2. Ensure the **App Server Agent** tab is active and click **Configure**.
3. Select the Application, Tier, and Node and then click **Use Custom Configuration**.
4. Search for `minimum-size-for-evaluation-in-mb` in the node properties list. Set the value to a smaller size.
5. Choose to overwrite the node configuration.

Object Instance Tracking for Java

This page describes how to configure and use object instance tracking for Java applications. For more information about why you may need to configure this, see Java Memory Thrash.

When object instance tracking is enabled, AppDynamics tracks the top 20 application and top 20 system (core Java) classes in the heap by default. You can also track specific classes.

> AppDynamics does not perform allocation tracking for core Java classes by default since doing so would add significant system overhead. However, it is possible to track core classes on a short-term basis (for example, while troubleshooting) or in pre-production environments. For more information, see Enabling Allocation Tracking for Core Java Classes.

Activating object instance tracking increases the amount of information captured by the agents, resulting in additional overhead. AppDynamics recommends using object instance tracking only while troubleshooting potential memory leaks. It does not normally need to be enabled during normal operation.

> You need the **Configure Agent Properties** permission to set object instance tracking. You need the **Configure Memory Monitoring** permission to configure the custom classes to track. See Create and Manage Custom Roles.

Prerequisites for Object Instance Tracking

- Review Java Supported Environments for information about platform support for object instance tracking.
- For JVMs prior to Java 9, object instance tracking uses tools.jar. If your application runs with the JDK, tools.jar should be already available. If you are running with the JRE, you must add tools.jar to `<JRE_HOME>/lib/ext` and restart the JVM. You can find `tools.jar` in `<JAVA_HOME>`/lib /tools.jar. For Java 9 onwards JEP220 moved the capabilities needed by OIT to the Core Java runtime, therefore `tools.jar` is no longer necessary.
- In some cases, you might also need to copy `libattach.so` (Linux) or `attach.dll` (Windows) from your JDK to your JRE.
- Depending on the JDK version, you may also need to specify the classpath as shown below (along with other -jar options).

> `jdk.jcmd` is no longer a required module for the custom runtime. However, it is required for the proper functioning of object instance tracking.

Specify the Classpath

When using the JDK runtime environment, set the classpath using the `-classpath` option for the application. For example:

- On Windows:
  ```
  java -classpath <complete-path-to-tools.jar>;%CLASSPATH% -jar myApp.jar
  ```
- On Unix:
  ```
  java -Xbootclasspath/a:<complete-path-to-tools.jar> -jar myApp.jar
  ```

Enable Object Instance Tracking

To start an object instance tracking session, follow these steps:

1. In the left navigation pane, click **Tiers & Nodes**.
2. In the right pane, expand the tier node and open the Node Dashboard for the node on which you want to enable object instance tracking.
3. Click the Memory tab.
4. Click the Object Instance Tracking subtab.
5. Click **ON**.

Tracked classes now appear in the Object Instance Tracking table. You can drill down to the tracked classes to see details.

Track Specific Classes

For performance reasons, only the top 20 application classes and the top 20 system (core Java) classes in the heap are tracked automatically.

Use the Configure Custom Classes to Track option on the Object Instance Tracking subtab to specify instances of specific classes to track. Note that the classes you configure here are tracked only if their instance count is among the top 1000 instance counts in the JVM.

To track instances of custom classes:

1. On the Object Instance Tracking tab, click **Configure Custom Classes to Track.**
2. On the Instrumentation page that displays, click the tier you want to customize.

3. In the Object Instance Tracking section for the tier, click **Add**.
4. Enter the fully-qualified class name of the class to track and click **Save**.

The class you added is now tracked during object instance tracking sessions.

Custom Memory Structures for Java

This page describes how to monitor custom memory structures for Java.

AppDynamics automatically tracks long-lived Java collections (HashMap, ArrayList, and so on) with Automatic Leak Detection. To track specific classes, you can use the Custom Memory Structures capability in the Controller UI.

You can use this capability to monitor a custom cache or other structure that is not a Java collection. For example, you may have a custom cache or a third-party cache such as Ehcache. In a distributed environment, caching can easily become a prime source of memory leaks. In addition, custom memory structures may or may not contain collections of objects that would be tracked using automatic leak detection.

> Monitoring custom memory structures with the Java Agent can result in increased CPU utilization. AppDynamics recommends you enable memory structure monitoring on a short-term basis only while troubleshooting or in pre-production environments.

To configure custom memory structures, ensure custom memory structures are supported in your JVM environment. See JVM Support.

- To activate or deactivate object instance tracking, you need the Configure Agent Properties permission.
- To configure the custom classes to track, you need the Configure Memory Monitoring permission. See Create and Manage Custom Roles.

Custom Memory Structures and Memory Leaks

Typically custom memory structures are used as caching solutions. In a distributed environment, caching can easily become a source of memory leaks. AppDynamics helps you to manage and track memory statistics for these memory structures.

AppDynamics provide visibility into:

- Cache access for slow, very slow, and stalled business transactions.
- Usage statistics rolled up to the Business Transaction level.
- Keys being accessed.
- Deep size of internal cache structures.

Automatic Leak Detection Versus Monitoring Custom Memory Structures

Automatic leak detection captures memory usage data for all map and collection libraries in a JVM session. However, custom memory structures may not contain all collection objects. For example, you may have a custom cache or a third-party cache such as Ehcache for which you want to collect memory usage statistics.

Using custom memory structures, you can monitor any custom object created by the app and the size data can be traced across JVM restarts. Automatic leak detection is typically used to identify leaks, while custom memory structures are used to monitor large coarse-grained custom cache objects.

The following provides the workflow for configuring, monitoring, and troubleshooting custom memory structures. You must configure custom memory structures manually.

1. On the **Tiers & Nodes** dashboard, use the **Automatic Leak Detection, On Demand Capture Session** feature to determine which classes aren't being monitored, for example, custom or third-party caches such as EhCache.
2. Configure **Custom Memory Structures** and then restart the JVM if necessary.
3. Enter the fully-qualified classname on the Create New Instance Tracker window and click **Save**.
   AppDynamics automatically tracks long-lived Java collections (HashMap, ArrayList, and so on) with Automatic Leak Detection.
4. Turn on **Custom Memory Structures** monitoring to detect potential memory leaks in the custom memory structures you have configured.
5. Drill down into leaking memory structures for details that will help you determine where the leak is.

To identify custom memory structures:

1. Navigate to **Memory** > **Automatic Leak Detection** and click **On**.
2. Click **Start On Demand Capture Session** to capture information on which classes are accessing which collections objects. Use this information to identify custom memory structures.

AppDynamics captures the top 1000 classes, by instance count.

Identify Potential Memory Leaks

Start monitoring memory usage patterns for custom memory structures. An object is automatically marked as a potentially leaking object when it shows a positive and steep growth slope. The **Memory Leak** dashboard provides the following information:

- **Heap & Garbage Collection**—Provides heap and garbage collection metrics.
- **Automatic Leak Detection**—Provides memory usage data for all map and collection libraries in a JVM session.
- **Object Instance Tracking**—Provides tracking data for the top 20 application and top 20 system (core Java) classes in the heap.
- **Custom Memory Structures**—Allows you to track specific classes and monitor a custom cache or other structure that is not a Java collection.

The **Custom Memory Structures** dashboard provides the following information:

- **Class**—The name of the class or collection being monitored.
- **Deep Size (bytes)**—The upper boundary of memory available to the structure. The deep size is traced across JVM restarts
- **% of Current Used Heap**—The percentage of memory available for dynamic allocation.
- **Potentially Leaking**—Potentially leaking collections are marked as red. We recommend that you start a diagnostic session on potentially leaking objects.
- **JVM Start Time**—Custom Memory Structures are tracked across JVM restarts.
- **Status**—Indicates if a diagnostic session has been started on an object.
- **Deep Size**—A positive and steep growth slope indicates a potential memory leak.

After the potentially leaking collections are identified, start the diagnostic session.

Diagnose Memory Leaks

On the **Custom Memory Structures** dashboard, select the class name to monitor and click **Drill Down.**

Isolate Leaking Collections

Use **Content Inspection** to identify to which part of the application the collection belongs. It allows monitoring histograms of all the elements in a particular memory structure. Start a diagnostic session on the object and then follow these steps:

1. Select the Content Inspection tab.
2. Click **Start Content Summary Capture Session**.
3. Enter the session duration. Allow at least 1-2 minutes for the data to generate.
4. Click **Refresh** to retrieve the session data.
5. Click a snapshot to view the details about that specific content summary capture session.

Access Tracking

Use **Access Tracking** to view the actual code paths and business transactions accessing the memory structure. Start a diagnostic session on the object and then follow these steps:

1. Select the Access Tracking tab.
2. Select **Start Access Tracking Session**.
3. Enter the session duration. Allow at least 1-2 minutes for data generation.
4. Click **Refresh** to retrieve the session data.
5. Click a snapshot to view the details about that specific content summary capture session.

JVM Crash Guard

This page describes how to view and monitor JVM crashes with JVM Crash Guard. When a JVM crash occurs, you need to know as soon as possible. A JVM crash may be a sign of a severe runtime problem in an application and often calls for immediate remediation steps.

View JVM Crash Information

When a JVM crash occurs, a corresponding event type is generated in the Controller UI.

To analyze and troubleshoot the crash:

1. In the **Events** panel, double-click the JVM Crash of interest.
2. Examine any logs associated with the JVM Crash event. (The local log folder is determined by the type of JVM and how it is configured. For more information, refer to the documentation for the specific JVM.)

The JVM Crash panel also displays information about actions executed as a result of the crash. These are actions that you specify when creating a policy that is triggered by a JVM crash event. See Policies.

The JVM Crash event details include this information:

- Timestamp
- Crash reason
- Hostname IP address
- Process ID
- Application name
- Node name
- Tier name

In the JVM Crash Details tab, the **Crash Reason** details field (if available) indicates the root cause of the crash. For example, the field could contain `java.lang.OutOfMemoryError` or Segmentation Fault.

To facilitate the discovery and display of the reason for the JVM crash, JVM Crash Guard supports:

- Hotspot JVM error log analysis
- IBM JVM system dump log analysis
- Jrockit JVM error log analysis

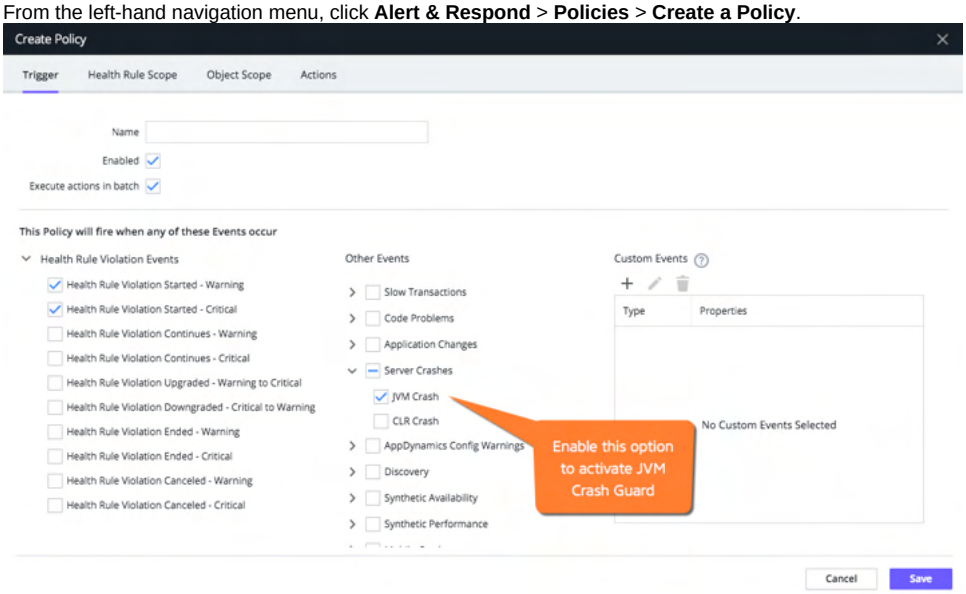
Enable Monitoring for JVM Crashes

Before you can monitor JVM crashes, you must:

- Install and enable a Machine Agent on the machine you want to monitor for JVM crashes. JVM Crash Guard works with the Machine Agent to trigger a policy when a JVM Crash event occurs.
- Ensure that the Machine Agent is running with the required privileges:
  - On Windows, the Machine Agent must run in Administrator root mode.
  - On Linux, JVM Crash Guard requires that the Machine Agent user be able to read all the processes in `/proc/*`. This may be the root user or another user with this privilege.
- Enable the JVM Crash Guard (it is disabled by default). Navigate to `extensions/CrashGuard/conf/crashGuardConfig.yml` and open the `crashGuardConfig.yml` file. Set `enabled` to `true`.

Once you have verified the requirements, follow these steps to create a policy for JVM crash events:

1. From the left-hand navigation menu, click **Alert & Respond** > **Policies** > **Create a Policy**.



2. In the **Other Events** section, expand the **Server Crashes** option and click **JVM Crash**. The JVM Crash event then becomes a trigger to fire a policy.
3. Proceed as usual to create the policy. See Policies.

> If an uninstrumented JVM crash occurs within less than a minute of a previous crash, it will not be reported by the Standalone Machine Agent. In some circumstances, the JVM may crash and then be restarted only to crash again within one minute. For this repetitive cycle crash and restart scenario, only the first JVM crash is reported by the agent.

Garbage Collection

This page describes how to monitor Garbage Collection for Java applications.

AppDynamics gathers Garbage Collection metrics and lets you analyze how periodic Garbage Collections affect the performance of your application. It is important to identify the impact of excessive Garbage Collection or memory-caused instability on the application. A typical Java application which runs on the Java Virtual Machine (JVM) creates objects such as strings, files, and arrays of primitives on the heap. The Java Garbage Collection is an automatic memory management process which finds and gets rid of the objects which are no longer used by the application.

The JVM periodically performs Garbage Collection to maximize available memory and the programmer need not explicitly mark the objects to be deleted. Garbage Collection requires a stop-the-world suspension of all application threads. This process affects the performance, especially for applications with large amounts of data, multiple threads, and high transaction rates.

See How to Master Your Java Memory for a review of how generational Garbage Collection works.

Before You Begin

If your application runs under JDK version 1.6.0_26-b03 and you have configured the monitored application to use G1GC, the Java Agent cannot capture memory statistics. To capture memory statistics, you can do any one of the following:

- Remove G1GC (`-XX:+UseG1GC`) from the application startup options, or
- Upgrade the JDK to >= 1.6.0_32.

In JVM >= 1.7, the agent attaches listeners to the Java event notification service to generate Garbage Collection metrics. In JVM < 1.7, the agent parses certain JVM log files to generate metrics, so you must verify that your JVM is generating the required logs. See Enable Log-based Garbage Collection.

Monitor Garbage Collection

The Java Agent reports certain Garbage Collection metrics at one-minute intervals. You can view these metrics on the Heap & Garbage Collection sub-tab of the Memory tab on the Node dashboard:

- **Heap utilization**: free, used, committed, and available.
  This is the most coarse-grained view of memory use.
- **Garbage Collection**: minor, major, and total on one timeline.
  This should give you some notion of the ratio of minor to major collections.
- **Minor Garbage Collection** on a timeline.
- **Major Garbage Collection** on a timeline.
- **Memory pool use**, including the use of all memory spaces: Young Generation, Old Generation, and PermGen.

For a finer-grained view of the impact of Garbage Collection on application performance, you can view Garbage Collection metrics in the Metric Browser. Navigate to **Application Infrastructure Performance > *tier* > JVM > Garbage Collection**.

In addition to the periodically-collected metrics, the Metric Browser shows the following metrics triggered by minor or major Garbage Collection events:

Metric	Triggering Event	Description
Allocated-Objects	Minor collection	The amount of memory allocated to the Young Generation. A high growth rate might indicate memory thrash. The allocation rate affects the frequency of minor collection events, which can impact application performance over time. The value for **Count** indicates how many collections were made.
Promoted-Objects	Major collection	The amount of memory in use for objects promoted from Young Gen space to Old Gen space. A high promotion rate is related to major collection events, which can have a significant impact on application performance due to the duration of a full major collection cycle. If the promotion rate is close to the allocation rate, this might indicate premature promotion. In this case, you might want to allocate more memory to Young Gen space. The value for **Count** indicates how many collections were made.
Freed Objects	Minor or Major collection	The amount of memory in use for objects being reclaimed in Young and Old space. In a normal system, the number of objects allocated and the free rate metrics should be roughly equal. The value for **Count** indicates how many collections were made.
LiveData	Major collection	The amount of memory in use that persists after major Garbage Collections. An upward slope in the size of live data indicates a possible memory leak.

Tune Garbage Collection in the JVM

After reviewing Garbage Collection diagnostic metrics, you can use these JVM arguments to tune space allocation in the JVM Garbage Collection memory pool. For example, you might want to increase the size of tenured space if your application needs to store many objects long term.

JVM Arguments	Meaning
`-Xms`	The amount of total memory allocated to young and old generation space.
`-XX:NewSize`	The amount of memory allocated to the young generation space.
`-XX:PermSize`	The amount of memory allocated to the permanent generation

Enable Log-based Garbage Collection

For applications running in JVMs < 1.7, Garbage Collection monitoring is based on periodically parsing certain Garbage Collection logs.

To set up Garbage Collection logging for your application, use these arguments:

```
-Xloggc:log-file-path
-XX:+Usecollector-type
-XX:+PrintGCDetails
```

The `log-file-path` option specifies where the log file is located. This table describes the possible values for collector types for the `-XX:+Use`*`collector-type`* option:

Collector Type	Effect
CMS Collector `-XX:+UseConcMarkSweepGC`	Good for applications that require low pause times and that can share resources with the garbage collector. Use the `-XX:ParallelCMSThreads=`<*n*> to set the number of threads to use.

Throughput or Parallel Collector
 	
`-XX:+UseParallelGC`
`-XX:+UseParallelOldGC`
	Can use multiple CPUs to speed up application throughput; good to use for work-intensive apps that can accept long pauses.

G1 Collector `-XX:+UseG1GC`	Available in Java 7 and designed to be a long term replacement for the CMS collector. This is a parallel, concurrent, and incrementally compacting low-pause collector.

To direct the Controller to display logged information, register the following node properties in the Controller UI:

```
enable-jmx-visibility=true
enable-log-based-gc=visiblity=true
```

To change the default log check interval, register the following node property:

```
logbased-visibility-log-check-interval-in-mills=1000
```

Specify Regular Expressions for Parsing Garbage Collection Logs

When you enable log-based Garbage Collection metrics, the agent uses built-in regular expressions to accommodate different JDK and Garbage Collection type combinations. If the built-in regular expressions don't return the Garbage Collection metrics for your system, you can register the following node properties to specify custom regular expressions for parsing the logs:

- `young-gc-custom-regex-1`
- `young-gc-custom-regex-2`
- `young-gc-custom-regex-3`
- `full-gc-custom-regex-1`

- `full-gc-custom-regex-2`
- `full-gc-custom-regex-3`

After you set a custom regular expression using a node property, the agent no longer uses any of the built-in regular expressions to parse the logs.

Monitor JMX

This page covers monitoring for Java Management Extensions (JMX). Java application environments usually support JMX or IBM Performance Monitoring Infrastructure (PMI). AppDynamics automatically discovers JMX and PMI attributes.

About JMX Monitoring Support

JMX uses objects called MBeans (Managed Beans) to expose data and resources from your application. In a typical application environment, there are three main layers that use JMX:

- JVMs provide built-in JMX instrumentation or platform-level MBeans that supply important metrics about the JVM.
- Application servers provide server or container-level MBeans that reveal metrics about the server.
- Applications often define custom MBeans that monitor application-level activity.

MBeans are typically grouped into domains to indicate where resources belong. Usually, in a JVM there are multiple domains. For example, for an application running on Apache Tomcat, there are *Catalina* and *Java.lang* domains. *Catalina* represents resources and MBeans relating to the Tomcat container, and *Java.lang* represents the same for the JVM Hotspot runtime. The application may have its own custom domains.

You can use MBean attributes to create persistent JMX metrics in AppDynamics as described here. In addition, you can import and export JMX metric configurations from one version or instance of AppDynamics to another.

See Writing PMI Applications Using the JMX Interface.

Requirements for JMX Monitoring

AppDynamics can capture MBean data if:

- The monitored system runs on Java >= 1.5.
- Each monitored Java process has JMX enabled. See JMX documentation.

MBean-Based Metrics

AppDynamics creates long-term metrics of the key MBean attributes that represent the health of the Java container. Depending on your application configuration, metrics may include:

- Session information such as the number of active and expired sessions, maximum active sessions, processing time, average and maximum alive times, and a session counter.
- Web container runtime metrics that represent the thread pool that services user requests. The metrics include pending requests and the number of current threads servicing requests. These metrics are related to Business Transaction metrics such as response time.
- Messaging metrics related to JMS destinations, including the number of current consumers and the number of current messages.
- JDBC connection pool metrics including current pool size and maximum pool size.

To view the JMX metrics discovered in a node, see the JMX tab on the Node Dashboard. For additional metrics not discovered automatically, you can confi gure JMX Metrics from MBeans yourself.

You can mask sensitive JMX and MBean data by setting the sensitive-data-filters property in the `app-agent-config.xml`. See Filter Sensitive Data.

View JMX Metric Data

You can view MBean-based metrics using the Node Dashboard and the Metric Browser. In addition, the MBean Browser enables you to view all the MBeans defined in the system.

To view JMX metrics in the Metrics Browser, click the **JMX** tab in the Node Dashboard. The JMX Metrics browser opens and displays the MBeans in a Metric Tree.

You can perform all the operations that are provided by the Metric Browser. See Metric Browser.

View Trending MBeans with Live Graphs

You can monitor the trend of a particular MBean attribute over time using the **Live Graph**.

To view live graphs:

1. In the Node Dashboard, click the JMX tab and then the MBean Browser sub-tab.
2. Select the domain for which you want to monitor MBeans.
3. In the domain tree, expand the domains to find and then select a MBean.
4. Expand the **Attributes** section and then choose an attribute of the MBean.
5. Click **Start Live Graph for Attribute** and then click **Start Live Graph**. The runtime values appear.
6. Select an attribute and click **Live Graph for Attribute** to see a larger view of a particular graph.

Working with MBean Values

When troubleshooting or monitoring a Java-based system, you may want to change the values of composite MBeans and execute MBean methods.

To change the value of an MBean attribute or invoke operation, you need the **Set JMX MBean Attributes and Invoke Operations** permission for the application. See Application Permissions.

To view and edit MBean attribute values:

1. From the **JMX** panel, select **MBean Browser**.
2. In the Domain tree, locate the MBean that interests you.
3. Select an editable attribute, one that has **Yes** in the **Editable** column, and then click **View/Edit Attribute**.
4. In the **MBean Attribute** panel that displays, you see the current value of the MBean Attribute.
5. You can change the value of an editable MBean Attribute by entering a new value in the **Value** field.

Invoke MBean Operations

Using the JMX viewer, you can invoke an MBean operation with standard Java language strings for parameters, and view return values.

To perform this action, a user must have the **Set JMX MBean Attributes and Invoke Operations** permission for the application

To invoke MBean operations:

1. Open the **MBean Browser**.
2. In the Domain tree, locate the MBean that interests you.
3. Open the **Operations** pane, scroll to find the operation that interests you, and double-click **Invoke Action**.
4. Enter the parameter values for the operation and then click **Invoke**. Scalar values for constructors of complex types, such as getMBeanInfo(java.util.Locale) allow you to enter "en-us".

A message appears indicating that the operation is in progress and the number of seconds elapsed. When the operation completes, the results display. The method return result from an invocation can also be a complex attribute. In this case, the name, description, type, and editable attributes of the method are also displayed in the MBean Operation Result area.

Available JMX Metrics

Java Management Extensions (JMX) is a public specification for monitoring and managing Java applications. Through JMX, AppDynamics can access Java class properties that collect management data, such as the resources your application is consuming.

For information on the specific metrics available for your environment, see the documentation provided by your vendor:

- Apache ActiveMQ, see ActiveMQ MBeans Reference, in the ActiveMQ Features documentation
- Apache Kafka, see Default JMX Metrics for Apache Kafka Backends
- Apache Solr, see Quick Demo in the Solr JMX documentation
- Apache Tomcat, see the descriptions of JMX MBeans for Catalina in the `mbeans-descriptor.xml` file for each package
- Cassandra, see Cassandra Metrics
- Coherence, see the Coherence MBeans Reference in Appendix A of the Coherence Management Guide
- GlassFish, see the Oracle Sun Glassfish Administration Guide where you can find a Metrics Information Reference
- HornetQ, see Using Management Via JMX
- JBoss, see An Introduction to JMX
- Kafka Broker, see Monitoring Kafka
- Oracle WebLogic Server, see Understanding JMX
- WebSphere PMI, see PMI data organization in the IBM Websphere Application documentation

Adding JMX Metrics

In addition to the preconfigured metrics, you can define a new persistent metric using a JMX Metric Rule that maps a set of attributes from one or more MBeans. See Configure JMX Metrics from MBeans.

Extending Monitoring with the Agent API

The Application Server Agent API lets you access metrics that are not supported by default or by MBeans. You can use the API to:

- Inject custom events and report on them
- Create and report on new metrics
- Correlate distributed transactions when using protocols that AppDynamics does not support

To learn more about the Application Server Agent API, see the Javadoc included with the Java Agent software at this location:

`<agent_home>/sdk/docs/index.html`

Default JMX Metrics for Apache Kafka Backends

This page describes default metrics for Apache Kafka Backends. The Java Agent includes rules for key metrics exposed by Apache Kafka producers and consumers. To monitor JMX metrics not collected by default, you can use the MBean browser to select the Kafka JMX metric and create a rule for it.

Kafka Producer JMX Metrics

- Response rate: the rate at which the producer receives responses from brokers
- Request rate: the rate at which producers send request data to brokers
- Request latency average: average time between the producer's execution of `KafkaProducer.send()` and when it receives a response from the broker
- Outgoing byte rate: producer network throughput
- IO wait time: percentage of time the CPU is idle and there is at least one I/O operation in progress
- Record error rate: average record sends per second that result in errors
- Waiting threads: number of user threads blocked waiting for buffer memory to enqueue their records
- Requests in flight: current number of outstanding requests awaiting a response
- Network IO rate: average number per second of network operations, reads or writes, on all connections

Kafka Consumer JMX Metrics

- Records lag max: maximum lag in terms of number of records for any partition within the timeframe
- Bytes consumed rate: average number of bytes consumed per second
- Fetch rate: number of fetch requests per second
- Records consumed rate: average number of records consumed per second
- Fetch latency max: maximum time this is taken for any fetch request

Kafka Server JMX Metrics

- `broker-request-total-time-ms`: Total end-to-end time in milliseconds.
- `broker-request-send-response-ms`: Responses dequeued are sent remotely through a non-blocking IO. The time between dequeuing the response and completing send is indicated by this metric.
- `broker-request-response-queue-ms`: Responses too are added to a queue. There is one queue per network processor. Network processor dequeues this response and sends it back. Time spent waiting in this queue is indicated by this metric.
- `broker-request-remote-time-ms`: If the request needs remote processing, the time spent in remote processing is indicated by this metric. For example, for the producer request, if acks is set to -1, the request is not completed until the acknowledgment is received from the followers. Time spent waiting for the followers in indicated by this metric. A fetch request can also be delayed if there is not enough data to fetch. That time too is accounted for by this metric.
- `broker-request-processing-ms`: The request is then processed by the KafkaAPI. The time spent in the processing is indicated by this metric. If this metric is high, debug the relevant request handler.
- `broker-request-queue-time-ms`: The request is added to a common queue. The items in the queue are processed by the request handler threads. The number of these handler threads can be configured through num.io.threads parameter. The average time, a request spends in this queue, is indicated by this metric. If this metric is high, increase the handler threads.

Monitor .NET Nodes

This page describes specific considerations for monitoring .NET applications and how to fine-tune the configuration for .NET frameworks and technologies. These include, for example, monitoring and configuration pages for your IIS applications, Windows services, and standalone applications.

Once you instrument your .NET application environment with the AppDynamics .NET Agent, you can start monitoring .NET application performance. See AppDynamics Essentials.

End-to-End APM for .NET

- Getting Started
- .NET Supported Environments
- .NET Agent
- Monitor CLRs
- Monitor Windows Hardware Resources

Monitor Windows Hardware Resources

This page describes how to monitor Windows hardware resources with the .NET Machine Agent. The AppDynamics .NET Agent includes an embedded .NET Machine Agent that runs as part of the AppDynamics.Agent.Coordinator service. The .NET Machine Agent regularly gathers system performance data metrics such as:

- CPU activity
- Memory usage
- Disk reads and writes
- Network traffic
- Percent free disk space and megabytes free

You can view Windows Hardware Resource metrics in the Metric Browser. When IIS is installed on the machine, the .NET Machine Agent also reports IIS, ASP.NET, and ASP.NET Application metrics. See Monitor IIS. The .NET Machine Agent also reports CLR metrics, which are based on performance counters. See Monitor CLRs.

For applications running on the Windows Azure platform, AppDynamics disables these hardware resource monitoring and machine agent features:

- CLR crash reporting
- Machine snapshots
- Performance counter metrics

Manage the .NET Machine Agent

You can manage the .NET Machine Agent in the Controller under **Settings** > **AppDynamics Agents** on the Machine Agents tab.

- To enable or disable all the machine agents, including the Standalone Machine Agent, for a business application, click **Enable Agents** or **Disable Agents**.
- To enable or disable an individual .NET Machine Agent, right-click the agent and click **Enable Selected Machine Agent** or **Disable Selected Machine Agent**.

  > Disabled agents maintain a 'heartbeat' connection to the Controller so you can enable it again. The agent persists its enabled/disabled state even after a restarted.

- To reset a .NET Machine Agent, right-click the agent and click **Reset Selected Machine Agent**. The reset operation purges all existing metrics for the agent. The agent restarts and begins gathering metrics again.

Machine Agent Tier

Immediately after you install and configure the .NET Agent, the .NET Machine Agent registers with the Controller and starts reporting performance data.

Frequently the machine agent metrics reach the Controller before the app agent has had time to instrument and register IIS applications, Windows services, or standalone applications. If there are no application tiers, then the machine agent registers as the Machine Agent tier.

Once the app agent begins reporting metrics for configured application tiers, the .NET Machine Agent reports to the application tiers and stops sending data to the Machine Agent tier. If you do not instrument any IIS applications, Windows services, or standalone applications on the server, the .NET Machine Agent always reports to the Machine Agent tier.

If you install the Standalone Machine Agent, a Java application, in a .NET environment, then you can add custom monitors and extensions such as the HTTP listener. See Configure the .NET Machine Agent.

Machine Snapshots for .NET

Sometimes environmental conditions cause trouble on the machines where your application runs. Issues that occur outside monitored application code don't show up on transaction snapshots. Machine snapshots provide critical details about CPU usage, memory usage, and the IIS queue on a server at a specific moment in time. Use the data in machine snapshots to uncover and resolve environmental problems.

AppDynamics generates machine snapshots to capture the state of a server at a specific moment in time. The machine snapshots show the processes running on the machine, the IIS application pool activity, and any related transaction snapshots. By default the .NET Machine Agent takes machine snapshots under these conditions:

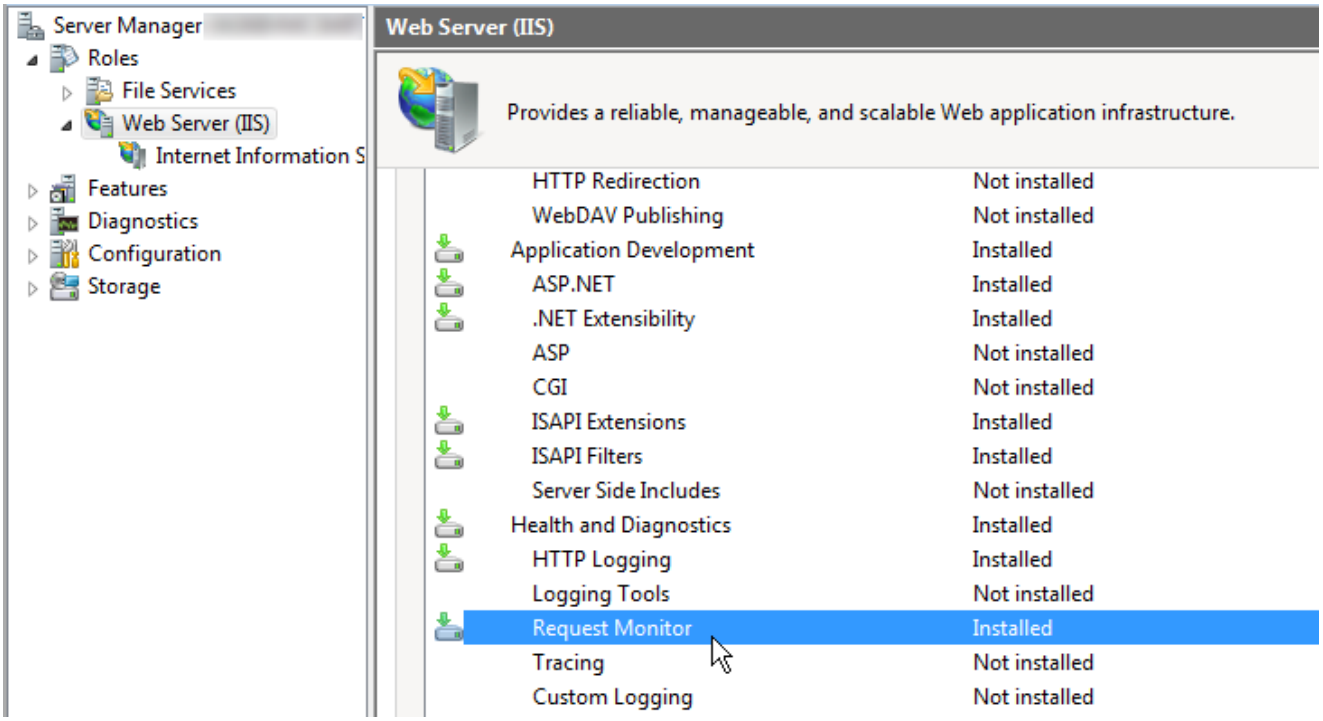
- Periodic collection: The agent takes one snapshot every 10 minutes.
- Breached thresholds: The .NET Machine Agent takes samples of machine statistics every 10 seconds within a 10-minute window. For each sample, the agent checks the CPU percent usage, the memory percent usage, and the oldest item in the IIS application pool queue. The agent flags a sample as a violation when the current usage meets or exceeds one of these thresholds:
  - CPU at 80% or higher
  - Memory at 80% or higher
  - IIS application pool queue item older than 100 milliseconds

  The agent takes a snapshot when it identifies 6 violations of a single type, such as CPU usage, within the window. The agent only takes one snapshot per window for breached thresholds.

To customize the periodic collection or threshold settings, see Configure Machine Snapshots for .NET.

Before Starting

The .NET Machine Agent requires >= IIS 7 to return machine snapshot data for IIS application pools. Additionally, you must enable the **Request Monitor** for the **IIS Health Monitoring** feature.



To enable Request Monitor from the Windows PowerShell command line, launch PowerShell as an administrator and run this command:

```
Install-WindowsFeature Web-Request-Monitor
```

Work With Machine Snapshots

The Machine Snapshot tab on the Application dashboard lists all the snapshots for the selected time range. Entries for individual snapshots show:

- Time the .NET Machine Agent took the snapshot
- Machine name for the snapshot
- Snapshot trigger, either periodic snapshot collection or threshold exceeded
- Percent CPU usage

- Percent memory usage

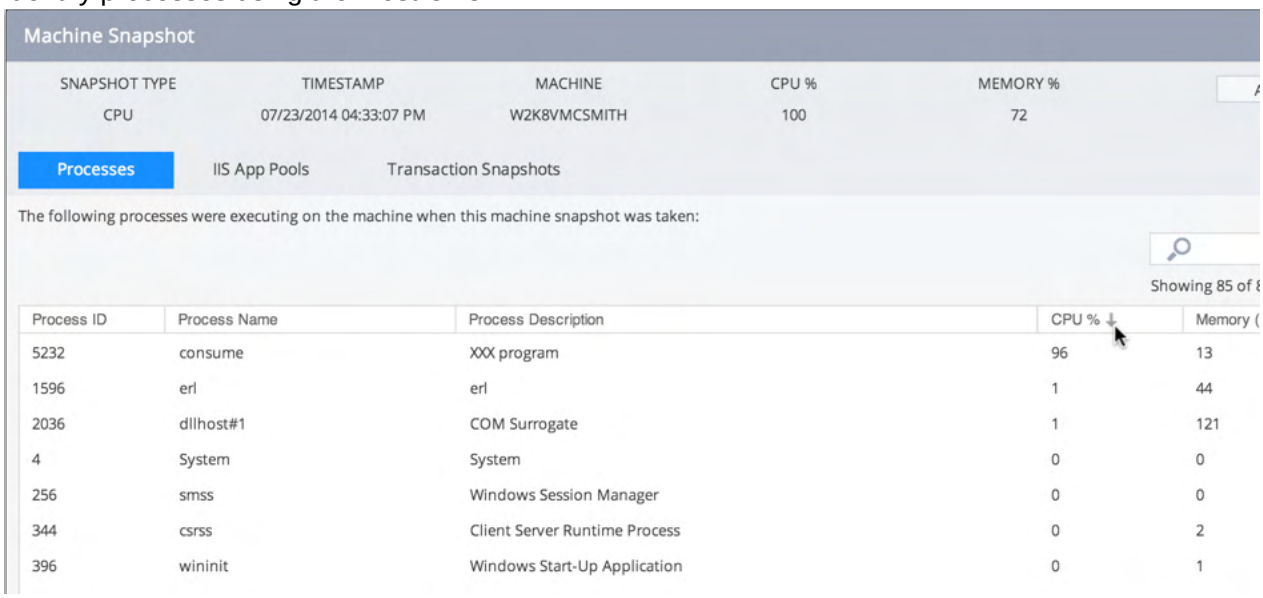
Use **Filters** to limit the snapshot list to a specific snapshot trigger:

- Periodic collection
- Memory events
- CPU events
- IIS events
- Machines where the agent took snapshots
- Archived snapshots

Double-click a snapshot to open the Machine Snapshot panel:

- The Processes tab shows information similar to that from the Windows Task Manager, including:
  - Process ID
  - Process name
  - Process description
  - Percent CPU used by the process
  - Percent memory used by the process

  Click a column heading to sort by the column. For example, click **CPU %** and sort descending to identify processes using the most CPU.



- The IIS App Pools tab shows information on the active IIS application pools:
  - Application pool name
  - Arrivals to the queue per second
  - Queue requests processed per second
  - Age of the oldest item in the queue

- The Transaction Snapshots tab displays all transaction snapshots involving the current machine for five minutes prior to and five minutes after the machine snapshot. This demonstrates how current environmental factors are affecting your business transaction performance. For example, when CPU usage is high, you may discover slow and stalled transactions. Double-click a transaction snapshot to open it.

Monitor CLRs

This page describes how to monitor CLRs with the .NET Machine Agent. The AppDynamics .NET Agent includes the .NET Machine Agent that runs as part of the AppDynamics.Agent.Coordinator service. The .NET Machine Agent regularly gathers CLR performance data and reports it back to the Controller.

CLR Events

The .NET Machine Agent monitors for CLR shutdown and restart events:

- The agent reports an App Server Restart event and indicates if the restart was graceful or not.
- For non-graceful shutdown, the agent reports a CLR Crash if it detects one.

> The default exit code for a graceful shutdown is "0". If your Windows service or standalone application uses a different exit code, see "Profiler - Successful Exit Code Element" on .NET Agent Configuration Properties.

CLR Metrics

CLR metrics provide insight into how the .NET runtime is performing. The AppDynamics preconfigured CLR metrics include:

- .NET CLR memory usage
- Total classes loaded and how many are currently loaded
- Garbage collection time spent, and detailed metrics about GC memory pools and caching
- Locks and thread usage
- Memory heap and non-heap usage, including the large object heap
- Percent CPU process usage

CLR Health Alerts

You can set up health rules based on infrastructure metrics. Once you have a health rule, you can create specific policies based on health rule violations. One type of response to a health rule violation is an alert.

In addition to the default metrics, you may be interested in additional metrics. You can specify additional performance counters to be reported by the .NET Machine Agent. See Manage Windows Performance Metrics.

Monitor CLR Crashes

This page describes monitoring for CLR crash events. The .NET Machine Agent monitors Windows for non-graceful CLR shutdowns on IIS, Windows services, and standalone applications. The agent raises CLR crash events in the Controller when such crashes occur. Use a policy to alert responsible parties when the agent reports a CLR crash.

Monitor for CLR Crash Events

Create a policy that sends notifications when a CLR crash event occurs.

1. Verify your **Email / SMS Configuration**. See Enable an Email Server.
2. Create a notification action configured to alert the parties who respond to CLR crashes. See Notification Actions.
3. Create a policy to trigger on **CLR Crash** under **Other Events** on the Create Policy panel. For the action, choose the notification action you created in step 2. See Configure Policies.

After you create the policy, the Controller sends a notification when the .NET Machine Agent raises CLR crash events.

Analyze and Respond to CLR Crashes

When a CLR crashes, the .NET Machine Agent raises an event in the Controller. The events page on the application dashboard displays the number of server crash events, including CLR crashes, during the selected time range.

1. Click the **Server Crashes** link in the application dashboard to display a list of all server crash events during the selected time range.
2. Optionally filter on the **CLR Crash** event type.
   Entries for individual CLR crashes display information about the crash event, including the process ID and the Windows event log ID.

   > After a CLR crash, IIS automatically tries to restart the CLR, so one issue frequently causes multiple CLR crash events.

3. Double-click a CLR Crash type event to display more information in the **CLR Crash** panel:
   - The Summary tab shows the Windows process ID of the w3wp process that crashed and the Windows event log ID for the crash. The summary also includes the affected tier and node names.

     > If multiple tiers have nodes on the same machine, you may see more than one tier in the CLR Crash window.

   - The Details tab displays essential information about the crash.
   - The Actions Executed tab shows any actions the event triggers. See Monitor for CLR crash events.
   - Read and add new comments on the Comments tab. For example, you can add a comment to the CLR crash event to notify colleagues that of the issue.

Disable CLR Crash Event Reporting

The .NET Machine Agent enables CLR crash event reporting by default. To disable it:

1. Edit the agent `config.xml` as an administrator. See Where to Configure App Agent Properties.
2. Set `enabled="false"` for the CLR Crash Reporting element. See CLR Crash Reporting Element.
3. Restart the AppDynamics.Agent.Coordinator service.

Crash Events Monitored by the .NET Machine Agent

The .NET Machine Agent listens on these Windows event logs for crash events:

- Application Log
- System Log

The agent listens for events logged at event-level `Warning` and higher on these sources:

- Application Error
- .NET Runtime
- WAS (Windows Process Activation Service)

The agent listens for events logged at event-level `Information` and higher on this source:

- Windows Error Reporting

The agent reports CLR crashes as events to the Controller:

- All w3wp process crashes
- Instrumented Windows service crashes
- Instrumented standalone application crashes

The Controller treats all events as `Warning` severity, which is not directly related to the Windows event level.

Object Instance Tracking for .NET

This page describes how to enable object instance tracking on a node. When you enable object instance tracking for a node, AppDynamics analyzes the heap to identify classes with the most instances on the heap. AppDynamics tracks the top 20 .NET framework classes and the top 20 application classes based upon the number of instances. Use object instance tracking to identify memory usage trends in classes with large numbers of instances.

Permissions

To enable object instance tracking, you need one of these permissions:

- Configure Memory Monitoring
  or
- Configure Agent Properties

See Create and Manage Custom Roles.

Before You Begin

- The .NET Agent only supports object instance tracking for >= .NET 4.
- The .NET Agent Coordinator Service must be the same architecture as the monitored application. For example, a 64-bit coordinator with a 64-bit IIS application.

Enable Object Instance Tracking on a Node

1. From the node dashboard, click the Memory tab.
2. Click the Object Instance Tracking subtab.
3. Click **ON**.
   Once the agent completes the heap analysis, AppDynamics begins to track the top 20 application classes and the top 20 system (Core .NET) classes in the heap.

   When you enable object instance tracking, the .NET application pauses during heap analysis and cannot process requests. Enable object instance tracking while you diagnose memory issues; and turn it off when you finish troubleshooting.

Identify Memory Usage Problems

Use these guidelines to identify memory usage problems:

- The Controller resolution for object instances is one minute, but the .NET Agent agent only sends data every ten minutes, so .NET memory appears as a series of peaks over time.
- It is normal for the Controller to display 0 for the Current Instance Count and Shallow Size in between instance count collection times.
- Hover over a peak to display information about the instance count.
- Look for trends where the peaks increase in size from left to right which may indicate a memory leak.

Track Object Instances for Custom Classes

If you want to track a class that doesn't appear in the top 20 on the Object Instance Tracking tab, you can configure a specific class to track.

1. Navigate to **Object Instance Tracking** > **Configure Custom Classes to Track** > **Configure Instrumentation** > **Memory Monitoring**.
2. Click **Add**. The Create New Instance Tracker panel opens.
3. Leave **Enabled** checked.
4. Enter the fully qualified class name for the instance to track.
5. Click **Save**.

Monitor IIS

This page describes how AppDynamics monitors Internet Information Services (IIS). The AppDynamics .NET Agent includes the .NET Machine Agent that runs as part of the AppDynamics.Agent.Coordinator service. The .NET Machine Agent regularly gathers IIS performance data and reports it back to the Controller as metrics.

IIS Events

The .NET Machine Agent monitors IIS for shutdown and restart events:

- The agent reports an App Server Restart event and indicates if the restart was graceful or not.
- For non-graceful shutdown, the agent reports a CLR Crash if it detects one.

Default IIS Metrics for .NET

You must install IIS on the machine to view the metrics for IIS, ASP.NET, and ASP.NET applications. The .NET Machine Agent uses Microsoft Windows Performance Counters to gather IIS metrics. In the Controller, you can view preconfigured metrics for IIS in the Metric Browser.

IIS Metrics

From the Metric Browser:

- To view the IIS metrics for a tier, expand **Application Infrastructure Performance** > **<Tier>** > **IIS**.
- To View the IIS metrics for a node, expand **Application Infrastructure Performance** > **<Tier>** > **Individual Nodes** > **<Node>** > **IIS**.

AppDynamics reports each metric for the entire tier, each individual application pool, and each individual node as follows:

- **Application Infrastructure Performance** > ***<Tier>*** > **IIS** = combined for all IIS processes in all Application Pools for this tier
- **Application Infrastructure Performance** > ***<Tier>*** > **Application Pools** > **<application pool name>** = combined for all processes in this specific Application Pool
- **Application Infrastructure Performance** > ***<Tier>*** > **Individual Nodes** > **<Node>** = metrics for the specific node

ASP.NET Metrics

To view the ASP.NET metrics in the Metric Browser, expand **Application Infrastructure Performance** > **<Node>** > **ASP.NET**.

AppDynamics reports these ASP.NET metrics:

- Application Restarts
- Applications Running
- Requests Disconnected
- Requests Queued
- Requests Rejected
- Request Wait Time
- Worker Process Restarts

ASP.NET Application Metrics

To view the ASP.NET Application metrics in the Metric Browser, expand **Application Infrastructure Performance** > ***<Node>*** > **ASP.NET Applications**.

AppDynamics reports these ASP.NET Application metrics:

- Anonymous Requests
- Anonymous Requests/sec
- Cache Total Entries
- Cache Total Hit Ratio
- Cache Total Turnover Rate
- Cache API Entries
- Cache API Hit Ratio
- Cache API Turnover Rate
- Errors Unhandled During Execution/sec
- Errors Total/sec
- Errors During Preprocessing
- Errors During Compilation
- Errors During Execution
- Errors Unhandled During Execution
- Errors Unhandled During Execution/sec
- Errors Total
- Errors Total/sec
- Output Cache Entries
- Output Cache Hit Ratio
- Output Cache Turnover Rate

- Pipeline Instance Count
- Requests Executing
- Requests Failed
- Requests In Application Queue
- Requests Not Found
- Requests Not Authorized
- Requests Succeeded
- Requests Timed Out
- Requests Total
- Requests/sec
- Session State Server Connections Total
- Session SQL Server Connections Total
- Sessions Active
- Sessions Abandoned
- Sessions Timed Out
- Sessions Total
- Transactions Aborted
- Transactions Committed
- Transactions Pending
- Transactions Total
- Transactions/sec

Monitor IIS Application Pools

You can monitor the health of IIS application pools for the instrumented .NET nodes in a tier. You can view the information by application pool, machine, and process IDs.

This view enables you to visualize key performance indicators for your infrastructure, such as node health and last CLR restart time.

To view the IIS application pools:

1. In the left navigation pane, click **Tiers & Nodes** > **Nodes**.
2. In the Show Data dropdown, select **IIS App Pools**.

If a machine or application pool name is not available for a .NET node, the .NET Agent creates the "Unknown App Pool" / "Unknown Machine" grouping.

Monitor Node.js Processes

This page describes how to monitor Node.js processes. The AppDynamics Node.js Agent helps you monitor Node.js applications in production to determine which applications are slower than normal or producing errors. It also provides tools for troubleshooting application problems so that you can take action before your users experience poor performance.

To access the data, log in to the Controller from a Web browser using your AppDynamics credentials. You can also access the data programmatically using the AppDynamics REST API.

Process Snapshots

The node dashboard for Node.js is similar to the node dashboards for other app agents except that it also includes a Process Snapshots tab, which you use to access process snapshots for the Node.js process.

In a single-threaded model, such as Node.js, one slow function forces other functions to wait. You can monitor Node.js processes using lists of process snapshots to identify which functions have high CPU times and which consume a lot of memory. From the list, you can select and examine process snapshots to identify exactly which functions in your code are blocking the CPU or leaking memory.

A process snapshot describes an instance of a CPU process on an instrumented Node.js node. It generates a process-wide call graph for a CPU process over a configurable time range. Process snapshots are independent of any running business transactions.

You can monitor process snapshots at the tier level or the node level.

Customizations

The Node.js Agent collects several metrics that do not appear in standard dashboards. You can see all the metrics in the Metric Browser, including special metrics related to Node.js processes in **Application Infrastructure Performance** > **Tier** > **Node.js.**

You can create custom dashboards that display any of these metrics using a variety of widgets to create a visual display of information customized for specific types of users in your organization: executives, ops, developers, QA and so forth.

You can also create health rules that stipulate certain levels of acceptable performance and then create policies that automatically send an alert or take an automated action when those rules are violated.

Object Instance Tracking for Node.js

This page describes how to enable object instance tracking for Node.js. The Node.js Agent provides object instance tracking (OIT) for monitoring memory usage. When you enable object instance tracking for a node, the Node.js Agent attempts to identify the object types with the most instances on the heap. The agent tracks the top 20 object types based upon the number of instances. Use object instance tracking to identify memory usage trends in objects with large numbers of instances.

Enable Object Instance Tracking on a Node

1. In the left navigation pane, click **Tiers & Nodes**.
2. In the **Tiers & Nodes** panel navigate to and select the node that you want to track.
3. Double-click or click **View Dashboard**.
4. In the node dashboard, click the Memory tab.
5. Click the **Object Instance Tracking** subtab.
6. Click **On** to start tracking. After completing the heap analysis, the agent begins tracking the top 20 object types in the heap.
7. When you are finished tracking, click **Off** because tracking can slow down the Node.js process. Use OIT for only for brief periods.

Although the Node.js OIT UI displays "Class" and "Classes" throughout, the Node.js Agent tracks object types, not classes. Substitute "object" for "class" wherever you see "class" for this feature.

Identify Memory Usage Problems

Use these guidelines to identify memory usage problems:

- The Node.js Agent attempts to report once per minute, but on a heavily loaded, memory-saturated application it could be less often.
- It is normal for the controller to display 0 for the Current Instance Count and Shallow Size between instance count collection times.
- Hover over a peak in the graph to display information about the instance count.
- Look for trends where the peaks increase in size from left to right. These may indicate a memory leak.

Track Object Instances for Custom Object Types

If you want to track an object that does not appear in the top 20 on the Object Instance Tracking tab, you can configure a specific object to track.

1. In the Object Instance Tracking tab, click **Configure Custom Classes to Track.**
2. In the **Define Custom Classes to Track** panel, click **Add**. The **Create New Instance Tracker** panel opens.
3. Leave **Enabled** checked.
4. Enter the object for the instance to track.
5. Click **Save**. The configured object is added to the objects to track when OIT is on.

Examine OIT Metrics in the Metric Browser

When enabled, OIT metrics are also reported under the **Application Infrastructure Performance** > ***<tier>*** > **Individual Nodes** > ***<node>*** > **Object Instance Tracking** branch in the Metric Browser.

Node.js Metrics

This page describes Node.js process metrics that are specific to the Node.js Agent.

You can view the metrics under these paths in the Metric Browser navigation tree:

- By tier at **Application Infrastructure Performance** > ***<TierName>*** > **Node.js**
- By node at **Application Infrastructure Performance** > ***<TierName>*** > **Individual Nodes** > **Nodejs_*<NodeName>*** > **Node.js**

CPU Usage Metric

- CPU Usage: % busy

Memory Metrics

Garbage Collection

- Full GC Per Min: Number of full garbage collection cycles per minute that the V8 JavaScript runtime has performed in the selected time range.
- Incremental GC Per Min: Number of incremental garbage collection cycles per minute that the V8 JavaScript runtime has performed in the selected time range.

Memory

- Heap size changed: Total amount of memory reclaimed by the full and incremental garbage collection cycles (as a percentage) in the selected time range.
- Current usage (V8 heap used in MB): Total size of the heap at the current time point. This reports how much memory the node process is using for data storage.
- RSS: Resident Set Size of the Node process. This reports the amount of memory (heap and stack) allocated for the process and in RAM, not swapped out.

I/O Metrics

Disk

- KB read per second: KB read from disk per second for the selected time range.
- KB written per second: KB written to disk per second for the selected time range.

Network

- Incoming: KB/sec received for the selected time range.
- Outgoing: KB/sec sent for the selected time range.

Socket.io Metrics

- Number of Connections: Number of currently open Socket.IO connections.
- Total Number of Connections: Number of connections that have been opened since the application started.
- Number of Messages Sent/Received: Number of messages that have been exchanged between the application and all connected Socket.IO clients.
- Size of Messages Sent/Received: Average size, in characters, of the messages exchanged. The underlying transport is text only, so non-string messages are JSON.serialized to determine their size.

Event Loop Metrics

- Average IO Time: Average number of milliseconds per event loop tick spent processing IO callbacks.
- Average Tick Length: Average amount of time between event loop ticks.
- Maximum Tick Length: Shortest amount of time between event loop ticks.
- Minimum Tick Length: Longest amount of time between event loop ticks.
- Tick Count: Number of times the event loop was ticked.

N|Solid Monitoring Data

This page describes available metrics and data for N|Solid monitoring. N|Solid is an enterprise-grade Node.js runtime produced by Nodesource that provides additional performance metrics about Node.js processes.

Metrics

When the Node.js Agent is installed on an N|Solid runtime, it collects these additional metrics and makes them available in the Controller so you can use them to diagnose latency issues and memory leaks.

You can view the metrics under these paths in the metric browser navigation tree, by node at **Application Infrastructure Performance** > ***<TierName>*** > **Individual Nodes** > **Nodejs_*<NodeName>*** > **Node.js**.

- NSolid -> 1-minute, 5-minute, and 15-minute load average
- NSolid -> System Uptime & Process uptime (ms)
- NSolid -> Memory -> JS heap -> Total Usage (MB)
    - The amount of the heap that is being used by JavaScript.
- NSolid -> Memory -> V8 heap -> Total Available (MB)
    - Total memory available to the V8 heap.
- NSolid -> Memory -> Total Available (MB)
    - Total memory available to the process.
- NSolid -> Memory -> Total Size (MB)
    - Total memory used by the process.
- NSolid -> Event Loop -> Active Handles:
    - The number of active handles the event loop will process. Handles tend to be longer-lived larger-scale asynchronous operations, such as open sockets or timers. An uptick in this metric could indicate a possible memory leak.
- NSolid -> Event Loop -> Active Requests:
    - The number of active requests the event loop will process. Requests tend to be shorter-lived smaller-scale operations such as writing to file handles and other file-related operations. This metric provides additional insight into load characteristics.
- NSolid -> Idle Percent:
    - Time spent waiting for I/O and not running Javascript.
- NSolid -> Estimated Lag
    - Average amount of time a I/O response may have to wait before being processed.
- NSolid -> Loops Per Second
    - Number of executions per second of the libuv event loop.
- NSolid -> Average Tasks:
    - Number of asynchronous Javascript tasks per turn of the loop.
- NSolid -> Total Count:
    - Total number of event loop turns.

Process Snapshots Data

You can view details on asynchronous activities in the Node.js event loop for N|Solid processes in **Process Snapshots** > **Async Activity**. These event loop activity categories display in Async Activity:

- Active Handles: active handles that the event loop will process
- Active Requests: the number of active requests the event loop will process
- Pending: lower level asynchronous activity

This information displays for each property:

- Type: The property type (e.g., TCP socket connection, setTimeout)
- Location: The source location associated with the activity, when available

Remote Services

This page describes the monitoring information available for remote services, also known as backends.

What is a Remote Service?

A remote service is a process that resides outside of the application server and provides a service to the application. An example of a remote service is a web service, message queue, or caching server.

AppDynamics automatically detects many common types of remote services when instrumented nodes make outbound requests. For more details on backend support by app agent type, refer to the supported environments page for your agent type under Install App Server Agents, such as Java Supported Environments.

To monitor call performance to a service, first make sure it shows up in the remote services list, which you can access by clicking the **Remote Services** link in the Applications menu. If a service you expect to see listed does not appear in the list, make sure the backend detection configuration is configured appropriately for your environment, as described in Backend Detection Rules.

Monitoring Information for Remote Services

AppDynamics monitors the overall performance of calls to a remote service, as well as the performance of those calls from within specific business transactions.

Metrics for remote services are presented in the Controller UI in the following locations:

- Business transaction metrics: The Transaction flow map shows the metrics for a specific business transaction for a specific service
- Tier metrics: The Tier flow map shows the metrics for all calls from a tier to the specified service
- Remote service metrics: The Application flow map and the Remote Services Dashboard show the overall remote service metrics across the application (all business transactions)

Remote Services Health Rules

You can create health rules to monitor the parameters that represent the normal or expected operations for your remote service. The parameters rely on metric values, for example, the average response time. When the performance of a remote service violates the conditions set by a health rule, a health rule is violated. Alerts notify you of any violation and initiate remediation actions to mitigate the violation event. It is important that you configure alerts appropriately to ensure that you do not miss any alerts or receive false alerts. Alert Sensitivity Tuning (AST) helps you configure alerts with appropriate sensitivity. AST provides historical data for the metric or the baseline being configured and hence helps you visualize the impact of the alerting configuration. To create a health rule to monitor remote service parameters and fine-tune the sensitivity of the health rule using AST, see Create a Health Rule and Fine-tune Metric Evaluation.

View Remote Service Performance on Flow Maps

Remote services detected during the specified time window appear on the Application Dashboard flow map. You can view the detected services in the context of the entire application's transaction flow. The application flow map displays calls per minute and average response time for calls made to remote services. These metrics include all calls made from a specific tier to a service across all business transactions. The tier and node flow maps display the same metric in their respective contexts.

The detected remote services show up on the Tier dashboard flow map. You can view the detected services in the context of the traffic on this specific tier.

For business transactions involving calls to remote services, the services appear on the Business Transaction dashboard flow map. You can view the detected services in the context of the traffic for this specific business transaction. The transaction flow map shows the average time spent in remote service calls for the business transaction. See Flow Maps.

View Discovered Remote Services

The Remote Services list shows all detected remote services along with key performance indicators. Services that are not active are removed after a configurable time period. See Stale Remote Service Removal.

From the Remote Services list, you can select a service and click **View Dashboard** to see the Remote Service Dashboard. The dashboard displays a Database Flow Map, backend properties, and graphs of the key performance indicators (KPIs). The properties indicate how the service is identified and determine how it shows in the flow map and how the metrics are aggregated. For a discussion of baselines and how they are used and configured, see Dynamic Baselines.

The Remote Services Dashboard has two tabs and an action option menu:

- Dashboard: Displays the flow map showing traffic from the calling tier to the remote service, the backend properties used for auto-detection and naming, and key performance indicators.
- Slowest Remote Services Calls: Lists up to ten calls to the service with the longest execution time, by tier and for all tiers.

- From the Action menu, you can also rename a backend, delete a backend, or resolve a backend to a tier.

Slow Remote Service Calls

AppDynamics displays a list of the slowest remote service calls with call details. Click **Troubleshoot > Slow Response Times > Slowest DB & Remote Service Calls** tab to view specific call details and related business transaction snapshots that can help you to troubleshoot.

The Slowest DB & Remote Service Calls tab lists up to ten calls to a remote service with the longest execution time over the selected time frame, by tier and for all tiers, and relevant metrics.

Max Time determines which calls are displayed in the **Slowest DB & Remote Service Calls** list. **Max Time** must exceed 50 ms before AppDynamics tracks the call as a potential candidate for this list. App agents aggregate and report call data to the Controller every 15 minutes.

If Query, Queue, or URL are not specified in the custom exit call, the details for the slowest service call will not be displayed.

Stale Remote Service Removal

A stale remote service is a service for which AppDynamics has previously captured metrics, but which has experienced no metric activity for a certain time period. If a backend is not called for 30 days (in other words, the call per minute metric is zero for 30 days) AppDynamics considers it a stale backend and removes it as a monitored artifact.

After a backend is removed, its metrics no longer appear in the Metric Browser and health rules that reference those metrics do not fire. You should remove any health rules conditions that reference metrics in stale backends.

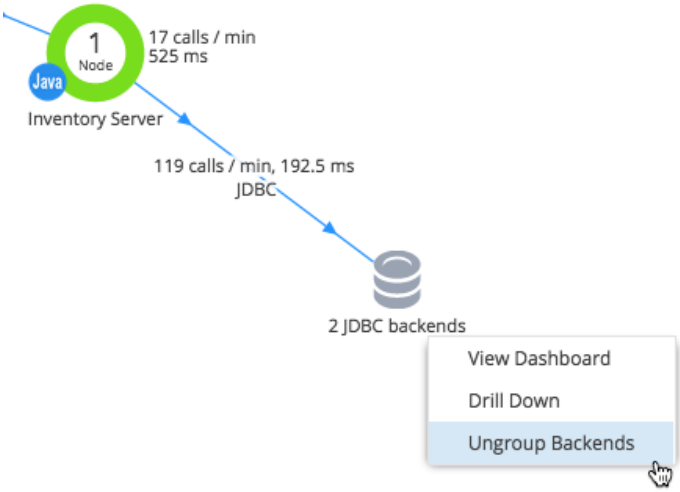
For an on-premises Controller, you can configure the interval by setting the `backend.permanent.deletion.period` property in the Administration Console. Reducing the period may be advisable for large installations, since the maximum number of backends removed in one pass is 50. The minimum interval is one week. Alternatively, you can disable automatic removal by setting the interval to 0.

Group Remote Services on Flow Maps

You can group remote services—or backends—in the flow map configuration to have two or more services of the same type to appear as a single icon in the flow map.

Backend grouping can improve readability and the focus of the flow map, for example, if individual databases or remote service instances are not important to the flow map users.

The following screenshot shows grouped databases on a flow map:

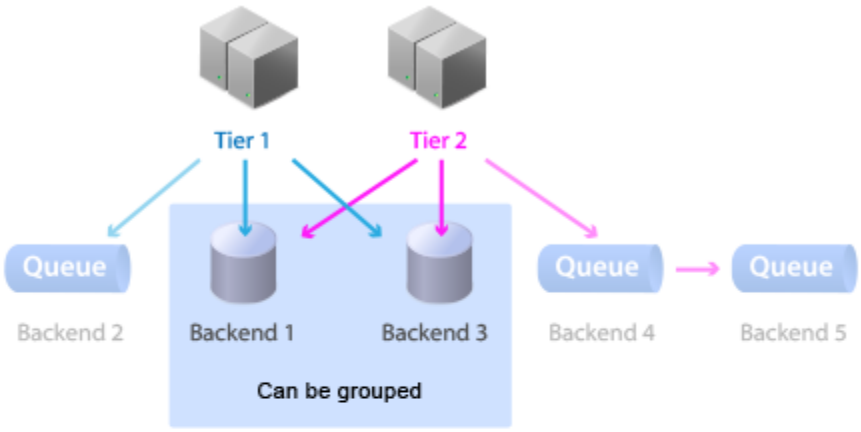


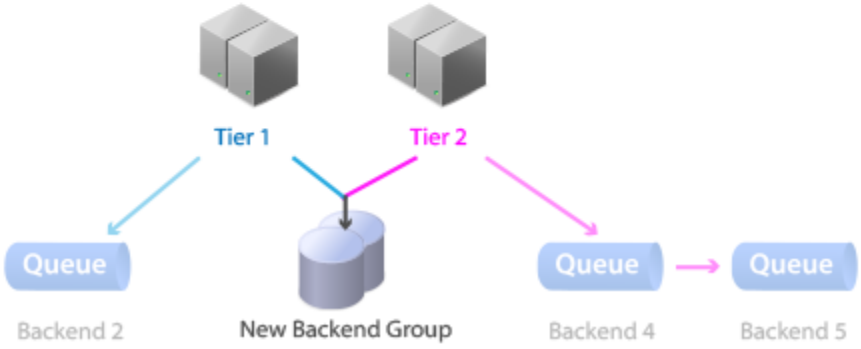
If you want to ungroup backends on a flow map, right-click the backend group and choose **Ungroup Backends**.

Grouped backend services must meet the following conditions:

- All backends must be of the same type
- All backends are called by the same tiers
- No backend in the group calls other backends or calls into other tiers

The following example shows the scenarios in which a set of backends could be grouped.





You can configure backend grouping in the Databases & Remote Services tab of the Configure Flow Map dialog.

You can set a few parameters around grouping, such as the minimum number of backends must be present before they are grouped. For example, if you set the minimum to 4 and only three backends are detected, they are not grouped.

You can exclude a specific backend server from ever being grouped by the flow map, regardless of the grouping configuration, by checking the **Ungroupable** checkbox for that backend in the Visibility and Grouping list.

If there are specific database or remote services that you do not want to see or group in the flow map, check the **Hidden** or **Ungroupable** check box.

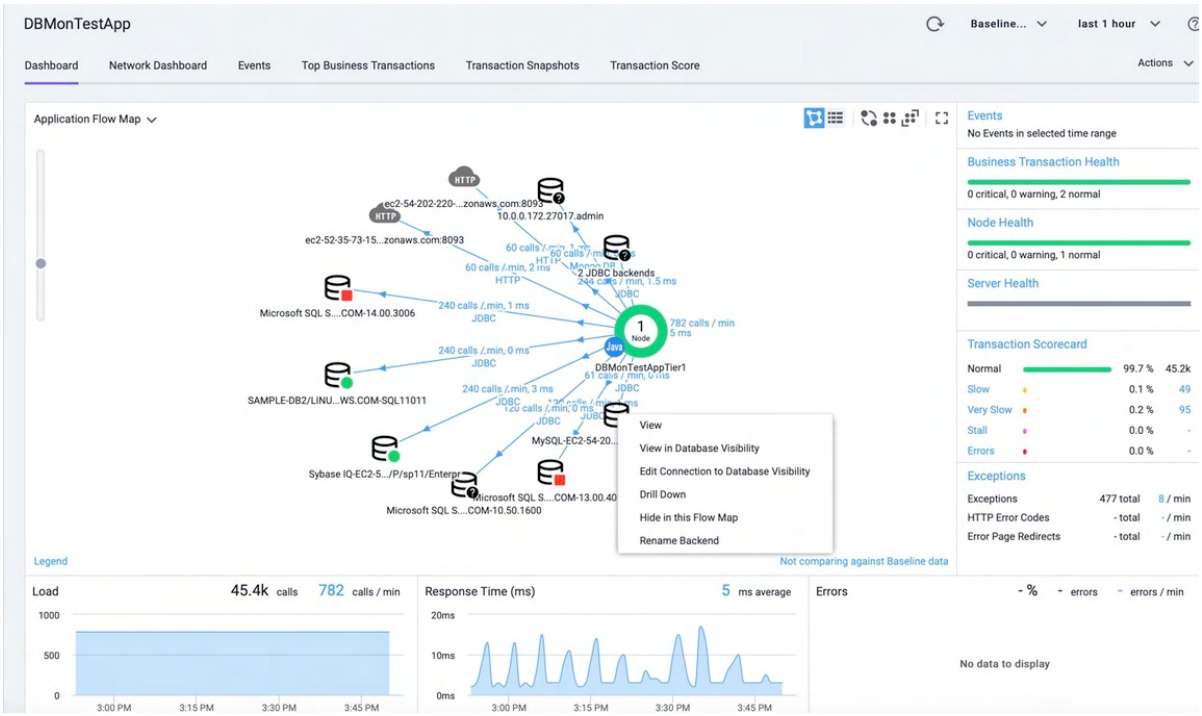
Monitor Databases

AppDynamics can monitor the performance of database calls made by instrumented applications.

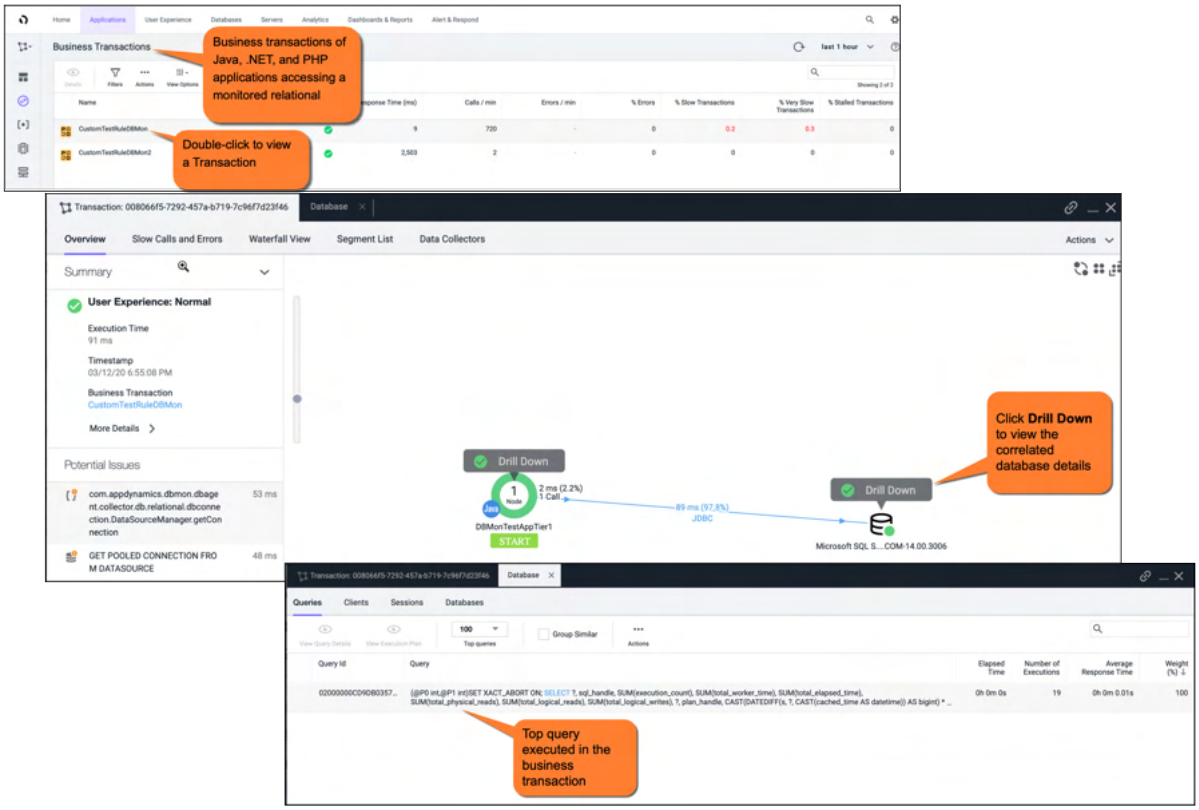
Measure Database Performance

AppDynamics collects metrics for database calls and response times at the following levels:

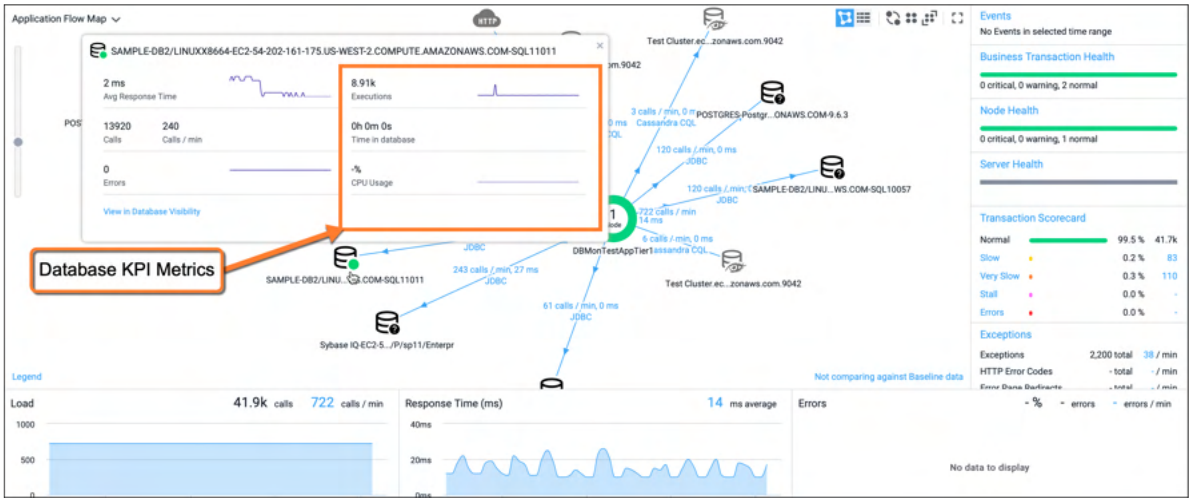
- Business transaction metrics: The metrics for a specific business transaction for a specific database are visible on the transaction flow map.
- Tier metrics: The metrics for all calls from a tier to the specified database are visible on the tier flow map.
- Database call metrics: The overall database access metrics across the application (all business transactions) are visible on the application flow map and the Database Calls dashboard.
- Integrated database metrics with **Database Visibility**:
    - When a database Collector has been set up in AppDynamics **Database Visibility**, you can link to that product from the Application and Database Calls dashboards. If you have already associated the database server with a Database Collector in Database Visibility, you can view the **Database Visibility** UI. If not, the disconnected database icon is displayed and you are prompted to link the database to an already configured server or cluster in **Database Visibility**. Also, you must have view permission to the corresponding collector configured in **Database Visibility**, to map/un-map it with the database server or cluster.



- A relational database backend of a Java application has the same hostname, port number, and database type as a database server already configured in a database Collector, the Oracle backend is automatically matched with the corresponding **Database Visibility** Collector. The Snapshot correlation view, which is available for relational database backends, shows the details of queries, clients, sessions, and schemas when the snapshot was captured.



- When a backend database is linked to a server or a cluster in **Database Visibility**, a click the database icon displays basic details with a link to **Database Visibility** UI. You can also view the database KPI metrics.



By default, many databases and data stores are automatically detected when calls are made from nodes instrumented with AppDynamics app agents. See Access Database Visibility from Application Monitoring Views.

To monitor call performance to a database, confirm that it appears in the Databases Calls list and has its own Database Calls dashboard. If a database is not appearing, check the configuration.

The database icons on the flow maps help you identify the status of the database. The following table lists the different database icons:

Database Icon	Status

	The database is healthy. No active health rule violations
	Health Rule Violation - Critical Condition
	Health Rule Violation - Warning Condition
	The database is either not linked to the appropriate server or cluster node. This icon also appears when the database is in the process of changing the state.
	The database is not connected to the server or cluster in **Database Visibility**. Click the database icon, then the **Connect** link to link the database backend to the appropriate server or cluster.

View Database Performance on Flow Maps

Databases detected during the specified time window show up on the Application Dashboard flow map, where you can view them in the context of the entire application's transaction flow. The application flow map displays calls per minute and average response time for calls made to databases. These metrics include all calls made from a specific tier to a database across all business transactions. The tier and node flow maps display a similar metric aggregating data from calls across all business transactions by tier or node respectively.

The detected databases appear on the Tier Flow Map, where you can view them in the context of the traffic on this specific tier.

For business transactions involving calls to databases, the databases appear on the Transaction Flow Map, where you can view them in the context of the traffic for this specific business transaction. The transaction flow map shows the average time spent in database calls for the business transaction.

Drill Down on Database Performance

In addition to seeing monitored databases in the flow map, you can view:

- Business transactions that make the most database calls. To see this, navigate to Database Business Transactions panel.
- Queries executed the most number of times by business transactions. To see this, double click on the business transaction and open the DB Queries tab.

Resolving Unexpected Databases on the Flow Map

AppDynamics can sometimes reveal unexpected connections from an application to a database on the flow map. If this occurs for you, try the following to determine why this database appears:

- From the left navigation menu, select **Tiers & Nodes > Databases**. Select the Slowest Database Calls tab and drill down into the snapshots to see the code that is calling the database. See To troubleshoot slow database and remote service calls.
- Run a diagnostic session to capture some transaction snapshots and look for calls to the database. See Diagnostic Sessions and Transaction Snapshots. If you have integrated AppDynamics for Databases, you can select a transaction snapshot that involves running SQL on an Oracle database and from the Transaction Flow Map you can link to AppDynamics for Database to see all queries executed in the SQL session that are associated with that transaction snapshot. See Use AppDynamics Pro with AppDynamics for Databases.
- Are any exceptions thrown when the database is seen? If so, look for error snapshots that point to the exception trace.

View Discovered Databases

The database list shows all detected databases along with key performance indicators. Stale databases can be configured to be automatically removed.

From the database list, you can select a database and click **View** to see the Database Calls dashboard. The dashboard displays a Database Flow Map, database properties, and graphs of the key performance indicators (KPIs). The database properties indicate how the agent identifies the database and control how it shows in the display map and how the metrics are aggregated. For a discussion of baselines and how they are used and configured, see Dyn amic Baselines.

The database dashboard has two tabs and an action options menu:

- Dashboard: Displays the flow map showing traffic from the calling tier to the database, the backend properties used for auto-detection and naming, and key performance indicators.
- Slowest Database Calls: Lists up to ten calls to the database with the longest execution time, by tier and for all tiers. See Slow Database Calls.
- The Action menu provides additional actions:
    - **Rename Backend**: Renames the database.

- **Resolve Backend to Tier**: Associates the database with the tier that you select so that the backend appears in the grid view of the tier and not as an independent component ("unresolved backend") on the application dashboard flow map. You can reverse this operation from the **Configure Backends resolving to this Tier** item in Actions menu in the Tier dashboard.
- **Delete Backends**: Removes instances of the database from the controller and all agents. An agent can re-discover the database and register it with the controller.

You can access the Database Server List by clicking **Servers > Databases**. See Backend Detection Rules.

Slow Database Calls

AppDynamics displays a list of the slowest database calls. For each call, you can view specific call details and related business transaction snapshots. The list shows up to ten database calls with the longest execution time over the selected time frame, by tier and for all tiers. Each call shows:

- **Call**: SQL Query
- **Avg. Time per Call (ms)**: the average time per call in milliseconds
- **Number of Calls**: the number of calls executed during the time range
- **Max Time (ms)**: the maximum execution time in milliseconds
- **View snapshots**: a link to view existing transaction snapshots

App agents aggregate and report call data to the Controller every 15 minutes. **Max Time** determines which calls are displayed in the **Slowest Database Calls** list. For example for JDBC calls, **Max Time** must exceed 10 ms before AppDynamics tracks the call as a potential candidate for this list.

Slowest database calls are defined as:

- Max Time greater than 10 ms
- Top ten slowest
- Reported every 15 minutes

View Slowest Database Calls

To view slowest database calls, click **Troubleshoot > Slow Response Times > Slowest DB and Remote Service Calls**.

On this page, you can do the following:

- If transaction snapshots are available for a call, you can click the **View Snapshots** link in the **Snapshots** column to select a snapshot and drill down to the root cause of the slowness.
- You can view explain plans by selecting a call and clicking **View Details**. In the dialog box, click **Explain Plans**. If parameter values are filtered out from the captured SQL, the Explain Plan feature is disabled.

NoSQL

AppDynamics displays NoSQL databases as Remote Services. See Remote Services.

Resolve Remote Services to Tiers

Resolving remote services to a tier can put the metrics for the services into an element of the AppDynamics application model that may provide a more useful view of the activities of the services in flow maps.

The tier may already exist in the business application model or you can create a new one. If it exists, after you resolve the backend to a tier it no longer appears as a backend icon in the flow maps.

AppDynamics automatically resolves some backends to tiers. In general, these are custom backends or HTTP, RMI, Thrift or web services, which are usually logically linked to a tier. If you want to see the backend on its own, you can unresolve it to display it on the flow map.

When to Resolve Backends to a Tier

You may want to resolve a backend to a tier if it represents a more logical view of your environment, for example, if a database runs on the same machine as an application server. Another reason to resolve backends to a tier is to combine similar backends.

For example, if there appear to be multiple databases that are actually the same database using different namespaces, the default flow map is likely to display the databases separately. You can resolve the database backends to a new tier of type "Database Server" so they display as one and the tier metrics are together. If a backend is taken out, the historical data for the backend is retained at the tier level.

Resolving Backends to Tiers

You can resolve a backend to a tier from the backend's dashboard page, either its Remote Service Dashboard or Database Dashboard. In the database dashboard, from the **Actions** menu, click **Resolve Backend to Tier** and select an existing tier or create a new one. Similarly, you can see backends that are associated with a tier and unresolve a backend from the action menu for the Tier dashboard.

Deleting the backend from the tier causes it to re-appear as an unresolved backend in the flow map or resolve it to a different tier.

Troubleshooting Applications

Related pages:

- Garbage Collection
- Error Detection

AppDynamics includes many tools and views designed to help you diagnose application-related problems.

Access Troubleshooting

When starting to troubleshoot an application problem, you should begun in the **Troubleshoot** section of the UI. You can access from the left-hand navigation pane of the Controller UI in an application context.

The area includes pages for analyzing slow response times, errors and exceptions, and health rule violations. It also provides access to war rooms, an area of the UI dedicated to troubleshooting a specific problem.

Additional Help

If slow response time persists even after you've completed the steps outlined above, you may need to perform deeper diagnostics. If you cannot find the information you need in the AppDynamics documentation, consider posting a note about your problem in the Community Discussion Boards. These discussions are monitored by customers, partners, and AppDynamics staff.

Slow Response Times

You may receive a notification based on a health rule violation, see performance indicators in flow maps or transaction scorecards that indicate slow response times. When you do, the following guidelines provide a strategy for troubleshooting and diagnosis.

The Slow Response Times Dashboard in the Troubleshoot menu lists the Business Transactions most responsible for slow Average Response Time (ART). From that dashboard, you can select a time range centered around a spike in ART that also captures more normal-looking time spans. This information is also available through the **Top Business Transactions** tab on the **By Contribution to App Average Response Time** tile.

Step 1: Check for slow or stalled business transactions.

AppDynamics uses transaction thresholds to detect slow, very slow, and stalled transactions. Follow these steps to determine if you complete Step 2 or move on to Step 3.

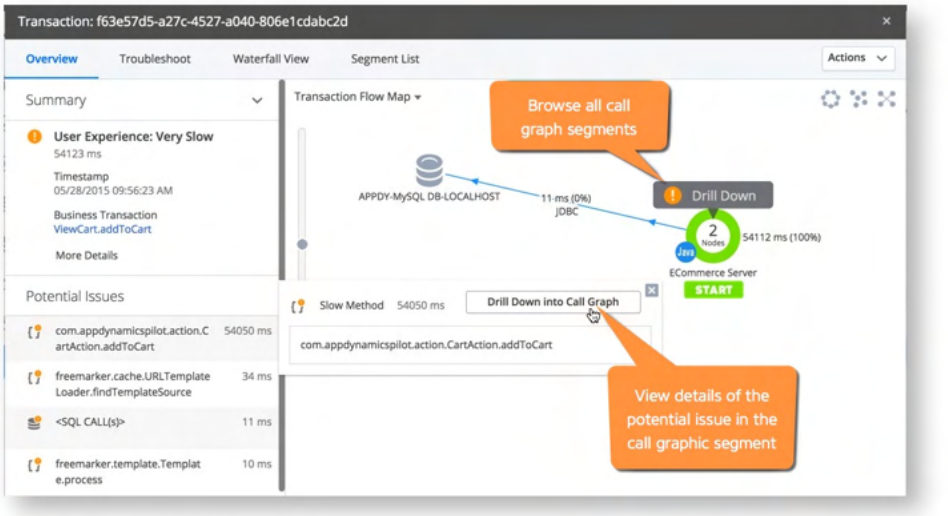
Do you have slow or stalled transactions?

1. Make sure that the time frame selected in the Controller UI encompasses the time when the performance issue occurred. If it's a continuing condition, you can keep the time frame relatively brief. Use the **Time Range** dropdown.
2. Click **Troubleshoot > Slow Response Times**.
3. Click the Slow Transaction**s** tab if it is not already selected.
4. Do you see one or more slow transaction snapshots on this page?

    - If **Yes** – Go to Step 2 to drill down to find the root cause.
    - If **No** – Go to Step 3 and check for slow backends.

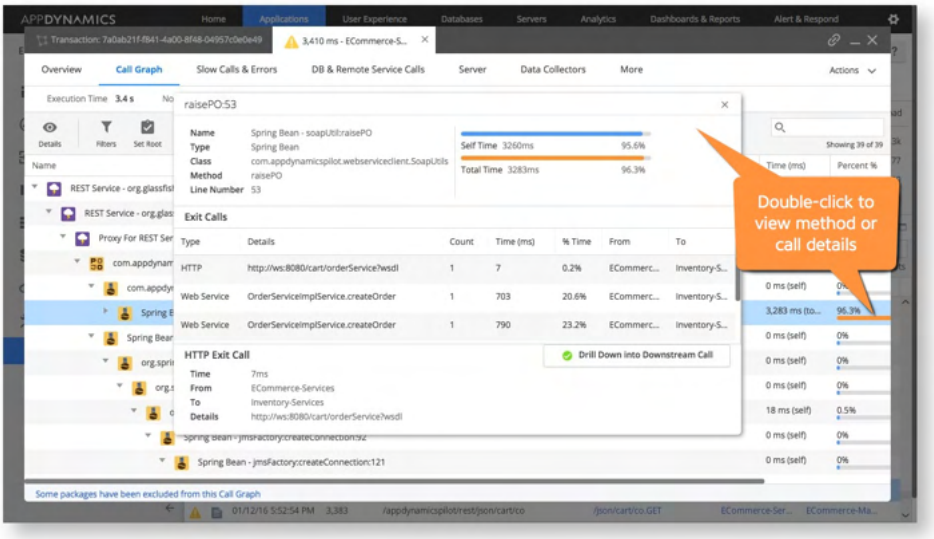
Step 2: Drill into slow or stalled transactions to determine the root cause.

1. From the left menu, navigate to **Troubleshoot** > **Slow Response Times**.
2. In the lower pane of the Slow Transactions tab, click the **Exe Time (ms)** column to sort the transactions from slowest to fastest.
3. Select a snapshot from the list and click **Details**.
4. Review the **Potential Issues** list to see the longest-running method and SQL calls in the transaction.
5. Click a potential issue and select **Drill Down into Call Graph** to go directly to that point in the call graph, or click **Drill Down** in the transaction flow map pane to see the complete set of call graph segments retained for this transaction.



6. View the **Time (ms)** column to see how long this method execution takes relative to the transaction execution time.

7. Click the **HTTP** link in the last column on the right to display the information details pain. In this example, the selected method is taking 96.3% of the transaction execution time.



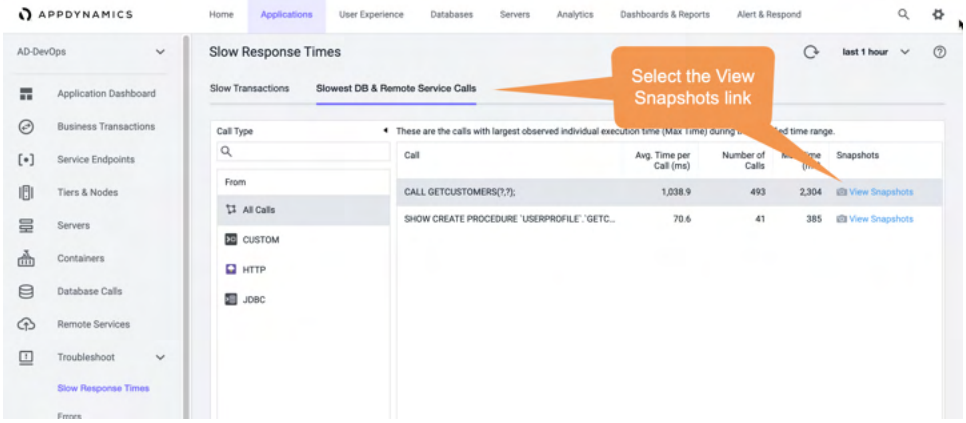
8. Note the *Class, Method,* and *Line Number* (if available) represented by the execution segment. This information provides a starting point for troubleshooting this code issue.

If there are multiple slow or stalled transactions, repeat this step until you have resolved them all and then continue to Step 3.

Step 3: Check for slow database or remote service calls on the backend.

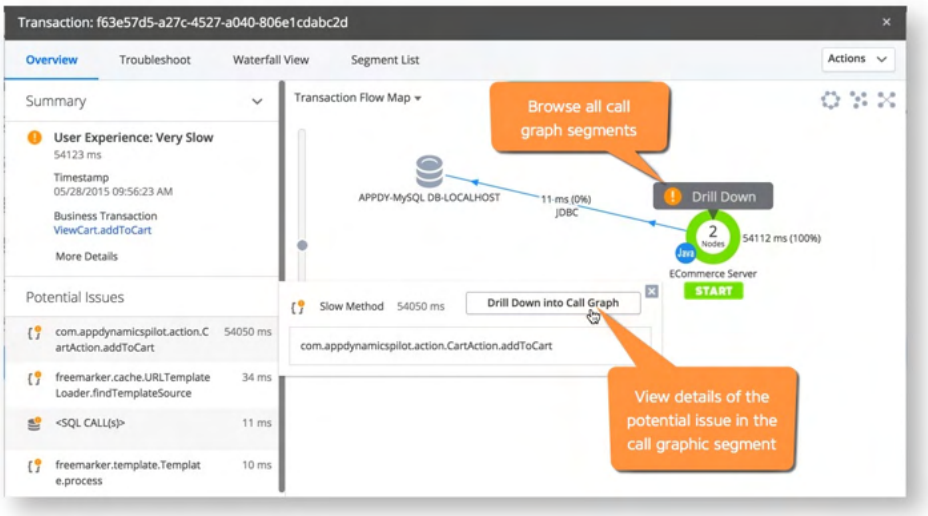
AppDynamics collects metrics about the performance of business transaction calls to the databases and remote servers from the instrumented app servers. You can drill down to the root cause of slow database and remote service calls.

1. Click **Troubleshoot > Slow Response Times**, then click the Slowest DB & Remote Service Calls tab.
2. Select a call from the list and click the **View Snapshots** link to show a list of Correlated Snapshots.



3. Click the **Exe Time (ms)** column to sort the transactions from slowest to fastest.
4. Select a transaction and click **Drill Down**.
5. Select a potential issue from the **Potential Issues** list

6. Click **Drill Down into Call Graph** to go directly to that point in the call graph, or click **Drill Down** in the flow map pane to see the complete set of call graph segments retained for this transaction.

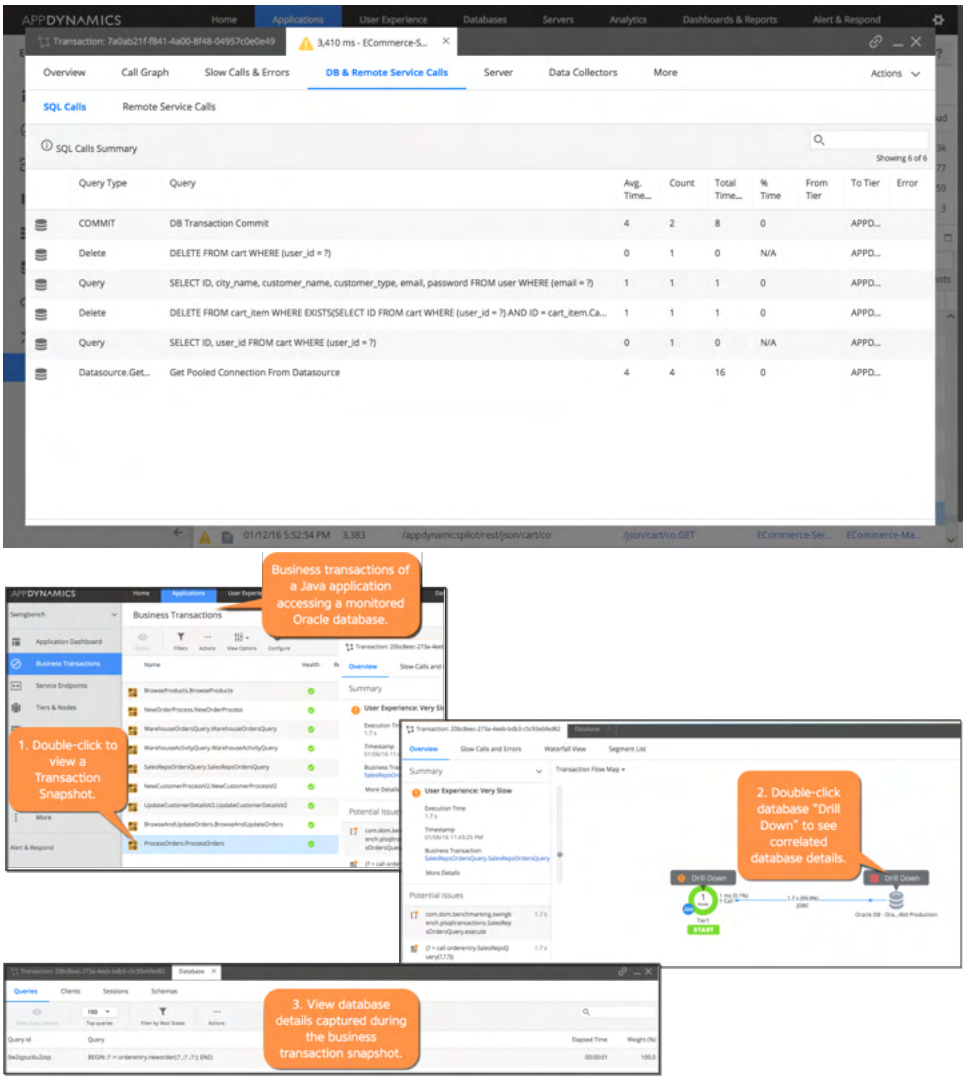


7. Review the **Time (ms)** column and select the transaction with the longest execution time for this method relative to the transaction execution time.
8. Select the DB & Remote Service Calls tab.
9. Do you see one or more slow calls on the **SQL Calls** or **Remote Service Calls** tabs?

    - If **Yes** – Go to Step 4 to drill down and find the root cause.
    - If **No** – Go to Step 5 to determine if the problem is affecting all nodes in the slow tier.

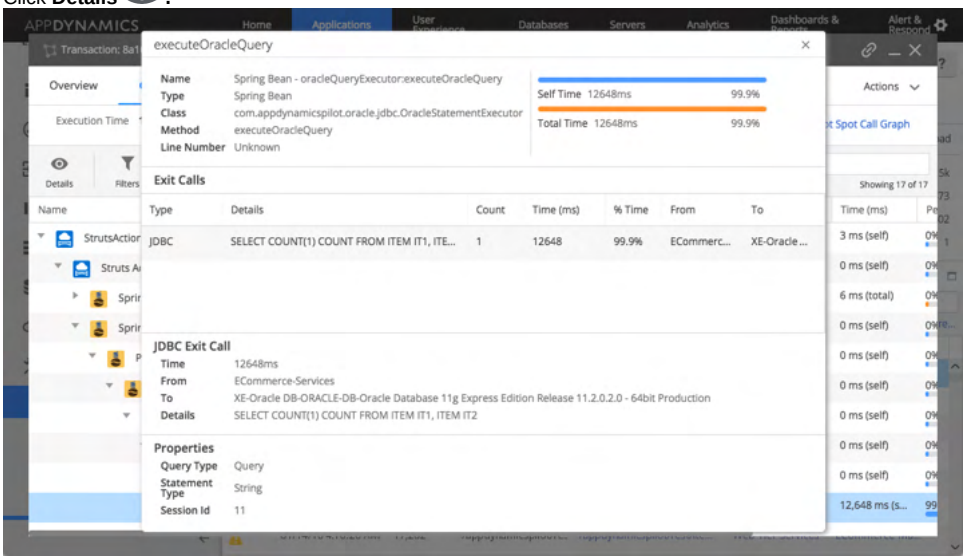
Step 4: Drill into SQL or Remote Service Calls to determine the root cause.

1. On the SQL Calls tab of the transaction snapshot, sort the SQL Calls by Avg. Time (ms).
    a. **Slow database call**– click the database call to gain information about the call.
    b. If you have **Correlated snapshots** between Java applications and Oracle databases – drill down into the Oracle database on the Transaction Snapshot to view database details captured during the snapshot.
    c. If you have **AppDynamics for Databases –** right-click the database on the Application, Tier, Node or Backend Flow Map, and choose **Link to AppDynamics for Databases**. You can use AppDynamics for Databases to diagnose database issues.
    d. If you have **Database Monitoring –** right-click the database on the Application, Tier, Node or Backend Flow Map, and choose **View** to review database problems.



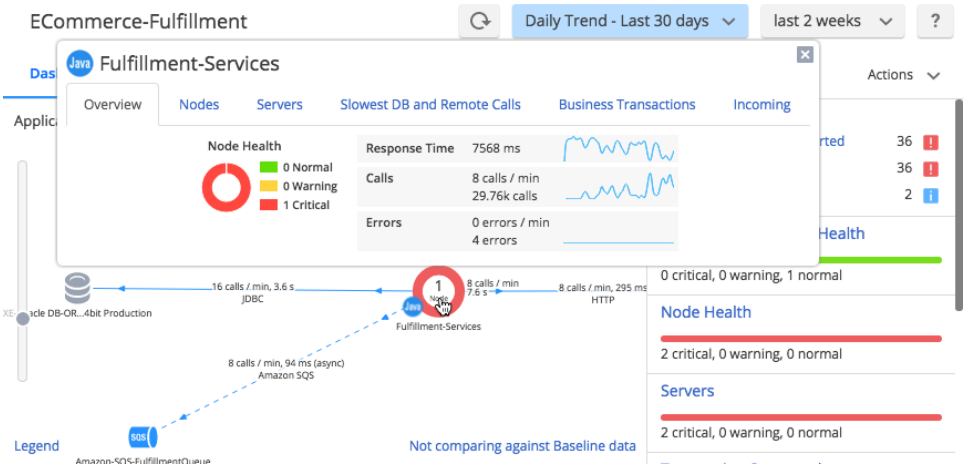
2. On the Remote Service Calls tab, sort the queries by Avg. Time (ms) .
3. Select the slow call.
4. Click **Drill Down into Downstream Call** to gain further insight into the methods of the service call.
5. Sort the methods by the **Time (ms)** column.
6. Select a slow method.

7. Click **Details** .



Step 5: Does the problem affect all nodes in the slow tier.

1. In the Application or Tier Flow Map, click the **tier** or **node** icon to see a quick overview of the health of each node in the tier.



2. Is the problem affecting all nodes in the slow tier? If all the nodes are yellow or red, the answer to this question is Yes. Otherwise, the answer is No.

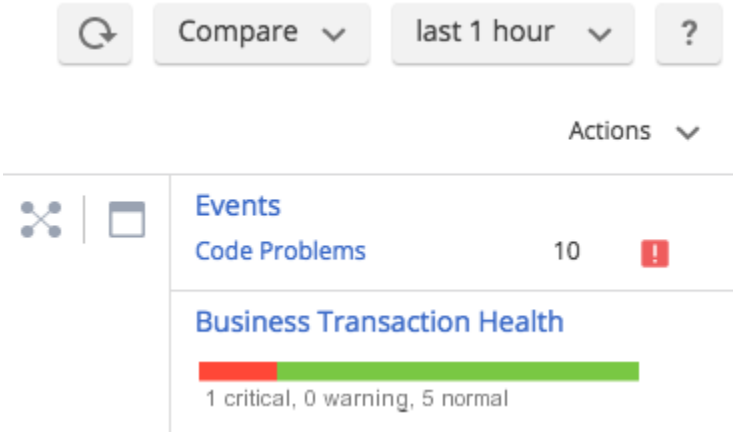
    - If **Yes** – Go to Step 6.
    - If **No** – The problem is either in the node's hardware or in the way the software is configured on the node. If only one node in a tier is affected, the problem is probably not related to the application code. Follow these steps to determine a hardware related problem.

        i. In the left navigation pane, click **Tiers & Nodes**.
        ii. Expand the Tier in the right pane and double-click the affected node to open its Node Dashboard.
        iii. Click the Memory tab
            1. Explore each of the available tabs to determine if you need to add memory to the node, configure additional memory for the application, or take some other corrective action.
        iv. Click the **Server** tab.
            1. If the Hardware tab indicates a hardware related problem, contact your IT department.

You have isolated the problem.

Step 6: Check to see whether the problem affects most business transactions

1. On the **Application Dashboard**, look at the *Business Transaction Health* pane on the right side of the screen.



2. Is the bar representing Business Transaction Health is primarily yellow or red? Yes or No?

    - If **No** – Then:

        i. Click **Business Transactions** in the left navigation pane.
        ii. Sort by Health, Transaction Score or other column headings to find the business transaction that is experiencing issues.
        iii. Double-click the problematic business transaction to see its dashboard, then use the tabs to diagnose the problem.

You have isolated the problem.

Additional Help

If you've tried to diagnose the problem using the previous steps and haven't found the problem, see additional information for your specific agent:

- Troubleshooting Applications
- Monitor Databases
- Troubleshoot Mobile Applications
- Slow Response Times for .NET

Errors and Exceptions

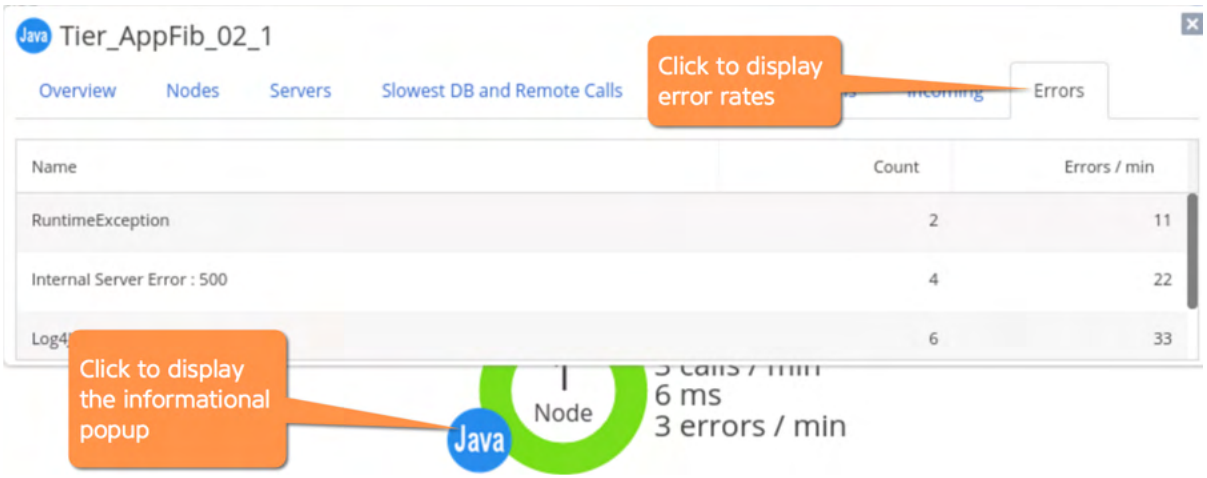
AppDynamics Application Intelligence Platform captures and presents information on business transaction errors in the monitored environment.

At a high-level, a business transaction is considered to have an error if its normal processing has been affected by a code-level exception or error event, including custom error events based on methods you specify.

View Error and Exception Information

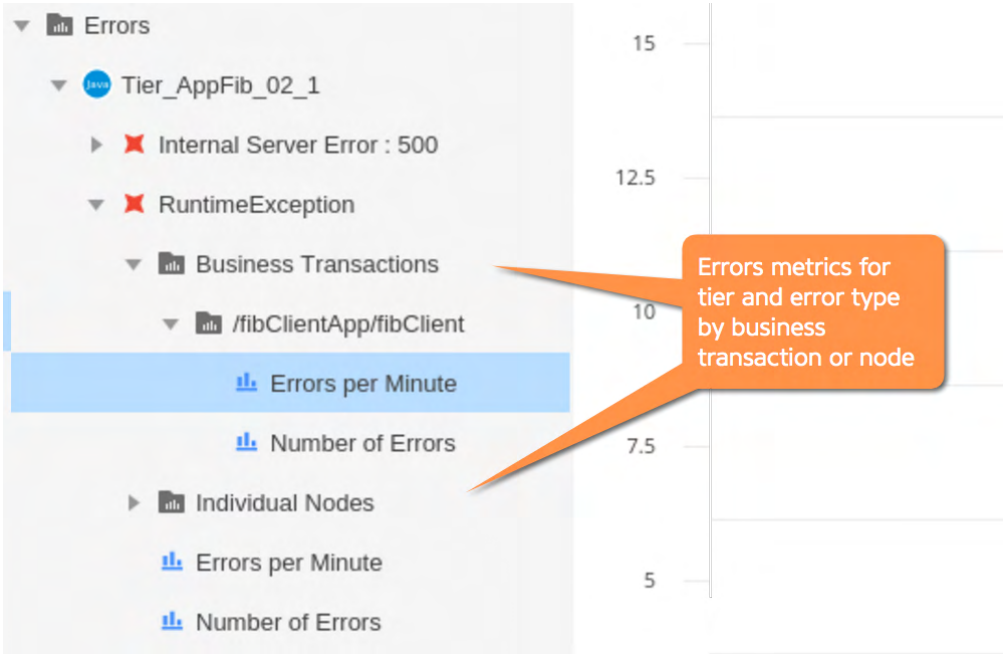
The Controller UI presents information on errors and exceptions in various places in the UI, including in transaction snapshots, metrics, and dashboards.

The informational popups for tiers in flow maps have an error tab that displays error rate metrics for the tier:



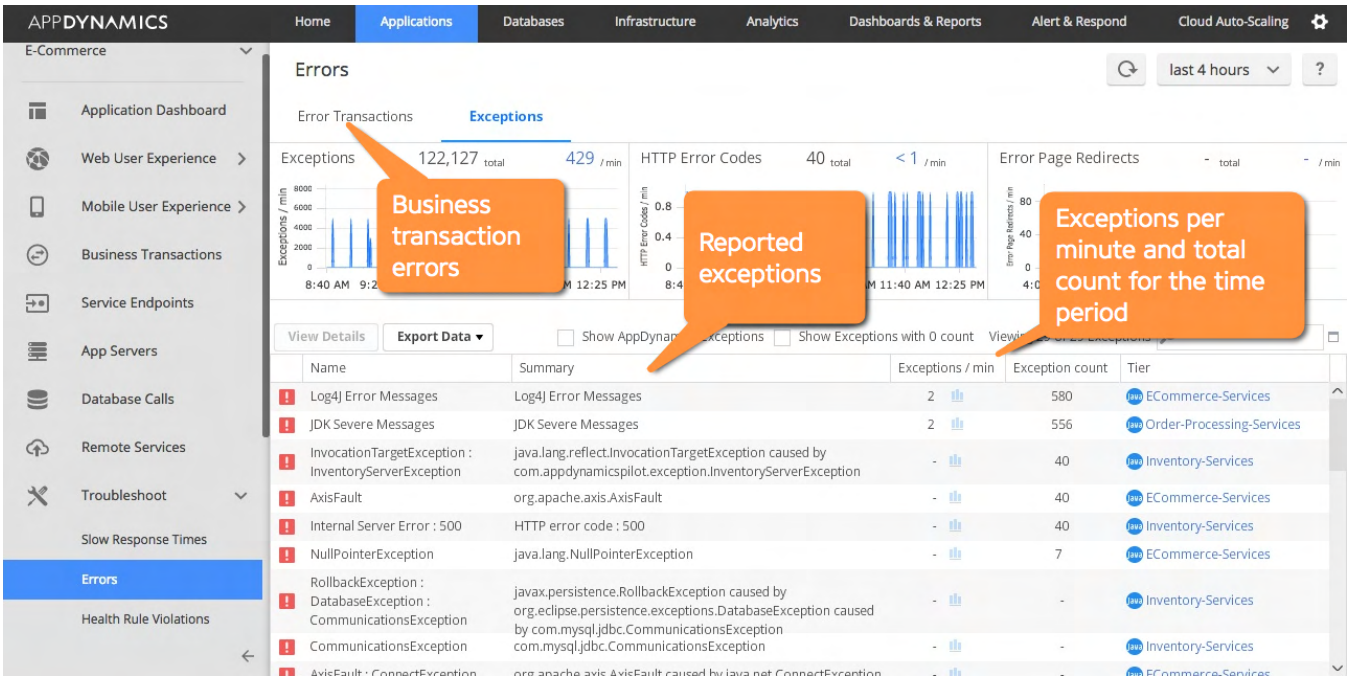
On the application and tier flow maps, the error rate is for all business transactions. On the business transaction flow map, errors apply only to the current business transaction.

The Metric Browser includes Error metrics:



The **Troubleshoot** > **Errors** page shows all error transactions. The page contains two tabs, one for transaction errors and one for Exceptions.

The tabs show information on the rate of errors or exceptions, and lets you drill down to the error or exception for more information, as shown:



Business Transaction Error

All transaction errors that have been detected according to the configured error detection rules in the selected time frame of the Controller UI appear in the Error Transactions tabs of the **Errors** page.

By default, AppDynamics considers a business transaction to be in error if it detects one of the following types of events in the context of the transaction:

- An unhandled exception or error. An exception that is thrown and never caught or caught after the business transaction terminates results in a transaction error, and the exception is presented in AppDynamics. An exception that is thrown and caught within the context of the business transaction is not considered a transaction error and the exception is not captured in AppDynamics.
- An exception caught in an exit call, such as a web service or database call.
- An HTTP error response, such as a status code 404 or 500 response.
- A custom-configured error method and error message.

Error detection configuration is described in Error Detection.

Errors that occur on a downstream tier that are not propagated to the originating tier do not result in a business transaction error. If the originating client receives a 200 success response, for example, the business transaction is not considered an error. The error contained within the downstream tier does count against the Error Per Minute metric for the continuing segment.

When a business transaction experiences an error, it is counted only as an error transaction. It is not also counted as a slow, very slow or stalled transaction, even if the transaction was also slow or stalled.

Code Exceptions in AppDynamics

Code exceptions are a common cause of business transaction errors. The Exceptions tab in the **Errors** page shows an aggregated view of the exceptions across all transactions. For purposes of this view, AppDynamics considers the following types of incidents to be exceptions:

- Any exception logged with a severity of Error or Fatal (using Log4j, java.util.logging, Log4Net/NLog, or another supported logger). This applies even if the exception occurs outside the context of a business transaction, in which case the exception type is specified as *Application Server*.
- HTTP errors that do not occur in the context of a Business Transaction.
- Error page redirects.

Exceptions that are thrown and handled within a business transaction are not captured by AppDynamics and do not appear in the Exceptions tab.

When troubleshooting errors, notice that the number of business transaction errors does not necessarily correspond to the number of exceptions in a given time frame. A single transaction that counts as an error transaction can correspond to multiple exceptions. For example, as the transaction traverses tiers, it can generate an exception on each one. Troubleshooting an error typically involves finding the exception closest to the originating point of the error.

If a stack trace for the exception is available, you can access it from the Exception tab in the Controller UI. A stack trace is available for a given exception if the exception was passed in the log call. For example, a logging call in the form of `logger.log(Level.ERROR, String msg, Throwable e)` would include a stack trace, whereas a call in the form of `logger.log(Level.ERROR, String msg)` would not.

Agent Errors

The Java Agent differentiates between agent internal errors and application errors. By default, agent internal errors no longer set off health rule violations. You can view agent internal errors in the following Metric Browser path: **Application Infrastructure Performance > <tier> > Agent > Internal Errors**.

Error and Exception Limits

AppDynamics limits the number of registered error types (based on error-logging events, exception chains, and so on) to 4000. It maintains statistics only for registered error types.

Reaching the limit generates the `CONTROLLER_ERROR_ADD_REG_LIMIT_REACHED` event. While it is possible to increase the limit, we recommend refining the default error detection rules to reduce the number of error registrations to have the error you are not interested in capturing ignored.

For more information, see information on configuring log errors and exceptions to ignore in Error Detection.

Configure Errors and Exceptions

AppDynamics automatically recognizes errors and exceptions for many common frameworks. You can customize the default error detection behavior as needed, for example, if you use your own custom error framework. See Error Detection.

Slow Response Times for .NET

You may notice that your application's response time is slow from these methods:

- You receive an alert: If you have received an email alert from AppDynamics that was configured through the use of health rules and policies, the email message provides a number of details about the problem that triggered the alert. See information about Email Notifications in Notification Actions. If the problem is related to slow response time, see Initial Troubleshooting Steps.
- You view the Application Dashboard for a business application and see slow response times.
- A user reported slow response time that relates to a particular business transaction, for example, an internal tester reports "Searching for a hotel is slow".

Initial Troubleshooting Steps

In some cases, the source of your problem might be easily diagnosed by choosing **Troubleshoot > Slow Response Times** in the left navigation pane. See Slow Response Times.

.NET Resource Troubleshooting

If you've tried to diagnose the problem using those techniques and haven't found the problem, use the following troubleshooting approaches to find other ways to determine the root cause of the issue.

Step 1 - CPU saturated?

Is the CPU of the CLR saturated?

1. Display the Tier Flow Map.
2. Click the Nodes tab, and then click the Hardware tab.
3. Sort by CPU % (current).

If the CPU % is 90 or higher, the answer to the question in Step 4 is Yes. Otherwise, the answer is No.

Yes – Go to Step 2

No – Review various metrics in the Metric Browser to pinpoint the problem.

In the left navigation pane, click **Servers > Tiers & Nodes > *slow tier***. Review these metrics in particular:

- ASP.NET -> Application Restarts
- ASP.NET -> Request Wait Time
- ASP.NET -> Requests Queued

- CLR -> Locks and Threads -> Current Logical Threads
- CLR -> Locks and Threads -> Current Physical Threads

- IIS -> Number of working processes
- IIS -> Application pools -> <*Business application name*> -> CPU%
- IIS -> Application pools -> <*Business application name*> -> Number of working processes
- IIS -> Application pools -> <*Business application name*> -> Working Set

You have isolated the problem and don't need to continue with the rest of the steps below.

Step 2 - Significant garbage collection activity?

1. Display the Tier Flow Map.
2. Click the Nodes tab, and then click the Memory tab.
3. Sort by Time Spent on Collections (%) to see what percentage of processing time is being taken up with garbage collection activity.

If Time Spent on Collections (%) is higher than acceptable (say, over 40%), the answer to the question in Step 5 is Yes. Otherwise, the answer is No.

Is there significant garbage collection activity?

Yes – Go to Step 3.

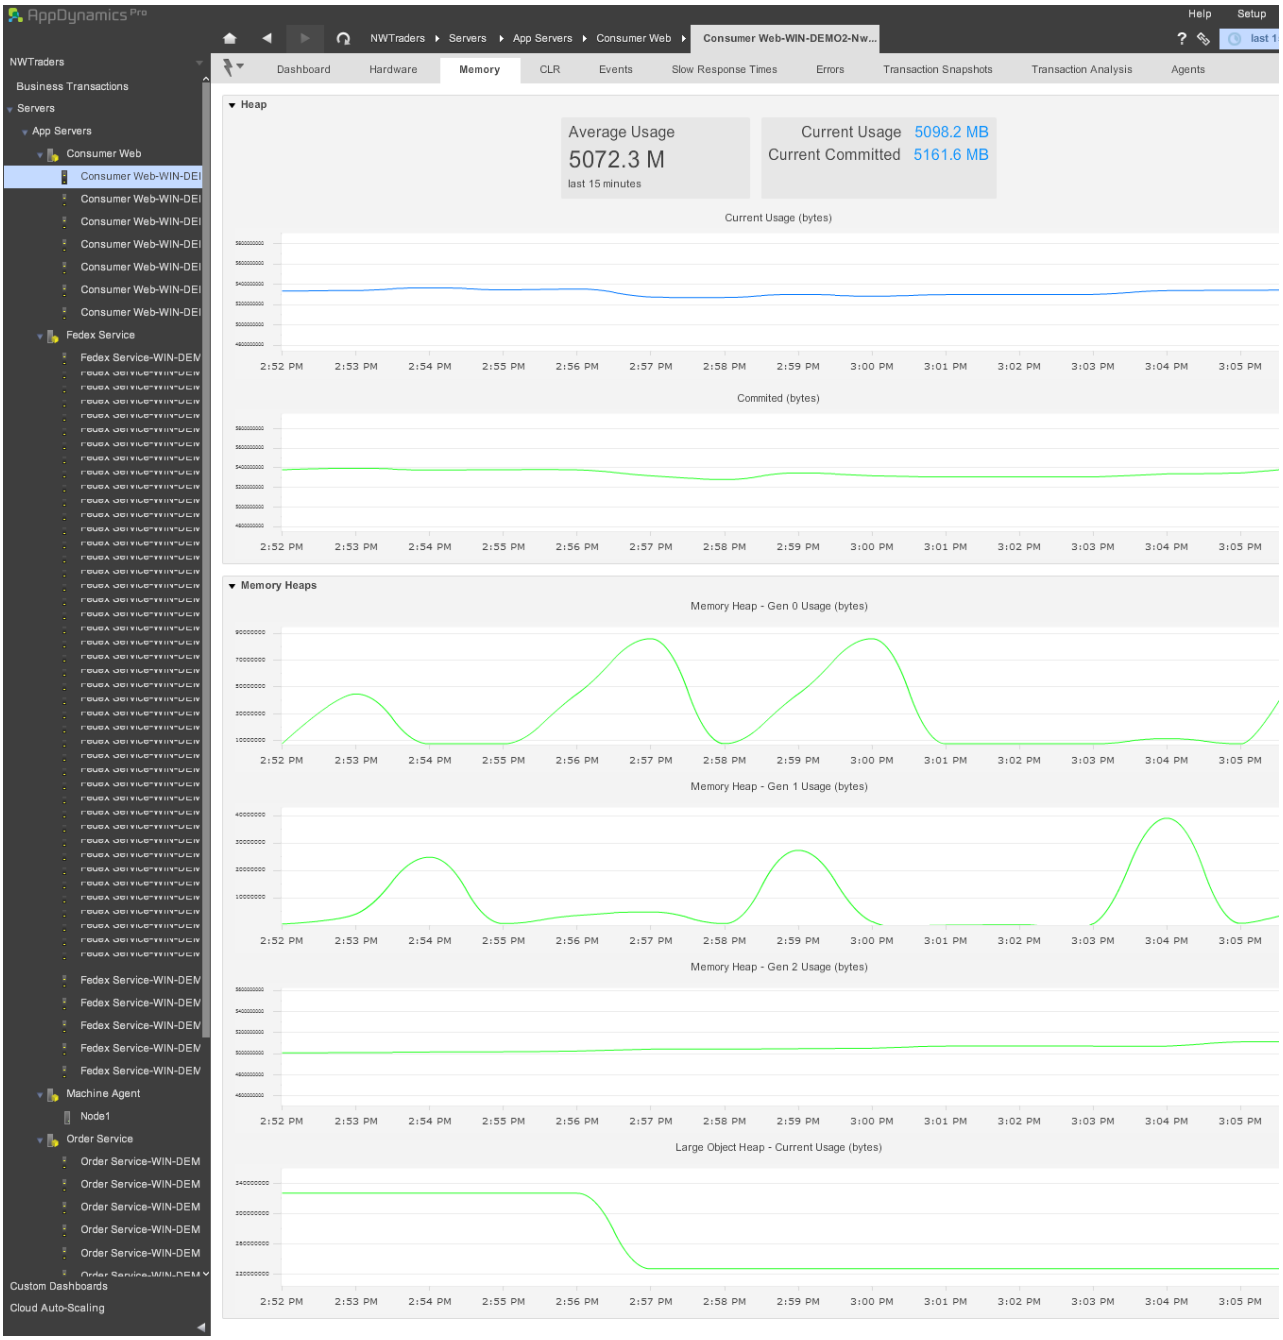
No – Use your standard tools to produce memory dumps; review these to locate the source of the problem.

You have isolated the problem and don't need to continue with the rest of the steps below.

Step 3 - Memory leak?

Is there a memory leak?

1. From the list of nodes displayed in the previous step (when you were checking for garbage collecting activity), double-click a node that is experiencing significant GC activity.
2. Click the Memory tab, then review the committed bytes counter and the size of the Gen0, Gen1, Gen2 and large heaps.



If memory is not being released (one or more of the above indicators is trending upward), the answer to the question in Step 6 is Yes. Otherwise, the answer is No.

Yes – Use your standard tools for troubleshooting memory problems. You can also review ASP.NET metrics; click **Tiers & Nodes > *slow tier* > ASP.NET**.

No – Use your standard tools to produce memory dumps; review these to locate the source of the problem.

Whether you answered Yes or No, you have isolated the problem.

Java Resource Issues

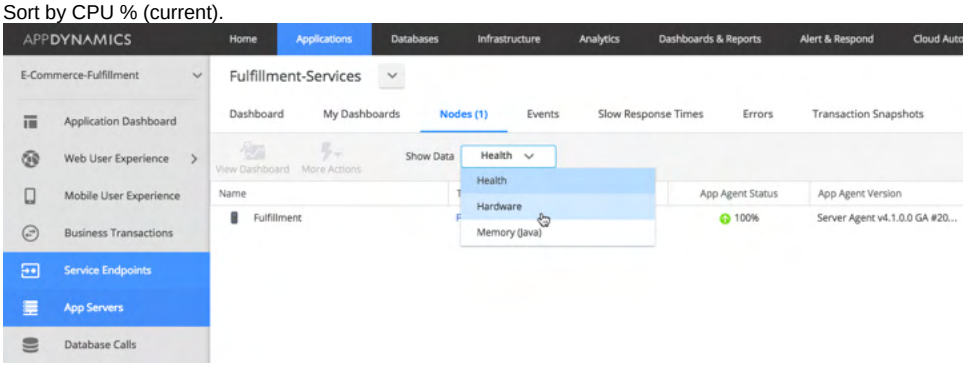
These troubleshooting guidelines may help you determine the root cause of many Java-related issues.

Step 1. CPU saturated?

Is the CPU of the JVM saturated?

How do I know?

1. Display the Tier Flow Map.
2. Click the Nodes tab, and then show **Hardware** data.
3. Sort by CPU % (current).



If the CPU % is 90 or higher, the answer to this question is Yes. Otherwise, the answer is No.

Yes – Go to Step 2.

No – The issue is probably related to a custom implementation your organization has developed. Take snapshots of the affected tier or node(s) and work with internal developers to resolve the issue.

Step 2. Significant garbage collection activity?

Is there significant garbage collection activity?

How do I know?

1. Display the Tier Flow Map.
2. Click the Nodes tab, and then click the Memory tab.
3. Sort by **GC Time Spent** to see how many milliseconds per minute is being spent on GC; 60,000 indicates 100%.
4. If GC Time Spent is higher than 500 ms, the answer to the question in Step 5 is Yes. Otherwise, the answer is No.

Result

Yes – Go to Step 3.

No – Go to Step 4.

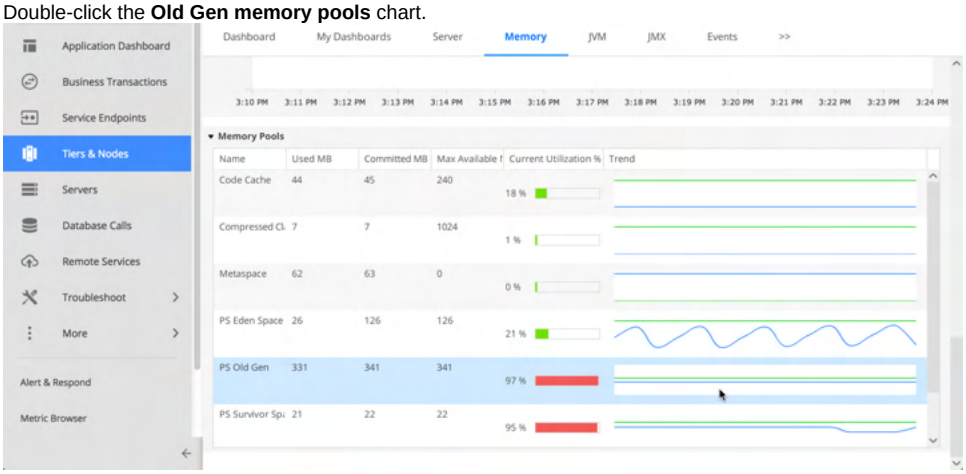
Step 3. Memory leak?

Is there a memory leak?

How do I know?

1. From the list of nodes displayed in the previous step (when you were checking for Garbage Collecting activity), double-click a node that is experiencing significant GC activity.
2. Click the Memory tab, then scroll down to display the Memory Pool graphs at the bottom of the panel.

3. Double-click the **Old Gen memory pools** chart.



If memory is not being released (use is trending upward), the answer to this question is Yes. Otherwise, the answer is No.

Result

Yes – Use various AppDynamics features to track down the leak. One useful tool for diagnosing a memory leak is object instance tracking, which lets you track objects you are creating and determine why they aren't being released as needed. Using object instance tracking, you can pinpoint exactly where in the code the leak is occurring. For instructions on configuring object instance tracking, as well as links to other tools for finding and fixing memory leaks, see Need more help?.

No – Increase the size of the JVM. If there is significant GC activity but there isn't a memory leak, then you probably aren't configuring a large enough heap size for the activities the code is performing. Increasing the available memory should resolve your problem.

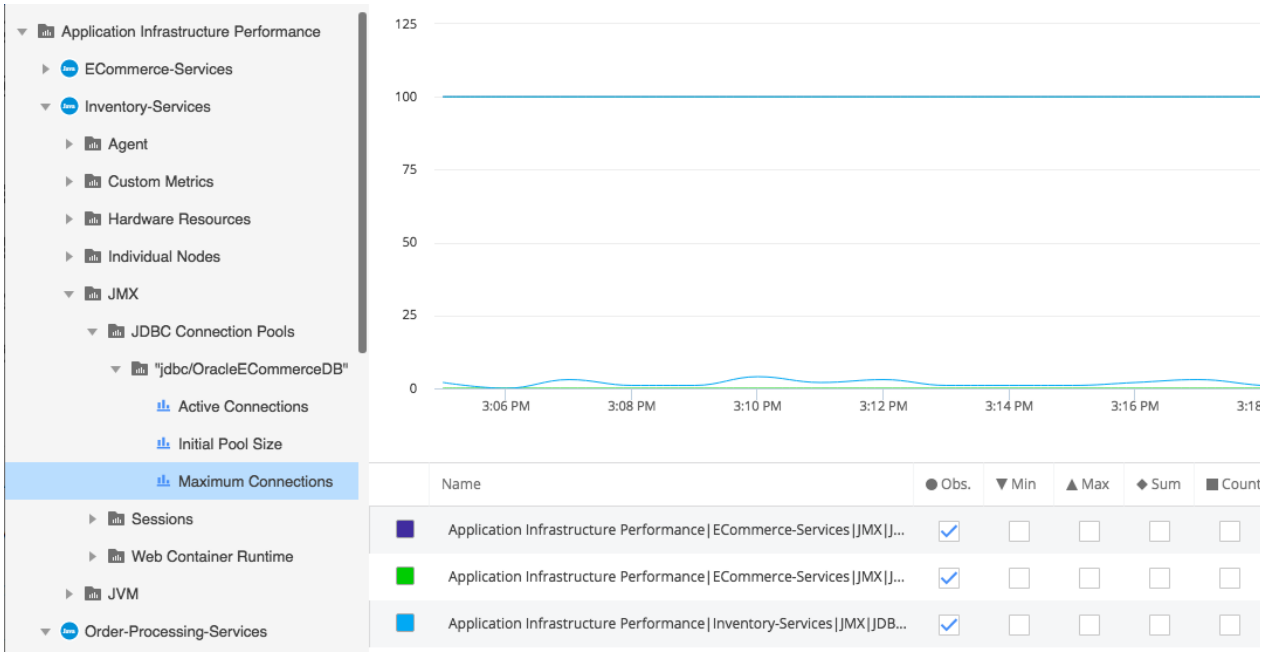
Whether you answered Yes or No, you have isolated the problem.

Step 4. Resource leak?

Is there a resource leak?

How do I know?

1. In the left Navigation pane, go to (for example) **Metric Browser > Application Infrastructure Performance > *TierName* > Individual Nodes > *NodeName* > JMX > JDBC Connection Pools > *PoolName***.
2. Add the **Active Connections** and **Maximum Connections** metrics to the graph.
3. Repeat as needed for various pools your application is using.



If connections are not being released (use is trending upward), the answer to the question in Step 7 is Yes. Otherwise, the answer is No.

Result

Yes – To determine where in your code resources are being created but not being released as needed, take a few thread dumps using standard commands on the problematic node. You can also create a diagnostic action within AppDynamics to create a thread dump; see *Thread Dump Actions* in Diagnostic Actions.

No – Restart the JVM. If none of the above diagnostic steps addressed your issue, it's possible you're simply seeing a one-time unusual circumstance, which restarting the JVM can resolve.

Java Memory Leaks

This page describes how to detect and troubleshoot Java memory leaks.

- To activate Automatic Leak Detection, you need the Configure Agent Properties permission.
- To start an On Demand Capture Session, you need the Advanced Agent Operation permission. See Create and Manage Custom Roles.

The garbage collection feature of the JVM greatly reduces the opportunities to introduce memory leaks into a codebase. However, because garbage collection does not eliminate memory leaks completely, AppDynamics includes Automatic Leak Detection for supported JVMs.

Automatic Leak Detection

You can access **Automatic Leak Detection** on the Memory tab of the Node Dashboard. **Automatic Leak Detection** is disabled by default because it increases overhead on the JVM. You should enable leak detection mode only when you suspect a memory leak problem. Turn off **Automatic Leak Detection** after you identify the cause for the leak.

Automatic Leak Detection uses **On Demand Capture Sessions** to capture actively used collections, any class that implements JDK Map or Collection interface during the capture period. The default capture period is 10 minutes.

AppDynamics tracks every Java collection that meets the following criteria:

- The collection has been alive for at least 30 minutes.
- The collection has at least 1000 elements.
- The collection Deep Size is at least 5 MB. The agent calculates Deep Size by traversing recursive object graphs of all the objects in the collection.

The following node properties define the defaults for leak detection criteria:

- `minimum-age-for-evaluation-in-minutes`
- `minimum-number-of-elements-in-collection-to-deep-size`
- `minimum-size-for-evaluation-in-mb`

See App Agent Node Properties.

The Java Agent tracks the collection and identifies potential leaks using a linear regression model. You can identify the root cause of the leak by tracking frequent access to the collection over a period of time.

After it qualifies a collection, AppDynamics monitors the collection size for a long-term growth trend. Positive growth indicates the collection is the potential source of a memory leak.

After AppDynamics identifies a leaking collection, the Java Agent automatically triggers diagnostics every 30 minutes. The diagnostics capture a shallow content dump and activity traces of the code path and business transactions that access the collection. You can drill down into any leaking collection monitored by the agent, to manually trigger Content Summary Capture and Access Tracking sessions.

You can also monitor memory leaks for custom memory structures. Typically custom memory structures are used as caching solutions. In a distributed environment, caching can easily become a prime source of memory leaks. It is therefore important to manage and track memory statistics for these memory structures. To do this, you must first configure custom memory structures. See Custom Memory Structures for Java.

Workflow to Troubleshoot Memory Leaks

You can use this workflow to troubleshoot memory leaks on JVMs that have been identified with a potential memory leak problem:

1. Monitor memory for potential JVM memory leaks.
2. Enable automatic leak detection.
3. Start an on demand capture session.
4. Detect and troubleshoot leaking conditions.

Monitor Memory for Potential JVM Leaks

Use the **Node** dashboard to identify the memory leak. A possible memory leak is indicated by a growing trend in the heap as well as the old/tenured generation memory pool.

An object is automatically marked as a potentially leaking object when it shows a positive and steep growth slope.

The **Automatic Memory Leak** dashboard shows:

- **Collection Size**—The number of elements in a collection.
- **Potentially Leaking**—Potentially leaking collections display as red. You should start diagnostic sessions on potentially leaking objects.
- **Status**—Indicates if a diagnostic session has been started on an object.
- **Collection Size Trend**—A positive and steep growth slope indicates a potential memory leak.

To identify long-lived collections, compare the JVM start time and Object Creation Time.

If no captured collections display, ensure that you have the correct configuration for detecting potential memory leaks.

Enable Memory Leak Detection

Memory leak detection is available through the **Automatic Leak Detection** feature. Once the **Automatic Leak Detection** feature is turned on and a capture session has been started, AppDynamics tracks all frequently used collections. Therefore, using this mode results in higher overhead.

1. Turn on **Automatic Leak Detection** mode only when a memory leak problem is identified
2. Click **Start On Demand Capture Session** to start monitoring frequently used collections and detect leaking collections.
3. After you identify and resolve the leak, turn the capture session and the leak detection modes off.
4. Start diagnosis on one individual collection at a time to achieve optimum performance.

Troubleshoot Memory Leaks

After detecting a potential memory leak, troubleshooting the leak involves performing these three actions:

- Select the Collection Object that you want to monitor
- Use Content Inspection
- Use Access Tracking

Select the Collection Object to Monitor

On the Automatic Leak Detection dashboard, right-click the class name and click **Drill Down**.

For performance reasons, start the troubleshooting session on a single collection object at a time.

Use Content Inspection

Content Inspection identifies which part of the application the collection belongs to so that you can start troubleshooting. It allows monitoring histograms of all the elements in a particular collection.

Enable Automatic Leak Detection by starting an On Demand Capture Session, select the object you want to troubleshoot, and then follow the steps listed below:

1. Click the Content Inspection tab.
2. Click **Start Content Summary Capture Session** to start the content inspection session.
3. Enter the session duration. Allow at least 1 – 2 minutes for data generation.
4. Click **Refresh** to retrieve the session data.
5. Click on the snapshot to view details about an individual session.

Use Access Tracking

Use Access Tracking to view the actual code paths and business transactions accessing the collections object.

As described above in Workflow to Troubleshoot Memory Leaks, enable Automatic Leak Detection, start an On Demand Capture Session, select the object you want to troubleshoot, and then follow the steps listed below:

1. Select the Access Tracking tab
2. Click **Start Access Tracking Session** to start the tracking session.
3. Enter the session duration. Allow at least 1-2 minutes for data generation.
4. Click **Refresh** to retrieve session data.
5. Click the snapshot to view details about an individual session.

The troubleshooting information pane shows the Java stack trace associated with the session. By default, the stack trace is shown to a depth of 10 lines. If you would like to temporarily increase the number of lines captures, you can use the `maximum-activity-trace-stack-depth` Java Agent property described on App Agent Node Properties Reference.

Increasing the stack trace depth can consume a significant amount of system resources. You must remove the property or set it back to the default value of 10 after you have captured the desired information.

Java Memory Thrash

Memory thrash is caused when a large number of temporary objects are created in very short intervals. Although these objects are temporary and are eventually cleaned up, the garbage collection mechanism may struggle to keep up with the rate of object creation. This may cause application performance problems. Monitoring the time spent in garbage collection can provide insight into performance issues, including memory thrash.

For example, an increase in the number of spikes for major collections either slows down a JVM or indicates potential memory thrash. Use object instance tracking to isolate the root cause of the memory thrash. To configure and enable object instance tracking, see Object Instance Tracking for Java.

AppDynamics automatically tracks object instances for the top 20 core Java (system) classes and the top 20 application classes.

The Object Instance Tracking subtab provides the number of instances for a particular class and graphs the count trend of those object in the JVM. It provides the shallow memory size (the memory footprint of the object and the primitives it contains) used by all the instances.

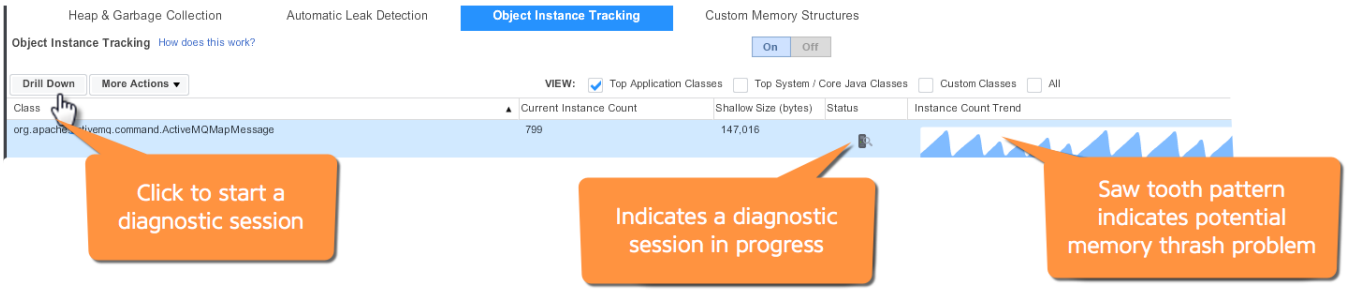
Analyze Memory Thrash

Once a memory thrash problem is identified in a particular collection, start the diagnostic session by drilling down into the suspected problematic class.

Select the class name to monitor and click **Drill Down** at the top of the Object Instance Tracking dashboard or right-click the class name and select the **Drill Down** option.

> For optimal performance, trigger a drill-down action on a single instance or class name at a time.

After the drill down action is triggered, data collection for object instances is performed every minute. This data collection is considered to be a diagnostic session and the Object Instance Tracking dashboard for that class is updated with this icon , to indicate that a diagnostic session is in progress.



The Object Instance Tracking dashboard indicates possible cases of memory thrash. Prime indicators of memory thrash problems indicated on the Object Instance Tracking dashboard are:

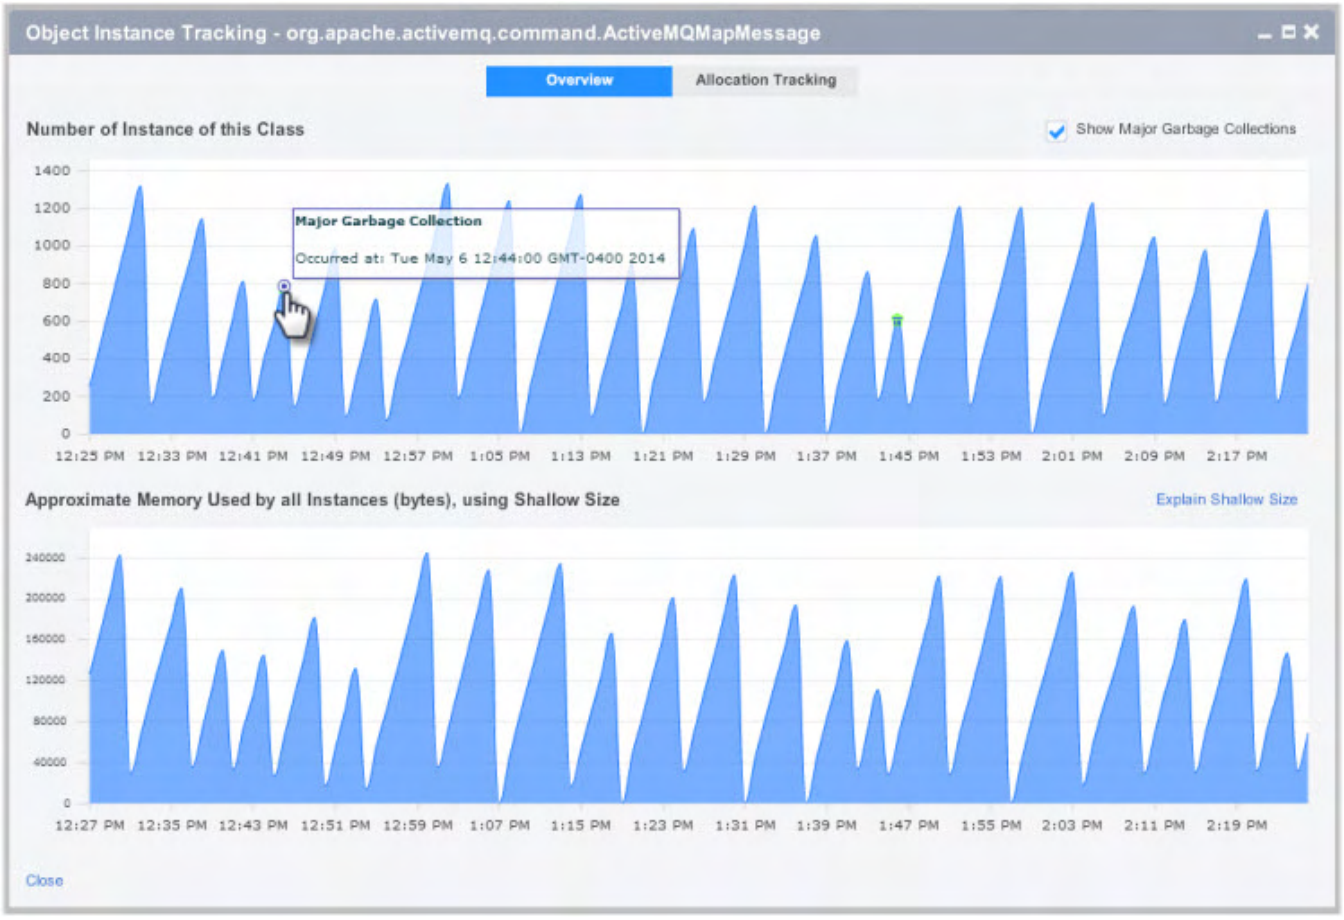
- **Current Instance Count:** A high number indicates the possible allocation of a large number of temporary objects.
- **Shallow Size**: Is the approximate memory used by all instances in a class. A large number for shallow size signals potential memory thrash.
- **Instance Count Trend:** A saw wave is an instant indication of memory thrash.

If you suspect you have a memory thrash problem at this point, then you should verify that this is the case. See To verify memory thrash.

Verify Memory Thrash

Select the class name to monitor and click **Drill Down** at the top of the Object Instance Tracking dashboard. On the Object Instance Tracking window, click **Show Major Garbage Collections**.

The following Object Instance Tracking Overview provides further evidence of a memory thrash problem.



If the instance count doesn't vary with the garbage collection cycle, it is an indication of a potential leak and not a memory thrash problem. See Java Memory Leaks.

Troubleshoot Java Memory Thrash Using Allocation Tracking

Allocation Tracking tracks all the code paths and those business transactions that are allocating instances of a particular class. It detects those code path /business transactions that are creating and throwing away instances.

To use allocation tracking:

1. Using the **Drill Down** option, trigger a diagnostic session.
2. Click the Allocation Tracking tab.
3. Click **Start Allocation Tracking Session** to start tracking code paths and business transactions.
4. Enter the session duration and allow at least 1 to 2 minutes for data generation.
5. Click **Refresh** to retrieve the session data.
6. Click a session to view its details.
7. Use the Information presented in the Code Paths and Business Transaction panels to identify the origin of the memory thrash problem.

Monitor Java Object Instances

If the application uses a JRE (rather than a JDK), use these steps to enable object instance tracking:

1. Ensure the tools.jar file is in the `jre/lib/ext` directory.
2. On the Node Dashboard, click the Memory tab.
3. On the Memory tab, click the Object Instance Tracking subtab.
4. Click **On** and then **OK**.

See Object Instance Tracking for Java.

Code Deadlocks for Java

By default, the Java Agent detects code deadlocks. You can find deadlocks and see their details using the Events list or the REST API.

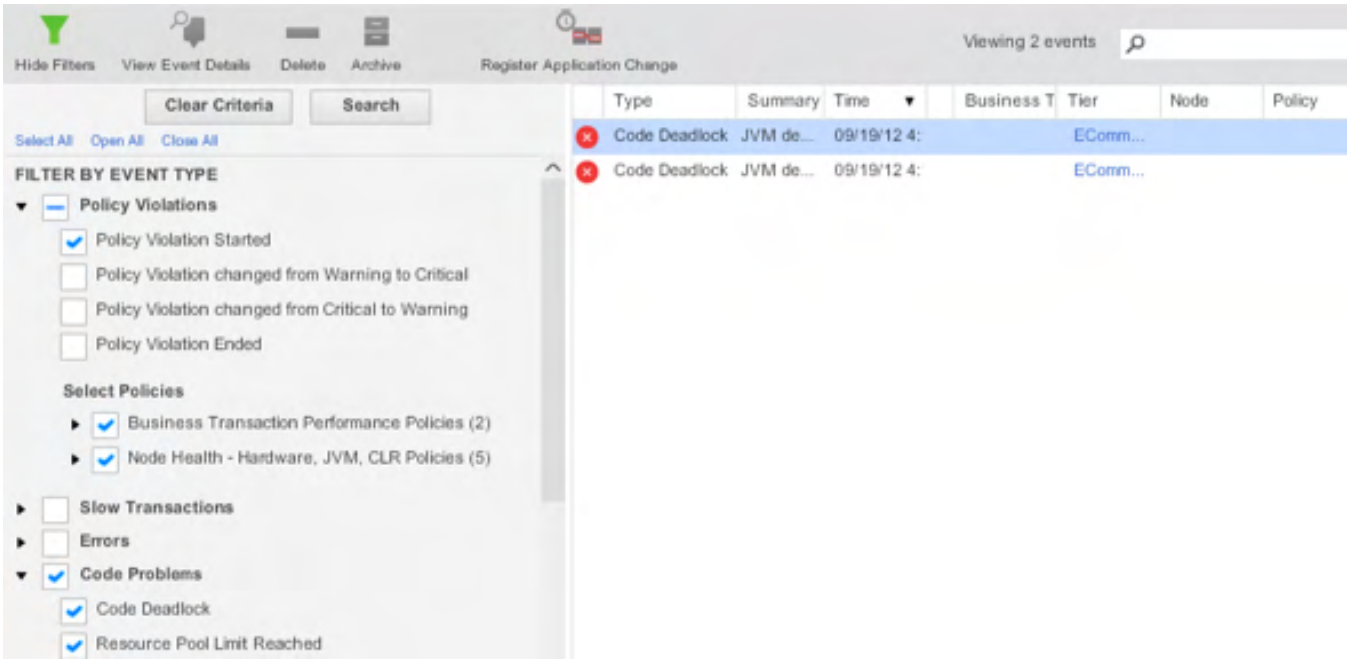
Code Deadlocks and Their Causes

In multi-threaded development environments, it is common to use more than a single lock. However, sometimes deadlocks will occur. Here are some possible causes:

- The order of the locks is not optimal
- The context in which they are being called (for example, from within a callback) is not correct
- Two threads may wait for each other to signal an event

Finding Deadlocks Using the Events List

Select **Code Problems** (or just **Code Deadlock**) in the Filter By Event Type list to see code deadlocks in the Events list. The following list shows two deadlocks in the ECommerce tier.



To examine a code deadlock, double-click the deadlock event in the events list and then click the Code Deadlock Summary tab. Details about the deadlock are in the Details tab. See Monitor Events.

Find Deadlocks Using the REST API

You can detect a DEADLOCK event-type using the AppDynamics REST API. For details, see the example Retrieve event data.

Thread Contention

Works with:

Thread contention arises when two or more threads attempt to access the same resource at the same time. This page describes how AppDynamics helps you diagnose and resolve thread contention issues.

Performance Issues Resulting from Thread Contention

Multithreaded programming techniques are common in applications that require asynchronous processing. Although each thread has its own call stack in such applications, threads may need to access shared resources, such as a lock, cache, or counter. See Enabling Thread Correlation.

While synchronization techniques can help to prevent interference between threads in such scenarios, they may nevertheless compete for access to shared resources. This can result in application performance degradation or even data integrity issues.

AppDynamics can help you identify and resolve problems relating to thread contention in business transactions and service endpoints. See Trace Multithreaded Transactions for Java.

Thread Contention Detection

AppDynamics detects thread contention based on the thread state of the instrumented application.

It identifies these block or waiting states in the JVM:

- Acquiring a lock (`MONITOR_WAIT`)
- Waiting for a condition (`CONDOR_WAIT`)
- Sleeping (`OBJECT_WAIT`)
- A blocking I/O operation

The `OBJECT_WAIT` state is triggered when the application makes one of the following calls:

- `Thread.sleep`
- `Object.wait`
- `Thread.join`
- `LockSupport.parkNanos`
- `LockSupport.parkUntil`
- `LockSupport.park`

The Controller alerts you to possible thread contention problems in the **Potential Issues** pane of the Business Transaction Flow Map. From there, you can use the browser to access additional information about blocked and waiting threads in business transactions or service endpoints, and determine the cause of the performance problem.

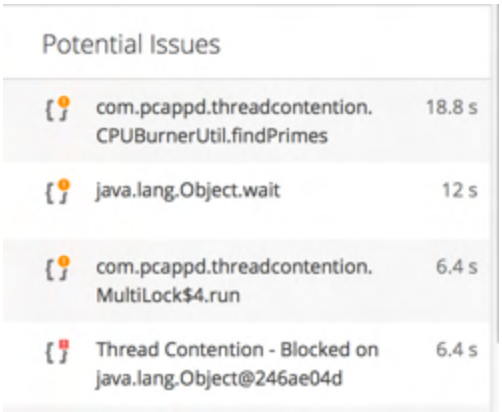
The following sections explain how you use the browser to surface contention information for business transaction and service endpoints.

Watch the Video: Monitoring and Analyzing Java Thread Contention

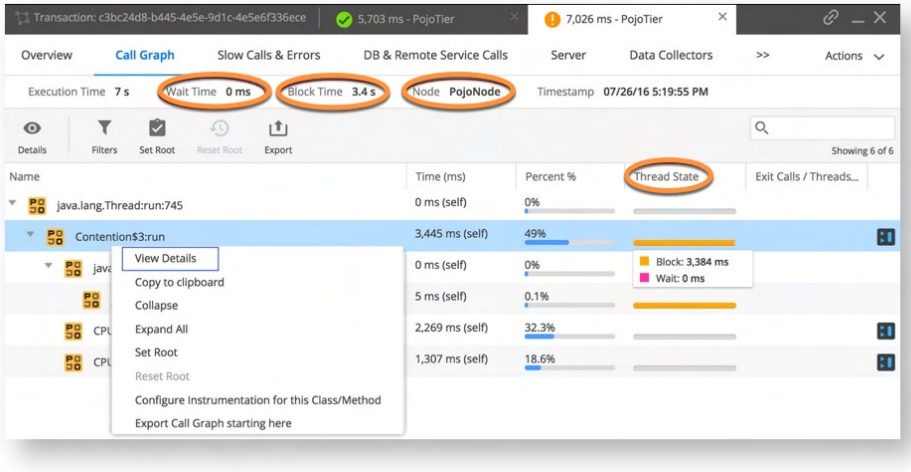
Thread Contention in Transaction Snapshots

To view information about thread contention:

1. In the transaction snapshot navigation page, look for items labeled as *Thread Contention* issues in the **Potential Issues** pane. The time column indicates blocked or wait time:



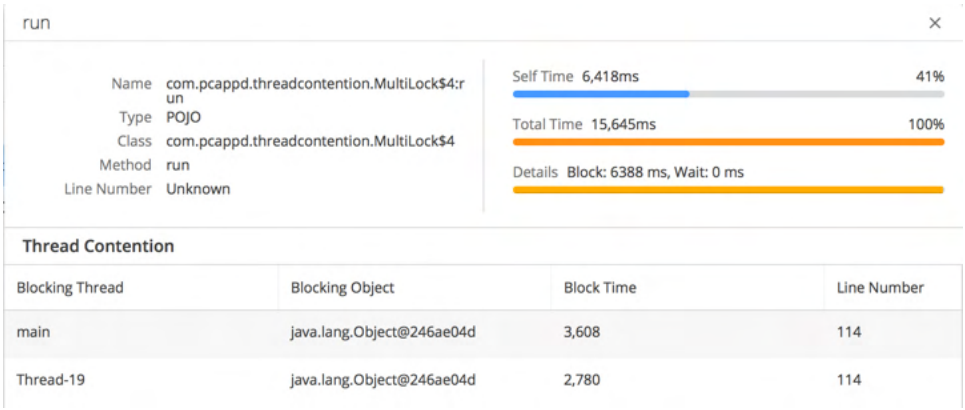
2. To display more information about the blocked method, click the thread contention item and select **Drill Down into Call Graph**:



The call graph shows the following information relevant to thread contention:

- In the **Call Graph** header, **Wait Time** and **Block Time** indicate aggregate measures for the thread in one segment of the business transaction.
- In the **Call Graph** header, **Node** specifies the name of the node hosting the contending threads, `PojoNode` in the example above.
- The **Time** column indicates the total self time for the method.
- The **Percent%** column shows the amount of time spent in the method as a percentage of overall time for the thread.
- The **Thread State** Column indicates the degree of thread contention issues for the method. Gray means no problems; yellow to red shading signals the severity of contention problems.
  (When you hover over the bar, a breakdown of the elements that make up the thread state is shown: This includes Block time and Wait time by default. To include Cpu Time in the Thread State detail, Dev mode must be enabled.)

3. Right-click on any method with a thread state that indicates block or wait times and select **View Details.** The Thread Contention details pane appears:



The Thread Contention details pane displays the name of the blocked method in the top left corner and adds the following information in the Threa d Contention table:

Element	Meaning
Blocking Thread	The thread holding a lock on the blocking object.
Blocking Object	The object that the blocked thread is waiting to access.
Block Time	The amount of time waiting to access the object.
Line Number	The line number in the blocked method where the blocking object is being accessed. With respect to the example above, `run` is attempting to access a locked object at line 114.

The order in which blocking threads are shown in the table is not significant; it does not imply a call order or time sequence.

In development mode, AppDynamics reports explicit locks such as `java.util.concurrent.locks.ReentrantLock` as Wait Time instead of Block Time in the Thread Details Call Graph view. Take this into consideration when monitoring business transactions and analyzing performance related to lock contentions.

Thread Contention in Service Endpoints

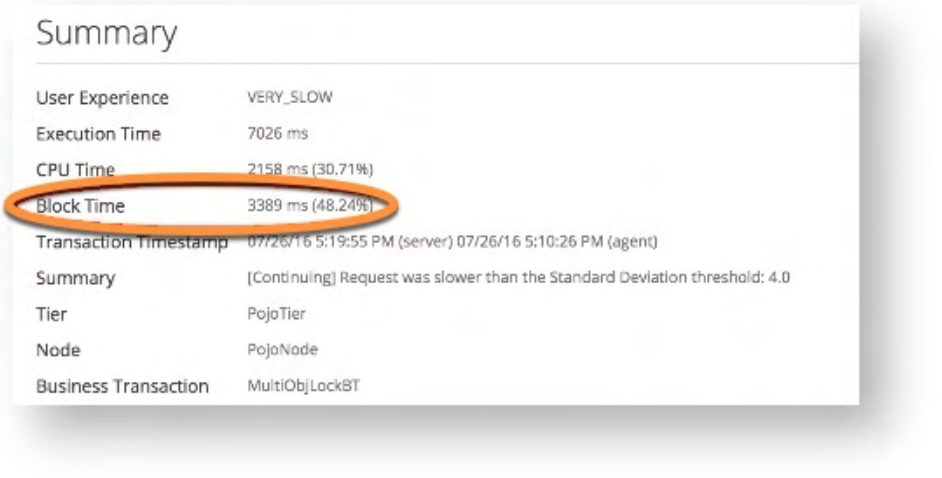
You can view thread contention information for service endpoint methods in AppDynamics. Call graphs identify service endpoint methods with this icon:  .

Select **More > Service Endpoints** from the menu bar to view thread contention information by service endpoint.

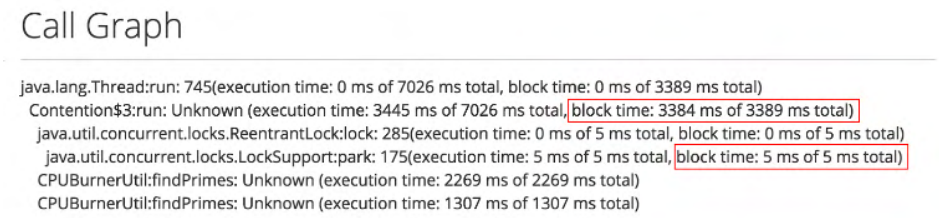
Export Contention Information

When you export the Call Graph for a Business Transaction, AppDynamics includes Transaction Contention information.

- The Summary pane includes **Block Time** data: the block time specified is the sum of all block times for the blocked methods shown in the CallGraph pane.



- The Call Graph pane lists block time by method:



Event Loop Blocking in Node.js

You can use process snapshots to examine Node.js event loop activity and identify functions with high CPU times that are blocking the event loop.

Latency in Node.js Event Loops

The event loop of a Node.js process is a single thread that polls for incoming connections and executes all application code. When a Node.js request makes a call to an external database, remote service or the filesystem, the event loop automatically directs the application's control flow to some other task, including other connections or callbacks.

CPU-intensive operations block the event loop, preventing it from handling incoming requests or finishing existing requests. A CPU-intensive operation in one business transaction may cause slowness in other business transactions.

Process Snapshots In AppDynamics

A process snapshot describes an instance of a CPU process on an instrumented Node.js node. It generates a process-wide flame graph for a Node.js process over a configurable time range.

Process snapshots provide visibility into the Node.js event loop across all business transactions for the duration of the process snapshot. Process snapshots are useful when the main troubleshooting tools (such as, business transaction snapshots) are inconclusive because the source of latency is a CPU-intensive operation in another business transaction. You can use lists of process snapshots to identify which functions have high CPU times. From the list, you can select and examine process snapshots to identify exactly which functions in your code are blocking the CPU.

For a given Node.js node or tier, you can access the list of process snapshots from the Process Snapshots tab of the node or tier dashboard. You can filter the process snapshot list to display only the snapshots that you are interested in. You can filter by execution time, whether the snapshot is archived, and the GUID of the request. If you access the list from the tier dashboard, you can also filter by node.

For more information on how process snapshots are generated and how to configure them, see Manage Node.js Process Snapshots.

To learn how process snapshots and business transaction snapshots are created, see Process Snapshots and Business Transaction Snapshots.

Process snapshots persist for 14 days, unless you archive them, in which case they are available forever.

A process snapshot contains these tabs:

- Overview
- Flame Graph
- Call Graph
- Allocation Call Graphs
- Hot Spots

Overview

Summarizes the snapshot. Contents vary based on the available information.

Usually contains at least the total execution time, tier and node of the process, timestamp, slowest method and request GUID.

Flame Graph

Provides a visualization of each stack frame’s frequency on the CPU over the duration of a process snapshot. The frame’s position relative to the bottom-most stack depicts the call-stack depth.

The flame graph contains the same information as the call graph, but allows you to quickly spot methods that are consuming more CPU resources relative to others.

The method corresponding to the stack frame on the top edge of the flame graph represents the method’s CPU resource consumption frequency.

To identify long-running CPU executions, look for long horizontal cells on the top edge of the flame graph.

A healthy Node.js process has minimal CPU-blocking activity; correspondingly, a flame graph for a healthy Node.js process has minimal long, horizontal cells along the top edge of its flame graph. See The Flame Graph.

Call Graph

Shows the total execution time and the percentage of the total execution time of each method on the process's call stack. The numbers at the ends of the methods are the line numbers in the source code. You can filter out methods below a certain time to simplify the graph and isolate the trouble spots.

The **Time** and **Percentage** columns identify which calls take the longest time to execute.

To see more information about a call, select the call and click **Details**.

Allocation Call Graph

Available only for process snapshots that are collected manually. See Manage Node.js Process Snapshots.

Shows the amount and percentage of the memory allocated and not freed by each method on the process's call stack during the process snapshot. You can use the **Method Size** slider to configure how much memory a method must allocate to be displayed in the allocation call graph. You can also filter out methods that consume less than a certain amount of memory to simplify the graph and isolate the trouble spots.

The **Size** and **Percentage** columns identify which calls consume the most memory.

The agent cannot report allocations made prior to the beginning of the allocation snapshot.

The allocation reported in the snapshot is the memory that is still referenced when the snapshot ends: memory allocated during the snapshot period minus memory freed during the snapshot period.

For more information about a call, select the call and click **Details**.

Hot Spots

This tab displays the calls by execution time, with the most expensive calls at the top. To see the invocation trace of a single call in the lower panel, select the call in the upper panel.

Use the **Method Time** slider in the upper right corner to configure how slow a call must be to be considered a hot spot.

Manage Node.js Process Snapshots

Related pages:

- Event Loop Blocking in Node.js
- Node.js Metrics
- Process Snapshots and Business Transaction Snapshots

This page describes how process snapshots are generated and viewed.

Automatic Process Snapshot Generation

When a business transaction snapshot is triggered by periodic collection or by a diagnostic session, a ten-second process snapshot is automatically started. By default, the agent starts no more than two process snapshots per minute automatically, but this behavior is configurable.

You can also start process snapshots manually on demand. See Collect Process Snapshots Manually.

Configure Automatic Collection

You can configure automatic process snapshot collection using these settings:

- `processSnapshotCountResetPeriodSeconds`: Frequency, in seconds, at which the automatic process snapshot count is reset to 0; default is 60 seconds.
- `maxProcessSnapshotsPerPeriod`: Number of automatic process snapshots allowed in `processSnapshotCountResetPeriodSeconds` seconds; default is 2 snapshots.
- `autoSnapshotDurationSeconds`: Duration of an automatically-generated process snapshot; default is 10 seconds.

To configure these settings, add them to the require statement in your application source code as described in Install the Node.js Agent. Then stop and restart the application.

Collect Process Snapshots Manually

If you want to generate some process snapshots now, you can start them manually.

1. Navigate to the dashboard for the tier or node for which you want to collect process snapshots.
2. Click the Process Snapshots tab.
3. Click **Collect Process Snapshots**.
4. If you are in the **Tier** dashboard, select the node for which you want to collect snapshots from the **Node** dropdown. If you are in the **Node** dashboard, you can only set up snapshot collection for that node.
5. Enter how many seconds you want to collect process snapshots for this node. The maximum is 60 seconds.
6. Click **Create**.

The agent collects process snapshots for the configured duration. Process snapshots that are started manually include an allocation call graph that shows how much memory has been allocated and not freed during the period recorded by the snapshot.

Process Snapshots and Business Transaction Snapshots

Related pages:

- Transaction Snapshots
- Manage Node.js Process Snapshots

This page explains the relationship between transaction snapshots and process snapshots created by the Node.js Agent.

V8 Sampler

Node.js is built on the V8 JavaScript engine, which includes a code sampler.

The Node.js Agent uses the V8 sampler to create process-wide process snapshots, which contain call graphs of the methods on the Node.js process's call stack.

Call Graph Data in Snapshots

Call graph data displays in business transaction snapshots as well as process snapshots.

When you view a business transaction snapshot, the displayed call graph specific to the transaction instance is derived from the concurrent process snapshot call graph.

When you view a process snapshot, the complete call graph of all the business transactions executed while the process snapshot was captured is displayed.

The call graph in a business transaction snapshot displays a view of the data from a concurrent process snapshot that is filtered to display only time in methods attributable to the specific business transaction. It is a subset of the concurrent process snapshot call graph.

For this reason, you might see an execution time for a method in a business transaction call graph that is less than the execution time for the same method in the concurrent process snapshot call graph. This would indicate that some calls to that method were made outside the context of the business transaction instance captured by the transaction snapshot.

The summary tab of a transaction snapshot includes a link to the process snapshot that was taken during the time covered by the transaction snapshot.

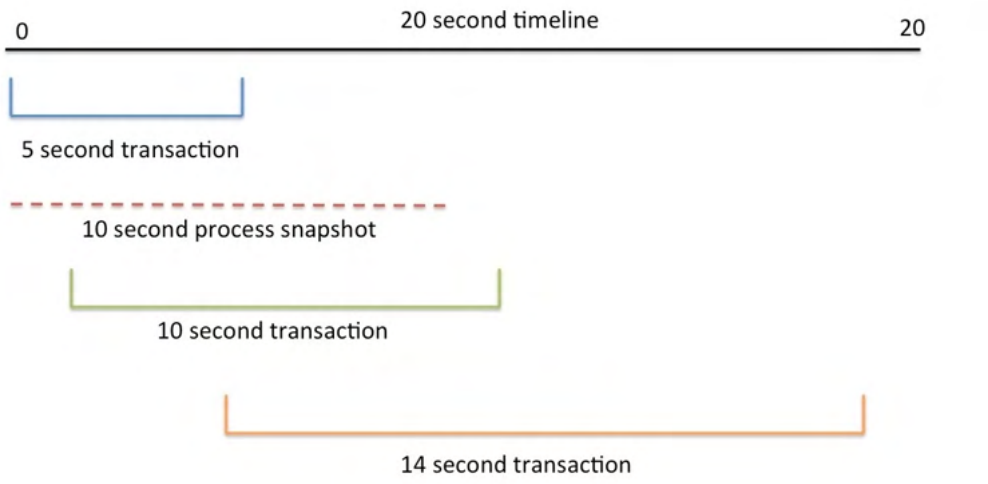
Business Transaction Snapshots Trigger Process Snapshots

To provide call graph data associated with business transaction snapshots, the agent starts a ten-second process snapshot whenever it starts a business transaction snapshot that is triggered by periodic collection or a diagnostic session if there is no existing process snapshot in progress for the current process. Process snapshots do not overlap. Periodic collection means that a business transaction is collected at periodic intervals, by default every ten minutes, but configurable. Diagnostic session means that either the agent has detected a pattern of possible performance issues and automatically started capturing transaction snapshots or a human has manually started a diagnostic session for the same reason.

Concurrent Business Transaction and Process Snapshots

The result presented is a process snapshot that ran concurrently with a business transaction. How well the two snapshots line up depends on the relative durations and start times of the transaction and the process snapshots.

In the scenario sketched below, all of the five-second blue transaction's calls, and most of the 10-second green transaction's calls are captured by a 10-second process snapshot, but only the about half of the 14-second orange transaction snapshot's calls.



If you find that your business transactions are running longer than your process snapshots, you can increase the default length of a process snapshot in the `autoSnapshotDurationSeconds` setting in the require statement.

Information Points

This page describes information points in AppDynamics. You can use information points to define custom metrics based on methods you configure. Information points are similar to data collectors; while data collectors show application data in the context of a business transaction, information points reflect data state across all invocations of a method, independent of business transactions. You can also apply computations to the values, for example, representing the sum or average for a method return value or input parameter.

To create, edit, or delete information points, you need the **Configure Information Points** permission.

Information Point Data: Code Metrics and Business Metrics

When you configure an information point, you automatically receive the KPI metrics (called *code metrics*) for the information point method.

The code metrics are:

- Total call count
- Calls per minute count
- Errors per minute
- Average response time

You can supplement the KPI metrics with custom business metrics for the information point.

Business metrics reflect the value of runtime data, such as the method parameter, return value, or a value captured by getter chain on the object on which the identified method was invoked. The business metric value represents either the sum or average of the values of the code point you identify as the information point.

Information points can give you significant insight into how the performance of an application corresponds to business performance. For example, depending on the nature of your application, you could use it to resolve business questions such as:

- What is the average value of the credit card total?
- How many credit cards did my application process in a certain time period, regardless of the business transaction?
- What was the average time spent processing a credit card transaction?

A example of a practical use of an information point is ignored exceptions. Exceptions, especially one that occurs frequently, can contribute to CPU spikes in a JVM. If you configure the exception to be ignored in AppDynamics, for example, if it is generated in the underlying application framework and does not have a direct bearing on your application performance, it may not be readily evident to you when the exception is affecting your application. An information point that counts the exception occurrence can help you identify the additional overhead.

Creating Information Points

To create information points, see Java and .NET Information Points and PHP Information Points.

Viewing Information Point Data

You can view information point values in various places in the Controller UI, including the following:

- Information Points page: The primary page for viewing and administering information points is the **Information Points** page. From there, click on an information point to view a histogram of the metrics for the information point for the selected time period.
- Metric Browser: The metrics also appear in the Metric Browser under the Information Points folder.
- REST API: Business metrics can be accessed from the AppDynamics REST API.
- Business Transaction Snapshots: Information point data does not appear in transaction snapshots by default, but you can configure it to appear by setting the `enable-info-point-data-in-snapshots` node property to `true`. When the `enable-info-point-data-in-snapshots` node property is set, information point calls appear in the User Data section of the snapshot. See App Agent Node Properties.

Java and .NET Information Points

Applies to:

This page describes how to create information points for Java and .NET applications. For PHP-based information points, see PHP Information Points.

Before Starting

Ensure that you have the ability to restart the application while minimizing user impact. To apply the configuration for a new information point for .NET and JVM 1.5 applications, you must restart the application server.

You must be logged in to the Controller as a user with Configure Information Points permissions. See Create and Manage Custom Roles.

Create an Information Point from a Transaction Snapshot

You can create an information point from the call graph of a transaction snapshot that includes the method.

When you locate an invocation of the method in the call graph, right-click it and select the option to configure instrumentation on this class or method. Your selection creates an information point

Create and Manage Information Points Manually

You can create, view, and modify information points on the **More > Information Points** page.

To create an information point, you must specify the class and method for which you want to collect information, along with other identifying information. For details on using the UI to configure code matching for an information point, see Data Collectors.

Information points are evaluated based on the execution of the method on which they are placed. Any match conditions apply to the state of the data at that time.

To collect business metrics from the method, from the **Edit Information Point** page, select **Add** to add a custom metric for the information point. You can configure and customize the type of data you want to collect for business metrics. Select **Save** when you are finished.

PHP Information Points

This page describes how to define information points for PHP applications.

Information points reflect key performance metrics and custom metrics for methods and code data points that you configure.

About PHP Information Points

To create an information point for PHP:

1. Define the information point using JSON notation.
2. In the definition, specify the method for the information point
3. Optionally, specify a point in the code that you want to capture as a custom metric, such as a parameter value or return value.
4. Navigate to **More** > **Information Points** and add an information point.
5. Choose **PHP** as the agent type and then paste the definition into the information point text box.

The elements of the definition correspond to configuration options available in the **Add Information Point** dialog for Java or .NET applications.

However, for PHP, the information point is defined in JSON syntax, and there are a few limits on configuration options. For one, class matching is limited to classname-based matches only. (Superclass matching or annotation matching are not available.) Also, you can only define a single match condition on a matched method. (A match condition refines the match of a method by testing a parameter or return value.)

If you do not configure a custom metric, the information point captures the generic KPIs for a matched method (response time, calls and calls per minute, errors an errors per minute). Custom metrics extend the information point by capturing the return or parameter value of a method, or the value of an invoked object.

Before Starting

To create information points in the Controller UI, you need to be logged in as a user with **Configure Information Points** permissions. See Create and Manage Custom Roles.

Method Match Conditions

A match definition specifies the method associated with the value you want to capture as an information point. The match definition must specify the method, but it may also specify the containing class and a refining match condition. The match condition can test the value of a method parameter, return value, or the return value of an invoked object.

Use this template to create a match definition:

```
{
  "probe": {
    "phpDefinition": {
      "classMatch": {
        "type": "MATCHES_CLASS",
        "classNameCondition": {
          "type": "EQUALS",
          "matchStrings": [
            "<class name>"
          ]
        }
      },
      "methodMatch": {
        "methodNameCondition": {
          "type": "EQUALS",
          "matchStrings": [
            "<method name>"
          ]
        }
      }
    }
  }
}
```

Edit the JSON objects in the following way:

- `classMatch` is optional. If you do not want to specify a class to match, delete the `classMatch` object from the `phpDefinition` object.
- If you are using the class match, set the value for the `classNameCondition` match string to the class name.
    - The class must be defined as a separate file from the file in which it is instantiated and invoked.
    - If your class names are defined in a namespace, escape the backslashes in the namespace with an escape backslash.
- `methodMatch` is required. Set the value for the `methodNameCondition` match string to the method name.

The following values are required for PHP information points:

- `classMatch` type: `MATCHES_CLASS`
- `classNameCondition` type: `EQUALS`
- `methodNameCondition` type: `EQUALS`

For example, the following JSON creates an information point on a class for which the class name equals `CheckoutManager` and the method name `processPayment`:

```
{
  "probe": {
    "phpDefinition": {
      "classMatch": {
        "type": "MATCHES_CLASS",
        "classNameCondition": {
          "type": "EQUALS",
          "matchStrings": [
            "Bundy\\ShoesBundle\\Entity\\CheckoutManager"
          ]
        }
      },
      "methodMatch": {
        "methodNameCondition": {
          "type": "EQUALS",
          "matchStrings": [
            "processPayment"
          ]
        }
      }
    }
  }
}
```

If creating an information point primarily to capture KPI metrics for the method, it is likely you will define the class for the method. However, if you are creating an information point to implement a code metric, you may only need to specify method name matching.

This example shows a method match that tracks how many times a method is called:

```
{
  "probe": {
    "phpDefinition": {
      "methodMatch": {
        "methodNameCondition": {
          "type": "EQUALS",
          "matchStrings": [
            "deleteCartItems"
          ]
        }
      }
    }
  }
}
```

Match Conditions

A match condition (defined by a `matchConditions` object) lets you refine the method matching criteria by specifying a match condition based on a parameter or return value or the value returned by an invoked object.

A match condition is optional, but there can be at most one for the information point. If you do not supply a match condition, the information point includes all invocations of the matched method.

The condition consists of a match type and the comparison operator that defines the data to be compared. The match types are:

- EQUALS
- NOT_EQUALS
- LT
- GT
- LE
- GE

- NOT
- AND
- OR

The comparison operator is an expression node that defines a left side (`lhs`) and a right side (`rhs`) of the operation. It contains:

- a type: `ENTITY`, `STRING`, or `INTEGER`
- a value, which is an `entityValue`, `stringValue`, or `integerValue`

If the type is `ENTITY`, the `entityValue` has one of the following types: `INVOKED_OBJECT`, `RETURN_VALUE`, or `PARAMETER`. If the type of the `entityValue` is `PARAMETER`, the `parameterIndex` indicates the 0-based numeric index of the parameter on which to match. So if the method takes two parameters, for example, the first being a string and second an integer, a `parameterIndex` of 0 matches against the string and a `parameterIndex` of 1 matches the integer value.

The information point in the following example only matches invocations of the `processPayment` method in which the second parameter (at parameter index 1) equals `VISA`.

```
{
  "probe": {
    "phpDefinition": {
      "methodMatch": {
        "methodNameCondition": {
          "type": "EQUALS",
          "matchStrings": [
            "processPayment"
          ]
        },
        "matchCondition": {
          "type": "EQUALS",
          "comparisonOp": {
            "lhs": {
              "type": "ENTITY",
              "entityValue": {
                "type": "PARAMETER",
                "parameterIndex": 1
              }
            },
            "rhs": {
              "type": "STRING",
              "stringValue": "VISA"
            }
          }
        }
      }
    }
  }
}
```

Metric Definitions

You can define custom metrics for data captured by an information point using the `metricDefinitions` object in your information point definition. Custom metrics appear in the Metric Browser and in the dashboard for the information point. You can create health rules based on a custom metric and retrieve custom metric values using the AppDynamics REST API.

There can be multiple custom metrics for a single information point. For example, one metric might be based on the average and one on the accumulated (sum) of the information point's values.

A `metricDefinitions` object consists of one or more definitions, each having the following structure:

- a name
- a rollup type (`AVERAGE` or `SUM`)
- data, which consists of a type, (`ENTITY`, `STRING`, or `INTEGER`) and a value (`entityValue`, `stringValue`, or `integerValue`)

  If the type is `ENTITY`, the `entityValue` has a type, which is `INVOKED_OBJECT`, `RETURN_VALUE`, or `PARAMETER`. If the type of the `entityValue` is `PARAMETER`, the zero-based `parameterIndex` indicates the parameter on which to base the match. A return value or parameter metric cannot be an array.

For example, the following `metricDefinitions` object defines two custom metrics: `VisaTotal`, which reports the sum of the Visa payments processed and `VisaAverage`, which reports the average value of the Visa payments processed.

```
"metricDefinitions": [
    {
      "name": "VisaTotal",
      "rollup": "SUM",
      "data": {
        "type" : "ENTITY",
        "entityValue": {
          "type": "RETURN_VALUE"
        }
      }
    },
    {
      "name": "VisaAverage",
      "rollup": "AVERAGE",
      "data": {
        "type" : "ENTITY",
        "entityValue": {
          "type": "RETURN_VALUE"
        }
      }
    }

  ]
```

Sample JSON Information Point Configuration

This is an example that you can copy and paste into the JSON text field in the PHP information point window. It produces two metrics, named `VisaTotal` and `VisaAverage`.

```
{
  "probe": {
    "phpDefinition": {
      "classMatch": {
        "type": "MATCHES_CLASS",
        "classNameCondition": {
          "type": "EQUALS",
          "matchStrings": [
            "CheckOutManager"
          ]
        }
      },
      "methodMatch": {
        "methodNameCondition": {
          "type": "EQUALS",
          "matchStrings": [
            "processPayment"
          ]
        },
        "matchCondition": {
          "type": "EQUALS",

          "entityValue": {
            "type": "RETURN_VALUE"
          }
        }
      }
    ]
}
```

Configure Instrumentation

In AppDynamics, instrumentation refers to how app agents interact with your application software to gather performance data and report it back to the AppDynamics Controller. The first step to instrumenting your application is installing the app agents on the servers where the code runs.

App agents ship with default instrumentation settings that cover the most common types of application frameworks and programming patterns. If your requirements are more complex, you can customize the instrumentation behavior to suit your environment.

See Configure Instrumentation Overview for information on how AppDynamics applies instrumentation settings across your business application.

Access Instrumentation Settings

Navigate to **Configuration > Instrumentation** to customize:

- Transaction detection rules that define entry points for business transactions.
- Backend detection rules that define exit points for your business transactions.
- Error detection settings that define which transactions qualify as error transactions.
- Service endpoints to view metrics specific to services and transaction segments outside the context of a single business transaction.
- Diagnostic data collectors for an app agent to extract additional context about a specific transaction at transaction snapshot time. You can also configure data collectors for Application Analytics.
- Call Graph Settings to tune the amount of data the app agent collects for call graphs.
- JMX metrics that the Java agent collects for specific products and frameworks. See "Configure JMX Metric Rules" on Configure JMX Metrics from MBeans.
- Memory monitoring settings for agents that collect instance tracking data for specific classes or objects. See the following topics:
    - Object Instance Tracking for Java
    - Object Instance Tracking for .NET
    - Object Instance Tracking for Node.js
- Asynchronous transaction demarcators to set endpoints for asynchronous transactions.

Configuration Page Items

In addition to the instrumentation configuration options described on this page, there are many other ways to customize AppDynamics for your environment. For more information on the items on the **Configuration** page, review these pages:

- "Configure Thresholds" on Transaction Thresholds.
- "View Baselines" on Dynamic Baselines.
- Information Points
- Development Level Monitoring

If you have an End-User monitoring license, review these pages on **User Experience App Integration**:

- Correlate Business Transactions for Browser RUM
- Automatic Injection of the JavaScript Agent
- Assisted Injection

Configure Instrumentation Overview

The scope configuration model reduces the number of steps it takes to apply transaction detection rules to multiple tiers.

Under the scope configuration model, you can apply settings to groups of tiers, in addition to individual tiers and nodes. Groups of tiers are called scopes. Only transaction detection settings for applications created in AppDynamics >= 4.3 adhere to the scope model.

Live Preview Mode

You can interactively experiment with transaction detection rule configurations using Live Preview. Live Preview streams data from an active node, providing real-time data for the following configurations:

- All transaction detection rules that apply to a node. See Business Transaction Discovery Sessions.
- A single custom match rule applied to a node. See Custom Match Rule Live Preview.

The following limits apply to Live Preview:

- 100 sessions on the Controller
- 20 sessions on an account
- 10 sessions on a business application

Programmatic Expressions

You can specify the following types of programmatic expressions when configuring detection rules:

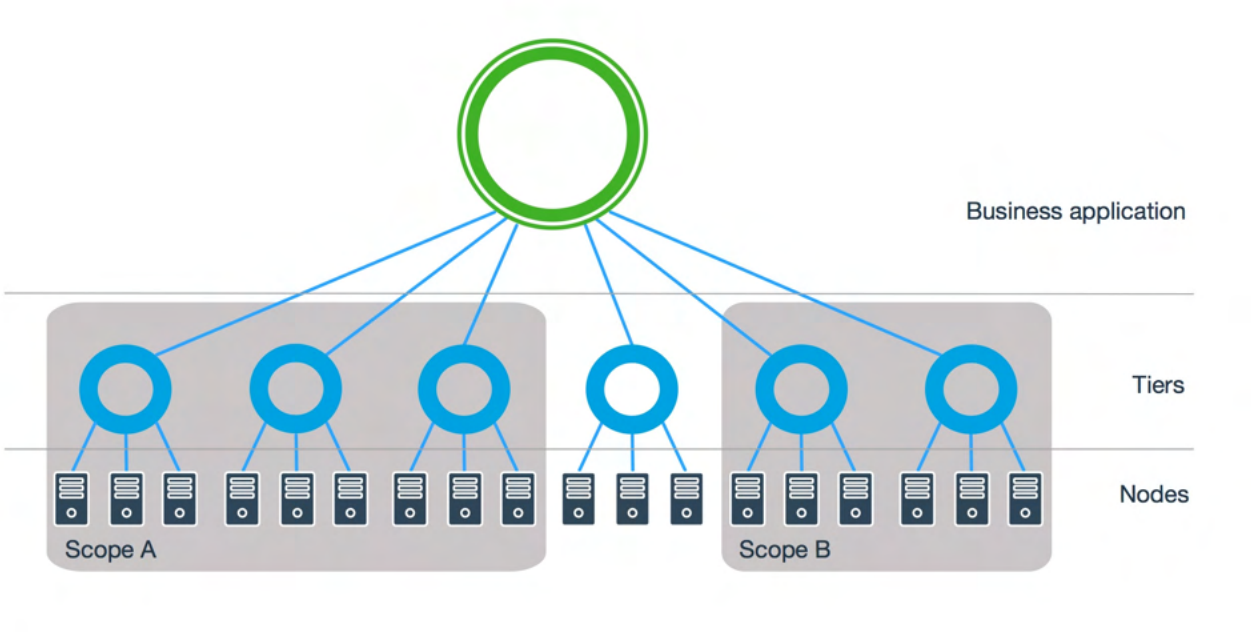
- Regular expression: A string or character search pattern
- Getter chains: Enable you to access data returned by methods in your application

Scope Configuration Model

The scope configuration model allows you to bundle multiple tiers into a scope, and apply transaction detection rules to that scope.

You can apply a rule to select tiers all at once. The Default Scope consists of all the tiers in the application.

In the diagram, you want to apply a rule to three of the six tiers in an application. Rather than manually applying the rule to each of the three tiers, you can bundle the tiers into a scope (Scope A) and apply the rule to the scope.



Creating a Custom Scope

You can create a custom scope by navigating to **Configuration > Instrumentation > Scopes**.

1. Click **Add**.
2. Enter a name for your scope.
3. In the **Include the following Tiers** dropdown, select one of these options:
    a. **All Tiers in the Application**: creates a scope that includes all the tiers in the application, except tiers that you specify. You can select tiers to exclude from the scope in the **Available Tiers** box and clicking the left-pointing arrow.
    b. **These Specific Tiers**: creates a scope that includes only tiers that you specify. You can select tiers to include in the scope in the **Availab le Tiers** box and clicking the left-pointing arrow.
4. Click **Save**.

To view the rules that are applied to a scope, select the scope in the Scopes tab. The rules applied to that scope display in the panel on the right.

Set the Scope for a Rule

When you create a new application, all rules for the application use the default scope. You can create additional scopes for that application, and choose which rules to apply to that scope. Each rule can only apply to one scope.

1. Click the Rules sub-tab.
2. Select the rule that you want to apply to a scope. The tiers that the rule is applied to are displayed in the panel on the right.
3. Click **Edit**.
4. Click **Change Scope**.
5. Select the scope that you want to apply this rule to.
6. Click **OK**.
7. Click **Save**.

To apply a rule to a scope, you need permissions to all the tiers in the scope. To apply a rule to the default scope, you need application-level permission.

Using Regular Expressions

Related pages:

- Transaction Detection Rules
- Custom Match Rules

Regular expressions display in various places in the AppDynamics configuration. These places include, for example, transaction detection rules, data collectors, EUM injection settings, health rules, and more. This page describes the use of regular expressions in AppDynamics.

Matching Guidelines

A match condition consists of a named property to match (such as a method name, Servlet name, URI, parameter, or hostname), a comparison operator, and a matching value. For complex match conditions, you can use a regular expression (often abbreviated to just regex).

Match rules are case sensitive. Also, matching is based on subsequence pattern matching. To match a complete string instead, you need to include "^" to match the start of the string and "$" to match the end of the string in your regular expression.

In the context of business transaction matching, the pattern does not include the protocol (e.g., "http://"), host, port, or query parameters in the URL. So for example, a URI of http://www.mysite.com:8000/account/settings.html?action=update would be matched by a business transaction regular expression with only "/account/settings.html".

Regular Expression Engines

The Java Agent uses Java libraries for regular expressions. See:

- Tutorial: http://download.oracle.com/javase/tutorial/essential/regex/index.html
- Javadoc: http://download.oracle.com/javase/1.5.0/docs/api/java/util/regex/Pattern.html

The .NET Agent uses the built in .NET regular expressions engine. See:

- MSDN: .NET Framework Regular Expressions

The Node.js Agent uses JavaScript regular expressions. See:

- https://developer.mozilla.org/en-US/docs/Web/JavaScript/Reference/Global_Objects/RegExp

The PHP Agent uses PHP's built-in PCRE regular expression engine and requires the same syntax, including delimiters (for example: /^Foo/). See:

- PCRE Manual

The Python Agent uses Python's regular expression syntax. See:

- https://docs.python.org/2/library/re.html

The Web Server Agent uses Perl regular expression syntax. See:

- http://www.boost.org/doc/libs/1_57_0/libs/regex/doc/html/boost_regex/syntax/perl_syntax.html

Regular Expression Examples

These examples show how to construct regular expressions to achieve different results.

Matching Non-Adjacent URL Segments

A typical use of regular expressions in the AppDynamics configuration is for business transaction custom match rules in which the expression is matched to a requested URI. In this context, it's common for an application's URI pattern to put information that would be useful for business transaction identification in different segments of the URI.

For example, given an example URL of `http://retailstore.example.com/store/jump/category/shoes/departments/view-all/cat630006p`, a business transaction might need to match on `/store/jump` and `all` to group user requests to view all of an available category.

A regular expression to match this case could be:

```
/store/jump.*\b?all\b
```

Matching Any Digit

Say you want to ignore numbers contained within a pattern. For example, consider the following URL examples:

- /group/1/session/

- /group/1/session/
- /group/31/session/
- /group/2/session/

Examples of matching regular expressions would be:

- ^/group/\d*/session/?$
- session
- /\d*/session/?$

Requiring a Digit

To group URLs that contain letters then numbers into one business transaction, such as the following:

- /aaa123.aspx
- /b1.aspx

You could use an expression such as the following:

```
/[a-z]+?[0-9]+?
```

Not matched would be a URL that does not have digits after the letters, for example: `/z.aspx`

Handling Letter Casing

Regular expression matching is performed in a case-sensitive manner. To match any case letters, you can use something similar to the following:

```
/[a-zA-Z]+?[0-9]+?
```

Or match in a case-insensitive manner using the `/` modifier. For example:

```
(?i)\w*cart\w*
```

Would match `addToCart` as well as `addTocart`.

Backend Discovery Rules

For an example of a JDBC backend regular expression, see the section JDBC with complex URLs in Example JDBC Backend Configuration.

You can find resources for testing your own regular expressions at http://www.regexplanet.com/advanced/java/index.html. There you can find regular expression test pages for many language engines, including Java, JS, .NET, PHP and more.

Performance Considerations

Although regular expressions are a powerful way to set AppDynamics configurations, you should consider the following to avoid performance issues:

- Do not use wildcard expressions unless absolutely needed. You do *not* need to use wildcard expressions (.*) before or after a match, and each wildcard regular expression results in approximately an order of magnitude performance impact.
- The number of configurations, the frequency the configuration is applied, and the content length of the target string: For example, if the configuration using a regular expression is applied in many places at high frequency for longer target strings, you might consider reducing the usage of the configuration or decrease the frequency of its application.

Using Getter Chains

Related pages:

- Transaction Detection Rules

Getter chains let you access method data in various contexts of the AppDynamics configuration. For example, getter chains enable you to name business transactions based on return values. This page describes how to use getter chains.

Getter Chains

You can use getter chains to:

- Create a new JMX Metric Rule and define metrics from MBean attributes. See Configure JMX Metrics from MBeans.
- Configure method invocation data collectors. See the Configuration Notes in Data Collectors.
- Define a new business transaction custom match rule that uses a POJO object instance as the mechanism to name the transaction. See POJO Entry Points.
- Configure a custom match rule for servlet entry points and name the transaction by defining methods in a getter chain. See "Split by POJO Method Call" on Split Servlet Transaction by Payload Examples.

As a best practice, you should use getter chains with simple getter methods only. Getter chains on processing-intensive methods, such as one that make numerous SQL calls, can result in degraded performance for the application and agent.

For example, the following shows a simple get method that returns a property for a class, such as `MyUser.Name`:

```
public class MyUser
{
   private String Name {get; set;}
   private String Url;
   public String GetUrl() {
      return this.Url;
   }
}
```

Special Characters in Getter Chains

Use the following special characters as indicated:

- Parentheses `( )` to enclose parameters
- Commas `,` to separate parameters
- Forward slashes `/` to separate type declarations from a value in a parameter
- Backslashes `\` to escape characters.
    - To search for a backslash `\`, escape the backslash with a backslash:

      ```
      GetString().Find(\\)
      ```

    - To split a string by a backslash `\`, escape the backslash in Java and within the Getter Chain:

      ```
      GetString.split(\\\\).[0]
      ```

- Dots `.` to separate methods and properties in the getter chain
- Dot `.` to represent "anything" must be escaped
- Curly braces `{ }` to delineate getter chains from static elements in custom expressions on HTTPRequest objects (including in the Java Servlet Transaction Naming Configuration window and in the Split Transactions Using Request Data tab of the servlet custom match and exclude rules)

Getter chains also treat spaces at the beginning or end of a string as special characters.

Escape Literal Characters

If the getter chain should treat a special character literally, escape it using a backslash. For parentheses, you only need to escape the closing parenthesis in a string.

- The following example shows the how to escape the dot in the string parameter.

  ```
  GetAddress().GetParam(a\.b\.c\.)
  ```

The agent executes `GetParam("a.b.c.")` on the result of `GetAddress()` and returns the value of the parameter.

- In the following example, the first dot is part of the string method parameter, which requires an escape character. The second and third dots don't require an escape character because they are used as method separators.

```
GetUser(suze\.smith).GetGroup().GetId()
```

- The following example shows how to escape the opening and closing parenthesis in a search for "()" within a string.

```
GetString.Find(\(\))
```

.NET Notes and Examples

These sections apply to getter chains used in .NET Agent configurations.

Escape backslashes within a getter chain for .NET with the double backslash.

Declare Parameter Types

The .NET Agent identifies parameter types as follows:

- Dictionaries, anything with property accessors, use a normal parameter set, which defaults to string.
- Arrays use single integers as parameters.

Therefore `0` means `string/0` if you have a hash, or anything that translates to `get_Item` (any kind of property). `0` means `int/0` if you have an array.

When your getter chain uses a method with parameters other than the default type, you need to declare the parameter type.

- The following example demonstrates how to declare the parameter types to resolve the overloaded `Susbstring()` method. The forward slash serves as the type separator.

```
GetAddress(appdynamics, sf).Substring(int/0, int/10)
```

  For instance, if `GetAddress(appdynamics, sf)` returns "303 2nd St, San Francisco, CA 94107", the full getter chain expression returns "303 2nd St".
- The following example shows how to declare the parameter types for a user-defined method that takes a float parameter, a boolean parameter, and an integer parameter. The forward slash serves as the type separator.

```
GetAddress(appdynamics, sf).MyMethod(float/0\\.2, boolean/true, boolean/false, int/5)
```

Access Indexed Properties and Dictionary Values

If your getter chain accesses a dictionary object, you can access the values using the following syntax:

- The following example returns the value for the key `suze.smith`.

```
UserDictionary.[string/suze\\.smith]
```

- The following example returns the value for the key suze.smith using the implied getter.

```
UserDictionary.get_Item(suze\\.smith)
```

Split by Character or Regular Expression Match in .NET Getter Chains

You can split values matched by character or as a string by matching a regular expression pattern. The result of a split operation is a string or character array that you can reference in your getter chain by an array index value.

The following examples illustrate how to use the character and string regular expression split operations in getter chains.

Split by Character

- The following chain splits a URL on the forward slash character. In this case, the first slash acts as a type separator. The getter chain returns the fourth item in the array.

```
GetUrl().Split(char[]//).[3]
```

  The agent returns "Search" when it applies the getter chain to the following URL: http://howdyworld.example.com/Search/Airfare
- In the following example, the split occurs on the forward slash character, and the result is the length of the resulting array.

```
GetUrl().Split(char[]//).Length
```

- This example illustrates a transaction splitting rule for URIs that use a semicolon delimiter. The getter chain splits on the forward slash, then splits the fourth element on the semicolon.

```
GetUri().Split(char[]//).[3].Split(char[]/;).[0]
```

  The agent returns `create-user` when it applies the getter chain to the following URL: `http://HowdyWorld.example.com/create-user;sessionid=BE7F31CC0235C796BF8C6DF3766A1D00?act=Add&uid=c42ab7ad-48a7-4353-bb11-0dfeabb798b5`

Split by Regular Expression

For more control, you can split values by string-based pattern matching. Pattern matching is particularly useful for situations that require complex matching, such as matching content within a request body.

