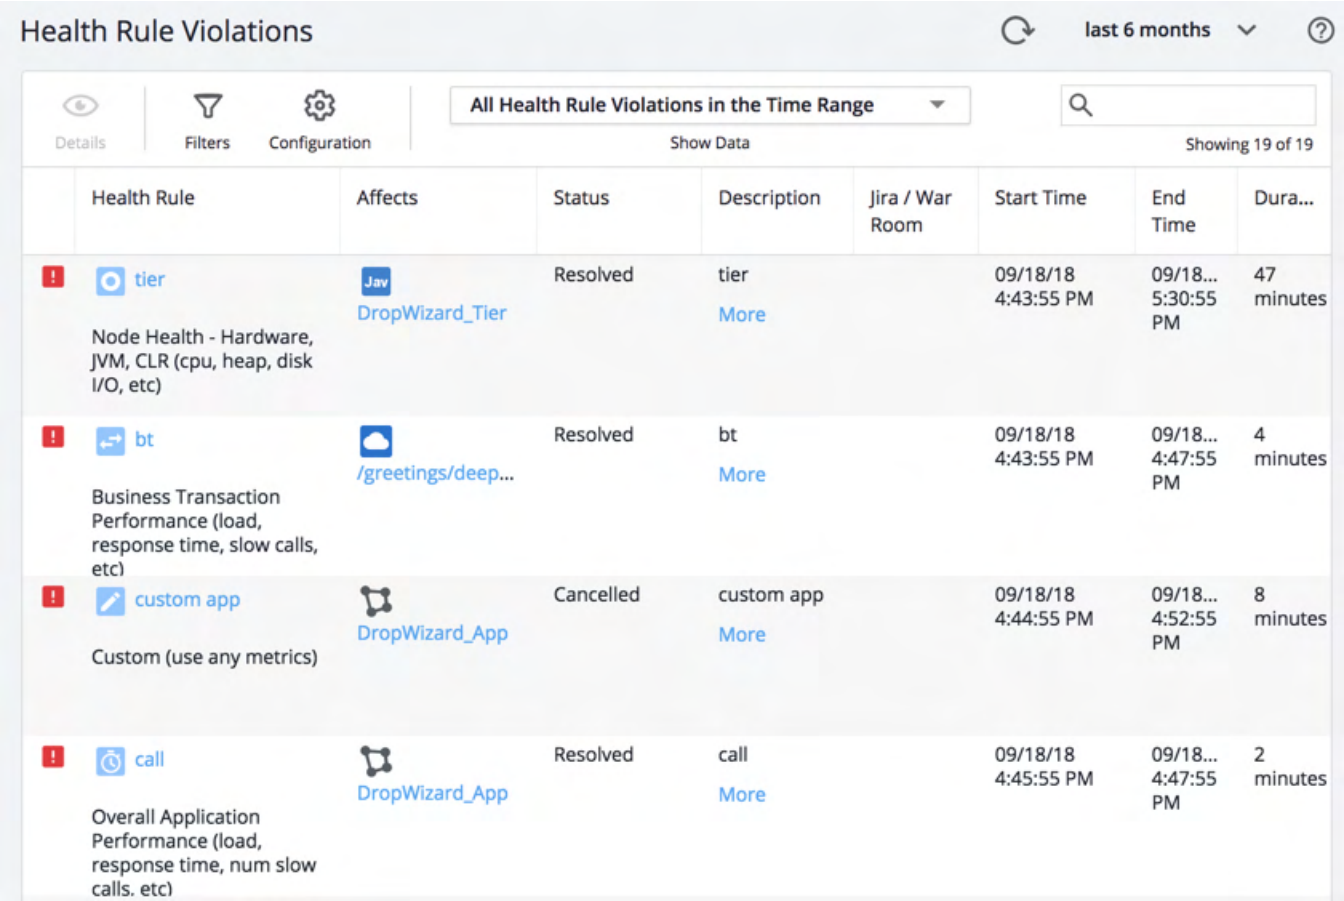
If the same health rule is violated after a violation of it has been resolved or canceled, a new health rule violation is started.

During the life of a single health rule violation, there may be other types of health rule violation events such as Health Rule Violation Ungraded/Downgraded /Continues events.

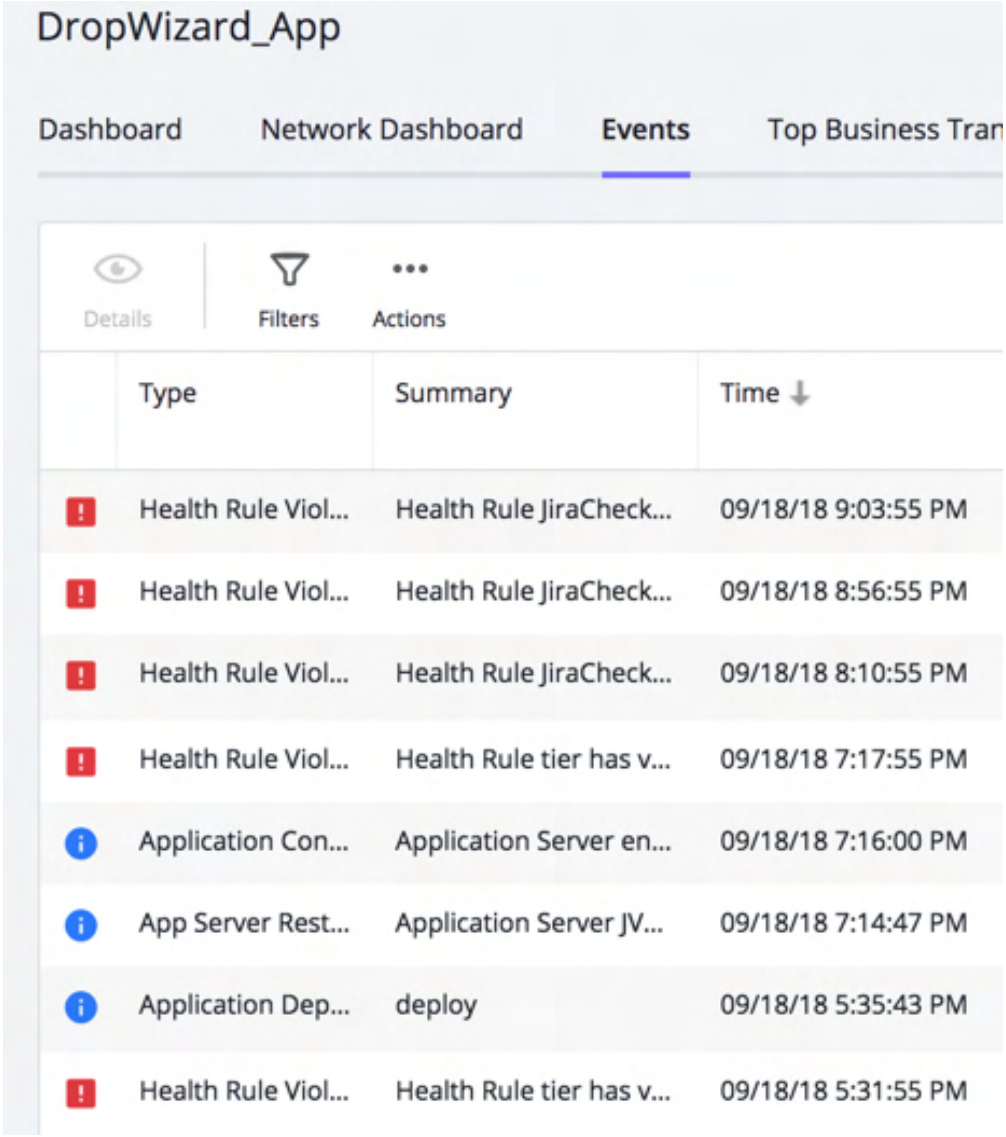
The figure below illustrates the health rule violation life cycle.



The boxes represent the health rules violation statuses that you see in the health rule violations list in **Troubleshoot > Health Rule Violations.** To get more information about a particular violation, select the violation in the list and click **Details**. You can also view the health rule violations in the Controller UI.



Health rule violation events are listed in the **Events** tab of various dashboards.



Because there is a set of default health rules, you may see health rule violations reported for your application even if you have not set up your own health rules. Violations reported for the `APPDYNAMICS_DEFAULT_TX` business transaction are for default health rule violations in the All Other Traffic business transaction.

Find Heath Rule Violations

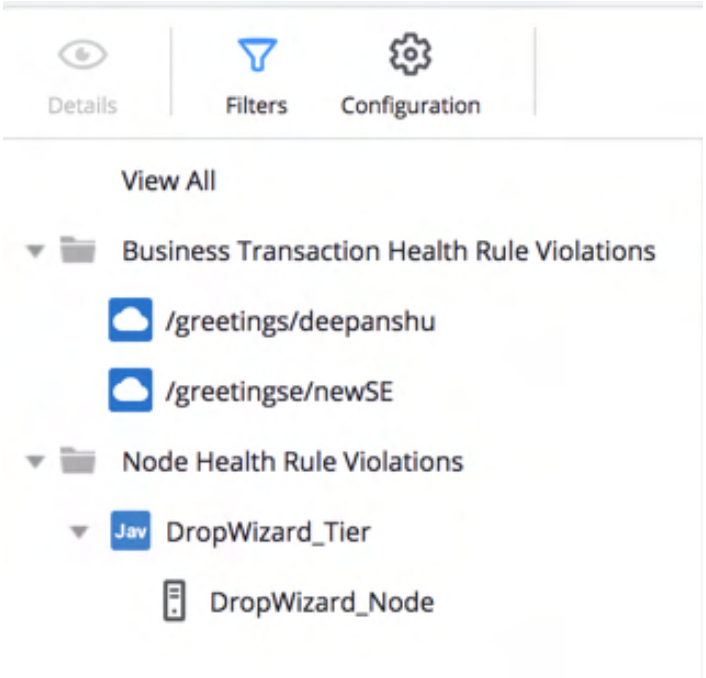
To find all health rule violations:

1. In the left navigation pane, click **Troubleshoot > Health Rule Violations**.
   The list of health rule violations displays.

   > You can also access this screen directly from the left navigation pane of an EUM application.

2. Select **All Health Rule Violations in the Time Range** or **Only Health Rule Violations Open Now** from the drop-down list.
   It is possible that health rule violations that were reported are no longer open because remedial action has been taken or performance has improved on its own.
3. You can filter the list. To see the filters, click **Filters**. To hide them, click **Filters** again.
   With the filters showing in the left filters panel, you can select the health rule violations that you want to troubleshoot.

You can view all health rule violations or expand the nodes in the tree to select by health rule type or affected entity, such as business transaction, tier or node.



You can filter health rule violations by entering the name of the health rule in the search field on the upper right.
The health rule violations are displayed in the right panel, with their affected entity, status, description, start time, end time and duration, if ended.

Examine a Health Rule Violation

To view details about a particular health rule violation:

1. Select the health rule violation row in the list.
2. Click **View Health Rule Violation Details**.

In the **Health Rule Violation** summary window, you can click the **Affects** link to see the dashboard of the entity affected by the health rule. Alternately can click the **View Dashboard During Health Rule Violation** button to view the dashboard at the time the violation occurred.

You can also access details of a health rule violation from the health indicators in the UI. For example, if you see the red indicator on the dashboard indicating that Business Transaction Health or Server Health is critical, click it to get the list of business transactions or tiers and then click the icon in the **H ealth** column of the list.

View Actions Triggered by a Health Rule Violation

For health rules that trigger actions configured by policies, you can get information about the action that was executed.

To view the action triggered by a health rule violation:

1. In the dashboard of the entity affected by the health rule violation, click the **Events** tab.
2. In the events list, locate the health rule violation that you are interested in examining. If an action was triggered by the health rule violation event, you will see an event icon in the **Actions** column of the list.
3. Select the row for the event.
4. Click **Details**.
5. In the health rule violation window, click the **Actions Executed** tab.

Alert Sensitivity Tuning Questions and Answers

As an on-prem customer, can I fine-tune a health rule using AST?

No, AST is available for SaaS customers only.

Can I use AST to fine-tune a health rule that monitors any entity?

You can use AST to fine-tune health rules that monitor business transactions, service endpoints, or remote services only. You must set the health rule evaluation scope to 'average for all nodes' of the affected entity.

How is the metric data presented in the AST graph?

If you define a persistence threshold for a condition, the metric data is plotted directly on the AST graph. If you do not define a persistence threshold, a 'moving average' for the selected metric is plotted. For more information, see Why use 'moving average'?.

What is a moving average? How is it helpful?

Unless persistence thresholds are used, health rules compare the moving average of a metric to a threshold or a baseline. Thus, representing the moving average in the graph is appropriate.

Can I define 'persistence threshold' for a heath rule if I plan to use AST?

Yes, you can define 'persistence threshold' for a health rule. However, you will not be able to use the moving average for the metric. For more information, see Moving Average.

How does AST help calibrate the sensitivity of the health rule?

Depending on the baseline configuration you define, AST presents a graphical view of the metric data for the given baseline configuration. The graphical view is instantly updated when you update any configuration. You can also view granular details by modifying the graphical view. The historical metric data presented in the graph helps you calibrate the sensitivity of the metric evaluation (thus the sensitivity of the health rule).

I am not able to see the AST graphical view, how can I get the graphical view?

The graphical view may not be displayed due to multiple reasons. Check if you have:

- created the health rule for a business transaction, a service endpoint, or a remote service.
- set the health rule evaluation scope to 'average of nodes'.

Can I use AST to configure 'Critical' and 'Warning' criteria?

Yes, you can use AST to configure conditions for both critical and warning criteria.

Will AST impact the evaluation of boolean expression for health rule conditions?

There is no change in the evaluation of boolean expressions for health rule conditions.

Can I use AST to edit an existing health rule?

Yes, you can use AST when editing an existing health rule.

Actions

This page provides an overview of actions in AppDynamics.

An action is a predefined, reusable, automated response to an event. You can use actions to automate your runbooks.

A policy can trigger an action in response to any event. You configure which actions are triggered by which events when you configure policies.

Types of Actions

You can create these types of actions:

- Notification
- Diagnostic
- Remediation
- JIRA
- HTTP Request
- Custom

Not all actions are applicable to all application environments or to all situations. Below are some general guidelines concerning different types of actions. For more details, see the pages on the specific actions before you assign an action to a policy.

- The diagnostic thread dump actions can be performed only on nodes running a Java agent.
- The diagnostic session actions can be triggered only by violations of business transaction performance health rules or by slow or stalled transaction events since these are the events that produce a view into transaction snapshots.
- Remediation actions run a local script in a node and are available on nodes running on machines that have an installed Machine Agent.
- Custom Actions require a dedicated Controller, deployed using either the on-premises or SaaS option. This feature is not supported for accounts on multi-tenant SaaS controllers.

Actions Limits

The Controller limits the actions invoked based on the number of triggering events per event type. There is a maximum of ten events for any single event type that can trigger actions in a given minute. If the number of triggering events per type exceeds the limit, the actions that would have been triggered by the excess events are not started. You will not see a visual indication that these actions are not being started.

For example, your application can have up to ten Health Violation Started events triggering actions and up to ten Resource Pool Limit Reached events triggering actions within the same minute. But if you have eleven Health Violation Started events firing, the action that would be triggered by the eleventh event is not started.

To reduce unnecessary actions, there is a limit on the number of diagnostic and remediation actions that AppDynamics will invoke. The default limit is five actions per minute per machine for each type of action.

If, for example, a policy is configured on all the nodes where there are 100 nodes triggering actions, AppDynamics randomly selects five of the actions to execute.

To avoid exceeding the limits, design your policies so that they do not trigger an excessive number of actions for any particular event. You can generate fewer events by configuring the affected entities of your health rules at the tier level. See entities affected by a health rule and by health rule types in Health Rules.

Actions Requiring Approval

For actions that take thread dumps or run a local script, you can optionally require email approval to run the action whenever it is triggered. If you check this option, human intervention is required before the automated action actually starts.

If you specify the approval required option when you configure the action, when the action is triggered an email containing a link is sent to the configured email address. The link presents a login screen (if the user is not already logged in to AppDynamics) and after the user logs in, a dialog requesting approval to take the thread dump or run the script. The user can click in this dialog to approve and start the action or cancel the action.

If you do not check the **Require Approval** option before executing the **Action** checkbox, the action will start automatically with no human intervention.

Create and Modify Actions

To configure actions, you need the Configure Actions permission.

To access the Actions configuration panels:

1. Click **Alert & Respond** in the menu bar.
2. Click **Actions** either in the right panel or the left navigation pane.

3. Select the context for the action (Application, User Experience Browser App, Databases, Servers, Analytics) from the pulldown menu.
   The list of configured actions displays. You can filter the types of actions by checking the type in the pulldown filter. If no action types are checked, there is no filtering; however if at least one type is checked, then only actions of that type display.
4. Do one of the following:
   - To create a new action, click the **Create Action (+)** icon. After you have clicked **Create Action**, the instructions provided depend on the type of action you are creating.
   - To edit an existing action, select the action and click the **Edit** (pencil) icon.
   - To remove an existing action, select the action and click the **Delete** (-) icon.

View Actions

While actions are being triggered by events, you can get a summary of their execution in the **Actions** column in the **Events** list. You can access the **Events** list from the Events tab of the application, tier, or node dashboard.

The icon type indicates action type; an icon in the **Actions** column indicates that an action was triggered for this event. If the action icon is greyed out, the action is either still executing or failed to complete. If the icon fully displays, then the action executed successfully.

Action Suppression

You can prevent policies from firing actions for a configurable time period.

Notification Actions

Related Pages:

- Alert and Respond
- Policies
- Email Templates
- Enable an Email Server

This page provides an overview of notification actions in AppDynamics. A notification action sends an email or SMS to a recipient or recipient list. If you are using a SaaS Controller, all notification timestamps are in Pacific Time (PST).

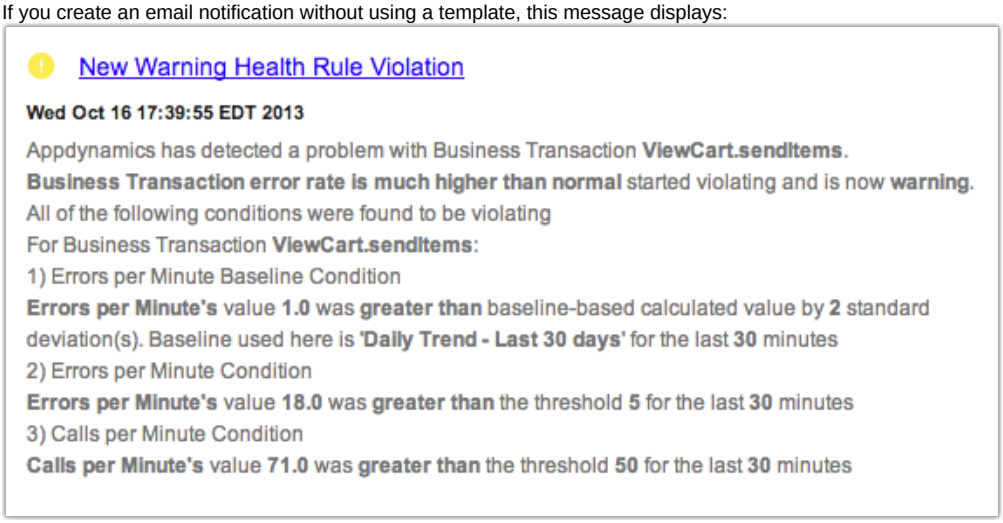
Email Notifications

You can create an email notification with or without an email template.

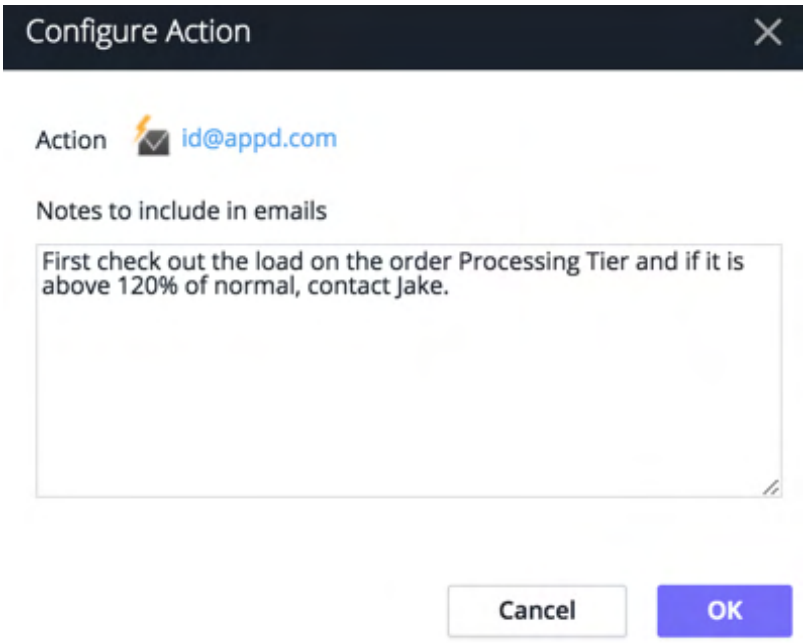
Create Email Notification Without a Template

If you create an email notification without a template, you need to provide the email address of the notification recipient. The name of the action is the name of the recipient. The contents of the email are automatically generated by the policy that triggers the action. The generated message contains a link directly to the Controller panel that details the triggering event, which is the place for the recipient to start troubleshooting the problem.

If you create an email notification without using a template, this message displays:



When you configure a policy to start an email notification action that has not been created with a template, you can add an optional note to the email. This note is applied only when the action is invoked by the particular policy. By adding an optional note, you can customize email notifications for the policies that invoke them.



Create Email Notification With a Template

If you create an email notification with a template, you provide the name of the action and the name of the email template to use. The template provides for addressing multiple recipients and you can add and delete recipients when you create an action using the template.

The template must already exist before you can use it in an action. Email templates are created by users who have account-level permissions to create templates. See Email Templates for information about creating templates.

The body of the message is specified in the email template. It is not generated automatically.

All the text in the message must be created in the template. Customization is accomplished through the use of variables in the message body, which are replaced by actual values when the message is sent.

You can use a template to:

- Reuse the notification in other policies
- Customize the body of the message
- Decorate the notification with your own branding
- Add custom SMTP headers to the email
- Control whether the email is sent once or several times for each event
- Control the maximum number of triggering events listed in the email using a clamp limit
- Integrate with third-party email APIs, such as Remedy

To create an email notification:

1. Access the **Create Action** panel. See Create and Modify Actions in Actions.
2. Under **Notifications**, select **Send an email** in the **Create Action** pane. To use a template to create the email notification, check **Use template?**
3. Click **OK**.
4. Do one of the following:
    - If you are not using a template, enter the email address to which to send the notification.
    - If you are using a template, name the action and select the appropriate template from the dropdown.
      Unless disallowed by the template, you can add recipients at this time but you cannot remove any of the required recipients that were configured in the email template.
5. Click **Save**.

> If email and SMS settings have not been configured for AppDynamics, configure them now. See Configure the SMTP Server.

SMS Notifications

The content of the SMS is automatically generated. It contains:

- Notification header
- Application name
- Triggered time

Notifications of health rule violations also include: Name of health rule violated

Event notifications also include:

- Event notification configuration name
- Map of event types to the number of these events

An SMS notification configuration specifies the phone number of the recipient.

To create an SMS notification:

1. Access the **Actions Configuration** panel. See Create and Modify Actions in Actions.
2. Under **Notifications**, select **Send an SMS message** in the **Create Action** panel.
3. Enter the phone number to send the notification.
4. Click **OK**.

If you have not configured email and SMS settings for AppDynamics, configure them now. See Enable an Email Server.

Email Templates

This page provides an overview of email templates in AppDynamics. Email templates are optional for email notification actions.

You must have account-level Configure Email Templates permission to create an email template. See Alert and Respond.

Access Email Templates

Although the configuration settings are self-explanatory, some template configuration features and options require additional information.

1. Click **Alert & Respond** > **Email Templates**.
2. Click an existing template to view, edit, or delete it or lick **New +** to create a template.
3. Edit or define the template.
4. Click **Save**.

Custom Templating Variables

You can use variables that replace values in the message body when the email is sent.

The template recognizes a set of predefined variables. Review Predefined Templating Variables to verify the variable you want does not already exist.

If the predefined variables do not meet your needs, you can optionally configure custom variables. When a predefined variable and a custom variable are both configured with the same variable name, the template uses the predefined variable.

The template uses Apache Velocity version 1.7 to process the variables. See the Velocity User Guide.

Admin Email Recipients

To add a recipient, enter an email address and click **+ Add**. To remove a recipient, click **–**.

If the **Allow custom email recipients** checkbox is selected in the template, users of the email template can add additional email recipients when they create the email notification. However, they cannot delete any of the recipients configured by the template. Clear this checkbox if you do not want to allow template users the ability to modify the recipient list.

The only way to remove a required recipient is by modifying the template.

Email Template

Enter the subject line and the body of the message. AppDynamics recommends including both an HTML version and a plain text version. You can use any predefined or custom templating variables in both the HTML and plain text message bodies. Use `background-color` instead of `background` for HTML email templates.

For-each loops are supported. See Predefined Templating Variables.

Custom Email Headers

Use this section to add custom SMTP headers to the message.

One Email Per Event

Several separate events, or separate occurrences of the same event, could potentially invoke the same notification action.

The **One Email Per Event** setting controls whether the action bundles the emails triggered by those events. The effect is:

- If selected, the email is sent once every minute, no matter how many events triggered the notification within that minute. This is the default.
- If not selected, an email is sent every time an event triggers it. In this case, if ten events trigger the action, the email is sent ten times, even if all those events occurred within a single minute.

Event Clamp Limit

If you have not selected the **One Email Per Event** checkbox, you might want to limit the display of the events that triggered the action in the email, especially if the potential list of events could be long. The clamp limit is the number of most recent triggering events to be shown in the email. This setting is disabled if **One Email Per Event** is selected.

Test Email Template

After you save the email template, you can test the template by sending an email.

Test Email Templates

This page provides instructions on testing email templates in AppDynamics.

After you save the email template, you can test the template by sending an email.

1. In the **Create Email Template** dialog, click **Test**.
2. In the **Email Template Test** dialog, specify the test variables to use for the test. These variables can be different from those in the real emails that are sent automatically.
3. Set the log level or the amount of detail that you want to see: **INFO**, **WARN**, **ERROR**, **TRACE**, and **DEBUG**.
   The log level defaults to **DEBUG**, but you can change this using the **Log Level** dropdown.
4. Specify the type of events that trigger the email action along with the count. You can add more triggers if required.
5. Click **Save**.

Run Test

When you run the test, an email is sent when the action is triggered. You also receive a transcript of the test.

If the results are not what you expect, you may need to modify the email template, the event triggers, or both, before you use the template in an action.

Diagnostic Actions

This page provides an overview of diagnostic actions in AppDynamics.

A diagnostic action can:

- Start a diagnostic session to collect snapshots
- Take a thread dump for Java only

When performance is slow or your application is experiencing a lot of errors, you can start a diagnostic action to find the root cause.

> ⚠ You can start a diagnostic session only for a health rule that monitors business transactions.

A diagnostic session provides a view into captured transaction snapshots with full call graphs. These snapshots help you diagnose violations of business transaction performance health rules or slow or stalled transaction events. The affected entity of the event triggering a diagnostic session must be a business transaction.

A thread dump is a general-purpose snapshot of the state of all threads that are part of a JVM process. The state of each thread is presented with a stack trace that shows the contents of each thread's stack. Thread dumps are used for diagnosing JVM performance problems, such as code deadlocks.

Diagnostic Session Actions

A diagnostic session is always associated with a business transaction. It shows transaction snapshots with full call graphs to help you drill down to the root cause of a problem.

To create a diagnostic session action:

1. Access the **Actions Configuration** pane. See Create and Modify Actions in Actions.
2. Under **Diagnostics**, select **Start a Diagnostic Session on the selected Business Transactions** in the **Create Action** pane and click **OK**.
3. After entering a name for the action, the duration of the diagnostic session in minutes and the number of snapshots to take per minute, select whether a diagnostic session will be started for any business transaction affected by the event or for specific business transactions.
   If you choose specific business transactions, specify the business transactions that will trigger the diagnostic session by moving them from the available list to the selected list. The business transactions that you can specify are not limited to those that triggered the action.
4. Click **OK**.

Diagnostic Action Results

The results of a diagnostic action that has executed are available in the events list for the event that triggered the action. To get the details of a diagnostic session or a thread dump that has been initiated by an action:

1. In the **Events** list, locate the row for the event that triggered the action for which you want to see the results.
2. In the **Actions** column:
   - Click  to see the details of a thread dump action.
   - Click  to see the details of a diagnostic session action.

On disk, the thread dumps are stored in the `app_agent_operation_logs` directory in the Controller Home. The files are named based on the ID in the a `pp_agent_operation` table.

Threads identified by `AD Thread` are threads initiated by the AppDynamics app agent code.

Thread Dump Actions 

You can direct the Java Agent to take a thread dump for a specified number of samples (maximum of 50) with each sample lasting for a specified number of milliseconds—a maximum of 500 ms. The thread dump is executed on the node monitored by the agent.

Users need the Agent Advanced Operation permission to request a thread dump.

Agent Limit on Thread Dumps

One thread dump operation is executed at a time. They are not executed in parallel. If additional thread dump requests are received while one is being executed, they are queued with a limit of five per agent.

If the five thread dumps per agent limit is exceeded, the console shows an event with a thread dump operation that was skipped because of the limit and the associated action dialog for the executed policy links to this event.

To create a thread dump action:

1. Access the Create Action pane.
2. Under **Diagnostics**, select **Take a thread dump** in the **Create Action** pane and click **OK**.
3. Enter a name for the action, the number of samples to take and the interval between the thread dumps in milliseconds. If you want to mandate an approval before the thread dump action can be started, check the **Require approval before executing this Action** checkbox and enter the email address of the individual or group that is authorized to approve the action. See Actions Requiring Approval for more information.
4. Click **OK**.

When a thread dump action is triggered by a backend discovery event, if the backend is not resolved quickly the policy will not start the thread dump.

Remediation Actions

A remediation action runs a local script in a node. The script executes on the machine from which it was invoked or on the node specified by the remediation action configuration. You can use this type of action to automate your runbook procedures. You can optionally configure the remediation action to require human approval before the script is started. See Actions Requiring Approval.

> Remediation actions are not available for servers. Select an **Application** and then create **Actions** to view the **Remediation Action** option.

Prerequisites for Local Script Actions

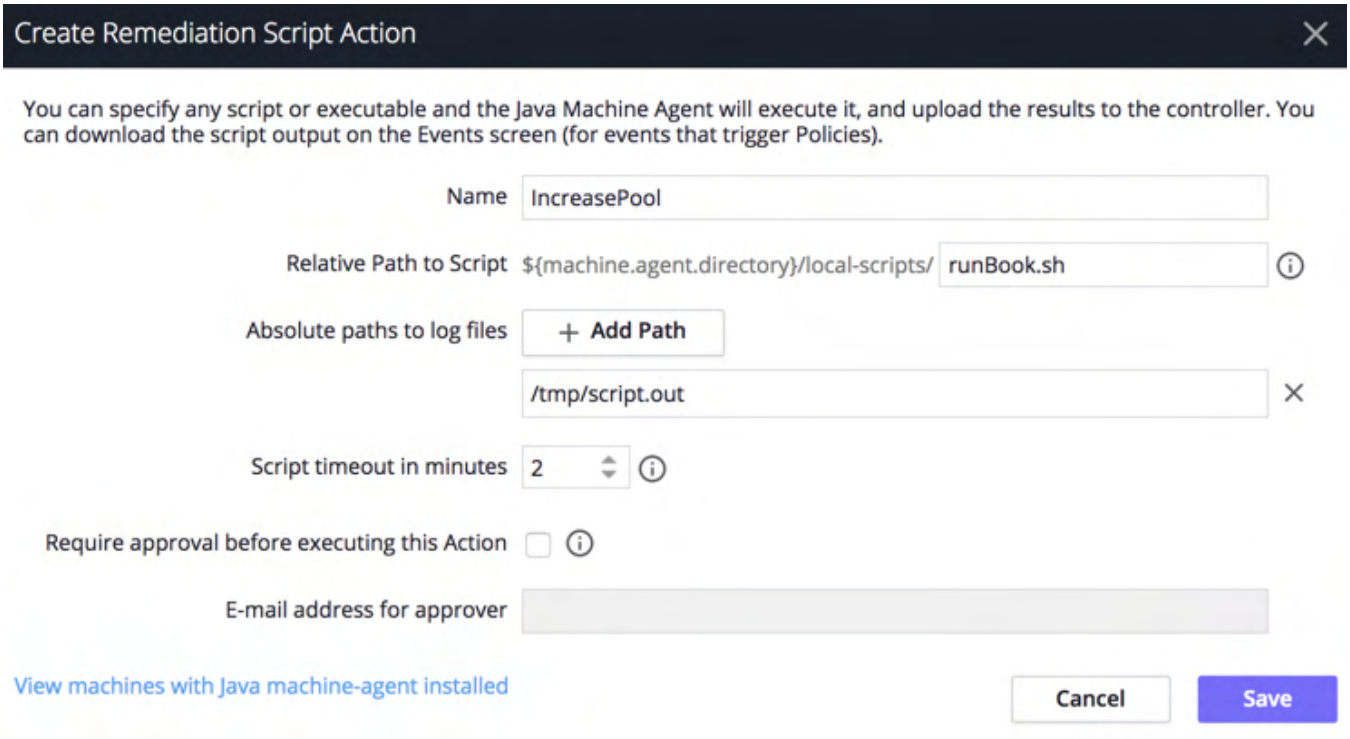
- The Standalone Machine Agent must be installed running on the host on which the script executes. To see a list of installed Machine Agents for your application, click **View machines with machine-agent installed** in the bottom left corner of the remediation script configuration window.
- To be able to run remediation scripts, the Machine Agent must be connected to an on-premises Controller or to a SaaS Controller via SSL. Remediation script execution is disabled if the Machine Agent connects to a SaaS Controller on an unsecured (non-SSL) HTTP connection.
- The Machine Agent OS user must have full permissions to the script file and the log files generated by the script and/or its associated child processes.
- The script must be placed in `<agent install directory>\local-scripts`.
- The script must be available on the host on which it executes.
- Processes spawned from the scripts must be daemon processes.

Remediation Scripts

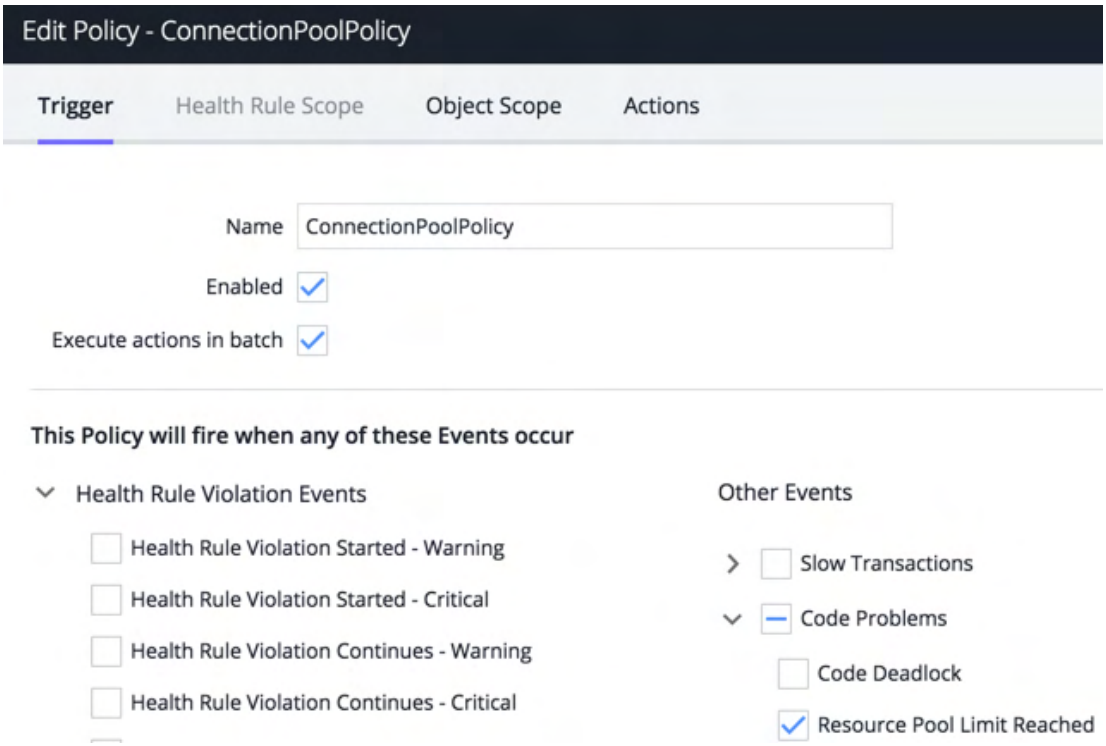
A remediation script is run on the machines that you specify in the remediation script configuration. You can run the script from the machine affected by the violation that triggered the action or from a central management server. It is not necessary for an app agent to be running on the machine on which the script executes; just a Machine Agent.

Remediation Example

The remediation action, named `increasePool`, executes a local script named `runbook.sh`, which increases the size of the connection pool on the JVM.



A policy named **ConnectionPoolPolicy** triggers this action when the Resource Pool Limit Event starts:



Create a Local Script (Remediation) Action

To create a remediation action:

1. Access the **Create Action** pane. See Create and Modify Actions in Actions.
2. Select **Run a script or executable on problematic Nodes** in the **Create Action** pane and click **OK**.
3. After entering a name for the action, in the field that terminates the Relative path to script entry, enter the rest of the path to the executable script. Remediation scripts must be stored in a sub-directory of the machine agent installation. The sub-directory must be named `local-scripts`. These paths are all valid:

```
${machine.agent.directory}/local-scripts/runMe.sh
${machine.agent.directory}/local-scripts/johns_scripts/runMe.sh
${machine.agent.directory}/local-scripts/ops/johns_scripts/runMe.sh
```

4. Click the **+** to enter the absolute paths of any log files that the script writes to that you want to be included in the script output.
5. Enter the timeout period for the script process in minutes.
6. To mandate an approval before the script action can be started, select the **Require approval before executing this Action** check box and enter the email address of the individual or group that is authorized to approve the action. See Actions Requiring Approval for more information.

Specify the Nodes on Which the Action Will Run

When you bind the action to a policy, you specify the nodes on which the script should execute. You can configure the number of nodes or the percentage of nodes or you can configure a specific node. This flexibility allows you to configure scripts to run from a central management server, not just the node on which the violation occurred.

In the **Configure Action** pane of the policy actions to execute, either:

- Select **Execute Action on Affected Nodes** and the percentage of the nodes or the number of nodes on which to run the script.
- To designate the specific node on which to run the script, select **Execute Action on Specified Node,** and select the node on which the script should run from the popup node browser. You can either save the configuration or change it to designate a different node.

Review the Local Script Output

1. In the **Events** list, locate the row for the event that triggered the action for which you want to see the results.
2. In the **Actions** column of the selected row, click the remediation script icon.
3. In the script results list, select the script output that you want and click **Download Local Script Result**.

When a remediation action is triggered by a backend discovery event, if the backend is not resolved quickly the policy will not start the local script.

Remediation Scripts

A remediation script is run on the machine that you specify in the remediation script configuration. You can run the script from the machine affected by the violation that triggered the action or from a central management server. It is not necessary for an app agent to be running on the machine on which the script executes; just a Machine Agent.

Guidelines for Remediation Scripts

By default, the script is a shell script in /bin/sh invoked with the `-ex` option, unless the script has a header, in which case the interpreter in the header is used. For example, if the script header is `#!/bin/`perl, the Perl interpreter is invoked.

A process exit code of zero indicates that the script execution succeeded. A non-zero exit code indicates that it failed.

The script should be written as generically as possible to allow it to run on any of the nodes for which is it invoked. AppDynamics exports the following environment variables to the script runtime to provide context regarding the environment and the event that triggered the action.

Environment Variable	Cardinality (1 or *M*)	Notes
`APP_ID`	1	Name of the Application
`EVENT_TIME`	1	Timestamp of the event
`EVENT_ID`	1	Event ID
`EVENT_TYPE`	1	type of event, such as: `ERROR, APPLICATION_ERROR, APPLICATION_INFO, STALL, BT_SLA_VIOLATION, DEADLOCK, MEMORY_LEAK, MEMORY_LEAK_DIAGNOSTICS, LOW_HEAP_MEMORY, ALERT, CUSTOM, APP_SERVER_RESTART, BT_SLOW, SYSTEM_LOG, INFO_INSTRUMENTATION_VISIBILITY, AGENT_EVENT, INFO_BT_SNAPSHOT, AGENT_STATUS, SERIES_SLOW, SERIES_ERROR, ACTIVITY_TRACE, OBJECT_CONTENT_SUMMARY, DIAGNOSTIC_SESSION, HIGH_END_TO_END_LATENCY, APPLICATION_CONFIG_CHANGE, APPLICATION_DEPLOYMENT, AGENT_DIAGNOSTICS, MEMORY, LICENSE`
`ENV_STARTUP_ARGS`	1	Process args
`ENV_SYSTEM_PROPERTIES`	1	JVM System Props, when Java
`AFFECTED_ENTITY`	1	Affected Entity that triggered the event

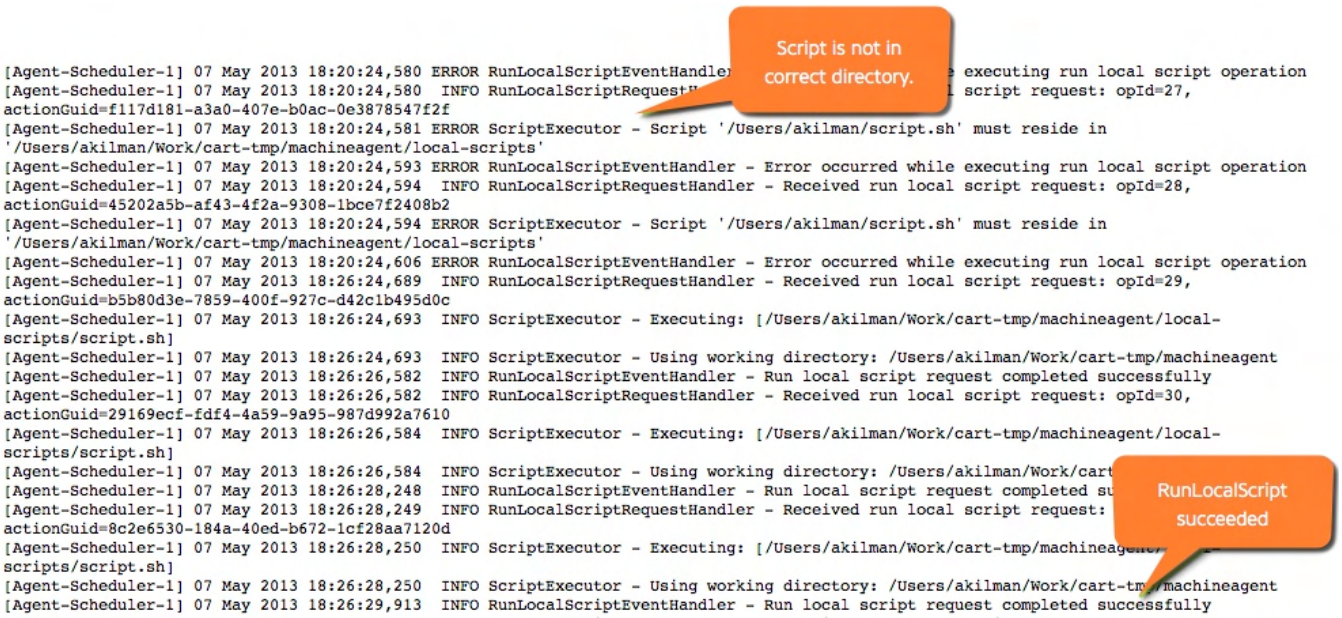
Remediation scripts must be stored in a sub-directory of the machine agent installation. The sub-directory must be named `local-scripts`. The following paths are all valid.

```
${machine.agent.home}/local-scripts/runMe.sh
${machine.agent.home}/local-scripts/johns_scripts/runMe.sh
${machine.agent.home}/local-scripts/ops/johns_scripts/runMe.sh
```

Troubleshooting Remediation Scripts

To troubleshoot your remediation script, look for the process in the Machine Agent log. The log location path is: `<machine_agent_home>/logs/machine-agent.log`

This snippet from the Machine Agent log shows both error and success messages from running a local script named `script.sh`.



```

HTTP Request Actions and Templates

An HTTP request action sends an HTTP request in response to an event. These types of actions allow you to integrate AppDynamics' policies with third-party HTTP APIs.

You can configure an HTTP/HTTPS proxy for an on-premise Controller to filter access to the web server. When you configure a proxy, the HTTP request actions are routed through the HTTP proxy or HTTPS proxy, depending on the endpoint. See Configure HTTP/HTTPS Proxy.

You create an HTTP request action using an HTTP request template. The template describes the HTTP request and is reusable by different HTTP request actions within an AppDynamics account.

After you create a template, users in the Controller UI can create actions that use it. The template displays as an option after the user selects the **Make an HTTP Request** option in the **Create Action** pane and accesses the **Configure Action** pane.

Required Permissions

To create or modify HTTP Request Templates, users need the account-level Configure HTTP Request Templates permission.

Access HTTP Action Templates

To access existing templates or to create new ones, click **Alert & Respond** in the menu bar, and then select **HTTP Request Templates**.

You can either:

- Click an existing template from the HTTP Request Templates list to view, edit, or delete it.
- Click the **New +** icon to create a template.

Create or Modify an HTTP Request Template

When creating or modifying templates, click the **Info** icons in the template to get information about how to complete the configuration.

After you have created a template, click **Save** at the bottom to save it.

Custom Templating Variables

You can use variables that replace values in the URL path and payload when the HTTP request is sent. For-each loops are supported.

The template already knows a set of predefined variables, which are described in Predefined Templating Variables. Check this list before you create any custom templating variables. Chances are the variable you want to use has already been defined.

You can optionally configure custom variables if the predefined variables do not meet all your needs. When a predefined variable and a custom variable are both configured with the same variable name, the template uses the predefined variable.

The template uses Apache Velocity version 1.7 to process the variables. See the Velocity User Guide for details about usage.

Request URL

Enter the URL for the request in the Raw URL field and select the URL encoding scheme from the pulldown menu. Only UTF-8 and ISO_8858-1 are supported. Verify that the Encoded URL is the exact request to send.

Authentication

You can define basic authentication for your HTTP request. Select **BASIC authentication type** from the **Type** dropdown only if the communication is encrypted. If the communication is not encrypted, we recommend not to use any authentication. After selecting the authentication type, specify the authentication username and password.

Custom Request Headers

You can define custom headers for the HTTP requests. Custom Request Headers can contain custom templating variables or predefined templating variables encoded as $(VARIABLE_NAME).

For a complete list of predefined variables, see Predefined Templating Variables. Check this list before you create any custom templating variable. See the Velocity User Guide for details.

Payload

To include a payload in your HTTP request, define the **MIME Type** from the dropdown. You can encode the payload using UTF-8 or ISO-8859-1 encoding.

Response Handling Criteria

Success or Failure

If you do not specify any response-handling criteria for either success or failure, the HTTP response is always success.

Otherwise:

- Failure criteria are evaluated before success criteria. As soon as a match is found on a fail criterion, the response is set to failure and the remaining fail match conditions, if there are any, are not evaluated.
- If no failure criteria are matched, the success criteria are then evaluated.

If no success criteria are configured, the response will always be success as long as no fail criteria were previously matched.

Otherwise:

- If you specify at least one success criterion, there must be a match on a success criterion for the response to be success. In other words, if any success criteria are configured but not matched, the response will be failure.

Both failure and success criteria are considered in the order in which they appear in the template.

Criteria With and Without Payload

You can set separate criteria for the same status code. For example, you can set one criterion on a status with payload as success and another criterion on the same code without payload as failure.

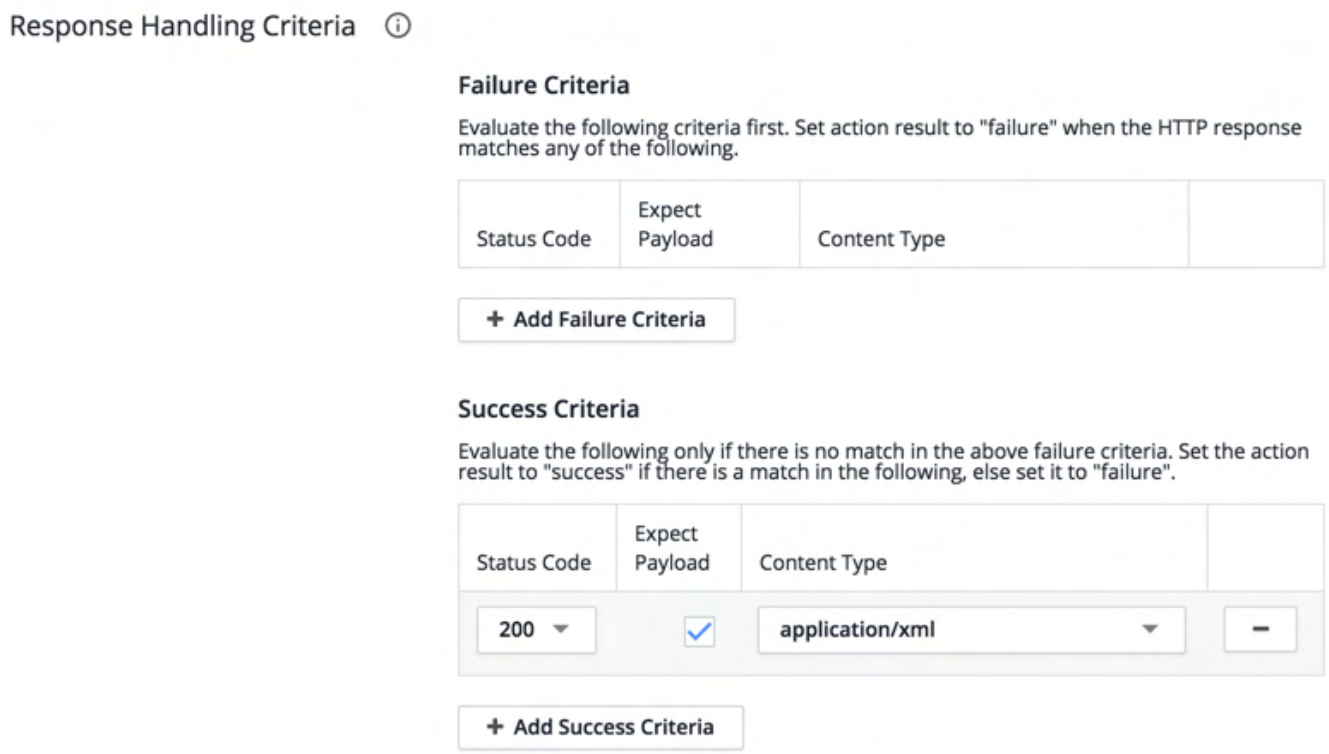
Or, you can set separate criteria for the same status code with payload of different content types. For example, payload of type `application/xml` and `application/xhtml+xml` might be success and payload of other types could be failure.

Content Types for Payload

You can specify the content type for the payload using the dropdown that displays for requests for which the **Expect Payload** checkbox is selected.

If you do not know the content type but the request expects payload, use `*/*` to specify all content types.

This configuration returns a success response for a 200 status code with an XML payload. Any other code will cause the request to return a failure response.



One Request Per Event

Several separate events, or separate occurrences of the same event, could potentially invoke the same HTTP action.

The **One Request Per Event** setting controls whether the action bundles the HTTP requests.

If this checkbox is clear, the HTTP request is sent once every minute, no matter how many events triggered the action within that time frame. This is the default.

If this checkbox is checked, the request is sent every time an event triggers it. In this case, if ten events trigger the action, the HTTP request is sent ten times, even if all those events occurred within a single minute.

You might want to send one request per event, checkbox checked, if you are trying to log tickets and your ticketing system API does not support bulk create. However, if it does, you probably want a single bulk request every minute, checkbox clear.

Event Clamp Limit

If you have not selected the **One Request Per Event** checkbox and the list of triggering events could be large, you might want to limit the display of the events that triggered the action in the response. The clamp limit is the *n* most recent triggering events. The default -1 indicates no limit. This setting is ignored if **One Request Per Event** is selected.

Timeouts and Redirects

- **Connect Timeout**: The maximum number of milliseconds to wait for the request to reach the server.
- **Socket Timeout**: The maximum number of milliseconds to wait to receive the response.
- **Max Redirects**: The maximum number of times that a single request can redirect.

Test the Template

To test the template, click **Test** at the bottom of the template configuration.

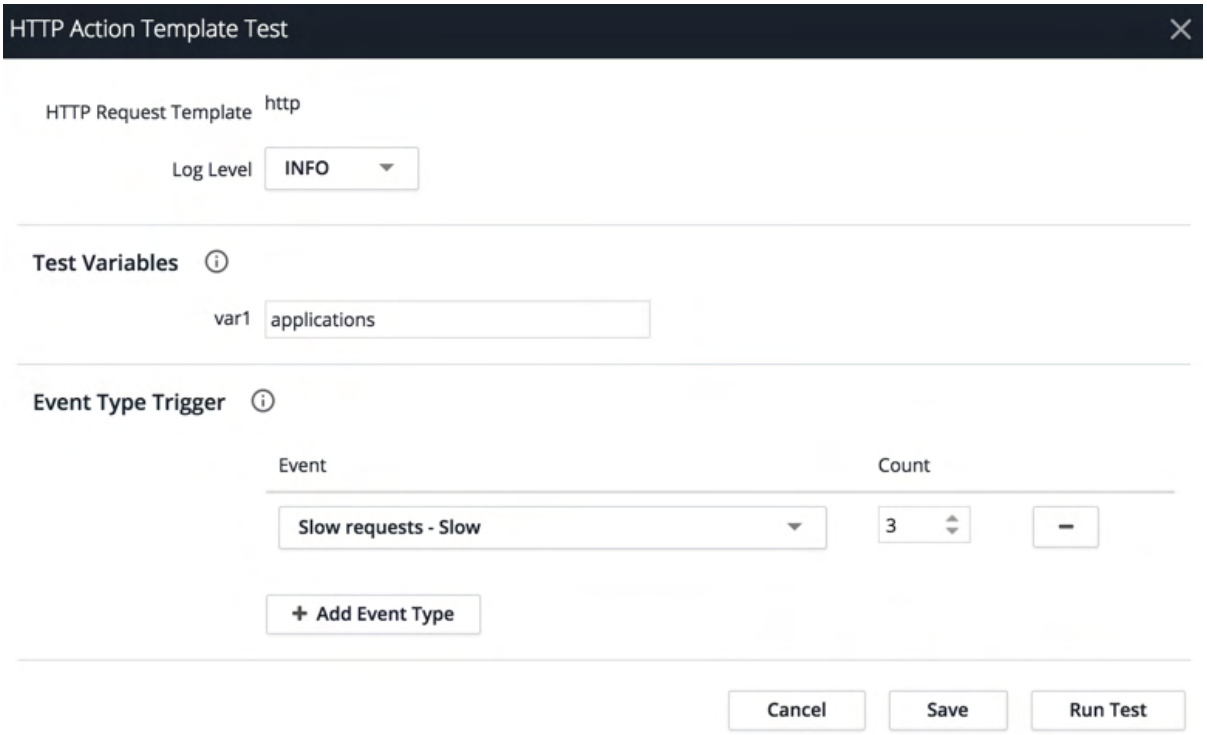
Configure Test

In the **Template Test** configuration pane, specify the test variables to use for the test. These variables may be different from those that will be used in the real requests that will be automatically sent when the HTTP action is live.

Also, specify the type of events that trigger for the test.

The log level defaults to **INFO**, but you can change this using the **Log Level** dropdown.

This sample test template configuration simulates three `POLICY OPEN CRITICAL` events triggering this action. More triggers could be added.



Run Test

When you run the test, the request is sent when it is triggered. You receive a transcript of the run.

If the results are not what you expect, you may need to modify the template test configuration, the HTTP action template, or both, before you use the template in an action.

JIRA Actions

A JIRA action allows AppDynamics to automatically create a JIRA issue when an AppDynamics event is triggered. The event triggers an HTTP custom action for creating a JIRA issue.

You can configure an HTTP/HTTPS proxy for an on-premise controller to filter access to the web server. When you configure a proxy, the JIRA actions are routed through the HTTP proxy or HTTPS proxy, depending on the endpoint. See Configure HTTP/HTTPS Proxy.

JIRA Action Details

The JIRA action is based on templates where each template can be preconfigured with the project, issue type, assignee, and priority. When a JIRA action is triggered, it creates a ticket with those fields in it.

There is a rate limit for the action, which is set to 100 by default. This means the JIRA action will not create more than 100 tickets a minute for an account. Administrators on on-prem Controllers can modify the default by configuring the flag, `max.jira.actions.per.min`, in the **Controller Settings** section of the Administration Console.

This new action needs to be created similar to the rest of the actions, and associated with a health rule for all transition events of the rule (OPEN, CONTINUES, UPGRADE, DOWNGRADE, CLOSE, CANCEL).

This table describes the JIRA action and transitions.

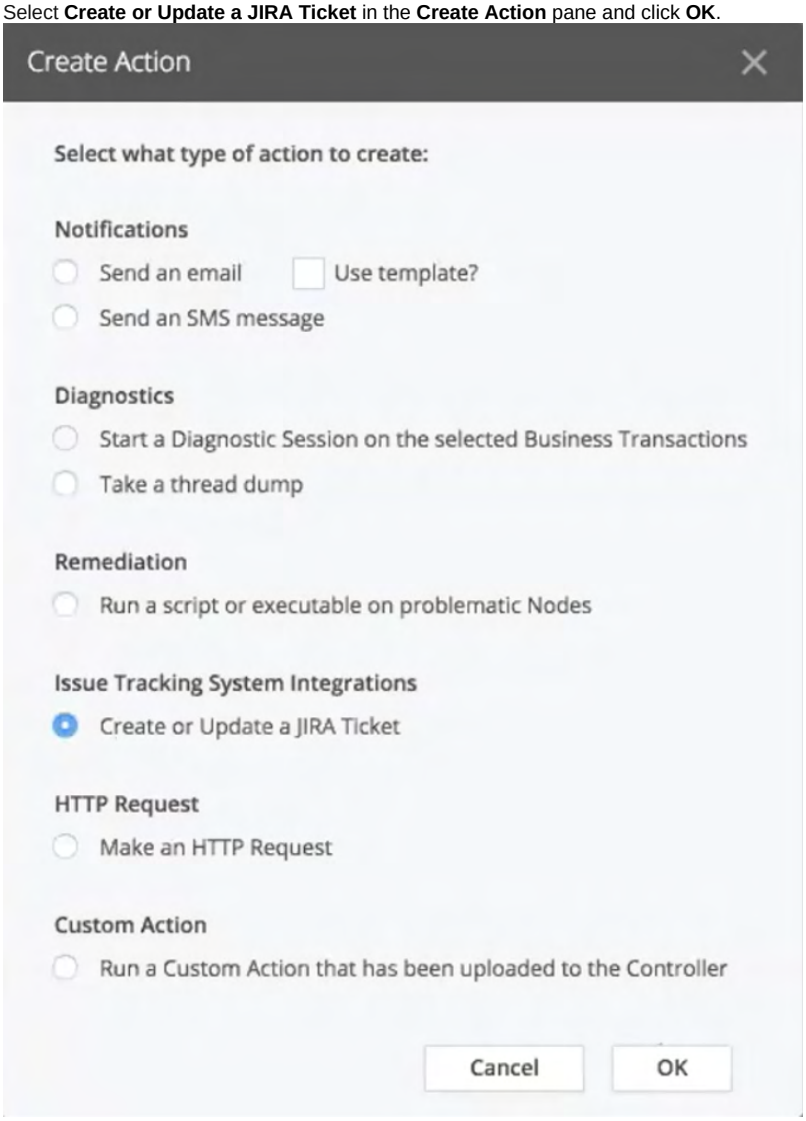
Health Rule Transition (Event)	Reason for Transition	JIRA Action
OPEN (CRITICAL or WARNING)	Health rule violation started.	Creates a JIRA issue. Response of this action provides the JIRA ID which is persisted against the incident.
CONTINUES (CRITICAL or WARNING)	Health rule violation continues.	Fetches the JIRA issue that corresponds to the health rule / affected entity, and updates the JIRA with a comment with the latest violation summary.
UPGRADE (WARNING CRITICAL)	Health rule violation now critical.	Fetches the JIRA issue that corresponds to the health rule / affected entity, and updates the JIRA with a comment with the latest violation summary. May change the priority of the issue.
DOWNGRADE (CRITICAL WARNING)	Health rule violation now warning.	Fetches the JIRA issue that corresponds to the health rule / affected entity, and updates the JIRA with a comment with the latest violation summary. May change the priority of the issue.
CLOSE	Health rule thresholds back within limits, incident closed.	Fetches the JIRA issue that corresponds to the health rule / affected entity, and resolves the JIRA.
CANCEL	Health rule configuration has changed or system lifecycle (restart, entity deleted) caused incident to be cancelled.	Fetches the JIRA issue that corresponds to the health rule / affected entity, and resolves the JIRA.

Create a JIRA Action

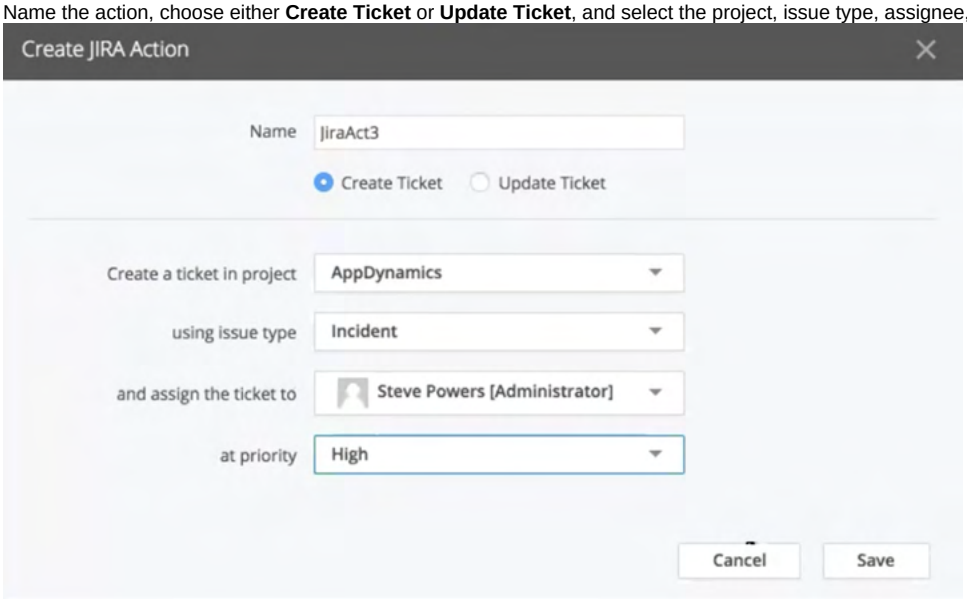
To create a JIRA action:

1. Access the **Actions Configuration** pane. See Create and Modify Actions in Actions.

2. Select **Create or Update a JIRA Ticket** in the **Create Action** pane and click **OK**.



3. Name the action, choose either **Create Ticket** or **Update Ticket**, and select the project, issue type, assignee, and priority from the dropdowns.



4. Click **Save**.

You can now associate a health rule with a policy that executes the JIRA action. The Atlassian JIRA integration must be set up for the alerts and policies to run.

Configure HTTP HTTPS Proxy

You can configure an HTTP/HTTPS proxy for an on-premise Controller. When you configure a proxy, the HTTP request actions or JIRA actions are routed through the HTTP proxy or the HTTPS proxy, depending on the endpoint.

Add HTTP Proxy Details to the Configuration File

The `domain.xml` configuration file is the global configuration for managed hosts. Add the HTTP proxy details to the `domain.xml` file as follows:

1. Locate and edit `domain.xml` for the domain.
   This is usually located under `$JBOSS_HOME/domain/configuration/`.
2. Add the following JVM option to enable the HTTP proxy support for alerting actions:

   ```
   <jvm-options>-Dappdynamics.alerting.actions.http.enable.proxy=true</jvm-options>
   ```

   The HTTP proxy support for alerting actions is disabled by default.

   > You can also enable the HTTP proxy support for alerting actions at, `/private/ControllerFlagsServlet` endpoint. You must have admin credentials to enable this option.

3. Add the following JVM options to configure the HTTP and HTTPS proxy authentication parameters, namely, host, port, user, and password.

   ```
   <jvm-options>-Dhttp.proxyHost=$HOST</jvm-options>
   <jvm-options>-Dhttp.proxyPort=$PORT</jvm-options>
   <jvm-options>-Dhttp.proxyUser=$USER</jvm-options>
   <jvm-options>-Dhttp.proxyPassword=$PASSWORD</jvm-options>
   <jvm-options>-Dhttps.proxyHost=$HOST</jvm-options>
   <jvm-options>-Dhttps.proxyPort=$PORT</jvm-options>
   <jvm-options>-Dhttps.proxyUser=$USER</jvm-options>
   <jvm-options>-Dhttps.proxyPassword=$PASSWORD</jvm-options>
   ```

   Ensure that you provide a plain text password only.
   Proxy parameter changes are not hot-swappable. This means that you need to restart the Controller to ensure that the changes are reflected.

Custom Actions

Deployment Support

This page provides an overview of custom actions in AppDynamics. A custom action is typically used to integrate third-party alerting and ticketing systems. A custom action differs from other actions on its singular execution on the controller instance.

The custom action is made up of a custom action script and a custom.xml file (you must create the file before you create an action that uses them). The custom action scripts include parameters for specifying the affected entity, for example, the tier, node, business transaction, and so on. See Build a Custom Action for details on how to create the custom action script and XML file.

Custom actions are commonly used when you want to trigger a human workflow or leverage an existing alerting system that is external to AppDynamics. For example, you could use a custom action to file a JIRA ticket when AppDynamics reports that a connection pool is near saturation.

Create a Custom Action

After the custom action script and custom.xml files have been tested manually and installed on the Controller, restart the Controller. Then, you can create the custom action.

To create a custom action:

1. Access the **Create Action** pane. See Create and Modify Actions in Actions.
2. Select **Run a Custom Action that has been uploaded to the Controller**.
3. Click **OK**.
4. Enter a name for the action.
5. Select the custom action from the dropdown. All the custom actions you have created are listed here.
6. Click **Save**.

The custom action is now available for assignment to a policy.

Disable Custom Actions on a Multi-Tenant Controller

Because a custom action script has access to the Controller file system, you may decide to disable this functionality in a multi-tenant environment for security reasons.

To disable custom actions:

1. Open the Controller admin console.
2. Go to **Controller Settings**.
3. Search for the `aas.multitenant.custom.action.local.execution.enabled` property.
4. Set to `false`.
5. Click **Save**.

Build a Custom Action

This page provides instructions on custom actions in AppDynamics.

You can set up a custom action on the Controller instance to integrate notification of AppDynamics health rule violations and events with an alerting or ticketing system. Use a push approach by creating custom notifications that pass the information to your alerting system.

Custom Notifications and Custom Actions

A custom notification lets you integrate alerts about AppDynamics health rule violations and events into your own alerting system. This integration extension requires:

- A `custom.xml` file that provides information about the custom notification.
- An executable script that accepts parameters from AppDynamics about the events and health rule violations that trigger an alert.
- Configuring AppDynamics events or policies to trigger the custom notification via a custom action.

Create a Custom Action

Create the Script

For each custom action that you want to implement, create an executable script (`.bat` extension for Windows, `.sh` extension for Linux) that can accept and process the parameters passed to it by AppDynamics. See Information Passed to the Custom Action Script from AppDynamics for details on the parameters.

For each script:

- Set correct executable permissions for the shell scripts in a Linux environment. For example, chmod `770 script1.sh`.
- Ensure that the script file has the correct character encoding. This is especially important when creating a Unix shell script on a Windows machine.

Install the Script on an On-Premises Controller

To install the script on an on-premises Controller:

1. At the top level of the Controller installation directory, create a directory named `custom` with a sub-directory named `actions`.

   ```
   <controller_home>/custom/actions
   ```

2. In the `<controller_home>/custom/actions` directory, create a subdirectory for each custom action script that you will install. For example, for an action that interfaces with a JIRA system.

   ```
   <controller_home>/custom/actions/jira
   ```

3. Move the script to the appropriate subdirectory that you created.

Create the XML File

1. Create a `custom.xml` file that describes the location and name of your custom action script. See Contents of the custom.xml File.
2. For an on-premises Controller, move the file to the `<controller_home>/custom/actions` directory. For a SaaS Controller, contact your AppDynamics account representative for instructions.

Verify the Script on an On-Premises Controller

1. After you have installed the script and the custom.xml file, restart the Controller.
2. Verify the script manually. To verify the script:
   a. Open a command-line console on the Controller host machine.
   b. Execute the script file from the command line console.

Create the Custom Action

To arrange how a custom action will be triggered, see Custom Actions.

Contents of the custom.xml File

The `custom.xml` file has an `<actions>` element for every custom action on the Controller.

The `<type>` element contains the subdirectory that contains the script file.

The <executable> element contains the name of the script.

Sample custom.xml File

```
<custom-actions>
  <action>
     <type>jira</type>
     <executable>script1.bat</executable>
  </action>
  <action>
    <type>bugzilla</type>
    <executable>script2.sh</executable>
  </action>
</custom-actions>
```

Information Passed to the Custom Action Script from AppDynamics

The custom action script must handle the parameters that the Controller passes from the health rule violation or other event. The parameter values are passed as an array of strings.

The parameters are passed as $0 for the script name, then $1, $2, . . . $*n*. $1 is the first parameter (application name), $2 is the application id, and so on in the order in which they are documented in the sections below.

Health rule violations have a different set of parameters from events.

Parameters Passed by a Health Rule Violation

The parameters describe the violated health rule violation that triggered the action.

The total number of elements in the array depends on the number of entities evaluated by the health rule and the number of triggered conditions per evaluation entity. Examples of evaluation entities are application, tier, node, business transaction, JMX. For each evaluation entity, the script expects the entity type, entity name, entity id, number of triggered conditions, and for each triggered condition, the set of condition parameters.

The parameter values are passed in the order in which they are described.

Structure of Parameters Sent by a Health Rule Violation

- APP_NAME
- APP_ID
- PVN_ALERT_TIME
- PRIORITY
- SEVERITY // INFO, WARN, ERROR
- ACTION_NAME
- HEALTH_RULE_NAME
- HEALTH_RULE_ ID
- PVN_TIME_PERIOD_IN_MINUTES
- AFFECTED_ENTITY_TYPE
- AFFECTED_ENTITY_NAME
- AFFECTED_ENTITY_ID
- NUMBER_OF_EVALUATION_ENTITIES–The following parameters are passed for each evaluation entity:
    - EVALUATION_ENTITY_TYPE
    - EVALUATION_ENTITY_NAME
    - EVALUATION_ENTITY_ID
    - NUMBER_OF_TRIGGERED_CONDITIONS_PER_EVALUATION_ENTITY–The following parameters are passed for each triggered condition for this evaluation entity:
        - SCOPE_TYPE_x
        - SCOPE_NAME_x
        - SCOPE_ID_x
        - CONDITION_NAME_x
        - CONDITION_ID_x
        - OPERATOR_x
        - CONDITION_UNIT_TYPE_x
        - USE_DEFAULT_BASELINE_x
        - BASELINE_NAME_x
        - BASELINE_ID_x
        - THRESHOLD_VALUE_x
        - OBSERVED_VALUE_x
- SUMMARY_MESSAGE
- INCIDENT_ID
- DEEP_LINK_URL
- EVENT_TYPE
- ACCOUNT_NAME

- ACCOUNT_ID
- TAG

Definitions of Parameters Sent by a Health Rule Violation

Health Rule Violation Parameter	Definition
APP_NAME	Name of the business application.
APP_ID	Application ID number.
PVN_ALERT_TIME	Alert time, such as Thu Dec 22 15:03:56 PST 2011.
PRIORITY	Integer designating how urgently a health rule violation should be fixed. The lowest number (0) is the most urgent.
SEVERITY	INFO, WARN, or ERROR. In the Controller UI, they are called Info, Warning, and Critical.
ACTION_NAME	Name of the action to be invoked post a health rule violation.
HEALTH_RULE_NAME	Name of the health rule that was violated.
HEALTH_RULE_ ID	Health rule ID.
PVN_TIME_PERIOD_IN_MINUTES	Health rule violation time period in minutes.
AFFECTED_ENTITY_TYPE	APPLICATION, APPLICATION_COMPONENT (aka Tier), APPLICATION_COMPONENT_NODE, BUSINESS_TRANSACTION, APPLICATION_DIAGNOSTIC_DATA (aka Error).
AFFECTED_ENTITY_NAME	The affected entity name.
AFFECTED_ENTITY_ID	The affected entity ID.
NUMBER_OF_EVALUATION_ENTITIES	Number of entities (Business Transactions, Applications, Tiers, Nodes, Errors, JMX counters, and so on) violating the health rule conditions
EVALUATION_ENTITY_TYPE	APPLICATION, APPLICATION_COMPONENT (aka Tier), APPLICATION_COMPONENT_NODE, BUSINESS_TRANSACTION, APPLICATION_DIAGNOSTIC_DATA (aka Error), JMX.
EVALUATION_ENTITY_NAME	The evaluation entity name (for JMX it is the counter name).
EVALUATION_ENTITY_ID	The evaluation entity ID or <NULL> for JMX.
NUMBER_OF_TRIGGERED_CONDITIONS_PER_EVALUATION_ENTITY	Number of times to loop through the triggered condition parameters for each evaluation entity; if more than one condition is triggered, the parameters repeat for each triggered condition, where x is the position of the condition.
SCOPE_TYPE_x	The scope of the parameter, whether the scope is the application, tier, or node: APPLICATION, APPLICATION_COMPONENT, APPLICATION_COMPONENT_NODE.
SCOPE_NAME_x	The name of the scope, such as ACME Book Store Application.
SCOPE_ID_x	The scope ID.
CONDITION_NAME_x	The health rule condition name.
CONDITION_ID_x	The health rule condition ID.
OPERATOR_x	Allowed operators: LESS_THAN, LESS_THAN_EQUALS, GREATER_THAN, GREATER_THAN_EQUALS, EQUALS, NOT_EQUALS.
CONDITION_UNIT_TYPE_x	The condition for the threshold parameter: ABSOLUTE, BASELINE_STANDARD_DEVIATION, BASELINE_PERCENTAGE, BASELINE_PERCENTILE.
USE_DEFAULT_BASELINE_x	A Boolean parameter (true or false) applies only when the condition unit type is one of the BASELINE_ types.
BASELINE_NAME_x	Applicable only when the condition unit type is one of the BASELINE_ types and the use *default baseline* parameter is false.
BASELINE_ID_x	Applicable only when the condition unit type is one of the BASELINE_ types and the use *default baseline* parameter is false.
THRESHOLD_VALUE_x	Health rule threshold setting.
OBSERVED_VALUE_x	Value that violated the health rule threshold.

SUMMARY_MESSAGE	Summary of the notification, such as Health rules have been violated.
INCIDENT_ID	The incident identifier number for this health rule violation. Incident ID is unique within the Controller. The field is defined as int(11) which means it takes four bytes of space that is 32 bits of space with 2^(31) - 1 = 2147483647 max value and -2147483648 min value. One bit is for sign.
DEEP_LINK_URL	Controller deep link URL, such as: `http://<controller-host-url>/#location=APP_INCIDENT_DETAIL&incident=<incident-id>` Append the incident ID to the URL to provide a link to the Controller UI for this policy violation.
EVENT_TYPE	POLICY_OPEN_WARNING, POLICY_OPEN_CRITICAL, POLICY_CLOSE_WARNING, POLICY_CLOSE_CRITICAL, POLICY_UPGRADED, POLICY_DOWNGRADED, POLICY_CANCELED_WARNING, POLICY_CANCELED_CRITICAL, POLICY_CONTINUES_CRITICAL, and POLICY_CONTINUES_WARNING.
ACCOUNT_NAME	Name of the account in which the action was triggered.
ACCOUNT_ID	ID of the account in which the action was triggered.
TAG	Tag specified by the user or the empty string if no tag was specified.

Parameters Passed by an Event

The parameters describe the event that triggered the action.

The total number of elements in the array depends on the number of event types and event summaries that triggered the action.

The parameter values are passed in the order in which they are described.

Structure of Parameters Sent by an Event

- APP_NAME
- APP_ID
- EN_TIME
- PRIORITY
- SEVERITY
- EN_NAME
- EN_ ID
- EN_INTERVAL_IN_MINUTES
- NUMBER_OF_EVENT_TYPES
  The following parameters are passed for each event type:
  - EVENT_TYPE_x
  - EVENT_TYPE_NUM_x
- NUMBER_OF_EVENT_SUMMARIES
  The following parameters are passed for each event summary:
  - EVENT_SUMMARY_ID_x
  - EVENT_SUMMARY_TYPE_x
  - EVENT_SUMMARY_SEVERITY_x
  - EVENT_SUMMARY_STRING _x
- DEEP_LINK_URL
- ACCOUNT_NAME
- ACCOUNT_ID
- TAG

Definitions of Parameters Sent by an Event

Event Notification Parameter	Definition
APP_NAME	Name of the business application.
APP_ID	Application ID number.
EN_TIME	Event notification time, for example, Wed Jan 04 09:36:55 PST 2012.
PRIORITY	Integer designating how urgently a health rule violation should be fixed, with the lowest number (0) the most urgent.
SEVERITY	Allowed values: INFO, WARN, or ERROR. In the AppDynamics UI they are called Info, Warning, and Critical.
EN_NAME	Name of the event notification.
EN_ID	Event notification ID number.
EN_INTERVAL_IN_MINUTES	Event notification interval in minutes.
NUMBER_OF_EVENT_TYPES	Determines how many times to loop through the event type map parameters.

EVENT_TYPE_x	If there is more than one event type, the parameters repeat for each event type, where x increments the number representing the event type.
EVENT_TYPE_NUM_x	Number of events of this type.
NUMBER_OF_EVENT_SUMMARIES	Number of event summaries in the notification that determines how many times to loop through the event summary parameters.
EVENT_SUMMARY_ID_x	Event summary ID number.
EVENT_SUMMARY_TIME_x	Event summary time, for example: Wed Jan 04 09:34:13 PST 2012.
EVENT_SUMMARY_TYPE_x	Type of event, such as: APPLICATION_CONFIG_CHANGE, APP_SERVER_RESTART, DIAGNOSTIC_SESSION, STALL.
EVENT_SUMMARY_SEVERITY_x	Event severity, such as: INFO, WARN or ERROR. In the Controller UI, they are called Info, Warning, and Critical.
EVENT_SUMMARY_STRING_x	Event summary string, such as: Application Server environment variables changed.
DEEP_LINK_URL	http://<controller-host-url>/#location=APP_EVENT_VIEWER_MODAL&eventSummary= Append each event summary ID to the URL to provide a link to the Controller UI for this event.
ACCOUNT_NAME	Name of the account in which the action was triggered.
ACCOUNT_ID	ID of the account in which the action was triggered.
TAG	Tag specified by the user or the empty string if no tag was specified.

Action Suppression

You can temporarily suppress a policy's automatic invocation of actions and alerts. You may want to do this while you are performing maintenance on or troubleshooting a component.

To see action suppression configurations created for an application, click **Alert & Respond** > **Actions** > **Action Suppression**.

Objects Affected by Action Suppression

You can configure action suppression for a specific time period to apply to a specific object or several objects. These entities can be the objects of action suppression:

- Application
- Business Transaction
- Tier
- Node
- Server

Within the time period configured for the action suppression, no policy actions are invoked for health rule violation events that occur on the specified object (s).

You can disable the reporting of metrics for agents associated with the object for which actions are suppressed. This option can cause reported metrics to change without notice.

If you see a sudden unexpected change in reported metrics for an object, review the action suppression configurations list to determine whether action suppression with reporting disabled is currently active for that object.

You can configure the entities that the action suppression affects for each object. This table lists the entities for which you can suppress the actions, depending on the configured object scope.

Object Scope	Affected Entities
Application	All entities within the application.
Business Transaction	• All business transactions in the application. • All business transactions within specific tiers. • Specific business transactions. • Business transactions with names having patterns that match certain criteria (such as all business transactions with names that start with "XYZ").
Tiers	• All tiers in the application. • Specific tiers. In a tier-level configuration, the suppression affects: • all the nodes in the specified tier(s) • individual node health rules as well as tier-level health rules For example, if a tier-level health rule is configured to invoke an action when a percentage of the nodes violates the condition, and then action suppression is configured on certain nodes in that tier, those nodes are still evaluated by the tier-level health rule.
Nodes	• All nodes • Java nodes • .NET nodes • PHP nodes Within these node types you can suppress actions for: • All nodes • Nodes in specific tiers • Specific nodes • Nodes with names, meta-info, environment variables or JVM system environment properties with specified matching criteria In a node-level configuration, the suppression affects node health rules only.
Servers	• All servers • Specific servers

Health Rules Affected by Action Suppression

By default, an action suppression configuration applies to actions triggered by all events that are generated by the configured objects.

You can refine the configuration to apply only to actions triggered by specific health rule violations. For example, if an application contains HealthRuleA, HealthRuleB and HealthRuleC, but only HealthRuleC is configured for action suppression, actions will continue to be invoked for violations of HealthRuleA and HealthRuleB during the configured time period.

Disable Health Rule Evaluation

Suppressing an action does not suppress the evaluation of any health rules linked to the action through a policy. Health rule violation events continue to be raised even when actions are suppressed. You can turn off the evaluation of a specific health rule or all health rules. See Disable All Health Rules.

Configure and Manage Action Suppressions

You can create, edit, or delete an action suppression in the Action Suppression tab. To access the action suppression configuration, click **Alert & Respond** > **Actions** > **Action Suppression**.

Create an Action Suppression

> When you create a new configuration, configure the panels in the same order as in the interface, because the configuration of the object scope determines the available affected entities presented in the object scope panel.

1. In the **Action Suppression** panel, click the **Create +** icon. The **Create Action Suppression** wizard appears.
2. In the **Overview** panel, enter a name for the action suppression. You can use alphanumeric characters to specify a name. Ensure that you specify a unique name.
3. To prevent the agents defined in the object scope from reporting metric data during the action suppression active time frame, select **Disable Agent Reporting**.
4. Select a time zone from the **Time Zone** dropdown.
5. To suppress actions only once, configure these **One Time** settings:
    a. The time to start action suppression. You can choose:
        - **Now**—to suppress actions immediately.
        - **After**—to suppress actions after the defined number of minutes.
        - **Date**—to suppress actions on a date, at a defined time.
    b. The time to stop action suppression. You can choose:
        - **After**—to stop suppressing the actions after the defined number of minutes.
        - **Date**—to stop suppressing actions on a date, at a defined time.
6. To suppress actions on a recurring basis, configure these **Recurring** settings:
    - **Daily**—to suppress actions every day from the defined **Start Time** to the **End Time**.
    - **Weekly**—to suppress actions on a specific day of a week from the defined **Start Time** to the **End Time.**
    - **Monthly—**to suppress actions on a specific date or a day of the month.
        - **Specific date—**to suppress actions starting on a specified **Start Date** and **Start Time** through the **End Date** and **End Time**.
        - **Specific day**—to suppress actions starting on a specified day and **Start Time** through the **End Time**.
7. In the **Object Scope** panel, select what entities that the action suppression affects.
   Depending on the type of object, you can configure the corresponding entities that are affected. See Entities Affected for information about the type of entities that can be affected by various objects.
8. To suppress actions only for the violations caused by specified health rules:
    a. In the **Health Rule Scope** panel, select **Suppress Action execution for these specified Health Rules.**
    b. Click **Add**. The **Health Rule Selection** dialog appears.
    c. Select the health rules and click **Select Health Rule(s)**.
9. Click **Create**.

Edit an Action Suppression

To modify an action suppression configuration, click the **Edit** icon.

Delete an Action Suppression

To delete a configured action suppression, click the **Delete** icon. A dialog asks you to confirm the deletion.

Predefined Templating Variables

This page describes the predefined variables that can be used in an HTTP request template or in an email template. The policy engine substitutes the value of the variable in the context of the triggering event(s) when it sends the actual request or email.

Form Variable Names

To form a predefined variable name, combine the base name of the variable with a field of its corresponding info class. You can use the base name with the corresponding info class only for example, you can use the base name action with info class `ActionInfo only`.

If an info class has no fields associated, use the base name as the variable. For example, to use the controller URL as a variable in a template, use `${controllerUrl}`.

If an info class comprises multiple fields, select a single field and associate it with the base name. For a list of fields associated with an info class, see Info Class Fields.

For example:

- To use the account name as a variable in a template, combine the base name `account` with the `name` field of the `EntityInfo` class to form the variable `${account.name}`.
- To use the trigger time of an action as a variable, combine the base name `action` with the `triggerTime` field of the `ActionInfo` class to form the variable `${action.triggerTime}`.

You can chain the segments of a variable name where the info class field type is yet another info class.

For example, to use the name of an application in which the latest triggering event occurred:

1. Combine the latestEvent base name with the `application` field of the `EventInfo` class.
2. The field type of the `application` field is `EntityInfo` which is yet another info class, hence select the name field of the `EntityInfo` class.
3. Form the variable name by appending the segments:

   ```
   { <base name>.<field name of info class1>.<field name of info class2>}

   ${latestEvent.application.name}.
   ```

Base Names

This tables describes the base names for the predefined variables with their corresponding info classes.

Base Name	Description	Info Class
`account`	Account in which the action was triggered.	`EntityInfo`
`policy`	Policy that triggered the action.	`PolicyInfo`
`action`	Triggered action.	`ActionInfo`
`topSeverity`	`INFO`, `WARN` or `ERROR`.	`NotificationSeverity`
`topSeverityImage`	Severity image or icon.	`ImageInfo`
`notificationConfigText`	Email actions only.	`String`
`controllerUrl`	URL of the controller.	`String`
`appDynamicsIcon`	-	`ImageInfo`
`appDynamicsLogo`	-	`ImageInfo`
`latestEvent`	Most recent triggering event.	`EventInfo`
`fullEventList`	List of events that triggered the action.	`List<EventInfo>`
`fullEventsByTypeMap`	List of events that triggered the action, grouped by type.	`Map<String, List<EventInfo>>`
`clampLimit`	Optional setting, limit on how many triggering events to display.	`int`
`clamped`	True if clamp limit is set.	`boolean`
`clampedEventList`	*n* most recent triggering events if clamped.	`List<EventInfo>`
`clampedEventsByTypeMap`	*n* most recent triggering events if clamped, grouped by type.	`Map<String, List<EventInfo>>`
`fullEventsNodeMap`	Node level variables to be used in email and HTTP templates.	`Map<EventInfo, NodeTemplateVariables>`

Info Class Fields

From the previous Base Names table, use the fields in the appropriate class to form the variable to use in a template.

```
class EventInfo {
  EventType eventType
  long id
  String guid
  String eventTypeKey
  Date eventTime
  String displayName
  String summaryMessage
  String eventMessage
  EntityInfo application
  EntityInfo tier
  EntityInfo node
  EntityInfo db
  List<EntityInfo> affectedEntities
  boolean healthRuleEvent
  EntityInfo anomaly // * Only defined in case of anomaly event
  EntityInfo healthRule // * Only defined when healthRuleEvent == true
  EntityInfo incident // * Only defined when healthRuleEvent == true
  boolean healthRuleViolationEvent
  NotificationSeverity severity
  ImageInfo severityImage
  boolean btPerformanceEvent // * true when eventType matches one of the BT performance event types
  String deepLink
}

class ImageInfo {
  String name
  String fileName
  String mimeContentRef
  String deepLink
}

class EntityInfo {
  EntityType entityType
  String entityTypeDisplayName
  long id
  String name
}

class ActionInfo extends EntityInfo {
 Date triggerTime
}

class PolicyInfo extends EntityInfo {
 boolean digest
 digestDurationInMins
}

class PolicyInfo {
  EntityType entityType
  String entityTypeDisplayName
  long id
  String name
  boolean digest
  int digestDurationInMins
}

class ActionInfo {
  EntityType entityType
  String entityTypeDisplayName
  long id
  String name
  Date triggerTime
}
```

```
enum NotificationSeverity { INFO, WARN, ERROR }

class NodeTemplateVariables {
    private long id;
    private String name;
    private long tierId;
    private String tierName;
    private long machineId;
    private String machineName;
    private boolean machineAgentPresent;
    private String machineAgentVersion;
    private boolean appAgentPresent;
    private String appAgentVersion;
    private String ipAddresses;
    private AgentType agentType;
}
```

The `private String ipAddresses` field contains hostnames instead of IP addresses.

Examples

HTTP request example for most recent triggering event:

```
http://myController:8080/controller/rest/applications/${latestEvent.application.name}/nodes/${latestEvent.node.name}
```

HTTP request example iterating through a list of triggering events:

```
#foreach(${event} in ${fullEventList})
  http://myController:8080/controller/rest/applications/${event.application.name}/nodes/${event.node.name}
#end
```

Email with dynamically varying subject example:

If you have several health rules to monitor your application and one policy to send email notification for all the health rules, you might find it difficult to search for the correct information in the notification. You can define a variable to dynamically update the email subject based on the event that triggered the notification.

Ensure that you define the subject variable in the email body and include it in the subject field.

```
Subject: $subject
Body:
...
 <!-- Subject changes dynamically based on the triggering event -->
#set($subject = #foreach(${events} in ${fullEventList}) ${events.eventType} #end )}
...
```

Email HTML body example:

AppDynamics uses this email template to notify the details of the events occurring on an application. You can customize the required event details you want notified by enabling the event types.

```
<!-- Default AppDynamics email template -->

#if( $!{notificationConfigText} != '' )
$!{notificationConfigText}
#else
AppDynamics
#end
Event Notification for the "${latestEvent.application.name}" Application
Event Notification Name: ${policy.name}
Event Notification Severity: ${topSeverity}

Summary of events occurring during the ${policy.digestDurationInMins}+ minute(s) prior to ${action.triggerTime}:
## Summary table
|| Event Type | Count ||
## Copy this row for each event type and count
#foreach($eventTypeEntry in $fullEventsByTypeMap.entrySet())
|| ${eventTypeEntry.getKey()} | ${eventTypeEntry.getValue().size()} ||
#end

## Full List of Events
The following events occurred during the time frame:
#if ($clamped)
Warning: The event list has been clamped at ${clampLimit} results! Please see the event and/or request snapshot
viewers for the full list of events.
#end
|| Event Time | Event Type | Severity | Tier | Node | Summary ||

#foreach($eventList in $clampedEventsByTypeMap.values())
  #foreach($event in $eventList)
    || ${event.eventTime} | ${event.displayName} | ${event.severity} | $!{event.db.name} | $!{event.tier.name}
| $!{event.node.name} | ${event.summaryMessage} ||
  #end
#end
Event Notification from AppDynamics.
This is an auto-generated email summarizing events on the "${latestEvent.application.name}" application. You
are receiving this because you are configured as a recipient on the "${policy.name}" event notification. This
is not necessarily an exhaustive list of all events during this time frame. Only those event types enabled in
the notification will appear in this message.
```

Example to extract event details using iteration:

These examples iterate through the `eventList` to extract the details of each event occurring during the specified time.

```
<h1>Summary of events occurring during the ${policy.digestDurationInMins}+ minute(s) prior to ${action.
triggerTime}:</h1>

<table>

#foreach(${eventList} in ${fullEventsByTypeMap.values()})
  #foreach(${event} in ${eventList})

    <tr>
        <td>
            <!-- Event icon -->
            <img src="${event.severityImage.mimeContentRef}" alt="${event.severity}" />
        </td>
        <td>
            <!-- Event name with event link -->
            <a href="${event.deepLink}">${event.displayName}</a>
        </td>
        <td>
            <!-- Event message -->
            ${event.eventMessage}
        </td>
    </tr>

  #end
#end

</table>
```

Example code to list all variables:

```
<h1>variables below </h1>

${fullEventsNodeMap}

<h2>map elements below</h2>

#foreach(${value} in ${fullEventsNodeMap.values()})
${value}
${value.name}
#end
```

If these predefined variables do not meet your needs, you can define your own custom variables for use in these templates in the **Create Template** pane.

Do not use any of the predefined variable names for your custom variables.

Email Digests

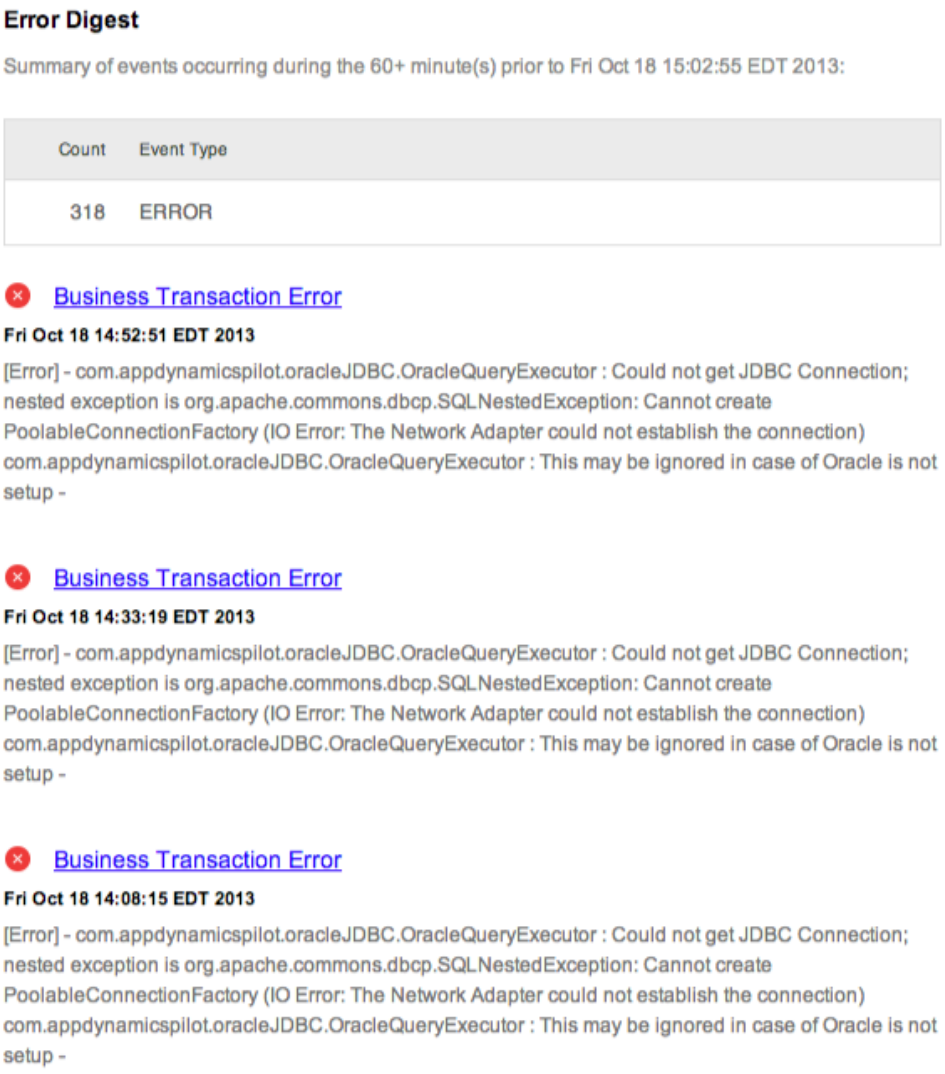
This page provides an overview of email digests in AppDynamics. In addition to specific actions that are triggered by specific events, you can create an email digest that reports a summary of specific events to a recipient list on a schedule.

Permissions

To create, edit, or delete email digests, a user must have the Configure Actions, Configure Health Rules, and Configure Policies permissions.

Sample Email Digest

This is a sample of an email digest that is sent every hour:



Error Digest

Summary of events occurring during the 60+ minute(s) prior to Fri Oct 18 15:02:55 EDT 2013:

Count	Event Type
318	ERROR

Business Transaction Error

Fri Oct 18 14:52:51 EDT 2013

[Error] - com.appdynamicspilot.oracleJDBC.OracleQueryExecutor : Could not get JDBC Connection; nested exception is org.apache.commons.dbcp.SQLNestedException: Cannot create PoolableConnectionFactory (IO Error: The Network Adapter could not establish the connection) com.appdynamicspilot.oracleJDBC.OracleQueryExecutor : This may be ignored in case of Oracle is not setup -

Business Transaction Error

Fri Oct 18 14:33:19 EDT 2013

[Error] - com.appdynamicspilot.oracleJDBC.OracleQueryExecutor : Could not get JDBC Connection; nested exception is org.apache.commons.dbcp.SQLNestedException: Cannot create PoolableConnectionFactory (IO Error: The Network Adapter could not establish the connection) com.appdynamicspilot.oracleJDBC.OracleQueryExecutor : This may be ignored in case of Oracle is not setup -

Business Transaction Error

Fri Oct 18 14:08:15 EDT 2013

[Error] - com.appdynamicspilot.oracleJDBC.OracleQueryExecutor : Could not get JDBC Connection; nested exception is org.apache.commons.dbcp.SQLNestedException: Cannot create PoolableConnectionFactory (IO Error: The Network Adapter could not establish the connection) com.appdynamicspilot.oracleJDBC.OracleQueryExecutor : This may be ignored in case of Oracle is not setup -

Create an Email Digest

To create an email digest, navigate to **Alert & Respond > Email Digests** on either the right panel or in the left navigation pane. Follow the steps in the wizard to create the digest.

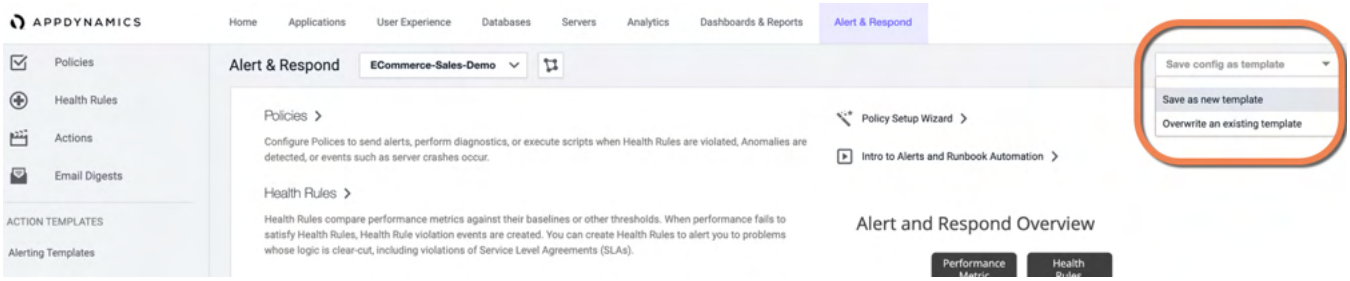
Alerting Templates

An alerting template is a configuration of features such as Health Rules, Policies, Actions, Action Suppression, Schedules, and Email Digests. You can save the **Alert & Respond** configuration of an existing application as a template. Templates help maintain consistent configuration across various applications regardless of their location, version, or environment.

How to Use an Alerting Template

You can save the **Alert and Respond** configuration of an existing application as a template. You can use the **Save as new template** option. You can apply the template to other applications to replicate the configuration.

After configuring an alerting template, if you require to change the configuration and apply the changes to all the applications, use the **Overwrite an existing template** option. The existing template is overwritten. You can then re-apply the template to the desired applications. For more information, see Configure and Manage Alerting Templates.



Alerting Template Operations

To view alerting templates, select **Alert & Respond > Alerting Templates**. The alerting templates list displays all templates. You can create and manage the templates using the **Alerting Template** interface.

This table lists the template operations:

Operation	Description
	View the configuration details of the selected template(s). For more information, see View Alerting Template Details.
	Create a new template. For more information, see Create an Alerting Template.
	Overwrite a selected template. Any changes you make, overwrite the existing configuration when you save the template. For more information, see Overwrite an Alerting Template. When you edit a template, the updates are not applied to applications using the template. You must re-apply the template to the desired applications.
	Delete an existing template. For more information, see Delete an Alerting Template. The configuration of applications using the template remains intact even after you delete the template.
	Import a saved template configuration. Use this option when you have saved the configured alerting template and want to apply it to other applications.
	Export a template configuration for future use. Use this option when you have configured an alerting template and want to save it for future use.
	Apply a template to the selected application(s). For more information, see Apply Template to Application(s).
	Search for a template.

Configure and Manage Alerting Templates

You can create a new alerting template in **Alert & Respond > Alerting Templates**. Alternatively, you can configure the **Alert and Respond** features in the Controller UI and save the configuration as an alerting template.

> JMX Health Rules are not supported.

View Alerting Template Details

To view the configuration details of an existing alerting template:

1. Select a template.
2. Click the view icon to view the configuration details.
3. To edit the template, view template history, or apply the template to other application(s), click **More**.

Create an Alerting Template

Ensure that you create and configure the health rules, policies, actions, action suppression, and email digests you plan to use to create the alerting template before you create the template.

1. Click the create icon. The **New Template** wizard displays.
2. Enter a name for the template. You can use alphanumeric characters to specify a name. Ensure that you specify a unique name.
3. If required, include a description. Click **Next**.
4. Select an **Application** from the list displayed in **Choose an Application**. The configuration you define for this application is saved as a template. Click **Next**.
5. Select the following feature configuration as required:
    a. Policies
    b. Health Rules
    c. Actions
    d. Action Suppression
    e. Email Digests
6. Click **Next**.
7. Review the configuration settings you have defined. Click **Save**.

Overwrite an Alerting Template

If you make any inadvertent updates to a template, the changes cannot be reverted. You can update the template using the overwrite option, which overwrites the existing configuration with the updates you made when you save the template.

1. Select the template and click the overwrite icon. The **Overwrite Existing Template** wizard displays.
2. Select the application whose configuration you want to save as a template. Click **Next**.
3. Modify the pre-configured features as necessary. Click **Next**.
4. Review the configuration settings you have defined. Click **Overwrite**.

Once you overwrite the configuration of a template and save it, you cannot revert the changes.

Any updates made to the template are not applied to all the applications using the template. You must re-apply the modified template to applications.

Delete an Alerting Template

You can delete a template if you no longer use it. When you delete a template, the applications using the template are not affected. The application configuration also remains intact. You can continue to use the applications as before.

1. Select the template and click the delete icon.
2. Click **Delete**.

> Once you delete a template, you cannot restore it.

Import an Alerting Template

You can import a saved alerting template and apply it to other applications.

1. Click the import icon. The **Import Template** dialog displays.
2. Click and select a file to import.

> Ensure that:
>
> - You select a JSON file to import.
> - The file you want to import has a unique name, otherwise the file is not imported.

3. Click **Import**. The selected file is imported and displays in the **Alerting Templates** UI.

Export an Alerting Template

You can export a saved alerting template and apply it to applications in other accounts.

1. Select a template to export.
2. Click the export icon. The **Template exported successfully** message displays.

Apply Template to Application(s)

After you create an alerting template, you can apply the template to multiple applications.

1. In the **Alert & Respond > Alerting Templates**, select the template and click 

. The **Apply Template** wizard displays.
2. In **Choose Application(s)**, select the applications to apply the template. Click **Next**. Use the **Search** option if the list of templates is too long.
3. To add the template configuration (such as policies, health rules, and actions) to the existing configuration of the selected applications:
    a. In **Choose How to Apply Template**, select **Add/Merge**. Click **Apply**. The **Add/Merge** operation status displays.
    b. The alerting configuration of the template is added to the selected application(s).
    c. If you see an error or warning for an application, refer to **Check the Status of the Applications** to fix it.

    > If the entities (such as Health Rule, Policy, Action, Action Suppression, or Email Digest) exist in the template and the application, the configuration of the template entity replaces the configuration of the application entity.

4. To replace the existing configuration of an application with the configuration of the selected template:
    a. Select **Replace**.
    b. Click **Apply**.
    c. A confirmation dialog displays. Click **Yes** to confirm. The **Replace** operation status displays.

    > This operation replaces the alerting configuration of all the entities of the selected application(s), such as the health rules, policies, and actions, with that of the alerting configuration of the template. The existing alerting configuration of the selected application(s) is deleted permanently. Perform this operation only if you want to replace all the entities you have configured.
    >
    > If you see an error or warning for an application, refer to **Check the Status of the Applications** to fix it.

Check the Status of the Applications

You can check if the template was successfully applied to all the applications.

1. Click the **Status** of the template. The **Template History** page listing the status of each application displays.
2. If an error is listed on the **Template HIstory** page, click the error to determine the cause of the error and the exact location.
3. Fix the error and then re-apply the template to the affected application.

Alerting Template Questions and Answers

This page lists some questions and answers that help you use the alerting template.

As an on-premises customer, will I be able to use the alerting template?

Yes, this feature is available for on-premises users.

Will this feature require an agent upgrade?

This feature does not require any agent upgrade.

Do I need role-based access privileges to use alerting templates?

No, any user can create and manage alerting templates.

When I update a template, will the changes be applied to all applications using the template?

No, when you update a template, you need to re-apply the template to the application(s) to ensure that the updates are reflected.

Where can I view all the templates I created?

You can view the template library in the **Alert & Respond > Alerting Templates** UI. For more details, see View Alerting Template Details.

What are two ways to create a template?

You can save the Alert and Respond configuration of an existing application as a template using the **Save as new template** option.

After configuring an alerting template, if you require to change the configuration, use the **Overwrite an existing template** option.

Can I apply a template without selecting an application?

No, you can apply a template only to an application. Hence, you must select an application.

Where can I track the status of applying a template?

You can check if the template was successfully applied to all the applications. From the **Alert & Respond > Alerting Templates** UI, click the **Status** of the template. The **TEMPLATE HISTORY** page listing the status of each application displays.

Will updates to a template be applied to an application that is being edited by someone?

No, the template history page displays an error in the status column. Complete your edits to the application, then apply the updated template.

When I update a template, will I be able to revert the changes?

No, once you configure a template and save it, you cannot revert the changes. If you make any inadvertent updates to a template, you can overwrite the configuration and save the template again. For more information, see Overwrite an Alerting Template.

Can I edit a template?

You can overwrite the configuration of an existing template. If you make any inadvertent updates to a template, you can overwrite the configuration and save it. For more information, see Overwrite an Alerting Template.

When I delete a template, what happens to the applications using the template?

When you delete a template, the applications using the template are not affected. The application configuration also remains intact. You can continue to use the applications as before.

When I update a feature (for example a Health Rule) and re-apply the template, will the other associated features (like Policies, Actions) get selected by default?

Yes, when you update a feature within a template and re-apply it, all other associated features are selected by default.

Can I restore a deleted template?

Once you delete a template, it is lost, you cannot restore it.

Can I make an update to a single application without affecting the other applications using the template?

1. In the **Alert and Respond** UI, select the application you want to update.

2. Select the feature you want to modify (for example, policy, health rule).
3. Update the required configuration and save.

I made an inadvertent change to a template, how can I correct it?

You can delete the template, create a new one, and apply the template to the required applications.

> Once you delete a template, you cannot restore it.

Can I overwrite a template?

You can overwrite the configuration of a template and save it. You must re-apply the template to all applications. You can either replace an existing application configuration or append to it.

How can I apply a template to an existing application?

You can apply a template to an existing application with two methods:

- **Add/Merge**—The alerting configuration of the template is added to the selected application(s). If the entities (such as Health Rule, Policy, Action, Action Suppression, or Email Digest) exist in both the template and the application, the configuration of the template entity replaces the configuration of the application entity.
- **Replace**—This operation replaces the alerting configuration of all the entities of the selected application(s), such as the health rules, policies, and actions, with that of the alerting configuration of the template. The existing alerting configuration of the selected application(s) is deleted permanently. Only perform this operation if you want to replace all the entities you have configured.

For more information, see Configure and Manage Alerting Templates.

Can I apply a template to multiple applications at a time?

Yes, you can. For more information, see Apply Template to Application(s).

Troubleshoot Alert and Respond Problems

Health Rules

Why do I see consistent false alerts; logs display an error 'Error sending metrics'?

This happens when you configure a highly sensitive condition for a health rule.

When you define a very small evaluation time frame (for example, 3 mins) for a health rule condition, few configured metrics may fail to report data during the short time frame due to reasons such as network errors. This may not be the norm, however, alerts are triggered even if a single data point is not reported leading to consistent false alerts.

AppDynamics recommends that you configure a higher time frame to evaluate a health rule condition.

Dashboards and Reports

This page provides an overview of dashboards and reports in AppDynamics.

Dashboards and Reports are useful for getting a high-level understanding of the health and performance of your system on a regular basis.

Dashboards provide a graphical overview of the selected data made available for quick access. Custom dashboards let you create and arrange widgets to give users a visual overview of the data of interest to them. A War Room is similar to a dashboard, but it is interactive. The chat facility in virtual war rooms enable visually-enhanced collaborative troubleshooting in real-time in response to high priority events.

Reports capture and share AppDynamics data from dashboards to recipients. Reports can be automatically generated on a regular schedule.

Custom Dashboards

Deployment Support

Related Pages:

- Create and Manage Custom Dashboards and Templates
- Virtual War Rooms
- Custom Dashboard Permissions
- Dashboard Recovery

This page provides an overview of custom dashboards in AppDynamics.

A custom dashboard enables you to display a specific set of metrics and data points on one screen. You can display application, server, and database metrics reported by AppDynamics agents. You can also supplement the AppDynamics built-in dashboards (such as the application dashboard, tier dashboard, and so on) and display metrics that are of interest to a particular audience.

You can use custom dashboards to present selected metrics for a user who only needs a relatively narrow or focused view of the data. For example, an executive may only need a high-level view of system performance and activity. You can assign such users to the predefined Custom Dashboard Viewer role. Any user with a custom dashboard viewer role can view custom dashboards.

> Regardless of application-level or other restrictions configured for that data, a custom dashboard viewer can view all data that the dashboard owner is permitted to view on the controller-level custom dashboards.

Instead of using the Custom Dashboard Viewer role, you can share a custom dashboard.

You can use Controller-level custom dashboards to:

- Provide a customized view of application, server, and database performance data.
- Aggregate data from different applications on the same Controller
- Compare data from different applications on the same Controller
- Show a single view of both live and historical data
- Share data with other users and stakeholders

Create Custom Dashboards

To create a Controller-level custom dashboard, navigate to **Dashboards & Reports > Dashboards > Create Dashboard**. In the **Dashboards** panel, click an existing dashboard to edit it.

> To create or edit a custom dashboard, a user needs to have the Can Create Custom Dashboards permission. See Visibility and Permissions.

Custom Dashboard Templates

Custom dashboard templates are an efficient way to display the same type of information for multiple tiers or nodes. You create a dashboard in the scope of a tier or node and then use that dashboard as a template to display the same type of data for other tiers or nodes in the same application. Associating the template with a specific tier or node sets the source of the dashboard's data.

> To create or edit a custom dashboard template, a user needs to have the Configure 'My Dashboards' for Tiers and Nodes permission.

Create a custom dashboard template to:

- Compare overall application or infrastructure performance against individual tier or node performance
- Show a standard set of metrics for multiple tiers and nodes

You create and access dashboard templates from the My Dashboards tab of the built-in tier or node dashboard. From there, you can create a new dashboard template for that tier/node or use dashboard templates that were created for other tiers/nodes in the same application by association.

Although the process for configuring Controller-level and tier or node-level dashboard templates is similar, the two sets of dashboards are separate. In other words, you cannot associate a Controller-level dashboard with a tier/node through the My Dashboards tab, nor can you access from the Controller-level dashboards list any tier and node level dashboards outside the application in which they were created.

The dashboard and template names must be unique Controller-wide. You cannot create a custom dashboard using an existing dashboard template name, nor can you create a dashboard template using an existing custom dashboard name.

You can export custom dashboards and dashboard templates to a JSON file and then import them where you need them.

View Strategies

For AppDynamics Users

If you have set up default view permissions to custom dashboards, any user who is logged in to the Controller can view a custom dashboard.

Users can also be granted view, edit, share, and delete permissions on specific dashboards.

The Dashboards Viewer predefined role has permissions to view custom dashboards. You can grant this role to users or groups who need access to custom dashboards. See Custom Dashboard Permissions for details.

For the Public

Sharing a Controller-level custom dashboard makes the dashboard available to viewers who do not have AppDynamics accounts.

If the dashboard is shared, anyone who has been sent a direct link to the dashboard URL can view it. If someone has the URL and the dashboard is not shared or no longer shared, they see a message that the resource is not available when they try to access that URL.

To control Controller-level custom dashboard sharing, click **Share** on the menu of the custom dashboard configuration.

There is no comparable sharing mechanism for external viewers without Controller credentials to access tier- and node-level custom dashboards based on templates. To access these types of dashboards, the user must be logged in to the Controller and have custom dashboard view permissions on the specific dashboard.

The availability of sharing mechanism is now controlled by the Share permission of the user.

Simplify the Data Displayed

If a chart in a custom dashboard is displaying more data than you want, click the legend for the data that you want to remove from the chart. You can click the greyed-out legend to restore the display.

Widgets

Related Pages:

- Create and Manage Custom Dashboards and Templates
- Use Wildcards in Metric Definitions
- Configuration Import and Export API
- Visualize Analytics Data

This page provides an overview of widgets in AppDynamics. You can use widgets to create visual representations of your data in custom dashboards and war rooms.

If your platform is licensed for Analytics, you can display the results of Analytics searches on custom dashboards as well. See Visualize Analytics Data for more information.

Widget Types

Most widgets types in custom dashboards and war rooms will be familiar to you if you have worked with numeric charts before. This section provides information for certain widget features that may require additional explanation.

Time Series Graph

The standard time-series graph displays one or more values over time in various formats: line, area, column, scatter diagram.

If you configure a widget for a war room that examines metrics on a Java node, consider the streaming graph widget described in Virtual War Rooms. The streaming widget updates more frequently (every five seconds) than the standard time series widget (every 60 seconds) for collaborative real-time troubleshooting.

Events are grouped by time of resolution at the bottom of the graph. You can choose what events to display when you enable **Events Overlay** and configure the event queries for the graph.

Pie Chart

Pie charts or donut charts display multiple values as proportional slices of a whole. The data series should meaningfully total 100% of some series. For example, CPU Busy + CPU Idle + CPU Stolen on a single node or tier.

Gauge Widget

The gauge widget displays the magnitude of a metric value with respect to minimum and maximum values, both by the extent to which the gauge is filled and by the color of the fill.

You can set the minimum and maximum values displayed by the widget. Set the maximum to the highest acceptable maximum or a value close to it so that the gauge is configured for metrics within acceptable values for your site. If you do not set them, default values are used.

This table explains the color coding for gauge widgets.

Percentage	Color	Status
0-10%	Green	OK
10-50%	Gradient from green to yellow	OK trending to WARNING
50-90%	Gradient from yellow to red	WARNING trending to CRITICAL
90-100%	Red	CRITICAL

This gauge example displays the calls per minute metric without any special configuration for minimum and maximum values. The current value is 74 cpm, which is midway between the minimum (0) and maximum (148) for the time period in the WARNING range.

If you set the **Max Value** to 1000, the gauge color changes to green because 74 cpm falls within the OK range.

Streaming Graph Widget

A streaming graph widget is similar visually to a time-series graph, but it is updated every five seconds in contrast to every 60 seconds in the time-series graph.

For Java nodes only, the war room supports the streaming graph widget. It displays data from only a single specified node and only a Java node. This feature is not supported for any of the other agents. To display streaming data from multiple nodes, you need to create multiple widgets.

Log Tail Widget

The war room supports a log tail widget used for Java nodes only to share a log file or parts of one.

The log tail widget displays the contents of the file specified by its Path property. The Path is the absolute path to the log file on the machine on which the selected node is running. If you provide a regular expression in the widget properties, the widget displays only those lines in the log file that match the regular expression. If no regular expression is provided, the widget displays the entire log file. Note that applying a regular expression filter will only adjust lines that come after you have specified the filter. Previous lines will remain filtered based on the previous rule. The widget uses the Java conventions for regular expressions.

If the log file rolls over during the request, the response to the log tail request is undefined.

Issue Tracking Widget

The issue tracking widget displays information about an issue or a list of issues that you have selected. You can choose any detail, people, and date fields that you would like to display. Any updates made to the tracked issue is reflected on the widget.

This widget is only available once you have integrated AppDynamics with Atlassian JIRA.

Metric Value

You can specify a title for the widget as well as a format string that adds the name of the selected metric, the time range, or the name of the function. Alternatively, you can use a separate label widget to explain the metric value.

You have the option of formatting metric values by abbreviating them and removing trailing zeros. Abbreviations only apply to numbers over one million. Metric values are always integers on dashboards with single metrics, therefore decimal formatting does not apply.

Metric Expression

The ability to set the number of decimal places allows you to display decimal values less than one, as well as decimals for larger numbers. If your decimal limit is set to zero, then the remove trailing zeros feature is turned off by default.

Health Status

This is a health bar, filtered table, or status light circle of health statuses for entities, such as applications, business transactions, tiers, nodes, databases, servers, and health rules. After choosing an entity type to show the health for, you have the option to narrow the scope or simply display all.

It is important to note that when selecting tiers as your entity, the color of the health status depends on the statuses of all the health rules that are configured for the tiers. For example, if there are four health rules for the tiers, then the color of the widget will reflect the cumulation of all of their statuses. The widget displays green for normal, yellow for warning, and red for critical status. See Configure Health Rule Conditions to learn how the metrics that define warning and critical health statuses are set.

When using the circle visual, you have the option of manipulating the display by choosing its aggregation type: either **Ratio Graph** or **Most Severe Status**.

Event List

This is a filtered table of events that occurred within the specified time range.

IFrame

You may want to include a shared custom dashboard in another custom dashboard when you have different operators who focus on particular dashboards and you want to roll them all up into a primary dashboard for management.

To display information from another dashboard or from another website inside this custom dashboard, you need the URL. You can get the URL for a pane by clicking **Settings > Copy a link to this screen to the clipboard.**

The IFrame widget is sandboxed. Advanced HTML features, such as forms and Javascript, will not work with the IFrame widget.

Widget Data

Some widgets, such as a time series graph, can display a single value or multiple values. Some widgets, such as a donut, must display multiple values to make sense. Others, such as a gauge or a metric value, display only a single value.

Specify a Function of a Metric Value for a Single Entity

When you specify the data to display in a widget, you use a pulldown menu in the **Add Series** panel to select which function of the value to display:

- **Minimum**: Minimum value, only available for averaged metrics
- **Maximum**: Maximum value, only available for averaged metrics
- **Value**: Contains the average or the sum across the time range depending on the metric
- **Sum**: Aggregated value of the metric over the time range
- **Count**: Count of the observed values over the time range
- **Current**: Sum of the most recent minute's metric data values across all the included nodes

You can also use a metric expression to specify a metric. The behavior is similar to using an expression for a health rule. For more details about metric expressions, see how to build an expression for Health Rules.

> ⚠ Dashboard widget metric expressions currently cannot properly handle fraction or float constants that are less than one. These metrics are treated as zero. They work properly when they are a fraction, or float values greater than one.

Specify Metrics in Multiple Entities Using a Wildcard

You can use a wildcard to specify a metric that evaluates across several similar entities for metrics in these metric hierarchy branches:

- Hardware Resource
- JVM
- CLR
- Custom Metrics

See Use Wildcards in Metric Definitions for instructions.

Empty Data Series

It is possible that no data is available for a particular metric within the specified time range while for other time ranges valid data is reported. When this occurs, the label for the empty data series appears in the legend but no data is displayed. For example, no line in a time-series graph or slice in a pie chart.

Enable Limits on the Number of JMX Instances or Nodes for a Single Entity

You can use account-level configurations to enable dashboard or widget limits on large numbers of JMX instances or nodes instrumented in one application while returning widget data. This also includes threshold checks for business transactions, errors, servers, and backend data. This applies to the JMX type metric in the widget **Type of Nodes** menu. The **All Nodes in the Application** option becomes disabled if the number of nodes exceeds the threshold. An error is returned if the number of any threshold is exceeded on the backend. This should help prevent outages.

Widget Properties

Widget properties vary to some extent based on the type of the widget.

Most of the widget properties in the configuration forms are self-explanatory. This list describes some of the less obvious properties:

- **Metric Display Name**: You can choose the display name for the metrics in a widget. Specify one or more of the following substitution variables to determine the metric display name:
  - ${#}: Number the displayed metrics based on sorting with the rollup value
  - ${m}: Metric name
  - ${e}: Entity name

  For example, if specify ${m}, the widget displays the full metric name.

- **Static Thresholds**: You can create static threshold with a specific value for graph widgets. The threshold appears as a line on the graph.
- **Double click action**: Some widgets have an option to define the result of double-clicking the widget. You can configure the double click action to open the **Metric Browser** or a URL specified by the Drilldown URL value.
- **Drilldown URL**: The Drilldown URL specifies the URL of an AppDynamics panel you want the widget to open when you double-click the widget. For example, if you see an increase in slow requests and want to investigate the cause, you may want to jump to the **App Servers List** of all tiers from your dashboard by double-clicking a widget. To get the URL for a specific panel, click **Settings > Copy a link to this screen to the clipboard**.
- **Time Range**: Widgets can use the global or dashboard time range or a time range that is specific to the widget. If you choose a widget-specific time range, select the widget time range from the pulldown menu.
- **Events Overlay**: You can configure specific events to overlay on the graph widget to show how specific events may correlate with performance. Check the **Show Events** checkbox and create the query to define which events should be overlaid.

Configuring Widgets

Set up or modify widgets with the widget palette in Edit mode.

If you configure widgets for a war room, you will see an additional category for Streaming Data widgets. To add widgets to the war room space the presenter must be in edit mode. To enter edit mode, click **Edit**. If it is not visible and you are the presenter, you are already in edit mode. You can duplicate one or more widgets at a time and delete any widget as required.

To configure a new widget:

1. Click **Edit**.
2. Click **Add Widget**. The widget palette displays.
3. Click the widget in the palette. The configuration form displays on the left side of the configuration panel.
4. Configure both the widget data and the widget properties. After you configure the data, a preview of the widget displays. The preview updates as you set more properties.
5. Click **Save**.

To modify an existing widget:

1. Click **Edit**.
2. Click the widget in the dashboard.
3. Click the settings icon in the upper right corner of the widget.
4. Use the form to modify the widget.
5. Click **Save**.

Use Wildcards in Metric Definitions

Related Pages:

- Configure Health Rules
- Create and Manage Custom Dashboards and Templates
- Metric Browser

This page provides an overview of wildcards in AppDynamics. In a Custom Dashboard widget or Health Rule, you can use a wildcard to specify a metric that evaluates across several entities, such as multiple hardware entities or memory pools.

The wildcard feature is supported for metrics in the Hardware Resources, JVM, and CLR branches of the metric hierarchy, and for custom metrics created with a monitoring extension as described in Extensions and Custom Metrics.

> The wildcard feature is not supported for custom metrics.

To use wildcards:

1. Define the relative metric path to the metric that you want to display. This involves getting the full metric path in the Metric Browser and then trimming it.
2. Modify the relative metric path to apply to multiple entities.
3. Paste the modified relative path in the metric selector for the widget or health rule that you are configuring.

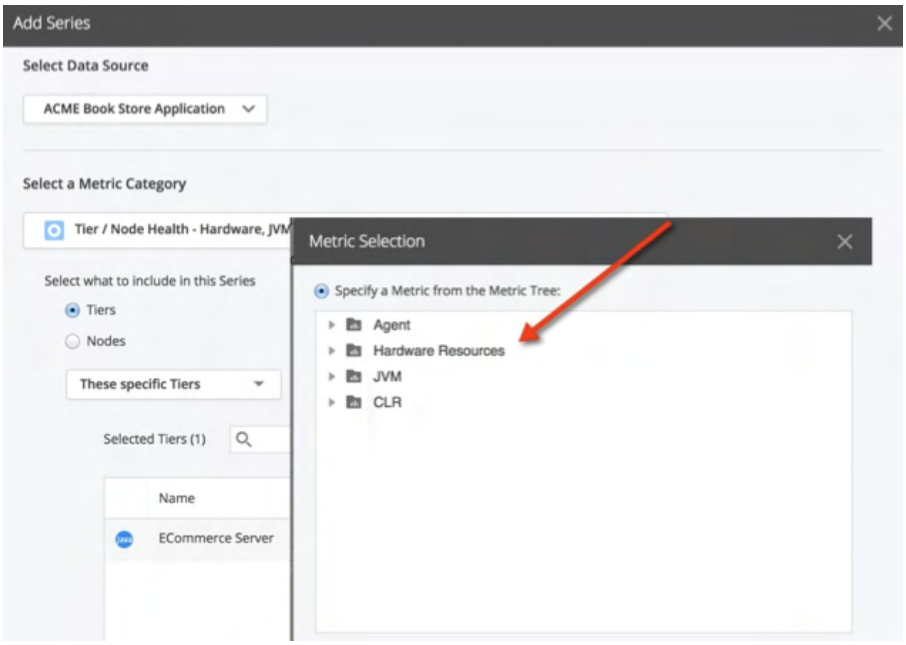
Define the Relative Metric Path

A metric path is a pipe-delineated path to a specific metric. In the Controller UI, hover over a metric in the Metric Browser to get the full metric path. Right-click the metric to view the **Copy Full Path** option.

To define the relative metric path, truncate the leftmost part of the full metric path.

To know how much to truncate for a particular use case, look at the embedded metric browser in the **Metric Selection** panel of the widget or health rule configuration that you are setting up. By the time you have reached this selector, you will have configured the application, tiers, or nodes of the metric that you want to select.

Use the category in the **Metric Selection** panel as the first segment of the relative metric path, truncating everything from the full metric path that comes before that segment. In the example, the first segment would be Agent, Hardware Resources, JVM, or CLR.



As per the preceding example, the full metric path copied from the Metric Browser is Application Infrastructure Performance|ECommerce Server|Hardware Resources|Disks|dev-dm-1|% CPU Time.

Truncate everything to the left of the category selected in the Metric Selection panel that is, Hardware Resources in this example, as the display in the embedded Metric Browser starts with Hardware Resources.

The relative metric path is: Hardware Resources|Disks|dev-dm-1|% CPU Time.

Consider another example where the full metric path copied from the Metric Browser is: Application Infrastructure Performance|ECommerce Server|Individual Nodes|ECommerceAppNode|Hardware Resources|Disks|dev-dm-1|% CPU Time.

The relative metric path after truncating everything to the left of the Hardware Resources is: Hardware Resources|Disks|dev-dm-1|% CPU Time.

Modify the Relative Metric Path

Replace a single segment in the relative metric path with an asterisk to indicate that the metric should be evaluated for all the entities represented by that segment.

> ⚠ Multiple asterisks in a single metric path are not supported.

For example:

The relative metric path is: Hardware Resources|Disks|dev-dm-1|% CPU Time, and you want to display or create a health rule condition on the % CPU time for all of the disks in that tier or node.

Substitute the asterisk for the disk name as: Hardware Resources|Disks|*|% CPU Time.

Configure the Metric for Multiple Entities

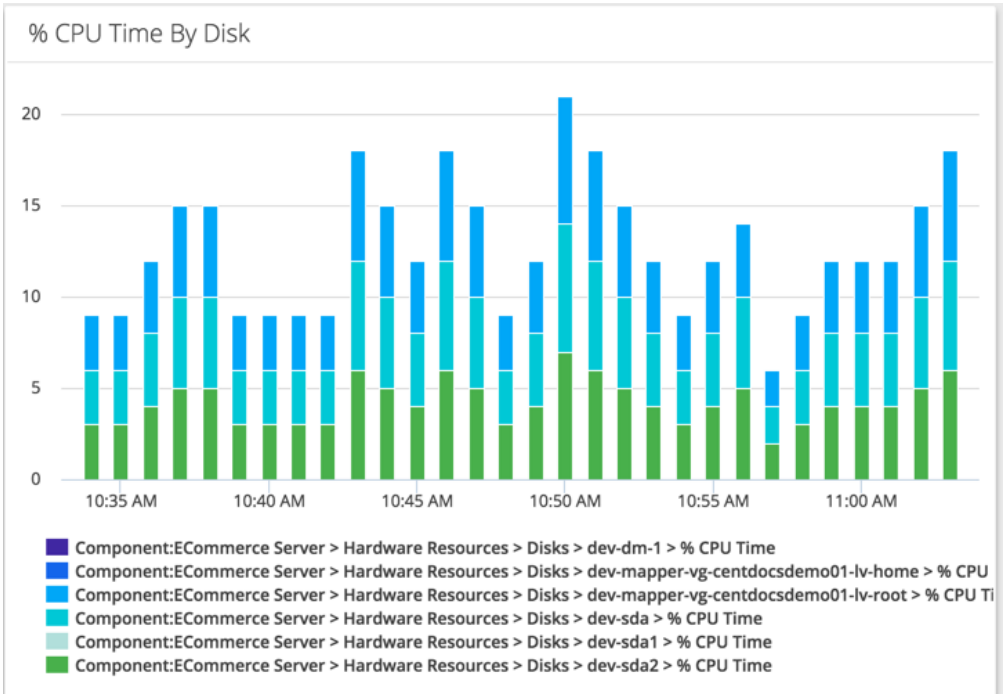
In the **Metric Selection** panel for the dashboard widget or health rule, you can configure metric for multiple entries.

To configure the metric for multiple entities:

1. Select **Specify Relative Metric Path** on the bottom of the **Metric Selection** panel.
2. Paste the modified, wild-carded relative metric path and click **Select Metric**.

Verify the Metric Specification

When you configure a relative metric specification for multiple similar entities in a custom dashboard, multiple metrics display in the widget.



Wildcards Replace Entire Path Segments

An asterisk replaces the entire segment in the path. You cannot use it to replace only a portion of a string because they are used in regular expressions.

For example, the following usage in an attempt to get the ART for all the business transactions beginning with **View** is not valid and not supported:

Business Transaction Performance|Business Transactions|ECommerce Server|View*|Average Response Time (ms).

Specify Average Response Time (ms) to get ART for all the business transactions on the ECommerce Server.

Colons in the Metric Path

The colon, if any, in the metric path is translated into a pipe. Only one segment is allowed between pipes. The colons and pipes can be used interchangeably.

For example:

The colon in the metric path, Application Infrastructure Performance|ECommerce Server|JVM|Memory:Heap|Committed (MB) is translated to Application Infrastructure Performance|ECommerce Server|JVM|Memory|Heap|Committed (MB).

For the relative metric path, to get metrics for both heap committed and non-heap committed, specify JVM|Memory|*|Committed (MB). Do not specify JVM|*|Committed (MB).

Create and Manage Custom Dashboards and Templates

Related Pages:

- Custom Dashboards
- Widgets
- Import and Export Custom Dashboards and Templates Using the UI

This page describes how to create and manage dashboards.

Permissions to create, view, edit, and delete custom dashboards are set through roles. See Custom Dashboard Permissions and Create and Manage Custom Roles.

Access and Create Custom Dashboards

For Controller-level dashboards:

1. Click **Dashboards & Reports** to view existing custom dashboards or to create a new one.
2. If existing dashboard names display, click **Dashboards**.
3. Click **+ Create Dashboard**.
4. Add widgets to the dashboard.
5. Click **OK**.

For tier/node-level dashboard templates:

1. In an application, in the built-in tier or node dashboard in which you want to create or use a custom dashboard template, click **My Dashboards**.
2. If there are no associated custom dashboards for the entity, click **+ Create a new Custom Dashboard**.
3. If you want to associate an existing dashboard with the entity, click **Associate Dashboards** from the dropdown of the dashboard with which you want to associate the entity. See Associate a Custom Dashboard Template with a Tier or Node.

A dashboard has no content until you add widgets to it. See Widgets.

General Dashboard Characteristics

- **Name**—Dashboard names must be unique per Controller.
- Two layout types:
  - **Grid—**This is the default type that gives you a flexible layout that is easy to rearrange on the canvas. The grid layout also scales in size when viewed on mobile devices. You cannot overlap widgets using this layout type.
  - **Absolute**—Use this type to control width and height and the exact placement of widgets on the canvas. With the absolute layout, you can overlap widgets and use **Send to Front** or **Send to Back** actions to control what displays.
- **Configurable auto-refresh Interval**—Sets the data refresh rate in seconds.
- **Dashboard Time Range**—This setting applies only to Controller-level dashboards. From the **Time Range** dropdown, you can set a global time range for the dashboard. When you add widgets, you can specify whether the widgets use this global time range or a widget-specific time range. If you do not specify a widget-specific time range, the global time range is used for all the widgets.

Access the Dashboard Operations

While you are in edit mode, your changes are automatically saved. To save changes manually, disable **Auto-Save** and click **Save**. There is no way to save your changes manually.

If you are accessing a dashboard on a mobile phone, click the **Mobile** icon for a better viewing experience. To access various operations concerning the dashboard, click **Actions**.

Widget Operations

You must be in edit mode to add and modify widgets. See Widgets.

Widget Operation	Procedure
Access the widget palettes	In the dashboard configuration panel, click **+ Add Widget**.
Add a widget to the dashboard	1. In the left panel of the **Add Widget** panel, select the context. 2. Click the widget in the palette on the right.
View and edit the widget properties panel	Click the **Gear** icon in the upper right corner of the widget.

Delete one or more widgets	• Select the widgets and click **Delete**, or; • Right-click the widget and select **Delete**.
Duplicate one or more widgets	• Select the widgets and click **Duplicate**, or; • Right-click the widget and select **Duplicate**.
Copy/paste a widget	• Select the widget and click **Copy**, then click **Paste**, or; • Select the widget, right-click, and select **Copy**. Then, right-click the widget again, and select **Paste**.
Edit the properties of multiple widgets	1. Hold down your command key and select the widgets you want to edit the properties for. 2. Click **Edit**. 3. From the **Edit <number of widgets> Widgets** dialog, select the properties you want to apply to all the widgets, and click **OK**.

Note that not all widgets share the same properties, and Analytics widgets cannot be edited using the multi-widget editing feature.

Delete or Modify a Custom Dashboard

For existing Controller-level custom dashboards:

1. Click **Dashboards & Reports**.
2. Click **Dashboards**.
3. In the Dashboards list, select the dashboard that you want to edit, delete, copy, share, or export, and click the appropriate button.

For existing dashboard templates:

In the My Dashboards tab of an entity associated with the dashboard:

- To modify an existing dashboard template, select it in the list and click **Edit** (pencil).
- To remove an existing dashboard, click **Manage Dashboards** from the dropdown, select the template in the list, and then click **Delete.**

Associate a Custom Dashboard Template with a Tier or Node

The My Dashboards tab of the built-in tier and node dashboards provides access to custom dashboards that are associated with the tier or node.

To view an associated custom dashboard populated with data from the entity, click the dashboard in the list displayed by the My Dashboards tab.

To associate one or more existing dashboard templates with the entity:

1. Click **Associate Existing Dashboard with the Tier/Node** for an entity that has no associated dashboards.
   Alternatively, click **Associate Dashboards** from the dropdown for an entity that already has at least one associated dashboard.
2. In the dashboard picker, move the dashboards to associate from the **Available Dashboards** list to the **Selected Dashboards** list.

To disassociate a dashboard template with an entity:

1. In the dropdown, click **Associate Dashboards**.
2. In the dashboard picker, move the dashboards to disassociate from the **Selected Dashboards** list to the **Available Dashboards** list.

Dashboard Templates Associated Across Applications

All the widgets in a custom dashboard template that is associated with a tier or node in a different application must use the default baseline if they use a baseline.

To set a widget's baseline to the default baseline, or to verify that it is set, in the **Select Baseline** section of the **Advanced** panel of the widget **Edit Series** pane, select **Default Baseline**.

Manage Custom Dashboard Templates

To perform miscellaneous operations on dashboard templates:

1. In the dropdown, click **Manage Dashboards**.
2. From the **Tier** or **Node Dashboards** panel, you can:

    - Delete, copy, import, or export a selected dashboard template.
    - Create a new dashboard template.

- Associate an existing template with tiers or nodes in the application.
- View and edit an existing dashboard template.

Import and Export Custom Dashboards and Templates Using the UI

This page provides instructions on importing and exporting custom dashboards in AppDynamics.

Exporting custom dashboards and templates generates a JSON file that you can import into another AppDynamics Controller.

You can import and export custom dashboards and templates, from the Controller UI, or programmatically with the REST API. See Configuration Import and Export API to import and export programmatically.

Export Custom Dashboards

To export a custom dashboard in the Controller UI:

- From the custom dashboard list, select the dashboard that you want to export and select **Export** in the **Dashboards** menu bar.
- From the dashboard editor of the dashboard that you want to export while in **Edit** mode, select **Export Dashboard** from the **More Actions** dropdo wn.

If you have edit permissions for dashboards, you can use either method. If you do not have edit permissions, use the **Export** option from the custom dashboard list.

The dashboard is exported to a file named `CustomDashboard_<dashboard_name>_<unique_id>.json`. Optionally, you can rename the file before importing it.

Export Custom Dashboard Templates

After creating a custom dashboard, you can export it as a template. Templates enable you to quickly create new dashboards.

To export a custom dashboard template, click **Export** in the toolbar of the custom dashboard.

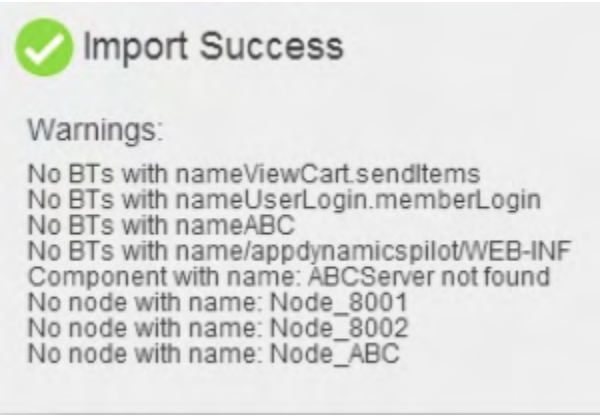
Importing and exporting are for re-using the template in a different application or a different Controller. If you want to use the template in another tier or node in the same application, you do not have to export and import it. You can simply associate it. See Associate a Custom Dashboard Template with a Tier or Node.

Import Custom Dashboards

You can import a dashboard file to create a new dashboard based on a previously exported one.

1. From the custom dashboards list, click **Import** in the menu bar.
2. Click **Choose File** and navigate to the previously exported JSON file that you want to import.
3. Click **Open**.
4. Click **Import**.

If the metrics, nodes, tiers, or applications used in the exported dashboard do not exist in the new Controller environment, warning messages display:



Even when the metrics are not available in the new Controller environment, your import succeeds and saves the widgets and layout of the dashboard. You can modify the widget properties substituting different metrics to create a similar-looking dashboard in the new environment.

Import Custom Dashboard Templates

1. From the pulldown of the My Dashboards tab of the tier or node dashboard from which you want to import a template, click **Manage Dashboards**.
2. In the Tiers/Nodes Dashboards list of dashboard templates, select the dashboard template that you want to import and click **Import**.

Dashboard Recovery

This page provides instructions on recovering custom dashboards in AppDynamics.

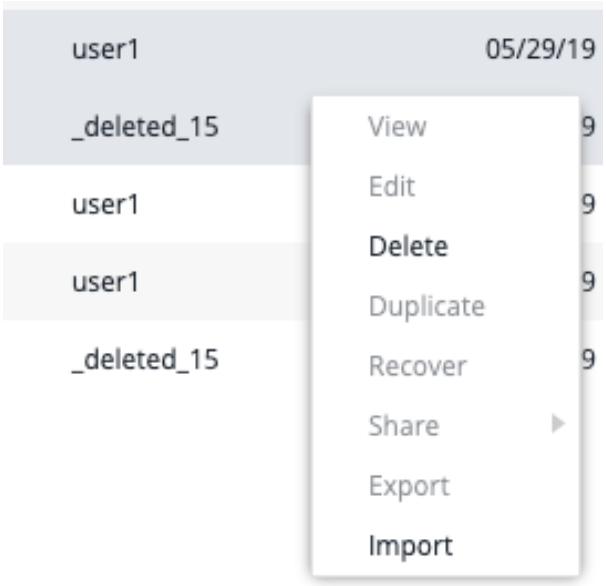
When you delete a user from the user list, any custom dashboard that the user created becomes non-functional with no permissions and is unable to execute properly. This impacts all associated dashboard-based reports and shares. To solve this problem, you can use the **Recover** option.

Recovering a non-functional dashboard reassigns ownership to the recovering user which automatically makes the custom dashboard, its shares, and related reports functional again.

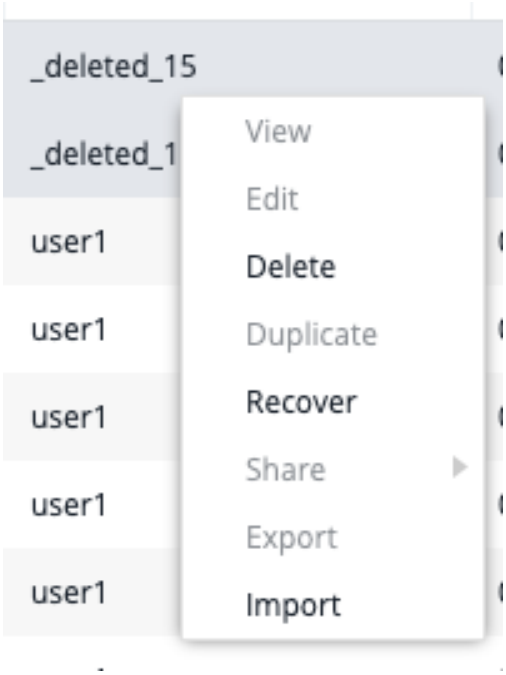
> The **Recover** option is active only when the dashboard owner is a deleted user.

To recover a non-functioning dashboard:

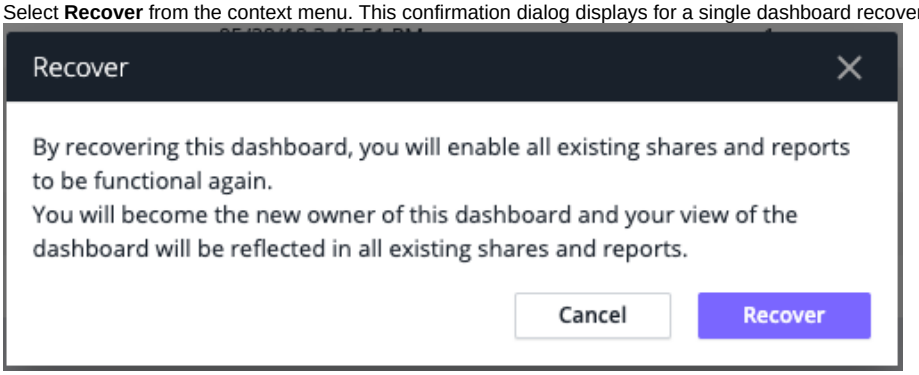
1. Log in to the Controller as a user with VIEW_DASHBOARDS and CREATE_DASHBOARDS permissions.
2. Access the custom dashboards listing page.
3. Select the non-functioning dashboard and right-click to access the context menu. When the owner of the dashboard is active, the **Recover** option remains disabled:



> When the owner is deleted, the **Recover** option is enabled automatically.

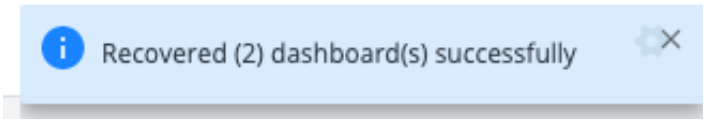


4. Select **Recover** from the context menu. This confirmation dialog displays for a single dashboard recovery:

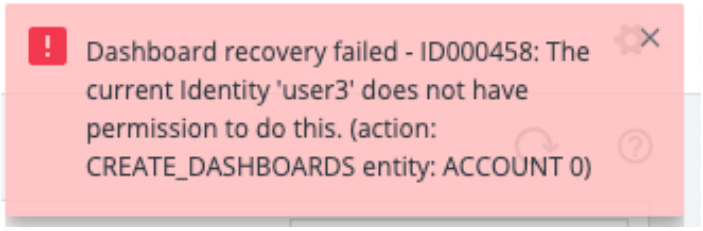


> You can select multiple non-functional dashboards and recover all of them at once. To select multiple custom dashboards, use **Ctrl-Click** for non-contiguous rows and **Shift-Click** for contiguous rows. You must ensure that the owners of all the selected dashboards are deleted users, otherwise the **Recover** option remains disabled.

5. Once the dashboard is recovered successfully, this message popover displays:



To recover a dashboard, you must have the CREATE_DASHBOARD permission. If you execute the **Recover** option without this permission, this message displays:



See Visibility and Permissions.

Duplicating a dashboard creates a new dashboard with the same capabilities as the non-functioning dashboard. However, duplication does not create the shares or the associated reports. The result is that the new dashboard operates using a deleted user's permissions (as with Recover), but you must create the shares and reports manually.

In some cases, duplicating the inactive dashboard helps you regain control over the shares and reports. However, there may be some cases when duplication would not work. You should use the Recover option to retain all existing shares and related reports instead of duplication.

Virtual War Rooms

Related Pages:

- Custom Dashboards
- Monitor Events
- Create and Manage Custom Roles
- Widgets

This page provides an overview of virtual war rooms in AppDynamics.

A war room is a combination of interactive dashboard and notes, integrating a real-time custom dashboard with collaborative troubleshooting in a focused chat room. When troubleshooting an issue, you can add notes and data using a timeline that is visible to all war room participants immediately.

The virtual war room:

- Orients everyone to the same page by viewing the same real-time data.
- Keeps the focus on metrics that translate to the business value the application delivers.
- Fosters communication among a broad audience.
- Identifies resolution criteria and assigns ownership for resolution tasks.

Start a War Room

Start a virtual war room or a collaborative chat room when you want to troubleshoot an issue.

You must have account-level permission (Create War Rooms) to start a war room.

1. Start creating a war room using one of these three options:
    - Navigate to **Applications** > **Troubleshoot** > **War Rooms** > **My Active War Rooms**, click **Start a War Room**.
    - Navigate to **Applications** > **Application Dashboard** > **Events** > **Actions**, click **Start a War Room**. Access the events list through the Events tab available in many of the built-in dashboards.
    - If you integrated Atlassian JIRA, navigate to **Applications > Troubleshoot > Health Rule Violations** and click **Start War Room** under t he JIRA/War Room column.
2. Navigate to **JIRA Issue** > **AppDynamics Incident** and click **Start or Join a War Room associated with this Incident**.
3. Name your war room and click **OK** to create a new room, or select **From Template** to create a new room using available war room templates. See War Room Templates.
4. Click **Add Widget** to add your widgets to the war room. See Widgets.
5. Click **Save**.

You can view all the war rooms you created on the **My Active War Rooms** page, and edit your widgets using the **Actions** menu.

War Room Templates

You can re-use the layout of an existing war room by saving a war room as a war room template. This can save time in creating new war rooms with numerous widgets. You can save an existing war room as a template while you are working on it, or just before you close it.

Create a War Room Template

1. From the Actions menu of the current war room from which you want to create a template, click **Save as Template**. Alternatively, when you end a war room, select **Save as Template**.
2. Provide a name for the template and an optional description.
3. Click **OK**.

The new template is now available to create other war rooms. You can view all your war room templates under **War Rooms > Templates**.

Delete a War Room Template

1. Click **War Rooms > Templates**.
2. From the list of war room templates, select the template to delete.
3. Click **Delete Template** and confirm the deletion.

Manage Presenters

The user who starts a war room is the first presenter.

Only the presenter can:

- Modify the collaboration space to add, delete, and configure widgets.
- Make any other participant a presenter. There can only be one presenter at a time.

- Share and stop sharing the war room with other participants.
- End the war room.

Presenters can also do everything that participants can do.

Change a Presenter

Right-click on any participant name in the participant list and select **Make Presenter**.

The ability to edit and control sharing of the collaborative dashboard and to end the war room passes to the new presenter. Other participants cannot see the war room until the presenter shares it. This enables the presenter to set up widgets privately before showing the war room to others.

End the War Room

Click **End War Room**. When prompted, confirm that you want to end it.

Only the presenter can end the war room. A war room is automatically ended after 60 minutes of inactivity. Inactivity means no participants are viewing the war room pane.

Manage Participants

Everyone who has joined the war room but who is not currently a presenter is a participant. A participant can be:

- An AppDynamics participant is an authenticated UI user with access to the AppDynamics account that is hosting the war room.
- A guest participant does not log in to the AppDynamics UI, but has been invited to join by an AppDynamics participant. This user type functions as an anonymous, read-only participant.

AppDynamics participants can:

- View a war room to which they have been invited.
- Invite other participants.
- Add notes.
- Start a new war room, if the participant has Create War Rooms permission.

Guest participants can view a war room to which they have been invited.

View a War Room

You can view only the war rooms in which you are a presenter or a participant. The list does not display all the war rooms currently in progress on the Controller.

To view a war room, you should have created one, got invited to one, or have access to the shared URL available to anonymous users.

To access a war room, either:

- Click the link in the invitation that you received to join the war room.
- Click **Troubleshoot** > **War Rooms**, and then select the war room to join from the war rooms list.

Invite Another Participant to the War Room

Send a link to invite another participant to the war room:

1. From your active war room, click **+ | Participants**.
2. From the **Invite Users** pane, copy the URL for joining this War Room.
3. Email or SMS the link to the persons whom you are inviting, with instructions to click the link from a browser.
4. Click **OK** to close the **Invite Users** pane.

After clicking the link, the recipient is invited to log in as an AppDynamics participant or as an anonymous guest.

Add a Note

1. From your active war room, click **+ | War Room Notes**.
2. From the **Enter Notes** pane:
    a. Enter your note in the text field.
    b. (Optional) Qualify your note as good or bad.
    c. Click **Post**.

Automatic Save, Synchronize, and Archive a War Room

The war room is automatically saved and all participants' views of it are synchronized whenever the presenter makes a modification to the dashboard. The saving and synchronizing happens continually and is transparent to the participants when it occurs. In addition, the presenter can always force a save and sync manually by clicking **Save** at the top of the war room dashboard.

If you restart the Controller while a war room is in progress, the war room is saved and you can access it after the Controller comes back online.

Reports

This page provides an overview of reports in AppDynamics.

AppDynamics extracts data from dashboards and creates scheduled reports. You can configure automatic report generation for a regular schedule or create reports manually.

Scheduled Reports

Scheduled reports are automatically created on a regular interval. AppDynamics creates reports with the data pulled from Dashboards and sends it to the configured list of email recipients, as scheduled. To deliver a report instantly, select the **Send Report Now** option available for a report.

You must have account-level permissions to view and configure scheduled reports. See account-level permissions.

Report Types and Formats

You can schedule periodic generation and delivery of the these report types to a list of email recipients:

<table>
<tr><th>Report Type</th><th>Captured Information</th></tr>
<tr><td>Application Health Report</td><td>Application health data from the application dashboard that includes:
Business transaction and server health data.
Transaction scorecard.
Events and exceptions.
Load, response time, and errors graphs.</td></tr>
<tr><td>Dashboard Report</td><td>Dashboard data in the selected custom dashboard.</td></tr>
<tr><td>Controller Audit Report</td><td>Audit entries that include:
User logins and information changes.
Controller configuration changes.
Environment properties changes.
Application properties and object changes such as policies, health rules, and the entities listed here:
<table><tr><td>Date and time range</td><td>ObjectType</td></tr><tr><td>UserName</td><td>ObjectName</td></tr><tr><td>Action</td><td>ApiKeyId (if applicable)</td></tr><tr><td>ApplicationName</td><td>ApiKeyName (if applicable)</td></tr></table>AppDynamics supports PDF, JSON, and CSV file formats for this report type.</td></tr>
<tr><td>Home Screen Report</td><td>Overview data from the home page.</td></tr>
<tr><td>All Applications Summary</td><td>Data summary from the applications page.</td></tr>
<tr><td>User Experience: Browser Apps</td><td>Browser RUM data from the Browser App Dashboard Overview page.</td></tr>
</table>

Manage Scheduled Reports

You can create and deliver scheduled reports on a regular interval. To create a report identical to the existing one, you can duplicate the existing scheduled report and modify relevant fields, as required. You can add a set of email recipients for the report delivery.

In addition to the scheduled delivery of reports, use the **Send Report Now** option to send the generated report immediately to the email recipients. From the **Reports** page, select your report and click **Send Report Now** from the right-click menu.

Create a Scheduled Report

You need to have the account-level Configure Scheduled Reports permission to create scheduled reports.

1. Click **Dashboards & Reports > Reports > Add Report**.
2. From the **Create Scheduled Report** page, you can customize your report:
    a. Enter **Report Title** and **Report Subtitle**.

> You can label a report CONFIDENTIAL using **Report Subtitle**.

b. Optionally, select **Show Title Page** to include a title page at the beginning of your report file.
c. Select your **Report Type** from the dropdown. Based on this selection, fields in the **Report Data** tab vary.
d. Make necessary changes in the Schedule, Report Data, and Recipients tabs, and then click **Save**.

Create a Controller Audit Scheduled Report

Use this report to view changes made to the user information, Controller configuration, and application properties.

1. Click **Dashboards & Reports > Reports > Add Report**.
2. Enter **Report Title** and **Report Subtitle**.

   > You can label a report CONFIDENTIAL using **Report Subtitle**.

   Optionally, select **Show Title Page** to include a title page at the beginning of your report file.
3. Select **Report Type** > **Controller Audit** to define the fields in the Reports Data tab.
4. Set the time ranges. You can create and manage custom time range, if required.

   > Custom time range options are available for all the Report Types.

5. Select your report file format as PDF, JSON, or CSV.
   Optionally, uncheck **Show Diff** to remove the *Object Changes* column from your report file.
6. Select the data to include or exclude from the dropdown. Repeat as necessary with these options:

Filter Type	Attribute	Attribute Value	Result
Exclude/Include	Same	Different	Audit entries matching with any of the attributes are excluded/included.
Exclude/Include	Different	Different	Only audit entries matching with all of the attribute values are excluded/included.

7. Enter the attribute value.
8. Click **+Add**.

> **Alternative**
>
> You can use the Controller audit log that replicates the Controller Audit Report. This audit log monitors user activities and configuration changes in the Controller. See Controller Audit Log.

Scheduled Report Management

You can manage scheduled reports from the **Dashboards & Reports > Reports > Scheduled Reports** page. To edit, duplicate, enable, disable, export, import, and delete reports, use the menu bar on the **Scheduled Reports** page, or the right-click menu options available for each report in the list.

Managing a report requires account-level permissions such as View Scheduled Reports and Configure Scheduled Reports.

To create and send the scheduled report on a regular interval, ensure that you have enabled the report. You can disable a scheduled report to put it on hold for a certain length of time. You can verify the current status of a report using the **Enabled** column in the list of reports. For any report in the list, you can use the **Send Report Now** option to generate and deliver it instantly.

Dash Studio

AppDynamics Dash Studio (Preview) is a next generation dashboard designed to make building dashboards faster and easier. It is available in the Dash Studio (Preview) tab under **Dashboards & Reports**. The previously created dashboards are still available unmodified, under the Dashboards tab.

Dash Studio is available as an early preview release and so we seek your feedback through the AppDynamics Community and through the **Feedback** button available in Dash Studio. Dash Studio is delivered through the UI Cloud App to SaaS customers.

> Enhancements and new capabilities will be added to Dash Studio (Preview) periodically.
>
> Dash Studio is available for on-premises customers >= 4.5.16.
>
> SaaS requires 4.5.15.1.

Visual Dashboard Editor

This page provides an overview of the Dashboard Editor in AppDynamics.

The Dashboard Editor is available next to the existing Dashboards tab.

> Dash Studio is not recommended for mission-critical dashboards as it is intended for an early customer preview.

The Dashboard Editor allows you to:

- Quickly align widgets.
- Resize widgets on a dashboard by grabbing the edges of the widget with a click-and-drag to resize.
- Select multiple widgets, copy and paste them using GUI controls, or using command-C or command-V controls, so that you can replicate them on a single dashboard.
- Edit widget titles by editing the widgets directly.
- Edit widget attributes such as: titles, line colors, and labels.
- Access commonly used tools from the toolbar with a single click.

What's New? Button

The **What's New** button provides information about the latest updates in the Dash Studio.

Click the **Show Documentation** button to access the online documentation for Dash Studio.

Dashboard Library

All dashboards created in the Dash Studio are available in the **Dashboard Library**, which provides a list of all Dash Studio dashboards. Select the **Show My Dashboards Only** toggle button to see a list of dashboards created in the Dash Studio.

Dashboard Editor

The new dashboard canvas offers a visually attractive and responsive display in both edit and view modes. The canvas and associated toolbars:

- Allow you to easily edit the dashboards manually.
- Allow widget data binding and editing of some widget properties (such as, titles and graph axes labels) on the canvas directly.
- Are architected to enable future functionality such as, repeating widgets and allowing column width lock in responsive dashboards.

Edit and View Modes

To optimize the Dash Studio (Preview) experience, you can switch between these two display modes:

- **View** mode (default mode for dashboards)
- **Edit** mode

In **View** mode, the toolbar disappears, and the dashboard displays to the largest extent possible in the browser panel in which it is housed.

The **Edit** mode enables you to edit the content of the selected dashboard. To return to the dashboard library from the **Edit** mode, click  on the top-left of the page.

You can apply these layouts to your dashboard:

- Responsive Layout
- Fixed Aspect Ratio

The **View** icon (available on the top-right of the page) allows you to preview the dashboard. On the preview page, click the **Edit** icon to return to the Dashboard Editor.

Feedback Button

Use the **Feedback** button to submit feedback about your experience using Dash Studio. The submitted feedback is sent to the AppDynamics product team.

Auto Refresh Interval

Enable the **Auto Refresh Interval** option under the **Dashboard Properties** panel to refresh the dashboard automatically at specific intervals. Auto-refresh ensures that the dashboard data and layout is refreshed regularly. You can select an option from the **Auto Refresh Interval** dropdown or select **Custom** fr om the list of options to customize the interval value. The default refresh interval is two minutes. The set interval value persists when you switch between edit and view mode, and when you share, import, or export a dashboard.

Help Popover

The **Help** popover appears at various places on the dashboard UI. This popover provides details about features, concepts, and product changes. Click "**Ok ay, got it**!" to close the popover.

Dashboard Sharing

The sharing capability in Dash Studio allows you to share the dashboard with business users and with those who do not have an AppDynamics account. This helps multiple users access the dashboard and enables effective collaboration among the users.

You can also:

- Stop sharing the dashboard.
- Copy the shared URL to the clipboard.
- Open the shared URL in a new panel.

Import and Export Dashboards

This feature allows you to export and import JSON dashboard metadata between Dash Studio instances running in different environments.

Export Dashboard

To export a dashboard in Dash Studio:

1. Select the dashboard to export from the dashboard list.

   > The **Export** icon) is enabled only when you select a dashboard from the dashboard list.

2. Click **Export** when available in the dashboard toolbar.
   The exported dashboard is generated as a JSON file on your system. You can rename the downloaded file later.

Export Dashboard with Edit Permissions

To export the selected dashboard with **Edit** permissions:

1. Right-click on the selected dashboard.
2. Select **Export** icon from the dropdown.
   The exported dashboard is generated as a JSON file on your system.

Import Dashboard

To import a previously exported dashboard file in Dash Studio:

1. Click **Import** to display the **Custom Dashboard Import** dialog.
2. Click **Choose File** and navigate to the previously exported JSON file that you want to import.
3. Click **Open**.
4. Click **Import** to open the imported dashboard and display it with a new name.

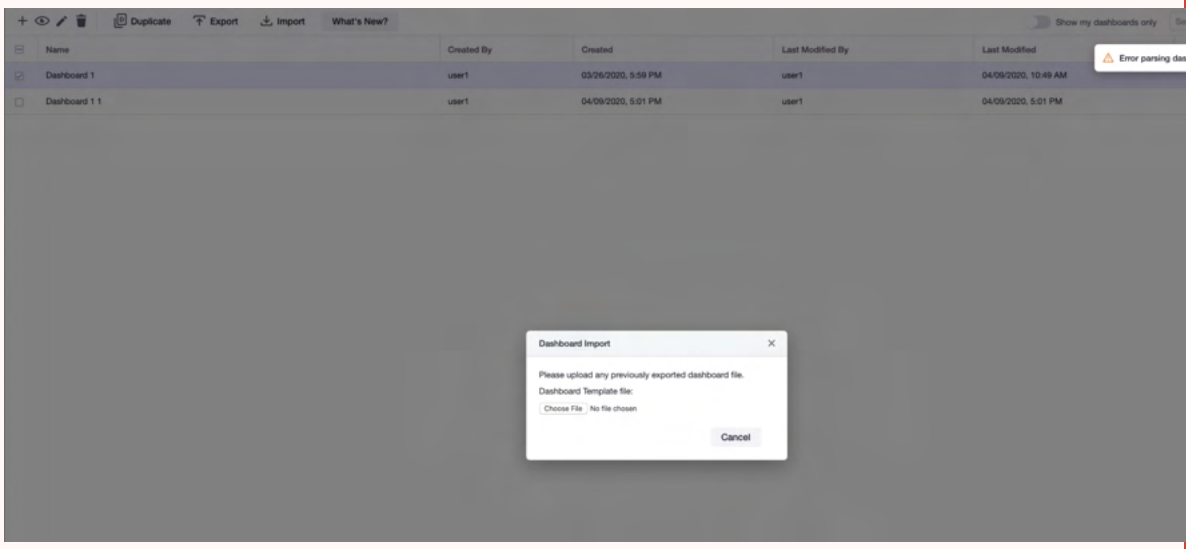
Import Dashboard with Edit Permissions

To import the selected dashboard with **Edit** permissions:

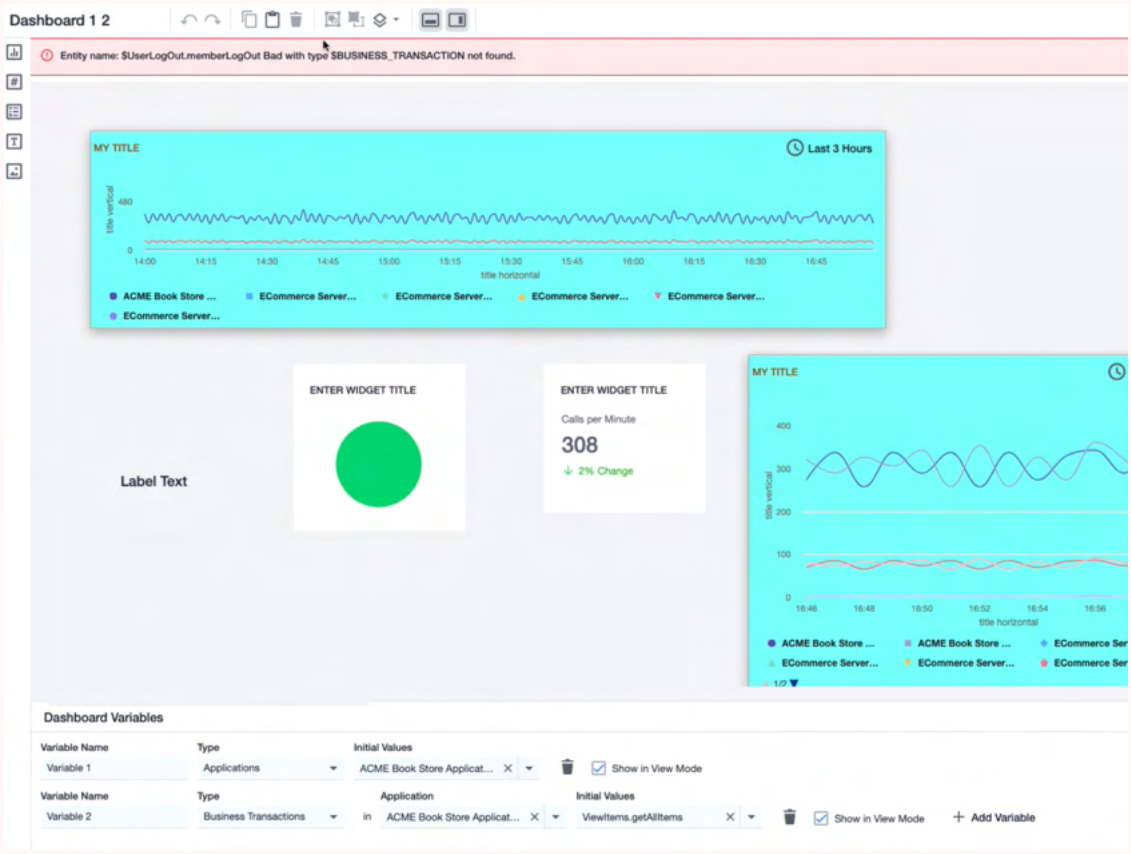
1. Right-click on the selected dashboard.
2. Select **Import** rom the dropdown.
3. Click **Choose File** to navigate to the dashboard file to import.
4. Click **Open**.
5. Click **Import** to open the imported dashboard and display it with a new name.

These errors may display when you try to import a dashboard file:

- Parsing error when you import a bad or malformed dashboard file.



- File Not Found error when you import a dashboard from another Controller.



Dash Studio Layout

This page provides an overview of the Dash Studio layout in AppDynamics.

You can organize the dashboard layout and explore important system data in the Dash Studio. You can find required dashboards, delete dashboards, and create new ones. You can also place widgets on the canvas in the Responsive Mode layout and Fixed Aspect Ratio layout. The canvas is a backdrop where you can drop content in, such as widgets.

Dashboard Organization

Create Dashboards

Dash Studio allows you to create a dashboard without having to name it, or indicate its layout or characteristics. If you accidentally close a dashboard without naming it, the dashboard is auto-saved and named "Untitled-X." X is the next untitled dashboard in the collection of dashboards that you are authorized to access and is saved in the Dashboard Creation Directory. Untitled-X displays as the dashboard title on the page as soon as the new dashboard canvas loads. You can rename the dashboard later.

Auto-Save

Dashboards are auto-saved by default.

Responsiveness and Sizing

You can resize the Dashboard canvas to any size which enables you to switch between editing and viewing mode. By default, the dashboard automatically resizes to fit on the page. The width of some columns in the dashboard are locked so that when you resize a dashboard, a locked column is not resized. The default canvas sizing fits the dimensions of a typical laptop.

Dashboard Editor Actions	Description
Adding Widget	You can drag and drop widgets from the toolbar onto the dashboard canvas.
Alignment and Placement	You can place the widgets anywhere on the dashboard canvas, including placing widgets on top of other widgets or running off the edge of the canvas itself. Use the red alignment lines as a quick visual to check the alignment of the widgets. These lines also indicate when the widgets are at an appropriate distance from other widgets.
Group Creation	You can select multiple widgets by dragging a box over them with a mouse, or holding **Shift** and selecting all widgets with a mouse click.
Selection and Undo/Redo /Copy/Paste	You can select widgets, or groups of widgets by clicking them, or dragging a mouse-generated box over by holding down the left mouse button. You can select multiple widgets by either dragging the box, or by a command-click action. • You can undo or redo an action using a toolbar command, or by command-Z and command-Y functionality on the keyboard. • You can copy, cut or paste groups of widgets using a toolbar command, or by command-C, command-X, or command-V functionality on the keyboard.
Selection in Edit Mode	You can select widgets or groups in edit mode by clicking them, or dragging a mouse-generated box over by holding down the left mouse button. You can select multiple widgets by either dragging the box, or by command-click action. In view mode, data queries are not exposed. To drill down to the next data level, you must double-click. • For Widgets: Single click selects a widget, enables its movement, and exposes an editing icon at the top right of the widget. To edit data, click on the editing icon. Double-click on the widget to drill down to the next data level. Google Data Studio is a good example of this interaction. • For Groups: Single click a group selects that group, enables its movement, and exposes the editing icon. Clicking again selects the widget. Double-clicking a widget in a group has the same effect as clicking once on the group, and then clicking the widget. To drill down on the widget, you must double-click again.

Edit and View Modes

You can view Dashboards in these two modes:

- **Edit** mode
- **View** mode

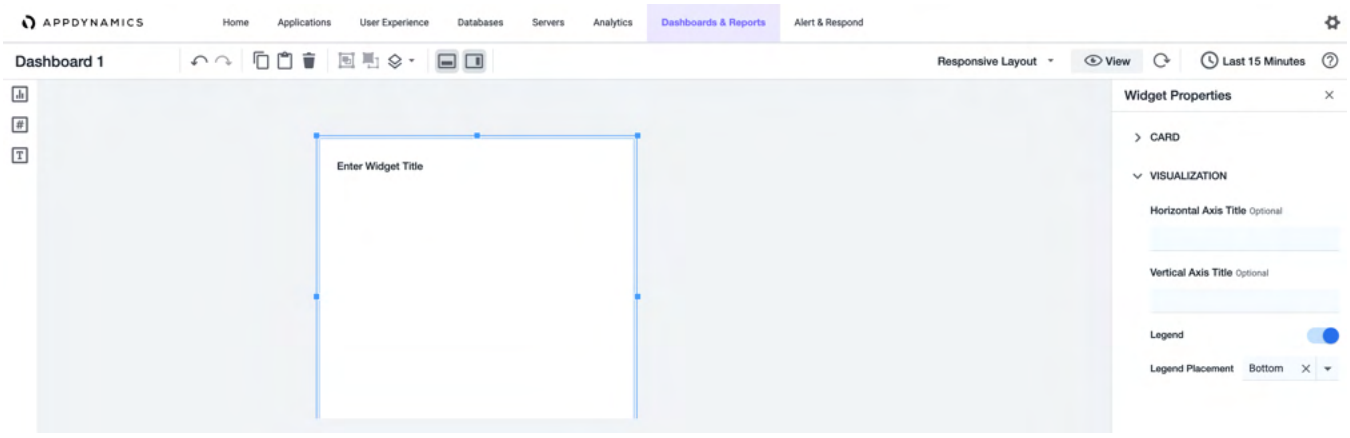
By default dashboards are in **View** mode. The toolbar does not display in **View** mode.

General Layout

Toolbar

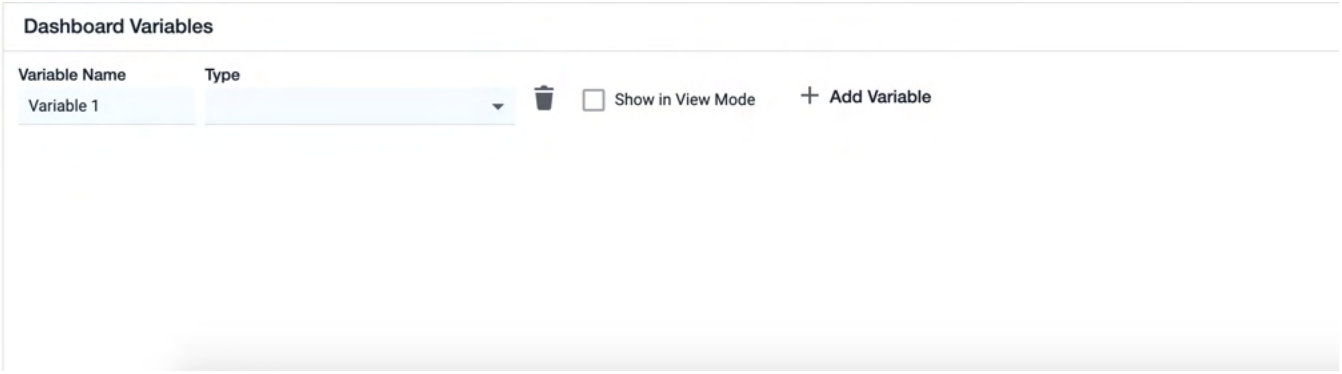
The dashboard editor tools available in the toolbar enable you to perform these actions:

Actions	Description
Undo and Redo	The toolbar has two buttons for undo and redo actions on a dashboard. You can also perform these actions using command+Z and command+Y keyboard functions.
Copy, Paste, and Delete	You can use tools from the editing toolbar to copy, paste, or delete widgets, or containers from a dashboard. You can also perform these actions using command-C, command-V, and the Delete keys on the keyboard.
Dashboard title	You can edit dashboard title. By default, a new dashboard is titled "Untitled Dashboard."



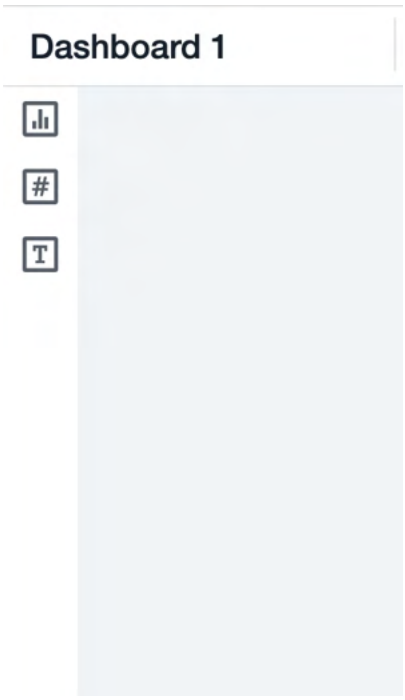
Data Panel

The Data Toolbar at the bottom of the Dashboard Editor enables you to bind containers and visualizations to data. See Data Binding for details.



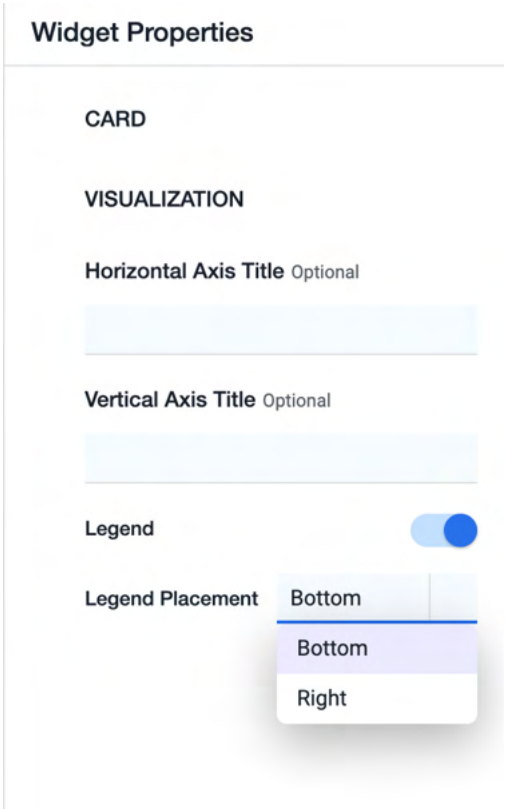
Widget Palette

The **Widget Palette** on the left-side of the Dashboard Editor allows you to drag and drop widgets from the palette on to the canvas.



Widget Properties Panel

The **Properties Panel** on the right-hand side of the Dashboard Editor enables you to set the properties of a widget, such as: background color, shadow, padding, and basic display options.



Dash Studio Widgets

This page provides an overview of existing Dash Studio widgets in AppDynamics. Widgets create a visual representation of your data in the dashboards.

> Only certain widgets of Beta Dash Studio have been included on this page. The page will be updated when new widgets release with the product.

Card Component

Cards are small containers for placing the widgets. Cards have a title, border, and sometimes a footer and actions related to the specific context of the Card. These containers have text labels to clearly describe the information. You can rename or delete them.

Grouped Widgets

The widget grouping functionality enables you to organize two or more widgets on a card component or on their respective cards. You can apply widget properties to the entire group of widgets instead of a single widget.

- Each widget is created on a card by default.
- A card component, for a widget or group of widgets, has a title and a background.

Create a Widget Group

To create a group:

1. Select two or more widgets.
2. Click the group icon  in the top panel.
   Select one of these options:
   - **Group -** Groups the widgets on their respective cards.
   - **Group In Card -** Groups the widgets on a card component.

To separate the widgets in a group, click the ungroup icon  in the top panel.

Group Properties

You can apply these properties to modify the appearance of grouped widgets:

Property	Description
Group In Card	Group all the selected widgets on a card.
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces between the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

See group time range.

Time Ranges

Global Time Range

The **Global Time Range Selector** option on the top right enables you to set a time range for the dashboard. This can be for the last five minutes, hours, weeks, or even months.

Widget Time Range

You can compare widgets across different time ranges by setting a time range that is distinct from the global time range.

To set the time range for a single widget independent of other widgets:

1. Select the widget to set its time range.
2. Go to **Widget Properties** on the left panel and click **Widget Time Range**. Two options display: **Global Time Range** and **Widget Specific Time Range**.
3. Select **Widget Specific Time Range** and set a time range distinct from Global Time Range. Select the **Show Time Range** toggle to display the time range on the top of the selected widget:

> You can enable the **Show Time Range** toggle for a widget to change its time range in **View** mode.

Group Time Range

You can set the time range for a set of grouped widgets using the **Group Time Range** option under **Group Properties** panel. It provides these options:

- **Inherit Time Range** - Set the same time range as the global time range for each widget of the group.
- **Group Specific Time Range -** Set the time range for each widget of the group by selecting an option from the dropdown. You can also click **Cust om** to create a customized time range.

Toggling the **Show Time Range** option hides or displays the time range in the upper-right corner of each widget in the group.

Simple Navigations

Simple navigation actions in Dash Studio enables basic user interactions and helps you to seamlessly navigate to any specific part of the product. The navigation actions allow you to drill down into complex and detailed information about a selected entity. You can utilize this capability as part of the troubleshooting processes and for root cause analysis.

> This feature is available only for Time Series, Pie, Label, Metric Number, and Image widgets.

Navigate with a Single Click

To perform navigation actions with just a click in the view mode, click the widget for which you want to set this action:

1. Click **Single Click Action** option available under the **Widget Properties** panel.
   It displays the following options:
   - **Destination Type** - You can select one of the following:
     - **Metric Browser -** This option is selected by default. Click the widget in the view mode to navigate to the selected metric browser.
     - **URL** - **Destination Link** field displays, where you must enter the desired link. Click the widget in the view mode to navigate to the selected link.
     - **Dashboard** - **Dashboard Name** field displays when you select this option. Enter the name of an existing dashboard or select an option from the dropdown list. The following option displays if the selected destination dashboard contains variables:
       - **Variable Passing 1** - This option allows you to modify the default value of multiple variables in an existing Dashboard.

> For example, if “Dashboard 1” has a variable named “Nodes 1” with value “Node_8000”, you can change the preset value of “Nodes” to any other desired Node value using **Variable Passing 1**. Similarly you can modify a second variable named “Nodes 2” in the same dashboard using the subsequent field, **Variable Passing 2**.

Click the widget in the view mode to navigate to the selected dashboard.

- **Show In** - Select **Current page** or **New Window**.

2. Click the **View** icon at the top right after entering valid details.
   In the View mode, click the widget to navigate to the appropriate destination.

Widget Types

These widget types are available in the Dash Studio.

Time Series Widget

A Time Series widget is a two-dimensional time-based series of data points connected by a line. There can be multiple lines on one chart.

Widget Properties

You can select the following options under the **Widget Properties** panel to modify the visual appearance of the Time Series widget:

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces between the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

Property	Description
Horizontal Axis Title	Set the title of the horizontal axis on the widget. This is optional.
Vertical Axis Title	Set the title of the vertical axis on the widget. This is optional.
Legend	Set the legend.
Legend Placement	Place the legend at the bottom or on the right-side of the widget.

You can define performance baselines in a widget by adding a **Threshold** value. You can add multiple thresholds to a widget, which enables you to set threshold values based on the severity.

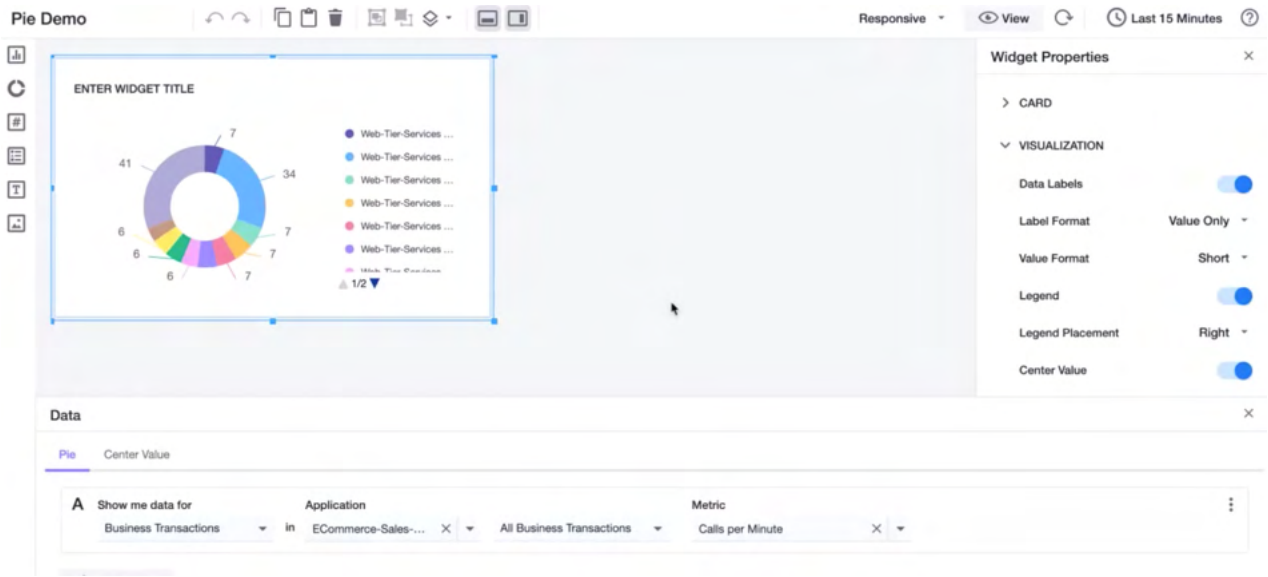
Property	Description
Label	Set name of the threshold.
Value	Set threshold value to be set.
Color	Set color of the threshold line. By default, it is black in color.

See widget time range.

See time range comparisons.

Pie Widget

Pie widget displays single consolidated values for a series of metrics for a given time range as a pie visualization.



Widget Properties

You can select these options under the **Widget Properties** panel to modify the appearance of the Pie widget:

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces between the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

Property	Description
Data Labels	Define the individual data points that you can turn on or off.
Label Format	Set the format of the label. You can select one of the following options: • **Value and Name** • **Value only**
Value Format	Set the format of the label value. You can select one of the following options: • **Long** • **Short** • **Percent**
Legend	Set the legend, which describes the value of each pie slice of the widget.
Legend Placement	Pace the legend on right side or bottom of the widget.
Center Value	Set the unit value.
Center Value Format	Set the format of the center unit value.
Center Value Unit:	Set the unit for the center value. This is optional.

See widget time range.

See single click action.

Metric Number

A Metric Number chart highlights a single value/KPI and is typically created by:

- A single measure which can be specified using the Data Panel.
- Combining or aggregating multiple metrics.

The value display shows:

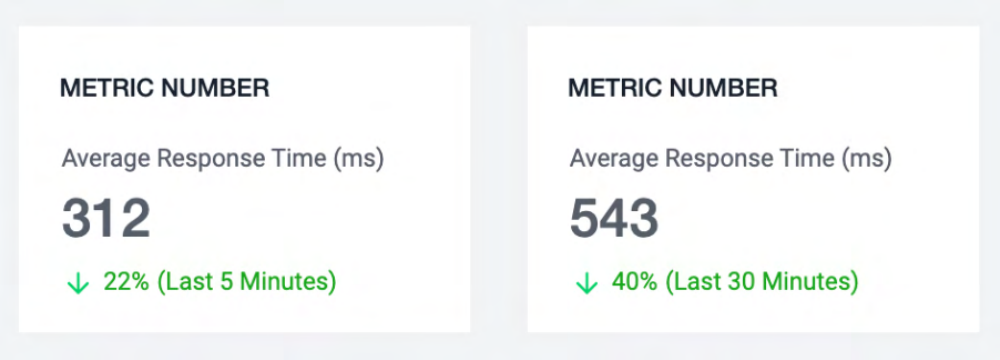
- A single measure or metric value at any instant.
- A comparison of two values (either two different metrics or a metric at different points of time).
- An aggregation of metrics across many objects or a large interval of time.

If the trend of a value over time is concerning, you can enrich these charts with contextual information to better interpret the present value, or the change in value over a time period. These charts can display numbers and text, for example, date and time of an incident.

You can also display the metric value, or a combination of these values in various ways, such as selecting a single metric:

- By name associated with a particular entity, or object that you want to learn more about.
- Aggregated across all entities of a certain type, or a provided sub-list of entities.
- Aggregated for a sub-list of entities which is dynamically determined.

The metric number helps you understand the metric value at the current point in time, and also the pattern of the metric value over a time interval.



Widget Properties

You can select these options under the **Widget Properties** panel to modify the appearance of the Metric Number widget:

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces between the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

Property	Description
Show Metric Name	Hide or show the name of the metric.
Unit Name	Set the unit of widget value. This is optional.

Number Format	Set the formal of the widget value. You can select one of the following options: • Short • Long • Percent
Show Trend	Hide or display the relative trend of the widget value.
Reverse Trend Color	Reverse the color of the relative trend of the widget value.

See widget time range.

See time range comparisons.

See single click action.

Gauge Widget

The Gauge widget enables you to present the metric data on a relative scale. The status is indicated by an arc, where the left end is the minimum value and the right end is the maximum value.

Following are the three types of Gauge widgets:

- Status Gauge - The default Gauge widget is the status Gauge.
- Target Gauge widget - The Gauge widget in the target mode is called the Target Gauge widget. The Target Gauge enables you to set a target value for the metrics. It is set on an arc with a triangular indicator that points to the target value. The threshold values are hidden on this type of widget.
- Threshold widget - This widget displays the threshold values. It provides a visual alert through color changes.

Gauge widget currently supports only two data binding options:

- ADQL Query
- Applications

Widget Properties

You can select these options under the **Widget Properties** panel to modify the visual appearance of the Gauge widget:

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces at the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

Property	Description
Metric Name	Hide or display the name of the metric.
Value	Hide or display the value of the metric.
Value Format	Set the format of the value. You can select one of the following options: • **Long** • **Short** • **Percent**.
Min and Max Values	Hide or display the maximum and minimum value to be displayed on the widget.
Set Value Range	Set the maximum and minimum value to a desired input.

Target	Enable this option to turns the status Gauge into a Target Gauge widget. You can set it to **None**, **Fixed**, or **Percentage.**

If **Target** option is enabled, all the threshold values on the widget are hidden.

Property	Description
Reverse Threshold Order	Reverse the color order for threshold values. By default, the color order is green for normal, yellow for warning, and red for critical but when you enable this toggle button the order changes to red for normal, yellow for warning, and green for critical.
All Threshold Values	Display all threshold values on the widget and the **Target** option gets disabled automatically.
Threshold Starting Values (%)	Set the threshold range between 0 to 100% where: • **Normal** range is between 0 and the defined normal threshold value. • **Warning** range is between the normal threshold value and warning threshold value • **Critical** is when it exceeds the warning threshold value

If threshold option is enabled, **Target** option is hidden from the panel.

See widget time range.

See single click action.

Health Widget

A Health Widget provides different visualizations of the health information of one or more entities for a specified time range. Use this widget to create and view health information of one, or more entities at a time, for Applications, Business Transactions, Tiers, Nodes, and Health Rules. By default, the Health widget displays health information as a ratio pie. The ratio pie visualization provides an additional option of displaying a metric value at the center of the donut pie.

Widget Properties

You can select these options under the **Widget Properties** panel to modify the appearance of the Health widget:

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces between the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

Property	Description

Display as	Display the widget on the dashboard as a:
	• **Ratio Donut**: By default, the Health Widget displays as a Ratio Donut.
	  • **Label Format**: Use to change the format of the label by showing either the **Count and Type** or just the **Count**.
	  • **Center Value Unit**: Use to set the unit value.
	  • **Data Labels**: Use to turn data labels on or off.
	• **Traffic Light**: Displays the health information of critical, warning, and normal status as a traffic light. The health status shown is the overall health status of a list of entities based on the **Aggregation Type**.
	"Worst Health" is the only **Aggregation Type** currently supported for the Health widget. It shows the worst health status in the given list of entities. Additional aggregation types will be included in future releases.
	• **Ratio Bar and List**: Displays health status as a ratio bar with the list of all the entities being monitored (with a health icon next to it). You can modify the size of the bar with **Bar Size** from small to medium. You can use the **Font Weight** option to change the appearance of the font inside the widget to **Light**, **Medium**, and **Strong**.
	• **Ratio Bar**: Displays the health status as a ratio bar.
	• **List:** Displays the health status as a list.

Data Labels	Hide or show the individual data points that you can turn on or off.
Label Format	Set the format of the label. You can select one of the following options: • **Count Only** • **Count and Type**
Center Value Format	Set the format of the center unit value.
Center Value Unit :	Set the unit for the center value. This is optional.

See widget time range.

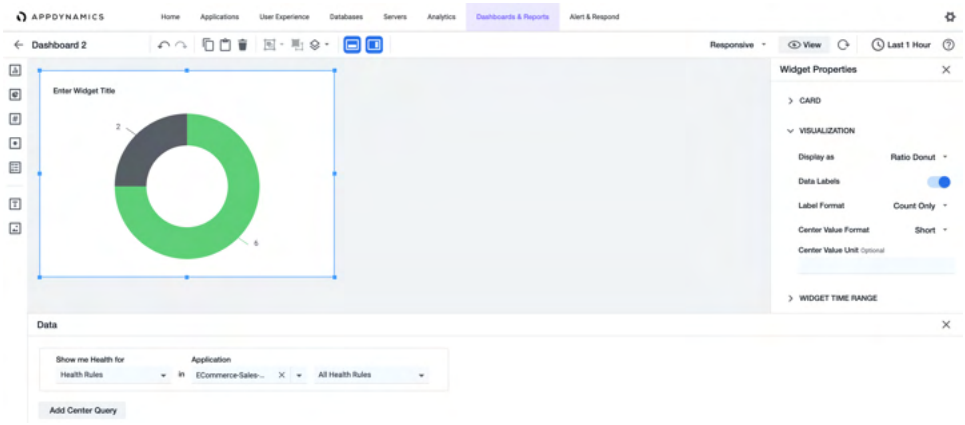
View Health Information

From a Data Panel, you can select the data type whose health information is to display on the Health widget.

For example, supposed you want to know the health status of the ECommerce application.

1. Choose a value from the **Show me data for** dropdown based on the data type you want to display.

   For this example, select Health Rules.
2. The subsequent input fields displayed in the **Data Panel** are specific to the data type selected in the previous step. Click the **Application** dropdown and select the application for which you want to drill down the data.
3. From the next dropdown, select a specific **Named** Health Rule from the popover list or select **All Health Rules**. For example, if you select **All Health Rules**, the Health widget displays as:



After you specify valid inputs for all fields, the widget will update on the canvas and display the results. To view the center value, click **Add Center Query**.

Datagrid Widget

The Datagrid widget provides a quick view of the list of entities associated with all the events on the Dash Studio. You can use this widget to present a collection of data in a tabular format. It improves the troubleshooting capabilities by reducing the number of drill-downs required to perform and navigate to other panels.

Widget Properties

You can select these options under the **Widget Properties** panel to modify the appearance of the Datagrid widget:

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces between the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

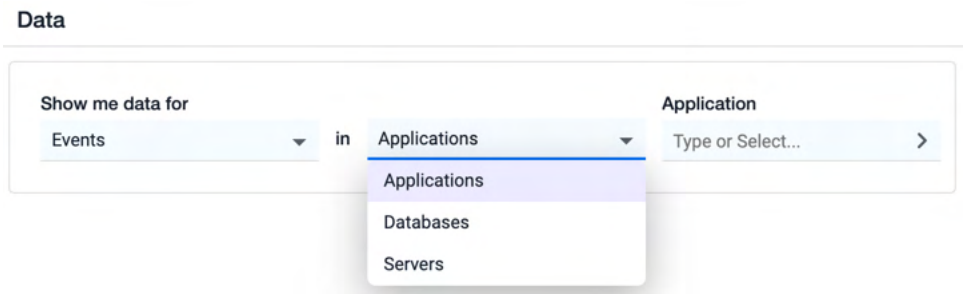
Property	Description
Column sorting	Sort items in the widget columns.
Column resizing	Adjust or resize the width of the widget columns based on the content contained in the viewport of the Datagrid.
Search	Search for objects in the widget.
Grid footer	Hide or display the footer content.
Row height	Adjust the height of the rows.
Filter panel	Display a list of filters.

See widget time range.

View List of Events

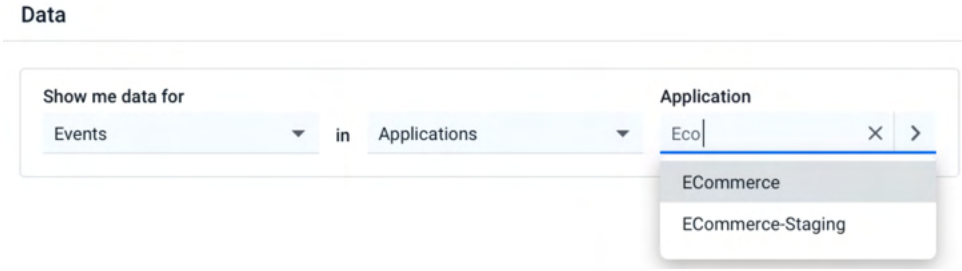
To view a list of events for a given data source, select the Datagrid widget icon from the widget palette:

1. Under **Data** panel, click **Show me data for** and select **Events**.
2. Click the subsequent dropdown and select the data source for which you want to see the list of events. **Applications** is selected in this example.

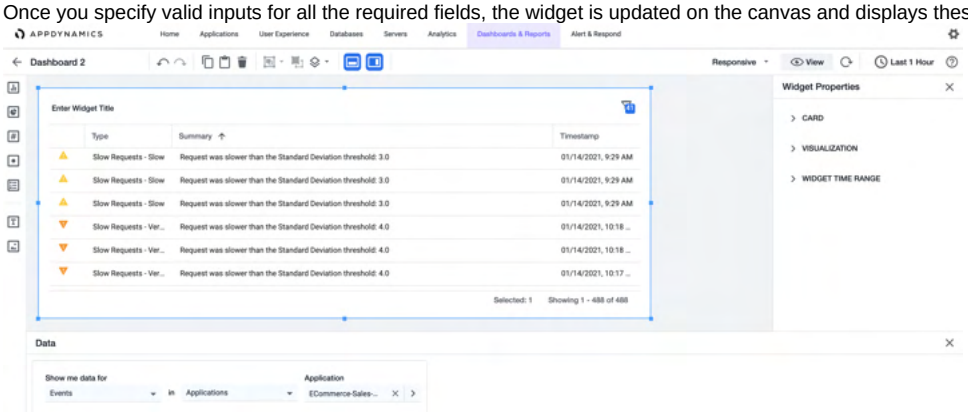


The subsequent inputs shown in the **Data** panel are specific to the data type selected from the previous step.

3. Click **Application** and select one from the list of options. You can also enter the name of the application manually.



Once you specify valid inputs for all the required fields, the widget is updated on the canvas and displays these results:



Click the **Filter Panel** icon on the top-right corner of the Datagrid widget to see the available filters to apply.

To view information such as summary, details, actions executed, and comments about the selected event, double-click the specific row of the widget. Based on your analysis of the event information, you can start a war room, delete the event, archive it, or test the action.

You can also resize the widget in vertical and horizontal directions by dragging the edges.

Label Widget

A Label Widget is a simple text string that enables you to add text on the dashboard canvas.

Widget Properties

You can select these options under the **Widget Properties** panel to modify the appearance of the Label widget:

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces between top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.

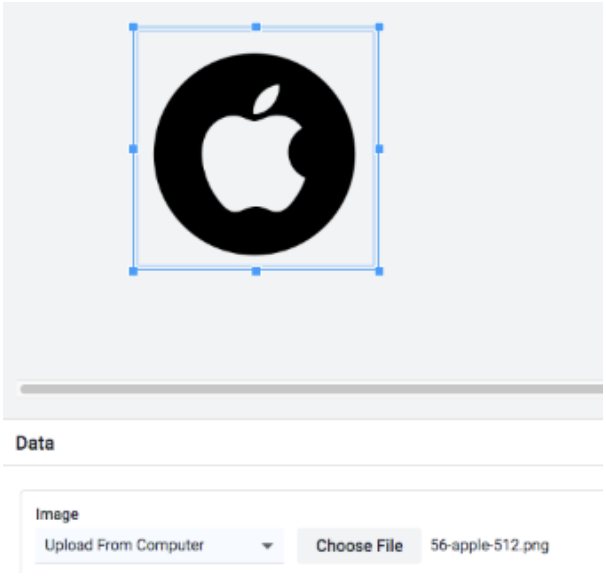
Shadow	Set a shadow around the widget.

Property	Description
Font Color	Specify the color of the text inside the widget.
Font Size	Specify the size of the text within the widget.
Horizontal Alignment	Define horizontal alignment of the text in the widget.
Vertical Alignment	Define vertical alignment of the text in the widget.

See single click action.

Image Widget

You can use the Image Widget to add images to a new dashboard.



Widget Properties

You can select these options under the **Widget Properties** panel to modify the appearance of the Image widget:

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces between top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.

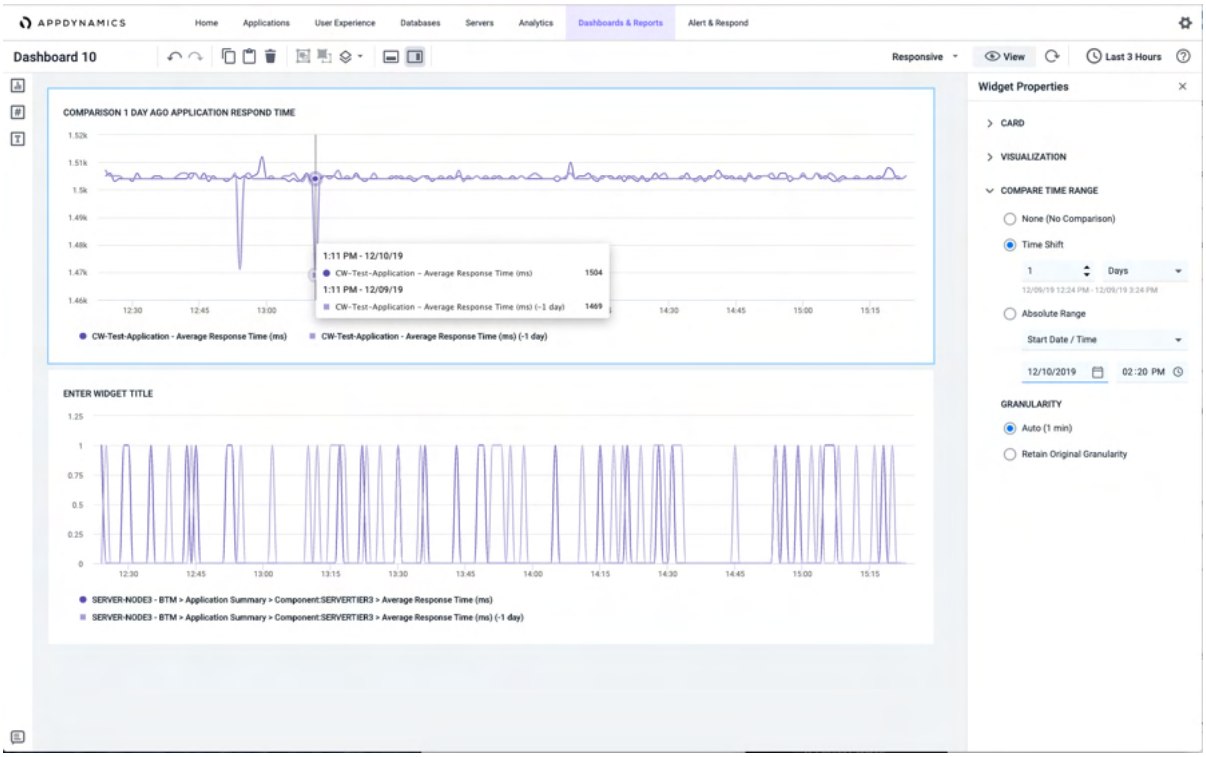
Property	Description
Image Scale	Set the image size. You can select one of the following options: • **Scale to Fit** • **Original Size** • **Stretch**

Time Range Comparisons

This page describes the time range comparison feature in AppDynamics.

You can use the time range comparison in Dash Studio to identify differences in the application performance trends for two time periods. You can align two time periods of the same data and compare. For instance, it might be useful to compare an application's average response time on the previous day with the same day last week.

- Comparisons are currently available only for Time Series widget and Metric Number widget.
- All Data Panel options for Time Series widget and Metric Number widget support comparisons.
- Global time range (for example "Last 4 hours") is selected for the entire dashboard by default.



The default global time range is denoted as T1 and time comparisons are performed using this time range.

Compare Two Time Periods

To compare two time periods on a widget:

1. Select the widget from the widget panel.
2. Expand the **Compare Time Range** section under the **Widget Properties** panel.
3. Set a second time range (denoted as T2) with the same duration as the global time range. You can shift T2 back in time based on the settings in the **Compare Time Range** section.
   You can select one of the following options:
   - **None**: This is the default setting for all the widgets when initially placed on the canvas. Select this option to exclude time comparison.
   - **Time Shift**: This option shifts current widget time range (T1) back by the selected amount of time to become T2. For example, if T1 is "Last 1 hour" and the Time Shift is set to 2 Hours, T2 is 2 hours earlier than T1. When you select this option, you first specify a whole number not less than one as the first input and then select one of the available time options (minutes, hours, days, or weeks) from the dropdown.
   - **Absolute Range**: Use this option to specify the T2 comparison time range by selecting either the **Start Date/Time**, or the **End Date /Time** of the range. For example, if T1 is "Last 1 hour" and you select this option, you can use the date and time inputs to select a start of 8 days ago at 11 am. T2 would thus be 11 am to 12 pm on that specific day. After you set the second or third options, T1 and T2 are superimposed over the same chart space in the Time Series widget.

Granularity

By default, Dash Studio matches granularities if there are differences between T1 and T2 time ranges. AppDynamics stores less recent data at a lower granularity which means fewer data points are displayed on the data series in Dash Studio. To perform an apples-to-apples comparison, Dash Studio is set to **Auto** by default and shows both T1 and T2 time ranges using the same granularity (even if they differ). However, you can change this behavior by selecting the **Retain Original Granularity** option instead of the **Auto** option. When you select **Retain Original Granularity** option, both T1 and T2 show data at their original granularities. This makes comparing behaviors difficult, but the newer data is highly granular.

- Showing the time range comparison doubles the number of data series on the chart. If initially three lines are shown in the widget time range without the comparison, six are shown when the comparison is defined. As new data is received, the widget and its comparisons are updated continuously.
- AppDynamics stores a reduced granularity (fewer data points) for older time ranges.
- Granularity is not available for Metric Number widget.

Time Zone Setting

You can adjust the time zone setting to collaborate and troubleshoot issues with more accuracy. You can align the time zone with other users working in different time zones and eliminate issues such as translating the timestamp of your location to another user's time zone.

To set the time zone:

1. Click the gear icon located at the top right of the page.
2. Select **My Preferences** from the listed options.
   The **My Preferences** page displays an option to select a time zone.
3. Select the **Display Time Zone** dropdown and choose your time zone from the available options. In this example,
4. Click **Reload** to reload the browser and reflect the time zone update.
5. To verify the new time zone setting, open an existing dashboard.

Dashboard Variables

This page provides an overview of dashboard variables in AppDynamics.

You can use dashboard variables to quickly change the data that widgets display without creating a new widget. You can create a series of widgets that show the same metric for a different entity, and view information from multiple applications by simply switching the variable linked to application name. You can also build a dashboard by copying groups of widgets and switching the variable set for each group.

Dash Studio enables you to toggle with ease between variables at the dashboard-level, or group-level. You can define and set variables at various levels of the dashboard, whether for the dashboard at a high level, or for the group at the group level. You can define the variables that you want to set for a group.

Define Variables

You can define variables in a dashboard and across an assembly.

Set Variables

You can set variables to change the values used by a variable across an assembly or within a container. This can occur at the container level and assembly level.

Inherit Variables

Group Variable Inheritance

For group level, variable inheritance is inherited from parents to children. For example, a group inherits its variable definition from the dashboard in which it sits, however the dashboard does not inherit variable definitions from a group. This is because you cannot define variables at the group level.

Assembly Variable Inheritance

For assemblies, the sibling assemblies inherit variable definition from their siblings. For example, an assembly inherits its variable definition from the assembly from which it was made.

Data Binding

You can use the **Data** panel to query and display data for a selected widget. Additionally, you can:

- Construct queries that span your environment.
- Add important attributes and relationships to your queries.
- Quickly access data when you do not know the metric path.
- Construct sophisticated queries.
- Query both metric and analytics data in the same query.

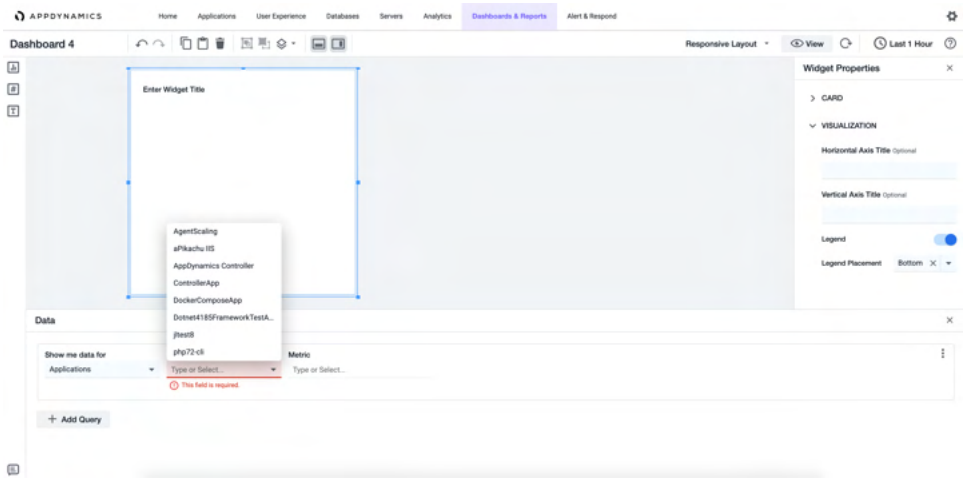
Data Queries

The **Data** panel is structured around queries. Each query follows a sentence-like format, starting with a selection of the data type of the query. Many fields in the **Data** panel support typeahead functionality.

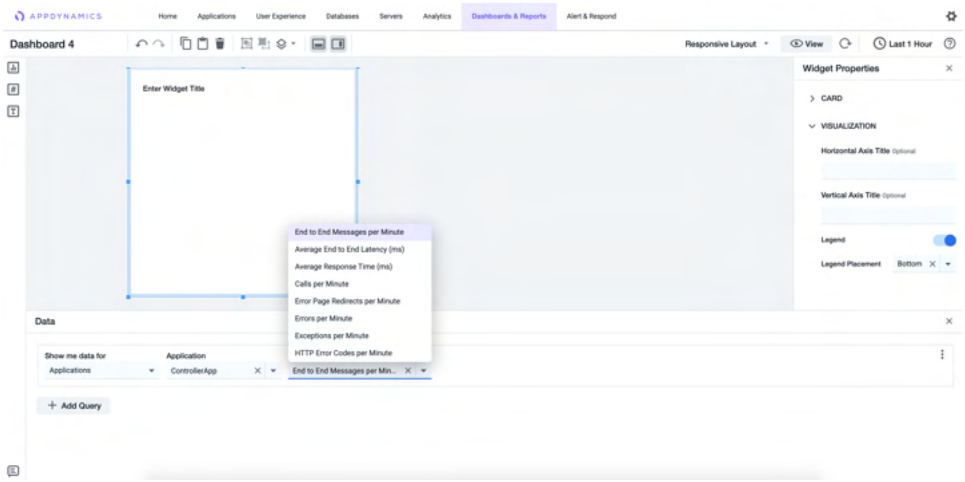
In this example, you want to know errors per minute for the nodes in an application.

1. Select a value from the **Show me data for** dropdown based on the data type you wish to display.

   In this example, select **Applications**.
2. The subsequent inputs shown in the **Data** panel are specific to the data type you selected in the previous step. In this example, use the **Applicatio** dropdown to select the application for which you want to drill down the data.



3. The next dropdown is **Metric**. The **Metric** dropdown changes based on the data type. For example, the node displays two more inputs before you select the metric.
4. Select the metric you wish to display on the widget. You can select the **More** icon on the right-corner of the **Data Panel** to set the limit and baseline.



After you have specified valid inputs for all fields in the query, the widget is updated on the canvas and shows the query result.

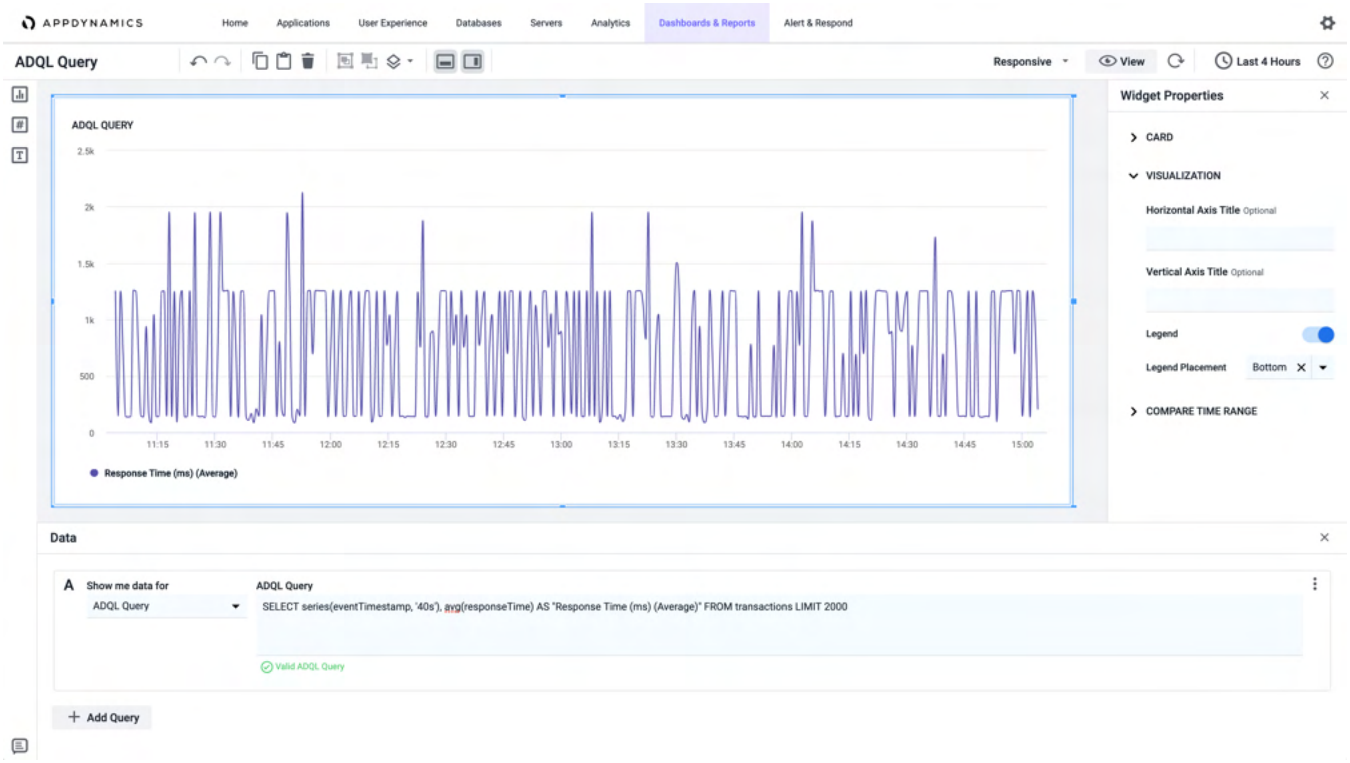
ADQL Queries

ADQL (AppDynamics Data Query Language) Query is a metrics query available in the **Data** panel for dashboards created in Dash Studio. Use this query to filter and create customized metrics for Analytics data.

ADQL Query data binding uses Analytics queries written in ADQL. After selecting the **ADQL Query** option from **Show me data for** dropdown, you can either type or paste an ADQL query. See ADQL Reference for the syntax of these query statements.

> To view data reflected in the Time Series widget in Dash Studio, you must enter a valid ADQL Query for series. You must include the `series` expression in the ADQL query statement otherwise it does not display a series. ADQL Query is available for the **Time Series** widget only.

After you type or paste the query in the input field, moving the cursor away from the input field automatically validates the query. For a **Valid ADQL Query** (displayed in green), the data displays in the widget on the canvas. For any invalid query, an error message displays in red.

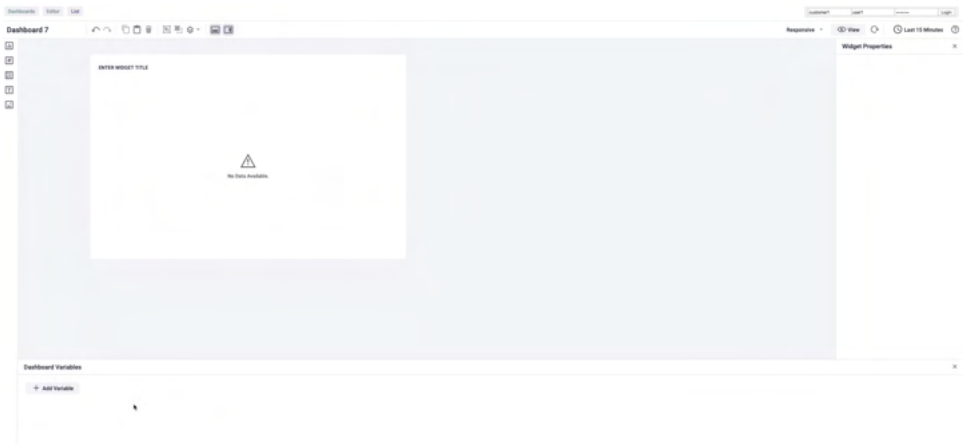


Variables in ADQL Queries

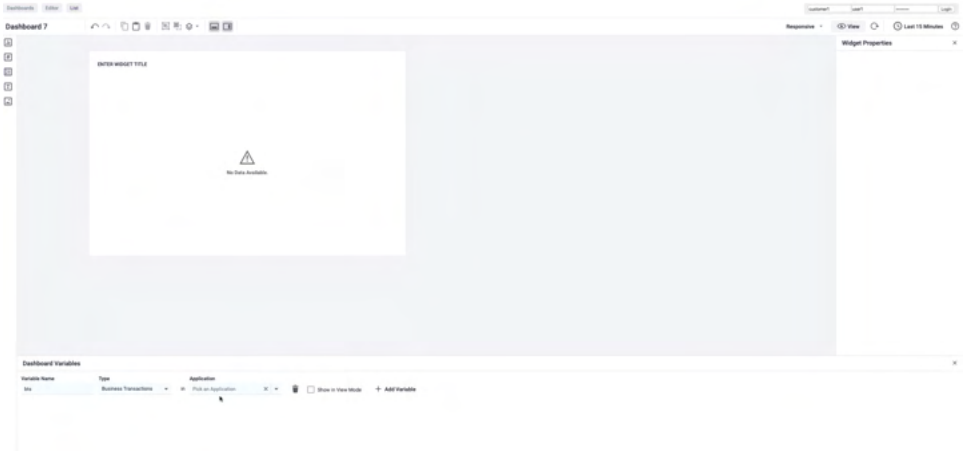
Variables in ADQL queries enable you to dynamically change the values passed into the queries.

For example, you want to use a variable for an application within an ADQL query.

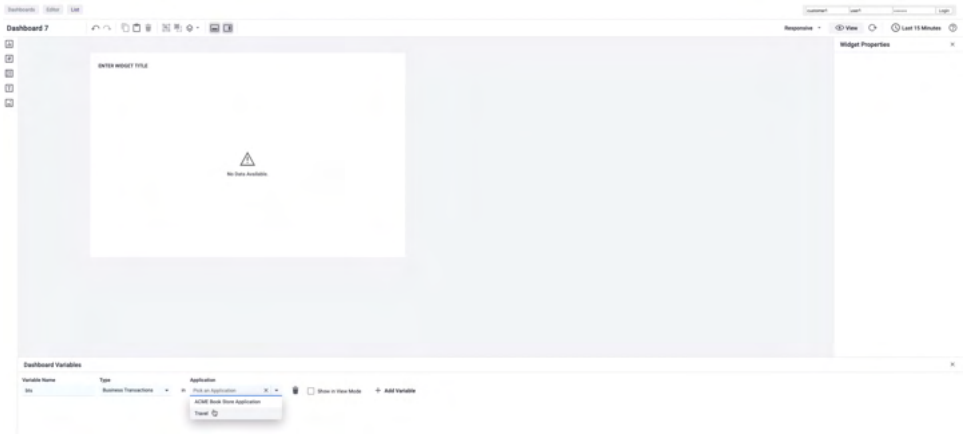
1. Click **+ Add Variable** under the **Dashboard Variables** panel.



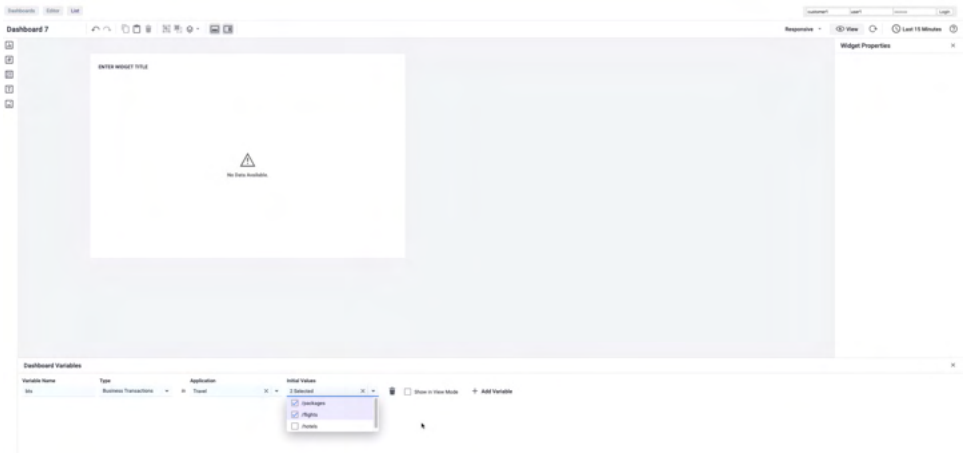
2. Enter a value in the **Variable Name** field and select the variable type in the **Type** dropdown.



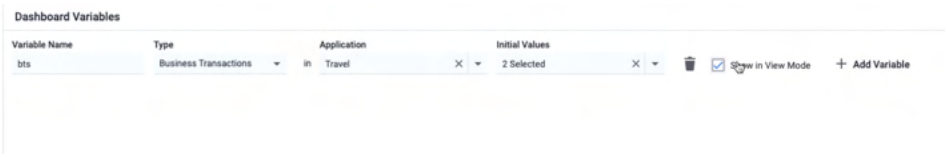
3. Select an application in the **Application** dropdown.



The subsequent inputs shown in the **Dashboard Variables** panel are specific to the data type selected in the previous step. In this example, it is the **Initial Values** dropdown, which enables you to select the business transaction for which you want to drill down the data.

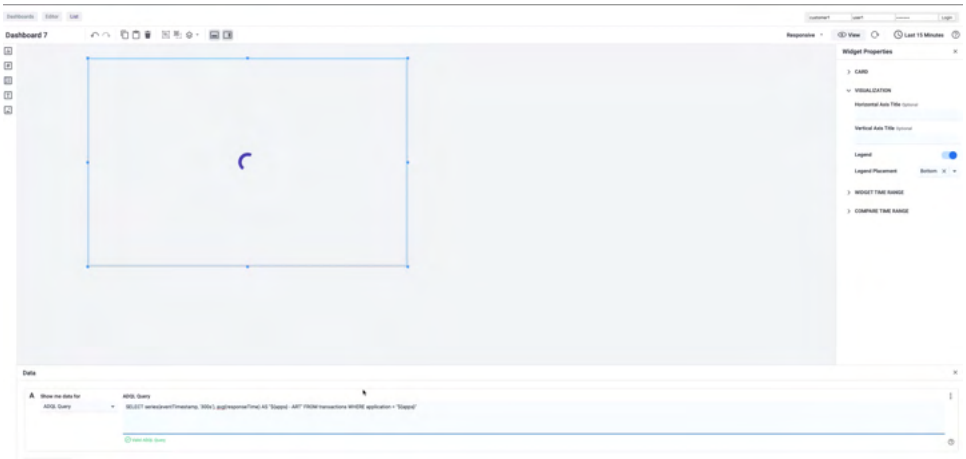


4. Select the **Initial Values**, and then select the **Show in View Mode** checkbox.

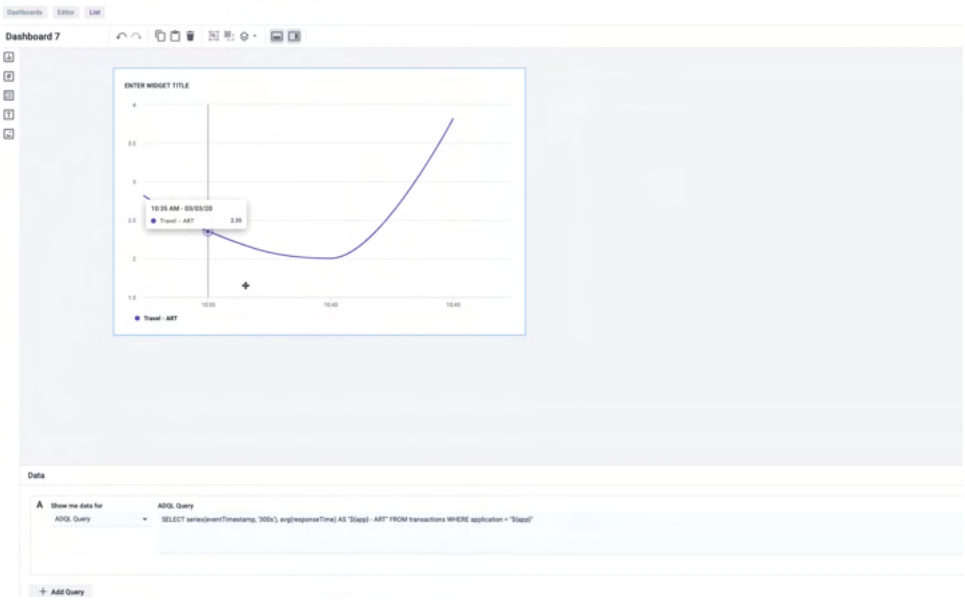


Click the widget to change **Data Panel** from variable data to widget data.

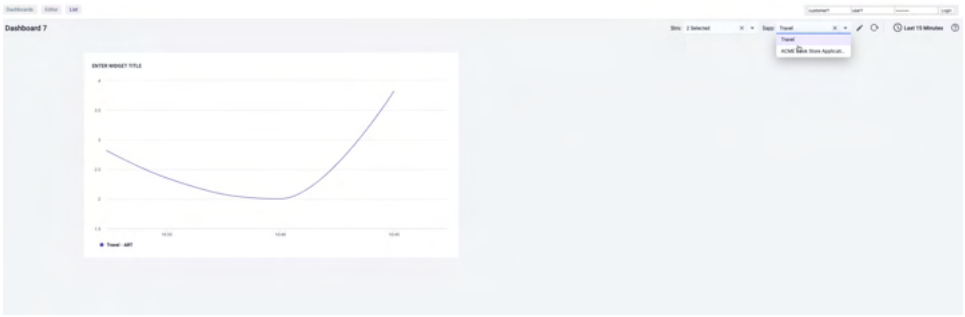
5. Choose a value from the **Show me data for** dropdown.
   In this example, select **ADQL Query**, and then enter the query in the **ADQL Query** field:



After you enter a valid query, the widget displays:



6. Click **View** on the top-right of the page. The subsequent dashboard page enables you to change the application by clicking the $**app** dropdown.

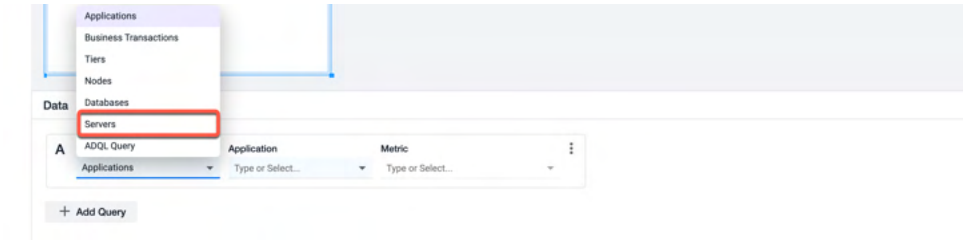


Server Metrics

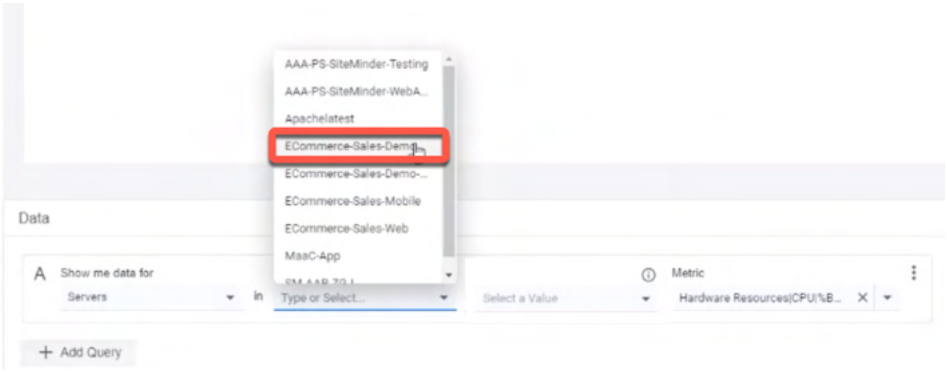
Server Metrics [also known Server Infrastructure Monitoring (SIM) Metrics] is a data binding option available in the **Data** panel of Dash Studio. Use this option to filter and create customized metrics for server monitoring.

To filter and create customized metrics for one or more servers:

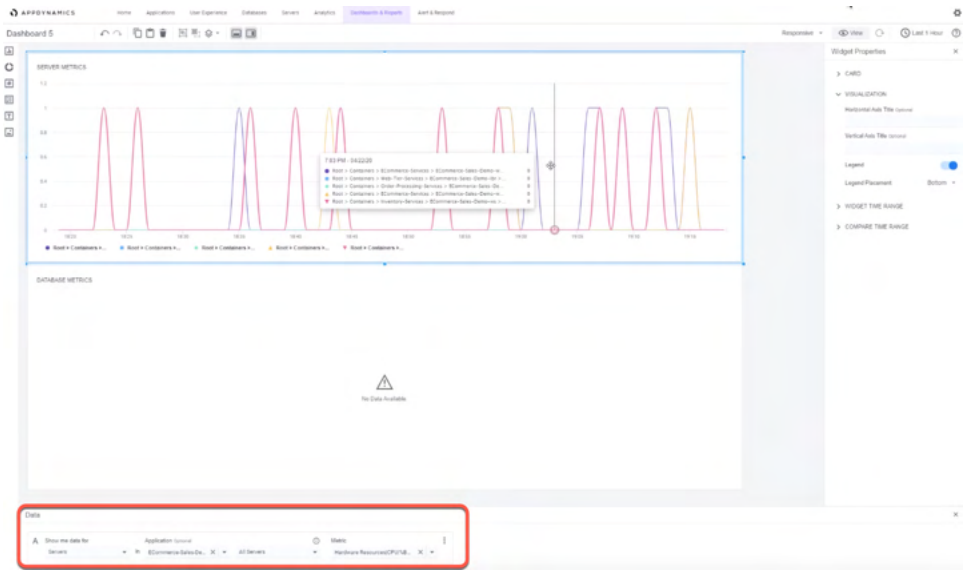
1. Click the **Show me data for** dropdown and select **Servers**.



2. Click the **Application** dropdown and select the application for which you want to drill down the data.

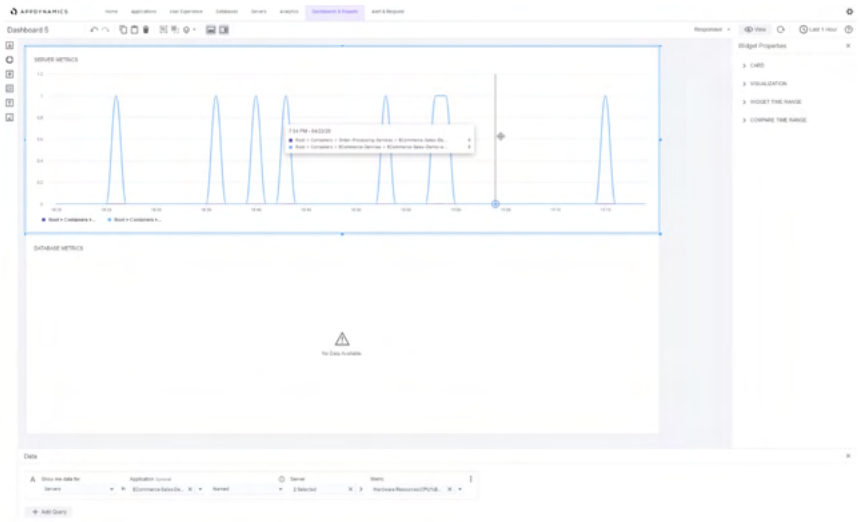


3. Click **Select a Value** and select one of these options:
    - **All Servers:** Select this option to show data across all applications. If you select this option, then the **Application** selected in the previous step becomes optional. If you select **All Servers,** the next input field in the **Data** panel automatically changes to **Metric.** Select the metric value you wish to display on the widget from the dropdown, or by manually entering a value in the input field.



> If none of the applications are selected, then the widget displays data for stand-alone applications only, and not for the applications included in the application tree.

    - **Named:** Select this option to specify individual servers known to the specific application that you chose in step 2. If you select **Named,** the next input field in the **Data** panel changes to **Server**. Select one or more servers from the **Server** dropdown, and the metric value from the **Metric** dropdown.



- **Within:** Select this option to select the tier, or tiers, of the server you wish to display in the server chart.

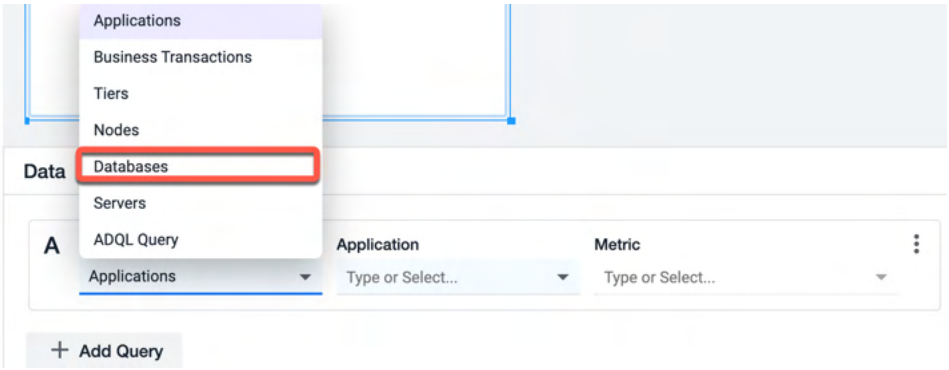
Database Metrics

Database Metrics is a data binding option available in the **Data** panel of Dash Studio. Use this option to filter and create customized metrics for database monitoring.

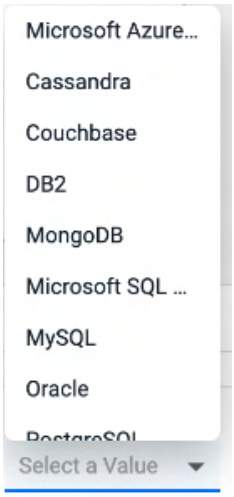
> The Metric Number widget does not support Database metrics.

For example, to monitor a specific database or multiple databases:

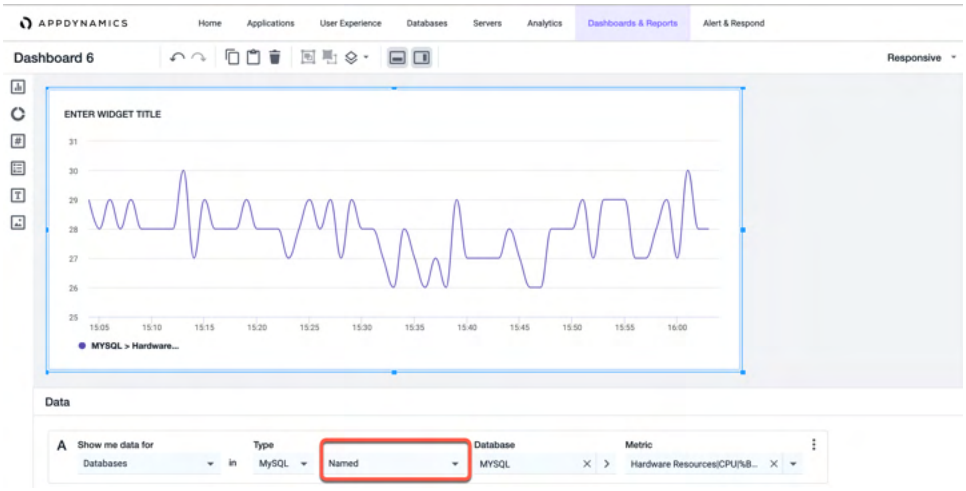
1. Click the **Show me data for** dropdown, and then select **Databases**.



2. Click **Type** and select the required database from the dropdown to display the metrics on the widget.



3. Click **Select a Value** and choose one of these options:
    - **All Databases:** Displays data for all the databases.
    - **Named:** Displays data for a specific database. You can select the required database from the subsequent input field **Database** that displays when you select **Named**.
4. Click **Metric** and select the metric value, or enter a value manually. The database metric chart displays.



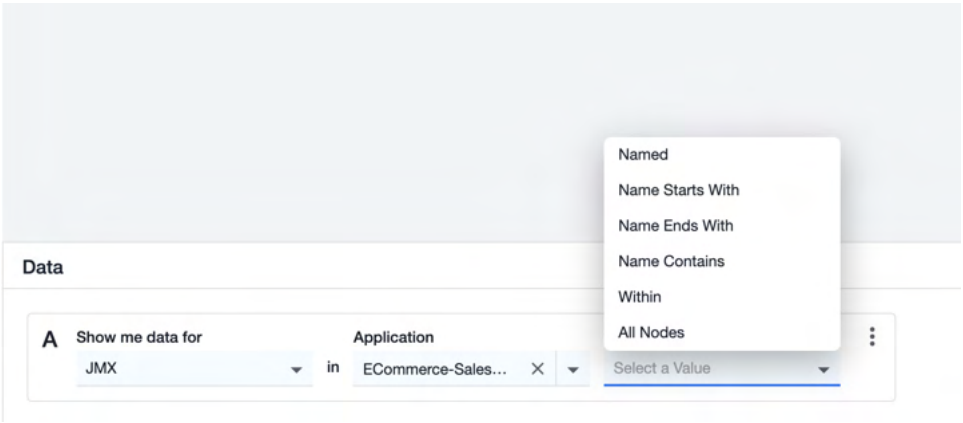
JMX

JMX (Java Management Extensions) is a data binding option available in the **Data** panel for dashboards created in Dash Studio. Use this option to filter the entities by nodes and monitor the JMX metrics for the given set of nodes.

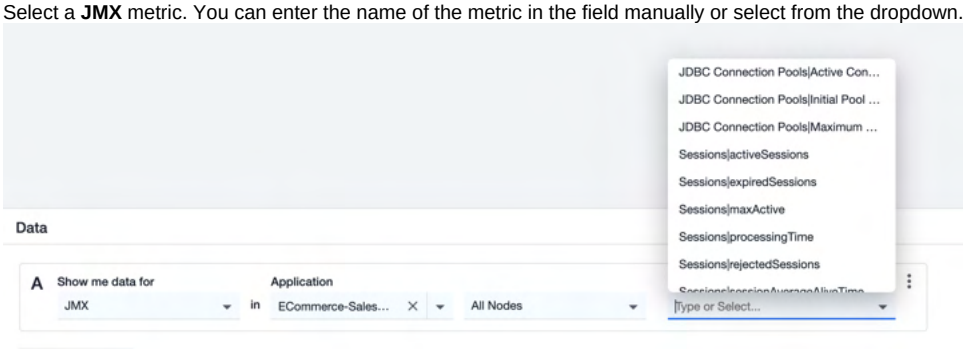
For example, to monitor JMX metrics of a node or multiple nodes:

1. Click the **Show me data for** dropdown and select **JMX**.

   The subsequent inputs shown in the **Data** panel are specific to the data type selected in this step.
2. Click the **Application** dropdown and select the application for which you want to drill down the data.
3. Click **Select a Value** and select a node filter from the dropdown.



4. Select a **JMX** metric. You can enter the name of the metric in the field manually or select from the dropdown. This list is dynamic.



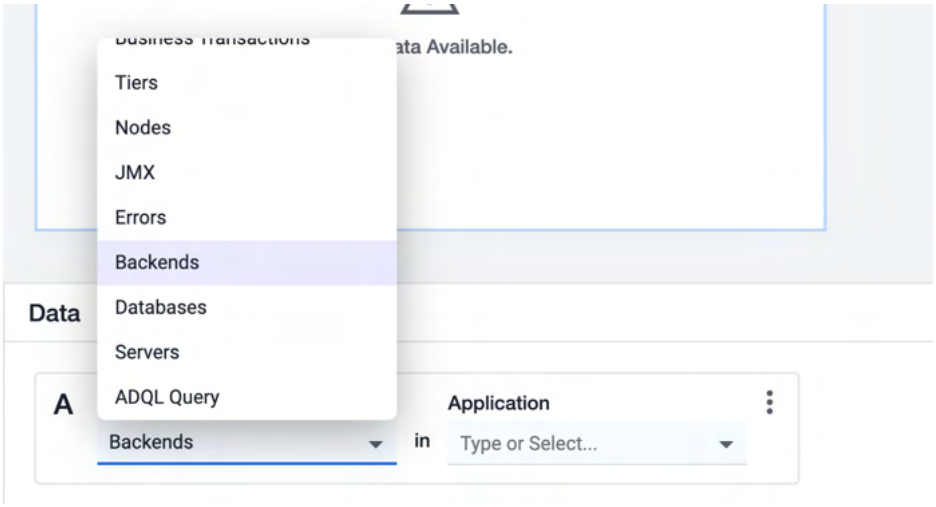
- Entries do not display if the selected entry is not a Java application, or if there are no JMX metrics for the selected application.
- The metric selector parses the Java Application metric tree dynamically for all available JMX metrics and displays them as a flattened list.
- Currently, only the JMX metrics that are 2 levels deep from a JMX folder in the metric tree are available in Dash Studio.

Backends

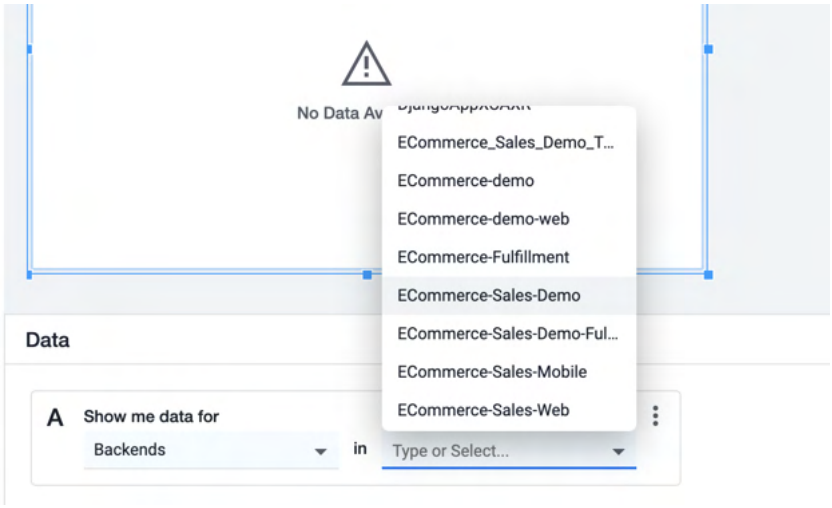
Backends is a data binding option available in the **Data** panel for dashboards created in Dash Studio. Use this option to filter the backend entities.

To monitor **Backends**:

1. Click the **Show me data for** the dropdown and select **Backends**.

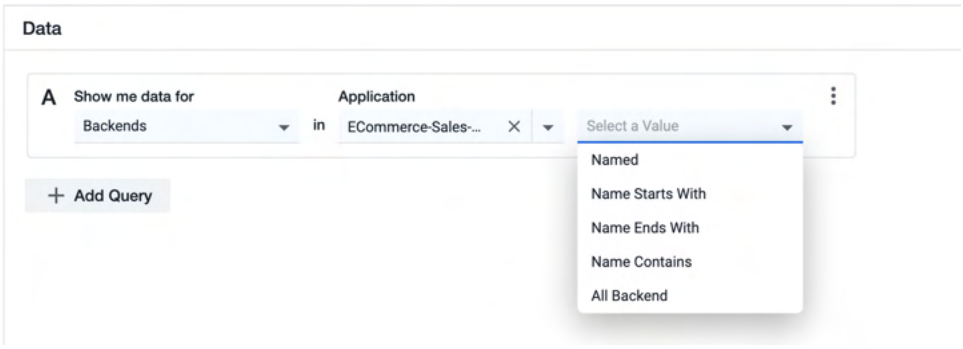


2. Click **Type or Select** and then select the application to display the metrics on the widget.

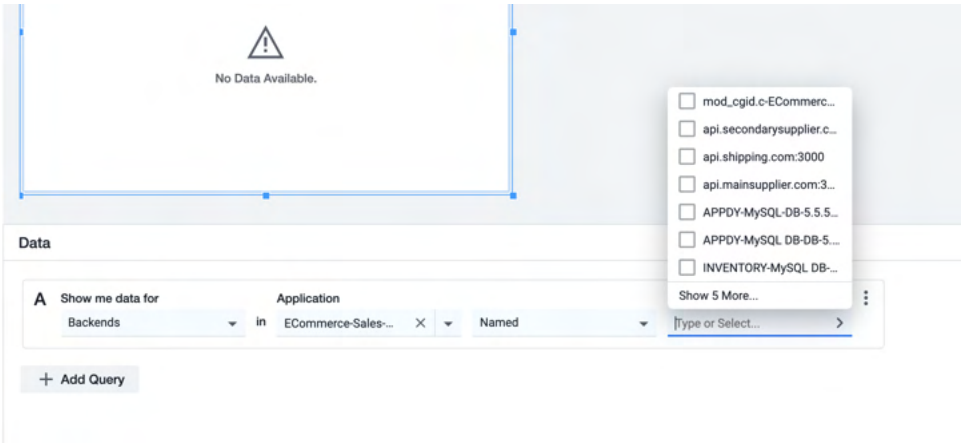


3. Click **Select a Value** and then select the filter you want to apply:

    - Named
    - Name Starts with
    - Name Ends With
    - Name Contains
    - All Backend



4. Click **Type or Select** and then select a named filter from the list of options.



5. Click **Metric** and select the backend metric value.

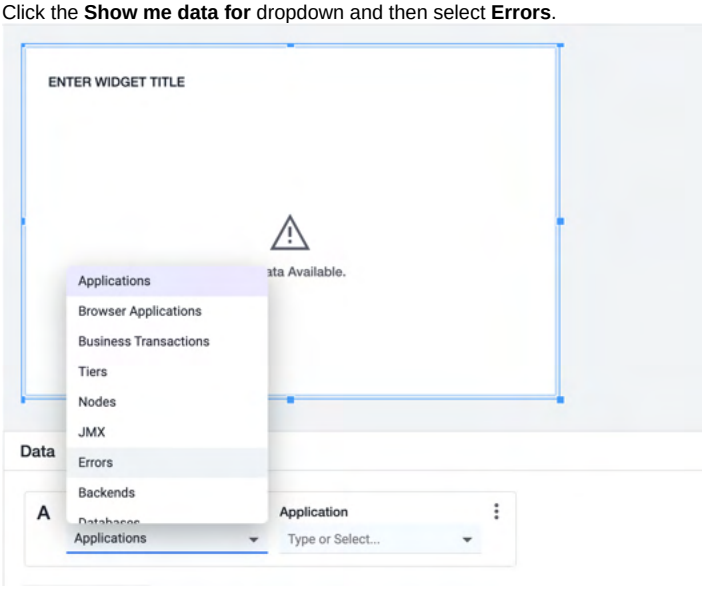
The metric chart displays:

Errors Data Binding

Errors is a data binding option available in the **Data** panel for dashboards created in Dash Studio. Use this option to filter the error entities.

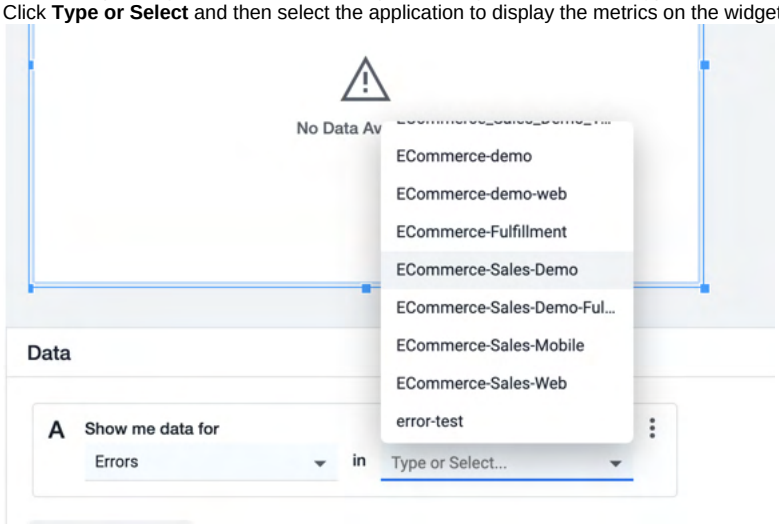
To monitor error entities:

1. Click the **Show me data for** dropdown and then select **Errors**.

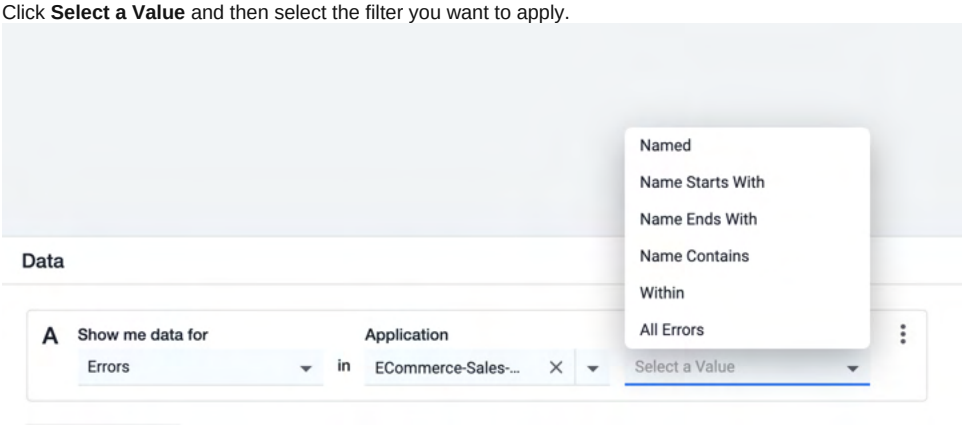


The subsequent inputs shown in the **Data** panel are specific to the data type selected in this step.

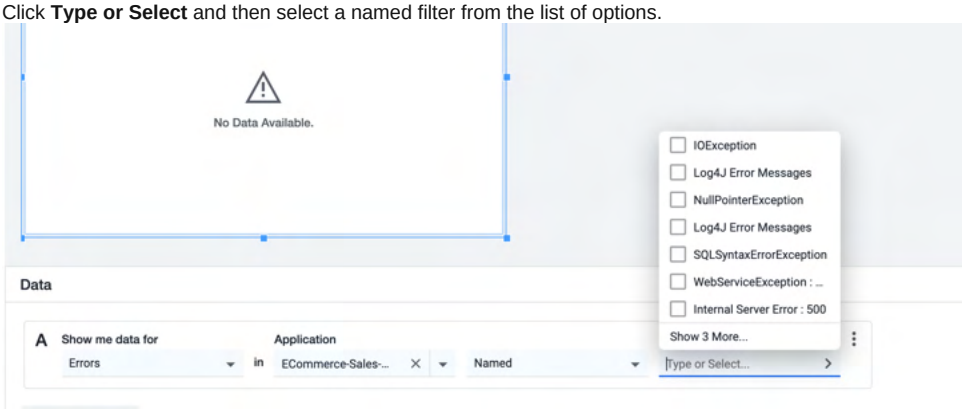
2. Click **Type or Select** and then select the application to display the metrics on the widget.



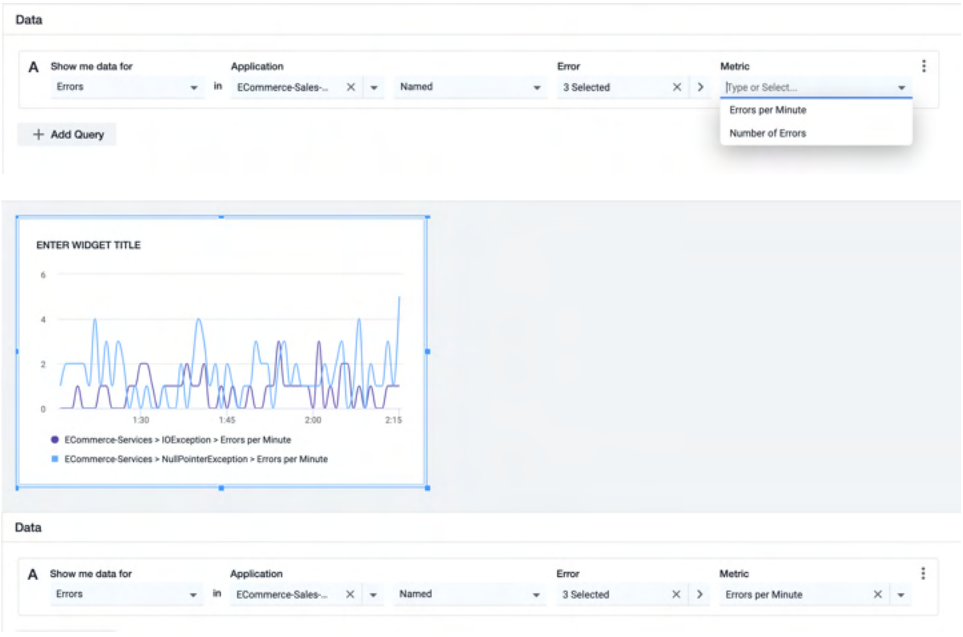
3. Click **Select a Value** and then select the filter you want to apply.



4. Click **Type or Select** and then select a named filter from the list of options.



5. Click **Metric** and select the metric value.



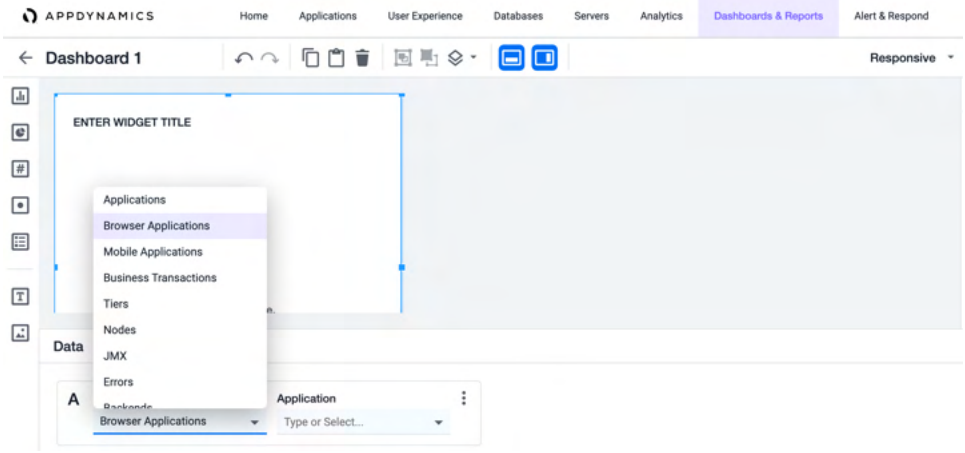
A chart that shows data for All Errors displays:

Browser Applications Metrics

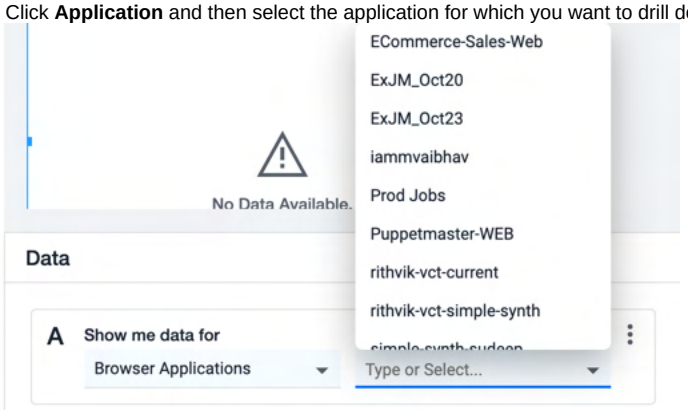
Browser Applications metrics [also known as the Browser Real-User Monitoring (BRUM) metrics] is a data binding option available in the **Data** panel of Dash Studio. Use this option to filter and create customized metrics to view the performance of the web applications.

To filter and create customized metrics for one or more browser applications:

1. Under **Data** panel, click the **Show me data for** dropdown and then select **Browser Applications**.

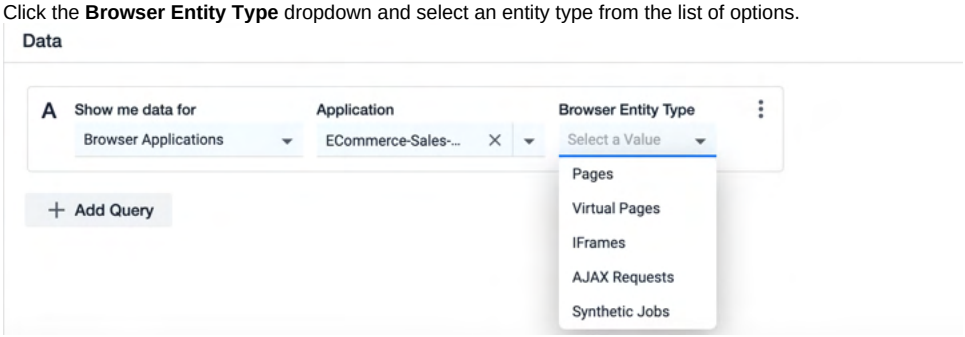


2. Click **Application** and then select the application for which you want to drill down the data.

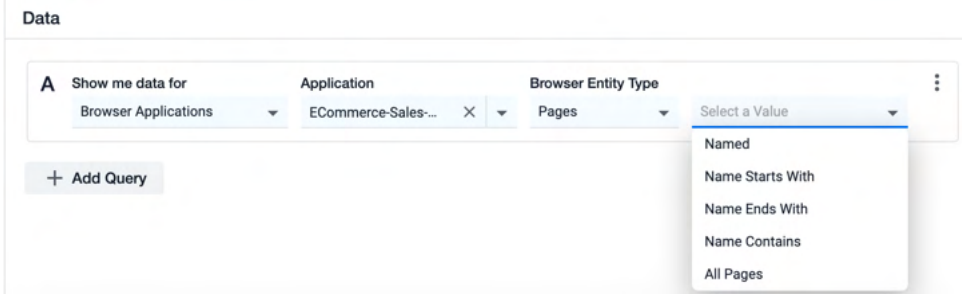


> The subsequent inputs shown in the **Data** panel are specific to the data type selected in the previous step.

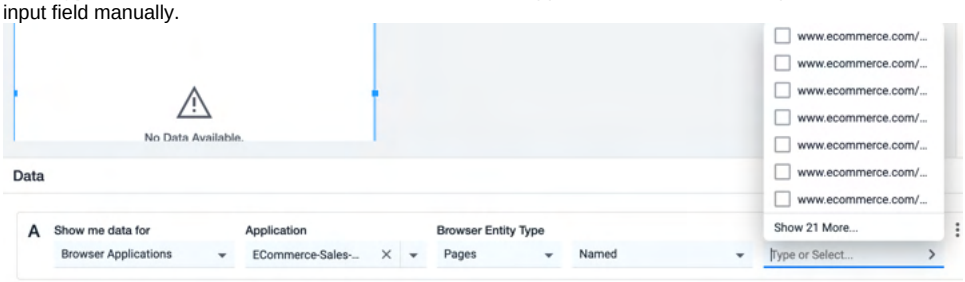
3. Click the **Browser Entity Type** dropdown and select an entity type from the list of options.



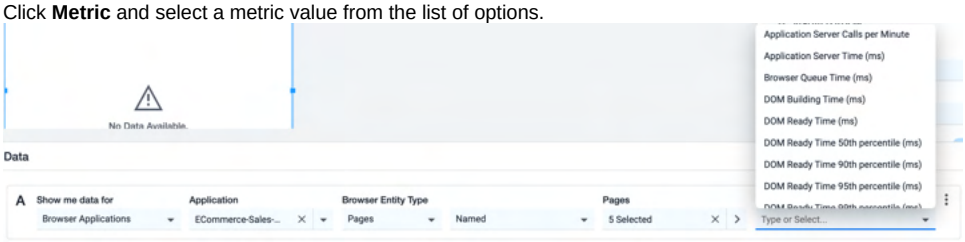
4. Click **Select a Value** and select the filter that you want to apply.



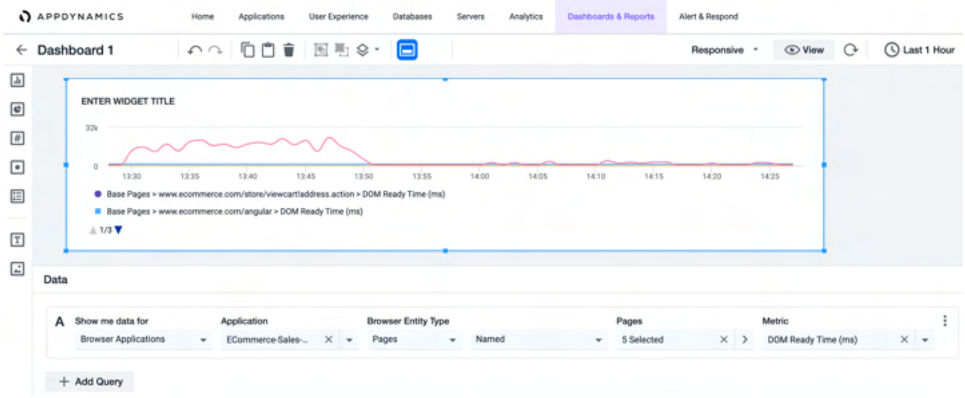
5. Click **Type or Select** and then select one or more browser applications from the list of options, or enter the name of the browser application in the input field manually.



6. Click **Metric** and select a metric value from the list of options.



The Browser Applications metric chart displays:

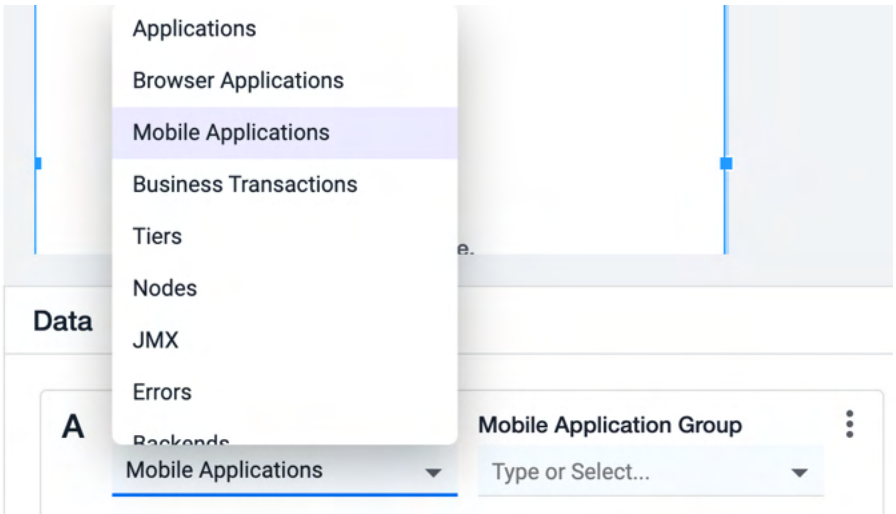


Mobile Applications Metrics

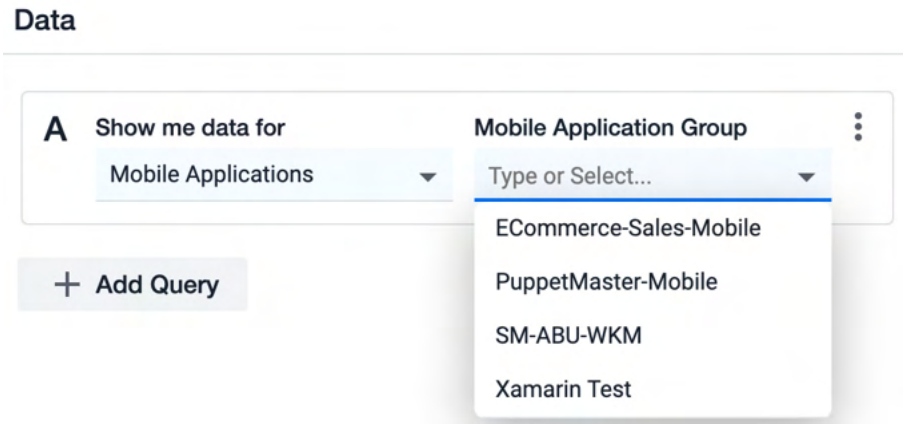
Mobile Applications metrics [also known as the Mobile Real-User Monitoring (MRUM) metrics] is a data binding option available in the **Data** panel of Dash Studio. Use this option to filter and create customized metrics to view the performance of mobile applications.

To filter and create customized metrics for one or more mobile applications:

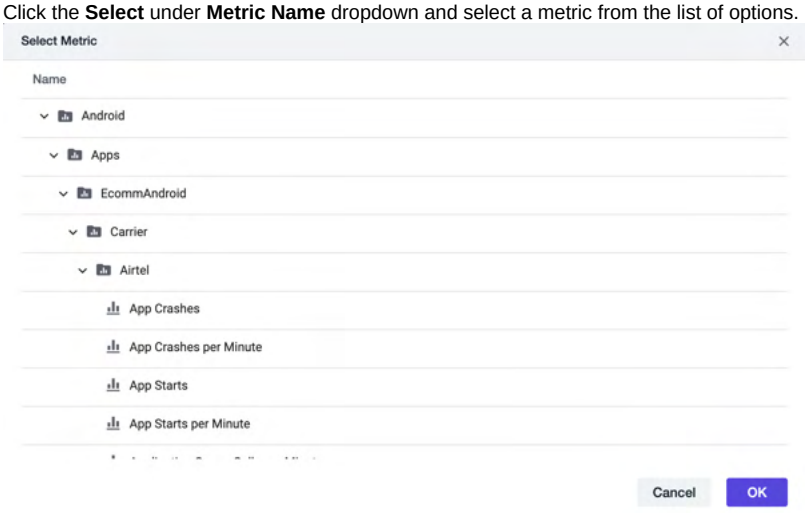
1. Under **Data** panel, click the **Show me data for** dropdown and select **Mobile Applications**.



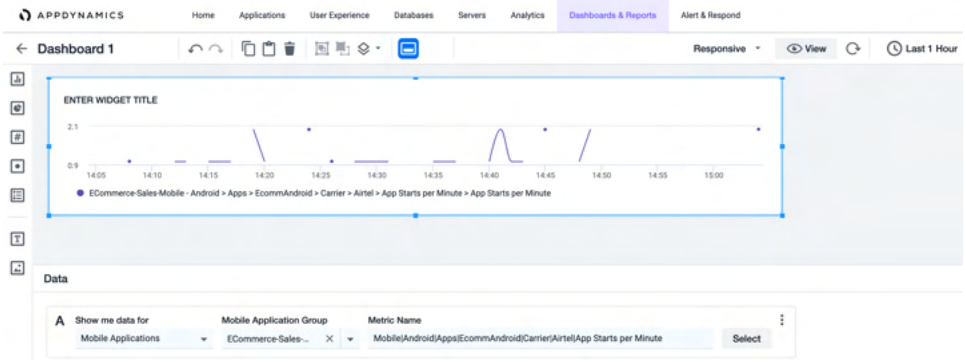
2. Click **Mobile Application Group** and then select the application for which you want to drill down the data.



3. Click the **Select** under **Metric Name** dropdown and select a metric from the list of options.



4. Click **OK**. The Mobile Applications metric chart displays:



ThousandEyes Integration with AppDynamics

ThousandEyes is a network intelligence SaaS platform that provides deep insights about the network and external dependencies. AppDynamics and ThousandEyes integration delivers a full stack solution you can use to correlate your network to the application performance. You can identify network related performance issues to reduce the impact on critical applications.

You can visualize ThousandEyes data along with application data on the dashboard created in Dash Studio.

- Analyze performance bottlenecks in your network at a glance
- Drill down to the root cause of performance issues
- Monitor key metrics
- Reduce Mean Time to Resolution (MTTR)

To configure the ThousandEyes token and to enable ThousandEyes query see:

- Enable the ThousandEyes Token
- Configure the ThousandEyes Dashboard

Configure the ThousandEyes Token

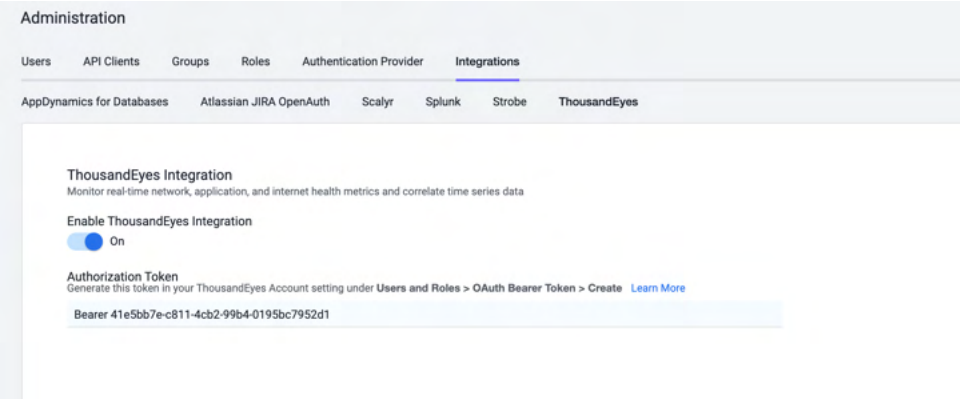
To enable the integration for a controller version lower than 21.5.0, you need to raise a ticket at help.appdynamics.com.

Before you can access the ThousandEyes network data, you must configure the ThousandEyes token in your ThousandEyes Account. See account settings.

To access the ThousandEyes data, configure the ThousandEyes token by performing the following steps:

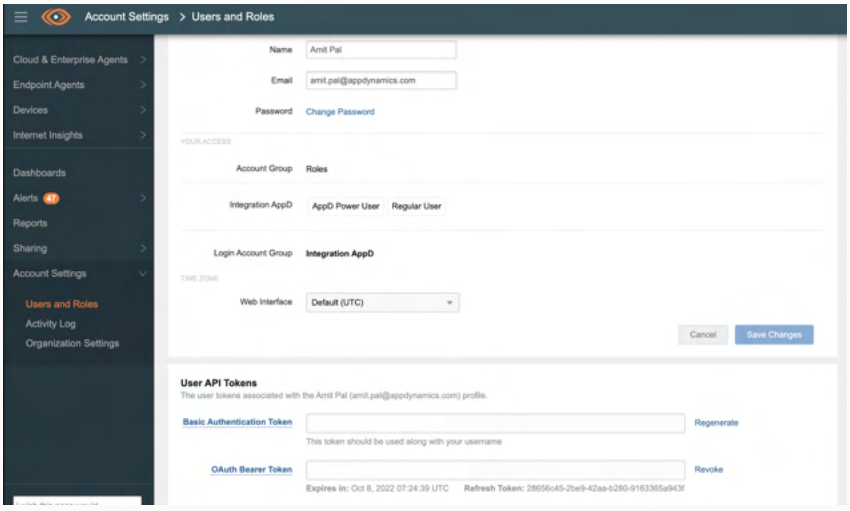
You must have ApDynamics admin privileges access to this page. To request access contact the AppDynamics support.

1. Click the gear icon at the top-right corner of the Home page and select **Administration**.
   The **Administration** page displays.
2. Click the **Integrations** tab.
3. Click the **ThousandEyes** tab. The **ThousandEyes Integration** page displays.
4. Click the **Enable ThousandEyes Integration** toggle.
5. Enter the token value in the **Authorization Token** field manually or you can copy and paste it.



The token must be in the format `Bearer<space><token>.`

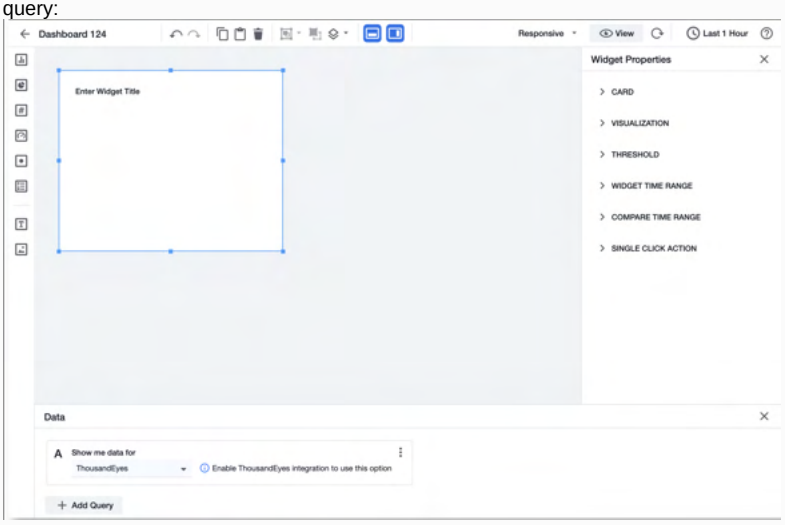
You can retrieve the authorization token by logging in to ThousandEyes Account.



6. Click **Save**.

On disabling the ThousandEyes integration on the **Administration** page:

- If you select ThousandEyes query in **Show me data for** dropdown list, it displays a warning message requesting you to enable the query:



- The existing widgets that use ThousandEyes query do not render ThousandEyes data.

Configure the ThousandEyes Dashboard

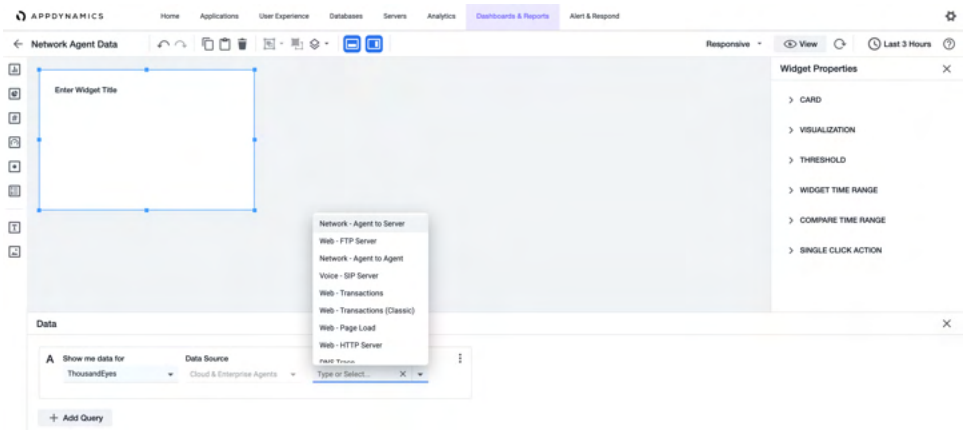
The ThousandEyes query is a metrics query available in the **Data** panel for dashboards created in Dash Studio. Enable this query to troubleshoot network performance issues related to latency, packet loss, and bandwidth utilization. See ThousandEyes platform.

To filter and create customized metrics to analyze the performance of your network:

1. Click **Dashboards and Reports** and select the **Dash Studio (Preview)** tab.
2. Click + to create a new dashboard or you can open an existing dashboard.
3. Select a widget from the widget panel.

> Only the Time Series and Metric Number widget support the ThousandEyes query.

4. Click the **Show me data for** dropdown in the **Data** panel.
5. Select **ThousandEyes** from the dropdown. You can add only one ThousandEyes query per widget. **Data Source** field displays with the **Cloud & Enterprise Agents** option set by default.



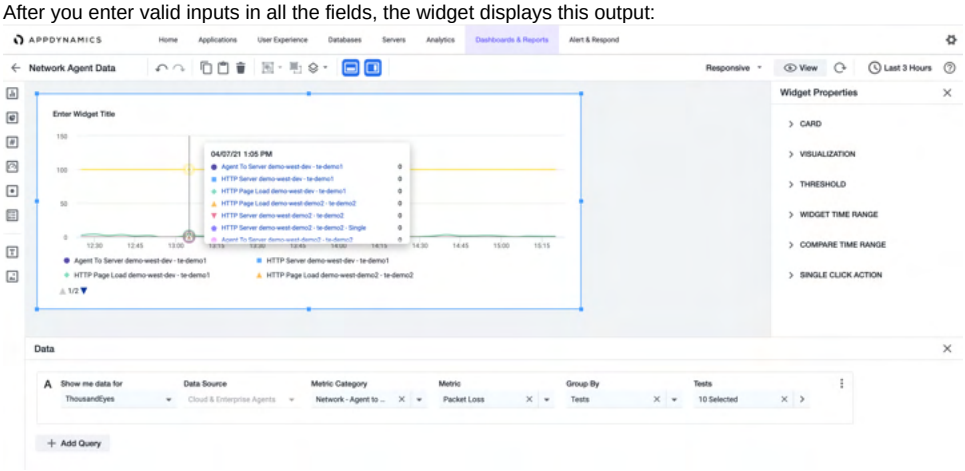
> - The Data Source option allows you to choose an agent type to gain insights about network and application performance. See agent types in ThousandEyes.
> - Dash Studio supports only one agent type, Cloud & Enterprise Agents.

6. Click **Metric Category** and select a category from the dropdown list.
7. Click **Metric** and select a metric value from the dropdown list.
8. Click **Group By** to select how to group the selected metric value. You can group the metrics using one of these options:
    - **Agent Labels** - Logical grouping of agents.
    - **Agents** - Agents installed at various locations.
    - **Tests** - Network assets to be monitored. See tests.
    - **Test Labels** - Logical grouping of multiple tests.

> The **Group By** option is available only for Time Series widget.

9. Click **Tests.**

After you enter valid inputs in all the fields, the widget displays this output:



On completing successful ThousandEyes binding, the **Powered by ThousandEyes** icon displays for Time Series widget.

- ThousandEyes test selection limit is ten per widget.
- Maximum supported time range is eight days, so you can view ThousandEyes data available over the past 8 days only.
- Time Range Comparison is not available for ThousandEyes data.

Application Monitoring

AppDynamics Application Performance Monitoring (APM), a component of the AppDynamics platform, provides end-to-end visibility into the performance of your applications.

AppDynamics works with popular programming languages such as Java, .NET, Node.js, PHP, Python, C/C++, and more, enabling you to:

- Troubleshoot problems such as slow response times and application errors.
- Automatically discover application topology and how components in the application environment work together to fulfill key business transactions for its users.
- Measure end-to-end business transaction performance, along with the health of individual application and infrastructure nodes.
- Receive alerts based on custom or built-in health rules, including rules against dynamic performance baselines that alert you to issues in the context of business transactions.
- Analyze your applications at the code execution level using snapshots.

Agent Installation

- Install the Java Agent
- Install the .NET Agent for Windows
- Install the Node.js Agent
- Install the Python Agent

Configuration

- Transaction Detection Rules
- Backend Detection Rules
- Error Detection
- Data Collectors

Monitoring Applications

- Business Transactions

Overview of Application Monitoring

Related pages:

- Flow Maps
- Metrics and Graphs

After you understand the basics of AppDynamics, you can learn how AppDynamics models application environments. The model serves as the framework around which AppDynamics organizes and presents performance information.

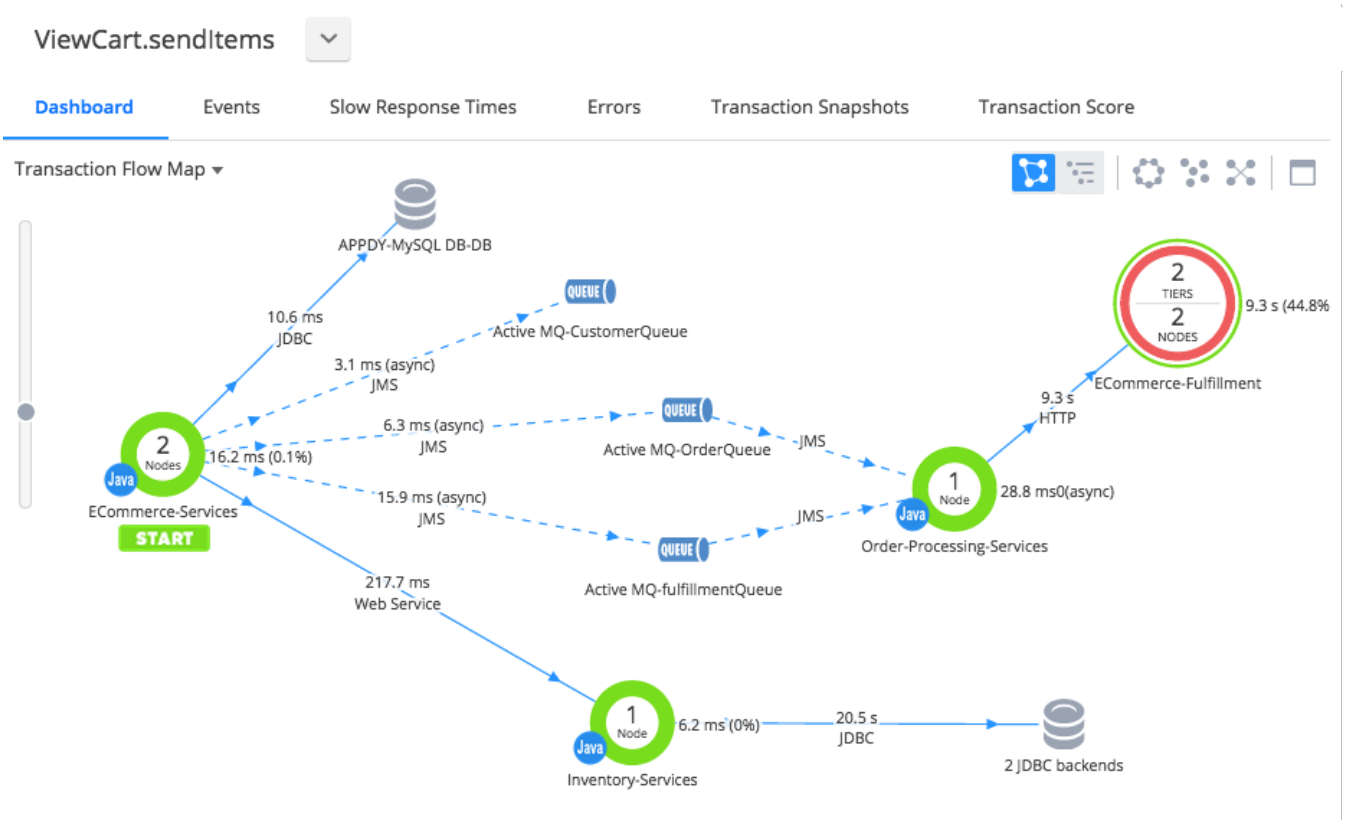
Application Model Overview

A typical application environment consists of different components that interact in a variety of ways to fulfill requests from the application's users:

- Web applications served from an application server
- Databases or other data stores
- Remote services such as message queues and caches

AppDynamics app agents automatically discover the most common application frameworks and services. Using built-in application detection and configuration settings, agents collect application data and metrics to build flow maps.

A flow map visually represents the components of your application to help you understand how data flows among the application components. For example, the business transaction flow map for a simple e-commerce application shows data flowing between web services, message queues, and databases:



Automatic detection lets you start exploring AppDynamics features quickly. As your understanding of AppDynamics matures and you identify areas unique to your environment, you can refine your application model.

Business Transactions

In the AppDynamics model, a business transaction represents the data processing flow for a request, most often a user request. In real-world terms, many different components in your application may interact to provide services to fulfill the following types of requests:

- In an e-commerce application, a user logging in, searching for items or adding items to a cart
- In a content portal, a user requests content such as sports, business, or entertainment news
- In a stock trading application, operations such as receiving a stock quote, buying or selling stocks

AppDynamics app agents discover requests to your application as entry points to a business transaction. Similar requests, such as user login, are treated as multiple instances of the same business transaction. The agents tag the request data and trace the request path as it passes from web servers to databases and other infrastructure components. AppDynamics collects performance metrics for each tier that processes the business transaction.

Because AppDynamics orients performance monitoring around business transactions, you can focus on the performance of your application components from the user perspective. You can quickly identify whether a component is readily available or if it is having performance issues. For instance, you can check whether users able to log in, check out or view their data. You can see response times for users, and the causes of problems when they occur.

Business Applications

A business application is the top-level container in the AppDynamics model. A business application contains a set of related services and business transactions.

In a small AppDynamics deployment, only a single business application may be needed to model the environment. In larger deployments, you may choose to divide the model of the environment into several business applications.

The best way to organize business applications for you depends on your environment. A leading consideration for most cases, however, is to organize business applications in a way that reflects work teams in your organization, since role-based access controls in the Controller UI are oriented by business application.

Nodes

A node in the AppDynamics model corresponds to a monitored server or JVM in the application environment. A node is the smallest unit of the modeled environment. Depending on the agent type, a node may correspond to an individual application server, JVM, CLR, PHP application, or Apache Web server.

Each node identifies itself in the AppDynamics model. When you configure the agent, you specify the name of the node, tier, and business application under which the agent reports data to the Controller.

Tiers

A tier is a unit in the AppDynamics model composed of a grouping of one or more nodes. How you organize tiers depends on the conceptual model of your environment.

Often a tier is used to a group of a set of identical, redundant servers. But that is not strictly required. You can group any set of nodes, identical or not, for which you want performance metrics to be treated as a unit into a single tier.

The single restriction is that all nodes in a single tier must be the same type. That is, a tier cannot have mixed types of agents, such as both .NET and Java nodes.

The traffic in a business application flows between tiers, as indicated by lines on the flow map, which are annotated with performance metrics.

In the AppDynamics model:

- There is no interaction among nodes within a single tier
- An application agent node cannot belong to more than one tier

Entities

An entity is any object that AppDynamics monitors, such as an application, tier, node, or even a business transaction. Entities typically have associated metrics, events, and a health status.

Historical and Live Entity Data

The Controller has an entity liveness module that tracks the "live" or "historical" status of the the four entity types: application, tier, node, and business transaction for 365+ days.

- **Historical:** Oldest time (a year before the latest Controller restart) to the latest Controller restart time
- **Live:** Latest Controller restart time until the current time

Anchor Metrics for Entities

The entities have special metrics called *anchor metrics* that are used to determine the *liveness* of the entity. This table lists the anchor metrics for each of the entities.

Entity	Anchor Metric
Application	Agent | App | Availability
Tier	Agent | App | Availability

Node	Agent | App | Availability
Business Transactions (BTs)	BTM | BTs | BT: %d | Component: %d | Calls per Minute

Liveness Status

The liveness of an entity affects the associated entities as the liveness is rolled up the hierarchy. If the entity type in the table is live, you can determine the liveness of the associated entities in the right column.

Live Entity	Liveness Status
Application	An app is alive if any tiers in this app are alive
Tier	A tier is alive if any nodes in this tier are alive
Node	Any metrics from the particular node
Business Transactions (BTs)	BT metrics, Calls per Minute

How the Controller Displays Live Entities

Based on entity liveness status of the selected time range, the Controller determines whether to count and display entities in these places:

- Flowmap
- Tier and Node list pages. This is also determined by the **Performance Data** checkboxes. See Live Entity Data in Flowmaps.
- Metric tree of the **Metric Browser**
- Custom dashboards
- AppDynamics REST APIs related to topology such as the Application Model API.

Backends

A backend is a component that is not instrumented by an AppDynamics agent but one that participates in the processing of a business transaction instance. A backend may be a web server, database, message queue, or another type of service.

The agent recognizes calls to these services from instrumented code (called exit calls). If the service is not instrumented and cannot continue the transaction context of the call, the agent determines that the service is a backend component. The agent picks up the transaction context at the response at the backend and continues to follow the context of the transaction from there.

Performance information is available for the backend call. For detailed transaction analysis for the leg of a transaction processed by the backend, you need to instrument the database, web service, or other application.

Integration with Other AppDynamics Modules

This section describes how other AppDynamics APM Platform products work with Application Monitoring to provide complete, full visibility on application health and user experience.

Application Monitoring and Infrastructure Visibility

Infrastructure Visibility provides end-to-end visibility into the hardware and networks on which your applications run. You can use Infrastructure Visibility to identify and troubleshoot problems that affect application performance such as server failures, JVM crashes, and hardware resource utilization. There are three classes of Infrastructure Visibility functionality:

- You use the Machine Agent to collect basic hardware metrics. One Machine Agent license is included with each App Agent license that you purchase. You can deploy this Machine Agent only on the same machine where the App Agent is installed. The functionality provided by the Machine Agent includes:
  - Basic hardware metrics from the server OS. For example, %CPU and memory utilization, disk and network I/O
  - Custom metrics passed to the Controller by extensions
  - Run remediation scripts to automate your runbook procedures. You can optionally configure the remediation action to require human approval before the script is started.
  - Run JVM Crash Guard to monitor JVM crashes and optionally run remediation scripts
- If you have a Server Visibility license, the Standalone Machine Agent provides this additional functionality:
  - Extended hardware metrics such as machine availability, disk/CPU/virtual-memory utilization, and process page faults
  - Monitor application nodes that run inside Docker containers and identify container issues that impact application performance
  - Tier Metric Correlator, which enables you to identify load and performance anomalies across all nodes in a tier
  - Monitor internal or external HTTP and HTTPS services
  - Group servers together so that health rules can be applied to specific server groups
  - Define alerts that trigger when certain conditions are met or exceeded based on monitored server hardware metrics
- Network Visibility monitors traffic flows, network packets, TCP connections, and TCP ports. Network Agents leverage the APM intelligence of App Server Agents to identify the TCP connections used by each application. Network Visibility includes this functionality:
  - Detailed metrics about dropped/retransmitted packets, TCP window sizes (Limited / Zero), connection setup/teardown issues, high round trip times, and other performance-impacting issues
  - Network Dashboard that highlights network KPIs (Key Performance Indicators) for tiers, nodes, and network links

- Right-click dashboards for tiers, nodes, and network links that enable quick drill-downs from transaction outliers to network root causes
- Automatic mapping of TCP connections with application flows
- Automatic detection of intermediate load balancers that split TCP connections
- Diagnostic mode for collecting advanced diagnostic information for individual connections

Application Monitoring and Browser Real User Monitoring

When you add End-User Monitoring to Application Performance Management, you can correlate business transaction performance to the user experience for those transactions. See Correlate Business Transactions for Browser RUM.

If server app agents run on the applications that serve your browser applications, you can further configure the app server agents to inject JavaScript agent into the code that runs on the browser. Access the settings to configure injection in the Applications Configuration page. See Automatic Injection of the JavaScript Agent and Assisted Injection.

Application Monitoring and Database Visibility

In Application Monitoring, a database called by an instrumented node is considered a remote service. You can get a significant amount of information on the interaction between the application node and database, but not from the database server perspective. When using Database Visibility with Application Monitoring, you can drill down to detailed database performance information directly from application flow maps. See Access Database Visibility from Application Monitoring Views.

Application Monitoring and Analytics

For those times when tracing application code does not provide enough clues to track down the cause of a problem, AppDynamics provides visibility into the transaction logs that can be correlated to specific business transaction requests. Log correlation visibility requires a license for both Transaction Analytics and Log Analytics. See Business Transaction and Log Correlation.

Install App Server Agents

Related pages:

- Agent and Controller Compatibility
- SELinux Installation Issues

Instrumenting an application adds the AppDynamics application agent (app agent) into the runtime process of the application. This page provides an overview of how to install agents in the application environment.

> All use cases for App Server agents are supported on AWS Outposts similarly as in other deployment options.

Agent Installation Quick Start

The **Getting Started Wizard** in the AppDynamics Controller walks you through the steps to download and configure an agent for your application. This section provides an overview of how to use the wizard.

The wizard generates a fully configured agent, including a node identity. You should run the wizard for each application instance you want to monitor, or until you understand how to customize the configuration manually.

Before Installing an Agent

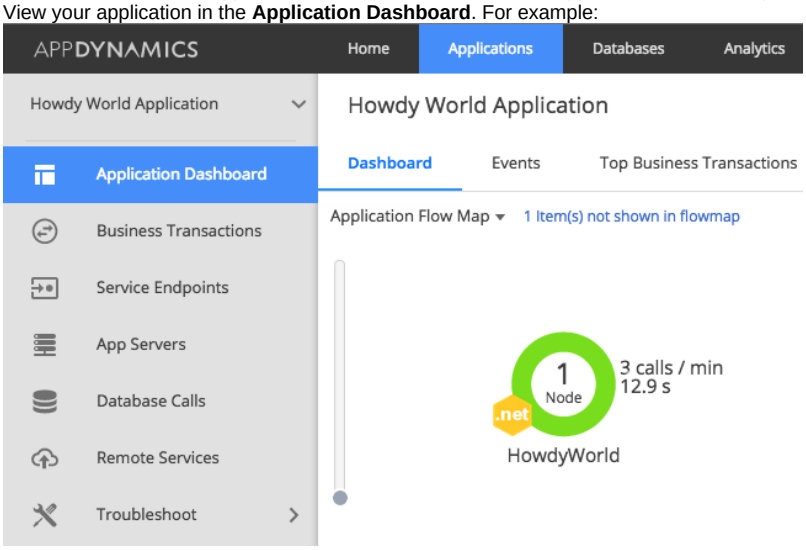
Ensure that:

- The agent supports your application environment. See App Server Supported Environments.
- You can access the application host with a user account that has sufficient privileges to install the agent and—for certain installation types—restart the application.
- The application host has network connectivity to the Controller. Proxies or firewalls on the network between the agent and Controller may require additional configuration.

Use the Getting Started Wizard

After verifying the requirements, follow the workflow as guided by the wizard:

1. Open the wizard from the home page in the Controller UI by clicking **Getting Started**.
2. Enter the configuration values for the application instance as described in the wizard. You name the node and indicate the tier and business application to which it will belong. If you are not sure of the best values to use, you can use temporary names and change them later.
3. When finished, download the agent. How you download the agent varies by agent type. In most cases, the agent comes as a ZIP file that you extract and install in the startup routine of your server. For other types of agents, you may need to modify the instrumented source code, for example, by including the agent library. The wizard walks you through it for each agent type.
4. Install the agent on your app server.
5. Apply load to your application. If you are instrumenting a production application, this will happen with customer interaction. Otherwise, create some test load on your application. The agent instruments the application code and reports metrics back to the Controller.
6. View your application in the **Application Dashboard**. For example:



The wizard makes it easy to perform a basic agent installation with minimally required settings, such as the Controller host and port, SSL, application name, and tier name. For advanced options or more complicated scenarios, you need to perform a manual installation of the agent. For more information, see the agent-specific link in the following section.

Agent Installation by Type

For detailed installation information by agent type, see these topics:

- Java Agent
- .NET Agent
- Node.js Agent
- PHP Agent
- Python Agent
- Serverless APM for AWS Lambda
- Apache Web Server Agent
- C/C++ SDK
- Go Language Agent
- IBM Integration Bus Agent
- Machine Agent
- SAP Monitoring Using AppDynamics
- Getting Started with Ruby Agent

For automated deployment guidelines, see Controller Deployment.

Tier and Node Naming Guidelines

The maximum length of a tier name is 100 characters, and the maximum length of a node name is 225 characters for Linux, and 500 characters for all other operating systems. In your tier, node and application names, you should avoid certain special characters. The characters you can use are listed on the Tiers and Nodes page.

Generally, node names should be unique. However, nodes that reside on different tiers and different machines (hosts) can have duplicate node names.

Within a business application, node names *should always be unique* in the following use cases:

- If the nodes reside on the same tier, but on different machines
- If the nodes reside on the same machine, but on different tiers
- Node names and machine names must unique. When a node is registered to a Controller, it is associated with the machine it is on, and cannot be moved to another machine without changing the node name.

If the nodes names are the same in the aforementioned use cases, the nodes will not register or report successfully.

Nodes on proxy-based agents can have duplicate names on the same tier and same machine.

To rename an application, see Business Applications.

For node naming conventions by agent type, see the installation page for that agent, such as Node.js Agent or PHP Agent.

App Agent Network Bandwidth Usage

These guidelines can help you estimate how much bandwidth overhead will be added to your environment by deploying AppDynamics agents.

Keep in mind that the exact bandwidth required for a deployment varies greatly depending on the nature of your application, the agent configuration, and the AppDynamics features you use. The best way to determine the bandwidth overhead is to test the AppDynamics deployment in a staging environment that mirrors as closely as possible the live operating environment.

1. The approximate bandwidth used by a single Java Agent with the default configuration is five to eight kilobytes per second.
2. Scaling of additional agents is linear. That is, if the average bandwidth usage for an app agent in a given deployment is five kilobytes, adding 10 means that bandwidth usage will be 5 × 10, or 50 kilobytes.
3. While the average bandwidth used is five to eight kilobytes per second, agents send data to the Controller in bursts rather than as a steady stream of data. When testing bandwidth usage, to determine the actual kilobytes per second used by an agent, you need to observe and average out traffic over the course of at least several minutes.
4. When testing bandwidth usage in the environment, keep in mind that different types of tiers will generate a different amount of load. For instance, a database tier tends to generate more traffic between the agent and Controller than an application server tier. For the best possible estimate, the test should take this into account.

Agent License Considerations

For agent-based license units—including APM, database monitoring, and server monitoring—licenses are allocated to the first agents that register with the Controller up to the licensed limit. For example, with five agent licenses, the first five agents that connect to the Controller are licensed.

Agent licenses are not bound to a particular machine or application. Therefore, a transfer of an agent-based license can be accomplished simply by shutting down the application that runs the licensed agent—uninstalling the agent if the application will need to be restarted—and starting up the new application with the newly installed agent. Once the agent disconnects, a license unit is freed for the second agent.

For application monitoring agents (Java, .NET, Node.JS, and so on), a license validation cycle runs every five minutes. It causes the agents to connect and validate that available license units are not exceeded. Historical usage data is captured during this cycle and stored as five-minute usage data. Every hour, the five-minute usage data is rolled up in hour usage data, which includes data on license unit usage. The five-minute data is purged after a few hours.

Container Installation Options

This page describes different options you can use to instrument containerized applications with an AppDynamics App Server Agent.

You can use these on-premises and cloud deployment platforms to deploy an application as a Docker container image:

- Kubernetes
- Cloud containerized platforms, such as Amazon ECS and Azure Container Instances
- Docker Swarm
- Hosts running Docker Engine

Each of these platforms supports different options to instrument a containerized application with an App Server Agent.

Kubernetes Platforms

For applications running on Kubernetes platforms (such as: OpenShift, Rancher, EKS, AKS, and GKE), you can use these options to instrument applications:

- Auto-Instrument Applications with the Cluster Agent
- Use Init Containers to Instrument Applications
- Use a Dockerfile to Instrument Applications

AppDynamics recommends auto-instrumentation because it provides the simplest operational experience. It avoids the need to change individual application images or deployment specs. It centralizes App Agent configuration to a single location and includes the App Server Agent version. This greatly simplifies initial rollouts of App Server Agents and subsequent upgrades. See Auto-Instrument Applications with the Cluster Agent.

If you cannot use auto-instrumentation, we recommend using init containers as the manual option to copy agent files to the application container at deploy time. See Use Init Containers to Instrument Applications.

You can also use Dockerfiles to copy the agent files to the Docker image at build time. See Use a Dockerfile to Instrument Applications.

Non-Kubernetes Platforms

For non-Kubernetes environments (such as: Docker Swarm, Amazon ECS, and Azure Container Instances), using Dockerfiles is the best option. See Use a Dockerfile to Instrument Applications.

Depending on the environment, you may be able to install the App Server Agent without changing the application image. For example, you can use a Docker shared volume to provide a running container access to the App Server Agent files. Amazon ECS supports container dependencies which provide a way to reference a second container at startup. You can then use the second container to copy the App Server Agent files to the application container.

Instrument Kubernetes Applications Manually

When Auto-Instrument Applications with the Cluster Agent is not available, you can manually instrument Kubernetes applications using one of these methods:

- Use Init Containers to Instrument Applications
- Use a Dockerfile to Instrument Applications

To configure agents for manually instrumented applications, see Best Practices to Configure Agents in Kubernetes.

To establish APM correlation between the Cluster Agent and manually instrumented applications, see Manually Configure App Agents to Correlate with the Cluster Agent.

Use Init Containers to Instrument Applications

This page describes how to use the init containers option to copy agent files into a Kubernetes application container at deploy time.

> When the Cluster Agent is installed in a cluster, AppDynamics recommends Cluster Agent auto-instrumentation. See Auto-Instrument Applications with the Cluster Agent.

The init containers option is available in Kubernetes environments used to run additional containers at startup that helps initialize an application. Once the init containers have completed their initialization tasks, they terminate but leave the application container(s) running. For the App Server Agent installation, init containers are used as a delivery mechanism to copy the agent files into the application container at deploy time. See Init Containers Option in Kubernetes.

Copying the agent files at deploy time (instead of at build time) provides advantages over explicitly copying the agent files and dependencies into the application image. The init containers option simplifies the image build process because:

- You do not need to update each application's Dockerfile to copy the agent files.
- You do not need to rebuild the application image for agent upgrades.

See the language-specific container installation page for how to use an init container:

- Install the Java Agent in Containers
- Install the .NET Agent for Linux in Containers
- Install the Node.js Agent in Containers

Kubernetes Init Container Deployment Spec Example

In the Kubernetes deployment spec example for a Java application, the init container is a second Docker image that contains the App Server Agent files. Because this Docker image is built separately from the application image, you do not need to rebuild the application image when you add or upgrade the App Server Agent.