The following example shows a getter chain that splits the value returned by `GetAddress()` and selects the seventh element in the resultant array:

```
GetAddress().Split(string/\\W+).[6]
```

Given an address such as `303 2nd St, San Francisco, CA 94107`, the example splits the value by word and references the sixth word in the array, `CA` in this case.

Compose Getter Chains for HTTP Requests

The .NET Agent requires special syntax for getter chains for HTTP Requests:

- For ASP.NET WebForms, MVC, and MVC WebAPI applications create getter chains based upon the `System.Web.HttpRequest` objects.
- For ASP.NET Core on the full framework, create getter chains based upon Microsoft.AspNetCore.Http.Internal.DefaultHttpRequest objects.

> If you have both ASP.NET and ASP.NET Core on the full framework apps in the same tier, you cannot use a getter chain to apply to both because the two frameworks use different objects to handle HTTP requests.

- Use the following syntax to delineate the boundaries of the getter chain:

```
${myobject.myproperty}
```

- The following example determines the user principal:

```
${Context.User.Identity.Name}
```

Places to use this syntax include:

- HTTP Request Data Collectors
- ASP.NET Transaction Detection custom expressions

Java Notes and Examples

The following sections apply to getter chains used in Java Agent configurations.

Values Passed in a Getter Chain

The value passed in a getter chain is always a string unless cast to another type.

The following cast types are supported:

- int
- float
- bool (the primitive Boolean value)
- boolean (a boxed boolean value; i.e. an object type that wraps a boolean)
- long
- object

The following section shows examples of how to refer to the types in parameters to getter chain methods. Notice that letter case is not important for the names of the types. Type casting is performed in a case-insensitive manner.

Java Getter Chain Examples

- Getter chain with integer parameters in the substring method using the forward slash as the type separator:

```
getAddress(appdynamics, sf).substring(int/0, int/10)
```

- Getter chain with various non-string parameter types:

```
getAddress(appdynamics, sf).myMethod(float/0.2, boolean/true, boolean/false, int/5)
```

- Getter chain with forward slash escaped; escape character needed here for the string parameter:

```
getUrl().split(\/) # node slash is escaped by a backward slash
```

- Getter chain with an array element:

```
getUrl().split(\/).[4]
```

- Getter chains that return Hashmap values:

```
get(object/myvalue).substring(int/0,int/10)
get(object/ACTION)
```

- Getter chain with multiple array elements separated by commas:

```
getUrl().split(\/).[1,3]
```

- Getter chain retrieves property values, such as the length of an array:

```
getUrl().split(\.).length
```

- Getter chain using backslash to escape the dot in the string parameter;
the call is getParam (a.b.c).

```
getAddress.getParam(a\.b\.c\.)
```

- In the following getter chain, the first dot requires an escape character because it is in a string method parameter (inside the parentheses). The second dot does not require an escape character because it is not in a method parameter (it is outside the parentheses).

```
getName(suze\.smith).getClass().getSimpleName()
```

The following getter chain is from a transaction splitting rule on URIs that use a semicolon as a delimiter.

```
getRequestURI().split(\/).[2].split(;).[0]
```

The call gets the URI using getRequestURI() and then splits it using the escaped forward slash. From the resulting array, it takes the third entry (as the split treats the first slash as a separator) and inserts what before the slash (in this case, nothing) into the first entry. Then it splits this result using the semicolon, getting the first entry of the resulting array, which in this case contains the API name.
For example, given the following URI:

```
/my-webapp/xyz;jsessionid=BE7F31CC0235C796BF8C6DF3766A1D00?act=Add&uid=c42ab7ad-48a7-4353-bb11-0dfeabb798b5
```

The getter chain splits on the API name, so the resulting split transactions are "API.abc", "API.xyz" and so on.

Tip: When using `string.split()`, remember that it takes a regex and you have to escape any special regex characters.

For example, if you want to split on the left square bracket ([):

```
Java syntax: split("\\[")
Getter chain syntax: split(\\\\[)
```

A Vertical Bar or Pipe (|) is a reserved character in Getter strings. For methods with a regular expression parameter, use Unicode as an alternative.

For example:

```
split(string/\\u007C).[0]   // return the first element of an string split by a Vertical Bar.
```

Blocklisted Classes or Packages and Methods of the Java Getter Chain

Certain packages and classes have been blocklisted from being accessed within getter chains.

The following methods and classes or packages have been blocklisted by the Java Agent for Getter Chains:

Methods:

- `getClassLoader`
- `loadClass`
- `invoke`

Classes or packages:

- `reflect`
- `nio.file`
- `ClassLoader`
- `io.File`
- `io.Socket`
- `net.Socket`
- `ProcessBuilder`
- `Runtime`

Transaction Detection Rules

Related pages:

- .NET Business Transaction Detection
- PHP Business Transaction Detection

AppDynamics uses different types of transaction detection rules to define entry points and name business transactions:

- Automatic transaction discovery rules include the default entry point types and naming configuration for each app agent type.
- Custom match rules offer finer control over transaction discovery and naming for a single entry point type.

In many cases, the built-in rules yield a useful set of business transactions. If not, you can create new rules or edit the existing rules to optimize the transaction detection for your environment.

Permissions

The *Configure Transaction Detection* permission is needed to customize transaction detection rules.

The *View Sensitive Data permission*, In combination with the *Configure Transaction Detection* permission, enables the use of Live Preview and Business Transaction Discovery features to stream live data from your application.

Live Preview

For Java and .NET environments, you can use interactive live preview tools to find business transaction entry points:

- Business transaction discovery sessions stream live data from the node to the Controller UI to help you make instrumentation decisions. These sessions display transactions based on all transaction detection rules active for the node.
- For certain types of entry points, custom match rule live preview enables you to preview transactions based on applying a single transaction detection rule on a node.

Business transactions within the context of the Live Preview, called transient transactions, do not persist after the Live Preview ends. Business transaction discovery sessions let you apply or discard rule changes when you end the session. Custom match live preview rules apply after you save the rule.

Some transient transactions may invoke exit calls to the same node where the Live Preview session is running. In certain cases, the agent may discover additional transient transactions and uninstrumented code on the downstream segment:

- The exit call and corresponding entry point are automatically discovered exit and entry points like HTTP or Web Service.
- Rare cases of custom activity in-process calls.

Manage Transaction Detection Rules

To customize transaction detection rules in the Controller UI, go to **Configuration > Instrumentation**. From the Business Transactions list, you can also click **Configure** to quickly access Transaction Detection settings.

You apply transaction detection rules to tiers using the flexible scope configuration model. From the Transaction Detection tab, you can manage rules as follows:

- Manage rules for individual scopes on the Transaction Detection tab.
- Manage rules application-wide on the Rules sub-tab. The Rules sub-tab also shows you the tiers where rules are applied and according to which scope.
- View or modify the rules for specific tiers on the Tiers sub-tab.

To modify an existing rule, you can double-click it to display the **Rule Editor**. Click **+/Add** to define a new rule.

Use **Live Preview** button to start a Business Transaction Discovery session for nodes running the Java and .NET Agent.

Transaction Detection Rule Priorities

AppDynamics app agents apply transaction detection rules of the same type in the following order of precedence:

1. Rule priority from highest to lowest. A priority of 0 is the lowest priority possible.
2. Creation date from oldest to newest.

For example, consider an HTTP request that matches a priority 2 custom match rule and a priority 6 custom match rule. The agent applies the priority 6 rule.

When an incoming request matches more than one type of detection rule, AppDynamics applies the detection rules in the following order of precedence:

1. Custom match *include* rules according to the include rule priority. If the request matches an include rule, the agent names the business transaction based on the rule.
2. Custom match *exclude* rules according to the exclude rule priority. If the request matches an exclude rule, the app agent excludes the transaction from discovery.

3. Default automatic detection rules. If the request matches a default automatic detection rule, it names the transaction according to the auto-detection naming scheme.

If two entry point types have the same priority where either can be used to define or register an entry point, then there is some precedence between them.

For example: If in Java just the Java Automatic Discovery Rule with all types is enabled, and there are entry points which can be considered as Web Services or Servlets - then the Servlets will take priority - a higher priority rule is needed if Web Services are the desired default.

To view the default order of transaction detection rules for a tier:

1. Navigate to **Configuration > Instrumentation > Transaction Detection > Tiers**.
2. Click a tier to see the rules ordered by precedence and priority.

For Java and .NET, you can set the `check-bt-excludes-early` node property to "true" to configure the app agent to evaluate custom match exclude rules before custom match include rules. This is a node-based configuration and does not affect the display order of rules in the Controller UI.

Export Detection Rules

You can migrate the rules between applications and tiers using the Controller API. See Configuration Import and Export API.

Automatic Transaction Discovery Rules

Each AppDynamics app agent type has a default automatic transaction discovery rule that applies to all the entry points for that agent. When an agent identifies a business transaction that matches an automatic transaction discovery rule, it names the business transaction based on naming rules for the entry point type.

Automatic Transaction Naming

The naming logic varies depending on the application technology. For example:

- For web-oriented technologies that have URI entry points such as Java Servlets, detection rules name the transaction using the first two segments of the URI by default. See URI Based Entry Points.
- For message-oriented technologies such as an asynchronous message listener or message-driven bean (JMS), the agent names the business transaction for the destination name (the queue name) or the listener class name (if the destination name is not available.)
- For Web services, the agent names the business transaction for the Web service name plus the operation name.

Customize Automatic Transaction Discovery Rules

You can customize automatic transaction discovery rules as follows:

- Add an automatic transaction discovery rule for an agent type.
- Enable or disable different types of automatically discovered entry points.
- Customize transaction naming for some entry points, such as most URI-based entry points.

To access the Rule Editor, double-click an Automatic Transaction Discovery rule for an app agent. Alternatively, you can create a new automatic transaction discovery rule for the agent type by clicking **Add**. Clicking the Rule Configuration tab displays the entry points for the automatic discovery rule.

When you edit, delete, or change the scope for an automatic transaction discovery rule, the Controller UI performs validation to ensure each tier has the correct automatic discovery rule available for its agent type.

If you are using the Java Agent you can preview the effects of your customizations before you apply them in production. See "Edit and Preview Transaction Discovery Rules" on Business Transaction Discovery Sessions.

Disable Transaction Monitoring for Entry Points

Automatic transaction detection rules have a **Transaction Monitoring Enabled** checkbox for each entry point type to control automatic discovery. By default, all entry point types are enabled. When you disable discovery for an entry point type, the agent stops counting, measuring, and recording all activity for that entry point type for the scope where the rule is applied.

> The **Transaction Monitoring Enabled** configuration affects custom match rules in the same scope for the entry point type. For example, if you disable POJO monitoring in the Java Default Automatic Transaction Discovery Rule for a scope, the Java Agent will not discover any POJO transactions for the scope.

Following are the cases when you might want to disable monitoring:

- You know that you don't want to monitor any business transactions of a specific entry point type.
- You want to monitor transactions from a downstream call.

For example, consider an application where Servlets implement Spring Beans and you are interested in monitoring the transaction starting at the Spring Bean level. Disable Servlet monitoring and the auto-detection rule for Spring Beans will be the entry point for the transaction.

Disable Automatic Transaction Detection for an Entry Point Type

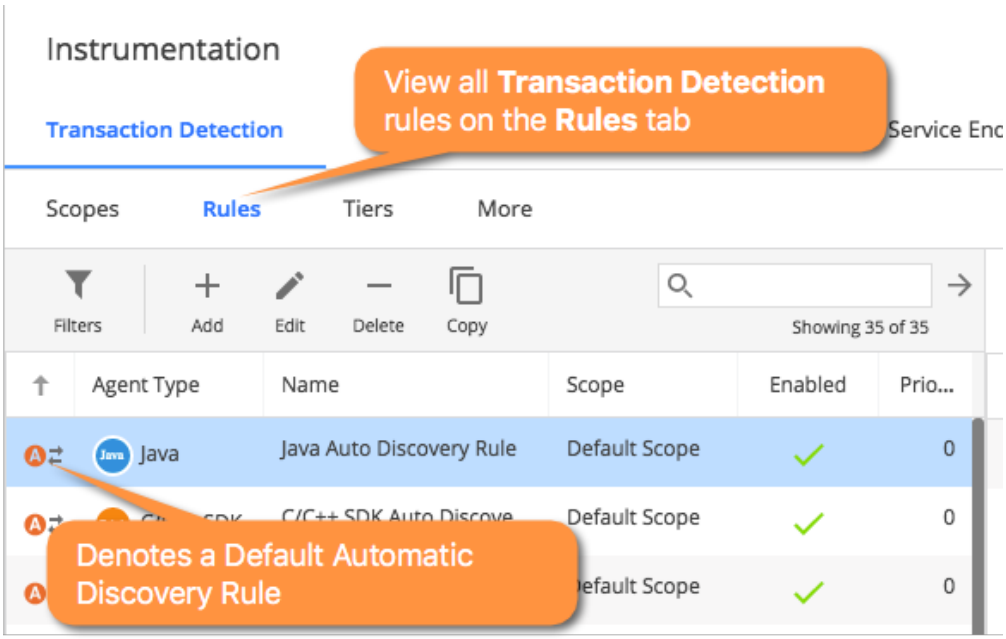
If you want to continue monitoring custom match rules, you can disable **Discover transactions automatically for <***entry point type***>**. When you disable automatic transaction discovery, the app agent stops reporting metrics for previously-detected transactions for the now disabled entry point type. The agent only detects transactions based on custom match rules. However, disabled transactions are not deleted or excluded. See Organize Business Transactions for information on deleting transactions.

- The agent does not discover any new transactions based on the Default Automatic Transaction Discovery Rule for the disabled type.
- The agent no longer auto-detects calls to methods and operations of the disabled entry point type.
- Custom match rules for the entry point type remain active and the agent reports metrics for transactions resulting from custom matches.
- Exit point detection remains enabled.

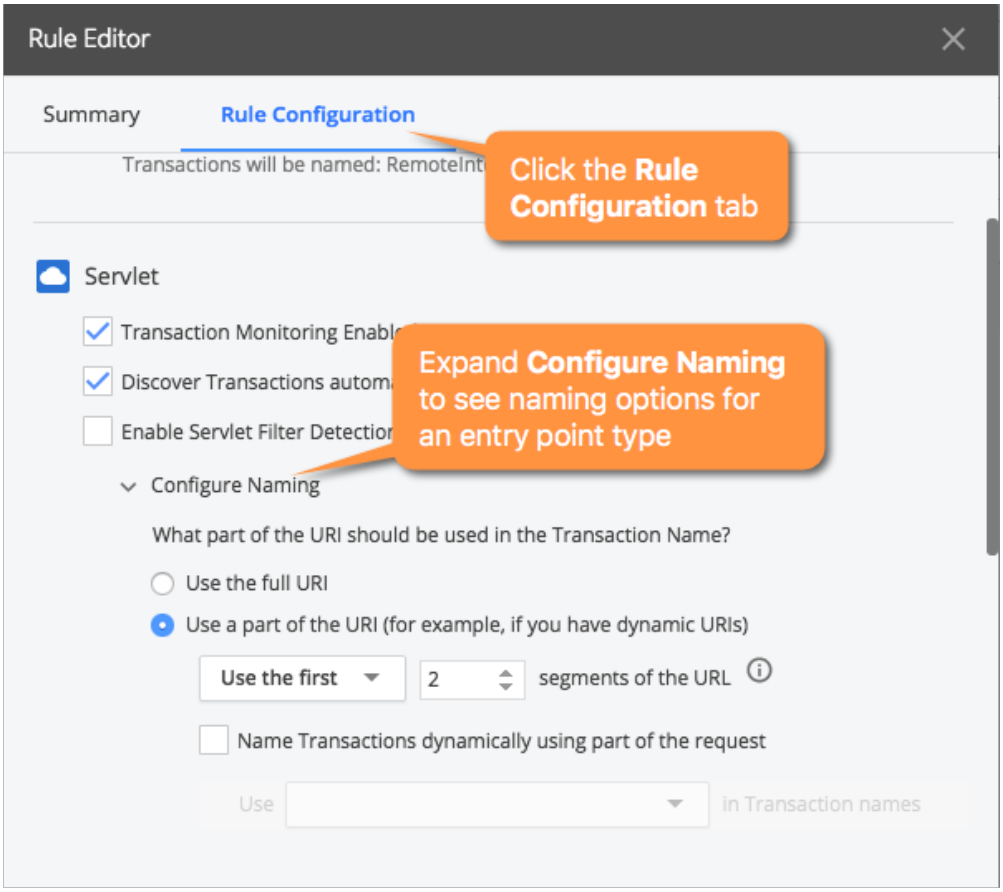
The *Discover Transactions automatically* configuration does not apply to POJO entry points or POCO entry points.

Customize Transaction Naming for an Entry Point

To view and edit the business transaction automatic discovery rules, go to **Configuration > Instrumentation > Transaction Detection**.



To customize transaction naming for an entry point type, double-click a Default Automatic Transaction Discovery rule for specific agent type. Click the Rule Configuration tab to see entry points for the rule. Entry point types that have customizable naming options have the **Configure Naming** expander, as shown below.



For more information specific to customizing naming for URI-based transactions, see URI Based Entry Points.

You can also customize transaction naming using a Custom Match Rule.

Transaction Detection for Apache Web Servers

The AppDynamics Apache Agent monitors web server entry points and names business transactions originating on Apache web server tiers based on the request URI. You can modify the default business transaction naming scheme if needed.

Default Automatic Naming for Web Transactions

By default, the AppDynamics auto-detection naming scheme identifies all web server transactions using the full URI before the query string. For example, the following URI represents a funds transfer operation for an online bank:

```
http://bank.example.com/Account/Transferfunds/California
```

Based on the default scheme, the business transaction would be named /Account/Transferfunds/California.

You can customize the auto-detected naming scheme by configuring identification based on:

- URI segments
- Headers, cookies, and other parts of HTTP requests

To customize auto-detected naming:

1. On the **Transaction Detection** page, select the application or tier to configure and click the Web Server tab.
2. Verify that Transaction Monitoring is enabled and click **Discover Transactions automatically for http web requests**.
   If you disable Discover Transactions automatically for WEB requests, the agent doesn't discover WEB transactions even if you configure custom naming.
3. Click **Configure Naming** for the Web type in the Entry Points panel.

Identify Transactions Using URI Segments

AppDynamics offers several options to automatically name web transactions based on the URI. Consider the following URL representing a checkout operation in an online store:

```
http://onlinestore.example.com/Web/Store/Checkout
```

You can configure AppDynamics to identify a more meaningful name using one of the following options:

- Click **Use the first** or **Use the last** to use the selected number of contiguous segments at the beginning or end of the URI. For example, to identify the checkout transaction using the last two segments of the URI: /Store/Checkout.
- If you need more flexibility, such as using non-contiguous segments in the name, click **Name Transactions dynamically using part of the requests** and specify the segments with the **Use URI segments in Transaction names** option.
- To name the transaction for specific URI segments, click **Use URI segment(s) in Transaction names**. This enables you to skip URI segments or use non-contiguous segments in the naming scheme.
  Enter the segment numbers separated by commas: 1, 3. For example, the following URL represents the checkout transaction requested by a customer with ID 1234:
  `http://onlinestore.example.com/Store/cust1234/Checkout`
  The checkout transaction is the same regardless of the customer, so it makes sense to omit the customer ID and name the transaction based on the first and third segments of the URI: /Store/Checkout.

Identify Transactions Using Headers, Cookies, and Other Parts of HTTP Requests

To identify business transactions using particular parts of the HTTP request, click **Name Transactions dynamically using part of the request** and configure the option that makes sense for your application.

Carefully consider your naming configuration choices. If you use a value such as the request originating address and you have many clients accessing your application, it's likely that you would quickly reach the maximum number of registered business transactions. See "About the "All Other Traffic" Business Transaction" in Business Transactions for information about this event.

The following provides sample results based on the configuration options:

- To name transactions based upon the parameter name, click **Use a parameter value in Transaction names** and enter the **Parameter Name**.
  For example, when you name the following transaction using the parameter name "category": http://example.com/Store/Inventory?category=electronics, AppDynamics names the transaction to include the category parameter value: /Store/Inventory.electronics.
- To use a header value in transaction names, click **Use header value in transaction names** and enter a **Header Name**.
  For example, if you name the transaction using a header such as "Version", AppDynamics names transactions with the header value as follows: /Store/Inventory.v2.5.
- To use a cookie value in transaction names, click **Use a cookie value in Transaction names** and enter the **Cookie Name**.
  For example, for a website that tracks a user's loyalty status in a cookie. Set the Cookie Name to "loyalty". AppDynamics names transactions for the loyalty cookie value: /Store/Inventory.Status=Gold.
- To Use a session attribute value in transaction names, Click **Use a session attribute in Transaction names** and enter the **Session Attribute Key**.
  For example, a website stores a customer's region in the session property. Set the Session Attribute name to "region". AppDynamics names transactions for the region session attribute value: /Store/Inventory.NorthAmerica.

- To use the request method in Transaction names, click **Use the request method (GET/POST/PUT)** in Transaction names.
  For example: /Store/Inventory.GET.
- To use the request host in Transaction names, click **Use the request host in Transaction names**. For example: `/Store/Inventory.192.0.2.0`
- To use the request originating address in Transaction names, click **Use the request originating address in Transaction names**.
  AppDynamics names transactions for the IP address of the request client. For example: `/Store/Inventory.192.0.2.10`.
- To use a regular expression on the URI to name the transaction, click **Apply a custom regular expression on the transaction name**.
  AppDynamics uses the following rules to name the transaction:
  - The Apache Agent uses Perl style regular expressions.
  - AppDynamics tests the regular expression against the segments specified in the configuration.
  - AppDynamics names the business transaction for the substring match.
  - If the regular expression pattern isn't found, the business transaction name follows the URI rules.
  - If you use groups in the regular expression, AppDynamics names the business transaction for the first matching group. If no matching groups are found in the pattern match, AppDynamics names the transaction for the fully matched substring.
    For example consider the following URL: `http://mywebapp.example.com/abc/;jsessionid=12345008;mykey=mytransaction;anotherkey=foo`.
    Use the first two segments of the URI with the following regular expression to name the transaction for the value of *mykey*: `.*mykey.(\w+).*`.
    In this instance AppDynamics names the transaction *mytransaction*.

Custom Match Rules and Exclude Rules

You can create custom match rules and exclude rules for Web type entry points for Apache Agent. The configuration parameters work the same as those for custom naming in this page. If an excluded request on the Web Server tier passes to another instrumented tier such as Java, PHP, or Python, the downstream agent will detect the transaction. See Custom Match Rules.

Validation for Automatic Transaction Discovery Rules

When you first create a business application in AppDynamics, the Default Scope ensures that all tiers for the application have a default automatic discovery rule for every agent type. Because the scope configuration model is highly configurable, the Controller UI enforces validations in the following cases:

- When you change the automatic discovery rules for a scope.
- When you assign or reassign tiers to a scope.

When you attempt to make an invalid change, the Controller prevents the change and displays a message in the Controller UI.

These validations ensure that after configuration updates every tier in your business application has the default automatic discovery rule for its agent type. They also ensure that there is an automatic discovery rule for all agent types to handle any prospective tiers you add to your application.

Existing Tiers

Every existing tier must belong to a scope that includes an automatic transaction detection rule for the tier's agent type. For example, a Java tier must belong to a scope with a Java automatic transaction detection rule.

The following rules apply:

- You can remove a tier from scope only when the tier has an auto-discovery rule from another scope.
- You can remove an automatic transaction detection rule from a scope only when tiers have auto-discovery rule from another scope.

Prospective Tiers

To ensure that any new tier you add to your application has an automatic transaction detection rule available, there must be at least one automatic transaction detection rule for each agent type in a scope of the following types:

- A scope that contains all tiers.
  OR
- A scope that contains all tiers excluding specific existing tiers.

Custom Match Rules

Related pages:

- Using Regular Expressions
- Custom Exclude Rule Examples
- .NET Agent for Linux Business Transaction Configuration

A custom match rule is a type of transaction detection rule that enables you to define criteria for business transaction discovery, and naming for an entry point type.

There are two types of custom match rules:

- A custom include rule defines an entry point to use in a new transaction.
- A custom exclude rule lets you prevent AppDynamics from detecting business transactions you are not interested in tracking. For example, application framework services, administrative console requests, or heartbeat pings, and so on.

Use Live Preview to experiment with certain custom match rule configurations and identify potential business transaction entry points:

- During a Business Transaction Discovery Session, you can use the Classes/Methods browser or Uninstrumented Code to create POJO and POCC custom match rules.
- When you create or edit a POJO or Servlet entry point, you can use Live Preview for the individual rule you are creating.

Transaction Naming

When an app agent detects a request that matches a custom include rule, it names the business transaction based on the rule name. You can further refine the transaction name using transaction splitting for URI based rules, for POJOs, or for POCOs.

If a request matches more than one custom include rule, it applies the rule with the highest number priority. See Transaction Detection Rules.

Create a Custom Match Rule

1. Navigate to **Configuration > Instrumentation** and select the **Transaction Detection** subtab.
2. Select the Rules subtab.

   > You can also add a rule within a specific scope on the Transaction Detection tab.

3. Select **Add** to open the Add Rule page with *Custom Match Rule* selected.
4. Select the **Agent Type** and the **Entry Point Type** and select **Next**.
5. On the Summary tab, make general rule configurations:
   - If you are creating a custom match exclude rule, click **Exclude Transactions discovered by this rule**.
   - Enter the rule *Name*. The app agent names requests that match the rule for the rule name.

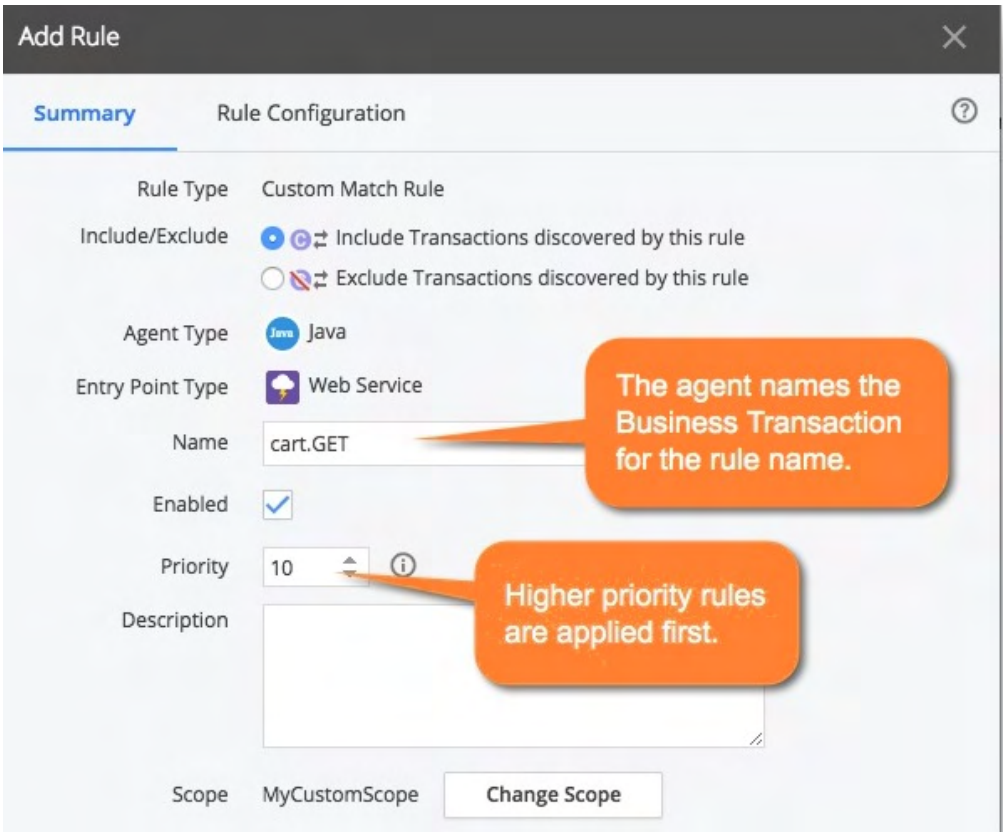
     > To avoid errors, do not include these special characters in the rule name: less than sign (<) and greater than sign (>).

   - Optionally disable the rule, set the rule *Priority* and assign the rule to a *Scope.*
     For information on rule priorities, see Transaction Detection Rules.
     For information on scopes, see Scope Configuration Model.
6. On the Rule Configuration tab, configure the match criteria based upon the entry point type. The PHP web choices, for example, let you specify HTTP-oriented match criteria, such as those for HTTP method, URI, and query parameters.

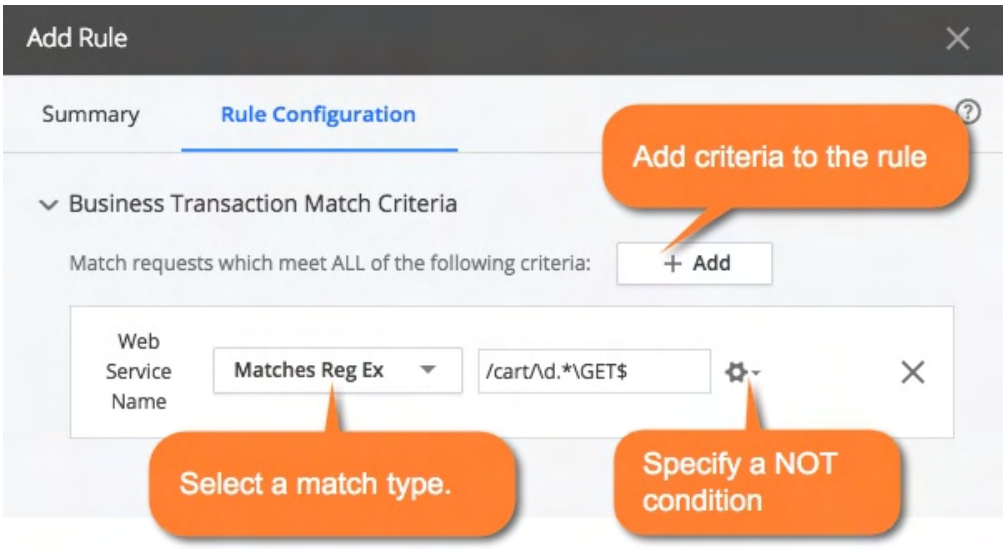
   > Servlet and POJO entry point types feature a *Live Preview* button to launch custom match rule live preview session. A live preview streams data from an active node so you can interactively experiment with rule configuration in the Add Rule window.

Custom Match Include Rule Example

This example shows a custom match include rule named *cart.GET* in a scope named MyCustomScope.



The "cart.GET" rule generates business transactions for Web Service GET requests where the URI begins with `/cart/` followed by a number. AppDynamics names the resulting business transaction `cart.GET`:



You can add conditions to the rule to match based on specific HTTP parameters or hostnames.

For certain HTTP-based request types, such as Servlets or ASP.NET, a match rule can have more than one HTTP Parameter match condition. A request must match all HTTP Parameter conditions to match this rule. There is an implicit AND operator between the parameters rather than an OR operator.

You can use more complex regular expression matching. For example, the following request URLs:

- `example.com/aaa123.aspx`
- `example.com/b1.aspx`

To match any incoming request URL to this business transaction, use:

```
example\.com/[a-zA-Z]]+?[0-9]+?
```

Any request to a URL that includes `example.com` followed by uppercase or lowercase letters and numbers would match this business transaction detection rule. A URL that has no digits after the letters, such as `example.com/z.aspx` does not match.

See Using Regular Expressions for more information on using regular expressions in the UI.

Transaction Splitting for URI Based Entry Points

You can configure business transaction splitting for these types of URI based entry points:

- Java Servlet
- ASP.NET
- PHP Web
- Node.js Web
- Python Web
- Web Server

When you enable transaction splitting, the agent resolves a subset of requests that match the custom include rule into a separate business transaction based on a dynamic part of a request. The app agent names the transaction:

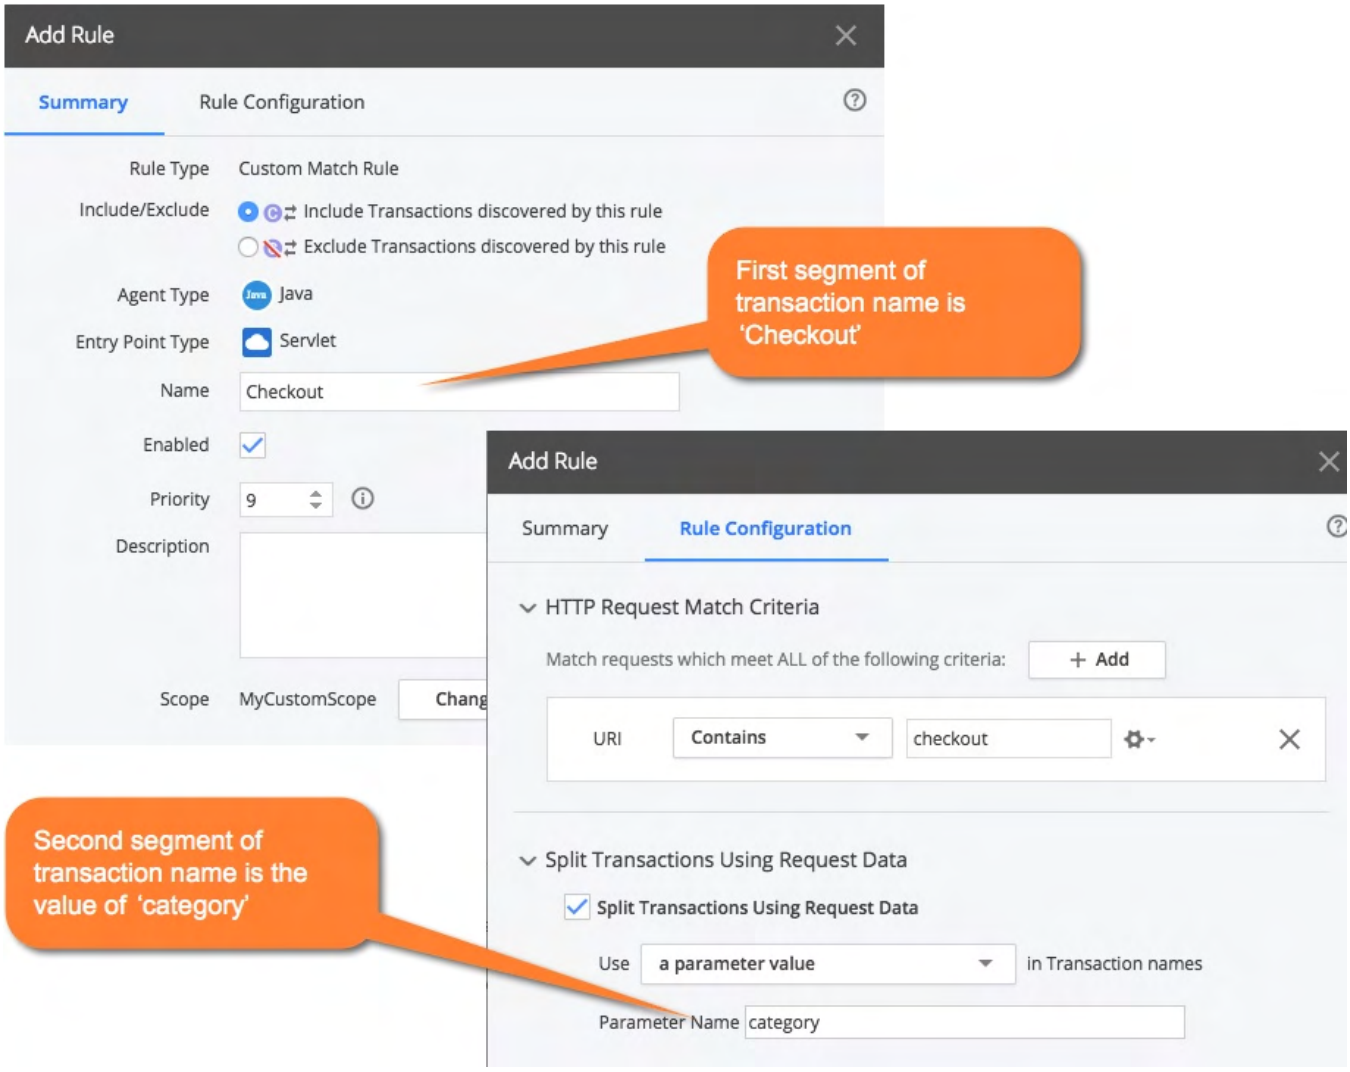
```
<custom match rule name>.<name derived from the split configuration>.
```

Consider an application with incoming requests:

- `http://nwtrader.com/checkout?category=electronics`
- `http://nwtrader.com/checkout?category=clothing`

This example shows how to configure transaction splitting to resolve two requests into two different business transactions, named:

- Checkout.electronics
- Checkout.clothing



You can split servlet transactions based upon the payload. See Split Servlet Transaction by Payload Examples.

Default Custom Exclude Rules

AppDynamics includes default exclude rules for the entry points for frameworks that are not usually of interest. Navigate to **Configuration** > **Instrumentation > Transaction Detection > Rules** and filter on **Rule Type: Custom Exclude** to view or modify the default custom match exclude rules. See Custom Exclude Rule Examples.

To configure exclude rules for Service Endpoints, see Service Endpoints.

Java Business Transaction Detection

This page lists different types of Java entry points for business transactions.

A tier can have multiple entry points. For example, a Java framework implementation may have a combination of pure Servlets or JSPs, Struts, Web services, and Servlet filters, all co-existing as monitored entry points on the same JVM.

The middle-tier components like EJBs and Spring beans are usually not considered entry points because they are normally accessed using either the front-end layers such as Servlets or from classes that invoke background processes.

For details on types of Java entry points and how to set up custom match rules, see:

- Servlet Entry Points
- Struts Entry Points
- Spring Bean Entry Points
- EJB Entry Points
- POJO Entry Points
- Web Service Entry Points
- Binary Remoting Entry Points for Apache Thrift
- CometD Support
- JAX-RS Support
- Spring Integration Support

Servlet Entry Points

AppDynamics automatically detects requests to servlet-based entry points and generates business transactions based on the requests. For general information on how to customize automatic transaction detection, see URI Based Entry Points.

Frameworks Supported as Servlets or Servlets Filter

AppDynamics supports many web frameworks based on servlets or servlet filters. The servlet configuration settings in AppDynamics apply to these frameworks as well as to plain servlets. Frameworks include:

- Spring MVC
- Wicket
- Java Server Faces (JSF)
- JRuby
- Grails
- Groovy
- Tapestry
- ColdFusion

Custom Match Rules for Servlet Transactions

Custom match rule let you control how business transactions are generated for Servlet-based requests.

Match Conditions

Match conditions can be based upon the URI, HTTP method, hostname, servlet name, or other characteristics of the request.

For HTTP Parameter conditions, you can add more than one. If you configure more than one HTTP Parameter match criteria, they must all be met by a request to be subject to this business transaction identification and naming rule, as must all conditions you configure for the rule.

Some of the options have NOT conditions that you can choose to negate the configured condition. Choose this option in the gear icon next to the condition.

Splitting Transactions using Request Data or Payload

If you match by URI, you can have the transaction identified (or split) based on values from the request, such as URI patterns, request data, or payload. See URI Based Entry Points for information on naming or splitting transactions by the request elements.

When you create the rule, it appears in the Custom Match Rule list, where you can enable, disable, edit or remove the rule.

See Split Servlet Transaction by Payload Examples for use case examples.

POST Request Body Parameter Matching Considerations

You can configure Servlet-based custom match that match POST requests based on HTTP body parameter values. To avoid interfering with the operation of the application, the Java Agent applies some special processing measures and limits on how it accesses the body parameters. This behavior can affect whether requests can be matched by POST body parameters for your particular application. If you are having trouble configuring matching by HTTP parameter in POST requests, you should understand this behavior.

Transaction Naming Match Criteria

For transaction match criteria, match conditions for HTTP parameters work under these conditions:

- If the parameter is a query string in the URL of the POST request, as opposed to the request body.
- If the Servlet Request body parameters have already been read and parsed by the application prior to the invocation of the servlet. A Servlet Filter, for example, may do this.

Otherwise, custom servlet match rules do not match HTTP parameter values in POST requests.

Transaction Splitting

For transaction split rules based on parameter matching in POST requests, the Java Agent defers transaction naming for incoming requests until the application servlet has accessed the request parameters.

The Java Agent considers the parameters "accessed" once the application invokes `getParameterMap()`, `getParameter()`, `getParameterNames()`, or `getParameterValues()` on the ServletRequest object. If the servlet does not call one of these methods, the agent will not apply the split rule and the transaction will not be named.

Exclude Rules for Servlets

To prevent specific Servlet methods from being monitored, add a custom exclude rule. The controls for selecting Servlets to exclude are the same as those for custom match rules.

Split Servlet Transaction by Payload Examples

AppDynamics lets you split servlet custom match rules according to the request payload. For each of these examples, you must create a servlet custom match rule and enable the URI option on the Rule Configuration tab.

Split by POJO Method Call

Using a Java method to name a transaction is useful when:

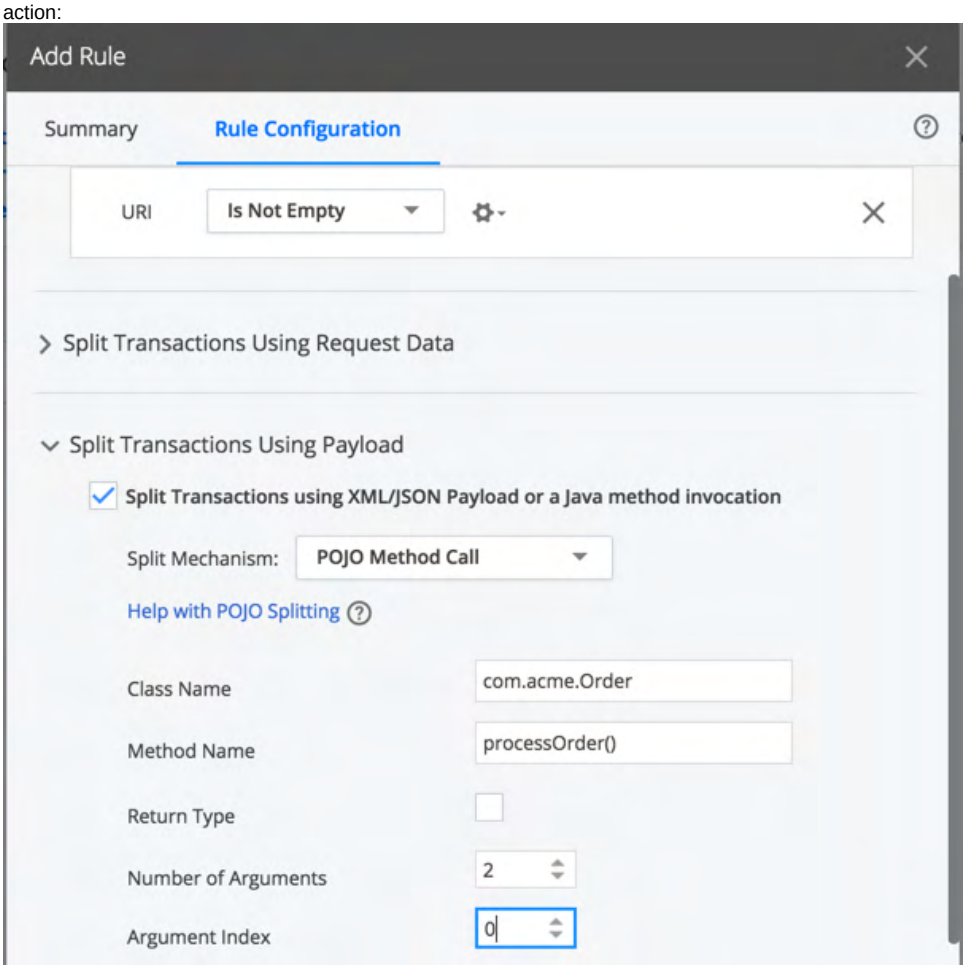
- You might not have a clear URI pattern, or
- You are using an XML/JSON framework not otherwise supported

For example, consider the `processOrder()` method in the `doPost()` method of the servlet at the following URL: `http://acmeonline.com/store`.

```
public void doPost(HttpServletRequest req, HttpServletResponse resp) {
   //process the data from the sevlet request and get the orderType and the items
   processOrder(orderType,item)
   ...
}
public void processOrder(String orderType,String item) {
   //process order
}
```

You want to derive transaction naming from the first parameter to the `processOrder()` method, `orderType`.

1. On the Rule Configuration tab for the custom match rule, enable the **Split Transactions using the XML/JSON payload or Java method invocation**.
2. Select **POJO Method Call** as the splitting mechanism.
3. For the method, choose the processOrder, and specify the parameter to use by numeric position in the parameter (0 index). The following screenshot displays the configuration of a custom match rule which will name all the qualifying requests into a `Store.order.creditcard` trans action:



In addition to the parameter, you can also specify either the return type or a recursive getter chain on the object to name the transaction. For example, if the method parameter points to a complex object like PurchaseOrder, you can use something like getOrderDetails().getType() to correctly name the transaction.

Split Transaction by JSP Name

You can identify transactions by JSP name, as follows:

1. On the Rule Configuration tab, enable the **Split Transactions using the XML/JSON payload or Java method invocation**.
2. Select **POJO Method Call** as the splitting mechanism.
3. Set the name of the class to `com.sun.faces.application.ViewHandlerImpl`.
4. Set the name of the method to `renderView()`.
5. Set the argument index to 1.
6. Define the Method Call Chain or getter as `getViewId()`. The agent appends the value to the name of the transaction as follows: *<Name of the Custom Rule>.<path to jsp>*.

You can later rename these business transactions to a more user-friendly name if you like.

Split Transactions on XPath Expression

You can access values in an XML payload for business transaction naming or splitting using an XPath expression. Consider the following example from an Ecommerce order transaction where the XML represents an order for three items. The order uses credit card processing, which is the distinguishing element for this body:

```
<acme>
   <order>
      <type>creditcard</type>
      <item>Item1</item>
      <item>Item2</item>
      <item>Item3</item>
   </order>
<acme>
```

The URL is:

```
http://acmeonline.com/store
```

The `doPost()` method of the Servlet is:

```
public void doPost(HttpServletRequest req, HttpServletResponse resp) {
   DocumentBuilderFactory docFactory =
   DocumentBuilderFactory.newInstance();
   DocumentBuilder docBuilder = docFactory.newDocumentBuilder();
   Document doc = docBuilder.parse(req.getInputStream());
   Element  element = doc.getDocumentElement();
   //read the type of order
   //read all the items
   processOrder(orderType,items)
   ...
}
```

Imagine you want to differentiate "Order" transactions based upon the type of order. You can use the XPath expression `//order/type` on this XML payload, which in this example evaluates to `creditcard`.

1. On the Rule Configuration tab, click **Split transactions using XML/JSON Payload or a Java method invocation**.
2. Choose **XPath Expressions** for the Split Mechanism.
3. Enter the XPath expression that points to the value of the XML element to use for naming. In this example, `//order/type`

The agent appends the value of the XPath expression to the name of the business transaction, for example, `Store.order.creditcard`. Even though the agent doesn't name the transaction until after XML parsing, AppDynamics measures the duration of the business transaction to include the execution of the `doPost()` method.

You can use one or more XPath expressions to chain the names generated for the Business Transaction.

You can specify whether the request results in transaction splitting when the expression does not evaluate to a value.

Split Transactions on Java XML Binding

You can identify transactions for Java XML data binding frameworks for these types of frameworks:

- Castor
- JAXB
- JibX
- XMLBeans
- XStream

In the following example, the posted XML is unmarshalled to the `PurchaseOrderDocument` object, and the `getOrderType()` method should be used to identify the type of the order:

```
<acme>
   <order>
     <type>creditcard</type>
      <item>Item1</item>
      <item>Item2</item>
      <item>Item3</item>
   </order>
<acme>
```

The following snippet shows the `doPost()` method for the Servlet:

```
public void doPost(HttpServletRequest req, HttpServletResponse resp) {
   PurchaseOrderDocument poDoc = PurchaseOrderDocument.Factory.parse(po);
   PurchaseOrder po = poDoc.getPurchaseOrder();
   String orderType = po.getOrderType();

   //read all the items
   processOrder(orderType,items)
   ...
}
```

To split the transaction based upon the XML Binding:

1. On the Rule Configuration tab, check **Split transactions using XML/JSON Payload or a Java method invocation**.
2. Select **Java XML Binding** as the split mechanism.
3. Enter these values for the match criteria:
    - Unmarshaled Class Name: `PurchaseOrderDocument`
    - Method name: `getOrderType()`

The agent identifies the business transaction for this example as `Store.order.creditcard`:

This custom rule ensures that the Java agent intercepts the method in XMLBeans (which unmarshalls XML to Java objects). If the name of the transaction is not on a first level getter on the unmarshalled object, you can also use a recursive getter chain such as `getOrderType().getOrder()` to get the name.

Although the transaction name is not obtained until the XML is unmarshalled, the response time for the transaction is calculated from the `doGet()` method invocation.

Split Transactions on JSON Payload

You can access JSON payload for transaction identification purposes using the method where the Servlet unmarshalls the payload.

For example, the following JSON payload posts an `order` for an item `car` and uses `creditcard` for processing the order. The URL is `http://acmeonline.com/store`:

```
order :{
  type:creditcard,
  id:123,
  name:Car,
  price:23
}}
```

The following code snippet shows the `doPost` method of the Servlet:

```
public void doPost(HttpServletRequest req, HttpServletResponse resp) {
   //create JSONObject from servlet input stream
   String orderType = jsonObject.get("type");
   //read the item for the order
   processOrder(orderType,item)
   ...
}
```

After the application unmarshalls the posted JSON payload to the JSON object, the *type* key is available to identify the type of the order. In this case, this key uniquely identifies the business transaction.

To use the JSON payload for transaction identification you must set the `enable-json-bci-rules` node property to `true` on each node to enable this rule. To configure the rule:

1. On the Rule Configuration tab, check **Split transactions using XML/JSON Payload or a Java method invocation**.
2. For the JSON object key, enter the name of the JSON object. For example, `type`.

The agent automatically intercepts the `JSONObject.get("$JSON_Object_Key")` method to name the transaction. Although the agent doesn't obtain the transaction name until the JSON object is unmarshalled, the response time for the transaction will be calculated from the `doGet()` method.

Struts Entry Points

When your application uses Struts to service user requests, AppDynamics intercepts individual Struts Action invocations and names the user requests based on the Struts action names. A Struts entry point is a Struts Action that is being invoked.

AppDynamics supports the following versions of Struts:

- Struts 1.x
- Struts 2.x

Struts Action invocations are typically preceded by a dispatcher Servlet, but identification is deferred to the Struts Action. This ensures that the user requests are identified based on the Struts Action and not from the generic URL for Dispatcher Servlet.

The response time for the Struts-based transaction is measured when the Struts entry point is invoked.

Struts Request Names

When a Struts Action is invoked, by default AppDynamics identifies the request using the name of Struts Action and the name of the method. All automatically discovered Struts-based transactions are thus named using the convention `<Action Name>.<Method Name>`.

For example, if an action called ViewCart is invoked with the SendItems(), the transaction is named `ViewCart.SendItems`.

For Struts 1.x the method name is always `execute`.

You can rename or exclude auto-discovered transactions. See Organize Business Transactions.

Custom Match Rules for Struts Transactions

For finer control over the naming of Struts-based transactions, use custom match rules.

A custom match rule lets you specify customized names for your Struts-based requests. You can also group multiple Struts invocations into a single business transaction using custom match rules. See Custom Match Rules for information about accessing the configuration screens.

The matching criteria for Struts transactions are: Struts Action class names, Struts Action names, and Struts Action method names.

Exclude Rules for Struts Actions or Methods

To prevent specific Struts Actions and methods from being monitored, add a custom exclude rule. The criteria for Struts exclude rules are the same as those for custom match rules. In particular, you may need to exclude custom-built dispatch servlets, as described next.

Exclude Custom-built Dispatch Servlet

When a Struts action is called, it can demarcate a transaction as an entry point. AppDynamics instruments the Struts invocation handler to get the action name because the Struts action is not an interface. The invocation handler provides the Java Agent with the name of the action being invoked. If the dispatcher Servlet is custom-built and has not been excluded from instrumentation, the wrong entry point could be instrumented and the business transaction could be misidentified.

To address this issue, add a custom exclude rule for the dispatcher servlet or add a BCI exclude for it.

Spring Bean Entry Points

This page describes how to configure transaction entry points for Spring Bean requests.

Spring Bean-based Transactions

AppDynamics allows you to configure a transaction entry point for a particular method for a particular bean in your environment. The response time is measured from when the Spring Bean entry point is invoked (after receipt at a dispatcher servlet).

Default Naming for Spring Bean Requests

When you enable automatic discovery for Spring Bean based requests, AppDynamics automatically identifies all the Spring Beans based transactions and names these transactions using the following format:

```
BeanName.MethodName
```

By default, the transaction discovery for Spring Bean-based requests is turned off. You can enable it in any Automatic Transaction Discovery rule for Java. Select **Discover Transactions automatically for all Spring Bean invocations** on the Rule Configuration tab.

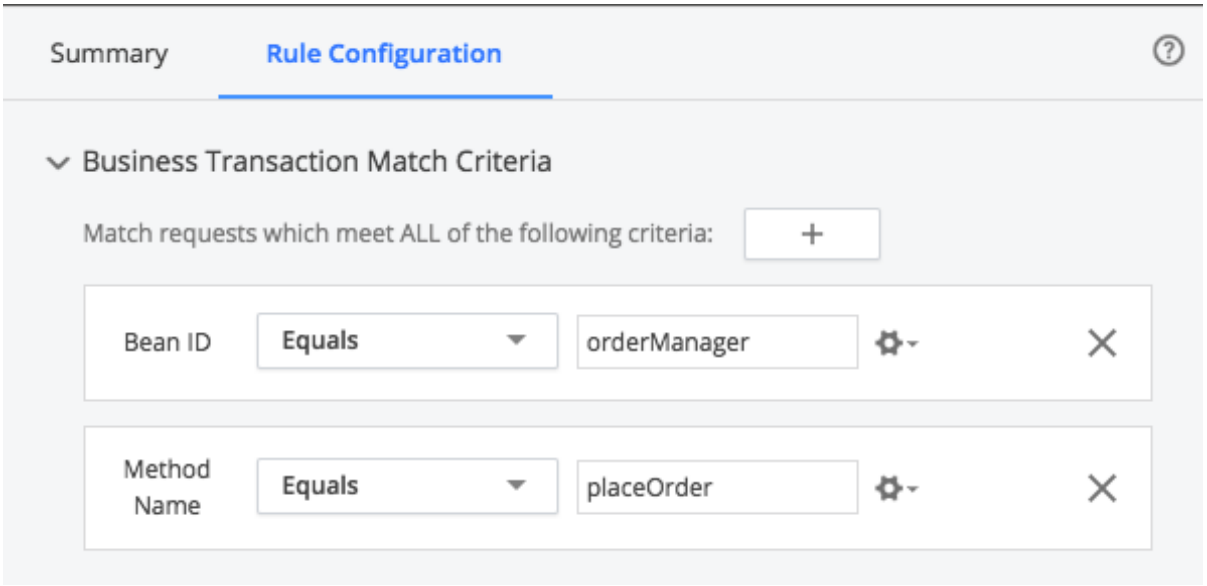
When a class is mapped to multiple Spring bean names, by default only the name of the first Spring bean found is used. This may not be ideal for your application such as cases where a call graph for web service A that has Spring beans from web service B. To contend with this scenario, you can remove the Bean name from the transaction name using the `capture-spring-bean-names` node property, as described on App Agent Node Properties (B-C).

Custom Match Rules for Spring Bean Requests

If you are not getting the required visibility with the auto-discovered transactions, you can create a custom match rule for a Spring Bean based transaction. You can match based on one or more of the following criteria:

- Bean ID
- Method Name
- Class Name
- Extends
- Implements

The following example creates a custom match rule for the `placeOrder` method in the `orderManager` bean.



Exclude Rules Spring Bean Transactions

To exclude specific Spring Bean transactions from detection, add a custom exclude rule.

The criteria for Spring Bean exclude rules are the same as those for custom match rules.

EJB Entry Points

AppDynamics allows you to configure an EJB-based transaction entry point on either the bean name or method name. The response time for the EJB transaction is measured when the EJB entry point is invoked.

Default Naming for EJB Entry Points

AppDynamics automatically names all the EJB transactions <*EJBName*>.<*MethodName*>.

Enabling EJB Transaction Detection

By default, automatic transaction discovery for EJB transactions is turned off. To get visibility into these transactions, enable the auto-discovery for EJB based transactions explicitly.

Before you enable auto-discovery for EJB based transactions, note that:

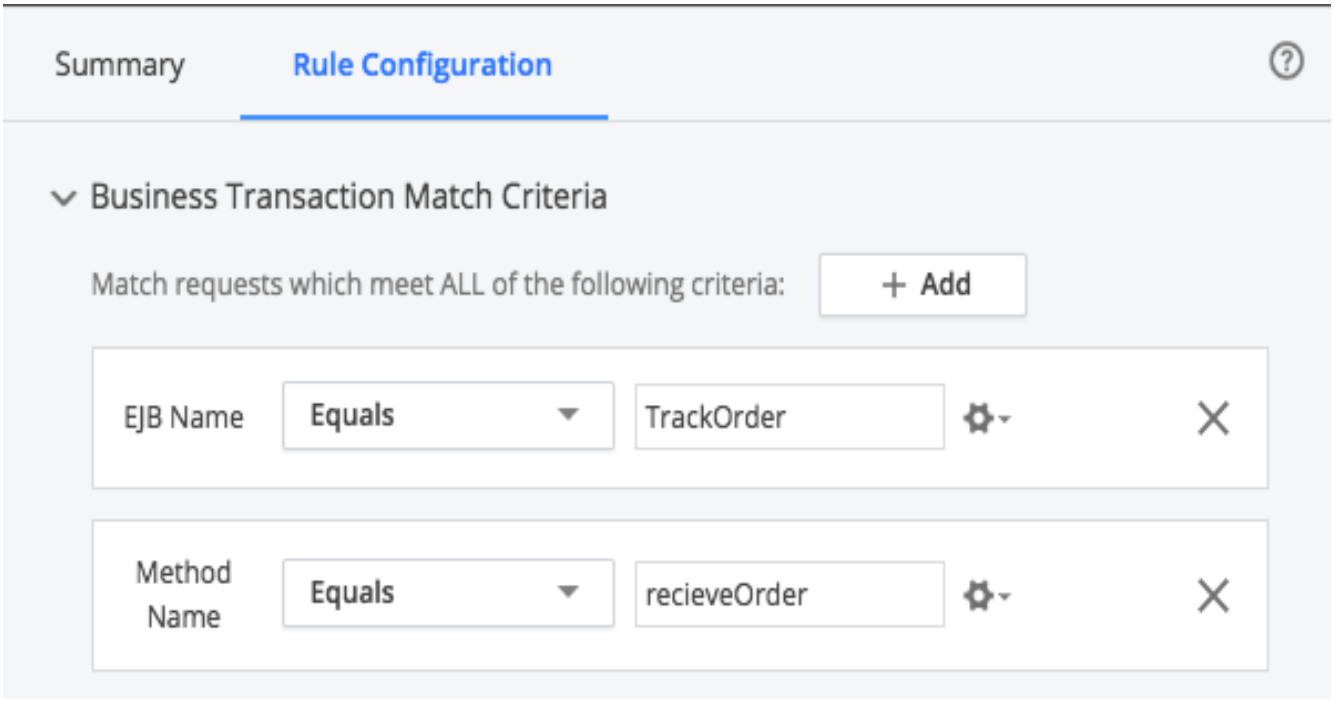
- If the EJBs use Spring Beans on the front-end, the transaction is discovered at the Spring layer and the response time is measured from the Spring Bean entry point.
- AppDynamics groups all the participating EJB-based transactions (with remote calls) in the same business transaction. However, if your EJBs are invoked from a remote client where the App Server Agent is not deployed, these EJBs are discovered as new business transactions.

You can enable auto-discovery for EJB transactions in any Automatic Transaction Discovery rule for Java. Check **Discover Transactions automatically for all Spring Bean invocations** on the Rule Configuration tab.

Custom Match Rules for EJB based Transactions

If you are not getting the required visibility with auto-discovered transactions, create a custom match rule for an EJB based transaction.

The following example creates a custom match rule for the receiveOrder method in the `TrackOrder` bean.



In addition to the bean and method names, other match criteria that could be used to define the transaction are the EJB type, class name, superclass name, and interface name.

Exclude Rules for EJB Transactions

To exclude specific EJB transactions from detection add a custom exclude rule. The criteria for EJB exclude rules are the same as those for custom match rules.

POJO Entry Points

This page describes how to create custom match rules for POJO (Plain Old Java Object) applications. See Custom Match Rule Live Preview for instructions about interactively working with live data to create a POJO.

About POJO Custom Match Rules

Custom match rules for POJOs let you configure business transaction detection in application environments that run pure Java applications or that use frameworks with entry points that are not automatically detected.

Unlike common frameworks, which are characterized by well-known entry points for applications, the logical entry point for a business transaction for a POJO entry point could be any method in the application.

To configure a custom POJO entry point, therefore, you need to identify the method that AppDynamics should consider the business transaction entry point. Keep in mind that the start and end of the execution of the method will correspond to the start and end of the business transaction, so the method should encapsulate the complete execution of the business transaction.

For example, consider the method execution sequence:

```
com.foo.threadpool.WorkerThread.run()
    calls com.foo.threadpool.WorkerThread.runInternal()
        calls com.foo.Job.run()
```

The first two calls to `run()` method are the blocking methods that accept a job and invoke it. The `Job.run()` method is the actual unit of work, because Job is executed every time the business transaction is invoked and finishes when the business transaction finishes.

Methods like these are the best candidates for POJO entry points. The response time for POJO transactions is measured from this entry point, and remote calls are tracked the same way as are remote calls for a Servlet's Service method.

Creating POJO Custom Match Rules

You can create a POJO entry point by adding a custom match rule with *POJO* as the Entry Point Type. The agent names business transactions for the custom match rule.

> In order for the agent to discover POJO transactions, your custom match rule must belong to a scope that also includes a Default Java Automatic Transaction Discovery rule with POJO transaction monitoring enabled.

You can classify matching transactions as background tasks by enabling the **Background Task** check box. When a request runs as a background task, AppDynamics reports only Business Transaction metrics for the request. It does not aggregate response time and calls metrics at the tier and application levels for background tasks. This ensures that background tasks do not distort the baselines for the business application. Also, you can set a separate set of thresholds for background tasks. For more information, see Monitor Background Tasks.

The custom match rule configuration offers several options for matching method invocations and splitting matched calls into separate business transactions, as described below.

> If you are running on IBM JVM v1.5 or v1.6, you must restart the JVM after defining the custom match rules.

Matching by Class and Method

You can specify matching criteria for the custom rule based on various forms of a method or class to which the method belongs.

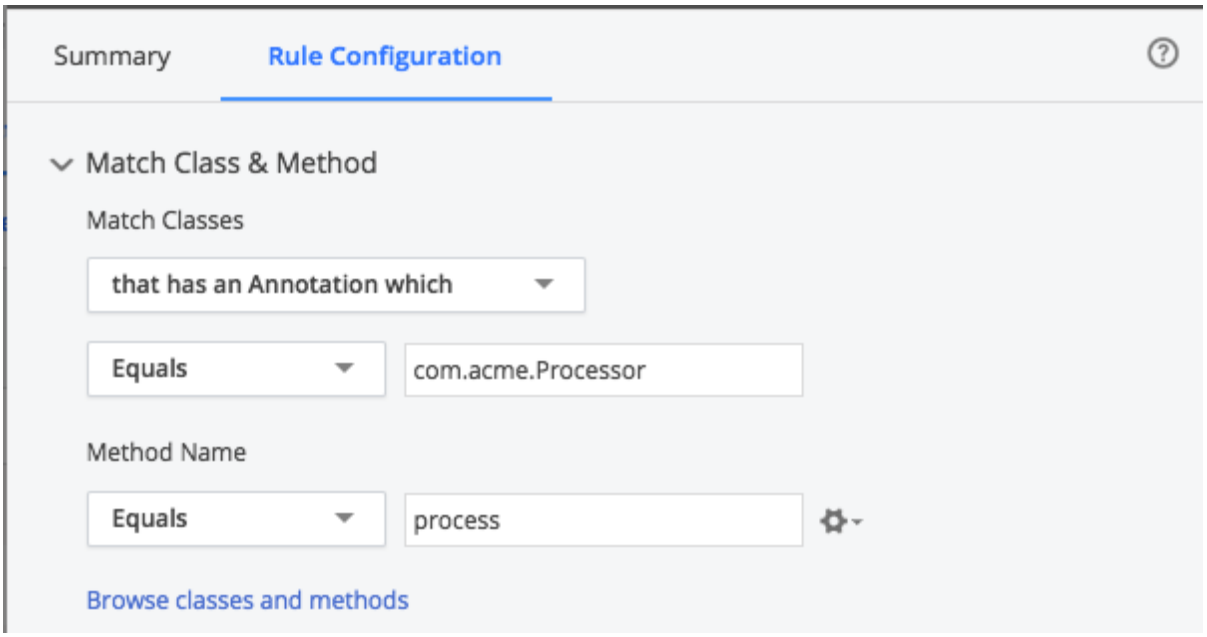
When specifying the method name matching criteria, use parameter matching to match against a particular method signature. For example, say you want t o instrument one of more methods in the following class:

```
class A
{
    public void m1();
    public void m1(String a);
    public void m1(String a, com.mycompany.MyObject b);
}
```

Configure instrumentation for each method based on its signature as follows:

- To instrument the first method signature (with no parameters), create a POJO-based business transaction match rule as follows:
  - Match Classes: with a Class Name that Equals A
  - Method Name: Equals m1()
- To instrument the second method, create a match rule as follows:
  - Match Classes: with a Class Name that Equals A
  - Method Name: Equals m1(java.lang.String)
- To instrument the third method, create a match rule as follows:
  - Match Classes: with a Class Name that Equals A
  - Method Name: Equals m1(java.lang.String, com.mycompany.MyObject)

You can also match methods that belong to classes with certain annotations. For example, say you want to match all classes that are annotated with `@com.acme.Processor`. The custom rule configuration can define the annotation as follows:



When calls to the process() method match, the result is a business transaction named for the custom match rule name.

Matching on Inner Classes and Inner Interfaces

You can match on inner classes and inner interfaces by adding a $ sign after the class name. For example, you could specify the following for the class name:

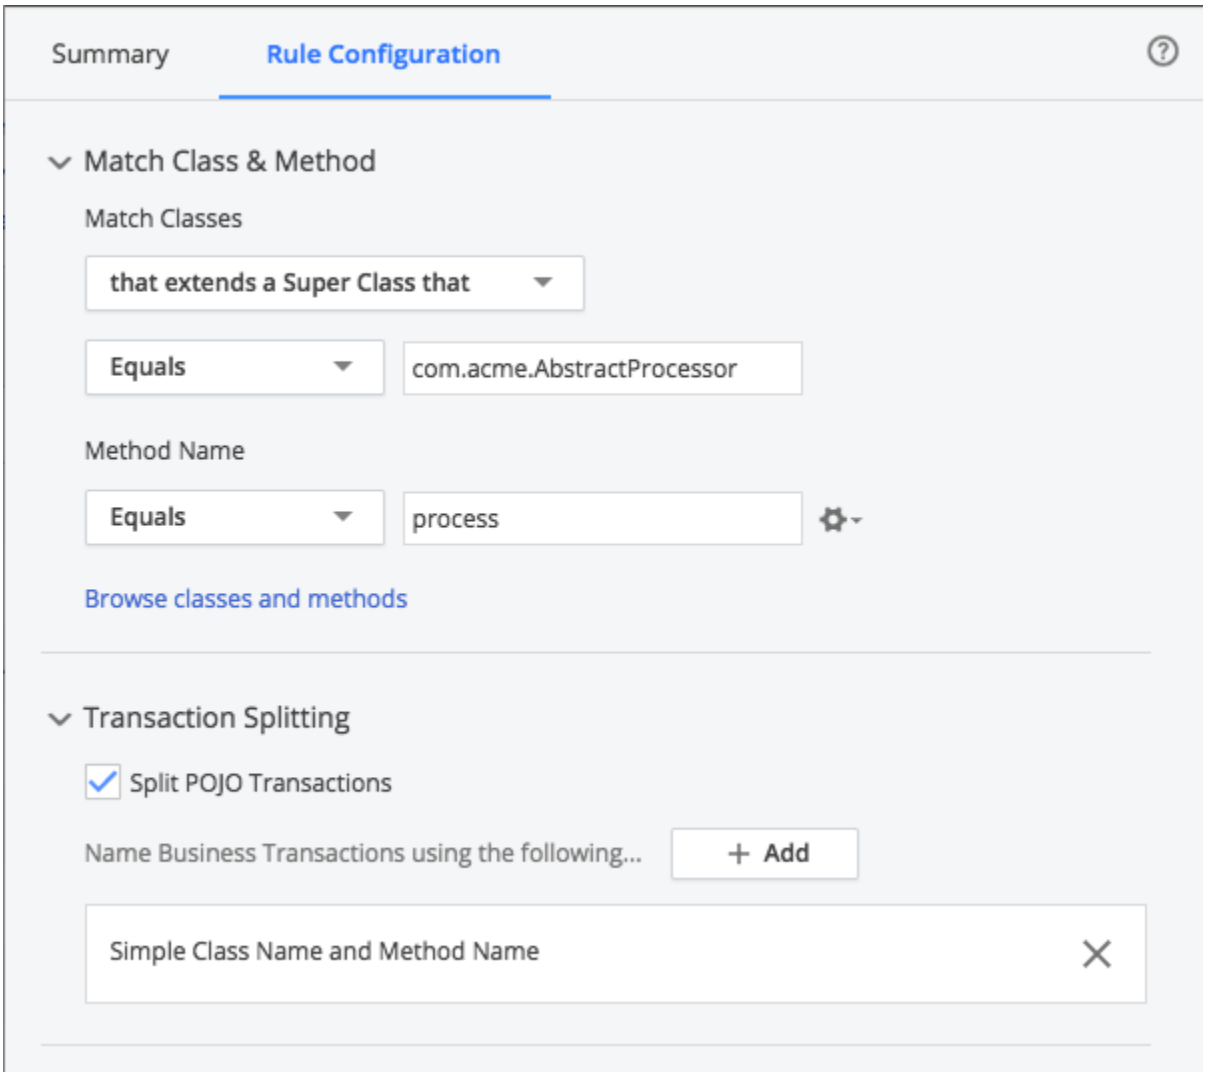
```
com.my.package.OuterClass$InnerClass
```

Splitting Matches into Separate Business Transactions

With only transaction matching configured, all requests matched by the match rule belong to the custom business transaction. Alternatively, you can create a match rule that generates multiple named business transaction based on criteria in the request.

For example, the following configuration defines a custom match rule that matches by superclass. In the example, the entry point matches the `process()` method defined in classes that extend the `com.acme.AbstractProcessor` superclass. In our example, the superclass is extended by the subclasses `SalesProcessor`, `InventoryProcessor`, `BacklogProcessor`.

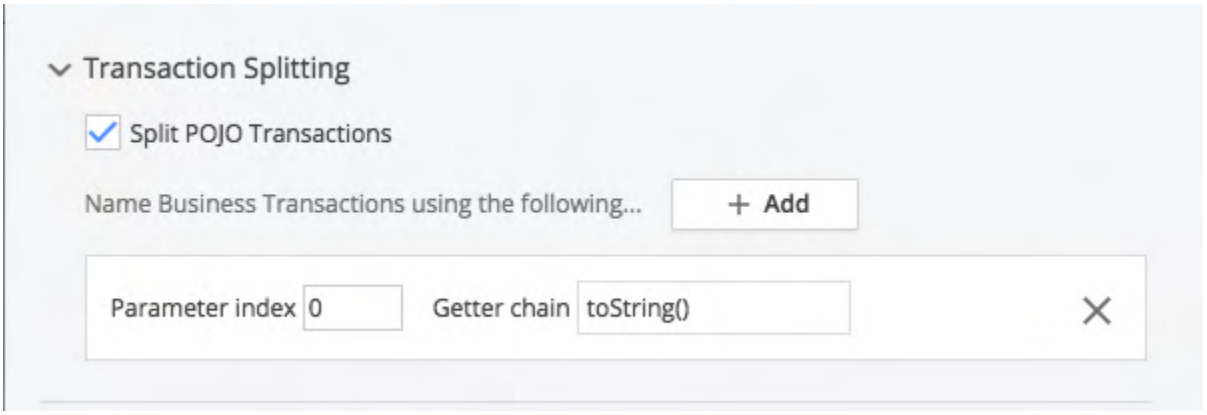
1. Create A custom rule that matches the superclass matches all of those subclasses:
2. Split the transaction on class name, you can have separate business transactions created for the respective subclasses. AppDynamics names the transactions with the class name, prepending the match rule name to the class name. For example, `Process.SalesProcessor`, `Process.InventoryProcessor`, and `Process.BacklogProcessor`.



It's possible that parameter values carry what would be meaningful identifiers for business transactions in your application. For example, say the `jobType` parameter in the following method may have the values of `Sales`, `Inventory` or `Backlog`.

```
public void process(String jobType,String otherParameters...)
```

You can split the transaction based on parameter value by indicating the zero-based position of the parameter in the method signature, 0 in the example:



The `toString()` method indicates how the value of the parameter should be rendered. See Using Getter Chains for more information. As indicated in the dialog, you can use other transaction splitting criteria as well, including thread ID, method name, class name, and so on.

The name of the rule is prepended to the dynamically-generated name to form the business transaction name.

Exclude Matches from Transaction Splitting

An exclude rule defines criteria which, when matched by a transaction instance, prevents transaction splitting from occurring as otherwise configured. In effect, this nullifies the effects of transaction splitting for the subset of transactions matched by the exclude condition.

Monitor Java Interface Static and Default Methods

As of Java 8, Java interfaces can include static and default methods. This page describes how to monitor these types of interface methods.

> Note that another Java language feature introduced in Java 8, lambda method interfaces, are not supported by the AppDynamics Java Agent.

Interface Static Methods

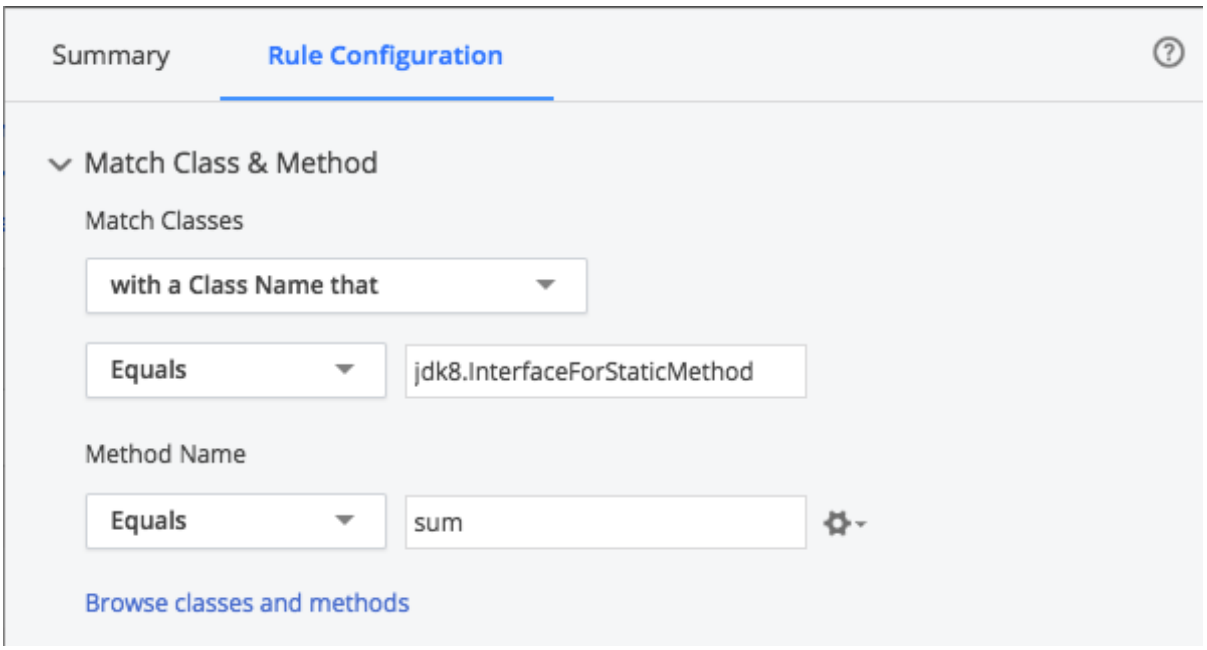
The following code snippet shows an example static interface method:

```
package jdk8;

interface InterfaceForStaticMethod
{
    static int sum(int acc, int x)
    {
        return acc + x;
    }
}
```

The actual bytecode for the method would reside in the compiled class file, so a class match against the interface class in the AppDynamics configuration would result in the instrumentation of that class for a business transaction.

To instrument such methods, create a POJO business transaction match rule for the `interfaceForStaticMethod`, such as:



In this case, the rule would match classes with a Class Name of `jdk8.InterfaceForStaticMethod`.

Interface Default Methods

Interfaces can also define default methods. As with interface static methods, the bytecode for default methods resides in the compiled class files.

When configuring instrumentation for a default method:

- If the targets are classes that do *not* override the default method, target the interface via a class match
- If the targets are classes that do override the default method, target the interface via an interface match

Instrument an Interface Default Method Directly

Given the following interface:

```
package jdk8;

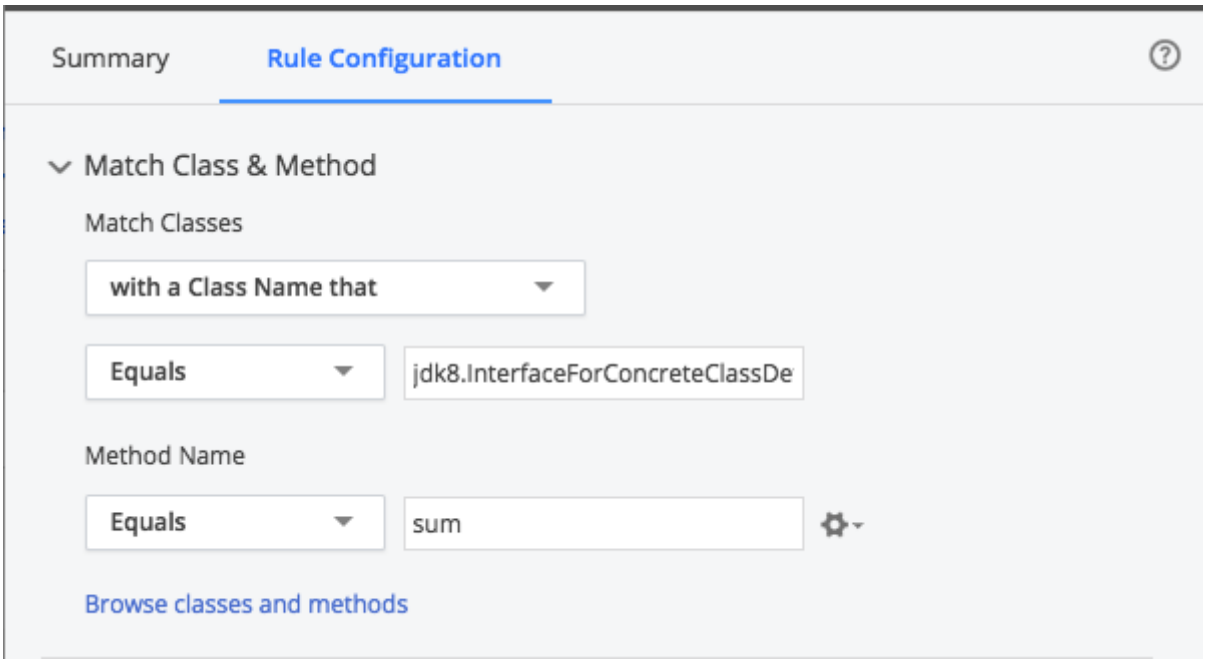
interface InterfaceForConcreteClassDefaultMethod
{
    default int sum(int acc, int x)
    {
        return acc + x;
    }
}
```

And its implementing class:

```
package jdk8;

class ClassForDefaultMethod implements InterfaceForConcreteClassDefaultMethod
{
}
```

In this example, the `ClassForDefaultMethod` does *not* override the default method. Therefore, you can use a class match against the interface such as:



Instrument an Overridden Default Method

Given the following interface:

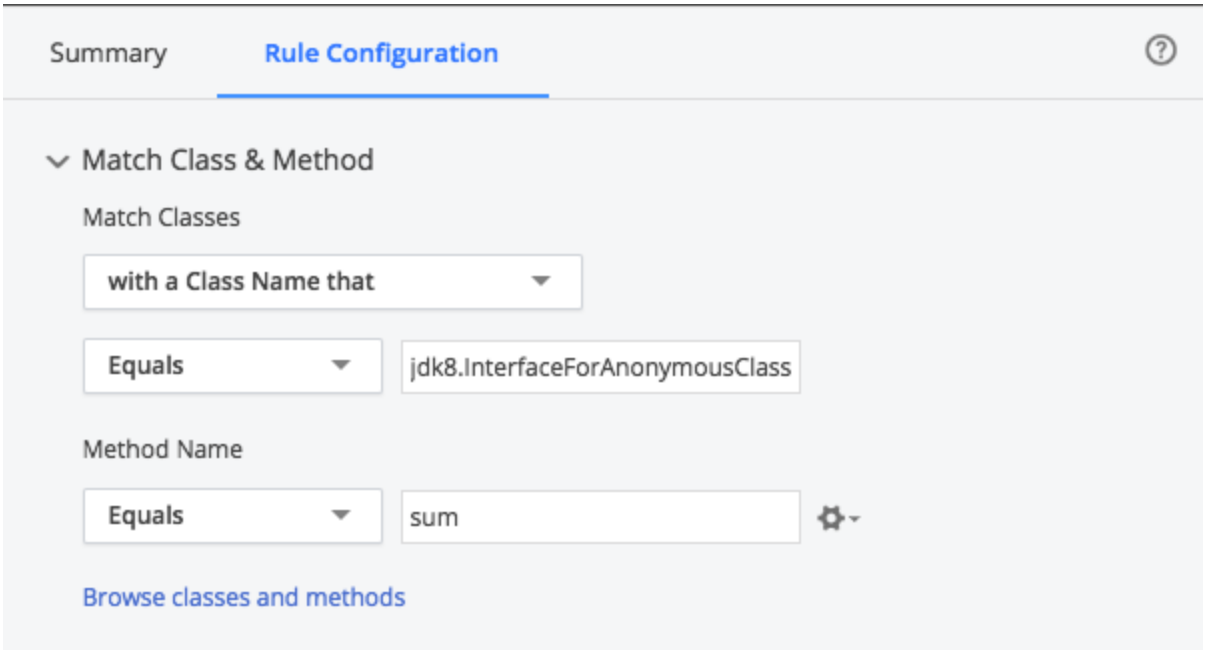
```
package jdk8;

interface InterfaceForAnonymousClassDefaultMethod
{
    default int sum(int acc, int x)
    {
        return acc + x;
    }
}
```

And:

```
InterfaceForAnonymousClassDefaultMethod i = new InterfaceForAnonymousClassDefaultMethod()
{
        @Override
        public int sum(int acc, int x)
        {
                return acc + x;
        }
};
```

Because the method is overridden, the target `bytecode` resides in the anonymous class, `InterfaceForAnonymousClassDefaultMethod`. So you need to create an interface match POJO business transaction match rule such as:



Instrument Java Lambda Expressions

This page describes Lambda expressions, a Java language feature introduced in Java 8 that enables a functional style of programming in Java.

Java Lambda

Here's a short example:

```
LambdaMethodInterface i = (acc, x) -> acc + x;
```

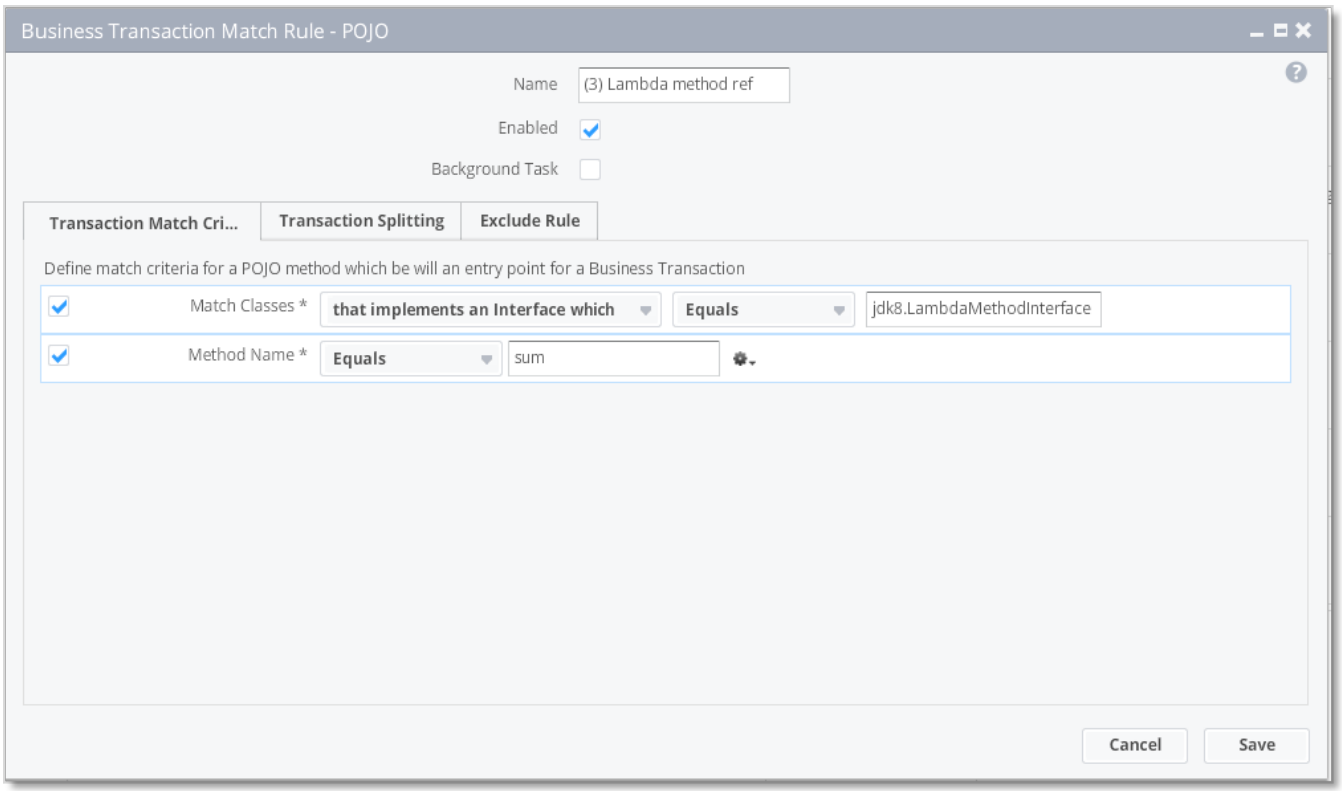
In the JVM, this creates an anonymous instance of the associated `FunctionalInterface`, as shown below:

```
package jdk8;

@java.lang.FunctionalInterface
interface LambdaMethodInterface
{
    int sum(int acc, int x);
}
```

Instrument Java Lambda Instances

To instrument lambda instances, create a POJO business transaction match rule for the `LambdaMethodInterface`, for example:



This sample rule matches classes that implement the interface name `jdk8.LambdaMethodInterface`.

Web Service Entry Points

When your application uses Web Services to service user requests, AppDynamics intercepts the Web Service invocations and names requests based on the Web Service action names and operation name. A Web Service entry point is a Web Service endpoint that is being invoked.

This is relevant only when the Web Service invocation is part of the entry point tier or in cases where the transaction should be continued in a downstream tier using a correlation header transported in the SOAP Envelope.

Web Service invocations are usually preceded by a dispatcher Servlet, but identification is deferred to the Web Service endpoints. This configuration ensures that the requests are identified or correlated based on the Web Service or its payload and not based on the generic URL for the dispatcher Servlet.

Default Naming

When the Web Service endpoint is invoked, the request is named after the Web Service name and the operation name.

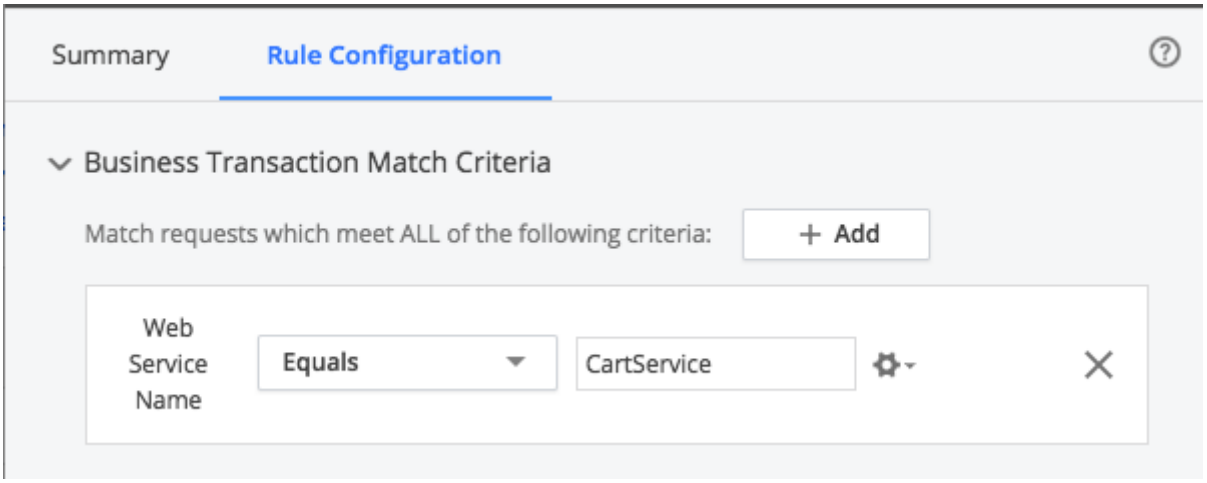
For example, if a service called `CartService` is invoked with the `Checkout` operation, the is named `CartService.Checkout`.

You can rename or exclude these automatically discovered transactions. See Organize Business Transactions.

Custom Match Rules for Web Services

You can aggregate different Web Service requests into a single business transaction using the web service name or the operation name. You do this by creating custom match rules for Web Services. See Custom Match Rules for information about accessing the configuration screens.

This example names all operations for the Web Service named `CartService`:



Exclude Rules

To exclude specific Web Services or operation names from detection, add an exclude rule. See Custom Match Rules. The criteria for Web Service exclude rules are the same as those for custom match rules.

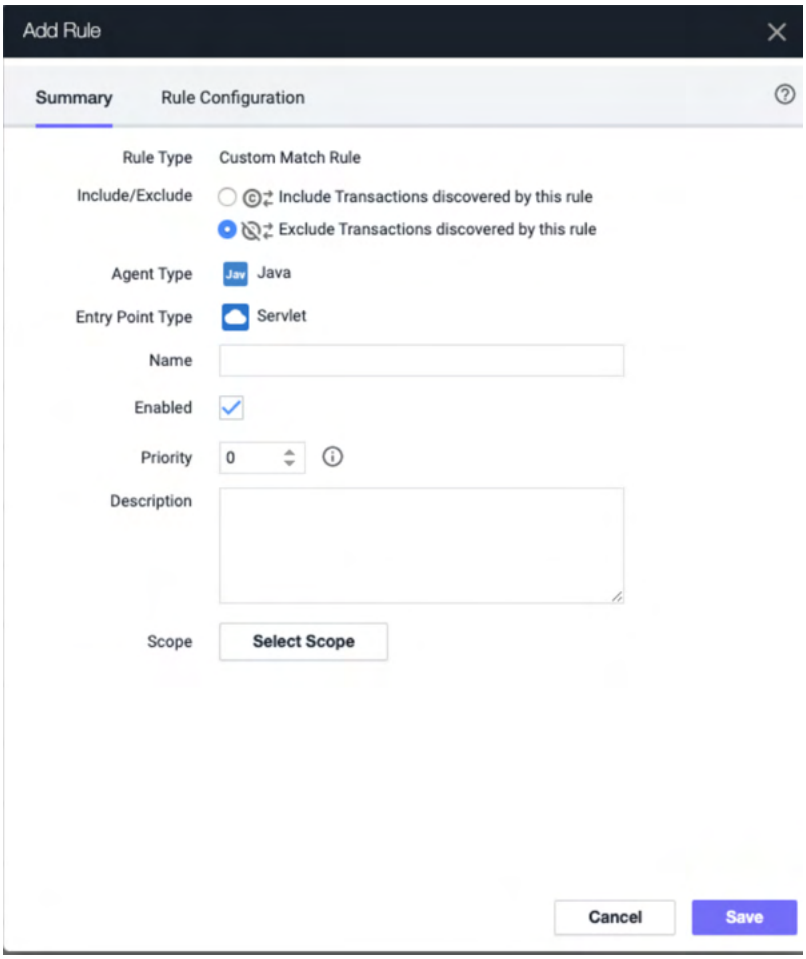
Transaction Splitting for Web Services Based on Payload

1. Disable the Web Service automatic transaction discovery.
2. Disable the following default exclude rules:
    - Apache Axis Servlet
    - Apache Axis2 Servlet
    - Apache Axis2 Admin Servlet
3. Add the custom match rule for Axis or Axis2 Servlet (based on the version being used) and split the transaction using payload or request depending on the pattern in your scenario.

Exclude Rule for JBoss Correlation

To detect Web Service entry and to support correlation in JBoss SOAP Web Service, you must create a Servlet exclude rule by excluding the class name, `org.jboss.wsf.stack.cxf.CXFServletExt` as follows:

1. In **Add Rule**, select **Custom Match Rule**.
2. Select **Servlet** as the **Entry Point Type**.
3. Select **Exclude Transactions discovered by this rule.**



4. Click **Save**.
5. In the Rule Configuration tab, specify the class name as `org.jboss.wsf.stack.cxf.CXFServletExt`.
6. Click **Save**.

Binary Remoting Entry Points for Apache Thrift

Apache Thrift is a binary remoting protocol. Cassandra uses the Thrift protocol to achieve portability across programming languages. Applications written in many different languages can make calls to the Cassandra database using the Thrift protocol.

AppDynamics is preconfigured to detect business transaction entry points for Cassandra with Thrift framework applications. Note that Binary Remoting entry points are not available as Service Endpoints.

AppDynamics measures performance data for Thrift transactions as for any other transaction. Thrift entry points are POJO-based. The response time for the transaction is measured from the POJO entry point, and the remote calls are tracked the same way as remote calls for a Servlet's Service method.

Default Naming for Binary Remoting (Thrift) Entry Points

When the automatic discovery for a request using Binary Remoting (Thrift) protocol is enabled, AppDynamics automatically identifies all the transactions and names them using the following format:

```
RemoteInterfaceClassName:MethodName
```

Enabling Detection for Binary Remoting (Thrift) Entry Points

Binary Remoting (Thrift) entry points are enabled by default, but if you are not seeing them in the Tier Flow Map, verify that they have been enabled in the Java automatic transaction detection rule. For more information, see Transaction Detection Rules.

When enabled, you can see Thrift calls from calling tiers to the Cassandra database in the List View of the Tier Dashboard. Since the transactions using the Thrift protocol are POJO-based, they appear as POJO in the Type column.

Creating Custom Match Rules for Binary Remoting (Thrift) Requests

If you are not getting the required visibility with the auto-discovered transactions, you can configure custom match rules and transaction splitting for specific classes and methods.

When creating the custom match rule, choose POJO as the rule type. The rule should be defined on the class and method you want to use as the entry point. Someone who is familiar with your application code may need to help you make this determination.

For information about and examples of the various POJO-based business transaction match rules you can create for Binary Remoting (Thrift), see POJO Entry Points. The rules for Binary Remoting (Thrift) entry points are the same as those for POJO entry points.

CometD Support

Related pages:

- Jetty Startup Settings
- Exclude Rules

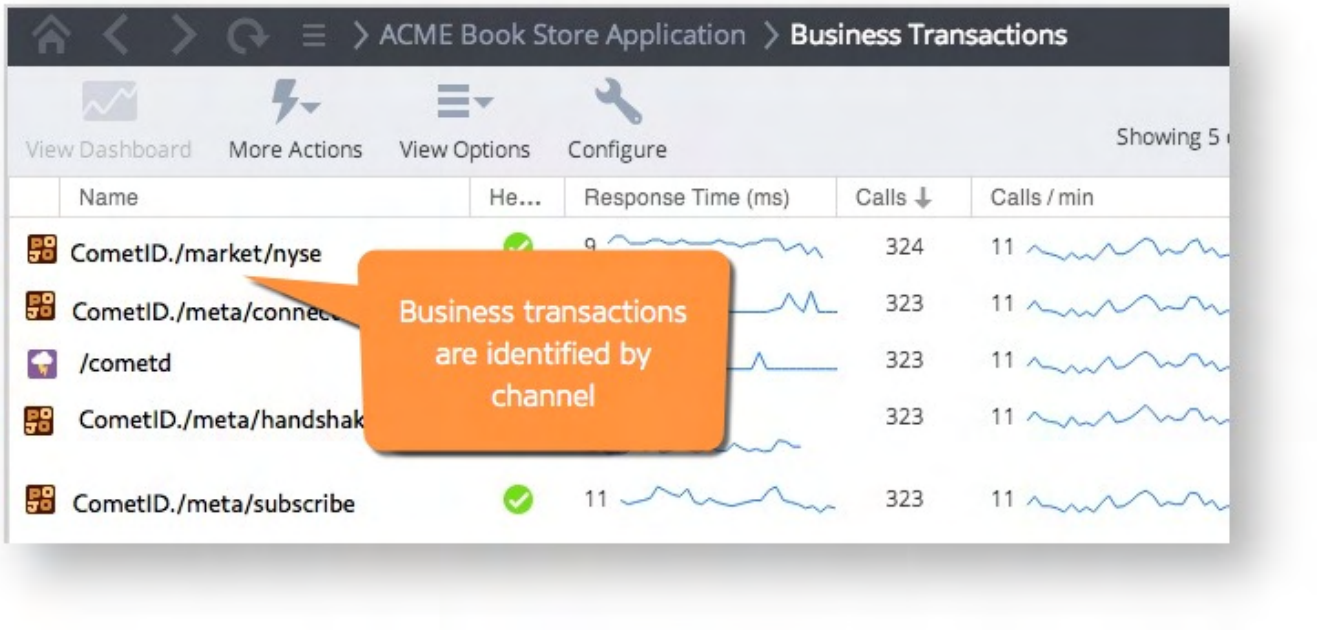
CometD is an HTTP-based event routing bus for transporting asynchronous messages over HTTP. CometD provides both a JavaScript API and a Java API and is often used for real-time interactive applications such as multi-player games and chat rooms.

CometD is distributed as a WAR file. When you instrument the CometD application container that runs the WAR (typically a Jetty server) with the Java agent, AppDynamics automatically detects and tracks CometD activity, as described in the following section.

About the Built-in Support

AppDynamics supports both the WebSocket and the HTTP long-polling client transports in CometD. It tracks CometD messages as they traverse channels using POJO rules that split business transactions based on channel name.

Accordingly, business transactions in AppDynamics correspond to CometD channels. The following screenshot shows a business transaction generated for the `/market/nyse` channel:



AppDynamics provides built-in exclude rules for the servlets that implement CometD transport functions, org.cometd.annotation.AnnotationComet and org.cometd.server.CometdServlet. For best results, you should exclude tracking for the container servlet as well, as described in the next section.

Create Container Transport Servlet Exclude Rules

CometD is implemented as a servlet. Since the servlet implements transport activity, you should create exclude rules for the servlets that perform the CometD transport function. This ensures that the results of business transaction discovery do not obscure the POJO-based BTs corresponding to CometD channels.

CometD is generally contained within a Jetty container, so the rules should exclude the Jetty container tracking in most cases. For Jetty, you should configure exclude rules for these Jetty servlets:

- EQUALS, `org.eclipse.jetty.server.handler.ContextHandler`
- EQUALS, `org.eclipse.jetty.servlet.ServletContextHandler`
- ENDSWITH, `jetty.plugin.JettyWebAppContext`

If using another type of container, you should create similar exclude rules for the equivalent supporting classes.

JAX-RS Support

The Java Agent supports Jersey 1.x and 2.x by default.

Business transaction entry points are named using the following app agent node properties:

- rest-num-segments
- rest-transaction-naming
- rest-uri-segment-scheme

Business Transaction Naming Scheme

By default, the Java Agent makes a best-effort basis to name JAX-RS-based transactions using the class annotation, method annotation, and HTTP method of the detected entry point, in the following form:

```
{class-annotation}/{method-annotation}.{http-method}
```

In some situations where the annotation values are not available, the agent may name the transaction as follows:

```
{fully qualified class name}.{method}
```

For example, when the JAX RS service endpoints don't have the class and method names in them explicitly, but the annotations are inferred in some other way.

For annotation inheritance cases, the agent attempts to fetch the annotations from the superclasses and interfaces as described by the JAX RS specification. The specification makes the following recommendation:

> *For consistency with other Java EE specifications, it is recommended to always repeat annotations instead of relying on annotation inheritance.*

Repeating annotations on the endpoint methods enables the Java Agent to name business transaction according to the default scheme.

rest-transaction-naming Variables

The `rest-transaction-naming` node agent property enables you to control naming for JAX-RS-based business transactions. You can use variables to have the transactions named with runtime values, for example, based on the method name, class name, parameter values, and more. For a full list of variables, see App Agent Node Properties Reference.

You can add a getter chain after any of the parameters to operate on the parameter values. To do so, add ':' followed by the getter chain. Standard getter chain escape requirements and rules apply.

Naming Examples

The following example shows naming based on a part of the value of the sixth parameter:

```
rest-transaction-naming={param-5:toString().toLowerCase().subString(5,20)}
```

The characters '{' and '}' are reserved. If used in getter chains or as text in the name the characters must be escaped with '\'. E.g. {{`class-name`}} would display as {`com.singularity.RestObject`}.

You can use characters in addition to parameters. For example, in the following example, the class name and method name are separated by a slash:

```
rest-transaction-naming={class-name}/{method-name}
```

Based on this example, when the Java Agent sees a REST resource with a class name of `com.company.rest.resources.Employees` with a `CreateNewEmployee` method, it names the business transaction `com.company.rest.resources.Employees/CreateNewEmployee`.

Spring Integration Support

In Spring-based applications, Spring Integration enables lightweight messaging and supports integration with external systems via declarative adapters.

The Java Agent automatically discovers entry points based on the `MessageHandler` interface. The Java Agent automatically discovers exit points for all Spring Integration Release 2.2.0 channels except `DirectChannel`.

The Java Agent supports tracking application flow through Spring Integration messaging channels. For pollable channels:

- A continuing transaction is tracked if the Spring Integration framework is polling for messages.
- If the application code polls for messages in a loop, the span of each loop iteration is tracked as a transaction. Tracking begins when the loop begins and end it when the iteration ends.

Entry Points

Originating transactions begin with `MessageHandler.handleMessage()` implementations. If the incoming message is already recognized by the Java Agent then a continuing transaction is started.

Exit Points

Exit points are based on `MessageChannel.send()`.

Most message channels exist inside the JVM. To represent this arrangement in a flow map, the Controller UI shows a link from the tier to the message channel component name (bean name) and then back to the tier.

Spring Integration Support Customizations

The following sections describe typical scenarios for tuning the default Spring Integration monitoring.

Track Application Flow Before Message Handler is Executed

In cases where a lot of application flow happens before the first MessageHandler gets executed, you should enable tracking the application flow as follows:

- Find a suitable POJO entry point and configure it.
- Set the enable-spring-integration-entry-points node property to `false`. This property is set to `true` by default.
- Restart the application server

Limit Tracking of Looping Pollable Channels

To safeguard against cases where `pollableChannel.receive()` is not called inside a loop, you can ensure that the Java Agent tracks a pollable channel loop only if it happens inside a class/method combination similar to that defined in the following example.

You can configure the spring-integration-receive-marker-classes node property for each class/method combination that polls messages in a loop, in which case only those class/methods identified in this node property are tracked.

```
class MessageProcessor {
   void process() {
      while(true) {
          Message message = pollableChannel.receive()
      }
   }
}
```

For example, for the loop above, set the `spring-integration-receive-marker-classes` node property as follows and restart the application server:

```
spring-integration-receive-marker-classes=MessageProcessor/process
```

The `spring-integration-receive-marker-classes` node property must be configured before the method `process()` gets executed for any changes to take effect. Restart the application server after setting this property.

.NET Business Transaction Detection

Related pages:

- Transaction Detection Rules
- Organize Business Transactions
- Configuration Import and Export API
- .NET Agent for Linux Business Transaction Configuration

The page lists different types of ASP.NET entry points for business transactions:

- POCO Entry Points
- ASP.NET Entry Points
- WCF Entry Points
- ASP.NET Web Service Entry Points
- ASP.NET Core Instrumentation Options
- Name MVC Transactions by Area, Controller, and Action

POCO Entry Points

Certain types of applications, such as Windows Services or standalone applications, may not have entry points that are automatically detected by the .NET Agent.

For these cases, you can create custom match rules for Plain Old CLR Objects (POCOs).

POCO Custom Match Rules Overview

To create a POCO custom match rule, define the custom match rule on the .NET class/method that is the most appropriate entry point for the business transaction. Someone who is familiar with your application code can help make this determination. You can also refer to the Custom Match Rules page.

You can optionally enable the Background Task option to have the transaction monitored as a background task. AppDynamics reports only Business Transaction metrics for background task transactions. It does not aggregate response time and call metrics at the tier and application levels for background tasks. See Monitor Background Tasks for more information.

After you create the rule, AppDynamics detects traffic on the matched entry point method and registers a business transaction for it, naming the transaction with the name of the custom match rule.

> By default, you have to wait one minute and then restart the application to apply instrumentation changes required for new POCO entry points. If you create an application-level POCO that applies to a tier that has not yet registered with the Controller, you may need to restart the application after the tier registers in order to see the business transaction.
>
> You can enable Runtime Reinstrumentation for the .NET Agent so that you don't need to restart your application after instrumentation changes.

As an alternative to defining POCO entry points as described here, you can use the transaction discovery tool to create match rules based on discovered transactions. See Business Transaction Discovery Sessions.

> The .NET Agent for Linux supports the configuration of simple POCO business transactions through the Controller UI. See .NET Agent for Linux Business Transaction Configuration

Define a POCO Entry Point

On an originating tier, a POCO entry point is the method that starts the business transaction. If the POCO entry point is on a downstream tier, it may correlate to an upstream exit point. When defining a POCO entry point, it is important to choose a method that begins and ends every time the business transaction executes. See Business Transactions.

Good candidates for POCO entry points include the following:

- A method in a socket application that executes every time a client connects
- A loop in a standalone application that batch processes records via a web service call. For example, an expense reporting system that loops through approved expenses to submit them for reimbursement.
- A Windows service that regularly executes a database call to check for new jobs to process. For example, consider the sample application logic below:

```
using System.Threading;
using System;
using System.Threading.Tasks;
using System.Configuration;
using System.Collections.Generic;

namespace JobProcessor {
    class JobProcessorCore {
        private void ProcessJob()
            {
            var logic = new JobManagement();
            while(running)
                {
                    var jobs = logic.GetJobs(); // Query in-memory Database for a list of jobs to process
                    foreach (var job in jobs)
                        {
                        logic.GetJobDetails(job, out type, out parameters); // Obtain the details on the
specific job at hand
                        ProcessJob(type, parameters);  // Execute the job in a separate thread
                        }

                    if (jobs.Count == 0)   // if there was no job to process, wait 1 minute
                        Thread.Sleep(60000);
                }
        }
    }
}
```

In the example, the POCO entry point would be defined on the namespace JobProcessor, class JobProcessorCore and method ProcessJob.

Task-Based POCO Entry Point Methods

AppDynamics automatically tracks POCO transactions for asynchronous, Task-based method entry points as end-to-end transactions. End-to-end latency metrics reflect the time it takes to complete the asynchronous actions associated with such methods.

To be tracked as an end-to-end transaction, the method you define as the POCO entry point must return a `Task` object and use the `async` modifier. In other words, the method signature should look similar to the following:

```
public async Task<int> SearchBestPrice()
{
   ...
}
```

AppDynamics records the response times for such methods as it does for other types of methods—the response time reflects the time from when the method is called to when it returns control to the calling thread. However, for asynchronous task-based methods, AppDynamics records the time it takes for the asynchronous task to be fulfilled as an end-to-end transaction latency metric.

> For .NET Agents >= 20.3.0, time spent on asynchronous tasks is reported in average response time (ART) but not reported in the end-to-end latency metric.

See End-to-End Latency Performance.

ASP.NET Entry Points

Related pages:

- Transaction Detection Rules
- Business Transactions

AppDynamics automatically detects entry points for client requests to ASP.NET applications. If the request occurs on an originating tier, the method or operation marks the beginning of a business transaction and defines the transaction name. In most cases, this type of entry point maps to a user request or action such as "Cart/Checkout". AppDynamics allows you to configure transaction naming based upon the ASP.NET request.

For information on how to configure default ASP.NET transaction detection, see URI Based Entry Points.

Custom Match Rules for ASP.NET Transactions

Custom match rules provide greater flexibility for transaction naming. When you define a match rule, AppDynamics uses the rule name for the business transaction name.

See Custom Match Rules for general information on how to create custom match rule.

The .NET Agent for Linux supports the configuration of simple ASP.NET business transactions through the Controller UI. See .NET Agent for Linux Business Transaction Configuration.

When AppDynamics detects a request matching your specified criteria, it identifies the request using your custom name. You can use the following criteria to match transactions:

Method: Match on the HTTP request method, GET, POST, PUT or DELETE.

With automatic discovery for ASP.NET transactions enabled, configuring the match on `GET` or `POST` causes the agent to discover both GET and POST requests. If you only want either `GET` or `POST` requests for the transaction, consider the following options:

- Disable automatic discovery for ASP.NET transactions.
- Create an exclude rule for the method you don't want: `GET` or `POST`.

URI: Set the conditions to match for the URI.

- For rules on regular expressions for .NET, see .NET Framework Regular Expressions.
- Optionally click the gear icon to set a NOT condition.
- You must set a URI match condition in order to use transaction splitting.

HTTP Parameter: Match on HTTP parameter existence or a specific HTTP parameter value.

Header: Match on a specific HTTP header's (parameter's) existence or a specific HTTP header value.

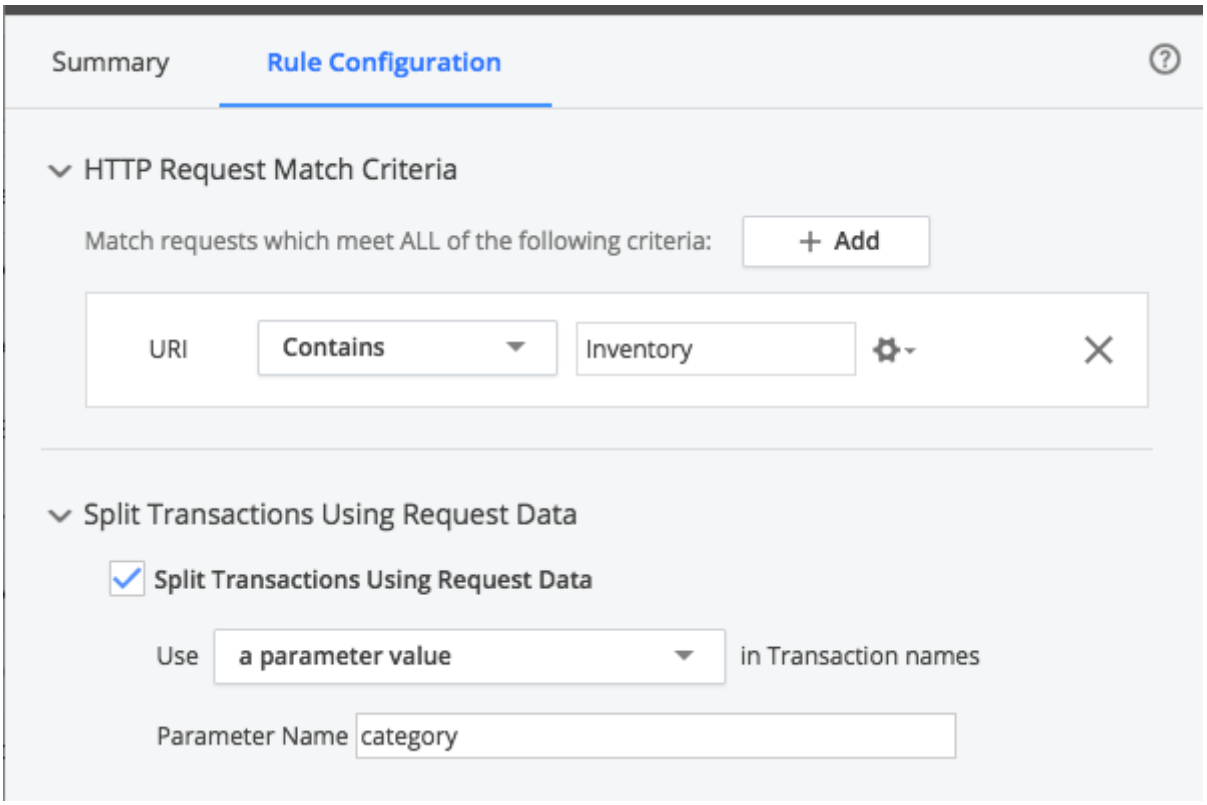
- Hostname: Match on the server hostname. Optionally click the gear icon to set a NOT condition.
- Port: Match on the server port number. Optionally click the gear icon to set a NOT condition.
- Class Name: Match on the ASP.NET class name. Optionally click the gear icon to set a NOT condition.
- Cookie: Match on cookie existence or specific cookie value.
- Hostname, Port, and Class Name options are non-functional in the .NET Agent 4.5.9 for Linux.

Split Custom ASP.NET Transactions

AppDynamics lets you further refine ASP.NET custom transaction names using transaction splitting.

- To use transaction splitting, you must specify URI match criteria for the custom match rule.
- The *Split Transactions Using Request Data* options work the like the automatic transaction detection configuration options described in URI Based Entry Points.

For example, you have a custom match rule named `MyTransaction` that matches the following URL: `http://example.com/Store/Inventory?category=electronics`. You can split the transaction on the parameter value as follows:



The .NET Agent names the resulting transaction `MyTransaction.electronics`.

WCF Entry Points

Related pages:

- Configure Business Transaction Detection for .NET
- Windows Communication Foundation (Microsoft Windows Reference)

AppDynamics automatically detects entry points for client requests to Windows Communication Foundation (WCF) services. If the request occurs on an originating tier, the method or operation marks the beginning of a business transaction and defines the transaction name. For information on originating tiers, see Business Transactions.

The .NET Agent detects async entry points for the following patterns:

- Task-based asynchronous operations
- IAsyncResult Begin-End Asynchronous pattern

Controlling Correlation Header Location

In 4.4 and earlier, when WCF calls execute on a downstream tier, AppDynamics includes them as part of the business transaction from the originating tier. If the downstream WCF service uses the NetTcpBinding in WCF, you must register the app agent node property `enable-soap-header-correlation` with a value of `true`. See 'enable-soap-header-correlation' on App Agent Node Properties Reference. Otherwise, the .NET Agent will detect the WCF call as the entry point for a new business transaction.

In the following table, when the node property is set to the default (false), the correlation message with header will only successfully deliver when sent over HTTP, not over SOAP with an HTTP wrapper or other protocol. When the node property is set to true, the correlation message with header will succeed in all scenarios.

	enable-soap-header-correlation	HTTP	SOAP (HTTP)	SOAP (other)
4.4 **default**	**false**	X	-	-
4.4	true	X	X	X

In 4.4.1 and later, the `enable-soap-header-correlation` node property and the default behavior for SOAP calls over non-HTTP protocols in WCF have changed. In addition, a new property, `disable-soap-header-correlation-non-http`, has been added. See `disable-soap-header-correlation-non-http` on App Agent Node Properties Reference. With the new default AppDynamics will, by default, include downstream WCF services using NetTcpBinding as part of business transactions.

The following table captures the changes and additions of the correlation data for the following use cases:

- When the node properties for both `enable-soap-header-correlation` and `disable-soap-header-correlation-non-http` are set to the default (false), the correlation message with header will only successfully deliver when sent over HTTP or SOAP wrapped in a protocol other than HTTP.
- When the node property for `enable-soap-header-correlation` is set to `true`, and the `disable-soap-header-correlation-non-http` node property is set to the default (`false`), the correlation message with header will succeed in all scenarios.
- When the node property for `enable-soap-header-correlation` is set to the default (`false`), and the `disable-soap-header-correlation-non-http` node property is set to `true`, the correlation message with header will only successfully deliver when sent over HTTP, not over SOAP with an HTTP wrapper or other protocol.
- When the node properties for both `enable-soap-header-correlation` and `disable-soap-header-correlation-non-http` are set to `true`, the correlation message with header will only successfully deliver when sent over HTTP or SOAP with an HTTP wrapper, not over SOAP with another protocol.

When upgrading from 4.4.0 to 4.4.1 or later, the `enable-soap-header-correlation` property retains its previous value and `disable-soap-header-correlation-non-http` defaults to `false`.

	enable-soap-header-correlation	disable-soap-header-correlation-non-http	HTTP	SOAP (HTTP)	SOAP (other)
4.5 **default**	**false**	**false**	X	-	X
4.5	true	**false**	X	X	X
4.5	**false**	true	X	-	-
4.5	true	true	X	X	-

By default, the .NET Agent does not correlate EUM transactions for WCF entry points. You can enable EUM correlation for WCF using the **wcf-enable-eum** node property. This feature is useful when an instrumented mobile application calls directly into a WCF entry point. See 'wcf-enable-eum' on App Agent Node Properties Reference.

Automatic Naming for WCF Transactions

By default, the AppDynamics auto-detection naming scheme identifies all WCF transactions using the service name and operation name:

```
ServiceName.OperationName
```

For example, a web service for a travel website books reservations from client front ends: `TravelService.BookTravel`. You can rename or exclude automatically discovered transactions from the Business Transactions List.

Custom Match Rules for WCF Transactions

Custom match rules provide flexibility for WCF transaction naming. When you define a match rule, AppDynamics uses the rule name for the business transaction name. See Custom Match Rules for more information.

When AppDynamics detects a request matching your specified criteria, it identifies the request using your custom name. You can match based upon:

Web Service Name

- For rules on regular expressions for .NET, see .NET Framework Regular Expressions.
- Optionally use the gear dropdown to set a NOT condition.

Operation Name

- For rules on regular expressions for .NET, see .NET Framework Regular Expressions.
- Optionally use the gear dropdown to set a NOT condition.

For example, you could report all operations for a TravelService, such as `SearchTravel` and `BookTravel`, as one business transaction.

ASP.NET Web Service Entry Points

AppDynamics automatically detects entry points for client requests to ASP.NET web services. If the request occurs on an originating tier, the method or operation marks the beginning of a business transaction and defines the transaction name. For more information on originating tiers, see Configure Business Transaction Detection for .NET.

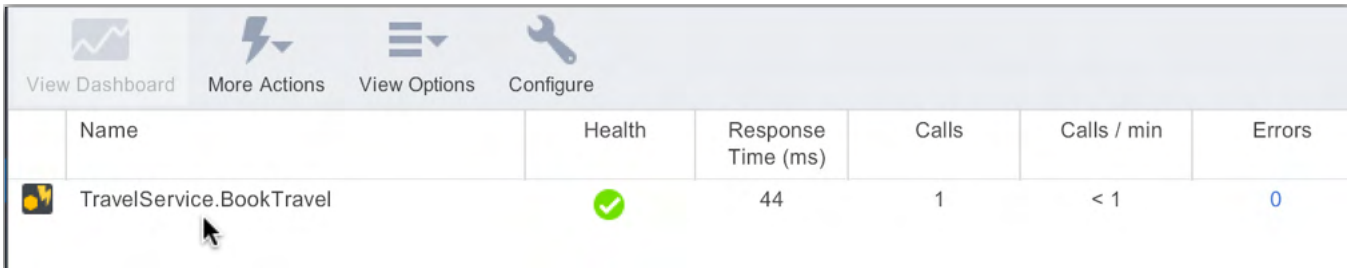
When web service calls execute on a downstream tier, AppDynamics includes them as part of the business transaction from the originating tier.

Automatic Naming for Web Service Transactions

By default, the AppDynamics auto-detection naming scheme identifies all web service transactions using the service name and operation name:

```
ServiceName.OperationName
```

For example, a web service for a travel website books reservations from client front ends.



You can rename or exclude automatically discovered transactions from the business transaction list.

Custom Match Rules for ASP.NET Web Service Transactions

Custom match rules provide flexibility for ASP.NET web service transaction naming. When you define a match rule, AppDynamics uses the rule name for the business transaction name.

To access the Custom Match Rules pane, see 'To create custom match rules for. NET entry points' on .NET Business Transaction Detection.

To create an ASP.NET web service custom match rule

1. In the **Custom Match Rules** pane, click the plus symbol (**+**) to add an entry point.
2. Click **Web Service** in the dropdown. Click **Next**.
3. Name the **New Business Transaction Match Rule**.
    - AppDynamics uses the rule **Name** to name the BT.
    - The Controller enables the rule by default. Disable it later if needed.
    - Set the **Priority** for the match rule. AppDynamics applies higher priority rules first.
4. Set one or more of the following match criteria. When AppDynamics detects a request matching your specified criteria, it identifies the request using your custom name.

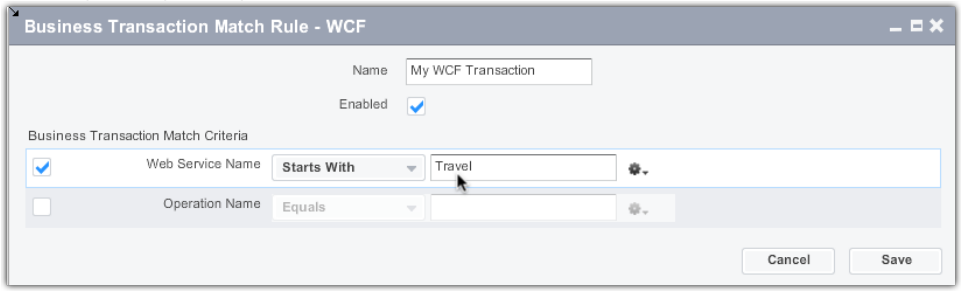
Web Service Name

- For rules on regular expressions for .NET, see .NET Framework Regular Expressions.
- Optionally use the gear dropdown to set a NOT condition.

Operation Name

- For rules on regular expressions for .NET, see .NET Framework Regular Expressions.
- Optionally use the gear dropdown to set a NOT condition.

For example, to report all operations for a TravelService, such as `SearchTravel` and `BookTravel`, as one business transaction:



5. Click **Create Custom Match Rule**.
   The rule appears in the **Custom Match Rule** list. The business application or tier you customized displays a green check in the **Select Application or Tier** pane.

After the agent receives the updated configuration, it discovers the new business transaction and displays it in the Business Transactions list.

ASP.NET Core Instrumentation Options

When you develop an ASP.NET Core application, a pipeline is built by connecting the configured middleware components together.

By default (for example, when you re-use the standard template application startup code), you do not have to define how to build the pipeline or the sequence of middleware components in this pipeline. Everything works as defined. For applications with more complex processing demands, you would typically modify the middleware pipeline and consider how the .NET Agent instruments ASP.NET Core applications. See middleware pipeline information from the Microsoft site.

The .NET Agent can instrument this middleware pipeline at different points along the pipeline. Each instrumentation option provides advantages and disadvantages:

- Resource invoker instrumentation
- Endpoint instrumentation
- HTTP instrumentation
- MVC routing instrumentation

Resource Invoker Instrumentation

- Default setting for ASP.NET Core 2.*x*.
- For ASP.NET Core 3.x and 5.0, set the node property `aspdotnet-core-instrumentation (string) = "ResourceInvoker"` to enable it.

This instrumentation occurs at the end of the pipeline just before it calls the controller action or page handler. This applies to Razor Page handlers, and MVC and Web API controller actions.

The advantage is that only actual action code is instrumented, and the .NET Agent instrumentation does not execute for any other web requests such as: static files and not found paths (`Error Code 404`).

This is the most lightweight instrumentation option. It is the optimal choice for most ASP.NET Core applications, especially where minimal or no customization was applied to the middleware pipeline from the default application code.

Endpoint Instrumentation

- Default setting for ASP.NET Core 3.x and 5.0 (as of .NET Agent 21.3).
- Not available for ASP.NET Core 2.x.

With the improved endpoint routing introduced in ASP.NET Core 2.2, all routing for Web API, MVC, and Razor Pages was merged into a new architecture enabling the .NET Agent to perform instrumentation just after the `EndpointRoutingMiddleware`.

The advantage of using Endpoint instrumentation (instead of Resource Invoker instrumentation) is that the Business Transaction is tracked through the execution of all middleware after the `EndpointRoutingMiddleware`. This provides more visibility into operations performed before the controller action is executed. This includes only middleware that participates in the routing process such as authentication and authorization, but excludes middleware such as health checks, serving up static files, and so on.

Endpoint instrumentation balances full pipeline visibility (which may introduce too much noise and overhead) with no visibility (using Resource Invoker instrumentation).

HTTP Instrumentation

- This setting is available for ASP.NET Core 2.x, 3.x, and 5.0 (as of .NET Agent 21.3).
- Set the node property `aspdotnet-core-instrumentation (string) = "HTTP"` to enable it.

This instrumentation option instruments the full middleware pipeline by instrumenting every single web request. It provides the most visibility of all options. However, when enabling this option, you must consider:

- MVC naming is not possible because the request URL has not been decoded by the routing middleware. It may not be an MVC request; if it is, then controller and action names have not been resolved. All business transactions will use the URL path as its name.
- Because the .NET Agent instrumentation runs and inspects every web request (even requests that result with `404 Errors`, and so on), it has a greater performance impact on the application. To understand the performance impact, you should test this option either in a pre-production environment, or on a limited node count before you enable the option for the entire tier or application.

MVC Routing Instrumentation

- This is the original instrumentation option introduced for ASP.NET Core 1.x. It is the default setting for ASP.NET Core 1.x, and a configurable option for 2.x.
- Set the node property `aspdotnet-core-instrumentation (string) = "Legacy"` to enable this for ASP.NET Core 2.x.

The MVC Routing instrumentation functionality has been deprecated with ASP.NET Core 3.0. It provides full pipeline visibility by instrumenting from the first middleware in the pipeline. However, when attempting to do MVC naming of incoming web requests, it may cause issues. It assumes that you built the middleware pipeline in a specific way, and contains very specific middleware request delegates.

If you are using ASP.NET Core 2.x, and need full pipeline visibility with MVC naming, then this is the only available option for you.

Name MVC Transactions by Area, Controller, and Action

Related pages:

- Business Transactions
- Transaction Detection Rules

By default, the AppDynamics .NET Agent names ASP.NET transactions based upon the URI. For ASP.NET Core on the full framework, the agent uses MVC area, Controller, and action naming by default, and can also be configured to use the URI. This page describes the MVC transaction naming configuration options for both ASP.NET and ASP.NET Core on the full framework.

> For transactions using the MVC naming conventions, the automatic transaction detection configuration settings apply to the MVC segments, not to the URI.

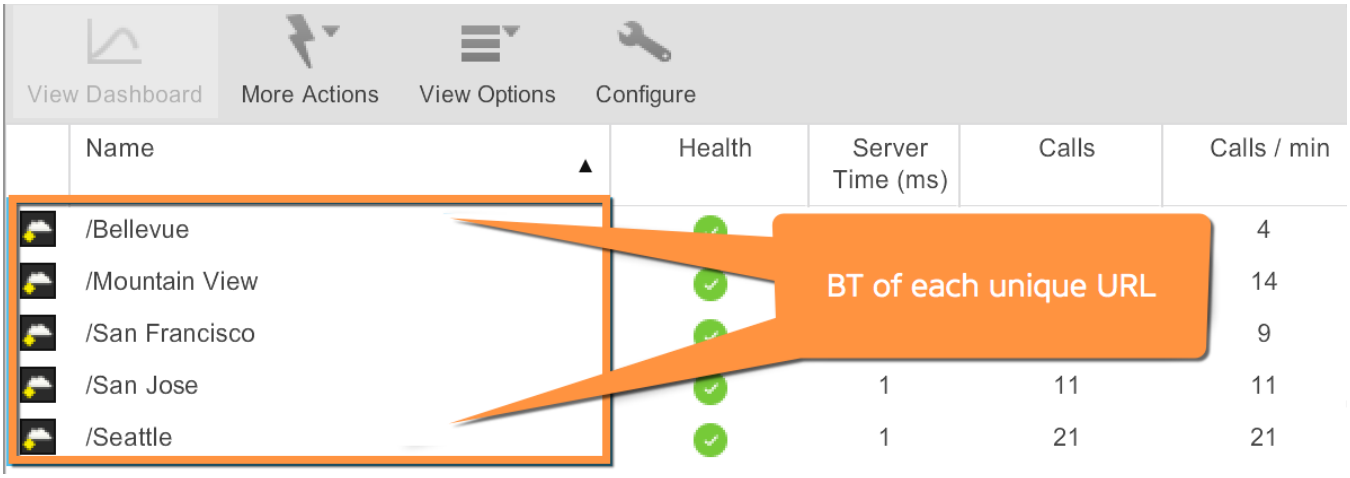
MVC Transaction Naming

For some MVC applications, URI-based naming may not produce meaningful business transaction names. Depending on the URI scheme, it might create many business transactions, pushing you quickly over your business transaction limit and causing most traffic to fall into the *All other traffic* business transaction.

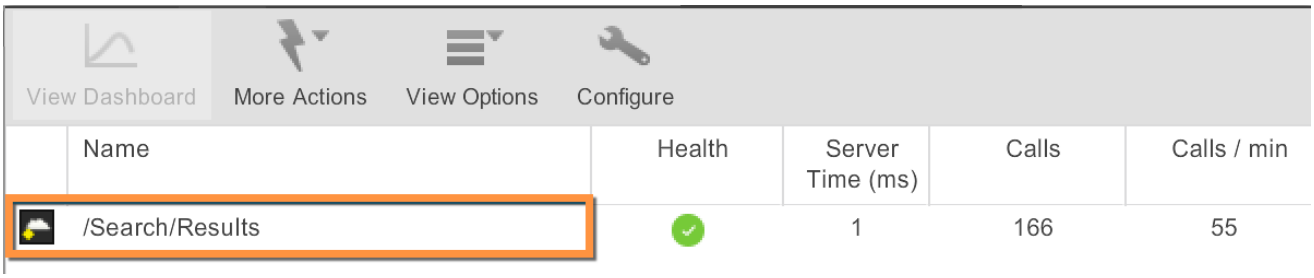
For example, consider an MVC application that indicates store locations in the URL as the result of a city location search, such as the following sample URL:

```
http://myapp.mycompany.com/Bellevue
```

Based on this URL, AppDynamics registers a business transaction named /Bellevue. Each search result with a unique city would similarly generate a unique business transaction.



Alternatively, you can configure the agent to identify transactions by the area, Controller, or action name. After you configure the agent to name transactions by Controller and action, the agent identifies the business transaction based on the Controller and action name, in this case, Search/Results.



In this example, the new business transaction combines search requests for all cities into one transaction, resulting in a more logical unit for measuring application performance.

Similarly, if your application uses areas to logically group Controllers, you can configure the use of area name in the business transaction.

For background information on ASP.NET Routing, see this Microsoft Developer Network article: msdn.microsoft.com/en-us/library/cc668201.aspx

Configure Node Properties for MVC Transactions

You can configure custom MVC transaction naming using node properties. This table describes how to configure node properties for MVC transactions based on the type of entry point.

> The node property supports: MVC 3, MVC 4, and WebAPI transactions.

Type of Entry Point	Name Business Transactions	Transaction Naming Configuration
ASP.NET hosted in IIS (`aspdotnet-mvc-`)	To name business transactions using the Controller and Action values	Register the `aspdotnet-mvc-naming-controlleraction` node property with a value = `true`
	To name business transactions using the Area and Controller values	Register the `aspdotnet-mvc-naming-controllerarea` node property with a value = `true`
	To include all three component values (Controller, Action, and Area) in business transaction names	1. Register both node properties 2. Configure the ASP.NET transaction naming to use three URI segments instead of two (default) See Automatic Transaction Discovery Rules.
ASP.NET Core on the Full Framework (`aspdotnet-core-`)	To name business transactions using the URI	Register both of these node properties with a value = `false` • `aspdotnet-core-naming-controllerarea **` • `aspdotnet-core-naming-controlleraction`
	To omit the Area value from your transaction names	Register the `aspdotnet-core-naming-controllerarea` node property with a value = `false`
.NET Agent for Linux	To use MVC Area, Controller, URI, and Action in business transactions name	Register the `aspdotnet-mvc-naming-controlleraction` node property with a value = `true`

To register a new node property, see App Agent Node Properties.

After you modify any transaction naming configuration, and traffic to the previously registered business transactions terminates, you can delete the old business transactions.

Node.js Business Transaction Detection

Related pages:

- Transaction Detection Rules

This page provides instructions about transaction detection and configuration for the Node.js Agent.

GraphQL Business Transactions

GraphQL is a query and schema definition language that allows servers to expose an API over a HTTP endpoint. You specify the required data in the request payload and send all the requests from the client to a server endpoint.

AppDynamics supports GraphQL when used with the `express-graphql` module, view GraphQL HTTP Server Middleware.

1. On the server side, you define a schema that describes the data and available operations on said data.
2. Then, you invoke operations defined by the schema to retrieve data (through URL requests that receive GraphQL queries) and mutate it.

In the current model, the Node.js Agent identifies an individual Business Transaction from the various requests coming to the server, but the agent does not capture the request payload.

GraphQL Business Transactions determines the business transaction through the incoming endpoint and incoming GraphQL payload, allowing further visibility into the GraphQL Node.js applications. Every GraphQL query that matches this URL is aggregated into one Business Transaction. With GraphQL Business Transactions, the Node.js Agent can be configured in the Controller to identify if an incoming business transaction matches a specific URI (for example, starting with `/QL`) and split that transaction with an operation into multiple transactions.

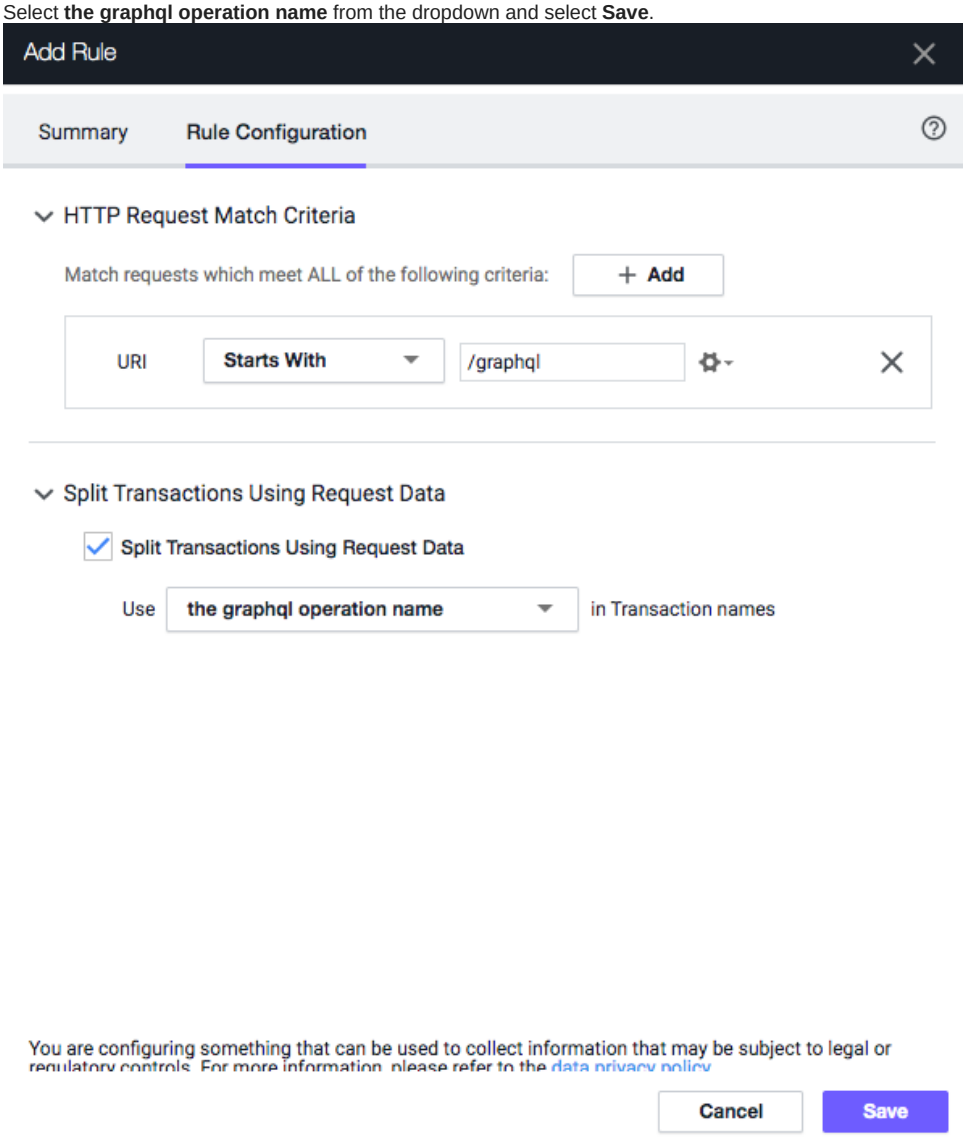
By default, GraphQL Business Transactions is disabled. To configure the Node.js Agent to enable GraphQL Business Transactions, set `enableGraphQL` to `true` in the call to `profile()`:

```
enableGraphQL: true,
```

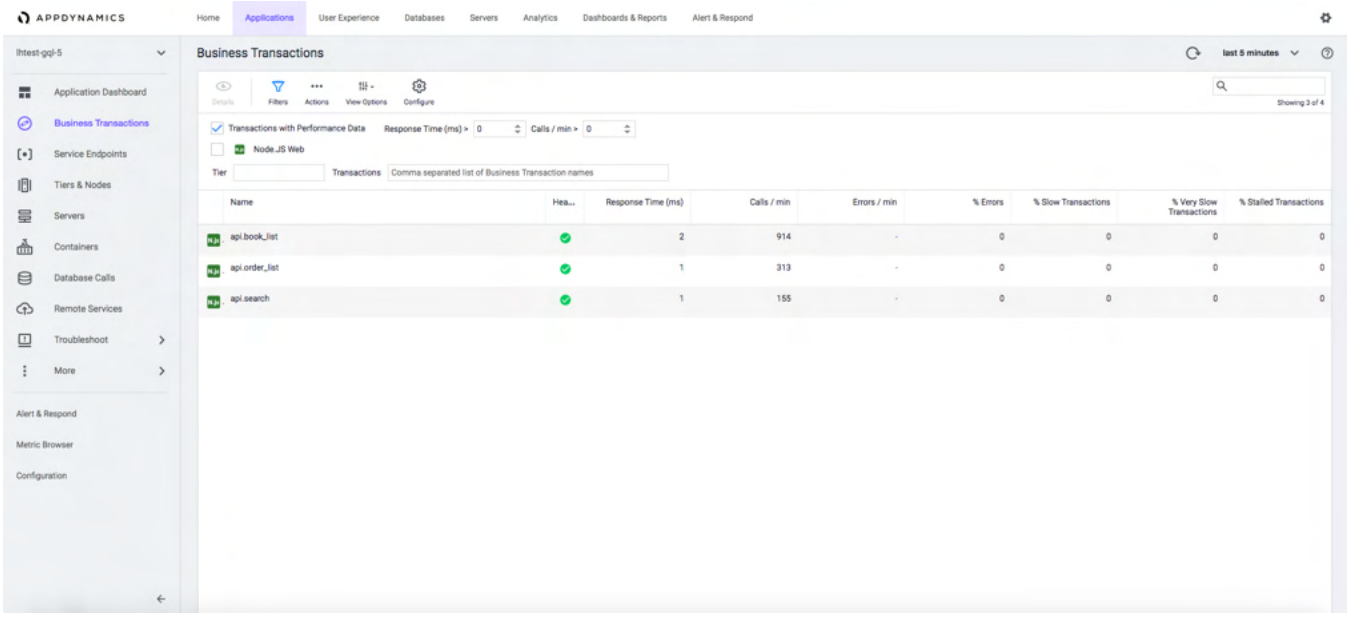
Once GraphQL Business Transactions is enabled, you can configure a GraphQL custom match rule for a Node.js application:

1. In the Controller, select **Configuration** > **Instrumentation** > **Transaction Detection**.
2. Click **Add Rule** > **Summary** > **Custom Match Rule**.
3. Select Node.js in the **Agent Type** dropdown. Click **Next**.
4. Enter a name for the match rule and ensure that the enabled checkbox is checked.
5. Click **Select Scope** and select the desired scope for the rule. Click **OK**.
6. Next, navigate to **Rule Configuration** > **HTTP Request Match Criteria** and click **Add**.
7. Select URI as the criteria and choose the desired operation from the dropdown list. Then, enter the desired value for the GraphQL incantation (for example, the URL prefix).
8. Navigate to **Split Transactions Using Request Data** and click the **Split Transactions Using Request Data** checkbox.

9. Select **the graphql operation name** from the dropdown and select **Save**.



Upon configuring the rule and sending a GraphQL queries in your application, the **Business Transactions** page displays separate transactions.



PHP Transaction Detection

Related pages:

- Configuration Import and Export API
- Configure PHP Custom Match and Exclude Rules

This page describes transaction detection and configuration procedures that related specifically to the PHP Agent. see Transaction Detection Rules.

PHP Entry Points

The entry point is where the business transaction begins, typically a URI or a page callback name, MVC controller action, page template name, or page template. The PHP Agent automatically detects and monitors the entry point types listed under PHP Frameworks and Protocols in PHP Supported Environments.

If the agent cannot detect the framework, the entry point type defaults to PHP Web. PHP Web automatically detects all HTTP requests to the application.

Enable Monitoring by Entry Point

You can enable and disable transaction monitoring for each entry point type.

When monitoring is disabled, the agent stops counting, measuring, and recording all activity on servers of that type.

Enable or disable monitoring by checking or clearing the **Transaction Monitoring** checkbox in the **Transaction Detection** panel for the PHP entry point type.

Transaction Naming

By default, PHP Agent names transactions are named after the first two segments in the service request URL. You can modify the default naming scheme in the same manner as for any web-based business transaction entry point.

For PHP-based entry point tiers that use a multi-layered framework architecture, the last framework that processes the transaction determines the name of the PHP business transaction. For example, for an incoming request processing path of PHP Web > MVC > Drupal 8, a new business transaction would be named based on the Drupal 8 invocation rather than the preceding layers in the request processing flow.

Virtual Host Naming by Entry Point

If you have multiple virtual hosts configured on a single web server, you can differentiate among the business transactions by adding the virtual host name as a prefix to the default business transaction name. Enable use of the prefix by checking the **Use Virtual Host in Business Transaction names** checkbox in the **Transaction Detection** panel for the PHP entry point type. Transactions discovered and named subsequent to this configuration will use the virtual host name as a prefix to the default name.

For example, an application has two exit.php actions running on the same physical host. One action runs on a virtual host named `phpagent1` and the other runs on a virtual host named `phpagent2`. Transaction naming will occur as follows:

- virtual host name is not used: agent identifies all requests to exit.php as a single business transaction named `exit.php`
- virtual host name is used: agent identifies requests as two different business transactions named `phpagent1 : exit.php` and `phpagent2 : exit.php`

Customize Transaction Detection and Naming

If the default contentions do not produce transactions to fit your needs, you can change the transaction configuration as follows:

- Create exclude rules to eliminate entry points that you do not need to monitor.
- Create custom match rules that specify matching rules for identifying and naming transactions.
- For PHP Web entry points, you can also configure transaction naming.

To access the transaction detection panes, select **Configuration > Instrumentation > Transaction Detection > PHP-Transaction Detection**.

Configure PHP Custom Match and Exclude Rules

Related pages:

- Transaction Detection Rules
- Using Regular Expressions

This page summarizes the criteria that you can use for creating custom match and exclude rules for each entry point type.

The criteria are the same for custom match and exclude rules.

If you disable automatic detection for an entry point type and then apply custom match rules, the agent discovers only requests defined by those match rules. For example, if you have a PHP MVC custom match rule that matches on “Action contains search”, and another rule that matches on "Action contains view", requests that contain "search" or "view" are the only MVC transactions that the agent detects.

On the other hand, if you do not disable automatic detection and you apply a custom match rule “Action contains search”, all the requests that match that criterion are grouped together as a single "search" transaction and then any other requests (those that do not contain “search”) are discovered using automatic detection.

Accessing Custom Rule Configuration

1. Click **Configuration Instrumentation > Transaction Detection > PHP-Transaction Detection**.
2. Scroll down to either the **Custom Match Rule** section or the **Exclude Rule** section.
3. Click **+** to create a new rule, then select from the dropdown the entry point type to which the rule applies.

PHP Web

Matching criteria can include one or more of the following:

- HTTP method
- URI segments
- HTTP parameter (value or existence)
- HTTP header (value or existence)
- Port
- Cookie (value or existence)

See Set Priority When Multiple Rules Apply in Custom Match Rules.

Transaction Splitting

For PHP Web, if a transaction is configured to identify the entry point based on the URI, you can optionally split the transaction into multiple transactions. For example, a login request may be automatically detected as a single transaction, but you want to split it into two transactions based on whether the request branches to a new-user or existing-user operation.

You can split a PHP Web transaction using request data from the transaction names such as URI segments, parameter values, header values, and cookie values.

PHP Web Splitting Example

For example, to split a custom match rule transaction "mobile checkout" by the mobile carrier parameter, so the agent detects separate transactions as follows:

- products/mobile/checkout?carrier=verizon
- products/mobile/checkout?carrier=sprint
- products/mobile/checkout?carrier=att

To split transactions based upon the carrier parameter:

1. On the Rule Configuration tab, set a URI match option.
2. Check **Split Transactions Using RequestData**.
3. Select **Use a parameter value in Transaction names**.
4. Enter "carrier" for the **Parameter Name**.

The agent creates the following transactions: "mobile checkout.verizon", "mobile checkout.sprint", and "mobile checkout.att".

PHP Web Custom Match Rules vs Auto-Detection Rules of Other Types

If a custom match rule configured for PHP Web matches the same criteria as an auto-detection rule for a business transaction of a different transaction type in the same application, the PHP Web custom match rule takes precedence and the business transaction appears as a PHP Web transaction type.

However, if a custom match rule for PHP Web and a custom match rule for another transaction type match the same criteria, precedence depends on the values of the rules' priorities. See Setting Match Rule Priority for information on rule priorities.

PHP MVC

By default, for most MVC frameworks, the business transaction is named using the controller:action. For modular MVC frameworks, the business transaction is named using the module:controller:action.

You can modify detection to match only a portion of the module, controller or view name (such as "Begins with" or "Contains") or on a regular expression, rather than the default which matches the entire name using "Equals" for the match condition.

You cannot configure a single match rule that matches on both the controller and the action. You can create MVC custom match rules using any of the following:

- controller name only
- action name only
- module name and action
- module and controller name

PHP Web Service

By default, for Web Services frameworks, the business transaction is named for the entire web service name and the entire operation name using "Equals" for the match condition.

You can modify detection with a custom rule that matches on only the web service name or only the operation name. You can match on a portion of either name or use a regular expression.

PHP Drupal

By default, AppDynamics automatically names Drupal transactions based on the entire page callback name of the Drupal module using "Equals" for the match condition.

You can modify detection with a custom match rule that uses just a portion of the page callback name or use a regular expression.

PHP Wordpress

By default, AppDynamics automatically names Wordpress transactions based on the entire Wordpress template name using "Equals" for the match condition.

You can modify detection with a custom match rule that uses just a portion of the template name, or use a regular expression.

PHP CLI

By default, AppDynamics automatically names PHP CLI transactions based on the last two segments of the script's directory path plus the name of the script.

The agent creates a business transaction instance every time the script is run.

You can modify detection with a custom match rule that matches on a different portion of the script path and name or uses a regular expression.

Custom Exclude Rule Examples

Custom exclude rules prevent detection of business transactions that match certain criteria. You might want to use exclude rules in the following situations:

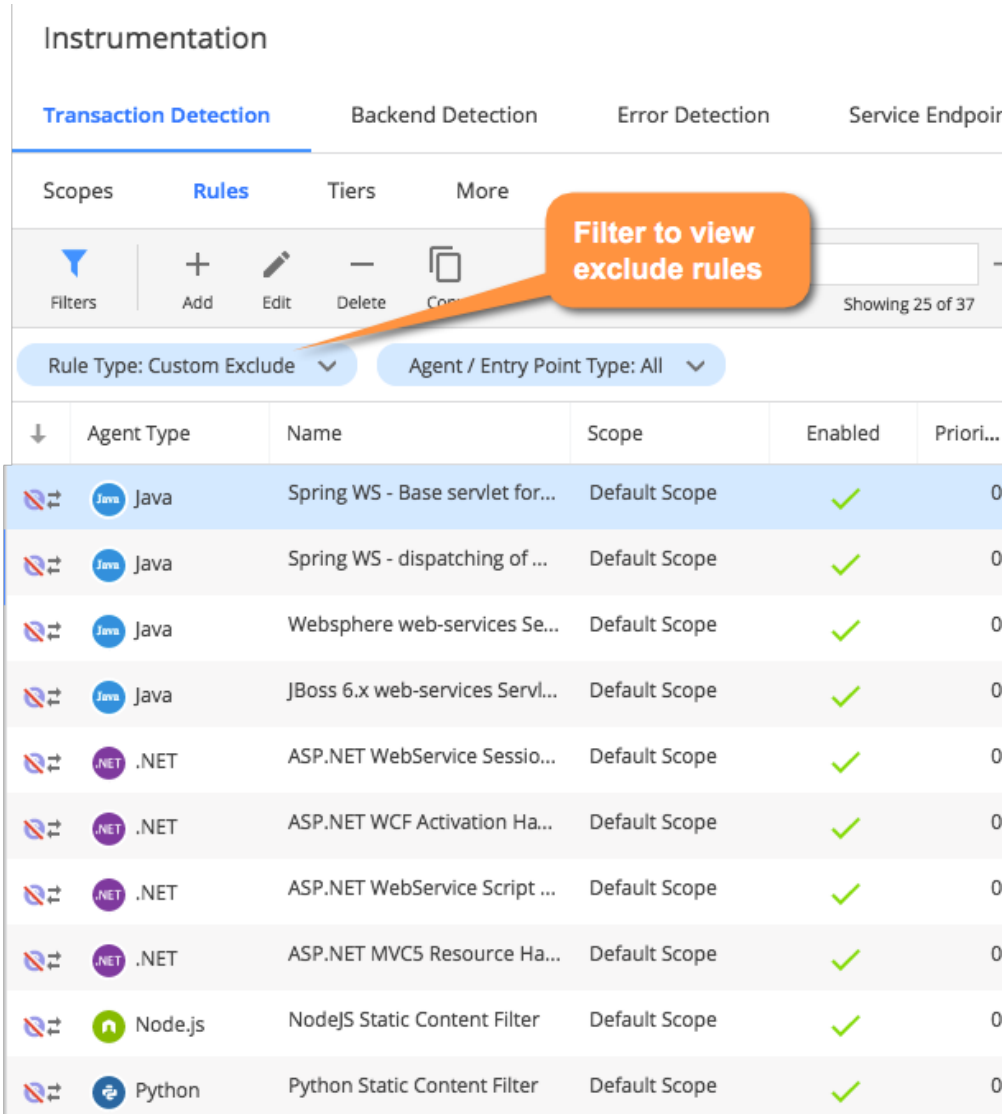
- AppDynamics detects business transactions that you do not want to monitor.
- To stay within agent and controller limits, you want to reduce the total number of business transactions.
- You need to suppress a default entry point to allow for the detection of a more precise entry point defined by a custom match rule.

You can customize existing rules or set up new rules. See Custom Match Rules.

Change the Default Exclude Rule Settings

AppDynamics has a default set of custom exclude rules for various agent types. Sometimes you need to disable a default rule or add a new custom exclude rule. Different entry point types include different match criteria that you can use to exclude transactions.

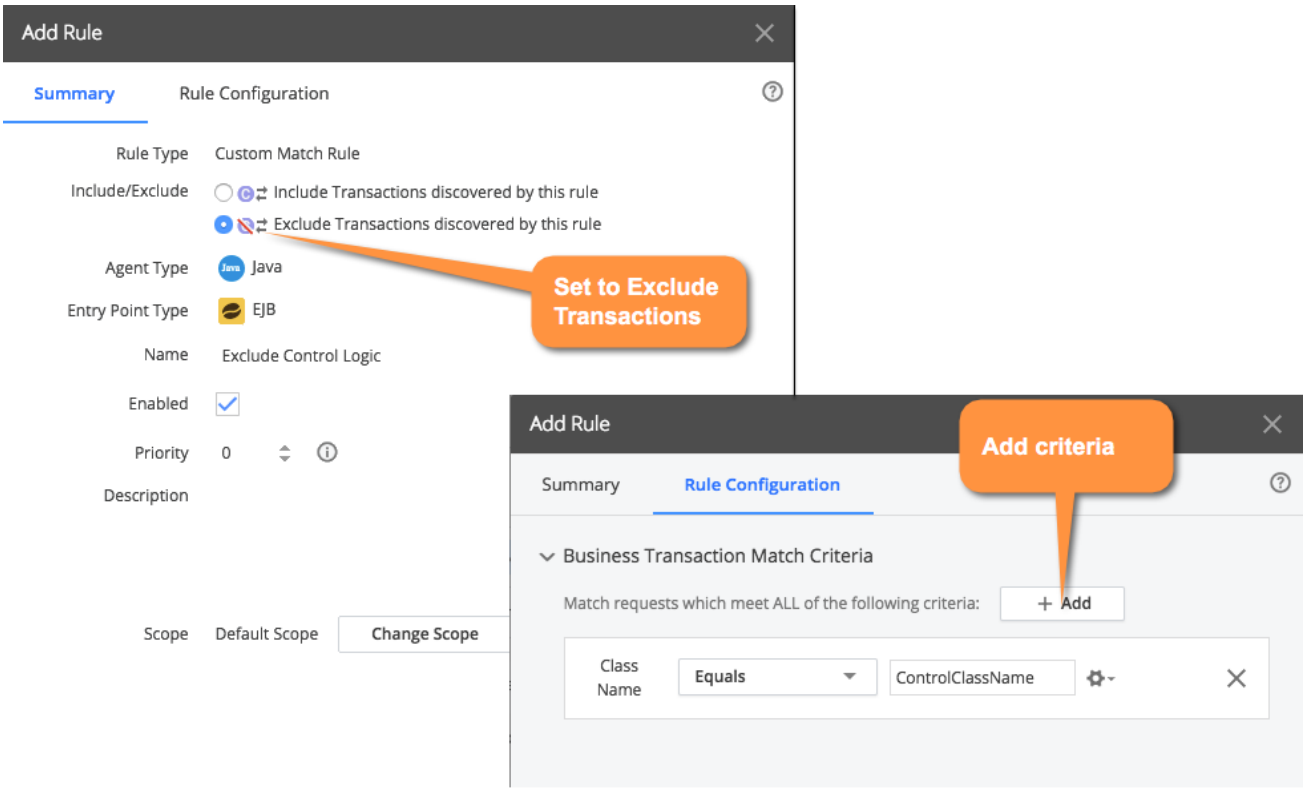
You can view the default rules on the **Transaction Detection** > **Rules** tab:



Define Transaction Names Using Downstream Application Logic

Sometimes an incoming request invokes control logic in your code that uses payload data to execute different business logic. In such cases, it makes sense to name your business transactions for the business logic class and method. You can use a custom exclude rule to prevent AppDynamics from naming the business transaction for control logic. Then you can identify the transaction by the business logic instead.

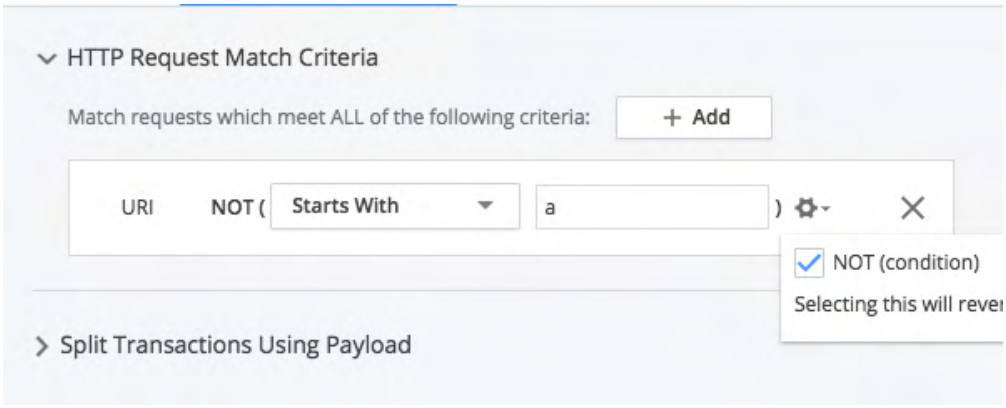
Consider an example where you have implemented both the control logic and business logic as EJBs. With **EJB** discovery enabled, AppDynamics discovers and names business transactions based on the control class and method. You can create an EJB exclude rule for the control class name using the **Class Name Equals** match criteria. After you create the rule AppDynamics discovers and names the business transactions for your business logic APIs:



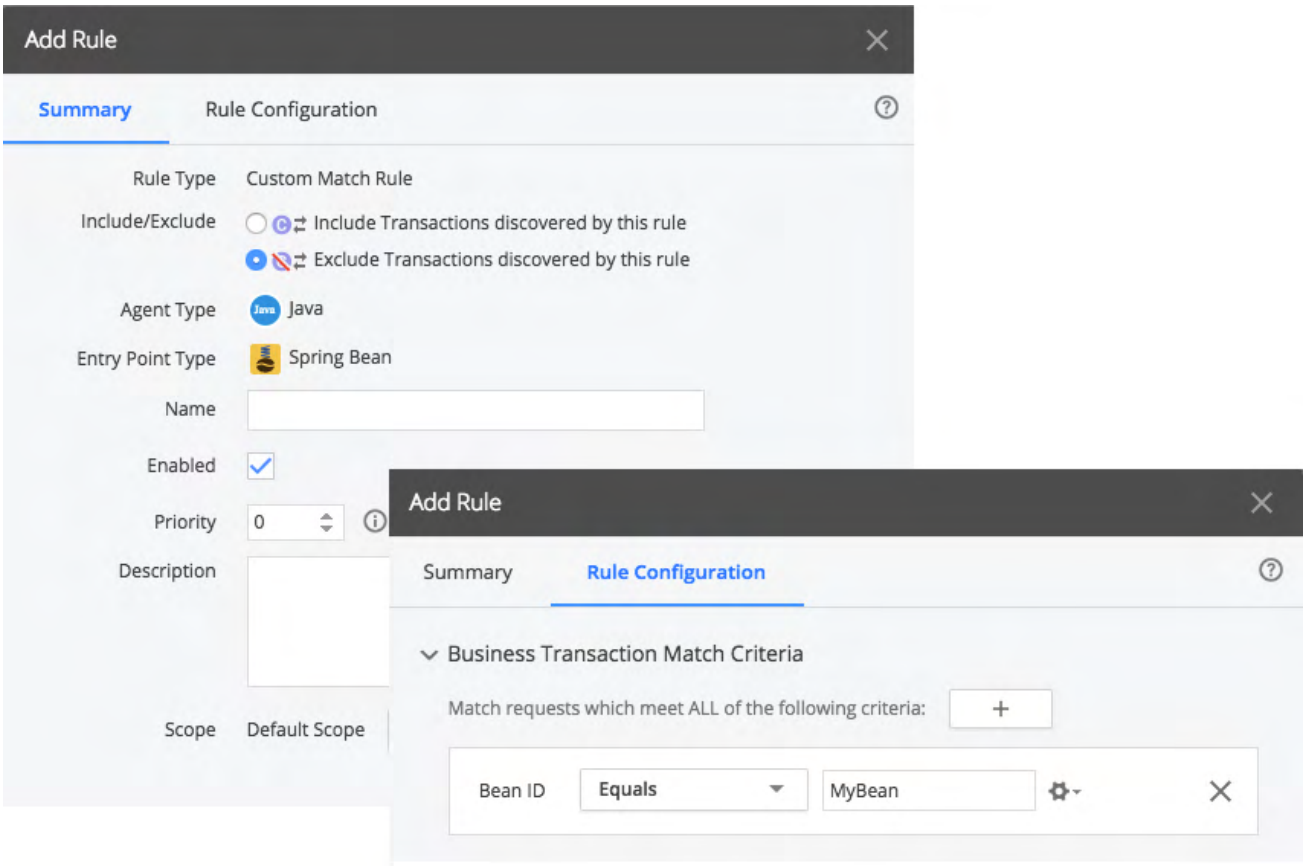
Use an Exclude Rule as a Filter

Custom exclude rules filter out unwanted requests from transaction discovery. You can specify match criteria that allow eligible requests but ignore everything else.

For example, you want to use default discovery rules. Your application receives URI ranges that start with : /a, /b ... /z. However, you only want to monitor URIs only when they start with /a . You can create a custom exclude rule that does a "Match : Doesn't Start With /a" as shown here:



In another example, imagine a specific an application that implements Spring Beans of the classes `java.lang.String` and `java.util.ArrayList`. This means that AppDynamics identifies all instances of these classes as Spring Beans with the same IDs. To fix the problem, you can define a custom exclude rule specific Spring Bean IDs:



Add Rule
Summary
Rule Configuration

MyBean

Custom Match Rule Live Preview

This page provides instructions and information for the custom transaction detection rule Live Preview.

You must have Configure Transaction Detection and View Sensitive Data permissions to use Live Preview. See Create and Manage Custom Roles.

When you create or edit servlet or POJO custom match rules in AppDynamics, you can click **Live Preview** to inspect pertinent transaction data from a node.

Custom transaction detection rule Live Preview session lets you interactively preview the effect of rule updates on your business transactions. Live Preview also provides tools for the different rule types to let you inspect the live data streaming from your application.

When you launch Live Preview, select the node where you want to preview transactions. Nodes are organized by tier. You can see which nodes have active agents and if there is a live preview session already running on a node.

Preview Business Transactions

When you initiate a custom match rule live preview session, the Controller shows the rule configuration in the left pane. Click **Preview Business Transactions** in the right pane to see resulting transactions. You can edit the rule and click **Apply** to update the changes within the session.

When the agent discovers an entry point for a rule but the transaction payload contains correlation data from an existing transaction, Live Preview displays a masked transaction.

POJO Match Rule Tools

You can use these tools to inspect data and configure the entry point for a POJO custom match rule:

- **Classes/Methods browser**—lets you search for classes.
    - You can right-click a class or method in the result to set the class and method match criteria for the POJO.
    - You can view method invocations for a selected method.

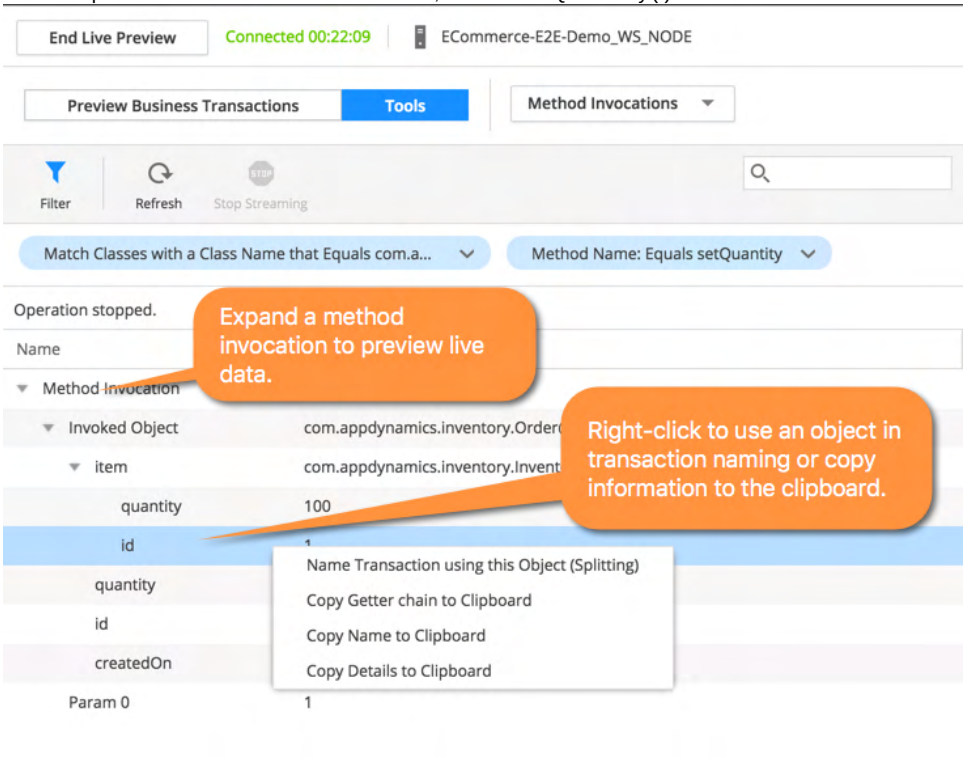
In live preview mode, the number of methods and classes that can be returned by an agent is now limit-bounded. The limits are:

- Maximum number of classes: 1000
- Maximum number of methods: 300

You can change limits by modifying the node properties `classmethodservice.max.no.of.classes.reported` and `classmethodservice.max.no.of.methods.reported`, respectively

- **Method Invocations**—lets you inspect live data from the server for the specified method.
    1. Expand a method invocation to see detailed information including invoked objects, parameters, and return values.
    2. Right-click on a data point to use it in transaction splitting.
       AppDynamics automatically creates a splitting rule following the `get<field>()` syntax.
       If your code follows another convention, you need to manually specify the getter method for the data point.

3. You can also copy a getter chain to the clipboard.
   The example below shows the data for a method, `Order.setQuantity()`:



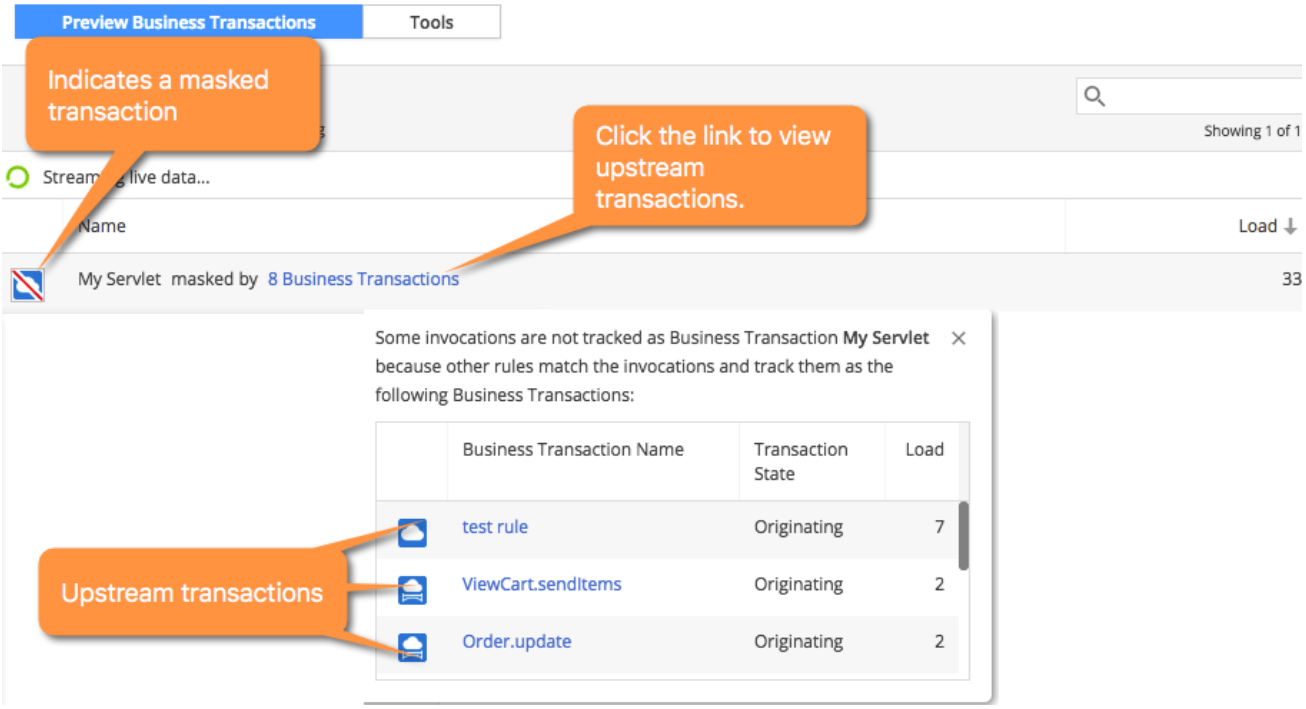
Servlet Match Rule Tools

When you use Live Preview to inspect data for a servlet custom match rule, AppDynamics shows live HTTP Requests that meet the rule criteria. You can click an individual Request URL to view detailed request data: headers, cookies, and parameters.

1. Right-click an individual data point, such as a header, to add the value to the match criteria or to set it as a transaction splitting option.
2. You can group the incoming HTTP requests by various parts of the request and its payload, such as the URI, an HTTP parameter, a header, etc. You can right-click a result from the **Values** column and add the value to the **HTTP Request Match** criteria.

Masked Transactions

Live Preview flags transactions that are downstream from another existing business transaction as masked transactions. To view the originating business transactions masking the current transaction, click the link indicating the number of transactions.



Click a business transaction name to view the business transaction dashboard for the masking transaction.

If you want to view metrics for the current entry point outside of a masking transaction or transactions, you can either:

- Deactivate the business transaction detection rules that created the upstream transactions, or
- Create a service endpoint for the entry point.

Otherwise, you can continue to track the performance of the masked entry point as a segment of the business transaction it currently belongs to.

URI Based Entry Points

For almost every web-based framework or platform, there is a URI based business transaction entry point for user requests. AppDynamics App Agents automatically discover the following URI-based entry points:

- Java Agent: Servlet entry points
- .NET Agent: ASP.NET entry points
- Node.js Agent: Node.js web entry points
- Python Agent: Python web entry points

The Web server Agent can detect Web request entry points, but automatic discovery is turned off by default so an agent on a downstream node can name the transaction.

URI based entry points all have similar configuration options for Automatic Transaction Discovery and Custom Match rules.

For additional functionality that applies to servlets, see Servlet Entry Points.

Default Naming

By default, when an app agent detects a URI request, it names the business transactions using the first two segments of the URI. For example, consider the following URI for a checkout operation in an online store: http://acmeonline.com/store/checkout.

The agent names the business transaction "/store/checkout" and assigns all requests that match that URI to the "store/checkout" business transaction.

If the first two segments of the URI do not contain enough information to effectively identify the business transaction in your environment, you can edit the a utomatic discovery rule to name the transaction based upon the URI and its context. Alternatively, you can create a custom match rule to specify a name.

For ASP.NET Core on the full framework, the default naming convention uses the Controller, action, and area. See Name MVC Transactions by Area, Controller, and Action for more information and configuration options.

Customize Automatic Naming Rules

When you edit or create a new Default Automatic Discovery Rule for URI based entry points, you can adjust naming to:

- Use the full URI to name transactions.
- Use part of the URI to dynamically name transactions.

Expand the **Configure Naming** option on the **Rule Configuration** tab to display the configuration options.

When you configure the rule to **Use the full URI**, the agent creates a business transaction name for the full request URI. There are no dynamic naming options. For example, for the URI http://acmeonline.com/store/coats/men, the agent names the transaction "`/store/coats/men`".

Use the full URI works well for Grails servlet transactions because the default naming scheme often doesn't differentiate between multiple transactions.

When you use parts of the URI to name transactions, you have several options to configure transaction naming:

- Use a Part of the URI
- Use Headers, Cookies, and Other Parts of HTTP Requests
- Use a Custom Expression

Use a Part of the URI

AppDynamics offers the following options to automatically name URI based transactions based upon the URI:

- Use the first or last URI segments
- Use specific URI segments

For the following URL the first two segments of the URI don't provide a significant name for the business transaction:

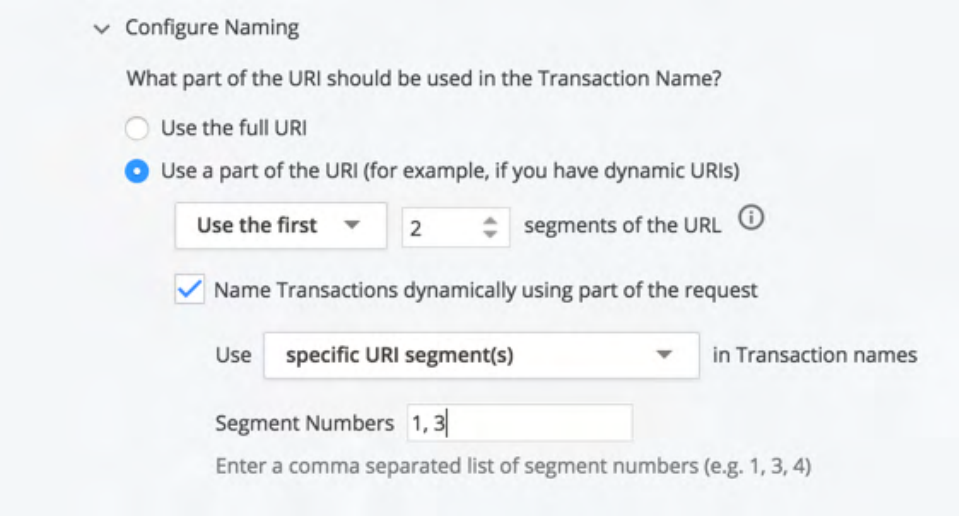
http://example.com/Web/Store/Checkout yields a default transaction name of "Web/Store".

You can use one of the following options to identify more meaningful transaction names:

- Click **Use the first** or **Use the last n** segments to use two contiguous segments at the beginning or end of the URI, where n is the number of segments. For example, if identify the checkout transaction using the last two segments of the URI, the agent names the transaction "/Store /Checkout".

- If you need more flexibility, such as using non-contiguous segments in the name, click **Name Transactions dynamically using part of the request**. Select **Use URI segments in Transaction names** option. To specify multiple segments, enter a comma-separated list of segment numbers.

  For example, the following URL represents the checkout transaction requested by a customer with ID 1234: `http://example.com/Store/cust1234/Checkout`
  The checkout transaction is the same regardless of the customer, so it makes sense to name the transaction based upon the first and third segments of the URI. AppDynamics names the transaction: "StoreCheckout".



Use Headers, Cookies, and Other Parts of HTTP Requests

When you use the **Name Transactions dynamically using part of the request** option, you can choose to identify your URI based transactions using particular parts of the HTTP request. Note that not all agents offer all the naming options below.

> Carefully consider your naming configuration choices. If you use a value such as the request originating address and you have many clients accessing your application, you may see the all other traffic business transaction.

- To use HTTP parameter values in transaction names, select **Use a parameter value in Transaction names** and enter the **Parameter Name**.
  For example, consider the following URL: `http://example.com/Store/Inventory?category=electronics`

  AppDynamics names the transaction to include the category parameter value "/Store/Inventory.electronics".

- To use a header value in transaction names, select **Use header value in Transaction names** and enter a **Header Name.**
  For example, consider a site that uses the custom header "Version", AppDynamics names transactions with the header value "/Store/Inventory.v2.5".
- To use a cookie value in transaction names, select **Use a cookie value in Transaction names** and enter the **Cookie Name**.
  For example, a website tracks a user's loyalty status in a cookie. Set the Cookie Name to "loyalty". AppDynamics names transactions for the loyalty cookie value "/Store/Inventory.Status=Gold"
- To Use a session attribute value in transaction names, Click **Use a session attribute in Transaction names** and enter the **Session Attribute Key**.
  For example, a website stores a customer's region in the session property. Set the Session Attribute name to "region". AppDynamics names transactions for the region session attribute value "/Store/Inventory.NorthAmerica".
- To use the request method in Transaction names, click **Use the request method (GET/POST/PUT) in Transaction names**.
  For example AppDynamics names the transaction "/Store/Inventory.GET".
- To use the request host in Transaction names, click **Use the request host in Transaction names**.
  For example AppDynamics includes the request host id in the transaction name "/Store/Inventory.192.0.2.0".

- To use the request originating address in Transaction names, click **Use the request originating address in Transaction names**. AppDynamics names transactions for the IP address of the request client "/Store/Inventory.192.0.2.10".

Use a Custom Expression

You can use a custom expression on the URI to name:

- Java servlet transactions
- .NET ASP.NET transactions

Select **Name Transactions dynamically using part of the request** and choose **Use a custom expression in Transaction names**. Enter your custom expression getter chain as follows:

For Java, you can use getter chains to access values from the `HTTPServletRequest` object. For example, suppose you want to use a combination of the authenticated user and the value of an `HttpServletRequest`:

```
${getParameter(myParam)}-${getUserPrincipal().getName()}
```

The equivalent code expression would evaluate to:

```
request.getParameter("myParam")+"-"+request.getUserPrincipal()
```

You can create a custom expression on the `HTTPServletRequest` to identify all Servlet based requests (modify global discovery at the transaction naming level) or for a specific set of requests (custom rule).

A custom expression for a servlet transaction can have a combination of any of the following getter methods on request attributes:

Getters on Request Attributes	Transaction Identification
getAuthType()	Use this option to monitor secure (or insecure) communications.
getContextPath()	Identify the user requests based on the portion of the URI.
getHeader()	Identify the requests based on request headers.
getMethod()	Identify user requests invoked by a particular method.
getPathInfo()	Identify user requests based on the extra path information associated with the URL (sent by the client when the request was made).
getQueryString()	Identify the requests based on the query string contained in the request URL after the path.
getRemoteUser()	Identify the user requests based on the login of the user making this request.
getRequestedSessionId()	Identify user requests based on the session id specified by the client.
getUserPrincipal()	Identify user requests based on the current authenticated user.

For .NET, you can use getter chains to access properties and methods for the `HttpRequest` object for ASP.NET or `Microsoft.AspNetCore.Http.Internal.DefaultHttpRequest` for ASP.NET Core on the full framework.

- Enclose getter chains inside braces: `${}` . The custom expression may contain multiple getter chains.
- Use getter chain syntax.
- Use any `HttpRequest` request attributes or methods.

For example, consider the URL http://mystore.example.com/Store/Inventory-Furniture .The following custom expression uses two getter chains to access properties of the `HTTPRequest` object:

```
${Url.ToString().Split(Char[]/-).[2]}-${UserAgent}
```

- The first getter chain fetches the URL, splits it on the dash character ("-"), and uses the second string in the array.
- The second getter chain fetches the `HttpRequest.UserAgent` property.
- The literal dash character "-" separates the two getter chains.

The result is the following business transaction name:

Furniture-Mozilla/5.0 (Windows NT 6.3; Trident/7.0; rv:11.0) like Gecko

Message Queue Entry Points

Most frequently an instrumented application calls to a message queue as a remote service or backend. However, in cases when an application uses asynchronous message listeners or message-driven beans as the primary trigger for business processing on an originating tier, AppDynamics can intercept the message listener invocations and track them as business transactions.

AppDynamics discovers the following types of business transaction entry points:

- Java JMS entry points.
- .NET Message Queue entry points

Message queue entry points all have similar naming configuration options for Automatic Transaction Discovery and Custom Match Rules.

Default Naming

By default, the AppDynamics auto-detection naming scheme identifies all message queue transactions using the destination name. Otherwise, if the destination name is not available, AppDynamics uses the listener class name.

Custom Match Rule Options

When you create a JMS or Message Queue custom match rule, the agent names matching transactions for the custom match rule name. See Custom Match Rules.

You have the option to specify the following match criteria as a combination of the following entry point properties:

- The **Message Destination** as **Queue, Topic** or **Unknown**.
- **Message Property**. You can match against a property's existence or against a property's value.
- **Message Content**.

Business Transaction Discovery Sessions

Business Transaction Discovery Sessions provide interactive tools to help you create the optimal set of transaction detection rules and discover crucial business transactions.

During a discovery session, you can preview the effects of all the transaction detection rules on a node. This way you can create rules that capture the precise business transactions that impact your business and avoid rules that generate too many transactions.

Within the context of the discovery session, you can:

- Edit Java Agent transaction detection rules and Preview Business Transactions. (Java only)
- Identify entry points from Uninstrumented Code.
- Browse Classes/Methods to identify entry points.

During the business transaction discovery session, you can test out various transaction detection rule configurations without impacting your production environment.

Any business transactions discovered within the context of the discovery session, called transient transactions, do not persist after the session ends. When you end the session you have the opportunity to discard the rule changes or to apply them to your production configuration.

Permissions

You need the following permissions to launch a Business Transaction Discovery Session:

- Configure Transaction Detection
- View Sensitive Data

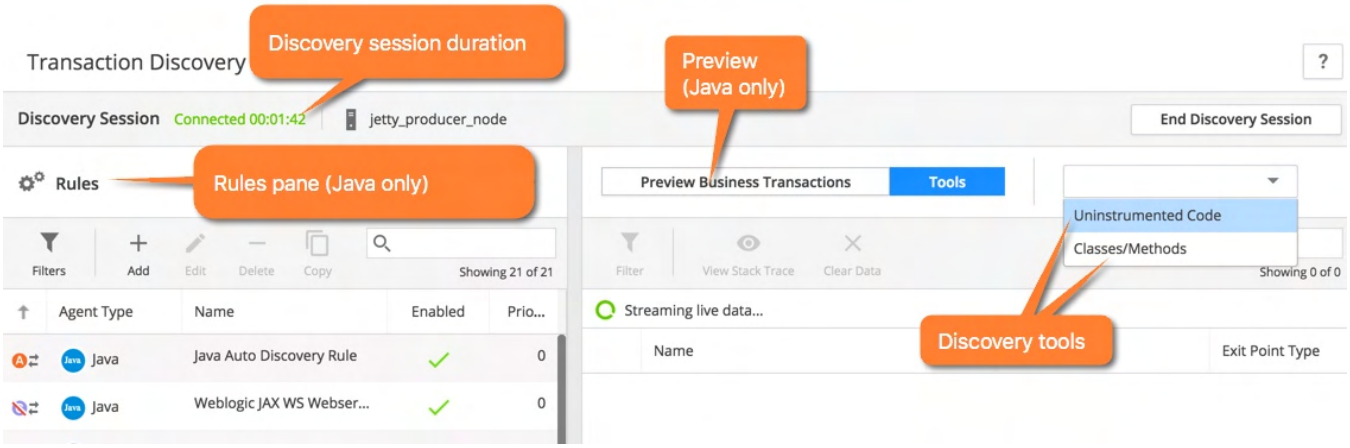
For information on AppDynamics Role Based Access Control, see Roles and Permissions.

Launch a Business Transaction Discovery Session

1. Navigate to **Configuration > Instrumentation** and click the Transaction Detection tab.
2. Click **Live Preview**.
3. Click **Start Discovery Session** to start a Business Transaction Discovery session.
4. Select the node to act as the source of the live data stream.

   Nodes are organized by tier. You can see which nodes have active agents and if there is a discovery session already running on a node.

The Transaction Discovery page displays information about the discovery session lets you navigate among the available interactive transaction discovery tools:



The transaction discovery tool works as it did in previous versions for upgraded business applications. See Business Transaction Discovery Sessions.

When you initiate a transaction discovery session on a Java node, the Rules pane displays the active transaction discovery rules that apply to the node. The right-hand pane lets you **Preview Business Transactions** or use the available interactive **Tools:** Uninstrumented Code detection and the Classes /Methods Browser.

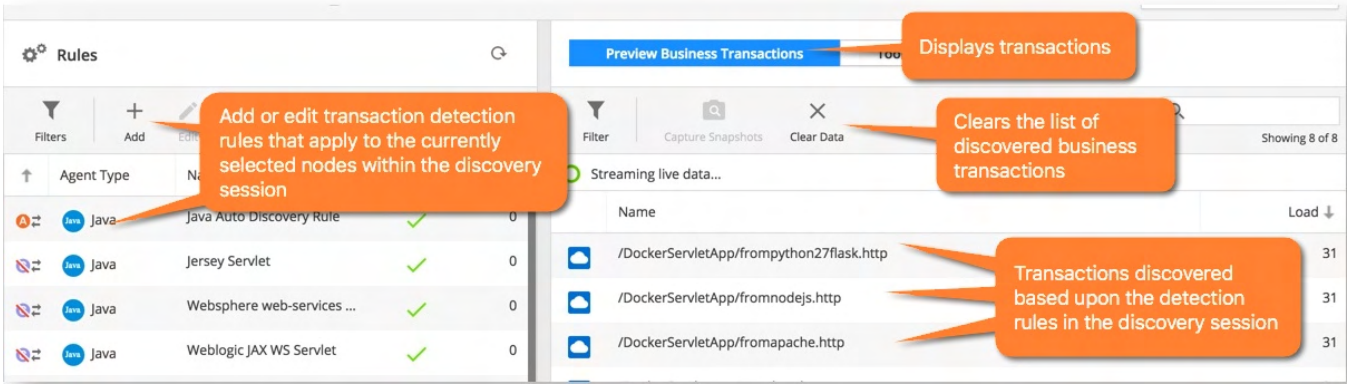
When you launch a discovery session on a .NET node, you see the available tools: Uninstrumented Code detection and the Classes/Methods Browser.

During a discovery session, you can use other features of AppDynamics while the discovery process continues in the background. This is useful for busy environments with many active transactions. You can give AppDynamics a few minutes to complete the discovery. When you are ready to return to the Transaction Discovery page click **Configuration > Instrumentation** and click the **Live Preview** button to resume your discovery session.

Edit and Preview Transaction Discovery Rules

You can add, edit, or delete any type of transaction detection rule for the Java Agent in the Rules pane. Click **Apply** to update the rule within the context of the discovery session.

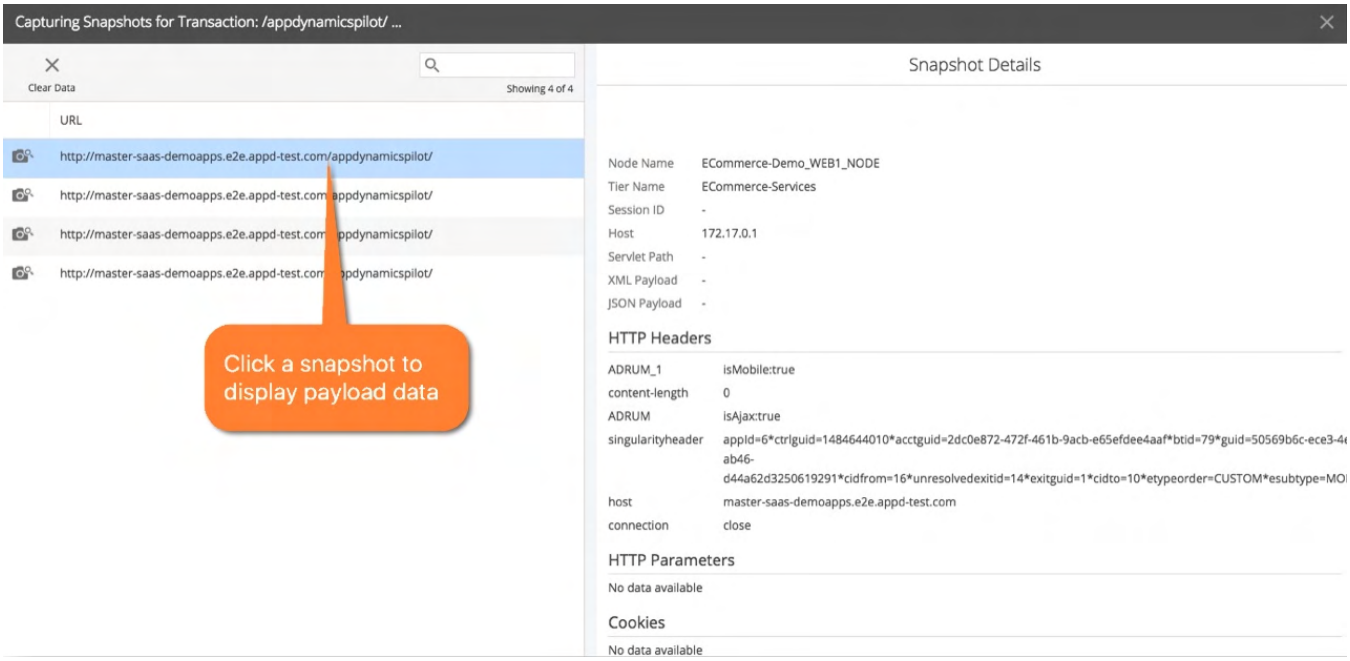
To see the effects of your changes, click **Preview Business Transactions**. As the app agent discovers business transactions based on the rule configuration, the transactions show up in a list in the right-hand pane:



You can select a transaction and click **Capture Snapshots** to collect transaction snapshots.

> The Capture Snapshots feature is only available for Servlets.

Click a specific snapshot to display the payload data for the business transaction in the Snapshot Details:

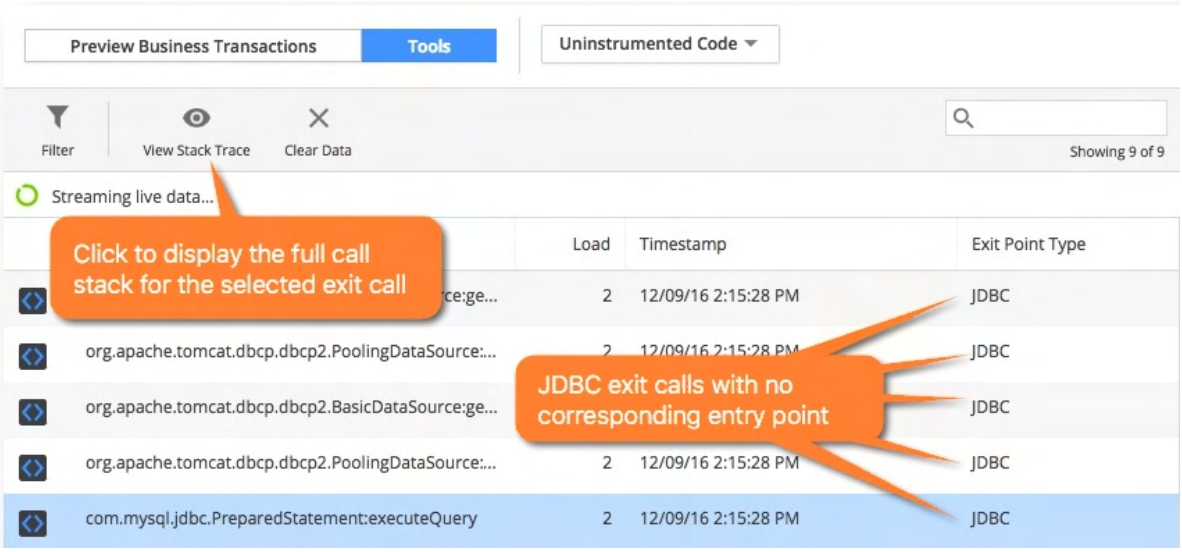


When you create custom match rules for servlets or for POJOs you can start a Live Preview session limited to the specific rule.

Inspect Uninstrumented Code to Discover Entry Points

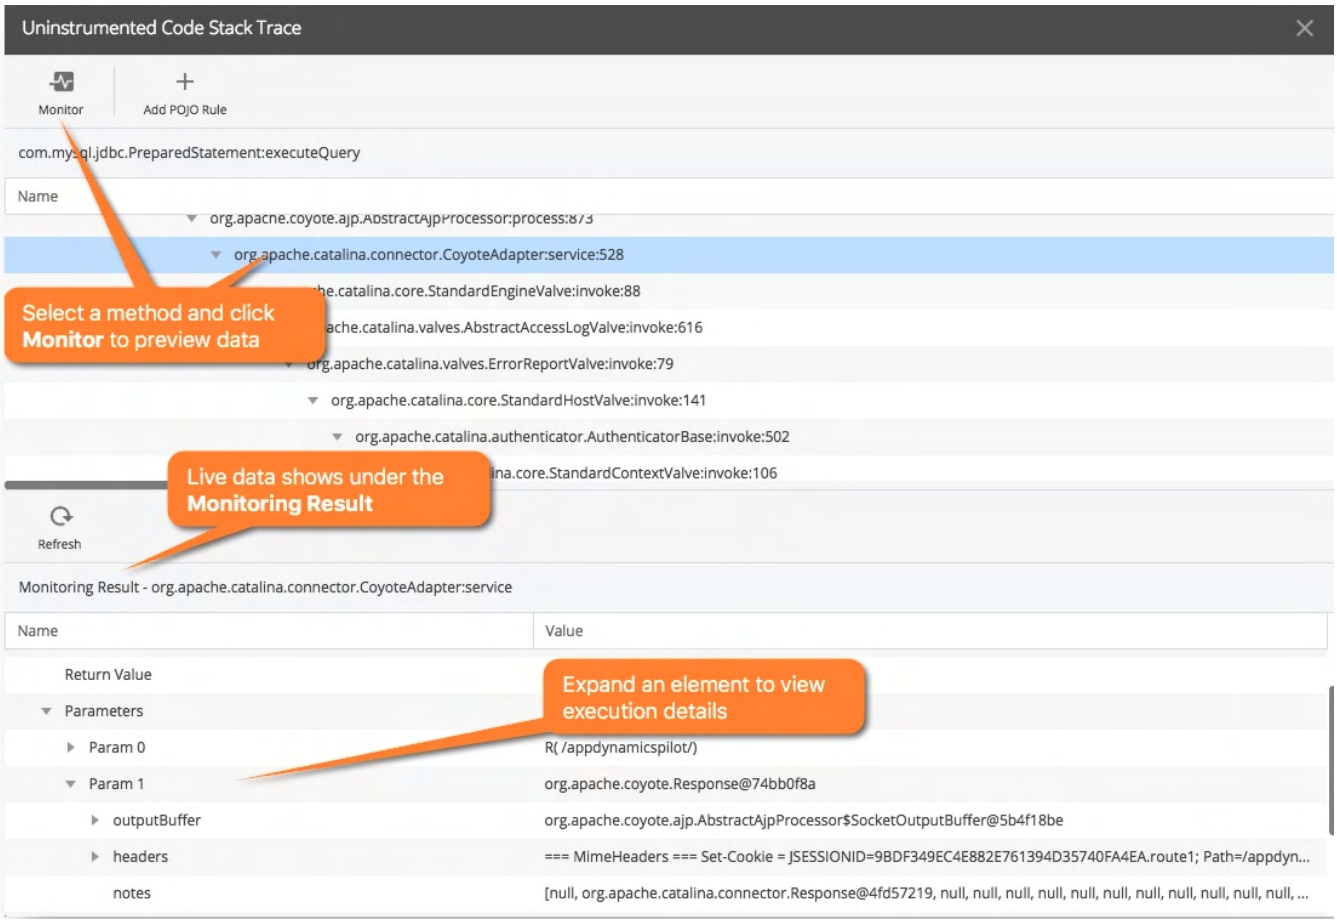
When the app agent doesn't automatically discover an entry point for a framework in your application, you can use Uninstrumented Code detection to find entry points for the framework. After you identify an entry point you want to track as a business transaction, you can create a custom match rule.

Uninstrumented Code detection identifies the support exit calls for an app agent on the node when the entry point is undetected. In the following example the Java Agent discovers some uninstrumented JDBC exit points:



You can select an exit point and click **View Stack Trace** to display the call stack for the exit point. Select any call in the stack trace and click **Monitor** to show interactive data for that specific call. When the agent returns the monitoring result, you can inspect the values for a specific method invocation including the **Invoked Object**, **Return Value**, **Parameters**, and more.

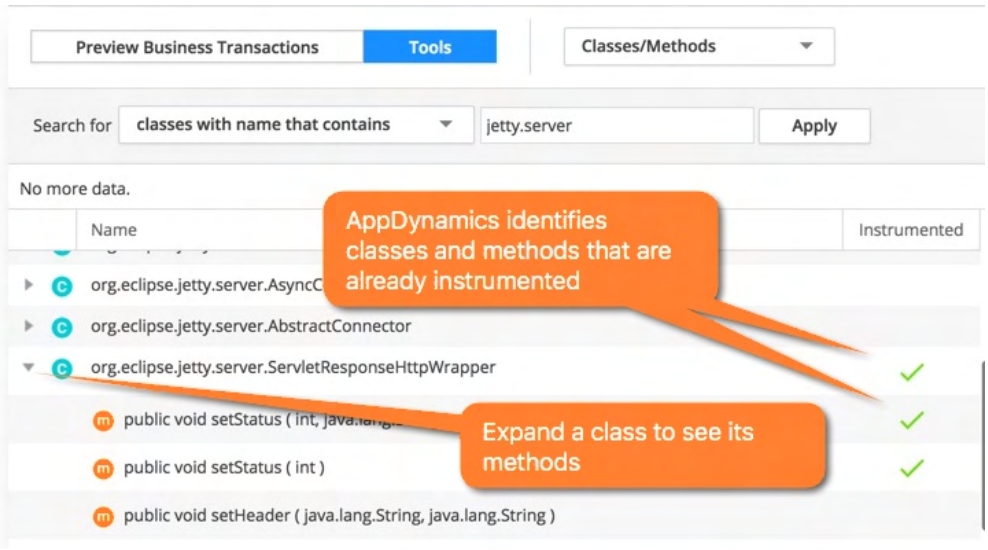
The example below shows the upstream stack trace for the `com.mysql.jdbc.PreparedStatement:executeQuery` JDBC exit call:



When you identify the method you want to instrument, you can click to add a POJO or POCO. The Controller UI automatically populates the Rule Configuration in the Add Rule editor with the class and method you want to instrument. Complete the custom match rule for the POJO or POCO as normal.

Search for Classes and Methods to Instrument

If you are familiar with your application code, you can use the Classes/Methods browser to search the running code for specific classes and methods to instrument. The example below illustrates how a search for `jetty.server` in a sample application returns both instrumented and uninstrumented classes and methods:



When you identify a method you want to instrument, right-click the method to open the Add Rule editor. AppDynamics automatically populates the class and method configuration based upon your search criteria from the Class/Method browser. You can right-click a class to instrument it, but you must add the method before you can save the POJO or POCO. Complete the custom match rule for the POJO or POCO as normal.

Backend Detection Rules

Related pages:

- Java Backend Detection
- .NET Backend Detection

In AppDynamics, databases and remote services (and in fact, any detected out of process components that are involved in Business Transaction processing) are collectively known as backends.

AppDynamics discovers backends from exit point instrumentation placed in the application code. An exit point is the precise location in the code where an outbound call is made from an instrumented node. AppDynamics automatically discovers a wide range of backends.

Default Automatic Backend Discovery

A discoverable backend is identified by its type and associated properties. The precise set of properties used to identify any given backend is dependent on its type. The type itself is defined in the built-in backend discovery rules for backend types supported out of the box. For exit calls to backends that are not instrumented with APM agents, AppDynamics uses the backend properties to identify and name the backend. Where a backend call is actually processed by a downstream tier also instrumented with AppDynamics, ensure that any given backend that is identified will always result in calls that will be processed by just one downstream tier.

This means, for example, that if tier A makes an HTTP call to an HTTP router on localhost:4040 which will forward the call to tier B or tier C depending on the URL, custom backend naming rules will be required to include enough segments of the request URL - as well as the host and port - such that requests destined for tier B will be associated with a backend with a different set of backend properties than those associated with tier C.

The **Automatic Backend Discovery** list in the **Configuration > Instrumentation >** Backend Detection tab shows the configurable backend discovery rules.

The automatic discovery rules vary according to the type of backend being identified, but generally include settings for enabling automatic discovery of the backend type, enabling correlation, and properties used to identify and name the backend. AppDynamics uses transaction correlation to track request processing across distributed tiers. Certain types of backends are automatically discovered as *high volume* exit points (sometimes called turbo exit points). These backend types include cache servers, EhCache, Danga Memcache, Memcached, and Oracle Coherence. For more about high volume exit points, see Exit Point Detection Rules.

When an exit point is identified for the first time, the exit call results in a backend discovery event.

Service Proxy

Sometimes an inaccurate identification of the backend destination causes each call that is sent (based on configuration) to a single backend, to arrive at one of several different downstream tiers.

For example, this situation may occur if the naming of the backend is based on the backend host and port where a particular backend's host:port combination actually identifies an Apache server. The Apache server then forwards requests to different downstream tiers based on the URL acting as a service proxy. When the AppDynamics Controller detects this situation, it will automatically instruct the upstream agent to identify the backend as a service proxy. Once that occurs, a service proxy icon will display on the flow map between the upstream tier and all of the possible target tiers shown downstream. See Service Proxy.

Permissions

To modify backend detection, you need the **Configure Backend Detection** permission.

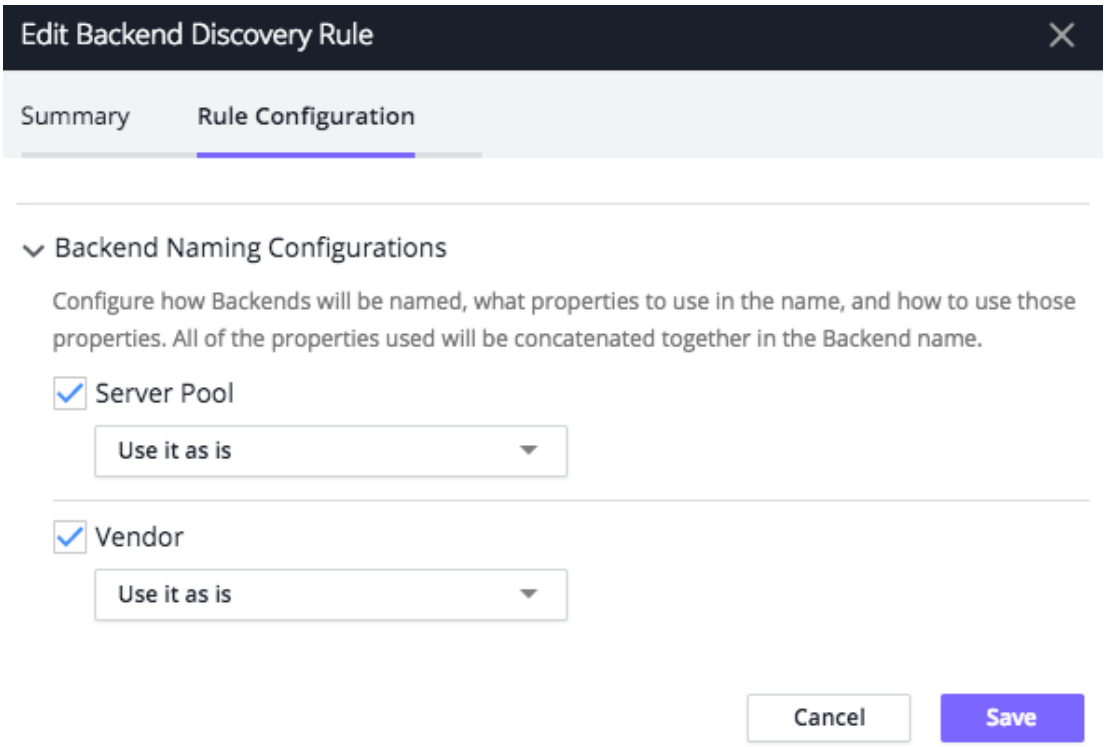
Modify Automatic Discovery

If you know that the application flow map should be showing a specific backend and you are not seeing it, you can modify the configuration to detect backends. You can:

- Edit the default backend discovery rules.
- Create new custom backend discovery rules.
- Create new custom exit points to provide visibility for backend types that are not automatically discovered.
- Disable automatic discovery of backends that are not of interest.
- Disable correlation for the backend.

In many cases, you can achieve the level of customization that you need by editing the default rules rather than creating new rules.

To edit a rule, in the Backend Detection tab, select the application and click **Edit Automatic Discovery**.



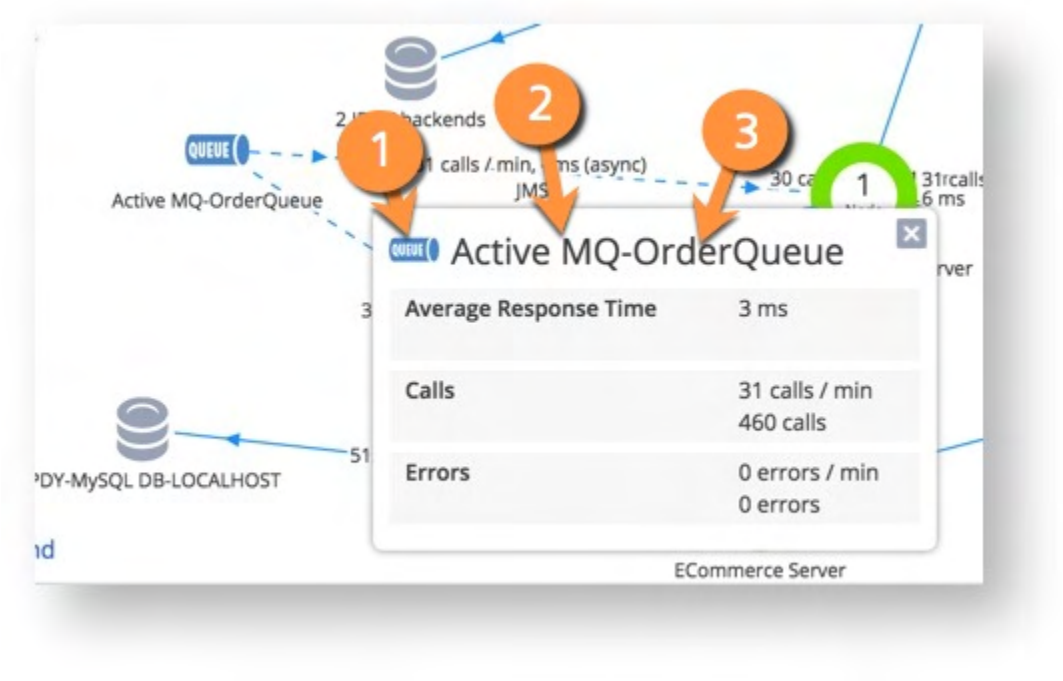
For certain backend types—particularly those named by URL—the name of the discovered backend instances include a port number. If the app agent is unable to discover the port number for some reason, the port number is displayed in the UI as "-1". This can happen, for example, when a port is not a public port or the API for discovering the port is not available on the application environment (often the case for an RMI backend type). Despite having an unknown port number, the backends are nonetheless uniquely identified.

Configurable Properties and Naming

For many of the automatically discovered backend types, AppDynamics uses a set of configurable properties to identify and name the backend. For example, the properties for a JMS messaging queue are something like this:

- DestinationType (for example, QUEUE)
- Destination (for example, OrderQueue)
- Vendor (for example, Active MQ)

The following informational popup shows how the values are used to identify a discovered backend. In the following example, callout 1 shows the value that corresponds to the destination type, callout 2 to the vendor name, and callout 3 to the destination queue name:



Aggregate or Split Backends

You can change the default configuration for the backend types shown in the UI to aggregate or split the backends. For example, you could disable the Vendor property for JMS backend detection to aggregate (join) all JMS backends with the same destination and destination type. The metrics for all JMS backends with the same destination and destination type would be aggregated as one backend.

For properties that you want to use, you can also configure how AppDynamics uses the property. For example, if the URL property is used to identify a backend and your URLs include a file name, the default configuration results in a separate backend for every file.

To reduce the number of backends identified using the URL property, configure which parts of the URL to use. For example, run a regular expression on the URL to discard the file name or any other parts of the URL that you do not want used for identification.

Add Custom Backend Discovery Rules

AppDynamics provides the additional flexibility to create new custom discovery rules for the automatically discovered backend types.

To create a custom discovery rule for an automatically discovered backend type, select the backend type in the **Automatic Backend Discovery** list. Click **Add** (the **+** icon) to create a new rule. Specify the following:

- **Name** for the custom rule.
- **Enabled** to enable or disable the rule.
- **Correlation Enabled** to specify whether or not to send business transaction correlation data to the backend**.**
- **Priority** for this custom rule compared to other custom rules for this backend type. The higher the number, the higher the priority. A value of 0 (zero) indicates that the default rule should be used.
- **Match Conditions** used to identify which backends are subject to the custom naming rules. AppDynamics applies the default rules to backends that do not meet all the defined match conditions.
- **Backend Naming Configuration** used to name the backends matching the match conditions. The naming configuration must include the property used by the match condition.

See specific exit points for examples.

All Other Traffic Backends

AppDynamics limits the number of backend systems that can be registered and tracked. Once the limit is reached (databases and remote services combined), additional backend are put in the "All other traffic for <type>" category.

The "type" is the backend type such as HTTP or Web Service. HTTP calls and JMS queues are the most common types that may reach the limit with the default configuration rules.

On a flow map, the category appears as follows:

Metrics for the backend calls grouped in the "All other traffic" category are aggregated. If the group includes backend instances that you want to be individually tracked, you can manage backend detection, as described in Manage Backend Discovery.

Backend Registration Limits

The limits on the number of backends that can be registered:

- The Controller enforces a limit of 1000 backend registrations in the business application for each type of backend (that is, 1000 HTTP backends, 1000 JMS backends, and so on). This setting is controlled by the `backend.registration.limit` Controller Setting. This limit applies whether the backends are resolved to a tier or unresolved.
- Agents apply a limit of 300 unresolved backends per application.

When the backend count exceeds the limit, the "All Other Traffic" category is automatically created. The logs indicate that a limit has been reached by a log entry such as the following:

```
[pool-1-thread-2] 21 Mar 2013 11:28:01,702 DEBUG AFastBackendResolver - Not discovering backend call [Exit
Point Type [WEB_SERVICE] Properties [{SERVICE_NAME=ZipCodeService002.wsdl}] Display Name [ZipCodeService002.
wsdl]] because maximum limit of discovered backends [300] reached.
```

Manage Backend Discovery

After reaching the backend registration limit, you should make sure that the systems being tracked as first-class registered backends are the ones that are important to you relative to those in the "All Other Traffic" category.

Also make sure that application environmental conditions are not causing an excess number of backends to be registered. These conditions may include:

- JMS queues that use the session ID in the destination. This causes each session to be identified as a separate backend.
- Calls to message queues hosted on the same server. In this case, you might not be interested in seeing each queue separately, and instead, want to aggregate everything for the same host and port to the same backend.
- Dynamic generation of IP addresses, such as when you host a service on Amazon Elastic Compute Cloud (Amazon EC2).
- Different JDBC drivers connecting to the same database may cause many backends. This can happen when there are slight variations in the driver metadata that AppDynamics uses to identify the database. For example, if two different JDBC drivers are used to access the same database, something as simple as a different spelling or format of the database name (ORACLE, oracle, or ORACL) can generate multiple database names when they are the actually the same physical database.

To manage backend registrations, you can change the configuration of the backend detection rules. For example, if a property causes excessive unique identification, consider removing the property or modifying its use in the detection and naming rule. If you created custom exit points, consider refining or removing them.

Delete Unnecessary Backends

Some backends may no longer have traffic. You can delete unused backends from the Remote Services List, any Remote Service dashboard, the Databases List, and any Database dashboard. If the backend has new traffic in the future, the app agent rediscovers it and reregisters it with the Controller.

You can also configure the Controller to automatically remove stale backends. See Stale Remote Service Removal.

Organize Backends in Flow Maps

Once you have configured detection for all the backends you require, you may need to organize the way they appear in the UI. See Group Remote Services on Flow Maps.

Exit Point Detection Rules

Custom exit points enable you to identify backend types that are not automatically detected. For example, you can define a custom exit point to monitor code calls to a file system read method.

After you have defined a custom exit point, the backend appears on the flow map with the type-associated icon you selected when you configured the custom exit point. See Custom Exit Points for Java.

Configuration Notes

You configure exit point detection in the **Configuration > Instrumentation** page. Select the Backend Detection tab and choose the application or tier on which to configure an exit point and the application type of the exit point, Java, .NET, and so on. From there you can add new exit points or modify existing ones.

The specific configuration options available differ based on the application type, but in general, you identify the exit point and specify the mechanism for it to be detected, such as a class and method name. These additional notes apply to exit point configuration:

- If the method you are using to identify the exit point is overloaded, you need to add the parameters that identify the signature for this form of the method.
- Match conditions let you restrict the method invocations for which you want AppDynamics to collect metrics based on runtime values tested by the condition. Match conditions can test parameter values or any value accessible by getter chain from the invoked object.
- Optionally, you can split an exit point based on a method parameter, the return value, or the invoked object.
- You can configure custom metrics and transaction snapshot data to collect for the backend.
- If you configure a custom backend for a method that encapsulates an automatically detected backend, such as an HTTP client call, you may lose correlation from the automatically detected exit call.
- Splitting a backend on return value may break correlation.

> ⚠ You are limited to 50 characters for the exit point value when adding a custom exit point or splitting/grouping exit points.

Adding a Custom Exit Point

When adding a custom exit point, you specify the class and method that identify an external call to the exit point. You can refine the call by specifying a return value, parameter, or getter chain match value.

The type you choose determines the icon that appears in the flow map for the custom exit point. If the type is not listed, select **Use Custom** and enter a string in the **Type** field to identify the exit point calls in the UI.

Note that you can also split the exit point based on these values. If you add a split condition for an exit point, it means that any exit point that matches the overall match condition for the custom exit point is further evaluated against the split condition. If its call matches the split condition, it is given the more specific name you configure in the split exit point configuration.

High Volume Exit Points

The **Is High Volume** option for custom exit points lets you create an optimized exit point configuration for backend systems with high-performance requirements, such as caching servers or in-memory databases.

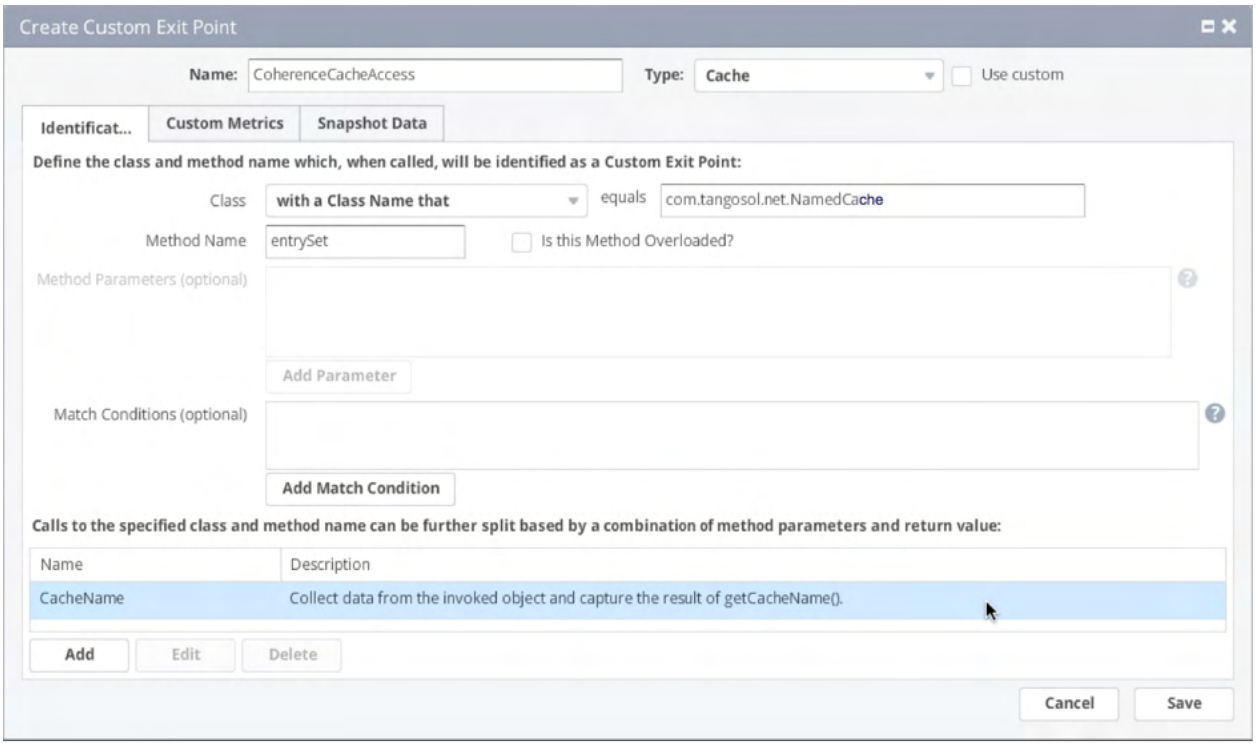
A "high volume" exit point keeps the overhead associated with the exit point to a negligible amount by bypassing certain processing operations on calls to this exit point. As a result, transaction correlation and error detail reporting are not available for the exit point, nor are match conditions in the exit point configuration.

With a high volume exit point, you do get the number of calls, number of errors, and average response time for calls.

Split and Group Exit Points

By splitting an exit point, you can use dynamic application values to identify an exit point. Specifically, you can use the value of either a method parameter, the method return value, or a value returned by a specified getter chain on the invoked object of the identified method. The configuration settings you use to configure exit point splitting are the same as used for Data Collectors. See Data Collectors for information on how to use the configuration UI.

A simple example of how you would use exit point splitting is for a cache exit point. In this example, say you configure splitting for an exit point that identifies a method for writing to the cache. The object on which the method for writing to the cache offers a method to get the current cache name, the `getCacheName()` method. By configuring a split on this method (as a getter chain on the invoked object), you can have the exit point named with the name of the cache node, as dynamically determined:



Splitting also lets you group exit points. Given an exit point for `NamedCache.entrySet()`, as shown in the example above, suppose we created another exit point. This one uses the `getAll()` method on the same class, `NamedCache`. It also has a split configuration that uses the `getCacheName()` method of the invoked object.

If the `getCacheName()` getter chain points to the same cache name when the `getAll()` and the `entrySet()` methods are invoked, they will be shown as calls to the same backend.

Java Backend Detection

Related pages:

- Exit Point Detection Rules
- Monitor Databases
- Remote Services

The AppDynamics Java Agent automatically discovers common types of remote services as backend systems based on the exit point associated with the backend. If AppDynamics does not automatically discover a backend system used in your environment, check whether it's an automatically discovered type (based on the list below) and compare the default exit points for the type to that used in your application environment.

Each automatically discovered backend type has a default discovery rule. Many backend types have a set of backend naming properties. Where individual properties are configurable, you can configure the property as follows:

- Use the property as is.
- Use segments of the property.
- Run a regular expression on the property. See Using Regular Expressions.
- Execute methods on the property. See Using Getter Chains.

For instructions to revise backend discovery rules, see Backend Detection Rules.

Amazon Simple Notification Service Backends

AppDynamics detects exit calls to the Amazon SNS messaging service using the Amazon SNS Client: `AmazonSNSClient.publish`.

Amazon SNS Naming Properties

You can enable or disable the use of the following properties for Amazon S3 backend identification:

Configurable Properties	Default Automatic Amazon SNS Backend Discovery/Naming
Vendor	Yes
Topic ARN	Yes

Amazon Simple Queue Service Backends

AppDynamics can detect the following types of Amazon Web Services SQS message queue actions:

- Basic send/receive
- Batched send/receive
- Asynchronous send/receive

Correlating SQS traffic requires you to configure the continuation entry point for the SQS message.

Amazon Simple Storage Service Backends

AppDynamics automatically detects the following exit points for Amazon Web Services S3 backends:

- `AmazonS3Client.deleteObject`
- `AmazonS3Client.getObject`
- `AmazonS3Client.getObjectMetadata`
- `AmazonS3Client.listObjects`
- `AmazonS3Client.putObject`

Amazon S3 Naming Properties

You can enable or disable the use of the following properties for Amazon S3 backend identification:

Configurable Properties	Default Automatic Amazon S3 Discovery/Naming
Bucket Name	Yes
Vendor	Yes
Object Key	No

Amazon Web Services Backends

AppDynamics detects the following exit calls to the following Amazon Web Services:

- DynamoDB requests using the `AmazonDynamoDBClient` create, read, update, and delete (CRUD) methods using the Amazon low-level DynamoDB API. The agent discovers the Document API calls as the underlying low-level API call.

Amazon Web Service Naming Properties

For Amazon Web Services, you can enable or disable the use of the following naming properties for backend identification:

Configurable Properties	Default Automatic Amazon Web Service Backend Discovery/Naming
Vendor	Yes
Service	Yes
Endpoint	Yes

Apache Cassandra CQL Backends

By default, AppDynamics automatically detects and identifies exit calls to Apache Cassandra using Thrift and DataStax drivers.

> Exceptions returned from Cassandra backends show up as separate exit calls. For the DataStax 1.0 driver, the Java Agent detects an "unknown" Cassandra backend in order to capture the error details.

Cassandra Backend Naming Properties

You can enable or disable the use of the properties below for Cassandra backend identification:

> When you configure Cassandra backend naming, consider the following:
>
> - For DataStax clients, AppDynamics does not recommend using the keyspace property. Due to driver limitations, the keyspace property is only available when `Statement.setKeyspace` is called explicitly in Cassandra. This can lead to the discovery of multiple backends.
> - Thrift clients don't support Cluster Name, Rack or Data Center properties, so those properties return null for Thrift.

Configurable Properties	Default Automatic Cassandra CQL Backend Discovery/Naming
Cluster Name	Yes
Keyspace	No
Host	Yes
Port	Yes
Data Center	No
Rack	No

Apache Kafka Backends

By default, the Java Agent detects publish activity to Apache Kafka as an exit point from a Java node. You can configure the Java Agent to detect Kafka consumer activity as an entry point, see Apache Kafka Consumer Backends.

Kafka Backend Naming Properties

You can enable or disable the use of the following properties for Kafka backend identification:

Configurable Properties	Default Automatic IBM MQ Backend Discovery/Naming
Vendor	Yes
Topic Name	Yes
Broker URL	No

Default Kafka JMX Metrics

There are lots of JMX metrics that are exposed by Kafka Producer and Consumer. We have selected a few of the metrics that we think could be useful for customers and created OOTB rules for them. PFB the list of metrics supported by Producer and Consumer respectively. In case you are interested in any of the other metric for which OOTB rule is not available you can go to MBean browser, select the metric and create a rule out of it.

Couchbase Backends

By default, AppDynamics automatically detects and identifies exit calls made to the Couchbase cluster node.

Couchbase Backend Naming Properties

You can enable or disable the use of the following properties for Couchbase exit backend identification:

Configurable Properties	Default Automatic Couchbase Backend Discovery/Naming
Server Pool	Yes
Vendor	Yes
Bucket Name	Yes

HTTP Backends

HTTP exit point activity includes all HTTP calls done outside of a web service call. Web service calls are not considered an HTTP exit point. By default, the Java Agent names the HTTP backend for the Host and Port properties. For instance, "myHTTPHost:5000".

HTTP Backend Naming Properties

You can enable or disable the use of the following properties for HTTP backend identification:

Configurable Properties	Default Automatic HTTP Backend Discovery/Naming
Host	Yes
Port	Yes
URL	No
Query String	No

For examples of common HTTP backend configurations, see HTTP Backend Detection.

For sample JDBC backend configurations, see Example JDBC Backend Configuration.

IBM Websphere Message Queue Backends

IBM MQ, also known as IBM WebSphere MQ and IBM MQSeries, is IBM's message-oriented middleware similar to JMS. Several additional properties are configurable, such as host and port. This is useful where you have lots of queues and you want to monitor them based on a subset of the properties.

IBM MQ Backend Naming Properties

You can enable or disable the use of the following properties for IBM MQ backend identification:

Configurable Properties	Default Automatic IBM MQ Backend Discovery/Naming
Destination	Yes
Destination Type	Yes
Host	Yes
Port	Yes
Major Version	Yes
Vendor	Yes

For examples of common message queue configuration scenarios, see Example Message Queue Backend Configuration.

Java Message Service Backends

JMS backend activity includes all JMS message send and publish activity. By default, AppDynamics identifies JMS back ends using the properties of the JMS server such as: vendor, destination name, and destination type. The default configuration uses all three properties of the JMS queue.

JMS Backend Naming Properties

You can enable or disable the use of the following properties for JMS backend identification:

Configurable Properties	Default Automatic JMS Backend Discovery/Naming
Destination	Yes
Destination Type	Yes
Vendor	Yes

Transaction names are derived from the enabled properties, for example, "ActiveMQ-OrderQueue".

For examples of common message queue configuration scenarios, see Example Message Queue Backend Configuration.

JDBC Backends

JDBC backend activity consists of all JDBC calls including inserts, queries, updates, getting connections from connection pools, and so on.

Class	Method
`oracle.jdbc.driver.PhysicalConnection`	• `prepareStatement` • `prepareCall` • `commit` • `rollback`
`oracle.jdbc.driver.OracleStatement`	• `executeQuery` • `executeUpdate` • `execute`
`oracle.jdbc.driver.OracleDataSource`	• `getConnection`
`oracle.jdbc.driver.OraclePreparedStatement`	• `executeQuery` • `addBatch` • `execute` • `executeUpdate`
`oracle.jdbc.driver.OraclePreparedStatementWrapper`	• `execute` • `executeQuery` • `executeUpdate`

The Java Agent measures the response time for a database call as the round trip time it takes for a JDBC call to return. The response time for a database call includes network round trip time + database connection time + SQL query time or any other time spent in the database.

By default, the agent identifies JDBC backends using the following logical properties of the database:

- URL
- Host name
- Port number
- Database schema
- Version
- Vendor

If a database backend has the same hostname, port number, and database type as a database server already configured in a database Collector, the database backend is automatically matched with the Collector, and drill-downs from the Application Flow Map, Tier Flow Map or Node Flow Map to Database Monitoring are enabled.

JDBC Backend Naming Properties

You can enable or disable the use of the following properties for JDBC backend identification:

Configurable Properties	Default Automatic JDBC Backend Discovery/Naming	Description
URL	Yes	JDBC URL provided to the driver
Host	Yes	Database host
Port	Yes	Database port
Database	Yes	Database schema
Version	Yes	Database version as reported by JDBC driver
Vendor	Yes	Database vendor as reported by JDBC driver

Jolt Backends

AppDynamics detects exit calls to Tuxedo services from the JoltRemoteService class in the Jolt Class Library.

Jolt Naming Properties

You can enable or disable the use of the following naming properties for Jolt backend identification.

Configurable Properties	Default Automatic Jolt Backend Discovery/Naming
Host	Yes
Port	Yes
Service	Yes

MongoDB Backends

By default, the Java Agent detects exit calls to MongoDB using the Mongo Java Driver over the MongoDB Wire Protocol. The agent detects the exit point on the Wire Protocol methods and excludes the methods between the external API and the Wire Protocol.

MongoDB Backend Naming Properties

Configurable Properties	Default Automatic MongoDB Backend Discovery/Naming
Host	Yes
Port	Yes
Database	Yes

RabbitMQ Backends

RabbitMQ is open source, commercially supported, messaging middleware that runs on many different operating systems. The Java Agent discovers exit points using the RabbitMQ Java API, amqp-client.jar in most distributions. By default, RabbitMQ backends are identified by Host, Port, Routing Key, and Exchange. For instance: "amqp://guest@127.0.0.1:5672/exchange/task_queue".

RabbitMQ Backend Naming Properties

You can enable or disable the use of the following properties for RabbitMQ backend identification:

Configurable Properties	Default Automatic RabbitMQ Backend Discovery/Naming
Host	Yes
Port	Yes
Routing Key	Yes
Exchange	Yes

For examples of common message queue configuration scenarios, see Example Message Queue Backend Configuration.

RMI Backends

The Java Agent automatically discovers backends called using the standard Java RMI API. For a list of supported RMI frameworks, see 'RPC/Web Services API/HTTP Client Support' on Java Supported Environments.

RMI Backend Naming Property

The JAVA Agent names the RMI backend for the URL. You can configure how the agent uses the URL to name the RMI backend.

Thrift Backends

By default, AppDynamics automatically detects and identifies Apache Thrift exit points (backends).
See Apache Thrift for details.

Thrift Backend Naming Properties

You can enable or disable the use of the following properties for Thrift exit backend identification:

Configurable Properties	Default Automatic Thrift Backend Discovery/Naming
Host	Yes
Port	Yes
transport	Yes

Web Services Backends

Web service backend activity includes all web service invocations. Web service backends are identified using the web service name.

Web Services Backend Naming Properties

Configurable Properties	Default Automatic Web Service Backend Discovery/Naming
Service	Yes
URL	No
Operation	No
Soap Action	No
Vendor	No

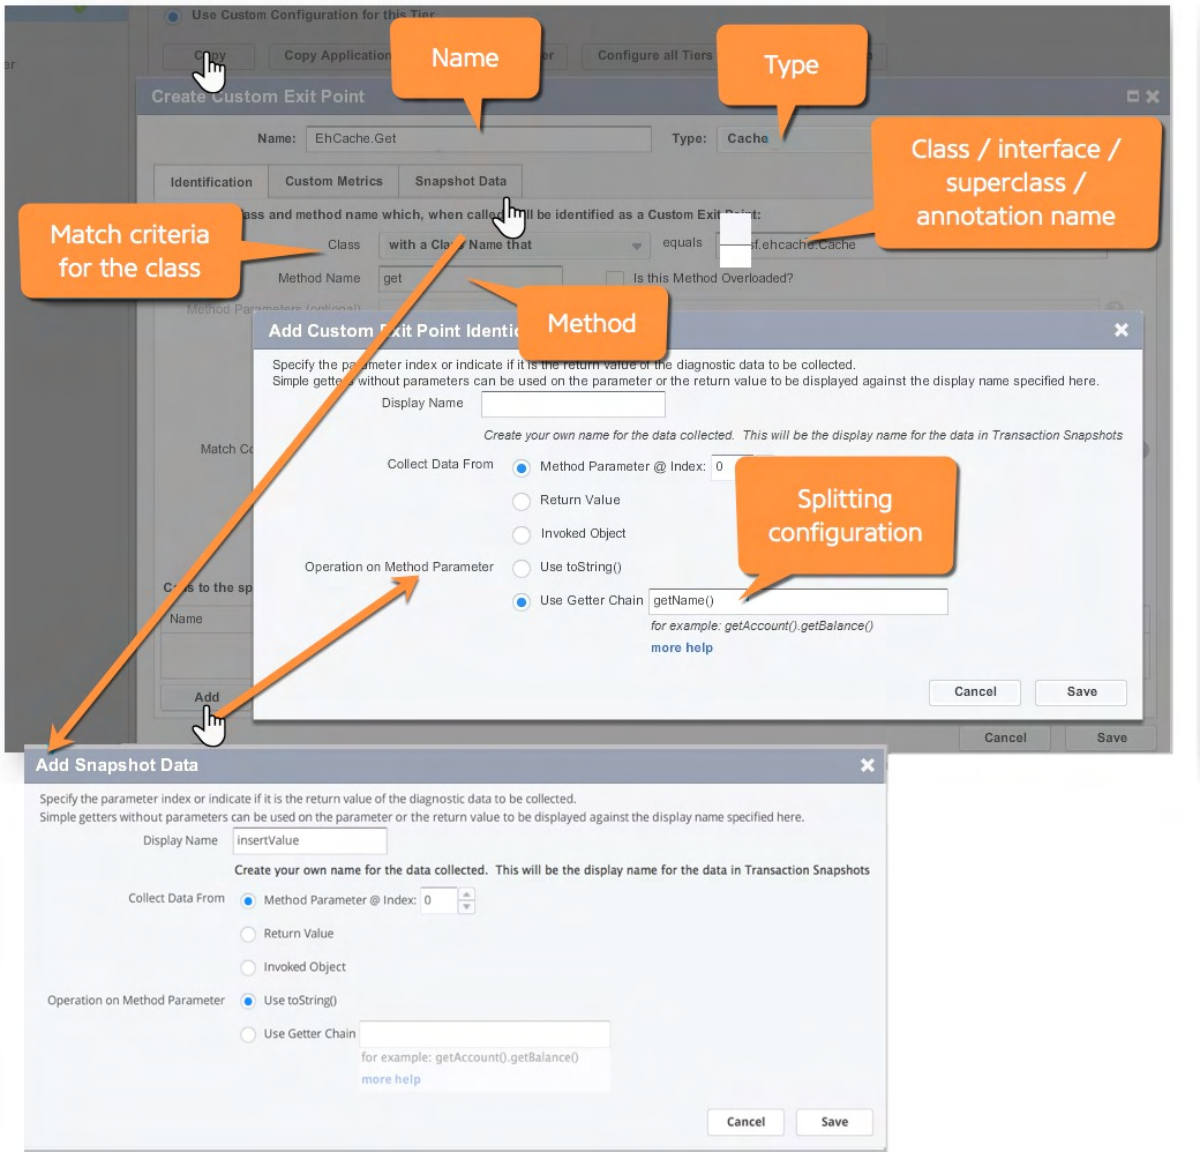
By default, the gRPC backend is identified as `ServiceName-gRPC`. This is also configurable under web services backend.

Custom Exit Points for Java

This page describes settings you can use to create custom exit point configurations for specific backends in Java environments.

In general, custom exit rules match calls to custom backends by class and method name. In some cases, you need to configure splitting as well. The following tables give you the class and method names to use for the various types.

Enter the configuration settings in the corresponding fields in the custom exit point UI. The following screenshot illustrates a sample configuration for an EhCache custom match rule:



For more about creating custom exit points, see create a custom exit point.

> Oracle Coherence, EhCache, and Memcached backends are detected automatically as high volume exit points. You can create custom exit points for the backends as described here for particular backend splitting and naming results.

Coherence Exit Points

Name of the Exit Point	Type	Method Name	Class Match Criteria	Class/Interface/Superclass /Annotation Name	Method Name	Splitting Configuration
Coherence.Put	Cache		that implements an interface which	com.tangosol.net.NamedCache	put	getCacheName()
Coherence.PutAll	Cache		that implements an interface which	com.tangosol.net.NamedCache	putAll	getCacheName()

Coherence.EntrySet	Cache		that implements an interface which	com.tangosol.net.NamedCache	entrySet	getCacheName()
Coherence.KeySet	Cache		that implements an interface which	com.tangosol.net.NamedCache	keySet	getCacheName()
Coherence.Get	Cache		that implements an interface which	com.tangosol.net.NamedCache	get	getCacheName()
Coherence.Remove	Cache		that implements an interface which	com.tangosol.net.NamedCache	remove	getCacheName()

EhCache Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/Superclass/Annotation Name	Method Name	Splitting Configuration
EhCache.Get	Cache	With a class name that	net.sf.ehcache.Cache	get	getName()
EhCache.Put	Cache	With a class name that	net.sf.ehcache.Cache	put	getName()
EhCache.PutIfAbsent	Cache	With a class name that	net.sf.ehcache.Cache	putIfAbsent	getName()
EhCache.PutQuiet	Cache	With a class name that	net.sf.ehcache.Cache	putQuiet	getName()
EhCache.Remove	Cache	With a class name that	net.sf.ehcache.Cache	remove	getName()
EhCache.RemoveAll	Cache	With a class name that	net.sf.ehcache.Cache	removeAll	getName()
EhCache.RemoveQuiet	Cache	With a class name that	net.sf.ehcache.Cache	removeQuiet	getName()
EhCache.Replace	Cache	With a class name that	net.sf.ehcache.Cache	replace	getName()

LDAP Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/Superclass/Annotation Name	Method Name
LDAPExitPoint.Bind	LDAP	With a class name that	javax.naming.directory.InitialDirContext	bind
LDAPExitPoint.Rebind	LDAP	With a class name that	javax.naming.directory.InitialDirContext	rebind
LDAPExitPoint.Search	LDAP	With a class name that	javax.naming.directory.InitialDirContext	search
LDAPExitPoint.ModifyAttributes	LDAP	With a class name that	javax.naming.directory.InitialDirContext	modifyAttributes
LDAPExitPoint.GetNextBatch	LDAP	With a class name that	com.sun.jndi.ldap.LdapNamingEnumeration	getNextBatch
LDAPExitPoint.NextAux	LDAP	With a class name that	com.sun.jndi.ldap.LdapNamingEnumeration	nextAux
LDAPExitPoint.CreatePooledConnection	LDAP	With a class name that	com.sun.jndi.ldap.LdapClientFactory	createPooledConnection
LDAPExitPoint.Search	LDAP	With a class name that	com.sun.jndi.ldap.LdapClientFactory	search
LDAPExitPoint.Modify	LDAP	With a class name that	com.sun.jndi.ldap.LdapClientFactory	modify

Mail Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/Superclass/Annotation Name	Method Name
MailExitPoint.Send	Mail Server	With a class name that	javax.mail.Transport	send
MailExitPoint.SendMessage	Mail Server	With a class name that	javax.mail.Transport	sendMessage

Memcached Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/Superclass/Annotation Name	Method Name
Memcached.Add	Cache	With a class name that	net.spy.memcached.MemcachedClient	add
Memcached.Set	Cache	With a class name that	net.spy.memcached.MemcachedClient	set
Memcached.Replace	Cache	With a class name that	net.spy.memcached.MemcachedClient	replace
Memcached.CompareAndSwap	Cache	With a class name that	net.spy.memcached.MemcachedClient	cas
Memcached.Get	Cache	With a class name that	net.spy.memcached.MemcachedClient	get

Memcached.Remove	Cache	With a class name that	net.spy.memcached.MemcachedClient	remove

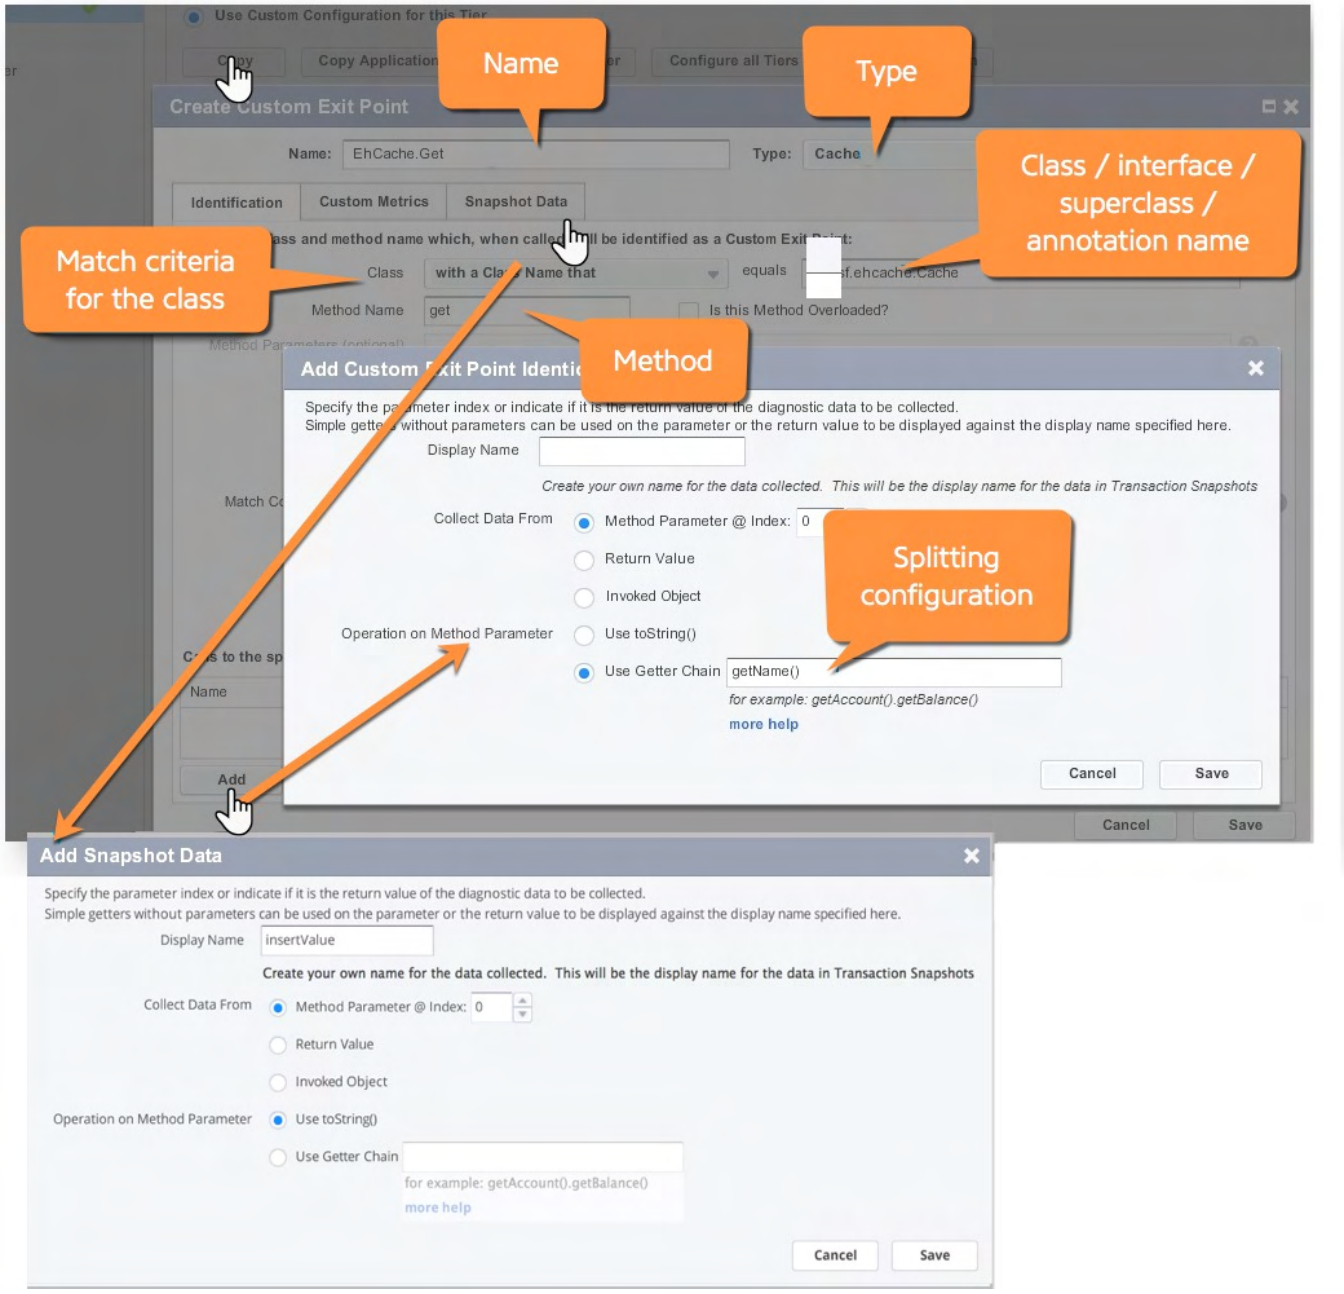
MongoDB Exit Points

Name of Exit Point	Type	Class Match Criteria	Class/Interface/Superclass/ Annotation Name	Method Name	Splitting Config/Custom Exit Point Identifier		Snapshot Data Operation on Invoked Object
					Collect Data From	Getter Chain Operation on Invoked Object	
MongoDB.Insert	JDBC	With a class name that	com.mongodb.DBCollection	insert	Invoked Object	getDB().getName()	Parameter_0.toString()
MongoDB.Find	JDBC	With a class name that	com.mongodb.DBCollection	find	Invoked Object	getDB().getName()	Parameter_0.toString()
MongoDB. Update	JDBC	With a class name that	com.mongodb.DBCollection	update	Invoked Object	getDB().getName()	Parameter_0.toString()
MongoDB. Remove	JDBC	With a class name that	com.mongodb.DBCollection	remove	Invoked Object	getDB().getName()	Parameter_0.toString()
MongoDB.Apply	JDBC	With a class name that	com.mongodb.DBCollection	apply	Invoked Object	getDB().getName()	Parameter_0.toString()

Avoiding high overhead

AppDynamics recommends that you avoid instrumenting highly-used methods, such as the find() method, because the activity around these methods can cause an undesired amount of overhead on the system.

Sample MongoDB Exit Point Configuration



SAP Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/Superclass/Annotation Name	Method Name
SAP.Execute	SAP	With a class name that	com.sap.mw.jco.rfc.MiddlewareRFC$Client	execute
SAP.Connect	SAP	With a class name that	com.sap.mw.jco.rfc.MiddlewareRFC$Client	connect
SAP.Disconnect	SAP	With a class name that	com.sap.mw.jco.rfc.MiddlewareRFC$Client	disconnect
SAP.Reset	SAP	With a class name that	com.sap.mw.jco.rfc.MiddlewareRFC$Client	reset
SAP.CreateTID	SAP	With a class name that	com.sap.mw.jco.rfc.MiddlewareRFC$Client	createTID
SAP.ConfirmTID	SAP	With a class name that	com.sap.mw.jco.rfc.MiddlewareRFC$Client	confirmTID

Example Message Queue Backend Configuration

Monitor the Server by Ignoring the Queue Name

In JMS example, the application is making calls to a message server that handles several queues. The sample destination names look like this:

- AccountQ
- AccountReplyQ
- AccountRecQ
- AccountDebitQ

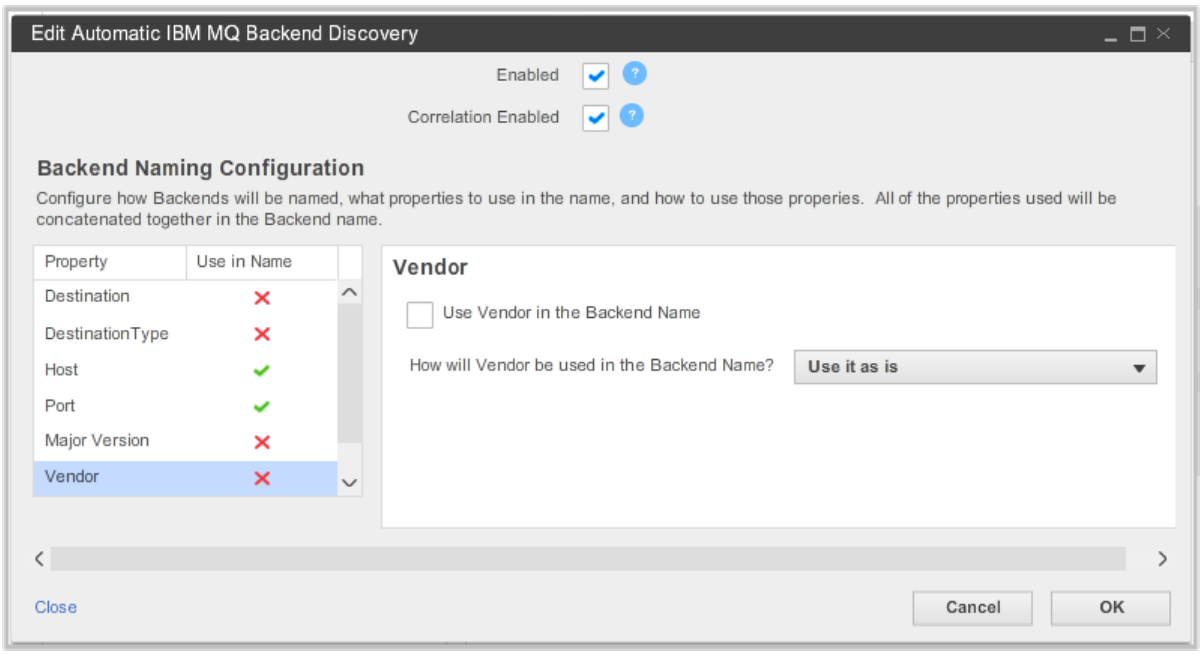
The default automatic discovery rule detects one backend for each unique destination and so the flow map shows one queue backend for each different queue name. In this example, each of the above would show as a separate backend on the application flow map. If you are interested in monitoring the performance of the server and not each queue name, you can modify the configuration to ignore the Destination property and use just the Type and Vendor.

To achieve this result, you create a new custom JMS Discovery Rule.

Taking IBM MQ for another example, the application is making calls to a message server that handles several queues. The sample destination names look like this:

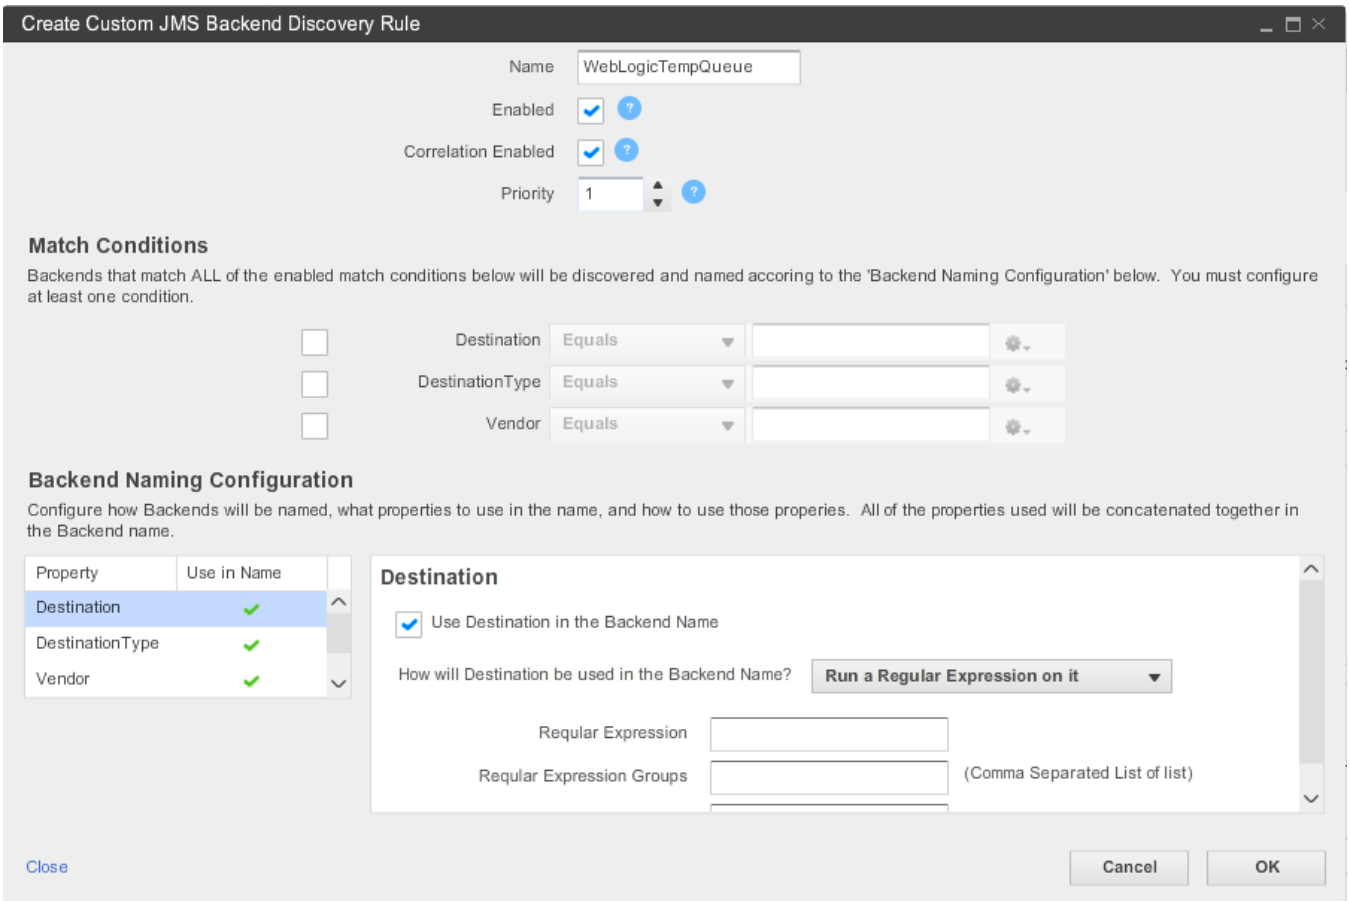
- MQhostwest-US:1521
- MQhosteast-US:1521
- MQhostsouth-US:1521

The default automatic discovery rule detects one backend for each unique destination and so the flow map shows one queue backend for each different queue name. In this example, each of the above would show as a separate backend on the application flow map. If you are interested in monitoring the performance of the server and not each queue name, you can create a discovery rule that just uses the Host and Port, as follows:



Temporary Queues

In this example an application creates many temporary JMS response queues that are deleted after the message is received. By default, AppDynamics discovers these queues separately and lists each one as a unique remote service. This default behavior probably does not enable effective monitoring. Instead, you can create a custom JMS discovery rule stating that if the destination name contains "TemporaryQueue", list it as "WeblogicTempQueue", or whatever name makes sense in your monitoring environment. In this way, you can monitor the performance that matters. The configuration to accomplish this is shown in the following screen shot:



Session ID in the Queue Name

If your JMS queues use the session ID in the destination, this causes each session to be identified as a separate backend. In this case, you might not be interested in seeing each queue separately, and instead want to aggregate everything for the same host and port to the same backend. You can generate the right name and the correct number of backends to monitor by editing the automatic discovery rule. Doing this enables you to monitor the key performance indicators (KPIs) that are of most interest to you.

Example JDBC Backend Configuration

Related pages:

- Java Backend Detection
- Using Regular Expressions

Depending on exactly what you need to monitor, you may want to change the default JDBC configuration. When you see the same physical database represented as multiple JDBC databases, you may need to revise the automatic discovery rule. Doing this enables you to more effectively monitor the key performance indicators (KPIs) that are of most value to you.

Multiple Databases from Same Vendor

JDBC connections to the same physical Oracle database (with the same URI) may appear as multiple backends. In some circumstances, the Vendor property captured for the database is different. This can happen when different drivers are used to access the database. For example, you might see JDBC backends with the following vendor names:

- Oracle DB
- Oracle

If the database driver package name matches the standard Oracle database driver, then the vendor name used is "Oracle DB". If it doesn't match, then the product name from the database metadata (using the java.sql.DatabaseMetaData class) is used as a vendor name. So database calls that use different drivers to reach the same physical database may be detected as separate databases. You can fix this by disabling the use of the Vendor property in the discovery rule.

JDBC with Complex URLs

In this example, the database URL is configured for high availability, so it is quite long and complex. Choosing the **Run a regular expression on it** URL option is the way to go. Disable the use of the Host and Port properties for JDBC automatic discovery. Instead enable the use of the URL that appears in the JDBC call, along with a regular expression to get the correct database naming and discovery.

For example, to extract all the hosts and all the ports from the following URL:

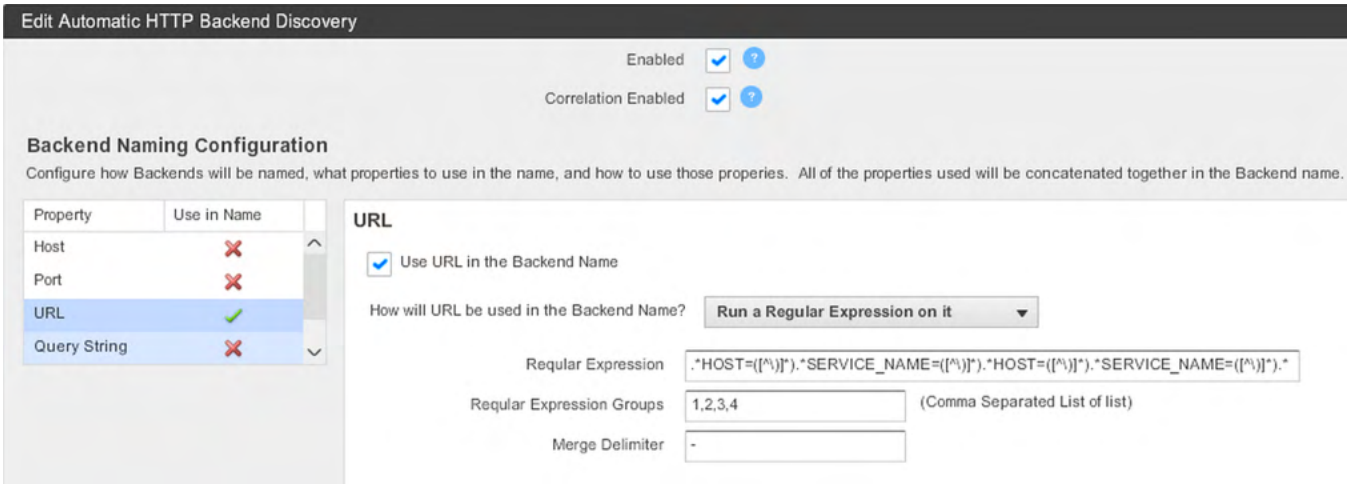
```
jdbc:oracle:thin:@(DESCRIPTION_LIST=(LOAD_BALANCE=OFF)(FAILOVER=ON)(DESCRIPTION=(ADDRESS_LIST=(LOAD_BALANCE=ON)
(ADDRESS=(PROTOCOL=TCP)(HOST=titanpfmcl01)(PORT=1521)))(CONNECT_DATA=(SERVICE_NAME=trafrefpfm01.global.
trafigura.com)))(DESCRIPTION=(ADDRESS_LIST=(LOAD_BALANCE=ON)(ADDRESS=(PROTOCOL=TCP)(HOST=titanpfmcl02)(PORT =
1521)))(CONNECT_DATA=(SERVICE_NAME=trafrefpfm01.global.trafigura.com))))
```

This sample is for a string that contains the host and service name twice. You can also use port in your regular expression if needed by your requirements.

The following regular expression applied to the previous high availability URL results in a backend name similar to this: titanpfmcl01-trafrefpfm01.global.trafigura.com-titanpfmcl02-trafrefpfm01.global.trafigura.com.

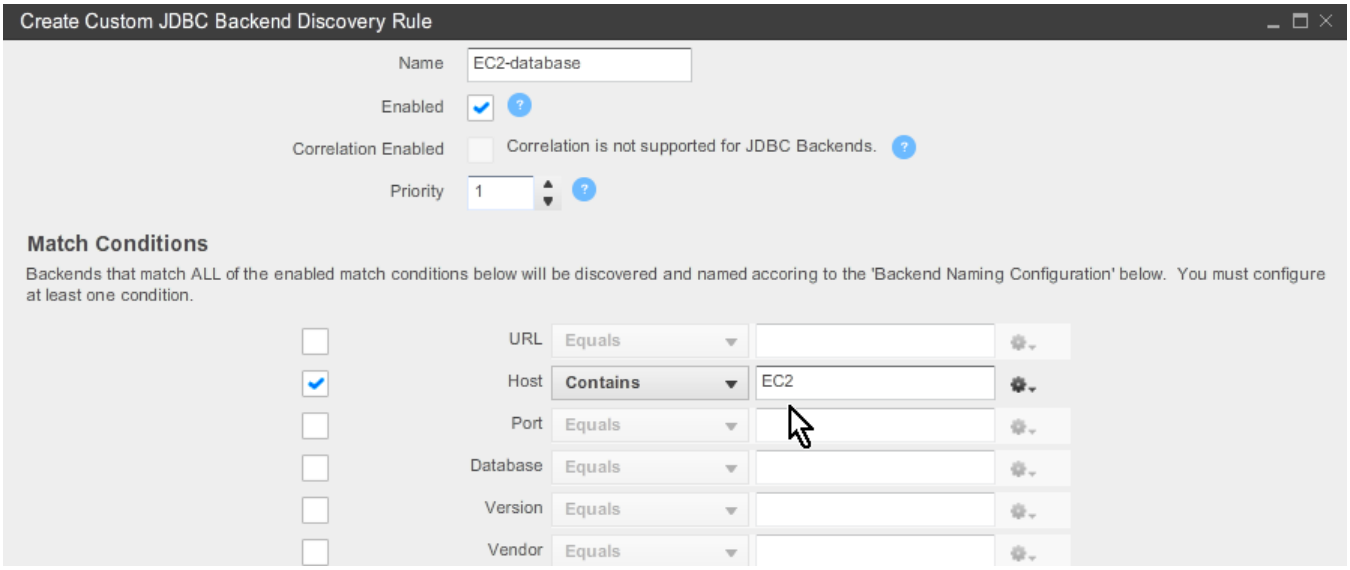
```
.*HOST=([^\)]*).*SERVICE_NAME=([^\)]*).*HOST=([^\)]*).*SERVICE_NAME=([^\)]*).*
```

Note: the expression starts and end with "." Set **Regular Expression Groups** to **1,2,3,4**.
Set the **Merge Delimiter** to "-".
This configuration looks like this in the UI:

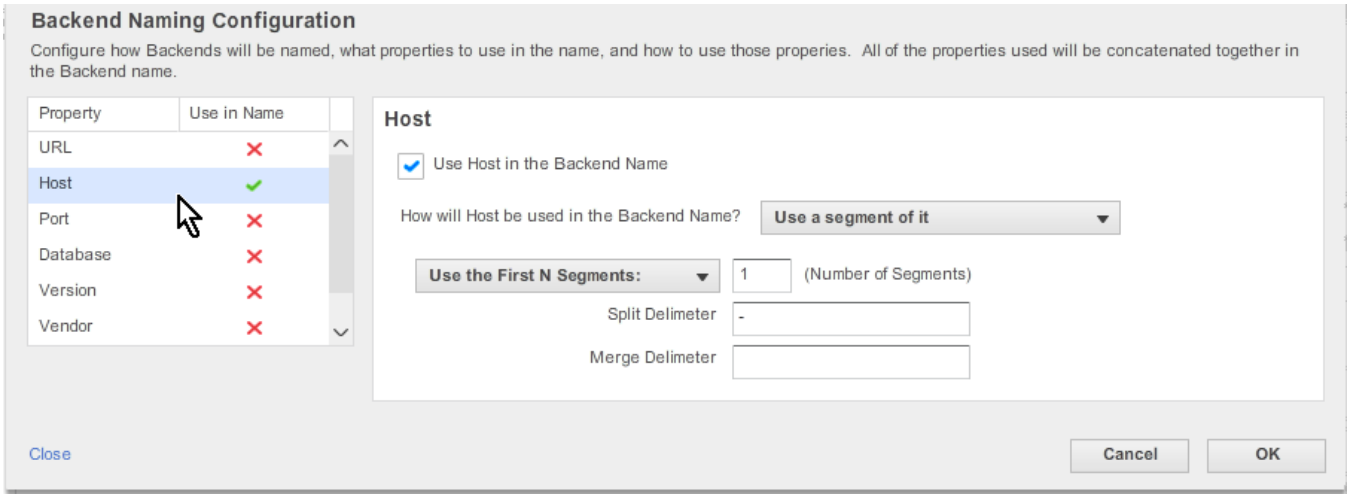


EC2 Hosted Databases

AppDynamics automatically discovers JDBC backends based on host, port, URL, database, version and vendor values. To monitor all JDBC databases that contain "EC2" in their host names as a single database, create a JDBC custom discovery rule and use the following match condition: Host Contains "EC2" as shown in the following screen shot.



Assuming host names of the format "EC2-segment2-segment3", use the following naming configuration:



This configuration results in a single database icon on the flow map named "EC2".

Apache Kafka Consumer Backends

You can configure the AppDynamics Java Agent to detect entry points for Apache Kafka consumer activity using `KafkaConsumer.poll()` (introduced in Kafka v0.10) and `Kafka SimpleConsumer.fetch()` (introduced in Kafka v0.9). Prior to version 0.11, the Kafka payload did not include a location to store correlation data, so end-to-end Business Transaction correlation is only possible with the Kafka client and broker >= 0.11.

KafkaConsumer.poll

To instrument Kafka consumer entry points using `KafkaConsumer.poll()`, identify the method in which the consumer reads messages in a loop with a custom interceptor definition. We instrument the iterator's next method to start and end the Business Transaction for each message. There could be many iterators used for iterating messages but we only support iterators of the following types:

- `kafka.consumer.ConsumerIterator`
- `org.apache.kafka.clients.consumer.ConsumerRecords$ConcatenatedIterable$1`

1. Identify the class and method of the loop that processes messages from Kafka. Consider, for example, a class `MyConsumer` that employs the following loop to poll and process messages from Kafka:

   ```
   ConsumerRecords<String, String> records = kafkaConsumer.poll(1000);
   pollMessages(records);
   private void pollMessages(ConsumerRecords<String, String>records) throws Exception {
      //AppDynamics instrumentation gets applied here
   for (ConsumerRecord<String, String> record : records) {
      //Processing of the records
      System.out.println(record.value());
      }
   }
   ```

   For this case, you want to intercept:

   - Class: `MyConsumer`
   - Method: `pollMessages`

   The interceptor can also be applied to a method that processes individual records, not just a loop. For example:

   ```
   ConsumerRecords<String, String> records = kafkaConsumer.poll(1000);
   pollMessages(records);
   private void pollMessages(ConsumerRecords<String, String>records) throws Exception {
      //AppDynamics instrumentation gets applied here
   for (ConsumerRecord<String, String> record : records) {
      processRecord(record)
      }
   }
   ```

2. Use your preferred text editor to create and edit a file named custom-interceptors.xml at the following path:
   `<agent_home>/<version_number>/conf`

   For example:
   `/usr/home/appdynamics/appagent/ver4.3.1.0/conf/custom-interceptors.xml`
3. Copy the following XML to `custom-interceptors.xml`:

   ```
   <custom-interceptors>
       <custom-interceptor>
           <interceptor-class-name>com.singularity.KafkaMarkerMethodInterceptor</interceptor-class-name>
           <match-class type="matches-class">
               <name filter-type="equals">my-fully-qualified-class-name</name>
           </match-class>
           <match-method>
               <name>my-method-name</name>
           </match-method>
       </custom-interceptor>
   </custom-interceptors>
   ```

4. Set the value of the class name to the name of your consumer class. For instance, to specify the `MyConsumer` class:

```
<match-class type="matches-class">
    <name filter-type="equals">com.mycompany.mypackage.MyConsumer</name>
</match-class>
```

5. Set the value of the method name to the name of your message processing loop method. For instance, to specify the `pollMessages` method:

```
<match-method>
    <name>pollMessages</name>
</match-method>
```

After the Java Agent reads the updated configuration, it detects consumer activity and upstream Kafka queue. The application flow map shows the tier receiving data from the Kafka queue.

Kafka SimpleConsumer Entry Points

To enable consumer entry points for Kafka clients that retrieve messages using `SimpleConsumer.fetch()`, register the `enable-kafka-consumer` node property with a value of "true."

Kafka consumer activity shows up as an exit call in this case.

.NET Backend Detection

The .NET Agent automatically detects many common backend types. Most backend types have a default discovery rule and a set of configurable properties. To revise backend discovery rules, see Backend Detection Rules and Exit Point Detection Rules.

For all other traffic transactions, see Business Transactions.

ADO.NET Backends

The .NET Agent automatically discovers ADO.NET data providers implementing standard Microsoft interfaces as database backends. See .NET Supported Environments.

Because the ADO.NET API is interface-based, AppDynamics instruments all ADO.NET database providers that implement these interfaces by default.

AppDynamics uses database identification information from the ADO.NET connection string. The connection string specifies the server address and schema, or the local file name. Most connection strings are formatted based on common rules that you can parse and distill to a database name. However because no standards exist for the connection string, the ADO.NET provider implementer determines the format.

For some providers, AppDynamics may fail to parse the connection string. In these cases, the .NET Agent uses the complete connection string minus any user password. The property is labeled ADO.NET connection string, and the value shows the connection string minus any user password.

For example, the .NET Agent names this database backend using the connection string pattern `<datasource name>-<database name>`

```
.\SQLEXPRESS-HowdyWorldDB
```

ADO.NET Configurable Properties

You can enable or disable the use of these properties for ADO.NET exit points:

Configurable Properties	Default Detection and Naming Property?	Description
`Host`	Yes	Data source or database server
`Database`	Yes	Database name
`Vendor`	No	Type of client-side ADO.NET library
`Connection String`	No	Full connection string with password filtered out
`Port`	No	Port number

Directory Service Backends

The .NET Agent automatically discovers exit calls to directory services that use the System.DirectoryServices.Protocols (S.DS.P) libraries.

The agent names the backend for the server name. If the agent cannot derive the server name from the request, it then constructs a name using Domain Component (DC) values.

For example: `activedirectory.example.com`

HTTP Backends

AppDynamics automatically detects HTTP exit points (backends). See HTTP Backend Detection.

.NET Agent for Windows

For the .NET Agent for Windows, the default HTTP automatic discovery rule uses the URL property. From the enabled properties, AppDynamics derives a display name using the URL.

For example: `http://api.example.com:8989/searchfares`

.NET Agent for Linux

For the .NET Agent for Linux, the default HTTP automatic discovery rule for backends uses the host name and port number.

For example: `http://api.example.com:8989/`

HTTP Configurable Properties

For both Windows and Linux versions of the .NET Agent, you can enable or disable the use of these properties for HTTP exit points:

Configurable Properties	Default Detection and Naming Property?		Description
	.NET Agent for Windows	.NET Agent for Linux	
`Host`	No	Yes	HTTP host
`Port`	No	Yes	HTTP port number
`URL`	Yes	No	Full URL
`Query String`	No	Yes	HTTP parameters/query string

As of 4.5.13, you can customize HTTP backend detection and naming for the .NET Agent for Linux through the Controller UI. Customizing HTTP backend detection and naming is a feature preview that is recommended for pre-production systems. See Enable Preview Features.

Message Queue Backends

By default, AppDynamics automatically detects and identifies many message queue exit points. For a list of the supported message-oriented middleware products, see Supported Remote Service Detection for .NET.

The default queue automatic discovery rule uses the destination property to name the message queue backend.

For example: `HowdyWorldQueue$\HWT_MQ_Server1_MsgQ`

Message Queue Configurable Properties

This table list the properties used for queue exit points. However, each message-oriented product is different and there may be variations in the properties, or their names.

Configurable Properties	Default Detection and Naming Property?	Description
`Host`	No	Queue server name
`Destination`	Yes	Name of topic or queue
`Destination Type`	No	Queue or topic
`Vendor`	No	Vendor from the client library

For specific queue types, see:

- MSMQ Backends for .NET
- NServiceBus Backends for .NET
- RabbitMQ Backends for .NET

MongoDB Backends

By default, the .NET Agent detects MongoDB exit calls for create, read, update, and delete (CRUD) operations using the C# and .NET MongoDB Driver versions: 1.10, 2.0, 2.2, and 2.4.

The default MongoDB automatic discovery rule uses the host, port, and database name to name the MongoDB backend.

For example: `mymongohost.27017.mymongodb`

MongoDB Configurable Properties

You can configure the use of these properties for MongoDB exit points:

Configurable Properties	Default Detection and Naming Property?	Description
`Host`	Yes	MongoDB host
`Port`	Yes	MongoDB port
`Database`	Yes	MongoDB database name

.NET Remoting

When an application uses .NET remoting, AppDynamics automatically detects and identifies remoting exit points (backends). See Enable Correlation for .NET Remoting to configure downstream correlation.

The default remoting automatic discovery rule uses the URL property.

For example: `tcp://remoting.example.com:8648/MovieTicketBooking`

.NET Remoting Configurable Properties

You can configure the use of this property for .NET Remoting exit points:

Configurable Properties	Default Detection and Naming Property?	Description
`URL`	Yes	Full URL

WCF Backends

AppDynamics automatically detects and identifies WCF exit points (backends) when an application uses the WCF client library. The default WCF automatic discovery rule uses the remote address property. The agent uses the enabled properties to derive a display name using the remote address.

For example: `http://wcf.example.com:8205/Services/Service1.svc`

Agent Compatibility

This table describes the WCF backend detection support for each variant of the .NET Agent:

Agent and Version	WCF Backend Detection Support
.NET Agent for Windows (.NET Framework)	Fully supported
.NET Agent for Linux >= 20.7.0	Partially supported • Works with .NET Core >= 3.1 • Compatible with asynchronous calls over HTTP • Does not support the `Operation Contract`, `Service Contract`, and `SOAP Action` properties.
.NET Agent for Windows (.NET Core) >= 21.3.0	

WCF Configurable Properties

You can enable or disable the use of these properties for WCF exit points:

Configurable Properties	Default Detection and Naming Property?	Description
`Remote Address`	Yes	URL minus the query, fragment, and user information (name and password)
`Operation Contract`	No	WCF operation contract name
`Service Contract`	No	WCF service contract name
`URL`	No	Full URL
`Host`	No	Host portion of URL
`Port`	No	Port number if present in the URL; otherwise, protocol default
`SOAP Action`	No	For web service calls, the SOAP action

.NET Web Services Backends

When an application uses the Microsoft Web Services client library, AppDynamics automatically detects and identifies web services exit points (backends) by default. The default web services automatic discovery rule uses the URL property. From the enabled properties, AppDynamics derives a display name using the URL.

For example: `http://webservice.example.com:8105/Services/Service1.asmx`

Web Services Configurable Properties

You can enable or disable the use of these properties for Web Services exit points:

Configurable Properties	Default Detection and Naming Property?	Description
`Service`	No	Web service name
`URL`	Yes	Full URL
`Operation`	No	Web service operation name
`Soap Action`	No	SOAP action

Custom Exit Points

To monitor a backend that is not included in .NET Supported Environments, you can configure a custom exit point.

By default, you have to restart the instrumented application for instrumentation changes to take effect. You can enable Runtime Reinstrumentation for the .NET Agent to avoid having to restart your application and the `AppDynamics.Agent.Coordinator` after instrumentation changes.

Asynchronous Exit Points for .NET

Related pages:

- .NET Backend Detection
- Using Asynchronous Methods in ASP.NET 4.5

Asynchronous programming patterns can enhance the scalability and performance of applications. Microsoft .NET lets you designate methods as asynchronous tasks.

The .NET runtime releases resources for asynchronous methods while tasks complete. When task processing finishes, the runtime calls back to the originating asynchronous method so the method may continue processing.

The .NET Agent detects certain asynchronous programming patterns as exit points. Because tasks may execute in parallel, AppDynamics sometimes represents asynchronous activity differently from synchronous activity in the Controller.

AppDynamics differentiates .NET async backend tracking from thread correlation. To configure thread correlation, see Thread Correlation for .NET.

Supported Asynchronous Exit Point Patterns

The agent discovers exit points for Microsoft .NET 4.5 *async* and *await* keywords. See Asynchronous Programming with Async and Await.

The agent detects asynchronous exit points for the following backend types:

- ADO.NET
- Azure Blob Storage, Azure File Storage, and Azure Table Storage
- CosmosDB
- HTTP
- MongoDB
- WCF
- Web Service

> Backend types are different for the .NET Core microservices agent. See .NET Core Microservices Agent Support.

Flow maps in the Controller UI represent asynchronous exit points as dotted lines labeled "async". Because calls in an asynchronous transaction may execute simultaneously, the Controller doesn't display end-to-end percentage times for individual asynchronous calls.

Troubleshoot Asynchronous Calls in Transaction Snapshots

Transaction snapshots include several features to help you discover problem areas in business transactions that use asynchronous methods. For an overview of transaction snapshots, see Transaction Snapshots.

Transaction Snapshot Flow Map

The Transaction Snapshot Flow Map graphically represents the business transaction. It displays the user experience, execution time, and timestamp of the transaction. The flow map also provides details of the overall time that is spent in a particular tier and in database and remote service calls. The *async* label indicates asynchronous calls.

Snapshot Execution Waterfall View

The transaction Snapshot Execution Waterfall View shows a timeline representation of the end-to-end execution of the business transaction. Synchronous and asynchronous processes appear on a bar diagram illustrating their relative execution time arranged in chronological order. Synchronous calls are represented by solid line arrows, and asynchronous calls are represented by dotted line arrows.

The waterfall view enables you to visually identify which processes are running the longest. Double-click a bar to drill down to a call graph and investigate problematic code.

Analyze Asynchronous Activity in the Metric Browser

The Metric Browser displays asynchronous activity in the following places:

- **Business Transaction Performance > Business Transactions > tier > business transaction > Thread Tasks > Asynchronous Operation > External Calls**
- **Overall Application Performance > *tier* > Thread Tasks > Asynchronous Operation > External Calls**
- **Overall Application Performance > *tier* > Individual Nodes > node name > Thread Tasks > Asynchronous Operation > External Calls**

MSMQ Backends for .NET

Related pages:

- .NET Backend Detection
- App Agent Node Properties

The AppDynamics .NET Agent (agent) automatically detects MSMQ backends when an instrumented tier makes a call to MSMQ. MSMQ exit points are methods that publish or push messages to a queue. If you are using NServiceBus over the MSMQ transport, see NServiceBus Backends for .NET.

MSMQ entry points are methods that listen or poll for new messages in the queue. Before the agent can detect entry points or perform downstream correlation for MSMQ you must define the correlation field and, for multithreaded architectures, specify threading architecture.

Exit Points and Backend Naming

The agent names the queue for the queue name returned from the system.

Entry Points

To enable downstream correlation for MSMQ, you must configure the agent.

Define the MSMQ Correlation Field

Register the *msmq-correlation-field* app agent node property on both the publishing tier and on the receiving tier. Specify the field where the agent will write and read correlation information.

The agent supports the following fields:

- Extension, the default field
- Label

By default, the .NET Agent writes to the Extension field. However, some frameworks built on MSMQ write data to the Extension field. In this case, the Extension field does not work because it is already in use, so you must configure the .NET Agent to write correlation data to the Label field.

> Choose a field not in use by your queue implementation. If your implementation uses both the "Label" and "Extension" fields, downstream correlation is not currently possible.

See "msmq-correlation-field" on App Agent Node Properties Reference. For instructions to register a node property, see App Agent Node Properties.

Specify the threading architecture

If your queue implementation uses a multithreaded architecture, you must register the *msmq-single-threaded* app agent node property to specify the threading architecture. Set msmq-single-threaded to "False" for multithreaded implementations of MSMQ. See "msmq-single-threaded" on App Agent Node Properties Reference. For instructions to register a node property, see App Agent Node Properties.

The threading architecture dictates how the agent calculates the call timing for the message queue:

- For single-threaded queues, the agent calculates the call time between receive requests. The call time begins at the end of the first receive method and ends when the next receive method starts.
  In the following example, the length of the `ProcessMessage()` method:

```
MessageQueue messageQueue;
for(;;)
{
        var message = messageQueue.Receive();
        ProcessMessage(message);
}
```

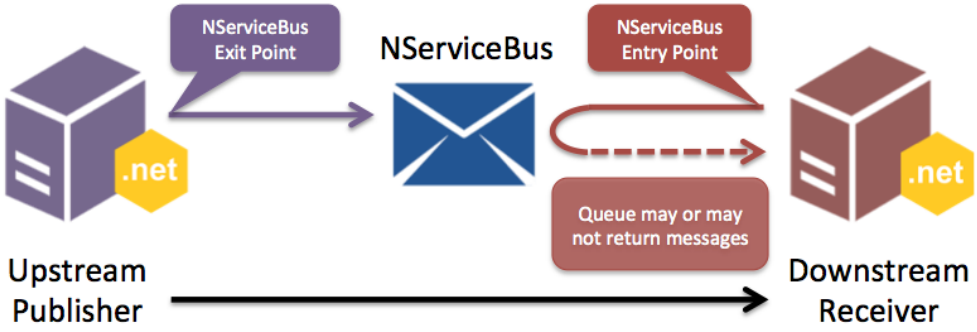
- For multithreaded queues, the agent does not capture timing.

NServiceBus Backends for .NET

Related pages:

- .NET Backend Detection

The AppDynamics .NET Agent automatically discovers exit points to NServiceBus backends when an instrumented tier makes a call to NServiceBus over MSMQ or RabbitMQ transports. The agent discovers NServiceBus entry points for downstream correlation from NServiceBus version 5.



Exit Points and Backend Naming

NServiceBus exit points are methods that publish or push messages to a queue from an upstream tier. The agent detects exit points regardless of the NServiceBus version or threading architecture. The agent names the queue for the queue name returned from the system.

Entry Points in a Single-threaded Architecture

NServiceBus entry points are methods that listen or poll for new messages in the queue. When the message receiver uses a single-threaded architecture, the .NET Agent automatically discovers entry points and correlates downstream activity without additional configuration.

The agent measures the call time from the end of the first receive method to the start of the subsequent receive method. In the following example loop, the length of the `ProcessMessage()` method:

```
MessageQueue messageQueue;
for(;;)
{
        // Call timing for previous iteration ends.
        var message = messageQueue.Receive();
        // Call timing begins.
        ProcessMessage(message);
}
```

Entry Points in a Multithreaded Architecture

For the .NET Agent to automatically detect NServiceBus entry points when the receiver is running a multithreaded architecture, set the *nservicebus-single-threaded* app agent node property to "false" on the receiver. See "nservicebus-single-threaded" on App Agent Node Properties Reference. For instructions to register a node property, see App Agent Node Properties.

For multi-threaded message receivers, the agent does not capture timing.

Resolve Issues with NServiceBus Backends

- If you have NServiceBus version 5 and are not seeing downstream correlation on the receiver, verify the threading architecture on the receiver. Set the *nservicebus-single-threaded* app agent node property to "false" on the multithreaded receivers.
- Only use the node properties for MSMQ, msmq-single-threaded and msmq-correlation-field, if you are using MSMQ independently of NServiceBus. The .NET Agent does not use MSMQ node properties when discovering and instrumenting NServiceBus over MSMQ transport.
- If you are using NServiceBus version 4, you can disable NServiceBus instrumentation on both the publisher and the receiver:
    - Copy the following Instrumentation element to a child of the Machine Agent element:

```
<!--Disable NServiceBus instrumentation-->
   <instrumentation>
     <instrumentor name="NServiceBusReceiveContextInstrumentor" enabled="false" />
     <instrumentor name="NServiceBusPublishExitInstrumentor" enabled="false" />
     <instrumentor name="NServiceBusEntryInstrumentor" enabled="false" />
     <instrumentor name="NServiceBusExitInstrumentor" enabled="false" />
   </instrumentation>
```

For more information, see "Instrumentation Element" on .NET Agent Configuration Properties.

- Configure the publisher and receiver as you would for MSMQ or RabbitMQ.

RabbitMQ Backends for .NET

Related pages:

- .NET Backend Detection
- RabbitMQ Monitoring Extension

The AppDynamics .NET Agent automatically detects RabbitMQ backends based upon calls from instrumented tiers. RabbitMQ exit points are methods that publish or push messages to a queue. RabbitMQ entry points are methods that listen or poll for new messages in the queue.

> .NET extends support for `BasicPublish` and `BasicConsume` in the RabbitMQ client >= 6.0.0.

If you are using NServiceBus over the RabbitMQ transport, see NServiceBus Backends for .NET.

Exit Points and Backend Naming

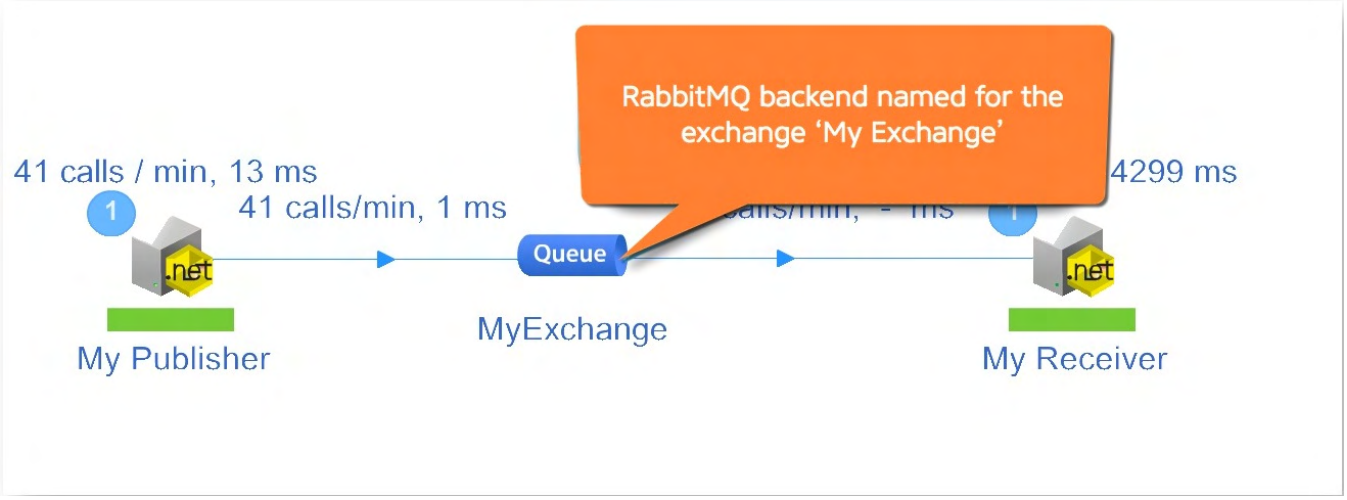
The agent discovers a RabbitMQ backend exit point when your application sends a message to the queue using the `BasicPublish()` method.

By default, the agent names the RabbitMQ backend for the exchange parameter of the `BasicPublish()` method.

For example:

```
model.BasicPublish("MyExchange", "", false, false,
    basicProperties, Encoding.UTF8.GetBytes(message));
```

In this case the agent names the queue **MyExchange**.



You can refine the backend name to include some or all segments of the routing key. To configure RabbitMQ naming you must be familiar with your implementation RabbitMQ exchanges and routing keys. See RabbitMQ Exchanges and Exchange Types.

Refine backend naming

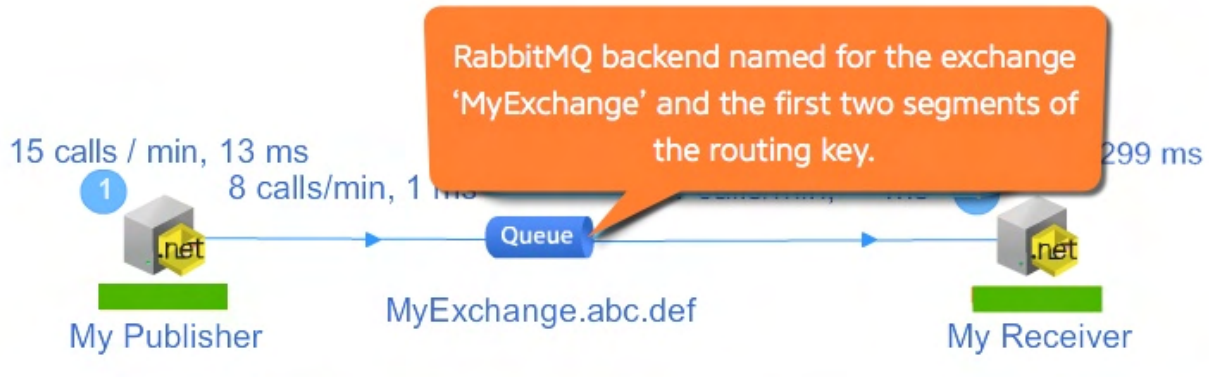
Register the *rmqsegments* node property. For instructions on how to set a node property, see App Agent Node Properties.

Name: rmqsegments
Description: "Configure RabbitMQ naming to include routing key segments."
Type: Integer
Value: <integer>
The routing key is a string. The agent treats dot-separated (".") substrings of the routing key as segments. Set the value to an integer that represents the number of routing key segments to include in the name.

In the following example the routing key is "abc.def.ghi". Set the rmqsegments value to "2" to name the queue "MyExchange.abc.def".

```
model.BasicPublish("MyExchange", "abc.def.ghi", false, false,
    basicProperties, Encoding.UTF8.GetBytes(message));
```

After you save the node property, the Controller sends the configuration to the agent. After some time the RabbitMQ backend shows up with the new name.



Entry Points

The agent discovers RabbitMQ backend entry point when your application polls the queue. AppDynamics auto-detects RabbitMQ based upon the following patterns:

- BasicGet
- HandleBasicDeliver

BasicGet Method

The agent detects the pattern below where the application periodically polls the message queue using the `BasicGet()` method. The call timing is limited to the time spent inside the `while` loop. The timer only starts when the `BasicGet` result returns a value at line 4. The timer ends when the next `BasicGet` executes. In this example, the application polls every five seconds, so the execution time equals the time in the `if` loop plus five seconds.

RabbitMQ Client before version 6.x:

```
while (true)
{
	var result = channel.BasicGet("MyExchange", true);
	if (result != null)
	{
		var body = result.Body;
		var message = Encoding.UTF8.GetString(body);
		Console.WriteLine("Received: {0}.", message);
	}

	Thread.Sleep(5000);
}
```

RabbitMQ Client version 6.x:

```
while (true)
{
	var result = channel.BasicGet("MyExchange", true);
	if (result != null)
	{
		var body = result.Body.ToArray()
		var message = Encoding.UTF8.GetString(body);
		Console.WriteLine("Received: {0}.", message);
	}

	Thread.Sleep(5000);
}
```

HandleBasicDeliver Method

The agent detects the `HandleBasicDeliver()` method for custom implementations of the `IBasicConsumer` interface. In this case, the call timing reflects the execution time for the `HandleBasicDeliver` method.

Correlation Over Microsoft BizTalk

When you install the .NET Agent on a Microsoft BizTalk Server, the agent automatically discovers BizTalk entry points and exit points so you can monitor your BizTalk integration.

Requirements

- Microsoft BizTalk 2010, 2013
- BizTalk must be a downstream tier from an originating tier for a business transaction. The agent doesn't discover BizTalk as the originating tier of a transaction.

Entry Points

The .NET Agent detects incoming BizTalk requests using the WCF Send Adapter or the SOAP Send Adapter.

Instrument the BizTalk Service

1. Install the .NET Agent on the BizTalk server. See Install the .NET Agent for Windows.
2. Register the "enable-soap-header-correlation" app agent node property with a value of "true" for the nodes upstream from the BizTalk tier. See App Agent Node Properties.
3. Instrument the BizTalk service executables: BTSNTSvc.exe and BTSNTSvc64.exe. See Configure the .NET Agent for Windows Services and Standalone Applications. For instance:

   ```
   <standalone-applications>
     <standalone-application executable="BTSNTSvc">
       <tier name="BizTalk Service"/>
     </standalone-application>
   </standalone-applications>
   ```

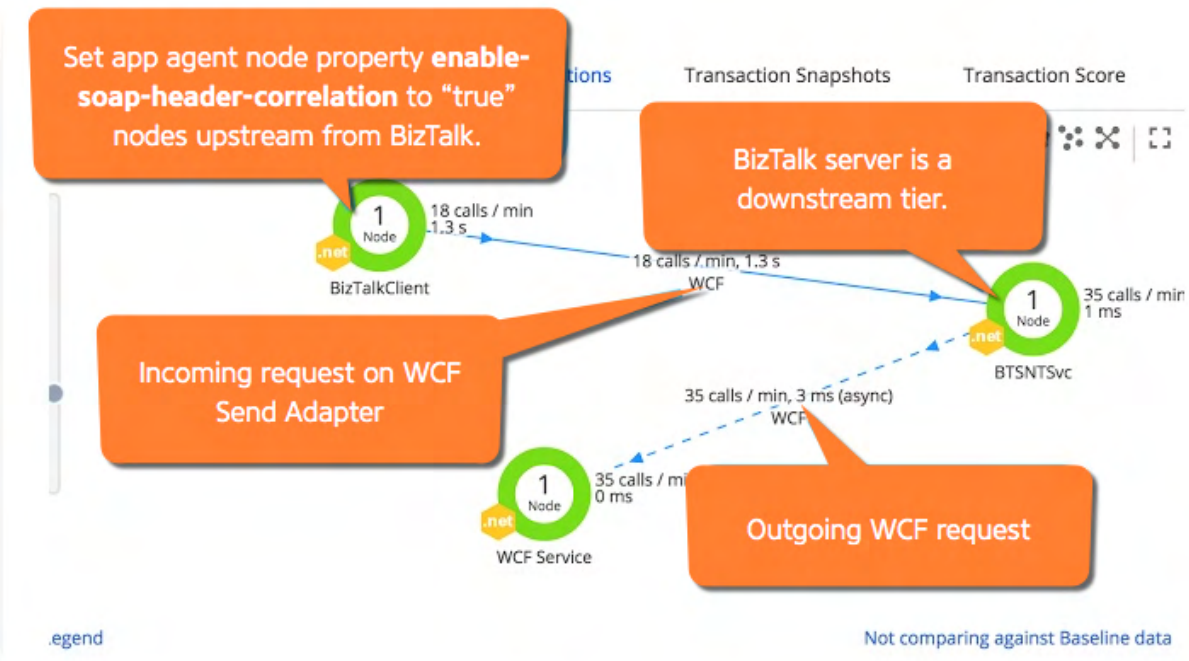
   If you run multiple instances of BizTalk on the same Windows server, you can assign the different instances to unique nodes using command line options. For example, to differentiate nodes within the same tier, specify the BizTalk Service command "name" parameter in the standalone application `command-line` attribute:

   ```
   <standalone-applications>
     <standalone-application executable="BTSNTSvc" command-line="-name &amp;quot;BizTalk1&amp;quot;">
       <tier name="BizTalk Service"/>
       <node name="BizTalk1"/>
     </standalone-application>
     <standalone-application executable="BTSNTSvc" command-line="-name &amp;quot;BizTalk2&amp;quot;">
       <tier name="BizTalk Service"/>
       <node name="BizTalk2"/>
     </standalone-application>
   </standalone-applications>
   ```

   Notice the use of quotes to enclose the name command-line parameter.
4. Optionally enable BizTalk performance counters. For more information, see Manage Windows Performance Metrics. Refer to the Microsoft BizTalk Server documentation for descriptions of individual performance counters.

```
<machine-agent>
  <!-- BizTalk Performance Counters -->
  <perf-counters>
    <perf-counter cat="BizTalk:Message Agent" name="High database session" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="High database size" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="High in-process message count" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="High message delivery rate" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="High message publishing rate" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="High process memory" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="High system memory" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="High thread count" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="Message delivery delay (ms)" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="Message delivery throttling state" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="Message publishing delay (ms)" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="Message publishing throttling state" instance="*"
/>
        <perf-counter cat="BizTalk:Message Agent" name="Message delivery incoming rate" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="Message delivery outgoing rate" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="Message publishing incoming rate" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="Message publishing outgoing rate" instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="Message delivery throttling state duration"
instance="*"/>
        <perf-counter cat="BizTalk:Message Agent" name="Message delivery throttling user override"
instance="*"/>
        <perf-counter cat="BizTalk:FILE Receive Adapter" name="Bytes received/Sec" instance="*"/>
        <perf-counter cat="BizTalk:FILE Receive Adapter" name="Lock failures/sec" instance="*"/>
        <perf-counter cat="BizTalk:FILE Receive Adapter" name="Messages received/Sec" instance="*"/>
        <perf-counter cat="BizTalk:FILE Send Adapter" name="Bytes sent/Sec" instance="*"/>
        <perf-counter cat="BizTalk:FILE Send Adapter" name="Messages sent/Sec" instance="*"/>
        <perf-counter cat="BizTalk:SOAP Receive Adapter" name="Messages received/Sec" instance="*"/>
        <perf-counter cat="BizTalk:SOAP Send Adapter" name="Messages sent/Sec" instance="*"/>
  </perf-counters>
</machine-agent>
```

Once you've completed instrumentation, the .NET Agent correlates traffic through your BizTalk server:



If you enabled Performance Counter metrics, they appear under the Custom Metrics tree in the Metric Browser.

Apache Web Server Backend Detection

The Apache Agent discovers Apache Modules as backends. To review general information about monitoring backends, see Backend Detection Rules.

Apache Modules

The Apache Agent automatically detects loaded Apache modules as remote services:

- Modules must be in the handler stage.
- The agent excludes a list of common modules from discovery, see "Remote Service Detection" on Supported Apache Web Servers.

By default, the Apache Agent includes metrics for module backends with the downstream backend or tier. The Controller doesn't display the module on flow maps. For example, if Apache calls mod_jk.c, the module backend doesn't show on flow maps and metrics are included with the downstream Tomcat backend or tier.

To view Apache modules on the flow map and to see separate metrics for Apache modules, set *AppDynamicsResolveBackends* to "OFF" in the appdynamics_agent.conf file. See Install the Apache Agent.

The agent names the Apache modules backend for the module name and the server: <module>-<host>:<port> . For example, mod_jk.c-myapache.example.com:80.

Previously, the backend name for requests routed through the reverse proxy was `mod_proxy.c-<ip and port of server >`. It is now resolved to the actual URL where the request is transferred to.

To add end segments that are displayed in the backend naming, set `AppDynamicsBackendNameSegments` with the required end segments. See Install the Apache Agent.

HTTP Backend Detection

Related pages:

- Java Backend Detection
- .NET Backend Detection

AppDynamics automatically detects HTTP backends when outbound calls are made through supported HTTP clients, and by default names them according to their host and port. If the default configuration results in names that are not meaningful for your application (such as EC2 host names, file paths, and ports in the name) you can change the default discovery rule.

Additionally, if an HTTP call is destined for an http router which could route the request to one of several instrumented downstream tiers then the default naming rules will need to be modified such that the name includes enough segments of the target URL such that each destination tier is associated with a differently named backend.

HTTP Backend Naming

To ensure that the HTTP backends detected in your application have meaningful names, and that Business Transaction correlation functions correctly, your custom configuration will need to take into account the specific format used in your environment.

The format can vary even within a single environment. For example, some backend systems may have hostnames prefixed with ec2storage, which may not be meaningful in naming, while others may use hostnames such as salesforce.com, which may be meaningful.

To account for different formats, you should create a custom rule rather than changing the automatic discovery rule. This lets you apply different rules for different URL formats.

You can then apply a specialized approach for each case, as in the following examples:

- For format "ec2storage/servicename", you would use the URL
- For format "salesforce.com", use the host name
- For the other backends, you may use a query string
- For calls that could hit one of several downstream tiers via an HTTP router, you should use sufficient segments of the target URL in the name such that each downstream tier that could process the request is associated with a differently named backend

In some cases, your HTTP backend discovery configuration might consist of a combination of the default rule and custom rules. The following section walks you through a specific example:

Use the URL Path in a Detection Rule

For example, when all the HTTP backends for a tier or application have a similar format, such as a prefix like "ec2storage", you can generate the right name and the correct number of backends to monitor by editing the automatic discovery rule. This enables you to monitor the KPIs that are interested in.

Consider an application with the following HTTP URLs:

```
http://ec2-17:5400/service1
http://ec2-17:5450/service2
http://ec2-18:5400/service1
http://ec2-18:5450/service2
```

In this case, measuring performance based on host name would not be useful, since the IP addresses are transient and all performance numbers would be irrelevant after the IP addresses recycle. Instead, you can monitor by service name by avoiding the use of Host and Port properties and using only the URL property, as follows:

1. Edit the **Automatic Backend Discovery** rule for HTTP for your agent type. See Backend Detection Rules for details on accessing this pane.
2. First, select and disable the use of **Host** and **Port**.
3. Then select and enable the property you want to use to uniquely identify the backend. In this case, select **URL** and check **Use URL in the Backend Name**.
4. For the field **How will URL be used in the Backend name?**, select **Use a segment of it**.
5. From the segment options dropdown, select **Use the first N Segments**.

   The important URL segment is for the "create" service, so your configuration is the same as in the previous screenshot.
6. Enter "/" slash for the **Split Delimeter**.
   Use a similar technique to strip out some segment of the URL, such as a user name as in the following URLs:

   ```
   [http://host:34/create/username1]
   [http://host:34/create/username2]
   ```

7. Once you change the configuration, delete all HTTP backends. When the agent rediscovers the backends with the new configuration, the flow map shows only the service backends.

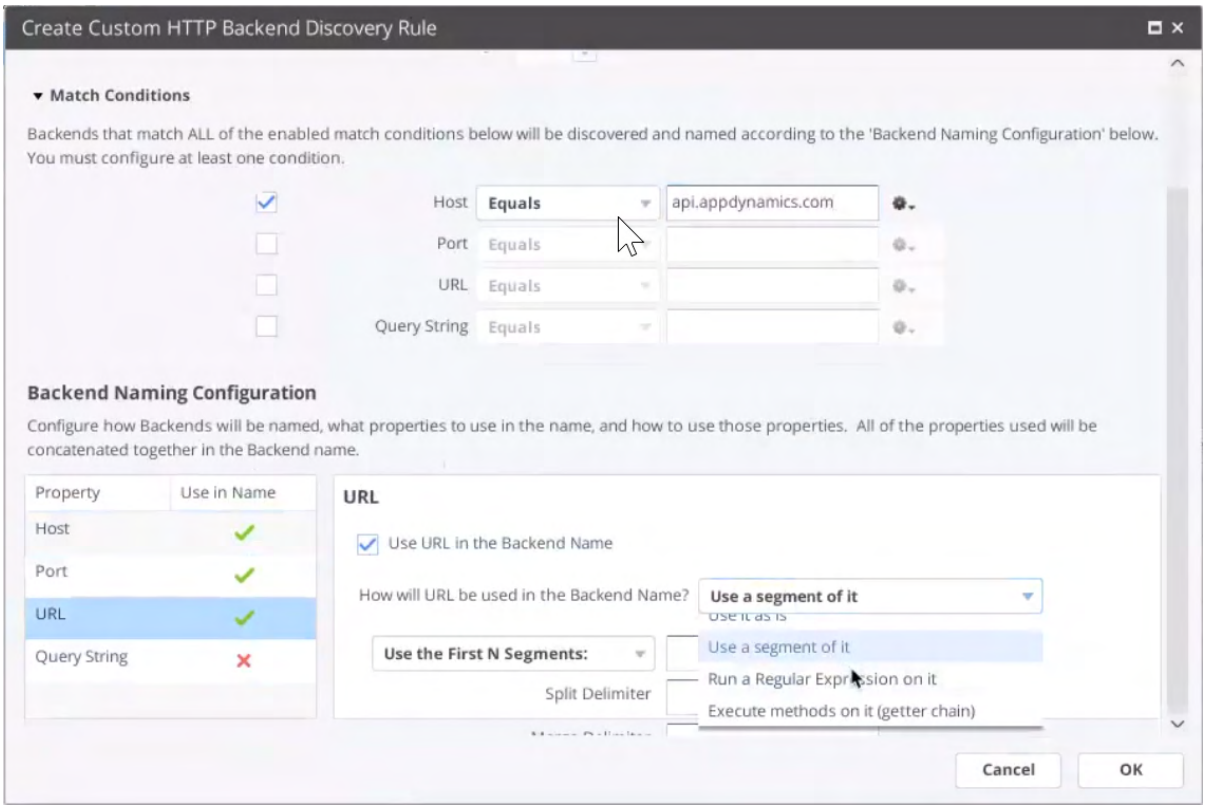
Custom HTTP Backend Detection and Naming Configuration

You can now customize HTTP backend detection and naming for the .NET Agent for Linux through the Controller UI.
Customizing HTTP backend detection and naming is a feature preview in the .NET Agent for Linux 4.5.13, recommended for pre-production systems. See Enable Preview Features.

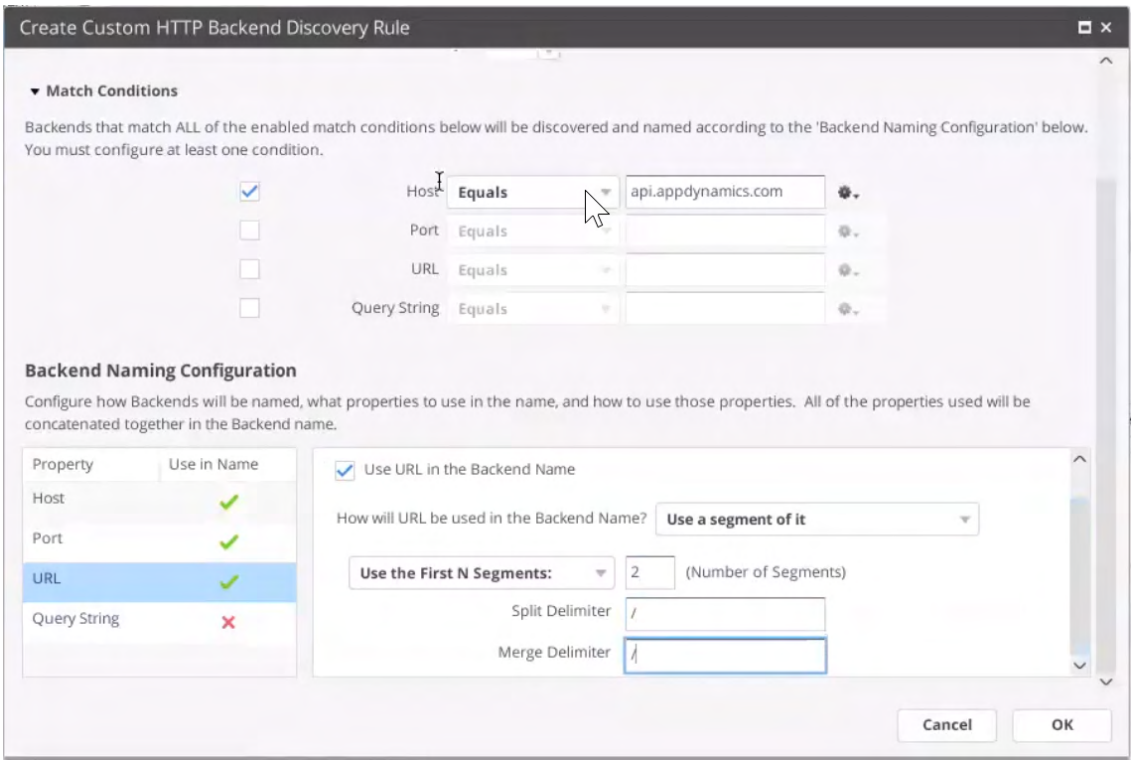
By default, AppDynamics uses the host name and port number to detect and name HTTP backends. This may be suitable in many cases, however, when your microservices, containers or serverlets are managed by an API gateway or portal, backend services communicating with a client or with each other cannot be correctly mapped to the proper tiers unless you edit automatic discovery to use a portion of the query string or use HTTP custom discovery rules to uniquely name them. AppDynamics recommends you create a custom HTTP backend discovery rule in this case.

The following screenshots provide an example configuration.

Here we choose Match Conditions to describe the API gateway host, in this case, api.appdynamics.com.



This screenshot shows where we choose to use the First 3 segments, using '/' as both the split and merge delimiters.



Configuring the HTTP Backend Discovery Rule as above detects backend metrics and reports them under a business transaction name that begins with api.appdynamics.com followed by the first three segments of the URL of the transaction, such as api.appdynamics.com/api/catalog or api.appdynamics/api/payment. Transactions matching the configured HTTP discovery rule are recognized as individual backends even when they share the same host name and port number. These transactions can be mapped to different tiers so you can analyze the metrics of the transactions that occur behind the API gateway.

There is a known issue in HTTP backend detection configuration in the current preview. When defining HTTP backend using URL segments, segment enumeration starts with number 2 instead of number 1, and segment 1 always returns empty.
For example, to define unique backends using the first two segments of the URL, you would need to configure HTTP backend detection to use the first 3 segments or segment 2 and 3.

Service Proxy Overview

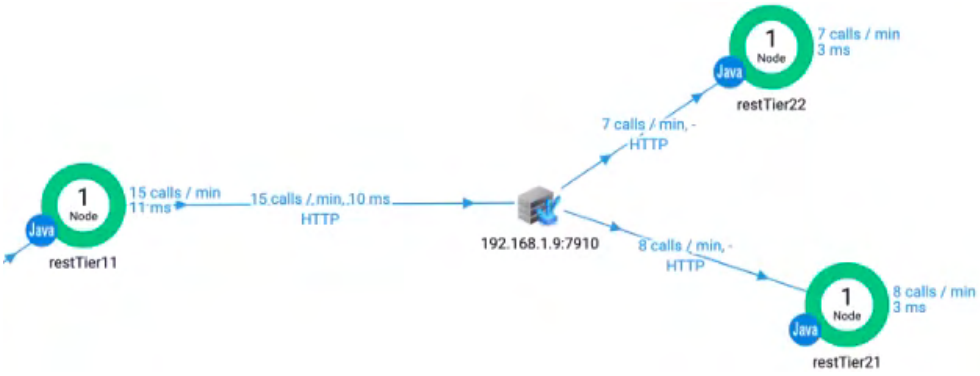
AppDynamics has identified an issue where Business Transactions have started reporting to all other traffic. Please see Support Advisory: Business Transactions Reporting to All Other Traffic before enabling Service Proxy Detection.

In Application Performance Management (APM), the service that is called in an application environment is usually identified by specific properties, such as the host or port properties. However in an environment with a gateway or service proxy, the host and port actually identify a *device* instead of the ultimate downstream tier that handles the request.

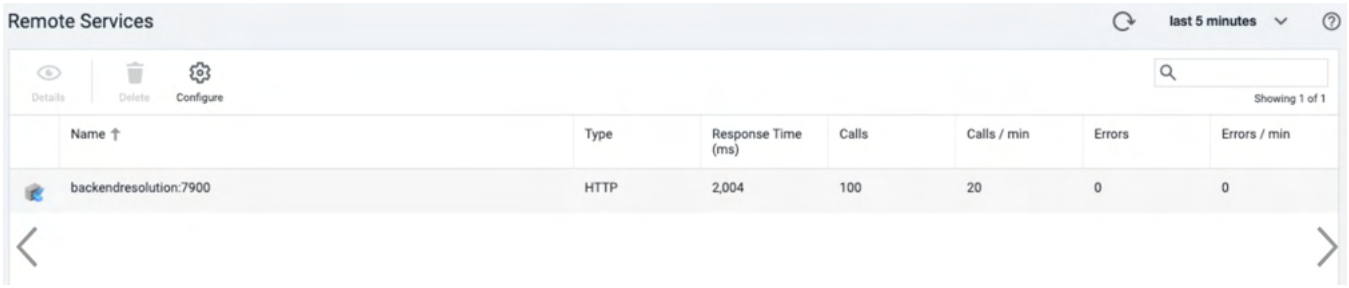
This inaccurate identification of the backend destination causes the system to periodically change the association of the single backend with one of the potential target downstream tiers to which the gateway could route. This results in the joining of incomplete flow maps and inconsistencies between tiers that are included within Business Transaction snapshots, and the corresponding Business Transaction flow map.

The service proxy identification feature enables the system to resolve and identify the correct backend and displays the correct component structure in the flow map. The service proxy detects these changes in the backend association and instructs the upstream agent to identify the affected backend(s) as a service proxy.

As a result, the flow map will show a service proxy (represented by this icon ) between the upstream and downstream tiers, for example:



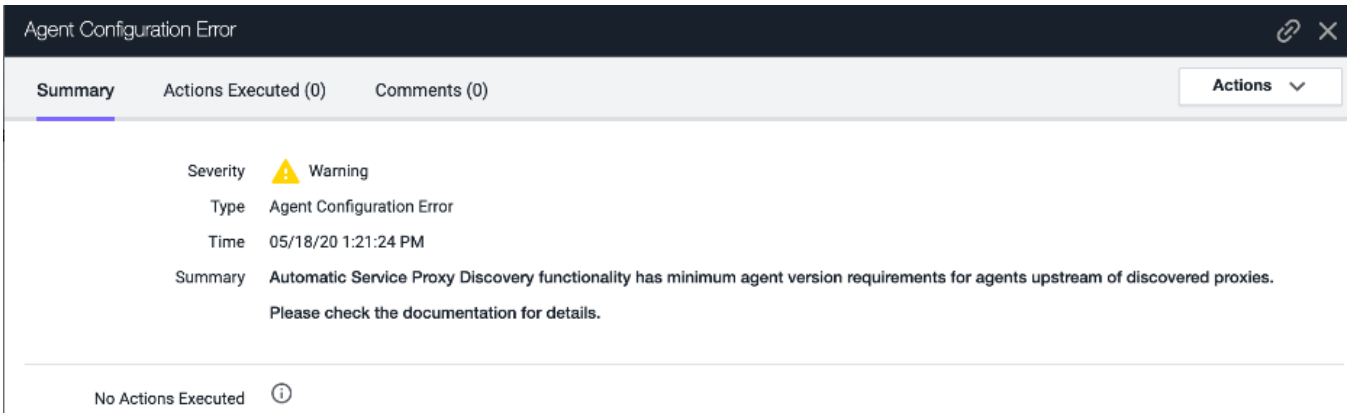
The service proxy is also visible in the **Remote Services** list:



If the upstream agent is an older version than what is currently supported, an event is generated with the following Agent Configuration Error message:

The service proxy feature is supported on these agents:

- Java Agent >= 20.5.0
- .NET Agent >= 21.3.0



The service proxy icon is also available on these flow maps:

- Application Dashboard
- Tiers and Nodes
- Drill Down Backend Node
- Transaction Snapshot (Waterfall View)

Enable Service Proxy Detection

The backend is identified as a service proxy in the Controller.

- For *SaaS customers*: To request that your Controller has the service proxy feature enabled, you should work closely with your AppDynamics account representative.
- For *on-premises customers*: To enable the service proxy feature:

  a. Access the Controller Administration Console.
  b. Open the admin.jsp page in the Controller from the url:
  <*controllerhost*>:<*controllerport*>/admin.jsp
  c. Access **Controller Settings**.
  d. Search for these two properties, and set each of them to `true`:
     - `backend.detect.loadbalancer.enabled = true`
     - `backend.detect.urimisconfig.enabled = true`
  e. Save your changes.

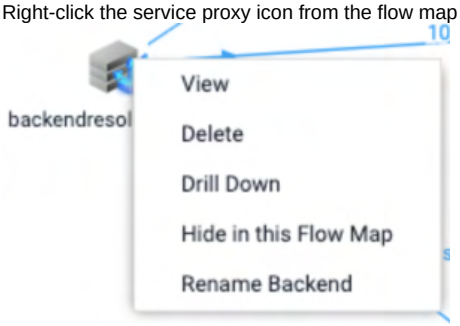
Once the Controller resolves the backend, it then sends the configuration information to the agent.

Delete a Service Proxy

If you remove the service proxy from the infrastructure but continue to use the same host and same port for the downstream nodes, then the service proxy will still show on the flow map. You must manually delete the service proxy to directly resolve the upstream and downstream tiers correctly.

To delete a service proxy for a backend node:

1. Right-click the service proxy icon from the flow map to open a popup menu.



2. Select **Delete**.

Error Detection

You can customize how AppDynamics associates code events with business transaction errors by adding or removing the methods, log messages, HTTP codes, or redirect pages that are configured to indicate business transaction errors.

Permissions

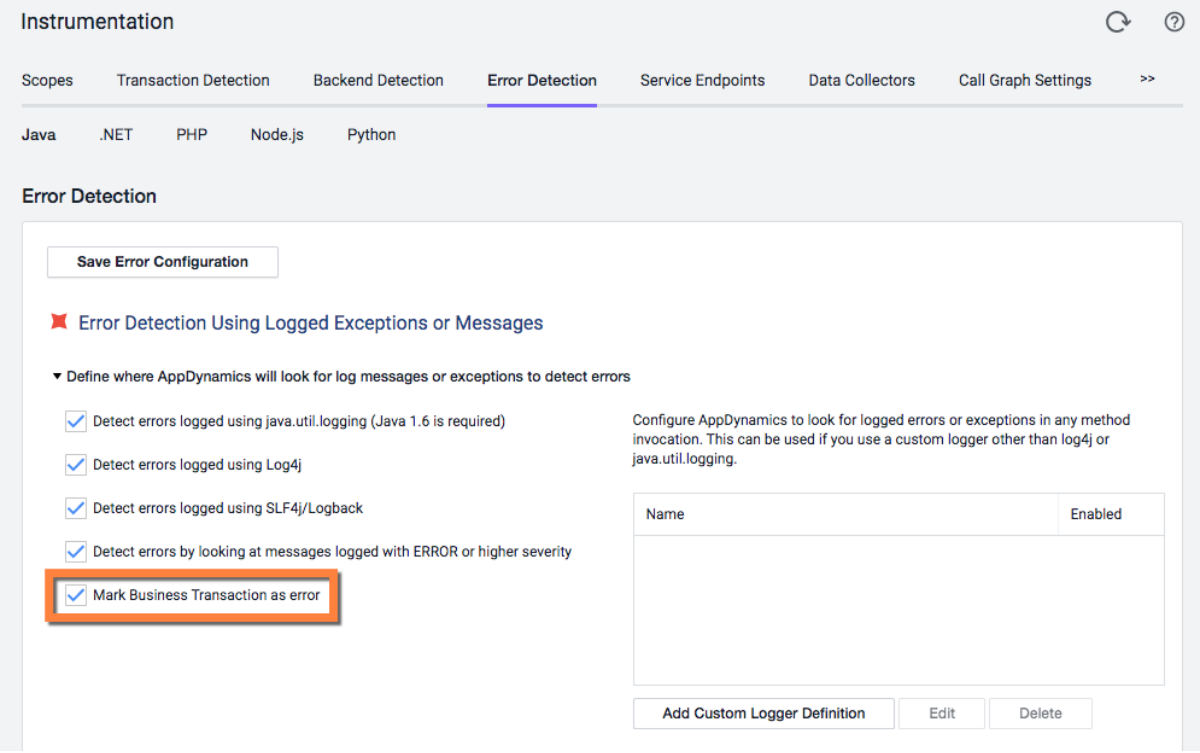
To configure error detection, you need the "Configure Error Detection" permission.

Error Detection Configuration

You can view or modify error detection configuration in the Error Detection tab. In the Controller UI, open an application and navigate to **Configuration** > **Instrumentation** > **Error Detection**.

The Error Detection tab takes you to the configurable options for each programming language or platform. You configure settings individually for each language or platform. Some settings are platform-specific. For example, custom loggers and error detection using redirect pages are available for Java and .NET only. Configuration changes made in the Error Detection tab apply to all business transactions for the selected application. You cannot make changes to individual transactions.

To prevent marking transactions as errors, uncheck the **Mark Business Transaction as error** for each applicable language or platform. If unchecked, the transactions are not added to the error count metric and are considered in other metrics, such as response time, despite the occurrence of the error.



Supplement Error Detection

For Java and .NET, you can supplement the methods that AppDynamics considers error methods from common error handling frameworks with your own, custom-defined error methods by defining a custom logger. When the application invokes the method in a business transaction, AppDynamics considers the transaction to be an error transaction for metric purposes.

In the custom logger configuration, you can specify the parameter that contains the exception or error information passed to the method. This information will appear as the error message in AppDynamics, which invokes `toString()` on the parameter to extract the message.

To configure a custom logger:

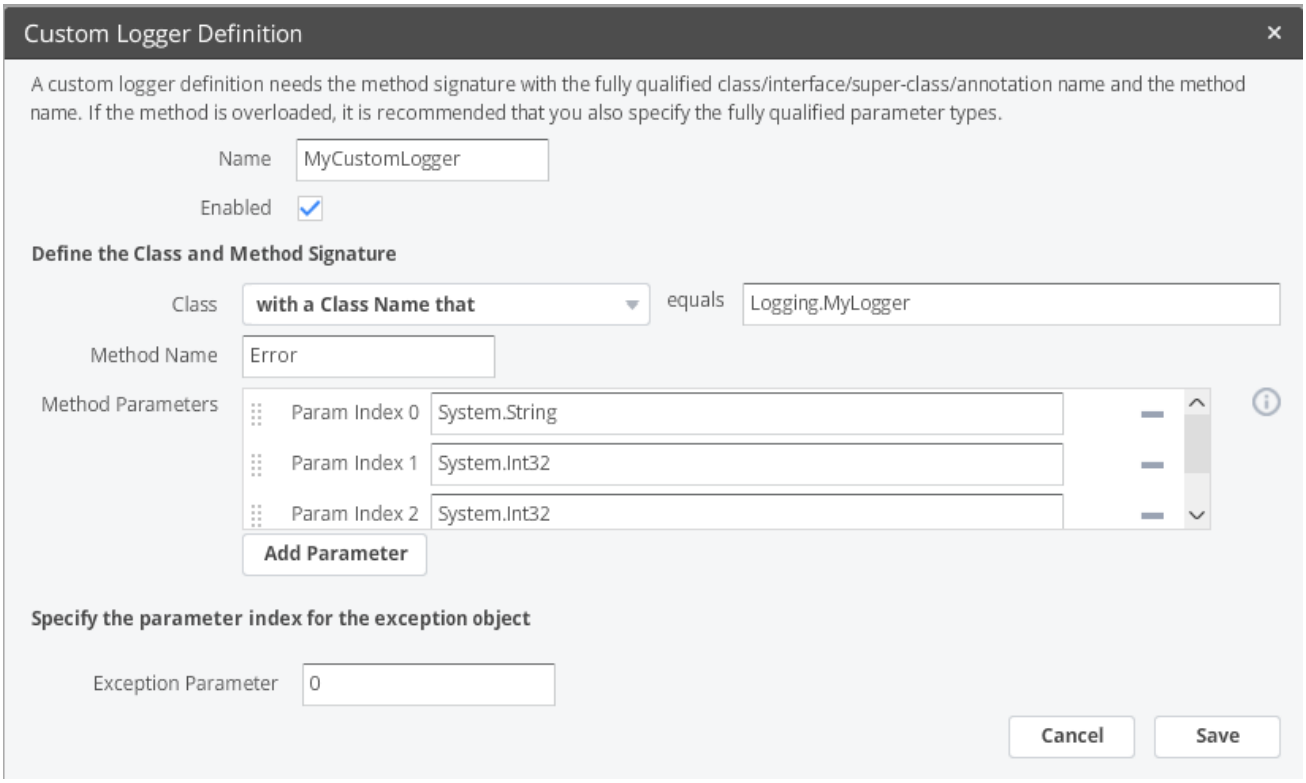
1. In the Controller UI, on the Error Detection configuration tab, click **Add Custom Logger Definition** in the error configuration panel.
2. Enter a descriptive name for the custom logger definition and use the settings to identify the class name and method for the custom logger. For more information on how to use the AppDynamics UI to identify classes and methods, see Data Collectors.
3. For the **Method Parameter** field, add a parameter definition for each parameter in the signature of the method.
   If the method is overloaded, create a logger definition for each form of the overloaded method where you want to detect errors. Your custom method must accept at least one parameter, which should be the parameter that conveys the logged error or exception information.
4. For the **Exception Parameter** field, identify the parameter in the method signature that contains the exception object by index number (0-based). This parameter, identified by an index, can be any type of object, including Arrays. If the object is not null, AppDynamics converts the object to a

string, the result of which constitutes the error details. A business transaction is considered to be an error only if a non-null exception object is passed to the logger method.

Consider the following custom logger class and methods in a .NET application:

- Namespace and class = Logging.MyLogger
- `logger.Error(string message, int param1)`
- `logger.Error(string message, int param1, int param2)`

Notice that the Error method is overloaded. To capture errors logged in the second form of the method using the first parameter as the error to log. This screenshot illustrates the configuration:



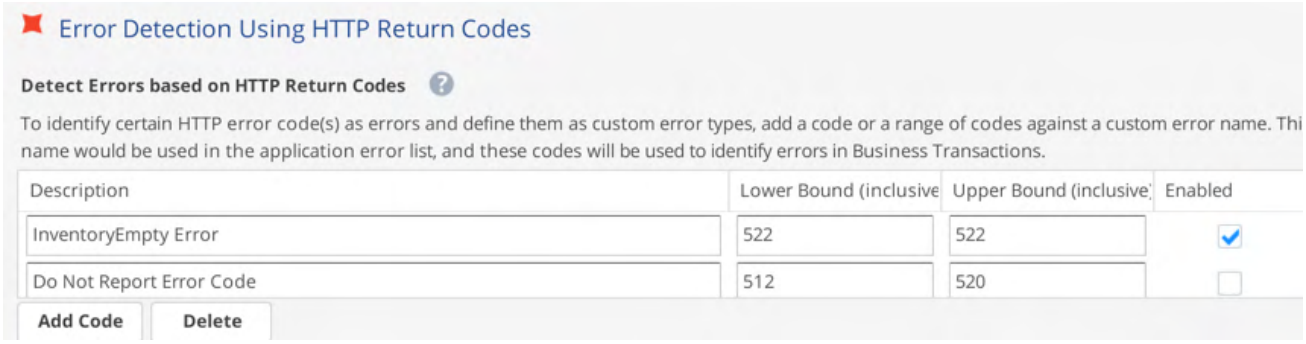
Notice that the exception parameter is set to 0, identifying the `string message` method parameter as the error message. When enabled, AppDynamics detects and reports the custom logger.

Detect HTTP Responses or Redirect Pages as Errors

In Java, .NET, Node.js, and Python you can configure errors based on HTTP response codes. If the error code is set as part of business transaction processing, the transaction is marked as an error. For PHP, it is possible to classify transactions as in error based on 4xx HTTP return codes using the PHP Agent Configuration Settings

By default, AppDynamics captures HTTP error codes from 400 to 505. HTTP response codes may convey errors that occur at the business level of an application. For example, in an e-commerce application, a 522 error might indicate that an item is out of stock. For this case, you may want to include the error as a default transaction error indicator.

To exclude a return code add them to the error detection list by creating a custom error code range and then disabling that error code by clearing its **Enabled** checkbox. This in effect excludes the error code as an error indicator.



For Java and .NET agents, you can specify custom redirect target error pages as error indicators. To specify a redirect page, click **Add Error Redirect Page** and add a name for the configuration and a regular expression to match the URL of the page, such as `AcmeErrorPage.jsp`.

Ignore Exceptions and Log Messages as Error Indicators

Certain types of exceptions, loggers or log messages as transaction error indicators may not reflect events that should be counted as transaction errors in your environment. They may include exceptions raised by application framework code or by user login failures.

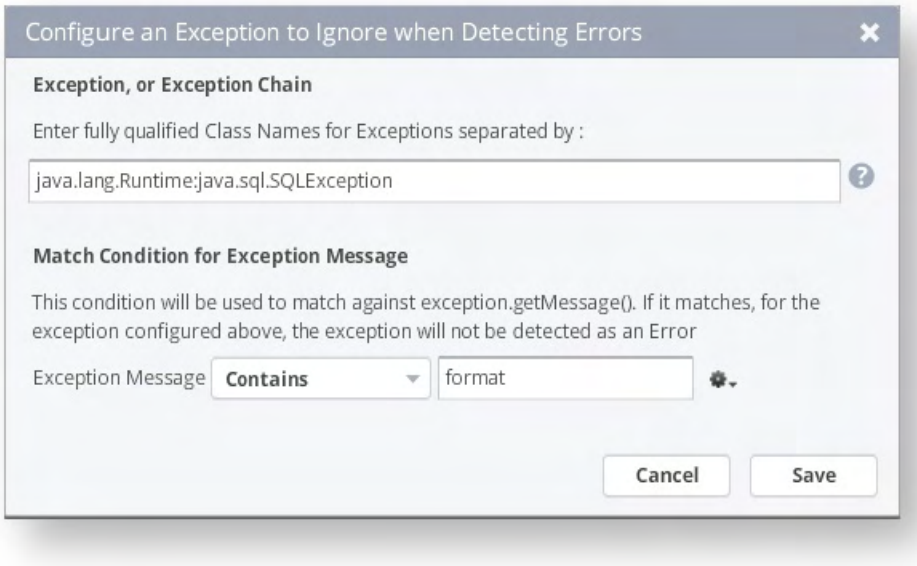
When you configure an exception to be ignored, the agent detects the exception, increments the exception count, and displays the exception in Exceptions lists in the UI, but the business transaction in which the error is thrown is not considered an "error transaction" for monitoring purposes. The transaction snapshot would not show the exception in the Summary or Error Details section and the user experience for the transaction instance would be unaffected by the exception.

To configure exceptions for the agent to ignore, click the **Add New Exception to Ignore** button in the error configuration window.

Enter the class name of the exception to be ignored and the match condition for the exception message. For the match condition, if you do not need to filter for specific messages in the exception, select "Is Not Empty". If you want to filter for Null, select "Is Not Empty" and use the gear icon to select NOT, which, in effect, tests for "is empty".

> The text field for **Match Condition for Exception Message** cannot contain the characters ", <, >, and &.

The following example directs the agent to ignore java.lang.RuntimeExceptions that wrap a javax.sql.SQLException only when the exception.getMessage() call in the root exception contains the string "format". (Other types of java.lang.Runtime exceptions will not be ignored.)



When you define the class of an exception to ignore by an exception chain, the exception message against which the match condition is applied must be in the root exception of the chain. The match is not applied to any nested exceptions.

In .NET and Java, you can specify that errors logged with certain loggers or logger categories be ignored. Click **Add New Category/Logger to Ignore**.

Error Detection Notes by Platform

The following sections list error detection configuration and error monitoring considerations, if any, by application platform.

Error Configuration for .NET

By default, the Windows .NET Agents can instrument calls using NLog and Log4Net. They can also gather information from System Trace and the Event Log. Beginning with Agents >= 4.5.19 on Linux, and >= 21.2.0 on Windows, Agents running on .NET Core can also instrument calls using loggers that implement the Microsoft.Extensions.Logging.ILogger API. To instrument calls using other loggers, add a custom logger definition. See Configuring a Custom Logger.

Messages logged as higher than ERROR include severe levels such as CRITICAL or FATAL.

If you do *not* want system trace or event log errors to be monitored, disable them by checking the appropriate box. System trace errors are anything written as an error message to the Listeners collection via TraceError.

Event log errors are anything written to the EventLog when the type is set to error. For example:

```
myEventLog.WriteEntry(myMessage, EventLogEntryType.Error, myID);
```

Error Configuration for PHP

The PHP Agent instruments the PHP reporting facility. PHP applications can use trigger_error to report errors through that facility. PHP extensions and PHP itself can also use the PHP facility for reporting errors.

By default, the agent can check for PHP errors using multiple thresholds:

- If you select Error, the agent reports only messages and exceptions marked Error.
- If you select Warning, the agent reports only messages and exceptions marked Error and Warning.
- If you select Notice, the agent reports messages and exceptions marked Error, Warning and Notice.

Error Configuration for Node.js

The Node.js Agent reports exceptions thrown by the Node.js application or by Node.js itself.

You can configure certain exceptions or logged messages not to cause transactions to be reported as errors using the ‘Ignored Exceptions’ and ‘Ignored Messages’ lists. See Ignoring Exceptions and Log Messages as Error Indicators.

Error Configuration for Python Notes

By default, the Python Agent reports error transactions for unhandled exceptions, HTTP status codes greater than or equal to 400, and messages logged at ERROR or higher by the Python logging module.

If you do not want any logged errors to cause transactions to be reported as errors, clear the "Mark Business Transaction as error" checkbox. If you do not want to capture logged messages at all, clear the "Detect Errors" checkbox.

You can configure certain exceptions or logged messages not to cause transactions to be reported as errors using the ‘Ignored Exceptions’ and ‘Ignored Messages’ lists. See Ignoring Exceptions and Log Messages as Error Indicators.

Service Endpoint Detection

AppDynamics automatically detects service endpoints for Java applications. You can configure custom service endpoints for Java or .NET to monitor the performance of services.

You can also configure exclude rules for service endpoints, which prevent agents from registering service endpoints for methods that match the exclude rules. The order of precedence for match, exclude and automatic rules are:

1. Exclude rules
2. Custom service endpoint rules
3. Automatic discovery

Permissions

To configure service endpoints your user account must have the Configure Service Endpoints permission for the business application. For information on AppDynamics Role Based Access Control, see Application Permissions.

Configure Custom Service Endpoints

You configure custom service endpoints like you configure custom match rules for business transactions:

1. From the **Service Endpoints** pane, click **Configure**.
2. Click the Custom Service Endpoint tab.
3. Choose the tier on which the service runs and click the plus icon to add a service endpoint configuration. The configuration settings are similar to business transaction entry point configuration settings. See Custom Match Rules.

As you choose a method for a service endpoint, avoid methods that occur within the following programming patterns:

- High-frequency loops, such as a for or while loop.
- Recursive functions.

Service endpoints inside such structures may cause performance overhead. Instead, consider adding a service endpoint at a point in the code upstream from a high-frequency loop or recursive function.

Configure service endpoint exclude rules in the same pane as the custom service endpoints. Click **Is Exclude Rule** on the **New Service Endpoint Definition** pane.

Automatic Discovery for Java

The Java Agent automatically discovers service endpoints. To configure service endpoint automatic detection settings, click to **Configure** on the **Service Endpoints** pane. You can configure the following settings:

- For existing service endpoint detection rules, you can enable or disable the detection rule.
- For servlet service endpoints, you can modify automatic naming as you would with servlet business transactions.

> The maximum limit for naming the service endpoints through automatic discovery is 99 characters.

POJO Service Endpoints

For the Java Agent to detect Plain Old Java Objects (POJO) service endpoints, you must do the following:

- Create at least one POJO custom service endpoint definition and enable it. The agent only detects POJO service endpoints for enabled custom service endpoint definitions.
- Verify automatic discovery for POJO service endpoints is enabled. It is enabled by default.

> When you disable automatic discovery for POJO service endpoints, the agent doesn't detect custom service endpoints.

Asynchronous Worker Thread Service Endpoints

The Java Agent automatically detects asynchronous worker threads spawned within a transaction as service endpoints. The agent names worker thread service endpoints for the class name, for example, "worker1". There is no end-to-end latency metric for worker thread service endpoints.

To disable worker thread service endpoints, register the enable-async-service-endpoints app agent node property with a value of "false". See App Agent Node Properties.

Configure Service Endpoints for .NET

The .NET Agent doesn't automatically discover service endpoints. To define a custom service endpoint for .NET, navigate to **Configuration > Instrumentation > Service Endpoints > Custom Service Endpoints**. Define the service endpoint as you would a custom match rule for a business transaction. See Service Endpoints and Transaction Detection Rules.

You can create service endpoints for the following entry point types:

- ASP.NET
- Message Queues
- POCO
- WCF
- Web Service

> The .NET Agent doesn't support service endpoints for MSMQ.

By default, you need to restart the instrumented application for instrumentation changes such as adding a POCO service endpoint to take effect. You can enable Runtime Reinstrumentation for the .NET Agent so that you don't need to restart your application and the AppDynamics.Agent.Coordinator after instrumentation changes.

After you configure a custom service endpoint, you can monitor it on the service endpoint dashboard that shows KPIs and transaction snapshots where the service endpoint executed. You can also use the metric browser to analyze service endpoint performance. See Service Endpoints.

Tips for Defining .NET Service Endpoints

The methods that serve as the entry points for business transactions are often the same methods that you want to monitor as service endpoints as well. You can create service endpoints on the originating entry point for a business transaction.

- For ASP.NET service endpoints, you can use the URL to define the service endpoint. For example, in the Travel Site tier above, set a URL match to "`/Travel/Search`"
- For WCF and ASP.NET web service entry points, you can use an existing transaction snapshot to find the URL for the service.
    1. Open a full transaction snapshot for the business transaction.
    2. From the upstream tier, click the exit call link, either **WCF** or **Web Service**.
    The exit call window shows the URL for the web service.

    3. Open the service URL in a browser.
    4. On the service page, use the URL to access the WSDL file.

    5. The `service name element shows the service name.`

```
<wsdl:service name="Service1">
```

- Define POCO service endpoints exactly as you would a POCO custom match rule for a business transaction.

Data Collectors

Works with:

You can use data collectors to supplement business transaction and transaction analytics data with application data. The application data adds context to business transaction performance issues. For example, they may show the values of particular parameters or return values for business transactions affected by poor performance.

This data shows the business context affected by performance issues, such as the specific user, order, or product.

Types of Data Collectors

There are two types of data collectors:

- Method invocation data collectors - Capture code data, such as method arguments, variables, and return values.
- HTTP data collectors - Capture the URLs, parameter values, headers, and cookies of HTTP messages exchanged in a business transaction.

See Collect Transaction Analytics Data.

View Collected Data

When applied to business transactions, the data collectors supplement the information shown in transaction snapshots. The information captured by HTTP data collectors appears in the HTTP DATA and COOKIES sections, while method invocation data appears in the Business Data section.

To view collected data:

1. Navigate to the **Transaction Snapshots** pane.
2. Double-click the transaction for which you want to view data.
3. Click **Data Collector** to view collected data.

Configure a Data Collector

To configure data collectors, you need the Configure Diagnostic Data Collectors permission. Follow these steps to configure a data collector:

1. Identify the method on which to capture data. To do this, define the method signature and (optionally) filters based on the value of a code point in the method (such as, return value or argument).
2. Specify the actual code point that serves as the source of the data.
3. If the data collector applies to business transactions, then select the applicable business transactions.

When creating a data collector, you typically need to know the code on which you are setting up the collector, and whether it is based on access to the source code for the application, or its documentation. For the JVM 1.5 and .NET application environments, you must restart the JVM or application server if your method invocation data collector results in modifications to instrumentation configuration (class name, method name, method parameters, and so on).

These platform-specific considerations apply to data collectors:

- For C/C++ SDK: Create a method data collector using the `appd_bt_add_user_data function()`, not the Controller UI as described here. See C/C++ SDK Reference.
- For Node.js Agent: Create a method data collector using only the `addSnapshotData()` Node.js API, not the Controller UI as described here. See Node.js Agent API Reference.
- For Python Agent: Create a method data collector using the `add_snapshot_data()` Python Agent API, not the Controller UI. See Python Agent API Reference.
- For PHP method data collectors, only the **with a Class Name that** option is valid. You cannot add a method data collector to a standalone PHP function.

Configure a Data Collector Automatically

You can add a data collector directly from a transaction snapshot through the call graph. This automatically adds the class and method for you.

1. Double-click a call graph.
2. Drill down to the node you want.
3. Right-click the method you want.
4. Click **Configure Instrumentation for this Class/Method**.
5. Complete the wizard.

Configure a Data Collector Manually

Data collectors can be manually configured in at least two ways.

From the left pane:

1. Click **Configuration** in the left pane.
2. Click **Instrumentation**.
3. Click the Data Collectors tab, and click **Add** below the data collector box for the type of data collector you want to add. The data collector configuration panel displays.

From a call graph:

1. Double-click a call graph.
2. Click **Data Collectors** in the menu bar.
3. Click **Actions**.
4. Click **Configure Data Collectors**.
5. Click **Add** at the bottom of the data collector box for the type of data collector you want to add. The data collector configuration panel displays.

Note the following platform-specific considerations applicable to data collectors:

- C/C++ SDK - Create a method data collector using the `appd_bt_add_user_data function()`, not the Controller UI as described here. See C/C++ SDK Reference.
- Node.js Agent - Create a method data collector only using the `addSnapshotData()` Node.js API, not the Controller UI as described here. See Node.js Agent API Reference.
- Python Agent - Create a method data collector using the `add_snapshot_data()` Python Agent API, not the Controller UI. See Python Agent API Reference.
- PHP method data collectors - Only the "with a Class Name that" option is valid. Also, you cannot add a method data collector to a standalone PHP function.

The general steps for configuring a data collector are:

1. Identify the method on which to capture data. To do this, define the method signature and (optionally) filters based on the value of a code point in the method (such as return value or argument).
2. Specify the actual code point that serves as the source of the data.
3. If the data collector applies to business transactions, choose the applicable business transactions.

Typically, creating a data collector requires knowledge of the code on which you are setting up the collector, whether based on access to the source code for the application or its documentation. For some application environments, including JVM 1.5 and .NET, you will need to restart the JVM or application server if your method invocation data collector results in modifications to instrumentation configuration (class name, method name, method parameters, and so on).

Configuration Notes

- The **Apply to new Business Transactions** option applies the collector to business transactions created after you have configured the data collector. Otherwise, the data collector applies only to the business transactions you select in the subsequent data collector configuration pane.
- For **Class**, select the match condition that the data collector can use to identify the class, such as class name, implemented interface name, and so on. If matching by class name, then use the fully qualified name of the class, as appropriate for the application platform. For example, the form of the equals field value would be:
  - In Java: `com.appdynamics.model.Item`
  - In .NET: `Bookstore.Item`
  - In PHP: `book`
- **Is this Method Overloaded**: If this is an overloaded method, then add parameters that identify the signature. You must create a data collector definition for each form of the method for which you want to capture data. For example, given the overloaded method in this table, to capture data for only the second two forms, you would need to create two data collectors. The parameters to configure are shown:

Signature	Parameters to Configure
`getName()`	• None
`getName(int studentId)`	• Param Index 0: java.lang.int
`getName(int studentId, string name)`	• Param Index 0: java.lang.int • Param Index 1: java.lang.String

- You can refine the method selection to meet specific conditions. If you configure more than one match condition, then all match conditions must be satisfied by the request for the data collector to be applied to the request.
- Once you identify the method, specify the code point from which you want to capture data, such as the method return value, argument, or a value captured by the getter chain on the invoked object. Configure this code point in the **Specify the Data to Collect from this Method Invocation** section of the configuration settings.
- HTTP data collector can capture data from HTTP parameters, request attributes, cookies, and other data. Notice that the Content-Length HTTP header is already captured in AppDynamics as the Average Request Size metric. However, you may choose to configure a data collector for this header to have the value appear in transaction snapshots, providing you insight into, for example, whether message size corresponds to slow performance.
- You can configure multiple data collectors. The effect of multiple data collectors is cumulative. For example, if you add a custom data collector that does not include the collection of the URL HTTP request attribute, but keep the Default HTTP Request Data Collector configuration in which the URL is configured to be collected, then the URL is collected.

Method Invocation Data Collector Example

Method invocation data collectors are applicable to Java and .NET.

In this example of a manual setup (not using the wizard), we'll set up a method invocation data collector on a Java application. We want to create a data collector on the method `getCartTotal()`, which is shown in this code snippet with the method `getUser()` and which we will use later as a data source.

```
package com.appdynamicspilot.model;
...
public class Cart implements java.io.Serializable {
    ...
    private Double fakeAmount = 0.0;
    ...
    private User user;
    ...
    public User getUser() {
        return user;
    }
    ...
    public Double getCartTotal() {
        if (fakeAmount == 0.0) {
            double total = 0;
            if (items != null) {
                for (Item item : items) {
                    total += item.getPrice();
                }
            }
            return total;
        } return fakeAmount;
    }
   ...
}
```

To configure a data collector for an application, add a data collector and then configure it:

1. When you add your data collector, make your selections as appropriate for your configuration.
2. Add a class and a method, if not already filled in. Class and Method Name are used to identify the method.
3. At the **Enable Data Collector for** checkboxes, select **Transactions Snapshots** to add metadata for troubleshooting purposes and for APM snapshots, or select **Transaction Analytics** to collect metadata about every execution of the transaction to use later in the analytics platform. It is recommended that you start with ONLY Transactions Snapshots. Enable Transactions Analytics after the targeted data collection is confirmed.
4. Click **Add Parameter** or **Add Match Condition** to select the correct parameter from the popup.
    a. Method Parameters are added if the method is overloaded. Clicking **Add Parameter** adds the Param Index 0. Add the fully qualified class name for the parameter.
    b. Match Conditions allow you to pick specific data when a method or line of code is called multiple times. Match Conditions engage method parameters or return values. Selecting **Add Match Condition** opens the Create Match Condition popup. Make your selections, and then click **Save**.
    c. When setting up your data collector, note the checkbox beside **Apply to new Business Transactions**.
        i. Checking this box automatically applies the rule to new business transactions.
        ii. Not checking this box requires you to manually apply the rule to business transactions by navigating to **Configuration > Instrumentation > Data Collectors**.
    d. To add multiple collection types, click **Add** beneath Specify the Data to Collect from this Method Invocation to configure the source of data. For this section of code, use an invoked object and a getter chain of `user.getCustomerName`. This code snippet is an example of how to capture the user name on the invoked object. The `Cart` class instantiates a `User` object based on the following class in the same package as `Cart`. Note that the User class includes a method for returning the name of the user, `getCustomerName()`.

    ```
    package com.appdynamicspilot.model;
    ...
    public class User implements java.io.Serializable {
        ...
        private String customerName = null;
        ...

        public String getCustomerName() {
            return customerName;
        }
        public void setCustomerName(String customerName) {
            this.customerName = customerName;
        }
        ...
    }
    ```

    Using a getter chain, you can identify this method as another data source in the same data collector. For example, you could select **Invoked Object** as the source of the data. The getter chain `getUser().getCustomerName()` is the operation on the invoked object.
    For the PHP agent, if a method return value collected by MIDC is not stored in any variable, it is seen as null in both snapshot and Analytics data.
5. When finished, click **Save**.

After you configure the method invocation data collectors, you can click **Configure Transactions using this Data Collector** on the Instrumentation pane to drag and drop (or highlight and move) the transactions to a given data collector.

When complete, transaction snapshots for slow, very slow, and stalled transactions, the transaction snapshots will include the specified user data.

HTTP Data Collector Example

In the HTTP Data Collector configuration, specify the request data that you want to display in the snapshot.

To configure a data collector, add a data collector and then configure it:

1. Make your selections as appropriate for your configuration.
2. Determine if you are collecting parameters, cookies, session keys, or header data.
3. Click **+Add** beneath a data type to specify the request data that you want to display in the snapshot, and fill in as appropriate. When setting up your data collector, note the checkbox beside **Apply to new Business Transactions**.
    a. Checking this box will automatically apply the rule to new business transactions.
    b. Not checking this box requires you to manually apply the rule to business transactions by navigating to **Configuration > Instrumentation > Data Collectors**.
4. When finished, click **Save**.

Call Graph Settings

Related pages:

- Transaction Thresholds
- Transaction Snapshot Collection

Works with:

You can control the data captured in call graphs with the **Call Graph Settings** panel.

Permissions

To configure call graph settings, you need the **Configure Call Graph Settings** permission.

Call Graph Granularity

To control the granularity for call graphs, use the following settings:

- **Control granularity for Methods**: To ensure low-performance overhead, choose a threshold in milliseconds for method execution time. Methods taking less than the time specified here are filtered out of the call graphs.
- **Control granularity for SQL calls**: You can specify a threshold for SQL queries. SQL queries taking less than the specified time in milliseconds are filtered out of the call graphs. See Tune Java Agent Performance.

> Only SQL Capture Settings apply to call graph configuration for the Node.js agent.

To access call graph configuration, click **Configuration > Instrumentation** and choose the Call Graph Settings tab. There are subtabs for each application type.

Exclude Packages or Namespaces from Call Graphs

A call graph can potentially contain hundreds of methods. You can exclude packages (Java) or namespaces (.NET) with classes that you do not want to monitor.

For Java, some packages are excluded by default. These are visible in the Excluded Packages list. The packages that are excluded by default cannot be removed. However, you can include a particular sub-package from an excluded package.

You can customize call graph instrumentation from the call graph instrumentation page. From there, choose from these configuration options:

- Use the **Add Custom Package Exclude** (Java) or **Add Custom Namespace Exclude** (.NET) configuration options to exclude specific packages or namespaces from call graphs.
- Use the **Add Always Show Package/Class** (Java) or **Add Always Show Namespace/Class** (.NET) configuration options to have a package or namespace always shown in call graphs.

When the Controller constructs a call graph it uses excluded packages and included sub packages to determine which calls to include. However, the Controller includes some calls even if they are listed among the excluded packages. For example, web service calls.

SQL Capture Settings

The SQL capture settings control whether SQL statements are captured and presented in the Controller UI with dynamic parameters bound to their runtime values. For example, consider Java code that constructs a SQL call as follows:

```
stmt = new PreparedStatement("select * from user where ssn = ?")
stmt.bind(1, "123-123-1234")
stmt.execute()
```

With the capture raw SQL option enabled, AppDynamics captures and presents the SQL call in the following form:

```
select * from user where ssn = '123-123-1234'
```

If capture raw SQL is disabled, the SQL call appears in its original form, with question mark parameters not bound to values. Disabling capture-raw-sql and using question mark parameters in SQL prepared statements gives you a mechanism for preventing sensitive data from appearing in the Controller UI.

It is important to note that the sensitive values must be parameterized in the original, prepared statement form of the SQL statement, as shown above. The following statement results in the potentially sensitive information (social security number) appearing in the Controller UI whether capture raw SQL is enabled or disabled since the sensitive data is not parameterized.

```
stmt = new PreparedStatement("select * from user where ssn ='123-123-1234'")
```

To configure SQL capture settings, in the Call Graph Settings tab, scroll down to the **SQL Capture Settings** section and choose one of the following options:

- **Capture Raw SQL:** Select this option to have SQL statements that are composed as prepared statements captured with dynamic parameters bound to runtime values. By default, private SQL data and queries that take less than 10 ms are not captured.

  > **Important**
  >
  > You can select this option to capture raw query details for NoSQL databases such as MongoDB, DynamoDB, and CassandraDB and the relational queries will not be scrubbed.

  > When you enable Capture Raw SQL in .NET environments, the agent captures the parameters for ADO.NET stored procedure calls even though the parameters are not represented by question marks. It does not capture stored procedure local variables that are not available to the CLR.

- **Filter Parameter values:** Select this option to have SQL statements that are composed as prepared statements captured without dynamic parameters bound to runtime values.

Configure JMX Metrics from MBeans

Related pages:

- Exclude JMX Metrics

This page describes how to create persistent JMX metrics from MBean attributes. See Monitor JMX.

There are many helpful JMX topics on the AppDynamics community to help you with platform-specific troubleshooting tips.

JMX Metric Rules and Metrics

You can add persistent JMX-based metrics to AppDynamics using metric rules. Once you create a persistent JMX metric, you can:

- View it in the Metric Browser.
- Add it to a Custom Dashboard.
- Create a health rule for it so that you can receive alerts.

You can use the MBean Browser or JMX Metrics Rules Panel to create new metrics. MBean query expressions are supported.

You must have Configure JMX permissions for the application to configure new JMX Metrics your user account. See Create and Manage Custom Roles.

Access the MBean Browser

If the MBean is already monitored and you want to create a metric from one of its attributes, you can do so from the MBean Browser.

To create a metric from an existing MBean attribute:

1. Open the Node Dashboard of the node that hosts the MBean, and navigate to **MBean Browser** > **JMX**.
2. Expand the domains listed in the left panel and select the MBean that contains the attribute of interest.
3. Expand the **Attributes** section, select the attribute, and click **Create Metric**.

Configure JMX Metric Rules

1. Navigate to **Configuration > Instrumentation** > **JMX** to add an MBean and attributes, possibly based on complex matching patterns.
2. From the JMX Metric Configurations panel, click the Java platform to add the metric to a platform group.
3. Alternatively, create a new group and add your metric to the group.
   Groups allow you to organize metrics to meet your needs. For example, you may choose to keep custom metrics with their Java platform, or put all metrics you add into a Custom group to differentiate them from out-of-the-box metrics.

JMX Metric Settings

The general settings for adding instrumentation for an MBean are:

- The **Name** is the identifier you want to display in the UI for the MBean.
- An **Exclude Rule** excludes matched MBeans that would otherwise be included by other rules. See Exclude MBean Attributes.
- **Enabled** means that you want this rule to be applied.
- The **Metric Path** determines where the metric appears in the metric browser. For example, in the screenshot below, the metric path is "Web Container Runtime" for JMX metric "Tomcat_HttpThreadPools".

In the MBeans subpanel, add matching criteria to identify the MBeans that you want to monitor.

- The **Domain name** is the Java domain. This property must be the exact name; no wildcard characters are supported.
- The **Object Name Match Pattern** is the full object name pattern. The property may contain wildcard characters, such as the asterisk for matching all the name/value pairs. For example, specifying `jmx:type=Hello,*` matches a JMX MBean ObjectName, jmx:type=Hello,name=hello1, key1=value1.
- The **Instance Identifier** is the MBean ID.
  Instance Identifier is a field in the JMX Object pattern that can be used to categorize the runtime context of MBean category that has the same set of attributes. For example, the user category has two HTTP ports: 8090 and 8181. But attributes such as `currentThreadsBusy` and `maxThreads` are the same. If a JMX pattern has both HTTP and AJP, but the user is interested in monitoring only HTTP and not AJP thread pool, then the user uses an identifier, a name that matches HTTP so that only HTTP ports related MBean data is collected.
- **Advanced MBean Matching Criteria** is an optional control for matching against attribute values. Identify the attribute name and value to test, along with matching criteria, such as a substring match.

Without any instance identifier specified, a tree of resources or attributes is shown on the JMX Metric browser that matches the Object Name Match Pattern.

Example1

```
JMX -->
        ConnectionPoolModules
                        ConnectionPoolA

                                        PoolSize
                        ConnectionPoolB

                                        PoolSize
```

If you specify an `instanceIdentifier` like `instance identifier = path2`, it will show the second level attributes on the top level also.

The above tree will be shown as in the following example. The `PoolSize`, which is in the second level, also appears in the top level.

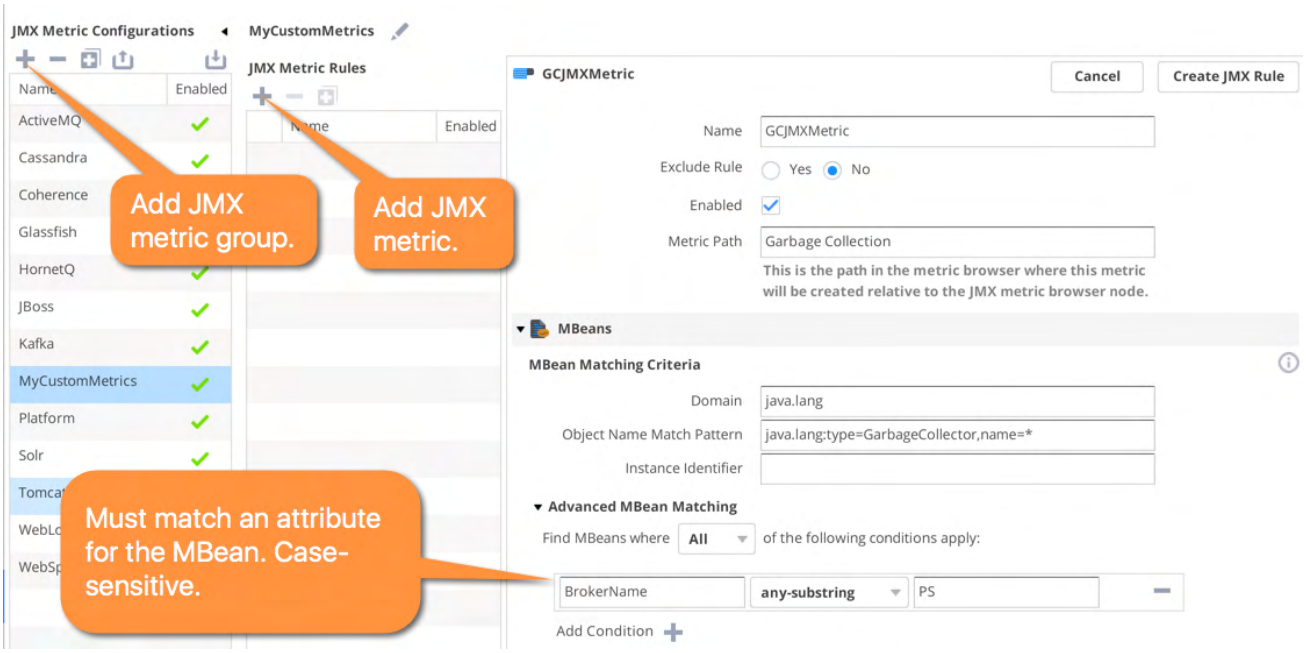
```
JMX -->
        ConnectionPoolModules
                        PoolSize

                        ConnectionPoolA

                                        PoolSize
                         ConnectionPoolB

                                        PoolSize
```

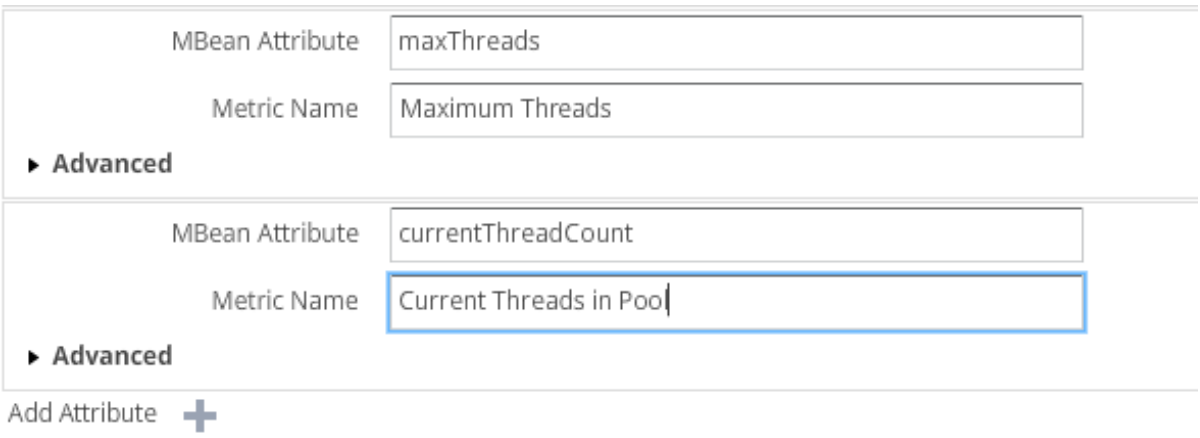
For example, this screenshot displays the MBean matching criteria for the `GCJMXMetric` rule.



For all matched MBeans, you can define one or more metrics for the attributes of those MBeans:

- **Metric Getter Chain**—Expressions can be executed against any value. In addition, getter chains for Strings and Booleans are supported using implicit conversion. See MBean Getter Chains.
- **Metric Time Rollup**—Determines how the metric will be aggregated over a period of time. You can choose to either average or sum the data points, or use the latest data point in the time interval.
- **Metric Cluster Rollup**—Defines how the metric will be aggregated for a tier, using the performance data for all the nodes in that tier. You can either average or sum the data.
- **Metric Aggregator Rollup**—Defines how the Agent rolls up multiple individual measurements (observations) into the observation that it reports once a one minute. For performance reasons, Agents report data to the Controller at one-minute intervals. Some metrics, such as Average Response Time, are measured (observed) many times in a minute. The Metric Aggregator Rollup setting determines how the Agent aggregates these metrics. You can average or sum observations on the data points or use the current observation. Alternatively, you can use the delta between the current and previous observation.

For example, the maxThreads MBean attribute is mapped to the Maximum Threads metric in the JMX metrics browser as shown here:



Example2

For instance, in a JBoss you get get the active count property from the following mbean:

jboss.as:subsystem=datasources,data-source=MyDatasource_01,statistics=pool

Define the metric rule:

Object name Match Pattern:jboss.as:subsystem=datasources,*,statistics=pool
Instance identifier: data-source
Attribute: ActiveCount

In the Object Name Match Patern, you can even use the wildcard to replace several branches, which is, if it were "jboss.as:subsystem=datasources, whatever=another_level,whatever=another_level,data-source=MyDatasource_01,statistics=pool" you can use "jboss.as:subsystem=datasources,*, statistics=pool".

The Instance Identifier is the instanced element that is separated:

jboss.as:subsystem=datasources,data-source=MyDatasource_01,statistics=pool

jboss.as:subsystem=datasources,data-source=MyDatasource_02,statistics=pool

...

jboss.as:subsystem=datasources,data-source=MyDatasource_07,statistics=pool

Therefore, you must use data-source as the instance identifier.

Export and Import JMX Configuration

After you modify the JMX configuration, you can backup or transfer the configuration using the JMX Configurations export and import icons at the top of the JMX Metric Configuration panel on the JMX instrumentation page. The configuration exports as an XML file.

Deactivate Transaction Monitoring for JMX Monitored Nodes

In some circumstances, such as for monitoring caches and message buses, you want to collect JMX metrics without the overhead of transaction monitoring.

You can do so by turning off transaction detection at the entry point. See Transaction Detection Rules.

MBean Getter Chains

Getter chains in custom MBean configuration specify the method that retrieves the value of interest.

Expressions can be executed against any value. In addition to getter chain support for numeric boxed primitives (Short, Integer, Long, and so on), Strings and Booleans are supported using implicit conversion.

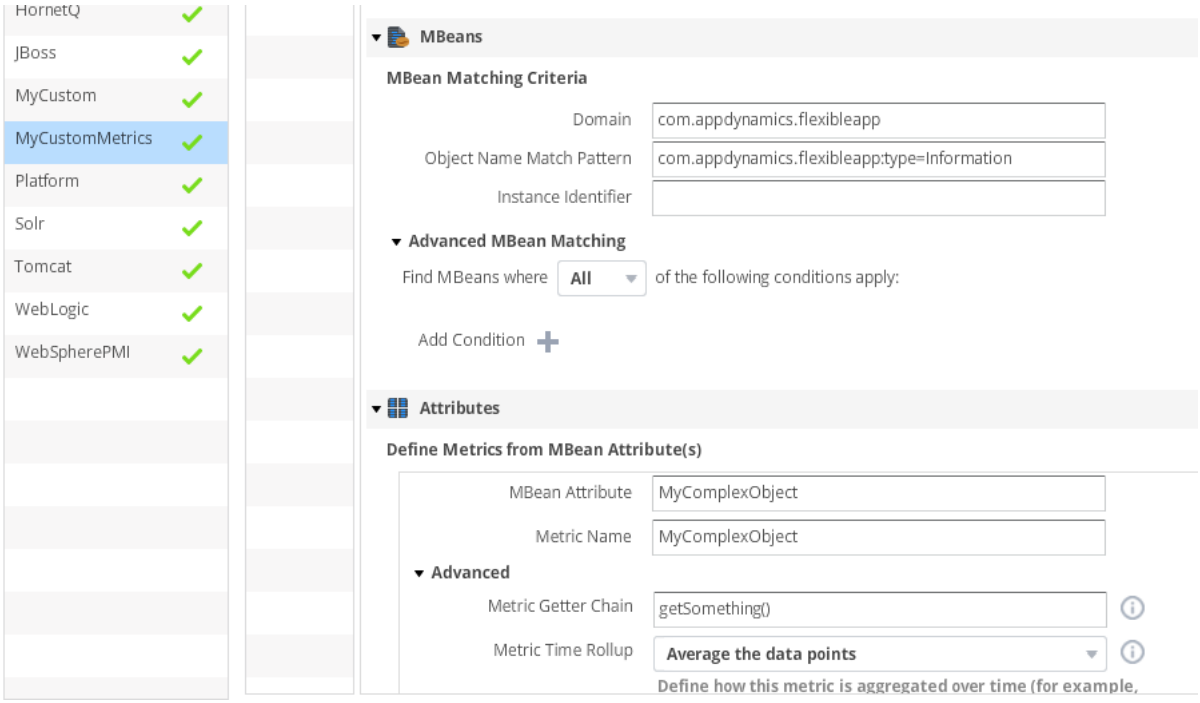
Boolean and String are implicitly converted to an Integer:

- Booleans are automatically converted to 0 (false) and 1 (true).
- Strings are converted to numeric values.

This example illustrates how to use a getter chain, given the class with a `getSomething()` method that returns the time:

```
1 package com.appdynamics.flexibleapp.mbean;
2
3 public class MyComplexObject
4 {
5     public long getSomething()
6     {
7         return System.currentTimeMillis();
8     }
9
```

In this example the metric getter chain configuration would be:



Exclude JMX Metrics

This page describes how to exclude MBean attributes from being monitored as JMX metrics. For background information about JMX metrics, see Monitor JMX.

Customize Metrics To Gather

AppDynamics provides a default configuration for certain JMX metrics. However, in situations where an environment has many resources, there may be too many metrics gathered. AppDynamics lets you exclude resources and particular operations on resources.

Exclude a Metric

For example, suppose you want to exclude monitoring for HTTP Thread Pools. Follow the procedure described in Create a new JMX Metrics Rule, using the following criteria:

1. Set the **Exclude Rule** option to **Yes**.
2. Provide the **Object Name Match Pattern**:

```
Catalina:type=ThreadPool,*
```

3. Provide the **Advanced MBean Matching** value:

```
http
```

This configuration directs AppDynamics to stop monitoring metrics for HTTP Thread Pools. You can clear the **Enabled** checkbox to disable the rule.

Exclude MBean Attributes

Some MBean attributes contain sensitive information that you do not want the Java Agent to report. You can configure the Java Agent to exclude these attributes using the `<exclude object-name>` setting in the `app-agent-config.xml` file.

To exclude an MBean attribute:

1. Open the `AppServerAgent/conf/app-agent-config.xml` file.
2. The new configuration takes effect immediately if the agent-overwrite property is set to true in the `app-agent-config.xml`. If `agent-overwrite` is `false`, which is the default, then the new configuration will be ignored and you have to restart the agent. Set the property to `true`.

```
<property name="agent-overwrite" value="true"/>
```

3. Locate the `JMXService` section. It looks like this:

```
<agent-service name="JMXService" enabled="true">
```

4. In the `JMXService <configuration>` section add the `<jmx-mbean-browser-excludes>` section and the `<exclude object-name>` property as per the instructions in the comment.

```
<configuration>
    <!--
       Use the below configuration sample to create rules to exclude MBean attributes from MBean Browser.
       <exclude object-name=<MBean name pattern> attributes=< * |comma separated list of attribute
names> >
       The example below will exclude all attributes of MBeans that match "Catalina:*".
       <jmx-mbean-browser-excludes>
          <exclude object-name="Catalina:*" attributes="*"/>
       </jmx-mbean-browser-excludes>
    -->
 </configuration>
```

5. Save the file.

JMX Logging

JMX logs contain information about JMX interactions between AppDynamics agents and the monitored server's JMX domains.

JMX log entries are useful for diagnosing problems associated with JMX metrics or with JVM metrics that rely on JMX. For example, they can help you determine why MBeans or metrics created from MBeans do not appear in the Controller UI.

The name of the log is JMX*Year_mon_day_hr_min*.#.log, where # is the log set. See Agent Log Files for information about the structure of the log files into sets.

The JMX log file can reach a maximum of 5MB within a set.

Collecting JMX log (sample):

```
<ADRRAFAppender name="JMXLogger" fileName="JMX.log">
            <PatternLayout pattern="[%t] %d{DATE} %5p - %m%n" />
            <SizeBasedTriggeringPolicy size="20 MB" />
            <ADRolloverStrategy max="5" />
        </ADRRAFAppender>
```

```
<AsyncLogger name="com.singularity.JMX" level="info" additivity="false">
            <AppenderRef ref="JMXLogger" />
        </AsyncLogger>
```

These configurations can be used in log4j2.xml file.

Asynchronous Transaction Demarcators

To monitor end-to-end transaction performance for an asynchronous transaction, you must identify the demarcator for the transaction's logical endpoint. There are two ways you can define a transaction demarcator:

- For Java applications, you can specify a tier on which the end to end transaction processing is completed. This lets you determine the logical transaction response time for transactions that perform asynchronous backend calls (such as JMS calls or web service calls). When the last of the threads spawned by the transaction terminates on that tier, the agent considers the transaction complete.

  > The Java Agent uses patent-pending heuristics to determine when the last thread associated with the Business Transaction has run. These heuristics are successful for many common cases. In complex environments with many thread handoffs unconstrained by frameworks, these heuristics may be inaccurate. For example Reactive Java, AKKA, or Scala environments.
  >
  > You should validate that the last thread on tier mechanism returns an end to end time consistent with the end to end latency shown within full transaction snapshots.

- For Java or .NET applications, you can identify the method that acts as the logical endpoint for the transaction processing sequence. For a response handler, this could be a method that watches for spawned threads to complete and when done, assembles the response and sends it back to the client. The end to end transaction time includes the time it takes for this configured method to finish processing, not when the method is invoked.

You may specify more than one endpoint demarcator for a particular business transaction. In this case, the first match ends the transaction for purposes of end-to-end latency monitoring. Be careful not to configure multiple demarcators that could be satisfied on different tiers for a given transaction.

For the last thread on tier demarcator type, the transaction endpoint is considered to be the time when the thread that receives the traced transaction terminates or the latest points at which any descendant threads terminate.

For the method-based transaction demarcator option, you can configure the demarcator to consider runtime state, such as the values of parameters passed to the method. This allows you to account for an application design in which the completion of a logical business transaction is signaled by the value of a method parameter or return value.

> For .NET POCO entry point on methods that return a `Task` class, AppDynamics tracks the return of the task object as an end to end latency transaction automatically. You can configure your own transactions as end to end transactions for Java and .NET applications as described here. See POCO Entry Points for information on `Task`-based POCO entry points.

To create the configuration:

1. Open the **Configuration** > **Instrumentation** page and choose **Asynchronous Transactions** from the top menu. You likely need to expand the menu list (**>>**) to view the **Asynchronous Transactions** item.
2. Click **Add** and choose the demarcator method:
   - Java only: **Transaction is complete when last thread on specified Tier is finished running**.
   - Java or .NET: **Transaction is complete when specified class/method is invoked**.
3. Follow the instructions that display for the option you choose. Note the following points:
   - You configure the class/method option using the standard method selector. See Configure Instrumentation for more information about identifying classes and methods in the AppDynamics configuration.
   - For the last thread on the tier approach, first, give a name for the transaction configuration and choose the tier.
4. Choose the business transaction where the configuration applies.

The threads in the logical transaction processing flow must be traceable by AppDynamics, including the thread that contains the end-point method. If needed, configure custom thread correlation to ensure that all threads are properly traced. For more information on thread correlation, see Configure the Thread Correlation in Java Agent and Thread Correlation for .NET.

Automatic Instrumentation of Specialist Packages and Frameworks

Related pages:

- Transaction Detection Rules
- Backend Detection Rules

One of the goals of the AppDynamics Application Performance Management (APM) Platform is to provide maximum visibility into Enterprise IT systems for the minimum of set-up effort.

To achieve this, AppDynamics configures its agents to place instrumentation on entry points, exit points, and thread hand-offs right out of the box. The user interface facilitates configuring naming rules for transactions and backends.

Within this documentation, you can find pages about Supported Environments, Transaction Detection, and Backend Detection for many common frameworks (including servlet, JAX-RS, and JDBC) and many HTTP clients.

In addition, the following pages describe the specialized out-of-the-box configuration for instrumenting off-the-shelf products, packages, or frameworks whose entry and exit points are too complex for the more general documentation:

- IBM-BPM Support
- Spring Batch Support
- OSB Support
- Open Tracing Support

IBM-BPM Support

IBM® Business Process Manager (IBM BPM) is a comprehensive business process management platform. It provides tools to enable authoring, testing, and deployment of business processes, as well as management capabilities. See IBM documentation.

IBM BPM 8.5.7 is used to define and execute Business Process Definitions (BPDs) which combine elements of human interaction Client-Side Human Services (CSHS) or 'user tasks' for example, manual loan approvals and so on with elements of system integration system tasks, for example, registering a loan approval in a CRM system and so on. These processes are critically important and it is, therefore, natural to use AppDynamics Business Transactions to monitor the system integration elements of the processes to ensure performance and reliability of these technical integrations. You can also use the AppDynamics Business Journeys capability to monitor the end to end progress of the processes, including the elements of human interaction.

AppDynamics Instrumentation Use Cases

To facilitate these monitoring use cases, the AppDynamics agent provides out-of-the-box configuration necessary to:

- Appropriately start and name Business Transactions originated within IBM BPM to allow management of system tasks with App iQ APM
- Correlate the processing within IBM BPM to facilitate end-to-end tracing of these Business Transactions
- Collect sufficient process metadata to allow these Business Transactions to be used within Business Journeys to provide visibility into the progress of processes including the human interactions

Agent Installation and Setup

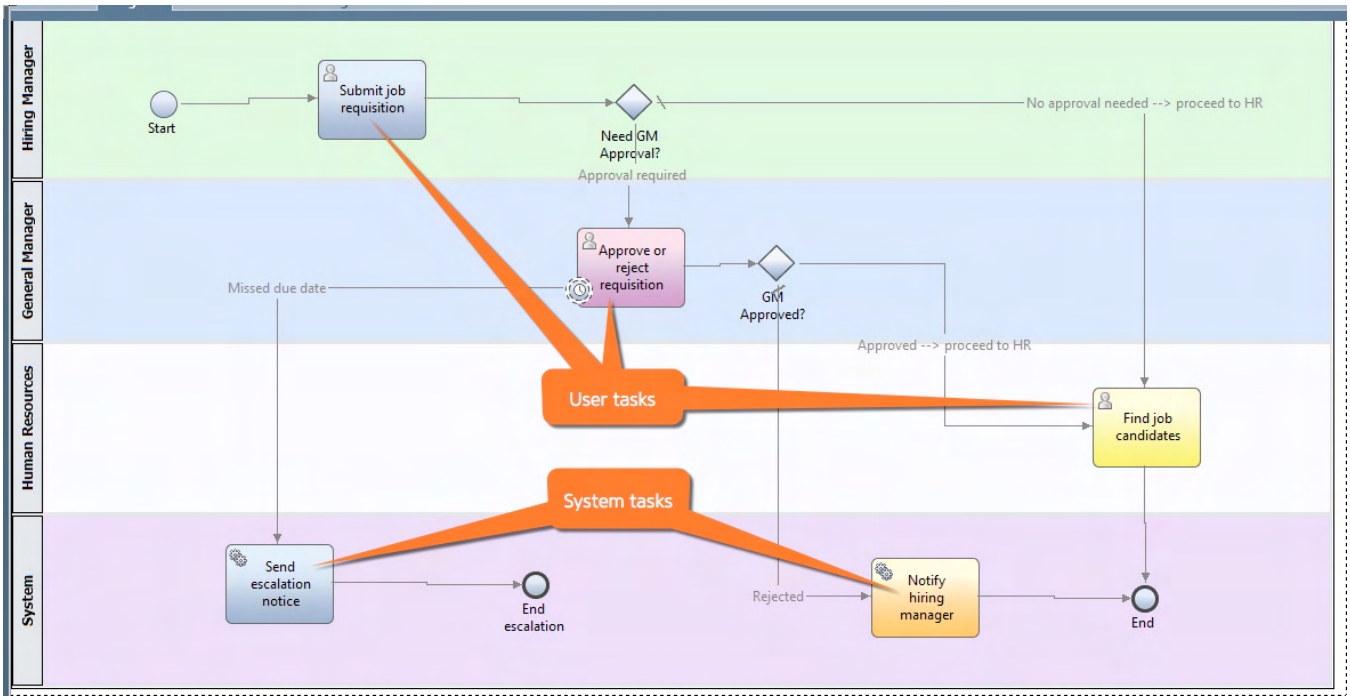
IBM BPM runs in WebSphere, see IBM WebSphere and InfoSphere Startup Settings for more details.

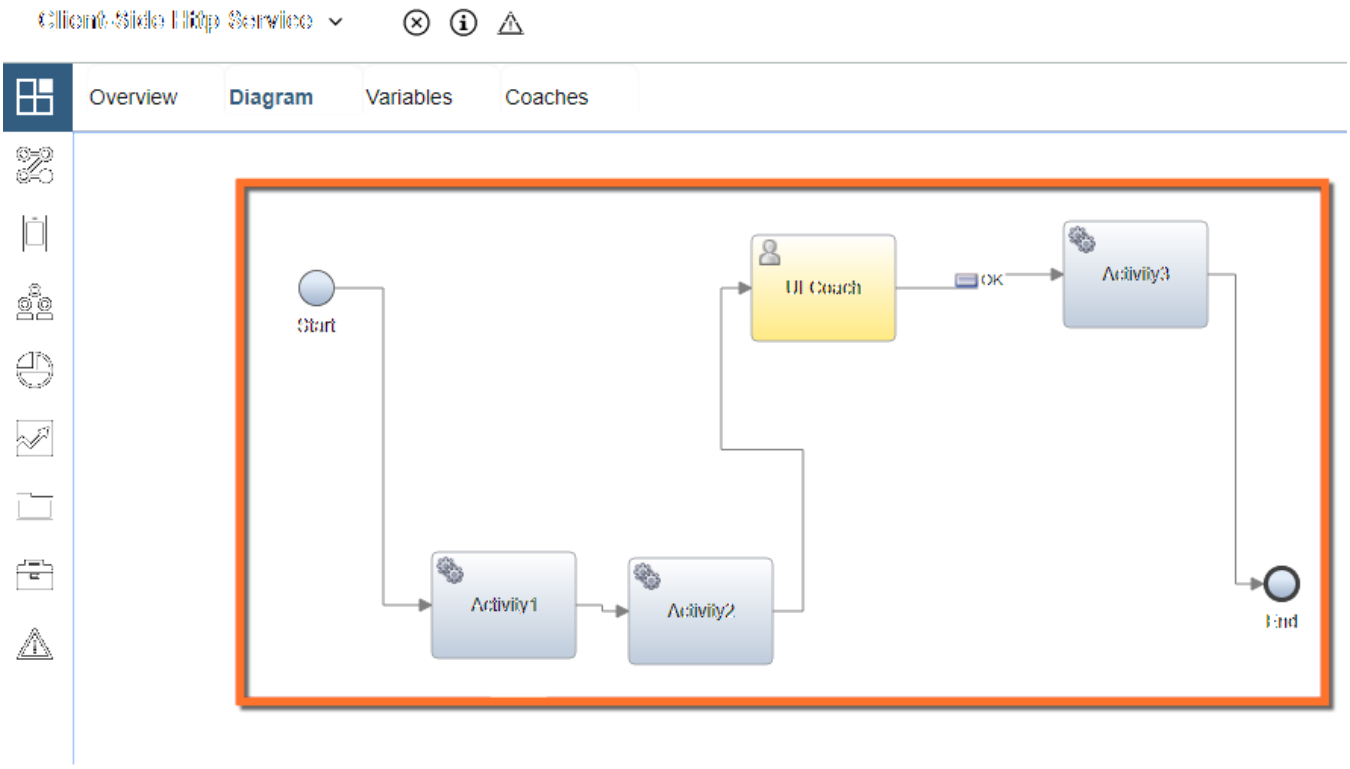
Business Process Definitions: System and User Tasks

A BPD process consists of the flow of a business process which may involve user interactions. It consists of User Tasks, System Tasks, and other logic.

The screenshot displays a sample process within the BPD designer:

User tasks, in turn, break down into one or more user interactions, such as submit a form and approve a decision. They can be implemented as a CSHS, one of which is shown below:





A CSHS always starts with a start event and consists of one or more activities each of which uses a system service as the underlying implementation, and one or more Coaches, which define the user interactions.

Business Transaction Support

Business Transaction Support for Client Side Human Services

CSHS Transaction naming

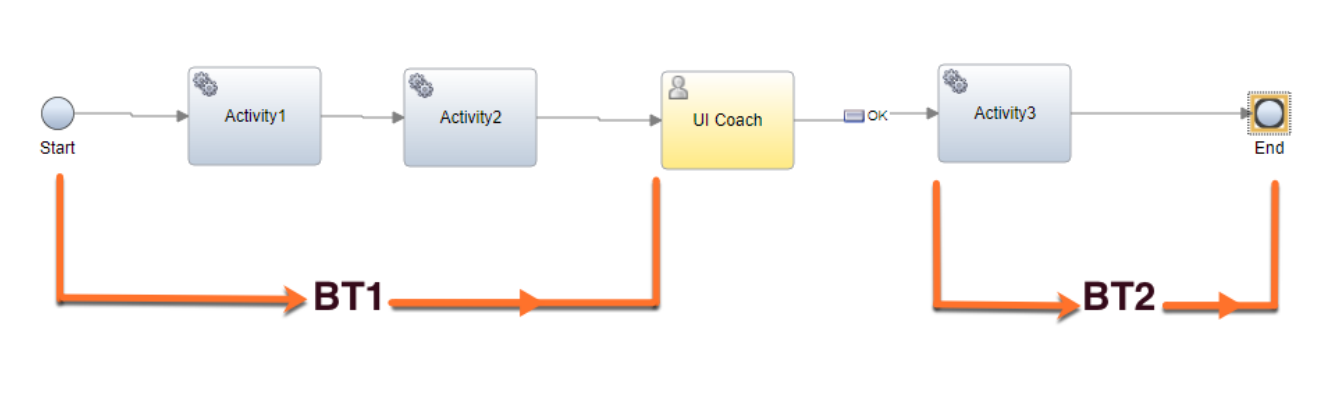
All Business Transactions detected within a CSHS are detected as servlet type transactions, and their naming can be configured using custom servlet naming rules. The default servlet naming rule uses only the first two segments of the URL for naming, hence, without custom naming configuration the Business Transactions will be detected as –

```
/<Project Name>/<BPD Name>
```

CSHS Transaction naming control

To disable the IBM BPM specific naming for CSHS Business Transactions use the `disable-ibmbpm-usertask-bt-naming` node property.

Since the Business Transaction is designed to monitor technical activity only, one CSHS may spawn multiple Business Transactions:



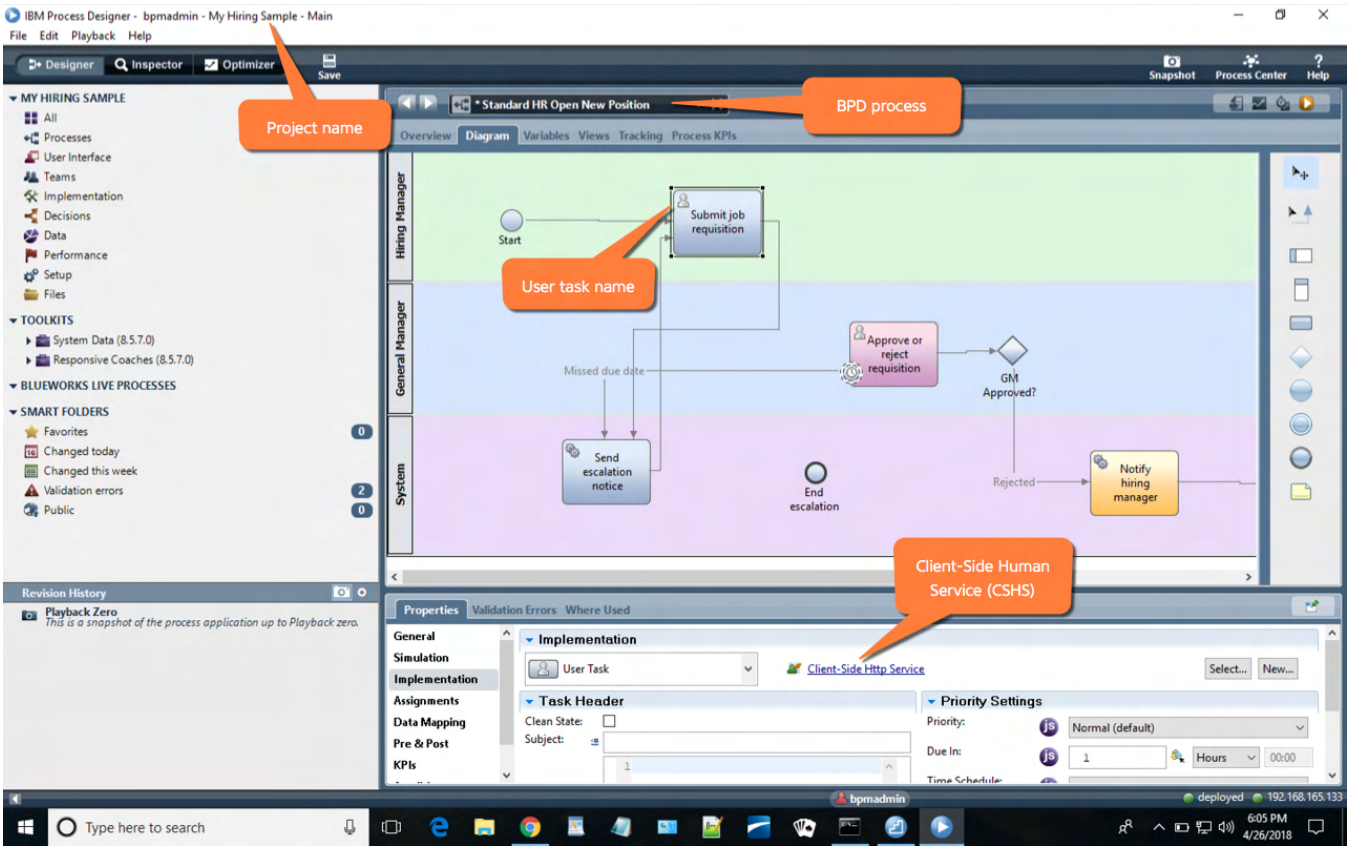
Any element inside a CSHS is associated with the following identifiers:

- Project Name
- BPD Process Name
- User Task Name
- CSHS Process Name
- Activity Name or Coach Name

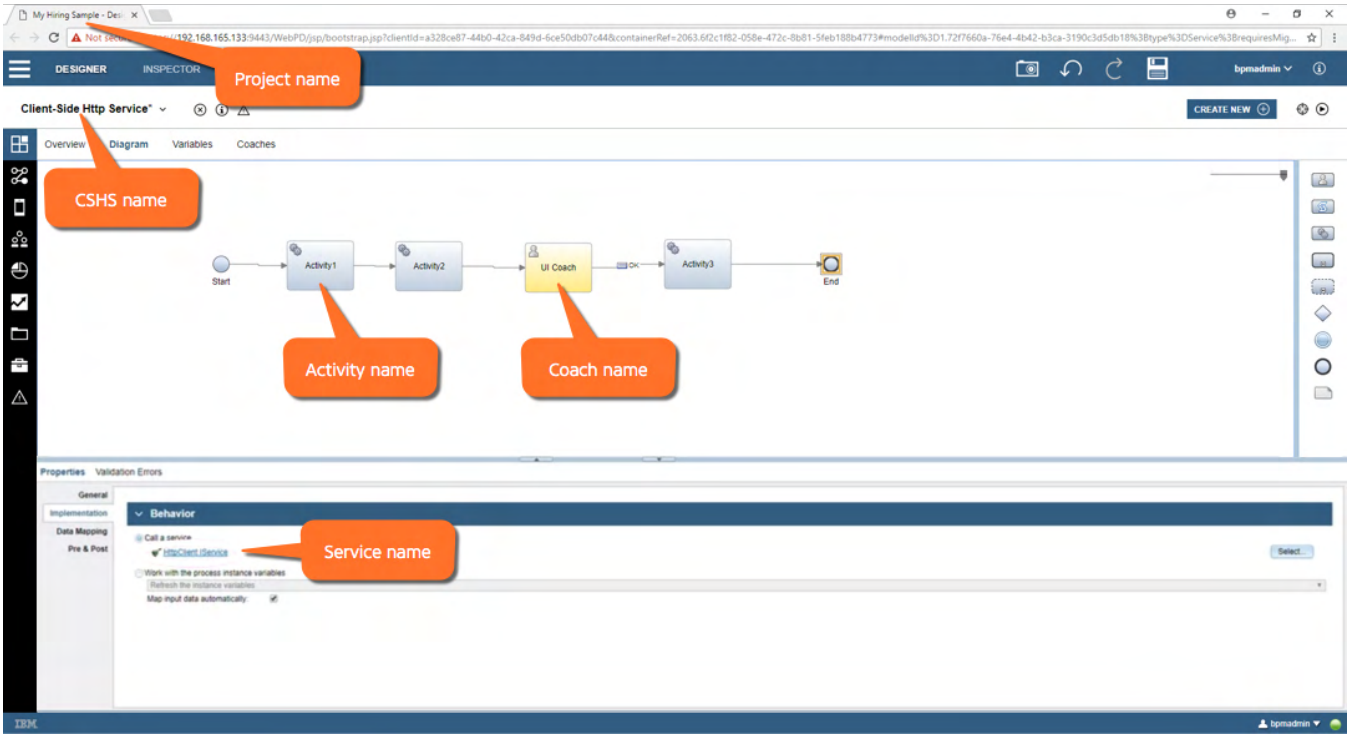
Additionally, for Activity (Service), the activity has a service as its implementation which has its own identifier (Service Name).