```
kind: Deployment
spec:
  containers:
  - name: java-app
        image: repo/java-app:v1
    volumeMounts:
    - mountPath: /opt/appdynamics
      name: appd-agent-repo
  initContainers:
  - command:
    - cp
    - -ra
    - /opt/appdynamics/.
    - /opt/temp
    name: appd-agent
        image: docker.io/appdynamics/java-agent:20.6.0
    volumeMounts:
    - mountPath: /opt/temp
      name: appd-agent-repo
  volumes:
    - name: appd-agent-repo
      emptyDir: {}
```

Best Practices to Configure Agents in Kubernetes

This page describes best practices to use when configuring App Server Agents in a Kubernetes environment and manually instrumenting applications using init containers or a Dockerfile.

> This page does not apply to applications that use the Cluster Agent auto-instrumentation to configure agents. See Auto-Instrument Applications with the Cluster Agent.

You can configure App Server Agents in Kubernetes using environment variables. Depending on the use case, you have three options to set environment variables:

- Use ConfigMaps to Configure the App Server Agent
- Use Secrets for the Controller Access Key
- Set Application-Specific Configuration in the Deployment Spec

See the language-specific container installation page to implement these best practices:

- Install the Java Agent in Containers
- Install the .NET Agent for Linux in Containers
- Install the Node.js Agent in Containers

Gather Login Credentials

To access AppDynamics, you need your login credentials and the URL from where you can access your organization's AppDynamics Controller(s). If you do not have this information, contact your AppDynamics administrator.

Use ConfigMaps to Configure the App Server Agent

When instrumenting a container running in Kubernetes, each App Server Agent requires that you set environment variables to configure:

- Connection parameters
- Application metadata
- Agent behavior

You can use ConfigMaps to store an application's environment variables in a Kubernetes object within the scope of a namespace. ConfigMaps are an optimal twelve-factor method used to manage agent configuration shared across multiple Kubernetes applications within a namespace.

Controller credentials configuration is stored in a single ConfigMap, and shared with each application in the namespace that reports to that Controller. If you use multiple Controllers across different environments, such as development, test, and production, you can store different ConfigMaps in the namespaces associated with those environments.

Use Secrets for the Controller Access Key

The Controller access key is another configuration that you can pass to App Server Agents as an environment variable. Sensitive data is stored in a Kubernetes namespace using a Secret, rather than a ConfigMap. You can use Kubernetes Secrets to obfuscate values rather than manipulate them in plaintext.

Set Application-Specific Configuration in the Deployment Spec

The AppDynamics Controller application tier name identifies a service that reports under a particular AppDynamics application. An application tier name is an example of agent configuration that is different for each Kubernetes application but typically does not vary across environments and namespaces. Application-specific configuration, similar to the tier name, is easier to define in the Kubernetes deployment spec directly.

Verify the Environment Variables

After you set the agent environment variables, you can verify that they were added to your application.

To verify the environment variables:

1. Create a ConfigMap.
2. Create a Secret.
3. Create an environment variable in the deployment spec.
4. Restart the application container.
5. Log in to the container using `kubectl exec`:

   ```
   kubectl -n ecommerce exec -it <pod name> /bin/sh
   ```

6. List the AppDynamics environment variables available in the container to confirm they are defined and have the correct values:

```
env | grep APPD
APPDYNAMICS_AGENT_APPLICATION_NAME=<value>
APPDYNAMICS_AGENT_ACCOUNT_NAME=<value>
APPDYNAMICS_CONTROLLER_HOST_NAME=<value>
...
```

Use a Dockerfile to Instrument Applications

This page describes how to use a Docker file to copy the App Server Agent files to the Docker image.

> When the Cluster Agent is installed in a cluster, AppDynamics recommends Cluster Agent auto-instrumentation. See Auto-Instrument Applications with the Cluster Agent.

A common method to instrument a containerized application is to include the AppDynamics App Server Agent when building the application image. You add a `COPY` command to the Dockerfile to copy the agent files to the image. The `COPY` command copies the application binary to the Docker container image. If an App Server Agent upgrade is required, you must rebuild the image with the new agent files.

See the language-specific container installation page for instructions on how to use a Dockerfile:

- Install the Java Agent in Containers
- Install the .NET Agent for Linux in Containers
- Install the Node.js Agent in Containers

Dockerfile Example

In this example for a Java application, the Java Agent files in the `AppServerAgent` folder are copied to the application image and the application JAR file. The agent environment variables are set before the start script runs.

```
FROM openjdk:8-jre-slim

COPY myapp.jar /app
COPY AppServerAgent/ /opt/appdynamics

ENV APPDYNAMICS_AGENT_APPLICATION_NAME=<value>
ENV APPDYNAMICS_AGENT_TIER_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=<value>
ENV APPDYNAMICS_CONTROLLER_HOST_NAME=<value>
ENV APPDYNAMICS_CONTROLLER_PORT=<value>
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED=<value>
ENV APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME=true
ENV APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME_PREFIX=<value>

COPY ./startup.sh /startup.sh
RUN chmod +x /startup.sh
ENTRYPOINT ["/bin/bash", "/startup.sh"]
```

Agent-to-Controller Connections

AppDynamics app agents need to connect to an AppDynamics Controller to retrieve configuration data and send back information about the monitored environment. This page provides information about the connections between the agents and Controller.

Connection Settings

The connection between the agent and Controller is a one-way connection initiated by the agent. Therefore, you only need to configure connection settings in the agent.

To connect an agent to the Controller, you must provide this information:

- Controller host: The hostname of the Controller to connect to. Agents may connect directly to the Controller or through a proxy.
- Controller port: The port on which the Controller listens for agent traffic. Agents use port 443, which is the same port as the browser connection to the Controller UI.
- Account name: The name of the account listed in the Controller. A single tenant Controller has two accounts, a default account name, customer1, and an internal system account. For most connections, use the default account name.
- Global Account name: The Global Account name is used for certain connections, such as to the Events Service or from the Analytics Agent.
- Account access key: A unique key associated with the Controller account. See Find Your Account and Access Key.
- SSL enabled: If the agent should connect using SSL.

If you downloaded the agent through the Getting Started Wizard in the Controller, the Controller host, port, and account settings are already configured.

To connect the agents in your environment to a SaaS Controller or an on-premises Controller through a proxy, configure the agent properties to use the host and port settings of the Controller. For an example, see Java Agent Configuration Properties for proxy settings descriptions.

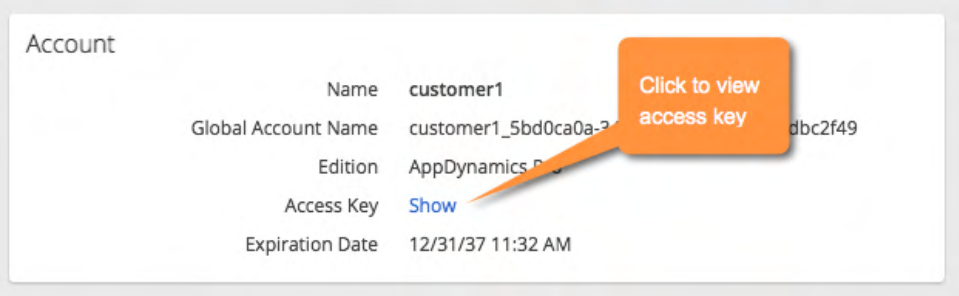
To connect to SaaS Controllers from agents in environments that limit outbound connections, set firewall rules that permit access to AppDynamics SaaS platform components. For a list of SaaS IP addresses, see SaaS Domains and IP Ranges.

Find Your Account Name and Access Key

To configure the agent manually rather than through the Agent Download Wizard, set the Controller host and port, account name, and account access key settings manually. If you have an Admin account, you can find your account name and access key in the AppDynamics Controller UI. If you are not an admin, ask your administrator for your access key.

To view your account name and default access key:

1. Log in to the Controller UI as a user with view license permissions.
2. Click the gear icon and select **License**.
3. Click on the Account tab. The account name appears next to the **Name** label. The account name is customer1 in a single tenant, on-premises Controller; the account name varies on SaaS Controllers.
4. Click **Show** next to the **Access Key** label to reveal the account default access key setting for this instance. Use this value as the Account access key setting in agent settings.



If you create license rules in addition to the default rule, the access key for each rule appears in the Rules tab.

Secure the Connection

The .NET Agent uses the settings in the container to negotiate the SSL protocol with the Controller. Normally you do not need to configure the security protocol for the .NET Agent.

For the Java Agent, see the Agent and Controller Compatibility for a list of the default security protocols for different versions of the Java Agent.

If the default security protocol for your version of the Java Agent is incompatible with the Controller or an intervening proxy, pass the `Dappdynamics.agent.ssl.protocol` system property to set the protocol to one of these security protocols:

- SSL
- TLS
- TLSv1.2
- TLSv1.1

Use the following format:

```
java -javaagent:<agent_home>/javaagent.jar ... -Dappdynamics.agent.ssl.protocol <protocol> ...
```

Controller-specific security considerations vary between SaaS and on-premises Controllers, as described below.

On-premises Controller Secure Connections

An on-premises Controller has both an active secure (HTTPS) port and an HTTP port. Agents can use either port to connect to the Controller. By default, the certificate used for the secure connection is a self-signed certificate. The .NET Agents cannot connect on a secure port that uses a self-signed certificate, so you must apply your own certificate to the secure port. App Agents connecting to an AppDynamics SaaS Controller must use an HTTPS connection.

To implement SSL for the Controller-agent connection:

- Set the application server primary port to the SSL port, 8181 by default. See Port Settings.
- Install a trusted certificate. See Controller SSL and Certificates.
- Configure your agents for SSL. See App Agent Security and Machine Agent Security.

SaaS Controller Secure Connections

SaaS Controllers require the use of SSL. Therefore, you only need to enable SSL in the configuration settings for your agents and connect them to the secure Controller port, 443. See App Agent Security and Machine Agent Security.

Using AWS PrivateLink with a SaaS Controller

Some customers may have a policy where they do not want agent traffic exposed to the public Internet even though the agent traffic is encrypted. AppDynamics customers can leverage Amazon Web Services (AWS) inter-region PrivateLink to privately connect their cloud-based applications between Virtual Private Clouds (VPC) and AppDynamics SaaS and on-premises Controllers. In this scenario, all agent traffic flows across Amazon's private network, even if VPCs reside in different AWS regions. Before you can ingest data from the AppDynamics endpoint to your AWS VPCs and AWS Accounts using AWS PrivateLink, you must complete several set up steps. See How do I use AWS PrivateLink to connect to an AppDynamics SaaS Controller?

App Agent Security

To configure your agents for SSL, set these SSL-related properties:

- Set `controller-ssl-enabled` to `true`.
- Set the `controller-port` to the correct value for either on-premises or SaaS Controller.

In multi-tenant and SaaS environments, App Agents authenticate themselves to the Controller using the required account name and account access key values set in the connection properties configuration file.

Standalone Machine Agent Security

For information on the security settings related to the Machine Agent connection to the Controller, see Machine Agent Configuration Properties.

Verify the Connection

You can verify that an app agent is reporting to the Controller from the **Tiers & Nodes** list in the Controller UI. See Tiers and Nodes. You can also verify the connection from the AppDynamics Agents page, under the gear icon, see Manage App Agents.

In the **Tiers & Nodes** pages, the **App Agent Status** column indicates the status of the agent connection to the Controller. A green arrow icon indicates active connected agents, a red down arrow indicates an agent that has been previously recognized but is not currently connected.

If the agent is not reporting to the Controller, see troubleshooting information:

- Troubleshooting Java Agent Issues
- Troubleshoot .NET Agent Issues
- Dynamic Language Agent Proxy
- Resolve PHP Agent Installation Issues

If traffic is not being properly correlated between tiers, make sure that any network components, such as load balancers or routers that sit between monitored nodes, are preserving the AppDynamics correlation header from HTTP traffic.

Agent-Controller Communication Intervals

Each AppDynamics agent has multiple communication channels for different purposes that initiate connections to the Controller independently, and at different time intervals.

- The agent configuration channel queries the Controller for any new configuration changes, and downloads these changes when available, every 60 seconds.
- The agent metric channel posts all new periodic metrics, including JMX, Windows performance counters, and business transaction metrics to the Controller every 60 seconds.
- If there are new business transactions that have not been seen before by the agent, they are posted to the Controller for registration every 10 seconds.
- If the agent has collected any new snapshots or events, they are posted to the Controller every 20 seconds.

Information Sent to the Controller

This table shows the types of information that is collected by an application agent and sent to the Controller.

Metric	Description
Server Request GUID	A unique GUID identifying a request, known as a Business Transaction, in the form of `xxxxxxxx-xxxx-xxxx- xxxx-xxxxxxxxxxxx` where x is a lower-case hexadecimal digit.
Application Entry Points	Transaction entry points are identified among various frameworks and technologies. This includes Servlet URIs, Strut Action and Method name, Spring Bean Name and Method Name, JMS queue destination or listener name, Web Service/WCF action/operation name, PHP Virtual Name, and more.
Application Exit Points	Transaction exit points are identified among various frameworks and technologies. This includes: HTTP URL end points, JMS queue /destination, type, and vendor; database URL endpoint and vendor/version, web service Service Name, cache name and URL endpoint.
Performance Metrics	In general, for each monitored metric in AppDynamics, a response time, call rate, and error rate are collected. Each of these metrics also have an automatic baseline derived for each respective metric value.
Thread Stack Traces	Code level method execution metrics that comprise the application request are collected. This data includes the class and method that executed and the line number within the source code. Note that less than 5% of transactions will have stack traces collected. Errors /Exceptions and stack trace of error data will be collected.
SQL Query Values	If assigned with administrative permissions, SQL query variables within a query can be enabled, collected, and viewed. Note that the parameter data is collected for less than 5% of transactions. Configuration changes are logged in an audit log that is available for security review.
Data Collectors	If assigned with administrative permissions, data in the form of HTTP values or method payload can be collected and viewed. Note that a specific data collectors and code payload accessors require explicit configuration to be collected. Note, data is collected for less than 5% of transactions. Configuration changes are logged in an audit log that is available for security review.
Hostname	The DNS hostname of the machine (virtual/physical) from where the agent is installed and reporting monitoring data.
IP Address Internet Protocol (IP)	IP Address Internet Protocol (IP) address of the machine (virtual/physical) where the agent is sending monitoring data from.
CPU Usage	The value of CPU that is consumed on the monitored machine/virtual machine.
Memory Usage	The value of physical memory that is consumed on the monitored/virtual machine.
Network I/O Usage	The value of network I/O that is consumed on the monitored machine/virtual machine.
Disk I/O Usage	The value of disk I/O that is consumed on the monitored machine/virtual machine.
JVM Performance	JVM Heap Usage, JVM Memory Pools Settings, Garbage Collection performance, JVM System/Start-up Options, MBean metric values (for example, connection pool names and metric values, such as active connections, maximum connections, and so on)

Blitz Load Profile

Blitz is a horizontally scalable data processing platform for SaaS deployments. It collects metric data from agents, which it then aggregates and stores.

The 10M metrics/min Blitz load profile includes the following agents and churn information:

- Active load 10MM with 24K nodes. Total registered metrics is 40M.
- Node distribution:
    - DotNet = 3K
    - SIM Machine Agents OR Docker Containers = 30K
    - DBMon Data Collectors = 1K

    - Java Nodes = 16K
    - EUM Browser Apps = 60

- Java Node Churn: 1K/hr
- Either SIM or Docker Churn

    - Sim Node Churn = 40/hr (1% of 4K SIM nodes)
    - Docker Churn = 200 containers/hr

- Node purger enabled with hard-limit of 4K and soft-limit of 10K
- SIM node purger enabled with a deletion max limit of 300/hr

Agent Installer

Deployment Support

> The Agent Installer requires microservices configuration performed by AppDynamics.

The AppDynamics Agent Installer simplifies deployment to instrument your applications faster. You can manage applications instrumented with the Agent Installer with minimal code changes in Monitoring Settings.

The Agent Installer:

- Deploys Infrastructure, Java, and Machine Agents, and is compatible with Linux

  > The Infrastructure Agent is in beta release only.

- Automatically instruments applications
- Assigns unique names to tiers and nodes

You can deploy other agents using the Getting Started Wizard.

Agent Installer Overview

The Agent Installer works with these items:

- *Agent Installer* - Executable installer inside the `appdynamics-zero-agent-<version>.zip`. file (representing the Agent Installer Platform). The Agent Installer installs the Agent Installer Platform with Infrastructure, Java, and Machine Agents on a system. You access the installer from the Controller UI.
- *Decorator* - Library responsible for automatically instrumenting new processes with AppDynamics APM agents. The library auto-instruments the application and auto-names tiers and nodes for the Controller.
- *Agent Installer Platform* - Software bundle that manages the Decorator, Infrastructure Agent, Java Agent, and Machine Agent. Enables automatic instrumentation and reports the status of various processes to the Controller UI. Collective term for the decorator, agent `daemon`, agent binaries.
- *Downloader* - Script (`zero-agent.sh`) that downloads individual zip files containing the Infrastructure, Java, and Machine (if applicable) Agents, and Agent Installer Platform.

Agent Installer Requirements

The Agent Installer requires the following components, permissions, and supported environments.

AppDynamics Components

- The Agent Installer requires SaaS Controller => 20.6.0.
- You also need sufficient APM licenses to use the Java and Machine Agents. No additional license is required for the Agent Installer Platform or the Infrastructure Agent.

Configure and Unblock Your Firewall

You may need to configure your firewall rules to allow outgoing traffic to certain URLs including:

- Access to your AppDynamics Controller: `<customername>.saas.appdyanamics.com/*` to allow APM traffic.
- Access to the AppDynamics download files site: `download-files.appdynamics.com` to download the agent binaries.
- (If Infrastructure Agent is installed as a Docker container) Access to Docker containerization software: `*.docker.io`.

> You can run the Infrastructure Agent in a container or directly on the host. If Agent Installer detects an operational Docker runtime, it attempts to install the Infrastructure Agent in the container mode whether or not you have configured the firewall to allow Docker Hub access.

Agent Installer Permission

> To configure access and roles, you must either be the AppDynamics Account owner, or have Administrator permissions. Additionally, Cloud Native Visualization requires configuration changes in the AppDynamics SaaS platform. The configurations began rolling out to SaaS Controllers on October 28, 2020.
>
> To visualize Infrastructure Agent entities, you need **View Infrastructure Entities** account-level permission. See Configure Cloud Native Visualization Permissions.

To use the Agent Installer, you need **Install Agent** account-level permission and at least one of the following:

- Any default role (except for the Analytics Administrator role)
- Any application-level permission
- **Execute Workflow** account-level permission

Install Agent permission is not added to any default role. See Roles and Permissions.

Supported Environments

This table lists the Agent Installer supported environments. JVM and Application Server requirements only apply if you install the Java Agent. The Agent Installer does not support Windows installations.

Agent Installer Supported Environments	
Operating System	Linux (64 bit). Fully tested flavors: • CentOS 7, 8 • Rhel 7, 8 • Ubuntu 18.04 • Fedora 31 • Debian 10 Other Linux operating systems and versions should work but are not certified by AppDynamics.
JVM	• Open => JDK 1.6 • Oracle => JDK 1.7 • IBM JDK => 1.6
Application Server	• Apache Tomcat • Jboss Wildfly • GlassFish • Websphere • Weblogic

See Java Supported Environments and Machine Agent Requirements and Supported Environments for version compatibility.

Agent and Process Limitations

This table lists the active agent registrations, process, and process group limitations for the Agent Installer:

Agent	Maximum Per-Account Limit
Active agent registrations	1000
Process	**Maximum Per-Account Limit**
Managed processes	10,000
Unmanaged processes	10,000
Managed processes in a single installation	100
Unmanaged processes in a single installation	100
Process Group	**Maximum Per-Account Limit**
Managed process groups	1000
Unmanaged process groups	1000

Managed process groups in a single installation	100
Unmanaged process groups in a single installation	100

Available Agents with the Agent Installer

The Agent Installer deploys the Agent Installer Platform, which downloads monitoring agents to your machine. You can install:

- Infrastructure Agent >= 21.1.0
- Java Agent >= 4.5.19
- Machine Agent >= 20.3.0

Use the Agent Installer to Deploy an Agent

To use the Agent Installer to deploy an agent:

1. From the Controller UI, select **Home** > **Agent Installer**.
2. From the **Specify Application to Deploy to** dropdown, select an existing application, or select **New application** and enter its name.

   > Application names cannot contain a single quotation mark (').

3. Download and run the Agent Installer using either an express installation or a custom installation method.

Express Installation Method

> The express installation method is not available for the Infrastructure Agent.

1. The **Express installation** method is selected as the default. With minimal effort, you can download and install the latest version of all available agents.
2. Copy and run the first command to download the latest available agents.
3. Select (top right corner of the second command) to copy and run the second command to install the agents. Additionally, you can select **Show command** to reveal the full command with your access key.
4. Restart the application processes you want to monitor.
5. Click **Next** to continue with the instrumentation.

After you finish installing the agents, you are redirected to the Monitoring Settings tab to view instrumented tiers and nodes.

Custom Installation Method

1. Select **Custom installation**.
2. Select the **Infrastructure**, **Java**, or **Machine Agent**(s) you want to install.

   > You must select at least one agent to proceed with the installation.

3. The default version displays next to the selected agent(s). You can edit the version from the corresponding dropdown. A command based on the agent(s) you selected is generated.
4. Copy and run the command into your terminal or automated tools.
5. Determine how to run the Agent Installer by setting user permissions:
   - Select **Instrument processes for all system users** (requires `sudo` access) to run the Agent Installer with `sudo` permission and enable the Agent Installer Platform for *all* users on the host.
   - Select **Instrument processes for an individual user** to run the Agent Installer without `sudo` permission and enable the Agent Installer Platform for the *current* user only.
     See Sudo vs. Non-Sudo Access for more information.
6. After confirming the user installation permissions, select (top right corner of the command) to copy and run the command. To reveal the full command with your access key, select **Show command**.

   > When you run the command on a designated host, the agent files download onto that host *only*. To install agents on multiple hosts, select Run the Agent Installer on Multiple Hosts.

7. Restart the application processes you want to monitor.
8. Click **Next** to continue with the instrumentation.

After you finish installing the agents, you are redirected to the Monitoring Settings tab to view instrumented tiers and nodes.

Sudo Versus Non-Sudo Access

You can run the Agent Installer with or without `sudo` permission.

> AppDynamics recommends using the `sudo` command to install the agents for all users in your system.

This table describes the differences between `sudo` and `non-sudo` installations:

	sudo Installation	**Non-sudo Installation**
Description	Installs the agents on all supported processes for all users in your system.	Installs the agents for the current user only.
Automatic Instrumentation Process	By default, integrates with `systemd` to ensure the agents always run. See Customize the Agent Installer to override this behavior.	Auto-instruments processes that are started by the installing user, running under a Linux shell such as `bash`.

Run the Agent Installer on Multiple Hosts

You can download the Agent Installer once and run on multiple hosts. To install the agent bundle across multiple hosts, distribute the binaries to all applicable machines.

For example, these steps show how to move files across hosts using the `tar` command.

1. Download the agent bundle (see Use the Agent Installer to Deploy an Agent).
2. Distribute the Agent Installer to multiple hosts.
    a. Make sure you are in the same directory in which you downloaded the agent bundle.
    b. Use the `tar` command to place the script in a single file:

    ```
    tar cvf zero-agent.tar *
    ```

    c. Copy the file to multiple hosts:

    ```
    scp zero-agent.tar <target host>:<directory>
    ```

    d. Extract the archived script in the same directory:

    ```
    tar xvf zero-agent.tar
    ```

3. Complete the Agent Installer deployment using the custom installation method.

Upgrade the Agent Installer

Before you can upgrade the Infrastructure, Java, and Machine Agents (which run through the Agent Installer), you must first uninstall your current agents. In the terminal, navigate to the directory where the Agent Installer Platform is installed and run this command:

```
<install-directory>/bin/zeroctl uninstall
```

You can now install the new versions of the Infrastructure, Java, and Machine Agents with the Agent Installer.

Customize the Agent Installer

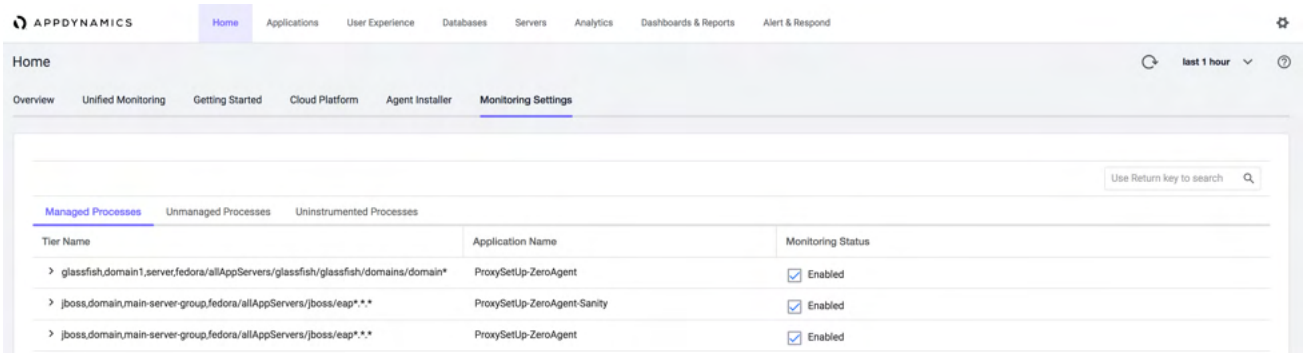
See Customize the Agent Installer to modify the agent configuration.

Monitoring Settings

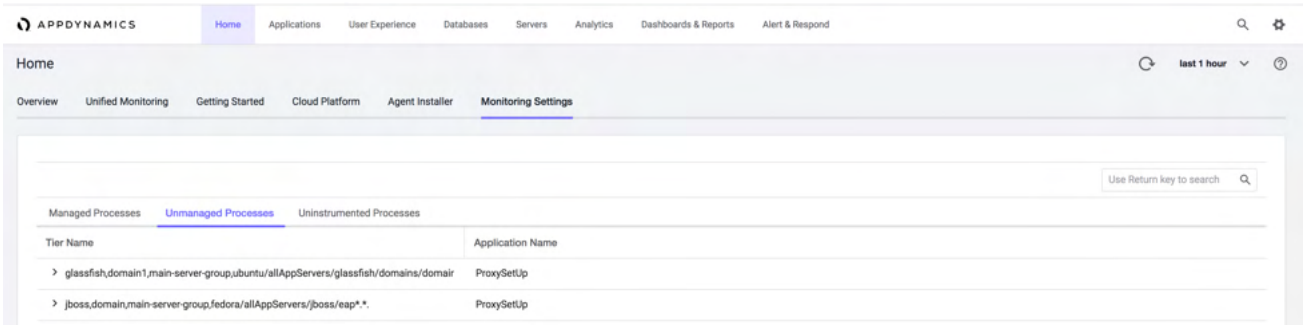
This page describes how to use Monitoring Settings to monitor and update the processes instrumented by the Agent Installer.

In the Controller UI, select **Home** > **Monitoring Settings**. The Monitoring Settings page is an interface that displays tiers, nodes, and applications associated with the Agent Installer. The Monitoring Settings page contains three tabs:

- Managed Processes
- Unmanaged Processes
- Uninstrumented Processes



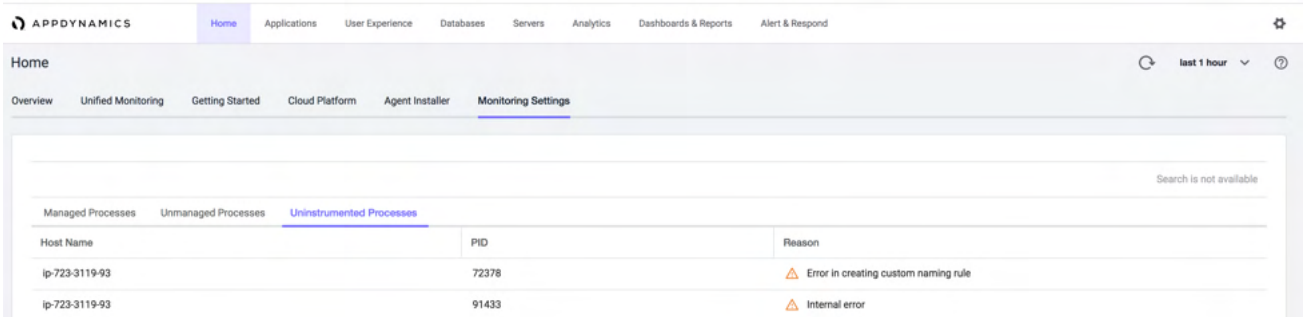
You can view and scroll through pages of processes and tiers where tiers are listed by their associated application. For example, a tier may be monitored by a Java Agent configured with Agent Installer.



From both the Managed Processes and Unmanaged Processes tabs:

- By default, all nodes under a tier are collapsed. To expand the tier and review its nodes, select the arrow next to the **Tier Name**.
- Search on a tier name, application name, or node name by entering the search string in the upper-right corner **Search** box and pressing Return. To facilitate searching, you can right-click an application name, and then select **Copy application name** from the popup to copy that name to the clipboard and then paste into the **Search** box.

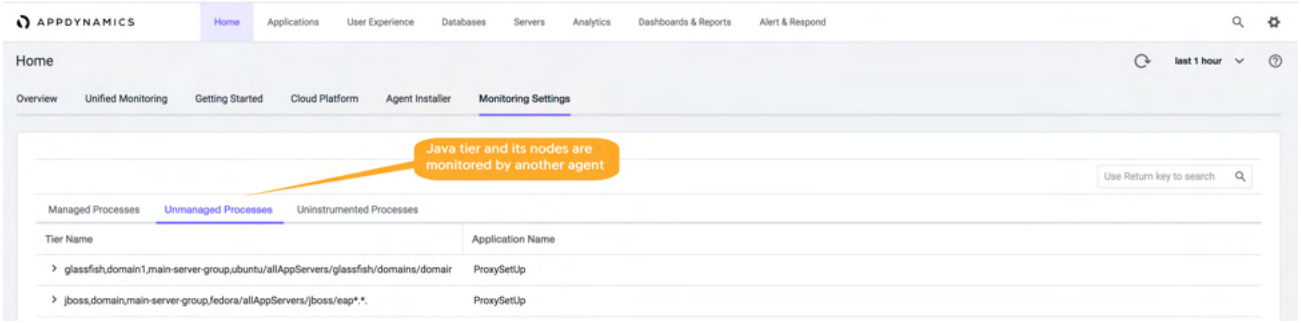
> Search is not available from the Uninstrumented Processes tab.



Managed and Unmanaged Tiers

A tier is considered "managed" when it has been instrumented with the Agent Installer. In the Monitoring Settings tab, managed tiers are those that you can enable or disable in the Controller UI.

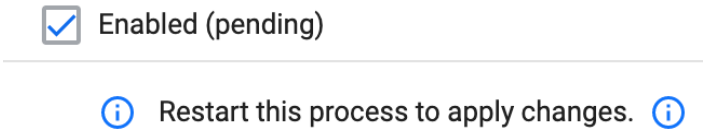
You may see tiers listed on the Monitoring Settings page that you cannot change in the UI. A tier is considered "unmanaged" when it cannot be instrumented by the Agent Installer. Unmanaged tiers include tiers that have been instrumented manually with the Java Agent or managed outside of AppDynamics. To monitor the unmanaged tiers, you must remove your previous configuration and restart the processes.



Change Managed Tiers and Nodes Status

To disable monitoring for specific tiers, uncheck one or more tiers you want to disable.

Restart all affected processes (on all affected hosts). This messages displays in the UI when the process is ready to restart:



When you disable monitoring, the changes are not immediately recognized by the Agent Installer Platform. Wait until you see a message to restart processes in the Monitoring Settings tab. If you restart processes before you see the message, the change does not take effect.

Disable Instrumentation of Specific Hosts

To reduce license consumption, you can disable the instrumentation of application server types that you do not want to monitor.

In the terminal, enter this command: `<install-directory>/bin/zeroctl configure --disable-instrumentors=java,<app-server-type>`

The location `<install-directory>` refers to the directory in which you installed the Agent Installer.

This table lists the supported values for `<app-server-type>`:

App Server	Accepted Value
Tomcat	`tomcat`
JBoss	`jboss`
GlassFish	`glassfish`
WebLogic	`weblogic`
WebSphere	`websphere`
Plain (non-application server) Java applications	`java`
All app server types	`all`

Customize Agent Installer

This page explains how to fine-tune the Agent Installer configuration. Changes apply to the Agent Installer Platform configuration file, `config.json`.

Customize Agent Installer Platform Configuration

The Agent Installer Platform has several commands available to customize the configuration. You can run the commands during or after installation. You can issue the commands to the `zeroctl` executable, a binary located in the Agent Installer Platform directory. The Agent Installer Platform periodically checks the configuration file and applies the changes.

You should only use these commands in the `zeroctl` executable. Do *not* modify the `zero-config.json` file directly as this may result in undefined behavior.

Command Name	Description
`configure`	Modify the Agent Installer Platform configuration file.
`stop`	Stop running the Agent Installer Platform.
`stop <agent>`	Stop running an individual agent on the Agent Installer Platform.
`start`	Start or restart the Agent Installer Platform. Automatically done for `sudo` installations.
`start <agent>`	Start or restart an individual agent on the Agent Installer Platform.
`status`	View or print the status of the managed agents.
`purge`	Remove the Agent Installer Platform, Infrastructure, Java, and Machine Agents and all configuration files from your machine.
`uninstall`	Remove the Agent Installer Platform, Infrastructure, Java, and Machine Agents from your machine, but retain the configuration files.

The Infrastructure Agent is in beta release only.

View Command Flags

To view the available flags for a command, enter:

```
<install-directory> bin/zeroctl <command> -h
```

For example, to view the available flags for the `install` command, enter:

```
<install-directory> bin/zeroctl install -h
```

The output example displays the flags with the data type for the parameters and descriptions for the `install` command:

```
<install-directory> bin/zeroctl install -h
...
Install Agent Installer Platform

Usage:
  zeroctl install [flags]

Flags:
      --log-level string                Logging level (choose from [panic fatal error warning info debug
trace])
      --max-log-rate int                Maximum log msg rate (default -2)
      --disable-instrumentors strings   Instrumentors to disable (choose from [java tomcat jboss glassfish
weblogic websphere all])
      --enable-instrumentors strings    Instrumentors to enable (choose from [java tomcat jboss glassfish
weblogic websphere all])
      --application string              Controller application name
      --account string                  Controller account name
      --access-key string               Account access key
      --service-url string              Service URL
      --javaagent string                Java agent (choose from [dynamic ibm sun])
      --jboss-log-manager-modify        LogManager args for JBoss (choose from [true false])
      --proxy-url string                Proxy URL
      --install-path string             Agent Installer Platform installation path (default "/opt/appdynamics
/zeroagent")
      --systemd                         Install in systemd (default true)
  -h, --help                            help for install
```

Run Commands with Flags During and After Installation

You can run commands in the `zeroctl` binary after installation. To make changes during installation, add flags to the installation script.

For example, to configure the log level to `info`:

- During installation (as a flag), enter:

  ```
  sudo ./zero-agent.sh install --application 'AgentInstallerTestApp' --account 'project-zero' --access-key
  'myaccesskey' --service-url 'https://test.saas.appd-test.com' --log-level=info
  ```

- After installation (using the `zeroctl` executable), enter:

  ```
  <install-directory> bin/zeroctl configure --log-level=info
  ```

Connect the Agent Installer Platform to a Proxy

The Agent Installer supports connections with unencrypted proxies only. To configure the `zeroctl` executable to use a proxy connection, enter:

```
<install-directory> bin/zeroctl configure --proxy-url=http://localhost:1001
```

Change Tier Names

The Agent Installer automatically creates a name for every instrumented tier. To create names, the installer extracts information from the Java process, such as the application server name.

Contact AppDynamics Support to change the name of an instrumented tier. Because an AppDynamics Support representative applies the changes, you need to create a new user named `appd_rule_user`, and then give `appd_rule_user` **Install Agent** permission only. This secures your sensitive data.

When you contact AppDynamics Support, provide the log in credentials for `appd_rule_user`.

Override `Systemd` Integration

If you do not want the Agent Installer to integrate with `systemd` in a `sudo` installation, add `-systemd false` to the install command (step 5a in Use the Agent Installer). For example:

```
sudo ./zero-agent.sh install --application 'AgentInstallerTestApp' --account 'project-zero' --access-key
'myaccesskey' --service-url 'https://test.saas.appd-test.com' --systemd=false
```

Maintain Continuous Operation with `watchdog`

The Agent Installer includes a `watchdog` process to ensure continued operation of these standalone agents and their related processes:

- Agent Installer Platform Daemon
- Infrastructure Agent
- Machine Agent

If you integrate the Agent Installer with `systemd`, a profile is created for the `watchdog` process to ensure that it starts after a planned or unplanned reboot of the system. The `systemd` profile also restarts the `watchdog` process if it was terminated during regular operation.

If you do not integrate the Agent Installer with `systemd` (by setting `--systemd=false`), you can create a `systemd` profile after installation.

If you do not have a `systemd` profile, then you must start the `watchdog` process manually to ensure operation of the standalone agents and their related processes.

> If you enabled the SELinux module on your system, then you must configure it to ensure that the `watchdog` and other Agent Installer Platform processes are not blocked.

To start the `watchdog` process, enter:

```
<install-directory> bin/zeroctl start
```

To stop the `watchdog` process, enter:

```
<install-directory> bin/zeroctl stop
```

See Agent Installer for more information.

Start or Stop Individual Agents

You can use the watchdog process to start and stop individual agents (Infrastructure, Machine, or Zero) on the Agent Installer Platform. You can also view or print the status of the managed agents.

For example, to start the Machine Agent, enter:

```
<install-directory> bin/zeroctl start machine
Starting Machine Agent
...
Machine Agent started successfully
```

For example, to stop the Zero Agent, enter:

```
<install-directory> bin/zeroctl stop zero
Stopping Zero Agent
...
Zero Agent stopped successfully
```

To view or print the status of the managed agents, enter:

```
<install-directory> bin/zeroctl status
```

Secure Agent Installer Platform

This page describes how to secure sensitive information in the Agent Installer Platform configuration file.

How to Secure the Agent Installer Platform Configuration File

The Agent Installer Platform configuration file, `config.json`, contains potentially sensitive information, such as the agent access key used by the Java and Machine Agent to connect to the Controller. By default, the Agent Installer Platform can be read by any user of the system after it is installed. The default permissions allow the Agent Installer Platform to auto-instrument new processes started on your system by any user.

Block Access to the Agent Installer Platform

You can block access to the Agent Installer Platform configuration file and still allow the agent to auto-instrument processes for authorized users or groups.

Change the default permissions:

1. Define an authorized group.

   ```
   groupadd appdynamics-zero-agent
   ```

2. Add users to the authorized group. For example, the `usermod` command adds a user named `tomcat-user` to the `appdynamics-zero-agent` group. Run this command for each user that creates Java processes you want the Agent Installer Platform to auto-instrument.

   ```
   usermod -a -G appdynamics-zero-agent tomcat-user
   ```

3. Navigate to the directory where the Agent Installer Platform was installed; the default directory is */*`opt/appdynamics/zeroagent`.

   ```
   cd <zero-agent-install-directory>
   ```

4. Change directories to the Agent Installer Platform's configuration file directory.

   ```
   cd configs
   ```

5. Change the group ownership of the `config.json` file to the authorized group created in Step 1.

   ```
   chgrp appdynamics-zero-agent config.json
   ```

6. Change the permissions associated with the `config.json` file.

   ```
   chmod 640 config.json
   ```

Configuration File Access

The Agent Installer Platform configuration file has the following access:

- Owning user - read and write
- Authorized group - read only
- All other users - no access

Unauthorized access to the file is not permitted. If a non-authorized user starts a Java process, it is not auto-instrumented by the Agent Installer Platform. However, it does not prevent the new Java process from starting.

Java Agent

Related pages:

- AppDynamics Essentials
- Install the Machine Agent
- Administer App Server Agents

To monitor Java applications in the Controller, you need to install the AppDynamics Java Agent on each server that hosts applications to be monitored. You can use the AppDynamics Agent Installer to streamline the deployment of the Java Agent. The Agent Installer simplifies the agent installation process.

If you downloaded the agent from the AppDynamics Downloads Center, see Install the Java Agent.

Before You Begin

1. Verify support for your application environment at Java Supported Environments.
2. Confirm you have access to a compatible controller. See Agent and Controller Compatibility.
3. Confirm the connection settings to the Controller where your agent will report data:
    - If you use a SaaS Controller, AppDynamics sent you the Controller hostname in your Welcome Email. Use port 443 for HTTPS or port 80 for HTTP.
    - If you use an on-premises Controller, you supplied hostname and port at install time.
4. Verify you have access to the machine where the application runs as a user account with privileges to install the agent software and restart the application.
5. Verify that the machine where the application runs can connect to the Controller. Proxies or firewalls on the network between the agent and Controller may require additional configuration.

Install the Agent

To install the agent using the **Agent Download Wizard** in the Controller UI:

1. Log in to the Controller UI and access the **Getting Started Wizard for Java**.
2. Follow the steps in the wizard to configure and download the agent. The agent guides you through some preliminary configuration steps.
3. As an administrator on the machine running your Java application, unzip the `AppServerAgent.zip` file.
   For example, on Linux unzip the agent to `home/appdynamics`. This is the `<agent_home>` directory.

   ```
   unzip AppServerAgent.zip -d /opt/appdynamics/appagent
   ```

4. Add the Java Agent binary to the application process, typically by passing the agent JAR file as a startup argument to the application. For information by framework and application type, see these pages:

When completed, you can restart your application and view data reported by the agent in the Controller UI. From there, you can install more agents or begin monitoring your application environment.

Tier and Node Naming in the Java Getting Started Wizard

Each monitored JVM must have a unique combination of tier and node name in AppDynamics. Naming the components in the wizard varies between the self-service trial edition of AppDynamics and the non-trial edition:

- For the self-service Pro Trial edition of AppDynamics Pro, the wizard names the application and tier for you using the format described in the following section. You can always change the names later.
- For a non-trial edition, you name the application and tier in the wizard, while the wizard generates the node name.

For self-service trials of AppDynamics Pro, the getting started wizard uses the following naming scheme to identify agents:

- Node name: `<app_server_type>@<hostname>:<port>`
  For example: `JBoss@appserver1.example.com:8080`
- Tier name: `MyTier`
- Application name: `MyApp`

The port number in the node name ensures that each node has a unique name if there is more than one app server on the same machine.

If the application server listens on multiple ports, the node name uses the lowest of the port numbers. Notice that the lowest port number may not be the primary port for the host. For instance, if a server listens for client requests at 8080 but listens for shutdown requests on port 8005, the node will be named with the 8005 port.

The Controller identifies distinct tiers based on traffic flow between nodes. All tiers belong to a single business application, MyApp.

Java Supported Environments

This page lists the application environments and versions supported by the AppDynamics Java Agent.

Java Agent Supported Platforms

In the following tables, note that:

- A dash ("-") in a table cell indicates that this column is not relevant or not supported for that particular environment.
- In cases where no version is provided, assume that all versions are supported. Contact AppDynamics Sales for confirmation.
- For environments that require additional configuration, a separate table describing or linking to configuration information follows the support matrix.
- For environments supported by AppDynamics End User Monitoring, see Supported Environments and Versions - Web EUM.
- For environments supported by AppDynamics Server Visibility, Machine Agent Requirements and Supported Environments.

JVM Support

The AppDynamics Java Agent uses the standard JVM Tool Interface (JVMTI) mechanism allowing it to instrument any software running on a JVM supporting this mechanism.

AppDynamics certifies the successful operation of the basic mechanisms of instrumentation used by the agent on the following Java runtimes. These capabilities are supported on both JRE or full JDK installations.

Where the agent supports the following advanced memory monitoring features, they are listed for the JVM: Object Instance Tracking (OIT), Automatic Leak Detection (ALD), Content Inspection (CI), and Access Tracking (AT).

JVM	OS	Memory Monitoring Features
AdoptOpenJDK 8, 9, 10, 11, 12, 13, 14, 15, 16 (supported for both Hotspot and OpenJ9 JVMs)	Linux, Windows, MacOS	OIT (supported only for Hotspot JVM), ALD, CI, AT
Amazon Corretto 8, 11	Linux, Windows	OIT, ALD, CI, AT
Azul Zing 15.x.	Linux x64	OIT, ALD
Azul Zulu OpenJDK 1.6, 1.7, 1.8, 9, 10, 11, 13, 14, 15, 16 JDK11 is supported from 4.5.6 onwards JDK13 is supported from 4.5.15 onwards JDK14 is supported from 20.4.0 onwards JDK15 is supported from 20.10.0 onwards JDK16 is supported from 21.4.0 onwards	Linux, Windows	OIT, ALD, CI, AT
GraalVM 20.0.0, 20.2.0, 21.1.0	Linux, Windows, MacOS	OIT, ALD, CI, AT
HP OpenVMS		
IBM JVM 1.6.x, 1.7.x, 1.8.x	AIX, HP-UX, Linux, Solaris, Windows, z/OS	ALD, CI Object instance tracking, automatic leak detection, and custom memory structure monitoring are not supported with the AppDynamics IBM Java Agent. IBM JVMs can be instrumented with the AppDynamics Sun Java Agent to work around this limitation; however, this only enables automatic leak detection and custom memory structure monitoring. Object instance tracking is not available. Working around this limitation can result in negative performance impact and is not recommended. In such cases, the IBM JVM needs to be restarted to enable custom memory structure monitoring.
Oracle Rockit JVM 28.1+	Linux Intel 64, Windows	

Oracle/BEA JRockit 1.6		
Oracle/Sun JVM 1.6, 1.7, 1.8, 9, 10, 11, 12, 13, 14, 15, 16 JDK11 is supported from 4.5.6 onwards JDK12 is supported from 4.5.11 onwards JDK13 is supported from 4.5.15 onwards JDK14 is supported from 20.4.0 onwards JDK15 is supported from 20.10.0 onwards JDK16 is supported from 21.4.0 onwards	Solaris Sparc 64, Windows, Linux	OIT, ALD, CI, AT Content Inspection and Access Tracking require a JVM restart.
Open Source OpenJDK 1.7, 1.8, 9, 10, 11, 12, 13, 14, 15, 16 OpenJDK11 is supported from 4.5.6 onwards OpenJDK12 is supported from 4.5.11 onwards JDK13 is supported from 4.5.15 onwards JDK14 is supported from 20.4.0 onwards JDK15 is supported from 20.10.0 onwards JDK16 is supported from 21.4.0 onwards	Solaris Sparc 64, Windows, Linux	OIT, ALD
SAP JDK 6+	Windows, Solaris, Linux, HP-UX, i5/OS, AIX	

JVM Application Server and Framework Support

AppDynamics supports the use of the Java Agent to instrument any application component running on a supported JVM, irrespective of how that component is built. The power of the AppDynamics platform is that it can automatically discover the topology and behavior of complex enterprise applications without requiring deep technical knowledge of the application's underlying code.

Frequently, Java-based systems employ standard framework code to implement business logic. Automatic instrumentation of framework code relies on knowledge of the business logic and programming patterns employed by the framework. AppDynamics instrumentation targets processing hand-offs between components, called entry points and exit points, either within the JVM or between JVMs. This includes hand-offs between frameworks in cases where multiple frameworks are being used together. This section covers the capabilities for frameworks for which AppDynamics provides automatic detection rules.

Monitoring application components built using frameworks not listed here may require custom configuration. The custom configuration may involve, for example, custom POJO entry or exit points. If you understand how the application behaves internally, you can easily configure this type of instrumentation. For more complex configuration tasks, contact your account representative to discuss how to engage the AppDynamics customer success organization.

JVM Language Frameworks Support

No additional configuration is required for these frameworks.

Vendor	JVM Language Framework	Version	Correlation/ Entry Points	Exit Points	Transports	Notes

Open Source	Akka Actor	2.1 – 2.5.x	Yes	Yes	Netty	4.3.1 required for 2.4.x 2.5x support includes Persistence Remoting exit/entry supported
Open Source	Akka HTTP Name: `akka-http-stream-entry-enabled` Type: Boolean Default: False	Akka Actor 2.5.x Akka HTTP upto 10.2.4 Scala 2.11, 2.12	Yes	Yes	HTTP	EUM is supported Support for Non-Route DSL
Open Source	Http4s Blaze Client	Blaze versions: 0.21.1, 0.21.0, 0.20.23, 0.20.5 scala 2.11, 2.12	No	Yes	HTTP	
Open Source	Groovy	-	Yes	Yes		
Open Source	Ktor	1.0.x -1.5.x	Yes (Netty Engine)	-	HTTP	EUM is supported
Open Source	Play for Scala Play for Java	2.1 – 2.8 Scala 2.11, 2.12	Yes	-	HTTP over Netty server Akka HTTP server	Includes framework specific entry and exit points Play EUM-APM correlation supported
Open Source	Scala	2.11.6				
Open Source	Spray toolkit (Spray.io)	1.1.x 1.1.3	Yes	Yes	HTTP	Entry points are detected and configurable as servlet entry point and exit points as HTTP exits
Pivotal	Grails	-	-	-	-	

Java Frameworks Support

The Java Agent supports these Java frameworks. Some require additional configuration as indicated in the Configuration Notes column.

Vendor	Framework	Version	SOA protocol (WebServices)	Auto Naming	Entry Points	Exit Points	Detection	Configuration Notes
Adobe	BlazeDS	-	HTTP and JMS adaptor	-	Yes		-	Example Message Queue Backend Configuration
Adobe	ColdFusion	8.x, 9.x	-	-	Yes	-	Configuration required for transaction discovery	Configuration is required for transaction discovery. See: • Java Business Transaction Detection • Servlet Entry Points
Apache	Cassandra with Thrift framework	-	-	-	Yes	Yes	Apache Thrift Entry and Exit points are detected	
Apache	Struts	1.x, 2.x	-	-	Yes		Struts Actions are detected as entry points; struts invocation handler is instrumented	Struts Entry Points
Apache	Tapestry	5	-	-	Yes	-	Not by default	See: • Java Business Transaction Detection • Servlet Entry Points
Apache	Wicket	-	-	No	Yes	-	Not by default	See: • Java Business Transaction Detection • Servlet Entry Points
Apple	WebObjects	5.4.3	HTTP	Yes	Yes	-	Yes	Apple WebObjects Startup Settings
axonframework.org	Axon	2.x, 3.x	-	-	Commands on the Command Bus continue existing Business Transactions	Correlation for Distributed Command Bus on JGroups and for Spring Cloud Connector transport as an exit		

Open Source	CometD	2.6	HTTP	Yes	Yes	-	-	See also "HTTP Exit Points" on Java Backend Detection.
Open Source	Spring Batch	-						Spring Batch Support
Eclipse	RCP (Rich Client Platform)	-	-	-	-	-	-	
Google	Google Web Toolkit (GWT)	2.5.1	HTTP	Yes	Yes	-	-	
JBoss	JBossWS Native Stack	4.x, 5.x	Native Stack	-	-	-	-	
IBM	IBM-BPM	8.5.7, 8.6	-	Yes	Yes	Yes	Yes	IBM-BPM Support
Open Source	Direct Web Remoting (DWR)	-	-	-	-	-	-	
Open Source	Eclipse Vert.x Core	3.3.3-3.5.4, 3.6.x, 3.7.x, 3.8.x, 3.9.x, 4.0.x	HTTP	Yes	Yes	Yes	Yes	EUM Correlation is supported
Open Source	Enterprise Java Beans (EJB)	2.x, 3.x	-	-	Yes	-	-	EJB Entry Points
Open Source	Grails	-	-	-	Yes	-	Not by default	
Open Source	Hibernate JMS Listeners	1.x	-	-	-	-	-	
Open Source	Java Abstract Windowing Toolkit (AWT)	-	-	-	-	-	-	
Open Source	Java Server Faces (JSF)	1.x, 2.x	-	Yes	Yes	-	-	Java Business Transaction Detection and Servlet Entry Points
Open Source	Java Server Pages	2.x	-	Yes	-	-	Yes	Servlet Entry Points
Open Source	Java Servlet API	2.x, 3.0	-	-	-	-	-	
Open Source	Jersey	1.x, 2.x	REST, JAX-RS	Yes	Yes	No	Not by default	JAX-RS Support and node properties: • `rest-num-segments` • `rest-transaction` • `rest-uri-segment-scheme` See App Agent Node Properties Reference for information on the properties.
Open Source	JRuby HTTP	-	-	-	Yes	-	Not by default	See: • Java Business Transaction Detection • Servlet Entry Points
Open Source	Micronaut	1.1.0, 2.5.3	-	Yes	Yes	Yes	By default	-
Open Source	Netty	3.x, 4.x	HTTP	Yes	Yes	Yes	By default	• Node property to disable Netty Instrumentation: `netty-enabled`, by default it is true
Open Source	Spring Annotated Web Services	2.x+	HTTP	Yes	Yes	No	-	
Open Source	Spring WebFlux	5.0, 5.1, 5.2, 5.3	HTTP	Yes	Spring Boot (Netty, Jetty, Tomcat, Undertow)	WebClient (Reactor Netty, Reactive Jetty)	By default	The node property `enable-webclient`, disables the Netty instrumentation and enables WebClient configuration. This node property should not be enabled unless there is some issue or loss in visibility with the OOTB support. By default, the value of this property is false.
Open Source	Spring Cloud Gateway	2.0.x, 2.1.x, 2.2.x, 3.0.2	HTTP	Yes	Yes	Yes	By default	
Open Source	WebSocket	1.0 (Java EE 7, JSR-356)	-	Yes, BT Naming not configurable	Yes, correlation not supported	Yes	Detection is automatic	Node property: websocket-entry-calls-enabled
Oracle	Coherence with Spring Beans	2.x, 3.x	-	-	-	-	-	
Oracle	Swing (GUI)	-	-	-	-	-	-	

Oracle	WebCenter	10.0.2,10.3.0	-	-	-	-	-	
Spring	Spring MVC	5.3	-	-	Yes	-	Not by default	See App Agent Node Properties Reference.

Application Servers

The Java Agent supports the following application servers. Some require additional configuration. Click the link on the server or OSGi Runtime for information about additional requirements or related configuration topics. The agent usually discovers application servers as an entry point.

Vendor	Application Server / OSGi Runtime	Version	SOA Protocol	RMI Supported	JMX	Entry Points	Configuration Notes
Adobe	Cold Fusion	8.x, 9.x	-	No	-	Yes	Requires configuration for transaction discovery; see Servlet Entry Points
	Equinox	-	-	-	-	Yes	OSGi Infrastructure Configuration
Apache	Felix	-	-	-	-	Yes	OSGi Infrastructure Configuration
Apache	Sling	-	-	-	-	Yes	OSGi Infrastructure Configuration
Apache	Tomcat	5.x, 6.x, 7.x, 8.x, 9, 10	-	-	Yes	Yes	Apache Tomcat Startup Settings
Apache	Resin	1.x - 4.x	-	-	-	-	Resin Startup Settings
Eclipse	Jetty	6.x, 7.x, 8x, 9x	-	-	-	-	Jetty Startup Settings
IBM	InfoSphere	8.x	-	-	-	Yes	IBM WebSphere and InfoSphere Startup Settings
IBM	WebSphere	6.1, 7.x, 8.x, 9.x	JAX-WS	Yes, detect and correlate	Yes for WebSphere PMI	Yes	IBM WebSphere and InfoSphere Startup Settings
Open Source	Liferay Portal	-	-	-	-	-	
Open Source	JBoss EAP	7.1.5 and 7.2.0		Yes		Yes	JBoss and Wildfly Startup Settings
Open Source	JBoss Wildfly (formerly JBoss Application Server)	4.x to 23.x		Yes		Yes	JBoss and Wildfly Startup Settings
Sun/Oracle	GlassFish Enterprise Server	2.x	-	-	Yes	Yes	GlassFish Startup Settings
Oracle	GlassFish Server and GlassFish Server Open Source Edition	3.x, 4.x	-	-	Yes for AMX	Yes	GlassFish Startup Settings
Oracle and BEA	WebLogic Server	9.x+	JAX-WS	Yes, detect and correlate for 10.x To enable correlation using a header transported in the `SOAP:Envelope` set node property enable-soap-header-correlation=true	Yes	Yes	Oracle WebLogic Startup Settings
Software AG	webMethods	9.5, 9.6	-	-	-	Yes	webMethods Startup Settings
Tibco	ActiveMatrix BusinessWorks Service Engine	5.x, 6.x	-	To enable correlation using a header transported in the `SOAP:Envelope` set node property `enable-soap-header-correlation=true`	-	Yes	Tibco ActiveMatrix BusinessWorks Service Engine Settings
	Application Server (OC4J)	-	-	Yes, detect and correlate for 10.x	-	Yes	
-	Grails, with Tomcat 7.x, Glassfish v3, Weblogic 12.1.1 (12c)	-	-	-	-		

Servlet 3.x detection is not supported.

PaaS Providers

PaaS Provider	Buildpack
Pivotal Cloud Foundry	Java Buildpack 3.4 and higher See Using AppDynamics with Java Applications on Pivotal Cloud for more information.
Red Hat Openshift 3	JBoss EAP 6.4 and 7.x WildFly 8.1 Docker images For documentation and download information, see the AppDynamics Java APM Agent page on the Red Hat Customer Portal.

Message Oriented Middleware Support

The Java Agent supports the following message oriented middleware environments. Some require additional configuration as indicated in the Configuration Notes column. Message oriented middleware servers are usually found by the Java Agent as an entry point.

Vendor	Messaging Server	Version	Protocol	Correlation /Entry Points	Exit Points	JMX	Configuration Notes
Amazon	Simple Queue Service (SQS)	-	-	Yes (correlation only)	Yes	-	See "Amazon Simple Queue Service Backends" on Java Backend Detection
Amazon	Simple Notification Service (SNS)	-	-	No	Yes	-	See "Amazon Simple Notification Service Backends" on Java Backend Detection
Apache	ActiveMQ	5.x+	JMS 1.x	Yes	Yes	Yes	
Apache	ActiveMQ	5.x+	STOMP	No	-	Yes	
Apache	ActiveMQ	5.8.x+	AMQP 1.0	No	-	Yes	Example Message Queue Backend Configuration
Apache	Axis	1.x, 2.x	JAX-WS	Yes	Yes	-	Default exclude rules exist for Apache Axis, Axis2, and Axis Admin Servlets. See aslo "Web Service Entry Points" on Java Backend Detection.
Apache	Apache CXF	2.1	JAX-WS	Yes	Yes	-	To enable correlation, set node property `enable-soap-header-correlation=true`.
Apache	Kafka	0.9.0.0 to 2.8.0	-	Yes	Yes	Yes	Kafka consumer entry points are disabled by default. Correlation is supported. See Apache Kafka Consumer Backends.
Apache	Synapse	2.1	HTTP	Yes	Yes	-	To enable correlation, set node property `enable-soap-header-correlation=true`
Fiorano	Fiorano MQ		-	-	-	-	
IBM	IBM Web Application Server (WAS)	6.1+, 7.x	Embedded JMS	-	Yes	-	Example Message Queue Backend Configuration
IBM	IBM MQ (formerly IBM WebSphere MQ)	6+	JMS	Yes	Yes	-	Example Message Queue Backend Configuration
Mulesoft	Mule ESB	3.4, 3.6, 3.7, 3.8, 3.9, 4.1.x, 4.2.0, 4.2.1	HTTP, JMS	Yes	Yes	-	Mule ESB Startup Settings
Open Source	Eclipse Vert.x verticles	3.3.x, 3.4.x, 3.5.0, 3.6.0	-	Yes (correlation only)	Yes	-	The Java Agent detects messaging exit calls between verticles.
Open Source	Open MQ	-	-	-	-	-	
Oracle	Java Message Service	2.0	JMS	Correlation of the listener is disabled by default	Yes		
Oracle	Oracle AQ	-	JMS	-	Yes	-	
Oracle	OSB deployed on WebLogic	12.2.1	HTTP JMS	Yes	Yes		OSB Support
Oracle / BEA	WebLogic	9.x+	JMS 1.1	Yes	Yes	Yes	Oracle WebLogic Startup Settings
Progress	SonicMQ	-	-	-	-	-	
Pivotal	RabbitMQ	-	HTTP	-	Yes	-	See "RabbitMQ Backends" on Java Backend Detection
Rabbit	RabbitMQ Spring Client	-	-	Yes	Yes	-	See "RabbitMQ Backends" on Java Backend Detection
Red Hat	HornetQ (formerly JBoss Messaging and JBoss MQ)	-				Yes	
Red Hat	JBoss A-MQ	4.x+	-	-	-	Yes	
Spring	Spring Integration	2.2.0+, 4.0+	JMS	Yes	Yes	Yes	Spring Integration Support See also "Java Message Service Backends" on Java Backend Detection
WSO2	ESB	4.7.0	-	Yes	Yes	-	EUM Correlation is not supported
WSO2	API Microgateway	3.1.x, 3.2.0, 3.2.1	HTTP1	Yes	Yes	-	See WSO2 API Microgateway Startup Settings

JDBC Drivers and Database Servers Support

The Java Agent supports these JDBC driver and database server environments. AppDynamics can follow transactions using these drivers to the designated database.

JDBC Vendor	Driver Version	Driver Type	Database Server	Database Version

Apache	10.9.1.0	Embedded or client	Derby	-
Apache	-	-	Cassandra	-
Progress	DataDirect	data connectivity for ODBC and JBDC driver access, data integration, and SaaS and cloud computing solutions	-	-
IBM	JDBC 3.0 version 3.57.82 or JDBC 4.0 version 4.7.85	DB2 Universal JDBC driver	DB2	9.x
IBM	JDBC 3.0 version 3.66.46 or JDBC 4.0 version 4.16.53	DB2 Universal JDBC driver	DB2	10.1
IBM	-	Type IV	Informix	-
Maria				1.4.x - 2.6.x
Microsoft	4	Type II	MS SQL Server	2012
Oracle MySQL, MySQL Community	5.x, 6.x, 8.x	Type II, Type IV	MySQL	5.x
Oracle	RAC			
Oracle	9i, 10g 11g, 12c, 18c, 19c	Type II, Type IV	Oracle Database	8i+
Open Source PostgreSQL	42.2.5	Type IV	Postgres	8.x, 9.x, 11x
Sybase	jConnect	Type IV	Sybase	-
Teradata			Teradata	-

Notes:

- Type II is a C or OCI driver
- Type IV is a thin database client and is a pure Java driver

NoSQL/Data Grids/Cache Servers Support

The Java Agent supports these NoSQL, data grids and cache server environments. Some require additional configuration. Click the link on the database, data grid or cache name in the following support matrix for information about additional configuration required or related configuration topics.

Vendor	Database/Data Grid /Cache	Version	Correlation/Entry Points	JMX	Configuration Notes
Amazon	DynamoDB	-	Exit Points	-	See "Amazon Web Services" on Java Backend Detection.
Amazon	Simple Storage Service (S3)	-	-	-	"Amazon Simple Storage Service Backends" on Java Backend Detection.
Apache	Casandra • DataStax drivers • Thrift drivers	1.x, 2.x	Correlation for Thrift drivers only	Yes	• "Cassandra Backends" on Java Backend Detection. • For Cassandra server-side support, see Apache Cassandra Startup Settings
Apache	Lucene - Apache Solr	1.4.1	Entry Points	Yes	Apache Solr Startup Settings
Couchbase	Couchbase	3.x	Exit Points	-	See "Couchbase Backends" on Java Backend Detection
JBoss	Cache TreeCache	-	-	-	JBoss Startup Settings
JBoss	Infinispan	5.3.0+	Correlation	-	-
Open Source	Memcached	-	-	-	Memcached Exit Points
Open Source	MongoDB Async Driver	3.4-3.12	-	-	See "MongoDB Backends" on Java Backend Detection
Open Source	MongoDB Sync Driver	3.1-3.12, 4.0.x	-	-	See "MongoDB Backends" on Java Backend Detection
Open Source	MongoDB Reactive Streams Driver	1.3-1.13, 4.0.x	-	-	See "MongoDB Backends" on Java Backend Detection
Oracle	Coherence	3.7.1	Custom-Exit	Yes	Coherence Startup Settings
Red Hat	JBoss DataGrid	-	-	-	JBoss Startup Settings
	JBoss Cache TreeCache	-	-	-	
	JBoss Infinispan	5.3.0+	Correlation	-	

Terracotta	EhCache	-	-	-	EhCache Exit Points

RPC/Web Services API/HTTP Client Support

The Java Agent supports these RPC, web services or API framework types. Some require additional configuration as indicated in the Configuration Notes column.

Vendor	RPC/Web Services API Framework /HTTP Client Support	Version	SOA Protocol-WebServices	Auto Naming	Correlation/Entry Points	Exit Points	Configurable BT Naming Properties	Detection	Configuration Notes
Apache	Apache CXF	2.1	JAX-WS	Yes	Yes	Yes	Yes	Yes	
Apache	Apache HTTP Client	-	HTTPClient (now in Apache HTTP Components)	Yes	Yes (correlation only)	Yes	-	Yes	See "HTTP Backends" on Java Backend Detection
Apache	Apache Async HTTP Client	4.1.x	-	-	-	-	-	-	-
Apache	Ribbon HTTP Client	2.1.0	HTTP Client	Yes	Yes (correlation) Entry - NA	Yes	NA	Yes	
Apache	Apache Thrift	-	-	Yes	Yes	Yes	Yes	Yes	Binary Remoting Entry Points for Apache Thrift
Eclipse	Jetty	8.x, 9.x	HTTP Client	Yes	Yes (correlation only)	Yes (ART supported)	-	Yes	See "HTTP Backends" on Java Backend Detection
Google	gRPC	1.6.x to 1.37.x	RPC	Yes	Yes (Asynchronous)	Yes (Asynchronous)	ServiceName /MethodName	Yes	See Web Service Backend
IBM	WebSphere	6.x, 7.x, 8.x	JAX-RPC	-	-	-	-	-	IBM WebSphere and InfoSphere Startup Settings; also see Default configuration excludes WebSphere classes
IBM	Websphere	7.x, 8.x	IIOP	-	-	-	-	-	IBM WebSphere and InfoSphere Startup Settings; also see Default configuration excludes WebSphere classes
IBM	Websphere	6.1, 7.x, 8.x, 9.x	JAX-WS	Yes	Yes, detect and correlate. To enable correlation using a header transported in the `SOAP:Envelope` set node property `enable-soap-header-correlation=true`	-	Web Service naming	Yes	-
JBoss		7,8,11,16, and 18	JAX-WS	Yes	Yes, detect and correlate. To enable correlation using a header transported in the `SOAP:Envelope` set node property `enable-soap-header-correlation=true`		Web Service naming	Yes	To detect Web Service entry and to support correlation you must create a Servlet exclude rule. See Web Service Entry Points to exclude a rule for JBoss.
Open Source	`java.net.Http`	-	HTTP	Yes	-	Yes	Yes	Yes	See "HTTP Backends" on Java Backend Detection.
Open Source	HTTPClient	0.3-3	Oracle SOA (and potentially others that embed this library)	-	Correlation: Yes; Entry: No	Yes	-	Yes	Oracle WebLogic Startup Settings; also see Default configuration excludes WebLogic classes

Open Source	Grizzly	Grizzly Async HTTP Client (`com.ning.http-client` 1.8.x, 1.9.x, grizzly-http-client 1.1x) • NingAsyncClient v1 with NettyProvider, GrizzlyProvider • NingAsyncClient v2 with NettyProvider	HTTP	-	Correlation: Yes; Entry:No	Yes	-	Yes	
Oracle	GlassFish Metro	-	JAX-WS	-	-	-	-	-	
Oracle	GlassFish Metro with Grails	-	JAX-WS	-	Yes	-	-	Not by Default	
Oracle	JAX-WS RI	2.3.1	JAX-WS	-	To enable correlation using a header transported in the `SOAP:Envelope` set node property en`able-soap-header-correlation=true`	-	Web Service naming	Yes	-
Spring WS	Web Services	3.x, 4.x, and 5.x	HTTP, SOAP	-	To enable correlation using a header transported in the `SOAP:Envelope set node property enable-soap-header-correlation=true`	-	Web Service naming	Yes	-
Oracle	Oracle Application Server	ORMI	-	no	-	-	-	-	
Oracle	WebLogic	10.x	T3, IIOP	Yes	Correlation: Yes; Entry: No	Yes	-	Yes	
Oracle	WebLogic	9.x, 10.x	JAX-RPC	-	-	-	-	-	
Oracle/Sun	Java	11	-	-	-	Yes (ART supported)	-	Yes	
Oracle/Sun	Sun RMI	-	IIOP	-	Not by Default	-	-	-	
Oracle/Sun	Sun RMI	-	JRMP	-	No	Yes	host/port	Yes	
Red Hat	JBoss A-MQ	4.x+	RMI	Yes	Yes	Yes	Yes	Yes	JBoss and Wildfly Startup Settings
Square	OkHttp	2.x, 3.x, 4.x (upto 4.22)	HTTP	Yes	Correlation: Yes Entry: No	Yes	-	Synchronous (2.x, 3.x, and 4.x upto 4.22) and Asynchronous (3.x and 4.x upto 4.22)	
-	Web Services	-	SOAP over HTTP	-	Yes	Yes	-	-	Create Match Rules for Web Services "Web Service Entry Points" on Java Backend Detection
jersey.github.io	Reactive JAX-RS client API	2.25+	HTTP Client	Yes	Yes (correlation) Entry – NA	Yes	NA	Yes	"Web Service Entry Points" on Java Backend Detection

Business Transaction Error Detection

The Java Agent supports the following logging frameworks for business transaction error detection:

- Apache `Log4j` and `Log4j 2`
- `java.util.logging`
- Simple Logging Facade for Java (SLF4J)
  Support for the following method has been added: `public void error(String format, Object... argArray)`
- Logback

To instrument other types of loggers, see Error Detection.

Install the Java Agent

Related pages:

- Download AppDynamics Software
- Java Agent Configuration Properties
- Enable SSL for the Java Agent
- SELinux Installation Issues

To begin monitoring a Java application using AppDynamics, you install the AppDynamics Java Agent into the application JVM:

1. Download the agent distribution to the machine where your Java application runs.
2. Configure the Java Agent settings. This configuration section of this page describes manual configuration. For more options, see Administer the Java Agent.
3. Add the agent to the JVM process.

Prepare to Install the Java Agent

Consider the following as you decide where and how to deploy the AppDynamics Java Agent:

- The user under which the JVM runs must have write privileges to the conf and logs directories in the Java Agent home (privileges to the conf *(*<JAVA_AGENT_HOME>/ver<VERSION>/*)*. To achieve this, you can install the agent as the same user that owns the JVM or as an administrator on the host machine. You can restrict the remaining contents of the agent directory to read-only access.
- To secure communications between the Java Agent and your Controller, see Enable SSL for the Java Agent.
- If the agent connects to the Controller through a local proxy, you must configure proxy settings for the agent. See "Proxy Properties for the Controller" in Java Agent Configuration Properties.
- The Java Agent supports sharing a single agent between multiple JVMs running on the same machine. If you choose this deployment scenario, you will want to specify settings in a combination of system properties and the versioned configuration file. See Instrument Multiple JVMs on a Single Machine for example configurations.

For cURL installation, see Download AppDynamics Software.

The AppDynamics Java Agent is one type of bytecode injection (BCI) agent. To prevent unforeseen issues with other BCI agents, AppDynamics only supports environments running the Java Agent as the sole BCI agent on the JVM.

You can run multiple BCI Agents on the JVM at your own risk. For Java Agent <= 4.5.16, you can decrease the chances of conflict with other agents by specifying the following command-line option:

```
-Dappdynamics.agent.prefer.retransformClasses=true
```

Java Agent >= 4.5.17 automatically enables this option if they detect the presence of other agents.

Instrument a Custom Java Runtime Image

You can use the Java Agent to instrument an application running on a custom Java runtime image constructed with J-link. To instrument the agent, the custom runtime requires these modules:

- `jdk.management`
- `java.logging`
- `jdk.unsupported`

`jdk.jcmd` is not a required module for the custom runtime. However, it is required for the proper functioning of Object Instance Tracking. See Object Instance Tracking for Java.

AppDynamics assumes that all packages from Java.se are installed.

Java Agent Resource Overhead

The Java Agent typically adds between 0% to 2% additional CPU consumption.

However, certain factors can increase CPU overhead from the agent beyond 2%. These include the use of resource-intensive AppDynamics features, such as asynchronous transaction tracking. Very active environments or configuration settings that result in a high number of metrics or snapshots reported per minute can also affect agent resource consumption.

In all cases, AppDynamics recommends that you test the agent in a staging environment, and monitor resource consumption of your application to ensure that it remains within proper operating parameters.

If your application operates within a small margin of its existing memory resource allocation, you may choose to increase the allocation for the application. AppDynamics recommends allocating the following amounts of additional Heap and PermGen space to accommodate the agent:

- Maximum heap size (`-Xmx`): 100 MB in addition to the amount required by the application

- Maximum PermGen (permanent generation) heap size (`-XX:MaxPermSize`): 20 MB in addition to the amount required by the application. The setting for MaxPermSize is applicable only for Java 6 or Java 7.
- For network bandwidth consumption, see Install App Server Agents.

Download and Unzip the Java Agent Distribution

You can get the agent from the Agent Download Wizard. If you have never installed an agent before, the wizard is a good place to start. The wizard populates the configuration file in the agent you download with Controller connection settings and identifying settings for the agent. After you download the agent, you can install it in the JVM.

Alternatively, you can download the agent manually, as follows:

1. Download the Java Agent ZIP file from AppDynamics Download Center.
2. Extract the ZIP file to the destination directory as the same user or administrator of the JVM. Note the following:
    - Extract the Java Agent to a directory that is outside of your container or application server runtime directories, such as to `\usr\local\appdynamics\appagent`.
    - All files should be readable by the user under which the JVM runs. The user must have write privileges to the `conf` and `logs` directories in the Java Agent home. One way to achieve this is to install the agent as the same user that owns the JVM or as an administrator on the host machine.
    - The application server's runtime directory should be writable by the Java Agent as well.

For information on the contents of the Java Agent home directory, see Java Agent Directory Structure.

Configure the Java Agent

If you downloaded the agent from the Agent Download Wizard in the Controller, you can skip to the next section, as the agent is already configured.

To configure the settings manually (or verify the wizard settings):

1. Edit the versioned configuration file:
   `<`*`agent_home`*`>/<version_`*`number`*`>/conf/controller-info.xml`
   The controller-info.xml is one of several approaches available for supplying configuration settings. For others, see Java Agent Configuration Properties.
2. Modify the connection settings to the Controller:
    - `controller-host`: Set to the IP address or hostname of the Controller. If the agent needs to connect through a proxy, see "Proxy Properties for the Controller" in Java Agent Configuration Properties.
    - `controller-port`: Set to the primary listening port number on the Controller. By default:
        - For a SaaS Controller, use 80 for HTTP or 443 for HTTPS
        - For an on-premises Controller, use 8090 for HTTP or 8181 for HTTPS
3. Direct the agent to connect to the Controller by SSL (HTTPS) by setting the `controller-ssl-enabled` value to true. See Enable SSL for the Java Agent.
4. Identify the business application, tier, and node that this the monitored JVM belongs to in the AppDynamics application model using these settings:
    - `application-name`
    - `tier-name`
    - `node-name`

   In a self-service Trial edition of AppDynamics Pro, the agent uses a default naming scheme, see Java Agent. You can use automatic naming with a standard edition of AppDynamics Pro by adding this property:
   `<auto-naming>true</auto-naming>`
5. If the agents connects to a SaaS Controller or other multi-tenant Controller, configure the Account Name. For all Controllers, configure the Account Access Key.
    - `account-name`
    - `account-access-key`

   This information is provided in the Welcome email from the AppDynamics Team when you acquired the Controller. For a multi-tenant on-premises Controller, you can find this information in
   `<`*`controller_home`*`>/initial_account_access_info.txt`
6. See Java Agent Configuration Properties and configure any additional properties required in your environment.

The following shows a `controller-info.xml` file with sample configuration values:

```
<controller-info>
    <controller-host>192.168.1.20</controller-host>
    <controller-port>8090</controller-port>
    <application-name>ACMEOnline</application-name>
    <tier-name>InventoryTier</tier-name>
    <node-name>Inventory1</node-name>
</controller-info>
```

Load the Java Agent in a JVM

After configuring the agent settings, you can add the agent to the JVM. The exact steps for doing so vary by framework. The general approach involves specifying the agent as a `javaagent` argument to the startup command for the JVM.

Ensure to add the `-javaagent` argument before the `-jar` argument.

The argument should indicate the location of the Java Agent JAR file:

```
-javaagent:<agent_home>/javaagent.jar
```

On Windows, include the drive letter in the path to the agent:

```
-javaagent:C:<agent_home>\javaagent.jar
```

Adding `javaagent` to the startup script requires a restart of the JVM. If it's not possible to restart the JVM when you are installing the agent and modifying the JVM start up script, you can attach the agent dynamically to the running Java process.

See Agent Installation by Java Framework for more information on how to install Java Agent by Java framework or technology.

Attach the Java Agent to a Running JVM Process

Attaching the agent to a running JVM allows you to install the Java Agent without requiring a JVM restart. This approach would normally be used alongside adding the `javaagent` argument to the JVM startup script, or some other persistent approach to ensure that the agent is loaded again at the next JVM restart. However, dynamic attachment allows you to install the agent when restarting the JVM is not possible or convenient.

Dynamic agent attachment works if:

- JVM is => 1.6.
- JVM is an Oracle (HotSpot) JVMs (unavailable for IBM or JRockit JVMs).

Other considerations include:

- Do not attach the agent dynamically to an environment that is already instrumented (either by the AppDynamics Java Agent or another type of agent). Doing so can cause unforeseeable issues and errors.
- Attaching the AppDynamics Java Agent to a running environment will impact the performance of the application while the agent performs the class retransformation needed to instrument the application. The agent overhead will return to its normal operating level when it finishes the process, but it is important to consider the potential performance impact to production services.

To attach the agent to the JVM:

1. Determine the PID of the JVM to which you want to attach.
   For Linux, use:

   ```
   ps -A | grep java
   ```

   On Windows, use:

   ```
   jps -l
   ```

2. Run the following command, replacing the placeholders for the path to the `tools.jar` file in your JDK, path to the AppDynamics Java Agent home directory, and the JVM process ID with values appropriate for your environment:

   ```
   java -Xbootclasspath/a:<path_to_jdk>/lib/tools.jar -jar /<agent_home>/javaagent.jar <jvm_process_id>
   appdynamics.controller.hostName=<controller_hostname>,appdynamics.controller.port=<controller_port_no>,
   appdynamics.controller.ssl.enabled=false,appdynamics.agent.applicationName=<app_name>,appdynamics.agent.
   tierName=<agent_tier_name>,appdynamics.agent.nodeName=<agent_node_name>
   ```

   Use the equivalent paths for Windows, including drive letter. The following shows an example with system output included:

   ```
   [appduser@my_centos6 ~]$ ps -A | grep java
    6780 pts/1    00:00:04 java
   [appduser@my_centos6 ~]$ java -Xbootclasspath/a:/usr/java/jdk1.7.0_79/lib/tools.jar -jar /home/appduser
   /appagent/javaagent.jar 6780
   Attaching to VM [6780]
   agent path >>>/home/appduser/appagent/javaagent.jar=
   ```

Verify Java Agent Installation

After an installation, the agent log in `<agent_home>/logs` will contain this message:

```
Started AppDynamics Java Agent Successfully
```

If the agent log file is not present, the Java Agent may not be accessing the `javaagent` command properties. To troubleshoot, check the application server log file where `STDOUT` is logged. It will have the fallback log messages, useful for troubleshooting the agent.

Also, verify that the agent is able to connect to the Controller in the Controller UI. To verify, log in to the Controller UI and click the **Settings** icon at the top right of the page, and then **AppDynamics Agents**. In the list, search for the agent by machine hostname.

Install the Java Agent in Containers

This page explains how to install the Java Agent in a containerized environment. See Container Installation Options to for your options. There are three options to install the Java Agent with containers:

- Use Auto-Instrumentation
- Use Init Containers
- Use a Dockerfile

Use Auto-Instrumentation

> This scenario applies to containers running in Kubernetes where the Cluster Agent is installed.

This option uses the Auto-Instrumentation feature of the Cluster Agent. It is the recommended option because it offers the highest level of automation and the simplest operational experience for instrumenting Java applications in a Kubernetes cluster.

To get started, see Auto-Instrument Applications with the Cluster Agent.

Use Init Containers

> This scenario applies to containers running in Kubernetes.

This option uses Kubernetes init containers to copy the agent binaries into the application container. It is the recommended option when Auto-Instrumentation is not possible. In this use case, it assumes there are two containers:

- Application image is built without any Java Agent binaries.
- Second init container image is built and only contains the Java Agent binaries.

The deployment spec for the application is configured to copy the agent binaries to the running application container. To use init containers to copy the agent binaries:

1. Build the Java Application Image
2. Build the Java Agent Init Container Image
3. Redirect Agent Output to Stdout
4. Add the Init Container to the Deployment Spec
5. Set the Java Agent Environment Variables
6. Add the -javaagent Argument to the Deployment Spec
7. (OpenShift only) Set the APPDYNAMICS_AGENT_UNIQUE_HOST_ID Environment Variable
8. (On-Premises Controller only) Copy the Controller Certificates to the Container

Build the Java Application Image

When building the Java application image, do not include the Java Agent binaries.

Build the Java Agent Init Container Image

The Java Agent image is built separately from the application image and can be reused across multiple Java application deployments. This Dockerfile is an example of building the Java Agent init container image using a multi-stage build. Alternatively, the init container can reference a pre-built image from AppDynamics on Docker Hub.

Redirect Agent Output to Stdout

It is a best practice to redirect agent output to `stdout` in containerized environments. If you build your own Java Agent init container image, you can redirect the Java agent output to `stdout` by updating the `ver<version>/conf/logging/log4j2.xml` file that is provided in the download package. Add two `<AppenderRef ref="Console"/>` elements as shown in the example log4j2.xml file. If you use a pre-built image from AppDynamics on Docker Hub, you can replace the default `ver<version>/conf/logging/log4j2.xml` file based on the example log4j2.xml file using a ConfigMap. Follow the same procedure shown for Copy the Controller Certificates to the Container.

Add the Init Container to the Deployment Spec

Edit the deployment spec to add the required sections that allow you to copy the agent binaries from the init container to the application image.

The following snippet from a deployment spec shows the required `volumes`, `volumeMounts`, and `initContainer` definitions. The code example assumes the Java application image is published to `myrepo/java-app:v1` and the init container image uses the pre-built image `docker.io/appdynamics/java-agent:20.6.0`:

```
kind: Deployment
spec:
  containers:
  - name: java-app
    image: myrepo/java-app:v1
    volumeMounts:
    - mountPath: /opt/appdynamics
      name: appd-agent-repo
  initContainers:
  - command:
    - cp
    - -r
    - /opt/appdynamics/.
    - /opt/temp
    name: appd-agent
        image: docker.io/appdynamics/java-agent:20.8.0
    volumeMounts:
    - mountPath: /opt/temp
      name: appd-agent-repo
  volumes:
    - name: appd-agent-repo
      emptyDir: {}
```

Set the Java Agent Environment Variables

To set all of the required Java Agent environment variables, you must follow these steps as explained in Best Practices to Configure Agents in Kubernetes.

- Use ConfigMaps to Configure the App Server Agent
- Use Secrets for the Controller Access Key
- Set Application-Specific Configuration in the Deployment Spec

Use ConfigMaps to Configure the App Server Agent

1. Use a ConfigMap to set the Java Agent environment variables that are shared across applications in a namespace:

   ```
   apiVersion: v1
   data:
     APPDYNAMICS_AGENT_APPLICATION_NAME: "eCommerce"
     APPDYNAMICS_AGENT_ACCOUNT_NAME: "<value>"
     APPDYNAMICS_CONTROLLER_HOST_NAME: "<value>"
     APPDYNAMICS_CONTROLLER_PORT: "<value>"
     APPDYNAMICS_CONTROLLER_SSL_ENABLED: "<value>"
     APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME: "true"
     APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME_PREFIX: "<value>"
   kind: ConfigMap
   metadata:
     name: ecommerce-java-config
   ```

2. Apply the ConfigMap to the namespace:

   ```
   kubectl -n ecommerce apply -f ecommerce-java-config.yaml
   ```

3. Update the deployment spec to reference the ConfigMap:

   ```
   spec:
     containers:
     - name: java-app
       envFrom:
       - configMapRef:
         name: ecommerce-java-config
    ...
   ```

Use Secrets for the Controller Access Key

1. Create a Secret using `kubectl`:

```
kubectl -n ecommerce create secret generic appd-agent-secret --from-literal=access-key=<access-key>
```

2. Update the deployment spec to reference the Secret:

```
spec:
  containers:
  - name: java-app
    env:
    - name: APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY
      valueFrom:
      secretKeyRef:
        name: appd-agent-secret
        key: access-key
 ...
```

Set Application-Specific Configuration in the Deployment Spec

Set the application-specific tier name environment variable APPDYNAMICS_AGENT_TIER_NAME in the deployment spec:

```
spec:
  containers:
  - name: java-app
    env:
    - name: APPDYNAMICS_AGENT_TIER_NAME
      value: ecommerce-service
```

Add the `-javaagent` Argument to the Deployment Spec

Edit the deployment spec to add the `-javaagent` argument to the application container startup command as shown in the example:

```
spec:
  containers:
    command: ["/bin/sh"]
    args: ["-c", "java -javaagent:/opt/appdynamics/javaagent.jar -jar /myapp.jar"]
```

Note that for some Java frameworks such as Spring Boot, you can leverage the standard `JAVA_TOOL_OPTIONS` environment variable to include the `-javaagent` argument.

(OpenShift Only) Set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` Environment Variable

For Java applications running in OpenShift, set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` environment variable to enable APM correlation with the Cluster Agent. Since the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` value depends on a runtime value, set this environment variable in the container startup command.

For example, for an OpenShift 3.10 or 3.11 environment, set the environment variable as shown:

```
spec:
  containers:
    command: ["/bin/sh"]
    args: ["-c", "APPDYNAMICS_AGENT_UNIQUE_HOST_ID=$(sed -rn '1s#.*/##; 1s/docker-(.{12}).*/\\1/p' /proc/self
/cgroup) && java -javaagent:/opt/appdynamics/javaagent.jar -jar /myapp.jar"]
```

For your use case, see values documented in Manually Configure App Agents to Correlate with the Cluster Agent.

(On-Premises Controller Only) Copy the Controller Certificates to the Container

If on-premises Controller certificates are required, define a ConfigMap to reference the `cert` file and use a `volume mount` in the deployment spec to mount the ConfigMap contents to the container.

```
$ kubectl create configmap appd-cert --from-file=cacerts.jks
```

Add the cert file, in this example, `appd-cert`, to the container file system using `volumes` and `volumeMounts` as shown in the deployment spec snippet:

```
kind: Deployment
spec:
  containers:
    image: myrepo/java-app:v1
    volumeMounts:
    - name: appd-cert
      subPath: cacerts.jks
      mountPath: /opt/appdynamics/ver4.5.11.26665/conf/cacerts.jks
  volumes:
    - name: appd-cert
      configMap:
        name: appd-cert
```

Example Configuration for Using an Init Container

A complete example of a deployment spec that uses an init container to copy the agent binaries can be found on Github: `java-app.yaml`.

Use a Dockerfile

This scenario applies to containers running in Docker and Kubernetes.

This option uses a Dockerfile to copy the Java Agent to the Docker image at build time. To use the option, create a single image that contains both the application and Java Agent binaries.

To copy the agent into the application image during the Docker image build:

1. Download and Unzip the Java Agent
2. Redirect Agent Output to Stdout
3. Copy the Agent Binaries to the Image
4. Set the Java Agent Environment Variables
5. Add the -javaagent Argument to the Startup Command
6. (OpenShift only) Set the APPDYNAMICS_AGENT_UNIQUE_HOST_ID Environment Variable
7. (On-Premises Controller only) Copy the Controller Certs to the Image

Download and Unzip the Java Agent

Download the Java Agent from or programmatically download the agent. The agent is packaged as a zip file. In a shell, unzip the AppServer Agent to the `AppServerAgent` directory:

```
$ unzip AppServerAgent-<version>.zip  -d AppServerAgent
```

Redirect Agent Output to Stdout

It is a best practice to redirect agent output to `stdout` in containerized environments. To redirect the output of the Java Agent to `stdout`, edit the ver<version>/conf/logging/`log4j2.xml` file and add two `<AppenderRef ref="Console"/>` elements as shown in the example log4j2.xml file.

Copy the Agent Binaries to the Image

Edit the Dockerfile to copy the unpackaged agent binaries to the target folder:

```
COPY AppServerAgent/ /opt/appdynamics/
```

Set the Java Agent Environment Variables

If you are running the application in a non-Kubernetes environment (using `docker run` for example), set the agent environment variables in the Dockerfile. For example:

```
ENV APPDYNAMICS_AGENT_APPLICATION_NAME=<value>
ENV APPDYNAMICS_AGENT_TIER_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=<value>
ENV APPDYNAMICS_CONTROLLER_HOST_NAME=<value>
ENV APPDYNAMICS_CONTROLLER_PORT=<value>
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED=<value>
ENV APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME=true
ENV APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME_PREFIX=<value>
```

For Kubernetes applications, omit these environment variables from the Dockerfile and set them using ConfigMaps and Secrets as described in Best Practices to Configure Agents in Kubernetes.

The reuse node name and prefix environment variables are required to support unique naming for multiple container instances for the same application image. See Reuse Node Name.

Add the `-javaagent` Argument to the Startup Command

Edit the Dockerfile to include the `-javaagent` argument in the image start command based on the location where the agent binaries were copied. For example:

```
ENV JAVA_OPTS -javaagent:/opt/appdynamics/javaagent.jar
CMD ["java", "$JAVA_OPTS", "-jar", "/myapp.jar"]
```

Note that for some Java frameworks such as Spring Boot, the existing `JAVA_TOOL_OPTIONS` environment variable can be leveraged to include the `-javaagent` argument.

(OpenShift Only) Set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` Environment Variable

For Java applications running in OpenShift, set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` environment variable to enable APM correlation with the Cluster Agent. Since the value depends on a runtime value, set this environment variable in the image startup script using the values documented in Manually Configure App Agents to Correlate with the Cluster Agent. For example, for an OpenShift 3.10 or 3.11 environment, add this startup script `startup.sh` to the Docker image:

```
#!/bin/bash
# OpenShift 3.10 or 3.11:
APPDYNAMICS_AGENT_UNIQUE_HOST_ID=$(sed -rn '1s#.*/##; 1s/docker-(.{12}).*/\\1/p' /proc/self/cgroup)
exec java $JAVA_OPTS -jar /myapp.jar
```

and update the startup command in the Dockerfile to reference it:

```
CMD ["/startup.sh"]
```

(On-Premises Controller Only) Copy the Controller Certs to the Image

For Java Agents communicating with an on-premises Controller, edit the Dockerfile to copy the cert file containing the on-premises certs to the agent `conf` folder. For example:

```
COPY ./onprem-cacerts.jks /opt/appdynamics/ver4.5.11.26665/conf/cacerts.jks
```

See Enable SSL for the Java Agent.

Example Configuration for Using a Dockerfile

This Dockerfile builds a single image with the application and agent binaries included and this Kubernetes deployment spec references that Docker image. This Dockerfile uses a multi-stage build and downloads and unzips the agent.

Example Log4j Configuration File

This updated `ver<version>/conf/logging/log4j2.xml` configuration file redirects the Java Agent logs to stdout. It adds `<AppenderRef ref="Console"/>` to the Root element.

```
<?xml version="1.0" encoding="UTF-8"?>
<Configuration status="INFO" monitorInterval="2">
   <Appenders>
      <Console name="Console" target="SYSTEM_OUT">
         <PatternLayout pattern="[%t] %d{ABSOLUTE} %5p %c{1} - %m%n" />
      </Console>
      <ADRRAFAppender name="DefaultAppender" fileName="agent.log">
         <PatternLayout pattern="[%t] %d{DATE} %5p %c{1} - %m%n" />
         <SizeBasedTriggeringPolicy size="20 MB" />
         <ADRolloverStrategy max="5" />
         <RegexFilter regex=".*REST.*" onMatch="DENY" onMismatch="ACCEPT" />
      </ADRRAFAppender>
      <ADRRAFAppender name="BCTAppender" fileName="ByteCodeTransformer.log">
         <PatternLayout pattern="[%t] %d{DATE} %5p - %m%n" />
         <SizeBasedTriggeringPolicy size="20 MB" />
         <ADRolloverStrategy max="5" />
      </ADRRAFAppender>
      <ADRRAFAppender name="RESTAppender" fileName="REST.log">
         <PatternLayout pattern="[%t] %d{DATE} %5p %c{1} - %m%n" />
         <RegexFilter regex=".*REST.*" onMatch="ACCEPT" onMismatch="DENY" />
         <SizeBasedTriggeringPolicy size="20 MB" />
         <ADRolloverStrategy max="5" />
      </ADRRAFAppender>
      <ADRRAFAppender name="DynamicServiceAppender" fileName="dynamic-service.log">
         <PatternLayout pattern="[%t] %d{DATE} %5p %c - %m%n" />
         <SizeBasedTriggeringPolicy size="20 MB" />
         <ADRolloverStrategy max="5" />
      </ADRRAFAppender>
      <ADRRAFAppender name="BusinessTransactionsLogger" fileName="BusinessTransactions.log">
         <PatternLayout pattern="[%t] %d{DATE} %5p - %m%n" />
         <SizeBasedTriggeringPolicy size="20 MB" />
         <ADRolloverStrategy max="5" />
      </ADRRAFAppender>
      <ADRRAFAppender name="DataPipelineAppender" fileName="data-pipeline.log">
         <PatternLayout pattern="[%t] %d{DATE} %5p %c - %m%n" />
         <SizeBasedTriggeringPolicy size="20 MB" />
         <ADRolloverStrategy max="5" />
      </ADRRAFAppender>
      <ADRRAFAppender name="APIAppender" fileName="api.log">
         <PatternLayout pattern="[%t] %d{DATE} %5p %c - %m%n" />
         <SizeBasedTriggeringPolicy size="20 MB" />
         <ADRolloverStrategy max="5" />
      </ADRRAFAppender>
   </Appenders>
   <Loggers>
      <!--  to control the logging level of the agent log files, change "level" attribute. level="
all|trace|debug|info|warn|error"-->
      <AsyncLogger name="com.singularity" level="info" additivity="false">
         <AppenderRef ref="DefaultAppender" />
         <AppenderRef ref="RESTAppender" />
      </AsyncLogger>
      <AsyncLogger name="com.singularity.BusinessTransactions" level="info" additivity="false">
         <AppenderRef ref="BusinessTransactionsLogger" />
      </AsyncLogger>
      <AsyncLogger name="com.singularity.dynamicservice" level="info" additivity="false">
         <AppenderRef ref="DynamicServiceAppender" />
      </AsyncLogger>
      <AsyncLogger name="com.singularity.ee.service.datapipeline" level="info" additivity="false">
         <AppenderRef ref="DataPipelineAppender" />
      </AsyncLogger>
      <AsyncLogger name="com.singularity.datapipeline" level="info" additivity="false">
         <AppenderRef ref="DataPipelineAppender" />
      </AsyncLogger>
      <AsyncLogger name="com.singularity.BCTLogger" level="info" additivity="false">
         <AppenderRef ref="BCTAppender" />
      </AsyncLogger>
      <AsyncLogger name="com.singularity.api" level="info" additivity="false">
         <AppenderRef ref="APIAppender" />
      </AsyncLogger>
      <AsyncLogger name="com.singularity.segment.TxnTracer" level="info" additivity="false">
         <AppenderRef ref="DefaultAppender" />
```

```
      </AsyncLogger>
      <Root level="error">
         <AppenderRef ref="DefaultAppender" />
         <AppenderRef ref="Console" />
      </Root>
   </Loggers>
</Configuration>
```

Agent Installation by Java Framework

These pages describe individual considerations and instructions for installing the Java Agent for some of the application servers supported for the Java Agent.

Apache Cassandra Startup Settings

The Java Agent bootstraps using the javaagent command line option. Add this option to the `cassandra` (Linux) or `cassandra.bat` (Windows) file.

Instrument Cassandra in a Windows Environment

1. Open the `apache-cassandra-x.x.x\bin\cassandra.bat` file.
2. Add the Java Agent `javaagent` path to the `JAVA_OPTS` variable. Make sure to include the drive in the full path to the Java Agent directory.

   ```
   -javaagent:<agent_home>\javaagent.jar
   ```

   For example:

   ```
   set JAVA_OPTS=-ea
       -javaagent:C:\appdynamics\agent\javaagent.jar
       -javaagent:"%CASSANDRA_HOME%\lib\jamm-0.2.5.jar
       . . .
   ```

3. Restart the Cassandra server for the changes to take effect.

Instrument Cassandra in a Linux Environment

1. Open the `apache-cassandra-x.x.x/bin/cassandra.in.sh` file.
2. Add the `javaagent` argument at the top of the file:

   ```
   JVM_OPTS=-javaagent:<agent_home>/javaagent.jar
   ```

   For example:

   ```
   JVM_OPTS=-javaagent:/home/software/appdynamics/agent/javaagent.jar
   ```

3. Restart the Cassandra server for the changes to take effect.

Apache Tomcat Startup Settings

To instrument applications on Apache Tomcat, add the Java Agent JAR location as a Catalina environment, or `CATALINA_OPTS` variable.

Instrument Apache Tomcat

1. Open (or create if it doesn't already exist) the `setenv.sh` (Linux) or `setenv.bat` (Windows) file. For Tomcat 6 and later, you can put the file in the `CATALINA_BASE/bin` directory. For previous versions of Tomcat, put the file in the `CATALINA_HOME/bin` directory
2. Add the `-javaagent` argument to the file as a Catalina environment variable, as follows:

   On Linux:

   ```
   export CATALINA_OPTS="$CATALINA_OPTS -javaagent:<agent_home>/javaagent.jar"
   ```

   Replace <agent_home> with the full path to the Java Agent JAR file.
   For example:

   ```
   export CATALINA_OPTS="$CATALINA_OPTS -javaagent:/home/appserver/appagent/javaagent.jar"
   ```

   On Windows:

   ```
   set CATALINA_OPTS=%CATALINA_OPTS% -javaagent:"Drive:<agent_home>\javaagent.jar"
   ```

   For example

   ```
   set CATALINA_OPTS=%CATALINA_OPTS% -javaagent:C:\appagent\javaagent.jar
   ```

3. Restart the application server for the changes to take effect. For more information on running Tomcat as a service, see Setting Properties and Options on Startup.

Instrument Tomcat When Running as a Windows Service

When running Tomcat as a Windows service, add the `javaagent` argument to your Tomcat startup properties. These instructions apply to Apache Tomcat >= 6.x.

To install the Java agent in Tomcat running as a Windows service:

1. Ensure that you are using administrator privileges.
2. Run the Apache `tomcat<version>w.exe` utility to configure your tomcat service to load the appdynamics agent (where `<version>` represents the major version number of the tomcat being instrumented).

   For example:

   ```
   tomcat8w //ES// <servicename>
   ```

3. Click the **Java** tab and in the **Java Options** add:

   ```
   -javaagent:"<agent_home>\javaagent.jar"
   ```

4. Restart the Tomcat service to have the changes take effect.

Apple WebObjects Startup Settings

This page describes how to instrument applications written with WebObjects 5.4.3 on OSX 10.9 systems.

We will use one of the developer examples to illustrate how to instrument an application created with Apple WebObjects. After installing WebObjects, you can find most of the artifacts in the following directories:

```
/Developer/Examples/JavaWebObjects
/Developer/Applications/WebObjects
```

When you run the `HelloWorld` application at `/Developer/Examples/JavaWebObjects/HelloWorld`, a script file is generated:

```
/Developer/Examples/JavaWebObjects/HelloWorld/dist/legacy/HelloWorld.woa/HelloWorld
```

Open the generated script file to edit. Towards the end of the file, line 310 in the following example, appears the Java execute line:

```
304 #
305 # Launch the application.
306 #
307 echo Launching ${SCRIPT_NAME}.woa ...
308
309 echo ${JAVA_EXECUTABLE} ${JAVA_EXECUTABLE_ARGS} -classpath WOBootstrap.jar com.webobjects._bootstrap.WOBootstrap ${COMMAND_LINE_ARGS}
310 eval exec ${JAVA_EXECUTABLE} ${JAVA_EXECUTABLE_ARGS} -classpath WOBootstrap.jar com.webobjects._bootstrap.WOBootstrap ${COMMAND_LINE_ARGS}
~
~
~
~
```

Add the standard Java Agent arguments to the Java execution script for the `HelloWorld` application:

```
307 echo Launching ${SCRIPT_NAME}.woa ...
308
309 echo ${JAVA_EXECUTABLE} ${JAVA_EXECUTABLE_ARGS} -classpath WOBootstrap.jar com.webobjects._bootstrap.WOBootstrap ${COMMAND_LINE_ARGS}
310 eval exec ${JAVA_EXECUTABLE} ${JAVA_EXECUTABLE_ARGS} -Dappdynamics.controller.hostName=localhost \
311 -Dappdynamics.controller.port=8080 \
312 -Dappdynamics.agent.accountName=customer1 \
313 '-Dappdynamics.agent.accountAccessKey=SJ5b2m7d1\$354' \
314 -Dappdynamics.controller.ssl.enabled=false \
315 -Dappdynamics.agent.applicationName=play-correlation \
316 -Dappdynamics.agent.uniqueHostId=play-correlation \
317 -Dappdynamics.agent.tierName=standalone-tier \
318 -Dappdynamics.agent.nodeName=standalone-node \
319 -javaagent:/Users/akilman/Work/codebase/agent/java/core/build/temp/javaagent.jar \
320 -agentlib:jdwp=transport=dt_socket,server=y,suspend=n,address=5006 \
321 -classpath WOBootstrap.jar com.webobjects._bootstrap.WOBootstrap ${COMMAND_LINE_ARGS}
NORMAL  /Developer/Examples/JavaWebObjects/HelloWorld/dist/legacy/HelloWorld.woa/HelloWorld
```

Note: Single quotes and extra escape to account for 'eval'

You can configure business transaction name using getter-chains. For more information, see

- Using Getter Chains
- See "Split by POJO Method Call" on Split Servlet Transaction by Payload Examples

Coherence Startup Settings

To add the `javaagent` command in Oracle Coherence:

1. In the `<coherence_home>/bin/cache-server.sh` file, update the following:

```
$JAVAEXEC -server -showversion $JAVA_OPTS -javaagent:<agent_home>/javaagent.jar -cp "$COHERENCE_HOME/lib
/coherence.jar" com.tangosol.net.DefaultCacheServer $1
```

2. Restart the application server to have the changes take effect.

GlassFish Startup Settings

Oracle GlassFish is an OSGi-based application container. This page describes how to set configure class bootloader settings and load the Java Agent in the runtime JVM.

Instrument Oracle GlassFish

1. Add the location of the Java Agent JAR file as a `-javaagent` JVM option in the `GlassFish` domain. You can add the agent using the `asadmin` tool as follows:

   For Windows:

   ```
   glassfish4\bin\asadmin.bat create-jvm-options '-javaagent:<Drive_letter>:<agent_home>\javaagent.jar'
   ```

   For Linux:

   ```
   glassfish4\bin\asadmin create-jvm-options "-javaagent\:/home/appduser/javaagent/javaagent.jar"
   ```

   Ensure you escape the colon character on Linux.
2. Configure the boot delegation entry for the AppDynamics package:
   - In GlassFish 3.x to 3.1.2, open the `config.properties` file located at `<glassfish_home>/glassfish/osgi/felix/conf` and add the following package prefix to the `config.properties` file:
     `org.osgi.framework.bootdelegation=com.singularity.*`
   - In GlassFish => 3.1.2, in the boot delegation list in the `<glassfish_home>/glassfish/config/osgi.properties` file, add `com.singularity.*`
     For example:

     ```
     eclipselink.bootdelegation=oracle.sql, oracle.sql.*

     # There is no need to use bootdelegation except for the following issues:
     # 1. EclipseLink
     # 4. NetBeans profiler packages exist in parent class loader (see issue #8612)
     # 5. BTrace exists in bootclasspath.
     org.osgi.framework.bootdelegation=${eclipselink.bootdelegation}, \
                                       com.sun.btrace, com.sun.btrace.*, \
                                       org.netbeans.lib.profiler, org.netbeans.lib.profiler.*, \
                                       com.singularity.*

     # The OSGi R4.2 spec says boot delegation uses the boot class loader by default. We need
     # to configure it to use the framework class loader because that class loader is
     ```
3. Restart the application server.

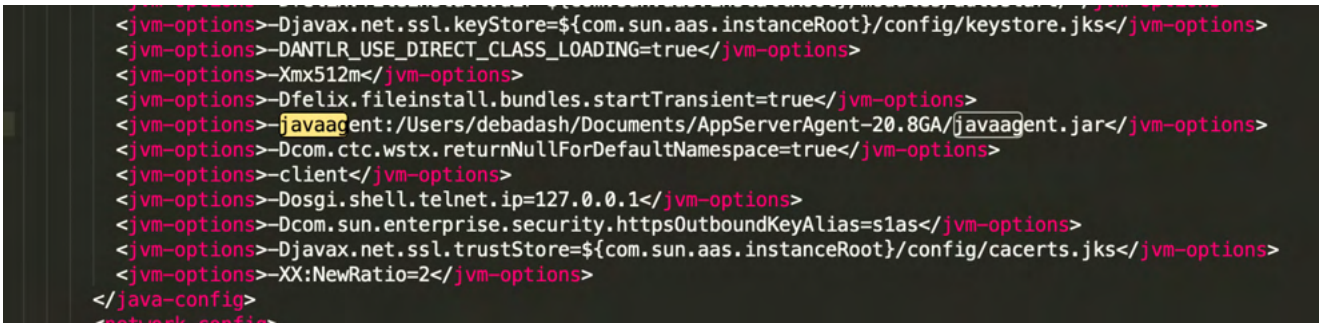
To verify the configuration, review the domain.xml file located at `<glassfish_home>\domains\<domain_name>\config`. The `domain.xml` file should have an entry for the `-javaagent` option.

Instrument Oracle GlassFish with the Admin Console

1. Start the GlassFish application server.
2. Navigate to the GlassFish admin console (`http://localhost:4848/`).
3. Navigate to **Configurations > server-config > JVM Settings**.
4. Click the **JVM Option**s tab and click **Add JVM Option** to add a blank field in the list.
5. Add the following path of the `javaagent.jar` file in the blank field:

   ```
   -javaagent:/home/appduser/javaagent/javaagent.jar
   ```

6. Click **Save** on the right top corner.
7. Restart the GlassFishapplication server and `<glassfish_home>\domains\<domain_name>\config`.
   The `domain.xml` file must contain an entry for the `-javaagent` option.



About Glassfish AMX Support

AppDynamics supports Glassfish AMX MBeans.

Set the `boot-amx` node property to enable AMX MBeans. See boot-amx.

You will see the AMX domain in the MBean Browser in the **JMX** tab of the node dashboard.

IBM WebSphere and InfoSphere Startup Settings

The Java Agent passes the `-javaagent` argument command line option to WebSphere to ensure the App Server Agent has the correct permissions to monitor your app.

Security Requirements and Configuration

Full permissions are required for the agent to function correctly with WebSphere. Grant all permissions on both the server level and the profile level.

Run WebSphere with Security Enabled

To run WebSphere while J2EE security or Global security is enabled, you must make changes to WebSphere's `server.policy` file to prevent problems with the interaction between WebSphere and the Java Agent.

A `codeBase` value indicates the location of the source code. You must grant permissions to the code from that location. The `codeBase` is a URL value, and depends on the characters at the end. A `codeBase` with a trailing `"/-"` matches all files, both class and JAR files, in the directory and recursively all files in subdirectories contained in the directory.

1. Navigate to the `server.policy` file, located in *<webshere_home>*`/properties` or in *<webshere_profile_home>*`/properties`.
2. Add this code block to the WebSphere `server.policy` file:

Syntax

```
grant codeBase "file:</full/path/to/agent_install_directory>/-" { permission java.security.
AllPermission; };
```

Example

```
grant codeBase "file:/opt/appdynamics/javagent/agent4.5.1.23676/-" { permission java.security.
AllPermission; };
```

3. Save the file.

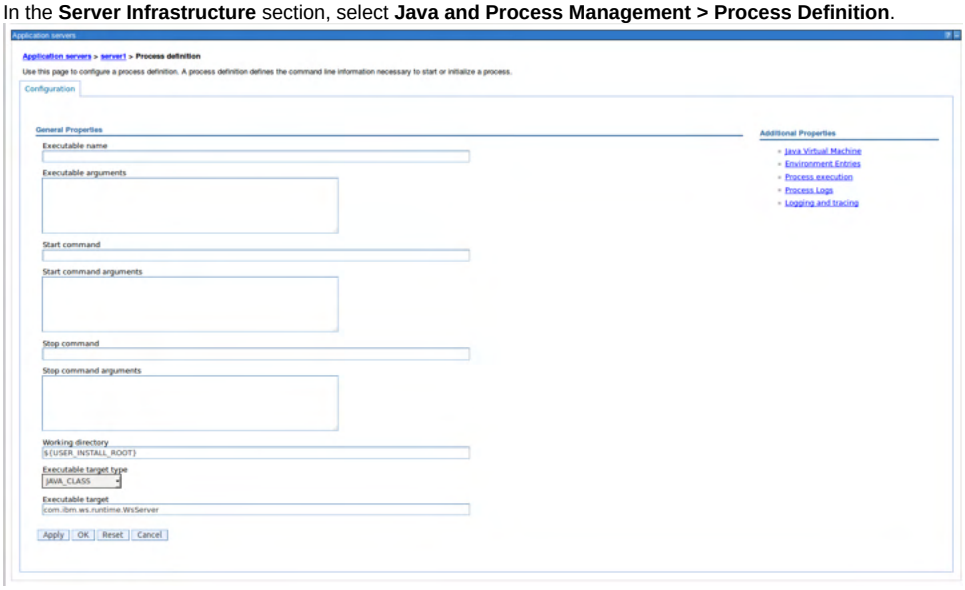
Performance Monitoring Statistic

Under **Application servers >** `<server_name>` **> Performance Monitoring Infrastructure (PMI)**, set a **Currently monitored statistic set** to an option other than **None** for the JMX functionality to work.

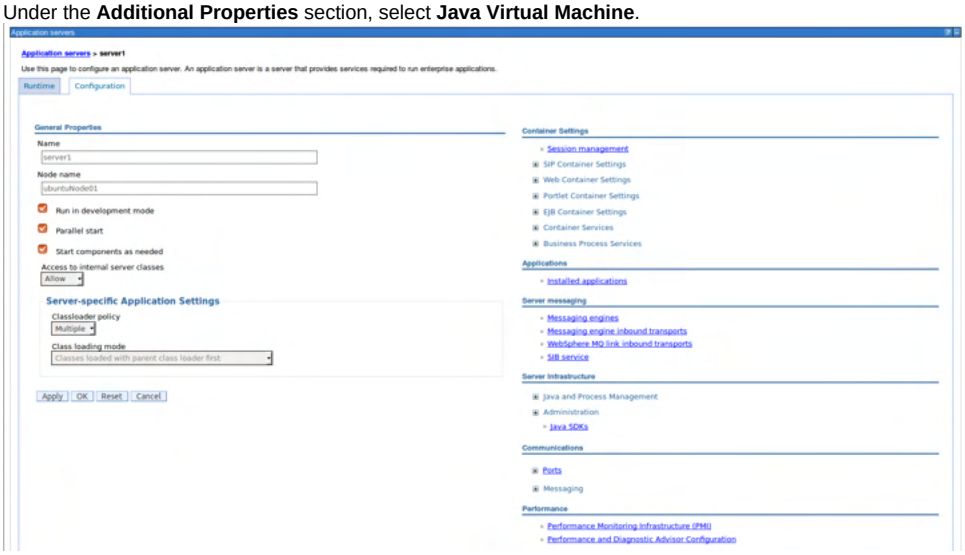
Instrument WebSphere 7.x, 8.x, and 9.x, or InfoSphere 8.x

1. Log in to the administrative console for the WebSphere node where you want to install the App Server Agent.
2. In the administrative console, select **Servers > Server Types > WebSphere application servers**.
3. Select the name of your server.

4. In the **Server Infrastructure** section, select **Java and Process Management > Process Definition**.



5. Under the **Additional Properties** section, select **Java Virtual Machine**.



6. Enter the `javaagent` option with the full path to the AppDynamics `javaagent.jar` file in the **Generic JVM** arguments field.

For Windows:

```
-javaagent:<Drive Letter>:<agent install location>\javaagent.jar
```

For Linux:

```
-javaagent:<agent install location>/javaagent.jar
```

7. Click **OK**.

WebSphere uses Equinox as its OSGi container. In some cases, you may also need to add the Java agent packages to the OSGi `bootdelegation` system property:

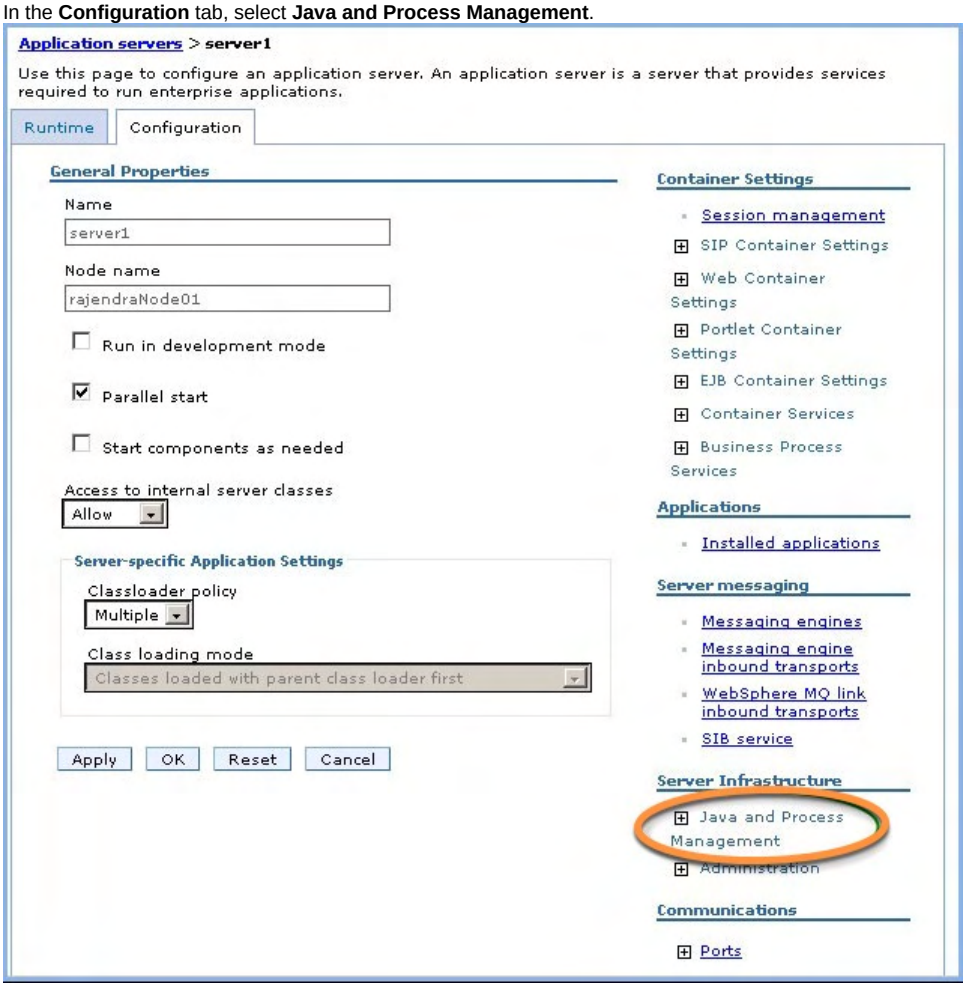
```
-Dorg.osgi.framework.bootdelegation=META-INF.services,com.singularity.*,com.ibm.*
```

Instrument WebSphere 6.x

1. Log in to the administrative console for the WebSphere node where you want to install the Java Agent.
2. In the left navigation tree, select **Servers > Application servers**.

3. Click the name of your server in the list of servers.

4. In the **Configuration** tab, select **Java and Process Management**.



5. Enter the `javaagent` option with the full path to the Java Agent `javaagent.jar` file in the **Generic JVM** arguments field.

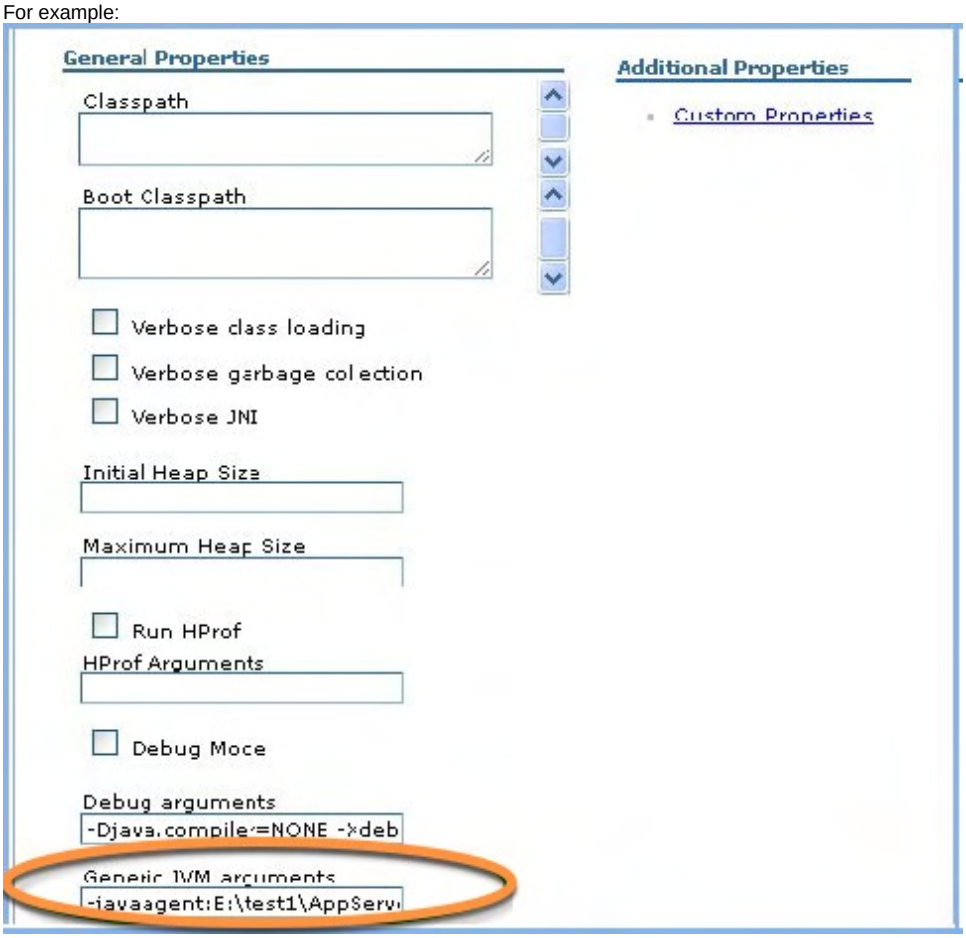
   For Windows:

   ```
   -javaagent:<Drive Letter>:<agent install location>\javaagent.jar
   ```

   For Linux:

   ```
   -javaagent:<agent install location>/javaagent.jar
   ```

For example:



6. Click **OK**.

Instrument WebSphere 5.x

1. Log in to the administrative console of the WebSphere node where you want to install the App Server Agent.
2. In the administrative console, click **Servers**.
3. Click **Application Servers**.
4. Click the name of your server.
5. Under **Additional Properties**, click **Process Definition**.
6. On the next page, under **Additional Properties**, click **Java Virtual Machine**.
7. Enter the `javaagent` option with the full path to the Java Agent `javaagent.jar` file in the **Generic JVM** arguments field.

   For Windows:

   ```
   -javaagent:<Drive Letter>:<agent install location>\javaagent.jar
   ```

   For Linux:

   ```
   -javaagent:<agent install location>/javaagent.jar
   ```

8. Click **OK**.

Verify the Java Agent Configuration

Verify the configuration settings by checking the `server.xml` file of the WebSphere node where you installed the Java Agent. The `server.xml` file should have this entry:

```
<jvmEntries ... genericJvmArguments='-javaagent:E:\test1\AppServerAgent\javaagent.jar' disableJIT="false"/>
```

JBoss and Wildfly Startup Settings

This page describes how to install the AppDynamics Java Agent on Red Hat JBoss Enterprise Application Server and JBoss Wildfly.

Before You Install

To install the agent on JBoss or Wildfly, you add the Java Agent and log manager packages to the server startup routine.

The configured location varies based on your framework version:

- In Linux, add the settings to `standalone.conf` or `standalone.sh`.
- In Windows, add the settings to `standalone.conf.bat`.
- If using JBoss 4.x or 5.x, add the configuration to `run.sh` for Linux or `run.bat` for Windows.

Initialize the JVM

To install the Java Agent on JBoss EAP or JBoss Wildfly, you need to initialize the JVM. Run this parameter:

```
JAVA_OPTS="$JAVA_OPTS -Djboss.modules.system.pkgs=org.jboss.byteman,com.singularity"
```

If you do not initialize the JVM, the installation generates a "class not found" exception.

Standalone Mode Agent Installation

These instructions assume the use of Red Hat JBoss (Application Server 7.x or Enterprise Application Server >= 6.x).

To install the Java Agent on JBoss Standalone:

Dynamic LogManager Location

On standalone JBoss instances, instead of hard coding the path and name of the log manager JAR, you can use glob pattern matching techniques to make the path to the log manager file dynamic, so that it is resilient to change or variances among systems.

The exact steps to accomplish this varies by environment. These sections provide an example of this configuration on Windows and Linux systems, and are meant as a starting point for your own implementation.

Windows

In Windows, the `standalone.conf.bat` gets this additional snippet:

```
...
rem jboss.modules.system.pkgs
set JAVA_OPTS=%JAVA_OPTS% -Djboss.modules.system.pkgs=org.jboss.byteman,com.singularity,org.jboss.logmanager

rem java.util.logging
set JAVA_OPTS=%JAVA_OPTS% -Djava.util.logging.manager=org.jboss.logmanager.LogManager

rem bootclasspath
set LOGMANAGER=
for /f %%i in ('dir /b "%JBOSS_HOME%\modules\system\layers\base\org\jboss\logmanager\main\jboss-logmanager-*.
jar"') do (
   set LOGMANAGER_JAR=%JBOSS_HOME%\modules\system\layers\base\org\jboss\logmanager\main\%%i
)
set JAVA_OPTS=%JAVA_OPTS% -Xbootclasspath/p:%LOGMANAGER_JAR%
```

The path to the LogManager JAR file under the JBoss home can vary by JBoss version. Be sure to check your system and adjust the path as shown in the example accordingly.

Linux

In Linux, you can populate the path dynamically with the following code:

```
JBOSS_MODULES_SYSTEM_PKGS ="org.jboss.byteman,com.singularity,org.jboss.logmanager"

JAVA_OPTS="$JAVA_OPTS -Djava.util.logging.manager=org.jboss.logmanager.LogManager"
JAVA_OPTS="$JAVA_OPTS -Xbootclasspath/p:$(ls ${JBOSS_HOME}/modules/system/layers/base/org/jboss/logmanager/main
/jboss-logmanager-*.jar)"
```

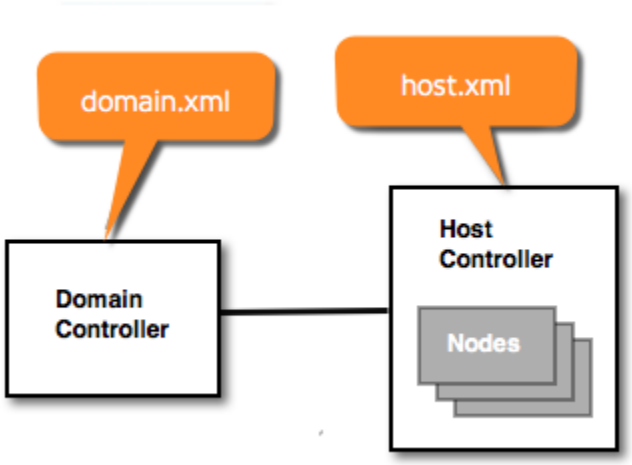
If using the `${JBOSS_HOME}` variable, as in the example, be sure to set the variable to the directory to the JBoss installation directory on your system.

The path to the `LogManager` JAR file under the JBoss home can vary by JBoss version. Be sure to check your system and adjust the path as shown in the example accordingly.

Domain Mode Agent Installation

For domain mode, the location in which you need to configure the settings depends upon specifics for your environment. Keep in mind that a domain is made up of these components:

- A domain controller, the administration and configuration server. The domain.xml configuration file is the global configuration for the managed hosts.
- Host controllers, which manage a particular host containing one or more application server nodes. There can be any number of host controllers and nodes. The `hosts.xml` file contains settings for the nodes on that host machine.



Where you put the configuration, therefore, varies as follows:

- `domain.xml`: Settings that can be identical for all hosts in the managed domain (i.e., the log manager and agent files are at the same location on all machines) can go into the domain.xml file for the Domain Controller.
- `host.xml`: Settings that need to be specialized for individual hosts (for example, if the paths to relevant files on hosts vary) need to go into the `host.xml` file.

You can add configuration settings to both `domain.xml` and `host.xml`, depending on which are global and which are host-specific. The following sections show an example of adding general settings to the domain configuration and node name setting to the host configuration.

Domain.xml Configuration

1. Locate and edit `domain.xml` for the domain. This is usually located under $JBOSS_HOME/domain/configuration/.
2. Find the the `system-properties` element and add a property named `jboss.modules.system.pkgs` with a value of `com.singularity` to the existing system properties. For example:

   ```
   <system-properties>
          <!-- IPv4 is not required, but setting this helps avoid unintended use of IPv6 -->
          <property name="java.net.preferIPv4Stack" value="true"/>
          <property name="jboss.modules.system.pkgs" value="com.singularity"/>
   </system-properties>
   ```

   This property tells the JBoss class loader to load the AppDynamics packages. This is required for the Java Agent to run.
3. Under the server group name where you want to enable your agents, add the JVM options using the appropriate values for your agent location, JBoss application name, and tier name.

```
<server-group name="main-server-group" profile="full">
    <jvm name="default">
         <heap size="1303m" max-size="1303m"/>
         <permgen max-size="256m"/>
         <jvm-options>
            <option value="-javaagent:<agent_install_dir>/javaagent.jar"/>
            <option value="-Dappdynamics.agent.applicationName=JBOSS-EAP-APP"/>
            <option value="-Dappdynamics.agent.tierName=JBOSS-EAP-TIER"/>
         </jvm-options>
    </jvm>
    <socket-binding-group ref="full-sockets"/>
 </server-group>
```

Changes to the `domain.xml` file require a restart of the management host to take effect. The changes are not propagated to server hosts until they are restarted as well.

Host.xml Configuration

For each host, specify the AppDynamics node name in the `host.xml` file, usually located under `$JBOSS_HOME/domain/configuration/`.

Add the `-Dappdynamics.agent.nodeName` JVM option to specify the node name for this instance:

```
<servers>
    <server name="server-one" group="main-server-group">
            <jvm name="default">
              <jvm-options>
                <option value="-agentlib:jdwp=transport=dt_socket,address=8787,server=y,suspend=n"/>
                <option value="-Dappdynamics.agent.nodeName=JBOSS-EAP-NODE-1"/>
              </jvm-options>
            </jvm>
     </server>
     <server name="server-two" group="main-server-group" auto-start="true">
            <socket-bindings port-offset="150"/>
            <jvm name="default">
              <jvm-options>
                <option value="-Dappdynamics.agent.nodeName=JBOSS-EAP-NODE-2"/>
              </jvm-options>
            </jvm>
      </server>
      <server name="server-three" group="other-server-group" auto-start="false">
            <socket-bindings port-offset="250"/>
      </server>
</servers>
```

For brevity, comments have been removed from the sample.

Troubleshooting JBoss Startup Issues

Most issues installing the Java Agent on JBoss result from conflicts between startup arguments. That is, settings you add for the Java Agent may be overridden or conflict in other ways with existing arguments. Such issues are not always easy to detect.

The best way to begin troubleshoot such startup issues is to print and inspect the startup arguments that JBoss actually gets when attempting to start. To do this, view JBoss process information during startup using the following command. You need to issue this command while the start up attempt is occurring but before it fails.

```
ps -ef | grep [o]rg.jbossas | tr ' ' '\n' | sed -e '/^$/d'
```

Troubleshooting JBoss Shutdown Issues

When enabling the JMXremote features of the JVM on a JBoss 5.1.2 server configuration, the following error is generated when calling the `/bin/shutdown.sh`:

```
javax.management.JMRuntimeException: Failed to load MBeanServerBuilder class org.jboss.system.server.jmx.
MBeanServerBuilderImpl:
java.lang.ClassNotFoundException: org.jboss.system.server.jmx.MBeanServerBuilderImpl
```

Resolution

Sometimes, there is JAVA_OPTS parameter in the environment, and it affects to a java process when the JVM start.
From the reason that EAP uses JAVA_OPTS parameter internally, it should not be in the environment.

To clear the parameter in the environment, executing the following from a console:

1. `export JAVA_OPTS=""`
2. `env|grep JAVA_OPTS`
   JAVA_OPTS= <You will see this message>
3. `shutdown.sh -s jnp://localhost:1099 -u USER -p PASSWORD`

Root Cause

JMX related options should not be set in JAVA_OPTS when calling shutdown.sh. Ensure JAVA_OPTS is only set when starting JBoss EAP, not when running.

Jetty Startup Settings

This page describes how details for instrumenting the Jetty web server with the AppDynamics Java Agent vary depending on the version of Jetty you are using.

Instrument Jetty Version 8.x or 9.x

You can instrument Jetty with the AppDynamics agent either from the server startup command, or by editing the Jetty startup configuration file.

- To add the agent to Jetty at the command line, pass the `javaagent` argument with the fully qualified location of the Java agent JAR file when starting the Jetty server. For example:

  ```
  java -javaagent:/<agent_home>/javaagent.jar -jar start.jar
  ```

- To use the startup configuration file, edit the `start.ini` file in the Jetty base directory by adding these lines:

  ```
  --exec
  -javaagent:/<agent_home>/javaagent.jar
  ```

Be sure to specify the location of the AppDynamics `javaagent.jar` file in the `javaagent` argument as appropriate for your system. Restart the Jetty server after modifying the configuration file to have your changes take effect.

Instrument Jetty Version 6.x or 7.x

For Jetty version 6.x or 7.x, you can add the `javaagent` command line option to your `jetty.sh` file:

1. Open the `jetty.sh` start script file.
2. Add the following `javaagent` argument to the beginning of the script.

   ```
   java -javaagent:/<agent_home>/javaagent.jar
   ```

3. Save the script file.
4. Restart the application server for the changes to take effect.

Custom Exclude Rule for WebAppContext

For the Eclipse version of Jetty, to enable AppDynamics to detect business transactions based on web services, you need to create a Servlet exclude rule for the default Jetty servlet `org.eclipse.jetty.webapp.WebAppContext`.

This ensures that AppDynamics can detect business transactions based on the web services provided by your web applications while ignoring unmapped URL or URLs for the underlying framework.

Mule ESB Startup Settings

To load the Java Agent in Mule ESB, pass the Java Agent JAR location as a JVM argument to Mule.

Mule ESB 3.X or later uses the Tanuki configuration environment. To specify JVM arguments in your Mule ESB environment, you need to configure them as additional parameters to the Tanuki Java Service Wrapper configuration file, `wrapper.conf`, as described below.

Configuring the Tanuki Service Wrapper

1. Open the Java Service Wrapper configuration file:
   `<MULE_HOME>/conf/wrapper.conf`
2. Find the location indicated for Java Additional Parameters:

   ```
   # Java Additional Parameters
   wrapper.java.additional.1=
   ```

3. Add the path to the Java Agent JAR file as a JVM argument using a `wrapper.java.additional.`*n* parameter, as follows.

   ```
   wrapper.java.additional.n="-javaagent:/path_to_appagent/javaagent.jar"
   wrapper.java.additional.n.stripquotes=TRUE
   ```

   Where "n" is the next available integer among the `wrapper.java.additional` parameters already in the `wrapper.conf` file, if any. The numbers serve to identify each Java Additional Parameter in the file. Do not skip numbers when adding the property. Replace `path_to_appagen` to the path to the `javaagent.jar` file in your system. The `stripquotes` parameter is necessary only if there are spaces in the path or filename, but is safe to include if not.

   For example, on a Linux system and with seven Java parameters already in the file, add the following properties:

   ```
   wrapper.java.additional.8="-javaagent:/opt/AppDynamics/Agent/app_agent/javaagent.jar"
   wrapper.java.additional.8.stripquotes=TRUE
   ```

   There may be additional `wrapper.java.additional` properties defined in other Mule files. These are generated by the system. As indicated by comments preceding these properties, you should not make changes directly to the properties. Mule automatically auto-increments the index number for these properties based on the highest integer number used in `wrapper.conf`, so you do not need to modify or otherwise account for the index numbers of auto-generated configuration properties.

Oracle WebLogic Startup Settings

To enable the AppDynamics Java Agent add the `javaagent` command-line option to the WebLogic startup file. If you start and stop clustered WebLogic servers using Node Manager, configure server startup in the WebLogic Server Administration Console.

Instrument Oracle WebLogic for Windows

1. Open the `startWebLogic.cmd` file, located at `<weblogic_version_install_dir>\user_projects\domains\<domain_name>\bin`.
2. Add following `javaagent` argument to the application server start script.

```
set JAVA_OPTIONS=%JAVA_OPTIONS% -javaagent:"<drive>:\<agent_home>\javaagent.jar"
```

   - The `javaagent` argument must reference the full path of the agent installation directory, including the drive letter.
   - The command must precedes the WebLogic start commands, for example:

```
@REM Enable the AppDynamics Java Agent
set JAVA_OPTIONS=%JAVA_OPTIONS% -javaagent:"E:\AppDynamics\AppServerAgent\javaagent.jar"
@REM AppDynamics Java Agent END

@REM START WEBLOGIC
echo starting weblogic with Java version:
%JAVA_HOME%\bin\java %JAVA_VM% -version
```

3. Restart the application server for the changes to take effect.

Instrument Oracle WebLogic for an Application Running as a Windows Service

Some applications have a pre-compiled startup method that installs WebLogic as a Windows service.

To add the agent to the service:

1. Open the script file that starts the application service, such as `install_XXXX_Server_Start_Win_Service.cmd`.
2. Add the `javaagent` command before the line starting with "`set CMDLINE=%JAVA_VM%...`" such as:

```
set CLASSPATH=%MYSERVER_CLASSPATH%;%PRE_CLASSPATH%;%WEBLOGIC_CLASSPATH%;%POST_CLASSPATH%;%
WLP_POST_CLASSPATH%

set JAVA_VM=%JAVA_VM% %JAVA_DEBUG% %JAVA_PROFILE%

set WLS_DISPLAY_MODE=Production

@REM Enable the AppDynamics Java Agent
set JAVA_OPTIONS=%JAVA_OPTIONS% -javaagent:"<drive>:\<agent_home>\javaagent.jar"
@REM AppDynamics Agent END

set CMDLINE=%JAVA_VM% %MEM_ARGS% -classpath %CLASSPATH% %JAVA_OPTIONS% weblogic.Server"
```

3. Open a command prompt and run the following script to remove the existing Windows Service for your application:

```
install_XXXXX_Server_Start_Win_Service.cmd  XXXXX_xxxxx_Production_Server  R
```

4. Install the updated Windows Service for your application:

```
install_XXXXX_Server_Start_Win_Service.cmd  XXXXX_xxxx_Production_Server  I
```

5. From the **WebLogic** web console, stop your application.
6. Start your application (which also starts WebLogic) from the Windows Services application, where the Windows service name = XXXXX_xxxx_Production_Server.
7. Ensure that your application is working properly.

See Creating a Server-Specific Script in the Oracle documentation.

Instrument Oracle WebLogic for Linux

1. Edit `startWebLogic.sh` located at `<weblogic_<version#>_install_dir>/user_projects/domains/<domain_name>/bin/startWebLogic.sh` .
2. Add the following to the beginning of your application server start script:

```
export JAVA_OPTIONS="$JAVA_OPTIONS -javaagent:/agent_home/javaagent.jar"
```

   - The `javaagent` argument must reference the full path of the agent installation directory.
   - The `export` command precedes the WebLogic start commands, for example:

```
#Enable the AppDynamics Java Agent
export JAVA_OPTIONS="$JAVA_OPTIONS -javaagent:/opt/AppDynamics/AppServerAgent/javaagent.jar"

# START WEBLOGIC
echo "starting weblogic with Java version:"
${JAVA_HOME}/bin/java ${JAVA_VM} -version
```

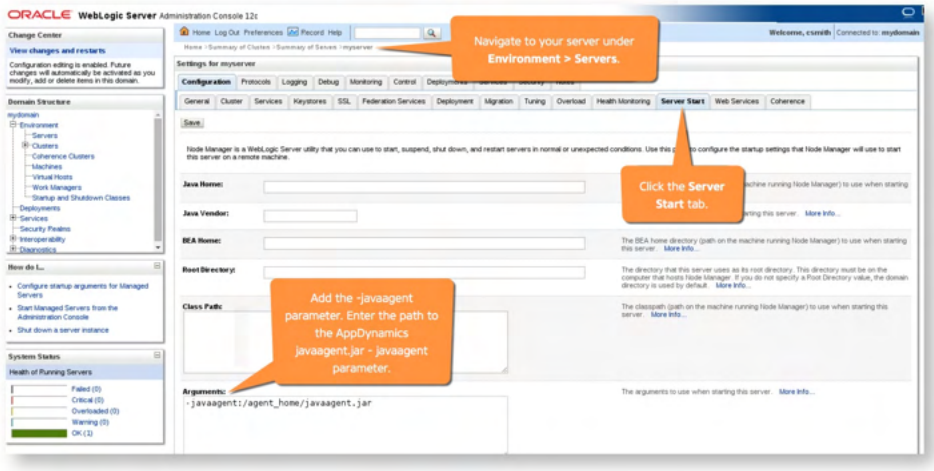
3. Restart the application server for the changes to take effect.

Instrument Clustered WebLogic Servers

For clustered WebLogic servers, you start and stop using Node Manager, and configure server startup in the WebLogic Server Administration Console.

1. Open the **WebLogic Server Administration Console**. See Overview of the Administration Console.
2. Navigate to **Environment > Servers** and click your server in the **Server List**.
3. Click the Server Start tab.
4. Add the `javaagent` argument and set the value to the path to the Java Agent:

```
-javaagent:/<agent_home>/javaagent.jar
```



5. Restart the application server.

Java 2 Security Configuration

If you have enabled Java 2 security on your WebLogic server, you must add this code block to the `weblogic.policy` file:

```
grant codeBase "file:/<agent_home>/-"
{ permission java.security.AllPermission; };
```

OSGi Infrastructure Configuration

The GlassFish application server versions 3.x and later uses OSGi architecture. By default, OSGi containers follow a specific model for bootstrap class delegation. Classes that are not specified in the container's `CLASSPATH` are not delegated to the bootstrap `classloader`; therefore you must configure the OSGi containers for the Java Agentclasses.

See GlassFish Startup Settings and GlassFish OSGi Configuration per Domain.

To ensure that the OSGi container identifies the Java Agent, specify this package prefix:

```
org.osgi.framework.bootdelegation=com.singularity.*
```

This prefix follows the regular boot delegation model so that the Java Agent classes are visible.

If you already have existing boot delegations, add "`com.singularity.*`" to the existing path separated by a comma. For example:

```
org.osgi.framework.bootdelegation=com.sun.btrace., com.singularity.
```

Configure Eclipse Equinox

If running Eclipse Equinox under Glassfish:

1. Open the `config.ini` file located at `<glassfish install directory>/glassfish/osgi/equinox/configuration`.
2. Add this package prefix to the `config.ini` file:

```
org.osgi.framework.bootdelegation=com.singularity.*
```

If running Eclipse Equinox under the WebSphere Application Server Liberty profile:

1. Open the bootstrap.properties file in the JVM directory <*WLP_home*>/usr/servers/<*server_name*> for editing.
2. Add this code line:

```
org.osgi.framework.bootdelegation=com.singularity.*
```

See Getting Started with Equinox.

Configure Apache Sling

1. Open the `sling.properties` file. The location of the `sling.properties` varies depending on the Java platform.
   In the Sun/Oracle implementation, the `sling.properties` file is located at `<java.home>/lib`.
2. Add this package prefix to the `sling.properties` file:

```
org.osgi.framework.bootdelegation=com.singularity.*
```

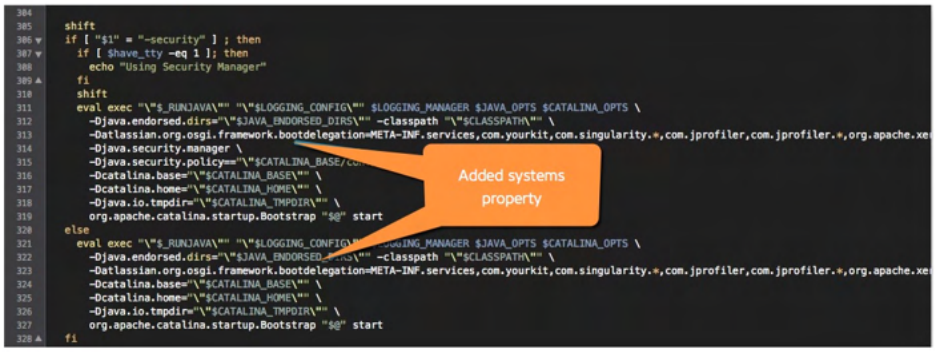
Configure JIRA or Confluence

For JIRA >= 5.1.8, and Confluence >= 5.3:

1. Open the startup script (that is, `catalina.sh`) for editing.
2. Look for the `start` command block (look for "`elif [ "$1" = "start" ] ; then`")
3. Add the following Java system property alongside the existing properties in both `else` blocks:

```
-Datlassian.org.osgi.framework.bootdelegation=META-INF.services,com.yourkit,com.singularity.*,com.
jprofiler,com.jprofiler.*,org.apache.xerces,org.apache.xerces.*,org.apache.xalan,org.apache.xalan.*,sun.
*,com.sun.jndi,com.icl.saxon,com.icl.saxon.*,javax.servlet,javax.servlet.*,com.sun.xml.bind.*\
```

4. Add the property to the run command block as well to instrument the application started in run mode. For example:



5. Before the comment line 'Execute The Requested Command', add the `-javaagent` argument to the file as a new Java option:
6. Restart the application.

Configure Other OSGi-based Containers

For other OSGI-based runtime containers, add this package prefix to the appropriate OSGi configuration.

```
file.org.osgi.framework.bootdelegation=com.singularity.*
```

Resin Startup Settings

The Java Agent bootstraps using the `javaagent` command-line option. Add this option to the `resin.sh` or `resin.bat` file.

Instrument Resin 1.x - 3.x for Windows

1. Open the `resin.bat` file, located at `<resin_home>/bin`.
2. At the beginning of your application server start script, add the `javaagent` argument with the full path (including drive) to the `javaagent.jar` file on your system:

```
exec JAVA_EXE -javaagent:"<drive>:\<agent_home>\javaagent.jar"
```

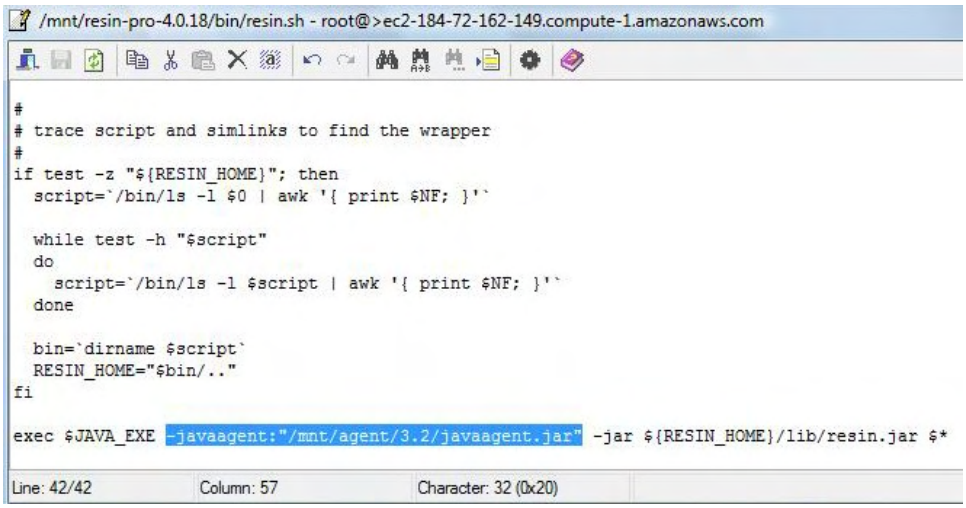
3. Restart the application server to have the changes take effect.

Instrument Resin 1.x - 3.x for Linux

1. Open the `resin.sh` file, located at `<resin_home>/bin`.
2. At the beginning of your application server start script, add the `javaagent` argument with the full path to the `javaagent.jar` file on your system:

```
exec $JAVA_EXE -javaagent:"<agent_home>/javaagent.jar"
```

For example:



3. Restart the application server for the changes to take effect.

Instrument Resin 4.x

1. To install the Java Agent into Resin => 4.X, edit the `./conf/resin.xml` file and add:

```
<jvm-arg>-Xmx512m</jvm-arg>
<jvm-arg>-javaagent:<agent_home>/javaagent.jar</jvm-arg>
```

2. Restart the application server for the changes to take effect.

Apache Solr Startup Settings

This page describes how to instrument Apache Solr with the Java Agent.

Instrument Solr in a Linux Environment

1. Open a terminal.
2. Execute the following commands to add the `javaagent` argument to the Solr server:

   ```
   >cd $Solr_Installation_Directory
   >java -javaagent:"<agent install directory>/javaagent.jar" -jar start.jar
   ```

   For the argument value, reference the full path to the Java Agent installation directory.

Instrument Solr in a Windows Environment

1. Add the Java Agent to the Solr configuration file, `solr.in`.
   You can find the file at:
   `<solr-install-dir>\bin\solr.in`
2. Add the following line just below "`REM set SOLR_OPTS=%SOLR_OPTS%`":

   ```
   set SOLR_OPTS=%SOLR_OPTS% -javaagent:"<java_agent_location>\javaagent.jar"
   ```

3. Restart the Solr service.

Standalone JVM Startup Settings

AppDynamics works with applications running outside of an application server or container.

To install the agent on a standalone JVM, pass the path to the Java Agent when running the Java application in the following form:

```
java -javaagent:"/<agent_home>/javaagent.jar" <classname>
```

Ensure to add the `-javaagent` argument before the `-jar` argument. The `javaagent` argument value must reference the full path to the Java Agent home directory, including the drive on Windows. The classname should be the fully qualified class name with `main` method.

For example, the is an example of the command on a Windows system:

```
java -javaagent:"C:\AppDynamics\agentDir\javaagent.jar"  com.main.HelloWorld
```

On Linux, it would be:

```
java -javaagent:"/mnt/AppDynamics/agentDir/javaagent.jar" com.main.HelloWorld
```

Tanuki Service Wrapper Settings

Related pages:

- Tanuki Service Wrapper Properties
- Example Configuration
- More Help On Tanuki Service Wrapper

The Java Agent bootstraps use the `javaagent` command-line option. Add this option to the Tanuki Service `wrapper.conf` file.

Configure the Tanuki Service Wrapper

1. Open the `wrapper.conf` file to edit.
2. Add a `wrapper.java.additional` property that contains the `javaagent` option with the location of the Java Agent JAR file. For example:

```
wrapper.java.additional.6=-javaagent:C://agent//javaagent.jar
```

Tibco ActiveMatrix BusinessWorks Service Engine Settings

Related pages:

- TIBCO Product Documentation
- TIBCO Community: tibbr

With Tibco ActiveMatrix BusinessWorks Service Engine, each application is started in its own JVM. As a result, for each application that you want to monitor, you must configure the Java Agent in the startup settings for the configuration file of that application.

The file to configure is usually the TRA file named for the application. For example:

`<application_name>.tra`

Instrument the Tibco Application

1. Open the TRA file for the application you want to monitor and add this code to the file:

   ```
   java.extended.properties=-javaagent:/opt/appagent/javaagent.jar
   ```

   AppDynamics recommends that you include all `-D` system property arguments in one `java.extended.properties` line. Otherwise, the `-javaagent` property may be overwritten.
2. Restart the application to have the changes take effect using the command-line tool `bwengine.sh` (or `.exe`) or the Tibco Admin UI.

Since Tibco traffic commonly takes the form of incoming SOAP actions sent through HTTP requests to a single URL (for example, `/BusinessServices/WebGateway`), it's likely that you will need to create a POJO split rule in the AppDynamics configuration to differentiate business transactions for Tibco. For information, see See "Split by POJO Method Call" on Split Servlet Transaction by Payload Examples.

webMethods Startup Settings

You can instrument the webMethods Integration Server or My webMethods Server by adding the Java Agent to the startup script of the server.

The Java agent settings can go in the `runtime.bat/runtime.sh` file, or the `server.bat/server.sh` file under the `bin` subdirectory of the server home.

Instrument webMethods with the Tanuki Wrapper

For webMethods servers that use the Tanuki Java service wrapper for start-up, you need to configure the agent in the `wrapper.conf` file. See Tanuki Service Wrapper Settings.

Note that the order of arguments in the file is important. Specifically, when instrumenting an OSGI-based platform, the agent configuration must precede the `bootclasspath` argument.

For example, the following listing shows the Java options used in a sample `wrapper.conf` file:

```
# Java Additional Parameters
...
wrapper.java.additional.4=-XX:MaxPermSize=256M
wrapper.java.additional.5=-javaagent:/opt/appd/appagent/javaagent.jar
wrapper.java.additional.6=-Xbootclasspath/a:"%OSGI_INSTALL_AREA%/lib/runtime/platform-jaasproxy.jar"
```

Java Security Manager Configuration

Run in a JVM with Security Enabled

To enable a Java Security Manager and instrument the JVM, you need to edit the active security policy file to prevent problems within the interaction between JVM and the Java Agent. The Java Agent requires the change listed in the code block. You can locate the policy file by inspecting the value of the `java.security.policy` system property.

Add this code block to the JVM `server.policy` file:

```
grant codeBase “file:\* AGENT_DEPLOYMENT_DIRECTORY \*/-”
{
   permission java.java security manager.AllPermission;
};
```

WSO2 API Microgateway Startup Settings

You can instrument WSO2 API Microgateway by adding the Java Agent to JVM arguments in the executable file of the gateway. Perform the following steps based on your environment to attach the Java Agent:

Java Agent supports only the HTTP1 protocol for entry and exit.

Automate Java Agent Deployment

Related pages:

- AppDynamics Cookbook on GitHub
- Deploy Multiple Machine Agents From a Common Directory

This page lists sample tools created by AppDynamics users to deploy Java Agents automatically. You can use these samples for ideas on how to automate AppDynamics agent deployment for your own environment.

In the samples, the agents are deployed independently of the application deployment:

- ChefExample1 and ChefExample2 use Opscode Chef recipes and provide examples of automating deployment on Java platforms. See Chef website.
- JavaExample1 uses a script, configuration file, and a package repository.

Click the sample to download:

- ChefExample1.tar
- ChefExample2.tar
- JavaExample1.tar

Install the AppDynamics Site Extension for Java

You can use the Windows Azure Portal to add the AppDynamics Azure Site Extension to your Azure App Service web app. Azure Site Extension is used by Ops teams that may not have access to source files, or would not like to modify or recompile them, yet still want to monitor their Azure projects and solutions.

Prepare to Install

To install the AppDynamics for Windows Azure Site Extension, you need:

- Connection information for your AppDynamics Controller. See Agent and Controller Compatibility.
- A Windows Azure account.
- An Azure web app to monitor.

If you are upgrading from a previous version, see Upgrade the AppDynamics Azure Site Extension.

Add the AppDynamics Azure Site Extension

Add the AppDynamics Azure Site extension as you would any site extension for any Azure web app.

1. Log in to the Windows Azure Portal.
2. Browse to your web app. To configure the Java Agent using environment variables, add the environment variables before you install the AppDynamics Azure Site Extension. See Configure the agent using environment variables.
3. From the **DEVELOPMENT TOOLS** list, click **Extensions**.
4. Click **+Add** to install the version of the **AppDynamics Java Agent** you want to add to your web app.
   After you install the AppDynamics Azure Site Extension, it displays in the installed extensions list.

Configure the Controller Connection

There are two options to configure the Java Agent to connect to the AppDynamics Controller:

- Configure the Controller connection using the Kudu Console.
- Configure the Controller connection settings using environment variables.

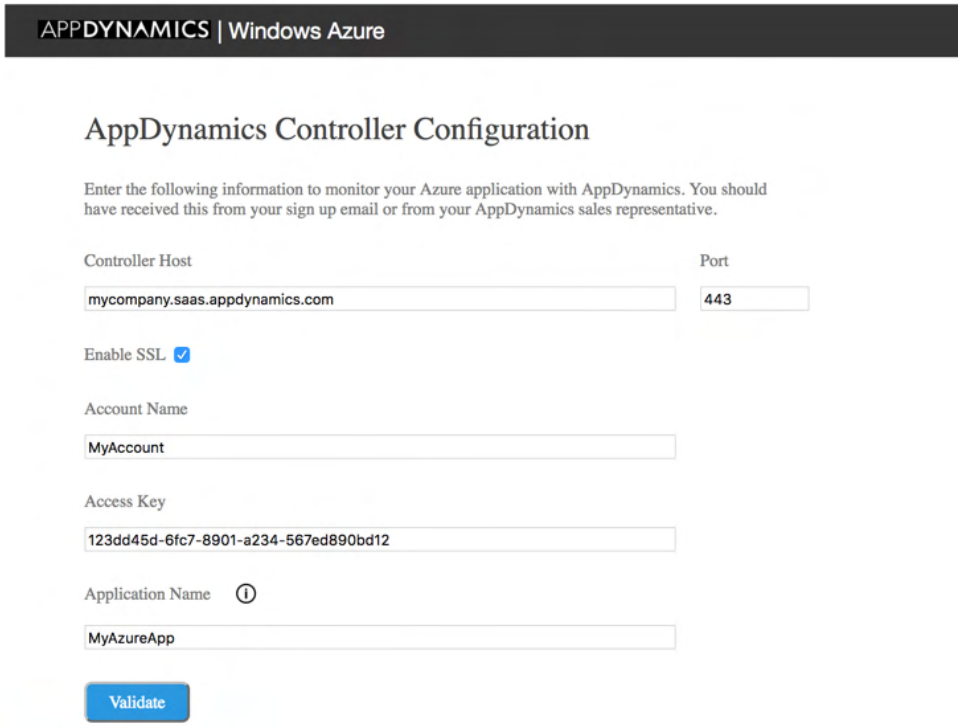
See Agent-to-Controller Connections.

Configure the Agent with the Kudu Console

When you add the AppDynamics Azure Site Extension to your web app, you can interactively configure the Java Agent using the Kudu Console.

1. Navigate to the AppDynamics Controller Configuration page in the Kudu Console:
   `http://{web app}.scm.azurewebsitesJava/appdynamics/`
   For example: `https://myazureexample.scm.azurewebsitesJava/appdynamics/`

2. On the AppDynamics Controller Configuration page, enter your Controller connection information. For example:



3. Click **Validate** to test the connection to the AppDynamics Controller and save your settings.
4. Restart your web app. After you apply some load to your web app, you can view it on flow maps in the AppDynamics Controller UI.

Configure the Agent Using Environment Variables

Configuring the Java Agent using environment variables allows for unattended configuration. To configure agents, add the environment variables before you install the AppDynamics Azure Site Extension:

1. Navigate to **SETTINGS > Application Settings** for your web app.
2. Add the Java Agent environment variables under **App settings:**
    - APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY: A unique key associated with the Controller account.
    - APPDYNAMICS_CONTROLLER_HOST_NAME: The hostname of the AppDynamics Controller.
    - APPDYNAMICS_CONTROLLER_SSL_ENABLED: Set it to `True` to enable SSL connection to the Controller. Otherwise set it to `False`.
    - APPDYNAMICS_AGENT_ACCOUNT_NAME: The account name you use to log on to the Controller.
    - APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY: The account key you use to log on the Controller.
    - APPDYNAMICS_AGENT_APPLICATION_NAME: The business application name in the Controller.
    - APPDYNAMICS_AGENT_TIER_NAME: The tier name in the Controller.
    - APPDYNAMICS_AGENT_NODE_NAME: The node name in the Controller.
3. Restart your web app. After you apply some load to your web app, you can view it on flow maps in the AppDynamics Controller UI.

Upgrade the AppDynamics Azure Site Extension

When you click the **Extensions** tab for your web app, the Microsoft Azure Portal displays the currently installed version of the AppDynamics Azure Site Extension. The **Update Available** column of the installed extensions list indicates if there is a more recent minor release of the Java Agent available. If so, you can click to update the extension from the list.

Upgrade a Major Version of the Java Agent

AppDynamics maintains major release versions of the Java Agent as separate site extensions. Therefore, you must uninstall the installed version of the AppDynamics Azure Site Extension before you upgrade to a new major release:

1. Log in to the Windows Azure Portal.
2. Stop your web app.
3. Click the **AppDynamics Azure Site Extension** from the list of installed extensions and click **Delete** to uninstall it.
4. Install the new version of the AppDynamics Azure Site Extension as normal.

Instrument Java System Classes

The Java Agent excludes system classes like `java.lang.*` from instrumentation by default. To enable instrumentation for a system class, use an agent configuration property.

Instrumented system classes add to the resource overhead introduced by the agent. The amount of overhead depends on the number of calls to the classes. AppDynamics recommends that you instrument a few nodes first and monitor the performance for these nodes before configuring all nodes in your system.

To instrument a Java system class:

1. Open the `<agent_home>/conf/app-agent-config.xml` file for the node where you want to enable instrumentation.
2. Add an `<override-system-exclude>` element with the fully qualified system class name to be instrumented in the `<bci-processing-excludes>` element. The `<override-system-exclude>` element is used to allowlist classes (for example, '`com.sun.jersey`') for instrumentation despite a blocklist (`'com.sun.*'`).

   For example:

   ```
   <bci-processing-excludes>
   <override-system-exclude filter-type="equals" filter-value="com.sun.jersey"/>
   </bci-processing-excludes>
   ```

   You can use these filter types:

   - `equals`
   - `startswith`
   - `contains`

3. Restart the JVM for which you have modified the XML file. Once you restart the JVM, the package will be included in the instrumentation.

Instrument JVMs in a Dynamic Environment

Application environments are increasingly dynamic. For example, in AWS or Rackspace hosted environments, an administrator can online or offline nodes quickly because of workload resulting in an environment where there can be many, short-lived JVMs.

Dynamic Environment Considerations

The AppDynamics app agent operates substantially the same way in a dynamic environment as it does in a traditional data center. However, these considerations apply when deploying agents in dynamic environments:

- Ensure that the agents can reach your Controller. Particularly if your Controller operates on-premises while the agents run on hosted servers, you need to ensure that the agents can access the Controller through the firewalls in your environment.
- Configure custom node expiration handling. By default, the Controller manages the lifecycle for a node based on default timeout settings. You will likely want to reduce the default expiration times for nodes, as described in Historical and Disconnected Nodes. To manage this directly, rather than relying on activity timeouts, a strategy would be to run a script in the JVM before it shuts down that invokes the mark-nodes-historical resource in the AppDynamics REST API to declare itself historical to the Controller.
- Depending on the nature of your environment, it may not make sense to track each JVM instance as a distinct node in AppDynamics, since the set of nodes, in this case, would be boundless. Also, since the JVMs are identical, representing them as different nodes in AppDynamics does not best reflect the logical model of the environment.

Configure the Agent for Dynamic Environments

You can configure AppDynamics to reuse node names for dynamic environments. With node name reuse enabled, after a node is shut down and marked as historical in AppDynamics, the name of the node becomes available for reuse in subsequently registered nodes. You can also specify a node name prefix when reusing node names to indicate the association between all concurrently running JVMs for the dynamic application.

To configure the agent for this environment, use these properties:

- Reuse Node Name Property - To enable re-use of node names.
- Auto Node Name Prefix Property - To set the prefix used for automatically-named nodes.

When enabled, the Controller manages name assignments for the agents. It forms node names by appending a sequentially incremented number as the suffix to the prefix you specify. Be sure to avoid specifying the node name using any other mechanism (such as in `controller-info.xml` file or through a system property).

This listing shows sample settings for the properties as they may appear in a startup script:

```
-Dappdynamics.agent.reuse.nodeName=true
-Dappdynamics.agent.reuse.nodeName.prefix=CloudActivator_
```

When you have enabled reuse node name, the Java Agent logs to standard output after starting up and before registration with the Controller. To troubleshoot agent registration failure, you may want to write the log files to a file instead.

To configure the agent to write logs to a file, edit the `log4j-unknown.xml` at `<agent_home>/<version_number>/conf/logging` and uncomment the `AgentLog Appender`:

```
<!-- To log files to an "unknown" folder before the agent registers
                         with the Controller, uncomment the line below -->
<appender-ref ref="AgentLogAppender"/>
```

This change causes the log files of an agent prior to registration to be written to a directory named "unknown" rather than standard output.

Mark Dynamic Nodes as Historical at Shutdown

As indicated in the Configuring the Agent for Dynamics Environments section, setting the node name reuse flag causes the JVM to report graceful shutdowns, allowing the Controller to mark the corresponding node as historical. If you are not reusing node names, you can use one of these alternative methods to mark a node as historical:

- Set this system property at JVM startup:

  ```
  -Dappdynamics.jvm.shutdown.mark.node.as.historical=true
  ```

- Set this property in `app-agent-config.xml` to `true`:

```
<app-agent-configuration>
   ...
   <configuration-properties>
      ...
      <property name="appdynamics.jvm.shutdown.mark.node.as.historical" value="true"/>
```

Note

If your application environment abortively terminates JVMs rather than allowing them to shut down gracefully, arrange for your orchestration framework to use the controller API (Configuration API > Mark Nodes as Historical) to mark the node as historical at the same time as it terminates the node.

Controller Handling of Historical Nodes

If a node has been out of contact with the Controller for a certain amount of time, the Controller marks the node as a historical node. The Controller suspends certain types of processing activities for the node, such as rule evaluation. See Historical and Disconnected Nodes.

Instrument JVMs in Restricted Environments

Some restricted environments do not allow any changes to the JVM startup script. For these environments, you can use the environmental variable JAVA_TOOLS_OPTIONS in a wrapper script that allows you to specify the initialization of tools, specifically, `-javaagent`.

Create the Wrapper Script

1. Create a wrapper script using this format:
   ```
   {{JAVA_TOOLS_OPTIONS="-javaagent:/opt/appdynamics/appserveragent/javaagent.jar -Dappdynamics.controller.hostName=<controller_host> -Dappdynamics.controller.ssl.enabled=false -Dappdynamics.controller.port=<port> -Dappdynamics.agent.applicationName=<application_name> -Dappdynamics.agent.tierName=<tier_name> -Dappdynamics.agent.nodeName=<node_name>" }}
   export JAVA_TOOLS_OPTIONS
   ```

   > To specify spaces for the application, tier, or node names, use backslashes and quotes around the value, for example: `-Dappdynamics.agent.applicationName=\"$APPLICATION_NAME\"`

2. Add the original startup script to the wrapper script.
3. Make the new script executable, for example, `chmod 750 wrapperscript.sh`.
4. Run your new wrapper startup script.

Full example: `startApplicationWithAppDynamics.sh`

```
#!/bin/bash

JAVA_TOOLS_OPTIONS="-javaagent:/opt/appdynamics/appserveragent/javaagent.jar -Dappdynamics.controller.hostName=<controller_host> -Dappdynamics.controller.ssl.enabled=false -Dappdynamics.controller.port=<port> -Dappdynamics.agent.applicationName=<application_name> -Dappdynamics.agent.tierName=<tier_name> -Dappdynamics.agent.nodeName=<node_name>"

export JAVA_TOOLS_OPTIONS

/path/to/original/script/startup.sh $*
```

Instrument JVMs Started by Batch or Cron Jobs

You can configure the Java Agent for those JVMs that run as cron or batch jobs where the JVM runs only for the duration of the job.

Configure the Java Agent

1. Add the application and tier name to the `controller-info.xml` file.
2. Add the `appdynamics.cron.vm` property to the AppDynamics `javaagent` command in the startup script of your JVM process:

```
-javaagent:<agent_home>/javaagent.jar -Dappdynamics.agent.nodeName=${NODE_NAME} -Dappdynamics.cron.
vm=true
```

The `appdynamics.cron.vm` property creates a delay between the end of the main method and the JVM exit so that the Agent has time to upload metrics to the Controller.

Use the Script Name as the Node Name

You can use the name of the script that executes a cron or batch job in the node name. These commands set the value of variable `NODE_NAME` using the combination of the script and hostname. Add these commands to the startup script of the JVM.

```
# Use the name of the script (no path, no extension) as the name of the node.
NODE_NAME=sample
NODE_NAME="${NODE_NAME%%.}"
echo $NODE_NAME
# Localize the script to the host.
NODE_NAME="$NODE_NAME@$HOSTNAME"
```

Use Environment Variables for Java Agent Settings

As an alternative to using system properties or `controller-info.xml` to configure the agent, you can use environment variables. Environment variables allow agent identity settings to be populated with dynamic environments which may be unique for the JVM.

Environment Variables

To configure the agent with environment variables, set the value of the environment variables. Environment variables exist for most of the agent settings you can configure in the `controller-info.xml` file, such as the application name, node name, and connection settings.

For example, set the node name for the agent using an environment variable using `APPDYNAMICS_AGENT_NODE_NAME`. On Linux, you would enter this command:

```
export APPDYNAMICS_AGENT_NODE_NAME=node23
```

When the agent subsequently starts up, the agent takes node23 as its node name. Typically, the environment variable would be set as part of the start-up routine of the JVM and populated with values determined at startup.

Environment Variables Used by the Agent

The Java Agent takes configuration settings from the following environment variables, when set:

Environment Variable	Equivalent property
`APPDYNAMICS_CONTROLLER_HOST_NAME`	<controller-host>
`APPDYNAMICS_CONTROLLER_PORT`	<controller-port>
`APPDYNAMICS_CONTROLLER_SSL_ENABLED`	<controller-ssl-enabled>
`APPDYNAMICS_AGENT_APPLICATION_NAME`	<application-name>
`APPDYNAMICS_AGENT_TIER_NAME`	<tier-name>
`APPDYNAMICS_AGENT_NODE_NAME`	<node-name>
`APPDYNAMICS_AGENT_ACCOUNT_NAME`	<account-name>
`APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY`	<account-access-key>
`APPDYNAMICS_AGENT_UNIQUE_HOST_ID`	Unique host name
`APPDYNAMICS_AGENT_BASE_DIR`	<agent-runtime-dir>
`APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME`	–Dappdynamics.agent.reuse.nodeName
`APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME_PREFIX`	–Dappdynamics.agent.reuse.nodeName.prefix

Notice that not all configurable agent settings are configurable through environment variables. For those settings, you need to use system properties or `controller-info.xml`, as described on Java Agent Configuration Properties.

Use System Properties for Java Agent Settings

The Java Agent can accept configuration settings specified as system properties. This is useful when you have more than one JVM running on a machine and need to set node properties dynamically.

The JVMs may be in the same tier, or on different tiers in the AppDynamics model. In either case:

- All common information should be configured using `controller-info.xml.`
- All information unique to a JVM should be configured using the system properties (`-D` option) in the startup script.
- Information in the startup scripts always overrides the information in the `controller-info.xml` file.

Java Agent Configuration Properties describes the system properties available for the Java Agent. See Install the Java Agent.

Reference System Properties

You can reference system properties from the command line, or in the agent configuration file to specify the node name, tier name, or other agent configuration properties dynamically.

For example, consider a Java application started with a script named `startserver.sh`. The script defines a system property as:

```
-Dserver.name=$1
```

The property `server.name` will get the value of the first argument passed when starting the script. For example, the following command to start the JVM would bind the `server.name` property to the value `ecommerce01`:

```
startserver.sh ecommerce01
```

You can use this value in your agent configuration by setting the `-Dappdynamics.agent.nodeName` property at startup:

```
-Dappdynamics.agent.nodeName=$server.name
```

Or, you can use the value in the `controller-info.xml` file, using this format:

```
${system_property_name}
```

For example:

```
<controller-info>
    ...
    <node-name>${server.name}</node-name>
</controller-info>
```

Note that `server.name` is the name of a sample system property used here to identify the node. Use an appropriate system property that is available in your environment for the Java Agent node name.

To have tier names assigned dynamically, supply a dynamic value to the tier name property:

```
java -javaagent:<agent_home>/javaagent.jar -Dappdynamics.agent.tierName=$tierName -Dappdynamics.agent.
nodeName=$nodeName
```

Combine Properties

You can combine multiple system properties to name nodes or tiers. For example, in `controller-info.xml`, combine properties as:

```
${system_property_name_1}${system_property_name_2}
```

You can combine system properties with literals. In the following example "_" and "inventory" are literals.

```
${myhost.name}_${myserver.name}.inventory
```

You can use existing system properties for the Controller host and port settings as well; however, combining properties as shown here is not supported for those settings.

Administer the Java Agent

This page describes how to maintain the AppDynamics Java Agent and how to tune its configuration for your requirements. These include, for example, how to upgrade the agent to a new version and how configure SSL for the agent.

Configuration Options and Precedence

You can control many aspects of the operation of the Java Agent through its configuration settings. The agent provides several approaches for specifying these settings, as listed below.

The order of the list matches the priority of the settings. The agent applies the first non-empty value for a configuration property it encounters, given the following order.

1. Environment variables**.** See Use Environment Variables for Java Agent Settings.
2. System properties passed in the start command for the JVM.
3. Versioned agent properties: `<agent_home>/<version_number>/conf/agent.properties`.
4. Global agent properties: `<agent_home>/conf/agent.properties`.
5. Versioned configuration file: `<agent_home>/<version_number>/conf/controller-info.xml`.
6. Global configuration file: `<agent_home>/conf/controller-info.xml`.

Not all properties are available as environment variables, system properties, or XML elements for the `controller-config.xml`. Property references include only the available configuration methods.

Choose an Effective Configuration Strategy

- Use versioned agent properties and versioned configuration files before using global agent properties and global configuration files. This minimizes any impact of configuration format changes in future agent releases.
- The agent only reads versioned agent properties and versioned configuration files from one versioned directory. During upgrades, manually migrate configurations from directories for previous versions. See Upgrade the Java Agent.
- The Agent Download Wizard automatically configures the agent using a versioned configuration file. The configuration in `controller-info.xml` statically defines the agent identity.
- For dynamic or elastic environments that require flexible agent identity, use an approach that provides for the dynamic node identification. For example, pass node identify or other agent configuration settings dynamically using environment variables or system properties.
- For shared binaries among multiple JVM instances, AppDynamics recommends you use a combination of configuration files and startup properties to configure the app agent. In this case, you configure properties common to all JVMs in the `controller-info.xml` file. Then specify the properties unique to each JVM using environment variables or system properties. See Instrument Multiple JVMs on a Single Machine f or example configurations.
- For some properties, you can use system properties already defined in the startup script as the Java Agent property values. For more information, see Use System Properties for Java Agent Settings.

System Properties Sample Configuration

The following command demonstrates a startup script that includes system properties to start and configure the Java Agent. The application is "ACMEOnline", the tier is "Inventory", and the node is "Inventory1". `SampleApplication` is the application file.

```
java -javaagent:/home/appdynamics/agent/javaagent.jar -Dappdynamics.controller.hostName=mycontroller.example.
com -Dappdynamics.controller.port=8090 -Dappdynamics.agent.applicationName=ACMEOnline -Dappdynamics.agent.
tierName=Inventory -Dappdynamics.agent.nodeName=Inventory1 MyApplication.jar
```

System property values are case-sensitive.

Agent Properties Sample Configuration

The Java Agent does not include an `agent.properties` file by default. The file is a list of key-value pairs of system properties. For example:

```
appdynamics.controller.hostName=mycontroller.example.com
appdynamics.controller.port=8090
```

- The JVM treats properties from the `agent.properties` file the same as system properties. Values in `agent.properties` do not override any properties passed explicitly in the JVM startup script.
- You can also include system properties not specific to AppDynamics in the `agent.properties` file. Values from `agent.properties` do not override values passed in the JVM startup script.
- Do not include `-D` switch for keys in the `agent.properties` file.

controller-info.xml Sample File

The controller-info.xml file resides in `<agent_home>/<version_number>/conf`. Comments in the file from the agent distribution describe the settings. They have been removed in the following example for brevity.

```
<?xml version="1.0" encoding="UTF-8"?>
<controller-info>
        <controller-host>192.168.1.20</controller-host>
        <controller-port>8090</controller-port>
        <controller-ssl-enabled>false</controller-ssl-enabled>
        <application-name>ACMEOnline</application-name>
        <tier-name>InventoryTier</tier-name>
        <node-name>Inventory1</node-name>
        <agent-runtime-dir></agent-runtime-dir>
        <enable-orchestration>false</enable-orchestration>
        <account-name>customer1</account-name>
        <account-access-key>341bf72e-7d7a-1234-b33d-9n712nn574</account-access-key>
        <force-agent-registration>false</force-agent-registration>
</controller-info>
```

For a complete list of configuration settings, see Java Agent Configuration Properties.

Java Agent Directory Structure

Unzipping the Java Agent distribution archive extracts the following files and directories to the current directory.

Java Agent Directory Contents

- `conf`: Common configuration files. The configuration files in this directory are used by an agent if a more specific version of the configuration file does not exist in the version-specific conf directory, `ver<version_number>/conf`.
- `javaagent.jar`: The common JAR file used to bootstrap the Java Agent. To enable the agent, pass the fully qualified location of this file as the `--javaagent` argument value to the JVM at startup.
- `readme.txt`: Instructions and notes for installing the Java Agent.
- `utils`: Binary files for utilities shared across versions of the agent.
- `ver<version_number>`: The `javaagent.jar` file, configuration files, and other resources specific for this version of the Java Agent. This directory is named to reflect the Java Agent version number, such as `ver4.4.0.5`.
  Among other things, the directory contains:
  - `conf`: The configuration files used by this version of the Java agent, including `controller-info.xml`, `app-agent-config.xml`, and more. These settings in these files take precedence over the configuration file in the `<agent_home>/conf` directory.
  - `external-services`: Dynamically loaded modules that extend the agent, such as the Analytics Data Sources dynamic service.
  - `javaagent.jar`: A version-specific JAR file that serves as the Java agent binary. Do not use this Java agent JAR when configuring instrumenting directly. Use `javaagent.jar` in the root directory instead.
  - `lib`: Libraries that support the operation of this version of the Java agent.
  - `logs`: Log files written by the agent.
  - `sdk`: Samples, APIs, and Javadoc for extending the capabilities of the AppDynamics Java Agent.
  - `utils`: Binary files for utilities that are specific to this version of the agent.

You can point the JVM argument at the top-level `javaagent.jar`, as it allows you to upgrade the agent without changing how you deploy your application (unzip the new agent version and place it at the old location on the file system). The top-level jar has a specific version that behaves the same as the `javaagent.jar` under the directory with the same version number in its name.

The version-specific `javaagent.jar` allows you to use different versions of the agent and at the same time re-use the same top-level config files. You can point different applications JVM arg at different versions of the agent.

Contents of the conf Directory

The files located in this directory are commonly used for agent configuration and deployment.

- `transactions.xml`: Configuration settings for business transactions identified by the agent.
- `controller-info.xml`: Configuration settings that identify the node, tier, and application associated with the data that this agent reports to the AppDynamics Controller, along with connection settings for the Controller. For more information, see Java Agent Configuration Properties.
- `app-agent-config.xml`: Local configuration settings for this agent. The settings in this file override any equivalent settings specified globally for the AppDynamics deployment. This file is typically used for short-term property settings or for debugging agent issues.
- `jmx`: Files for configuring the JMX and Websphere PMI metrics.
- `logging/log4j.xml`: Flags to control logging levels for the agent. It is highly recommended not to change the default logging levels.

Java Agent Logging

By default, the AppDynamics Java Agent writes log files to the `<agent_home>/ver<version_number>/logs/<node_name>` directory.

See Agent Log Files for information about how the logs are organized into sets that rollover.

Configure Appender Attributes

Each logger has one or more appenders. Each appender specifies where, and in what format, the data is logged. For each appender, you can configure these attributes:

Attribute	Description	Type	Default Value
`fileName`	The name of the log file.	String	-
`name`	The name of the appender.	String	-
`directory`	The directory that the log file is saved to.	String	""
`immediateFlush`	Whether or not to immediately flush log data. Options: `true`, `false`	String	true
`bufferSize`	The size, in MB, of the event buffer. The buffer temporarily stores messages before they are written to disk.	String	256 KB

Configure Log File Sizes and Rollovers

You may want to limit the length of your agent log files to make troubleshooting easier. To do this, you can specify a maximum size for your log files. When a log reaches that size, it is then rolled over: the log file gets zipped, and a new blank log file is generated to store the next batch of log data. By default, a log file has a maximum size of 20 MB and can be rolled over four times. See Troubleshooting Java Agent Issues.

You can configure log rollover attributes in the `log4j2.xml` file.

1. In `log4j2.xml`, find the `ADRRAFAppender` element that you want to configure rollover attributes for.
2. Modify the `ADRolloverStrategy` element and set values for these attributes:

Attribute	Description	Type
`max`	The maximum number of log files. When the maximum number of files is reached, the oldest log file after the initial log file is deleted.	String
`compressionLevel`	The degree of file compression, with 0 being uncompressed and 9 being the most compressed.	String
`format`	The file format that the log is saved in. Options: `zip`, `gz`	String

   For example:

```
<ADRRAFAppender name="BusinessTransactionsLogger" fileName="BusinessTransactions.log">
 <PatternLayout pattern="[%t] %d{DATE} %5p - %m%n" />
 <SizeBasedTriggeringPolicy size="20 MB" />
 <ADRolloverStrategy max="5", compressionLevel="8", format="zip" />
</ADRRAFAppender>
```

   In the above example, "5" is the total number of log files with backups per appender type per set that we keep. In essence, each agent restart will create {number of appenders} files as a set. Then each file can grow up to "5" files total consisting of the first file and 4 backup log files before it rolls over.
3. Modify the `SizeBasedTriggeringPolicy` element and set values for these attributes:

Attribute	Description	Type
`size`	The maximum log file size, in MB, before a log is rolled over. By default, the size is 20MB before the rollover, because t he logs are compressed.	String

Modify the Log Directory Location

To specify a different log directory, use this system property:

```
-Dappdynamics.agent.logs.dir
```

The default logging directory is `<agent_home>/ver<version_number>/logs/<node_name>`.

Set the Agent Log Level

The default logging level for most log files is `INFO`. Higher logging levels consume more disk space; you can change the logging level to `warn` or `error` to reduce the amount of logging. You can control the logging level for the Java Agent by changing the value of the "level value" parameter in the `log4j2.xml` file in the versioned logging configuration file directory: `<agent_home>/<version_number>/conf/logging`. A restart of the application or agent is not required when changing the agent log level. For example, to set the log level to `DEBUG`:

```
<!-- to control the logging level of the agent log files, use the level attribute below. value="
all|trace|debug|info|warn|error"-->
<AsyncLogger name="com.singularity" level="debug" additivity="false">
    <AppenderRef ref="Default"/>
    <AppenderRef ref="RESTAppender"/>
</AsyncLogger>
```

Direct Logging to Syslog

Instead of having the Java Agent write to the default log directory in the agent home directory, you can configure the agent to direct logging output to `syslog`. The agent supports syslog-based logging through `log4j SyslogAppender`.

Configure the Agent to Send Logs to syslog

1. Open this configuration file in the agent home to edit:
   `<agent_home>/ver<version_number>/conf/logging/log4j2.xml`
2. Add this section to the configuration file:

   ```
   <Syslog name="Syslog" facility="LOCAL1" host="localhost" port="514" protocol="TCP">
       <PatternLayout pattern="[%t] %d{DATE} %5p %c - %m%n"/>
   </Syslog>
   ```

3. Configure the agent to redirect its logs to this appender. Find and replace this section of the file:

   ```
   <!-- to control the logging level of the agent log files, use the level attribute below. value="
   all|trace|debug|info|warn|error"-->
   <AsyncLogger name="com.singularity" level="info" additivity="false">
       <AppenderRef ref="Default"/>
       <AppenderRef ref="RESTAppender"/>
   </AsyncLogger>
   ```

   With the following:

   ```
   <!-- to control the logging level of the agent log files, use the level attribute below. value="
   all|trace|debug|info|warn|error"-->
   <AsyncLogger name="com.singularity" level="info" additivity="false">
       <AppenderRef ref="SyslogAppender"/>
       <AppenderRef ref="RESTAppender"/>
   </AsyncLogger>
   ```

Enable SSL for the Java Agent

Related pages:

- Secure the Platform
- Controller SSL and Certificates
- Encrypt Agent Credentials
- Install the Java Agent

This page describes how to secure communication between the Java Agent and these AppDynamics components using SSL:

- AppDynamics Controller: Before you configure the agent to communicate with the Controller through SSL, you must either use a SaaS Controller or configure the on-premises Controller to use SSL.
- AppDynamics Analytics Agent: Before you configure the agent to communicate with the Analytics Agent through SSL, you must Enable SSL for the Analytics Agent.

The Java Agent supports extending and enforcing the SSL trust chain when in SSL mode.

Gather SSL Configuration Details

In preparation to secure Java Agent communications through SSL, you need information about the SSL configuration of the Controller or the Analytics Agent:

- The SSL port:
  - For SaaS Controllers, the SSL port is 443.
  - For on-premises Controllers, the default SSL port is 8181, but you may configure the Controller to listen for SSL on another port.
  - You configure the port for the Analytics Agent using the `ad.dw.http.port` property. See Enable SSL for the Analytics Agent.
- The signature method for the certificates:
  - A publicly known certificate authority (CA) signed the certificate. This applies for DigiCert, Verisign, Thawte, and other commercial CAs.
  - A CA internal to your organization signed the certificate. Some companies maintain internal certificate authorities to manage trust and encryption within their domain.
  - The Controller or Analytics agent uses a self-signed certificate.

Establish Trust for the Controller SSL Certificate

To establish trust between the Java Agent and the AppDynamics Controller, you must import the root certificate for the authority that signed the Controller's certificate into the agent truststore.

> If you secured your on-premises Controller with a self-signed certificate, see Keystore Certificate Extractor Utility for instructions to create the agent truststore.

1. Obtain the root certificate for the authority that signed the certificate for the Controller.
   a. For SaaS Controller deployments only: You can download the "DigiCert Global Root CA" certificate at the following location: https://www.digicert.com/digicert-root-certificates.htm.
   b. You must import only the Root CA Certificate into the Java SSL Trust Store because Host Certificates have a very short lifespan and change often. Trusting the Root CA Certificate ensures uninterrupted connectivity to the controller when the Host Certificate changes before expiry.
2. Run the Java `keytool` command to import the root certificate. The command creates the keystore in the versioned agent configuration directory if it does not exist:

   ```
   keytool -import -alias rootCA -file <root_certificate_file_name> -keystore <agent_home>/<version_number>
   /conf/cacerts.jks -storepass <truststore_password>
   ```

   For example:

   ```
   keytool -import -alias ControllerRootCA -file /usr/home/appdynamics/DigicertGlobalRootCA.pem -keystore
   /usr/local/appagent/4.3.0.0/conf/cacerts.jks -storepass MySecurePassword
   ```

   > Make note of the truststore password, you need it to configure the Java Agent.

Enable SSL between the Java Agent and the Controller

Configure these system properties in the versioned `controller-info.xml`: `<agent_home>/<version_number>/conf/controller-info.xml`. See SSL Configuration Properties for full details on each property.

- Controller Port: The SSL port for the controller. 443 for AppDynamics SaaS.

  ```
  <controller-port>443</controller-port>
  ```
- Controller SSL Enabled: true.

  ```
  <controller-ssl-enabled>true</controller-ssl-enabled>
  ```
- Controller Keystore Password: The plaintext password for the agent truststore.

  ```
  <controller-keystore-password>MySecurePassword</controller-keystore-password>
  ```

  If you enabled the Secure Credential Store, encrypt the password and enter it here. See Encrypt Agent Credentials.
- Controller Keystore Filename: **P**ath of the agent truststore relative to `<agent home>/<version>/conf`. Required if you use a truststore other than the default `<agent_home>/<version_number>/conf/cacerts.jks`.

  ```
  <controller-keystore-filename>../../conf/cacerts.jks</controller-keystore-filename>
  ```

  > You can specify the Controller port and enable SSL for the Controller in the JVM startup script, but you must specify the truststore password and filename in the versioned `controller-info.xml` file.

Restart the JVM after you complete the configuration changes.

Sample Controller-info.xml with SSL and Secure Credential Store Encryption Enabled

```
<?xml version="1.0" encoding="UTF-8"?>
<controller-info>
    <controller-host>mycompany.saas.appdynamics.com</controller-host>
    <controller-port>443</controller-port>
    <controller-ssl-enabled>true</controller-ssl-enabled>
    <!-- Encrypted Controller keystore / agent trust store password -->
    <controller-keystore-password>Tw49bd0hdCMBoQ5pfMMuYA/cA5B4pouVPkv48ovRm6c=</controller-keystore-password>
    <controller-keystore-filename>../../conf/cacerts.jks</controller-keystore-filename>
    ...
    <!-- Secure Credential Store configuration -->
    <!-- Enable the Secure Credential Store -->
    <use-encrypted-credentials>true</use-encrypted-credentials>
    <!-- Path to they secure credential keystore -->
    <credential-store-filename>/opt/appdynamics/secretKeyStore</credential-store-filename>
    <!-- Obfuscated secure credential keystore password -->
    <credential-store-password>n/8GvAZsKk4gM3Z6g+XQ1w==</credential-store-password>
</controller-info>
```

Establish Trust for the Analytics Agent SSL Certificate

To establish trust between the Java Agent and the Analytics Agent, you must import the root certificate for the authority that signed the Analytics Agent's certificate into the agent truststore.

1. Obtain the root certificate for the authority that signed the certificate for the Analytics Agent.
2. Run the Java `keytool` command to import the root certificate into the JRE truststore.

   ```
   keytool -import -trustcacerts -alias analytics-agent -file <root_certificate_file_name> -keystore
   $JAVA_HOME/jre/lib/security/cacerts
   ```

   For example:

   ```
   keytool -import -trustcacerts -alias analytics-agent -file /usr/home/appdynamics/MyAnalyticsCert.crt -
   keystore $JAVA_HOME/jre/lib/security/cacerts
   ```

Establish Trust for Analytics without an Analytics Agent

You can retrieve Transaction Analytics data through Java Agent >= 4.5.16 without the need for a dedicated Analytics Agent. In this deployment model, the Java Agent communicates with the Events Service directly.

If you use a custom trust store for the Java Agent, you need to establish trust with the Events Service to enable Transaction Analytics without an Analytics Agent. These commands demonstrate how to import the Events Service certificate to the Java Agent trust store:

- Using a signed certificate:

```
keytool -import -trustcacerts -v -alias events_service -file /path/to/CA-cert.txt -keystore cacerts.jks
```

- Using a self-signed certificate:

```
keytool -import -v -alias events_service -file events_service.crt -keystore cacerts.jks
```

If you do not establish trust for the private certificate, you cannot retrieve Transaction Analytics data through your Java Agent. Any applications and business transactions you have configured for Transaction Analytics cannot be enabled if the Java Agent cannot communicate with the Events Service.

You can override this behavior using the `-Dappdynamics.force.default.ssl.certificate.validation` property. See Java Agent Configuration Properties for details.

Enable SSL Between the Java Agent and the Analytics Agent

To enable the Java Agent to access the Analytics Agent over SSL, configure the `appdynamics.analytics.agent.url` system property for the JVM.

- Use the HTTPS protocol.
- Use the Analytics Agent SSL port. The port should be the same value as the Analytics Agent `ad.dw.http.port` property. See Enable SSL for the Analytics Agent.

```
-Dappdynamics.analytics.agent.url=https://<analytics_agent_host>:<analytics_agent_port>/v2/sinks/bt
```

For example:

```
java -javaagent:/home/appdynamics/agent/javaagent.jar -Dappdynamics.controller.hostName=mycontroller.
example.com -Dappdynamics.controller.port=8090 -Dappdynamics.analytics.agent.url=https://my.analytics.
host.example.com:9090/v2/sinks/bt -Dappdynamics.agent.applicationName=ACMEOnline -Dappdynamics.agent.
tierName=Inventory -Dappdynamics.agent.nodeName=Inventory1 ACMEOnline.jar
```

Restart the JVM after you complete the configuration changes.

Secure the Java Agent Truststore

To prevent tampering with the Java Agent truststore, you should:

- Secure the truststore file through filesystem permissions:
  - Make the agent truststore readable by any user.
  - Make the truststore owned by a privileged user.
  - Make the truststore writable only by the specified privileged user.
- Secure the agent configuration files so that they are only readable by the agent runtime user and only writable by a privileged user:
  - Versioned configuration file: `<agent_home>/<version_number>/conf/controller-info.xml`.
  - Global configuration file: `<agent_home>/conf/controller-info.xml`.

Keystore Certificate Extractor Utility

The Keystore Certificate Extractor Utility exports certificates from the Controller's Java keystore and writes them to an agent truststore. It installs to this location:

```
<agent_home>/<version_number>/utils/keystorereader/kr.jar
```

To avoid copying the Controller keystore to an agent machine, you can run this utility from the Controller server. Access the agent distribution on the Controller at this location:

```
<controller_home>/appserver/glassfish/domains/domain1/appagent
```

1. Execute `kr.jar` and pass these parameters:
   - The full path to the Controller's keystore:

```
<controller_home>/appserver/glassfish/domains/domain1/config/keystore.jks
```

- The truststore output file name. By default, the agent looks for a Java truststore file named `cacerts.jks` in the `<agent_home>/<version>/conf` directory in the agent home.
- The password for the Controller's certificate, which defaults to "changeit". If you don't include a password, the extractor applies the password "changeit" to the output truststore.

```
/<full path to application JRE>/bin/java -jar kr.jar <controller_home>/appserver/glassfish/domains
/domain1/config/keystore.jks cacerts.jks <controller_certificate_password>
```

2. Install the agent trust store to the versioned agent configuration directory:

```
<agent_home>/<version_number>/conf/
```

Resolve SSL Issues

If you run into problems with the version of TLS/SSL, see SSL Compatibility between Java Agent and Controller and AppDynamics Agent SSL Protocol.

Upgrade the Java Agent

To upgrade the AppDynamics Java Agent, you copy the existing agent directory to a backup location and replace it with the new agent directory. You then copy configuration file changes made in the old directory to the new agent directory and restart the application server.

This page provides additional background information and step-by-step instructions.

About the Upgrade

Before you begin, review the Release Notes for changes that affect your environment. If you are upgrading both the Controller and agents, first upgrade the Controller and then upgrade the Java Agents.

Also, if upgrading multiple agents in your monitored environment, upgrade the agents for the tiers on which business transactions are originated last. For more information about this requirement, along with Controller and agent compatibility information, see Agent and Controller Compatibility.

Upgrading the agent requires a restart of the application server.

An agent upgrade requires no action on the Controller.

Before starting, download the latest version of the Java Agent for your JVM from the AppDynamics Download Center.

Upgrade the Java Agent

1. Shut down the application server where the Java Agent is installed.
2. Create a backup copy of the current agent installation directory.
3. Extract the Java Agent archive to a new directory
4. Rename the existing agent directory.
5. Rename the new directory to the original name of the old agent directory. The new agent directory and its containing files should have the same directory path as the original one. Using the same directory path avoids the task of manually changing the agent-related configurations in your JVM startup script.
6. Copy `controller-info.xml` and, if necessary, agent.properties from the old agent config directory to the following location in the new directory :

   ```
   <agent_home>/<version>/conf
   ```

   For example:

   ```
   appd_javaagent/ver4.0.0.0/conf
   ```

7. If you previously made changes to the `app-agent-config.xml` or other configuration files, copy those changes to the new file as well.
8. Restart the application server.

Once completed, you can archive the original directory and remove it from the application server home.

Uninstall the Java Agent

Related pages:

- Manage App Agents
- Install the Java Agent
- Java Agent Configuration Properties

If you delete an app agent from the Controller UI, as described in Manage App Agents, but do not shut down the JVM that the Java Agent runs on, the Java Agent will reappear in the UI the next time it connects to the Controller.

To prevent a Java Agent from connecting to the Controller, you need to remove the Java Agent settings from the JVM configuration. This frees the license associated with the agent in the Controller and makes it available for use by another app agent. This page describes how to uninstall a Java Agent from the JVM configuration.

Uninstall the Java Agent

1. Stop the application server on which the Java Agent is configured.
2. Remove the `-javaagent` argument in the startup script of the JVM.
3. Remove any system properties configured for the Java Agent from the startup script of your JVM.
4. Restart the application server.

Tune Java Agent Performance

This page describes how to get the best performance from Java Agents. You can view performance statistics for deployed app agents in the diagnostic data panel.

View Agent Diagnostic Data

The agent diagnostic data shows you information about the performance of App Server agents. You can view the data from the Agents page in the Controller UI.

From the Node Dashboard of the node that contains the agent you want to view, click the Agent Diagnostic Stats subtab. Click **View Diagnostics for all Agents** to view statistics for all agents.

Business Transaction Thresholds

AppDynamics determines whether transactions are slow, very slow, or stalled based on the thresholds for Business Transactions. AppDynamics recommends using standard deviation based dynamic thresholds. See Transaction Thresholds.

Snapshot Collection Thresholds

Snapshot collection thresholds determine when snapshots are collected for a Business Transaction. Too many snapshots can affect performance. Therefore, you should consider snapshot collection thresholds carefully in production or load testing scenarios. See Transaction Thresholds.

Suggested Scheduling Settings

- 10 minutes for deployments with less than 10 BTs
- 20 minutes for deployments from 10 to 50 BTs
- 30 minutes for deployments from 50 to 100 BTs
- 60 minutes for deployments larger than 100 BTs

Suggested Diagnostic Session Settings

- Settings for Slow requests (%value): 20 – 30
- Settings for Error requests (%value): 10 – 20
- Click **Apply to all Business Transactions**.

Tune Call Graph Settings

You can tune call graph settings from the **Call Graph Settings** page, as described in Call Graph Settings.

Suggested SQL Query Time and Parameters

- Increase the **Minimum SQL query time** to 100 ms from the default of 10 ms.
- Enable **Filter SQL Parameter Values**.

Memory Monitoring

Memory monitoring features such as leak detection, object instance tracking, and custom memory should be enabled only for a specific node or nodes when debugging a memory problem. Automatic leak detection is on-demand, and therefore, the leak detection will execute only for the specified duration.

When you observe periods of growth in the heap utilization (%), you should enable on-demand memory leak capture. See Java Memory Leaks.

Agent Heap Storage Monitoring and Shutdown

The Java Agent monitors the heap storage used by the instrumented application and shuts itself down when conditions indicate excessive utilization of Java heap storage by the application. The agent takes this measure not necessarily because it is likely to be the source of the memory pressure—in fact, it can help you diagnose the root cause of the issue—but as a final protective measure to help relieve the pressure on available memory for the application.

Typical reasons for excessive heap utilization include:

- Java heap space is too small compared to your application traffic and footprint
- Java heap memory leak
- A rogue thread is consuming a large amount of memory in a short amount of time

Java Agent monitoring of heap storage works as follows. The agent check heap utilization every 30 seconds. When it detects that heap utilization has exceeded 95%, the Java Agent checks for a garbage collection event. When garbage collection occurs, it checks heap utilization again. If usage still exceeds the threshold, the agent shuts itself down and logs the following agent event:

```
ERROR HeapShortageMonitor - Agent shutdown triggered because max heap usage percentage reached
```

If heap memory utilization exceeds the threshold, but garbage collection never occurs, the agent resumes normal monitoring after 30 seconds. If the heap usage remains above the threshold, the heap shortage monitor resumes checking for garbage collection, as it did previously.

You can use a Java Agent node property to control whether heap storage monitoring is enabled and the action that results from excessive heap utilization. The heap-storage-monitor-enabled controls whether it is enabled (true, by default), and the heap-storage-monitor-shutdown-action property determines the triggered action, between:

- true: If the heap threshold is exceeded, the agent is disabled.
- false: If the threshold is exceeded, a warning-level message is written to the agent log and warning event is sent to the Controller (of type AGENT _EVENT with the text: "AppDynamics agent has detected shortage of JVM Heap Storage").

Troubleshooting Java Agent Issues

This page describes techniques for troubleshooting agent installation and operation. In particular, it describes how to find and interpret information in agent log files.

Resolve Java Agent Startup Issues

The first thing the Java agent does upon application startup is to register with the Controller. Once registered, the agent should appear in the **Settings** > **AppDynamics Agents** list.

If you do not see the agent in the list within a few minutes, check the following:

1. Make sure you have restarted the application server.
2. Verify that the `javaagent` argument has been added to the startup script of your JVM.
3. Verify that you configured the agent-controller communication properties and agent identification properties in the `controller-info.xml` file or as system properties in the startup script of your JVM. See Java Agent Configuration Properties.
4. Check the Agent logs directory located at `<agent_home>/ver<version_number>/logs/<node_name>` for the agent.log file.
5. Verify that the Agent is compatible with the Controller. See Agent and Controller Compatibility, and Troubleshoot Controller Issues.

Locate the Java Agent Log Files

Agent log files are located in the `<agent_home>/ver<version_number>/logs/<node_name>` folder.

The agent.log file is the recommended file to help you with troubleshooting. This log can indicate the following:

- Incomplete information in your Agent configuration
- The Controller port is blocked
- Incorrect file permissions

Error messages related to starting the Java Agent use this format:

```
ERROR com.singularity.JavaAgent - Could Not Start Java Agent
```

Resolve Incomplete Agent Configuration Issues

This table lists typical error messages for incomplete Agent configuration:

Error Message	Solution
Cannot connect to the Agent - ERROR com.singularity.XMLConfigManager - Incomplete Agent Identity data, Invalid Controller Port Value	This indicates that the value for the Controller port in controller-info.xml is missing. Add the Controller port and host value to resolve: • For on-premises Controller installations: 8090 for HTTP and 8181 for HTTPS. • For Controller SaaS service, use the default HTTPS port 443.
Caused by: com.singularity.ee.agent.configuration.a: Could not resolve agent-controller basic configuration	This is usually caused because of incorrect configuration in the Controller-info.xml file. Ensure that the information for agent communication (Controller host and port) and agent identification (application, tier and node names) is correctly configured. Alternatively, you can also use the system properties (-D options) or environment variables to configure these settings.

Unblock the Controller Port

This table lists the typical error message when the Controller port is blocked in your network:

Error Message	Solution

ERROR com.singularity.CONFIG.ConfigurationChannel - Fatal transport error: Connection refused WARN com.singularity.CONFIG.ConfigurationChannel - Could not connect to the controller/invalid response from controller, cannot get initialization information, controller host \x.x.x.x\, port 8090, exception Fatal transport error: Connection refused	Try pinging the Controller from the machine where you have configured the application agent. To check if a port is blocked in the network, use the commands: • `netstat -an` for Windows • `nmap` for Linux. The default ports are: • For on-premises Controller installations: 8090 for HTTP and 8181 for HTTPS. • For Controller SaaS service, use the default HTTPS port 443.

Correct File Permission Issues

This table lists typical error message when the file permissions are not correct:

Error Message	Solution
ERROR com.singularity.JavaAgent - Could Not Start Java Agent com.singularity.ee.agent.appagent.kernel.spi.c: Could not start services"	This is usually caused because of incorrect permissions for log files. To troubleshoot: Confirm whether the user who is running the server has read and write permission on the agent directories. If the user has **chmod a-r** equivalent permission, change the permission to **chmod a+r** "<agent_home>"

Maximum Async Handoff Call Graph Samples Error

This error indicates that the number of handoffs in an asynchronous has exceeded the limit:

```
"WARN AsyncHandOffIdentificationInterceptor - Reached maximum limit 500 of async handoff call graph samples. No more samples will be taken" Error
```

This can result from transactions being misidentified as async transactions. In AppDynamics >= 3.6, all Runnables, Callables, and Threads are instrumented by default except those that are excluded by the agent configuration in `app-agent-config.xml`.

In some environments, this may result in too many classes being instrumented, or cause common classes in a framework that implements the Runnable interface to be mistaken for asynchronous activity when it is not, for example, Groovy applications using Clojure.

To debug, check the call graph for asynchronous activities that are misidentified as asynchronous activities. If found, exclude the packages that are not really asynchronous activities. See Configure the Thread Correlation in Java Agent.

Java Agent Configuration Properties

Related pages:

- Administer the Java Agent
- Use System Properties for Java Agent Settings
- Instrument JVMs in a Dynamic Environment

This page is a reference for the configuration properties for the AppDynamics Java Agent. If you are also installing a Machine Agent on the same machine with the Java Agent, see Machine Agent Installation Scenarios.

Agent-Controller Communication Properties

The following are the Agent-Controller communication properties:

AWS Instance

The `appdynamics-aws-instance-enabled` property helps to enable agent retrieval of AWS instance-id by default during registration.

If Java Agent is running on an AWS instance, then the agent log includes *Agent AWS instance-id:<instance-id-of-host>* else the agent log includes *`Agent AWS instance-id:null`.*

The property is enabled by default and the agent log includes `Agent AWS instance-id retrieval enabled: true`. To disable the property, set `appdynamics.aws.instance.enabled=false`. The agent log includes `Agent AWS instance-id retrieval enabled: false`.

System Property: `-Dappdynamics.aws.instance.enabled`

Environment Variable: APPDYNAMICS_AWS_INSTANCE_ENABLED

Type: Boolean

Default: True

Required: Yes

Controller Host

The hostname or the IP address of the AppDynamics Controller. Example values are `192.168.1.22` or `myhost` or `myhost.example.com`. This is the same host that you use to access the AppDynamics browser-based user interface. For an on-premises Controller, use the value for Application Server Host Name that was configured when the Controller was installed. If you are using the AppDynamics SaaS Controller service, see the Welcome email from AppDynamics.

Element in controller-info.xml: `<controller-host>`

System Property: `-Dappdynamics.controller.hostName`

Environment Variable: APPDYNAMICS_CONTROLLER_HOST_NAME

Type: String

Default: None

Required: Yes, if the Enable Orchestration property is `false`.

If Enable Orchestration is `true`, and if the app agent is deployed in a compute cloud instance created by an AppDynamics workflow, do not set the Controller host unless you want to override the auto-detected value. See Enable Orchestration Property.

Controller Port

The HTTP(S) port of the AppDynamics Controller. This is the port used to access the AppDynamics browser-based user interface.

If the Controller SSL Enabled property is set to `true`, specify the HTTPS port of the Controller; otherwise specify the HTTP port. See Controller SSL Enabled Property.

Element in controller-info.xml: `<controller-port>`

System Property: `-Dappdynamics.controller.port`

Environment Variable: APPDYNAMICS_CONTROLLER_PORT

Type: Positive Integer

Default: For On-premises installations, port 8090 for HTTP and port 8181 for HTTPS are the defaults.
For the SaaS Controller Service, use port 443 for HTTPS connections.

Required: Yes, if the Enable Orchestration property is false.

If Enable Orchestration is true, and if the app agent is deployed in a compute cloud instance created by an AppDynamics workflow, do not set the Controller port unless you want to override the auto-detected value. See Enable Orchestration Property.

SSL Configuration Properties

Controller SSL Enabled

If true, specifies that the agent should use SSL (HTTPS) to connect to the Controller. If SSL Enabled is true, set the Controller Port property to the HTTPS port of the Controller. See Controller Port Property.

Element in controller-info.xml: `<controller-ssl-enabled>`

System Property: `-Dappdynamics.controller.ssl.enabled`

Environment Variable: APPDYNAMICS_CONTROLLER_SSL_ENABLED

Type: Boolean

Default: False

Required: No

Controller Keystore Password

The plain text value of the Controller certificate password. If Use Encrypted Credentials is true, encrypt the password. See Encrypt Agent Credentials.

Element in controller-info.xml: `<controller-keystore-password>`

Type: String

Default: None

Required: No

Controller Keystore Filename

By default, the agent looks for a Java truststore file named `cacerts.jks` in the `<agent_home>/<version>/conf` directory in the agent home. Use this property to enable full validation of Controller SSL certificates with a different Java truststore file. See Enable SSL for the Java Agent.

Element in controller-info.xml: `<controller-keystore-filename>`

Type: String

Default: None

Required: No

Force Default SSL Certificate Validation

Used to override the default behavior for SSL validation. The property can have three states:

- **true**: Forces the agent to perform full validation of the certificate sent by the controller, enabling the agent to enforce the SSL trust chain. Use this setting when a public certificate authority(CA) signs your Controller SSL certificate. See Enable SSL On-Premises with a Trusted CA Signed Certificate.
- **false**: Forces the agent to perform minimal validation of the certificate. This property disables full validation of the Controller's SSL certificate. Use this setting when full validation of a SaaS certificate fails.
- **unspecified**: The validation performed by the agent depends on the context:
    - If the agent is connecting to a SaaS controller, full validation is performed.
    - If the agent is connecting to an on-premises Controller and the `cacerts.jks` file is present, then full validation is performed using the c `acerts.jks` file.
    - If the agent is connecting to an on-premises Controller, and there is no `cacerts.jks` file, then minimal validation is performed

System Property: `-Dappdynamics.force.default.ssl.certificate.validation`

Type: Boolean

Default: None

Required: No

> The force default SSL validation property also applies when connecting the Java Agent to the Events Service for Transaction Analytics. See Enable SSL for the Java Agent.

AppDynamics Agent SSL Protocol

The SSL compatibility table in Agent and Controller Compatibility lists the default security protocol for the different versions of the Java Agent. If the default security protocol for your version of an agent is incompatible with the Controller or it is incompatible with an intervening proxy, pass the `-Dappdynamics.agent.ssl.protocol` system property to configure one of these security protocols:

- SSL
- TLS
- TLSv1.2
- TLSv1.1

System Property: `-Dappdynamics.agent.ssl.protocol`

Type: String

Default: See Agent and Controller Compatibility

Required: No

Configure Allowed TLS/SSL Protocols

Agent communication over TLS/SSL causes the agent to initialize the JVM security subsystem, which sets a permitted list of protocols. By default, AppDynamics excludes SSLv3 and TLSv1protocols due to the known vulnerabilities.

Once the JVM initializes, the list of permitted protocols cannot be changed. If you want to prevent the agent from disabling SSLv3 or TLSv1 protocols, you can configure them to be allowed by naming one (or both, separated by a comma) protocols using this property:

System Property: `-Dappdynamics.agent.tls.allowedAlgorithms`

Type: String

Default: None

Required: No

This example allows both SSLv3 and TSLv1 to be used by the JVM:

```
-Dappdynamics.agent.tls.allowedAlgorithms=SSLv3, TLSv1
```

> This property is applicable from the 4.5.13 version of Java Agent.

Secure Credential Store Properties

Use Encrypted Credentials

Before you enable Use Encrypted Credentials, see Encrypt Agent Credentials for instructions on how to initialize the Secure Credential Store.

Set Use Encrypted Credentials to True to configure the agent to use credentials encrypted with the Secure Credential Store. When you enable Use Encrypted Credentials, you must supply the Credential Store Filename and the obfuscated Credential Store Password.

When Use Encrypted Credentials is true, encrypt the following:

- Account Access Key
- Controller Keystore Password
- Proxy Password

Element in controller-info.xml: `<use-encrypted-credentials>`

Type: Boolean

Default: False

Required: No

Credential Store Filename

The absolute path to the Secure Credential Store keystore. See Encrypt Agent Credentials.

Element in controller-info.xml: `<credential-store-filename>`

Type: String

Default: None

Required: If Use Encrypted Credentials is set to True

Credential Store Password

The obfuscated keystore password for the Secure Credential Store. See Encrypt Agent Credentials.

Element in controller-info.xml: `<credential-store-password>`

Type: String

Default: None

Required: If Use Encrypted Credentials is set to True

Agent Identification Properties

Automatic Naming

If enabled and other agent identification properties are not specified in other settings, the tier and application for the agent are automatically named. The default names are in the format MyApp and MyTier.

Element in controller-info.xml: `<auto-naming>`

Type: Boolean

Default: None

Required: No

Application Name

The name of the logical business application that this JVM node belongs to. Note that this is not the deployment name(ear/war/jar) on the application server.

If a business application of the configured name does not exist, it is created automatically.

Element in controller-info.xml: `<application-name>`

System Property: `-Dappdynamics.agent.applicationName`

Environment Variable: `APPDYNAMICS_AGENT_APPLICATION_NAME`

Type: String

Default: None

Required: Yes

Tier Name

The name of the tier that this JVM node belongs to. Note that this is not the deployment name (ear/war/jar) on the application server.

If the JVM or application server startup script already has a system property that references a tier, such as `-Dserver.tier`, you can use `${server.tier}` as the tier name. See Use System Properties for Java Agent Settings.

The agent registers the named tier with the Controller, if the tier does not already exist, the first time it connects with the Controller. If a tier with the name already exists in the Controller model, the agent is associated with the existing tier.

Element in controller-info.xml: `<tier-name>`

System Property: `-Dappdynamics.agent.tierName`

Environment Variable: `APPDYNAMICS_AGENT_TIER_NAME`

Type: String

Default: None

Required: Yes

Node Name

The name of the node. Where JVMs are dynamically created, use the system property to set the node name.

If your JVM or application server startup script already has a system property that can be used as a node name, such as `-Dserver.name`, you could use `${server.name}` as the node name. You could also use expressions such as `${server.name}_${host.name}.MyNode` to define the node name. See Use System Properties for Java Agent Settings.

In general, the node name must be unique within the business application and physical host. If you want to use the same node name for multiple nodes on the same physical machine, create multiple virtual hosts using the Unique Host ID property. See Unique Host ID.

Element in controller-info.xml: `<node-name>`

System Property: `-Dappdynamics.agent.nodeName`

Environment Variable: `APPDYNAMICS_AGENT_NODE_NAME`

Type: String

Default: None

Required: Yes

Reuse Node Name

Set this property to true to reuse node names in AppDynamics. When you set the property to true, you do not need to supply a node name, but you do need to provide a node name prefix using `-Dappdynamics.agent.reuse.nodeName.prefix` .

> When `ReuseNodeName/prefix` and a node name is used, the `ReuseNodeName` property is given precedence.

This property is useful for monitoring environments where there are many JVMs with short life spans. When true, AppDynamics reuses the node names of historical JVMs for new JVMs. This avoids a proliferation of differently named nodes in AppDynamics over time, particularly when the nodes are essentially identical processes that run over different times. An example of this environment is a z/OS Dynamic Workload Manager based-environment where new JVMs are launched and shut down based on actual workload.

AppDynamics generates a node name with App, Tier and Sequence number. The node names are pooled. For example, the sequence numbers are reused when the nodes are purged (based on the node lifetime).

When the Java Agent starts up, it logs output to the console until it registers with the Controller and the Controller generates the node name. To configure the agent to write logs to a file, edit the log4j-unknown.xml at `<agent_home>/<version_number>/conf/logging`. See Instrument JVMs in a Dynamic Environment.

The Controller reuses node names based on the node retention period property.

System Property: `-Dappdynamics.agent.reuse.nodeName`

Environment Variable: APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME (New in 4.5.8)

Type: Boolean

Default: False

Required: No

Example: With the following configuration, the Controller generates a node name with the prefix "reportGen". Node names will have suffixes -1, -2, and so on, depending on the number of nodes are running in parallel. The name of a node that is shut down and qualifies as a historical node may be reused by a new node.

```
-Dappdynamics.agent.reuse.nodeName=true -Dappdynamics.agent.reuse.nodeName.prefix=reportGen
```

Reuse Node Name Prefix

When you configure the agent to reuse node names, use this property to specify the prefix the Controller uses to generate node names dynamically.

System Property: `-Dappdynamics.agent.reuse.nodeName.prefix`

Environment Variable: APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME_PREFIX (New in 4.5.8)

Type: String

Default: None

Required: When `-Dappdynamics.agent.reuse.nodeName=true`

Example: Using the following property specifications, the agent directs the Controller to generate a node name with the prefix "reportGen". Node names will have suffixes --1, --2, and so on, depending on how many nodes are running in parallel.

```
-Dappdynamics.agent.reuse.nodeName=true -Dappdynamics.agent.reuse.nodeName.prefix=reportGen
```

Self Service

Configure the Java Agent to automatically name nodes based upon the platform. For automatic node naming to work, you must specify an application name and a tier name.

System Property: `-Dappdynamics.agent.selfService`

Type: String

Values:

tibco: The Java Agent names nodes for the TIBCO process name. See Configure the Java Agent for TIBCO BusinessWorks for more information.

Default: None

Required: No

Account Properties

If the AppDynamics Controller is running in multi-tenant mode or if you are using the AppDynamics SaaS Controller, specify the account name and key for the agent to authenticate with the Controller.

If you are using the AppDynamics SaaS Controller, the account name is provided in the Welcome email sent by AppDynamics. You can also find this information in the `<controller_home>/initial_account_access_info.txt` file.

If the Controller is running in single-tenant mode, you only need to configure the account access key. You can find the unique access key for your Controller instance from the License Management page in the UI.

Account Name

The account name used to authenticate with the Controller.

Element in controller-info.xml: `<account-name>`

System Properties: `-Dappdynamics.agent.accountName`

Environment Variable: `APPDYNAMICS_AGENT_ACCOUNT_NAME`

Type: String

Default: None

Required: Yes for AppDynamics SaaS Controller and other multi-tenant users; no for single-tenant users.

Account Access Key

The account access key used to authenticate with the Controller. If Use Encrypted Credentials is true, encrypt the account access key. See Encrypt Agent Credentials.

Element in controller-info.xml: `<account-access-key>`

System Properties: `-Dappdynamics.agent.accountAccessKey`

Environment Variable: `APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY`

Type: String

Default: None

Required: Yes

If you provide application keys through JVM system properties or environment variables, ensure that you use quotes to wrap any shell special characters that may be contained within application keys to prevent the Shell from interpreting them. See the shell documentation for more detail.

Proxy Properties for the Controller

Use the proxy properties to configure the agent to connect to the Controller through a proxy.

Proxy authentication cannot be used in conjunction with agent SSL. To connect the agent through a proxy via SSL, the proxy must be open (not require the agent to authenticate).

Proxy Host

The proxy host name or IP address.

System Property: `-Dappdynamics.http.proxyHost`

Type: String

Default: None

Required: No

Proxy Port

The proxy HTTP(S) port.

System Property: `-Dappdynamics.http.proxyPort`

Type: Positive Integer

Default: None

Required: No

Proxy User Name

The name of the user that is authenticated by the proxy host.

System Property: `-Dappdynamics.http.proxyUser`

Type: String

Default: None

Required: No

Proxy Password

The absolute path to the file containing the password of the user that is authenticated by the proxy host. The password must be the first line of the file.

If Use Encrypted Credentials is false, enter the password in plain text. If Use Encrypted Credentials is true, encrypt the password. See Encrypt Agent Credentials.

System Property: `-Dappdynamics.http.proxyPasswordFile`

Type: String

Default: None

Required: No

Example: -Dappdynamics.http.proxyPasswordFile=/path/to/file-with-password

Other Properties

Enable Orchestration

When set to true, enables auto-detection of the controller host and port when the app server is a compute cloud instance created by an AppDynamics orchestration workflow. See Controller Host Property and Controller Port Property.

In a cloud compute environment, auto-detection is necessary for the Create Machine tasks in the workflow to run correctly.

If the host machine on which this agent resides is not created through AppDynamics workflow orchestration, this property should be set to false.

Element in controller-info.xml: `<enable-orchestration>`

Type: Boolean

Default: False

Required: No

Agent Runtime Directory

Sets the directory under which all files the agent writes at runtime. If this property is specified, all agent logs are written to <Agent-Runtime-Directory>/logs/node-name and transaction configuration is written to the <Agent-Runtime-Directory>/conf/node-name directory. The log folder location can be overridden with the `appdynamics.agent.logs.dir` property.

Element in controller-info.xml: `<agent-runtime-dir>`

System Property: `-Dappdynamics.agent.runtime.dir`

Environment Variable: `APPDYNAMICS_AGENT_BASE_DIR`

Type: String

Default: <agent_home>/nodes

Required: No

Redirect Logfiles

Sets the destination directory to which the logs will be written to.

System Property: `-Dappdynamics.agent.logs.dir`

Type: String

Default: <agent_home>/logs/<Node_Name>

Required: No

Custom Path for agent conf Directory

Sets a custom path for the agent conf directory. This is where the agent reads its static config files from. If you need to change `custom-activity-correlation.xml` or `app-agent-config.xml` and the agent installation is read-only, this instructs the agent to read the static config files from elsewhere.

System Property: `-Dappdynamics.agent.conf.dir`

Type: String

Default: <agent_home>/ver4.5.x.x.x/conf

Required: No

Force Agent Registration

Set to true only under these conditions:

- The agent has been moved to a new application or tier from the UI, and
- You want to override that move by specifying a new application name or tier name in the agent configuration

Element in controller-info.xml: `<force-agent-registration>`

Type: Boolean

Default: False

Required: No

Auto Node Name Prefix

Set this property if you want the Controller to generate node names automatically using a prefix that you provide.

The Controller generates node names by concatenating the specified prefix with a UUID suffix. For example, if you set the prefix as follows:

```
-Dappdynamics.agent.auto.node.prefix=JoannaAutoNode
```

The generated node name is

```
JoannaAutoNode_d39dbfc1-6f4b-4eb7-a788-c1c0135b6bcb
```

This property provides a similar function to the Reuse Node Name Prefix Property property. However, this property is not meant to be used in combination with reusing node names; use Reuse Node Name Prefix Property for those cases instead.

Element in controller-info.xml: Not applicable

System Property: -Dappdynamics.agent.auto.node.prefix=<your_prefix>

Type: String

Default: Serial number maintained by the Controller appended to the tier name

Required: No

Cron/Batch JVM

Set this property to true if the JVM is a batch/cron process. You can use this property to stall the shutdown to allow the agent to send metrics before shutdown.

Element in controller-info.xml: Not applicable

System Property: -Dappdynamics.cron.vm

Type: Boolean

Default: False

Required: No

Unique Host ID

Logically partitions a single physical host or virtual machine such that it appears to the Controller that the application is running on different machines. Set the value to a string that is unique across the entire managed infrastructure. The string may not contain any spaces. If you have a machine agent associated with the application monitored by the app agent, then this property must be set on the machine agent to the same value. See Machine Agent Installation Scenarios.

System Property: `-Dappdynamics.agent.uniqueHostId`

Environment Variable: APPDYNAMICS_AGENT_UNIQUE_HOST_ID

Type: String

Default: None

Required: No

Agent Meta Info

Allows you to associate arbitrary information with a node, which can then be used as a basis for applying health rules or policies by node. For example, you can exclude a health rule from applying to agents tagged as test agents based on a `meta-info` property. Pass the property in `key;value` format (for example, "`key1;value1;key2;value2`"). Do not use semicolons as value(s) as it is used as a delimiter.

For information on using the properties in health rules or policies (along with built-in `meta-info` properties), see Configure Health Rules or Configure Policies.

System Property: `-Dappdynamics.agent.node.metaInfo`

Type: String

Default: None

Required: No

Low Entropy

Addresses agent startup issues in systems with low to zero entropy available for seeding the PRNG algorithm. This is set to true by default. The NativePRNGNonBlocking algorithm is used through SecureRandom if the system property `appdynamics.low.entropy` is set. Windows is not affected by this change as it does not support NativePRNGNonBlocking, and continues to use the existing Secure Random implementation.

System Property: `appdynamics.low.entropy=true`

Element in controller-info.xml: No

Environment Variable: No

Type: Boolean

Default: True

Required: No

If `appdynamics.low.entropy=true` then the agent takes measures to ensure it does not block when generating random values, even in the absence of entropy.

For example: From Java Agent 20.11, the agent defaults to using NativePRNGNonBlocking as its SecureRandom implementation. This will try to use a non-blocking low entropy algorithm for UUID generation. Note that NativePRNGNonBlocking is not supported on Windows and defaults to the existing implementation of SHA1PRNG.

Analytics Agent

For use with the transaction analytics feature with a remote (or non-default) Analytics agent. See Enable the App Server Agent for a Remote Analytics Agent.

System Property: `-Dappdynamics.analytics.agent.url`

Element in controller-info.xml: No

Environment Variable: No

Type: String

Default: `http://localhost:9090/v2/sinks/bt`

Required: No

Use Simple Hostname

By default (unless overridden with the `uniqueHostId` system property), the agent determines the host name of the OS it is running in by reverse DNS lookup. In some circumstances, this host name may be set as the fully qualified domain name of the host name. If this property is set to true, the agent removes any domain name and uses the simple hostname to identify the host. In cases where the host name is an IP address (which happens if the DNS lookup fails) the full IP address in string form is used. The host name is used in mapping metrics gathered by the machine agent to application nodes (see Unique Host ID Property).

Element in controller-info.xml: `<use-simple-hostname>`

Type: Boolean

Default: False

Required: No

For example: If this property is set to true '`server.mydomain.com`' becomes 'server'.

Filter Sensitive Data

By default, the AppDynamics Java Agent sends transaction data to the Controller that your organization may classify as privileged information. Although such data is useful for diagnosis and troubleshooting, security considerations may require you to filter certain information from view in the Controller. You can use:

- Sensitive data filters to exclude environment variables, system property, and JMX data.
- Sensitive URL filters to exclude sensitive information from a URL in snapshot details.
- Sensitive message filters to exclude sensitive data that the application may place in log messages or exception detail messages.

Default Sensitive Data Filters

When you enable a sensitive data filter, the Controller displays asterisks for the values of matching environment variables or system properties. By default, the Java Agent enables two sensitive data filters in the `app-agent-config.xml`:

- Environment variables or system properties that contain the case insensitive substring "password".
- Environment variables or system properties that contain the case insensitive substring "key".

```
<sensitive-data-filters>
        <sensitive-data-filter applies-to="environment-variables,system-properties"
                               match-type="CONTAINS"
                               match-pattern="password"/>

        <sensitive-data-filter applies-to="environment-variables,system-properties"
                               match-type="CONTAINS"
                               match-pattern="key"/>
</sensitive-data-filters>
```

Add a Sensitive Data Filter

1. Edit a versioned app-agent-config.xml file: `<agent_home>/<version_number>/conf/app-agent-config.xml`.
2. Add a sensitive data filter element as a child of the Sensitive Data Filters element using one of these attributes.
    - Specify a comma-separated list in the `applies-to` attribute to filter:

      `environment-variables`

      `system-properties`

      `jmx-mbeans`
    - Set the `match-type` attribute as:

      `EQUALS`

      `CONTAINS`

      `STARTSWITH`

      `ENDSWITH`
    - Specify a string to match for the `match-pattern` attribute. String matches are case insensitive. The pattern matches against the environment variable and system property names, not values.
3. Restart the JVM.

In this example, the Java Agent checks for system properties and environment variables beginning with the string "DB_". The Controller displays the values of matching environment variables and system properties as asterisks. For instance, an environment variable "DB_USER" is replaced with an asterisk.

```
<sensitive-data-filter applies-to="environment-variables,system-properties"
                                    match-type="STARTSWITH"
                                    match-pattern="DB_"/>
```

Add a Sensitive URL Filter

You can use sensitive URL filters to configure the agent to obfuscate sensitive information from the URLs in transaction snapshot details.

1. Edit a versioned app-agent-config.xml file: `<agent_home>/<version_number>/conf/app-agent-config.xml`.
2. Add a sensitive URL filter element as a child of the sensitive URL filters element:

```
<sensitive-url-filter delimiter=""
   segment="" match-filter="EQUALS|INLIST|STARTSWITH|ENDSWITH|CONTAINS|REGEX|NOT_EMPTY"
   match-pattern="pattern"
   param-pattern=""/>
```

- `delimiter`: Specify the character that you want to use as URL segment endpoints. The agent splices the URL at each delimiter instance to create the segments. For HTTP, use the forward slash character "/". In the case of a forward slash, the agent does not split on the slashes immediately following the protocol. For example, "https://myapp.example.com/" constitutes a single segment. By default, the delimiter is "/".
- `segment`: Specify a comma-separated list to indicate the segments that you want the agent to filter. Segment numbering starts from 1.
- `match-pattern`: Specify the string that you want to be filtered by the `match-filter`.
- `param-pattern`: Specify the regular expression matching the query parameters to filter.

For example, the following configuration splits the URL on the "/" character and masks the second segment and the param-pattern in the third segment of the URL. In this case, the segmentation and obfuscation apply only to URLs containing "myapp".

```
<sensitive-url-filters>
<sensitive-url-filter delimiter="/"
 segment="2"
 match-filter="CONTAINS"
 match-pattern="myapp"
 param-pattern="[a-z]+_name"/>
</sensitive-url-filters>
```

The exit call to `https://myapp.example.com/sensitive/data?first_name=abc&last_name=xyz` breaks down to three segments: "`https://myapp.example.com/`", "sensitive", and "data?first_name=abc&last_name=xyz". The Controller shows the masked values of the URL and the param-pattern display `https://myapp.example.com/*****/data?first_name=***&last_name=***` in the snapshot details.

> In case you do not use any values for the query parameters, the Controller does not mask any query parameters in the URL.

Add a Sensitive Message Filter

You can use sensitive message filters to configure the agent to obfuscate sensitive information contained within text messages collected by the agent from log messages, or detail messages from exceptions.

1. Edit a versioned app-agent-config.xml file: `<agent_home>/<version_number>/conf/app-agent-config.xml`.
2. Add a sensitive message filter element as a child of the sensitive message filters element:

```
<sensitive-message-filter message-type="throwable,logger-message,all"
                                match-type="EQUALS|CONTAINS|STARTSWITH|ENDSWITH|REGEX"
                                match-pattern="CASESENSITIVE_PATTERN"
                                redaction-regex="SENSITIVE_INFO_REGEX_GROUP"/>
```

- `message-type` specify throwable, `logger-message` or all
- `match-type` specify the type of match that should be used to `opt-in` messages for redaction
- `match-pattern` specify the pattern that, when matched, opts the message in for redaction
- `redaction-regex` specify a regular expression identifying data that should be redacted from the `opted-in` messages

For example, if an application logs SQL queries including secret numeric values, the following configuration would remove all the numeric data from the logged messages:

```
<sensitive-message-filter message-type="logger-message"
                                match-type="CONTAINS"
                                match-pattern="SELECT"
                                redaction-regex="[0-9]+"/>
```

Resulting in –

```
"SELECT name from customer WHERE customer.id = 773"
```

Being collected as –

```
"SELECT name from customer WHERE customer.id = *****"
```

Optimize Heap Mode

The `enable-optimised-heap-mode` node property helps to fine-tune the agent heap consumption to deliver optimized performance. Additionally, exceptions are handled on the asynchronous entry maps to prevent stalled Business Transactions.

Element in controller-info.xml: `<enable-optimised-heap-mode>`

System Property: `-Dappdynamics.enable.optimised.heap-mode {{}}`

Type: `Boolean`

Default: `Disabled`

Required: `Yes`

IBM Java Agent

Under most circumstances, the IBM Java Agent works the same as the Java Agent. This page describes information specific to the IBM Java Agent.

Supported JVMs

IBM JVM 1.5.x, 1.6.x, 1.7.x, and 1.8.x

Instrument the IBM Java Agent

To change instrumentation for the IBM Java Agent, you must restart the IBM JVM. By default, the IBM Java Agent does not apply BCI changes without restarting the JVM. This is because in the IBM VM (J9 1.6.0) the implementation of re-transformation affects performance (changes the JIT behavior such that less optimization occurs).

These changes require that you restart the IBM JVM:

- Automatic leak detection
- Custom memory structures
- Information points
- Custom POJO rules for transaction detection
- Custom exit point rules
- End User Monitoring (EUM), when you enable it and/or disable it after first enabling it

Instrument WebSphere/InfoSphere with WebSphere Security Enabled

If your WebSphere/InfoSphere environment includes a security-enabled WebSphere Application Server, several InfoSphere Master Data Management (MDM) Server clients require security configuration.

See IBM WebSphere and InfoSphere Startup Settings.

Threading and the Java Agent

A pivotal part of the functionality of the Java Agent is tracing activity within the JVM such that all the activity (both internal and external to the JVM) that results from servicing any given inbound request can be associated with the request itself. In simple cases, each request is processed by one Java thread, making it only necessary to track the processing of that single thread, in a pattern widely known as 'thread per request'.

This was the case for JEE applications prior to the introduction of version 3.0 of the servlet specification (introduced in Java EE 6). In systems where a significant amount of time is spent waiting for external resources, the thread per request model is inefficient because many application threads spend most of their lifetime blocked awaiting external responses.

This observation motivated the asynchronous servlet capabilities provided as part of servlet 3 and also motivates many of the increasingly prevalent reactive frameworks that are in common usage (for example, Play, Akka, Vert.x and Spring Reactor). To correctly correlate transactions end to end in applications using this architectural approach, the agent must follow transactions from thread to thread to enable it to measure and link all the elements of work performed on behalf of each request, irrespective of which thread that work is executed on.

The agent provides two mechanisms for thread tracking, known as 'Constructor mode' and 'Executor mode' (for Java Agent >= 20.11.0).

These are two alternative approaches to the correlation of cross-thread transaction activity:

- Constructor Mode Thread Tracing - This is the mode that instruments *Threads*, *Runnables,* and *Callables* based on their creation. The agent used this mode formerly as the default mode.
- Executor Mode Thread Tracing - This tracking mode is the default mode and is based on instrumenting executor frameworks that are commonly used by the majority of applications and frameworks. This mode makes agent operation more efficient, especially in cases where large use of threading is in place, for example, in the presence of the Play, Akka, Vert.x, and Spring Reactor reactive frameworks.

Select the Thread Correlation Mode

You can select the thread correlation mode used by the agent using the `async-instrumentation-strategy` property within the `app-agent-config.xml` configuration file.

To run the applications in the Constructor mode, modify the value of `async-instrumentation-strategy` property, or use the following java command-line option:

```
-Dappdynamics.async.instrumentation.strategy=constructor
```

The system property takes precedence over the configuration file. You cannot change the configured thread instrumentation mode during runtime.

Constructor Mode Thread Tracing

When the agent is in Constructor Mode, transaction activity is tracked from thread to thread by instrumenting the constructors of Runnable objects, and their run methods, such that the agent can link the creation point of the object with their actual execution. Since in many cases the work executed by Runnable objects does not relate to the Business Transaction context within which they were created, the agent provides for exclude rules to limit which threads are tracked. The agent configuration maintains a default set which you can fine-tune when necessary.

Constructor Mode Configuration

You configure classes for multithreaded correlation in the `<excludes>` child elements of the `<fork-config>` element in the `<agent_home>/conf/app-agent-config.xml` file.

The default configuration excludes the Java, Org, WebLogic and WebSphere classes:

```
<fork-config>
    <!-- exclude java and org -->
    <excludes filter-type="STARTSWITH" filter-value="com.singularity/"/>
    <excludes filter-type="STARTSWITH" filter-value="java/,javax/,com.sun/,sun/,org/"/>
    <!-- exclude weblogic and websphere -->
    <excludes filter-type="STARTSWITH" filter-value="com.bea/,com.weblogic/,weblogic/,com.ibm/,net/sf/,com/mchange/""/>
    . . .
```

The agent supports package names where the levels in the hierarchy are either separated by dots (.) or slashes (/). The agent converts the dots to slashes internally.

Custom Configuration

You can edit the `app-agent-config.xml` file to exclude additional classes from thread correlation. All classes not excluded are by default included.

Use the `<excludes>` element to specify a comma-separated list of classes or packages to be excluded. Use the singular form, `<excludes>` , to specify a single class or a package.

For includes, you must specify each package or class individually using the `<include>` element. You can include a sub-package or subclass of an excluded element by specifying the sub-package or subclass with an `<include>` element. If a classname is matched by both an exclude and include pattern, the more specific pattern matched prevails. That is, an include match with `org.example.myclass` prevails over an exclude match for `org.example`.

Configuration Using Node Properties

You can also configure which classes or packages to include or exclude using a node property. See thread-correlation-classes and thread-correlation-classes-exclude.

Disable Thread Correlation at the Agent

To disable thread correlation (which disables end-to-end asynchronous transaction monitoring as well) at the agent, use one of these:

- Set the Java agent node property thread-correlation-classes-exclude to disable asynchronous monitoring for all the relevant classes.
  `thread-correlation-classes-exclude=a,b,c,d,e,f,...z`
- Add the following line under the fork-config section of the `app-agent-config.xml` file.

  `<exclude filter-type="REGEX" filter-value=".*"/>`

Executor Mode Thread Tracing

Executor mode is the default mode for instrumenting the asynchronous tasks beginning with the Java Agent 20.11 release.

When the agent is in Executor mode, transaction activity is tracked from thread to thread by instrumenting `Executor.exeute()`and similar method(s) such that the agent can identify application work to track as that work is being scheduled.

Benefits of Executor Mode

- Reduces the agent's resource consumption for most use cases
- Enables tracking thread hand-offs using the new agent API
- Improves reliability of last thread on tier asynchronous transaction demarcation
- Allows Service Endpoints to measure the response time of services implemented using asynchronous frameworks

Behavior of Service Endpoints in Executor Mode

The behavior of Service Endpoints differs between the Constructor and Executor modes. In Constructor mode, each asynchronous transaction segment is represented by its own Service Endpoint, and the Service Endpoint corresponding to the transaction entry point shows the execution time of the initiating thread as shown:

Name	Response Time (ms)	Calls	Calls / min	Errors	Errors / min	Type	Tier
/AsyncServletOne/one	112	15	3	0	0	Servlet	WebServer
RequestProcessor	1,126	15	3	0	0	Async	WebServer
AsyncServlet$RequestProcessor$$Lambda$7	119	15	3	0	0	Async	WebServer
AsyncServlet$RequestProcessor$$Lambda$8	95	15	3	0	0	Async	WebServer

With the Executor instrumentation strategy, metrics for a single Service Endpoint are reported, with a response time corresponding to the execution time of the entire asynchronous transaction as shown below.

Name	Response Time (ms)	Calls	Calls / min	Errors	Errors / min	Type	Tier
/AsyncServletOne/one	684	15	3	0	0	Servlet	WebServer

Currently**,** each service entry point must match a transaction entry point. Configuration of Service Endpoints at other points within the execution of asynchronous transactions is *not* supported in the Executor mode. Additionally, Service Endpoints only report if placed within the context of executing a Business Transaction when the agent is in Executor mode.

Raw Threads Support

Support for raw threads differs between the Executor and Constructor modes. While Constructor mode supports tracking of all threads created in the context of a transaction, the Executor mode supports only non-daemon threads that are started in the context of a transaction. The daemon status is inherited from the parent thread which can cause unexpected results. For example, the worker threads in an application server are often daemon threads, so any thread started directly within servlet code is not tracked in the Executor mode unless the application explicitly unsets its daemon status.

Node Properties

This table presents the node properties which are specific for the executor-based instrumentation strategy, or which work differently than for the constructor-based instrumentation strategy (default).

Property	Default value	Description
Property	**Default value**	**Description**
thread-correlation-classes	none	These properties have the same effect in the Executor mode as in Constructor mode, however, their use is discouraged in Executor mode, especially when used to limit the costs of thread tracking. Due to the differences in implementation of the async hand-offs, any performance gains achieved using these settings in constructor mode are likely to be available using the out of the box settings in Executor mode.

thread-correlation-classes-exclude		
min-transaction-stall-threshold-in-seconds	60	For Executor mode only, the transactions will not get checked for stall unless they run at least the specified number of seconds

Exclude Selected Activities from Transactions

Asynchronous frameworks use lower-level asynchronous mechanisms that are not related to the processing of user transactions (for example, a thread pool might grow and shrink automatically, depending on the load or a framework might initialize its thread pool upon the first use). You must ignore threads used in these contexts since their lifecycle is not bound to any individual application transaction.

To facilitate the exclusion of such asynchronous components (usually Threads and other Runnables), the Executor mode offers a mechanism called *capture suppression*. The suppression is tied to a specific method by a suppression rule in the async-config section of `app-agent-config.xml`. Consider the following example of such a rule provided by default:

```
<job>
  <match-class type="matches-class"><name filter-type="EQUALS" filter-value="java.util.concurrent.
ThreadPoolExecutor"/></match-class>
  <match-method><name filter-type="EQUALS" filter-value="addWorker"/></match-method>
  <action type="suppression"/>
</job>
```

The `addWorker` method on the `java.util.concurrent.ThreadPoolExecutor` class is a private method invoked by `ThreadPoolExecutor` whenever a new worker thread is to be created, started and added to the pool. Since such threads are not directly associated with any individual transaction at the point of creation, a suppression rule is used in order that any asynchronous task hands offs occurring within this method will not get associated with the transaction. Any asynchronous tasks subsequently executed by these threads will be associated with the transaction that created the task.

Trace Multithreaded Transactions for Java

Related pages:

- End-to-End Latency Performance
- Configure the Thread Correlation in Java Agent

The Java Agent can automatically track multithreaded applications. It correlates threads from classes that implement `Runnable` or `Callable` interfaces or extend the `Thread` class. Processes with such threads are identified in AppDynamics as asynchronous.

Monitor Asynchronous and Thread Processing Activity

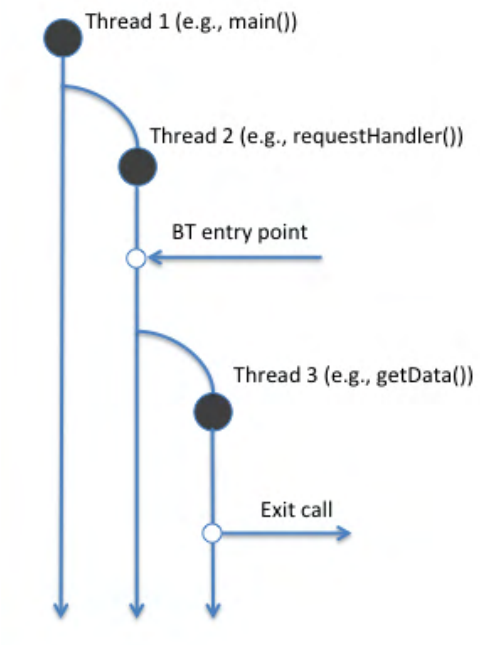
You can monitor performance around asynchronous calls and multithreaded activity in a variety of ways. It's helpful to understand what AppDynamics considers to be an asynchronous activity, what information it provides on that activity, and how that information relates to thread execution at the code level.

These sections describe the type of information available given various thread and exit call execution scenarios.

Asynchronous Exit Call

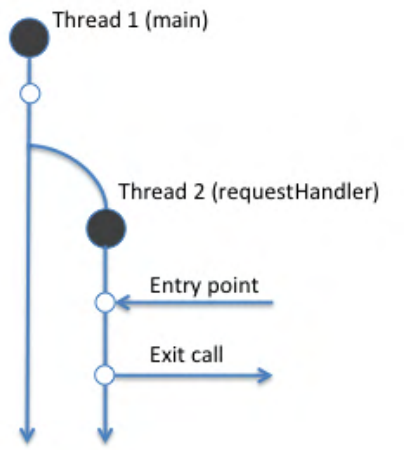
In the most common case, an asynchronous exit call is an exit call made by a thread that is spawned by a thread other than the primary business transaction thread.

The primary thread, in this case, is the one on which an entry point call is received. A common pattern for this case is when the main() function in the application spawns multiple threads as request handlers to receive and process requests. For example:



Flow maps in the Controller UI show this connection as a dotted line (asynchronous connection).

AppDynamics considers the call to be an asynchronous call only due to the context in which it was invoked. If the exit call is made from thread 2, as shown in the following illustration, the call may be considered asynchronous from the perspective of the overall design of the application, but is not considered asynchronous in the context of the business transaction:



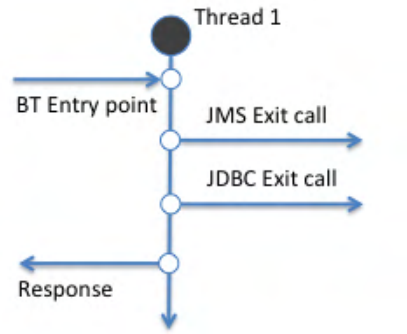
Without a business transaction, AppDynamics does not track asynchronous activity.

AppDynamics does not differentiate between the two common patterns in asynchronous processing, Wait-for-Completion (in which the threads report back into the primary thread) and Fire-and-Forget (in which the primary thread may finish processing before spawned threads do). Both are represented the same way in the Controller UI, although they would usually be distinguished by their execution time, in which the primary thread for a Wait-for-Completion transaction would exceed any of the child processes, whereas Fire-and-Forget the primary thread may be shorter than child processes.

Logical Asynchronous Exit Calls

An exception to the scenario described in the previous section exists for exit calls to backend systems which—from a conceptual point of view—are considered asynchronous in the AppDynamics model.

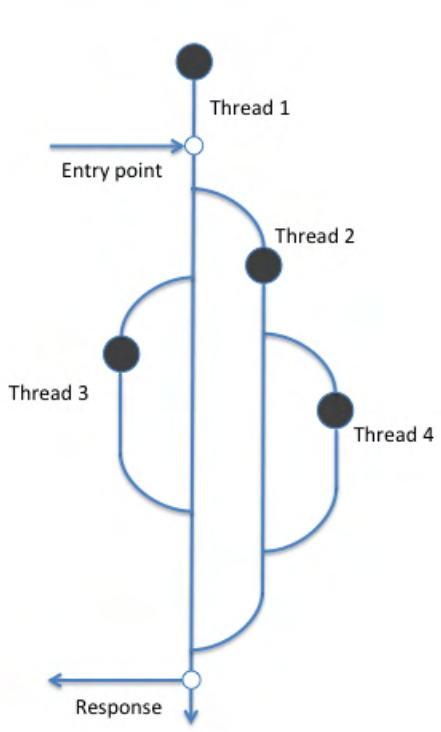
Message queue tiers such as JMS are considered logically asynchronous, so flow maps show connections to message queues as dotted lines (asynchronous connections) as well. Therefore, the following JMS exit call would be shown as an asynchronous call in a flow map, while the JDBC call would not be.



Time on Tier

Exit calls are one consideration in understanding multithreaded application performance; another consideration is the actual time spent processing a request.

For example, consider the following processing scenario. This occurs on a single tier. In fulfilling a request, the entry point thread spawns multiple child threads that report back to the primary thread to assemble the response.



For the transaction, the response time metric represents the time from when the request arrived at the entry point to the point the response was sent. However, while this may accurately represent the user experience of the transaction, it does not reflect the processing burden on the system, since many threads participate in the transaction. A slow performing thread may or may not be evident based on the user experience of the transaction.

To better understand the complete cost of the transaction in terms of time spent processing, you can use the time on tier metric. This metric shows the aggregate processing time for each of the threads involved in processing a request. In other words, the total execution time of threads 2, 3 and 4 from the figure, along with the processing time between the entry point and response for thread 1.

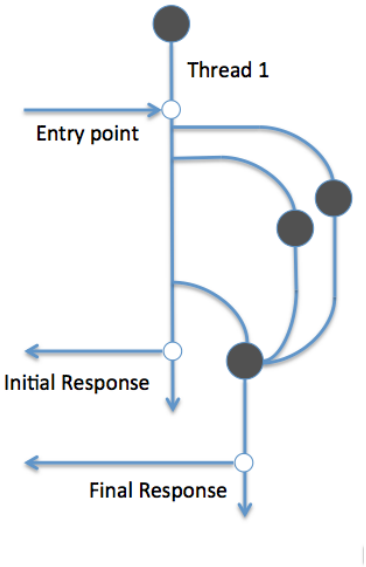
The value of the time on tier metric is indicated by the async tag in business transaction dashboards.

End-to-End Processing

A response from an entry point thread may not best represent the logical end of a business transaction.

For example, consider an application in which an entry point method in a request handler spawns multiple threads, including one to serve as the final response handler. The request handler then returns a preliminary response to the client. By default, this stops the clock for purposes of measuring the response time for that business transaction. Meanwhile, the spawned threads continue to execute until completion, at which point the response handler generates the final response to the client.

In this case, the initial response time is much shorter than the full logical transaction execution time.



End-to-end metrics let you monitor logical transactions that use this programming pattern. End-to-end metrics include the end-to-end transaction time, the number of end-to-end transactions per minute, and the number of slow end-to-end message processing events.

To enable end-to-end metrics, you configure an Asynchronous Transaction as described in Asynchronous Transaction Demarcators.

View Threads and Thread Tasks in the Metric Browser

In a multithreaded transaction, AppDynamics reports key business transaction performance metrics for individual threads in a Thread Tasks branch of the tier in the Metric Browser. The Thread Tasks branch is present in the Metric Browser only for multithreaded transactions. The Metric Browser path is **Business Transaction Performance > Business Transactions > *tier-name* > *business-transaction-name* > Thread Tasks**. Thread Tasks also appear for tiers under Overall Application Performance, where you can see metrics on specific calls made by each thread in a node or in a tier.

Thread Metrics in Health Rules

For each asynchronous thread spawned in the course of executing a business transaction, AppDynamics collects and reports these metrics:

- Average response time
- Calls per minute
- Errors per minute

You can create custom health rules based on the performance metrics for a thread task. When you click the metric icon in the Health Rule Wizard, the embedded metric browser includes the Thread Tasks if the entity for which you are configuring the health rule spawns multiple threads. See Configure Health Rules.

Use the Java Agent API and Instrumentation SDK

Related Pages

- AppDynamics APIs
- Data Collectors
- Add Custom Fields to Business Transactions
  Using the Java SDK

This page describes the Java Agent API, instrumentation SDK (iSDK), and the common use cases for the API.

Java Agent API and iSDK

AppDynamics automatically detects an application activity out-of-the-box. For supported application frameworks, the agent ships with an out-of-the-box configuration that applies instrumentation to the application that identifies the following:

- Where the Business Transaction activity starts
- Where thread handoffs occur
- Where calls to downstream systems are made, and how to inject correlation headers into outbound messages and retrieve them from inbound messages. This ensures that AppDynamics can establish the end-to-end transaction flow through the application architecture

For frameworks that do not benefit from out-of-the-box support, the agent provides a set of Agent APIs that allow the application developer to make code changes to add calls to the agent. This enables the agent to identify and follow Business Transactions as they execute, providing end-to-end visibility for any application.

For scenarios where it is not possible to change the application code, for example, to add instrumentation to a third-party product or framework, an 'instrumentation SDK' is provided that supports the use of these APIs. The iSDK enables developers to build 'interceptors', which the agent injects into application bytecode at specified points on startup. These interceptors can contain any Java code (including calls to the Agent API), which is executed when the code provided in the interceptor is run before, or after the intercepted method itself, executes.

You can seamlessly combine any Agent APIs with the out-of-the-box instrumentation to support situations where a mixture of supported and unsupported frameworks are in use (for example, a standard servlet making an external call using a proprietary API).

The Java Agent API enables you to programmatically:

- Define Business Transactions
- Define Exit Calls
- Inform the agent when the application hands-off transaction processing between threads
- Add application data to snapshots or transaction analytics
- Report custom metrics

When instrumenting any application, the Agent API design prioritizes the success of the application transactions over instrumentation. Therefore, if any of the Agent API calls fail, they do not throw exceptions disrupting the transaction flow, but log messages to aid diagnosis. This indicates that there is no hard dependency between the application and the presence of the AppDynamics Java Agent within the JVM.

See https://sdkdocs.appdynamics.com/javadocs/java-agent-api/v4.5/ for the Javadoc reference for the agent API. User guides for the Agent API and the instrumentation SDK are also provided to illustrate the usage and common use cases.

Install the Dependency

You can access the Agent API jar directly, or download it from Maven Central or from the AppDynamics portal. The library version changes with each new API release, and is not tightly coupled to the version of the underlying agent, which must be a minimum of version 4.5.11.

To use Maven Central, add the dependency to your build files in one of the following:

- Gradle:

```
dependencies {
    compile group: 'com.appdynamics.agent', name: 'agent-api', version: '4.5.18.29239'
}
```

or

- Maven:

```
<dependency>
     <groupId>com.appdynamics.agent</groupId>
     <artifactId>agent-api</artifactId>
     <version>4.5.18.29239</version>
</dependency>
```

iSDK Overview

The instrumentation SDK (iSDK) part of the Java Agent API enables you to create custom instrumentation to apply to the code in your application at runtime, and avoid making development time changes to instrument the code.

You can use the iSDK to implement interceptors making use of the imperative Java Agent APIs and apply custom instrumentation to proprietary applications or frameworks. This custom instrumentation works with the out-of-the-box instrumentation provided by the agent.

iSDK users need to create separate custom interceptor jar files that instrument their code at application startup when deployed with the Java Agent in the `sdk-plugins` directory. To remove custom instrumentation, remove the custom interceptor jar files from the agent deployment.

Use the iSDK

This procedure outlines how to use the iSDK:

1. Set up your development environment.
2. Set up your project.
3. Implement your interceptor(s).
4. Build your files.
5. Deploy.

Set Up Your Development Environment

To use the iSDK, you must write code with the external dependency of the iSDK library. To do this, these tools must be available:

- A Java IDE – Eclipse or IntelliJ. The following examples are for IntelliJ usage.
- Gradle.

Set Up Your Project

To set up your project:

1. In IntelliJ, create a new Gradle project for your work. The `build.gradle` file is created in the project directory that you specify.
2. Add the required information to your project's `build.gradle` file by following the procedure in the next section.

Install the Dependency

To use the iSDKs, do one of the following:

- Access the Agent API jar directly
- Download it from Maven Central
- Download it from the AppDynamics portal

The library version changes with each new API release, and is not tightly coupled to the version of the underlying agent, which must be a minimum of version 4.5.11.

For use with Maven Central, add the dependency to your build files in one of the following:

- Gradle:

```
dependencies {
    compile group: 'com.appdynamics.agent', name: 'agent-api', version: '4.5.18.29239'
}
```

or

- Maven:

```
<dependency>
     <groupId>com.appdynamics.agent</groupId>
     <artifactId>agent-api</artifactId>
     <version>4.5.18.29239</version>
</dependency>
```

See https://sdkdocs.appdynamics.com/javadocs/java-agent-api/v4.5/ for Javadoc reference for the Agent API.

Refresh your gradle project in intellij and run "gradlew idea" if you want intellij to reference the source properly when auto-populating methods and so on.

After this setup, you must be able to use Intellij to create a class, extend an iSDK template class, and auto-populate missing methods.

Deploy the iSDK with Agent API

To leverage Agent API functionality with the iSDK, you must package it with your custom interceptor jar. To accomplish this in Grade:

1. Create a configuration for iSDK:

```
configurations {
  isdk
}
```

2. Add the Agent-API dependency to this configuration:

```
dependencies {
    compile group: 'com.appdynamics.agent', name: 'agent-api', version: '4.5.18.29239'
        isdk group: 'com.appdynamics.agent', name: 'agent-api', version: '4.5.18.29239'
        …
}
```

3. Inside your task for generating the interceptors jar, include the `AppdynamicsAgent` class inside the jar:

```
jar {
  configurations.isdk.collect {
    it.isDirectory() ? from(it) : from(zipTree(it)) {
      include 'com/appdynamics/agent/api/AppdynamicsAgent.class'
    }
  }
  includeEmptyDirs = false
}
```

To accomplish this in Maven, you must write an Ant Task to include the AppdynamicsAgent class with your jar.

Implement Your Interceptor

Class or Method Identification

For all use cases, you must identify the class and method that you wish to instrument. This is also true when configuring custom POJO instrumentation using the User Interface but the technique is much different in the SDK.

Create Custom Interceptors and Rules

Implement Your Instrumentation Logic

The iSDK provides a class called `AGenericInterceptor`, which must be subclassed with the desired custom interceptor logic.

The agent examines .jar files deployed to the agent's `sdk-plugins` directory and looks for classes that extend `AGenericInterceptor`. These classes must implement the required abstract methods.

One key method all interceptors must implement is the `initializeRules` method, which returns a list of objects that extend the IRule interface. These IRules represent where in the code you must apply a given interceptor (class name, method name, method params, and so on).

If interceptors need to perform reflection on any of the java objects used in the instrumented code, an interface, `IReflector`, is provided to facilitate such reflection at runtime.

Important Methods to Implement in AGenericInterceptor

- `initializeRules` - Returns a list of objects that describe where in the code the interceptor must be placed
- `onMethodBegin` - Any code in the body of this method is run before the execution of the instrumented method
- `onMethodEnd` - Any code in the body of this method is run after the execution of the instrumented method

> `AGenericInterceptors` can be combined with the Agent API to start or end transactions, add data to snapshots, and so on.

These interceptors can be applied anywhere in the code, rather than just the beginning or end of a method. Also, they collect local variable information. Specific methods in the Rule builder, such as `atLineNumber`, `atField`, `atLocalVariable`, and so on only apply to this variety of iSDK interceptor.

- jars placed directly in the top-level "sdk-plugins" directory are also loaded.
- You can use the manifest attribute "Plugin-Classes: <comma separated list of fully qualified class names>" in your plug-in jar to specify specific classes to load as plug-ins. This improves jar loading performance, if the plug-in jar contains many classes that are not plug-ins.

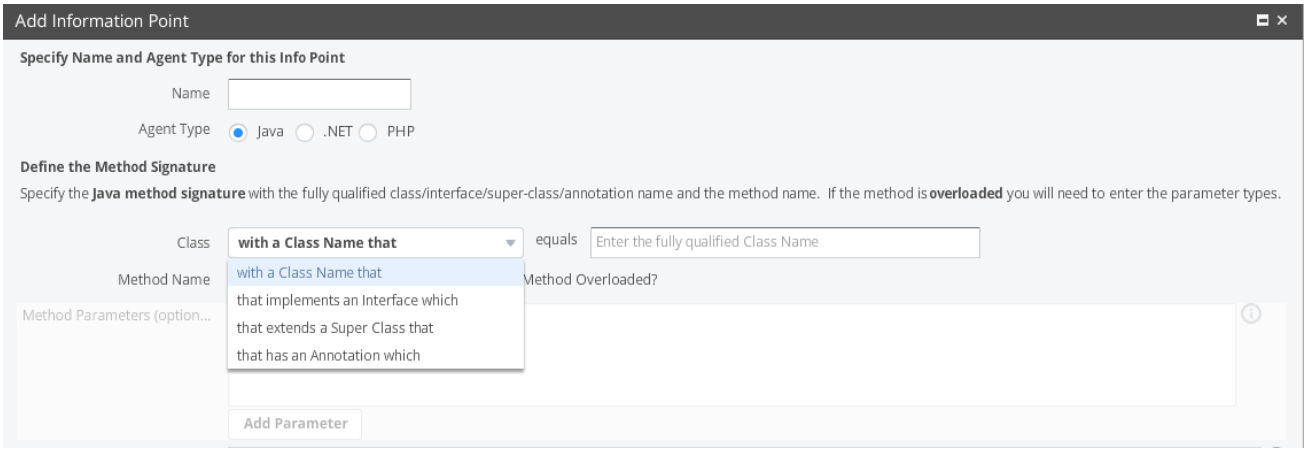
Use the Rule and Rule.Builder Classes

A `Rule` defines a set of classes to instrument. Your iSDK code returns a `java.util.List` of `Rule` objects from a method named *initializeRules*. `Rules` are created using the builder pattern – a `Rule.Builder` object is created using a match string:

```
Rule.Builder builder = new Rule.Builder("com.mynamespace.MyClass");
```

See the javadocs for all classes referenced in this section.

This is similar to what you have to do in the UI. For example, in the **Add Information Point** configuration screen, you must specify a name to match on – either a concrete class name, abstract class name, interface name or annotation name. The argument to the `Rule.Builder` constructor is the same as what you specify into the class match text box in the image below.



You then modify the `Rule.Builder` by calling APIs on the `Rule.Builder` class. `Rule.Builder` supports fluent style so that your code can be compact.

You need the following:

- Class match string: Given in the constructor to `Rule.Builder`
- Class match type: Set the `SDKClassMatchType` using `builder.setClassMatchType`
- Class match string match type: Set the `SDKStringMatchType` for the method using `builder.classStringMatchType`
- Method match string using `builder.setMethodMatchString`
- Method match type: Set the `SDKStringMatchType` for the method using `builder.methodStringMatchType`

The following is a screenshot of an initializeRules() method for creating an arbitrary interceptor. Note the following:

- The style is a mixture of fluent and iterative (lines have chained invocations, but multiple lines are still used)
- The class match is for an exact classname match to a concrete class (`SDKClassMatchType.MATCHES_CLASS` and `SDKStringMatchType.EQUALS` for `classStringMatchType`)
- The method match is for an exact method name string match (`SDKStringMatchType.EQUALS` for `methodStringMatchType`)

```
    private static final String CLASS_TO_INSTRUMENT = "com.appdynamics.util.async.TrackedCallable";
    private static final String METHOD_TO_INSTRUMENT = "linkContext";

    private static int pc = 0;

    public List<Rule> initializeRules() {

        Rule.Builder bldr = new Rule.Builder(CLASS_TO_INSTRUMENT);
        bldr = bldr.classMatchType(SDKClassMatchType.MATCHES_CLASS).classStringMatchType(SDKStringMatchType.EQUALS);
        bldr = bldr.methodMatchString(METHOD_TO_INSTRUMENT).methodStringMatchType(SDKStringMatchType.EQUALS);
        List<Rule> result =  new ArrayList<>();
        result.add(bldr.build());

        return result;
    }
```

Implement the Interceptor Logic

The Java code to be run when the custom interceptor is hit is provided in the `onMethodBegin` and/or `onMethodEnd` methods of the interceptor object.

A code example of a simple interceptor that leverages the Agent API is shown below.

```
public class SampleGenericInterceptor extends AGenericInterceptor {

    public SampleGenericInterceptor() {
        super();
    }

    @Override
    public List<Rule> initializeRules() {
        List<Rule> rules = new ArrayList<Rule>();
        rules.add(new Rule.Builder("Main").methodMatchString("genericInterceptorTarget").build());
        return rules;
    }

    public Object onMethodBegin(Object invokedObject, String className, String methodName, Object[]
paramValues) {
        System.out.print("In begin");
                AppdynamicsAgent.startTransaction("SampleGenericInterceptorBT", null, EntryTypes.POJO, false);
        Map<String, String> keyVsValue = new HashMap<String, String>();
        keyVsValue.put("foo", "bar");
        AppdynamicsAgent.getEventPublisher().publishEvent("an event happened", "INFO", "AGENT_STATUS",
keyVsValue);
        return null;

    }

    public void onMethodEnd(Object state, Object invokedObject, String className, String methodName,
            Object[] paramValues, Throwable thrownException, Object returnValue) {
        System.out.print("In end");
                Transaction currentTransaction = AppdynamicsAgent.getTransaction();
                Set<DataScope> dataScopes = new HashSet<DataScope>();
                dataScopes.add(DataScope.SNAPSHOTS); // collect data for BT snapshot.
                currentTransaction.collectData("key", "value", dataScopes);
                currentTransaction.end();
    }
}
```

Use the IReflector Interface

All iSDK classes have access to a toolbox interface called `IReflector`. This interface provides functionality that enables the use of Java reflection. Within any class that extends one of the template classes, the user can call `getNewReflectionBuilder()` to get an instance of `IReflectionBuilder`.

> `getNewReflectionBuilder()` must be called in the constructor of your plug-in class. You may hit a `NullPointerException` if it is called elsewhere.

This interface supports the following methods:

```
/**
 * load a class. classLoader specified in the IReflector.execute method
 **/
IReflectionBuilder loadClass(String className);

/**
 * Create a new object
 * @param className class to create
 * @param argTypes argument types
 * @return this
 */
IReflectionBuilder createObject(String className, String... argTypes);

/**
 * Invoke a static method
 * @param methodName method to invoke
 * @param searchSuperClass search super classes for the method. Else only declared methods are called
 * @param argTypes for overloaded methods
 * @return this
 */
IReflectionBuilder invokeStaticMethod(String methodName, boolean searchSuperClass, String... argTypes);

/**
 * Similar to invoke static method, invoke a instance method
 * @param methodName method to invoke
 * @param searchSuperClass search super classes for the method. Else only declared methods are called
 * @param argTypes for overloaded methods
 * @return this
 */
IReflectionBuilder invokeInstanceMethod(String methodName, boolean searchSuperClass, String... argTypes);

/**
 * Access a field
 * @param fieldName field name to access
 * @param searchSuperClass should search super class for the field name
 * @return this
 */
IReflectionBuilder accessFieldValue(String fieldName, boolean searchSuperClass);
These can be called in any order, essentially forming a getter chain. After crafting your chain of calls, the
build() method must be called, returning an IReflector.

The IReflector is used by invoking its execute() method:

/**
 * Execute the reflector chain
 * @param classLoader required - classloader referenced to load classes
 * @param target The steps will start executing on this object. null if first step is loadClass or staticMethod
 * @param params params to be passed to the steps
 * @return returns with correct cast
 * @throws ReflectorException
 */
<E> E execute(ClassLoader classLoader, Object target, Object[]... params) throws ReflectorException;

/**
 * Execute the reflector chain
 * @param classLoader required - classloader referenced to load classes
 * @param target The steps will start executing on this object. null if first step is loadClass or staticMethod
 * @param params params to be passed to the steps
 * @return returns with correct cast
 * @throws ReflectorException
 */
<E> E execute(ClassLoader classLoader, Object target, OperationParams params)
 throws ReflectorException;
```

The use of these reflectors is often critical for getting the desired functionality (extracting values from payloads, decorating objects with correlation headers, and so on).

Java Agent API Documentation

See the AppDynamics APM Agent API for the Java Agent.

Java Agent API User Guide

- Add Custom Fields to Business Transactions Using the Java SDK

This page provides examples that describe how you can implement common use cases for the Agent API. See the javadoc at https://sdkdocs.appdynamics.com/javadocs/java-agent-api/v4.5/.

Common Use Cases

The following are the common use cases for the Agent API.

Start and End a Synchronous Business Transaction

The following example shows code that starts a Business Transaction called 'Checkout' whenever the method `checkout()` is called. The Business Transaction ends when the method returns. Encapsulating the method body in a try or finally block ensures that you end the Business Transaction even if the method itself throws an exception or otherwise terminates without reaching the end.

```
public String checkout(List<ItemOrders> orders) {
   Transaction transaction = null;
   try {
        transaction = AppdynamicsAgent.startTransaction("Checkout", null, EntryTypes.POJO, false);

        /******************
         * Method Body Here
         ******************/
    } finally {
        if (transaction != null) {
           transaction.end();
        }
    }
}
```

Alternatively, you can use try-with-resources pattern:

```
public String checkout(List<ItemOrders> orders) {
   try (Transaction transaction = AppdynamicsAgent.startTransaction("Checkout", null, EntryTypes.POJO, false)) {
        /******************
         * Method Body Here
         ******************/
    }
}
```

In this case, the Business Transaction ends when the try block closes.

Start and End an Asynchronous Business Transaction

This example shows code that starts a Business Transaction called 'CheckoutAsync' whenever the method `checkoutAsync()` is called. The originating segment created for the Business Transaction ends when the method `endSegment()` is called on the Business Transaction, or when it is closed if used in a try-with-resources construct. Encapsulating the method body in a try/finally block ensures that we end the segment even if the method itself throws an exception or otherwise terminates without reaching the end.

```
//The thread where the Business Transaction starts
public String checkoutAsync(List<ItemOrders> orders) {
   Transaction transaction = null;
   try {
        transaction = AppdynamicsAgent.startTransaction("CheckoutAsync", null, EntryTypes.POJO, true);
                //mark handoff to link this segment with the end segment
                transaction.markHandoff(commonPayload);

        /******************
         * Method Body Here
         ******************/
    } finally {
        if (transaction != null) {
           transaction.endSegment();
        }
    }
}
```

Alternatively, the try-with-resources pattern is supported:

```
//The thread where the Business Transaction starts
public String checkoutAsync(List<ItemOrders> orders) {
   try (Transaction transaction = AppdynamicsAgent.startTransaction("CheckoutAsync", null, EntryTypes.POJO,
true)) {
                //mark handoff to link this segment with the end segment
                transaction.markHandoff(commonPayload);

        /******************
         * Method Body Here
         ******************/
    }
}
```

This ends the segment in the thread where the Business Transaction was started when the try block closes. The Business Transaction itself needs to be ended in the method where the asynchronous Business Transaction ends:

```
//The thread where the Business Transaction ends
public String checkoutAsyncEnd(List<ItemOrders> orders, Transaction transaction, Object commonPayload) {
   //link to the originating segment
   Transaction transactionSegment = AppdynamicsAgent.startSegment(commonPayload);

   /******************
   * Method Body Here
   ******************/
   if (transactionSegment != null) {
      transactionSegment.endSegment();
   }
   if (transaction != null) {
      transaction.end();
   }
}
```

Sett the Transaction Name After a Start

The following example shows how to set the transaction name after it has been started. This is useful if you want to split transactions based on events that happen in your application:

> Transaction name can only be set after a start on the originating segment, and if no async hand-offs or exits have been made.

```
public String checkout(List<ItemOrders> orders) {
   AppdynamicsAgent.startTransaction("Checkout", null, EntryTypes.POJO, false);
   /******************
    * Method Body Here
    ******************/
   if (orders.isEmpty()) {
              AppdynamicsAgent.setCurrentTransactionName("Empty Cart");
   }
   AppdynamicsAgent.getTransaction().end();
}
```

Start a Transaction Using OOTB Servlet Naming Rules

The following example shows how to leverage automatic servlet naming rules to name a transaction:

```
public String checkout(List<ItemOrders> orders) {
        Map<String, String> headers = new HashMap<String, String>();
        headers.put("header1", "headerValue1");
        Map<String, String[]> parameters = new HashMap<String, String[]>();
        Map<String, Object> cookies = new HashMap<String, Object>();
        cookies.put("chip", "ahoy");
        ServletContext.ServletContextBuilder contextBuilder = new ServletContext.ServletContextBuilder()
        .withURL(new URL("https://www.yourstore.com/endpoint/to/checkout"))
        .withParameters(parameters)
        .withHeaders(headers)
        .withCookies(cookies)
        .withSessionAttributes(new HashMap<String, Object>())
        .withRequestMethod("GET")
        .withHostValue("hostValue")
        .withHostOriginatingAddress("hostOriginatingAddress");
        Transaction t = AppdynamicsAgent.startServletTransaction(contextBuilder.build(), EntryTypes.HTTP, null,
false);
   /******************
    * Method Body Here
    ******************/
   t.end();
}
```

Define an Exit Call

For an `inventoryServer.verifyQuantities(orders)`, which makes a request to another process, you can monitor that request as an Exit Call. This helps to continue monitoring the Business Transaction through the call to the downstream server and identify the time spent in the remote service. You can do this by modifying the method as follows:

```
public void verifyQuantities(List<ItemOrders> orders) {
    ExitCall exitCall = null;
    try {
        exitCall = AppdynamicsAgent.getTransaction().startExitCall("Quantity Check", "Inventory Server",
ExitTypes.HTTP, false);

       /******************
        * Method Body
        ******************/
    } finally {
        if (exitCall != null) {
            exitCall.end();
        }
    }
}
```

Alternatively, if you want to use HTTP Backend detection rules, you can use the `startHttpExitCall` method:

```
public void verifyQuantities(List<ItemOrders> orders) {
    ExitCall exitCall = null;
    try {
         Map<String, String> identifyingProps = new HashMap<String, String>();
         URL url = new URL("https://www.appdynamics.com/solutions/microservices/");
           exitCall = AppdynamicsAgent.getTransaction().startExitCall(identifyingProps, url, false);
           /******************
           * Method Body
           ******************/
     } finally {
        if (exitCall != null) {
            exitCall.end();
        }
     }
}
```

The above code modifications define the Exit Call that manifests it as a remote service in the controller. To tag and follow the request into an instrumented downstream tier, add a correlation header:

```
public void verifyQuantities(List<ItemOrders> orders) {
    ExitCall exitCall = null;
    try {
        exitCall = AppdynamicsAgent.getTransaction().startExitCall("Quantity Check", "Inventory Server",
ExitTypes.HTTP, false);

        // Generate the appdynamics correlation header
        String correlationHeader = exitCall.getCorrelationHeader();

        // ... Method code including request creation

        // Modify the request/payload to include the correlation header
        inventoryRequest.addHeader(AppdynamicsAgent.TRANSACTION_CORRELATION_HEADER, correlationHeader);

    } finally {
        if (exitCall != null) {
            exitCall.end();
        }
    }
}
```

The following example shows how to instrument an asynchronous exit:

```
public class StartEndAsyncExitCall {

    private void makeAsyncExitTransaction() throws Exception {
        System.out.println("Starting transaction");
        try (Transaction transaction = AppdynamicsAgent.startTransaction("StartEndAsyncExitCall", null,
EntryTypes.POJO, true)) {
            Thread.sleep(1000);
            new TransactionEndingThread(transaction).start();
            System.out.println("Starting exitcall");
            ExitCall exitCall = null;
            exitCall = transaction.startExitCall("Custom", "Custom", ExitTypes.CUSTOM, true);
            new ExitCallEndingThread(exitCall).start();
        }
    }

    public class TransactionEndingThread extends Thread {
        Transaction transaction = null;

        TransactionEndingThread(Transaction transaction) {
            this.transaction = transaction;
        }

        public void run() {
            try {
                Thread.sleep(1000);
            } catch (InterruptedException e) {
                e.printStackTrace();
            }
            transaction.end();
            System.out.println("Ending transaction");
        }
    }

    public class ExitCallEndingThread extends Thread {
        ExitCall exitCall = null;

        ExitCallEndingThread(ExitCall exitCall) {
            this.exitCall = exitCall;
        }

        public void run() {
            try {
                Thread.sleep(50);
            } catch (InterruptedException e) {
                e.printStackTrace();
            }
            exitCall.end();
            System.out.println("Ending exitcall");
        }
    }
}
```

Define an Asynchronous Thread Handoff

If your checkout method also does a thread handoff and executes some business logic that you want to monitor in a separate thread, register the worker thread with the Business Transaction:

```
public String checkout(List<ItemOrders> orders) {
    Transaction transaction = null;
    try {
        transaction = AppdynamicsAgent.startTransaction("Checkout", null, EntryTypes.POJO, false);

        // ... Method code

        // Custom thread handoff using custom queue
        asyncTaskQueue.add(task);

    } finally {
        if (transaction != null) {
           transaction.end();
        }
    }
}
```

To instrument this, modify the add method to mark a thread handoff and then start a new segment where the thread begins running:

```
public class AsyncTaskQueue {
    public void add(Task task) {
        AppdynamicsAgent.getTransaction().markHandoff(task);

        /******************
         * Method Body
         ******************/
}
```

```
public class Task {
    public void run() {
        Transaction transaction = null;
        try {
            transaction = AppdynamicsAgent.startSegment(this);

            /******************
             * Method Body
             ******************/
        } finally {
            if (transaction != null) {
                transaction.endSegment();
            }
        }
    }

    public void cancel() {
        AppdynamicsAgent.cancelHandoff(this);

        /******************
         * Method Body
         ******************/
    }
}
```

The task object is used by the agent to link the segments. Correlating thread segments using the agent API requires that the agent is running in the Executor mode.

Add Data to Snapshot or Analytics

In many instances, there are values of interest in the code that are helpful to add to the snapshot. This aids in the root cause diagnosis of issues or to send to the AppDynamics Business Transaction analytics to help answer real-time business-oriented questions about your application. Data reported using this API appears in the same way as it had been collected with a Method Invocation Data collector.

To report a total checkout amount to Business Transaction analytics and have it presented in the APM snapshots, use the following code:

```
private static final Set<DataScope> dataScopeSet = new HashSet(Arrays.asList(DataScope.ANALYTICS, DataScope.
SNAPSHOTS));

public String checkout(List<ItemOrders> orders) {
    Transaction transaction = null;
    try {
        transaction = AppdynamicsAgent.startTransaction("Checkout", null, EntryTypes.POJO, false);

        // ... Method code

        double shoppingCartTotal = total(orders);
        transaction.collectData("cart total", Double.toString(shoppingCartTotal), dataScopeSet);

    } finally {
        if (transaction != null) {
           transaction.end();
        }
    }
}
```

Define a Custom Metric or Event

It can also be useful to report a value as a custom metric:

```
public String checkout(List<ItemOrders> orders) {

    // ... Method code

    double shoppingCartTotal = total(orders);
    AppdynamicsAgent.getMetricPublisher().reportSumMetric("Cart Total", (long) shoppingCartTotal);

}
```

It is recommended to provide a metric path along with the metric name in the code with format: `Server|Component:<TierName>|Custom Metrics|<MetricName>,` while publishing the metric.

Reporting custom metrics and events is possible irrespective of the Business Transaction context.

.NET Agent

To monitor .NET applications with AppDynamics, you install the .NET Agent on the servers where the applications run. You only need to install the agent once per server even to monitor more than one application on the server. This page describes how to install the .NET Agent for IIS applications using the Getting Started wizard in the Controller.

For alternative approaches, see:

- Install the .NET Agent for Windows, if you downloaded the agent directly from the AppDynamics Download Center.
- Configure the .NET Agent for Windows Services and Standalone Applications, if you monitor Windows services or standalone applications.

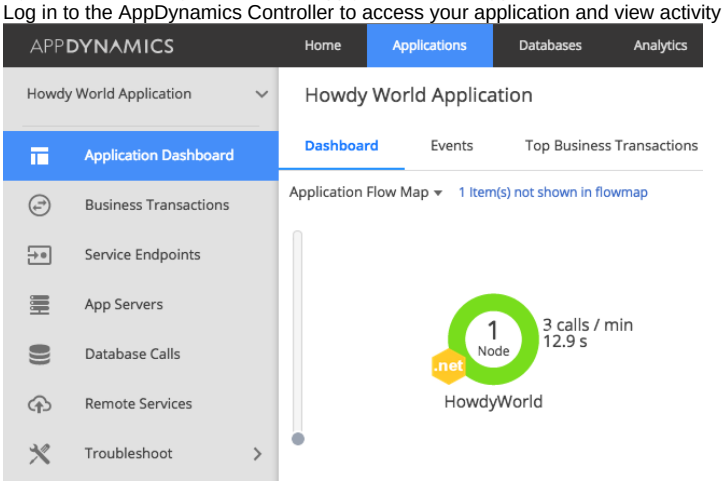
Before You Begin

1. Verify support for your environment at .NET Supported Environments.
2. Confirm that you have access to a compatible Controller. See Agent and Controller Compatibility.
3. Confirm the connection settings to the Controller where your agent will report data:
    - If you use a SaaS Controller, AppDynamics sent you the Controller hostname in your Welcome Email. Use port 443 for HTTPS, or port 80 for HTTP.
    - If you use an on-premises Controller, you supplied the hostname and port during installation.
4. Verify that you have access to the machine (where the application runs) as a user account with privileges to install the agent software, and restart the application.
5. Verify that the machine where the application runs can connect to the Controller. Proxies or firewalls on the network between the agent and Controller may require additional configuration.

Install the .NET Agent

To install the agent for IIS applications:

1. Log in to the Controller UI and access the Getting Started Wizard for .NET.
2. Follow the steps in the wizard to configure and download the agent. The wizard guides you through some preliminary configuration steps. When finished, the wizard enables you to download the agent as a ZIP archive named (in format of): `dotNetAgent-Portal-<architecture>-<version>.zip`.
3. Extract the agent archive on the destination computer.
4. Launch an elevated command prompt with full administrator privileges.
5. Execute the Installer.bat file you extracted. The batch file installs the agent and starts the AppDynamics Agent Coordinator service.
6. Restart IIS.
7. If you are in a testing environment, apply load to your application to view the activity in the Controller UI.
8. Log in to the AppDynamics Controller to access your application and view activity similar to:



Next, you can install more agents, or begin monitoring your application. See AppDynamics Essentials.

.NET Supported Environments

Supported Runtime Environments

This section lists the environments where the .NET Agent does some automatic discovery after little or no configuration. See Browser RUM Supported Environments for additional supported environments.

OS Versions

- Microsoft Windows Server 2012
- Microsoft Windows Server 2012 R2
- Microsoft Windows Server 2016
- Microsoft Windows Server 2019
- Microsoft Windows 8, 8.1, 10

Microsoft .NET Frameworks

Microsoft .NET Framework 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.2, 4.6, 4.7, and 4.8 on these runtime environments:

- Microsoft IIS 6.0, 7.0, 7.5, 8.0, 8.5, 10
- Managed Windows Services
- Managed Standalone Applications
- Microsoft SharePoint 2010, 2013 as services running inside IIS
- Microsoft ASP.NET Core 2.1 for Windows

Microsoft .NET Core and Microsoft .NET

Microsoft .NET Core 2.1, 3.1, and Microsoft .NET 5.0 with:

- Microsoft ASP.NET Core 2.1, 3.1, and Microsoft .NET 5.0 for Windows for .NET Agent >= 20.3

Microsoft Windows Azure

- Azure App Services for .NET 4.6 environments in the Azure Portal
  - Web Apps
  - Web Jobs
  - API Apps
  - Container Services

  For Azure App Services, the .NET Machine Agent disables certain .NET Machine Agent infrastructure monitoring features: CLR crash reporting, machine snapshots, and Windows performance counter monitoring.

- Azure Cloud Services
  - Web Roles
  - Worker Roles

Unsupported Frameworks

- Microsoft .NET 1.0 and 1.1
- Unmanaged native code

Automatically Discovered Business Transactions

The .NET Agent discovers business transactions for the following frameworks by default. The agent enables detection without additional configuration.

Type	Custom Configuration Options?	Downstream Correlation?
ASP.NET*	Yes	Yes
ASP.NET MVC 2 ASP.NET MVC 3 ASP.NET MVC 4 ASP.NET MVC 5	Yes	Yes
ASP.NET Core on the full framework	Yes	Yes
Open Web Interface for .NET (OWIN) web API	Yes	Yes
.NET Remoting	No	See Enable Correlation for .NET Remoting.
Windows Communication Foundation (WCF)	No	Yes

Web Services including SOAP	No	Yes
Message Queues		
Apache ActiveMQ NMS framework and related MQs	No	Yes
IBM WebSphere MQ	No	Yes
Microsoft Message Queuing (MSMQ)	No	Yes
Microsoft Service Bus / Windows Azure Service Bus	No	Yes
NServiceBus over MSMQ or RabbitMQ transport	No	Yes
RabbitMQ	Yes	Yes
TIBCO Enterprise Message Service	No	Yes
TIBCO Rendezvous	No	Yes
Windows Azure Queue	No	No

***** The .NET Agent automatically discovers entry points for ASP.NET web forms with the Async property set to "true" in the Page directive.

Supported Loggers for the .NET Agent

- Log4Net
- NLog
- System Trace
- Windows Event Log
- Loggers on .NET Core that implement the Microsoft.Extensions.Logging.ILogger API (Linux Agent >= 4.5.19 and Windows Agent >= 21.2.0)

If you are using a different logger, see Error Detection.

Remote Service Detection

The .NET Agent automatically detects these remote service types. The agent enables detection by default. You do not need to perform extra configuration.

Type	Custom Configuration Options?	Async Detection?*	Downstream Correlation?
CosmosDB: • v2.x (Microsoft.Azure.DocumentDB.Core) • v3.x (Microsoft.Azure.Cosmos) (Linux Agent >= 20.9.0, and Windows Agent >= 21.2.0)	No	See Asynchronous Exit Points for .NET.	N/A
Directory Services, including LDAP	No	No	N/A
HTTP	Yes	See Asynchronous Exit Points for .NET.	Yes
MongoDB: C# and .NET MongoDB Driver version 1.10, 2.0	No	See Asynchronous Exit Points for .NET.	N/A
.NET Remoting	Yes	No	See Enable Correlation for .NET Remoting.
WCF	Yes	See Asynchronous Exit Points for .NET.	Yes
WCF Data Services	Yes	No	No
Web Services, including SOAP	Yes	See Asynchronous Exit Points for .NET.	Yes
Azure Service Fabric Remoting v1 and v2—for the .NET Microservices Agent	-	-	-
Data Integration			
Microsoft BizTalk Server 2010, 2013	No	Yes	See Correlation Over Microsoft BizTalk.
Message Queues			
Apache ActiveMQ NMS framework and related MQs	Yes	No	Yes
IBM WebSphere MQ (IBM XMS)	Yes	No	Yes

Microsoft Message Queuing (MSMQ)	Yes	See MSMQ Backends for .NET	See MSMQ Backends for .NET
Microsoft Service Bus / Windows Azure Service Bus	No	Async exit points only	Yes
NServiceBus over MSMQ or RabbitMQ transport	No	See NServiceBus Backends for .NET	Yes
RabbitMQ	See RabbitMQ Backends for .NET	No	Yes
TIBCO Enterprise Message Service	Yes	No	Yes
TIBCO Rendezvous	Yes	No	Yes
Windows Azure Queue	No	No	No

* The agent discovers asynchronous transactions for the Microsoft .NET 4.5 framework. See Asynchronous Exit Points for .NET

Supported Windows Azure Remote Services

Type	Customizable Configuration?	Downstream Correlation?
Azure Blob	No	No
Azure Queue	No	No
Microsoft Service Bus	No	Yes

Cache Clients

Type	Customizable Configuration?	Async Detection?*	AppD for Databases?
StackExchange.Redis	No	Yes	No

Data Storage Detection

The .NET Agent automatically detects the following data storage types. The agent enables detection by default. You do not need to perform extra configuration.

Type	Customizable Configuration?	Async Detection?*	AppD for Databases?
ADO.NET (see supported clients below)	Yes	Yes	No
Windows Azure Blob Storage	No	Yes	No
Windows Azure File Storage	No	Yes	No
Windows Azure Table Storage	No	Yes	No

* The agent discovers asynchronous transactions for the Microsoft .NET 4.5 framework. See Asynchronous Exit Points for .NET

Supported ADO.NET Clients

AppDynamics can monitor any ADO.NET client version and type. Clients we've tested include the following:

Database Name	Database Version	Client Type
Oracle	10, 11, 12	ODP.NET
Oracle	10, 11, 12	Microsoft Provider for Oracle
MySQL	5.x	Connector/Net and ADO.NET
Microsoft SQL Server*	2005, 2008, 2012	ADO.NET

Install the .NET Agent for Windows

Related pages:

- Configure the .NET Agent
- Unattended Installation for .NET
- Upgrade the .NET Agent for Windows
- Download AppDynamics Software

To monitor IIS applications, Windows services, or standalone applications, install the AppDynamics .NET Agent once on each machine that hosts managed .NET applications. At startup, the agent initializes an individual instance of itself for each application running in the CLR.

This page describes a new installation for the .NET Agent using the MSI package.

- To install from the command line, see Unattended Installation for .NET
- To install the AppDynamics Site Extension for Windows Azure, see Install the AppDynamics Azure Site Extension for .NET
- To install the AppDynamics .NET Microservices Agent using one of the new AppDynamics NuGet Packages, see .NET Microservices Agent
- To upgrade, see Upgrade the .NET Agent

Installation Overview

1. Prepare to Install.
2. Install the agent.
3. Configure the agent.
4. Restart instrumented applications.
    - For Microsoft IIS, the configuration utility provides an option to restart IIS or not.
    - If you do not restart IIS, monitoring does not begin until the next time IIS restarts.
    - You must restart Windows services and standalone applications manually.

Prepare to Install

Review these requirements before you install the .NET Agent:

- You must enable Windows Management Instrumentation service on the machine where you are installing the .NET Agent, and the service must be running.
- To run the .NET Agent and the Standalone Machine Agent on the same machine, you must enable .NET Compatibility Mode on both the machine and .NET Agent. See .NET Compatibility Mode.

Install the .NET Agent

1. Download the MSI installer package from the AppDynamics Download Center.
2. Run the MSI installer package.
3. Read the End User Agreement and click to accept. Then, click **Next**.
4. (Optional) On the Confirm location panel, change the .NET Agent installation directories, including:
    - Destination directory for the .NET Agent executables and supporting files.
    - Parent directory for local data including agent configuration files and log files.

   See .NET Agent Directory Structure for the default directories.

   > You can also change the destination of the logs directory later using the AppDynamics Agent Configuration utility.

5. On the User Account Control panel, click **Yes** to allow the installer to make changes to the computer. If the current account does not have administrator privileges, the installer prompts you to supply the password for an administrator account.
6. Wait for the installation to complete.
7. For new installs, AppDynamics recommends you launch the AppDynamics Agent Configuration utility.

If you encounter problems installing, see Troubleshoot .NET Agent Issues

Configure the .NET Agent

Launch the AppDynamics Agent Configuration utility to configure the .NET Agent.

- For Microsoft IIS applications, see Configure the .NET Agent
- For Windows services or standalone applications, see Configure the .NET Agent for Windows Services and Standalone Applications

Configure the .NET Agent

Related pages:

- Install the .NET Agent for Windows
- Name .NET Tiers
- Configure the .NET Agent for Windows Services and Standalone Applications
- Unattended Installation for .NET

After you install the AppDynamics .NET Agent, configure the agent based on the types of applications to monitor:

- For Microsoft IIS applications, use the configuration utility with either automatic or manual tier naming.
- For Windows services or standalone applications, use the configuration utility, and then manually update the config.xml. See Configure the .NET Agent for Windows Services and Standalone Applications.

You can instrument any combination of IIS Applications, Windows services, and standalone applications on a single server. Run the configuration utility to configure IIS, then follow the instructions for Windows services and Standalone applications.

Use the AppDynamics Agent Configuration Utility to configure the agent immediately after installation, or make changes to existing agent configurations. Th e utility configures the agent for one machine at a time.

Prepare to Configure the .NET Agent

- Install the .NET Agent for Windows.
- You need these account credentials based on your installation type:
    - Single-tenant: Membership in a role with the View License account level permission. See Create and Manage Custom Roles.
    - Multi-tenant or SaaS: Your AppDynamics Welcome Email that contains your account credentials.
- Uninstall any pre-existing profiler, such as Ant, VS 2010 Performance Tools, or others. The configuration utility alerts you if it finds a pre-existing profiler.
- Determine your tier naming scheme:
    - Automatic
    - Manual
    - Pre-configured using Config Management in the Controller

> The configuration utility must restart IIS to apply configurations. The utility offers you the option to restart IIS or not. If you choose not to restart, configurations apply the next time IIS restarts.

File System Security Settings

These Windows accounts require specific file system permissions:

- The account you use to run your web application as defined by its application pool, or the Windows service account.
- The account you use to run the AppDynamics Agent Coordinator, by default the Local System account.

The required permissions are:

- Write permission to the .NET App Agent logs directory.
  Default: Windows Server 2008 and later: `%ProgramData%\AppDynamics\DotNetAgent\Logs`
- Read and Execute permissions to the .NET App Agent install directory.
  Default: `C:\Program Files\AppDynamics\AppDynamics .NET Agent`
- Read and Execute permissions in the web application installation directory.
  For example: `C:\inetpub\wwwroot\myapp`

Configure the .NET Agent

1. Start the Agent Configuration Utility. In the Windows pane, select **AppDynamics > .NET Agent > AppDynamics Agent Configuration**.
   If a warning message displays, click **Yes** to exit and uninstall any pre-existing profiler.

   > Use the Registry editor to check the Windows registry and ensure that the uninstall process cleaned up the registry entries. Use the warning message to identify any undeleted profiler environment variables. See Troubleshoot .NET Agent Issues.

2. If the configuration utility detects legacy agent configurations from the .NET Agent <= 3.7.7, it displays the **Upgrade Configuration** pane. Choose either:
    - **Yes** to remove legacy configurations. See Upgrade the .NET Agent for Windows.

      > Removing legacy configurations modifies `web.config` files and causes IIS to restart affected applications.

- **No** to retain legacy configurations.

When the utility discovers no further profiler conflicts, or after any configuration clean up, it displays the welcome pane.

3. From the Log directory permissions pane, you can optionally change the location of the log directory. Click **Change** and select a new location.
4. If needed, enter an account to grant log directory permissions. Click **Add**. If a warning message displays, verify that the account is valid on the system. The wizard confirms the list of accounts.
5. From the Controller Configuration pane, enter the Controller access information and credentials.
    - The AppDynamics Agent Configuration utility only supports the configuration of one Controller and business application per server.
        - Use tiers to organize different applications you instrument on a single server, or
        - Manually configure support for multiple business applications. See Configure Multiple Business Application Support for .NET.
    - Enter the Controller server name, or IP and port number.
    - For single-tenant accounts, enter your Account Access Key. Locate your credentials under **Settings > License** in the Controller.
    - For multi-tenant accounts, click **Multi-Tenant Controller**. Enter the Account Name and Account Access Key as provided to you by AppDynamics.
    - For a secure connection, click **Enable SSL**.
        - Make sure you have secured the Controller with a trusted certificate. See Enable SSL for the .NET Agent.
        - When you enable SSL, the agent secures communication to the Controller using the protocols set for `ServicePointManager.SecurityProtocol` in your application.
        - By default, the configuration utility enables TLS 1.2, making it the first option in the list of secure protocols. This affects all secure communications from your application, not just requests to the AppDynamics Controller. To disable TLS 1.2, click to deselect this option.
    - If needed, enter the HTTP proxy information. Proxies that use authentication require additional configuration.
6. Click **Test Controller Connection** to verify the connection.
   The Application Configuration pane displays existing business application information from the Controller and Controller connection status.
7. Configure the business application for the Controller:
    - If you already have a business application on the Controller, click **Existing Applications from the Controller** and click the appropriate business application. If you have not defined business applications in the Controller, the utility displays an empty list.
    - Click **New Application** to define a new business application. Be careful about spellings and capitalization and note down the exact name. Ampersands are not supported in application names.
    - To use Config Management in the Controller, click **Register Machine with No Application**.
8. Click **Next** to advance to Assign IIS applications to tiers where you can use one of the tier naming options.

Automatically Name IIS Tiers

1. In the Assign IIS applications to the tiers pane, click **Automatic**.
2. If prompted, click **OK** to confirm the Automatic configuration. The configuration utility summarizes the configuration settings.
3. By default when you click **Next**, the configuration utility restarts IIS.

> If you do not want to apply the configuration right away, uncheck the box. The Agent Configuration Utility saves the information and applies it the next time you restart IIS.

4. If you proceed and click **Next**, the configuration utility logs its activities, including stopping and restarting IIS, and reports any problems. Review the summary for any issues in red font. The green font indicates the logged events. The summary shows any Warnings (W) or Errors (E).
5. Click **Done**.

Manually Name IIS Tiers

1. From the Assign IIS applications to tiers pane, click **Manual**, then click **Next**.
2. Assign IIS Applications to AppDynamics tiers by selecting a tier on the right and a business application on the left. The utility highlights the assigned tier in boldface.

> For large IIS installations, use the Max IIS tree depth pulldown to display all the projects. A large tree depth may take some time to view.

   To create new tiers, enter a name and click **Add Tier**.
3. When you are done click **Next**.
4. On the **Configuration Summary** pane, uncheck **Restart IIS** if you do not want to immediately restart IIS. You may restart later to apply your changes, or they will take effect after a reboot.
5. If you proceed and click **Next**, the Configuration Utility logs its activities, including stopping and restarting IIS, and reports any problems.
6. Review the configuration log summary. As it applies the configuration, AppDynamics generates a log of the configuration activities and displays a summary. Review the summary for any issues in red font. The green font indicates the logged events. The summary shows any Warnings (W) or Errors (E).
7. When finished, click **Next**. The wizard completes.

Use Config Management

1. From the Assign IIS applications to the tiers pane, click **Register Machine with No Application**, and then click **Next**.

2. From the Configuration Summary pane, uncheck **Restart IIS** if you do not want to immediately restart IIS. You may restart later to apply your changes, or they will take effect after a reboot.
3. Follow the instructions on Manage Configuration for .NET to assign a configuration from the Controller. The .NET Agent and .NET Machine Agent do not report metrics to the Controller until after you assign a configuration using the Config Management tool.

See Troubleshoot .NET Agent Issues.

.NET Agent SSL Support

When a .NET Agent establishes a secure (SSL) connection with a Controller, the .NET Agent uses a default mechanism embedded in the .NET framework to verify a Controller (server) certificate which relies on the local Trust Store. As a result, the Controller certificate must be signed by one of the publicly trusted authorities.

Therefore, if the Controller uses:

- a self-signed certificate, or
- a certificate signed by a custom authority

Then the SSL connection cannot be established until:

- a self-signed certificate, or
- a custom authority are manually added to the local Trust Store.

> If a Controller uses a certificate signed by a publicly trusted authority, then no extra set up is required.

If you do not want to manually add a certificate to the local Trust Store, you can configure the .NET Agent to consume the Controller custom trusted certificate and establish a secured connection automatically.

Limitations

Custom trusted certificate validation is supported with these noted limitations for the .NET runtimes:

- .NET Core >= 2.0
- .NET Framework >= 4.7.2
- .NET Standard >= 2.1

> You may use applications that were complied using earlier .NET versions as long as the .NET runtime is later than or equal to the listed limitations.

If you reach a runtime limitation, then you can either:

- Upgrade the .NET runtime to a supported version, or
- Add a Controller custom certificate to the local Trust Store, disable the feature, and then continue using the SSL connection to a Controller based on the default validation mechanism.

Supported Configurations

You can configure the Controller Custom Trusted Certificates by providing either a:

- Path to one certificate file: A file may contain one, or multiple valid certificates, in one of these formats:
  - Base-64 Encoded X.509 (.cer)
  - DER Encoded Binary X.509 (.cer)
  - PKCS 7 (.p7b)
  - PKCS 12 (.pfx)

Or

- Folder containing multiple certificate files: A folder may contain several files with one or multiple certificates inside; and the folder may contain subfolders. There is no limitation on the structure except that all files in the folder must contain valid certificates; if one file is not a valid certificate, then all of them are ignored.

Select only one of these configurations. If you configure both a certificate file and a certificate folder, then a warning displays alerting you that only the certificate file will be used in the configuration.

> You are not required to provide a private key in your certificate files; only a public key is required. AppDynamics does not expose any sensitive information from the provided certificates. Use caution when providing files to an outside source.

Standalone Windows Agent Configuration

Configure the `config.json` file:

```
{
        "controller": {
                "certfile": "C:\certs\certificate.crt",
                "certdir": "C:\certs\",
        }
}
```

Environment Variables Used for Standalone Windows Agent

Using the command line, set these environment variables to override the `config.json` file:

```
APPDYNAMICS_CONTROLLER_SSL_CERTFILE=C:\certs\certificate.crt
APPDYNAMICS_CONTROLLER_SSL_CERTDIR=C:\certs\
```

Agent MSI Agent Configuration

Configure the `config.json` file without overriding the environment variables:

```
<appdynamics-agent xmlns:xsd="http://www.w3.org/2001/XMLSchema" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">
  <controller ssl-certificate-file = "C:\certs\certificate.crt" ssl-certificate-directory = "C:\certs\" >
    ...
  </controller>
  ...
</appdynamics-agent>
```

Parity Difference with Linux .NET Agent <= 20.11.x

These are the existing parity differences with Linux .NET Agent <= 20.11.x:

- Certificate files formats are extended.
- Multiple certificates are supported in files.
- There is no name constraint for the files.
- There is no constraint on the folder structure.
- Full framework is supported.
- You are not required to provide a full chain of the Controller certificates. You can configure the .NET Agent trust using an end leaf certificate, or just a custom authority certificate, or both; whichever is convenient.

Enable SSL for the .NET Agent

Related pages:

- Secure the Platform
- Administer the .NET Agent
- .NET Agent Configuration Properties

This page describes how to configure the AppDynamics .NET Agent to connect to the Controller with SSL.

Requirements

Before you configure the agent to enable SSL, gather this information:

- Identify the Controller SSL port:
  - For SaaS Controllers, the SSL port is 443.
  - For on-premises Controllers, the SSL port is 8181 by default, but it is possible to configure on-premises Controllers to use other ports at installation.
- Identify the signature method for the Controller's SSL certificate:
  - A publicly known certificate authority (CA) signed the certificate. This applies for Verisign, Thawte, and other commercial CAs.
  - A CA internal to your organization signed the certificate. Some companies maintain internal certificate authorities to manage trust and encryption within their domain.
  - .NET Agent supports self-signed certificates when these conditions exist:
    - The Common Name (CN) on the certificate matches the URL of the Controller that the agent is calling.
    - The public key for the self-signed certificate is installed on the Windows Trusted Root Certification Authorities store where the agent is installed.

Establish Trust for the Controller's SSL Certificate

The .NET Agent requires that the Common Name (CN) on the Controller certificate matches the DNS name of the Controller. Additionally, certificates for the root CA that signed the Controller's SSL certificate must reside in the Windows Trusted Root Certification Authorities store for the Local Computer.

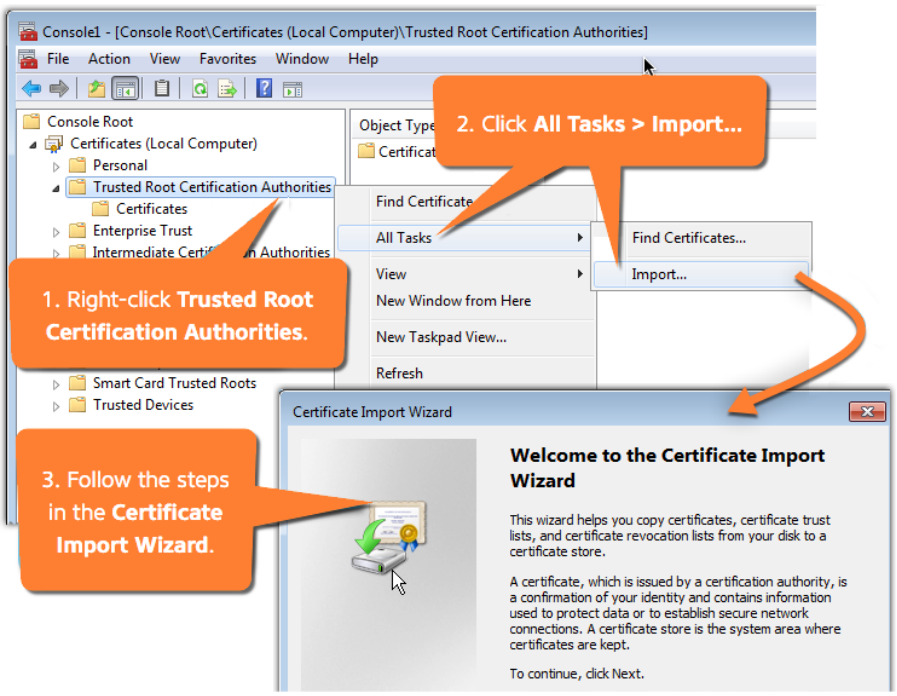
Certificates Signed by a Publicly Known Certificate Authority

The root certificates for most publicly trusted CA signing authorities, such as DigiCert, Verisign, Thawte, and other commercial CAs, are in the Trusted Root Certification Authorities store by default.

Certificates Signed by an Internal Certificate Authority

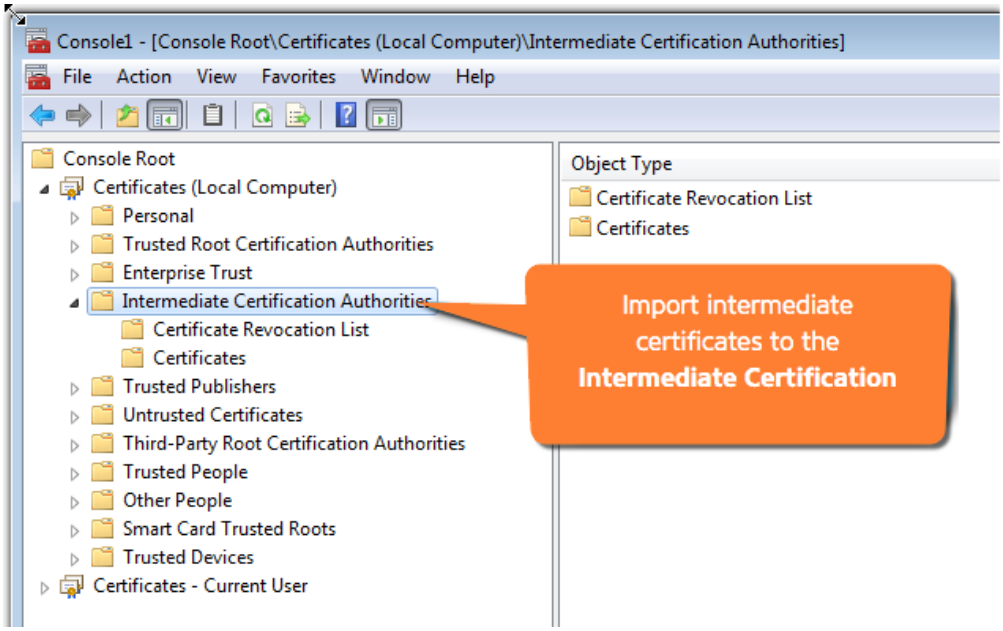
If your organization uses internal CA to sign certificates, you may need to obtain the root CA certificate from your internal security management resource. To import the root certificate, see Adding Certificates to the Trusted Root Certification Authorities store for a Local Computer.

This example shows how to use the Certificate snap-in for the Microsoft Management Console to import a certificate for a Trusted Root Certification Authority:



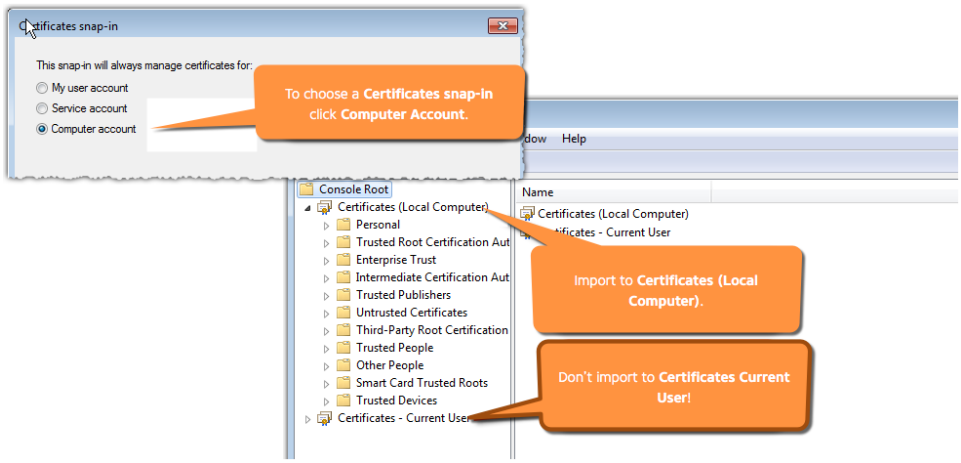
If an intermediate CA signed the Controller certificate, you must import the certificate for the intermediate CA in addition to the one for the root CA that signed the intermediate CA certificate. If your Controller is publicly accessible, you can use a certificate checker to identify the certificates required to complete the trust chain.

This example shows the **Intermediate Certification Authorities** store:



Certificate Management Tips

- If you imported certificates for a root or intermediate CA, verify the certificate store where you imported them. Import them to **Certificates (Local Computer)**.



- The AppDynamics SaaS Controller uses certificates signed by DigiCert. In some cases, SaaS customers must import the DigiCert root certificates into the **Windows Trusted Root Certification Authorities** store.
- In some cases system administrators set up group policies that require external certificates be imported to the **Third-Party Root Certification Authorities** store. If importing the certificate for the root CA to the **Windows Trusted Certification Authorities** store is not successful, then try the **Third-Party Root Certification Authorities** store.

Enable SSL for the .NET Agent

You can update the SSL settings for the agent by:

- Using the AppDynamics Agent Configuration Utility, or
- Editing the settings directly in the config.xml

When you enable SSL for the .NET Agent, you automatically enable SSL for the .NET Machine Agent.

Configure SSL Using the AppDynamics Agent Configuration Utility

1. Launch the AppDynamics Agent Configuration utility.
2. In **Controller Configuration**, set the **Port Number** to the SSL port for the Controller.
    - For a SaaS Controller, set the **Port Number** to `443`.
    - For an on-premises Controller, set the **Port Number** to the on-premises SSL port. The default is `8181`.
3. Click **Enable SSL**.
    - When you enable SSL, the agent secures communication to the Controller using the protocols set for `ServicePointManager.SecurityProtocol` in your application.
    - By default, the configuration utility enables TLS 1.2, making it the first option in the list of secure protocols. This affects all secure communications from your application, not just requests to the AppDynamics Controller. To disable TLS 1.2, click to deselect this option.
4. Click **Next** and proceed with the rest of the panes to complete the configuration.
5. Restart instrumented applications: IIS applications or application pools, Windows services, and standalone applications.

If you use automatic tier configuration, restart IIS. For example, open a command prompt and enter:

```
iisreset
```

Upon restart, the agent connects with the Controller via SSL.

Configure SSL Using config.xml

1. Open the config.xml file as administrator. See Administer the .NET Agent.
2. Update the following SSL settings:
    - Controller port attribute: set to the on-premises SSL port. The default is `8181`. See Controller Port Attribute.
    - Controller SSL attribute: set to `true`. See Controller SSL Attribute. When you enable SSL, the agent secures communication to the Controller using the protocols set for `ServicePointManager.SecurityProtocol` in your application.
    - Controller enable TLS 1.2 attribute: Optionally set to `true` to add TLS 1.2 as the first option in the list of protocols. This affects all secure communications from your application, not just requests to the Controller.
3. Save your changes.
4. Restart the `AppDynamics.Agent.Coordinator` service.
5. Restart instrumented applications: IIS applications or application pools, Windows services, and standalone applications.

If you use Automatic configuration, restart IIS. For example, open a command prompt and run:

```
iisreset
```

Upon restart, the agent connects with the Controller via SSL.

Sample SaaS SSL config.xml Configuration

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001
/XMLSchema">
  <controller host="mycompany.saas.appdynamics.com" port="443" ssl="true" enable_tls12="true">
    <application name="MyDotNetApplication" />
  </controller>
...
</appdynamics-agent>
```

Sample On-Premises SSL config.xml Configuration

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001
/XMLSchema">
  <controller host="mycontroller.mycompany.com" port="8181" ssl="true" enable_tls12="true">
    <application name="MyDotNetApplication" />
  </controller>
...
</appdynamics-agent>
```

Troubleshooting Issues

If you verified all prerequisites and still have communication issues, verify that the default ciphers are enabled in Windows Server.

Check this Registry key:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\SecurityProviders\SCHANNEL\Ciphers\
```

If subkeys exist, your operations team may have disabled certain ciphers.

Encrypt Credentials in .NET Agent Configuration

Related pages:

- Unattended Installation for .NET
- Upgrade the .NET Agent for Windows

By default, the AppDynamics .NET Agent stores these credentials in the `config.xml` file:

- Controller account authentication
- Proxy server authentication

For environments where security policies require you to secure credentials stored on disk, you can run an unattended installation that encrypts the credentials for the .NET Agent and writes them to the Windows Credential Manager.

> ⚠ Storing credentials for the .NET Agent using the Windows Credential Manager updates the `config.xml` file to use a schema which the AppDynamics Agent Configuration utility does not support. If you follow these instructions, then you cannot use the configuration utility to make configuration changes afterward. If you launch the configuration utility on a server where you have stored credentials in the Windows Credential Manager, the utility prompts you to delete the configurations.

Requirements

- You must run the `AppDynamics.Agent.Coordinator` service as the `LocalSystem` account.
- To modify credentials after installation, you need Windows Sysinternals.

Setup Configuration File

You must generate a setup configuration file to run an unattended installation. See 'Setup Configuration File Properties' on Unattended Installation for .NET.

New Installation

For new installations, use one of these methods to create the setup configuration file:

- Run the AppDynamics Agent Configuration utility from the command line and pass the `-s` parameter to specify the setup configuration file destination. For this option, you must execute the .NET Agent MSI installer package on one machine before running the configuration utility.

  ```
  %ProgramFiles%\AppDynamics\AppDynamics .NET Agent\AppDynamics.Agent.Winston.exe -s <path to setup configuration file>
  ```

- Manually create a setup configuration file from a sample template.

Remove any plain-text authentication elements from the setup configuration file. You pass the credentials as part of the unattended installation command:

- Controller Account element:
  `<account name="myaccount" password="myaccesskey"/>`
- Proxy Authentication element: If you are using a proxy authentication, use this format in the setup configuration file.

  ```
  <proxy host="myproxy.example.com" port="3128" enabled="true">
     <authentication enabled="true" domain="mydomain.com"/>
  </proxy>
  ```

Upgrade

If your upgrade meets the criteria for an in-place upgrade on Upgrade the .NET Agent for Windows, you can encrypt the credentials for the .NET Agent and upgrade the agent at the same time.

Copy the AppDynamics Agent element from your existing `config.xml` file to the setup configuration file. Remove any plain-text authentication elements from the setup configuration file. You pass the credentials as part of the unattended installation command:

- Controller Account element:
  `<account name="mycontroller.saas.appdynamics.com" password="myaccesskey"/>`
- Proxy Authentication element:
  `<authentication enabled="true" user_name="my_proxy_user" password="password" domain="my_windows_domain"/>`

Sample Setup Configuration File

This example shows a setup configuration file that instruments: two IIS Applications, `MainBC` and `SampleHTTPService`; a Windows service, `BasicWindowsService`; and a standalone application, MyStandaloneApp.exe.

```
<winston>
  <logFileDirectory directory="C:\ProgramData\AppDynamics\DotNetAgent\Logs" />
  <logFileFolderAccessPermissions defaultAccountsEnabled="false">
    <account name="NT AUTHORITY\LOCAL SERVICE" displayName="LOCAL SERVICE" />
    <account name="NT AUTHORITY\SYSTEM" displayName="SYSTEM" />
    <account name="NT AUTHORITY\NETWORK SERVICE" displayName="NETWORK SERVICE" />
    <account name="IIS_IUSRS" displayName="ApplicationPool Identity" />
  </logFileFolderAccessPermissions>
  <appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001
/XMLSchema">
    <controller host="mycontroller.appdyanmics.com" port="443" ssl="true">
      <application name="My Business Application" />
    </controller>
    <machine-agent />

    <app-agents>
      <IIS>
        <applications>
          <application path="/" site="MainBC">
            <tier name="Main Site" />
          </application>
          <application path="/" site="SampleHTTPService">
            <tier name="HTTP Services" />
          </application>
        </applications>
      </IIS>
      <standalone-applications>
         <standalone-application name="BasicWindowsService" args="-x">
            <tier name="Windows Service Tier"/>
         </standalone-application>
         <standalone-application executable="MyStandaloneApp.exe">
            <tier name="Standalone App" />
         </standalone-application>
      </standalone-applications>
    </app-agents>

  </appdynamics-agent>
</winston>
```

Install from the Command Line

To install the .NET Agent from the command line:

1. Download the .NET Agent MSI Installer Package from the AppDynamics Download Center.
2. Launch an elevated command prompt with full administrator privileges. See Start a Command Prompt as an Administrator.

   > Logging on to Windows as a member of the Administrators group does not grant sufficient permissions to run the installer.

3. Stop IIS and, if you are upgrading, stop instrumented Windows services and Standalone applications.
4. Run this command to install the agent with encrypted credentials. See command line options for descriptions.

   ```
   msiexec /i <path_to_MSI_installer_package> /l log.txt /q AD_SETUPFILE=<path_to_setup_configuration_file>
   AD_SECURED_CREDENTIALS=true AD_CONTROLLER_ACCOUNT_NAME=<SaaS or multi-tenant account>
   AD_CONTROLLER_ACCOUNT_ACCESS_KEY=<access key> AD_PROXY_USERNAME=<proxy user name>
   AD_PROXY_PASSWORD=<proxy password>
   ```

   For example:

   ```
   msiexec /i "%USERPROFILE%\Downloads\dotNetAgentSetup.msi" /l log.txt /q AD_SETUPFILE="%USERPROFILE%
   \Documents\SetupConfig.xml" AD_SECURED_CREDENTIALS=true AD_CONTROLLER_ACCOUNT_NAME=MyAppDynamicsAccount
   AD_CONTROLLER_ACCOUNT_ACCESS_KEY=changeme AD_PROXY_USERNAME=MyProxyUser AD_PROXY_PASSWORD=ProxyPass
   ```

   The MSI installer package installs the .NET Agent and encrypts the credentials and writes them to the Windows Credential Store. It adds the Controller secure attribute to the Controller element in the `config.xml` file and sets the value to `true`:

```
<controller host="mycontroller.appdyanmics.com" port="443" ssl="true" secure="true">
```

5. Start IIS. Restart or start instrumented Windows services and standalone applications.

Update Credentials in the Windows Credential Manager

The .NET Agent includes a Credentials Tool for you to modify credentials stored in the Windows Credential Manager. To change credentials under the Local System account, you need to use PsExec to launch the command prompt.

1. If you have not already, download and install Windows Sysinternals.
2. Use `PsExec` to launch a command prompt as the Local System account.

```
psexec -i -s cmd.exe
```

3. Run the Credentials Tool and pass the updated credentials.

```
"%programfiles%\AppDynamics\AppDynamics .NET Agent\AppDynamics.CredentialsTool.exe"
AD_CONTROLLER_ACCOUNT_NAME=<SaaS or multi-tenant account> AD_CONTROLLER_ACCOUNT_ACCESS_KEY=<access key>
AD_PROXY_USERNAME=<proxy user name> AD_PROXY_PASSWORD=<proxy password>
```

Command Line Options

- `AD_SECURED_CREDENTIALS`: Set to `true` to encrypt credentials to the Windows Credential Store and configure the agent to use the encrypted credentials.
- `AD_CONTROLLER_ACCOUNT_NAME`: The account name for the SaaS or multi-tenant Controller.
- `AD_CONTROLLER_ACCOUNT_ACCESS_KEY`: The account access key for the SaaS or multi-tenant Controller.
- `AD_PROXY_USERNAME`: The proxy server user account.
- `AD_PROXY_PASSWORD`: The password for the proxy server user account.

Private Key and Client Certificate for .NET Agents

To enable mutual SSL authentication, the .NET Agent loads the client certificate and private key from your local computer's personal Certificate Store. The instrumented application identities need the ability to access the private key of the client certificate.

Import the Private Key into the Certificate Store

To import the private key into the Certificate Store:

1. From your Microsoft Management Console (MMC), navigate to and expand **Certificates (Local computer) > Personal > Certificates**.
2. Right-click **Certificates**.
3. Expand **All Tasks > Import**.
4. From the Import panel, change the Filter to **All** or **.pfx** files.
5. Select the *.pfx file.
6. Enter your password and then complete the import procedure.

By default, for IIS applications (Full Framework and .NET Core hosted in- and out-of-process), the `IIS_IUSRS` group must have read access to the private key. For standalone, self-hosted .NET Core, and IIS applications running on application pools using custom service accounts, the appropriate accounts and groups have read access to the private key.

To add read access to the private key:

1. From your Microsoft Management Console (MMC), navigate to and expand **Certificates (Local computer) > Personal > Certificates**.
2. Right-click **Certificates**.
3. Expand **All Tasks > Manage Private Keys** to display a popup.
4. Add the application identities or user groups (as needed) and then add read access to the private key.

Configure the Certificate Attribute

To use the certificate from the Certificate Store, you must add the certificate thumbprint as the `certificate` attribute.

To obtain the certificate thumbprint:

a. From your Microsoft Management Console (MMC), navigate to and expand **Certificates (Local computer) > Personal > Certificates**.
b. Double-click the certificate.
c. From the **Details** tab, locate the thumbprint.
d. Add the thumbprint as the `certificate` attribute:

Configure the .NET Agent for Windows Services and Standalone Applications

Related pages:

- Configure the .NET Agent
- .NET Agent Configuration Properties

The .NET Agent automatically instruments IIS applications only. However, you can follow these instructions to manually configure the .NET Agent to instrument Windows services or standalone .NET applications.

If your web application is not configured to run as an in-process handler, the application may run as `dotnet.exe` or `mywebappapplication.exe`. In this scenario, the application's site name and application path are not discovered automatically. You must configure these applications manually, and provide tier and node names that best describe the application.

Before You Begin

To instrument Windows services and standalone .NET applications, edit the .NET Agent configuration file, `config.xml`.

> If your application runs using the default domain, you must manually instrument it. AppDynamics does not automatically instrument the default domain out-of-the-box. To determine whether you should use the default domain, and how to configure it, see Instrument the DefaultDomain for Standalone Applications.

Before starting, verify that the services or applications you want to instrument are .NET applications rather than native applications or another type of application. From a command line, enter:

```
tasklist /m "mscor*"
```

> This command is for 64-bit processes only. For 32-bit processes, use the process explorer to view the dependencies of the process, and determine if there are any .NET .dll files loaded into the file.

The output lists the processes with DLLs starting with mscor*, indicative of .NET processes. Processes not displaying on the list are not .NET processes, and you cannot instrument them with the .NET Agent.

If you have previously instrumented IIS applications on the server that hosts the Windows services and standalone applications, the server should already have a `config.xml` file that you can edit. If not, perform these steps to generate one:

1. Install the .NET Agent for Windows.
2. Run the AppDynamics Agent Configuration utility.

To avoid instrumenting IIS applications, select the manual tier naming approach and omit the step of assigning tiers for the IIS application. This disables instrumentation for the IIS applications and enables you to instrument only the intended Windows services or standalone applications.

The utility performs these configuration tasks:

1. Changes the location of the logs directory, and assigns permissions.
2. Configures and tests connectivity to the Controller.
3. Sets the business application for the agent.

Manually Configure the .NET Agent

Once you have configured the Controller properties for the .NET Agent, instrument your Windows service or standalone application by adding the Standalone Applications element to the `config.xml`.

1. Edit the `config.xml` file as an administrator. See Administer the .NET Agent.

   If you have not instrumented any IIS applications, the file contains the minimal configuration for the Controller connectivity and the Machine Agent. Verify the Controller properties and the Business Application name (shown in this example):

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org
/2001/XMLSchema">
  <controller host="mycontroller.example.com" port="8090" ssl="false">
    <application name="My Business Application" />
  </controller>
...
</appdynamics-agent>
```

If you have already instrumented IIS applications, those configurations display under the IIS element.

2. Add a single standalone applications element, `standalone-applications` under the app-agents element, and under the `standalone-applications` element, add a standalone application element, `standalone-application` for each Windows service or standalone application to instrument. For example:

```
...
<app-agents>
   ...
   <standalone-applications>
      <standalone-application executable="MyStandaloneApp.exe">
        <tier name="Standalone Tier 1" />
      </standalone-application>
      <!-- Instrument a standalone application using a partial path. -->
      <standalone-application executable="MyApplication\MyOtherStandaloneApp.exe">
        <tier name="Standalone Tier 2" />
      </standalone-application>
      <!-- Instrument a Windows service using arguments. -->
      <!-- The following example matches the command "MyWindowsService.exe -d -x -r". -->
      <standalone-application executable="MyWindowsService.exe" command-line="-x">
         <tier name="Windows Service Tier" />
      </standalone-application>
   </standalone-applications>
</app-agents>
...
```

In the standalone application element configuration:

- Use the `tier` element to assign the instrumented application to a tier in the Controller. See .NET Agent Configuration Properties.
- Identify the executable file of the application in the Standalone Application element `executable` attribute using one of these formats:
  - Executable name: For example, `MyStandaloneApp.exe` or `MyWindowsService.exe`. The file extension is optional, so `MyStandaloneApp` is valid. If you use `dotnet.exe` to start the .NET Core application, then specify `"dotnet.exe"` as the application executable (see Sample Configuration File).
  - Full or partial path to the executable: For example, `C:\Program Files\MyApplication\MyStandaloneApp.exe` or `MyApplication\MyStandaloneApp.exe`. Use the full or partial path to assign different AppDynamics tiers to separate instances of the same executable file running from different paths.
  - To differentiate between two instances of the same executable, specify any unique portion of the command line invocation format of the application, such as an argument, in the Standalone Application command-line attribute.

You can discover the path to a Windows service executable in the Services panel of the administrative tools. In Services, click the service and select **Properties**. The path display in the General tab.

3. Restart the `AppDynamics.Agent.Coordinator` service.
4. Restart the Windows service or standalone application.
5. If your Windows service or standalone application does not implement an auto-detected framework, you must configure a POCO entry point for a class or method in your service for the agent to begin instrumentation.

Sample Configuration File

This sample `config.xml` shows instrumentation for a Windows service and standalone application:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001
/XMLSchema">
  <controller host="mycontroller.mycompany.com" port="8090" ssl="false">
    <application name="My Business Application" />
  </controller>
  <machine-agent />
  <app-agents>
    <IIS>
        <applications />
    </IIS>
    <standalone-applications>
        <standalone-application executable="MyWindowsService.exe" command-line="-x">
           <tier name="Windows Service Tier" />
        </standalone-application>
        <standalone-application executable="MyStandaloneApp.exe">
           <tier name="Standalone Tier" />
        </standalone-application>
    </standalone-applications>
  </app-agents>
</appdynamics-agent>
```

If the .Net Core application is published as an executable, then you can configure it similar to .NET Framework applications by specifying the executable name, and optionally, the command line. However, if the application is published as a library, then you start it by by invoking the `dotnet.exe` tool.

This sample configuration shows how to instrument a .NET Core standalone application hosted by the `dotnet.exe`:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001
/XMLSchema">
  <controller host="mycontroller.mycompany.com" port="8090" ssl="false">
    <application name="My Business Application" />
  </controller>
  <machine-agent />
  <app-agents>
    <IIS>
        <applications />
    </IIS>
    <standalone-applications>
        <standalone-application executable="dotnet.exe" command-line="MyApp.dll"> //command-line option
instructs the agent to monitor only "MyApp"
           <tier name="DotNet Core Tier" />
        </standalone-application>
      </standalone-applications>
  </app-agents>
</appdynamics-agent>
```

Troubleshooting

Intermittent Loss of Windows Services Instrumentation

When instrumenting Windows Services, there may be cases where the instrumented service initializes before the `AppDynamics.Agent.Coordinator` service. When this happens, the Profiler shuts down and no instrumentation occurs. This problem is uncommon.

These procedures describe how to overcome this problem for Windows 2008, and Windows >= 2012.

Windows 2008

If you are using Windows 2008, please contact AppDynamics Support for assistance.

Windows >= 2012

To ensure the AppDynamics.Agent.Coordinator service initializes before the instrumented Windows Service, you must modify the registry.
Edit the Reg key `EarlyStartServices @HKLM:\SYSTEM\CurrentControlSet\Control`, and add AppDynamics.Agent.Coordinator_service to the list of early start services.

Name .NET Tiers

Related pages:

- Configure the .NET Agent
- Name .NET Nodes

In AppDynamics, a tier represents a service in your application environment, such as an ASP.NET front end, WCF service, .NET web service, or standalone application. Tiers display on flow maps, so you should name your tiers that is logical and easy to understand for your users.

Use the AppDynamics .NET Agent Configuration Utility to map IIS sites to tiers (see Configure the .NET Agent). Some manual configuration options require you to edit the `config.xml` file (see Administer the .NET Agent).

Name IIS Tiers Automatically

Name IIS tiers automatically using the configuration utility. Select Automatic on the Assign IIS applications to the tiers pane. The .NET Agent instruments all IIS sites except the Default Web Site and names the tiers using this scheme:

`IIS site/app`

> The agent omits `app` when the application is the root application for the IIS site.

Use this option when:

- You are new to AppDynamics and the .NET Agent.
- You want to instrument all IIS applications, and your team understands the form of IIS application names.

> Automatic Tier Naming for the .NET Agent does not automatically assign a virtual application to a tier. To map virtual applications to tiers, see Name IIS Tiers Manually.

Name Azure Tiers Automatically

The .NET Agent automatically names Azure tiers using these schemes:

- Cloud Services: `Azure role name`
- App Services: `Azure site name`

To customize tier naming for Azure, see Name IIS Tiers Manually.

Name IIS Tiers Manually

The .NET Agent provides two options to name IIS tiers manually, using the configuration utility, or editing the config.xml file directly.

Use the Configuration Utility

On the Assign IIS applications to tiers pane, select **Manual**. The configuration utility enables you to create new tiers and assign IIS applications to tiers.

Use this option when:

- You do not want to instrument all IIS applications on the server
- You want custom tier names
- You want to assign multiple applications to a single tier

Edit the config.xml Directly

Use this option to customize Azure tier names, or when it is not possible to use the configuration utility.

For each IIS tier to instrument, add an application element as a child element of the IIS applications element in the `config.xml` file. You can specify a static IIS tier name ,or a regular expression (which is helpful for variable Azure site names). For the full syntax and an example, see .NET Agent Configuration Properties.

For example, to add all Azure sites that begin with `MvcWebRole` to a tier named `My Azure Tier` using a regular expression:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsd="http://www.w3.org/2001/XMLSchema" xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance">
  <controller host="nativedemocon1.cloudapp.net" port="8090" ssl="false">
    <application name="AzureEmailService" />
    <account name="customer1" password="APJC234bcd$123" />
  </controller>
  <machine-agent />
  <app-agents azure="true" azure-role-name="" azure-role-instance-id="">

    <IIS>
        <applications>
              <!-- Configure IIS tier names with a regular expression. -->
            <application path="/" site="MvcWebRole.*" site-regex="true">
                 <tier name="My Azure Tier"/>
            </application>
        </applications>
    </IIS>
    <standalone-applications>
         <standalone-application executable="WaWorkerHost.exe">
            <tier name="" />
        </standalone-application>
    </standalone-applications>
  </app-agents>
</appdynamics-agent>
```

Name Windows Service or Standalone Application Tiers

See Configure the .NET Agent for Windows Services and Standalone Applications on how to name tiers for each instrumented Windows service or standalone application manually in the config.xml.

Name .NET Nodes

Related pages:

- Configure the .NET Agent
- Name .NET Tiers

IIS Node Naming

By default, AppDynamics .NET Agent names nodes use a combination of the Windows machine name, the tier name, and the name of the .NET application, as shown in this format:

```
<machine NetBIOS name>-<tier>-<IIS site>/<app>
```

However, you may omit elements in the name under these conditions:

- The app name is omitted when the application is the root application for the IIS site.
- The tier name is omitted when the tier name is the same as the IIS site name.

These examples show IIS node naming.

Example 1

```
WIN-86M7CEJO6P5-Order Server-OrderSvc
```

- `WIN-86M7CEJO6P5` is the machine NetBIOS name.
- `Order Server` is the tier name.
- `OrderSvc` is the IIS site name. The application is the site root, so the agent omits the application name.

Example 2

```
WIN-86M7CEJO6P5-Order Server-Store/ProcessOrder
```

- `Store` is the IIS site name.
- `ProcessOrder` is the application name within the site.

Different .NET versions of the same application have their own versions of the CLR and run on independent processes. Therefore, the agent identifies the two processes as different nodes.

IIS Web Gardens

The syntax for web gardens is the same as IIS Nodes, except that the agent appends a zero-based process index to differentiate the worker processes:

```
<machine NetBIOS name>-<tier>-<IIS site>/<app>-<process index>
```

When IIS first launches web garden processes, the agent assigns a sequential index to each process. However, when IIS recycles a process, the agent re-uses the available index freed by the terminated process. Therefore, there is no correlation between the index sequence and the chronological start of the process.

Sometimes more nodes display than the maximum number of worker processes. This occurs when a long-running request prevents a process from shutting down before its replacement launches.

Windows Service or Standalone Application Nodes Naming

By default, the agent names Windows service and standalone application nodes as:

```
<machine NetBIOS name>-<tier>-<Windows service name or executable name>
```

The agent omits tier when the tier name is the same as the service name or executable name.

These examples show Windows service and standalone application naming.

Example 1

```
WIN-86M7CEJO6P5-MyWindowsService
```

- `WIN-86M7CEJO6P5` is the machine name.
- `MyWindowsService` is the Windows service name.

Example 2

```
WIN-86M7CEJO6P5-MyStandaloneApp.exe
```

- `WIN-86M7CEJO6P5` is the machine name.
- `MyStandaloneApp.exe` is the executable file name.

Unattended Installation for .NET

Related pages:

- Configure the .NET Agent
- .NET Agent Configuration Properties
- Configure the .NET Agent for Windows Services and Standalone Applications

The .NET Agent provides a command-line unattended installation when you have multiple servers that require the same AppDynamics configuration. Using unattended installation, you only configure once, and then use the command-line scripts to automate installation and instrumentation on multiple servers

To install and configure the agent manually, see Install the .NET Agent for Windows.

Create a Setup Configuration File

You can use the .NET Agent MSI installer package to specify the path to a setup configuration file to perform an unattended installation. The setup configuration file contains all the properties you need to enable instrumentation for your .NET applications.

You must run the .NET Agent MSI installer package on one machine before you can use the AppDynamics Agent Configuration utility to create a setup configuration file. See Install the .NET Agent for Windows.

Setup configuration files created in previous versions of the AppDynamics Agent Configuration utility work with the 4.0 installer.

1. Launch the AppDynamics Agent Configuration utility from the command line. Use the `-s` parameter to specify the setup configuration file destination.

   ```
   %ProgramFiles%\AppDynamics\AppDynamics .NET Agent\AppDynamics.Agent.Winston.exe -s <path to setup configuration file>
   ```

   For example:

   ```
   %ProgramFiles%\AppDynamics\AppDynamics .NET Agent\AppDynamics.Agent.Winston.exe -s "c:\temp\configurationSavedSetupConfiguration.xml"
   ```

2. Complete the steps of the configuration wizard step.

   The configuration utility saves the setup configuration file to the path you specified.

   > The configuration utility only configures instrumentation for IIS applications.

3. (Optional) To perform the unattended installation for Windows services or for standalone applications, you must edit the setup configuration file manually. See Configure the .NET Agent for Windows Services and Standalone Applications.

Sample Setup Configuration File

This example shows a setup configuration file that instruments: two IIS Applications, MainBC and SampleHTTPService; a Windows service, MyWindowsService.exe; and a standalone application, MyStandaloneApp.exe.

The configuration file sets the log directory to `C:\ProgramData\AppDynamics\DotNetAgent\Logs`, and grants write permission to four accounts.

```
<winston>
  <logFileDirectory directory="C:\ProgramData\AppDynamics\DotNetAgent\Logs" />
  <logFileFolderAccessPermissions defaultAccountsEnabled="false">
    <account name="NT AUTHORITY\LOCAL SERVICE" displayName="LOCAL SERVICE" />
    <account name="NT AUTHORITY\SYSTEM" displayName="SYSTEM" />
    <account name="NT AUTHORITY\NETWORK SERVICE" displayName="NETWORK SERVICE" />
    <account name="IIS_IUSRS" displayName="ApplicationPool Identity" />
  </logFileFolderAccessPermissions>
  <appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001
/XMLSchema">
    <controller host="mycontroller.mycompany.com" port="8090" ssl="false">
      <application name="My Business Application" />
      <account name="customer1" password="changeme" />
    </controller>
    <machine-agent />
    <app-agents>
      <IIS>
        <applications>
          <application path="/" site="MainBC">
            <tier name="Main Site" />
          </application>
          <application path="/" site="SampleHTTPService">
            <tier name="HTTP Services" />
          </application>
        </applications>
      </IIS>
      <standalone-applications>
         <standalone-application executable="MyStandaloneApp.exe">
            <tier name="Standalone App" />
         </standalone-application>
         <standalone-application executable="MyWindowsService.exe">
            <tier name="Windows Service" />
         </standalone-application>
      </standalone-applications>
    </app-agents>
  </appdynamics-agent>
</winston>
```

Unattended Installation

Before you perform an unattended installation, verify these requirements:

- Microsoft Distributed Transaction Coordinator (MSDTC): MSDTC must run under the NT Authority\NetworkServices account. See Verify MSDTC on the Troubleshoot .NET Agent Issues page.
- Windows Management Instrumentation (WMI)

To perform an unattended installation:

1. Launch an elevated command prompt with full administrator privileges. See Start a Command Prompt as an Administrator. Logging on to Windows as a member of the Administrators group does not grant sufficient permissions to run the installer.
2. Run the agent MSI installer package from the elevated command prompt. Use the `AD_SetupFile` parameter to pass the absolute file path to the setup configuration file.

   ```
   msiexec /i dotNetAgentSetup64.msi /q /norestart /lv %TEMP%\AgentInstaller.log AD_SetupFile=<absolute
   path to setup config.xml>
   ```

   You can set these optional parameters:

   `INSTALLDIR`: Specify the directory to install the .NET Agent executables and supporting files.