These are annotated on screenshots of the IBM design tools:

BPD Screen



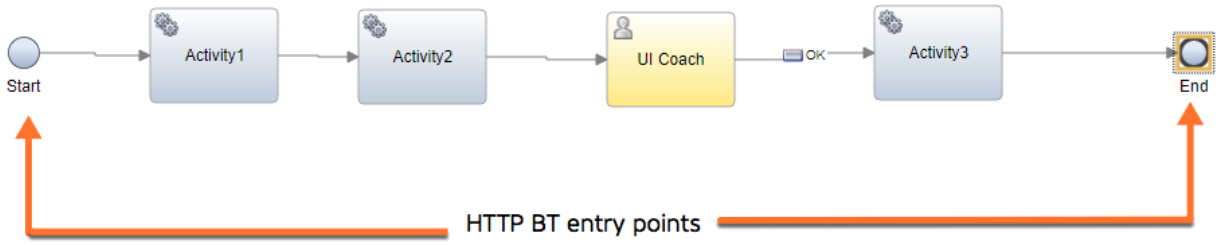
CSHS Screen



Business Transaction Detection and Naming at the Start and End Points within a CSHS

Within a CSHS, there can be one or more activity-services involved in the flow. Each of this hits a specific REST URL. Hence, an HTTP entry point is defined for each of these services.

- For example, the default URL for the **Start** BT – `/teamworks/process.lsw`
- For example, the default URL for the **End** BT – /teamworks/cfecontroller



.

Business Transactions originating from the start of a user task are detected as servlet Business Transactions and are named according to the following scheme:
`/<Project Name>/<BPD Name>/<Task Name>/<CSHS Name>/Start:Event`

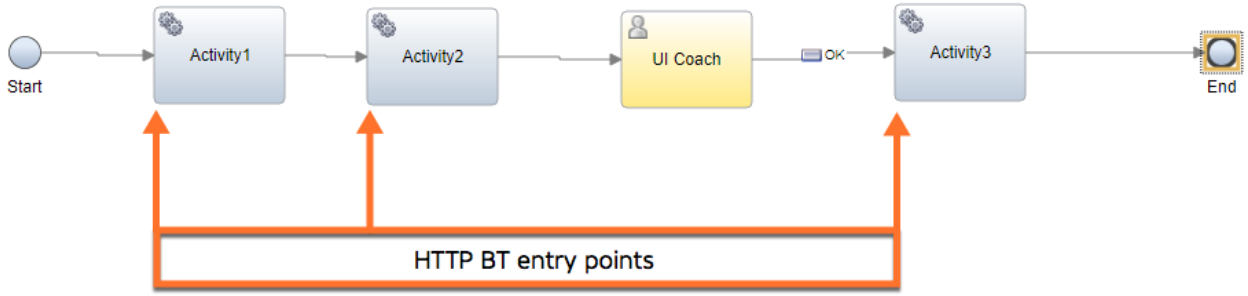
For example (corresponding to the images shown above, BPD image and CSHS image), the Business Transactions would be named –
`/My Hiring Sample/Standard HR Open New Position/Step: Submit job requisition/Client-Side Http Service/Start:Event`
`/My Hiring Sample/Standard HR Open New Position/Step: Submit job requisition/Client-Side Http Service/End:Event`

Business Transaction Detection and Naming at an Activity (Service) Node Within a CSHS

Each user task in the BPD process has a CSHS as its implementation. Within a CSHS, there can be one or more activity-services involved in the flow. Each of them hits a specific REST URL. Hence, HTTP entry point is defined for each of these services.

For example, the default URL is –

`/rest/bpm/wle/v1/coachflow/service/1.a22ce595-1573-4fdd-90f6-734884753610`



Business Transactions originating within a CSHS activity service are detected as servlet Business Transactions and are named according to the following scheme:
`/<Project Name>/<BPD Name>/<Task Name>/<CSHS Name>/<Activity Name>/<Implementation Service Name>:Service`

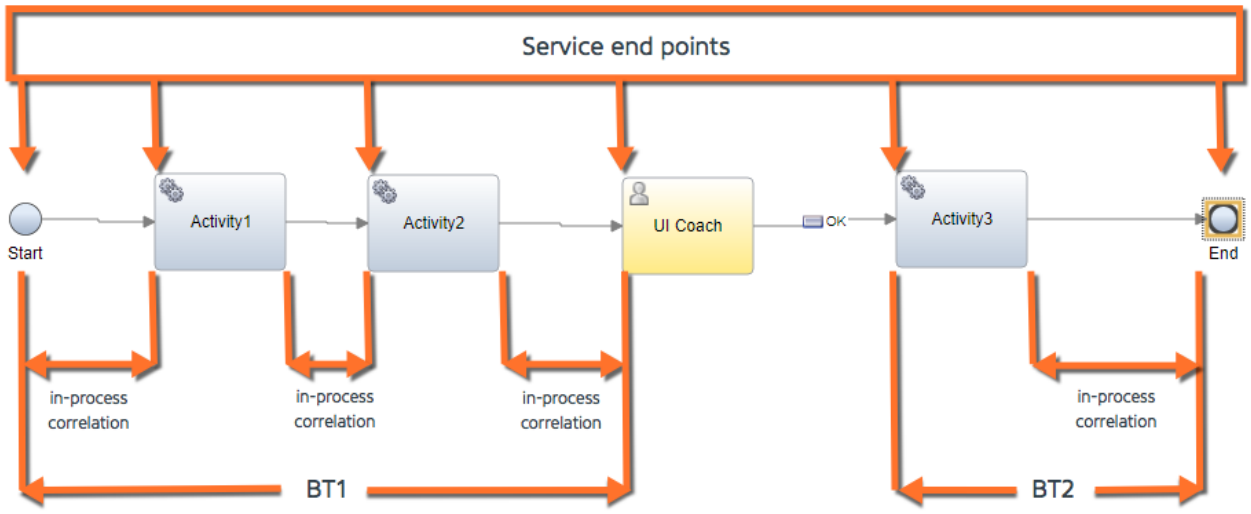
For example (corresponding to the images BPD image and CSHS image), the Business Transactions would be named:
`/My Hiring Sample/Standard HR Open New Position/Step: Submit job requisition/Client-Side Http Service/Activity1`
`/HttpClient IService:Service`

Business Transaction Detection at the CSHS Coach

A User Task in a BPD process has a CSHS as its implementation. Within a CSHS, there can be one or more UI Coach(es) involved in the flow. Each UI Coach represents the UI page(s) which opens up for the user to perform some actions (like completing a form, approving something, and so on). Each of these hits a specific REST–URL. Hence, the servlet entry point is used for the naming of the UI Coach.

For example, the default URL for this Business Transactions is –

`/teamworks/generatecoachng`



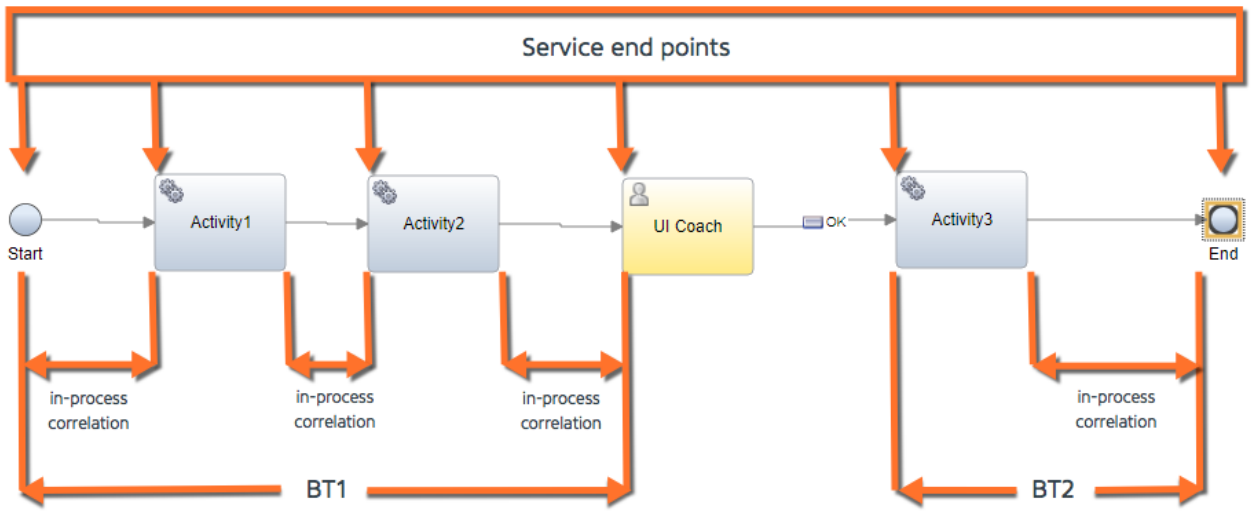
Business Transaction Naming Scheme at Coach of CSHS

The Business Transactions originating on entry to a UI coach are detected as Servlet Business Transactions –
`/<Project Name>/<BPD Name>/<Task Name>/<CSHS Name>/<Coach Name>:Coach`

For example (corresponding to the images BPD image and CSHS image), the business transaction would be named:
`/My Hiring Sample/Standard HR Open New Position/Step:Submit job requisition/Client-Side Http Service/UI Coach: Coach`

In-Process Correlation Between Elements within a CSHS

There can be more than one element involved within a User Task (CSHS) with no user interaction in between them. These form a part of the same business transaction. Service Endpoints give visibility of the individual steps within the resulting business transaction as illustrated below:



Business Transaction Support for System Tasks within a BPD Process

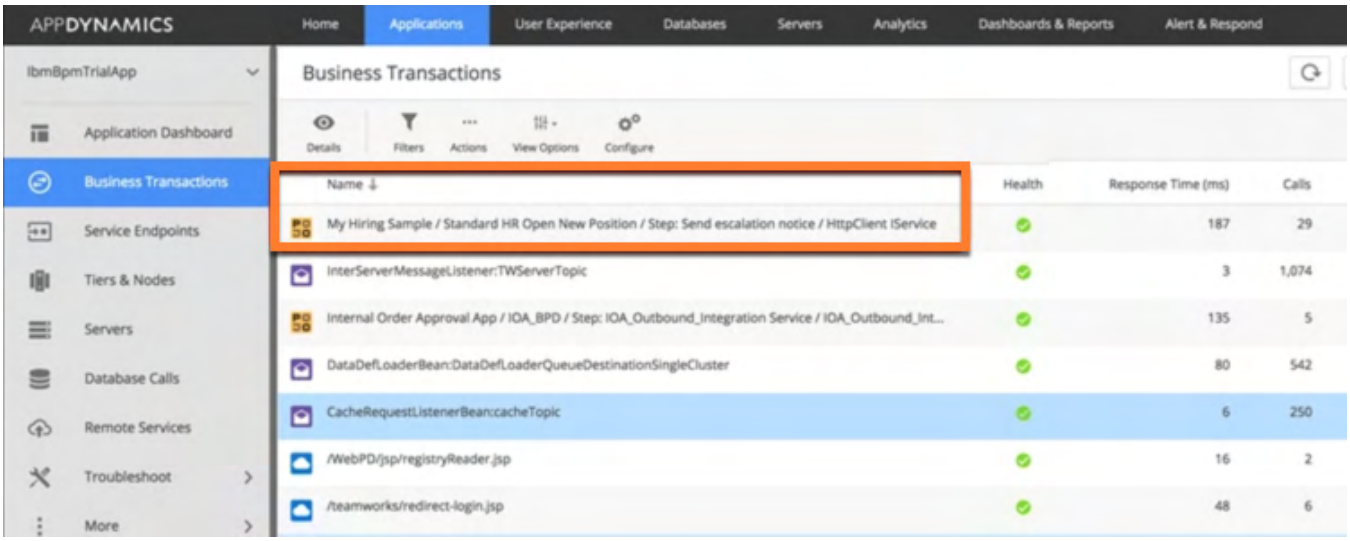
POJO business transactions are generated for System Tasks within a BPD process.

The POJO business transactions are named using four identifiers:

1. Project Name (*<project-name>*)
2. BPD Process Name (*<bpd-name>*)
3. System Task Name (*<task-name>*)
4. Implementation Process Name (*<implementation-name>*)

If any identifier's value is not available, it is replaced with <UNKNOWN> in the resulting transaction name.

For example, a business transaction detected for default configuration (*<project-name> / <bpd-name> / <task-name> / <implementation-name>*) is:



The default naming scheme can be customized using the ibmbpm-systemtask-bt-naming node property.

The property value is comma-separated identifiers chosen from project, bpd, task, implementation, and is order sensitive.
For example if,

value = "project, task" means POJO Business Transactions are named as: <project-name>/<task-name>

value = "task, project" means POJO Business Transactions are named as: <task-name>/<project-name>
value = "none" means POJO Business Transactions are not detected (disabled)
value = "default" means all the identifiers are used for Business Transactions naming in a default order, that is, they are named as *<project-name>/<bpd-name>/<task-name>/<implementation-name>*

Set ibmbpm-systemtask-bt-naming property to "none" to disable detection of Business Transactions for system tasks.

Built-in Data Collectors

> **Controlling the Built in Data Collectors**
>
> To disable the out of the box data collectors use the `disable-ibmbpm-data-collectors` node property.

For a System Task or a User Task, the following data collectors are available:

- PROCESS NAME
- TASK ID
- TASK NAME
- BPD INSTANCE ID
- BPD NAME
- PROJECT NAME

In addition to these, for a CSHS implementation of a User Task, if the IBM BPM specific naming Business Transactions naming scheme is enabled, an additional data collector, **ACTUAL URL**, will also be present, populated with the actual URL hit when the business transaction is initiated.

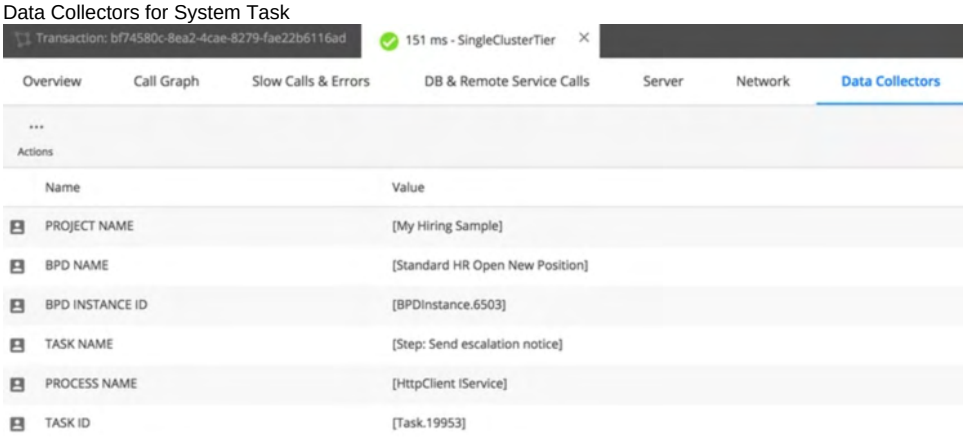
Additional data collectors defined for a User Task depending upon the element of the CSHS being called can be:

- COACH NAME for Coach
- EVENT TYPE for Start and End (value is either **Start** or **End** depending upon on the event)
- ACTIVITY NAME for Activity (Service)
- SERVICE NAME for Activity (Service – denoting the implementation service of the activity)

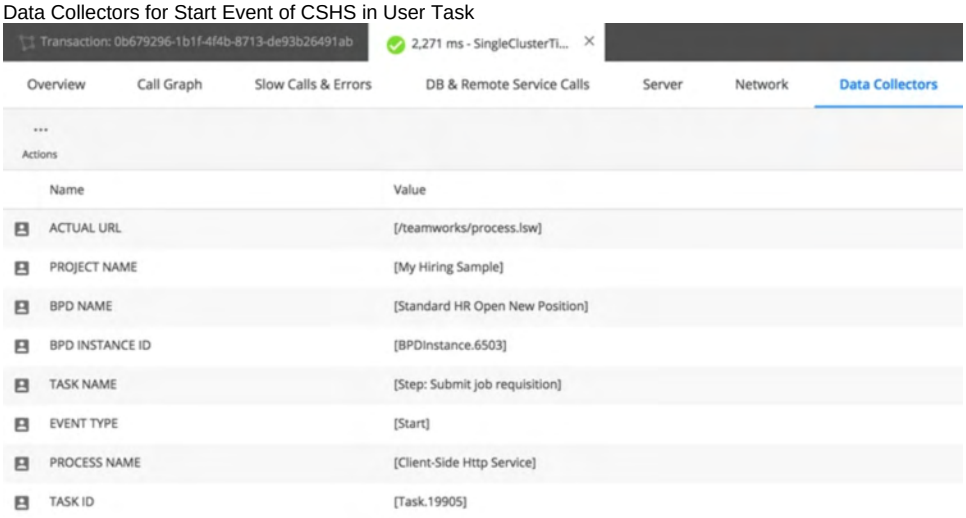
Sample Data Collectors

You can view the snapshot data collectors as:

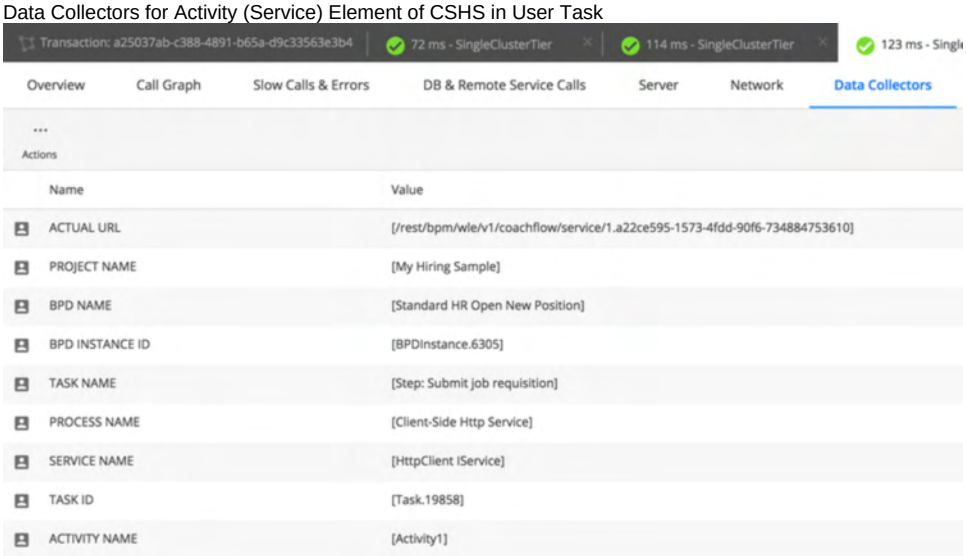
- Data Collectors for System Task



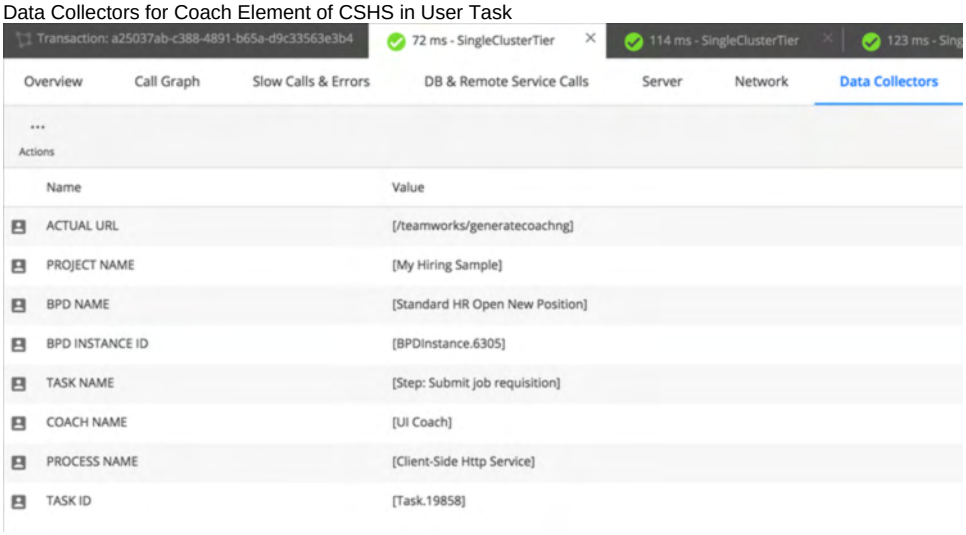
- Data Collectors for Start Event of CSHS in User Task



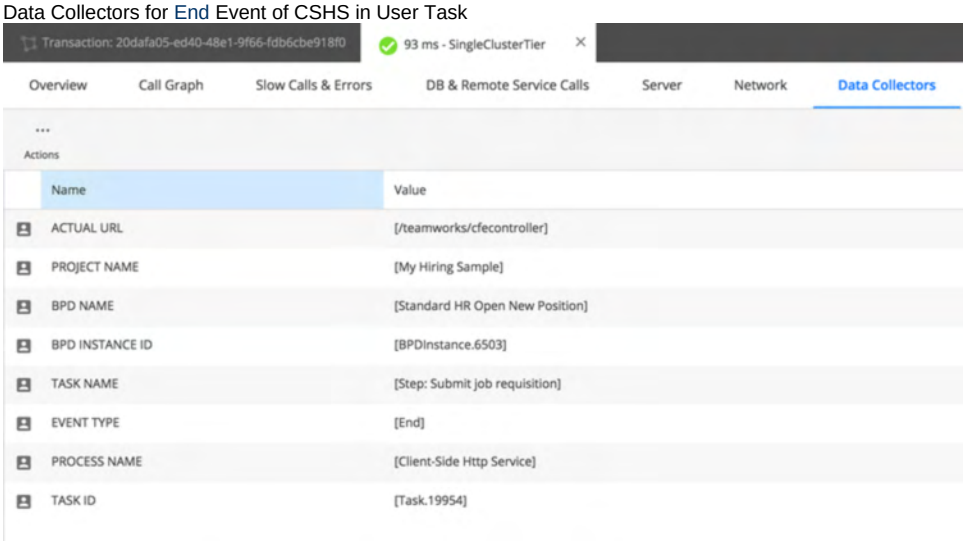
- Data Collectors for Activity (Service) Element of CSHS in User Task



- Data Collectors for Coach Element of CSHS in User Task



- Data Collectors for End Event of CSHS in User Task



Configuration Notes

There are some other configuration settings that may be helpful when implementing AppDynamics for IBM BPM monitoring:

- Increase the value of the node-property `max-business-transactions` if necessary, to accommodate the number of tasks involved in the BPD process (the default = 50).
- Add a node property `framework-support` with a value of "none" to disable CometD and GWT POJO Business Transactions a large number of which otherwise get detected. These correspond to activity within the IBM tooling and are not valuable for BPM monitoring.
- Exclude Servlet Business Transactions like `/portal/login`, `/webasset/..`, which are not valuable for BPM monitoring.

Node Properties That Control IBM BPM Instrumentation

Node Properties available when using IBM-BPM support:

- disable-ibmbpm-usertask-bt-naming: Sets whether Business Transactions naming scheme for IBM-BPM UserTask Business Transactions should be disabled (value = true) or enabled (value = false).
  When it is set to "true", the Business Transactions would be named as per the default URL and not the meaningful names.
- disable-ibmbpm-usertask-bt-in-process-correlation: Sets whether Business Transactions in-process correlation for IBM-BPM UserTask Business Transactions should be disabled (value = true) or enabled (value = false).
- ibmbpm-systemtask-bt-naming: Decides Business Transactions naming scheme for IBM-BPM System Task POJO Business Transactions.
- disable-ibmbpm-data-collectors: Sets whether data-collectors for IBM-BPM task Business Transactions should be disabled (value = true) or enabled (value = false).

Spring Batch Support

Spring Batch is an open-source project for batch processing (execution of a series of jobs).

A Batch Job is composed of one or more Steps. Each step consists of a Tasklet (explicitly or implicitly using ItemReader and ItemWriter). Each level (Job, Step and Tasklet) has an execute method.

Step execution can be parallelized using multiple threads. Remote Chunking (processing of part of Step, chunk on a remote JVM) can also be done with the help of JMS. Different steps in a job can be executed in separate threads use-case permitting.

From an APM perspective, tracking batch workloads at the Job level brings limited value, since batch Jobs are usually very long-running and an alert that the Job overran would come too late for remedial action to be taken. For this reason, the AppDynamics Business Transactions should be placed at the Tasklet level, meaning one batch Job will be composed of many Tasklet Business Transaction executions.

You can turn off spring batch instrumentation using the spring-batch-enabled node property.

Alerting on the response times of these Business transactions allows AppDynamics users to:

- Proactively detect that a Batch Job is progressing more slowly than usual, and thus predict if it will overrun any batch window
- Troubleshoot the root-cause of any unusual slow-downs in the progress of batch jobs in order that the issue can be remediated before the Job overruns

To achieve this, from Java Agent 4.5:

- Creates BTs at Tasklet.execute, named after the Job, Step, and Tasklet
- Correlates chunks across thread boundaries or process boundaries through JMS

OSB Support

Oracle Service Bus (OSB) is Oracle's Enterprise Service Bus (ESB) implementation. It is configuration-based and policy-driven and provides reliable service-oriented integration, service management, and traditional message brokering across heterogeneous IT environments.

This service-infrastructure software adheres to the SOA principles of building coarse-grained, loosely coupled, and standards-based services. Additionally, OSB acts as a message brokering, service monitoring, administration, dynamic routing, and message transformation layer to infrastructure.

OSB relies on Oracle WebLogic Server run-time facilities. OSB supports various service types and transports.

From agent release 4.5.8, AppDynamics supports Business Transaction entries and exits for the HTTP and JMS transports and correlates activity through the broker to give end-to-end transaction visibility. Outbound flows using other transports will be shown as uncorrelated custom backends on the flowmap.

If you want to use custom configuration to influence how the agent instruments non-http and jms outbound transportation, you can use the `ignore-exit-types` node property to disable the default behavior.

For Business Transactions originating in OSB itself, the transaction naming scheme that will be used is dependent on the OSB Proxy Service Type.

Service Type	Naming Scheme
REST, WSDL, SOAP	WebService Entry
Messaging, XML	Servlet Entry

For more details on proxy service types and transports in OSB, see Oracle documentation.

Open Tracing Support

OpenTracing is an open standard for Tracing in-process and out-of-process distributed transactions. At a high level, it performs shallow stitching of method executions involved in a business flow, and hence enables measuring it end to end.

AppDynamics Tracer is an implementation based on OpenTracing 0.31.0 standards.

Prerequisite

For the OpenTracer to work correctly, use the Executor strategy in the Java agent. You can specify it in `app-agent-config.xml` or as node property:

```
<!--As part of app-agent.config.xml-->
<property name="async-instrumentation-strategy" value="executor"/>

Or, just specify the following node property in the Controller:

async-instrumentation-strategy = "executor"
```

Obtain the AppDynamics OpenTracer

Install the Dependency

The OpenTracer jar can be accessed directly, or downloaded from Maven Central, or it can be downloaded from the AppDynamics portal. The library version changes with each new OpenTracer release, and is not tightly coupled to the version of the underlying agent, which must be at least = 4.5.13.

Enable or Disable the Tracer

By default when plugged in, OpenTracer is enabled. There are two ways to disable it:

- Programmatically you can enable and/or disable using:

  ```
  AppdynamicsTracerConfiguration.appdTracingConfiguration().setTracingEnabled();
  ```

  Optionally,

- At startup, you can specify the system property to enable and/or disable using:

  ```
  -Dappdynamics.opentracing.enabled=false
  ```

Plug the Tracer into Lightbend Telemetry

The first OpenTracing use case validated by AppDynamics is its use with Lightbend telemetry (also known as the Cinnamon agent), which allows transaction tracing through applications built on the Lightbend reactive platform, for example those built on Akka HTTP. For more details, refer to the Lightbend documentation, in particular as it relates to OpenTracing integration.

Full instructions as to how to set up Lightbend Telemetry are beyond the scope of the AppDynamics documentation. At a high level, the necessary steps for configuration are:

1. Configure the Lightbend telemetry agent. For Lightbend instructions, see Instructions.
2. Enable tracing for the Akka HTTP endpoints you want the AppDynamics agent to trace. For Lightbend instructions, see OpenTracing Configuration.

   > Ensure the active sampler is set to `const-sampler` in your `cinnamon.opentracing` file. (The low-overhead nature of the AppDynamics Java agent means that you can safely ignore the comment in the sample configuration file that states this should only be used for non-production).

3. Plug the AppDynamics OpenTracing implementation in to Lightbend Telemetry as a custom OpenTracing tracer using the AppdynamicsTracerFactory as described in the Lightbend documentation. A sample AppDynamics tracer factory is provided below:

```
import com.appdynamics.opentracing.core.AppdynamicsTracerFactory;
import com.lightbend.cinnamon.opentracing.TracerFactory;
import io.opentracing.Tracer;

public class AppdynamicsTracerPlugin implements TracerFactory {
    @Override
    public Tracer create() {
        return AppdynamicsTracerFactory.getTracer();
    }
}
```

Development Level Monitoring

Works with:

Development Level Monitoring and AppDynamics

AppDynamics monitors your production applications in a way that is designed to provide maximum visibility with the least amount of overhead. Development level monitoring is a mode in which certain default limits on the data that AppDynamics collects are turned off, giving you additional visibility on application activities.

This default mode is production-level monitoring and applies limits to the retention of certain types of information. In a testing environment or other environments where overhead is not an issue, you can enable development level monitoring. Development mode is intended for temporary use while setting up AppDynamics or for occasional application troubleshooting.

You apply development monitoring to a specific business transaction and originating node combination. An *originating node* is one or more of the nodes that serve as the entry points for the transaction.

Transactions originating on an enabled node are subject to development level monitoring on downstream nodes that participate in processing that business transaction. Note that this applies for that business application only, however. Processing for a continuing transaction in another business application is not monitored at the development level unless you have enabled development level monitoring at the continuing business application as well.

While development monitoring increases the retention of call graphs and SQL statement capture, certain limits still apply. The limits specify maximum thresholds for calls per minute, Java heap utilization, and snapshot segments generated across the Controller. If the thresholds are exceeded, development level monitoring is turned off. See Development Level Monitoring Limits.

Effects of Development Mode

Enabling development level monitoring affects the capture of the following information:

- **Exit Calls—**AppDynamics increases information collected for exit calls to backend systems. For database backends, the agent collects all SQL statements without per-transaction limits. The agent also collects all JDBC and ADO.NET calls attached to methods, even when the call duration is less than 10 ms.
- **Snapshots**—The agent attempts to take a snapshot for every transaction, ignoring the values for these agent node properties:
  - max-concurrent-snapshots
  - on-demand-snapshots

> Development mode does not guarantee snapshots for every transaction since it was not designed to capture data on every request.

- **Call Graphs**—The agent captures full call graphs in development mode.

Users must belong to a role with the Configure Monitoring Level (Production/Development) permission for the application to set development level m
and Manage Custom Roles.

Enable Development Level Monitoring

You enable development level monitoring in the context of a particular business transaction/originating node combination. To avoid exceeding development mode limits described in Development Level Monitoring Limits, it is recommended that you enable development monitoring at the smallest scope possible.

To enable development level monitoring:

1. In the business application for which you want to enable monitoring, click **Configuration** > **Development Level Monitoring**.
2. Enable the **Development Level Monitoring** switch at the top of the page.
   For agents <= 4.3, enabling development level monitoring applies globally, rather than for a particular business transaction. For agents >+ 4.3, you need to configure the business transaction and node to which the configuration applies, as described in the following step.
3. Select the Business Transaction for which you want to enable development monitoring.
4. Click the **Enabled** checkbox next to the originating nodes on which you want to enable development level monitoring.

Turn Off Development Level Monitoring

Even in pre-production environments, enabling development level monitoring would normally be a temporary measure done in select cases. When finished, turn off development level monitoring for the business application, as described here.

To turn off development level monitoring:

1. In the business application for which you want to turn off development level monitoring, click **Configuration** > **Development Level Monitoring**.
2. Use the **Development Level Monitoring** switch at the top of the page to turn off develop level monitoring. The switch turns off such monitoring for all business transactions in the business application.

Development mode may also be turned off automatically.

Development Level Monitoring Limits

The following agent-applied and Controller-applied limits prevent excessive resource consumption during development mode.

App Agent Limits

These limits apply for an App Agent:

- For each node, a maximum of 500 calls per minute. (See dev-mode-suspend-cpm.)
- For each JVM, the maximum heap utilization percentage of 90%. (See heap-storage-monitor-devmode-disable-trigger-pct.)

If a limit is exceeded, an agent log event is generated indicating that the development mode has been turned off because limits were exceeded

Controller Limits

The Controller monitors the number of snapshot segments collected during development monitoring across business transactions. A snapshot segment corresponds to the processing activities for a business transaction on a particular tier. A single business transaction that traverses many tiers can generate more data than several business transactions that only traverse a few tiers.

When the threshold of 5000 snapshot segments per minute is exceeded, the Controller turns off development mode for the top contributing business transactions. The Controller turns off development mode on as many business transactions as are needed to reduce the snapshot segment contribution by 20%.

For example, if a single business transaction is accountable for 25% of the snapshot segments when the threshold is exceeded, only it is turned off. As another example, given the following business transactions and the percentage of snapshot segments, they each contributed when the threshold was exceeded, the first two are turned off:

1. BT1: 17%
2. BT2: 16%
3. BT3: 15%
4. BT4: 15%
5. BT5: 13%
6. BT6: 12%
7. BT7: 12%

You cannot configure this Controller limit.

App Server Agents Supported Environments

This page provides an aggregated view of the supported environments for the App Server agents.

App Server agents have been tested successfully on AWS Outposts using these instructions: Install App Server Agents

Java Agent

This page lists the application environments and versions supported by the AppDynamics Java Agent.

Java Agent Supported Platforms

In the following tables, note that:

- A dash ("-") in a table cell indicates that this column is not relevant or not supported for that particular environment.
- In cases where no version is provided, assume that all versions are supported. Contact AppDynamics Sales for confirmation.
- For environments that require additional configuration, a separate table describing or linking to configuration information follows the support matrix.
- For environments supported by AppDynamics End User Monitoring, see Supported Environments and Versions - Web EUM.
- For environments supported by AppDynamics Server Visibility, Machine Agent Requirements and Supported Environments.

JVM Support

The AppDynamics Java Agent uses the standard JVM Tool Interface (JVMTI) mechanism allowing it to instrument any software running on a JVM supporting this mechanism.

AppDynamics certifies the successful operation of the basic mechanisms of instrumentation used by the agent on the following Java runtimes. These capabilities are supported on both JRE or full JDK installations.

Where the agent supports the following advanced memory monitoring features, they are listed for the JVM: Object Instance Tracking (OIT), Automatic Leak Detection (ALD), Content Inspection (CI), and Access Tracking (AT).

JVM	OS	Memory Monitoring Features
AdoptOpenJDK 8, 9, 10, 11, 12, 13, 14, 15, 16 (supported for both Hotspot and OpenJ9 JVMs)	Linux, Windows, MacOS	OIT (supported only for Hotspot JVM), ALD, CI, AT
Amazon Corretto 8, 11	Linux, Windows	OIT, ALD, CI, AT
Azul Zing 15.x.	Linux x64	OIT, ALD
Azul Zulu OpenJDK 1.6, 1.7, 1.8, 9, 10, 11, 13, 14, 15, 16 JDK11 is supported from 4.5.6 onwards JDK13 is supported from 4.5.15 onwards JDK14 is supported from 20.4.0 onwards JDK15 is supported from 20.10.0 onwards JDK16 is supported from 21.4.0 onwards	Linux, Windows	OIT, ALD, CI, AT
GraalVM 20.0.0, 20.2.0, 21.1.0	Linux, Windows, MacOS	OIT, ALD, CI, AT
HP OpenVMS		

IBM JVM 1.6.x, 1.7.x, 1.8.x	AIX, HP-UX, Linux, Solaris, Windows, z/OS	ALD, CI Object instance tracking, automatic leak detection, and custom memory structure monitoring are not supported with the AppDynamics IBM Java Agent. IBM JVMs can be instrumented with the AppDynamics Sun Java Agent to work around this limitation; however, this only enables automatic leak detection and custom memory structure monitoring. Object instance tracking is not available. Working around this limitation can result in negative performance impact and is not recommended. In such cases, the IBM JVM needs to be restarted to enable custom memory structure monitoring.
Oracle Rockit JVM 28.1+	Linux Intel 64, Windows	
Oracle/BEA JRockit 1.6		
Oracle/Sun JVM 1.6, 1.7, 1.8, 9, 10, 11, 12, 13, 14, 15, 16 JDK11 is supported from 4.5.6 onwards JDK12 is supported from 4.5.11 onwards JDK13 is supported from 4.5.15 onwards JDK14 is supported from 20.4.0 onwards JDK15 is supported from 20.10.0 onwards JDK16 is supported from 21.4.0 onwards	Solaris Sparc 64, Windows, Linux	OIT, ALD, CI, AT Content Inspection and Access Tracking require a JVM restart.

JVM Application Server and Framework Support

AppDynamics supports the use of the Java Agent to instrument any application component running on a supported JVM, irrespective of how that component is built. The power of the AppDynamics platform is that it can automatically discover the topology and behavior of complex enterprise applications without requiring deep technical knowledge of the application's underlying code.

Frequently, Java-based systems employ standard framework code to implement business logic. Automatic instrumentation of framework code relies on knowledge of the business logic and programming patterns employed by the framework. AppDynamics instrumentation targets processing hand-offs between components, called entry points and exit points, either within the JVM or between JVMs. This includes hand-offs between frameworks in cases where multiple frameworks are being used together. This section covers the capabilities for frameworks for which AppDynamics provides automatic detection rules.

Monitoring application components built using frameworks not listed here may require custom configuration. The custom configuration may involve, for example, custom POJO entry or exit points. If you understand how the application behaves internally, you can easily configure this type of instrumentation. For more complex configuration tasks, contact your account representative to discuss how to engage the AppDynamics customer success organization.

JVM Language Frameworks Support

No additional configuration is required for these frameworks.

Vendor	JVM Language Framework	Version	Correlation/ Entry Points	Exit Points	Transports	Notes
Open Source	Akka Actor	2.1 – 2.5.x	Yes	Yes	Netty	4.3.1 required for 2.4.x 2.5x support includes Persistence Remoting exit/entry supported
Open Source	Akka HTTP Name: `akka-http-stream-entry-enabled` Type: Boolean Default: False	Akka Actor 2.5.x Akka HTTP upto 10.2.4 Scala 2.11, 2.12	Yes	Yes	HTTP	EUM is supported Support for Non-Route DSL
Open Source	Http4s Blaze Client	Blaze versions: 0.21.1, 0.21.0, 0.20.23, 0.20.5 scala 2.11, 2.12	No	Yes	HTTP	
Open Source	Groovy	-	Yes	Yes		
Open Source	Ktor	1.0.x -1.5.x	Yes (Netty Engine)	-	HTTP	EUM is supported
Open Source	Play for Scala Play for Java	2.1 – 2.8 Scala 2.11, 2.12	Yes	-	HTTP over Netty server Akka HTTP server	Includes framework specific entry and exit points Play EUM-APM correlation supported
Open Source	Scala	2.11.6				
Open Source	Spray toolkit (Spray.io)	1.1.x 1.1.3	Yes	Yes	HTTP	Entry points are detected and configurable as servlet entry point and exit points as HTTP exits
Pivotal	Grails	-	-	-	-	

Java Frameworks Support

The Java Agent supports these Java frameworks. Some require additional configuration as indicated in the Configuration Notes column.

Vendor	Framework	Version	SOA protocol (WebServices)	Auto Naming	Entry Points	Exit Points	Detection	Configuration Notes
Adobe	BlazeDS	-	HTTP and JMS adaptor	-	Yes		-	Example Message Queue Backend Configuration
Adobe	ColdFusion	8.x, 9.x	-	-	Yes	-	Configuration required for transaction discovery	Configuration is required for transaction discovery. See: • Java Business Transaction Detection • Servlet Entry Points
Apache	Cassandra with Thrift framework	-	-	-	Yes	Yes	Apache Thrift Entry and Exit points are detected	
Apache	Struts	1.x, 2.x	-	-	Yes		Struts Actions are detected as entry points; struts invocation handler is instrumented	Struts Entry Points

Apache	Tapestry	5	-	-	Yes	-	Not by default	See: • Java Business Transaction Detection • Servlet Entry Points
Apache	Wicket	-	-	No	Yes	-	Not by default	See: • Java Business Transaction Detection • Servlet Entry Points
Apple	WebObjects	5.4.3	HTTP	Yes	Yes	-	Yes	Apple WebObjects Startup Settings
axonframework.org	Axon	2.x, 3.x	-	-	Commands on the Command Bus continue existing Business Transactions	Correlation for Distributed Command Bus on JGroups and for Spring Cloud Connector transport as an exit		
Open Source	CometD	2.6	HTTP	Yes	Yes	-	-	See also "HTTP Exit Points" on Java Backend Detection.
Open Source	Spring Batch	-						Spring Batch Support
Eclipse	RCP (Rich Client Platform)	-	-	-	-	-	-	
Google	Google Web Toolkit (GWT)	2.5.1	HTTP	Yes	Yes	-	-	
JBoss	JBossWS Native Stack	4.x, 5.x	Native Stack	-	-	-	-	
IBM	IBM-BPM	8.5.7, 8.6	-	Yes	Yes	Yes	Yes	IBM-BPM Support
Open Source	Direct Web Remoting (DWR)	-	-	-	-	-	-	
Open Source	Eclipse Vert.x Core	3.3.3-3.5.4, 3.6.x, 3.7.x, 3.8.x, 3.9.x, 4.0.x	HTTP	Yes	Yes	Yes	Yes	EUM Correlation is supported
Open Source	Enterprise Java Beans (EJB)	2.x, 3.x	-	-	Yes	-	-	EJB Entry Points
Open Source	Grails	-	-	-	Yes	-	Not by default	
Open Source	Hibernate JMS Listeners	1.x	-	-	-	-	-	
Open Source	Java Abstract Windowing Toolkit (AWT)	-	-	-	-	-	-	
Open Source	Java Server Faces (JSF)	1.x, 2.x	-	Yes	Yes	-	-	Java Business Transaction Detection and Servlet Entry Points
Open Source	Java Server Pages	2.x	-	Yes	-	-	Yes	Servlet Entry Points
Open Source	Java Servlet API	2.x, 3.0	-	-	-	-	-	
Open Source	Jersey	1.x, 2.x	REST, JAX-RS	Yes	Yes	No	Not by default	JAX-RS Support and node properties: • `rest-num-segments` • `rest-transaction` • `rest-uri-segment-scheme` See App Agent Node Properties Reference for information on the properties.
Open Source	JRuby HTTP	-	-	-	Yes	-	Not by default	See: • Java Business Transaction Detection • Servlet Entry Points
Open Source	Micronaut	1.1.0, 2.5.3	-	Yes	Yes	Yes	By default	-
Open Source	Netty	3.x, 4.x	HTTP	Yes	Yes	Yes	By default	• Node property to disable Netty Instrumentation: `netty-enabled`, by default it is true
Open Source	Spring Annotated Web Services	2.x+	HTTP	Yes	Yes	No	-	

Open Source	Spring WebFlux	5.0, 5.1, 5.2, 5.3	HTTP	Yes	Spring Boot (Netty, Jetty, Tomcat, Undertow)	WebClient (Reactor Netty, Reactive Jetty)	By default	The node property `enable-webclient`, disables the Netty instrumentation and enables WebClient configuration. This node property should not be enabled unless there is some issue or loss in visibility with the OOTB support. By default, the value of this property is false.
Open Source	Spring Cloud Gateway	2.0.x, 2.1.x, 2.2.x, 3.0.2	HTTP	Yes	Yes	Yes	By default	
Open Source	WebSocket	1.0 (Java EE 7, JSR-356)	-	Yes, BT Naming not configurable	Yes, correlation not supported	Yes	Detection is automatic	Node property: websocket-entry-calls-enabled
Oracle	Coherence with Spring Beans	2.x, 3.x	-	-	-	-	-	
Oracle	Swing (GUI)	-	-	-	-	-	-	
Oracle	WebCenter	10.0.2,10.3.0	-	-	-	-	-	
Spring	Spring MVC	5.3	-	-	Yes	-	Not by default	See App Agent Node Properties Reference.

Application Servers

The Java Agent supports the following application servers. Some require additional configuration. Click the link on the server or OSGi Runtime for information about additional requirements or related configuration topics. The agent usually discovers application servers as an entry point.

Vendor	Application Server / OSGi Runtime	Version	SOA Protocol	RMI Supported	JMX	Entry Points	Configuration Notes
Adobe	Cold Fusion	8.x, 9.x	-	No	-	Yes	Requires configuration for transaction discovery; see Servlet Entry Points
	Equinox	-	-	-	-	Yes	OSGi Infrastructure Configuration
Apache	Felix	-	-	-	-	Yes	OSGi Infrastructure Configuration
Apache	Sling	-	-	-	-	Yes	OSGi Infrastructure Configuration
Apache	Tomcat	5.x, 6.x, 7.x, 8.x, 9, 10	-	-	Yes	Yes	Apache Tomcat Startup Settings
Apache	Resin	1.x - 4.x	-	-	-	-	Resin Startup Settings
Eclipse	Jetty	6.x, 7.x, 8x, 9x	-	-	-	-	Jetty Startup Settings
IBM	InfoSphere	8.x	-	-	-	Yes	IBM WebSphere and InfoSphere Startup Settings
IBM	WebSphere	6.1, 7.x, 8.x, 9.x	JAX-WS	Yes, detect and correlate	Yes for WebSphere PMI	Yes	IBM WebSphere and InfoSphere Startup Settings
Open Source	Liferay Portal	-	-	-	-	-	
Open Source	JBoss EAP	7.1.5 and 7.2.0		Yes		Yes	JBoss and Wildfly Startup Settings
Open Source	JBoss Wildfly (formerly JBoss Application Server)	4.x to 23.x		Yes		Yes	JBoss and Wildfly Startup Settings
Sun/Oracle	GlassFish Enterprise Server	2.x	-	-	Yes	Yes	GlassFish Startup Settings
Oracle	GlassFish Server and GlassFish Server Open Source Edition	3.x, 4.x	-	-	Yes for AMX	Yes	GlassFish Startup Settings
Oracle and BEA	WebLogic Server	9.x+	JAX-WS	Yes, detect and correlate for 10.x To enable correlation using a header transported in the `SOAP:Envelope` set node property enable-soap-header-correlation=true	Yes	Yes	Oracle WebLogic Startup Settings
Software AG	webMethods	9.5, 9.6	-	-	-	Yes	webMethods Startup Settings
Tibco	ActiveMatrix BusinessWorks Service Engine	5.x, 6.x	-	To enable correlation using a header transported in the `SOAP:Envelope` set node property `enable-soap-header-correlation=true`	-	Yes	Tibco ActiveMatrix BusinessWorks Service Engine Settings
	Application Server (OC4J)	-	-	Yes, detect and correlate for 10.x	-	Yes	

-	Grails, with Tomcat 7.x, Glassfish v3, Weblogic 12.1.1 (12c)	-	-	-	-		

Servlet 3.x detection is not supported.

PaaS Providers

PaaS Provider	Buildpack
Pivotal Cloud Foundry	Java Buildpack 3.4 and higher See Using AppDynamics with Java Applications on Pivotal Cloud for more information.
Red Hat Openshift 3	JBoss EAP 6.4 and 7.x WildFly 8.1 Docker images For documentation and download information, see the AppDynamics Java APM Agent page on the Red Hat Customer Portal.

Message Oriented Middleware Support

The Java Agent supports the following message oriented middleware environments. Some require additional configuration as indicated in the Configuration Notes column. Message oriented middleware servers are usually found by the Java Agent as an entry point.

Vendor	Messaging Server	Version	Protocol	Correlation /Entry Points	Exit Points	JMX	Configuration Notes
Amazon	Simple Queue Service (SQS)	-	-	Yes (correlation only)	Yes	-	See "Amazon Simple Queue Service Backends" on Java Backend Detection
Amazon	Simple Notification Service (SNS)	-	-	No	Yes	-	See "Amazon Simple Notification Service Backends" on Java Backend Detection
Apache	ActiveMQ	5.x+	JMS 1.x	Yes	Yes	Yes	
Apache	ActiveMQ	5.x+	STOMP	No	-	Yes	
Apache	ActiveMQ	5.8.x+	AMQP 1.0	No	-	Yes	Example Message Queue Backend Configuration
Apache	Axis	1.x, 2.x	JAX-WS	Yes	Yes	-	Default exclude rules exist for Apache Axis, Axis2, and Axis Admin Servlets. See aslo "Web Service Entry Points" on Java Backend Detection.
Apache	Apache CXF	2.1	JAX-WS	Yes	Yes	-	To enable correlation, set node property `enable-soap-header-correlation=true`.
Apache	Kafka	0.9.0.0 to 2.8.0	-	Yes	Yes	Yes	Kafka consumer entry points are disabled by default. Correlation is supported. See Apache Kafka Consumer Backends.
Apache	Synapse	2.1	HTTP	Yes	Yes	-	To enable correlation, set node property `enable-soap-header-correlation=true`
Fiorano	Fiorano MQ		-	-	-	-	
IBM	IBM Web Application Server (WAS)	6.1+, 7.x	Embedded JMS	-	Yes	-	Example Message Queue Backend Configuration
IBM	IBM MQ (formerly IBM WebSphere MQ)	6+	JMS	Yes	Yes	-	Example Message Queue Backend Configuration
Mulesoft	Mule ESB	3.4, 3.6, 3.7, 3.8, 3.9, 4.1.x, 4.2.0, 4.2.1	HTTP, JMS	Yes	Yes	-	Mule ESB Startup Settings
Open Source	Eclipse Vert.x verticles	3.3.x, 3.4.x, 3.5.0, 3.6.0	-	Yes (correlation only)	Yes	-	The Java Agent detects messaging exit calls between verticles.
Open Source	Open MQ	-	-	-	-	-	
Oracle	Java Message Service	2.0	JMS	Correlation of the listener is disabled by default	Yes		
Oracle	Oracle AQ	-	JMS	-	Yes	-	
Oracle	OSB deployed on WebLogic	12.2.1	HTTP JMS	Yes	Yes		OSB Support
Oracle / BEA	WebLogic	9.x+	JMS 1.1	Yes	Yes	Yes	Oracle WebLogic Startup Settings
Progress	SonicMQ	-	-	-	-	-	
Pivotal	RabbitMQ	-	HTTP	-	Yes	-	See "RabbitMQ Backends" on Java Backend Detection

Rabbit	RabbitMQ Spring Client	-	-	Yes	Yes	-	See "RabbitMQ Backends" on Java Backend Detection
Red Hat	HornetQ (formerly JBoss Messaging and JBoss MQ)	-				Yes	
Red Hat	JBoss A-MQ	4.x+	-	-	-	Yes	
Spring	Spring Integration	2.2.0+, 4.0+	JMS	Yes	Yes	Yes	Spring Integration Support See also "Java Message Service Backends" on Java Backend Detection
WSO2	ESB	4.7.0	-	Yes	Yes	-	EUM Correlation is not supported
WSO2	API Microgateway	3.1.x, 3.2.0, 3.2.1	HTTP1	Yes	Yes	-	See WSO2 API Microgateway Startup Settings

JDBC Drivers and Database Servers Support

The Java Agent supports these JDBC driver and database server environments. AppDynamics can follow transactions using these drivers to the designated database.

JDBC Vendor	Driver Version	Driver Type	Database Server	Database Version
Apache	10.9.1.0	Embedded or client	Derby	-
Apache	-	-	Cassandra	-
Progress	DataDirect	data connectivity for ODBC and JBDC driver access, data integration, and SaaS and cloud computing solutions	-	-
IBM	JDBC 3.0 version 3.57.82 or JDBC 4.0 version 4.7.85	DB2 Universal JDBC driver	DB2	9.x
IBM	JDBC 3.0 version 3.66.46 or JDBC 4.0 version 4.16.53	DB2 Universal JDBC driver	DB2	10.1
IBM	-	Type IV	Informix	-
Maria				1.4.x - 2.6.x
Microsoft	4	Type II	MS SQL Server	2012
Oracle MySQL, MySQL Community	5.x, 6.x, 8.x	Type II, Type IV	MySQL	5.x
Oracle	RAC			
Oracle	9i, 10g 11g, 12c, 18c, 19c	Type II, Type IV	Oracle Database	8i+
Open Source PostgreSQL	42.2.5	Type IV	Postgres	8.x, 9.x, 11x
Sybase	jConnect	Type IV	Sybase	-
Teradata			Teradata	-

Notes:

- Type II is a C or OCI driver
- Type IV is a thin database client and is a pure Java driver

NoSQL/Data Grids/Cache Servers Support

The Java Agent supports these NoSQL, data grids and cache server environments. Some require additional configuration. Click the link on the database, data grid or cache name in the following support matrix for information about additional configuration required or related configuration topics.

Vendor	Database/Data Grid /Cache	Version	Correlation/Entry Points	JMX	Configuration Notes
Amazon	DynamoDB	-	Exit Points	-	See "Amazon Web Services" on Java Backend Detection.
Amazon	Simple Storage Service (S3)	-	-	-	"Amazon Simple Storage Service Backends" on Java Backend Detection.
Apache	Casandra • DataStax drivers • Thrift drivers	1.x, 2.x	Correlation for Thrift drivers only	Yes	• "Cassandra Backends" on Java Backend Detection. • For Cassandra server-side support, see Apache Cassandra Startup Settings
Apache	Lucene - Apache Solr	1.4.1	Entry Points	Yes	Apache Solr Startup Settings

Couchbase	Couchbase	3.x	Exit Points	-	See "Couchbase Backends" on Java Backend Detection
JBoss	Cache TreeCache	-	-	-	JBoss Startup Settings
JBoss	Infinispan	5.3.0+	Correlation	-	-
Open Source	Memcached	-	-	-	Memcached Exit Points
Open Source	MongoDB Async Driver	3.4-3.12	-	-	See "MongoDB Backends" on Java Backend Detection
Open Source	MongoDB Sync Driver	3.1-3.12, 4.0.x	-	-	See "MongoDB Backends" on Java Backend Detection
Open Source	MongoDB Reactive Streams Driver	1.3-1.13, 4.0.x	-	-	See "MongoDB Backends" on Java Backend Detection
Oracle	Coherence	3.7.1	Custom-Exit	Yes	Coherence Startup Settings
Red Hat	JBoss DataGrid	-	-	-	JBoss Startup Settings
	JBoss Cache TreeCache	-	-	-	
	JBoss Infinispan	5.3.0+	Correlation	-	
Terracotta	EhCache	-	-	-	EhCache Exit Points

RPC/Web Services API/HTTP Client Support

The Java Agent supports these RPC, web services or API framework types. Some require additional configuration as indicated in the Configuration Notes column.

Vendor	RPC/Web Services API Framework /HTTP Client Support	Version	SOA Protocol-WebServices	Auto Naming	Correlation/Entry Points	Exit Points	Configurable BT Naming Properties	Detection	Configuration Notes
Apache	Apache CXF	2.1	JAX-WS	Yes	Yes	Yes	Yes	Yes	
Apache	Apache HTTP Client	-	HTTPClient (now in Apache HTTP Components)	Yes	Yes (correlation only)	Yes	-	Yes	See "HTTP Backends" on Java Backend Detection
Apache	Apache Async HTTP Client	4.1.x	-	-	-	-	-	-	-
Apache	Ribbon HTTP Client	2.1.0	HTTP Client	Yes	Yes (correlation) Entry - NA	Yes	NA	Yes	
Apache	Apache Thrift	-	-	Yes	Yes	Yes	Yes	Yes	Binary Remoting Entry Points for Apache Thrift
Eclipse	Jetty	8.x, 9.x	HTTP Client	Yes	Yes (correlation only)	Yes (ART supported)	-	Yes	See "HTTP Backends" on Java Backend Detection
Google	gRPC	1.6.x to 1.37.x	RPC	Yes	Yes (Asynchronous)	Yes (Asynchronous)	ServiceName /MethodName	Yes	See Web Service Backend
IBM	WebSphere	6.x, 7.x, 8.x	JAX-RPC	-	-	-	-	-	IBM WebSphere and InfoSphere Startup Settings; also see Default configuration excludes WebSphere classes
IBM	Websphere	7.x, 8.x	IIOP	-	-	-	-	-	IBM WebSphere and InfoSphere Startup Settings; also see Default configuration excludes WebSphere classes
IBM	Websphere	6.1, 7.x, 8.x, 9.x	JAX-WS	Yes	Yes, detect and correlate. To enable correlation using a header transported in the `SOAP:Envelope` set node property `enable-soap-header-correlation=true`	-	Web Service naming	Yes	-

JBoss		7,8,11,16, and 18	JAX-WS	Yes	Yes, detect and correlate. To enable correlation using a header transported in the `SOAP:Envelope` set node property en `able-soap-header-correlation=true`		Web Service naming	Yes	To detect Web Service entry and to support correlation you must create a Servlet exclude rule. See Web Service Entry Points to exclude a rule for JBoss.
Open Source	`java.net.Http`	-	HTTP	Yes	-	Yes	Yes	Yes	See "HTTP Backends" on Java Backend Detection.
Open Source	HTTPClient	0.3-3	Oracle SOA (and potentially others that embed this library)	-	Correlation: Yes; Entry: No	Yes	-	Yes	Oracle WebLogic Startup Settings; also see Default configuration excludes WebLogic classes
Open Source	Grizzly	Grizzly Async HTTP Client (`com.ning.http-client` 1.8.x, 1.9.x, grizzly-http-client 1.1x) • NingAsyncClient v1 with NettyProvider, GrizzlyProvider • NingAsyncClient v2 with NettyProvider	HTTP	-	Correlation: Yes; Entry:No	Yes	-	Yes	
Oracle	GlassFish Metro	-	JAX-WS	-	-	-	-	-	
Oracle	GlassFish Metro with Grails	-	JAX-WS	-	Yes	-	-	Not by Default	
Oracle	JAX-WS RI	2.3.1	JAX-WS	-	To enable correlation using a header transported in the `SOAP:Envelope` set node property en `able-soap-header-correlation=true`	-	Web Service naming	Yes	-
Spring WS	Web Services	3.x, 4.x, and 5.x	HTTP, SOAP	-	To enable correlation using a header transported in the `SOAP:Envelope set node property enable-soap-header-correlation=true`	-	Web Service naming	Yes	-
Oracle	Oracle Application Server	ORMI	-	no	-	-	-	-	
Oracle	WebLogic	10.x	T3, IIOP	Yes	Correlation: Yes; Entry: No	Yes	-	Yes	
Oracle	WebLogic	9.x, 10.x	JAX-RPC	-	-	-	-	-	
Oracle/Sun	Java	11	-	-	-	Yes (ART supported)	-	Yes	
Oracle/Sun	Sun RMI	-	IIOP	-	Not by Default	-	-	-	
Oracle/Sun	Sun RMI	-	JRMP	-	No	Yes	host/port	Yes	
Red Hat	JBoss A-MQ	4.x+	RMI	Yes	Yes	Yes	Yes	Yes	JBoss and Wildfly Startup Settings
Square	OkHttp	2.x, 3.x, 4.x (upto 4.22)	HTTP	Yes	Correlation: Yes Entry: No	Yes	-	Synchronous (2.x, 3.x, and 4.x upto 4.22) and Asynchronous (3.x and 4.x upto 4.22)	
-	Web Services	-	SOAP over HTTP	-	Yes	Yes	-	-	Create Match Rules for Web Services "Web Service Entry Points" on Java Backend Detection
jersey.github.io	Reactive JAX-RS client API	2.25+	HTTP Client	Yes	Yes (correlation) Entry – NA	Yes	NA	Yes	"Web Service Entry Points" on Java Backend Detection

Business Transaction Error Detection

The Java Agent supports the following logging frameworks for business transaction error detection:

- Apache `Log4j` and `Log4j 2`
- `java.util.logging`
- Simple Logging Facade for Java (SLF4J)
  Support for the following method has been added: `public void error(String format, Object... argArray)`
- Logback

To instrument other types of loggers, see Error Detection.

.NET Agent

Supported Runtime Environments

This section lists the environments where the .NET Agent does some automatic discovery after little or no configuration. See Browser RUM Supported Environments for additional supported environments.

OS Versions

- Microsoft Windows Server 2012
- Microsoft Windows Server 2012 R2
- Microsoft Windows Server 2016
- Microsoft Windows Server 2019
- Microsoft Windows 8, 8.1, 10

Microsoft .NET Frameworks

Microsoft .NET Framework 2.0, 3.0, 3.5, 4.0, 4.5, 4.5.2, 4.6, 4.7, and 4.8 on these runtime environments:

- Microsoft IIS 6.0, 7.0, 7.5, 8.0, 8.5, 10
- Managed Windows Services
- Managed Standalone Applications
- Microsoft SharePoint 2010, 2013 as services running inside IIS
- Microsoft ASP.NET Core 2.1 for Windows

Microsoft .NET Core and Microsoft .NET

Microsoft .NET Core 2.1, 3.1, and Microsoft .NET 5.0 with:

- Microsoft ASP.NET Core 2.1, 3.1, and Microsoft .NET 5.0 for Windows for .NET Agent >= 20.3

Microsoft Windows Azure

- Azure App Services for .NET 4.6 environments in the Azure Portal
  - Web Apps
  - Web Jobs
  - API Apps
  - Container Services

  For Azure App Services, the .NET Machine Agent disables certain .NET Machine Agent infrastructure monitoring features: CLR crash reporting, machine snapshots, and Windows performance counter monitoring.

- Azure Cloud Services
  - Web Roles
  - Worker Roles

Unsupported Frameworks

- Microsoft .NET 1.0 and 1.1
- Unmanaged native code

Automatically Discovered Business Transactions

The .NET Agent discovers business transactions for the following frameworks by default. The agent enables detection without additional configuration.

Type	Custom Configuration Options?	Downstream Correlation?

ASP.NET*	Yes	Yes
ASP.NET MVC 2 ASP.NET MVC 3 ASP.NET MVC 4 ASP.NET MVC 5	Yes	Yes
ASP.NET Core on the full framework	Yes	Yes
Open Web Interface for .NET (OWIN) web API	Yes	Yes
.NET Remoting	No	See Enable Correlation for .NET Remoting.
Windows Communication Foundation (WCF)	No	Yes
Web Services including SOAP	No	Yes
Message Queues		
Apache ActiveMQ NMS framework and related MQs	No	Yes
IBM WebSphere MQ	No	Yes
Microsoft Message Queuing (MSMQ)	No	Yes
Microsoft Service Bus / Windows Azure Service Bus	No	Yes
NServiceBus over MSMQ or RabbitMQ transport	No	Yes
RabbitMQ	Yes	Yes
TIBCO Enterprise Message Service	No	Yes
TIBCO Rendezvous	No	Yes
Windows Azure Queue	No	No

***** The .NET Agent automatically discovers entry points for ASP.NET web forms with the Async property set to "true" in the Page directive.

Supported Loggers for the .NET Agent

- Log4Net
- NLog
- System Trace
- Windows Event Log
- Loggers on .NET Core that implement the Microsoft.Extensions.Logging.ILogger API (Linux Agent >= 4.5.19 and Windows Agent >= 21.2.0)

If you are using a different logger, see Error Detection.

Remote Service Detection

The .NET Agent automatically detects these remote service types. The agent enables detection by default. You do not need to perform extra configuration.

Type	Custom Configuration Options?	Async Detection?*	Downstream Correlation?
CosmosDB: • v2.x (Microsoft.Azure.DocumentDB.Core) • v3.x (Microsoft.Azure.Cosmos) (Linux Agent >= 20.9.0, and Windows Agent >= 21.2.0)	No	See Asynchronous Exit Points for .NET.	N/A
Directory Services, including LDAP	No	No	N/A
HTTP	Yes	See Asynchronous Exit Points for .NET.	Yes
MongoDB: C# and .NET MongoDB Driver version 1.10, 2.0	No	See Asynchronous Exit Points for .NET.	N/A
.NET Remoting	Yes	No	See Enable Correlation for .NET Remoting.
WCF	Yes	See Asynchronous Exit Points for .NET.	Yes
WCF Data Services	Yes	No	No

Web Services, including SOAP	Yes	See Asynchronous Exit Points for .NET.	Yes
Azure Service Fabric Remoting v1 and v2—for the .NET Microservices Agent	-	-	-
Data Integration			
Microsoft BizTalk Server 2010, 2013	No	Yes	See Correlation Over Microsoft BizTalk.
Message Queues			
Apache ActiveMQ NMS framework and related MQs	Yes	No	Yes
IBM WebSphere MQ (IBM XMS)	Yes	No	Yes
Microsoft Message Queuing (MSMQ)	Yes	See MSMQ Backends for .NET	See MSMQ Backends for .NET
Microsoft Service Bus / Windows Azure Service Bus	No	Async exit points only	Yes
NServiceBus over MSMQ or RabbitMQ transport	No	See NServiceBus Backends for .NET	Yes
RabbitMQ	See RabbitMQ Backends for .NET	No	Yes
TIBCO Enterprise Message Service	Yes	No	Yes
TIBCO Rendezvous	Yes	No	Yes
Windows Azure Queue	No	No	No

* The agent discovers asynchronous transactions for the Microsoft .NET 4.5 framework. See Asynchronous Exit Points for .NET

Supported Windows Azure Remote Services

Type	Customizable Configuration?	Downstream Correlation?
Azure Blob	No	No
Azure Queue	No	No
Microsoft Service Bus	No	Yes

Cache Clients

Type	Customizable Configuration?	Async Detection?*	AppD for Databases?
StackExchange.Redis	No	Yes	No

Data Storage Detection

The .NET Agent automatically detects the following data storage types. The agent enables detection by default. You do not need to perform extra configuration.

Type	Customizable Configuration?	Async Detection?*	AppD for Databases?
ADO.NET (see supported clients below)	Yes	Yes	No
Windows Azure Blob Storage	No	Yes	No
Windows Azure File Storage	No	Yes	No
Windows Azure Table Storage	No	Yes	No

* The agent discovers asynchronous transactions for the Microsoft .NET 4.5 framework. See Asynchronous Exit Points for .NET

Supported ADO.NET Clients

AppDynamics can monitor any ADO.NET client version and type. Clients we've tested include the following:

Database Name	Database Version	Client Type

Oracle	10, 11, 12	ODP.NET
Oracle	10, 11, 12	Microsoft Provider for Oracle
MySQL	5.x	Connector/Net and ADO.NET
Microsoft SQL Server*	2005, 2008, 2012	ADO.NET

Node.js Agent

This page provides an overview of supported environments for the Node.js Agent.

Node.js Agent Versions

Agent Versions	Node.js Versions
>= 21.1.0	8.6+, 9, 10, 11, 12, 13, 14, 15
>= 20.5.0	8.6+, 9, 10, 11, 12, 13, 14
20.4.0	8.6+, 9, 10, 11, 12, 13
>= 4.5.21	8.6+, 9, 10, 11, 12
>= 4.5.12	6, 7, 8, 9, 10, 11
4.5.11	0.8, 0.10, 0.12, 4, 5, 6, 7, 8, 9, 10, 11

For agent >= 4.5.12, the `npm install` command will stop and print a message for the following scenarios.

- Node.js version less than 6.x:
  - This version of AppDynamics agent supports Node.js versions 6.0 and above.
  - For older versions of Node.js, use the AppDynamics agent 4.5.11 by installing with `npm install appdynamics@4.5.11`.
- Node.js version less than 8.x on Mac:
  - This version of AppDynamics agent on Mac OS supports Node.js >= 8.0.
  - For older versions of Node.js, use the AppDynamics agent 4.5.11 by installing with `npm install appdynamics@4.5.11`.

Operating Systems

- Alpine Linux Docker >= 3.7 on 64-bit platform
- Linux distribution based on glibc 2.5 and later and the x86/x86-64 architecture
- Mac OS X >= 10.8
- Windows Server 2012 R2 and later on 64-bit platform with Node.js >= 0.12.0

Transaction Naming

Entry Type	Default Transaction Naming
Node.js Web	URI

HTTP Exit Points

Supported HTTP Exit Points
Node.js HTTP client library

See Node.js Documentation for the Node.js HTTP client library.

Database Exit Points

Supported Database Exit Points

Cassandra
Couchbase
DynamoDB (using AWS SDK Driver)
Redis
Memcached
MongoDB
MSSQL
MySQL
PostgreSQL

PHP Agent

Related pages:

- PHP Business Transaction Detection

PHP Agent Support

PHP Versions

PHP Agent supports these versions of PHP:

- 5.6
- 7.0
- 7.1
- 7.2
- 7.3
- 7.4

PHP Web Servers

Apache 2.2 and 2.4 in these modes:

- `prefork` mode using `mod_php`
- worker MPM mode using `mod_fastcgi` with `php-fpm` or `mod_fcgid` with php-cgi

Any web server compatible with `php-fpm`.

Operating Systems

- Any Linux distribution based on `glibc 2.5`+ and the x86 32-bit or x86 64-bit architecture
- Mac OS X 10.9+

PHP Agent supports 32-bit operating system only on PHP 5.6.

PHP Frameworks and Protocols

Framework/Protocol	Version	Entry Point Type
Drupal	7	Drupal
Drupal	8	PHP MVC
WordPress	3.4+, 4.x, 5.x	Wordpress
Zend	1, 2, 3	PHP MVC
CodeIgniter	2.x, 3.x, 4.x	PHP MVC
FuelPHP	1.5x, 1.6x, 1.8x	PHP MVC

Magento	1.5, 1.6, 1.7, 2.3	PHP MVC
Symfony	1, 2, 3, 4	PHP MVC
CakePHP	2.x, 3.x, 4.x	PHP MVC
Laravel	5.7, 6, 8	PHP MVC
HTTP		PHP Web
CLI		PHP CLI

If your PHP framework is not listed here, the agent detects your entry points as PHP Web and names the business transactions based on the first two segments of the URI — the default naming convention for PHP Web transactions. So it is still possible to monitor applications on *unsupported* frameworks. Laravel BTs are detected as symfony, as laravel itself is built on top of symfony.

There are few limitations of the PHP Agent. The PHP Agent does not:

- Monitor PHP applications in Zend Thread Safety (ZTS) mode. If you are using ZTS, AppDynamics suggests that you review your dependencies on ZTS to confirm that you actually need it, and if you do not, to switch to the non-ZTS mode
- Support Zend Monitor
- Officially support plug-ins that encrypt and, or obfuscate PHP code such as Zend Guard or ionCUBE Loader
- Support compatibility with the Xdebug module

Transaction Naming

Framework/Environment	Default Transaction Naming
Drupal	page callback name
Wordpress	template name
PHP MVC Frameworks	controller:action
PHP Modular MVC Frameworks	module:controller:action
PHP Web	URI
PHP Web Service	service name.operation name
PHP CLI	last two segments of the script's directory path plus the name of the script

Virtual host prefixing is available for all supported entry point types except PHP CLI.

PaaS Providers

PaaS Provider	Buildpack
Pivotal Cloud Foundry	https://github.com/Appdynamics/php-buildpack See http://docs.pivotal.io/appdynamics/index.html for information about integration with PCF.

Exit Points

Supported HTTP Exit Points
`curl/curl-multi`*
`drupal_http_request()`
`fopen(), file_get_contents()`
`Zend_HTTP_Client::request()`

*The total time reported for a curl/multi_curl request in the Controller is the same as reported by the function `curl_getinfo`. Also, we report the the following execution metrics in the exit call details for the curl/multi_curl request which are included in the total time:

- `namelookup_time`
- `connect_time`

- `pretransfer_time`
- `redirect_time`

Supported Database Exit Points
MySQL old native driver (removed for PHP 7)
MySQLi Extension*
OCI8
PDO
PostgreSQL accessed via PDO and pgsql extensions

* `mysqli_multi_query` is not supported.

Supported Cache Exit Points
Memcache
Memcached
Predis 0.8.5 and 1.1.1, on PHP versions 5.6 and higher
Phpredis 4.1

Although Predis is a full PHP client library, the PHP Agent supports Predis as an exit point only, not as an entry point.

Supported Web Service Exit Points
PHP SOAPClient
NuSOAP 0.9.5

Supported Message Queue Exit Points
RabbitMQ

RabbitMQ support requires the amqp extension.

Opcode Cache Compatibility

Alternative PHP Cache (APC)	

Python Agent

Related pages:

- Python Agent

Python Agent Support

Python Versions

The Python agent supports Python 2.7, 3.4, 3.5, 3.6, 3.7, 3.8, and 3.9.

Operating Systems

The Python agent operates on any Linux distribution based on glibc 2.12+ and the x86 32-bit or x86 64-bit architecture.

- Support for Mac OS X will be deprecated from the 20.7.0 version of the Python Agent.
- Support for centos5 has been deprecated.

Python Frameworks and Protocols

Framework /Protocol	Version	Entry Point Type	Default Transaction Naming
WSGI	1.0	Python Web	First two segments of URI
Tornado	3.2 - 4.5 (all versions), Tornado 5.x without asyncio library, Tornado 6 (for Python 3.5.3+)	Python Web	First two segments of URI

AppDynamics has tested the Python Agent on Tornado, Django, Flask, CherryPy, Bottle, and Pyramid.

You can configure the agent to instrument any WSGI-based application or framework as Python Web, including but not limited to those listed below.

At present, the Python agent fully supports exception detection in Django, Flask, CherryPy, Bottle, Pyramid, and Tornado frameworks. Other WSGI frameworks and custom WSGI applications may install exception handlers that effectively hide some exceptions from the agent. In such cases, the agent will only detect exceptions during exit calls, missed exceptions that are propagated to the WSGI server, and exceptions reported via the custom business transaction API.

WSGI-Based Frameworks	Notes
Bottle	0.12.19
CherryPy	18.6.0
Django	3.1.5
Flask	1.1.2
PasteDeploy	2.1.0
Pyramid	1.10.5
mod_wsgi	4.7.1

Database Exit Points

Supported Database Exit Points	Version
cx_Oracle	5.1.x
MongoDB	3.1+
MySQL-Python	
mysqlclient	
MySQL Connector/Python	
Psycopg 2	
PyMySql	
TorMySql	

HTTP Exit Points

Supported HTTP Exit Points
httplib*
httplib2
requests
urllib
urllib2
urllib3
tornado.httpclient

* The agent detects calls to any external library built on top of `httplib`. Therefore, backend calls to such services, such as, boto, dropbox, python-twitter are detected and displayed as HTTP exit calls.

Cache Exit Points

Supported Cache Exit Points
Memcache
Redis-py

Apache Web Server Agent

Unable to render {include} The included page could not be found.

C++ Agent

C/C++ Supported Platforms

Operating Systems

- Any Linux distribution based on glibc >= 2.5 and the x86 32-bit or x86 64-bit architecture
- Windows Server >= 2012 R2
    - Visual Studio >= 2015

To develop with the C++ SDK, you need Visual Studio >= 2015 . However, the SAP ABAP Agent on Windows leverages the same SDK and does not require development work.

You must install the Visual Studio C++ Redistributable; the full development environment is not required.

Go Language Agent

Go Supported Platforms

Language Support

All Go language versions are currently supported.

Operating Systems

- Any Linux distribution based on `glibc` >= 2.5, and the x86 32-bit or x86 64-bit architecture
- Mac OS X >= 10.8

IIB Agent

IIB Agent Support

This page provides describes the supported versions, operating systems, and node types of the IIB agent. The AppDynamics IIB agent supports the Linux and AIX operating systems.

Operating Systems

The IIB agent supports these operating systems:

- Linux x86-64
- AIX v7.1 and v7.2

IIB Versions

The IIB Agent supports these versions of IIB for the Linux and AIX operating systems:

Operating System	IIB Version
Linux (Any Linux distribution based on glibc >= 2.5)	• IIB v9 • IIB v10 • ACE v11
AIX 7.1 (minimum patch level 7100-03-09-1717 or 7100-04-04-1717)	• IIB v9 • IIB v10
AIX 7.2	• IIB v9 • IIB v10 • ACE v11 (requires ACE Fix Pack >= v11.0.0.9)

IIB Node Types

The agent can continue business transactions detected upstream at these node types:

- SOAPInput
- HTTPInput
- JMSInput
- MQInput

The agent can detect and tag exit calls for downstream correlation at these node types:

- SOAPRequest
- HTTPRequest
- JMSOutput, JMSReply
- MQOutput, MQReply

> For MQ, we use the MQRFH2 message header to provide correlation. Any applications consuming MQ messages from IIB with the IIB agent must support the MQRFH2 header.

The agent can detect database backend calls for these node types:

- DatabaseRetrieve
- DatabaseRoute

All nodes are represented within AppDynamics Business Transactions as Threads. You can view the per node timings in the tree view of the Business Transaction dashboard and in the transaction snapshots.

AppDynamics Universal Agent

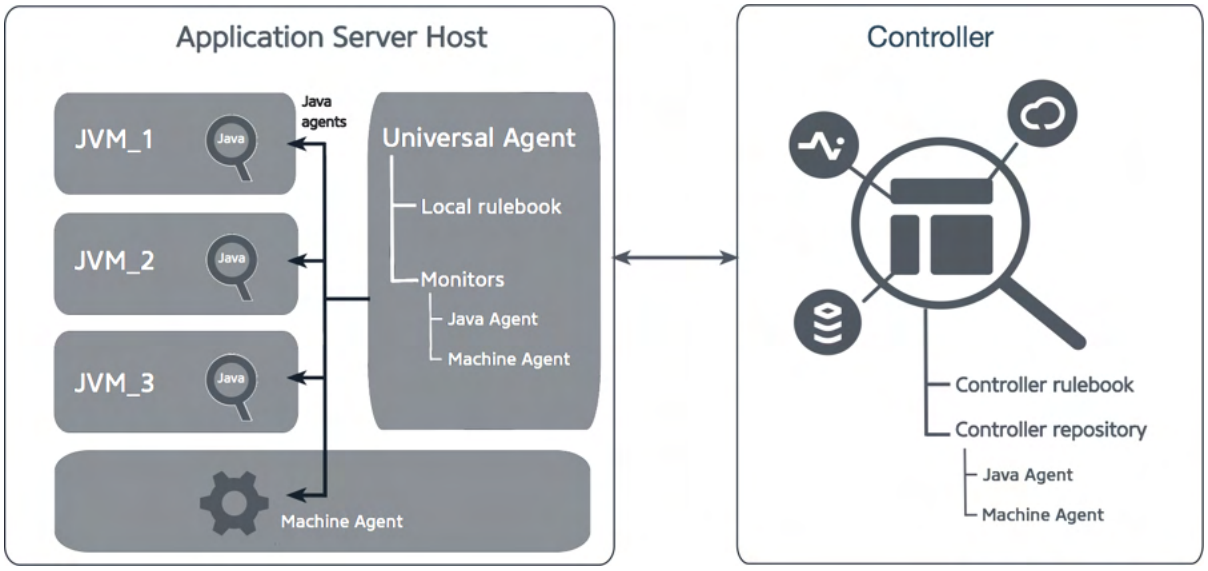
The Universal Agent provides a central management point for administering runtime agents for diverse application environments and eases the management of large environments. The Universal Agent automates the tasks of installing, running, and maintaining AppDynamics runtime agents, such as the Machine Agent and Java Agent.

After you setup the Universal Agent, you can update the versions of the runtime agents by putting new distributions in a central repository and updating the configuration with the latest version. To further ease agent management in large and dynamic environments, the Universal Agent configuration supports remote JVM attachment and dynamic node naming.

Universal Agent

The Universal Agent enables you to run and manage AppDynamics runtime agents by using a single configuration file, called a rulebook. The rulebook determines whether the Universal Agent installs, starts, and stops runtime agents. By default, the Universal Agent runs in controller mode and applies a shared rulebook stored and served by the Controller. Alternatively, you can run the Universal Agent in local mode, in which it uses a rulebook (stored in the Universal Agent home directory) that is specific to the instance of the agent. See Universal Agent Rulebooks.

When the Universal Agent finds a new rule for a runtime agent in the rulebook, it retrieves the runtime agent from a shared repository, installs the agent as a local monitor, and starts the agent. You can manage multiple runtime agents on a single host, which allows for having different versions of the runtime agents for each JVM or each host in your environment.



Set Up Tasks

To use the Universal Agent, you need to do the following tasks:

1. Set up the runtime agent source repository as either a Controller repository or file system repository. A file system repository would typically be on a shared repository accessible to the Universal Agent host machines.
2. Install the Universal Agent on the machines to be monitored.
3. Create the rulebooks to manage your runtime agent instances.

Getting Started

The following procedures walk you through the three set-up tasks for a simple scenario using a single Linux-based application server with an on-premises Controller. On Linux, these steps require `sudo` access to the application server machine, because the setup establishes the Universal Agent as a service.

When following these steps, adjust the values in the commands for your specific Controller, user, account, and so on. Before starting, review additional information in Install the Universal Agent.

Set Up the Runtime Agent Source Repository

To set up a Controller source repository:

1. Confirm that you have an on-premises Controller installed and running and you have access to the Controller machine.
2. On the controller, create the *<controller-home>*`/agent-binaries directory`. This directory serves as your Controller source repository for the runtime agent binaries.
3. Put the Universal Agent ZIP file in the directory.
4. Rename it to `universalagent-`*<version>*`-64bit-linux.zip`.
5. Download the Machine Agent ZIP file to the Controller source repository, *<controller-home>*`/agent_binaries` directory.

6. Rename the Machine Agent file to `machine-<version>-64bit-linux.zip.`
7. Download the Java Agent ZIP to the Controller source repository, <*controller-home*>`/agent_binaries` directory.
8. Rename the Java Agent file to `java-<version>.zip`. (Note there is no bitness in this name.)
9. Continue to the next section to install the Universal Agent.

Install the Universal Agent on the Machines to be Monitored

1. Get the account key for your Controller:
    a. From the Controller UI, open the **License** page and click the Accounts tab.
    b. Click the link to show the key.
2. From the application server machine, get the Universal Agent distribution. You can use the following CURL command to get the Universal Agent from the Controller repository. Replace the `<controller_user>`, <controller_account>, <controller_password>, and <controller_host> address and <primary_port> with values for your system. The Controller user should be an account in the Controller UI that has Universal Agent administration permissions. Replace <account_access_key> with your key and use the version of your specific Universal Agent.

```
curl -u '<controller-user>@<controller-account>:<controller-password>' -X POST -d
'action=downloadAgent&agentVersion=<version>&agentName=universalagent&classifier=64bit-linux' -o
ua<version>.zip 'http://<controller-host:primary-port>/controller/FileDownloadServlet'
mkdir ua_install
unzip ua<version>.zip -d ua_install/
sudo ./ua-install/ua<version>/bin/install.sh --account-access_key <account-access_key>
```

By default, the script installs the agent in the directory, `/opt/appdynamics/universal-agent/`. You can change that using the argument `--target`, but the steps (below) for creating your rulebooks assume the default installation location, `/opt`.

Create the Rulebook

1. From the application server machine, where you installed the Universal Agent, execute a REST API command against your Controller to add a single default rulebook.
Replace <controller-user>, <controller-account>, <controller-password>, <controller-host>, and <controller-port> with the values for your Controller.

```
curl -i -X PUT -su '<controller-user>@<controller-account>:<controller-password>' -H "Content-type:
application/json" -H "Accept:application/json"\
        "http://<controller-host>:<controller-port>/controller/universalagent/v1/user/rulebooks/byName
/default-controller" --data '{
        "name": "default-controller",
        "comments": "An example rule book to monitor Java Agent, Machine Agent and Universal Agent
itself.",
        "rules": [
        {
            "config": {
                "state": "started",
                "version": "<version>"
            },
            "monitor": "machine",
            "comments": "Rule to monitor Machine Agent",
            "condition": "True",
            "name": "Machine monitor"
        },
        {
            "name": "Universal Agent rule",
            "comments": "Rule to monitor Universal Agent",
            "monitor": "universal",
            "config": {
                "version": "<version>",
                "state": "started"
            },
            "condition": "True"
       },
       {
            "config": {
                "version": "<version>",
                "state": "started",
                "application_name": "YourAppName",
                "tier_name": "1stTier"
            },
            "condition": "True"
            "name": "Java Monitor",
            "comments": "Rule to monitor Java Agent",
            "monitor": "java"
       }
    ]
 }'
```

2. After a few moments, verify that the Universal Agent retrieves and installs the Machine Agent and the Java Agent. The corresponding agent files should now appear in the following directories:
    - Machine Agent: /opt/appdynamics/universal-agent/monitor/machine
    - Java Agent: /opt/appdynamics/universal-agent/monitor/java
    - or <target_dir>/appdynamics/universal-agent/monitor/... if you specified `--target <target_dir>` in the installation step
3. Check the status of the Universal Agent as reported to the Controller using the REST API, `universalagent/v1/user/agents/summary`. For instance, using cURL, enter the following command: Replace the username, password, and Controller address with values appropriate for your environment. The response should list the running agents with the version number and the applied rulebook for each.

```
curl -s -X GET -u '<controller-user>@<controller-account>:<controller-password>' -H 'Content-type:
application/json' http://<controller-host>:<controller-port>/controller/universalagent/v1/user/agents
/summary
```

Install the Universal Agent

This page provides an introduction to installing the Universal Agent in AppDynamics.

The AppDynamics Universal Agent runs on each app server machine where you want to deploy runtime agents. The first step in using the Universal Agent to manage your agent deployment, therefore, is installing the Universal Agent on the monitored machines.

When you are ready to install the Universal Agent, review the page specific to your operating system:

- Install the Universal Agent on Windows
- Install the Universal Agent on Linux

Supported Environments and Requirements

The Universal Agent occupies about 20 MB of disk space. When you start the installation, the script first checks the system for sufficient space. Using the Universal Agent to add more runtime agents to your target machine later will require additional space.

The installation process installs the Universal Agent as an automatically started system service. Therefore, you need to install on the system as a user with sufficient privileges for this type of installation. On Linux, for example, you typically need to run the script as a user with sudo privileges. See Permissions for Running the Universal Agent.

The Universal Agent can support the deployment and management of these runtime agents:

- Standalone Machine Agent
- Java Agent
- .NET Agent (Windows only)
- Analytics Agent
- Network Agent (Linux only)

Supported environments and requirements for the runtime agents still apply even when the Universal Agent is managing them. For example, in 4.4, the Network Agent is only available on Linux. Be sure to review the requirements for each runtime agent.

Some Universal Agent features (such as automatic JVM attachment and dynamic rulebook value propagation) have additional requirements and limitations, which are discussed in separate topics.

The Universal Agent is available on the following Linux and Windows versions:

Windows

Installing the Universal Agent on Windows requires the Universal C Runtime. If it the Universal C Runtime is not installed on your Windows server you should install the Update for Universal C Runtime in Windows.

AppDynamics supports the Universal Agent on:

- Windows Server >= 2008 SP2

Linux

Installing the Universal Agent on Linux requires the GNU C Library version 2.12, commonly known as glibc 2.12. The minimum versions of the common distributions that meet this requirement are:

- Ubuntu >= 11.04
- CentOS >= 6
- Red Hat Enterprise Linux >= 6

Controller Connection Settings

The initial configuration for the Universal Agent specifies the Controller host, port, account name, and account key, so you will need to know the values to use before starting. These settings are equivalent to those used by other types of agent. You can find out more in the Agent-to-Controller Connections topic . Note that, on Linux, if you acquire the Universal Agent from the Controller, the settings are preconfigured.

Maintaining Universal Agents

After initial installation, you can update new versions of the Universal Agent itself using the Universal Agent rulebook. See Universal Agent Rules.

Install the Universal Agent on Windows

This page describes how to install the AppDynamics Universal Agent on Windows systems.

Install the AppDynamics Universal Agent on every machine you want to manage runtime agents. When invoked, the installer checks your system for requirements (such as sufficient disk space). When complete, it leaves the agent running and installed it as a Windows service.

Install the Universal Agent on Microsoft Windows

The two files on the download site for Microsoft Windows installations are MSI and ZIP. The ZIP file is designed to be uploaded to the repository and used for Universal Agent self-upgrade via rulebook rules. To install the Universal Agent on Windows, use the MSI installer.

1. Prepare to install: Installing the Universal Agent on Windows requires the Universal C Runtime. If you have not installed the Universal C Runtime on your Windows server, you should install the Update for Universal C Runtime in Windows.
2. Download the MSI installation package from the AppDynamics download site.
3. Start the installation from the command line as follows. For your package, you must use the path of your MSI file and specify a location for the installation log.

   ```
   msiexec /i "C:\MyPackage\Example.msi" /L*V "C:\log\example.log"
   ```

   The installer starts and the End User Agreement appears.
4. As you review the license information, scroll to the end of the agreement.
5. Select the checkbox that indicates your acceptance of the agreement, and then click **Next** to continue the installation.
6. In the Configure pane, enter the following information and then click **Next**:
   a. **Controller host**: The hostname or IP address for the Controller.
   b. **Controller port**: The primary listening port for the Controller. If not specified, the Universal Agent uses port 80 or 443 (with SSL enabled), by default.
   c. **Account name**: The name and access key for the Controller account where the agents should report data. You can get the Account Name and Access Key value from the License Management page in the Controller UI.
   d. **Account access key**: The name and access key for the Controller account where the agents should report data. You can get the Account Name and Access Key value from the License Management page in the Controller UI.
7. Confirm the destination directory for the Universal Agent runtime files and local data and click **Install**.

   The local data directory will contain the configuration files for the agent. The installer installs and configures the agent.
8. When the installation is complete, click **Finish**.

When complete, the Universal Agent is running and installed as an automatically starting service.

Windows Installer Command Line Arguments

Instead of the GUI installer, you can pass Universal Agent configuration settings to the MSI program from the command line in the following format:

```
msiexec.exe /i <name_of_UA_package>.msi  /qn [ CONTROLLERHOST=<hostname> ] [ CONTROLLERPORT=<primaryport>] [
ACCOUNTNAME=<accountname> ] [ ACCOUNTACCESSKEY=<accountkey>] [ SSL_ENABLED= ]
```

The /qn switch suppresses the UI.

The command arguments are:

- CONTROLLERHOST=<value>
- CONTROLLERPORT=<value>
- ACCOUNTNAME=<value>
- ACCOUNTACCESSKEY=<value>
- CONTROLLERSSLENABLED=<value>

CONTROLLERHOST=<value>

Required. AppDynamics Controller hostname.

CONTROLLERPORT=<value>

Required. AppDynamics controller port number.

ACCOUNTNAME=<value>

Required. Name of the account under which the Universal Agent will report to the controller. If you are running a single tenant controller, use the name of the default, built-in account, `customer1`.

ACCOUNTACCESSKEY=<value>

Required. Account access key for the Universal Agent to authenticate with the controller.

CONTROLLERSSLENABLED=<value>

Optional. Specifies whether or not to use SSL for the connection. If included in the command line and set to any value, the Controller uses SSL. If excluded from the command line, SSL is not required.

- CONTROLLERHOST=<value>
- CONTROLLERPORT=<value>
- ACCOUNTNAME=<value>
- ACCOUNTACCESSKEY=<value>
- CONTROLLERSSLENABLED=<value>

Example

The command line is in the following format:

```
msiexec.exe /i universalagent-setup-4.3.0.0-64bit-windows /qn CONTROLLERHOST=controller.sample.host
CONTROLLERPORT=8090 ACCOUNTNAME=customer1 ACCOUNTACCESSKEY=ABCd-10123-XYZD-0123 CONTROLLERSSLENABLED=1
```

Start and Stop the Universal Agent Windows Service

You can stop and start the Universal Agent from the Windows services manager. Find the Universal Agent service and use the services manager controls to stop and start it.

Uninstall the Universal Agent

To uninstall the Universal Agent, use the Windows MSI program, as follows:

1. Disable auto-java (if you enable it) before uninstalling the Universal Agent. Use the --disable-auto-java command.
2. From the command terminal, enter the following command:

   ```
   msiexec.exe /x <name_of_UA_package>.msi
   ```

3. Follow the MSI tool prompts to complete the uninstallation.

4. Reboot the machine after the uninstall is complete.

Install the Universal Agent on Linux

This page describes how to install the AppDynamics Universal Agent on Linux systems.

About the Linux Installation

To install the Universal Agent on Linux, you use the installation script, `install.sh`. The script accepts configuration parameters in various forms:

- As settings in the `conf/universalagent.yaml` file. (If you download the Universal Agent from the Controller, this file may be preconfigured for your environment.)
- As command-line arguments you enter when invoking the install script.
- As settings in a parameter file named by the `-p` argument.

If the installer does not find the Controller host or port settings in one of these sources, it prompts you for the values at the command line.

The following steps illustrate a simple installation scenario. The procedure assumes you already have an AppDynamics Controller installed and running. When the installation is completed, the installation process leaves the Universal Agent running on the target machine.

Install the Universal Agent on Linux

1. Download the Universal Agent ZIP file to the machine where you want to deploy runtime agents.
    - To download from the controller source repository, use the following command. Substitute the placeholders with your username, account name and password, as indicated. Also, replace `<controller_host>` with your controller hostname or IP address and `<controller_port>` with the primary listening port for your Controller.

      ```
      curl -u <user_name>@<account_name>:<password> \
      -X POST \
      -d 'action=downloadAgent&agentVersion=4.4.0.0&agentName=universalagent&classifier=64bit-linux' \
      -o ua4.4.0.0.zip 'http://<controller_host>:<controller_port>/controller/FileDownloadServlet'
      ```

    - If you are not using the Controller repository, you can directly copy the Universal Agent binary onto the machine where you want to deploy runtime agents.
2. Extract the contents to the agent installation directory. This directory is referred to as *<universal_agent_home>* in these instructions.

   ```
   unzip ua4.4.0.0.zip
   ```

3. Specify the initial configuration settings for the Universal Agent. For example, to configure the settings in the Universal Agent configuration file, follow these steps:
    a. Navigate to the `conf` directory and open `universalagent.yaml` for editing. This file contains the configuration properties for the Universal Agent.
    b. Configure the settings with values that correspond to your Controller environment. The Universal Agent, and unless otherwise configured, the deployed runtime agents, use this information to connect to your Controller:
        - controller_host: The hostname or IP address for the Controller.
        - controller_port: The primary listening port for the Controller. If not specified, the Universal Agent uses port 80 or 443 (with SSL enabled), by default.
        - account_name and account_access_key: The name and access key for the Controller account where the agents should report data. You can get the Account Name and Access Key from the License Management page.
    c. If you want your agent to be registered with a given name, un-comment the `name` tag under the `agent` section and provide a value such as:

       ```
       name: your_agent_name
       ```

       If you do not provide an agent name, the name of the agent defaults to the hostname of the machine.

       > Note that `.yaml` files use a fixed indentation scheme. Therefore, be careful that all the sections are indented correctly. Make sure that the sections `controller` and `agent` are indented correctly with the right number of spaces (not tabs). For example, if you un-comment `account_name, account_access_key` under `controller` section, you need to add a space to make it align with the other tags.
       >
       > Do not use tabs in `universalagent.yaml`. The YAML loader used by the agent does not support tabs.

4. Specify the repository location. This is either the file location or network location where the Universal Agent gets the app agents to install. If using a local repository, see Runtime Agent Repository for instructions on setting up the repository.
5. Review and set any other properties in the configuration file applicable to your environment, as indicated by the inline comments.
6. Run the install script to install the Universal Agent into a Linux or Unix system.

```
sudo ./ua4.5.0.0/bin/install.sh
```

The Universal Agent starts immediately when installation is complete. It is registered as an automatically started service, so the Universal Agent starts automatically upon system reboots.

Linux Install Script Format

Run the install script.

```
install.sh [ -p <param file>] [ --controller_host <controller host>] [ --controller_port <controller port>] [ --account_name <account name>] [ --account_access_key <account access key>] [ --target <target directory>]
```

The following sections describe each setting:

-p <param_file>

Optional. This optional argument specifies the full or partial path name of a text file that contains all of the arguments supported by the script.

When specified, the file must contain the same keywords and values specified on the `install.sh` command. For readability, these can be contained on multiple lines. For example:

Example param file

```
--controller_host localhost
--controller_port 8080
```

A value specified on the command-line of `install.sh`, overrides a value specified in the file referenced by the `-p` argument.

--controller_host <value>

Required. AppDynamics Controller host name.

--controller_port <value>

Required. AppDynamics Controller port number.

--account_name <value>

Required. Name of the account under which the Universal Agent will report to the Controller. If you are running a single-tenant Controller, use the name of the default, built-in account, `customer1`.

--account_access_key <value>

Required. Account access key for the Universal Agent to authenticate with the Controller.

--target <value>

Optional. Specifies the target directory where the Universal Agent is installed. Default is `/opt.`

--no_service

Optional. Specifies that the `ua` daemon should not be defined as a service. In this case, you must manually start the `ua` daemon.

Example

In this example, the Controller host and account access key are found in `paramfile.txt`.

```
ua4.5.0.0/bin/install.sh -p paramfile.txt --controller_port 8081 --account_name customer1
```

Sample contents of the paramfile.txt are:

```
--controller_host localhost --controller_port 8080 --account_access_key 'abcdef$ghi'
```

The Controller port value specified in this file is ignored, because '-controller_port 8081' is specified on the command invocation.

Start and Stop the Universal Agent Linux Service

When the install script completes successfully, the Universal Agent is defined as a system service. You can start and stop it using Linux service commands.

In a `systemd` environment, use the following commands to start, stop, and restart the service:

- `systemctl start appdynamics-universal-agent`
- `systemctl stop appdynamics-universal-agent`
- `systemctl restart appdynamics-universal-agent`

In a non-systemd environment, use the following commands:

- `service appdynamics-universal-agent start`
- `service appdynamics-universal-agent stop`
- `service appdynamics-universal-agent restart`

Uninstall the Universal Agent

To uninstall the agent as a `sudo` user, run the `CLI` command passing the uninstall switch:

```
./ua --uninstall
```

Permissions for Running the Universal Agent

Related Pages:

- Install the Universal Agent

This page provides an overview of permissions needed to run the Universal Agent.

When the Universal Agent installs and starts other runtime agents, it starts them using the same user as the Universal Agent itself. During installation, the default user for running the Universal Agent is set to root. You can create a non-root user, for example, `<universal_agent_user>`, and assign the appropriate permissions to that user.

The installation process installs the Universal Agent as an automatically started system service. Therefore, you need to perform the installation on the system as a user with sufficient privileges for this type of installation. On Linux, for example, you typically need to run the script as a user with `sudo` privileges.

For all environments you can create a specific user with the necessary read/write/execute permissions for running the Universal Agent:

- All files in the `<universal-agent-home>` installation directory should be readable by the Universal Agent.
- The user that runs the Universal Agent must have write privileges to the logging output directory and to the `/conf` directory in the agent installation directory.
- The user that runs the Universal Agent must have write privileges to the `conf` and `logs` directories in the `<universal_agent_home>` directory.
- In addition, the user that runs the Universal Agent needs execute access as described below.

Linux

SystemD

- `systemctl stop`: Stops the Universal Agent service.
- `systemctl restart`: Restarts the Universal Agent after upgrade.
- `systemctl disable` - uninstalls the Universal Agent service.

Non-SystemD

- `service stop`: Stops the Universal Agent service.
- `chkconfig --del`: Uninstalls the Universal Agent service.
- `service restart`: Restarts Universal Agent after upgrade.

Other Commands

- `java` - to start and stop standalone Analytics JVM (usually only on Windows).
- `java -version` - to determine version of Java.
- `sudo -u <user-id> java .../javaagent.jar` - to remote attach to a JVM, if JVM is running with a different user id than the Universal Agent.
- `java .../javaagent.jar` - to remote attach to a JVM, if JVM running with same user id as UA.
- `machine-agent` - invokes machine-agent script to start machine agent.
- `/opt/appdynamics/universal-agent/ua --daemon` - to start the Universal Agent daemon, when it is not defined as a Linux service.

Setting up the Non-root User for Universal Agent

In most Linux installations, you can configure `sudo` ability for the Universal Agent by editing the `/etc/sudoers` file using `visudo`. The following steps provide an example of this configuration change:

1. Edit `/etc/sudoers` using the `visudo` command.
2. Find the line with "`Defaults requiretty`" and change it to "`Defaults !requiretty`".
3. Find the line with "`rootALL=(ALL) ALL`". After this line, add the line "`<user_name> ALL=(ALL) ALL`", where "<*user*>" is the user ID that the Universal Agent service is running under.
4. (For Java Agent Remote Attach) When deploying Java Agents into environments using remote attach, if the Universal Agent runs as root or as the same user that runs the JVMs to which you want to remotely attach, no additional user configuration is required. However, if the Universal Agent runs as a non-root user that is not the same user used to run the target JVM, then you need to authorize the Universal Agent user to use sudo privileges to enable the Universal Agent to retrieve environment variables used in dynamic variable binding.
   At the end of the /etc/sudoers file, add the following line:

   ```
   <ua_user> ALL = NOPASSWD: /opt/appdynamics/universal-agent/ua, /usr/bin/java
   ```

   The value of `<ua_user>` is the user id that the Universal Agent service is running under. Note that `/usr/bin/java` represents the fully-qualified path name for Java on this system. This value can be found by entering the `which java` command, and may be different from `/usr/bin/java`.
5. (For deploying the Network Agent) Installing the Network Agent using the Universal Agent requires elevated privileges for some commands. At the end of the `/etc/sudoers` file, add the following line:

```
<ua_user> ALL = NOPASSWD: /bin/chmod, /bin/chown, /sbin/setcap
```

Note that `/sbin/setcap` represents the fully-qualified path name for `setcap` binary on this system. This value can be found by entering the `which setcap` command, and may be different from `/sbin/setcap`.

Windows

Windows permissions for files and subfolders are inherited by default from the parent folder (<universal_agent_home>). It is good practice to restrict permissions to users authorized to start, stop, and configure the Universal Agent:

- Read and Write permissions to all files and subfolders under `<universal-agent-home>` .
- Permission to install and uninstall software.
- Start, Stop, and Restart permissions for the Universal Agent service. You need admin privileges to install and run the service.

Runtime Agent Repository

The Universal Agent can retrieve the runtime agent installation software from the Controller repository or from a local repository. See Download AppDynamics Software.

This page describes how to create each type of repository.

Configure the Repository Location

The repository types and locations are defined in the Universal Agent configuration file, `universalagent.yaml`, using the `repositories` keyword. You can specify a list of repository URLs (in order of preference) for retrieving AppDynamics monitor (agent) binaries and Universal Agent updates. The format is:

```
repositories:
     - file:///local/path
     - http://host:port/path
     - https://host:port/path
     - https://<username>:<password>@<host>:<port>/<path>
```

To configure a local repository, use the `file://` protocol prefix for the location. For example, if the local repository is in the `/users/appduser/repository` directory, configure the repository location as follows:

```
repositories:
    - file:///Users/appduser/repository
```

Notice that there are three slashes after `file:`. The first two slashes indicate the file protocol, and the third slash refers to the root directory of the file system. All slashes should be forward slashes, even on Windows machines.

To configure a local repository on an HTTP server. Define the URL in any of the formats below:

```
repositories:
    - https://host:port/path
    - http://host:port/path
```

You can also use basic authentication for an HTTP repository in the form:

```
repositories:
    - https://<username>:<password>@<host>:<port>/<path>
    - http://<username>:<password>@<host>:<port>/<path>
```

You can specify more than one repository location, in which case the Universal Agent uses the first agent file that matches a rule that it finds in the sequentially checked repositories. To use a combination of a local and Controller repository, include both, as follows:

```
repositories:
    - file:///Users/appduser/repository
    - https://<username>:<password>@<host>:<port>/<path>
    - controller
```

The Universal Agent first checks the local repository and then the Controller for the runtime agent downloads.

Use a Controller Repository

This type of Universal Agent Repository is not available for SaaS Controllers. Use a local repository instead.

Downloading the .NET Agent from a Controller repository is not supported. Place the .NET Agent distribution file in a local repository.

Using the Controller as the repository location gives the Universal Agents in your environment a single, central point for accessing the runtime agents. To use the Controller repository, you need to be able to access the Controller installation directory.

1. Create a subdirectory named `agent_binaries` in the Controller home directory.
2. Download the runtime agent distribution files to the Controller home subdirectory `agent_binaries` from the download site.

3. Rename the downloaded agents to the format expected by the Universal Agent. Use the following naming conventions where <*version*> is the agent version number:
   `java-<version>.zip` for non-IBM versions of the Java agent
   `java-<version>-ibm.zip` for IBM versions of the Java agent
   For example, `java-4.5.0.0.zip` or `java-4.5.0.0-ibm.zip`
   Your directory should look similar to the following:

```
<appdynamics_home>/
    Controller/
       agent_binaries/
          java-4.5.0.0.zip
          java-4.5.0.0-ibm.zip
          universalagent-4.45-64bit-linux.zip
```

4. Specify the repository location to the Universal Agent, as described in Configure the Repository Location.

Use a Local Repository

If putting the repository in the Controller directory structure is not feasible, you can serve the agent distribution files from a local repository. The likely location for the repository, in this case, would be a shared network directory. The directory would need to be mounted by the machines running the Universal Agent.

The Universal Agent depends upon a defined directory structure within the repository directory and conventionally named runtime agent distribution files, as described in the following steps.

To create your own local Universal Agent repository:

1. Create the `repository` directory with the structure shown in the following example:

```
repository/
   monitor/
      java/
         4.5.0.0
            java-4.5.0.0.zip
         4.5.0.0
            java-4.5.0.0.zip
      machine/
         4.5.0.0
            machine-4.5.0.0-64bit-linux.zip
```

   Your local directory should similarly have a directory named `monitor` that contains subdirectories for the runtime agent types, including `java` and `machine` and their respective versions, as illustrated by the example.
2. Download the agent files to the appropriate location in the directory based on the agent type and version.
3. Rename the downloaded agents to the format expected by the Universal Agent. For example, rename `AppServerAgent-<`*`version`*`>.zip` to `java-<`*`version`*`>.zip`. See Agent Naming Format.
4. Specify the repository location to the Universal Agent, as described in Configure the Repository Location.

Agent Naming Format

The Universal Agent requires the downloaded runtime agent ZIP file in the repository to have a specific name format. When placing runtime agent files in the repository, ensure that they are named using the following format:

Format	Examples	Description
`java-<version>.zip`	`java-4.5.0.0.zip`	Java App Server Agent
`machine-<` *`version`* `>- <` *`bitness`* `>bit- <` *`os`* `>.zip`	`machine-4.5.0.0-64bit-windows.zip`	Machine Agent for 64-bit Windows
	`machine-4.5.0.0-32bit-windows.zip`	Machine Agent for 32-bit Windows
	`machine-4.5.0.0-64bit-linux.zip`	Machine Agent for 64-bit Linux
	`machine-4.5.0.0-32bit-linux.zip`	Machine Agent for 32-bit Linux
`universalagent-<version>-<bitness>bit-<`*`os`*`>.zip`	`universalagent-4.5.0.0-64bit-windows.zip`	Universal Agent for 64-bit Windows

	`universalagent-4.5.0.0-32bit-windows.zip`	Universal Agent for 32-bit Windows
	`universalagent-4.5.0.0-64bit-linux.zip`	Universal Agent for 64-bit Linux
	`universalagent-4.5.0.0-32bit-linux.zip`	Universal Agent for 32-bit Windows
`analytics-agent-<version>.zip`	`analytics-agent-4.5.0.zip`	Analytics Agent
`analytics-agent-bundle-<`*`bitness`*`>bit-<`*`os`*`>-<`*`version`*`>.zip`	`analytics-agent-bundle-64bit-linux-4.5.0.0.zip`	Bundled Analytics Agent
`dotNetAgentSetup<`*`bitness`*`>-<`*`version`*`>.msi`	`dotNetAgentSetup64-4.5.0.0.msi`	Windows .NET Agent
`network-<`*`version`*`>-<`*`bitness`*`>bit-<`*`os`*`>.zip`	`network-4.5.0.0-64bit-linux.zip`	Network Agent

Notice that the Universal Agent and the Machine Agent include the bit number of the target operating system because the downloads bundle the JRE.

Universal Agent CLI

You can perform administrative tasks and configuration changes for a Universal Agent using the Universal Agent command-line interface (CLI), as described on this page.

Run the Universal Agent CLI Tool

You can start the Universal Agent, or administer and configure a running Universal Agent, from the command line by invoking the `/opt/appdynamics/universal-agent/ua` program.

Configuration changes you make with the Universal Agent command-line tool do not impact the content of the Controller rulebook. All rulebook changes affect only the local copy of the rulebook, `local.json`. Command-line arguments that cause rulebook changes also direct the background Universal Agent daemon task to switch to Local mode, so that it operates from the `local.json` rulebook rather than the Controller rulebook.

CLI Tool Command Syntax

The following listing shows the CLI tool syntax:

```
/opt/appdynamics/universal-agent/ua [ --daemon] [ --start-rule <rule_names> ]  [ --stop-rule <rule_names> ] [ --display-mode ] [ --set-mode [local | controller ] [ --modify-config <rule.attribute=value> ] [ --show-java-arguments <process_ids> ] [ --check-config ] [ --show-daemon-status ] [ --setup-win-service [ --data-dir <data-directory-path>] ] [ --restart-service ] [ --start-service ] [ --enable-auto-java ] [ --disable-auto-java ] [ --uninstall ]
```

You can pass more than one argument to the command. For example:

```
/opt/appdynamics/universal-agent/ua --start-rule rule1 rule2  --stop-rule rule3  --display-mode
```

Command Line Arguments

Quotes are necessary if the rule name contains spaces, otherwise, quotes are optional. This is true for all commands that reference rule names.

--daemon

Starts the Universal Agent as a daemon process. It is mutually exclusive with all other command-line arguments.

--start-rule <rule_names>

Changes the state of one or more rules in the rulebook to a value of `started`. The rules to be modified are identified by their rule names. The use of the **--start-rule** argument switches the operation mode of the Universal Agent to Local. You can change the state of multiple rules within a single invocation. For example, `/opt/appdynamics/universal-agent/ua --start-rule rule1 rule2` changes the state of both `rule1` and `rule2` to `started`.

The meaning of this state change varies from one monitoring agent to another.

- Machine Agent and Network Agent: A state value of `started` causes the Universal Agent background task to start the specified agent.
- Java Agent: A value of `started` activates the Java Agent within a matching JVM when that JVM starts. If the JVM has already started, it needs to be restarted for the Java Agent start to take effect.
- .NET Agent: Changing the state of the rule to `started` rules causes the specified rule to become `started` and installs and starts the .NET agent on the machine.

- Analytics Agent
    - For Linux platforms, the Analytics Agent runs as a Machine Agent extension. A value of `started` causes the Machine Agent to be configured to start the analytics extension the next time it is started.
    - For Windows platforms, the Analytics Agent runs in a standalone JVM. A value of `started` causes this JVM to be started if it is not already running.

--stop-rule <rule_names>

Changes the state of one or more rules in the rulebook to a value of `installed`. The rules to be modified are identified by their rule names. Using the `--stop-rule` argument switches the operation mode of the Universal Agent to Local. You can change the state of multiple rules within a single invocation. For example, `/opt/appdynamics/universal-agent/ua --stop-rule rule1 rule2` changes the state of both `rule1` and `rule2` to `installed`.

The meaning of this state change varies from one monitoring agent to another.

- Machine Agent and Network Agent: A state value of `installed` causes the Universal Agent background task to stop the specified agent if it is running.
- Java Agent: The Universal Agent cannot stop a Java Agent because it runs as part of an application JVM. A state value of `installed` prevents the auto-java feature (if enabled) from activating the Java Agent within a matching application JVM.
- .NET Agent: Changing the state of the rule to `installed` stops the .NET agent and uninstalls it.
- Analytics Agent:
    - For Linux platforms, the Analytics Agent runs as a Machine Agent extension. A value of `installed` causes the Machine Agent to be configured to not start the analytics extension the next time it is started.
    - For Windows platforms, Analytics Agent runs in a standalone JVM. A value of `installed` causes this JVM to be stopped, if it is currently running.

--display-mode

Displays the operation mode of the background Universal Agent daemon. It does not change anything.

--set-mode [local | controller]

Changes the operation mode of the background Universal Agent daemon to the specified mode.

If `local` is specified, and the daemon is currently in controller mode, then the current controller rulebook (as saved in the `controller-book.json` file) is renamed `local.json.`

If `controller` is specified, and the daemon is currently in local mode, then the `local.json` file is renamed `local.json.backup` (if possible).

--modify-config <rule_name> <attribute_name>=<new_value>

Changes an arbitrary attribute within the current rulebook to a new value. The use of the `--modify-config` argument switches the operation mode of the Universal Agent to Local.

You can specify the attribute in two ways:

- `<rule_name> <attribute_name>=<new_value>` this form changes a non-config attribute within the rule. `<rule_name>` identifies the name of the rule to be changed; `<attribute_name>` identifies the specific attribute; and `<new_value>` specifies the new value to be assigned to the attribute.
  For example: `/opt/appdynamics/universal-agent/ua --modify-config rule1 condition=False` changes the condition attribute of `rule1` to a value of `False`.
- `<rule_name> config.<attribute_name>=<new_value>` this form changes a config attribute within the rule. A config attribute is a monitor-specific attribute that is defined within the "config" attribute set for the rule. `<rule_name>` identifies the name of the rule to be changed; `<attribute_name>` identifies the specific config attribute; and `<new_value>` specifies the new value to be assigned to the attribute. For example: `/opt/appdynamics/universal-agent/ua --modify-config rule1 config.state=started` has the effect of changing the `state` config attribute of `rule1` to a value of `started`.

--show-java-arguments [<process_ids> | all]

Displays the changes that need to be made to a Java command line to correctly deploy the Java app agent. This command is helpful if you need to manually configure one or more Java startup scripts.

One or more arguments can be provided for this option. If a single `all` argument is provided, then this command displays the command line arguments that need to be defined for each JVM in the system that matches at least one of the Java rules. Otherwise, the arguments following `ua --show-java-arguments` should be the process ids for the processes that should be tested. If a process id represents a Java process, then the process is tested against the current Java monitoring rules. If the process matches at least one rule, the command line arguments that should be added to the process startup script are displayed.

Example:

Example of --show-java-arguments

```
ua --show-java-arguments 123

Java arguments for pid 123
    -javaagent:/opt/appdynamics/universal-agent/monitor/java/javaagent.jar
    -Dappdynamics.agent.applicationName=MyApp,-Dappdynamics.agent.tierName=MyTier,-Dappdynamics.agent.reuse.
nodeName=true,-Dappdynamics.ua.appagent.version=4.3.0.0
```

--check-config

Enables the Universal Agent to validity check the `conf/universalagent.yaml` configuration file for syntax errors. Reports if there are errors in the file that would cause the `ua` daemon process to fail initialization. The Universal Agent install script uses this argument to ensure a valid configuration file prior to installing the Universal Agent as a system service.

--show-daemon-status

Reports the status of the `ua` daemon process by scanning the processes running in the current OS and reporting the process ids of all the processes that are running the Universal Agent as a daemon. Run this command as the root user or by using `sudo`.

Linux only: When the Universal Agent daemon runs as a system service, it is normal for two process ids to be reported

--setup-win-service

Configures the Universal Agent as a service in the Windows environment. This command starts the Windows service (if it is not already running), and configures the registry so that the service starts automatically when the system is rebooted.
The `--data-dir` command-line option can be specified with `--setup-win-service`. The `<data-directory-path>` argument specifies the path name of the directory where the Universal Agent's data directories reside. These directories include `log`, `conf`, `download`, and `rulebook`. If the `--data-dir` option is not specified, then these directories must be located in the main installation directory of the Universal Agent.

--restart-service

Stops and starts the Windows Universal Agent service.

--start-service

Starts the Windows Universal Agent service, unless it is already started.

--enable-auto-java

Usage: Windows only.

Enables the "auto-java" feature. The auto-java feature enables automatic start of the Java app agent for all new JVMs. It directs the Universal Agent to inspect the command line arguments of each new process and add the "`-javaagent:...`" argument to all new Java processes. This option only modifies the command lines for processes that are recognized as JVMs. This option does not directly impact the background Universal Agent daemon.

This is an optional facility that is disabled by default. For Windows systems, this interface can potentially be used to deploy viruses or other types of potentially dangerous software. The intent of the feature is to ease the deployment of the AppDynamics Java agent when it is installed by the Universal Agent, by eliminating the requirement for users to modify Java startup scripts. The code has been thoroughly tested and peer-reviewed, as is the case of all of our product code.

This feature is not supported on Windows 2008 SP2 32-bit and 64-bit.

--disable-auto-java

Disables the auto-java feature that was previously enabled with the `--enable-auto-java` argument. This command-line option does not directly impact the background Universal Agent daemon.

--enable-ldpreload

Usage: Linux only. Exactly like `--enable-auto-java`, but on Linux.

--disable-ldpreload

Usage: Linux only. Exactly like `--disable-auto-java`. Disables the auto-java feature that was previously enabled with the `--enable-ldpreload` argument. This command-line option does not directly impact the background Universal Agent daemon.

--uninstall

Uninstalls the Universal Agent. The Universal Agent Daemon process is stopped and, if the Universal Agent is defined as a service, the service definition is deleted. On Windows, the Universal Agent definition is removed from the registry. Requires a reboot of the machine.

Universal Agent Rulebooks

The Universal Agent uses rulebooks to manage the deployment and maintenance of runtime agents. This page introduces rulebooks and strategies for applying them.

Work with Rulebooks

The Universal Agent operates according to rules that you define in rulebooks. A rulebook is a JSON-formatted configuration file that can direct the Universal Agent to install, stop, or start runtime agents.

The rulebook contains general properties, subject to condition evaluation logic, for the Universal Agent itself, along with rules for individual types of runtime agents.

So for instance, when you add a runtime agent rule to the rulebook, the Universal Agent to which the rule applies retrieves the runtime agent from an agent repository and installs the agent in the `monitor` directory in the Universal Agent home. The `monitor` directory contains the base install directories for each runtime agent.

Operation Mode

The Universal Agent may run in one of two modes: Controller mode or local mode. The mode it uses depends on the rulebooks that it finds in the rulebook directory, `<universal_agent_home>/rulebook`.

The following describes the rulebooks that apply in each mode:

- Local mode: If a rulebook file named `local.json` exists in the directory, the Universal Agent operates in local mode. It does not attempt to contact the Controller and `controller-book.json` is ignored if it exists. You can put the Universal Agent into local mode by using the Universal Agent CLI or by creating `local.json` manually.
- Controller mode: Otherwise, the Universal Agent operates in Controller mode. When in Controller mode, the Universal Agent tries to get the operative rulebook from the Controller. If successful, the Universal Agent writes the contents of the Controller rulebook to a file named `controlle r-book.json` in its own rulebook directory. If the `controller-book.json` file exists in the rulebook directory, from that read or a previous read, then it is used as the rulebook.
  Otherwise, it operates using the `default.json` rulebook .

For information on creating and managing controller rulebooks, see Universal Agent REST APIs.

Polling Interval

The Universal Agent reads the rulebook at regular intervals and applies changes in the rulebook as they occur, reporting the event to the Controller. By default, the Universal Agent checks the rulebook every 300 seconds (five minutes).

For testing and initial investigatory work, you may want to reduce this interval to induce more frequent polling. Use the `interval` property found in `univer salagent.yaml` to change the polling frequency.

Rulebook Structure

The basic parts of a rulebook are shown below in tabular format. The header section tab contains settings that apply globally to all runtime agents controlled by this rulebook. In this example, the values identify the Universal Agent version and the Controller connection settings. Global properties enable you to avoid repeating the property in each rule.

The rules section tab contains rules that define runtime agents, in this case, two Java Agents and one Machine Agent. The header section and each rule can contain a config object. Any value specified in the rule overrides the global value.

Rulebook Property Reference

Header Rulebook Properties

- `name`: Name for this rulebook.
- `comments`: An optional description for this rulebook.
- `config`: This object contains global properties that apply to all runtime agents in the rulebook. The `config` object notably contains connection properties for the Controller. See Controller Connection Properties.
- `rules`: Rules entries contain the specific rules for controlling one or more agents. There are common properties in the agent rules and properties that are specific to the agent type. See Runtime Agent Rule Properties.

The following sections provide more information on the `config` object and `rules` sections of the rulebook.

Controller Connection Properties

The rulebook example above shows properties that runtime agents use to connect to the Controller and how the agent instance is identified in the Controller UI. These properties correspond to values typically configurable for the runtime agents, particularly for the Java app agent configuration file, `con troller-info.xml`.

Using the Universal Agent, you can set any of the usual properties found in the runtime agent configuration file. In the Universal Agent rulebook, the properties have the same names that are in `controller-info.xml`, *except* that a hyphen in the `controller-info.xml` property name is replaced by an underscore in the rulebook version of the property name.

Specifically, the rulebook supports the following properties:

- `account_access_key`
- `account_name`
- `agent_runtime_dir`
- `application_name`
- `controller_host`
- `controller_port`
- `controller_ssl_enabled`
- `credential_store_filename`
- `credential_store_password`
- `enable_orchestration`
- `force_agent_registration`
- `machine_path`
- `node_name`
- `tier_name`
- `use_encrypted_credentials`
- `use_simple_hostname`

For more information on usage, see inline comments in the `controller-info.xml` file and the topic: Administer App Server Agents.

When you set the connection values in the rulebook, the Universal Agent updates the `controller-info.xml` on disk for the runtime agent. The following values are taken from `universalagent.yaml` if they are not specified in the rulebook:

- `controller_host`
- `controller_port`
- `controller_ssl_enabled`
- `account_name`
- `account_access_key`

Specifying the values in the rulebook, however, enables you to configure the Universal Agent and its configured runtime agents to talk to different Controllers, if necessary.

Runtime Agent Rule Properties

The rules section in the Universal Agent rulebook contains rules governing the presence and status of a runtime agent on the Universal Agent host. The default rulebook, `default.json`, is installed with the following predefined rule:

```
"rules": [
    {
        "name": "Universal Agent rule",
        "comments": "Universal Agent rule",
        "monitor": "universal",
        "config": {
            "version": "4.5.0.0",
            "state": "started"
        },
        "condition": "True"
   }
]
```

The properties for each rule are:

- `name`: Name for this rule.
- `comments`: An optional description for this rule.
- `monitor`: The agent type. Valid values are:
    - `java` for the Java Agent
    - `machine` for the Machine Agent
    - `universal` for the Universal Agent
    - `dotnet` for the .NET Agent
    - `analytics` for the Analytics Agent
    - `network` for the Network Agent
- `condition`: A statement that must be true to be applied by a particular Universal Agent. Typically a "condition" tests an environment variable or system property on the host on which the Universal Agent runs.
- `config`: A JSON Object containing agent-level configuration properties such as operating state, node name, and so on. These can be specified per runtime agent in the rule (as illustrated by the state and application_name properties in the sample) or globally (as illustrated by the version property in the header section). Values specified in the rule override the global value. The `config` properties include:
    - `version`: The AppDynamics version of the app agent to use
    - `state`: The action to be applied to the agent, such as `installed`, which installs the agent or `started`, which both installs and starts it. For agent specific state information, see Java Agent Rules and Machine Agent Rules.
    - `application_name`, `tier_name`, and `node_name`: Applicable to Java Agents, these properties are equivalent to application-name, tier-name, and node-name in `controller-info.xml` for the traditional agent configuration. They specify the business application, tier, and node by which the current monitored process is identified in the Controller UI. For additional connection related properties, see Controller Connection Properties. Other runtime agents may have agent-specific properties that can be defined in the rule-level `config` object.

Rulebook Strategies

Use Groups

Universal Agent groups are a way to manage multiple Universal Agents as a logical group. By default, Universal Agents are part of the default group and run the default rulebook, `default-controller`. As additional Universal Agents start and register with the controller, they join the default group.

You can create groups and add Universal Agents to them using the Universal Agent REST API.

A Universal Agent can be part of multiple groups. When the Universal Agent is added to the groups and those groups have different rulebooks, the Controller sends multiple rulebooks to the Universal Agent and the rulebooks are logically merged into a single rulebook.

The resulting merged rulebook is written to `controller-book.json`. You should not modify this rulebook directly.

Conditional Rules

You can use conditions to specify criteria for applying rules. In the simplest (and default) case, the value can simply be set to "true" to enable the rule as shown in the example:

```
"condition": "True"
```

You can also create test conditions that enable or disable the rule based on the environment in the Universal Agent host.

Condition property syntax in Universal Agent rulebooks is similar to conditions in Python—the condition should evaluate to a Boolean expression with identification data keys as the operands (which should match the regular expression "[a-zA-Z0-9_]+").

To install only on Linux machines and given the "platform_system" environment variable, you could specify the following condition:

```
"condition": "platform_system == '\''Linux'\''"
```

Notice that single quotes in the value are escaped using '\'.

In the following example, the condition checks for Linux and a version of the Universal Agent higher than 4.5.1:

```
"condition": "platform_system == '\''Linux'\'' and universalagent_version > '\''4.5.1'\''"
```

Operators you can use are:

- Logical operators: and, or, not
- Comparison operators: ==, !=, <, <=, >, >=
- Special operators:
    - Regular expression compare, where regular expression comes after the operator
    - ~ (AWK-like regular expression match)
    - !~ (AWK-like regular expression inverse match)
- Membership test: in

Instead of using dynamically evaluated conditions, you can put the static values of true or false in the condition property. When used in this way, the condition property gives you a convenient way to enable or disable individual rules.

Configuration Templates

Configuration templates enable you to define a set of default configuration values that apply across a set of rulebooks. See Rulebook Configuration Templates.

Uninstall a Runtime Agent

To uninstall a runtime agent, remove the rule for it in the rulebook and save the file.

The Universal Agent first stops the runtime agent, if it is running, and then uninstalls the runtime agent from the application or machine and removes the directory for it.

Universal Agent Rules

In addition to maintaining runtime agents, the Universal Agent can manage itself through the rulebook.

Define Universal Agent Rules

In a Universal Agent rulebook, a `monitor` value of `universal` identifies a Universal Agent rule.

```
...
"monitor": "universal",
...
```

The state property has the following values for the Universal Agent:

- `installed`: The Universal Agent binaries for the specified version should be downloaded and installed.
- `started`: The Universal Agent binaries for the specified version should be download and installed, and that this version should be running

When you install the Universal Agent, you get a default rulebook that includes a rule for the Universal Agent.

To upgrade the Universal Agent, you simply load the new version of the agent in the repository and increment the version number in the rule. When the Universal Agent detects that the rulebook specifies a different version than the version currently running, it automatically restarts itself with the new version.

Example Universal Agent Rule

The default rulebook includes a default rule for the Universal Agent, as follows:

```
       {
           "name": "Universal Agent rule",
           "comments": "Universal Agent rule",
           "monitor": "universal",
           "config": {
               "version": "4.5.0.0",
               "state": "started"
           },
           "condition": "True"
      }
```

Use Multiple Universal Agent Rules

You can have multiple Universal Agent rules in a rulebook. Each should specify a different name and a different version. Only one rule at a time can specify a state of `started`.

If multiple rules specify a state of `started`, only the first one is recognized, and the other `started` Universal Agent rules are ignored. As with other rules in the rulebook, Universal Agent rules are ignored if the `condition` expression yields a value of `False`.

Standalone Machine Agent Rules

The AppDynamics Universal Agent uses a rulebook to determine which versions of the runtime agents should be installed and deployed. You manage the deployment, versioning, and status of Standalone Machine Agents on a monitored machine by adding Machine Agent rules to the Universal Agent rulebook. This page describes the syntax and usage for Machine Agent rules.

Define Standalone Machine Agent Rules

A `monitor` value of `machine` identifies a Machine Agent rule.

The valid values for the `state` property for a Machine Agent rule are:

- `installed`
- `started`

The started state both installs the agent (if not installed yet) and starts it. The `sim_enabled` property enables Server Visibility for the machine agent. When a value is not specified in the rule, the value defaults to `true`. See Server Visibility for details on licensing and functionality.

The other properties shown in the example, such as `name` and `comments`, are common across the agent types. See Universal Agent Rulebooks.

Example Standalone Machine Agent Rule

The rule containing `"name": "Machine monitor"` specifies the configuration for a Machine Agent.

```
[
{
    "name": "default-controller",
    "comments": "An example rule book with a rule to start a machine monitor",
    "config": {
    },
    "rules": [
        {
            "config": {
                "state": "started",
                "version": "4.5.0.0"
                "sim_enabled": ["true"|"false"]
            },
            "monitor": "machine",
            "comments": "This is a Machine rule",
            "condition": "True",
            "name": "Machine monitor"
        },
        {
            "name": "Universal Agent rule",
            "comments": "Universal Agent rule",
            "monitor": "universal",
            "config": {
                "version": "4.5.0.0",
                "state": "started"
            },
            "condition": "True"
       }
    ]
}
]
```

Java Agent Rules

The AppDynamics Universal Agent uses a rulebook to determine which versions of the runtime agents should be installed and deployed. You manage the deployment, versioning, and status of Java Agents on a monitored machine by adding Java Agent rules to the Universal Agent rulebook. This page describes the syntax and usage for those Java Agent rules.

Define Java Agent Rules

The `monitor` value of `java` in the Universal Agent rule identifies it as a Java Agent rule.

A Java Agent rule contains properties common to all Universal Agent rules, such as the name, description and monitor type of the agent. It also includes properties that are unique to Java Agents.

One example of a Java Agent rule is the following:

```
{
    "name": "Java Rule 1",
    "comments": "Java agent rule",
    "monitor": "java",
    "config":
    {
        "version": "4.5.0.0",
        "state": "started",
        "application_name": "My Application",
        "tier_name": "Commerce Tier",
        "node_name_prefix": "$network_hostname.Commerce",
        "deploy_cmd": ".*-Dnode_type=commerce.*",
        "do_not_deploy_cmd": ".*-Dproduction=true.*"
    }
}
```

The following 'Deployment Options' section provides more information on using the state property. See the Java Agent Rule Syntax Reference for information about the other fields in the example.

Deployment Options

Using the `state` property, you can direct the Universal Agent to deploy the Java Agent using one of the following approaches:

- Remote attach: Universal Agent installs the Java Agent and if `auto-java` is enabled, automatically deploys the Java Agent into the JVM at startup time. If the target JVM is already running, then the Java Agent tries to remotely attach itself to the JVM without forcing a restart, regardless of whether auto-java is enabled.
- At JVM startup: Universal Agent installs the Java Agent and if `auto-java` is enabled, deploys the Java Agent into the JVM at JVM startup. If the JVM is already running, the agent does not try to remotely attach to it, so a restart is required to deploy the Java Agent.
- Install manually: Universal Agent installs the Java Agent, but does not deploy it to a JVM. In this approach, you deploy to a JVM by manually adding the Java Agent to the JVM startup routine.

Attach the Java Agent into Running JVMs

Remote attach enables the Java Agent to load itself into a running JVM, without a JVM restart or modification of the JVM startup commands.

When using this approach, take note of the following points:

- The same requirements apply to using remote attach with the Universal Agent as apply when using it directly with the Java Agent. These requirements include the use of Oracle HotSpot JVM, for example. See Install the Java Agent for more information on these requirements.
- The user under which the Universal Agent runs, must adhere to the following conditions:
    - On Windows, the Universal Agent must run under the Local System account.
    - On Linux, the Universal Agent must run as one of the following users:
        - root
        - the same user that runs the JVMs
        - a user authorized to use sudo. See more information at Permissions for Running the Universal Agent.

Remote attach can affect the performance of the application during the attachment initialization process. Be sure to use this feature only after careful testing in a staging environment.

To attach the Java Agent into running JVMs:

1. Ensure that `tools.jar` is in the `JAVA_HOME/lib/ext` directory on the monitored hosts.
2. In the Java Agent rule of the Universal Agent rulebook, set the value of the `state` property to `attached`.

3. If the Universal Agent is not running as `root` or as the same user that runs the JVM, authorize the user for `sudo` privileges, as described in Permissions for Running the Universal Agent.
4. Specify conditions for attaching the Java Agent to your JVMs by using the `deploy_cmd` and `deploy_env_vars` properties in the Java Agent rule. For example, you can set conditions on installation based on startup commands that match Tomcat startup commands.
5. Save the rulebook. The Universal Agent applies the rule change the next time it reads the active configuration.

Install the Java Agent Automatically at JVM Startup

When you set the `state` to `started`, the Universal Agent examines each new process started on the host. If the process is a new JVM, the Universal Agent injects the javaagent argument into the startup arguments for the process. With this approach, you do not need to modify the Java startup script and it is supported on all JVMs types.

Since this affects the JVM startup process, JVMs that are already running will not be affected. Also, the Java Agent version must be 4.2.3 or later.

> AppDynamics Java Agent versions 4.2.6.x and 4.2.7.x include an issue that prevents the Universal Agent from being able to install those versions directly. The issue was addressed in Java Agent version 4.2.8.
>
> If you are using version 4.2.6.x or 4.2.7.x, you can work around this incompatibility by having the Universal Agent first install Java Agent 4.2.8, or a later version. You do not need to deploy the later version to your application; simply create a rule for it with a `state` value of `installed`, while specifying `attached` or `started` as the state for the 4.2.6.x or 4.2.7.x agent rules.

If you are testing this feature on Linux, keep in mind, this feature relies on the Linux `LD_PRELOAD` facility, along with environment variables set in the JVM startup environment. Command shells that are open before you have enabled `auto-java` may not have the environment variables properly set.

On Windows, the auto-java feature is analogous to the LD_PRELOAD feature on Linux. When the auto-java feature is enabled, the Universal Agent gains visibility to the command line arguments for any new JVM process being started and adds two new arguments to the command line as follows:

- `-javaagent:`<FQPN_`javaagent.jar`>, where <FQPN_javaagent.jar> is the fully-qualified path name of the `javaagent.jar` file, as installed by the Universal Agent. The addition of this command line argument causes the Java agent to be loaded into the new JVM
- `-Dappdynamics.ua.rule.dir=`<FQPN_UA_ `rule_ dir`>, where <FQPN_UA_ rule_ dir> is the fully-qualified path name of the directory containing the Universal Agent rulebook.

If the Java command line arguments already contain the `-javaagent` argument, referring to `javaagent.jar`, or `javaagent.jar` cannot be located, then the Universal Agent does not modify the Java command line.

To insert the Java Agent into the JVM at JVM start up:

1. Specify `started` as the value of the `state` property for the matching Java agent rule in the rulebook:
    a. Set the `state` property for the matching Java agent rule in the rulebook to started.
    b. When using the "started" (or auto-java) mode, it is likely that you will want to specify conditions for attaching the Java Agent to JVMs. For example, you can set conditions on installation based on startup commands that match Tomcat startup commands. Use the `deploy_cmd` and `deploy_env_vars` configuration attributes in the Java Agent rule for this type of control.
2. Enable the `auto-java` feature by executing the following command from a command prompt:

    ```
    ua --enable-auto-java
    ```

3. When you save the rulebook, the Universal Agent applies the rule change the next time it reads the active configuration.

See Universal Agent CLI for more details on the auto-java command line arguments.

Install the Java Agent Manually

Instead of relying on the Universal Agent to install the Java Agent into JVMs, you can modify the startup scripts for the JVM to inject the Java Agent. This is the traditional method for installing Java Agents, as described in Install the Java Agent. However, by using the Universal Agent, you can rely on it to manage the download and maintenance of the agent on the host.

The Universal Agent CLI tool lets you inspect the arguments for a given Java process. You can use this to determine any other command line options that need to be added in addition to the `-javaagent` option. Use the CLI command `ua --show-java-arguments` <`pid`> argument—where <`pid`> is the process ID of the target application JVM—to see what command line options are required.

To install the Java Agent but inject into JVMs manually:

1. Set the value of the `state` property for the matching Java agent rule in the rulebook to `installed`.
2. Add the Java Agent JAR file to the startup routine of the JVM, as described for your Java framework type in Install the Java Agent. The agent JAR should be the Java Agent located in the <`ua_home`>`/monitor/java directory`.

Java Agent Rule Matching

A rulebook can have multiple Java Agent rules. When applying rules, the Universal Agent applies the first rule that matches the JVM, ignoring other possibly matching rules.

The `condition` property also affects rule selection. If the evaluation of `condition` yields a value of `False`, the rule is not applied for a JVM.

Because a single rule can match multiple JVMs, you should use the auto-node naming feature to ensure that each matching JVM is given a unique node name. To do this, do not include the `node_name` property in the rule. Instead, either provide a `node_name_prefix` property to provide a node name prefix, or omit the `node_name_prefix` property to enable the Controller to generate a node name using the default prefix. In either case, a unique node name is generated for the JVM.

Java Agent Rule Syntax Reference

The syntax of the Java Agent rule is illustrated in the following rulebook entry:

```
{
    "name": "<name of rule>",
    "comments": "<comments>",
    "monitor": "java",
    "config":
    {
        "version": "<Java agent version>",
        "state": "installed | started | attached",
        "controller_host": "<name of host running controller>",
        "controller_port": "<controller primary port>",
        "account_name": "<controller account name>",
        "account_access_key": "<controller account access key>",
        "application_name": "<business application>",
        "tier_name": "<tier name>",
        "node_name": "<node name>",
        "node_name_prefix": "<node name prefix for auto-naming>",
        "deploy_cmd": "<regular expression matching Java command line>",
        "deploy_env_vars": "<regular expression matching JVM environmental variables>",
        "do_not_deploy_cmd": "<regular expression matching Java command line to be excluded>",
        "crash_age_threshold_days": "<prevents installation to JVMs with recent crash logs>",
                "runtime_directory": "...identifies the runtime directory for the Java agent...",
        "additional_props": "...additional properties to be passed to the JVM...",
        "kind": "...indicates whether or not IBM version of Java agent is to be installed..."
    },
    "condition": "<rule status>" "...boolean expression indicating status of this rule..."
}
```

The name, comments, monitor, and condition properties are common for all Universal Agent monitor rules, and have no special meaning for the Java Agent. See Universal Agent Rulebooks for information on these values.

The `config` object contains properties specific to the Java Agent. The following table describes the config properties.

Keyword	Description	Example
`version`	The version of the Java Agent to run.	`"version" : "4.5.0.0"`
`state`	Indicates how the Java Agent deploys itself into the target JVM. Also related to the auto-java feature. Valid values are installed, started and attached. For more information, see Deployment Options.	`"state": "started"`
`controller_host`	The name of the controller host where the Java Agent should connect. Optional. Can be inherited from the `controller_host` property defined in the header section of the rulebook or from the Controller identified in the `universalagent.yaml` file.	`"controller_host": "localhost"`
`controller_port`	The Contoller port number where the Java Agent should connect. Optional. Can be inherited from the `controller_host` property defined in the header section of the rulebook or from the Controller identified in the `universalagent.yaml` file.	`"controller_port": "8080"`
`account_name`	The account name that is passed to the Controller when the Java Agent attempts to connect. Optional. Can be inherited from the `controller_host` property defined in the header section of the rulebook or from the Controller identified in the `universalagent.yaml` file.	`"account_name": "customer1"`
`account_access_key`	The account access key that is passed to the Controller when the Java Agent attempts to connect. Optional. Can be inherited from the `controller_host` property defined in the header section of the rulebook or from the Controller identified in the `universalagent.yaml` file.	`"account_access_key": "APJC234bcd$123"`
`application_name`	The application name to be provided by the Java Agent when it connects to the controller.	`"application_name"`

	Optional. Can be inherited from the header section of the rulebook defined in a global `config` object or from the Controller identified in the `universalagent.yaml` file.	`: "ACME Book Store Application"`
`tier_name`	The tier name to be provided by the Java Agent when it connects to the controller. Optional. Can be inherited from the header section of the rulebook defined in a global `config` object or from the Controller identified in the `universalagent.yaml` file.	`"tier_name": "ECommerce Server"`
`node_name`	The node name to be provided by the Java Agent when it connects to the controller. Optional. If this property is missing and the `node_name_prefix` property is provided, then the `node_name_prefix` is used to name the node of the JVM. If both the `node_name` and the `node_name_prefix` properties are missing, then the auto-node name feature is used to name the node. The controller provides a unique name for the node, using the tier name as a prefix for the node name.	`"node_name": "Node_8000"`
`node_name_prefix`	Indicates that the Java Agent should use the "auto node name" feature to define a unique name dynamically for the JVM. The value of the "node_name_prefix" property specifies a prefix for the generated node name; the controller supplies a suffix to make the node name unique. If the "node_name" property is specified, then the "node_name_prefix" property is ignored, and the "node_name" property explicitly names the node. In the example Java Agent rule, "$network_hostname.Commerce" serves as a prefix. Notice that "$network_hostname" refers to a Universal Agent environment value, which the Universal Agent binds to a value at runtime. (Environment variable references always begin with '$'). If both the "node_name" or the "node_name_prefix" properties are missing, then the "auto node name" feature is used to name the node. The controller provides a unique name for the node, using the tier name as a prefix for the node name.	`"node_name_prefix": "Commerce"`
`unique_host_id`	The value of the "appdynamics.agent.uniqueHostId" property. Optional. Can be inherited from the header section of the rulebook (defined in a global "config" object) or from the Controller identified in the `universalagent.yaml` file.	`"unique_host_id": "cart-machine"`
`deploy_cmd`	A regular expression that identifies the JVMs that the rule applies to. This regular expression is matched against the command line arguments that are used to start the JVM. If the expression matches the command line, then this rule is considered a candidate for deploying the Java Agent within the JVM. If the `deploy_env_vars` property is also provided, then the value of that property must also match the set of environmental variables associated with the JVM. If the `do_not_deploy_cmd` property is also provided, then JVMs whose command line arguments match the `deploy_cmd` are not considered candidates for deployment if the command line also matches the value of the `do_not_deploy_cmd` property. In the example Java Agent rule, the `deploy-cmd` regular expression is looking for a Java property "`node_type=commerce`". If the command line for a starting JVM matches the regular expression, it is considered a candidate for the rule. (However, because the `do_not_deploy_cmd` property is also specified in this example, the rule is not applied to a JVM if it's command line matches the value of `deploy_cmd` but also matches the value of `do_not_deploy_cmd`.	`"deploy_cmd": ".*/TIER1TOMCAT/.*"`
`deploy_env_vars`	A regular expression that identifies the JVMs that the rule applies to. The set of environmental variables associated with the JVM is formed into a string, consisting of "key=value" pairs, delimited by blanks, and sorted alphabetically based on the key name. If the resulting string matches the regular expression defined by the "deploy_env_vars" property, then this rule is considered a candidate for deploying the Java Agent within the JVM. If this property is not provided, then the contents of the environmental variables are not used to select JVM(s) for deployment. If the "deploy_cmd" property is also provided, then the value of that property must also match the command line used to start the JVM. If the "do_not_deploy_cmd" property is also provided, then JVMs whose command line arguments match the "deploy_cmd" property are not considered candidates for deployment if the command line also matches the value of the "do_not_deploy_cmd" property.	`"deploy_env_vars": ".*SHOULD_APPLY=true.*"`
`do_not_deploy_cmd`	A regular expression that is used to exclude JVMs that the rule should not apply to. This regular expression is matched against the command line arguments being used to start the JVM. If the expression matches the command line, then this rule is explicitly excluded from being considered a candidate for deploying the Java Agent within the JVM. In the example Java Agent rule, the regular expression will match those Java command lines that contain "-Dproduction=true". JVMs whose command lines match this expression are excluded from deployment for this rule.	`"do_not_deploy_cmd": ".*-Ddo_not_apply=true.*"`
`crash_age_threshold_days`	Indicates that the Universal Agent should not remotely attach itself to a JVM where there are one or more recent Java crash log files. The value of this property represents the number of days since the crash log file was created in order to be considered 'recent'. For example, if a value of 10 is specified for this property, then only crash log files created in the last 10 days prevent the Universal Agent from attempting remote attach. Crash logs older than 10 days do not prevent the attempted attach.	

	If this property is not specified, then the Universal Agent does not look for recent Java crash log files, and does not use their presence to prevent remote attach attempts.	
`additional_props`	A comma-separated list of key=value pairs providing additional property definitions to be passed to the JVM. Passed to the JVM if the value of the **state** keyword is specified as either "started" or "attached".	`"additional_props": "appdynamic.agent.uniqueHostId=host"`
`kind`	Use this property when the IBM version of the Java agent is being deployed. The value should be "ibm". If the property is missing, then the non-IBM version of the agent is deployed.	`"kind": "ibm"`

Dynamic Configuration Values

Configuration settings can be set to static or dynamic values. Dynamic values may be bound to environment variables or system properties from the target application JVM itself. This lets you name nodes, tiers, or applications based on JVM-specific variables. This is particularly useful for elastic environments, in which node or tier identity cannot be known in advance.

To reference dynamic elements in rules, use the following format:

- For Java environmental variables, prefix the variable name with `$javaenv_`;
- For system properties, use the syntax `${property-name}`, where `property-name` is the name of the Java system property.

When determining whether or not a Java rule applies to a particular JVM, the Universal Agent extracts the values of each environment variable, and perform symbolic substitution into the config values in the rule for each `$javaenv_` reference. The Universal Agent does not resolve Java system properties within the configuration rule. Instead, the references are resolved by the Java Agent itself when it starts running within the JVM.

Example

The following shows a rule with sample dynamic values:

```
{
    "name": "Java rule",
    "comments": "...comments...",
    "monitor": "java",
    "config":
    {
        "version": "4.5.0.0",
        "state": "attached",
        "application_name": "$javaenv_APP_NAME",
        "tier_name": "${tierName}",
        "node_name": "$javaenv_APP_NAME-$javaenv_NODE_NAME",
        "deploy_cmd": "...regular expression matching Java command line..."
    },
    "condition": "...boolean expression indicating status of rule..."
}
```

In this example, several of the properties have values referencing either JVM environment variables or system properties:

- `application_name: $javaenv_APP_NAME` indicates that the value of the `application_name` config property is the value of the `APP_NAME` environmental variable within a JVM for which the rule applies.
- `tier_name: ${tierName}` indicates that the value of the `tier_name` config property is the value of the `tierName` system property within a JVM for which the rule applies.
- `node_name: $javaenv_NODE_NAME` indicates that the value of the `node_name` config property is the value of the `APP_NAME` environmental variable within a JVM for which the rule applies, concatenated with a '-', followed by the value of the `NODE_NAME` environmental variable within the JVM.

Suppose a JVM is started with the following commands:

```
export APP_NAME=MyApplication
export NODE_NAME=MyNode

java -DtierName=MyTier  -jar app.jar
```

If matched to the sample rule, the result would the following configuration bindings for the JVM:

- `"application_name": "MyApplication"`

- `"tier_name": "MyTier"`
- `"node_name": "MyApplication-MyNode"`

Notes on Dynamic Configuration

- References to Java system properties are not resolved by the Universal Agent when evaluating rule conditions, since the property values from the JVM are not available to the Universal Agent.
- For environment variable substitution, if a Java Agent is introduced into a JVM at startup time (as opposed to remote attach), the `javaagent.jar` file must be version 4.3 or later. Note that the Java Agent must be installed by the Universal Agent, but it does not need to be deployed—installing the Java Agent causes the supporting `javaagent.jar` file to be loaded into each JVM.

.NET Agent Rules

You can install, maintain, and run .NET Agents with the AppDynamics Universal Agent. The Universal Agent uses a rulebook to determine which versions of the .NET Agent should be installed and deployed. You need to define and configure the .NET Agent entry in the Universal Agent rulebook. See Universal Agent Rulebooks.

Define .NET Agent Rules

A `monitor` value of `dotnet` identifies a .NET Agent rule.

The valid values for the `state` property for a .NET Agent rule are:

- `installed`
- `started`

.NET Agent Rule Syntax

```
{
   "condition":"platform_family == 'windows'",
   "comments":"...comments...",
   "name":"...name of rule...",
   "monitor":"dotnet",
   "config":{
      "version":"....NET agent version...",
      "state":"installed | started",
      "controller_host":"...name of host running controller...",
      "controller_port":"...port number controller is listening on...",
      "account_name":"...controller account name...",
      "account_access_key":"controller account access key...",
      "controller_ssl_enabled":"true",
      "controller_tls12_enabled":"false",
      "controller_secure_enabled":"false",
      "config_xml":[
         "list of repositories where a paired config.xml can be found"
      ]
   }
}
```

The following properties are defined for the Universal Agent and common to all agent types. The values have no special meaning for the .NET agent:

- `name`: A string for quickly identifying the rule.
- `comments`: A long string describing the rule's purpose.
- `monitor`: Name of the targeting monitoring agent, for .NET Agent, must be dotnet.
- `condition`: The conditions for applying the rule. This consists of a Boolean expression where the operands are the values collected by the Environment Modules.

Keyword	Description	Example
`version`	The version of the .NET Agent to run.	`"version": "4.5.0.0"`
`state`	Indicates how the .NET Agent should deploy on the target machine. • "installed": downloads the specified version of the .NET Agent • "started": a version of the .NET Agent is installed and is active	`"state": "started"`
`controller_host`	Identifies the name of the Controller host where the agent should connect. This property is optional in the rule; it can be inherited from the controller_host property defined in the header section of the rulebook or from the Controller identified in the `universalagent.yaml` file.	"controller_host": "localhost"
`controller_port`	Identifies the port number of the Controller where the agent should connect. This property is optional in the rule; it can be inherited from the controller_host property defined in the header section of the rulebook or from the Controller identified in the `universalagent.yaml` file.	"controller_port": "8080"
`account_name`	Identifies the account name that is passed to the Controller when the agent attempts to connect. This property is optional in the rule; it can be inherited from the controller_host property defined in the header section of the rulebook or from the Controller identified in the `universalagent.yaml` file.	"account_name": "customer1"

`account_access_key`	Identifies the account access key that is passed to the Controller when the agent attempt to connect. This property is optional in the rule; it can be inherited from the controller_host property defined in the header section of the rulebook or from the Controller identified in the `universalagent.yaml` file.	"account_access_key": `"APJC234bcd$123"`
`controller_ssl_enabled`	SSL is enabled	"controller_ssl_enabled": "true"
`controller_enable_tls12`	tls12 is enabled	"controller_enable_tls12": "false"
`controller_secure`	Secure is enabled	"controller_secure": "false"
`config_xml`	Specifies, in JSON format, a list of repository URLs where `config.xml`, related scripts, and binaries are located. See Configuring the .NET Agent.	"config_xml": ["`repository`,repository,`...`"] where `repository=server URL`, such as `http://server/path` or `file://local/path`

Example .NET Agent Rule

In this .NET Agent rule example, the Controller and account settings are not shown because they are inherited from the global Universal Agent `config` or from the `universalagent.yaml` file.

```
{
   "condition":"platform_family == 'windows'",
   "comments":"This is an .NET Agent rule",
   "name":".NET Agent rule for Windows",
   "monitor":"dotnet",
   "config":{
      "state":"started",
      "version":"4.5.0.0",
      "config_xml":[
         "file:///C:/Tools/Repo"
      ]
   }
}
```

Configure the .NET Agent

The Universal Agent installs the .NET Agent and deploys the configuration file (`config.xml`) specified in the rulebook. The .NET Agent uses the config.xml file to determine which processes to instrument upon restart of the process. It is up to you to build the `config.xml` file and specify its location using the `config_xml` property in the .NET rule. A sample setup configuration file can be viewed in Unattended Installation for .NET.

For each .NET Agent version, you can specify a corresponding value for the `config.xml property`. This config file is retrieved from the repository specified by the `config_xml property`. The location can be local to the machine in a shared director or can be external.

Analytics Agent Rules

The AppDynamics Universal Agent uses a rulebook to determine which versions of the runtime agents should be installed and deployed. You can manage the deployment, versioning, and status of Analytics Agents collecting Transaction Analytics on a monitored machine by adding Analytics Agent rules to the Universal Agent rulebook. This page describes the syntax and usage for the Analytics Agent rules.

The supported functionality includes:

- Running the Analytics Agent as either an extension to the Standalone Machine Agent or in a standalone JVM
- Configuring the Analytics Agent property files, to run as either an extension to the Standalone Machine Agent or in a standalone JVM as indicated with the `mode` property
- Upgrading the standalone Analytics Agents to new versions
- Downgrading standalone Analytics Agents to prior versions
- Using the Analytics Agent to collect Transaction Analytics

You typically run the Analytics Agent in standalone mode if you are collecting only analytics data from the target machine. If you also need to collect hardware metrics or need to run other Machine Agent extensions, you would use the machine agent mode.

When deploying the Analytics Agent on Linux using the Universal Agent, Standalone mode is not supported, you must use machine-agent mode.

If you have an existing Machine Agent running outside of Universal Agent control and you want to install the Analytics Agent, you should either manage both with the Universal Agent, or manage each separately (not using the Universal Agent).

Define Analytics Agent Rules

A `monitor` value of `analytics` identifies an Analytics Agent rule.

The valid values for the `state` property for an Analytics Agent rule are:

- `installed`
- `started`

Analytics Agent Rules Syntax

The syntax for an Analytics Agent rulebook entry is as follows:

```
{
    "name": "...name of rule...",
    "comments": "...comments...",
    "monitor": "analytics",
    "config":
    {
        "mode": "machine-agent" | "standalone",
        "version": "...Analytics agent version...",
        "state": "installed" | "started",
        "controller_host": "...name of host running controller...",
        "controller_port": "...port number controller is listening on...",
        "account_name": "...controller account name...",
        "global_account_name": "...global account name...",
        "account_access_key": "controller account access key...",
        "deploy_in": [ "<machine-agent-rule-name>", ... ],
        "props": { "<prop-name-1>": "<prop-value-1>", "<prop-name-2>": "<prop-value-2>", ..., "<prop-name-n>":
"<prop-value-n>" },
        "vmoptions: [ "<vmoption-1>", "<vmoption-2>",..., "<vmoption-n>" ],
        "force_recycle": "true" | "false"
    },
    "condition": "...boolean expression indicating status of rule..."
}
```

The name, comments, monitor, and condition properties are common to all agent rules and have no special meaning for the Analytics Agent:

- `name`: A short string to identify the rule.
- `comments`: A long string describing the rule's purpose.
- `monitor`: Name of the target runtime agent (for Analytics Agent, must be "analytics").
- `condition`: Conditions for applying this rule. A condition consists of a Boolean expression where the operands are the values collected by the environment modules.

The properties within the `config` object have specific meanings for the Analytics Agent. They identify the following:

- Analytics Agent execution mode
- Property values for the Universal Agent to use to override the default values in the analytics property files
- Network location of the Controller that the agent connects with
- Whether or not changes to the Analytics Agent configuration should cause the hosting Machine Agent to be recycled.

Keyword	Description	Example
`mode`	Indicates whether the analytics agent is to run as a machine agent (machine-agent) or as a standalone JVM (standalone)	`"mode": "machine-agent"`
`version`	Identifies the version of the analytics agent to run. This is applicable only if the mode is "standalone". When running as a machine agent extension, the analytics agent uses the same version as the machine agent	`"version": "4.5.0.0"`
`state`	Indicates the state of the analytics agent: • `installed`: The analytics agent should be installed, but should not be started • `started`: The analytics agent should be installed and started	`"state": "started"`
`controller_host`	Identifies the name of the host that the controller the agent should connect to is running on. This property is optional in the rule; it can be inherited from the controller_host property defined in the header section of the rulebook or from the Controller identified in the `universalagent.yaml` file.	`"controller_host": "localhost"`
`controller_port`	Identifies the port number that the controller the agent should connect to is listening on. This property is optional in the rule; it can be inherited from the controller_host property defined in the header section of the rulebook or from the Controller identified in the `universalagent.yaml` file.	`"controller_port": "8080"`
`account_name`	Identifies the account name that is passed to the controller when the agent attempt to connect. This property is optional in the rule; it can be inherited from the controller_host property defined in the header section of the rulebook or from the Controller identified in the `universalagent.yaml` file.	`"account_name": "customer1"`
`global_account_name`	Identifies the global account name that is used to populate the `http.event.accountName` property in the `analytics-agent.properties` file. This property is optional in the rule; it can be inherited from the controller_host property defined in the header section of the rulebook or from the Controller identified in the `universalagent.yaml` file.	`"global_account_name": "customer1"`
`account_access_key`	`Identifies the account access key that is passed to the Controller when the agent attempts to connect. This property is optional in the rule. The account access key can be inherited from the controller_host` property defined in the header section of the rulebook `or from the Controller identified in the universalagent.yaml file.`	`"account_access_key": "AB1a2b3c4$123"`
`events_services_host`	Identifies the network name or address of the Events Service host. This value is used to populate the `http.event.endpoint` property in the `analytics-agent.properties` file. If this property is missing, then the value of the `"controller_host"` property is used.	`"event_services_host": "1.2.3.4"`
`events_services_port`	Identifies the port that the Events Service is listening on. This value is used to populate the `http.event.endpoint` property in the `analytics-agent.properties` file. If this value is missing, then the default value `9080` is used.	`"event_services_port": "444"`
`deploy_in`	Applies only when the mode is `machine-agent`. This property identifies the Machine Agent where the Analytics Agent runs as an extension. The value is a list of one or more strings, each of which contains the name of a Machine Agent rule within the Universal Agent rulebook. This argument is required if `"mode": "machine-agent"` is specified.	`"deploy_in" : [ "machine-agent-1" ]`
`props`	Contains one or more property definitions. Each property definition is added (or modified, if the property already exists) in the `conf/analytics-agent.properties` file for the analytics agent.	`"props": { "http.event.error.retryAttempts": "500" }`
`vmoptions`	Contains one or more JVM options definitions. Each JVM options is added to the `conf/analytics-agent.vmoptions` file	`"vmoptions" : [ "-verbose:class" ]`
`force_recycle`	If `true` is specified, then the Universal Agent restarts any Machine Agents hosting this Analytics Agent if any of the configuration arguments change. The default is `false`. Applicable only if `"mode": "machine-agent"` is specified.	`"force_recycle": "true"`

Example for Machine Agent Mode

This example specifies that the Analytics Agent should run as a Machine Agent extension. In this example:

- `mode: machine-agent` indicates machine-agent mode

- `state: "started"` indicates that the Analytics Agent should be started within the Machine Agent.
- `deploy_in:` Identifies the Machine Agents where the Analytics Agent should run.
- `props:` Defines a property that will be added to, or modified within, the `analytics-agent.properties` file of the Analytics Agent.
- `force_recycle:` A value of `true` indicates that the hosting Machine Agent should be recycled if the any of the config properties of the Analytic Agent change.

The following example illustrates these properties.

```
{
      "mode": "machine-agent",
      "state": "started",
      "deploy_in": [ "machine-agent-1" ],
      "props": { "http.event.error.retryAttempts": "500" },
      "force_recycle": true
}
```

Example for Standalone Mode

This example specifies that the Analytics Agent should run in a standalone JVM. In this example:

- `mode: standalone` indicates standalone mode.
- `state: started` indicates that the Analytics Agent should be started
- `props:` Defines a property that will be added to, or modified within, the `analytics-agent.properties` file of the Analytics Agent.

The following is an example of the Analytics Agent rules:

```
{
      "mode": "standalone",
      "version": "4.5.0.0",
      "state": "started",
      "props": { "http.event.error.retryAttempts": "500" }
}
```

Special Considerations for Standalone Mode

When you specify `"mode": "standalone"` for your Analytics Agent rule, there are some special considerations:

- Although a rulebook can contain multiple entries defining a standalone Analytics Agent, only one Analytics Agent runs at a time. When multiple rules are present that specify `"state": "started"`, the agent defined by the first rule is started. Analytics Agents identified by subsequent rules are not started. If other agents are currently running, they are stopped.
- If any configuration properties change for an Analytics Agent that is currently running, that agent is restarted.

Network Agent Rules

The Universal Agent can download, install, configure, and deploy the Network Agent. The Universal Agent uses a rulebook to determine which version of the Network Agent should be installed and deployed. You need to define and configure the Network Agent rule in the Universal Agent rulebook. See Universal Agent Rulebooks.

Define Network Agent Rules

The Network Agent is currently supported only on Linux. Therefore, Universal Agent support only works when running on a Linux machine. Installing the Network Agent using the Universal Agent requires elevated privileges for some commands. See Permissions for Running the Universal Agent.

A monitor value of `network` identifies a Network Agent rule.

Valid values for the Network Agent rule's `state` property are:

- `"installed":` Downloads and installs the Network Agent.
- `"started":` Starts the Network Agent. (Also installs the Network Agent if its not already installed.)
- `"stopped":` Stops the Network Agent.

Add to the Source Repository

When you place the Network Agent in the source repository, the installation distribution must have the following format:

```
network-<version>-<word_size>-<os>.zip
```

- `version`: Agent version. For example, `4.5.0`
- `word_size`: `32bit` or `64bit`
- `os`: `linux`

Network Agent Syntax

Network Agent rulebook is similar to the following.

```
{
    "name": "network",
    "comments": "Example Network Agent rulebook",
    "config": {
    },
    "rules": [
        {
            "name": "Network Agent rule",
            "comments": "Install and start the Network Agent",
            "monitor": "network",
            "condition": "True",
            "config": {
                "version": "4.5.0.0",
                "state": "started"
            }
       }
    ]
}
```

Dynamic Configuration Values

In rulebooks, you can set configurations with either static or dynamic values. Static values are set with literals, such as a literal string, whereas, dynamic values are based on environment variables. For most rulebook configurations, using static values is sufficient. For an elastic environment where the identity of nodes or tiers cannot be known in advance, however, you may want to use dynamic configuration values to name nodes, tiers, or applications.

This page describes the types of environment variables, how they are referenced in rulebooks, which agents have access to them, and how they are set. The last section provides a rulebook example using dynamic values for the configurations for rules for both the Java and Machine Agents.

Types of Environment Variables

The Universal Agent can access the three types of environment variables shown in this table to set dynamic configuration values.

Type	Syntax	Example	Agents with Access to Environment Variable
Java environment variables	`$javaenv_<variable_name>`	`$javaenv_APP_NAME`	Java Agent
Java system properties	`"${property-name}"`, where `property-name` is the name of the Java system property.	`${tierName}`	Java Agent
system environment variables	`$env_<variable_name>`	`$env_TIER_NAME`	Java Agent, Machine Agent

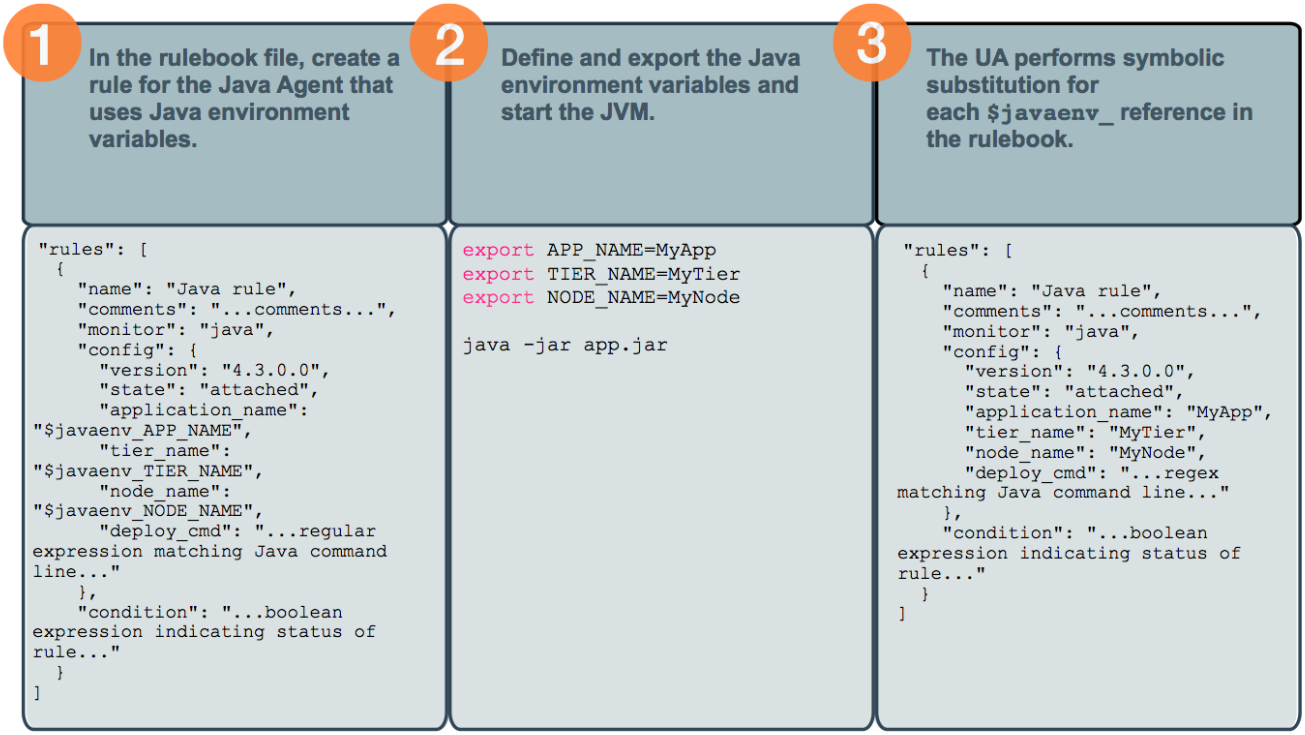
Define Environment Variables

The following sections describe the process for defining, setting, and applying different types of environment variables.

Java Environment Variables

To set Java environment variables, you define export environment variables and then start the JVM with the environment variables as command-line arguments. The JVM will then set the Java environment variables so that they are accessible to the Universal Agent. If the Java rule applies to a particular JVM, the Universal Agent then extracts the values of each environment variable and performs symbolic substitution into the config values in the rule for each `$javaenv_` reference.

The flow for setting and applying Java environment variables is illustrated in the diagram:

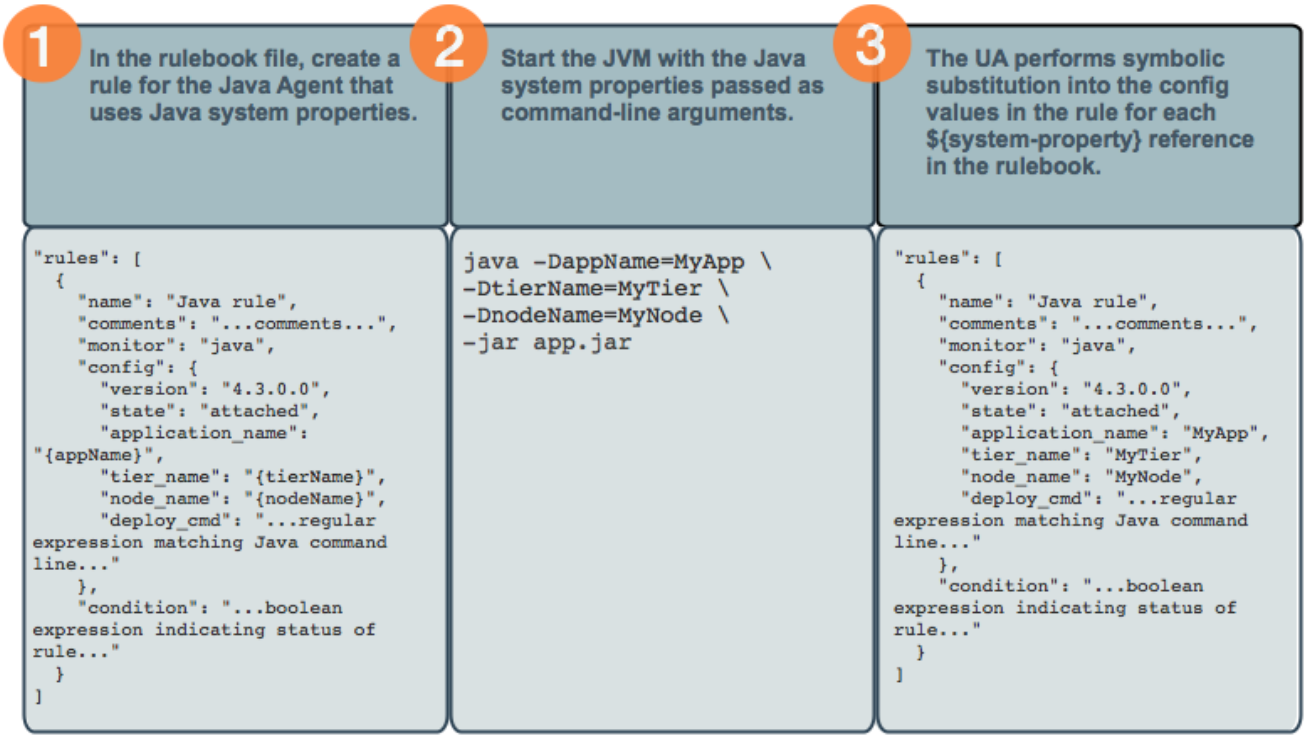


For environment variable substitution, if a Java Agent is introduced into a JVM at startup (as opposed to being remote attached), the `javaagent.jar` file must be version 4.3 or later. The 4.3 Java Agent must be installed by the Universal Agent, but it does not need to be deployed—simply installing the 4.3 Java Agent causes the supporting `javaagent.jar` file to be loaded into each JVM.

Java System Properties

As with Java environmental variables, you can also set Java system properties by passing command-line arguments when you start the JVM. In addition, you can programmatically set Java system properties. If the Java rule applies to a particular JVM, the Universal Agent extracts the values of each environment variable and performs symbolic substitution into the config values in the rule for each `${system-property}` reference.

The flow for setting and applying Java system properties is illustrated in the diagram below:



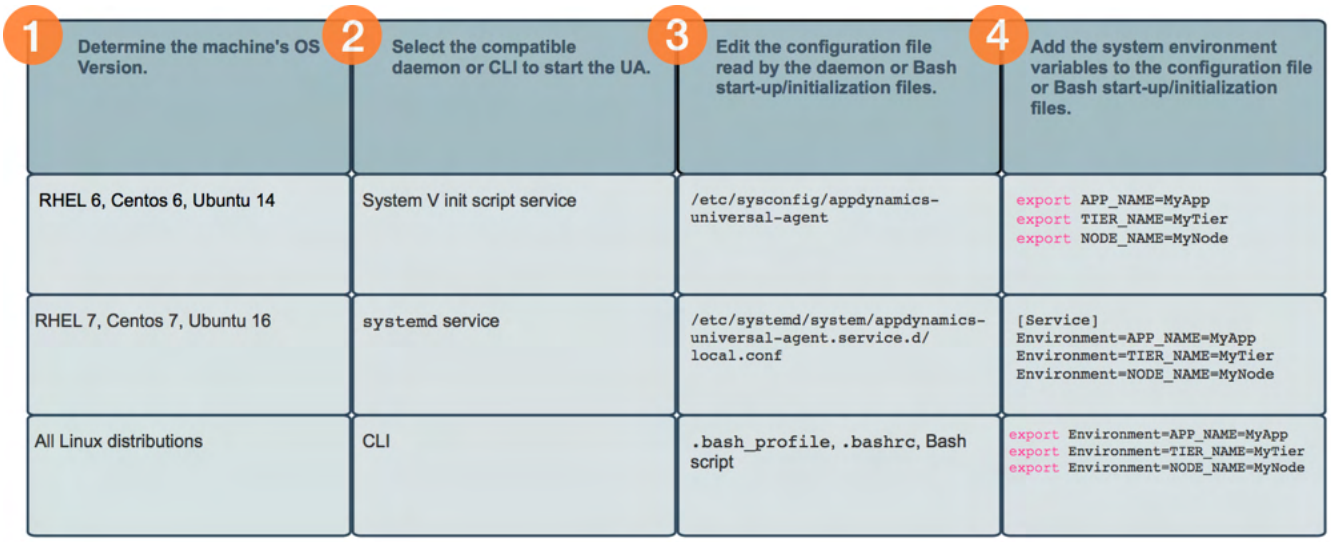
As mentioned above, you can also programmatically set a Java system property through the `System` class as shown below.

```
Properties props = System.getProperties();
props.setProperty("tierName", "MyTier");
```

System Environment Variables

The method of setting system environment variables and starting the Unified Agent depends on the version of the machine OS. The general process is to set system environment variables in a configuration file and then use the system-specific daemon or the CLI to start the Unified Agent. If a rule applies to either a particular JVM or system, the Universal Agent extracts the values of each system environment variable and performs symbolic substitution into the config values in the rule for each `$env_` reference.

The flow for setting and applying system environment variables is illustrated in the diagram:



1 Determine the machine's OS Version.	2 Select the compatible daemon or CLI to start the UA.	3 Edit the configuration file read by the daemon or Bash start-up/initialization files.	4 Add the system environment variables to the configuration file or Bash start-up/initialization files.

RHEL 6, Centos 6, Ubuntu 14	System V init script service	`/etc/sysconfig/appdynamics-universal-agent`	`export APP_NAME=MyApp`
			`export TIER_NAME=MyTier`
			`export NODE_NAME=MyNode`

RHEL 7, Centos 7, Ubuntu 16	`systemd` service	`/etc/systemd/system/appdynamics-universal-agent.service.d/local.conf`	`[Service]`
			`Environment=APP_NAME=MyApp`
			`Environment=TIER_NAME=MyTier`
			`Environment=NODE_NAME=MyNode`

All Linux distributions	CLI	`.bash_profile`, `.bashrc`, Bash script	`export Environment=APP_NAME=MyApp`
			`export Environment=TIER_NAME=MyTier`
			`export Environment=NODE_NAME=MyNode`

Example Rulebook with Dynamic Configuration Values

The following example rulebook has rules containing dynamic configuration values for both Java and Machine Agents. For more information about the dynamic configuration values, see the explanation following the example.

> The `env` and `javaenv` variables can be used in condition fields. In condition fields you should leave off the $ sign from the `env` and javaenv variables. Review the java rule in the rulebook that follows for an example.

```
{
  "name": "AD-Capital",
  "comments": "Agents for AD-Capital",
  "config": {},
  "rules": [
    {
      "name": "Java rule",
      "comments": "...comments...",
      "monitor": "java",
      "config":
      {
        "version": "4.5.0.0",
        "state": "attached",
        "application_name": "$env_APP_NAME",
        "tier_name": "${tierName}",
        "node_name": "$javaenv_APP_NAME-$javaver_NODE_NAME",
      },
      "condition": "env_DEPLOYMENT==\"PROD\""
    },
    {
      "name": "machine-4.5.0.0",
      "monitor": "machine",
      "comments": "Update Machine Agent to 4.5.0.0",
      "config": {
        "state": "started",
        "version": "4.5.0.0",
        "application_name": "$env_APP_NAME",
        "tier_name": "$env_TIER_NAME",
        "node_name": "$env_NODE_NAME"
      },
      "condition": "platform_system == '\''Linux'\'' and universalagent_version > '\''4.5.0'\''"
    },

    {
      "name": "Universal Agent rule",
      "monitor": "universal",
      "comments": "Update Universal Agent to 4.5.0.0",
      "config": {
        "state": "started",
        "version": "4.5.0.0"
      },
      "condition": "True"
    }
  ]
}
```

In the previous rulebook example, the rule for the Java Agent contains the following attributes having values referencing JVM environment variables, Java system properties, and system environment variables:

- `"application_name": "$env_APP_NAME":` Indicates that the value of the `application_name` config attribute is the value of the `APP_NAME` environment variable set by the system (daemon/CLI) for which the rule applies.
- `"tier_name": "${tierName}":` Indicates that the value of the `tier_name` config attribute is the value of the `tierName` system property within a JVM for which the rule applies.
- `"node_name": "$javaenv_APP_NAME-$javaver_NODE_NAME":` Indicates that the value of the `node_name` config attribute is the value of the `APP_NAME` environment variable within a JVM for which the rule applies, concatenated with a `'-'`, followed by the value of the `NODE_NAME` environment variable within the JVM.
- "`env_DEPLOYMENT`": This variable is used in the `condition` field. This checks whether there is an environment variable `DEPLOYMENT` set with a value equal to `PROD`. Note that although the `env` and javaenv variables can be used in condition fields, the format is different. You should not specify the $ sign.

The rule for the Machine Agent contains the following attributes having values referencing system environment variables:

- `"application_name":"$env_APP_NAME":` Indicates that the value of the `application_name` config attribute is the value of the `APP_NAME` environment variable set by the system (daemon/CLI) when the Universal Agent is started, for which the rule applies.
- `"tier_name": "$env_TIER_NAME":` Indicates that the value of the `tier_name` config attribute is the value of the `TIER_NAME` environment variable set by the system (daemon/CLI) when the Universal Agent is started, for which the rule applies.
- `"node_name": "$env_NODE_NAME":` Indicates that the value of the `node_name` config attribute is the value of the `NODE_NAME` environment variable set by the system (daemon/CLI) when the Universal Agent is started, for which the rule applies.

Rulebook Configuration Templates

Configuration templates enable you to define a set of default configuration values that apply across a set of rulebooks. The configuration templates are stored on the AppDynamics Controller and used to update the rulebooks on machines where the Universal Agent manages the runtime agents. The use of configuration templates is optional, however, using them can reduce the size of your rulebooks and simplify rulebook management across a set of machines.

Rulebook Background

The rulebook for each Universal Agent instance uses a JSON object called `config` to define a set of key-value pairs containing configuration values that are specific for the agent that is being monitored. These `config` objects can be large and in many cases may contain redundant fields across numerous runtime agents that are being managed by a single Universal Agent instance.

Configuration templates implement a JSON object that defines a basic, default configuration for your runtime agents. The template object is a set of key-value pairs that can be referenced in your rulebooks at both the header level (applying globally to all runtime agents in the rulebook) and in agent-specific rules.

The configuration template is applied to the rulebook first, and properties in the `config` object in the rulebooks can override the default values if needed for specific use cases.

Users with the `Configure Universal Agent` permission can create and update configuration templates using the REST APIs. See Universal Agent REST APIs.

- Configuration templates can be used only when running the Universal Agent in controller mode.
- The rulebooks reference applicable configuration templates using the `configEntity` property.
- Individual rules in your rulebook can override values defined in the templates using the rule-level `config` object.
- When the Universal Agent processes a rule that contains a `configEntity` property, a request is sent to the Controller for the content of the specified template. The template values are then pushed to the Universal Agent, where they are applied to the rulebook.
- The Universal Agent reports the version ID of each rulebook and template that was sent in the prior cycle back to its Controller. If necessary, the Controller then sends more recent versions of the rulebooks and templates back to the Universal Agent.

Workflows for Using Configuration Templates

Knowledge and understanding of the Universal Agent rulebook structure is a prerequisite to understanding and using configuration templates. See Universal Agent Rulebooks before using configuration templates.

Specify Global Configuration Values in a Template

When you have common configuration values across different rulebooks, instead of repeating all the fields in a header config section in each separate rulebook, you can create a configuration template that contains the common values and then add a reference to the template in the relevant rulebooks.

This scenario uses the Configuration Template to specify configuration values that apply across multiple rulebooks. The configuration values in the template will be incorporated into the referring rulebook.

1. Create the configuration template using the Configuration Template `PUT` API. The following tabs show a sample command and the response format.
2. Create a rulebook that refers to the configuration template using the rulebook `PUT` API and the `configEntity` keyword. The following tabs show a sample command and the response format.

This scenario is the equivalent of having the following config in the rulebook:

```
"config": {
            "controller_host":"host.controller.com",
            "controller_port":"8080",
            "account_name":"customer1",
            "account_access_key":"Acces$$Key"
           }
```

If both `config` and `configEntity` are provided in a rulebook, the resulting configuration is computed by over-riding `configEntity` fields with `config` fields.

For example, if the rulebook request shown in step 2 above, contains the config shown here in Config section and also specifies the "`configEntity`": "`controllerConfig`" property, the result is equivalent to what is shown in Config block:

Placeholder for Rule Configurations in Rulebooks

Configuration templates can also be used as placeholders for individual rule configurations. This means a "`configEntity`":*<configuration_template_name>* can be used to replace the "`config`" key-value pairs.

1. Create the configuration template. The tabs show a sample command and the response format.
2. Create or update a rulebook that refers to the template. This example updates a previously created rulebook. You can use the same procedure to create a new rulebook with `configEntity` reference. The tabs show a sample command and the response format.

Reuse Configuration Templates

The primary use of templates is for reuse across multiple rulebooks (or even rules). In this scenario, we create a rulebook with different controller settings but the same rule configuration as the Java rule in the previous example.

1. Create the Controller configuration template.
2. Create a rulebook referring to `OtherControllerConfig` and sharing `javamonitorconfiguration.`
3. View the shared configuration `referredRuleBooks` field by doing a `GET controller/universalagent/v1/user/configurations/javamonitorconfiguration.`

Universal Agent REST APIs

The Universal Agent API is a Controller REST API that enables you to monitor and manage a Universal Agent deployment programmatically.

The Universal Agent API enables you to act on Universal Agent groups, individual Universal Agents, rulebooks, and Universal Agent events.

Permissions

The following RBAC permissions and roles authorize the use of the Universal Agent REST APIs.

- Permissions
  - Configure Universal Agent: Allows all `PUT` and `DELETE` APIs
  - View Universal Agent: Allows all `GET` APIs
- Roles
  - Universal Agent Administrator with both view and configure permissions
  - Universal Agent User with view permission

Universal Agent Administrator and Universal Agent User roles are added to all new and existing accounts. Also, Universal Agent Administrator and Universal Agent User roles are added to users who have *Account Administrator* role. Configure Universal Agent and View Universal Agent permissions are added to *Account Administrator* role of all accounts.

See Roles and Permissions for AppDynamics permissions and roles.

Using Environment Data

Using the API calls described in Get Complete Information for Universal Agents, you can get information about the running environment for each Universal Agent and the runtime agents. You can then use the values to populate rulebook properties, such as tier and application names. See Dynamic Configuration Values.

To read environment variable data from JVM environments, the Universal Agent needs to have sufficient permissions. See more information about how to provision the Universal Agent with sudo access if necessary in Permissions for Running the Universal Agent.

As an API response, the environment data is made up of the following name/value pairs:

- Information about the underlying platform:
  - `platform_machine`: Machine type. For example, `i386`
  - `platform_processor`: Processor name. For example, `amdk6`
  - platform_release: System/OS release. For example, `2.2.0` or `NT`
  - platform_system: System/OS name. For example, `Linux` or `Windows`
  - platform_version: System release version. For example, `Darwin Kernel Version 14.4.0`
- Network-related information:
  - `hostname`: Fully qualified domain name
  - `ip_addresses`: List of IP addresses for machines where the Universal Agent is running
  - `mac_addresses`: List of MAC addresses for machines where the Universal Agent is running
- Names and values of each environment variable. The keys are the name of each environment variable, prefixed with env_. For example, if the environment contains the variables HOME and SHELL, then this section may look like:
  - `env_HOME: /Users/john.smith`
  - `env_SHELL: /bin/bash`
- Time information:
  - `time_utc`: Current UTC date and time in ISO 8601 format
- Information about the Universal Agent
  - `universalagent_version`: Current version. For example, 4.5.0.0.
  - `universalagent_build`: Build number
- Information about the Java Agent:
  - `java_targets`: List of running Java processes on the machine. This is organized as a map of process IDs (PID) to process command line
  - `java_installs`: Absolute paths of the Java runtime agents installed by the Universal Agent. The path is organized as nested maps, using the app/tier/node name as the key. For example:

```
"java_installs": {
    "MyApp": {
        "MyTier": {
            "MyNode1": "/path/to/java/app/monitor/1",
            "MyNode2": "/path/to/java/app/monitor/2",
        }
    },
    "MyApp2": {
        "MyTier2a": {
            "Node": “/path/to/java/app/monitor/3"
        },
        "MyTier2b": {
            "Node": “/path/to/java/app/monitor/4"
        },
        "null": {
            "null": "/path/to/java/app/monitor/that/only/had/app/specified/in/controller/info/xml"
        }
    }
}
```

- Information about the Machine Agent
    - `machine_installs`: List of absolute paths to Machine Agents installed by the Universal Agent
    - `machine_starts`: List of absolute paths to the Machine Agents started by the Universal Agent
- Information about .NET Agent
    - `dotnet_frameworks`: List of the installed .NET frameworks
    - `dotnet_version`: .NET Agent version, if installed
- Information about the Network Agent
    - none
- Information about Analytics Agent
    - none

API Rate and Total Count Limits

The following rate limits apply by default:

- Maximum 5000 agent registrations per minute per account
- Maximum 5000 event registrations per minute per account
- Maximum 500 user requests per minute per account

The following total count limits apply by default:

- Maximum 5000 agents per account
- Maximum 500 rulebooks per account
- Maximum 500 groups per account

For on-premises Controllers, you can configure rate and total count limits from the Controller Administration Console.

Get Complete Information for Universal Agents

Returns information about running and previously running Universal Agents. When used with the `groups` query parameter, this API returns information only for the agents under the specified groups.

```
GET controller/universalagent/v1/user/agents?agents=<value1, value2>
GET /controller/universalagent/v1/user/agents?agents=<value1, value2>&groups=<value>
GET /controller/universalagent/v1/user/agents?groups=<value1, value2>
```

Query Parameters

Parameter Name	Value	Required
agents	A comma-delimited string of Universal Agent names. When present, returns the relevant matching subset of agents.	No
groups	A comma-delimited string of group names. When present, returns only agents under the specified groups.	No

Example Command

```
curl -i -X GET -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/agents
```

Response Format

```
{
    "agent1": {
        "version": <string>,
        "ruleBookName": <string>,
        "environment": {
            "key1": <object>,
            ...
        }
    },
    ...
}
```

Response Fields

- `agent1`: Name of the Universal Agent
- `version`: Property specifying the version of the Universal Agent
- `ruleBookName`: Property specifying the name of the rulebook of the Universal Agent
- `environment`: Object holding the environment data collected by the Environment Modules

Get Summary Information for Universal Agents

View summary information about all running Universal Agents. The environment data is suppressed. When used with the `groups query` parameter, this API returns information only for the agents under the specified groups.

```
GET /controller/universalagent/v1/user/agents/summary?agents=<value>
GET /controller/universalagent/v1/user/agents/summary?agents=<value1, value2>&groups=<value>
GET /controller/universalagent/v1/user/agents/summary?groups=<value1, value2>
```

Query Parameters

Parameter Name	Value	Required
`agents`	A comma-delimited string of Universal Agent names. When present, the relevant matching subset of agents is returned.	No
`groups`	A comma-delimited string of group names. When present, returns only agents under the specified groups.	No

Example Command

```
curl -i -X GET -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/agents/summary
```

Response Format

```
{
    "agent1": {
        "version": <string>,
        "ruleBookName": <string>
    },
    ...
}
```

Response Fields

- `agent1`: Name of the Universal Agent
- `version`: Version of the Universal Agent
- `ruleBookName`: Name of the rulebook of the Universal Agent

Get Universal Agent By Name

View details for the Universal Agent with a specified name.

```
GET /controller/universalagent/v1/user/agents/byName/<name>
```

Path Parameters

Parameter Name	Value	Required
`name`	Name of the Universal Agent. For example, `agent1.`	Yes

Example Command

```
curl -i -X GET -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/agents/byName/agent1
```

Response Format

```
{
    "version": <string>,
    "ruleBookName": <string>,
    "environment": {
        "key1": <object>,
        ...
    }
}
```

Response Fields

- `agent1`: Name of the Universal Agent
- `version`: Version of the Universal Agent
- `ruleBookName`: Name of the current rulebook of the Universal Agent

Delete Universal Agent by Name

Delete an agent by name.

```
DELETE /controller/universalagent/v1/user/agents/byName/<name>
```

Deleting an agent also deletes events associated with it.

Path Parameters

Parameter Name	Value	Required
`name`	Name of the Universal Agent	Yes

Example Command

```
curl -i -X DELETE -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/agents/byName/agent1
```

Create or Update a Group

Universal Agent groups are a logical way of grouping different Universal Agents that are running on different machines. You can add different Universal Agents to a group and then add a common rulebook to that group. All Universal Agents in the group execute the same set of rules (that apply to their environment). For details on groups: see the section 'Rulebook Strategies' in Universal Agent Rulebooks

Create the group. If the group exists, it is updated.

```
PUT /controller/universalagent/v1/user/groups/byName/<name>
```

Path Parameters

Parameter Name	Description	Required
`name`	Name of the group. In the example that follows, `"name": ""` is overridden by the path parameter `name`	Yes

Example Command

```
curl -i -X PUT -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
-H 'Accept:application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/groups/byName/group1
-d '{"name":"","comments":"This is group1"}'
```

Response Format

```
{
    “name": <string>,
    “comments": <string>
}
```

Add Universal Agent to a Group

Add the specified Universal Agent to the specified group.

```
PUT /controller/universalagent/v1/user/agents/membership/<agentName>/groups/<groupName>
```

Path Parameters

Parameter Name	Value	Required
`agentName`	Name of the Universal Agent	Yes
`groupName`	Group name. For example: `group1`	Yes

Example Command

```
curl -i -X PUT -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
-H 'Accept:application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/agents/membership/agent1/groups/group1
```

Response Format

```
{
    "agent1": {
        "version": <string>,
        "ruleBookName": <string>,
        "environment": {
            "key1": <object>,
            ...
        }
    },
    ...
}
```

Delete Universal Agent From a Group

Delete the specified Universal Agent from the specified group.

```
DELETE /controller/universalagent/v1/user/agents/membership/<agentName>/groups/<groupName>
```

Path Parameters

Parameter Name	Value	Required
`agentName`	Name of the Universal Agent. For example, `agent1`	Yes
`groupName`	Group name. For example, `group1`	Yes

Example Command

```
curl -i -X DELETE -su '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
-H 'Accept:application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/agents/membership/agent1/groups/group1
```

Move Universal Agent to Multiple Groups

Universal Agent is added to multiple groups and removed from previous groups.

```
PUT /controller/universalagent/v1/user/agents/groupsMembership/<agentName>
```

Path Parameters

Parameter Name	Value	Required
`agentName`	Name of the Universal Agent. For example, `agent1`	Yes
`groupName`	A list of group names formatted as JSON data. For example: `-d '[{"groupName":"group1"},{"groupName":"group2"}]'`	

Example Command

```
curl -i -X PUT -su '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
-H 'Accept:application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/agents/groupsMembership/agent1
-d '[{"groupName":"group1"},{"groupName":"group2"}]'
```

Response Format

```
{
    "agent1": {
        "version": <string>,
        "ruleBookName": <string>,
        "environment": {
            "key1": <object>,
            ...
        }
    },
    ...
}
```

Get a Group By Name

Return information for the named group.

```
GET /controller/universalagent/v1/user/groups/byName/<name>
```

Path Parameters

Parameter Name	Description	Required
`name`	Name of the group. For example, `group1`	Yes

```
curl -i -X GET -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/groups/byName/group1
```

Response Format

```
{
    "name": <string>,
    "comments": <string>
}
```

Get Multiple Groups

Get all groups or specific groups, groups having specific agents or groups having specific rulebooks.

```
GET /controller/universalagent/v1/user/groups?groups=group1,group2&agents=agent1,agent2&rulebooks=rulebook1
```

Query Parameters

Parameter Name	Description	Required
`groups`	Use to get specific groups, such as /controller/universalagent/v1/user/groups?groups=group1,group2	No
`agents`	Use to get groups having specific agents.	No
`rulebooks`	Use to get groups specific rulebooks.	No

Example Command

```
curl -i -X GET -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/groups
```

Response Format

```
{
    "name": <string>,
    "comments": <string>
},
{
    "name": <string>,
    "comments": <string>
}
```

Delete a Group

Deletes the group. Deletion of the default group named `default` is not allowed.

Format

DELETE /controller/universalagent/v1/user/groups/byName/<name>

Path Parameters

Parameter Name	Description	Required
`name`	Name of the group, for example, `group1`.	Yes

Example Command

```
curl -i -X DELETE -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/groups/byName/group1
```

Create or Update a Rulebook

Create a rulebook. If a rulebook with "`name`" already exists, it is updated.

Format

PUT /controller/universalagent/v1/user/rulebooks/byName/<name>

Path Parameters

Parameter Name	Value	Required
`name`	Name of the group. This path parameter overrides `"name": "rulebook1"`	Yes

Example Command

```
curl -i -X PUT -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
-H 'Accept:application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/rulebooks/byName/rulebook1
-d ' {
 "name": "rulebook1",
 "comments": "An example rulebook with a rule to start a machine agent",
 "config": {
     "controller_host": "localhost",
     "controller_port": "8080",
     "account_name": "",
     "account_access_key": ""
 },
 "rules": [
     {
         "name": "Example rule to start a 4.5.0.0 machine agent",
         "comments": "Enable by changing 'condition' to 'True'. Controller information is inherited from the
'config' section above. The machine agent will be installed in <universal_agent_dir>/monitor/machine/4.5/...",
         "monitor": "machine",
         "config": {
             "version": "4.5.0.0",
             "state": "started"
         },
         "condition": "True"
     }
 ]
}'
```

Response Format

```
{
    "name": <string>
    "comments": <string>,
    "config": {
        "key1": <object>
        ...
    },
    "rules": [
        {
            "name": <string>,
            "comments": <string>,
            "monitor": <string>,
            "config": {
                "key1": <object>
                ...
            },
            "condition": <string>
        },
        ...
    ]
}
```

Response Fields

- name: Name of the rulebook
- comments: Comments describing the rulebook
- config: Optional set of name-value configuration settings inherited by each rule or specified in a specific rule
- rules: Object with a list of rules in the rulebook

Get Rulebooks

View specific rulebooks by name or group or view a list of all rulebooks.

```
GET /controller/universalagent/v1/user/rulebooks
GET /controller/universalagent/v1/user/rulebooks/byName/<name>
GET /controller/universalagent/v1/user/rulebooks/current/<groupName>
```

Returns the name, comments, and the configuration rules.