   `DOTNETAGENTFOLDER`: Specify the parent directory for local data including agent configuration files and log files.

   For example:

   ```
   msiexec /i dotNetAgentSetup64.msi /q /norestart /lv %TEMP%\AgentInstaller.log AD_SetupFile=C:
   \temp\SetupConfig.xml INSTALLDIR=D:\AppDynamics DOTNETAGENTFOLDER=D:\AppDynamicsData
   ```

If you specify the DOTNETAGENTFOLDER on the command line and a logFileDirectory in the setup configuration file, the agent creates config and data folders under DOTNETAGENTFOLDER but writes the log files to the logFileDirectory specified in the setup configuration file.

3. Start the AppDynamics.Agent.Coordinator process.

```
net start AppDynamics.Agent.Coordinator
```

4. Restart applications you have instrumented: IIS services, Windows services, and standalone applications.

   For example, to restart IIS:

```
iisreset
```

Setup Configuration File Properties

Winston Element

The Winston element is the root element of the configuration file.

Required element: <winston>

Log File Directory Element

The Log File Directory element is a child element of the Winston element. Use the directory attribute to specify the log directory. If you omit the logFileDirectory element, AppDynamics uses the default directory:

Windows Server 2008 and later: %ProgramData%\AppDynamics\DotNetAgent\Logs

Optional element: <logFileDirectory directory="C:\ProgramData\AppDynamics\DotNetAgent\Logs" />

Log File Folder Access Permissions Element

The Log File Folder Access Permissions is a child element of the Winston element. Unless you set the defaultAccountsEnabled attribute to false, AppDynamics grants write access to the Logs folder for the default accounts:

- LOCAL SERVICE
- SYSTEM
- NETWORK SERVICE
- ApplicationPool Identity

Optional element: <logFileFolderAccessPermissions defaultAccountsEnabled="false">

Account Element

The Account element is a child element of the Log File Folder Access Permissions element. Create an Account element for the Windows account you use to run your application.

Set the name attribute to the name of the account you use to run your application, that is the account for the application pool for IIS or the Windows service account.

The display name attribute is a user-friendly name you choose for the account. The display name shows up in log entries about assigning permissions for the account.

Optional element: <account name="MyAppPoolIdentity" displayName="Custom ApplicationPool Identity" />

For example, if you run a Windows service under a domain account:

<account name="MYDOMAIN\service_acct" displayName="Domain Service Account" />

AppDynamics Agent Element

The AppDynamics Agent element is a child of the Winston element. It follows the same format as the config.xml file to define the agent configuration for all your .NET applications. See .NET Agent Configuration Properties.

Required element: <appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">

Upgrade the .NET Agent for Windows

Related pages:

- Agent and Controller Compatibility
- Install the .NET Agent for Windows
- Configure the .NET Agent
- .NET Agent Directory Structure
- Troubleshoot .NET Agent Issues

The MSI installer package for AppDynamics .NET Agent installs updated agent files and maintains legacy configurations. When you upgrade from .NET Agent > 3.9, you must first uninstall the existing .NET Agent.

If you use the AppDynamics Azure Site Extension, see Install the AppDynamics Azure Site Extension.

Requirements

- Before you begin, review the Release Notes.
- AppDynamics requires an account access key for agent connections to single-tenant Controller accounts. AppDynamics <= 4.1 only required an account access key for multi-tenant Controller accounts.
  If you have a single-tenant Controller, you can locate the account access key in the Controller under **Settings** > **License** > **Account**. You must be a member of a role with the View License account level permission, see Create and Manage Custom Roles.

The .NET Agent only supports in-place upgrade for these versions:

- >= 3.9

Major and minor releases after the currently installed version. For patch releases, you must uninstall the existing agent before upgrading.

For example, to install the patch release 4.1.0.1 over 4.1.0.0, uninstall the existing agent before upgrading.

Upgrade the .NET Agent from >= 3.9

Except for patches to the current version, you do not need to uninstall the old agent first when you upgrade from the .NET Agent >= 3.9.

1. Stop `w3wp` processes for instrumented IIS applications. Stop instrumented Windows services or standalone applications.
2. Download the MSI installer package from AppDynamics Downloads.
3. Launch an elevated command prompt with full administrator privileges. Logging on to Windows as a member of the Administrators group does not grant sufficient permissions to run the installer. See Start a Command Prompt as an Administrator.
4. If you use a single-tenant Controller account, in the Controller click **Settings > License > Account** to view your access key.
5. Run a command-line agent install. For single-tenant Controller accounts, specify your account access key using the `AD_CONTROLLER_ACCOUNT_ACCESS_KEY` parameter. For example:

   ```
   msiexec /i "%USERPROFILE%\Downloads\dotNetAgentSetup.msi" /l log.txt /q
   AD_CONTROLLER_ACCOUNT_ACCESS_KEY=changeme
   ```

   The installation runs silently in the background.

   > If you forget to add the account access key for a single-tenant Controller account, you can run the Agent Configuration Utility or manually add it to the config.xml later, see Account Element.

6. Restart IIS:
   - Launch the AppDynamics Agent Configuration utility and click **Restart IIS** on the Configuration Summary window.
     or
   - Execute `iisreset` from the command line.

   Restart Windows services and standalone applications.

Upgrade the .NET Agent from 3.7.8 through 3.8.6

Uninstall the Old Agent Version

1. Stop IIS, instrumented Windows services, and instrumented standalone applications.

   > If you shut down IIS but continue to see active IIS Worker Processes, check the Application Pools pane in the IIS Manager and stop any started application pools.
   >
   > Failing to stop instrumented applications before uninstalling the .NET Agent may require you to reboot the machine.

2. Stop the `AppDynamics.Agent.Coordinator` service.
3. In the Control Panel, select Add/Remove Programs. Remove the `AppDynamics .NET Agent`.

> In some cases, another process interferes with the .NET Agent uninstallation process by locking the profiler.dll. If uninstallation fails, use a utility such as Process Explorer to see if a process is using profiler.dll. If so, terminate the process. Otherwise, try rebooting the machine. Then retry the uninstallation.

Install the New Agent Version

1. Stop `w3wp` processes for instrumented IIS applications. Stop instrumented Windows services or standalone applications.
2. Download the MSI installer package from the AppDynamics Downloads.
3. Launch an elevated command prompt with full administrator privileges. Logging on to Windows as a member of the Administrators group does not grant sufficient permissions to run the installer. See Start a Command Prompt as an Administrator.
4. If you use a single-tenant Controller account, in the Controller click **Settings > License > Account** to view your access key.
5. Run a command-line agent install. For single-tenant Controller accounts, specify your account access key using the `AD_CONTROLLER_ACCOUNT_ACCESS_KEY` parameter. For example:

```
msiexec /i "%USERPROFILE%\Downloads\dotNetAgentSetup.msi" /l log.txt /q
AD_CONTROLLER_ACCOUNT_ACCESS_KEY=changeme
```

   The installation runs silently in the background.

> If you forget to add the account access key for a single-tenant Controller account, you can run the Agent Configuration Utility or manually add it to the config.xml later, see Account Element.

6. Restart IIS:
   - Launch the AppDynamics Agent Configuration utility and click **Restart IIS** on the Configuration Summary window.
     or
   - Execute `iisreset` from the command line.

   Restart Windows services and standalone applications.

Upgrade the .NET Agent from <= 3.7.7

Identify the right upgrade path based upon the method of tier naming and assignment (manual or automatic) and the type of application you instrument:

- If you use manual tier naming and assignment, the installer package upgrades configurations for IIS applications and Windows services.
- If you used automatic tier naming and assignment, run the configuration utility to update configurations.
- If you used standalone applications with 3.7.7 or earlier, follow the steps for standalone applications on Configure the .NET Agent for Windows Services and Standalone Applications.

After installation, you may need to run the configuration utility to update your configuration and optionally remove legacy configurations.

Uninstall the Old.NET Agent Version

1. Stop IIS and instrumented Windows services.

> If you shut down IIS but continue to see active IIS Worker Processes, check the Application Pools pane in the IIS Manager and stop any started application pools.
>
> Failing to stop instrumented applications before uninstalling the .NET Agent may require you to reboot the machine.

2. Stop the `AppDynamics.Agent.Coordinator` service.
3. In the Control Panel, select Add/Remove Programs. Remove the `AppDynamics .NET Agent`.

> In some cases, another process interferes with the .NET Agent uninstallation process by locking the profiler.dll. If uninstallation fails, use a utility such as Process Explorer to see if a process is using profiler.dll. If so, terminate the process. Otherwise, try rebooting the machine. Then retry the uninstallation.

Install the New .NET AgentVersion

1. Stop `w3wp` processes for instrumented IIS applications. Stop instrumented Windows services or standalone applications.
2. Download the MSI installer package from AppDynamics Downloads.
3. Launch an elevated command prompt with full administrator privileges. Logging on to Windows as a member of the Administrators group does not grant sufficient permissions to run the installer. See Start a Command Prompt as an Administrator.
4. Optional, if you use a single-tenant Controller account, in the Controller click **Settings > License > Account** to view your access key.

5. Run a command-line agent install. For single-tenant Controller accounts, specify your account access key using the `AD_CONTROLLER_ACCOUNT_ACCESS_KEY` parameter. For example:

```
msiexec /i "%USERPROFILE%\Downloads\dotNetAgentSetup.msi" /l log.txt /q
AD_CONTROLLER_ACCOUNT_ACCESS_KEY=changeme
```

   The installation runs silently in the background.

   > If you forget to add the account access key for a single-tenant Controller account, you can run the Agent Configuration Utility or manually add it to the config.xml later, see Account Element.

6. Restart IIS:
   - Launch the AppDynamics Agent Configuration utility and click **Restart IIS** on the Configuration Summary window.
   - Execute `iisreset` from the command line.

   Restart Windows services.

If you used the following environment variables with the earlier version, the MSI installer migrates the configurations to the new configuration file:

- `AppDynamicsAgent_CallGraphOptions`
- `AppDynamicsAgent_DisableAppPools`
- `AppDynamicsAgent_EnableInProcesses`
- `AppDynamicsAgent_IgnoreCLREnv`
- `AppDynamicsAgent_Profiler_Classes`

Configure the .NET Agent

Configure the agent based on your method of tier generation and assignment: automatic or manual.

> The .NET Agent configuration utility only supports the configuration of one Controller per server. To configure multiple business applications, see Configure Multiple Business Application Support for .NET

Configure the Agent Using Automatic Tier Generation and Assignment

If you used automatic configuration with the earlier version of the .NET Agent, run the configuration utility to configure the agent:

1. Use the .NET Agent Configuration utility to reconfigure instrumentation for IIS applications. Choose **Automatic** for the method of tier generation and assignment. See Configure the .NET Agent.
2. Configure instrumentation for Windows services manually. See Configure the .NET Agent for Windows Services and Standalone Applications.

Configure the Agent Using Manual Tier Generation and Assignment

For agents using manual tier generation and assignment, the installer package migrates the configurations for IIS applications and for Windows services to the `config.xml`. At this stage, the configuration for IIS applications and Windows services is complete.

Clean Up Legacy Configurations

You can clean up legacy configurations by launching the AppDynamics Agent Configuration utility. When the utility detects agent settings from a previous version, it offers you the option to clean up.

The cleanup procedure modifies the `web.config` files causing an IIS restart.

1. Launch the AppDynamics Agent Configuration utility.
2. Select **Yes** to clean up old AppDynamics configurations.
3. Proceed through the wizard.
   - Verify or update the log directory, and grant write permissions to it.
   - Verify the controller connection information.
   - Verify or update manual tier assignment.

The utility removes these configurations:

- AppDynamics configurations from `web.config` files for IIS applications and `application.config` files for Windows services.
  Environment variables:
  - `AppDynamicsAgent_IgnoreCLREnv`
  - `AppDynamicsAgent_CallGraphOptions`
  - `AppDynamicsAgent_EnableInProcesses`
  - `AppDynamicsAgent_DisableAppPools`
  - `AppDynamicsAgent_Profiler_Classes`

Resume Monitoring

Start IIS and instrumented Windows services.

Troubleshoot .NET Agent Issues

Related pages:

- Install the .NET Agent for Windows
- Configure the .NET Agent
- Instrument SharePoint
- .NET Instrumentation Topics on the Community Knowledge Base

This page describes issues you may encounter when installing the .NET Agent.

Verify Agent Controller Communication

Use the AppDynamics UI to verify that the agent can connect to the Controller.

1. In a browser open:

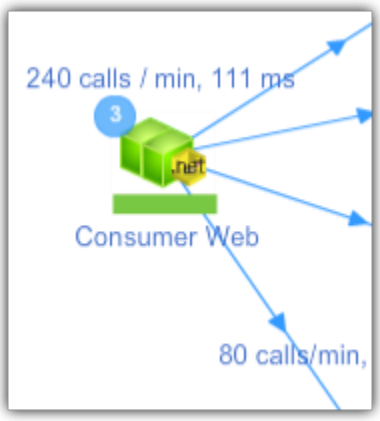
   ```
   http://<controller-host>:<controller-port>/controller
   ```

   If you cannot connect to the Controller in Internet Explorer, see Check Internet Explorer proxy settings.
2. Log in to the AppDynamics UI.
3. Select the application to open the Application Dashboard.
4. In the left navigation panel, select **Servers > Tiers & Nodes** and open the Health tab.

The Health tab lists the tiers, their nodes, and App Agent Status. When an agent successfully reports to the Controller, an *up* arrow symbol displays.

See Agent-to-Controller Connections.

- When deploying multiple agents for the same tier, determine if the correct number of nodes reports into the same tier.
- After sending a request to your web application, data should display on the AppDynamics UI. The agents should display in the Application Flow Map of the Application Dashboard.



If no data displays after a few minutes:

- Verify that the Agent is writing its log files.
  Windows Server 2008 and later: `%ProgramData%\AppDynamics\DotNetAgent\Logs\AgentLog.txt`
- If the log file exists, open it and review for errors.
- If the log file does not exist, run the Windows Event Viewer and review the application messages.
- If there are no AppDynamics event messages, look for messages from the .NET Runtime.

Check Internet Explorer Proxy Settings

> Use this procedure to resolve issues connecting to the AppDynamics Controller when step 1 of 'Verify Agent Controller Connection' fails. To configure the .NET Agent to work through a proxy, see 'Controller Element' on .NET Agent Configuration Properties.

Misconfigured proxy settings in Internet Explorer may cause the App Agent for .NET to fail to connect to the Controller.
If the test Controller connection fails on the Controller Configuration pane in the AppDynamics Agent Configuration utility:

1. Verify the Controller host and port settings are correct.
2. In Internet Explorer, open:

```
http://<controller-host>:<controller-port>/controller
```

3. If the connection also fails in Internet Explorer, check the proxy settings. See Change IE Proxy Settings.
4. Correct or remove any incorrect proxy settings.

Checklist for Resolving .NET Agent Installation Issues

	Item	Notes
✓	Run the installer as Administrator.	Verify Administrative privileges
✓	Verify that MSDTC is enabled and that it is running under the correct account.	Verify MSDTC is enabled and running under the correct account
✓	Verify permissions for Agent directory.	Verify that the .NET Agent directory has the correct permissions based on the site's application pool identity.
✓	Verify that the Agent is compatible with the Controller.	Agent and Controller Compatibility
✓	Verify the correct settings in the `config.xml`: Windows Server 2008 and later: `%ProgramData%\AppDynamics\DotNetAgent\Config\config.xml`	Update the config.xml file to include the .NET Agent Configuration Properties.

Resolve .NET Agent Installation Issues

If the Agent installation is failing, check these configurations in your environment:

Verify Administrative Privileges

Ensure that you have the administrative privileges when you launch the installer. If the current user doesn't have sufficient privileges, the installer prompts you for an administrator password.

Verify MSDTC is Enabled and Running for the Correct Account

If you encounter an error that MSDTC is not enabled or it is running for the wrong account, launch an elevated command prompt with full administrative privileges and execute the this command:

```
msdtc -install
```

Even if MSTDC is already installed, this command resets the service to run using the "NT Authority\NetworkServices" account.

Generate a Log for Agent Installation Failures

If the installer fails, use this command line utility to launch the installer:

```
msiexec /i $Path_to_the_MSI_File /l*v verbose.log
```

A verbose log for the .NET Agent is created at the same location where you saved the installer file.

Correct Failed Installation Caused by other APM Products

The .NET Agent installation may fail if there are other Application Performance Management (APM) products installed in the same managed environment. Remove the associated *Environment* subkey for certain services for the installed APM products.

To remove the associated environment subkey for W3SVC and WAS services in the registry:

1. Run Regedit or regedt32.

2. In regedit.exe, locate these registry keys:
   `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\W3SVC`
   `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\WAS`
3. Expand the keys.
4. Modify the `Environment` subkey to delete these values:

```
COMPLUS_ProfAPI_ProfilerCompatibilitySetting=EnableV2Profiler
    COR_ENABLE_PROFILING=1
    COR_PROFILER= {a GUID}
```

5. Restart the services. See How to restart the W3SVC and WAS services?

Resolve Configuration Errors

- Set your IIS applications to a Full trust level. .NET Agent reporting will not work if an IIS application is set to anything other than a Full trust level.
- Ensure that you have correctly configured the `config.xml` file for the App Agent for .NET. See .NET Agent Configuration Properties.
- If you manually edited the `config.xml` file, check the `AgentLog.txt` file and `WarnLog.txt` file for errors. Invalid XML displays in the log as:

```
2014-03-13 10:49:18.7199 1232 dllhost 1 1 Error ConfigurationManager Error reading the configuration file
```

- Resolve Log Issues

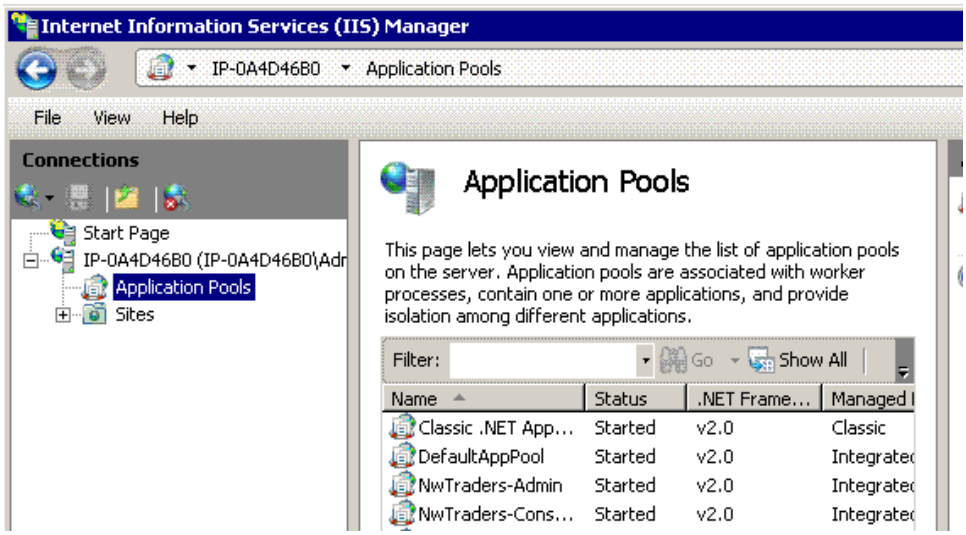
The .NET Agent writes logs to these directories:

`%ProgramData%\AppDynamics\DotNetAgent\Logs`

The agent will not generate logs if the agent directory does not have sufficient permissions.

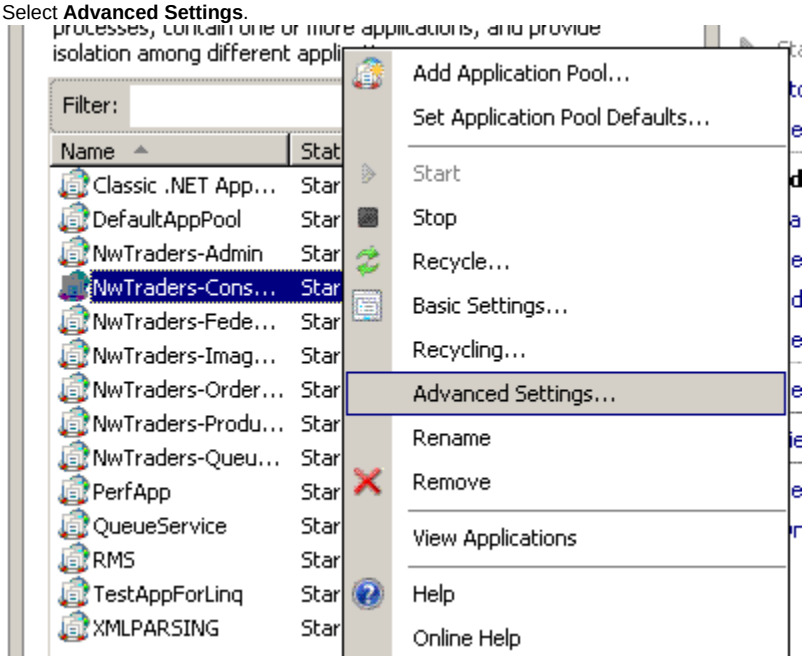
Verify that the .NET Agent Directory has the Correct Permissions

1. Select **IIS > Application pools**.
   IIS displays the list of application pools for your machine.

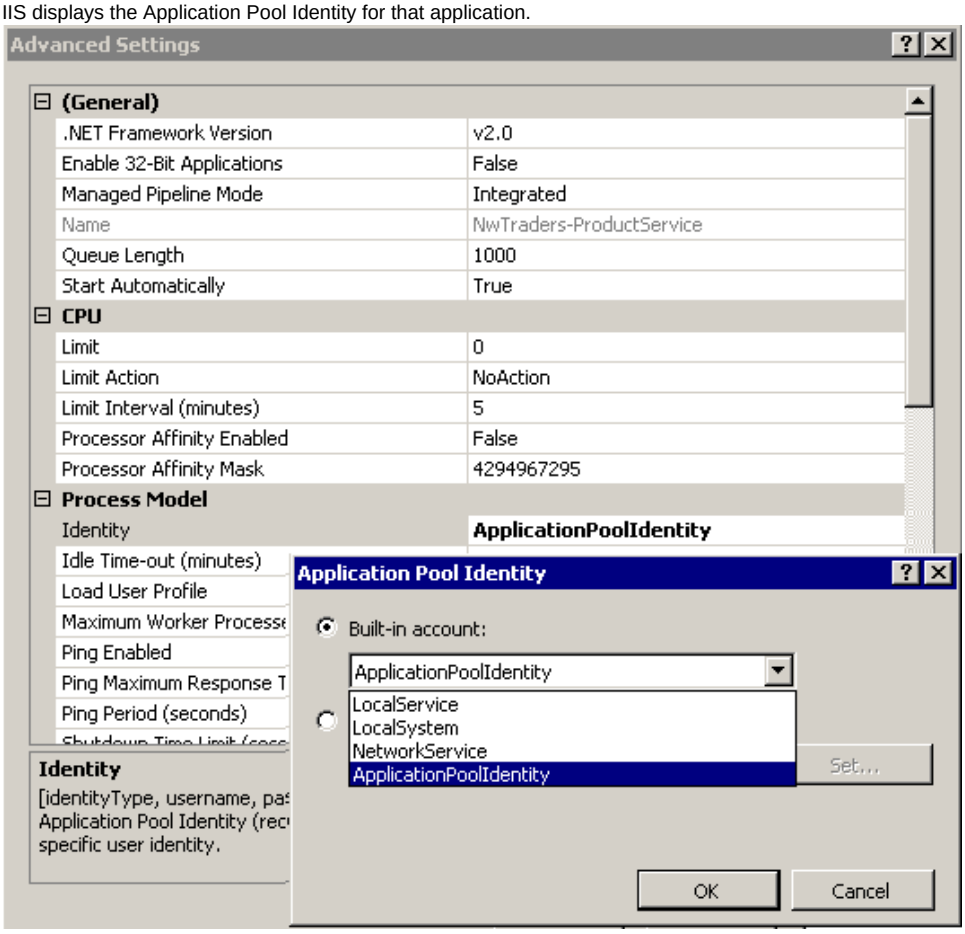


2. Right-click a particular application pool.

3. Select **Advanced Settings**.

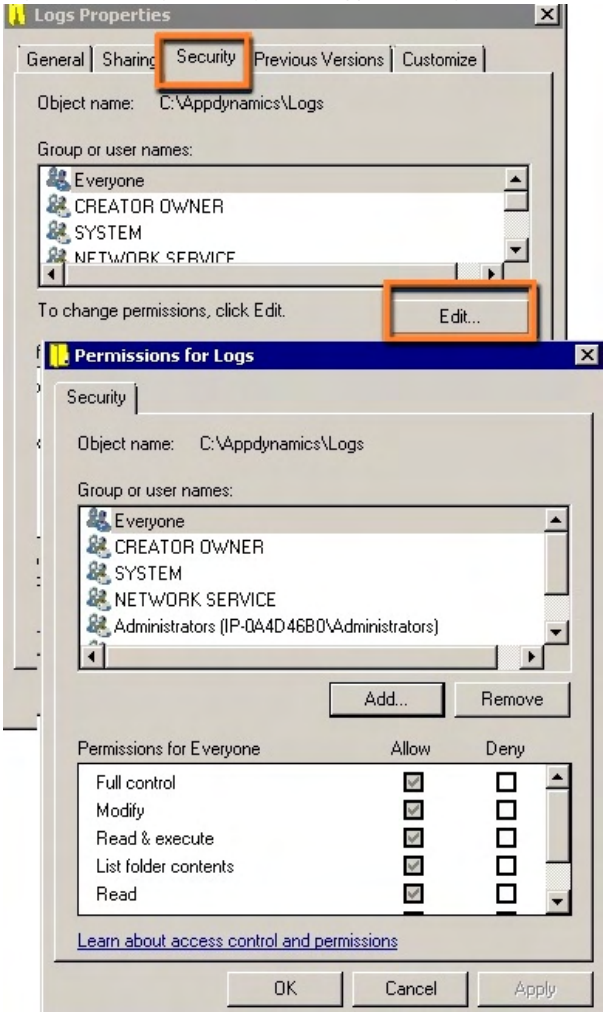


IIS displays the Application Pool Identity for that application.

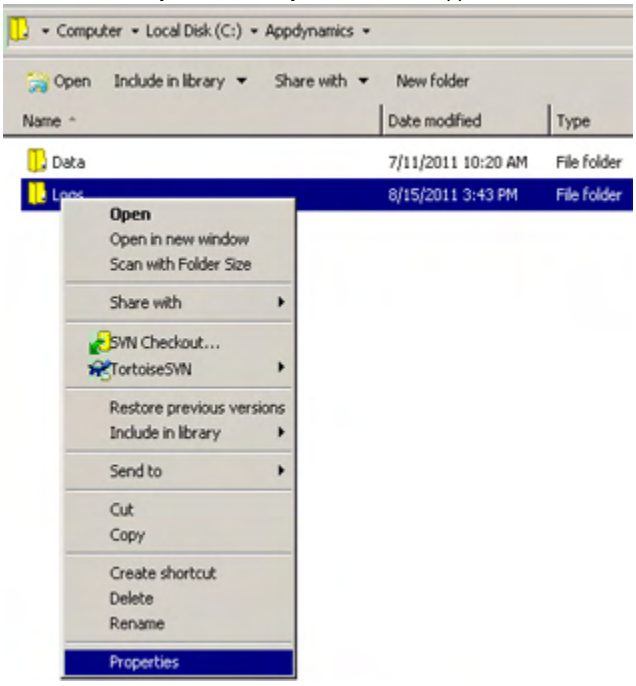


4. Ensure that your Agent Directory also has the same permissions as your site application pools.
    - Navigate to AppDynamics .NET App Server Agent directory location.

- Right-click the `logs` directory for the App Server Agent and select **Properties**.

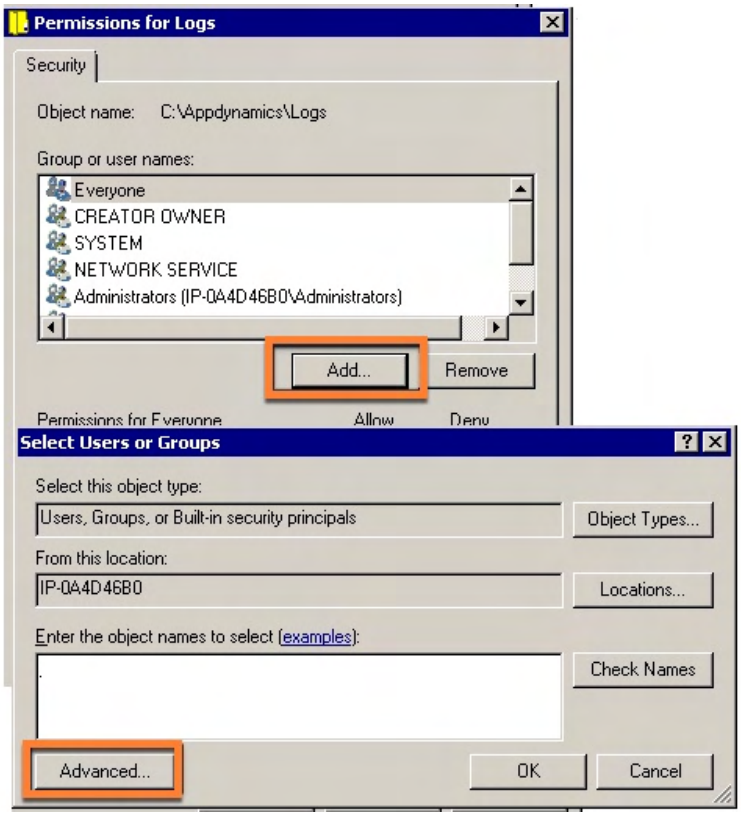


- Select the Security tab, and verify that the same Application Pool Identity is specified for the .NET Agent directory.



If the Agent logs directory does not have the required permissions:

1. In the Security tab, select **Edit**.
2. Select **Add** to add new permissions to the Agent directory.
3. Select **Advanced**.



4. Click **Find Now** to find all the users, groups, or built-in security principals on your machine.
5. Select the required group from the list and click **OK**. Review the information that follows for Allowed groups.
6. Provide the read and write permissions for the selected user/group/security principal to the Agent directory and click **OK**.
7. Click **Apply**.

Allowed Groups for Different IIS Versions

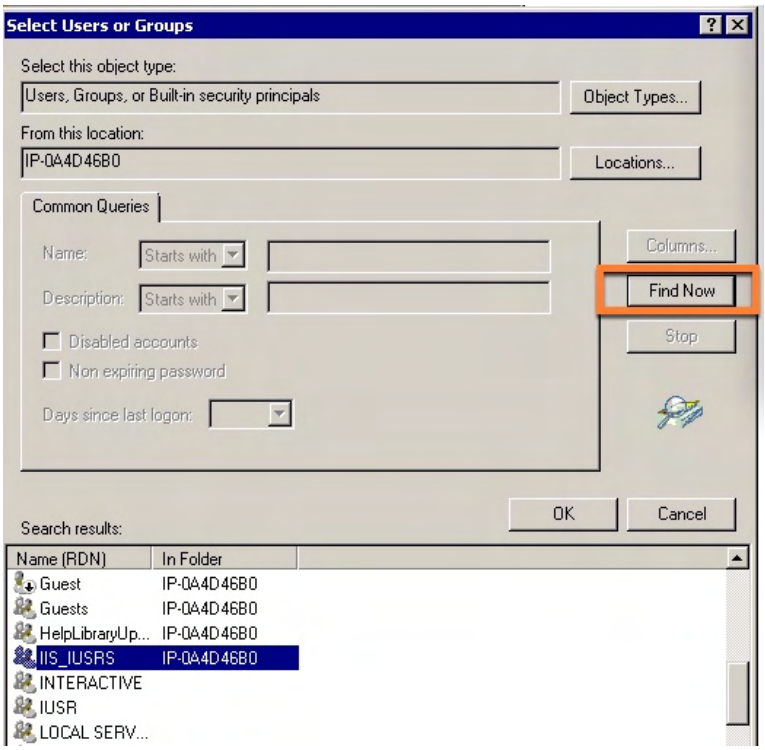
For IIS 6.x, these settings are applicable for Application Pool Identities:

Application Pool Identity	Permission Level
`LocalService`	`LOCAL SERVICE`
`LocalSystem`	`SYSTEM`
`NetworkService`	`NETWORK SERVICE`
`Custom Account`	Provide the exact name of the account.

For IIS >= IIS 7.0, these settings are applicable for Application Pool Identities:

Application Pool Identity	Permission Level
`LocalService`	`LOCAL SERVICE`
`LocalSystem`	`SYSTEM`
`NetworkService`	`NETWORK SERVICE`
`ApplicationPoolIdentity`	Provide the group level permissions for `IIS_IUSRS` Group See the screenshot that follows
`Custom Account`	Provide the exact name of the account.

For example, if your application has the identity `ApplicationPoolIdentity`, you must provide the permissions for `IIS_IUSRS` group to your agent directory.



Another Version of AppDynamics Detected

AppDynamics recommends that you contact support to resolve this issue.

.NET Agent >= 20.3 supports .NET Core. If you used the Microservice Agent to monitor .NET Core applications you can monitor .NET Core with the full .NET Agent. You may receive an error message in the MSI Installer stating that another version of AppDynamics is detected.

The Microservice Agent uses a JSON file to store configuration information while the .NET Agent uses an XML file. The data does not migrate between these files.

To fix this issue, you need to map the data in the JSON file to the XML file, `config.xml` and remove environment variables. If you have completed the instructions above and still see the error, you may need to reboot your machine. You may want to plan reboots according to your planned outage schedule.

Known Issues

You may ignore the following error from the `AppDynamics.Agent.Coordinator` service in the agent.log or warn.log:

```
2015-12-01 10:12:03.0435 3872 AppDynamics.Coordinator 1 7 Warn MaxQueueItemAgePolicy MaxQueueItemAge is beyond
the integer limit: 13093467123
```

Instrument SharePoint

Business operations must ensure their internal and external teams have full access to the content and collaborative services that SharePoint offers. To do that, administrators need an APM solution with total visibility across the SharePoint environment. AppDynamics works with SharePoint to provide details for complex tasks such as end-user monitoring, log analytics, and server support.

By using AppDynamics to monitor SharePoint, you can:

- Monitor most SharePoint components (web applications, search components, workflow and Office Web Apps), using a mixture of .NET APM agents, EUM agents, analytics agents, and machine agents.
- Understand what is occurring on the end-user page, and document navigation and browsing using End User Monitoring.
- View APM partitions of user activity by content web applications.
- Gain insights into Office Web Apps document rendering behavior.
- View more details on search and query usage.

> AppDynamics is not a replacement for the Systems Center Operations Management (SCOM) pack or a well-planned IBM Tivoli implementation, particularly when just interpreting PerfMon counters. SharePoint Server 2013 integrates with SCOM, which is very useful but still optional. AppDynamics is not meant to be a replacement for native monitoring tools but rather work together with tools from Microsoft and its robust partner ecosystem.

Before implementing this solution, download and read this eBook, and work with an AppDynamics expert in your organization, or AppDynamics Professional Services.

Uninstall the .NET Agent

This page describes how to uninstall the .NET Agent. This procedure frees the license associated with the agent and makes it available for another app agent to use.

> Do not follow these instructions if you are doing an upgrade. To upgrade to a new version, see Upgrade the .NET Agent for Windows.

To uninstall the .NET Agent completely:

1. Stop IIS, instrumented Windows services, and instrumented standalone applications.

   > Failing to stop instrumented applications before uninstalling the agent requires you to reboot the machine to complete the uninstall.

2. Stop the `AppDynamics.Agent.Coordinator` service.
3. From the Control Panel, select **Add/Remove Programs**, and remove the **AppDynamics .NET Agent**.
4. The uninstall procedure does not remove configuration files. You must delete the configuration directory: `%ProgramData%\AppDynamics`
5. Restart IIS, Windows services, and standalone applications.

> In some cases, another process interferes with the .NET Agent uninstallation process by locking the `profiler.dll`. If uninstallation fails, use a utility such as Process Explorer to see determine if a process is using `profiler.dll`. If so, then terminate the process; otherwise, reboot the machine. Then, retry the uninstallation.

Administer the .NET Agent

Related pages:

- .NET Agent Configuration Properties
- Manage Configuration for .NET

The .NET Agent uses a single configuration file to control agent behavior and .NET Machine Agent behavior. The configuration file specifies Controller connectivity, .NET Machine Agent operations, and app agent functionality for IIS applications, Windows services, and standalone applications. The single configuration file enables you to:

- Maintain agent configurations separately from `web.config` files
- Instrument Windows services and standalone applications without environment variables
- Control agent behavior for specific applications with hierarchical configuration

You use the AppDynamics Controller to upload and manage .NET Agent configuration files. From the Controller, you can deploy a configuration to a machine or multiple machines where the agent is installed. See Manage Configuration for .NET.

Configure Agent Properties

You configure the agent properties in the `config.xml` file in the agent `Config` directory. To edit the `config.xml`, you must launch the editor as an administrator. When you run the .NET Agent Configuration Utility, it writes the `config.xml` file to one of these locations:

- Windows Server 2008 and later
  `%ProgramData%\AppDynamics\DotNetAgent\Config\config.xml`
- Windows Azure
  For Windows Azure deployments, the .NET Agent NuGet package contains the `config.xml` file.
  Sample config.xml files install to this location:
  `%ProgramFiles%\AppDynamics\AppDynamics .NET Agent\SampleConfigurations`

> After you edit the `config.xml` file, you must restart the `AppDynamics.Agent.Coordinator` service. Then restart your IIS services, Windows services, or standalone applications for your instrumentation changes to take effect.

Customize .NET Agent Behavior in `config.xml`

Some .NET Agent configurations require that you edit the `config.xml`:

1. Shut down the `AppDynamics.Agent.Coordinator` service.
2. Edit the `config.xml` file as an administrator.
3. Modify the XML file according to the configuration instructions.
4. Save the `config.xml` file.
5. Start the `AppDynamics.Agent.Coordinator` service.
6. In some cases, you may need to restart IIS, instrumented Windows services, or instrumented Standalone applications. See individual .NET Agent administration topics.

Example Minimal `config.xml`

The most basic configuration shows the required sections for agent configuration. This example instruments all IIS applications using the automatic element, `<automatic />`. For this example, AppDynamics does not instrument Windows services or standalone applications.

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001
/XMLSchema">
  <controller host="mycontroller.mycompany.com" port="8090" ssl=false">
    <application name="MyDotNetApplication" />
        <account name="customer1" password="changeme" />
  </controller>
  <machine-agent />
  <app-agents>

    <IIS>
      <automatic />
    </IIS>

  </app-agents>
</appdynamics-agent>
```

Agent Log Files

The configuration file that controls log files for the .NET Agent is located here:

```
%ProgramFiles%\AppDynamics\AppDynamics .NET Agent\AppDynamicsAgentLog.config
```

The configuration file uses NLog configuration format.

.NET Agent Directory Structure

Related pages:

- Install the .NET Agent for Windows
- Administer the .NET Agent

This page describes the .NET agent directory structure for Windows Server 2008 and later.

Executables

The .NET Agent executables and supporting files install to the `AppDynamics .NET Agent` directory:

```
%ProgramFiles%\AppDynamics\AppDynamics .NET Agent
```

Log files

The `Logs` directory defaults to this location:

```
%ProgramData%\AppDynamics\DotNetAgent\Logs
```

Agent Configuration Files

The .NET Agent writes the `config.xml` configuration file to the `Config` directory:

```
%ProgramData%\AppDynamics\DotNetAgent\Config
```

If you use Config Management, the .NET Agent stores backup configuration files in the `Config\Backup` directory.

Coordinator Service Configuration Files

The AppDynamics Agent Coordinator service writes configuration files from the Controller to the `Data` directory:

```
%ProgramData%\AppDynamics\DotNetAgent\Data
```

About Windows Server System Directory Variables

`%ProgramData%` is located at `<system drive>\Program Data`.

.NET Agent Configuration Properties

Related pages:

- Administer the .NET Agent
- Configure the .NET Agent
- Name .NET Tiers
- Configure the .NET Agent for Windows Services and Standalone Applications
- .NET Agent for Linux Environment Variables

This page is describes the .NET Agent configuration properties that you set in the agent `config.xml` file. You can set some of these properties using Windows System Environment Variables. See .NET Agent Environment Variables. To edit the file and apply your changes, see Administer the .NET Agent.

> **Environment Variables Reference**
>
> You can use environment variables in the agent config.xml file for node, tier, and application names. To include an environment variable, reference it by specifying `%<variable>%`, which you can combine with other characters; for example, `Web-%COMPUTERNAME%` translates to `Web-HOST23`.

AppDynamics Agent Element

The `appdynamics-agent` element is the root container element for configurations in the config.xml.

Required Element:

```
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001
/XMLSchema">
```

Controller Element

The `controller` element is a child of the `appdynamics-agent` element. It specifies the connection information for the AppDynamics Controller.

The .NET Agent configuration utility only supports the configuration of one Controller per server.

Required Element:

```
<controller host="mycontroller.mycompany.com" port="8090" ssl="false" enable_tls12="false" high_availability="
false" secure="false" enable_config_deployment="true"
```

Controller host attribute

The `controller host` attribute indicates the hostname or the IP address of the AppDynamics Controller. For an on-premises Controller, use the value for Application Server Host Name you provided when you installed the Controller. If you use the AppDynamics SaaS Controller, see the Welcome email from AppDynamics.

Type: String
Default: None
Required: Yes

Environment Variable: APPDYNAMICS.CONTROLLER.HOSTNAME

Controller port attribute

The `controller port` attribute specifies the HTTP or HTTPS port of the AppDynamics Controller. If the `controller` ssl attribute is set to `true`, specify the HTTPS port of the Controller; otherwise, specify the HTTP port.

Type: Positive Integer
Default: 8090

- For On-premises installations, the defaults are port 8090 for HTTP and port 8181 for HTTPS.
- For the SaaS Controller, use port 80 for HTTP or port 443 for HTTPS.

Required: Yes

Environment Variable: APPDYNAMICS.CONTROLLER.PORT

Controller ssl attribute

To enable encryption over SSL between the agent and the Controller, set the controller `ssl` attribute to true.

Type: Boolean
Default: false
Required: No

Environment Variable: APPDYNAMICS.CONTROLLER.SSL.ENABLED

Controller enable TLS 1.2 attribute

When you enable SSL, the agent secures communication to the Controller using the protocols set for `ServicePointManager.SecurityProtocol` in your application. Set the controller `enable TLS 1.2` attribute to `true` to add TLS 1.2 as the first option in the list of protocols. This affects all secure communications from your application, not just requests to the AppDynamics Controller.

Type: Boolean
Default: false
Required: No

Controller high availability attribute

If you have your Controller setup for high availability, set the controller `high availability` attribute to `true`.

Type: Boolean
Default: false
Required: No

Controller secure attribute

If you set up the .NET Agent to encrypt credentials, the MSI installer package automatically sets the `controller secure` attribute to `true`. When `controller secure` is `true`, the .NET Agent ignores any credentials in the Account element or the Proxy element and uses the credentials from the Windows Credential Store. See Encrypt Credentials in .NET Agent Configuration

Type**:** Boolean
Default**:** false
Required: No

Controller enable config deployment attribute

By default, the .NET Agent checks for configuration updates to the `config.xml` from the Controller. If you want to disable the agent from `config.xml` configuration files from the Controller set the `controller enable config deployment` attribute to `false`. See Manage Configuration for .NET

Type: Boolean
Default: true
Required: No

Controller Application Element

The `controller application` element is a child of the `controller` element. It indicates the name of the logical business application you see in the Controller interface.

The .NET Agent configuration utility only supports one business application per server. Use one of the following methods to support multiple applications:

- Use tiers to organize different applications you instrument on a single server.
- Or manually configure support for multiple business applications, see Configure Multiple Business Application Support for .NET
  Multiple application support requires different configuration elements, including the `<applications>` container element.

Required Element: `<application name="MyDotNetApplication"/>`

Application name attribute

Set the `application name` attribute to the business application you use in the Controller. If the application name does not exist, the Controller will create it when the agent registers. All instrumented applications in the `config.xml` register with the same business application in the Controller. See Overview of Application Monitoring

Type: String, may also reference an environment variable. See Reference of Environment Variables
Default: None
Required: Yes

Environment Variable: APPDYNAMICS.AGENT.APPLICATIONNAME

You specify a Tier for individual applications in the App Agents Element

Account Element

The `account` element is a child of the `controller` element. If the AppDynamics Controller runs in multi-tenant mode or if you use the AppDynamics SaaS Controller, specify the account name. For single-tenant accounts the default account name is `customer1`. If you are using the AppDynamics SaaS Controller, the account name is provided in the Welcome email from AppDynamics.

The agent requires to use your account access key as a password to authenticate with the Controller. For single-tenant accounts, you can view the access key in the Controller under Settings > License. If you are using the AppDynamics SaaS Controller, the account access key is provided in the Welcome email from AppDynamics.

Required Element: `<account name="mycompany" password="myaccesskey"/>`

Account name attribute

The `account name` attribute indicates the account name for the SaaS or multi-tenant Controller.

Type: String
Default: For single-tenant Controllers, the agent assumes the default of `customer1` if you do not specify an account name.
Required: Only for SaaS or multi-tenant Controllers.

Environment Variable: APPDYNAMICS.AGENT.ACCOUNTNAME

Account password attribute

The `account password` attribute indicates the account access key for the Controller.

Type: String
Default: None
Required: Yes

Environment Variable: APPDYNAMICS.AGENT.ACCOUNTACCESSKEY

Proxy Element

The `proxy` element is a child of the `controller` element. Use it to configure the connection to the Controller through a proxy server with no authentication.

Optional Element: `<proxy host="proxy-name" port="3128" enabled="true"/>`

Proxy host attribute

The `proxy host` attribute indicates the proxy server hostname or IP address.

Type: String
Default: None
Required: host is required for the proxy element

Proxy port attribute

The `proxy port` attribute indicates the proxy server port.

Type: Positive Integer
Default: None
Required: port is required for the proxy element

Proxy enabled attribute

To enable Controller access through a proxy server, set the `proxy enabled` attribute to `true`.

Type: Boolean
Default: true
Required**:** No

Proxy - Authentication Element

The `authentication` element is a child of the `proxy` element. Use the `authentication` element to enable proxy authentication and to supply the credentials for your proxy server. For environments where security policies require you to secure credentials stored on disk, you can encrypt the credentials and store them in the Windows Credential Manager.

Optional Element: `<authentication enabled="true" user_name="my_proxy_user" password="password" domain="my_windows_domain"/>`

Proxy authentication enabled attribute

Set the `proxy authentication enabled` attribute to `true` to configure the agent to send credentials to a proxy server.

Type: Boolean
Default: false
Required: No

Proxy authentication username attribute

The `proxy authentication username` attribute indicates the name of the proxy user.

Type: String
Default: None
Required: The username attribute is required for the Authentication element

Proxy authentication password attribute

The `proxy authentication password` attribute indicates the password for the proxy user.

Type: String
Default: None
Required: No

Proxy authentication domain attribute

The `proxy authentication domain` attribute specifies the domain or realm where the username is located. This could be the host computer name, an Active Directory domain or DNS domain.

Type: String
Default: None
Required: No

Sample Controller Configuration with Proxy Authentication enabled

In this example, the agent accesses the controller through the proxy, `myproxy.example.com` using proxy authentication. The .NET Agent uses the credentials `MyProxyUser@mydomain.com` with password `password` to access the proxy server.

```
<controller host="mycontroller.example.com">
  <application name="MyDotNetApplicaition" />
  <proxy host="myproxy.example.com" port="3128" enabled="true">
     <authentication enabled="true" user_name="MyProxyUser" password="password" domain="mydomain.com"/>
  </proxy>
</controller>
```

Machine Agent Element

The `machine-agent` element is a child of the AppDynamics Agent element. An empty `machine-agent` element enables the default instrumentation for the .NET machine agent. See Monitor CLRs and Monitor IIS

Enable optional additional Microsoft Performance Counters or .NET Agent instrumentors as children of the Machine Agent element.

Required Element: `<machine-agent/>`

Machine Snapshot Element

The `machine-snapshot` element is a child of the `machine-agent` element. Use it to tune the settings for machine snapshots in your environment. If you do not specify an attribute, the agent uses the default values for that attribute. See Machine Snapshots for .NET and Configure Machine Snapshots for .NET

Optional Element: `<machine-snapshot enabled="true" window-size="600" samples-per-window="60" violations-per-window="6" max-percent-cpu="80" max-percent-memory="80" max-queue-item-age="100" periodic-collection="600" />`

Machine Snapshot enabled attribute

Set the `machine-snapshot enabled` attribute to `false` to disable machine snapshots.

Type: Boolean
Default: true
Required: No

Machine Snapshot window size attribute

Specify the window size time range in seconds for the .NET Machine Agent to take samples. During a window, the agent takes samples and checks them for breached thresholds: `max percent CPU`, `max percent memory`, and `max queue item age`.

Type: Integer
Default: 600
Required: No

Machine Snapshot samples per window attribute

Specify the number of samples the .NET Machine Agent takes during the specified window. For example, if the `window size` is 600 and the `samples per window` is 60, the agent takes a sample once every 10 seconds.

Type: Integer
Default: 60
Required: No

Machine Snapshot violations per window attribute

When the .NET Machine Agent detects the number of violations per window for one threshold, it takes a snapshot. The agent only takes one snapshot per window for thresholds exceeded. For example, if `violations per window` is set to 6, and six samples show memory usage at 80% or greater, the agent takes a snapshot. The counters for each threshold are separate.

Type: Integer
Default: 6
Required: No

Machine Snapshot max percent memory attribute

When the .NET Machine agent detects memory usage on the machine equals or exceeds the `max percent memory` value, it flags the sample as a violation. The minimum value is 20. The maximum value is 100.

Type: Integer
Default: 80
Required: No

Machine Snapshot max percent CPU attribute

When the .NET Machine agent detects CPU usage on the machine equals or exceeds the `max percent cpu` value, it flags the sample as a violation. The minimum value is 20. The maximum value is 100.

Type: Integer
Default: 80
Required: No

Machine Snapshot max queue item age attribute

When the .NET Machine agent detects the oldest item in the IIS queue equals or exceeds the `max queue item age` value in milliseconds, it flags the sample as a violation.

Type: Integer
Default: 100
Required: No

Machine Snapshot periodic collection attribute

The .NET Machine agent takes one snapshot per periodic collection time range. Specify the value in seconds. The minimum is 60 seconds.

Type: Integer
Default: 600
Required: No

CLR Crash Reporting Element

The `clrcrash-reporting` element is a child element of the `machine-agent` element. Use the `clrcrash-reporting` element to control whether or not the .NET Machine Agent reports CLR crash events to the Controller. See Monitor CLR Crashes

Optional Element: `<clrcrash-reporting enabled="true"/>`

CLR Crash Reporting enabled attribute

Set the `clrcrash-reporting enabled` attribute to `false` to stop reporting CLR Crash events to the controller.

Type: Boolean
Default: true
Required: No

Process Monitor Element

The `process-monitor` element is a child element of the `machine-agent` element. By default, the agent enables process monitoring for all IIS processes.

Optional Element: <process-monitor report-all-iis-processes="true"/>

Process Monitor report all IIS processes attribute

Set the `report-all-iis-processes` attribute to `false` to enable process monitoring only for instrumented IIS processes.

Type: Boolean
Default: true
Required: No

Metrics Element

The `metrics` element is a child element of the `machine-agent` element. By default, the machine agent registers a maximum of 200 metrics. Use the `metrics` element to increase the number of metrics the .NET Machine Agent can register. See Metrics Limits

Use caution when increasing the metric registration limits. Increasing the limit can increase the resource overhead for agents and Controller.

Optional Element: <metrics max-metrics="200"/>

Metrics max-metrics attribute

Specify the maximum number of metrics the .NET Machine Agent can register.

Type: Integer
Default: 200
Required: No

Perf-metrics Element

The `perf-metrics` element is a child element of the `metrics` element. By default, the machine agent collects and reports a full set of performance metrics. You can modify the priority level for the performance metrics to limit the metrics the agent collects and thereby decrease agent overhead. For a full list of metrics and their priorities, see Manage Windows Performance Metrics Optional Element: `<perf-metrics priority-level="3">`

Perf-metrics priority-level attribute

Specify the set of performance metrics for the machine agent to collect as follows:

- 0 - disable metric collection
- 1 - collect only high priority metrics
- 2 - collect high and medium priority metrics
- 3 - collect all metrics: high, medium, and low priority

Type: Integer in the range 0 - 3
Default: 3
Required: If you use the `perf-metrics` element.

Perf-metric Element

The `perf-metric` element is a child element of the `perf-metrics` element. If you set the `perf-metric` priority to `0` to disable general collection of performance metrics, you can use the `perf-metric` element to enable individual performance metrics. You cannot enable individual metrics with `perf-metric` priority greater than 0.

Optional Element: `<perf-metric name="<metric_path>"/>`

Perf-metric name attribute

Specify the full path of the performance metric. See the example below for the `% Busy` metric and the `Errors Unhandled During Execution` metric.

Type: String: metric path
Default: N/A
Required: If you use the `perf-metric` element.

Sample Machine Agent Configuration with Individual Performance Metrics

```
<machine-agent>
   <metrics>
        <!-- Disable collection of performance metrics in general. -->
     <perf-metrics priority-level="0">
       <!-- Enable collection of individual performance metrics. -->
       <perf-metric name="Hardware Resources|CPU|%Busy"/>
       <perf-metric name="ASP.NET Applications|Errors Unhandled During Execution"/>
     </perf-metrics>
   </metrics>
 </machine-agent>
```

Performance Counters Element

The `perf-counters` element is a child of the `machine-agent` element. It is a container for all performance counters.

Optional Element: `<perf-counters>`

Performance Counter element

The `perf-counter` element is a child of the `perf-counters` element. For a list of performance counters to enable, see Performance Counters in the .NET Framework

Optional Element: `<perf-counter cat="category" name="name" instance="instance"/>`

Performance Counter cat attribute

The `perf-counter cat` attribute indicates the performance counter category.

Type: String
Default: None
Required: Category is required for the `perf-counter` element.

Performance Counter name attribute

The `perf-counter name` attribute indicates the performance counter name.

Type: String
Default: None
Required: Name is required for the `perf-counter` element.

Performance Counter instance attribute

The `perf-counter instance` attribute is the performance counter instance value.

Type: String
Default: None
Required: Instance is required for the `perf-counter` element.

Sample Machine Agent Configuration with Performance Counters

```
<machine-agent>
  <!-- Additional machine level Performance Counters -->
  <perf-counters>
    <perf-counter cat="Network Interface" name="Bytes Sent" instance="Local Area Connection"/>
  </perf-counters>
</machine-agent>
```

Instrumentation Element

The `instrumentation` element is a child of the `machine-agent` element. It allows you to enable additional .NET Agent instrumentors such as thread correlation or correlation for .NET remoting.

Optional Element: `<instrumentation>`

Instrumentor Element

The `instrumentor` element is a child of the `instrumentation` element. The `instrumentor` element specifies the .NET Agent instrumentor to implement.

Optional Element: `<instrumentor name="instrumentor name" enabled="true"/>/>`

Instrumentor name attribute

The `instrumentor name` attribute indicates the instrumentor name.

Type: String
Default: None
Required: Name is required for the Instrumentor element.

Instrumentor enabled attribute

Set the `instrumentor enabled` attribute to `true` to enable instrumentation.

Type: Boolean
Default: false
Required: No.

The current configuration syntax is `enabled="true"`. Versions prior to 3.7.8 used disabled="false".

Sample Machine Agent Configuration with Thread Correlation Instrumentors

```
<machine-agent>
   <!--Enable thread correlation-->
   <instrumentation>
     <instrumentor name="ThreadCorrelationThreadPoolCLR2Instrumentor" enabled="true"/>
     <instrumentor name="ThreadStartCLR2Instrumentor" enabled="true"/>
     <instrumentor name="ThreadStartCLR4Instrumentor" enabled="true"/>
   </instrumentation>
 </machine-agent>
```

Additional .NET Agent Instrumentors

- See Thread Correlation for .NET
- See Enable Correlation for .NET Remoting
- See Enable Instrumentation for WCF Data Services

App Agents Element

The `app-agents` element is a child of the `appdynamics agent` element. It is a container for app agent configurations for IIS applications, Windows services, and standalone applications.

Required Element: `<app-agents enabled="true">`

App agents enabled attribute

To disable application monitoring on the server, set the `app-agents enabled` attribute to `false`.

Type: Boolean
Default: true
Required: No

Default Profiler Element

The default `profiler` element is a child of the `app-agents` element. It defines customizations to the default profiler behavior for all instrumented .NET applications on the machine: IIS applications, application pools, Windows services, and standalone applications.

Optional Element: `<profiler>`

Profiler - Disabled Features Element

The `disabled-features` element is a child of the `profiler` element. Use this property to disable data collection mechanisms at the agent level for security or privacy reasons. This configuration overrides any configuration set by the Controller.

Optional Element: <disabled-features value="NONE"/>

Disabled features value attribute

The `disabled-features value` attribute is a comma-separated list of features to disable. The available values are as follows:

- LOG_PAYLOAD: Override the log-request-payload node property to suppress logging HTTP request payloads
- RAW_SQL: Override the `capture-raw-sql` node property to suppress logging raw SQL output
- CUSTOM_EXIT_SNAP_DATA: Suppress snapshot data from custom exits points
- METHOD_INV_DATA_COLLECTOR: Suppress method invocation data collector user data
- HTTP_DATA_COLLECTOR: Suppress HTTP request data collector user data
- INFO_POINT: Suppress information point metrics
- ALL: Disable all the available features
- NONE: Don't disable features

Type: String
Default: NONE
Required: No

Profiler - Successful Exit Code Element

The `successful-exit-code` element is a child of the `profiler` element. The default successful exit code determines whether or not the agent flags a CLR restart event as graceful or not for Windows services or standalone applications. This configuration does not apply to IIS.

Optional Element: `<successful-exit-code value="0"/>`

Successful exit code value attribute

Type: Integer
Default: 0
Required: No

Profiler - Runtime Reinstrumentation Element

The `runtime-reinstrumentation` element is a child of the `profiler` element. Use this property to configure runtime reinstrumentation. See Configure Runtime Reinstrumentation for .NET

Optional Element: `<runtime-reinstrumentation enabled="true" interval="60000" optimize="true" />`

Runtime reinstrumentation enabled attribute

Set to `true` to enable runtime reinstrumentation.

Type: Boolean
Default: false
Required: No

Runtime reinstrumentation interval attribute

The frequency in milliseconds that the agent checks for configuration updates that initiate runtime reinstrumentation.

Type: Integer
Default: 60000 milliseconds
Minimum: Because runtime reinstrumentation adds a small amount of system overhead, AppDynamics recommends a minimum interval of 1 minute or 60000 milliseconds.
Required: No

Sample Default Profiler Configuration

```
<app-agents>
    <profiler>
      <disabled-features value="LOG_PAYLOAD,RAW_SQL,CUSTOM_EXIT_SNAP_DATA"/>
          <!-- Set the successful exit code for Windows services and standalone applications to "1." -->
      <successful-exit-code value="1"/>
      <!-- Enable Runtime reinstrumentation -->
      <runtime-reinstrumentation enabled="true" interval="60000" />
    </profiler>
...
</app-agents>
```

App Agents - IIS Element

The `IIS` element is a child of the `app-agents` element. There are three options to configure IIS applications:

- Automatic configuration
- Application pool configuration
- Application configuration

The settings for any application pool apply to all applications within the app pool unless the individual application has a specific configuration.

Explicit child-level configurations override parent-level configurations. Otherwise, children inherit parent configurations.

Optional Element: `<IIS>`

Exclude child applications attribute

By default, when you instrument an IIS application, the .NET Agent instruments any child applications and assigns them to the same tier as the parent. To prevent the agent from automatically instrumenting child applications, set `exclude-child-applications` to `true`. For instance: `<IIS exclude-child-applications="true">`

If you disable instrumentation for child applications in general, you can instrument-specific child applications using the IIS Application element.

Type: Boolean
Default: false
Required: No

IIS Automatic Instrumentation Element

The `automatic` element is a child of the `IIS` element. Use the `automatic` element to enable or disable automatic instrumentation for all IIS apps. You can configure automatic instrumentation and manual instrumentation both. Manual configurations override automatic ones.

Optional Element: `<automatic enabled="false" />`

Automatic enabled attribute

Set the automatic `enabled` attribute to `true` to enable instrumentation for all IIS applications. This is the default setting if you use the .NET Agent Configuration Utility automatic configuration option. To disable automatic instrumentation for all IIS applications, set the value to `false`.

Type: Boolean
Default: true
Required: No

IIS Application name enabled attribute

By default, the agent does not report an IIS application name. To view the IIS application name in the CLR metadata, set the `iis-application-name-enabled` attribute to `true`. For example, `<automatic iis-application-name-enabled="true" />`. When enabled, the name appears as the `iis-application-name` value in the CLR metadata.

Type: Boolean
Default: false
Required: No

IIS Application Pools Element

The `IIS application pools` element is a child of the `IIS` element. It is a container element for all the IIS application pools you configure for instrumentation.
Optional Element: `<application-pools>`

IIS Application Pool Element

The `application-pool` element is a child of the `application-pools` element. You may have multiple application pool elements distinguished by the name attribute. Use the application pool element to configure the app agent for all applications within an application pool. For more information on IIS application pools, see Managing Application Pools in IIS

⚠️ Application-specific configurations in the IIS Applications element override application pool configurations.

Optional Element: `<application-pool name="DefaultAppPool" enabled="false">`

Application pool name attribute

The `application-pool name` attribute indicates the name of the IIS Application Pool.

Type: String
Default: None
Required: Name is required for the application-pool element.

Application pool enabled attribute

Set the `application-pool enabled` attribute to `false` to disable instrumentation for all applications in the application pool. Set the value to `true` to instrument all applications in the application pool.

Type: Boolean
Default: None. Defaults to `true` if not specified.
Required: No

Application Pool Tier Element

The `tier` element is a child of the `application-pool` element. If you enable instrumentation for an application pool, you must use a `tier` element to assign the applications of a pool to a tier in the Controller. See Overview of Application Monitoring

Required Element: `<tier name="Inventory" />`

Tier name attribute

Use the `tier name` attribute to specify the tier.

Type: String, may also reference an environment variable. See Reference of Environment Variables
Default: None
Required: Yes

IIS Applications Element

The IIS `applications` element is a child of the `IIS` element. It is a container element for all the IIS applications you configure for instrumentation.
Optional Element: `<applications>`

Application Element

The `application` element is a child of the `applications` element. Use multiple application elements to instrument different sites and applications. To learn more about IIS sites and applications, see Understanding Sites, Applications, and Virtual Directories on IIS 7 and Above

Optional Element: `<application path="/" site="FirstSite" port="8008"site-regex="false">`

Application site attribute

The `application site` attribute indicates the root site in IIS for the application. The site name accepts a regular expression for cases like Windows Azure where you may only know a partial site name. If you use a regular expression, set the Application site-regex attribute to true.

Type: String
Default: None
Required: The site is required for the Application element.

Application site-regex attribute

Set the `application site-regex` attribute to `true` to treat the value of the Application `site` attribute as a regular expression.

Type: Boolean
Default: false
Required: No

Application path attribute

The application `path` attribute indicates the path of the application, relative to the root site. Use the forward slash to indicate the root site and instrument all children applications. Use the path to an application to instrument the specific application and any children.

For example, Site1 hosts two applications `AppX` and `AppY`. To instrument Site 1, `AppY` and `AppZ`, set the path to "/". To instrument `AppY`, but not `AppZ`, set the path to `/AppY`.

Type: String
Default: /
Required: `path` is required for the `application` element.

Application port attribute

For cases where two or more sites in IIS 6 have the same site name, set the site `port` attribute to differentiate between the sites.

Type: Positive Integer
Default**:** None
Required: No

Application enabled attribute

In certain cases you may want to enable instrumentation for a parent application, but disable it for a child application. In this case create an `application` element for the child application to disable and set the `application enabled` attribute to `false`.

Type: Boolean
Default: true
Required: No

Application Tier Element

The `tier` element is a child of the `application` element. If you enable instrumentation for an application, you must use a `tier` element to assign the application to a tier in the Controller. See Overview of Application Monitoring

Required Element: `<tier name="Consumer" />`

Tier name attribute

The `tier name` attribute indicates the business application tier.

Type: String, may also reference an environment variable. See Reference of Environment Variables
Default: None
Required: Yes

Sample IIS Application Configuration

```
<IIS>
  <!-- Automatic instruments all IIS applications when enabled. -->
  <automatic enabled="false" />

  <!-- Application Pool agent configurations -->
  <application-pools>
    <!-- Do not instrument applications in DefaultAppPool when "enabled" attribute is set to false. -->
    <application-pool name="DefaultAppPool" enabled="false">
      <tier name="Tier Name"/>
    </application-pool>

    <!-- Instrument applications in the OtherAppPpool and assign them to the Inventory tier. -->
    <application-pool name="OtherAppPool">
      <tier name="Inventory"/>
    </application-pool>
  </application-pools>
  <applications>
    <!-- Instrument all applications in the First Site. -->
    <application path="/" site="FirstSite">
      <tier name="Order"/>
    </application>
    <!-- Instrument the /app application and child apps in the Second Site -->
    <!-- but not the root Second Site application. -->
    <application path="/app" site="SecondSite">
      <tier name="Consumer"/>
    </application>
    <!-- Regular expression for site name -->
    <!-- assigns all sites beginning with "MyRole" to the Credit Services tier. -->
    <application path="/" site="MyRole_\w+" site-regex="true">
        <tier name="Credit Services"/>
    </application>

  </applications>
</IIS>
```

App Agents - Standalone Applications Element

The `standalone-applications` element is a child of the `app-agents` element. It is a container element for all the Windows services and standalone applications you configure for instrumentation. See Configure the .NET Agent for Windows Services and Standalone Applications

Optional Element: `<standalone-applications>`

Standalone Application Element

The `standalone-application` element is a child of the `standalone-applications` element. It specifies a Windows service or standalone application to instrument.

Optional Element: `<standalone-application executable="MyWindowsApplication.exe" command-line="">`

Standalone Application executable attribute

The `standalone-application executable` attribute specifies the file name of the Windows application to instrument. Set the Standalone Application element executable attribute to one of the following:

- Executable name: for example, `MyStandaloneApp.exe` or `MyWindowsService.exe`. The file extension is optional, so `MyStandaloneApp` also works.
- Full path to the executable: for example, `C:\Program Files\MyApplication\MyStandaloneApp.exe`
- Partial path to the executable: for example, `MyApplication\MyStandaloneApp.exe`. Use the full or partial path to the executable when you want to assign different tiers to separate instances of the same executable running from different paths.

Type: String
Default: None
Required: Yes

Standalone Application command-line attribute

To differentiate between two instances of the same executable, specify any unique portion of the application command line, such as an argument, in the `standalone-application command-line` attribute.

Type: String
Default: None
Required: No

Standalone application app-domain-name attribute

For applications with multiple application domains, the `app-domain-name` attribute enables you to limit instrumentation to specific application domains. See Configure Application Domain Monitoring

Type: String
Default: None
Required: No

Standalone Application Tier Element

The `tier` element is a child of the `standalone-application` element. If you enable instrumentation for an application, you must use a `tier` element to assign the application to a tier in the Controller. See Overview of Application Monitoring

Required Element: `<tier name="Consumer" />`

Tier name attribute

The `tier name` attribute indicates the business application tier.

Type: String, may also reference an environment variable. See Reference of Environment Variables
Default: None
Required: Yes

Environment Variable: APPDYNAMICS.AGENT.TIERNAME

Sample Windows Service and Standalone Application Configuration

```
<standalone-applications>
  <standalone-application executable="ExampleApplication.exe">
    <tier name="Standalone Application Tier"/>
  </standalone-application>
  <!-- Instrument a Windows service using arguments. -->
  <!-- The following example matches the command "MyWindowsService.exe -d -x -r". -->
  <standalone-application executable="MyWindowsService.exe" command-line="-x">
    <tier name="Windows Service Tier"/>
  </standalone-application>
</standalone-applications>
```

.NET Agent Environment Variables

Related pages:

- .NET Agent Configuration Properties
- Administer the .NET Agent
- Configure the .NET Agent
- Name .NET Tiers
- Configure the .NET Agent for Windows Services and Standalone Applications

This page describes the .NET configuration properties you can set using Windows System Environment Variables.

Agent Account Name

Specifies the account name for the SaaS or multi-tenant Controller.

Environment Variable: APPDYNAMICS.AGENT.ACCOUNTNAME
Type: String
Default: For single-tenant Controllers, the agent assumes the default of "customer1" if you do not specify an account name.
Required: Only for SaaS or multi-tenant Controllers.

Agent Application Name

Specifies the business application you use in the Controller. If the application name does not exist, the Controller will create it when the agent registers. See Overview of Application Monitoring.

Environment Variable: APPDYNAMICS.AGENT.APPLICATIONNAME
Type: String
Default: None
Required: Yes

Agent Account Password

Specifies the account access key for the Controller.

Environment Variable: APPDYNAMICS.AGENT.ACCOUNTACCESSKEY
Type: String
Default: None
Required: Yes

Agent Node Name

The name of the node.

In general, the node name must be unique within the business application and physical host. If you want to use the same node name for multiple nodes on the same physical machine, create multiple virtual hosts using the Unique Host ID property. See Unique Host ID.

Environment Variable: APPDYNAMICS_AGENT_NODE_NAME
Type: String
Default: None
Required: Yes

Agent Reuse Node Name

Set this environment variable to true to reuse node names in AppDynamics. When you set the property to true, you don't need to supply a node name, but you do need to provide a node name prefix using appdynamics.agent.reuse.nodeName.prefix.

This property is useful for monitoring environments where there are many CLRs with short life spans. When true, AppDynamics reuses the node names of historical CLRs for new CLRs. This avoids a proliferation of differently named nodes in AppDynamics over time, particularly when the nodes are essentially identical processes that run over different times.

AppDynamics generates a node name with App, Tier, and Sequence number. The node names are pooled. For example, the sequence numbers are reused when the nodes are purged (based on the node lifetime).

When the .NET Agent starts up, it logs output to the console until it registers with the Controller and the Controller generates the node name.

The Controller reuses node names based on the node.retention.period property.

Environment Variable: appdynamics.agent.reuse.nodeName
Type: Boolean
Default: False
Required: No

Example: Using the following environmental variable specifications, the Controller generates a node name with the prefix "reportGen". Node names will have suffixes --1, --2, and so on, depending on the number of nodes are running in parallel. The name of a node that is shut down and qualifies as a historical node may be reused by a new node.

appdynamics.agent.reuse.nodeName=true

appdynamics.agent.reuse.nodeName.prefix=reportGen

Agent Reuse Node Name Prefix

When you configure the agent to reuse node names, use this property to specify the prefix the Controller uses to generate node names dynamically.

Environment Variable: appdynamics.agent.reuse.nodeName.prefix
Type: String
Default: None
Required: When appdynamics.agent.reuse.nodeName=`true`
Example: Using the following environmental variable specifications, the agent directs the Controller to generate a node name with the prefix "reportGen". Node names will have suffixes --1, --2, and so on, depending on how many nodes are running in parallel.

appdynamics.agent.reuse.nodeName=true

appdynamics.agent.reuse.nodeName.prefix=reportGen

Agent Tier Name

Specifies the name of the tier that this .NET node belongs to. Note that this is not the deployment name on the application server.

Environment Variable: APPDYNAMICS_AGENT_TIER_NAME
Type: String
Default: None

Required: Yes

Agent Unique Host ID

Logically partitions a single physical host or virtual machine such that it appears to the Controller that the application is running on different machines. Set the value to a string that is unique across the entire managed infrastructure. The string may not contain any spaces. If you have a machine agent associated with the application monitored by the app agent, then this property must be set on the machine agent to the same value. See Standalone Machine Agent Installation Scenarios.

Environment Variable: APPDYNAMICS_AGENT_UNIQUE_HOST_ID
Type: String
Default: None
Required: No

AWS Instance ID

If the app that you are instrumenting runs on AWS, then .NET Agent supports collecting the AWS Instance ID. To collect the AWS Instance ID, set `APPDYNAMICS.AWS.INSTANCE.ENABLED=true`

Environment Variable: APPDYNAMICS.AWS.INSTANCE.ENABLED
Type: Boolean
Default: false
Required: No

Controller Hostname

Specifies the hostname or the IP address of the AppDynamics Controller. For an on-premises Controller, use the value for Application Server Host Name you provided when you installed the Controller. If you use the AppDynamics SaaS Controller, see the Welcome email from AppDynamics for the name of your Controller.

Environment Variable: APPDYNAMICS.CONTROLLER.HOSTNAME
Type: String
Default: None
Required: Yes, may also be set in the agent config.xml file or using the agent configuration utility.

Controller Port Number

Specifies the HTTP(S) port of the AppDynamics Controller. If the APPDYNAMICS.CONTROLLER.SSL.ENABLED environment variable is set to true, specify the HTTPS port of the Controller; otherwise, specify the HTTP port.

Environment Variable: APPDYNAMICS.CONTROLLER.PORT
Type: Positive Integer
Default: 8090

- For On-premises installations, the defaults are port 8090 for HTTP and port 8181 for HTTPS.
- For the SaaS Controller, use port 80 for HTTP or port 443 for HTTPS.

Required: Yes, may also be set in the agent config.xml file or using the agent configuration utility.

Controller SSL Enabled

When set to "true" enables encryption over SSL between the agent and the Controller.

Environment Variable: APPDYNAMICS.CONTROLLER.SSL.ENABLED
Type: Boolean
Default: false

Required: No, may also be set in the agent config.xml file or using the agent configuration utility.

Reference of Environment Variables

The .NET Agent (through the config.xml file) can reference any environment variables when configuring Agent Node Name, Agent Tier Name, or Controller Application Name.

These environment variables can be referenced in the configuration file or in the agent environment variables for the node, tier, and application names listed above. To include an environment variable, reference it by specifying `%<variable>%` which can be combined with the other characters; for example, `Web-%COMPUTERNAME%` will be translated to `Web-HOST23`.

Configure Multiple Business Application Support for .NET

Related pages:

- .NET Agent Configuration Properties
- Overview of Application Monitoring

By default, applications on a single Windows host are mapped to a single business application in the Controller. If needed, you can manually configure the .NET Agent to map different applications on the same Windows host to different business applications in the Controller.

To map applications on a single host to a different business application, you must edit the `config.xml` file manually. The AppDynamics Agent Configuration utility does not offer this configuration option.

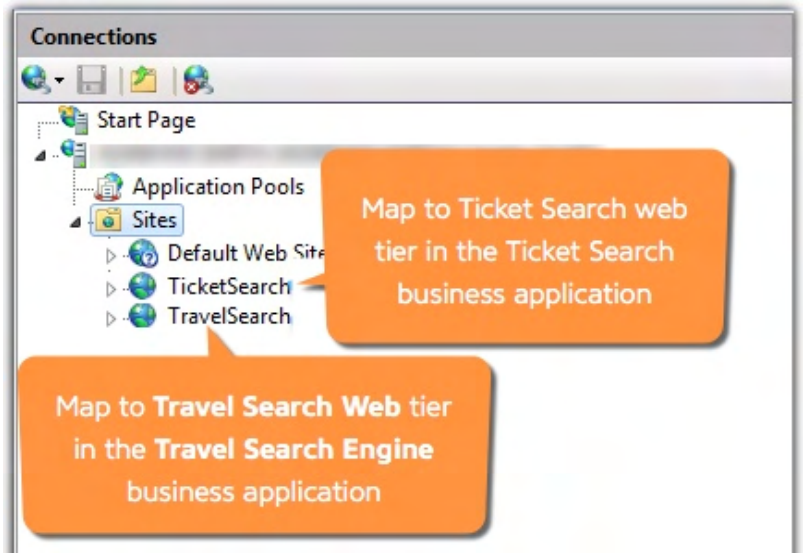
After configuring multiple application support, you cannot use the configuration utility to make configuration changes afterward. If you launch the configuration utility on a server where you configured multiple application support, the utility prompts you to delete the configurations.

Prepare to Configure Multiple Business Applications

Before you configure the .NET Agent, you must install the agent. Use the AppDynamics Agent Configuration utility to perform basic configuration tasks.

1. Identify how to organize your business applications and identify the business application names.

   For example, consider a Windows host running IIS. The IIS instance serves two applications for two separate customers: Ticket Search and Travel Search. The applications perform similar functions, but it makes sense to monitor them separately because they function independently. In this case, create two business applications based upon the application name: Ticket Search Engine and Travel Search Engine.
2. Map your IIS applications or application pools, Windows services, and standalone applications to tiers in the different business applications. For example, map the TicketSearch site to the Ticket Search Web tier in the Ticket Search Engine business application. Map the TravelSearch site to the Travel Search Web tier in the Travel Search Engine business application.



3. If you have not already done so, install the .NET Agent. See Install the .NET Agent for Windows.
4. Run the AppDynamics Agent Configuration utility to generate a config.xml and configure the Controller connection. See Configure the .NET Agent.
5. When prompted, select **Manual** for the method of tier generation and assignment.

> The configuration utility only supports mapping one business application per server.

Manually Configure the .NET Agent

Once you have configured the Controller properties for the .NET Agent, instrument your .NET Applications in the config.xml.

1. Open the `config.xml` file as administrator and edit the file. See 'Where to Configure Agent Properties' on Administer the .NET Agent.
2. Copy the `controller applications` block and paste it as a child element of the `controller` element. Replace any existing `<applications>` or `<application>` elements:

```
 <!--Configure multiple business applications-->
    <applications>
      <application name="ApplicationName1" default ="true"/>
      <application name="ApplicationName2"/>
    </applications>
```

3. Add an `application` element for each of the business applications in the Controller.

   - Edit the `name` attribute for the `application` elements to match the business application names in the Controller. If the application does not exist, the Controller creates it.
   - Set the `default` attribute to `true` for one `application` element. If the agent cannot find a match for the business application name in the IIS application, Windows service, or standalone application configuration, the tier reports to the default business application.

   In this example, `Ticket Search` is the default business application:

```
 <?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org
/2001/XMLSchema">
  <controller host="mycontroller.mycompany.com" port="8090" ssl="false">
        <account name="customer1" password="changeme" />
    <!--Configure multiple business applications-->
    <applications>
      <application name="Ticket Search" default ="true"/>
      <application name="Travel Search"/>
    </applications>
  </controller>
...
```

4. Add configuration elements for the IIS applications or application pools, Windows services, or standalone applications to instrument.
   For IIS applications, add the `applications` block as a child of the `IIS` element. Replace the existing `applications` element. See IIS Applications Element.

```
<applications>
     <application path="/" site="FirstSite" controller-application="Application1">
         <tier name="FirstSite Tier"/>
     </application>
     <application path="/" site="SecondSite" controller-application="Application2">
         <tier name="SecondSite Tier"/>
     </application>
</applications>
```

   For IIS application pools, add the `application pools` block as a child of the `IIS` element. Replace the existing `<application-pools>` element. See IIS Application Pools Element.

```
<application-pools>
    <application-pool name="MyAppPool1" controller-application="Application1">
        <tier name="App1 AppPool Tier"/>
    </application-pool>
    <application-pool name="MyAppPool2" controller-application="Application2">
        <tier name="App2 AppPool Tier"/>
    </application-pool>
</application-pools>
```

   For Windows services or standalone applications, add the `standalone-applications` block as a child of the `app-agents` element. See Standalone Applications Element.

```
<standalone-applications>
    <standalone-application executable="MyStandaloneApp.exe" controller-application="ApplicationName1"
>
        <tier name="Standalone App Tier"/>
    </standalone-application>
    <standalone-application executable="MyWindowsService.exe" command-line="-x" controller-
application="ApplicationName2">
        <tier name="Windows Service Tier"/>
    </standalone-application>
</standalone-applications>
```

5. Configure your application elements:
    - Add the corresponding element for each IIS application or application pool, Windows service, or standalone application to instrument. See .NET Agent Configuration Properties.
    - For each application element set the `controller-application` attribute to the name of the corresponding business application. If you omit the controller-application attribute, the agent adds the application to a tier in the configured default business application.
    - Set the `tier` element `name` attribute to the business application tier name.
6. After you complete configuration, save the changes to the `config.xml` file.
7. Restart the `AppDynamics.Agent.Coordinator` service.
8. Restart IIS applications or application pools, Windows services, and standalone applications.
9. As your applications begin processing traffic, the agent registers them with the Controller. Log on to the Controller to see that your applications have registered with the corresponding business application.

Sample Configuration

This sample `config.xml` file demonstrates configuration for multiple business applications in the Controller. Because the Windows service TicketService does not specify a `controller-application` attribute, it reports to the default business application, `Ticket Search Engine`. All applications in the `TravelAPIPool` pool report to the `Travel Search Engine`.

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001
/XMLSchema">
<controller host="mycontroller.mycompany.com" port="8090" ssl="false">
<!--Configure multiple business applications-->
  <applications>
    <application name="Ticket Search Engine" default ="true"/>
    <application name="Travel Search Engine"/>
  </applications>
</controller>
<machine-agent />
<app-agents>
  <IIS>
    <automatic enabled="false" />
    <application-pools>
      <application-pool name="TravelAPIPool" controller-application="Travel Search Engine">
        <tier name="Travel APIs"/>
      </application-pool>
    </application-pools>
    <applications>
      <application path="/" site="TicketSearch" controller-application="Ticket Search Engine">
        <tier name="Ticket Search Web"/>
      </application>
      <application path="/" site="TravelSearch" controller-application="Travel Search Engine">
        <tier name="Travel Search Web"/>
      </application>
    </applications>
  </IIS>
<standalone-applications>
  <standalone-application executable="StandaloneApp.exe" controller-application="Ticket Search Engine">
    <tier name="Ticket Standalone Tier"/>
  </standalone-application>
  <standalone-application executable="WindowsService.exe" command-line="-x" controller-application="Travel
Search Engine">
    <tier name="Travel Windows Service Tier"/> </standalone-application>
  </standalone-applications>
</app-agents>
</appdynamics-agent>
```

Agent Configuration Properties for Multiple Application Support

Multiple business application support includes configuration properties for the .NET Agent. These configuration properties supersede the ones documented in .NET Agent Configuration Properties.

Controller Applications Element

The `applications` element is a child of the `controller` element. It is a container element for all controller applications elements that map to business applications in the Controller.

Required Element: `<applications>`

Controller Application Element

The `controller application` element is a child of the `controller applications` element. It indicates the name of the logical business application you see in the Controller. When you have more than one Controller Application element, you must set the default attribute to `true` for one of them.

Required Element: `<application name="MyDotNetApplication" default="true"/>`

Application name attribute

Set the application `name` attribute to the business application name in the Controller. If the application name does not exist, the Controller creates it when the agent registers.

Type: String
Default: None
Required: Yes

Application default attribute

Set the application `default` attribute to `true` for one `controller application` element. Instrumented applications without the `controller application` attribute register with the default business application in the Controller.

Type: Boolean
Default: false
Required: For one application in multiple application configurations

Controller-Application Attribute

The `IIS application`, `IIS application-pool`, `windows-service`, and `standalone-application` elements accept the `controller-application` attribute. Set the value to the `controller application` element name. If you do not include a `controller-application` attribute, the application registers with the default business application.

For example, an IIS application:

```
<application path="/" site="MySite" controller-application="My Business Application">
```

Type: String
Default: None
Required: No

Disable Instrumentation for an IIS Application Pool

Related pages:

- Administer the .NET Agent
- .NET Agent Configuration Properties

When you install the .NET Agent on a machine and use automatic tier naming, the agent instruments every IIS application by default. If you do not need to monitor all application pools, disable monitoring for selected pools.

1. Open the `config.xml` file for editing as administrator. See 'Where to Configure Agent Properties' on Administer the .NET Agent
2. Add the `application-pools` block as a child of the `IIS` element. See .NET Agent Configuration Properties

```
<application-pools>
   <!-- Do not instrument applications in DefaultAppPool when "enabled" attribute is set to false -->
   <application-pool name="DefaultAppPool" enabled="false" >
      <tier name="Disabled App Pool" />
   </application-pool>
</application-pools>
```

> `tier` is a required element even if you are disabling an app pool.

3. Set the `application-pool` element name attribute to the application pool name. This example disables instrumentation for the `DefaultAppPool`. You may add multiple `application-pool` elements.
4. Restart the `AppDynamics.Agent.Coordinator` service.
5. Restart IIS.

Configure Application Domain Monitoring

Related pages:

- Instrument DefaultDomain for Standalone Applications
- Application Domains
- .NET Agent Configuration Properties
- Configure the .NET Agent for Windows Services and Standalone Applications

*Y*ou can configure the .NET Agent to monitor ASP.NET applications with multiple Application Domains (AppDomains). This page assumes that you have a working knowledge of AppDomains and are familiar with the AppDomain implementation in your application.

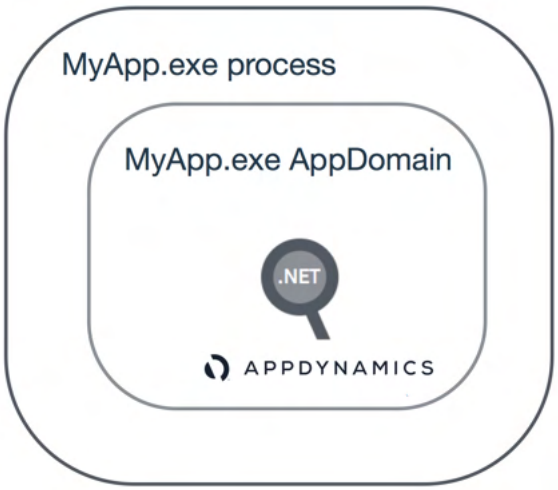
This page does not describe the System Domain, Shared Domain, or DefaultDomain AppDomains that the CLR instantiates before it executes the managed code. If your standalone application runs in the DefaultDomain, see Instrument the DefaultDomain for Standalone Applications.

AppDomains in .NET

Windows uses processes to manage security and performance isolation between running applications. Process isolation ensures that the application's running code does not interfere with another application. However for applications that share data, making calls between Windows processes can introduce complications and performance issues. AppDomains enable developers to create several applications that run inside a single process but maintain application isolation.

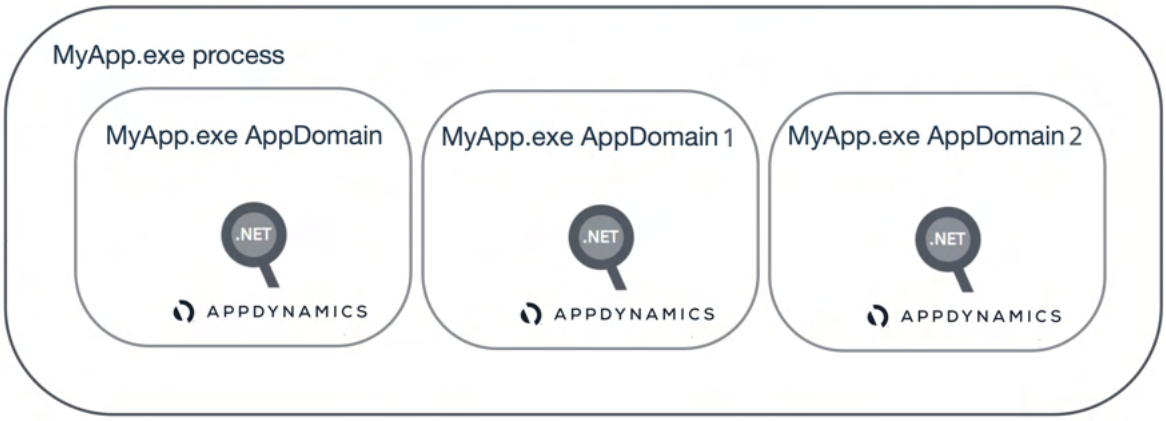
Single Application Domain

When a single application runs inside its own process, the runtime host manages the AppDomain. The application executable and the AppDomain have the same name. The .NET Agent installs itself inside the single AppDomain and creates a node for the application.



Multiple Application Domains

When developers include multiple AppDomains in an application, all the AppDomains run inside a single process. The application executable may have the same name as one AppDomain, but there are other, uniquely-named AppDomains. By default, the agent installs itself inside all the AppDomains and creates nodes for them.



Configure Monitoring for Multiple Application Domains

If the application you monitor contains multiple AppDomains, the App Agent for .NET automatically instruments each AppDomain and creates a node. You can configure the .NET Agent to instrument only the AppDomains you specify. Use this to exclude AppDomains you do not want to monitor, and to limit the number of nodes in a tier.

You can configure application domain monitoring for:

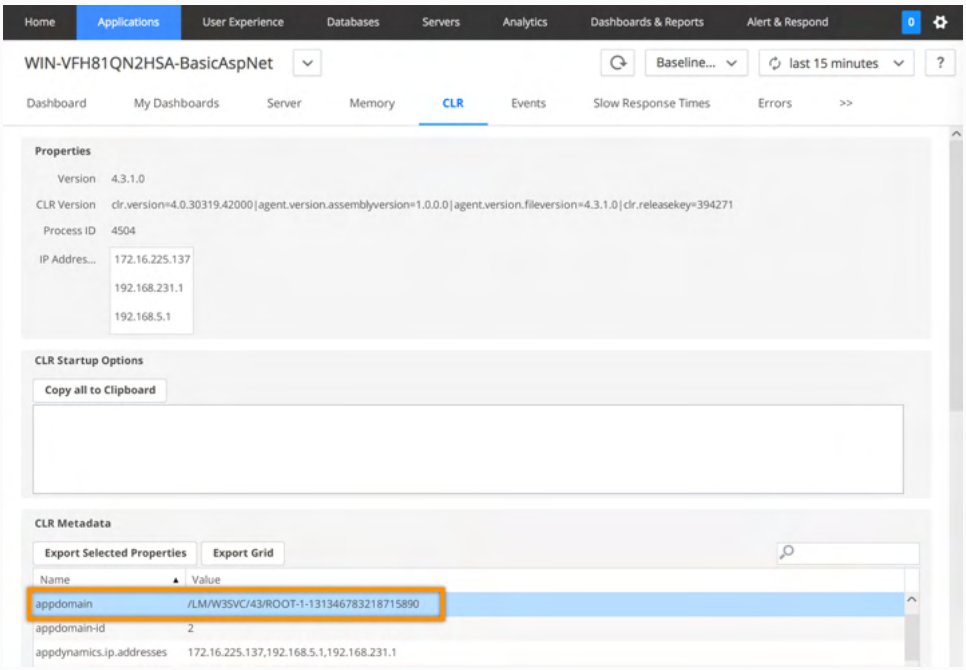
- Windows Services
- Standalone Applications

Configure all instrumentation settings for the .NET Agent in the config.xml file. See Administer the .NET Agent.

1. Identify the name of the AppDomains to instrument.

   If you have already instrumented your application, the AppDomain names display in the Node Dashboard.

   Click the node in the left navigation pane, then click **CLR**.

2. Launch a text editor as administrator.
3. Edit the `config.xml` file as an administrator. See Administer the .NET Agent.
4. Find the element that corresponds to your application with multiple AppDomains:
   Standalone Application element: `<standalone-application executable="MyWindowsApplication.exe">`
5. Add the `app-domain-name` attribute to the element.
   For example, to instrument the `MyApp.exe AppDomain` for the `MyApp.exe` standalone application:

   ```
   <standalone-application executable="MyApp.exe" app-domain-name="MyApp.exe">
       <tier name="StandaloneApplication Tier"/>
   </standalone-application>
   ```

   As soon as you instrument one AppDomain in the `config.xml` file, the agent instruments only the AppDomains you specify. Other AppDomains are not instrumented.

6. To instrument additional AppDomains, add an element for each AppDomain as if they were separate applications.
   For example, to instrument `MyAppDomain1` in `MyApp.exe`:

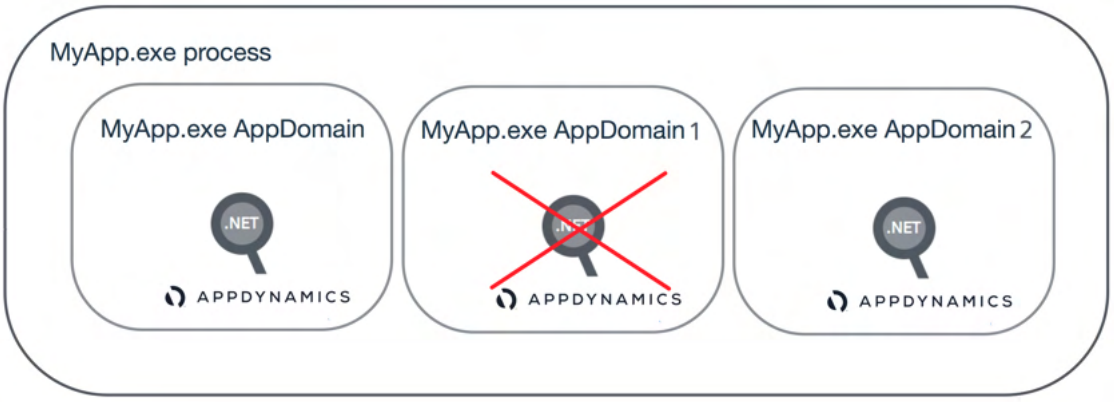
   ```
   <standalone-application executable="MyApp.exe" app-domain-name="MyAppDomain1">
     <tier name="StandaloneApplication Tier"/>
   </standalone-application>
   ```

7. Save the `config.xml` file.

8. Restart the `AppDynamics.Agent.Coordinator` service.
9. Restart instrumented applications: Windows services or standalone applications.

Sample Standalone Application Configuration with Multiple AppDomains

This sample `config.xml` file shows the configuration for the application, `MyApp.exe`. Instrumentation only applies to the AppDomains specified in the `config.xml` file: `MyApp.exe` and `MyAppDomain2`.



```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001
/XMLSchema">
  <controller host="mycontroller.mycompany.com" port="8090" ssl=false">
        <account name="customer1" password="changeme" />
    <application name="MyDotNetApplication" />
  </controller>
  <machine-agent />
  <app-agents>
    <standalone-applications>
      <standalone-application executable="MyApp.exe" app-domain-name="MyApp.exe">
        <tier name="StandaloneApplication Tier"/>
      </standalone-application>
      <standalone-application executable="MyApp.exe" app-domain-name="MyAppDomain2">
        <tier name="StandaloneApplication Tier"/>
      </standalone-application>
    </standalone-applications>
  </app-agents>
</appdynamics-agent>
```

Instrument the DefaultDomain for Standalone Applications

Related pages:

- Configure the .NET Agent for Windows Services and Standalone Applications
- POCO Entry Points
- .NET Agent Configuration Properties

By default, the .NET Agent does not instrument the .NET `DefaultDomain AppDomain`. Before you instrument the `DefaultDomain`:

- Follow the instructions to instrument a standalone application
- Create a POCO entry point for a class/method in the application

If you complete those steps and still do not see business transactions in the Controller, check if your managed code runs in the `DefaultDomain`. If so, you must configure the agent to instrument the `DefaultDomain`.

Check if Your Application Runs in the DefaultDomain

If you are unfamiliar with your application's managed code, you can use the agent logs to identify the AppDomain.

1. Open the agent log:
   Windows Server 2008 and later: `%ProgramData%\AppDynamics\DotNetAgent\Logs\AgentLog.txt`
2. Search the agent log for `AppDomain`.

   Few log entries contain `AppDomain` when the agent starts up. Look for an entry by `dllhost` or your instrumented application similar to the following:

   ```
   2013-12-16 08:23:02.3120 3068 MYPROGRAM 1 1 Info Configuration appDomainName=DefaultDomain appDomainId=1
   iis-app=null site=null port=null appPoolId=
   2013-12-16 08:23:02.6240 3192 dllhost 1 17 Info ConfigurationManager Not instrumenting DefaultDomain for
   pid 3068
   ```

   In this example, `MYPROGRAM` is the name of the instrumented standalone application. You can see the name of the AppDomain in the log entry, `appDomainName=DefaultDomain.`

Instrument the DefaultDomain

1. Open the `config.xml` file for editing as administrator. See 'Where to Configure Agent Properties' on Administer the .NET Agent
2. Copy the code block below to a child element of the `standalone-application` element. See .NET Agent Configuration Properties

   ```
   <profiler>
       <instrument-defaultdomain enabled="true"/>
   </profiler>
   ```

   ⚠️ The Profiler element must follow the Standalone Application Tier element.

   For example:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org
/2001/XMLSchema">
  <controller host="mycontroller.mycompany.com" port="8090" ssl="false">
    <application name="My Business Application" />
        <account name="customer1" password="changeme" />
  </controller>
  <machine-agent />
  <app-agents>
    <IIS>
        <applications />
    </IIS>
    <standalone-applications>
      <standalone-application executable="MyStandaloneApp.exe">
        <tier name="Standalone Tier" />
        <profiler>
            <instrument-defaultdomain enabled="true"/>
        </profiler>
      </standalone-application>
    </standalone-applications>
  </app-agents>
</appdynamics-agent>
```

3. Save the `config.xml` file.
4. Restart the `AppDynamics.Agent.Coordinator` service.
5. Restart the standalone application for your changes to take effect.

Configure the .NET Machine Agent

Related pages:

- Administer the .NET Agent
- .NET Agent Configuration Properties
- Monitor Windows Hardware Resources

The AppDynamics .NET Agent includes an embedded .NET Machine Agent that runs as part of the `AppDynamics.Agent.Coordinator` service. Among other things, the Machine Agent regularly gathers system performance data and reports it back to the Controller as metrics.

> Do not confuse the .NET Machine Agent with the Standalone Machine Agent, a Java application. The Standalone Machine Agent provides the capability to use extensions such as plugins, metric listeners, and orchestrations. See Standalone Machine Agent.

The app agent MSI file and .NET Agent Configuration Utility automatically install and configure the .NET Machine Agent to connect to the Controller. The connection information is the same for the app agent and the .NET Machine agent. See Configure the .NET Agent.

To manage the .NET Machine Agent from the Controller, see 'Manage the .NET Machine Agent' on Monitor Windows Hardware Resources.

Customize .NET Machine Agent Behavior

Customize instrumentation settings for the Machine Agent element in the config.xml file. See 'Where to Configure Agent Properties' on Administer the .NET Agent.

1. Shut down the AppDynamics.Agent.Coordinator service.
2. Edit the `config.xml` file as an administrator. See 'Where to Configure Agent Properties' on Administer the .NET Agent.
3. Modify the `machine-agent` element and add any children elements according to the .NET Machine Agent configuration topics.
4. Save the `config.xml` file.
5. Start the `AppDynamics.Agent.Coordinator` service.
6. In some cases, you may need to restart IIS, instrumented Windows services or instrumented Standalone applications. See individual .NET Machine Agent configuration topics.

.NET Machine Agent Configuration Options

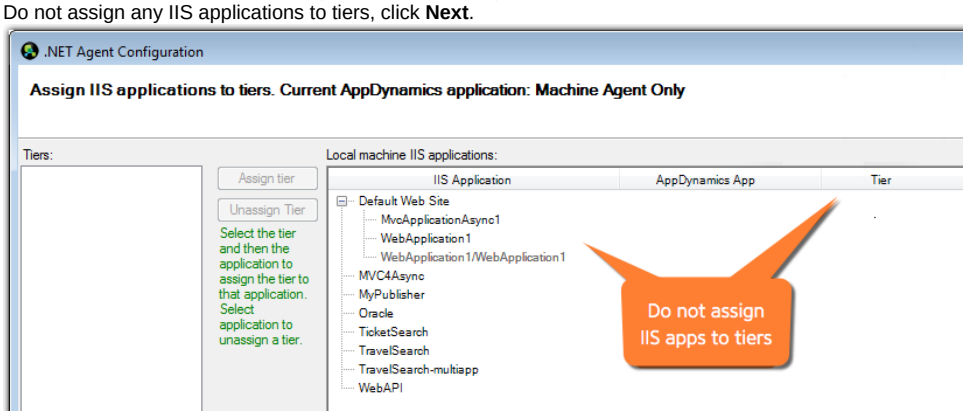
These topics describe specific customizations for the .NET Machine Agent:

- Manage Windows Performance Metrics
- Thread Correlation for .NET
- Enable Correlation for .NET Remoting
- Enable Instrumentation for WCF Data Services
- Configure Machine Snapshots for .NET

Configure the .NET Machine Agent Without App Agents

If you want to monitor the Windows hardware performance data, but do not want to monitor any .NET applications, you can configure the .NET Machine agent to run without the .NET Agent.

1. Install the .NET Agent for Windows.
2. Launch the AppDynamics Agent Configuration utility and follow the steps until you reach the Assign IIS applications to tiers pane.
3. Click **Manual** for the method of tier generation and assignment and click **Next**.
4. Do not assign any IIS applications to tiers, click **Next**.



> If you configured any Windows services or standalone applications, manually disable those agents in the `config.xml` file.

5. Continue with the remaining steps and click **Done**.

   Monitoring resumes for the .NET Machine Agent only. Metrics appear in the Controller under the Machine Agent tier, see Monitor Windows Hardware Resources.

Manage Windows Performance Metrics

The AppDynamics .NET Machine Agent uses Microsoft Performance Counters to gather and report .NET metrics. To manage the metrics that the agent collects:

- Tune the set of metrics that the agent automatically collects
- Configure the agent to collect metrics from additional counters that are not part of the default settings

Tune the Default Performance Metrics for the .NET Agent

The .NET Agent prioritizes the default set of Performance Counters into three categories: low, medium, and high. By default, the agent is set to collect metrics for all three categories.

Metric Browser Location	Metric	Priority
ASP.NET	Application Restarts	3 - Low
ASP.NET	Applications Running	3 - Low
ASP.NET	Request Wait Time	2 - Medium
ASP.NET	Requests Disconnected	3 - Low
ASP.NET	Requests Queued	1 - High
ASP.NET	Requests Rejected	3 - Low
ASP.NET	Worker Process Restarts	3 - Low
ASP.NET Applications	Anonymous Requests	3 - Low
ASP.NET Applications	Anonymous Requests/Sec	3 - Low
ASP.NET Applications	Cache API Entries	3 - Low
ASP.NET Applications	Cache API Hit Ratio	3 - Low
ASP.NET Applications	Cache API Turnover Rate	3 - Low
ASP.NET Applications	Cache Total Entries	3 - Low
ASP.NET Applications	Cache Total Hit Ratio	3 - Low
ASP.NET Applications	Cache Total Turnover Rate	3 - Low
ASP.NET Applications	Errors During Compilation	3 - Low
ASP.NET Applications	Errors During Execution	3 - Low
ASP.NET Applications	Errors During Preprocessing	3 - Low
ASP.NET Applications	Errors Total	2 - Medium
ASP.NET Applications	Errors Total/sec	2 - Medium
ASP.NET Applications	Errors Unhandled During Execution	3 - Low
ASP.NET Applications	Errors Unhandled During Execution/sec	3 - Low
ASP.NET Applications	Output Cache Entries	3 - Low
ASP.NET Applications	Output Cache Hit Ratio	3 - Low
ASP.NET Applications	Output Cache Turnover Rate	3 - Low
ASP.NET Applications	Pipeline Instance Count	3 - Low
ASP.NET Applications	Requests Executing	3 - Low
ASP.NET Applications	Requests Failed	3 - Low
ASP.NET Applications	Requests in Applicaton Queue	1 - High
ASP.NET Applications	Requests Not Authorized	3 - Low
ASP.NET Applications	Requests Not Found	3 - Low

ASP.NET Applications	Requests Succeeded	3 - Low
ASP.NET Applications	Requests Timed Out	2 - Medium
ASP.NET Applications	Requests Total	2 - Medium
ASP.NET Applications	Requests/sec	2 - Medium
ASP.NET Applications	Session SQL Server Connections Total	3 - Low
ASP.NET Applications	Session State Server Connections Total	3 - Low
ASP.NET Applications	Sessions Abandoned	3 - Low
ASP.NET Applications	Sessions Active	3 - Low
ASP.NET Applications	Sessions Timed Out	3 - Low
ASP.NET Applications	Sessions Total	3 - Low
ASP.NET Applications	Transactions Aborted	3 - Low
ASP.NET Applications	Transactions Committed	3 - Low
ASP.NET Applications	Transactions Pending	3 - Low
ASP.NET Applications	Transactions Total	3 - Low
ASP.NET Applications	Transactions/sec	3 - Low
CLR	Process CPU Burnt %	2 - Medium
CLR -> Classes	Current Loaded Class Count	3 - Low
CLR -> Classes	Total Classes Loaded	3 - Low
CLR -> Locks and Threads	Contention Rate Per Sec	2 - Medium
CLR -> Locks and Threads	Current Logical Threads	2 - Medium
CLR -> Locks and Threads	Current Physical Threads	2 - Medium
CLR -> Locks and Threads	Sink Blocks in Use	2 - Medium
CLR -> Memory -> Heap	Committed (bytes)	1 - High
CLR -> Memory -> Heap	Current Usage (bytes)	1 - High
CLR -> Memory -> Heap	Gen 0 Usage (bytes)	1 - High
CLR -> Memory -> Heap	Gen 1 Usage (bytes)	1 - High
CLR -> Memory -> Heap	Gen 2 Usage (bytes)	1 - High
CLR -> Memory -> LOH	Current Usage (bytes)	1 - High
Hardware Resources -> CPU	%Busy	1 - High
Hardware Resources -> CPU	%Idle	3 - Low
Hardware Resources -> Disks	%Free	1 - High
Hardware Resources -> Disks	KB read/sec	3 - Low
Hardware Resources -> Disks	KB written/sec	3 - Low
Hardware Resources -> Disks	MB Free	1 - High
Hardware Resources -> Disks	Reads/sec	1 - High
Hardware Resources -> Disks	Writes/sec	1 - High
Hardware Resources -> Memory	Free %	3 - Low
Hardware Resources -> Memory	Free (MB)	3 - Low
Hardware Resources -> Memory	Total (MB)	1 - High
Hardware Resources -> Memory	Used %	1 - High
Hardware Resources -> Memory	Used (MB)	2 - Medium

Hardware Resources -> Network	Incoming KB/sec	2 - Medium
Hardware Resources -> Network	Incoming packets/sec	3 - Low
Hardware Resources -> Network	Outgoing KB/sec	2 - Medium
Hardware Resources -> Network	Outgoing packets/sec	3 - Low
IIS	CPU %	1 - High
IIS	Number of Working Processes	3 - Low
IIS	Working Set	1 - High
IIS -> Application Pools -> <name>	CPU %	1 - High
IIS -> Application Pools -> <name>	Number of Working Processes	3 - Low
IIS -> Application Pools -> <name>	Working Set	1 - High
IIS -> INFO	VersionMajor	3 - Low
IIS -> INFO	VersionMinor	3 - Low

To reduce the number of metrics that the agent sends to the Controller, or to view less than a full set of metrics, you can configure that agent to collect fewer performance metrics. You can also set the agent to only collect specific metrics from the list. See .NET Agent Configuration Properties.

Configure Additional Performance Counters for .NET

If the agent does not monitor performance counters you are interested in, you can add additional performance counters.

1. Shut down the `AppDynamics.Agent.Coordinator` service.
2. Open the `config.xml` file for editing as an administrator. See 'Where to Configure Agent Properties' on Administer the .NET Agent.
3. Add the Performance Counters block as a child of the Machine Agent element.

```
<perf-counters>
  <perf-counter cat="" name="" instance=""/>
</perf-counters>
```

4. Create a Performance Counter element for each performance counter you want to add. Use any of the performance counters as specified in Performance Counters in .NET Framework.

    - Set the `cat` attribute to the category of the performance counter.
    - Set the `name` attribute to the performance counter name.
    - Set the `instance` attribute to the instance of the performance counter.
      If the counter does not have an instance name, leave an empty string `""`.
      If a particular performance counter has many instances you can specify the following options:
        - instance =`"*"` OR
        - instance =`"all"` (This reports the sum of all instances)

    For example, to add the performance counter for measuring CPU Idle time(%), add this element in the `<perf-counters>` block:

```
<perf-counter cat="Processor" name="% Idle Time" instance="_Total"/>
```

5. Save the `config.xml` file.
6. Start the `AppDynamics.Agent.Coordinator` service.

After you enable Performance Counter metrics, they display under the Custom Metrics tree in the Metric Browser.

Sample .NET Machine Agent Configuration with Performance Counters

```
<machine-agent>
  <!-- Additional machine level Performance Counters -->
  <perf-counters>
    <perf-counter cat="Processor" name="% Idle Time" instance="_Total"/>
    <!-- Perf counter with no instance name -->
    <perf-counter cat="Memory" name="Available MBytes" instance="" />
  </perf-counters>
</machine-agent>
```

Enable Correlation for .NET Remoting

Related pages:

- .NET Backend Detection
- Remote Services

Developers use .NET remoting to build distributed applications that share objects across processes or across application domains running in the same process. AppDynamics disables correlation for .NET remoting functions by default.

Instrument Applications that Use .NET Remoting

You can configure the .NET Agent to discover .NET remoting entry and exit points.

1. Open the `config.xml` file for editing as administrator. See 'Where to Configure Agent Properties' on Administer the .NET Agent
2. Copy the code block below to a child element of the Machine Agent element. See .NET Agent Configuration Properties

   ```
       <instrumentation>
           <instrumentor name="RemotingMscorlibEntryInstrumentor" enabled="true"/>
           <instrumentor name="RemotingExitInstrumentor" enabled="true"/>
       </instrumentation>
   ```

   For example:

   ```
   <?xml version="1.0" encoding="utf-8"?>
   <appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org
   /2001/XMLSchema">
   ...
    <machine-agent>
       <!--Enable correlation for .NET remoting-->
       <instrumentation>
           <instrumentor name="RemotingMscorlibEntryInstrumentor" enabled="true"/>
           <instrumentor name="RemotingExitInstrumentor" enabled="true"/>
       </instrumentation>
     </machine-agent>
   ...
   </appdynamics-agent>
   ```

3. Save the `config.xml` file.
4. Restart the `AppDynamics.Agent.Coordinator` service.
5. Restart instrumented applications for your changes to take effect.

If the agent does not discover the entry points after configuration, specify an agent trigger.

Specify an Agent Trigger

.NET remoting entry point functions execute in low-level .NET libraries that may not trigger automatic agent instrumentation. If the agent does not discover the .NET remoting entry points after configuration you can specify a function that triggers the agent to begin instrumentation.

1. Identify a function to trigger the agent to begin instrumentation. The function can be any function that executes as part of the application process.

   For example, consider the following code for a `MovieTicket` remoting object. In this case, use the function `GetTicketStatus` to trigger the agent.

```
using System;
namespace MovieGoer
{
    public class MovieTicket : MarshalByRefObject
    {
        public MovieTicket()
        {
        }
        public string GetTicketStatus(string stringToPrint)
        {
            return String.Format("Enquiry for {0} -- Sending back status: {1}", stringToPrint, "Ticket
Confirmed");
        }
    }
}
```

2. Edit the `config.xml` file as an administrator. See Administer the .NET Agent.
3. Update the Instrumentation element to include the `AgentTriggerInstrumentor` attribute. See .NET Agent Configuration Properties.

```
    <instrumentation>
                <instrumentor name="AgentTriggerInstrumentor" enabled="true" args="" />
        <instrumentor name="RemotingMscorlibEntryInstrumentor" enabled="true"/>
        <instrumentor name="RemotingExitInstrumentor" enabled="true"/>
    </instrumentation>
```

4. Set the `AgentTriggerInstrumentor args` value to the name of the trigger function, using information in the code block in step 1. The `args` value should be formatted as follows: `namespace.public_class.public_string`.

   For example:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org
/2001/XMLSchema">
...
 <machine-agent>
    <!--Enable correlation for .NET remoting-->
    <instrumentation>
        <instrumentor name="AgentTriggerInstrumentor" enabled="true" args="MovieGoer.MovieTicket.
GetTicketStatus" />
        <instrumentor name="RemotingMscorlibEntryInstrumentor" enabled="true"/>
        <instrumentor name="RemotingExitInstrumentor" enabled="true"/>
    </instrumentation>
  </machine-agent>
...
</appdynamics-agent>
```

5. Save the `config.xml` file.
6. Restart instrumented applications for your changes to take effect.

Thread Correlation for .NET

Related pages:

- Configure Backend Detection for .NET
- Remote Services

By default, the AppDynamics .NET Agent enables multi-threaded correlation for these patterns on the Common Language Runtime (CLR) >= 4.x:

- `Task.Start`
- `Task.Run`
- `TaskFactory.StartNew`

The .NET Agent also supports thread correlation for the following patterns which are disabled by default:

- `Thread.Start` on the CLR 2.x and CLR 4.x
- `ThreadPool.QueueUserWorkItem` on the CLR 2.x and CLR 4.x

For AppDynamics < 4.3, for the .NET Agent, you did not need to configure correlation for `ThreadPool.QueueUserWorkItem` for the CLR 4 in the `config.xml` file. If you explicitly call `ThreadPool.QueueUserWorkItem` for the CLR 4, when you upgrade to the .NET Agent 4.5 from an earlier version, you must enable the instrumentor for `ThreadPool.QueueUserWorkItem` on the CLR 4 in the `config.xml` file.

Configure Thread Correlation for .NET

Configure all instrumentation settings for the .NET Agent in the `config.xml` file. See Administer the .NET Agent

1. Open the `config.xml` file for editing as an administrator. See Administer the .NET Agent.
2. Copy the code block below to a child element of the Machine Agent element. See Machine Agent Element.

   ```
       <instrumentation>
           <instrumentor name="ThreadCorrelationThreadPoolCLR2Instrumentor" enabled="true"/>
           <instrumentor name="ThreadCorrelationThreadPoolCLR4Instrumentor" enabled="true"/>
           <instrumentor name="ThreadStartCLR2Instrumentor" enabled="true"/>
           <instrumentor name="ThreadStartCLR4Instrumentor" enabled="true"/>
       </instrumentation>
   ```

   For example:

   ```
   <?xml version="1.0" encoding="utf-8"?>
   <appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org
   /2001/XMLSchema">
   ...
    <machine-agent>
       <!--Enable thread correlation-->
       <instrumentation>
           <instrumentor name="ThreadCorrelationThreadPoolCLR2Instrumentor" enabled="true"/>
           <instrumentor name="ThreadCorrelationThreadPoolCLR4Instrumentor" enabled="true"/>
           <instrumentor name="ThreadStartCLR2Instrumentor" enabled="true"/>
           <instrumentor name="ThreadStartCLR4Instrumentor" enabled="true"/>
       </instrumentation>
     </machine-agent>
   ...
   </appdynamics-agent>
   ```

   The configuration syntax is `enabled="true"`.
3. Save the `config.xml` file.
4. Restart the `AppDynamics.Agent.Coordinator` service.
5. Restart instrumented applications for your changes to take effect.

Enable Instrumentation for WCF Data Services

Related pages:

- .NET Business Transaction Detection
- .NET Agent Configuration Properties

This page describes how to configure the AppDynamics .NET Machine agent to enable instrumentation for Windows Communication Foundation (WCF) Data Services including WCF RIA Services for Microsoft LightSwitch.

1. Open the `config.xml` file for editing as administrator. See Administer the .NET Agent.
2. Copy the code block below to a child element of the Machine Agent element. See .NET Agent Configuration Properties.

   ```
       <instrumentation>
           <instrumentor name="WCFDSEntryInstrumentor" enabled="true" />
       </instrumentation>
   ```

   For example:

   ```
   <?xml version="1.0" encoding="utf-8"?>
   <appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org
   /2001/XMLSchema">
   ...
    <machine-agent>
       <!--Enable instrumentation for WCF Data Services correlation-->
       <instrumentation>
           <instrumentor name="WCFDSEntryInstrumentor" enabled="true" />
       </instrumentation>
     </machine-agent>
   ...
   </appdynamics-agent>
   ```

   The configuration syntax is `enabled="true"`.
3. Save the `config.xml` file.
4. Restart the `AppDyanmics.Agent.Coordinator` service.
5. Restart instrumented applications for your changes to take effect.

Configure Machine Snapshots for .NET

The .NET Machine Agent takes machine snapshots to capture vital system data for Windows and IIS. Use these guidelines to tune the frequency the .NET Machine Agent takes machine snapshots in your environment. See Machine Snapshots for .NET.

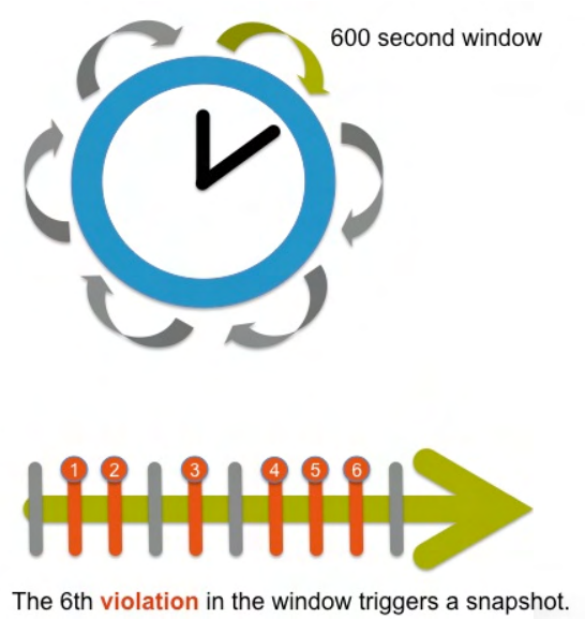
Default Settings and Configuration Considerations

By default, the .NET Machine Agent takes machine snapshots under these conditions:

- Periodic collection: The agent takes one snapshot every 10 minutes.
- Breached thresholds: The .NET Machine Agent takes samples of machine statistics every 10 seconds within a 10-minute window. For each sample, the agent checks the CPU percent usage, the memory percent usage, and the oldest item in the IIS application pool queue. The agent flags a sample as a violation when the current usage meets or exceeds one of these thresholds:
  - CPU at 80% or higher
  - Memory at 80% or higher
  - IIS application pool queue item older than 100 milliseconds

  The agent takes a snapshot when it identifies 6 violations of a single type, such as CPU usage, within the window. The agent only takes one snapshot per window for breached thresholds.

With the default window size of ten minutes and the violations per window of six, the sixth violation of a single type triggers a machine snapshot:



Before you change the machine snapshot settings, determine which configuration options work best for your environment. Use these questions and considerations to help determine your threshold settings:

- What percentage CPU or memory usage might flag the beginnings of an issue in your environment?
- How long is too long for items to wait in the IIS queue?
- Do you expect occasional CPU or memory spikes?
- Are periodic collections every ten minutes frequent enough?
- Make sure the value for violations is larger than the number of samples per window.

For example, if you decrease the window size to 60 seconds and take six samples per window, the agent takes samples at the same frequency as the default settings, once every 10 seconds. However, you are likely to get more snapshots because the agent only takes one snapshot per window. If you set the violations per window to five, the agent takes a snapshot any time half the samples in the window violate a specific threshold. See .NET Agent Configuration Properties.

Configure Machine Snapshots for the .NET Machine Agent

Configure all instrumentation settings for the .NET Machine Agent in the config.xml file:

1. Open the `config.xml` file for editing as an administrator. See Administer the .NET Agent.
2. Copy the code block below to a child element of the AppDynamics Agent element. See AppDynamics Agent Element.

```
<machine-agent>
        <machine-snapshot enabled="true" window-size="600" samples-per-window="60" violations-per-
window="6" max-percent-cpu="80" max-percent-memory="80" max-queue-item-age="100" periodic-collection="
600" />
</machine-agent>
```

If you have already customized the .NET Machine Agent, only copy the `machine-snapshot` element and paste it as a child of the `machine-agent` element.

3. Edit the values for the `machine-snapshot` element attributes:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org
/2001/XMLSchema">
...
 <machine-agent>
    <!--Configure machine snapshots-->
        <machine-snapshot enabled="true" window-size="60" samples-per-window="10" violations-per-window="
5" max-percent-cpu="80" max-percent-memory="80" max-queue-item-age="100" periodic-collection="600"/>
  </machine-agent>
...
</appdynamics-agent>
```

4. Save the `config.xml` file.
5. Restart the `AppDynamics.Agent.Coordinator` service.

Configure Runtime Reinstrumentation for .NET

By default, you must restart your monitored application after you create or update:

- POCO transaction detection entry points
- POCO service endpoints
- Custom exit points
- Method invocation and HTTP data collectors
- Information points

When you enable runtime reinstrumentation, the .NET Agent detects the types of instrumentation changes and automatically requests the CLR to recompile the affected code. With runtime reinstrumentation enabled, you do not need to restart your application for the instrumentation changes to take effect. See Administer the .NET Agent.

Requirements

Runtime reinstrumentation works for .NET Framework >= 4.5.2. To verify the framework version in the `web.config` file of your application, enter:

```
<system.web>
    <compilation targetFramework="4.5.2" />
    <httpRuntime targetFramework="4.5.2" />
</system.web>
```

Configure Runtime Reinstrumentation for .NET

*C*onfigure all instrumentation settings for the .NET Agent in the `config.xml` file:

1. Open the `config.xml` file for editing as an administrator. See Administer the .NET Agent.
2. Copy the code block below to a child element of the `app-agents` element. See Default Profiler Element.

   ```
   <profiler>
      <runtime-reinstrumentation enabled="true" interval="60000" />
   </profiler>
   ```

   For example:

   ```
   <?xml version="1.0" encoding="utf-8"?>
   <appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org
   /2001/XMLSchema">
   ...
   <app-agents>
       <profiler>
         <!-- Enable runtime reinstrumentation -->
         <runtime-reinstrumentation enabled="true" interval="60000"/>
       </profiler>
   ...
   </app-agents>
   </appdynamics-agent>
   ```

3. If appropriate configure the `runtime-reinstrumentation` options:
   - `enabled`: Set to `true` to enable runtime reinstrumentation. Default: `false`
   - `interval`: The frequency the agent checks for configuration updates in milliseconds. Default: `60000`.

   > Because runtime reinstrumentation adds a small amount of system overhead, AppDynamics recommends a minimum interval of 1 minute or 60000 milliseconds.
   >
   > The .NET Agent checks for configuration updates every minute, so it may take up to 2 minutes for reinstrumentation to take effect with the default setting of 60000 milliseconds.

4. Save the `config.xml` file.
5. Restart the `AppDynamics.Agent.Coordinator` service.
6. Restart instrumented applications for your changes to take effect.

Filter Sensitive Data with the .NET Agent

By default, the AppDynamics .NET Agent sends transaction data to the Controller that your organization may classify as privileged information. Although this data is useful for diagnosis and troubleshooting, security considerations may require you to filter certain information from view in the Controller. You can use sensitive data filters to exclude environment variables or URLs in the Controller or information in snapshot details.

Sensitive Data Filters are available for the .NET Windows and Linux Agents (as of 21.4).

Add a Sensitive Data Filter

To instrument sensitive data filters, you edit the .NET Agent configuration file. See Administer the .NET Agent.

1. Edit a versioned agent configuration file:
   - Full .NET Agent: `config.xml`
   - Standalone Agent: `config.json`
2. Add a `sensitive-data-filter` element as a child of the Sensitive Data Filters element using one of these attributes:

```
<!-- Filter environment variable values sent to controller -->
<sensitive-data-filters>
        <sensitive-data-filter applies-to="environment-variables, system-properties, http-headers, http-
cookies",
                                    match-type="EQUALS|CONTAINS|STARTSWITH|ENDSWITH"
                                    match-pattern=""/>
</sensitive-data-filters>
```

   Sensitive Data Filter Attributes:

   - Specify a comma-separated list in the `applies-to` attribute to filter `environment-variables, system-properties`, or data collectors (`http-headers`, `http-cookies`)
   - Set the match-type attribute as:

     `EQUALS`

     `CONTAINS`

     `STARTSWITH`

     `ENDSWITH`
   - Specify a string to match for the `match-pattern` attribute. String matches are case insensitive. The pattern matches the environment variable and system property names, not values.
3. Restart the .NET Agent and application.

In this example, the .NET Agent checks for environment variables beginning with the string "DB_". The Controller displays the values of matching environment variables and system properties as asterisks. For example, an environment variable `DB_USER` is obfuscated and replaced with an asterisk in the Controller.

Example config.xml file:

```
<sensitive-data-filter applies-to="environment-variables, system-properties",
                                    match-type="STARTSWITH"
                                    match-pattern="DB_"/>
</sensitive-data-filters>
```

Example config.json file:

```
sensitive-data-filters: [
{
"applies-to": "environment-variables, system-properties",
"match-type": "STARTSWITH",
"match-pattern": "DB_"
}
]
```

Add a Sensitive URL Filter

You can use sensitive URL filters to configure the agent to obfuscate sensitive information in the URLs in the Controller.

To instrument sensitive URL filters, you edit the .NET Agent configuration file. See Administer the .NET Agent.

1. Edit a versioned agent configuration file:
    - Full .NET Agent: `config.xml`
    - Standalone Agent: `config.json`
2. Add attributes to the `sensitive-url-filters` element:

```
<sensitive-url-filters>
        <sensitive-url-filter delimiter=""
                                          segment=""
                                          match-filter=
“EQUALS|INLIST|STARTSWITH|ENDSWITH|CONTAINS|REGEX|NOT_EMPTY"
                                          match-pattern="pattern"
                                          param-pattern=""/>
</sensitive-url-filters>
```

Sensitive URL Filter Attributes:

- `delimiter`: Specify the character that you want to use as URL segment endpoints. The agent splices the URL at each delimiter instance to create the segments. For HTTP, use the forward-slash character "/". In the case of a forward slash, the agent does not split on the slashes immediately following the protocol. For example, "`https://myapp.example.com/`" constitutes a single segment. By default, the delimiter is "/".
- `segment`: Specify a comma-separated list to indicate the segments that you want the agent to filter. Segment numbering starts from 1.
- `match-pattern`: Specify the string that you want to be filtered by the `match-filter`.
- `param-pattern`: Specify the regular expression matching the query parameters to filter.

For example, this configuration splits the URL on the "/" character and masks the second segment, and the param-pattern in the third segment of the URL. In this example, the segmentation and obfuscation apply only to URLs containing "`myapp`".

```
<!-- Filter URL/URI segments and query parameters -->
<sensitive-url-filters>
        <sensitive-url-filter delimiter="/"
                                           segment="2"
                                           match-filter="CONTAINS"
                                           match-pattern="myapp"
                                           param-pattern="[a-z]+"/>
</sensitive-url-filters>
```

If you do not use any values for the query parameters, the Controller does not mask any query parameters in the URL.

The exit call to `https://myapp.example.com/sensitive/data?first_name=abc&last_name=xyz` breaks down to three segments:

- `"https://myapp.example.com"`
- `"sensitive"`
- `"data?first_name=abc&last_name=xyz"`

The Controller shows the masked values of the URL and the param-pattern displays `https://myapp.example.com/*****/data?first_name=***&last_name=***` in the snapshot details.

Add a Sensitive Message Filter

You can use the `sensitive-message-filters` element to obfuscate sensitive information contained within text messages collected from exception messages.

1. Edit a versioned agent configuration file.
2. Add attributes to the `sensitive-message-filters` element:

```
<sensitive-message-filters>
        <sensitive-message-filter message-type="all"
                                  match-type="EQUALS|CONTAINS|STARTSWITH|ENDSWITH|REGEX"
                                  match-pattern="CASESENSITIVE_PATTERN"
                                  redaction-regex="SENSITIVE_INFO_REGEX_GROUP"/>
</sensitive-message-filters>
```

Sensitive Message Filter Attributes:

- `message-type`: Specify `all`
- `match-type`: Specify the type of match that should be used to opt-in messages for redaction
- `match-pattern`: Specify the pattern that, when matched, opts the message in for redaction
- `redaction-regex`: Specify a regular expression identifying data that should be redacted from the opted-in messages

This example filters out a test where `match-pattern` contains `"Sensitive"`.

```
<sensitive-message-filters>
        <sensitive-message-filter message-type="all"
                                  match-type="CONTAINS"
                                  match-pattern="Sensitive"
                                  redaction-regex="[0-9]+"/>
</sensitive-message-filters>
```

Manage Configuration for .NET

Related pages:

- Administer the .NET Agent
- .NET Agent Configuration Properties

Highly-scaled environments frequently contain multiple machines that run the same .NET applications and therefore use the same AppDynamics .NET Agent configuration. Manual configuration updates to several machines can be tedious and error-prone.

Use the Config Management tool in the AppDynamics Controller to upload and manage .NET Agent `config.xml` files. By default the .NET Agent checks for configuration updates from the Controller every minute. Use the Config Management tool to assign configurations to machines where the .NET Agent is running.

Click **Settings > AppDynamics Agents > Config Management** to manage all the .NET Agent configurations files for your machines.

Requirements

- Membership in a role with 'Administer user, groups, roles, authentication, and so on' account level permission.
- A valid `config.xml` configuration file. The Config Management tool does not validate the `config.xml` file.
- .NET Agent >= 4.1 installed on machines where you plan to deploy configuration.

.NET Agents deployed on Azure Cloud Services using the AppDynamics NuGet package do not register for Config Management because web role and worker role machine names are not always unique. Duplicate machine names may lead to unexpected consequences.

Identify the Configuration File

To start managing your configurations in the Controller, identify a configuration file or set of configuration files to upload. If you are not familiar with .NET Agent configuration, AppDynamics recommends you use the Agent Configuration Utility on each machine to configure the agent. See Administer the .NET Agent and Configure the .NET Agent.

For a full list of configuration properties, see .NET Agent Configuration Properties.

- Use `config.xml` files configured with the AppDynamics Agent Configuration Utility to help ensure the XML is valid.
- Use the `config.xml` file from a previously-configured machine as a template for similar machines that need the exact same configuration.

Import Configuration

The Import Config dialog enables you to upload a `config.xml` file to the Controller, and specify a unique name for the configuration.

- Use a naming convention that helps you identify the type of machine for the configuration.
- Consider using a date or version scheme for the configuration name.
- Click a configuration, then click **Edit Config** to modify the configuration name.
- Double-click a config to display the XML. You can copy the XML, but you cannot modify it.

Assign Configuration to Machines

The Config Management tool enables you to assign machines to a configuration, or change the configuration from one to another. After you assign the configuration in the Controller, the .NET Agent automatically downloads the configuration file.

- If a machine does not have a managed configuration, the Config Management tool displays it following `Machine with no assigned templates`.

  
  If you select the **Register Machine with No Application** option on the Application Configuration pane in the AppDynamics Agent Configuration utility, the Controller lists the machine in the **Machines** section with no assigned templates.

- Drag and drop to assign a machine to a configuration.
- The .NET Agent checks for updated configurations every minute.
- The agent backs up the old `config.xml` file as `config-<date>.xml` in the backup subdirectory of the `econfig` directory. See .NET Agent Directory Structure.
- If the agent detects an invalid `config.xml file`, it does not apply the managed configuration and it raises an Agent Configuration Error event in the Controller. The event summary indicates the affected tiers and nodes.
- Regardless of the Controller connection information in the managed configuration, the agent always retains existing Controller connection information.
- After the agent receives and validates the assigned configuration, any changes take effect after the app pools recycle or IIS restarts. You must restart Windows services or standalone applications. It is unnecessary to restart the AppDynamics Agent Coordinator service.

Opt Out of Configuration Management

To configure an agent so that it does not receive configuration files from the Controller, set the `enable_config_deployment` Controller attribute to `false` in the `config.xml` file. See .NET Agent Configuration Properties.

For example:

```
<controller host="mycontroller.saas.appdynamics.com" port="443" ssl="true" enable_config_deployment="false">
```

Restore an Old Configuration

If you mistakenly assign a configuration, follow this procedure to restore a previous version of the config.xml:

1. On the Config Management pane, drag the machine from its currently assigned configuration to **Machine with no assigned templates**.
2. On the machine itself, rename the existing configuration file, `config.xml`, to a name such as `config.old.xml`.
3. Copy the backup config file from the Backup subdirectory to the `Config` directory. Backup files are named using this format: `config-<date>.xml`.
4. Rename the backup config file to `config.xml`.
5. Optionally edit the `config.xml` to opt out of Config Management.
6. Restart the AppDynamics Agent Coordinator service.
7. Restart Windows services, instrumented Windows services, and instrumented standalone applications.

.NET Agent on Windows Logging

Related pages:

- Agent Log Files
- Troubleshoot Agentless Analytics Issues
- Troubleshoot .NET Agent Issues

This page provides an overview of logging for the .NET Agent on Windows.

The .NET Agent hosts log files in the `%ProgramData%\AppDynamics\DotNetAgent\Logs` directory.

To learn how logs are organized into sets that rollover, see Agent Log Files.

Log File Size

Within a set, the first file for the agent log can reach 5 MB. This file never gets deleted because it contains valuable information about the context in which the agent was started.

Each of the remaining logs in the set can reach a maximum of 5 MB.

To allow for several restarts and all possible logs that could be generated (.NET Agent, Business Transaction, and REST), the maximum number of rollover logs is five. The maximum size per set is 5 MB + (5 X 5M B) = 30 MB.

Some log files, such as SamplingInfo and Winston are configured differently and can be 9 MB in size with only two archive files.

Profiler logging is different; a logging framework called Boost logs to the Profiler folder and creates one file per instrumented process. While Boost uses the archive files and max size, it has two other limits: one to limit the number of files in the Profiler folder (defaults to 50) and the other to limit the max size (defaults to 30 MB).

Control the .NET Agent Logging Level

You control the logging level for the .NET Agent by changing the value of the `minlevel` parameter in the `AppDynamicsAgentLog.config` file found in the .NET Agent logs directory.

The log configuration is per server. The .NET Machine Agent and the .NET Agent read the same configuration file and write to the same set of output files.

```
<logger name="com.appdynamics.REST.HeartBeatLog" minlevel="Info" writeTo="RESTHearbeat" final="true" />
    <logger name="*" minlevel="Warn" writeTo="warnfile" />
    <logger name="com.appdynamics.BusinessTransactions" minlevel="Info" writeTo="btlog" final="true" />
    <logger name="com.appdynamics.bci.*" minlevel="Info" writeTo="bcifile" final="true" />
    <logger name="com.appdynamics.REST.*" minlevel="Info" writeTo="RESTfile" final="true" />
    <logger name="AppDynamics.Agent.Coordinator.Recovery.*" minlevel="Info" writeTo="CoordinatorRecovery"
final="true" />
    <logger name="com.appdynamics.METRICS.MetricSender" minlevel="Info" writeTo="RESTfile" final="true" />
    <logger name="AppDynamics.Winston.*" minlevel="Info" writeTo="Winston" final="true" />

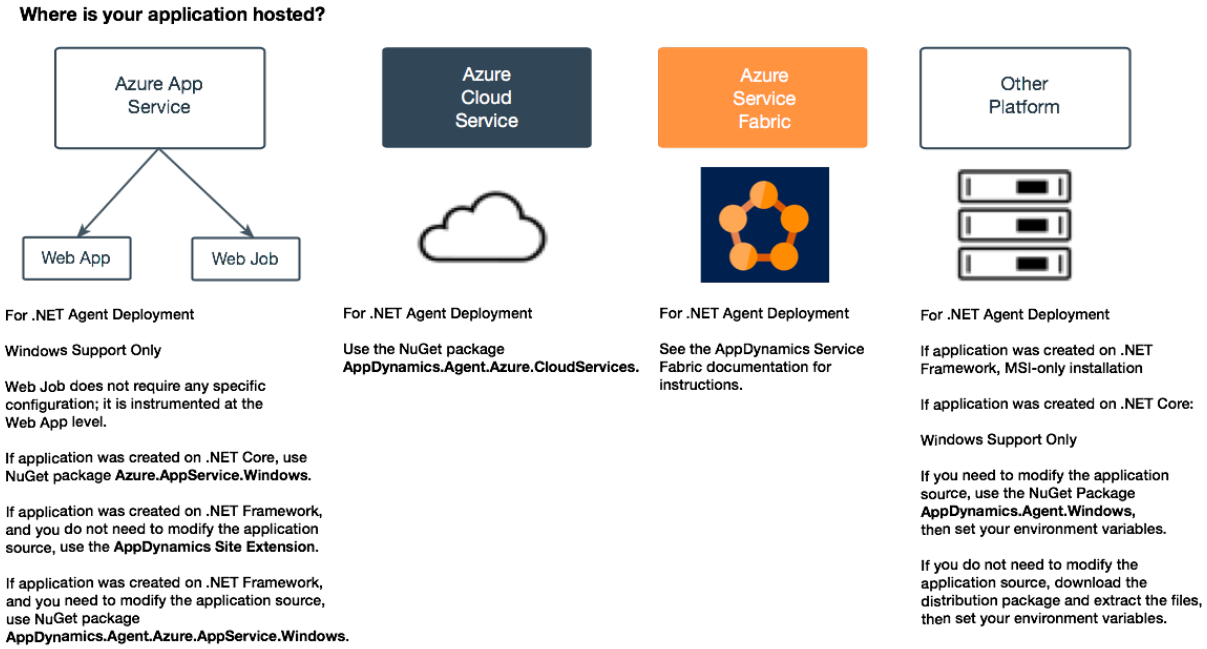
```

.NET Microservices Agent

To monitor standalone applications on different platforms, install the .NET *microservices agent* on the solution of your choice. Where and how you install the .NET microservices agent depends on your platform—for example, Azure App Service or Service Fabric—and what applications you want to monitor. For example, you can now monitor applications developed using .NET Core for Windows using the .NET microservices agent.

Before You Begin

To accurately determine the steps you need to take to deploy a .NET microservices agent to your solution, review this decision matrix to determine the appropriate path for your platform and applications.



Install the .NET Microservices Agent

Review this table to determine which NuGet package you should use to install the .NET microservices agent. For details about managing NuGet packages, see the documentation for your version of Visual Studio.

`AppDynamics.Agent.Distrib.Micro.Windows`	AppDynamics NuGet package for .NET. This package *should not* be installed directly and is intended for download and file distribution. This package is used for Azure Service Fabric deployments. See Install AppDynamics for Azure Service Fabric.
`AppDynamics.Agent.Windows`	AppDynamics .NET Core microservices agent for Windows. Recommended for standalone installations. See Install the .NET Core Microservices Agent for Windows. This package does not support .NET Framework, only .NET Core for Windows.
`AppDynamics.Agent.Azure.CloudServices`	AppDynamics .NET agent for Azure Cloud Services. See Install AppDynamics for Azure Cloud Services.
`AppDynamics.Agent.Azure.AppService.Windows`	AppDynamics .NET microservices agent for Azure App Service. This package is intended for applications deployed to Azure App Service (Azure Web Apps and Azure API Apps). See Install the AppDynamics .NET Microservices Agent and Install AppDynamics for Azure App Service.

.NET Core Microservices Agent Support

Supported Runtime Environments

This section lists the environments where the .NET Microservices Agent does some automatic discovery after little or no configuration.

The .NET microservices agent works with .NET Core 2.0, 2.1, 3.0, and 3.1 on these operating systems:

- Microsoft Windows Server 2012
- Microsoft Windows Server 2012 R2
- Microsoft Windows Server 2016
- Microsoft Windows Server 2019
- Microsoft Windows 8, 8.1, 10

Microsoft Windows Azure

- Azure App Services for .NET Core 2.0, 2.1, 3.0, and 3.1 environments in the Azure Portal:
  - Web Apps
  - API Apps
  - Container Services

Automatically Discovered Business Transactions

The .NET Microservices Agent discovers business transactions for the following frameworks by default. The agent enables detection without additional configuration.

Type	Custom Configuration Options?	Downstream Correlation?
ASP.NET Core 3.0	Yes	Yes
Web Services including SOAP	No	Yes
Message Queues		
Microsoft Service Bus	No	Yes
RabbitMQ	Yes	Yes

Supported Loggers for the .NET Agent

- Log4Net
- NLog
- System Trace
- Windows Event Log
- Loggers on .NET Core that implement the Microsoft.Extensions.Logging.ILogger API (Linux Agent >= 4.5.19 and Windows Agent >= 21.2.0)

If you are using a different logger, see Error Detection.

Remote Service Detection

The .NET Agent automatically detects the following remote service types. The agent enables detection by default. You don't need to perform extra configuration.

Type	Custom Configuration Options?	Async Detection? *	Downstream Correlation?
HTTP	Yes	See Asynchronous Exit Points for .NET	Yes
MongoDB: C# and .NET MongoDB Driver version 1.10, 2.0	No	See Asynchronous Exit Points for .NET	N/A
Web Services, including SOAP	Yes	See Asynchronous Exit Points for .NET	Yes
Data Integration			
Microsoft BizTalk Server 2010, 2013	No	Yes	See Correlation Over Microsoft BizTalk
Message Queues			
Apache ActiveMQ NMS framework and related MQs	Yes	No	Yes

RabbitMQ	See RabbitMQ Backends for .NET.	No	Yes

* The agent discovers asynchronous transactions for the Microsoft .NET 4.5 framework. See Asynchronous Exit Points for .NET

Data Storage Detection

The .NET Agent automatically detects the following data storage types. The agent enables detection by default. You don't need to perform extra configuration.

Type	Customizable Configuration?	Async Detection?*	AppD for Databases?
ADO.NET (see supported clients below)	Yes	Yes	No

* The agent discovers asynchronous transactions for the Microsoft .NET 4.5 framework. See Asynchronous Exit Points for .NET

Supported ADO.NET Clients

AppDynamics can monitor any ADO.NET client version and type. Clients we have tested include the following:

Database Name	Database Version	Client Type
MySQL	5.x	Connector/Net and ADO.NET

Install the .NET Core Microservices Agent for Windows

To monitor an application executed on Windows, you install the AppDynamics .NET Core microservices agent for Windows to your project. Additionally, you can instrument .NET standalone services or IIS services using the MSI installer. Then, set the environment variables for your Controller.

Install the .NET Core Microservices Agent

Before you install the .NET Core microservices agent, ensure that you have access to the AppDynamics Controller where your application metrics will display.

You can deploy the .NET Core microservices agent using either of these methods:

- Deploy the .NET Core microservices agent during development using IDE and Visual Studio
- Deploy the .NET Core microservices agent separately to different development teams to divide controls, pipelines, and CI/CD processes

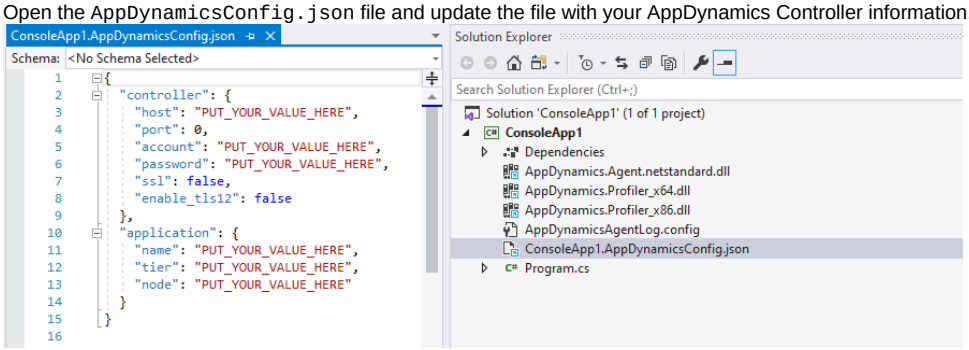
Deploy the .NET Core Microservices Agent During Development

1. Install the `AppDynamics.Agent.Windows` NuGet package in your project. See your IDE documentation.

   When you install the NuGet package, the `AppDynamicsConfig.json` file is copied to the project's root directory. A link file prefixed with the project name is included as content to the project. All the files are copied to the app's output directory after the build.
2. Set up these environment variables for your system application:

   ```
   CORECLR_ENABLE_PROFILING=1
   CORECLR_PROFILER={39AEABC1-56A5-405F-B8E7-C3668490DB4A}
   CORECLR_PROFILER_PATH_32=<actual_path>\AppDynamics.Profiler_x86.dll
   CORECLR_PROFILER_PATH_64=<actual_path>\AppDynamics.Profiler_x64.dll
   ```

   Where `<actual_path>` is the complete path to the `AppDynamics.Profiler` dll.
3. Open the `AppDynamicsConfig.json` file and update the file with your AppDynamics Controller information.



4. Use these options to configure the .NET Agent to connect to the AppDynamics Controller:

   - During development: As shown in the previous screenshot, you can enter your environment variables in the `AppDynamicsConfig.json` file, and save it in source control.
   - During build: Define your msbuild parameters or environment variables that are passed to the `AppDynamicsConfig.json` file at build time. The `AppDynamicsConfig.json` file does not exist at build time, so if you are defining your msbuild parameters or environment variables at build time, you will need to ignore it in source control so that the new `AppDynamicsConfig.json` file can be created.
   - During runtime: Enter your environment variables in Azure.
5. Deploy the application.

Deploy the .NET Core Microservices Agent Separately to Different Development Teams

By using this deployment method, you divide controls, pipelines, and CI/CD processes among different development teams. Additionally, you may encounter a situation where it may not be possible to return to the project solution and add the agent (particularly if the software was developed by a third party).

1. From nuget.org, download the NuGet package AppDynamics.Agent.Distrib.Micro.Windows from https://www.nuget.org/packages/AppDynamics.Agent.Distrib.Micro.Windows/.
2. Extract (unzip) the `dlls` and `AppDynamicsConfig.json` configuration file from the Nuget package to a folder.
3. Update the `AppDynamicsConfig.json` configuration file as required.
   a. Make a copy of the of the `AppDynamicsConfig.json` file and rename it to *<<executable_name>>*`.AppDynamicsConfig.json.` For example, `<<servicefabricapplicationname>>.AppDynamicsConfig.json.`
   b. Copy `AppDynamics.Agent.dll`, `AppDynamics.Profiler_x64.dll`, `AppDynamicsAgentLog.config`, `AppDynamicsConfig.json` from `<<nuget_package>>\content\AppDynamics` and add these files in the solution of each of the service project at the top level, not under any subfolders.
   c. Make a copy of `AppDynamicsConfig.json` and rename it to:`<<executable_name>>.AppDynamicsConfig.json`, for example, `<<servicefabricapplicationname>>.AppDynamicsConfig.json`. Put it into the root of each service project.

   > When you rename the `.json` file to the application name, do not include `.exe` at the end of your application name.

d. Right-click the files in the AppDynamics sub-folder, and then select **Copy Always**.
e. Update `<<executable_name>>.AppDynamicsConfig.json` with your configuration information:

```
{
 "controller":
 {
 "host":"",
 "port":0,
 "account":"",
 "password":""
 },
 "application":
 {
 "name":""
 }
}
```

Do not specify node; it will be assigned automatically. Specifying tier is optional because it could be assigned automatically.

4. Set up these environment variables for your system application:

```
CORECLR_ENABLE_PROFILING=1
CORECLR_PROFILER={39AEABC1-56A5-405F-B8E7-C3668490DB4A}
CORECLR_PROFILER_PATH_32=<actual_path>\AppDynamics.Profiler_x86.dll
CORECLR_PROFILER_PATH_64=<actual_path>\AppDynamics.Profiler_x64.dll
```

Where `<actual_path>` is the complete path to the `AppDynamics.Profiler dll`.

.NET Core for Linux SDK

Related pages:

- .NET Core for Linux SDK Use Cases
- .NET Core for Linux SDK Reference
- .NET Core for Linux SDK Supported Environments
- Overview of Application Monitoring
- Business Transactions

You can use the AppDynamics .NET Core for Linux SDK to monitor the performance of .NET Core applications running on Linux.

The SDK supports these features:

- Business transaction registration and error reporting
- Exit call with correlation and error reporting
- Metrics
- Snapshots with user properties but without callgraphs

Together, these tools provide visibility on application load and response times, and any custom metrics you define.

You monitor .NET Core applications by deploying the .NET Core for Linux SDK to your application directory and project.

Once running, the agent registers business transactions with the AppDynamics Controller. Then, you can view your application flow map and monitor performance in the Controller.

Before You Begin

1. Confirm that you have access to a compatible Controller. See Agent and Controller Compatibility.
2. Confirm the connection settings to the Controller where your agent will report data:
    - If you use a SaaS Controller, AppDynamics sent you the Controller host in your Welcome Email. Use port 443 for HTTPS or port 80 for HTTP.
    - If you use an on-premises Controller, you supplied the host and port during installation.
3. Verify that you have access the machine where the application runs as a user account with privileges to install the agent software, and restart the application.
4. Verify that the machine where the application runs can connect to the Controller. Proxies or firewalls on the network between the agent and Controller may require additional configuration.

Prepare to Install

Ensure you have:

- .NET Core SDK
- .NET Core application running on Linux
- AppDynamics.AgentSDK NuGet package
- Visual Studio or other IDE
- The .NET Core command-line interface (CLI)

Install the SDK

Complete these steps manually, using Visual Studio, or another integrated development environment (IDE).

1. To add the `AppDynamics.AgentSDK` NuGet package in the project, from the command line, enter:

    ```
    dotnet add package AppDynamics.AgentSDK_x64
    ```

    Once you enter the command, there's a compatibility check runs to ensure the package is compatible with the frameworks in the project. If the check passes, then a `<PackageReference>` element is added to the project file, and `dotnet restore` is run implicitly.
2. Modify your project to use the AppDynamics SDK. See .NET Core for Linux SDK Reference.
   Add the SDK namespace and SDK code to the application. For example:

```
using AppDynamics;
...
namespace coremvc.Controllers
{
   public class HomeController : Controller
   {
      public IActionResult SomePage()
      {
          var currCtxId = AgentSDK.StartBusinessTransaction("DemoBT", "ASP_DOTNET", "");
          // Code here calls to other ASP_DOTNET component
                        ...
          AgentSDK.StopBusinessTransaction(currCtxId);
          return View();
       }
       ...
```

3. Run `dotnet build` or `dotnet publish`.
   A warning message displays stating the AppDynamics configuration has not been updated. This is normal.
   - Running `dotnet build` adds this AppDynamics configuration file to your application:
     `<application_directory>: AppDynamicsConfig.json`
   - Running `dotnet publish` renames the AppDynamicsConfig.json file and copies it to the publish directory for the .NET Core for Linux SDK to reference and use:
     `<publish_directory): <project_name>.AppDynamicsConfig.json`
4. Proceed to Using .NET Core for Linux SDK for instructions to update the `AppDynamics.Config.json` file and connect the agent to the Controller.

Known Issues

The requirement to disable loading of native images (NGEN) for self-contained apps compiled with .NET Core 2.0.

Due to a bug in the .NET Core runtime (see **https://github.com/dotnet/coreclr/issues/13021**), the command the .NET Core for Linux SDK profiler sends to the runtime to disable loading of native images is ignored. This prevents AppDynamics from instrumenting any methods in these assemblies which include most of the .NET Standard libraries.

To work around this issue, disable using native images by setting this environment variable:

```
COMPLUS_ReadyToRun=0
```

.NET Core for Linux SDK Supported Environments

You must use the `StartBusinessTransaction` and `CreateExitCall` methods with the entry and exit point types listed below in order for the .NET Core for Linux SDK to recognize them. See .NET Core for Linux SDK Reference.

.NET Core 1.x, 2.0.x, 2.1.x, and 3.1 for Linux SDK Support

Operating Systems

- CentOS 7
- Ubuntu 14.04

Entry Point Types

- ASP.NET
- POCO

Exit Point Types

- HTTP
  - HOST
  - PORT
  - URL
  - QUERY STRING
- WCF
  - URL
  - OPERATION
- ADO.NET
  - HOST
  - PORT
  - DATABASE
  - VENDOR
  - CONNECTION STRING

Using .NET Core for Linux SDK

Before you instrument your applications with the .NET Core for Linux SDK, you must have the current version of the .NET Core for Linux SDK. The page describes how to connect the .NET Core for Linux Agent in your application to the Controller.

Once you have the deployed the SDK, you can configure your application instrumentation. The SDK provides routines to create and manage business transactions, transaction snapshots, backends, exit points and custom metrics collection.

Configuration

1. Edit the `AppDynamicsConfig.json` file with this information:

```
{
  "controller": {
    "host": "<controller_host_name>",
    "port": <controller_port_name>,
    "account": "<controller_account_name>",
    "password": "<controller_account_key>",
    "ssl": <true if using https controller, or false>
    "proxy" : {
        "host": "proxy-host",
        "port": 9090,
           "authentication": {
              "username": "proxy-user",
              "password": "proxy-password"
            }
      }
  },
  "application": {
    "name": "<application_name>",
    "tier": "<tier_name>",
    "node": "<node_name>"
  },
  "log": {
    "directory": "<log_folder_path>",
    "level": "<log_level>"
  }
}
```

2. Add these environment variables to your application, and then rebuild or republish your application.

Environment Variable Name	Value
`CORECLR_PROFILER`	`{57e1aa68-2229-41aa-9931-a6e93bbc64d8}`
`CORECLR_ENABLE_PROFILING`	`1`
`CORECLR_PROFILER_PATH`	Path to the `libappdprofilerdynamic` library. For example, `<application_folder_path> /libappdprofiler.so`

The .NET command that you used to install the SDK determines the location of the `libappdprofiler.so` library. AppDynamics recommends using `dotnet build`, which is the first deployment command option in this table:

Type of Deployment	Command	Work Directory	Profiler Location	Executable Path
Development	`dotnet build, dotnet run`	`<project_path>`	`~/.nuget/packages/appdynamics.agentsdk/4.5.0 /runtimes/linux-x64/native/libappdprofiler.so`	N/A
Framework Dependent	`dotnet publish`	`<project_path>`	`<project_path>/bin/<Flavor>/publish/runtimes /linux-x64/native/libappdprofiler.so`	`bin/<flavor>/publish /linux-x64/<appname.dll>`
Self-contained	`dotnet publish -r linux_x64`	`<project_path>`	`/<project path>/bin/<Flavor>/linux_x64/publish /libappdprofiler.so` `<project path>` is the root directory of the application	`bin/<flavor>/linux_x64 /publish/<appname>` `<flavor>` can be something like `release/netcoreapp2.0`

After you rebuild or republish your application, the agent registers to the Controller, and AppDynamics starts instrumenting your application. See .NET Core for Linux SDK Use Cases.

.NET Core for Linux SDK Use Cases

Related pages:

- .NET Core for Linux SDK
- Overview of Application Monitoring
- Business Transactions

Business Transaction Definition

You define a custom business transaction using the `StartBusinessTransaction` and `StopBusinessTransaction` SDK calls.

A downstream transaction in a distributed transaction cannot start until its upstream transaction has made its exit call.

The order of transactions respects the nonlinear nature of .NET applications. An upstream transaction might end immediately after its exit call completes or sometime later. It is not necessary for an upstream transaction to end before or after its downstream transaction starts or ends. A downstream transaction can end before its upstream transactions have ended.

Sample Business Transaction Creation

This example shows how you use the `StartBusinessTransaction` and `StopBusinessTransaction` SDK calls to define the entry point and exit point of a business transaction.

```
using AppDynamics;
...
namespace coremvc.Controllers
{
   public class HomeController : Controller
   {
      public IActionResult SomePage()
      {
//define start of an ASP_DOTNET type business transaction named DemoBT
          var currCtxId = AgentSDK.StartBusinessTransaction("DemoBT", "ASP_DOTNET", "");
          // Code here calls to other ASP_DOTNET component
                        ...
          AgentSDK.StopBusinessTransaction(currCtxId);
          return View();
       }
       ...
```

Exit Call Management

An exit call is either a custom exit call or an automatically detected exit call. A transaction needs its exit call object to create correlation information to provide to a downstream transaction that needs to correlate with it.

Custom Exit Calls

If you want an exit call to be reported to the Controller, and it is not automatically detected by the agent, create a custom exit call with `CreateExitCall( )` and then define the start and end of the exit call —`startExitCall()` and `endExitCall()`. Use `AddIdentifyingPropertyToExitCall` to help you to identify this exit call in the transaction snapshot.

See .NET Core for Linux SDK Supported Environments for the list of backends that are automatically detected by the .NET Core for Linux SDK. If the exit call invokes a backend not listed on this page, you probably need to create a custom exit call.

Sample Exit Call Creation

```
using AppDynamics;
...
namespace coremvc.Controllers
{
        public class HomeController : Controller
        {
      public IActionResult SomePage()
      {

//define start of an ASP_DOTNET type business transaction called DemoBT. StartBusinessTransaction statement
equals the value of the currCtxId variable
          var currCtxId = AgentSDK.StartBusinessTransaction("DemoBT", "ASP_DOTNET", "");

//define HTTP type exit call named CorrelationExit for the DemoBT business transaction. CreateExitCall
statement equals the value of the exitCall variable
                  var exitCall = AgentSDK.CreateExitCall(currCtxId, "HTTP", "CorrelationExit");

//add identifying properties Host and Port, along with their respective values to the exit call

                AgentSDK.AddIdentifyingPropertyToExitCall(exitCall, "Host", request.RequestUri.Host);
                AgentSDK.AddIdentifyingPropertyToExitCall(exitCall, "Port", request.RequestUri.Port.ToString());

//define the beginning of the exit call
        AgentSDK.StartExitCall(exitCall);

                //code here to make exit call
        ...

//define end of the exit call

         AgentSDK.StopExitCall(exitCall);

                //code here calls to other ASP_DOTNET component
         ...
//define end of the DemoBT business transaction
          AgentSDK.StopBusinessTransaction(currCtxId);
          return View();
       }
       ...
```

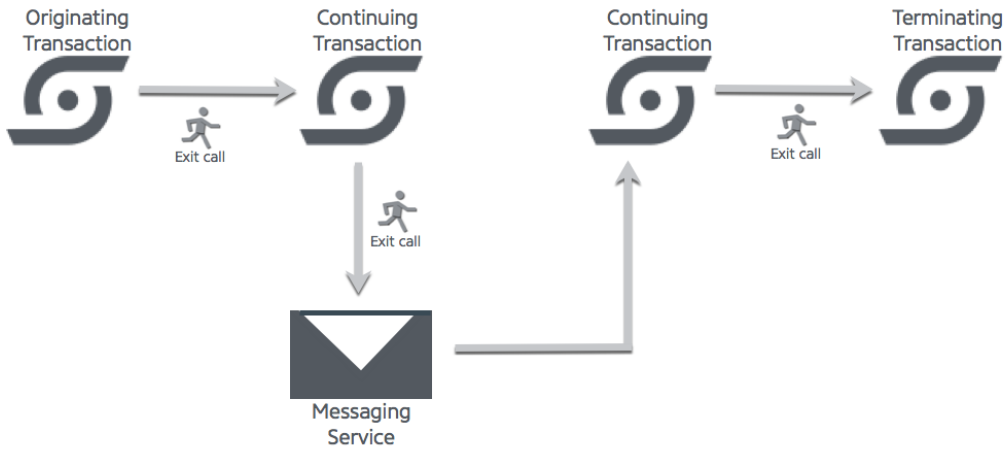
Transaction Correlation Management

Transaction correlation is the functionality that maintains the business transaction context across all tiers (servers) traversed by a distributed transaction. The tiers may be built on platforms other than .NET. For example, Java, Node.js, and PHP tiers may participate in a distributed business transaction in which a .NET tier participates as the originating, continuing or terminating tier in the transaction.

The .NET Core for Linux SDK provides facilities for managing transaction correlation among various transactions, which can be custom or automatically-detected.

While the AppDynamics default auto-detection mechanism obtains transaction correlation information from an incoming HTTP request, the .NET Core for Linux SDK allows you to obtain this information from other sources, such as a custom field in a Redis cache entry, and to supply it to your custom transactions. You can use the Agent SDK classes to support forward correlation by supplying transaction correlation information on exit calls that you make to downstream transactions.

A downstream transaction starts after its immediate upstream transaction makes its exit call. That exit call could be a direct exit call to the next tier or a call to a backend service that does some processing, such as publishing a message onto a queue.



Sample Transaction Correlations Between Upstream and Downstream Tiers

Use Case 1: .NET Core on Linux application calling an upstream .NET Core on Linux application.

Both applications are monitored by AppDynamics.

```
using AppDynamics;
...
namespace coremvc.Controllers
{
public class HomeController : Controller
   {
      public IActionResult SomePage()
      {
        var currCtxId AgentSDK.StartBusinessTransaction("DemoBT", "ASP_DOTNET", "");
            var client = new HttpClient();
            var request = new HttpRequestMessage()
            {
                        RequestUri = new Uri("http://localhost:8080 "),
                        Method = HttpMethod.Get,
                };

            var exitCall = AgentSDK.CreateExitCall(currCtxId, "HTTP", "CorrelationExit");
            AgentSDK.AddIdentifyingPropertyToExitCall(exitCall, "Host",   request.RequestUri.Host);
            AgentSDK.StartExitCall(exitCall);
            var correlationHeader = AgentSDK.GetCorrelationHeader(exitCall);
            request.Headers.Add("singularityheader",correlationHeader);
            await client.SendAsync(request);
            AgentSDK.StopExitCall(exitCall);
            AgentSDK.StopBusinessTransaction(currCtxId);       }
       ...
```

Use Case 2: .NET Core on Linux application calling a downstream .NET Core on Linux application.

Both applications are monitored by AppDynamics.

```
using AppDynamics;
...
namespace coremvc.Controllers
{
public class HomeController : Controller
   {
      public IActionResult SomePage()
      {

bool hasCorrelationHeader = Request.Headers.TryGetValue("singularityheader", out var correlationHeader);

var currCtxId = AgentSDK.StartBusinessTransaction("DemoBT", "ASP_DOTNET",

hasCorrelationHeader ? (string)correlationHeader:"");

          // Code here calls to other ASP_DOTNET component

          AgentSDK.StopBusinessTransaction(currCtxId);

          return View();
       }
     ...
```

Use Case 3: Non .NET Core on Linux application monitored by AppDynamics calling a .NET Core on Linux application.

To correlate, the .NET Core on Linux application must include this code:

```
using AppDynamics;
...
namespace coremvc.Controllers
{
public class HomeController : Controller
   {
      public IActionResult SomePage()
      {

//Obtain the HTTP header value of the page via the TryGetValue method and use that value to define
correleationHeader
        bool hasCorrelationHeader = Request.Headers.TryGetValue("singularityheader", out var correlationHeader);

//Define the start of the ASP_DOTNET type business transaction DemoBT to include the correleation header if
available.
        var currCtxId = AgentSDK.StartBusinessTransaction("DemoBT", "ASP_DOTNET",
        hasCorrelationHeader ? (string)correlationHeader:"");

          // Code here calls to other ASP_DOTNET component
                       ...

//Define the end of the DemoBT business transaction
          AgentSDK.StopBusinessTransaction(currCtxId);
          return View();
       }
       ...
```

Use Case 4: .NET Core on Linux application calling a non .NET Core on Linux application monitored by AppDynamics.

To correlate, the .NET Core on Linux application must include this code:

```
using AppDynamics;
...
namespace coremvc.Controllers
{
public class HomeController : Controller
   {
      public IActionResult SomePage()
      {
           var currCtxId AgentSDK.StartBusinessTransaction("DemoBT", "ASP_DOTNET", "");

            var client = new HttpClient();

            var request = new HttpRequestMessage()
            {
                        RequestUri = new Uri("http://localhost:8080 "),
                        Method = HttpMethod.Get,
                };

            var exitCall = AgentSDK.CreateExitCall(currCtxId, "HTTP", "CorrelationExit");
            AgentSDK.AddIdentifyingPropertyToExitCall(exitCall, "Host",   request.RequestUri.Host);
            AgentSDK.StartExitCall(exitCall);
            var correlationHeader = AgentSDK.GetCorrelationHeader(exitCall);
            request.Headers.Add("singularityheader",correlationHeader);
            await client.SendAsync(request);
            AgentSDK.StopExitCall(exitCall);
            AgentSDK.StopBusinessTransaction(currCtxId);       }
       ...
```

.NET Core for Linux SDK Reference

Related pages:

- .NET Core for Linux SDK
- Overview of Application Monitoring
- Business Transactions

To instrument .NET Core for Linux applications, you use the .NET Core for Linux SDK. Once you have deployed the .NET Core for Linux SDK into your application, AppDynamics automatically instruments the application. You can customize the application instrumentation using these business transaction and exit call methods.

You must start all transactions using the `StartBusinessTransaction` method in the .NET Core for Linux SDK.

This page describes the methods defined in the SDK.

Using the SDK

Namespace: `AppDynamics.AgentSDK`
Assembly: `AppDynamics.Agent.SDK.dll`

Business Transaction Methods

StartBusinessTransaction

Starts the Business Transaction.

Format: `StartBusinessTransaction(<name>, <entryPointType>, <correlationHeader>)`

Parameters:

- `name` – Business Transaction name.
- `entryPointType` – Type of entry point, such as ASP_DOTNET and POCO
- `correlationHeader` – AppDynamics correlation header. Optional.

Return Type: `AppDynamics.BusinessTransaction`

StopBusinessTransaction

Stop the Business Transaction

Format: `AgentSDK.StopBusinessTransaction(<bt>)`

Parameters: `bt` – Business transaction object returned by the StartBusinessTransaction method.

Return Type: void

AddDataToTransactionSnapshot

Add identifying information to the transaction snapshot.

Format: `AgentSDK.AddDataToTransactionSnapshot(<bt>, <key>, <value>)`

Parameters:

- `bt` – The business transaction for which AppDynamics creates a snapshot. Returned by the StartBusinessTransaction method.
- `key` – Key in key/value pair
- `value` – Value in key/value pair

Return Type: void

Exit Call Methods

CreateExitCall

Create an Exit Call

Format: `AgentSDK.CreateExitCall(<bt>, <exitPointType>, <name>, <isAsync>)`

Parameters:

- `bt` – BusinessTransaction on which to create an exit call.
- `exitPointType` – Type of exit call, such as HTTP, WCF, and ADO.NET
- `name` – Name of exit call.
- `isAsync` – Boolean value to identify exit call as asynchronous. Optional. Default value: false

Return Type: `AppDynamics.ExitCall`

AddIdentifyingPropertyToExitCall

Add properties to the exit call.

Format: `AgentSDK. AddIdentifyingPropertyToExitCall(ExitCall <exitCall>, <string_property>, <string_value>)`

Parameters:

- `exitCall` – Business transaction for which AppDynamics creates a the snapshot. Returned by StartBusinessTransaction.
- `string_property` – Name of the property. For example, the URL.
- `string_value` – Value of the property. For example, http://www.google.com.

Return Type: void

StartExitCall

Start an exit call to the specified backend as part of a business transaction

`Format: AgentSDK.StartExitCall(ExitCall <exitCall>)`

Parameters: `exitCall` – ExitCall type returned by CreateExitCall.

Return Type: void

StopExitCall

Complete the exit call

Format: `AgentSDK.StopExitCall(ExitCall <exitCall>)`

Parameters: `exitCall` – ExitCall type returned by CreateExitCall.

Return Type: void

AddErrorToTransaction

Register an error for the business transaction

Format: `AgentSDK. AddErrorToTransaction (<bt>, <name>, <message>, <errorCode>, <markBtAsError>)`

Parameters

- `bt` – BusinessTransaction for which AppDynamics creates a snapshot. Returned by StartBusinessTransaction.
- `name` – Name of Error.
- `message` – Error message.
- `errorCode` – Integer value of the error.
- `markBtAsError` – Boolean value to qualify the BusinessTransaction as an error. (optional. Default Value: false)

Return Type: void

AddErrorToExitCall

Register an error for the exit call

Format: `AgentSDK.AddErrorToExitCall(ExitCall <exitCall>, string <errorName>, string <errorMessage>, bool <markBtAsError>)`

Parameters

- `exitCall` – ExitCall on which the error should be registered.
- `errorName` – Name of Error
- `errorMessage` – Error message
- `markBtAsError` – Boolean value to qualify the ExitCall as an error.

Return Type: void

GetCorrelationHeader

Sets the AppDynamics correlation header at the upstream tier. The downstream tiers read this value to continue correlation. Example available below.

Format: `AgentSDK.GetCorrelationHeader(<exitCall>)`

Parameters: `exitCall` – Exit Call created for business transaction to downstream tier monitored by AppDynamics.

Return Type: string

.NET Agent for Linux

Related pages:

- .NET Core for Linux SDK
- Create an ASP.NET Core web app in Azure
- Overview of Application Monitoring
- Business Transactions

You use the AppDynamics .NET Agent for Linux to monitor the performance of .NET Core applications running on Linux OS.

The agent supports these features:

- ASP.NET MVC transactions. See Name MVC Transactions by Area, Controller, and Action.
- ASP.NET WebAPI transactions
- ASP.NET Razor Pages transactions
- HttpClient backend calls
- ADO.NET backend calls such as SqlClient, MySql, SQLite, and PostgreSQL
- EntityFramework
- Upstream and downstream correlation using HTTP
- Snapshot waterfall view with async support
- Redis exit calls
- Detects and monitors calls to an Oracle database

You can run the AppDynamics .NET Agent for Linux on microservice platforms, such as those based on Docker containers and Pivotal Cloud Foundry (PCF). See AppDynamics Pivotal Cloud Foundry and .NET Agent for Linux Advanced Configuration Options.

The .Net Agent for Linux is supported on AppDynamics Controller >= 4.4.1. See .NET Agent for Linux Supported Environments.

Install the .NET Agent for Linux

Related pages:

- .NET Agent for Linux
- Create an ASP.NET Core web app in Azure
- Overview of Application Monitoring
- Business Transactions

Getting Started

Before you begin, review these prerequisites:

1. Confirm you have access to a compatible Controller. See Agent and Controller Compatibility.
2. Confirm the connection settings to the Controller where your agent will report data:
    - If you use a SaaS Controller, AppDynamics sent you the Controller host in your Welcome Email. Use port 443 for HTTPS or port 80 for HTTP.
    - If you use an on-premises Controller, you supplied the host and port during installation.
3. Verify you have access to the machine where the application runs as a user account with privileges to install the agent software and restart the application.
4. Verify that the machine where the application runs can connect to the Controller. Proxies or firewalls on the network between the agent and Controller may require additional configuration.
5. Verify that the application environment meets the requirements on .NET Agent for Linux Supported Environments prior to running the agent.

Applications and Licenses Overview

Ensure you have these applications and licenses:

- .NET Core application running on Linux
- .NET license for each .NET Core application running on Linux. See License Management.

Binaries Overview

Download the agent binaries from the AppDynamics Download Site and then extract them from the zip file into the desired folder.

The archive contains these files:

- `AppDynamics.Agent.netstandard.dll`
- `libappdprofiler.so`
- `libappdprofiler_glibc.so`
- `libappdprofiler_musl.so`
- `README.md`

> You must extract all four of the agent binaries from the zip file.

Deployment

There are two options for starting your deployment using Docker:

- Create Your Own Image, start your agent from scratch
- Run an Existing Image, if you already have the .NET Agent enabled

Create Your Own Image

You can use the ASP.NET sample application from Microsoft and a Dockerfile to build your own image and get started:

1. Download the binaries.
2. Update the Dockerfile variables to configure the connection to the Controller and your application identity in AppDynamics.
3. Create the Docker image.

This is an example Dockerfile with commented instructions:

```
FROM mcr.microsoft.com/dotnet/core/samples:aspnetapp

####### Requirements
# Have the following files alongside the Dockerfile:
# * libappdprofiler.so
# * AppDynamics.Agent.netstandard.dll

####### Instructions
# Building image: docker build --rm -t appdynamicstest:latest .
# Running container: docker run --rm -p 8000:80 appdynamicstest:latest
# Open the application using http://localhost:8000/

# Copy agent binaries to the image from current folder
RUN mkdir -p /opt/appdynamics/dotnet
ADD libappdprofiler.so /opt/appdynamics/dotnet/
ADD libappdprofiler_glibc.so /opt/appdynamics/dotnet/
ADD libappdprofiler_musl.so /opt/appdynamics/dotnet/
ADD AppDynamics.Agent.netstandard.dll /opt/appdynamics/dotnet/

# Mandatory settings required to attach the agent to the .NET application
ENV CORECLR_PROFILER={57e1aa68-2229-41aa-9931-a6e93bbc64d8} \
    CORECLR_ENABLE_PROFILING=1 \
    CORECLR_PROFILER_PATH=/opt/appdynamics/dotnet/libappdprofiler.so

# Configure connection to the controller
ENV APPDYNAMICS_CONTROLLER_HOST_NAME=controller.saas.appdynamics.com
ENV APPDYNAMICS_CONTROLLER_PORT=443
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED=true
ENV APPDYNAMICS_AGENT_ACCOUNT_NAME=account-name
ENV APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=access-key

# Configure application identity in AppDynamics
ENV APPDYNAMICS_AGENT_APPLICATION_NAME="My Application"
ENV APPDYNAMICS_AGENT_TIER_NAME="Sample Tier"
ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME=true
ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX="Instance"

# It is possible to configure .NET agent using AppDynamicsConfig.json configuration file instead of environment
variables
# ADD AppDynamicsConfig.json /opt/appdynamics/dotnet/
```

Configuration with AppDynamicsConfig.json: If you are configuring your agent using environment variables with the json configuration file or only with the json configuration file, include the FULL_AGENT feature in the json file. Otherwise, the agent will not work. See the AppDynamicsConfig.json file example on .NET Agent for Linux Advanced Configuration Options.

```
,
  "feature": [
    "FULL_AGENT"
  ]
```

FULL_AGENT feature mode is automatically enabled when configuring the agent purely by environment variables.

On Alpine OS

Applications running on Alpine require an additional mandatory environment variable, `LD_LIBRARY_PATH`, such as `ENV LD_LIBRARY_PATH=/opt/appdynamics/dotnet`.

Run an Existing Image

You can run an existing image with an agent enabled. This is the simplest way to start because it does not require building a new image:

1. Download the aforementioned binaries.
2. Update the Docker command variables to configure the connection to the Controller and your application identity in AppDynamics.
3. Run the command in the desired folder where you extracted the agent binaries from the zip file.
   You can replace `$(pwd)` in the command with this folder.

This example runs the sample application. It assumes you have AppDynamics binaries in the current directory:

Example command to run existing image with .NET agent enabled

```
docker run \
-p 8000:80 \
-e CORECLR_PROFILER={57e1aa68-2229-41aa-9931-a6e93bbc64d8} \
-e CORECLR_ENABLE_PROFILING=1 \
-e CORECLR_PROFILER_PATH=/opt/appdynamics/dotnet/libappdprofiler.so \
-e APPDYNAMICS_CONTROLLER_HOST_NAME=controller.saas.appdynamics.com \
-e APPDYNAMICS_CONTROLLER_PORT=443 \
-e APPDYNAMICS_CONTROLLER_SSL_ENABLED=true \
-e APPDYNAMICS_AGENT_ACCOUNT_NAME=account-name \
-e APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=access-key \
-e APPDYNAMICS_AGENT_APPLICATION_NAME="My Application" \
-e APPDYNAMICS_AGENT_TIER_NAME="Sample Tier" \
-e APPDYNAMICS_AGENT_REUSE_NODE_NAME=true \
-e APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX="Instance" \
-v "$(pwd)":/opt/appdynamics/dotnet/ \
mcr.microsoft.com/dotnet/core/samples:aspnetapp
```

On Alpine OS

Applications running on Alpine require an additional mandatory environment variable, `LD_LIBRARY_PATH`, such as `-e LD_LIBRARY_PATH=/opt/appdynamics/dotnet \`

The command mounts agent files as a volume and sets environment variables required for the agent to attach.

Startup Flow

During the application startup, the AppDynamics agent writes messages to the console as well as the application and .NET framework.

This .NET Agent startup console output indicates proper agent initialization:

```
appd.agent.profiler(Info): ...
```

See .NET Agent for Linux Troubleshooting.

.NET Agent for Linux Container Installation

You can install the .NET Agent for Linux in container environments, such as Docker and Kubernetes.

Overview of Container Installation

To learn more about installation AppDynamics agents in containers, see:

- Container Installation Options
- Configuring Agents in Kubernetes

Install the .NET Agent in Containers

To install the .NET Agent in containers, see:

- Prepare to Install the .NET Agent in Containers
- Install the .NET Agent in Containers

Prepare to Install the .NET Agent for Linux in Containers

Related pages:

- .NET Agent for Linux
- Install the .NET Agent for Linux in Containers
- Create an ASP.NET Core web app in Azure
- Overview of Application Monitoring
- Business Transactions

Before you install the .NET Agent for Linux in a container environment, make sure you meet the requirements and complete the steps listed on this page.

General Requirements

Verify that:

- The machine where the application runs can connect to the Controller. Proxies or firewalls on the network between the agent and Controller may require additional configuration.
- The application environment meets the requirements on .NET Agent for Linux Supported Environments prior to running the agent.

Ensure you have these applications and licenses:

- .NET Core application running on Linux
- .NET license for each .NET Core application running on Linux. See License Management in the Controller.

Controller Requirements

Confirm you meet the following Controller requirements:

- Access to a compatible Controller. See Agent and Controller Compatibility for details.
- Confirm the connection settings to the Controller where your agent reports data:
    - SaaS Controllers: AppDynamics sent you the Controller host in your Welcome Email. Use port 443 for HTTPS or port 80 for HTTP.
    - On-premises Controller: you supplied the host and port at install time.

.NET Agent Environment Variables

The `FULL_AGENT` environment variable is required to instrument the agent in a container environment. This variable is automatically enabled when configuring the .NET Agent by environment variables only.

However, if you configure your agent using environment variables along with the JSON configuration file, `AppDynamicsConfig.json`, or just with the JSON configuration file, you need to include the `FULL_AGENT` feature in the JSON file. For example:

```
{
  "feature": [
    "FULL_AGENT"
  ]
}
```

See the `AppDynamicsConfig.json` file example on .NET Agent for Linux Advanced Configuration Options for details.

Applications running in an Alpine Linux container require an additional mandatory environment variable, `LD_LIBRARY_PATH`, which can be defined in the Dockerfile as follows:

```
ENV LD_LIBRARY_PATH=/opt/appdynamics/dotnet
```

Install the .NET Agent for Linux in Containers

This page explains how to install the .NET Agent for Linux in a Docker or Kubernetes containerized environment. There are three ways to install the .NET Agent for Linux with containers:

- Use Auto-Instrumentation
- Use Init Containers
- Use a Dockerfile

Use Auto-Instrumentation

> This scenario applies to containers running in Kubernetes where the Cluster Agent is installed.

This option uses the Auto-Instrumentation feature of the Cluster Agent. It is the recommended option because it offers the highest level of automation and the simplest operational experience for instrumenting .NET applications in a Kubernetes cluster.

To get started, see Auto-Instrument Applications with the Cluster Agent.

Use Init Containers

> Init container installation requires a Kubernetes environment.

You can use Kubernetes init containers to instrument the .NET Agent. In this method, the init container copies the agent binaries into the application container at runtime. The deployment spec used by the application references two containers:

- Application container based on an image that does not contain any .NET Agent binaries
- Second init container based on an image that only contains the .NET Agent binaries.

The deployment spec is updated to reference these two containers and copy the agent binaries from the init container to the application container at deployment time. Once the copy is performed, the init container terminates.

To use init containers to copy the .NET Agent for Linux binaries, perform these steps:

1. Build the .NET Core Application Image
2. Build the .NET Agent for Linux Init Container Image
3. Add the Init Container to the Deployment Spec
4. Set the .NET Agent for Linux Environment Variables
5. Set the APPDYNAMICS_AGENT_UNIQUE_HOST_ID Environment Variable
6. Copy the AppDynamicsConfig.json File to the Container
7. (On-Premises Controller Only) Copy the Controller Certs to the Container
8. Example Configuration for Using an Init Container

Build the .NET Core Application Image

Build a .NET Core application image. Do not include the .NET Agent for Linux binaries.

Build the .NET Agent for Linux Init Container Image

Build the .NET Agent for Linux image separately from the application image. You can reuse this image across multiple .NET Core application deployments.

Alternatively, the init container can reference a pre-built image from AppDynamics on Docker Hub.

Add the Init Container to the Deployment Spec

Edit the deployment spec to add the required sections that allow you to copy the agent binaries from the init container to the application image.

The following snippet from a deployment spec shows the required `volumes`, `volumeMounts`, and `initContainer` definitions. The code example assumes the .NET Core application image is published to `dotnet-samples:aspnetapp` and the init container image uses the pre-built image `docker.io/appdynamics/dotnet-core-agent:<version>` (where `<version>` is the .NET Agent version; for example, 21.5.0):

```
kind: Deployment
spec:
  containers:
  - name: dotnet-app
    image: microsoft/dotnet-samples:aspnetapp
    volumeMounts:
    - mountPath: /opt/appdynamics
      name: appd-agent-repo
  initContainers:
  - name: appd-agent
        image: docker.io/appdynamics/dotnet-core-agent:<version>
    volumeMounts:
    - mountPath: /appdynamics
      name: appd-agent-repo
  volumes:
    - name: appd-agent-repo
      emptyDir: {}
```

Set the .NET Agent for Linux Environment Variables

To set all of the required .NET Agent environment variables, you must follow the steps in Best Practices to Configure Agents in Kubernetes listed below:

1. Use ConfigMaps to Configure the App Server Agent
2. Use Secrets for the Controller Access Key
3. Set Application-Specific Configuration in the Deployment Spec

Use ConfigMaps to Configure the App Server Agent

1. Use a ConfigMap to set the .NET Agent for Linux environment variables that are shared across applications in a namespace:

   ```
   apiVersion: v1
   data:
     CORECLR_PROFILER: "{57e1aa68-2229-41aa-9931-a6e93bbc64d8}"
     CORECLR_ENABLE_PROFILING: "1"
     CORECLR_PROFILER_PATH: "/opt/appdynamics/libappdprofiler.so"
     APPDYNAMICS_AGENT_APPLICATION_NAME: "<value>"
     APPDYNAMICS_AGENT_ACCOUNT_NAME: "<value>"
     APPDYNAMICS_CONTROLLER_HOST_NAME: "<value>"
     APPDYNAMICS_CONTROLLER_PORT: "<value>"
     APPDYNAMICS_CONTROLLER_SSL_ENABLED: "<value>"
     APPDYNAMICS_AGENT_REUSE_NODE_NAME: "true"
     APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX: "<value>"
     # variables required to send transaction analytics data
     APPDYNAMICS_ANALYTICS_HOST_NAME: "<value>"
     APPDYNAMICS_ANALYTICS_PORT: "<value>"
     APPDYNAMICS_ANALYTICS_SSL_ENABLED: "<value>"
   kind: ConfigMap
   metadata:
     name: appd-dotnet-config
   ```

   Note that the analytics host, port and ssl settings depend on how the Analytics Agent is deployed. See Deploy Analytics in Kubernetes for options.

2. (Optional) If you are running your .NET Core application in an Alpine Linux container, set `LD_LIBRARY_PATH` in the ConfigMap:

   ```
   apiVersion: v1
   data:
     CORECLR_PROFILER: "{57e1aa68-2229-41aa-9931-a6e93bbc64d8}"
     CORECLR_ENABLE_PROFILING: "1"
     CORECLR_PROFILER_PATH: "/opt/appdynamics/libappdprofiler.so"
     LD_LIBRARY_PATH: "/opt/appdynamics"
     ...
   kind: ConfigMap
   metadata:
     name: appd-dotnet-config
   ```

3. Apply the ConfigMap to the namespace:

```
kubectl -n dotnetapp apply -f appd-dotnet-config.yaml
```

4. Update the deployment spec to reference the `ConfigMap`:

```
spec:
  containers:
  - name: dotnet-app
    envFrom:
    - configMapRef:
      name: appd-dotnet-config
 ...
```

Use Secrets for the Controller Access Key

1. Create a Secret using `kubectl`:

```
kubectl -n dotnetapp create secret generic appd-agent-secret --from-literal=access-key=<access-key>
```

2. Update the deployment spec to reference the Secret:

```
spec:
  containers:
  - name: dotnet-app
    env:
    - name: APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY
      valueFrom:
      secretKeyRef:
        name: appd-agent-secret
        key: access-key
 ...
```

Set Application-Specific Configuration in the Deployment Spec

1. Set the application-specific tier name environment variable `APPDYNAMICS_AGENT_TIER_NAME` in the deployment spec:

```
spec:
  containers:
  - name: dotnet-app
    env:
    - name: APPDYNAMICS_AGENT_TIER_NAME
      value: dotnet-service
```

Set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` Environment Variable

The `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` environment variable is supported in version 20.7.0+ of the .NET Agent for Linux. For earlier versions, a property must be set in `AppDynamicsConfig.json` based on a runtime value. See this example deployment spec.

Set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` environment variable to enable APM correlation with the Cluster Agent. Since the value depends on a runtime value, set this environment variable in the container startup command using the values documented in Configure App Agents to Correlate with Cluster Agent. For example, for a Kubernetes environment with the Docker runtime, set the environment variable as shown (`export` is required):

```
kind: Deployment
spec:
  containers:
    image: microsoft/dotnet-samples:aspnetapp
    command: ["/bin/sh"]
    args: ["-c", "export APPDYNAMICS_AGENT_UNIQUE_HOST_ID=$(sed -rn '1s#.*/##; 1s/(.{12}).*/\\1/p' /proc/self
/cgroup) && dotnet aspnetapp.dll"]
...
```

Copy the AppDynamicsConfig.json File to the Container

Some .NET Agent for Linux options must be set in the `AppDynamicsConfig.json` file. This includes setting the `outputtype` to `console`, which facilitates sending the agent logs to log aggregation tools and viewing the logs using `kubectl logs`. When `AppDynamicsConfig.json` is required, the `FULL_AGENT` feature must be set to support the use of environment variables and the configuration file. See .NET Agent for Linux Advanced Configuration Options.

1. Create the `AppDynamicsConfig.json` file with the required configuration. For example:

   ```
   {
       "feature": [
           "FULL_AGENT"
       ],
       "log": [
           {
           "outputtype": "console"
           }
       ]
   }
   ```

2. Create a ConfigMap based on the contents of `AppDynamicsConfig.json`:

   ```
   $ kubectl -n dotnetapp create configmap appd-config --from-file=AppDynamicsConfig.json
   ```

3. Update the deployment spec to add the `AppDynamicsConfig.json` file to the container file system. Use `volumes` and `volumeMounts` that reference the ConfigMap contents:

   ```
   kind: Deployment
   spec:
     containers:
       image: microsoft/dotnet-samples:aspnetapp
       command: ["/bin/sh"]
       args: ["-c", "export APPDYNAMICS_AGENT_UNIQUE_HOST_ID=$(sed -rn '1s#.*/##; 1s/(.{12}).*/\\1/p' /proc
   /self/cgroup) && dotnet aspnetapp.dll"]
       volumeMounts:
       - name: appd-config
         subPath: AppDynamicsConfig.json
         mountPath: /opt/appdynamics/AppDynamicsConfig.json
     volumes:
       - name: appd-config
         configMap:
           name: appd-config
   ```

(On-Premises Controller Only) Copy the Controller Certs to the Container

If the .NET Agent for Linux communicates with an on-premises Controller, the Controller certs must be copied to the container. See Controller SSL and Certificates.

1. Define a ConfigMap to reference the cert file. Use a volume mount in the deployment spec to mount the ConfigMap contents to the container:

   ```
   $ kubectl create configmap appd-cert --from-file=cacerts
   ```

2. Add the cert file to the container file system using `volumes` and `volumeMounts` as shown in the deployment spec snippet:

```
kind: Deployment
spec:
  containers:
    image: microsoft/dotnet-samples:aspnetapp
    volumeMounts:
    - name: appd-cert
      subPath: cacerts
      mountPath: /opt/appdynamics/cacerts
  volumes:
    - name: appd-cert
      configMap:
        name: appd-cert
```

3. Set the `APPDYNAMICS_CONTROLLER_SSL_ENABLED` and `APPDYNAMICS_CONTROLLER_SSL_CERTFILE` environment variables in the ConfigMap. See .NET Agent for Linux Environment Variables.

```
apiVersion: v1
data:
  CORECLR_PROFILER: "{57e1aa68-2229-41aa-9931-a6e93bbc64d8}"
  CORECLR_ENABLE_PROFILING: "1"
  CORECLR_PROFILER_PATH: "/opt/appdynamics/libappdprofiler.so"
  APPDYNAMICS_CONTROLLER_SSL_ENABLED: true
  APPDYNAMICS_CONTROLLER_SSL_CERTFILE: /opt/appdynamics/cacerts
  ...
kind: ConfigMap
metadata:
  name: appd-dotnet-config
```

Example Configuration for Using an Init Container

This Dockerfile is an example of building the .NET Agent for Linux init container image using a multi-stage build. A complete example of a deployment spec that uses an init container to copy the agent binaries can be found on Github: dotnet-app.yaml.

Use a Dockerfile

This scenario applies to containers running in Docker and Kubernetes.

You can use a Dockerfile to copy the .NET Agent for Linux to the Docker image at build time. To use the option, create a single image that contains both the application and .NET Agent for Linux binaries.

To copy the agent into the application image during the Docker image build:

1. Download and Unzip the .NET Agent for Linux
2. Copy the Agent Binaries to the Image
3. Set the .NET Agent for Linux Environment Variables
4. Set the APPDYNAMICS_AGENT_UNIQUE_HOST_ID Environment Variable
5. Copy the AppDynamicsConfig.json File to the Image
6. (On-Premises Controller only) Copy the Controller Certs to the Image
7. Example Configuration for Using a Dockerfile

Download and Unzip the .NET Agent for Linux

Download the .NET Agent for Linux programmatically or from the downloads portal. The agent is packaged as a zip file. In a shell, unzip it to the `AppDynamics-DotNetCore-linux-x64` folder:

```
$ unzip AppDynamics-DotNetCore-linux-x64-<version>.zip -d AppDynamics-DotNetCore-linux-x64
```

Copy the Agent Binaries to the Image

Edit the Dockerfile to copy the unpackaged agent binaries to the target folder:

```
COPY AppDynamics-DotNetCore-linux-x64/ /opt/appdynamics/
```

Set the .NET Agent for Linux Environment Variables

If your application runs in a non-Kubernetes environment (for example, using `dockerrun`), set the agent environment variables in the Dockerfile. For example:

```
ENV CORECLR_PROFILER="{57e1aa68-2229-41aa-9931-a6e93bbc64d8}"
ENV CORECLR_ENABLE_PROFILING=1
ENV CORECLR_PROFILER_PATH="/opt/appdynamics/libappdprofiler.so"
ENV APPDYNAMICS_AGENT_APPLICATION_NAME=<value>
ENV APPDYNAMICS_AGENT_TIER_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=<value>
ENV APPDYNAMICS_CONTROLLER_HOST_NAME=<value>
ENV APPDYNAMICS_CONTROLLER_PORT=<value>
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED=<value>
ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME=true
ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX=<value>
# variables required to send transaction analytics data
ENV APPDYNAMICS_ANALYTICS_HOST_NAME=<value>
ENV APPDYNAMICS_ANALYTICS_PORT=<value>
ENV APPDYNAMICS_ANALYTICS_SSL_ENABLED=<value>
```

For Kubernetes applications, omit these environment variables from the Dockerfile and set them using ConfigMaps and Secrets.

The reuse node name and prefix environment variables are required to support unique node naming for multiple container instances for the same application image. See .NET Agent for Linux Environment Variables. The analytics host, port and ssl settings depend on how the Analytics Agent is deployed. See Deploy Analytics in Kubernetes for options.

If you are running your .NET Core application in an Alpine Linux container, set `LD_LIBRARY_PATH` to the location of the agent binaries. For a Docker application, set `LD_LIBRARY_PATH` in the Dockerfile:

```
ENV CORECLR_PROFILER="{57e1aa68-2229-41aa-9931-a6e93bbc64d8}"
ENV CORECLR_ENABLE_PROFILING=1
ENV CORECLR_PROFILER_PATH="/opt/appdynamics/libappdprofiler.so"
ENV LD_LIBRARY_PATH="/opt/appdynamics"
...
```

For a Kubernetes application, set LD_LIBRARY_PATH in the ConfigMap.

Set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` Environment Variable

> The `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` environment variable is supported in version 20.7.0+ of the .NET Agent for Linux. For earlier version, a property must be set in `AppDynamicsConfig.json` based on a runtime value. This must be performed in the container startup script.

For Kubernetes applications, set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` environment variable to enable APM correlation with the Cluster Agent. Since the value depends on a runtime value, set this environment variable in the container startup command using the values documented in Manually Configure App Agents to Correlate with the Cluster Agent. For example, for a Kubernetes environment with a Docker runtime, set the environment variable as shown (`export` is required):

```
kind: Deployment
spec:
  containers:
    image: microsoft/dotnet-samples:aspnetapp
    command: ["/bin/sh"]
    args: ["-c", "export APPDYNAMICS_AGENT_UNIQUE_HOST_ID=$(sed -rn '1s#.*/##; 1s/(.{12}).*/\\1/p' /proc/self
/cgroup) && dotnet aspnetapp.dll"]
...
```

Copy the AppDynamicsConfig.json File to the Image

Some .NET Agent for Linux options must be set in the `AppDynamicsConfig.json` file. This includes setting the `outputtype` to `console`, which facilitates sending the agent logs to log aggregation tools. When `AppDynamicsConfig.json` is required, the `FULL_AGENT` feature must be set to support the use of environment variables and the configuration file. See .NET Agent for Linux Advanced Configuration Options.

1. Create the `AppDynamicsConfig.json` file with the required configuration. For example:

```
{
    "feature": [
        "FULL_AGENT"
    ],
    "log": [
        {
        "outputtype": "console"
        }
    ]
}
```

2. Edit the Dockerfile to copy `AppDynamicsConfig.json` to the image:

```
COPY ./AppDynamicsConfig.json /opt/appdynamics/AppDynamicsConfig.json
```

(On-Premises Controller only) Copy the Controller Certs to the Image

For .NET Agent for Linux agents communicating with an on-premises Controller, the Controller certs must be copied to the image. See Controller SSL and Certificates.

1. Edit the Dockerfile to copy the file containing the on-premises certs to the image. For example:

```
COPY ./onprem-cacerts /opt/appdynamics/conf/cacerts
```

2. Set the `APPDYNAMICS_CONTROLLER_SSL_ENABLED` and `APPDYNAMICS_CONTROLLER_SSL_CERTFILE` environment variables. See .NET Agent for Linux Environment Variables. For a Docker application, set these environment variables in the Dockerfile:

```
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED="true"
ENV APPDYNAMICS_CONTROLLER_SSL_CERTFILE="/opt/appdynamics/cacerts"
```

   For a Kubernetes application, set these environment variables in the ConfigMap.

Example Configuration for Using a Dockerfile

This Dockerfile builds a single image with the application and agent binaries included and this Kubernetes deployment spec references that Docker image.

.NET Agent for Linux Supported Environments

Supported Environments

The AppDynamics .NET Agent for Linux is supported on these environments:

Operating Systems

- CentOS 7+
- Red Hat Enterprise Linux 7
- Debian 9+
- Ubuntu 14+
- Alpine 3.11+

.NET Versions

- .NET Core 2.0, 2.1, 3.0, and 3.1
- .NET 5.0

ASP.NET Core

- MVC
- Razor
- WebAPI

Backend Calls

- HttpClient backend calls
- ADO.NET backend calls (SqlClient, MySql, SQLite, PostgreSQL)
- EntityFramework
- Redis
- Oracle
- MongoDB
- RabbitMQ

Application Environment

- Applications running in a container (needs to match OS)
- Applications running on a host/VM (needs to match OS)

AppDynamics Controller >= 4.4.1

The ability to customize Business Transaction detection is supported by .NET Agent for Linux 4.5.9 and requires Controller >= 4.5.2. The .NET Agent 4.5.9 works with Controller >= 4.4.1, however the customizable transaction detection and configuration capabilities require >= 4.5.2.

Current Version Limitations

EUM for .NET Core on Linux is currently not supported.

These locations in the Controller do not support the .NET Agent for Linux. Their panes appear empty in such cases:

- Node memory
- Tier IIS AppPools
- Tier network dashboard

.NET Core 3.0 Limitations

.NET Agent >= 4.5.16 supports .NET Core 3.0 with limitations. These items are not supported:

- Partial snapshots do not include callgraph support
- Callgraph granularity
- Snapshot configuration using node properties
- .NET Core 3.0 assembly linking
- .NET Core 3.0 assembly unloadability

.NET Agent for Linux Environment Variables

Related pages:

- .NET Agent Configuration Properties
- Administer the .NET Agent
- Configure the .NET Agent
- Name .NET Tiers

This is a reference page for the configuration properties for the .NET Agent for Linux that you can set using system environment variables.

Agent Account Name

Specifies the account name for the SaaS or multi-tenant Controller.

Environment Variable: `APPDYNAMICS_AGENT_ACCOUNT_NAME`
Type: String
Default: For single-tenant Controllers, the agent assumes the default of `customer1` if you do not specify an account name.
Required: Only for SaaS or multi-tenant Controllers.

Agent Application Name

Specifies the business application you use in the Controller. If the application name does not exist, the Controller will create it when the agent registers. See Overview of Application Monitoring.

Environment Variable: `APPDYNAMICS_AGENT_APPLICATION_NAME`
Type: String
Default: None
Required: Yes

Agent Account Password

Specifies the account access key for the Controller.

Environment Variable: `APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY`
Type: String
Default: None
Required: Yes

Agent Node Name

The name of the node.

In general, the node name must be unique within the business application and physical host. To use the same node name for multiple nodes on the same physical machine, create multiple virtual hosts using the Unique Host ID property. See Unique Host ID.

Environment Variable: `APPDYNAMICS_AGENT_NODE_NAME`
Type: String
Default: None
Required: Yes

Agent Reuse Node Name

Set this environment variable to true to reuse node names in AppDynamics. When you set the property to true, you don't need to supply a node name, but you do need to provide a node name prefix using `APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX`.

This property is useful for monitoring environments where there are many CLRs with short life spans. When true, AppDynamics reuses the node names of historical CLRs for new CLRs. Reusing node names avoids a proliferation of differently named nodes in AppDynamics over time, particularly when the nodes are essentially identical processes that run over different times.

AppDynamics generates a node name with App, Tier, and Sequence number. The node names are pooled. For example, the sequence numbers are reused when the nodes are purged (based on the node lifetime).

When the .NET Agent for Linux starts up, it logs output to the console until it registers with the Controller and the Controller generates the node name.

The Controller reuses node names based on the `node.retention.period` property. See Historical and Disconnected Nodes.

Environment Variable: `APPDYNAMICS_AGENT_REUSE_NODE_NAME`
Type: Boolean
Default: False
Required: No

Example: Using the following environmental variable specifications, the Controller generates a node name with the prefix `reportGen`. Node names will have suffixes `--1`, `--2`, and so on, depending on the number of nodes are running in parallel. The name of a node that is shut down and qualifies as a historical node may be reused by a new node.

```
APPDYNAMICS_AGENT_REUSE_NODE_NAME=true

APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX=reportGen
```

Agent Reuse Node Name Prefix

When you configure the agent to reuse node names, use this property to specify the prefix the Controller uses to generate node names dynamically.

Environment Variable: `APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX`
Type: String
Default: None
Required: When `APPDYNAMICS_AGENT_REUSE_NODE_NAME=true`
Example: Using the following environmental variable specifications, the agent directs the Controller to generate a node name with the prefix `reportGen`. Node names will have suffixes `--1`, `--2`, and so on, depending on how many nodes are running in parallel.

```
APPDYNAMICS_AGENT_REUSE_NODE_NAME=true

APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX=reportGen
```

Agent Tier Name

Specifies the name of the tier that this .NET node belongs to. Note that this is not the deployment name on the application server.

Environment Variable: `APPDYNAMICS_AGENT_TIER_NAME`
Type: String
Default: None

Required: Yes

Analytics SSL Enabled

Specifies whether or not the .NET Agent for Linux sends the default transaction data to the Analytics Agent via SSL.

Environment Variable: `APPDYNAMICS_ANALYTICS_SSL_ENABLED`
Type: String
Default: False
Required: No

Analytics Hostname

Specifies the hostname or IP address of the analytics host.

Environment Variable: `APPDYNAMICS_ANALYTICS_HOST_NAME`
Type: String
Default: None
Required: No

Analytics Port

Specifies the port number of the analytics port.

Environment Variable: `APPDYNAMICS_ANALYTICS_PORT`
Type: Positive integer
Default: None
Required: No

Controller Hostname

Specifies the hostname or the IP address of the AppDynamics Controller. For an on-premises Controller, use the value for Application Server Host Name you provided when you installed the Controller. If you use the AppDynamics SaaS Controller, see the Welcome email from AppDynamics for the name of your Controller.

Environment Variable: `APPDYNAMICS_CONTROLLER_HOST_NAME`
Type: String
Default: None
Required: Yes, may also be set in the agent `AppDynamicsConfig.json` file as `"host"`.

Controller Port Number

Specifies the HTTP(S) port of the AppDynamics Controller. If the `APPDYNAMICS.CONTROLLER.SSL.ENABLED` environment variable is set to `true`, specify the HTTPS port of the Controller; otherwise, specify the HTTP port.

Environment Variable: `APPDYNAMICS_CONTROLLER_PORT`
Type: Positive Integer
Default: `8090`

- For On-premises installations, the defaults are port `8090` for HTTP and port `8181` for HTTPS.
- For the SaaS Controller, use port `80` for HTTP or port `443` for HTTPS.

Required: Yes, may also be set in the agent AppDynamicsConfig.json file as `"port"`.

Controller SSL Enabled

When set to `true` enables encryption over SSL between the agent and the Controller.

Environment Variable: `APPDYNAMICS_CONTROLLER_SSL_ENABLED`
Type: Boolean
Default: false

Required: No, may also be set in the agent `AppDynamicsConfig.json` file as `"ssl"`.

Controller SSL Certfile

The path to the folder containing certificate files used to connect to the SSL-enabled Controller.

Environment Variable: `APPDYNAMICS_CONTROLLER_SSL_CERTFILE`
Type: String
Default: None

Required: No. Optionally, you can set in the agent `AppDynamicsConfig.json` file as `"certfile"`.

Controller SSL Certdirectory

The path to the folder containing the certificate directory used to connect to the SSL-enabled Controller.

> Certificate directory values are valid only if you do not input certificate files (`APPDYNAMICS_CONTROLLER_SSL_CERTFILE`).

Environment Variable: `APPDYNAMICS_CONTROLLER_SSL_CERTDIR`
Type: String
Default: None

Required: No. Optionally, you can set in the agent `AppDynamicsConfig.json` file as `"certdir"`.

HTTP Proxy Host

The name of the proxy host.

Environment Variable: APPDYNAMICS_PROXY_HOST_NAME
Type: String
Default: None

Required: No, may also be set in the agent `AppDynamicsConfig.json` file in the `"proxy"` section.

HTTP Proxy Port

The port number of the proxy.

Environment Variable: APPDYNAMICS_PROXY_PORT
Type: Positive integer
Default: None

Required: No, may also be set in the agent `AppDynamicsConfig.json` file in the `"proxy"` section.

HTTP Proxy User

The name of the user that connects to the proxy.

Environment Variable: APPDYNAMICS_PROXY_AUTH_USER
Type: String
Default: None

Required: No, may also be set in the agent `AppDynamicsConfig.json` file in the `"proxy"` section.

HTTP Proxy Password

The password of the user that connects to the proxy.

Environment Variable: APPDYNAMICS_PROXY_AUTH_PASSWORD
Type: String
Default: None

Required: No, may also be set in the agent `AppDynamicsConfig.json` file in the `"proxy"` section.

Sample Agent Configuration File

The following environment variables can be set in the `AppDynamicsConfig.json` file:

- `APPDYNAMICS_CONTROLLER_HOST_NAME`
- `APPDYNAMICS_CONTROLLER_PORT`
- `APPDYNAMICS_CONTROLLER_SSL_ENABLED`
- `APPDYNAMICS_CONTROLLER_SSL_CERTFILE`
- `APPDYNAMICS_CONTROLLER_SSL_CERTDIR`

The example file below demonstrates how to set these variables:

```
"controller":
{
   "host": "ControllerHost",
    "port": 8181,
     "account": "customer1",
      "password": "test",
       "ssl": true,
       "certdir": "/opt/appdynamics/dotnet/conf/",
       "certfile": "/opt/appdynamics/dotnet/conf/cacerts.pem",
        "enable_tls12": true,
        "proxy":
                {
                        "host" : "proxy",
                        "port" :900,
                        "authentication" :
                        {
                                "username" : "user",
                                "domain"  : "domainname",
                                "password" :"pwd"
                        }
                }
}
```

Configure Analytics for .NET Agent for Linux

Related pages:

- Analytics
- .NET Agent for Linux Environment Variables

AppDynamics Application Analytics enables you to do real-time analysis of business performance that is correlated with the performance of your application software.

Configure Analytics Settings

If you are configuring the .NET Agent for Linux to send the default transaction data to the Analytics Agent, add a setting for the analytics host and port using either environment variables or in the agent json configuration file, config.json.

Configure Analytics Settings via JSON

The following json syntax shows the analytics configuration settings:

```
"analytics: { "host": <analyticsHostName>, "port: <analyticsPort>, "ssl": <true || false> }"
```

Configure Analytics Settings via Environment Variables

The following are the environment variables that you can use to configure Analytics:

- APPDYNAMICS_ANALYTICS_SSL_ENABLED
- APPDYNAMICS_ANALYTICS_HOST_NAME
- APPDYNAMICS_ANALYTICS_PORT

See .NET Agent for Linux Environment Variables

.NET Agent for Linux Advanced Configuration Options

This page describes the advanced configuration properties for the AppDynamics .NET Agent for Linux you use to enable the .NET Agent to work without Docker. Before you start instrumenting your applications with the .NET Agent, you must use the current version of the .NET Core 2.0+. See .NET Agent Configuration Properties.

Agent Configuration File

The agent configuration file is similar to the one used to configure .NET Core Agent on Windows.

Once you have deployed the agent, you can customize the instrumentation of your application.

You can edit the `AppDynamicsConfig.json` file using this information:

```
{
  "controller": {
    "host": "controller.saas.appdynamics.com",
    "port": 443,
    "account": "account-name",
    "password": "access-key",
    "ssl": true
    "proxy" : {
        "host": "proxy-host",
        "port": 9090,
           "authentication": {
              "username": "proxy-user",
              "password": "proxy-password"
           }
      }
  },
  "application": {
    "name": "My Application",
    "tier": "Sample tier",
    "node": "Instance1",
        "reusenodename": "true",
        "nodenameprefix": "prefix"
  },
  "analytics": {
        "host": "localhost",
        "port": 9090
  },
  "feature": [
    "FULL_AGENT"
  ]
}
```

The .NET Agent for Linux supports reuse node name configuration to help manage monitoring environments where there are many CLRs with short life spans. The CLR node names are reused to avoid a proliferation of differently named nodes in AppDynamics. Include the `"reusenodename": "true"` configuration, with `"nodenameprefix": "prefix"` to enable reuse node name without having to supply a specific node name.

You can also use environment variables to configure reuse node name, such as `ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME=true` and `ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX=<prefix>`.

Configure Using AppDynamicsConfig.json: If you are configuring your agent using environment variables with the json configuration file, or just with the json configuration file, you must include the FULL_AGENT feature in the json file; otherwise, the agent will not work.

```
,
  "feature": [
    "FULL_AGENT"
  ]
```

FULL_AGENT feature mode is automatically enabled when configuring the agent just using environment variables.

.NET Agent for Linux does not support extended functionality, such as specifying instrumentors and allowlisting. Do not specify these if you copy the configuration from .NET Core Agent on Windows.

Configuration Options

You can enable the agent to work without Docker. However, you must ensure that the OS is supported by the current agent.

1. Make these files available to the application. They can be located next to the application files or in a separate folder:
    - `AppDynamics.Agent.netstandard.dll`
    - `libappdprofiler.so`
    - `libappdprofiler_musl.so`
    - `libappdprofiler_glibc.so`
2. Create these environment variables by adding them to your application:

Environment Variable Name	Value
CORECLR_PROFILER	{57e1aa68-2229-41aa-9931-a6e93bbc64d8}
CORECLR_ENABLE_PROFILING	1
CORECLR_PROFILER_PATH	Path to the `libappdprofilerdynamic` library. For example, `<application_folder_path>/libappdprofiler.so` See Using .NET Core for Linux SDK to determine the location of the `libappdprofiler.so` library.

   You can create environment variables on multiple levels so it is important that you set them in the context of the monitored application:
    - Environment variables are inherited from global host level.
    - Environment variables are parent process or service.
    - Environment variables are set prior to the start of the application using the shell script or similar.
3. Place the agent configuration file next to the appropriate binaries. There are two supported options:
    - Global agent configuration file - You can place the AppDynamicsConfig.json file next to the agent binaries. This method ensures that the default option to monitor each application configured is used for the agent.

      The .NET Agent for Linux does not support overriding node name in the agent configuration. Therefore, monitoring multiple applications on the same host using global configuration is not supported. Only the first application reports.

    - Local agent configuration - You can place the `[appname].AppDynamicsConfig.json` file next to the application binaries, where [app name] should match your application DLL/EXE name. Using this option, you can attach AppDynamics configuration to the application package and deploy it as a bundle. It is activated when you set the proper environment variables and the agent binaries are present.

      Local agent configuration has higher priority than global configuration.

Log Configuration Options

By default, you can use the boost log for both the profiler and the .NET Agent. Logging occurs even if no log file exists. By default, these three log files are created:

- Agent Log - Filename is `Agent_%N.log` and the default log level is `INFO`.
- Profiler Log - Filename is `Profiler_%N.log` and the default log level is `INFO`.
- Warn Log - Filename is `Warn_%N.log` and the default log level is `WARN`.

The log configuration is read during the profiler initialization. Before the log configuration is read, some logs are printed to the console.

This table describes the properties that you can configure in the log configuration file.

Log Property	Description	
`max_size`	Maximum total size of stored files, in bytes. Default value is 10485760 bytes (10 MB).	• Maximum capacity per logger is: `max_size * max_files`. • Rotation occurs when the file size reaches `max_size`. For example, if you configure the Agent log using the default values for `max_size` and `max_files`:

max_files	Maximum total number of stored files. Default value is 10.	• When a log file (Agent_0.log) reaches its max_size (10 MB), a new file named (Agent_1.log) is created. • Once it reaches the maximum number of files, the older file is deleted and a new file is created. The log directory is updated with a new set of files [Agent_1.log, Agent_2.log, ... Agent_9.log, Agent_10.log], Agent_0.log is deleted, and a new file named Agent_10.log is created. If the log directory contains the log files from a previous run, then the newly initiated agent creates a log file using an incremental value from the previous run. For example, If the previous run has two agent logs, Agent_0.log and Agent_1.log, then the newly initiated Agent creates Agent_3.log.
directory	The root directory. It accepts both relative and absolute path; however, no environment variable is accepted. Default value is %TEMP%/appd/dotnet.	
filename	The file name. By default, no process ID is included in the file name; however, you can include and configure the process ID in the filename (%P). For example, if you configure the filename as Log_%P_%N.log, then the filename appears as Log_1123_0.Log (where 1123 is the process ID). Default value is Agent_%N.log (where %N represents the incremental value starting from 0).	
exclude_tid	Determines whether to include the native thread ID in the log file. Default value is false.	
level	The minimum log level. Accepts these values: Trace, Debug, Info, Warn, Error, and Fatal. Default value is Info. These values are case-insensitive.	
channel	This field accepts: • Fully qualified class name. • Class name with wildcard (*) at the start, end, or at both the ends of the name. • Empty channel name, or .* or * These values are used as the default channel names.	

To incorporate any changes you made to the logging configuration, you must restart the application. The auto reload feature for logging configuration is not supported.

Log Content Example

This log example shows content for the Agent_0.log file:

Agent_0.log

```
2021-05-24 15:26:03.741862 2056 11672 3 INFO [com.appdynamics.LifetimeManager] Initializing via agent bootstrap
```

Whereas:

- 2021-05-24 15:26:03.741862 is the timestamp.
- 2056 is the process ID.
- 11672 is the native thread ID.
- 3 is the managed thread ID.
- INFO is the log level.
- com.appdynamics.LifetimeManager is the channel name.
- Initializing via agent bootstrap is the log content.

Log Structure

This log example contains two processes: 11120 and 76890. Based on the log configuration, each process has its own set of log files.

- If process 11120 is initiated first, then it may create Agent_0.log (for Agent logs) and Profiler_0.log (for Profiler logs).
- When process 76890 is initiated, then it may create Agent_1.log (for Agent logs) and Profiler_1.log (for Profiler logs).
- Whichever log file reaches its maximum size first, its next log file is created by adding an incremental number to the file name. Log ordering is not maintained and differs for each process.

Logs
Profiler_0.log Profiler_1.log Warn_0.log BusinessTransactionsLog_0.log .... Agent_0.log Agent_1.log Profiler_2.log .... Agent_2.log

Supported Features

This table describes the supported Boost log features:

Feature	Description
Log order rules	No rules are processed after a final rule matches. Rules are applied: • Based on the order of the logging configuration in the `AppDynamicsConfig.json` file. • When the log message channel name matches the channel name of the log configuration. • When the severity of the log message =< the level of the log configuration. ⓘ However, if the log is written using the first logger, and the channel name is matched using the second logger with a wildcard, the second logger will not write messages to log files.
`minlevel`	Minimal level to log.

Wildcard character (*)	• If the wildcard is in the middle of a word (for example, com.*.test), then it is used as the default channel name (*)
	• You can include a wildcard at:
	  • The beginning (for example, *.appdynamics.test
	  • The end (for example, com.appdynamics.*)
	  • Both the beginning and end (for example, *.appdynamics.*)

Log Order Rules Examples

For this log order rules example, there are N loggers: logger1, logger2 ... loggerN.

where loggerN depends on logger(N-1) ... logger1.
and logger(N-1) depends on logger(N-2) ...logger1, and so on.

1. The "`ByteCode`" log is part of the "`AgentLog`". As a result, no logging occurs through `ByteCode` logger.