Path Parameters

Parameter Name	Value	Required
name	Name of the rulebook	Yes
group_name	Name of the group	Yes

Example Command for a List of All Rulebooks

```
curl -i -X GET -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/rulebooks
```

Response Format

This version returns a list of rulebooks similar to the following:

```
[
    {
        "name": <string>,
        "comments": <string>,
        "config": {
            "key1": <object>
            ...
        },
        "rules": [
            {
                "name": <string>,
                "comments": <string>,
                "monitor": <string>,
                "config": {
                    "key1": <object>,
                    ...
                },
                "condition": <string>
            },
            ...
        ]
    },
    ...
]
```

Example Command for Specific Rulebook by Name

```
curl -i -X GET -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/rulebooks/byName/rulebook1
```

Example Command for Rulebooks in a Group

```
curl -i -X GET -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/rulebooks/current/group1
```

Response Format

The versions using `name` and `groupName` return a single rulebook similar to the following:

```
{
        "name": <string>,
        "comments": <string>,
        "config": {
            "key1": <object>
            ...
        },
        "rules": [
            {
                "name": <string>,
                "comments": <string>,
                "monitor": <string>,
                "config": {
                    "key1": <object>,
                    ...
                },
                "condition": <string>
            },
            ...
        ]
    }
```

Response Fields

- `name`: Name of the rulebook
- `comments`: Comments describing the rulebook
- `config`: Optional set of name-value configuration settings inherited by each rule or specified in a specific rule
- `rules`: Object with a list of rules in the rulebook

Add a Rulebook to a Group

Indicate which rulebook should be used by the Universal Agents in the group indicated by `groupName.`

```
PUT /controller/universalagent/v1/user/rulebooks/current/<groupName>
```

Path Parameters

Parameter Name	Value	Required
`groupName`	name of the group	Yes

Example Command

```
curl -i -X PUT -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
-H 'Accept:application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/rulebooks/current/group1
-d '{"ruleBookName":"rulebook1"}'
```

Response Format

```
{
    "name": <string>
    "comments": <string>,
    "config": {
        "key1": <object>
        ...
    },
    "rules": [
        {
            "name": <string>,
            "comments": <string>,
            "monitor": <string>,
            "config": {
                "key1": <object>
                ...
            },
            "condition": <string>
        },
        ...
    ]
}
```

Response Fields

- `name`: The name of the rulebook
- `comments`: Comments describing the rulebook
- `config`: Optional set of name-value configuration settings inherited by each rule or specified in a specific rule
- `rules`: Object with a list of rules for each agent in the rulebook

Get a Rulebook Associated with a Group

View the name of the current rulebook for the specified group of Universal Agents.

```
GET /universalagent/v1/user/rulebooks/current/<groupName>
```

Path Parameters

Parameter Name	Value	Required
`groupName`	The name of the group.	Yes

Example Command

```
 curl -i -X GET -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/rulebooks/current/group1
```

Response Format

```
{
    "name": <string>
    "comments": <string>,
    "config": {
        "key1": <object>
        ...
    },
    "rules": [
        {
            "name": <string>,
            "comments": <string>,
            "monitor": <string>,
            "config": {
                "key1": <object>
                ...
            },
            "condition": <string>
        },
        ...
    ]
}
```

Response Fields

- `name`: Name of the rulebook
- `comments`: Comments describing the rulebook
- `config`: Optional set of name-value configuration settings inherited by each rule or specified in a specific rule
- `rules`: Section for a list of rules in the rulebook

Delete a Rulebook By Name

Remove the rulebook with the specified name.

```
DELETE /controller/universalagent/v1/user/rulebooks/byName/<name>
```

Deleting a rulebook also removes it from any group association. Deletion of the default rulebook named "default-controller" is not allowed.

Path Parameters

Parameter Name	Value	Required
`name`	name of the rulebook	Yes

Example Command

```
curl -i -X DELETE -u '<user_name>@<account_name>:<password>'
-H 'Content-type: application/json'
http://<controller_host>:8080/controller/universalagent/v1/user/rulebooks/byName/rulebook1
```

Delete a Rulebook From a Group

Remove a rulebook for Universal Agents by group.

```
DELETE /controller/universalagent/v1/user/rulebooks/current/<groupName>
```

Universal Agents without a rulebook execute local rulebooks (thus allowing manual rulebook creation). Deletion of the default rulebook named "default-controller" is not allowed.

Path Parameters

Parameter Name	Value	Required

groupName	name of the group	Yes

Example Command

```
curl -i -X DELETE -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/rulebooks/current/group1
```

Get All Events

View events that have occurred across all the Universal Agents. When the query parameters are present, the relevant matching subset of events is returned. By default, all events are shown up to the maximum limit of 600 events.

```
GET /controller/universalagent/v1/user/events?agentIds=<value1,value2>&eventTypes=<value1,
value2>&subTypes=<value>&timeRange=<value>
```

Query Parameters

Parameter Name	Value	Required
agentIds	A comma-delimited strings of Universal Agent names. When present, events for the relevant matching subset of agents is returned.	No
eventTypes	A comma-delimited string of event types. When present, returns only relevant events. The valid event types are: • UNIVERSAL_AGENT_STARTUP • UNIVERSAL_AGENT_SHUTDOWN • UNIVERSAL_AGENT_EXECUTE_RULE	No
subTypes	The success or error code. The valid subtypes are: • Success • Error	No
timeRange	Time range specifier string as used in other parts of the Controller. For example: • last_1_hour.BEFORE_NOW.-1.1424287621109.60 • last_5_minutes.BEFORE_NOW.-1.-1.5	No

Example Command

```
curl -i -X GET -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/events
```

Response Format

```
[
 {
"id":<long>,
"version":<long>,
"eventType":<string>,
"eventTime":<Date>,
"severity":<string>,
"eventSummary":<string>,
"affectedEntities":[
   {
     "id":<long>,
     "version":<long>,
 "entityType":<string>,
     "entityId":<long>,
     "prettyToString":<string>
   }...,
],

"correlationKeys":[],
"properties":<string>,
"markedAsRead":<boolean>,
"markedAsResolved":<boolean>,
"archived":<boolean>,
"endTime":<long>,
"guid":<string>,
"subType":<string>,
"triggeredEntity":{
    "id":<long>,
    "version":<long>,
 "entityType":<string>,
    "entityId":<long>,
   "prettyToString":<string>
   }
},...
]
```

Response Fields

- `id`: ID of the event
- `version`: Version of the event
- `eventType`: Type of the event
- `eventTime`: Time when the event was generated
- `severity`: Can be INFO or ERROR
- eventSummary: Brief description of the event
  affectedEntities:
    - `entityType`: A string representing universal agent, UNIVERSAL_AGENT
    - `entityId`: ID of the Universal Agent
- `correlationKeys`: Not applicable for Universal Agent
- `properties`: Not applicable for Universal Agent
- markedAsRead: Not applicable for Universal Agent
- `markedAsResolved`: Not applicable for Universal Agent
- `archived`: Not applicable for Universal Agent
- `endTime`: Not applicable for Universal Agent
- guid: Not applicable for Universal Agent
- `subtype`: Success or error code
- triggeredEntity:
    - `entityType`: A string representing universal agent: UNIVERSAL_AGENT
    - `entityId`: ID of the Universal Agent

Get Event Details

Get event details for all events. The number of events that can be returned is limited to 600.

```
GET /controller/universalagent/v1/user/events/details&timeRange=<value>
```

Query Parameters

Parameter Name	Value	Required
timeRange	Time range specifier string as used in other parts of the Controller. For example: • last_1_hour.BEFORE_NOW.-1.1424287621109.60 • last_5_minutes.BEFORE_NOW.-1.-1.5	

Example Command

```
curl -i -X GET -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/events/details?timeRange=last_5_minutes.
BEFORE_NOW.-1.-1.5
```

Response Format

```
[
  {
   "eventDetails": [
       {
        "id":<long>,
        "version":<long>,
        "name":<string>,
        "value":<string>
       }
    ]
    eventProperties: [],
    userComments: [ ],
    eventId: <long>
  },...
]
```

Response Fields

- `eventId`: ID of the event
- `version`: Version of the event
- `name`: Details of the event
- `value`: Not applicable for Universal Agent

Get Event Details By Event ID

Get details for a specific event by event id.

```
GET /controller/universalagent/v1/user/events/detailsByEventId/<eventId>
```

Path Parameters

Parameter Name	Value	Required
eventId	ID of the event	Yes

Example Command

```
curl -i -X GET -u '<userName>@<accountName>:<password>'
-H 'Content-type: application/json'
http://<controller-host>:8080/controller/universalagent/v1/user/events/detailsByEventId/1
```

Response Format

```
{
   "eventDetails": [
       {
        "id":<long>,
        "version":<long>,
        "name":<string>,
        "value":<string>
       }
    ]
    eventProperties: [],
    userComments: [ ],
    eventId: <long>
 }
```

Response Fields

- `eventDetails`: Not applicable for Universal Agent
    - `id`: ID of the event
    - version: Version of the event
    - `name`: Details of the event
    - `value`: Not applicable for Universal Agent
- eventProperties: Not applicable for Universal Agent
- userComments: Not applicable for Universal Agent
- `eventId`: Not applicable for Universal Agent

Create a Configuration Template

Create a configuration template to reference in your rulebooks using:

```
PUT /controller/universalagent/v1/user/configurations/{name}
```

The template is stored on the Controller and can be referenced from multiple rulebooks. See Rulebook Configuration Templates.

Path Parameters

Parameter Name	Value	Required
`name`	Name of the configuration template.	Yes

Example Create Template

```
curl -i -X PUT -u '<userName>@<accountName>:<password>' -H 'Content-type: application/json' -H 'Accept:
application/json' http://localhost:8080/controller/universalagent/v1/user/configurations/440startedconfig -d ' {
"name": "450startedconfig",
 "config": {
 "state":"started",
 "version": "4.5.0"
 },
 "model": "NameValue"
}'
```

Response Format

Response Payload: Created template

```
 {
    "name": "450startedconfig",
    "model": "NameValue",
    "config": {
        "state": "started",
        "version": "4.5.0"
    },
    "referredRuleBooks": []
}
```

HTTP Response Status Code: 200 OK

Response Fields:

- `name`: Name of the configuration template
- `model`: Model of the template. NameValue is the only supported model.
- `config`: Configuration properties, a list of name-value pairs.
- `referredRuleBooks`: A list of the rulebooks that refer to this template.

Update a Configuration Template

Update an existing configuration template using:

```
PUT /controller/universalagent/v1/user/configurations/{name}
```

Parameter Name	Value	Required
`name`	Name of the configuration template.	Yes

Example Update Template Command

```
curl -i -X PUT -u '<userName>@<accountName>:<password>' -H 'Content-type: application/json' -H 'Accept:
application/json' http://localhost:8080/controller/universalagent/v1/user/configurations/450startedconfig -d ' {
"name": "450startedconfig",
 "config": {
 "state":"started",
 "version": "4.5.0" # changed
 },
 "model": "NameValue"
}
```

Response Format

Response Payload: Changed template

HTTP Response Status Code: 200 OK

```
{
    "name": "450startedconfig",
    "model": "NameValue",
    "config": {
        "state": "started",
        "version": "4.5.0"
    },
    "referredRuleBooks": []
}
```

Response Fields

- `name`: Name of the configuration template
- `model`: Model of the template. NameValue is the only supported model.
- `config`: Configuration properties, a list of name-value pairs.
- `referredRuleBooks`: A list of the rulebooks that refer to this template.

Delete a Configuration Template

Delete a configuration template using:

```
DELETE /controller/universalagent/v1/user/configurations/{name}
```

Path Parameters

Parameter Name	Value	Required
name	Name of the configuration template.	Yes

Example Delete Template Command

```
curl -i -X DELETE -su '<controller-user>@<controller-account>:<controller-password>' -H "Content-type:
application/json" -H "Accept:application/json" \
        "http://<controller-host>:<controller-port>/controller/universalagent/v1/user/configurations
/450startedconfig"
```

Response

Response Payload: None

HTTP Response Status Code: 200 OK, if the template is present, 404 Not Found, for non-existent templates.

Fields: Not Applicable

View Configuration Templates

View specific templates by name or view a list of all templates using:

```
GET /controller/universalagent/v1/user/configurations
GET /controller/universalagent/v1/user/configurations/{name}
```

Path Parameters

Parameter Name	Value	Required
name	Name of the configuration template.	Yes

Example Command: View Specific Template

```
curl -i -X GET -su '<controller-user>@<controller-account>:<controller-password>' -H "Content-type: application
/json" -H "Accept:application/json" \
        "http://<controller-host>:<controller-port>/controller/universalagent/v1/user/configurations
/450startedconfig"
```

Example Command: View All Templates

```
curl -i -X GET -su '<controller-user>@<controller-account>:<controller-password>' -H "Content-type: application
/json" -H "Accept:application/json" \
        "http://<controller-host>:controller-port>/controller/universalagent/v1/user/configurations"
```

Response Payload for Specific Template

```
 {
    "name": "450startedconfig",
    "model": "NameValue",
    "config": {
        "state": "started",
        "version": "4.5.0"
    },
    "referredRuleBooks": []
}
```

Response Payload: All Templates

```
[
    {
        "name": "450startedconfig",
        "model": "NameValue",
        "config": {
            "state": "started",
            "version": "4.5.0"
        },
        "referredRuleBooks": []
    },
    {
        "name": "controllerConfig",
        "model": "NameValue",
        "config": {
            "controller_key": "some",
            "controller-port": "9000",
            "controller-host": "localhost"
        },
        "referredRuleBooks": []
    }
]
```

HTTP Response Status Codes:

- `200` OK
- `404 Not Found`: when template is not present.

Response Fields

- `name`: Name of the configuration template
- `model`: Model of the template. NameValue is the only supported model
- `config`: Configuration properties, a list of name-value pairs
- `referredRuleBooks`: A list of the rulebooks that refer to this template
- `for view all templates`: List of configuration templates
- `[]` if no configuration templates are present

Troubleshoot Universal Agent Setup

Universal Agent Log Files

The Universal Agent log files can help you troubleshoot your Universal Agent configuration. These logs provide detailed information on the activities of the Universal Agent itself, but for a complete picture of the setup, they may not be the only resource you rely upon. Since the JVM has its own log context, you may need to check its logs to analyze unexpected behavior or results.

Troubleshooting Workflow

The general recommended workflow for troubleshooting Universal Agent setup issues is:

1. Missing or incorrect connection settings are a common agent misconfiguration issue. Check the rulebooks applied by the Universal Agent to make sure that the connection settings are correct. Verify the account name and key, along with the controller host and port.
2. Check the Universal Agent log file. The log files are located in the `log` directory for the monitor. This log file may be in one of the following locations:

    a. If the runtime_directory attribute is not specified in the Java Agent rule:
    `<universal_agent_home>/monitor/java/ua<version>/logs`
    b. If the runtime_directory attribute is specified in the Java Agent rule:
    `<runtime_directory>/logs`
    Where the exact location of runtime_directory is defined by the rule attribute.
3. Enrich the JVM log with Universal Agent logging by setting the following environmental variable in the JVM environment. Note that this requires a restart of the JVM:

    ```
    export APPDYNAMICS_UA_DEBUG=true
    ```

Application Security Monitoring

> Cisco Secure Application is available for the SaaS environment only.

AppDynamics with Cisco Secure Application reduces the risk of security exposure without compromising the delivery speed for an APM-managed application. Normally, the traditional vulnerability scanning occurs before the application is launched to production, and then continues on a monthly, or quarterly cadence. As soon as the app is deployed to production, new security gaps, and zero-day exploits make the application vulnerable despite pre-production testing. Cisco Secure Application enables continuous vulnerability assessment and protection by scanning code execution to prevent possible exploits.

Cisco Secure Application enables:

- The IT Operations team responsible for performance monitoring to gain real-time access to all security events.
- Application security (AppSec) developers and application developers to gain insights into violations of best practices and to collaborate on a solution without friction.
- AppSec and DevOps to add security into the existing automation, which benefits the DevSecOps environment.
- Businesses to operate at a faster pace with a lower risk profile due to constant run-time protection, real-time remediation, and security automation.

The Cisco Secure Application features are built into AppDynamics Java Agent. To monitor the application security, you must enable the security for the application using the Cisco Secure Application dashboard. Use the **Security Events** widget on the AppDynamics Application dashboard to navigate to the Cisco Secure Application dashboard. To view the **Security Events** widget within AppDynamics Performance Monitoring (APM), enable your SaaS account with the subscription license for Secure Application. See License Entitlements and Restrictions.

Cisco Secure Application Components

Cisco Secure Application uses the combination of the APM Agent, Controller, and Cisco Secure Application dashboard to monitor the security of the applications.

- **Java APM Agent**: Cisco Secure Application library is bundled with the Java Agent. The agent communicates with the Cisco Secure Application se rvice within the Controller, which is maintained in the cloud.

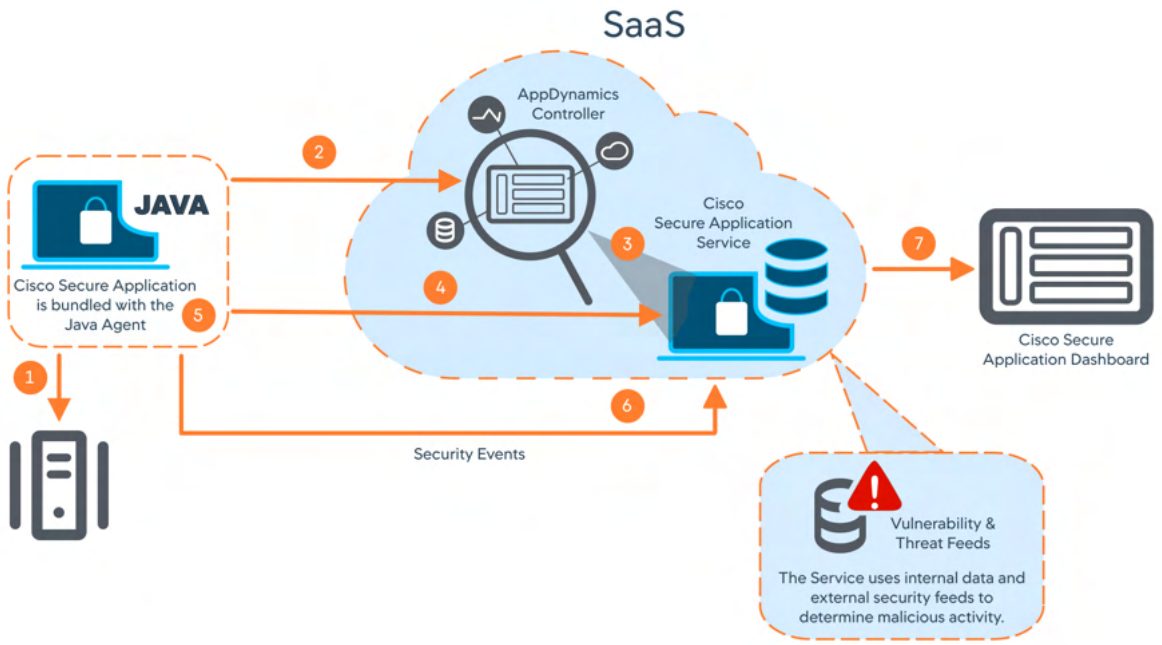
- **AppDynamics Controller**: The Cisco Secure Application service is maintained in the cloud by AppDynamics.
  The APM Agent sends data to the service within the Controller. The service analyzes the data to protect against different types of attacks and vulnerabilities and then the service provides the analysis to the dashboard. For information about the attacks and vulnerabilities that Cisco Secure Application detects, see Cisco Secure Application Policies.
  It uses external feeds along with internal data to analyze the behavior of the application. It analyzes the CVEs (Common Vulnerabilities and Exposures) against a curated vulnerability feed.
  The service can detect:
  - An attack when it is enabled in the policy and abnormal behavior is detected.
  - A vulnerability when it is enabled in the policy and when the associated behavior and the library used are considered vulnerable.

- **Cisco Secure Application Dashboard**: A graphical representation of all the analyzed data. You can view this dashboard based on the role defined in the AppDynamics Controller. The data is updated on the dashboard when the service within the Controller sends the analyzed data to the dashboard.

Cisco Secure Application Architecture

This is a high-level architecture of Cisco Secure Application.

> The APM Agent (Java Agent) communicates to the Cisco Secure Application service through the AppDynamics Controller.



1. You install the APM Agent and then add the Cisco Secure Application license.
2. The APM-managed application runs and the Java Agent retrieves the data to send to the Controller.
3. The Cisco Secure Application service retrieves the application, tiers, and nodes data from the Controller.
4. The APM Agent communicates with the Cisco Secure Application service to check if the security is enabled for the application.
5. If the security is enabled, then the agent downloads the configuration along with the policies from the Cisco Secure Application service.
6. Based on the configured policies, the agent sends the security events to the Cisco Secure Application service.
7. The service collects all the data, analyzes the application behavior, and then provides the analyzed data to the Cisco Secure Application dashboard.

Cisco Secure Application Requirements

This page describes the requirements, supported environments, and versions supported by the Cisco Secure Application.

Software Requirements

The Cisco Secure Application capabilities are integrated with the Java APM Agent, and therefore works on the following platforms:

- Operating Systems - AIX, Linux, and Windows
- Containers - All major container systems
- Languages - Java versions 7 to 14, inclusive, Oracle, OpenJDK, Azul, and BM
- Application Framework Support - All major frameworks such as Spring (see Java Supported Environments)
- Application Server Platform Support - All major Application Servers (see Java Supported Environments)

Review Install App Server Agents for instructions and guidance. AppDynamics provides an Agent Installer that simplifies the agent installation process and streamlines the deployment of Java and Machine Agents.

Resource Utilization and Performance Impact

Within the Java Agent, the Cisco Secure Application capabilities require:

- Disk - 4 MB (install) and <15 mb (daily usage)
- Memory - consistently heap/mem usage should be 4-6 MB
- CPU - consistently < 1% - spikes < 5%
- Latency - consistently < 4-6 ms per transaction (average is lower) - spikes < 10ms
- Classes Instrumented: rules (12) classes (generally < 30 - based on implementations of some of the interface rules)

Browser Requirements

Currently, Google Chrome is the supported browser for accessing Cisco Secure Application dashboard.

Before You Begin

To use Cisco Secure Application within the Java APM Agent, ensure:

- That you have met the preceding Cisco Secure Application Requirements.
- You have enough Cisco Secure Application licenses to cover your Java APM agent usage within the applications you plan on securing. To get a Cisco Secure Application license, contact the AppDynamics sales representative, or email salesops@appdynamics.com.
- A Java APM Agent >= 21.3.0 is installed and licensed.
- Controller >= 21.4.2.
- That you have successfully configured the Java Agent in your application environment.

Getting Started with Cisco Secure Application

This page provides a step-by-step procedure on how to get started with Cisco Secure Application.

Step	Task	Reference
Step 1: Ensure: • All requirements are met • The licensed version of APM Agent is installed.	Check the required version of the Controller and APM Agent. Cisco Secure Application is supported on a SaaS Controller only.	• Install the Java Agent • Cisco Secure Application Requirements
Step 2: Get the Cisco Secure Application license	Contact the AppDynamics sales representative or email salesops@appdynamics.com.	Cisco Secure Application Requirements
Step 3: Assign roles using the AppDynamics Administration Console.	• Assign the **Configure Cisco Secure Application** account permission to the users who are required to modify configurable fields on the Cisco Secure Application dashboard. • Assign **View Cisco Secure Application** account permissions to users who are required to only monitor the dashboard.	Account Permissions
Step 4: Click the **Security Events** widget on an application flowmap.	Launch the required AppDynamics Application dashboard using your account, and then click **Security Events** on the right pane. This redirects you to the Cisco Secure Application dashboard.	Monitor Application Security Using Cisco Secure Application
Step 5: From the Cisco Secure Application Dashboard navigate to the **Applications** page, and then set **Security Setting** as **Enabled** for the target application. This is applicable for all users with Configure permission for Cisco Secure Application.	The **Security Setting** value is set to **Inherit** by default for all applications that inherit the non-configurable tenant setting of **Disabled**. To enable security for an application you must set **Security Setting** to **Enabled**.	Monitor Security Status of Applications
Step 6: From the **Applications** page, verify that the application nodes are registered and active.	From the **Applications** page, check the **Active Nodes** and **Registered Nodes** fields for the specific application. Ensure that the application nodes are active. If the nodes are not active, then the application security data is not displayed on the dashboard.	Monitor Security Status of Applications
Step 7: From the **Policies** page, create **Vulnerability** policies for all applications. This is applicable for all users with Configure permission for Cisco Secure Application.	Create required **Vulnerability** policies for all applications to detect the **Library** vulnerabilities.	
Step 8: From the **Libraries** page view the risk-sorted libraries of secured applications.	The **Libraries** page displays all the existing libraries of application(s) based on the selected application scope. You can use the risk score to prioritize the remediation task.	Monitor Libraries

Based on your analysis from the dashboard you can create or modify policies and then view the different pages on the dashboard to monitor the security of APM-managed applications. See Cisco Secure Application Policies.

Monitor Application Security Using Cisco Secure Application

Monitor the Home Page of Cisco Secure Application

Monitor Security Status of Applications

Cisco Secure Application Policies

Cisco Secure Application **Policies** specify actions when an attack or vulnerability matches your defined criteria. They also determine what types of attacks and vulnerabilities are addressed. You can create and configure policies to specify an action to mitigate the attacks and vulnerabilities.

To monitor the security of the application, you must create policies. To create policies, you require the Configure permission for Cisco Secure Application. By default, Cisco Secure Application includes a policy that provides the best detection of all the attacks and vulnerabilities, reducing the false positives.

Cisco Secure Application scans these types of attacks and vulnerabilities:

Attack Type	Description
Local File Inclusion (LFI)	Software imports, requires, or includes executable functionality (such as a library) from a source that is outside the intended control sphere.
Path Traversal (PATH)	Uses external input to construct a pathname that is intended to identify a file or directory that is under a restricted parent directory. However, the software does not properly neutralize special elements within the pathname. This may cause the pathname to resolve to a location outside of the restricted directory.
Remote Code Execution (RCE)	Triggers arbitrary code execution over a network. This occurs through the framework's backdoor, using content such as XML, JSON, and Java serialization.
Untrusted Deserialization (DESERIAL)	The application deserializes untrusted data without sufficiently verifying that the resulting data is valid.

Vulnerability Type	Description
Cookie: HttpOnly (C_HTTP)	Cookie: HttpOnly: A cookie with the HttpOnly attribute is inaccessible to the JavaScript Document.cookie API; it is sent only to the server. For example, cookies that persist server-side sessions do not need to be available to JavaScript, and should have the HttpOnly attribute. This precaution helps mitigate cross-site scripting (XSS) attacks.
Cookie: SameSite (C_SITE)	Cookie: SameSite: The SameSite attribute enables servers to prevent cookies from being sent with cross-origin requests (where Site is defined by the registrable domain). This provides protection against cross-site request forgery attacks (CSRF).
Cookie: Secure (C_SECURE)	Cookie: Secure: A cookie with the Secure attribute is sent to the server only with an encrypted request over the HTTPS protocol. It is never sent with unsecured HTTP, and therefore cannot be accessed by a man-in-the-middle attacker.
HTTP Header: X-Content-Type-Options (H_CONTENT)	The X-Content-Type-Options response HTTP header is a marker used by the server to indicate that the MIME types advertised in the Content-Type headers should not be changed. This provides a way to opt-out of MIME type sniffing, or, in other words, to say that the MIME types are deliberately configured.
HTTP Header: Content-Security-Policy (H_CSP)	HTTP Header: Content-Security-Policy: The HTTP Content-Security-Policy response header allows web site administrators to control resources the user agent is allowed to load for a given page. With a few exceptions, policies mostly involve specifying server origins and script endpoints.
HTTP Header: X-Frame-Options (H_FRAME)	HTTP Header: X-Frame-Options: The X-Frame-Options HTTP response header can be used to indicate whether or not a browser should be allowed to render a page in a <frame>, <iframe>, <embed> or <object>. Sites can use this to avoid click-jacking attacks, by ensuring that their content is not embedded into other sites.
HTTP Header: Strict-Transport-Security (H_STS)	The HTTP Strict-Transport-Security response header (HSTS) is used in a website to send information to the browsers that the website should only be accessed using HTTPS, instead of using HTTP. This header is used to prevent man-in-the-middle attacks or sensitive data leakage.
HTTP Header: X-XSS-Protection (H_XSS)	HTTP Header: X-XSS-Protection: The HTTP X-XSS-Protection response header is a feature of Internet Explorer, Chrome and Safari that stops pages from loading when they detect reflected cross-site scripting (XSS) attacks.
Uncaught Exception (EXC)	Uncaught Exception: this is a very common issue - the runtime generally has built in security detection mechanisms in the form of Exceptions that are often times not "caught" and/or "not logged" - or if they are - it's buried in a file that is not reviewed until days or weeks after a security breach has occurred. This reviews ALL security related Exceptions across the entire runtime and using the security policy can report and/or take other additional actions on the information.
Vulnerable Libraries (LIB)	Detect all applicable vulnerabilities to the application's services and tiers as reported in the National Vulnerability Database (NVD) .

Create a Security Policy

To create a policy for an attack or vulnerability, perform the following steps:

1. Click **Policies** > **Create New Policy**.
2. From the **Add Policy** dialog, select the required criteria for the attacks in these fields:
    - **Policy Type**: Select **Attack Policy** to create a policy for a specific attack. Select **Vulnerability Policy** to create a policy for a specific vulnerability.
    - **Name**: Select the type of attack or vulnerability for which you require the policy.
    - **Application**: Select the application that includes the tiers or services on which you require to apply the policy.
      Select **All** to apply the policy on specified tiers or services of all the applications.
    - **Tier**: Select the required application-specific tier or service to apply the policy.
      Select **All** to apply the policy on all the tiers or services.

      > AppDynamics recommends that you review the default policy and if needed create a policy for specific applications and tiers.

    - **Action**: Select the action for this policy.
        - For Attacks: Select **None** for no notifications on the **Attacks** page; select **Detect** to detect the attack and display the details on the **Attacks** page; or select **Block** to block a specific attack and to display it as **Blocked** on the **Attacks** page.
        - For Vulnerabilities: Select **None** for no notifications on the **Vulnerabilities** page; select **Detect** to detect the vulnerability and display the details on the **Vulnerabilities** page; select **Patch** to fix the security issues.

      > **Block** is unavailable for some of the supported attacks and **Patch** is unavailable for some of the supported vulnerabilities.

3. Click **Save**.

Modify a Security Policy

To view and modify a policy for an attack or vulnerability, perform the following steps:

> You can use the **Search** filter to search based on the values of the **Name** or **Application Name** fields.

1. Click **Policies**.
2. Select the application and the tier or service whose policy you want to modify.
3. Click **Attacks** to view the list of attack policies. Click **Vulnerabilities** to view the list of vulnerability policies.
   At the bottom right corner of the page, you can view 5, 10, 20, or 50 policies in the list by selecting the **Show<*number of policies*>** dropdown.
4. Click the **Modify** icon.
5. Modify the required fields.
6. Click **Update** or click **Delete Policy** based on the requirement.

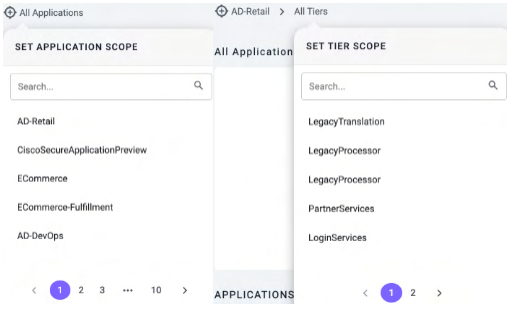
Monitor Application Security Using Cisco Secure Application

Cisco Secure Application provides a real-time dashboard that provides visibility on the security health of your applications. This dashboard is available when an application is registered with an APM agent and has the appropriate licensing. The agent sends the security events to Cisco Secure Application through the Controller.

The **Security Events** widget on the AppDynamics Application Dashboard provides high-level information about the security of a registered application. This widget displays the number of critical, warning, and normal security events. To view the details of security for the selected application on Cisco Secure Application, click the **Security Events** widget.

Select Scope for the Dashboard

Cisco Secure Application dashboard provides an option to select the required application and tier scope that will be applied across all views within this dashboard except **Policies**. By default, the application scope is the selected application on the AppDynamics dashboard prior to navigating to Cisco Secure Application.

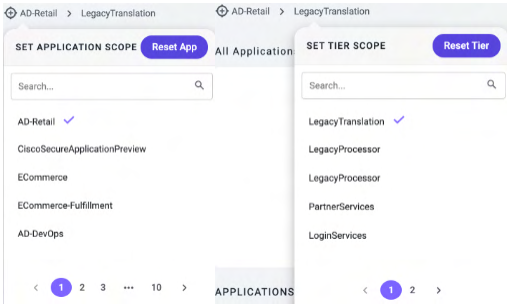


Application Scope

Perform the following to view the data on the dashboard for a specific application:

1. Click the **Application Scope Selector icon** ( ) on the top left corner of the dashboard.
2. Search for the specific application.
3. Select the application.

   To return to the default view of all applications, click the **Application Scope Selector icon** ( ) > **Reset App**



Tier Scope

Perform the following to view the data on the dashboard for a specific application tier:

1. Click **All Tiers** next to the **Application Scope Selector icon** ( ).
2. Search for the specific tier.
3. Select the tier.
   To return to the default tier view, click ***<service name>*** > **Reset Tier**.

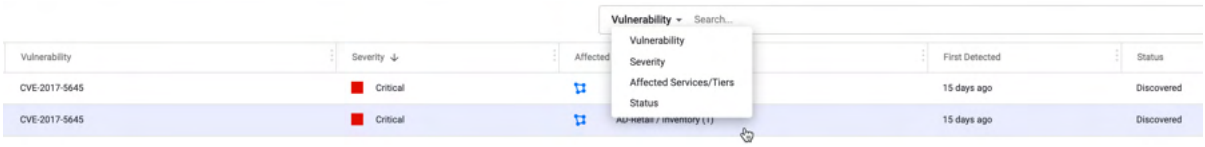
View Data Using Search Filter

The Cisco Secure Application provides a **Search** filter on various pages in the dashboard. This filter helps in getting the required data quickly.

The search filter allows you to search based on the selected category.

For example, in the following image these are the categories:

- Vulnerability
- Severity
- Affected Tiers
- Status



You can select the required search category from the dropdown list, then click the **Search** field to view the list of values corresponding to the category. You can also find the required value as you type.

If you do not require the exact match, you can enter the required generic value in the **Search** field.

For example, consider that you want to search for all applications that start with a specific prefix, AD. You can select the search category as **Application** an d enter AD in the **Search** field.

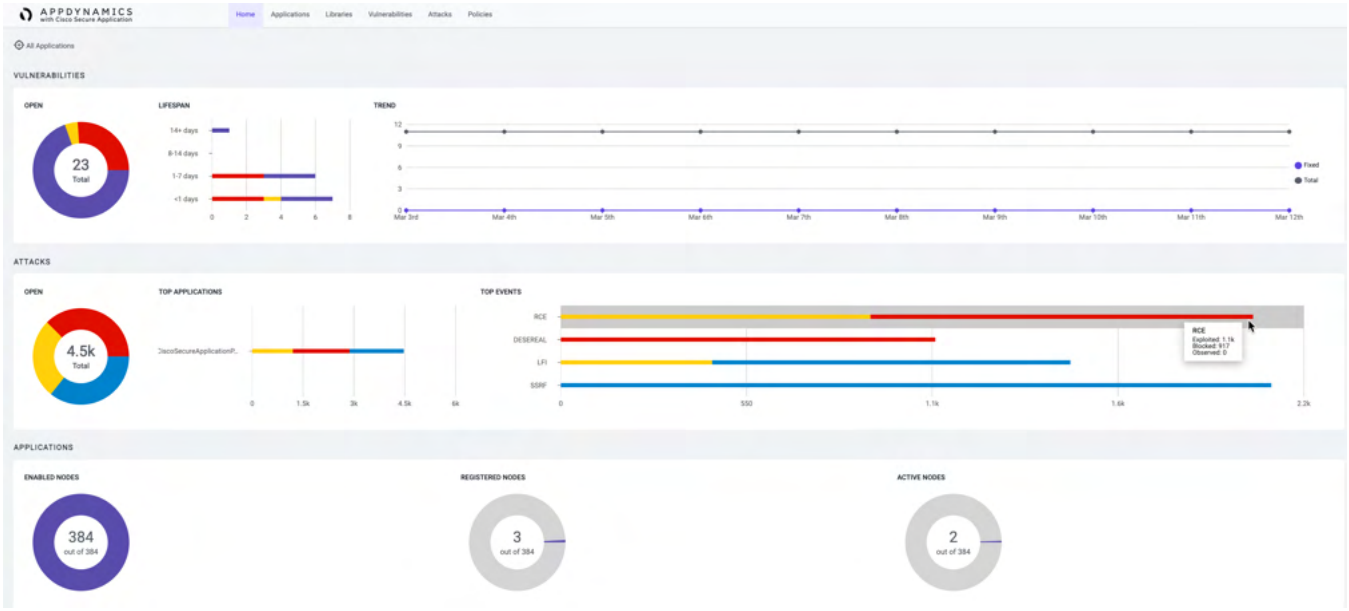
> You can search using one or all the categories, but each category can have a single search value. A category is disabled when you specify a search value for that category, but you can continue to select another available category and specify its search value. These search values act as filters. You can remove the search values to remove the search filter.

Cisco Secure Application provides a real-time dashboard that displays these pages:

- **Home**: This page provides an overall overview of attacks and vulnerabilities of monitored applications.
  See Monitor the Home Page of Cisco Secure Application.
- **Applications**: This page provides the details of monitored nodes that are registered with Cisco Secure Application for the managed applications.
  See Monitor Security Status of Applications.
- **Libraries**: This page provides details of the existing libraries that require remediation.
  See Monitor Libraries.
- **Vulnerabilities**: This page provides information about all discovered vulnerabilities.
  See Monitor Vulnerabilities.
- **Attacks**: This page provides information about all detected attacks.
  See Monitor Attacks.
- **Policies**: This page allows you to create or customize the policies for vulnerabilities and attacks.
  See Cisco Secure Application Policies.

Monitor the Home Page of Cisco Secure Application

The **Home** page is the landing page for Cisco Secure Application. This page provides a quick view of the security of the selected application. The following image is an example of the **Home** page:



The Home page includes the following panes:

- Vulnerabilities
- Attacks
- Applications

> By default, this page displays an overview of the selected application. For information about selecting a specific application or service, see Select Application Scope at Monitor Application Security Using Cisco Secure Application.

Vulnerabilities

The Vulnerabilities pane includes a real-time trend graph that shows the number of both fixed and open vulnerabilities.

Chart	Description
OPEN	The pie chart represents the total number of open vulnerabilities. For example, the preceding image shows 23 open Vulnerabilities. This chart displays visualization for the number of vulnerabilities based on these severity levels: • Critical = Red • High = Orange • Medium = Yellow • Low = Purple Hover on each severity to view the number of related open vulnerabilities. To display all charts in a pane based on a specific severity, click the severity on the pie chart. To return to the complete chart, click the same severity again.
LIFESPAN	This chart displays the number of days the vulnerability is open versus the severity of the vulnerability (critical, high, medium, or low)
TREND	This chart displays the number of open tickets versus the number of fixed tickets. This shows the trend of fixing the open vulnerabilities.

Attacks

The **Attacks** pane includes the visualization for the number of open attacks.

Chart	Description

OPEN	This pie chart represents the total number of open attacks. For example, the preceding image shows 4.5K open attacks. This chart displays the number of attacks based on these states: • Observed = Blue • Exploited = Red • Blocked = Yellow Hover on the required state to view the number of open attacks in that state. To display all charts of the data based on a specific state, click the state on the pie chart. To return back to the complete chart, click the same state again.
TOP APPLICATIONS	This chart displays the top 10 applications based on open attacks per application. If you select a specific application scope, then only that application is displayed. To view all the applications, you require to reset the application scope. For more information about changing the scope of the application, see Monitor Application Security Using Cisco Secure Application. These applications are in either an **exploited**, **blocked**, or **observed** state versus the total number of open attacks on the application. Hover on each state to view the number of blocked, exploited, and observed open attacks.
TOP EVENTS	This chart displays the top 10 attack events that are in an **exploited**, **blocked**, or **observed** state versus the total number of open attacks on the events. Hover on each state to view the number of blocked, exploited, and observed open attacks.

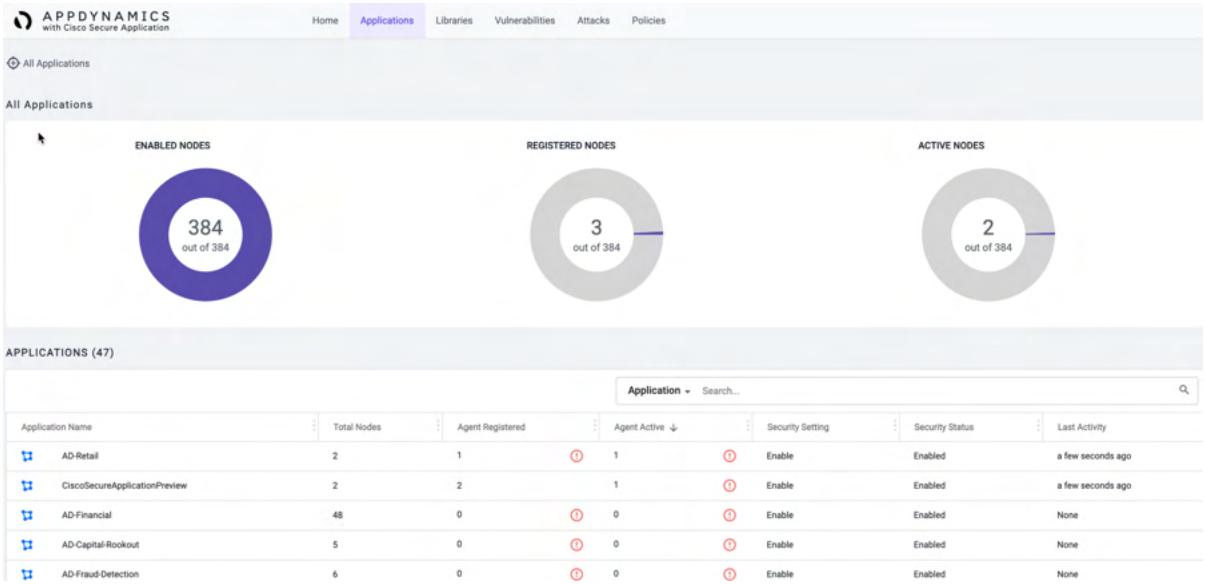
Applications

The Applications pane includes the visualization for the nodes of the managed applications.

Chart	Description
ENABLED NODES	The pie chart highlights the total number of nodes that have security enabled for the applications. The purple color represents the number of nodes enabled for security.
REGISTERED NODES	The pie chart highlights the number of nodes registered with the Cisco Secure Application. The purple color represents the number of nodes that are registered for the security setting.
ACTIVE NODES	The pie chart highlights the number of nodes that are actively communicating with the Controller. The purple color represents the number of active nodes.

Monitor Security Status of Applications

This page focuses on the current state of security capabilities across applications, tiers, and nodes. You can control the security setting (with the configure permission) and identify the issues with the agents that are not registered or are inactive. This image is an example of the **Applications** page:



The top pane includes the visualization of the number of enabled, registered, and active nodes for all applications.

- ENABLED NODES - nodes with security enabled.
- REGISTERED NODES - nodes with APM agents that are registered with Cisco Secure Application.
- ACTIVE NODES - nodes with currently active registered APM agents.

- Use the **Application Scope Selector icon** ( ) to view the data for a specific application, then select the required tier to view the data for a specific service of the selected application. For information about selecting the application and tier scope, see Monitor Application Security Using Cisco Secure Application.
- In the **Applications** table, you can click the application row to drill down to all the tiers for that application. Also, you can click a tier row to drill down to the corresponding nodes.
- You can use the **Search** filter for the following categories**:**
  - **(Applications) Application**, and **Security Status**
  - **(Tiers) Tier**, and **Security Status**
  - **(Nodes) Node**, **Security Status**, and **Active Node**

  For more information about the **Search** filter, see **View Data Using Search Filter** in Monitor Application Security Using Cisco Secure Application.

The bottom pane provides the following details:

The total number of applications is mentioned in parenthesis.

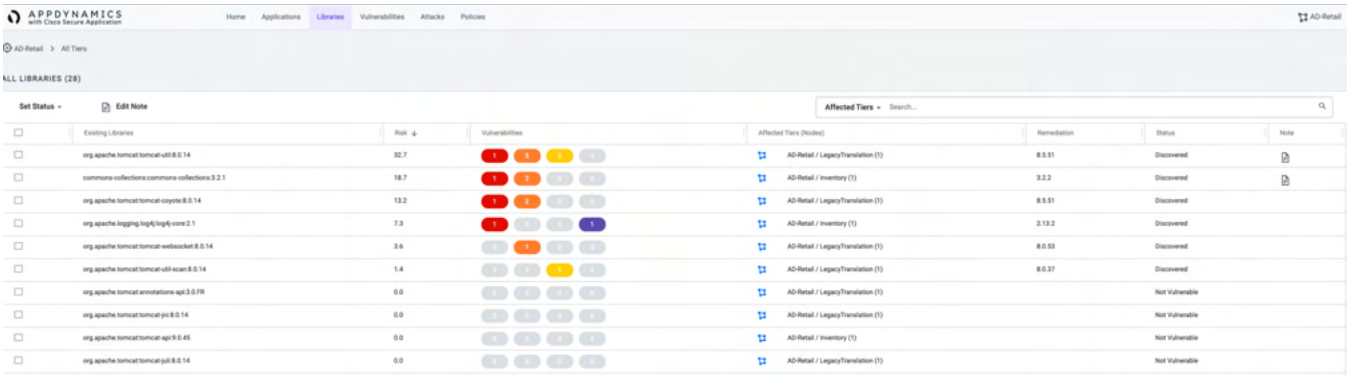
Field Name	Description
Application Name	This field displays the list of all applications. Click the flowmap icon ( ) next to an application to view the application flow map in the AppDynamics dashboard. Click this field to sort in alphabetical order. This field changes when you click to drill down to the tier list, then the node list. You can use the respective **Search** filter for each list view to quickly search the application, tier, or node.
Total Nodes	This field displays the total number of nodes that exist in the corresponding application. You can drill down to tiers or nodes list to view the total number of nodes in a tier, or a node respectively. Click this field to sort the number of nodes in increasing or decreasing order.

Registered Nodes	This field displays the number of nodes that are registered with the Cisco Secure Application for the corresponding application. You can drill down to tiers or nodes list to view the number of registered nodes in a tier, or a node respectively. The info icon () indicates that there are security-enabled nodes that are not registered with the agent. Click this field to sort the number of registered nodes in increasing or decreasing order.
Active Nodes	This field displays the number of nodes that are active for the corresponding application. You can drill down to tiers to view the number of active nodes in a tier. When you drill down to the nodes list, this field indicates if the node is active or not. The info icon () indicates a difference in the number of enabled nodes compared to active nodes. (For application and tiers) Click this field to sort the number of active nodes in increasing or decreasing order. (For nodes) Click this field to sort based on the values **Yes** or **No**.
Security Setting	The security setting is disabled by default. If you require to enable the security, select **Enable**. This field displays these security settings for the corresponding application: • **Enable**: When the security setting is enabled for the nodes. • **Disable**: When the security setting is disabled for the nodes. • **Inherit**: When the security setting is inherited from the Controller. By default, the security setting is **Disabled**. Therefore, **Security Status** is **Disabled** for the application. For tiers and nodes, the security setting is inherited from the parent application and tier respectively. You can drill down to tiers or nodes list to view the security settings of a tier, or a node respectively. You can update these settings if you have the Configure Cisco Secure Application permission. Be aware that changing security settings at one level affect other levels. When you update **Security Setting** for any object (application, tier, or node), it can affect all the nodes in the object hierarchy (**Application**>**Tier**>**Node**). This happens when **Security Setting** is set to **Inherit** for either the object or its parent object. Click this field to sort the security setting in alphabetical order.
Security Status	This field displays the security status for the corresponding application based on the security setting. This field displays if the security status is enabled or disabled for the corresponding application based on the security setting. You can drill down to tiers or nodes list to view the security status of a tier, or a node respectively. Click this field to sort the status based on whether the status is enabled or disabled. If you have the Configure permission, you can change the security status using the **Set Status** option.
Last Activity	This field provides the timeframe when the last activity is detected.
Node Version	This field is displayed only when you drill down to the nodes list. This displays the version of the APM Agent used by the tier.

Monitor Libraries

The **Libraries** page provides a list of all libraries that are in use by the corresponding applications. The page highlights the vulnerabilities and associated risks introduced by the use of those libraries.

This image is an example of the **Libraries** page:



- You can use the **Search** filter for the **Affected Tiers**, **Status**, and **Existing Libraries** categories**.** For more information about the **Search** filter, see **View Data Using Search Filter** in Monitor Application Security Using Cisco Secure Application.
- The **Set Status** and **Edit Note** bulk edit options are available if you have the **Configure Cisco Secure Application** permission.

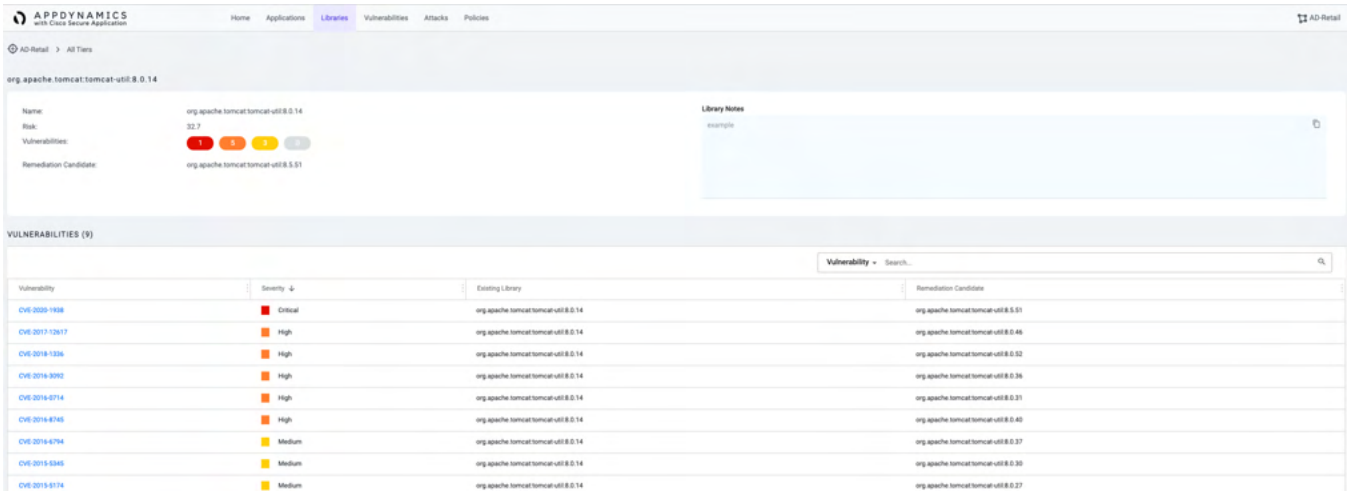
The libraries page includes these details:

Field Name	Description
Existing Libraries	Existing libraries in the selected application. You can click on the row to view the details of the library. See View Vulnerabilities for a Library. Click this field to sort the libraries in alphabetical order.
Risk	The risk score given to the library. This helps to identify which libraries require immediate remediation. The higher the risk score, the higher the impact of the collection of vulnerabilities within the library. Click this field to sort the risk score from high to low or low to high.
Vulnerabilities	The number of vulnerabilities based on severity. Severity is represented with the following colors: Red = Critical Orange = High Yellow = Medium Purple = Low If any of the preceding colors are replaced with the grey color, it indicates that there are no vulnerabilities with that specific severity. For example, **Vulnerabilities** display the grey, orange, yellow, and purple colors instead of the red, orange, yellow, and purple colors. This indicates that there are no critical vulnerabilities. Click this field to sort in increasing or decreasing order based on the number of vulnerabilities.
Affected Tiers	The application tier that is vulnerable because of its relationship to the corresponding library. Click the flow map icon ( ) next to an application to view the application flow map in the AppDynamics dashboard.
Remediation	The recommended version of the library that can be used for remediation.

Status	The status of the vulnerable libraries. By default, when a vulnerability is detected the value is **Discovered**. The status value can be: • **Discovered** (at least one vulnerability is discovered in the library) • **Confirmed** (Library is reviewed) • **Fixed** (Library is fixed) • **Ignored** (the library does not require to be considered when remediating vulnerability libraries because of some mitigations or exception) • **Not Vulnerable** (no vulnerabilities are found in the library) The **Discovered** and **Fixed** status are auto-populated. If you have the **Configure Cisco Secure Application** permission, you can change the **Status** by selecting the required libraries and using the **Set Status** option. ⓘ You must have the configure permission to view and use the **Set Status** option.
Note	Notes can be used to share information with other users or document findings during the review of a vulnerability. If you have the Configure permission, you can add notes by selecting a library and using the **Edit Note** option. Without the Configure permission, the **Edit Note** option is unavailable.

View Vulnerabilities for a Library

To view all the vulnerabilities within a specific library, click the row on the **Libraries** page. This directs you to the library details page with the following information:



The upper pane displays the details about the vulnerable library including the risk involved, any remediation to be taken, and the **Library Notes**. You can copy the notes if required.

If you have the Configure Cisco Secure Application permission, then you can add or edit the **Library Notes**.

The bottom pane provides the following details:

ⓘ You can use the **Search** filter to view the vulnerability details list based on the **Severity** or the **Vulnerability** value. For more information about the **Search** filter, see **View Data Using Search Filter** in Monitor Application Security Using Cisco Secure Application.

Field Name	Description
Vulnerability	The vulnerabilities scanned for the selected library. Click the field to sort in increasing or decreasing order. Click the CVEs to view the vulnerability details. For information about Vulnerabilities, see Monitor Vulnerabilities.
Severity	The severity of the vulnerability. Click the field to sort the severity in alphabetical order.

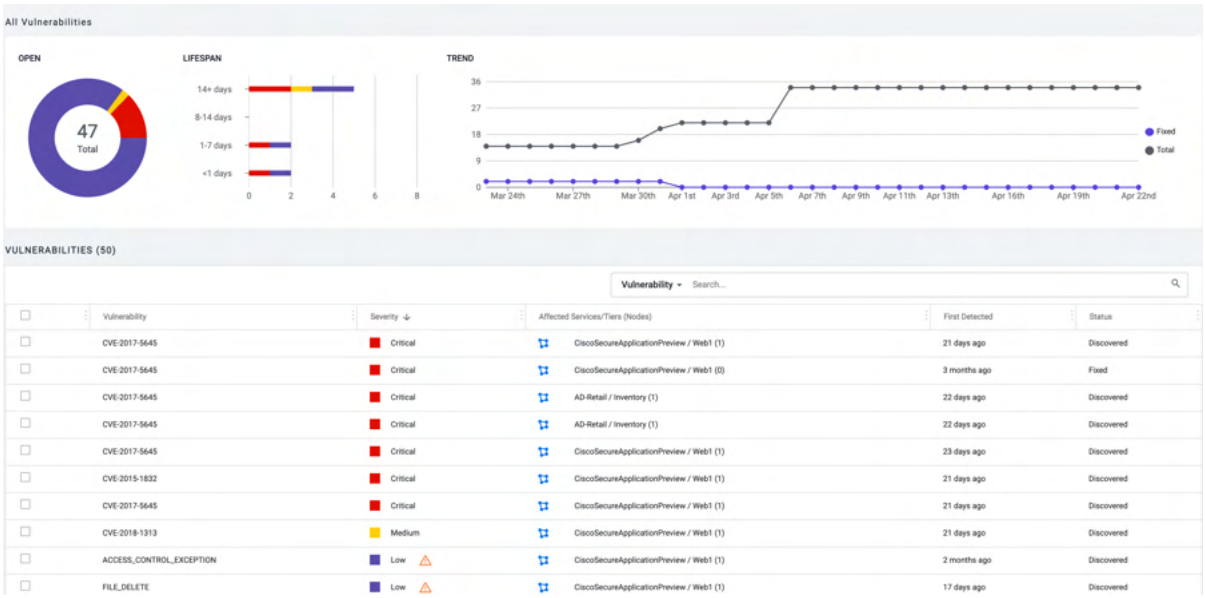
Existing Library	The library that introduced the vulnerability to the application.
Remediation Candidate	The version of the library that should be used to remediate the vulnerability.

Monitor Vulnerabilities

An application registered with Cisco Secure Application is scanned and continuously monitored for vulnerabilities. The **Vulnerabilities** page displays the list of all the scanned vulnerabilities.

When vulnerabilities are detected, a user with Configure permission can prioritize the vulnerabilities and change the status based on the details on this page.

This image shows you the scanned vulnerabilities on the **Vulnerabilities** page:



> By default, this page displays an overview of the selected application. For information about selecting a specific application or service, see Select Application Scope at Monitor Application Security Using Cisco Secure Application.

The top pane includes these charts:

Chart	Description
OPEN	This pie chart represents the total number of open vulnerabilities. Open vulnerabilities are vulnerabilities that currently exist in the runtime application, which are not patched or fixed yet and are not explicitly marked **Ignored** by the user. The chart displays the number of vulnerabilities based on the following severity: • Critical = Red • High = Orange • Medium = Yellow • Low = Purple Hover on the required severity to view the number of open vulnerabilities with that severity. If you require all the charts in the pane to display based on a specific severity, click the severity on the pie chart. To return back to the complete chart, click the same severity again.
LIFESPAN	This chart displays the number of days the vulnerability is open versus the severity of the vulnerability (critical, high, medium, or low)
TREND	This chart displays the number of open tickets versus the number of fixed tickets. This shows the trend of fixing the open vulnerabilities.

The bottom pane includes different fields and corresponding columns that provide details of the vulnerabilities:

> • Use the **Search** filter to search based on the **Vulnerability**, **Severity**, **Affected tiers**, and **Status** values. For more information about the **Search** filter, see **View Data Using Search Filter** in Monitor Application Security Using Cisco Secure Application.
> • There are few options such as **Set Status** and **Set Severity** that are available only if you have the Configure permissions for Cisco Secure Application.

Name	Description

Vulnerability	The vulnerability name and Common Vulnerabilities and Exposure (CVE) identifier.
Severity	The severity level of the corresponding vulnerability. The warning icon () next to a severity indicates that the exploit is detected in your application. You can click this icon to view the attack details page. The red icon () next to a severity indicates that this exploit is detected somewhere else in the Secure Application network. If you have Configure permission, you can change the severity by selecting the checkbox next to required vulnerabilities, and then click **Set Severity** to choose the appropriate severity. You can sort this column alphabetically.
Affected Tiers (Nodes)	The services or the tiers affected because of the corresponding vulnerability. The number in parenthesis indicates the number of nodes. Click the flow map icon() to view the AppDynamics flow map for that tier.
First Detected	The time elapsed after the vulnerability was first detected.
Status	The status of the corresponding vulnerability. The status value can be: • **Discovered** (at least one vulnerability is discovered in the library) • **Confirmed** (Library is reviewed) • **Fixed** (Library is fixed) • **Ignored** (not a library) • **Not Vulnerable** (no vulnerabilities are found in the library) The status Ignored can be updated by the developer with Configure permission for Cisco Secure Application. If you have Configure permissions, you can select the vulnerabilities using the checkbox, and then set the status by using the **Set Status** option. Without Configure permission, the **Set Status** option is unavailable.

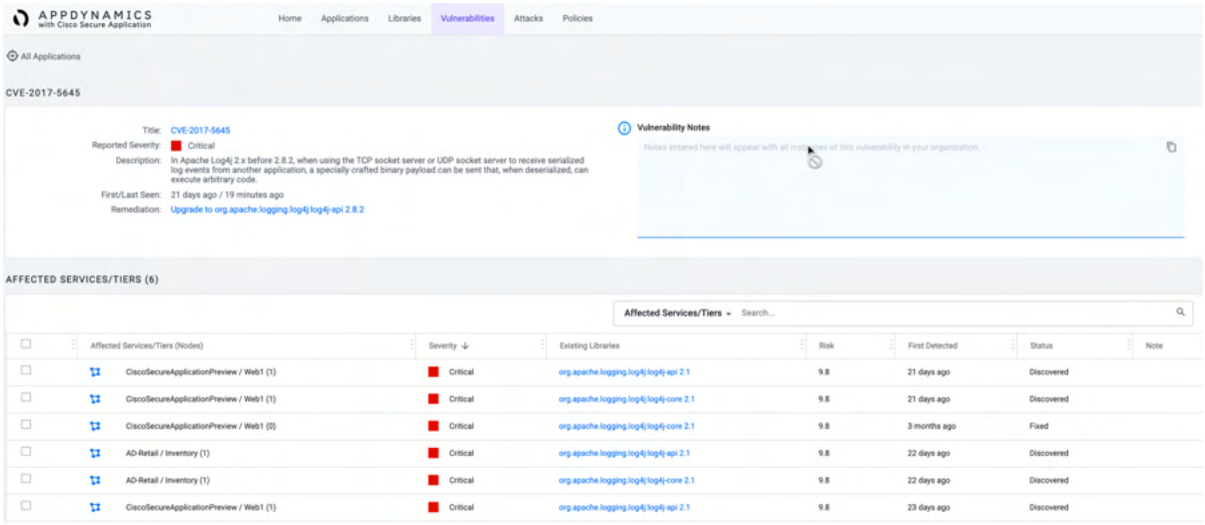
View Vulnerability Details

To prioritize vulnerabilities, you may require additional information. Click a vulnerability row to view detailed information about a vulnerability. The vulnerability details view is displayed.

The top pane displays the following details:

Field Name	Description
Title	The name of the vulnerability.
Reported Severity	The severity of the vulnerability, which can be critical, high, medium, or low.
Description	Details of the vulnerability.
First/Last seen	The timeframe when the vulnerability was first detected and when the vulnerability was last detected.
Remediation	The recommended remediation action. In the case of a vulnerable library, the version to upgrade the library for remediation.
Vulnerability Notes	If you have the Configure permission, you can add the notes under **Vulnerability Notes**. You can use the copy icon to copy the notes, if required.

The bottom pane displays the following details:

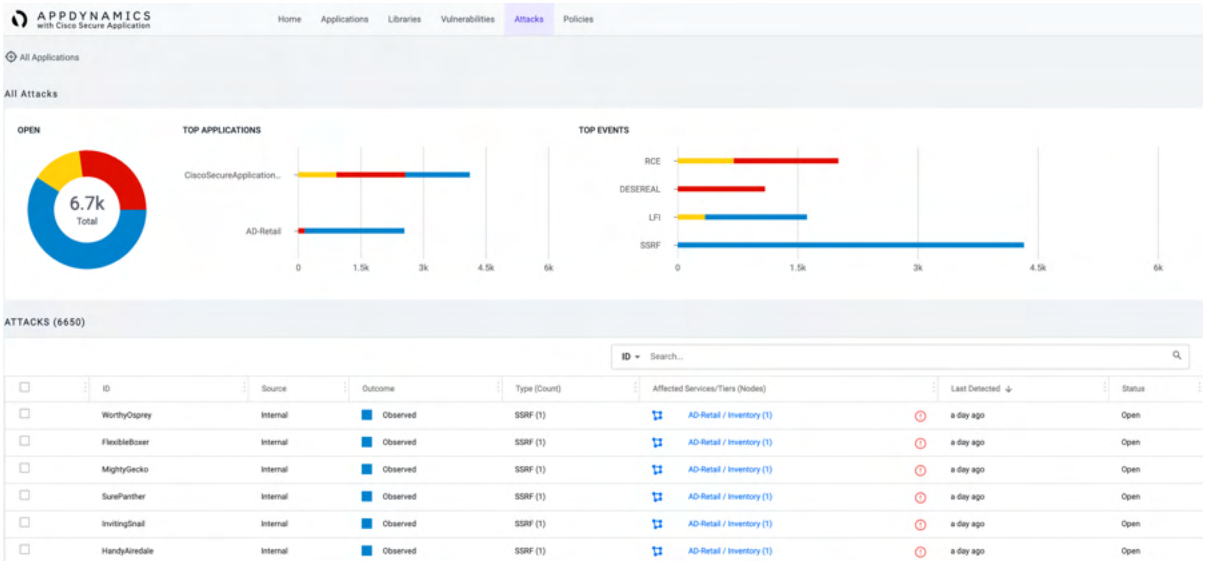


Field Name	Description
Affected Tiers (Nodes)	The services or the tiers that are affected because of the selected vulnerability. The number indicates the number of affected nodes. The flow map icon( ) directs to the AppDynamics flow map for that tier.
Severity	The severity of the vulnerability. You can edit the severity if you have Configure permission.
Existing Library	The library affected because of the vulnerability. You can click the library to view the details of the library. See Monitor Libraries.
Risk	The risk score of the vulnerability. This helps in prioritizing the affected services. A higher risk score indicates that the corresponding library on the corresponding service is at risk.
First Detected	The time elapsed since the vulnerability is detected.
Status	The status of the selected vulnerability. The status value can be: • **Discovered** (at least one vulnerability is discovered in the library) • **Confirmed** (vulnerability is reviewed) • **Fixed** (vulnerability is fixed) • **Ignored** (not a vulnerability) • **Not Vulnerable** (no vulnerabilities are found in the library) If you have Configure permissions, you can select the rows using the checkbox, and then set the status by using the **Set Status** option. Without Configure permission, the **Set Status** option is unavailable. ⓘ The **Discovered** and **Fixed** status are automatically detected based on the libraries used in the application.
Note	Under **Note**, if you have the Configure permission, you can select required checkboxes and then use the **Note** option to add notes.

Monitor Attacks

The **Attacks** page includes details of all the open and closed attacks on the managed applications.

The following image is an example of the **Attacks** page:



> By default, this page displays an overview of the selected application. For information about selecting a specific application or service, see **Select Scope for the Dashboard** at Monitor Application Security Using Cisco Secure Application.

The top pane includes these details:

Chart	Description
OPEN	This pie chart represents the total number of open attacks and displays the number of attacks based on the following state: • Observed = Blue • Exploited = Red • Blocked = Yellow Hover on the required state to view the number of open attacks in that state. If you require all the charts to display the data based on a specific state, click the state on the pie chart. To return to the complete chart, click the same state again.
TOP APPLICATIONS	This chart displays the top 10 applications based on open attacks per application. If you select a specific application scope, then only that application is displayed. To view all the applications, reset the application scope. For more information about changing the scope of the application, see Monitor Application Security Using Cisco Secure Application. These applications are in either an **exploited**, **blocked**, or **observed** state versus the total number of open attacks on the application. Hover on each state to view the number of blocked, exploited, and observed open attacks.
TOP EVENTS	This chart displays the top 10 attack events that are in an **exploited**, **blocked**, or **observed** state versus the total number of open attacks on the events. Hover on each state to view the number of blocked, exploited, and observed open attacks.

The bottom pane displays these details:

You can use the Search filter for the following categories:

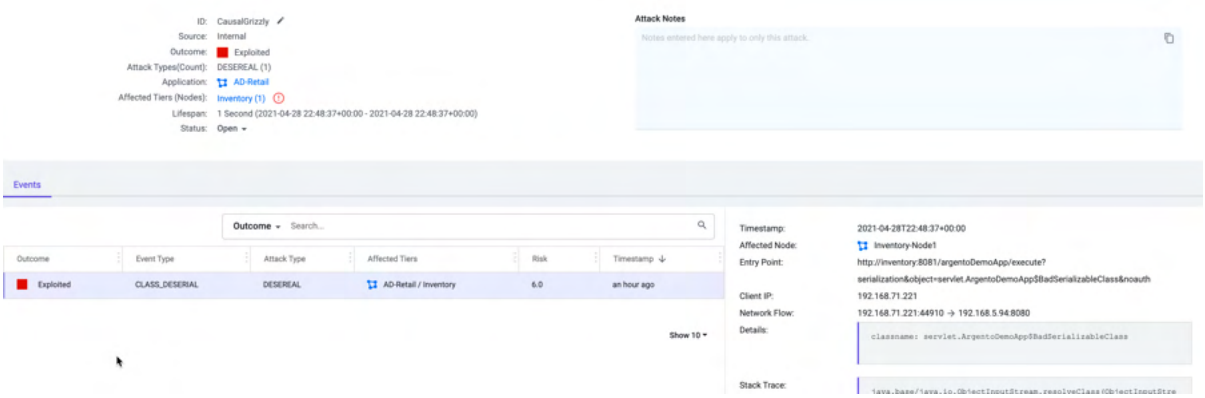
- **ID**
- **Source**
- **Outcome**
- **Affected Services/Tiers**
- **Attack Type**
- **Attack Status**

For more information about the **Search** filter, see **View Data Using Search Filter** in Monitor Application Security Using Cisco Secure Application.

Name	Description
ID	The ID of the corresponding Attack. Cisco Secure Application generates this ID. You can modify this ID on the attacks details page. To view the attack details page, click the desired row. Click this field to sort the ID alphabetically.
Source	The source of the corresponding attack. The value can be: • **Unknown** (Source is not identified) • **Internal** (Source of the attack is an internal asset) • **External** (Source of the attack is an external asset) For the attack events that are triggered by a web transaction, Cisco Secure Application uses these criteria to identify the source of attack: • **Internal:** The client is on a localhost or a local network of the server. • **External:** The client is outside the local network. Click the row for detailed information about the source of an attack. Click this field to sort the values alphabetically.
Outcome	The outcome of the corresponding attack. This provides information on these state of the attack: • **Observed**: When the events may impact the security, but any malicious intent is not determined. For example, an application opening a file outside the application directory causes **Observed** state. • **Blocked**: When the events are blocked based on the attack policy. • **Exploited**: When malicious activity is performed to impact the application's security. Click this field to sort the values alphabetically.
Type (Count)	The type of the attack and count of that attack type.
Affected Tiers (Nodes)	The application affected by the attack along with the tier name and the number of nodes. You can click to launch the application flowmap in the Appdynamics Dashboard. The info icon ( ) next to an affected tier indicates that the attacked nodes in the tier include critical or medium vulnerability.
Last Detected	The time that is elapsed since the last event within the attack. Click this field to sort the values in ascending or descending order.
Status	The status of the attack is defined as either **open** or **closed**. If you have Configure permissions, click the checkboxes for the required rows and then click the **Set Status** option to set the appropriate status. Click this field to sort based on the **Open** or **Closed** state.

View Attack Details

The attack details page provides more details of the attack. Click any attack to view the attack details page.



The top pane provides a summary of the attack.

A user (with Configure permission) can add notes under **Attack Notes** if desired. This note is visible to all users when monitoring attack details.

The bottom pane is split into left pane (a list of events correlated to the attack automatically) and right pane (the details of a selected event).

You can use the **Search** filter to filter based on the following categories:

- **Outcome**
- **Event Type**
- **Attack Type**
- **Affected Tiers**

For more information about the **Search** filter, see **View Data Using Search Filter** in Monitor Application Security Using Cisco Secure Application.

The left pane displays these details:

Field Name	Description
Outcome	The outcome of the event. This provides information on whether the selected event is **Observed**, **Blocked**, or **Exploited**.
Event Type	The type of the attack event or the vulnerability name.
Attack Type	The type of the attack such as RCE and so on.
Affected Services/Tiers	The affected application and the tier.
Risk	The risk score given for the specific event within the attack.
Timestamp	The time the event is detected.

The right pane displays the following details based on the selected event:

These fields are displayed when the events are triggered during a web transaction.

Field Name	Description
Timestamp	The date and time when the event is detected.
Affected Node	The name of the affected node. You can click the flowmap icon ( ) to view the **Tiers and Nodes** flowmap on the AppDynamics dashboard.
Vulnerabilities	The type of vulnerability used for the attack. Based on the event type, this field may not be displayed. If the value is displayed, click the value to view the vulnerability details. For information about Vulnerabilities, see Monitor Vulnerabilities.
Entry Point	The webserver URL accessed by the client in the transaction that triggered the event. Based on the event type, this field may not be displayed.

Client IP	The IP address of the remote endpoint of the connection in the transaction. This IP address can be the IP address of client machine, load balancer or proxy in a client network.
Network Flow	The network flow as observed from the node that includes the source and the destination IP address.
Details	The details about the resulting behavior of the node triggered by an inbound request. The details may change based on the event and attack type. Click **Show More** to view the **Details** dialog box. You can copy the details as per your requirement.
Stack Trace	Details of the stack trace for the corresponding event. Click **Show More** to view the **Stack Trace** dialog box. You can use this information to guide developers to the lines of code that were used to achieve the result of the event. You can copy the details as per your requirement.
Policy	The action that is used for this event based on the existing policy when the event is detected. If you have the Configure permission, you can change the policy by clicking the modify icon next to the policy. See Cisco Secure Application Policies.

Troubleshooting Cisco Secure Application Issues

This page provides common troubleshooting actions that you can take to solve Cisco Secure Application issues.

Cisco Secure Application Permissions Are Unavailable in the Role Configuration

- Check if the Controller version meets the requirements. See Cisco Secure Application Requirements.
- If the permissions are unavailable even when the Controller version is supported, ensure that you have activated the Cisco Secure Application license for the Controller. To get a Cisco Secure Application license, contact the AppDynamics sales representative, or email salesops@appdynamics.com.

Security Events Widget Is Not Displayed in an Application Flow Map

- You can view the **Security Events** widget after the license activation. Ensure that you have the Cisco Secure Application license. To get a Cisco Secure Application license, contact the AppDynamics sales representative, or email salesops@appdynamics.com.
- If the widget is not displayed even when the license is activated, then confirm with the administrator that the account has the necessary permissions to view or configure Cisco Secure Application. See Account Permissions.

Number of Registered Nodes and Active Nodes Does Not Match

On the **Applications** page, drilldown in the application to identify the inactive node. Check the APM agent logs on the inactive node(s). See Troubleshooting Java Agent Issues.

Vulnerabilities or Attacks Are Not Displayed on the Home, Vulnerabilities, or Attacks Page

- Ensure that the **Security Setting** is set to **Enabled** on at least one of the applications, tiers, or nodes within the **Applications** page. Also, that the agents are registered and active. See Monitor Security Status of Applications.
- If the vulnerabilities and attacks are not displayed even when the **Security Setting** is enabled, review the following troubleshooting scenarios to identify other potential issues.

Number of Enabled Nodes and Registered Nodes Does Not Match

- Check if the nodes that have **Security Status** set to **Enabled** use the APM Agent version that meets the requirements. See Cisco Secure Application Requirements.
- If the agent version is supported, then drilldown in the **Application** view to identify the unregistered node(s). Check the APM agent logs on the unregistered node(s). See Troubleshooting Java Agent Issues.

Security Setting is Enabled and No Libraries Are Listed

- Confirm that there are active nodes in the **Application** view. See Monitor Security Status of Applications.
- It is also possible that there are no third-party libraries used in the monitored applications.

Security Setting is Enabled and No Vulnerabilities Are Listed

- Confirm that there are active nodes in the **Application** view. See Monitor Security Status of Applications.
- Verify that there is a vulnerability policy enabled, and that it has an action of **Detect** or **Patch** for a monitored application with active nodes. See Cisco Secure Application Policies.
- It is also possible that there are no vulnerabilities within the third-party libraries used within the monitored applications or observed in the application behavior.

Security Setting is Enabled and No Attacks Are Listed

- Confirm that there are active nodes in the **Application** view. See Monitor Security Status of Applications.
- Verify that there is an attack policy enabled, and that it has an action of **Detect** or **Block** for a monitored application with active nodes. See Cisco Secure Application Policies.
- It is also possible that there are no attacks detected in the monitored applications.

End User Monitoring

AppDynamics End User Monitoring (EUM) provides end-to-end visibility on the performance of your web and mobile applications. EUM helps you troubleshoot problems such as slow web responses, Ajax errors, mobile network requests, and IoT application errors. EUM provides metrics on application performance and user activity, such as:

- How server performance impacts your web, mobile, and device performance
- How third-party APIs impact your web, mobile, and device performance
- Where your heaviest loads originate
- How your users connect to and navigate your application

Installation

- Inject the JavaScript Agent
- Instrument iOS Applications
- Instrument Android Applications
- Instrument Applications with the IoT C/C++ SDK
- Instrument Applications with the IoT Java SDK

Configuration

- Configure the Controller UI for Browser RUM
- Configure the Controller UI for Mobile RUM
- Configure IoT Application Monitoring
- Configure the JavaScript Agent

Using EUM

- Browser Snapshots
- Pages & Ajax Requests View
- Synthetic Scripts
- Mobile App Dashboard
- Monitor Applications with the IoT Dashboards

Extensibility and Reference

- Customize the iOS Instrumentation
- Customize the Android Instrumentation
- Browser RUM Metrics
- Browser Synthetic Metrics
- Mobile RUM Metrics

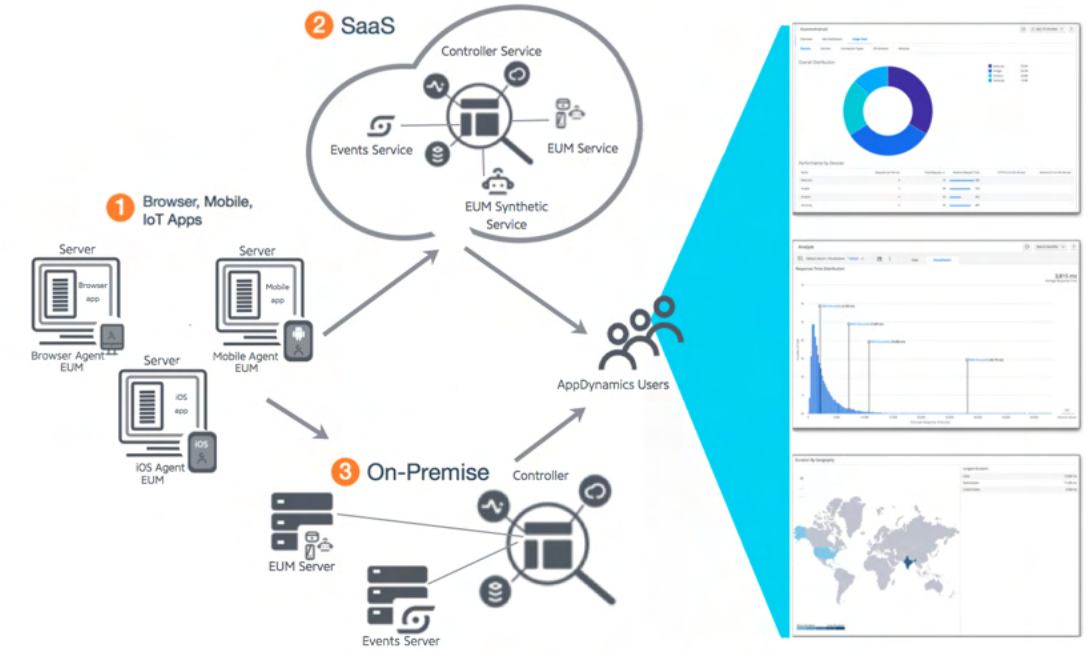
Overview of End User Monitoring

AppDynamics End User Monitoring (EUM) gives you visibility on the performance of your application from the viewpoint of the end user.

While Application Performance Monitoring (APM) measures user interaction starting at the web server or application server entry point, EUM extends that visibility all the way to the web browser, mobile, or IoT application. As a result, EUM reveals the impact the network and browser rendering time have on the user experience of your application.

The diagram below provides an overview of the different components, deployment models (SaaS/on-premises), and the Controller UI as seen by AppDynamics end users. The SaaS deployment uses services (Controller Service, Events Service, EUM Service, EUM Synthetic Monitoring Service) to collect, store, and process data. The on-premises deployment requires DevOps to install discrete components such as the Controller and servers (Events Server, EUM Server) to collect, store, and process data.

How EUM Works



Step	Description	Component(s)
1	The Browser, Mobile, and IoT Agents run in end user applications, collect metrics, and then transmit that data to either a SaaS or an on-premises deployment of AppDynamics.	• Browser/Mobile/IoT Apps • EUM Agents
2	The SaaS Cloud stores, processes, and analyzes data, and then delivers EUM metrics to the Controller UI.	• **Controller Service**: stores data and metadata, makes calls to the EUM Server for raw data and to the Events Service for analytics data • **Events Service**: stores short-term EUM data (sessions, network requests, snapshots, etc.) for heavier analysis • **EUM Service**: verifies, aggregates, and packages raw app metrics • **EUM Synthetic Monitoring Service**: schedules and executes Browser Synthetic jobs and returns session data to the Controller

3	The on-premises deployment has most of the same components and data as the SaaS model. DevOps installs and administers their own Controller, Events Service, and EUM Server. The EUM Synthetic Monitoring Service and sessions data, however, are not available in the on-premises deployment.	• Controller • Events Server • EUM Server See the descriptions for each component above in step 2. The EUM Server performs the same functions as the EUM Service.
4	Users can go to the Controller UI to view and analyze EUM metrics as snapshots, pages, Ajax requests, sessions, network requests, or in the form of charts and graphs.	• Controller UI

Understand End User Activity

Using EUM, you can determine:

- Where geographically your heaviest application load is originated
- Where geographically your slowest End User response times occur
- How performance varies by
  - location
  - client type, device, browser and browser version, and network connection for web requests
  - application and application version, operating system version, device, and carrier for mobile requests
- What your slowest web/Ajax requests are, and where the problem may lie
- What your slowest mobile and IoT network requests are, and where the problem may lie
- How application server performance impacts the performance of your web and mobile traffic
- Whether your mobile or IoT applications are experiencing errors or crashes and the root cause of the issues. For example, for mobile applications, EUM provides stack traces and event trails for the crash or error, helping you troubleshoot and optimize mobile applications.

View EUM Data

The performance information generated by EUM is distinct from the application monitoring data generated by app server agents.

EUM data appears in various locations in the Controller UI, including in the **User Experience** dashboard, **Metric Browser**, and AppDynamics **Analytics** pa ges.

When linked to application business transactions, EUM data gives you a complete view of your end users' experience from the client request, through the application environment, and back to the client as the user response.

You can view EUM performance data in the Controller UI in the **User Experience** tab. From there, you can access information specific to browser applications, mobile applications, or connected devices (IoT applications).

On-Premises EUM Deployments

By default, EUM is configured to use an AppDynamics-hosted component called the EUM Cloud. For a fully on-premises installation, the EUM Server provides the functionality of the EUM Cloud. For information, see EUM Server Deployment.

Some functionality for EUM depends on the AppDynamics Platform Events Service. In a SaaS environment, this is managed by AppDynamics, but it is also possible to use this functionality in an on-premises form.

To host the Events Service on premises, see:

- Custom Install
- Events Service Deployment

If you are adding EUM to an existing on-premises Controller installation, you should evaluate your current configuration's ability to handle the additional load imposed by EUM. For more information, see Additional Sizing Considerations.

Access the SaaS EUM Server

The SaaS EUM Server consists of the components listed below. Each component may have different endpoints depending on the region of your Controller.

- EUM Services - The Mobile Agents, JavaScript Agent, and IoT SDKs send data to the EUM Services. The Controller fetches data from the EUM Server.
- Events Service - The EUM Server sends analytics data to the Events Service. The Controller also queries the Events Service.
- Synthetic Services - The Synthetic Private Agent and Synthetic Hosted Agent send data to the Synthetic Services.

If your SaaS or on-prem deployment requires access to any of these components on the Internet, make sure the URLs given in SaaS Domains and IP Ranges are accessible from your network.

> For on-prem deployments, however, the EUM Server can either be located on the Internet or hosted inside your own data center/network. On-premises access points are configured at installation or through the UI. See EUM Server Deployment and Events Service Deployment for more information.

How EUM Works with other AppDynamics Products

This section describes how other App iQ Platform products work with EUM to provide complete, full visibility on application health and user experience.

EUM and Application Performance Monitoring

Using APM with EUM provides you with greater insight into how the performance of your business application affects the end-user experience. To integrate APM with EUM, you correlate business transactions with browser snapshots. This enables you to trace bad user experiences to issues with your backends such as an unresponsive web service, bad database query or slow server response. To learn how to integrate APM with EUM, see Correlate Business Transactions for EUM.

You can also use the server app agents running on business applications that serve your browser applications to inject JavaScript agent into the code that runs on the browser. This obviates the need to manually inject the JavaScript agent. For more information, see Automatic Injection and Assisted Injection.

> You must assign unique names to EUM applications and business applications. For example, if you created the business application "E-Commerce", you cannot create a browser, mobile, or IoT application with that same name or vice versa.

EUM and Application Analytics

AppDynamics Application Analytics enables you to use the powerful AppDynamics Query Language (ADQL) to analyze different types of EUM data through complex queries. The Analytics components are based on the Events Service, which is also the source of data for Browser Analyze, Crash Analyze , Network Requests Analyze, and all IoT data. Analytics requires a license separate from the EUM licenses except for IoT Monitoring.

Learn More

For more information on the type of user monitoring you interested in, see:

- Browser Real User Monitoring
- Browser Synthetic Monitoring
- Mobile Real User Monitoring
- IoT Monitoring

Experience Journey Map

Experience Journey Map provides real-time insights into business and application performance, visualizing key user journeys and the correlation between performance and traffic. This perspective unifies all application stakeholders: application owners, developers, and IT operations.

Experience Journey Map visualizes:

- Performance metrics for each step in a user journey
- Top incoming and outgoing traffic data for each step
- Drop-off rates

Learn about use cases for Experience Journey Map.

Requirements

To use Experience Journey Map, the following requirements must be met:

- SaaS: Controller >=20.6.0
- On-premise: Controller >=20.7.0
- EUM Peak license (RUM Peak, Browser RUM Peak, or Mobile RUM Peak)
- Instrumented browser or mobile application

Access Experience Journey Map

To access Experience Journey Map:

1. Under the **User Experience** tab, go to a browser or mobile app.
2. In the left application panel, click **Experience Journey Map**.

Experience Journey Map UI

The sections below provide an overview of the Experience Journey Map UI. In the Controller, click on the **Legend** for key terms.

Experience Journey Map Dashboard

The Experience Journey Map dashboard displays the top user journeys, or the most trafficked parts of an app. The default time frame is set to one hour, but you can adjust the time and the dashboard automatically updates the user journeys and data for that time frame.

End User Events

Each step in a user journey is visualized with an end user event. An end user event is a browser page or mobile view/activity. Experience Journey Map displays the most trafficked end user events.

Click an end user event to see:

- Total user visits from all sources
- Incoming and outgoing traffic sources
- Performance breakdowns for each traffic source
- Drop-off rate

Traffic Segments

A traffic segment connects two end user events and contains data about users who journeyed from one end user event to the next. Traffic segments display a health status icon for errors and exceeded performance thresholds. To edit performance thresholds, see Configure Experience Journey Map.

Click a traffic segment to see:

- Number of users who came from the previously mapped end user event
- Performance metrics for those users
- Option to analyze individual browser or mobile sessions for that end user event

Refresh Loops

A refresh loop is a type of traffic segment and contains data for users who refresh an end user event.

Click a refresh loop to see:

- Number of users who refreshed the end user event
- Performance metrics for those users
- Option to analyze browser or mobile sessions for that end user event

Experience Journey Map for Browser vs. Mobile Apps

The table below describes the differences in **Experience Journey Map** data for browser vs. mobile apps.

Component	Browser App	Mobile App
End User Event	An end user event shows data for one browser page. To customize end user event names, see Configure Page Identification and Naming.	An end user event shows data for one iOS view or Android activity. To customize how the mobile agent reports the view/activity names via the `SessionFrame` API, see the following: • Customize the iOS Instrumentation • Customize the Android Instrumentation • Customize the Xamarin Instrumentation • Customize the Cordova Instrumentation Hybrid agents (Cordova, React Native, and Xamarin) do not support individual screen tracking, which affects how Experience Journey Map displays events in a user journey. To ensure each screen is displayed in a user journey, we recommend using the `SessionFrame` API to define when a screen starts and ends. See documentation for each hybrid agent: • Customize the Xamarin Instrumentation • Customize the Cordova Instrumentation • Customize the React Native Instrumentation
Default performance threshold metric	Performance thresholds (Slow, Very Slow, Stall, and Normal) are set to End User Response Time (EURT), or page load time.	Performance thresholds (Slow, Very Slow, Stall, and Normal) are set to the average time of mobile network requests.
Types of errors captured	JavaScript and AJAX errors.	Crashes and Application Not Responding (ANRs).
Analyze functionality	When you click **Analyze**, you are redirected to Browser RUM Analyze with filters applied for that mapped browser page.	When you click **Analyze**, you are redirected to Mobile Sessions with filters applied for that mapped mobile view/activity.
Misc.	Iframes are captured and included as a node with performance metrics, such as for SPA2 base pages.	You may notice that sometimes the metric breakdowns of performance thresholds do not add up to 100%. See Analyze Traffic for an example. This is because for mobile apps, performance thresholds are set to an average of only the network request(s) triggered from a view/activity. If the number of triggered network requests is less than the number of total network requests, the performance threshold breakdown does not add up to 100%.

Using Experience Journey Map

- Make a Custom Map
- Filter Experience Journey Map
- Analyze Traffic

- Configure Experience Journey Map
- Browser RUM Analyze
- Mobile Sessions

How to Use Experience Journey Map

This page covers how to use Experience Journey Map to view select user journeys.

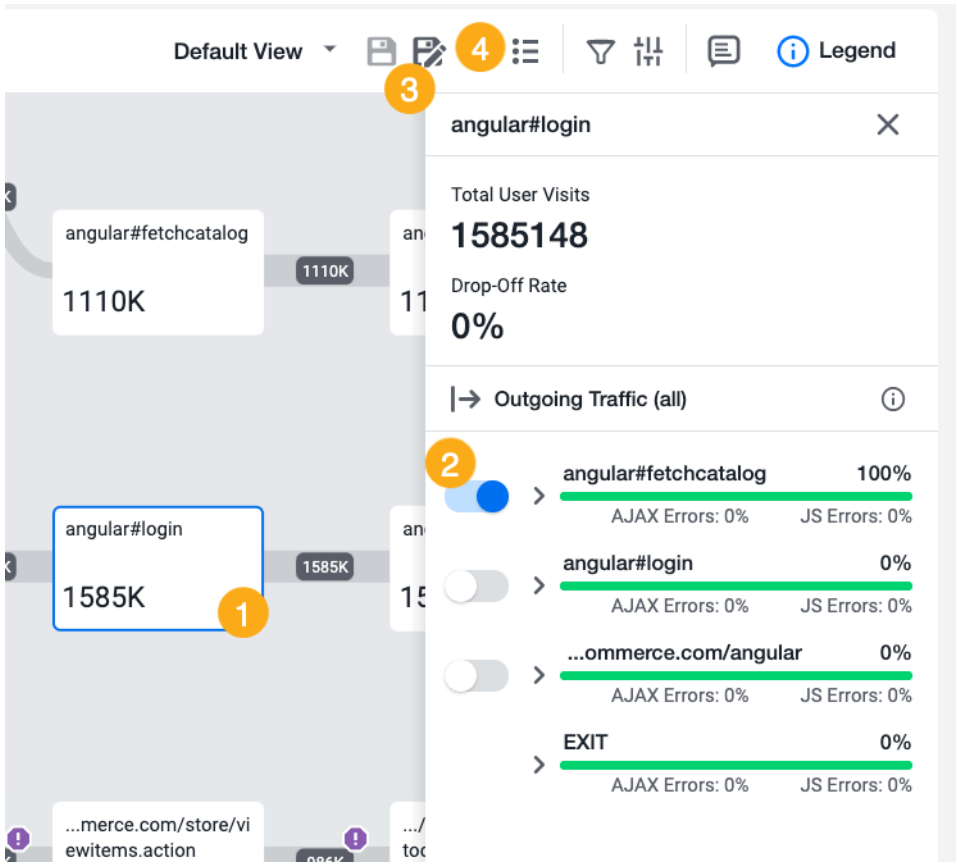
Create a Custom View

The default Experience Journey Map view shows top user journeys for the entire application. If you want to see the top journeys for specific flows and events, you can create a custom view. For example, if you designed for different flows, such as a travel booking app for booking a hotel, a flight, and a rental car, you can create three custom views for each flow.

> Custom views are available with SaaS Controller >= 21.4.0.

To create a custom view:

1. Click on any event of a user flow.
2. Toggle the next event you want to see.
3. Click and name the custom view.
4. Click to view, edit, and delete your custom views.



Filter Experience Journey Map

You can filter user journeys by the fields listed below to see user journeys through a helpful context, such as troubleshooting a crash by mobile device version. When you apply a filter, such as a mobile device version iOS 10, Experience Journey Map shows the top journeys for iOS 10 users.

To use the filters:

1. In the upper right-hand corner, click on the **Filter Panel** .
2. Select a filter(s).
3. Click **Apply**.

Available Filters

The table below lists available filters for Experience Journey Map.

Application Type	Fields

Browser	• Browser • Country • Device • Device OS • Internet Service Provider (ISP) • Custom User Data
Mobile	• Application Version • Carrier • Connection Type • Country • Device Model • Device Version • OS Version • Custom User Data

Using the Custom User Data Filter

The custom user data filter allows you to filter user journeys by user data strings you previously configured (strings with a maximum of 5000 values).

> Custom user data you configure is automatically included in the Experience Journey Map data collection.

To filter by custom user data:

1. Click on the **Filter Panel** .
2. In the panel, click on > **Select Visible Filters**.
3. In the **Filter Panel** , check the "Custom User Data" box.
4. Start typing a data string. The screen will auto-populate with data available.
5. In the pop-up, check data you want to filter.
6. Click **Apply**.

> To configure custom user data, see:
>
> - Add Custom User Data to a Page Browser Snapshot
> - Customize the iOS Instrumentation
> - Customize the Android Instrumentation

Analyze Traffic

A traffic segment connects two end user events and contains data about users who journeyed from one end user event to the next. The **Analyze** functionali ty allows you to drill down into individual browser or mobile sessions for that traffic segment. When you click **Analyze**, you are redirected to Browser RUM Analyze or Mobile Sessions with applied filters for the users who navigated from the previous end user event to the next.

Analyze User Journeys with Applied Filters

If you apply a filter and click **Analyze** on a traffic segment or end user event, the applied filters will carry over to Browser RUM Analyze or Mobile Sessions.

Use Cases for Experience Journey Map

Related pages:

- Experience Journey Map
- Configure Experience Journey Map
- Browser RUM Analyze
- Mobile Sessions

This page describes top use cases for Experience Journey Map and is categorized by application stakeholder: IT operations, developers, and application owners.

IT Operations

Goal	Use Case
Prioritize performance-related incidents	Investigate why users are experiencing Ajax errors on a browser application: 1. In Experience Journey Map, you see that a correlation of Ajax errors, a high drop-off rate, and the majority of Ajax errors occurs on Internet Explorer browsers. 2. Filter user journeys by browser and notice that the trend maintains. 3. Click on **Analyze** to see Browser Sessions with the criteria you filtered in Experience Journey Map.
Create real-world, data-backed testing	Create a data-backed Synthetic script for browser application testing: 1. In Experience Journey Map, look at top user journeys within the default time frame. 2. Adjust the time frame to one day, one week, and one month. 3. Identify the top user journeys in each time frame and note if there are consistencies throughout. 4. Write a synthetic script to test those top user journeys.
	Investigate if crashes correlate with a specific mobile device version: 1. In Experience Journey Map, click on a few iOS views containing crashes. You see that most users experiencing those crashes are using iPhone 8. 2. Filter user journeys by mobile device version to diagnose if one version is causing those crashes. 3. Fix the issue related to the device version. 4. Filter Experience Journey Map by that device version again and validate the fix.

Developers

Goal	Use Case
Prioritize and resolve errors	Identify the source of iOS application crashes in the last 24 hours: 1. In Experience Journey Map, click the traffic segment to identify the top user device and OS. 2. Use this data to reproduce the crashes. 3. Click **Analyze** on the traffic segment to view each mobile session crash and identify the mobile crash stack trace. 4. Once you fix the issue, use Experience Journey Map to validate the fix.

Application Owners

Goal	Use Case
Manage and prioritize resource investments	Evaluate user interactions with a new banking application feature: 1. In Experience Journey Map, filter user journeys to see traffic metrics for the new feature. 2. Depending on whether the new feature is gaining more or less traffic than expected, collaborate with IT operations and developers to increase or decrease resources around the feature.

Configure Experience Journey Map

Related pages:

- Configure Mobile Network Request Naming

This page describes how to configure Experience Journey Map. Though Experience Journey Map does not require configuration, you can adjust performance thresholds and change end user event names to better suit your business needs.

Configure User Experience Thresholds

You can configure the timing and standard deviations for performance thresholds such as Slow, Very Slow, and Stall. When you configure these deviations, the changes apply to all Controller views of that application, not just to Experience Journey Map. To configure from Experience Journey Map, go to **Info** > **Configure thresholds**.

Configure Performance Thresholds and Drop-off Rates

To configure performance thresholds, you must have Controller >=20.8.0 and a "Configure EUM" user permission. To configure user and role permissions in the Controller UI, go to **Settings** > **Administration**.

Toggle On or Off

You can toggle performance thresholds and drop-off rates on or off. When a threshold or drop-off rate is toggled off, the marker does not appear on Experience Journey Map. When you toggle a threshold on, the threshold resets to the previous value (and not necessarily the default value).

Configure Values

For performance thresholds and drop-off rates, the percentage is set to the minimum traffic for a marker to appear on a user journey event. For example, if Ajax Errors is set to 30%, Experience Journey Map displays an error icon when 30% and more of user traffic experiences Ajax Errors. You can configure the values for performance thresholds and drop-off rates. The table below lists default performance thresholds values for existing and new applications.

Change End User Event Names

In Experience Journey Map, a user journey is a collection of end user events. End user events represent browser pages or mobile views/activities.

Browser Applications

For browser apps, you can rename and group end user events that are meaningful to your business. For example, if you have a collection of ecommerce URLs of user steps to place an order, you can rename those URLs with pages names like "Order info," "Order review," and "Order confirmation." To rename end user events, see Configure Page Identification and Naming.

Mobile Applications

For mobile apps, you cannot change mobile view/activity names in the Controller, but you can customize how the mobile agent reports the event names via the `SessionFrame` API. See these pages for instructions:

- Customize the iOS Instrumentation
- Customize the Android Instrumentation

About Hybrid Applications

Hybrid agents (Cordova, React Native, and Xamarin) do not support individual screen tracking, which affects how Experience Journey Map displays events in a user journey. To ensure each screen is displayed in a user journey, we recommend using the `SessionFrame` API to define when a screen starts and ends. See documentation for each hybrid agent:

- Customize the Xamarin Instrumentation
- Customize the Cordova Instrumentation
- Customize the React Native Instrumentation

Correlate Business Transactions for EUM

This page describes how to correlate business transactions for End User Monitoring (EUM). You can correlate the network request events of EUM applications with the business transactions of Business Applications. The EUM application can be a browser, mobile, or IoT application. The correlation is made between EUM application beacons containing network request event information and instances of business transactions (transaction snapshots).

For detailed information, including how and what is correlated for each type of EUM application, see these pages:

- Correlate Business Transactions for Browser RUM
- Correlate Business Transactions for Mobile RUM
- Correlate Business Transactions for IoT Monitoring

Benefits of Correlating Business Transactions

By correlating business transactions with network request snapshots, you can identify potential issues with the backend application that are causing bad user experiences. For example, you might find that a server error or a database query is causing a slow user experience.

Before You Begin

To correlate business transactions:

1. Purchase licenses for Application Performance Monitoring (APM) and End User Monitoring (EUM).
2. Instrument a business application with a supported app server agent.
3. Instrument an EUM application (browser, mobile, or IoT application).

> If automatic business transaction correlation is not supported for your app server agent, you can manually enable business transaction correlation in the Controller UI.

Business Transaction Correlation Support for App Server Agents

This table shows the app server agents that support business transaction correlation.

- Automatic correlation support means that business transactions are automatically correlated.
- For manual correlation, you must manually enable business transaction correlation.

App Server Agent	Type of Correlation Support
Java Agent	Automatic (Java Agent >= 20.3.0, and Controller >= 20.4.0)
.NET Agent	.NET Framework: Automatic (.NET Agent >= 20.9.0, and Controller >= 20.10.0)
	.NET Core: Automatic (.NET Agent >= 21.1.0, and Controller >= 20.10.0), Windows only
	Linux: Automatic (.NET Agent >= 21.5)
Node.js Agent	Manual
PHP Agent	Manual
Python Agent	Manual

Access Business Transaction Correlation

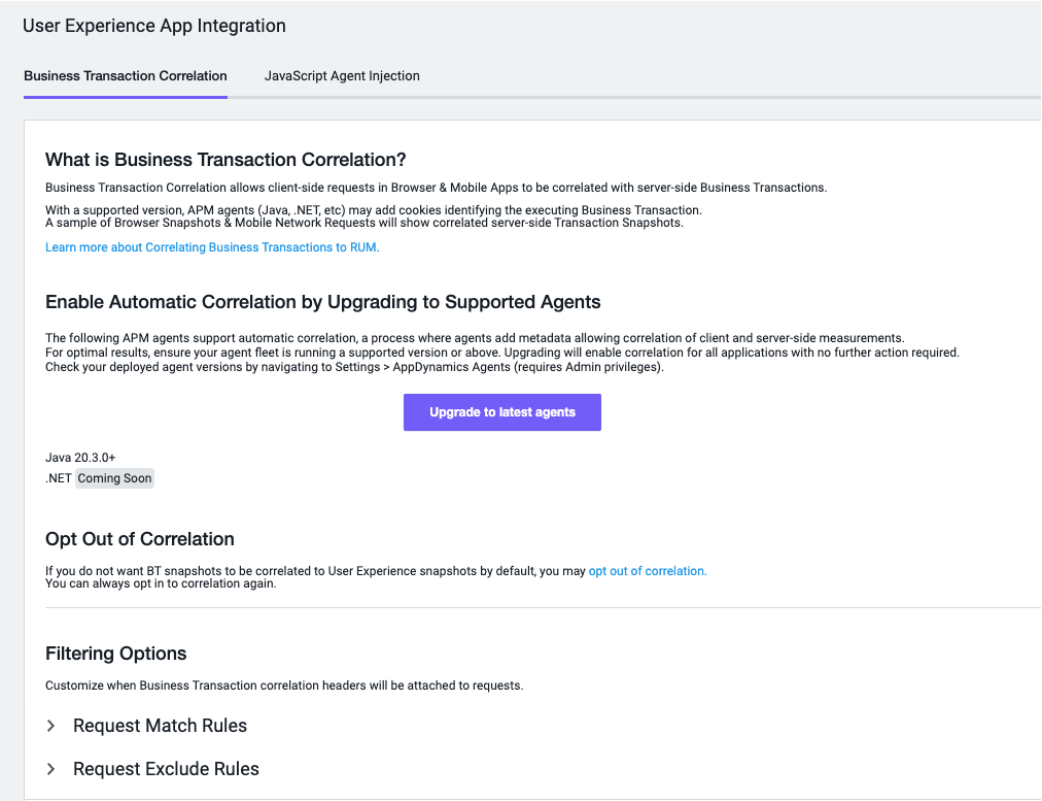
To configure business transaction correlation:

1. In the **Application Dashboard**, click **Configuration** > **User Experience App Integration**.
2. Under the **Business Transaction Correlation** tab, there are two options depending on the correlation support for your App Server Agents:
    - For agents with support for automatic correlation, see Automatic Correlation of Business Transactions.
    - For agents without support for automatic correlation, see Manually Enable Business Transaction Correlation.

Automatic Correlation of Business Transactions

By default, the correlation of business transactions of business applications instrumented with Java Agent >= 20.3.0 is enabled.

Under the **Business Transaction Correlation** tab, you can choose to opt out or filter requests with match or exclude rules.



Opt In to Automatic Correlation

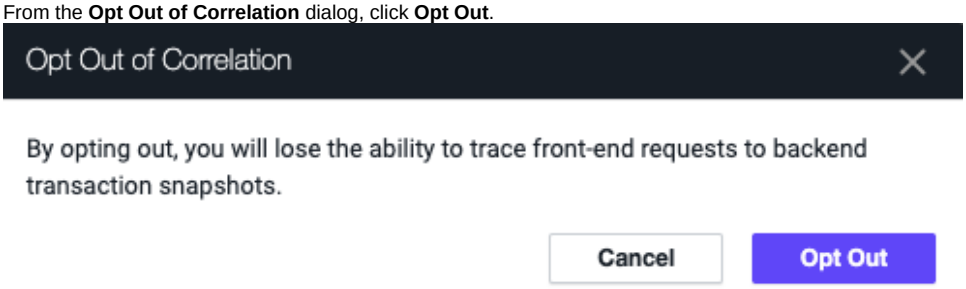
To opt in to have business transactions automatically correlated, you must use Java Agent >= 20.3.0. If you are using an older version of the Java Agent, you must upgrade the agent.

For unsupported agents, you need to manually enable business transaction correlation.

Opt Out of Automatic Correlation

If business transaction correlation is enabled by default, you can opt out by:

1. In the **Application Dashboard**, click **Configuration** > **User Experience App Integration**.
2. Under the **Business Transaction Correlation** > **Opt Out of Correlation**, click **opt out of correlation**.
3. From the **Opt Out of Correlation** dialog, click **Opt Out**.

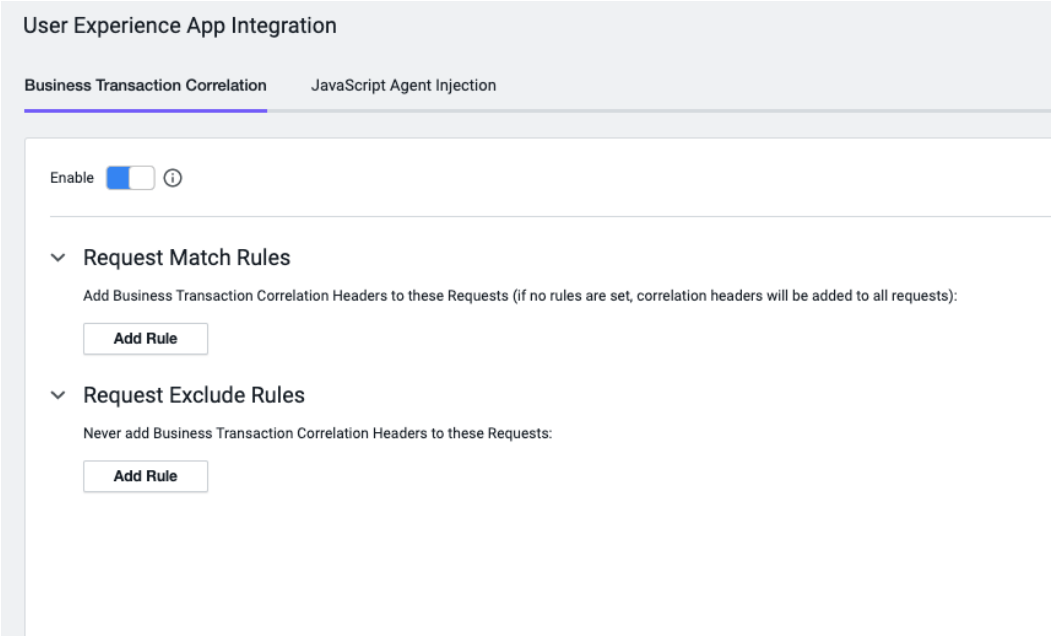


Manually Enable Business Transaction Correlation

For app agents that do not have automatic correlation support, you need to manually enable business transaction correlation.

To manually enable business transaction correlation:

1. In the **Application Dashboard**, click **Configuration** > **User Experience App Integration**.
2. Under the **Business Transaction Correlation** tab, check the **Enable Business Transaction Correlation** checkbox.



Disable Business Transaction Correlation

To disable business transaction correlation:

1. In the **Application Dashboard**, click **Configuration** > **User Experience App Integration**.
2. Under the **Business Transaction Correlation** tab, toggle the **Enable** button.

Filter Business Transactions for Correlation

You can also specify which business transactions includes or excludes correlation headers. If you do not add request match rules or request exclude rules, all requests have correlation headers by default.

To add a request match or exclude rule:

1. From **Filtering Options**, expand **Request Match Rules** or **Request Exclude Rules**.
2. Click **Add Rule**.
3. Check the **Method** to use the default `HTTP` method `GET` or select a different `HTTP` method.
4. Check the **URI** checkbox and select one of the matching methods from the dropdown:
    - **Starts With**
    - **Ends With**
    - **Contains**
    - **Equals**
    - **Matches RegEx**
    - **Is in List**
5. (Optional) Click  and check the **NOT** checkbox. This condition reverses the results by excluding the requests that match the specified parameters.
6. Click **Add Rule**.

EUM Data

Related pages:

- Using the Controller APIs

With the iOS 14 release (supported by iOS Agent 20.10.0), Apple introduced a new data collection policy. See iOS Data Collection Disclosure for details.

This page describes the types of EUM data, how data is collected, where data is store, and where data is displayed in the Controller. For data retention and license consumption details, see License Entitlements and Restrictions.

Types of EUM Data

Metric Data

Metrics are data that reflect your application's performance. Browser RUM captures metrics from browser applications, such as timing and Ajax metrics. Mobile RUM captures metrics from mobile applications, such as crash metrics and network request metrics. You can view and analyze EUM metrics in the Metric Browser.

To learn more about EUM metrics, see:

- Browser RUM Metrics
- Browser Synthetic Metrics
- Mobile RUM Metrics
- Extensions and Custom Metrics

Custom Data

Browser RUM

You can add specific user information a browser snapshot of your application. The information is expressed as key-value pairs, appears in the **User Data** s ection of the snapshot, and is available for page snapshots, Ajax requests, and virtual pages. To learn how to set custom user data, see Add Custom User Data to a Page Browser Snapshot.

Mobile RUM

Mobile RUM custom data such as Info Points, Custom Timers, and Custom Metrics are considered metrics and stored as mobile request event data. User data is another type of Mobile RUM custom data. Custom user data can be reported through network request events because user data is attached to each network request.

To learn how to set user data, see User Data (iOS SDK) or User Data (Android SDK).

EUM Analytics Data

You can view EUM data in Analytics if you have a Real User Monitoring Peak license. The EUM Analytics data consists of event data and is stored in the Events Service and visualized in widgets. EUM Analytics provides data for these event types:

- Browser Requests Event Data
- Browser Sessions Event Data
- Mobile Requests Event Data
- Mobile Sessions Event Data
- Mobile Crash Report Event Data
- Synthetic Sessions
- Connected Device Data

Cookies for Browser Applications

Browser RUM uses two different kinds of short-lived cookies for the JavaScript Agent to collect data and correlate events. Both type of cookie do not contain any personally identifiable information (PII) and are immediately deleted after being read.

- The `ADRUM` cookie: Written by the JavaScript Agent, this cookie contains the referral page URL and some timing information to assist gathering First Byte Time for some browser types. When the agent loads on the subsequent page, it reads the information and then deletes the cookie. If there is no agent on that page, the cookie is deleted when the browser is closed. For privacy purposes, the URL of the referral page is hashed.
- The `ADRUM_BT` cookies: Written by the server-side agent when the page is served from an instrumented server. These cookies help correlate browser data with related server-side performance data.
    - `ADRUM_BTa`: Contains the backend transaction ID as well as timing info and is used to correlates end-user experience with the health of the backend app.
    - `ADRUM_BTg`: Contains the backend transaction ID and is used as an alternative method to correlate end-user experience with the health of the backend app.

- `ADRUM_BT[1-5]`: Contains the business transaction numbers as well as timing and error info for the first five business transactions, such as `ADRUM_BT1`, `ADRUM_BT2`, etc.
- `ADRUM_BTs`: Contains a link from a browser snapshot to a server snapshot.
- `ADRUM_BTh`: Written only if there was a server-side error.

If Browser RUM detects that the page is HTTPS, the `Security` attribute is set for cookies. The `Security` attribute is a flag that forbids a cookie from being transmitted via an unencrypted HTTP connection.

Web Storage

Browser RUM stores key-value pairs in web storage to associate page views with a particular session and browser. The value for each key is a randomly generated ID.

The following lists the keys and the expiration time for each key-value pair:

- `ADRUM_AGENT_INFO` (never)
- `ADRUM_CLIENTINFO` (never)
- `ADRUM_XD_AGENT_ID` (never)
- `ADRUM_XD_AGENT_INFO` (1 week)

Mobile Local Storage

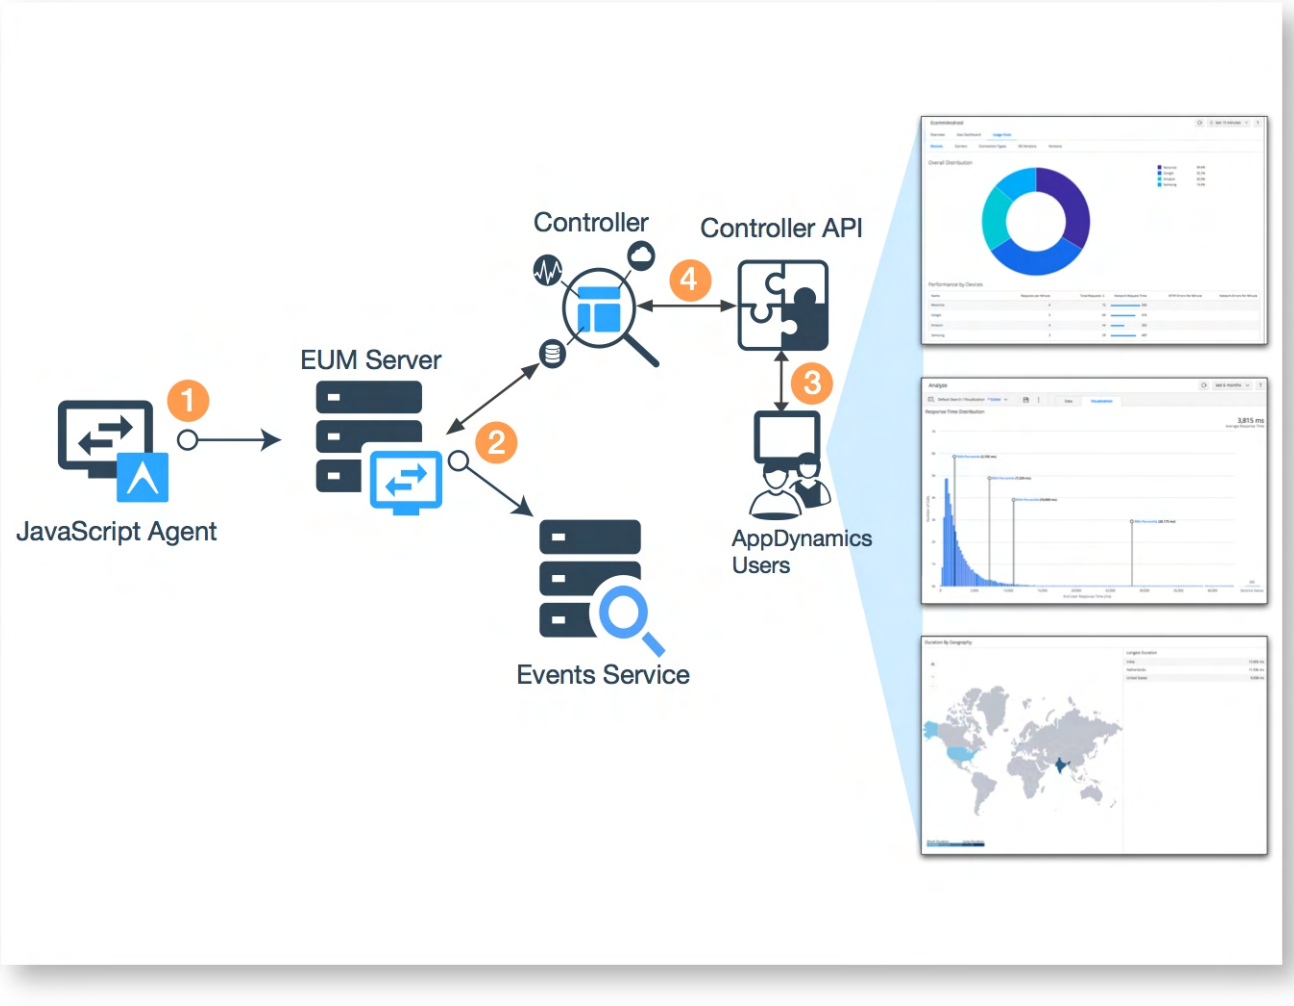
Mobile agents use beacons to transmit metrics, app metadata, network requests, crashes, and custom data. When a beacon cannot be transmitted, the data is persisted in permanent storage within the container of the application and subject to the security configuration of the device and application. No encryption is currently being utilized. Once the network connection is restored, the beacons resume transmitting data. Because some of the data is provided by the developer's instrumentation of the app, such as breadcrumbs, user info, and the app (URLs, crash reports), some information is not explicitly collected by AppDynamics.

Mobile agents also locally stores a randomly generated ID for tracking sessions and license usage. The ID is stored in the Events Service.

How Data Is Stored and Retrieved

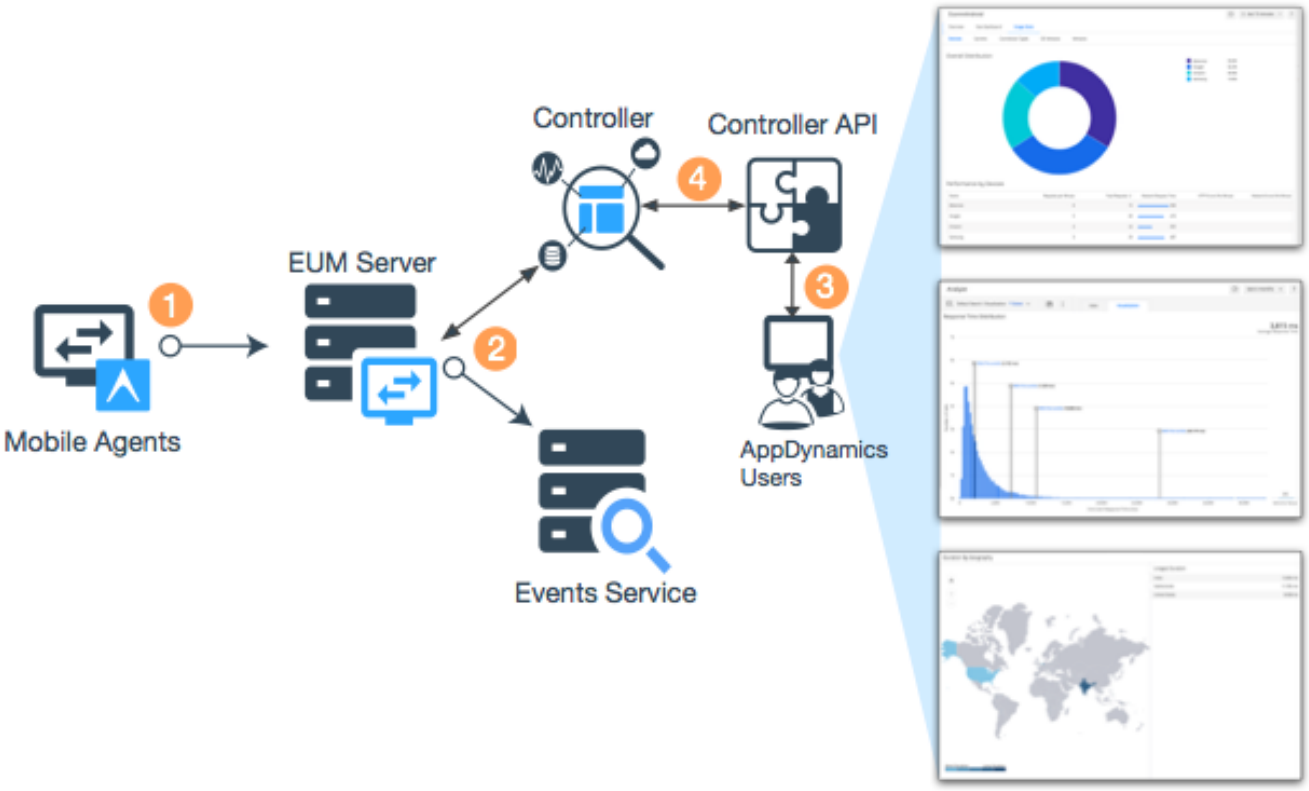
Browser RUM

Browser RUM data is stored in the Controller, the Events Service, and the EUM Server. 1 The JavaScript Agent sends raw data to the EUM Server, where the data is verified, aggregated, and packaged every minute. 2 The EUM Server then sends data to the Events Service. 3 The Controller UI makes requests to the 4 Controller API, which fetches data from one of the three data stores (EUM Server, Events Service, Controller). Because the Controller UI only interacts with the Controller API, it does not need to know where the data is stored.



Mobile RUM

Mobile RUM data is stored in the Controller, the Events Service, and the EUM Server. 1 The Mobile agents send raw data to the EUM Server, where the data is verified, aggregated, and packaged every minute. 2 The EUM Server then sends the data to the Events Service. 3 The Controller UI makes requests to the 4 Controller API, which fetches data from one of the three data stores (EUM Server, Events Service, Controller). Because the Controller UI only interacts with the Controller API, the Controller UI does not need to know where the data is stored.



Data Storage Details

Browser RUM

This table shows where different Browser RUM data is stored. To see how long the data is retained, see License Entitlements and Restrictions. Resource details are only available for those browser snapshots with resource timing.

	Controller	Events Service	EUM Server (SaaS/On-Premises)
Browser Metrics			
Browser Snapshots			
Resource Details			(filesystem)
EUM Page Configuration			(filesystem)
Page View Events			
Ajax Events			
Session Events			
Metadata			(MySQL)
Licenses (SaaS)			(MySQL)
Licenses (On-Premises)			(MySQL)

Browser RUM Default Data Limits per App Key

- Metrics: 100k
- Pages: 500
- Ajax Requests: 500

- Max Event Size: 1 MB

Mobile RUM

This table shows where different Mobile RUM data is stored. To see how long the data is retained, see License Entitlements and Restrictions.

	Controller	Events Service	EUM Server (SaaS/On-Premises)
Mobile RUM Metrics			
Network Request Snapshots			
Custom Data			
Crash Analyze			(filesystem)
Events			
Session Events			
Metadata			(MySQL)
ProGuard/dSYM Files			(filesystem)
Screenshot Files			(S3 for SaaS, filesystem for on-prem)
Licenses (SaaS)			(MySQL)
Licenses (On-Premises)			(MySQL)

Mobile RUM Default Data Limits per Mobile App and App Key

Unit	Metric Limit	Network Requests	Max Event Size
Mobile App	N/A	500	1 MB
App Key	100,000	2000	

Controller Mapping of Data

Browser RUM

This table shows the relationship between the Controller UI components and their data sources.

Controller Component	Storage Mechanism
Overview	Controller
Geo Dashboard	Controller
Browser Snapshots	Controller (no resource details) / EUM Server (SaaS/On-Premises) (resource details)
Usage Stats	Controller
Sessions	EUM Server (SaaS/On-Premises), Events Service
Pages & Ajax Requests	Controller / Events Service (limited)
Analyze	Events Service

Mobile RUM

This table shows the relationship between the Controller UI components and their data sources.

Controller Component	Storage Mechanism
Overview	Controller
Geo Dashboard	Controller
Usage Stats	Controller

Sessions	Events Service
Network Requests	Controller, Events Service (limited)
Network Requests Snapshots	Controller
Crashes	Events Service, EUM Server (SaaS/On-Premises)
Crashes Analyze	Events Service
Custom Data	Controller
Events	Controller

How to Access EUM Data

In addition to accessing EUM data through the Controller UI, you can also access event data through Analytics and the AppDynamics APIs. The AppDynamics APIs include the Analytics Events API and the Metric and Snapshot API that you can use to access EUM metric data.

If you have enabled Analytics and Browser RUM, you can use Browser Analytics to view data for these event types:

- Browser Requests
- Browser Sessions

If you have enabled Analytics and Browser Synthetic Monitoring, you can use Synthetic Analytics to view data for this event type:

- Synthetic Sessions

If you have enabled Analytics and Mobile RUM, you can use Mobile Analytics to view data for these event types:

- Mobile Requests
- Mobile Sessions
- Mobile Crash Reports

If you have enabled IoT Monitoring, you can use Connected Devices Analytics to view data for the event types below. You *do not* need to enable Analytics to use IoT Analytics.

- Connected Device Data

Data and Deployment Models

AppDynamics offers SaaS and on premises deployment models. You can access most Browser and Mobile RUM data from either deployment model.

EUM Accounts, Licenses, and App Keys

This page covers account and licensing information for End User Monitoring (EUM).

View License Usage

To view your EUM license consumption in the Controller, go to  > **License**.

Overages

If your license does not allow overages, AppDynamics stops reporting metrics after your license limit has been reached. If your license does allow overages and your usage exceeds the limit, AppDynamics continues reporting EUM metrics and bills you for the overages at the unit rate stipulated by your license agreement.

License Key

If you have at least one EUM license type, you have an EUM Account, which has a name and a license key associated with it. This is the unique identifier that AppDynamics uses to associate EUM data to your account. You only need to know this information for troubleshooting purposes. The same key applies to all four EUM services. However, each product has its own types and metrics for allowed usage.

EUM App Key

This is the unique identifier that AppDynamics uses to associate end user data to specific EUM applications. Each EUM application will be associated with one EUM App Key. For your applications to be monitored, they will need to include the EUM App Key when reporting data. The EUM App Keys are also associated with an EUM account name and license key.

Changing the license key does not affect existing EUM App Keys.

License Optimization and Usage Periods

For EUM license metric definitions and data retention, see License Entitlements and Restrictions.

EUM License	License Optimization	Usage Period
Real User Monitoring	See Browser and Mobile RUM rows below.	See the Browser and Mobile RUM rows below.
Browser RUM	If the value of Pageviews is greater than **Pageviews Allocated** and your license allows overages, you are incurring overage charges. If you need to stop incurring overage charges, you can disable Browser RUM to stop end user monitoring and stop Pageviews from being charged (once disabled, expect a delay of approximately one minute).	The Browser RUM usage period is per year, even if you have a multi-year license. The meter resets every year based on the expiration of your license agreement. For example, if your license expires at 12:00pm PST on May 1, 2020, your usage period resets every year starting 12:00pm PST on May 1, 2021.

Mobile RUM	License consumption is affected when you have one instrumented application installed on multiple devices, multiple applications on the same device, or uninstalls followed by reinstalls: • If you install one instrumented application on two devices within a month, each device uses one Monthly Active Agent. • If you uninstall and then reinstall an instrumented application multiple times within a month, each reinstall uses one Monthly Active Agent. • If you install two different instrumented applications on the same device within a month, each instrumented application consumes one Monthly Active Agents, so. Through SDKs, you can customize application instrumentation to choose which agents send data. For further instructions, see the following: • Customize the Android Instrumentation • Customize the iOS Instrumentation • Customize the Xamarin Instrumentation • Customize the Cordova Instrumentation	The Mobile RUM usage period begins and the meter resets on the first day of each month at 12:00pm PST. When your license consumption reaches 90% of your Monthly Active Agent allocation, you will see a warning in the Mobile RUM dashboard.
Synthetic	To help you optimize the use of your Synthetic Agent license, keep the following in mind: • Synthetic jobs are measured in terms of the time it takes to actually run the test in AppDynamics systems. Because it is not possible to know in advance how long a given test may take, you can set a timeout value when you create the job. If the job times out, you receive partial results. • Once you have used up your monthly allotment, all synthetic jobs are paused until the following month. • If there is a problem accessing a site, such as receiving a 5xx error, the system automatically runs the job again. You are charged for these retests. • If you see a session with the status INTERNAL_ERROR, this means there is a problem with AppDynamics infrastructure, and you will not be charged, even if the session contains partial results. • Adjusting synthetic job configurations, such as the number of browser types, frequency, and duration, may have an impact on license consumption. To gauge estimated consumption in the Controller, create a new job and see the section **Set a Timeout** (step 6). • Locations are user-defined. You can add multiple servers (agents) to a location to increase capacity, and this does not impact your license.	The usage period begins and the meter resets on the first day of each month at 12:00pm PST.
IoT	License consumption is based on Application Instances. We recommend that you register each Application Instance and each device so that you can correlate data with each data source. To reduce license consumption, you can register just one device with multiple Application Instances, or one Application Instance on multiple devices. However, in doing so, AppDynamics cannot differentiate data, such as errors, for each application instance or device unless each one is registered.	The usage period begins and the meter resets on the first day of each month at 12:00pm PST. The usage period for IoT is always the current month, even if you have a multi-year license.

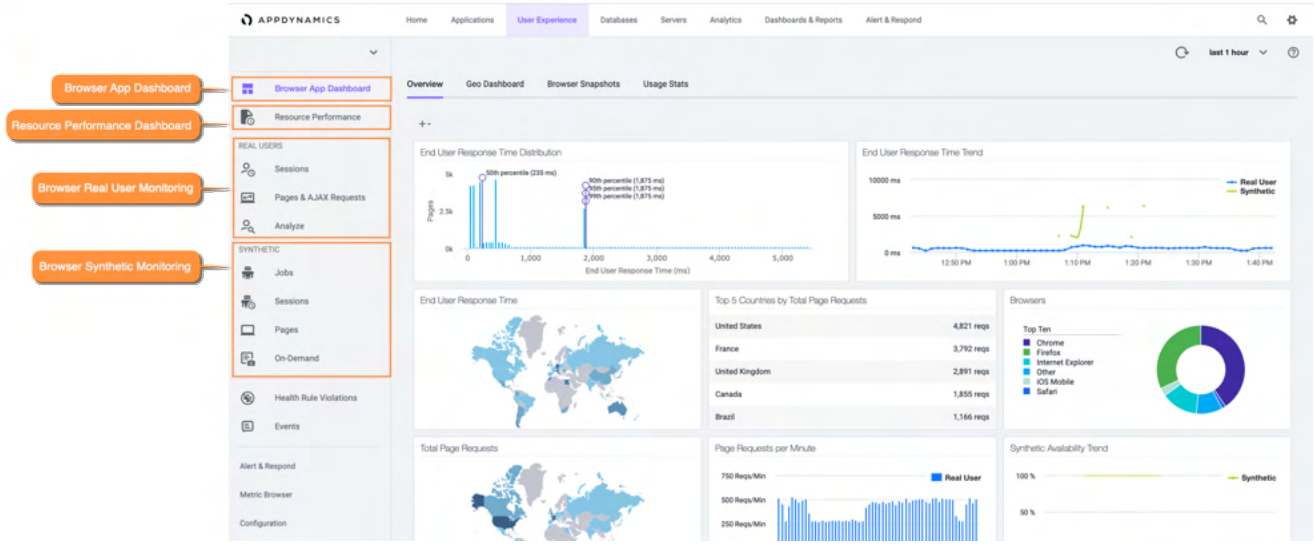
Browser Monitoring

AppDynamics offers two products to monitor browser applications:

- Browser Real User Monitoring (Browser RUM) - Monitors how your web application is performing, using real user data to analyze application performance and user experience.
- Browser Synthetic Monitoring - Analyzes application availability and performance, using scheduled testing to analyze website availability.

Overview of the Controller UI for Browser Monitoring

Browser RUM and Browser Synthetic Monitoring share two dashboards: Browser App Dashboard and Resource Performance Dashboard.



Browser App Dashboard

The Browser App Dashboard provides a high-level understanding of how your application's overall performance. When you first navigate to a browser application, you are defaulted to the **Browser App Dashboard** > **Overview** tab. The **Overview** tab contains widgets for both Browser and Synthetic data.

Resource Performance Dashboard

The Resource Performance Dashboard provides a high-level understanding of how your resources affect the performance of your browser application. You can use this dashboard to pinpoint resource-related performance issues affecting the user experience. You can toggle between viewing Browser and Synthetic data.

Real Users

Browser RUM contains these UI tabs for more detailed real-user data analysis:

- Browser RUM Sessions
- Pages & AJAX Requests
- Browser RUM Analyze

Synthetic

Browser Synthetic Monitoring contains these UI tabs for more detailed synthetic user data analysis:

- Synthetic Jobs
- Synthetic Sessions
- Synthetic Pages
- Synthetic On-Demand

Differences Between Browser RUM and Browser Synthetic Monitoring

Although Browser Synthetic Monitoring and Browser RUM report similar metrics, there are differences in:

- Hardware
- Network connections
- Different browsers
- Browser caching is not present in synthetic sessions

If you see a sudden change in any of those metrics, you should compare the results of Browser Synthetic Monitoring and Browser RUM to determine if there is an existing problem.

Performance Versus Workflows

Browser RUM excels at capturing the full breadth of performance and your real users' experience. Browser Synthetic Monitoring gives you confidence that your key workflows are always working and performing.

Synthetic Metrics and Screenshots

Browser Synthetic Monitoring can collect certain data that Browser RUM cannot. For example, Browser Synthetic Monitoring provides screenshots, which help you see per-page testing. You can also use the Visually Complete Time metric and other related metrics to understand how users experience page load time.

How to Use Browser RUM and Browser Synthetic Monitoring Together

Identify Issues

Although Browser RUM can detect certain kinds of problems (like JavaScript exceptions), it cannot comprehensively test for functional correctness. For example, you may want to verify that your online store has reasonable prices a list of items. If your site is down entirely, then the JavaScript Agent will never be loaded, so errors or verifications will not be reported. Fortunately, Browser Synthetic Monitoring will keep running, discover the error, alert you, and provide detailed information about the problem.

Control Environmental Factors

Hardware, browsers, operating systems, and networks complicate performance analysis in Browser RUM. Browser Synthetic Monitoring uses consistent hardware, software, and network configurations you set when you create a synthetic job, so if you see deviations in performance, you can be fairly certain a problem exists.

Browser App Dashboard

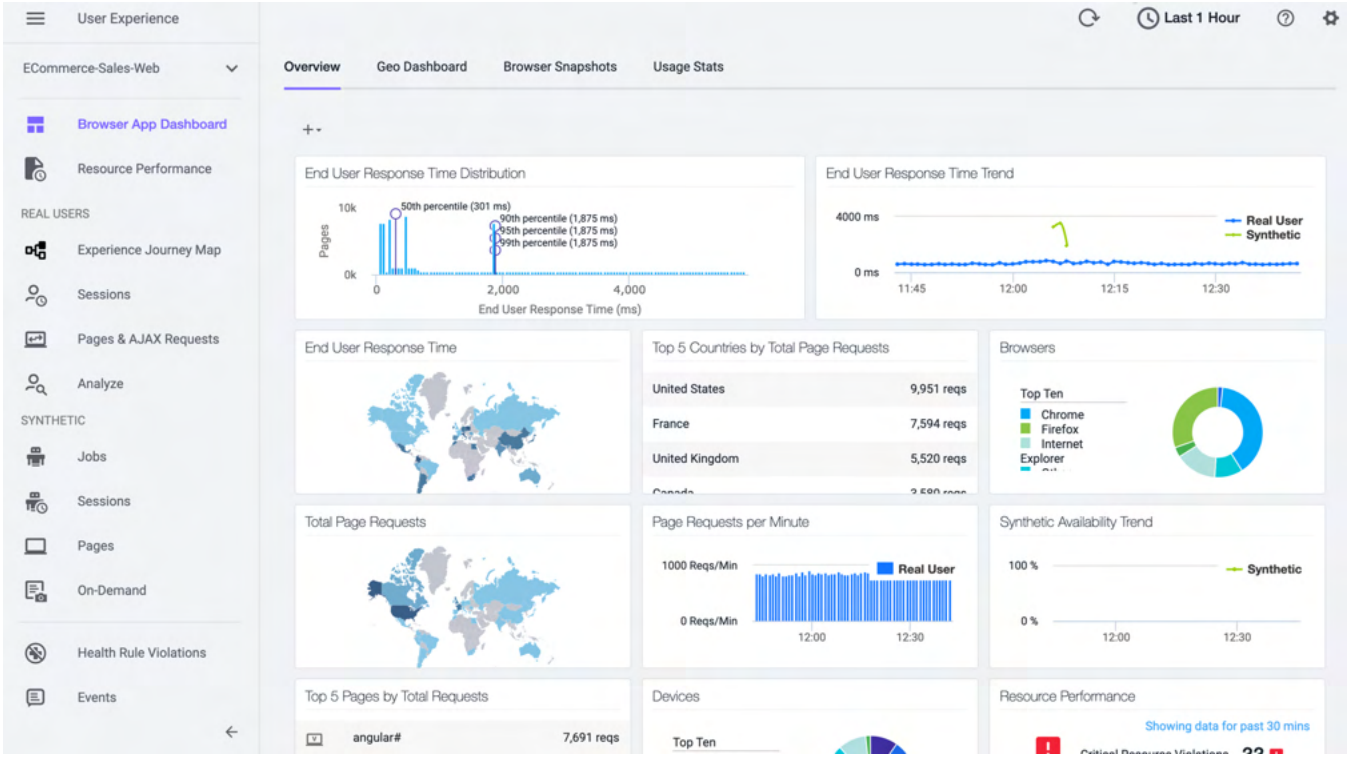
The **Browser App Dashboard** gives you a high-level overview of your browser application performance. To access the **Browser App Dashboard**:

1. In the Controller, go to **User Experience.**
2. Under **Browser Apps**, select an application.
3. In the left navigation bar, click **Browser App Dashboard**.

Overview

The **Overview** tab displays a set of configurable widgets. The default widgets contain multiple graphs and lists featuring common high-level indicators of application performance. You can remove a widget by clicking the X icon and add a widget using the + icon.

> For SPA2 applications, the **Overview** tab only displays data for base pages and virtual page events. Data from Iframe and Ajax requests is not included. If you have an application that only has Iframe and Ajax requests, then the **Overview** tab will not display any data.

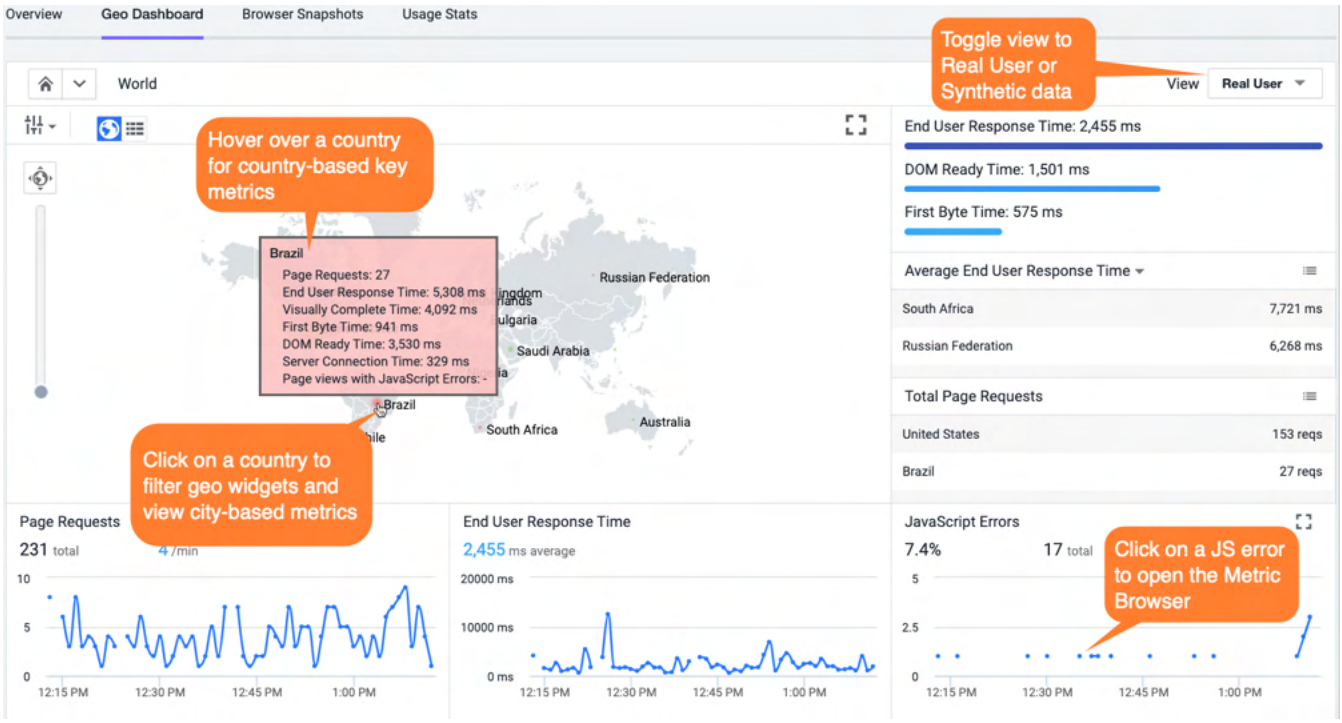


Geo Tab

The **Geo** tab displays key performance metrics by geographic location based on page loads. If you are using Browser Synthetic Monitoring for an application, you can view either Real User or Synthetic data using the **View** dropdown. See Browser Synthetic Monitoring Versus Browser Real User Monitoring.

The metrics displayed throughout the dashboard are for the region currently selected on the Map or in the Grid. For example, on the map if click on France, the widgets and trend graphs update to display data for France.

See Browser RUM Metrics for definitions of the metrics.



Map View Labels

The Map view displays load circles with labels for countries that are in the key timing metrics given in the right panel. Some countries and regions, however, are only displayed in the Grid view.

Regions and Countries

Regions are subdivisions of a country, such as a state, province, or city. In the default Map view, key performance metrics are displayed by country. You can check the **Show regions in Global View** box to view the key performance metrics by region. The default Grid and Map views display key performance metrics by country, but you can view metrics based on region. Because the Map view displays fewer regions than the Grid view, if you do not see a region displayed in the Map view, switch to the Grid view.

See Browser RUM Countries and Regions by Geo Dashboard for a list of the countries and regions available in the Map and Grid views.

Unknown Locations

An unknown location means the agent cannot determine the country from which the request originated.

You may also see metrics reported for a location named "Anonymous Proxy". This means that the agent cannot identify one or more private IP addresses, and the "Anonymous Proxy" represents aggregated metrics from those IP addresses.

One of the effects of Unknown regions is that it possible for a country to display as slow (red circles) on the global map, but when you drill down to the country all its regions appear normal (green circles). Or a country may display as normal on the global map, but some sub-regions may display as slow when you drill down.

Browser Snapshots

The **Browser Snapshots** tab captures and displays a broad set of metrics associated with a single request. You can drill down into errors and view any server-side transaction snapshots associated with that request (if your app server is instrumented with server-side app agents). See Browser Snapshots for more information.

Usage Stats

The **Usage Stats** tab presents aggregated page load usage data based on your users' browser type, device, and platform.

Usage Stats data helps you discover:

- The slowest browsers in terms of total end-user response time.
- The slowest browsers to render the response page.
- The browsers that most of your end users use.
- The browsers that most of your end users use in a particular country or region.

Devices data shows mobile access only via browsers on the device. **Devices** helps you discover:

- The slowest devices in terms of total end-user response time
- The slowest devices to connect to the server
- The devices that most of your end users use
- The devices that most of your end users use in a particular country or region

Browser Snapshots

Related pages:

- Transaction Snapshots
- Configure Browser Monitoring Snapshot Thresholds
- Add Custom User Data to a Page Browser Snapshot

This page describes browser snapshots. When Browser RUM is enabled, the JavaScript Agent collects browser snapshots for:

- Every base page (including virtual pages), iframe, and Ajax request; these serve as a heartbeat snapshot
- The slowest page for every region, every device, and every browser
- Unique JavaScript errors; identified by script name and line number
- Unique Ajax errors; identified by the HTTP error code in the Ajax response

For more information about browser snapshot collection, see Configure Browser Snapshot Collection.

Browser Snapshots Tab

A list of available browser snapshots appears. You can change the time frame of your search by changing the **Time Frame** dropdown.

List Key

 Normal user experience

 Slow user experience

 Very slow user experience

 JavaScript errors (Hover over the icon for a popup with summary information)

 Correlated server-side transaction snapshot exists

 Snapshot includes resource timing information

Browser Snapshot Types

There are three browser snapshot types, depending on whether the original object was a page, an iframe, or an Ajax request.

- Page Browser Snapshots
- Ajax Request Snapshots
- Iframe Snapshots

Page Snapshots

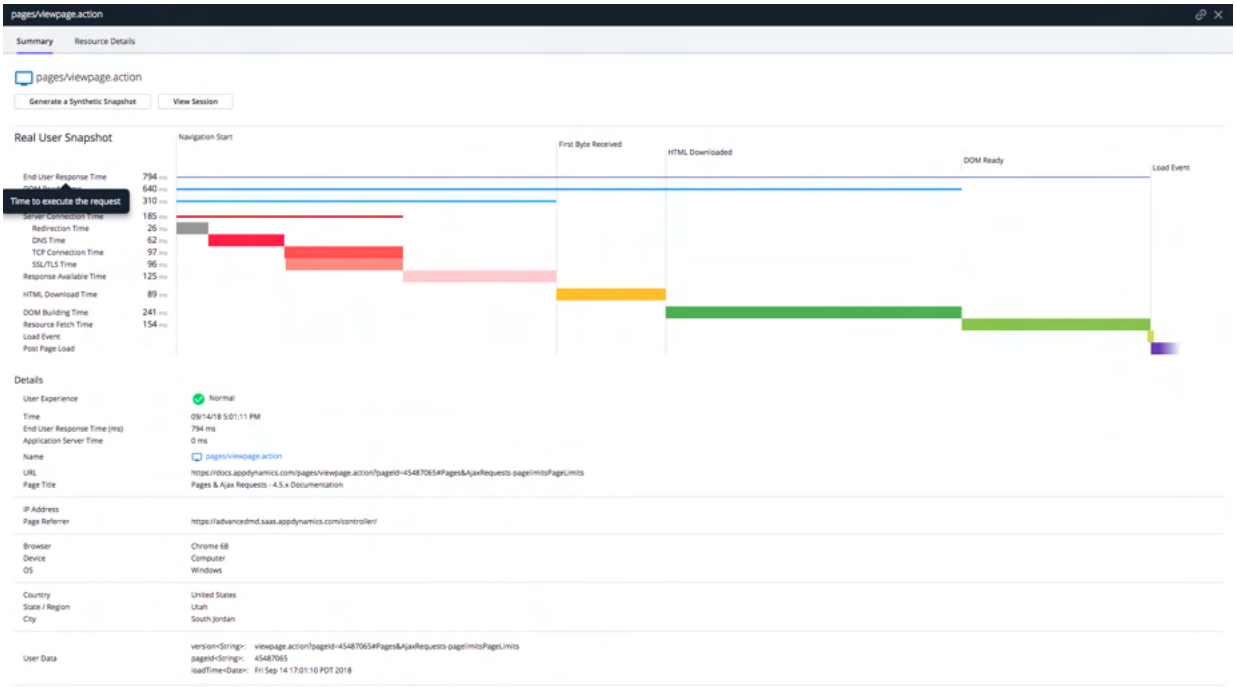
Related pages:

- Ajax Request Snapshots
- Iframe Snapshots

Page snapshots give you a detailed look at individual browser page requests. The **Summary** tab covers the general characteristics of the page.

Waterfall Graph

The top of the page snapshot **Summary** tab displays a waterfall graph of the overall transaction timing for the page. You can hover over each of the metrics to see a popup definition for that metric.



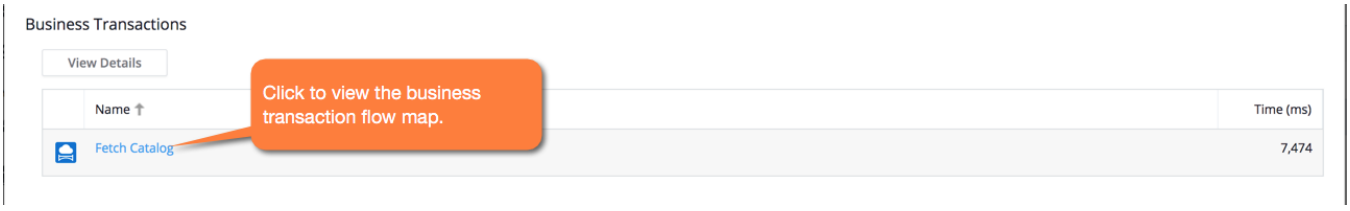
For more information about metrics, see Browser RUM Metrics. Additional details associated with the snapshot, including any related snapshots and any custom user data, are displayed as a table below the graph.

Generate a Synthetic Snapshot - SaaS Only

Synthetic snapshots use geographically distributed agents to create snapshots of web page download performance without the idiosyncratic and potentially skewing effects of real-user, last-mile performance. Click **Generate a Synthetic Snapshot** to create an on-demand synthetic snapshot to compare with a problematic real user monitoring snapshot.

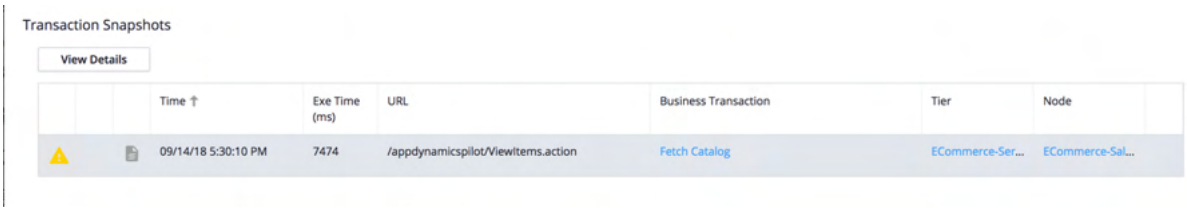
Correlated Transaction Snapshots and Business Transactions

If server-side correlation has been set up, a link to any related business transaction is shown:

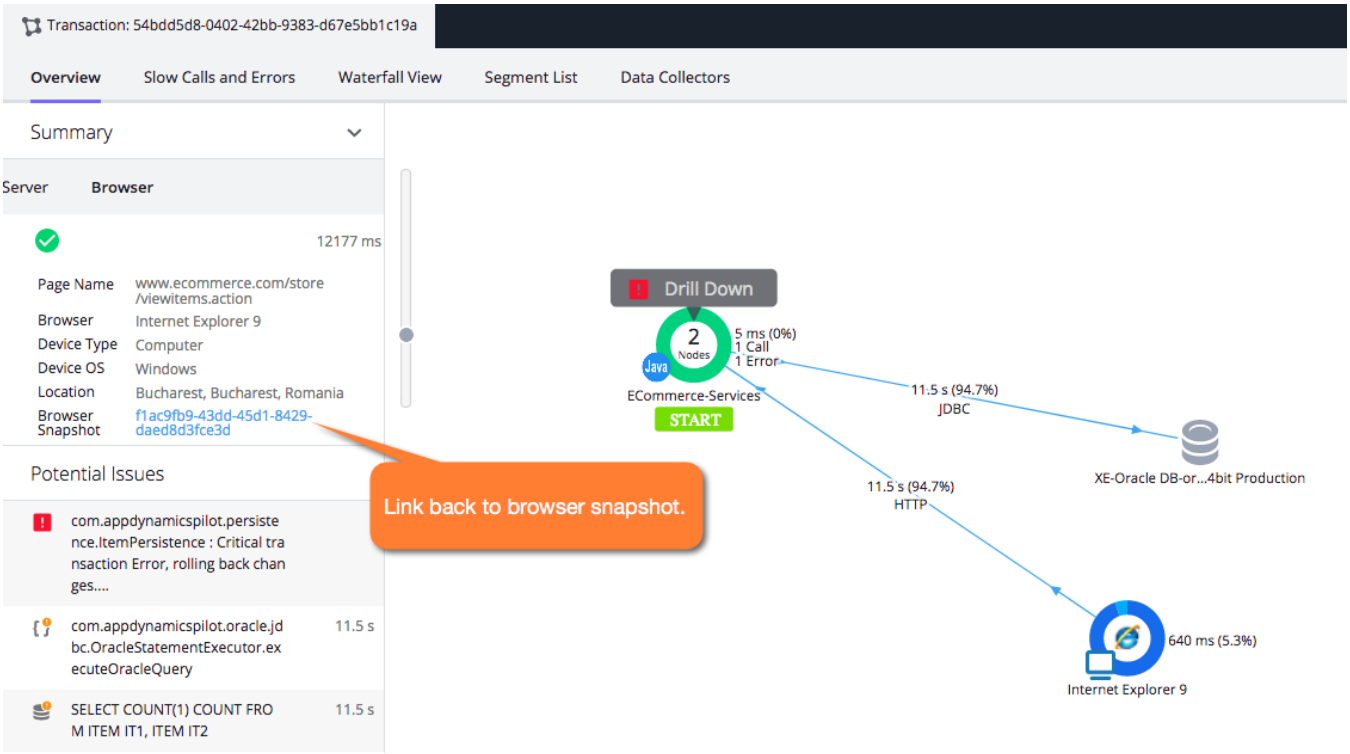


Clicking the link takes you to the flow map for that business transaction on the server side.

If the business transaction created a transaction snapshot, links to the business transaction, tier, and node flow maps are displayed, along with a direct link to the transaction snapshot flow map. Cross-app correlation is supported.

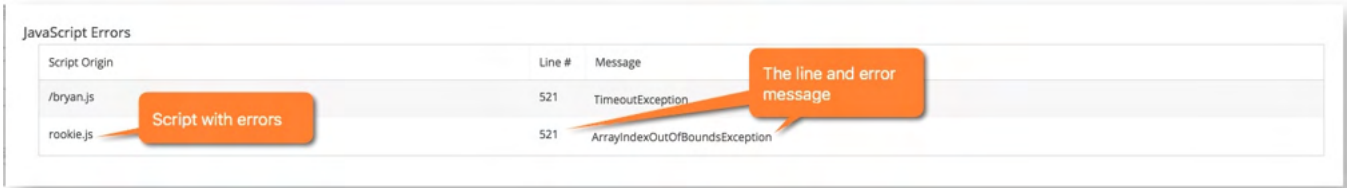


In this case, the transaction snapshot also has a link back to the browser snapshot.



JavaScript Errors

If there are JavaScript errors on the page, they are displayed below the waterfall graph.



You can configure to ignore errors if you are seeing too many irrelevant or excessive errors. See Configure JavaScript and Ajax Error Detection for instructions.

> When an error occurs in a script that is hosted on a domain other than the domain of the current page, most browsers prevent the JavaScript Agent from recording any details of the error. In such cases, the string `CROSSDOMAIN` is displayed as the **Script Origin**.

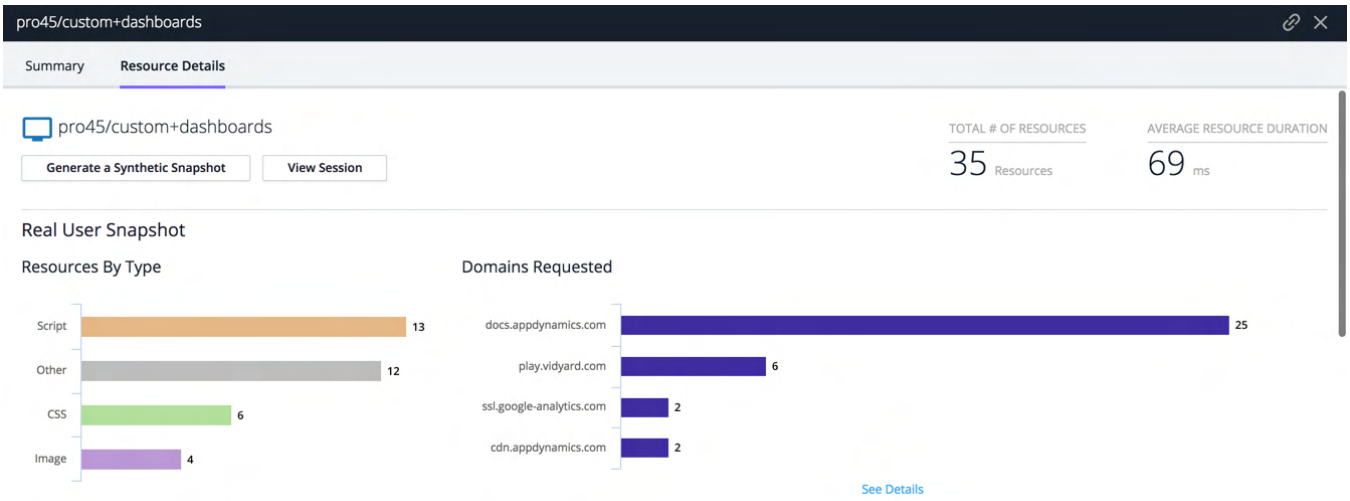
User Data

If you have custom user data set up, the data appears in the **Details** section:

User Data	algo<String>:	LOG(N)
	Random Number<String>:	1938299132
	hotel<String>:	AppDynamics Resort

Resource Details

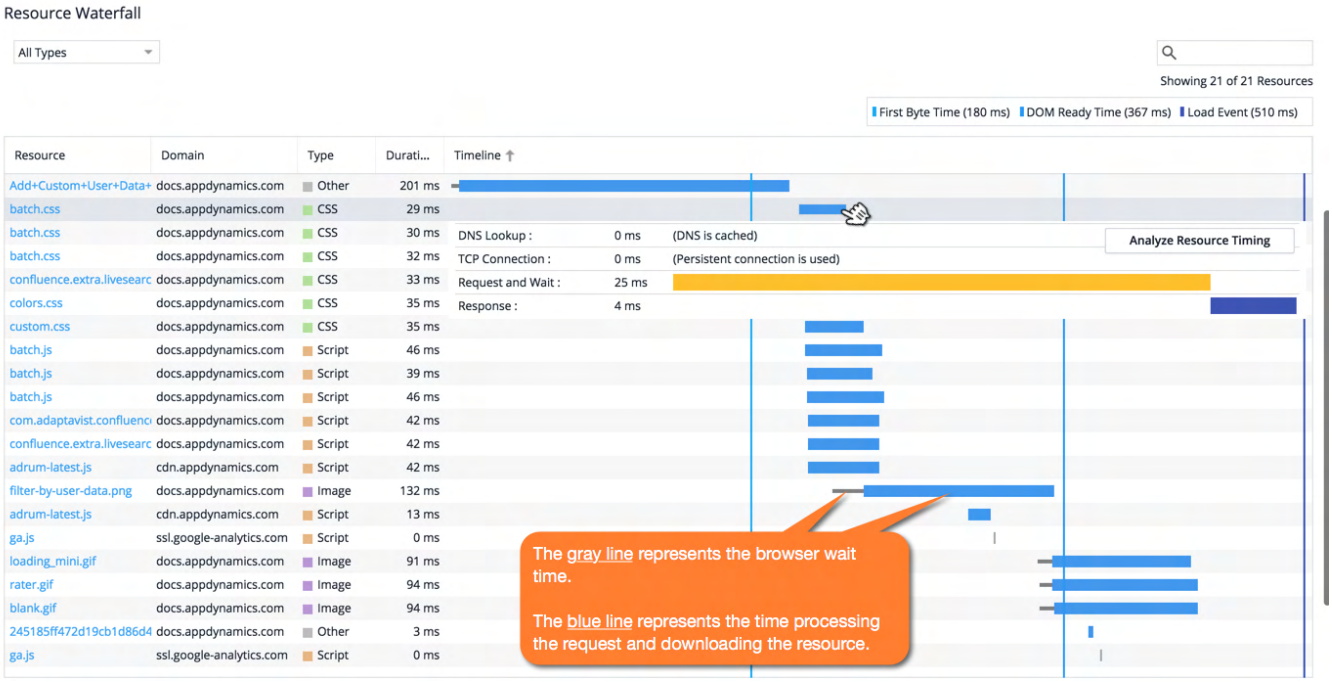
If the browser supports the Resource Timing API, the Resource Details tab gives you a detailed breakdown of the performance of resources—scripts, CSS files, fonts, SVGs, and images—as they are loaded into the page.



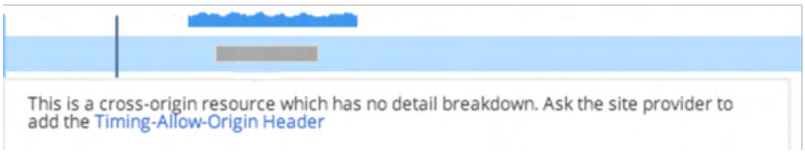
Resource Waterfall

The **Resource Waterfall** provides a snapshot of when each resource was loaded in the page load process (before First Byte Time, before DOM Ready Time, before Onload), including the name of the resource, the domain from which it was fetched, the type of resource, and how long it took. You can filter the items by type using the upper-right dropdown and search using the search box.

To see more details, click any of the blue timelines. These are from the primary domain or cross-domains that have set the `Timing-Allow-Origin` HTTP header. See Resource Timing Metrics for descriptions and explanations about how the metrics are calculated.



Grey timelines indicate cross-domains that have not set the `Time-Allow-Origin` HTTP header. Working with your CDN provider to add this header can mean you get better information on shared and CDN-served content.



Unknown Metrics in Page Snapshots

Browser RUM captures metrics using your end-users' web browsers. Occasionally, you may see unknown data reported for one or metrics in a browser snapshot. This occurs on older or less sophisticated browsers that do not support the collection of a given metric.

See Browser Monitoring Metrics for details about which metrics may not be captured based on browser capabilities.

Ajax Request Browser Snapshots

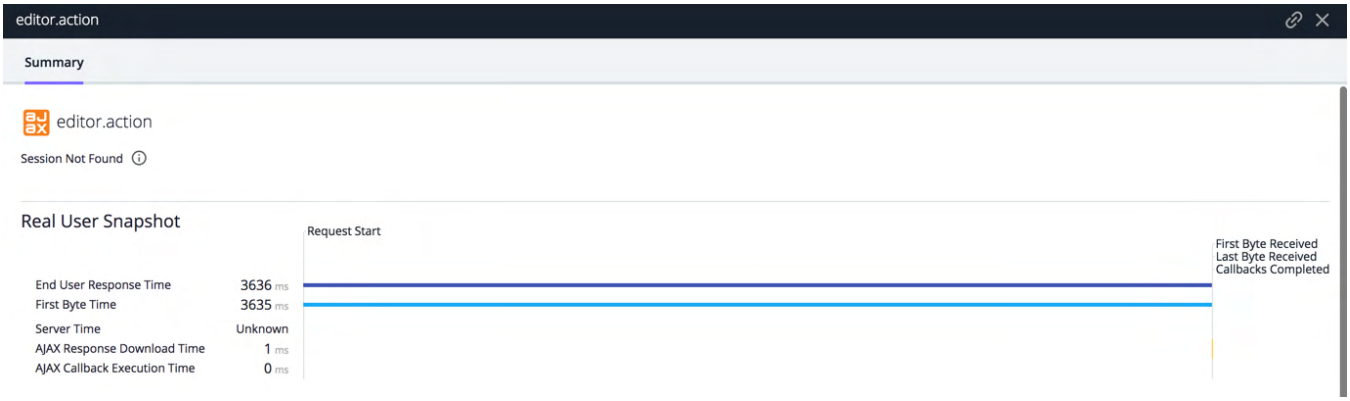
Related pages:

- Page Snapshots
- Iframe Snapshots

Ajax request snapshots give you a detailed look at an individual Ajax request. The **Summary** tab of the snapshot describes the general characteristics of the page.

Waterfall Graph

The top of the Ajax snapshot displays a waterfall graph of the overall transaction timing for the Ajax request. The snapshot is labeled either a **Real User Snapshot** or a **Synthetic Snapshot** based on the origin of the request. You can hover over each of the metrics to see a popup definition for that metric.



For a detailed description of what these metrics mean, see Browser RUM Metrics.

Details

Much of the information is the same as you see for page snapshots. The main differences are:

- If there is an Ajax error, the error code returned with it is listed.
- The parent page from which the Ajax call originates is listed.

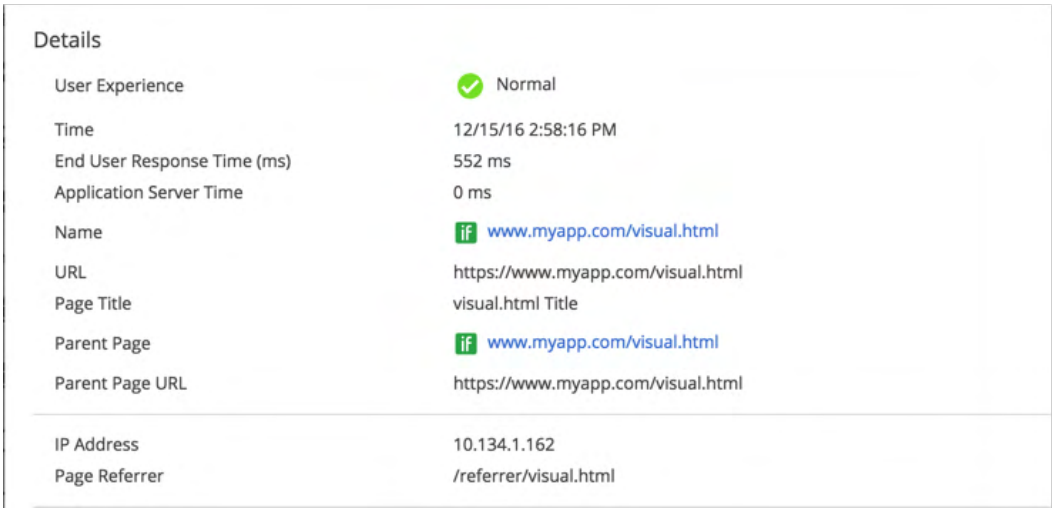
You can configure errors to ignore if you are seeing too many errors that are not of interest. See Configure JavaScript and Ajax Error Detection.

Iframe Browser Snapshots

Related pages:

- Page Snapshots
- Ajax Request Snapshots

Iframe-based snapshots give you a detailed look at an individual iframe request. The UI display is identical to Page Snapshots except in the **Details** section , where the parent page may also be displayed.



Resource Performance Dashboard

Deployment Support

Related pages:

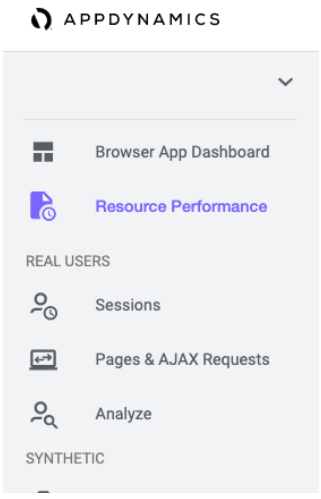
- Use Cases for the Resource Performance Dashboard
- Browser RUM Metrics
- Configure Resource Violation Rules

The **Resource Performance Dashboard** provides a high-level overview of how your resources affect the performance of your browser application. You can use this dashboard to pinpoint resource-related performance issues affecting the user experience, such as the following:

- A prioritized list of resource performance issues by comparing their performance against thresholds
- Changes in the number of resources
- Large resources (images, JavaScript, CSS, etc.)
- Size increase of resources impacting performance. For example, a page banner might be replaced with an uncompressed image, slowing down the page load.
- Slow CDNs
- Resources that haven't been compressed
- Comparison of real user and synthetic resource performance

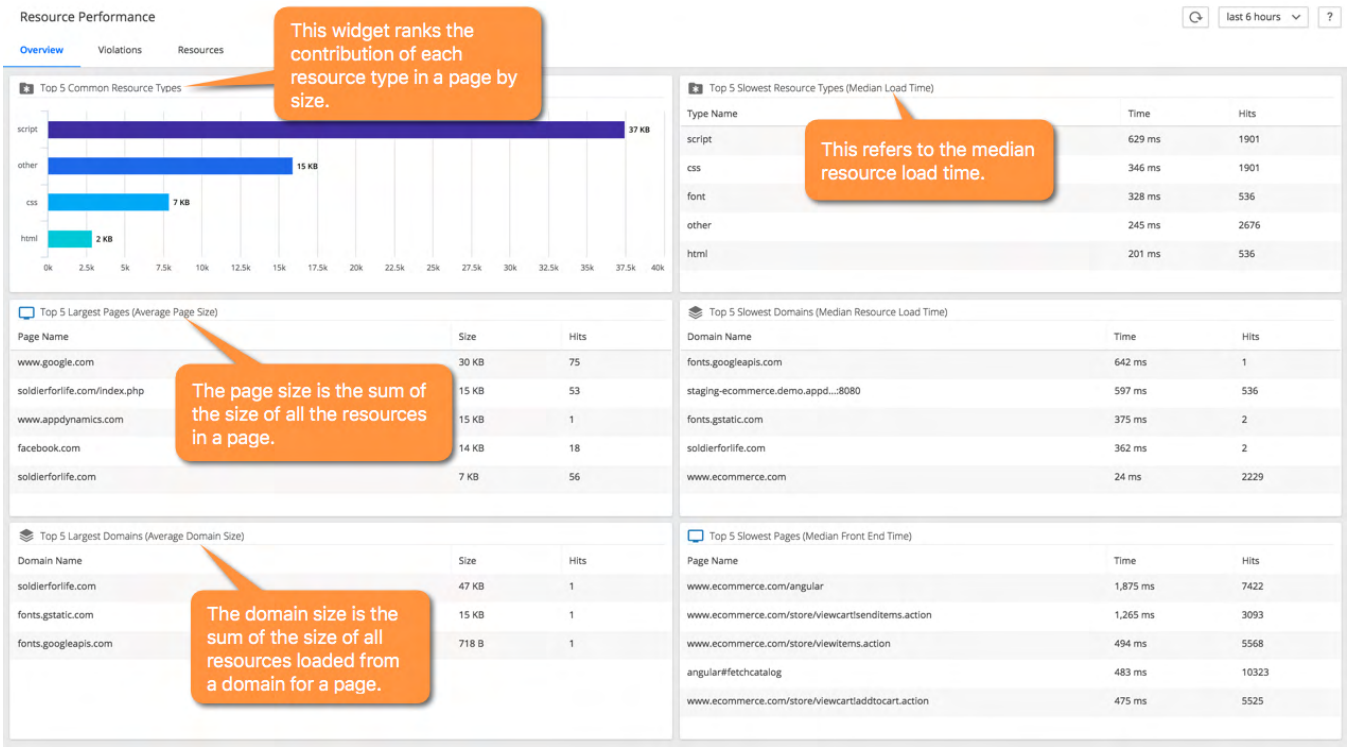
Overview of the Resource Performance Dashboard UI

Once you navigate to a browser application, the **Resource Performance Dashboard** is located on the left-side panel.



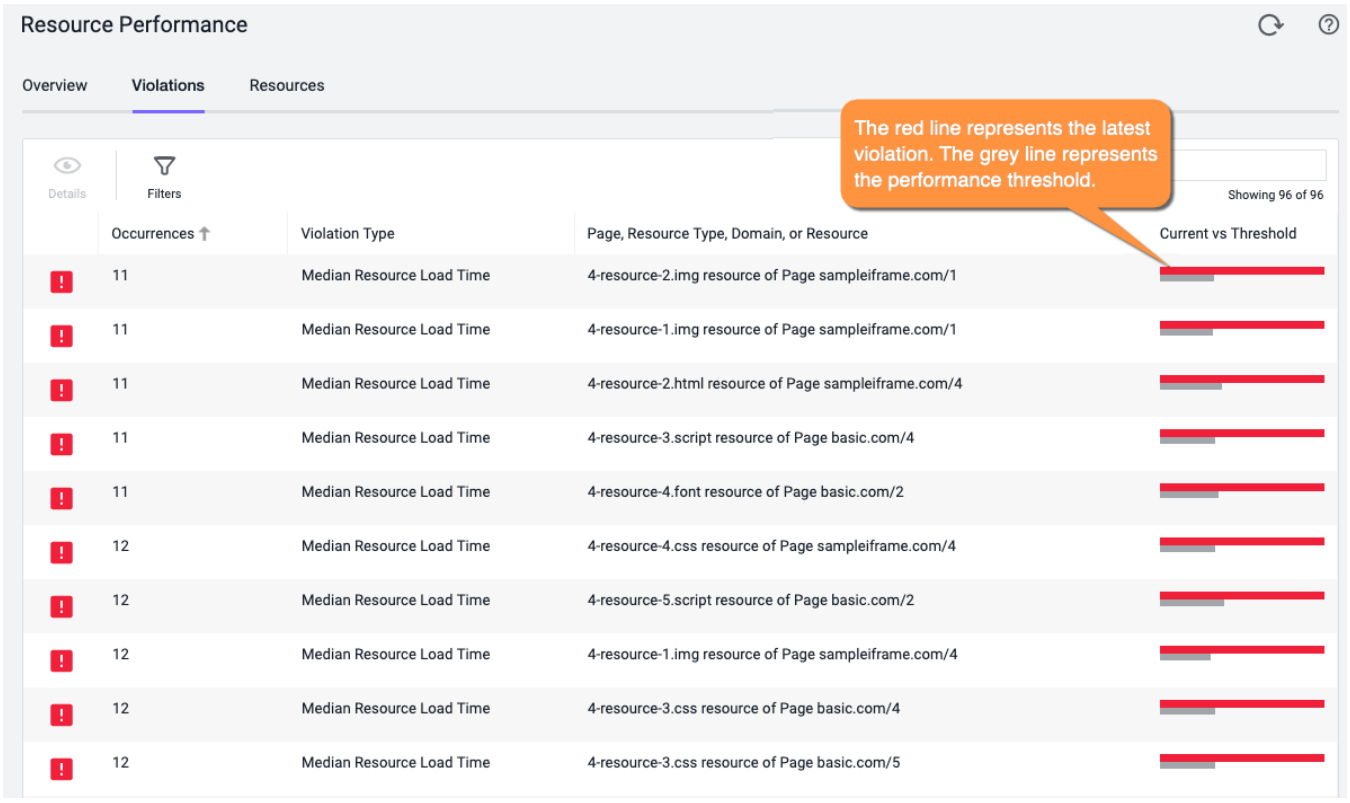
Overview Tab

The **Overview** tab displays widgets providing high-level indicators of resource performance over a specified time period. The dashboard can be filtered to real user or synthetic data. The widgets only show a small number of resources, but you can click **See More** to view up to 100 resources per widget.



Violations Tab

The **Violations** tab shows a list of pages, resource types, and domain or resource violations that have exceeded performance thresholds. You can use the **Violations** tab to not only find problematic resources, but also to become aware of sudden changes that negatively impacted the performance of a resource. Clicking a specific violation leads to the **Resources** tab, and the data is filtered with that violation for further diagnostics. The configured violation rules are evaluated every 10 minutes for the last 30 minutes.



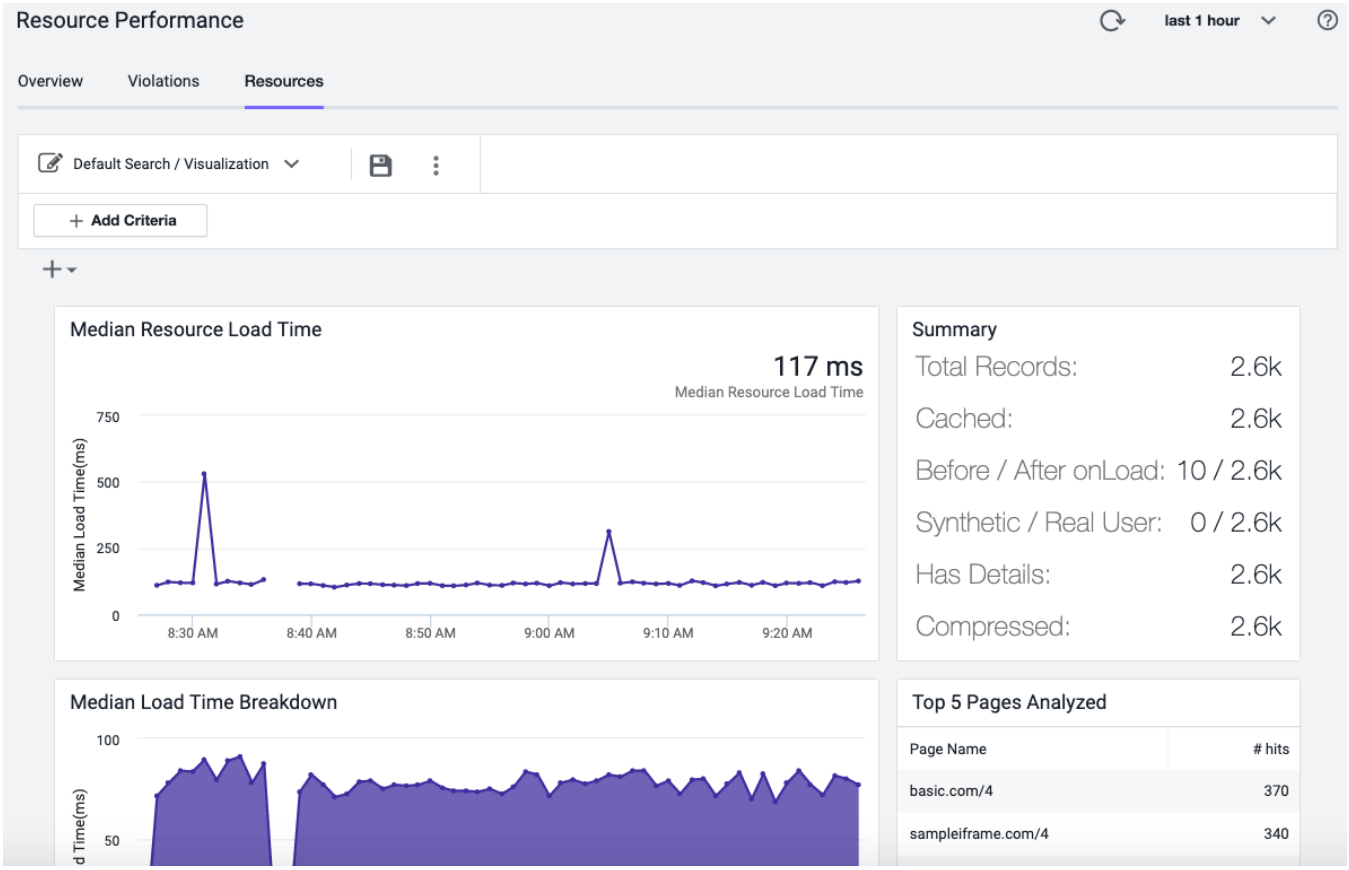
Violation Types

The supported violation types include:

- Median Domain Load Time
- Average Domain Size
- Average Page Size
- Median Resource Load Time
- Average Resource Size
- Median Resource Type Load Time
- Average Resource Type Size

Resources Tab

You can use the **Resources** tab to diagnose a problematic resource. You can also add criteria as a filter to the widgets. All use cases to troubleshoot a resource leads to the **Resources** tab where you can learn more about an individual resource's impact on an application. See Use Cases for examples.



Additional Resource Performance Data Information

For the **Resource Performance Dashboard** to be effective, it is highly recommended that you set the `Timing-Allow-Origin` HTTP header in all of your CORS domains to enable access to resource timing information. Without this header, the JavaScript Agent cannot capture the resource size, and, of the supported Resource Timing Metrics, only the resource load time can be calculated.

For information about resource performance data retention, see License Entitlements and Restrictions.

Use Cases for the Resource Performance Dashboard

The Resource Performance Dashboard provides a high-level overview of how your resources affect the performance of your browser application.

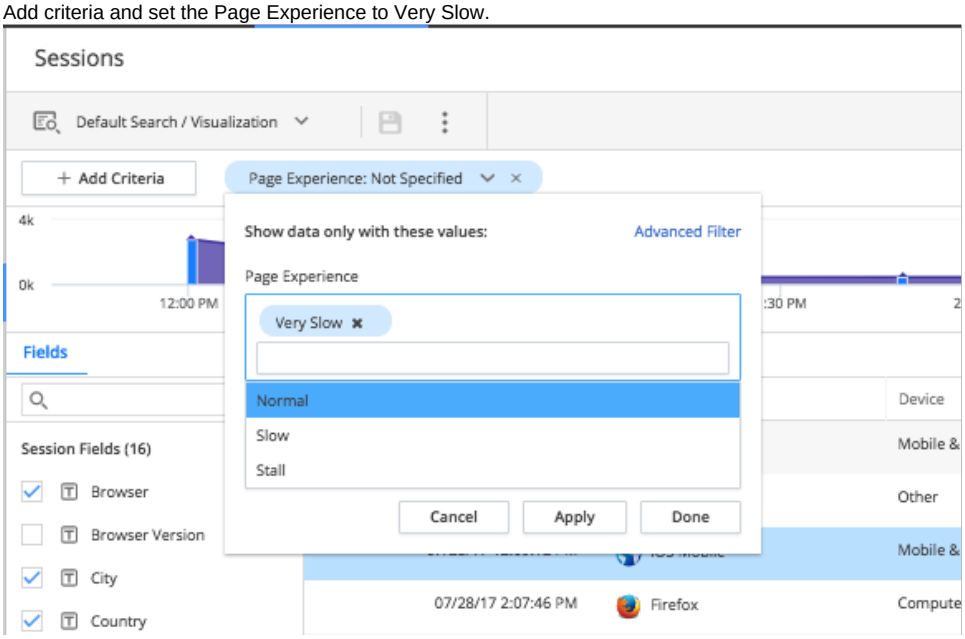
The table presents common troubleshooting and analysis use cases for resource performance.

Goal	Use Case
Detect and resolve poor performance issues	Troubleshoot from Sessions
Track and monitor resource violations	Discover Top Resource Violations
View a resource's performance from a particular region	Analyze Resources by Region
Diagnose cause of lengthy load time for image resources	Diagnose Problematic Resources

Troubleshoot a Resource from Sessions

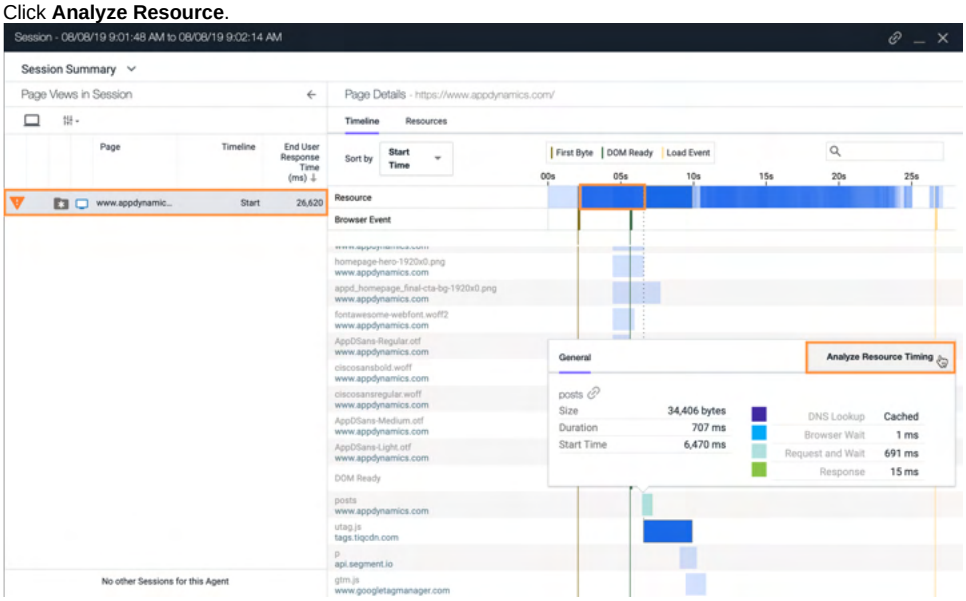
Follow these steps to troubleshoot a resource from **Sessions**:

1. Go to **Sessions**.
2. Add criteria and set the Page Experience to Very Slow.

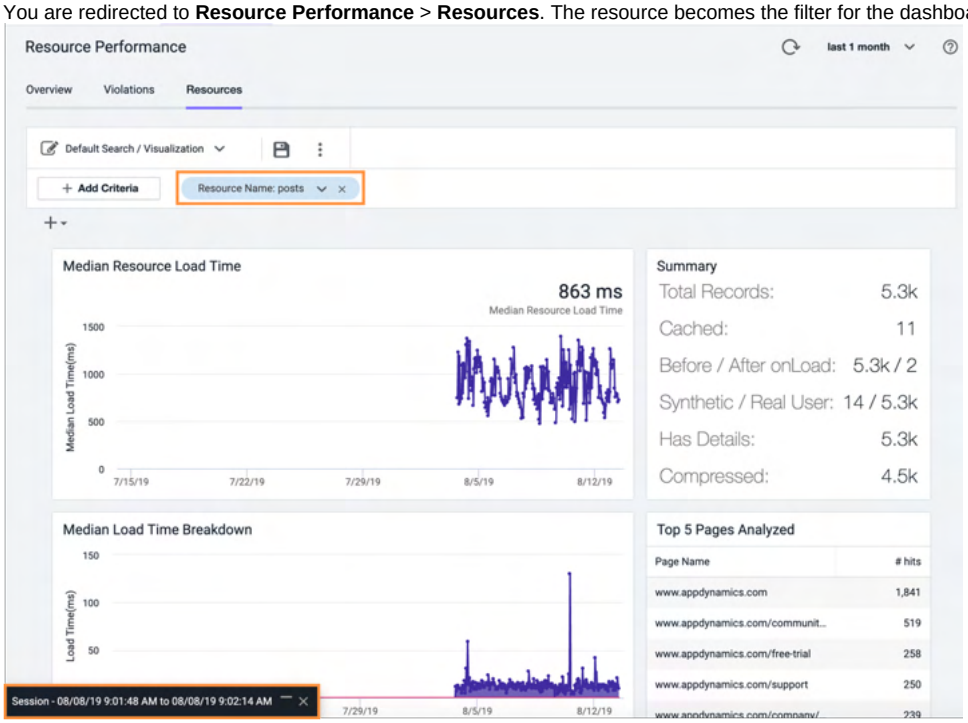


3. Double-click on a session record.
4. In the **Session Summary** select the page with the longest **End User Response Time**.
5. In the **Waterfall** tab, click a problematic resource to open the **Resource Details** dialog.

6. Click **Analyze Resource**.



7. You are redirected to **Resource Performance** > **Resources**. The resource becomes the filter for the dashboard data.



8. In the widgets, look for patterns or possible factors such as geographic location, domains, and so on. See Diagnose Problematic Resources to learn some strategies for diagnosing resource issues.

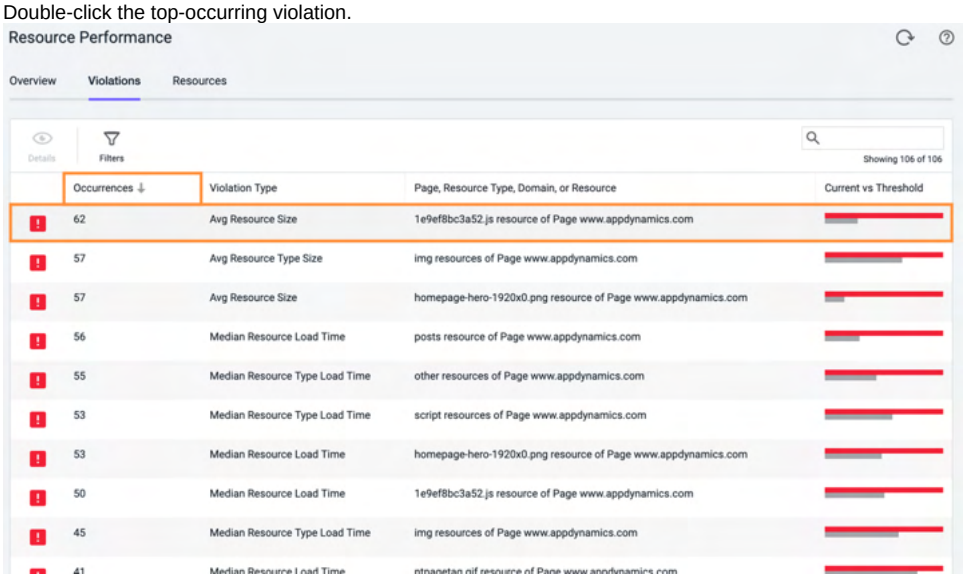
> To rule out environmental factors such as network connections, browser, and so on, create a synthetic job that calls a page with the resource to confirm the resource is the problem.

Discover Top Resource Violations

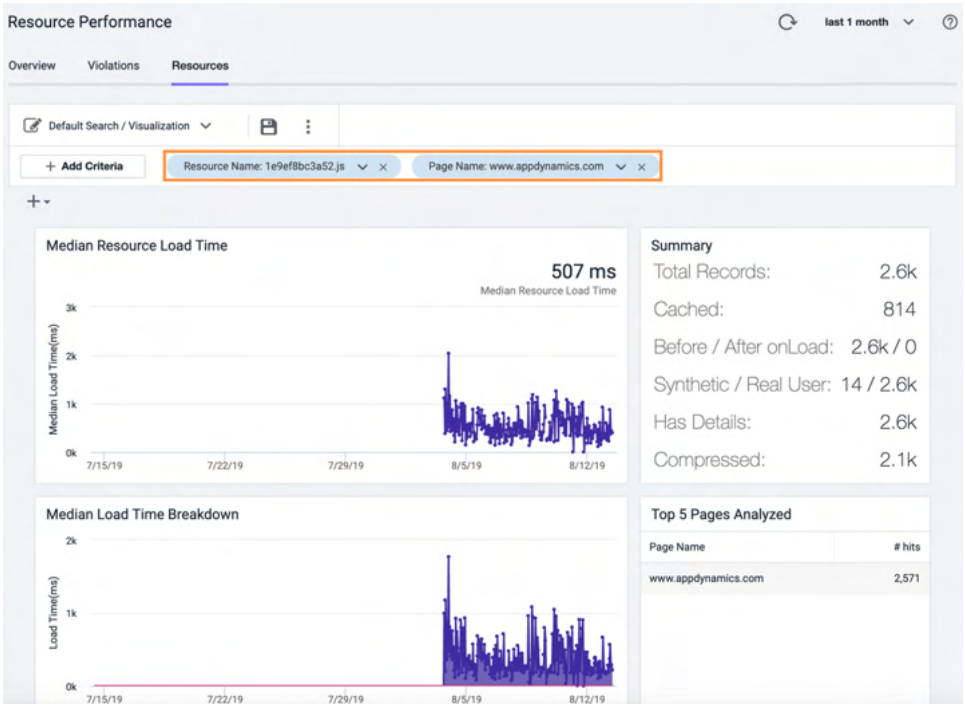
Follow these steps to determine which resource is causing the most performance violations:

1. Go to the **Resource Performance** > **Violations**.
2. Select the **Occurrences** column so that number of occurrences is in descending order.

3. Double-click the top-occurring violation.



4. You are redirected to the **Resources** tab with information for the resource in violation.

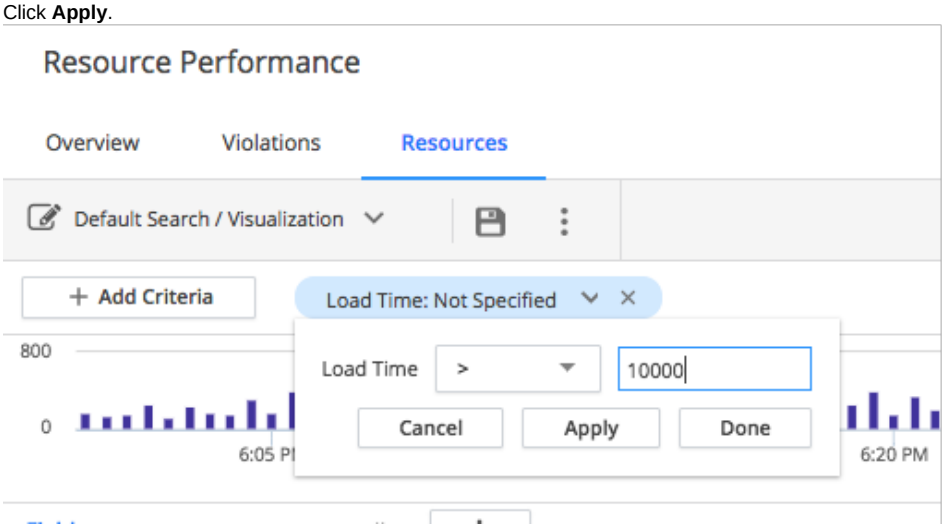


Analyze Resources by Region

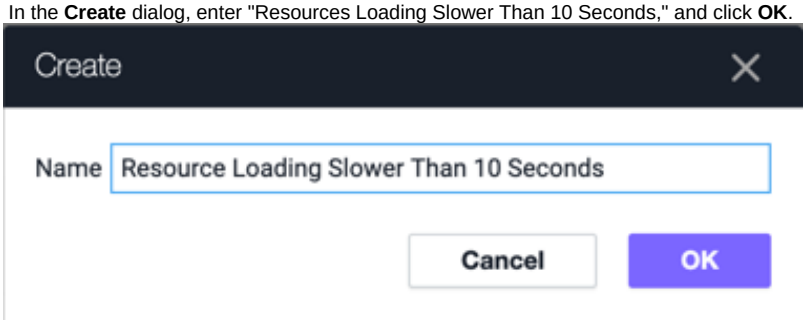
Follow these steps to analyze and monitor a resource based on a region:

1. Go to the **Resources** tab.
2. From the **Add Criteria** drop-down, select **Load Time** and specify the value to be greater than 10000 (10 seconds).

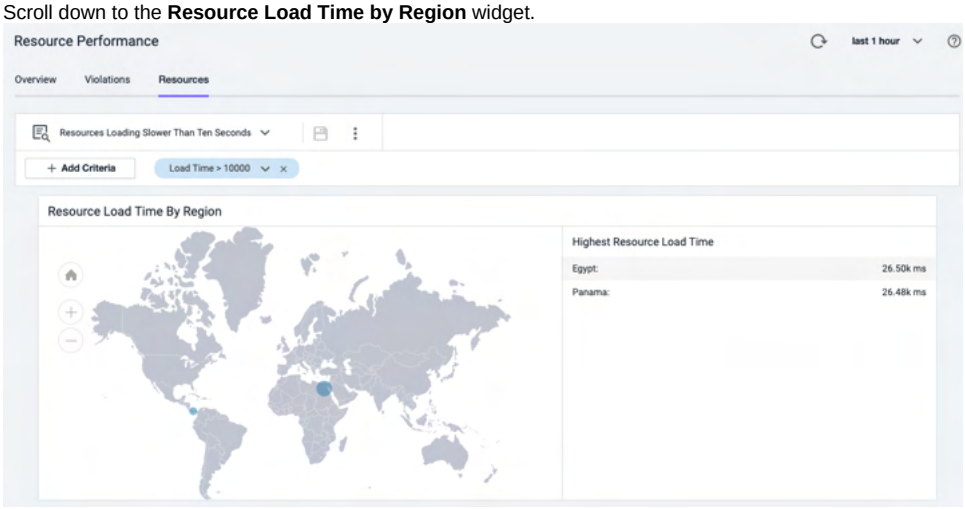
3. Click **Apply**.