```
{"filename" : "RESTHearbeat", "level" : "Info", "channel" : "com.appdynamics.REST.HeartBeatLog" },
{"filename" : "AgentLog", "level" : "Info", "channel" : "*" },
{"filename" : "ByteCode","level" : "Info","channel" : "com.appdynamics.bci.*" }
```

2. The "`RESTHeartbeat`" log is part of "`REST`". As a result, the "`RESTHeartbeat`" log is ignored.

```
{"filename" : "REST", "level" : "Info", "channel" : "com.appdynamics.REST.*" },
{"filename" : "RESTHeartbeat", "level" : "Info", "channel" : "com.appdynamics.REST.HeartBeatLog" }
```

3. Although "RESTHeartbeat" and "REST" log have the exact same channel name, only the `minLogLevel` of the first logger is considered. In this case, it is "Info".

```
{"filename" : "REST", "level" : "Info", "channel" : "com.appdynamics.REST.HeartBeatLog" },
{"filename" : "RESTHeartbeat", "level" : "Info", "channel" : "com.appdynamics.REST.HeartBeatLog" }
```

4. Channels not written through loggers "RESTHearbeat" and "ByteCode" are written through the "AgentLog" logger though the channel name with "com.appdynamics.bci.test" which matches both the ByteCode and AgentLog loggers.

```
{"filename" : "RESTHearbeat", "level" : "Info", "channel" : "com.appdynamics.REST.HeartBeatLog" },
{"filename" : "ByteCode", "level" : "Info", "channel" : "com.appdynamics.bci.*" },
{"filename" : "AgentLog","level" : "Info","channel" : ".*" }
```

Log Configuration Examples

This example shows how to set logging configuration. Each log file can have its own set of configurations.

AppDynamicsConfig.json

```
{
  "controller": {
    "host": "......"
  },
  "application": {
    "name": "..."
  },
  "log": [
    {
      "filename": "WarnLog",
      "level": "WARN",
      "channel": "*"
    },
    {
      "filename": "Profiler",
      "level": "INFO",
      "directory": "/temp/appd/logs",
      "channel": "appd.agent.Profiler"
    },
    {
      "filename": "BusinessTransactionsLog",
      "level": "INFO",
      "channel": "com.appdynamics.BusinessTransactions"
    },
    {
      "filename": "RESTHearbeat",
      "level": "INFO",
      "channel": "com.appdynamics.REST.HeartBeatLog"
    },
    {
      "filename": "ByteCode",
      "level": "INFO",
      "channel": "com.appdynamics.bci.*"
    },
    {
      "filename": "RESTCommunications",
      "level": "INFO",
      "channel": "com.appdynamics.REST.*"
    },
    {
      "filename": "RESTCommunications",
      "level": "INFO",
      "channel": "com.appdynamics.METRICS.MetricSender"
    },
    {
      "filename": "SamplingTrace",
      "level": "TRACE",
      "channel": "com.appdynamics.ManagedAgentAPI.DumpStats"
    },
    {
      "filename": "Analytics",
      "level": "INFO",
      "channel": "com.appdynamics.ee.service.analytics.Analytics",
      "max_size": 31457280,
      "max_files": 2,
      "directory": "./logs",
      "exclude_tid": false
    },
    {
      "filename": "Agent",
      "level": "INFO",
      "channel": "*"
    }
  ]
}
```

This example shows multiple log entries for the same file (both the directory and filename have the same value). The file log configuration uses the first entry, and all subsequent configuration for `max_size`, `max_files` and `exclude_tid` is ignored.

AppDynamicsConfig.json

```
{
     "filename": "agent",
     "level": "TRACE",
     "max_size":1000,
     "max_files":2,
     "channel": "com.appdynamics.METRICS.MetricSender"
    },
    {
     "filename": "agent",
     "level": "DEBUG",
     "max_size":2000,
     "max_files":2,
     "channel": "com.appdynamics.METRICS.*"
    },
    {
     "filename": "agent",
     "level": "INFO",
     "max_size":3000,
     "max_files":1,
     "channel": "com.appdynamics.*"
    }
}
```

Enable Preview Features

Preview features have been thoroughly tested inhouse at AppDynamics but because of the wide variety of possible use cases, AppDynamics releases these features for you to test and use at your discretion. We do not recommend that you use preview features in a production environment.

Enable Preview Features

To use features released under the preview feature flag, you must first enable them.

There are two ways to turn on the preview feature flag:

- Add the flag `PREVIEW_FEATURE` in the feature section of the `AppDynamicsConfig.json` file. For example:

  ```
  "feature": [ "FULL_AGENT", "PREVIEW_FEATURE" ],
  ```

- Define the environment variable `APPDYNAMICS_PREVIEW_FEATURE_ENABLED` as `true`.

Enabling Preview Features enables HTTP Custom Discovery Rules for the .NET Agent for Linux.

.NET Agent for Linux Troubleshooting

This page describes general techniques when troubleshooting the AppDynamics .NET Agent for Linux deployment problems, and provides a few specific scenarios you may encounter with workarounds.

Agent Startup Situations

The agent startup is dependent on three basic steps:

1. .NET Core loads the agent using profiler settings in the environment variables.
2. AppDynamics agent loads the configuration and additional library.
3. AppDynamics agent registers on the Controller using connection details found in the configuration file.

The sample startup console output on .NET Agent for Linux indicates a successful startup when going through these steps.

The following situations may occur:

Symptom	Probable root causes
No console output from AppDynamics was written to the console	• Environment variables were not set correctly • Agent binaries do not match the OS version
Agent complains about failing to load the configuration file	`AppDynamicsConfig.json` or `[appname].AppDynamicsConfig.json` were not found in the corresponding folders.
Agent complains about HTTP errors	Agent failed to communicate to the Controller using connection settings provided in the configuration file.

Accessing Logs While Running Docker Container in the Background

The default agent configuration redirects all agent output to the console. This is enabled for troubleshooting purposes.

If you are running the container in the background—-d for detach—it is possible to access all output using the following Docker command:

```
docker logs <container id>
```

Default Agent Log Files Location

The agent log files location is at `/tmp/appd/dotnet` by default.

You can change this setting to redirect all logs to the console output for a single view troubleshooting by adding the following configuration to the `AppDynamicsConfig.json` file as follows:

```
"log": [
   {
     "outputtype": "console"
   }
 ]
```

.NET Agent for Linux Business Transaction Configuration

Related pages:

- .NET Agent for Linux
- Overview of Application Monitoring
- Business Transactions
- ASP.NET Entry Points
- POCO Entry Points
- Custom Match Rules

As of 4.5.9, you can configure simple POCO or ASP.NET business transactions for the .NET Agent for Linux through the Controller UI.

The .NET Agent for Linux 4.5.9 works with Controller >= 4.4.1, but the customizable transaction detection and configuration capabilities require Controller >= 4.5.2. For Controller 4.4.2 - 4.5.1, and the .NET Agent for Linux, AppDynamics defaults to using the first two segments of the URI for ASP.NET business transaction naming.

Define Custom ASP.NET Business Transactions Using the Controller UI

You can create ASP.NET business transactions detection include and exclude rules with criteria that match HTTP Requests against:

Transaction splitting is supported for the HTTP request criteria.

- Method
- URI
- HTTP parameter
- Header
- Cookie

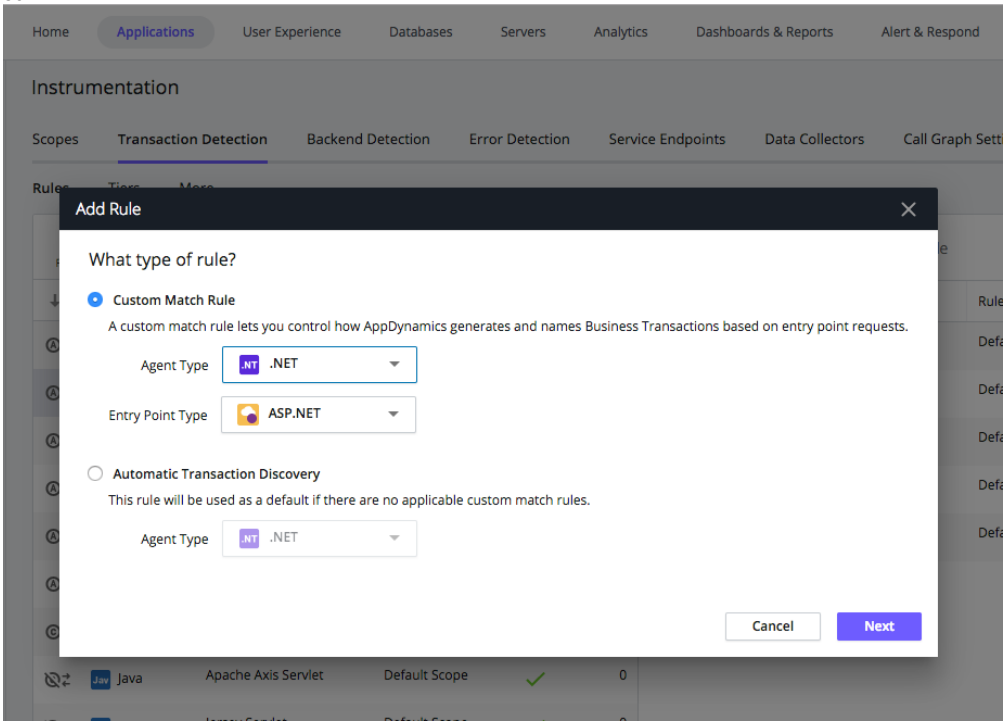
Although these HTTP request options display in the dropdown list, they are not supported by the .NET Agent for Linux. There is no effect if you configure them in the UI.

- Hostname
- Port
- Class name

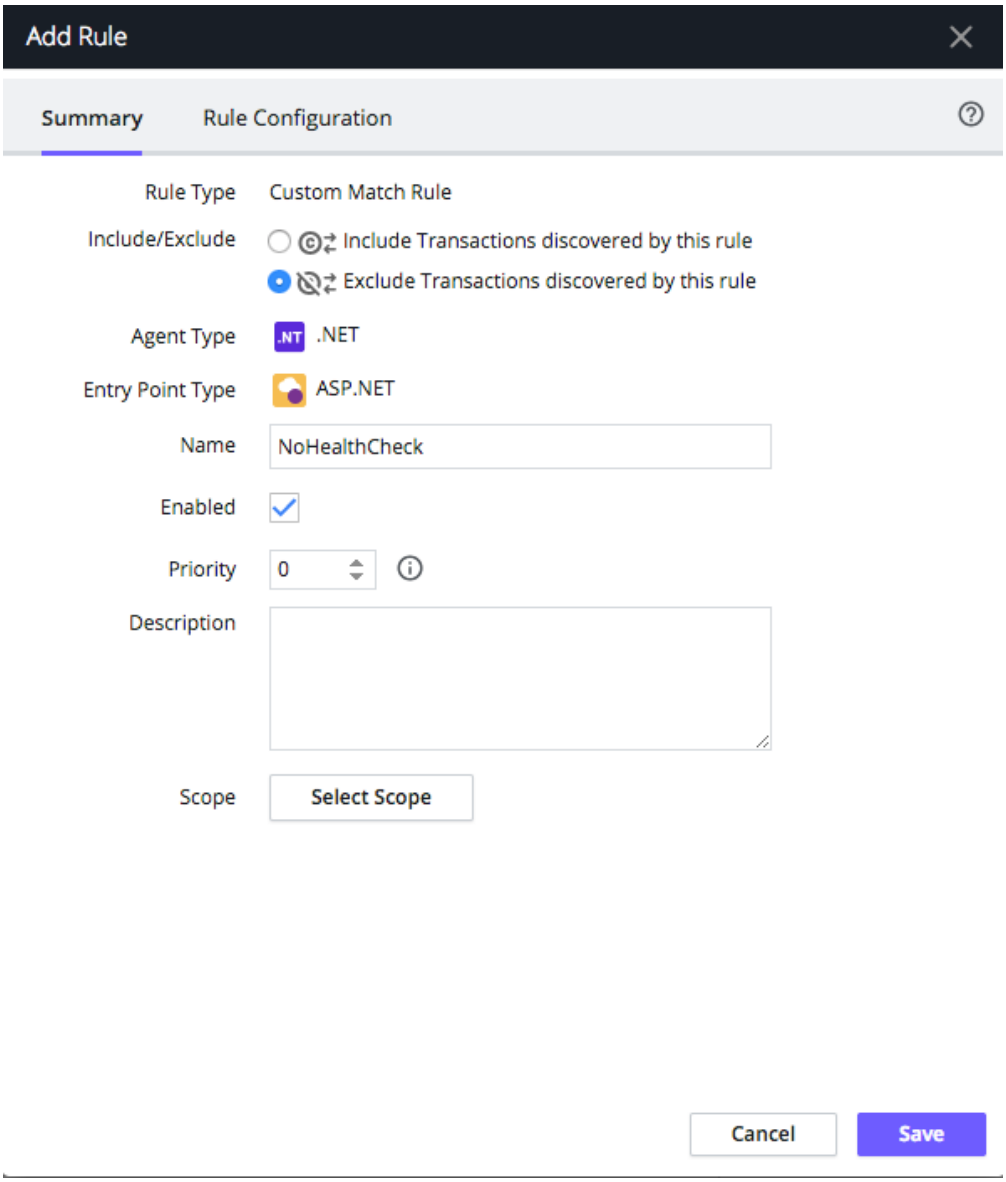
You customize business transactions for the .NET Agent for Linux similarly as other agents. Click **Configure > Instrumentation > Add Rule** and then select to create either an include or exclude rule.

ASP.NET Business Transaction Detection Rule Example

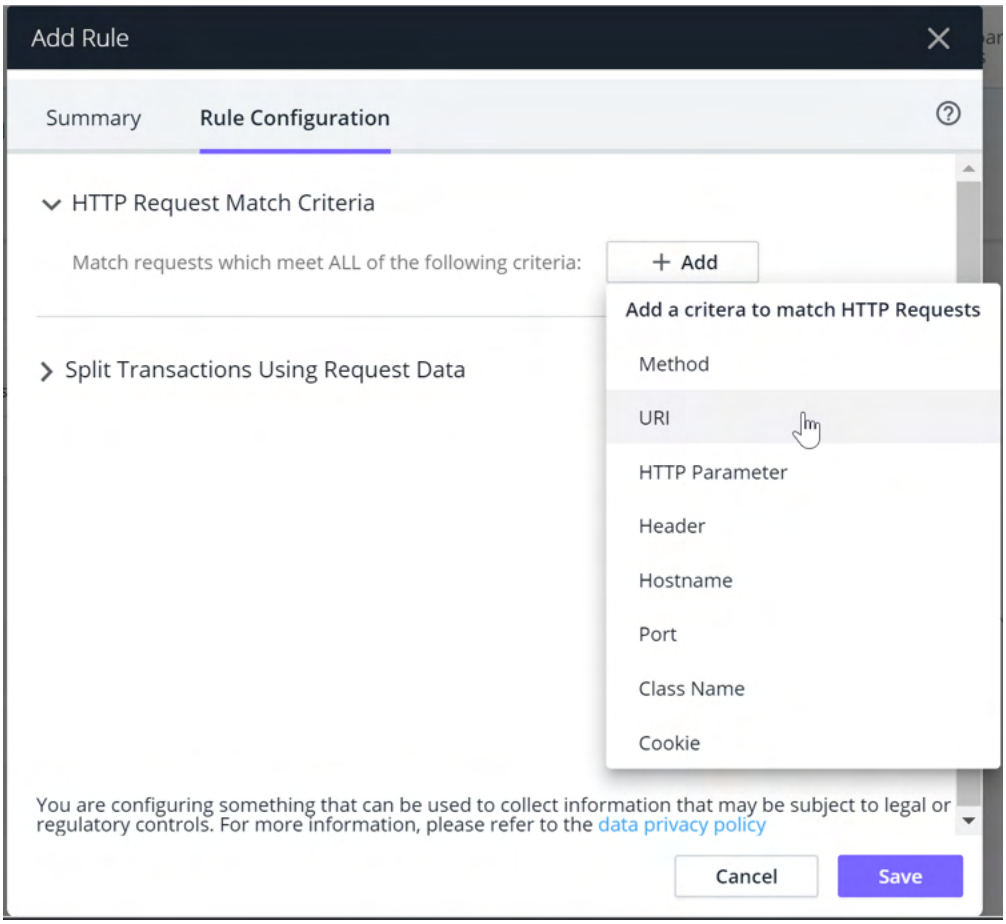
This example shows how to create a .NET Agent custom match rule that uses an ASP.NET entry point to exclude all requests whose URI equals `/healthcheck`.



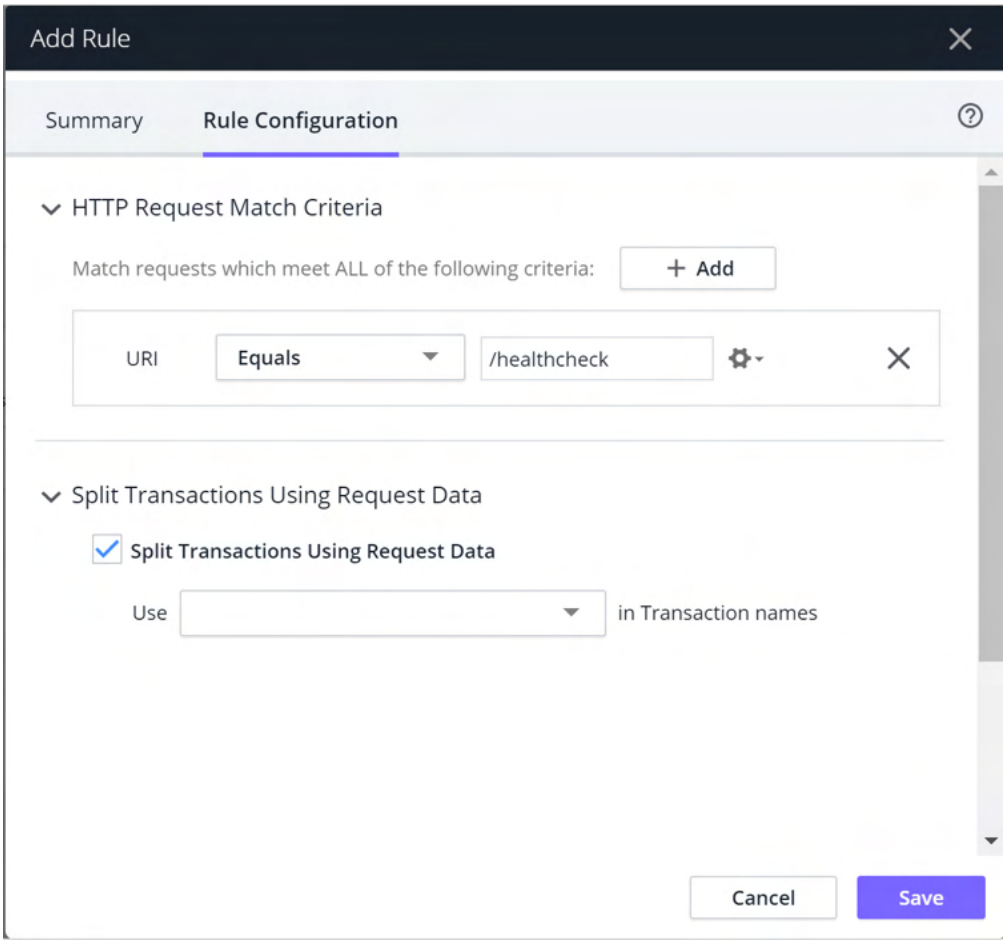
This Rule Summary specifies an *exclude* match rule. You must create an *include* rule before you can create an *exclude* rule to omit some of the transactions monitored by the include rule.



You specify the HTTP request criteria by using the URI attribute of the HTTP request to compare against. Valid criteria are **Method**, **URI**, **HTTP Parameter**, **Header**, and **Cookie**. You can split the transactions based on these request match criteria.



This HTTP request match criteria specifies where the URI equals ***/healthcheck***.



Define Custom POCO Business Transactions Using the Controller UI

Using the .NET Agent for Linux, you can create POCO business transaction rules that match synchronous or asynchronous transactions by:

- Method name
- Class name

Although these Match Classes options display in the dropdown list, they are not supported. However, there is no effect if you configure them in the UI:

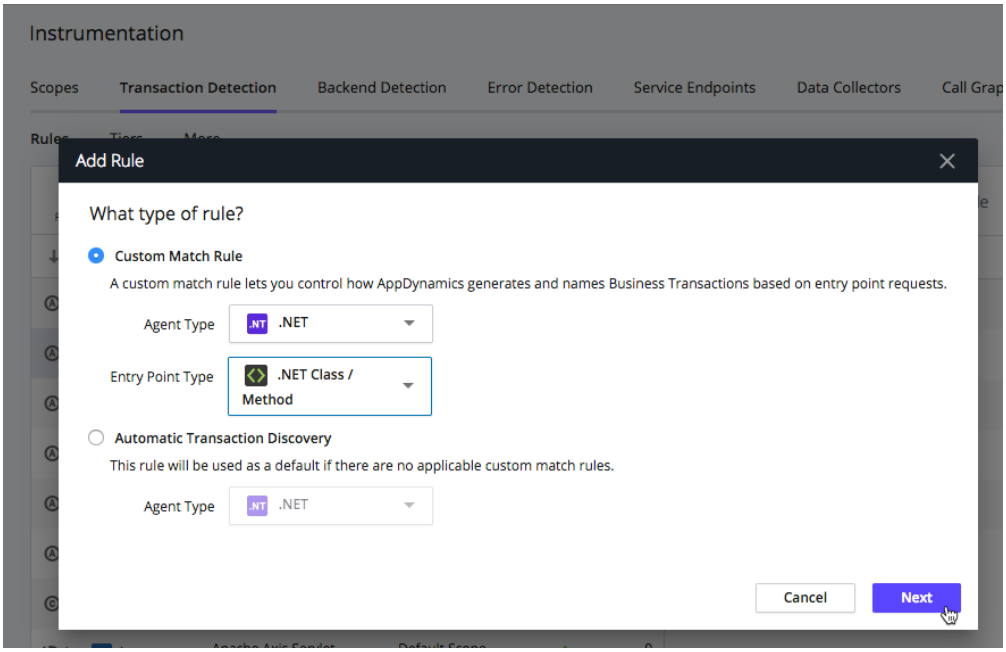
- that implements an interface which
- that extends a super class that
- that has an Annotation which

Additionally, these criteria are not supported:

- Transaction splitting using method/class data
- Background jobs
- Interface, base class or annotation POCO conditions

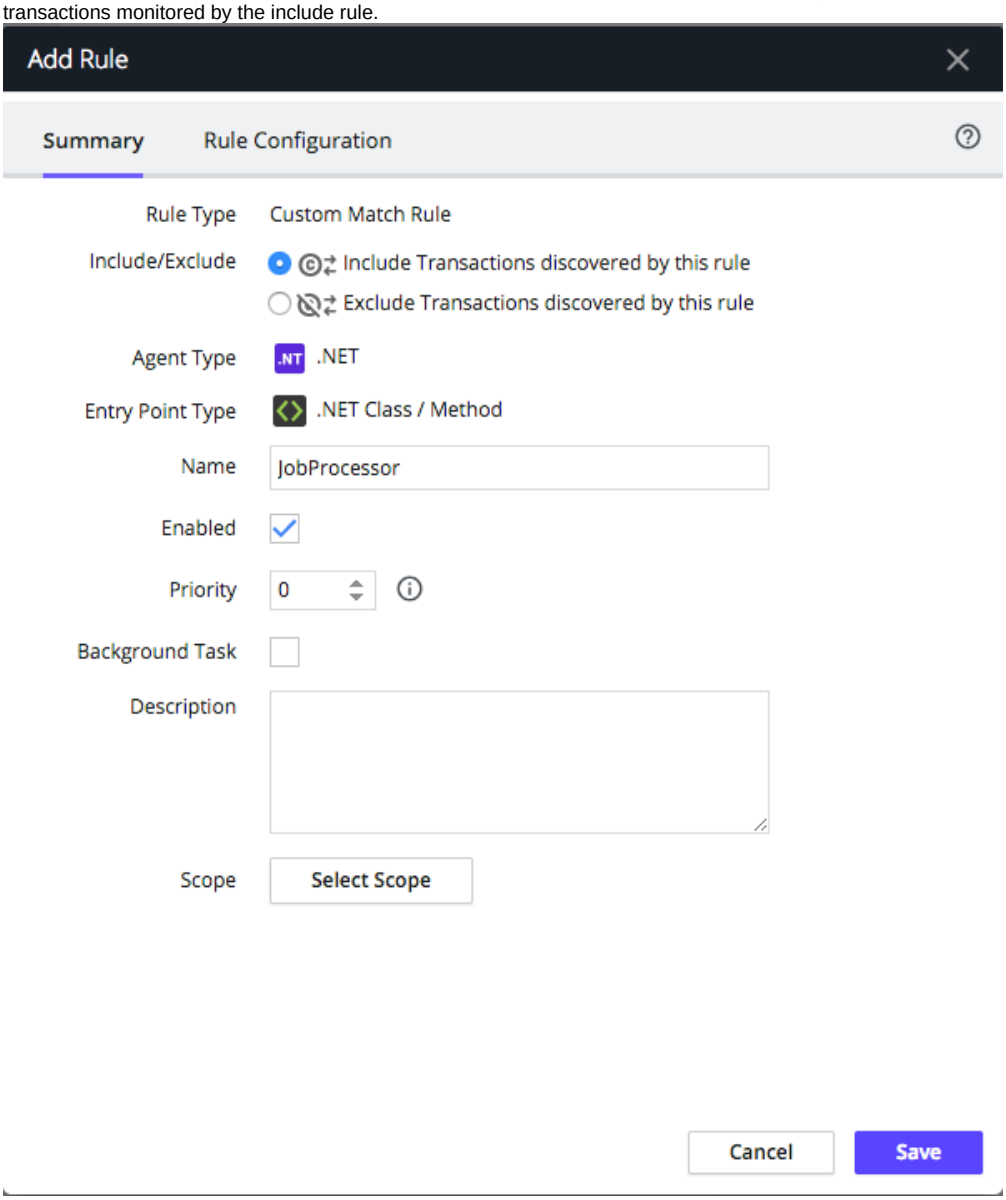
Example POCO Business Transaction Detection Rule Example

This example shows how to create a .NET Agent custom match rule that uses a POCO entry point to include all requests whose class equals `MyCompanyJobs.JobProcessor` and the method name equals `OnEvent`.

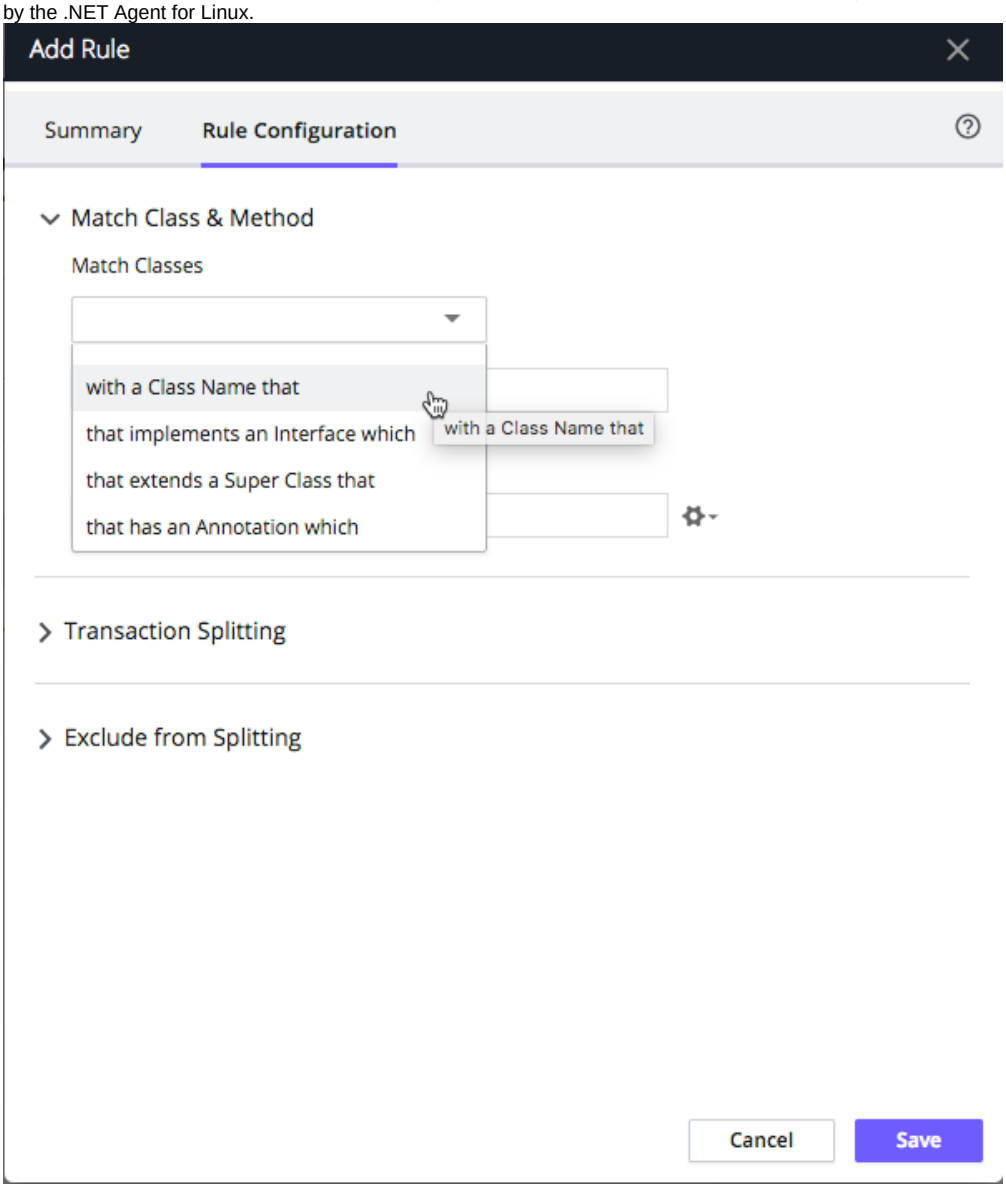


Instrumentation
Scopes
Transaction Detection
Backend Detection
Error Detection
Service Endpoints
Data Collectors
Call Grap
Rules
Add Rule
What type of rule?
Custom Match Rule
A custom match rule lets you control how AppDynamics generates and names Business Transactions based on entry point requests.
Agent Type
.NET
Entry Point Type
.NET Class / Method
Automatic Transaction Discovery
This rule will be used as a default if there are no applicable custom match rules.
Agent Type
.NET
Cancel
Next

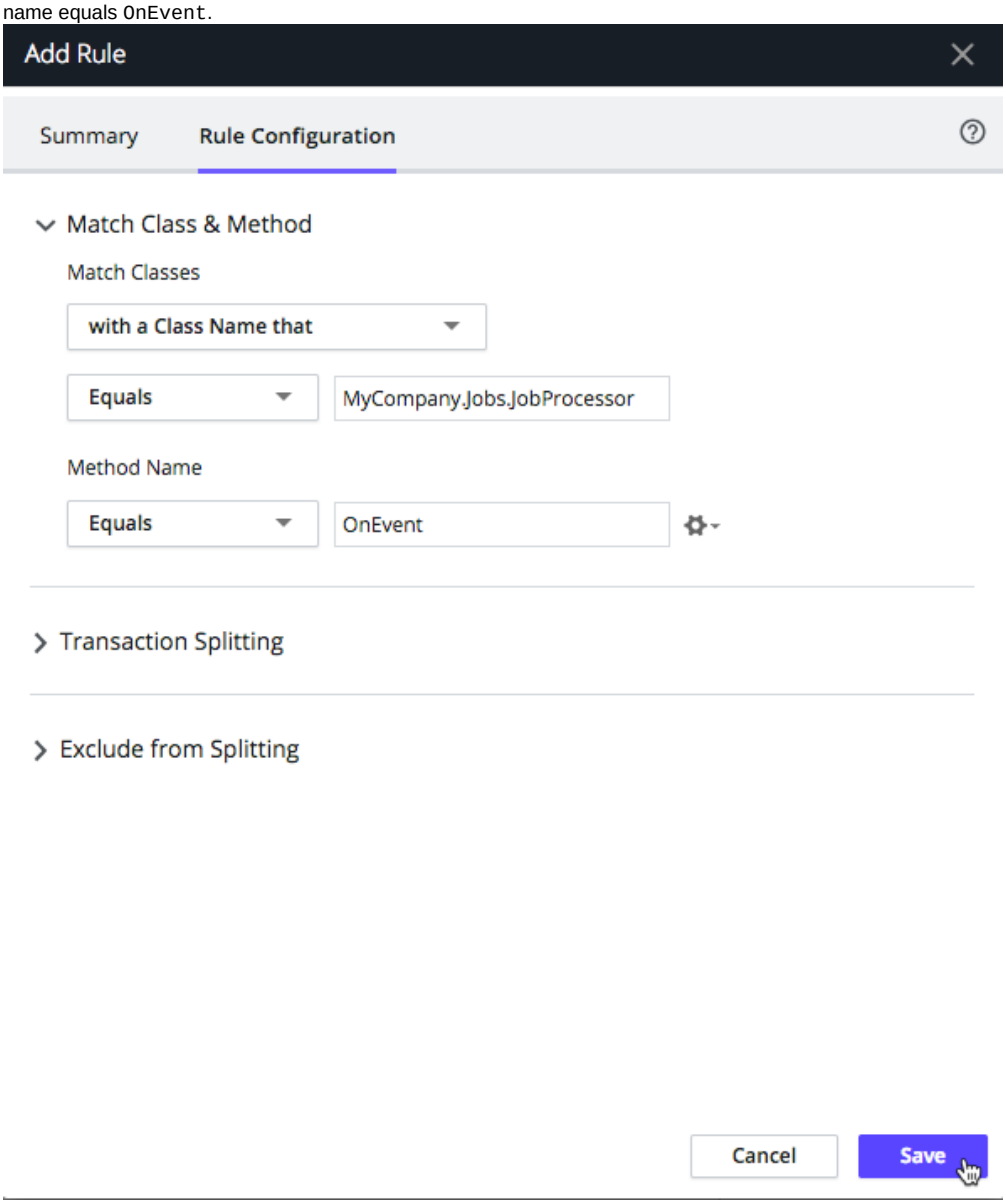
This Rule Summary specifies an *include* match rule. You must create an include rule before you can create an exclude rule to omit some of the transactions monitored by the include rule.



You can configure the rule to match classes using the ***with a Class Name that*** Match Classes option, which is the only Match Classes option supported by the .NET Agent for Linux.



The Match Class & Method specifies match criteria to match classes with a class name that equals `MyCompanyJobs.JobProcessor` and the method name equals `OnEvent`.



Transaction splitting is not supported for the .NET Agent for Linux.

Upgrade the .NET Agent for Linux

Related pages:

- Agent and Controller Compatibility
- Install the .NET Agent for Windows
- Configure the .NET Agent
- .NET Agent Directory Structure
- Troubleshoot .NET Agent Issues

This page describes how to upgrade the .NET Agent for Linux on VMs such as Docker and on hardware running Linux.

Upgrading the .NET Agent for Linux updates the agent files and maintains legacy configurations.

.NET Agent for Linux 21.5

.NET Agent for Linux 21.5 incorporates significant architectural changes to accelerate the development of missing features in the Linux Agent relative to .NET Agent for Windows.

> These architectural changes do not affect .NET Agent for Windows (MSI and Microservices).

Generally, .NET Agent for Linux 21.5 maintains parity with existing features in .NET Agent for Linux < 21.5. However due to architectural updates, there are differences between .NET Agent for Linux >= 21.5 and .NET Agent for Linux < 21.5. Before you upgrade to .NET Agent for Linux 21.5, please review the differences in this table:

Difference	.NET Agent for Linux >= 21.5	.NET Agent for Linux < 21.5
HTTP URL backend for: Default naming	.NET Agent uses the full URL including http://host:port in the naming. Full URL address is used. For example, two calls to these addresses: • http://service.cisco.com/api/add/12 • http://service.cisco.com/api/add/32 Results with these two backend names: • http://service.cisco.com/api/add/12 • http://service.cisco.com/api/add/32	.NET Agent uses the URI path of the URL for the naming. It excludes http://host:port, but assumes the "/" prefix as the name. Uses the URI path prefixed with a "/". For example, two calls to these addresses: • http://service.cisco.com/api/add/12 • http://service.cisco.com/api/add/32 Results with these two backend names: • /api/add/12 • /api/add/32

HTTP URL backend for: Custom naming	.NET Agent uses the full URL including http://host:port in the naming. The URL address split by "/" counts http://host:port as the first three segments: • "http:" • "" • "host:port" For example, two calls to these addresses with first five URL segments using "/" as the split and merge delimiter: • http://service.cisco.com/api/add/12 • http://service.cisco.com/api/add/32 Results with one backend name: • http://service.cisco.com/api/add	.NET Agent uses the URI path of the URL for the naming. It excludes http://host:port, but assumes the "/" prefix as the name. The URL address split by "/" counts segments starting from the prefixed "/" in the URI path. For example, two calls to these addresses with first three URL segments using "/" as the split and merge delimiter: • http://service.cisco.com/api/add/12 • http://service.cisco.com/api/add/32 Results with one backend name: • /api/add

Sensitive data filtering for environment variables	To filter sensitive data for environment variables:
	
	1. Add this sensitive data filter to the `AppDynamicsConfig.json` configuration file (located next to the Agent DLL file) :
	
	`{`
	`  "applies-to": "environment-variables",`
	`  "match-type": "CONTAINS",`
	`  "match-pattern": ""`
	`}`
	
	2. To integrate this filter with the Agent configuration file, see Filter Sensitive Data with the .NET Agent.
		Available using the `APPDYNAMICS_AGENT_MASK_ENV_VARS` environment variable with the Linux Agent.

Process identity	Not available	Available
In-process async call chain segments limit	5 per node (default)	10 per node (default)
POCO definitions for the generic format changes any existing generic method POCO definitions and must be re-defined using the new format. Similar to POCO definitions, the new format applies to any similar definitions for Custom Exits, Custom Data collectors, and so on because their support is enabled in the .NET Agent for Linux.	This shows the common format used to define generic POCO rules for all .NET Agents: Format `class: GenericClass`2` `method: GenericMethod<T1,T2>(T1,T2,T1,T2)`	This shows the common format used to define generic POCO rules for all .NET Agents: Format `class: GenericClass`2` `method: GenericMethod(!T1,!T2,!!M1,!!M2)`
Alpine 3.9 and 3.10	Not supported	Supported
Analytics Agent connection configuration through the `AppDynamicsConfig.json` configuration file or through the `APPDYNAMICS_ANALYTICS_*` environment variables.	Not supported Use the single environment variable `appdynamics.analytics.agent.url` to specify the full Analytics Agent URL, such as `http://localhost:9090/v2/sinks/bt`.	Supported
Analytics Agent SSL trust configuration in JSON or agent specific environment variables.	Not supported The SSL connection works if the certificate used by the Analytics Server is trusted by the operating system. As a workaround, you can configure the certificate using the `SSL_CERT_FILE/SSL_CERT_DIR` environment variable. This is a global setting that overrides your SSL configuration for all connections.	Supported with these environment variables: • `APPDYNAMICS_CONTROLLER_SSL_CERTFILE` • `APPDYNAMICS_CONTROLLER_SSL_CERTDIR`

Usage of multiple Base-64 encoded certificate (PEM) in a single file with `APPDYNAMICS_CONTROLLER_SSL_CERTFILE`.	Not supported
	
	Possible workarounds are:
	
	• Use the SSL_CERT_FILE and SSL_CERT_DIR system environment variables instead.
	
	ⓘ This is a global setting that overrides your SSL configuration for all connections.
	
	• Split certificates into multiple files. For example, enter this command:
	
	`csplit -sz INPUT_FILE '/.*BEGIN/' '{*}' --suffix-format=%i.cer --prefix=cert_`
	
	ⓘ The INPUT_FILE is the PEM certificate.
	
	• Convert PEM to PKCS#7. For example, enter this command:
	`openssl crl2pkcs7 -nocrl -certfile INPUT > OUTPUT`
	
	ⓘ The INPUT_FILE is the PEM certificate, and the OUTPUT is the PKCS#7 certificate. INPUT and OUTPUT should not be the same file.
		Supported

Requirements

- Before you begin, review the Release Notes for changes that affect your environment.
- AppDynamics requires an account access key for agent connections to single-tenant Controller accounts. AppDynamics < 4.1 only requires an account access key for multi-tenant Controller accounts.

  Single-tenant Controller customers can find the account access key in the Controller under **Settings** > **License** > **Account**.

  You must be a member of a role with the View License account level permission, see Create and Manage Custom Roles.

Binaries Overview

After downloading the agent binaries, you must extract them from the zip file into the folder you want.

The folder should contain these files:

- `AppDynamics.Agent.netstandard.dll`
- `libappdprofiler.so`
- `libappdprofiler_glibc.so`
- `libappdprofiler_musl.so`

Upgrade the .NET Agent for Linux

1. Unzip the .NET Agent for Linux installation package to a temporary directory.
2. Replace the existing agent binaries with their latest versions. The files to replace are:
   - `libappdprofiler.so`
   - `AppDynamics.Agent.netstandard.dll`
3. Copy these files to the same directory:
   - `libappdprofiler_glibc.so`
   - `libappdprofiler_musl.so`
4. Restart your application, or rebuild and then run your container image with the new versions of the agent binaries.

Node.js Agent

Related pages:

- Dynamic Language Agent Proxy
- Monitor Node.js Processes

This page provides an overview of the Node.js Agent, which enables automated transaction detection and correlation across your Node.js-enabled environment.

Node Naming for Node.js Agents

Each instrumented Node.js process corresponds to a node in the AppDynamics model.

The nodes are named by combining the prefix that you specify for the nodeName in the requires statement that you add to the application source code when you install the Node.js agent with a hyphen and a digit.

For example, if you designate a prefix of MyNode for the nodes in the MyTier tier, the nodes in that tier are named MyNode-0, MyNode-1, MyNode-2, and so on.

Instrument a Node.js Application Overview

The Getting Started Wizard provides instructions on installing the agent. In the Controller **Home** page, click **Getting Started > Node.js**.

The wizard provides the minimum information that the agent needs to communicate with the AppDynamics Controller:

- Controller Host
- Controller Port
- SSL (optional)
- Application Name
- Tier Name

Node.js Supported Environments

This page provides an overview of supported environments for the Node.js Agent.

Node.js Agent Versions

Agent Versions	Node.js Versions
>= 21.1.0	8.6+, 9, 10, 11, 12, 13, 14, 15
>= 20.5.0	8.6+, 9, 10, 11, 12, 13, 14
20.4.0	8.6+, 9, 10, 11, 12, 13
>= 4.5.21	8.6+, 9, 10, 11, 12
>= 4.5.12	6, 7, 8, 9, 10, 11
4.5.11	0.8, 0.10, 0.12, 4, 5, 6, 7, 8, 9, 10, 11

For agent >= 4.5.12, the `npm install` command will stop and print a message for the following scenarios.

- Node.js version less than 6.x:
  - This version of AppDynamics agent supports Node.js versions 6.0 and above.
  - For older versions of Node.js, use the AppDynamics agent 4.5.11 by installing with `npm install appdynamics@4.5.11`.
- Node.js version less than 8.x on Mac:
  - This version of AppDynamics agent on Mac OS supports Node.js >= 8.0.
  - For older versions of Node.js, use the AppDynamics agent 4.5.11 by installing with `npm install appdynamics@4.5.11`.

Operating Systems

- Alpine Linux Docker >= 3.7 on 64-bit platform
- Linux distribution based on glibc 2.5 and later and the x86/x86-64 architecture
- Mac OS X >= 10.8
- Windows Server 2012 R2 and later on 64-bit platform with Node.js >= 0.12.0

Transaction Naming

Entry Type	Default Transaction Naming
Node.js Web	URI

HTTP Exit Points

Supported HTTP Exit Points
Node.js HTTP client library

See Node.js Documentation for the Node.js HTTP client library.

Database Exit Points

Supported Database Exit Points

Cassandra
Couchbase
DynamoDB (using AWS SDK Driver)
Redis
Memcached
MongoDB
MSSQL
MySQL
PostgreSQL

Node.js Settings Reference

Related pages:

- Configure Transaction Analytics for Node.js and PHP Applications
- Install the Node.js Agent

This page describes the available settings that configure the Node.js Agent.

You can use environment variables for some of the settings. To apply the settings, add them to the `require` statement for the Node.js Agent in the monitored application.

General Settings

This is the complete list of settings in the require statement that you insert into your application code. Not all of these settings are required.

Property Name	Description
`controllerHostName`	The IP address or hostname of your Controller. For SaaS, you will receive this URL in your welcome email from AppDynamics. F will set these when you install the Controller.
`controllerPort`	The port to which the agent connects to the Controller. It is 8090 for an on-premises Controller and 443 for a SaaS Controller.
`controllerSslEnabled`	Set this property to true if connecting to the Controller via SSL.
`accountName`	The account name on the Controller to which this agent will report. See Account Name and Access Key Requirements for details
`accountAccessKey`	Account access key on the Controller.
`applicationName`	Name that represents the entire application in the AppDynamics console.
`tierName`	Name that represents your Node.js app or service in the flow maps.
`nodeName`	Name of the Node.js process to be monitored by this agent. See Node Names.
`noNodeNameSuffix`	Optional, set to true if you do not want the agent to add a suffix, such as -0, -1, -2, and so on, to the node name. See Node Nam
`proxyHost`, `proxyPort`	Set these options to route data to the Controller through a proxy server. The `proxyHost` is the hostname or IP address of the p `Port` is the proxy server's HTTP or HTTPS port, whichever you are using. If you set the host, you must set the port as well.
`proxyUser`, `proxyPasswordFile`	Configure the proxy username and password file if the proxy server requires credentials.
`proxy`	Set this property to true if you want to use the Java proxy version of the Node.js Agent.
`alwaysAddEumMetadataInHttpHeaders`	Set this property to true to have the Node.js Agent write business transaction metadata to the XHR header and in a cookie even considered cross-origin. See the description for the equivalent setting `always-add-eum-metadata-in-http-headers` in A Properties Reference.
`btEntryPointDelayDisabled`	true | false - Optional, defaults to false. Setting this property to true can accelerate the startup of business transactions, but it car drill-down in distributed transactions.
`debug`	Set this property to true to enable debug level logging for the agent. The default is false.
`logging`	The location, level, and other settings related to agent logging. See Node.js Agent Logging.
`maxProcessSnapshotsPerPeriod`	Optional. The default is 2. The number of automatic process snapshots allowed in `processSnapshotCountResetPeriodSec`
`processSnapshotCountResetPeriodSeconds`	Optional. The default is 60. Frequency, in seconds, at which the automatic process snapshot count is reset to 0.
`autoSnapshotDurationSeconds`	Optional. The default is 10. Length, in seconds, of automatically-triggered process snapshots.
`proxyAutolaunchDisabled`	true | false - Optional, defaults to false. Set this property to true if you need to manually launch the proxy for this agent. See Star for Node.js.
`proxyCtrlDir`	Directory path for the directory containing the domain control socket, which the agent uses to start an AppDynamics node. Optio Set manually if you are setting up a multi-tenant proxy. See Share a Proxy Among Node.js Agents.
`rootTmpDir`	Directory path for the root of the directory that stores the agent files. Optional, defaults to `/tmp/appds`.

`tmpDir`	Directory path for the subdirectory of the root directory for the monitored node. Optional, defaults to a hash of the Controller info node.
`reuseNode`	Set this property to true to enable reusing node names. This property is useful for monitoring environments where there are mar spans. The default is false.
`reuseNodePrefix`	Set this property to the string that prefixes the node name when reuseNode is set to true. The Controller uses this prefix to gene dynamically.
`certificateFile`	Directory path for the directory containing the .pem SSL certificate.
`uniqueHostId`	The unique host ID can be set to any value that will identify the host. If a value is not specified, the agent will generate the host I available for the proxyless version of the Node.js Agent.

Analytics Settings

You can configure the Node.js Agent to send default transaction data to the Analytics Agent.

To add a setting for the Analytics host and port with the following format, specify the host and port numbers. The Analytics Agent may report on the same or different host and port numbers from the Node.js Agent.

```
analytics: {
    host: <analyticsHostName>,
    port: <analyticsPort>,
    ssl: <true || false>
}
```

To configure Analytics data limits, see Configure Transaction Analytics for Node.js and PHP Applications.

Windows Settings

On Windows, the Node.js Agent requires three additional ports:

- `proxyCommPort`: default is `10101`
- `proxyRequestPort`: default is `10102`
- `proxyReportingPort`: default is `10103`

See Run the Node.js Agent on Windows for more information.

Filter Sensitive Data

If your application contains sensitive data that should not be displayed in the Controller, you can apply the following data filters to the require statement of the Node.js Agent.

Add a Sensitive Data Filter

When you enable a sensitive data filter, the Controller displays asterisks for the values of matching environment variables or system properties.

```
dataFilters: [{
   "appliesTo": "http-headers",
   "matchPattern": "host"
}],
```

Environment Variable Filter

By default, the Node.js Agent enables a sensitive data filter with an environment variables/system properties that contain the case-insensitive substring `password|key`.

```
dataFilters: [{
   "appliesTo": "env-vars",
   "matchPattern": "password|key"
}],
```

Sensitive URL Filter

You can use sensitive URL filters to configure the agent to obfuscate sensitive information from the URLs in the **Transaction Snapshot** details.

```
urlFilters: [{
   "delimiter": "/",
   "segment": "1",
   "matchPattern": "a",
   "paramPattern": "bar"
}],
```

The sensitive URL filter checks for the `matchPattern` in one segment. To check for additional segments, you can add an additional JSON array.

The filter processes requests in the following format: `/aa/bb/cc ***/bb/cc`.

The `matchpattern/parampattern` is a standard regex.

Property Name	Description
`urlFilters`	An array that you can add more objects to if you want more rules on the segment.
`delimiter`	Specifies the desired character as the URL segment endpoints. The agent splices the URL at each delimiter instance to create the segments.
`segment`	Needs to be at least one number and in ascending order (such as `3,5` or `2,6`). Wildcards (`*`) are not possible.

URL Segment Filter

With the `matchpattern` regex, the Node.js Agent decides whether or not to filter a specified segment.

If you have multiple rules, list the more specific rule before the more general rule. The rules listed in the array are evaluated based on order.

Rule A:

```
{
 'delimiter': '/',
 'matchPattern': '[0-9a-z]{8}-[0-9a-z]{4}-[0-9a-z]{4}-[0-9a-z]{4}-[0-9a-z]{12}\/.{50,}',
 'segment': '3,5'
}
```

Rule B:

```
{
 'delimiter': '/',
 'matchPattern': '[0-9a-z]{8}-[0-9a-z]{4}-[0-9a-z]{4}-[0-9a-z]{4}-[0-9a-z]{12}',
 'segment': '3'
}
```

In this example, the first rule, Rule A, should be listed before Rule B because rule A masks the third and fifth segment.

If Rule B were to be listed and evaluated before Rule A, the third segment will be masked and the fifth segment will not masked, potentially revealing sensitive information.

URL Parameter Filter

With the paramPattern regex, the Node.js Agent decides whether or not to filter a specified query parameter.

If you need to mask all URL parameters, you can add further instruction to the array.

```
{ "delimiter": "/", "matchPattern": "", "segment": "99", "paramPattern": ".+"}
```

The Node.js Agent will filter out all URL parameters.

Sensitive Message Filter

You can use sensitive message filters to configure the agent to obfuscate sensitive information contained within text messages collected by the agent from log messages or detail messages from exceptions.

```
messageFilters: [{
   "messageType":
"throwable",
   "matchPattern":
"Error.*MySQL.",
   "redactionRegex": "SQL"
}]
```

Environment Variables

If you have not provided the required settings in the require statement, the agent uses the values of the following environment variables if those variables are set. If both are set, the `require` statement value takes precedence over the environment variable.

Environment Variable	Maps to
APPDYNAMICS_CONTROLLER_HOST_NAME	controllerHostName
APPDYNAMICS_CONTROLLER_PORT	controllerPort
APPDYNAMICS_CONTROLLER_SSL_ENABLED	controllerSslEnabled
APPDYNAMICS_AGENT_ACCOUNT_NAME	accountName
APPDYNAMICS_LOGGER_OUTPUT_TYPE	You can stream logs to `stdout` by setting its value to `console`.
APPDYNAMICS_LOGGER_LEVEL	You can set the logging level of the agent. Possible values include: `FATAL`, `ERROR`, `WARN`, `INFO`, `DEBUG`, and `TRACE`.
APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY	accountAccessKey
APPDYNAMICS_AGENT_APPLICATION_NAME	applicationName
APPDYNAMICS_AGENT_TIER_NAME	tierName
APPDYNAMICS_AGENT_NODE_NAME	nodeName
APPDYNAMICS_AGENT_UNIQUE_HOST_ID	
APPDYNAMICS_ANALYTICS_HOST_NAME	host—in Analytics settings
APPDYNAMICS_ANALYTICS_PORT	port—in Analytics settings
APPDYNAMICS_ANALYTICS_SSL_ENABLED	ssl—in Analytics settings
UNIQUE_HOST_ID	uniqueHostId The unique host ID can be set to any value that will identify the host. If a value is not specified, the agent will generate the host ID. This environment variable is available by default (not for Java proxy mode).

Install the Node.js Agent

Related pages:

- Download AppDynamics Software
- Install the Node.js Agent (Java Proxy)

This page provides instructions on how to install the Node.js Agent.

The Getting Started Wizard in the Controller provides the easiest way to get started with the AppDynamics Node.js Agent. The wizard constructs a pre-configured require statement for the agent based on your input.

Before You Begin

You must add a require statement to the source code of your Node.js application to install the Node.js Agent. In addition to running the AppDynamics Controller, you need to have write access to the application source code and the ability to restart the Node.js application, which installs the agent.

The Getting Started Wizard in the Controller generates the require statement for you. It populates the statement with the connection settings for the Controller and the values you provide for the wizard to model the Node.js application in AppDynamics.

For installation on Windows, see Supported Environment for your version of Windows and install the Visual C++ Redistributable for Visual Studio 2015.

About Node.js Agent Node Identity

You configure the identify of a Node.js application instance using the node name setting. By default, the agent uses the value configured for `nodeName` as a prefix and adds a dash and number as a suffix. For example, given the following setting:

```
nodeName=MyNode
```

The first node to start with this configuration would be named `MyNode-0`. Auto-numbered suffixes on node names are most useful for machines with more than one worker process.

If you are not running multiple worker processes, you can prevent auto-numbering in node names by setting `noNodeNameSuffix` to `true`. In the following example, the node would be named `MyNode`.

```
nodeName=MyNode
noNodeNameSuffix=true
```

If you are instrumenting worker processes on different machines, keep in mind that each application and node name combination must be unique. Therefore, be sure to specify different node name prefixes for each server, for example, by configuring `nodeName=Server1` for the first server and `nodeName=Server2` for the second server.

If you are instrumenting a Node.js application that uses the PM2 process manager, set the node suffix name to `process.env.pm_id`.

Use the Node.js Agent with the Machine Agent

If you install the Machine Agent on the machine hosting the instrumented Node.js node and you specify the tier and node name in the `controller-info.xml` file of the Machine Agent, the Node.js Agent will fail to register.

To avoid this problem:

- Install the Node.js Agent before you install the Machine Agent.
- If you install the Machine Agent on the machine hosting the instrumented Node.js node, do not specify the application, tier, or node name in the machine agent's `controller-info.xml` file. If you do, the Node.js Agent may fail to register.

Install the Node.js Agent

To install the agent, run the install command in the directory of your application and add a `require` command to add the agent module to your application.

If you are using Node.js 0.8.1 through 0.8.18, see Set User Agent for Node.js 0.8.1 through 0.8.18 before running the install command.

Install via `npm`

Refer to Agent and Controller Compatibility to determine which versions of the Node.js Agent are compatible with your Controller.

To install the latest agent, run the following command:

```
npm install appdynamics@next
```

If you know which specific version of the Node.js agent you want to install, you can specify it:

```
npm install appdynamics@<x.y.z>
```

If you are using npm 5, you must disable the lock file by setting `package-lock=false` in the npm configuration settings.

The version of npm that ships with Node.js v6 does not automatically run post-install scripts used by 4.5.12 and later versions of the agent. AppDynamics recommends using the latest Node.js version.

If Node.js v6 must be used, npm needs to be updated prior to installing the agent:

```
npm install -g npm
npm install appdynamics
```

Add the Require Statement

Paste the following require statement as the very first line of your application source code before any other require statement. Then, replace the variables with the values for your setup. To find your account name and access key, select **Settings** and then **License**.

```
require("appdynamics").profile({
  controllerHostName: '<controller host name>',
  controllerPort: <controller port number>,
  controllerSslEnabled: false,  // Set to true if controllerPort is SSL
  accountName: '<AppDynamics_account_name>',
  accountAccessKey: '<AppDynamics_account_key>', //required
  applicationName: 'your_app_name',
  tierName: 'choose_a_tier_name',
  nodeName: 'choose_a_node_name'
 });
```

For reference information on the settings, along with other settings you can use, see Node.js Settings Reference.

You can place the `require` statement as the first line in the require statement of another module that appears as the first line of code.

In this case, you would need to modify your point-of-entry source file; this it can be just a single line to the `require()` the file that you place the call to the agent into; for example, `require("<script-that-initializes-the-agent>")`. You could also parameterize the `profile()` call to name different instances without having to have multiple versions of the agent initialization script.

If it is not possible to place the require statement as the first line of code, you can insert the statement elsewhere, but it must occur before the `require()` of any core or third party module that needs to be instrumented. In general, the `require("appdynamics")` statement should occur as early as possible in the code.

Test the Configuration

To verify the installation, restart the application and put load on it. The new node should appear in the flow map for the business application you specified in the configuration.

Stop the Node.js Application

By default, closing the Node.js application stops the application.

Run with Other Profiling Tools

The agent is incompatible with other profiling tools, such as running the node process with the `--inspect` flag.

Instrument a Node.js Cluster

If your application uses the cluster module, place the `appdynamics.profile require` statement in both the primary and worker processes.

Set User Agent for Node.js 0.8.1 through 0.8.18

If running a Node.js version between 0.8.1 and 0.8.18, inclusive, you need to set the `user-agent npm` property before you run the `npm install` command.

The syntax is:

```
npm config set user-agent "node/<version> {linux|darwin} {x64|i86}"
```

For example:

```
npm config set user-agent “node/v0.8.14 linux x64"
```

Resolve Installation Issues for Node.js

If you are trying to install the Node.js Agent on a version of Node.js that the agent does not support, the installation will fail and you will see a message similar to the following:

```
npm ERR! notsup Unsupported
npm ERR! notsup Not compatible with your version of node/npm: appdynamics@3.9.3
npm ERR! notsup Required: {"node":">=0.8.0 <=0.10.31"}
npm ERR! notsup Actual:   {"npm":"1.4.28","node":"0.10.32"}
...
```

See Node.js Supported Environments.

Install the Node.js Agent in Containers

Related pages:

- Container Installation Options

This page explains your options to install the Node.js Agent in a containerized environment:

- Use Auto-Instrumentation
- Use Init Containers
- Use a Dockerfile

Use Auto-Instrumentation

> This scenario applies to containers running in Kubernetes where the Cluster Agent is installed.

This option uses the Auto-Instrumentation feature of the Cluster Agent. It is the recommended option because it offers the highest level of automation and the simplest operational experience for instrumenting Node.js applications in a Kubernetes cluster.

To get started, see Auto-Instrument Applications with the Cluster Agent.

Use Init Containers

> This option applies to containers running in Kubernetes.

This option uses Kubernetes init containers to copy the Node.js Agent binaries into the application container when the application starts up. It assumes that the application image is built without any Node.js Agent binaries and that a second init container image is built which contains the Node.js Agent binaries. The deployment spec for the application is configured to copy and send the agent binaries to the running application container.

To copy the agent binaries with init containers:

1. Build the Node.js Application Image
2. Build the Node.js Agent Init Container Image
3. Add the Init Container to the Deployment Spec
4. Set the Node.js Agent Environment Variables
5. Set the `UNIQUE_HOST_ID` Environment Variable
6. (On-Premises Controller Only) Copy the Controller Certs to the Container

> These steps assume the application image is built using Node.js version 8 and later, which supports the `NODE_OPTIONS` environment variable. This environment variable is set in a ConfigMap. For Node.js versions 7 and earlier, refer to this example that uses a start script to include the a `ppdynamics` package.

Build the Node.js Application Image

Build the Node.js application image based on the application binaries and dependencies. Do not include the Node.js Agent binaries or settings in the application image.

Build the Node.js Agent Init Container Image

The agent init container image is built separately from the application image and can be reused across multiple Node.js application deployments.

> For Linux and Alpine environments, the Node.js Agent init container images are available on Dockerhub. For all other deployment environments, continue with the following instructions to build the init container image.

The Node.js and operating system versions of the init container image should match the Node.js and operating system versions of the application image to ensure that compatible Node.js Agent binaries are selected when running `npm install`. For more information, see Node.js Supported Environments.

The Node.js and operating system versions are determined by the `FROM node:14.4-alpine` statement in the Dockerfile:

```
FROM node:14.4-alpine
…
```

Follow these steps to build the init container image:

1. Create a `shim.js` file that contains a `require` statement for `appdynamics`. Set the `reuseNode` property to `true`. Set `reuseNodePrefix` to the value of an environment variable that will be provided in a ConfigMap in a later step:

```
require("appdynamics").profile({
  reuseNode: true,
  reuseNodePrefix: process.env.APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX
});
```

2. If the Node.js Agent should report Transaction Analytics data, add the analytics properties to the require statement and set the value to environment variables that will be provided in a ConfigMap in a later step. See Node.js Settings Reference.

```
require("appdynamics").profile({
  reuseNode: true,
  reuseNodePrefix: process.env.APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX,
  analytics: {
    host: process.env.APPDYNAMICS_ANALYTICS_HOST_NAME,
    port: process.env.APPDYNAMICS_ANALYTICS_PORT,
    ssl: process.env.APPDYNAMICS_ANALYTICS_SSL_ENABLED
  }
});
```

3. If the Node.js Agent communicates with an on-premises Controller, add the `certificateFile` property and set it to the location where the `cert` file will be copied in a later step:

```
require("appdynamics").profile({
  reuseNode: true,
  reuseNodePrefix: process.env.APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX,
  certificateFile: /opt/appdynamics/cacerts
});
```

4. In the Dockerfile, copy `shim.js` to the image:

```
COPY ./shim.js /opt/appdynamics/shim.js
```

5. Run the `npm install` command to resolve the `appdynamics` package:

```
$ cd appdynamics
$ npm install appdynamics@next
```

6. In the Dockerfile, copy the contents of the folder containing the `appdynamics` package to the image:

```
COPY appdynamics/ /opt/appdynamics/
```

For a complete example of building the Node.js Agent init container image using a multi-stage build, see this Dockerfile.

Add the Init Container to the Deployment Spec

Edit the deployment spec to add the sections required to copy the agent binaries from the init container to the application image.

The following snippet from a deployment spec shows the required `volumes`, `volumeMounts`, and `initContainer` definitions. It assumes the Node.js application image is published to `myrepo/nodejs-app:v1` and the init container image is published to `myrepo/appd-nodejs:latest`. The `shim.js` file from the init container image is copied to `/opt/appdynamics/shim.js` in the application container.

```
kind: Deployment
spec:
  containers:
  - name: nodejs-app
        image: myrepo/nodejs-app:v1
    volumeMounts:
    - mountPath: /opt/appdynamics
      name: appd-agent-repo
  initContainers:
  - command:
    - cp
    - -r
    - /opt/appdynamics/.
    - /opt/temp
       name: appd-agent
    image: myrepo/appd-nodejs:latest
    volumeMounts:
    - mountPath: /opt/temp
      name: appd-agent-repo
  volumes:
    - name: appd-agent-repo
      emptyDir: {}
```

Set the Node.js Agent Environment Variables

To set all of the required Node.js Agent environment variables, try the following options depending on your use case:

- Use ConfigMaps to Configure the App Server Agent
- Use Secrets for the Controller Access Key
- Set Application-Specific Configuration in the Deployment Spec

See Best Practices to Configure Agents in Kubernetes for more information.

Use ConfigMaps to Configure the App Server Agent

1. Use a ConfigMap to set the agent environment variables that are shared across Node.js applications in a namespace. For example, see this `appd-nodejs-config.yaml` snippet:

   ```
   apiVersion: v1
   data:
     APPDYNAMICS_AGENT_APPLICATION_NAME: eCommerce
     APPDYNAMICS_AGENT_ACCOUNT_NAME: <value>
     APPDYNAMICS_CONTROLLER_HOST_NAME: <value>
     APPDYNAMICS_CONTROLLER_PORT: <value>
     APPDYNAMICS_CONTROLLER_SSL_ENABLED: <value>
     APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX: <value>
     APPDYNAMICS_AGENT_NODE_NAME: <value> # not used in node name but required by Node.js agent
     APPDYNAMICS_LOGGER_OUTPUT_TYPE: console
     NODE_OPTIONS: '--require /opt/appdynamics/shim.js'
     # variables required to send transaction analytics data
     APPDYNAMICS_ANALYTICS_HOST_NAME: <value>
     APPDYNAMICS_ANALYTICS_PORT: <value>
     APPDYNAMICS_ANALYTICS_SSL_ENABLED: <value>
   kind: ConfigMap
   metadata:
     name: appd-nodejs-config
   ```

   The `NODE_OPTIONS` environment variable, supported in Node.js 8 and later, sets the `--require` option to the location of the `shim.js` file copied from the init container image. The analytics host, port and ssl settings depend on how the Analytics Agent is deployed. See Deploy Analytics in Kubernetes for options.

2. Apply the ConfigMap to the namespace:

   ```
   $ kubectl -n ecommerce apply -f appd-nodejs-config.yaml
   ```

3. Update the deployment spec to reference the ConfigMap:

```
spec:
  containers:
  - name: nodejs-app
    envFrom:
    - configMapRef:
      name: appd-nodejs-config
 ...
```

Use Secrets for the Controller Access Key

1. Create a Secret using `kubectl`:

```
$ kubectl -n ecommerce create secret generic appd-agent-secret --from-literal=access-key=<access-key>
```

2. Update the deployment spec to reference the Secret:

```
spec:
  containers:
  - name: nodejs-app
    env:
    - name: APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY
      valueFrom:
      secretKeyRef:
        name: appd-agent-secret
        key: access-key
 ...
```

Set Application-Specific Configuration in the Deployment Spec

Set the application-specific tier name environment variable `APPDYNAMICS_AGENT_TIER_NAME` in the deployment spec:

```
spec:
  containers:
  - name: nodejs-app
    env:
    - name: APPDYNAMICS_AGENT_TIER_NAME
      value: nodejs-service
```

Set the `UNIQUE_HOST_ID` Environment Variable

Set the `UNIQUE_HOST_ID` environment variable to enable APM correlation with the Cluster Agent. Since the value depends on a runtime value, set this environment variable in the container startup command with the values in Manually Configure App Agents to Correlate with the Cluster Agent.

For a Kubernetes environment with the Docker runtime, set the environment variable as shown in the following example:

```
spec:
  containers:
    command: ["/bin/sh"]
    args: ["-c", "export UNIQUE_HOST_ID=$(sed -rn '1s#.*/##; 1s/(.{12}).*/\\1/p' /proc/self/cgroup) && node
/nodejsapp/myapp.js"]
```

(On-Premises Controller Only) Copy the Controller Certs to the Container

If on-premises Controller certs are required, define a ConfigMap to reference the `cert` file and use a volume mount in the deployment spec to mount the ConfigMap contents to the container. See Controller SSL and Certificates.

```
$ kubectl create configmap appd-cert --from-file=cacerts
```

Add the cert file to the container file system using `volumes` and `volumeMounts` as shown in the deployment spec snippet:

```
kind: Deployment
spec:
  containers:
    image: myrepo/nodejs-app:v1
    volumeMounts:
    - name: appd-cert
      subPath: cacerts
      mountPath: /opt/appdynamics/cacerts
  volumes:
    - name: appd-cert
      configMap:
        name: appd-cert
```

The `mountPath` value should match the `certificateFile` property in the `shim.js` file used when building the init container image.

Example Configuration for Using an Init Container

See this deployment spec for a complete example using an init container to copy the agent binaries.

Use a Dockerfile

> This option applies to containers running in Docker and Kubernetes.

This option uses a Dockerfile to include the Node.js Agent binaries in the Docker image at build time. It assumes a single image is built that contains the application and Node.js Agent binaries.

To include the agent in the application image during the image build:

1. Perform the Node.js Agent Installation Steps
2. Copy the Application Folder to the Image
3. Set the Node.js Agent Environment Variables
4. Set the UNIQUE_HOST_ID Environment Variable
5. (On-Premises Controller only) Copy the Controller Certs to the Image

Perform the Node.js Agent Installation Steps

Perform the installation steps described in Install the Node.js Agent.

1. Run the NPM command to include the `appdynamics` package from your application folder:

   ```
   $ cd nodejsapp
   $ npm install appdynamics@next
   ```

2. Add the `require` statement to the application source code and include `reuseNode` and `reuseNodePrefix` properties. Set the `reuseNodePrefix` property to refer to an environment variable that will be set in a later step:

   ```
   require("appdynamics").profile({
     reuseNode: true,
     reuseNodePrefix: process.env.APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX
   });
   ```

   The reuse node name and prefix properties are required to support unique naming for multiple container instances for the same application image. See Node.js Settings Reference.

3. If the Node.js Agent should report transaction analytics data, add the analytics properties to the require statement and set the value to an environment variable that will be set in a later step. See Node.js Settings Reference.

```
require("appdynamics").profile({
  reuseNode: true,
  reuseNodePrefix: process.env.APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX,
  analytics: {
    host: process.env.APPDYNAMICS_ANALYTICS_HOST_NAME,
    port: process.env.APPDYNAMICS_ANALYTICS_PORT,
    ssl: process.env.APPDYNAMICS_ANALYTICS_SSL_ENABLED
  }
});
```

Copy the Application Folder to the Image

Edit the Docker file to copy the application folder to the image:

```
COPY nodejsapp/ /nodejsapp/
```

Set the Node.js Agent Environment Variables

If you are running the application in a non-Kubernetes environment (using `docker run` for example), set the agent environment variables in the Dockerfile. For example:

```
ENV APPDYNAMICS_AGENT_APPLICATION_NAME=<value>
ENV APPDYNAMICS_AGENT_TIER_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=<value>
ENV APPDYNAMICS_CONTROLLER_HOST_NAME=<value>
ENV APPDYNAMICS_CONTROLLER_PORT=<value>
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED=<value>
ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX=<value>
ENV APPDYNAMICS_AGENT_NODE_NAME=<value> # not used in node name but required by Node.js agent
ENV APPDYNAMICS_LOGGER_OUTPUT_TYPE=console
# variables required to send transaction analytics data
ENV APPDYNAMICS_ANALYTICS_HOST_NAME=<value>
ENV APPDYNAMICS_ANALYTICS_PORT=<value>
ENV APPDYNAMICS_ANALYTICS_SSL_ENABLED=<value>
```

For Kubernetes applications, omit these environment variables from the Dockerfile and set them using ConfigMaps, Secrets, and the deployment spec as described in Use Init Containers. The analytics host, port and ssl settings depend on how the Analytics Agent is deployed. See Deploy Analytics in Kubernetes for options.

Set the `UNIQUE_HOST_ID` Environment Variable

Set the `UNIQUE_HOST_ID` environment variable to enable APM correlation with the Cluster Agent. Since the value depends on a runtime value, set this environment variable in the image startup script using the values documented in Manually Configure App Agents to Correlate with the Cluster Agent.
For a Kubernetes environment with a Docker runtime, add the following startup script `startup.sh` to the Docker image in the following example:

```
#!/bin/bash
# OpenShift 3.10 or 3.11:
UNIQUE_HOST_ID=$(sed -rn '1s#.*/##; 1s/(.{12}).*/\\1/p' /proc/self/cgroup)
exec node /nodejsapp/myapp.js
```

(On-Premises Controller only) Copy the Controller Certs to the Image

For Node.js Agents communicating with an on-premises Controller, edit the Dockerfile to copy the cert file containing the on-premises certs to the image.

For example:

```
COPY ./onprem-cacerts /opt/appdynamics/cacerts
```

Update the application source code to add the `certificateFile` property in the `require` statement. Set the `certificateFile` path to the location of the cert file.

```
require("appdynamics").profile({
  reuseNode: true,
  reuseNodePrefix: process.env.APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX,
  certificateFile: /opt/appdynamics/cacerts
});
```

Node.js Agent API User Guide

Related pages:

- Node.js Agent API Reference
- Node.js Supported Environments
- Backend Detection Rules

The AppDynamics Node.js Agent APIs enable the Node.js Agent to monitor business transactions that a web application performs outside the context of an HTTP request or an application that is not web-based.

Business Transaction Definition

You define a custom business transaction using `appd.startTransaction()` and `end()`.

If the custom transaction runs for a long time or if it crosses an asynchronous boundary, you can use `resume()` to rejoin the running transaction.

A downstream transaction in a distributed transaction cannot start until its upstream transaction has made its exit call.

The order of transactions respects the nonlinear nature of Node.js applications. An upstream transaction might end immediately after its exit call completes or sometime later. It is not necessary for an upstream transaction to end before or after its downstream transaction starts or ends. It is possible for a downstream transaction to end before its upstream transactions have ended.

Marking a Transaction as an Error Transaction

An error transaction is one in which an exception occurred. It is reported as an error transaction and not as a slow, very slow or stalled transaction, even if the transaction in which the error occurred was also slow or stalled.

To attach a JavaScript error object to a transaction using the Node.js APIs do one of the following:

- Use `trx.markError()` passing in the JavaScript error object.
- Attach the error object to the HTTP response associated with the transaction as response.error.

When an error is marked, the status code defaults to 500, unless you set it using one of the following techniques:

- Use `trx.markError()` passing in the JavaScript error object and the optional status code.
- Set the `statusCode` property in the error object passed to `trx.markError()` as `error.StatusCode`.
- Set the `statusCode` property on the `response.error` object as `response.error.StatusCode`.

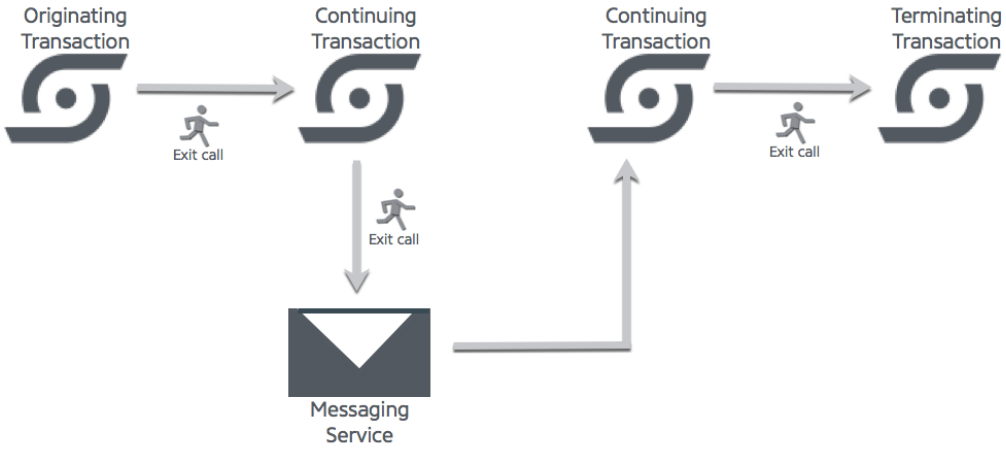
Transaction Correlation Management

Transaction correlation is the functionality that maintains the business transaction context across all tiers—servers—traversed by a distributed transaction. The tiers may be built on platforms other than Node.js. For example, Java, .NET, and PHP tiers may participate in a distributed business transaction in which a Node.js tier participates, as originating, continuing or terminating tiers in the transaction.

The Node.js Agent APIs provide facilities for managing transaction correlation among various transactions, which may be custom or automatically-detected.

While the AppDynamics default auto-detection mechanism obtains transaction correlation information from an incoming HTTP request, the Node.js Agent APIs allow you to obtain this information from other sources, such as a custom field in a Redis cache entry, and to supply it to your custom transactions. You can use the APIs to support forward correlation by supplying transaction correlation information on exit calls that you make to downstream transactions.

A downstream transaction starts after its immediate upstream transaction makes its exit call. That call could be a direct exit call to the next tier or a call to a backend service that does some processing, such as publishing a message onto a queue.



.

Exit Call Management

An exit call is either a custom exit call or an automatically-detected exit call. A transaction needs its exit call object to create correlation information to provide to a downstream transaction that needs to correlate with it.

Custom Exit Calls

If you want an exit call to be reported to the controller, and it is not automatically detected by the agent, create a custom exit call with `startExitCall()` and end it with `endExitCall()`.

See Node.js Supported Environments for the list of backends that are automatically detected by the Node.js Agent. If the exit call invokes a backend not listed on this page, you probably need to create a custom exit call.

You can also use a `beforeExitCall()` callback function to check for the existence of an automatically-detected exit call.

Processing a custom exit call is straightforward. First, create the exit call and then pass its returned `ExitCall` object to `createCorrelationInfo()` to create a string-encoded correlation information object that a downstream transaction can fetch later.

Workflow for a custom exit call

```
// start a custom transaction
var trx = appd.startTransaction(. . . )
. . .

// start a custom exit call
exit = trx.startExitCall(. . .);

// create correlation information
cinfo = trx.createCorrelationInfo(exit)
//store cinfo where it can be made available to a downstream transaction

// make the exit call
. . .
trx.endExitCall(. . .)
```

Automatically Detected Exit Calls

The code executing in your custom transaction might make an exit call that is automatically detected by the Node.js Agent.

In this case, you can provide a `beforeExitCall()` callback function to process that exit call. When your code makes an automatically-detected exit call, the agent intercepts the exit call request and invokes the callback, if you have provided one. Then it allows the application to proceed with the exit call request.

You would install a `beforeExitCall()` callback function for the following purposes:

- To test for the existence of an automatically-detected exit call
  If you are uncertain that the exit call will be automatically detected, you can install a callback function to test for the exit call. If the callback is not invoked, the exit call is not automatically detected.

```
// start a custom transaction
var trx = appd.startTransaction(. . . )
. . .

var detected = false;
trx.beforeExitCall = function(call) { detected = true; return call; };

// make the exit call
. . .

// test whether the exit call was automatically detected
if (detected == false)
. . .
```

If `detected` is `false` after the exit call, you need to create a custom exit call to report the exit call to the Controller. If `detected` is `true`, you can capture the exit call and create the correlation information with the callback.

- To capture the ExitCall object to create correlation information

```
// start a custom transaction
var trx = appd.startTransaction(. . . )
. . .

trx.beforeExitCall = function getExitInfo(exitCall) {
    // create the correlation header from the captured exit call
    var c = trx.createCorrelationInfo(exitCall);
    // store c somewhere
    // … (c)
    return exitCall;
}
// make the exit call
```

- To modify the exit call that is reported to the Controller

```
// start a custom transaction
var trx = appd.startTransaction(. . . )
. . .

trx.beforeExitCall = function customExitCallHandler(exitCall) {
    // don't report database access for this transaction
    if (exitCall.isSql) return;
    // customize label for all other exit calls in this transaction
    exitCall.label += " (my custom transaction)";
    return exitCall;
}
// make the exit call
```

Workflow: Create Originating Transaction with Correlation Information

In this scenario, you create a custom originating transaction and the correlation header that a downstream transaction will need to correlate with it.

1. Start a custom transaction: `var trx=appd.startTransaction(...)`.
2. Either start a custom exit call using `e=trx.startExitCall(einfo)` or capture a detected exit call by installing a callback function to `e=trx.beforeExitCall(e)`.
3. Create correlation information from the exit call: `c=trx.createCorrelationInfo(e)`.
4. Store the correlation information.
5. Make the exit call.
6. Optionally provide a `trx.exitCallCompleted(e)` callback function, if you want to modify what is reported to the controller based on information obtained from the execution of the exit call.
7. If you created a custom exit call, end the exit call after you have processed the exit call response: `trx.endExitCall(e)`.
8. End the transaction: `trx.end()`.

Workflow: Create Terminating Transaction Correlated with Upstream Transaction

In this scenario, you create a custom transaction, which needs to correlate with an upstream transaction but not with another downstream transaction.

1. Retrieve the correlation information stored by the previous transaction.
2. Parse the retrieved correlation information into a correlation header: `ch=appd.parseCorrelationInfo(c)`.
3. Start a custom transaction using the correlation header: `trx=appd.startTransaction(ch)`.
4. Optionally make an exit call.
5. End the transaction: `trx.end()`.

Workflow: Create Continuing Transaction Correlated with Upstream and Downstream Transactions

In this scenario, you create a continuing transaction that needs to correlate both with an upstream originating transaction and a downstream transaction. It uses the correlation techniques described in both of the previous workflows.

1. Retrieve correlation information stored by the previous transaction.
2. Parse the retrieved correlation information into a correlation header: *c*`h=appd.parseCorrelationInfo(c1)`.
3. Start a custom transaction using the correlation header: `trx=appd.startTransaction(ch`*)*.
4. Either start a custom exit call using `e=trx.startExitCall(einfo)`, or capture a detected exit call by installing a callback function to `e=trx.beforeExitCall(e)`.
5. Create correlation information from the exit call in this transaction: `c2=trx.createCorrelationInfo(e)`.
6. Store the correlation information for the next downstream transaction.
7. Make the exit call.
8. Optionally provide a `trx.exitCallCompleted(e)` callback function, if you want to modify what is reported to the controller based on information obtained from the execution of the exit call.
9. If you created a custom exit call, end the exit call after you have processed the exit call response: `trx.endExitCall(e)`.
10. End the transaction: `trx.end()`.

Node.js Agent API Reference

Related pages:

- Node.js Agent API User Guide
- Backend Detection Rules

This page describes the Node.js Agent API. The Node.js Agent APIs include methods to manage business transactions and exit points in Node.js applications.

API Call List

Loading the AppDynamics Module

You can use the APIs in your application by adding the `appdynamics` Node.js module in a require statement, after `appd.profile()`.

```
var appd = require('appdynamics');
appd.profile({ . . . })

...

var transaction = appd.startTransaction(...);
...

transaction.end();
```

Basic Business Transaction Management

appd.startTransaction(transactionInfo)

- `transactionInfo` string, HttpRequest or `CorrelationHeader`

The `transactionInfo` parameter can be one of the following:

- A string specifying the name of the custom transaction. The following characters cannot be used in transaction names: `{`, `}`, `[`, `]`, `|`, `&`, and `;`.
- A `HttpRequest` object. Normal transaction matching and naming rules are applied, and any included RUM and/or transaction correlation information is picked up automatically.
- A `CorrelationHeader` object providing information to correlate with a transaction that is upstream to this one. See parseCorrelationInfo().

Creates and starts a custom business transaction and returns a transaction handle as a `TimePromise` instance, which is used for subsequent operations on this transaction.

TimePromise.prototype.resume()

Re-joins a long-running or asynchronous transaction.

Call `resume()`:

- When a long-running transaction needs to be kept alive beyond the default transaction timeout of five minutes. This prevents the agent from assuming the transaction has failed and then deleting the transaction.
- When the code being instrumented crosses an async boundary. This re-associates the current execution context with the correct transaction and ensures any exit calls performed are charged to the right transaction.

TimePromise.prototype.end(error)

- `error:` any; optional

Ends the transaction and reports transaction information to the Controller.

If an `error` is passed, the error is associated with the transaction and the transaction is flagged as an error transaction.

appd.getTransaction(request)

- `request:` HTTP request object

Returns a handle to the business transaction associated with the specified request, if one exists. If no associated business transaction exists, returns false.

Use `appd.getTransaction()` to access both custom and automatically detected business transactions.

appd.addAnalyticsData (key, value)

- `key:` key to custom data being added
- `value:` value being added for this key

Attaches custom data to Analytics generated for the current transaction. Your application does not require a transaction handle.

To enable this feature, the Analytics settings in the require statement must be set. See Node.js Settings Reference. For information about Analytics, see Analytics Data Sources.

appd.addSnapshotData (key, value)

- `key:` key to custom data being added
- `value:` value being added for this key

Attaches custom data to snapshots generated for the current transaction.

`addSnapshotData()` can be called on a transaction at any time, but the added data is used only when a transaction snapshot is generated. For information on when transaction snapshots are generated, see Transaction Snapshots.

The following sample adds session count to USER DATA in the snapshot:

```
txn.addSnapshotData(“active sessions”, my.api.getSessionCount());
```

If the data to be added to the snapshot is available after the transaction completes, it can be attached using a txn.onSnapshotCaptured(txn) callback. This technique avoids overhead for collecting the data when no snapshot has been generated. The custom data is exposed in the **USER DATA** tab of the transaction snapshot details in the Controller UI.

appd.markError(error, [statusCode])

- `error:` JavaScript error object
- `statusCode:` optional transaction status code

This value can also be passed as a statusCode property on the `error` object.

If neither a `statusCode` parameter nor an `error.statusCode` property in the `error` parameter is provided, the status code defaults to 500.

See also TimePromise.prototype.end(error) for another way to attach an error object to a business transaction.

Marks the transaction as an error transaction. The marked transaction is reported as an error transaction and not as a slow, very slow or stalled transaction, even if the transaction was also slow or stalled.

txn.markError(error, [statusCode])

- `error` JavaScript error object
- `statusCode` optional transaction status code. This value can also be passed as a `statusCode` property on the `error` object.

If neither a `statusCode` parameter nor an `error.statusCode` property in the `error` parameter is provided, the status code defaults to 500.

See also TimePromise.prototype.end(error) for another way to attach an error object to a business transaction.

Marks the transaction as an error transaction. The marked transaction is reported as an error transaction and not as a slow, very slow or stalled transaction, even if the transaction was also slow or stalled.

txn.addSnapshotData(key, value)

- `key:` key to custom data being added
- `value:` value being added for this key

Attaches custom data to snapshots generated for this transaction.

`addSnapshotData()` can be called on a transaction at any time, but the added data is used only when a transaction snapshot is generated. For information on when transaction snapshots are generated, see Transaction Snapshots.

The following sample adds session count to USER DATA in the snapshot.

```
txn.addSnapshotData(“active sessions”, my.api.getSessionCount());
```

If the data to be added to the snapshot is available after the transaction completes, it can be attached using a txn.onSnapshotCaptured(txn) callback. This technique avoids overhead for collecting the data when no snapshot has been generated. The custom data is exposed in the **USER DATA** tab of the transaction snapshot details in the Controller UI.

txn.onSnapshotCaptured(txn)

- `txn`: transaction

Callback method that can be set on a transaction to add custom data to the transaction snapshot. Used with txn.addSnapshotData(key, value).

When the `callback` function is supplied, the agent invokes this API immediately after capturing a transaction snapshot.

If specified, the `callback` is invoked on transaction completion, if the transaction triggers a snapshot.

You must define a function to call and assign it to the callback.

```
mytxn.onSnapshotCaptured = customTitle (txn) {
    // get book title for current transaction instance
    title = getBookTitle();
    txn.addSnapshotData ("book title", title);
}
```

Note that `txn === mytxn`. It is passed into the callback so the callback does not need to be defined in the same scope as `mytxn`.

txn.addAnalyticsData(key, value)

- `key:` key to analytics data being added
- `value:` value being added for this key

Attaches custom data to Analytics generated for this transaction. If your application has a transaction handle, you can call `txn.addAnalyticsData (key, value)`. If not, use `appd.addAnalyticsData(key, value)`.

To enable this feature, the Analytics settings in the require statement must be set. See Node.js Settings Reference. For more information about Analytics, see Analytics Data Sources.

txn.onResponseComplete(req, res)

- `req`: HTTP request for the transaction
- `res`: HTTP response for the transaction

Callback method that can be set on a transaction to be notified when the associated HTTP response has been completed. This can be used with `txn.addAnalyticsData(key, value)` to add data from response after it is complete, before the transaction completes. When the callback function is supplied, the agent invokes this API immediately after the HTTP response completes, before closing out the transaction. You must define a function to call and assign it to the callback.

```
mytxn.onResponseComplete = function customTitle (req, res) {
    // get status code of HTTP response
    code = res.statusCode;
    txn.addAnalyticsData ("http response code", code);
};
```

Exit Call Management

exitCall.addAnalyticsData (key, value)

- `key:` key to analytics data being added
- `value:` value being added for this key

Attaches existing Analytics data generated for this transaction to the exit call.

Attaches custom data to Analytics generated for this transaction. If your application has a transaction handle, you can call `txn.addAnalyticsData (key, value)`. If not, use `appd.addAnalyticsData(key, value)`.

To enable this feature, the Analytics settings in the require statement must be set. See Node.js Settings Reference.

TimePromise.prototype.startExitCall(exitCallInfo)

- `exitCallInfo` object

  The `exitCallInfo` object has the following required properties:

  - `exitType`: string—the type of exit call, one of "`EXIT_HTTP`", "`EXIT_DB`", "`EXIT_CACHE`", "`EXIT_RABBITMQ`", "`EXIT_WEBSERVICE`"
  - `label`: string—label for the exit call in the AppDynamics UI
  - `backendName`: string—name of the backend remote system or service
  - `identifyingProperties`: Object—a hash of name/value pairs uniquely identifying the remote system or service being called. See Backend Identifying Properties.

Creates and starts a custom exit call, described by the `exitCallInfo` object.

You can supply more identifying properties in addition to the required ones.

Returns an `ExitCall`. See Exit Call Properties.

Sample exitCallInfo Object for MySQL

```
{
  exitType: “EXIT_DB”,
  label: "New SQL",
  backendName: "NewDB"
  identifyingProperties: {
    “HOST”: “database-server”,
    “PORT”: “12345”,
    “DATABASE”: “my-database”,
    "VENDOR" = “MYSQL"
  },
  …etc...
}
```

TimePromise.prototype.endExitCall(exitCall, error)

- `exitCall`: `ExitCall` instance returned by `startExitCall()`
- error: any; optional

Ends a custom exit call and attaches it to this transaction.

If an `error` is passed, the error is associated with the exit call, and the exit call is flagged as being in an error state.

TimePromise.prototype.beforeExitCall(exitCall)

- `exitCall: ExitCall`

Returns an `ExitCall`.

Optional callback for modifying an automatically-detected (not custom) exit call.

The agent invokes this API immediately before your application makes the exit call when you supply a callback function. You can use the callback to:

- Modify the exit call that is reported to the controller.
- Suppress all reporting of the exit call by returning nothing.
- Capture the exit call to create correlation information for a downstream transaction.

The following is an example of a modify exit call reported to the Controller.

```
txn.beforeExitCall = function customExitCallHandler(exitCall) {
    // don't report database access for this transaction
    if (exitCall.isSql) return;
    // customize label for all other exit calls in this transaction
    exitCall.label += " (my custom transaction)";
    return exitCall;
}
```

TimePromise.prototype.exitCallCompleted(exitCall)

- `exitCall`: ExitCall

Optional. Returns an ExitCall. Callback for modifying either a custom exit call created by `startExitCall()` or an automatically-detected exit call on completion of the exit call.

The agent invokes this API immediately after an exit call completes when you supply a callback function.

Use `exitCallCompleted()` to modify how the exit call is reported to the Controller by returning a modified exit call. Do not modify the backend identifying properties using this callback.

The following code is an example that modifies the exit call reported to the Controller.

```
txn.exitCallCompleted = function customExitCallPostProcessor(exitCall) {
    // report MongoDB read and write operations as distinct exit calls
    if (exitCall.backendName === "MongoDB")
        exitCall.label += " " + exitCall.category;
}
```

Transaction Correlation Management

appd.parseCorrelationInfo(source)

- `source:` String or `HttpRequest`

Describes the upstream transaction with which to correlate. If a `HttpRequest` object is passed, it must have a transaction correlation header attached.

On success, returns a `CorrelationHeader` object that can be used by startTransaction() to create a transaction that is correlated with the upstream transaction described by `source`. Returns `false` if `source` could not be parsed. This can occur if the source is an HTTP request with no correlation header attached or the string parameter is not recognized as a correlation header.

HTTP requests made through the standard `http.request()` API have correlation information added automatically. You can correlate a custom transaction created in response to an HTTP request made from another Node.js process by passing the incoming request as `source`.

For other exit call types, you need to define how correlation information is attached to the originating transaction and retrieved in the downstream transaction.

TimePromise.prototype.createCorrelationInfo(exitCall, doNotResolve)

- `exitCall:` ExitCall
- `doNotResolve:` optional, true|false

The input `exitCall` is one of the following:

- For a custom exit call, value returned from startExitCall().
- For an automatically-detected exit call, input parameter to the beforeExitCall() callback.

Set the `doNotResolve` parameter to `true` if you do not want the backend to be resolved to a tier. It defaults to false, which means that the backend is resolved to the calling tier. You may want to set this for an exit call to a service, such as a messaging queue, that does not have a 1:1 relationship between the consumer and producer of the service. For more information see Resolve Remote Services to Tiers.

Returns a string-encoded correlation header, which a downstream transaction can use to correlate with this transaction.

Exit Call Properties

This table describes the properties of the exit call object for each detected exit call type.

A dash (–) in a table cell indicates that the property is present in a discovered exit call but its format is unspecified. This allows you to set your own values when you create custom exit calls.

N/A indicates that the property is not used with that exit call type. Discovered exit calls may have additional properties not documented here.

Property	HTTP	MySQL	Postgres	MongoDB	Memcached	Redis
`backendName`	`"HTTP"`	`"MySQL"`	`"PostgresSQL"`	`"MongoDB"`	`"Memcached"`	`"Redis"`
`label`	String	String	String	String	String	String
`method`	String	N/A	N/A	N/A	N/A	N/A
`requestHeaders`	Object	N/A	N/A	N/A	N/A	N/A
`responseHeaders`	Object	N/A	N/A	N/A	N/A	N/A
`statusCode`	Integer	N/A	N/A	N/A	N/A	N/A
`category`	`"read"|"write"`	N/A	N/A	`"read"|"write"`	N/A	N/A
`user`	N/A	String	String	N/A	N/A	N/A
`command`	String (URL)*	SQL query executed	SQL query executed	N/A	N/A	N/A
`commandArgs`	N/A	SQL query positional parameters	SQL query positional parameters	N/A	N/A	N/A
isSql	N/A	`true`	`true`	`false`	N/A	N/A
`stackTrace`	--	--	--	--	--	--
`exitType`	`"EXIT_HTTP"`	`"EXIT_DB"`	`"EXIT_DB"`	`"EXIT_DB"`	`"EXIT_CACHE"`	`"EXIT_CACHE"`
`identifyingProperties`	See Backend Identifying Properties and TimePromise.prototype.startExitCall(exitCallInfo).					

* host, port and path; does not include query string.

Backend Identifying Properties

This table lists the identifying properties for the backends that are automatically detected by the Node.js Agent.

In the Controller UI, these properties are visible in the upper right panel of the backend dashboards.

Backend Service	Exit Call Type	Identifying Properties
HTTP Server	`"EXIT_HTTP"`	`"HOST", "PORT"`
MySql Server	`"EXIT_DB"`	`"Host", "Port", "Database", "Vendor" = "MYSQL"`
Postgres Server	`"EXIT_DB"`	`"Host", "Port", "Database", "Vendor" = "POSTGRESQL"`
MongoDB Server	`"EXIT_DB"`	`"Server Pool"`[1]`, "Database", "Vendor" = "MONGODB"`
Memcached	`"EXIT_CACHE"`	`"EXIT_CACHE", "Server Pool"`[1]
Redis Server	`"EXIT_CACHE"`	`"Server Pool"`[2]

[1] "\n" separated list of server addresses in <host>:<port> format.
[2] single server address in <host>:<port> format.

Node.js Agent Logging

Related pages:

- Dynamic Language Agent Proxy
- Node.js Java Proxy Mode

This page explains logging for the default mode of the Node.js Agent.

By default, the Node.js Agent generates log information at the informational level. You can increase/decrease the logging verbosity, change the log file location, and configure other logging settings.

Node.js Agent Logging Location

The log file appears at the following location on the machine where the Node.js Agent runs:

```
/tmp/appd/<hash>/appd_node_agent_<datetime>.log
```

If you are running the Node.js Agent, <hash> is generated by the agent.

In Windows, you can find the tmp directory with `cd %tmp% d` and then look for the <hash> directory.

Configure Node.js Agent Logging

To configure logging, use the logging module configuration in the Node.js require statement. You can change the level, maximum size/number of files, and mode.

The following sample shows the logging settings in default mode:

```
{
...

  logging: {
    'logfiles': [
      {
        'root_directory': '/tmp/appd',
                'filename': 'echo_%N.log',
        'level': 'TRACE',
        'max_size': 5242880,
        'max_files': 10,
        'outputType': 'console'  // Set this parameter if you want to log to STDOUT/STDERR. Omit this parameter
if you want to log to a file.
      }
    ]
  }

...
}
```

The level determines the verbosity of logging output and can contain one of the following values listed from least to most verbose:

- FATAL
- ERROR
- WARN
- INFO
- DEBUG
- TRACE

By default, once the size of the logging files on disk reaches the maximum size, old logs are purged. You can reduce or increase the size, depending on your needs and the disk space available on the machine.

Debug Logging

Instead of the logging configuration above, you can use this shortcut to set DEBUG to true, resulting in debug level logging.

```
debug : true,
```

The location of the debug log file is written to standard output.

See Node.js Agent Settings.

Node.js Agent Node Properties

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

max-continuing-concurrent-snapshots

A limit for the number of concurrent snapshots continuing on this tier or node. For example, if too much overhead is being taken by snapshots, then tweak this value to reduce the snapshots.

Type:	Integer
Default Value:	200
Platform(s):	Node.js

max-continuing-snapshots-per-minute

A limit for the number of snapshots continuing on this tier or node per minute. For example, if too much overhead is being taken by snapshots, then tweak this value to reduce the snapshots.

Type:	Integer
Default Value:	100
Platform(s):	Node.js

max-error-snapshots-per-minute

A limit for the number of snapshots on this tier or node per minute to capture errors. For example, if too many error snapshots are being seen, then tweak this value to reduce *noise* in the snapshots.

Type:	Integer
Default Value:	5
Platform(s):	Node.js

max-originating-concurrent-snapshots

A limit for the number of concurrent snapshots originating on this tier or node. For example, if too much overhead is being taken by snapshots, then tweak this value to reduce the snapshots.

Type:	Integer
Default Value:	10
Platform(s):	Node.js

max-originating-snapshots-per-minute

A limit for the number of snapshots originating on this tier or node per minute. For example, if too much overhead is being taken by snapshots, then tweak this value to reduce the snapshots.

Type:	Integer
Default Value:	20
Platform(s):	Node.js

Upgrade the Node.js Agent

If you are upgrading both the Controller and agents, first upgrade the Controller and then upgrade the agents.

Also, if you are upgrading multiple agents in your monitored environment, upgrade the agents for the tiers on which business transactions originate last. For more information about this requirement, along with Controller and agent compatibility information, see Agent and Controller Compatibility.

To upgrade the Node.js agent:

1. Stop the Node.js application.
2. From the root directory of the application for which you want to upgrade the agent, uninstall the old version of the agent by entering:

   ```
   npm uninstall appdynamics
   ```

3. From the same directory install the new version by entering:

   ```
   npm install appdynamics@<version>
   ```

   The version is the three-digit version number of the new version that you are installing; for example, 4.1.1.
4. Restart the Node.js application.

Uninstall the Node.js Agent

To uninstall the Node.js Agent:

1. From the application root directory of the application from which you want to uninstall the agent enter:

   ```
   npm uninstall appdynamics
   ```

2. Remove the `"require("appdynamics")"` statement from your Node.js applications.
3. Restart the Node.js application.

gRPC Support for the Node.js Agent

This page describes how to use the HTTP naming rules required to name gRPC Business Transactions.

To form the gRPC URI, you link the `SERVICE_NAME` and the `OPERATION_NAME` resulting in: `URI = SERVICE_NAME/OPERATION_NAME`. Then , the naming rule uses the `URI = SERVICE_NAME/OPERATION_NAME` to generate the gRPC Business Transactions name.

Automatic Naming Rules

To add automatic naming rules:

1. From the **Add Rule** tab, click **Rule Configuration**.
2. Under the **Configure Naming** tab, select which part of the URI to use in the **Transaction Name**:
    a. Click **Use the full URI** to use the full URI in the **Transaction Name**.
    b. Click **Use a part of the URI** to use only a part of the URI in the **Transaction Name**. If you select **Use a part of the URI**, you can only use one or two segments of the URL.
3. Click **Save**.

Custom Naming Rules

To add custom naming rules:

1. From the **Add Rule** tab, click **Rule Configuration**.
2. Under **HTTP Request Match Criteria**, click **+Add**.
3. Click **URI**.
4. Select **Split Transactions Using Request Data**.
5. In the dropdown, you can select the **first few URI segment(s)** or the **last few URI segment(s)** in the **Transaction names**.
    a. You can only use one or two segments of the URL.
6. Click **Save**.

Node.js Java Proxy Mode

Related pages:

- Dynamic Language Agent Proxy

This page provides an overview of the existing Java proxy mode for the Node.js Agent.

Every Node.js Agent on a machine launches a proxy instance, creating a control directory for the proxy based on a unique combination of application, tier, and node names for the agent. The control directory contains the configuration for the agent and the domain control socket, which is what the agent uses to start an AppDynamics node.

If you are running multiple Node.js Agents on a single machine, you can configure them to use a shared Java proxy. Referred to as a "multi-tenant proxy," the shared proxy reduces the overhead of additional proxies and is a required configuration for external process managers, such as PM2.

You can use the Java proxy mode as the Node.js Agent supports the existing Java proxy.

Install the Node.js Agent (Java Proxy)

Related pages:

- Run the Node.js Agent on Windows
- SELinux Installation Issues

This page provides instructions on how to install the Node.js Agent in the Java proxy mode.

The Getting Started Wizard in the Controller provides the easiest way to get started with the AppDynamics Node.js Agent. The wizard constructs a pre-configured require statement for the agent based on your input.

Before You Begin

You must add a require statement to the source code of your Node.js application and install the Node.js Agent. In addition to running the AppDynamics Controller, you need to have write access to the application source code and the ability to restart the Node.js application, which installs the agent.

The Getting Started Wizard in the Controller generates the require statement for you. It populates the statement with the connection settings for the Controller and the values you provide for the wizard to model the Node.js application in AppDynamics.

For installation on Windows, see Supported Environment to determine the appropriate version of Windows and install the Visual C++ Redistributable for Visual Studio 2015.

Install the Node.js Agent

To install the agent, run the install command in the directory of your application and add a `require` command to add the agent module to your application.

If you are using Node.js 0.8.1 through 0.8.18, see Set User Agent for Node.js 0.8.1 through 0.8.18 before running the install command.

Install via `npm`

Refer to Agent and Controller Compatibility to determine which versions of the Node.js Agent are compatible with your Controller.

To install the latest agent in the Java proxy mode, run the following command:

```
npm install --appd_include_java_proxy=true appdynamics
```

To run the Node.js Agent on Windows with the Java proxy, see Run the Node.js Agent on Windows.

Add the Require Statement

Paste the following require statement as the very first line of your application source code before any other require statement. Replace the variables with the values for your setup. To find your account name and access key, select **Settings**  and then **License**.

```
require("appdynamics").profile({
  controllerHostName: '<controller host name>',
  controllerPort: <controller port number>,
  controllerSslEnabled: false,  // Set to true if controllerPort is SSL
  accountName: '<AppDynamics_account_name>',
  accountAccessKey: '<AppDynamics_account_key>', //required
  applicationName: 'your_app_name',
  tierName: 'choose_a_tier_name',
  nodeName: 'choose_a_node_name',
  proxy: true
 });
```

For reference information on the settings, along with other settings you can use, see Node.js Settings Reference.

You can place the `require` statement as the first line in the require statement of another module that appears as the first line of code.

In this case, you would need to modify your point-of-entry source file; this it can be just a single line to the `require()` the file that you place the call to the agent into; for example, `require("<script-that-initializes-the-agent>")`. You could also parameterize the `profile()` call to name different instances without having to have multiple versions of the agent initialization script.

If it is not possible to place the require statement as the first line of code, you can insert the statement elsewhere, but it must occur before the `require()` of any core or third party module that needs to be instrumented. In general, the `require("appdynamics")` statement should occur as early as possible in the code.

Test the Configuration

To verify the installation, restart the application and put load on it. The new node should appear in the flow map for the business application you specified in the configuration.

Stop the Node.js Application

When running the Node.js Agent with the Java proxy, configure the script/mechanism that stops an instrumented Node.js instance to use the SIGTERM signal if possible. SIGKILL (`kill -9`) prevents the resources for the agent's Java proxy from being released.

When running the Node.js Agent in the multi-tenant mode, you must manually shut down the Java proxy after stopping your Node.js application.

Run with Other Profiling Tools

The agent is incompatible with other profiling tools, such as running the node process with the `--inspect` flag.

Instrument a Node.js Cluster

If your application uses the cluster module, place the `appdynamics.profile require` statement in both the primary and worker processes.

Running the Node.js Agent with the Java proxy does not require a manual launch of the proxy. Running the Node.js Agent with the Java proxy and an external process manager (such as PM2) for your application requires a manual launch of the proxy component.

See Sharing a Proxy Among Node.js Agents.

Run the Node.js Agent on Windows

Related pages:

- Install the Node.js Agent
- Start the Proxy Manually for Node.js
- Share a Proxy Among Node.js Agents
- Dynamic Language Agent Proxy
- SELinux Installation Issues

This page provides instructions on how to run the Node.js Agent in the Java proxy mode on a Windows machine.

Proxy Ports

Depending on your Node.js environment on Windows, you may need to configure three ports in the Node.js require statement. These port settings are:

- `proxyCommPort`: Default is `10101`
- `proxyRequestPort`: Default is `10102`
- `proxyReportingPort`: Default is `10103`

All three ports must be inclusive of the 1024—65535 range.

Auto-Launch Windows Environments

The default behavior is for the agent to auto-launch the Java proxy, where `proxyAutolaunchDisabled` is `false`.

If you allow the agent to auto-launch and you have one Node.js process per machine, the agent will automatically use the default port values if they are available. In this case, you do not have to configure these settings.

If the default ports are not available, configure these settings to ports that are available in the require statement in the `require` statement.

If you have multiple Node.js processes on a single machine each reporting to its own proxy, each process needs its own set of ports. In this case, configure unique settings for all three ports in the `require` statement for each process.

Manual-Launch Windows Environments

Some environments have multiple Node.js processes on the same machine, all reporting to a single proxy. In these environments, it is necessary to launch the proxy manually, where `proxyAutolaunchDisabled` is `true` and to configure the three port settings.

The `proxyCommPort` setting in the `require` statement and the `commPort` option to the `runProxy.cmd` must be the same value. The agent and the proxy must use the same port.

The `proxyRequestPort` and the `proxyReportingPort` are two unused TCP ports that the user running the proxy has permission to bind to on Windows.

Each distinct app-tier-node combination on a single machine must use different request and reporting ports. Two processes reporting as the same app-tier-node may use the same request and reporting ports. Set these ports in the `require` statement for each app/tier/node combination.

Execute runProxy Manually on Windows

By default, the proxy component is automatically started when you start the agent. If you have configured the agent to manually launch the proxy, use the following command.

Before any traffic is run on the instrumented server, execute `runProxy.cmd` to start the proxy using the following syntax. If you use the optional `-d` option, it must precede the `-j` option.

```
Usage: runProxy.cmd [-d <proxyDir>] -j <jreDir> [logDir] [commPort]

Options:
  -d <proxyDir> the directory where the proxy is installed; optional, defaults to the directory containing the
runProxy.cmd script
  -j <jreDir> the directory where the JRE is installed; required
  logDir the directory the proxy should log to; optional, defaults to <proxyDir>\logs
  [commPort] port used for the proxy control channel on Windows; defaults to 10101; if specified it must match
the proxyCommPort setting in the require statement
```

The following example assumes that the command is run from the root of the Node.js application instrumented by the agent.

```
.\node_modules\appdynamics\node_modules\appdynamics-proxy\proxy\runProxy.cmd
                -j .\node_modules\appdynamics\node_modules\appdynamics-jre\jre /var/log/proxy
                .\node_modules\appdynamics\node_modules\appdynamics-proxy\proxy\logs
                10101
```

Execute the runProxy Command Manually on Windows Task Scheduler

You can schedule the runProxy command in the Windows Task Scheduler.

1. Open Task Scheduler.
2. Click **Create Basic Task**.
3. In the General tab, enter a name for your task.
4. Select **Run whether user is logged on or not**.
5. Check **Run with highest privileges**.
6. In the Triggers tab, add a new trigger. Set the trigger to when the device starts.
7. In the Actions tab, create a new action. Set the action to **Start a program**.
8. In the **Program/script** field, enter:
   `<app_root>/node_modules/appdynamics-proxy/proxy/runProxy.cmd`
9. In the **Add arguments** field, enter:
   `-d <app_root>/node_modules/appdynamics-proxy -j <app_root>/node_modules/appdynamics-jre/jre %TEMP% 10101`
10. In the **Start in** field, enter:
    `<app_root>/node_modules/appdynamics-proxy/proxy`
11. Click **OK** to finish the wizard.
12. Reboot the system, and check the Task Manager for a Java process.

- Start the Proxy Manually for Node.js
- User Preferences

This page describes how to configure multiple Node.js Agents on a machine to share a single, multi-tenant Java proxy.

Configure a Shared Proxy

1. Stop the Node.js application.
2. Create directories for the agent and the agent logs and for the proxy control directory. The permissions on this directory must be readable and executable by the application user that the application and writable by the proxy user.
   For example:

   ```
   mkdir /tmp/appd /tmp/appd/logs /tmp/appd/proxy_ctrl_dir
   ```

   When you upgrade the Node.js Agent, you may want to create these directories automatically.
3. Disable automatic proxy launching for each agent. In the AppDynamics `require.profile()` block, set `proxyAutolaunchDisabled` to true and set the `proxyCtrlDir` to the directory that you created.
   For example:

   ```
   ...
   proxyAutolaunchDisabled: true,
   proxyCtrlDir: '/tmp/appd/proxy_ctrl_dir',
   ...
   ```

4. Ensure that each agent that reports to the multi-tenant proxy is configured with a unique node name.
5. Before you start the agents, start the shared Java proxy and pass the agent control directory from the `proxyCommunicationDir` argument to the `runproxy` script. AppDynamics recommends that you configure the proxy to start on system startup. See Start the Proxy Manually for Node.js.
6. Restart the Node.js application. The nodes should appear in the Controller UI flow maps in a couple minutes.

Proxy Sharing Limits

By default, a single proxy can handle up to ten agents. If you need to run more, you will have to adjust the `maxHeapSize` and `maxPermSize` settings in the `runproxy` script.

When adding agents, use debug mode and monitor the `proxy.out` file, which indicates whether the proxy is running out of heap. The file is visible when running in debug mode.

Start the Proxy Manually for Node.js

Related pages:

- Run the Node.js Agent on Windows

This page describes how to manually launch the Java proxy for Node.js.

Upon startup, the Node.js Agent automatically executes the `runproxy` shell script, which starts the Java proxy. This process is suitable for most situations, but there are some cases where you may want to suppress automatic proxy startup and manually launch the proxy.

For example, you are using an external process manager or you are running a Node.js cluster on a machine and want to reduce overhead of multiple proxies.

As the Node.js process owner, you will need to launch the proxy manually.

The following example configures the manual Java proxy launch:

```
nohup /<application_root_dir>/node_modules/appdynamics-proxy/proxy/runProxy -j /<application_root_dir>
/node_modules/appdynamics-jre/jre -- /tmp/appd/proxy_ctrl_dir /tmp/appd/logs &
```

For the full description of the runProxy script syntax for PHP applications, see Start the PHP Agent Proxy Manually.

Node.js Agent Logging (Java Proxy)

Related pages:

- Proxy Logging
- Dynamic Language Agent Proxy

This page explains Node.js Agent logging for the Java proxy mode.

By default, the Node.js Agent generates log information at the informational level. You can increase/decrease the logging verbosity, change the log file location, and configure other logging settings.

Node.js Agent Logging Location

The log file appears at the following location on the machine where the Node.js Agent runs:

```
/tmp/appd/<hash>/appd_node_agent_<datetime>.log
```

If you are running the Node.js Agent, <hash> is generated by the agent.

On Windows, you can find the tmp directory with `cd %tmp% d` and then look for the <hash> directory.

Configure Node.js Agent Logging

To configure logging, use the logging module configuration in the Node.js require statement. You can change the level, maximum size/number of files, and mode.

The following sample shows the logging settings when you are in the Java proxy mode:

```
{
...

  logging: {
     'root_directory': '/tmp/appd',
         'filename': 'echo_%N.log',
     'level': 'TRACE',
     'max_size': 5242880,
     'max_files': 10,
     'outputType': 'console'  // Set this parameter if you want to log to STDOUT/STDERR. Omit this parameter if
you want to log to a file.
  }

...
}
```

The level determines the verbosity of logging output and can contain one of the following values listed from least to most verbose:

- FATAL
- ERROR
- WARN
- INFO
- DEBUG
- TRACE

By default, once the size of the logging files on disk reaches the maximum size, old logs are purged. You can reduce or increase the size, depending on your needs and the disk space available on the machine.

Proxy Logging

The Java proxy logs the transactions that are accepted from the agent and sent to the Controller. The proxy generates logs independently of the Node.js Agent's logging level or activity.

When the Node.js Agent launches the proxy, it prints the directory path at which the proxy is logging to its own log. By default, the proxy log is in `/tmp/appd/<hash>/proxy/logs`.

See Dynamic Agent Proxy Logging.

Debug Logging

Instead of the logging configuration above, you can use this shortcut to set `DEBUG` to true, resulting in debug level logging.

```
debug : true,
```

The location of the debug log file is written in standard output.

See Node.js Agent Settings.

PHP Agent

Related pages:

- AppDynamics Essentials
- PHP Supported Environments
- Dynamic Language Agent Proxy

This page describes the PHP Agent, the application monitoring agent for web and CLI PHP applications in AppDynamics.

About the PHP Agent

The PHP agent component discovers and monitors business transactions, application services, and backends in your PHP application. It injects AppDynamics instrumentation into the application at runtime.

The AppDynamics agent proxy is a Java process that handles the communication between the PHP agent and the Controller. The proxy reports performance metrics to the Controller, where the data is stored, baselined, and analyzed. You can access this performance data interactively using the Controller console or programmatically using the AppDynamics REST API.

The proxy component starts automatically when you start the PHP Agent. For some applications, such as for PHP CLI applications, you need to start the proxy separately from the agent. You need to provide for proxy startup either manually or in scripts.

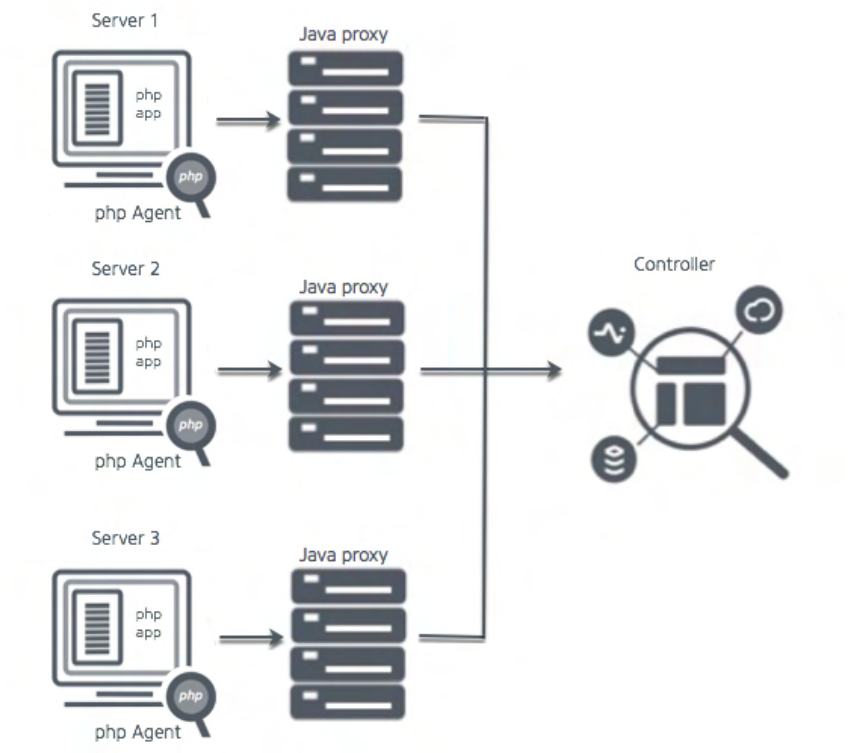
Deployment Overview

The proxy is the component that connects the agent and the controller. If you can ping the Controller but the agent is not connecting, it is possible that the proxy did not start or that the proxy is not configured correctly. See Resolve PHP Agent Installation Issues and Dynamic Language Agent Proxy.

When the connection is successfully established, log in to the Controller to monitor your application. See AppDynamics Essentials to get started.

Single Application Per Web Server Instance

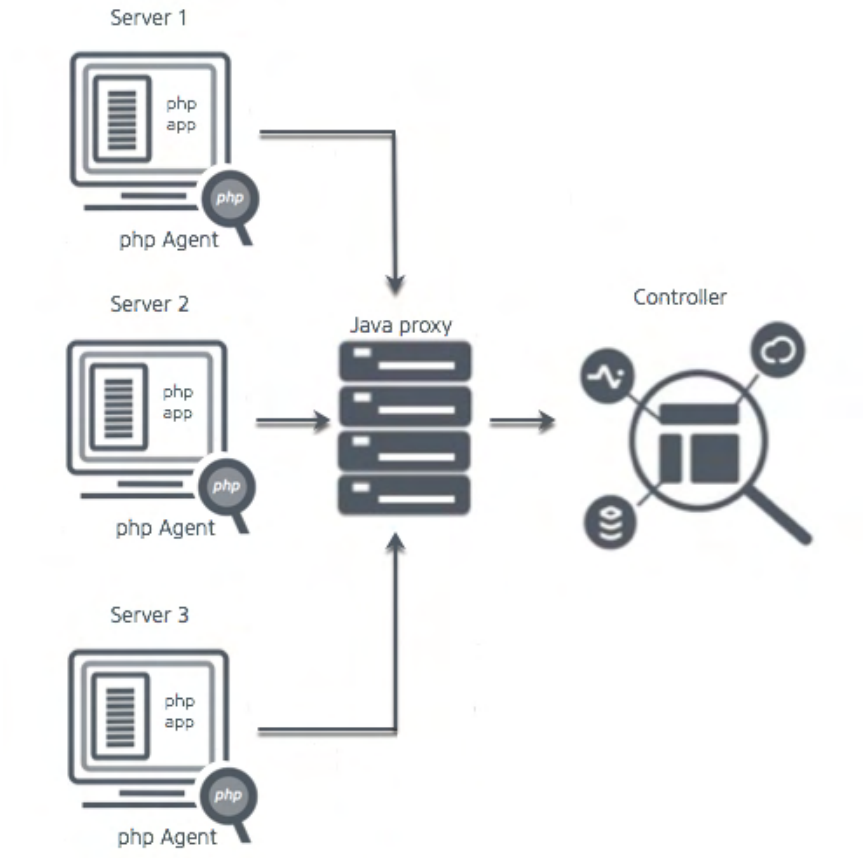
This is the default setup assumed by the installer—multiple servers, each with a single application.



Each application has its own agent and its own agent and proxy. There is a single tier and a single node for each application.

Single Application Per Web Server Instance with Multi-Tenant Proxy

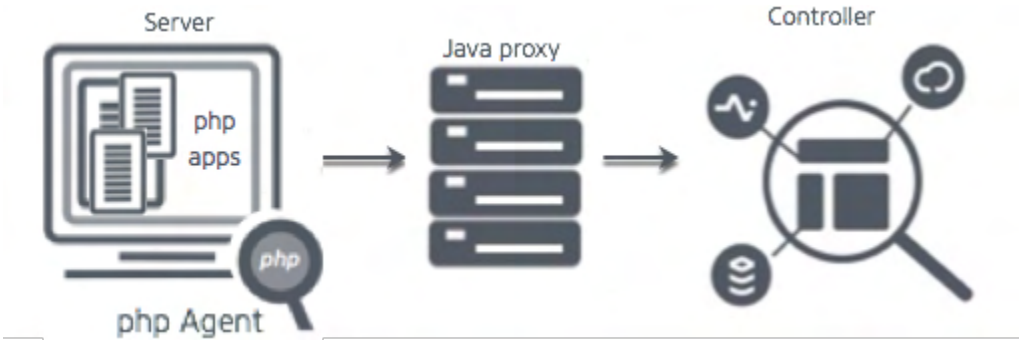
This scenario also assumes multiple servers, each with a single application.



In this case, each application has its own agent component but all the agents share a single proxy. There is a single tier and a single node for each application. Sharing a proxy can save some overhead in some situations. See Use a Shared Proxy for PHP Agents.

Multiple Applications on a Single Server

This scenario assumes multiple applications running in a single server**.**



There is one agent and one proxy supporting multiple applications. By default, the proxy automatically starts when the server starts. The applications can be configured with different tiers and nodes. See Multiple PHP Apps on a Single Server for information on how to configure the Apache vhosts or FPM pool config blocks.

Getting Started with the Download Wizard

If you have never installed the agent, the best way to start is with the Getting Started Wizard in the Controller. The Getting Started Wizard walks you through configuration steps and helps you download the agent. To access the wizard, in the **Home** page of the Controller, click **Getting Started** and then **P HP**.

The wizard provides the minimum information that the agent needs to communicate with the AppDynamics Controller: Controller host and port, optionally SSL, application name and tier name.

Node Naming in a PHP Environment

A PHP runtime instance maps to a node. Your naming convention may depend on your exact environment. Use a name that clearly identifies the Web service that corresponds to the node. Some options are:

- `hostName-appName-nodeName`
- `hostName-tierName-nodeName`
- `appName-nodeName`
- tierName-nodeName
- `IP address`
- `fully qualified domain name`

PHP Supported Environments

Related pages:

- PHP Business Transaction Detection

PHP Agent Support

PHP Versions

PHP Agent supports these versions of PHP:

- 5.6
- 7.0
- 7.1
- 7.2
- 7.3
- 7.4

PHP Web Servers

Apache 2.2 and 2.4 in these modes:

- `prefork` mode using `mod_php`
- worker MPM mode using `mod_fastcgi` with `php-fpm` or `mod_fcgid` with `php-cgi`

Any web server compatible with `php-fpm`.

Operating Systems

- Any Linux distribution based on `glibc 2.5`+ and the x86 32-bit or x86 64-bit architecture
- Mac OS X 10.9+

PHP Agent supports 32-bit operating system only on PHP 5.6.

PHP Frameworks and Protocols

Framework/Protocol	Version	Entry Point Type
Drupal	7	Drupal
Drupal	8	PHP MVC
WordPress	3.4+, 4.x, 5.x	Wordpress
Zend	1, 2, 3	PHP MVC
CodeIgniter	2.x, 3.x, 4.x	PHP MVC
FuelPHP	1.5x, 1.6x, 1.8x	PHP MVC
Magento	1.5, 1.6, 1.7, 2.3	PHP MVC
Symfony	1, 2, 3, 4	PHP MVC
CakePHP	2.x, 3.x, 4.x	PHP MVC
Laravel	5.7, 6, 8	PHP MVC
HTTP		PHP Web
CLI		PHP CLI

If your PHP framework is not listed here, the agent detects your entry points as PHP Web and names the business transactions based on the first two segments of the URI — the default naming convention for PHP Web transactions. So it is still possible to monitor applications on *unsupported* frameworks. Laravel BTs are detected as symfony, as laravel itself is built on top of symfony.

There are few limitations of the PHP Agent. The PHP Agent does not:

- Monitor PHP applications in Zend Thread Safety (ZTS) mode. If you are using ZTS, AppDynamics suggests that you review your dependencies on ZTS to confirm that you actually need it, and if you do not, to switch to the non-ZTS mode
- Support Zend Monitor
- Officially support plug-ins that encrypt and, or obfuscate PHP code such as Zend Guard or ionCUBE Loader
- Support compatibility with the Xdebug module

Transaction Naming

Framework/Environment	Default Transaction Naming
Drupal	page callback name
Wordpress	template name
PHP MVC Frameworks	controller:action
PHP Modular MVC Frameworks	module:controller:action
PHP Web	URI
PHP Web Service	service name.operation name
PHP CLI	last two segments of the script's directory path plus the name of the script

Virtual host prefixing is available for all supported entry point types except PHP CLI.

PaaS Providers

PaaS Provider	Buildpack
Pivotal Cloud Foundry	https://github.com/Appdynamics/php-buildpack See http://docs.pivotal.io/appdynamics/index.html for information about integration with PCF.

Exit Points

Supported HTTP Exit Points
`curl/curl-multi`*
`drupal_http_request()`
`fopen(), file_get_contents()`
`Zend_HTTP_Client::request()`

*The total time reported for a curl/multi_curl request in the Controller is the same as reported by the function `curl_getinfo`. Also, we report the the following execution metrics in the exit call details for the curl/multi_curl request which are included in the total time:

- `namelookup_time`
- `connect_time`
- `pretransfer_time`
- `redirect_time`

Supported Database Exit Points
MySQL old native driver (removed for PHP 7)
MySQLi Extension*
OCI8
PDO
PostgreSQL accessed via PDO and pgsql extensions

* `mysqli_multi_query` is not supported.

Supported Cache Exit Points
Memcache
Memcached
Predis 0.8.5 and 1.1.1, on PHP versions 5.6 and higher
Phpredis 4.1

Although Predis is a full PHP client library, the PHP Agent supports Predis as an exit point only, not as an entry point.

Supported Web Service Exit Points
PHP SOAPClient
NuSOAP 0.9.5

Supported Message Queue Exit Points
RabbitMQ

RabbitMQ support requires the amqp extension.

Opcode Cache Compatibility

Alternative PHP Cache (APC)	

Install the PHP Agent

Related Pages:

- Download AppDynamics Software
- AppDynamics Download Portal
- SELinux Installation Issues

This page provides an overview of AppDynamics PHP Agent installation.

Installation Overview

In the Controller UI, the Getting Started Wizard walks you through the configuration and installation steps for the PHP Agent.

The installer that you get from the wizard uses the PHP directory specified in your environment PATH variable to determine where to install the agent. If you are instrumenting a PHP installation not specified in your PATH, you can manually configure and invoke the RPM or script installer.

The PHP Agent runs on Linux and MacOS machines. The PHP Agent is designed for PHP operating environments in which:

- There is a single PHP installation
- PHP is running in a single Apache or FPM pool
- Standard packages have been used to install PHP, Apache and/or PHP-FPM
- No customizations have been made to the PHP configuration

The PHP Agent may work in environments that do not meet all assumptions. However, you should use extra care in installing and thoroughly testing the PHP agent and application in a staging environment.

Before Starting

Before attempting to install the AppDynamics PHP Agent, confirm that you use a supported PHP version. You can check your PHP version using this command:

```
php -i
```

The PHP Agent *does not work* with PHP applications that are built with the `enable-debug` configuration option or in any build otherwise compiled with debugging symbols. To determine whether the application was built with debugging symbols, you can use this command:

```
php -i | grep -e "Debug Build"
```

The response should be:

```
Debug Build => no
```

You can get the PHP Agent distribution from the AppDynamics Download Portal. Be sure to get the distribution file appropriate for your system:

- For RedHat or CentOS, use the RPM Package Manager distribution, such as PHP Agent—64-bit RPM.
- For all other Linux distributions, use the distribution identified PHP Agent—64-bit Linux.
- For MacOS, use PHP Agent—64-bit OSX

At installation time, you will need to provide Controller connection settings and identifying information for this PHP node. The Getting Started Wizard walks you through this configuration, so if it is your first time installing an AppDynamics Agent, we recommend using the Getting Started Wizard. For general information about the Controller connection settings, see Agent-to-Controller Connections.

To complete the instrumentation, you will need to stop and start the Apache Server. Be sure to perform the installation in a way that minimizes disruption to service users, if applicable.

> Do not install the PHP Agent along with other non-AppDynamics Application Performance Management (APM) tools, especially in a production environment. The PHP Agent installation may fail if there are other APM products installed in the same managed environment.

Installing the PHP Agent

These topics provide installation details for various scenarios:

- To use install.sh, see Install the PHP Agent by Shell Script. Use install.sh to install on OSX as well as Linux.
- To use RPM, see Install the PHP Agent by RPM.
- To instrument PHP CLI, see also Configure the Agent for PHP CLI Applications.

- To instrument an application on MacOS, see MacOS X Installation Considerations.
- To instrument multiple PHP applications running on the same server, see Multiple PHP Apps on a Single Server.

For cURL installation, see Download AppDynamics Software.

Files Added by Installation

PHP configuration files

For AppDynamics, the PHP configuration files of interest are the `php.ini` and `appdynamics_agent.ini` fragment. AppDynamics settings can be found in either `.ini` file, depending on the operating system under which your PHP is installed.

The PHP Agent installer adds the `appdynamics_agent.ini` file to the directory that contains your `php.ini` file. You can find this directory using the following command:

```
php -i | grep -e "Additional .ini files parsed"
```

If the installer is not able to determine the directory where the ini fragments for your PHP deployment live, it displays the required AppDynamics ini fragment and prompts you to copy and paste it into your main `php.ini` file.

Also, see http://php.net/manual/en/configuration.file.php for information about possible locations.

.so files

The installer also installs the appdynamics_`agent.so` file in your PHP extensions directory. You can find this directory using the following command:

```
php -i | grep  extension_dir
```

Logs

There is an agent log and a proxy log for each application.

By default, the agent log is written to `$<php_agent_install>/logs/agent.log`. The log contains the transactions that the agent processes and then sends to the proxy. The default pattern for agent log naming is:

- `agent.log`: the current log
- `agent.log.1`: most recent log
- `agent.log.2`: second most recent log
- `agent.log.3`: third most recent log
- `agent.log.4`: fourth most recent log
- `agent.log.5`: fifth recent log

By default, the proxy log is written to `$<php_agent_install>/logs/proxy_$date.log`. This log contains the transactions that the proxy accepts from the agent and then sends to the Controller.

If you configure the logs directory with the `--log-dir` option, the proxy logs are written to the same directory as the agent logs.

For information about the location of log files generated by an RPM installation, see RPM Log file in Install the PHP Agent by RPM.

Using a Machine Agent on a PHP Node

You can install a machine agent on a node that runs the PHP Agent. However, note that if you install the machine agent on a PHP Agent node and you specify the tier and node name in the `controller-info.xml` file of the machine agent, the PHP Agent will not successfully register with the Controller.

To avoid this problem:

- Install the PHP Agent before you install the machine agent
- If you install the machine agent on the machine hosting the instrumented PHP node, do not specify the application, tier or node name in the `controller-info.xml` file of the machine agent. If you do, the PHP Agent may fail to register.

Install the PHP Agent by Shell Script

Related pages:

- AppDynamics Downloads
- Install the PHP Agent

This page describes how to install the PHP Agent using the included `install.sh` script.

Installing the PHP Agent

These steps describe how to install the PHP Agent with the installation script, `install.sh`.

1. Verify support and system requirements for your environment as described in Install the PHP Agent.
2. Create the `php-agent` installation directory. The directory should be owned by the same user that runs Apache or PHP-FPM (FastCGI Process Manager). AppDynamics recommends naming the directory `/opt/appdynamics/php-agent`.

   > This document refers to the PHP Agent installation directory as: `<php_agent_install>`. Replace the `<php_agent_install>` syntax with the full path to your agent installation directory. For example, change `<php_agent_install>` to `/opt/appdynamics/php-agent`

3. If there is more than one Apache instance on a machine, run `install.sh` once for each Apache instance, each time with the appropriate node, p `hp_ini` dir and `php_ext` dir options.

   See Run the PHP Proxy Daemon Manually

   See Files Added to Your Installation

   From the command line, change directories to the PHP agent installation directory and untar the agent distribution tarball, as in the following example:

   ```
   cd <php_agent_install>
   tar -xvjf appdynamics-php-agent-x64-linux.tar.bz2
   ```

4. Set the following permissions on your `<php_agent_install>` directory.

   - `php`: Make every directory that leads to the PHP agent logs directory readable and executable by all and writable by the directory owner:

     ```
     chmod -R 755 <php_agent_install>
     ```

   - `logs`: If possible, make the logs subdirectory readable/writable/executable by all:

     ```
     chmod 777 <php_agent_install>/logs
     ```

     Directory access permissions of 777 may be too permissive for some organizations. In this case, simply make sure that the directory is owned by the `apache/php/proxy` user.

5. Run the installation script using this syntax:

   ```
   <php_agent_install>/install.sh  [-s] -a=<account_name>@<account_access_key>
   [--http-proxy-host=<proxy_host>] [--http-proxy-port=<proxy_port>] [-e <php_ext_dir>] [-i <php_ini_dir>]
   [-p <php_binary_dir>] [-v <php_version>]
    <controller-host> <controller-port> <app_name> <tier_name> <node_name>
   ```

   The command arguments are described as follows:

   - -s option: You can optionally specify the `-s` option if you want the agent to use SSL (HTTPS) to connect to the controller. In this case, set the Controller port to the HTTPS port of the controller.
   - `-a account_name@account_access_key`: The required controller account name and account key. To find your account name and access key, click  in the upper right corner of the AppDynamics UI, then click **License**.
   - `http-proxy-host` and `http-proxy-port`: Set the `<http-proxy-host>` and `<http-proxy-port>` to route data to the controller through a proxy server. The `<http-proxy-host>` is the hostname or IP address of the proxy server. The `<http-proxy-port>` is the proxy server HTTP or HTTPS port, whichever you are using. If you set the `http-proxy-host` you must set the `http-proxy-port` as well.
   - `http-proxy-user`, `http-proxy-password-file:` The username and password file if using a proxy and the proxy server requires credentials.

- `-e` option: Extensions directory for the `appdynamics_agent.so` file. Needed on Ubuntu as well as when the default PHP CLI binary cannot be determined.
- `-i` option: `ini` directory for the `appdynamics_agent.ini` file. Needed on Ubuntu as well as when the default PHP CLI binary cannot be determined.
- `-v` option: version of PHP that you are instrumenting. Valid formats are version numbers to one or two decimal positions, for example, `5.4` and `5.4.21` are both valid. Needed only when the default PHP CLI binary cannot be determined or there is no PHP CLI binary.
- `-p` option: path to the PHP binary
- `enable-cli-long-running`: Set to `true` to defend PHP in long-running CLI applications. Defaults to `false`. See Long-Running CLI Applications with the Suhosin Patch.
- `--log-dir=<dir>`: The directory to which the agent and proxy logs should be written. Defaults to the `<php_agent_install>/logs` directory.
- `--proxy-ctrl-dir=<dir>`: The proxy control directory. If not specified, the installer creates a temporary directory.

If all options are used, the `-e`, `-i` and `-v` options have precedence over the -p option.

> On Ubuntu, the installation needs to be performed as the root user. Also, you need to use the `-e` option to indicate the correct extensions directory for the `appdynamics_agent.so` file and the `-i` option for the correct `ini` directory for the `appdynamics_agent.ini` file.

6. Restart the webserver, unless you are installing an agent to monitor PHP-CLI only.

If your installation failed, see Resolve PHP Agent Installation Issues.

Installation Command Samples

The following illustrates a sample command to install the agent:

```
install.sh controller 8090 -a=PHPCust@XC6v2n8m2$543 myApp myTier myNode
```

To install the agent using SSL, use the `-s` switch, as follows:

```
install.sh -s -a=PHPCust@XC6v2n8m2$543 controller1.appdynamics.com 8818 myApp myTier myNode
```

The following sample command illustrates installation with a proxy server present:

```
install.sh --http-proxy-host=myproxyhost --http-proxy-port=8099 -a=PHPCust@XC6v2n8m2$543 controller 8090 myApp
myTier myNode
```

Install the PHP Agent by RPM

Related pages:

- Resolve PHP Agent Installation Issues
- Install the PHP Agent
- Download AppDynamics Software
- AppDynamics Download Portal

You can use the AppDynamics PHP Agent RPM to install the PHP Agent on RedHat or CentOS Linux systems.

About the RPM Installer

You must use the PHP Agent RPM installer as the root user.

You pass configuration settings for the agent to the installer using environment variables rather than command-line arguments. Before starting—or as part of your installation script—you need to set the environment variables. You can configure settings such as node name, tier name, business application name, and others for the agent. However, the installer will provide sensible defaults if not provided.

The RPM installer determines the location of your PHP installation based on the PATH environment variable. It uses the first PHP installation that it encounters in the PATH to configure the installer. If you have installed PHP in a non-standard location, you must provide the directory of your PHP binary in the `APPD_PHP_PATH` environment variable.

Before starting, get the RPM package from the AppDynamics Download Portal.

Installing the PHP Agent with RPM

To install PHP Agent with RPM:

1. Verify support and system requirements for your environment as described in Install the PHP Agent.
2. Set environment variables with the configuration settings for the agent if needed. The account key is a required setting. Other settings may be required depending on your environment. See RPM Environment Variables for more information. Alternatively, you can pass environment variables to the installation script directly.
3. Run the installer.

   ```
   sudo rpm -i <package_name>
   ```

   Replace `<package_name>` with the name of the package you downloaded.

   If you are using `sudo` to pass the environment variables to the installation script you can use:

   ```
   sudo APPD_PHP_PATH=/opt/php rpm -i <package_name>
   ```

   or

   ```
   APPD_PHP_PATH=/opt/php sudo -E rpm -i <package_name>
   ```

   If the install reports errors, check the log file as described in RPM Log File.
4. Restart Apache. Not required if you are installing an agent to monitor PHP CLI only.

The RPM installs a single agent. If you have more than one PHP installation on the machine, run the RPM once for each PHP installation, each time with the appropriate `APPD_PHP_PATH` and `APPD_CONF_NODE` settings.

RPM Environment Variables

Environment Variable	Description	Default	Required?
`APPD_PHP_PATH`	Directory containing the PHP binary	None	If your PHP binary is not in a standard location. By default, the installer uses the PHP CLI binary to determine where to install the app agent.
`APPD_PHP_CONFIGURATION_DIR`	INI directory in which to install the `appdynamics_agent.ini` file. Takes precedence over the `APPD_PHP_PATH` setting.	Directory containing your `php.ini` file. See information on files added to your installation in Install the PHP Agent.	If your PHP binary is not in the standard location or if no PHP CLI binary is available.

APPD_PHP_EXTENSION_DIR	Extensions directory in which to install the appdynamics_agent.so file. Takes precedence over the APPD_PHP_PATH setting.	Your PHP extensions directory. See information on files added to your installation in Install the PHP Agent.	If your PHP binary is not in the standard location or if no PHP CLI binary is available.
APPD_PHP_VERSION	Version of PHP that you are instrumenting. Valid formats are version numbers to one or two decimal positions, for example, 5.4 and 5.4.21 are both valid. Takes precedence over the APPD_PHP_PATH setting.	Version used by your PHP CLI binary	If no PHP CLI binary is available, along with the APPD_PHP_CONFIGURATION_DIR and APPD_PHP_EXTENSION_DIR variables.
APPD_CONF_CONTROLLER_HOST	Controller hostname	localhost	
APPD_CONF_CONTROLLER_PORT	Controller port	8080	
APPD_CONF_APP	Application name	MyApp	
APPD_CONF_TIER	Tier name	Hostname of the machine running the script—same as the node name	
APPD_CONF_NODE	Node name	Hostname of the machine running the script	
APPD_CONF_ACCOUNT_NAME	Account name	Defaults to customer1.	If you have an on-premises AppDynamics Controller running in multi-tenant mode or if you are using the AppDynamics SaaS Controller.
APPD_CONF_ACCESS_KEY	Account key	None	Yes. To find your access key, click  in the upper right corner of the AppDynamics UI, then click **License**.
APPD_CONF_SSL_ENABLED	True to enable SSL communication with the controller, false otherwise	false	
APPD_CONF_HTTP_PROXY_HOST	Hostname or IP address of the http proxy server	None	If you want to route data to the controller through a proxy server.
APPD_CONF_HTTP_PROXY_PORT	HTTP or HTTPS port of the http proxy server; must be set if APPD_CONF_HTTP_PROXY_HOST is set	None	If you want to route data to the controller through a proxy server.
APPD_CONF_HTTP_PROXY_USER	Username on the http proxy server	None	If you want to route data to the controller through a proxy server that requires a username.
APPD_CONF_HTTP_PROXY_PASSWORD_FILE	Password on the http proxy server	None	You want to route data to the controller through a proxy server that requires a password.
APPD_PROXY_CTRL_DIR	Initial control communication directory between the agent and the Java proxy	None	
APPD_CONF_LOG_DIR	Directory to which the agent writes the agent and proxy logs	<php_agent_install>/logs	
APPD_CONF_CLI_LONG_RUNNING_ENABLED	Defends PHP in long-running CLI applications.	false	Advisable if instrumenting long-running CLI applications. See Long-Running CLI Applications with the Suhosin Patch in Configure the Agent for PHP CLI Applications.

Updating the Installation

Any changes that you made to the configuration files are preserved when you re-run the installer. RPM saves your original settings and appdynamics_agent_log4cxx.xml files with the settings from the previous installation.

RPM Installation Log File

If errors occurred during installation, a message displays the location of the log file generated in the /tmp directory. Examine this log file to identify the cause of the problem. A successful installation does not produce a log file.

Uninstall the PHP Agent using RPM

If you installed the agent using RPM, use RPM to uninstall it, as follows:

```
sudo rpm -e appdynamics-php-agent-<version>
```

Notice that you need to identify the version of the package. To find the version of the package that you installed, you can enter:

```
rpm -qa | grep appdynamics-php-agent
```

The existing configurations are saved in a tar file in `/tmp`, as indicated upon completion of the uninstall process.

Configure the Agent for PHP CLI Applications

Related pages:

- Start the PHP Agent Proxy Manually
- PHP Agent Configuration Settings

If you are instrumenting a PHP CLI Application with the AppDynamics PHP Agent, after installing the agent you need to take a few additional configuration steps described here.

Instrumenting PHP CLI Applications

When instrumenting a PHP CLI application, you need to provide for the startup of the proxy daemon, as follows:

1. Create the proxy control directory, which is used for agent/proxy communication.
2. In your PHP configuration file—`php.ini` or `appdynamics_agent.ini` depending on your environment. Include the following settings:
    - `agent.cli_enabled = 1`
    - `agent.auto_launch_proxy = 0`
    - `agent.proxy_ctrl_dir  = <proxy control directory>`
      If you are using the RPM installer to install the agent you may have configured the proxy control directory using the `APPD_PROXY_CTRL_DIR` environment variable. See Install the PHP Agent by RPM. This environment variable takes precedence over the setting in the ini file.
3. Before running any traffic through the CLI, run the proxy from the directory into which you installed the PHP agent, passing the proxy control directory and proxy log directory as arguments.

    ```
    proxy/runProxy <proxy_control_dir> <log_dir>
    ```

    For example:

    ```
    proxy/runProxy /tmp/proxy.communication /tmp/agentLogs
    ```

For the full set of options to runProxy, see Start the PHP Agent Proxy Manually.

PHP CLI and the Apache Web Server

If you have PHP CLI applications and an Apache web server on the same machine, your setup depends on whether you want all the traffic reported against a single AppDynamics node or separate nodes. A separate proxy is required for each AppDynamics node that you want to monitor in the controller.

If you want all the CLI traffic to be reported against one node and all the web traffic to be reported against a different node, configure Apache to auto-launch the proxy (the default) and configure CLI to use a manually-launched proxy. This requires separate `.ini` files—one for the web PHP with `agent.auto_launch_proxy` set to `1` and another for PHP CLI with `agent.auto_launch_proxy` set to `0`.

If you want the web traffic and the CLI traffic to be reported against the same node, configure both Apache and CLI to use the same manually launched proxy.

Long-Running CLI Applications with the Suhosin Patch

A side effect of the Suhosin patch is that it prevents the PHP Agent from ensuring cleanup in long-running CLI applications.

If your PHP has the Suhosin patch, it is possible that resources will not be freed in long-running applications. Thus memory leaks could result if the application itself does not explicitly free these resources.

The `long-running-cli` feature defends PHP applications in an environment in which both of the following conditions exist:

- PHP with the Suhosin patch is running on Debian or Ubuntu. It is common for Debian and Ubuntu PHPs to have this patch.
  This feature is not needed for PHPs with only the Suhosin extension, which is different from the patch. Be aware that some PHPs use both the extension and the patch.
- Using the PHP Agent API, you are instrumenting a CLI application that has multiple unbounded business transactions running on the same process,

How the Long-Running CLI Feature Works

At installation time, if the installer determines that PHP has the Suhosin patch and CLI is enabled—`agent.cli_enabled=1`—the value of the installer option results as follows:

- If `true`, a fatal error is generated and the installer terminates. With the option set, the installer refuses to instrument a long-running CLI application on a PHP installation with the Suhosin patch.
- If `false`—the default—the installation continues and warns that memory leaks could occur in long-running CLI processes.

If the installer determines that PHP does not have the Suhosin patch, the installation continues. Long-running CLI processes are supported by the agent, since there is no Suhosin patch.

If the agent could not determine whether your PHP has the Suhosin patch at installation but it does detect the patch at runtime, having set the installer option to 'true' prevents the agent from instrumenting any CLI processes, not just long-running ones. This prevents the Suhosin-patched PHP from exiting.

If CLI is enabled and the installer did not terminate because of the detection of the Suhosin patch, AppDynamics recommends that you install the agent with the `enable-cli-long-running` option—shell script installs—or the `APPD_CONF_CLI_LONG_RUNNING_ENABLED` environment variable —for RPM installs—set to `true`. This will defend your PHP if the patch is detected at runtime.

If the CLI part of your application does not get instrumented, because the installer detected the Suhosin patch, you can unset the option by setting the `agent.cli_long_running` option in the PHP ini file to `off`. Or alternatively, you can re-install with the installer.

Multiple PHP Apps on a Single Server

Related pages:

- Install the PHP Agent
- PHP Business Transaction Detection
- Overview of Application Monitoring

If you follow only the default installation instructions, the PHP Agent treats your entire PHP deployment as a business application with a single tier with a single node. It models your AppDynamics environment this way even if in reality you have multiple PHP applications running in the same Apache or PHP-FPM pool.

You may have configured your PHP applications as different virtual hosts or FPM pools. With multi-application/single-server (MASS) support, you can monitor several PHP applications running on the same server as separate AppDynamics entities, represented as different business applications, different tiers or different nodes. Multiple applications running in the same PHP server can have separate metrics, dashboards, health rules, events, and so on. You can monitor them on different controllers, even from different AppDynamics accounts. You can mix and match the settings to configure the AppDynamics model that works best for monitoring your entire PHP application environment.

AppDynamics recommends that you not instrument more than ten applications on a single server.

Download and Install

To set up your PHP installation for multiple nodes, download a single agent from AppDynamics.

Then follow the instructions in Install the PHP Agent by RPM—RedHat and CentOSX—and Install the PHP Agent by Shell Script—all other Linux and Mac OS—for instrumenting the agent. Configure the required settings using an app/tier/node configuration that fits one of the applications you are instrumenting. Make sure you configure the required settings listed below.

Then, for each additional application that you want the agent to monitor, add an AppDynamics configuration with different settings that reflect how you want the performance metrics to be reported in your AppDynamics model.

Required Configuration Settings for Multi-Node Support

The required settings for multi-node support for each monitored app are:

- `agent.controller.hostName`
- `agent.applicationName`
- `agent.tierName`
- `agent.nodeName`
- `agent.accountName`

It may be necessary to configure additional settings depending on your environment, for example, if you need to route data to the AppDynamics controller through a proxy server.

Where to Configure Settings

There are three files from which the PHP Agent configuration settings are read:

1. appdynamics_agent.ini
2. Apache (vhost) or FMP (fpm-pool) configuration (overrides 1)
3. .htaccess for Apache or .user.ini for FPM (overrides 1 and 2)

When you instrument your first application, passing the required settings on the command-line—shell script install—or through environment variables (RPM install), those settings are written to `appdynamics_agent.ini`.

To apply different sets of settings for the different applications, as best practice specify the settings in each vhost or FPM pool config block.

Sample Apache Configuration

Here are sample virtual host configurations for two applications running on the same server.

Virtual Host Configuration for the `api` App

```
<VirtualHost *:80>
    ServerName api.myhost.com
    DocumentRoot "/var/www/api"
    ErrorLog "/private/var/log/apache2/api_error.log"
    CustomLog "/private/var/log/apache2/api_access.log" common

    php_value agent.applicationName API
    php_value agent.tierName api-tier1
    php_value agent.nodeName api-node1
    php_value agent.controller.hostName appd1.saas.appdynamics.com
    php_value agent.controller.port 8080
    php_value agent.accountName customer1
    php_value agent.accountAccessKey 123456789
</VirtualHost>
```

Virtual Host Configuration for the `frontend` App

```
<VirtualHost *:80>
    ServerName www.myhost.com
    DocumentRoot "/var/www/frontend"
    ErrorLog "/private/var/log/apache2/www_error.log"
    CustomLog "/private/var/log/apache2/www_access.log" common

    php_value agent.applicationName FrontEnd
    php_value agent.tierName frontend-tier1
    php_value agent.nodeName frontend-node1
    php_value agent.controller.hostName appd1.saas.appdynamics.com
    php_value agent.controller.port 8080
    php_value agent.accountName customer1
    php_value agent.accountAccessKey 123456789
</VirtualHost>
```

Sample FPM Configuration

Here are sample FPM configurations for two applications running on the same server.

.conf Configuration for the "api" App

```
api.conf:

php_value[agent.applicationName] = API
php_value[agent.tierName] = api-tier1
php_value[agent.nodeName] = api-node1
php_value[agent.controller.hostName] = appd1.saas.appdynamics.com
php_value[agent.controller.port] = 8080
php_value[agent.accountName] = customer1
php_value[agent.accountAccessKey] = 123456789
```

.conf Configuration for the `frontend` App

```
www.conf:

php_value[agent.applicationName] = FrontEnd
php_value[agent.tierName] = frontend-tier1
php_value[agent.nodeName] = frontend-node1
php_value[agent.controller.hostName] = appd1.saas.appdynamics.com
php_value[agent.controller.port] = 8080
php_value[agent.accountName] = customer1
php_value[agent.accountAccessKey] = 123456789
```

MacOS X Installation Considerations

If you are instrumenting an application running on MacOS X, you need to instrument it manually using the shell script.

If you are installing the PHP Agent on MacOS X, set `max_execution_time` to `0` in the `appdynamics_agent.ini` file

If you have another INI file that is loaded after `appdynamics_agent.ini`, and sets `max_execution` time to a non-zero value, set `max_execution_time` to `0` in the `php.ini` file instead.

Use a Shared Proxy for PHP Agents

Related pages:

- Install the PHP Agent

By default, if you are running multiple agents, each agent automatically launches its own Java proxy to communicate with the controller.

However, if you are running multiple PHP Agents on the same machine, you can reduce your overhead by setting up the agents to report to a single shared or multi-tenant proxy. In this case, you would need to start that proxy manually.

The number of nodes that can report to a single proxy is limited by the size of the heap given to the proxy. You may need to adjust the maxHeapSize and maxPermSize settings in the `runproxy` script if you have a large number of agents reporting to a single proxy.

Setting up a Multi-Tenant Proxy

1. Configure each agent for manual launch of the proxy. To do this, in the PHP configuration file—`php.ini` or `appdynamics_agent.ini` depending on your setup—for each agent, set the agent.auto_launch_proxy value to 0.
2. Configure a single proxy control directory for all the agents that will share the proxy. They must all be on the same machine. To do this, in the PHP configuration file for each agent, set `agent.proxy_ctrl_dir` to the same proxy control directory.
   The permissions on this directory should be readable and executable by the process that runs Apache and writable by the process that runs the proxy.
3. Before you start the agents, arrange to launch the proxy manually, passing the proxy control directory configured in step 2 as the `proxyCommunicationDir` argument to the `runProxy` script. See information on executing the runProxy in Start the PHP Agent Proxy Manually. AppDynamics recommends launching the proxy on system startup.
4. Verify that each agent reporting to the multi-tenant proxy is configured with a unique `app_name`/`node_name` combination. The `app_name` and `node_name` are arguments to the agent install script.

Start the PHP Agent Proxy Manually

Related pages:

- Use a Shared Proxy for PHP Agents
- Configure the Agent for PHP CLI Applications

When the PHP agent starts, it automatically starts the Java proxy that handles communication between the PHP agents and the controller.

Automatic startup of the proxy works for the great majority of situations. However, you can suppress the automatic startup of this script and run it manually. You would do this if:

- You plan to instrument a PHP CLI entry point. The PHP CLI entry point requires manual startup of the proxy and immediate creation of the node on startup.
- You have multiple Apache or FPM pools on the same machine reporting to the same proxy.

To do this, you first need to configure the agent for manual proxy launch. Then you need to launch the proxy manually.

Configure the Agent for Manual Proxy Launch

The PHP Agent configuration needs to be modified to reflect manual launching.

To configure the agent for manual launching:

1. Open the PHP configuration file for editing. The file is `php.ini` or `appdynamics_agent.ini`, depending on your setup.
2. Set the `agent.auto_launch_proxy` setting to 0.
3. Set the `agent.proxy_script` to the path of the `runproxy` that you want to use. The file in the script is relative to the root of the PHP agent. You can specify the absolute path if you prefer.
4. Set the `agent.proxy_ctrl_dir` to the directory to use for initial control communication between the agent and the proxy. This directory contains the domain control socket, which the agent uses to start an AppDynamics node. This directory is where the agent gets the configuration for the node. The application user must have read permission on the `proxy_ctrl_dir`.

Whenever you install the PHP agent, the installer overwrites the `runproxy` script and the `appdynamics_agent.ini` file, but not the `php.ini`. If you re-install, you need to reset the `agent.auto_launch_proxy` setting in the `appdynamics_agent.ini` file before you restart the server.

Run the Proxy

Before any traffic runs on the instrumented server, execute the `runProxy` script to start the proxy.

The following lists the full set of options for the `runProxy` script. The proxy control directory is required.

```
Usage: runProxy options -- proxyCommunicationDir logDirectory [jvmOption [ jvmOption [...] ]

Options:
  -r <dir>, --proxy-runtime-dir=<dir>   Specifies proxy runtime directory
  -d <dir>, --proxy-dir=<dir>           Specifies root proxy directory
  -j <dir>, --jre-dir=<dir>             Specifies root JRE directory
  -v, --verbose                         Enable verbose output
  -h,--help                             Show this
```

The following shows an example:

```
./proxy/runProxy -d ./proxy -r <agent.proxy_ctrl_dir> /tmp/proxy.communication /tmp/agentLogs
```

A node is created when the agent first detects traffic on it.

Every time you reboot the server, you need to execute the `runProxy` script if you have opted to start the proxy manually.

Resolve PHP Agent Installation Issues

If traffic does not display in the Controller after you have installed the AppDynamics PHP Agent and started the instrumented server, try these troubleshooting steps.

Ensure that the Agent is Installed in the Correct Directory

It is possible that the agent was installed in the wrong directory. Verify the location of your PHP installation.

- Verify the location of your PHP by running `phpinfo`. See http://us1.php.net/phpinfo.

Then check where the installer actually installed the agent files.

- The `appdynamics_agent.ini` file should be in the same directory that contains the php.ini file for your PHP installation.
- The `appdynamics_agent.so` file should be in the extensions directory for your PHP installation.

See Files Added to Your Installation for information about how to locate these directories.

In addition, on Linux you can use `pstree` to locate the agent. The `pstree` command displays the AppDynamics agent running under Apache if the agent is installed properly. See http://freecode.com/projects/pstree.

If the agent files are not in the correct directories, re-install the agent with the `-i` and `-e` options.

Re-install the agent

If the app agent is not installed in the right directory, re-install the agent using the `install.sh` installer with the `-i` and -e options. Use the `-i` to install the `appdynamics_agent.ini` file in the same directory as your `php.ini` file and the -e option to install the `appdynamics_agent.so` file in the same directory as your PHP extensions directory. See Install the PHP Agent by Shell Script.

If you initially installed the agent using the RPM installer, you can find the shell script installer at `/usr/lib/appdynamics-php5/install.sh`.

Check error messages in the installation output

When you reinstall, examine carefully any error messages in the output of the install script, especially those that direct you to copy some settings into your `php.ini` file.

If necessary copy those settings into the php.ini file. See PHP Agent Configuration Settings for information on common settings that may be missing.

Check the AppDynamics Settings Block in the Configuration

Run this command:

```
php -i | less
```

and examine the output. You should see an `appdynamics_agent.ini` file and a configuration block listing appdynamics `ini` values.

Confirm User Permissions

Check that the following permissions are set:

```
chown -R <apacheuser>:<apacheuser> <php_agent_install>
chmod -R 755 <path_to_php_agent_install_logs>
chmod 777 <php_agent_install>/logs
```

Verify that the Proxy is Running

The Java proxy is the part of the agent that communicates with the Controller. If the agent is installed in the right place, confirm that the Java proxy is running.

1. From the command line enter, `ps aux | grep java`.
2. Inspect the list. You should see output similar to the following if the proxy is running:

```
/usr/lib/appdynamics-php5/proxy/jre/bin/java -server -Xmx120m -classpath /usr/lib/appdynamics-php5/proxy/conf
/logging/*:/usr/lib/appdynamics-php5/proxy/lib/*:/usr/lib/appdynamics-php5/proxy/lib/tp/*:/usr/lib/appdynamics-
php5/proxy/* -Djava.library.path=/usr/lib/appdynamics-php5/proxy/lib/tp -Dappdynamics.agent.logs.dir=/usr/lib
/appdynamics-php5/logs -Dcomm=/tmp/ad-siJ4rp -DagentType=PHP_APP_AGENT -Dappdynamics.agent.runtime.dir=/usr/lib
/appdynamics-php5/proxy com.appdynamics.ee.agent.proxy.kernel.Proxy
```

If you are instrumenting a PHP CLI script, you need to start the proxy manually. You may also need to start the proxy manually if you have special requirements for running Java processes. See Start the PHP Agent Proxy Manually.

Check the Configuration Properties

It is possible that the properties that the proxy uses to communicate with the Controller were not set properly.

You can modify these properties in the `php.ini` or `appdynamics_agent.ini` file, wherever they are set in your environment. See PHP Agent Configuration Settings.

Upgrade the PHP Agent

Related pages:

- Install the PHP Agent
- Uninstall the PHP Agent
- Resolve PHP Agent Installation Issues

If you are upgrading both the Controller and agents, first upgrade the Controller and then upgrade the agents.

Also, if you are upgrading multiple agents in your monitored environment, upgrade the agents for the tiers on which business transactions originate last. For more information about this requirement, along with Controller and agent compatibility information, see Agent and Controller Compatibility.

Upgrade the PHP Agent

1. Shut down the web server or `php-fpm`.

2. Copy the controller host, controller port, application name, tier name and node name property values from your `ini` file.
If you are running in multi-tenant mode, also copy the account name and account access key property values.

3. Recursively remove or rename the old AppDynamics PHP installation directory.

4. Download and extract the most recent agent tarball.

5. Run the installation script.
   Beginning in 4.1, you must pass the controller access key as one of the options to the installer.

   To find your access key, click  **> License > Account**.

6. Restart Apache or php-fpm.

> If you are using the agent to monitor PHP CLI without running a web server, you can omit steps 1 and 6.

Uninstall the PHP Agent

Related pages:

- Install the PHP Agent by Shell Script
- Install the PHP Agent by RPM

The method you use to install the agent varies based on the installation mechanism you used. If you are not sure which method was used, see Checking the Installation Method.

Uninstall an RPM-Installed PHP Agent

1. If one is running, shut down the web server. This may not apply for a PHP CLI application.
2. Run the following command:

   ```
   rpm -e appdynamics-php-agent-<version>
   ```

   where `<version>` is the package you installed. You can find the version using:

   ```
   rpm -qa | grep appdynamics-php-agent
   ```

Uninstall a Script-Installed PHP Agent

If you installed the agent using `install.sh`, uninstall that agent as follows:

1. Shut down the web server, if one is running. This may not apply for PHP CLI application.
2. From the PHP agent install directory, run the PHP installer with the `-u` option:

   ```
   install.sh -u
   ```

3. Delete the `<php_agent_install>` directory.

Checking the Installation Method

If you used the Agent Download Wizard, it might not be obvious which installer was used since the installer is called by the `runme.sh` wizard script.

Normally, if **RHEL and CentOS** was selected in the wizard, the RPM installer was used. If **All Other Linux OS** was selected in the wizard, the shell script installer was used. So use the appropriate uninstall command based on the command that was used to install the agent.

If you do not know which selection was checked in the wizard, run:

```
rpm -qa | grep appdynamics-php-agent
```

If this does not list any results, assume that the shell script installer was used to install the agent.

PHP Agent Configuration Settings

The PHP installers write information that the agent uses to communicate with the Controller to the AppDynamics Agent section of the PHP configuration files.

By default, the PHP Agent marks an HTTP error response, such as status code 4xx response as an error. When the following setting is added to the php.ini file, it will not mark the HTTP error response as an error.

```
agent.http_error_detection = false
```

This is different from some of the other AppDynamics application agents, which write this information to an XML file called `controller-info.xml`.

If you re-install the agent, the installer overwrites your settings only if you are using a fragments directory. It never overwrites the `php.ini` file. You can edit the PHP configuration files after installation to add, delete or modify these settings.

If a setting documented as *required* is not provided, the agent will not start. In this case, the agent logs the error to the web server error log. For example, if the `controller.Hostname` is not set you would see the following message in the Apache error log:

```
[AD agent] agent.controller.hostName is not set. Agent is disabled.
```

If after successful startup you remove a required setting or set it to an empty value, the change is ignored as long as the application is running, using the original value of the setting as it was at startup. If you change a required setting to a different valid value, restart the web server to apply the change.

The Controller information settings are described below:

agent.controller.hostName

This is the host name or the IP address of the AppDynamics Controller. Example values are 192.168.1.22, `myhost` or `myhost.abc.com`. This is the same host that you use to access the AppDynamics browser-based user interface. For an on-premises Controller, use the value for application server hostname that was configured when the Controller was installed.

This setting is required.

agent.controller.port

This is the HTTP(S) port of the AppDynamics Controller. This is the same port that you use to access the AppDynamics browser-based user interface.

If `agent.controller.ssl.enabled` is `true`, specify the HTTPS port of the Controller; otherwise, specify the HTTP port. See agent.controller.ssl.enabled.

For on-premises installations, port 8090 for HTTP and port 8181 for HTTPS are the defaults.

This setting is required.

agent.applicationName

This is the name of the logical business application that the instrumented node belongs to.

If a business application of the configured name does not exist, it is created automatically.

This setting is required.

agent.tierName

This is the name of the logical tier that this node belongs to.

This setting is required.

agent.nodeName

This is the name of the instrumented node.

This setting is required.

agent.accountName

This is the account name used to authenticate with the Controller.

This setting is required if the AppDynamics Controller is running in multi-tenant mode or if you are using the AppDynamics SaaS Controller. It specifies the account name for the agent to use to authenticate with the Controller. If you are using the AppDynamics SaaS Controller, the Welcome email sent by AppDynamics provides the account name.

This setting is not required if the Controller is running in single-tenant mode.

agent.accountAccessKey

This is the account access key used to authenticate with the Controller.

This setting is required. To find your access key, click the gear () icon in the upper right corner of the AppDynamics UI, then click **License**.

agent.controller.ssl.enabled

When set to `true`, this setting specifies that the agent should use SSL (HTTPS) to connect to the Controller. If `agent.controller.ssl.enabled` is `true`, set the `agent.controller.port` to the HTTPS port of the Controller.

agent.proxy_ctrl_dir

This specifies the initial control communication directory between the agent and the proxy. Needed only for a manual proxy start. See Start the PHP Agent Proxy Manually

agent.uniqueHostId

When you add this setting to the `php.ini` file in the PHP Agent, you can set a unique host ID for the App agents.

```
agent.uniqueHostId = <Insert uniqueHostId>
```

For example, `agent.uniqueHostId =  AppDynamics`

agent.http_error_detection=true

When adding this setting to `php.ini`, the PHP agent, marks HTTP error response, such as status code 4xx response as an error.

Node Reuse for PHP Agent

This page describes how to use the node reuse feature for the PHP Agent.

Reuse Node Name

This property is useful for monitoring environments where there are many VMs (Virtual Machines) with short life spans. When set to `true`, AppDynamics reuses the node names of historical VMs for new VMs. Therefore, this prevents the rapid increase of differently named nodes, especially when the nodes are identical processes that run over different times.

AppDynamics generates a node name with App, Tier, and Sequence number, and the node names are pooled. For example, the sequence numbers are reused when the nodes are purged (based on the node lifetime).

1. Edit the PHP configuration file, `php.ini` or `appdynamics_agent.ini` depending on your environment.
2. In the PHP configuration file, configure the following settings:

```
agent.nodeReuse
```

When the value of `agent.nodeReuse` is set to `true`, the agent uses reuse node name. The default value is `false`.

```
agent.nodeReusePrefix
```

When you configure the agent to reuse node names, use the `agent.nodeReusePrefix` property to specify the prefix that the controller uses to generate node names dynamically.

This setting is required when `agent.nodeReuse` is set to `true`.

An example of the reuse node feature:

With the following configuration in the `php.ini` file, the Controller generates a node name with the prefix *reportGen*. Node names will have suffixes -1, -2, and so on, depending on the number of nodes are running in parallel. The name of a node that is shut down and qualifies as a historical node that may be reused by a new node.

```
agent.nodeReuse=true agent.nodeReusePrefix=reportGen
```

Note

When `agent.nodeReuse` and a node name is used, the `agent.nodeReusePrefix` property is given precedence.

PHP Agent API User Guide

Related pages:

- PHP Agent API Reference
- PHP Supported Environments

This page describes the PHP Agent API and provides example use cases for the API.

About the PHP Agent API

The PHP Agent API enables you to:

- Define custom business transactions programmatically
- Provide correlation headers for entry points not supported by default detection
- Create custom exit calls to discover backends that are not automatically detected by the PHP Agent

Include the AppDynamics API Header

You should include the `appdynamics_api_header.php` file in your application to ensure that it works correctly if the agent is uninstalled or temporarily disabled. This file contains empty API functions that will prevent the application from throwing errors if the agent is not present.

The `appdynamics_api_header.php` file is located in the PHP Agent package in the same directory as the `install.sh` script.

To include the header file:

1. Copy `appdynamics_api_header.php` to where you keep the header files for the monitored application.
2. Make sure that `appdynamics_api_header.php` is in your include path.
3. Then add the following to your script:

```
require 'appdynamics_api_header.php';
```

Backend Detection with the MySQLi Driver

As noted on PHP Supported Environments, the PHP Agent does not work with PHP 5.2 applications that use the `new` keyword to instantiate a database backend with the MySQLi database driver. For example, AppDynamics does not detect the MySQLi backend created as follows in a PHP 5.2 application:

```
$db = new mysqli("localhost", "user", "password", "database");
```

You can work around this by using `mysqli_connect()` instead:

```
$db = mysqli_connect("localhost", "user", "password", "database");
```

Parts of a Script are Business Transactions

If you have a long PHP script application that performs a number of discrete tasks, but you want the agent to detect only one or more of them as business transactions, enclose the code for each of those tasks within `appdynamics_start_transaction()` and `appdynamics_end_transaction()` calls. The agent detects those blocks as separate business transactions. Otherwise, the agent detects the entire script as a single business transaction.

Handling Business Transaction Code Executing in a Loop

For a script-based CLI application that executes in a loop, perhaps fetching items from a database or remote service, you may want the agent to detect every iteration of the loop as a separate business transaction. In this case, enclose the code inside the loop within `appdynamics_start_transaction()` and `appdynamics_end_transaction()` calls.

If you do not do this, the agent will aggregate each iteration through the loop into a single business transaction.

In the following example, the agent detects a business transaction named `getItem` for every iteration.

```
while (true){
    appdynamics_start_transaction("getItem", AD_CLI);
    //your code goes here
    . . .
    appdynamics_end_transaction();
}
```

Correlating with an Upstream Service

If you have a distributed business transaction in which a tier needs to correlate with an upstream service that is not an entry point supported by the PHP Agent, you can maintain transaction correlation using `appdynamics_continue_transaction()` in the downstream tier, passing it the correlation header from the service.

You need to extract the correlation header from the service as shown in the following sample. The sample function extracts the correlation header from each message in an AMQP message queue and passes it to `appdynamics_continue_transaction()`.

After processing the message, it calls `appdynamics_end_transaction()`, which ends the continuation of the transaction on the calling tier. The `appdynamics_end_transaction()` call does not end the entire distributed transaction in the case where that tier makes a distributed call to another downstream tier.

```
function amqp_receive($exchangeName, $routingKey, $queueName) {
    $amqpConnection = amqp_connection();
    $channel = new AMQPChannel($amqpConnection);
    $queue = new AMQPQueue($channel);
    $queue->setName($queueName);
    $queue->bind($exchangeName, $routingKey);
    while($message = $queue->get()) {
        // Extracting the correlation header.
        echo("Message #".$message->getDeliveryTag()." '".$message->getBody()."'");
        echo("Correlation header: " . $message->getHeader("singularityheader"));
        // Passing correlation header to API.
        appdynamics_continue_transaction($message->getHeader("singularityheader"));
        doStuff($message);
        // End transaction.
        appdynamics_end_transaction();
    }
    if(!$amqpConnection->disconnect()) {
        throw new Exception("Could not disconnect !");
    }
}
```

If the service is not a supported entry point and you do not do this, the tier will not be correlated with the upstream transaction.

Make Socket-based HTTP Calls Example

While the API does not include built-in calls for socket-based HTTP call, you can implement monitoring of socket-based HTTP exit calls yourself as shown in the following example:

```
<?php

function doSocketHTTPCall($url, $corrHeader = null)
{
    $parts = parse_url($url);
    $fs = @fsockopen($parts['host'], isset($parts['port']) ? $parts['port'] : 80, $errno, $error);
    if (!$fs)
        return null;
    $send = "GET {$parts['path']} HTTP/1.1\r\n" .
        "Host: {$parts['host']}\r\n" .
        "Connection: Close\r\n";
    if ($corrHeader)
        $send .= "singularityheader: $corrHeader\r\n";
    $send .= "\r\n";
    fwrite($fs, $send);
    $data = stream_get_contents($fs);
    fclose($fs);
    return $data;
}

$url = 'http://httpstat.us/200';
$parts = parse_url($url);

$exitCall = appdynamics_begin_exit_call(
                AD_EXIT_HTTP,
                'HTTP Status Service',
                array('HOST' => $parts['host'],
                      'PORT' => (string)$parts['port'])
            );

doSocketHTTPCall($url);

appdynamics_end_exit_call($exitCall);
?>
```

Inject a Correlation Header into an HTTP Payload Example

The next example injects a correlation header into the socket-based HTTP payload.

```
<?php

$url = 'http://myhost.mydomain/continue.php';
$parts = parse_url($url);

$exitCall = appdynamics_begin_exit_call(
                AD_EXIT_HTTP,
                'HTTP Status Service',
                array('HOST' => $parts['host'],
                      'PORT' => (string)$parts['port'])
            );

$corrHeader = $exitCall->getCorrelationHeader();

doSocketHTTPCall($url, $corrHeader);

appdynamics_end_exit_call($exitCall);
?>
```

The next example shows how to use a non-exclusive flag to start an exit call that may be wrapping other exit calls. The outer socket-HTTP call is started, then the `file_get_contents()` call is processed by the agent normally, and finally, the outer call is finished. We also pass the exception object to report any errors. The end result is that both backends are displayed on the flowmap.

```
<?php

class SocketHTTPException extends Exception
{
}

$url = 'http://httpstat.us/200';
$javaTierURL = 'http://myhost.mydomain/process.jsp';
$parts = parse_url($url);

$exitCall = appdynamics_begin_exit_call(
                AD_EXIT_HTTP,
                'HTTP Status Service',
                array('HOST' => $parts['host'],
                      'PORT' => (string)$parts['port']),
                false
            );

$contents = file_get_contents($javaTierURL);

if (doSocketHTTPCall($url) == null) {
    $error = new SocketHTTPException("something bad happened");
}

appdynamics_end_exit_call($exitCall, $error);

?>
```

PHP Agent API Reference

Related pages:

- PHP Agent API User Guide

The PHP Agent APIs support custom business transaction definition and correlation. They provide a way to generate multiple business transactions in a single PHP request.

They also enable you to monitor exit calls that are not automatically detected by the PHP Agent.

API Reference Overview

The operations in the API fall into two categories, business transaction management and exit call management.

Business transaction management methods are:

- bool appdynamics_start_transaction($transaction_name, $entry_point_type)
- bool appdynamics_continue_transaction($correlation_header, $entry_point_type)
- bool appdynamics_end_transaction()

Exit call management methods are:

- ADExitCall appdynamics_begin_exit_call($type, $label, $properties, $exclusive=true)
- void appdynamics_end_exit_call(ADExitCall $exitCall, $exception = null)
- string ADExitCall::getCorrelationHeader()
- void ADExitCall::setSQLQueryInfo($querystring, $boundparams)

The following sections detail the methods in the API.

Start Transaction

Starts a custom business transaction.

Format

```
bool appdynamics_start_transaction($transaction_name, $entry_point_type)
```

Description

If the business transaction initiated by this call is not matched by an appdynamics_end_transaction() call, the transaction terminates at the end of the request or script.

Custom business transactions cannot be nested. If you call appdynamics_start_transaction() multiple times before calling `appdynamics_end_transaction()`, the last `appdynamics_start_transaction()` is used and the previous calls are discarded.

Parameters

`$transaction_name`: The name used for the transaction in the controller. The following characters are not allowed in transaction names: { } [ ] | & ;

`$entry_point_type`: Indicates the framework or protocol of the entry point. Valid entry point types are provided as PHP extension constants, shown below:

- `AD_WEB`
- `AD_MVC`
- `AD_DRUPAL`
- `AD_WORDPRESS`
- `AD_CLI`
- `AD_WEBSERVICE`

Entry point types are case sensitive.

Returns

True on success, false on failure.

Failure conditions are reported in the Apache log. Reasons for failure include:

- Invalid transaction name, contains disallowed characters
- Invalid entry point type
- Agent not initialized
- EUM headers were sent prior to the `appdynamics_start_transaction()` call.
- Correlation headers were sent prior to the `appdynamics_start_transaction()` call.

Continue Transaction

Correlates a custom business transaction with an upstream service.

Format

```
bool appdynamics_continue_transaction($correlation_header, $entry_point_type)
```

Description

Used by a downstream tier to correlate with a service that is not an entry point supported by the PHP Agent.

Parameters

`$correlation_header`: Correlation header of the upstream service with which to correlate.

It is the developer's responsibility to extract the correlation information from the service to provide the $correlation_header. See getCorrelationHeader() .

`$entry_point_type`: Optional parameter that indicates the framework or protocol of the entry point for the continued transaction. By default, the value is automatically set to AD_CLI when the application is running in CLI mode, and AD_WEB otherwise.

Use this parameter to indicate a different originating PHP application type for continuing transactions that cross PHP types, such as for a transaction originating at a PHP web application that crosses to a PHP CLI leg of the transaction.

Valid entry point types are provided as PHP extension constants:

- `AD_WEB`
- `AD_MVC`
- `AD_DRUPAL`
- `AD_WORDPRESS`
- `AD_CLI`
- `AD_WEBSERVICE`

Entry point types are case sensitive.

Return

Returns true on success, false on failure.

End Transaction

Ends a transaction created by a previous call to `appdynamics_begin_transaction()` or continued by `appdynamics_continue_transaction()`.

Format

```
bool appdynamics_end_transaction()
```

Description

When paired with an `appdynamics_continue_transaction() call`, this call ends the transaction on the tier being continued but does not end any subsequent calls downstream from that tier that are part of the distributed transaction.

If the business transaction is invalid or if there were no previous `appdynamics_begin_transaction()` or `appdynamics_continue_transaction()` calls in the request/script, this function returns false and throws a warning message that is captured by the application and reported as an exception.

Your application is recommended to wrap `appdynamics_begin_transaction()` and handle possible exceptions so that they are not logged as application exceptions.

Begin Exit Call

Marks the start of an exit call.

Format

```
ADExitCall appdynamics_begin_exit_call($type, $label, $properties, $exclusive=true)
```

Parameters

`$type:` The type of exit call. Must be one of the following:

- `AD_EXIT_HTTP`
- `AD_EXIT_DB`
- `AD_EXIT_CACHE`

- AD_EXIT_RABBITMQ
- AD_EXIT_WEBSERVICE

$label

Label for the exit call in the AppDynamics UI. Use a label under 40 characters long so that it fits in flowmaps.

$properties

An associative array of identifying properties—name/value pairs—for the exit call. Property names and values must be strings.

Each exit call type has its own properties. There is no validation of property names, but each exit type has traditionally used the names listed below.

type					
AD_EXIT_HTTP	"HOST"	"PORT"	"URL"	"QUERY_STRING"	
AD_EXIT_DB	"HOST"	"PORT"	"DATABASE"	"VENDOR"	"URL"
AD_EXIT_CACHE	"SERVER POOL"	"VENDOR"			
AD_EXIT_RABBITMQ	"HOST"	"PORT"	"EXCHANGE"	"ROUTING KEY"	
AD_EXIT_WEBSERVICE	"SERVICE"	"OPERATION"	"SOAP ACTION"	"VENDOR"	"URL"

For AD_EXIT_DB exit call type it is advisable to specify at least HOST, PORT and VENDOR, as these properties are used by the AppDynamics DB integration. The VENDOR property for AD_EXIT_DB backends should be one of the following:

- MYSQL
- POSTGRESQL
- SQLSERVER
- ORACLE
- SYBASE
- DB2

$exclusive: Boolean that Indicates whether the exit call is exclusive.

Only one exclusive exit call can be in progress at a time. For example, if this API is used to start an HTTP exit call and there is a mysql_connect() call immediately following it, the MySQL call will not be detected while the HTTP call is in progress. An exclusive exit call has to be explicitly ended before subsequent exit calls can be detected or initiated.

Exit calls are exclusive by default, but you can make them non-exclusive by setting this parameter to false.

See the last code sample in the 'Scenario: Application makes socket-based HTTP calls' in PHP Agent API User Guide for an example of how setting this flag to `false` can be used to support nested exit calls.

Return

Returns an instance of the `ADExitCall` class on success, `NULL` on error.

End Exit Call

Marks the end of an exit call.

Format

```
void appdynamics_end_exit_call(ADExitCall $exitCall, $exception = null)
```

Parameters

`$exitCall`: An object representing the exit call to be ended, and returned from its `appdynamics_begin_exit_call()`.

$exception: An exception object—either Exception class or one derived from it—specifying if an error occurred during the exit call.

Get Correlation Header

Returns the correlation header for this exit call. The returned correlation header can be passed to appdynamics_continue_transaction to correlate with this exit call.

See also the 'Scenario: Application makes socket-based HTTP calls" 'ample in PHP Agent API User Guide for an example of injecting the correlation header into an HTTP payload.

Format

```
string ADExitCall::getCorrelationHeader()
```

Set SQL Query Info

Sets the SQL query for this exit custom call.

Format

`void ADExitCall::setSQLQueryInfo($querystring, $boundparams)`

Parameters

`$querystring`: String containing the SQL query. Use question marks to indicate the bound parameters.

`$boundparams`: Optional comma-separated array of bound parameters as quoted strings.

Example

```
$exitCall->setSQLQueryInfo("SELECT * FROM mytable where id1=? and id2=?;", ('Susie', '12345'));
```

PHP Agent Logging

For the PHP Agent there is an agent log and a proxy log for each instrumented application.

Agent Log

The agent log is located at `$<php_agent_install>/logs/agent.log`. The log contains the transactions that the agent processes and then sends to the proxy.

The default pattern for agent log naming is the following:

- `agent.log`: the current log
- `agent.log.1`: most recent log
- `agent.log.2`: second most recent log
- `agent.log.3`: third most recent log
- `agent.log.4`: fourth most recent log
- `agent.log.5`: fifth recent log.

The agent creates and rotates a maximum of six log files. Maximum log size is 20 MB, which gives you a maximum of the most recent 120 MB of log data at one time.

Proxy Log

The proxy log is located `$<php_agent_install>/logs/proxy_$date.log.` This log contains the transactions that the proxy accepts from the agent and then sends to the Controller. See Proxy Logging and Dynamic Language Agent Proxy.

Filter Data

By default, AppDynamics PHP Agent sends transaction data to the Controller that your organization may classify as privileged information. Though this data is useful for diagnosis and troubleshooting, security considerations may require you to filter certain sensitive information from being displayed on the Controller. You can use the following for the security considerations:

- URL filters to exclude sensitive information from a URL in snapshot details.
- Data filters to exclude sensitive HTTP cookies.

Add a URL Filter

1. Edit the PHP configuration file, `php.ini` or `appdynamics_agent.ini` depending on your environment.
2. In the PHP configuration file, configure the following settings. If a value in the ini file for any of the following config contains any non-alphanumeric characters, it must be enclosed within double-quotes (") as per the PHP guidelines.

    - Config Delimiter: Specify the character that you want to use as the configuration delimiter for the sensitive data filter for redaction. The config delimiter must be chosen such that it should not occur in the redaction config strings. This value is REQUIRED.

        For example:

```
agent.sensitive_data_filter.configDelimiter = "|"
```

    - URL Delimiter: Specify the character that you want to use as URL segment endpoints. The agent splits the URL at each delimiter instance to create the segments. For HTTP, use the forward-slash character "/". For a forward slash, the agent does not split on the slashes immediately following the protocol. For example, "https://myapp.example.com/" constitutes a single segment. By default, the delimiter is "/" but this is REQUIRED for successful redaction.

        For example:

```
agent.sensitive_data_filter.delimiter = "/"
```

> ‘#’ and ‘;’ cannot be used as a delimiter or configDelimiter because the ini file considers it as a comment.

    - Segment: Specify a comma-separated list to indicate the segments that you want the agent to filter. Segment numbering starts from 1 and providing 0 or negative value fails to redact the segments with an error message in the agent logs. The segment numbers must be in the ascending order. This value is REQUIRED.

        For example:

```
agent.sensitive_data_filter.segment = "2,3"
```

    - Matchfilter: Specify the type of filter to be used to match the URL among - `NOT_EMPTY|EQUALS|STARTSWITH|ENDSWITH|CONTAINS|REGEX`. PERL standard must be followed if REGEX is used. The value is REQUIRED.

        For using this correctly, query parameters must not be considered for match-filtering. With an example of the call "https://myapp.example.com/sensitive/data?first_name=abc&last_name=xyz", to specify match-filter as STARTSWITH, it matches a specified string starting with the hostname “https://myapp.example.com” in this example. If the URL contains the port in the hostname, it must be present in the config string. Similarly for ENDSWITH, it will correspond to the last segment leaving out the query parameters, “data” in this case, as query parameters are never reported in the snapshots.

        For example:

```
agent.sensitive_data_filter.matchFilter = "CONTAINS"
```

    - MatchPattern: Specify the string that you want to be filtered by the match-filter. This value is REQUIRED.

        For example:

```
agent.sensitive_data_filter.matchPattern = "myapp"
```

    - ParamPattern: Specify the regular expression matching the query parameters to filter. PERL Standard should be followed for the regular expression. This value is OPTIONAL.

        For example:

```
agent.sensitive_data_filter.paramMatcher = "[a-z]+_name"
```

For example, the following configuration splits the URL on the "/" character and masks the second segment and the `ParamPattern` in the third segment of the URL. Here, the segmentation and obfuscation apply only to URLs containing "myapp".

```
agent.sensitive_data_filter.configDelimiter = "|"
agent.sensitive_data_filter.delimiter = "/"
agent.sensitive_data_filter.segment = "2"
agent.sensitive_data_filter.matchFilter = "CONTAINS"
agent.sensitive_data_filter.matchPattern = "myapp"
agent.sensitive_data_filter.paramMatcher = "[a-z]+_name"
```

The exit call to "https://myapp.example.com/sensitive/data?first_name=abc&last_name=xyz" breaks down to three segments: "https://myapp.example.com", "sensitive", and "data?first_name=abc&last_name=xyz". The Controller shows the masked values of the URL and the param-pattern display "https://myapp.example.com/*****/data?first_name=***&last_name=***" in the snapshot details.

If you do not use any values for the query parameters, the Controller does not mask any query parameters in the URL.

Redaction of Multiple URLs

Due to the limitations of the PHP configurations, if you want to redact multiple URLs separately, arguments must be written separated by the config delimiter as described below:

```
agent.sensitive_data_filter.configDelimiter = "|"
agent.sensitive_data_filter.delimiter = "/|/"
agent.sensitive_data_filter.segment = "1,2,3|1,4"
agent.sensitive_data_filter.matchFilter = "CONTAINS|ENDSWITH"
agent.sensitive_data_filter.matchPattern = "One|.php"
agent.sensitive_data_filter.paramMatcher = "[a-z]+_name|[a-z]+_name"
```

Each ‘|’ separated values correspond to an additional URL filter added. For ‘n’ number of separate URL filters, you need to have ‘n’ different ‘I’ configurations correspondingly. These filters work independently on the URLs and will redact based on the configurations specified for each filter. The first matching configuration is used for the redaction.

For a successful redaction, ensure that each configuration contains the same number of configuration segments.

Data Filter for Cookies

You can use Cookie filters to configure the agent to obfuscate sensitive information from the URLs in transaction snapshot details.

1. Edit the PHP configuration file, `php.ini` or `appdynamics_agent.ini` depending on your environment.
2. Add sensitive cookie filter element as directives:

    - AppDynamicsCookieMatchPattern: Specify a regular expression identifying cookies that must be redacted.

    For example:

```
agent.sensitive_data_filter.cookieMatcher = "cookieKey"
```

    - For masking multiple cookies values simultaneously, provide names of all those cookies separated by the config delimiter as a single string as follows:

```
agent.sensitive_data_filter.cookieMatcher = "PHPSESSID|X-CSRF-TOKEN|cookiekey"
```

If the config delimiter is present in the cookie name itself, change it to something else such that it should not occur in the cookie matcher strings.

PHP Agent Node Properties

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

max-business-transactions

The number of business transactions discovered once an agent is started. This is done to prevent business transaction metric explosion because an unsuitable discovery scheme can potentially produce thousands of transactions,

Warning: Changing this setting can affect the resource consumption of your deployment. Before you change this setting, verify that your application environment and Controller can handle any increased resource requirements.

Type:	Integer
Default value:	50
Range:	Minimum=N/A; Maximum=300
Platform(s):	PHP

on-demand-snapshots

Collect snapshots for all Business Transactions executed in this node. Does not need a restart.

Type:	Boolean
Default value:	false
Platform(s):	PHP

Python Agent

Related pages:

- Dynamic Language Agent Proxy

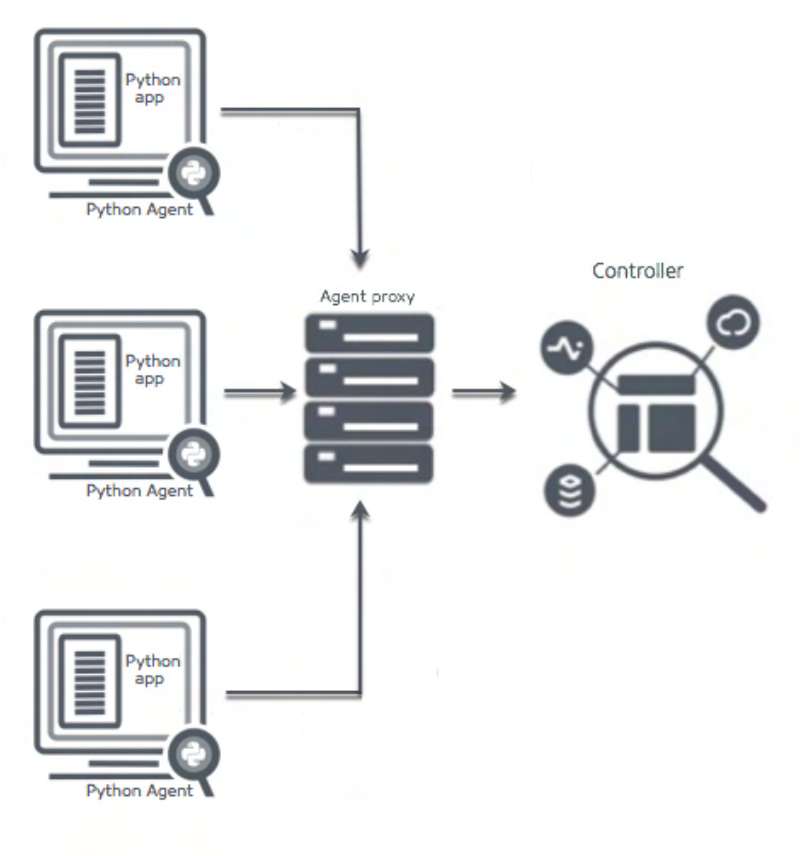
This page describes how to install and administer the Python Agent, the runtime agent used to monitor Python with AppDynamics Application Monitoring.

Python Agent Architecture

The Python Agent discovers, and maps and tracks metrics for business transactions, app services, and backends in your web application by injecting instrumentation into the Python application at runtime. The agent operates from inside the WSGI server that contains the instrumented application.

The agent proxy is a Java process that handles the communication between the Python Agent and Controller. The proxy reports performance metrics to the Controller, where the data is stored, analyzed, and presented.

As shown in the following figure, the proxy can serve multiple Python Agents simultaneously.



In pure Python environments, the proxy is automatically started when you start the Python Agent. In other types of environments, you need to start the proxy manually.

However the proxy is started, the commands that start the agent check whether the proxy is running before attempting to start it.

Install the Agent Overview

If you have never installed the agent, the best way to start is with the Getting Started Wizard in the Controller. This installer configures your agents with the values that you supply in the wizard.

If you downloaded the agent from PyPI, use the instructions in Install the Python Agent to instrument your application manually. In this case, see Python Agent Settings for a complete list of all the Python Agent settings that you can use to instrument the agent.

Getting Started with the Download Wizard

The Getting Started Wizard walks you through configuration steps and helps you download the agent. To access the wizard, from the home page of the Controller, click **Getting Started** and then **Python**.

The wizard provides for a minimally configured agent, with settings for the Controller connection, the business application name, and tier name. For advanced scenarios, see Install the Python Agent.

Python Supported Environments

Related pages:

- Python Agent

Python Agent Support

Python Versions

The Python agent supports Python 2.7, 3.4, 3.5, 3.6, 3.7, 3.8, and 3.9.

Operating Systems

The Python agent operates on any Linux distribution based on glibc 2.12+ and the x86 32-bit or x86 64-bit architecture.

- Support for Mac OS X will be deprecated from the 20.7.0 version of the Python Agent.
- Support for centos5 has been deprecated.

Python Frameworks and Protocols

Framework /Protocol	Version	Entry Point Type	Default Transaction Naming
WSGI	1.0	Python Web	First two segments of URI
Tornado	3.2 - 4.5 (all versions), Tornado 5.x without asyncio library, Tornado 6 (for Python 3.5.3+)	Python Web	First two segments of URI

AppDynamics has tested the Python Agent on Tornado, Django, Flask, CherryPy, Bottle, and Pyramid.

You can configure the agent to instrument any WSGI-based application or framework as Python Web, including but not limited to those listed below.

At present, the Python agent fully supports exception detection in Django, Flask, CherryPy, Bottle, Pyramid, and Tornado frameworks. Other WSGI frameworks and custom WSGI applications may install exception handlers that effectively hide some exceptions from the agent. In such cases, the agent will only detect exceptions during exit calls, missed exceptions that are propagated to the WSGI server, and exceptions reported via the custom business transaction API.

WSGI-Based Frameworks	Notes
Bottle	0.12.19
CherryPy	18.6.0
Django	3.1.5
Flask	1.1.2
PasteDeploy	2.1.0
Pyramid	1.10.5
mod_wsgi	4.7.1

Database Exit Points

Supported Database Exit Points	Version
cx_Oracle	5.1.x
MongoDB	3.1+
MySQL-Python	
mysqlclient	
MySQL Connector/Python	

Psycopg 2	
PyMySql	
TorMySql	

HTTP Exit Points

Supported HTTP Exit Points
httplib*
httplib2
requests
urllib
urllib2
urllib3
tornado.httpclient

* The agent detects calls to any external library built on top of `httplib`. Therefore, backend calls to such services, such as, boto, dropbox, python-twitter are detected and displayed as HTTP exit calls.

Cache Exit Points

Supported Cache Exit Points
Memcache
Redis-py

Install the Python Agent

Related Pages:

- SELinux Installation Issues

This page describes how to prepare the application environment and install the AppDynamics Python Agent.

Before You Begin

1. Verify support for your application environment at Python Supported Environments.
2. Verify that the machine where you will install the agent can access the Python Package Index.
3. Provide a WSGI-based application to monitor.
4. Verify that you can access the machine where the application runs as a user with privileges to install the agent software and restart the application. Verify that you have a user account with these privileges.
5. If you are using uWSGI, set `enable-threads=1` in the uWSGI configuration file. The agent requires multi-threading.
   There is a known incompatibility between the Python Agent and versions of uWSGI installed via OS packages managers such as 'apt-get'. For this reason, AppDynamics recommends installing uWSGI from pip to avoid this issue.
6. If the application to monitor runs in a virtual environment, activate the virtual environment. For example, the following source command activates a virtual environment:

   ```
   source /<path_to_virtual_environment>/bin/activate
   ```

   Activating a virtual environment is not necessary if the application runs in the global Python environment.

Install the Agent

Log in to the machine on which the Python application runs using appropriate user credentials, as follows:

- For a virtual environment, you need to be the user who owns the virtual environment.
- For the global Python environment, you need to run the install command as root.

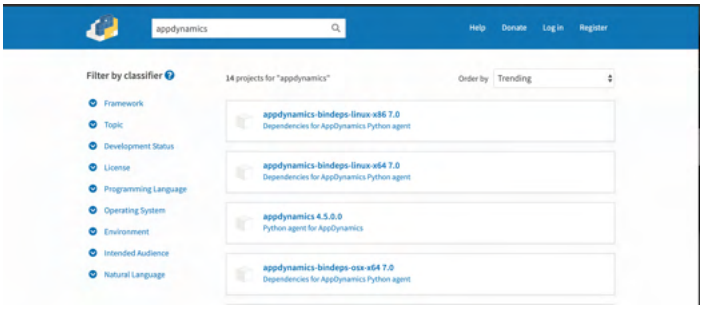
You can install the agent using one of the installation methods explained in the following sections.

pip Installation

To install or upgrade to the latest version of the agent, run the `pip install` command as follows:

```
pip install -U appdynamics
```

When there are multiple packages, you can locate the agent using the `pip list` command or using the List packages facility at https://pypi.python.org/pypi and then find `appdynamics` in the output. Here is a sample output:



For production deployments, AppDynamics recommends that you freeze the versions of dependencies so that they are not upgraded in production without first being deployed to your test/staging environments. The command to install or upgrade to a particular version of the AppDynamics Python Agent is:

```
pip install -U appdynamics==<released_agent_version>
```

For example:

```
pip install -U appdynamics==4.4.0.0
```

This command always installs the exact same version of the agent each time it is run.

Installation from AppDynamics Download Portal

1. Download `PythonAgent*.tar.bz2` file (based on target platform) from the portal and untar the contents to a folder.
   Run the following command to ensure that you have latest pip to support wheel installation:

   ```
   pip install --upgrade pip
   ```

2. Run the following command to install the wheel format:

   ```
   pip install -f <untar_folder> appdynamics
   ```

Configure the Agent

Provide a configuration file that specifies the required AppDynamics settings for agent-Controller communication. The file should be in Python ConfigParser format. The Python application user must have read access on the configuration file.

Note that lines in the configuration file must not start with spaces. Lines that begin with a # are comments and are ignored by the agent.

The following is a simple sample configuration file with minimum required settings.