4. Click  .
5. In the **Create** dialog, enter "Resources Loading Slower Than 10 Seconds," and click **OK**.



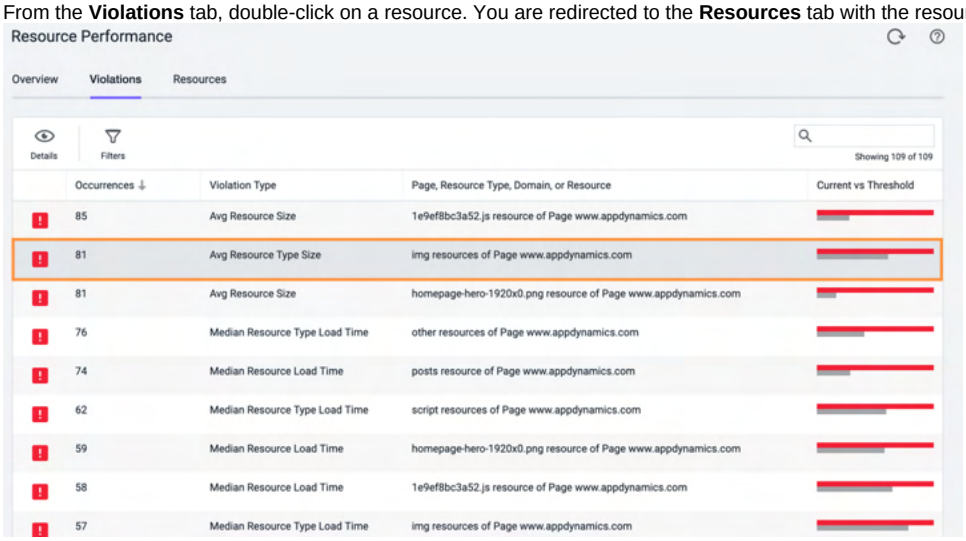
6. Scroll down to the **Resource Load Time by Region** widget.



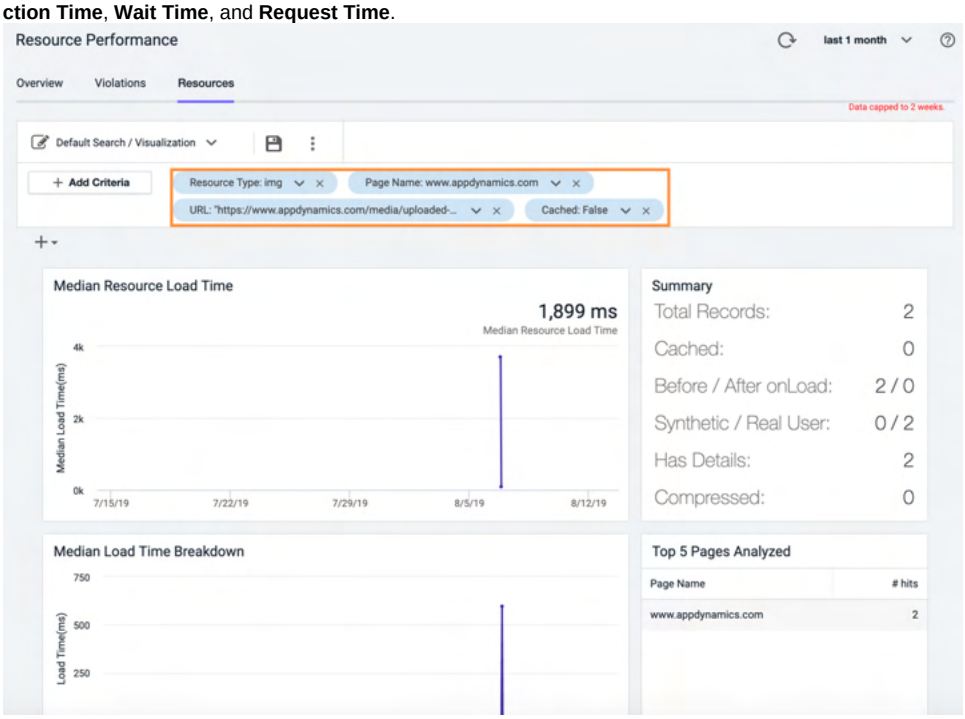
Diagnose Problematic Resources

Follow these steps to diagnose why certain image resources are taking a long time to load:

1. From the **Violations** tab, double-click on a resource. You are redirected to the **Resources** tab with the resource applied as a data filter.



2. Select criteria fields to determine possible causes, such as **Region**, **Cached**, **Compressed**, **Load Time**, **Domain**, and so on.
    - Example: Confirm that resources are cached or compressed.
    - Example: Add criteria that may indicate issues with the server based on the location of the resource, such as **DNS Lookup Time**, **Connection Time**, **Wait Time**, and **Request Time**.



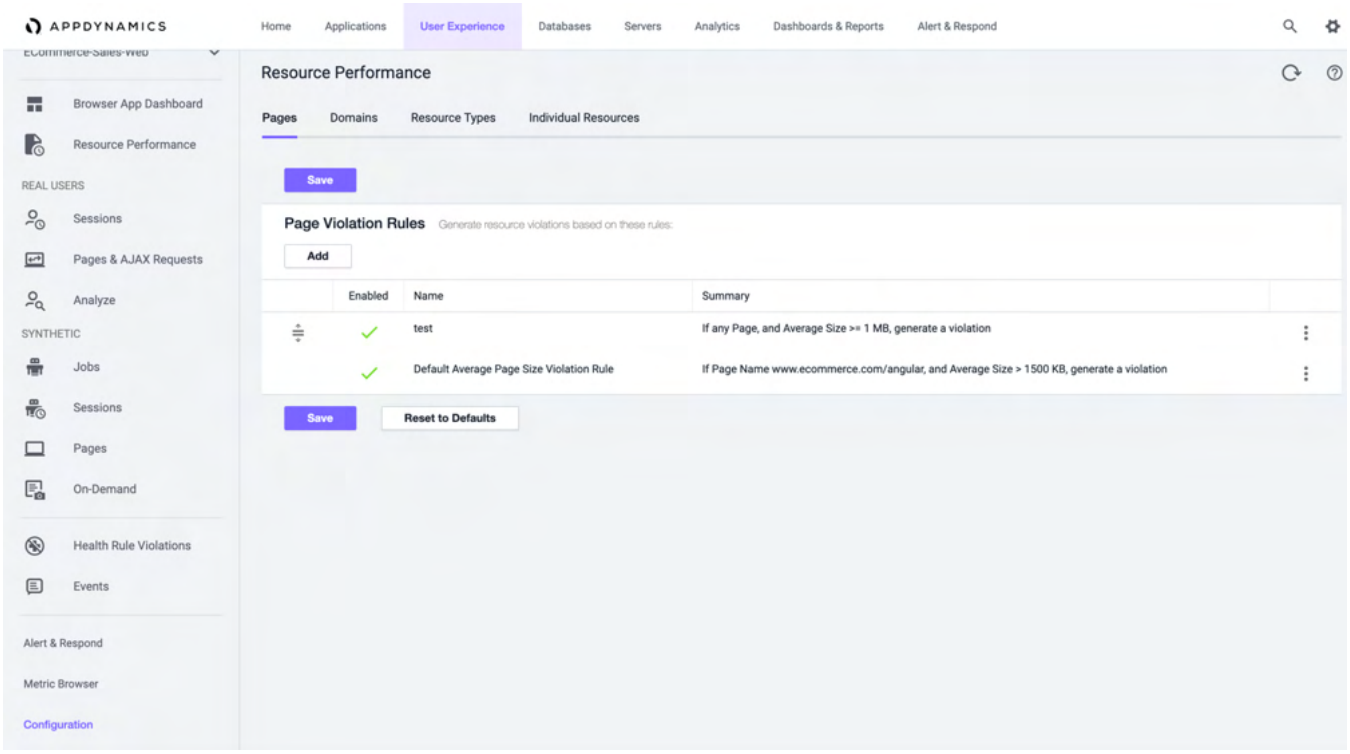
3. Search for patterns that indicate the cause within the widgets, providing insights such as:
    - Resource load time speed in certain regions
    - Top pages using the resource
    - Median load time breakdown showing that load time slows down at certain intervals
    - Resource size increases

To rule out environmental factors such as network connections, browser, and so on, create a synthetic job that calls a page with the resource to confirm the resource is the problem.

Configure Resource Violation Rules

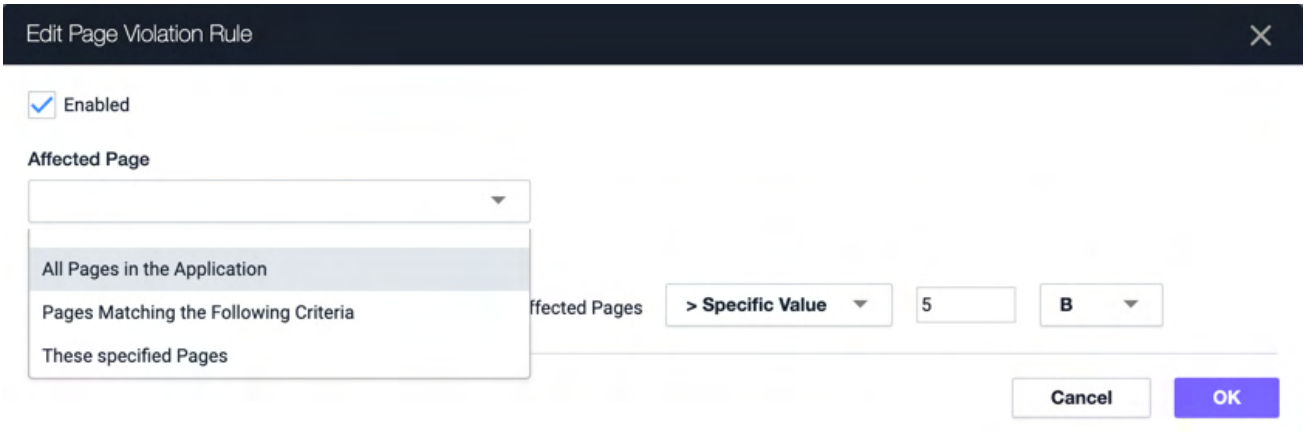
This page describes how to configure resource violation rules for the Resource Performance Dashboard. You can configure violation rules for pages, domains, resource types, and individual resources. You can use or edit the default rules per category or create your own rules. Resource Performance configuration is only available to admin-level users.

To configure resource violation rules, navigate to **Configuration** > **Resource Performance**.



Pages Violation Rules

Page violations help monitor your most important pages and ensure they are light and efficient for end users. You can set violation rules for all pages, individual pages, or by pages matching query criteria within an application. The average page size can be set to megabytes, kilobytes, or bytes. This helps you troubleshoot application performance based on pages.

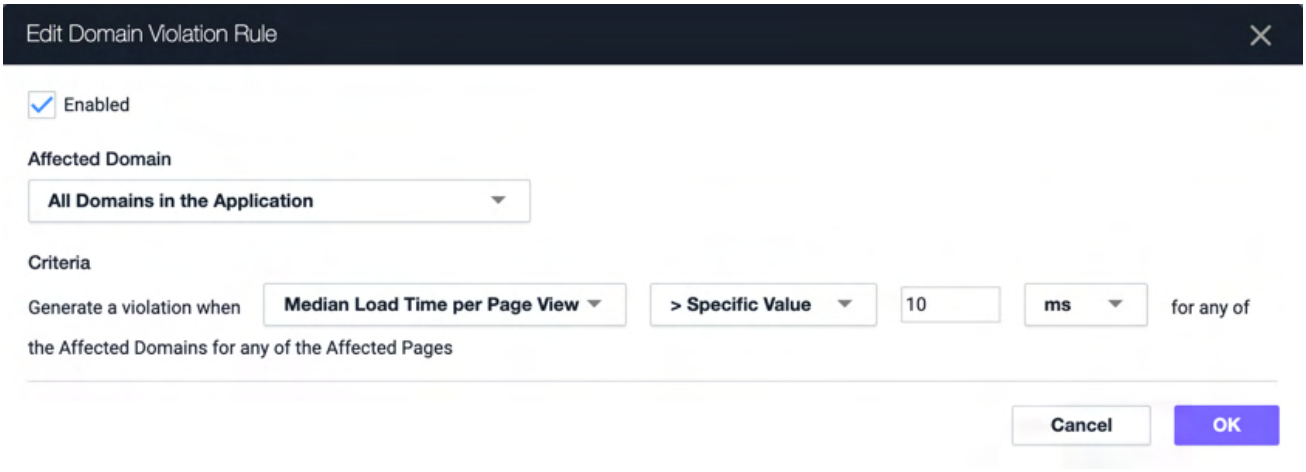


Use Case

In this scenario, your home page size average is 1500 KB, and you want to be notified when it surpasses that threshold. You can set your home page at a maximum size of 1500 KB. If the violation rule is triggered, you will see the violation in the Violations tab as well as in the "Resource Performance" widget in the Browser App Dashboard.

Domain Violation Rules

Domain violations help monitor the effects of domain performance on your application. You can set violation rules for all affected domains, individual domains, or by domains matching query criteria within an application. The median load time per page view can be set to milliseconds or seconds, and the average domain size can be set to megabytes, kilobytes, or bytes. This helps you troubleshoot poor application performance based on domains.

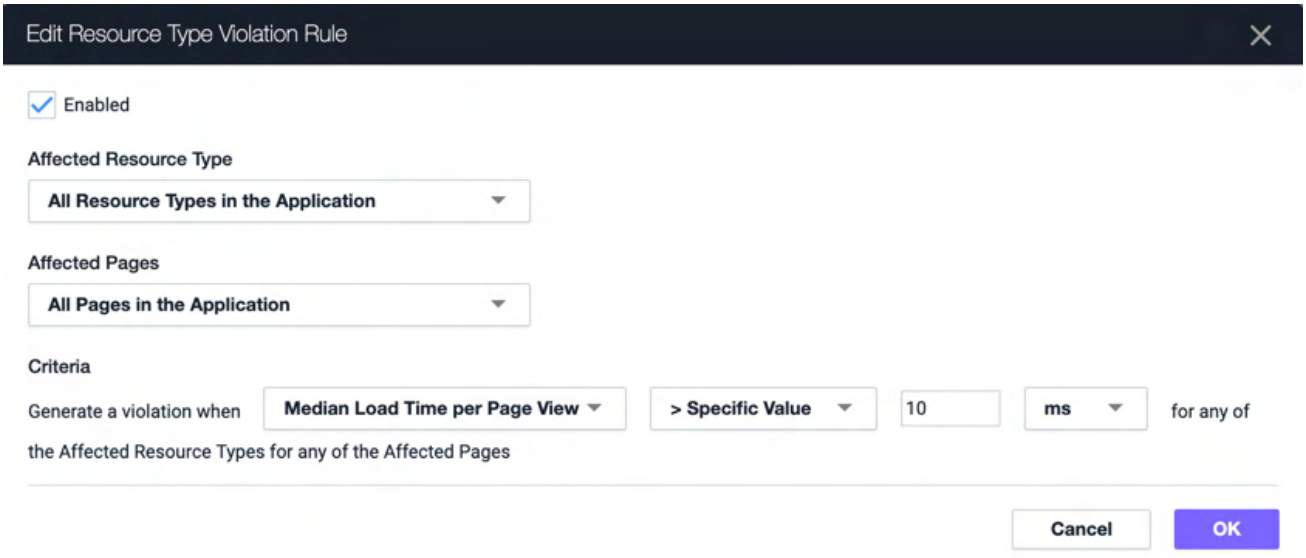


Use Case

In this scenario, you want to monitor the performance of your CDN. You can set your CDN domains to a maximum median load time of 1000 ms for all domains in the application. If the violation rule is triggered, you will see the violation in the Violations tab as well as in the "Resource Performance" widget in the Browser App Dashboard.

Resource Type Violation Rules

Resource type violations help monitor the effects of resource types, such as images, html, css, and so on, within your application. You can set violation rules for all affected resource types or by individual resource type within an application. You can also set the rule to one page, pages matching query criteria, or all pages in the application. The median load time per page view can be set to milliseconds or seconds, and the average domain size can be set to megabytes, kilobytes, or bytes. This helps you troubleshoot poor application performance based on resource types.

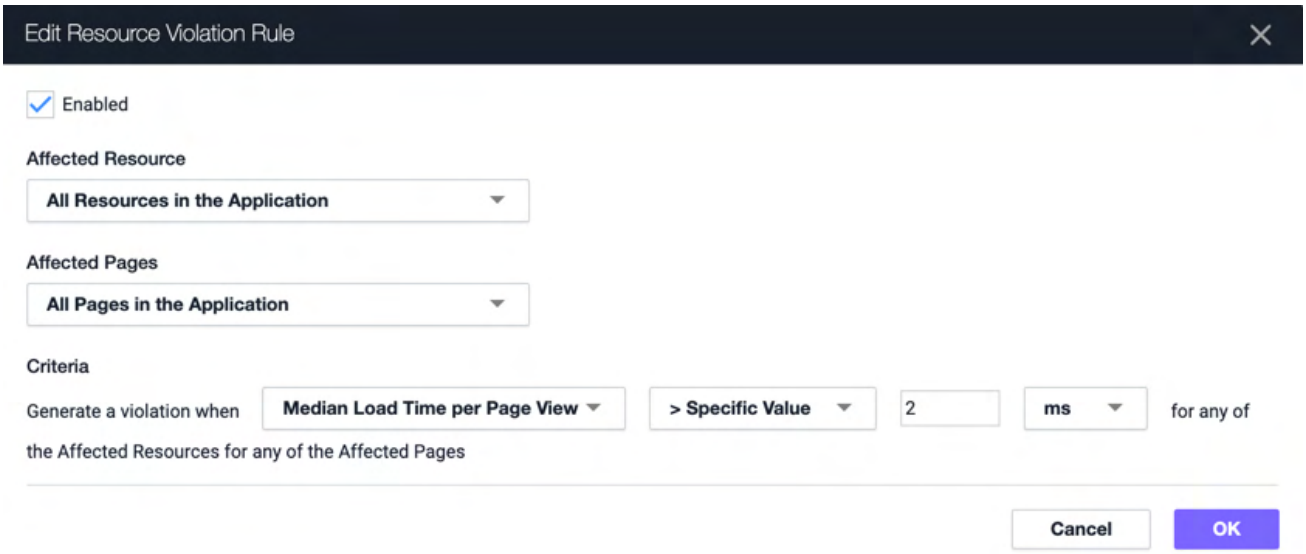


Use Case

In this scenario, you want to monitor all the images in all pages across your application. You can set all images to maximum average size of 500 KB for all pages in the application. If the violation rule is triggered, you will see the violation in the Violations tab as well as in the "Resource Performance" widget in the Browser App Dashboard.

Individual Resource Violation Rules

Individual resource violations help monitor the effects of one resource across your application. You can set violation rules for all affected resources or by resources matching query criteria within an application. The median load time per page view can be set to milliseconds or seconds, and the average domain size can be set to megabytes, kilobytes, or bytes. This helps you troubleshoot poor application performance based on individual resources.



Use Case

In this scenario, you want to monitor all resources on your home page. You can set all resources to a maximum load time per page view at 2 ms within the scope of the home page. If the violation rule is triggered, you will see the violation in the Violations tab as well as in the "Resource Performance" widget in the Browser App Dashboard.

Browser Real User Monitoring

Related pages:

- End User Monitoring

This page provides an overview of AppDynamics Browser Real User Monitoring (Browser RUM).

Browser Real-User Monitoring (Browser RUM) allows you to see how your web application is performing from the point of view of a real end user. You can drill into the data to explore how users experience your application in their web browsers and answer questions like:

- Which 1st or 3rd-party Ajax or iframe calls are slowing down page load time?
- How does server performance impact end-user experience in aggregate or in individual cases?

Monitor Your Application

Browser RUM offers multiple ways to look at your data in real time. You can:

- Understand and improve your web page's performance
  - Know how your pages, Ajax requests (XHR, Fetch API calls), and IFrames are performing over time. See The Pages & Ajax Requests View.
  - Gain insight into individual requests, with detailed charts on how your pages, Ajax requests, and IFrames load and build in your end user's browsers, with links, if enabled, to reports on server-side performance. See Browser Snapshots.
  - Find your worst performing pages by multiple common metrics. See Top Pages.
- Reduce errors
  - Learn which pages are loading with JavaScript errors, including the script file and line number that are creating the problem. See Browser Snapshots.
- Learn about your users
  - See how your web users are connecting to your application by device/platform and browser. See Browser App Dashboard.
  - Find out where geographically your web users are and how your application is performing across countries and regions. See Browser App Dashboard.
  - Understand how users are navigating through your website and what actions they are taking. See Browser RUM Sessions.

For more information on using Browser RUM, see Overview of the Controller UI for Browser RUM.

How Browser RUM Works

Browser RUM works in the following way:

1. An end user requests the first page from your web application.
2. Your web application executes whatever business logic that particular page requires.
3. Your web application creates the response page to return to the end user. The response page includes:
   a. application-specific information.
   b. a copy of a small JavaScript script that knows how to collect relevant performance information about that page. This script is called the JavaScript Agent.
4. The page, with the JavaScript Agent included, is returned to the end user.
5. As the page is being constructed in the browser, the script collects relevant information about the page's performance.
6. At approximately the same time as the `onload` event for the page fires, a copy of a somewhat larger JavaScript file, the JavaScript Agent extension, is downloaded asynchronously by the injected agent.
7. This second script packages the collected performance information and sends it via a web beacon to the EUM Server collector for processing.
8. The two scripts work together to collect and send performance information as the end user navigates through the instrumented pages of your application.

Set Up and Configure Browser RUM

Browser RUM is easy to set up. It is also highly configurable. You can:

- Set up and enable Browser RUM. See Set Up and Access Browser RUM.
- Instrument your application to work with Browser RUM. For more information, see Configure the JavaScript Agent.
- Set up how your information appears in the Controller UI. For more information, see Configure the Controller UI for Browser RUM.

License and Enable Browser RUM

- Browser RUM requires a separate license and must be enabled before it is available for use. For information about licensing, including a description of the types of licenses, see EUM Accounts, Licenses, and App Keys.
- For information on enabling or disabling Browser RUM, see Enable and Disable Browser RUM.

Set Up and Access Browser RUM

Related pages:

- EUM Accounts, Licenses, and App Keys.
- Inject the JavaScript Agent

This page explains how to set up Browser Real User Monitoring (Browser RUM). Browser RUM collects metrics on your end user's web browsers via the AppDynamics JavaScript Agent. Your web application must be configured to insert this agent into the web pages. This process is called injection. See Inject the JavaScript Agent on how to inject the JavaScript Agent into your web pages.

To access Browser RUM, you need an EUM Account and a Browser RUM license. EUM must be enabled through the Controller UI. You can Enable and Disable EUM if you decide not to use the feature.

EUM Account

A special EUM account is required. An EUM account is created when you have a license for Browser RUM, Browser Synthetic, or Mobile RUM. There is an account license key associated with this account.

For on-premises customers, the account license key is set up within the Controller license file. If you added EUM after your initial installation, you may need to upload and install the new Controller license file. If you are a SaaS customer, the EUM license is set up in the SaaS Controller for you.

Each Browser RUM license provides a certain number of page views per year. For information on how to examine your current page view usage, see EUM Accounts, Licenses, and App Keys.

Access Browser Monitoring Configuration

Your data is displayed in the Controller UI in the context of an EUM application. You must assign unique names to EUM applications and business applications. For example, if you created the business application "E-Commerce", you cannot create a browser, mobile, or IoT application with that same name or vice versa. An EUM application name is associated with an EUM App Key, which identifies data coming into the Controller.

1. If you do not yet have an EUM application, click the **User Experience** tab, the **Browser Apps** tab, and the **+Add** button. You can create an application name either by using the **Getting Started Wizard** or by simply choosing an application name.
2. Open the EUM application you are interested in by double-clicking on the application name in the **Browser Apps** list.
3. In the left navigation bar of the application UI, click **Configuration.**

Browser RUM Prerequisites

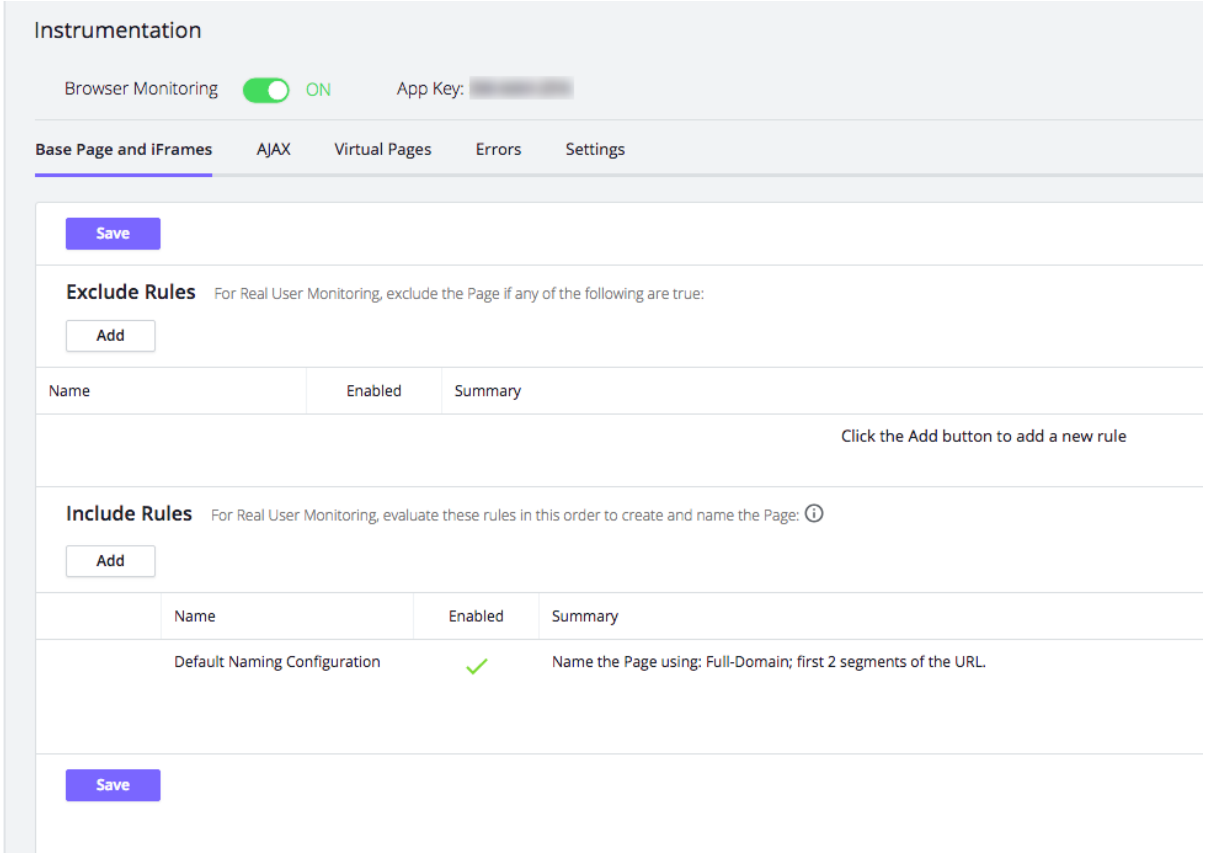
To turn on Browser RUM, you need to:

- Enable Browser RUM
- Inject the JavaScript Agent into your application pages

If you are an on-prem customer, your JavaScript Agent version should be equal to or less than your EUM Server version.

Enable and Disable Browser RUM

At the top of the **Configuration** > **Instrumentation** page, toggle the **Browser Monitoring**:



To disable Browser RUM, toggle the switch to **OFF**.

Inject the JavaScript Agent for Browser RUM into Your Application Pages

The JavaScript Agent for Browser RUM collects Browser RUM metrics. See Browser RUM Metrics for more detail.

The JavaScript Agent for Browser RUM must be inserted into the headers of the pages for which you want to see these metrics. This process is called *injection*. There are several ways to accomplish this. See Inject the JavaScript Agent.

External Access Locations

Browser RUM is made up of several components, which, in various configurations, can either be located on the Internet or hosted inside your own data center/network. On-premises access points are configured at installation or through the UI. If your installation requires access to any of these components on the Internet, see Access the SaaS EUM Server for more information.

If you are using the AppDynamics CDN to fetch the JavaScript Agent (`adrum.js`) and JavaScript Agent extension (`adrum-ext.js`), you also need to make sure that `cdn.appdynamics.com` is accessible from your network.

Additional Browser RUM Configurations

You can also configure:

- Page Identification and Naming
- JavaScript and Ajax Error Detection
- Browser Snapshot Thresholds
- Browser Snapshot Collection Rules

Correlate Business Transactions for Browser RUM

Related pages:

- Correlate Business Transactions for EUM
- Business Transactions

You can correlate page and Ajax requests with business transactions. The correlation is made between instances of page/Ajax requests (browser snapshots) and instances of business transactions (transaction snapshots).

How Browser Application Network Requests Are Correlated

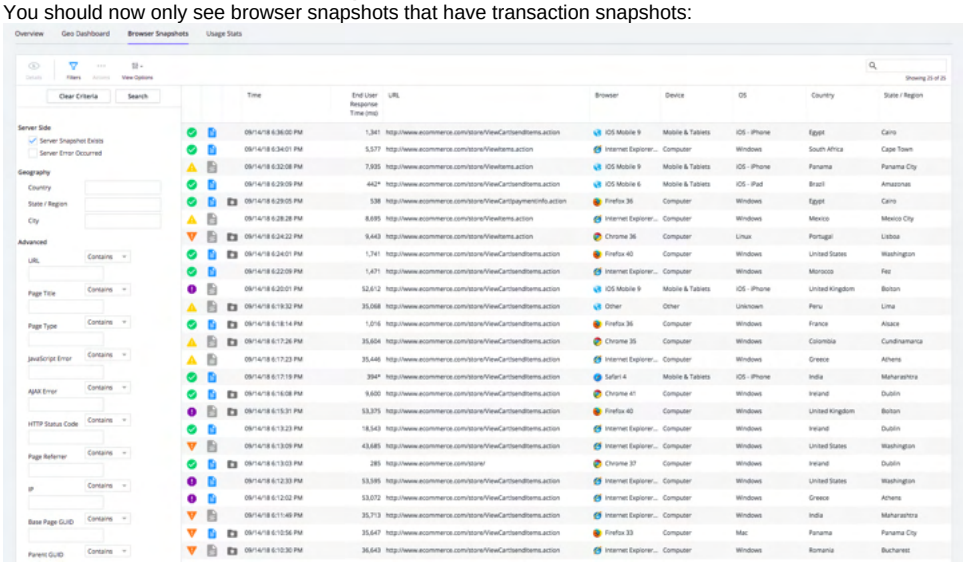
When an end user requests a page from your browser app:

1. The App Agent:
    - Sends HTTP headers identifying the business transaction and the HTML with the injected JavaScript Agent to the end user's browser.
    - Aggregates backend metrics and sends them along with the business transaction identifiers to the Controller. This serves as the content for the transaction snapshot.
2. The JavaScript Agent sends browser metrics and the business transaction identifiers (from the HTTP header) to the EUM Server. This serves as the content for the browser snapshot.
3. The Controller fetches the metrics and business transaction identifiers from the EUM Server. These business transaction identifiers are then used to correlate the browser snapshot with the transaction snapshots.

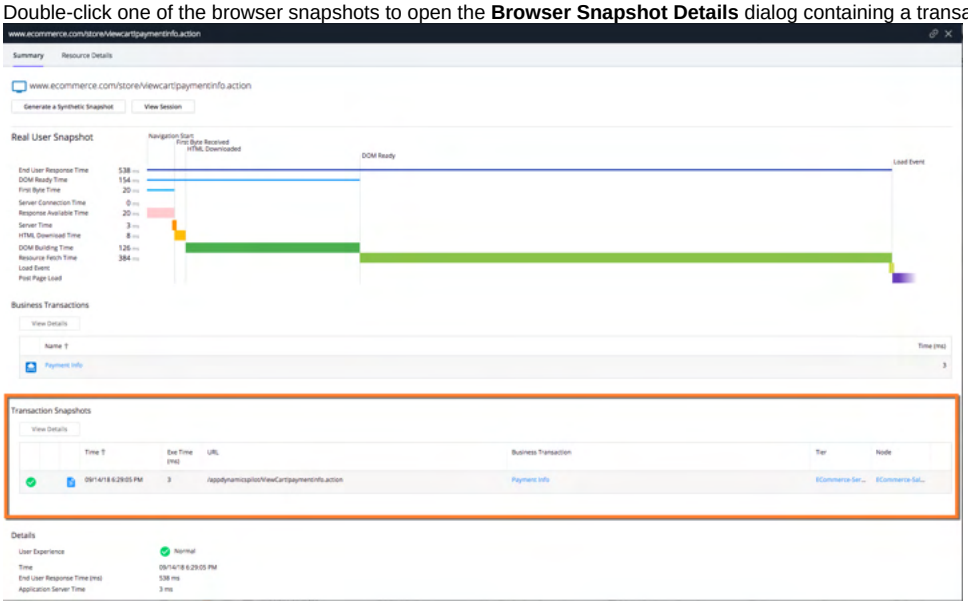
View Business Transactions Correlated with Browser Applications

There are several ways to navigate from a browser snapshot to its correlated business transaction. The following steps show you one possible way.

1. From the **Browser App Dashboard**, click **Browser Snapshots**.
2. Click **Filters** and check the **Server Snapshot Exists** checkbox.
3. You should now only see browser snapshots that have transaction snapshots:



4. Double-click one of the browser snapshots to open the **Browser Snapshot Details** dialog containing a transaction snapshot.



5. You can then click links in the transaction snapshot or transaction snapshot itself to view corresponding pages in APM.

Get Complete Timing Data for Correlated Business Transactions

> This functionality is currently not supported for .NET Core.

To get the full real execution time for correlated business transactions, your injection method may need to write the `JS_FOOTER` variable to your page. Manual injection gives the server-side agent the ability to write data only to the header of the page as it is being constructed by your web application.

It is possible that complete business-transaction timing information is not available at the moment that the header data is written. Using the footer allows the server-side agent to write timing data at the footer of the page, by which time a fuller picture of business transaction timing may be available.

You can write the `JS_FOOTER` data variable into the footer of a web page using the following techniques:

- If you use automatic injection for the injecting into the `head` element, you automatically get an injection into the footer as well.
- If you use manual injection for the `head` element, for applications built on Java platforms you can use assisted injection to inject into the footer. Or for applications built on Java servlet or ASP.NET platforms, you can use assisted injection using attribute injection.

If you cannot add the `JS_FOOTER` variable to your page, the timing shown for correlated business transactions may be the average response time for that transaction rather than the real execution time for that specific page.

Avoid Tagging Cookies with the HttpOnly Flag

Servers set the `HttpOnly` flag on cookies to prevent their contents from being accessed by JavaScript. This is often done for session cookies to hide the session identifier as a security measure. The JavaScript Agent, however, needs to be able to read special cookies set by the AppDynamics server-side agent (all prefixed with `ADRUM`) to collect correlation information. If `HttpOnly` is set on these cookies, no server-side correlation information can be transmitted. Thus, make sure that your server does *not* set the `HttpOnly` flag on any cookies prefixed with `ADRUM`.

If you want to securely transmit cookies, use HTTPS. The app agent sets the `secure` flag if the originating base page is loaded over HTTPS.

These can be turned off, but that would prevent correlation from working for base pages unless the customer changes the page source code to use footer injection.

Configure the JavaScript Agent

Related pages:

- Injection Problems
- Inject the JavaScript Agent

This page describes configuration and hosting options for the JavaScript Agent.

Configure the JavaScript Agent

To configure the JavaScript Agent in the Controller:

1. Go to a browser application.
2. In the left-hand panel, go to **Configuration** > **Configure the JavaScript Agent**.
3. Select a hosting option.
4. Customize the code snippet in **Step 2: Advanced settings (Optional)**.
5. Click **Save**.

Advanced Configurations

This table describes advanced configurations for the JavaScript Agent snippet. You can add these advanced configurations manually or using Controller >=21.7.0. When you check a box in the UI, such as **Use HTTPS by default**, the JavaScript snippet automatically updates to reflect the selection, such as c `onfig.useHTTPSAlways = true` added to the UI snippet.

Available in SaaS Controller >=21.7.0	Manual Configuration Instructions	Summary
✓	Use HTTPS by default	Use HTTPS as the default transport protocol for the JavaScript Agent. If unchecked, the agent chooses the transport protocol used to load the base page.
✓	Set cookie to strict domain	Limit the cookie to the full strict domain name. If unchecked, the cookie is set to the broadest version of the originating domain (such as, `*.domain.com`).
✓	Set GeoServer URL	If your application uses internet IP addresses or users connect through a VPN, enter your custom GeoServer URL to map internal IP addresses to physical locations. If unchecked, end-user locations are resolved using the default GeoServer.
✓	Configure URL length	Set the maximum number of segments and characters in resource URLs to view more or less of a URL in the Controller UI.
✓	Hide URL query string	By default, URL query strings may be long or contain sensitive information. Check this box to hide the full string from the Controller UI.
✓	Cross-domain session correlation	Enable sessions to continue across subdomains. If unchecked, sessions are restricted to one domain and navigating from one domain to another will end the session.
✓	Configure request origin location	Set a specific IP address or location as the origin of the request. You can specify only the IP address, or the complete location (IP, country, region, and city).
✓	Configure resource options	Configure which resources are monitored based on how they are ordered, the maximum number of resources that will be evaluated, and whether the resource timing buffer should be cleared when it's full.
✓	Modify resource sampling options	Modify how the resources are ordered (using the sampling algorithm) and the maximum number of resources to be evaluate.
✓	Capture page title	Capture the page title as part of the beacon, displayed in **Browser Snapshots**. Uncheck this setting to hide the page title for security or privacy reasons. Check this setting to set a custom page title with an arbitrary URL string.
✓	Enable SPA2 monitoring	Monitor single-page applications (SPAs) to detect virtual pages and correlate resources, JavaScript errors, and AJAX requests.
✓	Enable resource timing buffer clearing for SPAs	For SPAs, the JavaScript Agent by default clears the resource timing buffer after it is full and saves the data in a local buffer. You can configure the JavaScript Agent so that the resource timing buffer is not cleared to capture resource timing data.
✓	Set the custom page name	The page name is used to identify and group pages in **Pages & AJAX Requests**. If unchecked, the default page name consists of the hostname, port, and path.
✓	Filter virtual pages	Configure rules to exclude specific virtual pages from being monitored.

✓	Monitor Fetch API calls	By default, the JavaScript Agent monitors Fetch API calls for all SPAs except applications using Zone libraries, including Angular applications. Only consider disabling this setting for specific use cases.
✓	Set AJAX request limit	To prevent an overload of AJAX requests, you can limit the number of requests sent per base and virtual pageview. The limit is 250 requests for single-page applications (SPAs) and 50 requests for non-SPAs.
✓	Filter XHR calls by URL	Include or exclude specific XHR calls to be monitored.
	Report events with the JavaScript API	The JavaScript API enables you to manually report events to the agent so that it can time the various parts of your virtual page loads and correlate Ajax calls to those page loads. You can also capture and report errors with this API.
	Limit beacon types	By default, sending image beacons is disabled and beacons are only sent with Cross-Origin Resource Sharing (CORS). If you have an older browser that does not support CORS beacons, you can enable sending image beacons.
	Disable browser monitoring programmatically	For pages in which the JavaScript Agent was injected manually, you can disable the agent programmatically by adding a script to the header.
	Handle the window.onerror event	If any script on your monitored web pages or library code sets the JavaScript `window.onerror` event, add the method `ADRUM.listenForErrors()`to the page immediately after setting `window.onerror`.
	Set Ajax request names based on captured POST parameters	You can configure the JavaScript Agent to capture `POST` parameters and then use the parameter(s) to name the Ajax request in Pages & Ajax Requests. This configuration enables you to identify and sort Ajax requests from the same page based on `POST` parameter(s).
	Set custom virtual page names	You can configure the JavaScript Agent to use any arbitrary string (that is not necessarily a part of the URL) to name a virtual page.
	Add custom user data to a page browser snapshot	You can add user information that is specific to your application to a browser snapshot. The information is expressed as key-value pairs that are attached the JavaScript Agent configuration and later included in the beacons sent to the EUM Server.

Configure Shared-Hosting

If you are using shared-hosting and do not want to use the default CDN, follow these instructions to provide your own CDN for only hosting the main JavaScript Agent file (`adrum-[version].js`):

1. From **Controller Admin,** go to **Controller Settings**.
2. For the values of settings `eum.jsagent.cdn.host.http` and `eum.jsagent.cdn.host.https`, enter the URLs where the JavaScript Agent files are being hosted.
3. Confirm these URLs match the URLs in the JavaScript snippet you want to inject.

Configure Self-Hosting

If you are self-hosting and do not want to use the default CDN, follow these instructions to provide your own CDN for hosting all of the JavaScript Agent files:

1. From the **Controller Admin,** go to **Controller Settings**.
2. For the values of settings `eum.jsagent.cdn.host.http` and `eum.jsagent.cdn.host.https`, enter the URLs where the JavaScript Agent files are being hosted.
3. Confirm these URLs match the URLs in the JavaScript snippet you want to inject.

Next Steps

After you configure the JavaScript Agent, inject the JavaScript snippet in your page HTML with one of these methods:

- Manual Injection of the JavaScript Agent
- Automatic Injection of the JavaScript Agent
- Assisted Injection

See Overview of Injection Types for differences between the injection methods.

Add Custom User Data to a Page Browser Snapshot

Related pages:

- Page Browser Snapshots

You can add user information that is specific to your application to a browser snapshot. The information is expressed as key-value pairs that are attached the JavaScript Agent configuration and later included in the beacons sent to the EUM Server.

The JavaScript Agent initializes user data differently depending on the page type (base, Ajax, virtual) and the method used (immediately invoked function expressions, function pointers, and literals). See Methods for Setting Custom User Data to learn when the JavaScript Agent initializes the user data for each page type and method.

The maximum size allowed for user data in a page is 2048 characters (CORS beacon) or 100 bytes (image beacon). The maximum size includes the keys-value pairs, syntax characters such as braces, and quotation marks.

View Custom User Data

Custom user data appears in **Browser Analyze**, **Browser Snapshots**, and **Sessions**. View the following tabs to learn more about how user data is viewed and used in the Controller UI.

Methods for Setting Custom User Data

You can use several methods to set custom data for each page type (base, Ajax, virtual). Each method has its own syntax, execution time, and use case. This table outlines the execution time and potential use case for each method and page type.

Method Type	Page Type	Execution Time	Potential Use Cases
Immediately Invoked Function Expressions (IIFE)	Base	These are JavaScript functions that run as soon as they are defined. They're also known as self-executing anonymous functions.	If your base/virtual page or Ajax request depends on information from different resources, you can set static information for custom user data with IIFE. For example, if two different server scripts generate content for the base page, you could use the IIFE on the client to set the static user data.
	Ajax		
	Virtual		
Function pointers	Base	The JavaScript Agent executes function pointers when the `onload` event is triggered.	Data extracted from cookies, the page, and meta data.
	Ajax	This event is triggered when an Ajax call is made. Custom user data for the Ajax events are attached to AJAX requests.	Meta data regarding the Ajax request such as the URL, HTTP method, or the request payload.
	Virtual	This event is triggered when the virtual page is created. The virtual page is a dynamically recreated version of the base page, and custom user data set for `VPageView` events are attached to the virtual page records.	Use if the information is derived or found somewhere on the page because of the creation of the virtual page. User-specific fields or user data set based on the URL and DOM changes.
Literals	Base	You can simply use literal values to set custom data. The values, as with IIFE, are set as soon as the values are defined.	Constants, static data extracted and set on the server.
	Ajax		
	Virtual		

User Data Types

For each event callback that is triggered, you can add user data by returning objects containing key-value pairs of different data types. Each user data type is an object containing properties of a specific data type.

⚠ Failing to send the wrong type of data as values to the keys inside the `userData` object will throw a generic error, so use with caution.

Data Type	Description	Example

`userData`	This data type is for setting one or more properties of type `string`. The value must be in a string, even if the value is set to a numeric value.	`{`
		`  user: "john_thompson",`
		`  cart: "100.00"`
		`};`

`userDataLong`	This data type is for setting one or more properties of type `long` and must be a numeric value without decimals.	`{ numberOfProducts: 17, numberOfSales: 1213 };`
`userDataDouble`	This data type is for setting one or more properties of type `double` and must be a numeric value with decimals.	`{ monthlyVisitFrequency: 0.13333333, avgCustomerConversion: 0.0361922 };`
`userDataBoolean`	This data type is for setting one or more properties of type boolean.	`{ returnCustomer: true, subscriber: false };`
`userDataDate`	This data type is for setting one or more properties of type `date`. The value must be the converted Epoch value of the date.	`{ epoch1: 1448675019877, epoch2: 1418475982737 };`

Syntax of User Data Objects

You add user data as objects for each page event to the JavaScript Agent configuration. The base page, Ajax, and virtual pages have the following corresponding user data objects:

- `PageView`
- `Ajax`
- `VPageView`

The `PageView`, `Ajax`, and `VPageView` objects have slightly different syntaxes. `UserPageName` is only available for `PageView` and `VPageView`, and not for `Ajax` and `Error`.

Capture Ajax Data for Setting User Data

When setting user data for the Ajax event, the JavaScript Agent configuration provides a `context` object that has properties for the HTTP method, the request URL, and the request payload of the Ajax request. You can use this information to set values for the user data configuration object.

The JavaScript Agent does not intercept or expose the response from the Ajax request. Thus, you can only include the request information (HTTP method, request URL, and request payload) in the user data that you report.

Ajax Context Object

To access the URL and HTTP method of the Ajax request, you can simply access the `method` and `url` properties of the `context` object. For the request payload of the Ajax request, you need to first match the payload parameters (HTTP method or Ajax URL) to access the `data` property. See Match the Ajax Payload Parameters to learn how to define the filters to match the payload parameters.

The `context` object has the following properties:

Property	Description	Data Type	Requirement to Access Property
`method`	The HTTP method used to make the Ajax request.	string	XHR call

`url`	The URL used to make the Ajax request.	string	XHR call
`data`	The request payload attached to the Ajax request.	Any data type that can be passed as the body to xhr.send.	• XHR call • XHR filter for the payload parameter

Match the Ajax Payload Parameters

To access the request payload, you need to use `xhr.payloadParams` array to match the HTTP method and/or the Ajax URL. To match the Ajax URL, you can specify one or more patterns. To match the HTTP method, you include one or more objects specifying HTTP methods.

In the "Match HTTP Methods" example, the `payloadParams` array is used to match the HTTP methods "POST" and "GET". In the "Matching URLs" example, the `payloadParams` array is used to match URLs with the following string: `'.*/xhr/uptime'`.

Ajax Payload Filter Examples

Conventional Ajax Requests

In the following examples, the data from a conventional Ajax request payload is used to set custom user data. For capturing the request payload for Fetch API calls, see Ajax Requests Using the Fetch API.

Ajax Requests Using the Fetch API

The example below demonstrates how to use the JavaScript Agent configuration to match the HTTP method, the request URL, and the request body for Ajax calls using the Fetch API. The Fetch API call is also provided to add context. The JavaScript Agent **cannot access** the request body, however, if you supply your own Request object to the `fetch` method.

Custom User Data Examples

The following examples show you how to set custom data for different page types and using the different methods:

- Setting User Data with Function Pointers
- Setting User Data with an Anonymous Function
- Setting User Data with Multiple Methods

Setting User Data with Function Pointers

The example below assigns a value to the `userPageName` property of the `PageView` object by executing the function `extractUserData`, which extracts data from the cookies.

```
< script type = 'text/javascript'
charset = 'UTF-8' >
        (function (config) {
                (function (info) {
                        info.PageView = extractUserData;
                })(config.userEventInfo || (config.userEventInfo = {}))
        })(window['adrum-config'] || (window['adrum-config'] = {}));

function extractUserData() {
        var cookies = document.cookie.split(';');
        for (var i = 0; i < cookies.length; i++) {
                var cookie = cookies[i].trim();
                if (cookie.indexOf("role=") === 0) {
                        var role = cookie.substring(5);
                }
        }
        return {
                userPageName: role
        };
} <
/script> <
script src = '//cdn.appdynamics.com/adrum/adrum-latest.js'
type = 'text/javascript'
charset = 'UTF-8' > < /script>
```

Setting User Data with an Anonymous Function

You can also use anonymous functions that return an object as shown in this example for setting user data for virtual pages.

```
< script type = 'text/javascript'
charset = 'UTF-8' >
        (function (config) {
                (function (info) {
                        info.VPageView = function () {
                                return {
                                        userData: {
                                                version: window.location.href.split("/")[4],
                                                space: space(),
                                                email: getEmail()
                                        },
                                        userPageName: $('title').get(0).text,
                                        userDataDate: {
                                                currentTime: ((new Date()).getTime())
                                        },
                                        userDataBoolean: {
                                                watchingPage: watchingPage()
                                        }
                                }
                        }
                })(config.userEventInfo || (config.userEventInfo = {}))
        })(window['adrum-config'] || (window['adrum-config'] = {})); <
/script> <
script src = '//cdn.appdynamics.com/adrum/adrum-latest.js'
type = 'text/javascript'
charset = 'UTF-8' > < /script>
```

Setting User Data with Multiple Methods

You might also want to use a combination of literal values, named and anonymous functions as this example does for setting user data for the `Ajax` event. Note, the `context` object is only available for `Ajax` events, and this object has the properties `data` (stores the request payload), `method` (HTTP method used to make Ajax request), and `url` (the Ajax request URL).

```
<script type='text/javascript' charset='UTF-8'>
    (function(config){
        (function(info) {
            info.Ajax = function(context) {
                return {
                    userPageName: $('title').get(0).text,
                    userData: extractUserData(context)
                    userDataBoolean: {
                                    "visited": true
                    }
                }
            };
        })(config.userEventInfo || (config.userEventInfo = {}))
   })(window['adrum-config'] || (window['adrum-config'] = {}));

   function extractUserData(context) {
        var cookies = document.cookie.split(';');
        for (var i = 0; i < cookies.length; i++) {
            var cookie = cookies[i].trim();
            if (cookie.indexOf("email=") === 0) {
                var role = cookie.substring(5);
            }
        }
        return {
            role: role,
            url: context.url,
            method: context.method
        };
    }
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
```

Set Custom Page Names

Related pages:

- Configure Naming for Ajax Requests
- Configure Virtual Page Naming

This page describes how to set custom page names. In the **Configuration > Instrumentation** page, you can configure rules that name pages, iframes and Ajax requests based on various parts of the page URL. See Configure Page Identification and Naming.

You can also configure the JavaScript Agent to use any arbitrary string, not necessarily a part of the URL, to name a page or an iframe, but not an Ajax request. To do so, you assign a string of 760 characters or less to the `userPageName` property of the `PageView` object. If the string length exceeds 760 characters, the page name will not be set.

For example, this configuration shown below would set the page name to "My Custom Page". That page name would then be used to identify and group pages in the **Pages & AJAX Requests** page in the Controller UI.

```
<head>
    <script type='text/javascript' charset='UTF-8'>
        (function (config) {
            (function (info) {
                info.PageView = {
                    userPageName: "My Custom Page"
                }
            })(config.userEventInfo || (config.userEventInfo = {}));
        })(window['adrum-config'] || (window['adrum-config'] = {}));
    </script>
    <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
    ....
</head>
```

The default page name consists of the hostname, port, and path. For example, if the page URL is `http://example.com:8080/yourpath`, the default page name would be `example.com:8080/yourpath`.

Set Custom Virtual Page Names

Related pages:

- Configure Page Identification and Naming
- Configure Naming for Ajax Requests
- Configure Virtual Page Naming

This page explains how to create custom virtual page names.

To name virtual pages with the JavaScript Agent, you need to enable SPA2 monitoring. You can configure the JavaScript Agent to use any arbitrary string, not necessarily a part of the URL, to name a virtual page. The virtual page name must consist of a string of 760 or fewer alphanumeric characters. If the string length exceeds 760 characters, the page name will not be set.

If you are using SPA1 monitoring, the method called to set the name the virtual page will be ignored.

To name a virtual page, you execute the method `setVirtualPageName` with `ADRUM.command` as shown below. The `ADRUM` object is globally accessible after you load the JavaScript Agent (`adrum-latest.js`).

```
<head>
    <script charset='UTF-8' type='text/javascript'>
        window['adrum-start-time'] = new Date().getTime();
        (function(config){
            config.appKey = '<EUM_APP_KEY>';
            ...
        })(window['adrum-config'] || (window['adrum-config'] = {}));
    </script>
    <script charset='UTF-8' src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' ></script>
    <script type='text/javascript' charset='UTF-8'>
        ...
        ADRUM.command("setVirtualPageName", "myCustomVPName");
    </script>
</head>
```

When you name a virtual page with `setVirtualPageName`, the custom name will be applied to the next virtual page you manually mark with `markVirtualPageBegin`. Thus, the virtual page currently being monitored will not get the custom name.

The code example below shows how to call the methods to manually mark the beginning and end of the virtual page as well as execute `setVirtualPageName` to name the next virtual page that is monitored. See Report Virtual Pages to learn how to manually mark the beginning and end of virtual pages with the JavaScript API.

```
.controller('VPNaming', ['$scope', '$http', function ($scope, $http) {
            $scope.startVirtualPageWithCustomUrl = function () {
                console.log("Marking the beginning of the virtual page and waiting for the end to be manually
marked.");
                ADRUM.markVirtualPageBegin("homepage", true);
            }
            $scope.startVirtualPageNotWaitingForMarkVirtualPageEnd = function () {
                console.log("Marking the beginning of the virtual page and allowing the JS Agent to mark the
end of the virtual page.");
                ADRUM.markVirtualPageBegin("homepage", false);
            }
            $scope.endVirtualPage = function () {
                console.log("Manually marking the end of the virtual page.");
                ADRUM.markVirtualPageEnd();
            }
            $scope.setVirtualPageName = function () {
                console.log("Setting a custom name for the next virtual page to be monitored: have it's
beginning and end marked.");
                ADRUM.command("setVirtualPageName", "myCustomVPName");
            }
        }
    ]
);
```

Set Ajax Request Names Based on Captured POST Parameters

Related pages:

- Configure Virtual Page Naming
- Page, Ajax, and Iframe Dashboards
- Set Custom Page Names

You can configure the JavaScript Agent to capture POST parameters and then use the parameter(s) to name the Ajax request in the **Pages & Ajax Requests** page. This enables you to identify and sort Ajax requests from the same page based on POST parameter(s).

For example, customers on your home page of your website can either register an account or log in. The Ajax request may pass the parameter `action` to reflect one of these user actions. By capturing the `action` parameter, you can differentiate the Ajax requests to monitor performance and debug issues.

Configure the JavaScript Agent to Capture Parameters

You use the `xhr` object to configure the JavaScript Agent to capture POST parameters. The `xhr` object has the property `parameter` that is used to match resource URLs and define a callback for parsing the request body and return the desired results.

In the example below, the configuration sets a pattern to match the URL `http://www.mystore.com`, parses the request body, and returns an object containing the parameter `action`. As mentioned earlier, you could use a configuration like this to differentiate Ajax requests that are sending requests to register or log in users.

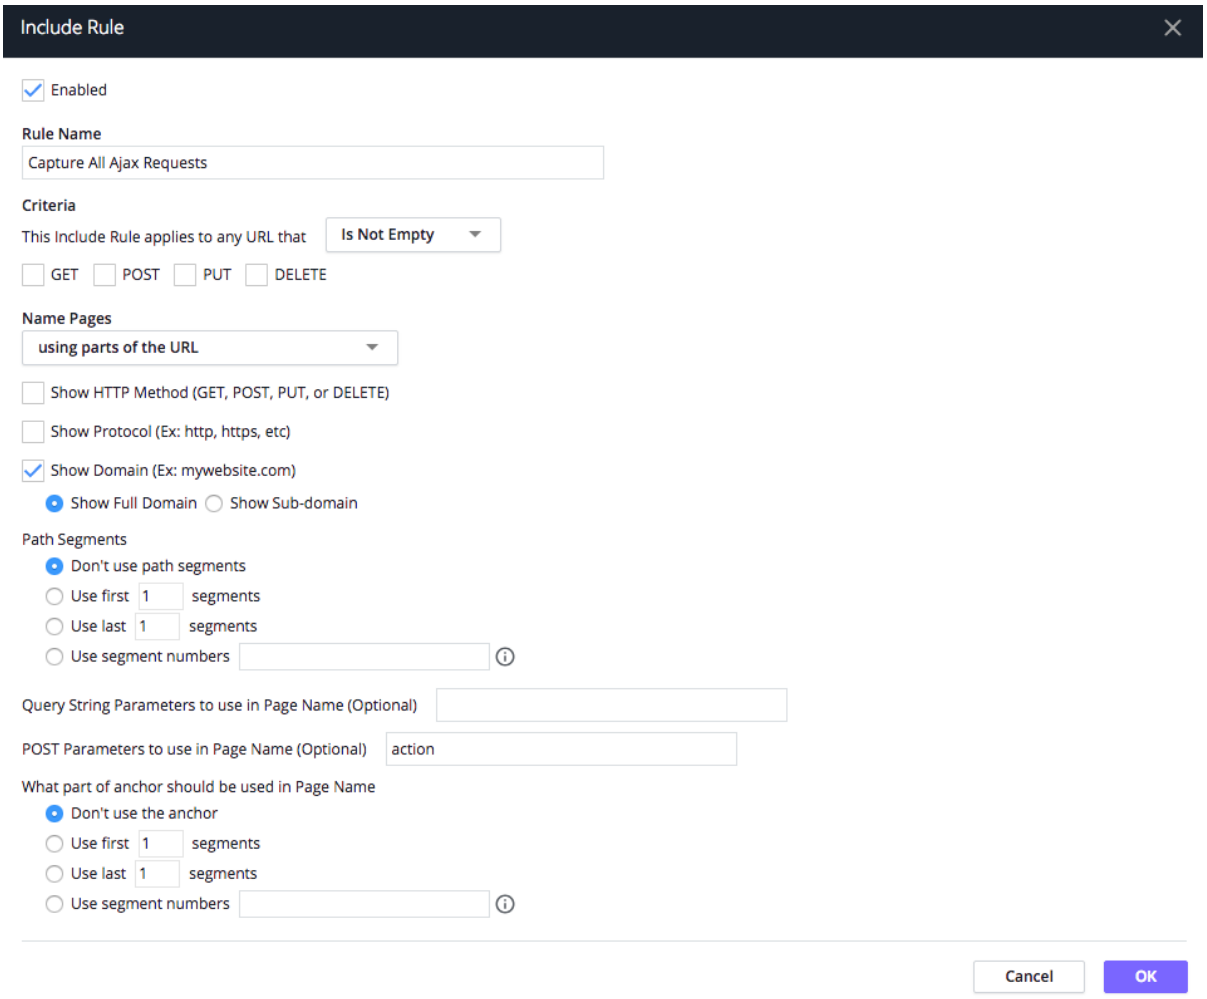
```
<script type='text/javascript' charset='UTF-8'>
    window['adrum-start-time'] = new Date().getTime();
    window['adrum-config'] =  {
        xhr: {
            parameter : {
                urls : [{pattern : '^https?:\\/\\/www\\.mystore\\.com'}],
                getFromBody: function(data) {
                    if (typeof data === 'string') {
                        var fields = data.split("&");
                        for (var i = 0; i < fields.length; i++) {
                            var keyAndValue = fields[i].split('=');
                            if (keyAndValue.length > 1) {
                                var key = keyAndValue[0],
                                value = keyAndValue[1];
                            if (key === 'action')
                                return {action: value};
                            }
                        }
                    }
                }
            }
        }
    }
</script>
<script charset='UTF-8'>
    (function(config){
        config.appKey = '<EUM_APP_KEY>';
        config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
        config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
        config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
        config.beaconUrlHttps = 'https://col.eum-appdynamics.com';
        config.xd = {enable : true};
    })(window['adrum-config'] || (window['adrum-config'] = {}));

    (function (cfg) {
        if (cfg.beacon) cfg.beacon.neverSendImageBeacon = true;
        else cfg.beacon = { neverSendImageBeacon: true };
    })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
```

Create an Ajax Include Rule

To name an Ajax request based on a captured request parameter, you need to define an include rule that specifies the captured POST parameter. See Configure Naming for Ajax Requests to learn how to create include rules for Ajax requests.

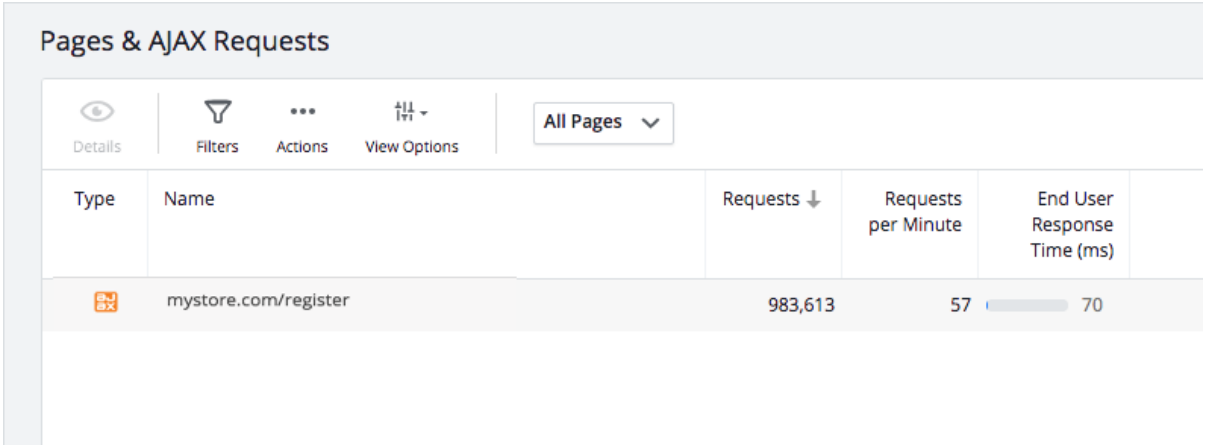
The example include rule below uses the full domain and the captured POST parameter to name the Ajax request in the **Pages & Ajax Requests** page. For example, if an Ajax request is made to `www.mystore.com` and the value of the `action` parameter is `register`, the Ajax request will be named `www.mystore.com/register`.



View Results in Pages & Ajax Requests

From the **Pages & Ajax Requests** page, you can view the Ajax requests that are named based on your include rule.

Using the configuration and include rule shown above, you might see the following Ajax request with the name **mystore.com/register.**



Handle the window.onerror Event

Related pages:

- JavaScript Errors
- Configure JavaScript and Ajax Error Detection
- Visualize JavaScript Errors

If any script on your monitored web pages, including library code, sets the JavaScript `window.onerror` event, add the following method to the page immediately after setting `window.onerror`:

```
<script>
ADRUM.listenForErrors()
</script>
```

The JavaScript Agent (`adrum.js`) sets `window.onerror` to listen for uncaught JavaScript errors. If this listener is overwritten, errors are not reported.

The agent invokes your original `onerror` handler.

Disable Browser Monitoring Programmatically

Related pages:

- Enable and Disable Browser RUM

For pages in which the JavaScript Agent was injected manually, you can disable the agent programmatically by adding a script to the header.

To disable Browser Monitoring add the snippet below before `adrum.js` agent is injected.

```
window["adrum-disable"] = true
```

For example:

```
<head>
    <script type='text/javascript' charset='UTF-8'>
        // before adrum.js
        window["adrum-disable"] = true
    </script>

    <script>
        window["adrum-start-time"] = new Date().getTime();
    </script>
     <!-- adrum.js injection -->
    <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
    ...
</head>
```

Old Browser Monitoring data is preserved, but no new monitoring data is collected while the agent is disabled.

You can re-enable monitoring by removing the disable script statement.

Set the Exact Current Domain in the JavaScript Agent Cookie

This page describes how to set the current domain in the JavaScript Agent cookie.

The JavaScript Agent itself writes a session cookie to the page, for timing purposes. This cookie is set when the user clicks a link and the `unload` event is fired. By default, the cookie is set to the broadest possible version of the originating domain (such as, `*.domain.com`) to increase the likelihood that the next page opened in the same domain can access that cookie. See Cookies and Browser Monitoring Data.

In some cases, however, it may be necessary to limit the cookie to the full exact domain name. To do this, add a flag in the `"adrum-start-time"` script to the header of each page right *after* the `<head>` tag and *before* the entry that includes the location of the agent (`adrum.js`). The flag should read: `windo w["adrum-use-strict-domain-cookies"] = true`.

After you include the start-time line, the strict domain flag, and the agent, the `<head>` section in your monitored web pages should look something like this:

```
<head>
    <script type='text/javascript' charset='UTF-8'>>
        window["adrum-start-time"] = new Date().getTime();
        window["adrum-use-strict-domain-cookies"] = true;
    </script>
    <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
    ...
</head>
```

Limit Beacon Types

Related pages:

- Alter or Eliminate the Page Title Captured in the Beacon

The JavaScript Agent collects and sends information to the EUM Server via a beacon, either through Cross-Origin Resource Sharing (CORS) or an image beacon which returns a small, transparent `.gif` file.

If you want the agent to only use CORS to transport the beacon, you can turn off the image beacon request mechanism. To turn off the image beacon request, add the following snippet to your HTML preceding the injected `adrum.js` script:

```
<head>
    <script type='text/javascript' charset='UTF-8'>
       (function (cfg) {
           if (cfg.beacon) cfg.beacon.neverSendImageBeacon = true;
           else cfg.beacon = { neverSendImageBeacon: true };
        })(window['adrum-config'] || (window['adrum-config'] = {}));
    </script>
    <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
    ...
</head>
```

Alter or Eliminate the Page Title Captured in the Beacon

Related pages:

- Limit Beacon Types
- Set Custom Page Names

In a standard Browser RUM beacon, the value for `document.title` is collected as part of the data to be sent in the beacon. You may want to alter or eliminate the page title for security or privacy reasons.

You can choose to:

- Not collect a page title at all
- Use a title that is created by a function with 0 arguments
- Use a title that is an arbitrary string

The page title is different than the page name. The page title is just additional information included in browser snapshots, whereas, the page name is used to identify and group records in the **Pages & AJAX Requests** page.

Remove a Page Title

To remove the page title entirely, add the following snippet to your page before you inject the `adrum.js` script:

```
<head>
    <script type='text/javascript' charset='UTF-8'>
        (function (config) {
           (function (page) {
               page.captureTitle = false;
           })(config.page || (config.page = {}));
        })(window['adrum-config'] || (window['adrum-config'] = {}));
   </script>
   <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
   ...
</head>
```

Use a Page Title Created by a Function

To use a function with no arguments to create a page title, before you inject the `adrum.js` script, define your function and call it, as in this example:

```
<head>
    <script type='text/javascript' charset='UTF-8'>
        function title() { return document.title.split('-').slice(1,3).join('-'); } // define a function
        (function (config) {
            (function (page) {
                page.title = title; // call your function
            })(config.page || (config.page = {}));
        })(window['adrum-config'] || (window['adrum-config'] = {}));
    </script>
    <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'/>
    ...
</head>
```

Something like this could be used, for example, to remove sensitive data from the page title.

Use an Arbitrary String as a Page Title

To use any arbitrary string as the page title, before you inject the `adrum.js` script, set `page.title`.

```
<head>
    <script type='text/javascript' charset='UTF-8'>
        (function (config) {
           (function (page) {
               page.title = "My Special Page Title";
           })(config.page || (config.page = {}));
        })(window['adrum-config'] || (window['adrum-config'] = {}));
    </script>
    <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
    ...
</head>
```

This would set the page title in the beacon to "My Special Page Title".

Modify Resource Sampling Options

Related pages:

- Page Browser Snapshots
- Capture Resource Timing Data Without Loss

Some pages use a very large number of resource files, more than can usefully be monitored. By default, the JavaScript Agent decides which resource files to monitor based on two factors:

- How the resources are ordered (the sampling algorithm used)
- The maximum number of resources to be evaluated

Both of these factors can be modified.

To modify the sampling algorithm, use `resTiming.sampler`. Possible values are:

- Top N: the resources that take the most time to load, up to the maximum number
- First N: the resources that load first, up to the maximum number
- Relevant N: the resources that are deemed "most relevant" by an algorithm that takes into account both overall load time and when in the sequence the resource loads. So, for example, something that takes a long time to load and is early in the load sequence is "more relevant" than something that takes exactly the same time to load, but does so later in the sequence, on the assumption that the former would have more impact on the overall user experience. This is the default.

To modify the maximum number of resources to be evaluated, use `resTiming.maxNum.`

For example, to sample based on Top N and to set the max number at 100, you could add the following snippet to your page, *before* you inject the `adrum.js` script.

```
<head>
    <script type='text/javascript' charset='UTF-8'>
        (function (config) {
            config.resTiming = {
                sampler: "TopN",
                maxNum: 100
            };
        })(window['adrum-config'] || (window['adrum-config'] = {}));
    </script>
    <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
    ...
</head>
```

Set the Origin Location of the Request

Related pages:

- Geo Dashboard

There are some cases where it would be useful to be able to set a specific IP address/location as the origin of the request by modifying the JavaScript Agent itself. Add the following snippet to your page, before you inject the `adrum.js` script:

```
<head>
    <script type='text/javascript' charset='UTF-8'>
        window['adrum-config'] = (function(config) {
            config.geo = {
                localIP: "192.168.200.255",
                city: "San Francisco",
                region: "California",
                country: "USA"
            };
            return config;
        })(window['adrum-config'] || {});
    </script>
   <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
</head>
```

You can use this snippet in two ways:

- Specify only the IP address, in which case this IP address has the highest precedence for use by the geo server, local or cloud-based, in resolving the request location.
- Specify all of IP, `country`, `region`, and `city`, in which case the request location is set by the script, and is not resolved by the Geo Server.

If you specify only some of the location parameters, the entire configuration is ignored. For example, if you only specified country, but not region, the entire configuration is ignored.

The value for `city` is only displayed in snapshots and can be any string. Using this value it is possible to specify location more precisely, as desired, for example, `San Francisco, Sutter Street.`

Hide All or Parts of the URL Query String

Related pages:

- Configure the Number and Length of URL Segments

By default, we capture URLs with their query strings. Because query strings may result in very long URLs or contain information that you don't want to expose, you may want to prevent all or parts of the query string from being displayed in the Controller UI.

You can do this by configuring the JavaScript Agent to remove query strings from URLs for the following:

- pages
- virtual pages
- XHR calls
- referrers
- scripts
- resources

Filter for URL Query Strings

The filter `filterURLQuery` is used to remove query strings from URLs. You can use it to remove all query strings or specific key-value pairs from query strings. The table below specifies the supported values and describes the result of the filter.

Filter	Value	Default	Description
`filterURLQuery`	`true`	No	Removes query strings from all URLs.
`filterURLQuery`	`false`	Yes	Retains the query strings for all URLs.
`filterURLQuery`	array of strings	No	Each string represents a key in the query string. The given keys are removed from the query string. Strings that do not match keys in the query string will have no effect on the filtering.

Unsupported values will result in the default behavior of retaining the entire query string for all URLs.

Remove All Query Strings

The configuration below will remove all URL query strings, so you'll only see the domain name and the URL path in the Controller UI.

```
<head>
    <script type='text/javascript' charset='UTF-8'>
       (function (config) {
           config.urlCapture = {
               filterURLQuery: true
           }
       })(window['adrum-config'] || (window['adrum-config'] = {}));
    </script>
    <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
    ....
</head>
```

Remove Specific Keys From Query Strings

This configuration will remove the key-value pairs from the query string where the keys match the strings `"name"`, `"page"`, and `"id"` given in the array.

```
<head>
    <script type='text/javascript' charset='UTF-8'>
        (function (config) {
            config.urlCapture = {
                filterURLQuery: ["name", "page", "id"]
            }
        })(window['adrum-config'] || (window['adrum-config'] = {}));
    </script>
</head>
```

Configure the JavaScript Agent to Use HTTPS

Related pages:

- Limit Beacon Types
- Enable the Content Security Policy (CSP)

By default, the JavaScript Agent chooses the same transport (protocol) used to load the base page, but you can configure the JavaScript Agent to use HTTPS for a more secure network connection.

When configured to use HTTPS, the JavaScript Agent will use HTTPS to do the following:

- fetch `adrum-ext.js`
- fetch geolocation data
- send CORS beacons
- send image beacons

Set the useHTTPSAlways Flag

Following the code example below, you can set the boolean `useHTTPSAlways` to `true` to configure the JavaScript Agent to always use HTTPS.

```
<head>
    <script type='text/javascript' charset='UTF-8'>
        (function(cfg) {
            cfg.useHTTPSAlways = true;
        })(window['adrum-config'] || (window['adrum-config'] = {}));
    </script>
    <script src='https://cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'><
/script>
    ...
</head>
```

Configure the Number and Length of URL Segments

Related pages:

- Hide All or Parts of the URL Query String

When the number of segments or the length of a segment exceeds the default maximum, the URL will appear truncated in the Controller UI. For example, the resources shown in the Resource Details tab or the **Session Details** dialog may display truncated because of the number of URL segments or the length of the segments in the URL.

You can set configurations for the JavaScript Agent that set the maximum number of segments and the maximum number of characters for each segment. This allows you to view more or even less of the resource URLs in the Controller UI.

Segment Definition

A segment is a fragment of a URL. The following constitute one segment:

- `<protocol>://<domain-name>:<port>`
- `?key=value&key=value (query string)`
- `#someAnchor (anchor)`
- `/file-path/` (file path specified between two forward slashes)

For example, this URL consists of five segments: `http://example.com:8090/a/b.html#someAnchor?test=true&segments=5`

Truncation Rules and Examples

The maximum number of segments determines how many segments will be displayed in the Controller UI. The last segment will always be shown, and then the first *n* number of segments until the maximum number is reached.

For example, if the original URL is `http://example.com:8090/a/b.html#someAnchor?test=true&segment=5` and the configured maximum number of segments is 3, then the Controller UI would display the following: `http://example.com:8090/a/...?test=true&segment=5`

The maximum length of segments determines how many characters of a segment will be displayed in the Controller UI. The truncation rules are slightly more complicated as they depend on the type of segment:

- For the segment `<protocol>://<domain-name>:<port>`, the `<protocol>` and `<port>` are displayed, and if the remaining amount of the maximum length is greater than the length of `<domain-name>`, then the entire domain name is displayed. If the remaining amount of the maximum length is less than the length of `<domain-name>`, then the Controller UI would only display `http...8090`.
- For query strings, anchors, and file paths, the first character (?, #, /) is displayed as well as the last *n* number of characters until the maximum length is reached. For example, for the segment `?test=true&segment=5`, if the maximum length is 10, then the segment will be displayed as the following: `?...segment=5`

Default Values for Segments

The variable for setting the maximum number of segments to display is `maxResUrlSegmentNumber`. The variable for setting the maximum length of segments is `maxResUrlSegmentLength.`

The following are the default values for the two variables:

- `maxResUrlSegmentNumber=10`
- `maxResUrlSegmentLength=64`

Set the Maximum Number of Segments

The code snippet below sets the maximum number of segments to display at 15.

```
<head>
    <script type='text/javascript' charset='UTF-8'>
        (function(config){
            config.maxResUrlSegmentNumber = 15;
        })(window['adrum-config'] || (window['adrum-config'] = {}));
    </script>
    <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
    ...
</head>
```

Set the Maximum Length of Segments

The code snippet below sets the maximum number of characters of segments to display at 100.

```
<head>
    <script type='text/javascript' charset='UTF-8'>
        (function(config){
            config.maxResUrlSegmentLength = 100;
        })(window['adrum-config'] || (window['adrum-config'] = {}));
    </script>
    <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
    ...
</head>
```

Exclude Virtual Pages from Being Monitored

You can exclude virtual pages from being monitored based on the virtual pages' URLs. You define `exclude` filters to match URLs of virtual pages that you don't want to be monitored. You cannot, however, exclude virtual pages that you are manually reporting with the SPA2 JavaScript API.

Virtual Page Object

The `vp` object contains the `exclude` filter that specifies an array of patterns to match the URLs of virtual pages to exclude. By defining an `exclude` filter, you automatically enable SPA2 monitoring.

```
"spa": {
    "spa2": {
        "vp": {
            "exclude": {
                 "urls": [{"pattern": 'api'}, {"pattern": "resources"}]
            }
        }
 }
```

Virtual Page Filter Example

To use the virtual page filter, you set the JavaScript Agent with the `exclude` filter before you inject the `adrum.js` script.

For example, in the code snippet below, the pattern would match and exclude all virtual pages with URLs that have the strings "contact", "api", or "api" followed by one or more characters.

```
<head>
    <script type='text/javascript' charset='UTF-8'>
        (function(config){
            config.spa = {
                spa2: {
                    vp: {
                        exclude: {
                            "urls": [{"pattern": "contact"}, {"pattern": "api*"}]
                        }
                    }
                }
                        };
        })(window["adrum-config"] || (window["adrum-config"] = {}));
    </script>
    <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
    ...
</head>
```

Limit the Number of Ajax Requests

Related pages:

- Ajax Dashboard
- Ajax Request Snapshots
- Configure Naming for Ajax Requests
- Configure JavaScript and Ajax Error Detection

This page covers how to set the number of Ajax Requests.

By default, the JavaScript Agent limits the Ajax requests (using XHR or the Fetch API) sent for base or virtual pages. The limit is 250 requests for single-page applications (SPAs) and 50 for non-SPAs. Although base or virtual pages normally do not send large amounts of Ajax requests, in some cases, a page may send redundant Ajax requests, especially those containing error reports.

For example, a series of redundant Ajax requests containing a dead loop of errors and exceptions with no new information could overload the EUM Server. To prevent an overload of Ajax requests, you can configure the JavaScript Agent to limit the number of Ajax requests sent for base and virtual pages.

Set the Number of Ajax Requests

The code example below limits the number of Ajax request per base or virtual page to 7.

```
<head>
   <script type='text/javascript' charset='UTF-8'>
      window["adrum-start-time"] = new Date().getTime();
      window['adrum-config'] = {
         xhr: {
            maxPerPageView: 7
         }
      };
      ...
   </script>
   <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
   ...
</head>
```

Set an Unlimited Number of Ajax Requests

For use cases where all Ajax requests for a page need to be captured, you can configure the JavaScript Agent to report an unlimited number of Ajax requests per page with the configuration `xhr.maxPerPageView`.

> To prevent an overload of Ajax requests, it is highly recommended to only use this configuration for use cases when you absolutely need to capture all Ajax requests.

The following code example configures the JavaScript Agent to report an unlimited number of Ajax requests per page:

```
<head>
   <script type='text/javascript' charset='UTF-8'>
      window["adrum-start-time"] = new Date().getTime();
      window['adrum-config'] = {
         xhr: {
            maxPerPageView: "UNLIMITED"
         }
      };
      ...
   </script>
   <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
   ...
</head>
```

Capture Resource Timing Data Without Loss

Most browsers stop capturing resource timing data in a page when the number of resources reaches 150 because of the limit set by the Resource Timing API. You can configure the JavaScript Agent for conventional web pages (non-single page applications) and single-page applications (SPAs), however, to overcome this limitation.

> For Internet Explorer, you currently *cannot* use the JavaScript Agent configuration above to override the Resource Timing API's default limit of resources returned by the browser.

Because the JavaScript Agent configuration is different for non-SPA and SPA, see these sections for details and instructions:

Set and Clear the Resource Timing Buffer for Non-SPAs

For non-SPAs, you can configure the JavaScript Agent to use a buffer to capture resource timing data and then set a flag to clear the buffer once the beacon has transmitted the resource timing data to the EUM Server. Clearing the buffer clears the browser's resource buffer array and ensures that new resources will be sent in the next beacon.

> Overriding the Resource Timing API and clearing the buffer may affect JavaScript code on your page that is using the Resource Timing API. Thus, the JavaScript Agent uses the default set by the Resource Timing API unless you override the default by configuring the JavaScript Agent to set and clear the resource timing buffer.

JavaScript Configuration Example

The `resTiming` object is used for configuring the buffer size (maximum number of resources to return) and whether the buffer is reset once the beacon is transmitted to the EUM Server. The code snippet below shows you how to specify the buffer size and set the flag for clearing the buffer with the properties `bufSize` and `clearResTimingOnBeaconSend`.

```
<head>
    <script type='text/javascript' charset='UTF-8'>
        window['adrum-config'] = {
            resTiming: {
                bufSize: 200,
                clearResTimingOnBeaconSend: true
            }
        };
    </script>
    <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
</head>
```

Disable the Clearing of the Resource Timing Buffer for SPAs

For SPAs, the JavaScript Agent by default clears the resource timing buffer after it's full and saves the data in a local buffer. You can configure the JavaScript Agent so that the resource timing buffer is not cleared to capture resource timing data.

> If the resource timing buffer is not cleared, the resource timing correlation may miss some resources due to the buffer limit of the browser.

JavaScript Configuration Example

The default for `clearResTiming` is `true`. Setting `clearResTiming` to `false`, as shown below, disables the automatic clearing of the resource timing buffer. The resource timing buffer for virtual pages will also not be cleared.

```
 window['adrum-config'] = {
      ...
      "spa": {
           "spa2": {"clearResTiming": false}
      }
}
```

Filter XHR Calls by URLs

Related pages:

- Set the Number of Ajax Requests
- Configure Naming for Ajax Requests
- Configure Which Ajax Requests Are Sent to the Events Service

If you have many XHR calls (using XMLHttpRequest or the Fetch API) from your page that you do not need to monitor, you can use XHR filters so that the Agent only monitors a regex-defined list of specified calls.

When XHR calls are monitored, the absolute path of the XHR calls is provided to the JavaScript Agent. In the Controller UI, those monitored XHR calls will be displayed as configured by naming rules. If there are no naming rules, the absolute path of the XHR call is displayed.

XHR Filters

You can use the XHR filters below to include or exclude XHR calls. The filters can be in the form of an XHR filter object or an array of XHR filter objects.

- `xhr.include`
- `xhr.exclude`

Filter Object Structure

The XHR filter object has two properties: `urls` and `method`. The `urls` property is an array of objects containing a `pattern` property that specifies a regular expression for matching URLs. The `method` property is a string that specifies an HTTP method. You can use one or both of the properties. If you only use the `urls` array, the matched URLs will be either included or excluded for all HTTP methods. If you only specify `method`, all calls using the specified HTTP method will be either included or excluded.

The following is the general structure for the filter object:

```
{
    urls:
      [
        {
          pattern: ".*foo.*"
        },
        {
          pattern: ".*bar.*"
        }
      ],
    method: 'GET'
}
```

XHR Filter Example

To use XHR filters, you must assign XHR filters to `xhr.include` and `xhr.exclude` before you inject the `adrum.js` script. It's important to note that the exclude patterns override the include patterns, so those URLs that are matched by both the include and exclude patterns will ultimately be excluded.

For example, in the code snippet below, the include pattern would match all HTTP requests to `http://somedomain/app_status/user-profile.jsp`, but the exclude pattern would exclude POST calls to that URL.

```
<head>
    <script type='text/javascript' charset='UTF-8'>
        (function(config){
            (function(xhr) {
                xhr.include = {
                    urls: [
                        {
                            pattern: ".*ajax_info.txt"
                        },
                        {
                            pattern: ".*app_status.*"
                        }
                    ]
                };
                xhr.exclude = {
                    urls = [
                        {
                            pattern: ".*user-profile.*"
                        }
                   ],
                   method: "POST"
                };
            })(config.xhr || (config.xhr = {}));
        })(window["adrum-config"] || (window["adrum-config"] = {}));
    </script>
    <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
    ...
</head>
```

Report Events with the JavaScript API

The JavaScript API enables you to manually report events to the agent so that that it can time the various parts of your virtual page loads and correlate Ajax calls to those page loads. You can also capture and report errors using this API.

Notify the Agent of Events

Events are reported to the JavaScript Agent (ADRUM) by calling the `ADRUM.report` method and passing in an event tracker object.

API	Description
`ADRUM.report(tracker: eventTracker);`	Notifies the agent of an event.

Report Virtual Pages

SPA1 Monitoring

For SPA1 monitoring, use the event tracker VPageView to manually report virtual pages.

SPA2 Monitoring

You are required to enable SPA2 monitoring to use the API below to manually report virtual pages for SPAs. These APIs will also work in non-SPAs if you enable SPA2 monitoring.

To report virtual pages, you mark the beginning and end of virtual pages with the methods below. Both methods are called from the `ADRUM` object. See also Set Custom Virtual Page Names.

API	Parameter (s)	Default Value	Descriptions
`markVirtualPageBegin(VPName: string, manuallyMarkVPEnd?: boolean)`	`VPName`	N/A	Used to set the label for the virtual page. This label will be displayed in the Controller UI. The virtual page name must consist of a string of 760 or fewer alphanumeric characters. If the string length exceeds 760 characters, the page name will not be set.
	`manuallyMarkVPEnd`	`true`	A flag that indicates whether you or the JavaScript Agent mark the end of the virtual page. When set to true, you need to call `markVirtualPageEnd` to report the virtual page. When set to `false`, the JavaScript Agent will automatically mark the end of the virtual page.
`markVirtualPageEnd()`	N/A	N/A	Calling this method marks the end of the virtual page and triggers the JavaScript Agent to send a beacon with the virtual page information.

How the API Works

The steps below describe the process of manually reporting virtual pages with the API:

1. Start monitoring a virtual page by manually marking the beginning of the virtual page with `ADRUM.markVirtualPageBegin(VPName, manuallyMarkVPEnd)`.
2. A beacon with the set virtual page name is sent to the EUM Server. If `manuallyMarkVPEnd` is set to `true`, the JavaScript Agent will wait for you to call `ADRUM.markVirtualPageEnd` to report the virtual page. If `manuallyMarkVPEnd` is set to `false`, the JavaScript Agent will automatically mark the end of the virtual page.
3. You either call `ADRUM.markVirtualPageEnd()` to mark the end of the virtual page or the JavaScript Agent automatically marks the end of the virtual page.
4. The JavaScript Agent reports the virtual page metrics to the EUM Server.

Example of Reporting Virtual Pages

The Angular example below shows both ways to mark the beginning of a virtual page. The function `manualMarkVPEnd` calls `ADRUM.markVirtualPageBegin` that uses the default requiring you to manually mark the end of the virtual page. The function `allowJSAgentMarkVPEnd` passes the value `false` as the second parameter, so that the JavaScript Agent will automatically mark the end of the virtual page for you.

```
angular.module('myApp.controllers', [])
    .controller('VPCtrl', ['$scope', '$http', function ($scope, $http) {
            $scope.manualMarkVPEnd = function () {
                console.log("Mark the beginning of the virtual page and wait for markVirtualPageEnd() to be
called.");
                ADRUM.markVirtualPageBegin("VPExample-ManuallyMarkEnd");
            }
            $scope.allowJSAgentMarkVPEnd = function () {
                console.log("Mark the beginning of the virtual page and allow the JS Agent to mark the virtual
page end.");
                ADRUM.markVirtualPageBegin("virtualPageExample-JSAgentMarksEnd", false);
            }
            $scope.endVirtualPage = function () {
                console.log("Mark the end of the virtual page.");
                ADRUM.markVirtualPageEnd();
            }
            ...
        }
    ]
);
```

Report Events

Events are reported to the agent using event trackers. There are three different kinds of event trackers:

Event Tracker	Enabled for SPA2 Monitoring?	Description
VPageView	No	Used to track the stages of a virtual page view.
Ajax	Yes	Used to track Ajax requests.
Error	Yes	Used to track errors.

Common Properties

There are also two properties that are common to all tracker types:

- Gets or sets a URL

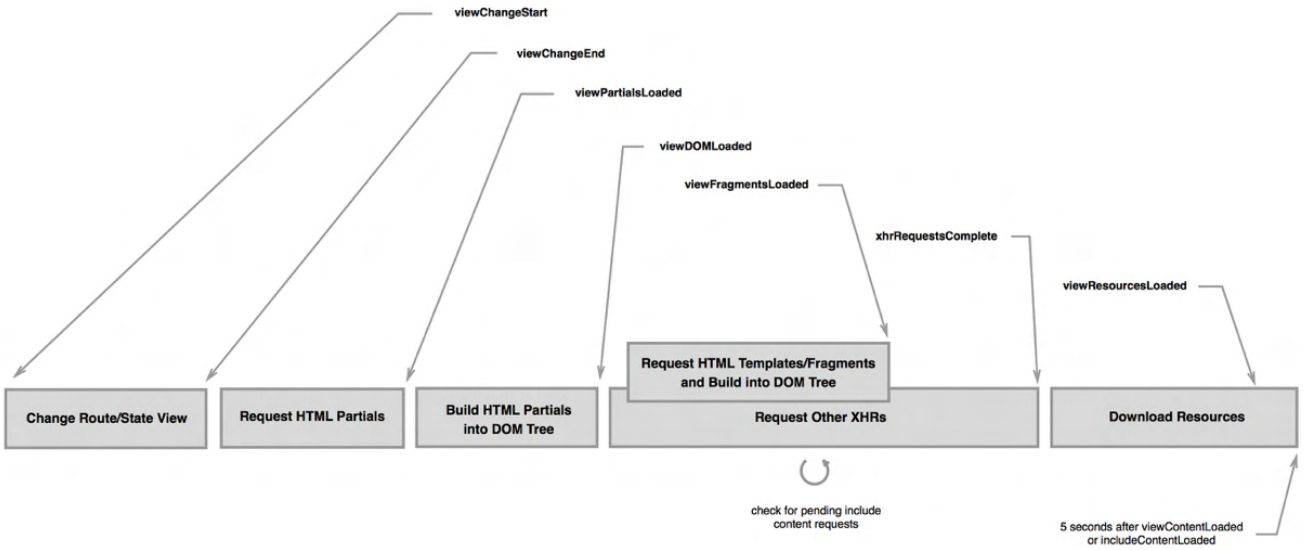
API	Description
`url(url?: string)`	Gets or sets a URL.

- Gets or sets the parent event identifier

API	Description
`parent(parent?: object)`	Gets or sets the parent event identifier.

VPageView

The following is the page view load flow in SPA1 monitoring. You'll use the SPA1 monitoring API below to set timing marks to match the below workflow as closely as possible in your own single page app framework. For SPA2 monitoring, see Report Virtual Pages: SPA2 Monitoring to learn about the SPA2 APIs for manually reporting virtual pages.



Based on the marks you set, AppDynamics derives the following key timing metrics. Marks should be called in the order in which they occur in the flow. The following table describes which marks used to calculate each metric.

Full Metric Name	Short Metric Name	How Calculated
End User Response Time (not used for waterfall UI)	PLT	`virtualPageStart` to `virtualPageEnd`
HTML Download Time	DDT	`viewChangeStart` to `viewChangeEnd`
HTML Download and DOM Building Time	DRT	`viewChangeStart` to `viewDOMLoaded`
DOM Building Time	DPT	`viewChangeEnd` to `viewDOMLoaded`
DOM Ready Time (used instead of PLT for waterfall UI)	DOM	`viewChangeStart` to `viewDOMLoaded`

Instantiate using `ADRUM.events.VPageView()`.

API	Description
`start()`	Indicates when a virtual page starts. It automatically calls: • `startCorrelatingXhrs()` • `markVirtualPageStart()`
`end()`	Indicates when a virtual page ends. It automatically calls: • `stopCorrelatingXhrs()` • `markVirtualPageEnd()`
`startCorrelatingXhrs()`	Correlates the Ajax requests sent after this call with the virtual page view event. The last tracker calling this method wins. This method is called automatically in the VPageView constructor. When a VPageView is created, the AJAX requests made after that call are automatically correlated to that VPageView. Use this separate call only when you want to set up manual correlation.
`stopCorrelatingXhrs()`	Stops correlating Ajax requests to the virtual page view event. Use this separate call only when you wish to set up manual correlation.
Setters	The default value for these is the time when the API is called.

`markViewChangeStart()`	Sets the view change start time.
`markViewChangeEnd()`	Sets the view change end time.
`markViewDOMLoaded()`	Sets the view DOM loaded time.
`markXhrRequestsCompleted()`	Sets the XHR requests completed time.
`markViewResourcesLoaded()`	Sets the view resources loaded time. This includes images, CSS files, and scripts.
`markVirtualPageStart()`	Sets the virtual page start time.
`markVirtualPageEnd()`	Sets the virtual page end time.
Getters	
`getViewChangeStart()`	Gets the view change start time.
`getViewChangeEnd()`	Gets the view change end time.
`getViewDOMLoaded()`	Gets the view DOM loaded time.
`getXhrRequestsCompleted()`	Gets the XHR requests completed time.
`getViewResourcesLoaded()`	Gets the view resources loaded time.
`getVirtualPageStart()`	Gets the virtual page start time.
`getVirtualPageEnd()`	Gets the virtual page end time.

Ajax

Instantiate using `ADRUM.events.Ajax()`.

API	Description
Property Setters/Getters	Call this without a parameter to get the value and with a parameter to set the value.
`method(method?: string)`	Gets or sets the method ("GET" or "POST") of the Ajax.
Timing Setters	The default value for these is the time when the API is called.
`markSendTime(sendTime?: number)`	Sets the time the request is sent.
`markFirstByteTime(firstByteTime?: number)`	Sets First Byte Time.
`markRespAvailTime(respAvailTime?: number)`	Sets Response Available Time.
`markRespProcTime(RespProcTime?: number)`	Sets the time the response is completely processed.
Timing Getters	
`getSendTime()`	Gets the time the request was sent.
`getFirstByteTime()`	Gets First Byte Time.
`getRespAvailTime()`	Gets Response Available Time
`getRespProcTime()`	Gets the time the response was completely processed.

Errors

Instantiate using `ADRUM.events.Error()`.

API	Description
Property Setters/Getters	Call these without a parameter to get the value and with a parameter to set the value.
`msg(msg?: string)`	Gets or sets the error message.
`line(line?: number)`	Gets or sets the line number of source code where the error happened.

Correlate Ajax Requests

Ajax requests can be correlated to virtual page views automatically or manually. When you create a vPageView tracker, `startCorrelatingXhrs()` is called automatically in the constructor, correlating any subsequent Ajax calls with that VPageView event. To set up manual correlation, call `stopCorrelatingXhrs()` to stop the automatic process and then call `startCorrelatingXhrs()` where you wish correlation to re-commence.

Sample Code

Report a custom Error event by passing properties via setters

```
var errorT = new ADRUM.events.Error();
errorT.msg('I am a custom error at line 100');
errorT.line(100);
ADRUM.report(errorT);
```

Report a custom Error event by passing properties via the constructor

```
var errorT = new ADRUM.events.Error({
msg: 'I am a custom error at line 100',
line: 100
});
ADRUM.report(errorT);
```

Report a custom Ajax event passing properties via setters

```
var ajaxT = new ADRUM.events.Ajax();

// set url
ajaxT.url('your xhr Url');

// mark timings
ajaxT.markSendTime(100);
ajaxT.markFirstByteTime(200);
ajaxT.markRespAvailTime(300);
ajaxT.markRespProcTime(400);
ADRUM.report(ajaxT);
```

Set up backbone SPA monitoring

```
var AppRouter = Backbone.Router.extend({
    routes: {
        "wines/:id": "wineDetails"
    },
    wineDetails: function (id) {
        var vpView = new ADRUM.events.VPageView();
        vpView.markVirtualPageStart();
        // vpView.markViewChangeStart();
        var wine = new Wine({id: id});
        wine.fetch({success: function(){
            vpView.markXhrRequestsCompleted();
            $("#content").html(new WineView({model: wine}).el);
            vpView.markViewDOMLoaded();
            vpView.markVirtualPageEnd();
            ADRUM.report(vpView);
        }});
        this.headerView.selectMenuItem();
    }
});
```

Correlate Ajax requests wih VPageView Events

```
var vPageView = new ADRUM.events.VPageView({
    url: 'http://localhost/#virtualpage1',
});

vPageView.start();

// SPA view routing and HTML partials fetching
vPageView.markViewChangeStart()
// AJAX requests for the HTML partials are automatically correlated with the VPageView
...
vPageView.markViewChangeEnd();

// HTML partials inserted into Browser DOM tree
...
vPageView.markViewDOMLoaded();

// SPA HTML AJAX data fetching
// Data AJAX requests are automatically correlated with the VPageView
...

vPageView.markXhrRequestsCompleted();

// call this when ending a new virtual page
vPageView.end();

ADRUM.report(vPageView);
```

You can exclude certain Ajax calls from being monitored by configuring ADRUM itself Before you invoke the `adrum.js` script at the top of your page, add lines similar to the following:

Exclude Ajax from VPageView using ADRUM configuration

```
window['adrum-config'] = {
  "spa": {
    "angular": {
      "vp": {
        "xhr": {
          "exclude": {
            "urls": [{
              "pattern": 'heartBeatAjax'
            }]
          }
        }
      }
    }
  }
}
```

Or you can exclude certain Ajax calls using the `vPageView.stopCorrelatingXhrs()` call, and then turn correlation back on with `vPageView.startCorrelatingXhrs()`, as in the following:

Exclude Ajax from VPageView event manually

```
var vPageView = new ADRUM.events.VPageView();
vPageView.stopCorrelatingXhrs();

var xhr = new XMLHttpRequest();
xhr.open('GET', '/heartBeatAjax');
xhr.send();

vPageView.startCorrelatingXhrs();
```

Disable Monitoring of Fetch API Calls

By default, the JavaScript Agent reports Ajax requests made with XMLHttpRequest object (XHR) and the Fetch API.

You should only consider disabling monitoring support for the Fetch API for these use cases:

- You just started using the JavaScript Agent 4.5.6 and start to see JavaScript errors caused by Ajax requests.
- Your browser app uses one of these libraries:
  - Bluebird
  - shim.js
  - Zone.js

To disable monitoring for the Fetch API, you set `config.fetch` to `false` as shown below.

```
<script type='text/javascript' charset='UTF-8'>
    (function(config){
       config.fetch = false;
    })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
```

To disable monitoring for the Fetch API for single-page applications:

```
<script type='text/javascript' charset='UTF-8'>
    (function(config){
       config.fetch = false;
       config.spa = {
            "spa2": true
        };
    })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
```

Inject the JavaScript Agent

Related pages:

- Overview of Injection Types
- Undo Injection

This page describes how JavaScript Agent injection works, including the different injection types.

To instrument your application for Browser RUM, you must configure your JavaScript Agent and insert it into the page that is returned to the end user as part of the normal process it follows. The act of inserting the agent is called *injection*. There are several ways to inject the JavaScript Agent for Browser RUM into your web pages. You also have several JavaScript hosting options to choose from that offer differing degrees of control, simplicity, and reliability.

To configure the JavaScript Agent, see Configure the JavaScript Agent.

How the JavaScript Agent Works

The JavaScript Agent consists of two files: `adrum.js` and `adrum-ext.js.`

1. The file `adrum.js` is injected into each instrumented page, as close to the top as possible, as the page is served. The file loads synchronously at around 90 KB (30 KB with compression).
2. This first JavaScript file starts a timer and does some quick configuration and setup.
3. At the `onload` event, `adrum-ext.js` is fetched *asynchronously* to prevent blocking the page load. This is the code that does most of the heavy lifting. Once it has been fetched, it is cached for 24 hours on the browser.
4. When cross-domain session correlation is enabled, the first time a user visits a domain, the browser additionally loads the file `adrum-xd.html` to generate or load a piece of common information that enables cross-domain sessions. Future visits will not load `adrum-xd.html` again.
5. When the page has completed loading, the collected data is bundled into a beacon and sent to the EUM Server by `adrum-ext.js`.
6. The data is processed by the EUM Server and then made available for pickup by the Controller.

Not all types of injection are supported on all frameworks and platforms. See the Script Injection columns in the Supported Platform Matrix for Browser Monitoring matrices to find out what types are supported for your application.

Injection Methods

There are three methods for injecting the JavaScript Agent. See the following for each injection method:

- Manual Injection of the JavaScript Agent
- Automatic Injection of the JavaScript Agent
- Assisted Injection

JavaScript Agent Hosting Options

The `adrum.js` file is inserted into the page when it is downloaded from your web application. The `adrum-ext.js` (and `adrum-xd.html` when cross-domain session correlation is enabled) file is loaded asynchronously by the `adrum.js` file. By default, `adrum-ext.js` and `adrum-xd.html` are fetched by the highly available Amazon CloudFront CDN infrastructure.

There are three hosting options for the JavaScript Agent:

- AppDynamics CDN - All the JavaScript Agent files are from the host `cdn.appdynamics.com`. This is the simplest hosting option and ideal for testing.
- Self-Hosting - You host all of the JavaScript Agent files. This option gives you the most control and is recommended for production.
- Shared Hosting - You host the main file `adrum.js`, but the other files that are loaded asynchronously are from the AppDynamics CDN. This choice offers control of the most important file of the JavaScript Agent and is ideal for small to medium-sized businesses that don't have the resources or prefer not to host the entire JavaScript Agent.

See Manual Injection of the JavaScript Agent for step-by-step instructions.

Cross-domain session correlation

By default, Browser RUM sessions are restricted to one domain. Thus, when an end user navigates to a page in another domain or even subdomain, the session for that user is ended. You can, however, configure Browser RUM to enable sessions to continue across subdomains. Thus, when an end user navigates from `http://example1.com/` to `http://example2.com/`, the session will continue as long as the configured session inactivity time has not expired.

How Sessions Are Correlated Across Multiple Domains

For sessions to be correlated across domains, each page is required to use HTTPS to load the file `adrum-xd.html` from the same URL. If your pages are fetching the files `adrum-ext.js` and `adrum-xd.html` files from the AppDynamics CDN (this includes the shared hosting use case), sessions will automatically be correlated across domains because the pages will be fetching the file `adrum-xd.html` from the AppDynamics CDN.

For those *self-hosting* the JavaScript Agent files, you will need to configure the JavaScript Agent to use HTTPS to load the `adrum-ext.js` file from the same URL. The `adrum-xd.html` file is served from the location of the `adrum-ext.js` file. See the sections below for configuration instructions for the two use cases.

Configuration for Session Correlation Across Multiple Domains

AppDynamics CDN / Shared Hosting

When using the AppDynamics CDN or shared hosting, your JavaScript Agent configurations must enable cross-domain session correlation and use HTTPS to call the `adrum-ext.js` file. Thus, in your JavaScript Agent configuration make sure you have the following lines:

```
...
config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';;
config.xd = {enable : true};
...
```

Self-Hosting

When using self-hosting, your JavaScript Agent configurations must enable cross-domain session correlation and use HTTPS to call the `adrum-ext.js` file from the same URL. Thus, in your JavaScript Agent configuration make sure you have the following lines and that the value for `adrumExtUrlHttps` is the same for all pages requiring cross-domain session correlation.

```
...
// HTTPS is needed to fetch adrum-xd.html.
config.adrumExtUrlHttps = 'https://<your-adrum.ext-host>';
// This config enables cross-domain session correlation.
 config.xd = {enable : true};
...
```

Set the Geo Server URL

By default, end-users' locations are resolved using public geographic databases. You can host an alternate geo server for your countries, regions, and cities instead of using the default geo server hosted by AppDynamics. See Install and Host a Custom Geo Server for Browser RUM.

Custom Configuration

You can add configuration for `adrum.js` to customize and extend the functionality of the JavaScript Agent. See Configure the JavaScript Agent for instructions and examples on adding custom configuration.

JavaScript Agent Limitations

The JavaScript Agent cannot monitor and report the activity of service workers or web workers. For example, if you use a service worker to make an XHR request, the JavaScript Agent will not be able to report it.

Overview of Injection Types

You need to inject the JavaScript Agent into your web pages to use Browser RUM. There are several injection types that you can use depending on your use case. This page describes the different injection types, how they work, and when to use each type.

Choosing an Injection Method

If you are uncertain which procedure to use to inject the agent into your web pages, follow these guidelines in the given order:

- If you want to use Browser RUM and do not have any app agents on the server side, use manual injection. See Manual Injection of the JavaScript Agent.
- If automatic injection is available and works for your framework, use automatic injection. Automatic injection requires the least amount of effort because you do not have to manually instrument every page. Check the matrices at Browser RUM Supported Environments to see if automatic injection has been tested in your environment. Also, see Automatic Injection of the JavaScript Agent.
- If you cannot use automatic injection, and you can edit the source code of *your web pages*, use manual injection. See Manual Injection of the JavaScript Agent.
- If you cannot use automatic injection, and you can edit the source code of *your web application*, use one of the kinds of assisted injection. See Using Injection Rules (Java Only) or Assisted Injection-Using Attribute Injection.

Manual Injection

Manual injection is supported on all platforms and frameworks. To set up a manually injected page:

- Choose a JavaScript Agent hosting option. See JavaScript Agent Hosting Options to learn what hosting option best suits your use case.
- Manually configure each page to find the location of the JavaScript Agent, so that it can be executed as the page is constructed by the browser.

For detailed instructions on using manual injection in your application, see Manual Injection of the JavaScript Agent.

Automatic Injection

If you are using a Java or .NET app agent on the server-side, and your application is running in an environment that supports any of the following:

- Apache Jasper JSP compiler (for Java) or
- ASP.NET or ASPX (for .NET) or
- ASP.NET Core (for .NET; Windows support only)

You *may* be able to use automatic injection, where the server-side app agent completely manages injecting the code at runtime. For instructions on using automatic injection in your application, see Automatic Injection of the JavaScript Agent.

Assisted Injection

Assisted injection is available in two variants. In both cases, some of the work is done manually by you and some of the work is done by the server-side Java or .NET app agent.

> Assisted injection is currently not supported for .NET Core.

Assisted Injection Using Injection Rules (Java Only)

In this type of assisted injection, you configure rules that define which app server Java classes and methods write to the output stream of your application and the writer object that is used to do that writing. AppDynamics intercepts the method and injects the JavaScript Agent into the output stream. You also specify which server-side business transactions you wish to have instrumented in this way.

For detailed information on using this form of assisted injection, see Assisted Injection.

Assisted Injection Using Attribute Injection

In this type of assisted injection, you copy small code snippets appropriate to your framework into your page templates or other code that creates your pages. This snippet contains the two variables `JS_HEADER` and `JS_FOOTER`, which the app agent replaces with the appropriate information in the response object at runtime.

For detailed information on using this form of assisted injection, see Using Attribute Injection.

Container-Based Injection

If you are using Nginx or Apache as a web container or as a reverse proxy in front of your web container, you can use directives to inject the agent into the response object. See Injection Using Nginx or Injection Using Apache.

Manual Injection of the JavaScript Agent

This page describes how to instrument a browser application by manually injecting the JavaScript Agent. To configure the JavaScript Agent before injection, see Configure the JavaScript Agent.

Manually Inject the JavaScript Agent

The Controller UI allows you to configure the JavaScript Agent, generate an HTML snippet, and add that snippet to the header of the web pages.

1. In the Controller UI, go to a browser application.
2. In the left navigation menu, select **Configuration** > **Configure JavaScript Agent**.
3. Configure the JavaScript Agent.
4. Save and copy the HTML snippet.
5. Add the HTML snippet to the header of the web pages.

JavaScript Agent Placement

The recommended location for the JavaScript Agent is at the top of the `<head>` section. The `adrum.js` file captures the time as the page begins to load and measures that amount of time against the time that other timings are calculated for all browsers. Many modern browsers, however, support the Navigation Timing API (see this list), and for these browsers, timings can be acquired via the API. In this case, it is possible to place the JavaScript Agent somewhere else on the page, but useful timing information is only available for those `NavTime`-capable browsers.

Synchronous Versus Asynchronous Script Load

AppDynamics recommends that the `adrum.js` file loads synchronously because once downloaded, the JavaScript Agent begins monitoring for page data such as Ajax events, resources, and errors. If `adrum.js` loads asynchronously for the first time (through the `async` attribute), the JavaScript Agent might not report all page data.

Use Previous JavaScript Agent Versions

Previous versions of the agent can be found at the following location, where `VERSION` is the version number you want to access (for example, 4.5.0.).

```
http://cdn.appdynamics.com/adrum/adrum-VERSION.js
```

- If you are using a SaaS EUM Cloud and want a hosted version of `adrum.js`, AppDynamics recommends you use the `adrum-latest.js` version. However, you can use any version of the JavaScript Agent as it is compatible with any SaaS EUM Cloud version currently being deployed.
- If you are using an on-premises EUM Server and want to use a hosted version of `adrum.js`, you need to match the `adrum.js` version to your EUM Server version.
- For Controller versions, a JavaScript Agent version is compatible with Controller versions with the same or older versions. For example, JavaScript Agent 20.6.0 is compatible with Controller <= 20.6.0.

Verify Manual Injection

Once the agent is injected, it can take the AppDynamics Controller a few minutes to discover and recognize the page, which must happen before data will begin to appear. If, however, you have configured your page using manual injection and are not seeing Browser RUM metrics after running load for a while, check the web page to confirm that the JavaScript Agent for Browser RUM is present in the page. If not, try injecting the script again.

If, after two attempts, you still do not see Browser RUM metrics, try one of the other injection schemes if they are available for your platform. See Troubleshoot Browser RUM.

Automatic Injection of the JavaScript Agent

This page describes how to instrument a browser application by automatically injecting the JavaScript Agent. Automatic injection uses AppDynamics server-side agents to automatically add the `adrum` header and footer to each of your web pages.

Automatic Injection Support for Server-side Agents

The Java Agent and .NET Agent support automatic injection. See .NET Supported Environments for version specifics.

Automatic injection is available only for server-side applications built on these environments:

- Jasper-supported JSP (Java)
- ASP.NET
- ASP.NET Core
- ASPX (.NET) Framework

- Although the Apache Agent does *not* support automatic injection, you can configure Apache or Nginx to inject the JavaScript Agent.
- If the server-side application does not return well-formed HTML, the JavaScript Agent may not be able to instrument the page. For example, the JavaScript Agent may not be able to instrument HTML pages that are missing elements or have unclosed tags.

JavaScript Agent and Controller Versions

The table below lists the Javascript Agent version deployed for auto-injection in each Controller version.

The JavaScript Agent version does not match the Controller version because the Controller and agents have different release cycles.

Controller Version	JavaScript Agent Version Supported for Auto-Injection
21.4.0	20.12.0

Access the User Experience App Integration Panel

1. From the **Applications** page, open the business application that you want to automatically inject the JavaScript Agent into your browser application.
2. From the left navigation bar, select **Configuration**.
3. Click **User Experience App Integration**.

Enable Business Transaction Correlation

From the **Business Transaction Correlation**, check the **Enable Business Transaction Correlation** check box to correlate Pages and Ajax requests with server-side business transactions.

Specify Business Transactions to Include Correlation Headers

You can also specify which business transactions will include or exclude correlation headers. If you do not add request match rules or request exclude rules, correlation headers will be added to all requests.

To add a request rule:

1. Click the **plus** icon. The **Create HTTP Request Match Rule** will display.
2. Check the **Method** checkbox and select an HTTP method that you want to match.
3. Check the **URI** checkbox and enter your criteria.
4. Click **Save**.

Enable Automatic Injection

1. Select the JavaScript Agent Injection tab.
2. From the **Inject the JavaScript Agent configured for this Browser App** dropdown, select the browser application you want to use automatic injection.
3. Check the **Enable Automatic Injection of JavaScript** check box to enable automatic injection.
4. If you enabled automatic injection, click **OK** in the **Confirm Enabling Automatic Injection** dialog.
5. Click **Save** in the outer configuration pane.

Configure Automatic Injection

After you have enabled automatic injection:

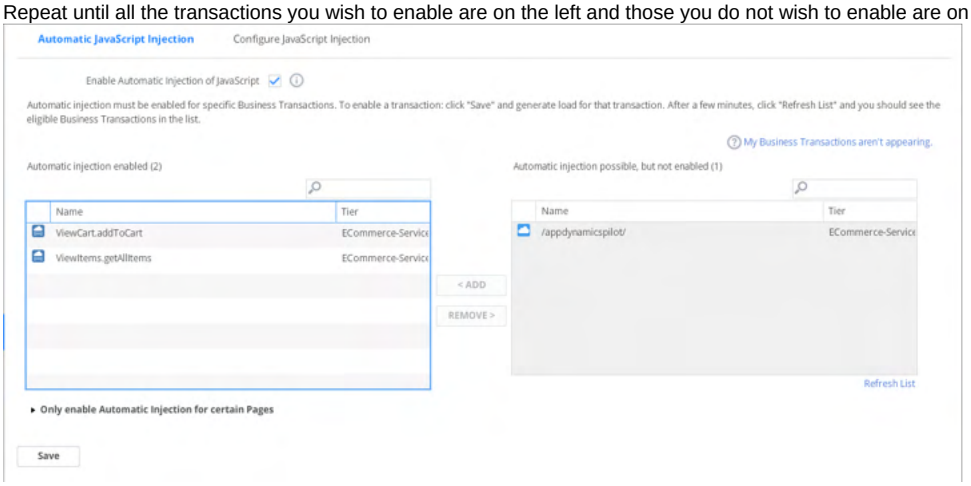
- You must specify the server-side business transactions for which automatic JavaScript injection is enabled.
- You can limit which pages to inject by creating custom match and exclude rules for automatic injection. If you do not configure these rules, by default AppDynamics injects all pages visited by the enabled business transactions.

Use these rules to fine-tune which business transactions to include or exclude from injection based on match criteria. For example, you can exclude all business transactions that have a certain string in their URLs or set a certain cookie. The configurations for include rules and exclude rules are similar. It depends on your situation whether it is more convenient to restrict transactions based on inclusion or exclusion.

Specify Business Transactions for Automatic Injection

You must select at least one business transaction for automatic injection.

1. From the list on the right shown in the screenshot, select one or more business transactions. (If you don't see any business transactions, click **Refresh List**.) Not all your business transactions may appear here—the list includes only those transactions that AppDynamics can parse for automatic injection, those based on Jasper-compiled JSPs or ASP.NET, ASP.NET Core, or ASPX.NET pages.
2. Click **< Add** to move the business transaction to the list on the left.
3. Repeat until all the transactions you wish to enable are on the left and those you do not wish to enable are on the right.



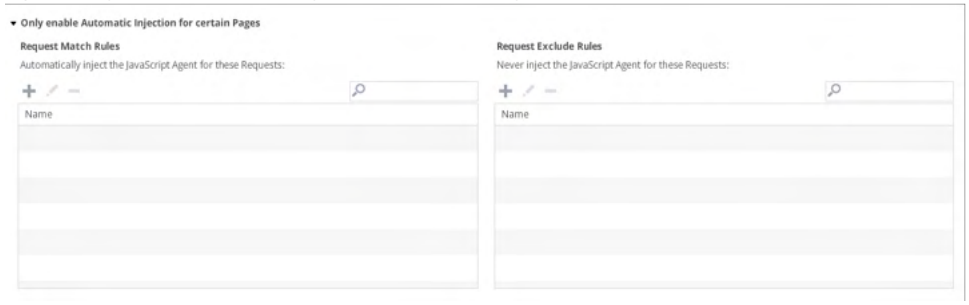
4. Click **Save**.

Create Match Rules for Automatic Injection

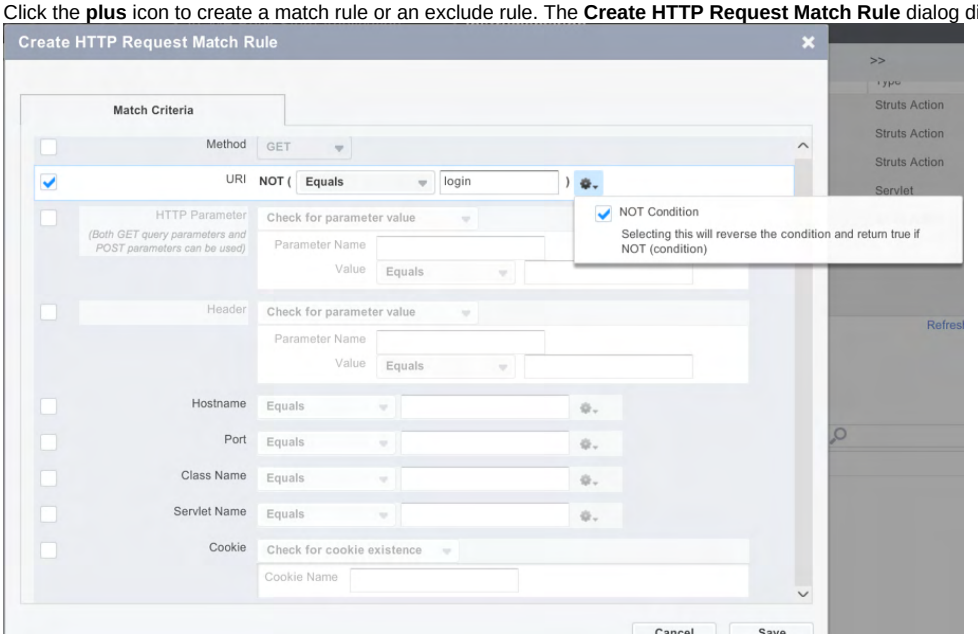
You may not wish to instrument every page in your application. For example, if your application has a very large number of pages, you might want to instrument only the key ones for your business, to avoid hitting licensing limits. Or, when you are in the setup and test phase, you might only want to instrument a few pages to keep your initial sample manageable.

Use match rules to include or exclude certain pages:

1. Expand **Only enable Automatic Injection for certain Pages** if it is closed.



2. Click the **plus** icon to create a match rule or an exclude rule. The **Create HTTP Request Match Rule** dialog displays.



3. Select one or more criteria to match. If you select multiple criteria, **all** must match for the rule to come into effect. Use the **gear** icon to set a NOT condition. See Using Regular Expressions for general information about match rules.
4. Click **Save**.
5. Click **Save** in the outer configuration pane.

You can later edit or remove a match rule by selecting it in the list and clicking the edit or delete icon.

Injection Using Nginx

Related pages:

- Manual Injection of the JavaScript Agent
- Automatic Injection of the JavaScript Agent
- Using Attribute Injection

If you are using Nginx as your web container, or use Nginx as a reverse proxy, you can use a container substitution module to automatically inject the JavaScript Agent into your pages. The module intercepts the response object as it is being returned and makes a string substitution.

Download the Agent

You must first download the JavaScript Agent from the **Configuration** screen.

1. Open the browser application in which you are interested.
2. From the left navigation menu, select **Configuration**.
3. Click the **Configure and download JavaScript Agent**.
4. For the JavaScript hosting option, select **I will host all the JavaScript agent files.**
5. Click **Download** to download the JavaScript Agent.
6. Place the file somewhere accessible to the Nginx instance. The name of the saved file should be `adrum.js`.

Configure Nginx with `ngx_http_sub_module`

The `ngx_http_sub_module` module is a filter that modifies a response by replacing one specified string by another. You can use this feature to have the server automatically inject the header portion of the JavaScript Agent into a served page. For more information on the process, see the Nginx documentation, Module ngx_http_sub_module.

For example, modify the location context to replace the <head> tag with the <head> tag and the JavaScript Agent scripts.

Sample Nginx Configuration

```
location / {
    sub_filter      <head>
        '<head><script>window["adrum-app-key"]="<EUM_APP_KEY>";window["adrum-start-time"]=new Date().getTime();<
/script><script type="text/javascript" src="//cdn.appdynamics.com/adrum/adrum-latest.js"></script>';
    sub_filter_once on;
}
```

In the sample above, note that `/adrum-latest.js` is the path to a copy of the `adrum` file that is accessible to the server. Also, note the timer initialization `<script>window['adrum-start-time'] = new Date().getTime();</script>`. Keep these as close as possible to the top of the document, preferably right after the <head> tag, ensures the best possible timings.

If you use <meta> tags, you should place them right after your <head> tag, and then place the JavaScript Agent directly after the last <meta> tag. This can avoid issues with some versions of IE.

You may need to escape some characters, depending on your platform. For example, on Mac OS:

```
location / {
    sub_filter      <head>
        '<head><script>window[\'adrum-start-time\'] = new Date().getTime();</script><script src="/adrum.js"><
/script>';
    sub_filter_once on;
}
```

This Nginx module is often used for adding the Google Analytics script. Be careful not to overwrite any existing GA script when you do this.

Possible variations on the script string can be found in Configure the JavaScript Agent.

Configure Ngnix without `ngx_http_sub_module`

You can configure Ngnix without the `ngx_http_sub_module` module if you prefer. Insert the required script into the `conf.d/default.conf` location.

Sample Nginx Configuration

```
location / {
    sub_filter                 <head>
                '<head><script>window["adrum-app-key"]="<EUM_APP_KEY>";window["adrum-start-time"]=new Date().
getTime();</script><script type="text/javascript" src="//cdn.appdynamics.com/adrum/adrum-latest.js"></script>';
    sub_filter_once on;
}
```

Injection Using Apache

Related pages:

- Manual Injection of the JavaScript Agent
- Automatic Injection of the JavaScript Agent
- Using Attribute Injection
- Using Injection Rules

This page describes how to instrument a browser application using Apache to automatically inject the JavaScript Agent. If you are using Apache as your web container, or you are currently using, or willing to use, Apache as a reverse proxy, you can use a container substitution module to automatically inject the JavaScript Agent into your pages. The module intercepts the response object as it is being returned and makes a string substitution.

This method uses the two Apache modules `mod_substitute` and `mod_filter`.

Download the Agent

You must first download the JavaScript Agent from the Browser Monitoring configuration pane.

1. Open the browser application in which you are interested.
2. From the left navigation menu, select **Configuration**.
3. Click the **Configure and download JavaScript Agent**.
4. For the JavaScript hosting option, select **I will host all the JavaScript agent files.**
5. Click **Download** to download the JavaScript Agent.
6. Place the file somewhere accessible to the Apache instance. The name of the saved file should be `adrum.js`.

Configure Apache

The basic configuration procedure includes:

1. Make Sure the Modules are Loaded
2. Create an Adrum Configuration File
3. Add the Location of the Adrum Configuration File to httpd.conf
4. Restart the Web Server

Make Sure the Modules are Loaded

Check your global Apache `httpd.conf` file and make sure that the following two `LoadModule` commands are in the file:

```
LoadModule substitute_module modules/mod_substitute.so
LoadModule filter_module modules/mod_filter.so
```

Create an Adrum Configuration File

Create a file named `adrum.conf` with contents similar to the example below, based on your Apache version. (See this Stack Overflow post for details.) In this case, the substitution rule covers the location of the entire site (`Location /`) but you can also recursively select a specific directory and its subdirectories by using `/somedirectory`.

Sample adrum.conf Apache 2.2

Replace the sample code below with your own JavaScript Agent script.

```
<Location "/">
    SetOutputFilter INFLATE;SUBSTITUTE;DEFLATE
    AddOutputFilterByType SUBSTITUTE text/html
    Substitute "s#<head>#<head><script>window['adrum-start-time'] = new Date().getTime();</script><script>
(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] || (window['adrum-config'] = {}));<
/script><script src='./adrum.js'></script>#inq"
</Location>
```

If you use `<meta>` tags, you should place them right after your `<head>` tag, and then place the JavaScript Agent directly after the last `<meta>` tag and before other `<script>` tags. This can avoid issues with some versions of IE and improve the accuracy of the resource timing.

Sample adrum.conf Apache 2.4

Replace the sample code below with your own JavaScript Agent script.

```
<Location "/">
    AddOutputFilterByType SUBSTITUTE text/html
    Substitute "s#<head>#<head><script>window['adrum-start-time'] = new Date().getTime();</script><script>
(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] || (window['adrum-config'] = {}));<
/script><script src='./adrum.js'></script>#inq"
</Location>
```

Where `./adrum.js` is the path to a copy of the adrum file that is accessible to the server. The flags after the `#` are:

- `i` - matching is case-insensitive
- `n` - pattern is treated as a fixed string (removing the n means the pattern is treated as a regular expression)
- `q` - module does not flatten the buckets after each substitution - this can speed performance.

For more information, see the Apache module docs here.

If your <head> tag has an attribute like `<head lang="en">`, you can use a regex in the substitution string and omit the n flag. Replace the sample code below with your own JavaScript Agent script.

```
Substitute "s#(<head[^>]*>)#$1<script>window['adrum-start-time'] = new Date().getTime();</script><script>
(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] || (window['adrum-config'] = {}));<
/script><script src='./adrum.js'></script>#iq"
```

Note the timer initialization: `<script>window['adrum-start-time'] = new Date().getTime();</script>`. Injecting these scripts as close as possible to the top of the document, preferably right after the <head> tag, ensures the best possible timings.

Also, if you use <meta> tags, you should place them right after your <head> tag, and then place the JavaScript Agent directly after the last <meta> tag and before other `<script>` tags. This can avoid issues with some versions of IE and again improve the accuracy of the resource timing.

(Optional) Adjust for gzipped resources

If your page is compressed, the substitution won't work unless the content is INFLATEd, the substitution is made, and then the content is DEFLATEd. There are multiple ways to do this. For example, in the `FilterProvider` line:

```
FilterProvider AdrumFilter INFLATE;SUBSTITUTE;DEFLATE resp=Content-Type $text/html
```

See this Stack Overflow post for more information. If you are using Apache as a proxy, you can also instruct it not to accept gzip-encoded content.

Add the Location of the Adrum Configuration File to httpd.conf

Add the following line to your global Apache `httpd.conf` file:

```
Include [absolutePathTo]/adrum.conf
```

Alternatively, you can add the directives to the `httpd.conf` file directly instead of creating a separate adrum file.

Restart the Web Server

To pick up the new configuration, restart:

```
sudo apchectl -k restart
```

If you get a warning "Useless use of AllowOverride in line 2 of [absolutePathTo]/adrum.conf", it can be ignored. It simply means `AllowOverride` is redundant. You can remove it if you wish.

Possible variations on the script string can be found in Configure the JavaScript Agent.

Other Alternatives

If you are setting up your automatic injection using an Apache instance that is configured as a reverse proxy, you *must* use the `Location` directive method described above, with the `ProxyPass` and `ProxyPassReverse` directives also in the `Location` directive. If you are using an Apache instance that is your primary web container you have two additional options for describing the actual substitution step:

- Using the Directory Directive
- Using .htaccess

Use the Directory Directive

You can use the `Directory` directive instead of the `Location` directive.

Use .htaccess

Add lines similar to this to an `.htaccess` file in the base document directory for your site, replacing your filter name for `<MyFilter>`. If you don't have an `.htaccess` file, create one:

Apache 2.2

Replace the sample code below with your own JavaScript Agent script.

```
Substitute "s#<head>#<head><script>window['adrum-start-time'] = new Date().getTime();</script><script>(function
(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] || (window['adrum-config'] = {}));<
/script><script src='./adrum.js'></script>#inq"
```

```
AllowOverride Options
FilterDeclare <MyFilter>
FilterProvider <MyFilter> SUBSTITUTE resp=Content-Type $text/html
FilterChain <MyFilter>
Substitute "s#<head>#<head><script>window['adrum-start-time'] = new Date().getTime();</script><script>(function
(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] || (window['adrum-config'] = {}));<
/script><script src='./adrum.js'></script>#inq"
```

Apache 2.4

Replace the sample code below with your own JavaScript Agent script.

```
Substitute "s#<head>#<head><script>window['adrum-start-time'] = new Date().getTime();</script><script>(function
(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] || (window['adrum-config'] = {}));<
/script><script src='./adrum.js'></script>#inq"
```

```
AddOutputFilterByType SUBSTITUTE text/html
Substitute "s#<head>#<head><script>window['adrum-start-time'] = new Date().getTime();</script><script>(function
(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] || (window['adrum-config'] = {}));<
/script><script src='./adrum.js'></script>#inq"
```

Where `./adrum.js` is the path to a copy of the adrum file that is accessible to the server. Make sure `.htaccess` is world-readable.

Assisted Injection

Related pages:

- Automatic Injection of the JavaScript Agent
- Injection Using Nginx
- Injection Using Apache

This page describes how to instrument a browser application through assisted injection of the JavaScript Agent. Assisted injection is when your server-side application injects the JavaScript Agent into your browser application. You can configure your business applications to inject the JavaScript Agent into your browser applications.

Types of Assisted Injection

You can perform assisted injection with rules or through attributes. This table summarizes the platforms supported for each type of assisted injection and the process for performing the assisted injection.

Type of Assisted Injection	Supported Platforms	Description
Injection Rules	Java	Type of assisted injection uses rules to configure which Java classes should be intercepted. You create the injection rules in the **User Experience App Integration Panel** of the Controller UI for the business application that will inject the JavaScript Agent.
Attribute Injection	Java, ASP.NET	Type of assisted injection relies on templates that tell the app agent where to inject information. You enable attribute injection in the **User Experience App Integration Panel** of the Controller UI for the business application that will inject the JavaScript Agent. Additionally, you add code snippets in the page templates that determine where the JavaScript Agent is injected.

Injection Rules (Java Only)

To have your server-side application use assisted injection of the JavaScript Agent using injection rules, you define rules to configure:

- The Java classes and methods that should be intercepted
- The Java writer object and method to use to add the agent to the response object

> Assisted injection using rules is available for Java frameworks only.

Access the User Experience App Integration Panel

1. From the **Applications** page, open the business application that you want to automatically inject the JavaScript Agent into your browser application.
2. From the left navigation bar, select **Configuration**.
3. Click **User Experience App Integration**.

Create JavaScript Injection Rules

1. In the JavaScript Agent Injection tab, select a browser application from the **Inject the JavaScript Agent configured for this Browser App** dropdown.
2. From the Configure JavaScript Injection tab, expand **Create Injection Rules.**
3. Click the **+** icon to open the **Create Manual Injection Rule** dialog.
4. From the Where to Inject JavaScript tab:
    a. In the **Name** field, enter a name for the rule.
    b. Check **Enable**.
    c. In the **Class and Method to intercept** section, define match conditions for the class and method that write to the output stream in your application. This is the class that server-side agent intercepts for injection.
    d. If the write method is overloaded:
        i. Check the **Is this Method Overloaded?** checkbox.
        ii. Click **Add Parameter.**
        iii. Add the parameters that define the method.
    b. In the **Pointer to the writer** section:
        i. Select how to obtain a reference to the writer object using either the selected method with a configured number of parameters, return value, or invoked object.
        ii. Specify a getter chain.

c. In the **Injection options** section, specify:
   - the output stream write method the server-side agent should use to inject the JavaScript Agent
   - when the injection should occur: when the method begins or when the method ends
   - which part of the script should be injected: the header or the footer
   - optional prefix to output before writing the header or footer, such as `<DOCTYPE. . . >`
5. Click **Create Injection Rule**.

Attribute Injection

To have your server-side application use assisted injection of the JavaScript Agent using attribute injection, you:

- Enable attribute injection
- Copy code snippets into your page template

> Only Servlet containers supported assisted injection.

Access the User Experience App Integration Panel

1. From the **Applications** page, open the business application that you want to automatically inject the JavaScript Agent into your browser application.
2. From the left navigation bar, select **Configuration**.
3. Click **User Experience App Integration.**

Access the JavaScript Injection Configuration Panel

1. From the **User Experience App Integration** page, click the JavaScript Agent Injection tab.
2. In the JavaScript Agent Injection tab, select a browser application from the **Inject the JavaScript Agent configured for this Browser App** dropdown.

Copy Code Snippets into Your Page Template

These examples show code snippets that you can copy directly into your page templates or into other pages. These code snippets direct the app agent where to inject information. The header value must be injected at the very top of the `<head>` section and the footer value must be added at the very end of the code creating the page.

If you have already injected the header portion of the agent using manual injection, you can use these code snippets to automatically inject the footer data portion only. In this case, add only the `JS_FOOTER` values shown in the sections below.

JSF

```
<h:outputText rendered="#{AppDynamics_JS_HEADER != null}" value='#{request.getAttribute
("AppDynamics_JS_HEADER")}' escape="false"/>
<h:outputText rendered="#{AppDynamics_JS_FOOTER != null}" value='#{request.getAttribute
("AppDynamics_JS_FOOTER")}' escape="false"/>
```

JSP

```
<% if (request.getAttribute("AppDynamics_JS_HEADER") != null) { %> <%=request.getAttribute
("AppDynamics_JS_HEADER")%> <% } %>
<% if (request.getAttribute("AppDynamics_JS_FOOTER") != null) { %> <%=request.getAttribute
("AppDynamics_JS_FOOTER")%> <% } %>
```

Servlet

```
if (request.getAttribute("AppDynamics_JS_HEADER") != null)
{
    out.write(request.getAttribute("AppDynamics_JS_HEADER".toString());
}
if (request.getAttribute("AppDynamics_JS_FOOTER") != null)
{
    out.write(request.getAttribute("AppDynamics_JS_FOOTER").toString());
}
```

Groovy

```
<g:if test="${AppDynamics_JS_HEADER}">
    ${AppDynamics_JS_HEADER}
</g:if>

<g:if test="${AppDynamics_JS_FOOTER}">
    ${AppDynamics_JS_FOOTER}
</g:if>
```

Velocity Template

```
#if ($AppDynamics_JS_HEADER)
    $AppDynamics_JS_HEADER
#end
#if ($AppDynamics_JS_FOOTER)
    $AppDynamics_JS_FOOTER
#end
```

ASP.NET C#

```
<% if (Context.Items.Contains("AppDynamics_JS_HEADER"))
    Response.Write(Context.Items["AppDynamics_JS_HEADER"]); %>
<% if (Context.Items.Contains("AppDynamics_JS_FOOTER"))
    Response.Write(Context.Items["AppDynamics_JS_FOOTER"]); %>
```

MVC Razor

```
@if(HttpContext.Current.Items.Contains("AppDynamics_JS_HEADER"))
{ @Html.Raw((string)HttpContext.Current.Items["AppDynamics_JS_HEADER"]) }
@if(HttpContext.Current.Items.Contains("AppDynamics_JS_FOOTER") )
{ @Html.Raw(HttpContext.Current.Items["AppDynamics_JS_FOOTER"].ToString()) }
```

Undo Injection

Related pages:

- Manual Injection of the JavaScript Agent
- Automatic Injection of the JavaScript Agent
- Assisted Injection

If you try one way to inject and it does not work, AppDynamics recommends that you undo the current injection configuration before implementing another one.

Reverse Manual Injection

To undo manual injection, simply delete the JavaScript Agent from your web pages.

Undo Automatic Injection

To undo automatic injection:

1. Navigate to the **Application Dashboard** of the application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration**.
3. From the **Inject the JavaScript Agent configured for this Browser App** dropdown, select your browser application.
4. From the Automatic JavaScript Injection tab, clear the **Enable Automatic Injection of JavaScript** check box.

Undo Assisted Injection Using Attribute Injection

To undo assisted injection using attribute injection:

1. Navigate to the **Application Dashboard** of the application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration**.
3. From the **Inject the JavaScript Agent configured for this Browser App** dropdown, select your browser application.
4. From the Configure JavaScript Injection tab, clear the **Request Attribute Injection** check box.

Undo Assisted Injection Using Injection Rules

To undo assisted injection using injection rules:

1. Navigate to the **Application Dashboard** of the application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration**.
3. From the **Inject the JavaScript Agent configured for this Browser App** dropdown, select your browser application.
4. From the Configure JavaScript Injection tab, double-click the rule that you'd like to disable.
5. Clear the **Enabled** check box.

You can also simply delete rules by selecting the rule and then clicking the **Delete** icon.

Upgrade the JavaScript Agent

Related pages:

- Manual Injection
- Automatic Injection
- Assisted Injection
- Undo Injection

This page covers how to upgrade the JavaScript Agent version. Upgrading to the latest version of the JavaScript Agent will allow you to use the latest features and get the latest bug fixes.

The following sections will discuss possible compatibility issues, show you a new way to include the JavaScript Agent, and provide you with manual injection code examples for the different JavaScript Agent hosting options.

Compatibility Issues

For on-premises deployments, your JavaScript Agent version should the same or older than your EUM Server version. For example, if you have deployed the EUM Server 20.3.0, the latest version of the JavaScript Agent you can use is 20.3.0. We recommend to upgrade your EUM Server to the latest version so you can take advantage of the latest JavaScript Agent features.

- If you are using a SaaS EUM Cloud and want a hosted version of `adrum.js`, AppDynamics recommends you use the `adrum-latest.js` version. However, you can use any version of the JavaScript Agent as it is compatible with any SaaS EUM Cloud version currently being deployed.
- If you are using an on-premises EUM Server and want to use a hosted version of `adrum.js`, you need to match the `adrum.js` version to your EUM Server version.
- For Controller versions, a JavaScript Agent version is compatible with Controller versions with the same or older versions. For example, JavaScript Agent 20.6.0 is compatible with Controller <= 20.6.0.

Injection Code Changes

If the URL to the server hosting your JavaScript Agent is the same for both HTTP and HTTPS, you should no longer use `document.write` to inject the `<script>` tag. Instead, just hardcode the `<script>` tag with the following syntax:

```
<script src="//cdn.appdynamics.com/adrum/adrum.js"></script>
```

Injection Code for Different Hosting Options

The injection code will vary slightly depending on your deployment (SaaS/on-premises). The following provides you with code snippets for each type of deployment. Be sure to place the code snippets below right after the `<head>` tag.

Overview of the Controller UI for Browser RUM

Browser RUM presents information in these views:

- An **Overview** dashboard, with sections for:
  - widgets for graphic display of common metrics
  - map-based performance display
  - snapshots of individual requests
  - usage statistics by browser and device/platform
- Unified data for entire sessions, following an individual user's path as they navigate through your site
- Detailed information on the performance of individual pages, as
  - aggregated lists of page, Ajax, iframe, and virtual page request types
  - multi-faceted data from a complete data store

Access a Browser RUM Application

To see the data for your app in the Controller UI, you must first open your application:

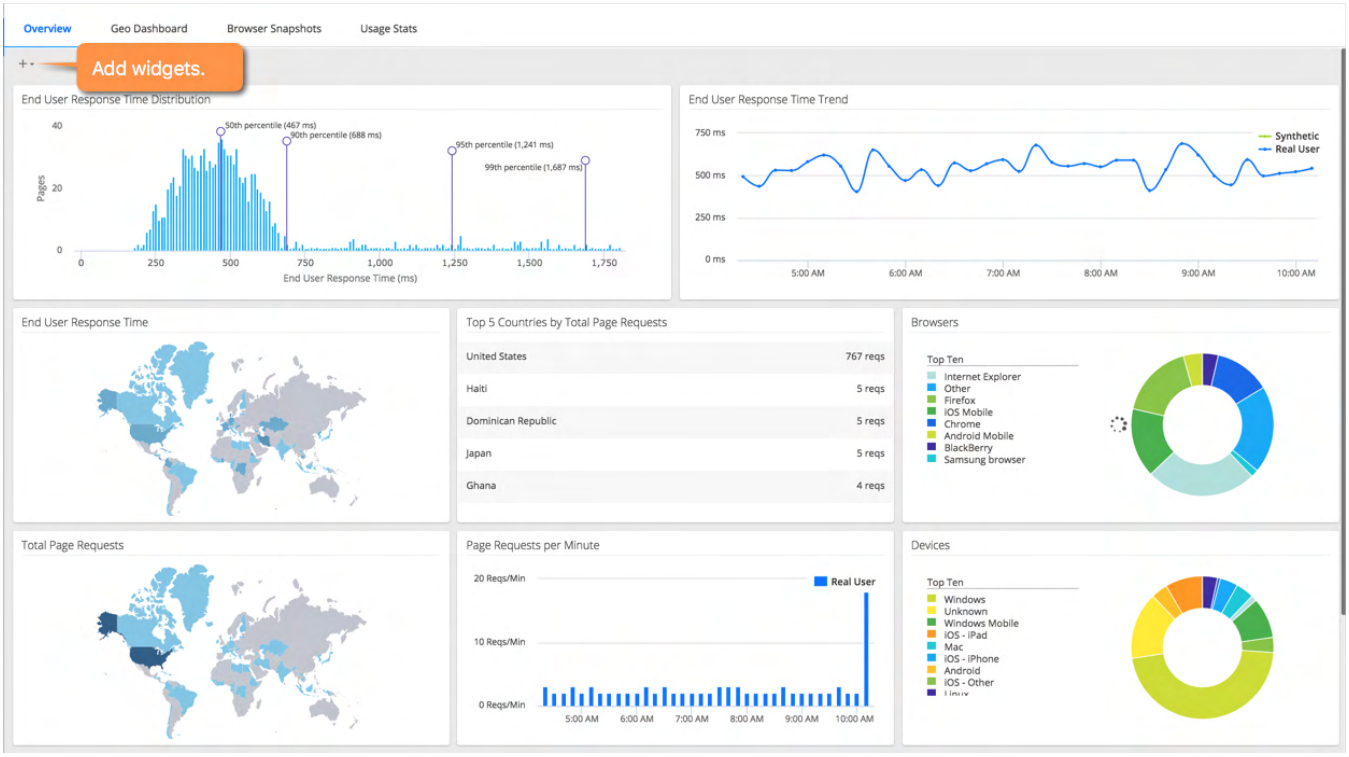
1. In the top tab bar, select **User Experience**. The list of instrumented Browser and Mobile Apps is displayed.
2. Make sure the **Browser App** tab is selected.
3. Double-click on the app you are interested in. The monitoring UI opens.

Browser App Dashboard

This view is good for getting a high-level understanding of how your app is performing overall.

Overview

The **Overview** tab is made up of a set of widgets showing common usage metrics. You can add, delete, move, and resize widgets as you wish. If you see a metric that interests you, click through to the main view. If you are using Synthetic, data from both RUM and Synthetic (separated by color) show up in some of the widgets.

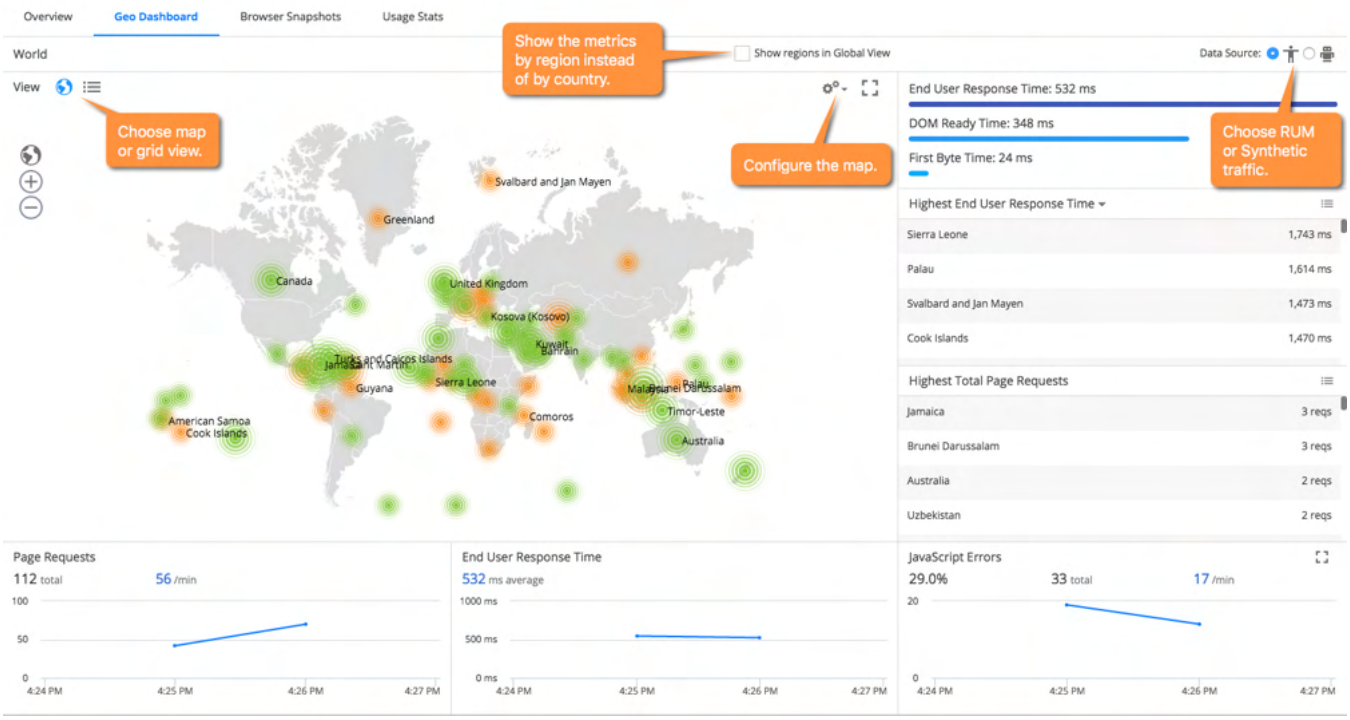


For more information, see Browser App Dashboard.

Browser App Geo Dashboard

The **Geo Dashboard** view provides high-level insight into how your application is performing across the world for your users. The size of a dot indicates the number of page views from that region, and the color indicates the average page load End User Response time in that region (red is slow). You can click to drill down to areas of specific interest. You can also see the same information presented in tabular form by clicking the grid icon in the upper left of the panel.

If you are using Synthetic, you can also select to see either RUM or Synthetic data displayed here. By default, the **Geo Dashboard** displays key performance metrics by country, but you can view performance metrics by region by checking the **Show regions in Global View**.

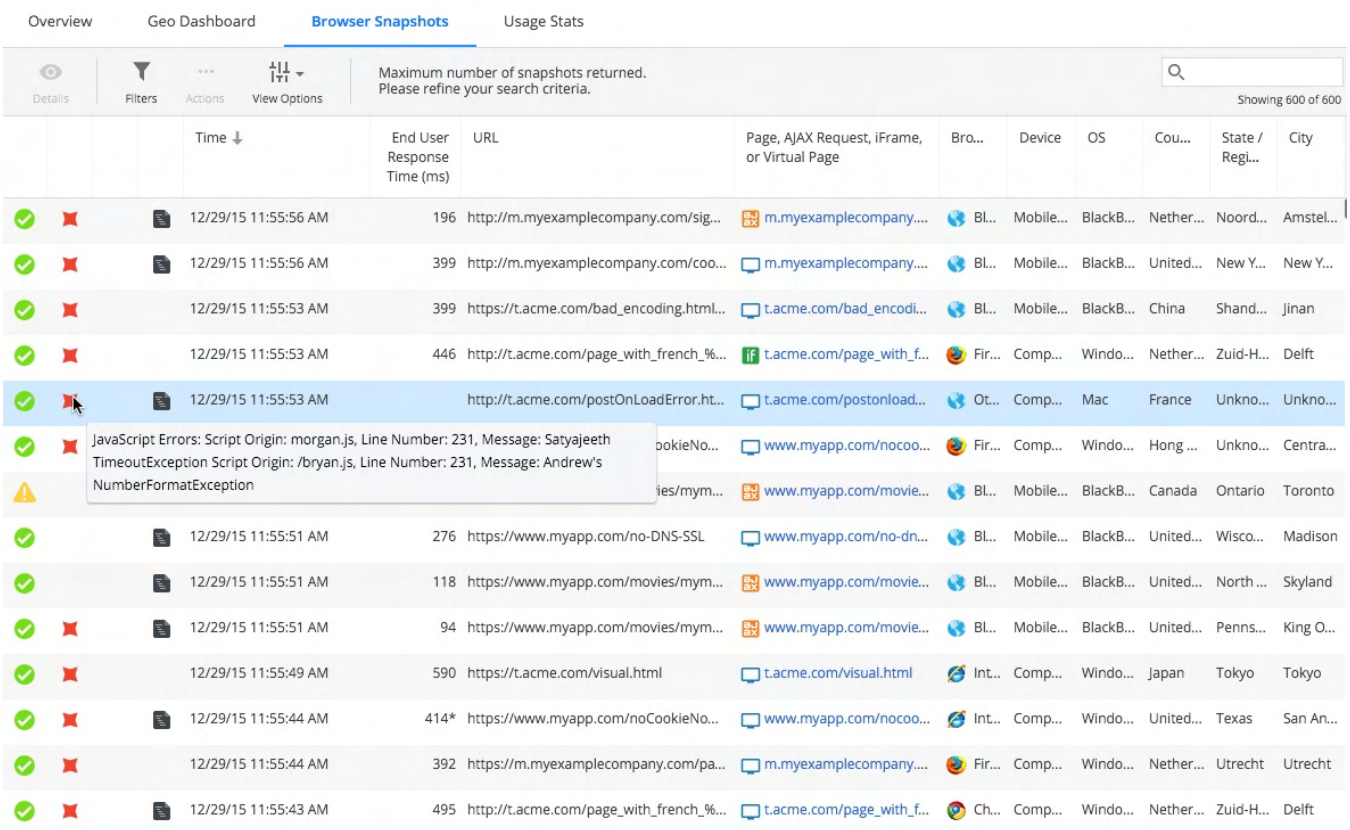


For more information, see Browser App Dashboard.

> The option **View Dark Mode** has been removed from the **Geo Dashboard**.

Browser Snapshots

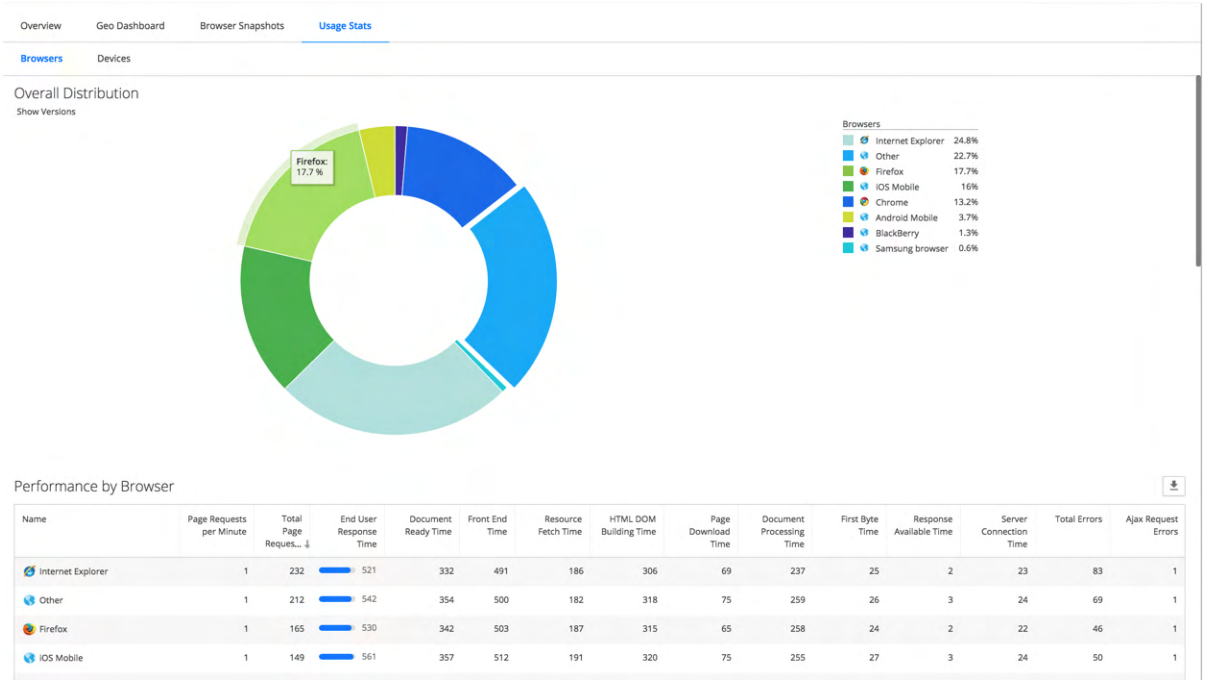
The **Browser Snapshot** view provides access to detailed information for individual requests. The list includes both periodic snapshots of requests operating within normal boundaries and problem snapshots of requests that have exceeded one or more configurable performance criteria. Double-clicking a specific item takes you to a detailed graphical representation of the execution flow of that request and other data associated with it.



For more information, see Browser Snapshots.

Usage Stats

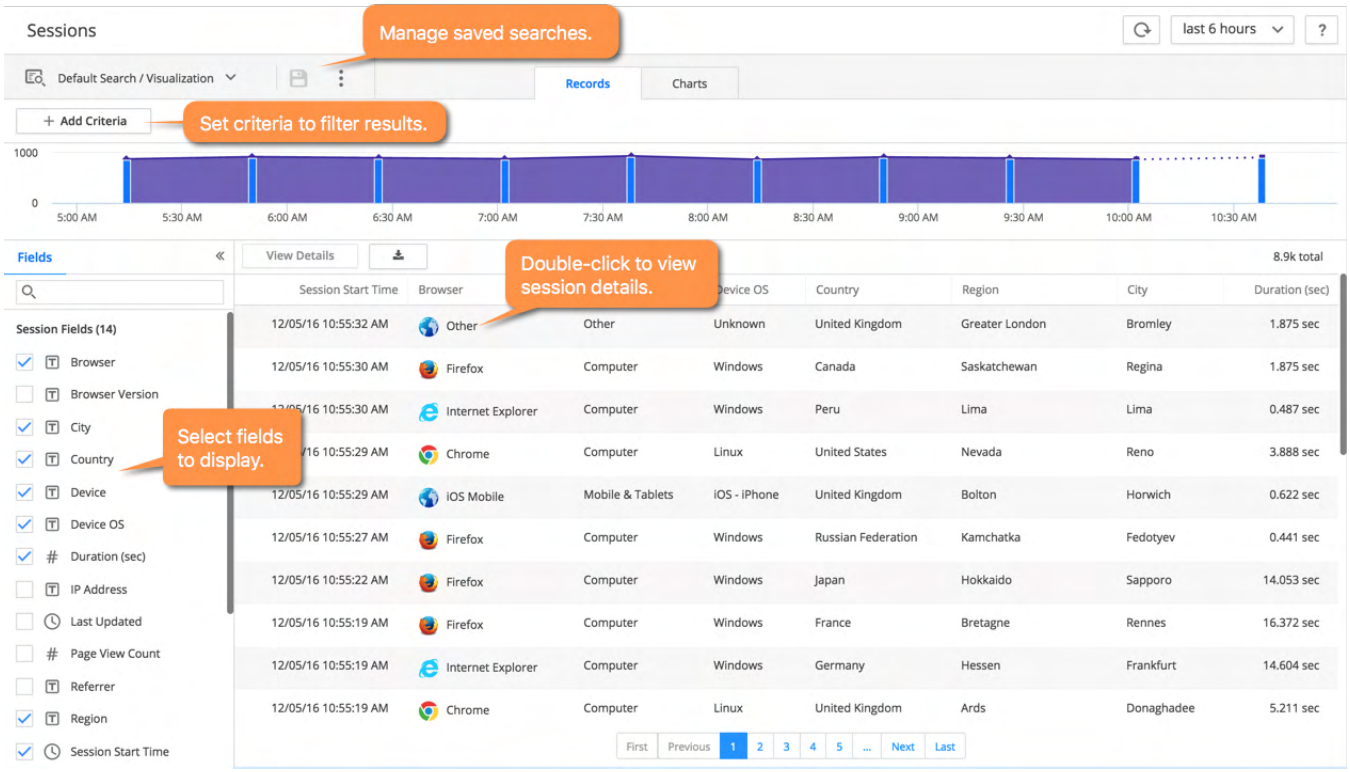
The **Usage Stats** view presents aggregated page load usage data based on the browser type and device/platform employed by your users. The view also breaks down performance by type and usage by country.



For more information, see Browser App Dashboard.

Sessions

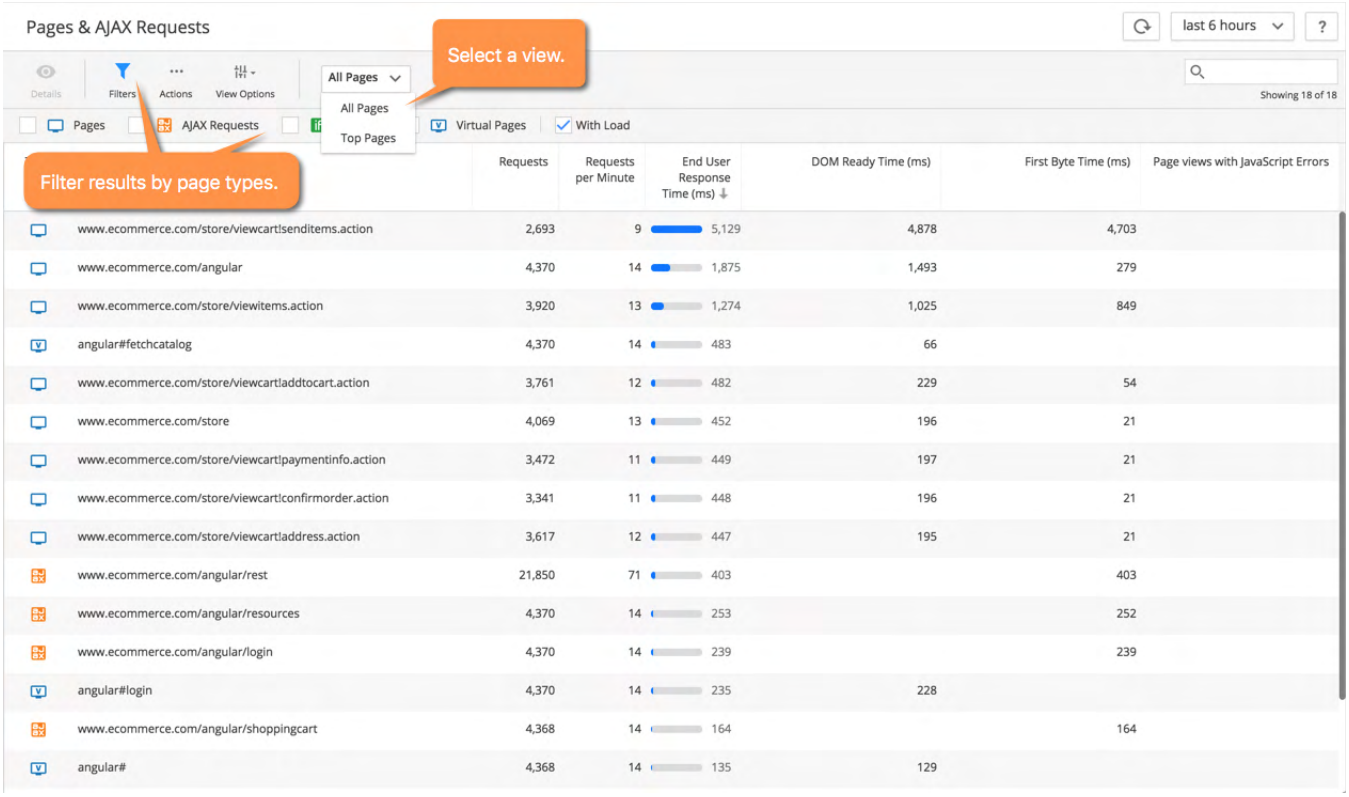
In most cases, users interact with your web application over a series of real (or virtual) pages. Sessions allow you to track your users' interactions across time, as they navigate through an entire engagement period with your app. Using Browser RUM Sessions, you can analyze session results from all requests, as stored in the AppDynamics Events Service. Use the **Records** tab to focus on pertinent data and the **Charts** tab to view a dashboard of useful graphics widgets. Or follow a session from page to page using the **Session Detail** dialog.



For more information, see Browser RUM Sessions.

Pages & Ajax Requests

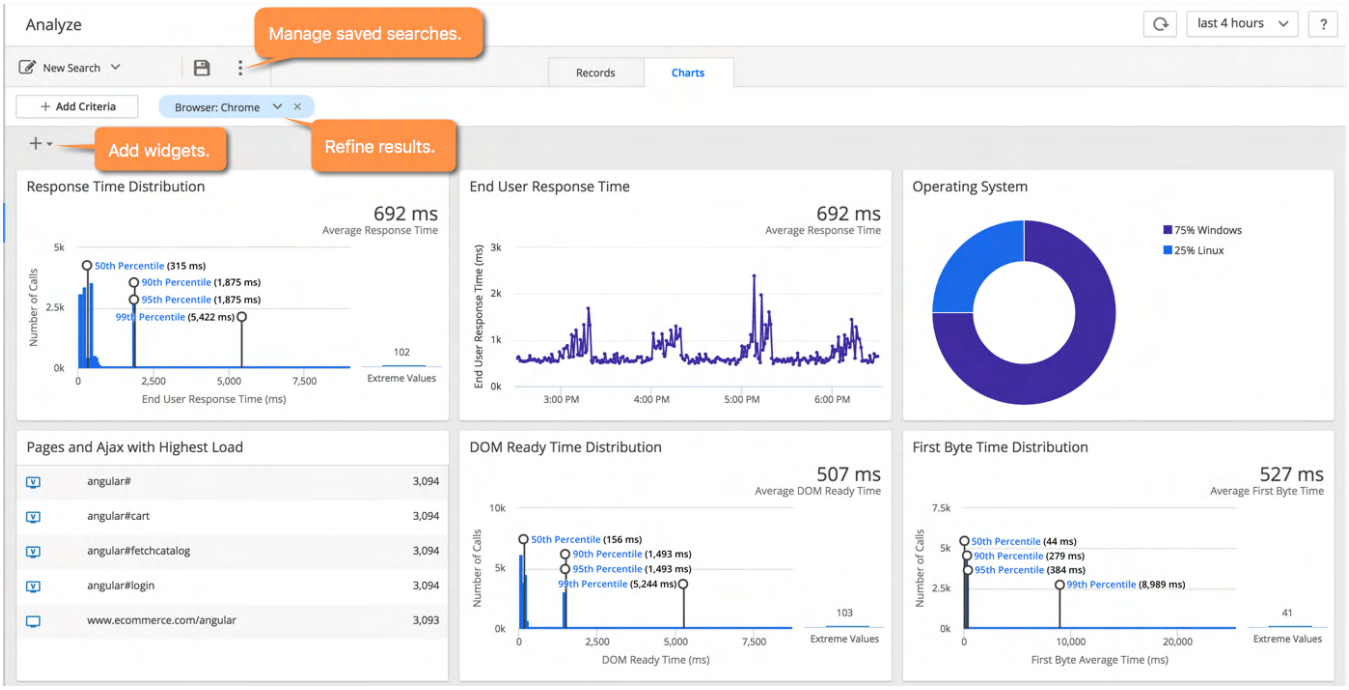
This view is good for tracking the performance of individual pages and components as well as understanding any issues that may be emerging. The **Pages & Ajax Requests** view shows you an aggregated view of how each of your page, Ajax request, iframe, and virtual page types are performing over time. You can look at **All Pages** for an overall sense or select a **Top Pages** view to see the worst performing pages sorted by common metrics like Page views with JavaScript Errors and First Byte Time. And you can drill down to a graphical dashboard showing a wide range of charted performances characteristics for any specific request type.



For more information, see The Pages & Ajax Requests View.

Analyze

The **Analyze** view allows you to query a complete repository of all traffic data that Browser RUM has collected in the past two weeks and display that data in multiple ways.



For more information, see Browser RUM Analyze

Enable Browser RUM

Browser RUM requires a separate license and must be enabled before it is available for use.

For information about licensing, see EUM Accounts, Licenses, and App Keys.

For information on enabling or disabling Web User Experience, see Set Up and Access Browser RUM.

Browser RUM Sessions

This page describes Browser RUM sessions, and the **Session UI** you use to to view session data.

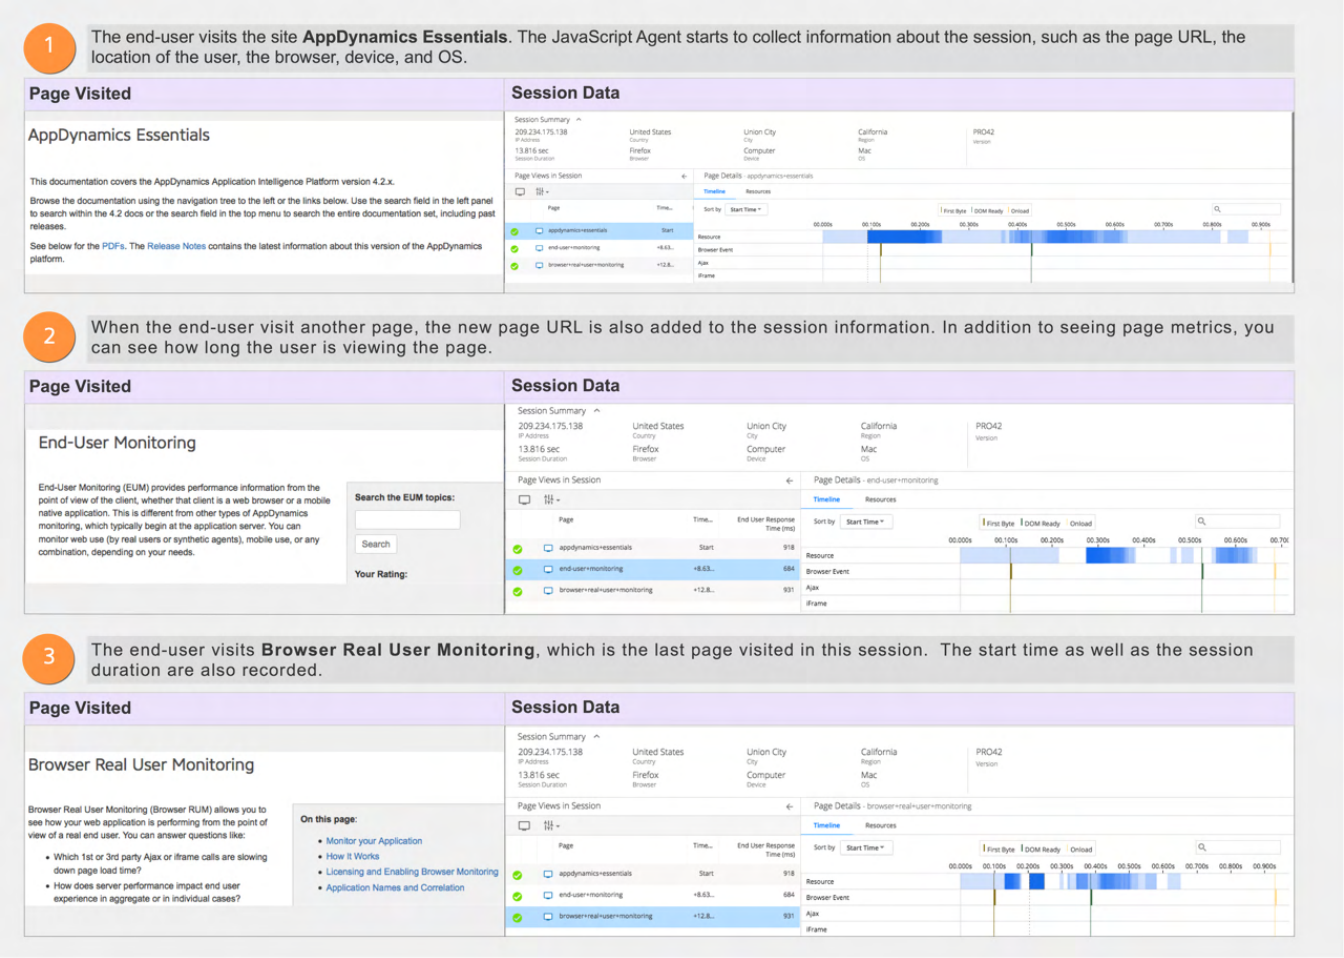
Browser RUM Session

A Browser RUM session is a collection of chronological events for a particular end user from the start of a session to a configurable period of inactivity. An event represents an activity occurring at the moment in time that can be recorded, aggregated, and correlated at certain levels. In Browser RUM, events are limited to page loads, virtual page loads, iFrames, and Ajax requests.

> Only Ajax requests configured to be published to the Events Service are included in sessions.

For example, when a user purchases product from an e-commerce site, the session might capture the page/virtual page loads, iFrames, or Ajax requests for the user logging in (start), selecting and paying for products, and logging out (end).

This figure describes how the user's actions cause events that are tracked in the session.



RUM Sessions Importance

You can think of sessions as a time-based context to analyze a user's experience interacting with an application. By examining RUM sessions, you can understand how your applications are performing and how users are interacting with them. This enables you to better manage and improve your application, whether that means modifying the UI or optimizing performance.

Use Cases

In some use cases, you can use RUM sessions to analyze a user's or a group's behavior. You analyze a user's behavior based on the user's unique ID across multiple sessions in what is called *sniping*. In addition, you can query for a segment of users with similar behavior, such as visiting a certain specific page or using a particular device. This technique of grouping users with similar behavior is called *bucketing*. Browser RUM sessions allow you to query users on a wide array of criteria such as the type of browser, device, location, landing page, IP address, and more.

How EUM Captures RUM Sessions

The JavaScript Agent loads a temporary GUID into the browser local storage and then transmits beacons to the EUM Cloud or EUM Server that include this GUID. We can then use the GUID to track the user's device over the duration of one or more sessions. The EUM Cloud then publishes these events into a session record stored in the Events Service.

Session Persistence

Sessions persist until a period of user inactivity that you configure in the controller. Sessions can also end when the GUID is removed from local storage, which can happen for a number of reasons. For example, the user could clear local storage or the browser is configured to clear the local storage when the browser is closed.

Maximum Session Time

We don't technically limit the time of a session. Instead, we restrict the maximum number of events to 1000. You can, however, configure the maximum time for each event by configuring session monitoring timeouts and then derive the maximum time for a session by multiplying the configured session inactivity timeout by 1000. For example, if you configure the session inactivity timeout for each event to be five minutes, the maximum session time would be 5000 minutes. Of course, in this case, most sessions would not last 5000 minutes because end users would trigger events well before the maximum time of five minutes.

Single Page / Multiple Page Sessions

When the browser cannot write the GUID to local storage, Browser RUM cannot track the user's device over one or more sessions. Instead, Browser RUM uses the temporary GUID in memory to create one-page or multiple *virtual* page sessions. Virtual pages are simply those sections of the DOM that are dynamically created and loaded into the current page.

Privacy/Security of Session Data

We do not perform browser or device fingerprinting. By default, we do not store user IP addresses. If you configure the Controller to store IP addresses, then the IP addresses are stored for up to 14 days.

Browser RUM Support for Sessions

JavaScript Agent Version Requirement for Sessions

You are required to use the JavaScript Agent >= 4.2. Older versions of the JavaScript Agent do not support sessions.

Browser Requirements for Sessions

To use Browser RUM sessions, your browser is required to support for the following:

- cross-origin resource sharing (CORS) for beacons
- local storage for multiple-page sessions (single-page / multiple virtual page sessions don't need local storage)

Browser RUM sessions do not support beacons implemented with GIFs.

Session Limits

The table below lists the limits for session operations per account.

Session Operations	Maximum Per Account
Stored session resource snapshots	10k per minute
Pending uploads of resource timing snapshots	100k
Published session beacons	10k per minute
Tracked sessions	5k per minute

After the pending uploads of resource timing snapshots reach 100k, no further resource-timing snapshots are queued.

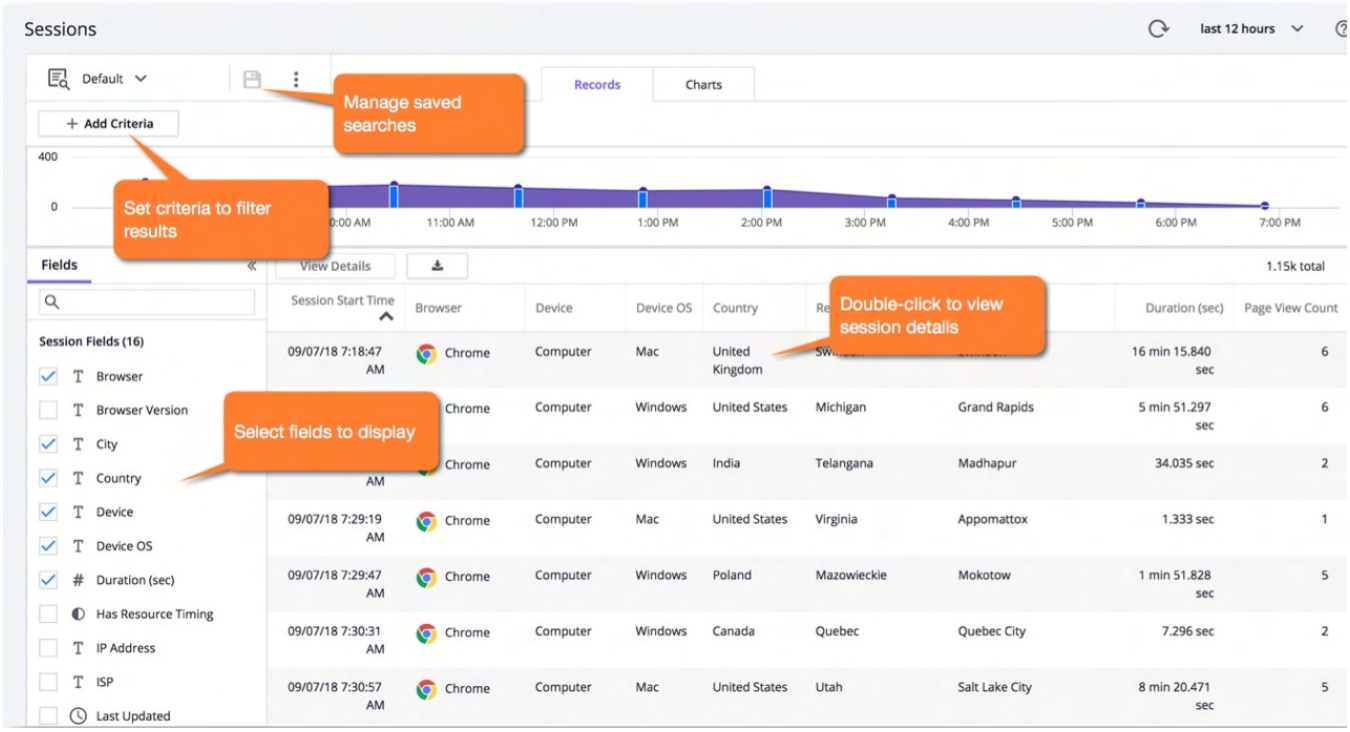
Sessions UI

As in Browser RUM Analyze, the main **Sessions** page is made up of two tabs:

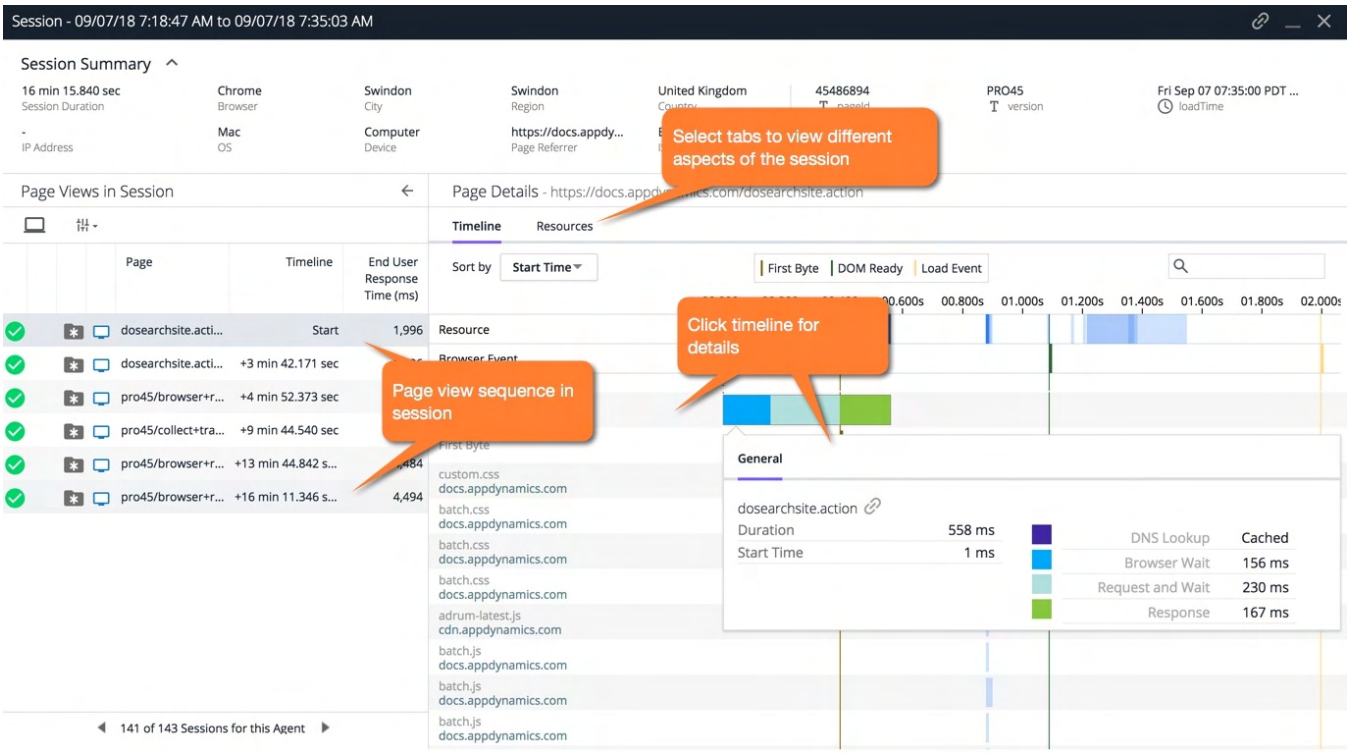
- Records
- Charts

Records

The Records tab lets you scan individual sessions and allows you to filter and sort to get exactly the data in which you are interested.

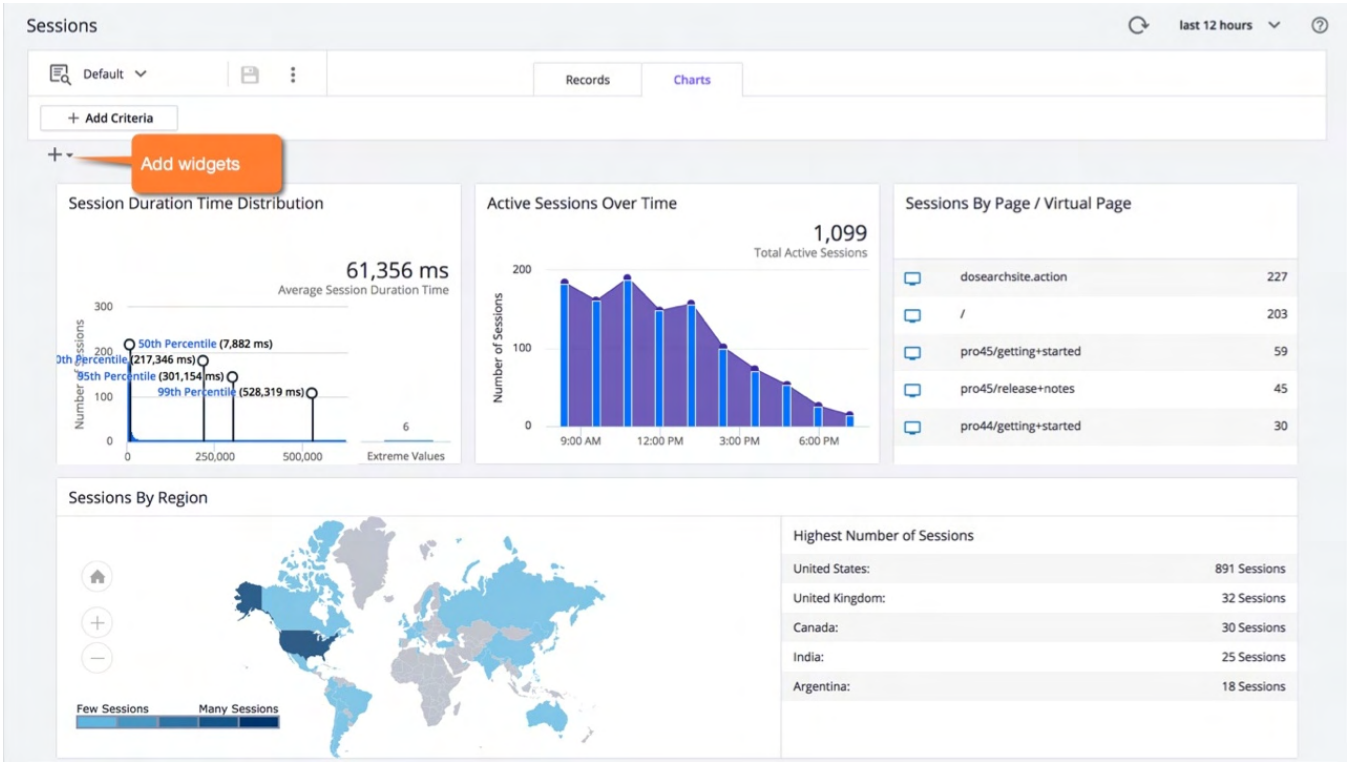


Click **View Details** or double-click an item to see the information for a specific session. The sequence of page views for the session is shown on the left side of the screen. Select a specific page view to see detailed information, including a page load waterfall, tabular details for resources, and, if your backend is instrumented with AppDynamics, correlated server-side business transactions.



Charts

The Charts tab provides you with a set of predefined widgets of the data set you have created plus a custom widget builder. As with the Charts tab of the **A nalyze** UI, you can delete, re-add, resize, and drag-and-drop to move the widgets.



Pages and Ajax Requests

The **Pages & Ajax Requests** page provides detailed information on how your pages, Ajax requests, iframes, and virtual pages perform over time.

Access Pages & Ajax Requests

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Pages & Ajax Requests**.

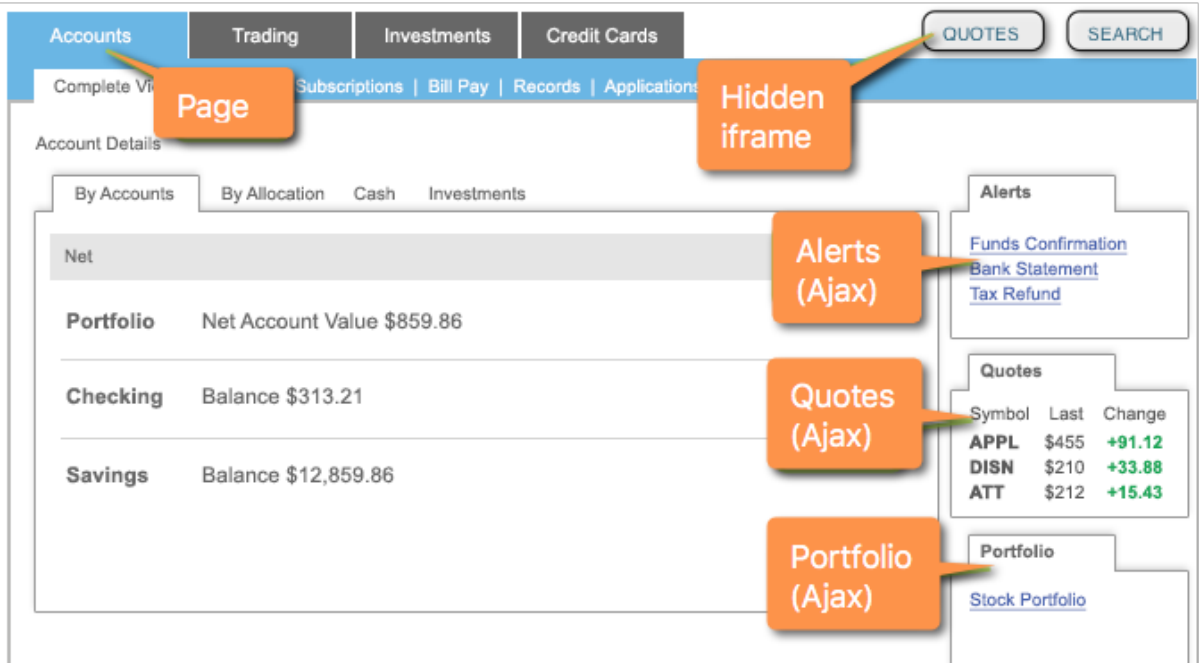
What is a Page?

In Browser RUM, a page represents an individual source for the information that an end-user sees in one browser window.

Types of Pages

A base page is the core HTML page, and may also include one or more iframes, which you can nest.

A base page or an iframe can also make one or more Ajax requests (using `XMLHttpRequest` or the Fetch API) to fetch data to display on the Web page.



You can collect Browser RUM metrics for base pages, iframes, Ajax requests, and virtual pages.

Each base page, iframe, Ajax request, and virtual page type is assigned a unique name, which you can configure. See Configure Page Identification and Naming.

Pages & Ajax Requests

The **Pages & Ajax Requests** page has two options: **All Pages** and **Top Pages**, selected using the dropdown in the upper right. **All Pages** displays a list showing a high-level summary of all the monitored types, along with their key performance indicators. **Top Pages** displays the ten worst performing items grouped by common metrics: Requests per Minute, Page Render Time, and so forth. Use this option for a quick start to troubleshooting.

How the All Pages List is Organized

The **All Pages** list displays each monitored base page, iframe, Ajax request, and virtual page type.

Click a column header to sort the pages based on the column's metric.

To view a dashboard for a specific page item in the list, select it and click **View Dashboard** or just double-click the page. See Page, Ajax, and Iframe Dashboards.

To filter the types of pages displayed in the list, select the type at the top of the list. Check **With Load** to see only pages currently reporting load.

More Actions Menu

Using the **More Actions** menu, you can select a page in the list and make changes to it, including directing the agent to ignore the page and stop reporting metrics for it.

Access Top Pages

Click the **View** dropdown on the upper-right side of the page and select **Top Pages** as a shortcut to troubleshooting the ten worst performing pages regarding various metrics.

Page Limits

There is a limit of 500 total base pages (including virtual pages) plus iframes and 500 Ajax calls that can be individually tracked per application. If your usage exceeds these limits, the Controller begins to drop metrics. If your installation is approaching these limits, you can modify how your metrics are collected by:

- Limiting the number of pages you instrument. If you are using manual injection, remove the JavaScript Agent from pages that are less important. See Inject the JavaScript Agent for more on injection types. If you are using automatic injection, create request match rules and request exclude rules to restrict injection to pages that meet certain criteria. See To Create Match Rules for Automatic Injection.
- Using custom naming rules to group similar pages together. See Configure Page Identification and Naming.

If you reached your page limit, you need to delete the affected old page names before any new page names can be added to the database. Doing so also deletes any accumulated metrics for those page names.

Page, Ajax, and Iframe Dashboards

Dashboards provide quick access to graphic representations of metrics for pages (including virtual pages), iframes, and Ajax request types. Each page, iframe, and Ajax request type has a dashboard. See Page and IFrame Dashboards and Ajax Dashboard.

Access These Dashboards

To view a dashboard for a page, iframe or Ajax request type:

1. Open the browser application in which you are interested.
2. On the left navigation bar of your application, select **Pages & AJAX Requests**.
3. From the list, select the page, iframe or Ajax request type in which you are interested.
4. Either double-click the item, or select the item and then click **Details**.

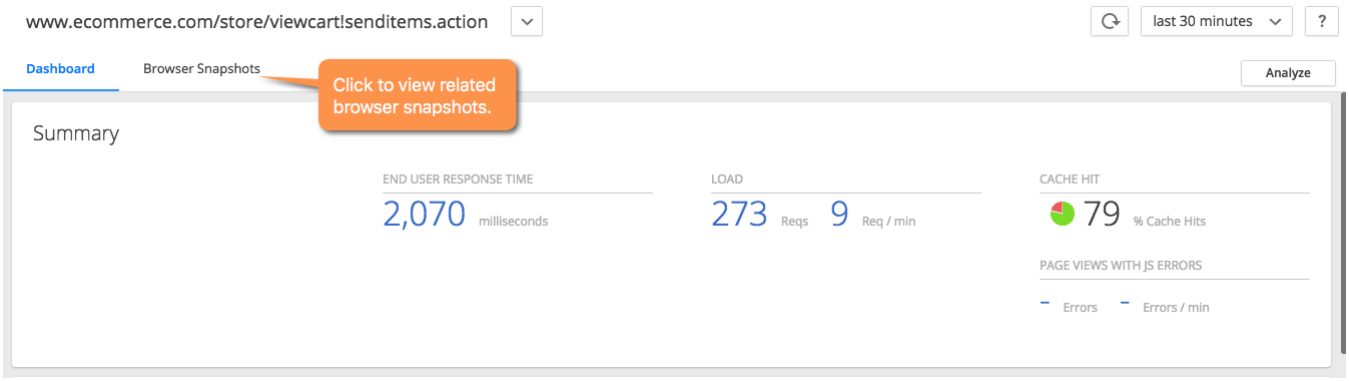
Page and IFrame Dashboards

Page and **iframe** dashboards are divided into six areas:

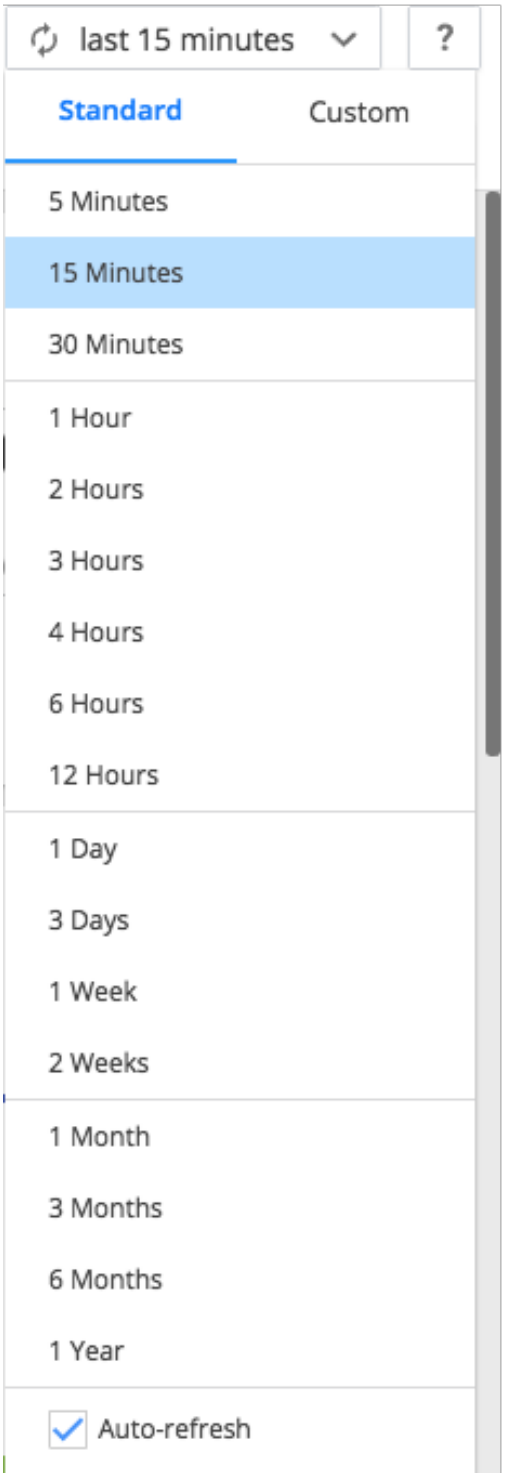
- A summary of key performance indicators. To see browser snapshots associated with these instances of this page type, open the Browser Snapshots tab. To move to the **Analyze** view, click **View Analyze**.
- A waterfall graph of the entire load sequence. To see details for each set of data, use the **Trends/Details** checkboxes.
- Four sections of **Trends/Details** across time for the main performance categories:
    - Overall performance
    - Time between the request and the first byte of the response
    - Time taken by the server to process the request through the completion of the HTML download for the item
    - Time taken to process and render the item, including any external resources, in the browser
- Detailed information on the performance of Ajax requests and iframes for this item.

Page Dashboard Summary Section

This section provides a quick overview of the item's performance over time.

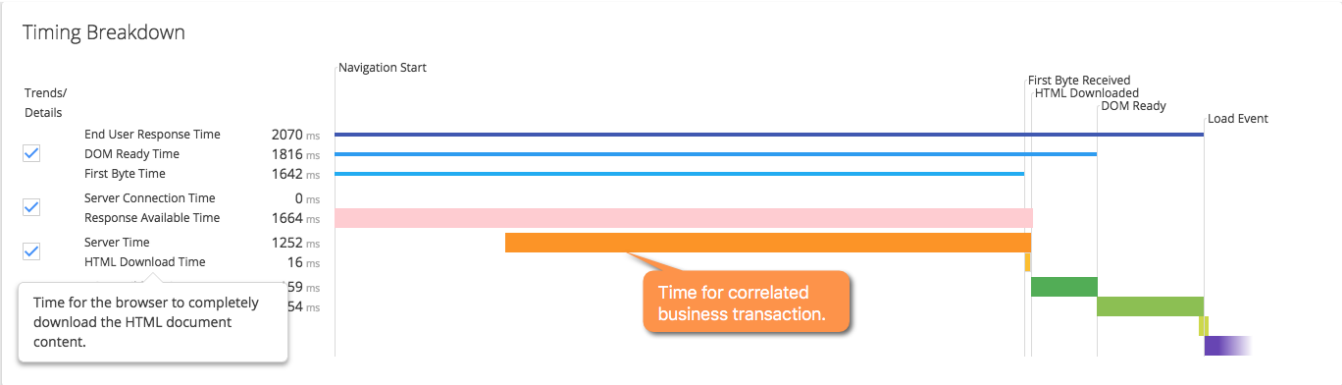


Key performance indicators—End User Response Time, Load, Cache Hits, and Page Views with JS errors—across the period selected in the timeframe dropdown from the upper-right side of the Controller UI are displayed across the top of the summary area. Cache Hits indicates a resource fetched from a cache, such as a CDN, rather than from the source. This metric is only reported when there is a correlated AppDynamics agent on the server-side source.



Timing Breakdown

The waterfall graph shown below displays the average times needed for each aspect of the page load process. For more information on what each of the metrics measures, hover over its name on the left. A popup appears with a definition. See Browser RUM Metrics.



To see detailed breakouts of the data behind the graph, check the **Trend/Detail** checkbox by the data group in which you are interested. To turn the details off, uncheck the checkbox.

> Some metrics—for example, TCP Connection Time—only appear if they have a non-zero value.

Overall Performance

This section displays detailed trend graphs of key performance metrics measured across the selected timeframe. To see detailed information for a particular moment, hover over the graph and a popup with that information appears. To see any of the listed total metrics in the context of the metric browser, click the desired value (shown in link blue) on the left side of the panel. The Metric Browser appears, with that metric displayed. You can then use the **Metric Browser** to compare other related values in one display.

Key Performance Times / Load

This section displays detailed trend graphs of key performance indicators and the request load across the selected timeframe. They measure:

- Time between the user's request and the completion of the page load of the response.
- Time between the user's request and the DOM being loaded.
- Time between the user's request and the browser receiving the first response byte.
- Number of requests per minute.

Server Connect Time Breakdown / Response Available Time

This section displays detailed trend graphs of initial server connection metrics measured across the selected timeframe. They measure:

- Time the user's request takes in negotiating its initial connection with the server, which may include the DNS, TCP Connect, and SSL/TLS time. The **Total Server Connect** value is always displayed.
- Time between that initial connection and the time the first byte of information begins to arrive at the browser.

Server Time / HTML Download Time / Related Business Transactions

This section displays detailed graphs for the time spent acquiring the page data:

- Time the request takes on the server.
- Time it takes to complete the download of the HTML to the page.
- If the request is correlated with a server-side app agent, related business transactions on the server are displayed. Cross-app correlation is supported.