```
[agent]
app = <app_name>
tier = <tier_name>
node = <node_name>

[controller]
host = <controller_host>
port = <controller_port>
ssl = true
account = <your AppDynamics controller account name>
accesskey = <your AppDynamics controller account access key>
```

Note the following points in the configuration:

1. The ssl settings determines whether the agent connects to the Controller by SSL. This is required for SaaS Controllers.
2. The `account` value is required if you are using a SaaS account or a multi-tenant on-premises controller. It defaults to `customer1` for a single tenant controller.
3. The accesskey is required for all controllers. To find your account name and access key, click  in the upper right corner of the AppDynamics UI, then click **License**.
4. Other settings, such as `ssl`, `http-proxy` or `wsgi_module`, may be required for your environment. See Python Agent Settings for a complete list of settings.

When you instrument an application using `pyagent run`, you pass the configuration file path as a parameter to the pyagent run command. In other deployments set the `APPD_CONFIG_FILE` environment variable as illustrated below in the samples for uWSGI with Emperor and Apache with mod_wsgi.

Instrument the Application

Which instrumentation instructions to use depends on how the application is deployed, from these deployment options:

- pyagent run
- uWSGI with Emperor
- Apache with mod_wsgi

Irrespective of your Python environment, if you built your application using PasteDeploy, you can install the Python Agent by modifying the PasteDeploy configuration. See PasteDeploy.

pyagent run

If you can control the way your WSGI server is invoked, you can instrument the application using `pyagent run`. This command runs your WSGI server with the Python agent enabled. This option is generally possible if you use a process launcher/manager that takes a command to execute. For example, frameworks managed by Supervisor, uWSGI without Emperor, init.d scripts, and so on.

To use the `pyagent run` command, prepend to your existing application run command the `pyagent run` command, passing the AppDynamics configuration file described in Configure the Agent as a parameter.

Do not overwrite `PYTHONPATH` for any reason. Doing so will prevent the `pyagent run` command from loading the agent. If you need to add to PYTHONPATH, use the pythonpath configuration variable. For example, these commands add `/foo` and `/bar` to the `PYTHONPATH` instead of overwriting it:

Correct way to add to PYTHONPATH:

```
pythonpath = /foo
pythonpath = /bar
```

Do not add the values to PYTHONPATH using the follwoing syntax. This is the wrong way to add to PYTHONPATH:

```
env = PYTHONPATH=/foo:/bar
```

Using supervisorctl

If you use `supervisorctl`, after updating your Supervisor configuration you must use the `supervisorctl reload` command to have the Python agent loaded. Supervisor does not re-read its configuration files when you use the `supervisorctl restart` command.

To verify that the agent was loaded, look for the Python agent log file. Its default location is `/tmp/appd/logs/<app_name>-<node_name>.log`. For example, if your application name is `myapp` and your node name is `mynode` as specified in the agent configuration file, and you have not changed the location of the log file, the log file will be `/tmp/appd/logs/myapp-mynode`.

If the log file exists, the agent was loaded. If the log file does not exist, the agent was not loaded, in which case you should try reloading the Supervisor configuration with `supervisorctl reload`.

Django and Flask

If your framework is Django or Flask, simply prepend `pyagent run` to your run command. For example, if your current run command looks like this:

```
gunicorn -w 8 -b '0.0.0.0:9000' example.app:application
```

Replace it with the following:

```
pyagent run -c <path_to_appdynamics_config_file> -- gunicorn -w 8 -b '0.0.0.0:9000' example.app:application
```

Other Pure Python WSGI-Based Frameworks

If you use a WSGI-based framework that is not Django or Flask:

1. In the AppDynamics configuration file, specify your WSGI application by setting the `APPD_WSGI_MODULE` directive to point to your app module. See Python Agent Settings.
2. Prepend `pyagent run` to your run command.
3. Run the AppDynamics-generated application.

For example, if your run command looks like this:

```
gunicorn -w 8 -b '0.0.0.0:9000' example.app:application
```

Replace it with these two commands:

```
pyagent run -c /path/to/appdynamics.cfg -- gunicorn -w 8 -b '0.0.0.0:9000'
appdynamics.scripts.wsgi:application
```

uWSGI with Emperor

If your environment is uWSGI with Emperor, you need to modify your WSGI configuration files and then manually launch the proxy.

uWSGI Emperor is a process manager specific to the uWSGI server. It does not allow you to control how the uWSGI processes that it manages are launched and therefore cannot be used with the `pyagent run` command.

The location of the WSGI configuration files is deployment-dependent. See http://uwsgi-docs.readthedocs.org/en/latest/Emperor.html for details of Emperor deployment.

To instrument an application for uWSGI with Emperor:

1. Create the configuration file described in Configure the Agent.
2. Modify the uWSGI configuration file. Do one of the following, depending on whether the configuration uses a module directive or a wsgi-file directive:
   Module Directive
   If the uWSGI configuration has a module directive such as the following:

   ```
   module = yourcompany.sample:app
   ```

   modify that configuration by changing the module setting and adding the `APPD_WSGI_MODULE` and `APPD_CONFIG_FILE` settings to look like this, assuming that you have stored the configuration file in `/etc/appdynamics.cfg`:

   ```
   env = APPD_CONFIG_FILE=/etc/appdynamics.cfg
   env = APPD_WSGI_MODULE=yourcompany.sample:app
   module = appdynamics.scripts.wsgi:application
   ```

   WSGI-File Directive
   If the uWSGI configuration has a `wsgi-file` directive:

   ```
   wsgi-file = /var/www/yourcompany/sample.py
   callable = app
   ```

   Modify the configuration to look like the following, assuming you have stored the configuration file in `/etc/appdynamics.cfg`:

   ```
   env = APPD_CONFIG_FILE=/etc/appdynamics.cfg
   env = APPD_WSGI_SCRIPT_ALIAS=/var/www/yourcompany/sample.py
   env = APPD_WSGI_CALLABLE_OBJECT=app
   module = appdynamics.scripts.wsgi
   ```

3. Before running any traffic through the instrumented application, manually launch the proxy by executing:

   ```
   pyagent proxy start
   ```

Apache with mod_wsgi

The Python Agent beta supports only `mod_wsgi` configurations that use `WSGIScriptAlias` that point to a single WSGI file. For example, the following type of configuration is supported:

```
WSGIScriptAlias /books /var/www/acme/bookstore/app.wsgi
```

If, instead, the script alias points to a directory, or if the script is using the `WSGIScriptAliasMatch` directive, contact python@appdynamics.com to discuss how the Python Agent can be deployed in your environment.

If the environment is Apache with `mod_wsgi` with a supported configuration as described above, you need to modify its `mod_wsgi` configuration files and manually launch the proxy.

To instrument an app for Apache with mod_wsgi:

1. Create the configuration file described in Configure the Agent.
2. Modify the `mod_wsgi` configuration file.
   If the `mod_wsgi` configuration file has an entry like this:

   ```
   WSGIScriptAlias /books /var/www/acme/bookstore/app.wsgi
   WSGICallableObject application
   ```

   modify it to look like this, assuming that you have stored the configuration file in `/etc/appdynamics.cfg`:

   ```
   SetEnv APPD_CONFIG_FILE /etc/appdynamics.cfg
   SetEnv APPD_WSGI_MODULE acme.bookstore:app
   WSGIScriptAlias /books /<path_to_virtualenv>/lib/python2.7/site-packages/appdynamics/scripts/wsgi.py
   ```

3. Before running any traffic through the instrumented app, manually launch the proxy by executing:

   ```
   pyagent proxy start
   ```

PasteDeploy

You can instrument a Python application built with PasteDeploy by modifying your PasteDeploy configuration to use a composite factory supplied by AppDynamics. This feature can be used to instrument applications described by the other deployment options if they were built with PasteDeploy.

The AppDynamics composite factory is named `egg:appdynamics#instrument`. It requires a parameter named `target` that points to the application to the original application and the full path to the APPD_settings.

To instrument an application built with PasteDeploy:

1. Manually launch the AppDynamics proxy:

   ```
   pyagent proxy start
   ```

2. In the PasteDeploy configuration file, rename the existing composite to a unique name.
   For example, if the existing composite configuration for an application named `metadata` is:

   ```
   [composite:metadata]
   use = egg:Paste#urlmap
   /: meta
   ```

   you could rename it:

   ```
   [composite:_orig_metadata]
   use = egg:Paste#urlmap
   /: meta
   ```

3. Create a new composite section for the `metadata` application above the original one that you just renamed, as follows:

   a. Give the name of the old renamed application to the new composite application.
   b. Configure it to use the AppDynamics composite factory: `egg:appdynamics#instrument`.
   c. Set its target to the renamed application.
   d. Set the AppDynamics configuration file environment variable, `APPD_CONFIG_FILE`, to the path of your configuration file. For example:

      ```
      [composite:metadata]
      use = egg:appdynamics#instrument
      target = orig_metadata
      APPD_CONFIG_FILE = /etc/appdynamics.cfg
      ```

      You can also set other APPD_ configuration variables here. For example, `APPD_LOGS_DIR=/var/log/appdynamics`.

4. Restart the application.

Start the Python Agent Proxy Manually

Related pages:

- Install the Python Agent
- Python Agent Settings

If you use the `pyagent run` command to instrument your application, the proxy is automatically started when you start the agent.

However, you may need to arrange to start the proxy separately from the agent. The most likely reason you would need to do this is because your Python environment uses uWSGI with Emperor or Apache with mod_wsgi. You can do so using the `pyagent run` command described here. Only use this command only if you need to launch the proxy manually.

Directory Configuration Setting

The command you use to start the proxy needs to read the directory configuration setting, APPD_DIR, the base directory for the AppDynamics Python Agent configuration. Make sure it is correctly set. The default is `/tmp/appd/`.

You can make this setting available to the proxy in any of the following ways:

- Setting the environment variable `APPD_DIR` manually.
- Setting the `APPD_CONFIG_FILE` environment variable to point to the configuration file and then setting the base directory in the configuration file. See Install the Python Agent.
- Passing in the path to the configuration file to the pyagent proxy command using -c (—config-file) option as illustrated below.

Start, Stop, and Restart Options for the pyagent proxy

To start, stop, or restart the proxy, use the `pyagent run` command, passing the desired operation and any options. The options include:

- —debug (-d): starts the proxy in debugging mode
- —no-watchdog: disables the proxy watchdog (not recommended)
- —config-file (-c): path to the Python Agent configuration file

Usage:

```
pyagent proxy start|stop|restart start_options  -- [jvmOption [jvmOption [...] ]
```

Examples:

```
pyagent proxy start -c appdynamics.config -d
pyagent proxy restart -c appdynamics.config -d
pyagent proxy stop -c appdynamics.config
```

When agent is stopped without stopping the proxy it continues to be shown as active for the next 10 minutes. To avoid the application from reappearing in the controller, it is recommended that you wait for at least 10 minutes before deleting the application after the agent shut down.

Upgrade the Python Agent

If you are upgrading both the Controller and agents, first upgrade the Controller and then upgrade the agents.

To upgrade the Python to the latest version of the 4.5 agent, run this command:

```
pip install -U appdynamics\<4.5
```

The upgrade will take effect the next time you restart the agent.

Uninstall the Python Agent

Related pages:

- Python Agent

You can remove Python Agent instrumentation from your application by reverting deployment script changes made when installing the agent to remove all `pyagent` commands and APPD environment variables.

Removing instrumentation is generally sufficient for most purposes when it comes to uninstalling the Python Agent, however, you can additionally remove the Python Agent packages using `pip`.

Because `pip install appdynamics` installed a separate dependencies package as well as the agent, two `pip uninstall` commands are required:

```
pip uninstall appdynamics
pip uninstall <python_agent_package>
```

If you do not know which package is installed, you can find out using `pip freeze` and `grep`:

```
pip freeze | grep appdynamics
```

Python Agent Settings

You can configure operating settings for the Python Agent using a configuration file or by setting environment variables in the application environment. This page lists the Python Agent settings.

See Configure the Agent for information about the configuration file.

> Older version of the environment variables are backward compatible and are deprecated which will eventually be removed in future releases. You will have to update the environment variables to the latest version.
> The new environment variables take precedence over the deprecated variables in case both are set in an environment (eg. `APPDYNAMICS_AGENT_APPLICATION_NAME` takes precedence over the deprecated `APPD_APP_NAME` if both are set).

[agent]

Directive	Description	Example	Default	Environment Variable
`app`	App Name	`MyApp`	*Required*	`APPDYNAMICS_AGENT_APPLICATION_NAME`
`tier`	Tier Name	`web-fe`	*Required*	`APPDYNAMICS_AGENT_TIER_NAME`
`node`	Node Name	`web-fe1`	*Required*	`APPDYNAMICS_AGENT_NODE_NAME`
`dir`	Base directory for files related to the AppDynamics agent	`/mysite/appd/agent/python/`	`/tmp/appd/`	`APPDYNAMICS_AGENT_BASE_DIR`
`nodereuse`	Reuse Node Name	`true` or `false`	*Optional*	`APPDYNAMICS_AGENT_REUSE_NODE_NAME`
`nodereuseprefix`	Reuse Node Name Prefix	`My Node Name`	*Optional*	`APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX`
`uniquehostid`	Unique host id for the app agents		Optional	`APPDYNAMICS_AGENT_UNIQUE_HOST_ID`

[wsgi]

Directive	Description	Example	Default	Environment Variable
`script`	Path to WSGI script file	`/var/www/acme/bookstore.py`	*n/a*	`APPDYNAMICS_WSGI_SCRIPT_ALIAS`
`callable`	Name of WSGI callable in script/module	`app`	`application`	`APPDYNAMICS_WSGI_CALLABLE_OBJECT`
`module`	Fully-qualified name of app module	`acme.bookstore:app`	*n/a*	`APPDYNAMICS_WSGI_MODULE`

If both the `script` and `module` directives are specified, the `module` directive takes precedence.

The `module` value may be the fully-qualified name of a module, or it may be the fully-qualified name of a module followed by a colon and the name of the WSGI callable in that module. In the latter form, the `module` directive overrides the `callable` directive.

Both the long-form of the `module` directive and the `callable` directive may take either the name of a symbol, or the name of a symbol followed by an empty pair of parentheses. In the latter form, the callable is taken to be the result of calling the callable specified by the directive. This latter form can be used with Django; for example:

```
module = django.core.handlers.wsgi:WSGIHandler()
```

[log]

Directive	Description	Example	Default	Environment Variable
`dir`	The directory to write proxy and agent logs to	`/var/log/appdynamics`	`/tmp/appd/logs`	`APPDYNAMICS_LOGS_DIR`
`level`	The level to log at one of: warning, info, or debug	`debug`	`warning`	`APPDYNAMICS_LOGGING_LEVEL`
`debugging`	On to write DEBUG level logs to stderr and log files	`on`	`off`	`APPDYNAMICS_DEBUG_LOG`

[controller]

This section specifies configuration for the AppDynamics Controller.

Directive	Description	Example	Default	Environment Variable
`host`	Controller host	`mycontroller.example.org`	*Required*	`APPDYNAMICS_CONTROLLER_HOST_NAME`
`port`	Controller port	`9000`	8090 for HTTP on-prem 443 for HTTPS, in which case SSL must also be set	`APPDYNAMICS_CONTROLLER_PORT`
ssl	Is SSL set be used to talk to the controller? `on` or `off`	`on`	`off`	`APPDYNAMICS_CONTROLLER_SSL_ENABLED`
`account`	AppDynamics Controller account	`user1`	For a single-tenant controller defaults to `customer1`. Otherwise required.	`APPDYNAMICS_AGENT_ACCOUNT_NAME`
`accesskey`	AppDynamics Controller account access key	`XC6v2n8m2$543`	*Required*. To find your account name and access key, click  in the upper right corner of the AppDynamics UI, then click **License**.	`APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY`
`certfile`	Controller Certificate This certfile must be the default agent keystore (found under `site-packages/appdynamics_proxysupport/lib/security/cacerts`) with necessary additional `.pem/.crt` certs embedded within it using keytool.	/tmp/ssl/cacerts	Optional	`APPDYNAMICS_CONTROLLER_SSL_CERTFILE`

[controller:http-proxy]

If you need to use an HTTP proxy to talk to your Controller, use this section to configure the HTTP proxy.

Directive	Description	Example	Default	Environment Variable
`host`	HTTP proxy host	`proxy.example.org`	*n/a*	`APPDYNAMICS_HTTP_PROXY_HOST`
`port`	HTTP proxy port	`8090`	`80`	`APPDYNAMICS_HTTP_PROXY_PORT`
`user`	HTTP proxy user	`proxyuser`	*n/a*	`APPDYNAMICS_HTTP_PROXY_USER`
`password-file`	HTTP proxy password file	`/etc/http-proxy.passwd`	*n/a*	`APPDYNAMICS_HTTP_PROXY_PASSWORD_FILE`

[proxy]

Directive	Description	Example	Default	Environment Variable
`max-heap-size`	Max heap size for proxy	450m	300m	`APPDYNAMICS_MAX_HEAP_SIZE`
`min-heap-size`	Min heap size for proxy	100m	50m	`APPDYNAMICS_MIN_HEAP_SIZE`
`max-perm-size`	Max permanent generation size	150m	120m	`APPDYNAMICS_MAX_PERM_SIZE`
`proxy-debug-port`	Port number to which to attach the JAVA debugger	8092	None	`APPDYNAMICS_PROXY_DEBUG_PORT`
`start-suspended`	Specifies whether to debug proxy startup with a JAVA debugger.	on	off	`APPDYNAMICS_START_SUSPENDED`
`debug-opt`	Specifies the debug opt for debugging	-agentlib:jdwp=transport=dt_socket,server=y,suspend=n,address=8090	None	`APPDYNAMICS_DEBUG_OPT`
`agent`	Specifies the Agent type (Eg PYTHON_APP_AGENT, NODEJS_APP_AGENT etc)	NODEJS_APP_AGENT	PYTHON_AGENT	`APPDYNAMICS_AGENT_TYPE`

If `PROXY_DEBUG_PORT` is defined, then `-agentlib:jdwp=transport=dt_socket,server=y,suspend=${START_SUSPENDED},address=${PROXY_DEBUG_PORT}` is used as the debug opt. `PROXY_DEBUG_PORT` takes priority over `DEBUG_OPT` if both are specified. Also ensure that `PROXY_DEBUG_PORT` is not set if you want to use a self defined `DEBUG_OPT`.

[eum]

Directive	Description	Example	Default	Environment Variable
`disable-cookie`	If set, the agent does not add EUM correlation data to WSGI response headers.	`on`	`off`	`APPDYNAMICS_EUM_DISABLE_COOKIE`
`user-agent-whitelist`	If specified overwrites the default whitelist for user agent added as EUM correlation data headers Use this setting to specify alternate user agents as a comma separated list. Use '*' to allow all user agents.	`'iPad, Android'`	`'Mozilla, Opera, WebKit, Nokia'`	`APPDYNAMICS_EUM_USER_AGENT_WHITELIST`

[services:snapshot]

Directive	Description	Example	Default	Environment Variable
`exit-call-details-length`	Specifies the number of characters in the details string describing exit calls in transaction snapshots.	`200`	`100`	`APPDYNAMICS_EXIT_CALL_DETAILS_LENGTH`

[services:transaction-monitor]

Directive	Description	Example	Default	Environment Variable
`bt-max-duration-ms`	Maximum duration of a business transaction in milliseconds.	`60000`	`120000`	`APPDYNAMICS_BT_MAX_DURATION_MS`

Node Reuse for Python Agent

Reuse Node Name

To reuse node names in AppDynamics, you have to set `nodereuse` property to `true`. When you set this property to true, you do not have to supply a node name, but you do need to provide a node name prefix using `nodereuseprefix` .

> When `nodereuse` and a node name is used, the `nodereuseprefix` property is given precedence.

This property is useful for monitoring environments where there are many VMs (Virtual Machines) with short life spans. When set to true, AppDynamics reuses the node names of historical VMs for new VMs. This avoids a proliferation of differently named nodes in AppDynamics over time, particularly when the nodes are essentially identical processes that run over different times.

AppDynamics generates a node name with App, Tier, and Sequence number, and the node names are pooled. For example, the sequence numbers are reused when the nodes are purged (based on the node lifetime).

System Property: `nodereuse`

Type: Boolean

Default: False

Required: No

Reuse Node Name Prefix

When you configure the agent to reuse node names, use this property to specify the prefix that the Controller uses to generate node names dynamically.

System Property: `nodereuseprefix`

Type: String

Default: None

Required: When `nodereuse=true`

> Reuse node feature example:
>
> With the following configuration, the Controller generates a node name with the prefix "reportGen". Node names will have suffixes -1, -2, and so on, depending on the number of nodes are running in parallel. The name of a node that is shut down and qualifies as a historical node may be reused by a new node.
>
> ```
> nodereuse=true nodereuseprefix=reportGen
> ```

Python Agent Debugging and Logging

Logging Settings

Logging is configured in the logging section of the AppDynamics configuration file. See Python Agent Settings and Python Agent.

Logging Levels

Set the logging level for the amount of detail that you want to see: `INFO`, `WARNING` or `DEBUG`. The default is level is `WARNING`.

For maximum debugging information, set the logging level to `DEBUG`. Debug-level logs show the information that the Python Agent is sending to the proxy, which can be useful for debugging the agent.

For quick debugging, set the debugging configuration option to on. This causes debug-level logs to be written to both stderr and log files.

This is the behavior you can expect with various combinations of logging level and debug settings:

The various combinations of logging level and debug settings produce behavior as follows:

- `level=info, debugging=off`: Info-level logs are written to the log file
- `level=warning, debugging=off`: Warning-level logs are written to the log file
- `level=debug, debugging=off`: Debug-level logs are written to the log file
- `level=info, debugging=on`: Debug-level logs are written to the log file and to stderr
- `level=warning, debugging=on`: Debug-level logs are written to the log file and to stderr
- `level=debug, debugging=on`: Debug-level logs are written to the log file and to stderr

The Proxy logging level is separate and is not affected by the configuration settings of the Agent logging levels. Proxy logging level is "info" by default. Typically, you can redirect that output to a file if desired. In case if you wish to increase the logging level output, you must do so by starting the Proxy manually. First assign the new logging level within the Proxy's configuration file (`proxy/conf/logging/log4j.xml`) and then invoke the Proxy task.

There is no way to automatically adjust the Proxy logging level from the Agent configuration file settings.

Location and Names of Agent Log Files

Agent logs are written in the directory specified by the dir directive, `APPD_LOGS_DIR` in the logging section of the configuration file.

For each node, the log is output to a file named `APP_NAME-<NODE_NAME>.log`. These files live in the log dir directory, `APPD_LOGS_DIR`.

The agent creates and rotates a maximum of five log files. Maximum log size is 20 MB, which gives you a maximum of the most recent 100 MB of log data at one time.

For example:

1. myApp-myNode.log
2. myApp-myNode.log.1
3. myApp-myNode.log.2
4. myApp-myNode.log.3
5. myApp-myNode.log.4

Location of Proxy Logs

The proxy logs are always written to dir `APPD_LOGS_DIR`, which defaults to `/tmp/appd/logs`, `APPD_DIR/logs`.

Python Agent API

Related pages:

- Python Agent API Guide
- Python Agent API Reference

The Python Agent APIs provide facilities to support:

- Custom business transactions
- Custom exit points
- Custom data collectors

Python Agent API Guide

On this page:

Related pages:

- Python Agent API Reference
- Python Supported Environments
- Business Transactions
- Backend Detection Rules

The Python Agent APIs:

- Let you programmatically define custom business transactions that would not automatically be detected by the agent.
- Let you create custom exit calls to discover and monitor backends and that are not automatically detected by the agent.

If your instrumented application starts up and you do not see all the business transactions or backends that you expect to see, first check Python Supported Environments to see if your framework or exit point is supported. If not, you can use the APIs to instrument your code manually.

Custom Business Transactions

You can use the `start_bt()` and `end_bt()` methods to surround the code that you want to monitor as a custom business transaction.

Or you can use the "bt" context manager. Consider using the `bt` context manager where you start and end the business transaction in the same code. For example, where you can wrap the whole business transaction in a `with` statement.

For example, given the code:

```
setup()
do_work()
teardown()
```

you want to report `do_work()` as a business transaction.

Use start_bt() and end_bt()

This example uses `start_bt()` and `end_bt()` to create a business transaction named `do_work`.

```
from appdynamics.agent import api as appd
setup()

bt_handle = appd.start_bt('do work')
try:
    do_work()
except Exception as exc:
    raise
finally:
    appd.end_bt(bt_handle, exc)

teardown()
```

Use bt context manager

If the business transaction starts and ends in the same context, you can use the `bt` context manager instead. This is simpler:

```
setup()

with bt('do work'):
    do_work()

teardown()
```

Custom Exit Calls

You can use the `start_exit_call()` and `end_exit_call()` methods to create a custom exit call from a specific business transaction to a backend that the Python Agent does not automatically detect.

The business transaction must be a custom business transaction.

If you want to make a custom exit call from a business transaction that is normally automatically detected, you can exclude that business transaction to prevent it from being automatically detected and then create it as a custom business transaction. This enables you to get the BtHandle that you need to create the custom exit call. See Configure Python Web Custom Match and Exclude Rules for information on excluding a business transaction.

Given the code:

```
try:
    db = custom_db.connect(host='financials-lb', port=3456)
    all_employees = db.query_path('/financials/employees')
    individual_contributors = all_employees.filter(lambda r: r.level < 3)
    salaries_by_dept = individual_contributors.sum(value='salary', group='dept', as='total')

    for dept, total in salaries_by_dept.extract('dept', 'total'):
        report_salary_data(dept, total)
```

You want to send the query via an exit call to a proprietary database.

You want the database to be labeled `Financials Database` in the Controller UI.

You want the backend properties that appear in the backend dashboard to appear as:

Host:

`financials-lb`

Port:

`3456`

Vendor:

custom db

The following examples assume you are wrapping the exit call in a custom business transaction named `department rollup`, created in another part of your code.

Use start_exit_call() and end_exit_call()

This example uses `start_exit_call()` and `end_exit_call()`.

```
from appdynamics.agent import api as appd
appd.init()

# Set the identifying properties
FINANCIALS_ID_PROPS = {'Host': 'financials-lb', 'Port': 3456, 'Vendor': 'custom db'}

with appd.bt('department rollup') as bt_handle:
    # Start the exit call
    exit_call = appd.start_exit_call(bt_handle, appd.EXIT_DB, 'Financials Database', FINANCIALS_ID_PROPS)
    exc = None

    try:
        db = custom_db.connect(host='financials-lb', port=3456)
        all_employees = db.query_path('/financials/employees')
        individual_contributors = all_employees.filter(lambda r: r.level < 3)
        salaries_by_dept = individual_contributors.sum(value='salary', group='dept', as='total')

        for dept, total in salaries_by_dept.extract('dept', 'total'):
            report_salary_data(dept, total)
    except Exception as exc:
        raise  # Assuming something above handles exceptions for you
    finally:
        #End the exit call
        end_exit_call(exit_call, exc)
```

Use exit_call context manager

If the business transaction starts and ends in the same context, you can use the simpler `exit_call` context manager instead.

```
from appdynamics.agent import api as appd
appd.init()

with appd.bt('department rollup') as bt_handle:
    with appd.exit_call(bt_handle, appd.EXIT_DB, 'Financials Database', FINANCIALS_ID_PROPS):
        db = custom_db.connect(host='financials-lb', port=3456)
        all_employees = db.query_path('/financials/employees')
        individual_contributors = all_employees.filter(lambda r: r.level < 3)
        salaries_by_dept = individual_contributors.sum(value='salary', group='dept', as='total')

        for dept, total in salaries_by_dept.extract('dept', 'total'):
            report_salary_data(dept, total)
```

The next example starts a custom exit call to a Cassandra backend from a business transaction that was auto-detected by the Python Agent default Flask instrumentation. It uses the Flask import feature to get the request object which it passes to `appd_get_active_bt_handle()`.

Get bt handle using the flask request context

```
from flask import request
from appdynamics.agent import api as appd

@app.route('/metrics/recent')
def metrics_recent():
    bt = appd.get_active_bt_handle(request)  # Get the active BT from the Flask request object
    with appd.exit_call(bt, appd.EXIT_DB, 'cassandra time-series', {'VENDOR': 'Cassandra', 'SERVER POOL':
'10.0.0.1'}):
        load_recent_data_from_cassandra()
```

Other supported frameworks have different mechanisms for getting the request object.

Python Agent API Reference

On this page:

Related pages:

- Install the Python Agent
- Python Agent Settings
- Python Agent API Guide

The Python Agent APIs provide facilities to support:

- Custom business transactions
- Custom exit points
- Custom data collectors

List of the APIs:

Access to the APIs

Before your app can access the Python Agent APIs, install the Python Agent using:

```
pip install appdynamics
```

Then at the top of the instrumented application add:

```
from appdynamics.agent import api as appd
```

Start and Stop Agent

init(*environ*=None, *timeout_ms*=NO_TIMEOUT)

Initializes the Python Agent.

Call this function at the very beginning of your instrumented application, preferably before any other imports and before creating any other threads.

Agent initialization occurs `asynchronously. init()` returns immediately if no timeout is specified but it is possible that the agent will not immediately be ready to report business transactions. In this case, the start_bt() method will return `None`.

This function will never raise an exception.

Returns True if the agent is properly configured, False if the agent is not properly configured.

To be properly configured the agent configuration file must contain the minimal settings and possibly some additional settings if they are required for your environment. See Configure the Agent in Install the Python Agent for the minimal settings and Python Agent Settings for the complete list.

environ: dict, optional

If specified, a dictionary of environment variables to use to override the agent's configuration, derived from the actual OS environment variables.

timeout_ms: int or None, optional

Timeout interval in milliseconds.

By default, `init()` returns immediately, even if the Python agent has not received its configuration from the controller. If timeout_ms is None, init() blocks until the agent is properly configured. Otherwise, `init()` waits for up to timeout_ms for agent to become properly configured.

shutdown(timeout_ms=None)

Shuts down the Python Agent. The agent stops reporting metrics to the Controller.

This function ends all active business transactions and waits for them to finish reporting to the controller before returning.

timeout_ms: int, optional

By default, this function waits until all pending business transactions have been reported before returning. If `timeout_ms` is set, this function will return after `timeout_ms`, regardless of whether all business transactions have been reported.

Business Transaction Management

start_bt(*name*, *correlation_header*=None)

Starts a business transaction of the specified name.

There can only be one active business transaction per thread. Attempts to start subsequent business transactions in the same thread will return None.

Returns a BtHandle on starting the transaction or None if no transaction was started.

name: str

Name of the business transaction being started. The following characters cannot be used in business transaction names: `{ } [ ] | & ;`

correlation_header: str, optional

If specified, a correlation header that has been generated by another AppDynamics agent and passed to this agent as a string. A correlation header provides information to enable this transaction to correlate with a transaction that is upstream to this one.

end_bt(*bt_handle*, *exc*=None)

Ends the business transaction identified by bt_handle.

bt_handle: BtHandle

Identifies the business transaction being ended. The handle is returned by start_bt().

exc: Exception, optional

If an exception occurred during processing this business transaction that you have caught with a try-except block, and you wish to report the exception as part of the business transaction, pass the exception as the `exc`.

add_snapshot_data(*bt_handle*, *key*, *value*)

Attaches custom data to transaction snapshots generated for the business transaction identified by `bt_handle`.

The custom data is exposed in the `USER DATA` tab of the transaction snapshot details in the Controller UI.

The custom data is added to the business transaction but reported only when a transaction snapshot is generated. See Transaction Snapshots for information on when transaction snapshots are generated.

bt_handle: BtHandle

Identifies the business transaction to which custom data is added. The handle is returned by start_bt().

key: bytes or unicode

Name of the data item to be reported in the snapshot.

If passed as bytes, the buffer must represent a UTF-8 encoded string.

value: any

Value of the data.

If passed as bytes, the data is treated as a UTF-8 encoded string. If passed as unicode, it is directly reported.
All other objects are converted to `str(value)`.

get_active_bt_handle(request)

Returns a BtHandle to the business transaction associated with the request object or None if no such business transaction was found.

This is useful for passing a business transaction handle to another API function, such as `start_exit_call()` when the business transaction was created by the default Python Agent instrumentation rather than through the APIs.

request object

The request object associated with an active business transaction. Varies depending on the framework in which the business transaction was started.

See the documentation for the applicable framework to find out how to get the request object.

Framework	Documentation for the Request Object
Flask	https://flask-cn-doc.readthedocs.io/en/latest/reqcontext.html
Django	https://docs.djangoproject.com/en/1.8/ref/request-response/
CherryPy	https://cherrypy.readthedocs.io/en/latest/basics.html
WSGI environ	https://www.python.org/dev/peps/pep-0333/

Exit Call Management

start_exit_call(*bt_handle*, *exit_type*, *display_name*, *identifying_properties*, *optional_properties*=None)

Starts a custom exit call from within the specified business transaction.

There can be only one active exit call per business transaction. Attempts to start subsequent exit calls will return None.

Returns an ExitCallHandle that identifies this exit call.

bt_handle: BTHandle

Identifies the business transaction making the exit call. Handle is returned from start_bt().

exit_type: int

The type of exit call. Valid values are:

- `appd.EXIT_HTTP`
- `appd.EXIT_DB`
- `appd.EXIT_CACHE`
- `appd.EXIT_QUEUE`

display_name:str

Name used to identify this exit call in the controller. This is the label that will be used to display the exit call in the AppDynamics UI.

identifying_properties: dict

A dictionary of name/value pairs that uniquely identify the downstream component being called.

In the Controller UI, these properties are visible in the upper right panel of the backend dashboards.

The key of the dict is the name of the property; the value is the value of the property.

operation: str, optional

A string describing the operation that is being performed, such as the URL of an HTTP request or an SQL query.

optional_properties: dict, optional

A dictionary of name/value pairs that identify additional properties for this exit call. In the Controller UI, these properties are visible in the Exit Calls and Async Activities modal in the snapshot drill-down pane.

end_exit_call(exit_call_handle, exc=None)

Ends the exit call identified by `exit_call_handle`.

exit_call_handle: ExitCallHandle

Identifies the exit call being ended. The handle is returned from start_exit_call().

exc: Exception

If an exception occurred during the exit call that you have caught with a `try-except` block, and you wish to report the exception as part of the exit call, pass the exception as the `exc` argument.

make_correlation_header(bt_handle, exit_call_handle)

Make a correlation header for a custom exit call.

If you are performing custom exit calls to other instrumented tiers, adding a correlation header allows continuing business transactions on the downstream tier.

It is up to you to send the header, as well as parse it at the other end and pass it to start_bt().

Returns a tuple of header name and header value, or None if correlation is disabled.

bt_handle: BtHandle

A handle identifying the business transaction.

exit_call_handle: ExitCallHandle

A handle identifying the exit call.

Context Managers

bt(*name*, *correlation_header*=None)

Context manager for reporting some work as a business transaction. Yields a `BtHandle`.

If you need to start and end the transaction in different places in the code, use start_bt() and end_bt().

exit_call(*bt_handle*, *exit_type*, *display_name*, *identifying_properties*, *optional_properties*=None)

Context manager for adding exit calls to a business transaction. Yields an `ExitCallHandle`.

If you need to start and end exit calls in different places in your code, you can use start_exit_call() and end_exit_call().

HTTP Status Codes

HTTP status codes will not cause error transactions when you use the using the Python Agent API to instrument your application, regardless of the error detection configuration.

Serverless APM for AWS Lambda

Deployment Support

SaaS

AppDynamics Serverless Application Performance Monitoring (Serverless APM) for AWS Lambda gives you visibility into the performance of your application's components that run as functions on serverless compute environments.

Serverless APM gives you an end-to-end view of applications through business transaction correlation. Serverless APM correlates business transactions between AWS Lambda functions and:

- Components instrumented with AppDynamics app agents
- Devices instrumented with AppDynamics End User Monitoring (EUM) agents

Additionally, Serverless APM correlates business transactions through serverless functions, such an AWS Lambda function that invokes another function.

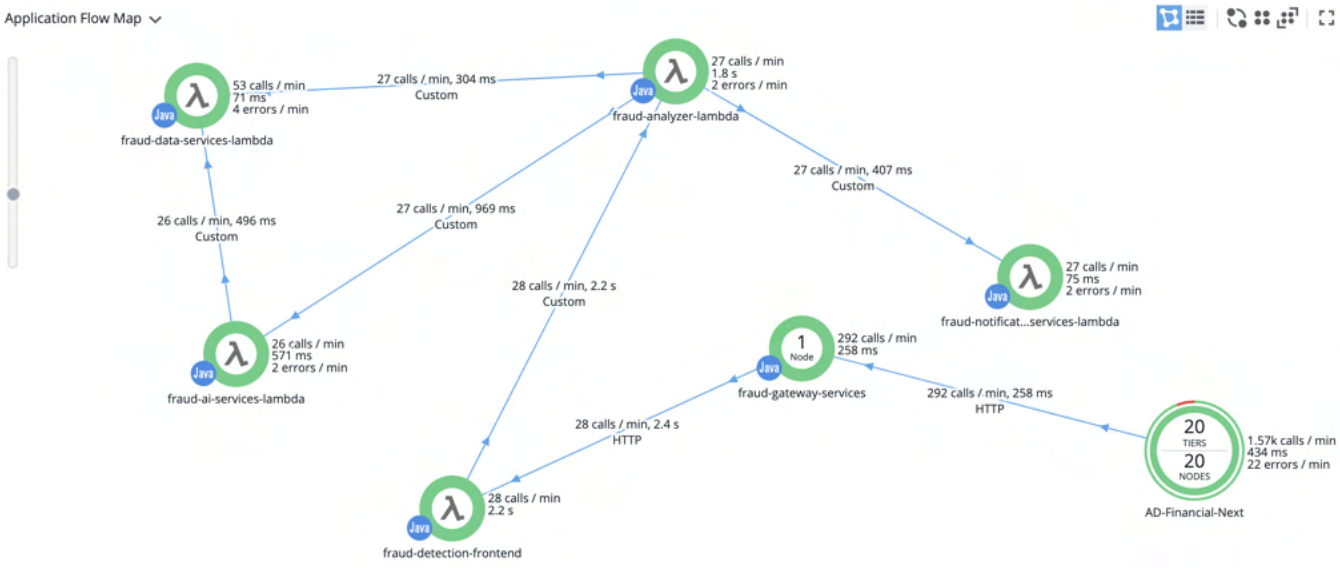
Serverless APM in the Controller

When business applications contain serverless functions, the Controller experience differs slightly in flow maps, dashboards and metric browser pages, and health rules.

Flow Maps

Flow maps are a dynamic visual representation of your monitored environment's components and activities. When business applications have serverless functions, you cannot view the nodes within flow map tiers because of the opaque nature of serverless platforms. A serverless icon replaces the node count in the application flow map.

The screenshot below depicts an application composed of AWS Lambda tiers:



Dashboards and Metric Browser Pages

You can view AWS Lambda functions on your application dashboards and metrics pages. All functionality is identical to that which you would get with any other tier type, with the exception of node-level granularity. AWS Lambda tiers do not offer node-level dashboards or metrics because serverless platform runtime instances spin up and down on demand.

Health Rules

When you configure a health rule for an application comprised of serverless functions, you can choose to monitor the serverless tiers or business transactions that originate in or flow through the serverless functions. See Configure Health Rules.

Get Started

Serverless APM requires a subscription through AWS Marketplace. See Subscribe to Serverless APM for AWS Lambda to get started.

If you have already subscribed to Serverless APM, you can begin instrumentation. See:

- Learn how Serverless APM correlates business transactions with the Serverless Tracer.
- Set environment variables to enable Tracer-to-Controller communication.
- Instrument the Java Serverless Tracer, Node.js Serverless Tracer, or Python Serverless Tracer. The tracer's language matches your AWS function code's implementation.

Subscribe to Serverless APM for AWS Lambda

> This page contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation because Amazon controls its own documentation.

This page explains how to subscribe to Serverless APM for AWS Lambda. AppDynamics provides Serverless APM functionality in the form of a tracer library. See Serverless APM.

Requirements

Serverless APM for AWS Lambda supports AWS Lambda functions implemented in Java, Node.js, or Python. A subscription to Serverless APM requires:

- AppDynamics SaaS Controller >= 4.5.11.
- An active AppDynamics Pro account.
- Your Controller access key. This requires you to be an AppDynamics Account Owner or have Administrator privileges.
- AWS Identity and Access Management (IAM) role with permission to one of these policies:
  - **AWSMarketplaceManageSubscriptions**
  - **AWSMarketplaceFullAccess**

Subscribe to Serverless APM

Subscribe to AppDynamics Serverless APM for AWS Lambda through AWS Marketplace.

1. In the AWS Marketplace, navigate to the **AppDynamics Serverless APM for AWS Lambda** listing.
2. Click **Continue to Subscribe**.
3. Sign in to your AWS account.
4. Click **Subscribe**. A message, Congratulations! You are now subscribed!, appears confirming your subscription.
   If the Subscribe button is unavailable:
   a. Navigate to **Having issues signing up for your product?**
   b. Select **click here**.
   c. Proceed to step six.
5. Click **Set Up Your Account**.
6. Enter your SaaS Controller URL and Controller Access Key (Default), then click **Continue**.

   - The SaaS Controller URL must be a full path URL with no whitespace or trailing slashes.
   - Registration may take up to 30 seconds.
   - You can only access the registration page through AWS Marketplace.
   - Do not close the registration page while it attempts to connect to the Controller. If you close the registration page, you will have to subscribe again through AWS Marketplace.
7. Click **Getting Started** to learn more about Serverless APM for AWS Lambda.

Subscribe Multiple Controllers

You can subscribe multiple Controllers to Serverless APM, as long as each Controller meets the requirements described on this page. Begin with step 4a in Subscribe to Serverless APM above and complete the steps for each Controller.

Unsubscribe from Serverless APM for AWS Lambda

Unsubscribe from Serverless APM for AWS Lambda to stop all tracing by AppDynamics.

1. Sign in to the AWS Management Console.
2. Go to **Your Account** > **Your Software Subscriptions** > **SaaS**. Locate the **AppDynamics Serverless APM for AWS Lambda** subscription.
3. Select **Cancel Subscription**. **Cancel Subscription** unsubscribes all Controllers from Serverless APM.

You can disable Serverless APM at any time. When you disable Serverless APM, the tracer continues to monitor any instances currently executing until those instances finish. Requests executed by instances started after you disable the tracer are not monitored.

> Technical support is available through AppDynamics Support. All billing related questions are handled by AWS Marketplace.

View the Serverless APM Subscription

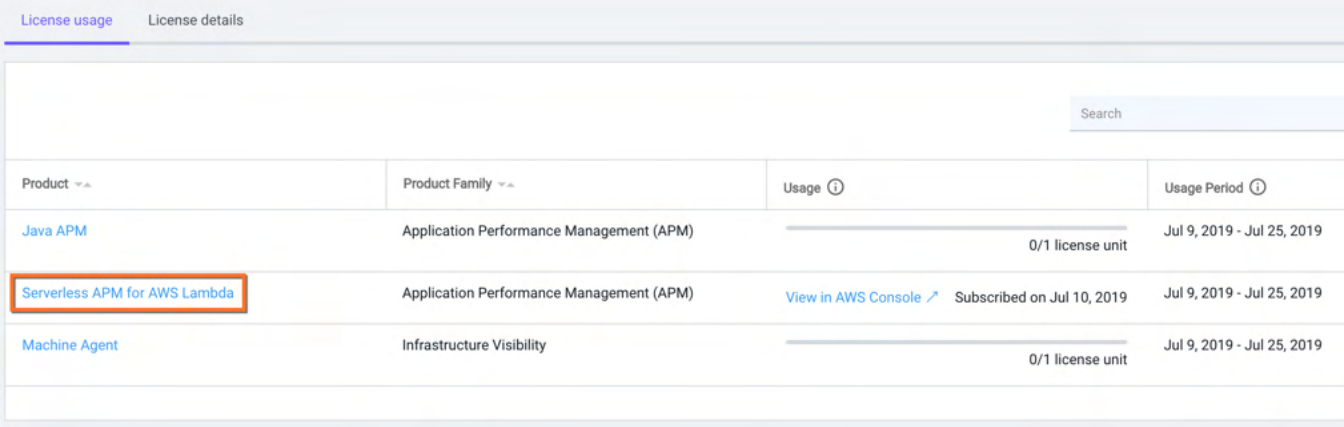
After you have subscribed to Serverless APM for AWS Lambda, you can view your subscription and its status through your AppDynamics account.

Verify Your Serverless APM Subscription

You can verify your subscription to Serverless APM for AWS Lambda in your AppDynamics account.

1. Go to https://accounts.appdynamics.com/subscriptions.
2. Sign in to your account.
3. Select the Controller you subscribed to Serverless APM.
4. Confirm that **Serverless APM for AWS Lambda** subscription is activated in the License usage tab.

Under the **Usage** column, you can view the date your subscription began, and access billing information on the AWS Console. Serverless APM for AWS Lambda matches the **Usage Period** of your APM license, regardless of the Serverless APM subscription status.

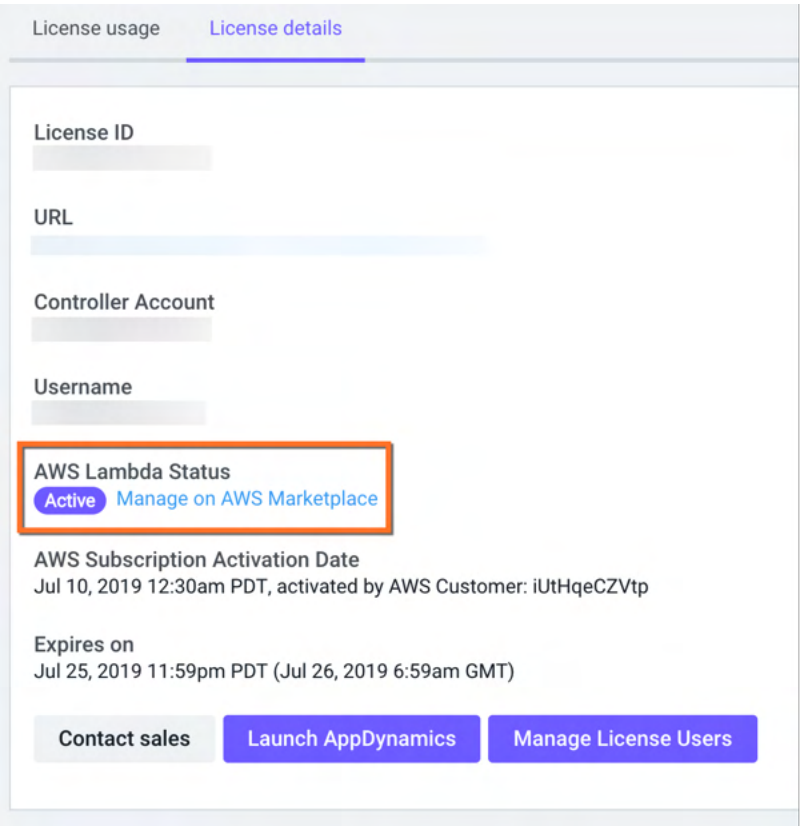


Check Your Serverless APM Subscription Status

You can check your Serverless APM for AWS Lambda subscription status in your AppDynamics account. To access your account see the instructions in Verify Your Serverless APM Subscription. Click the License details tab and navigate to **AWS Lambda Status**.

Active status indicates you are currently subscribed to Serverless APM for AWS Lambda. You can see the date your subscription began and the encrypted AWS Customer ID of the user who subscribed.

Inactive status indicates you have canceled your subscription to Serverless APM for AWS Lambda for all Controllers. You can see the cancellation date and the encrypted AWS Customer ID of the user who unsubscribed.



Troubleshoot the Serverless APM Subscription

> This document contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation because Amazon controls its own documentation.

This page provides troubleshooting information for issues that may arise when subscribing to Serverless APM for AWS Lambda.

Subscribe Button Unavailable

After an AWS user clicks **Subscribe** on the AWS product listing, the button is unavailable for future visits to the AWS Marketplace subscription page. To complete the subscription process, see step four in Subscribe to Serverless APM for AWS Lambda.

Error Messages

You may encounter error messages while subscribing through the AWS Marketplace.

Upgrade to Enable Serverless APM for AWS Lambda

This error message refers to your current Controller version and AppDynamics edition. To subscribe to serverless monitoring, you need SaaS Controller 4.5.11 and an active AppDynamics Pro edition.

- **AppDynamics SaaS Controller >= 4.5.11**

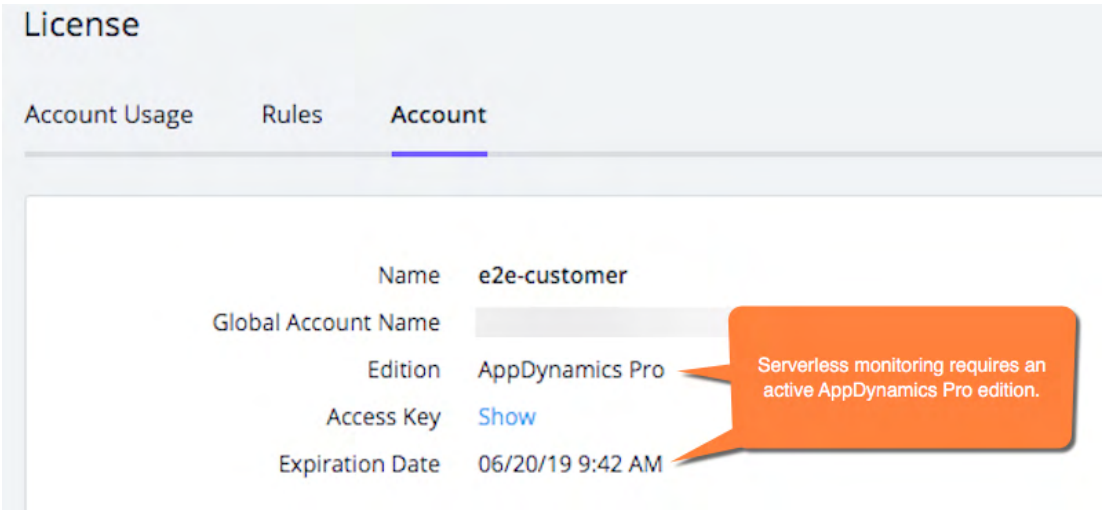
  Serverless APM for AWS Lambda is available for AppDynamics Pro SaaS Controllers. Your Controller must be >= 4.5.11. You can request an upgrade if you have a previous version of the Controller. To view your current AppDynamics build version in the Controller UI, select > **About AppDynamics**.

  Serverless monitoring is not available for on-premises Controllers at this time.

- **Active AppDynamics Pro Edition**

  You need an active AppDynamics Pro edition to enroll in serverless monitoring. If you are currently enrolled in a trial or unpaid edition, or if your account is inactive, purchase a license.

  To view your current AppDynamics edition and expiration date in the Controller UI, select > **License** > **Account**.



Incorrect Credentials

You need your SaaS tenant URL and the access key for the Controller you want to enable. You must be an AppDynamics Account Owner or Administrator to view the Controller access key. To find your Controller access key, see Agent-to-Controller Connections.

Controller Already Registered

You cannot register a single Controller for serverless monitoring multiple times. You can view your current Serverless APM for AWS Lambda subscriptions in your AppDynamics account.

1. Go to https://accounts.appdynamics.com/subscriptions.

2. Sign in to your account.
3. Select the desired Controller.
4. In the License Usage tab, find **Serverless APM for AWS Lambda**.

Technical support is available through AppDynamics Support. All billing related questions are handled by AWS Marketplace.

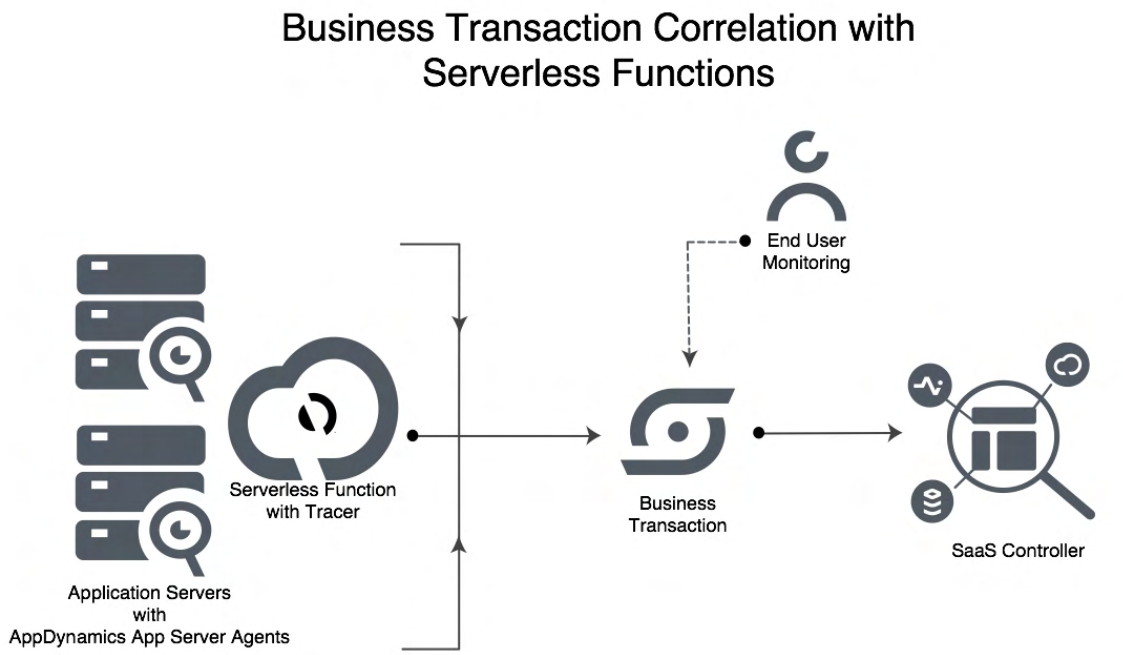
Serverless APM Business Transaction Correlation

AppDynamics provides Serverless Application Performance Monitoring (Serverless APM) functionality in the form of a serverless tracer, available in Java, Node.js, and Python. This page discusses how the tracer correlates business transactions.

Business Transaction Correlation Architecture

The Serverless Tracer correlates business transactions with upstream and downstream components. Business transactions can be started or continued within application components instrumented with APM agents or Lambda tracers providing end to end transaction visibility in AppDynamics.

This diagram illustrates how the tracer correlates business transactions through a serverless function to APM and EUM agents:



Business Transaction Correlation Process

Business transaction correlation occurs through an opaque correlation string that the application passes across the wire. First, the tracer generates the correlation string at an exit call, and then the application passes the correlation string to the downstream components. The downstream component retrieves the correlation string to continue the business transaction. This process enables the Serverless Tracer to correlate business transactions.

Correlation String Transportation

Your application needs to pass the correlation string, generated by the tracer, to correlate a business transaction between multiple services. The correlation string must be serialized and communicated alongside the application payload.

Inbound HTTP Calls

If you pass the correlation string through an HTTP call, the string is passed as an HTTP header. The tracer searches for the key that holds the correlation header string in your function's invocation object. Correlation occurs when the Serverless Tracer finds the correlation header key. If the key cannot be found, the tracer creates a new business transaction.

Other Protocols

For protocols other than HTTP, you need to define protocol-specific transportation of the correlation string to enable business transaction correlation.

The tracer creates a new business transaction if:

- You have not arranged for the correlation string to be passed, or
- The tracer cannot find the correlation string.

To get started, see Set Up the Serverless APM Environment.

Set Up the Serverless APM Environment

This page describes required and optional environment variables, including HTTP proxy support, and how to input the variables in the AWS Management Console.

Configure Environment Variables

To instrument Serverless APM for AWS Lambda, you must configure the environment variables listed in the table below. Enter all applicable information as key-value environment variables in the AWS Management Console.

> When you change an environment variable, any existing instances complete execution using the previous value. All new requests execute with the updated value.

Environment Variable	Description	Default	Required	Example Value
`APPDYNAMICS_ACCOUNT_NAME`	Account name associated with the Controller used by your AWS Lambda function.	`<AppDynamics_account_name>`	Yes	`customer1`
`APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY`	Access key for your Controller. See Agent-to-Controller Connections.	`<AppDynamics_account_key>`	Yes	`AB1a2b3c4$123`
`APPDYNAMICS_APPLICATION_NAME`	Name of the application where the tracer is instrumented.	`<Your_app_name>`	Yes	`testApp`
`APPDYNAMICS_CONTROLLER_HOST`	Host associated with the Controller used by your AWS Lambda function. Do not include `http://` or `https://`	`<Controller_host_name>`	Yes	`<accountname>.saas.appdynamics.com`
`APPDYNAMICS_CONTROLLER_PORT`	Port associated with your Controller.	`443`	No	8080
`APPDYNAMICS_DISABLE_AGENT`	Disables the Serverless Tracer and stops all serverless application monitoring. Accepted values are `true` and `false`.	`false`	No	`true`
`APPDYNAMICS_ENABLE_EUM`	Used by the Node.js Serverless Tracer to enable End User Monitoring for AWS Lamba functions. Set to `true` to enable EUM or `false` to disable EUM. See Integrate the Node.js Serverless Tracer with End User Monitoring for details.	`false`	No	`true`
`APPDYNAMICS_EUM_AJAX`	When set to `true` ensures EUM data is always returned in Ajax form. For example, `ADRUM_0, ADRUM_1`, and so on.	`false`	No	`true`
`APPDYNAMICS_HTTP_TIMEOUT_MS`	HTTP timeout in milliseconds for the tracer to send data downstream.	`2000`	No	3000
`APPDYNAMICS_LOG_LEVEL`	Log level for the tracer. Accepted values are `DEBUG`, `INFO`, `WARN`, `ERROR`, and `FATAL`.	`INFO`	No	`INFO`
`APPDYNAMICS_SERVERLESS_API_ENDPOINT`	AppDynamics endpoint that the tracer to reports to. Serverless API endpoints are available for the following AWS regions: Sydney, Frankfurt, and Oregon.	`<https://your-endpoint-name-api.saas.appdynamics.com/>`	Yes	• Asia Pacific (Sydney): `https://syd-sls-agent-api.saas.appdynamics.com` • EU (Frankfurt): `https://fra-sls-agent-api.saas.appdynamics.com` • US West (Oregon): `https://pdx-sls-agent-api.saas.appdynamics.com`
`APPDYNAMICS_TIER_NAME`	The name of your AWS Lambda function.	`<Your_tier_name>` Defaults to the name of your AWS Lambda function.	No	`serverlessTestTier`

HTTP Proxy Support

To enable HTTP Proxy Support, define the following variables in the AWS Management Console:

Environment Variable	Description	Example Value
APPDYNAMICS_HTTP_PROXY_HOST	Publicly-accessible hostname of the proxy.	myproxy.example.com
APPDYNAMICS_HTTP_PROXY_PORT	Port on which the proxy is running.	8080
APPDYNAMICS_HTTP_PROXY_SERVER_CERTIFICATE	Relative path to the proxy server's certificate. Required if your proxy server runs on a self-signed certificate for your AWS Lambda function to trust the proxy. If you have configured your runtime environment to trust your proxy server, you do not need this variable.	resources/proxy-cert.pem

Additionally, you can add credentials for your proxy server's basic authentication. Add the following variables in the AWS Management Console:

Environment Variable	Description	Example Value
APPDYNAMICS_HTTP_PROXY_USER	Username associated with your basic authentication.	user1
APPDYNAMICS_HTTP_PROXY_PASSWORD	Relative path to the proxy server's basic authentication password. Required for your proxy server's password to trust your AWS Lambda function.	password123
APPDYNAMICS_HTTP_PROXY_PASSWORD_FILE	Plaintext file to the proxy server's basic authentication password file. Update your deployment package to contain the proxy server's password file. Required for your proxy server's password to trust your AWS Lambda function.	resources/proxy-password.txt

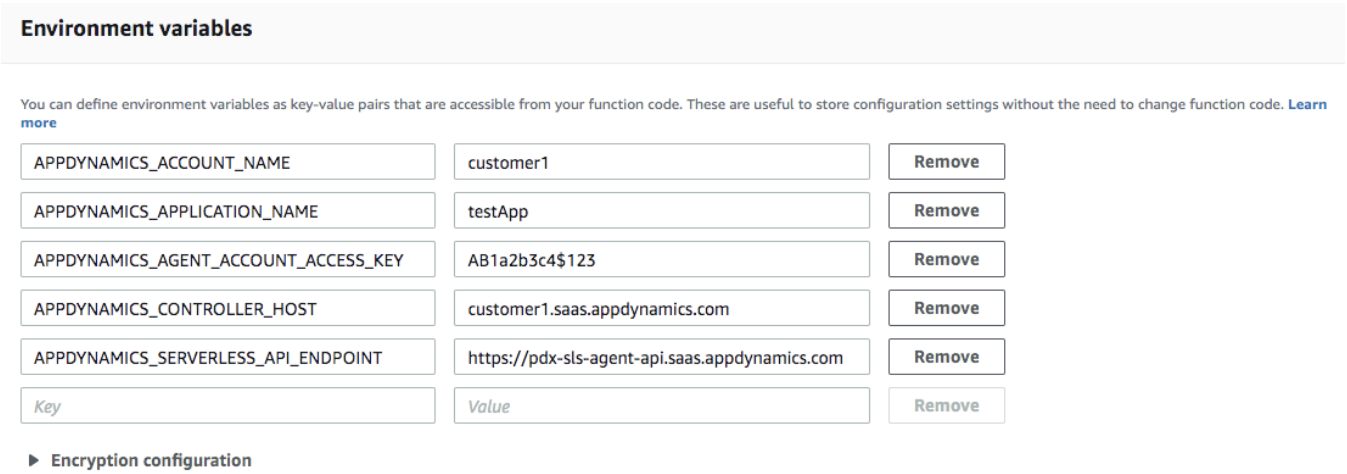
When you add basic credentials, you are required to include either APPDYNAMICS_HTTP_PROXY_PASSWORD or APPDYNAMICS_HTTP_PROXY_PASSWORD_FILE. If you include both, the tracer only passes APPDYNAMICS_HTTP_PROXY_PASSWORD_FILE.

Add Environment Variables in the AWS Console

To add environmental variables through the AWS Management Console:

1. Sign in to the AWS Management Console.
2. Go to **AWS Services** and open **Lambda**.
3. Select your AWS Lambda function.
4. Go to **Environment variables** and enter your function's key-value pair environment variables.
5. Click **Save**.

The following image shows an example of all required environment variables:



Java Serverless Tracer

This page describes requirements, download instructions, and an instrumentation overview for the Java Serverless Tracer.

Before You Begin

Ensure that your setup meets these requirements:

- Existing AWS Lambda functions implemented in Java
- Active Serverless APM for AWS Lambda subscription
- AppDynamics SaaS Controller >= 4.5.11

Instrumentation Overview

Instrumentation of Serverless APM for AWS Lambda consists of three steps:

1. Declare a Dependency on the Java Serverless Tracer
2. Choose an Instrumentation Method
    a. Automatic Tracer Instrumentation
    b. Manual Tracer Instrumentation
3. Verify the Serverless Tracer instrumentation

Declare a Dependency on the Java Serverless Tracer

AppDynamics provides Serverless APM functionality in the form of a tracer library.

Express your project's dependency on the Java Serverless Tracer using Apache Maven or Gradle as follows:

If you do not use Apache Maven or Gradle, contact AppDynamics to obtain the Serverless Tracer JAR file.

Instrumentation Options

You can instrument the tracer:

- Automatically, using AppDynamics class `MonitoredRequestStreamHandler`, or
- Manually, using AppDynamics method `AppDynamics.getTracer(context)`.

Automatic Tracer Instrumentation

You can automatically instrument the tracer if your function uses the `RequestStreamHandler` interface.

In automatic instrumentation, your function inherits the tracer's configurations. Automatic instrumentation preconfigures the tracer to:

- Create, start, and stop a transaction
- Locate any correlation header
- Report transaction errors

`RequestStreamHandler` and `RequestHandler` are predefined handlers provided by AWS. See AWS documentation.

Manual Tracer Instrumentation

In manual tracer instrumentation, the method `AppDynamics.getTracer(context)` instantiates the tracer at the beginning of your function's entry point method. Manually instrument the tracer if:

- Your AWS Lambda function does not implement the `RequestStreamHandler` interface.
- You do not want your function to inherit configurations from the `MonitoredRequestStreamHandler`.
- Your AWS Lambda functions are multi-threaded, to ensure that behavior is defined. See **Synchronize the Tracer** for more details.

Manual tracer instrumentation requires you to perform these actions:

- Instantiate the tracer
- Create, start, and stop a transaction
- Locate a correlation header
- Report transaction errors

The AWS Lambda context object in Java, `context,` is provided by AWS. See AWS documentation.

Synchronize the Tracer

For both instrumentation options, you should synchronize any access to the tracer.

In automatic instrumentation, you need to synchronize the transaction object returned by the `getTransaction()` method.

In manual instrumentation, you need to synchronize the tracer object returned by the `getTracer()` method. Manual tracer instrumentation is required for multi-threaded use of the tracer.

Automatic Tracer Instrumentation

Automatic tracer instrumentation consists of these steps:

1. Instantiate the Tracer
2. (Optional) Override Correlation Header Method
3. Obtain a Transaction Object
4. Create External Exit Calls

Instantiate the Java Serverless Tracer

> ⚠ Automatic instantiation is compatible with `RequestStreamHandler` interfaces. All other interfaces require manual instantiation.
>
> `RequestStreamHandler` is a predefined handler provided by AWS. See AWS documentation for more information.

To automatically instantiate the tracer:

1. Make your current handler class extend AppDynamics `MonitoredRequestStreamHandler`.
2. Rename your handler class's existing method `handleMonitoredRequest`.

The code snippet demonstrates how to instantiate the tracer automatically:

```
package <MyTestPackage>;
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;

//AppDynamics tracer imports
import com.appdynamics.serverless.tracers.aws.api.AppDynamics;
import com.appdynamics.serverless.tracers.aws.api.MonitoredRequestStreamHandler;
import com.appdynamics.serverless.tracers.aws.api.ExitCall;
import com.appdynamics.serverless.tracers.aws.api.Tracer;
import com.appdynamics.serverless.tracers.aws.api.Transaction;

//Keyword extends makes MonitoredRequestStreamHanlder your project's superclass
public class <MaryHadALittleLambda> extends MonitoredRequestStreamHandler {

   @Override
        //Change your method to handleMonitoredRequest
    public void handleMonitoredRequest(InputStream input, OutputStream output, Context context) throws
IOException {
           }

       // Your AWS Lambda function code starts here, for example
               int letter = 0;
               while((letter = input.read()) >= 0) {
                       output.write(Character.toUpperCase(letter));
       }
    }
```

(Optional) Override Correlation Header Method

Automatic instrumentation uses the `MonitoredRequestStreamHandler` class, which provides default logic to find a correlation header.

If you need to use a custom transport mechanism for your correlation header, you must override the tracer's default logic in the `getCorrelationHeader()` method. Insert your custom logic to find the inbound correlation header so the tracer can return the inbound header.

The code snippet demonstrates how to override the `getCorrelationHeader()` method:

```
//(Optional)Override getCorrelationHeader().
//Only override if the tracer will not be able to find a correlation header using its pre-configured logic.

@Override
public String getCorrelationHeader(InputStream input, Context context) {
//Logic to find the inbound header goes here, so the inbound header can be returned
return "correlation-header";
```

Obtain a Transaction Object

The `MonitoredRequestStreamHandler` class creates a transaction for you automatically. However, you need to obtain the `transaction` object for use with exit calls.

The code snippet below demonstrates how to obtain the `transaction` object:

```
//Obtain your transaction for use with exit calls.
Transaction transaction = getTransaction();
```

Create External Exit Calls

The `createExitCall` method is used to obtain an `exitCall` object. Exit call objects record the time spent in external exit calls and allow for correlation of downstream activity.

Exit Call Types and Identifying Properties

In the Controller, each exit call has a distinct type, determined by a set of identifying properties.

The `exitCall` types and identifying properties are listed below:

`exitCall` Type	**Identifying Properties**
HTTP	HOST PORT URL QUERY STRING
JDBC	URL HOST PORT DATABASE VERSION VENDOR
WEB SERVICE	SERVICE URL OPERATION SOAP ACTION VENDOR
CUSTOM	Any user-defined set of properties

Create an Exit Call

Call `createExitCall()` on your `transaction` object.

The following code sample demonstrates how you might perform an external exit call:

```
public void makeExitCall(URL url){

HttpURLConnection conn = (HttpURLConnection)url.openConnection();

String outgoingHeader = null;
String callType = null;
Map<String, String> identifyingProperties = new HashMap<>();

//Below properties are appropriate for an inter-AWS Lambda call
identifyingProperties.put("DESTINATION", functionName);
identifyingProperties.put("DESTINATION_TYPE", "LAMBDA");
callType="CUSTOM";

//Below properties are appropriate for an external HTTP call
identifyingProperties.put("HOST", url.getHost());
identifyingProperties.put("PORT", String.valueOf(url.getPort()));
callType="HTTP";

//Define the createExitCall method to obtain an exitCall object.
ExitCall exitCall = transaction.createExitCall(callType, identifyingProperties);
outgoingHeader =  exitCall.getCorrelationHeader();
exitCall.start();

try {
// Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY is the name of the header that should be set

    if (outgoingHeader != null) {
        conn.setRequestProperty(Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY, outgoingHeader); // set
the correlation header on an HttpURLConnection
    }

// Make the exit call here

} finally {
        exitCall.stop();
    }
}
```

Making Multiple External Exit Calls

If one AWS Lambda function makes multiple exit calls, each function should be identified by a unique `exitCall` object. To make multiple exit calls, create new `exitCall` objects for each distinct exit call. The `exitCall` objects are not reusable.

Manual Tracer Instrumentation

Manual tracer instrumentation consists of these steps:

1. Instantiate the Tracer
2. Create a Transaction
3. Start and Stop a Transaction
4. Create External Exit Calls

Instantiate the Java Serverless Tracer

To instantiate the tracer, call the `AppDynamics.getTracer(context)` method. Place the method at the beginning of your function's entry point method.

The code snippet demonstrates how to instantiate the tracer:

```
@Override
    public void handleRequest(InputStream input, OutputStream output, Context context) throws IOException {

                //Instantiate the tracer.
                  Tracer tracer = AppDynamics.getTracer(context);

                //Your AWS Lambda function code begins here.
                int letter = 0;
            while((letter = input.read()) >= 0) {
                output.write(Character.toUpperCase(letter));
                }
    }
```

Create a Transaction

Next, you need to create transactions. A transaction is a monitored segment in a larger business transaction. Creating a transaction involves locating the correlation header, which the tracer uses to pass contextual information downstream.

Transactions either:

- Start a new business transaction, or
- Continue an existing business transaction

Start a New Business Transaction

A transaction that originates in the current function does not have an inbound correlation header. To create a business transaction, use the `createTransaction()` method and provide an empty correlation header.

Continue an Existing Business Transaction

To continue an existing business transaction, you need to locate an inbound correlation header. You can locate a correlation header automatically or manually.

If the tracer cannot find the correlation header, the tracer creates a new business transaction.

Continue a Business Transaction by Locating the Correlation Header Automatically

Use the `createTransaction(inputStream, context)` method to create a transaction that locates the correlation header automatically. This method searches your code's object schema for a key called `singularityheader` in the `inputStream` object. The correlation header finds the `singularityheader` key, then continues the business transaction.

> The tracer reads the `inputStream` object, which is configured to be read once. If your application needs to read the `inputStream` object, you must use a converter method to allow both the tracer and your application to read the stream.

The code snippet shows an example of how to create a transaction and automatically locate the correlation header:

```
public class <LambdaChops> implements RequestStreamHandler {
    @Override
    public void handleRequest(InputStream input, OutputStream output, Context context) throws IOException {
          Tracer tracer = AppDynamics.getTracer(context);

        //Use a converter method if you need to read your inputStream more than once. The tracer reads your
inputStream once.
          inputStream = InputStreamConverter.convertToMarkSupportedInputStream(input);

        //Create a transaction.
        Transaction transaction = tracer.createTransaction(input, context);

        //Your AWS Lambda function code begins here.
        int letter = 0;
        while((letter = input.read()) >= 0) {
            output.write(Character.toUpperCase(letter));
        }
    }
}
```

Create a Transaction by Locating the Correlation Header Manually

To create a transaction that locates the correlation header using custom logic, you need to manually parse a `correlationHeader` string. Next, call the c`reateTransaction()`method and provide the `correlationHeader` object. This process gives you full control over the parsing of your function's input payload.

The code snippet shows an example of how to obtain the correlation header string and create a transaction:

```
public class <LambdaChops> implements RequestHandler {
    @Override
        public O handleRequest(InputStream input, OutputStream output, Context context) {
        Tracer tracer = AppDynamics.getTracer(context);

        //Manually parse the correlation string.
     String inputAsString = IOUtils.toString(inputStream, Charset.forName("UTF-8"));
     JsonParser parser = new JsonParser();
     JsonObject inputObject = parser.parse(inputAsString).getAsJsonObject();

        String correlationHeader = "";
        if (inputObject.has(Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY)) {
            correlationHeader = inputObject.get(Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY).
getAsString();
        } else {
            // Try reading from HTTP headers
            if (inputObject.has("headers")) {
                JsonObject httpHeaders = inputObject.getAsJsonObject("headers");
                if (httpHeaders.has(Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY)) {
                    correlationHeader = httpHeaders.get(Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY).
getAsString();
        }
    }
}

        // Create transaction object using the correlation header. If the correlationHeader string is empty,
the transaction you create uses the default transaction name.
        Transaction transaction = tracer.createTransaction(correlationHeader);

        //Your AWS Lambda function code starts here
        ...

}
```

Start and Stop a Transaction

After creating a transaction, you need to set transaction boundaries. Use the `transaction.start()` and `transaction.stop()` methods to place boundaries around any section of code that you want the tracer to monitor.

As a best practice, you can report all events, even if your function crashes, by running your entire function within a `try` block, and then stopping the transaction within a `finally` block.

This code sample demonstrates how to start and stop a transaction that monitors an entire function:

```
@Override
 public void handleRequest(InputStream input, OutputStream output, Context context) throws IOException {
  Tracer tracer = AppDynamics.getTracer(context);
  Transaction transaction = tracer.createTransaction(input, context);

        //Start the transaction monitoring.
          transaction.start();
          try {
                   int letter = 0;
        while((letter = input.read()) >= 0) {
            output.write(Character.toUpperCase(letter));
                }

        //Stop the transaction monitoring. Place in a finally block to monitor all events.
        } finally {
                   transaction.stop();
                 AppDynamics.cleanup();
          }
 }
```

Create External Exit Calls

The `createExitCall` method is used to obtain an `exitCall` object. Exit call objects record the time spent in external exit calls and allow for correlation of downstream activity.

Exit Call Types and Identifying Properties

In the Controller, each exit call has a distinct type, determined by a set of identifying properties.

This table lists the `exitCall` types and identifying properties:

`exitCall` Type	**Identifying Properties**
HTTP	HOST PORT URL QUERY STRING
JDBC	URL HOST PORT DATABASE VERSION VENDOR
WEB SERVICE	SERVICE URL OPERATION SOAP ACTION VENDOR
CUSTOM	Any user-defined set of properties

Create an External Exit Call

Call `createExitCall()` on your transaction object.

The following code sample demonstrates how you might perform an external exit call:

```
public void makeExitCall(URL url){

HttpURLConnection conn = (HttpURLConnection)url.openConnection();

String outgoingHeader = null;
String callType = null;
Map<String, String> identifyingProperties = new HashMap<>();

//Below properties are appropriate for an inter-AWS Lambda call
identifyingProperties.put("DESTINATION", functionName);
identifyingProperties.put("DESTINATION_TYPE", "LAMBDA");
callType="CUSTOM";

//Below properties are appropriate for an external HTTP call
identifyingProperties.put("HOST", url.getHost());
identifyingProperties.put("PORT", String.valueOf(url.getPort()));
callType="HTTP";

//Define the createExitCall method to obtain an exitCall object.
ExitCall exitCall = transaction.createExitCall(callType, identifyingProperties);
outgoingHeader =  exitCall.getCorrelationHeader();
exitCall.start();

try {
// Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY is the name of the header that should be set

    if (outgoingHeader != null) {
        conn.setRequestProperty(Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY, outgoingHeader); // set
the correlation header on an HttpURLConnection
    }

// Make the exit call here

} finally {
        exitCall.stop();
    }
}
```

Create Multiple External Exit Calls

If one AWS Lambda function makes multiple exit calls, each function should be identified by a unique `exitCall` object. To make multiple exit calls, create new `exitCall` objects for each distinct exit call. The `exitCall` objects are not reusable.

Java Serverless Tracer API

This page describes how to use the Java Serverless Tracer API to fine-tune your configuration.

Transaction Error Reports

If you automatically instrument the tracer, transaction errors are reported if an exception is thrown. If you manually instrument the tracer, transaction error reports are optional and require manual configuration.

If your business logic defines the transaction as in error for any reason, you can customize the error report method to mark the transaction in error.

To create transaction error reports, use `transaction.reportError()`.

The `transaction.reportError()` method reports one error per invocation. You can also use `transaction.reportError()` for any `errorName` or `errorMessage`:

```
transaction.reportError(errorName, errorMessage);
```

Exit Call Error Reports

You can report errors and exceptions that occur during exit call execution using the `exitCall.reportError()` method. You must call the method before `transaction.stop()`.

Use `exitCall.reportError()` for any exception or subclass:

```
exitCall.reportError(exception);
```

You can also use `exitCall.reportError()` for a specific `errorName` or `errorMessage`.

```
exitCall.reportError(errorName, errorMessage);
```

Override the Tracer's Default Behavior

If you prefer to customize the function and business transaction names, or keep the tracer settings in your code, you can override the environment variables using the `AppDynamics.Config.Builder` object. This option allows you to retrieve values at runtime from any desired source.

```
AppDynamics.Config.Builder configBuilder = new AppDynamics.Config.Builder();
configBuilder.accountName(accountName)
   .applicationName(appName)
   .tierName(tierName)
   .controllerHost(controllerHost)
   .controllerPort(controllerPort)
   .defaultBtName(context.getFunctionName() + "_bt")
   .controllerAccessKey(controllerAccessKey)
   .lambdaContext(context);
```

Implementation of the `configBuilder` object differs slightly depending on which instrumentation method you choose, automatic or manual.

Automatic Instrumentation

Automatic instrumentation uses the `MonitoredRequestStreamHandler` class, which implements a factory method, `getConfigBuilder()`, to instrument the tracer.

You can override this factory method and use any builder method to configure environment variables.

The code snippet shows how to enter variables in your code for automatic instrumentation:

```
@Override
public AppDynamics.Config.Builder getConfigBuilder(Context context) {
String controllerHost = System.getenv("APPDYNAMICS_CONTROLLER_HOST");
int controllerPort = Integer.parseInt(System.getenv("APPDYNAMICS_CONTROLLER_PORT"));
String accountName = System.getenv("APPDYNAMICS_ACCOUNT_NAME");
String appName = System.getenv("APPDYNAMICS_APPLICATION_NAME");
String tierName = System.getenv("APPDYNAMICS_TIER_NAME");
String controllerAccessKey = System.getenv("APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY");

AppDynamics.Config.Builder configBuilder = new AppDynamics.Config.Builder();
configBuilder.accountName(accountName)
   .applicationName(appName)
   .tierName(tierName)
   .controllerHost(controllerHost)
   .controllerPort(controllerPort)
   .defaultBtName(context.getFunctionName() + "_bt")
   .controllerAccessKey(controllerAccessKey)
   .lambdaContext(context);
return configBuilder;
  }
```

Manual Instrumentation

In manual instrumentation, the overloaded version of the `AppDynamics.getTracer()` method configures the tracer's settings. The overloaded method takes a `configBuilder` object as a parameter, instead of the `context` object, to instrument the tracer.

When you use this variant of `AppDynamics.getTracer()`, you must pass the `context` object via the `AppDynamics.Config.Builder.lambdaContext()` method.

The code snippet shows how to enter variables in your code for manual instrumentation.

```
@Override
public void handleRequest(InputStream input, OutputStream output, Context context) throws IOException) {
        String controllerHost = System.getenv("APPDYNAMICS_CONTROLLER_HOST");
        int controllerPort = Integer.parseInt(System.getenv("APPDYNAMICS_CONTROLLER_PORT"));
        String accountName = System.getenv("APPDYNAMICS_ACCOUNT_NAME");
        String appName = System.getenv("APPDYNAMICS_APPLICATION_NAME");
        String tierName = System.getenv("APPDYNAMICS_TIER_NAME");
        String controllerAccessKey = System.getenv("APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY");
        AppDynamics.Config.Builder configBuilder = new AppDynamics.Config.Builder();
        configBuilder.accountName(accountName)
                .applicationName(appName)
                .tierName(tierName)
                .controllerHost(controllerHost)
                .controllerPort(controllerPort)
                .defaultBtName(context.getFunctionName() + "_bt")
                .controllerAccessKey(controllerAccessKey)
                .lambdaContext(context);

        //Replace the context object with config.Builder.build()
        Tracer tracer = AppDynamics.getTracer(configBuilder.build());
```

Integrate the Java Serverless Tracer with End User Monitoring

> This document contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation since Amazon controls its own documentation.

Serverless APM for AWS Lambda is designed to integrate with your existing End User Monitoring (EUM) configurations. The EUM integration provides complete end-to-end visibility on the performance of your web and mobile applications, linking calls from an end-user device through your serverless functions to continue your business transactions

AWS Lambda functions can correlate EUM and AWS Lambda-originated business transactions, in conjunction with the following EUM agents:

- Browser Real User Monitoring (Browser RUM)
- Mobile Real User Monitoring (Mobile RUM)
- IoT Monitoring

Integration of the Java Serverless Tracer with End User Monitoring consists of these steps:

1. Add and Return EUM Metadata
2. Configure Response Header Mappings
    a. Use the Amazon API Gateway
    b. Use AWS Lambda Proxy Integration
3. Update the Front End Application
4. Enable CORS configuration (If applicable)
5. Troubleshoot the EUM Integration

> This document assumes you are familiar with AppDynamics End User Monitoring. See End User Monitoring for more information.

Before You Begin

Ensure your deployment has:

- An AWS Lambda function instrumented with the Java Serverless Tracer
- Active EUM licenses and JavaScript agents

Add and Return EUM Metadata

To integrate EUM with the tracer, you need to query the `transaction` object and return EUM metadata.

Call the method below after stopping a transaction. Assign each string separately, in the order specified, to the headers ADRUM_0, ADRUM_1, ADRUM_2, and ADRUM_3 for consumption by the downstream JavaScript Agent.

```
public void stopTransactionAndRecordEUM(OutputStream output) throws IOException {
        Transaction transaction = getTransaction();

// Your AWS Lambda function code

//You must call transaction.stop(); before calling transaction.getEumMetadata();
 transaction.stop();
// call transaction.getEumMetadata(); function to query transaction object for EUM metadata
List<String> eumMetadata = transaction.getEumMetadata();
```

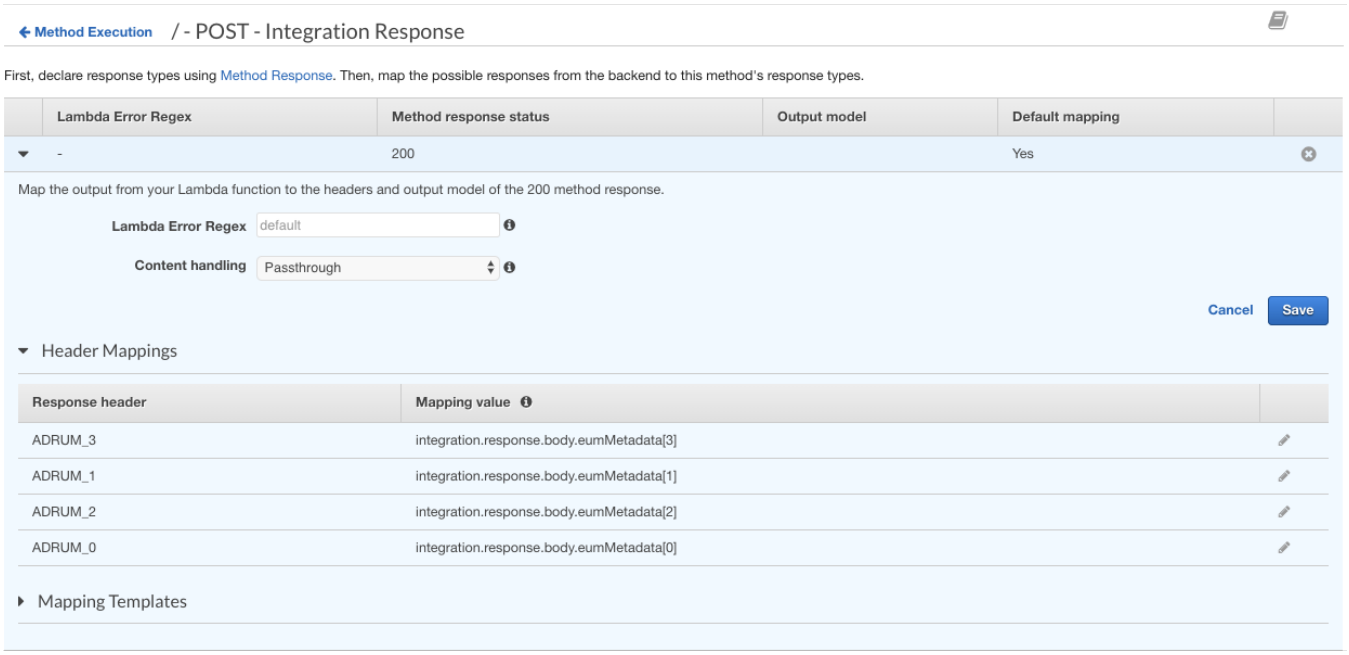
Configure Response Header Mappings

Configure response header mappings to pass ADRUM_*n* headers back to the browser. You can configure response header mappings using the AWS API Gateway or pass them directly using AWS Lambda Proxy Integration.

Response Header Mappings in Amazon API Gateway

Add header mappings for each ADRUM_*n* header in the Amazon API Gateway. To configure response header mappings in the Amazon API Gateway, refer to the Amazon documentation.

The screenshot illustrates how to map these headers in the AWS API Gateway:



Next, return the ADRUM_*n* headers as part of the AWS Lambda function output. You can use another field name, as long your function code is consistent with the response header mappings.

This code snippet shows how to add the headers field to an output object class:

```
// add the field eumMetadata to your output object class
// return the EUM ADRUM_n headers in the output object
String outputString = "success";
Output outputObj = new Output(outputString);
OutputObj.eumMetadata = eumMetadata;
output.write(new Gson().toJson(outputObj).getBytes(StandardCharsets.UTF_8));
```

Response Header Mappings in AWS Lambda Proxy Integration

As an alternative to custom integration, AWS Lambda proxy integration allows the client to call each function in the backend and returns output in a JSON format. Map these responses by adding each single-value ADRUM_*n* header directly to the headers field in your output object class. Refer to the Amazon documentation for details.

Update the Front End Application

To see the correlation between EUM and AWS Lambda-originated business transactions, you must inject the JavaScript Agent into your browser's HTML, as described in the EUM documentation.

Enable CORS Configuration

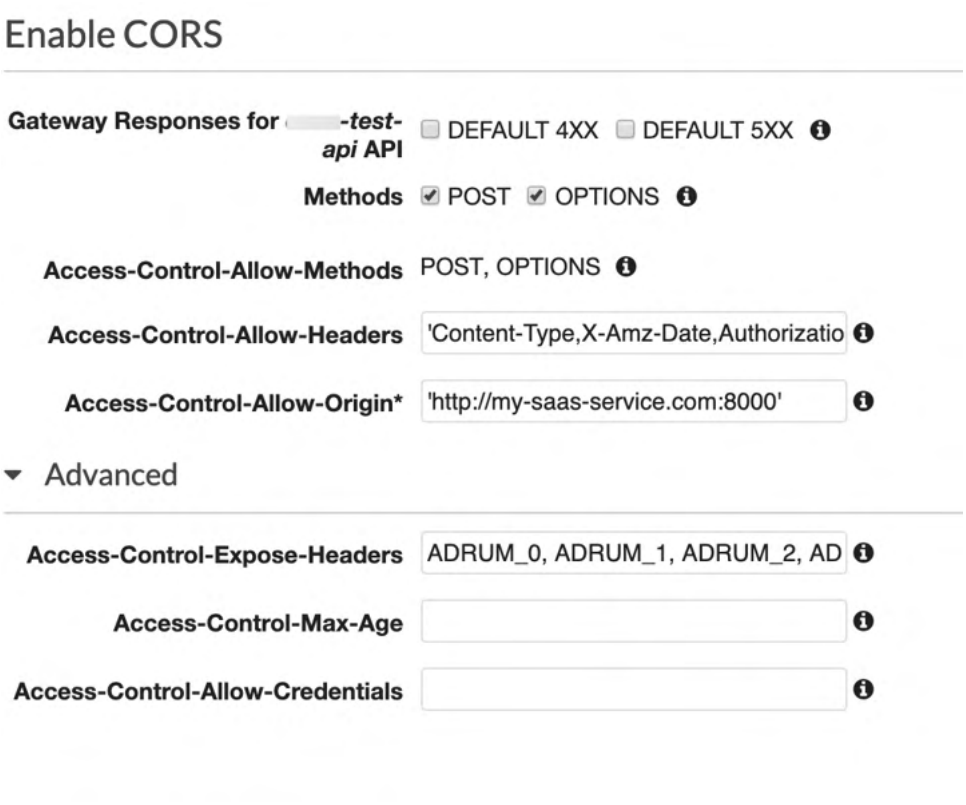
Browsers require cross-origin resource sharing (CORS) for functions that access responses from browser requests to a domain other than the base page's domain. You must explicitly grant cross-domain access to all applicable ADRUM_*n* headers.

To enable CORS configuration, define the required AWS response headers in the Amazon API Gateway:

- **Access-Control-Expose-Headers** - maps the custom ADRUM headers. These headers must have the names ADRUM_0 through ADRUM_3 to be compatible with the JavaScript Agent.
- **Access-Control-Allow-Methods** - check the header(s) with the appropriate method.
- **Access-Control-Allow-Origin** - set to the full URL of the web page that originated the request, including schema, hostname, and port.

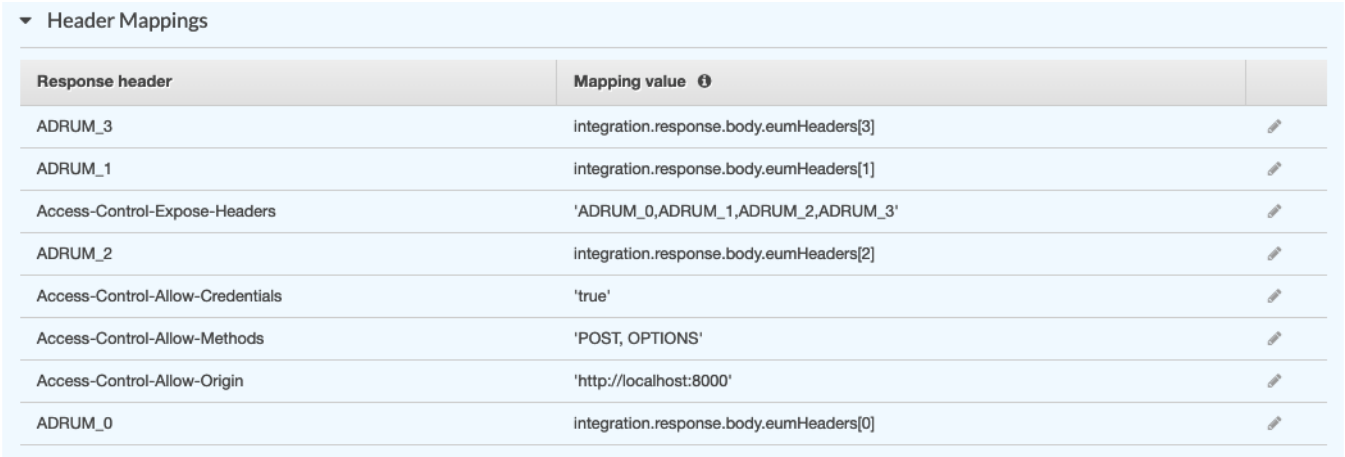
See AWS documentation for advanced headers and additional details.

The screenshot illustrates how to enable CORS in the Amazon API Gateway:



After you have enabled CORS, you must define the response header mappings. To configure response header mappings in the Amazon API Gateway, refer to the Amazon documentation.

The screenshot illustrates response header mappings after CORS configuration:



Troubleshoot the EUM Integration

If you do not see a correlation between EUM data and business transactions, collect an HTTP Archive (HAR) file that captures the activity in your browser. Use the HAR file to confirm all necessary CORS headers are set and expected data populates in the ARUM_*n* headers.

The EUM documentation provides additional troubleshooting advice.

Use the AppDynamics AWS Lambda Extension to Instrument Serverless APM at Runtime

This page explains how to use the AppDynamics AWS Lambda Extension for Serverless APM (the AppDynamics Lambda extension), the recommended way to inject the Serverless Tracer at runtime. Use this option to dynamically add a layer to a Node.js or Python application.

This document is intended to provide information specifically for using the AppDynamics AWS Lambda Extension for Serverless APM in conjunction with AppDynamics. AWS Lambda is managed by AWS and is a separate product from AppDynamics solutions.

- For questions related to AWS Lambda, see AWS Lambda Documentation.
- For questions related to AppDynamics AWS Lambda Extension for Serverless APM, see Serverless APM for AWS Lambda.

Before You Begin

After you have subscribed to Serverless APM for AWS Lambda and set up your environment variables, you can begin instrumentation. Ensure that your setup meets the following requirements:

- Existing AWS Lambda functions built with Node.js version 10.x or later or Python 3.6 or later
- Active Serverless APM for AWS Lambda subscription
- AppDynamics SaaS Controller version 4.5.11 or later
- Supported AWS Regions: eu-central-1, eu-north-1, eu-west-1, eu-west-2, eu-west-3, ap-northeast-1, ap-northeast-2, ap-south-1, ap-southeast-1, ap-southeast-2, ca-central-1, sa-east-1, us-east-1, us-east-2, us-west-1, us-west-2

Use AWS Lambda Layers to Inject the Serverless Tracer at Runtime

To install the Node.js or Python Serverless Tracer, configure your Lambda function to use the layer implementing the AppDynamics AWS Lambda Extension for Serverless APM. The method for doing this differs, depending on whether your Lambda function is packaged as a zip archive or as a container image.

Add the AWS Lambda Extension to Your Function when packaged as a zip archive

To pull the AppDynamics layer from Amazon, add the Amazon Resource Number (ARN) to your Lambda using either the AWS Management Console UI or the AWS CLI.

1. Add the AWS Lambda Extension to Your Function
2. Configure Environment Variables

Instrument a Lambda Function using the AWS UI

1. In the AWS Management Console console, select **Compute > Lambda**.
2. From the **AWS Lambda** panel, select a lambda that you want to instrument.
3. Select **Layers**.
4. Click **Add a layer.**
5. Under **Choose a layer**, select **Specify an ARN.**
6. Under **Specify an ARN,** enter the AWS Layer information:

```
arn:aws:lambda:us-west-2:338050622354:layer:appdynamics-lambda-extension:10
```

The ARN region changes based on the AWS region where the lambda is deployed. For example, if your lambda is **Europe (Frankfurt) eu-central-1**, use:

```
arn:aws:lambda:eu-central-1:338050622354:layer:appdynamics-lambda-extension:10
```

7. Click **Add.**
8. To verify the layer is added to the lambda, click **Layers**. Under **Layers**, the **appdynamics-lambda-extension** displays.
9. See Configure the Environment Variables.

Instrument a Lambda Function using AWS CLI

To pull the AppDynamics layer from Amazon, using the AWS CLI:

1. See Configuring a function to use layers.
2. See Configure the Environment Variables.

Configure Environment Variables

To finish injecting the tracer into AWS Lambda, configure environment variables depending on your programming language and version:

Node 10.x, Node 12.x, Node 14.x, and Python 3.8

Add the environment variable `AWS_LAMBDA_EXEC_WRAPPER` with the value: `/opt/appdynamics-extension-script:`

```
AWS_LAMBDA_EXEC_WRAPPER = /opt/appdynamics-extension-script
```

For Python 3.6 and Python 3.7

Add an environment variable `APPDYNAMICS_PYTHON_AUTOINSTRUMENT` with the value set to `true:`

```
APPDYNAMICS_PYTHON_AUTOINSTRUMENT = true
```

Add the AWS Lambda Extension to Your Function when packaged as a container image

When your Lambda functions are deployed as container images, Lambda layers cannot be added via the function configuration. Instead, you must package the extension as part of your container image during the build process. For more details refer to this AWS Blog article.

To add the AppDynamics Lambda extension to your Lambda container, you will need to use a Dockerfile like those provided below:

To build the container image containing your code as well as the AppDynamics Lambda extension, make sure you have the correct Dockerfile in your current directory and use the docker build command; for example:

```
docker build --build-arg version_number=$version_number --build-arg access_key=$(aws configure get
aws_access_key_id) --build-arg secret_key=$(aws configure get aws_secret_access_key) --build-arg region=$(aws
configure get region) -t <your tag> --build-arg cachebust=$(date +%s) .
```

Verify your Serverless Tracer Instrumentation

See Verify the Serverless Tracer Instrumentation.

Node.js Serverless Tracer

This page describes how to use the Node.js Serverless Tracer with AWS Lambda functions during development. The preferred method is to use the AppDynamics AWS Lambda Extension. See Use the AppDynamics AWS Lambda Extension to Instrument Serverless APM at Runtime.

Before You Begin

After you have subscribed to Serverless APM for AWS Lambda and set up your environment variables, you can begin instrumentation. Ensure that your setup meets the following requirements:

- Existing AWS Lambda functions built with Node.js >= 10.x
- Active Serverless APM for AWS Lambda subscription
- AppDynamics SaaS Controller >= 4.5.11

This document contains links to Amazon Web Services (AWS) documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation because Amazon controls its own documentation.

Install the Node.js Serverless Tracer Using `npm` During Development

To instrument your lambda we recommend the AWS Lambda Extension. You can also install the Node.js Serverless Tracer using these steps:

1. Download the Node.js Serverless Tracer
2. Add the Require Statement
3. Instrument the Function with the Node.js Serverless Tracer

Download the Node.js Serverless Tracer

To install the tracer, navigate to the directory where the `package.json` file resides. Run the following `npm` command:

```
npm install appdynamics-lambda-tracer --save
```

The command downloads the tracer dependency into a `node_modules/` folder.

Add the Require Statement

To add the tracer to your application, add a `require` statement in your application code's primary file that includes the AWS Lambda `handler` function:

```
const tracer = require('appdynamics-lambda-tracer');
```

Remember to add the tracer's `require` statement before any other `require` statement.

Instrument the Function with the Node.js Serverless Tracer

Initialize the Node.js Serverless Tracer below the `require` statement, by calling the `tracer.init` method.

To complete instrumentation, call `tracer.mainModule(module)` as the last line of your code.

The code snippet below demonstrates how to instrument a serverless function with the tracer:

```
const tracer = require('appdynamics-lambda-tracer');
//Initialize the tracer
tracer.init();

// Your AWS Lambda handler function code here, for example:
exports.handler = async (event) => {
    // TODO implement
    const response = {
        statusCode: 200,
        body: JSON.stringify('Hello from Lambda!'),
    };
    return response;
};
//Complete the instrumentation
tracer.mainModule(module);
```

By default, the Node.js Serverless Tracer automatically discovers exit calls passed over HTTP or inter-AWS Lambda calls. You need to create an exit call if your function does not use these protocols. See Node.js Serverless Tracer API.

Next Steps

You are ready to Verify the Serverless Tracer Instrumentation.

You can also Integrate the Node.js Serverless Tracer with End User Monitoring or use the Node.js Serverless Tracer API.

Customize the Node.js Serverless Tracer

This page describes how to fine-tune your configuration with the Node.js Serverless Tracer API.

Create or Modify Exit Calls

If your function does not use HTTP or inter-AWS Lambda exit calls, you will need to create an exit call.

The following code snippet demonstrates how to create an exit call for an AWS Lambda function that calls a MySQL database:

```
// Use the exit call API in your AWS Lambda handler function

module.exports.myLambdaHandler = async function () {
  const queryPromise = new Promise(function (resolve, reject) {
    const dbConfig = {
      host: '127.0.0.1', // The host where MySQL server runs
      port: 3306, // Note that this is not an identifying property. Identifying properties must be strings
      user: 'root',
      database: 'movies'
    };
    const mysql = require('mysql');
    const mysqlClient = mysql.createPool(dbConfig);
    mysqlClient.getConnection(function (err, connection) {
      if (err) {
        reject({
          statusCode: 500,
          body: 'Couldn\'t make the connection to mysql client.'
        });
        return;
      }
      // Create an Exit Call
      var exitCall = tracer.startExitCall({
        exitType: 'DB',
        exitSubType: 'DB',
        identifyingProperties: {
          'HOST': '127.0.0.1', // The host where MySQL server runs
          'PORT': '3306',
          'DATABASE': 'movies',
          'VENDOR': 'MYSQL'
        }
      });
      connection.query('SELECT * FROM ClassicHits', function (err, results) {
        connection.release();
        if (err) {
          reject({
            statusCode: 500,
            body: 'Mysql query failed'
          });
          return;
        }

                // Stop the Exit Call
        tracer.stopExitCall(exitCall);
        resolve({
          statusCode: 200,
          body: JSON.stringify(results)
        });
      });
    });
  });
  return queryPromise;
}
```

Exit Call Types and Identifying Properties

Each exit call in the Controller has a distinct type determined by a set of identifying properties. The exit call types, subtypes, and identifying properties are listed below. For exit call subtypes, you can use the examples in the table or an empty string. Identifying properties must be strings.

Exit Call Type	Exit Call Subtype	Identifying Properties
HTTP	HTTP	HOST PORT URL QUERY STRING
DB	DB	URL HOST PORT DATABASE VERSION VENDOR
CACHE	CACHE	VENDOR SERVER POOL
CUSTOM	CASSANDRA CQL COUCHBASE AMAZON WEB SERVICES MONGODB	Any user-defined set of properties.

Transaction Correlation through API-defined Exits

If you manually create an exit call for the Node.js Serverless Tracer, you need to locate the correlation header. This is required if your function does not use HTTP or inter-AWS Lambda exit calls.

The code snippet below demonstrates how you can create the correlation header:

```
module.exports.myLambdaHandler = function () {
    // Start Exit Call
    var exitCall = tracer.startExitCall({
      // Fill in with the exit call information
    });

    //Get your correlation header
    if (exitCall) {
        var correlationHeader = tracer.createCorrelationInfo(exitCall);
    }

    /*
     * Your exit call code.
     * Pass the correlation header in the exit call for downstream correlation.
     */

    // Stop the exit call
    if (exitCall) {
        tracer.stopExitCall(exitCall);
    }
}
```

Transaction Error Reports

By default, exceptions are automatically detected by the tracer. If your business logic defines the transaction as "in error" for any other reason, you can customize the error report method to mark the transaction in error.

The following code snippet demonstrates how to create a transaction error report:

```
// Transaction Error Report
module.exports.apiTransactionErrorReport = function(event, context, callback) {
  setTimeout(function () {
    tracer.reportTransactionError(new Error('API Error'));
    callback(null, {
      statusCode: 200,
      body: 'Transaction Error Reported'
    });
  }, 100);
}
```

Exit Call Error Reports

By default, the tracer automatically discovers exit calls passed over HTTP or inter-AWS Lambda calls. Use the `reportExitCallError` method to report errors and exceptions that occur during exit call execution.

The following code snippet demonstrates how to create an exit call error report:

```
// Use the Exit Call API in your AWS Lambda handler function

module.exports.myLambdaHandler = async function () {
  const queryPromise = new Promise(function (resolve, reject) {
    const dbConfig = {
      host: '127.0.0.1', // The host where your MySQL server runs
      port: 3306, // Note that this is not an identifying property. Identifying properties must be strings
      user: 'root',
      database: 'movies'
    };
    const mysql = require('mysql');
    const mysqlClient = mysql.createPool(dbConfig);
    mysqlClient.getConnection(function (err, connection) {
      if (err) {
        reject({
          statusCode: 500,
          body: 'Couldn\'t make the connection to mysql client.'
        });
        return;
      }
      // Create an Exit Call
      var exitCall = tracer.startExitCall({
        exitType: 'DB',
        exitSubType: 'DB',
        identifyingProperties: {
          'HOST': '127.0.0.1', // The host where your MySQL server runs
          'PORT': '3306',
          'DATABASE': 'movies',
          'VENDOR': 'MYSQL'
        }
      });
      connection.query('SELECT * FROM ClassicHits', function (err, results) {
        connection.release();

                //Create an Exit Call error report
        if (err) {
          tracer.reportExitCallError(exitCall, 'MYSql error', 'Failed in making the query');
          reject({
            statusCode: 500,
            body: 'Mysql query failed'
          });
          return;
        }
        resolve({
          statusCode: 200,
          body: JSON.stringify(results)
        });
      });
    });
  });
  return queryPromise;
}
```

Override the Tracer's Default Behavior

If you prefer to customize the function/business transaction names or keep the tracer settings in your source code, override the environment variables to retrieve values at runtime from any desired source.

The following code snippet demonstrates how to override the default behavior of the tracer:

```
tracer.init({
  controllerHostName: 'controllerHost',
  controllerPort: 8080,
  accountAccessKey: 'controllerAccountAccessKey',
  accountName: 'controllerAccountName',
  applicationName: 'applicationName',
  tierName: 'tierName',
  serverlessApiEndpoint: 'serverlessApiEndpoint',
  proxyHost: 'proxyHost',
  proxyPort: '80',
  proxyUser: 'proxyUser',
  proxyPassword: 'proxyPassword',
  certificateFile: 'proxyCertFile',
  debug: true
});
```

Integrate the Node.js Serverless Tracer with End User Monitoring

This document contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation since Amazon controls its own documentation.

Serverless APM for AWS Lambda is designed to integrate with your existing End User Monitoring (EUM) configurations. EUM integration provides complete end-to-end visibility on the performance of your web and mobile applications, linking calls from an end-user device through your serverless functions to continue your business transactions

AWS Lambda functions can correlate EUM and AWS Lambda-originated business transactions, in conjunction with the following EUM agents:

- Browser Real User Monitoring (Browser RUM)
- Mobile Real User Monitoring (Mobile RUM)
- IoT Monitoring

This document assumes you are familiar with AppDynamics End User Monitoring. See EUM documentation for more information.

Before You Begin

Ensure your deployment has:

- An AWS Lambda function instrumented with the Node.js Serverless Tracer
- Active EUM licenses and JavaScript Agents

Add the EUM Environment Variable

By default, EUM integration is turned off for the Node.js Serverless Tracer.

To enable EUM integration, set the `APPDYNAMICS_ENABLE_EUM` environment variable to `true`. See Set Up the Serverless APM Environment for more details.

Configure Response Header Mappings

Configure response header mappings to pass ADRUM_*n* headers back to the browser. You can configure response header mappings:

- Using the AWS API Gateway
- Passing directly via AWS Lambda Proxy Integration
- Returning EUM metadata in your function code

Response Header Mappings in Amazon API Gateway

Add header mappings for each ADRUM_*n* header in the Amazon API Gateway. To configure response header mappings in the Amazon API Gateway, refer to the Amazon documentation.

The table below lists the required response headers and their mapping values:

Response Header	Mapping Value
`ADRUM_3`	`integration.response.body.headers.ADRUM_3`
`ADRUM_2`	`integration.response.body.headers.ADRUM_2`
`ADRUM_1`	`integration.response.body.headers.ADRUM_1`
`ADRUM_0`	`integration.response.body.headers.ADRUM_0`

Response Header Mappings in AWS Lambda Proxy Integration

As an alternative to custom integration, AWS Lambda proxy integration allows the client to call each function in the backend and returns output in a JSON format. Map these responses by adding each single-value ADRUM_*n* header directly to the headers field in your output object class. Refer to the Amazon documentation for details.

Response Header Mappings for All Other Invocations

To gather EUM metadata, you need to configure response header mappings. This code sample invokes an `appDEumHeaders` method on the tracer. This method returns an object containing the ADRUM_*n* headers. Pass this object to the downstream service for consumption by the downstream JavaScript Agent.

The code snippet below demonstrates how you can return EUM metadata:

```
module.exports.myLambdaHandler = function (event, context, callback) {
  setTimeout(function () {

        ////Call a transaction object
    let appDBusinessTxn = tracer.getCurrentTransaction();

        //Stop the transaction
    tracer.stopTransaction();

        //Return EUM Metadata
    let appDEumHeaders = tracer.getEumMetadata(appDBusinessTxn);
    callback(null, {
      eumMetadata: appDEumHeaders,
      data: 'Call to Lambda is a success'
    });
  }, 300);
}
```

Update the Front End Application

To see the correlation between EUM and AWS Lambda-originated business transactions, you must inject the JavaScript Agent into your browser's HTML, as described in Inject the JavaScript Agent.

Enable CORS Configuration

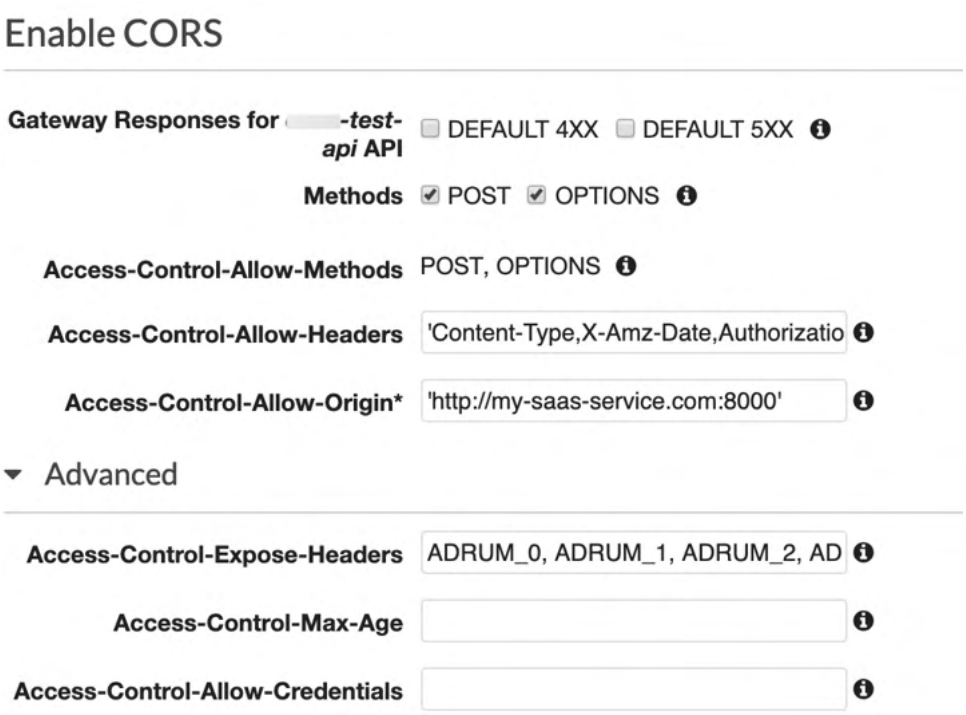
Browsers require cross-origin resource sharing (CORS) for functions that access responses from browser requests to a domain other than the base page's domain. You must explicitly grant cross-domain access to all applicable ADRUM_*n* headers.

To enable CORS configuration, define the required AWS response headers in the Amazon API Gateway:

- **Access-Control-Expose-Headers** - maps the custom ADRUM headers. These headers must have the names ADRUM_0 through ADRUM_3 to be compatible with the JavaScript Agent.
- **Access-Control-Allow-Methods** - check the header(s) with the appropriate method.
- **Access-Control-Allow-Origin** - set to the full URL of the web page that originated the request, including schema, hostname, and port.

See AWS documentation for advanced headers and additional details.

The screenshot illustrates how to enable CORS in the Amazon API Gateway:



After you have enabled CORS, you must define the response header mappings. To configure response header mappings in the Amazon API Gateway, refer to the Amazon documentation.

The table below lists response header mappings and example mapping values for CORS configuration:

Response Header	Example Mapping Value
`Access-Control-Expose-Headers`	`` `ADRUM_0,ADRUM_1,ADRUM_2,ADRUM_3` ``
`Access-Control-Allow-Credentials`	`` `true` ``
`Access-Control-Allow-Methods`	`` `POST,OPTIONS` ``
`Access-Control-Allow-Origin`	`` `http://my-saas-service.com:8000` ``

(Optional) If you connect your function to the Amazon API Gateway via a proxy integration, define the CORS response header mappings in your function code:

```
//Return EUM Metadata
    let appDEumHeaders = tracer.getEumMetadata(appDBusinessTxn);
    let returnHeaders = {
      'Access-Control-Allow-Origin': 'http://my-saas-service.com:8000',
      'Access-Control-Allow-Credentials': true,
      'Access-Control-Expose-Headers': 'ADRUM_0,ADRUM_1,ADRUM_2,ADRUM_3'
    };
```

Troubleshoot the EUM Integration

If you do not see a correlation between EUM data and business transactions, collect an HTTP Archive (HAR) file that captures the activity in your browser. Use the HAR file to confirm all necessary CORS headers are set and expected data populates in the ARUM_*n* headers.

The EUM documentation provides additional troubleshooting advice.

Python Serverless Tracer

This page provides requirements and an overview of the instrumentation process for Python functions during development. The preferred method is to use the AppDynamics AWS Lambda Extension. See Use the AppDynamics AWS Lambda Extension to Instrument Serverless APM at Runtime.

> This document contains links to Amazon Web Services (AWS) documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation because Amazon controls its own documentation.

Before You Begin

Ensure that your setup meets the following requirements:

- Existing AWS Lambda functions implemented in Python >= 3.6
- Python Package Installer (the `pip` version must match the Python version of your AWS Lambda function)
- AppDynamics SaaS Controller >= 4.5.16

Install the Python Serverless Tracer

> The Python Serverless Tracer is available for Python >= 3.6. The version of the tracer you obtain from PyPi needs to match the version of Python you use to run your function code in AWS.

The Python Serverless Tracer is available for download in PyPi repository. You can install the Python Serverless Tracer locally or package it with your AWS Lambda function code.

Install Locally

Run a `pip install` command to install the tracer in your local environment:

```
pip install appdynamics-lambda-tracer
```

If you install the tracer locally, you need to package the tracer with your AWS Lambda function at runtime.

Package with AWS Lambda Functions

Run the following command to include the tracer in your function's package:

```
pip install --target ./package/ appdynamics-lambda-tracer
```

See AWS documentation to learn more about packaging dependencies in your functions.

Instrument Your Function Code

To instrument your AWS Lambda function, add these lines of code:

```
import appdynamics # Add AppDynamics libraries. Must be the first line of code

@appdynamics.tracer # Must come before the handler function
def my_handler(event, context):
        print("Hello world!")
```

Exit Call Instrumentation

By default, the Python Serverless Tracer automatically discovers HTTP, Amazon DynamoDB, and inter-AWS Lambda exit calls. Use the Python Tracer API to create an exit call if you want visibility into other types of external calls made by your function. See Python Serverless Tracer API.

> This document contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation because Amazon controls its own documentation

Python Serverless Tracer API

This page describes how to use the Python Serverless Tracer API to modify the behavior of the tracer within your AWS Lambda function.

Create Exit Calls

Exit calls are automatically instrumented for HTTP, Amazon DynamoDB, and inter-AWS Lambda calls. All other protocols need to manually create an exit call.

To create an exit call, use the `ExitCallContextManager` method in a `with` statement to wrap the exit call. The method takes the following *required* parameters:

- `exit_point_type`: Type of the exit call
- `exit_point_sub_type`: Subtype of the exit call
- `identifying_properties`: Properties defining the exit call

The `ExitCallContextManager` method automatically reports any runtime exceptions that occur within the method's scope as exit call errors.

The code sample below demonstrates how to use the exit call method for a MySQL database:

```
import appdynamics # Add AppDynamics libraries. Must be the first line of code

@appdynamics.tracer
def handler(event, context):
    with appdynamics.ExitCallContextManager(exit_point_type="DB", exit_point_sub_type="DB",
identifying_properties={"VENDOR": "MYSQL"}) as ec:
        data = fetch_from_db()
```

Exit Call Types and Identifying Properties

In the Controller, each exit call has a distinct type, determined by a set of identifying properties. Include at least one identifying property for each exit call type.

The `exitCall` types, subtypes, and identifying properties are listed below. For exit call subtypes, you can use the examples listed in the table or use an empty string.

Exit Call Type	Exit Call Subtype	Identifying Properties

`HTTP`	`HTTP`	`HOST`
		`PORT`
		`URL`
		`QUERY STRING`

`DB`	`DB`	`URL`
		`HOST`
		`PORT`
		`DATABASE`
		`VERSION`
		`VENDOR`

`CACHE`	`CACHE`	`VENDOR` `SERVER POOL`

`CUSTOM`	`Cassandra CQL`
	`Couchbase`
	`Amazon Web Services`
	`Mongo DB`
		Any user-defined set of properties

Create Exit Call Error Reports

The `ExitCallContextManager` method automatically reports errors. If you want to add custom error reports, use the `report_exit_call_error` method. The method takes the following parameters:

- `error_name:` Name of the error
- `error_message` (Optional): Descriptive error message
- `http_status_code` (Optional): The HTTP status code if available.

The code sample below demonstrates how you can use the exit call error report method:

```
import appdynamics
@appdynamics.tracer
def handler(event, context):
        #Create an exit call
    with appdynamics.ExitCallContextManager("DB", "DB", {"HOST": "ec2-12-123-123-12.us-west-2.compute.amazonaws.
com", "PORT": "3306", "DATABASE": "movies", "VENDOR": "MYSQL"}) as ec:
        movies = fetch_movies_from_mysql_db()
        if movies == None:
                        #Create an exit call error report
            ec.report_exit_call_error(error_name="DBError", error_message="Item not found") #ec is the object
returned by ExitCallContextManager above
```

Create Transaction Error Reports

By default, the Python Tracer automatically detects transaction error reports. You can customize these error reports using the `appdynamics.report_error(error_name: str, error_message: str)` method to report transaction errors. The method takes the following parameters:

- `error_name`: Name of the error
- `error_message` (Optional): Descriptive error message

The code sample below demonstrates how you can use the transaction error report method:

```
import appdynamics # Add AppDynamics libraries. Must be the first line of code
import requests #Add request library

@appdynamics.tracer # Must come before the handler function
def my_handler(event, context):
        try:
        r = requests.get('https://api.github.com/events')
    except Exception as e:
        appdynamics.report_error(error_name=type(e).__name__, error_message=str(e)) # Reports a transaction
error
```

Integrate the Python Tracer with End User Monitoring

Serverless APM for AWS Lambda is designed to integrate with your existing End User Monitoring (EUM) configurations. EUM integration provides complete end-to-end visibility on the performance of your web and mobile applications, linking calls from an end-user device through your serverless functions to continue your business transactions

AWS Lambda functions can correlate EUM and AWS Lambda-originated business transactions, in conjunction with the following EUM agents:

- Browser Real User Monitoring (Browser RUM)
- Mobile Real User Monitoring (Mobile RUM)
- IoT Monitoring

This document assumes you are familiar with AppDynamics End User Monitoring. See End User Monitoring.

Before You Begin

Ensure your deployment has:

- An AWS Lambda function instrumented with the Python Serverless Tracer
- Active EUM licenses and JavaScript Agents

Add the EUM Environment Variable

By default, EUM integration is turned off for the Python Serverless Tracer.

To enable EUM integration, set the `APPDYNAMICS_ENABLE_EUM` environment variable to `true`. See Set Up the Serverless APM Environment.

Configure Response Header Mappings

Configure response header mappings to pass ADRUM_*n* headers back to the browser. You can configure response header mappings:

- Using the AWS API Gateway
- Passing directly via AWS Lambda Proxy Integration
- Returning EUM metadata in your function code

Response Header Mappings in Amazon API Gateway

Add header mappings for each ADRUM_*n* header in the Amazon API Gateway. To configure response header mappings in the Amazon API Gateway, refer to the Amazon documentation.

This table lists the required response headers and their mapping values:

Response Header	Mapping Value
`ADRUM_3`	`integration.response.body.headers.ADRUM_3`
`ADRUM_2`	`integration.response.body.headers.ADRUM_2`
`ADRUM_1`	`integration.response.body.headers.ADRUM_1`
`ADRUM_0`	`integration.response.body.headers.ADRUM_0`

Response Header Mappings in AWS Lambda Proxy Integration

As an alternative to custom integration, AWS Lambda proxy integration allows the client to call each function in the backend and returns output in a JSON format. Map these responses by adding each single-value ADRUM_*n* header directly to the headers field in your output object class. See the Amazon documentation.

Response Header Mappings for All Other Invocations

To gather EUM metadata, you need to configure response header mappings. This code sample invokes an `appDEumHeaders` method on the serverless tracer. This method returns an object containing the ADRUM_*n* headers. Pass this object to the downstream service for consumption by the downstream JavaScript Agent.

The code snippet below demonstrates how you can return EUM metadata:

```
@appdynamics.tracer
def my_lambda_handler(event, context):

        #Get the current transaction object
    transaction = appdynamics.get_current_transaction()

        #Stop the transaction
    appdynamics.stop_transaction()

        #Return EUM metadata
    eum_headers = appdynamics.get_eum_metadata(transaction)
    return {
        "eum_metadata": eum_headers,
        "data": "call to Lambda is a success"
    }
```

Update the Front End Application

To see the correlation between EUM and AWS Lambda-originated business transactions, you must inject the JavaScript Agent into your browser's HTML, as described in the Inject the JavaScript Agent.

Enable CORS Configuration

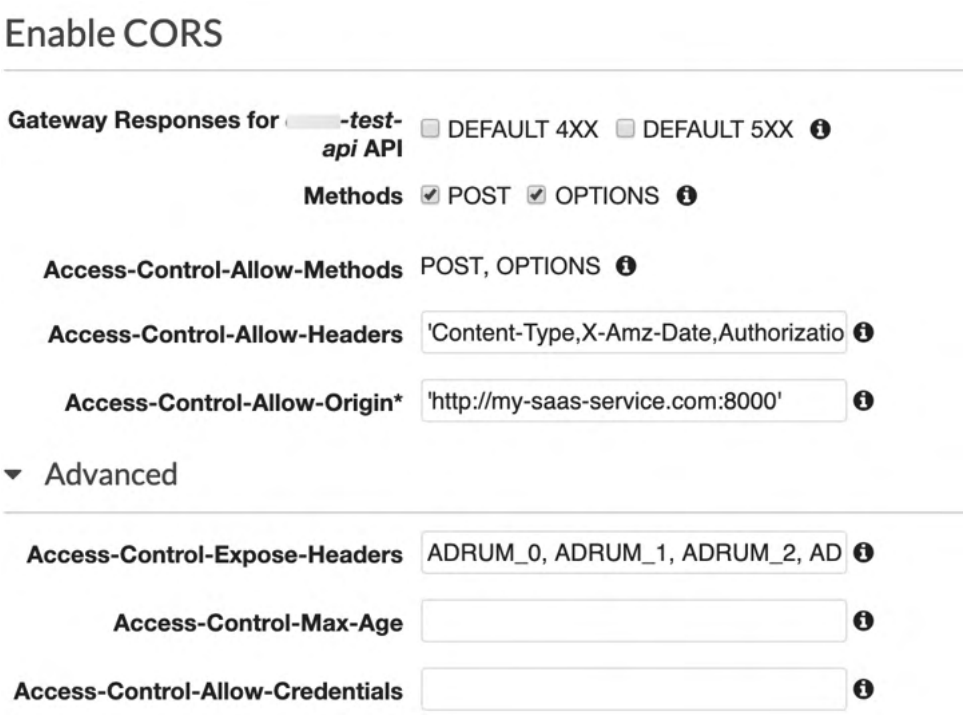
Browsers require cross-origin resource sharing (CORS) for functions that access responses from browser requests to a domain other than the base page's domain. You must explicitly grant cross-domain access to all applicable ADRUM_*n* headers.

To enable CORS configuration, define the required AWS response headers in the Amazon API Gateway:

- **Access-Control-Expose-Headers** - maps the custom ADRUM headers. These headers must have the names ADRUM_0 through ADRUM_3 to be compatible with the JavaScript Agent.
- **Access-Control-Allow-Methods** - check the header(s) with the appropriate method.
- **Access-Control-Allow-Origin** - set to the full URL of the web page that originated the request, including schema, hostname, and port.

See AWS documentation for advanced headers and additional details.

The screenshot illustrates how to enable CORS in the Amazon API Gateway:



After you have enabled CORS, you must define the response header mappings. To configure response header mappings in the Amazon API Gateway, see the Amazon documentation.

This table lists response header mappings and example mapping values for CORS configuration:

Response Header	Example Mapping Value
`Access-Control-Expose-Headers`	`` `ADRUM_0,ADRUM_1,ADRUM_2,ADRUM_3` ``
`Access-Control-Allow-Credentials`	`` `true` ``
`Access-Control-Allow-Methods`	`` `POST,OPTIONS` ``
`Access-Control-Allow-Origin`	`` `http://my-saas-service.com:8000` ``

(Optional) If you connect your function to the Amazon API Gateway via a proxy integration, define the CORS response header mappings in your function code:

```
# Return EUM Metadata
eum_headers = appdynamics.get_eum_metadata(transaction)
        return_headers = {
      'Access-Control-Allow-Origin': 'http://my-saas-service.com:8000',
      'Access-Control-Allow-Credentials': True,
      'Access-Control-Expose-Headers': 'ADRUM_0,ADRUM_1,ADRUM_2,ADRUM_3'
        }
```

Troubleshoot the EUM Integration

If you do not see a correlation between EUM data and business transactions, collect an HTTP Archive (HAR) file that captures the activity in your browser. Use the HAR file to confirm all necessary CORS headers are set and expected data populates in the ARUM_*n* headers.

The EUM documentation provides additional troubleshooting advice.

This document contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation since Amazon controls its own documentation.

Verify the Serverless Tracer Instrumentation

This document contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation because Amazon controls its own documentation.

After you set environment variables and instrument the Serverless Tracer, you can verify successful instrumentation.

Test the Function

Deploy your function to AWS and test in the AWS Management Console.

You need to create a test load on your function to see activity within AppDynamics. If your test log yields no errors, the tracer successfully instrumented.

To protect your production code, the tracer never fails your function. Your function may execute successfully yet fail to instrument the tracer. Check the logs of each AWS Lambda test in the AWS Management Console to confirm Serverless APM successfully instrumented.

View in the Controller

Your AWS Lambda function appears on the flow map after a few minutes of processing application load.

To view your function in AppDynamics:

1. Log in to your AppDynamics Controller.
2. Navigate to **Applications** and find your new application.

Apache Web Server Agent

Related pages:

- Apache Web Server Backend Detection
- Transaction Detection for Apache Web Servers

The Apache Web Server Agent discovers, maps and tracks metrics for business transactions, app services, and backends in your web application by injecting instrumentation into the Apache server at runtime.

About the Apache Web Server Agent

The Apache Agent automatically discovers incoming HTTP requests to Apache Web Server nodes as business transaction entry points. AppDynamics uses URI-based naming for transactions originating at Apache Agent nodes. The agent discovers exit points to Apache modules and resolves them to the downstream tier or backend. See Apache Web Server Backend Detection.

Business transaction naming is limited to URLs or the WEB type. This provides limited options for match and split rules.

The Apache Agent tracks the following metrics for web servers:

- Calls per minute and time spent in the web server tier
- Calls per minute and time spent in Apache module backends
- Number of errors

The agent identifies slow and stalled transactions according to dynamic baselines. When it detects an HTTP response code greater than 400, the agent identifies the transaction as an error transaction.

Transaction snapshots taken on Apache Web Server nodes include the following data:

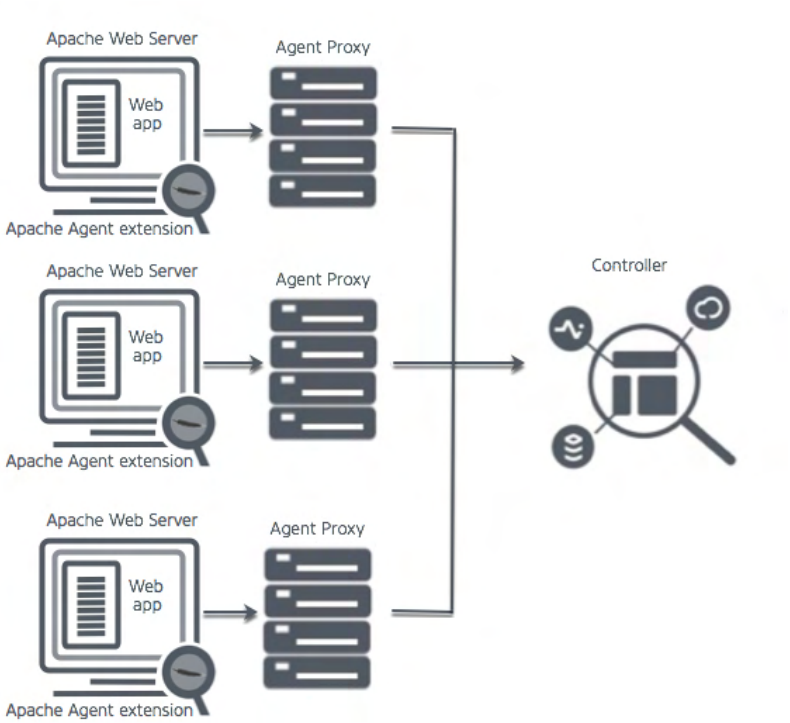
- URL
- HTTP error codes
- HTTP request data:
    - Cookie, including JSESSIONID
    - Referer
    - X-Forwarded-For
    - SM_USER
- Exit calls to Apache modules

Agent Deployment Architecture

The Apache Web Server Agent consists of these components:

- Apache extension
- AppDynamics agent proxy

The agent proxy is a Java process that handles communication between the Apache Web Server Agent and Controller. The proxy transmits the raw performance data from the agent to the Controller, which stores, analyzes, and presents the data.



As a separate process, the agent proxy must be started separately from the monitored web server. You can start the proxy manually or configure it to start automatically by setting `AppDynamicsLaunchProxy` in `appdynamics_agent.conf`. Whether the proxy is started automatically or manually, the commands that start the agent check whether the proxy is already running and do not attempt to start it again if it is.

Naming Apache Web Server Nodes

Each web server instance maps to a node in the AppDynamics model. When naming Apache Web Server nodes, be sure to use a meaningful name. Some options are:

- `hostName-appName-nodeName`
- `hostName-tierName-nodeName`
- `appName-nodeName`
- `tierName-nodeName`
- IP address
- fully qualified domain name

Supported Apache Web Servers

Related pages:

- Browser RUM Supported Environments

Apache Server Agent Support

Apache Web Servers

Supported Apache Web Server Version
• Apache HTTP Server 2.2.x • Apache HTTP Server 2.4.x • IBM HTTP Server >= 7.0 • Oracle HTTP Server >= 11g

Operating Systems

- Any Linux distribution based on glibc >= 2.12
- RHEL5 is not supported from 20.x onwards. Support is applicable for glibc2.5+ (RHEL6 or later).

> If you encounter an ELF warning message, it may be related to the incorrect version of glibc. Verify that your operating system has the suitable glibc version.

Automatically Discovered Business Transactions

The Apache Agent automatically discovers the following business transactions:

Type	Custom Configuration Options	Downstream Correlation
Web (HTTP)	Yes	Yes

By default the agent excludes requests for the following static file types:

bmp
cab
class
conf
css
doc
gif
ico
jar
jpeg
jpg
js
mov
mp3
mp4
pdf
png
pps
properties
swf
tif
txt
zip

Remote Service Detection

Apache Modules

The Apache Agent automatically detects loaded Apache modules as remote services. The agent excludes a list of common modules from detection.

Install the Apache Agent

Related pages:

- Download AppDynamics Software
- Install the Machine Agent
- SELinux Installation Issues

To monitor the performance of your Apache HTTP Server, IBM HTTP Server (IHS) or Oracle HTTP Server, install the AppDynamics Apache Agent on the servers where you run Apache, IHS or OHS. The agent instruments the Apache server and sends performance data to a Java proxy, which in turn sends data to the AppDynamics Controller.

If you are using the Apache Monitoring Extension with the Standalone Machine Agent, you can continue to use it. You may need to restart the Standalone Machine agent after installing the Apache Agent.

Before Starting

Ensure that the web server version and operating system are supported. See Supported Apache Web Servers.

Also verify the following requirements on the machine on which you are installing the agent:

- Perform the installation under the same user and group that Apache is using when spawning worker processes and threads.
- Ensure that the machine on which the agent runs has random or urandom set appropriately. This is because certain functions in the Apache Agent are dependent on random number generation.
  Else, it can lead to abrupt behavior such as log files or directories may not be created, nothing is reported from the agent to the Controller, and so on.
- Ensure that the ulimit setting for open file descriptors is set such that neither the Apache worker process or the Proxy task does not exceed it to avoid resource contention. **
- Check the open file descriptor limit of the userid that the proxy and/or Apache worker process must have:
  For the MPM_Worker mode, the number of file descriptors must be set using the following calculation: **1024 + ServerLimit + (2 * ServerLimit * ThreadsPerChild)**.
  For all other modes, you must set the number of file descriptors using the calculation: **(Total number of concurrently active Apache workers * 2) + 1024.**
  The open file descriptor setting can be found in /etc/security/limits.conf, but the setting requires a host reboot to become effective, or set through the "ulimit -n" command for the current userid's session only.
- Check for modules with dependencies on `libstdc++.so.5`. See Special Considerations for Apache Web Servers with libstdc++.so.5 Modules. T his is most common with IHS and OHS.
- Ensure that the machine on which the agent runs has a locale environment set properly. As some functions in the Apache Agent have a dependency on the locale it could lead to a crash otherwise.
  Based on the agent's requirement, you can select one of the following and set the environment variable as:

```
export LANG=en_US.UTF-8
export LANGUAGE=$LANG
export LC_ALL=$LANG
```

Or

```
export LANG=en_US.UTF-8
```

Or

```
export LC_ALL=C
```

Download and Install the Apache Agent

To guarantee performance and stability, you should install one agent for each Apache instance. Do not exceed two Apache instances per agent.

1. Download the Apache Agent from the Getting Started wizard or https://accounts.appdynamics.com/downloads.
2. Extract the agent to `/opt`.

   ```
   tar -xzvf ./appdynamics-sdk-native.<version>.tar.gz -C /opt
   ```

   The agent installs to `/opt/appdynamics-sdk-native`. This is the `<agent_install_directory>`. If you are installing multiple agents, you must create separate install directories for each agent.
3. Grant the Apache, IHS, or OHS owner read and write permissions to the logs directory: `<agent_install_directory>/logs`.
4. Run `install.sh`. This script installs the agent proxy.

```
<agent_install_directory>/install.sh
```

5. For an agent to monitor your Apache instance, you must launch the proxy. If you are monitoring multiple Apache instances, we recommend that you manually launch each proxy, and set `AppDynamicsLaunchProxy` to `NO` for every Apache instance.

   The next step is to create the agent configuration file and configure the agent.

For cURL installation, see Download AppDynamics Software.

Configure the Apache Agent

1. Create a configuration file for the AppDynamics Apache Web Server agent, such as `appdynamics_agent.conf`, in the Apache, IHS, or OHS configuration directory. For example:

```
touch /etc/<path_to_webserver_dir>/conf/appdynamics_agent.conf
```

2. In the `appdynamics_agent.conf` file, configure the following settings. If you have multiple agents installed, you must edit the appdynamics_agent.conf file for each agent, specifying which directory the agent load modules are located. Ensure that each Apache instance references a different `appdynamics_agent.conf` file, and that each file specifies a different agent install directory.

For multiple Apache web server instances that share the same Apache Agent, ensure that Comm dirs, set using `AppdynamicsProxyCommDir` dire ctive, for each proxy process is different. Also ensure that the node names in each server configuration file, `appdynamics_agent.conf`, are also different.

- `LoadFile`: Loads the AppDynamics Agent SDK shared library. Assuming the agent is installed in `/opt`, the setting would be `/opt/appdynamics-sdk-native/sdk_lib/lib/libappdynamics_native_sdk.so`. Required.
  For example:

```
LoadFile /opt/appdynamics-sdk-native/sdk_lib/lib/libzmq.so.3
LoadFile /opt/appdynamics-sdk-native/sdk_lib/lib/libuuid.so.1
LoadFile /opt/appdynamics-sdk-native/sdk_lib/lib/libappdynamics_native_sdk.so
```

  libappdynamics_native_sdk.so has a runtime dependency on libzmq and libuuid. These libraries can be found in the same directory as ibappdynamics_native_sdk.so.
- `LoadModule`: Loads the AppDynamics Apache Agent shared library. The correct module is `libmod_appdynamics.so` for Apache 2.4 and `libmod_appdynamics22.so` for Apache 2.2. Required. IHS and OHS require the Apache 2.2 module.
  Apache 2.4 example:

```
LoadModule appdynamics_module /opt/appdynamics-sdk-native/WebServerAgent/Apache/libmod_appdynamics.
so
```

  Apache 2.2 example:

```
LoadModule appdynamics_module /opt/appdynamics-sdk-native/WebServerAgent/Apache
/libmod_appdynamics22.so
```

- `AppDynamicsEnabled`: Must be included and set to ON for web server monitoring to be enabled. Otherwise, monitoring is disabled by default. For example:

```
AppDynamicsEnabled ON
```

  To disable monitoring, set to `OFF` or remove the AppDynamics module `include` statement (see Configure the Apache Server for AppDynamics) from the Apache configuration file.

- `AppDynamicsControllerHost`: Hostname or IP address of the AppDynamics controller to connect to. Required.
  For example

```
AppDynamicsControllerHost mycontroller.saas.appdynamics.com
```

- `AppDynamicsControllerPort`: Controller HTTP(S) port. For SaaS, use 443 for HTTPS or 80 for HTTP. For on-premises, HTTP defaults to 8090 and HTTPS defaults to 8181. Optional. Configure if you do not want to use these defaults. If you are using HTTPS, the SSL setting (`AppDynamicsControllerSSL`) must also be set.
  For example:

```
AppDynamicsControllerPort 80
```

- `AppDynamicsControllerSSL`: Set to connect to the Controller over SSL. Default is `OFF`. Set to `ON` to enable SSL connection and also set the `AppDynamicsControllerPort` to an HTTPS port.
  Example:

```
AppDynamicsControllerSSL OFF
```

- `AppDynamicsAccountName`: AppDynamics account name. For on-premises controllers, find your credentials under  **> License** in the Controller. For SaaS Controllers, AppDynamics provides your credentials in your Welcome email. Required.
  Example:

```
AppDynamicsAccountName MyCompany
```

- `AppDynamicsAccessKey`: AppDynamics account access key. For on-premises Controllers, find your credentials under  **> License** i n the Controller. For SaaS Controllers, AppDynamics provides your credentials in your Welcome email. Required.
  Example:

```
AppDynamicsAccessKey zd8yjh5yuy5k
```

- `AppDynamicsProxyHost`: Proxy server hostname or IP address. Optional. Use if the agent connects to the Controller through a HTTP proxy server.
- `AppDynamicsProxyport`: Proxy server port. Optional. Use if the agent connects to the Controller through a HTTP proxy server
- `AppDynamicsApplication`: AppDynamics application name. See Overview of Application Monitoring. Required.
  For example:

```
AppDynamicsApplication MyWS2App
```

- `AppDynamicsTier`: AppDynamics tier name. See Overview of Application Monitoring. Required.
  For example:

```
AppDynamicsTier MyWS2
```

- `AppDynamicsNode`: AppDynamics node name. See Overview of Application Monitoring. The node name is required and each node name must be unique.
  For example:

```
AppDynamicsNode WS2_1
```

```
#Load the AppDynamics SDK.
LoadFile /opt/appdynamics-sdk-native/sdk_lib/lib/libzmq.so.3
LoadFile /opt/appdynamics-sdk-native/sdk_lib/lib/libuuid.so.1
LoadFile /opt/appdynamics-sdk-native/sdk_lib/lib/libappdynamics_native_sdk.so

#Load the Apache Agent. In this example for Apache 2.4
LoadModule appdynamics_module /opt/appdynamics-sdk-native/WebServerAgent/Apache/libmod_appdynamics.so

AppDynamicsEnabled On

#AppDynamics Controller connection.
AppDynamicsControllerHost mycontroller.saas.appdynamics.com
AppDynamicsControllerPort 80
AppDynamicsControllerSSL OFF

#Account credentials
AppDynamicsAccountName MyCompany
AppDynamicsAccessKey zd8yjh5yuy5k

#Configure Controller connection through an HTTP proxy server.
#AppDynamicsProxyHost <proxy host>
#AppDynamicsProxyPort <proxy port>

#Business application, tier, node
AppDynamicsApplication MyApache2App
AppDynamicsTier Apache2
AppDynamicsNode Apache2_1
```

Launch the Proxy

To launch the proxy manually, run `runSDKProxy.sh` using the user ID of the Apache worker threads.

```
nohup <agent_install_directory>/runSDKProxy.sh >>/dev/null 2><agent_install_dir>/logs/proxy.out &
```

It is recommended that you create a Unix System Service that automatically starts the proxy at system startup.

The Proxy expects the appropriate (64- vs. 32-bit) `libstdc+6` library location. If you are installing the Apache Agent on a 64-bit OS that supports running a 32-bit Apache HTTP Server, make sure that the downloaded Apache Agent matches (i.e., is 32-bit), and that the `libstdc+6` library is 32-bit as well. If you have both 64-bit and 32-bit versions of that library, make sure you are pointing to the correct version using the command `export LD_PRELOAD=<path to 32bit library>` before starting `runSDKProxy`.

Additional Directives

You may need to set the following optional directives unless instructed by AppDynamics support:

- `AppDynamicsBackendNameSegments-` The number of URL segments that are displayed in the backend naming. This is only applicable for requests routing through the mod_proxy, when Apache is acting as a reverse proxy server, also-known-as a gateway server. Specify the rule configuration for backend naming in the `appdynamics_agent.conf` file. The default value is 0 and only the IP address of the request URL is displayed. If you set a value of 2, then the first two segments along-with the IP address are displayed. Therefore for a request proxying to `http://1.1.1.1/services/admin/abc`, the backend isnamed as `http://1.1.1.1/services/admin`.

  For example:

```
AppDynamicsBackendNameSegments 2
```

- `AppDynamicsResolveBackends-` Controls the way Apache module backends appear in the Controller UI. If ON, metrics for Apache modules are shown as part of downstream tiers or backends. Module backends do not appear on flow maps.
  If OFF, Apache module backends appear in the flow maps with their own metrics. See 'Apache Modules' on Install the Apache Agent .
  Defaults to ON. Optional.
  For example:

  ```
  AppDynamicsResolveBackends OFF
  ```

- `AppDynamicsTraceAsError-` If `ON`, tracepoints are written as errors to the Apache logs, by default `error_log`. Default is `OFF`. Optional.
  For example:

  ```
  AppDynamicsTraceAsError OFF
  ```

- `AppDynamicsReportAllInstrumentedModules-` If `OFF`, the agent reports only modules that occur during the `HANDLER` stage of Apache request processing. If ON, the agent reports modules during all stages of Apache request processing. The default is `OFF`.

  For example:

  ```
  AppDynamicsReportAllInstrumentedModules OFF
  ```

- `AppDynamicsLaunchProxy-` If `ON`, the agent launches the proxy automatically when on startup. If `OFF`, you need to manually launch the proxy. If your system uses any command to do a graceful restart of Apache, such as log rotate, or if your system encounters heavy loads, you should set this property to `OFF`. The default is `OFF`.
  For example:

  ```
  AppDynamicsLaunchProxy OFF
  ```

  For information about how to examine and resolve proxy issues that may prevent an application agent from connecting to the Controller, see Dynamic Language Agent Proxy.

  You may want to launch the proxy manually for debugging. For example, to set a different proxy root directory or runtime directory or to output additional debugging information.
- `AppDynamicsProxyCommDir-` Path to the directory containing the domain control socket, which the agent uses to start an AppDynamics node. Defaults to `<agent_install_directory>/logs/appd-sdk`. If you modify this setting, make sure that the directory path does not exceed 107 characters, which is the Linux limit to the socket file name size. If the directory path is too long, you will get an error message when the agent attempts to start.

  ```
  AppDynamicsProxyCommDir <agent_install_directory>/proxy/altcommdir
  ```

- For Filtering sensitive-data and privileged information, see Filter Sensitive Data.

Configure the Apache Server for AppDynamics

1. Add an include for the AppDynamics Apache Agent configuration to the server configuration. Ensure that the AppDynamics module is loaded after any modules you want to be instrumented. Any modules loaded after the AppDynamics agent are excluded from instrumentation and monitoring. For example, add the following as the last line in the httpd`.conf` file—on Ubuntu and Debian, this file is called `apache2.conf`:

   ```
   #Include AppDynamics Apache Agent Configuration
   Include conf/appdynamics_agent.conf
   ```

   If you are running multiple instances of the web server, modify the `.conf Include` path to match the configuration file name for that instance.
   For example:

   ```
   #Include AppDynamics Apache Agent Configuration.
   Include conf/appdynamics_agent1.conf
   ```

   > For versions upto 4.x, if you set values for Apache thread limits such as ServerLimit, ThreadsPerChild, and ThreadLimit, you need to ensure that the concurrent thread limit does not exceed 4095. For versions, 20.x and later this limit is not applicable. Users can create as many threads as allowed by their system, depending on the available resources.

2. Restart the web server. For example, for Apache on CentOS:

   ```
   apachectl restart
   ```

3. Apply load to your web server to activate instrumentation.

The AppDynamics Apache Agent automatically detects the incoming HTTP calls as business transactions. It detects loaded modules as backends. Log in to the AppDynamics Controller to begin monitoring.

Map Virtual Hosts to AppDynamics Tiers

By configuring virtual hosts, Apache Web Server administrators can have a single Apache Web Server instance act as the entry point for what appears to be different websites from the end user's perspective.

In the AppDynamics application model, it will usually make sense to represent each virtual host configured in an Apache Web Server as its own tier. This tends to better represent the logical model of the environment and reduces the likelihood of quickly exhausting tier business transaction limits for an Apache Web Server that proxies a large application environment.

To associate different virtual hosts with different tiers, add the AppDynamicsApplicationContext directive to the virtual host configuration, supplying the application, tier and node name as arguments, as follows:

```
AppDynamicsApplicationContext <application> <tier> <node>
```

For example:

```
Listen 80
<VirtualHost *:80>
    DocumentRoot "/www/example1"
    ServerName site1.example.com
    ...
    AppDynamicsApplicationContext MyApp site1.example.com:80 node01
</VirtualHost>

<VirtualHost *:80>
    DocumentRoot "/www/example2"
    ServerName site2.example.org
    ...
    AppDynamicsApplicationContext MyApp site2.example.org:80 node01
</VirtualHost>
```

In the example above, the tier name is a combination of the virtual machine ServerName and port number. You are not required to include the ServerName and port number in the tier name, but they can be useful for identifying which virtual machines are creating business transactions. We recommend using a tier name that best represents the purpose of the virtual machine.

The Apache Web Server Agent associates incoming requests to the AppDynamics context based upon the virtual host server and port in the request.

Note that instead of using virtual hosts to multi-host from Apache, an administrator may run multiple instances of the Apache Web Server with a distinct `httpd.conf` file—on Ubuntu and Debian, this file is called `apache2.conf`—for each instance. In this case, you would instrument the Apache Web Server by creating an AppDynamics agent configuration file for each instance, and include each configuration file in the `httpd.conf` file of the corresponding instance. See Configure the Apache Agent.

Apache Agent Directories

This page describes the directories for the Apache Agent.

Agent Install Directory

The agent install directory <agent_install_directory> is the appdynamics-sdk-native directory where you installed the agent.

For example, if you un-tarred the agent to /opt, the agent home would be: /opt/appdynamics-sdk-native.

It contains the following files:

- install.sh to install the Apache Agent and the agent proxy.
- runSDKProxy.sh to start the agent proxy.

WebServerAgent Directory

The <agent_install_directory>/WebServerAgent directory contains the Apache Agent libraries.

The Apache subdirectory contains the Apache modules for the Apache Agent:

- For Apache 2.2: libmod_appdynamics22.so
- For Apache 2.4: libmod_appdynamics.so

Conf Directory

The <agent_install_directory>/conf directory contains the logging configuration files:

- A logging configuration template: appdynamics_sdk_log4cxx.xml.template
- A log configuration file: appdynamics_sdk_log4cxx.xml

Logs Directory

The logs <agent_install_directory>/logs directory contains the logs for the Apache Agent and the agent proxy.

Proxy Directory

The proxy <agent_install_directory>/proxy directory contains the agent proxy files.

Proxy Control Directory

The proxy control directory contains the domain control socket, which the agent uses to start an AppDynamics node. Defaults to <agent_install_directory>/logs/appd-sdk. You need to pass this path to the runProxy script if you are starting the proxy manually.

Troubleshoot Apache Agent Installation

If you installed the Apache Agent and are experiencing problems, try these troubleshooting suggestions.

Undefined Symbol Error

An error message similar to the following typically indicates that you have loaded the incorrect agent library for the version of Apache you are using.

```
ERROR
httpd: Syntax error on line 953 of /srv/jas/app/embcms/HTTPServer/cma1-dev2/conf/httpd.conf: Syntax error on
line 7 of /srv/jas/app/embcms/HTTPServer/cda0-dev2/conf/appdynamics.conf: Cannot load /srv/jas/data/AppDynamics
/WebAgent/WebServerAgent/Apache/libmodappdynamics.so into server: /srv/jas/data/AppDynamics/WebAgent
/WebServerAgent/Apache/libmod_appdynamics.so: undefined symbol: ap_log_error
```

Check the description of LoadModule on Install the Apache Agent to make sure that you are loading the correct module. For example, for Apache 2.2, your LoadModule directive should be:

```
LoadModule appdynamics_module /srv/jas/data/AppDynamics/WebAgent/ApacheAgent/Apache/libmod_appdynamics22.so
```

App Crash Caused by libstdc++ Mismatch

The AppDynamics agent uses libstc++ v6. If your application uses a different version of libstc++ and the modules were not loaded in the correct order, the wrong library routines could be called. If you get a dump with a long stack trace, this could be the cause. See Apache with libstdc++5 Considerations for information on how to prevent this.

Tier Name Not Specific to the Apache Agent

When the Apache Agent and Machine Agent are hosted on the same server, and the Machine Agent is started before the Apache Agent, then the tier is registered as a Java tier that prevents the Apache Agent from registering itself.

An error message is displayed in the Apache Agent logs:

```
Is your agent attempting to register to the wrong tier?
```

Workaround

1. Stop the Machine Agent and Apache Agent.
2. Delete the tier from the Controller UI.
3. Restart the Apache Agent first and allow it to register the tier.
4. Restart the Machine Agent.

Apache with libstdc++5 Considerations

Related pages:

- Install the Apache Agent

The Apache Agent depends on libstdc++6. Some servers, primarily IHS and OHS, have modules built with libstdc++.so.5. This conflict can prevent Apache from starting successfully.

Check for libstdc++5 Dependencies

To determine if your web server has libstdc++.so.5 dependencies:

1. Change directory to your web server's modules directory.
2. Run this command:

```
ldd *.so 2>&1 | grep -v 'execution permission' | grep 'libstdc++.so.5'
```

3. If this command returns any results—for example, `libstdc++.so.5 => /lib64/libstdc++.so.5`—your server has a dependency on libstdc++.so.5.

Resolution Overview

To avoid libstdc++5 conflicts, force libstdc++6 to load before libstdc++5 when Apache is started. The general steps for performing this configuration are:

1. Identify the paths to libstdc++.so.6.
2. Determine the correct libstdc++.so.6 path for your installation.
3. Use the `LD_PRELOAD` environment variable to have libstdc++6 preloaded.

These steps are detailed in the following sections.

Identify the Paths to libstdc++.so.6

From a command prompt, run:

```
ldconfig -p | grep libstdc++.so.6
```

This will return one or more paths. For example:

```
/lib64/libstdc++.so.6
/lib/libstdc++.so.6
```

Determine the Correct libstdc++.so.6 Path for the Installation

If more than one path is returned, determine which is the correct path for your Apache Server installation.

If you are running a 64-bit operating system, but a 32-bit version of IHS or OHS, choose the 32-bit version, which in our example would be:

```
/lib/libstdc++.so.6
```

Add the Export LD_PRELOAD Command

Open the envvars** file, which is located in the `/bin` directory of your IHS or OHS installation. Add the following line, using the path to the `libstdc++.so.6` path that you determined in the previous step.

```
export LD_PRELOAD=<path-to-libstdc++.so.6>
```

This will cause `libstdc++.so.6` to be loaded before `libstdc++.so.5`, and the conflict will be averted.

Upgrade the Apache Agent

To upgrade the Apache Agent, back up the current agent install directory elsewhere. Then download and install the new agent into the same directory as the old one was.

Then follow these steps to upgrade the agent:

1. Kill the `proxy` process.
   If you do not know the PID of the `proxy` process you can get it by running this command:

   ```
   ps -aux | grep "proxy"
   ```

   Then kill the process as follows:

   ```
   kill <PID>
   ```

2. Shut down the web server.
3. Move/rename the agent install directory, `/opt/appdynamics-sdk-native` to make a backup.
4. Download the new version of the agent and extract it into `/opt/appdynamics-sdk-native`.
5. Change directory to the agent install directory:

   ```
   cd <agent_install_directory>
   ```

6. Run the installer:

   ```
   ./install.sh
   ```

   It is not necessary to change the configuration when you use the same directory location as the old agent installation.

7. Restart the web server.

Uninstall the Apache Agent

1. Remove the include statement for the AppDynamics Apache Agent from the HTTP server configuration. For example in httpd.conf–on Ubuntu and Debian, this file is called apache2.conf—remove this line:

```
Include conf/appdynamics_agent.conf
```

2. Restart the web server.
3. Optionally remove the following files:
    - libmod_appdynamics.so–for Apache 2.4.x—or libmod_appdynamics22.so—for Apache 2.2.x—from the web server modules directory, if your administrator put it there
    - appdynamics_agent.conf or similar from the web server configuration directory
4. Kill the proxy process.
5. Uninstall the agent:

```
<agent_install_directory>/install.sh -u
```

6. Optionally remove any remaining AppDynamics files:

    - <agent_install_directory>
    - /tmp/appd-sdk

Apache Agent Logging

Related pages:

- Dynamic Language Agent Proxy

The Apache Agent generates these two logs:

- Agent log
- Proxy log

Agent Log

The agent log contains information about the transactions that the agent processes and sends to the proxy.

The log is located at `$<apache_agent_install>/logs/agent.log`. By default this is `/opt/appdynamics-sdk-native/logs/agent.log`.

The default pattern for agent log naming is the following:

- `agent.log`: the current log
- `agent.log.1`: most recent log
- `agent.log.2`: second most recent log
- `agent.log.3`: third most recent log
- `agent.log.4`: fourth most recent log
- `agent.log.5`: fifth recent log.

The agent creates and rotates a maximum of six log files. Maximum log size is 20 MB, which gives you a maximum of the most recent 120 MB of log data at one time.

Proxy Log

The proxy log contains information about the transactions between the proxy and the Controller.

The proxy log consists of a file named `proxyCore.log` located at `$<apache_agent_install>/logs/proxyCore_$date.log` and other files named `agent.<datestamp>.log` located at `$<apache_agent_install>/logs/<node_name>/agent.<datestamp>.log.`

See Dynamic Agent Proxy Logging.

Filter Sensitive Data for Apache Agent

Related pages:

- Install the Machine Agent

Add Sensitive Data Filter for Cookies

You can use sensitive Cookie filters to configure the agent to obfuscate sensitive information from the URLs in transaction snapshot details.

1. Edit the Apache Agent configuration file: `<path_to_webserver_dir>/conf/appdynamics_agent.conf`
2. Add sensitive cookie filter element as directives:
    - `AppDynamicsMaskCookie ON`
    - `AppDynamicsCookieMatchPattern pattern`
        - `AppDynamicsMaskCookie:` Specify if filtering is enabled or not. Set it `ON` for cookie filtering to be enabled. Default value is `OFF.`
        - `AppDynamicsCookieMatchPattern:` Specify the pattern that when matched, filters value of that cookie.
3. Enabling AppDynamicsMaskCookie masks values of all the cookies associated with the given request. To filter selective cookies, set the following:
    - Add `AppDynamicsCookieMatchPattern` and provide the full name of the cookie whose value needs to be masked as `AppDynamicsCookieMatchPattern <pattern>`.

        For example:

```
AppDynamicsCookieMatchPattern PHPSESSID
```

        A substring of a cookie name does not mask any value in the transaction snapshot. Ensure that you enter the Full name of the cookie for this directive.

    - For masking multiple cookies values simultaneously, provide names of all those cookies separated by '|' as a single string:

        `AppDynamicsCookieMatchPattern <pattern1|pattern2|pattern3>`

        For example:

```
AppDynamicsCookieMatchPattern PHPSESSID|X-CSRF-TOKEN|cookiekey
```

        If '|' is present in the cookie name itself, the agent cannot mask those cookies as '|' is used as a name separator in `AppDynamicsCookieMatchPattern` directive.

Add Sensitive Data Filter for the SM_USER

You can use SM_USER filter to configure the agent to obfuscate sensitive information from the URLs in transaction snapshot details.

1. Edit the Apache Agent configuration file: `<path_to_webserver_dir>/conf/appdynamics_agent.conf.`
2. Add sensitive SM_USER filter element as directive:

    - `AppDynamicsMaskSmUser ON`
    - `AppDynamicsMaskSmUser:` Specify if filtering is enabled or not. Set it `ON` for sm_user filtering to be enabled. Default value is `OFF`.

    Enabling this masks the values of all the SM_USER associated with the given request.

Filter Certain URL Segments or Query Parameters

By default, the AppDynamics Apache Agent sends transaction data to the Controller that your organization may classify as privileged information. Although such data is useful for diagnosis and troubleshooting, security considerations may require you to filter certain sensitive information from view in the Controller. You can use `Sensitive URL` filters to exclude sensitive information from a URL in snapshot details.

Add a Sensitive URL Filter

1. Edit the `appdynamics_agent.conf` configuration file in the path: `<path_to_webserver_dir>/conf/appdynamics_agent.conf`.
2. In the `appdynamics_agent.conf` file, configure the following settings:

    - `AppDynamicsDelimiter`: Specify the character that you want to use as URL segment endpoints. The agent splices the URL at each delimiter instance to create the segments. For HTTP, use the forward slash character "/". For the forward slash, the agent does not split on the slashes immediately following the protocol. For example, "https://myapp.example.com/" constitutes a single segment. By default, the delimiter is "/" but this is REQUIRED for successful filtering.

        For example:

```
AppDynamicsDelimiter /
```

Note that #' cannot be used as a delimiter as the configuration file cannot process it.

- `AppDynamicsSegment`: Specify a comma-separated list to indicate the segments that you want the agent to filter. Segment numbering starts from 1. If you specify 0 or negative values, the agent fails to redact the segments. This attribute is REQUIRED.

  For example:

```
AppDynamicsSegment 2,3
```

- `AppDynamicsMatchfilter`: The type of filter to be used to match the URL amongst the following: `NOT_EMPTY|EQUALS|STARTSWITH|ENDSWITH|CONTAINS|REGEX`. Default is `NOT_EMPTY,` but REQUIRED.

  For using this correctly, query parameters should not be considered for match-filtering. With an example of the call "https://myapp.example.com/sensitive/data?first_name=abc&last_name=xyz", to specify match-filter as STARTSWITH, it matches a specified string starting with the hostname “myapp.example.com” in this case. Similarly for ENDSWITH, it will correspond to the last segment leaving out the query parameters, “data” in this case, as query parameters are never reported in the snapshots.

  For example:

```
AppDynamicsMatchfilter CONTAINS
```

- `AppDynamicsMatchpattern`: Specify the string that you want to be filtered with the match-filter. This attribute is REQUIRED.

  For example:

```
AppDynamicsMatchpattern one
```

For example, the following configuration splits the URL on the "/" character and masks the third and fifth segments of the URL. In this case, the segmentation and obfuscation apply only to URLs containing "myapp":

```
AppDynamicsDelimiter /
AppDynamicsSegment 3,5
AppDynamicsMatchfilter CONTAINS
AppDynamicsMatchpattern myapp
```

The exit call to "https://myapp.example.com/customer/customerid/account/accountid/data?first_name=abc&last_name=xyz" breaks down to six segments: " https://myapp.example.com", "customer", "customerid", “account”, “accountid” and "data?first_name=abc&last_name=xyz". The Controller shows the masked values of the URL: “ /customer/*****/account/*****/data” in the snapshot details. "https://myapp.example.com" corresponds to segment number 1 and so on.

As the query parameters are never sent to the controller, so they are not filtered. In the transaction snapshots, the URLs are sent by default without the query parameters but now after masking the corresponding URL segments.

Filter Multiple URLs

Due to the limitations of the Apache configurations, if you want to filter multiple URLs separately, the arguments need to be written with '|' separated as described below:

```
AppDynamicsDelimiter /|/
AppDynamicsSegment 1,2,3|1,4
AppDynamicsMatchfilter CONTAINS|ENDSWITH
AppDynamicsMatchpattern One|.php
```

Each ‘|’ separated values correspond to an additional URL filter added. For ‘n’ number of separate URL filters, you need to have ‘n’ different ‘I’ configurations correspondingly. These filters behave independently on the URLs and will filter based on the configurations specified for each filter.

You must define all the configuration settings, though the configurations assume the default values. If you miss defining a particular setting in case of multiple filtering, the filtering fails.

CCPP SDK

- SELinux Installation Issues

This page provides an overview of the C/C++ SDK for C/C++ applications in AppDynamics.

The SDK Agent provides transaction/backend reporting, automatic tier mapping, automatic dynamic baselining, health rules, data collectors, and transaction snapshots. Altogether, these tools provide visibility into application load and response times, as well as any custom metrics you define.

To monitor the C and C++ applications, add some API calls to the source code. Once running, the SDK registers Business Transactions with the Controller. You can then see your application flow map monitor performance in the Controller.

CCPP SDK Supported Environments

C/C++ Supported Platforms

Operating Systems

- Any Linux distribution based on glibc >= 2.5 and the x86 32-bit or x86 64-bit architecture
- Windows Server >= 2012 R2
    - Visual Studio >= 2015

To develop with the C++ SDK, you need Visual Studio >= 2015 . However, the SAP ABAP Agent on Windows leverages the same SDK and does not require development work.

You must install the Visual Studio C++ Redistributable; the full development environment is not required.

Use the CCPP SDK

- Business Transactions

This page provides an overview of how to use the C/C++ SDK.

The SDK provides routines for creating/managing business transactions, transaction snapshots, backends, exit points, and custom metrics.

To instrument your applications with the C/C++ SDK, obtain the most current version of the C/C++ SDK. See C/C++ SDK.

Add the AppDynamics Header File to the Application

After downloading the SDK, you are ready to add AppDynamics instrumentation to your C/C++ application. The first step is to include the AppDynamics header file at the top of your `main` function file:

```
#include <path_to_SDK>/sdk_lib/appdynamics.h
```

Initialize the Controller Configuration

Controller information settings permit the agent to connect to the Controller. Some settings are required for all applications, while others are needed only for certain types of application environments. For example, if the agent needs to connect to the Controller via an internal proxy in your network, you need to set up the connection settings for the proxy. See C/C++ SDK Reference for a list of the settings and information about which ones are required.

In your application, assign values to the required settings.

For example, to set the Controller connection information:

```
const char APP_NAME[] = "SampleC";
const char TIER_NAME[] = "SampleCTier1";
const char NODE_NAME[] = "SampleCNode1";
const char CONTROLLER_HOST[] = "controller.somehost.com";
const int CONTROLLER_PORT = 8080;
const char CONTROLLER_ACCOUNT[] = "customer1";
const char CONTROLLER_ACCESS_KEY[] = "MyAccessKey";
const int CONTROLLER_USE_SSL = 0;
```

To create the default application context, declare an `appd_config struct` with the Controller settings.

For example:

```
struct appd_config* cfg = appd_config_init(); // appd_config_init() resets the configuration object and pass
back an handle/pointer
appd_config_set_app_name(cfg, APP_NAME);
appd_config_set_tier_name(cfg, TIER_NAME);
appd_config_set_node_name(cfg, NODE_NAME);
appd_config_set_controller_host(cfg, CONTROLLER_HOST);
appd_config_set_controller_port(cfg, CONTROLLER_PORT);
appd_config_set_controller_account(cfg, CONTROLLER_ACCOUNT);
appd_config_set_controller_access_key(cfg, CONTROLLER_ACCESS_KEY);
appd_config_set_controller_use_ssl(cfg, CONTROLLER_USE_SSL);
```

Initialize the SDK

In your `main` function, call these initialization functions:

1. Initialize the `config` structure as shown in the previous section.
2. Initialize the SDK by passing the configuration structure to `appd_sdk_init()`.

If `appd_sdk_init()` returns zero, the SDK is initialized successfully. Non-zero indicates failure because the SDK could not reach the Controller.

The following example illustrates how to initialize the SDK:

```
int initRC = appd_sdk_init(cfg);

if (initRC) {
      std::cerr <<  "Error: sdk init: " << initRC << std::endl;
      return -1;
}
```

All SDK calls including `appd_sdk_init()` and `fork()` should only occur in the forked process, never in the parent process. Each child call should behave independently and cannot share handles between the process and other SDK-instrumented child processes.

Create Alternate Application Contexts

The SDK presumes a default application context that has no name associated with it.

To create the default application context, use the `appd_config_init()` command which returns a pointer to the default configuration structure. Then, use setter commands to modify the fields within the structure. Once all relevant fields are set, use the `appd_sdk_init()` call to initialize the SDK with the default application context.

All other application contexts are created with an associated name and a collection of separate setter methods.

To create an alternate application context, pass the `appd_context_config_init()` command the name of your alternate application context. This will return a pointer to the alternate application context configuration structure. Then, use the `_context_` setter commands to modify the fields within the structure. Once all relevant fields are set, use the `appd_sdk_add_app_context()` call to initialize the SDK, passing it the alternate application context structure pointer.

```
// create the alternate application context
appd_context_config* cfg2 = appd_context_config_init("My_Context");
...

// add additional setter commands to initialize the alternate application context
appd_context_config_set_controller_account(cfg2, ac.second.ac_account_get().c_str());
appd_context_config_set_controller_access_key(cfg2, ac.second.ac_access_key_get().c_str());
appd_context_config_set_controller_host(cfg2, ac.second.ac_host_get().c_str());
appd_context_config_set_controller_port(cfg, ac.second.ac_port_get());
appd_context_config_set_controller_use_ssl(cfg2, ac.second.ac_use_ssl_get() ? 1 : 0);
appd_context_config_set_app_name(cfg2, ac.second.ac_app_get().c_str());
appd_context_config_set_tier_name(cfg2, ac.second.ac_tier_get().c_str());
appd_context_config_set_node_name(cfg2, ac.second.ac_node_get().c_str());

// initialize the alternate application context
appd_sdk_add_app_context(cfg2);
```

Create Business Transactions

Define a Business Transaction by enclosing the code that constitutes the request that you want to monitor between `appd_bt_begin()` and `appd_bt_end()` calls. `appd_bt_begin()` returns a handle to use in subsequent routines that affect that business transaction.

If you are creating a business transaction that correlates with an upstream business transaction, pass the correlation header of the upstream transaction so the new transaction that you are creating can correlate with it. See `appd_exitcall_get_correlation_header()` in C/C++ SDK Reference. If the transaction does not need to correlate with another transaction, pass `NULL` for the correlation header parameter.

You can optionally store the business transaction handle in the global handle registry with a guid for easy retrieval later using `appd_bt_store()`. Retrieve the handle from the global handle registry using `appd_bt_get()`.

The following example demonstrates setting a business transaction:

```
// start the "Checkout" transaction
appd_bt_handle btHandle = appd_bt_begin("Checkout", NULL);

// Optionally store the handle in the global registry
appd_bt_store(btHandle, my_bt_guid);
...

// Retrieve a stored handle from the global registry
appd_bt_handle myBtHandle = appd_bt_get(my_bt_guid);
...

// end the transaction
appd_bt_end(btHandle);
```

Between starting and ending the transaction, you can perform operations such as adding errors to the business transaction, defining the transaction snapshot attributes, adding backends and exit calls, and so on.

When the business transaction ends, via a call to `appd_bt_end()`, the agent stops reporting metrics for the business transaction.

Create Business Transactions With an Alternate Application Context

You can create a business transaction with an alternate application context using `appd_bt_begin_with_app_context()` and `appd_bt_end()` calls. In addition to the parameters passed to `appd_bt_begin()`, the `appd_bt_begin_with_app_context()` also takes an application context name string, as defined by the call to `appd_context_config_init()`.

`appd_bt_begin_with_app_context()` returns a handle to use in subsequent routines that affect that business transaction.

The following example demonstrates setting a business transaction with an alternate application context:

```
// create the alternate application context
appd_context_config* cfg2 = appd_context_config_init("My_Context");
...

// add additional setter commands to initialize the alternate application context
appd_context_config_set_controller_account(cfg2, ac.second.ac_account_get().c_str());
appd_context_config_set_controller_access_key(cfg2, ac.second.ac_access_key_get().c_str());
appd_context_config_set_controller_host(cfg2, ac.second.ac_host_get().c_str());
appd_context_config_set_controller_port(cfg, ac.second.ac_port_get());
appd_context_config_set_controller_use_ssl(cfg2, ac.second.ac_use_ssl_get() ? 1 : 0);
appd_context_config_set_app_name(cfg2, ac.second.ac_app_get().c_str());
appd_context_config_set_tier_name(cfg2, ac.second.ac_tier_get().c_str());
appd_context_config_set_node_name(cfg2, ac.second.ac_node_get().c_str());

// initialize the alternate application context
appd_sdk_add_app_context(cfg2);

// start the "Checkout" transaction with the alternate application context
appd_bt_handle btHandle = appd_bt_begin_with_app_context("My_Context", "Checkout", NULL);

// end the transaction
appd_bt_end(btHandle);
```

When the business transaction ends, via a call to `appd_bt_end()`, the agent stops reporting metrics for the business transaction. Between starting and ending the transaction, you can perform operations such as adding errors to the business transaction, defining the transaction snapshot attributes, adding backends and exit calls, and so on.

Add Business Transaction Errors

Use `appd_bt_add_error()` to report business transaction errors. If you set this function parameter, `markBTAsError` the transaction is reported as an error transaction when the error occurs. For the function `{{appd_bt_add_error,}},` the Controller database truncates log messages that exceed 5,000 characters.

The SDK provides an `enum` to classify the error level as `APPD_LEVEL_NOTICE`, `APPD_LEVEL_WARNING`, or `APPD_LEVEL_ERROR`.

Manage Business Transaction Snapshots

When the agent is monitoring a business transaction, it automatically creates transaction snapshots, which describe instances of the business transaction at certain points in time. Transaction snapshots are extremely useful for troubleshooting poor performance because they contain a lot of detail.

You do not have to modify anything to create these snapshots, other than create the business transaction, but you can add calls to:

- Find out if a snapshot is being taken
- Provide additional data in a snapshot
- Set the URL for a snapshot

Determine if the Agent is Taking a Snapshot Now

The agent does not constantly collect screenshot due to high cost. By default, it collects a snapshot every ten minutes, but this schedule is configurable. See Configure Snapshot Periodic Collection Frequency.

You can determine if a snapshot is happening using `appd_bt_is_snapshotting()`, which returns non-zero if the agent is collecting a snapshot. The main reason to do this is to avoid the wasted overhead for collecting user data for a snapshot or setting the snapshot URL if no snapshot is currently being collected.

Add Business Transaction User Data

You can optionally add data to transaction snapshots. For example, you might want to know which users are getting a lot of errors, from which regions users are experiencing slow response times or which methods are slow. In the Controller UI, the data appears in the USER DATA tab of the transaction snapshot.

If a snapshot is occurring, use `appd_bt_add_user_data()` passing a key and value for the data that you want the snapshot to collect. For the function `{{appd_bt_add_user_data,}}`, the Controller database truncates log messages that exceed 5,000 characters.

Add Snapshot URL

A snapshot URL allows Controller users to share a snapshot with others. You can set a URL for the current snapshot using `appd_bt_set_url()`.

Set Snapshot Example

```
void setSnapshotAttributes(appd_bt_handle btHandle, int minute, int halfsec)
{
    // do this only if the agent is collecting a snapshot
    if (appd_bt_is_snapshotting(btHandle))
    {
        char nameBuf[30];
        char valueBuf[30];
        // add custom data to the snapshot
        snprintf(nameBuf, sizeof(nameBuf), "BT:%p\n", btHandle);
        snprintf(valueBuf, sizeof(valueBuf), "Minute:%d Second:%d\n", minute, halfsec/2);
        appd_bt_add_user_data(btHandle, nameBuf, valueBuf);

        static int snapCount = 0;
        int switchVal = snapCount % 4;

        // report errors, but only ERROR_LEVEL errors are marked as error transactions
        if (switchVal)
        {
            appd_error_level errorLevel;
            bool markBtAsError;
            switch (switchVal)
            {
            case 1:
                errorLevel = APPD_LEVEL_NOTICE;
                markBtAsError = false;
                snprintf(nameBuf, sizeof(nameBuf), "NOTICE BT:%p M:%d S:%d\n", btHandle, minute, halfsec/2);
                break;
            case 2:
                errorLevel = APPD_LEVEL_WARNING;
                markBtAsError = false;
                snprintf(nameBuf, sizeof(nameBuf), "WARNING BT:%p M:%d S:%d\n", btHandle, minute, halfsec/2);
                break;
            case 3:
                errorLevel = APPD_LEVEL_ERROR;
                markBtAsError = true;
                snprintf(nameBuf, sizeof(nameBuf), "ERROR BT:%p M:%d S:%d\n", btHandle, minute, halfsec/2);
                break;
            }
            appd_bt_add_error(btHandle, errorLevel, nameBuf, markBtAsError, markbtaserror);
        }
        snapCount++;
        // set the snapshot url
        snprintf(nameBuf, sizeof(nameBuf), "http://bt-%p.com", btHandle);
        appd_bt_set_url(btHandle, nameBuf);
    }
}
```

Create Backends

A backend is a database or a remote service such as a message queue, HTTP service or cache service that your application uses. A backend component is not itself monitored by the application agent, but the agent monitors calls to it from instrumented servers. You need to create backends in the instrumented environment so that the agent can discover them. This involves:

- Declaring the backend
- Setting its identifying properties
- Optionally configuring how the backend is presented in the AppDynamics UI
- Adding the backend to the instrumented application

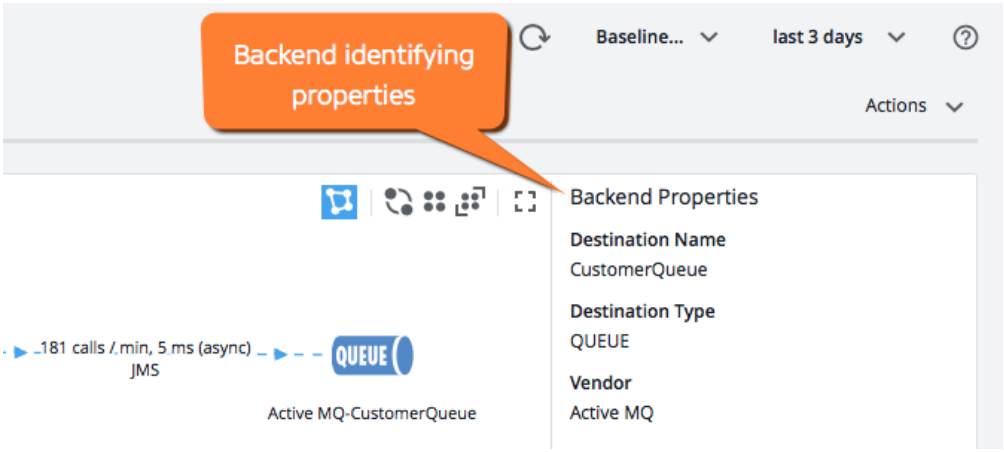
Declare the Backend

You must declare a backend using `appd_backend_declare()` before the agent can detect it. After you declare a backend, you don't need to declare it again if the backend is used by other business transactions in a single SDK instance. A backend must be of one of the supported types listed under 'Exit Call Types' in C/C++ SDK Reference.

Identify the Backend

A backend also has identifying properties, which you set using `appd_backend_set_identifying_property()`. The properties vary depending on the type of the backend and the types of information that you want to display. The Controller displays identifying properties in backend dashboards. You must set at least one identifying property for the type of any backend that you plan to add.

The following shows the backend properties in the Controller UI for an ActiveMQ:



Resolve to a Tier

By default, the Controller doesn't display a detected backend as a separate entity in flowmaps, but the agent reports its metrics as part of the downstream tier. If you want to display the backend as a separate component and not resolved to the tier, use `appd_backend_prevent_agent_resolution()`. See Resolve Remote Services to Tiers.

Add to Application

After you declare and configure the backend, add it to the application so the agent can detect it.

Backend Example

The following listing shows an example of setting up a database backend.

```
// declare a backend, only once for this SDK instance
const char backendOne[] = "first backend";
appd_backend_declare(APPD_BACKEND_HTTP,  backendOne);

// set the host property
rc = appd_backend_set_identifying_property(backendOne, "HOST", "sqs-us-west-hostname");
if (rc) {
   std:cerr << "Error: appd_backend_set_identifying_property: " << rc << ".";
   return -1;
}

// do not resolve the backend to the tier
rc = appd_backend_prevent_agent_resolution(backendOne);
if (rc) {
   std:cerr << "Error: appd_backend_prevent_agent_resolution: " << rc << ".";
   return -1;
}

// add the backend
rc = appd_backend_add(backendOne);
if (rc)
{
   std:cerr << "Error: appd_backend_add: " << rc << ".";
   return -1;
}
```

Manage Exit Calls

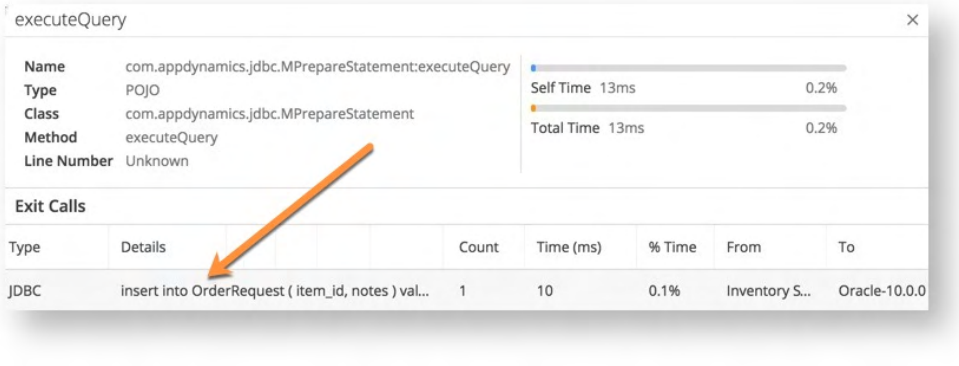
When an application makes a call to another component—a detected backend or another application server—the agent reports metrics on those calls.

Define an exit call by enclosing the code that constitutes the exit call between `appd_exitcall_begin()` and `appd_exitcall_end()` calls. `appd_exitcall_begin()` returns a handle to use in subsequent routines that affect that exit call. An exit call occurs in the context of a business transaction.

You can optionally store the exit call handle in the global handle registry with a guid for easy retrieval later with `appd_exitcall_store()`. Retrieve the handle from the global handle registry with `appd_exitcall_get()`.

Pass the business transaction handle and the destination backend to `appd_exitcall_end()`.

You can optionally add details to an exit call as any arbitrary string. The details are reported in the exit call details in the transaction snapshots in the Controller UI:



You can also add errors to an exit call using `appd_exitcall_add_error()`. Use the enum for the error levels. You can also add an error message.

Simple Exit Call Example

```
// start the exit call to backendOne
appd_exitcall_handle ecHandle = appd_exitcall_begin(btHandle, backendOne);

...

// optionally store the handle in the global registry
appd_exitcall_store(ecHandle, my_ec_guid);

...
// retrieve a stored handle from the global registry
appd_exitcall_handle myEcHandle = appd_exitcall_get(my_ec_guid);

// set the exit call details
rc = appd_exitcall_set_details(ecHandle, "backend ONE");
if (rc) {
   std:cerr << "Error: exitcall details1";
   return -1;
}

// add an error to the exit call
appd_exitcall_add_error(ecHandle, APPD_LEVEL_ERROR, "exitcall1 error!", true);

// end the exit call
appd_exitcall_end(ecHandle)
```

Correlate with Other Business Transactions

A correlation header contains the information that enables the agents to continue the flow of a business transaction across multiple tiers.

An SDK can correlate with other SDKs as well as other AppDynamics agents—such as Java, .NET or PHP—that perform automatic correlation for certain types of entry and exit points.

Correlate with an Upstream Tier

When your instrumented process receives a continuing transaction from an upstream agent that supports automatic correlation:

1. Using a third-party `http_get_header()` function, extract the header named `APPD_CORRELATION_HEADER_NAME` from the incoming HTTP payload.
2. Pass the header to `appd_bt_begin()`. For example:

```
const char* hdr = http_get_header(req, APPD_CORRELATION_HEADER_NAME);
appd_bt_handle bt = appd_bt_begin("fraud detection", hdr);
```

If the header retrieved by the `http_get_header()` function is valid, the business transaction started by the `appd_bt_begin()` call will be a continuation of the business transaction started by the upstream service.

Correlate with a Downstream Tier

The downstream agent is watching for a correlation header named `singularityheader` in the HTTP payload.

If your SDK agent is making an exit call to a downstream agent that supports automatic correlation:

1. Set the name of the correlation header using `APPD_CORRELATION_HEADER_NAME`.
2. Begin the exit call.
3. Retrieve the correlation header from the exit call using the `appd_exitcall_get_correlation_header()` function.
4. Using third-party HTTP functions, prepare an HTTP POST request.
5. Inject a header named `APPD_CORRELATION_HEADER_NAME` with the value of the correlation header retrieved in step 3 into the outgoing payload of the HTTP request.
6. Make the request. For example:

```
const char* const APPD_CORRELATION_HEADER_NAME = "singularityheader";

appd_exitcall_handle inventory = appd_exitcall_begin(bt, "inventory");
const char* hdr = appd_exitcall_get_correlation_header(inventory);
http_request req;
http_init(&req, HTTP_POST, "https: //inventory/holds/%s", sku);
http_set_header(&req, APPD_CORRELATION_HEADER_NAME, hdr);
http_perform(&req);

...
```

cURL Downstream Correlation Example

The following example uses the cURL library to correlate with a downstream transaction.

```
#include <curl/curl.h>
. . .
. . .
// get the correlation header into the response
class LibcurlURLGet
{
public:
    LibcurlURLGet(const std::string& url) : url(url), curlHandle(NULL) {}
    std::string GetResponse(const char* correlationHeader)
    {
        CURLcode res;
        Response response;
        curlHandle = curl_easy_init();
        if (curlHandle)
        {
            curl_easy_setopt(curlHandle, CURLOPT_URL, url.c_str());
            curl_easy_setopt(curlHandle, CURLOPT_WRITEFUNCTION, WriteDataCallback);
            curl_easy_setopt(curlHandle, CURLOPT_WRITEDATA, &response);
            if(correlationHeader && strlen(correlationHeader))
            {

// start new added code

                std::string singularityHeader(APPD_CORRELATION_HEADER_NAME);
                singularityHeader.append(": ");
                singularityHeader.append(correlationHeader);

// end new added code

                curl_slist* slistNewHeaders = 0;
                slistNewHeaders = curl_slist_append(slistNewHeaders, correlationHeader);
                curl_easy_setopt(curlHandle, CURLOPT_HTTPHEADER, slistNewHeaders);
```

```
            }
            res = curl_easy_perform(curlHandle);
            if(res != CURLE_OK)
            {
            }
        }
        curl_easy_cleanup(curlHandle);
        return response.GetResponseString();
    }
private:
    class Response
    {
    public:
        std::string GetResponseString()
        {
            return sResponse;
        }
        void AppendResponse(void* ptr, size_t sizeBytes)
        {
            sResponse.append((char*)ptr, sizeBytes);
        }
    private:
        std::string sResponse;
    };
    static size_t WriteDataCallback(void* ptr, size_t size, size_t nmemb, Response* response)
    {
        response->AppendResponse(ptr, size * nmemb);
        return size * nmemb;
    }
    std::string url;
    CURL* curlHandle;
};

...
// start an exit call from the current transaction
appd_exitcall_handle ecHandle1 = appd_exitcall_begin(btHandle1, tier2);

...
// before exiting get the correlation header
const char* corrHeader1 = appd_exitcall_get_correlation_header(ecHandle1);

// put the correlation in the HTTP response
std::string response = urlGet.GetResponse(corrHeader1);

...
// start the next business transaction to correlate with the previous one
appd_bt_handle btHandle = appd_bt_begin("Verify", response)
```

Create Custom Metrics

You can create custom metrics to supplement built-in metrics such as Business Transaction call count and response time. You can also create metrics for multiple application contexts.

Custom metrics are dependent on the application context; in situations with multiple contexts, you must specify the correct context name for custom metrics to apply to the associated application context. See Create Alternate Application Contexts.

> ⚠ If you create a custom metric in a node, the custom metric will appear in every other node in the tier.

For example, the default application context uses a null pointer or empty string as its name. The `appd_sdk_init` method tells the SDK to connect to the Controller and create the default application context (i.e. no name is specified).

```
struct appd_config* cfg = appd_config_init();
appd_config_set_controller_host(cfg, host.c_str());
appd_config_set_controller_port(cfg, port);
appd_config_set_controller_account(cfg, account_name.c_str());
appd_config_set_controller_access_key(cfg, access_key.c_str());
appd_config_set_controller_use_ssl(cfg, useSSL?1:0);
appd_config_set_app_name(cfg, app_name.c_str());
appd_config_set_tier_name(cfg, tier_name.c_str());
appd_config_set_node_name(cfg, node_name.c_str());
appd_sdk_init(cfg);
```

To specify an alternative application context, you must provide a name string (not a default null pointer). Use the `appd_sdk_add_appd_context` method to create an alternative application context. In the example below, we create an alternative application context called "context2." You will use that name string to create custom metrics, not the actual configuration structure.

```
const char* name = "context2";
struct appd_context_config* cfg2 = appd_context_config_init(name));
appd_context_config_set_controller_account(cfg2, ac.second.ac_account_get().c_str());
appd_context_config_set_controller_access_key(cfg2, ac.second.ac_access_key_get().c_str());
appd_context_config_set_controller_host(cfg2, ac.second.ac_host_get().c_str());
appd_context_config_set_controller_port(cfg, ac.second.ac_port_get());
appd_context_config_set_controller_use_ssl(cfg2, ac.second.ac_use_ssl_get() ? 1 : 0);
appd_context_config_set_app_name(cfg2, ac.second.ac_app_get().c_str());
appd_context_config_set_tier_name(cfg2, ac.second.ac_tier_get().c_str());
appd_context_config_set_node_name(cfg2, ac.second.ac_node_get().c_str());

appd_sdk_add_app_context(cfg2);
```

The Custom Metrics path may or may not go the same Controller; similar to business transactions in separate nodes, your program can process two business transactions from different nodes: one aligns with the default application context and the other with the alternative application context. You must specify that your method strings begin with `Custom Metrics|`, not `Custom Metric|`.

You can use the following methods to create a custom metric:

- `appd_custom_metric_add()`
- `appd_custom_metric_report()`

The `appd_custom_metric_report` creates a default application context and an alternative application context named `my_second_custom_metric`.

In the Controller, the custom metrics folder appears under the associated tier as "Custom Metrics" in the **Metric Browser** with two entities: `my_default_custom_metric` and `my_second_custom_metric`.

The following example illustrates a call with both method signatures.

```
appd_custom_metric_add("app_context", "Custom Metrics|Memory|Total Memory Usage",
APPD_TIMEROLLUP_TYPE_AVERAGE, APPD_CLUSTERROLLUP_TYPE_INDIVIDUAL,
APPD_HOLEHANDLING_TYPE_RATE_COUNTER);
```

The method passes the application context ("Total Memory Usage") and the path to the metric (**Custom Metrics** > **Memory** in the **Metric Browser**) to the Controller. The additional parameters define how the metric is processed. With the metric declared, your code can then report data to the metric with the `appd_custom_metric_report()` method, as follows:

```
appd_custom_metric_report("app_context", "Custom Metrics|Memory|Total Memory Usage", 1234);
```

See C/C++ SDK Resource Management to simplify your instrumentation on C++ applications.

Metric Handling Parameters

Like built-in metrics, the Controller applies some standard processing functions to custom metric values. These functions can define, for example, how the metric is rolled up over time. How the Controller processes a custom metric depends on the nature of the metric; for a metric that represents the state of the machine, the Controller captures the last observed value for the metric. For a call rate metric, the Controller uses an average value. The following section provides information about the parameters you can use to define metric handling by the Controller.

Time Rollup Type

The `time_rollup_type` parameter tells the Controller how to roll up values for the metric over time. There are three ways in which the Controller can roll up metrics, as follows:

- It can calculate the average of all reported values in the time period. An example of a built-in metric that uses this is the `Average Response Time` metric.
- Sum of all reported values in that minute. This operation behaves like a counter. An example metric is the `Calls per Minute` metric.
- Current is the last reported value in the minute. If no value is reported in that minute, the last reported value is used. An example of a metric that uses this would be a machine state metric, such as `Max Available (MB)` metric.

Cluster Rollup Type

The `appd_cluster_rollup_type` parameter tells the Controller how to aggregate metric values for the tier—a cluster of nodes.

- Individual: Aggregates the metric value by averaging the metric values across each node in the tier. For example, `Hardware Resources|Memory|Used %` is a built-in metric that uses the individual rollup type.
- Collective: Aggregates the metric value by adding up the metric values for all the nodes in the tier. For example, `Agent|Metric Upload|Metrics uploaded` is a built-in metric that uses the collective rollup type.

Hole Handling Type

A particular metric may not report data for a given minute. The `appd_hole_handling_type` parameter tells the Controller how to set the metric count for that time slice. The count is set to zero if the hole handling type is `REGULAR_COUNTER`, and set to one if `RATE_COUNTER`. In effect, `REGULAR_COUNTER` does not affect aggregation while `RATE_COUNTER` does.

For example, consider four time slices with the data 9, 3, 0, 12. Notice that the third time slice is zero filled, with no metric being reported for that time slice. The sum of the values is 9+3+0+12 = 24.

If the metric is `REGULAR_COUNTER`, the count for the third times slice would be zero, and therefore the overall count would be 1+1+0+1 = 3. If the metric is RATE_COUNTER the overall count would be 1+1+1+1 = 4. In the case of the `REGULAR_COUNTER`, the average would be 24/3 = 8, while for the `RATE_COUNTER` the average would be 24/4 = 6.

Built-in metrics that use the regular counter hole-handling type include `Average Response Time`, `Average CPU Used`, and `Number of Stalls`. Built-in metrics that use the rate counter hole-handling type include `BT Calls per minute` and `Errors per minute`.

Generate Call Graphs

You can use the C/C++ SDK to instrument methods so that they are reported and displayed in the call graph. You can instrument methods in one of the following ways:

- Use the `APPD_AUTO_FRAME` macro, C++ only
- Use `appd_frame_begin` and `appd_frame_end`

Instrument Methods with the `APPD_AUTO_FRAME` Macro

You can use the `APPD_AUTO_FRAME` macro to instrument applications built on C++ frameworks. The macro is equivalent to calling the `appd_frame_begin` and `appd_frame_end` methods.

1. Specify the business transaction that you want to instrument calls for, and configure the root of the call graph.

```
appd::sdk::BT bt("mybt");
APPD_AUTO_FRAME(bt);
method1(bt);
method2(bt);
```

2. Instrument the methods as shown below.

```
void method1(appd::sdk::BT& bt)
{
 APPD_AUTO_FRAME(bt);
 // Code for method1...
}
void method2(appd::sdk::BT& bt)
{
 APPD_AUTO_FRAME(bt);
 // Code for method2...
}
```

The methods must have access to the business transaction so the business transaction can be passed into the method as an argument.

Instrument Methods with the `appd_frame_begin` and `appd_frame_end` Functions

You can instrument methods for applications that are built on non-C++ frameworks. To instrument a method, you call `appd_frame_begin` at the beginning of the method, and `appd_frame_end` at the end of the method. When you do this, the duration of the method call is automatically calculated and reported in the call graph.

If your method makes an exit call, you can instrument the exit call by wrapping the exit call code between `appd_exitcall_begin` and `appd_exitcall_end`.

The code samples below show three methods that are each instrumented using `appd_frame_begin` and `appd_frame_end`, and then called in a root method, `main()`. The second sample method, `method2()`, contains an exit call.

```
void method1( )
{
 appd_frame_handle frameHandle = appd_frame_begin(btHandle, APPD_FRAME_TYPE_CPP, nullptr, APPD_FUNCTION_NAME,
__FILE__, __LINE__);
 // code for method1
 appd_frame_end(btHandle, frameHandle);
}
```

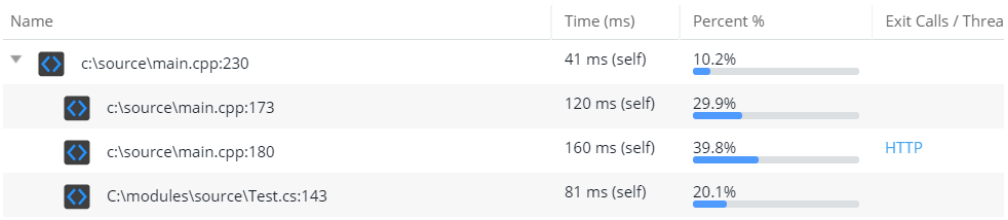
```
void method2()
{
 appd_frame_handle frameHandle = appd_frame_begin(btHandle, APPD_FRAME_TYPE_CPP, nullptr, APPD_FUNCTION_NAME,
__FILE__, __LINE__);
 // code for method2
appd_exitcall_handle exitCallHandle = appd_exitcall_begin(btHandle, BACKEND_NAME);
 // code for exit call
 appd_exitcall_end(exitCallHandle);
 appd_frame_end(btHandle, frameHandle);
}
```

```
void method3()
{
 // To illustrate instrumenting a method where this SDK cannot be used
 // method3 is a wrapper for the call of the actual method which will show up in the call graph
 appd_frame_handle frameHandle = appd_frame_begin(btHandle, APPD_FRAME_TYPE_CPP, "Test", "Compute", "C:
\\modules\\source\\Test.cs", 143);
 // call the wrapped method
 appd_frame_end(btHandle, frameHandle);
}
```

The `main()` method below is the root of the call graph. It specifies the business transaction that invokes the three methods above by passing the transaction into `appd_bt_begin` and `appd_bt_end`.

```
int main(int argc, char **argv)
{
 // initialize AppDynamics
 btHandle = appd_bt_begin(TRANSACTION_NAME, "");
 appd_frame_handle frameHandle = appd_frame_begin(btHandle, APPD_FRAME_TYPE_CPP, nullptr, APPD_FUNCTION_NAME,
__FILE__, __LINE__);
 // code for main
 method1();
 method2();
 method3();
 appd_frame_end(btHandle, frameHandle);
 appd_bt_end(btHandle);
}
```

The sample methods above are represented by the call graph shown below:



Generate Pre-populated Call Graphs (C++ Only)

The previous section describes instrumenting your C/C++ application by calling the instrumentation methods in your code. However, if you do not have the option of modifying your source code, you can generate call graphs that are populated with data from sources such as log files.

To generate a pre-populated call graph:

1. Create the root of the call graph by instantiating a `CallGraph` class.
   The `CallGraph` class takes the following parameters:

   - `bt`: The business transaction.
   - `class_name`: The name of the class that contains the root of the call graph.
   - `method_name`: The name of the method that represents the root of the call graph.
   - `file_path`: The file path to the class.
   - `line_number`: The line number of the method.
   - `time_msec`: The time taken by this frame (method) in milliseconds.
   - `frame_type`: The type of the frame (the language for the method). Currently, `APPD_FRAME_TYPE_CPP` is the only option.

   The following example demonstrates a `CallGraph` instantiation.

   ```
   appd::sdk::CallGraph callGraph(bt, "Class1", "main", "/src/file1.cc", 276, 100, APPD_FRAME_TYPE_CPP);
   ```

2. Create the call graph tree by calling `add_child` on the root and on any of the added children:

   ```
   callGraph.root() .add_child("Class2", "method1", "/src/file2.cc"), 101, 40, APPD_FRAME_TYPE_CPP) .
   add_child("Class2", "method2", "/src/file2.cc"), 523, 30, APPD_FRAME_TYPE_CPP); auto& cge1 = callGraph.
   root() .add_child("Class3", "method1", "/src/file3.cc"), 27, 30, APPD_FRAME_TYPE_CPP); cge1.add_child
   ("Class3", "method2", "/src/file3.cc"), 430, 15, APPD_FRAME_TYPE_CPP);
   ```

3. Call `add_to_snapshot`on the call graph. For this to work, the business transaction must be snapshotting.

   ```
   callGraph.add_to_snapshot();
   ```

Analytics Support for C++ SDK

Two of the existing API methods, which were previously only used for adding data to a snapshot, will now send Analytics data if Analytics is enabled for the current Business Transaction on the Controller:

- Set URL for a snapshot: the URL is set for a snapshot if one is occurring. The data should be either 7-bit ASCII or UTF-8. You can call this function when a snapshot does not occur. When the given Business Transaction is not snapshotting, this function returns immediately. However, if extracting the data to pass to this function is expensive, you can use `appd_bt_is_snapshotting` to check if the Business Transaction is snapshotting before extracting the data and calling this function.

  ```
  void appd_bt_set_url(appd_bt_handle bt, const char* url);
  ```

  - param bt: The business transaction to add the user data to, if it is taking a snapshot.
  - param url: The value of the URL for the snapshot as 7-bit ASCII or UTF-8.
- Add user data to a snapshot: the data should be either 7-bit ASCII or UTF-8. You can call this function when a snapshot does not occur or if Analytics is not enabled. If the data is only for snapshotting and extracting the data to pass to this function is expensive, you can use `appd_bt_is_snapshotting` to check if the Business Transaction is snapshotting before extracting the data, and calling this function.

  ```
  void appd_bt_add_user_data(appd_bt_handle bt, const char* key, const char* value);
  ```

- param bt: The business transaction to add the user data to, if it is taking a snapshot.
- param key: The name of the user data to add to the snapshot as 7-bit ASCII or UTF-8.
- param value: The value of the user data to add to the snapshot as 7-bit ASCII or UTF-8.

These API methods existed previously, but their behavior did not extend to reporting data to Analytics. To correctly connect to Analytics, initialize using the following configuration APIs:

```
void appd_config_set_analytics_host(struct appd_config* cfg, const char* host);
```

- param host: The host for the Analytics Agent, which defaults to `localhost`.

```
void appd_config_set_analytics_port(struct appd_config* cfg, const unsigned short port);
```

- param port: The port that the Analytics Agent listens on, which defaults to 9090.

Terminate the Agent

Just before the application exits, terminate the SDK:

```
appd_sdk_term();
```

Enable SSL for CCPP SDK

Related pages:

- Use the C/C++ SDK

This page explains how to configure the C/C++ Agent to connect to the Controller using SSL.

To enable the SSL on the C/C++ Agent:

1. Open your application to the file where you configure the Controller settings.
2. Set `const int CONTROLLER_USE_SSL = 1;`
3. In the `appd_config` struct, include the following method:

```
appd_config_set_controller_use_ssl(cfg, CONTROLLER_USE_SSL);
```

If you are using a self-signed certificate, you must do the following:

1. Get the Controller certificate by running the following command:

```
openssl s_client -connect <hostname>:<port> -showcerts < /dev/null | openssl x509 > cert.pem
```

2. Update the `certificate_file` Controller setting to point to absolute path to certificate.

```
appd_config_set_controller_certificate_file(cfg, <Path to Cert File>);
```

Check the Certificate `CommonName`

The certificate `CommonName` must match the Controller hostname. If they do not match, you must re-configure the certificate on the Controller.

You can check the `CommonName` by running the following command:

```
openssl s_client -connect <CONTROLLER_HOST>:<CONTROLLER_PORT> -showcerts
```

The `CommonName` appears above the `BEGIN CERTIFICATE` line.

CCPP SDK Reference

On this page:

- appd_exitcall_set_details
- appd_exitcall_store
- appd_frame_begin
- appd_frame_end

Related pages:

- Use the C/C++ SDK
- C++ SDK RAII (Resource Management Is Initialization)

This page describes the functions, structures, and environment variables defined in the C/C++ SDK to instrument C/C++ applications.

The API includes functions to create business transactions, transaction backends/exit points, and define custom metrics.

Basic Types

The C/C++ SDK defines the following opaque types:

- `appd_bt_handle`: A handle to an active business transaction
- `appd_exitcall_handle`: A handle to an active exit call
- `struct appd_config*`: A pointer to a configuration object
- `struct appd_context_config*`: A pointer to a context configuration object

appd_config_init

Initializes an empty configuration structure. Call this function before before calling `appd_sdk_init()`.

Format

```
APPD_API struct appd_config * appd_config_init ()
```

Parameters

- `cfg`: AppDynamics configuration object.

appd_config_set_analytics_enabled

Set an enable/disable flag for Analytics Agent reporting. When disabled, Analytics-related logging messages are suppressed.

Format

```
APPD_API void appd_config_set_analytics_enabled(struct appd_config* cfg, const unsigned short enable)
```

Parameters

- `cfg`: AppDynamics configuration structure for the C/C++ SDK.
- `enable`: The enable/disable flag for the Analytics Agent. If the value is non-zero, the agent is enabled. If the value is zero (default setting), then the agent is disabled.

appd_config_set_app_name

Set business application name.

Format

```
appd_config_set_app_name(cfg, APP_NAME);
```

Parameters

- cfg: AppDynamics configuration object.
- `APP_NAME`: Name of the application.

appd_config_set_tier_name

Set tier name.

Format

```
appd_config_set_tier_name(cfg, TIER_NAME);
```

Parameters

- cfg: AppDynamics configuration object.
- `TIER_NAME`: Name of the tier.

appd_config_set_node_name

Set node name.

Format

```
appd_config_set_node_name(cfg, NODE_NAME);
```

Parameters

- `cfg` – AppDynamics configuration object.
- `NODE_NAME` – Name of the node.

appd_config_set_controller_host

Set hostname of the Controller.

Format

```
appd_config_set_controller_host(cfg, CONTROLLER_HOST);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `CONTROLLER_HOST`: Name of the Controller host.

appd_config_set_controller_port

Set the port number on which the Controller is listening.

Format

```
appd_config_set_controller_port(cfg, CONTROLLER_PORT);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `CONTROLLER_PORT`: Port number that the Controller is listening on.

appd_config_set_controller_account

Set the account name for connecting to the Controller.

Format

```
appd_config_set_controller_account(cfg, CONTROLLER_ACCOUNT);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `CONTROLLER_ACCOUNT`: Account name that the Controller is connected to.

appd_config_set_controller_access_key

Set the access key for connecting to the Controller.

Format

```
appd_config_set_controller_access_key(cfg, CONTROLLER_ACCESS_KEY);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `CONTROLLER_ACCESS_KEY:` Access key for connecting to the Controller.

appd_config_set_controller_use_ssl

Specify whether SSL should be used to communicate with the Controller.

Format

```
appd_config_set_controller_use_ssl(cfg, CONTROLLER_USE_SSL);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `CONTROLLER_USE_SSL:` Whether to use SSL to connect with the Controller. Set to a non-zero integer for true. Set to the integer zero for false. Note that SaaS Controllers require this to be set to non-zero.

appd_config_set_controller_http_proxy_host

Optional. Set the hostname of the HTTP proxy if using an HTTP proxy to talk to Controller.

Format

```
appd_config_set_controller_http_proxy_host(cfg, CONTROLLER_HTTP_PROXY_HOST);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `CONTROLLER_HTTP_PROXY_HOST`: Hostname of the HTTP proxy if using an HTTP proxy to talk to Controller.

appd_config_set_controller_http_proxy_port

Optional. Set the port number of the HTTP proxy. Default is 80.

Format

```
appd_config_set_controller_http_proxy_port(cfg, CONTROLLER_HTTP_PROXY_PORT);
```

Parameters

- `cfg:` AppDynamics configuration object.
- `CONTROLLER_HTTP_PROXY_PORT`: Port name of the HTTP proxy. Default is 80.

appd_config_set_controller_http_proxy_username

Optional. Set the username to connect to the HTTP proxy with.

Format

```
appd_config_set_controller_http_proxy_username(cfg, CONTROLLER_HTTP_PROXY_USERNAME);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `CONTROLLER_HTTP_PROXY_USERNAME`: Username to connect to the HTTP proxy with**.**

appd_config_set_controller_http_proxy_password

Optional. Set the password to connect to the HTTP proxy with.

Format

```
appd_config_set_controller_http_proxy_password(cfg, CONTROLLER_HTTP_PROXY_PASSWORD);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `CONTROLLER_HTTP_PROXY_PASSWORD`: Password to connect to the HTTP proxy with.

appd_config_set_controller_http_proxy_password_file

Optional. Set the file containing password to connect to the HTTP proxy with.

Format

```
appd_config_set_controller_http_proxy_password_file(cfg, CONTROLLER_HTTP_PROXY_PASSWORD_FILE);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `CONTROLLER_HTTP_PROXY_PASSWORD_FILE`: File containing password to connect to the HTTP proxy with.

appd_config_set_controller_certificate_file

Optional. Set the the CA certificate file name. Set this if you choose to use your own certificate file.

Format

```
appd_config_set_controller_certificate_file(cfg, CONTROLLER_HTTP_CERTIFICATE_FILE);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `CONTROLLER_CERTIFICATE_FILE`: Name of the certificate file. Defaults to the included `ca-bundle.crt` file.

appd_config_set_controller_certificate_dir

Optional. Set the full path to the CA certificate file. Set this if you have multiple certificate files.

Format

```
appd_config_set_controller_certificate_dir(cfg, CONTROLLER_HTTP_CERTIFICATE_DIR);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `CONTROLLER_CERTIFICATE_DIR`: Full path to the certificate files.

appd_config_set_flush_metrics_on_shutdown

Specify whether to collect metrics in the final minute before SDK shutdown—via `appd_sdk_term`. By default, metrics reported in the minute before shutdown are lost. If you enable metric flushing, then you can retain the metrics reported in the final minute before shutdown.

Format

```
APPD_API void appd_config_set_flush_metrics_on_shutdown(struct appd_config* cfg, int enable);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `int`: Set to a non-zero integer to enable flushing metrics to the Controller. Default is 0.

By setting this flag, the `appd_sdk_term()` is blocked until the underpinning agent logic has uploaded the metric data. By not using this flag, any metrics collected since the last Controller update is discarded. Depending on the load on the Controller, flushing the metrics can take anywhere between 60 and 120 seconds on average or longer. Do not use this flag if you need the termination/tear-down logic to complete immediately.

appd_config_set_logging_min_level

Set the minimum level of logging that is allowed. If `APPD_LOG_LEVEL_TRACE`, all log messages are allowed. If `APPD_LOG_LEVEL_FATAL`, only the most severe errors are logged. The default is `APPD_LOG_LEVEL_INFO`.

Format

```
appd_config_set_logging_min_level(cfg, LOGGING_MIN_LEVEL);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `LOGGING_MIN_LEVEL`: The minimum level of logging that is allowed.
- `APPD_LOG_LEVEL_TRACE`
- `APPD_LOG_LEVEL_DEBUG`
- `APPD_LOG_LEVEL_INFO`
- `APPD_LOG_LEVEL_WARN`
- `APPD_LOG_LEVEL_ERROR`
- `APPD_LOG_LEVEL_FATAL`

appd_config_set_logging_log_dir

Set the directory to log to. The process running the SDK must have permissions to create this directory, if it does not already exist, to list the files within it, and to write to the files within it.

Format

```
appd_config_set_logging_log_dir(cfg, LOGGING_LOG_DIR);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `LOGGING_LOG_DIR:` The directory where you want to store log files. Defaults to `/tmp/appd`.

appd_config_set_logging_max_num_files

Set the maximum number of log files allowed per tenant. Log files are rotated when they reach this number.

Format

```
appd_config_set_logging_max_num_files(cfg, LOGGING_MAX_NUM_FILES);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `LOGGING_MAX_NUM_FILES`: The maximum number of log files allowed per tenant. Default is 10.

appd_config_set_logging_max_file_size_bytes

Set the maximum size of an individual log file, in bytes. Log files are rotated when they reach this size.

Format

```
appd_config_set_logging_max_file_size_bytes(cfg, LOGGING_MAX_FILE_SIZE_BYTES);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `LOGGING_MAX_FILE_SIZE_BYTES:` The maximum size of an individual log file, in bytes. Default is `5 * 1024 * 1024`.

appd_config_set_init_timeout_ms

Set the number of milliseconds you want `appd_sdk_init` (an asynchronous action) to wait until it has received controller configuration and is ready to capture business transactions. Set this if you want to capture short-running business transactions that occur at application startup and you don't mind the delay of waiting for the Controller to send the configuration.

Format

```
appd_config_set_init_timeout_ms(cfg, INIT_TIMEOUT_MS);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `INIT_TIMEOUT_MS`: The number of milliseconds you want `appd_sdk_init` (an asynchronous action) to wait until it has received controller configuration and is ready to capture business transactions.
    - X: Wait up to X milliseconds for Controller configuration.
    - 0: Do not Wait for Controller configuration.
    - -1: Wait indefinitely until Controller configuration is received by agent
    - Default is 0.

appd_config_getenv

Set the environment variable for configuring the SDK. Environment variables are not read by default. You must call this function to configure the SDK via environment variables.

For a list of available environment variables, see Environment Variables.

Format

```
APPD_API void appd_config_getenv(struct appd_config * cfg, const char * prefix);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `prefix:` The prefix of the environment variable name, where the environment variable name is <prefix>.<base>.

appd_context_config_init

Initializes and returns an empty context configuration structure.

Format

```
APPD_API struct appd_context_config* appd_context_config_init(const char* context_name)
```

Parameters

- `context_name:` Name for this context.

appd_context_config_set_controller_host

Add the Controller host to the application context.

Format

```
APPD_API void appd_context_config_set_controller_host (struct appd_context_config * context_cfg, const char * host)
```

Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier and node name for this context.
- `host`: Name of the Controller host.

appd_context_config_set_controller_port

Add the Controller port to the application context.

Format

```
APPD_API void appd_context_config_set_controller_port (struct appd_context_config * context_cfg, const unsigned short port)
```

Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `port:` Port number that the Controller is listening on.

appd_context_config_set_controller_account

Add the Controller port to the application context.

Format

```
APPD_API void appd_context_config_set_controller_port (struct appd_context_config * context_cfg, const char * acct)
```

Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `account:` Account name that the Controller is connected to.

appd_context_config_set_controller_access_key

Add the Controller access key to the application context.

Format

```
APPD_API void appd_context_config_set_controller_port (struct appd_context_config * context_cfg, const char * key)
```

Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `key:` Access key for connecting to the Controller.

appd_context_config_set_controller_use_ssl

Add the Controller access key to the application context.

Format

```
APPD_API void appd_context_config_set_controller_port (struct appd_context_config * context_cfg, unsigned int * ssl
)
```

Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `ssl`: Set to a non-zero integer for true. Set to the integer zero for false. Note that SaaS Controllers require this to be set to non-zero.

appd_context_config_set_controller_http_proxy_host

Optional. Set the hostname of the HTTP proxy if using an HTTP proxy to talk to controller.

Format

APPD_API void appd_context_config_set_controller_http_proxy_host(struct appd_context_config * *context_cfg*, const char * *host*);

Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `host`: Hostname of the HTTP proxy if using an HTTP proxy to talk to Controller.

appd_context_config_set_controller_http_proxy_port

Optional. Set the hostname of the HTTP proxy if using an HTTP proxy to talk to Controller.

Format

```
APPD_API void appd_context_config_set_controller_http_proxy_host(struct appd_context_config * context_cfg, const unsigned short port);
```

Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `port:` Port name of the HTTP proxy. Default is 80.

appd_context_config_set_controller_http_proxy_username

Optional. Set the username to connect to the HTTP proxy with**.**

Format

```
APPD_API void appd_context_config_set_controller_http_proxy_host(struct appd_context_config * context_cfg, const char * user);
```

Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `user`: Username to connect to the HTTP proxy with.

appd_context_config_set_controller_http_proxy_password

Optional. Set the password to connect to the HTTP proxy with.

Format

```
APPD_API void appd_context_config_set_controller_http_proxy_host(struct appd_context_config * context_cfg, const char * pwd);
```

Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `pwd`: Password to connect to the HTTP proxy with.

appd_context_config_set_controller_http_proxy_password_file

Optional. Set the password to connect to the HTTP proxy with.

Format

```
APPD_API void appd_context_config_set_controller_http_proxy_host(struct appd_context_config * context_cfg, const char * file);
```

Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `file`: File containing password to connect to the HTTP proxy with.

appd_context_config_set_controller_certificate_file

Optional. Set the CA certificate file name. Set this if you choose to use your own certificate file.

Format

```
APPD_API void appd_context_config_set_controller_http_proxy_host(struct appd_context_config * context_cfg, const char * file);
```

Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `file`: Name of the certificate file. Defaults to the included `ca-bundle.crt` file.

appd_context_config_set_controller_certificate_dir

Optional. Set the full path to the CA certificate file. Set this if you have multiple certificate files.

Format

```
APPD_API void appd_context_config_set_controller_http_proxy_host(struct appd_context_config * context_cfg, const char * dir);
```

Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `dir`: Full path to the certificate files.

appd_custom_event_start

This function starts the definition of a custom event. Returns a handle to the defined event. By calling `appd_custom_event_end()`, the definition of the event is signaled as complete. The event handle returns null on failure.

Format

```
APPD_API appd_event_handle appd_custom_event_start(const char* application_context, enum appd_event_severity severity, const char* event_sub_type, const char* summary)
```

Parameters

- `application_context`: This string picks one agent out of multiple agents running in multi-tenant mode. If the value is null, the default agent is used.
- `severity`: This is an enum representing the severity of the event. Valid values are `APPD_EVENT_SEVERITY_INFO`, `APPD_EVENT_SEVERITY_WARNING`, and `APPD_EVENT_SEVERITY_ERROR`.
- `event_sub_type`: The string containing the subtype of the custom event. This can be used in the Controller to filter the custom events belonging to a specific subtype.
- `summary`: A string with a brief description of the event.

appd_custom_event_add_detail

This function adds a detail made up of a name and a value to the definition of a custom event. Returns a non-zero value on success, otherwise zero. This call can be made between the calls of `appd_custom_event_start()` and `appd_custom_event_end()`. This function can be called multiple times to add details to the event. The event handle returned by `appd_custom_event_start()` identifies the right event to add the detail to. If multiple calls to this function are made with the same detail name, then the detail value from the most recent call will be used to associate that detail name.

Format

```
APPD_API int appd_custom_event_add_detail(appd_event_handle event_handle, const char* detail_name, const char* detail_value)
```

Parameters

- `detail_name`: This string contains the name of the detail that needs to be added. If the value is null or empty, the API fails and returns zero.
- `detail_value`: This string contains the name of the value that needs to be added. If the value is null or empty, the API fails and returns zero.
- `event_handle`: Refers to the event to which the detail needs to be added to. If the value is null or invalid, the API fails and returns zero.

appd_custom_event_add_property

This function adds a property made up of a name and a value to the definition of a custom event. Returns a non-zero value on successful, otherwise zero. This call can be made between the calls of `appd_custom_event_start()` and `appd_custom_event_end()`. This function can be called multiple times to add properties to the event. The event handle returned by `appd_custom_event_start()` identifies the right event to add the property to. This property can be used in the Controller to filter the custom events. If multiple calls to this function are made with the same property name, then the property value from the most recent call will be used to associate that property name.

Format

```
APPD_API int appd_custom_event_add_property(appd_event_handle event_handle, const char* property_name, const char* property_value)
```

Parameters

- `event_handle`: Refers to the event to which the property needs to be added to. If the value is null or invalid, the API fails and returns zero.
- `property_name`: This string contains the name of the property to be added. If the value is null or empty, the API fails and returns zero.
- `property_value`: This string contains the value of the property to be added. If the value is null or empty, the API fails and returns zero.

appd_custom_event_end

Signals to the C++ SDK that the event definition is complete and queues the event to be sent to the Controller. Returns a zero value on success, otherwise a non-zero value.

Format

```
APPD_API int appd_custom_event_end(appd_event_handle event_handle)
```

Parameters

- `event_handle`: Used to refer to the event. If the value is null or invalid, the API fails and returns zero.

appd_eum_get_cookie

Returns an EUM–ADRUM cookie for a business transaction in an EUM-enabled browser application. You can call this function between `appd_bt_begin()` and `appd_bt_end()`.

At this time, `appd_eum_get_cookie` works only on snapshots that contain call graphs. See Correlate Business Transactions for EUM for more information.

Format

```
APPD_API const char* appd_eum_get_cookie(appd_bt_handle bt, int https, int short_form, const char* referrer_url,
const char* path)
```

Parameters

- `bt`: The handle to the business transaction that the EUM-ADRUM cookie is generated for.
- `https`: When set to a non-zero value, this flag indicates that the incoming request uses the HTTPS protocol. This flag is used to make the EUM cookie secure.
- `short_form`: When set to a non-zero value, this flag indicates that shortened names will be used for sub-cookie names inside the EUM cookie.
- referrer_url: The URL of the page from which user made the request. This can be set to `NULL` or `""` if the referrer URL is unknown.
- `path`: The URL path where the cookie will be stored. This can be set to `"/"` in most cases. If set to `NULL` or `""`, the default value `"/"` is used.

Returns

On success, the function returns a string that contains a cookie key and a cookie value separated by =. Do not free the memory associated with the returned cookie string; when you call `appd_bt_end()`, memory is automatically released.

If EUM is disabled or no configuration information has been received from the Controller, then NULL is returned.

appd_sdk_add_app_context

Initialize the AppDynamics SDK.

Format

```
APPD_API int appd_sdk_add_app_context (struct appd_context_config *  context_cfg)
```

Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.

appd_sdk_init

Initialize the AppDynamics C/C++ SDK. An instrumented application must call this function once, preferably during application startup.

When using `fork()`, the `appd_sdk_init()`, and all other SDK calls, should occur only in the forked process, never in the parent, and each child should behave as its own process, and never share handles between the process itself and other SDK instrumented child processes.

Format

```
APPD_API int appd_sdk_init (const struct appd_config *  config)
```

Parameters

- `config`: AppDynamics configuration settings that enable communication between the agent and the Controller.

Returns

Zero on success, otherwise a non-zero value. If the return value is not zero, a log message describes the error.

appd_sdk_term

Stop the C/C++ SDK. Ends all active business transactions for this agent and stops agent metric reporting to the controller.

If you execute the agent for less than a few minutes, the agent may not have enough time to fully report to the Controller, as this action is done once every 60 seconds. To ensure that any remaining data is transmitted to the Controller, wait at least one minute before issuing the `appd_sdk_term()` call.

Format

```
APPD_API void appd_sdk_term()
```

appd_bt_begin

Start a Business Transaction or continue an existing transaction.

Keep in mind that each application is limited to 200 registered business transactions, and each agent is limited to 50 registered business transactions. Like transactions discovered by other types of agents, business transactions that exceed the limit that are reported by the C/C++ SDK are included in the "all other traffic" grouping. Ensure that your agent does not create excessive business transactions and that your implementation does not introduce the possibility of business transaction explosion.

Format

```
APPD_API appd_bt_handle appd_bt_begin (const char *  name, const char *  correlation_header)
```

Parameters

- `name`: The name for the business transaction. In the case of a continuing transaction in the current business application with a valid correlation header, the SDK uses the name from the header. Do not use the following characters in transaction names: `{ } [ ] | & ;`
- `correlation_header`: A correlation header if this is a continuing transaction, else `NULL`. If specified, the correlation header has been generated by another AppDynamics agent and made available to this agent as a string. The correlation header provides information to enable this transaction to correlate with an upstream transaction.

Returns

An opaque handle for the business transaction that was started.

appd_bt_begin_with_app_context

Start a business transaction or continue an existing transaction in a multi-tenant Controller environment.

Format

```
APPD_API appd_bt_handle appd_bt_begin_with_app_context (const char *  context, const char *  name, const char *  correlation_header)
```

Parameters

- `context`: The application context name that this business transaction belongs to.
- `name`: The name for the business transaction. In the case of a continuing transaction in the current business application with a valid correlation header, the SDK uses the name from the header. Do not use the following characters in transaction names: `{ } [ ] | & ;`
- `correlation_header`: A correlation header if this is a continuing transaction, else `NULL`. If specified, the correlation header has been generated by another AppDynamics agent and made available to this agent as a string. The correlation header provides information to enable this transaction to correlate with an upstream transaction.

appd_bt_enable_snapshot

Enables a snapshot for a given business transaction. This call can be made between the calls of `appd_bt_begin()` and `appd_bt_end()`. Returns a non-zero value if the snapshot is successfully enabled, otherwise returns a zero.

Format

```
APPD_API int appd_bt_enable_snapshot(appd_bt_handle bt)
```

Parameters

- `bt`: The handle to the business transaction for which the snapshot needs to be enabled.

appd_bt_end

End the given business transaction.

Format

```
APPD_API void appd_bt_end (appd_bt_handle  bt)
```

Parameters

- `bt`: The handle to the business transaction to end.

appd_bt_get

Get a BT handle associated with the given GUID by `appd_bt_store`.

Format

```
APPD_API appd_bt_handle appd_bt_get (const char *  guid)
```

Parameters

- `guid`: The globally unique identifier that was passed to `appd_bt_store`.

Returns

The handle to the business transaction associated with the given GUID.

In the following cases the SDK logs a warning and returns a handle that you may safely use in other API functions but that will cause these functions to immediately return without doing anything:

- The SDK does not find a handle associated with the GUID.
- The call ended before the SDK could retrieve the handle.

appd_bt_is_snapshotting

Reports whether the agent is currently taking a transaction snapshot. Useful before calling `appd_add_user_data()` or `appd_bt_set_url()`, since those potentially expensive functions would do nothing if called when a snapshot is not being taken.

Format

```
APPD_API char appd_bt_is_snapshotting (appd_bt_handle  bt)
```

Parameters

- `bt:` The handle to the business transaction to check for snapshotting.

Returns

Non-zero if the given business transaction is taking a snapshot. Otherwise, zero.

appd_bt_set_url

Set URL for a snapshot (if one is being taken).

URL is set for a snapshot if one is occurring. Data should be either 7-bit ASCII or UTF-8.

It is safe to call this function when a snapshot is not occurring. When the given business transaction is NOT snapshotting, this function immediately returns. However, if extracting the data to pass to this function is expensive, you can use `appd_bt_is_snapshotting` to check if the business transaction is snapshotting before extracting the data and calling this function.

Format

```
APPD_API void appd_bt_set_url (appd_bt_handle  bt, const char *  url)
```

Parameters

- `bt`: The business transaction to add the user data to, if it's taking a snapshot.
- url: The value of the URL for the snapshot as 7-bit ASCII or UTF-8.

appd_bt_override_start_time_ms

Takes a time, in milliseconds, representing the number of milliseconds elapsed since Jan 1, 1970 UTC. The time specified for this function overrides the default start time, which is the time at which the `appd_bt_begin()` API is called according to the system clock. By overriding the start time with a specific value, the BT internal start time is disabled, and the specified start time is reported to the Controller.

This function is located in the `appdynamics_advanced.h` file, and is only used in special cases.

Format

```
APPD_API void appd_bt_override_start_time_ms(appd_bt_handle bt, unsigned int timeMS);
```

Parameters

- `bt`: The business transaction to override the timing of
- `timeMS` : Time in milliseconds since start of epoch (midnight, Jan 1, 1970 UTC).

appd_bt_override_time_ms

Takes a time, in milliseconds, that overrides the business transaction response time as reported for this business transaction to the Controller.

The C/C++ SDK maintains its own, internal timer for the response time for the business transaction. This timer reflects the elapsed time spent between the `bt_begin` and `bt_end` calls. In some cases, you may want to set the business transaction timer directly, overriding the default business transaction response timer. For instance, this may be useful for integrating external monitoring systems with AppDynamics.

It is important to note that when calling this function, the reported business transaction will be either the time you specify or the sum of all exit call timings for the transaction, whichever is greatest. This is because a business transaction cannot be reported to take less time than the total of the exit calls it contains.

This function is located in the `appdynamics_advanced.h` file, and is only used in special cases.

Format

```
APPD_API void appd_bt_override_time_ms(appd_bt_handle bt, unsigned int timeMS);
```

Parameters

- `bt`: The business transaction for which to set the response time.
- `timeMS`: The time the business transaction took, in milliseconds.

appd_bt_store

Store a BT handle for retrieval with `appd_bt_get`.

This function allows you to store a BT in a global registry to retrieve later. This is convenient when you need to start and end a BT in separate places, and it is difficult to pass the handle to the BT through the parts of the code that need it.

When the BT is ended, the handle is removed from the global registry.

Format

```
APPD_API void appd_bt_store (appd_bt_handle  bt, const char *  guid)
```

Parameters

- `bt:` The BT to store.
- `guid:` A globally unique identifier to associate with the given BT.

Example

```
int begin_transaction(uint64_t txid, uint64_t sku, float price)
{
    appd_bt_handle bt = appd_bt_begin("payment-processing", NULL);
    appd_bt_store(bt, std::to_string(txid).c_str());
    // ...
}
```

appd_bt_add_error

Add an error to a business transaction.

Errors are reported as part of the business transaction. However, you can add an error without marking the business transaction as an error (e.g., for non-fatal errors).

Format

```
APPD_API void appd_bt_add_error (appd_bt_handle  bt, enum appd_error_level  level, const char *  message, int  mark_bt_as_error)
```

Parameters

- `bt:` The handle to the business transaction to which the error is added.
- `level:` The error levels are `APPD_LEVEL_NOTICE`, `APPD_LEVEL_WARNING`, and `APPD_LEVEL_ERROR`.
- `message:` Error message for this error.
- `mark_bt_as_error:` If true, the business transaction experiencing this error is marked as an error transaction. In this case, the business transaction is counted only as an error transaction. It is not also counted as a slow, very slow or stalled transaction, even if the transaction was also slow or stalled. If false, the business transaction is not marked as an error transaction.

appd_bt_add_user_data

Attaches user data to transaction snapshots generated for the specified business transaction.

The user data is added to the business transaction but reported only when a transaction snapshot is occurring. In the Controller UI, the user data appears in the **Business Data** tab of the transaction snapshot details.

It is safe to call this function when a snapshot is not occurring. When the specified business transaction is not taking a snapshot, this function immediately returns.

If extracting the data to pass to this function is expensive, you can use `appd_bt_is_snapshotting()` to check if the business transaction is actually taking a snapshot before extracting the data and calling this function.

Data should be either 7-bit ASCII or UTF-8.

Format

```
APPD_API void appd_bt_add_user_data (appd_bt_handle  bt, const char *  key, const char *  value)
```

Parameters

- `bt`: The business transaction to add the user data to, if it's taking a snapshot.
- `key:` The name of the user data to add to the snapshot as 7-bit ASCII or UTF-8.
- `value:` The value of the user data to add to the snapshot as 7-bit ASCII or UTF-8.

appd_backend_add

Add a declared backend to the current business application. Use `appd_backend_declare` to declare a backend before adding it.

This function fails if the type of the backend being added does not have at least one identifying property.

Format

```
APPD_API int appd_backend_add (const char *  backend)
```

Parameters

- `backend:` Pointer to the backend.

Returns

Zero on success, otherwise a non-zero value. If the return value is not zero, a log message describes the error.

appd_backend_declare

Declare the existence of a backend. Call this only if the backend is not already registered with the C++ SDK instance.

Format

```
APPD_API void appd_backend_declare (const char *  type, const char *  unregistered_name)
```

Parameters

- `type:` The type of the backend, from these options:
    - `APPD_BACKEND_HTTP`
    - `APPD_BACKEND_DB`
    - `APPD_BACKEND_CACHE`
    - `APPD_BACKEND_RABBITMQ`
    - `APPD_BACKEND_WEBSERVICE`
    - `APPD_BACKEND_JMS`
- `unregistered_name:` The name of the backend. Must be unique to the C++ SDK instance.

appd_backend_prevent_agent_resolution

Call to prevent a downstream agent from resolving as this backend. If used, this must be called before `appd_backend_add()`.

Normally, if an agent picks up a correlation header for an unresolved backend, it will resolve itself as that backend. This is usually the desired behavior.

However, if the backend is actually an uninstrumented tier that is passing through the correlation header (for example, a message queue or proxy), then you may wish the backend to show up distinct from the tier that it routes to. If you call this function, correlation headers generated for exit calls to this backend in the SDK will instruct downstream agents to report as distinct from the backend.

For example: if you have Tier A talking to uninstrumented Backend B which routes to instrumented Tier C, if you do NOT call this function, the flow map will be A > C. If you DO call this function, the flow map will be A > B > C.

Format

```
APPD_API int appd_backend_prevent_agent_resolution (const char *  backend)
```

Parameters

- `backend:` Pointer to the declared backend.

Returns

Zero on success, otherwise a non-zero value. If the return value is not zero, a log message describes the error.

appd_backend_set_identifying_property

Sets an identifying property of a backend. Call once for every identifying property that you want to set. Call this function after `appd_backend_declare()` and before `appd_backend_add()`.

A backend's identifying properties uniquely identify the downstream component being called. In the Controller UI, these properties are visible in the upper right panel of the backend dashboards.

You must set at least one identifying property when you add a backend of one of the built-in exit call types. The valid properties vary by the following exit call type.

Exit Call Type	Valid Identifying Properties
APPD_BACKEND_HTTP	HOST, PORT, URL, QUERY STRING
APPD_BACKEND_DB	HOST, PORT, DATABASE, VENDOR, VERSION
APPD_BACKEND_CACHE	SERVER POOL, VENDOR
APPD_BACKEND_RABBITMQ	HOST, PORT, ROUTING KEY, EXCHANGE
APPD_BACKEND_WEBSERVICE	SERVICE, URL, OPERATION, SOAP ACTION, VENDOR
APPD_BACKEND_JMS	DESTINATION, DESTINATIONTYPE, VENDOR
APPD_BACKEND_WEBSPHEREMQ	HOST, PORT, DESTINATION, DESTINATIONTYPE, MAJOR VERSION, VENDOR

Format

```
APPD_API int appd_backend_set_identifying_property (const char *  backend, const char *  key, const char *  value)
```

Parameters

- `backend:` Pointer to the backend.
- `key:` Name of the property. For example, DESTINATION or PORT.
- `value:` Value of the property. For example, Order Queue or 3304

Returns

Zero on success, otherwise a non-zero value. If the return value is not zero, a log message describes the error.

appd_custom_metric_add

Report a custom metric.

Format

```
APPD_API void appd_custom_metric_add (const char *  application_context, const char *  metric_path, enum appd_time_rollup_type  time_rollup_type, enum appd_cluster_rollup_type  cluster_rollup_type, enum appd_hole_handling_type  hole_handling_type)
```

Parameters

- `application_context:` The application context for this custom metric.
- `metric_path:` The path of the custom metric. This path defines where the custom metric appears in the Metric Browser. Use a pipe character to separate branches in the path. For example, `Custom Metrics|MyCustomMetric` defines `MyCustomMetric` as a top-level metric in the tree.
- `time_rollup_type:` Specifies how to rollup metric values for this metric over time, from the following:
  - `APPD_TIMEROLLUP_TYPE_AVERAGE:` Compute the average value of the metric over time.
  - `APPD_TIMEROLLUP_TYPE_SUM:` Compute the sum of the value of the metric over time.
  - `APPD_TIMEROLLUP_TYPE_CURRENT:` Report the current value of the metric.
- `cluster_rollup_type`: Specifies how to rollup metric values for this metric across clusters, from the following:
  - `APPD_CLUSTERROLLUP_TYPE_INDIVIDUAL`: Roll-up the value individually for each member of the cluster.
  - `APPD_CLUSTERROLLUP_TYPE_COLLECTIVE`: Roll-up the value across all members of the cluster.
- `hole_handling_type`: Specifies how to handle holes—gaps where no value has been reported from this metric, from the following:
  - `APPD_HOLEHANDLING_TYPE_RATE_COUNTER`: Considers the gap or 0 value to be meaningful in the aggregation of the metric.

- `APPD_HOLEHANDLING_TYPE_REGULAR_COUNTER`: Does not consider the gap or 0 value to be meaningful in the aggregation of the metric.

For additional information on these parameters, see Create Custom Metrics.

appd_custom_metric_report

Report a value for a given metric.

Format

```
APPD_API void appd_custom_metric_report (const char *  application_context, const char *  metric_path, long  value)
```

Parameters

- `application_context`: The application context for this custom metric.
- `metric_path`: The path of the metric to report, as defined by `appd_custom_metric_add`.
- `value`: The value to report for the metric. The way the value is aggregated is specified by the roll-up parameters to `appd_custom_metric_add`.

appd_exitcall_add_error

Add an error to the exit call.

Format

```
APPD_API void appd_exitcall_add_error (appd_exitcall_handle  exitcall, enum appd_error_level  level, const char
*  message, int  mark_bt_as_error)
```

Parameters

- `exitcall`: Handle to the exit call.
- `level`: The level of this error are `APPD_LEVEL_NOTICE`, `APPD_LEVEL_WARNING`, and `APPD_LEVEL_ERROR`.
- `message`: Error message for this error.
- `mark_bt_as_error`: If true, the business transaction making the exit call that is experiencing this error is marked as an error transaction. In this case, the business transaction is counted only as an error transaction. It is not also counted as a slow, very slow or stalled transaction, even if the transaction was also slow or stalled. If false, the business transaction is not marked as an error transaction.

appd_exitcall_begin

Start an exit call to the specified backend as part of a business transaction.

Format

```
APPD_API appd_exitcall_handle appd_exitcall_begin (appd_bt_handle  bt, const char *  backend)
```

Parameters

- `bt:` Handle to the business transaction making the exit call.
- `backend`: The destination backend of the exit call. AppDynamics does not automatically detect backends for Go applications, so you must specify the destination backend.

Returns

An opaque handle to the exit call that was started.

appd_exitcall_end

Complete the exit call.

Format

```
APPD_API void appd_exitcall_end (appd_exitcall_handle  exitcall)
```

Parameters

- `exitcall`: Handle to the exit call being ended.

appd_exitcall_get

Get a handle to an exit call associated with a GUID via `appd_exitcall_store()`.

Format

```
APPD_API appd_exitcall_handle appd_exitcall_get (const char * guid)
```

Parameters

- `guid:` The globally unique identifier that was passed to `appd_exitcall_store()`.

Returns

The handle to the exit call associated with the given GUID.

In the following cases, the SDK logs a warning and returns a handle that you may safely use in other API functions but that will cause these functions to immediately return without doing anything:

- The SDK doesn't find a handle associated with the GUID.
- The call ended before the SDK could retrieve the handle.

appd_exitcall_get_correlation_header

Get the header for correlating a business transaction.

If a business transaction makes exit calls that you wish to correlate across, you should retrieve the correlation header and inject it into your exit call's payload.

The returned string is freed when the exit call ends. Do not free it yourself.

Format

```
APPD_API const char* appd_exitcall_get_correlation_header (appd_exitcall_handle  exitcall)
```

Parameters

- `exitcall`: Handle to the exit call.

Returns

On success returns a 7-bit ASCII string containing the correlation information. You can inject this string into the exit call's payload. A downstream agent can then extract the header from that payload and continue the business transaction.

On error, returns the default header that prevents downstream business transaction detection.

appd_exitcall_override_start_time_ms

Takes a time, in milliseconds, representing the number of milliseconds elapsed since Jan 1, 1970 UTC. The time specified for this function overrides the default start time, which is the time at which the `appd_exitcall_begin()` API is called according to the system clock. By overriding the start time with a specific value, the exit call's internal start time is disabled, and the specified start time is reported to the Controller.

This function is located in the `appdynamics_advanced.h` file, and is only used in special cases.

Format

APPD_API void appd_exitcall_override_time_ms(appd_exitcall_handle exitCall, int64_t timeMS);

Parameters

- `exitCall`: The exit call for which to override the start time
- `timeMS:` The time that you want to override the exit call start time

appd_exitcall_override_time_ms

Takes a time, in milliseconds, that overrides the exit call time reported to the Controller.

The C/C++ SDK maintains its own internal timer for the time it takes to complete the exit call. In some cases, you may want to disable the exit call's internal timer. For instance, this can be useful for reporting exit calls that are recorded in external monitoring systems and read into an SDK program.

This function is located in the `appdynamics_advanced.h` file, and is only used in special cases.

Format

```
APPD_API void appd_exitcall_override_time_ms(appd_exitcall_handle exitCall, int64_t timeMS);
```

Parameters

- `exitCall`: The exit call for which to set the completion time
- `timeMS`: The time that you want to override the exit call time.

appd_exitcall_set_details

Set the details string for an exit call. This can be used, for example, to add the SQL statement that a DB backend has executed as part of the exit call. This data is then visible in the exit calls details UI for the transaction snapshot.

Format

```
APPD_API int appd_exitcall_set_details (appd_exitcall_handle  exitcall, const char *  details)
```

Parameters

- `exitcall`: Handle to the exit call.
- `details`: An arbitrary string to add to the exit call.

Returns

Zero on success, otherwise a non-zero value. If the return value is not zero, a log message describes the error.

appd_exitcall_store

Store an exit call handle for retrieval with `appd_exitcall_get()`.

This function allows you to store an exit call in a global registry to retrieve later. This is convenient when you need to start and end the call in separate places, and it is difficult to pass the handle through the parts of the code that need it.

The handle is removed when the exit call (or the BT containing it) ends.

Format

```
APPD_API void appd_exitcall_store (appd_exitcall_handle  exitcall, const char *  guid)
```

Parameters

- `exitcall`: The exit call to store.
- `guid`: A globally unique identifier to associate with the given call.

Example

```
appd_exitcall_handle ec = appd_exitcall_begin(bt, "authdb");
appd_exitcall_store(ec, "login-exit");
```

appd_frame_begin

Records the start of a method call in the call stack. To track the duration of your method call, you must call `appd_frame_begin` near the start of the method code, and `appd_frame_end` when the method returns.

Format

```
APPD_API appd_frame_handle appd_frame_begin(appd_bt_handle bt, enum appd_frame_type frame_type,
const char* class_name, const char* method_name, const char* file, unsigned int line_number);
```

Parameters

- `bt`: The business transaction for the call graph.
- `frame_type`: The type of the frame. When used in C or C++ code, use `APPD_FRAME_TYPE_CPP`.
- `class_name`: The name of the class if this method is a member of the class. If not, then set to NULL.
- `method_name`: The name of the method.
- `file`: The path of the source file.
- `line_number`: The line number in the source file.

Returns

An opaque handle for the frame. NULL if an error occurred.

appd_frame_end

Records the end of a method call in the call stack. To track the duration of your method call, you must call `appd_frame_begin` near the start of the method code, and `appd_frame_end` when the method returns.

Format

```
APPD_API void appd_frame_end(appd_bt_handle bt, appd_frame_handle frame);
```

Parameters

- `bt`: The business transaction for the call graph.
- `frame`: The handle of returned by the corresponding `appd_frame_begin` call.

Environment Variables

You can configure the following environment variables for the C/C++ SDK.

Environment Variable	Value
`APP_NAME`	The name of the application.
`CONTROLLER_ACCESS_KEY`	The access key for connecting to the Controller.
`CONTROLLER_ACCOUNT`	The account name for connecting to the Controller.
`CONTROLLER_HOST`	The hostname of the Controller.
`CONTROLLER_PORT`	The port number on which the Controller is listening.
`CONTROLLER_HTTP_PROXY_HOST`	If using an HTTP proxy to talk to the Controller, the hostname of that HTTP proxy.
`CONTROLLER_HTTP_PROXY_PASSWORD`	The password for connecting to the HTTP proxy.
`CONTROLLER_HTTP_PROXY_PASSWORD_FILE`	The file containing password to connect to the HTTP proxy with.
`CONTROLLER_HTTP_PROXY_PORT`	The port number of the HTTP proxy.
`CONTROLLER_HTTP_PROXY_USERNAME`	The username to connect to the HTTP proxy with.
`CONTROLLER_USE_SSL` (optional)	To disable SSL, set to `off`, `0`, `f`, or `false`. To enable SSL, set to `on`, `1`, `t`, or `true`.
`CONTROLLER_CERTIFICATE_FILE`	The SSL certificate file name for connecting to the Controller.
`CONTROLLER_CERTIFICATE_DIR`	The directory where the SSL certificate is located.
`FLUSH_METRICS_ON_SHUTDOWN`	To enable metric flushing before shutdown, set to a non-zero integer. To disable metric flushing before shutdown, set to `0` (default).
`INIT_TIMEOUT_MS`	The number of milliseconds that you want `appd_sdk_init,` an asynchronous action, to wait until it has received Controller configuration and is ready to capture business transactions.
`LOGGING_LOG_DIR`	The directory that the logs are saved to.
`LOGGING_LEVEL`	The level of severity for which activity is logged. Options: all, trace, debug, info, warn, error.
`LOGGING_MAX_NUM_FILES`	The maximum number of log files that can be saved.
`LOGGING_MAX_FILE_SIZE_BYTES`	The maximum log file size that can be saved.
`NODE_NAME`	The name of the node.
`TIER_NAME`	The name of the tier.
`UNIQUE_HOST_ID` (optional)	The identifier of the physical host or virtual machine that the agent is installed on.

CPP SDK Resource Management

Related pages:

- C/C++ SDK Reference

This page describes the Resource Acquisition Is Initialization (RAII) functions defined in the C/C++ SDK to instrument C++ applications.

For C++ applications, you can use the `BT` and `ExitCall` classes to simplify your instrumentation. With these classes, you do not need to manually call `appd_bt_end()` and `appd_exitcall_end()`. When the `BT` or `ExitCall` object goes out of scope, the SDK calls its destructor and the business transaction/exit call automatically ends.

The following code example use these classes.

```
{
   appd::sdk::BT bt("mybt");
   appd::sdk::ExitCall ec(bt, "auth");
   if (!make_auth_call())
   {
      bt.add_error(APPD_LEVEL_ERROR, "Authorization failed");
      return -1;
   }
   issue_api_call();
}
```

The above code example is equivalent to this:

```
{
    appd_bt_handle bt = appd_bt_begin("mybt", NULL);
    appd_exitcall_handle ec = appd_exitcall_begin(bt, "auth");
    if (!make_auth_call())
    {
       appd_bt_add_error(bt, APPD_LEVEL_ERROR, "Authorization failed", 0);
       appd_exitcall_end(ec);
       appd_bt_end(bt);
       return -1;
    }
    issue_apI_call();
    appd_exitcall_end(ec);
    appd_bt_end(bt);
}
```

When the BT lifetime depends on the non-deterministic lifetimes of other objects, you can use a shared pointer to a `BT` to keep the `BT` alive for the lifetimes of its dependencies. In this example, the `BT` ends when the last reference to it ends.

```
{
   //Initialize the BT with a shared pointer
   auto bt = std::make_shared<appd::sdk::BT>("compute");
   auto prod = createProducer(bt);
   auto consumers = createConsumers(bt, NUM_WORKERS);
   //Variable BT goes out of scope with no further references.
   //BT ends automatically.
}
```

For managing exit calls with complex lifetimes, consider using smart pointers `std::unique_ptr<appd::sdk::ExitCall>` or `std::shared_ptr<appd::sdk::ExitCall>`.

appd:sdk::BT

A RAII pattern constructor for C++ applications. For a new Business Transaction, this constructor creates the business transaction object and a handle to that object. This function continuous existing transactions and adds the correlation header if one is passed.

When the business transaction object goes out of scope, the SDK automatically ends the business transaction. A business transaction object cannot be copied.

Format

```
appd::sdk::BT(const std::string& name)
appd::sdk::BT(const std::string& name, const std::string& correlation_header)
appd::sdk::BT(const char* name, const char* correlation_header=NULL)
```

Parameters

- `name:` Business transaction name, passed as either a `string&` or `char *`, depending on which constructor you choose. In the case of a continuing transaction in the current business application with a valid correlation header, the SDK uses the name from the header.
- `correlation_header`: Optional correlation header, passed as either a `string&` or `char *`, depending on which constructor you choose.

appd::sdk::Event

This class is used to create an event in C++ and provides a convenient way of creating events. See C/C++ SDK Reference.

Format

```
appd::sdk::Event::Event
(const std::string& application_context,
enum appd_event_severity severity,
const std::string& even_sub_type,
const std::string& summary,
const std::map<std::string, std::string>& properties,
const std::map<std::string, std::string>& details)
```

Parameters

- `application_context`: This string picks an agent out of multiple agents running in multi-tenant mode. If this value is empty, then the default agent is used.
- `details`: A map of name and value pairs. An empty map is a valid argument. The name and value associated with a detail cannot be empty; that is an error.
- `event_sub_type`: The string containing the subtype of the custom event. This can be used in the Controller to filter the custom events belonging to a specific subtype.
- `properties`: A map of name and value pairs. An empty map is a valid argument. The name and value associated with a property cannot be empty; that is an error.
- `severity`: This is an enum representing the severity of the event. Valid values are `APPD_EVENT_SEVERITY_INFO`, `APPD_EVENT_SEVERITY_WARNING` and `APPD_EVENT_SEVERITY_ERROR`.
- `summary`: A string giving a brief description about the event.

appd::sdk::Event::report

This method in Event class is equivalent to `appd_custom_event_end()` in functionality. See C/C++ SDK Reference.

This function returns boolean value as `true` if the definition of the event is successful and queuing of the event (to send to the Controller) is successful. Otherwise, returns false.

Format

```
appd::sdk::Event event(<arguments>);
bool status = event.report();
```

appd:sdk::ExitCall

A RAII pattern constructors for C++ applications. Constructs an ExitCall object and creates a handle to that object. You must declare a backend and assign it at least one identifying property before you use the backend to instantiate the ExitCall object.

When the ExitCall object goes out of scope, the SDK automatically ends the ExitCall.

An ExitCall object cannot be copied.

Format

```
appd::sdk::ExitCall(BT& bt, const char* backend)
appd::sdk::ExitCall(BT& bt, const std::string& backend)
```

Parameters

- `BT& bt`: Handle to the business transaction making the exit call.
- `backend`: The destination backend of the exit call. Passed as either a `string&` or `char *`, depending on which constructor you choose.

appd::sdk::Frame

Use the Frame class to enable call graphs for your C++ application. You can use the Frame class to instrument the methods that you want to track, as an alternative to calling `appd_frame_begin` and `appd_frame_end`. You must pass the following parameters into the Frame class:

Format

```
Frame(BT& bt, appd_frame_type frame_type, const char* class_name, const char* method_name, const char* file, unsigned int line_number)
```

Parameters

- `bt`: The BT object that owns this function call.
- `frame_type`: The type of the frame. When used in C++ RAII code, use `APPD_FRAME_TYPE_CPP`.
- `class_name`: The name of the class if this method is a member of the class, else `NULL`.
- `method_name`: The name of the method. You can use `__FUNCTION__` or `__PRETTY_FUNCTION__`; any available compiler macro.
- `file`: The path of the source file. You can use `__FILE__` or any available compiler macro.
- `line_number`: The line number in the source file. You can use `__LINE__` or any available compiler macro.

Install the CCPP SDK on Windows

Related pages:

- Download AppDynamics Software
- Install the C/C++ SDK on Linux

To install the C/C++ SDK on Windows:

1. Download the C/C++ SDK from the AppDynamics Downloads Portal that corresponds to the bit number for your operating system (32-bit or 64-bit). The incorrect bit–SDK version compatibility will cause a linker error about missing symbols.
2. Extract the downloaded SDK zip file to the directory where you want to place the SDK, such as `C:\AppDynamics`.
3. Add the SDK lib directory to the system PATH, for example, add `C:\AppDynamics\appdynamics-cpp-sdk\lib to %PATH%`.
4. Configure your Visual Studio project to have the include path and link the AppDynamics library in **Open Project** > **Properties**.
    a. From the sidebar, unfold **C/C++** and choose **General**. In the new pane, change **Additional Include Directories** to add: `C:\AppDynamics\appdynamics-cpp-sdk\include`.
    b. From the sidebar, unfold **Linker** and choose **Input**. In the new pane, change **Additional Dependencies** to add: `C:\AppDynamics\appdynamics-cpp-sdk\lib\appdynamics.lib`.
5. Modify your program to use the AppDynamics C/C++ SDK. See C/C++ SDK Reference and Use the C/C++ SDK.

Install the CCPP SDK on Linux

Related pages:

- Download AppDynamics Software
- Install the C/C++ SDK on Windows

To install the C/C++ SDK on Linux:

1. Download the C/C++ SDK from the AppDynamics Downloads Portal.
2. Extract the SDK to the desired SDK home directory location, such as in `/opt`:

   ```
   sudo tar xvzf appdynamics-sdk-native-64bit-linux-VERSION.tar.gz -C /opt
   ```

   Replace `VERSION` in the file name with the version of the downloaded SDK.
3. Update your build scripts to be able to access the AppDynamics SDK library files:
   a. Add `/opt/appdynamics-cpp-sdk/lib` to your library path. For example, `-L/opt/appdynamics-cpp-sdk/lib`.
   b. Add `-lappdynamics` to your link options.
4. Modify your program to use the AppDynamics C/C++ SDK. See C/C++ SDK Reference and Use the C/C++ SDK.
5. Ensure that the `ulimit` setting for open file descriptors on the operating system is set to a sufficient number. At a minimum, you will need two file descriptors for each active thread that calls the C++ SDK `appd_sdk_init()` function.

Go SDK

Related pages:

- SELinux Installation Issues

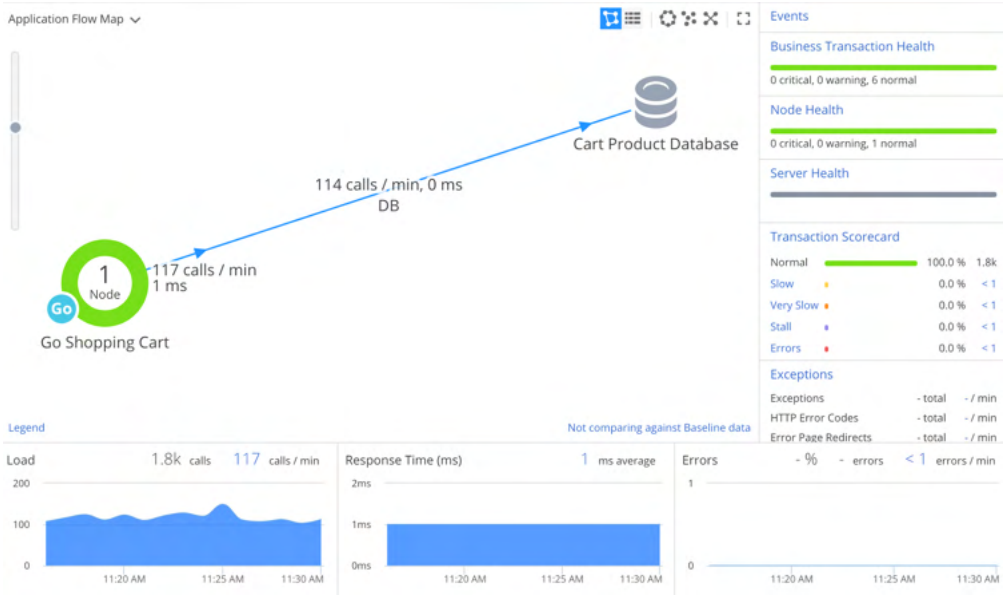
This page describes how to install and instrument the app server agent for Go applications.

AppDynamics monitors applications that have been created with the Go SDK.

The Go SDK can:

- Trace transactions through Go tiers
- Surface Go runtime errors
- Report backend calls made by Go services

Once the agent connects to the Controller, you can see flow maps, key performance indicators, errors, and more for the Go tier.



Limitations

The Go SDK uses cGo in the background. In Go, when you are calling out to C/C++, the code converts the current Goroutine to an OS thread. This is a limitation of the runtime, not the Go SDK. If you are running the agent with many Go routines and make Go SDK calls within the Go routines in your application code, there may be a risk of reaching the OS thread limit. If you encounter this limitation, contact AppDynamics Support.

Go Language Supported Environments

Go Supported Platforms

Language Support

All Go language versions are currently supported.

Operating Systems

- Any Linux distribution based on `glibc` >= 2.5, and the x86 32-bit or x86 64-bit architecture
- Mac OS X >= 10.8

Using Go SDK

On This Page:

This page provides instructions and an overview of the GO SDK, which provides routines for creating and managing Business Transactions, Transaction Snapshots, backends, and exit calls in AppDynamics.

Before You Begin

Before instrumenting your applications with the Go SDK, you will need the current version of the Go SDK. See Go Language Agent and Download AppDynamics Software to install the SDK.

Import the AppDynamics Package to the Application

After downloading the SDK, you are ready to add AppDynamics instrumentation to your Go application. The first step is to import the AppDynamics package:

```
import appd "appdynamics"
```

Initialize the Controller Configuration

Controller information settings permit the SDK to connect to the Controller. Some settings are required for all applications while others are required only for certain types of application environments. For example, if the SDK needs to connect to the Controller via an internal proxy in your network, set up the connection settings for the proxy. See Go SDK Reference for a complete list of settings and which ones are required.

Assign values to the required settings in your application. For example, to set the Controller connection information:

```
cfg := appd.Config{}

cfg.AppName = "exampleapp"
cfg.TierName = "orderproc"
cfg.NodeName = "orderproc01"
cfg.Controller.Host = "my-appd-controller.example.org"
cfg.Controller.Port = 8090
cfg.Controller.UseSSL = false
cfg.Controller.Account = "customer1"
cfg.Controller.AccessKey = "secret"
cfg.InitTimeoutMs = 1000  // Wait up to 1s for initialization to finish
```

Notice the `InitTimeoutMs` field. Once you initialize the configuration, you pass the configuration object to the call to initialize the agent via `InitSDK()`. The `InitTimeoutMs` field can have these values:

- When set to `0`, the default, the `InitSDK()` function operates as an asynchronous action, so that the initialization call does not block your program.
- Setting the value to `-1` instructs the program to wait indefinitely until the controller configuration is received by the agent, that is, the `InitSDK()` method returns control. This is useful when you want to capture short-running Business Transactions that occur at application startup and you do not mind the delay of waiting for the Controller to send the configuration.
- Alternatively, set it to a specific number of milliseconds to wait.

If you use a multi-tenant Controller (SaaS or on-premises multi-tenant), you need to create the context for the multi-tenant environments using the `AddAppContextToConfig()` method. You can then pass the context as a parameter to methods for performing particular operations, such as starting a Business Transaction or adding custom metrics. See Go SDK Reference for `AddAppContextToConfig()` and related methods.

Initialize the Agent

Initialize the agent by passing the configuration structure to `InitSDK()` in your main function.

If `InitSDK()` returns `nil`, the agent is initialized successfully. If an error returns, it is likely because the agent could not reach the Controller.

For example, to initialize the SDK:

```
if err := appd.InitSDK(&cfg); err != nil {
        fmt.Printf("Error initializing the AppDynamics SDK\n")
} else {
        fmt.Printf("Initialized AppDynamics SDK successfully\n")
}
```

Create Business Transactions

Define a Business Transaction by enclosing the code that constitutes the request you want to monitor between `StartBT()` and `EndBT()`calls. `StartBT()` returns a handle to use in subsequent routines that affect that business transaction.

If you are creating a Business Transaction that correlates with an upstream Business Transaction, pass the correlation header of the upstream transaction so the new transaction that you are creating can correlate with it. See Go SDK Reference for `GetExitcallCorrelationHeader()`. If the transaction does not need to correlate with another transaction, pass an empty string for the correlation header parameter.

You can optionally store the Business Transaction handle in the global handle registry with a GUID for easy retrieval later using `StoreBT()`. Retrieve the handle from the global handle registry `using GetBT()`.

For example, to set a Business Transaction:

```
// start the "Checkout" transaction
btHandle := appd.StartBT("Checkout", "")

// Optionally store the handle in the global registry
appd.StoreBT(btHandle, my_bt_guid)
...

// Retrieve a stored handle from the global registry
myBtHandle = appd.GetBT(my_bt_guid)

// end the transaction
appd.EndBT(btHandle)
```

Between starting and ending the transaction, you can perform operations such as adding errors to the business transaction, defining the transaction snapshot attributes, adding backends and exit calls, and so on.

When the business transaction ends via a call to `EndBT()`, the agent stops reporting metrics for the business transaction.

Add Business Transaction Errors

Use `AddBTError()` to report Business Transaction errors. If you set this function's `markBTAsError` parameter, the transaction is reported as an Error Transaction when the error occurs.

The SDK provides constants classifying the error level as `APPD_LEVEL_NOTICE`, `APPD_LEVEL_WARNING` or `APPD_LEVEL_ERROR`.

Manage Business Transaction Snapshots

The agent automatically creates Transaction Snapshots when monitoring a Business Transaction. Transaction snapshots are useful for troubleshooting poor performance because they describe instances of the business transaction at certain points in time.

Other than creating the Business Transaction, you do not have to modify anything to create these snapshots, but you can add calls to:

- Determine if a snapshot is being taken
- Provide additional data in a snapshot
- Set the URL for a snapshot

Determine if the Agent is Taking a Snapshot Now

Due to high cost, the agent does not constantly collect snapshots. By default, it collects a snapshot every ten minutes, but this schedule is configurable. See Configure Snapshot Periodic Collection Frequency.

You can determine if a snapshot is happening using `IsBTSnapshotting()`, which returns `true` if the agent is collecting a snapshot. This method avoids wasted overhead in collecting user data for a snapshot or setting the snapshot URL if no snapshots are being collected.

Add Business Transaction User Data

You can optionally add data to transaction snapshots. For example, you might want to know which users are getting a lot of errors, or from which regions users are experiencing slow response times, or which methods are slow. In the Controller UI, the data appears in the USER DATA tab of the transaction snapshot.

If a snapshot is occurring, use `AddUserDataToBT()` passing a key and value for the data that you want the snapshot to collect.

Add Snapshot URL

If a snapshot is occurring, you can set a URL for the current snapshot using `SetBTURL()`.

Set Snapshot Example

```
func setSnapshotAttributes(bt appd.BtHandle, key, value string) {
        if appd.IsBTSnapshotting(bt) {
                appd.AddUserDataToBT(bt, key, value)
                appd.SetBTURL(bt, "user/login")
        }
}
```

Create Backends

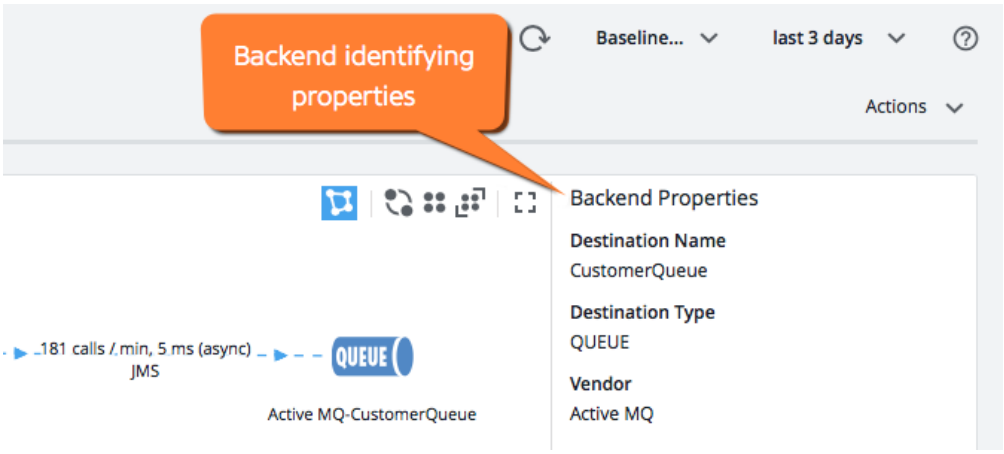
A backend is a database or a remote service such as a message queue, HTTP service, or cache service that your application uses. A backend component is not itself monitored by the application agent, but the agent monitors calls to it from instrumented servers. You need to create backends in the instrumented environment so that the agent registers them. Creating and adding the backend to the instrumented application involves:

- Naming the backend
- Setting its identifying properties
- Optionally, configuring how the backend is presented in the Controller UI

Identifying Properties

A backend has identifying properties. These vary depending on the type of the backend and the types of information that you want to display. The Controller displays identifying properties in backend dashboards. You must set at least one identifying property for the type of any backend that you plan to add.

The following shows the backend properties in the Controller UI for an Oracle database:



Resolve to a Tier

By default the Controller doesn't display a detected backend as a separate entity in flow maps, but the agent reports its metrics as part of the downstream tier. If you want to display the backend as a separate component and not resolved to the tier, set `resolve` to `false`. See Resolve Remote Services to Tiers.

Backend Example

The following listing shows an example of setting up a database backend.

```
backendName := "Cart Product Database"
backendType := "DB"
backendProperties := map[string]string {
        "DATABASE": "sqlite3",
}
resolveBackend := false

appd.AddBackend(backendName, backendType, backendProperties, resolveBackend)
```

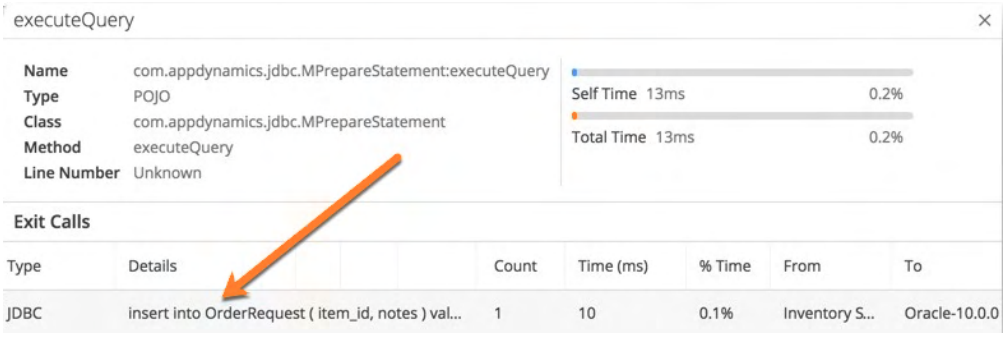
Manage Exit Calls

When an application makes a call to another component, such as a detected backend or another application server, the agent reports metrics on those calls.

Define an exit call by enclosing the code that constitutes the exit call between `StartExitCall()` and `EndExitcall()` calls. `StartExitcall()` returns a handle to use in subsequent routines that affect that exit call. An exit call occurs in the context of a Business Transaction.

You can optionally store the exit call handle in the global handle registry with a guid for easy retrieval later using `StoreExitcall()`. Retrieve the handle from the global handle registry `using GetExitcall()`.

You can optionally add details to an exit call as any arbitrary string with `SetExitcallDetails()`. The details are reported in the exit call details in the transaction snapshots in the Controller UI:



You can also add errors to an exit call using `AddExitcallError()`. Use the enum for the error levels. You can also add an error message.

Simple Exit Call Example

```
// start the exit call to backendName
ecHandle := appd.StartExitcall(btHandle, backendName)

...

// optionally store the handle in the global registry
appd.StoreExitcall(ecHandle, my_ec_guid)

...
// retrieve a stored handle from the global registry
myEcHandle := appd.GetExitcall(my_ec_guid)

// set the exit call details
if err := appd.SetExitcallDetails(myEcHandle, "Exitcall Detail String"); err != nil {
        log.Print(err)
}

// add an error to the exit call
appd.AddExitcallError(myEcHandle, appd.APPD_LEVEL_ERROR, "exitcall error!", true)

// end the exit call
appd.EndExitcall(myEcHandle)
```

Correlate with Other Business Transactions

A correlation header contains the information that enables the agents to continue the flow of a Business Transaction across multiple tiers.

An SDK agent can correlate with other SDK agents as well as other AppDynamics agents, such as Java, .NET, or PHP, that perform automatic correlation for certain types of entry and exit points.

Correlate with an Upstream Tier

When your instrumented process receives a continuing transaction from an upstream agent that supports automatic correlation:

1. Using a third-party `Header.Get()` function, extract the header named `APPD_CORRELATION_HEADER_NAME` from the incoming HTTP payload.
2. Pass the header to `StartBT()`. For example:

```
hdr := req.Header.Get(appd.APPD_CORRELATION_HEADER_NAME)
bt := appd.StartBT("Fraud Detection", hdr)
```

If the header retrieved by the `Header.Get()` function is valid, the business transaction started by the `StartBT()` call will be a continuation of the Business Transaction started by the upstream service.

Correlate with a Downstream Tier

The downstream agent is watching for a correlation header named `singularityheader` in the HTTP payload.

If your SDK agent is making an exit call to a downstream agent that supports automatic correlation:

1. Set the name of the correlation header using `APPD_CORRELATION_HEADER_NAME`.
2. Begin the exit call.
3. Retrieve the correlation header from the exit call using the `GetExitcallCorrelationHeader()` function.
4. Using third-party HTTP functions, prepare an HTTP POST request.
5. Inject a header named `APPD_CORRELATION_HEADER_NAME` with the value of the correlation header retrieved in Step 3 into the outgoing payload of the HTTP request.
6. Make the request. For example:

```
inventoryEcHandle := appd.StartExitcall(btHandle, "Inventory DB")
hdr := appd.GetExitcallCorrelationHeader(inventoryEcHandle)

client := &http.Client{
        CheckRedirect: redirectPolicyFunc,
}

req, err := http.NewRequest("POST", "https://inventory/holds/xyz", nil)
// ...
req.Header.Add(appd.APPD_CORRELATION_HEADER_NAME, hdr)
resp, err := client.Do(req)
// ...

...
```

Terminate the Agent

Terminate the agent right before the application exits:

```
appd.TerminateSDK()
```

Go SDK Reference

Use the AppDynamics Go SDK to instrument Google Go applications. The API includes functions for creating business transactions, transaction backends, exit points, and so on. See Use Go SDK.

Basic Types

The AppDynamics Go SDK defines these opaque types:

- `BtHandle`: A handle to an active business transaction
- `ExitcallHandle`: A handle to an active exit call

Config Struct

The `Config` struct contains settings used by the agent to connect to the AppDynamics Controller. The structure serves an equivalent function of the agent configuration files described in Agent-to-Controller Connections.

The `Config` struct is defined as follows:

```
type Config struct {
    AppName, TierName, NodeName string
    Controller Controller
    InitTimeoutMs int
    Initialized uint // a special field used by the underlying AppDynamics libraries. Do not use.
    Logging LoggingConfig
    UseConfigFromEnv bool
    EnvVarPrefix string
}
```

The structure is made up of these fields:

- `AppName`: Name of the business application to which this node belongs.
- `TierName`: Name of the tier to which this node belongs. A tier is a group of identical or similar nodes. An *originating tier* is the tier that receives the first request of a business transaction. A *downstream tier* is a tier that is called from another tier, thus continuing a business transaction.
- `NodeName`: The monitored application server to be monitored by this agent.
- `Controller`: Connection settings for the Controller. This struct is defined as:

  ```
  type Controller struct {
      Host string
      Port uint16
      Account, AccessKey string
      UseSSL bool
      HTTPProxy HTTPProxy
      CertificateFile
      CertificateDir
  }
  ```

  The `Controller` struct contains these fields:

  - `Host`: Controller host.
  - `Port`: Controller port; defaults to 8080.
  - `Account`: Name of your AppDynamics account.
  - `Access_key`: Key to your AppDynamics account. To find your access key, click the settings (gear) icon in the upper right corner of the AppDynamics UI, then click License.
  - `UseSSL`: Enable SSL communication with the controller; the default is false. Set to true to enable. If you set UseSSL to true, the default certificate, ca-bundle.crt, is used. To use your own certificate, specify your certificate file and directory in the CertificateFile and CertificateDir parameters.
  - `HTTPProxy`: If the agent needs to connect to the Controller via a local HTTP proxy, use this struct to specify connection settings for the proxy.
  - `CertificateFile` : The file name of the SSL certificate.
  - `CertificateDir` – The directory where the certificate is located.
- `InitTimeoutMs`: The initialization function, `InitSDK` relies on the Controller configuration to start business transactions. To prevent the initialization function from blocking your application, you can use this setting. It lets you instruct `InitSDK` whether to wait for the Controller configuration and if so how long to wait before starting business transactions. Valid values are:

  - N: Wait for up to N milliseconds for the Controller configuration.
  - 0: Do not wait for the Controller configuration. This is the default.
  - -1: Wait indefinitely until the Controller configuration is received by the agent.
- `Logging:` Logging settings for the controller. This struct is defined as:

```
const (
    APPD_LOG_LEVEL_DEFAULT LogLevel = iota
    APPD_LOG_LEVEL_TRACE
    APPD_LOG_LEVEL_DEBUG
    APPD_LOG_LEVEL_INFO
    APPD_LOG_LEVEL_WARN
    APPD_LOG_LEVEL_ERROR
    APPD_LOG_LEVEL_FATAL
)
type LoggingConfig struct {
    BaseDir             string
    MinimumLevel        LogLevel
    MaxNumFiles         uint
    MaxFileSizeBytes    uint
}
```

The `Logging` struct contains these fields:

  - `BaseDir:` The absolute path to the directory where log files are written. If left empty, the default is `/tmp/appd`.
  - `MinimumLevel`: One of the APPD_LOG_LEVEL_xxx constants that are shown above. The default is `APPD_LOG_LEVEL_INFO`.
  - `MaxNumFiles`: The maximum number of logging files to store on disk. Once this maximum is hit, older logs are rotated out.
  - `MaxFileSizeBytes`: The maximum size of the log files before they are rotated.
- `UseConfigFromEnv:` Set to `true` if you want the SDK to check for any configuration environment variables and use those configuration values for initialization. Note that because this happens on initialization, the environment variable settings override the configuration you set in your program.
- `EnvVarPrefix:` If `UseConfigFromEnv` is set to `true`, use this property to specify the prefix to use for environment variable names. The default prefix is `APPD_SDK`.

If the agent needs to connect to the Controller via a local HTTP proxy server, you need to configure the settings for the proxy server. You can do so using the `HTTPProxy` struct, defined as follows:

```
type HTTPProxy struct {
    Host string
    Port uint16
    Username, PasswordFile string
}
```

The `HTTPProxy` struct has the following fields:

- `Host:` Hostname or IP address of the HTTP proxy server
- `Port:` Port of the proxy server
- `Username:` Proxy server user name
- `PasswordFile:` Proxy server password file

ContextConfig Struct

You use the `ContextConfig` struct for calls that apply to multi-tenant Controller environments.

```
type ContextConfig struct {
    AppName string
    TierName string
    NodeName string
}
```

The `ContextConfig` struct has these fields:

- `AppName:` Name of the business application to which this node belongs.
- `TierName:` Name of the tier to which this node belongs. A tier is a group of identical or similar nodes. An *originating tier* is the tier that receives the first request of a business transaction. A *downstream tier* is a tier that is called from another tier, thus continuing a business transaction.
- `NodeName`: The monitored application server to be monitored by this agent.

AddAppContextToConfig

Add application context to the AppDynamics configuration for a multi-tenant Controller.

Format

```
func AddAppContextToConfig(cfg *Config, context string, contextCfg *ContextConfig) error
```

Parameters

- `cfg`: AppDynamics configuration object.
- `context:` A unique identifier used to refer to this context.
- `contextCfg:` An AppDynamics context configuration object indicating the business application, tier, and node name for this context.

InitSDK

Initialize the AppDynamics Go SDK. An instrumented application must call this function once, preferably during application startup.

Format

```
func InitSDK(cfg *Config) error
```

Parameter

`cfg:` AppDynamics configuration settings that enable communication between the agent and the Controller.

Returns

nil on success, otherwise an error value

TerminateSDK

Stop the AppDynamics Go SDK. Ends all active business transactions for this agent and stops agent metric reporting to the Controller.

Format

```
func TerminateSDK()
```

StartBT

Start a business transaction or continue an existing transaction.

Keep in mind that each application is limited to 200 registered business transactions, and each agent is limited to 50 registered business transactions. Unlike transactions discovered by other types of agents, business transactions that exceed the limit that are reported by the Go SDK are not included in the all other traffic grouping. This means that it's up to you to ensure that your agent does not create excessive business transactions. Use care to ensure that your implementation does not introduce the possibility of business transaction explosion.

Format

```
func StartBT(name, correlation_header string) BtHandle
```

Parameters

- `name:` The name for the business transaction. In the case of a continuing transaction in the current business application with a valid correlation header, the SDK uses the name from the header. Do not use the following characters in transaction names: { } [ ] | & ;
- `correlation_header:` A correlation header if this is a continuing transaction, else NULL. If specified, the correlation header has been generated by another AppDynamics agent and made available to this agent as a string. The correlation header provides information to enable this transaction to correlate with an upstream transaction.

Returns

An opaque handle for the business transaction that was started.

StartBTWithAppContext

Start a business transaction or continue an existing transaction in a multi-tenant Controller environment.

Format

```
func StartBTWithAppContext(context, name, correlation_header string) BtHandle
```

Parameters

- `context:` The application context name that this business transaction belongs to.
- `name:` The name for the business transaction. In the case of a continuing transaction in the current business application with a valid correlation header, the SDK uses the name from the header. Do not use the following characters in transaction names: { } [ ] | & ;
- `correlation_header:` A correlation header if this is a continuing transaction, else NULL. If specified, the correlation header has been generated by another AppDynamics agent and made available to this agent as a string. The correlation header provides information to enable this transaction to correlate with an upstream transaction.

EndBT

End the given business transaction.

Format

```
func EndBT(bt BtHandle)
```

Parameter

`bt:` The handle to the business transaction to end.

GetBT

Get a BT handle associated with the given guid by `appd_bt_store`.

Format

```
func GetBT(guid string) BtHandle
```

Parameter

`guid:` The globally unique identifier that was passed to `appd_bt_store`.

Returns

The handle to the business transaction associated with the given guid.

In the following cases the SDK logs a warning and returns a handle that you may safely use in other API functions but that will cause these functions to immediately return without doing anything:

- The SDK doesn't find a handle associated with the guid
- The call ended before the SDK could retrieve the handle

IsBTSnapshotting

Reports whether the agent is currently taking a transaction snapshot. Useful before calling `AddUserDataToBT` or `SetBTURL`, since those potentially expensive functions would do nothing if called when a snapshot is not being taken.

Format

```
func IsBTSnapshotting(bt BtHandle) bool
```

Parameter

`bt:` The handle to the business transaction to check for snapshotting.

Returns

true if the given business transaction is taking a snapshot. Otherwise, false.

SetBTURL

Set the URL for a snapshot, if one is being taken. It is safe to call this function when a snapshot is not occurring. When the given business transaction is not snapshotting, this function immediately returns. However, if extracting the data to pass to this function is expensive, you can use `IsBTSnapshotting` to check if the business transaction is snapshotting before extracting the data and calling this function. The `url` argument data should be either 7-bit ASCII or UTF-8.

Format

```
func SetBTURL(bt BtHandle, url string)
```

Parameters

- `bt:` The business transaction to add the user data to, if it is taking a snapshot.
- `url:` The value of the URL for the snapshot as 7-bit ASCII or UTF-8.

StoreBT

Store a BT handle in a global registry to retrieve later with `GetBT`. This is convenient when you need to start and end a business transaction in separate places, and it is difficult to pass the handle to the business transaction through the parts of the code that need it.

When the business transaction is ended, the handle is removed from the global registry.

Format

```
func StoreBT(bt BtHandle, guid string)
```

Parameters

- `bt:` The BT to store.
- `guid:` A globally unique identifier to associate with the given BT.

AddBTError

Add an error to a business transaction. Errors are reported as part of the business transaction. However, you can add an error without marking the business transaction as an error (e.g., for non-fatal errors).

Format

```
func AddBTError(bt BtHandle, level ErrorLevel, message string, mark_bt_as_error bool)
```

Parameters

- `bt:` The handle to the business transaction to which the error is added.
- `level:` The error level, from the following:
    - `APPD_LEVEL_NOTICE`
    - `APPD_LEVEL_WARNING`
    - `APPD_LEVEL_ERROR`
- `message:` Error message for this error.
- `mark_bt_as_error:` If true, the business transaction experiencing this error is marked as an error transaction. In this case, the business transaction is counted only as an error transaction. It is not also counted as a slow, very slow or stalled transaction, even if the transaction was also slow or stalled. If false, the business transaction is not marked as an error transaction.

AddUserDataToBT

Attaches user data to transaction snapshots generated for the specified business transaction.

The user data is added to the business transaction but reported only when a transaction snapshot is occurring. In the Controller UI, the user data appears in the USER DATA tab of the transaction snapshot details.

It is safe to call this function when a snapshot is not occurring. When the specified business transaction is not taking a snapshot, this function immediately returns.

If extracting the data to pass to this function is expensive, you can use `IsBTSnapshotting` to check if the business transaction is actually taking a snapshot before extracting the data and calling this function.

The data in the `value` argument should be either 7-bit ASCII or UTF-8.

Format

```
func AddUserDataToBT(bt BtHandle, key, value string)
```

Parameters

- `bt` –The business transaction to add the user data to, if it's taking a snapshot.
- `key` – The name of the user data to add to the snapshot as 7-bit ASCII or UTF-8.
- `value` – The value of the user data to add to the snapshot as 7-bit ASCII or UTF-8.

AddBackend

Add a backend to the business application.

This function fails if the type of the backend being added does not have at least one identifying property.

Format

```
func AddBackend(name, backendType string, identifyingProperties map[string]string, resolve bool) error
```

Parameters

- `name:` The name of the backend. Must be unique to the Go SDK instance.
- `backendType:` The type of the backend, from these options:
    - `APPD_BACKEND_HTTP`
    - `APPD_BACKEND_DB`
    - `APPD_BACKEND_CACHE`

    - APPD_BACKEND_RABBITMQ
    - APPD_BACKEND_WEBSERVICE
    - APPD_BACKEND_JMS
- identifyingProperties: A map of key/value pairs that contain the backend's identifying properties. The properties uniquely identify backend. In the Controller, these properties appear in the upper right panel of the backend dashboards. You must set at least one identifying property when you add a backend of one of the built-in exit call types. The valid properties vary per exit call type as indicated below.

Exit Call Type	Valid Identifying Properties
APPD_BACKEND_HTTP	"HOST", "PORT", "URL", "QUERY STRING"
APPD_BACKEND_DB	"HOST", "PORT", "DATABASE", "VENDOR", "VERSION"
APPD_BACKEND_CACHE	"SERVER POOL", "VENDOR"
APPD_BACKEND_RABBITMQ	"HOST", "PORT", "ROUTING KEY", "EXCHANGE"
APPD_BACKEND_WEBSERVICE	"SERVICE", "URL", "OPERATION", "SOAP ACTION", "VENDOR"
APPD_BACKEND_JMS	"DESTINATION", "DESTINATIONTYPE", and "VENDOR"

  For example, a key PORT would have a value of 3304.
- resolve: Set the property to false to prevent a downstream agent from resolving as this backend.
  If true, the default, an agent that detects a correlation header for an unresolved backend resolves itself as that backend. However, if the backend is actually an uninstrumented tier that is passing through the correlation header—for example, a message queue or proxy—you may wish the backend to show up distinct from the tier that it routes to. If false, correlation headers generated for exit calls to this backend will instruct downstream agents to report as distinct from the backend.

  For example, if you have Tier A connecting to uninstrumented Backend B, which routes to instrumented Tier C, the setting affects the flow map as follows:

    - True, the flow map will be A > C.
    - False, the flow map will be A > B > C.

Returns

nil on success, otherwise an error value

AddExitcallError

Add an error to the exit call.

Format

```
func AddExitcallError(exitcall ExitcallHandle, level ErrorLevel, message string, mark_bt_as_error bool)
```

Parameters

- exitcall: Handle to the exit call.
- level: The level of this error, from the following:
    - APPD_LEVEL_NOTICE
    - APPD_LEVEL_WARNING
    - APPD_LEVEL_ERROR
- message: Error message for this error.
- mark_bt_as_error: If true, the business transaction making the exit call that is experiencing this error is marked as an error transaction. In this case, the business transaction is counted only as an error transaction. It is not also counted as a slow, very slow or stalled transaction, even if the transaction was also slow or stalled. If false, the business transaction is not marked as an error transaction.

StartExitcall

Start an exit call to the specified backend as part of a business transaction.

Format

```
func StartExitcall(bt BtHandle, backend string) ExitcallHandle
```

Parameters

- bt: Handle to the business transaction making the exit call.
- backend:The destination backend of the exit call. AppDynamics does not automatically detect backends for Go applications, so you must specify the destination backend.

Returns

An opaque handle to the exit call that was started.

EndExitcall

Complete the exit call.

Format

```
func EndExitcall(exitcall ExitcallHandle)
```

Parameter

`exitcall:` Handle to the exit call being ended.

GetCRollupType

Specify how to roll up values for the metric over time.

Format

```
func GetCRollupType(rollUp RollupType)
```

Parameters

- `rollUp:` The approach for rolling up metrics. The following roll-up options are valid:
  - `APPD_TIMEROLLUP_TYPE_AVERAGE`: The average of all metric values across each node in the tier.
  - `APPD_TIMEROLLUP_TYPE_SUM`: Sum of all reported values in the minute.
  - `APPD_TIMEROLLUP_TYPE_CURRENT`: The last reported metric in the minute.

GetCClusterRollupType

Specify how to aggregate metric values for the tier (a cluster of nodes).

Format

```
func GetCClusterRollupType(rollUp ClusterRollupType)
```

Parameters

- `rollUp:` The approach for rolling up metrics. The following roll-up options are valid:
  - `APPD_CLUSTERROLLUP_TYPE_INDIVIDUAL`: The average of all metric values across each node in the tier.
  - APPD_CLUSTERROLLUP_TYPE_COLLECTIVE: The sum of all metric values for all the nodes in the tier.

GetExitcall

Get a handle to an exit call associated with a guid via `StoreExitcall`.

Format

```
func GetExitcall(guid string) ExitcallHandle
```

Parameter

`guid:` The globally unique identifier that was passed to `appd_exitcall_store()`.

Returns

The handle to the exit call associated with the given guid.

In the following cases the SDK logs a warning and returns a handle that you may safely use in other API functions but that will cause these functions to immediately return without doing anything:

- The SDK doesn't find a handle associated with the guid
- The call ended before the SDK could retrieve the handle

GetExitcallCorrelationHeader

Get the header for correlating a business transaction.

If a business transaction makes exit calls that you want to correlate across, retrieve the correlation header using this function and inject it into your exit call's payload.

The returned string is freed when the exit call ends. Do not free it yourself.

Format

```
func GetExitcallCorrelationHeader(exitcall ExitcallHandle) string
```

Parameter

`exitcall:` Handle to the exit call.

Returns

On success, returns a 7-bit ASCII string containing the correlation information. You can inject this string into the payload of the exit call. A downstream agent can then extract the header from that payload and continue the business transaction.

On error, returns the default header that prevents downstream business transaction detection.

SetExitcallDetails

Set the details string for an exit call. This can be used, for example, to add the SQL statement that a DB backend has executed as part of the exit call. This data is then visible in the exit calls details UI for the transaction snapshot.

Format

```
func SetExitcallDetails(exitcall ExitcallHandle, details string) error
```

Parameters

- `exitcall:` Handle to the exit call.
- `details:` An arbitrary string to add to the exit call.

Returns

Nil on success, otherwise an error value

StoreExitcall

Store an exit call handle in a global registry for later retrieval with `GetExitcall`. This is useful when you need to start and end a call in separate places, and it is difficult to pass the handle through the parts of the code that need it.

The handle is removed when the exit call, or the BT containing it, ends.

Format

```
func StoreExitcall(exitcall ExitcallHandle, guid string)
```

Parameters

- `exitcall:` The exit call to store.
- `guid:` A globally unique identifier to associate with the given call.

Example

```
ExitcallHandle ec = StartExitcall(bt, "authdb");
StoreExitcall(ec, "login-exit");
```

Install the Go SDK

Related pages:

- Download AppDynamics Software

To install the Go SDK:

1. Download the Go SDK distribution from the AppDynamics Downloads Portal.
2. Extract the Go SDK Zip in your Go workspace.

After installing the Go SDK, you are ready to instrument your Go application with the API.

IBM Integration Bus Agent

The IBM Integration Bus (IIB) Agent allows you to see the activity flow in your IIB instance. You can use the AppDynamics IIB Agent to do the following:

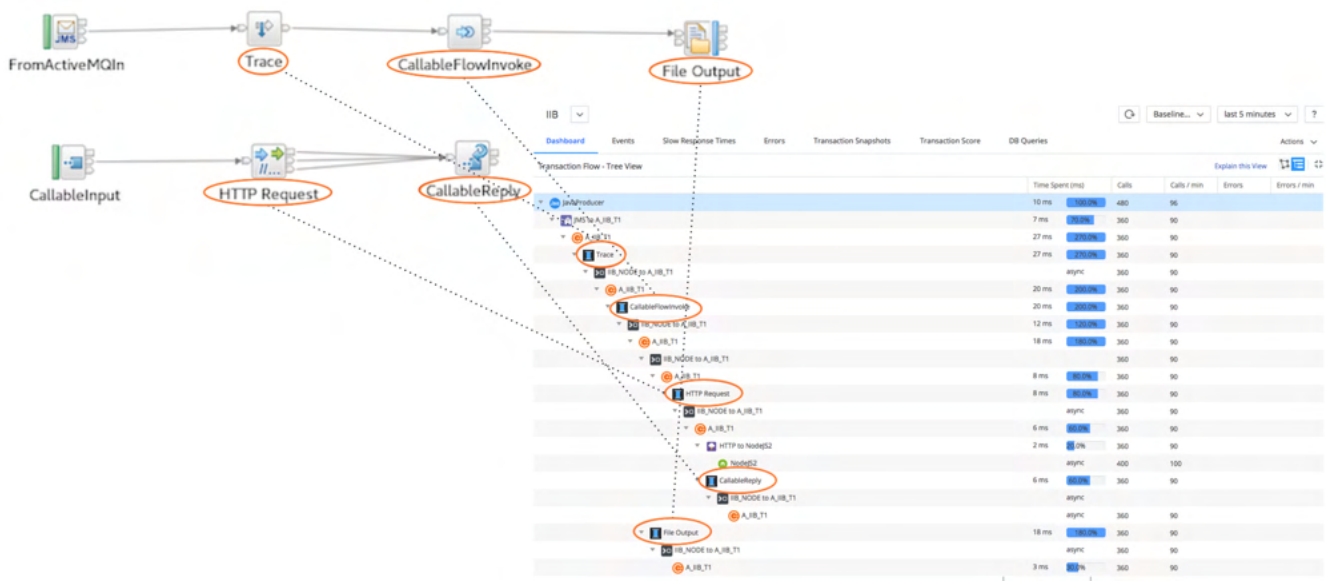
- Correlate business transactions that flow through IIB to identify where time is spent processing transactions in the larger end-to end architecture.
- Measure where business transaction processing time is spent within IIB flows, allowing operations staff and flow developers to identify any bottlenecks within the flows.

> This page describes IBM IIB in the context of it being monitored by AppDynamics. For a full description of IBM IIB and its capabilities, refer to the IBM product documentation.

How It Works

The agent supports inbound and outbound correlation for HTTP, JMS, and IBM MQ messaging nodes. You can identify business transactions that originate in the broker itself by the transaction name, which contains the message flow name and the message flow node name where the BT originated.

To measure where the time is spent within the flows, the agent models each message flow node as a thread (with thread names corresponding to the message flow node name). You can view the per-node timings in the tree view of the Business Transactions dashboard for any business transaction that passed through IIB, as shown below:



The IIB Agent also reports message flow node timing data, represented as thread segments in transaction snapshots, for business transactions that flow through IIB. Message flow node timing data is displayed in the Waterfall View.

Each broker is represented in the AppDynamics flow map as a tier, which is named as you specified in the configuration. Individual broker processes register with AppDynamics as nodes. The node names are generated from the Broker name and the Execution Group name.

IIB Supported Environments

IIB Agent Support

This page provides describes the supported versions, operating systems, and node types of the IIB agent. The AppDynamics IIB agent supports the Linux and AIX operating systems.

Operating Systems

The IIB agent supports these operating systems:

- Linux x86-64
- AIX v7.1 and v7.2

IIB Versions

The IIB Agent supports these versions of IIB for the Linux and AIX operating systems:

Operating System	IIB Version
Linux (Any Linux distribution based on glibc >= 2.5)	• IIB v9 • IIB v10 • ACE v11
AIX 7.1 (minimum patch level 7100-03-09-1717 or 7100-04-04-1717)	• IIB v9 • IIB v10
AIX 7.2	• IIB v9 • IIB v10 • ACE v11 (requires ACE Fix Pack >= v11.0.0.9)

IIB Node Types

The agent can continue business transactions detected upstream at these node types:

- SOAPInput
- HTTPInput
- JMSInput
- MQInput

The agent can detect and tag exit calls for downstream correlation at these node types:

- SOAPRequest
- HTTPRequest
- JMSOutput, JMSReply
- MQOutput, MQReply

> For MQ, we use the MQRFH2 message header to provide correlation. Any applications consuming MQ messages from IIB with the IIB agent must support the MQRFH2 header.

The agent can detect database backend calls for these node types:

- DatabaseRetrieve
- DatabaseRoute

All nodes are represented within AppDynamics Business Transactions as Threads. You can view the per node timings in the tree view of the Business Transaction dashboard and in the transaction snapshots.

Install the IIB Agent

Related pages:

- Download AppDynamics Software
- mqsichangeflowuserexits command
- cciRegisterUserExit
- SELinux Installation Issues

To begin monitoring IIB, you must install the IIB agent.

Install the Agent

1. Download the agent from https://download.appdynamics.com/download/.
2. Extract the IIB agent zip file into your chosen installation directory.

For cURL installation, see Download AppDynamics Software.

Configure the IIB Agent

The page guides you on how to integrate Appdynamics IIB Agent on Linux and AIX. The installation steps for IIB agent for IIB v9 and v10 are the same for Linux and AIX. The installation steps for IIB ACE 11 are provided in a separate tab.

> ACE is currently supported on Linux and AIX v7.2.

1. Specify the settings for the agent-controller communication. In the `controller-info.xml` file, set these properties:
    - `account-name`: Account name of the controller login.
    - `account-access-key`: Access key. This key is used for verification with the controller.
    - `application-name`: Name of the application that the IIB server belongs to.
    - `controller-host`: Hostname of the controller.
    - `controller-port`: Port number of the controller.
    - controller-proxy-host: Host name or IP address of any proxy required for the agent to connect to the controller.
    - controller-proxy-port: Port number of any proxy required for the agent to connect to the controller.
    - controller-proxy-username: Username for authenticating with the proxy.
    - controller-proxy-password: Password for authenticating with the proxy user.
    - controller-proxy-passwordfile: Full path name of a file containing the password for authenticating with the proxy user.
    - `controller-ssl-enabled`: SSL login. Set `1` to enable, `0` to disable.
    - `controller-cert-file`: Full path to the PEM format X509 certificate for SSL.
      See, Enable SSL for the C/C++ SDK for more information on obtaining the file.
    - `log-dir`: Path to the directory containing the IIB agent log files. The default path is `/tmp/appd`. Logs that are written before this configuration are logged in this path.
    - `log-level`: Level of the logs. Set this property to `trace|debug|info|warning|error`. `Error` is the highest priority and `trace` is the lowest priority.
    - `tier-name`: Name of the tier representing the broker.
    - `user-exit`: Exit name of the user. This must be in the alphanumeric format, as provided to the `mqsichangebroker` command.
    - <log-settings> </log-settings>: Log settings of the agent. For more information, see Configure Agent Log File Size.
    - disable-correlation: Enable or disable correlation of specific backends. Set 1 to enable, 0 to disable.
      disable-http-correlation: Set 1 to enable, 0 to disable.
      disable-jms-correlation: Set 1 to enable, 0 to disable.
      disable-mq-correlation: Set 1 to enable, 0 to disable.
    - flow-level-visibility-enabled: Flow level visibility option. Set 1 to enable, 0 to disable. The default value is 0. See IIB Agent Flow Level Visibility.
2. Run the following command to stop the broker. To configure user exits, your broker must be stopped.

    ```
    mqsistop <broker_name>
    ```

3. Install the IIB agent user exit. Ensure that the IIB agent user exit is enabled by default, for all the flows. Perform the steps based on the version applicable to you.

    > The agent starts and stops with the broker, if it is installed on the broker.

4. Run the following command to start the broker.

    ```
    mqsistart <broker_name>
    ```

For IIB 10, you can monitor a subset of your message flows. You can exclude flows that are of less importance from being monitored by running the following command:

```
mqsichangeflowuserexits <broker_name> -e <integrationServerName> -f <MessageFlow> -k <application_name> -i
<user_exit_name>
```

Partial Instrumentation of Brokers

Configure Agent Log File Size

AppDynamics IIB Agent creates a separate log file for each execution group. Therefore, each log continuously grows, even if the execution group is not instrumented.

Hence, a need to stop pushing the updates to the logs for non-instrumented execution groups arises. AppDynamics IIB Agent now allows you to configure the log file size according to your requirement.

The following setting in the configuration file, `controller-info.xml` allows you to configure the log file size of the agent:

```
<log-settings>
<log-setting broker="" execution-group="">
<max-file-size></max-file-size>
</log-setting>
</log-settings>
```

The settings are defined as follows:

Setting	Description
<log-settings></log-settings>	Header tag
<log-setting broker="" execution-group="">	Broker name and the execution group name, which must be strings
<max-file-size> < /max-file-size>	The maximum size of the log file. The format is <number><unit>. For example, 5 MB. Valid units are "MB" or "KB". The accepted range in KB is [200KB, 999KB] and in MB it is [1MB, 999MB]. Every execution group has its own log file.

However, you need to note the following guidelines for the configuration:

- If a broker is not named, the setting applies to all the brokers.
- If an execution group is not named, the setting applies to all the execution groups.
- An execution group name must be accompanied by a broker name.

If you include the log setting, log-rotation is set to 1, else the default value of 5 is considered as the log rotation.

For example, in the following configuration, there are three instances of log setting:

```
<controller-info>
<controller-host></controller-host>
<controller-port></controller-port>
<controller-ssl-enabled></controller-ssl-enabled>
<account-name></account-name>
<account-access-key></account-access-key>
<application-name></application-name>
<tier-name></tier-name>
<user-exit></user-exit>
<log-level></log-level>
<enable-extended-logging></enable-extended-logging>
<controller-cert-file></controller-cert-file>
<controller-cert-dir></controller-cert-dir>
<log-settings>
<log-setting broker="" execution-group="">
<max-file-size>200KB</max-file-size>
</log-setting>
<log-setting broker="Broker1" execution-group="EG1">
<max-file-size>2MB</max-file-size>
</log-setting>
<log-setting broker="Broker1" execution-group="">
<max-file-size>3MB</max-file-size>
</log-setting>
</log-settings>
</controller-info>
```

The order of preference is mentioned in the following table. The preference order is defined as `1 2 3 4`. Hence, if an order is invalid or does not match, then the next valid order is considered.

Order Number	Preferences	Order Template
1	Execution-Group	`<log-setting broker="Broker1" execution-group="EG1">`
2	Broker	`<log-setting broker="Broker1" execution-group="">`
3	Across multiple-broker	`<log-setting broker="" execution-group="">`
4	Default	Agent default is applied which is 10MB

The following are the valid values, for different execution groups when used with the above example configurations.

Broker Name	Execution Group Name	Valid Values (max-file-size)
Broker1	EG1	2MB
Broker1	All other EGs	3MB
All other Brokers	All other EGs	200KB

Troubleshooting

If you experience any functional issues with the agent, review the following information and supply it to the AppDynamics Support.

- The agent log. The IIB agent writes status information into the configured log directory, or `/tmp/appd` if the configuration has not been read at the time the message is logged. The status information can help diagnose issues with the agent.
- The system log. The IIB broker writes status messages into the system log. The messages include information about the loading and operation of user exits, such as the AppDynamics IIB agent.
- Abend files in the IIB errors directory. The default location is `/var/mqsi/common/errors`.
- Core files, if they exist.

If the user-exit name provided in the `controller-info.xml` file is not alphanumeric, the broker cannot load the agent and fails to start.

If you have an issue with the agent or if you want to disable it, perform the following:

1. Stop the broker `mqsistop <broker-name>.`
2. Perform the following based on the version applicable to you.

3. Start the broker `mqsistart <broker-name>.`

Disable the IIB Agent

Turn off MQRFH2 Injection Added by AppDynamics Monitor Agent Tool

For IIB Agents that use the MQ mechanism, the MQRFH2 message header is used to provide correlation to downstream tiers. Any applications consuming MQ messages from an upstream IIB agent must support the MQRFH2 header standards to provide end-to-end correlation.

In a situation where the downstream agent reports the error MQRC_HEADER_ERROR (MQRC 2142) while parsing the message from an IIB agent via MQ, you can perform one of the following:

- Update the downstream consumer to accept the `MQRFH2` header structure by upgrading the downstream software to a version that supports `MQRFH2`.
- Disable MQ correlation in IIB Agent by setting <disable-mq-correlation>1</disable-mq-correlation> in the controller-info.xml file and restart the agent.
- Change the `MQ PROPCTL` property to `NONE` on the destination queue. See https://www.ibm.com/support/knowledgecenter/en/SSFKSJ_7.5.0/com.ibm.mq.mig.doc/q008230_.htm.

Troubleshooting for IBM MQ .NET Clients

AppDynamics Monitor Agent tool adds an additional RFH header to the MQ message before adding the message to the queue. Because of this additional RFH header, IBM MQ .NET Clients may report an `MQRC_HEADER_ERROR (MQRC 2142)` while parsing the message. Following is the sample RFH header that gets added to MQMessage.

```
RFH ….x…″…3…MQSTR …….P…<usr><singularityheader
dt=″string″ >notxdetect
=True</singularityheader></usr>
```

The RFH2 structure begins with <usr><singularityheader dt=”string” >. This RFH header is added by the AppDynamics Monitor Agent tool and not by MQ.

Perform these steps to disable the additional header on the tool:
1. Go to **Configuration > Instrumentation > Backend Detection.**
2. Click on your application name, go to the .NET tab and click **Queues**.
3. Click **Edit Automatic Discovery** and in the popup, clear the **Correlation Enabled** checkbox.

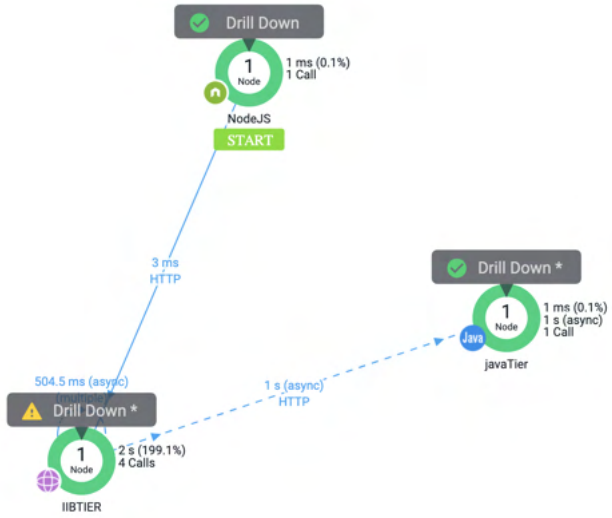
IIB Agent Flow Level Visibility

Flow Level Visibility feature captures the time spent on each message flow and any exit calls made from the message flow. Unlike the existing agent flow, Flow level does not capture the time spent on every node in the message flow. All the other features such as BT correlation, snapshots, exit calls, and so on remain unchanged. The difference is only visible in the Tree View in Business Transaction and Water Fall View in Transaction Snapshots. This difference is demonstrated with an example below:

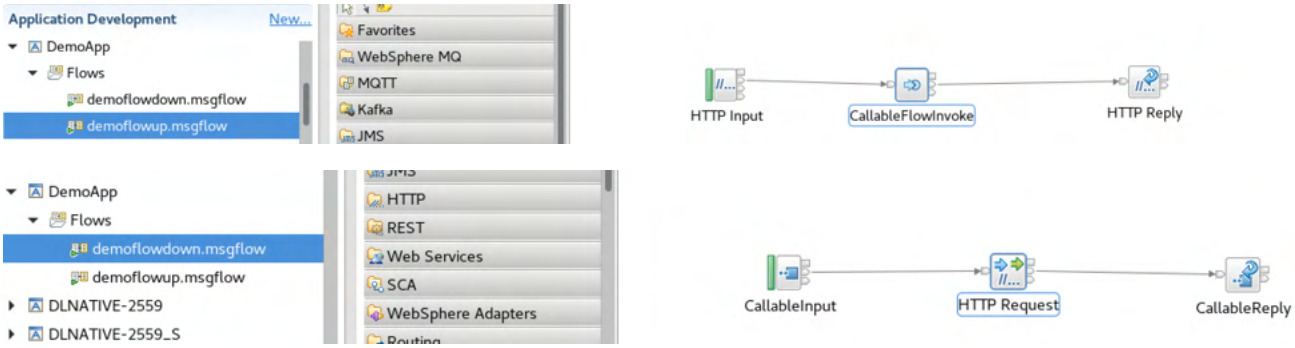
Existing IIB Agent Flow

In the existing IIB Agent default visibility, the agent gathers timings for each node in an IIB flow.

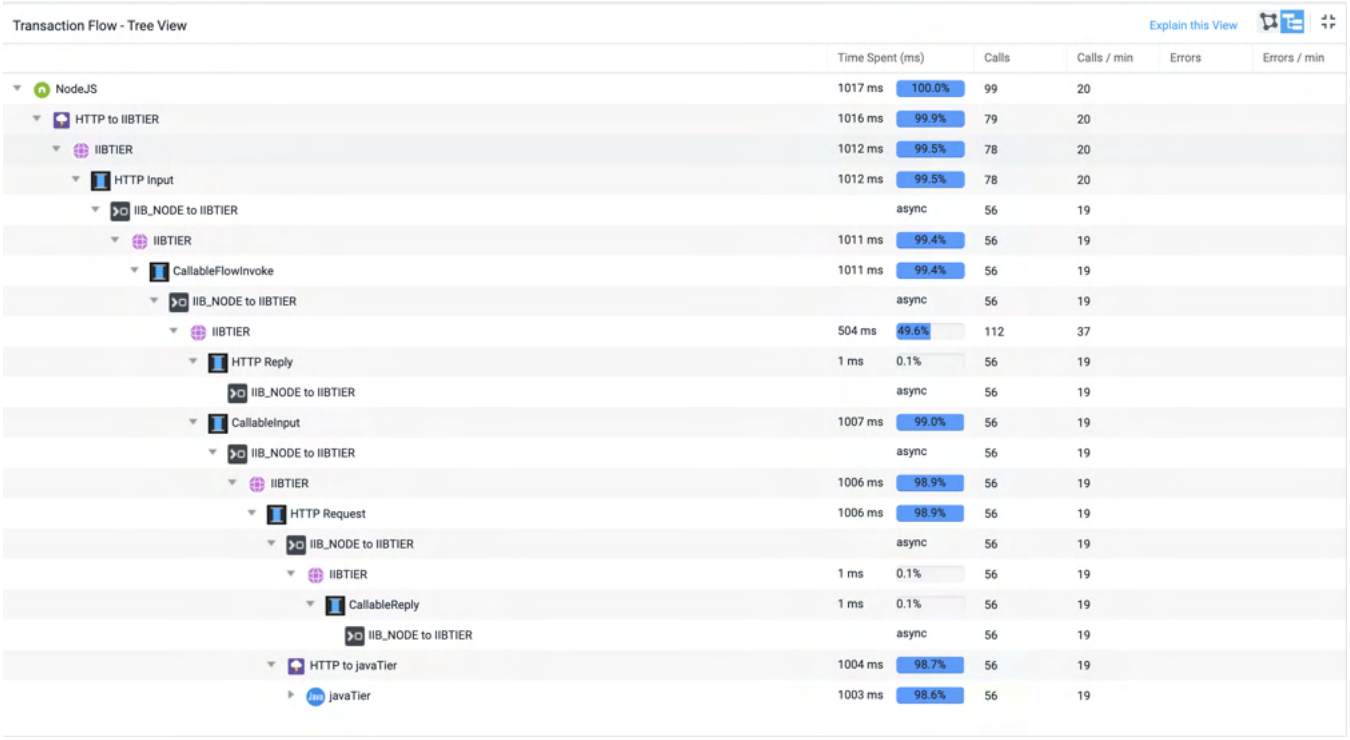
Consider the following illustration that shows the information captured by the existing framework for the flow **NodeJS--->IIB--->Java**:

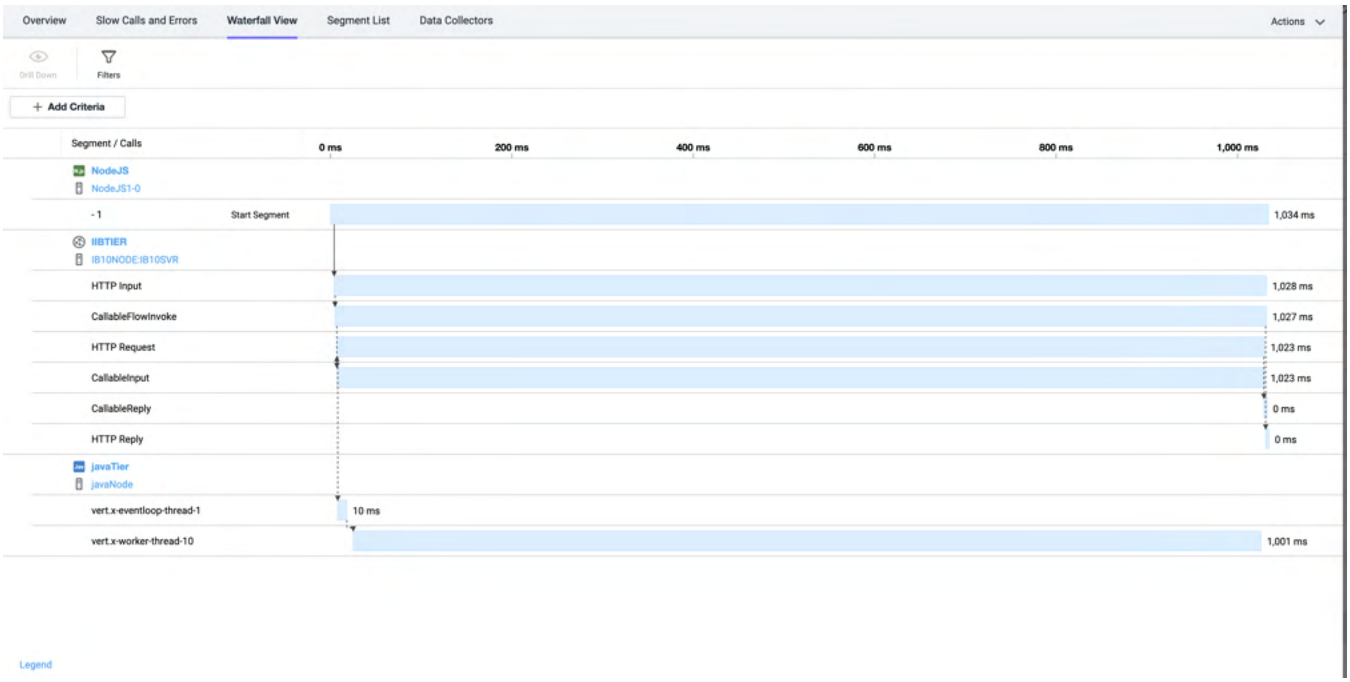


The broker within the IIB tier runs the following two message flows: demoflowup and demoflowdown. demoflowup makes a call to demoflowdown, which in turn, makes a backend call.



The following image displays the business transaction tree view and the transaction snapshot waterfall view for transactions flowing through the IIB application:

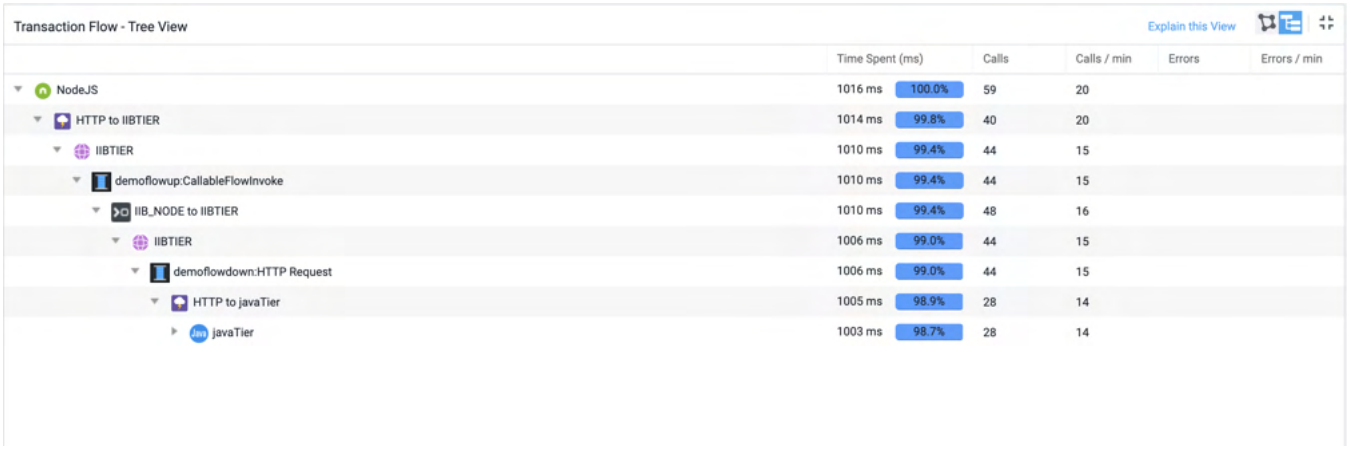


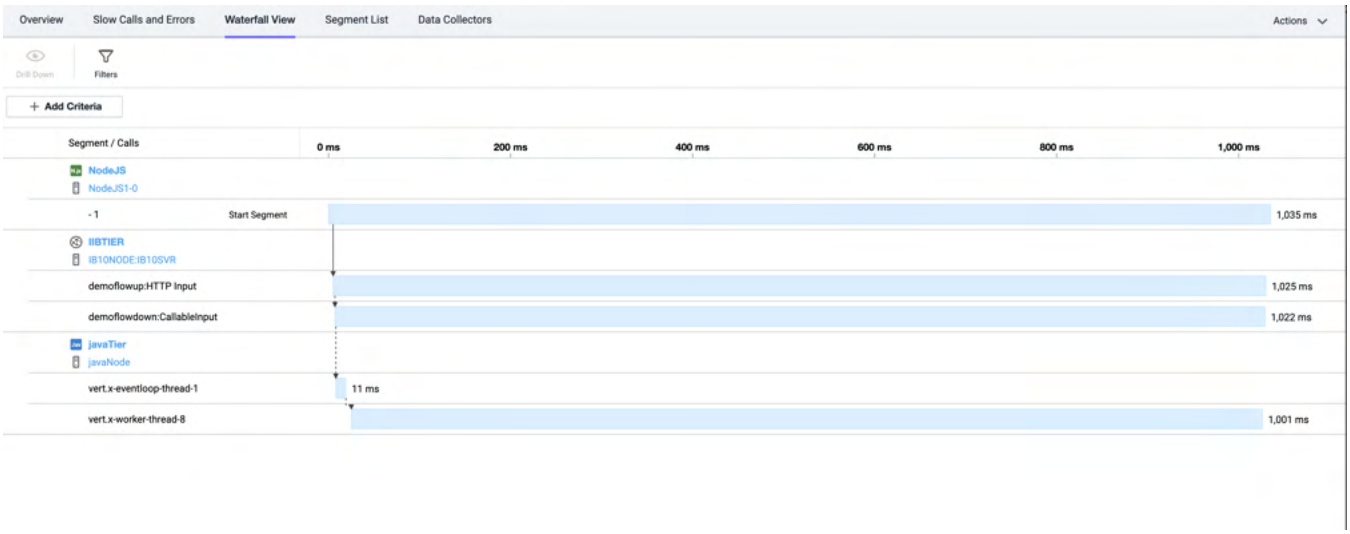


Flow Level Visibility

To reduce the cost of collecting the node level data, a new mode for the agent to provide flow-level visibility is introduced. In this mode, timings are collected only for flow start and end and any external calls made from within a flow. Therefore, the expected CPU cost of instrumenting the flows with the agent is reduced, especially for complex flows.

The business transaction tree and snapshot views from the sample application are provided below to illustrate the difference in data granularity with flow-level visibility enabled.





When you set the flow-level-visibility-enabled flag as 0 or 1, you might need to delete the BT in the tree view so that the tree view gets updated appropriately.

Deploy AppDynamics for Azure

AppDynamics integrates seamlessly with Microsoft Azure. AppDynamics offers visibility into .NET code execution and Microsoft Azure services out of the box, allowing you to troubleshoot performance bottlenecks and optimize the performance of your Microsoft Azure applications.

AppDynamics for Azure App Service

To install and deploy AppDynamics for Azure App Service:

- For Ops teams: Install the AppDynamics Azure Site Extension for .NET or Java:
  - See Install the AppDynamics Azure Site Extension for .NET
  - See Install the AppDynamics Site Extension for Java
- For Dev teams: Install the **AppDynamics.Agent.Azure.AppService.Windows** NuGet package and configure the .NET agent in Azure App Service. See Install the AppDynamics .NET Microservices Agent and Install AppDynamics for Azure App Service.

AppDynamics for Azure Cloud Services and Azure Service Fabric

To install and deploy AppDynamics for Azure Service Fabric, see Install AppDynamics for Azure Service Fabric.

If you are instrumenting Cloud Services, see Install AppDynamics for Azure Cloud Services.

Upgrade the AppDynamics for Windows Azure NuGet Package

If you are currently using the AppDynamics.WindowsAzure NuGet Package, you will need to upgrade to a new NuGet package, depending on your Azure platform. See Upgrade AppDynamics.WindowsAzure NuGet Package.

Install AppDynamics for Azure App Service

Related Pages:

- SELinux Installation Issues

There are two ways to install the .NET microservices agent into Azure App Service:

- Use the AppDynamics Azure Site Extension for .NET or Java:
  - See Install the AppDynamics Azure Site Extension for .NET
  - See Install the AppDynamics Site Extension for Java
- Use the AppDynamics for Windows Azure NuGet Package: See Install the AppDynamics .NET Microservices Agent

Azure Site Extension is used by Ops teams that may not have access to source files, or would not like to modify or recompile them, yet still want to monitor their Azure projects and solutions.

The NuGet Package is used by Dev teams to deploy the .NET agent so they can include the agent binaries, scripts, and configurations in their project and configure it using Visual Studio or other IDE.

Install the AppDynamics Azure Site Extension for .NET

You can use the Microsoft Azure Portal to add the AppDynamics Azure Site Extension to your Azure App Service web app. Azure Site Extension is used by Ops teams that may not have access to source files, or would not like to modify or recompile them, yet still want to monitor their Azure projects and solutions.

Prepare to Install

To install the AppDynamics for Microsoft Azure Site Extension, you need:

- Connection information for your AppDynamics Controller. See Agent and Controller Compatibility.
- A Microsoft Azure account.
- An Azure web app to monitor.

If you are upgrading from a previous version, see Upgrade the AppDynamics Azure Site Extension.

Add the AppDynamics Azure Site Extension

Add the AppDynamics Azure Site extension as you would any site extension for any Azure web app.

1. Log in to the Microsoft Azure Portal.
2. Browse to your web app.

   > To configure the .NET Agent using environment variables, add the environment variables before you install the AppDynamics Azure Site Extension. See Configure the Agent Using Environment Variables.

3. From the **DEVELOPMENT TOOLS** list, click **Extensions**.
4. Click **+Add** to install the version of the **AppDynamics Azure Site Extension** you want to add to your web app.
   After you install the AppDynamics Azure Site Extension, it appears in the installed extensions list.

Add the AppDynamics Azure Site Extension Using an ARM Template

You can deploy the AppDynamics Azure Site Extension to Azure App Services using an Azure Resource Manager (ARM) template.

The following procedure uses Visual Studio Community 2017.

To create and deploy an ARM template:

1. From your web application in Visual Studio, select **File > New Project**.
2. Click **Cloud**, then click **Azure Resource Group**, then click **OK**.
3. From the **Select Azure Template** dialog, click **Web App**, then click **OK**.
4. Under your newly-created Resource Group, click the Website.json file.
5. Under JSON outline in the left pane, right-click **resources**, then select **Add New Resource**.
6. In the Add Resource dialog box, select **Application Settings for Web Apps**, enter a name, then click **OK.**
7. Under the properties section, enter your AppDynamics Controller information. The following example shows the Website.json file with the application properties for AppDynamics.
8. Add a new apiVersion section with your Azure Site Extension details:

```
{
     "apiVersion": "2015-08-01",
     "name": "[variables('webSiteName')]",
     "type": "Microsoft.Web/sites",
     "location": "[resourceGroup().location]",
     "tags": {
       "[concat('hidden-related:', resourceGroup().id, '/providers/Microsoft.Web/serverfarms/', parameters('hostingPlanName'))]
       "displayName": "Website"
      },
      "dependsOn": [
        "[resourceId('Microsoft.Web/serverfarms/', parameters('hostingPlanName'))]"
      ],
      "properties": {
        "name": "[variables('webSiteName')]",
        "serverFarmId": "[resourceId('Microsoft.Web/serverfarms', parameters('hostingPlanName'))]"
      },
      "resources": [
        {
          "apiVersion": "2016-08-01",
          "name": "appsettings",
          "type": "config",
          "dependsOn": [
            "[resourceId('Microsoft.Web/Sites', variables('webSiteName'))]"
           ],
          "properties": {
            "appdynamics.controller.hostName": "<host_name>",
            "appdynamics.controller.port": "<port_name>",
            "appdynamics.controller.ssl.enabled": "true",
            "appdynamics.agent.accountName": "<account_name>",
            "appdynamics.agent.accountAccessKey": "[paraeters(<InKeyVault>)]",
            "appdynamics.agent.applicationName": "<application_name>",
            "appdynamics.agent.tierName": "<tier_name>",
            "appdynamics.agent.nodeName": "node_name>"
          }
        },
        {
          "apiVersion": "2015-08-01",
          "name": "AppDynamics.WindowsAzure.SiteExtension.4.5.release",
          "type": "siteextensions".
          "dependsOn":
            "[resourceId('Microsoft.Web/Sites', variables('webSiteName'))]"
          ]
        },
```

Here is the sample text for copying or pasting:

```
{
      "apiVersion": "2015-08-01",
      "name": "[variables('webSiteName')]",
      "type": "Microsoft.Web/sites",
      "location": "[resourceGroup().location]",
      "tags": {
        "[concat('hidden-related:', resourceGroup().id, '/providers/Microsoft.Web/serverfarms/', parameters
('hostingPlanName'))]": "Resource",
        "displayName": "Website"
      },
      "dependsOn": [
        "[resourceId('Microsoft.Web/serverfarms/', parameters('hostingPlanName'))]"
      ],
      "properties": {
        "name": "[variables('webSiteName')]",
        "serverFarmId": "[resourceId('Microsoft.Web/serverfarms', parameters('hostingPlanName'))]"
      },
      "resources": [
        {
          "apiVersion": "2016-08-01",
          "name": "appsettings",
          "type": "config",
          "dependsOn": [
            "[resourceId('Microsoft.Web/Sites', variables('webSiteName'))]"
          ],
          "properties": {
            "appdynamics.controller.hostName": "mycompany.saas.appdynamics.com",
            "appdynamics.controller.port": "443",
            "appdynamics.controller.ssl.enabled": "true",
            "appdynamics.agent.accountName": "mycompany",
            "appdynamics.agent.accountAccessKey": "[parameters('AppDAccessKeyInKeyVault')]",
            "appdynamics.agent.applicationName": "HelloWorldSecureAppDKey",
            "appdynamics.agent.tierName": "TestTier",
            "appdynamics.agent.nodeName": "TestNode"
          }
        },
        {
          "apiVersion": "2015-08-01",
          "name": "AppDynamics.WindowsAzure.SiteExtension.4.5.Release",
          "type": "siteextensions",
          "dependsOn": [
            "[resourceId('Microsoft.Web/Sites', variables('webSiteName'))]"
          ]
        },
```

Configure the Controller Connection

You have the following options to configure the .NET Agent to connect to the AppDynamics Controller:

- Configure the Controller connection using the Kudu console.
- Configure the Controller connection settings using environment variables.

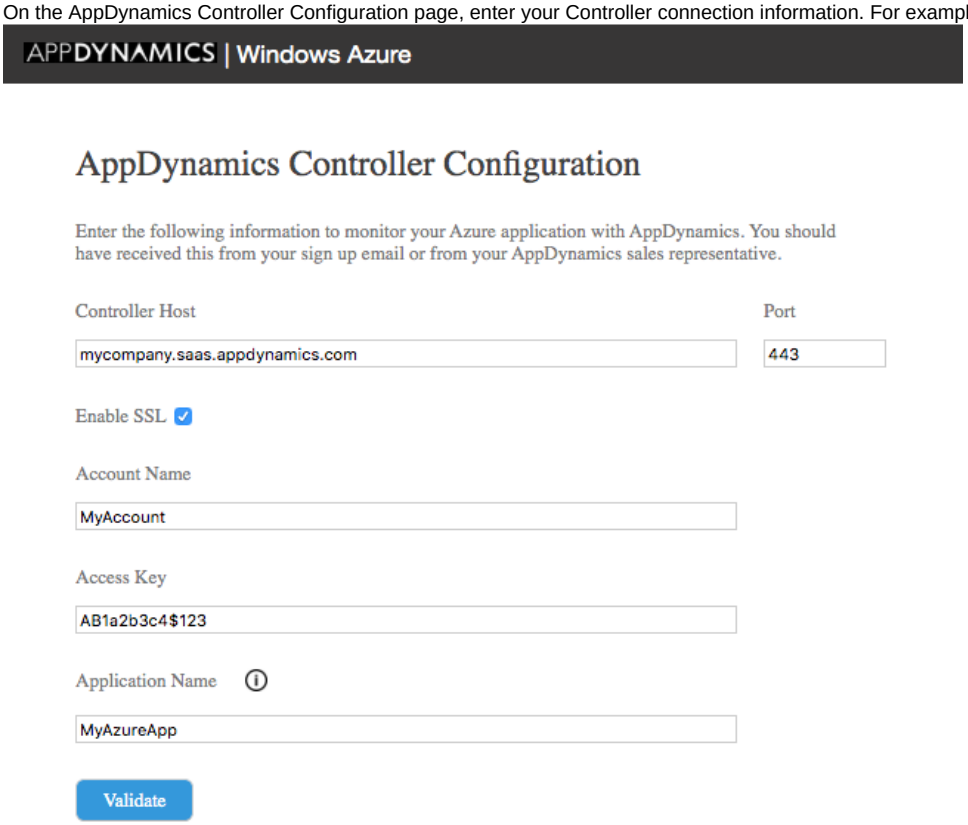
See Agent-to-Controller Connections.

Configure the Agent with the Kudu Console

When you add the AppDynamics Azure Site Extension to your web app, you can interactively configure the .NET Agent using the Kudu Console.

1. Navigate to the AppDynamics Controller Configuration page in the Kudu Console:
   http://{web app}.scm.azurewebsites.net/appdynamics/
   For example: https://myazureexample.scm.azurewebsites.net/appdynamics/

2. On the AppDynamics Controller Configuration page, enter your Controller connection information. For example:



3. Click **Validate** to test the connection to the AppDynamics Controller and save your settings.
4. Restart your web app.
   After you apply some load to your web app, you can view it on flow maps in the AppDynamics Controller UI.

Configure the Agent Using Environment Variables

You can use environment variables to configure the .NET Agent for unattended configuration.

To configure .NET Agents, add the environment variables before you install the AppDynamics Azure Site Extension:

1. Navigate to **SETTINGS > Application Settings** for your web app.
2. Add the .NET Agent environment variables under **App settings:**
   - appdynamics.controller.hostName: address for the AppDynamics Controller
   - appdynamics.controller.port: Controller port
   - appdynamics.agent.accountName: account name you use to log in to the Controller
   - appdynamics.agent.accountAccessKey: account key you use to log in to the Controller
   - appdynamics.agent.applicationName: business application name in the Controller
   - appdynamics.controller.ssl.enabled: set to `True` to enable SSL connection to the Controller; otherwise set to `False`.
   - appdynamics.proxy.hostName: name of the proxy host
   - appdynamics.proxy.authDomain: (Windows only) domain name of the proxy server
   - appdynamics.proxy.port: port number of the proxy
   - appdynamics.proxy.authName: name of the user who connects to the proxy
   - appdynamics.proxy.authPassword: password of the user who connects to the proxy
   - appdynamics.enable.tls12: set to True to enable transport layer security (TLS) 1.2; otherwise set to False.
3. Restart your web app. After you apply some load to your web app, you can view it on flow maps in the AppDynamics Controller UI.

Specify Which WebJobs to Monitor

Use the `APPDYNAMICS.PROCESSLIST` environment variable to specify which WebJobs the .NET Agent monitors.

Environment Variable: `APPDYNAMICS.PROCESSLIST`
Type: Strings separated by "|"
Default: None. When undefined, the agent instruments all WebJob running in the app service. When defined, the .NET Agent instruments only the specified processes.

Required: No

Usage Cases:

- Environment 1: An Azure app service with no WebJobs, where the Appdynamics .NET Agent site extension is installed and configured. After defining the environment variable `AppDynamics.ProcessList` with the value `w3wp.exe`, the `Daasrunner.exe` WebJob, which is a default WebJob that is added to all app services, is not instrumented.
- Environment 2: An Azure app service, with two WebJobs, `webjob1.exe` and `webjob2.exe`, where the Appdynamics .NET Agent site extension is installed and configured. After defining the environment variable `AppDynamics.ProcessList` with the value `w3wp.exe`, only the worker process serving the actual web app will be instrumented and no WebJobs will be instrumented. With the environment variable value set to `w3wp.exe|webjob1.exe`, the worker process serving the web app and the webjob1.exe are instrumented, but the webjob2.exe is not instrumented. With the `AppDynamics.ProcessList` removed from the App settings of the Azure app service, all the WebJobs, including `Daasrunner.exe` are are instrumented, including the worker process serving the web app.

Upgrade the AppDynamics Azure Site Extension

When you click on the Extensions tab for your web app, the Microsoft Azure Portal displays the currently installed version of the AppDynamics Azure Site Extension. The Update Available column of the installed extensions list indicates if there is a more recent minor release of the .NET Agent available. If so, you can click to update the extension from the list.

Upgrade a Major Version of the .NET Agent

AppDynamics maintains major release versions of the .NET Agent as separate site extensions. Therefore you need to uninstall the installed version of the AppDynamics Azure Site Extension before you upgrade to a new major release:

1. Log in to the Microsoft Azure Portal.
2. Stop your web app.
3. Click on the AppDynamics Azure Site Extension from the list of installed extensions and click **Delete** to uninstall it.
4. Install the new version of the AppDynamics Azure Site Extension as normal.

If you are upgrading from .NET Agent 4.2 and you used environment variable configuration, you must update your web app environment variables. See configure the agent using environment variables. Note that the `APPD_UNATTENDED` variable is no longer required.

Install the AppDynamics .NET Microservices Agent

Install the NuGet package **AppDynamics.Agent.Azure.AppService.Windows** to add the .NET microservices agent directly to projects you plan to deploy to Windows Azure. This package works for Azure App Service (formerly Azure Websites): Web Apps and API Apps.

Prepare to Install the NuGet Package

To install the AppDynamics for Windows Azure NuGet package you need:

- Connection information for your AppDynamics Controller 4.4
- Visual Studio >= 2012
- A Visual Studio solution to monitor
- Windows Azure SDK
- Windows Azure account

These instructions assume you are familiar with NuGet package management in Visual Studio and with the Microsoft Azure Portal. You can also try the step-through tutorial on how to instrument an App Service on the community knowledgebase.

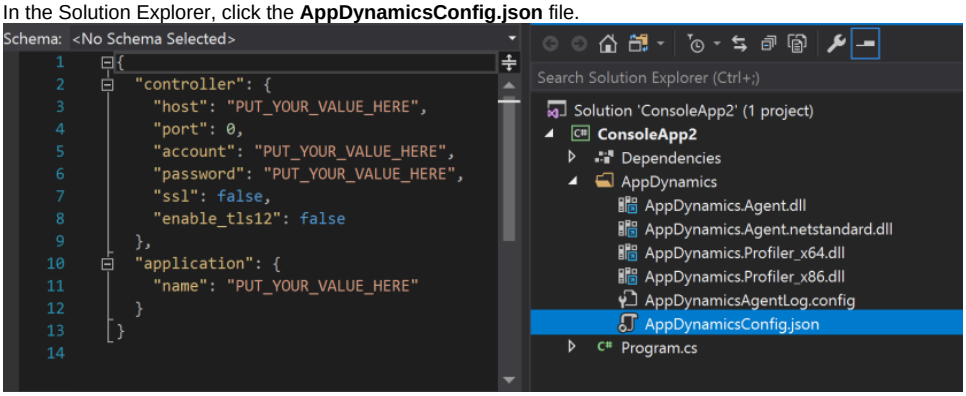
Add the .NET Microservices Agent to Your Azure Solution

Use the NuGet package manager to browse the nuget.org package source and install the **AppDynamics.Agent.Azure.AppService.Windows** package to your Azure solution in Visual Studio.

> For details about managing NuGet packages, see the documentation for your version of Visual Studio.

The **AppDynamics.Agent.Azure.AppService.Windows** package installation prompts you as follows:

1. The installer may ask you to verify your changes. If so, click **OK**.
2. Click **I accept** to agree to the terms of the license.
3. In the Solution Explorer, click the **AppDynamicsConfig.json** file.



4. Enter the connection information for your AppDynamics Controller in the area on the left.

For information about the AppDynamicsConfig.json file, see AppDynamicsConfig.json File.

Configure the Controller Connection

You have the following options to configure the .NET Agent to connect to the AppDynamics Controller:

- During development: As shown in the previous screenshot, you can enter your environment variables in the AppDynamicsConfig.json file, and save it in source control.
- During build: Define your msbuild parameters or environment variables that are passed to the AppDynamicsConfig.json file at build time. AppDynamicsConfig.json does exist at build time. So, if you're defining your msbuild parameters/env variables at build time, you will need to ignore it in source control so that the new AppDynamicsConfig.json file will be created.
- During runtime: Enter your environment variables in Azure.

By default, the .NET microservices agent names Azure tiers as site name. The .NET microservices agent names Azure nodes by machine name appended with the website hostname.

Monitor Virtual Applications of Azure Web Apps

Related links:

- Deploy AppDynamics for Azure

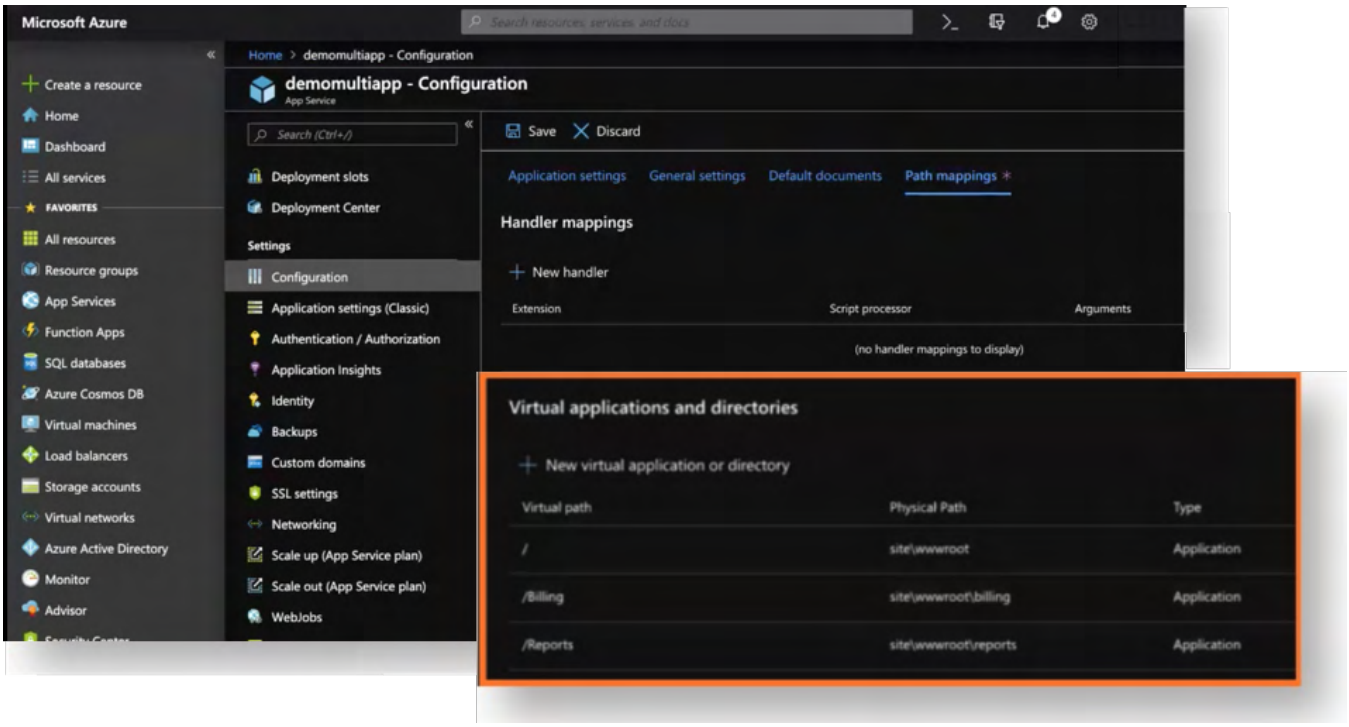
This page applies to the .NET Agent in the Azure App services environment. It describes how the .NET Agent by default names your virtual application tiers and nodes and also how you can customize tier names.

You can automatically name the tiers of virtual applications using either a default or custom method:

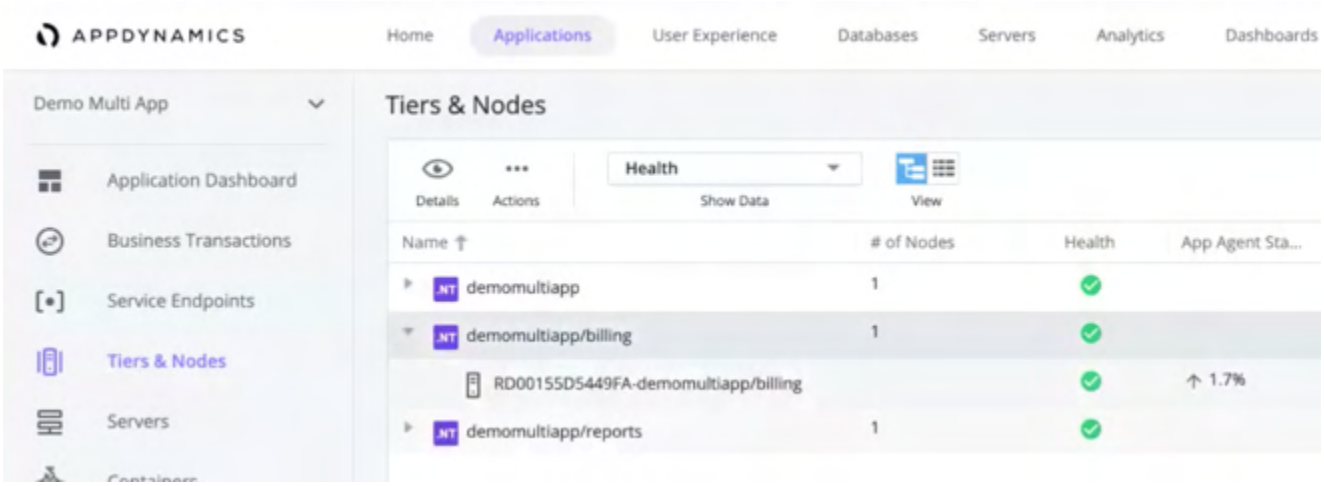
- Default: AppDynamics creates new tiers for each virtual directory. Each tier contains a node representing the virtual directory.
- Custom: When you specify a tier name in the `AppDynamicsConfig.json` file, all virtual directory applications will report as nodes under this tier.

Default Behavior

The following shows the Azure Web Apps configuration of the *demomultiapp* application with three virtual apps, the main application and two sub-applications.



Once you instrument the application with the .NET Agent, restart the application and apply load to it, the .NET Agent reports metrics for the application and virtual applications. In the Controller UI, each virtual application node appears under a separate tier. The name of the tier consists of the name of the application appended with the virtual path of the sub-application. For example, *demomultiapp/billing* as shown below. The name of the node is the same as the tier name prepended with the name of the virtual machine on which it runs.



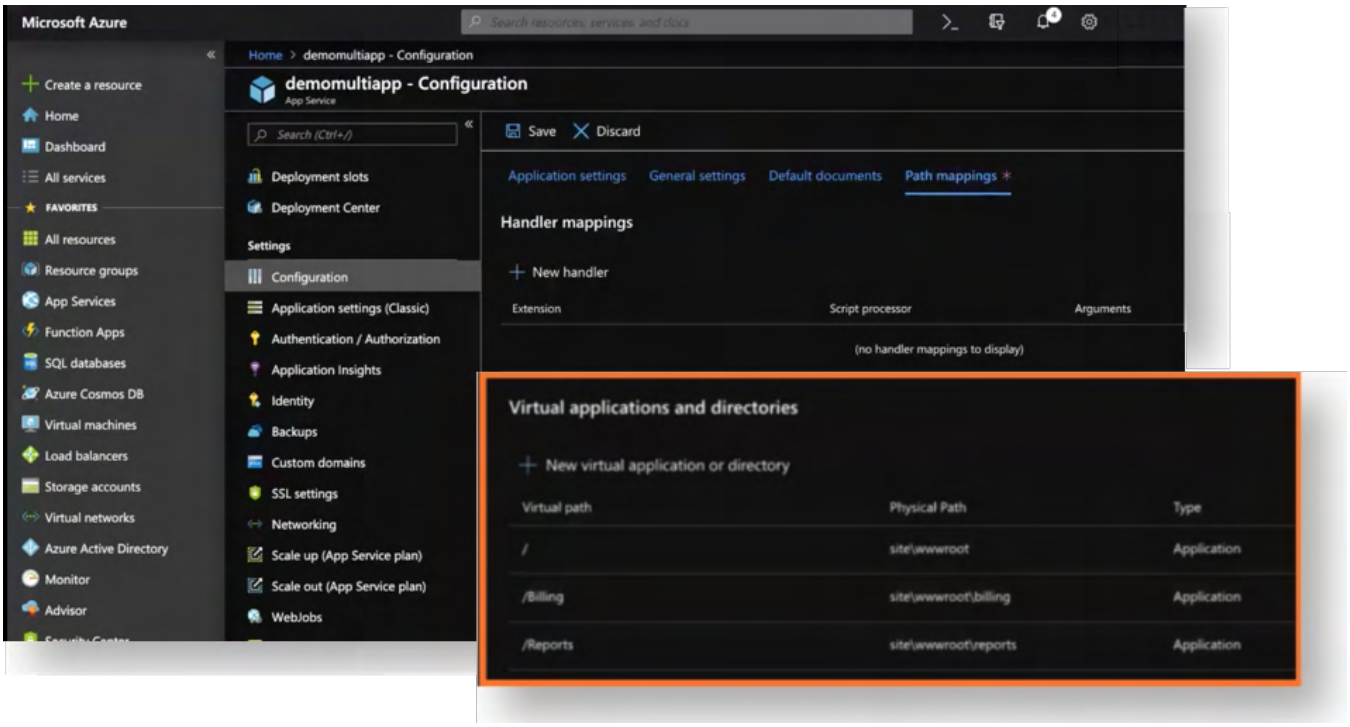
You can manually edit the tier name in the Controller UI.

Customize Tier Names

Rather than creating a tier for each virtual application, all virtual applications can report as nodes under a single tier. The tier name specified in the `AppDynamicsConfig.json` file sets the tier name.

- When you instrument your application using the .NET Agent site extension, the .NET Agent automatically instruments all virtual directories and applications. However, all AppSettings set at the root app are inherited by all virtual applications.
- For NuGet-based deployments, the agent uses the `AppDynamicsConfig.json` file deployed in the same path as the Profiler DLL and ignores the `AppDynamicsConfig.json` file settings for individual virtual apps in the deployment.

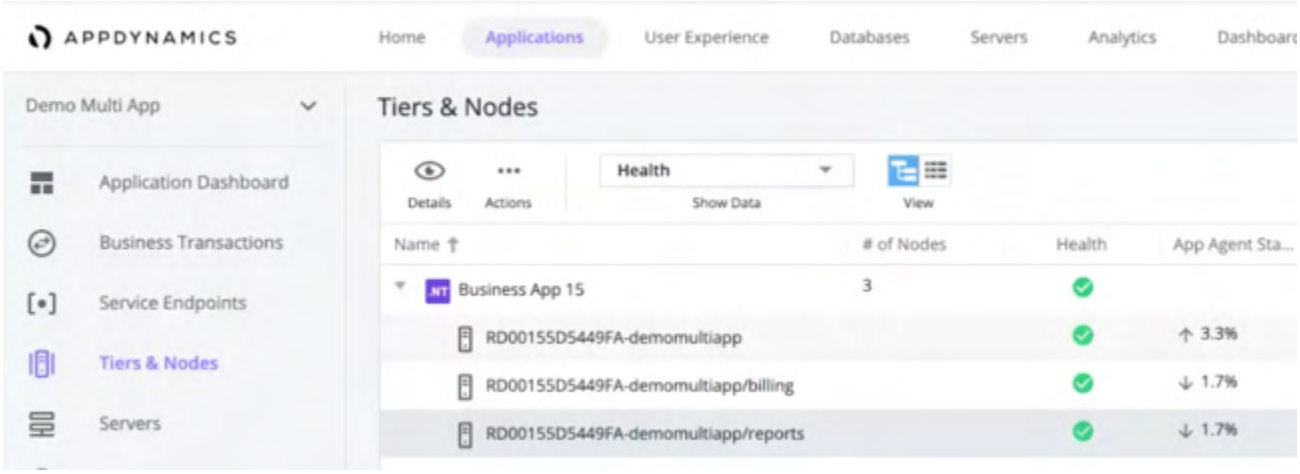
For example, in Azure Web Apps we have the following virtual app and sub-applications.



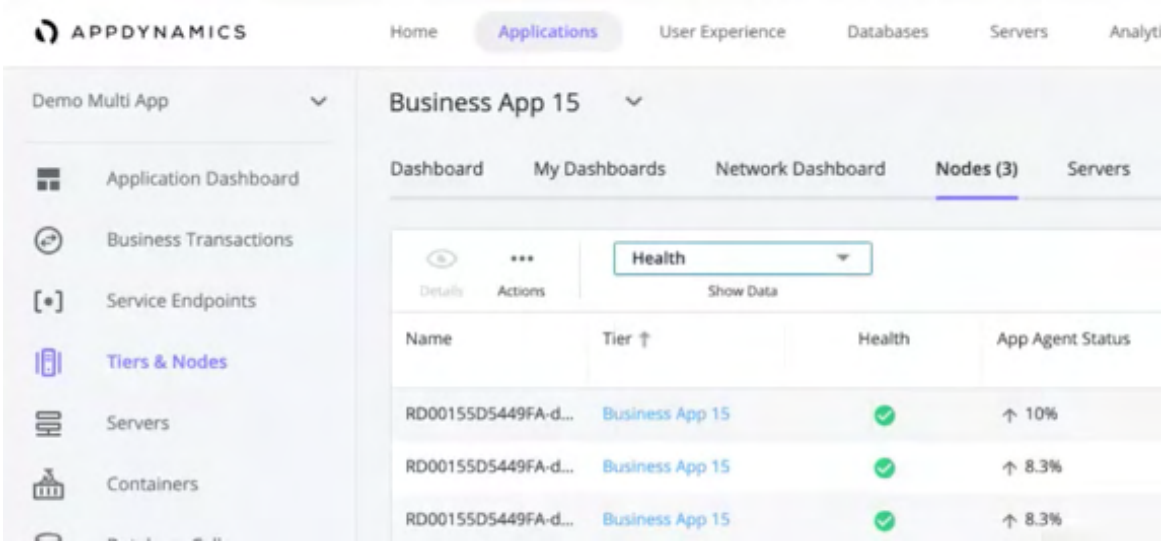
By default, the tier name of the application in the `AppDynamicsConfig.json` file is `null`. The following edited version of the `AppDynamics.Config.json` file shows a tier name of *Business App 15*. Note that the node name cannot be changed as its value is automatically updated as the application scales vertically and horizontally.

```
{
  "controller": {
    "host": "[redacted]",
    "port": [redacted],
    "account": "[redacted]",
    "password": "[redacted]",
    "ssl": [redacted],
    "enable_tls12": [redacted],
    "proxy": [redacted]
  },
  "application": {
    "name": "Demo Multi App",
    "tier": "Business App 15",
    "node": null
  },
  "instrumentors": {
    "customCorrelationConfig": null,
    "enable": [],
    "disable": []
  }
}
```

After the application is restarted, the virtual app tier name appears as *Business App 15*. When you expand the tier on the Tiers & Nodes Dashboard, you see the nodes of the virtual applications and the root application.



The Nodes Dashboard displays the nodes of the tier *Business App 15* in a similar manner.



Nodes of the virtual application are displayed in the Controller UI using the name of the virtual machine the app is running on, followed by the name of the virtual application as it appears in Azure Web Apps.

The current agent configuration file does not support targeting different virtual applications for customized tier naming, however, you can manually create .NET tiers and move the nodes to different tiers in the Controller UI.

Prevent Daas Instrumentation

You can prevent the agent from instrumenting the Daasrunner process by creating the environment variable `AppDynamics.Processlist` and setting it to `w3wp.exe`. This environment variable acts as an allowlist, where only the processes specified will be instrumented. Then delete the Daas tier and the Daasrunner node on the **Tiers & Nodes Dashboard**. You might also want to include WebJob processes in this list. See Install the AppDynamics Azure Site Extension for .NET.

Limitations

In this version, you cannot customize the tier names of virtual sub-applications in the `AppDynamicsConfig.json` file.

Also, this version does not support monitoring virtual apps together with deployment slots.

Instrument the .NET Agent with Azure Functions

AppDynamics serverless monitoring for Azure Functions gives you visibility into the performance of your applications that run as functions on Microsoft Azure. The .NET Agent supports Azure Functions hosted on App Service plans. Once installed, the .NET Agent automatically discovers business transactions in your Azure Functions.

You can monitor your applications running in Azure Functions exactly as you would any other application instrumented with the .NET Agent. Correlate business transactions between and through Azure Functions receive snapshots, create callgraphs, and integrate functions with End User Monitoring.

Before You Begin

Before you start instrumenting the .NET Agent with Azure Functions, make sure you meet the following requirements:

Microsoft Azure Requirements

- Applications hosted on the AppService plan
- Azure Functions versions 1.*x*, 2.*x*, and 3.*x*
- An instrumented Azure Function that is
    - implemented in .NET and
    - hosted on Windows OS

AppDynamics Requirements

- Microservice licenses
- .NET Agent version >= 4.5.16

Install AppDynamics Azure Site Extension

To add the AppDynamics Azure Site extension:

1. Log in to the Windows Azure Portal.
2. Browse to **Function App** and select the desired function.
3. Select **Platform Features** > **Site Extensions** > **+Add**.
4. Click **Choose Extensions** and select AppDynamics Azure Site Extension 4.5.
5. Click **Legal Terms**. Review AppDynamic's legal terms and conditions and select **OK**.
6. Click **OK** in the **Add Extension** menu to complete the installation.
7. Restart the function app.

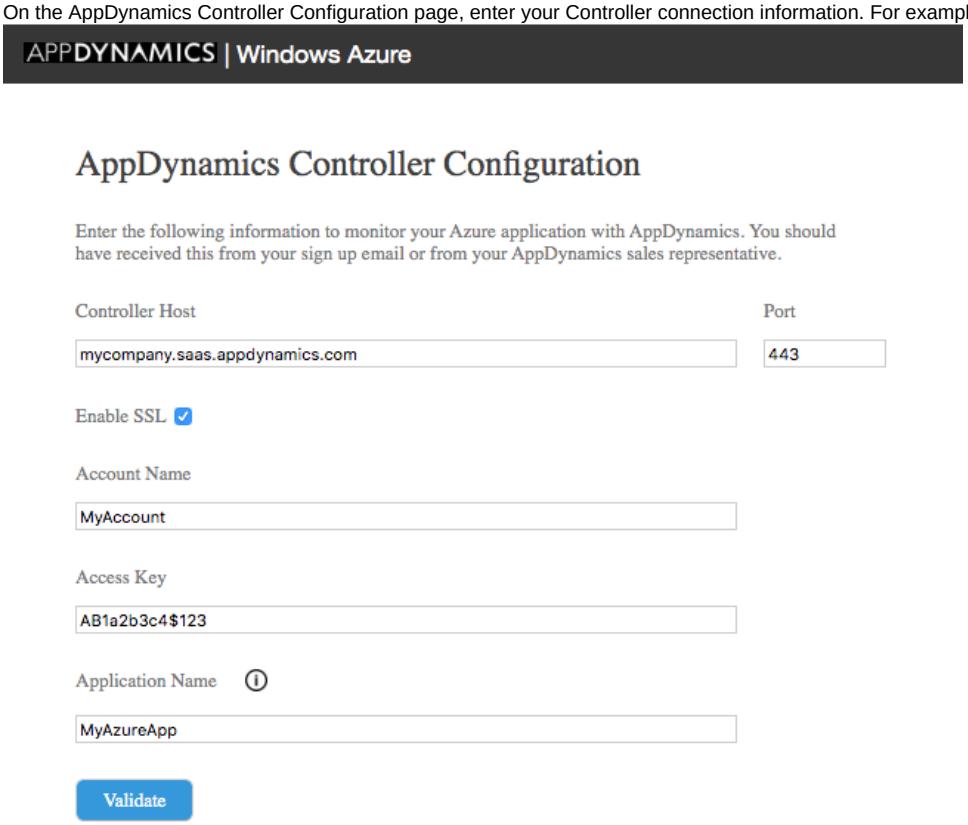
After you install the AppDynamics Azure Site Extension, it appears in the list of the installed extensions.

Connect the .NET Agent to the Controller

You can connect your Azure Function apps to your Controller using the Kudu Console.

1. Navigate to the AppDynamics Controller Configuration page in the Kudu Console:
   `http://{web app}.scm.azurewebsites.net/appdynamics/`
   For example: `https://myazureexample.scm.azurewebsites.net/appdynamics/`

2. On the AppDynamics Controller Configuration page, enter your Controller connection information. For example:



3. Click **Validate** to test the connection to the AppDynamics Controller and save your settings.
4. Restart your function app.

Verify Instrumentation

To verify Azure Function instrumentation, view the function on flow maps in the AppDynamics Controller UI.

Azure Function Names in the Controller UI

In the Controller, the business transaction names match the Azure Function name.

HTTP Trigger functions are named using two segments of the function URL. You can change the name of HTTP Trigger functions in custom transaction naming.

Automate .NET for Azure Functions Deployment

This page describes how to scale instrumentation of Azure Functions with the .NET Agent.

Add the AppDynamics Azure Site Extension Using an ARM Template

You can deploy the AppDynamics Azure Site Extension to Azure App Services using an Azure Resource Manager (ARM) template. This procedure uses Visual Studio Community 2017.

To create and deploy an ARM template:

1. From your web application in Visual Studio, choose **File > New Project**.
2. Click **Cloud**, then click **Azure Resource Group**, then click **OK**.
3. From the **Select Azure Template** dialog box, click **Web App**, then click **OK**.
4. Under your newly-created Resource Group, click the Website.json file.
5. Under JSON outline in the left pane, right-click **resources**, then choose **Add New Resource**.
6. In the Add Resource dialog box, select **Application Settings for Web Apps**, enter a name, then click **OK.**
7. Under the properties section, enter your AppDynamics Controller information. The following example shows the Website.json file with the application properties for AppDynamics.
8. Add a new resource for the Site Extension, as shown in the following example:

```
{
      "apiVersion": "2015-08-01",
      "name": "[variables('webSiteName')]",
      "type": "Microsoft.Web/sites",
      "location": "[resourceGroup().location]",
      "tags": {
        "[concat('hidden-related:', resourceGroup().id, '/providers/Microsoft.Web/serverfarms/', parameters
('hostingPlanName'))]": "Resource",
        "displayName": "Website"
      },
      "dependsOn": [
        "[resourceId('Microsoft.Web/serverfarms/', parameters('hostingPlanName'))]"
      ],
      "properties": {
        "name": "[variables('webSiteName')]",
        "serverFarmId": "[resourceId('Microsoft.Web/serverfarms', parameters('hostingPlanName'))]"
      },
      "resources": [
        {
          "apiVersion": "2016-08-01",
          "name": "appsettings",
          "type": "config",
          "dependsOn": [
            "[resourceId('Microsoft.Web/Sites', variables('webSiteName'))]"
          ],
          "properties": {
            "appdynamics.controller.hostName": "mycompany.saas.appdynamics.com",
            "appdynamics.controller.port": "443",
            "appdynamics.controller.ssl.enabled": "true",
            "appdynamics.agent.accountName": "mycompany",
            "appdynamics.agent.accountAccessKey": "[parameters('AppDAccessKeyInKeyVault')]",
            "appdynamics.agent.applicationName": "HelloWorldSecureAppDKey",
            "appdynamics.agent.tierName": "TestTier",
            "appdynamics.agent.nodeName": "TestNode"
          }
        },
        {
          "apiVersion": "2015-08-01",
          "name": "AppDynamics.WindowsAzure.SiteExtension.4.5.Release",
          "type": "siteextensions",
          "dependsOn": [
            "[resourceId('Microsoft.Web/Sites', variables('webSiteName'))]"
          ]
        },
```

Configure the Agent Using Environment Variables

If you want to configure the .NET Agent using environment variables, add the environment variables before you install the AppDynamics Azure Site Extension.

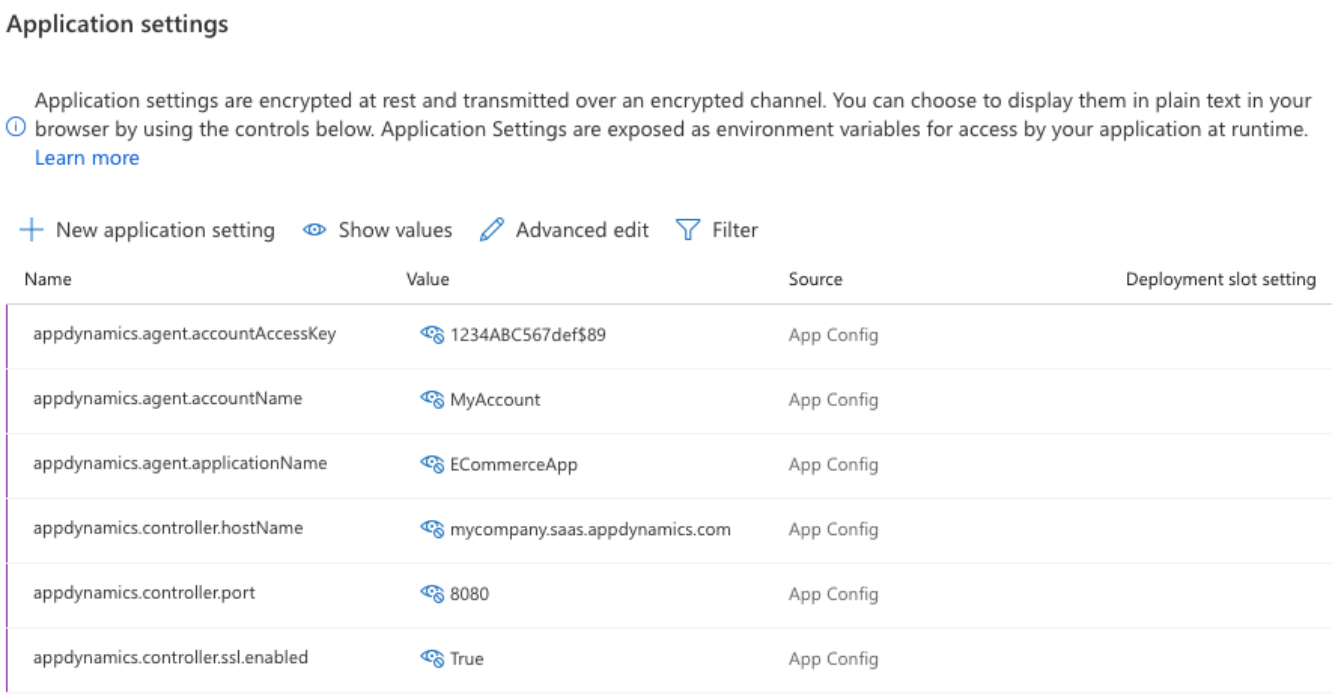
Configuring the .NET Agent using environment variables allows for unattended configuration. To configure agents in this manner, add the environment variables before you install the AppDynamics Azure Site Extension, as follows:

1. In the Azure Portal, open your Azure Function.
2. Navigate to **Function app settings > Manage application settings**.
3. Click **+New Application Setting** and enter your environment variables as name/value pairs.

The table below lists the available environment variables:

Environment Variable (Application Setting)	Description (Value)	Required
`appdynamics.controller.hostName`	Host associated with the Controller used by your Azure Function. Do not include http:// or https://	Yes
`appdynamics.controller.port`	Port associated with your Controller. If the port is left blank or is invalid, defaults to 443.	No
`appdynamics.agent.accountName`	Account name associated with the Controller used by your Azure Function.	Yes
`appdynamics.agent.accountAccessKey`	Access key for your Controller. See Agent-to-Controller Connections.	Yes
`appdynamics.agent.applicationName`	Name of the Azure Function App.	Yes
`appdynamics.controller.ssl.enabled`	Sets SSL connection to the Controller. Value "True" enables SSL, while value "False" disables SSL.	No

For example:



Install AppDynamics for Azure Service Fabric

The following instructions explain how to deploy the .NET microservices agent for AppDynamics for Azure Service Fabric.

Before you Install

From nuget.org, download the NuGet package `AppDynamics.Agent.Distrib.Micro.Windows` from https://www.nuget.org/packages/AppDynamics.Agent.Distrib.Micro.Windows/, then extract it to a folder. Then, use the following instructions to deploy the agent package.

Choose a procedure below to match your environment:

- Deploy the Package using Visual Studio
- Deploy the Package using another IDE

Deploy the Package using Visual Studio

1. From your editor, open `ServiceManifest.xml` in *each* folder in the published `application` root.
2. Add the following environment variables in each `CodePackage`:

```
<CodePackage ...>
  <EntryPoint>
    ...
  </EntryPoint>
  <EnvironmentVariables>
    <EnvironmentVariable Name="COR_ENABLE_PROFILING" Value="1" />
    <EnvironmentVariable Name="COR_PROFILER" Value="{39AEABC1-56A5-405F-B8E7-C3668490DB4A}" />
    <EnvironmentVariable Name="COR_PROFILER_PATH" Value="<PathToDeploymentFolder>/AppDynamics.
Profiler_x64.dll" />
  </EnvironmentVariables>
</CodePackage>
```

3. Make a copy of the `AppDynamicsConfig.json` file and rename it to `<executable_name>.AppDynamicsConfig.json`. For example, `<servicefabricapplicationname>.AppDynamicsConfig.json`.
4. Copy `AppDynamics.Agent.dll`, `AppDynamics.Profiler_x64.dll`, `AppDynamicsAgentLog.config`, `AppDynamicsConfig.json` from `<nuget_package>\content\AppDynamics` and add these files in the Visual Studio solution of each of the service projects at the top level, not under any subfolders.
5. Make a copy of `AppDynamicsConfig.json` and rename it to:`<executable_name>.AppDynamicsConfig.json`, for example, `<servicefabricapplicationname>.AppDynamicsConfig.json`. Put it into the root of each service project.

> When you rename the `.json` file to the application name, do not include `.exe` at the end of your application name.

6. Right-click on the AppDynamics related files and select **Copy Always** in **Properties**.
7. Update `<executable_name>.AppDynamicsConfig.json` with your configuration information:

```
{
 "controller":
 {
 "host":"",
 "port":0,
 "account":"",
 "password":""
 },
 "application":
 {
 "name":""
 }
}
```

Do not specify node; it will be assigned automatically; Specifying tier is optional, it could be assigned automatically.

For information about the `AppDynamicsConfig.json` file, see AppDynamicsConfig.json File.

The next steps are optional and should only be used if you need per service-instance control of the controller/application/tier.

1. Add the following environment variables to each CodePackage:

```
<EnvironmentVariable Name="appdynamics.controller.hostName" Value="< >" />
<EnvironmentVariable Name="appdynamics.controller.port" Value="<  >" />
<EnvironmentVariable Name="appdynamics.agent.accountName" Value="<  >" />
<EnvironmentVariable Name="appdynamics.agent.accountAccessKey" Value="<  >" />
<EnvironmentVariable Name="appdynamics.agent.applicationName" Value="<  >" />
<EnvironmentVariable Name="appdynamics_agent_tier_name" Value="<  >" />
```

2. Modify `ApplicationManifest.xml`. In each `ServiceManifestImport` and `CodePackage` folder add:
    - In `ServiceManifestImport`:

      ```
      <EnvironmentOverrides CodePackageRef="Code">
        <EnvironmentVariable Name="appdynamics.controller.hostName" Value="<AppD_ControllerHostName>" />
        <EnvironmentVariable Name="appdynamics.controller.port" Value="<AppD_ControllerPort>" />
        <EnvironmentVariable Name="appdynamics.agent.accountName" Value="<AppD_AccountName>" />
        <EnvironmentVariable Name="appdynamics.agent.accountAccessKey" Value="<AppD_AccountAccessKey>" />
        <EnvironmentVariable Name="appdynamics.agent.applicationName" Value="<AppD_ApplicationName>" />
        <EnvironmentVariable Name="appdynamics_agent_tier_name" Value="<AppD_Service_Name_TierName>" />
      </EnvironmentOverrides>
      ```

    - In `Parameters`:

      ```
      <Parameter Name="AppD_ControllerHostName" DefaultValue="<Your_Controller_Name>" />
      <Parameter Name="AppD_ControllerPort" DefaultValue="<Your_Controller_Port>" />
      <Parameter Name="AppD_AccountName" DefaultValue="<Your_Controller_Account_Name>" />
      <Parameter Name="AppD_AccountAccessKey" DefaultValue="<Your_Controller_Access_Key>" />
      <Parameter Name="AppD_ApplicationName" DefaultValue="<Your_Controller_App_Name>" />
      ```

    - For each service: `<Parameter Name="AppD_%SERVICE_NAME%_TierName" DefaultValue="<Tier_Name_For_Service>" />`
3. If you need to provide the AppDynamics configuration during application package deployment, you can now do it using the `-ApplicationParameter` switch of the `New-ServiceFabricApplication cmdlet`.

Deploy the Package using another IDE

1. From your editor, open `ServiceManifest.xml` in each folder in the published application root.
2. Add the following environment variables in each CodePackage:

```
<CodePackage ...>
  <EntryPoint>
    ...
  </EntryPoint>
  <EnvironmentVariables>
    <EnvironmentVariable Name="COR_ENABLE_PROFILING" Value="1" />
    <EnvironmentVariable Name="COR_PROFILER" Value="{39AEABC1-56A5-405F-B8E7-C3668490DB4A}" />
    <EnvironmentVariable Name="COR_PROFILER_PATH" Value=AppDynamics/AppDynamics.Profiler_x64.dll" />
   </EnvironmentVariables>
</CodePackage>
```

3. Using PowerShell, unpack `AppDynamics.Agent.dll`, `AppDynamics.Profiler_x64.dll`, `AppDynamicsAgentLog.config`, `AppDynamicsConfig.json` from <nuget_package>\content\AppDynamics to the code package folder that contains the executable you want to run.
4. Make a copy of the of the `AppDynamicsConfig.json` file and rename it to `<executable_name>.AppDynamicsConfig.json`. For example, <servicefabricapplicationname>.AppDynamicsConfig.json.

> When you rename the `.json` file to the application name, do not include .exe at the end of your application name.

5. Make a copy of `AppDynamicsConfig.json` and rename it to:<executable_name>.AppDynamicsConfig.json. For example, `<servicefabricapplicationname>.AppDynamicsConfig.json`. Put it into the root of each service project.
6. Update `<executable_name>.AppDynamicsConfig.json` with your configuration information:

```
{
 "controller":
 {
   "host":"",
   "port":0,
   "account":"",
   "password":""
 },
 "application":
 {
 "name":""
 }
}
```

Do not specify the node; it will be assigned automatically. Specifying the tier is optional; it could be assigned automatically.

For information about the AppDynamicsConfig.json file, see AppDynamicsConfig.json File.

The next steps are optional and should only be used if you need per service-instance control of the controller/application/tier.

1. Add the following environment variables to each CodePackage:

```
<EnvironmentVariable Name="appdynamics.controller.hostName" Value="" />
<EnvironmentVariable Name="appdynamics.controller.port" Value="" />
<EnvironmentVariable Name="appdynamics.agent.accountName" Value="" />
<EnvironmentVariable Name="appdynamics.agent.accountAccessKey" Value="" />
<EnvironmentVariable Name="appdynamics.agent.applicationName" Value="" />
<EnvironmentVariable Name="appdynamics_agent_tier_name" Value="" />
```

2. Modify `ApplicationManifest.xml`. In each `ServiceManifestImport` and `CodePackage` folder add:
   - In `ServiceManifestImport`:

```
<EnvironmentOverrides CodePackageRef="Code">
  <EnvironmentVariable Name="appdynamics.controller.hostName" Value="<AppD_ControllerHostName>" />
  <EnvironmentVariable Name="appdynamics.controller.port" Value="<AppD_ControllerPort>" />
  <EnvironmentVariable Name="appdynamics.agent.accountName" Value="<AppD_AccountName>" />
  <EnvironmentVariable Name="appdynamics.agent.accountAccessKey" Value="<AppD_AccountAccessKey>" />
  <EnvironmentVariable Name="appdynamics.agent.applicationName" Value="<AppD_ApplicationName>" />
  <EnvironmentVariable Name="appdynamics_agent_tier_name" Value="<AppD_Service_Name_TierName>" />
</EnvironmentOverrides>
```

   - In `Parameters`:

```
<Parameter Name="AppD_ControllerHostName" DefaultValue="<Your_Controller>" />
<Parameter Name="AppD_ControllerPort" DefaultValue="<Your_ControllerPORT>" />
<Parameter Name="AppD_AccountName" DefaultValue="<Your_Controller_AccountName>" />
<Parameter Name="AppD_AccountAccessKey" DefaultValue="<Your_Controller_AccessKey>" />
<Parameter Name="AppD_ApplicationName" DefaultValue="<Your_Controller_App_Name>" />
```

   - For each service: `<Parameter Name="<AppD_Service_Name_TierName>" DefaultValue="<Tier_Name_For_Service>" />`
3. If you need to provide the AppDynamics configuration during application package deployment, you can now do it using the `-ApplicationParameter` switch of the `New-ServiceFabricApplication cmdlet`.

Install AppDynamics for Azure Cloud Services

You can use Microsoft Visual Studio with the NuGet package **AppDynamics.Agent.Azure.CloudServices** to add the .NET Agent directly to Azure Cloud Services projects: Web Roles and Worker Roles.

Prepare to Install the NuGet Package

To install the AppDynamics for Windows Azure NuGet package you need:

- Connection information for your Agent-to-Controller Connections 4.4
- Visual Studio >= 2012
- A Visual Studio solution to monitor
  The user account running Visual Studio must have the following permissions to the solution:
  - **Read** and **Write** permissions to each **project directory**
  - **Read** and **Write** permissions to each **Visual Studio .NET C# Project** (*.csproj) file
  - **Read** and **Write** permissions to the **Service Definition** (ServiceDefinition.csdef) file
- Windows Azure SDK
- Windows Azure account

These instructions assume you are familiar with NuGet package management in Visual Studio and with the Microsoft Azure Portal. You can also try the step-through tutorial on how to instrument an App Service on the community knowledgebase.

If you are upgrading to a new version of the AppDynamics for Windows Azure NuGet Package, see Upgrade AppDynamics.WindowsAzure NuGet Package.

Add the .NET Agent to Your Azure Solution

Use the NuGet package manager to browse the nuget.org package source and install the **AppDynamics.Agent.Azure.CloudServices** package to your Azure solution in Visual Studio.

> For details about managing NuGet packages, see the documentation for your version of Visual Studio.

The **AppDynamics.Agent.Azure.CloudServices** package installation prompts you as follows:

- The installer may ask you to verify your changes. If so, click **OK**.
- Click **I accept** to agree to the terms of the license.

The package manager installs the .NET agent into your project.

The configuration file installs to `<project_root>/App_Data/AppDynamics/Config/config.xml`. Enter the connection information for your AppDynamics Controller in the config.xml file. For details about Controller connection settings, see Agent-to-Controller Connections.

NuGet - Solution

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsd="http://www.w3.org/2001/XMLSchema" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <controller host="" port="0" ssl="false" enable_config_deployment="false">
    <application name="" />
    <account name="" password="" />
  </controller>
  <machine-agent />
  <app-agents azure="true" azure-role-name="" azure-role-instance-id="">
    <IIS>
      <automatic />
    </IIS>
    <standalone-applications>
      <standalone-application executable="WaWorkerHost.exe">
        <tier name="" />
      </standalone-application>
    </standalone-applications>
  </app-agents>
</appdynamics-agent>

```

By default the .NET Agent names Azure tiers as role name for Cloud Services.

If you want to customize the tier name, edit config.xml under `<project_root>/App_Data/AppDynamics/Config.xml`. For more information and examples, see "Name IIS Tiers Manually" on Name .NET Tiers.

After you finish any configuration changes, publish your solution to Windows Azure. For Cloud Services solutions, you can put load on your published project and log on to the AppDynamics Controller and begin monitoring your solution.

Update .NET Agent Configuration for Cloud Services

If you have already published your solution, you can update the .NET Agent configuration for the currently installed version without upgrading the agent.

1. Edit the config.xml file to make configuration changes.
2. Edit the startup.cmd file under `<solution_root>/AppDynamics`.
3. By default, the APPD_AGENT_CONFIGUPDATE variable is set to true. If you want to modify the configuration on your Azure Cloud Services machine, and you want to prevent the AppDynamics script from overwriting it, set APPD_AGENT_CONFIGUPDATE to false.

Upgrade AppDynamics.WindowsAzure NuGet Package

If you are currently using the AppDynamics.WindowsAzure NuGet package to monitor your Azure solutions, you must upgrade to one of the newest packages on nuget.org, depending on your platform and the applications that you want to monitor. For a list of packages, see .NET Microservices Agent.

To upgrade your Azure NuGet package:

1. In Visual Studio or other IDE, uninstall the AppDynamics.WindowsAzure NuGet package.

   > For Azure App Service only: After you uninstall the NuGet package, you *must* delete the AppDynamics folder from the Azure portal and your Visual Studio solution. You may need to stop your application first before deleting this folder. During uninstallation, the webconfig modification that is responsible for filtering user requests against the AppDynamics folder is removed, but this does not remove the AppDynamics folder. You must manually delete this folder. You must also remove the AppDynamics-specific information from `apphostconfig.xdt`.

2. Install one of the new NuGet packages.

Release Notes and PDFs

Release Notes	Associated PDF
4.4.3 Azure Enhancements and Resolved Issues	

4.4.3 Azure Enhancements and Resolved Issues

Enhancements:

- Microsoft Orleans is supported on the .NET and .NET microservices agents.
- .NET Core 2.0 for Windows is supported on the .NET microservices agent.
- Support for Azure Service Fabric Remoting v2.

The following NuGet packages are now available. If you have used a previous version of an AppDynamics NuGet package, you will need to upgrade to the new version. See Upgrade AppDynamics.WindowsAzure NuGet Package.

AppDynamics.Agent.Distrib.Micro.Windows	AppDynamics NuGet package for .NET. This package *should not* be installed directly and is intended for download and file distribution. This package is used for Azure Service Fabric deployments. See Install AppDynamics for Azure Service Fabric for instructions.
AppDynamics.Agent.Windows	AppDynamics .NET Core microservices agent for Windows. Recommended for standalone installations. See Install the .NET Core Microservices Agent for Windows for deployment instructions. NOTE: This package does not support .NET Framework, only .NET Core for Windows.
AppDynamics.Agent.Azure.CloudServices	AppDynamics .NET agent for Azure Cloud Services. See Install AppDynamics for Azure Cloud Services.
AppDynamics.Agent.Azure.AppService.Windows	AppDynamics .NET microservices agent for Azure App Service. This package is intended for applications deployed to Azure App Service (Azure Web Apps and Azure API Apps). See Install the AppDynamics .NET Microservices Agent and Install AppDynamics for Azure App Service for instructions.

Machine Agents

Related Pages:

- SELinux Installation Issues

Machine Agents and Network Agents give you end-to-end visibility into the hardware and networks on which your applications run. These agents can help you identify and troubleshoot problems that can affect application performance such as server failures, JVM crashes, and network packet loss.

You use the Machine Agent to collect basic hardware metrics. The functionality provided by the Machine Agent includes:

- Reporting basic hardware metrics from the server OS, for example, %CPU and memory utilization, disk and network I/O
- Reporting metrics passed to the Controller by extensions
- Running remediation scripts to automate your runbook procedures. You can optionally configure the remediation action to require human approval before the script is started.
- Running JVM Crash Guard to monitor JVM crashes and optionally run remediation scripts

If you have a Server Visibility license, the Machine Agent provides the following additional functionality:

- Extended hardware metrics such as machine availability, disk/CPU/virtual-memory utilization, and process page faults
- Monitor internal or external HTTP and HTTPS services
- Group servers together so that health rules can be applied to specific server groups
- Define alerts that trigger when certain conditions are met or exceeded based on monitored server hardware metrics

SELinux Installation Issues

SELinux is a security mechanism that works on top of the native file and directory read/write/execute permissions within the Linux file system. It is available for most Linux distributions and is installed by default in newer RHEL (Red Hat Enterprise Linux) & Fedora distributions.

As SELinux may prevent the installation and/or operation of any software being executed, ensure that you create appropriate policy file for it.

> Ensure that you consult with your security team to determine the correct level of access for the APM.

SELinux allows you to set a finer granularity of restrictions on access and execution. This control is represented by "policy files", typically created and maintained by the SecOps team within your organization. For more details about SELinux, see https://selinuxproject.org/page/Main_Page.

The policy files are found in `/etc/sestatus.conf` by default. To determine if SELinux exists on your system, run the `getenforce` command which returns the string `Enforcing` if it is active.

Alternatively, you can run this command:

```
sestatus
```

which generates this output:

```
SELinux status: enabled
SELinuxfs mount: /selinux
Current Mode: permissive
Policy version: 16
sestatus
```

If `SELinux status` is `disabled`, it indicates that the system has not installed the package. However, if the status returned is `enabled`, but the `Current Mode` is `permissive`, then SELinux policy files are not enforced. To install and test the APM Agent:

- Set the mode to permissive and then enable it
- Follow the SELinux guidelines to create the appropriate policy statements for the agent in question

> For more details on how to customize your policy files, see https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/5/html/deployment_guide/sec-sel-policy-customizing.
>
> To enable SELinux, use the command `setenforce 1` to enable enforcing mode; to disable SELInux use `setenforce 0` (set to `permissive` mode).
>
> For more details about enabling/disabling SELinux, see: https://docs.fedoraproject.org/en-US/Fedora/11/html/Security-Enhanced_Linux/sect-Security-Enhanced_Linux-Working_with_SELinux-Enabling_and_Disabling_SELinux.html

Administer App Server Agents

These pages provide general information about installing App Server agents.

For Agent-to-Controller version compatibility information, see Agent and Controller Compatibility.

Planning Agent Deployment

When planning your deployment, you should consider whether to install agents manually or automatically.

If deploying a relatively small number of agents, you may choose to install the agent manually.
For larger environments involving hundreds of agents, you should develop an automated deployment strategy.

For specific agents, see these links:

- Java: Java Agent or Install the Java Agent
- .NET: .NET Agent or Install the .NET Agent for Windows
- Node.js: Node.js Agent or Install the Node.js Agent
- PHP: PHP Agent or Install the PHP Agent
- Python: Python Agent or Install the Python Agent
- Database Agent: Administer the Database Agent
- Standalone Machine Agent: Install the Machine Agent

For automated deployment guidelines, see Controller Deployment.

Encrypt Agent Credentials

Related pages:

- Encrypt Credentials in .NET Agent Configuration
- Java Agent Configuration Properties

This page provides an overview of securing agent credentials in AppDynamics.

AppDynamics agents store several types of credential information on disk, including:

- Controller account access key
- Controller keystore/agent truststore password
- Proxy server password

Secure Credential Store

You can use the Secure Credential Store to encrypt credentials in the agent configuration for environments where security policies require secure credentials on disk.

The Secure Credential Store is comprised of two components:

- `scs-tool.jar`: A utility to create the secure credential store, encrypt credentials, and obfuscate the credential store password.
- Secure credential keystore: A keystore for the secret encryption key.

The Secure Credential Store encrypts plain text using the strongest encryption available according to the system's encryption jurisdiction policy.

For the .NET Agent, see Encrypt Credentials in .NET Agent Configuration.

After you set up the Credential Keystore, you must specify the following settings.

For the Analytics Agent:

- `ad.secure.credential.store.filename`
- `ad.secure.credential.store.password`

See Analytics Agent Rules.

For the Java, Machine, and Database Agents:

- `<controller-ssl-enabled>`
- `<controller-keystore-filename>`
- `<controller-keystore-password>`

See Java Agent Configuration Properties, Machine Agent Properties, and Database Agent Properties.

Initialize the Secure Credential Store

Before you can encrypt or obfuscate passwords, you must run the Secure Credential Store utility to create the keystore for your secret encryption key. The agent distribution includes the Secure Credential Store utility in the following locations:

- Java Agent: `<javaagent_home>/verX.X.X.X/utils/scs/scs-tool.jar`
- Machine Agent: `<machine_agent_home>/lib/secure-credential-store-tool-1.3.0.0.jar`
- Database Agent: `<database_agent_home>/lib/scs-tool.jar`
- Analytics Agent: `<analytics_agent_home>/bin/tool/scs-tool.jar`

Run the Secure Credential Store utility `generate_ks` command with the following parameters:

- `filename`: Absolute path where the utility will create the secure credential keystore. Use this path for `<credential-store-filename>` in agent configuration.
- `storepass`: The secure credential keystore password. Use the obfuscated version of this password as the value for `<credential-store-password>` in agent configuration.

For example:

```
/<full path to application JRE>/bin/java -jar ./scs-tool.jar generate_ks -filename '/opt/appdynamics
/secretKeyStore' -storepass 'MyCredentialStorePassword'
```

The Secure Credential Store utility confirms it created and initialized the keystore:

```
Successfully created and initialized new KeyStore file: /opt/appdynamics/secretKeyStore
Verification - New KeyStore file: /opt/appdynamics/secretKeyStore is properly initialized.
```

Encrypt Passwords

To encrypt passwords using the secure credential store utility, run the `encrypt` command with the following parameters:

- `filename`: Absolute path to the secure credential keystore file.
- `storepass`: Password for the secure credential keystore. You can use either a plain-text password or a password that has been obfuscated as described in the following section.
- `plaintext`: Any plain text to encrypt. For instance, account access key or password.

The following example uses a plain-text password—`storepass` argument—for the secure credential keystore:

```
/<full path to application JRE>/bin/java -jar ./scs-tool.jar encrypt -filename '/opt/appdynamics
/secretKeyStore' -storepass 'MyCredentialStorePassword' -plaintext 'MyAccessKeyOrPassword'
```

The same example uses an obfuscated password:

```
/<full path to application JRE>/bin/java -jar ./scs-tool.jar encrypt -filename '/opt/appdynamics
/secretKeyStore' -storepass 's_gsnwR6+LDch8JBf1RamiBoWfMvjjipkrtJMZXAYEkw8=' -plaintext 'MyAccessKeyOrPassword'
```

The Secure Credential Store utility writes out an encrypted password for use in agent configuration files:

```
r9iDWPzHRCNDM1B6KTag4A/cA5B4pouVPkv48ovRm6c=
```

Obfuscate the Secure Credential Store Password

In order to access the secret key in the secure credential keystore, the agent needs the obfuscated credential store password.

Run the secure credential store utility `obfuscate` command with the following parameter:

- `plaintext`: The plain text secure credential keystore password.

For example:

```
/<full path to application JRE>/bin/java -jar /opt/appdynamics/scs-tool.jar obfuscate -plaintext
'MyCredentialStorePassword'
```

The Secure Credential Store utility writes out an obfuscated password for use in the `<credential-store-password>` in agent configuration.

For example:

```
s_gsnwR6+LDch8JBf1RamiBoWfMvjjipkrtJMZXAYEkw8=
```

Encrypt a Plain Text Property

After you obfuscate the Secure Credential Store password, you can encrypt plain text properties.

The following example demonstrates how to encrypt properties in the Analytics Agent:

```
$ /<full path to application JRE>/bin/java -jar scs-tool.jar encrypt -filename /opt/appdynamics/secretKeyStore -
storepass 'Welcome' -plaintext 'MyAccountAccessKey'
```

The property generates an encrypted credential:

```
-001-24-pFoSE/xdPcinkBj9iiKvpQ==Rznx8Kt3sPZHQnKfYyubVuhorrBEbYFtDTPm8c/1kFO+Z2eR2WEHtBRg4vy1GyvJ
```

Sample Agent Configuration

The following example demonstrates the agent configuration properties for the Secure Credential Store. For more information, see the agent-specific configuration property documentation.

Java Agent Configuration

```
<?xml version="1.0" encoding="UTF-8"?>
<controller-info>
        ...
    <!-- Encrypted account access key -->
    <account-access-key>r9iDWPzHRCNDM1B6KTag4A/cA5B4pouVPkv48ovRm6c=</account-access-key>

    <!-- Encrypted Controller keystore / agent trust store password -->
    <controller-keystore-password>Tw49bd0hdCMBoQ5pfMMuYA/cA5B4pouVPkv48ovRm6c=</controller-keystore-password>

    <!-- Enable the Secure Credential Store -->
    <use-encrypted-credentials>true</use-encrypted-credentials>

    <!-- Path to they secure credential keystore -->
    <credential-store-filename>/opt/appdynamics/secretKeyStore</credential-store-filename>

    <!-- Obfuscated secure credential keystore password -->
    <credential-store-password>n/8GvAZsKk4gM3Z6g+XQ1w==</credential-store-password>
        ...
</controller-info>
```

Analytics Agent Configuration

```
ad.credential.store.filename=/opt/appdynamics/secretKeyStore
ad.credential.store.password=s_gsnwR6+LDch8JBf1RamiBoWfMvjjipkrtJMZXAYEkw8=
```

Encrypt Data on the Analytics Agent

You can encrypt any data on the Analytics Agent using `secure://<your-encrypted-credentials>`. You can encrypt data in the Analytics Agent properties file or in System Properties.

The following example demonstrates how to encrypt `http.event.accessKey` in the Analytics Agent properties file.

```
http.event.accessKey=secure://-001-24-Dr9FQGC179o4vPnuljnx8A==ZGVw/P4OONvpUidIhJ2u78FpRVVW8fbgr8J1HBHXwnE=
ad.secure.credential.store.filename=/opt/appdynamics/secretKeyStore
ad.secure.credential.store.password=s_gsnwR6+LDch8JBf1RamiBoWfMvjjipkrtJMZXAYEkw8=
```

Manage App Agents

From the AppDynamics Agents page, you can manage, reset, and disable app agents connected to the Controller, and view agent status and information.

Permissions

To manage app agents, you must belong to a role with the Account level permission:

- Administer users, groups, roles, authentication, and so on
- View license
- View AppDynamics agents
- Use Agent Download Wizard

The predefined Account Owner role includes the required permission.

To access app agent administration settings, click **Settings** > **AppDynamics Agents** > **App Server Agents**.

Associate App Agents with a Business Application

If you start an application server with an app agent without specifying the business application, the agent appears in the App Server Agents tab as an unassociated agent. You can associate an agent with an application manually:

1. From the agents list in the App Server Agents tab, select the unassociated app agent from the list.

   In the **View** menu, click **Agents not associated with an Application** to filter the list of App Server Agents.

2. Click **Associate with Application**. This button is enabled only for app agents that are connected to the Controller but not associated with a business application.

Reset App Agents

To reset app agents, users need the "Agent Advanced Operation" permission.

Resetting the app agent causes the agent to register itself with the Controller in the same way it does at JVM or application startup, but without restarting the JVM or application. Resetting the app agent purges in-memory data for the agent. It also applies certain configuration changes to the app agent, such as app agent node property changes.

Resetting an app agent causes the Controller to:

- Purge data such as in-memory business transactions and metrics, exit calls, and registration information for the agent
- Reset the business transaction limit counter to zero for the selected agent

Resetting an agent does not re-instrument or remove existing instrumentation. After a reset, the agent re-registers business transactions and backends and it creates new metrics. You may lose a few minutes worth of data between the reset and re-registration operations.

You may need to reset agents after you have reconfigured business transaction or backend detection and the agent is not applying the updated rules:

1. Delete all existing transactions and backends. See information on deleting unwanted business transactions in Transaction Detection Rules, Monitor Databases, and Remote Services.
2. Choose a reset option:
   - To reset all the app agents for a business application, click **Reset Agents**.
   - To disable a individual app agents, select one or more agents and click **Reset Selected App Agent(s).**

Enable and Disable App Agents

Disabling an app agent stops the agent from reporting metrics to the Controller. Disabling an agent can help you diagnose agent installation or application issues. It also lets you compare the difference in overhead between when the agent when capturing data versus when it is not, for example, without removing the agent. Disabling the agent does not require you to shut down or restart the application server.

Disabling an app agent does not stop the agent from operating or remove the bytecode instrumentation added by the agent. To fully remove the agent including remove bytecode instrumentation, follow the steps to uninstall the app agent or fully disable agent instrumentation under the Install App Server Agents page specific for the agent type. Uninstalling an app agent or fully disabling an app agent in this manner typically requires an application restart.

All agents connected to the Controller count against the agent license limits for that Controller. Even though it only reports minimal app server-related data, a disabled app agent is still connected to the Controller and consumes an app agent license.

To enable or disable all the app agents for a business application, the App Server Agents tab, click **Enable Agents** or **Disable Agents**.

Permission:

You must have the application-level permission, *configure agent properties* to enable and disable agents.

You can enable or re-enable individual agents by selecting them and clicking **Enable Selected App Agent** or **Disable Selected App Agent**. Alternatively, enable or disable app agents individually from the Agents tab on the Node Dashboard:

- To disable the agent, click Agent is **Off**.
- To enable the agent, click Agent is **On**.
  It takes about a minute for the operation to take effect.

By default turning the agent **Off** completely disables monitoring. For Java agents, un-check **Disable all monitoring including JVM and JMX metrics** on the Disable This App Agent pane to continue collecting JVM and JMX metrics such as heap memory, memory pools, garbage collection, and thread count.

Delete App Agents

Deleting an app agent removes the agent and any associated data from the Controller database. This does not affect the instrumentation of the application server. If the application server is still running with an app agent, or if it is subsequently restarted with an app agent, the agent re-registers and appears again in the Controller.

You can delete an app agent by clicking **Delete Agent from System**.

To completely remove an app agent completely so that it does not register again, uninstall it. See uninstallation instructions for your agent platform under Install App Server Agents.

Agent Log Files

Related pages:

- PHP Agent Logging
- Node.js Agent Logging
- Python Agent Debugging and Logging
- Apache Agent Logging
- Dynamic Agent Proxy Logging
- Business Transactions Logging
- Bytecode Transformer Logging
- REST Logging
- Analytics Agent Logging

You can use agent logs to resolve agent configuration and application instrumentation issues. The Controller can generate and archive agent log files that you can submit to AppDynamics Support for troubleshooting assistance. See Request Agent Log Files.

Agent Log File Information

The beginning of the log file shows the startup of the agent monitoring services and the configuration settings. The agent log also contains the sequence of agent runtime activity and exceptions that are encountered. You can use this information to troubleshoot deployment issues.

Examples of log information:

- Agent version and build date
- JVM runtime version (Java only)
- Configuration changes
- Backend detection
- Exceptions
- Output from logging session requests

Logging Levels

The logging levels, listed in order from collecting the most information to the least, are:

- ALL: Logs all events.
- TRACE: Reports finer-grained informational events than the debug level that may be useful to debug an application.
- DEBUG: Reports fine-grained informational events that may be useful to debug an application.
- INFO: Default log level. Reports informational messages that highlight the progress of the application at coarse-grained level.
- WARN: Reports on potentially harmful situations.
- ERROR: Reports on error events that may allow the application to continue running.

Not all agents log at all levels.

Log Structure

This section describes how the agent logs are rolled over for these agents:

- Java Agent
- .NET Agent
- Proxy
- BytecodeTransformer
- Business Transactions
- JMX
- REST
- Machine Agent
- Dynamic Services (used internally)

When the maximum file size is reached, a new log file is created. The first file is named ...0.log, second file is ...1.log, and so on. There is a maximum of five files per set and a maximum of five sets for each instrumented node. If the maximum number of sets is reached, when a new set is created, the oldest set is deleted.

While the agent rotates away old log files, it retains the initial log file. The first log file contains information that reflects the specific context in which the agent was started, along with other information that can be useful for troubleshooting and record keeping. On agent restart, a new set is created and the oldest set is deleted

Each set includes not only the application agent log but also, depending on which logs exist, the `ByteCodeTransformer` log, the `REST` log and the `BusinessTransaction` log. A single set might consist of:

- `agent.<timestamp>.#.log`
- `ByteCodeTransformer.<timestamp>.#.log`
- `REST.<timestamp>.#.log`
- `BusinessTransaction.<timestamp>.#.log`

where # is the number of the set.

For example, these logs in the logs directory were created on April 3 or the first set, set 0. The agent is a Java Agent; this is indicated by the prefix *agent*. Other app agents use different naming conventions. See the agent-specific information.

```
agent.2015_04_03__14_49_38.0.log
agent.2015_04_03__14_49_46.0.log
agent.2015_04_03__14_51_04.0.log
BusinessTransactions.2015_04_03__14_49_38.0.log
BusinessTransactions.2015_04_03__14_49_46.0.log
BusinessTransactions.2015_04_03__14_51_04.0.log
ByteCodeTransformer.2015_04_03__14_49_40.0.log
ByteCodeTransformer.2015_04_03__14_49_47.0.log
ByteCodeTransformer.2015_04_03__14_51_04.0.log
REST.2015_04_03__14_49_38.0.log
REST.2015_04_03__14_49_46.0.log
REST.2015_04_03__14_51_04.0.log
```

On the next agent restart a new set is created. The logs in this set, set 1, will have names such as:

```
agent.2015_04_03__14_53_05.1.log
. . .
```

and the next set, set 2,

```
agent.2015_04_04__15_12_06.2.log
. . .
```

and so on through the five potential sets.

Agent-Specific Information

AppDynamics app server agents have different logging locations and different maximum log sizes.

Bytecode Transformer Logging

Related pages:

- Agent Log Files
- Java Agent Logging
- .NET Agent on Windows Logging
- Dynamics Agent Proxy Logging

The Bytecode Transformer log is generated by the Java Agent, the .NET Agent and the proxy. It contains the information associated with the AppDynamics platform bytecode instrumentation (BCI) engine. The BCI engine is used to inject interceptors. The BCI engine logs the classes being loaded in the application.

This log is useful for troubleshooting issues that depend on bytecode instrumentation including entry points, exit points, missing metrics, loggers, errors, exceptions, and asynchronous threads.
This log includes:

- Agent version and build date
- Each Java class that was examined and whether the methods were considered for bytecode instrumentation
- Each method that was instrumented

For the Java Agent and the proxy, the log is named ByteCodeTransformer*Year_mon_day_hr_min.#*.log, where # is the logging set number.

For the .NET Agent, the log is named `ByteCode.txt`.

See Agent Log Files for details about how the sets are organized that roll over.

REST Logging

Related pages:

- Agent Log Files
- Java Agent Logging
- .NET Agent on Windows Logging
- Dynamic Agent Proxy Logging

The REST log contains information about the AppDynamics agent and Controller communication. The log contains request and response payload data between the agent and the Controller, and the raw details of communications between the agent and the Controller. By default, the REST log contains INFO level logging for all registration requests up to a limit of one MB every five minutes.

You can use this log to troubleshoot issues with detecting and reporting business transactions, backends, events, and metric reporting.

The communication between the agent and Controller consists of:

- Configuration data
- Node identification
- Machine registration
- Business transaction registration
- Metric registration
- Event registration
- Snapshot capture/upload to controller database
- Metric data upload to controller database
- Event data upload to the Controller database
- Output from Logging Session requests

The naming convention for the REST log is `REST.<timestamp>.#.log` where # is the set.

See Agent Log Files for information about the structure of the log files into sets that roll over.

Within a set, a REST log file can reach a maximum of 5 MB.

Metrics Limits

To ensure that metric information that is most relevant to your application displays, agents have limits for the number of metrics they can store. Different limits apply to app agents and machine agents:

- For an app agent, the default maximum number of registered metrics is 5000.
- For the Standalone Machine Agent, the default maximum number of registered metrics is 450. This includes both basic hardware metrics and the expanded metrics available with Server Visibility.

If the limit is reached, an error event is generated of type `AGENT_METRIC_REG_LIMIT_REACHED` with a summary of *Metric registration limit of n reached*. No new metrics are created until the agent restarts. If necessary, you can increase the default limit.

Agent Metric Limits

You can increase or decrease the default metric registration limits for machine agents or app agents.

> Changing these limits can affect the resource consumption of your deployment. Before you change this setting verify your application environment and Controller can handle the increased resource requirements.

For the Java agent, modify the limit using the `agent.maxMetrics` system property. For example, to increase the machine agent metric limit, specify the maximum number of metrics as an argument when starting the machine agent in the following format:

```
-Dappdynamics.agent.maxMetrics=<max-number-of-metrics>
```

For example, when starting the machine agent, increase the maximum number of metrics that can be registered to 2000 as follows:

```
nohup java -Dappdynamics.agent.maxMetrics=2000 -jar machineagent.jar &
```

For the .NET Agent, set the `maxMetrics` property as an environment variable. This setting only affects the app agent. For example:

```
appdynamics.agent.maxMetrics=5500
```

For the .NET Agent for Linux, use the node property below to set agent metric limits. See App Agent Node Properties (A) for more information.

```
appdynamics.agent.metricLimits
```

For the .NET Machine Agent, specify the maximum number of metrics using the Metrics element in the config.xml. See 'Machine Agent Element' on .NET Agent Configuration Properties. See also Administer the .NET Agent.

```
<metrics max-metrics="300"/>
```

Controller Metric Limits

The Controller applies its own limits on metric registration. For an on-premises Controller, you can view and modify the properties that control the metric registration limit in the Controller settings page in the Controller Administration Console.

The relevant Controller settings are:

- `metric.registration.limit`: The maximum number of metrics that can be registered for an account in the Controller. The default is 2 million.
- `application.metric.registration.limit`: The maximum number of metrics that can be registered for a business application in the Controller. The default is 1 million.

Historical and Disconnected Nodes

If a node has been out of contact with the Controller for a certain amount of time, the Controller marks the node as a historical node. The Controller suspends certain types of processing activities for the node, such as rule evaluation.

If the node resumes contact with the Controller before the node deletion period expires, the Controller restores it to an active state. Otherwise, the node is permanently removed from the Controller and the node level data is no longer accessible in the UI. Tier and application level historical metric data for the node remains available after the node is deleted.

By default, the Controller considers a node historical after about 20 days of inactivity and deletes the node after 30 days. For a highly dynamic application environment in which nodes are created and destroyed frequently, AppDynamics recommends that you shorten the node activity timeout period to allow recycled nodes to be treated as such in the Controller.

The node activity timeout period is determined by the node retention period or activity settings.

The names of historical nodes can be assigned to new nodes. Node name reuse is a Java Agent option that, when enabled, directs the Controller to reuse node names so that data generated by multiple, short-lived nodes in a given tier is associated with a single logical node.

Node Activity and Agent Licensing

For licensing purposes, the Controller releases the license for the agent if the Controller has not received data from the agent in the previous 5 minutes. This license availability behavior is not affected by the historical node status or node deletion timeout settings.

Configure Node Activity Settings

The node activity settings are account level settings that the root AppDynamics administrator can modify from the Administration Console:

- `node.permanent.deletion.period`: Time (in hours) after which a node that has lost contact with the Controller is deleted permanently from the system. The data is removed. If the agent starts reporting again after this period, it will start like a new node. Therefore, no historical data will be available at the node level. You will see historical data at the tier and app level, and cluster roll up will take place as normal.
  The default is 720 hours, the minimum value is 6 hours, and the maximum value for this setting is unlimited.
- `node.retention.period`: Time (in hours) after which a node that has lost contact with the Controller is deleted. In this case, the Controller UI will not display the node, however, the system will continue to retain it. If the agent starts reporting again within these hours, it will reappear in the UI and the counter will reset. The data is persisted.
  The default is 500 hours, the minimum value is 1 hour, and the maximum value for this setting is unlimited.
  Additional notes about the node retention period:
  - A node will be impacted by the node retention period even if a Machine Agent is associated with that node. If a Machine Agent associated with the App Server Agent is running, the node retention period will still be in effect.
  - You can have any number of Machine Agents running in background that will never appear in the Controller unless the Machine Agent:
    - runs on a host machine that has been shut down or cannot connect to the Controller.
    - is not instrumented or has been uninstalled.
    - has been stopped.
  - If you need a node to be considered for the node retention period, it should be marked as historical on shutdown:

    ```
    Dappdynamics.jvm.shutdown.mark.node.as.historical=true
    ```

Agent Behavior When Disconnected from the Controller

If there are network problems or agent errors, the Controller may become unreachable. The Controller server may also be down for a variety of reasons.

If the Controller is unreachable for one minute:

- The agent goes into standby mode during which it does not detect any transactions.
- Any collected snapshots and events are dropped and lost. Snapshots and events are dropped because they consume too much memory to cache.
- All metrics that have not been posted to the Controller are stored in memory. The memory impact of retaining metrics is minimal.
- New business transaction registrations that have not been posted to the Controller are stored in memory.
- The agent attempts to connect to the Controller every minute and resumes normal activity when it can download its full configuration.

If the Controller becomes reachable in the following minute or two:

- All metrics that have been stored in memory are posted to the Controller.
- New business transaction registrations that have been stored in memory are posted to the Controller.
- Snapshots and events collected in the 20 seconds prior to the reconnection are posted to the Controller.

If the Controller is not reachable after three failed attempts that are one minute apart:

- The agent is muted and all business transaction interceptors are disabled. The interceptors are still called when monitored application entry point methods are executed, but they are unproductive. No new business transactions are discovered or registered. Correlation exit points will set a header such as "`notxdetect=true`", which tells downstream tiers to also ignore the transaction.
- JMX metrics are stored in the application server memory and transmitted to Controller after reconnection; so, there are no gaps in the metric history.
- Periodic metrics for the last three minutes are stored in memory. Metrics older than three minutes are purged from memory.

- The agent configuration channel and the metric channel continue to attempt to connect to the Controller once each minute.

The agent attempts to connect to the Controller in seven one-minute intervals and in five minute intervals afterwards. If the Controller is not able to reconnect after five minutes, the license is freed for another agent to use.

If the connection is successful and the agent is able to download its full configuration and a license:

- All periodic metrics, such as JMX metrics and Windows performance counters for the last three minutes, are posted to the Controller. The Controller drops metrics that were collected too long ago in the past, such as when rollups are already completed.
- The agent is reactivated, business transaction interceptors are re-enabled, business transactions are monitored and possibly snapshotted, new business transactions will be discovered and registered, and downstream correlation is re-enabled.

Request Agent Log Files

You can use agent logging information to troubleshoot issues that are local to an AppDynamics app agent.

> The Controller cannot access the log files generated by the .NET Microservices Agent.

This page describes how to work with agent logs. To access agent logging operations in the Controller UI, navigate to **Node Dashboard > Agents > App Server Agent > Agent Operations**.

Permissions

To request agent thread dumps or agent debug logs, users need the *Agent Advanced Operation* permission.

Get Agent Log Files and Thread Dump Samples

Requesting log files causes the agent to send the contents of its logs directory as a zip file to the Controller. From there, you can download the zip to your local machine.

These agent-specific considerations apply to logging sessions:

- For the Database Agent, Java Agent or PHP Agent, you can get all logs or choose from these alternatives:
  - Output *from a specific logger* at a set level, for a fixed duration. For a list of supported loggers, see Java Supported Environments.
  - *Thread dump samples*. The agent takes a thread dump according to the specified collection interval and specified number to collect. After the interval elapses the thread dumps are uploaded by the agent as a zip file.
- For the Node.js agent, the proxy logs are available.
- For the Python Agent, if you choose *All logs in the logs directory*, you get both the proxy logs and the agent logs. The agent log contains the log messages that it is configured to log in the agent configuration file. See Python Agent Settings.

While the status is PENDING, you can click **Refresh** to update the status field. Once the request succeeds, as indicated by the status, right-click the agent operation name for your request and choose Download Data. Enter a name for your request to prepend the generated zip file with your name. For example, the name of `CurrentTime` produces a zip file named similar to `CurrentTime_Node_8000_1390503141046.zip`.

If SUCCESSFUL doesn't eventually appear in the status for the request, the request may have timed out. A request can timeout due to incorrect request parameters or if the server becomes unavailable. In this case, right-click the request and choose **Delete Data** and retry the request.

Start an Agent Logging Session

For Java and Database Agents, you can generate log information with the specific type of logging information. For the Node.js and Python agents, the log information generated is from the proxy only.

1. Confirm that you have enough disk space to create the logs before starting a logging session. Log file requests fail if there is not enough disk space available. The disk space required depends on application activity. If you are uncertain about the amount of space required, try conducting an agent logging session with the shortest duration and closely monitor the disk space on the monitored machine.
2. Click **Start Agent Logging Session** in the **Agent Operations** panel.
3. Choose the duration for the logging session and the debug logger types to initiate. The logger type determines the type of information captured with these options:

Logging Session Type	Type of Information
Application Wide Configuration	Application configuration changes
Business Transaction Registration	Transaction, exit identification, self-resolution
Current Time	Requests to synch up the clock skew between the controller and the agent
Events	Changes in application state that are of potential interest
Metric Data	Metric data
Metric Registration	Metric registration
One Way Agent	For system (machine) agent only, information from the capture feature
Request Segment data	Snapshot upload of request segment
System Agent Registration	System (machine) agent registration
System Agent Reregistration	System (machine) agent reregistration

System Agent Polling Handler	System (machine) agent configuration request
Task Execution	Relates to the machine agent where you can create a task to execute on a machine, such as to restart the application server and run a script
Top Summary Stats	Request to upload the 'most expensive backend' summary
Application Configuration	Configuration change requests
Transient Channel	The activity of the transient channel that is used to upload and download instructions for JMX console live data

4. Click **Start Agent Logging Session**. Each selected session type displays in the **Session** panel with a start and end time based on the selected **Duration** of the logging session.

Submitting Log Files to Support

When submitting log files to AppDynamics Support, ensure you send the entire contents of the agent logs directory available as a zip file for download when you request the agent logs.

App Agent Node Properties

Related Pages:

- Monitor JVMs
- Monitor .NET Nodes

You can register app agent node properties to customize app agent behavior at the application, tier, or node level.

App Agent Node Properties

App agent node properties control the features and preferences for the Java Agent and .NET Agent. Such agent-specific settings include limits on the number of business transactions, the minimum number of requests to evaluate before triggering a diagnostic session, and so on.

Node properties follow an inheritance model similar to instrumentation detection, so you can set an individual property globally for an application, tier, or node level.

It is possible to set node properties in the Controller UI for the PHP, Node.js, Python, Web Server Agent, and C/C++ SDK agents, however, doing so may lead to unexpected behavior or agent failure, and is therefore not supported for those agent types.

Even though it is possible to configure node properties in the `app-agent-config.xml` file in the agent home directory, AppDynamics recommends that you use the Controller UI to configure node properties. The Controller UI displays only those node properties that are registered to the agent.

The App Agent Node Properties Reference reference includes additional properties that do not display in the UI by default. You can register these properties yourself, but unregistered properties are intended for specific application or troubleshooting scenarios and can impact the performance of your deployment. You should register properties or configure properties directly in `app-agent-config.xml` only under the guidance of AppDynamics Support or as specifically instructed by the documentation.

Permissions

Users need the Configure Agent Properties permission to create, edit, or delete agent configuration.

Edit a Registered Node Property

In the Controller UI, you can access node properties for a particular node or for all nodes from the dashboard of any node in the application, as follows:

1. Access the node dashboard by going to the App Servers page. See Tiers and Nodes.
2. Expand the tier that contains the node on which you want to configure a node property and double-click the node.
3. In the node dashboard, click **Actions > Configure App Server Agent**.
4. Select **Use Custom Configuration**, and then double-click the property to modify.

After customizing a configuration, you can copy the configuration to other nodes, to the tier, or apply it to the entire application.

Add a Registered Node Property

You can register and configure unregistered App Agent Node Properties Reference as instructed by AppDynamics Support.

To register a node property, create a custom configuration for the node (see Edit Registered Node Property). Add properties by clicking the **+** icon at the top of the list of current node properties.

In the **Create Agent Property** panel, use the values from App Agent Node Properties Reference to provide values for the name, description, type, and value of the property.

App Agent Node Properties Reference

This reference page describes the app agent node properties by type. Additionally, the reference includes these pages containing information about the app agent node properties:

- App Agent Node Properties (A)
- App Agent Node Properties (B-C)
- App Agent Node Properties (D-E)
- App Agent Node Properties (F-I)
- App Agent Node Properties (J-L)
- App Agent Node Properties (M)
- App Agent Node Properties (N-R)
- App Agent Node Properties (S)
- App Agent Node Properties (T-Z)

Use caution when modifying the agent default settings. If increasing limits specified for an agent, you must carefully assess and monitor memory consumption by the agent after the change.

App Agent Node Properties by Type

This table groups the app agent node properties by type to browse properties by functionality and feature area.

App Agent Node Properties (A)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

adaptive-callgraph-granularity

This property enables adaptive snapshots. The call graph granularity for adaptive snapshots is based on the average response time for the business transaction during the last one minute and is thus adaptive. The following distribution is used:

- Granularity of 10 ms for average response time of <= 10 seconds
- 50 ms for 10 to 60 seconds
- 100 ms for 60 to 600 seconds
- 200 ms for > 600 seconds

Type:	Boolean
Default value:	false
Platform(s):	Java, .NET

ado-new-resolvers

Enable database detection and naming for ODP.NET backends labeled `Unknown0`.

Type:	Boolean
Default value:	true
Platform(s):	.NET

agentless-analytics-disabled

Disable agentless Transaction Analytics on a particular node or tier.

Type:	Boolean
Default value:	false
Platform(s):	Java

always-add-eum-metadata-in-http-headers

By default, the Java Agent, .NET Agent, and Node.js Agent set business transaction correlation data in a cookie for HTTP responses, except when the JavaScript Agent has already set an `isAjax`:true header in the request. When it finds the `isAjax`:true header, the agent sets the correlation metadata in the XHR header.

For cross-origin AJAX requests, the JavaScript Agent does not set `isAjax`:true so that the app agent doesn't write correlation data to the header of those responses.

Set `always-add-eum-metadata-in-http-headers` to `true` to configure the app agent to write business transaction metadata to the XHR header and in a cookie even if the request is considered cross-origin.

Type:	Boolean
Default value:	false
Platform(s):	Java, .NET, Node.js

analytics-sql-cpm-limit

This property specifies the per minute upper limit on the number of SQL queries that collect parameter data for analytics. The number is a cumulative total. It is not the number of distinct SQL queries, but the overall number of invocations of the SQL queries that have been configured to collect analytics data.

Type:	Integer
Default value:	10000
Platform(s):	Java, .NET

api-thread-activity-timeout-in-seconds

This property provides a time-out value that comes into play when you have added global transactions to your application using APIs from the AppDynamics SDK. In the event that the added transaction spawns additional threads that do not return or complete, this property provides a safety valve time-out value. The value is in seconds. The removeCurrentThread method is invoked after the specified timeout period.

Type:	Integer
Default value:	300 (seconds)
Range:	Minimum =1; Maximum=3600
Platform(s):	Java

api-transaction-timeout-in-seconds

This property provides a time-out value that comes into play when you have added global transactions to your application using APIs from the AppDynamics SDK. In the event that the added transaction does not return or complete, this property provides a safety valve time-out value. The time-out value is in seconds. The `endTransaction` method is invoked after the specified time-out period.

Type:	Integer
Default value:	300 (seconds)
Range:	Minimum =1; Maximum=3600
Platform(s):	Java

appdynamics-agent-metricLimits

This property increases the metric limit for the .NET Agent for Linux.

Type:	Integer
Default value:	5000
Platform(s):	.NET Agent for Linux

apply-reactive-rules

This property provides a switch to flip the entire reactor instrumentation. If you set it to false, all rules pertaining to reactor thread correlation are unapplied.

Type:	Boolean
Default value:	true
Platform(s):	Java

apply-additional-reactive-rules

This property provides a switch to apply in process correlation rules for prospective thread hand-offs. By default these rules are disabled. These rules can only be applied if 'apply-reactive-rules' node property is set to true. If 'apply-reactive-rules' property is set to false, setting this property to 'true' will not apply any rules.

Type:	Boolean
Default value:	false
Platform(s):	Java

aspdotnet-core-legacy-instrumentation

When you set this property, ASP.NET Core entry instrumentation is restored to `RequestServicesContainerMiddleware.Invoke` for .NET Core 2.1 and 2.2 apps. You can use this when Business Transactions are missing from .NET Core apps after you upgrade an agent.

Type:	Boolean
Default value:	false
Platform(s):	ASP.NET Core

aspdotnet-core-naming-controllerarea

If true, causes the agent to identify ASP.NET Core on the full framework business transactions as Area/Controller/Action. See Name MVC Transactions by Area, Controller, and Action.

Type:	Boolean
Default value:	true
Platform(s):	.NET

aspdotnet-mvc-naming-controlleraction

If true, causes the agent to identify ASP.NET MVC business transactions as Controller /Action. See Name MVC Transactions by Area, Controller, and Action.

Type:	Boolean
Default value:	false
Platform(s):	.NET

aspdotnet-mvc-naming-controllerarea

If true, causes the agent to identify ASP.NET MVC business transactions as Area /Controller. See Name MVC Transactions by Area, Controller, and Action.

Type:	Boolean
Default value:	false
Platform(s):	.NET

async-tracking

Enable or disable detection of asynchronous exit points. See Asynchronous Exit Points for .NET.

Type:	Boolean
Default value:	true
Platform(s):	.NET

async-transaction-demarcator

This class name and method name combination marks the end of an asynchronous distributed transaction. Use the format ClassName/MethodName. For example, foo/bar where foo is the class name and bar is the method name.

Type:	String
Default value:	none
Platform(s):	Java

App Agent Node Properties (B-C)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

bci-log-config

Use this property to configure the bytecode transformer log (BCT log). This log shows what AppDynamics instruments and what classes are loaded in the JVM. The initial file (the *0.log*) is saved to preserve the context of the server startup and is not rolled over. The subsequent files rotate. The format of the file name is ByteCodeTransformer.*<timestamp>*.*<N>*.log. The time stamp is represented as `YYYY_MM_DD_HH_mm_ss`. N increments starting from zero.

Type	String
Default value:	20,5,4
Platform(s):	Java

Examples

```
ByteCodeTransformer.2012_09_12_20_17_57.0.log
```

Because the file size is checked every 15 seconds, the files may be a bit larger than the specified threshold value before they are rolled over.

The first log file generated is named as follows: `ByteCodeTransformer.<timestamp>.0.log`

The format for this property value is illustrated by the default value, `20,5,4`. The numbered segments have the following meaning:

- 20 is the size, in MB, of the first log file, the *.0* version
- 5 is the size in MB for each subsequent rolling file
- 4 is the number of ByteCodeTransformer log files to keep

bciengine-disable-retransformation

Disable or enable bytecode retransformation. By default, the Sun and JRockit variant of the Java Agent applies configuration changes requiring bytecode retransformation, such as new POJO rules, without a restart to the JVM. Set `bciengine-disable-retransformation` to `true` to prevent the agent from performing automatic retransformation to apply such rules.

Type	Boolean
Default value:	false
Platform(s):	Java

boot-amx

If set to true, enables support for Glassfish AMX MBeans. See GlassFish Startup Settings fo r more information about Glassfish server support.

Type	Boolean
Default value:	false
Platform(s):	Java

callgraph-granularity-in-ms

Specifies the granularity for call graphs for this node. The global configuration is ignored if this property is used. This value is ignored if the adaptive-callgraph-granularity property is set to true. A default value of zero means the global configuration, from **Configuration > Instrumentation > Call Graph Settings** is used. Does not need a restart.

Type	Integer
Default value:	0
Range:	Minimum=0; Maximum=5000
Platform(s):	Java, .NET

capture-404-urls

This property disables or enables the capture of the URLs causing 404 errors. The URLs are reported as ERROR events every 15 minutes and are viewable through the Event Viewer. The JVM needs a restart if retransformation is not supported for the JVM version.

404 errors usually mean that no application code is executed, resulting in nothing to be captured in a snapshot. You can get insight into the 404 error by setting this property to true. It reports all the URLs which caused 404 error.

The `capture-404-urls` node property is *deprecated* in AppDynamics v. 3.6 and replaced with `capture-error-urls`.

Type	Boolean
Default value:	false
Platform(s):	Java

capture-error-urls

This property enables or disables the capture of the following HTTP errors:

- 401 - Unauthorized
- 500 - Internal Server Error
- 404 - Page Not Found
- All other error codes are put in a generic HTTP error code bucket.

For these four categories, the agent collects URLs, limited to 25 per category per minute, and sends an event out every 5 minutes.

You can see these URLs when you drill down on an error code by clicking Troubleshoot > Errors > Exceptions tab > HTTP Error Codes.

Type	Boolean
Default value:	true
Platform(s):	Java

capture-raw-sql

If `capture-raw-sql` is enabled, SQL calls with dynamic parameters—such as question mark parameters—are captured by the agent and shown in the Controller UI with the dynamic parameters bound to their runtime values.

Type	Boolean
Default value:	false
Platform(s):	Java, .NET

Examples

For example, consider Java code that constructs a SQL call as follows:

```
stmt = new PreparedStatement("select * from user where ssn = ?")
stmt.bind(1, "123-123-1234")
stmt.execute()
```

With capture-raw-sql enabled, AppDynamics captures the SQL call in the following form:

```
select * from user where ssn = '123-123-1234'
```

If `capture-raw-sql` is disabled, the SQL call appears with question mark parameters not bound to values.

Disabling `capture-raw-sql` and using question mark parameters in SQL prepared statements gives you a mechanism for preventing sensitive data from appearing in the Controller UI.

It is important to note that the sensitive values must be parameterized in the original, prepared statement form of the SQL statement, as shown above. The following statement would result in the potentially sensitive information—the ssn value—appearing in the UI whether `capture-raw-sql` is enabled or disabled.

```
stmt = new PreparedStatement("select * from user where ssn ='123-123-1234'")
```

If you change this node property in an environment that is using the IBM JVM, you need to restart the JVM. This is because the feature requires retransformation of certain JDBC classes, which is not possible with the IBM agent.

Setting the option as an agent property affects the SQL capture mode for the node. You can configure the behavior for all nodes using the Capture Raw SQL option described in Call Graph Settings.

capture-set-status

Directs the agent to capture errors where the webservice is using setStatus() to send back an error. By default, only `sendError()` is instrumented by the agent.

Type	Boolean
Default value:	false
Platform(s):	Java

capture-spring-bean-names

When a class is mapped to multiple Spring bean names, by default only the name of the first Spring bean found displays. This can be misleading. For example, when you see a call graph for web service A that has Spring beans from web service B. Setting this property to false shows only the class name when these conflicts occur and does not show the Spring bean name.

Type	Boolean
Default value:	true
Platform(s):	Java

check-bt-excludes-early

Reverses the default order in which Java and .NET agents evaluate rules. If true, exclude rules are evaluated before match rules.

Type	Boolean
Default value:	false
Platform(s):	Java, .NET

collect-user-data-sync

Collect user data from diagnostic POJO data collectors synchronously. Does not require a restart.

Type	Boolean
Default value:	true
Platform(s):	Java

collection-capture-period-in-minutes

Total interval in minutes since server restart for which collections are captured for leak evaluation. The property takes effect only after the node restart.

Type	Integer
Default value:	30
Range:	Minimum=5; Maximum=N/A
Platform(s):	Java

App Agent Node Properties (D-E)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

disable-agent

This property enables/disables the agent. When this property is set to true, TransactionEntryPoints will not be monitored. No new BTs or metrics will be registered, metrics, and snapshots will not be reported. Agent background threads will not be stopped. When set to false, the agent becomes active immediately. It does not need a restart.

Type:	Boolean
Default value:	False
Platform(s):	Java

disable-agent-api

This property disables all calls to the agent-api library. The calls function as no-ops when disabled.

Type:	Boolean
Default value:	False
Platform(s):	Java

disable-custom-exit-points-for

Disables certain types of automatically detected exit points: SAP, Mail, LDAP, and so on. Type names are case sensitive. Use commas to separate multiple types.

Type:	String
Default value:	none
Supported values:	CASSANDRA, Coherence, DangaMemcache, EHCache, LDAP, Memcache, MongoDB, RABBIT_MQ, REDIS, RMI, SAP, THRIFT
Platform(s):	Java

disable-exit-call-correlation-for

Disable exit call correlation for a specific type of call. For example, KAFKA, WCF, WEB_SERVICE, HTTP, JMS, and RMI. By default, all exit call correlations are enabled.

Type:	String
Default value:	none
Platform(s):	Java, .NET

disable-exit-call-metrics-for

Disables exit call monitoring for a specific type of exit call; for example, HTTP, JMS, WEB_SERVICE. If this property is set, the average data—calls/min, avg response time—for the specific exit call type is not collected. However, for a snapshot, all details are collected. Set this property if the application makes a large number of exit calls per transaction and the avg metrics are not important.

Type:	String
Default value:	By default, all exit call metrics are enabled.
Platform (s):	Java, .NET

disable-percentile-metrics

App agents that support percentile metrics enable collection by default. Disable percentile metrics on the Configuration > Slow Transaction Thresholds window or set this node property manually to `true` to disable percentiles.

Changes to this property do not require an agent restart.

Type:	Boolean
Default value:	false
Platform(s):	Java, .NET

disable-service-monitoring-metrics

This property stops the BT-to-BT incoming cross-application metrics to be reported (but normal cross-application metrics continue to be reported, as expected).

Type:	Boolean
Default value:	True
Platform(s):	Java

disable-soap-header-correlation-non-http

This property controls correlation with web service transactions. When enabled, it prevents i njection of the correlation header into a SOAP message if the WCF transport is not over HTTP or HTTPS.

Type:	Boolean
Default value:	false
Platform(s):	Java, .NET

For more information, see WCF Entry Points

disabled-features

Specifies types of data for which agent reporting to suppress. Use this property provides to disable data collection mechanisms at the agent to limit data reported by the agent for security or privacy reasons. This agent configuration overrides any Controller configuration that affects the data.

You can disable

- `LOG_PAYLOAD`: Log payload, such as the node property `log-request-payload`
- `RAW_SQL`: Raw SQL statements
- `CUSTOM_EXIT_SNAP_DATA`: Snapshot data in custom exits
- `METHOD_INV_DATA_COLLECTOR`: Diagnostic data collectors, method invocation
- `HTTP_DATA_COLLECTOR`: Diagnostic data collectors, HTTP requests
- `INFO_POINT`: Information points
- `ALL`: All of the above
- `NONE`: None of the above. This is equivalent to the default agent behavior.

Type:	String
Default value:	none
Platform(s):	Java

Examples

Configure disabled features in the app-agent-config.xml in the versioned conf directory for the agent. Specify the data category as the value attribute of the disabled-features property. You can have multiple data categories excluded by listing each separated by commas. For example:

With `capture-raw-sql` enabled, AppDynamics captures the SQL call in the following form:

```
<app-agent-configuration>
  <configuration-properties>
        ....
        <property name="disabled-features" value="RAW_SQL,LOG_PAYLOAD"/>
  </configuration-properties>
  .....
</app-agent-configuration>
```

disable-ibmbpm-data-collectors

Sets whether data-collectors for IBM-BPM task business transactions should be disabled (v alue=true) or enabled (value=false).

Type:	Boolean
Default value:	false
Platform(s):	Java

disable-ibmbpm-usertask-bt-in-process-correlation

Sets whether business transactions in-process correlation for IBM-BPM UserTask business transactions should be disabled (value=true) or enabled (value=false).

Type:	Boolean
Default value:	false
Platform(s):	Java

disable-ibmbpm-usertask-bt-naming

Sets whether business transactions naming scheme for IBM-BPM UserTask Business Transactions should be disabled (value=true) or enabled (value=false).
When it is set to `true`, the Business Transactions would be named as per the default URL and not the meaningful names.

Type:	Boolean
Default value:	false
Platform(s):	Java

dev-mode-suspend-cpm

The maximum number of transactions monitored per minute during development mode before the system switches out of development mode into normal operation mode.

Type:	Integer
Default value:	500
Range:	Minimum=0; Maximum=N/A
Platform(s):	Java

dont-show-packages

Do not show these packages / class names in addition to the ones configured in the global call graph configuration, for the call graphs captured on this node. Does not need a restart.

Type:	String
Default value:	none
Platform(s):	Java, .NET

downstream-tx-detection-enabled

If the agent cannot reach the controller for a prolonged period, it turns off most services and notifies the continuing tiers that upstream transaction was detected and is not being monitored. Set this property to `true` to enable the continuing tiers to detect their own transactions in the event of network failure on the upstream tiers.

Type:	Boolean
Default value:	false
Platform(s):	Java, .NET

enable-all-rsd-error-propagation

This property enables the agent to recognize errors that occur in calls outside of or tangential to business transactions.

`false`: All business transaction errors are reported, but errors outside of the business transaction are not reported.

`true`: All business transaction errors are reported. In addition, errors outside of the business transaction are reported. For example, errors generated from tracking analytics for a business transaction are reported.

`full-disable`: No asynchronous errors are recognized.

Type:	Boolean
Default value:	false
Platform(s):	Java, .NET

enable-async-service-endpoints

By default the Java Agent automatically detects service endpoints for worker threads. Set this property to "false" to disable service endpoint detection for worker threads. This has the same effect as the *Automatic Service Endpoint Detection* checkbox for other types of service endpoints on Configuration > Instrumentation > Service Endpoints.

Type:	Boolean
Default value:	true
Platform(s):	Java

enable-async2-eum-context-lookup

When EUM is enabled on applications implemented using the Servlet3 async dispatch mechanism, it is possible that multiple EUM correlation headers are added to the response.

This node property prevents duplicate ADRUM headers being injected in the HTTP response from Java Agent.

Type:	Boolean
Default value:	false
Platform(s):	Java

enable-axon-entry

This node property is used to disable axon entry. By default, it is enabled.

Type:	Boolean
Default value:	true (By default, axon entry is enabled.)
Platform (s):	Java

enable-axon-exit

This node property is used to disable axon exit. By default, it is enabled.

Type:	Boolean
Default value:	true (By default, axon entry is enabled.)
Platform (s):	Java

enable-bt-block-wait-time-monitoring

This property controls capture of per BT block and wait time metrics. It is disabled by default.

Type:	Boolean
Default value:	false - (Disabled by default)
Platform(s):	Java

enable-bt-cpu-time-monitoring

This property controls whether the agent captures the CPU time taken by a business transaction.

Type:	Boolean
Default value:	true
Platform(s):	Java

enable-default-http-error-code-reporter

This property disables or enables automatic HTTP error code reporting for error codes between 400 to 505.

Type:	Boolean
Default value:	true
Platform(s):	Java, .NET

enable-info-point-data-in-snapshots

This property disables or enables the capture of information point calls in snapshots. When this property is set to true, information point calls appear in the User Data section of the snapshot.

Type:	Boolean
Default value:	false
Platform(s):	Java, .NET

enable-instance-monitoring

This property enables or disables Instance tracking on this node. Does not need a JVM restart.

Type:	Boolean
Default value:	false
Platform(s):	Java

enable-interceptors-for-security

This property enables or disables security interceptors on this node. Set this property to true in environments where the Java 2 Security Manager is enabled. If the Java 2 Security Manager is enabled, and this property is not set to true, then the agent will encounter SecurityExceptions, and will not be able to collect the data that it should. Does not need a JVM restart.

Type:	Boolean
Default value:	false
Platform(s):	Java

enable-json-bci-rules

Set this property to true to enable JSON bytecode instrumentation rules. AppDynamics instruments the `get` and `getString` methods within the package/class `org.json.JSONObject` when you set this value to true. Needs a JVM restart.

Type:	Boolean
Default value:	true (This only affects new applications; applications created with a 3.7.x controller will still have this property set by default to false.)
Platform(s):	Java

enable-kafka-consumer

Set the `enable-kafka-consumer` to `true` to enable Apache Kafka consumer entry points. For more information see 'Apache Kafka Backends' on Java Backend Detection.

Type:	Boolean
Default value:	false
Platform(s):	Java

enable-object-size-monitoring

This property is related to Automatic Leak Detection (ALD) and enables or disables Object Size monitoring on this node. Changing this property does not need a JVM restart. ALD is supported for JVM version 1.6 and up.

Type:	Boolean
Default value:	false
Platform(s):	Java

enable-soap-header-correlation

This property controls correlation with web service transactions. When enabled, a node which receives a web service transaction may correlate that transaction with any downstream transactions. The ability to correlate depends on the particular web services framework. Currently, correlation is supported only by Apache Synapse and CXF frameworks. When disabled, the agent will not perform correlation through any web service tiers.

Type:	Boolean
Default value:	false
Platform(s):	Java, .NET

enable-spring-integration-entry-points

This property disables or enables the default detection of Spring Integration entry points. Set to `false` to disable.

Default detection of Spring Integration entry points is based on MessageHandler. In cases where a lot of application flow happens before the first MessageHandler is executed:

- Set this property to `false`
- Configure suitable POJO entry points
- Specify the property spring-integration-receive-marker-classes

See also Spring Integration Support.

Type:	Boolean
Default value:	true
Platform(s):	Java

enable-spring-ws-dom-parser-rules

This property enables to split web service business transactions on the SOAP XML payload. Set the value to true to enable the property. You can modify namespace context mapping (mapping of the prefix to URI) to parse SOAP message property in the `app-agent-config.xml` file.

Type:	Boolean
Default value:	false
Platform(s):	Java

enable-startup-snapshot-policy

This property disables or enables the policy for start-up transaction snapshot. This means snapshots are collected for all BTs for all invocations for the first 15 minutes of application server startup.

Type:	Boolean
Default value:	false
Platform(s):	Java, .NET

enable-transaction-correlation

This property disables or enables transaction correlation. It does not require a restart.

Type:	Boolean
Default value:	true
Platform(s):	Java, .NET

enable-vertx-http

Enable or disable servlet HTTP entry points and exit points for Vert.x.

Type:	Boolean
Default value:	true
Platform(s):	Java

enable-vertx-message-entry

Enable or disable Vert.x verticle message entry points for continuing transactions.

Type:	Boolean
Default value:	true
Platform(s):	Java

enable-xml-bci-rules

This property enables Java XML Binding and DOM Parser bytecode instrumentation rules.
Set to `true` to enable. The change takes effect after a JVM restart.

Type:	Boolean
Default value:	true (This only affects new applications; applications created with a 3.7.x Controller will still have this property set by default to false.)
Platform(s):	Java

end-to-end-message-latency-threshold-millis

Enables end-to-end message latency monitoring for distributed asynchronous systems by setting up a threshold. Any message taking more time than the threshold is viewable through the Event Viewer.

Type:	Integer
Default value:	0
Range:	Minimum=0; Maximum=36000
Platform(s):	Java

exceptions-to-ignore

By default, configuring an exception to be ignored in the error detection settings prevents the ignored exception thus marking any Business Transaction that experiences it as in error. However, it does not prevent the occurrences of the exception being tracked in the Errors and Exceptions dashboard.

To completely ignore certain exceptions, provide their fully qualified class names in this node property.

For example, oracle.jdbc.DatabaseException.

Multiple exceptions can be added that are comma-separated.

It is recommended to use this property with caution because it removes all visibility of the impact of exceptions configured in this way.

Type:	String
Default value:	0
Platform(s):	Java

App Agent Node Properties (F-I)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

find-entry-points

Set this property to `true` to log all potential entry points that are hitting instrumented exit points or loggers to the Business Transactions log file.

Use this property when you suspect that some traffic is not being detected as business transactions. You should only enable this property for debugging purposes. You should deactivate this property in a production setup.

Tip: For new applications, you can use the interactive Live Preview tools to discover entry points.

Type:	Boolean
Default value:	false
Platform(s):	Java, .NET

heap-storage-monitor-devmode-disable-trigger-pct

The maximum Java heap utilization percentage for development mode. If the heap utilization exceeds this value, development mode is automatically deactivated.

Type:	Integer
Default value:	90
Range:	Minimum=0, Maximum=100
Platform(s):	Java

ibmbpm-systemtask-bt-naming

Decides BT naming scheme for IBM-BPM System Task POJO business transactions.

The property value is comma-separated identifiers chosen from *project*, *bpd*, *task*, and *implementation*, and is order-sensitive.

Type:	String
Default value:	default
Platform(s):	Java

Example

For example:

value = `project, task` means that the POJO business transactions are named as: `<project-name> / <task-name>`
value = `task, project` means that the POJO business transactions are named as: `<task-name> / <project-name>`
value = `none` means that the POJO business transactions are not detected, in other words, deactivated.
value = `default` would mean that all the identifiers are used for BT naming are in the default order, that is, they are named as:

```
<project-name> / <bpd-name> / <task-name> / <implementation-name>
```

App Agent Node Properties (J-L)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

jdbc-callable-statements

Use this property to indicate the implementation classes of the `java.sql.CallableStatement` interface that should be instrumented.

Type:	String
Default value:	none
Platform(s):	Java

Examples

For example, to instrument calls to Times Ten (an unsupported database), you could set this property to the following:

```
com.timesten.jdbc.JdbcOdbcCallableStatement
```

jdbc-connections

Use this property to indicate the implementation classes of the `java.sql.Connection` interface that should be instrumented.

Type:	String
Default value:	none
Platform(s):	Java

Examples

For example, to instrument calls to Times Ten (an unsupported database), you could set this property to the following:

```
com.timesten.jdbc.JdbcOdbcConnection
```

jdbc-dbcam-integration-enabled

Use this property to integrate the Java Agent with AppDynamics for Databases and Database Monitoring. Changes to this property do not require a JVM restart for JDK 1.6 and higher. Older 1.5 JVMs do not support class reloading, so for those environments, a restart is required.

Type:	Boolean
Default value:	false
Platform(s):	Java

More Info

AppDynamics for Databases: When this property is enabled, you can link to AppDynamics for Databases from a Transaction Snapshot Flow Map where an exit call is to an Oracle database, and analyze the SQL statements that were running at the time of the snapshot. This property works in conjunction with the AppDynamics for Databases license and database collector that has been previously set up. Integration must also be set up from the Admin pages of the Controller UI. For more information, see Integrate and Use AppDynamics for Databases with AppDynamics Pro.

Database Monitoring: Set this property to enable snapshot correlation between Java applications and Oracle databases. This property configures Globally Unique Identifier (GUID) session tagging between business transactions monitored by the Java Agent and Oracle databases monitored by Database Monitoring. Each snapshot is identified by a GUID which Database Monitoring instrumentation injects into the Oracle session using a standard JDBC API. This enables AppDynamics to collect the session properties, including the GUID. When the queries are correlated with the GUID, AppDynamics can correlate the backend database activity with the business transaction snapshot.

jdbc-prepared-statements

Use this property to indicate the implementation classes of the `java.sql.PreparedStatement` interface that should be instrumented.