DOM Building Time / Resource Fetch Time / Page Resources Requested

This section displays detailed graphs for the time spent creating the page and getting resources. They measure:

- Time required by the browser to create the DOM from the end of the HTML download.
- Time required to fetch any external resources. For example, the results of a third-party Ajax request.

The **Page Resources Requested** section displays detailed graphs of when in the page load cycle individual external—first and third-party—resources are fetched, and how much time is taken to fetch them, based on the selected timeframe. They measure:

- Average time and load associated with that resource
- If the request is blocking or non-blocking

- Request and response time per resource request
- Type—iframe or Ajax—of the resource

To see the dashboard for any of the listed resources, click the name.

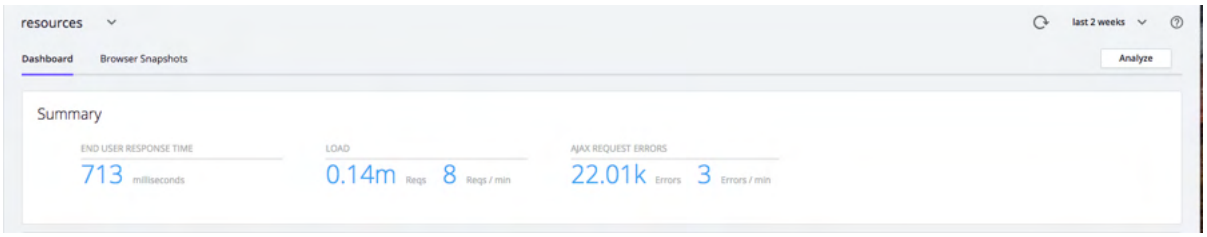
Ajax Dashboard

The **Ajax Dashboard** is divided into three areas:

- A summary, with a waterfall graph of the entire load sequence. To see details for each set of data, use the **Trends/Details** checkboxes.
- Two sections of **Trends/Details** across time for the main performance categories:
  - Overall performance
  - Time used by the server to process the request through the browser's incorporation of the data into the HTML document

Ajax Dashboard Summary Section

This section provides a quick overview of the item's performance over time.



Key performance indicators—End User Response Time, Load, Cache Hits and Views with Errors—across the period selected in the timeframe dropdown from the upper-right side of the GUI—are displayed across the top of the summary area.

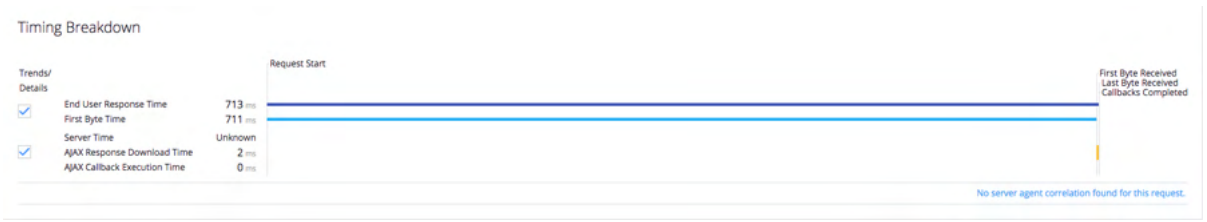
A waterfall graph displays the average times needed for each aspect of the Ajax request load process.

For more information on what each of the metrics measures, hover over its name on the left side of the graph. A popup appears with a definition. See the graphic above for an illustration. See Browser RUM Metrics.

To see detailed breakouts of the data behind the graph, check the **Trend/Detail** checkbox by the data group in which you are interested.

Timing Breakdown

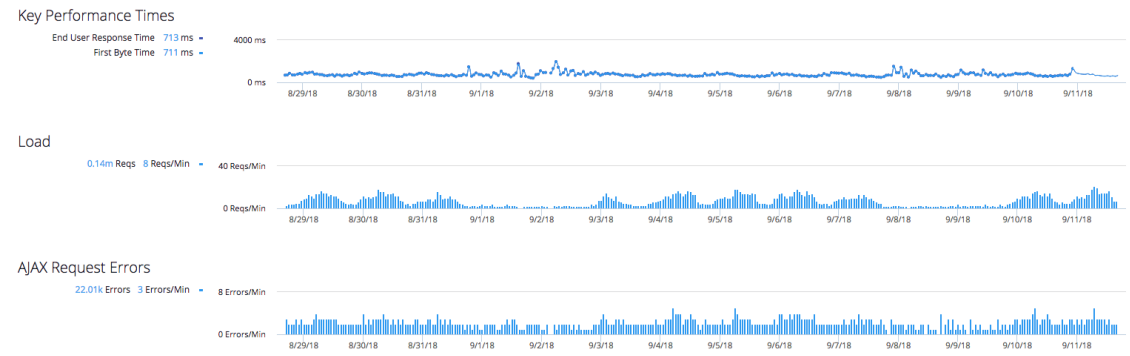
A waterfall graph shown below displays the average times needed for each aspect of the Ajax request. For more information on what each of the metrics measures, hover over its name on the left. A popup appears with a definition. See Browser RUM Metrics.



To see detailed breakouts of the data behind the graph, check the **Trend/Detail** checkbox by the data group in which you are interested. To turn off details, uncheck the checkbox.

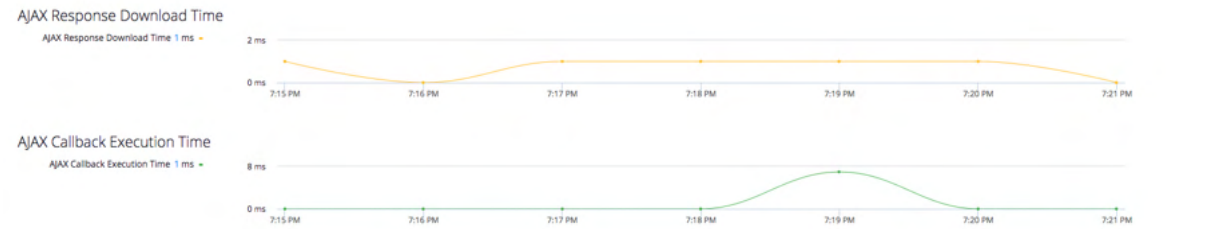
Overall Performance

This section displays detailed trend graphs of key performance metrics, load requests, and Ajax request errors measured across the selected timeframe. To see detailed information for a particular moment, hover over the graph and a popup with that information appears. To see any of the listed total metrics in the context of the metric browser, click the desired value (shown in link-blue) on the left side of the panel. The metric browser appears, with that metric displayed. You can then use the metric browser to compare other related values in one display.



Ajax Response Download and Ajax Callback Execution Time

This section displays detailed trend graphs of the Ajax response download time and the Ajax callback execution time. To see detailed information for a particular moment, hover over the graph to view a popup.



These metrics measure the total time for processing all server-side business transactions for this item.

- Total time for the browser to completely download all of the Ajax responses
- Time for the browser to complete any Ajax callbacks

Browser RUM Analyze

Related pages:

- Analytics Browser Requests Data
- Analytics Browser Sessions Data

Browser RUM collects data on every load event that you have instrumented, and it also takes detailed snapshots periodically and when performance issues are detected. Over time, the load event metrics are rolled up based on averages and percentiles. Sometimes you want to see results based on *all* of the data.

With **Browser Analyze**, every event is collected and stored for a license specified period in the AppDynamics Platform Events Service. Using the Analyze tab you can see results based on this cumulative data.

The **Analyze** view is comprised of two tabs:

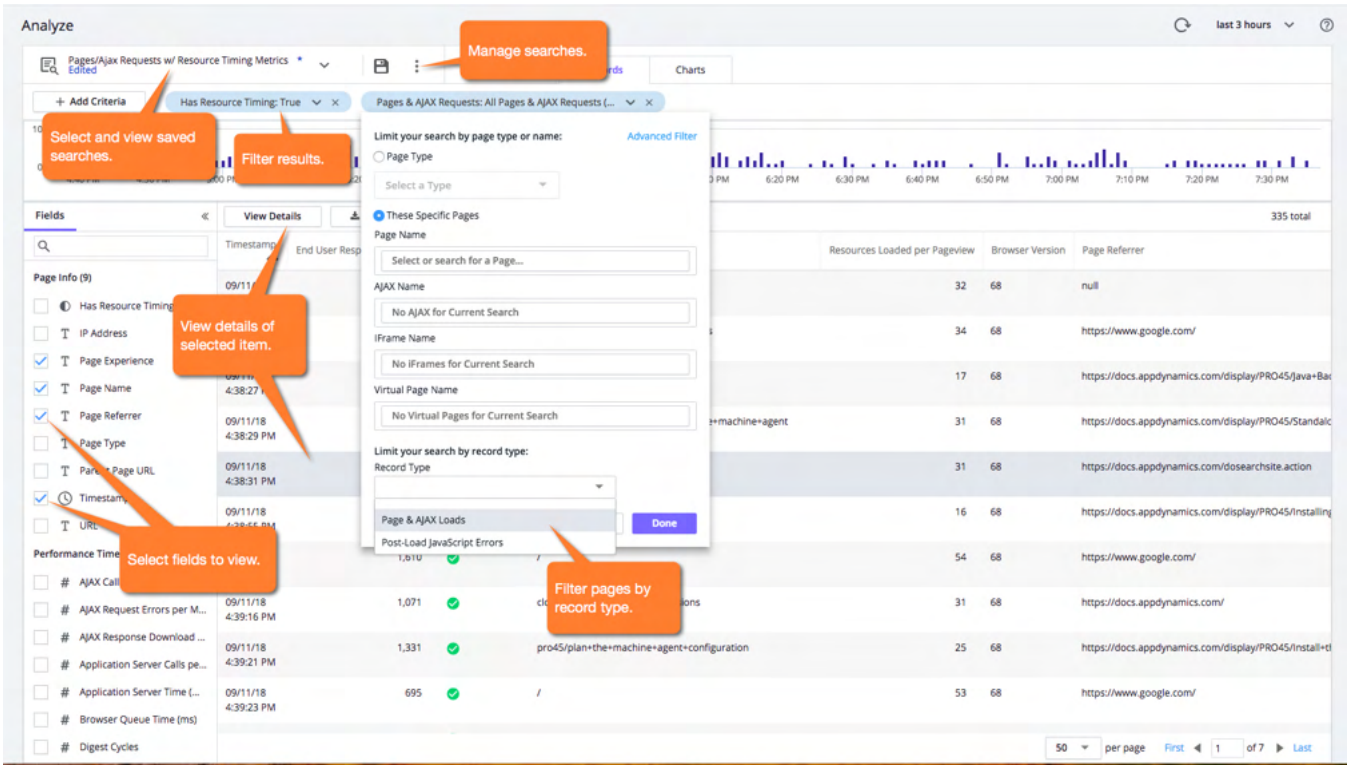
- Records
- Charts

Access the Browser Analyze View

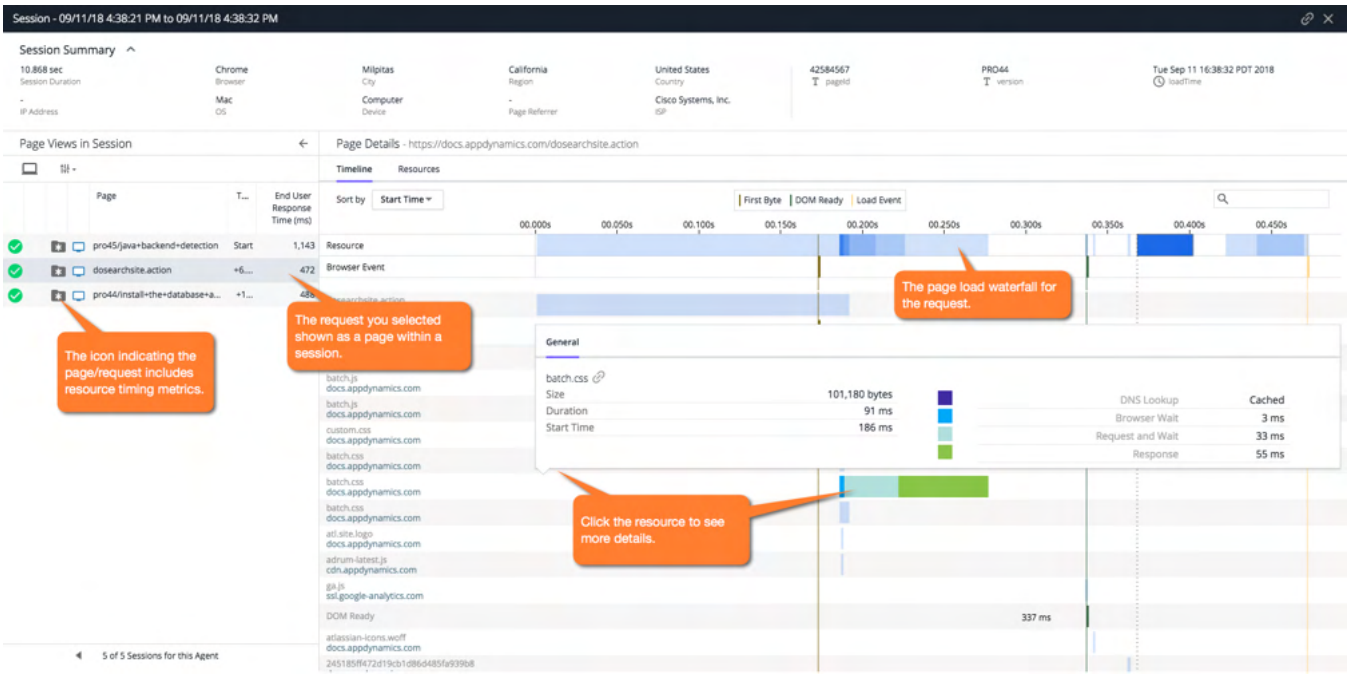
1. Open the application in which you are interested.
2. On the left navigation bar, select **Analyze**.

Records

The Records tab lets you scan individual events and filter and sort to get exactly the data set in which you are interested.



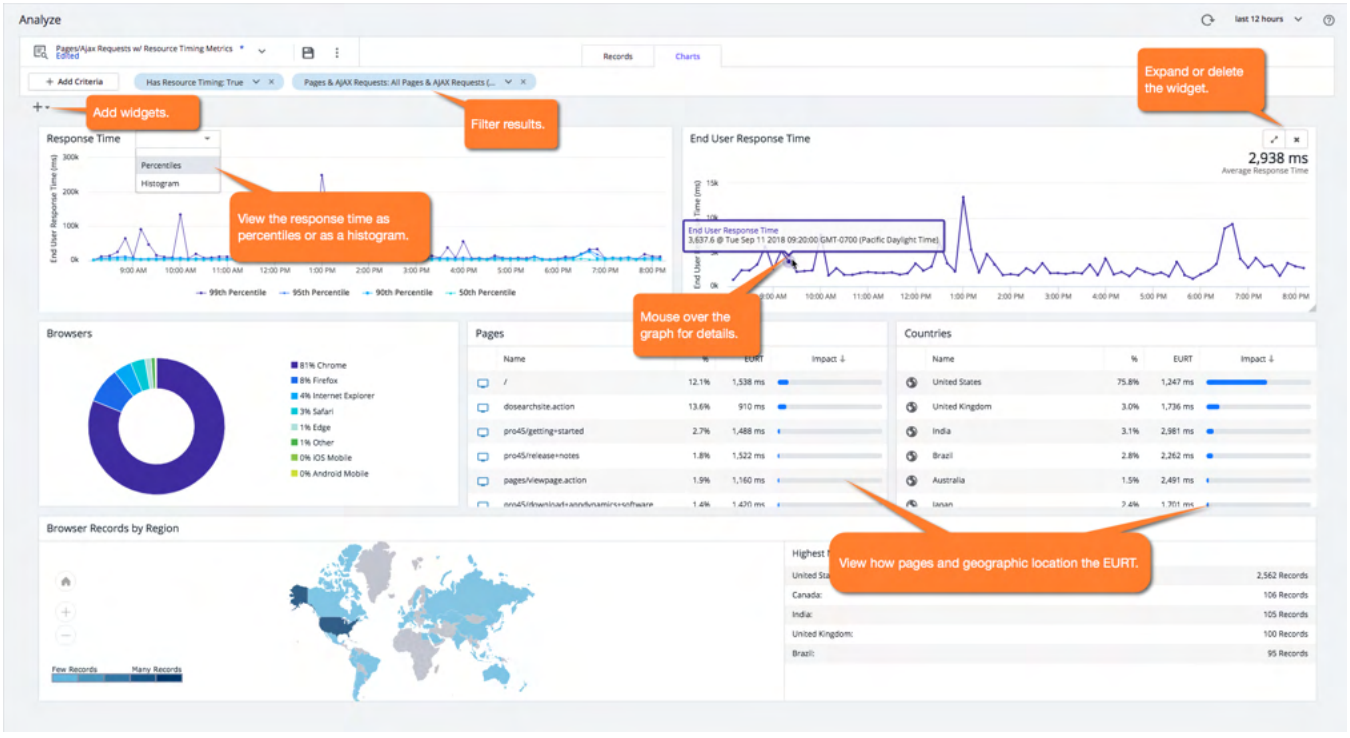
After you click **View Details**, you see the details of a particular request as a page with a browser session in the **Session Details** dialog.



Charts

The Charts tab provides you with a set of predefined widgets that offer visualizations of the data set you have created.

You can quickly see how pages, browsers, and geographic location (such as, dimensions) affect the end user response time (EURT). You can also delete, re-add, resize, and drag-and-drop to move all of the widgets.



The time series widgets such as **Response Time** and **End User Response Time** use median values, not averages.

Request Number Differences in Browser Analyze and Pages & AJAX Requests

The number of requests for a page over a period of time should be the same in **Pages & AJAX Requests** and **Browser Analyze**, but they may vary for these reasons:

- If there are fewer requests given in **Browser Analyze**, the Events Service, which is responsible for the data in **Browser Analyze**, has probably not received all of the records yet. To verify this, compare the time of the last request for the page in **Browser Analyze** and **Pages & AJAX Requests**. The latter will most likely have a later timestamp.
- If there are more requests given in **Browser Analyze**, it's possible that the reason is because error records are included in the total number of requests in **Pages & AJAX Requests**, but listed separately in **Browser Analyze**. The errors are listed separately in **Browser Analyze** to enable you to investigate and understand the cause of the error.

Browser Analyze versus Browser Request Analytics

The data shown on the **Analyze** page is processed and stored by the AppDynamics Platform Events Service. The **Charts** tab displays a set number of widely used chart types to let you explore your application's performance. A separate product, AppDynamics Application Analytics, has a component called Browser Analytics. This component is based on the same Events Service and uses the same data, but it offers additional capabilities, including:

- Additional predefined widgets, such as the funnel widget
- ADQL for searching the data
- Creating custom widgets
- Manipulating multiple dashboard types
- Longer retention time for data storage

Browser Analytics requires a license separate from the Browser RUM license.

To reduce noise in data stored in the Event Service, Ajax calls from the following tracker domains are no longer published to the Events Service:

- `.mixpanel.com`
- `.google-analytics.com`
- `.altocloud.com`
- `.optimizely.com`
- `inspectlet.com`

Configure the Controller UI for Browser RUM

You can enable or disable Browser RUM with the **Browser Monitoring** toggle.

You can manage how Browser RUM information is displayed in the Controller UI, including:

- The display names for your pages, Ajax requests, and iframes
- The display names for your virtual pages
- The errors that should be shown in the UI, and the ones that should not be shown

You can also configure:

- The thresholds for slow, very slow, and stalled transactions
- When browser snapshots should be taken
- Percentile levels you would like to display, if any
- Which Ajax requests should be sent to the Event Service
- The session timeout period
- Whether to store request IP addresses or not

In addition, you can do the following:

- Choose a hosting option for the JavaScript Agent

To configure Browser RUM from the Controller UI, your user account must belong to a role that has the **Configure EUM** permission. See End User Monitoring Permissions for more information.

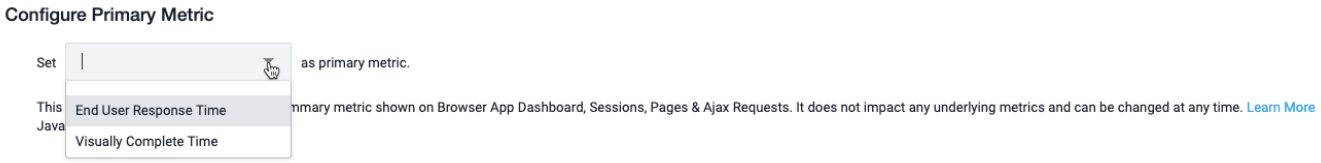
Access the Browser RUM Instrumentation Configuration

To access the instrumentation configuration for a browser app:

1. Open the browser application in which you are interested.
2. From the left-hand navigation menu, click **Configuration**.
3. From the **Configuration** page, click **Instrumentation >**.

Configure the Primary Metric

The primary metric is a way to customize your browser application widgets. The default primary metric is set to End User Response Time (EURT), but you can choose between EURT and Visually Complete Time (VCT). Once the primary metric is configured, the various dashboards, summaries, and charts will automatically update to show trending data for that configured metric. This allows you to view the EUM event timing that is most relevant to your business needs.



To configure the primary metric, go to **Configuration** > **Instrumentation** > **Settings**.

Available Metrics

You can set the primary metric to EURT or VCT. The default primary metric is EURT. EURT tracks the total amount of time for all content on a web page to be loaded. VCT tracks the total amount of time for all visual content to be loaded in the viewport. To see how EURT and VCT are calculated for SPA pages, see SPA2 Metrics.

Primary Metric Visibility

The primary metric is visible across several dashboards, charts, and summaries. The following screenshots are examples of primary metric visibility when configured to VCT.

Configure Page Identification and Naming

Related pages:

- Configure Virtual Page Naming
- Page, Ajax, and Iframe Dashboards
- Set Custom Page Names

You can configure the display names by which various pages and iframes are referred to and sorted in Controller lists and dashboards.

You can:

- Use the AppDynamics default naming rule, which you can leave as is or modify.
- Create custom include rules to override the default convention.
- Create custom exclude rules to exclude from monitoring pages that meet certain criteria.
- Disable the default naming configuration and use only your custom include rule(s).

On this page, the term "pages" includes iframes and base pages.

No matter how the page is named, AppDynamics always reports the page name in lowercase.

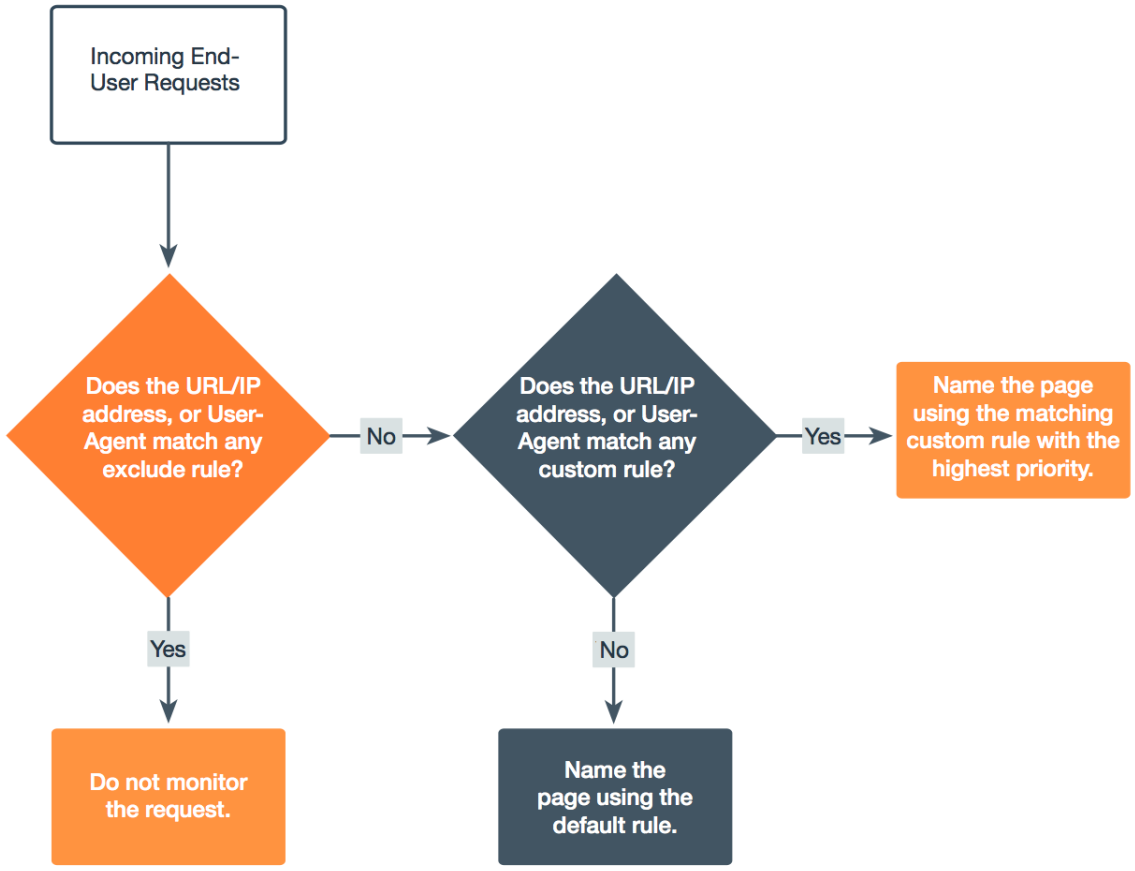
Access Exclude/Include Rules

1. Open the browser application in which you are interested.
2. On the left navigation bar, click **Configuration.**
3. Click **Instrumentation >**.
4. From the Base Page and iFrames tab, you can define include/exclude rules or modify the **Default Naming Configuration**.

To save any configuration changes, click **Save**.

Evaluation Logic for Exclude/Include Rules

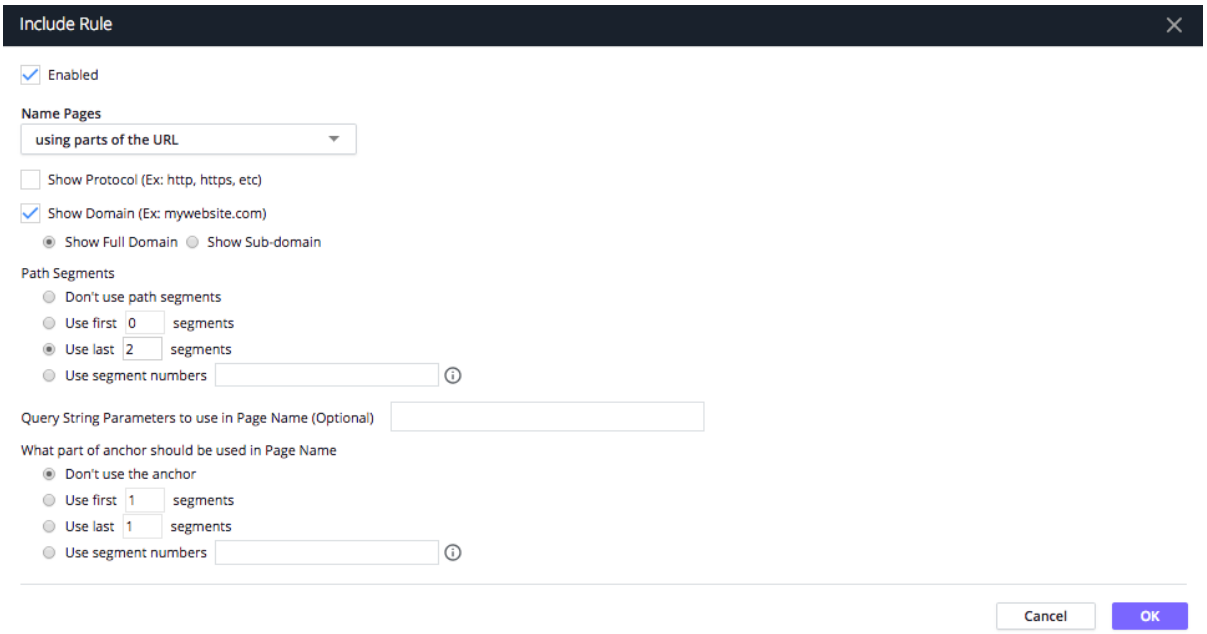
This is the order in which AppDynamics evaluates the page naming rules.



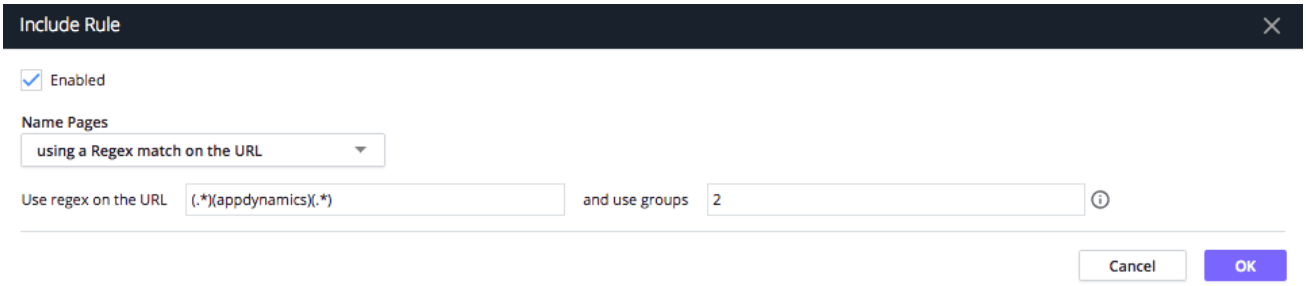
Default Page Naming Rules

If you enable the default naming configuration and do not modify it, AppDynamics identifies and names your pages using the first two segments of the page URL.

You can modify the default configuration by double-clicking **Default Naming Configuration** in the **Include Rules** section. This opens the **Include Rule** popup, where you can select the dropdown list **using parts of the URL** to include the protocol or domain in the name, use different segments of the URL, or include query parameters or anchors in the name.



You can also choose the dropdown **using a Regex match on the URL** to match page names by running a regular expression.



If you do not want to use the default convention at all, disable it by clearing the **Enabled** checkbox. In this case, you must configure at least one custom page naming rule so that AppDynamics can identify and name pages.

Custom Include Rules

You can create custom include rules for identifying and naming pages.

To create a custom include naming rule, from the **Include Rules** section, click **Add**. Then you use the same **Include Rule** popup to configure the custom include rule to identify and name the page.

The order of the include rules in the list determines the priority of the rules: The rules at the top are evaluated first, and the rules at the bottom are evaluated last. You cannot change the priority of **Default Naming Configuration**, but you can modify or disable it.

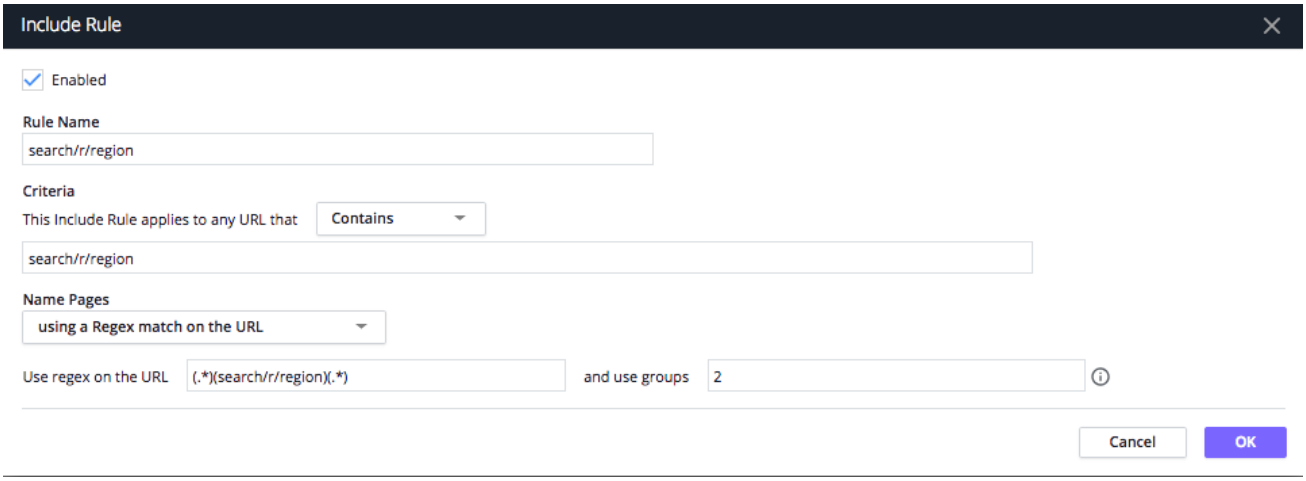
Guidelines for Using Regular Expressions in Include Rules

When using regular expressions to match URLs in your include rules, you should note the following:

- URL strings are case-sensitive. So, although the page names displayed in Pages & Ajax Requests are converted to lowercase, your regular expressions still need to match the case used in URLs that your include rule are trying to capture.
- Your regular expression should match the entire URL, from beginning to end, not just a section; otherwise, the rule will not match. This differs from using regular expressions in custom match rules for naming transactions, which only need to match sections of the URL.
- Beacons for older browsers (primarily Internet Explorer 6-8) are sent using image requests, and therefore, have an inherent length limitation. To manage this limitation, Browser RUM does not support URLs longer than 180 characters, page names longer than 50 characters, and user data longer than 128 characters for these browsers.

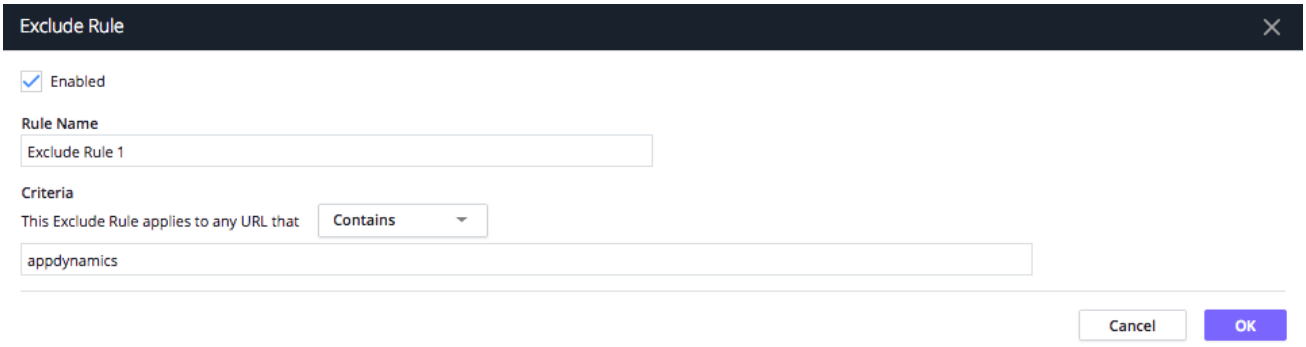
Example Include Rule

Suppose you have multiple pages that include the string `search/r/region` in their URLs, such as `search/r/region01`, `search/r/region23`, etc., and you want to name all the pages from that set as a single-page named `search/r/region`. By selecting the dropdown **using a Regex match on the URL**, you can enter a regular expression to remove the domain name and the number at the end of the URL, grouping all your `/search/r/region` URLs into one set. Because all the URLs contain `search/r/region`, AppDynamics now collects information for them all under the single-page name `search /r/region`. Otherwise, AppDynamics uses the default page naming rule or a rule with higher priority.



Custom Page Exclude Rules

You can configure custom exclude rules for pages in the same way you configure include rules. Any page with a URL matching the configuration is excluded from monitoring.



Configure Naming for Ajax Requests

Related pages:

- The Pages & Ajax Requests View
- Configure Page Identification and Naming
- Page, Ajax, and Iframe Dashboards
- Set Custom Page Names

You can configure the display names by which Ajax requests are referred to and sorted in controller lists and dashboards.

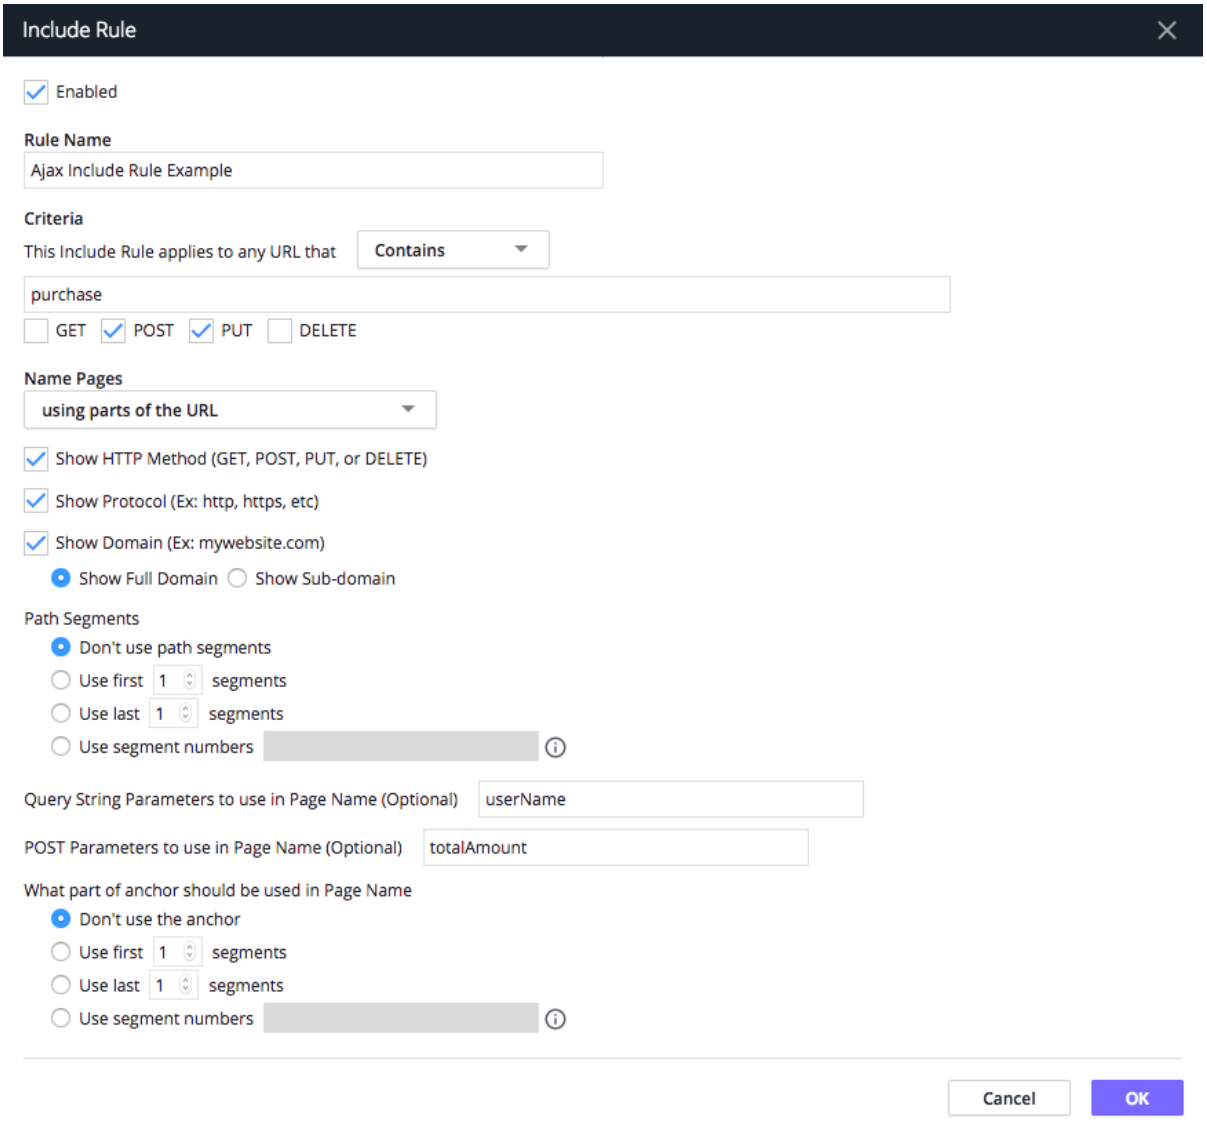
Access Naming Rules for Ajax Requests

1. Open the browser application in which you are interested.
2. On the left navigation bar, go to **Configuration** > **Instrumentation** > **AJAX** > **Monitor.**

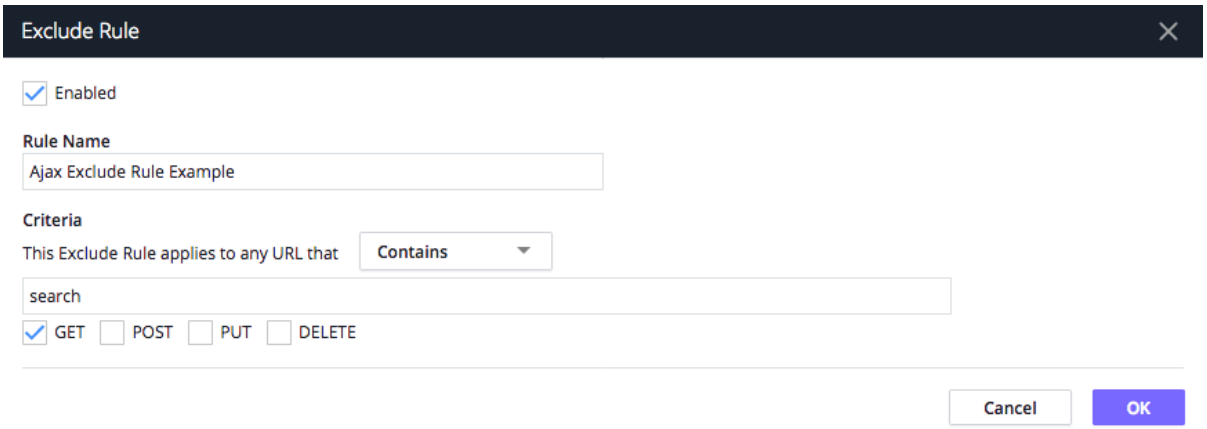
Naming Rules for Ajax Requests

The logic for naming Ajax requests is nearly identical to that for naming virtual pages in that they can use anchors (the part of the URL after the #) to distinguish among Ajax requests. In these cases, using the **What part of anchor should be used in page name** section allows you to specify which Ajax request is being accessed correctly. The difference in naming rules for Ajax requests is that you can also specify the HTTP method(s) to filter in the rule.

For example, the Ajax naming include rule below specifies the HTTP methods POST and PUT and is configured to show the HTTP method in the results displayed in the Controller UI:



You can also create exclude rules that specify which Ajax requests to filter based on the specified HTTP method(s) as shown here:



Exclude Rule
Enabled
Rule Name
Ajax Exclude Rule Example
Criteria
This Exclude Rule applies to any URL that
Contains
search
GET
POST
PUT
DELETE
Cancel
OK

Configure Which Ajax Requests Are Sent to the Events Service

Modern web pages often include a large number of Ajax requests. Not all of these Ajax requests may be equally important to monitor, but they all equally affect license entitlements and restrictions. Thus, you may want to configure which Ajax requests are sent to the Events Service to manage the impact on your overall Events Service usage.

To do this, you can create rules to specify the requests to be sent to the Events Service, either by excluding a request entirely, including a particular request or a sample of that request types by percentage or by just allowing the request to be sent. In general, the behavior follows this pattern:

- If no rules are specified, no data on Ajax requests is sent.
- If exclude rules are specified, and an Ajax request satisfies a rule, that data is *not* sent.
- If include rules are specified, any Ajax request that satisfies a rule is sent, based on sampling defined by the percentage indicated in the rule.
- If both include and exclude rules are specified, an Ajax request that satisfies an include rule but does *not* satisfy an exclude rule is sent.
- If you *only* configure exclude rules and the sample percentage, the non-excluded calls would be sampled at the specified rate.

See Configure Page Identification and Naming for more information about default naming rules and how rules are evaluated.

Access Ajax Requests Rules

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation** >.
4. Select the **Ajax** > **Events Service** tab.

Configure Exclude Rules

1. Click **Add** to create a new rule. The **Exclude Rule** popup appears.
2. Specify a display name for the rule.
3. Check **Enabled** to enable the rule.
4. Enter a string and select one of the options in the dropdown to match the URLs that you want to exclude from the Ajax requests.
5. Click **OK** to save the rule.

Configure Include Rules

1. From the **Events Service Include Rules** section, click **Add** to create a new rule. The **Include Rule** popup appears.
2. Give your rule a display name.
3. Check **Enabled** to enable the rule.
4. For **Criteria**, enter a string and select one of the options in the dropdown to match URLs for including Ajax requests.
5. Configure how to name pages:
    - Select one of the options from the dropdown to determine the part of the URL.
    - Select the path segment.
    - Enter the query string to use in the page name.
    - Select the part of the anchor (or none) to use in the page name.
6. Click **Save**.

Configure Virtual Page Naming

Related pages:

- The Pages & Ajax Requests View
- Page, Ajax, and Iframe Dashboards
- Set Custom Page Names

Web applications built using Single Page Application (SPA) principles minimize network traffic by transferring computing work for creating what the user sees to the browser. The initial page request downloads necessary data for constructing the application, with some possible exceptions. For example, HTML partials and fragments may be fetched dynamically from the backend in response to user interaction.

The individual views that the user sees are known as virtual pages. Browser RUM supports virtual pages created using the AngularJS framework, sometimes known simply as Angular.

In AngularJS, a virtual page is an individual view, comprised of the rendered template of the current route in the context of the main layout file. You can configure how AngularJS virtual pages are referred to and sorted in UI lists and dashboards. For more information on using Browser RUM with virtual pages, see AngularJS Support.

Access Virtual Page Naming Rules

1. Open the browser application in which you are interested.
2. On the left navigation bar, click **Configuration**.
3. Click **Instrumentation >**.
4. Select the **Virtual Pages** tab.

Virtual Page Naming Rules

The logic for naming virtual pages is identical to that for naming regular pages, with one exception. Because AngularJS pages can use anchors (the part of the URL after the #) to distinguish among virtual pages, in these cases, using the **What part of anchor should be used in page name** section allows you to specify which virtual page is being accessed correctly.

Configure JavaScript and Ajax Error Detection

Related pages:

- Set Up and Access Browser RUM
- Browser Snapshots

You can enable and disable reporting of JavaScript and Ajax request errors. When enabled, the Browser Monitoring UI reports Ajax request errors in the following places:

- **Geo Dashboard**
- **User Stats** page and device dashboards
- Page list
- Browser snapshots

Also, you can configure which errors are included in the error count by specifying the errors to "ignore". You can specify errors to ignore by:

- The script and/or error message
- Page
- URL

"Ignored errors" are not actually ignored. They are still tracked, but the error count in the places where error totals are reported on the user interface is not incremented.

Access Error Detection Rules

1. From the browser application you are interested in, click **Configuration**.
2. Click **Instrumentation >**.
3. Select the Errors tab.

Enable and Disable Browser RUM Error Detection

In the Errors tab:

- Check/clear the **Enable JavaScript Error Capture** checkbox to enable/disable JavaScript error display.
- Check/clear the **Enable AJAX Request Error Capture** check box to enable/disable Ajax error display.

When both checkboxes are clear, no JavaScript or Ajax request errors are displayed.

Even if capture is enabled globally, you can configure certain errors to be ignored so that they are not counted in the error totals.

Configure Rules to Ignore Errors based on Script or Error Message

You can configure the agent to ignore specific JavaScript errors that are identified by:

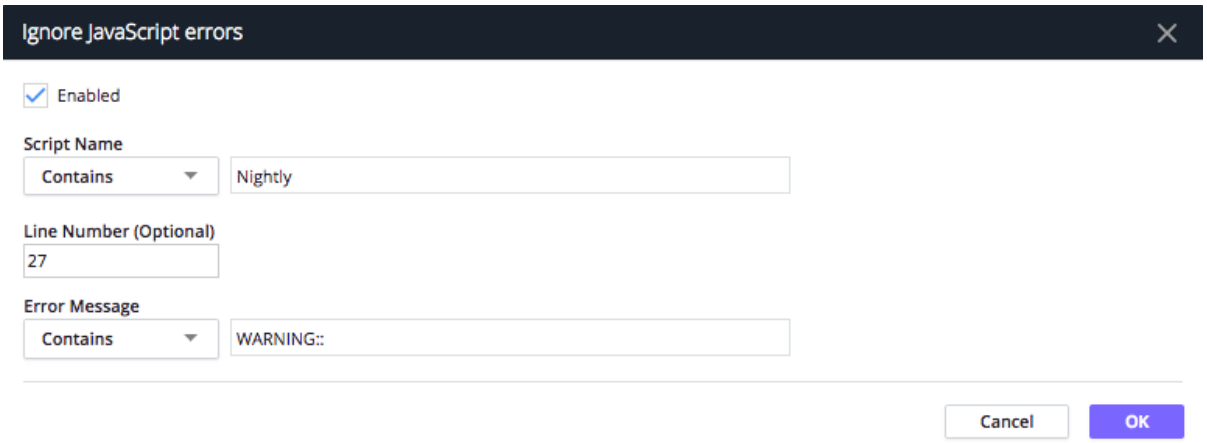
- a matching string pattern in the name of the script that generated the error
- the line number in the script
- a matching string pattern in the error message

You can specify one, two, or all three of these criteria. Configure more criteria to increase the granularity of which errors you ignore.

Add Rules to Ignore Errors

From the **Ignore JavaScript Error Rules** section, click **Add** to open the **Ignore JavaScript Errors** popup. From there, you can enable the rule, specify the script name, line number, and optionally, the error message.

For example, the following configuration in the **Ignore JavaScript errors** section where all three fields are specified means "Ignore all errors generated by line 27 of a script whose name starts with "Nightly" and whose error message contains the string "WARNING::".



If the line number were not specified (e.g., set to 0), the configuration would mean "Ignore all errors generated any line of a script whose name starts with "Nightly" and whose error message contains the string "WARNING::".

If neither the line number nor the error message field was specified, the configuration would mean "Ignore all errors generated by any line of a script whose name starts with "Nightly".

If the error message were the only field specified, the configuration would mean "Ignore all errors generated by any script when the error message contains the string "WARNING::".

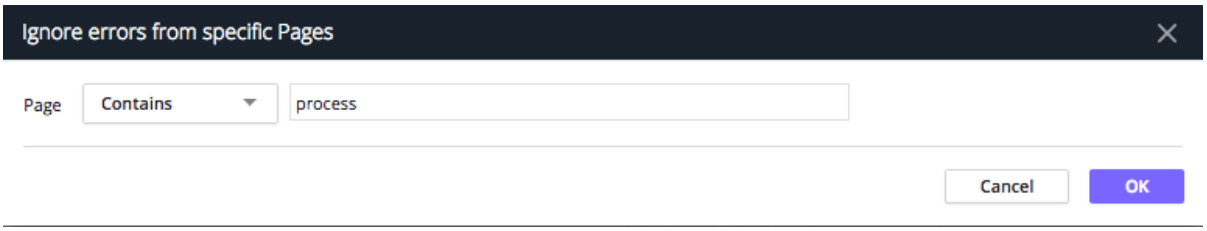
Modify Rules

To modify an existing ignore rule, you can either double-click the rule in the list or select the rule and then click **Edit** from the dropdown. To remove an ignore rule, select the rule in the list and then click **Delete** from the dropdown.

Configure Rules to Ignore Errors by Page

You can also ignore all errors generated by a specific page, iframe, or Ajax request.

From the **Ignore Errors from these Pages** section, click **Add** to open the **Ignore errors from specific Pages** popup, where you can create a rule for every page for which you want to ignore all errors.

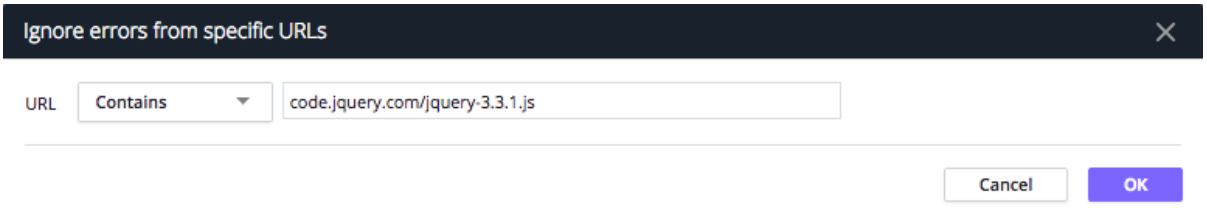


To remove an ignore rule, select it in the list and click **Delete** from the dropdown.

Configure Rules to Ignore Errors by URL

You can ignore all errors generated by a specific URL.

From the **Ignore Errors from these URLs** section, click **Add** to open the **Ignore errors from specific URLs** popup, where you can create a rule for every URL for which you want to ignore all errors.



To remove an ignore rule, select it in the list and click **Delete** from the dropdown.

Configure Browser RUM Performance Thresholds

You can configure the thresholds that define slow, very slow, and stalled end-user requests. These thresholds are used to trigger browser snapshots. See Transaction Thresholds for a detailed discussion about static, dynamic, percentage, and standard deviation thresholds.

You can define Browser Monitoring thresholds as one of the following:

- a multiple of the standard deviation. The default standard deviation threshold duration is two hours. For example: "Experience is slow if end-user response time is slower than 3 X the standard deviation."
- a static value; For example: "Experience is stalled if end-user response time is slower than 30000 ms."

The default thresholds are:

- Slow = 3 x standard deviation
- Very Slow = 4 x standard deviation
- Stalled = 45000 ms

Access Browser RUM Threshold Rules

1. Open the browser application in which you are interested.
2. On the left navigation bar, click **Configuration**.
3. Click **Instrumentation >**.
4. From the Settings tab, find the **Thresholds for Slow End User Experience** section.

Configure Browser RUM Threshold Rules

1. Select the relevant radio button to indicate whether the threshold is based on standard deviations or static values.
2. Type the values in the fields or select them using the scrollbars for one or more of the following:
    a. **Slow greater than**
    b. **Very slow greater than**
    c. **Stall greater than**
3. Click **Save**.

Configure Browser Snapshot Collection

Related pages:

- Browser Snapshots
- Set Up and Access Browser RUM

Every page view and AJAX request sends a beacon to the EUM server. Every minute, the EUM server evaluates the collection of beacon samples and sends what are called "snapshots" to the Controller.

With browser snapshots, you can enable or disable:

- Slow snapshot collection, that is snapshots of requests where the End User Response Time is higher than the configured threshold.
- Periodic snapshot collection.
- Error snapshots, that is snapshots of requests for which a JavaScript error is reported or an Ajax request receives an HTTP error response. An error response is any HTTP code equal to or greater than 400.

If all three kinds of browser snapshot types—periodic, error, and slow response time—are disabled, the agent does not collect any browser snapshots.

Access Snapshot Collection Rules

1. Open the browser application in which you are interested
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation >**.
4. Select the Settings tab.
5. Find the **Event Policy Configuration** section.

Configure Snapshot Collection Rules

1. Check or clear the checkbox for one or more of the following:

- **Enable Slow Snapshot Collection** to enable/disable slow response time snapshot collection.
- **Enable Periodic Snapshot Collection** to enable/disable periodic snapshot collection.
- **Enable Error Snapshot Collection** to enable/disable error snapshot collection.

2. Click **Save**.

Configure Web Percentile Metrics

Related pages:

- Browser App Dashboard
- EUM Data

Parts of the Controller UI for Browser RUM rely on the processing done by the Events Service, including some of the widgets in the **Browser App Dashboard** and the **Analyze** page. For these metrics, you can choose to display either averages or percentiles.

A percentile is a measure that indicates a value below which a given percentage of values in a set falls: for example, the 99th percentile means that 99% of all values are below this level. Using percentiles can be a good way to reduce the impact of extreme outliers in performance metrics, which can be useful in the often noisy environments of end-user monitoring. The Metric Browser also displays the percentiles.

You can:

- Enable/disable percentile metric display
- Set up to four different percentile levels to be applied to metrics

Access Configure Percentile Metrics

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation >**.
4. Select the **Settings** tab.
5. Find the **Configure Percentile Metrics** section.

Configure Percentile Metrics

1. Check the **Enable Percentile Metrics** checkbox.
2. Enter up to four percentile levels to collect in the **Percentiles to Collect** fields. Each value must be a whole number between 1 and 99.

Configure Session Monitoring Timeouts

You can control the timeframe for browser sessions by setting an inactivity limit. No activity beyond this limit is connected to previous activity as part of an individual session. See Session Persistence to learn more about how the duration of a session is determined.

Access Session Monitoring

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation >**.
4. Select the Settings tab.
5. Find the **Configure Session Monitoring** section.

Set Inactivity Timeout

From **Configure Session Monitoring**, set the number of minutes for the **Session Inactivity Timeout** field.

Configure Request IP Address Storage - Browser

For security and privacy reasons, Browser RUM does *not* store source IP addresses associated with requests. To have Browser RUM store IP addresses associated with requests, follow the instructions below.

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation >**.
4. Select the Settings tab.
5. At the bottom of the Settings tab, check the **Store IP Address** checkbox to enable IP address storage. (By default, the box is *not* checked.)
6. Click **Save**.

Monitor Single-Page Applications

Browser RUM's single-page application (SPA) monitoring enables you to:

- Monitor the performance/throughput of user experiences of SPAs.
- Troubleshoot and resolve SPA problems within the context of the page load.
- Assist with business decisions by analyzing SPA data through analytics.
- Enable developers to quickly ship better web applications to the marketplace.

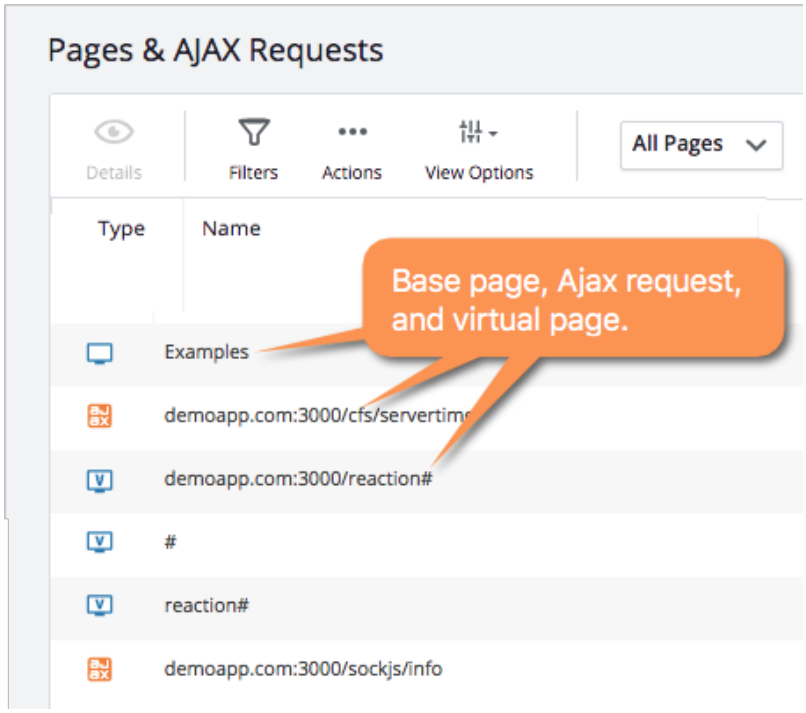
What Is SPA?

A single-page application (SPA) is a web technology and design paradigm that reduces browser-level page loads by using JavaScript to fetch resources and build pages. This creates a smoother, faster user experience more similar to a desktop or mobile application than a traditional web page. React and Angular are two popular JavaScript frameworks used to create SPAs.

Base Pages vs. Virtual Pages

When a user navigates to a SPA, the initial page download is considered the "base page." The base page includes the HTML skeleton, the core CSS, and the JavaScript framework for fetching and constructing new content. The ensuing pages are constructed from resources downloaded with the base page or fetched dynamically from the backend in response to user interaction. This new content (or views) constructed from different sources by the SPA are called "virtual pages."

For SPAs, you will have base pages, virtual pages, and Ajax requests. From **Pages & AJAX Requests**, you are able to view all three types and details for each as shown below.



SPA1 and SPA2 Monitoring

Until 4.4.3, Browser RUM only provided auto-instrumentation for AngularJS 1 SPA applications. For other frameworks, you had to manually report events with the JavaScript Agent API. This limited auto-instrumentation for SPA is known as *SPA1 monitoring*.

From JavaScript Agent >= 4.5.16, Browser RUM has been certified for Angular 1-9. This support for the auto-instrumentation for all SPA frameworks is known as *SPA2 monitoring*.

This table describes the support for SPA1 and SPA2 monitoring:

SPA Monitoring Version	Auto-Instrumentation	Metrics	JavaScript API

SPA1	AngularJS 1 only	• **Base / Virtual Pages:** Browser RUM page timing metrics • **Ajax Requests:** All available Ajax metrics	Yes
SPA2	All SPA frameworks. Auto-instrumentation is certified for React and Angular 1-9 (JavaScript Agent >=4.5.16.	• **Base pages:** Browser RUM page timing metrics, including End User Response Time (EURT), Visually Complete Time (VCT), and Page Complete Time (PCT) • **Virtual Pages:** End User Response Time (EURT), Visually Complete Time (VCT) • **Ajax Requests:** All available Ajax metrics	Yes

Which SPA Monitoring to Use?

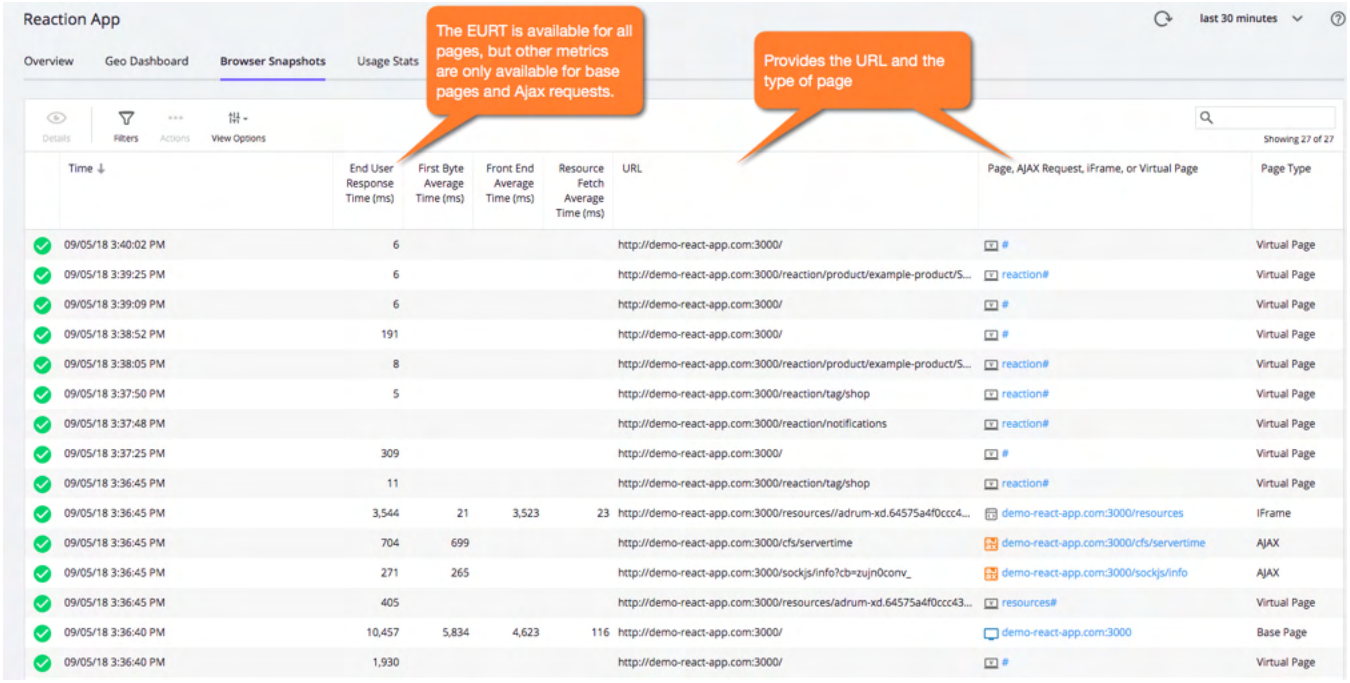
In general, you are highly recommended to use SPA2 monitoring. For most applications, the JavaScript Agent using SPA2 monitoring identifies the SPA transitions deterministically and captures the metrics and resources correctly without you having to write any special configuration or call methods from the JavaScript Agent API. If your SPA applications are built with AngularJS 1, you can simply add some configuration to enable auto-instrumentation.

View SPA2 Monitoring Data

Throughout the Controller, you can view SPA2 Metrics in various EUM dashboards in the Controller. You can also Configure the Primary Metric to choose a default displayed SPA2 metric for Browser RUM dashboards and widgets.

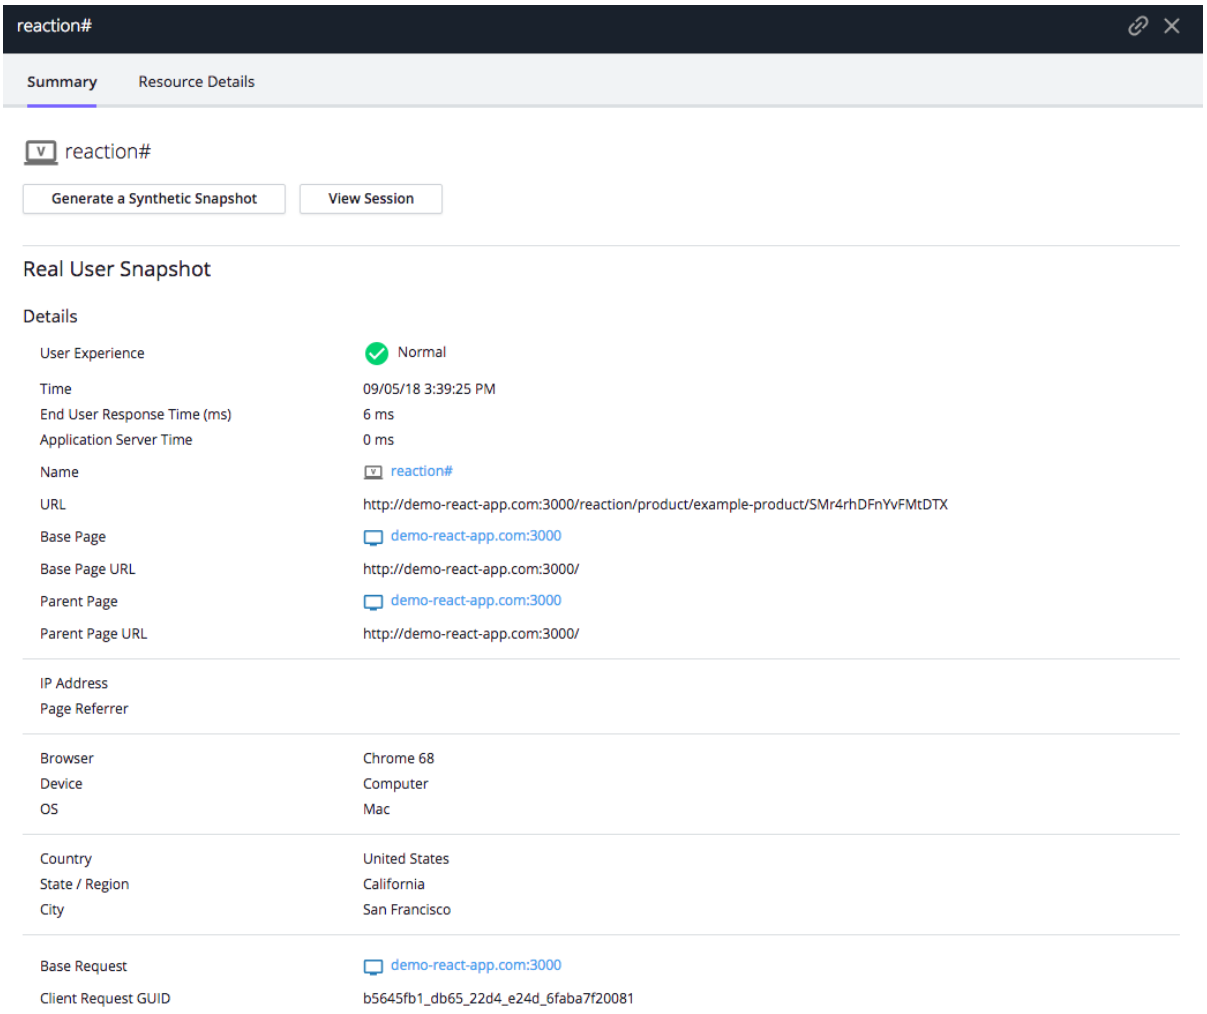
Browser Snapshots

The Browser Snapshots tab displays a list of different types of pages as shown below. You can view relevant metrics for all the pages and other metrics for base pages and Ajax requests.



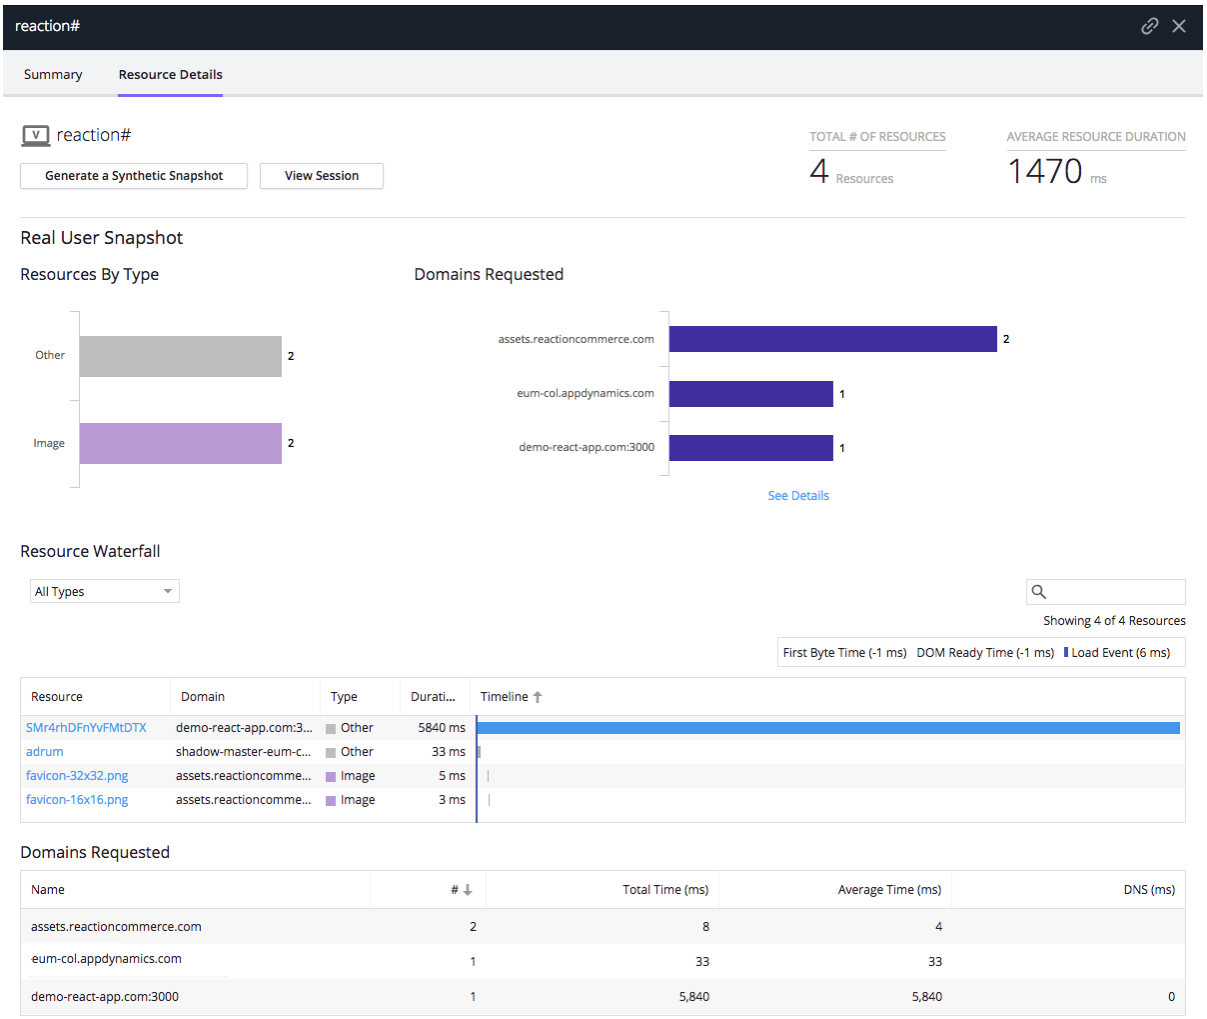
Snapshot Details: Summary

To access the **Snapshot Details** dialog shown below, you double-click one of the browser snapshots in the **Browser Snapshots** page. The Summary tab is the default tab for the dialog, and it gives some additional information such as the parent page URL.



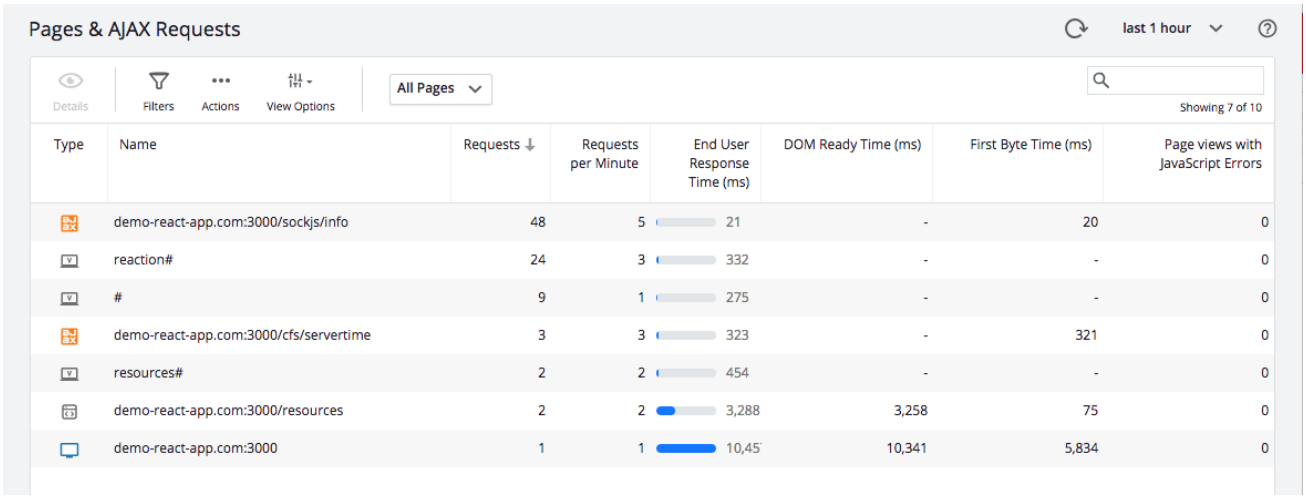
Snapshot Details: Resource Details

The Resource Details tab shown below provides details about resources such as the number and type of resources, the domains where the resources were requested, and resource load times.



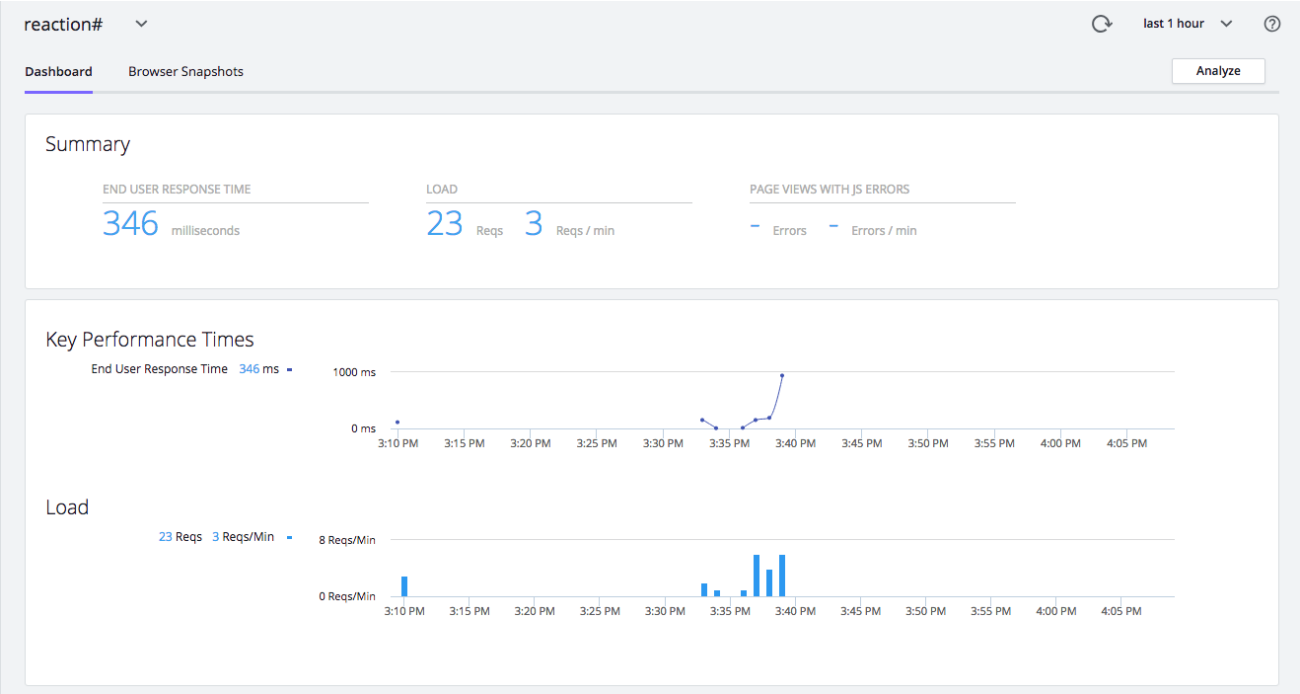
Pages & AJAX Requests

The **Pages & AJAX Requests** page as shown below enables you to view the number of requests for each type of page and the average metrics per page. You can also select which page types to view, such as virtual pages.



Page, Ajax, and Iframe Dashboards

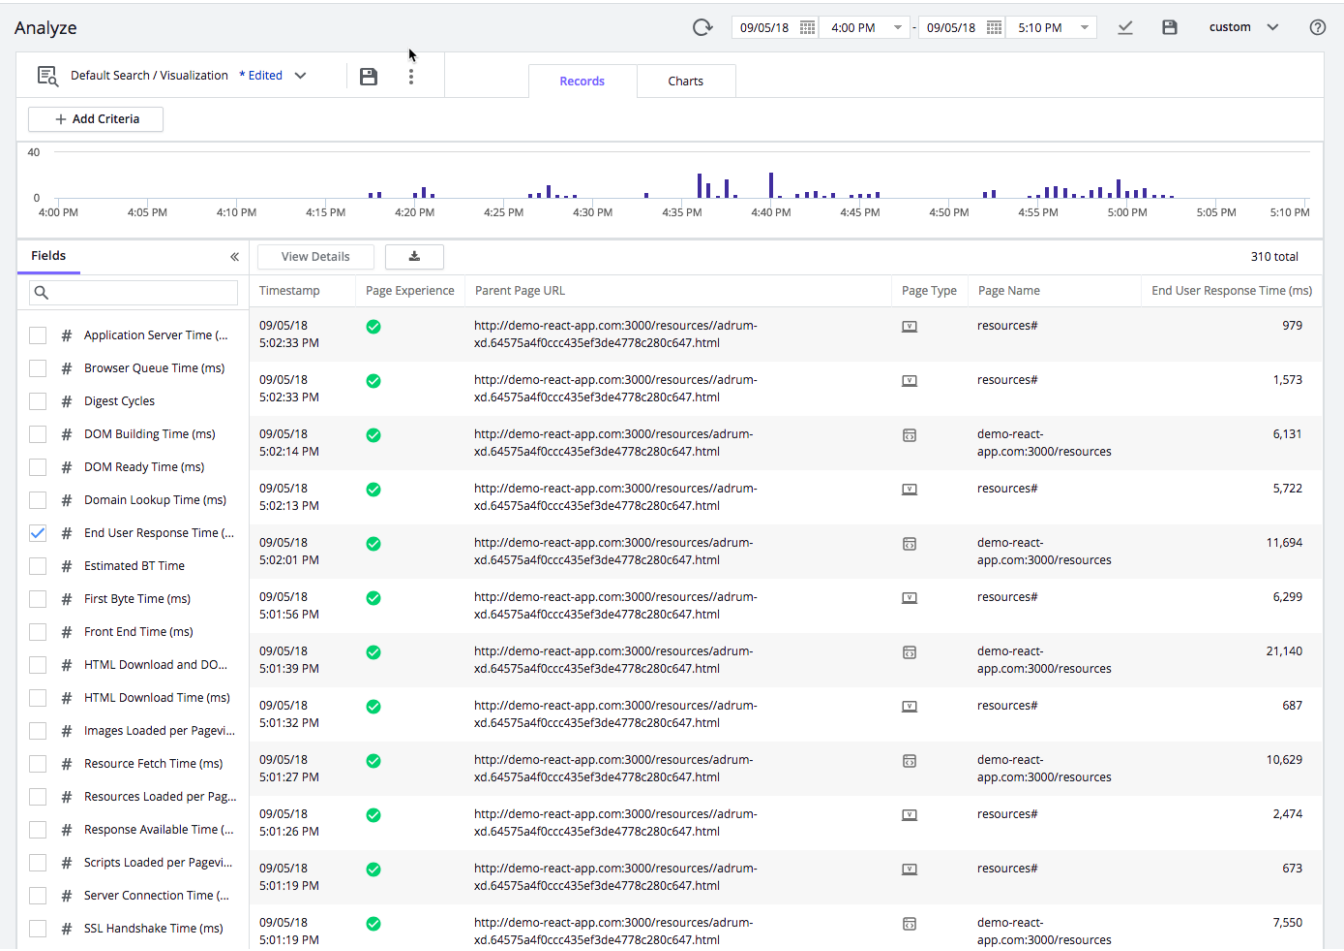
From the **Pages & AJAX Requests** page, you can double-click a page to view the Page and IFrame Dashboards. Dashboards for each page type will have a **Summary** section displaying the average metrics as well as a **Key Performance Times** section showing the requests and the metrics on a timeline**.**



The tabs below show the differences in the dashboard for each page type.

Browser Analyze

From **Browser Analyze**, you can filter by criteria, such as page types shown in the screenshot below, and configure the fields you want to view.



SPA1 Monitoring

We recommend you use SPA2 Monitoring for all SPA frameworks, especially Angular 1–5 and React.

This page describes how to use SPA1 monitoring for AngularJS 1 applications and manually report events for Ember.js applications. This page also provides information about the AngularJS 1 support for SPA1 monitoring.

SPA Requirements

- IE 10 and Edge is supported. IE >=10 and Edge *cannot* be in compatibility mode with <=IE 9 browsers.
- For non-AngularJS frameworks, the JavaScript Agent >=4.2 is required.

Manual Injection for Angular 1.x Applications

For non-Angular applications, `adrum.js` needs to be loaded before any other JavaScript on the page. When you are using AngularJS 1, however, you need to inject `adrum.js` after `angular.js`, but before `angular.js` is bootstrapped.

To learn which Angular versions have monitoring support, see Monitoring Support for AngularJS.

Manual Injection for Ember.js Applications

For Ember.js applications, you manually inject the JavaScript Agent much in the same way you would do for web pages loaded from an HTTP request. To monitor virtual pages, you manually start and end Virtual Page events based on events triggered when pages are dynamically created. You can also monitor virtual pages to report errors for pages.

The following sections will show you how to inject the JavaScript Agent and monitor virtual pages.

Manual Injection of the JavaScript Agent

The file `app/index.html` is the HTML skeleton for all dynamics pages in Ember.js. Thus, you can inject the JavaScript Agent in this file so it is included in every page.

Monitor Virtual Pages

When a user requests a new page, the route handler renders the associated template to form the new content of the virtual page. You can listen for events in the route handler indicating when the handler is started and completed, which in effect mark the lifetime of the virtual page. To monitor the virtual page, you start a Virtual Page Event when the `activate` event is triggered, close the Virtual Page when the `deactivate` event is triggered, and then report the completed virtual page.

The code snippet below listens to the `activate` and `deactivate` events and reports the created virtual page event.

```
import Ember from 'ember';
import config from '.././config/environment';

export default Ember.Route.extend({
  beforeEnterAbout: Ember.on('activate', function(){
    console.log('hello about');
    config.aboutVpView = new ADRUM.events.VPageView();
    config.aboutVpView.start();
  }),
  afterEnterRental: Ember.on('deactivate', function(){
    console.log('goodbye about');
    config.aboutVpView.end();
    ADRUM.report(config.aboutVpView);
  })
});
```

Use Virtual Pages to Capture Errors

You can also create actions in the routing handlers that can be monitored through virtual pages. For example, you might want to monitor Ajax calls. You can create an action that performs the Ajax call and then use a Virtual Page event to capture the results and errors as shown in the code snippet below.

```
 actions: {
    makeXhrCall() {
      config.xhrVpView = new ADRUM.events.VPageView();
      config.xhrVpView.start();
      var xmlHttp = new XMLHttpRequest();
      xmlHttp.onreadystatechange = function () {
        if (xmlHttp.readyState === 4) {
          console.log(xmlHttp.responseText);
          config.xhrVpView.end();
          ADRUM.report(config.xhrVpView);
        }
      };
      xmlHttp.open("GET", "http://localhost:3000", true);
      xmlHttp.send(null);
    }
}
```

Monitoring Support for AngularJS 1

The JavaScript Agent supports monitoring by default for AngularJS versions 1.x.

Routing Engines

AngularJS 1 applications that have multiple Views use a *route* to move from one virtual page to another. You can use Browser RUM to instrument any virtual page that uses either of two routing engines, `ngRoute` or `ui-router`.

Metrics

Because virtual pages are constructed in the browser, normal page view metrics must be adjusted. In essence, what a metric for AngularJS 1 must do is correlate the time between various routing events, using their timestamps. Metrics are calculated as follows:

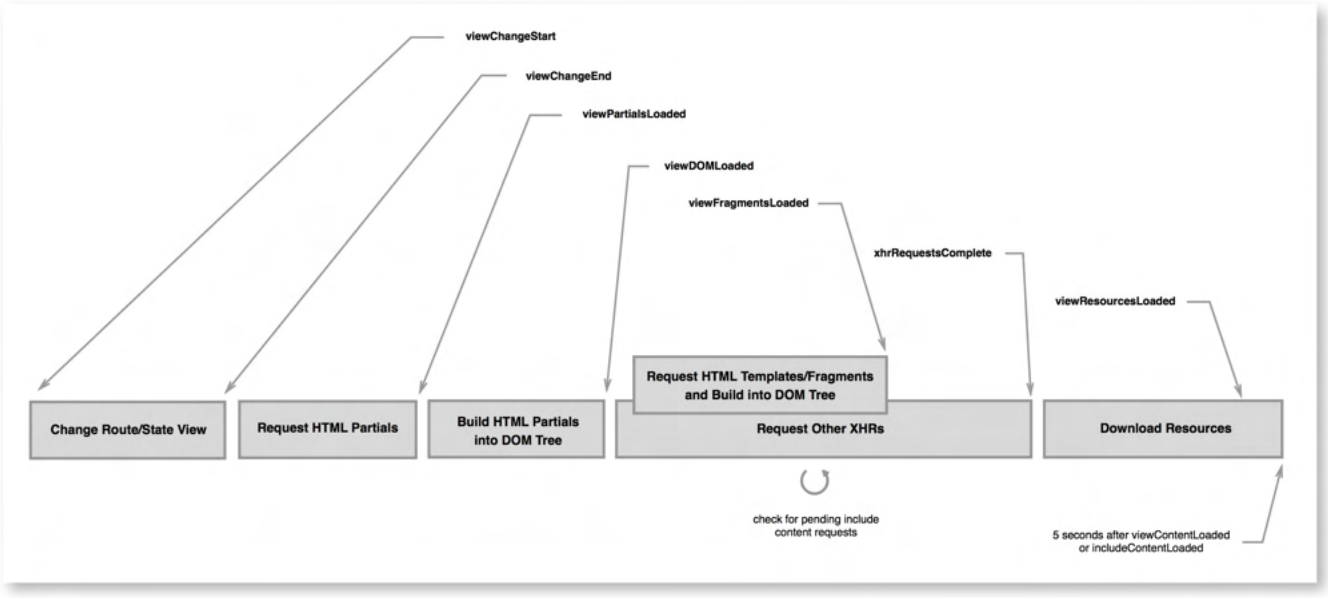
Full Metric Name	Short Metric Name	Calculation
End User Response Time (not used for waterfall UI)	PLT	`virtualPageStart` to `virtualPageEnd`
HTML Download Time	DDT	`viewChangeStart` to `viewChangeEnd`
HTML Download and DOM Building Time	DRT	`viewChangeStart` to `viewDOMLoaded`
DOM Building Time	DPT	`viewChangeEnd` to `viewDOMLoaded`
DOM Ready Time (used instead of PLT for waterfall UI)	DOM	`viewChangeStart` to `viewDOMLoaded`

Because the two routing engines function in slightly different ways, what the AppDynamics event consists of differs slightly, based on the engine.

AppDynamic Event Name	ngRoute Equivalent	ui-router Equivalent
`virtualPageStart`	`locationChangeStart`	`stateChangeStart`
`viewChangeStart`	`routeChangeStart`	`stateChangeStart`
`viewChangeEnd`	`routeChangeSuccess`	`stateChangeSuccess`
`viewDOMLoaded`	`viewContentLoaded`	`viewContentLoaded` (may happen multiple times - timestamp overwritten each time)
`viewFragmentsLoaded`	load time of the last HTML fragment	
`xhrRequestsCompleted`	response time of the last XHR requests	
`viewResourcesLoaded`	load time of the last resources	
`virtualPageEnd`	the latest one among `viewContentLoaded`, `xhrRequestsCompleted`, and `viewResourcesLoaded`	

Page Load Process Visualized

Visualized the page load process looks something like this:



Compare these to the standard page metrics, which are shown in Browser RUM Metrics.

Exclude Heartbeats or Background Requests from Timings

You may wish to exclude certain events from your virtual page timings. To do this, you can customize the JavaScript Agent when you inject it.

Add the following snippet *before* you add the JavaScript Agent file, `adrum.js`, to the page:

Option for excluding XHRs

```
<script type="text/javascript">
(function(config) {
   (function(spa) {
        (function(angular) {
            (function(vp) {
                vp.xhr = {
                    "exclude": {
                        "urls": {
                            pattern: '.*/dealActiveUsers'
                        }
                    }
                };
            })(angular.vp || (angular.vp = {}));
        })(spa.angular || (spa.angular = {}));
    })(config.spa || (config.spa = {}));
})(window["adrum-config"] || (window["adrum-config"] = {}));
</script>
```

Enable Resource Timing Collection for Virtual Pages

By default, Virtual Pages for AngularJS 1 do not include resource timing metrics. You need to set the Angular virtual page property `includeResTimingInEndUserResponseTiming` to `true`.

The JavaScript configuration below shows you how to enable resource timing collection for AngularJS 1 virtual pages. The configuration also sets limits for XHR calls per page, the buffer size for resource timings, and sets the flag for clearing resource timing metrics when a beacon is sent.

```
window['adrum-config'] = {
    "xhr": {
        "maxPerPageView": 10000
    },
    "resTiming": {
        bufSize: 300,
        "clearResTimingOnBeaconSend": true
    },
    "spa": {
        "angular": {
            "vp": {
                "metrics": {
                    "includeResTimingInEndUserResponseTiming": true
                }
            }
        }
    }
}
```

View Correlated Server Times

Since there isn't a regular HTML page timing to which correlated server timings can be linked, to view server times you must drill down from the Dashboard or Snapshot virtual page view to the component XHR requests. The server times can be seen there.

SPA2 Monitoring

For SPA2, you only need to set a flag to enable the JavaScript Agent to auto-instrument SPAs. When SPA2 auto-instrumentation is enabled, the JavaScript Agent:

- Detects virtual pages
- Measures the end-to-end time for virtual pages
- Correlates resources, JavaScript errors, and Ajax requests
- Names virtual pages

To enable SPA2 monitoring, see Configure SPA2 Monitoring.

How SPA2 Monitoring Works

The diagram below demonstrates how the JavaScript Agent defines the start and end points for the End User Response Time (EURT) metric and correlates with Ajax requests, resources, and JavaScript errors.

Step	Browser Activity	JavaScript Agent Actions
1	The user navigates to the base page of a SPA. The HTML skeleton, core CSS, and JavaScript are loaded into the browser.	The JavaScript Agent sends a beacon for the base page.
2	From the base page, the user clicks a button to view products. The URL changes as the virtual page is loaded through a combination of previously downloaded content and from new content fetched through Ajax requests.	The JavaScript marks the user action as the start time of the virtual page.
3	User actions and the browser activity cease for five seconds. The browser activity includes requesting resources, making Ajax calls, and so on.	The JavaScript Agent or your code using the JavaScript API marks the end time of the virtual page as the last time browser activity was seen after the URL changed. The JavaScript Agent then sends a beacon for the virtual page; however, if the virtual-page load stalls on one slow activity, the JavaScript Agent waits eight seconds before marking the end of the virtual page. Any activities such as Ajax requests, resource loads, and JavaScript errors that happened during the virtual page load will be correlated to that virtual page. There are some kinds of browser activities that aren't accessible to JavaScript. For example, the time that the browser takes render the DOM to the screen after the DOM has been updated. Therefore, if your virtual pages don't request any resources, you will likely see a very fast EURT (<10ms).

SPA2 Metrics

Browser RUM calculates metrics differently for base pages, Ajax requests, and virtual pages. The diagrams below demonstrate the differences between base page and virtual page metrics from the end-user perspective. See Browser RUM Metrics for metric definitions.

For base pages, Browser RUM calculates End User Response Time (EURT), Visually Complete Time (VCT), and Page Complete Time (PCT). For virtual pages, Browser RUM calculates EURT and VCT.

End User Response Time

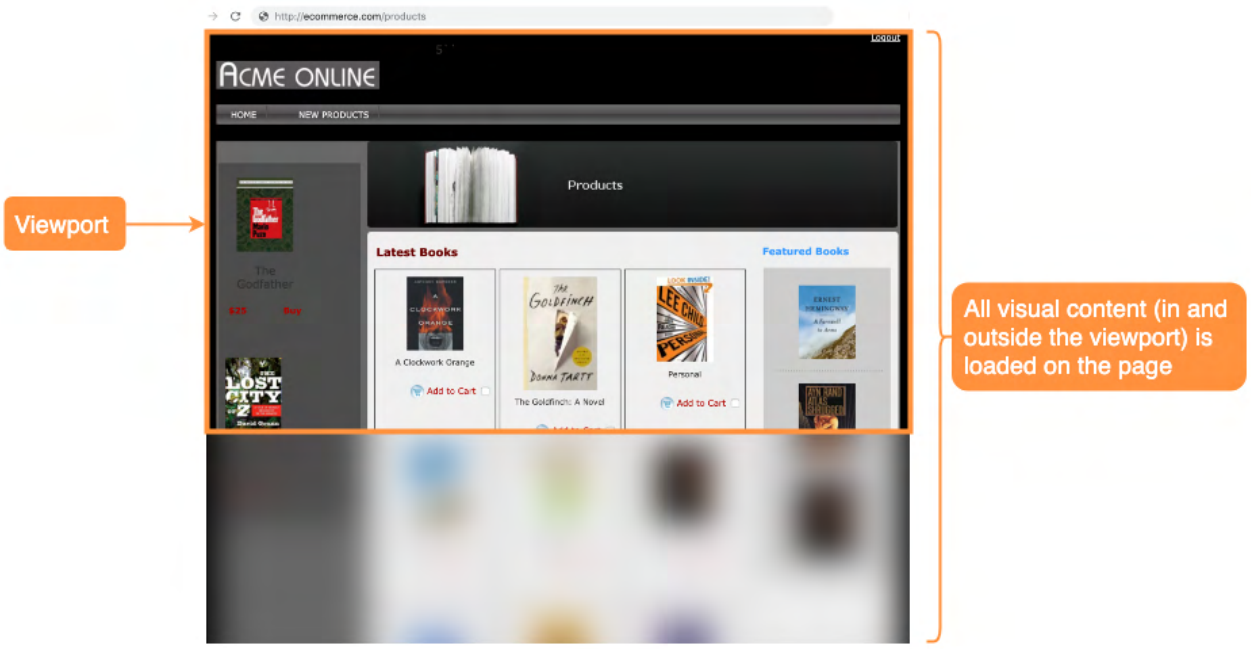
End User Response Time (EURT) calculates the total time for all content (visual and non-visual) to be loaded on a page.

Visually Complete Time

Visually Complete Time (VCT) calculates the point in time when the browser has finished loading all visual content in the viewport.

Page Complete Time

Page Complete Time (PCT) is a SPA2 metric for base pages only. PCT calculates the point in time when the browser has finished loading all visual content on the page, regardless of whether the content is in or outside the viewport.



Configure SPA2 Monitoring

SPA2 Requirements

- JavaScript Agent >= 4.4.3
- Controller / EUM Server >= 4.4.3 (for on-premises deployments)
- Enable SPA2 monitoring
- IE 10 and Edge are supported. IE >= 10 and Edge *cannot* be in compatibility mode with IE <= 9 browsers.
- For non-AngularJS frameworks, the JavaScript Agent >= 4.2 is required.

Angular 6-9 SPAs are supported by JavaScript Agent version >= 4.5.16. To manually report and name virtual pages with the JavaScript Agent API, you will need to use the JavaScript Agent >= 4.5. The JavaScript Agent >= 4.4.3 does not support the use of the JavaScript Agent API to manually report events.

Enable/Disable SPA2 Monitoring

In the JavaScript Agent configuration, set `spa2` to `true` and then inject the JavaScript Agent as shown below. You can use either manual or automatic inje ction. The default value for `spa2` is `false`, so to enable SPA2 monitoring, you must set `spa2` to `true`.

Make sure you set the configuration, including enabling SPA2 monitoring, *before* you load the JavaScript Agent.

```
<script charset='UTF-8'>
    window['adrum-start-time'] = new Date().getTime();
    (function(config){
        config.appKey = '<EUM_APP_KEY>';
        config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
        config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
        config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
        config.beaconUrlHttps = 'https://col.eum-appdynamics.com';
        config.xd = {enable : false};
        config.spa = {
            "spa2": true
        };
    })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
```

Disable SPA2 Monitoring

To disable SPA2 auto-instrumentation, just set `spa2` to `false`. Although the default value for `spa2` is `false`, you are recommended to set the configuration to false and *not* just remove it.

Migrate from SPA1 to SPA2 Monitoring

To migration from SPA1 to SPA2 monitoring:

1. Read SPA1 and SPA2 Monitoring to confirm that your use case is suitable for SPA2.
2. Meet the SPA2 requirements.
3. Enable SPA2 monitoring.

Fetch API Support for SPA2 Monitoring

The JavaScript Agent monitors Fetch API calls by default for all SPAs except for Angular applications.

For Angular.js and Angular 2-9 applications, follow these steps to ensure Fetch API calls are monitored.

1. The JavaScript Agent is configured to monitor Fetch API calls by default. Make sure that your JavaScript Agent configuration *doesn't* have the following:

   ```
   config.fetch = false
   ```

2. Load the JavaScript Agent before Angular (recommended, but not required).

```
<script src="adrum.js"></script>
<script src="angular.js"></script>
```

3. Add the following configuration to ensure the JavaScript Agent monitors the Angular application correctly.

Troubleshoot SPA Monitoring

This page describes how to troubleshoot issues with monitoring SPAs.

Problems With Dynamically Loading the JavaScript Agent

Because Angular allows you to dynamically load modules with `AppdInitServlet`, you may be tempted to dynamically load `adrum.js`. The problem with dynamically loading `adrum.js`, however, is that this could cause a race condition between the time `adrum.js` is evaluated and the time `angular.js` is bootstrapped. This race condition can result in JavaScript Agent missing virtual pages or XHR events.

You can avoid this race condition by doing the following:

- Loading Angular first and then immediately loading the JavaScript Agent. See Load Angular and the JavaScript Agent.
- Bootstrap Angular after you have loaded the JavaScript Agent.

Load Angular and the JavaScript Agent

The key here is simply to make sure that you load `angular.js` first and then immediately load `adrum.js` as shown below.

```
<script src="angular.js"></script>
<script src="adrum.js"></script>
```

Bootstrap Angular

Manual (Recommended)

After you have loaded `adrum.js`, you can then bootstrap Angular through manual initialization. You should load both `angular.js` and `adrum.js` as soon as possible, so that the JavaScript Agent can get more accurate metrics about the page load and the HTML DOM Ready /Build time. The examples below follow the recommended procedure of first loading `angular.js`, then `adrum.js`, and then bootstrapping `angular.js`

Deferred (Optional)

If manual bootstrap is not possible, you can use deferred bootstrap. What this means is that you pause the bootstrap until `adrum.js` is successfully loaded, at which point, you resume the bootstrapping with `angular.resumeBootstrap()` as shown in the example below.

```
<!doctype html>
<html>
    <head>
        <script src="http://code.angularjs.org/snapshot/angular.js"></script>
        <script>
            // This defers the bootstrap.
            window.name = 'NG_DEFER_BOOTSTRAP!';
            angular.module('angularApp', [])
            .controller('TestController', ['$scope', function ($scope) {
                $scope.currentTime = new Date().toLocaleString();
            }]);
            angular.element(document).ready(function() {
                angular.bootstrap(document, ['angularApp']);
            });
        </script>
        // For simplicity, we're just showing the injection snippet using the AppDynamics CDN.
        <script charset='UTF-8'>
            window['adrum-start-time'] = new Date().getTime();
            (function(config){
                config.appKey = '<EUM_APP_KEY>';
                config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
                config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
                config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
                config.beaconUrlHttps = 'https://col.eum-appdynamics.com';
                config.xd = {enable : false};
            })(window['adrum-config'] || (window['adrum-config'] = {}));
        </script>
        <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'><
/script>
  </head>
<body>
  <div ng-controller="TestController">
    It's {{currentTime}}!
  </div>
  <script>
    // Resume the bootstrapping.
    angular.resumeBootstrap()
  </script>
</body>
</html>
```

Manually Initializing the JavaScript Agent (Optional)

If `adrum.js` loads successfully, but does not initialize, you can manually initialize it by calling `ADRUM.ng.ngMonitor.init()` as shown below. This will force the JavaScript Agent to initialize even after the Angular bootstrap.

```
 <html>
     <head>
         <script src="http://code.angularjs.org/snapshot/angular.js"></script>
         <script>
             // This defers the bootstrap.
             window.name = 'NG_DEFER_BOOTSTRAP!';
             angular.module('angularApp', [])
             .controller('TestController', ['$scope', function ($scope) {
                 $scope.currentTime = new Date().toLocaleString();
             }]);
             angular.element(document).ready(function() {
                 angular.bootstrap(document, ['angularApp']);
             });
         </script>
<!doctype html>
<html>
    <head>
        <script src="http://code.angularjs.org/snapshot/angular.js"></script>
        <script>
            // This defers the bootstrap.
            window.name = 'NG_DEFER_BOOTSTRAP!';
            angular.module('angularApp', [])
            .controller('TestController', ['$scope', function ($scope) {
                $scope.currentTime = new Date().toLocaleString();
            }]);
            angular.element(document).ready(function() {
                angular.bootstrap(document, ['angularApp']);
            });
        </script>
        // For simplicity, we're just showing the injection snippet using the AppDynamics CDN.
        <script charset='UTF-8'>
            window['adrum-start-time'] = new Date().getTime();
            (function(config){
                config.appKey = '<EUM_APP_KEY>';
                config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
                config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
                config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
                config.beaconUrlHttps = 'https://col.eum-appdynamics.com ';
                config.xd = {enable : false};
            })(window['adrum-config'] || (window['adrum-config'] = {}));
        </script>
        <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'><
/script>
    </head>
    <body>
        <div ng-controller="TestController">
        It's {{currentTime}}!
        </div>
        <script>
            // Resume the bootstrapping.
            angular.resumeBootstrap();
            ADRUM.ng.ngMonitor.init();
        </script>
    </body>
</html>
```

In some cases, you may be able to place `ADRUM.ng.ngMonitor.init()` before `angular.resumeBootstrap()`.

Enable the Content Security Policy

This page describes how to enable Content Security Police (CSP) so your application is compatible with Browser RUM.

Directives Required for CSP

To enable CSP for instrumented applications, you add the following required directives in the `Content-Security-Policy` header:

- `script-src`
- `connect-src`

In certain cases, you are also required to use the following directives:

- `child-src`
- `frame-ancestors`
- `img-src`

script-src

The `script-src` directive specifies the location of `adrum-ext.js`. By default, `adrum-ext.js` is loaded from our content delivery network (CDN) at `cdn.appdynamics.com`. The example below shows how you might use the `script-src` directive.

```
script-src cdn.appdynamics.com;
```

To measure first-byte time accurately, include the following line at the top of pages:

```
window["adrum-start-time"] = new Date().getTime();
```

For this line to be read, you also need to set the `script-src` directive to `'unsafe-inline'` as shown here:

```
script-src 'unsafe-inline';
```

connect-src

The `connect-src` directive specifies the location where beacons are sent. If you are using the SaaS-based EUM, you might use something like the following:

```
connect-src col.eum-appdynamics.com;
```

If you are using on-prem EUM, you would have `connect-src` point to your EUM Server.

child-src

For cross-domain sessions, we load `adrum-xd.html` into an iframe. By default, this is loaded from our CDN, so you need to have `child-src` specify a CDN as shown below.

```
child-src cdn.appdynamics.com;
```

frame-ancestors

If `adrum-xd.html` is hosted locally, you would use the `frame-ancestors` directives in the following way:

```
frame-ancestors /path/to/adrum-xd.html;
```

img-src

In older browsers, we send our beacons as image beacons. Although older browsers don't support CSP, you can configure the JavaScript Agent to always send image beacons. You do this using `img-src` directive to specify the beacon location as shown in the example below.

```
img-src col.eum-appdynamics.com;
```

Example Content-Security-Policy Header

The following `Content-Security-Policy` header loads the `adrum` files from our CDN and then sends beacons to our SaaS-based EUM.

```
Content-Security-Policy: connect-src 'self' col.eum-appdynamics.com; script-src 'unsafe-inline' cdn.appdynamics.
com; img-src cdn.appdynamics.com; child-src cdn.appdynamics.com
```

Host a Geo Server

Related pages:

- EUM Server Requirements
- EUM Server Deployment
- Configure the EUM Server
- Browser RUM Countries and Regions by Geo Dashboard

AppDynamics hosts a Geo Server that resolves the user's geographic location based on the request's reported IP address. You may prefer to host your own Geo Server if:

- You have intranet applications where the public IP address does not provide meaningful location information but the user's private IP does.
- You have a hybrid application where some users access the application from a private location and some access it from a public one. If a user doesn't come from a specific private IP range mapped by the custom geo server, the system can be set to default to the public Geo Server.

The custom Geo Server supports an HTTP header, `AD-X-Forwarded-For`. You can use this to declare an IP address specifically for the purpose of geo resolution. As of version 4.2, the custom Geo Server also supports modifying the JavaScript Agent itself to specify a particular IP or location. Custom Geo Server also supports the HTTP header `X-Real-IP`.

See Install and Host a Custom Geo Server for Browser RUM for more information on setting up your own Geo Server and private IP mapping file.

The AppDynamics Geo Server requires JDK >= 7.

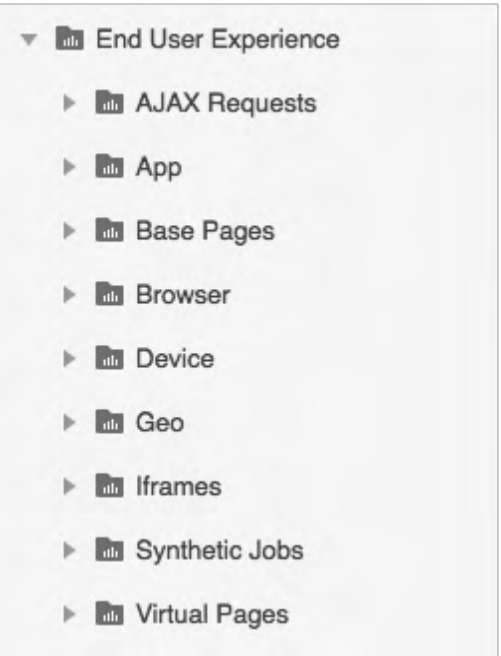
Browser RUM Metrics

Related pages:

- AppDynamics APIs
- The Pages & Ajax Requests View
- WC3 Navigation Timing API

Key Browser RUM metrics display on the **Geo**, **Pages & AJAX Requests**, and **Usage Stats** dashboards. They are also visible on the **All Pages** and **Top Pages** lists and in the Metric Browser.

In addition, the **Metric Browser** enables you to view these metrics in the context of Ajax requests, iframes, applications, base pages, browsers, devices, and geographic locations.



You can build custom health rules based on Browser RUM Page, Ajax, and iframe metrics in the health rule builder. Use these rules to automatically monitor key metrics in your installation. See Health Rules.

Browser RUM Timing Metrics Overview

The following provides an overview of the first Browser RUM page and iframe timing metrics. For key Ajax metrics, see Ajax Metrics Availability. Metrics in blue are available only from NavTime browsers. You may see a value of `unknown` for some metrics taken using older browsers.

When users begin to load the first instrumented page, the JavaScript Agent starts a timer. The timer or the NavTime `responseStart` starts the first-page timing.

> Because a NavTime browser always sets `navigationStart`, you can retrieve this information even on the first page a user loads from your site.

NavTiming-capable browsers also provide highly granular information on connection details.

Browser RUM Metrics Defined

Timing metrics are the average times, in milliseconds, over the time range selected in the Controller UI or REST API call. The three-letter abbreviation is the short name as it is recorded in the web beacon.

Name (Short Name)	NavTiming Capable Browsers[1]	Browsers without NavTiming Support	Available For . . .	Definition

Ajax Callback Execution Time (DPT)	`responseEnd` to `domContentLoadedEventStart` (context of the Ajax object)	`responseEnd` to `domContentLoadedEventStart` (context of the Ajax object)	Ajax Requests (XHR, Fetch API)	Time for the browser to process the Ajax response. This typically includes the time to apply the response data to the DOM.
Ajax Response Download Time (DDT)	`responseStart` to `responseEnd` (context of the Ajax object)	`responseStart` to `responseEnd` (context of the Ajax object)	Ajax Requests (XHR, Fetch API)	Time for the browser to download the complete Ajax response.
Ajax Request Errors per Minute (Short name based on ARE entries)			• Ajax Requests (XHR, Fetch API) • App • Browser • Device • Geo	Total number of Ajax requests that generate an error per minute.
Ajax Requests per Minute (Short name based on PLC entries)			• App • Browser • Device • Geo	Total number of Ajax requests per minute.
Application Server Calls per Minute			• Ajax Requests (XHR, Fetch API) • App • Base Pages • Browser • Device • Geo • iframes	Number of requests that actually hit the application server, rather than a cache.
Application Server Time (also called Server Time in the UI)			• Ajax Requests (XHR, Fetch API) • App • Base Pages • Browser • Device • Geo • iframe	Processing time for requests on the application server.
Browser Queue Time			• Ajax (XHR, Fetch API) • App • Base Pages • Browser • Device • Geo • iframes	
DOM Building Time (DPT)	`responseEnd` to `domContentLoadedEventStart`	N/A	• App • Base Pages • Browser • Device • Geo • iframes	Time for the browser to build the Document Object Model (DOM) and make it available for JavaScript to apply rendering logic.

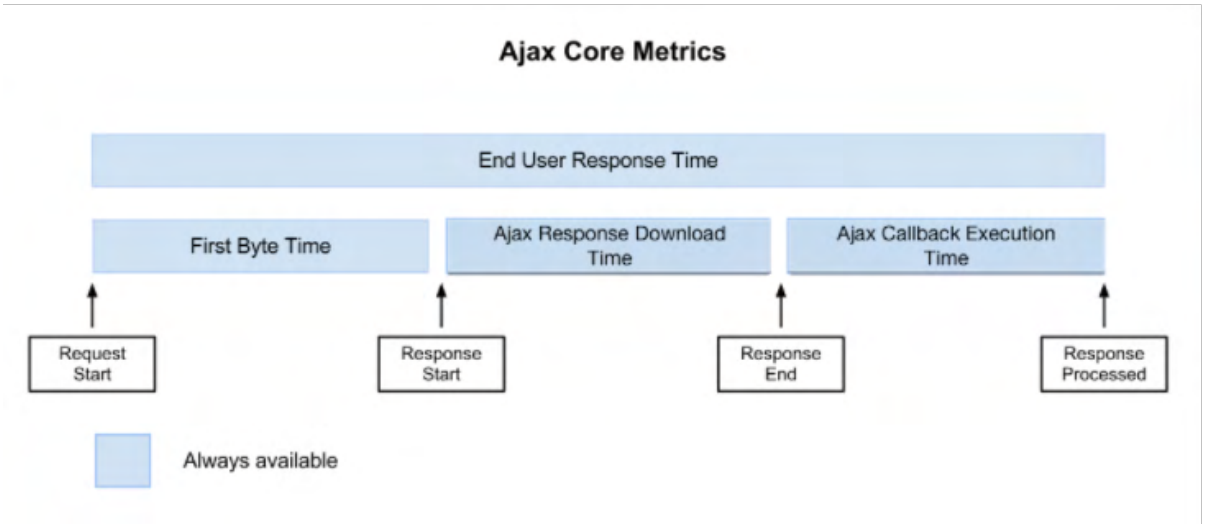
DOM Ready Time (DOM)[2]	`navigationStart` to `domContentLoadedEventStart`	Time between the writing of the `starttime` cookie on the previous page and an internal handler's `onready` event, similar to `jquery.onready()`.	• App • Base Pages • Geo	Interval between the time that a user initiates a request and the time that the `DOMContentLoaded` event (or the internal handler's `onready` event) occurs.
Domain Lookup Time (DNS)	`domainLookupStart` to `domainLookupEnd`	N/A	• App • Base Pages • Browser • Device • Geo • iframes	Time to complete the domain lookup portion of the server connection time.
End User Response Time (PLT)[2]	`navigationStart` to `loadEventEnd`	Time between the writing of the `starttime` cookie on the previous page and the `onload` event.	• Ajax Requests (XHR, Fetch API) • App • Base Pages • Browser • Device • Geo • iframes	Average interval between the time that a user initiates a request and the completion of the page load of the response in the user's browser. In the context of an Ajax request, it ends when the response has been completely processed. For information about End User Response Time for SPA2 pages, see SPA2 Metrics.
First Byte Time (FBT)[2]	`navigationStart` to `responseStart`	Time between the writing of the `starttime` cookie on the previous page and when the page's JavaScript Agent begins executing.	• Ajax Requests (XHR, Fetch API) • App • Base Pages • Browser • Device • Geo • iframes	Interval between the time that a user initiates a request and the time that the browser receives the first response byte. In the context of an Ajax request, First Byte Time is the interval between the Ajax request dispatch and the time that the browser receives the first response byte.
Front End Time (FET)	`responseStart` to `loadEventEnd`	Time between when the page's JavaScript Agent begins executing and the `onload` event.	• App • Base Pages • Browser • Device • Geo • iframes	Interval between the arrival of the first byte of text response and the completion of the response page rendering by the browser. Includes HTML Download, DOM Building Time, and Resource Fetch Time.
HTML Download and DOM Building Time (DRT)	`responseStart` to `domContentLoadedEventStart`	Time between when the page's JavaScript Agent begins executing and an internal handler's `onready` event, similar to `jquery.onready()`.	• App • Base Pages • Browser • Device • Geo • iframes	Time to make the complete HTML document (DOM) available for JavaScript to apply rendering logic. Includes the HTML Download and the DOM Building Time.
HTML Download Time (DDT)	`responseStart` to `responseEnd`	N/A	• App • Base Pages • Browser • Device • Geo • iframe	Time for the browser to download the complete HTML document content.

Iframe Requests per Minute (Short name based on PLC entries)			• App • Browser • Device • Geo	Total number of iframe requests per minute.
Images Loaded per Pageview			• Ajax (XHR, Fetch API) • App • Base Pages • Browser • Device • Geo • iframes	Total number of images in a `pageview`. Calculated after page has completely loaded.
Page Complete Time (PCT)	N/A	N/A	• App • Base Pages • Browser • Device • Geo	Total time for the browser to render all visual page elements (both in and out of the viewport). Available for SPA base pages only. For information about Page Complete Time for SPA2 pages, see SPA2 Metrics.
Page Requests per Minute (Short name based on PLC entries)			• App • Browser • Device • Geo	Total number of Page requests per minute. This is the metric displayed across most of the UI.
Page views with JavaScript Errors per minute (Short name based on EPM entries)			• App • Base Pages • Browser • Device • Geo • iframes	Total number of page views that contain JavaScript errors per minute.
Resource Fetch Time	`domContentLoadedEventStart` to `loadEventEnd`	Time between an internal handler's `onready` event, similar to `jquery.onready()`, and `onload`.	• App • Base Pages • Browser • Device • Geo • iframes	Time for the browser to complete the download of remaining resources, including images, and finish rendering the page.
Resources Loaded per Pageview			• Ajax (XHR, Fetch API) • App • Base Pages • Browser • Device • Geo • iframes	Total number of resources in a `pageview`. Calculated after the page has completely loaded.
Requests per Minute (Short name based on PLC entries)			• Ajax Requests (XHR, Fetch API) • App • Base Pages • Browser • Device • Geo • iframes	Total number of requests (Page + Ajax + iframe) per minute.

Scripts Loaded per Pageview			• Ajax (XHR, Fetch API) • App • Base Pages • Browser • Device • Geo • iframes	Total number of scripts in a `pageview`. Calculated after the page has completely loaded.
Server Connection Time (SCT)	`navigationStart` to `requestStart`	N/A	• App • Base Pages • Browser • Device • Geo • iframes	Interval between the time that a user initiates a request and the start of fetching the response document from the server or application task. Includes the time spent on redirects, domain lookups, TCP connects and SSL handshakes.
SSL Handshake Time (SSL)[3]	`secureConnectionStart` to `connectEnd`	N/A	• App • Base Pages • Browser • Device • Geo • iframes	Time taken to complete the SSL handshake.
TCP Connect Time (TCP)	`connectStart` to `connectEnd`	N/A	• App • Base Pages • Browser • Device • Geo • iframes	Time to complete the TCP connect portion of the server connection time, the equivalent of one network roundtrip of latency.
Total Resource Redirect Time			• Ajax (XHR, Fetch API) • App • Base Pages • Browser • Device • Geo • iframes	Time for all redirects associated with fetching resources. Calculated after the page has completely loaded.
Visually Complete Time (VCT)	N/A	N/A	• App • Base Pages • Browser • Device • Geo • iframes	Total time for all visual elements within the first screen (above-the-fold content) to load in an end user's browser. Calculated using the last visual change to the page in a browser window. For information about Visually Complete Time for SPA2 pages, see SPA2 Metrics.

Ajax Metrics Availability

Because Ajax requests occur in the context of the larger page, these four core metrics are always available, regardless of the browser type.



For more information on which browsers support the Navigation Timing API, see the Can I Use website.

Resource Timing Metrics

Resource timing metrics are the median times in milliseconds. The resource timing metrics shown in the Resource Performance Dashboard are raw data. For a visual representation of the resource timing, see the Resource Timing Overview diagram.

Metric Name	How It's Calculated	Description
Browser Wait	`startTime` or `redirectEnd` to `fetchStart`	Time from the redirection or request start until the browser begins to fetch the resource.
Redirect Time	`redirectStart` to `redirectEnd`	Time for all redirects associated with fetching resources.
DNS Wait Time	`fetchStart` to `domainLookupStart`	Time from when the browser starts to fetch the resource until the browser starts the domain name lookup for the resource.
DNS Time	`domainLookupStart` to `domainLookupEnd`	Time to complete the domain lookup portion of the server connection time.
TCP Wait Time	`domainLookupEnd` to `connectStart`	Time for the browser to find the domain name for the resource before a connection is made.
Connection Time	`connectStart` to `connectEnd`	Time to complete the establish the TCP connection for a resource: the equivalent of one network roundtrip of latency.
SSL Time	`secureConnectionStart` to `connectEnd` (if `secureConnectionStart` exists)	Time to establish a secure connection to the server.
Request Wait Time	connectEnd to requestStart	Time for the request is made for a resource from the server, cache, or local resource before the connection is closed.
Request Time	`requestStart` to `responseStart`	Time for the browser to complete the request for a resource from the server, cache, or local resource.
Response Time	responseStart to responseEnd	Time for the browser to download the complete HTML document content. In the context of an Ajax request, the time for the browser to download the complete Ajax response.
First Byte Time	`startTime` to `responseStart`	Time from when the request is made until the first byte of the resource is received by the browser.
Resource Load Time	`startTime` to `responseEnd`	Time for the browser to start a request and receive a response for a resource.
Browser Queue Time	Browser Wait + DNS Wait Time + Request Wait Time	Total wait time of the resource.

TCP Time	`secureConnectionStart` to `connectStart`	Time spent to establish a secure connection to the server (same as SSL Time).

Browser RUM Supported Environments

This page describes the supported environments and versions for Browser RUM.

Browser RUM Support

Browser Compatibility

- IE 10, 11, Edge
- Chrome >= 1.0.154.60, including Mobile
- Headless Chrome >= 59
- Firefox, including Mobile
- Safari >= 4 , including Mobile
- Opera >= 12

> Browsers are rapidly evolving, and not all versions have been individually tested with Browser RUM. You can view the browser versions *likely* to support the Resource Timing API.

Browser Requirements for Sessions

To use Browser RUM sessions, your browser is required to support for the following:

- cross-origin resource sharing (CORS) for beacons
- local storage for multiple-page sessions (single-page / multiple virtual page sessions don't need local storage)

> Browser RUM sessions do not support beacons implemented with GIFs.

JavaScript Agent Version Requirement for Sessions

You are required to use the JavaScript Agent >= 4.2. Older versions of the JavaScript Agent do not support sessions.

Injection Types for Browser RUM in Java Environments

Listed below are the injection types with their supported frameworks/technologies:

- **Automatic Injection**: JavaServer Pages (JSP) compiled using the Jasper compiler. Jasper is the default JSP compiler in Tomcat, Glassfish, and J Boss.
- **Assisted Injection:** All Servlet frameworks.
- **Manual Injection**: All technologies that generate HTML pages.

See Inject the JavaScript Agent for details.

Injection Types for Browser RUM in .NET Environments

AppDynamics certifies Browser RUM instrumentation for the following .NET environments:

- .NET Framework
- .NET Core

Browser RUM Instrumentation for .NET Framework

Supported Runtime Environments for Browser RUM .NET Framework include:
Microsoft IIS versions 6.0, 7.0, 7.5, 8.0, 8.5

- All listed frameworks support manual injection of the JavaScript Agent for Browser RUM.
- The Script Injection column lists additionally supported script injection strategies. See Inject the JavaScript Agent for details.

Web Application/AJAX Frameworks	Versions	Additional Supported Script Injection Methods
ASP.NET Web Forms (.aspx)	3, 4	Automatic, Using Attribute Injection
ASP.NET MVC Web Forms (.aspx)	3 - 5	Automatic, Using Attribute Injection
ASP.NET MVC Razor	3 - 5	Automatic, Using Attribute Injection
Microsoft SharePoint	2007, 2010	Automatic

AppDynamics does not support Browser RUM instrumentation of legacy ASP (`.asp`) pages.

Browser RUM Instrumentation for .NET Core

AppDynamics currently supports .NET Agent for Windows >= 21.1, and .NET Agent for Linux >= 21.5.

Web Application/AJAX Frameworks	Versions	Supported Script Injection Methods
ASP.NET Core MVC	3.1, 5	Automatic
ASP.NET Core Razor Pages	3.1, 5	Automatic

Browser RUM Countries and Regions by Geo Dashboard

The countries and regions in the sections below can be displayed in the **Geo Dashboard**. Each of these countries and regions also displays their own aggregate Browser RUM data. Data can be collected from areas not in the following list, but it will not be displayed in these parts of the interface. Some countries and regions are only displayed in the grid view.

Countries

Grid View

The following countries are displayed in the grid view of the **Geo Dashboard**.

Troubleshoot Browser RUM

These pages provide methods to solve common problems:

- Browser RUM License Troubleshooting
- Browser RUM Metrics Not Reported
- Pages Not Monitored
- Injection Problems
- Browser Snapshot Problems
- Connection Problems
- Create a HAR File to Troubleshoot Web Download Issues

Browser RUM License Troubleshooting

Related pages:

- EUM Accounts, Licenses, and App Keys

The following sections discuss how to solve common license problems.

No EUM Account License Key

The EUM account license is separate from the Controller license. Although the license file includes the EUM license key, the EUM account license is provisioned separately.

Controllers cannot share an EUM license key, but applications can.

If you need an EUM license, call your AppDynamics sales representative or email salesops@appdynamics.com.

Browser RUM Not Working in Production

If you are running more than one Controller, each instance requires a unique license. Make sure you are not trying to use the same license on more than one Controller.

Browser RUM Metrics Not Reported

This page provides a high-level overview to check your Browser RUM setup.

Check for Load

Make sure there is load running on your app for the pages that you want to monitor for the selected period.

When Browser RUM discovers a new page, iframe, or Ajax call for the first time, there will be a several minute delay before data for it appears in the Controller UI.

- It takes up to two or three minutes for the agent to register with the Controller. No metrics are captured during this time.
- After the page is registered and traffic starts flowing, it can take an additional two or three minutes for the metrics to appear in the AppDynamics console.
- After that, the delay between an end-user click and the appearance of Browser RUM data is two to three minutes.

Confirm Browser RUM Is Enabled

Make sure you enable Browser RUM for the app. Enable it if it is disabled. See Enable and Disable Browser Monitoring.

Ensure Pages Are Instrumented

Examine the source of your web page to ensure that you have instrumented the pages that you want to monitor.

Check Connectivity

Make sure there is connectivity from the browser to the EUM Cloud.

Examine Beacons for Issues

If beacons are not present or their status is not valid, verify your Browser RUM configuration. See Set Up and Access Browser RUM.

To examine your instrumented application for issues, verify the following:

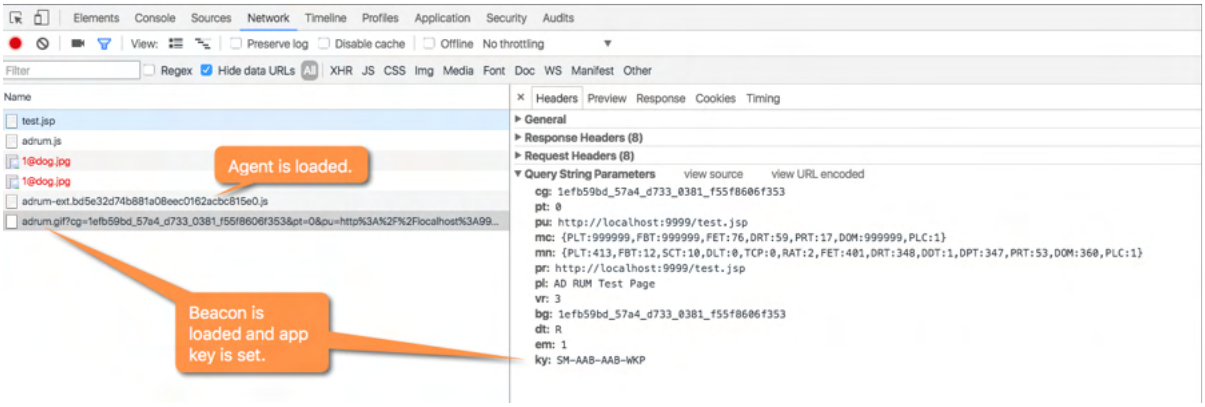
- The JavaScript Agent extension (`adrum.ext`) is loaded and its status is OK (200).
- The EUM beacon is sent:
    - As a `.gif` request—older browsers
    - A GET request for `adrum.gif` is loaded, and its status is OK (200).
    - The `ky` parameter in the beacon is set to your application key.
    - As a CORS-based request—deprecated
    - A POST request has been sent with a status of OK (200).
    - The app key is sent in the body of the beacon.
    - As a CORS-based request
    - A POST request has been sent with a status of OK (200).
    - The app key is sent in the URL.

Beacons for using image requests have an inherent length limitation. Because of this, URLs longer than 180 characters, page names longer than 50 characters, and user data (key and value combined) longer than 113 characters are not supported in these browsers.

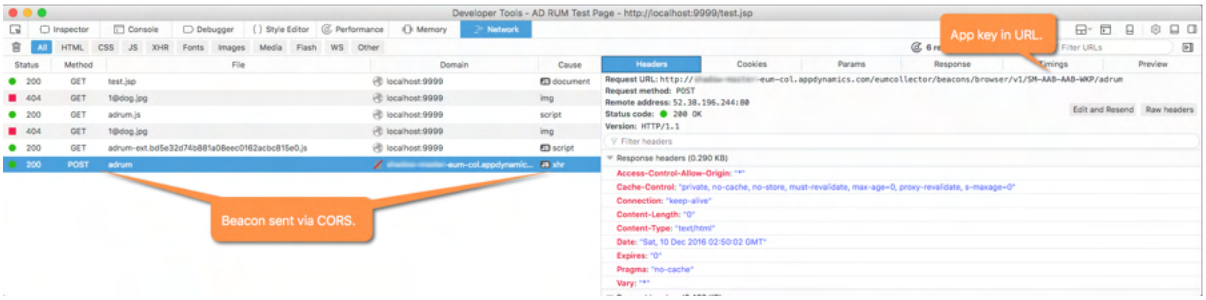
Use Developer Tools to Examine Your Application

You can use the developer tools in your web browser to examine your application.

This screenshot shows a `.gif`-based beacon in Chrome.



This screenshot shows a CORS-based beacon with a key in the URL path.



Create a HAR file to confirm that the browser is downloading the expected resources for your web page.

Pages Not Monitored

You may find that some pages have not been monitored as expected. This page may help you determine the reason why these pages have not been monitored.

Verify Pages Have Been Injected

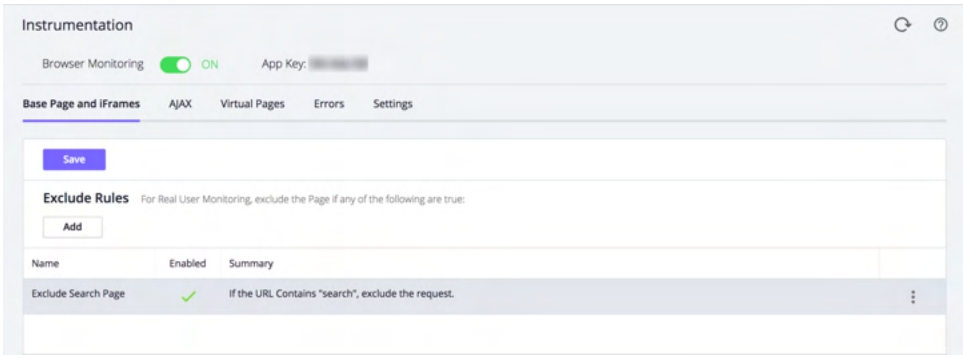
If only some web pages are not reporting data, first verify that those pages have been injected with the JavaScript Agent. See Verifying that the JavaScript Agent for Browser RUM was injected.

Check Exclude Rules

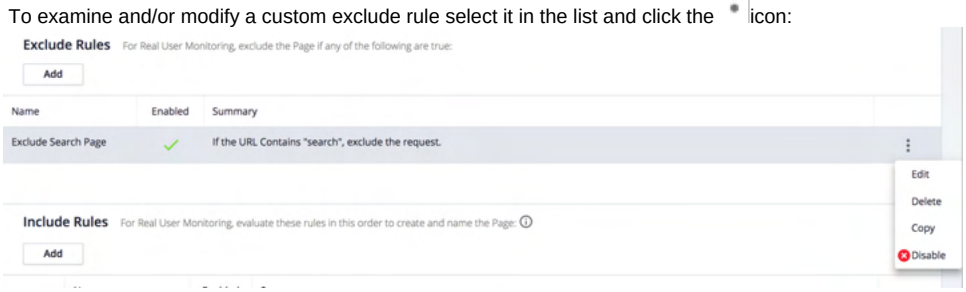
It the agent has been injected, the page may have been excluded from monitoring by custom exclude rules. You can check and modify these rules.

To access custom exclude rules for pages:

1. Click **Configuration > Instrumentation**.
2. Click the Base Pages and iFrames tab.
3. From **Base Pages and iFrames**, check the custom rules under the **Exclude Rules** section.



4. To examine and/or modify a custom exclude rule select it in the list and click the icon:



5. If you want to remove a custom exclude rule, select and click **Delete**.

Check Automatic Injection Configuration

In addition, certain pages could have been excluded by the injection configuration. This can happen when automatic injection is used with a limited set of pages enabled for injection. If you used automatic injection, check your automatic injection configuration to see if the missing pages are enabled for injection.

Examine the **Request Match Rules** and **Request Exclude Rules** lists under **Only enable Automatic Injection for certain Pages** in the Automatic JavaScript Injection tab. See Automatic Injection of the JavaScript Agent. Pages can also be bypassed by assisted injection using injection rules when an injection rule specifies only classes and methods to be injected. If you used assisted injection with injection rules, check your injection rules. See Assisted Injection.

Configure the JavaScript Agent to Monitor Older Browsers

The JavaScript Agent by default supports modern browser and no longer tests or certifies the collection and reporting of data from older browsers. If you find that older browsers are accessing your web pages and that they are not being monitored, you can configure the JavaScript Agent to monitor older browser with the following configuration.

```
(function(config){
  ...
  "beacon": { "neverSendImageBeacon": false },
  ...
})(window['adrum-config'] || (window['adrum-config'] = {}));
```

Ajax Requests Not Monitored

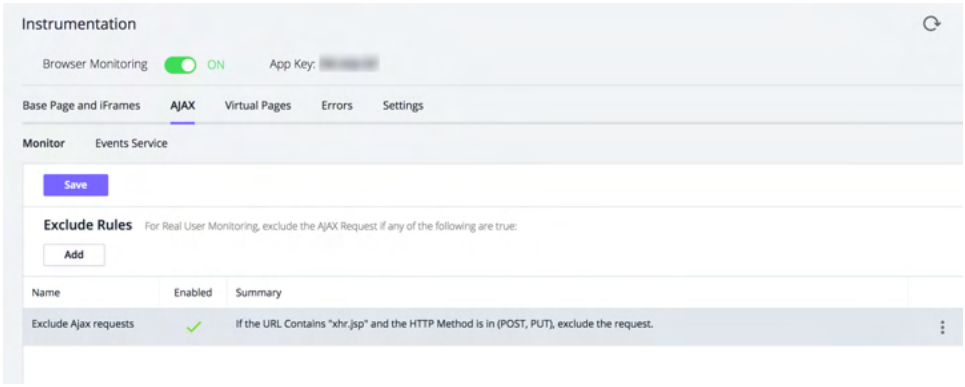
You may find that some Ajax requests have not been monitored as expected. The page may help you determine why these pages have not been monitored.

Check Exclude Rules

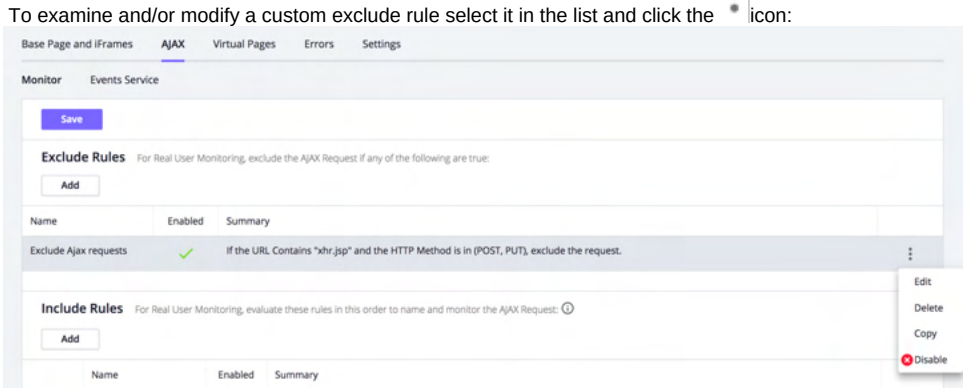
It the agent has been injected, the Ajax event may have been excluded from monitoring by custom exclude rules. You can check and modify these rules.

To access custom exclude rules for pages:

1. Click **Configuration > Instrumentation**.
2. From the AJAX tab, check the custom rules under the **Exclude Rules** section.



3. To examine and/or modify a custom exclude rule select it in the list and click the icon:



4. If you want to remove a custom exclude rule, select and click **Delete**.

Verify That XHR Objects Were Reused Correctly

Browser RUM can monitor multiple Ajax calls made from a reused `XMLHttpRequest` object, but if the `XMLHttpRequest` object is reused (opened) before the last request is completed, the JavaScript agent cannot collect all the metrics for all the Ajax requests.

Incorrect Method to Reuse XMLHttpRequest Object

In the example below, the `xhr` object is making a request to `/multi-bt` before the request to `/xhr/uptime` has completed, so the JavaScript Agent only reports the second Ajax request to `/multi-bt`.

```
function reuseXHRBeforeReady() {
    var xhr = newXhr();
    xhr.open("GET", "/xhr/uptime");
    xhr.onreadystatechange = safe(function() {
        if (xhr.readyState == 4) {
            if (typeof(console) !== "undefined" && console !== null && console.log)
                console.log("onreadystatechange for xh1: " + xhr.responseText);
                document.getElementById("result").innerHTML = xhr.responseText;
        }
    });
    xhr.send(null);
    xhr.open("GET", "/multi-bt");
    xhr.onreadystatechange = safe(function() {
        if (xhr.readyState == 4) {
            if (typeof(console) !== "undefined" && console !== null && console.log)
                console.log("onreadystatechange for xhr2: " + xhr.responseText);
                document.getElementById("result").innerHTML = xhr.responseText;
        }
    });
    xhr.send(null);
}
```

When an Ajax request cannot be reported because the `XMLHttpRequest` object is reused (opened) before the last request is completed, the JavaScript Agent logs that an Ajax request was *not* reported in a message similar to the one below. You will most likely have to modify your JavaScript so that new Ajax requests are only made after previous requests are completed.

```
EXT~ The reused XHR object calls open() before finishes last job. No event of XHR to '" + this._adrumAjaxT.url()
+ "' is reported.
```

Correct Method to Reuse XMLHttpRequest Object

The correct method to reuse the `XMLHttpRequest` object to make more than one request is to nest the calls so that new calls are only made when previous calls have been completed. In the example below, the call to `/xhr/multi-bt2` is only made when the call to `/multi-bt` has completed, so both calls are reported as Ajax requests.

```
function reuseXHR() {
    var xhr = newXhr();
    xhr.open("GET", "/xhr/uptime");
    xhr.onreadystatechange = safe(function() {
        if (xhr.readyState == 4) {
            document.getElementById("result").innerHTML = xhr.responseText;
            xhr.open("GET", "/multi-bt");
            xhr.onreadystatechange = safe(function() {
                if (xhr.readyState == 4) {
                    if (typeof(console) !== "undefined" && console !== null && console.log)
                        console.log("onreadystatechange for xhr2: " + xhr.responseText);
                    document.getElementById("result").innerHTML = xhr.responseText;

                    // Reuse xhr again
                    xhr.open("GET", "/xhr/multi-bt2");
                    xhr.onreadystatechange = safe(function() {
                        console.log("/xhr/multi-bt2 responded.");
                    });
                    xhr.send(null);
                }
            });
            xhr.send(null);
        }
    });
    xhr.send(null);
}
```

Check Injection Configuration

In addition, certain Ajax requests could have been filtered out by the injection configuration. This can happen when the injection uses XHR filters to limit which Ajax requests are monitored. Check your injection configuration to verify that the filtering did not prevent the calls from being monitored.

Injection Problems

You must inject the JavaScript Agent for Browser RUM into every page that you want to monitor.

Verify Injection

View the source of your web page. When automatic or assisted injection is used, you should see the script for the JavaScript Agent inline in the web page. When manual injection is used, you will see:

```
<script src="/path_to_adrum.js"/>
```

If you used manual injection, use the normal procedures that you use to verify other types of code changes in your web pages. Keep in mind that various caches, such as the server page, CDN or browser caches, can prevent the page from actually being reloaded. If you cannot get manual injection to work, try one of the other injection schemes if they are available for your platform. See Inject the JavaScript Agent for information about the various injection strategies.

Verify Automatic Injection is Enabled

To verify that automatic injection is enabled:

1. Open the business application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration > JavaScript Agent Injection**.
3. From **Inject the JavaScript Agent configured for this Browser App**, confirm that your browser app receiving the automatic injection is selected.
4. Select the Automatic Injection tab.
5. Confirm that the **Enable Automatic Injection of JavaScript** checkbox is checked.
6. Verify that automatic injection is enabled for all of the business transactions that you want to monitor. If some of those business transactions are in the **Automatic injection possible, but not enabled list**, move them to the **Automatic injection enabled** list. If the business transaction that you want to monitor does not appear in either list, automatic injection is not possible for that business transaction.
7. Click **Save** if you made any changes.

See Automatic Injection of the JavaScript Agent for information about creating and enabling injection rules.

Verify Assisted Injection is Enabled

To verify that assisted attribute injection is enabled:

1. Open the business application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration > JavaScript Agent Injection**.
3. From **Inject the JavaScript Agent configured for this Browser App**, confirm that your browser app receiving the automatic injection is selected.
4. Select the Configure JavaScript Injection tab.
5. Confirm that the **Request Attribute Injection** is checked.
6. Click **Save** if you made any changes.

To verify that assisted injection using injection rules is enabled:

1. Open the business application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration > JavaScript Agent Injection**.
3. From **Inject the JavaScript Agent configured for this Browser App**, confirm that your browser app receiving the automatic injection is selected.
4. Select the Configure JavaScript Injection tab.
5. Confirm that there are enabled injection rules in the table under **Create Injection Rules**.
6. From the Where to Inject JavaScript tab, confirm that the rules are correct.
7. From the Inject for these Business Transactions tab, confirm that the rules are applied for the desired business transactions.
8. Click **Save** if you made any changes.

See Assisted Injection for information about creating and enabling injection rules.

Change Your Injection Strategy

If you try one way to inject the JavaScript Agent and it does not work, it is best to undo the current injection configuration before implementing another one.

- To undo automatic injection, clear the **Enable Automatic Injection of JavaScript** check box.
- To undo assisted injection using attribute injection, clear the **Request Attribute Injection** check box, and manually delete the code snippets.
- To undo manual injection, manually delete the JavaScript Agent code from your web pages.
- To undo assisted injection using injection rules, clear the **Enable** check box for each injection rule in the injection rules list.

If multiple copies of the agent exist on a page, the second copy does not execute.

Fix Page Rendering Issues

The rendering of pages in some browsers, in particular, Internet Explorer (IE), may be adversely affected by the JavaScript Agent injection.

After you have confirmed that the JavaScript Agent injection is causing the issue, try the following:

1. Inject the JavaScript Agent after the last <meta> element.
2. Inject the JavaScript Agent just before the closing <head> element.

If you are using automatic injection, see Troubleshoot Automatic Injection.

> Injecting the JavaScript Agent just before the closing <head> tag is *not* the recommended practice because the JavaScript Agent will not capture the resource timing metrics for resources loaded before it. Thus, only do this as a last resort.

Inject After Last Meta Element

To avoid rendering issues and capture resource timing metrics, you are recommended to inject the JavaScript injection right after the last <meta> element in the <head> as shown below.

```
<head>
  <meta charset="UTF-8">
  <meta name="description" content="Fancy Web Page">
  <meta name="keywords" content="HTML,CSS,XML,JavaScript">
  <meta name="author" content="John Doe">
  <meta name="viewport" content="width=device-width, initial-scale=1.0">

  // Injection of the JavaScript Agent after the last <meta> tag
  <script charset='UTF-8'>
    window['adrum-start-time'] = new Date().getTime();
    (function(config){
      config.appKey = 'SH-AAB-AAC-XAR';
      config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
      config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
      config.beaconUrlHttp = 'http://eum-col.appdynamics.com';
      config.beaconUrlHttps = 'https://eum-col.appdynamics.com';
      config.xd = {enable : false};
    })(window['adrum-config'] || (window['adrum-config'] = {}));
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'/>
  // The rest of the JS and CSS files
  <script src="https://code.jquery.com/jquery-<version>.js" integrity="sha256-DZAnKJ/6XZ9si04Hgrsxu
/8s717jcIzLy3oi35EouyE=" crossorigin="anonymous"></script>
  <script src="js/custom-script.js"></script>
  <link type="text/css" rel="stylesheet" href="css/custom-style.css" />
  ...
</head>
```

Inject Before the Closing Head Element

On rare occasions, some browsers, in particular, Internet Explorer (IE), will still render the page incorrectly because of where the JavaScript Agent is injected. In such cases, as a last resort, try injecting the JavaScript Agent right before the closing <head> element:

```
<head>
  <meta charset="UTF-8">
  <meta name="description" content="Fancy Web Page">
  <meta name="keywords" content="HTML,CSS,XML,JavaScript">
  <meta name="author" content="John Doe">
  <meta name="viewport" content="width=device-width, initial-scale=1.0">
  <script src="https://code.jquery.com/jquery-<version>.js" integrity="sha256-DZAnKJ/6XZ9si04Hgrsxu
/8s717jcIzLy3oi35EouyE=" crossorigin="anonymous"></script>
  <script src="js/custom-script.js"></script>
  <link type="text/css" rel="stylesheet" href="css/custom-style.css" />
  ...
  // Injection of the JavaScript Agent before the closing <head> tag
  <script charset='UTF-8'>
    window['adrum-start-time'] = new Date().getTime();
    (function(config){
      config.appKey = 'SH-AAB-AAC-XAR';
      config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
      config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
      config.beaconUrlHttp = 'http://eum-col.appdynamics.com';
      config.beaconUrlHttps = 'https://eum-col.appdynamics.com';
      config.xd = {enable : false};
    })(window['adrum-config'] || (window['adrum-config'] = {}));
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'/>
</head>
```

Troubleshoot Automatic Injection Issues

If you are using the .NET Agent to automatically inject the JavaScript Agent into pages and the pages are not rendering correctly:

1. Use manual injection and make sure that the JavaScript Agent is injected after the last <meta> element.
2. If you cannot use manual injection, add the registered node property `eum-header-beforeendofheadtag` to a Web tier or particular nodes. This node property configures the .NET Agent in the specified tier or nodes to inject the JavaScript Agent right before the closing `<head>` tag.

Browser Snapshot Problems

This page provides help with troubleshooting problems with browser snapshots.

No Browser Snapshots

If you do not see any browser snapshots, it is possible that browser snapshot collection has been disabled. If periodic collection and error collection and slow collection are all disabled, the agent does not collect any browser snapshots. See Configure Browser Snapshot Collection.

Also, check the thresholds that define slow end-user experience. AppDynamics collects browser snapshots only for slow-performing requests, so if the thresholds are set too high, no requests are flagged as slow. See Configure Browser RUM Performance Thresholds.

No Correlation between Browser Snapshots and Business Transactions

You get server-side correlation with browser snapshots only if the business transactions associated with the browser snapshot are running on application servers instrumented with AppDynamics app agents. This could explain why you do not see any or do not see all of the business transactions that you expect to see. Check which of your servers are instrumented by app agents and which are not. You may need to get more AppDynamics app agent licenses to get correlation.

If the app servers are all instrumented with AppDynamics app agents, it is possible that the business transactions that you expect to see were not injected with the JavaScript Agent for Browser Monitoring. This can happen when automatic injection is used with a limited set of business transactions enabled for injection. If you used automatic injection, check your automatic injection configuration to see if the missing business transactions are enabled for injection. See Verifying that the JavaScript Agent for Browser RUM was injected and Automatic Injection of the JavaScript Agent. Business transactions can also be excluded with assisted injection using injection rules when an injection rule specifies only certain business transactions to be injected. If you used assisted injection with injection rules, check your injection rules. See Assisted Injection.

No Transaction Snapshots Associated with Browser Snapshots

Even if all your app servers are instrumented with AppDynamics app agents, it is possible that no associated transaction snapshots were captured at the time of the browser snapshot. For example, if no transactions were slow at the time of the browser snapshot, you probably will not see any transaction snapshots. See Transaction Snapshots for information about when transaction snapshots are captured. You can modify transaction snapshot capture.

On the browser side, if a browser snapshot is associated with a transaction snapshot, you will see it in the **Transaction Snapshots** section of the browser snapshots. See Business Transactions in Browser Snapshots. On the server side, if a transaction snapshot is associated with a browser snapshot, you will see an EUEM GUID in the **ADDITIONAL DATA** tab in the transaction snapshot. See Transaction Snapshots.

Not Getting Full Timing Data for Business Transactions Associated with Browser Snapshots

To ensure full business transaction timing information using older agents and controllers (3.8 and before), you need to inject the JavaScript footer for Browser RUM into the footer of your web pages. Manual injection of the agent does not inject into the footer, so you need to use another injection method to get this functionality.

See Getting Full Timing Data for Associated Business Transactions and Choosing Your Injection Method.

No Correlation between Cross Domain AJAX Requests and Business Transactions

Your JavaScript Agent may not be able to correlate Ajax requests with business transactions because browsers restrict access to certain HTTP response headers. Your application, however, can explicitly give browsers access to HTTP headers by sending the HTTP response header `Access-Control-Expose-Headers` with a list of the headers that you want the JavaScript Agent to access.

The process of correlating cross-domain Ajax requests and business transactions consists of the following two steps:

1. Set the agent, tier, or application node property `always-add-eum-metadata-in-http-headers` to `true`. If this property doesn't exist, you need to add and register it as described in Add a Registered Node Property.
2. Modify the application code, so that the returned response header includes the field `Access-Control-Expose-Headers` as shown below:

```
Access-Control-Expose-Headers: ADRUM_0,ADRUM_1,ADRUM_2,ADRUM_3,ADRUM_4,ADRUM_5,ADRUM_6,ADRUM_7,ADRUM_8,
ADRUM_9,ADRUM_10,ADRUM_11,ADRUM_12,ADRUM_13,ADRUM_14,ADRUM_15,ADRUM_16,ADRUM_17,ADRUM_18
```

Connection Problems

If your browser cannot connect to the AppDynamics EUM cloud and you use an on-premises Controller, but not an on-premises EUM Server, it is possible that:

- You have no Internet connectivity
- A firewall is blocking the port

Verify Connectivity

Navigate to SaaS Domains and select your geolocation. Find the EUM API Domain and add the following endpoint: `eumaggregator/ping`

If you receive a "ping" in the panel, you should be able to connect to the EUM Cloud.

> If you are using IE on a Windows system, make sure the browser itself does not have a proxy (with authentication) set up. If it does, the test link may work but not the actual connection.

Make sure you have also unblocked any firewalls and verified the keystore entries.

Unblock Your Firewall

The Controller needs to be able to use HTTP over SSL (HTTPS) on port 443 to reach the EUM Cloud Aggregator in your region.

Navigate to SaaS Domains and select your geolocation. Find the EUM API Domain and add the following endpoint: `eumaggregator/ping`

If your Controller is behind a firewall, you can either open your Controller's firewall or use a forward proxy.

To open the firewall, see the instructions unique to your firewall.

> You only need to open the firewall for the specific host and port, not for the entire `*.eum-appdynamics.com` domain.

Use a Forward Proxy:

1. Set up an HTTP proxy to your SaaS EUM API Server. Navigate to SaaS Domains and select your geolocation. Find the EUM API Domain and add the following endpoint: `eumaggregator/ping`

   > This is a cleartext/pass-through proxy. Authentication is not supported on the first level. If the client network itself requires authentication, you must set up an intermediate proxy between your Controller and this proxy to pass on the credentials you need to get out of your network.

2. Configure the HTTP proxy host and port in the `<Controller-Installation-Directory>/appserver/glassfish/domains/domain1/config/domain.xml` file by adding the following JVM options to the existing `java-config` element:

   ```
   <jvm-options>
        -Dappdynamics.controller.http.proxyHost=myhost
   </jvm-options>
   <jvm-options>
        -Dappdynamics.controller.http.proxyPort=8888
   </jvm-options>
   ```

3. Restart the Controller's app server.

JavaScript Errors

This page provides helpful tips for finding and solving common JavaScript errors.

Enable Error Reporting

It is possible that reporting is disabled or that certain JavaScript or Ajax errors that you would like to be reported have been configured to be ignored. See Configure JavaScript and Ajax Error Detection.

If another script on your monitored pages sets the JavaScript `window.onerror` event, this setting can interfere with Browser RUM error capture. See Handle the window.onerror Event.

Visualize JavaScript Errors

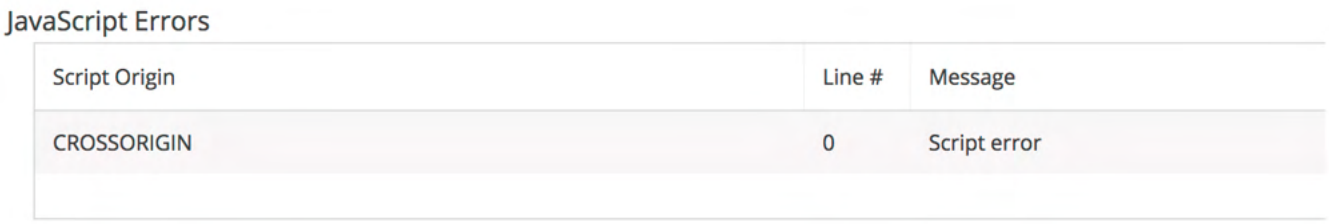
You can use Analytics to query your Browser Request event data and create a JavaScript exception and error summary dashboard.

See Visualize JavaScript Errors.

View Error Information for Cross-Domain JavaScript

By default and for security reasons, most modern browsers do not provide access to the error information in `window.onerror` for scripts that are loaded from other domains. To access this error information, you need to enable cross-origin resource sharing (CORS). Firefox and Chrome both allow you to enable CORS by making small changes to your server and `script` element in your HTML.

If you have **not** enabled CORS, the error message "CROSSORIGIN" displays:



Once CORS is enabled, you will able to see error details like those shown here.

Also, when you can navigate to your page from Chrome and then open **JavaScript Console > Network > Headers**, you'll see the HTTP response header `access-control-allow-origin: *`.

In the following sections, we're going to show you how to make changes to access the error information in `window.onerror` cross-domain scripts.

Server Change

To enable CORS, you need to add this header to responses that are not from the same domain as the caller:

```
Access-Control-Allow-Origin: *
```

Script Tag Change

The `script` element has a new non-standard attribute called `crossorigin`. The most secure value for `crossorigin` would be `anonymous`. So, you'll have to modify your script tags to look like the following.

```
<script src="http://sub.domain.com/adrum.js" crossorigin="anonymous"></script>
```

Browser Support for CORS

In the future, we expect most browsers to enable CORS. Internet Explorer 10+ already has native support for CORS and reports errors to `window.onerror` for both local and cross-domain scripts. See CORS: Browser support to see a list of browsers/layout engines that support CORS.

Browser Synthetic Monitoring

Related pages:

- Browser Synthetic Monitoring versus Browser Real User Monitoring
- Get Started with Browser Synthetic Monitoring

Browsers Synthetic Monitoring uses geographically distributed Synthetic Agents to continuously test key user workflows in your application. This allows you to monitor the correctness and performance of multi-step flows independently of the user-generated load.

There are two ways of using Synthetic:

- **Scheduled jobs**: Use this to test your pages on a recurring basis to ensure they continue to perform well. Upload a Python WebDriver script to exercise multi-step workflows. Using this feature requires a Synthetic Pro license. See Browser Synthetic Licenses for more information.
- **On-demand snapshots**: Use this to collect performance data right now. This is useful for ad-hoc analysis. This feature is available with both Synthetic Lite and Pro licenses.

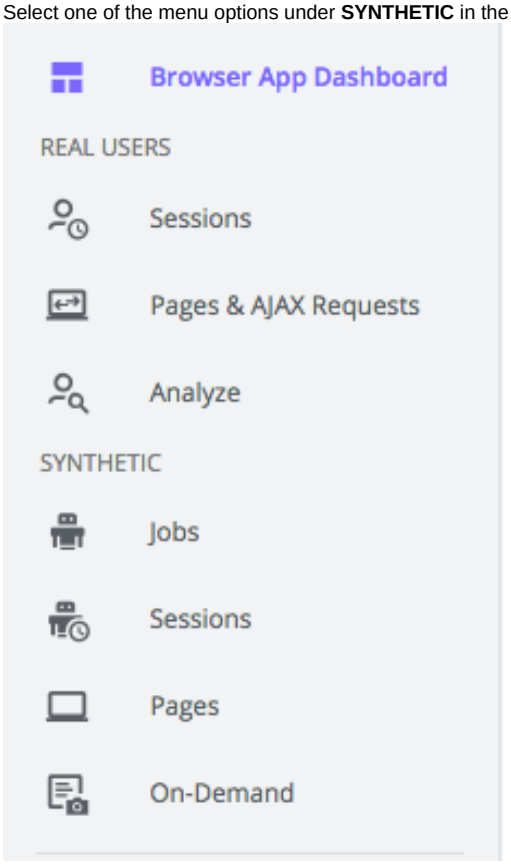
There are two deployment types for Synthetic Agents:

- **Synthetic Hosted Agents:** AppDynamics hosts these Synthetic Agents. This deployment is recommended for testing public websites.
- **Synthetic Private Agents:** You install and host Synthetic Agents on your machines. This enables you to test internal sites and services. For more information, see Synthetic Private Agent Deployment.

Separate licenses are required for the Synthetic Hosted Agent and the Synthetic Private Agent. See Synthetic Agent Licenses for details.

Access Synthetic

1. Open the browser application that you want to test with Synthetic or create a new one if you're just getting started.
2. Select one of the menu options under **SYNTHETIC** in the left navigation bar.



Scheduled Jobs

The **Jobs**, **Sessions**, and **Pages** options are only displayed if you have a Browser Synthetic Pro license.

- **Jobs:** Create and manage recurring jobs. See Get Started with Browser Synthetic Monitoring.
- **Sessions:** View individual executions of your jobs (i.e., "sessions") and perform an analysis to understand where the problems are.
- **Pages:** View aggregated page-level statistics collected from Synthetic. This is particularly useful for comparing Browser RUM with Synthetic.

You can also see some synthetic results in the context of real user traffic in the Browser App Dashboard.

On-Demand Snapshots

Create and view on-demand snapshots using On-Demand.

Website Authentication Methods

The following table lists the authentication methods that are supported and not supported in Synthetic Monitoring.

Supported	Not Supported
Websites that authenticate through an explicit login page	Integrated Windows Authentication (see windows authentication)

Browser Support

Agent	Supported Browsers
Hosted Agent	• Chrome 86 • Chrome 63 • Firefox 72.0.1 • IE 11
Private Synthetic Agent (Windows)	• Chrome 81.0.4044.0 • Firefox 72.0.1 • IE 11
Private Synthetic Agent (K8S Container Agent)	• Chrome 86

Limitations

Browser Extensions

Browser Synthetic Monitoring does not support monitoring for the browser extensions Adobe Flash, Microsoft Silverlight, or Java applets.

Single-Page Applications (SPAs)

Browser Synthetic Monitoring does not fully support SPA. Instead of reporting the base page and virtual pages separately like Browser RUM does, Browser Synthetic Monitor reports all the virtual pages with the base page, so you will only see one page in the Synthetic Sessions.

Multiple Window Tests

Browser Synthetic Monitoring supports running tests in multiple windows for Firefox and Chrome, but *not* for Internet Explorer Browser.

Chrome Version 86

This page provides details about the impact of updating the current browser version to headless Chrome Version 86.

- Chrome version 86 is now available in all 16 AWS locations and the 5 Azure locations will be available shortly.
- When you select Chrome browser, jobs are executed only from the 16 AWS locations even if other locations are selected.
- When a browser other than chrome is selected, jobs continue to be executed in that browser from all the selected locations.
- Chrome version 86 is available only for the SaaS controllers.

Browser Version

Current Browsers	New Browser	Impact	Action
Chrome versions - 64, 79,81, and 83	Headless Chrome Version 86	Headless version includes major security enhancements and changes in the browser engine that results in increased page load time and session duration.	• Increase the timeout configuration as required in the scripts. • Update the performance and alerting configurations as required.
		Some Python based Selenium scripts that run successfully in Chrome version 64 fail with "Script broken" error in Chrome version 86. This happens due to incompatibility between the Selenium commands and the latest Chrome web-driver.	• Update the scripts to fix this issue. • If the scripts pass locally with Chrome version 86 (Headless Chrome), reach out to the AppDynamics support team.
		Current Behaviour: Sessions with 4xx errors are not treated as client errors in certain cases	No action required.

		Headless Chrome does not support extensions or embedded PDF viewer. The PDF is downloaded and viewable in resource waterfall but screenshot is not present. Hence, you can verify the availability of a PDF file but cannot take a screenshot.	You can verify the availability of the PDF document by sending an HTTP request using Python's request library and asserting on the response code.
			Following is a sample script:
			`import requests`
			
			`response = requests.get ("https://www.mohfw.gov.in /pdf /PreventionandManagementof COVID19FLWEnglish.pdf") print ("Got response " + str(response.status_code)) assert (response. status_code == 200)`

Agent Machine Configuration

Current Browser	New Browser	Impact	Action
Machine configuration: 2vCPU 8GB RAM	• Container configuration: min 0.75 vCPU - max 1.25 vCPU, 2GB RAM. • Uses burst-able limits of Kubernetes for better resource utilisation.	The page load time and session duration might increase.	• Increase the timeout configuration as required in the scripts. • Update the performance and alerting configurations as required.

Job execution environment

Current Browser	New Browser	Impact	Action
Jobs are executed in Windows environment.	Jobs are executed in K8S based Alpine containers.	If the website serves content based on operating system (OS), the scripts created based on windows environment fail.	Update the scripts with Linux environment based content.

		Scripts fail with 4xx error in some cases. This issue might occur when the server denies access to Linux agents or when website access is restricted only in Windows environment.	Provide access to Linux agent.
		• The NAT based address can be different from the existing whitelisted IPs. So the existing whitelisting may not work. • Session might fail with '4XX client error'	Update the IP whitelisting based on the AWS IP ranges. IP ranges used in our AWS locations are available here.
		The jobs with OS or file system based commands fail. As per AppDynamics security standards, jobs are executed in stateless environments meant only for the execution of web tests. Hence, OS/file system based commands are not supported.	If you have used OS or file system based commands in your scripts, remove those commands.

Network Throttling

Current Browser	New Browser	Impact	Action
Network throttling feature is implemented using a third party library.	Network throttling is implemented using Chrome browser dev tools protocols.	• The network throttling accuracy is improved. • Jobs which have configured network throttling may observe increased session duration.	Either increase the timeout value or re-configure the throttling speed of the job.

Browser Synthetic Monitoring Versus Browser Real User Monitoring

Browser Synthetic User Monitoring (Browser SUM) and Browser Real-User Monitoring (Browser RUM) both have the same goal of helping you improve your user's experience. The difference between the two is how they are used to accomplish this goal.

This page describes the monitoring differences, and how to use the two monitoring types together.

Identify Issues

Although Browser RUM can detect certain kinds of problems (like JavaScript exceptions), it cannot comprehensively test for functional correctness. For example, you may want to verify that your online store has reasonable prices a list of items. If your site is down entirely, then the JavaScript Agent will never be loaded, so errors or verifications will not be reported. Fortunately, Browser SUM will keep running, discover the error, alert you, and provide detailed information about the problem.

Control Environmental Factors

Performance analysis in Browser RUM is complicated by the wide range of hardware, browsers, operating systems, and networks with which users access your site. Browser SUM uses consistent hardware, software, and network configurations, so if you see deviations in performance, you can be fairly certain a problem exists.

Use Synthetic Metrics and Screenshots to Understand the User Experience

Browser SUM can collect certain data that Browser RUM cannot. For example, Browser SUM provides screenshots, which shows you the current situation. You can also use the Visually Complete and related metrics to understand how users experience page load time.

Performance Versus Workflows

Browser RUM excels at capturing the full breadth of performance that your real users experience. Browser SUM gives you confidence that your key workflows are always working and performing.

Differences Between Synthetic and Browser RUM Metrics

Although Browser SUM and Browser RUM report similar metrics, you should be wary of comparing them because of these differences:

- Hardware
- Network connections
- Different browsers
- Browser caching is not present in synthetic sessions

If you see a sudden change in any of those metrics, however, you should compare the results of Browser SUM and Browser RUM to see if there is an existing problem.

Get Started with Browser Synthetic Monitoring

Related pages:

- Configure Synthetic Jobs
- Synthetic Scripts
- Synthetic Sessions

This page describes Browser Synthetic Monitoring, including how to access the **Jobs** page, create a job that measures a URL, view the results from the **Sessions** page, and finally how to edit and delete your job.

Create a Job

1. Open one of your browser applications.
2. Click **Jobs** to open the **Jobs** page.
3. If you don't have any previous jobs, click **Create a New Job >**. If you have previous jobs, click **Add**.
4. From the **New Job** dialog:
    a. For **Specify your Test**, enter a URL in the **URL** field and "Example Job" in the **Name** field.
    b. For **Choose Browsers**, select Chrome.
    c. For **Choose Locations**, click **+** and select any location.
    d. Click **Save**.

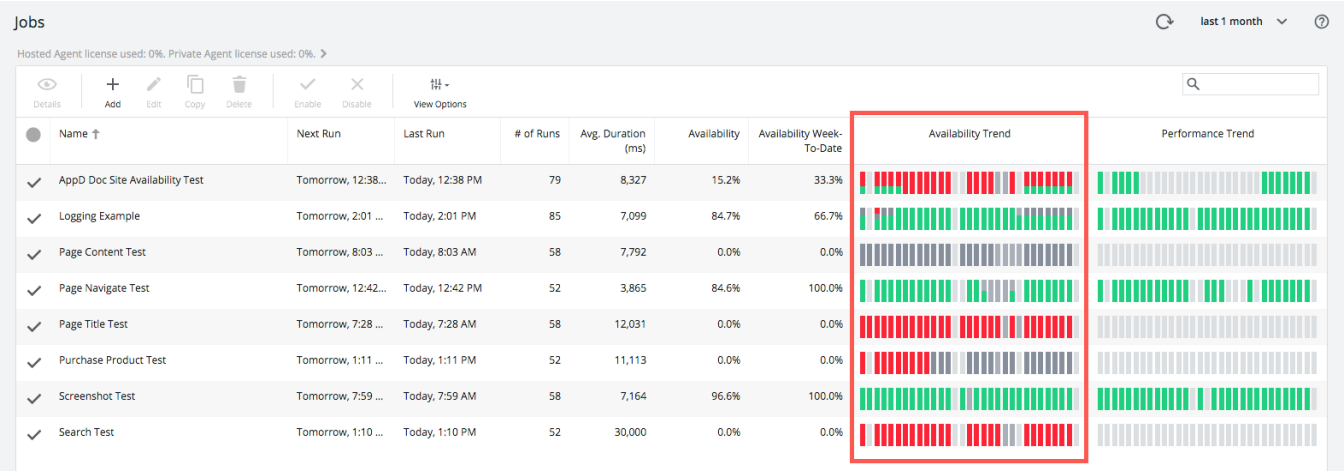
See Configure Synthetic Jobs.

Monitor Job Trends

From the Synthetic Job Dashboard, you can quickly monitor the availability and performance trends of synthetic jobs.

Availability Trends

The **Availability Trend** column that displays the status of the executed jobs as shown in the screenshot below. The **Availability Trend** shows the session status based on the coloring codes listed in Availability Trend Status Codes. The session status is not based on health rules. See Session Status.



> The session status is not based on health rules. See Session Status.

Availability Trend Status Codes

The **Availability Trend** shows the session status based on the coloring codes listed in this table.

Availability Trend Status Color	Session Status
Green	OK
Yellow	WARNING
Red	FAILED
Dark gray	BROKEN

Light gray	INTERNAL_ERROR

Understanding the Availability Metric

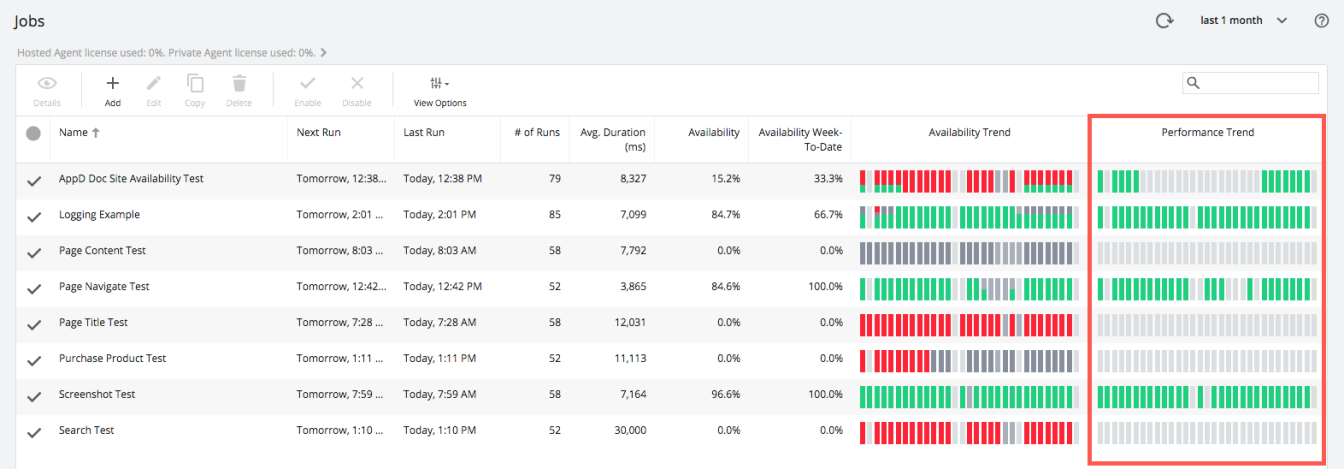
The Availability metric is the percentage of successful sessions for a given time range. That is the percentage of sessions with status as OK or WARNING within the given time range.

The **View Options** enables you to view the availability over periods not restricted to the specified time frame. The following list describes the availability options:

- **Availability Last-24-Hours** - The availability for the last 24 hours from the moment the page is refreshed/opened.
- **Availability Month-to-Date** - The availability from the starting moment (12 AM) of the current month according to user's timezone until the current time (page refreshed/opened).
- **Availability Week-to-Date** - The availability from the starting moment (12 AM) of the current week Monday according to user's timezone, considering week starts on Monday, till now (page refreshed/opened).

Performance Trends

The **Performance Trend** column displays the performance threshold status of the executed jobs as shown in the screenshot below. The **Performance Trend** column only displays successful sessions: those with the status of OK or WARNING. The performance trend statuses are based on the configured performance thresholds for the synthetic job.



For example, if the **Availability Trend** column shows 5 OK and 5 FAILED status counts (50% green, 50% red), then the corresponding **Performance Trend** column will show only 5 OK counts (100% green). If the **Availability Trend** column has 5 failed and 5 broken (50% red, 50% gray) jobs, that is all unsuccessful, then corresponding Performance Trend column will show no count that is an empty bucket (light gray).

Performance Trend Status Codes

As with the availability status, colors are used in the trend column to indicate performance status:

Performance Trend Status Color	Description
Green	No threshold violated: Green.
Yellow	Warning threshold violated.
Red	Critical threshold violated.

A job can have a warning violation for one metric and a critical violation for another metric. In this case, the critical violation will override the warning violation.

View the Results

1. From the **Jobs** page, verify that your job has a check next to it indicating that the job has been enabled.
2. After a few minutes, you should see a time that your job was last run and some metrics.
3. Select your job and click **Details**.
4. You should now see the results for your job on the **Sessions** page.

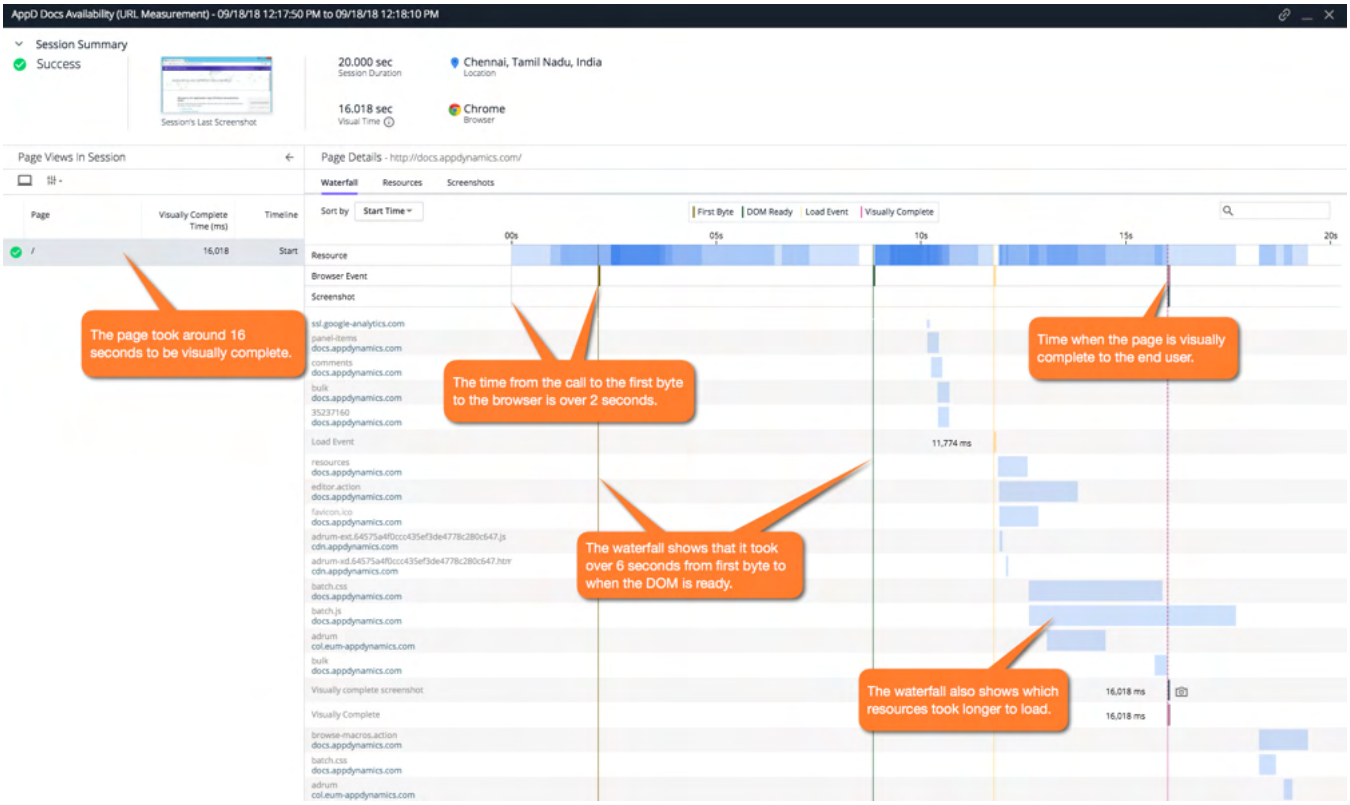
Understand the Results

You can understand the results in several different ways and levels from the **Sessions** page. You can sort session results by criteria and then examine the details of a specific session in the **Session Details.** From the Charts tab of the **Sessions** page, you can then view widgets representing aggregated session data in charts and a configurable set of fields for each session.

Examine Session Details

You can double-click any session to get a summary of the session, page details, and a breakdown of details for each page in the session. You'll be able to view how the page loaded, the resources that were requested, and the business transaction for each page. You can use this information to find where network latency occurs or where scripts break.

For example, from the **Session Details** dialog, you can determine that the visually complete (when the user would see the completely loaded page) took around 16 seconds and then examine the duration of the page load from the HTTP request to the first byte, from the first byte to DOM ready, and finally from DOM ready to visually complete.



Get a Quick Overview

From the **Sessions** page, you can click the Charts tab to view widgets representing aggregated session data. For example, the **Lowest Availability** widget shows you what locations are the least available, so you can confine and focus on issues in specific locations.

Synthetic Jobs

Synthetic jobs are configurable, scheduled tests that mimic end-user actions in remote browsers in supported locations. Synthetic jobs consist of URL measurements or synthetic scripts. To create a job, see Get Started with Browser Synthetic Monitoring.

Support

The table below describes supported versions and libraries for Synthetic Jobs.

Support Type	Description
Browser Versions	• IE 11 • Chrome 81.0.4044.0 • Firefox 72
Python Versions	• Python 2 • Python 3
Python Libraries	• selenium • Requests • pysftp

Locations

For URL measurements and synthetic script jobs, the Synthetic Agent is always executed in isolation within a Docker container. This location is then mapped to the configured browser location. The synthetic script, however, is run on a different machine or location from the configured browser for security reasons. See Synthetic Agent Locations for more details.

Maturity Levels

When you create a synthetic job, it is added to a queue based on the creation timestamp. Scheduled jobs are assigned a maturity level that influences when they will be executed in the synthetic job queue. The table below describes the two supported maturity levels.

Maturity Level	Description
Junior	The Junior maturity level consists of synthetic jobs that are created or updated within two hours. Once two hours have passed since the last update or creation of the job, the Junior job maturity level is promoted to Senior maturity level. The promotion from Junior to Senior maturity is only performed only if enough capacity has been allocated. This avoids negatively affecting jobs which are currently executing.
Senior	The Senior maturity level consists of synthetic jobs that have been created or updated more than two hours ago. Synthetic jobs with Senior maturity level have ample allocated resources to be executed.

Execution Order

The execution order of synthetic jobs depends on the job priority and the job creation time. Synthetic jobs are only executed if they are in the job queue. Job priority is based on several factors: job type, job maturity, and your Browser Synthetic Monitoring license. The table below shows how the job priority is calculated. The actual job execution order depends on the job priority and job creation timestamp.

Synthetic jobs are only executed if they are in the job queue. If the max job queue size has been reached, however, no additional synthetic jobs will be added to the queue until the queue size decreases. The max queue size is defined by the priority, license, type, and maturity level.

Queue	Job Type	Job Seniority
High-priority	Scheduled	Senior
	On-demand	N/A
Low-priority	Scheduled	Junior

Execution Cadence

The synthetic job scheduler executes jobs according to the following cron-based expression:

```
<second> <minute> <hour> <day-of-month> <month> <day-of-week> <year>
```

When you schedule a job, you choose how frequently the job runs. It is recommended you choose a larger unit of time (hours or days) that can evenly divide into the smaller unit of time (minutes or hours). For example, if a job is scheduled to run every 15 minutes, the job runs four times within the hour. This results in the job consistently repeating every hour without interruption to the schedule.

However, if you schedule a job such that a larger unit of time that does not divide evenly into the smaller unit of time, such as running every 50 minutes, then the job does not run at consistent times. For example, if the first job starts at 7:03, then the job will run at 7:53, 8:03, 8:53, and so on, resulting in a disruption to the schedule.

Execution Errors

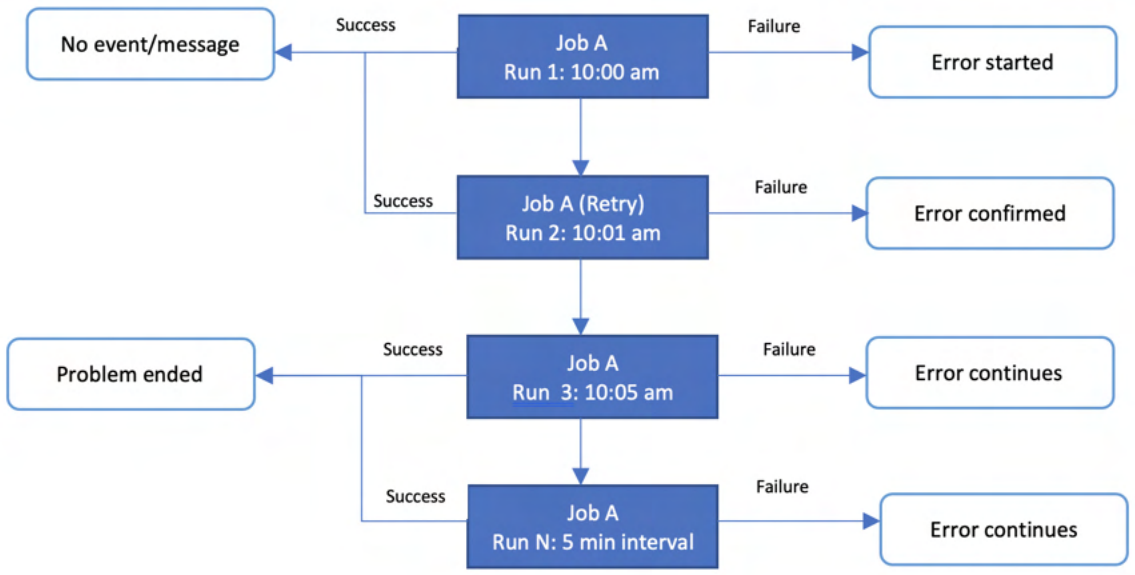
The following table provides job execution error messages, the cause of the error, and the associated error code.

Error Message	Cause of Error	Error Code
Skipped; still waiting for a previous job execution	An attempt was made to queue a high-priority measurement request from a scheduled job before the previous measurement request from the same job, and location-browser combination has been processed.	`TARDY`
Skipped while new capacity is being added	An attempt was made to queue a low-priority measurement request from a scheduled job before the previous measurement request from the same job, and location-browser combination has been processed.	`TARDY_ONBOARDING`
Skipped while new capacity is being added	An attempt was made to queue a measurement request from a junior job beyond the maximum respective queue capacity.	`ONBOARDING`
Testing location is overloaded	An attempt was made to request measurement from a senior job beyond the maximum respective queue capacity.	`THROTTLED`

Health Rule Violation Events

You can configure health rule violation events, such triggering an event when a job fails. To set health rule violation events, create an alerting policy for synthetic jobs.

The diagram below shows the retest process when a job fails, and what events are triggered. In this example, a job is scheduled to run at 10:00 am. If successful, no event or message is triggered; if it fails, "Error started" is triggered and the job retests. If successful, no even or message is triggered; if it fails, "Error started" is triggered and the job retests. If successful, "Problem ended" is triggered; if it fails, "Problem ended" is triggered and the job retests. As long as the job continues to fail, the job will retest every 5 minutes and continue triggering "Error continues."



Configure Synthetic Jobs

Related Pages:

- Get Started with Browser Synthetic Monitoring
- Alerts for Browser Synthetic Monitoring

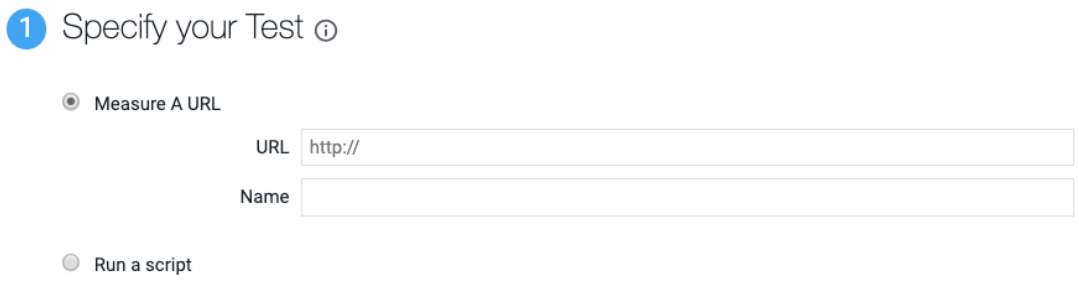
This page describes how to use the Controller UI to configure a synthetic job. You can schedule when, where, and how often a job runs, set timeouts, configure performance thresholds to trigger warning and critical events, and customize connection speeds. Before configuring a job, see Getting Started with Browser Synthetic Monitoring.

Specify your Test

Synthetic Jobs use either a specific URL or webdriver script to test one or more web pages. If your site requires authentication, you must create a script which performs the authentication to log onto your site. See Synthetic Scripts for more information.

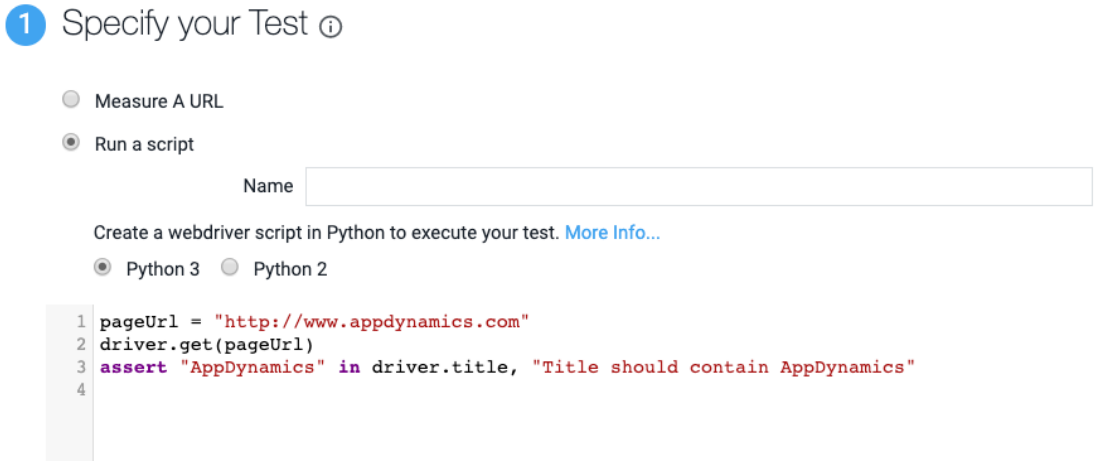
To use a URL:

1. Select "Measure a URL".
2. In the URL field, enter a site or page URL.
3. In the Name field, enter a name for the job. This name appears in the Jobs list in the Controller UI.



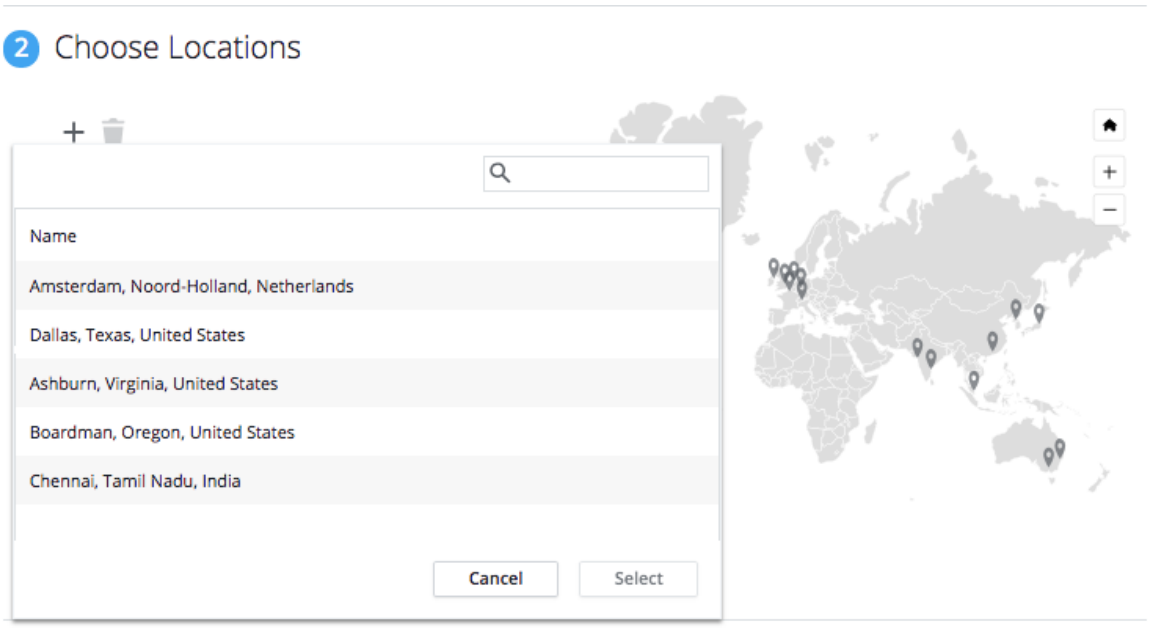
To use a webdriver script:

1. Select "Run a Script".
2. Select Python 3 or Python 2.



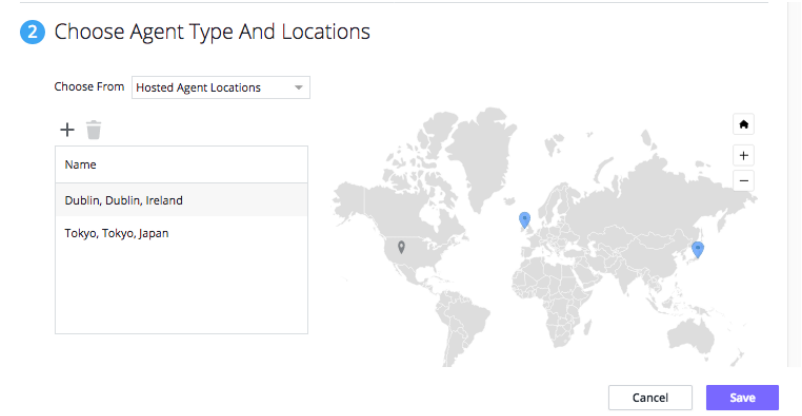
Choose Locations

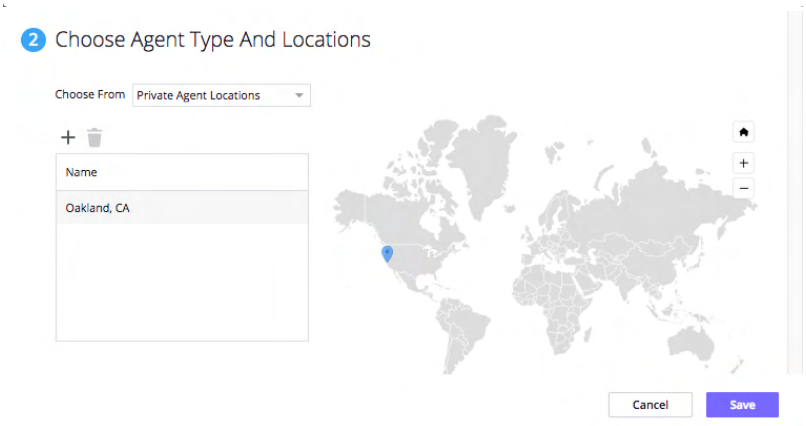
You can choose one or more locations in which the job runs. This can also be configured to test all of the locations every time or one location each time the job runs. For a complete list of Synthetic Agent locations, see Synthetic Agent Locations.



Hosted Agent Locations and Synthetic Private Locations

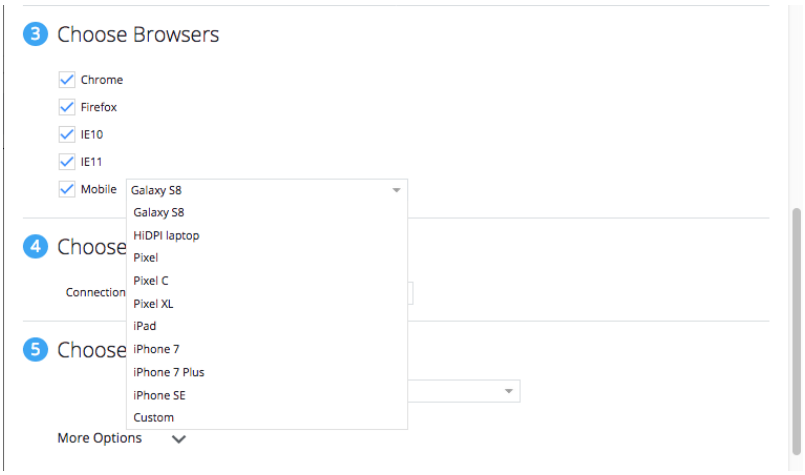
If you have deployed a Synthetic Private Agent Deployment, you can choose from **Hosted Agent Locations** or **Private Agent Locations**. The **Hosted Agent Locations** are where AppDynamics hosts public synthetic agents. The **Private Agent Locations** are where you are hosting your synthetic private agents.





Choose Browsers

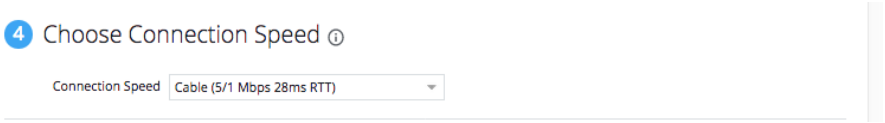
A job can run on one or more different types of browsers. For mobile browsers, you can specify a platform, such as the iPhone 7 Plus or Pixel. When a job runs on mobile browsers, it is actually running a Chrome browser emulator with the specified platform properties.



All the browsers are running on either Windows 2012 or Windows 2012 R2.

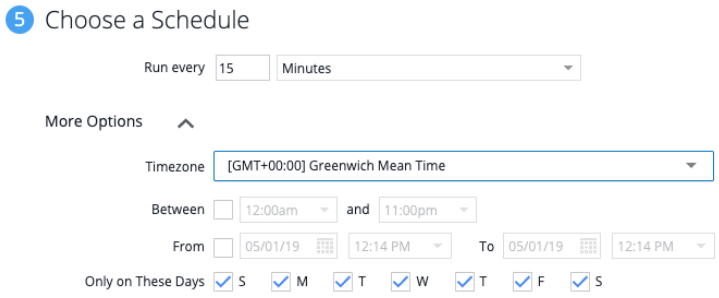
Customize Connection Speeds

The connection speed helps keep performance consistent and realistic. If you choose **Native Connection**, the job will run at the maximum speed available to AppDynamics data centers. The default is **Cable (5/1 Mbps 28ms RTT)**.