Type:	String
Default value:	none
Platform(s):	Java

Examples

For example, to instrument calls to Times Ten (an unsupported database), you could set this property to the following:

```
com.timesten.jdbc.JdbcOdbcPreparedStatement
```

jdbc-resultsets

Use this property to indicate the implementation classes of the `java.sql.ResultSet` interface that should be instrumented.

Type:	String
Default value:	none
Platform(s):	Java

Examples

For example, to instrument calls to Times Ten (an unsupported database), you could set this property to the following:

```
com.timesten.jdbc.JdbcStatement
```

jdbc-statements

Use this property to indicate the implementation classes of the `java.sql.Statement` interface that should be instrumented.

Type:	String
Default value:	none
Platform(s):	Java

Examples

For example, to instrument calls to Times Ten (an unsupported database), you could set this property to the following:

```
com.timesten.jdbc.JdbcOdbcStatement
```

jmx-appserver-mbean-finder-delay-in-seconds

When an app server starts up, the associated MBean server starts and the MBeans are discovered. The timing of these activities varies by app server and by configuration. If this activity is not completed in the time that the AppDynamics agent is expecting to discover the MBeans, then the MBean Browser will not show them. Using this node property, you can delay the discovery of MBeans to make sure that agent discovers all the domains after complete startup of the app server. For example, you can set the delay to a time which is 1.5 times of the server startup time. The default delay for the AppDynamics agent is two minutes.

Type:	Integer
Default value:	120
Platform(s):	Java

jmx-operation-timeout-in-milliseconds

Controls the length of time the Java Agent waits before timing out an MBean operation. If you have MBean operations that run longer than the default of 10 seconds, you can increase the timeout value up to 5 minutes.

Type:	Integer
Default value:	10000 (10 seconds)
Platform(s):	Java

jmx-rediscover-mbean-servers

When an app server starts up, the associated MBean server starts and the MBeans are discovered. The timing of these activities varies by app server and by configuration. If this activity is not completed in the time that the AppDynamics agent is expecting to discover the MBeans, then the MBean Browser will not show them. Using this node property, you can trigger the rediscovery of MBeans to make sure that the agent discovers all the domains after complete startup of the app server. Set this property to `true` and reset the app agent, as described in Manage App Agents.

Type:	Boolean
Default value:	false
Platform(s):	Java /td>

jmx-rediscover-mbean-servers-periodic-in-min

This property helps to trigger the rediscovery of Mbeans periodically for every "x" mins (x being the value specified by this node property). When enabled, this property causes the agent to refresh its Mbean server cache for every specified amount of time. By default, no periodic rediscovery of Mbean servers is done. Set the value of this property to 0 to stop the periodic rediscovery task if enabled.

Type:	String
Default value:	0
Platform(s):	Java

jmx-query-timeout-limit

This property sets the timeout limit. Setting this property to negative will disable timeout. For example, if you set the property to –1, timeout is disabled.

Type:	Long
Default value:	5
Platform(s):	Java

jrmp-enable

This property enables or disables AppDynamics support for Sun RMI over Java Remote Protocol (JRMP). You should test Sun RMI JRMP support in a staging environment before using it on production systems. Enable Sun JRMP support by setting this property to `true`.

Type:	Boolean
Default value:	false
Platform(s):	Java

leak-diagnostic-interval-in-minutes

The interval at which diagnostic data, content summary and activity trace, is captured for leaking collections.

Type:	Integer
Default value:	30
Range:	Minimum=2; Maximum=N/A
Platform(s):	Java, .NET

log-request-payload

Set this property to true to log the request payload—HTTP parameters, cookies, session keys, and so on— as part of a transaction snapshot. The log-request-payload property includes logging of WCF HTTP parameters for .NET.

This property dumps all the HTTP data in the app agent logs. But data collectors "diagnostic data collectors" HTTP type are specific to show only the particular HTTP data and not everything, which is: cookies, header, session. The node property gives a complete HTTP dump.

Type:	Boolean
Default value:	false
Platform(s):	Java, .NET

logbased-visibility-log-check-interval-in-millis

How often the agent checks application log files for information related to garbage collection performance.

Type:	Integer
Default value:	1000 ms
Platform(s):	Java, .NET

App Agent Node Properties (M)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

In general, be cautious when modifying the agent default settings. After increasing limits specified for an agent, you need to assess and monitor memory consumption by the agent after the change.

maximum-activity-trace-stack-depth

This property determines the depth of the stack trace to capture as part of an activity trace session. By default, the size of the code paths for OIT (Object Instance Tracking), ALD (Automatic Leak Detection) and MIDS (Memory Intensive Data Structures) are set to 10. To increase this limit, use this property.

Warning: A larger depth has higher overhead on the system. AppDynamics recommends that you increase the default value of this property only temporarily, and remove it or set it back to 10 once you get the desired output.

Type:	Integer
Default value:	10
Platform(s):	Java

max-analytics-collectors-allowed

This property sets an upper limit for Analytics collectors in the agent.

Type:	Integer
Default value:	2000
Platform(s):	Java, .NET

max-async-task-registration-requests-allowed

Adjust this property to increase or decrease the number of asynchronous task registration requests allowed.

Type:	Integer
Default value:	500
Platform(s):	Java

max-async-task-registrations-allowed

Adjust this property to increase or decrease the number of asynchronous task registrations allowed.

Type:	Integer
Default value:	500
Platform(s):	Java, .NET

max-business-transactions

Sets a limit on the number of business transactions discovered once an agent is started. The limit helps to ensure that the Controller I/O processing capability and agent memory requirements are appropriate for a production environment. See Business Transactions.

Warning: Changing this setting can affect the resource consumption of your deployment. Before you change this setting, verify that your application environment and Controller can handle any increased resource requirements.

Type:	Integer
Default value:	50
Range:	Minimum=N/A; Maximum=300
Platform(s):	Java, .NET, Node.js, SAP/ABAP, C++ SDK (any non-proxied Dynamic Language Agent)

max-call-elements-per-snapshot

This property represents the maximum number of elements that are collected for any call graph for a snapshot. When the limit is reached, the agent stops collecting more data for this call graph, reports what has been collected to that point, and marks the call graph with a warning that the limit was reached. AppDynamics does not recommend dramatically increasing this number as it may have overhead implications.

Type:	Integer
Default value:	5000
Platform(s):	Java, .NET

max-concurrent-snapshots

The maximum number of total snapshots that are allowed, including continuing transactions. When the queue goes over the value set, additional snapshots are dropped. This property is ignored in Development mode.

Type:	Integer
Default value:	20
Range:	Values must be positive integers. No other constraints.
Platform(s):	Java, .NET

max-correlation-header-size

The maximum size of the correlation header.

Type:	Integer
Default value:	4096
Range:	Values must be positive integers. No other constraints.
Platform(s):	Java

max-error-snapshots-per-minute

A limit for the number of snapshots per minute due to errors. For example, if too many error snapshots are being seen, then tweak this value to reduce noise in the snapshots.

Type:	Integer
Default value:	5
Platform(s):	Java, .NET

max-jdbc-calls-per-callgraph

The maximum number of JDBC/ADO.NET exit-call stack samples per call graph. Only queries taking more time than the value of `min-duration-for-jdbc-call-in-ms` are reported. Changing the value does not require a restart.

Type:	Integer
Default value:	100
Range:	Minimum=1; Maximum=1000
Platform(s):	Java, .NET

max-jdbc-calls-per-snapshot

The maximum number of JDBC/ADO.NET exit calls allowed in a snapshot. Calls after the limit are not recorded. Changing the value does not require a restart.

Type:	Integer
Default value:	500
Range:	Minimum=1; Maximum=5000
Platform(s):	Java, .NET

max-metrics-allowed

This property sets the upper limit to the number of metrics that can be registered by the agent.

Note: If the number of metrics—registered + unregistered—is greater than the new node property value, then the new metrics will not be created.

Type:	Integer
Default value:	5000 or as set with – `Dappdynamics.agent.maxMetrics=`
Platform(s):	Java

max-prepared-statement-sql-length

Maximum length of the SQL statement for SQL prepared statements. The length of the SQL statement is truncated if it exceeds the value set by this property.

Type:	Integer
Default value:	500
Range:	Minimum=0; Maximum=NA
Platform(s):	Java, .NET

max-service-end-points-per-async-type

Maximum total number of service endpoints that can be registered for each asynchronous entry point type, such as worker thread. Because a single transaction may spawn many threads, you may expect more asynchronous service endpoint types than for synchronous service endpoint types.

Type:	Integer
Default value:	40
Range:	Minimum=0; Maximum=N/A
Platform(s):	Java

max-service-end-points-per-entry-point-type

Maximum total number of service endpoints that can be registered for each entry point type, such as servlet, struts action, web service, and so on.

Type:	Integer
Default value:	25
Range:	Minimum=0; Maximum=N/A
Platform(s):	Java, .NET

max-service-end-points-per-node

Maximum total number of service endpoints that can be detected on a single node. Increasing the value of this property enables more service endpoints to be detected on a particular node.

Type:	Integer
Default value:	100
Range:	Minimum=0; Maximum=N/A
Platform(s):	Java, .NET

max-service-end-points-per-thread

Maximum number of service endpoints detected on a single thread of transaction execution.

If this property is set to the default value of one and two service endpoints are detected that impact one specific transaction, only one service endpoint will be evaluated at any time. If a second service endpoint is detected in the context of the first one, the second is ignored. But, if the second service endpoint starts after the first one ends, the second service endpoint will be evaluated.

Increase this property to monitor additional service endpoints on a thread. This number ensures a maximum limit on overhead and number of metrics due to service endpoints on each thread execution.

Type:	Integer
Default value:	1
Range:	Minimum=0; Maximum=N/A
Platform(s):	Java, .NET

max-urls-per-error-code

This property increases the number of URLs the agent can track that produced a certain error. Once the maximum has been reached, all remaining errors are classified as unknown.

Type:	Integer
Default value:	50
Platform(s):	Java

min-duration-for-jdbc-call-in-ms

A JDBC/ADO.NET call taking more time than the specified time (in milliseconds) is captured in the call graph. The query continues to show up in a transaction snapshot. Setting this value too low (< 10ms) may affect application response times. Changing the value does not require a restart.

Type:	Integer
Default value:	10
Range:	Minimum=0; Maximum=N/A
Platform(s):	Java, .NET

min-load-per-minute-diagnostic-session-trigger

This property indicates the number of requests per Business Transaction to evaluate before triggering a diagnostic session. This property is useful to prevent diagnostic sessions when there is not enough load.

Type:	Integer
Default value:	10
Range:	Minimum=0; Maximum=N/A
Platform(s):	Java, .NET

minimum-age-for-evaluation-in-minutes

Automatic Leak Detection (ALD) tracks all frequently used Collections. For a Collection object to be identified and monitored, it must meet the conditions defined by the ALD properties. This property is the first criteria that needs to be met. The value is the minimum age of the Collection in minutes. This property takes effect after the node restarts.

From the point the collection is captured, it is monitored if it is still available for the specified period without collecting garbage. If it survives, then it is evaluated for size checks. If it meets the criteria, then it is monitored for long term growth in size.

Warning: If you reduce the default, there may be a performance hit on the CPU and memory because ALD needs to process more collections.

Type:	Integer
Default value:	30
Range:	Minimum=5; Maximum=N/A
Platform(s):	Java

minimum-number-of-elements-in-collection-to-deep-size

Automatic Leak Detection (ALD) tracks all frequently used Collections. For a Collection object to be identified and monitored for it must meet the conditions defined by the ALD properties. This property sets the number of elements threshold.

Warning: If you reduce the default there may be a performance hit on the CPU and memory because AD is processing more collections.

Type:	Integer
Default value:	1000
Platform(s):	Java

minimum-size-for-evaluation-in-mb

Automatic Leak Detection (ALD) tracks all frequently used Collections. For a Collection object to be identified and monitored it must meet the conditions defined by the ALD properties. This property sets the minimum initial size in megabytes for a collection to qualify for monitoring. The collection must also survive for the period specified in the minimum-age-for-evaluation-in-minutes property.

Warning: If you reduce the default there may be a performance hit on the CPU and memory because AD is processing more collections.

Type:	Integer
Default value:	5
Range:	Minimum=1; Maximum=N/A
Platform(s):	Java

min-transaction-stall-threshold-in-seconds

For Executor mode only, the asynchronous transactions do not get checked for stall unless they run at least the specified number of seconds.

Type:	Integer
Default value:	60
Platform(s):	Java

msmq-correlation-field

By default, the .NET agent disables downstream correlation for MSMQ message queues. Register this node property on both the publishing and receiving tiers to enable downstream correlation for MSMQ and to specify the field where the agent writes correlation data.

The agent supports Extension or Label fields. By default, the agent writes correlation data to the Extension field, however, some frameworks built on MSMQ write data to the Extension field. Only use Label when the Extension field is not available because it is already in use by the framework. The NServiceBus implementation of MSMQ uses the Extension field, so for NServiceBus, use Label. See MSMQ Backends for .NET.

Type:	String
Supported values:	• `None`: Disable downstream correlation for MSMQ • `Label`: Store correlation information in the label field • `Extension`: Store correlation information in the extension field
Default value:	None
Platform(s):	.NET

msmq-single-threaded

Specify the threading architecture for the MSMQ message queue. The default value is `false`. For multithreaded queue implementations, change the value to `false`. See MSMQ Backends for .NET.

Type:	Boolean
Default value:	false
Platform(s):	.NET

App Agent Node Properties (N-R)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

In general use caution when modifying the agent default settings. If increasing limits specified for an agent, you need to carefully assess and monitor memory consumption by the agent after the change.

normalize-prepared-statements

When this flag is set to `true`, any variables in prepared statement SQL would be substituted with '?' before query text is added to any snapshots.

Type:	Boolean
Default value:	true
Platform(s):	Java

nservicebus-single-threaded

Specify the threading architecture for the NServiceBus message queue. The value defaults to `true`. For multithreaded queue implementations, change the value to `false`. See NServiceBus Backends for .NET.

Type:	Boolean
Default value:	true
Platform(s):	.NET

osb-ignore-exit-types

This comma-separated property defines which exits protocols (as configured in the Transport Configuration pane) are excluded from detection as uncorrelated custom backends.

Set the property to 'all', if you do not want to detect any exit.

Type:	String
Default value:	http,jms
Platform(s):	Java

on-demand-snapshots

Collect snapshots for all Business Transactions executed in this node. Does not need a restart. This property is ignored in the Development mode.

Type:	Boolean
Default value:	false
Platform(s):	Java, .NET

percentile-method-option

You can choose one of two different algorithms to calculate percentiles in AppDynamics:

- P Square algorithm (default): This option consumes the least amount of storage and incurs the least amount of CPU overhead. The accuracy of the percentile calculated varies depending on the nature of the distribution of the response times. You should use this option unless you doubt the accuracy of the percentiles presented.
- Quantile Digest algorithm: This option consumes slightly more storage and CPU overhead but may offer better percentiles depending on how the response times are distributed.

Changes to this property do not require that you restart the agent.

Type:	Numeric
Supported Values:	• 1: P Square • 2: Quantile Digest
Default value:	1
Platform(s):	Java, .NET

queue-single-threaded

Specify the threading architecture for the IBM MQ message queue. The value defaults to `false`.

When the IBM MQ `Get()` method is called, the transaction/snapshot is ended prematurely. To prevent this, set the agent node property: queue-single-threaded=true.

Type:	Boolean
Default value:	false
Platform(s):	Java, .NET

reportingFrequencyInMillis

The agent property specifies the frequency of Request Segment Data (RSD) uploads from the agent.

Type:	Numeric
Default value:	10000 ms
Platform(s):	Java

rest-num-segments

The property, `rest-num-segments` specifies the *n* in the first-*n*-segments parameter in rest-uri-segment-scheme. If this property is 0 or less, then the value of this property is ignored. The value of this property is also ignored if rest-uri-segment-scheme=full.

Type:	String
Default value:	2
Platform(s):	Java

rest-transaction-naming

This node property determines the format in which REST-based business transactions are named. You can use variables to populate the name with values bound at runtime. Any characters in the property value that do not match a variable are treated as literal text in the business transaction name, so you can, for example, separate variables with a colon, slash, or another character.

The agent takes each parameter and fills in the proper value based on the annotations and properties of the Java class:

- `{class-name}`: The app agent will fill in the name of the Java class mapped to the REST resource.
- `{method-name}`: The method being called.
- `{class-annotation}`: Class annotation values.
- `{method-annotation}`: Method annotation applied to the method (not always present).
- `{rest-uri}`: URI of the REST resource. The REST URI is further configured using the following properties:
  - rest-uri-segment-scheme
  - rest-num-segments
- `{http-method}`: HTTP method of the request, GET, POST, and so on.
- `{param-%d}`: A parameter to the method identified by position. Replace %d with the position of the parameter (ZERO-based).

Type:	String
Default value:	{class-annotation}/{method-annotation}.{http-method}
Platform(s):	Java

Examples

See Using Default Settings and Using rest-transaction-naming Properties.

rest-uri-segment-scheme

The property, `rest-uri-segment-scheme` has three valid values: `first-n-segments`, `last-n-segments`, and `full`. This property indicates how many segments of the URI to use for the URI in {rest-uri}. This option is case-sensitive. If the value of this property is `full`, then the value of rest-num-segments is ignored.

Type:	String
Default value:	first-n-segments
Platform(s):	Java

rmqsegments

The App Agent for .NET (agent) automatically discovers RabbitMQ remote services. Use the rmqsegments node property to refine the queue backend name to include some or all segments of the routing key. You must be familiar with your implementation RabbitMQ exchanges and routing keys. See RabbitMQ Exchanges and Exchange Types.

The RabbitMQ routing key is a string. The agent treats dot-separated (".") substrings of the routing key as segments. Set the value for rmqsegments to an integer that represents the number of routing key segments to include in the name. For more details, see information on refining backend naming in RabbitMQ Backends for .NET.

Type:	Numeric
Value:	Integer representing the number of routing key segments to include in the name.
Default value:	0
Platform(s):	.NET

App Agent Node Properties (S)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

show-packages

For the call graphs captured on this node, show the specified packages or class names in addition to the ones configured in the global call graph configuration. Does not need a restart.

Type:	String
Default value:	none
Platform(s):	Java, .NET

slow-request-deviation

The value in milliseconds for the deviation from the current average response time. This setting is used for evaluation of slow in-flight transactions. Also, see the `slow-request-threshold` property for more details.

Type:	Integer
Default value:	200
Range:	Minimum=10; Maximum=3600
Platform(s):	Java, .NET

slow-request-monitor-interval

In-flight requests are checked for slowness in the interval specified by this property. The value is specified in milliseconds.

Type:	Integer
Default value:	100
Range:	Minimum=0; Maximum=3600
Platform(s):	Java, .NET

slow-request-threshold

In-flight requests taking more time than this threshold (in ms) with a deviation greater than the `slow-request-deviation` property from the current average response time are monitored to capture hot spots.

Type:	Integer
Default value:	500
Range:	Minimum=0; Maximum=3600
Platform(s):	Java, .NET

socket-enabled

Use this property to enable NetViz monitoring of .NET and Java apps running on Windows.

Type:	Boolean
Default value:	false
Platform(s):	.NET

spring-batch-enabled

Use this property to enable or disable OOTB BT Detection for Spring Batch.

Type:	Boolean
Default value:	true
Platform(s):	Java

spring-integration-receive-marker-classes

Use this property to specify the class and method you have identified as suitable POJO entry points for Spring Integration.

Based on the MessageHandler interface, the App Agent for Java by default automatically discovers exits for all channels except *DirectChannel*. In cases where a lot of application flow happens before the first MessageHandler is executed,

- Set enable-spring-integration-entry-points=false
- Configure suitable POJO entry points,
- Declare each suitable POJO entry point class/method in this property spring-integration-receive-marker-classes

If the application code polls for messages in a loop, the span of each loop iteration is tracked as a transaction. Tracking begins when the loop begins and end it when the iteration ends. To safeguard against cases where `pollableChannel.receive()` is not called inside a loop, specify this property for each class/method combination that polls messages in a loop.

After setting this property, restart the application server for changes to this property to take effect.

Type:	Comma-separated string of fully-qualified class /method name, such as spring-integration-receive-marker-classes = ,<> ....
Default value:	none
Platform(s):	Java

Examples

For example, to enable tracking for the following:

```
class MessageProcessor
{
void process()
{
   while(true)
   {
          Message message = pollableChannel.receive()
   }
}
}
```

set this property as follows:

```
spring-integration-receive-marker-classes = MessageProcesser/process
```

See also Spring Integration Support.

spring-mvc-naming-scheme

Register this node property to modify the naming scheme for Spring MVC transactions. Bean ID cannot be used as a global naming type. Use the bean ID and method name for global.

Type:	String
Allowed values:	bean-id, simple-class-name, fully-qualified-class-name, business-interface-name, bean-method-name, ben-id-and-method-name, class-and-method-name
Default value:	none
Platform(s):	Java

App Agent Node Properties (T-Z)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

thread-correlation-classes

For multi-threaded applications, use this property to configure classes to be included in Java thread correlation when simple prefix-matching (matching on `STARTSWITH`) is sufficient to identify the classes.

The `thread-correlation-classes` property specifies the classes to include for thread correlation. This property can be used together with the `thread-correlation-classes-exclude` property.

The configured correlation takes effect without requiring a restart of the managed application.
Also see, Configure the Thread Correlation in Java Agent.

Type:	Comma-separated string of fully-qualified class names or package names
Default value:	none
Platform(s):	Java

This property is not recommended for use in the Executor Mode.

thread-correlation-classes-exclude

For multithreaded applications, use this property to configure classes to be excluded in Java thread correlation when simple prefix-matching (matching on `STARTSWITH`) is sufficient to identify the classes. This property specifies the classes to exclude from thread correlation. This property can be used in conjunction with the `thread-correlation-classes` node property.

The configured correlation takes effect without requiring a restart of the managed application.
See Configure Multithreaded Transactions (Java only)

Type:	Comma-separated string of fully-qualified class names or package names
Default value:	none
Platform(s):	Java

This property is not recommended for use in the Executor Mode.

thread-cpu-capture-overhead-threshold-in-ms

Determines the timeout allotted for collecting and calculating Thread CPU Time for 1000 iterations. If the timeout is exceeded, the Java Agent automatically disables CPU time collection for threads. CPU usage information will then be absent from the BT overview or snapshots in the Controller UI. In addition, an INFO-level log similar to the following appears in the logs:

```
[Thread-0] 22 Oct 2013 14:19:26,346 INFO
JVMThreadCPUTimeCalculator - Disabling BT CPU
Monitoring. Time taken to calculate Thread CPU Time for
[1000] iterations is [15 ms] which is greater than the
allowed budget of [10 ms].
```

This issue may particularly affect JDK 1.6 on Linux due to the issue getCurrentThreadCpuTime is drastically slower than Windows Linux.

Type:	Integer
Default value:	10 ms
Platform(s):	Java

Examples

You can increase the `thread-cpu-capture-overhead-threshold-in-ms` property, but it is important to note that this may result in increased overhead on your application. We recommend you use this Java HotSpot VM option instead to speed up the API call itself:

```
-XX:+UseLinuxPosixThreadCPUClocks
```

Restart is needed after changing this value.

wcf-enable-eum

Enable and disable EUM correlation from a WCF node.

Type:	Boolean
Default value:	false
Platform(s):	.NET

Examples

The enable EUM correlation, the WCF application must also have the following entry in the `Web.Config`:

```
<serviceHostingEnvironment aspNetCompatibilityEnabled="true" />
```

See serviceHostingEnvironment.

websocket-entry-calls-enabled

When set to false, no WebSocket entry calls are detected.

Type:	Boolean
Default value:	true
Platform(s):	Java

Dynamic Language Agent Proxy

Related pages:

- Configure the Agent for PHP CLI Applications
- Use a Shared Proxy for PHP Agents
- Start the PHP Agent Proxy Manually
- Start the Proxy Manually for Node.js
- Share a Proxy Among Node.js Agents
- Start the Python Agent Proxy Manually

The AppDynamics proxy is a Java daemon process that handles communication between the Controller and these agents:

- Node.js
- PHP
- Python
- Web Server

The proxy reports data collected by the agent to the Controller, which stores, baselines, and analyzes it.

This page describes information you can use to examine and resolve proxy issues that may prevent an application agent from connecting to the Controller, or reporting data correctly. For detailed information about how the proxy works with a specific agent, see the appropriate *Related pages*.

Proxy Basics

Single or Multi-Tenant

For the Node.js and PHP agents, the proxy can be single-tenant (one proxy per agent) or multi-tenant (multiple agents communicating through a single proxy), depending on the way the agents are configured. The default setup for these agents is single-tenant, but there are circumstances for which a multi-tenant proxy is required or desirable. The Apache Web Server and Python agents always communicate through a multi-tenant proxy when there are multiple agents on a machine.

Automatic or Manual Startup and Shutdown

Typically the proxy is automatically started when the application agent starts up, but in some cases, you need to launch it manually. These cases vary depending on both the particular agent and the application environment.

After the proxy is started (automatically or manually) it registers with the Controller and requests the agent configuration. The agent must receive the configuration from the Controller via the proxy before it can report metrics.

If the proxy was automatically started, the agent is supposed to shut down the proxy as part of its own cleanup procedures. If the proxy was manually started, it must be shut down manually.

Proxy Logs

If the proxy is running, you can check the proxy log to examine connection issues.

The proxy log files are named `proxy.<timestamp>.log`.

If the proxy is not running, examine the agent logs for the typical Java startup signature to see if the proxy started.

See the agent-specific documentation for the location of these logs:

- Node.js: Default is `/tmp/appd/logs`. See Install the Node.js Agent.
- PHP: Default is `<php_agent_install_dir>/logs`. See Install the PHP Agent.
- Python: Default is `/tmp/appd/logs`. See Python Agent Debugging and Logging.
- Web Server: `<webserver_agent_install>/logs/proxy_$date.lo`

Proxy Not Started Issues

The agent will not work if the proxy did not start.

Determine whether the proxy started by running this command:

```
ps aux|grep java
```

If the proxy is running, you should see `java` and `proxy` in the output, something like this:

```
/usr/lib/appdynamics-php5/proxy/jre/bin/java -server -Xmx120m -classpath /usr/lib/appdynamics-php5/proxy/conf
/logging/*:/usr/lib/appdynamics-php5/proxy/lib/*:/usr/lib/appdynamics-php5/proxy/lib/tp/*:/usr/lib/appdynamics-
php5/proxy/* -Djava.library.path=/usr/lib/appdynamics-php5/proxy/lib/tp -Dappdynamics.agent.logs.dir=/usr/lib
/appdynamics-php5/logs -Dcomm=/tmp/ad-siJ4rp -DagentType=PHP_APP_AGENT -Dappdynamics.agent.runtime.dir=/usr/lib
/appdynamics-php5/proxy com.appdynamics.ee.agent.proxy.kernel.Prox
```

If the proxy did not start, the most common reason is insufficient permissions.

- The agent installation directory, and its proxy control subdirectory, must be readable and executable by all and writable by the directory owner:

  ```
  chmod -R 755 <agent_install_dir>
  ```

- The agent installation directory must be owned by the instrumented application user. Who this user is depends on the platform. It could be the Apache user, the python container user, the nginx user, the `node.js` process, etc.

  ```
  chown -R <appuser>:<appsuser> <agent_install_dir>
  ```

If the proxy did not start, set these permissions and try again.

Proxy Connection Issues

If the proxy started but you don't have a connection to the Controller, you may be using incorrect Controller information.

Examine the proxy log and verify that there are no typos in the Controller domain name or port and that SSL setting is enabled for an SSL connection. If there are mistakes, edit the Controller/port/SSL values in the configuration. These settings are on the first page of the Agent Download and Install Wizard or the agent settings (require statement for Node.js) if you installed the agent manually.

If you have verified that the Controller settings are correct and the proxy still does not connect to the Controller, telnet to the SaaS Controller:

```
telnet <your_account>.saas.appdynamics.com 443
```

If you cannot access the Controller through telnet, examine the agent-registered messages in the logs that indicate why the proxy is unable to connect, such as the existence of a firewall or other obstacle at your site. Work with your administrator to see if you can resolve the issue.

If you can reach the Controller through telnet, there may be a problem on the Controller.

Dynamic Agent Proxy Logging

Proxy logs are created for app server agents that use the Dynamic Agent Proxy to communicate with the Controller. See Dynamic Language Agent Proxy.

The PHP Agent, Node.js Agent (Java proxy mode), Python Agent, and the Web Server Agent generate logs for the Dynamic Agent Proxy. The logs determine why snapshots are not being taken and diagnose communication issues with the Controller.

The proxy logs consist of a top-level file named `proxyCore`*Year_mon_day_hr_min*`.#.log` and files named `proxy`*Year_mon_day_hr_min*`.#.log`, where # is the log set. See Agent Log Files for information about how the logs are organized into sets that roll over.

Other logs associated with each proxy log include:

- Bytecode Transformer log
- REST log
- Dynamic Services (used internally for debugging) log

Each proxy log has a maximum size of five MB.

Allowing for the possibility of several restarts and all the possible logs that could be generated (Proxy, BytecodeTransformer, REST, and Dynamic Services), the maximum number of logs is 20 files (four log files times five sets). The maximum size is 100 MB per set.

Business Applications

As described in Overview of Application Monitoring, a business application serves as the top-level container in the AppDynamics APM model. Business applications contain a set of related business transactions and service endpoints, along with the infrastructure components and artifacts that interact to provide the services.

Organize Business Applications

You can model your environment into one or more business applications. When you have multiple business applications within the same AppDynamics account, you can use the cross application flow map to view relationships between the different applications.

Since access permissions in the Controller UI can be assigned by business application, organizing business application by teams in your organization may make the most sense. Keep in mind that configuration settings such as Health Rules are scoped to a business application, avoid having more business applications than needed to ease configuration.

> When you model your environment, be sure to assign unique names to your business applications. Names must be unique among both Application Performance Monitoring and End User Monitoring.

Permissions

Creating applications requires the *Can Create Applications* permission. Permission to view, edit, or delete applications can be set as part of the default application permissions for a custom role or for specific applications. See Application Permissions.

View Applications

The Applications page, accessible from the menu bar in the Controller UI, provides a high-level view of the business applications in your environment. At a glance, you can see the performance for the applications.

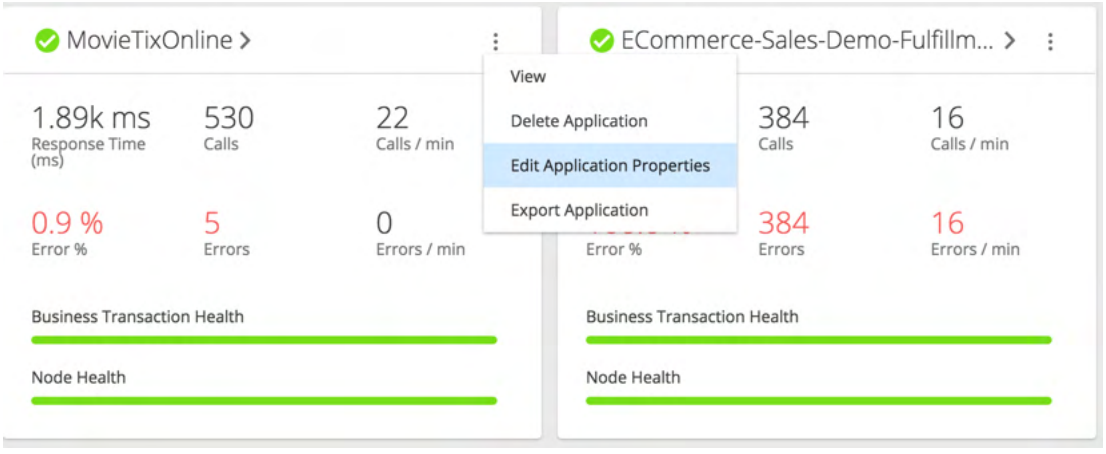
There are several views and sorting options in the page. To view relationships between business application (such as, when a business transaction in one invokes a service in another), select the **Flow View** icon.

Modify Applications

You can create new business applications from the Applications page, but it's not necessary to create the business application manually. The Controller creates a new business application automatically the first time an app agent registers itself using a new business application name.

Rename Applications

You can rename applications by selecting **Edit Application Properties** from the drop-down of an application.



> If you change the name of an application, you also need to change it in the agent configuration at `controller-info.xml`. If you do not change the controller-info.xml application name field, agents will re-create the old application name and report to the old application.

Deleting Applications

To delete an application:

Select the application in the **Applications** drop-down, and select **Actions > Delete**.

The Controller prompts you to acknowledge a list of related items that will be deleted including:

- Number of tiers and nodes
- Number of business transactions (see Business Transactions)
- Browser RUM Apps
- Mobile Apps

Application Performance Details

From the Applications page, click a listed application to configure and monitor the business application. In the business application instance Application Dashboard page, you can view:

- Top Business Transactions: The key performance indicators for the most expensive business transactions sorted by the various criteria, such as load, response time, errors and so on. Click View All in any of the panels in this tab to see a list displaying all the key performance indicators for the top business transactions in one panel.
- Transaction Snapshots: The transaction snapshots for the selected time range. From a transaction snapshot, you call drill down to the root cause of a performance problem.
- Transaction Analysis: Application performance over the selected time range as a graph. Use the graph to analyze the impact of different events on the application response time.
- Machine Snapshots: When an application has at least one .NET tier, this appears as a list of the machine snapshots for the selected time range. From a machine snapshot, you can drill down to view environmental conditions, such as running processes and memory usage for a particular machine. See Machine Snapshots for .NET.

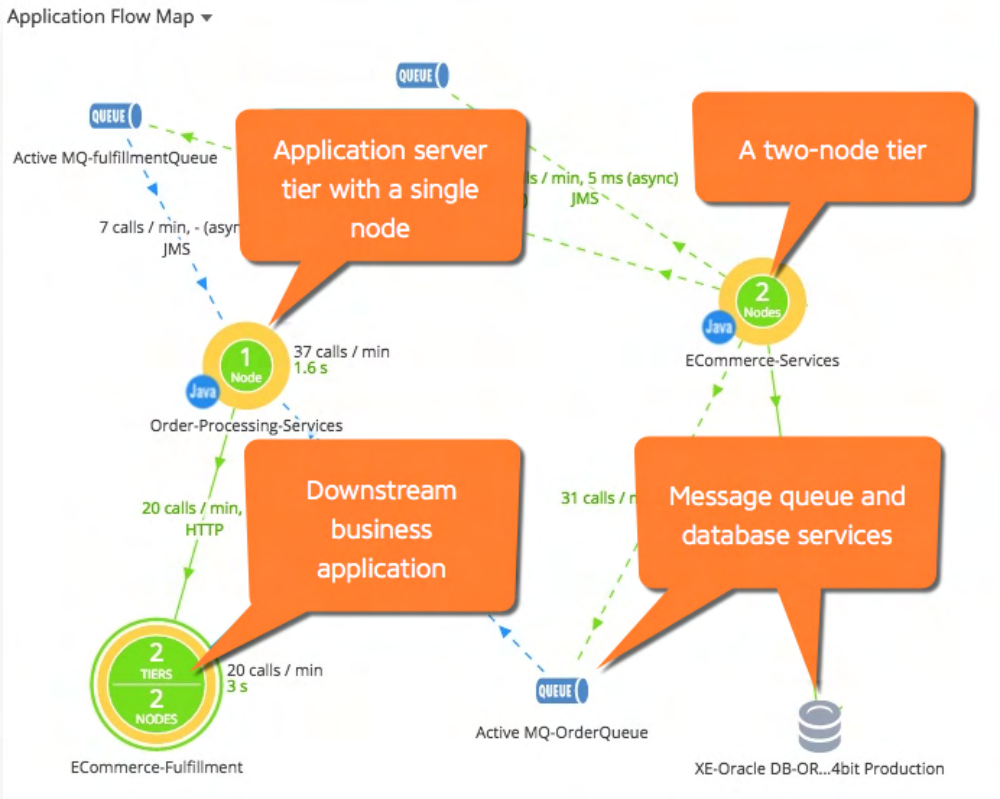
Flow Maps

Flow maps present a dynamic visual representation of the components and activities of your monitored application environment. See Overview of Application Monitoring.

This page describes how to view and use flow maps.

Flow Map Overview

Flow maps show the tiers, nodes, message queues, and databases in the environment, and the business transactions that flow through them. This sample shows a basic flow map for an e-commerce application. In the sample, three server tiers interact with databases and an Apache ActiveMQ message broker.



Connection Types

Flow lines represent connections between components in the flow map. Solid lines indicate synchronous connections, while dashed lines indicate asynchronous connections.

Many modern frameworks use asynchronous patterns even if you do not explicitly call an asynchronous function or method. For example, your application code may employ a synchronous call to a framework or an Object-relational mapping style API, but the framework itself invokes an asynchronous executor to handle the call. These types of asynchronous segments show up as a dotted line on the flow map. For more about asynchronous exit calls, see Trace Multithreaded Transactions for Java or Asynchronous Exit Points for .NET.

Request Times

The numbers above the flow lines indicate the calls made per minute to the tier and the average time taken for the request to be serviced; that is, the round-trip time for the request. The round-trip time includes time spent on the network, if applicable to your topology, and the time that the backend server or other process spends processing the request. The calls per minute for a given context, such as a tier, must be one or more for the flow map to display.

Performance Baselines

If performance baselines are set for transactions represented in the flow map, the flow lines use color to indicate the performance of the service represented by the flow line relative to the baseline. For example, a green flow line indicates that that response times in the time range do not differ significantly from the baseline. A yellow line indicates that response times are slower than the baseline. It takes some time for the Controller to establish baselines for a new installation. If there are no baselines for comparison, the flow lines are blue.

Live Entity Data

By default, the flow map only shows the nodes receiving performance data to optimize the rendering of the flow map and to enable you to quickly view the active nodes. You can set a filter to view the nodes not receiving performance data or all nodes. Choosing to view the nodes not receiving performance data can help you troubleshoot node issues.

When an entity is alive, it will affect other associated entities:

- When a business transaction entity is alive, the associated node, tier, and application will be alive.
- When a node is alive, the associated tier, and application will be alive.
- When a tier is alive, the associated application will be alive.

> If the Controller detects that a flow map is taking a long time to load, it does not load the flow map automatically. In this case, you can click **Show Flow Map** to display the flow map if you choose.

Types of Flow Maps

Flow maps appear in several of the built-in dashboards in the UI, and show different information depending upon the context in which they appear:

- *Cross Application flow maps* show exit calls between applications within the monitored environment. A pattern of such calls is known as cross-application flow.
- *Application flow maps* show the topology and activities within an application. It displays metric values across all business transactions in the application for the selected time range. For example, the application flow map displays calls per minute; average response time for calls made to databases and remote services; and business transaction errors per minute. These metrics are based on all calls made from a specific tier to a database or remote service across all business transactions.
    - When an application is one of several in a one-app-per-service architecture, business transactions can represent service endpoints. For these applications, the application flow map displays a *Cross-BT Hovercard* that shows calls to upstream and downstream business transactions which represent endpoints of other services.
- *Tier and node flow maps* display these metric values across all business transactions for the subset of the application flow related to the selected tier or node.
- *Business transaction flow maps* show the activity for a business transaction. The START label indicates the tier where the transaction starts (the originating tier). The business transaction flow map shows metrics that are calculated based on all executions of the business transaction during the selected time range.
- Snapshot flow maps illustrate the metrics associated with a single snapshot. The metrics values shown in the map are specific to a particular execution of the transaction.

AppDynamics shows cross-application flow on all flow maps where appropriate. For example, a tier flow map shows correlation when there are exit calls from the tier to another instrumented application.

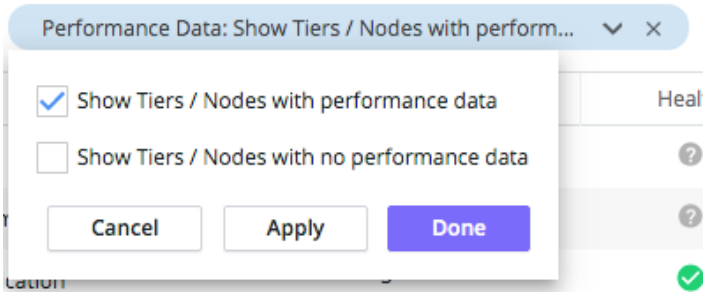
Context can determine the meaning of what flow maps represent. For example, consider the average response time (ART) for calls to a database.

- In the context of an application, ART averages all calls to the database that happen *within the application*. Suppose that the application flow map shows that ART for those calls is 20 milliseconds.
- In the context of a business transaction, ART represents average execution time *for the business transaction as a whole*. Suppose that in a BT within the same application, the database gets called twice each time the business transaction executes. In the business transaction flow map, ART represents the average duration of *a pair of* database calls, meaning that ART is 40 milliseconds.

Flow Map Interactions

On flow maps you can:

- Click items in the flow map to see key performance indicators in an informational popup. For some components of the flow map, like tiers, the popup displays additional details.
- Change the Time Range setting to have the flow map represent the activity of the system within the selected time frame.
- For SaaS Controllers, note that the flow maps show a maximum of the last 60 minutes of data, even if the time range in the UI is set to a greater range. This only applies to flow maps; the data in other graphs on the dashboard represent the selected time range.
- Click **Legend** to learn more about how flow maps represent data.
- Use a filter to view tiers and nodes (all associated entities) receiving performance data, not receiving performance data, or all nodes.
    - Select **Show Tiers / Nodes with performance data** to show entities and metrics for live entities over the specified time range.
    - Select **Show Tiers / Nodes with no performance data** to show metrics/entities of entities that are not alive over the specified time range.
    - Select both **Show Tiers / Nodes with performance data** and **Show Tiers / Nodes with no performance data** checkboxes to show metrics and entities without checking the liveness of entities.



- Drag and drop items to rearrange the flow map layout or use automatic arrangement options using the controls at the top right of the flow map:

  Use the controls to view the mapped components as a list, auto arrange the flow map—in which components are arranged for the fewest crossing flows—maximize the view, and more.

The Cross-BT Hovercard in the Application Flow Map

For an application in a one-app-per-service architecture, the application flow map displays a *Cross-BT Hovercard* showing calls from upstream and to downstream business transactions representing endpoints of other services.

This enables you to isolate the service which is the origin of any problem that arises, to one of three possibilities:

1. The service whose endpoint is a BT that you are monitoring ("your" service)
2. An upstream or downstream service, that "your" service communicates with through cross-BT calls
3. Yet another upstream or downstream service, that "your" service communicates with indirectly through a chain of cross-BT calls between several services

To access the Cross-BT Hovercard, select the line representing either the incoming or outgoing cross-application call, and then select the Business Transactions tab.

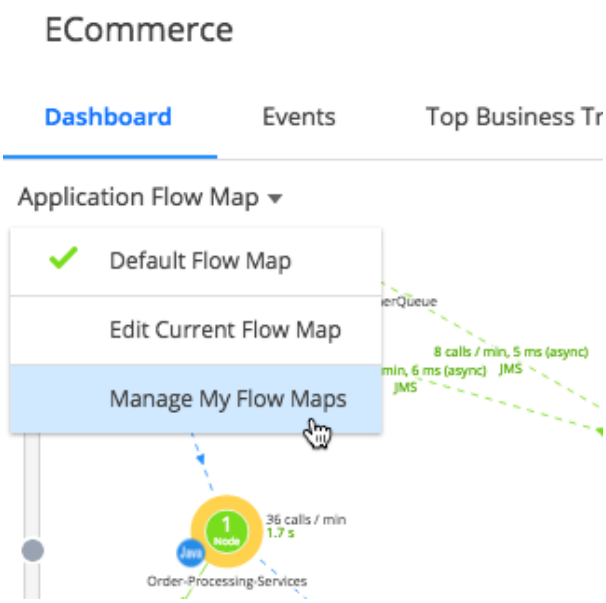
Manage Flow Maps

In a large scale deployment, the flow map may show hundreds of monitored nodes, not all of which may be of interest to specific users or teams. You can create flow maps that are targeted to specific areas of interest by creating custom flow maps.

The custom flow map can be configured to show only certain tiers or those based on performance thresholds, for example:

- Only tiers from where the load exceeds fifty calls per minute and the average response time exceed 10,000 ms
- Only backends receiving at least 400 calls per minute and generating more than 10 errors per minute

To create, copy, or delete a flow map, click the flow map menu and click **Manage My Flow Maps**.



When you create a flow map, the new flow map inherits the context of the flow map in which it was created, whether created from an application, business transaction, tier, or node flow map. To customize your new flow map, see Customize Flow Maps.

Customize Flow Maps

Deployment Support

Related pages:

- Flow Maps
- License Management
- Network Visibility

You can customize flow maps to show information based on performance criteria or to have specific tiers or databases and remote services visible.

You can customize a built-in flow map, but in most cases, you will likely want to customize a flow map you have created. To customize a flow map, choose **Edit Current Flow** from the flow map menu. You can make the flow map shared or private. When shared, your custom flow map appears in the flow map menu for all users.

Add ELBs to the Flow Map

> This document contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation because Amazon controls its own documentation.

AppDynamics users can now view Amazon-hosted entities and data in several AppDynamics products by connecting their Amazon account to AppDynamics. This topic explains how to connect and view Amazon CloudWatch Elastic Load Balancing (ELB) data on a Network Visibility flow map, and describes what metric data is reported. AppDynamics uses the Amazon CloudWatch API to obtain metrics in near real-time from your Amazon Web Services (AWS) resources and applications. This combination of AppDynamics and AWS cloud-native monitoring helps identify and diagnose a variety of issues from a single Controller.

Requirements

- AppDynamics SaaS Controller >= 4.5.13.
    - Role Delegation in AWS is available from >= 4.5.16.
- A Network Visibility license.
- An AWS Classic Load Balancer with at least one EC2 instance showing a status of InService. See Getting Started with Elastic Load Balancing.
- An AWS Identity and Access Management (IAM) role with permission to create a user and assign a role to that user.

AppDynamics provides two ways to connect to Amazon CloudWatch and start monitoring:

- Connect AppDynamics to Amazon CloudWatch using Role Delegation
- Connect AppDynamics to Amazon CloudWatch using Access Key Credentials

You can connect your AWS account using Role Delegation, granting additional permissions to a new or existing role. Alternatively, you can create Access Key Credentials, a new user with a new pair of access keys.

Connect AppDynamics to Amazon CloudWatch Using Role Delegation

Setting up Role Delegation requires configuring values and settings in your Controller and your AWS account:

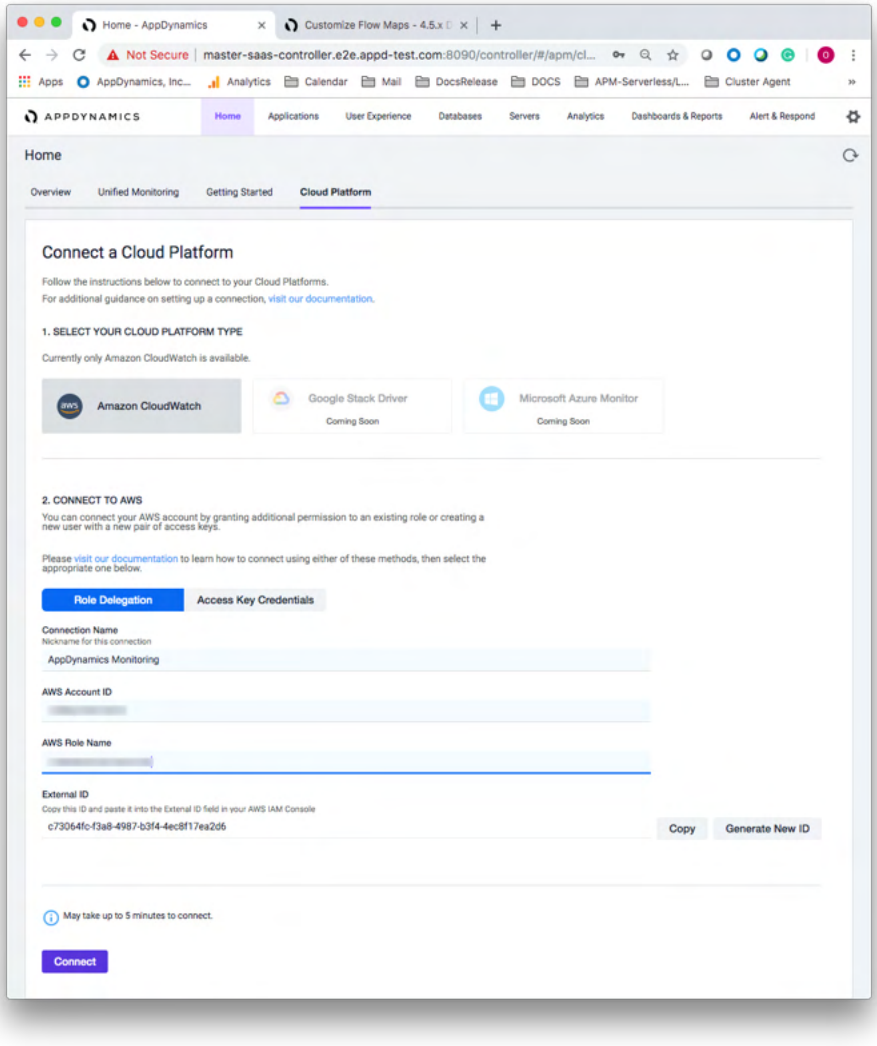
1. Create a Role Name and Copy External ID in the Controller
2. Create an AWS IAM Service Policy
3. Create an AWS IAM Role
4. Connect your AWS IAM Service Role to AppDynamics

Create a Role Name and Copy External ID in the Controller

To connect your AppDynamics Controller:

1. Go to https://accounts.appdynamics.com/subscriptions.

2. Sign in to your account.
3. Select the Controller that you want to connect to Amazon CloudWatch.
4. Navigate to **Home > Cloud Platform** tab.
5. Under **Connect a Cloud Platform**, select **Amazon CloudWatch**.
6. Click **Role Delegation**.



7. Enter your Amazon Credentials:
    a. Enter a Connection Name (in our example, we chose **AppDynamicsMonitoring**).
    b. Enter your organization's AWS Account ID without dashes.
    c. Enter an AWS Role Name, for example, **AppDynamicsMonitoringRole**, the name should not contain spaces or special characters.
    d. Under the **External ID** field, click **Copy**. Save this information somewhere, as you'll need this External ID to enter into your AWS IAM Console.

    > ⚠ If you close this window without capturing the External ID, you will have to generate a new ID for your **AppDynamicsMonitoring** account.

    Leave this browser window open. In a separate browser, log in to your AWS Account.

Create an AWS IAM Service Policy

In the AWS IAM Management Console, there are two ways to attach permissions policies, using JSON or the AWS UI. We recommend using JSON, as it contains the minimum required permissions. If you prefer you can also do this manually using the AWS UI, see Creating IAM Policies - AWS Identity and Access Management.

JSON

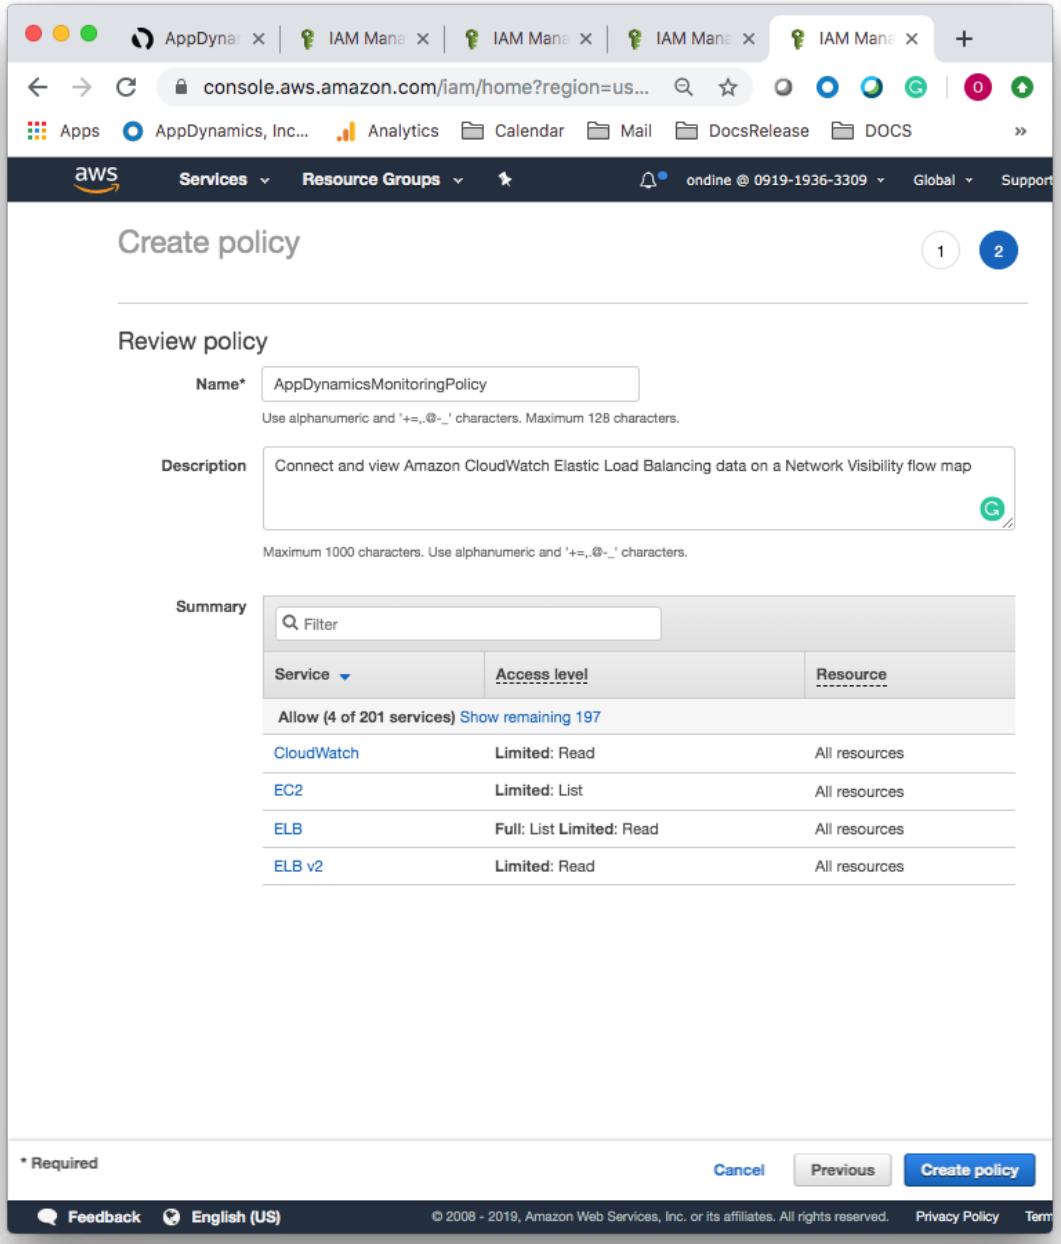
Navigate to the AWS Management Console and open the IAM console.

1. Click **Create policy**.
2. Click the **JSON** tab.

3. Copy the code below.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "elasticloadbalancing:DescribeLoadBalancers",
                "ec2:DescribeInstances",
                "cloudwatch:GetMetricData",
                "ec2:DescribeRegions",
                "elasticloadbalancing:DescribeInstanceHealth"
            ],
            "Resource": "*"
        }
    ]
}
```

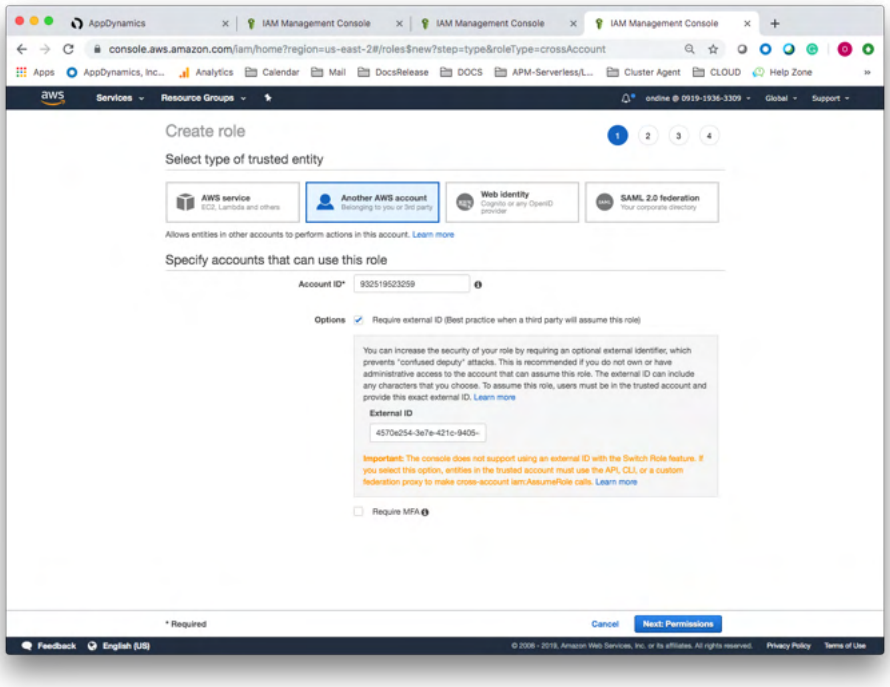
4. Paste the code under the **JSON** tab.
5. Click **Review policy**.
6. Enter a name for the policy, such as **AppDynamicsMonitoringPolicy,** and optionally, add a description**.**



Click **Create policy**. A success message displays: AppDynamicsMonitoringPolicy has been created.

Create an AWS IAM Role

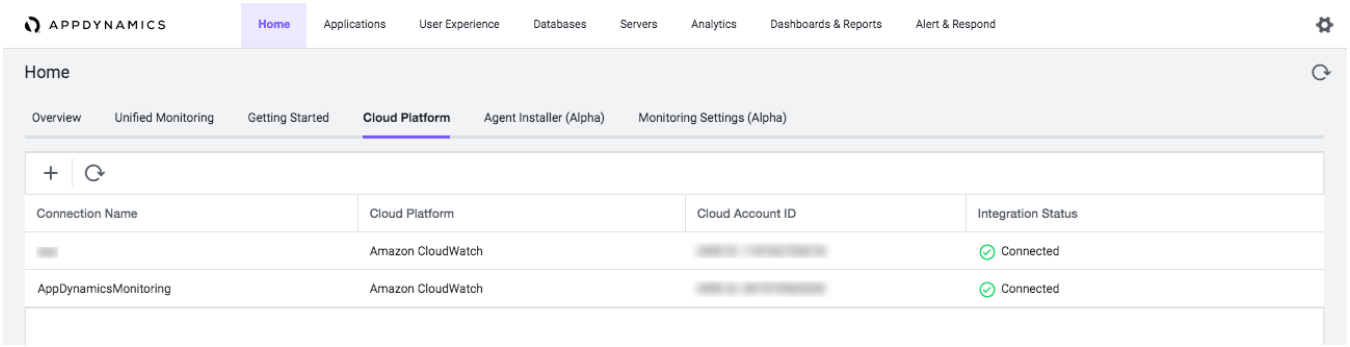
1. In the Identity and Access Management (IAM) console left navigation pane, select **Roles**.
2. Click **Create role**.
3. Select: **Another AWS account**.
4. For **Account ID**, enter AppDynamics Account ID: **932519523259**.
5. For **Options**, check **require external ID**.
    a. Navigate to your AppDynamics Controller browser window. Copy the External ID, if you have not already done so.



6. Return to the AWS Management Console browser window.
7. Paste or enter the **External ID** generated by the AppDynamics Controller. Leave the **Require MFA** option disabled.
8. Click **Next: Permissions**.
9. Under **Attach permissions policies**, search for and select **AppDynamicsMonitoringPolicy**.
10. Click **Next: Tags** (optional).
11. Click **Next: Review.**
12. Enter a name for the role, such as **AppDynamicsMonitoringRole**, and optionally, add a description**.**
13. Click **Create role**. A message displays: The role AppDynamicsMonitoring role has been created.

Connect your AWS IAM Service Role to AppDynamics

1. Return to the Controller browser window. The AppDynamicsMonitoring connection uses the **AppDynamicsMonitoringRole** to connect.
2. Make certain that the AWS Role Name in the Controller matches the role name with permissions policy created in the AWS IAM Management Console. In our example, we used the name: **AppDynamicsMonitoringRole**.
3. Click **Connect**. This initiates the AppDynamics data connection with Amazon CloudWatch.
4. The **Home > Cloud Platform > Integration Status** tab displays the connection status of your Amazon CloudWatch integration. After five minutes, use the refresh icon in your browser to verify the connection has succeeded.



Confirm that the Integration Status of your AWS account shows **Connected** before navigating to the Network Dashboard.

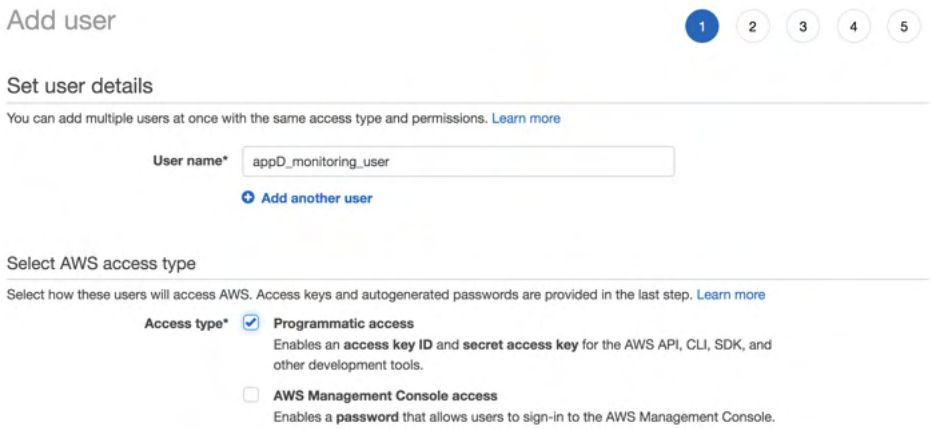
Connect AppDynamics to Amazon CloudWatch Using Access Key Credentials

To integrate AppDynamics with Amazon CloudWatch, create an AWS Identity and Access Management (IAM) user within your AWS account. Once you create the IAM user, attach read-only policies to limit the permissions that this policy grants to the user.

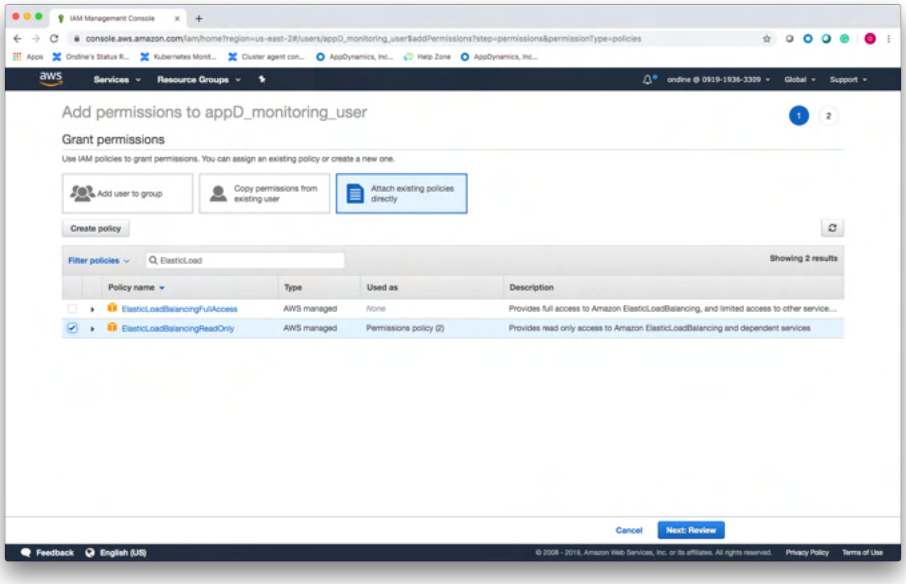
1. Create an AWS IAM User
2. Connect your AWS IAM User to AppDynamics

Create an AWS IAM User

1. Navigate and sign in to the AWS Management Console.
2. Open the IAM console.
3. In the Identity and Access Management (IAM) left navigation pane, select **Users**.
4. Click **Add user**. If you are unable to add a user, see Access Management in the Amazon documentation.
5. Enter the **User name:** `appD_monitoring_user` or a `username` of your choice.
6. Under **Select AWS access type**, check **Programmatic access**.



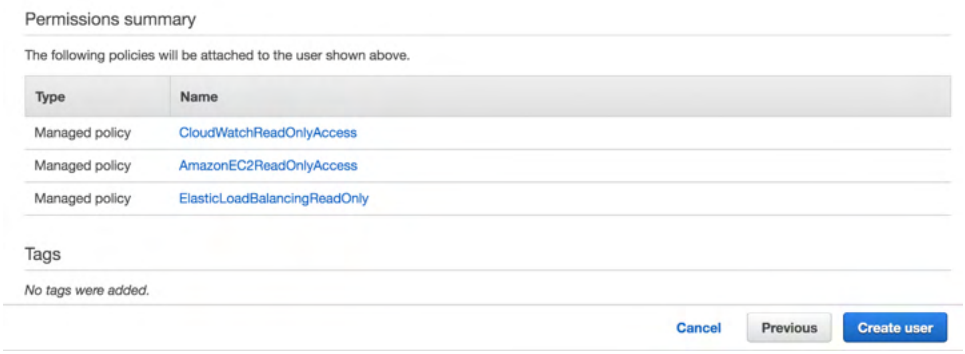
7. Click **Next: Permissions**.
8. Under **Grant permissions**, select **Attach existing policies directly**.



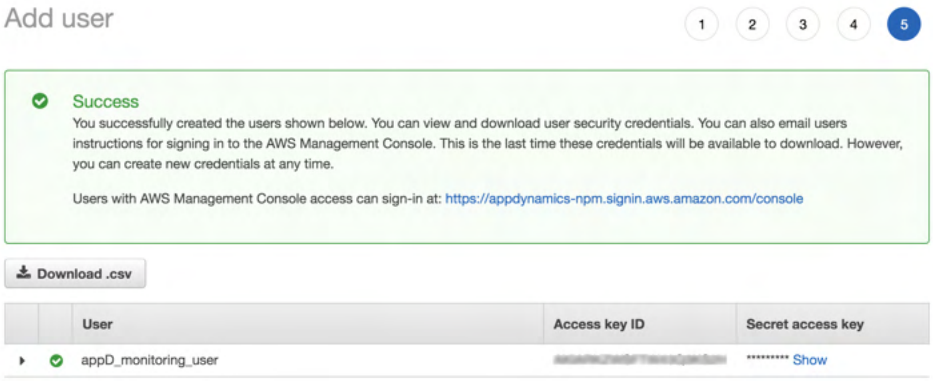
9. Choose appropriate policies for the **`appD_monitoring_user`** monitoring account. We recommend ReadOnlyAccess policies. You can also use custom policies specific to the active resource that you want to ingest Amazon CloudWatch metrics. See Access Management and Example IAM Identity-Based Policies. In our example, we chose these policies:
    - AmazonEC2ReadOnlyAccess
    - CloudWatchReadOnlyAccess
    - ElasticLoadBalancingReadOnly

    Set permissions boundary (optional).
10. Click **Next: Tags** (optional).

11. Click **Next: Review**.



12. Click **Create user**.



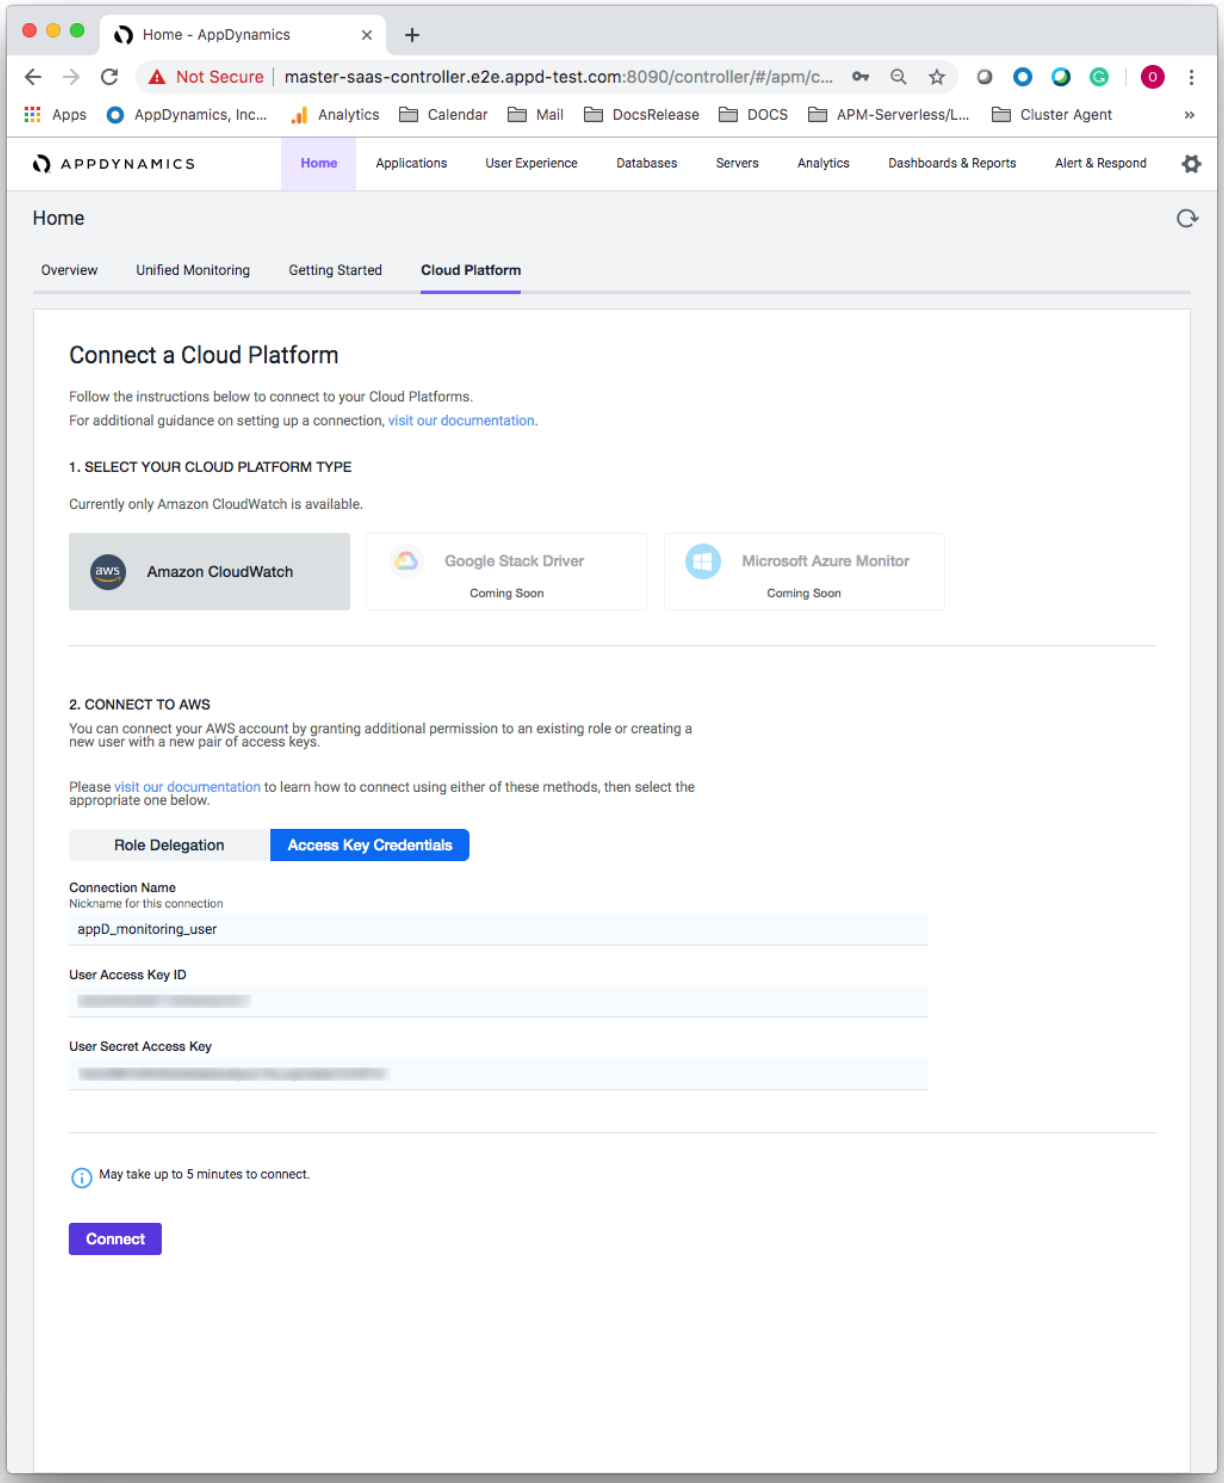
13. Note the **Access Key ID** and the **Secret Access Key** for the user, or click **Download .csv**. You'll need the keys to add Amazon CloudWatch to your AppDynamics account.

If you navigate away from this window without capturing these keys, you won't be able to access them again. You will have to create a new **`appD_monitoring_user`** monitoring account. See Creating IAM Users (Console).

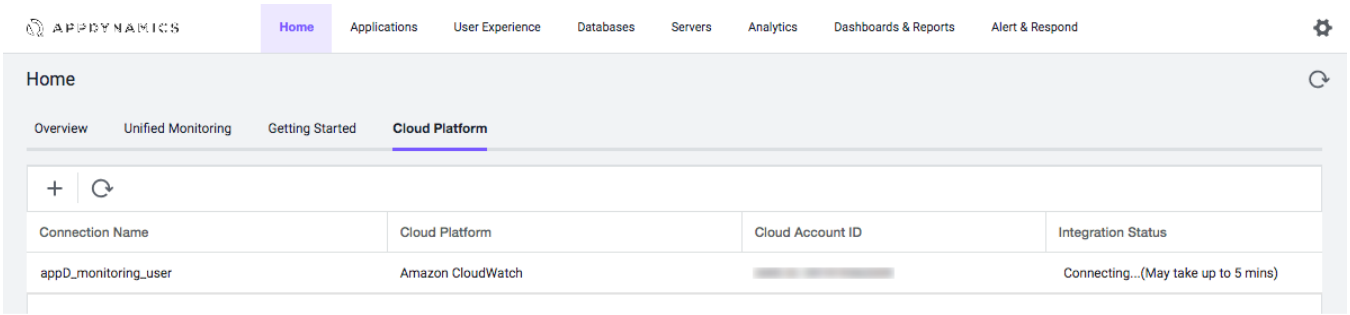
Connect your AWS IAM User to AppDynamics

To connect your AWS IAM user account to AppDynamics:

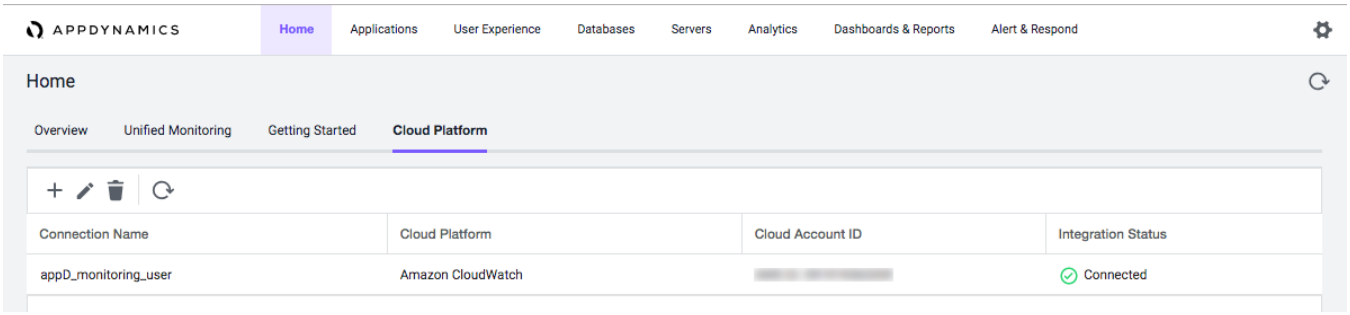
1. Go to https://accounts.appdynamics.com/subscriptions.
2. Sign in to your account.
3. Select the Controller that you want to connect to Amazon CloudWatch.
4. Navigate to **Home > Cloud Platform** tab.
5. Under **Connect a Cloud Platform**, select **Amazon CloudWatch**.
6. Click the **Access Key Credentials** tab.
7. Enter a Connection Name.
8. Enter your Amazon **appD_monitoring_user** Access Key ID.
9. Enter your Amazon **appD_monitoring_user** Secret Access Key.
10. Click **Connect**. This initiates the AppDynamics data connection with Amazon CloudWatch.



The **Home > Cloud Platform > Integration Status** tab displays the connection status of your Amazon CloudWatch integration.



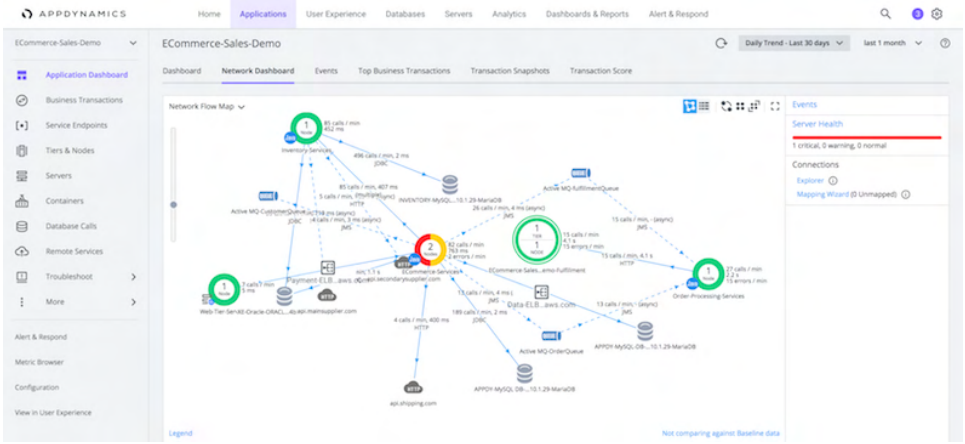
After five minutes, use the refresh icon in your browser to verify the connection has succeeded. Confirm that the Integration Status of your AWS account shows **Connected** before navigating to the Network Dashboard. See View and Monitor Elastic Load Balancing Data.



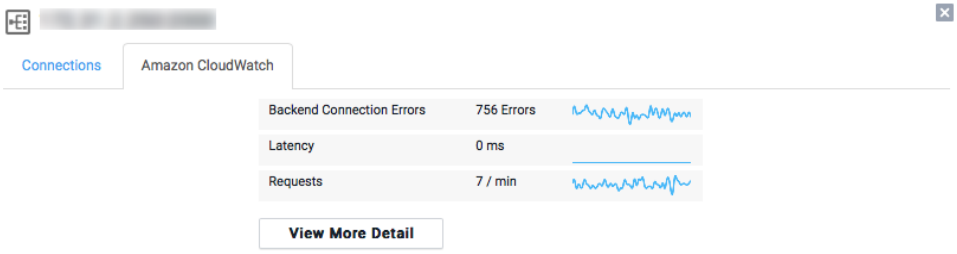
View and Monitor Elastic Load Balancing Data

To view and analyze Amazon CloudWatch metrics in the Controller UI:

1. Go to https://accounts.appdynamics.com/subscriptions.
2. Sign in to your account.
3. Select the Controller that you want to connect to Amazon CloudWatch.
4. Go to **Applications** and select the desired application.
5. Click **Network Dashboard.** A flow map displays.

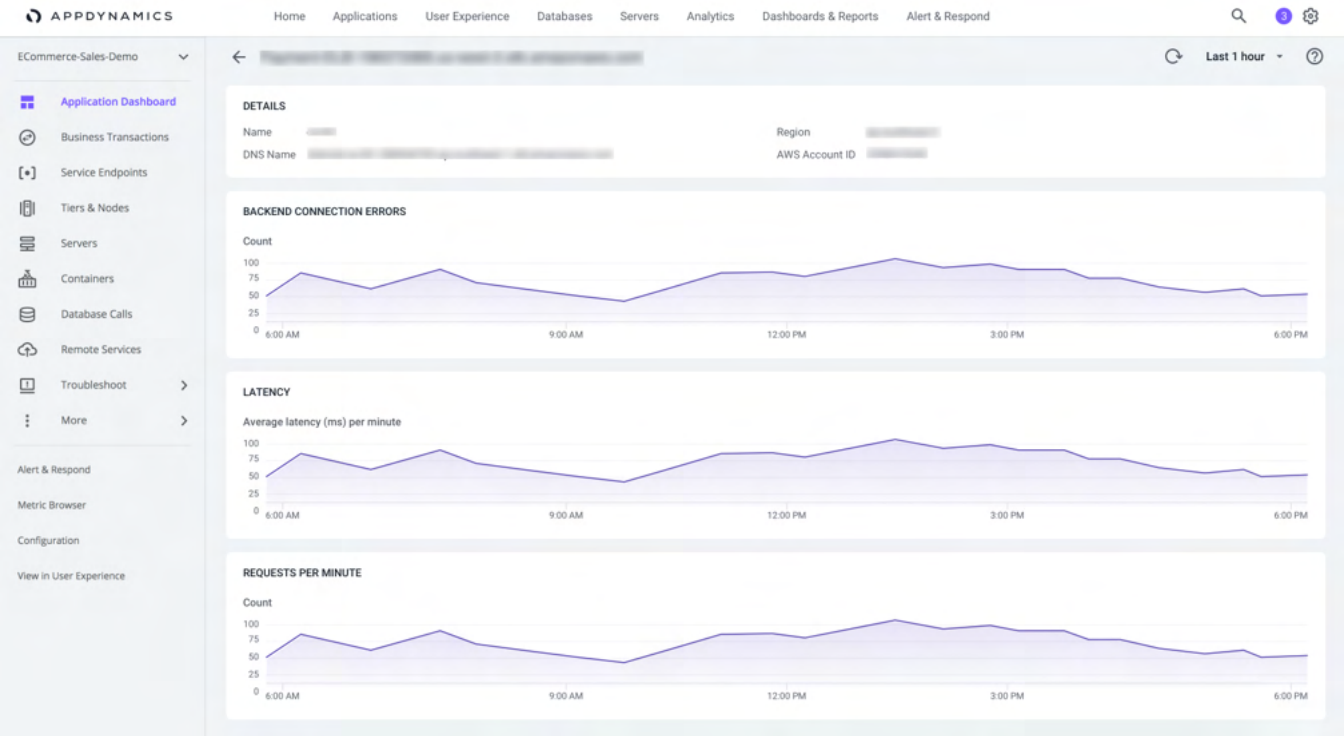


6. Click on an Amazon Elastic Load Balancer (ELB) icon. A dialog appears displaying **Connections** and **Amazon CloudWatch** tabs.



7. Click the Amazon CloudWatch tab. The following metrics appear:
   - **Backend Connection Errors**: Count of backend connection errors per minute.
   - **Latency**: Average request latency per minute.
   - **Requests**: Average requests per minute.

8. Click **See More Detail**.
9. Amazon CloudWatch ELB metrics appear in a time-series chart on the **Application Dashboard**.
10. To modify the time interval, in the top right corner of the page, click **Last 1 hour** drop-down list, and choose your desired time range.



Edit an Elastic Load Balancing Connection

As an account administrator, to edit an existing connection:

1. Go to https://accounts.appdynamics.com/subscriptions.
2. Sign in to your account.
3. Select the Controller that you want to connect to Amazon CloudWatch.
4. Navigate to the **Home > Cloud Platform** tab. A list of connections display.
5. Select the connection name that you want to edit.
6. Click the Edit (pencil) icon.
7. Click **Connect**.

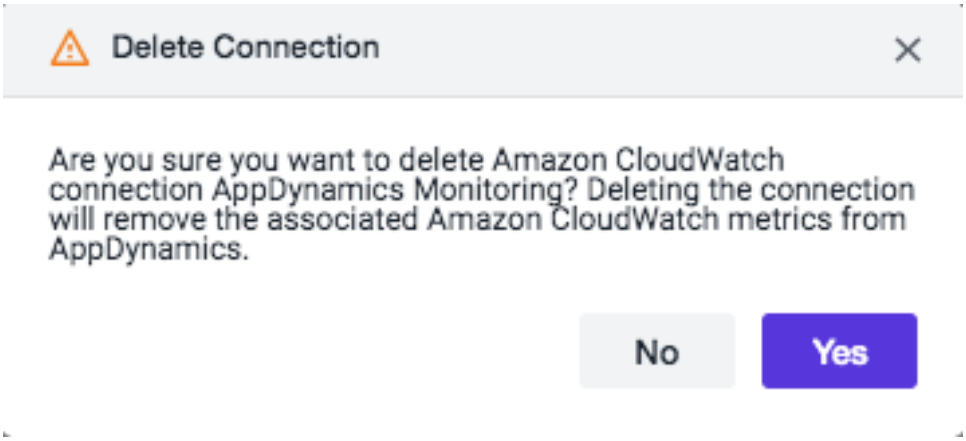
It may take several minutes for your edits to be synced. Refresh your browser after five minutes to verify the connection. Confirm that the Integration Status of your Amazon account shows success before navigating to the Network Dashboard.

Delete an Elastic Load Balancing Connection

As an account administrator, to delete an existing connection:

1. Go to https://accounts.appdynamics.com/subscriptions.
2. Sign in to your account.
3. Select the Controller that you want to connect to Amazon CloudWatch.
4. Navigate to the **Home > Cloud Platform** tab. A list of connections display.
5. Select the connection name that you want to delete.

6. Click the Delete icon . A dialog asks you to confirm that you understand the consequences of deleting the connection.



7. Click **Yes**. If the connection has any metrics, deleting the connection also deletes these metrics.

Troubleshoot AWS Integration Issues

Connection Status is Pending

Navigate to the **Home > Cloud Platform** list of connections. If a connection in the Amazon CloudWatch **Integration Status** column is stuck showing a "connecting" state, check the following:

- Confirm that you are using classic ELBs in your account.
- Confirm there is at least one EC2 instance with the status of InService connected to at least one classic ELB in that account.

If a connection in the Amazon CloudWatch **Integration Status** column is continuing to display "connecting":

- Manually refresh your browser to verify the connection.
- Wait an additional 5 minutes for the integration to connect.

Cross Application Flow

In the AppDynamics model, business applications usually represent a complete application environment. However, it is possible that different business applications share services or infrastructure components.

The cross application flow map displays dependencies and points of contact between business applications in the Controller. This page describes the cross application flow map.

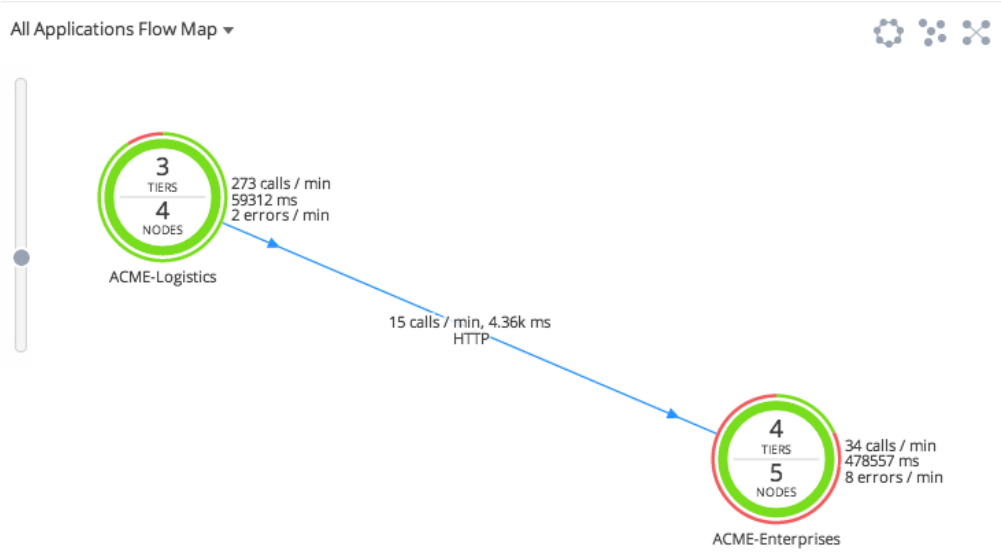
To view the cross application flow map, the user must have the account-level View Business Flow permission.

Access the Cross Application Flow Map

The Applications tab in the AppDynamics Controller UI provides several views of the business applications in your account: a card view, list view, and flow view. To access the cross application flow map, click the flow view link in the tab.

Use the Cross Application Flow Map

Click **View All Applications** on the Controller UI Home page to view the cross application flow.



In the context of a given business application, the call to another application is considered an exit call. If the other application is an AppDynamics-instrumented business application, the call is shown as cross application flow. For an example, see the All Applications Flow Map on Flow Maps.

All users of one application can see correlated applications on the flow map. However, to drill into metrics and snapshots for a correlated application, a user must be a member of a role with view permissions to the correlated application. See Create and Manage Custom Roles.

Hide Components or Business Application on the Flow Map

You can hide backend components, applications, or queues in the right-clicking menu for the component on the cross application flow map.

For applications monitored with the Java Agent, you can exclude a node from being resolved to a cross application flow by setting the following app agent node property to false:

```
support-cross-app-correlation=false
```

This property must be set in the downstream application and prevents calls from external apps registering as cross application flows.

You may choose to do this, for example, if you wanted the cross application call to be represented as a backend call in the calling applications flow map—and metric scheme—rather than as a call to another application. This ensures that metric data reflecting interactions with the tier in the external business application are retained as backend call metrics.

Note

The node property `support-cross-app-correlation=false` works only for the Java Agent.

Export and Import Business Application Settings

This page describes how to export and import the application configuration in the Controller. Application export/import allows you to back up just a single application configuration in the Controller, as opposed to the entire Controller instance, as described in Controller Data Backup and Restore.

For information on exporting other settings from the Controller, see Configuration Import and Export API. For JMX configurations, see Configure JMX Metrics from MBeans.

What Settings Are Exported?

You can export a business application configuration and import it as a new business application. The two applications can be on the same or different Controllers. If on different Controllers they must be using the same major version of AppDynamics.

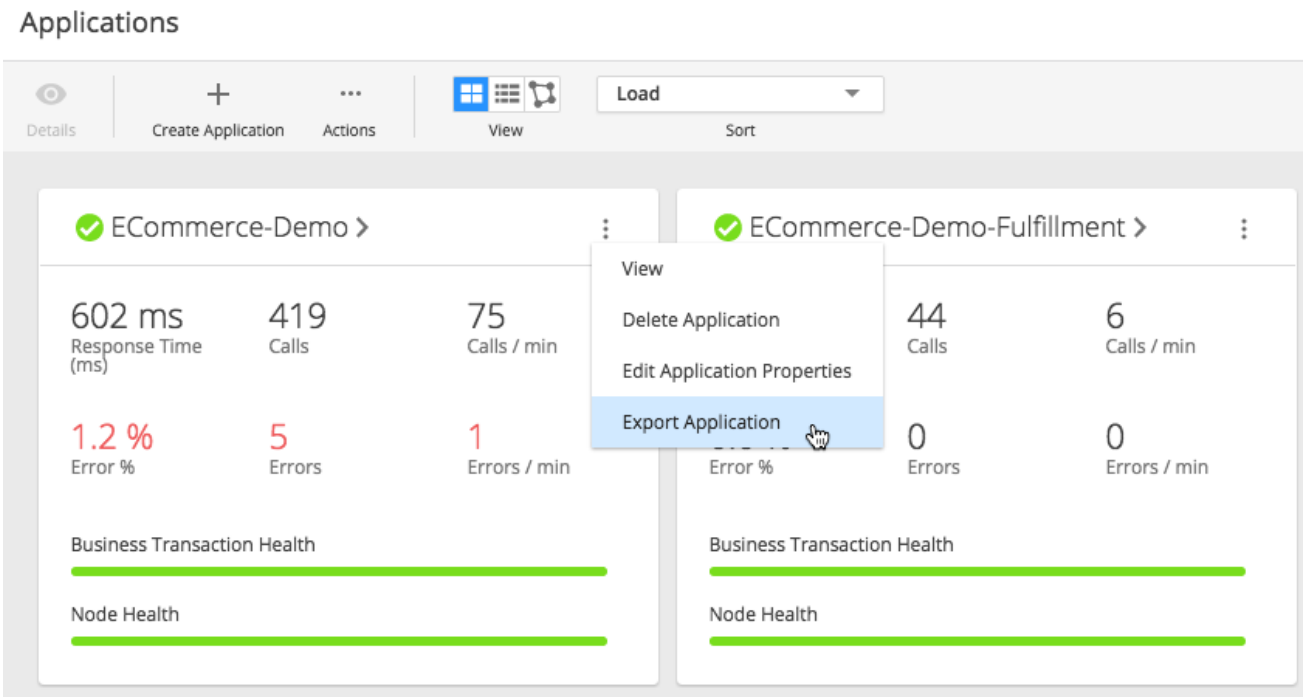
The export is an XML file that includes:

- Snapshot collection settings
- Call graph settings
- Error configuration
- Stall configuration and Business Transaction thresholds
- HTTP and SQL Data gatherer settings
- Tier and Node definitions
- Custom entry point configurations for Business Transactions
- Metric baselines
- Information point configurations

The configuration information does not include data such as Events, Health Rule Violations, and metrics. Nor does it include configuration artifacts not related to the business application, such as users, dashboards, policies, database, and remote services, or schedules.

Export a Business Application

To export the application, from the Applications home page, choose **Export Application** from the action menu for the business application you want to export.



Your browser downloads the XML-formatted configuration file for the application.

Import a Business Application

To import an application configuration, you must be logged in as a user with Administrator user role privileges. You also need access to a previously exported configuration file.

To import the configuration, follow these steps:

1. From the **Applications** page, click **Actions** > **Import**.

2. Select the XML file that contains the configuration you want to import. You can choose to import into an existing business application or create a new one.
3. Choose the configuration settings you want to import. Options include configuration settings for app agents, data collectors, health rules, MDS (scoped instrumentation settings), and more.
4. Click **OK** to start importing. The import process first validates the file. As it proceeds, it shows the status for each type of artifact in the **Import Application** dialog.
5. When done, close the **Import Application** dialog.

Application import does not work over HTTPS if the Controller uses a self-signed SSL certificate. Use a trusted, CA-signed certificate instead. See Controller SSL and Certificates.

Ingest OpenTelemetry Trace Data

Beta Disclaimer

This documentation mentions a product that is currently beta. AppDynamics reserves the right to change the product at any time before making it generally available as well as never making it generally available. Any buying decisions should be made based on features and products that are currently generally available. Please speak to your account representative if you are interested in participating in the beta, or in being notified when the feature becomes generally available.

OpenTelemetry is a single, standardized vendor-agnostic solution used to generate, collect, and export telemetry data. Telemetry data consists of traces, metrics, and logs. OpenTelemetry uses a set of APIs and SDKs to function as a pipeline to ingest and distribute data.

AppDynamics provides an OpenTelemetry Protocol compliant backend to ingest OpenTelemetry trace data generated from applications monitored using OpenTelemetry components. The ingested data is processed by the AppDynamics backend to provide monitoring and alerting capabilities in your application and cloud environments. This page describes how to configure AppDynamics and OpenTelemetry to send OpenTelemetry trace data to the AppDynamics backend.

Review AppDynamics and OpenTelemetry Requirements

AppDynamics

OpenTelemetry is not available for on-premises Controllers.

- To use AppDynamics OpenTelemetry, you need a SaaS Controller version >= 21.2.0.
- Active AppDynamics Pro edition license.
- API Key to authenticate with AppDynamics backend.

Users must have a role defined with the **View and Configure Licenses** permission for license management activity.

- To view your current AppDynamics build version in the Controller UI, go to > **About AppDynamics**.
- To view your current AppDynamics edition in the Controller UI, go to > **License**.
- To obtain your AppDynamics API Key, work closely with your account representative. To learn more, see `x-api-key` in the Attributes Description section.

OpenTelemetry

- Ensure that you have OpenTelemetry Collector >= 0.14.0 downloaded and installed on your deployment. See the OpenTelemetry Collector Getting Started documentation.
- Verify that the OpenTelemetry Collector can connect and report traces to the AppDynamics backend.

Configure the OpenTelemetry Collector YAML File

To send the distributed traces to the AppDynamics backend, you must configure the OpenTelemetry Collector YAML file.

1. Install the OpenTelemetry Collector.
2. Configure Your Applications to Send Service Resource Attributes.
3. Configure the OpenTelemetry Collector for AppDynamics.
4. Verify Configuration.

Install the OpenTelemetry Collector

Install the OpenTelemetry Collector in your computing environment. The OpenTelemetry Collector acts as the receiver in your pipeline and gathers telemetry data from various applications.

Configure Your Applications to Send Service Resource Attributes

AppDynamics relies on the `service.name` and `service.namespace` trace resource attributes to map the services to AppDynamics tiers and applications, respectively.

- `service.name`: Your AppDynamics tier name. Set the corresponding `service.name` resource attribute for every service being monitored.
- `service.namespace`: Your AppDynamics application name. Set the corresponding `service.namespace` trace resource attribute for every application being monitored.

You can set these `service.name` and `service.namespace` attributes using the `OTEL_RESOURCE_ATTRIBUTES` environment variable, or from inside your application code. Please consult the appropriate OpenTelemetry language-specific documentation for your code.

Configure OpenTelemetry Collector for AppDynamics

By default, the OpenTelemetry Collector enables and accepts OTLP (OpenTelemetry Protocol) trace data and sends it to the AppDynamics backend using the default configuration through the OTLP HTTP Exporter.

To configure your OpenTelemetry collector to report data to your AppDynamics Controller, edit your `otel-config.yml` configuration file using this information:

- Processors: (Resource and Batch): Convert data into chosen formats.
- Receivers: Send data to the OpenTelemetry Collector.
- Exporters: Send the converted data to the desired locations.
- Service: Ensures that all previously noted exporters, receivers, and processors are included in the service pipeline.
- Attributes Description: Sets the trace attributes for every service being monitored.

Processors

Resource

Use the resource processor to add the AppDynamics Controller account, host, and port.

- `appdynamics.controller.account`: Your AppDynamics Controller account name.
- `appdynamics.controller.host`: Your AppDynamics Controller hostname.
- `appdynamics.controller.port`: Your AppDynamics Controller port number.

Resource Processor

```
processors:
  resource:
    attributes:
          - key: appdynamics.controller.account
      action: upsert
      value: "acme"
          - key: appdynamics.controller.host
      action: upsert
      value: "acme.saas.appdynamics.com"
          - key: appdynamics.controller.port
      action: upsert
      value: 443
```

Batch

Use the batch processor to improve performance. The `batch` setting accumulates data received through the OpenTelemetry Observability Collector pipeline and sends it to the backend efficiently. The '`batch`' setting defaults the collection and processing to a timeout of 30 seconds, or when a batch size of 8,192 is reached.

- `timeout:` Time duration after which a batch is sent regardless of size. The default is 30 seconds.
- `send_batch_size`: Number of spans or metrics after which a batch is sent. The default is 8,192.

Batch Processor

```
processors:
  batch:
    timeout: 30s
    send_batch_size: 8192
```

Receivers

Receivers use OTLP to support transaction-oriented application data processing. For more information, see OpenTelemetry's OTLP Receiver documentation.

Specify your receivers endpoints:

```
receivers:
  otlp:
    protocols:
      grpc:
        endpoint: localhost:55680
      http:
        endpoint: localhost:55681
```

Exporters

Use the OTLP HTTP Exporter to send data, including the <x-api-key> in the header, to the AppDynamics endpoint <appd-endpoint>. To learn more, see <appd-endpoint> in the Attributes Description section. To obtain your <x-api-key>, work closely with your AppDynamics account representative.

```
exporters:
  otlphttp:
    endpoint: "<appd-endpoint>"
    headers: {"x-api-key": "<x-api-key>"}
```

Service

Ensure that all previously noted exporters, receivers, and processors are included in the service pipeline:

```
service:
  pipelines:
    traces:
      receivers: [otlp]
      processors: [resource, batch]
      exporters: [otlphttp]
```

Attributes Description

Key	Location	Type	Example	Required	Description
appd-endpoint	otlphttp exporter	string	• Asia Pacific (Sydney): https://syd-sls-agent-api.saas.appdynamics.com/ • EU (Frankfurt): https://fra-sls-agent-api.saas.appdynamics.com/ • US West (Oregon): https://pdx-sls-agent-api.saas.appdynamics.com/	Yes	Your AppDynamics endpoint where the OpenTelemetry Collector sends the ingested traces. AppDynamics endpoints are available in the following regions: Sydney, Frankfurt, and Oregon.
x-api-key	otlphttp exporter	string	<alpha numeric key>	Yes	Your AppDynamics API key must be defined as an HTTP header. [1]
appdynamics.controller.account	resource attribute	string	acme	Yes	AppDynamics Controller account name.
appdynamics.controller.host	resource attribute	string	acme.saas.appdynamics.com	Yes	AppDynamics Controller host used by OpenTelemetry. Do not include http:// or https://.
appdynamics.controller.port	resource attribute	integer	443	Yes	AppDynamics Controller port number.
service.name	resource attribute	string	shoppingcart	Yes	Logical name of the service; equivalent to your AppDynamics tier name. Set the corresponding service.name trace resource attribute for every service being monitored using either the SDK, or by setting the OTEL_RESOURCE_ATTRIBUTES environment variable. [2]

`service.namespace`	resource attribute	string	`Shop`	Yes	A namespace for the `service.name`; equivalent to your AppDynamics application name. Set corresponding `service.namespace` trace resource attribute for every service being monitored using either the SDK, or by setting the OTEL_RESOURCE_ATTRIBUTES environment variable. [3]

[1]: To obtain your unique `x-api-key`, you should work closely with your AppDynamics account team.
[2]: MUST be the same for all instances of horizontally scaled services.
[3]: A non-null, non-empty string value for `service.namespace` is required.

AppDynamics Configuration File Example

This example includes configuration for the processors, receivers, exporters, service, and attributes:

```
processors:
  resource:
    attributes:
    - key: appdynamics.controller.account
      action: upsert
      value: "acme"
    - key: appdynamics.controller.host
      action: upsert
      value: "acme.saas.appdynamics.com"
    - key: appdynamics.controller.port
      action: upsert
      value: 443
  batch:
    timeout: 30s
    send_batch_size: 8192
receivers:
  otlp:
    protocols:
      grpc:
        endpoint: localhost:55680
      http:
        endpoint: localhost:55681
exporters:
  otlphttp:
    endpoint: "https://pdx-sls-agent-api.saas.appdynamics.com"
    headers: {"x-api-key": "****************"}
service:
  pipelines:
    traces:
      receivers: [otlp]
      processors: [resource, batch]
      exporters: [otlphttp]
```

Verify Configuration

To validate that your configuration is working properly, review your OpenTelemetry Collector logs.

Visualize Your OpenTelemetry Data

AppDynamics Open Telemetry ingests and aggregates traces into Business Transaction flow metrics. A trace represents an end-to-end request which can be made up of single or multiple spans. Each span represents a single event within a component in the application triggered in the trace. The Business Transaction represents the entire graph of all traces sharing an origin span, and shows how these related traces flow between services.

Flow maps are a dynamic visual representation of your monitored environment's components and activities. Services monitored using OpenTelemetry are represented by the OpenTelemetry icon in the AppDynamics User Interface.

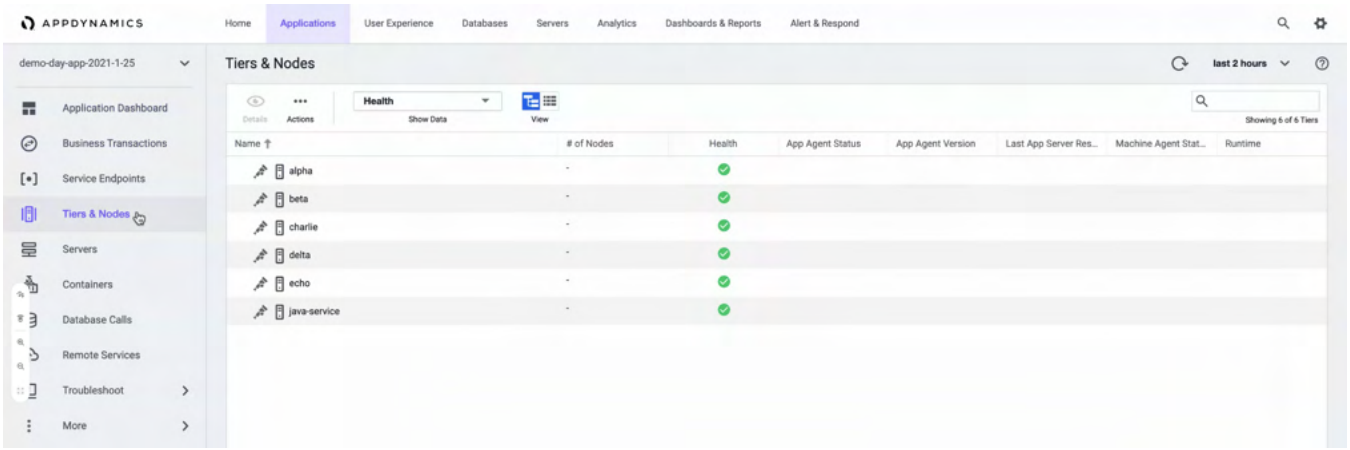
To view your OpenTelemetry data:

1. Select the OpenTelemetry-enabled Controller.
2. Navigate to the application name that you specified with the `service.namespace` resource attribute value.
3. Select **Application Dashboard > Dashboard > Application Flow Map**.

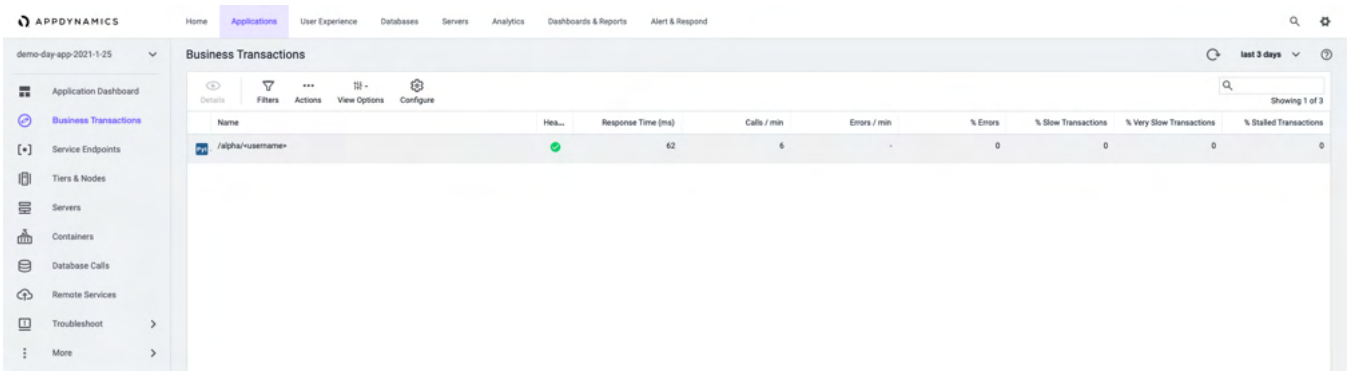
This example shows an application with OpenTelemetry enabled.

This example application consists of six tiers: **alpha**, **beta**, **charlie**, **delta**, **echo**, **java-service**. Next to each tier icon, a telescope icon displays. These telescope icons indicate that OpenTelemetry is successfully enabled for the tiers listed.

Under **Applications > Tiers & Nodes**, the tiers represent the services (defined by `service.name`) encountered by the ingested traces.



The **Applications > Business Transactions** view displays the Business Transactions. The names of the Business Transactions are derived from the name of the first span of each trace (also known as the root span). In this example, the first span is reported from the **alpha** tier and is named **/alpha /<username>**. The health status, response time, number of calls, and additional Business Transaction metrics are reported for the Business Transaction.



The AppDynamics Flow Map supports these programming language icons: C++, C#, Elixir, Erlang, Go, Java, JavaScript, Python, and Rust. C++ and C# programming languages default to a .NET icon in the Flow Map.

Troubleshooting

Flow Map

If you do not see the Flow Map in the Controller, review your configuration procedure. If the issue persists, please work with AppDynamics Support.

Business Transactions

Related pages:

- Organize Business Transactions
- Transaction Detection Rules
- Service Endpoints

In the AppDynamics application model, a business transaction represents the end-to-end, cross-tier processing path used to fulfill a request for a service provided by the application. This topic introduces and describes business transactions.

View Business Transactions

To view business transactions for a business application, click Business Transactions in the application navigation tree. The business transaction list shows key metrics for business transactions for the selected time range.

Only business transactions that have performance data in the selected time range appear in the list by default. You can show inactive business transactions for the time range by modifying the filter view options.

Other ways to modify the default view include showing transactions that belong to business transaction groups or transactions that exceed a configurable average response time. You can also choose which performance metrics appear for business transactions in the list from the View Options menu.

To see the actions you can perform on business transactions, open the More Actions menu. Actions include viewing health rule violations, configuring thresholds, renaming business transactions, grouping business transactions, starting a diagnostic session for the transaction, and classifying a business transaction as a background task.

Transaction Entry Points and Exit Points

When you install an app agent, the agent detects incoming calls and registers transactions based on the default transaction detection rules. Automatic detection rules describe entry points for transactions based on supported frameworks.

Usually, more than one tier participates in the processing of a transaction. A request to the originating tier may invoke services on:

- Another instrumented tier, called a downstream tier.
- Remote services that are not instrumented.

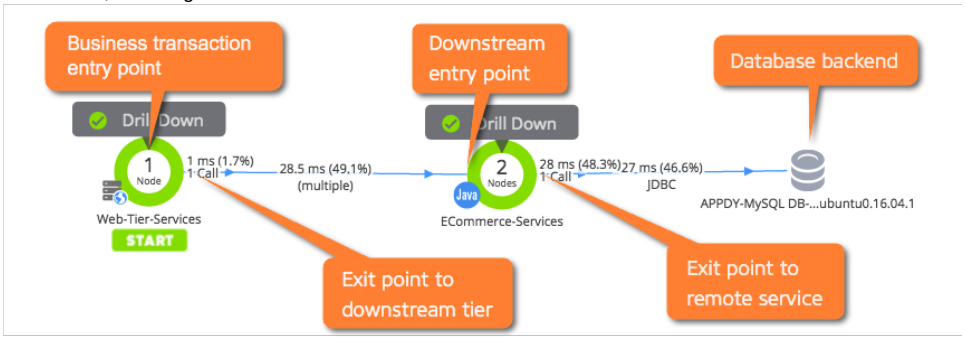
Outbound requests from an instrumented application tier are called exit points. Downstream tiers may, in turn, have exit points that invoke other services or backend requests.

App agents tag exit point calls with metadata describing the existing transaction. When an agent on a downstream tier detects an entry point that includes transaction metadata from another AppDynamics app agent, it treats the entry point as a continuation of the transaction initiated on the upstream tier. This linking of upstream exit points to downstream entry points is called correlation. Correlation maintains the client request context as it is processed by various tiers in your business application.

Sample Business Transaction

Consider, for example, the fictional ACME Online application. The application exposes a checkout service at `http://acmeonline.example.com/checkout`. A user request to the service triggers the following distributed processing flow and actions:

1. The business transaction entry point at the originating tier is `/checkout` URI, which is mapped to a Servlet called CheckoutServlet.
2. The request results in the originating tier invoking the createOrder method on a downstream tier, the ECommerce-Services server.
3. The inventory tier application calls a backend database, which is an exit point for the business transaction. The request context is maintained across tiers, including calls to backend tiers.



4. Any user request on the entry point is similarly categorized as this business transaction, the Checkout business transaction.

To enable detection of all the components in a distributed business transaction, downstream agents must be at the same AppDynamics release or newer than upstream agents. This is true whether the tiers are all built on the same platform—for example all Java—or multiple platforms—a Node.js tier calling a Java tier, calling a .NET tier and so on.

Refine Business Transactions

While the default rules can go a long way towards getting you a useful list of business transactions to track, an important part of implementing AppDynamics is verifying and refining the business transactions used to monitor your application. The business transaction you are monitoring should reflect those operations that are important to your application and business. It is important to consider the limits on business transactions, and apply your refinements accordingly.

Refining your business transaction list requires a solid understanding of the important business processes in your environment. Identify the 5 to 20 most important operations in the application. These are the key operations that must work well for the application to be successful.

Important services can be indicated by the number of calls or calls per minute received by the business transactions generated for the services. You can refine the list of transactions you want to monitor by locking down critical transactions and enabling automatic cleanup of stale transactions. For the Java and .NET environments, you can use interactive Live Preview tools to help identify important transactions.

You can add business transactions manually from a virtual business transaction called *All Other Traffic*, which is populated with transactions once the business transaction registration limits are reached, as described below.

To customize the business transaction list, you can use either of these approaches:

- You can modify existing business transactions by grouping, renaming, or removing the business transactions. Most of these operations are available from the business transaction list. Use this approach to apply relatively minor, small scale changes to the current business transaction list. For more information, see Organize Business Transactions.
- You can affect how business transactions are created by modifying the automatic discovery rules. You can modify rules to similarly achieve business transaction grouping and naming, and to exclude transactions. Discovery rules also enable you to define new entry points for business transactions. Discovery rule modification is a powerful mechanism for changing transaction discovery on a larger scale. For more information, see Transaction Detection Rules.

Business Transaction Limits

When reviewing and refining your business transaction limits, it is important to consider the business transaction limits for the Controller and app server agents. Business transaction limits prevent boundless growth of the business transaction list.

The default limits are:

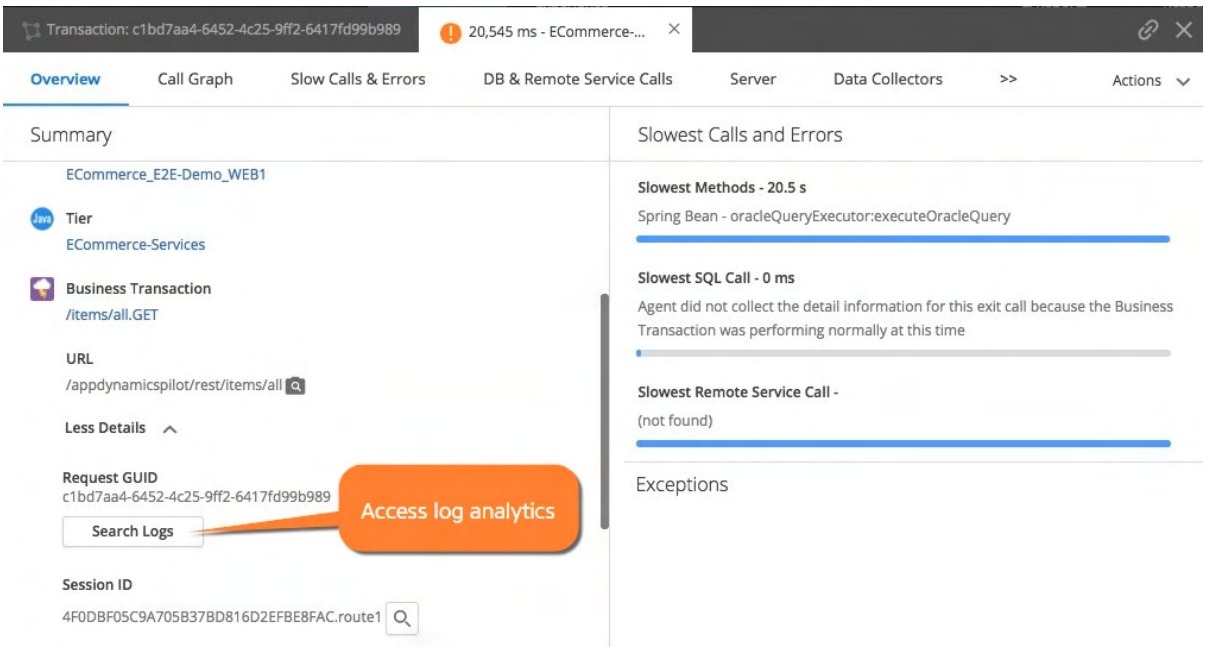
- Business Application Limits: Each application is limited to 200 registered business transactions.
- App Server Agent Limits: Each agent is limited to 50 registered business transactions.

There is no limit at the tier level.

Also note that the app agent limit applies to each app agent, not to the machine. If you have multiple app agents on a single machine, the machine the business transactions originating from the machine could be up to the number of agents times 50.

Correlate Business Transaction Logs

For those times when tracing application code doesn't provide enough clues to track down the cause of a problem, AppDynamics provides visibility into the transaction logs that can be correlated to specific business transaction requests. Log correlation visibility requires a license for both Transaction Analytics and Log Analytics. See Business Transaction and Log Correlation.



Business Transaction Health Rules

You can create health rules to monitor the parameters that represent the normal or expected operations for your business transactions (BT). The parameters rely on metric values, for example, the average response time.

When the performance of a business transaction violates the conditions set by a health rule, a health rule is violated. Alerts notify you of any violation and initiate remediation actions to mitigate the violation event. It is important that you configure alerts appropriately to ensure that you do not miss any alerts or receive false alerts. Alert Sensitivity Tuning (AST) helps you configure alerts with appropriate sensitivity. AST provides historical data for the metric or the baseline being configured and helps you visualize the impact of the alerting configuration. See Alert Sensitivity Tuning.

Create a BT Health Rule and Fine-Tune Metric Evaluation

You can create a health rule to monitor BT parameters and fine-tune the sensitivity of a BT health rule using AST. See Create a Health Rule and Fine-tune Metric Evaluation for instructions.

Organize Business Transactions

Organize and manage registered business transactions on the business transaction list to ensure that you are monitoring the most critical transactions. You can rename transactions, delete transactions, exclude transactions, or create custom transaction detection rules.

Especially for busy applications with lots of transactions, identify the best strategy for maximizing visibility into business-critical operations. Consider these strategies:

- Set transaction detection priorities and delete old transactions to ensure that AppDynamics instruments your most important transactions.
- Combine multiple transactions into rules and exclude unimportant transactions to ensure that you stay within the business transaction limits.
- Rename transactions to informative names and group together similar transactions so that your metrics are easier to read.

Rename Business Transactions

AppDynamics names the business transactions it discovers based on the default naming scheme for the application type of the entry point for the transaction. See Business Transactions.

You can change the name for the business transaction by selecting the business transaction and choosing Rename from the More Actions menu. This change only affects the label for the business transaction in the user interface. You can also modify the default naming scheme for subsequently discovered business transactions, as described in the discussion on naming in Transaction Detection Rules.

> By default, AppDynamics uniquely names business transactions according to the tier name and entry point type, along with an internal name. When you rename a business transaction, ensure its new name is unique; otherwise, there will be multiple business transactions reporting metrics under the same name.

Group Business Transactions

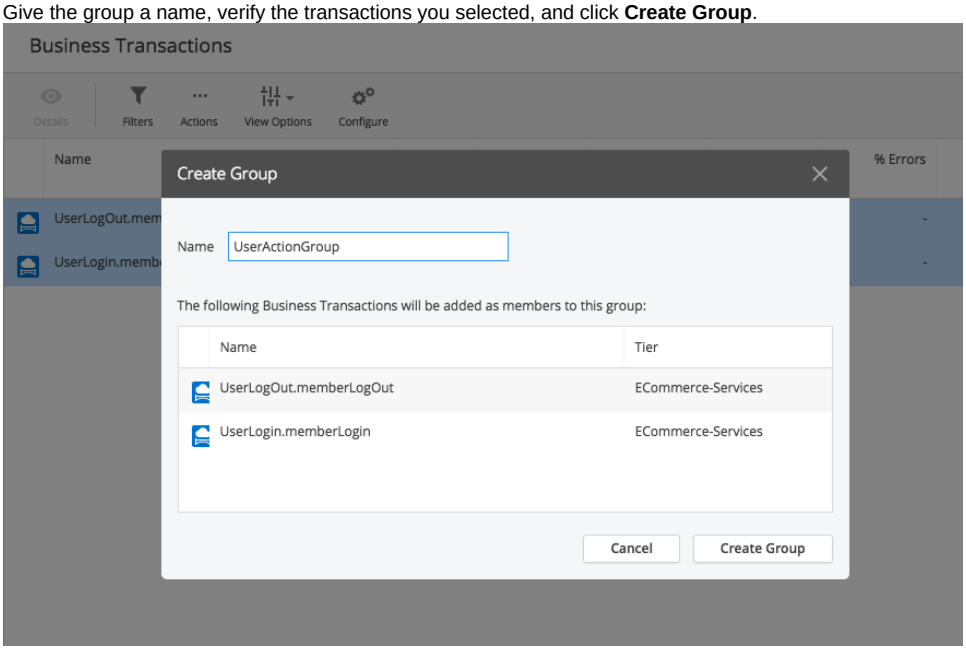
A transaction group lets you collect multiple related transactions into a single organizational unit in the AppDynamics model of your environment. For example, you may wish to group business transactions all of which have entry points in a specific WAR file. Groups could also be used to collect transactions of a specific organization, region, or category.

After grouping transactions, you can see aggregate metrics for the group. Metrics for individual transactions that make up the group remain available.

Grouping transactions does not affect the overall count of registered business transactions. To manage your transaction count, see Custom Match Rules.

To create a business transaction group:

1. Select the transactions you want to group from the Business Transactions list. Use the control or shift keys to multi-select business transactions.
2. Right-click the selected transactions and choose **Create Group**.
3. Give the group a name, verify the transactions you selected, and click **Create Group**.



Delete or Exclude Business Transactions

Excluding and deleting business transactions reduce the business transaction registration count. You can choose to exclude a short-lived business transaction temporarily or delete a stale business transaction permanently.

Exclude a Business Transaction

In effect, excluding the transaction disables the business transaction for metric processing purposes; it works even if the processing path that the business transaction represents remains active in the monitored application. Both serve to reduce the business transaction count considered against transaction registration limits.

> Excluding a business transaction in the business transaction list is not to be confused with using custom exclude rules to control business transaction detection. While the two approaches achieve similar goals, custom exclude rules operate at the transactions detection point and are most useful for preventing discovery and registration of a range or multiple ranges of business transactions at a time. See Custom Match Rules f or more information.

To exclude a business transaction:

1. Select your transaction from the list of business transactions.
2. Right-click the selection and click **Exclude Transactions**.
3. On the Exclude Business Transactions page, select the transaction and click **Exclude Transactions**.

Restore an Excluded Business Transaction

When you exclude a business transaction, the accumulated metrics for the transaction along with its underlying configuration is retained. You can restore the excluded transaction, if required.

1. From the Business Transactions page, click **Actions > View Excluded Transactions**.
2. From the Excluded Business Transactions page, select your transaction, and click **Unexclude Selected**.

Delete a Business Transaction

When you delete a business transaction from the list, the accumulated transaction metrics are removed. However, the deleted transaction is rediscovered if the corresponding function in the application is used. To delete a business transaction permanently, modify the discovery rules after deleting a transaction.

A business transaction can be considered stale in these scenarios:

- You have decommissioned an application, and you want to delete the historical data associated with business transactions that made up the application.
- You have changed business transaction discovery rules to either eliminate or reorganize business transactions and need to remove unwanted or otherwise obsolete business transactions.

To delete a business transaction:

1. Select your transaction from the list of business transactions.
2. Right-click the selection and click **Delete Transactions**.
3. From the Delete Business Transactions page, select the transaction and click **Delete Business Transactions**.

Automatic Cleanup of Stale Business Transactions

Automatic cleanup keeps less active transactions from cluttering your business transaction list. Enabling automatic cleanup deletes business transactions t hat are flagged as stale. You can set the activity threshold for a business transaction after which the transaction is considered stale.

To configure automatic cleanup threshold:

1. From the left pane, click **Configuration > Instrumentation > Transaction Detection > More**.
2. Under Business Transaction Automatic Cleanup, check **Enable Business Transaction Automatic Cleanup**.
3. Update the automatic cleanup threshold that qualifies a business transaction as stale:
    a. Specify your threshold time in, **Monitor Business transactions for __ minutes since creation**.
    b. Specify the number of calls in, **Remove Business transactions that have less than or equal to __ calls**.

Since creation, a business transaction is monitored for 15 minutes when automatic cleanup is enabled with default settings. If there are no calls reported within the first 15 minutes since the business transaction is registered, the business transaction is qualified as short-lived and the automatic cleanup deletes that business transaction. Automatic cleanup keeps a business transaction intact if it is reporting data for days.

However, automatic cleanup ignores the business transactions that are:

- Marked as *Permanent*
- Older than three days

Business Transaction Purger

There are Controller configurations for the business transaction purger:

- `max.bt.to.purge.per.execution`: the number of business transactions that can be purged when the purger executes once. The default is 1000, min is 0, and the max is 100000.
- `max.bt.to.purge.per.transaction`: in order to reduce db lock, the purger tries to purge business transactions in multiple transactions if there are too many business transactions to purge in each execution. This configuration specifies the number of business transactions that can be purged in each transaction. The default is 10, min is 0, and the max is 1000.

Manage Business Transaction Detection

If your system has hundreds of business transactions, you can leverage the rule system to fine-tune which transactions you want to detect and monitor. Creating rules gives you the exact transaction visibility that you want. For example, you can create rules to:

- Detect transactions that are not automatically detected.
- Prioritize monitoring some transactions over others.
- Stay under the transaction limit. When you combine multiple transactions in a rule, the individual transactions no longer count towards the transaction limit; the rule is counted as a single transaction.
- Exclude transactions that you are not interested in monitoring.

Suppose John is creating transaction detection rules for an ECommerce application. John discovers that the most critical transaction, `user-checkout`, is grouped into *All Other Traffic*, which obscures its visibility. To ensure that AppDynamics collects detailed metrics for `user-checkout`, John creates a rule that detects `user-checkout`, and sets the rule priority to a high value, 50. For less critical transactions, John creates a rule that detects multiple transactions: `createaccount`, `billing`, and `delivery-options`. He sets the rule priority to a lower value, 15. Combining multiple transactions into one rule helps John stay within the transaction limit. See Transaction Detection Rules.

All Other Traffic Business Transactions

As an organizational unit in the AppDynamics model, business transactions are meant to be used for the most important transactions in your environment. The Controller limits the number of business transactions (50 for a node and 200 for a business application). This limit helps control resource utilization on the Controller, and also helps you focus on the most important services performed by your application environment.

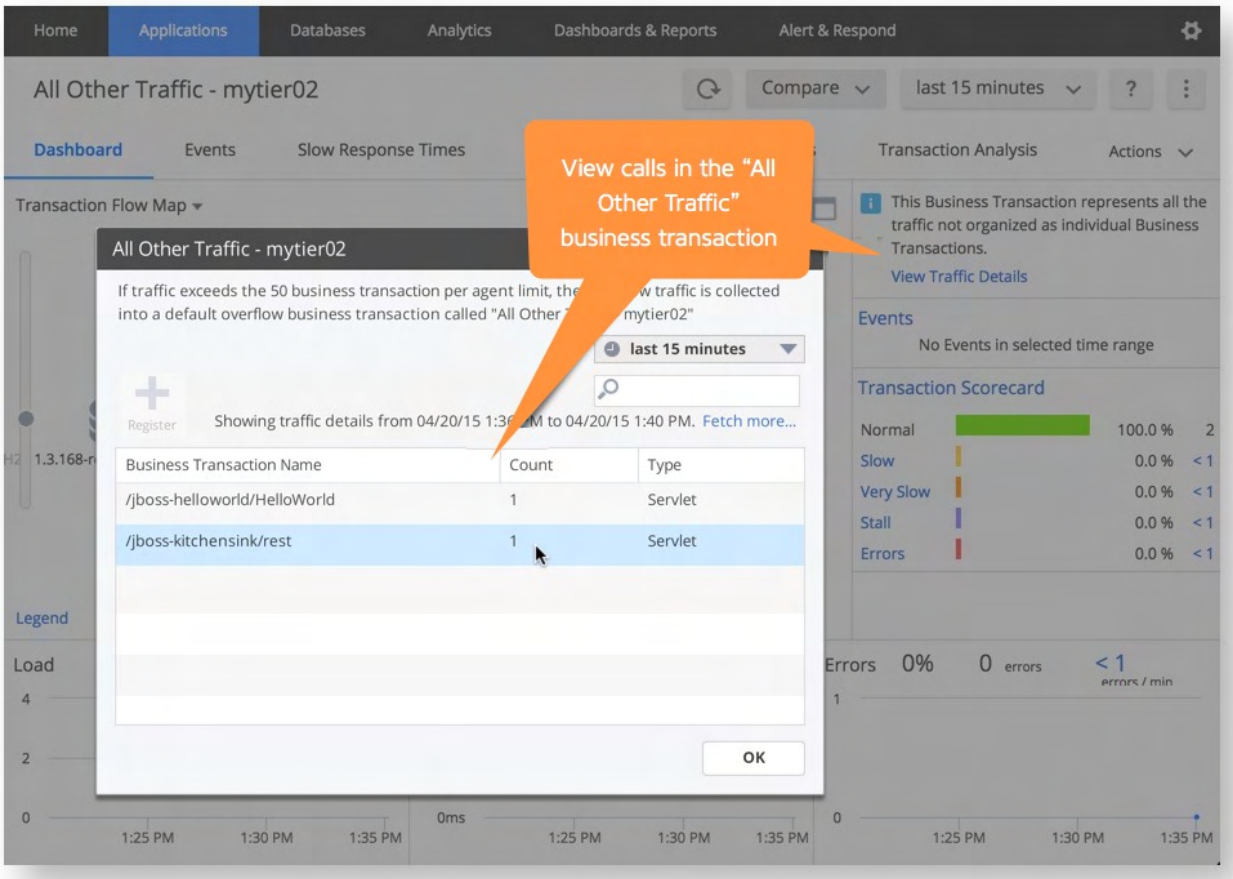
Once the business transaction registration limit is reached or transaction lockdown is enabled, newly detected transactions are not registered as business transactions, but they are monitored and reported by AppDynamics. The transactions are grouped to a virtual business transaction named `All Other Traffic - tier_name`. An *All Other Traffic* group exists for each tier on which the limit is reached.

All Other Traffic appears alongside other business transactions in the Business Transactions list. Like you can for any business transaction, you can view the dashboard and key performance metrics for All Other Traffic in the Metric Browser.

When refining business transactions, it's likely that you'll want to move certain transactions from the All Other Traffic bucket to make them first-class business transactions. You can keep within the limits by deleting or excluding other business transactions, such as those that have little or no load, by using a custom exclude rule. If the number of business transactions is under the limit and lockdown is enabled, you can promote a transaction from the list of All Other Traffic by registering it from the Traffic Details window.

To view incoming calls categorized in the All Other Traffic transaction:

1. Open the dashboard for the All Other Traffic business transaction.
2. Click **View Traffic Details**.



The **Traffic Details** panel lists transaction entry points that were hit by incoming requests after the registration limits were exceeded or after business transaction detection was locked down. The **Business Transaction Name** column contains auto-generated names for the transactions. The **Call** column shows the number of instances of the transaction and the **Type** column shows the entry point type.

If the *Fetch more* link appears, click to view more calls. You retrieve up to 600 calls each time you click the link. If the *Fetch more* link does not appear, there are no more calls to retrieve for the selected time range.

> The name used for All Other Traffic in the REST API is `APPDYNAMICS_DEFAULT_TX`. For an example, see Use the AppDynamics REST API.

Lock Down Business Transactions

A production implementation of AppDynamics usually involves an initial period of assessing, organizing and refining business transactions by customizing your default business transaction discovery rules.

Once you arrive at the set business transactions to monitor, you may want to *lock down* business transactions. Locking down business transactions prevents application changes, upgrades to the agent software, or other changes from affecting the number or selection of business transactions you monitor as the primary, first-class business transactions in the AppDynamics model of your environment.

With business transaction lockdown enabled, the Controller puts newly discovered transactions into the *All Other Traffic* transaction collection for the tier. You can promote a business transaction from the *All Other Transactions* list by registering it as a first-class business transaction manually.

Business transaction lockdown gives you a way to register business transactions individually, by manual selection. In certain scenarios, it may make sense to enable business transaction lockdown before discovery occurs and registering transactions manually. For example, this may be useful if your environment would otherwise generate a large number of business transactions and you only want to monitor a relative few as first class business transactions.

To enable business transaction lock down, select the **Enable Business Transaction Lock down** option in the application instrumentation settings page.

After locking down business transactions, you can promote a transaction manually by accessing the Traffic Details dialog from the All Other Transactions d ashboard. In the dialog, select the transaction and click **Register** to promote the transaction. If the agent is at the business transaction registration limit, you will need to delete a registered business transaction before registering one from the *All Other Traffic* list.

If you enable automatic cleanup, business transactions that you lock down but that do not meet the activity threshold are still deleted. To override automatic cleanup for a business transaction, right-click the transaction and select **Mark As Permanent**.

Business Transaction Performance

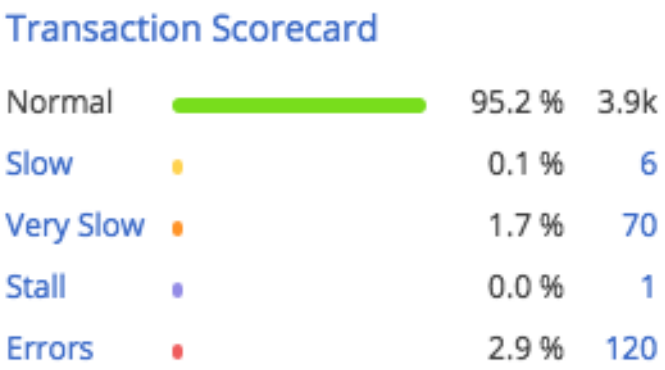
This page describes different options for viewing business transaction performance.

After verifying and refining your business transaction scheme, you can focus on monitoring business transaction performance. The monitoring and troubleshooting tools within the AppDynamics Controller UI provide a business transaction-oriented view of performance. For example, transaction snapshots tie together all the code call graphs across the monitored tiers that participated in processing a particular instance of a business transaction.

The business transaction list contains a high-level look at business application performance by transaction. You can click a particular business transaction to access additional information on the business transaction, such as information on slow performing instances of this transaction, errors, and the transaction analysis view.

Performance at a Glance

The transaction scorecard summarizes the performance of a business transaction at the application, tier, or node level within a specified time range. It covers the number and percentage of business transaction instances (calls) that are normal, slow, very slow, stalled, or errors based on the configured thresholds for these criteria.



The call counts in the scorecards in different dashboards have different meanings:

- In the application dashboard, the business transaction health scorecard aggregates the metrics for all the completed business transactions in the application, including the default business transactions. The number of calls is based on the number of business transactions that are completed. The percentages for those calls are based on the average for all the completed business transactions in the application. For example, if the scorecard displays 3% for very slow transactions, on average 3% of the calls for completed business transactions in the application were slow.
- In a tier dashboard, the transaction scorecard aggregates the metrics for all the nodes in the tier. The number of calls is based on the number of requests that the tier handled, including continuing transactions, threads spawned, and so forth.
- A node dashboard is similar to the tier dashboard in that it is based on the number of requests the node handled. The transaction scorecard displays the metrics for the single node.
- In a business transaction dashboard, the transaction scorecard displays the metrics for the entry point of a business transaction.

Transaction Score View

For a more detailed view of the performance of a transaction over time, navigate to the business transaction dashboard and click the Transaction Score tab. The graph in the tab shows the user experience for the selected business transaction, showing its performance relative to the performance thresholds as a bar chart.

For each time slot, the bar reflects the total calls, while the color segments—green, yellow, and so on—indicate the relative number of those calls that were normal, slow, very slow, stall, or errors.

The solid blue line in the graph indicates the average response time for the transaction over time, while the dotted line shows the baseline, if available.

Automated Transaction Diagnostics

Deployment Support

This capability is available in the SaaS >= 20.10.1.

AppDynamics continuously collects Transaction Snapshots that capture all events in a transaction path for use in performance troubleshooting and root cause analysis. Although there are Rules and Limits in place to prevent excessive resource consumption, you can still have hundreds of individual snapshots to sort through as you investigate a particular performance issue.

The Automated Transaction Diagnostics (ATD) capability allows you to be proactive rather than reactive when it comes to anomalous transaction behavior. ATD uses machine learning to capitalize on the collected snapshots by automatically recognizing anomalies not yet severe enough to trigger alerts but significant enough to cause future production issues. In seconds you have a prioritized list of causal factor transactions that you can use to manage problematic business transactions before they become visible production slowdowns or outages for your customers.

ATD's guided root-cause analysis clearly exposes the offending anomalies along with the contributing tiers, exit calls, or inter-tier network issues. This allows a broader range of less specialized users to more accurately analyze the behavior and significantly reduce repair time.

Technical Overview

AppDynamics uses a systematic approach to identify problematic transactions, determine the probable root cause, and provide a list of snapshots used in the diagnosis. The diagnostic process:

- Analyzes business transaction response time data to determine if there was an issue and how long it lasted.
- Analyzes metrics data across the business transaction path to identify the suspected cause and type of issue.
- Uses snapshot data to provide detailed root cause analysis that diagnoses the business transaction anomaly.

Automated Transaction Diagnostics Workflow

The Transaction Diagnostics panel becomes visible after you select a business transaction.

The diagnostic process detects performance issues, automatically identifies the contributing transactions, and provides a report that simplifies root cause analysis allowing you to spend your time fixing the problems before they become production issues.

1. From the Home or Applications tab, choose the application you want to analyze.
2. Select **Business Transactions**.
3. Double-click a transaction you want to investigate.
4. From the Dashboard tab, review **Transaction Diagnostics** in the right panel.
    a. The server may take a few seconds to display issues. If the server finds no issues, a message displays that none were identified in that time range. Try selecting a longer time range of up to eight days.
    b. The performance issues listed may not directly correspond to the business transaction flow map being shown if the health rule was violated in the past.
5. Select a highlighted anomaly to open the **Transaction Diagnostics** details page.

The interactive graph consists of two charts. The upper graph displays transaction response times that correspond to the time range you choose in the lower navigation bar. The yellow plot bands highlight periods of abnormally slow response times.

1. Use the slider in the lower navigation chart to select a time range from five minutes to eight days.
2. Click any plot band in the navigation bar to view details for that time range. The chart automatically adapts to display the incidents for your time range choices and includes a baseline for the transaction.
3. Review the **Details of Performance Issue** section to view the **Suspected cause.** If you wish to manually review snapshots from the anomalous period, they are available in the lower **Snapshots of Impacted Transactions** list.
4. Double-click a snapshot in the list to view the transaction details.

Transaction Thresholds

A threshold is a boundary of acceptable or normal business transaction performance. AppDynamics provides default thresholds against which it compares the performance of every business transaction. Each transaction is classified into a user experience: normal, slow, very slow, stall or error transaction.

The user experience reflects the performance of a transaction instance relative to the usual performance of the business transaction. AppDynamics makes some intelligent guesses and calculations based on existing traffic flow to establish the default user experience profiles.

This page provides information about refining the criteria by which the classification is applied, according to your requirements.

Transaction Threshold Values

As soon as a transaction starts, the particular thread representing that transaction is monitored for a stall. Every five seconds, the in-flight transactions are evaluated to determine if they have met or exceeded the stall threshold.

If a transaction execution finishes before the stall threshold value, the execution time is first compared against the very slow threshold, then the slow threshold, and so on, and marked accordingly.

If a transaction hits the stall threshold (takes more than 300 deviations above the average for the last two hours) or the set stall threshold, a stall transaction event is generated. Whether the transaction eventually finishes successfully or times out, it is considered a stall for performance monitoring purposes.

If the standard deviation is large (that is, > 50% of average), the moving average is used in the calculation.

Transactions errors are not determined by thresholds. Instead, transactions are marked as errors when the HTTP response status code is in the 400–505 range or when any exception occurs that is not excluded in the custom error configuration.

Static and Dynamic Thresholds

Thresholds can be based on a static value or dynamic value. A dynamic threshold is based on performance for a most recent period of time, the previous two hours, by default. A dynamic threshold can be specified using either a percentage deviation or a standard deviation measure.

To understand how a transaction is compared to this moving window, consider a two-hour moving average window from 11:00 AM to 1:00 PM. All transactions that come in during 1:00 PM and 1:01 PM are measured against the response time and standard deviation of this window. For the next minute, between 1:01 and 1:02 PM, the window moves to 11:01 AM to 1:01 PM. The moving average itself is calculated based on the exponential moving average formula.

Note that:

- Data for minutes where there is no load is not counted.
- The data is maintained locally on each node for the starting tier for a business transaction. The Controller does not hold any of this data.

Percentage Deviation Threshold

Percentage deviation defines a threshold based on the moving average of the requests over a certain interval. The default time interval is 2 hours. If the average response time for the last two hours is X milliseconds, and if the request takes the percentage deviation over X ms, the transaction violates threshold.

For example, a transaction occurs at 10:00:01 AM. The average of the requests between 8:00:00 and 10:00:00 is 100 ms and the slow threshold is defined as 20% over the threshold. If the transaction takes 120 ms, it will be considered a slow transaction.

Standard Deviation Threshold

Standard deviation defines a threshold based on the moving average over a certain interval. The default time interval is two hours. This means if the average response time for the last two hours is X milliseconds, and if the request takes the standard deviation over X ms, it violates the threshold.

To understand how a standard deviation threshold works, consider a moving average that is 1500 ms with a standard deviation of 100 ms. If you set the threshold to 3, as in the following example, it means that the threshold will be three times the standard deviation. In other words, a transaction that takes more than 1500 + (3*100) or 1800 ms will violate the threshold.

Alternatively, you can set the threshold to a static value or use a percentage of the average.

You can also disable stall detection. If you disable stall detection, a transaction that might qualify as a stall is reported as very slow if it completes. If it does not complete, nothing is reported for the incomplete transaction.

Configure Thresholds

You can configure thresholds in **Configuration > Slow Transaction Thresholds**. You will need Configure Business Transaction application permissions.

Thresholds apply to various levels, by application or business transaction, including background task transactions. You can also configure thresholds for diagnostic sessions.

You can specify thresholds for User Transactions—regular business transactions—or background transactions tab, depending on the type of entity for which you want to configure thresholds.

> ⚠ Thresholds for Browser Real User Monitoring (RUM) are configured separately. For information about these thresholds, see Configure Browser RUM Performance Thresholds.

You can configure thresholds for slow, very slow, and stalled transactions. When a transaction exceeds a threshold, AppDynamics starts capturing snapshots of it. Because snapshots are not normally captured while performance is within normal range, the snapshots may not contain the full call graph for the transaction.

Dynamic Baselines

This page describes how AppDynamics automatically calculates the baseline performance for your applications. Once it establishes these prevailing performance characteristics, it can detect anomalous conditions for your application. AppDynamics uses baselines to:

- Color the Flow Map.
- Show transaction score dashboards.
- Compare metrics in metric graphs and the metric browser.
- Evaluate health in health rules (see Health Rules).

How Baselines Work

AppDynamics calculates baselines by using the underlying hourly data. A baseline can be calculated for every metric. Baselines have two main variables:

- The time over which accumulated data should be considered in calculating the baseline.
- Seasonality of the baseline.

Baselines Help Identify Trends

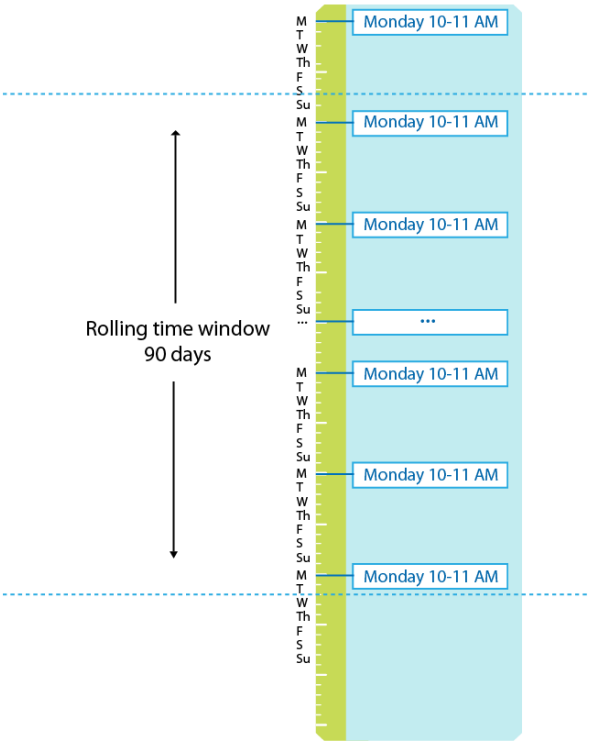
Performance expectations can differ between hours of the day, days of the week, or even months of the year. For example:

- A retail application may experience heavier traffic on the weekend than the rest of the week.
- A payroll application may experience a higher load at the beginning and end of the month compared to the rest of the month.

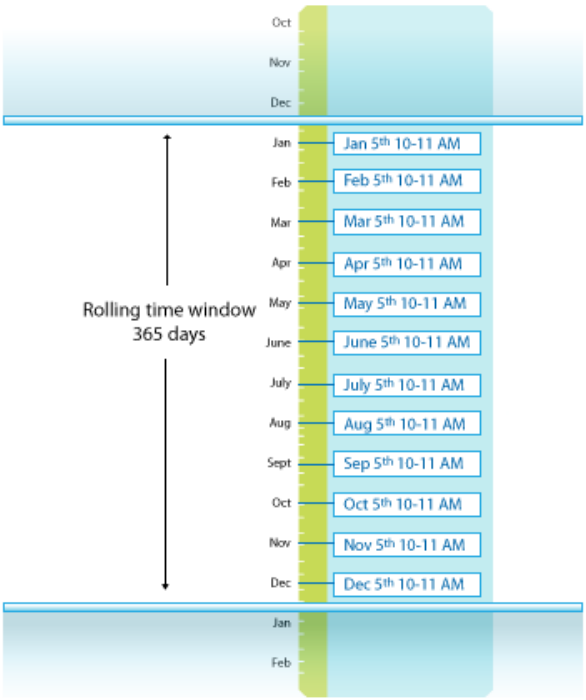
To account for this variation, you can use a rolling time period as the baseline context. A rolling time period establishes the baseline against data from the current hour taken at a daily, weekly, or monthly interval over the course of the time period.

For example, you have a baseline that uses the weekly trend with the time period configured for 90 days; this is one of the default baseline configurations available in AppDynamics.

At a given day and time, the baseline in effect is one that considers only the data accumulated on the same hour and day of the week over the last 90 days. This is illustrated in the following diagram.



A monthly trend calculates the baseline from data accumulated at the same hour but only on the same day of the month. So, for example, on January 5th at 10:30 AM, the baseline is established based on data accumulated at the same hour on the 5th of each month for the prior 365 days:



Baselines are not available immediately upon startup. It takes time and application load for the AppDynamics platform to collect data and create its initial baselines. The time depends on the type of baseline being used, whether daily, weekly, monthly, or none. Using none requires several hours before a baseline is available, daily takes several days, weekly takes several weeks, and so on.

> By default, baselines are not computed for metrics if there are fewer than 20 calls per minute. To configure the calls per minute threshold, contact your AppDynamics account representative.

How Standard Deviations are Calculated

The following standard formula is used to calculate the standard deviation:

```
standard deviation = sqrt [(B - A^2/N)/N]
```

where:
A = sum of the data values
B = sum of the squared data values
N = number of data values

The standard deviations calculations differ based on the type of metric used:

- If the time rollup type = Sum or Average
- If the cluster rollup type = Individual or Collective
  The cluster roll-up type is applicable only at the tier or app level (node-level metrics will have the same calculations).

The following example shows a standard deviation using metric types of:

- Time rollup type = Average
- Cluster rollup type = Collective

```
Metric - Calls Per Minute (Average, Collective)

(Hourly Metric Table)
```

Time	Sum	Count	Weight-Value	Weight-Value-Squared
09:00	180	2	180	300
10:00	300	2	300	780
11:00	150	2	150	195

For these metric values, the baseline of `type = All Data` lasts three hours (at 12:00) using the above values for calculations.

In the case of daily, weekly, or monthly seasonality, the data points considered are values for the same hour for all days, the same day of the week, or the same day of the year, respectively.

The baseline calculations, in this case, would be:

`Value` = `(180+300+150)/360 = 1.75`

`Standard deviation` = `sqrt(((300+780+195) - (((180+300+150)^2)/360))/360) = 0.69`

View Baselines

A baseline deviation is the standard deviation from a baseline at a point in time, represented as an integer value. You can set health rule conditions based on baseline deviations. For example, you can configure a warning condition as two standard deviations from the baseline and a critical condition as four standard deviations from the baseline. You can view built-in baselines and add new ones by navigating to **Configuration > Baselines**.

The daily trend is the default baseline. This is the baseline used by health rules if another baseline is not specified during health rule creation.

You can choose another as the default by selecting the baseline in the baseline list and choosing **Set as Default**.

> ⚠ Changing the default baseline changes the actual baseline for all existing health rules that rely on this default and do not specify another baseline. Be aware of your existing baselines and health rule definitions before you select this option.

Configure the Time Period

When configuring a baseline, you set the trend time period and the trend. The base time period comes in two forms:

- Fixed time range: from some specific date and time to a second specific date and time. For example, if you have a release cycle at a specific time you might limit your data collection to that specific time.
- Rolling time range: in which the most recent X number of days is used. This is the more common choice.

Transaction Snapshots

This page describes how to view transaction snapshot data to monitor and troubleshoot business transaction performance. To learn about when AppDynamics takes transaction snapshots or how to configure transaction snapshot settings, see Transaction Snapshot Collection.

AppDynamics monitors every execution of a business transaction in the instrumented environment, and the metrics reflect all such executions. For troubleshooting purposes, AppDynamics takes snapshots of specific instances of a transaction. A transaction snapshot gives you a cross-tier view of the processing flow for a single invocation of a transaction.

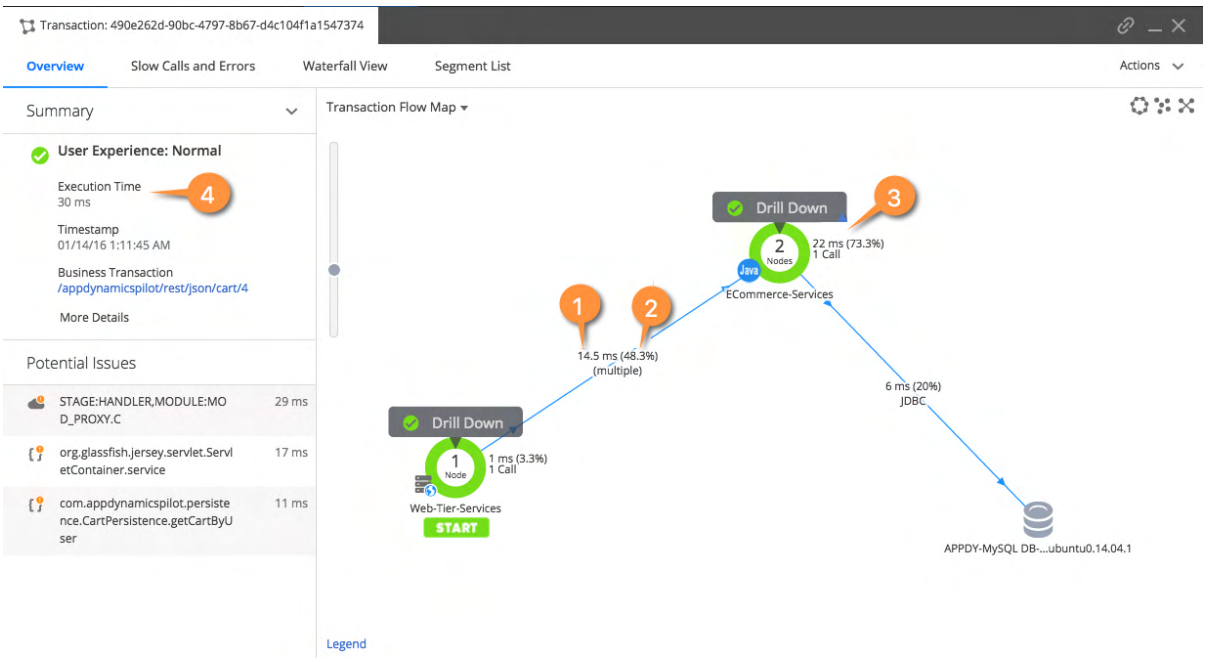
Call drill downs, where available, detail key information including slowest methods, errors, and remote service calls for the transaction execution on a tier. A drill down may include a partial or complete call graph. Call graphs reflect the code-level view of the processing of the business transaction on a particular tier.

View Transaction Snapshots

You can access business transaction snapshots from these locations in the AppDynamics Controller:

- **Troubleshooting** > **Slow Response Times** or **Troubleshooting** > **Errors** (left navigation tree for a business application)
- Transaction Snapshots tab on the Business Transaction Dashboard

Double-click a business transaction snapshot to display the snapshot viewer. This image and its accompanying table identify the metrics available in the transaction flow map:



Callout	Metric Name	Explanation
1	Tier Response Time (ms)	The total response time for the call as measured at the calling tier. This includes the processing time on the called tier as well as on any tiers and backends it calls in turn.
2	Percentage of Time Spent (%)	The time spent downstream processing at all downstream tiers and backends as measured by the calling tier and represented as a percentage of the entire execution lifespan of a business transaction. This metric does not include the processing time of asynchronous activities, if any.
3	Asynchronous Activity Processing Time (ms)	The processing time of all asynchronous activities at this tier. This metric does not contribute to the overall tier response time because the activity is asynchronous by nature. This metric is calculated by adding the execution times of all asynchronous activities at a tier and the time spent in communication between other tiers and backends as follows: *Asynchronous Activity Processing Time = Asynchronous-activity-1-processing-time + Asynchronous-activity-2-processing-time + so on.* In the Metric Browser, you can view the Average Async Processing Time metric, which shows the average of the async activity processing time over the selected time range.

4	Execution Time (ms)	Total time spent processing by the business transaction in all affected tiers and communication with other tiers and backends. This metric does not include the processing time of the asynchronous activities. However, in the case of Wait-for-Completion, the originating business transaction will take longer to process the request due to blocking and waiting for all the activities to complete before proceeding. The formula for this metric is calculated by summing up the processing times of a Business Transaction at a particular Tier /communication between Tiers/Backends as follows: *Execution Time = Time-spent-processing-in-Tier-1 + Time-spent-processing-in-Tier-2 + Time-spent-communicating-with-Tier-2 + so on.*

The **Potential Issues** panel highlights slow methods and slow remote service to help you investigate the root causes for performance issues. Click an item in the **Potential Issues** list to view the call in the call graph.

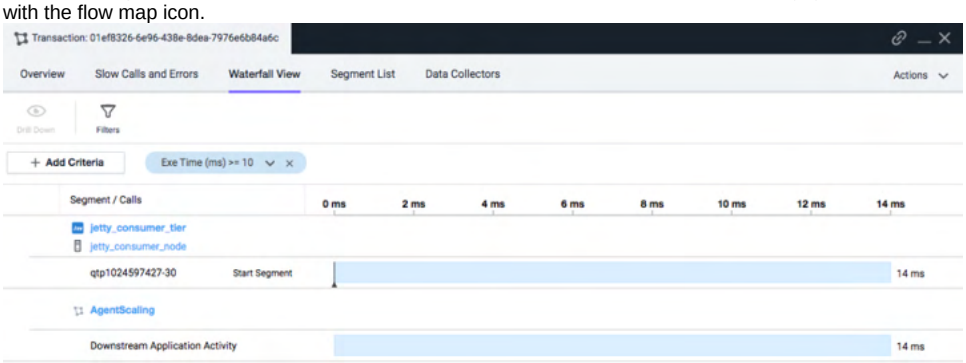
In the flow map for a business transaction snapshot, a tier with a drill-down link indicates AppDynamics has taken a call graph for that tier.

To drill into a call graph for a correlated application in a transaction with cross-application flow, you need *view* permissions to the destination busines

If you use the Java Agent and monitor Oracle databases with Database Monitoring and you have configured snapshot correlation between the Java Agent and the Database Agent, the flow map may also include database drill-downs.

The flow map or **Overview** is one of several views of the business transaction in the snapshot viewer. Other views include:

- **Slow Calls and Errors**, which presents information on the slowest database and remote service calls, slowest methods, and errors. You can gain further insight into these slow calls and errors either by viewing their details on by drilling down into their call graphs.
- **Waterfall View**, which shows the execution of an individual business transaction broken into execution segments. Each segment (shown as a blue bar) represents the time spent executing code on a particular thread within an instrumented application runtime, or the time spent waiting for responses from un-instrumented backends. Handoffs between segments are shown as solid lines for synchronous requests, and dotted for asynchronous requests. The waterfall view allows you to quickly determine which calls consumed the transaction time for a given snapshot. You can click a segment to view the resource wait time for its business transaction. Additionally, you can review downstream applications indicated with the flow map icon.



- **Segment List**, which shows the various legs of the transaction in descending order of duration and give access to their snapshots and allows you to drill down into their details.

Call Drill Downs

A call drill down contains details for that business transaction execution on a particular tier. It provides the code-level information for the transaction.

The contents of a transaction snapshot containing asynchronous segments look slightly different if you access the snapshot through the **Business Transaction** view or through the **App**/**Tier**/**Node** views:

- Initially the **Business Transaction** view only displays the originating segments for the transaction. You have the option to drill down into the asynchronous segments as desired.
- The **App**/**Tier**/**Node** views surface all the segments that are relative to that specific entity. When you access one of these views, you can see all segments, originating and asynchronous.

Node Drill Down

The node drill down organizes diagnostic data among these tabs:

- The Overview tab includes a problem summary, execution times, CPU time stamp, tier, node, process ID, thread name, etc.
- The Call Graphs tab lists call graphs showing the execution flow for the transaction on a given tier. For details, see Call Graphs.
- The Slow Calls and Errors tab lists all the slow method calls and calls that resulted in an error. You can use the *Hot Spots* slider to sort calls by execution time with the most expensive calls in the snapshot at the top.
- The Error Details tab exposes exception stack traces and HTTP error codes.
- The DB & Remote Service Calls tab shows all SQL query exit calls to databases and exit calls to other remote services such as web services, message queues, or caching servers. See Database queries and batching for more information about how AppDynamics handles SQL exit calls.

- The Server tab displays graphs for hardware—CPU Memory, Disk IO, Network IO— Memory—Heap, Garbage Collection, Memory Pools—JMX, and more. If you have Server Visibility, you will have access to full performance details for the server hardware and operating system
- For customers using Network Visibility, the Network tab shows charts related to the impact of the network on the transaction and other pertinent data. For information on network KPIs and troubleshooting see KPI Metrics in Network Dashboard and Application Flow Map and KPI Metrics in Right-Click Dashboards.
- The Data Collectors tab shows pertinent application data for the transaction snapshot. For configuration options, see Data Collectors.

  HTTP Data: HTTP payloads contain basic data such as the URL and session ID, and additional data for Servlet entry points, Struts, JSF, Web Services, etc. You can use HTTP data collectors to specify which query parameter or cookie values should be captured in the transaction snapshot.

  Cookies: The snapshot can use cookie values to help identify the user who initiated the slow or error transaction.

  User Data: User data from any method executed during a transaction, including parameter values and return values, to add context to the transaction. You can use method invocation data collectors to specify the method and parameter index.
  In cases where an exit call is made just before a business transaction starts, exit call information can show up in this field, particularly if the transaction is marked as slow or having errors. Please note that sensitive information on the exit call may be shown in this situation.

- The More tab shows how metrics for the node that deviate the most from the established baselines as Node Problems. It also shows all the Service Endpoints invoked during the snapshot and the Servlet URI and Process ID of the transaction.

Database Queries and Batching

AppDynamics normalizes SQL queries and by default does not display raw/bind values. You can configure SQL capture settings to monitor raw SQL data in the queries. Individual calls that take less than 1 second are not reported.

When returning data to a JDBC client, database management systems often return the results as a batched response. Each batch contains a subset of the total result set, with typically 10 records in each batch. The JDBC client retrieves a batch and iterates through the results. If the query is not satisfied, the JDBC client gets the next batch, and so on.

In the **SQL query** panel, a number followed by an X in the **Query** column means that the query ran the number of times indicated within a batch. The value in the **Count** column indicates the number of times that the batch job executed.

Database Drill down

Database drill downs provide this transaction information:

- **Queries**: lists the queries consuming the most time in the database as top SQL statements and Stored Procedures. Comparing the query weights to other metrics such as SQL wait times may point you to SQL that requires tuning.
- **Clients:** displays the hostname or IP addresses of the Top N clients using the database. A database client is any host that accesses the database instance.
- **Sessions:** displays the Session ID of the Top N sessions using the database sorted by time spent.
- **Schemas:** shows the names of the Top N busiest schemas on the database server.

Use the Transaction Snapshot List

You can view transaction snapshots generated in the UI time range from the **Transaction Snapshots** tab of the application, tier, node, or business transaction dashboards. From there you can:

- **Compare Snapshots** shows the performance of calls in two snapshots as a side-by-side comparison.
- Identify the most expensive calls / SQL statements in a group of Snapshots shows the calls that take the most time across the snapshots you have selected. You can select up to 30 snapshots.
- Find snapshots using the filter options.

The Controller purges transaction snapshots after two weeks by default, but you can configure the snapshot retention period. You can archive a snapshot to preserve it beyond the normal snapshot lifespan; for example, to retain a snapshot associated with a particular problem for future analysis. To archive a snapshot, select it from the list and choose **Actions** > **Archive**.

To archive a snapshot, you need the **Application level - Can create applications** permission.

The file cabinet icon in the far right column indicates that the snapshot is an archive snapshot ().

To display only archived snapshots in the snapshot list, filter the snapshot list and check **Only Archived**.

Call Graphs

Related pages:

- Call Graph Settings
- Data Collectors

A call graph in a transaction snapshot shows you business transaction processing information on a particular tier that participated on the business transaction. A call graph lists the methods in a call stack and provides information about each call.

A call graph can tell you general information such as the total execution time, the node name, the time stamp for the start of execution, and the unique identifier for the business transaction instance. Call graphs help you diagnose performance issues and optimize the flow of a complex business transaction.

Call graphs are also captured by the Node.js agent in process snapshots, which describe an instance of a CPU process on an instrumented Node.js node. See Event Loop Blocking in Node.js.

Call Graph Types

A call graph can be one of these types:

- Full call graphs capture the entire call sequence for the business transaction invocation. In this case, call graphs exist for each monitored node involved in the processing of the business transaction. Periodically collected and diagnostic snapshots are always full call graphs.
- Partial call graphs represent the subset of the call sequence for processing a business transaction, typically from the point at which the transaction has been determined to be slow or have errors. Partial call graphs are identified as such in the transaction snapshot.

View Call Graphs

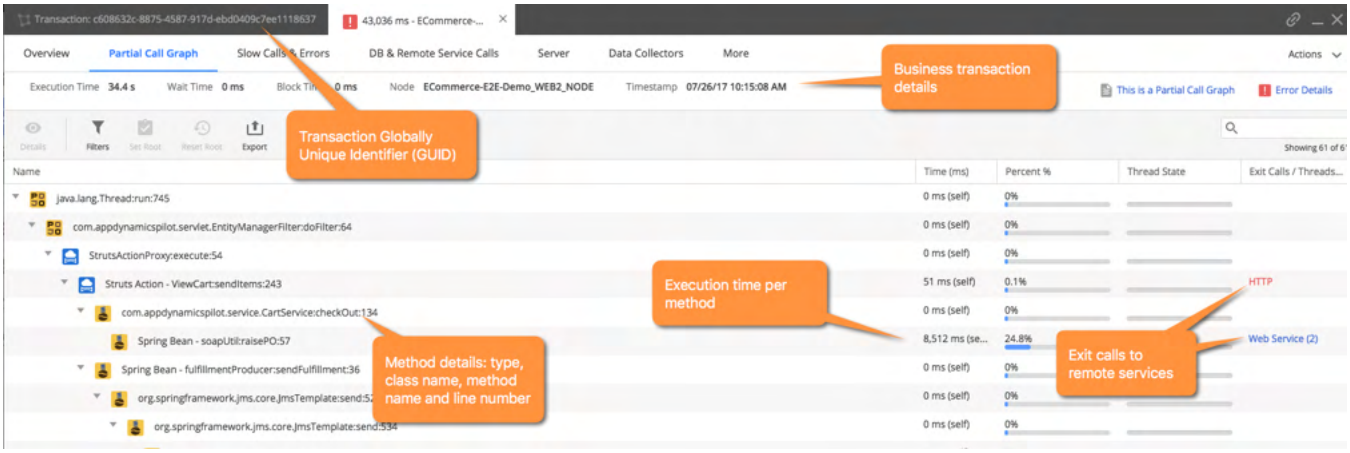
To view a call graph:

1. Open the dashboard for the business transaction for which you want to see a call graph and click the Transaction Snapshots tab.
2. In the transaction snapshot list, double click a snapshot.
3. Click the Drill Down link for the tier on which you want to see a call graph. An asterisk next to the link means that multiple calls were made at this tier for the transaction, which a dialog offers as choices to drill down into.

In the panel, the method execution sequence shows the names of the classes and methods that participated in processing the business transaction on this node, in the order in which the flow of control proceeded.

For each method, you can see the time spent processing and the line number in the source code, enabling you to pinpoint the location in code that could be affecting the performance of the transaction.

The call graph panel includes UI controls for navigating large call graphs. For instance, you can use the filter field to have only a particular method or types of methods displayed. When you find a method of interest, you can set it as the root method in the tree to view only the portion of the call graph that occurs from that point forward.



The call graph displays exit call links for methods that make calls to outside applications and services such as database queries and web service calls. Exit calls that do not exceed a minimum time threshold may not be represented.

SQL Query Exit Calls in Call Graphs

Often times application code executes database calls in multiple phases. For example:

- Construct and execute a SQL query
- Iterate over the result set

For example:

```
stmt = con.createStatement();
# Execute the query
ResultSet rs = stmt.executeQuery(query);
# Iterate through the results
while (rs.next()) {
        String PizzaType = rs.getString("PIZZA_TYPE");
    float price = rs.getFLoat("PRICE");
}
```

The Java Agent represents JDBC SQL query executions and the iterations over the result set separately in the call graph:

- For the execute call, the call graph shows the SQL query and the execution time. You can access the exit call details via a database link in the **External Call** column.
- For the iteration over the shows a count of the number of iterations and the total time. You can access the exit call details via a result set iteration link in the **External Call** column.

The .NET Agent does not separate ADO.NET SQL query execution exit calls from iteration over the result set in the call graph.

The Python Agent and the Node.js Agent sometimes separate out iterations as separate exit calls based upon the database driver used to make the call.

> AppDynamics does not always represent every database call as a separate exit call. Therefore you may see a greater number of database calls than the number of exit calls in the call graph.

Minimum Capture Threshold Times for SQL Calls

The query and result set iteration are both subject to the minimum capture threshold times for SQL calls, 10 ms by default. If the execution time for a query or result set iteration does not exceed the threshold it does not appear in the call graph. This means a given database interaction may be represented in a call graph in one of three ways depending on which parts of the operation took longer than 10 ms, if any:

1. Only the query appears (callout 1 in the image below)
2. Only the ResultSet iteration appears (callout 2)
3. Both appear (callout 3)

Click the link to view more details for the SQL exit call, or the result set iteration.

Maximum Number of SQL Queries in Snapshots

The maximum number of SQL queries in snapshots is set to 500 by default. For Java Agents, you can increase the value of the `max-jdbc-calls-per-snapshot` node property if you do not see expected SQL queries in a call graph.

Request Root Node

The call graphs in transaction snapshots of the Node.js, PHP, and Python agents have an artificial root node named `{request}` .

For Python and PHP, the purpose of this node is to reconcile time differences between the total business transaction time and the sum of the observed call graph nodes, to act as a single entry point for the call graph, and to contain any exit calls which could not be attributed to any other nodes.

For Node.js, the `{request}` node in a business transaction call graph signals the availability of a process snapshot call graph that intersects with the transaction snapshot. If there is no `{request}` node, no process snapshot is available. See Process Snapshots and Business Transaction Snapshots.

Node.js Call Graphs

When the Node.js agent captures a complete call graph, the call graph tab of the transaction snapshot displays the total execution total time of the transaction, including wait times, at the top the call graph.

The execution time shown in the call graph pane is the sum of the times of the individual method calls inside the call graph. This value may be less than the total execution time because it does not include wait times between calls.

Display Excluded Classes in Call Graphs

The sequence of method invocations in a call graph may involve hundreds of classes. These classes include user application classes, framework classes (such as Tomcat or Websphere runtime classes), Java/J2EE core libraries, .NET Framework classes, and more.

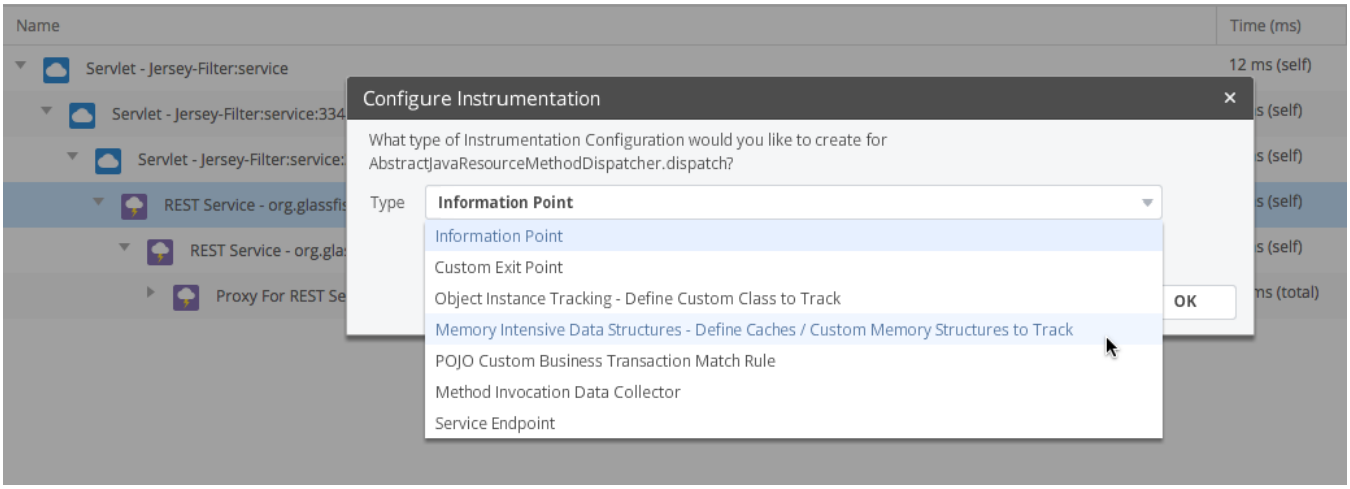
Not all of those classes may be relevant to the type of troubleshooting you normally do. In most cases, your primary interests are the custom application classes you have built on top of the framework or language platform. Other classes may be needed, but only on rare occasions.

To make the call graph more readable and to avoid the overhead of processing the timing information for non-user-application classes, other classes are not shown in the call graph.

If packages (Java) or namespaces (.NET) have been excluded, you can click the *packages/namespaces have been excluded* link to view the packages, and optionally configure the classes to be included in call graphs.

Configure Instrumentation

You can right-click any item in a call graph and select **Configure Instrumentation for this Class/Method**.



The Configure Instrumentation panel presents a drop-down from which you can select the type of configuration that you want to create for the method.

Diagnostic Sessions

By default, AppDynamics retains transaction snapshots that it captures at regular intervals and when a transaction is detected to be performing abnormally. The snapshots may have full, partial, or no call graphs. See Transaction Snapshots.

Diagnostic sessions let you trigger a timed session in which AppDynamics captures transaction snapshots for a business transaction at a more frequent interval that you set. In the session, AppDynamics captures full call graphs for the transactions.

Diagnostics sessions can also be triggered automatically by a health rule violation or in response to an abnormal amount of slow or error transactions. By default, if more than 10% of the requests in a minute are slow, AppDynamics starts a diagnostic session.

If the diagnostic session is triggered manually, the diagnostic session collects snapshots on all the nodes that the selected business transaction passes through. If the diagnostic session is triggered to start automatically, the diagnostics session collects snapshots on the triggering node.

Trigger a Diagnostic Session Manually

To start a diagnostic session manually, you need the **Start Diagnostic Sessions** permission.

You can start a diagnostic session from the business transaction list. In the list, select the transactions and start the session from the **More Actions** menu.

To view the transaction snapshots gathered in the session, in the business transaction dashboard, choose **Transaction Snapshots > Diagnostic Sessions**.

Configure Automatic Diagnostic Sessions for Slow and Error Transactions

You configure settings that trigger automatic diagnostic sessions from the transaction threshold configuration page. You can configure the threshold settings that trigger a diagnostic session as well as the snapshot collection frequency and duration once the session is triggered.

For performance reasons, you want to limit the duration and frequency of diagnostic sessions to the minimum required time to obtain the maximum amount of information for troubleshooting purposes. To avoid continuous collection when there are ongoing performance problems, configure the wait period between sessions and increase the time as needed.

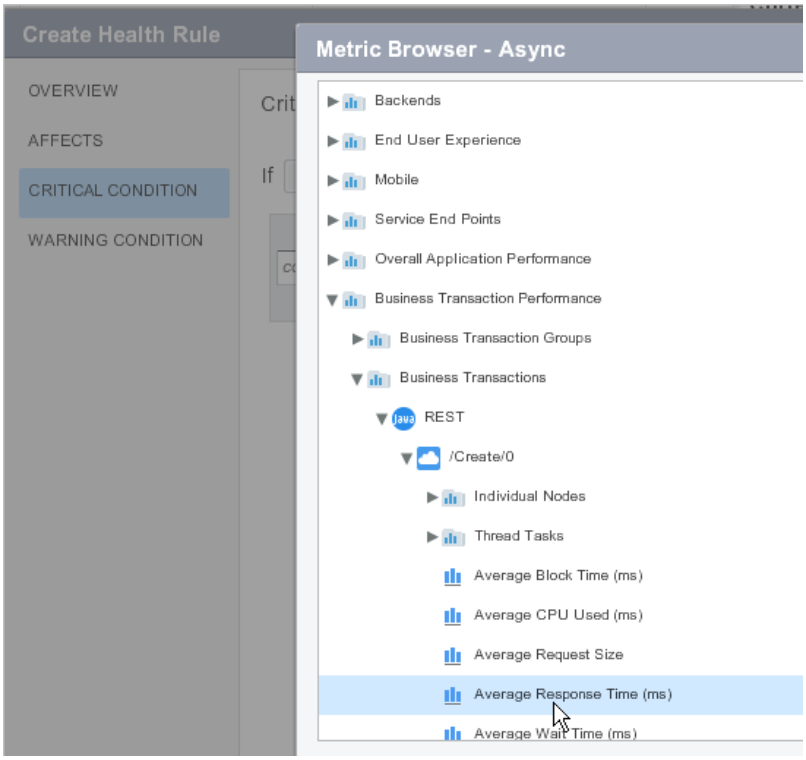
Use Diagnostic Sessions for Asynchronous Activity

Diagnostic sessions are usually triggered based on the overall performance of a business transaction. However, the overall performance of the business transaction may not reflect the execution time of asynchronous activity. It's possible that the originating transaction executes within normal bounds, while the asynchronous activity takes much longer.

To initiate diagnostic sessions for these scenarios, you can use health rules based on a performance metric (such as response time) of the asynchronous activity. Then create a policy that triggers a diagnostic session when the health rule violates. The general steps to do this are:

1. Create a custom health rule based on the asynchronous metric, such as average response time. The metrics for thread tasks are visible in the metric browser under the **Thread Tasks** node for transactions with asynchronous activity. Each thread task has an individual node (usually its

simple class name). Remember to select **Custom** as the type for the health rule.



2. Create a policy that is based on the baseline of the asynchronous metric of interest, for example, the average response time.
3. Configure the policy to trigger a diagnostic session on the affected business transaction. See Business Transactions.

Transaction Snapshot Collection

This page describes scenarios that trigger AppDynamics to take a Transaction Snapshot and how to configure transaction snapshot settings.

AppDynamics takes transaction snapshots of select instances of a transaction and provides a cross-tier view of the processing flow for a single invocation of a transaction. For information about the content of a transaction snapshot, see Transaction Snapshots.

Subject to the guidelines and limits described in the following sections, snapshots are taken in these cases:

- The app agent determines the user experience for the business transaction to be slow or the transaction incurred an error.
- The app agent collects snapshots during periodic snapshot collection.
- The app agent collects snapshots during a diagnostic session.

Snapshot and Call Graph Retention Rules

For a given transaction instance, a call graph may be available for some tiers but not all. The following guidelines describe the rules for when the app agent captures transaction snapshots for the originating and downstream tiers in a transaction. They also describe the type of call graphs a snapshot might include depending on the cause for the snapshot. The guidelines apply to business transaction correlation as well as cross-application flow.

- Any tier (originating or continuing) takes a snapshot when it recognizes that it is experiencing slow, very slow, or stalled response times or has errors.
- An originating tier takes a transaction snapshot:
    - When the agent starts a diagnostic session on the originating tier because it has detected a pattern of performance problems. You can also manually start a diagnostic session from the **Business Transaction Dashboard**. See Diagnostic Sessions.
    - When the agent identifies slow, very slow, or stalled response times, or errors on the originating tier. These snapshots may have partial call graph information because they start at the time when the transaction slowed or experienced an error.
    - Based on the periodic collection schedule. By default, the agent captures one snapshot every 10 minutes.
- The downstream tier captures snapshots when the tier immediately upstream to it tells it to take a snapshot. An upstream tier might direct its downstream tier to take a snapshot under these circumstances:
    - The upstream tier is taking a snapshot for a diagnostic session.
    - The upstream tier is taking a snapshot based on the periodic collection schedule.

Within the guidelines, snapshot retention is also subject to snapshot retention limits.

Transaction Snapshot Limits

Snapshot retention limits prevent excessive resource consumption at the node level:

- Originating transaction snapshots are limited to a maximum of 20 originating—5 concurrent—snapshots per node per minute.
- Continuing transaction snapshots are limited to a maximum of 200—100 concurrent—snapshots per node per minute.

AppDynamics applies snapshot retention limits to error transactions as well. As a result, not every error occurrence that is represented in an error count metric, for example, will have a corresponding snapshot. For error transactions, the following limits apply:

- For a single transaction, there is a maximum of two snapshots per minute.
- Across transactions, the maximum is limited to five snapshots per minute (specified by the node property `max-error-snapshots-per-minute`).

Configure Snapshot Periodic Collection Frequency

By default, AppDynamics collects a snapshot every 10 minutes.

Navigate to **Configuration > Slow Transaction Thresholds**. You can modify this default in the **Slow Transaction Thresholds** configuration page.

The value will apply to subsequently created business transactions, but if you check **Apply to all Existing Business Transactions**, all existing business transactions are affected by the change as well.

If you have a high load production environment, it is important that you do not use low values for snapshot collection, or configure collection on a very frequent basis. When there are thousands or millions of requests per minute, collecting snapshots too frequently may result in many extra snapshots that are not highly useful. Either turn off the periodic snapshots and apply to all Business Transactions, or choose a very conservative (high) rate depending on the expected load. For example, if you have a high load on the application, choose every 1000th executions or every 20 minutes, depending on the load pattern.

End-to-End Latency Performance

Works with:

The response time metric for a business transaction can tell you a lot about the performance of the transaction. In asynchronous applications, however, it may not tell you everything.

Consider a method that spawns other threads, possibly on other tiers, and then immediately returns control to the calling thread. The return of control stops the clock on the transaction in terms of measuring response time, but meanwhile, the logical processing for the transaction continues.

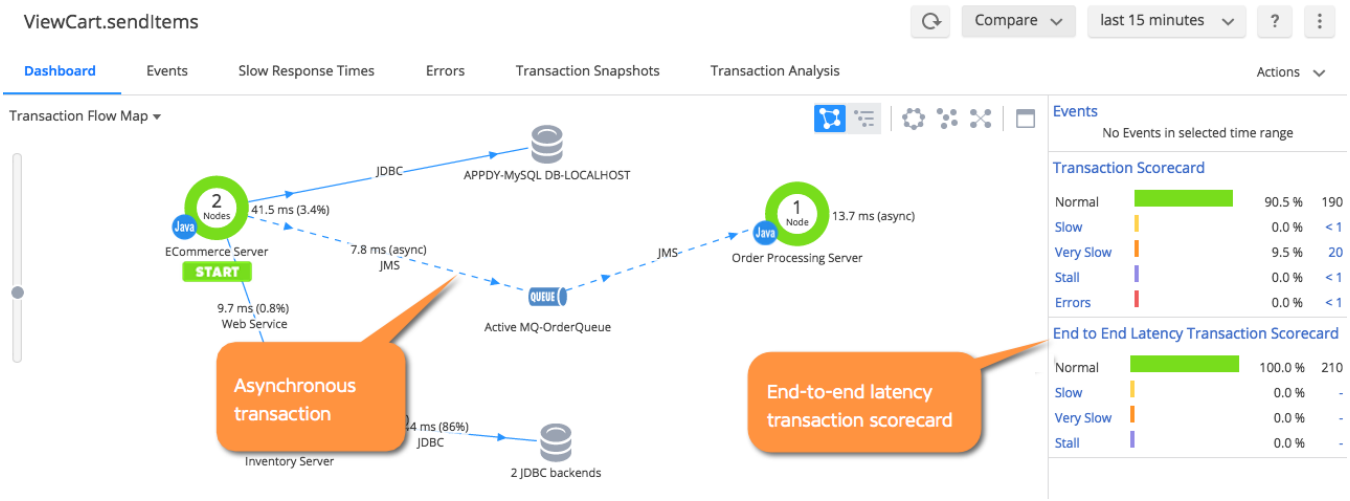
End-to-end latency metrics can reflect the response times for such asynchronous transactions.

Before You Begin

To monitor end-to-end metrics in AppDynamics, you must first configure the endpoints for your asynchronous transactions. See Asynchronous Transaction Demarcators.

Monitor End-to-End Performance

After you enable end-to-end latency transaction monitoring, end to end metrics appear in the metric browser for individual nodes and the overall application. The business transaction flow map also shows the *End to End Latency Transaction Scorecard*.



The End to End Latency Transaction Scorecard shows health based on the end-to-end asynchronous transaction time. The scorecard criteria—normal, slow, very slow and stall—for asynchronous transactions are the same as for the standard transaction scorecard. See Transaction Thresholds for more information. Note that the Transaction Scorecard reflects the data for the originating business transaction only, not end-to-end transactions.

End-to-End Performance Metrics

The performance metrics for end-to-end message transactions, which can be found in the overall application metric tree in the metric browser, are:

- Average End to End Latency: The average time in milliseconds spent processing end to end message transactions over the selected time frame.
- Number of Slow End to End Messages: The number of end to end transactions that exceeded the slow threshold for the business transaction over the selected time frame. The slow user experience is based on the slow transactions thresholds applicable to the general business transaction. Separate thresholds do not apply to end-to-end latency.
- Number of Very Slow End to End Latency Times: The number of end to end transactions that exceeded the very slow threshold for the business transaction over the selected time frame. The very slow user experience is based on the very slow transactions thresholds applicable to the general business transaction. Separate thresholds do not apply to end to end latency.

If you enable **End to End Latency Time (ms)** view option for the **Business Transactions** list, the waterfall view shows the end-to-end transaction performance for asynchronous transactions.

Monitor Background Tasks

Related pages:

- POCO Transaction as a Background Task - .NET

A background task is a processing activity such as an administrative task or internal process that you want to monitor separately from primary business transactions, such as a cron job that backs up a server.

While the process may be important to your environment, it is likely that you do not want to monitor them in the same way as primary business transactions. Background task performance metrics do not count toward the average response time of the tier or node.

During business transaction discovery, AppDynamics attempts to identify processes in the environment that are background tasks and classify them accordingly. You can modify the default configuration based on your requirements and manually change business transactions to background tasks.

View Background Tasks

Although background tasks are monitored separately, they display with the other business transactions in the Business Transactions list. Background tasks are identified in the list by the background task icon ().

This information is available on background tasks:

- The Business Transactions list shows currently executing background tasks and their statistics.
- The Metric Browser shows the response time for each background task.
- Transaction snapshots are generated for each execution of a background task. However, if a particular job runs frequently, the snapshot may not capture all details for each execution.

The tier and application-level metrics do not reflect background task activity. In addition, background tasks are not reflected on the application dashboard.

Reclassify a Business Transaction as a Background Task

You can reclassify any existing business transaction as a background task by right-clicking it in the business transaction list and choosing **Set as Background Task** option. Choosing **Set as User Transaction** turns a background task into a primary business transaction.

Enable Automatic Discovery for Background Tasks

At transaction discovery, a transaction is categorized as a background task based on a setting in a custom match rule that matches the transaction.

AppDynamics includes preconfigured match rules for Java frameworks that are likely to be background tasks, including for JCronTab, JavaTimer, Cron4J and Quartz frameworks. The match rules are disabled by default.

You can enable the match rules, modify them, or create your own custom match rules to have matched transactions categorized as background transactions.

To enable background task detection configuration, from the application or custom tier level configuration, edit an existing match rule or create a new one. Enable the rule, and check the Background Task option to business transactions discovered by this rule categorized as background tasks.

Configure Thresholds for Background Tasks

You can configure performance thresholds for background tasks separately from primary business transactions. From the **Configuration > Slow Transaction Thresholds** page, click the Background Tasks Thresholds tab to access settings specific for background tasks.

AppDynamics recommends that you configure a threshold that is suitable for the background task in your environment. Use static thresholds for slow and very slow background tasks, if they have infrequent load patterns such as once every night. This is because the dynamic moving average-based thresholds are more suitable for production load scenarios and will automatically classify a background process as slow or very slow.

Business Transactions Logging

Related pages:

- Agent Log Files
- Java Agent Logging
- .NET Agent on Windows Logging
- Dynamic Agent Proxy Logging

The Business Transactions log contains this information:

- Discovered business transactions
- Discovery stack trace for each entry point
- Dropped business transactions, which show up in the "All Other Traffic" business transaction when there is business transaction overflow. Only executed methods show up in the business transaction log. If the business functionality is not exercised by the application, the code is not executed, and the methods are not examined as potential entry points.

For the Java Agent and the proxy, the name of the Business Transactions log is `BusinessTransactions`*`Year_mon_day_hr_min`*`.#.log` where # is the log set.

For the .NET Agent, the name of the Business Transactions log is `BusinessTransactionsLog.#.txt` where # is the log set.

See Agent Log Files for information about how the logs are organized into sets that roll over. Within a set, the Business Transactions log file can reach a maximum of five MB.

Service Endpoints

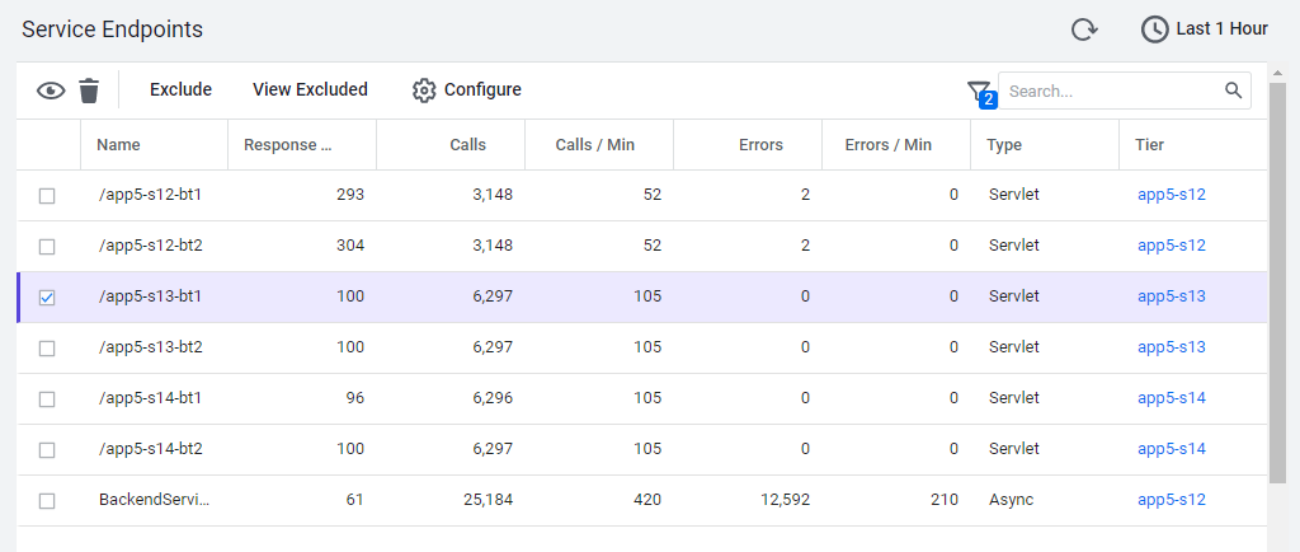
Works with:

A business transaction offers a view of application performance that cuts across the environment, reflecting all services that participate in fulfilling the transaction. However, another way of viewing application performance focuses on the performance of a particular service independently of the business transactions that use it.

Like business transactions, service endpoints provide key performance indicators, metrics, and snapshots. However, they provide that information exclusively in the context of that service, omitting business transaction context or downstream performance data.

Monitor Service Endpoints

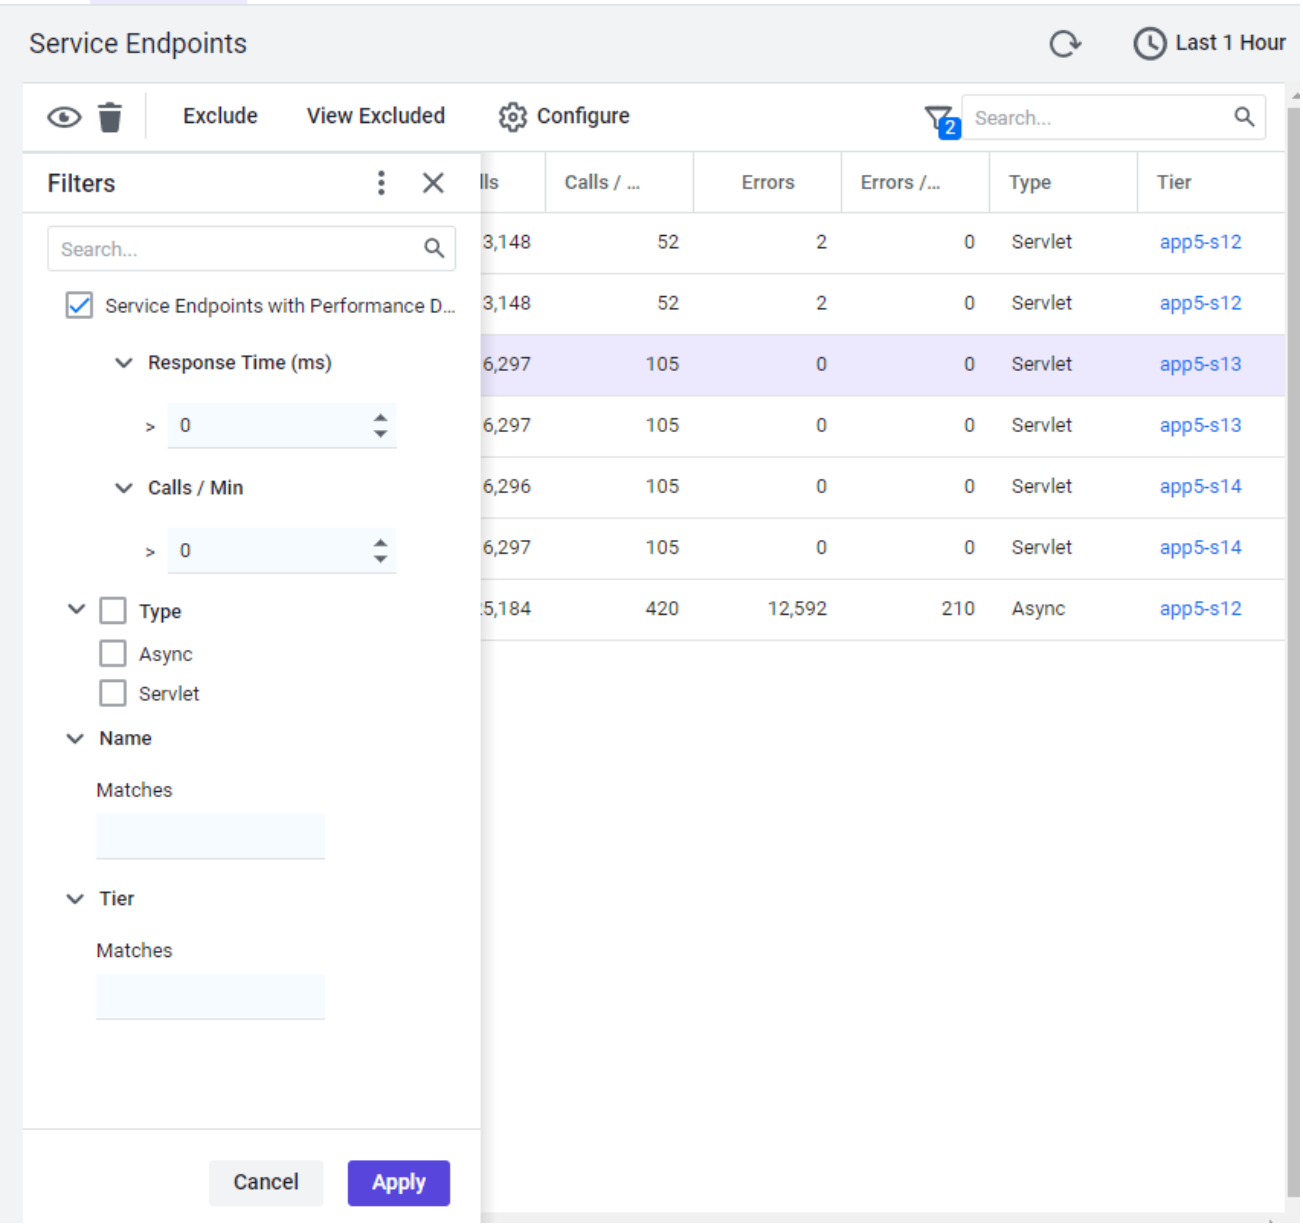
From the **Applications** navigation menu in the Controller, select **Service Endpoints** to view a list of service endpoints with key performance metrics.



Name	Response ...	Calls	Calls / Min	Errors	Errors / Min	Type	Tier
/app5-s12-bt1	293	3,148	52	2	0	Servlet	app5-s12
/app5-s12-bt2	304	3,148	52	2	0	Servlet	app5-s12
/app5-s13-bt1	100	6,297	105	0	0	Servlet	app5-s13
/app5-s13-bt2	100	6,297	105	0	0	Servlet	app5-s13
/app5-s14-bt1	96	6,296	105	0	0	Servlet	app5-s14
/app5-s14-bt2	100	6,297	105	0	0	Servlet	app5-s14
BackendServi...	61	25,184	420	12,592	210	Async	app5-s12

Service endpoints that contain performance data within the selected time range display in the list.

Select the **Filter** icon (on the top right of the page) to set various filtering options for active and inactive service endpoints within the designated time range. Other view options include showing transactions of certain types or ones that exceed a configurable average response time. After you set the desired filters, select **Apply**.



Additionally, you can view, delete, and exclude selected service endpoints by selecting the options from the top menu bar. Select **Exclude** to hide the service endpoint from the list.

To completely disable metric collection for the service endpoint, you can create an exclude rule by selecting **Configure**. See Service Endpoint Detection.

Diagnostic sessions are not intended to run in the context of a service endpoint alone. As a result, you cannot directly start a diagnostic session from a service endpoint. If you run a diagnostic session on the business transactions that include calls to the service endpoint, the transaction snapshots from these diagnostic sessions display in the service endpoint dashboard.

Service Endpoint Health Rules

You can create health rules to monitor the parameters that represent the normal or expected operations for your Service Endpoints. The parameters rely on metric values, for example, the average response time. When the performance of a service endpoint violates the conditions set by a health rule, a health rule is violated. Alerts notify you of any violation and initiate remediation actions to mitigate the violation event. It is important that you configure alerts appropriately to ensure that you do not miss any alerts or receive false alerts. 'Alert Sensitivity Tuning' (AST) helps you configure alerts with appropriate sensitivity. AST provides historical data for the metric or the baseline being configured and hence helps you visualize the impact of the alerting configuration. To create a health rule to monitor service endpoint parameters and fine-tune the sensitivity of the health rule using AST, see Create a Health Rule and Fine-tune Metric Evaluation.

Service Endpoint Limits

A service endpoint adds a small amount of system overhead. Agents capture approximately three metrics per service endpoint, so monitoring each service endpoint results in additional metric traffic.

To prevent the possibility of a boundless expansion of service endpoints, the Controller and agent configurations apply the following limits:

Element	Limit	For more information
Application Agent	25 service endpoints per entry point type	See `max-service-end-points-per-entry-point-type` on App Agent Node Properties Reference.
Java Agent	40 asynchronous worker thread service endpoints	See `max-service-end-points-per-async-type` on App Agent Node Properties Reference.
Node	100 service endpoints	See `max-service-end-points-per-node` on App Agent Node Properties Reference.
Controller account	4000 service endpoints	For an on-premises Controller, the limit is configurable using the `sep.ADD.registration.limit` configuration property accessible in the Administration Console.
Execution thread	1 endpoint	See `max-service-end-points-per-thread` on App Agent Node Properties Reference.

Service Endpoint Metrics

Service endpoint metrics display under **Service Endpoints** in the metric browser. Service endpoint metrics are subject to the same operations as other metrics, including those around metric registration, metric rollups for tiers, and limits on the number of metrics. Custom metrics are not available for service endpoints.

Customize Service Endpoints

For Java applications, AppDynamics automatically detects and registers service endpoints. For either Java or .NET, you can configure custom service endpoint detection rules. See Service Endpoint Detection.

Tiers, Nodes, and Naming

Related pages:

- Monitor Windows Hardware Resources
- Troubleshooting Machine Agent Installation
- Java Agent Configuration Properties
- Configure the .NET Machine Agent
- Node.js Setting Reference
- Node Naming in a PHP Environment

This page describes to view, create, and name tiers and nodes. In the Controller UI, you can use **Tiers & Nodes** to view and organize tiers, and the monitored nodes within each tier.

View All Tiers and Nodes

To view the list of tiers and nodes, click **Tiers & Nodes** in the left application panel. The tier list shows all tiers and health data for each tier.

In the tiers list, the **Machine Agent** column indicates whether the Standalone Machine Agent is reporting to the Controller. If the Machine Agent is not reporting, the column is empty. In this case, either an agent is not installed or it is not reporting.

You can change descending and ascending order of the list by clicking on any of the columns.

View Tier and Node Dashboards

In **Tiers & Nodes,** select a tier or node and click **Details**. The tier and node dashboards contain a flow map view at the tier or node level, including widgets for health statuses, load time, response time, and errors. The Memory tab shows memory information relevant to your application environment. Note that the specific information shown for each environment can vary, depending on the environment. PHP memory management is different than other languages. The relevant memory metrics supplied by the App Agent for PHP are in the Metric Browser.

Create a Tier

You can create a tier in the AppDynamics model of your environment by specifying the new tier in the agent configuration of your instrumented application (recommended method). However, you can also create tiers manually by navigating to **Tiers & Nodes > Actions > Create App Server Tier**.

After creating a tier, you can add nodes to the tier through the app agent configuration, or by reassigning an existing node to the new tier.

Rename Node, Tier, or Business Application in the UI

To rename a node, tier, or business application, see interacting with flow maps.

The UI prevents you from using certain special characters for nodes, tiers, and business applications names. Besides numbers, and upper and lower case characters, you can use these special characters in the names :

```
: ~ ! @ # $ % ^ * ( ) - _ + = / \ \ , . [ ] { } | ? .
```

Moving and Renaming Nodes

This page describes how to move and rename nodes. In the Controller UI, you can move and rename nodes between business applications or tiers to reflect changes in your environment model. See Overview of Application Monitoring.

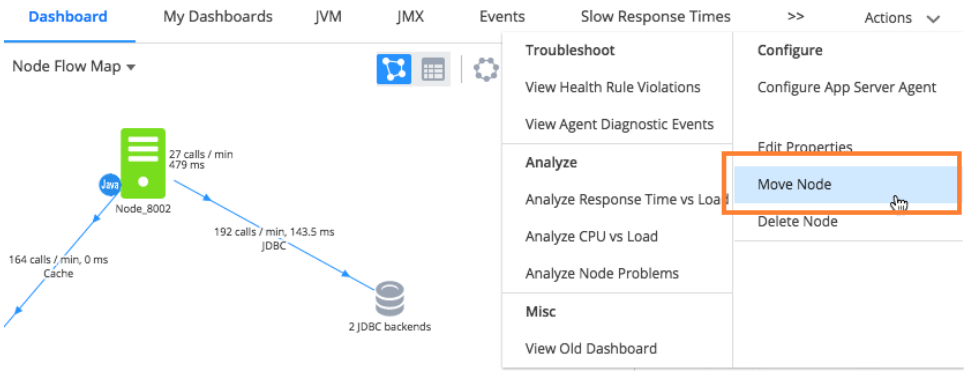
Move a Node

When you move a node to another tier or application in the Controller UI:

- All historical data is removed for that node, with no possibility for data recovery. Moving nodes in the UI is primarily intended for refining the AppDynamics application model of your environment, or other non-production scenarios. To retain historical data for the node, you can either change the tier name (without changing the application or node name) in the agent's `controller-info.xml` file or move the node to a different tier of the same application without data loss.
- The tier or application association in the agent's configuration file no longer reflects the actual tier or application association. The UI association is maintained unless the `force-agent-registration` flag is set to true in the agent's `controller-info.xml`.

You can move a node to a new application or tier with two methods:

- Controller UI: In the node dashboard, click **Actions** > **Move Node**. You do not need to restart the JVM using this method.



- `controller-info.xml`: Update the tier or application setting in the agent's `controller-info.xml` configuration file and restart the JVM.

Force Node Registration

If you moved a node in the UI and you want to move it again elsewhere using `controller-info.xml`, set the `force-agent-registration` property in the configuration file to `true` and restart the JVM. See Force Agent Registration Property.

Data Retention

When you move a node to another tier or application, all node-level historical data (metrics, events, and snapshots) is lost. The historical data is not recoverable. If retaining historical data for the node is important to you, you can change the tier, application or node name in the agent's `controller-info.xml` file.

Any tier-level data that was generated by the moved node is retained in the former tier. Similarly, when moving nodes between tiers in the same application, the tier-level data generated by the node is retained in the former tier.

Moving a Java Node and Machine Agent

If your JVM machine has both a Java Agent and a Machine Agent, you cannot change the associations in the Machine Agent `controller-info.xml` file. You can only change these associations either through the UI or by modifying the Java Agent `controller-info.xml` file described in Java Agent Configuration Properties.

Rename a Node

To rename a node, change the name in Controller UI and then in the app agent configuration file. Changing the node name in the configuration file ensures that the new name is retained through the next agent restart.

If you rename a node from the app agent configuration file only, the effect is that a new node is created with the restarted agent reporting data as that node. AppDynamics retains the historical data previously collected for the node, but the data is associated with the old node name. For most purposes, renaming the node involves changing it in the UI first, and then in the configuration file.

To change the name in the UI, follow the instructions for moving the node, but choose **Edit Properties** from the **Actions** menu, and enter the new name in the **Node Properties** dialog.

For information on changing the node name in the configuration files, see the agent installation or configuration documentation for your agent under Install App Server Agents.

For information on renaming a business application, see Business Applications.

Troubleshoot Node Problems

The page describes how to use the **Node Problem** viewer to troubleshoot node problems.

AppDynamics categorizes the ten items that deviate the most from the baseline performance as node problems. The Machine Agent must be installed on the machine hosting the node that you are troubleshooting.

Use the Node Problem Viewer

If accessed from the **Snapshot** viewer, the **Node Problem** viewer displays node problems for the time range of the snapshot. If accessed from the Node dashboard, the **Node Problem** viewer uses the time range set in the Node dashboard. You can edit the time range in the **Node Problem** viewer and then apply the new time range. You can also define and save a custom time range.

The right panel of the **Node Problem** viewer displays the metrics that deviate the most from their baselines for the specified time range.

On the left, you can set filters on what data appears. Options include:

- The baseline to use to define node problems.
- The type of metrics, whether custom, hardware metrics, JVM, and so on.
- Specify whether to display problems with values that are:
    - Higher than baseline
    - Lower than the baseline
    - Higher and lower than baseline

  For example, if you are only interested in CPU that is too high, set the **Analysis Type** to **Higher for Hardware Resources**. However, if you want to monitor the load on your machine continuously because low CPU usage would also be a problem, set the **Analysis Type** to **Higher and Lower** . The right panel shows the ten items that deviate the most from the baseline.

After changing an option, click **Analyze Node Problems** to apply the change.

Monitor JVMs

This page provides an overview of some of the tools AppDynamics provides for monitoring Java applications and troubleshooting common issues.

JVM Key Performance Indicators

A typical JVM may have thousands of attributes that reflect various aspects of the JVM's activities and state. The key performance indicators that AppDynamics focuses on as most useful for evaluating performance include:

- Total classes loaded and how many are currently loaded
- Thread usage
- Percent CPU process usage

On a per-node basis, AppDynamics reports:

- Heap usage
- Garbage collection
- Memory pools and caching
- Java object instances

You can configure additional monitoring for:

- Automatic leak detection
- Custom memory structures

View JVM Performance

You can view JVM performance information from the Tiers & Nodes dashboard or from the Metric Browser.

In the Tiers & Nodes dashboard, see the following tabs for JVM-specific information:

- The Memory subtab of the Tiers & Nodes dashboard allows you to view various types of JVM performance information: Heap and Garbage Collection, Automatic Leak Detection, Object Instance Tracking, and Custom Memory Structures.
- The JMX subtab of the Tiers & Nodes dashboard allows you to view information about JVM classes, garbage collection, memory, threads, and process CPU. In the JMX Metrics subtab metric tree, click an item and drag it to the line graph to plot current metric data.

In the Metric Browser, click **Application Infrastructure Performance** and expand the JVM folder for a given node to access information about Garbage Collection, Classes, Process CPU, Memory, and Thread use.

Alert for JVM Health

You can set up health rules based on JVM or JMX metrics. Once you have a health rule, you can create specific policies based on health rule violations. One type of response to a health rule violation is an alert. See Alert and Respond for how to use health rules, alerts, and policies.

You can also create additional persistent JMX metrics from MBean attributes. See Configure JMX Metrics from MBeans.

JVM Crash Guard

Using the Machine Agent, when a JVM crash occurs on a machine or node, you can be notified almost immediately and take remediation actions. A JVM crash is because it may be a sign of a severe runtime problem in an application. Implemented as part of JVM Crash Guard, JVM crash is an event type that you can activate to provide the critical information you need to expeditiously handle JVM crashes.

Memory Management

Memory management includes managing the heap, certain memory pools, and garbage collection. This section focuses on managing the heap. You can view heap information in the metric browser or in the Memory tab for a given node as directed in **Monitoring JVM Information**.

The size of the JVM heap can affect performance and should be adjusted if needed:

- A heap that is too small will cause excess garbage collections and increases the chances of `OutOfMemory` exceptions.
- A heap that is too big will delay garbage collection and stress the operating system when needing to page the JVM process to cope with large amounts of live data.

See Garbage Collection.

Detect Memory Leaks

By monitoring the JVM heap and memory pool, you can identify potential memory leaks. Consistently increasing heap valleys might indicate either an improper heap configuration or a memory leak. You can identify potential memory leaks by analyzing the usage pattern of either the survivor space or the old generation. To troubleshoot memory leaks, see Java Memory Leaks.

Detect Memory Thrash

Memory thrash is caused when a large number of temporary objects are created in very short intervals. Although these objects are temporary and are eventually cleaned up, the garbage collection mechanism might struggle to keep up with the rate of object creation. This might cause application performance problems. Monitoring the time spent in garbage collection can provide insight into performance issues, including memory thrash. For example, an increase in the number of spikes for major collections affects the JVM's ability to serve Business Transaction traffic and might indicate potential memory thrash.

The **Tiers & Nodes > Memory > Object Instance Tracking** subtab helps you isolate the root cause of possible memory thrash. To troubleshoot memory thrash, see Java Memory Thrash.

Monitor Long-lived Collections

AppDynamics automatically tracks long-lived Java collections (HashMap, ArrayList, and so on) with Automatic Leak Detection. Custom Memory Structures that you have configured, display in **Tiers & Nodes** > **Memory** > **Custom Memory Structures**.

AppDynamics provides visibility into:

- Cache access for slow, very slow, and stalled business transactions
- Usage statistics (rolled up to Business Transaction level)
- Accessed keys
- Deep size of the internal cache structure

Automatic Leak Detection for Java

This page describes how to view the Automatic Memory Leak dashboard and enable automatic leak detection. See Java Memory Leaks.

JVM Requirements

- Oracle JVM >= 1.5
- JRockit JVM >= 1.5
- IBM JVM >= 1.6

Automatic Memory Leak Dashboard

The Automatic Memory Leak dashboard shows:

- **Collection Size**: The number of elements in a collection.
- **Potentially Leaking**: Potentially leaking collections are marked as red. You should start diagnostic sessions on potentially leaking objects.
- **Status**: Indicates if a diagnostic session has been started on an object.
- **Collection Size Trend**: A positive and steep growth slope indicates a potential memory leak.

To identify long-lived collections, compare the JVM start time and Object Creation Time.

You must have the Configure Agent Properties permission to activate or deactivate automatic leak detection. See Create and Manage Custom Roles.

Enable Automatic Leak Detection

1. In the left navigation pane, click **Tiers & Nodes**.
2. In the right pane, expand the tier of the node you want to configure.
3. Select the node and click **View Dashboard**.
4. Click **Memory** > **Automatic Leak Detection**.
5. Click **On**.
6. Click **Start On Demand Capture Session** to detect leaking collections.

Test before implementing

Leak Detection may affect performance, so test this functionality in a preproduction environment or on a single node first.

AppDynamics begins to automatically track the top 20 application classes and the top 20 system (core Java) classes in the heap.

Troubleshoot Leak Detection

If you cannot see any captured collections, ensure that you have the correct configuration for detecting potential memory leaks. As described in the on-screen instructions you may need to lower the minimum collection size from the default, 5 MB:

To configure the agent of a specific node to capture smaller collections:

1. On the **Tiers & Nodes** list, expand a tier and double-click the node you want to configure.