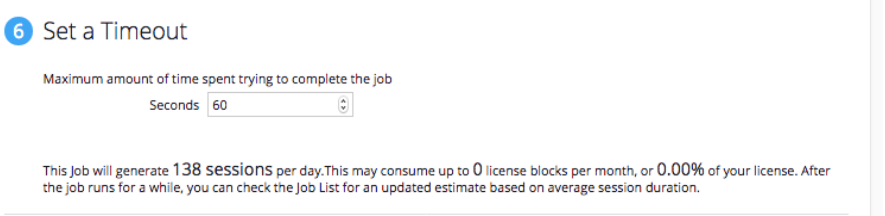
Schedule Jobs

When you create or edit your job, you can define the job schedule. The job will run within the specified timezone. When you choose a timezone, the job schedule will not be affected by time changes in any other timezone, such as daylight saving time. The default timezone is GMT.



Set Timeouts

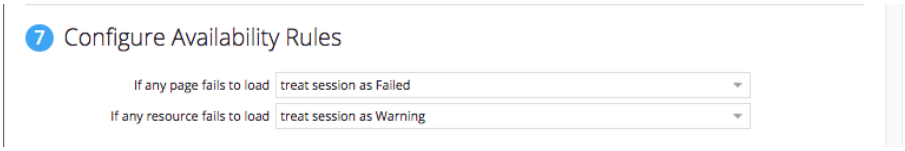
Synthetic jobs consume licenses based on the duration of the job, so you can set a timeout to help limit the license consumption. If the job times out, data will still be collected until the timeout expires. The default suggestion for job timeout is 15 seconds for a URL and 30 seconds for a script. You can adjust the timeout as preferred, but keep in mind that short timeouts might result in unsuccessful sessions, and long timeouts might result in overconsumption of licenses.



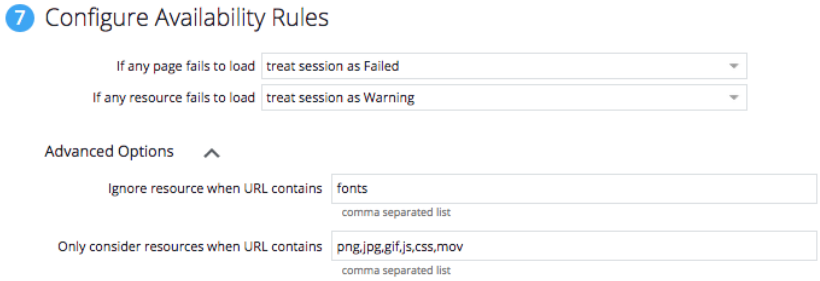
Configure Availability Rules

You can configure the synthetic job to check the availability of pages and resources. For example, you can set the session status for when a page fails to load or when a resource is missing or inaccessible.

The screenshot below is a configuration to treat the session as **Failed** if any page fails to load and to treat the session as **Warning** if any resource fails to load. If the job navigates to a page with an HTTP 4xx or 5xx status code, the session status will be set to `FAILED`. This will trigger a Critical Event. If a resource fails to load, the session status will be set to `WARNING`, which will trigger a Warning Event. To set up alerts, see Alerts for Browser Synthetic Monitoring.



Use the **Advanced Options** to ignore or only consider selected resources. For example, the screenshot below might be used to ignore the font resource (which browsers may not have) and only consider high-impact resources like CSS, JavaScript, etc.

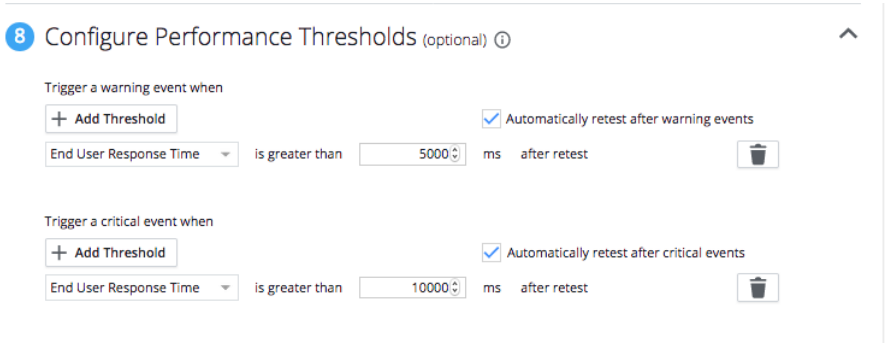


> Favicons are always ignored when checking the availability of resources.

Configure Performance Thresholds

You can specify the job performance thresholds to send alerting events. For an example of the health rule violation process, see Health Rule Violation Events.

If you check one or both of the "**Automatically retest after warning events"** or "**Automatically retest after critical events"** boxes, and the event is generated, then the job will be triggered to re-execute immediately per unconfirmed warning or critical event. For example, if the **Critical Events** threshold is exceeded, the event **Critical Started** will be triggered and the job will rerun until the event **Critical Continues** is confirmed. Learn more about the synthetic job retest process.



From the **Events** page shown below, you can see that the results of the first and successive tests exceeded the threshold for synthetic availability and triggered the **Error Started**, **Error confirmed after restart**, **Error Continues**, and **Problem Ended** events.

Synthetic Scripts

Browser Synthetic Monitoring allows you to write Python scripts using the Selenium WebDriver library to create scheduled tests that can mimic end-user actions in remote browsers in supported locations. For supported Python versions and libraries, see Synthetic Jobs.

You can use synthetic scripts to test performance, features, end-user flows, and the end-user experience.

For example, your synthetic script might do the following:

1. Visit your website.
2. Search for products.
3. Add items to a shopping cart.
4. Check out the shopping cart and assert that the total price of the cart is correct.
5. Enter payment details.
6. Complete the purchase.

Benefits of Using Synthetic Scripts

Using synthetic scripts, you can:

- find broken user flows
- improve the performance of your site by finding where response times in your web applications are slow
- test new features

How Scripts Are Run

The entire process can be simplified into the following steps:

1. You add your script to a synthetic job in the Controller UI.
2. The synthetic job is transmitted to the Synthetic servers, where it is scheduled to be run.
3. When it's time for your job to run, a container is created just for your script.
4. Your script runs in the container, controlling a web browser using Remote WebDriver.
5. After the script finishes running, the agent collects browser metrics and sends them to the Controller UI.

The Controller UI receives and displays the metrics from your synthetic job.

Get Help

In the Knowledge Base forum, read our Synthetic Scripts FAQ. If you can't find the answer to your question, submit your questions to the community.

Write Your First Script

Related pages:

- Locate DOM Elements
- Wait for DOM Elements

- Verify Program Correctness

This page describe how to create a synthetic job and view the results.

Write a Script

Before you create a Synthetic Job with a custom script, you will need to write a Python WebDriver script and get it working locally. For a good introduction to scripting, AppDynamics recommends reading the Selenium Python Bindings documentation.

Before running your scripts in Synthetic Jobs, AppDynamics recommends reading the differences between Python and synthetic scripts as you may need to make some modifications.

Tools for Writing Scripts

For a full-fledged script recorder, use the Firefox add-on Katalon Recorder (Selenium IDE for Firefox 55+). The resulting script will work with Browser Synthetic, but as with most auto-generated code, expect to make manual changes to improve it.

Constraints for Writing Scripts

`driver.get` should always point to a proper HTML page and not to resources.

- `driver.get()` works well for HTML pages.
- Some of the session data might be incomplete or incorrect if you try to get resources directly.

Test Scripts Locally

Testing scripts locally is one of the best ways to take advantage of utilities to help you write scripts and then run them locally. To run scripts locally, complete the installation instructions given in the Selenium Python Bindings documentation and then run the script as you would any Python script.

Understand the Differences Between Python and Synthetic Scripts

When you are ready to write synthetic scripts, you should be aware that although Browser Synthetic can run unmodified Python scripts, there are few differences:

- The driver initialization code can be *removed* because the variable `driver` is automatically created and initialized with the browser selected in the **Job** creation UI. Thus, the example code below that initializes a driver would be replaced by our logic that then returns the variable `driver`.

```
# This initialization code or any initialization code
# will be replaced with Synthetic Monitoring logic, and
# the singleton `driver` will be available.
from selenium import webdriver

driver = webdriver.Firefox()
```

If your script initializes a driver, it is okay to keep it: Synthetic will just ignore your initialized driver and instead return the driver it automatically created.

- Only one driver can be run within a synthetic session. Any attempt at creating new drivers will return the automatically instantiated driver (a singleton).
- Scripts interacting with multiple windows will work; however, the session results will merge the results for all windows into one waterfall.

Create a Synthetic Job with Your Script

Once you have completed and tested your scripts, the next step is to create a Synthetic Job with your script:

1. From the **New Job** dialog, check the **Run a script** radio button.
2. Enter **My First Script** in the **Name** field.
3. Take a look at the sample WebDriver script, but do not change it.
4. For **Choose Browsers**, select **Chrome** and **Firefox.**
5. For **Choose Locations**, add a couple of different locations.
6. Click **Save**.

View Results

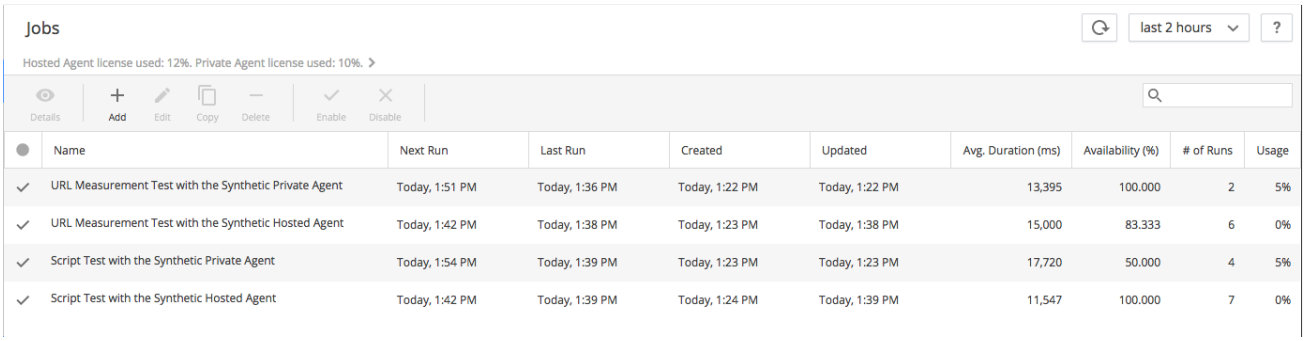
All date and time functions in the synthetic script return time in the UTC time zone. For example, if a script is scheduled on July 30 at 12am PST from the San Francisco location, and in the script it calls the following function:

```
import datetime
.....
dt = datetime.datetime.now()
print(str(dt))
```

It will return the time as:

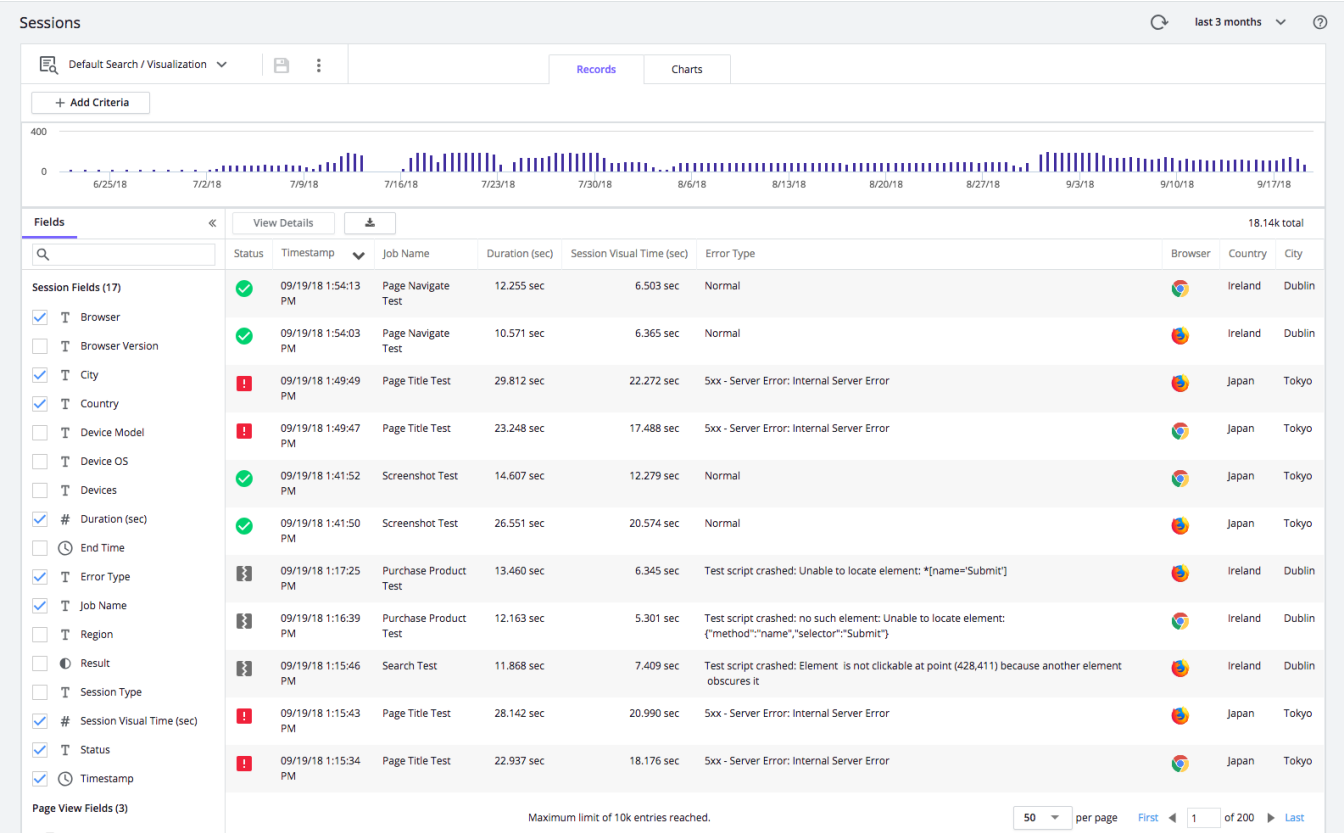
```
2020-07-30 07:00:00.000000
```

You have two types of views for the results. From the **Jobs** page, where you create a job, you can see your job and a summary of the results after the job has been run for both Synthetic Hosted/Private Agents.

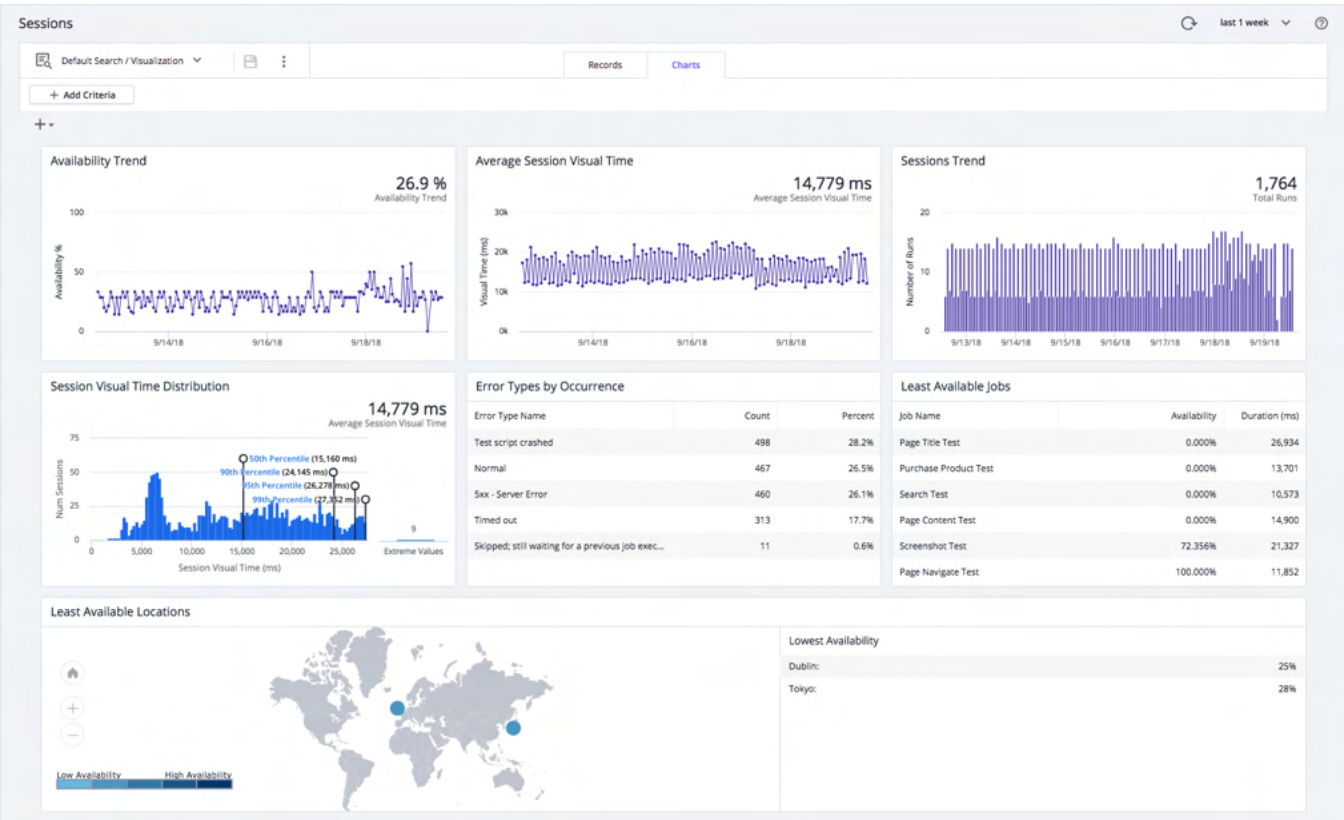


Name	Next Run	Last Run	Created	Updated	Avg. Duration (ms)	Availability (%)	# of Runs	Usage
URL Measurement Test with the Synthetic Private Agent	Today, 1:51 PM	Today, 1:36 PM	Today, 1:22 PM	Today, 1:22 PM	13,395	100.000	2	5%
URL Measurement Test with the Synthetic Hosted Agent	Today, 1:42 PM	Today, 1:38 PM	Today, 1:23 PM	Today, 1:38 PM	15,000	83.333	6	0%
Script Test with the Synthetic Private Agent	Today, 1:54 PM	Today, 1:39 PM	Today, 1:23 PM	Today, 1:23 PM	17,720	50.000	4	5%
Script Test with the Synthetic Hosted Agent	Today, 1:42 PM	Today, 1:39 PM	Today, 1:24 PM	Today, 1:39 PM	11,547	100.000	7	0%

You can also see more detailed results from the **Sessions** page. You can get there by either double-clicking your job or by clicking **Sessions** in the left navigation bar.



To see the metrics as charts, click the Charts tab:



From the Records tab, you can double-click a session to view the **Session Details** dialog:

Locate DOM Elements

Related pages:

- Write Your First Script
- Wait for DOM Elements
- Work with Screenshots
- Add Logs to Troubleshoot
- Verify Program Correctness

Your synthetic script simulates end-user interactions, so you'll need to be able to locate the DOM elements of your web pages. For example, your script might click on buttons, links, or enter text into text fields: this requires your script being able to locate and then select relevant HTML elements.

Methods for Locating Elements

The Selenium WebDriver library provides CSS selectors and XPath statements for selecting HTML elements. See 4. Locating Elements for the list of the library methods and usage examples.

Best Practices for Locating Elements

When locating elements, you are recommended to do the following. Think of it as a checklist.

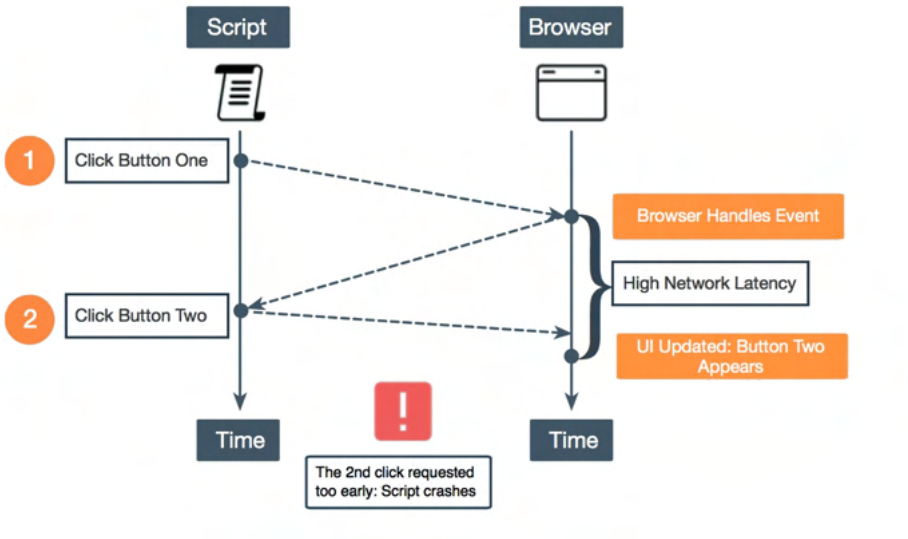
- Understand the following about your application:
    - the DOM structure
    - which pages are dynamically and statically loaded
    - which elements of a page are loaded and visible.
- Use unique IDs for elements and selectors that are as short as possible: Selectors break all the time. Long hierarchical selectors break more easily than shorter ones, and using short selectors will reduce script maintenance over time.
- Click on the user-visible element instead, or send a **Return** key instead of submitting forms using the method `submit()`.
- Pay attention to element visibility. The specification is complex, and the results are not always what users expect. See the WebDriver specification for more information.

Wait for DOM Elements

Related pages:

- Write Your First Script
- Locate DOM Elements
- Work with Screenshots
- Add Logs to Troubleshoot
- Verify Program Correctness

Your script might be accessing a UI component that is not available in the DOM. The cause could be network latency, as shown in the diagram below, or the DOM simply isn't ready to access.

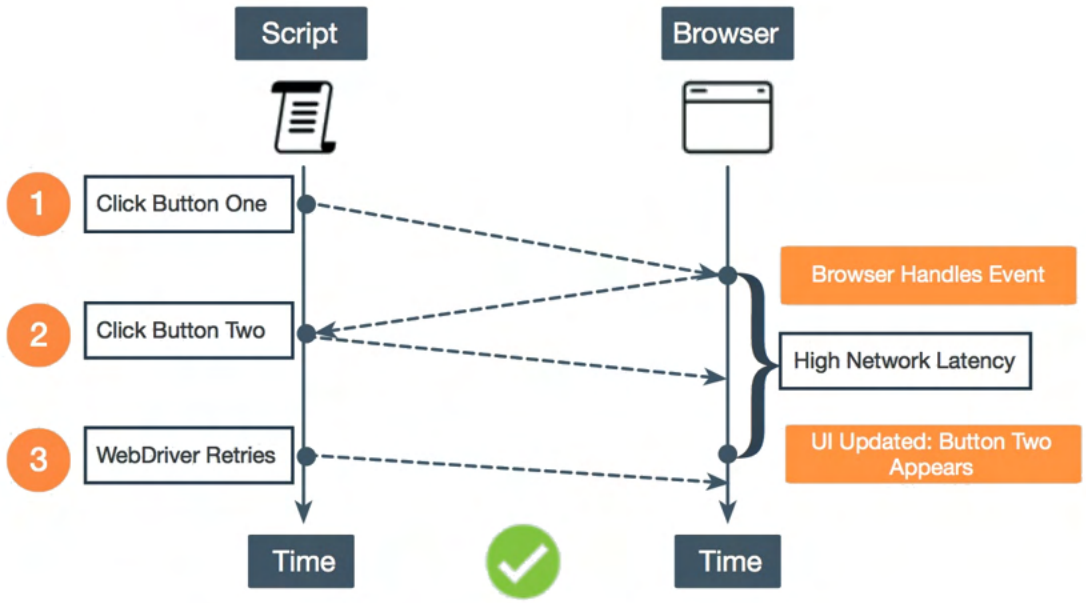


You can avoid this issue by using either an explicit or implicit wait. The following section discusses the different types of waits and when to use each.

Explicit Versus Implicit

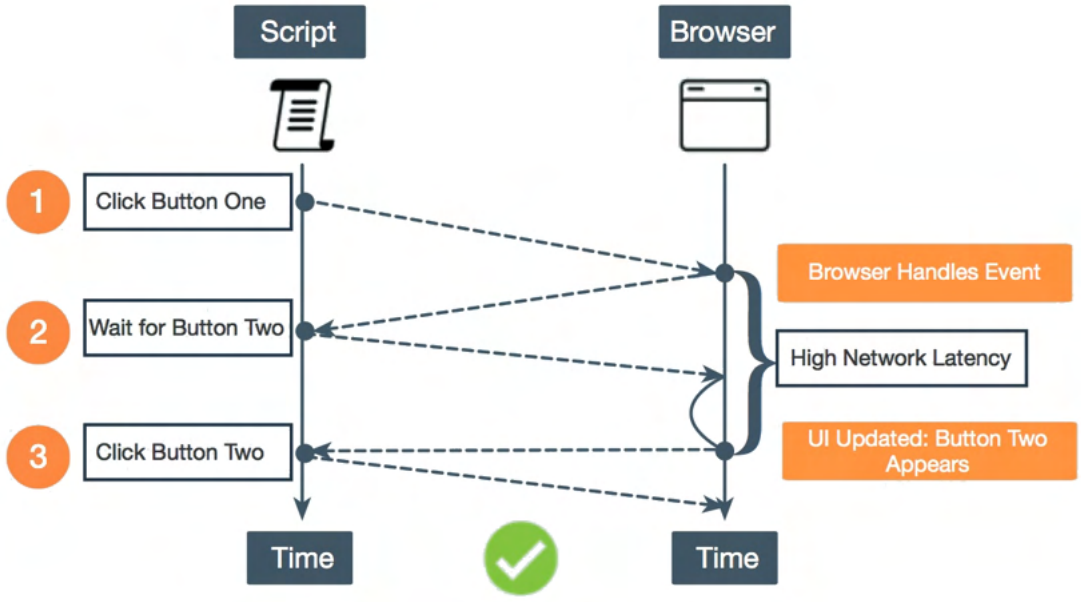
The WebDriver function `driver.implicitly_wait(n)` configures WebDriver for the remainder of a session. If you try to access an element that is not available, WebDriver will retry for up to n seconds to find that element in the DOM. This simple approach is often sufficient to make your scripts work reliably.

In the diagram below, the `WebDriver` retries to click **Button 2** until it's available.



An explicit wait is code that requires a certain condition to occur before continuing to execute code. Although you may be tempted to use `time.sleep()` to wait for an element to be available, you should avoid doing this. Instead, use the WebDriver API methods given in 5.1. Explicit Waits of the Selenium Python Bindings documentation that enable you to wait for *expected conditions*.

In the diagram below, the explicit wait stipulates to click **Button 2** (action) only when the button is available (the condition).



Work with Screenshots

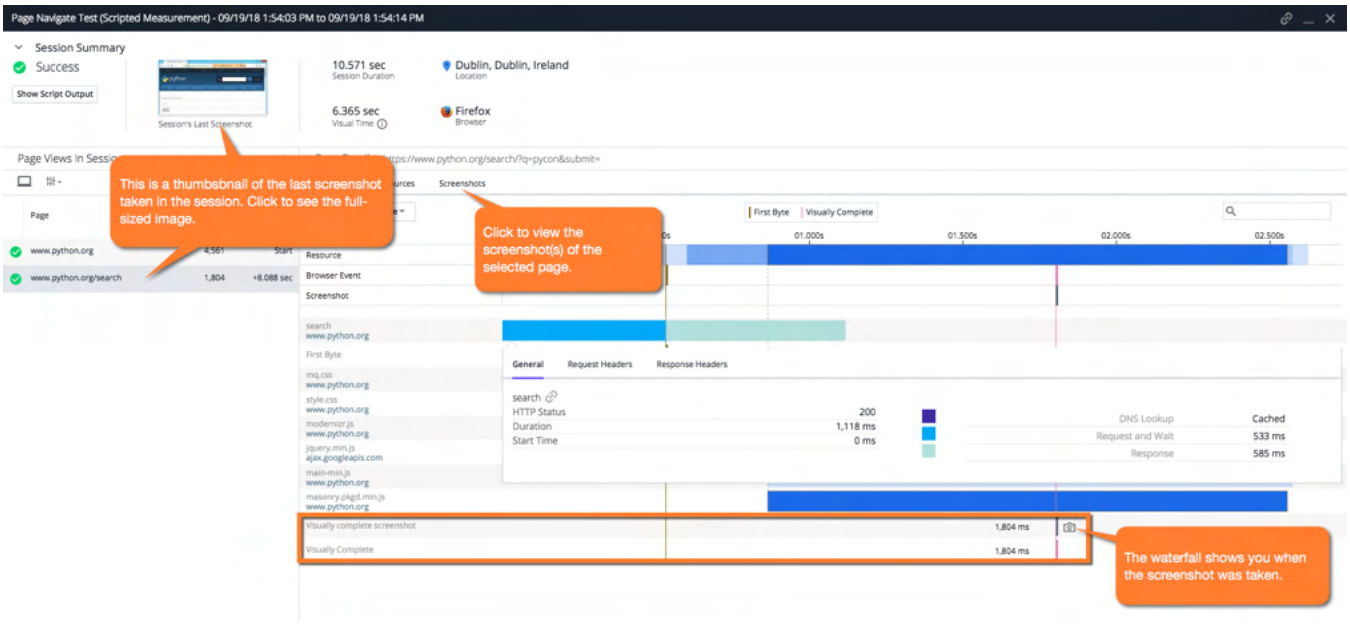
Related pages:

- Write Your First Script
- Locate DOM Elements
- Wait for DOM Elements
- Add Logs to Troubleshoot
- Verify Program Correctness

Synthetic jobs will automatically take screenshots for you, but you might want to manually take screenshots to debug issues.

Where to Find Screenshots

The **Session Details** dialog displays screenshots for each page, the last screenshot taken in the session, and a screenshot icon in the waterfall showing when the screenshot was taken. You can also view the larger version of the page screenshot from the Screenshots tab.



When to Use Screenshots to Debug

If interactions with a page are resulting in failures, you can use a screenshot to detect whether the UI component is on the page. For example, a screenshot can be used to determine if you are trying to click a button that isn't on the page or that is being overlapped by another HTML component. You may also want to manually take a screenshot if your job is timing out to diagnose an issue with the page because screenshots are not be automatically taken for timed out jobs.

How to Take Manual Screenshots

Although screenshots are taken by default, you can manually take screenshots at any point during the execution of your script using either of the following:

```
driver.get_screenshot_as_file("homepage.png")
driver.save_screenshot("myscreenshot.png")
```

Add Logs to Troubleshoot

Related pages:

- Write Your First Script
- Locate DOM Elements
- Wait for DOM Elements
- Work with Screenshots
- Verify Program Correctness

You can use logs to track the progress of your scripts and to better understand what is happening while the script is executing.

Print Statements

The simplest way to log messages is with print statements. You can use them to inspect objects or to determine where an issue is located.

For example, you can determine whether an element was selected on a page by displaying the contents of the object:

```
elem = driver.find_element_by_id("wiki-content")
print(elem)
```

If the script results are incomplete, you can use a series of print statements to pinpoint where the problem might have occurred:

```
print("Getting the web page 'appdynamics.com'.")
driver.get("http://docs.appdynamics.com")

print("Getting the content for the container with the ID 'wiki-content'.")
elem = driver.find_element_by_id("wiki-content")

element = driver.find_element_by_xpath("//select[@name='name']")
all_options = element.find_elements_by_tag_name("option")
for option in all_options:
    print("Value is: %s" % option.get_attribute("value"))
    option.click()
```

Logging Package

You can import the `logging` package to log different types of error messages.

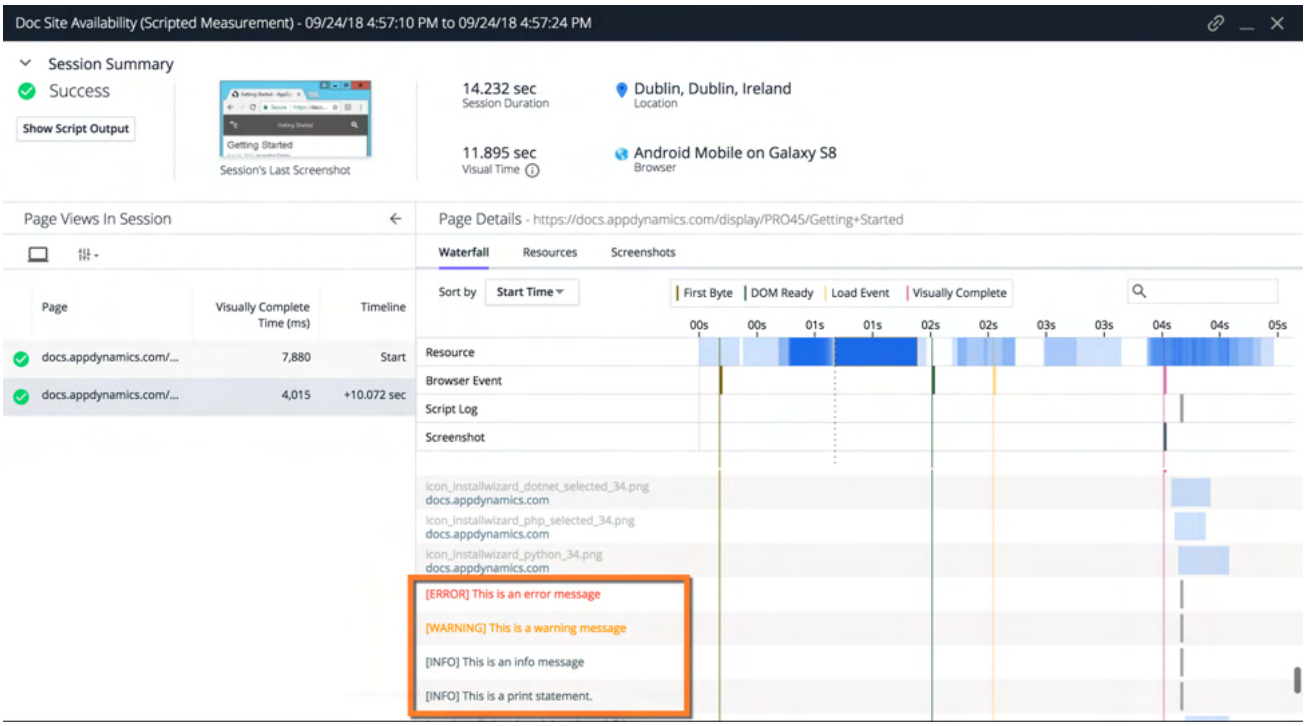
To import the `logging` package:

```
import logging
```

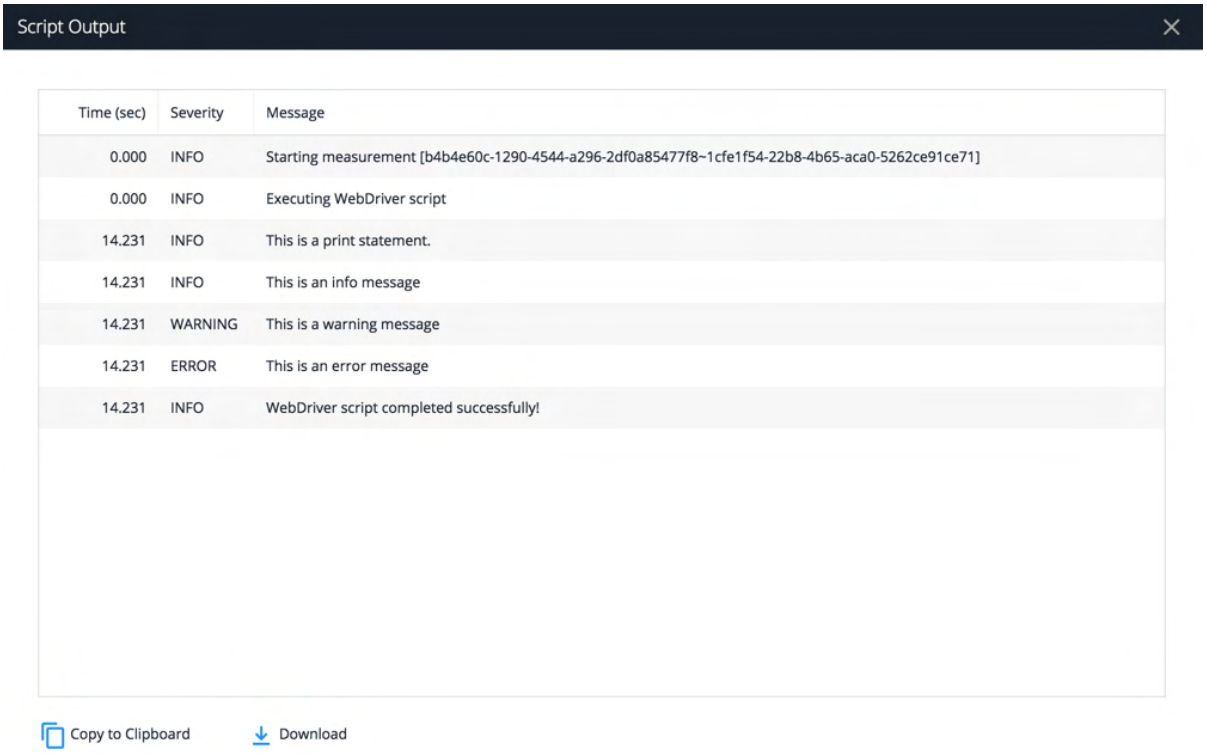
Once you have imported the `logging` package, you can generate different types of logs:

```
print("This is a print statement.")
logging.info("This is an info message")
logging.warn("This is a warning message")
logging.debug("This is a debug message")
logging.error("This is an error message")
```

The different types of errors are then color-coded in the waterfall of the **Session Details** dialog.



The script output will label the different log messages by the severity as shown below.



Import Python Packages in Synthetic Scripts

Synthetic scripts are executed in short-lived containers where you can use pre-installed Python packages. Your script is restricted to the container and the container's lifespan.

Pre-installed Libraries

The following modules are installed in containers and can be accessed by importing them in your synthetic scripts.

- os
- selenium
- Requests
- pysftp

- ‘os’, ‘socket’, and, ‘subprocess’ modules will be disallowed for any new job.
- All existing jobs will continue to run.

Environmental Variables

With the `os` module available, you can access the environment variables through `os.environ`.

For example, to display the variables, you can use a script similar to the following:

```
import os
for i, j in os.environ.items():
        print(i, j)
```

Upload and Download Files with SFTP

One of the packages installed on these containers is `pysftp`, which you can use to upload and download files with SFTP.

The following code sample shows the basic functionality of the package.

```
import pysftp
cnopts = pysftp.CnOpts()
cnopts.hostkeys = None
# The <hostname> can be in either of the following formats: ftp.domain.ca || http://ftp.domain.ca
with pysftp.Connection('<hostname>', username='xxxx', password='xxxxxx', cnopts=cnopts) as sftp:
        # Change to the dictory 'public'
        with sftp.cd('public'):
            # Fetch the remote file
            sftp.get('<remote_file_name>')
            # Upload the same file to a remote location
                      sftp.put('<local_file_name>')
```

Make HTTP Requests

You can use the HTTP library `requests` to make HTTP requests within your synthetic scripts. The following example makes a GET request to the public GitHub Events API. See Requests: HTTP for Humans™ to learn more about the library's functionality and usage.

```
import requests

r = requests.get('https://api.github.com/events?per_page=1')
print("Status Code: %s\n" %(r.status_code))
print ("Headers: \n%s\n" %(r.headers))
print("Response: \n%s" %(r.text))
```

Verify Program Correctness

You can use assertion statements to determine that your script is receiving the expected results. You use the session status to determine session status whether your jobs have failed because of an uncaught exception or an assertion statement failed.

This page provides an assertion example that shows how to use the session status to determine which scripts have issues.

Use Assertions to Verify Expected Results

Assert statements use a simple syntax to verify an expected result. You can also provide a message to display if the assertion fails. In the example below, the message "Title should contain AppDynamics" will be displayed if the assertion fails.

```
# Get page and check the title
driver.get("http://https://ecommerce.com/view.html/ref=nav_cart")
assert "E-Commerce Shopping Cart" in driver.title, "Title should contain E-Commerce Shopping Cart"

# Click link and confirm URL is correct
driver.find_element_by_link_text("Place your order").click()
assert "ThankYouCart" in driver.current_url
```

You can also verify that a string is not in the result or the truth of a mathematical expression. Assert statements that are false will result in a session status of `FAILED`.

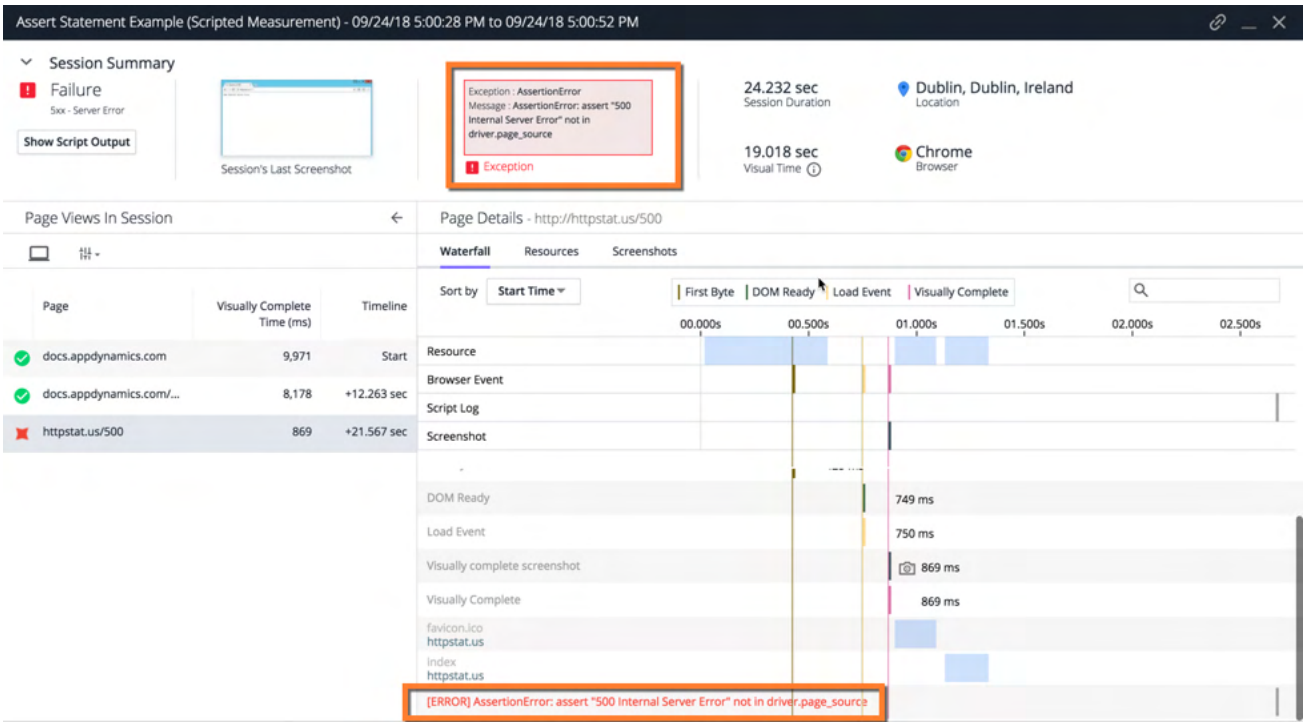
```
 # Confirm the page doesn't gives a 500 error.
assert "500 Internal Server Error" not in driver.page_source
# Confirm the footer is on the page.
footer = driver.find_elements_by_class_name('footer-body')
assert len(footer) > 0, "Footer couldn't be found."
```

Use the Session Status to Find Script Issues

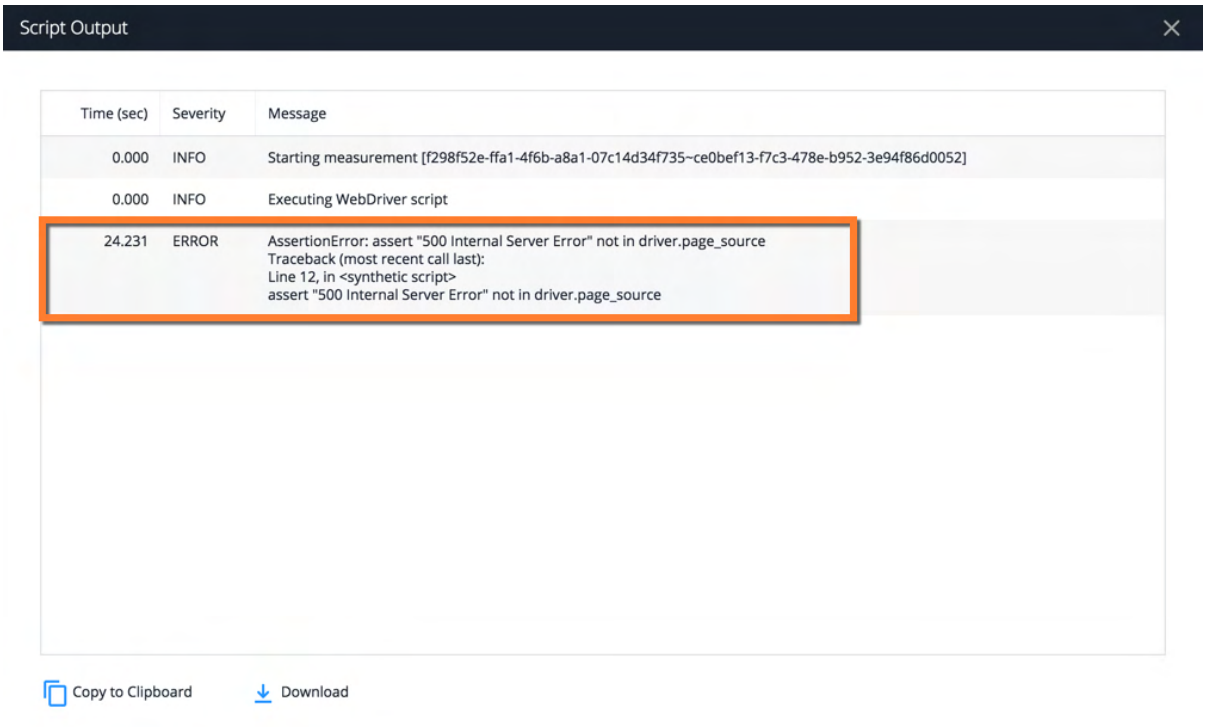
The two-session statuses `BROKEN` and `FAILED` indicate that the script had an issue. If the session status is `BROKEN`, it means that your script threw an uncaught exception. You'll most likely need to review your code and look for errors. See Exceptions for a list of common exceptions.

If the session state is `FAILED`, an assert statement failed or if you checked "Fail on page load error" and the page failed to load. You'll need to determine why your assertion statement failed or why the page couldn't be loaded.

You can view the results of assertion statements in the session status detail and script output. From the **Session Details** page, you can view failed assert statements in a red exception box at the top and from the Waterfall tab:



Failed assert statements will also appear in the **Script Output** dialog:



Select Client Certificates

This page is solely intended for use with the Synthetic Private Agent. You will *not* be able to run some of the synthetic scripts below with the Synthetic Hosted Agent.

When using client certificates, you may need to select the certificate from a dialog. To do this, you will need to install the Python pyautogui library on the host machine of your Synthetic Private Agent. The `pyautogui` library enables you to navigate the UI to select a client certificate.

Install the PyAutoGUI Library

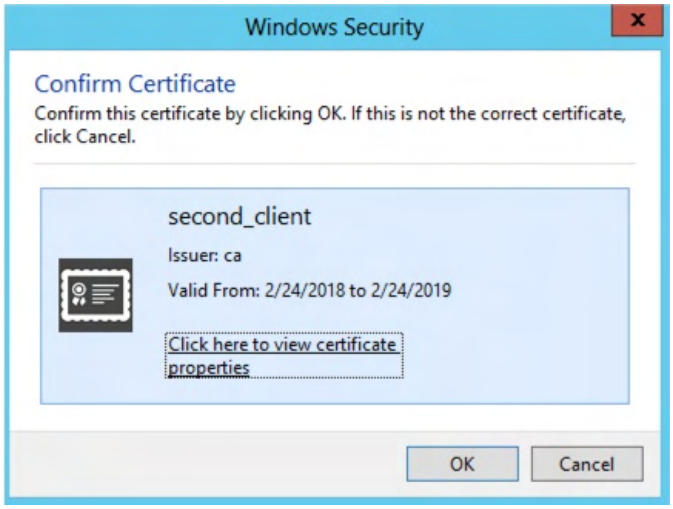
To install the PyAutoGUI Library:

1. Log in to the host machine for the Synthetic Private Agent as the `agent_user`.
2. Open a PowerShell console.
3. Use `pip` to install the library:

```
```

Select the Only Client Certificate

When you manually navigate to a site that uses client certification, IE10 may prompt you with an alert dialog to select one client certificates as seen below:

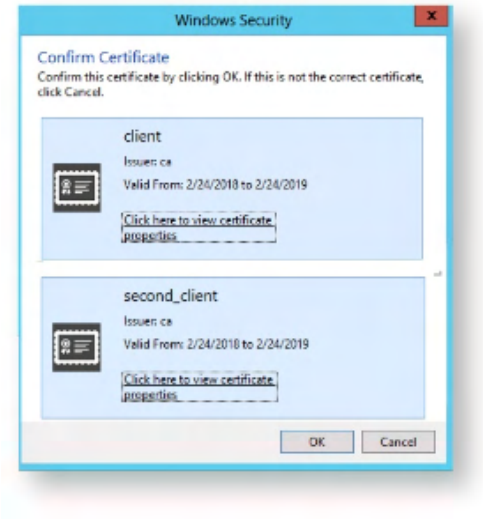


To select the client certificate from a synthetic script, your code could focus on the alert dialog and accept the given client certificate as performed by the synthetic script below.

```
sslUrl = "https://yourdomain.com/"
driver.get(sslUrl)
# Move focus to the dialog
alert = driver.switch_to_alert()
# Accept the client cert
alert.accept()
```

Select Certificate from List

In the case where your synthetic job needs to select one client certificate from a list presented in the alert dialog as shown below, you can use the PyAutoGUI Library to select and accept the client certificate that you want.



In the example below, you use `switch_to_alert` to focus on the alert dialog, and then use the `pyautogui` library to navigate to the correct certificate (tab), select it (enter), and then navigate to the OK button to select it (tab, enter).

```
import pyautogui
pyautogui.FAILSAFE = False
sslUrl = "https://yourdomain.com/"
driver.get(sslUrl)
driver.switch_to_alert()
pyautogui.press(['tab', 'enter', 'tab', 'enter'])
```

You may have many more client certificates to choose from, so you will have to figure out the best way to use the PyAutoGUI APIs to navigate around the alert dialogue to select and accept the correct client certificate. See Keyboard Control Functions in the PyAutoGUI documentation for more information.

Synthetic Agent Locations

The primary purpose of Browser Synthetic Monitoring is to perform browser-based testing. To help you test browsers in the locations of your users, Browser Synthetic provides agents in locations around the world. Your scripts, however, are run in a separate location for the security reasons discussed in the next section.

Security Considerations for Scripting

The browsers configured in synthetic jobs are run on shared Windows machines. Because synthetic scripts are written in native Python, they are not run on the shared Windows machines. Instead, each synthetic script is executed in isolation within a Docker container in a location mapped to the configured browser location. This isolation of the agents and scripts guarantees the safety of the data handled by the scripts and has no effect on the performance of the agent.

How This Affects Your Synthetic Jobs

You should understand how the locations of the agent/browser and where the script is executed may affect your synthetic job. For example, if the location of the execution container and the configured browser are not in the same region, you may expect to see some network latency. Also, if you are using the Python Requests library to make HTTP requests, you should know where the request is being made from.

The following sections provide some insight as to how your job may be affected.

URL Measurements

URL Measurements are used to test site availability and will not be affected because no script is being executed.

Synthetic Scripts

Your script can use different libraries to make HTTP requests. The WebDriver API is used to mimic the browser making HTTP requests. To make cURL-like requests to test REST APIs or to retrieve data, you can use an HTTP library such as the Requests library. The tables below describe how the script is executed and the types of problems you may encounter.

Mapping of Execution Containers and Browser Locations

The table below lists the available browser locations as well as the corresponding provider and container location.

Browser Location	Provider	Container Location
Ashburn, Virginia	AWS	US East (N. Virginia)
Montreal, Québec	AWS	
Toronto, Ontario	Azure	
Amsterdam, Netherlands	Azure	EU (Ireland)
Dublin, Ireland	AWS	
Frankfurt, Germany	AWS	
London, United Kingdom	AWS	
Milan, Italy	AWS	
Paris, France	AWS	
Hong Kong, China	AWS	Asia Pacific (Tokyo)
Seoul, South Korea	AWS	
Tokyo, Japan	AWS	
Chennai, India	Azure	Asia Pacific (Singapore)
Mumbai, India	AWS	
Singapore	AWS	

Melbourne, Australia	Azure	Asia Pacific (Sydney)
Sydney, Australia	AWS	
Boardman, Oregon	AWS	US West (Oregon)
San Francisco, California	AWS	
Sao Paulo, Brazil	AWS	
San Antonio, Texas	Azure	

Hosted Agent Coverage Variations

Synthetic hosted agents have the following coverage variations:

- The US EUM cloud has access to both AWS and Azure locations.
- The Frankfurt EUM cloud has access to only AWS locations.
- The Sydney EUM cloud has access to only AWS locations.
- The Bombay EUM cloud has access to only AWS locations.

Synthetic Credential Vault

Deployment Support

Synthetic Credential Vault securely stores credentials used in synthetic jobs. When you create a job with a synthetic script, you can add a credential, such as a username and password to log in to an application, and inject a reference to the stored credential into the script. When the job runs, the synthetic script uses that reference to retrieve the credentials stored in Synthetic Credential Vault.

How to Use Synthetic Credential Vault

1. Go to ⚙ > **Tools** > **Manage Synthetic Credentials**.
2. Add a credential in a key-value pair to Synthetic Credential Vault.
3. Create a synthetic job using a synthetic script.
4. Inject the credential key into the synthetic script.
5. The synthetic job runs and retrieves the credential value associated with the credential key.

Add Synthetic Credentials

In Synthetic Credential Vault, you can add credentials one-by-one or import multiple credentials.

Syntax Rules

This table describes credential syntax rules used for creating credentials and adding credentials to synthetic scripts.

Element	Rule
Keys	• 1-100 characters • Alphanumeric characters, hyphens, and underscores only • Keys must be unique per EUM account
Values	• 5000 characters • Any non-control, printable UTF-16 characters
Credential key name (used in synthetic scripts)	`"<%key%>"`

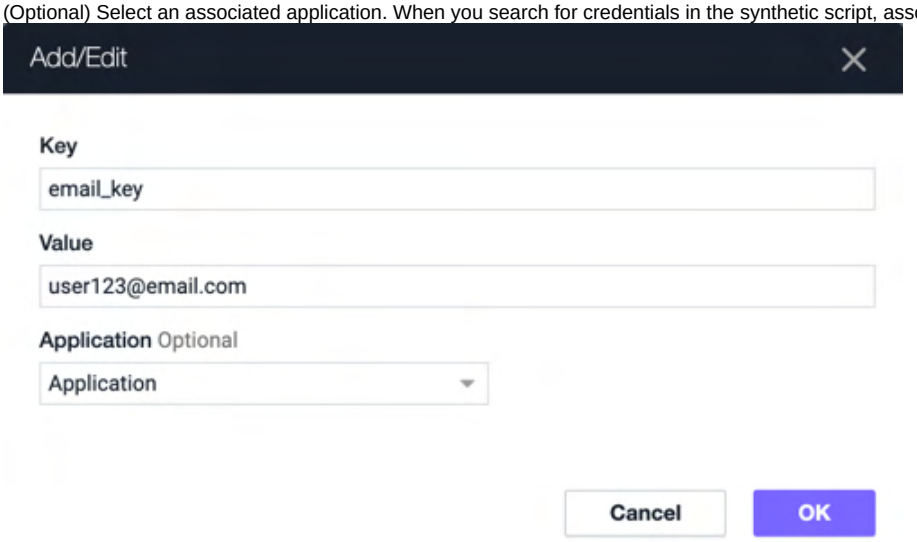
Add a Single Credential

> ⓘ If you want to use a combination of credentials, such as a username and password combination, you must create two separate credentials: one credential for the username and one for the password.

To add a single credential for a sample email:

1. Go to ⚙ > **Tools** > **Manage Synthetic Credentials**.
2. Click **Add**.
3. Enter a key and value. Make sure you follow syntax rules.

4. (Optional) Select an associated application. When you search for credentials in the synthetic script, associated credentials are suggested first.



Import Multiple Credentials

You can add multiple credentials at once using the **Import** button.

To add multiple credentials for sample emails and passwords:

1. Go to > **Tools** > **Manage Synthetic Credentials**.
2. Click **Import**.
3. Copy and paste credentials or type them line by line. Make sure you follow syntax rules.

- The maximum number of credentials that can be imported at once is 250.
- You cannot add associated applications to imported credentials. After importing, you must edit each credential individually to add the associated application.

Example

```
email_key=user123@email.com
password_key=Password123
email_key=user456@email.com
password_key=Password456
```

Use Credentials in a Synthetic Script

You can retrieve a credential value by inserting the corresponding credential key in a synthetic script. Credentials associated to a specific application appear first when you start typing the key in the script.

To create a synthetic job:

1. Go to **User Experience** > **Jobs** > **Add**.
2. Add your synthetic script. See Write Your First Script.
3. Locate the DOM element associated with your credential.
4. Enter the credential key using the syntax `"<%key%>"`.

Synthetic Script

```
driver.find_element_by_id("email").send_keys("<%email_key%>")
driver.find_element_by_id("pass").send_keys("<%password_key%>")
```

User Permissions

In the Controller UI, you can configure roles, users, and groups with Account-level, read-only permission for Synthetic Credential Vault. See Roles and Permissions for more information. As an admin-level user, we recommend you add a read-only role for Synthetic Credential Vault and assign that role to multiple users and/or groups.

To create a role in the Controller UI with read-only permission:

1. In the Controller UI, go to  > **Administration** > **Roles**.
2. Under **Roles**, click **Create**.
3. Add a role name, such as "Synthetic Credential Vault (read-only)."
4. Under **Account**, click **Add+**.
5. Check the "View Synthetic Credential Vault" box.
6. Under **User and Groups within this Role**, add users and/or groups.

The table below describes permission differences between admin and read-only users for using Synthetic Credential Vault.

User Level	Permission
Admin	Requires "Administration," "Agents," and "Getting Started Wizard" permissions to: • Manage all users • Add, edit, and delete credentials • View both keys and values of stored credentials • View users, timestamps, and associated applications
Read-only	• View keys of stored credentials • View users, timestamps, and associated applications

Alerts for Browser Synthetic Monitoring

Related pages:

- Policies
- Health Rules
- Actions

You can set policies and alerts based on synthetic events, or you can set thresholds to trigger alerts when you create or edit a synthetic job.

Synthetic Event Types

The following two types of synthetic events are supported and can be used to trigger policies and actions:

- Synthetic Availability
- Synthetic Performance

You can set policies with alerts for these synthetic events, selecting either or both warning or critical conditions.

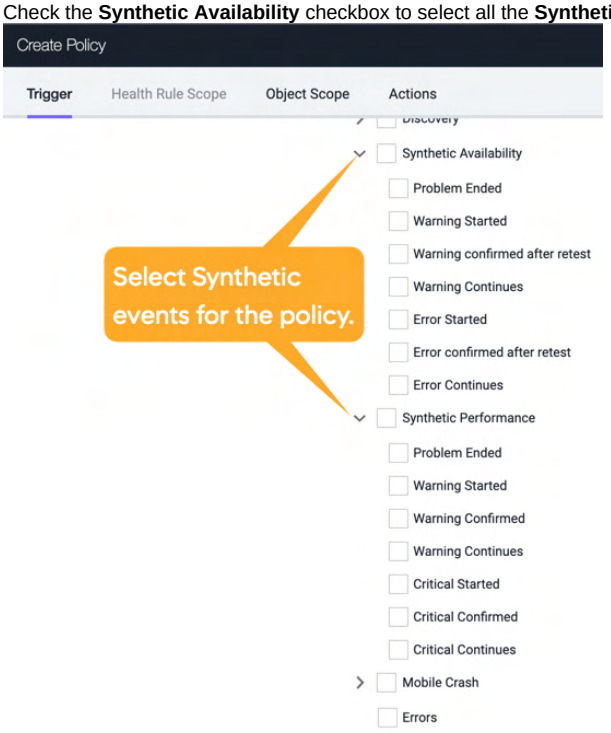
Synthetic Policies

You can use Synthetic Availability and Performance events to trigger policies, which can, for example, send an alerting email. See Configure Policies for more information.

Create Policy for Synthetic Availability

You can select warning and/or error events for policies for Synthetic Availability.

1. From the **Browser App** menu, click **Alert & Respond**.
2. Click **Policies**.
3. From the **Policies** page, click **Create Policy Manually**.
4. From the **Create Policy** dialog, enter a name for your policy.
5. Check the **Synthetic Availability** checkbox to select all the **Synthetic Availability** events or check one or more specific events.



6. Click **Next**.
7. Create an action to be executed when any of the **Synthetic Availability** events are triggered. See Actions for more information.

Site Availability

Availability is based on the session status:

- Single URL jobs
  - Warning = 4xx response, (session status is either `WARNING` or `BROKEN`)

    - Error = 5xx response, timeout, cannot contact application (`FAILED`)
- Scripted jobs
    - Warning = your script threw an uncaught exception (`BROKEN`) or the session status is `WARNING`.
    - Error = your script had an assertion failure or timed out (`FAILED`)

Performance Issues

Performance events are based on the criteria you set up when you set up scheduled jobs. For an example of the health rule violation process, see Health Rule Violation Events.

Create Policy for Synthetic Performance Events

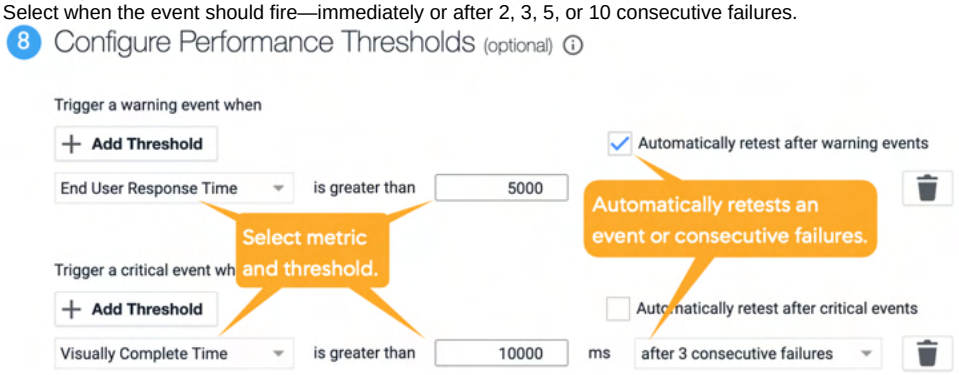
You can select warning and/or error events for policies for Synthetic Performance.

1. From the **Browser App** menu, click **Alert & Respond**.
2. Click **Policies**.
3. From the **Policies** page, click **Create Policy Manually**.
4. From the **Create Policy** dialog, enter a name for your policy.
5. Check the **Synthetic Performance** check box to select all the **Synthetic Performance** events or check one or more specific events.
6. Click **Next**.
7. Create an action to be executed when any of the **Synthetic Performance** events are triggered. See Actions for more information.

Configure Performance Thresholds

You can also configure performance thresholds that will trigger events when the thresholds are exceeded.

1. Click **+ Add** to add a new job.
2. In the **New Job** popup, scroll down to **Configure Performance Thresholds**:
3. From either **Trigger a warning event when** or **Trigger a critical event when**:
    - Click **+ Add Threshold** to add a performance threshold for triggering a warning/critical event.
    - Select a performance threshold, enter a value that will trigger a warning event.
    - Select when the event should fire—immediately or after 2, 3, 5, or 10 consecutive failures.



4. You can select multiple performance thresholds by clicking **+ Add Threshold** multiple times.

Performance Thresholds

The following are the supported performance thresholds. Follow the links for descriptions of the performance thresholds.

- End User Response Time
- Fully Loaded Time
- Visually Complete Time
- First Byte Time
- Start Render Time
- Bytes per Pageview

Synthetic Sessions

You use the **Session** page to analyze synthetic sessions. A synthetic session is a record of the complete sequence of events that make up one synthetic test. A session can cover one page or, in the case of scripted jobs, can extend to multiple pages. All session timestamps are in local time, regardless of the configured scheduled job's timezone.

A session begins at the first navigation start in the sequence and continues until the last page is fully loaded. In the case of single-page sessions, the session begins and ends when the *page* is fully loaded (the session duration represented by the metric Visually Complete). Like Browser RUM Analyze and Network Request Analyze, the Synthetic Sessions view enables you to analyze results from *all* synthetic sessions.

> For single-page applications (SPAs), sessions will include the base page and its virtual pages as *one* page: the base page.

Session Status

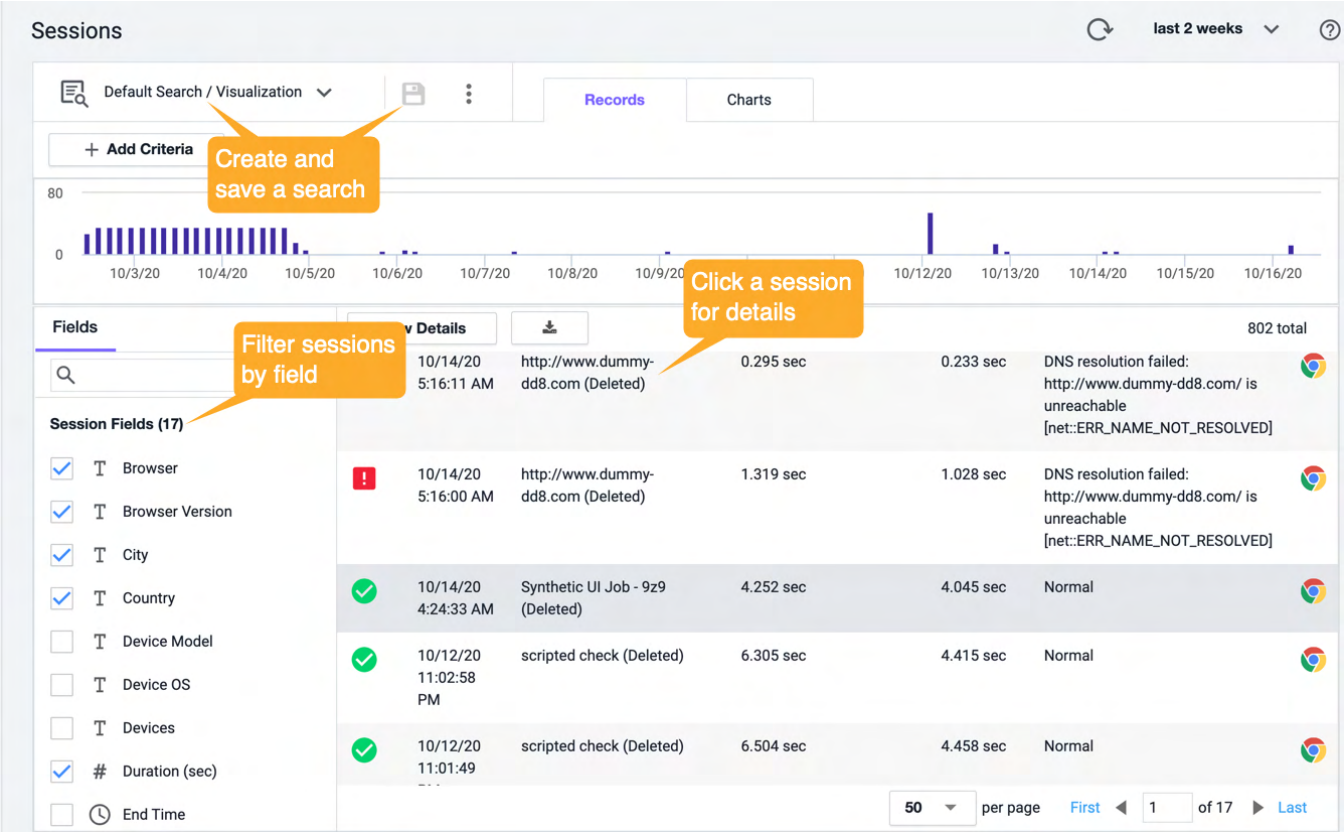
Sessions can have one of four statuses:

- `OK`: The test ran successfully and returned data.
- `WARNING`: The test ran successfully, but there were inaccessible resources.
- `BROKEN`: Your job has an error. You can find the error in the script console output. When the status is `BROKEN`, no event is created and the job is not retested.
    - In single URL jobs, the test received a 4xx response.
    - In scripted jobs, your script threw an uncaught exception. This can, for example, happen if you try to perform an action, like a click, on an element which is not on the page you are testing.
- `FAILED`: The synthetic test has detected a problem with your site. When failed jobs have the status `FAILED`, an event is created and the job is run again to confirm there was an error.
    - In single URL jobs, one of the following occurred:
        - the browser couldn't reach the URL
        - the browser received a 5xx response
        - the session timed out
    - In scripted jobs, your script had an assertion failure or timed out.

Session UI

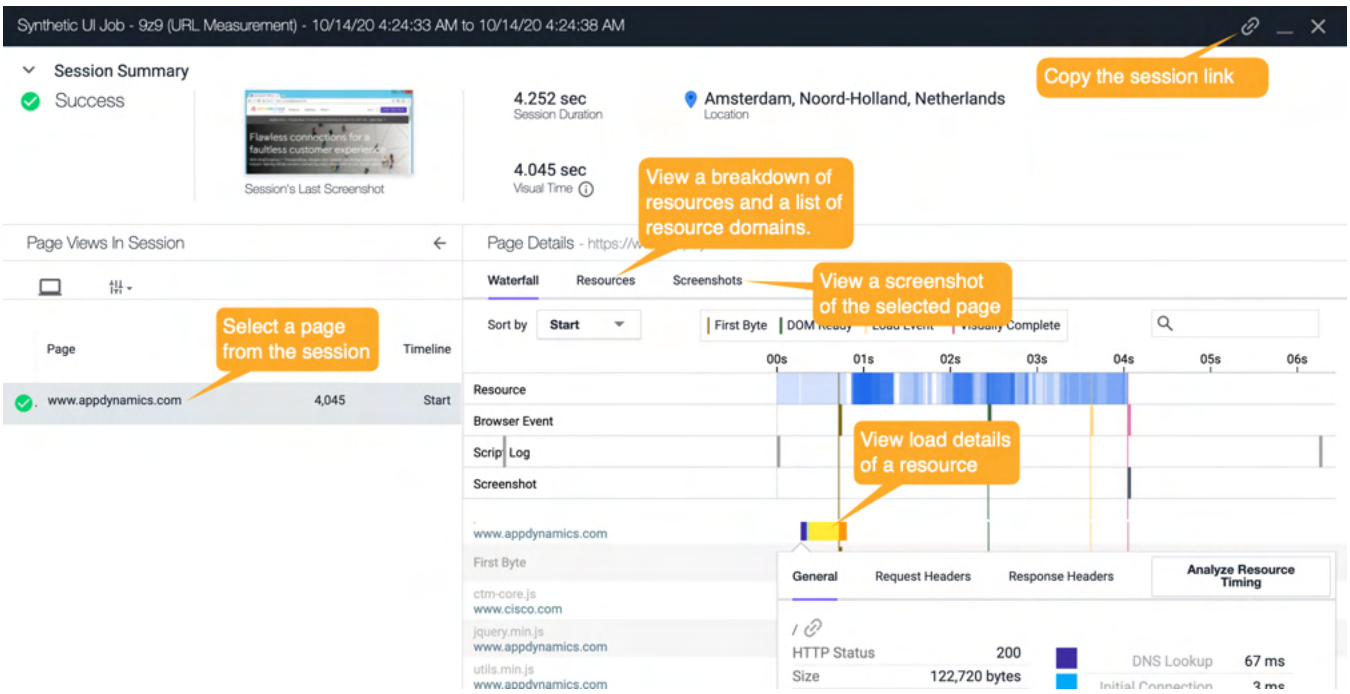
Records

The Records tab enables you to scan individual requests and allows you to filter and sort to get exactly the data set in which you are interested.



Session Details

Select a specific session and click **View Details** to see detailed information, including a page load waterfall and tabular details for resources. In multi-page sessions, the left navigation allows you to select each page from the sequence.



Business Transactions

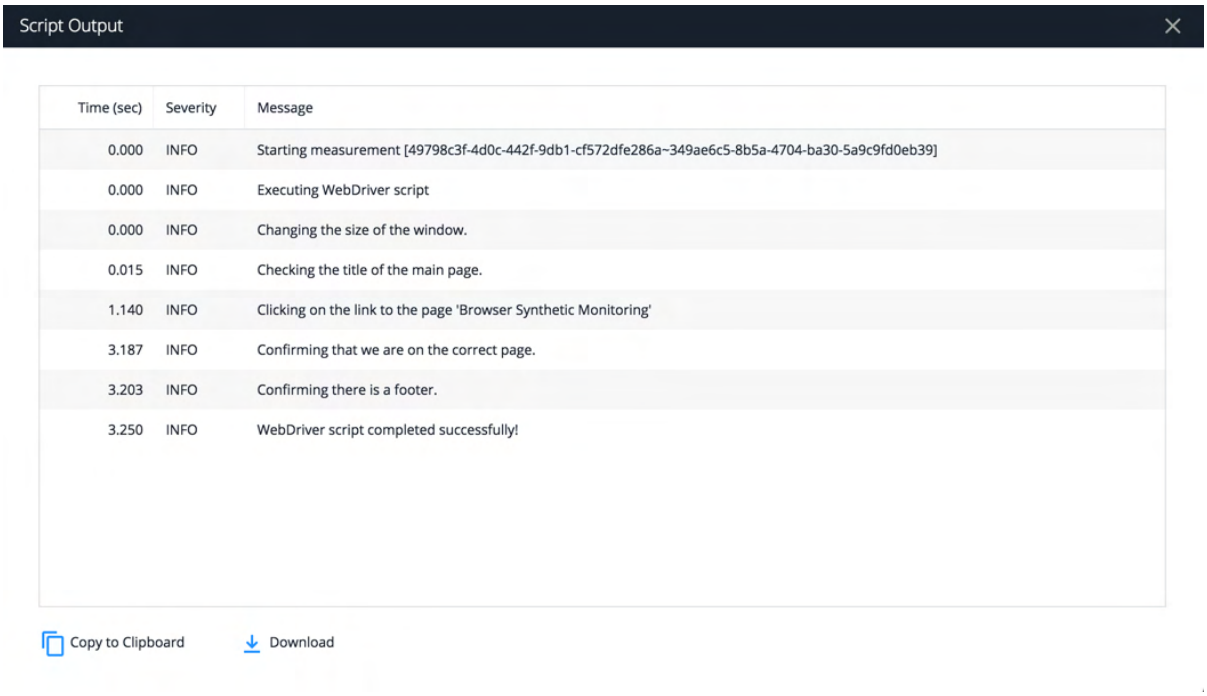
When a business and a browser application have correlated business transactions, you can also create synthetic jobs from that browser application that makes requests to the business application to get business transactions in synthetic sessions. You can view business transactions in the Waterfall and the Business Transactions tabs of the **Session Details** dialog.

If you see **View Snapshot >** next to resource in the waterfall, that indicates that there was a correlated business transaction. Clicking it will take you to the business transaction snapshot from the backend.

You can also click the Business Transactions tab to see a list of the server-side business transactions this request initiated. Click through to the related **Business Transaction** dashboards.

Script Output

If you used a script, you can click through to see any script output.



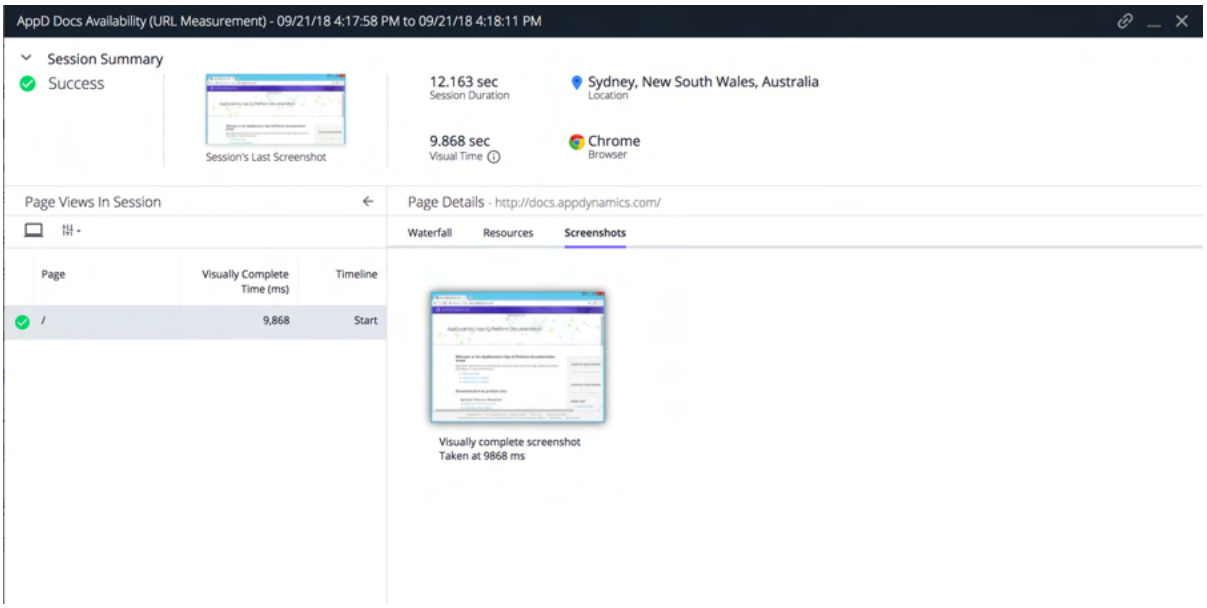
Click **Copy to Clipboard** to copy the script output to your clipboard or **Download** to download the script output.

Session Screenshots

Synthetic captures screenshots of the browser as your job runs. By default, it takes one screenshot per page, when the page is finished rendering. Screenshots are retained for 30 days.

In scripted jobs, you can call an API from your script to take a maximum of 10 screenshots per page. The screenshot will be of the visibly complete content in the viewport (won't include the browser chrome).

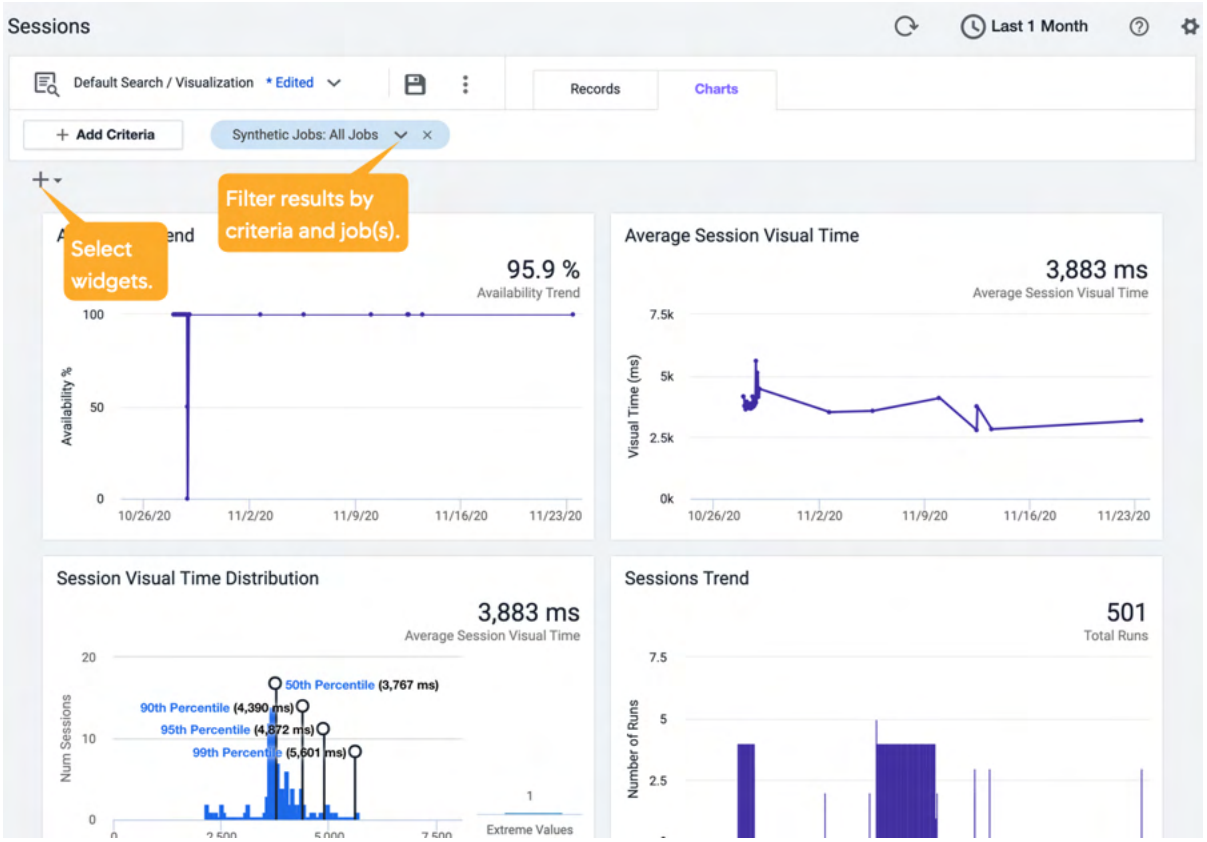
The Screenshots tab shown below displays the screenshot as a 200 x 150 image. The resolution of the screenshot will be the same as the device where the screenshot was taken.



The Waterfall tab will contain the visually complete screenshot and any custom screenshots (e.g., `screenshot2` in the screenshot below) triggered by the script.

Charts

The Charts tab provides you with a set of widgets that offer predefined visualizations of the data set you have created, allowing you to create a dashboard. You can delete, re-add, resize, and drag-and-drop to move the widgets.



Analyze Session Results

You understand the results of your synthetic jobs through sessions. From session details, you can determine if there were errors, what type of errors, and diagnose what factors are affecting performance. The following sections show you how to analyze synthetic session results for errors and performance issues.

Errors

Determine Type of Error

At this time, you should be able to determine the type of error by the **Status** and **Error Type** fields. The session status indicates whether your jobs are passing, failing (there is a problem with the system being tested), or broken (there is a problem with the job itself). The **Error Type** field gives more information about the cause of the error.

Understand the Error

1. From the **Sessions** > **Records** tab, select a session with an error and click **View Details**.
2. From the **Session Details** dialog, you can view when the error occurred and the returned error message in the Waterfall tab.
3. If your job used a custom script, you can click **Show Script Output** to view the script results. You can download or copy the results as well.
4. You can also view the screenshot to see how the error might be manifested to end users. You might want to display the errors in a more user-friendly way and possibly omit error details.

Performance

One of the best ways to see if your job is having performance issues is to view widgets representing aggregated metrics in the Charts tab. With a quick glance, you can see if there are site availability issues, where end users might be having bad user experiences, how long sessions are lasting, and how long it's taking for pages to be visually complete.

Network Latency

The Waterfall tab shows you a timeline of when resources are loaded and plots the events First Byte, DOM Ready, Load Event, and Visually Complete that mark significant and discreet moments from the time the browser receives data until the user can see a complete page.

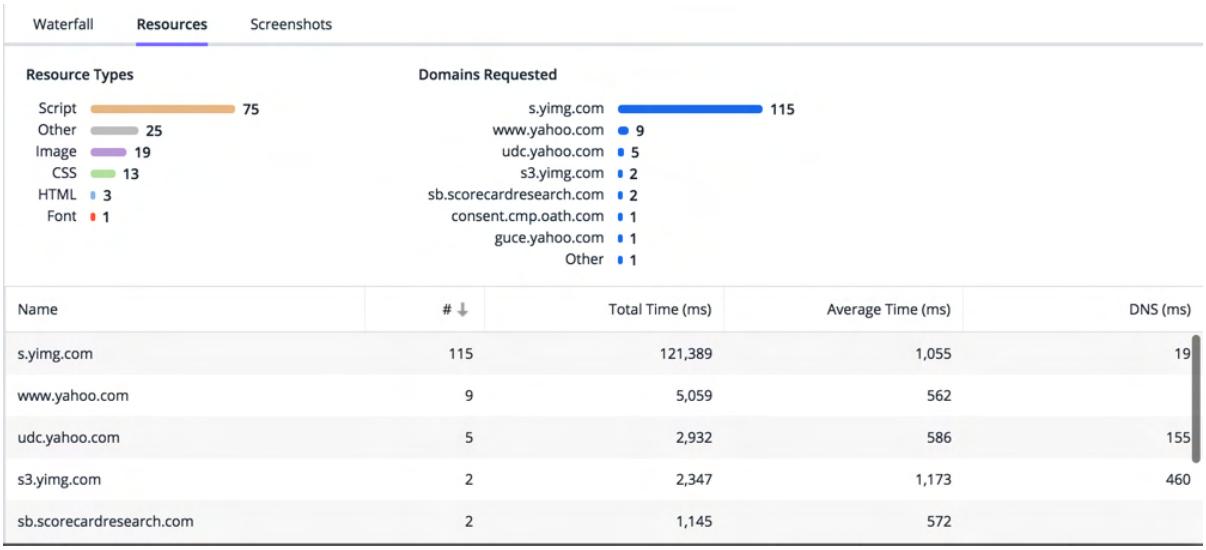
To understand session performance, you can compare the end user response time (the same as the `onload` time) of a page with the session duration. This gives you an idea of which pages are taking too long to load and how that might be affecting the session.

You can also click one of the bars to determine if a resource is taking a long time to load. For example, if an image is taking too long to load, you can take actions to optimize the loading time such as caching the image, reducing its size, confirm that the image is the size that you're displaying it, or not use the image at all.

Problematic Resources

The **Session Details** dialog shows you the final session state and the session state set by each page. The final session state is indicated in the top-left corner, whereas, the session state set by each page is shown in the **Page Views in Session** sidebar. In the screenshot below, the ⚠ icon indicates that the first page set the session status to "Warning". From the Waterfall tab, you can also discover which resources didn't load, either marked in yellow for the "Warning" state or in red for the "Failed" state.

The Resources tab shows you the number of resources by category, the domains requested, and key performance metrics that you can use to sort the results. You can quickly identify resources that are slowing the page load and potential DNS problems.



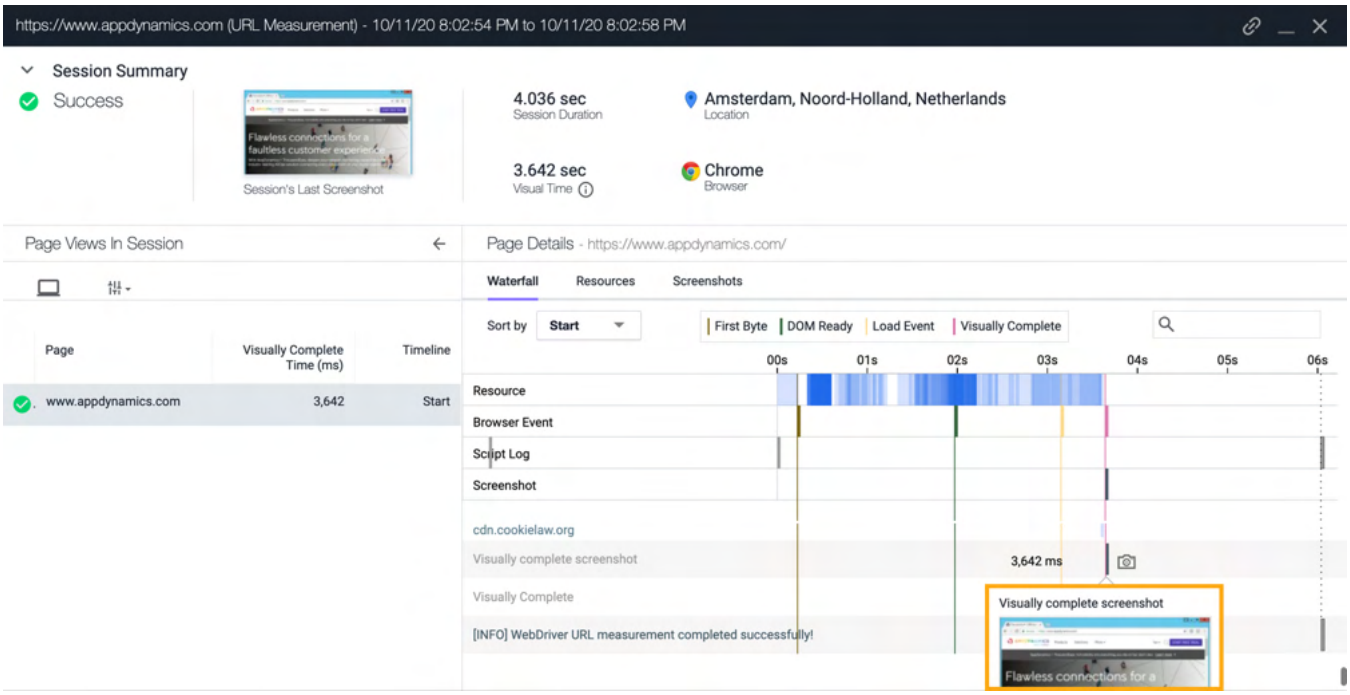
Name	# ↓	Total Time (ms)	Average Time (ms)	DNS (ms)
s.yimg.com	115	121,389	1,055	19
www.yahoo.com	9	5,059	562	
udc.yahoo.com	5	2,932	586	155
s3.yimg.com	2	2,347	1,173	460
sb.scorecardresearch.com	2	1,145	572	

You can also configure your synthetic jobs to check the availability of resources. You can set the session status to **Failed** or **Warning** when resources are unavailable. See Configure Availability Rules for configuration instructions. When the session status is set to **Failed** or **Warning**, Browser Synthetic Monitoring triggers corresponding events that can be used to create alerts. This enables you to be alerted when resources are missing. See Alerts for Browser Synthetic Monitoring to learn how to create availability policies.

View the Effects of Performance Issue

Screenshots will show you what your user is seeing. From the screenshot, you can determine whether the content has completely loaded (text, images, containers, UI components) and the page is styled correctly (CSS).

From the Waterfall tab, you can determine when the screenshot (visually complete) and view a small thumbnail by hovering over the camera icon.

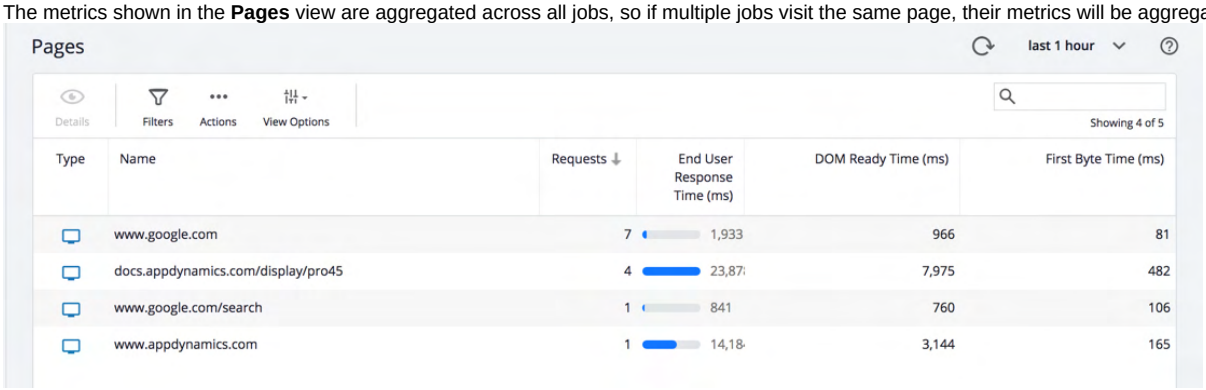


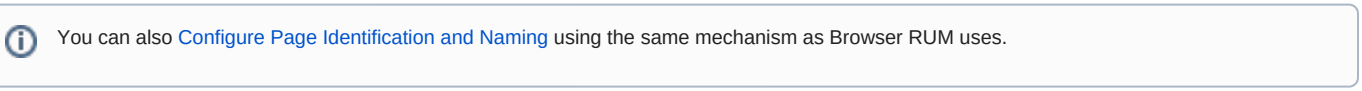
By navigating to the Screenshots tab and double-clicking the screenshot, you can view a larger screenshot to see details such as the styling, UI components, and content.

Synthetic Pages

You use the **Pages** view to see an aggregated view of how each page visited in your jobs is performing over time.

The metrics shown in the **Pages** view are aggregated across all jobs, so if multiple jobs visit the same page, their metrics will be aggregated.



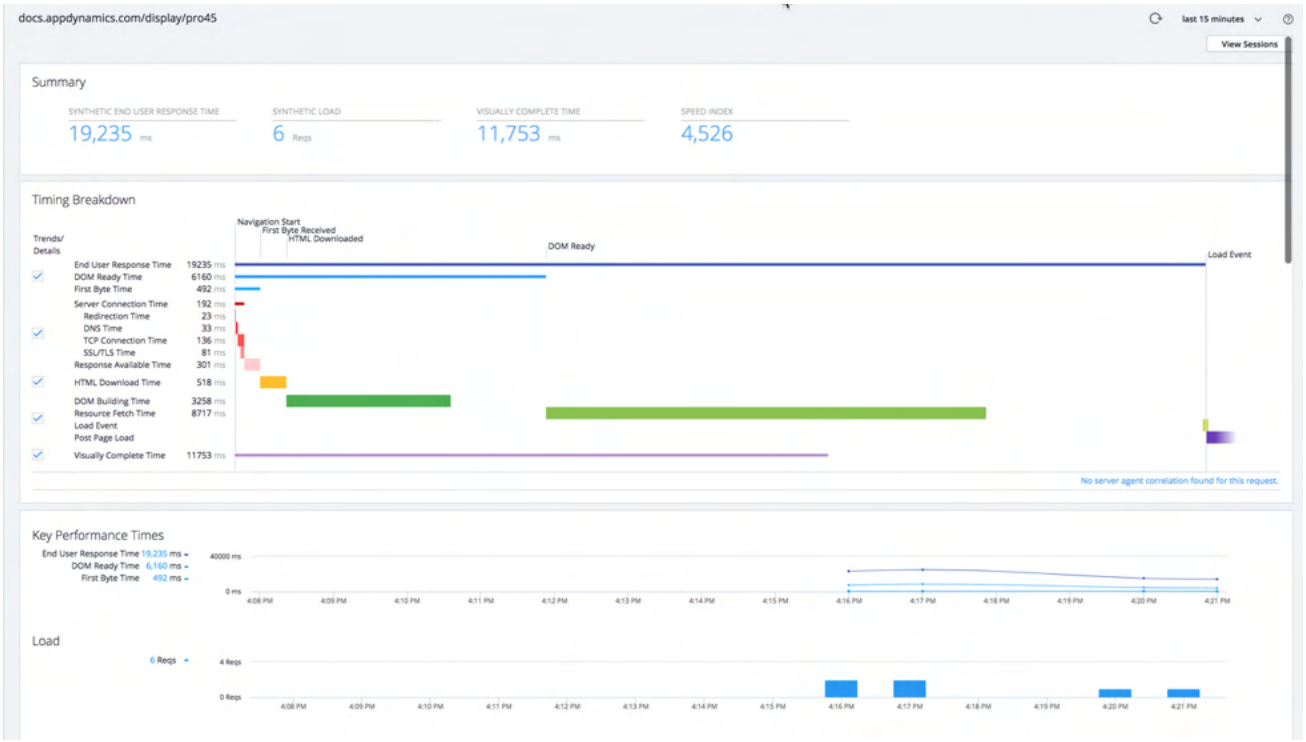


You can also Configure Page Identification and Naming using the same mechanism as Browser RUM uses.

Pages Details

Just as in the Browser RUM view you can filter the dataset and manage which pages are displayed and which metrics are shown. If you select an individual page and click **Details**, you are shown a **Page** dashboard very similar to the Browser RUM Pages Dashboard.

The **Synthetic Pages Dashboard**, however, includes some additional metrics. To understand these added synthetic metrics, you can hover over the metric name and a tooltip explaining the metric popup. See Browser Synthetic Metrics.



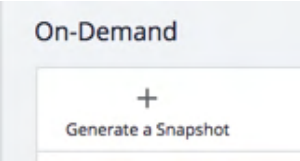
Request Synthetic Snapshots On-Demand

Browser Synthetic On-Demand allows you to take quick snapshots of single pages whenever you wish. See Browser Synthetic Metrics.

> Browser Synthetic On-Demand is only available on SaaS deployments of the Controller.

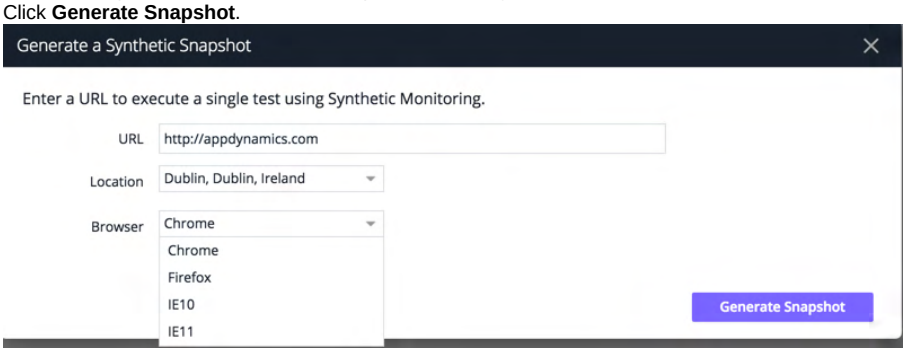
Create an On-Demand Snapshot

To create an on-demand session, click **+ Generate a Snapshot** at the top of the **On-Demand** list page.



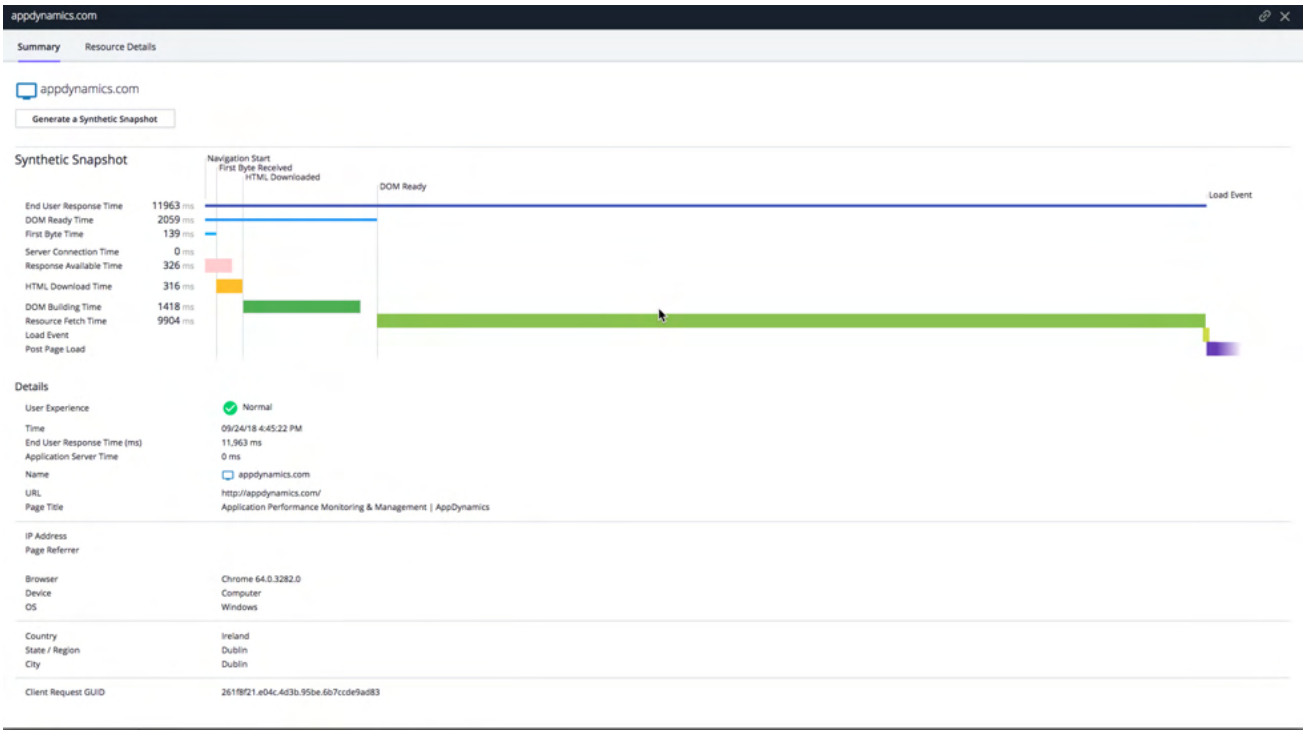
After the **Generate a Synthetic Snapshot** popup appears:

1. Provide the URL of the page you wish to test.
2. From the dropdown, select where the request should originate and which browser should be used.
3. Click **Generate Snapshot**.

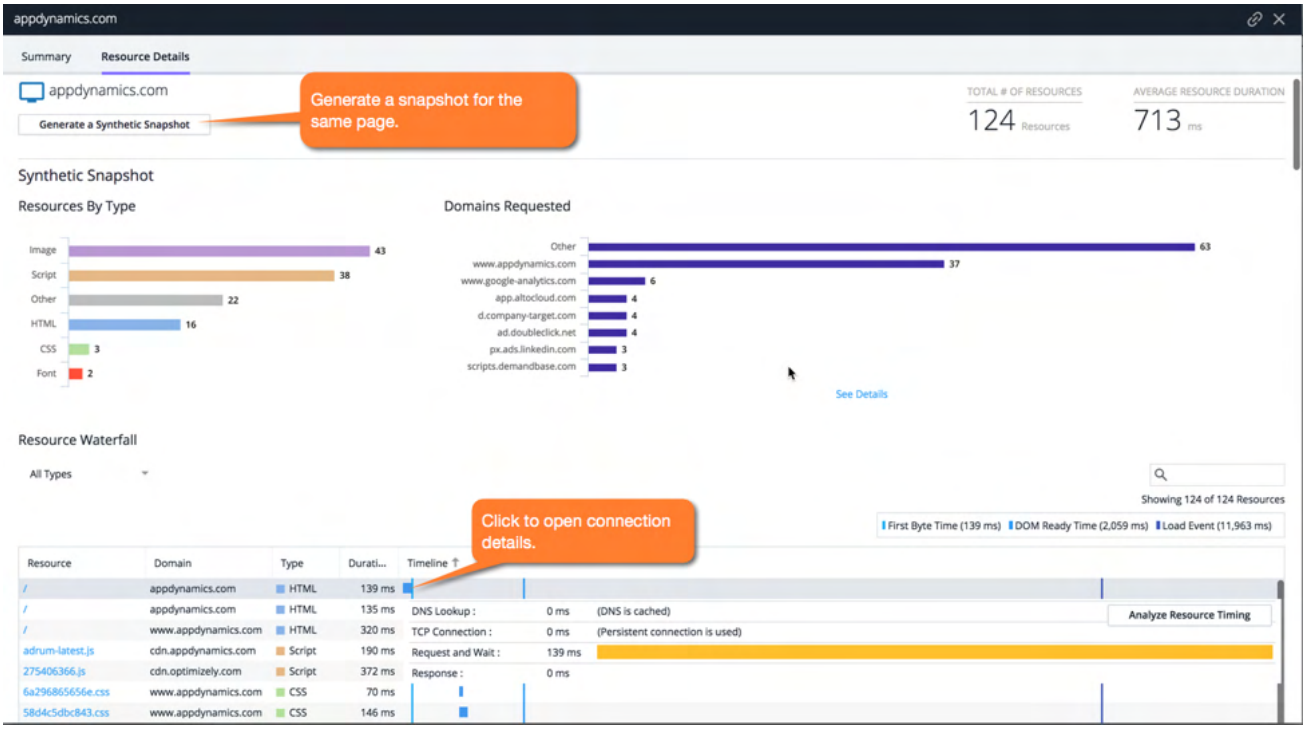


View On-Demand Snapshot Results

When the test completes, it is marked as **Done** in the Snapshot list. To see the detailed results, click the test. The Summary tab provides a waterfall of the page load and additional request details.



The Resource Details tab provides visualizations of **Resources by Type** and **Domains Requested** and a waterfall displaying the download of every resource. Click a waterfall bubble to see connection details. **Domains Requested** is also presented as a table.



Browser Synthetic Metrics

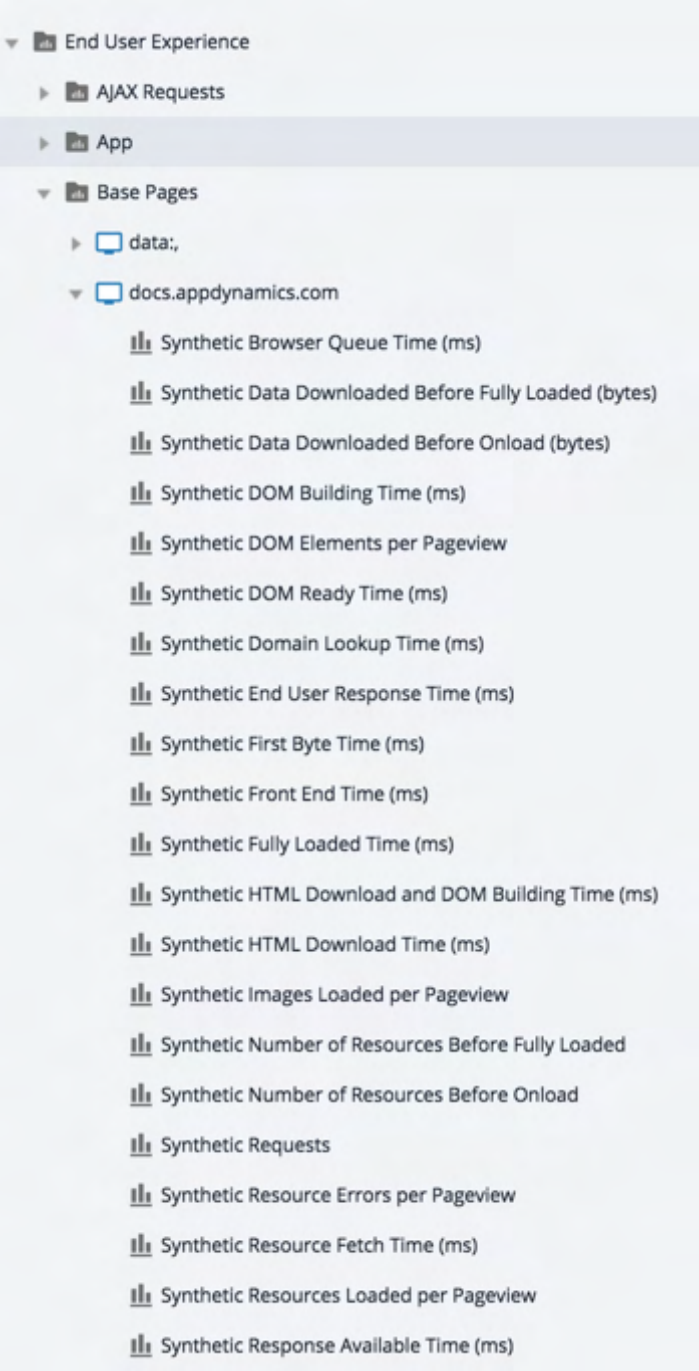
Related pages:

- Browser RUM Metrics
- Analytics Synthetic Sessions Data

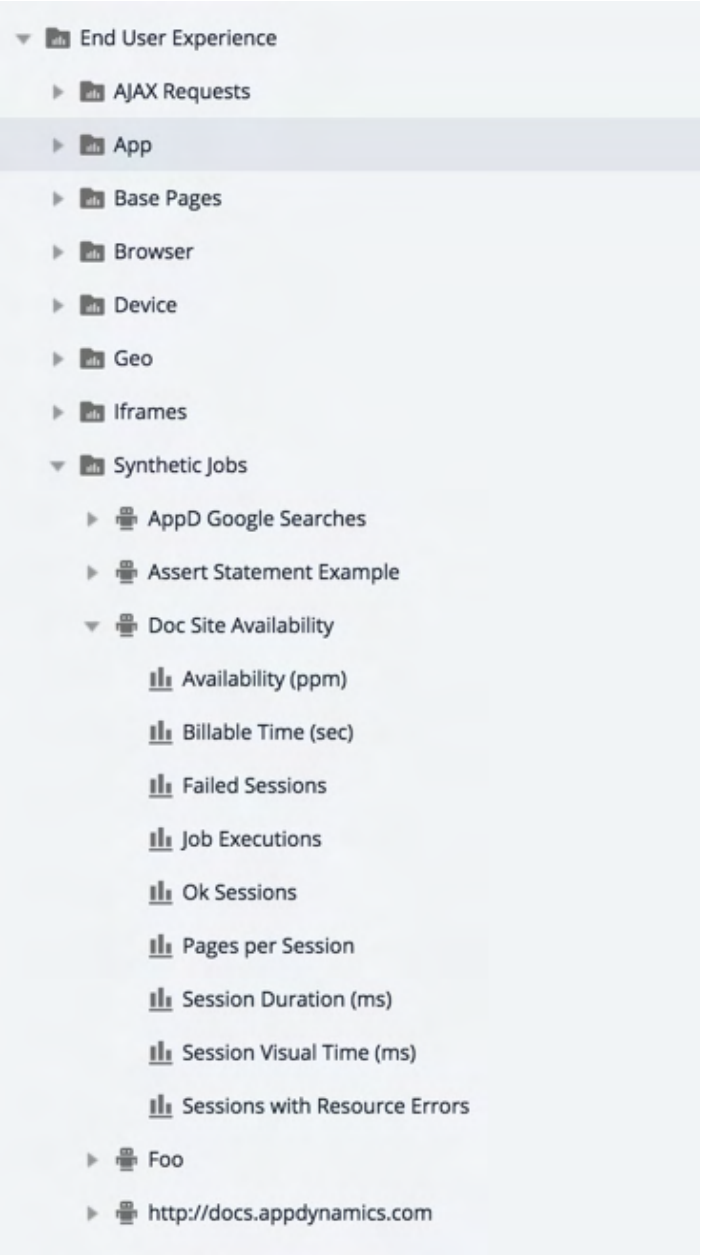
Many of the metrics collected by Browser Synthetic are identical to those collected by Browser RUM. Additional synthetic-only metrics are defined in Browser Synthetic Metrics Defined.

Key Browser RUM metrics are displayed on the **Geo**, **Sessions**, and **Pages** dashboards. They can also be seen in the **Metric Browser**, just like RUM metrics, giving you the ability to view these metrics in the context of Ajax requests, iframes, applications, base pages, browsers, devices, and geographic locations.

Metrics will only appear in the **Metric Browser** if there is synthetic data. For example, if your synthetic jobs do not have failed sessions, the metric **Failed Sessions** will not appear.



There are also metrics for specific tests and, under the **Synthetic Jobs** heading, for Synthetic job health overall.



Browser Synthetic Metrics Defined

Name	Definition
Availability	The ratio of OKAY sessions (successful) to all sessions, expressed per-million: 0 (for all failed) to 1,000,000 (for all succeeded). The ratio is calculated using the following: (# of successful sessions/# of total sessions) * 1,000,000. Availability is represented in per-million instead of as a percentage because Controller metrics are given as integers, making expressing the availability as a percentage less precise. For example, although the availability percentage in actuality might be 99.99%, it would only be able to be expressed as an integer such as 100% or 99%. To convert per-million to a percentage, just divide by Availability (ppm) by 10,000. For example, if Availability (ppm) is 999,800, then Availability (%) is 99.98%. Most Controller UI components display metrics as percentages, but the **Metric Browser**, which shows "raw data", shows the value per-million.
Billable Time	The seconds that were billed against your Synthetic license.
Broken Sessions	The number of sessions that completed with the session status BROKEN, indicating that the job has an error. You can find the error in the script console output.

Data Downloaded Before Fully Loaded	The bytes of data downloaded by the browser between the navigation start of a page and the navigation start of the next page or the end of the session. In particular, includes any resources loaded after the page `load` event.
Data Downloaded Before Onload	The bytes of data downloaded by the browser between the navigation start for a page and the `load` event for that page.
DOM Elements per Pageview	The number of DOM elements present on a page at the time of the page's `load` event. Includes sub-documents in frames.
Failed Sessions	The number of sessions that completed with the session status `FAILED`, indicating the synthetic test has detected a problem with your site. See Session Status for more information.
Fully Loaded Time	The time from the start of the initial navigation until 2 seconds of no network activity has passed after Document Complete. This will usually include any activity that is triggered by JavaScript after the main page loads. The Fully Loaded Time is given in milliseconds and percentiles.
Job Executions	Total number of sessions (per browser, per location) for a given job.
Number of Resources Loaded Before Fully Loaded	See **Data Downloaded Before Fully Loaded** above.
Number of Resources Loaded Before Onload	See **Data Downloaded Before Onload** above.
Ok Sessions	The number of sessions that completed with the session status `OK`, indicating the synthetic job ran successfully and returned data.
Pages per Session	The number of pages per session.
Session Duration	For scripted jobs: the time needed to execute the script from the first line to the last line. For URL jobs: the time from when the browser initiated the first HTTP request until the last resource was loaded.
Sessions with Resource Errors	The number of sessions that had missing or inaccessible resources.
Session Visual Time (SVT)	This metric captures the time the browser spent loading pages. Relative to **Session Duration**, this excludes the script process time and the time your script was interacting with content on a given page. Specifically, the **Session Visual Time** for a session is the sum of the **Visually Complete Times** for each page.
Speed Index	This metric captures whether a page renders incrementally or all at once. For example, if two pages both take five seconds to finish rendering, but one is mostly rendered after a second, while the other is blank until the last moment. Then the first page will have a **Speed Index** close to 1000, while the second will have a **Speed Index** close to 5000 (the **Visually Complete** time in milliseconds).
Visually Complete	The time when an end-user would determine that the page is visually complete in the viewport. This time is calculated by using the last visual change to the page and is in milliseconds. The page represents the viewable content (the viewport) in a browser window. The default size for a browser window is 1024 x 768.
Warning Sessions	The number of sessions that completed with the session status `WARNING`, indicating the test ran successfully, but there were inaccessible resources.

Private Synthetic Agent (Linux Based Agent in Kubernetes Container

This page describes the hardware components required for the Private Synthetic Agent (PSA) to run on the Kubernetes (K8S) cluster.

Linux based PSA supports these platforms:

- SaaS Controllers
- Python >=3
- Chrome browser

Prerequisites

- Kubernetes cluster version from 1.15 to 1.18
- License units:
  - Browser Synthetic Monitoring - Private Agent - Per Location (SaaS) or
  - Browser Synthetic Monitoring - Private Agent - Unlimited Locations (SaaS)

Hardware Requirements

This table lists the hardware components and their recommended configuration:

Component	Description	Minumum Configuration		Recommended Configuration	
		# Instances	Per Instance	# Instances	Per Instance
Heimdall (Orchestrator)	Orchestrator that connects to the Synthetic Cloud to fetch measurement jobs for the PSA cluster.	1	Processor: 2 vCPU Memory: 4 GB RAM	2	Processor: 3 vCPU Memory: 5 GB RAM
Postgres (DB)	Database (DB) for the local storage of in-progress measurement metadata. This DB does not store any business data. Any DB data loss or crash impacts on-going measurements only. Instead of setting up a new DB, you can use the existing Postgres DB set up with HA (High Availability) as a DB Java Database Connectivity (JDBC) url (part of configuration to Heimdall).	1	Processor: 2 vCPU Memory: 4 GB RAM	1	Processor: 3 vCPU Memory: 6 GB RAM
Measurement Container	A temporary or short-lived container auto-orchestrated by Heimdall to execute every measurement. The measurement container image can be customised to install additional libraries.	Based on need, a temporary container instance is scheduled for every measurement	Burstable CPU-RAM Min: 0.5 vCPU, 1 GB RAM Max: 1.25 CPU, 2 GB RAM	Based on need, a temporary container instance is scheduled for every measurement	Burstable CPU-RAM Min: 0.5 vCPU, 1 GB RAM Max: 1.25 CPU, 2 GB RAM

Number of Measurement Containers

You can calculate the number of required concurrent containers using this formula:

((Number of Jobs) x (Average job duration in minutes) / (Frequency in minutes))

For example, the number of containers required for 10 jobs with an average duration of 30 seconds per job executed at 5 minute interval needs:

(10 x (30/60)) / 5) = 1 container

Concurrent measurements

The Kubernetes cluster specifications determine the number of concurrent measurements that can be executed. Any submission of jobs beyond the infra limits leads to the queuing of jobs in the Kubernetes cluster. To scale the number of concurrent jobs automatically, enable cluster auto-scaler. K8S auto-scaler functionality depends on the cloud or the managed service provider.

To set up Private Synthetic Agent in any of the these environments, see:

- Set up Private Synthetic Agent in Amazon Elastic Kubernetes Service
- Set up the Private Synthetic Agent in Minikube
- Set up the Private Synthetic Agent in Azure AKS
- Set up the Private Synthetic Agent in Bare Metal K8s
- Configure Private Synthetic Agent

Set up Private Synthetic Agent in Amazon Elastic Kubernetes Service

To set up the Synthetic Private Agent in Amazon Elastic Kubernetes Service (Amazon EKS), perform the following:

1. Create the Kubernetes Cluster.
2. Build and customise the Docker image.
3. Tag and push images to the Registry.
4. Deploy the Private Synthetic Agent.
5. Monitor the Kubernetes cluster.

> This document contains links to AWS CLI documentation. AppDynamics makes no representation as to the accuracy of AWS CLI documentation because AWS CLI controls its own documentation.

Create the Kubernetes Cluster

To create a Kubernetes cluster in Amazon EKS:

1. Install and configure AWS CLI.
2. Based on your platform, install `eksctl` following the instructionshere.
3. Create a Kubernetes cluster using one of these valid Kubernetes version options: 1.14, 1.15, 1.16, 1.17, or 1.18.

```
EKSCTL_CLUSTER_NAME=eks-heimdall-onprem-cluster
EKSCTL_NODEGROUP_NAME=eks-heimdall-onprem-worker-nodes
EKSCTL_KUBERNETES_VERSION=1.18

eksctl create cluster \
--name ${EKSCTL_CLUSTER_NAME} \
--version ${EKSCTL_KUBERNETES_VERSION} \
--region us-west-2 \
--zones us-west-2a,us-west-2b,us-west-2c \
--nodegroup-name ${EKSCTL_NODEGROUP_NAME} \
--node-type t3.2xlarge \
--nodes 4 \
--nodes-min 2 \
--nodes-max 6 \
--ssh-access \
--ssh-public-key ~/.ssh/id_rsa.pub \
--managed \
--vpc-nat-mode Disable
```

> The node-type, nodes, nodes-min, and nodes-max in the code snippet are selected based on the recommended configuration type. You can specify a configuration of your choice with a different type and number of nodes. See EC2 instance types.

Access the Cluster

To access the Kubernetes cluster, follow these instructions to install kubectl, a utility to interact with the cluster.

To verify that the cluster is running, enter:

```
kubectl get nodes
```

Build and Customise the Docker Image

You can download the zip file for Simple Synth PSA installation from the Appdynamics Downloads Portal or from the beta upload tool. This file contains Dockerfiles for sum-chrome-agent, sum-heimdall, and Helm charts used to install the agent and set up monitoring. To build an image for sum-chrome-agent and sum-heimdall, ensure that Docker is installed. If it is not installed, you can download and install Docker from here.

For sum-chrome-agent:

1. Unzip the zip file to access the sum-chrome-agent directory.
2. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-chrome-agent:<agent-tag> .
```

For sum-heimdall:

1. Unzip the zip file to access the sum-heimdall directory.
2. Navigate to this directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-heimdall:<heimdall-tag> .
```

You can use any value for <heimdall-tag> and <agent-tag>, but ensure that you use the same value in the subsequent steps.

Add Custom Python Libraries

In addition to the available standard set of libraries, you can add custom Python libraries to the agent to use in scripted measurements. You build a new image based on the image you loaded as the base image.

1. Create a Dockerfile and then create `RUN` directives to run `python pip`. For example, to install the library `algorithms` you can create a Dockerfile:

```
# Use the sum-chrome-agent image we just loaded as the base image
FROM sum-chrome-agent:<agent-tag>

# Install algorithm for python3 on top of that
RUN python3 -m pip install algorithms==0.1.4

# We can add more RUN directives for installing more libraries
# RUN python3 -m pip install ...
```

   You can create any number of `RUN` directives to install the required libraries.

2. To build the new image, enter:

```
docker build -t sum-chrome-agent:<agent-tag> - < Dockerfile
```

   The newly built agent image contains the required libraries.

Tag and Push Images to the Registry

You must tag and push the images to a registry for the cluster to access it. The Amazon EKS clusters pull the images from Elastic Container Registry (ECR), which is the managed registry provided by AWS.

To tag the images, enter:

```
docker tag sum-heimdall:<heimdall-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall:
<heimdall-tag>
docker tag sum-chrome-agent:<agent-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-chrome-agent:
<agent-tag>
```

You need to replace `<aws_account_id>` & `<region>` with your account id and region values.

To create repositories, enter:

```
aws ecr create-repository --repository-name sum/sum-heimdall
aws ecr create-repository --repository-name sum/sum-chrome-agent
```

To push the images, enter:

```
aws ecr get-login-password --region us-west-2 | docker login --username AWS --password-stdin <aws_account_id>.
dkr.ecr.<region>.amazonaws.com
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall:<heimdall-tag>
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-chrome-agent:<agent-tag>
```

Deploy the Private Synthetic Agent

The application is deployed to the cluster after the images are in the Registry. You use Helm chart to deploy and create all Kubernetes resources in the required order.

1. Install Helm following these instructions.
2. Create a new measurement namespace where Heimdall, Postgres database, and measurement pods will run.

   To create a new measurement namespace, enter:

   ```
   kubectl create namespace measurement
   ```

   Using a single command, you can deploy the Helm chart which contains the deployment details. To deploy the agent, you use the Helm chart `sum-psa-heimdall.tgz` in the zip file that you downloaded previously. Before you deploy the Private Synthetic Agent, you must set some configuration options. To view the configuration options, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

   ```
   helm show values sum-psa-heimdall.tgz > values.yaml
   ```

   These are the configuration key value pairs that you need to edit in the `values.yaml` file:

Configuration Key	Value
`heimdall > repository`	`<aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall`
`heimdall > tag`	`<heimdall-tag>`
`agent > repository`	`<aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-chrome-agent`
`agent > tag`	`<agent-tag>`
`shepherd > url`	`Shepherd URL`
`shepherd > credentials`	`credentials`
`shepherd > location`	`agent location`

   You can leave the rest of the values set to their defaults or configure them based on your requirements. See Configure Private Synthetic Agent for details on shepherd URL, credentials, location, and optional key-value pairs.

   > You need to replace `<aws_account_id>` and `<region>` with your account and region values.

3. To deploy the Helm chart using the above mentioned configuration, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

   ```
   helm install heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
   ```

   All the Kubernetes resources are created in the cluster and you can use Heimdall. After a few seconds, Heimdall initializes and is visible in the Controller.
4. To verify if the pods are running, enter:

   ```
   kubectl get pods --namespace measurement
   ```

   To make any changes to the `values.yaml` after the initial deployment, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm upgrade heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
```

To remove the deployment:

```
helm uninstall heimdall-onprem --namespace measurement
```

This is not recommended unless it required.

Monitor the Kubernetes Cluster

The Helm chart `sum-psa-monitoring.tgz` in the zip you downloaded installs the monitoring stack. This Helm chart installs kube-prometheus-stack alon g with a custom Grafana dashboard to monitor the Private Simple Synthetic Agent.

Monitoring the deployment is optional; however, we highly recommended that you monitor the cluster to periodically check its health.

Install the Monitoring Stack

1. To create a separate `monitoring` namespace, enter:

   ```
   kubectl create namespace monitoring
   ```

   To review configuration options, enter:

   ```
   helm show values sum-psa-monitoring.tgz > values.yaml
   ```

   This generates a `values.yaml` file which contains all the configuration options. To modify and pass the generated `values.yaml` file while installing the Helm chart, enter:

   ```
   helm install psa-monitoring sum-psa-monitoring.tgz --values values.yaml --namespace monitoring
   ```

2. After the monitoring stack is installed, you can Launch Grafana (which runs inside the cluster) to view the dashboard. To access Grafana from outside of the cluster, you can configure port forwarding or set up Ingress. To configure port forward to access it locally, enter:

   ```
   kubectl port-forward svc/psa-monitoring-grafana 3000:80 --namespace monitoring
   ```

3. Launch localhost:3000 from the browser and log in using the default credentials with username as `admin` and password as `prom-operator`. A dashboard named Private Simple Synthetic Agent displays and provides details about the Kubernetes cluster, Heimdall, Postgres, and running measurements.

Set up the Private Synthetic Agent in Minikube

To set up the Private Synthetic Agent in Minikube, follow the steps given below:

1. Create the Kubernetes Cluster.
2. Build and customise the Docker image.
3. Save Images to Minikube's Docker Daemon.
4. Deploy the Private Synthetic Agent.
5. Monitor the Kubernetes cluster.

> This document contains links to Kubernetes documentation. AppDynamics makes no representation as to the accuracy of Kubernetes documentation because Kubernetes controls its own documentation.

Create the Kubernetes Cluster

To create a Kubernetes cluster in Minikube:

1. Install Minikube following these instructions.
2. To start the cluster, enter:

```
minikube start --kubernetes-version=v1.18.3
```

> Minikube installs the latest version of Kubernetes available at the time of Minikube release by default. For latest information on supported versions, see `OldestKubernetesVersion` and `NewestKubernetesVersion` in constants.go.

Access the Cluster

To access the Kubernetes cluster, follow these instructions to install kubectl, a utility to interact with the cluster.

To verify that the cluster is running, enter:

```
kubectl get nodes
```

Build and Customise Image

You can download the zip file for Simple Synth PSA installation from the Appdynamics Downloads Portal or from the beta upload tool. This file contains Dockerfiles for sum-chrome-agent, sum-heimdall, and Helm charts used to install the agent and set up monitoring. To build an image for sum-chrome-agent and sum-heimdall, ensure that Docker is installed. If it is not installed, you can download and install Docker from here.

For sum-chrome-agent:

1. Unzip the zip file to access the sum-chrome-agent directory.
2. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-chrome-agent:<agent-tag> .
```

For sum-heimdall:

1. Unzip the zip file to access the sum-heimdall directory.
2. Navigate to this directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-heimdall:<heimdall-tag> .
```

> You can use any value for <heimdall-tag> and <agent-tag>, but ensure that you use the same value in the subsequent steps.

Add Custom Python Libraries

In addition to the available standard set of libraries, you can add custom Python libraries to the agent to use in scripted measurements. You build a new image based on the image you loaded as the base image.

1. Create a Dockerfile and create RUN directives to run python pip. For example, to install the library `algorithms` you can create a Dockerfile:

```
# Use the sum-chrome-agent image we just loaded as the base image
FROM sum-chrome-agent:<agent-tag>

# Install algorithm for python3 on top of that
RUN python3 -m pip install algorithms==0.1.4

# We can add more RUN directives for installing more libraries
# RUN python3 -m pip install ...
```

> You can create any number of RUN directives to install the required libraries.

2. To build the new image, enter:

```
docker build -t sum-chrome-agent:<agent-tag> - < Dockerfile
```

The newly built agent image contains the required libraries.

Save Images to Minikube's Docker Daemon

You must tag and push the images to a registry for cluster to access it. Execute the following command to save the images to Minikube docker:

```
docker save sum-heimdall:<heimdall-tag> | (eval $(minikube docker-env) && docker load)
docker save sum-chrome-agent:<agent-tag> | (eval $(minikube docker-env) && docker load)
```

Deploy the Private Synthetic Agent

The application is deployed to the cluster after the images are in the Registry. You use Helm chart to deploy and create all Kubernetes resources in the required order.

1. Install Helm following these instructions.
2. Create a new measurement namespace where Heimdall, Postgres database, and measurement pods will run.

   To create a new measurement namespace, enter:

```
kubectl create namespace measurement
```

   Using a single command, you can deploy the Helm chart which contains the deployment details. To deploy the agent, you use the Helm chart `sum-psa-heimdall.tgz` in the zip file that you downloaded previously. Before you deploy the Private Synthetic Agent, you must set some configuration options. To view the configuration options, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm show values sum-psa-heimdall.tgz > values.yaml
```

   These are the configuration key value pairs that you need to edit in the `values.yaml` file:

Configuration Key	Value
heimdall > repository	sum-heimdall
heimdall > tag	<heimdall-tag>
heimdall > pullPolicy	Never
agent > repository	sum-chrome-agent
agent > tag	<agent-tag>
shepherd > url	Shepherd URL
shepherd > credentials	credentials

`shepherd > location`	`agent location`

You can leave the rest of the values set to their defaults or configure them based on your requirements. See Configure Private Synthetic Agent for details on shepherd URL, credentials, location, and optional key-value pairs.

> You need to replace `<aws_account_id>` and `<region>` with your account and region values.

3. To deploy the Helm chart using the above mentioned configuration, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm install heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
```

All the Kubernetes resources are created in the cluster and you can use Heimdall. After a few seconds, Heimdall initializes and is visible in the Controller.

4. To verify if the pods are running, enter:

```
kubectl get pods --namespace measurement
```

To make any changes to the `values.yaml` after the initial deployment, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm upgrade heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
```

> To remove the deployment:
>
> ```
> helm uninstall heimdall-onprem --namespace measurement
> ```
>
> This is not recommended unless it required.

Monitor the Kubernetes Cluster

The Helm chart `sum-psa-monitoring.tgz` in the zip you downloaded installs the monitoring stack. This Helm chart installs kube-prometheus-stack alon g with a custom Grafana dashboard to monitor the Private Simple Synthetic Agent.

> Monitoring the deployment is optional; however, we highly recommended that you monitor the cluster to periodically check its health.

Install the Monitoring Stack

1. To create a separate `monitoring` namespace, enter:

```
kubectl create namespace monitoring
```

To review configuration options, enter:

```
helm show values sum-psa-monitoring.tgz > values.yaml
```

This generates a `values.yaml` file which contains all the configuration options. To modify and pass the generated `values.yaml` file while installing the Helm chart, enter:

```
helm install psa-monitoring sum-psa-monitoring.tgz --values values.yaml --namespace monitoring
```

2. After the monitoring stack is installed, you can Launch Grafana (which runs inside the cluster) to view the dashboard. To access Grafana from outside of the cluster, you can configure port forwarding or set up Ingress. To configure port forward to access it locally, enter:

```
kubectl port-forward svc/psa-monitoring-grafana 3000:80 --namespace monitoring
```

3. Launch localhost:3000 from the browser and log in using the default credentials with username as `admin` and password as `prom-operator`. A dashboard named Private Simple Synthetic Agent displays and provides details about the Kubernetes cluster, Heimdall, Postgres, and running measurements.

Set up the Private Synthetic Agent in Azure AKS

To set up the Private Synthetic Agent in Azure AKS, perform the following:

1. Create the Kubernetes Cluster.
2. Build and customise the Docker image..
3. Tag and push images to the Registry.
4. Deploy the Private Synthetic Agent.
5. Monitor the Kubernetes cluster.

This document contains links to Azure CLI documentation. AppDynamics makes no representation as to the accuracy of Azure CLI documentation because Azure CLI controls its own documentation.

Create the Kubernetes Cluster

To create a Kubernetes cluster in Azure AKS:

1. Install and authenticate Azure CLI.
2. To create a resource group, enter

```
RESOURCE_GROUP=heimdall-onprem
az group create --name $RESOURCE_GROUP --location eastus
```

3. To create a container registry, enter:

```
ACR_NAME=heimdallonprem
az acr create --resource-group $RESOURCE_GROUP --name $ACR_NAME --sku Basic
```

4. To create a cluster, enter:

```
CLUSTER_NAME=heimdall-onprem
az aks create \
    --resource-group $RESOURCE_GROUP \
    --name $CLUSTER_NAME \
    --enable-managed-identity \
    --kubernetes-version 1.18.10 \
    --node-count 4 \
    --node-vm-size Standard_D8s_v3 \
    --generate-ssh-keys \
    --attach-acr $ACR_NAME
```

The `node-vm-size` and `node-count` in the above code are selected according to the recommended configuration type. You can specify a configuration of your choice with a different type and number of nodes. See node-vm-size.

Access the Cluster

To access the Kubernetes cluster, follow these instructions to install kubectl, a utility to interact with the cluster.

To verify that the cluster is running, enter:

```
kubectl get nodes
```

Build and Customise the Docker Image

You can download the zip file for Simple Synth PSA installation from the Appdynamics Downloads Portal or from the beta upload tool. This file contains Dockerfiles for sum-chrome-agent, sum-heimdall, and Helm charts used to install the agent and set up monitoring. To build an image for sum-chrome-agent and sum-heimdall, ensure that Docker is installed. If it is not installed, you can download and install Docker from here.

For sum-chrome-agent:

1. Unzip the zip file to access the sum-chrome-agent directory.
2. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-chrome-agent:<agent-tag> .
```

For sum-heimdall:

1. Unzip the zip file to access the sum-heimdall directory.
2. Navigate to this directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-heimdall:<heimdall-tag> .
```

You can use any value for <heimdall-tag> and <agent-tag>, but ensure that you use the same value in the subsequent steps.

Add Custom Python Libraries

In addition to the standard set of libraries, you can add the custom Python libraries to the agent for the scripted measurements. To add the custom Python libraries, build an image using the downloaded base image.

1. Create a Dockerfile and create `RUN` directives to run python pip. For example, to install the library `algorithms` you can create a Dockerfile:

```
# Use the sum-chrome-agent image we just loaded as the base image
FROM sum-chrome-agent:<agent-tag>

# Install algorithm for python3 on top of that
RUN python3 -m pip install algorithms==0.1.4

# We can add more RUN directives for installing more libraries
# RUN python3 -m pip install ...
```

   You can create any number of `RUN` directives to install the required libraries.

2. To build the new image, enter:

```
docker build -t sum-chrome-agent:<agent-tag> - < Dockerfile
```

   The newly built agent image contains the required libraries.

Tag and Push Images to the Registry

You must tag and push the images to a registry for cluster to access it. You have to use the `ACR_NAME` environment variable while creating the cluster.

To tag the images, enter:

```
ACR_LOGIN_SERVER=$ACR_NAME.azurecr.io
docker tag sum-heimdall:<heimdall-tag> $ACR_LOGIN_SERVER/sum-heimdall:<heimdall-tag>
docker tag sum-chrome-agent:<agent-tag> $ACR_LOGIN_SERVER/sum-chrome-agent:<agent-tag>
```

You need to replace `<aws_account_id>` & `<region>` with your account id and region values.

To push the images, enter:

```
az acr login --name $ACR_NAME
docker push $ACR_LOGIN_SERVER/sum-heimdall:<heimdall-tag>
docker push $ACR_LOGIN_SERVER/sum-chrome-agent:<agent-tag>
```

Deploy the Private Synthetic Agent

The application is deployed to the cluster after the images are in the Registry. You use Helm chart to deploy and create all Kubernetes resources in the required order.

1. Install Helm following the instructions here.
2. Create a new measurement namespace where Heimdall, postgres database, and measurement pods will run.

   To create measurement namespace:

   ```
   kubectl create namespace measurement
   ```

   Using a single command, you can deploy the Helm chart which contains the deployment details. To deploy the agent, you use the Helm chart `sum-psa-heimdall.tgz` in the zip file that you downloaded previously. Before you deploy the Private Synthetic Agent, you must set some configuration options. To view the configuration options, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

   ```
   helm show values sum-psa-heimdall.tgz > values.yaml
   ```

   These are the configuration key value pairs that you need to edit in the `values.yaml` file:

Configuration Key	Value
`heimdall > repository`	`$ACR_LOGIN_SERVER/sum-heimdall`
`heimdall > tag`	`<heimdall-tag>`
`agent > repository`	`$ACR_LOGIN_SERVER/sum-chrome-agent`
`agent > tag`	`<agent-tag>`
`shepherd > url`	`Shepherd URL`
`shepherd > credentials`	`credentials`
`shepherd > location`	`agent location`

   You can leave the rest of the values set to their defaults or configure them based on your requirements. See Configure Private Synthetic Agent for details on shepherd URL, credentials, location, and optional key-value pairs.

   > You need to replace `<aws_account_id>` and `<region>` with your account and region values.

3. To deploy the Helm chart using the above mentioned configuration, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

   ```
   helm install heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
   ```

   All the Kubernetes resources are created in the cluster and you can use Heimdall. After a few seconds, Heimdall initializes and is visible in the Controller.
4. To verify if the pods are running, enter:

   ```
   kubectl get pods --namespace measurement
   ```

   To make any changes to the `values.yaml` after the initial deployment, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

   ```
   helm upgrade heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
   ```

   > To remove the deployment:
   >
   > ```
   > helm uninstall heimdall-onprem --namespace measurement
   > ```
   >
   > This is not recommended unless it required.

Monitor the Kubernetes Cluster

The Helm chart `sum-psa-monitoring.tgz` in the zip you downloaded installs the monitoring stack. This Helm chart installs kube-prometheus-stack alon g with a custom Grafana dashboard to monitor the Private Simple Synthetic Agent.

> Monitoring the deployment is optional; however, we highly recommended that you monitor the cluster to periodically check its health.

Install the Monitoring Stack

1. To create a separate `monitoring` namespace, enter:

   ```
   kubectl create namespace monitoring
   ```

   To review configuration options, enter:

   ```
   helm show values sum-psa-monitoring.tgz > values.yaml
   ```

   This generates a `values.yaml` file which contains all the configuration options. To modify and pass the generated `values.yaml` file while installing the Helm chart, enter:

   ```
   helm install psa-monitoring sum-psa-monitoring.tgz --values values.yaml --namespace monitoring
   ```

2. After the monitoring stack is installed, you can Launch Grafana (which runs inside the cluster) to view the dashboard. To access Grafana from outside of the cluster, you can configure port forwarding or set up Ingress. To configure port forward to access it locally, enter:

   ```
   kubectl port-forward svc/psa-monitoring-grafana 3000:80 --namespace monitoring
   ```

3. Launch localhost:3000 from the browser and log in using the default credentials with username as `admin` and password as `prom-operator`. A dashboard named Private Simple Synthetic Agent displays and provides details about the Kubernetes cluster, Heimdall, Postgres, and running measurements.

Set up the Private Synthetic Agent in Bare Metal K8s

To set up the Private Synthetic Agent in Bare Metal K8s, perform the following:

1. Create the Kubernetes Cluster.
2. Build and customise the Docker image.
3. Save Images to Minikube's Docker Daemon.
4. Deploy the Private Synthetic Agent.
5. Monitor the Kubernetes cluster.

> This document contains links to AWS CLI documentation. AppDynamics makes no representation as to the accuracy of AWS CLI documentation because AWS CLI controls its own documentation.

Create the Kubernetes Cluster

> You can use kops to create your own managed Kubernetes cluster on AWS. If you want to create self-managed cluster on a different cloud or your own datacenter, you might want to look into other tools like Kubeadm or Kubespray. See installing Kubernetes with deployment tools.

To create a Kubernetes cluster in Bare Metal K8s:

1. Install and configure AWS CLI.
2. To create IAM Role, enter.

```
aws iam create-group --group-name kops

aws iam attach-group-policy --policy-arn arn:aws:iam::aws:policy/AmazonEC2FullAccess --group-name kops
aws iam attach-group-policy --policy-arn arn:aws:iam::aws:policy/AmazonRoute53FullAccess --group-name
kops
aws iam attach-group-policy --policy-arn arn:aws:iam::aws:policy/AmazonS3FullAccess --group-name kops
aws iam attach-group-policy --policy-arn arn:aws:iam::aws:policy/IAMFullAccess --group-name kops
aws iam attach-group-policy --policy-arn arn:aws:iam::aws:policy/AmazonVPCFullAccess --group-name kops

aws iam create-user --user-name kops

aws iam add-user-to-group --user-name kops --group-name kops

aws iam create-access-key --user-name kops
```

3. Configure AWS CLI credentials using `aws configure` with the access key obtained in the previous step.
4. Based on your platform, install kops following these instructions.
5. To create S3 bucket, enable versioning by entering:

```
bucket_name=heimdall-onprem-kops-state-store
aws s3api create-bucket \
--bucket ${bucket_name} \
--create-bucket-configuration LocationConstraint=us-west-2

aws s3api put-bucket-versioning --bucket ${bucket_name} --versioning-configuration Status=Enabled
```

6. To create cluster, enter:

```
export KOPS_CLUSTER_NAME=heimdall-onprem.k8s.local
export KOPS_STATE_STORE=s3://${bucket_name}
export KOPS_KUBERNETES_VERSION=1.18.10

kops create cluster \
--node-count=4 \
--node-size=t3.2xlarge \
--zones=us-west-2a \
--kubernetes-version=${KOPS_KUBERNETES_VERSION} \
--name=${KOPS_CLUSTER_NAME}

kops update cluster --name ${KOPS_CLUSTER_NAME} --yes
```

The `node-size` and `node-count` in the above code snippet are selected according to recommended configuration type. You can specify a configuration of your choice with a different type and number of nodes. See EC2 instance types.

7. To validate if the cluster is running (might take some time for cluster to set up and run), enter:

```
kops validate cluster
```

Access the Cluster

To access the Kubernetes cluster, follow these instructions to install kubectl, a utility to interact with the cluster.

To verify that the cluster is running, enter:

```
kubectl get nodes
```

Build and Customise the Docker Image

You can download the zip file for Simple Synth PSA installation from the Appdynamics Downloads Portal or from the beta upload tool. This file contains Dockerfiles for sum-chrome-agent, sum-heimdall, and Helm charts used to install the agent and set up monitoring. To build an image for sum-chrome-agent and sum-heimdall, ensure that Docker is installed. If it is not installed, you can download and install Docker from here.

For sum-chrome-agent:

1. Unzip the zip file to access the sum-chrome-agent directory.
2. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-chrome-agent:<agent-tag> .
```

For sum-heimdall:

1. Unzip the zip file to access the sum-heimdall directory.
2. Navigate to this directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-heimdall:<heimdall-tag> .
```

You can use any value for <heimdall-tag> and <agent-tag>, but ensure that you use the same value in the subsequent steps.

Add Custom Python Libraries

In addition to the available standard set of libraries, you can add custom Python libraries to the agent to use in scripted measurements. You build a new image based on the image you loaded as the base image

1. Create a Dockerfile and create `RUN` directives to run python pip. For example, to install the library `algorithms` you can create a Dockerfile:

```
# Use the sum-chrome-agent image we just loaded as the base image
FROM sum-chrome-agent:<agent-tag>

# Install algorithm for python3 on top of that
RUN python3 -m pip install algorithms==0.1.4

# We can add more RUN directives for installing more libraries
# RUN python3 -m pip install ...
```

You can create any number of `RUN` directives to install the required libraries.

2. To build the new image, enter:

```
docker build -t sum-chrome-agent:<agent-tag> - < Dockerfile
```

The newly built agent image contains the required libraries.

Tag and Push Images to the Registry

You must tag and push the images to a registry for cluster to access it. It can be done in the following ways:

Bare Metal K8S using EC2

Vanilla K8S runs on AWS infrastructure. As kops create and assign appropriate roles to the cluster nodes, they can directly access Elastic Container Registry (ECR), without any other configuration.

To tag images, enter:

```
docker tag sum-heimdall:<heimdall-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall:
<heimdall-tag>
docker tag sum-chrome-agent:<agent-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-chrome-agent:
<agent-tag>
```

Replace `<aws_account_id>` and `<region>` with your account and region values.

To create repositories, enter:

```
aws ecr create-repository --repository-name sum/sum-heimdall
aws ecr create-repository --repository-name sum/sum-chrome-agent
```

To push the images, enter:

```
aws ecr get-login-password --region us-west-2 | docker login --username AWS --password-stdin <aws_account_id>.
dkr.ecr.<region>.amazonaws.com
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall:<heimdall-tag>
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-chrome-agent:<agent-tag>
```

Bare Metal K8S using Private Registry

If you are managing your own Kubernetes cluster which is not on AWS, then you must deploy your own registry server. See deploy a registry server.

To tag images, enter:

```
docker tag sum-heimdall:<heimdall-tag> <REGISTRY_HOST>:<REGISTRY_PORT>/sum-heimdall:<heimdall-tag>
docker tag sum-chrome-agent:<agent-tag> <REGISTRY_HOST>:<REGISTRY_PORT>/sum-chrome-agent:<agent-tag>
```

Replace <REGISTRY_HOST> and <REGISTRY_PORT> to what you configured while deploying the registry.

To push the images, enter:

```
docker login <REGISTRY_HOST>:<REGISTRY_PORT>
docker push <REGISTRY_HOST>:<REGISTRY_PORT>/sum-heimdall:<heimdall-tag>
docker push <REGISTRY_HOST>:<REGISTRY_PORT>/sum-chrome-agent:<agent-tag>
```

Deploy the Private Synthetic Agent

The application is deployed to the cluster after the images are in the Registry. You use Helm chart to deploy and create all Kubernetes resources in the required order.

1. Install Helm following these instructions.
2. Create a new measurement namespace where Heimdall, Postgres database, and measurement pods will run.

   To create a new measurement namespace, enter:

   ```
   kubectl create namespace measurement
   ```

   Using a single command, you can deploy the Helm chart which contains the deployment details. To deploy the agent, you use the Helm chart `sum-psa-heimdall.tgz` in the zip file that you downloaded previously. Before you deploy the Private Synthetic Agent, you must set some configuration options. To view the configuration options, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

   ```
   helm show values sum-psa-heimdall.tgz > values.yaml
   ```

   These are the configuration key value pairs that you need to edit in the `values.yaml` file:

   Using EC2

Configuration Key	Value
heimdall > repository	<aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall
heimdall > tag	<heimdall-tag>
agent > repository	<aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-chrome-agent
agent > tag	<agent-tag>
shepherd > url	Shepherd URL
shepherd > credentials	credentials
shepherd > location	agent location

   Using Private Registry

Configuration Key	Value
heimdall > repository	<REGISTRY_HOST>:<REGISTRY_PORT>/sum-heimdall
heimdall > tag	<heimdall-tag>
agent > repository	<REGISTRY_HOST>:<REGISTRY_PORT>/sum-chrome-agent
agent > tag	<agent-tag>
privateRegistry	true
shepherd > url	Shepherd URL
shepherd > credentials	credentials
shepherd > location	agent location

After configuring using Private Registry

Create registry credentials:

```
kubectl create secret docker-registry regcred --docker-server=<REGISTRY_HOST>:<REGISTRY_PORT> --
docker-username=<your-name> --docker-password=<your-pword> --docker-email=<your-email> --
namespace measurement
```

Patch the default service account of measurement namespace to use the `regcred` registry credentials:

```
kubectl patch serviceaccount default -p '{"imagePullSecrets": [{"name": "regcred"}]}' --
namespace measurement
```

You can leave the rest of the values set to their defaults or configure them based on your requirements. See Configure Private Synthetic Agent for details on shepherd URL, credentials, location, and optional key-value pairs.

You need to replace `<aws_account_id>` and `<region>` with your account and region values.

3. To deploy the Helm chart using the above mentioned configuration, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm install heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
```

All the Kubernetes resources are created in the cluster and you can use Heimdall. After a few seconds, Heimdall initializes and is visible in the Controller.

4. To verify if the pods are running, enter:

```
kubectl get pods --namespace measurement
```

To make any changes to the `values.yaml` after the initial deployment, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm upgrade heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
```

To remove the deployment:

```
helm uninstall heimdall-onprem --namespace measurement
```

This is not recommended unless it required.

Monitor the Kubernetes Cluster

The Helm chart `sum-psa-monitoring.tgz` in the zip you downloaded installs the monitoring stack. This Helm chart installs kube-prometheus-stack along with a custom Grafana dashboard to monitor the Private Simple Synthetic Agent.

Monitoring the deployment is optional; however, we highly recommended that you monitor the cluster to periodically check its health.

Install the Monitoring Stack

1. To create a separate `monitoring` namespace, enter:

```
kubectl create namespace monitoring
```

To review configuration options, enter:

```
helm show values sum-psa-monitoring.tgz > values.yaml
```

This generates a `values.yaml` file which contains all the configuration options. To modify and pass the generated `values.yaml` file while installing the Helm chart, enter:

```
helm install psa-monitoring sum-psa-monitoring.tgz --values values.yaml --namespace monitoring
```

2. After the monitoring stack is installed, you can Launch Grafana (which runs inside the cluster) to view the dashboard. To access Grafana from outside of the cluster, you can configure port forwarding or set up Ingress. To configure port forward to access it locally, enter:

```
kubectl port-forward svc/psa-monitoring-grafana 3000:80 --namespace monitoring
```

3. Launch localhost:3000 from the browser and log in using the default credentials with username as `admin` and password as `prom-operator`. A dashboard named Private Simple Synthetic Agent displays and provides details about the Kubernetes cluster, Heimdall, Postgres, and running measurements.

Configure Private Synthetic Agent

This page describes how to configure the Private Synthetic Agent (PSA).

In-Script Metadata Configuration

When you run Synthetic Jobs as scripted measurements, you can specify certain configuration options using in-script metadata. You must include these yaml based configurations at the beginning of the script in the form of a comment block.

Set Custom User Agent for Synthetic Scripts

To modify the default browser specific `user-agent` header to a custom `user-agent` header, add this in-script metadata at the beginning of the Synthetic script:

```
'''yml
requestHeader:
  userAgent: "custom user agent"
'''
driver.get('http://127.0.0.1:20000/green.html')
```

Include Synthetic Traffic in Browser RUM Traffic

The `user-agent` request headers in the Synthetic scripts are tagged so that the requests are not included in Browser RUM pages. You can set `tagUserAgent` to `false` to include the Synthetic traffic in the Browser RUM pages.

Enter the following in-script metadata at the beginning of the Synthetic script:

```
'''yml
requestHeader:
  userAgent: "custom user agent"
  tagUserAgent: false
'''
driver.get('http://127.0.0.1:20000/green.html')
```

Kubernetes Configuration

After you set up the Kubernetes cluster, push the images to the Docker registry, and deploy the Private Synthetic Agent using `sum-psa-heimdall.tgz` Helm chart, a `values.yaml` file is generated. Use the `values.yaml` file to dynamically configure the values while deploying the PSA.

Key-Value Pairs Configuration

You can replace the optional configuration values in the `values.yaml` file with the values in the table:

Configuration	Key-Value Pair	Description
Heimdall replica count	`heimdall > replicaCount`	Indicates the Heimdall replica count.
Heimdall Resource allocations	• `heimdallResources > min_cpu` • `heimdallResources > max_cpu` • `heimdallResources > min_mem` • `heimdallResources > max_mem`	Indicates the Heimdall Resource allocation.

Measurement Container Resource allocations	• `agentResources > min_cpu` • `agentResources > max_cpu` • `agentResources > min_mem` • `agentResources > max_mem`	Indicates the measurement container resource allocations.
Postgres DB Resource allocations	• `postgresResources > min_cpu` • `postgresResources > max_cpu` • `postgresResources > min_mem` • `postgresResources > max_mem`	Indicates the Postgres DB resource allocations.
Custom Postgres DB	• postgres > enable to false • databaseConfig >	To set up Postgres DB instance and to configure Heimdall to connect to the DB instance, ensure that the DB is running in the same namespace as Heimdall (measurement namespace).
Logging level	`logging > level to ERROR, WARN, INFO, DEBUG, or TRACE`	Indicates the logging level. The default value is `DEBUG`.
Node selectors	• `heimdallNodeSelector >` • `agentNodeSelector >`	Apply Node selectors for Heimdall and measurement containers to schedule these components on specific nodes.

Connect Agent to the Synthetic Server

When deploying the Synthetic Private Agent in the Kubernetes cluster, you must specify the agent registration information in the `values.yaml` file. Heimdall uses this information to register itself with the Synthetic Server. Once registered you can view the agent in the Controller and run measurements.

Shepherd URL

To connect the agent to a specific region, enter one of these shepherd URLs in the `values.yaml` file.

Region	Shepherd URL
us-west-2	https://synthetic.api.appdynamics.com
eu-central-1	https://fra-synthetic.eum-appdynamics.com
ap-southeast-2	https://syd-synthetic.eum-appdynamics.com
ap-south-1	https://bom-synthetic.eum-appdynamics.com

You can connect the Agent to only one Synthetic Cloud only. You cannot connect it to your on-premise Controllers and on-premise Synthetic Servers.

EUM Account and License Key

To connect the agent to the Controller, you need the EUM account and license key.

Follow the given steps to obtain this information:

1. Navigate to the SaaS Controller.
2. Click the settings icon at the top-right corner to navigate to **License > Account Usage**.
3. Scroll down to the **User Experience** section.
   Enter Account Name and License Key in the `values.yaml` file.

Configuration Key	Configuration Value
`shepherd > credentials > eumAccount`	`Account Name`

`shepherd > credentials > eumKey`	`License Key`

Location Information

To identify the location of the agent, enter the following `shepherd > location` details in the `values.yaml` file:

- `name` - A user-friendly string for the location.
- `code` - A unique alphanumeric string with four to ten characters which identifies the location where the agent is running. You must create this ID based on the location name.
- `latitude, longitude` - Navigate to the GPS Coordinates with Google Maps to get the latitude and longitude of your location.

Mobile Real User Monitoring

Related pages:

- Set Up and Access Mobile RUM

Mobile Real User Monitoring (Mobile RUM) allows you to understand your native iOS, Android, Xamarin, Cordova-based, or React Native mobile application as your end users actually use it.

It provides you with visibility into the functioning of the application itself and the application's interactions with the network it uses and any server-side applications it may talk to. This page introduces Mobile RUM.

Benefits of Mobile RUM

With Mobile RUM, you can:

- Understand and improve your mobile application's performance
  - Know when your application is slow because of networking problems. See Network Requests List.
  - Determine whether a request is slow because of your servers or because of the network connection. See Network Request Dashboard.
  - Trace an individual request from the initial user action in the mobile application through the associated business transaction(s) on the application server(s). See Network Request Snapshots.
  - Estimate the network performance you can expect for different requests, carriers, devices, and geographies by viewing current metrics. See **Usage Stats** in Mobile App Dashboard.
  - Detect slow UI issues known as "application not responding" (ANR). You can track ANRs in the Code Issues Dashboard, identify sessions where ANRs occurred, and configure ANR thresholds to define severity levels.
- Reduce crashes
  - Observe when your application crashes and what caused each crash. See Crash Analyze and Crash Snapshots.
  - Learn which environments experience the most crashes. See Crash Dashboard.
- Reduce errors
  - Observe how many network errors occur and which requests caused them. See Network Requests List and Network Request Dashboard.
  - Capture errors and exceptions from your mobile applications, so that they are displayed in the Code Issues Dashboard and the session records and details. To learn how to use the SDKs to report errors, see Report and Exceptions (iOS/Android).
- Learn about your users
  - Learn which devices and technologies most of your users are running. See **Usage Stats** in Mobile App Dashboard and Crash Dashboard.
  - View where your users are located in the world. See **Geo Dashboard** in Mobile App Dashboard.
  - Understand how users are navigating through your application and what actions they are taking. See Mobile Sessions.
  - Capture user interactions with your mobile application such as button clicks and when text is edited. See "Enable User Interaction Capture Mode" (iOS/Android) to learn how.
- Customize the data that Mobile RUM returns
  - Create new metrics and timers. See Customize the iOS Instrumentation, Customize the Android Instrumentation, Customize the Xamarin Instrumentation, and Customize the Cordova Instrumentation.
  - Collect diagnostic data from your executing code via information points. See Customize the iOS Instrumentation, Customize the Android Instrumentation, Customize the Xamarin Instrumentation, and Customize the Cordova Instrumentation.

How It Works

To use Mobile RUM, you add a small piece of highly performant code, the Mobile Agent, to the source of your mobile application. This process is called *instrumenting* and is described in Instrument iOS Applications, Instrument Android Applications, Instrument Xamarin Applications, Instrument Cordova Applications, and Instrument React Native Applications.

As your end users interact with your application, the agent collects metrics and any error information on the application's performance and sends that information to the EUM Server, where it is processed. The EUM Server then makes the data available to the AppDynamics controller UI, where it is displayed in a series of dashboards and charts.

If your application crashes, the agent also creates a *crash snapshot* with information to help you analyze what happened, including the crashed function, the source file containing the crashed function, the line number, if available, and a stack trace of the application at the time of the crash, along with various other identifying data. And if the server-side application with which your mobile app interacts is also instrumented, you can get correlated metric information for the entire round-trip request life cycle.

Data Collection

When the agent detects that something of interest has occurred in the application, it collects data describing that event and stores it in a local buffer. Typically, this data consists of approximately 200-400 bytes per event. The agent periodically flushes this local buffer by sending the events in the buffer to the EUM Server in a request called a beacon. To minimize power consumption, the agent schedules these flushes, if possible, when the application is using the network.

If a network connection to the EUM Server is not available, the agent deletes older events to prevent unbounded growth in the buffer. The maximum size of the buffer is 200 events.

If the EUM Server is unavailable for extended periods of time, the agent may delete older data to prevent unbounded growth in the buffer.

License and Enable Mobile RUM

- Mobile RUM requires a separate license from that of your application server. For information about licensing, see License Entitlements and Restrictions.
- For information on enabling or disabling Mobile RUM monitoring, see Enable Mobile RUM on Your Controller.

AppDynamics Mobile RUM allows you to investigate the performance of your mobile application. AppDynamics Mobile App allows you to monitor your Controller from your mobile device.

Set Up and Access Mobile RUM

You set up and configure Mobile RUM in two areas:

- Your AppDynamics Controller
- Your iOS, Android, Xamarin, or Cordova application

To prepare Mobile RUM you need to make changes in both these areas in a particular order.

You need to do the following:

1. Check your prerequisites
2. Review Controller capacity
3. Evaluate your mobile application
4. Complete the Getting Started Wizard
5. Instrument and verify your app
6. Configure network request naming and thresholds

Check Your Prerequisites

Before you can use AppDynamics to monitor your mobile application, you need to make sure you have the following prerequisites:

- An AppDynamics account, with access to an AppDynamics Controller
- A Mobile RUM License. See License Entitlements and Restrictions.
- Access to your mobile application source code

Review Your Controller Capacity

If you use an on-premises Controller and plan to monitor mobile applications, assess your Controller's capacity to accommodate the increase in the number of metrics that Mobile RUM will generate. The number of individual metric data points generated depends on the level of activity of your mobile applications. As a rough guide, the use of Mobile RUM can increase the number of metric data points by as much as 15 to 25K per instrumented application, if your applications are heavily accessed by mobile users. The actual number depends on how many network requests your applications receive.

> The number of separate RUM metric *names* saved in the Controller database can be larger than the kinds of individual data points saved. For example, a metric name for a metric for iOS 5 might still be in the database even if all your users have migrated away from iOS 5. So, the metric name would no longer have an impact on resource utilization, but it would count against the default limit in the Controller for metric names per application. The default limit for *names* is 200,000 for Browser RUM and 100,000 for Mobile RUM.

For more information about Controller sizing, see Hardware Requirements per Performance Profile.

Evaluate Your Mobile Application

By default, Mobile RUM can monitor your application in two ways: network requests and crash reporting.

If you want to collect information on network requests, your application must make HTTP calls using specific classes:

- An iOS application must use `NSURLConnection` or `NSURLSession` to generate network requests.
- An Android application must itself (i.e., not via an external framework) use `HttpURLConnection`, `HttpsURLConnection`, `HttpClient`, `OkHttp`, or `ch.boye.httpclientandroidlib` to generate network requests.
- Using the SDK, custom HTTP libraries can also be monitored and used by the agent itself. See Customize the iOS Instrumentation and Customize the Android Instrumentation for more information.

Even if your application does not generate network requests, or if you do not want to monitor that activity, you can use AppDynamics purely to monitor crashes. You can also extend the Mobile Agents using the SDK to collect other data, like how your application is functioning internally.

Complete the Getting Started Wizard

Use the **Getting Started Wizard** to create a mobile app group, get an EUM App Key, and guide you through the instrumentation process. Once you have successfully completed the steps in the wizard, Mobile RUM will automatically be enabled for the created mobile app group.

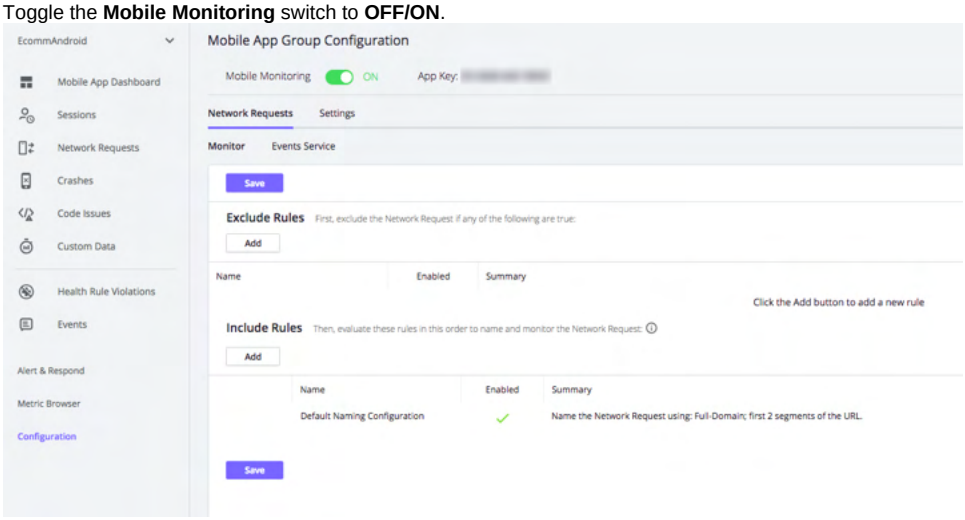
> Your Controller must have a Mobile RUM license before you can enable the Mobile RUM functionality.

Disable Mobile RUM

To later disable/enable Mobile RUM:

1. Open your mobile application.

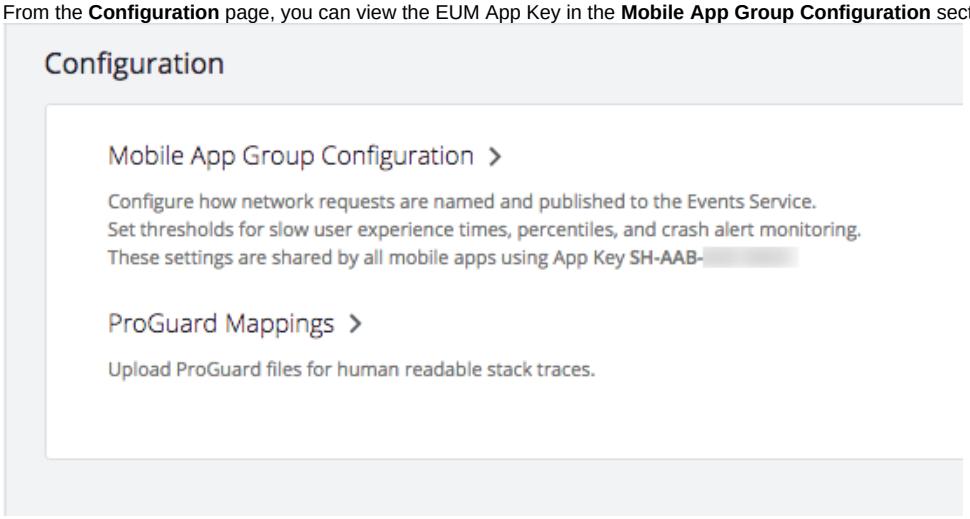
2. From the left-hand navigation bar, click **Configuration**.
3. Toggle the **Mobile Monitoring** switch to **OFF/ON**.



Get Your Application Key

To find your App Key after you've completed the **Getting Started Wizard**:

1. Open your mobile application.
2. From the left-hand navigation bar, click **Configuration**.
3. From the **Configuration** page, you can view the EUM App Key in the **Mobile App Group Configuration** section as shown below.



Instrument and Verify Your App

The method you follow to instrument your app depends on your platform:

- Instrument iOS Applications
- Instrument Android Applications
- Instrument Xamarin Applications
- Instrument Cordova Applications

Configure Network Request Naming and Thresholds

You can customize how you want the Controller to name your application's requests and what performance thresholds you want to be in effect. See Configure Mobile Network Request Naming and Thresholds.

External Access

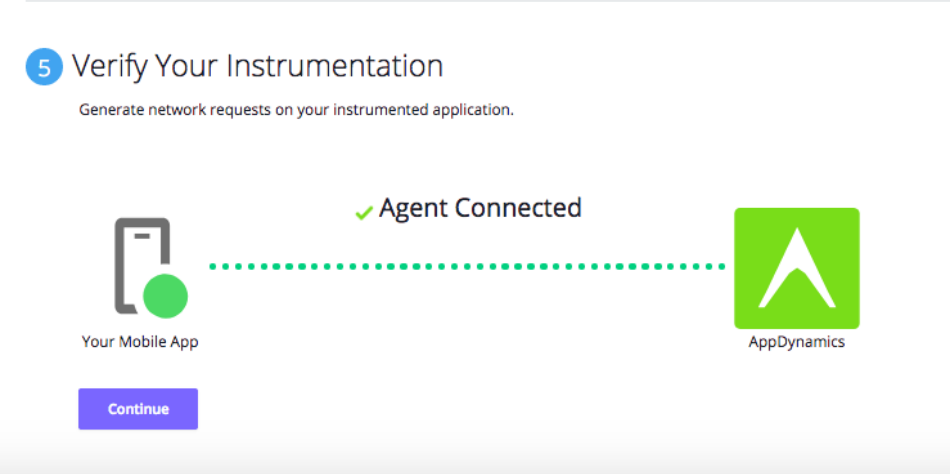
Mobile RUM is made up of several components, any or all of which can either be located on the Internet or hosted inside your own data center/network. On-premises access points are configured at installation or through the UI. If your installation requires access to any of these components on the Internet, see Access the SaaS EUM Server for more information.

Confirm the Mobile Agent Connected to the Controller

Related pages:

- Instrument iOS Applications
- Instrument Android Applications
- Instrument Xamarin Applications

After you have instrumented your application, the **Getting Started Wizard** will show you a verification that the Mobile Agent has connected to the Controller.



If you left the **Getting Started Wizard**, you can always verify the instrumentation by doing the following:

1. In the Controller UI, open **User Experience > Mobile Apps.**
2. Check the list of registered mobile applications to verify that the application is registered with the Controller. You can also use view some basic information about the app such as the health, sessions, crashes, network request information, and whether the monitoring is enabled.

3. Start monitoring your application! See Overview of the Controller UI for Mobile RUM.

Correlate Business Transactions for Mobile RUM

Related pages:

- Correlate Business Transactions for EUM
- Business Transactions

You can correlate mobile network requests with business transactions. In actuality, the correlation is made between instances of network requests (network request snapshots) and instances of business transactions (transaction snapshots).

Mobile Network Requests Correlation

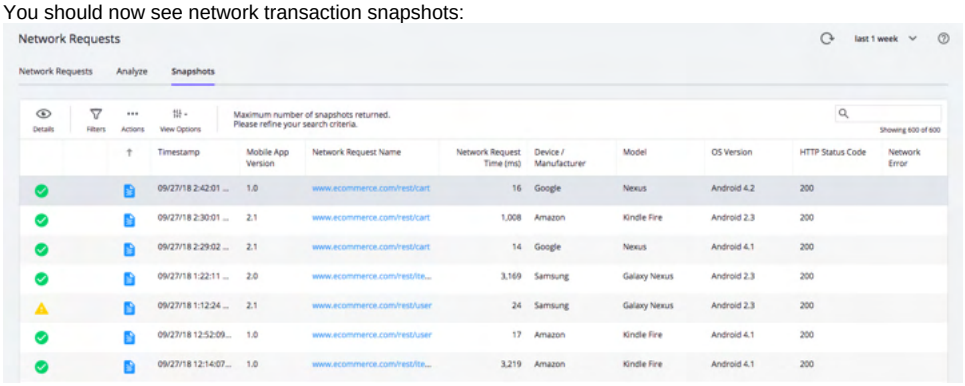
When an end user takes an action with your mobile application that requires a network request:

1. The App Agent:
    - Sends HTTP headers identifying the business transaction to the end user's mobile device.
    - Aggregates backend metrics and sends them along with the business transaction identifiers to the Controller. This serves as the content for the transaction snapshot.
2. The Mobile Agent sends metrics and the business transaction identifiers (from the HTTP header) to the EUM Server. This serves as the content for the network request snapshot.
3. The Controller fetches the metrics and business transaction identifiers from the EUM Server. Using the business transaction identifiers, the Controller correlates the network request snapshot with the transaction snapshots.

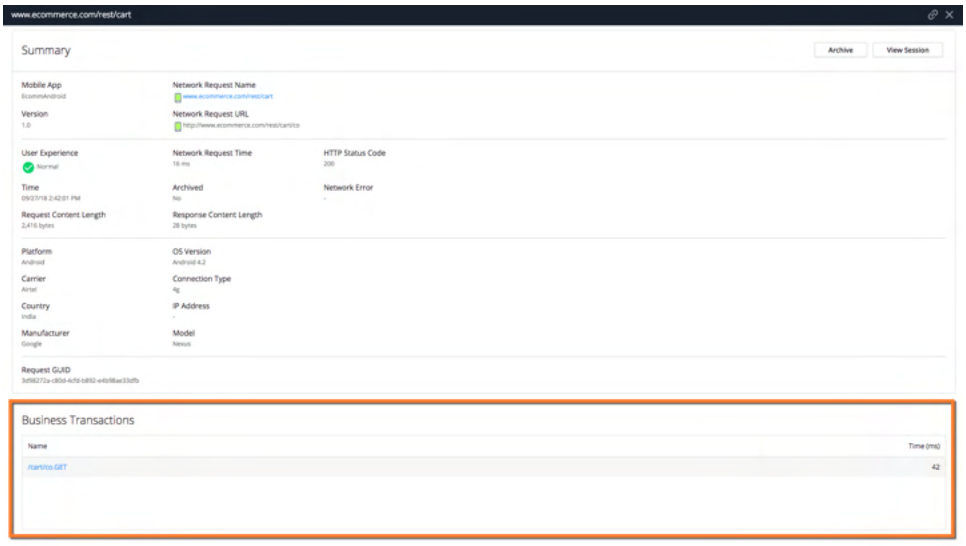
View Business Transactions Correlated with Mobile Applications

There are several ways to navigate from a mobile network request snapshot to its correlated business transaction. This procedure provides a sample navigation:

1. From the **Mobile App Dashboard**, click **Network Requests**.
2. Click **Snapshots.**
3. You should now see network transaction snapshots:



4. Double-click one of the browser snapshots to open the **Network Request Snapshot Details** dialog. If a correlated transaction snapshot exists, a link displays in the **Business Transactions** section:



5. You can then click links in the transaction snapshot or transaction snapshot itself to view corresponding pages in APM.

Monitor Your Applications with Mobile RUM

This page provides an overview of the Controller UI for Mobile RUM applications. Mobile RUM presents your application information in the following ways:

- Mobile App Dashboard: An overview dashboard, with tabs for
  - Widgets for visually displaying common metrics
  - Map-based performance display
  - Usage statistics
- Mobile Sessions: A detailed list of mobile sessions, following users as they interact with your application
- Network Requests Lists: A detailed list of network requests with dashboards
- Crashes: A dashboard displaying of application crash trends and detailed snapshots of individual crashes with stack traces
- Custom Data: A dashboard specific data you want the agent to collect for you

Access a Browser RUM Application

To see application data in the Controller UI:

1. In the top tab bar, select **User Experience**. The list of instrumented Browser and Mobile Apps displays.
2. Select the Mobile App tab.
3. Double-click a mobile application.

Mobile App Dashboard

The **Mobile App Dashboard** provides a high-level overview of how your application is performing, including the following:

- Widget-based overview
- Geo dashboard, displaying where your requests originate, including a variety of key performance metrics
- Set of aggregated usage statistics, by device, carrier, connection type, OS version, and app version

Access the Mobile App Dashboard View

1. Open the application you want.
2. From the left navigation bar of your application, select **Mobile App Dashboard**.
3. Click the tab for the view you want to access.

Overview Dashboard

The **Overview Dashboard** displays a set of configurable widgets, showing multiple graphs and lists featuring common high-level indicators of application performance. You can delete widgets, re-add them, resize them, and drag them to different locations.

Geo Dashboard

The Mobile App **Geo Dashboard** displays key performance metrics by geographic location.

The dashboard is divided into three panels:

- A main panel in the upper left that displays geographic distribution of mobile users on a map, if you clicked the map view icon, or on a grid, if you clicked the grid view icon.
- A panel on the right displaying key timings.
- A lower panel with dynamic trend graphs of KPIs.

The metrics displayed throughout the geo dashboard are for the country currently selected on the map or in the grid. For example, if you zoom down from the world view to France on the map, the panel on the right disappears and the trend graphs display data for France.

See Mobile RUM Metrics for definitions of the metrics.

Map View Labels

The map view displays load circles with labels for countries that are in the key timing metrics given in the right panel. Some countries and regions, however, are only displayed in the grid view.

Regions and Countries

Regions are subdivisions of a country, such as a state, province, or city. In the default map view, key performance metrics are displayed by country. The grid view, like the map view, by default displays key performance metrics by country, but can also be configured to show the metrics by region. Because the map view displays fewer regions than the grid view, if you do not see a region displayed in the map view, switch to the grid view.

See Browser RUM Countries and Regions by Geo Dashboard for a list of the countries and regions available in the map and grid views.

Unknown Locations in Map and Grid Views

An unknown location is one for which the agent cannot determine the country from which the request originated.

You may also see metrics reported for a location named **Anonymous Proxy**. The data for **Anonymous Proxy** represents the aggregated metrics from one or more private IP addresses that the agent cannot identify.

One of the effects of Unknown regions is that it possible for a country to display as slow (red circles) on the global map, but when you drill down to the country all its regions appear normal (green circles). Or a country may display as normal on the global map, but some sub-regions may display as slow when you drill down.

Usage Stats

This tab shows graphical and tabular breakdowns of usage by device, carrier, connection type, OS version, and app version. The breakdowns for the connection type are based on network requests. The other usage breakdowns are based on "app opens", *not* network requests. App opens are counted when a mobile application is booted or brought to the foreground. In the case of Android, the app opens occur when the method `onResume` is called for an activity. For iOS, the app opens occur when the method `applicationDidBecomeActive` is called.

The Android Agent obtains the carrier name by calling the Android SDK method `android.telephony.TelephonyManager.getSimOperatorName` and obtains the device name with the Android SDK property `android.os.Build.MANUFACTURER`. If the value for either the carrier or device name is "unknown", this indicates that the method `getSimOperatorName` or the property `MANUFACTURER` did not return a value.

Mobile Sessions

Related pages:

- EUM Data
- Mobile RUM Metrics

In most cases, a user's interaction with your app is not limited to one action in one panel view. Sessions allow you to track your users' interactions across time, as they navigate an entire session with your app.

By default, sessions begin when a user starts using your application and ends after a configurable period of user inactivity. You can also programmatically control sessions through the Mobile Agents SDKs (Android, iOS, Xamarin, Cordova). Using Mobile Sessions, you can analyze *sessionized* results from all requests, as stored in the AppDynamics Events Service.

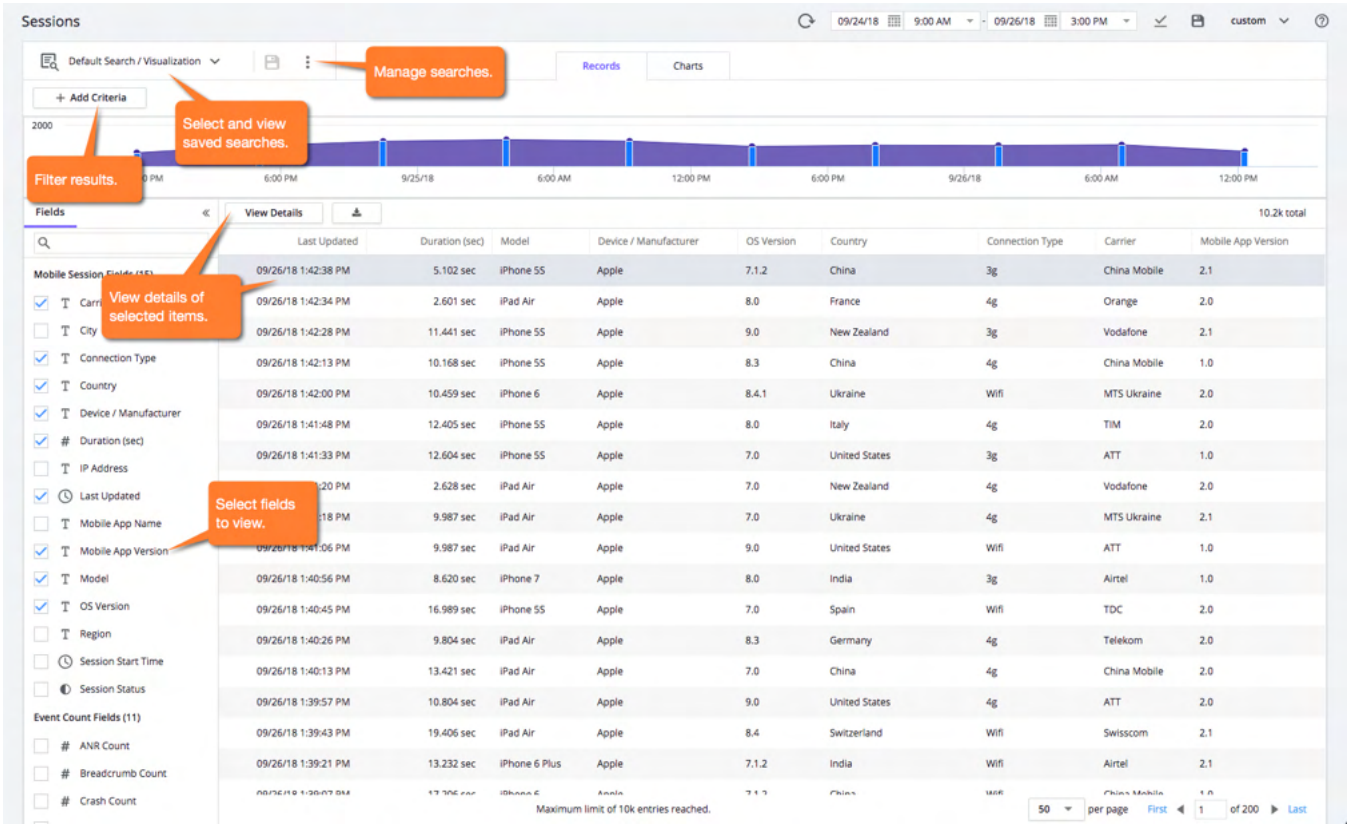
As in Network Request Analyze, the main Sessions panel is comprised of these tabs:

- Records
- Charts

You can also view detailed information about each session in the Session Details dialog.

Records

The Records tab lets you scan individual sessions and allows you to filter and sort to get exactly the data in which you are interested.

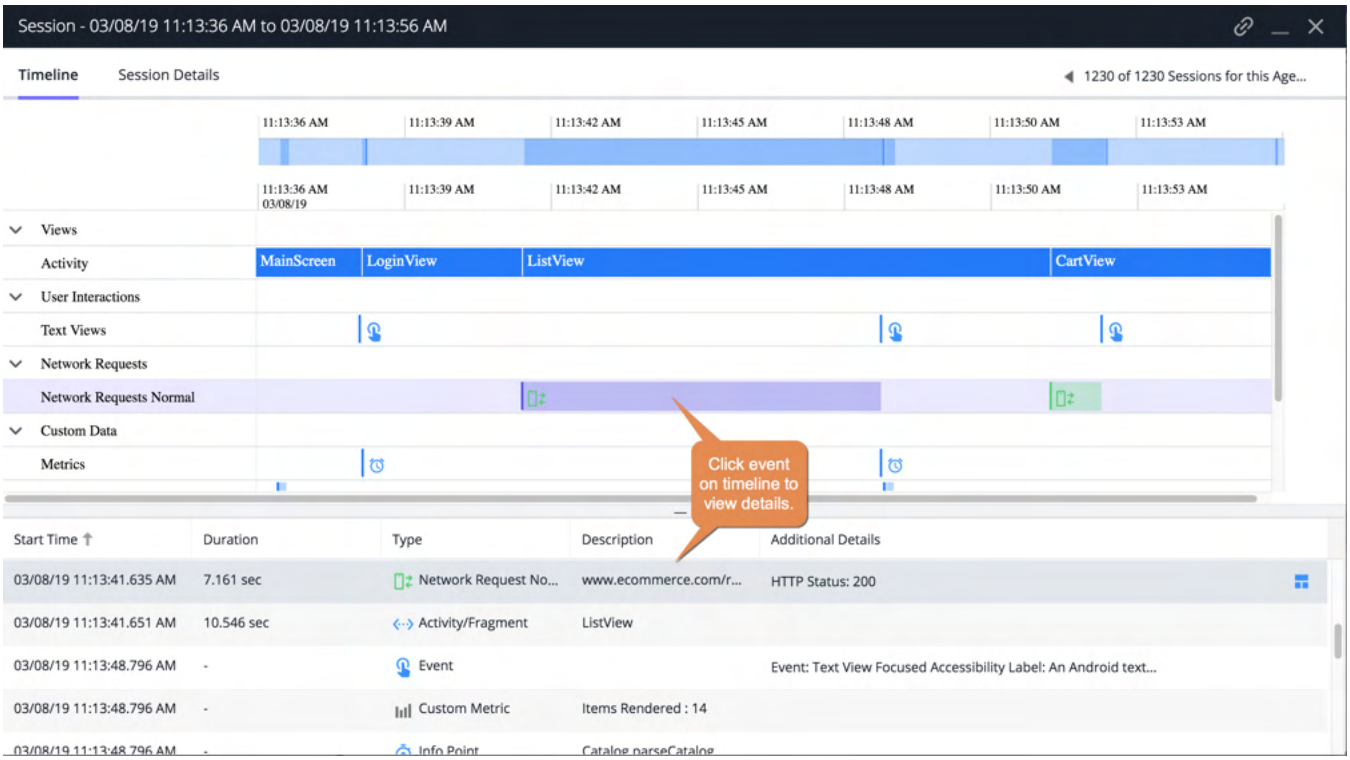


Session Details

Click **View Details** or double-click an item to see the information for a specific session.

Session Timeline

The sequence of session frames for the session is shown on the session timeline and on the bottom of the panel. Select a specific frame by clicking on an icon on the timeline to see details highlighted at the bottom of the panel. You can also select a frame row at the bottom to see it highlighted on the timeline.



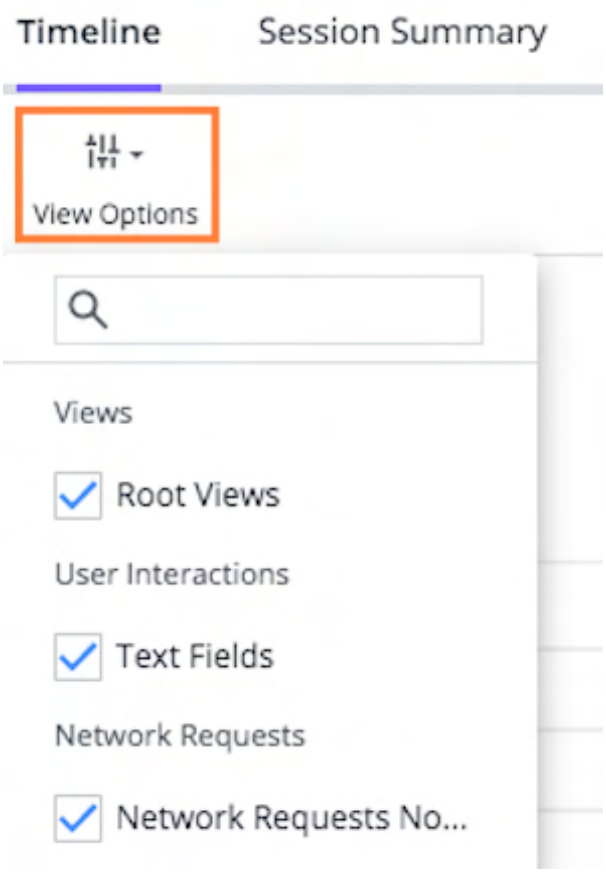
Session Details Categories and Types

Categories	Subcategories	Type	About
Views	Activity	Activity /Fragment	The current Activity in the foreground of an Android app. If the current Activity is not sufficient to understand what the user is doing, consider using the Session Frame APIs.
	RootViews	RootView	The current RootView in the foreground of the iOS App. If the current RootView is not sufficient to understand what the user is doing, consider using the Session Frame APIs.
	Session Frames	Session Frame	A manual API to label large user activities that are not captured out of the box by Activity or RootView tracking.
Screenshots	-	Screenshot	If you have configured mobile screenshots, they will appear in the timeline. They capture user events, and they can also be collected when in automatic mode.
User Interactions	Touches	Event	If you have enabled the Mobile Agent to capture UI events, you can view the UI events triggered by user interactions in the **Timeline**. See "Enable User Interaction Capture Mode" (iOS/Android) to learn how to capture UI events. If automatic screenshots are enabled, touches will be captured and include the screenshot that was captured at the same time. The touches are drawn on the screenshot.
	Buttons		
	Table Cells		
	Text Views		
	Text Fields		
Network Requests	Network Requests Normal	Network Request Normal	Network requests include the requested URL, duration, and status details of the HTTP request. To jump to more Network Requests details, click .
	Network Requests Slow	Network Requests Slow	
	Network Requests Very Slow	Network Requests Very Slow	
	Network Requests Stall	Network Requests Stall	

Errors And Warnings	Application Not Responding Issues (ANRs)	 ANR	You can view when the application was non-responsive in the timeline. ANRs are reported when the UI thread does not respond to an event for two seconds or more. To download or view the ANR Summary, click  or  , respectively.
	Crashes	 Crash	When an app crashes the subsequent activity will appear in the timeline. To download or view the Crash Summary, click  or  , respectively.
	Errors	 Error	If you have reported errors with the Mobile Agent SDKs, the errors will also appear in the timeline. See "Report Errors and Exceptions" (iOS/Android) to learn how to instrument your mobile apps to report errors and exceptions. To download or view the Error Summary, click  or  , respectively.
Custom Data	Metrics	 Custom Metric	Custom metrics display integer-based data on any metric you define in your application.
	Timers	 Custom Timer	Custom timers display how long something takes between any arbitrary start point and end point, even if they span multiple methods.
	Info Points	 Info Point	Information points display information on how a specific method in your code is performing.
	Breadcrumbs	 Breadcrumb	Breadcrumbs are short messages to mark interesting events in a session, controlled by the Breadcrumb APIs in the agent.
System Events	Connection Transition	 System Event	Connection transition indicates when a broadband transition has taken place, such as from Wifi to cellular.
	Agent Init	 System Event	Agent Init indicates when the Mobile Agent was first initialized. It can help with debugging the application lifecycle.

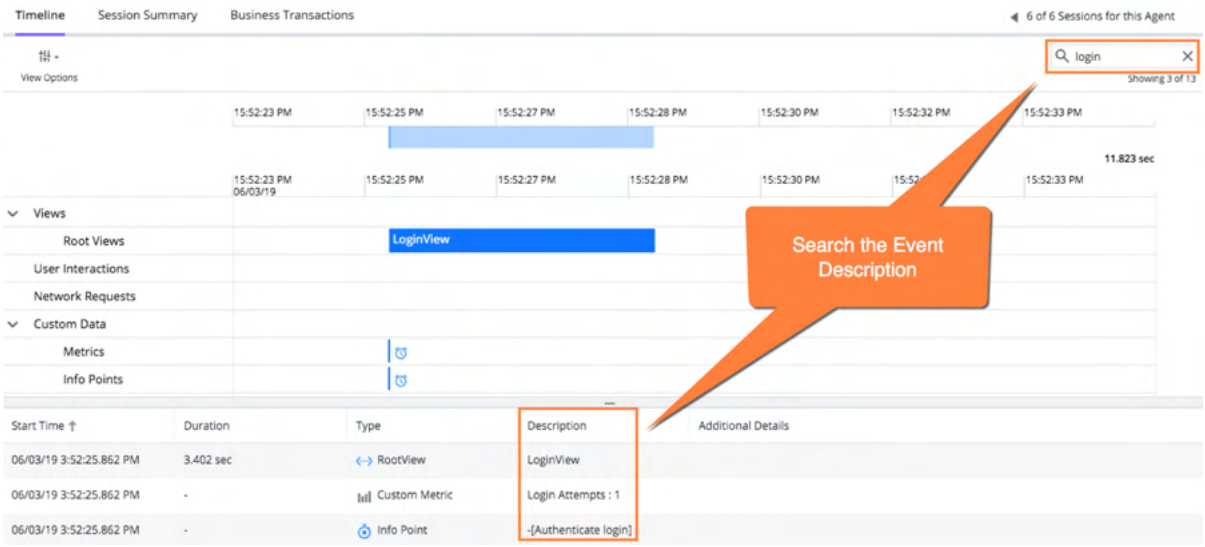
View Options

You can filter the categories in your timeline view by clicking **View Options**. Check all relevant categories for your search. All view options are checked by default.



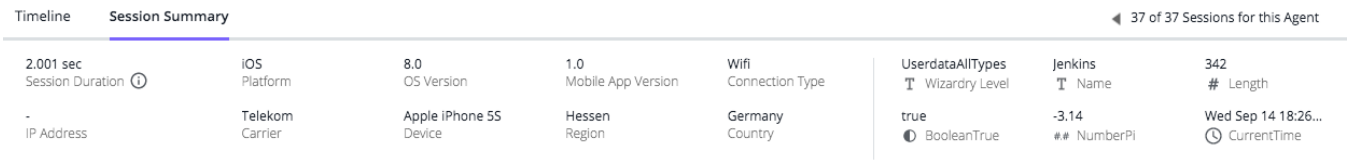
Search Events

You can search for a specific event **Description** using the search box located in the top right of the session timeline panel.



Session Summary

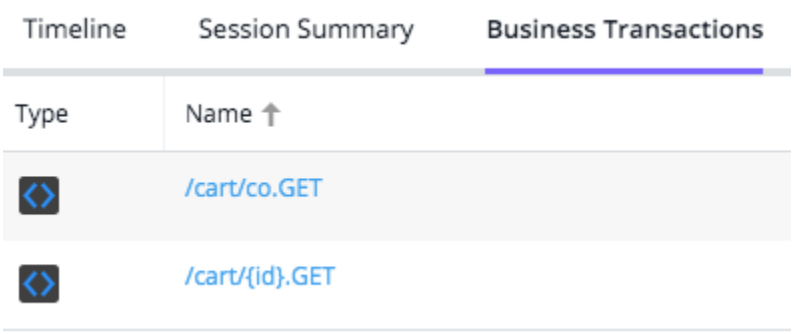
You can see a summary of the session by clicking **Session Summary**.



Business Transactions

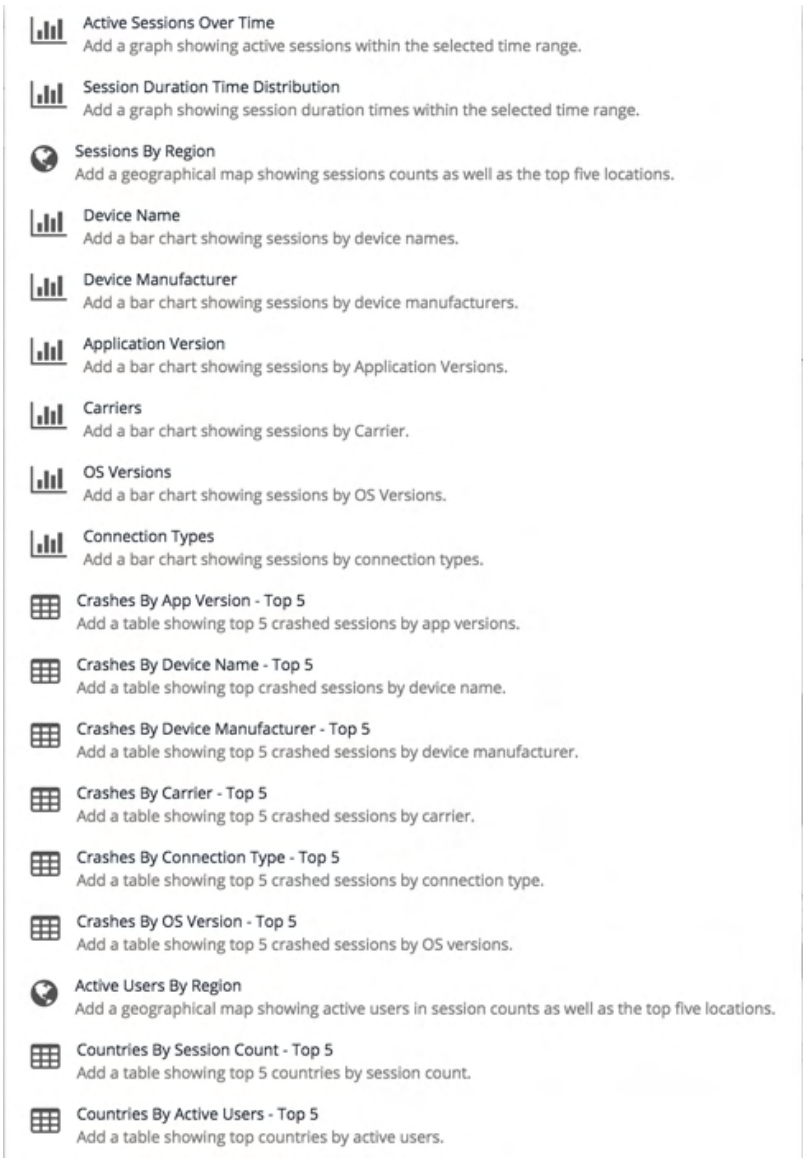
You can see a list of business transactions in the session if applicable. This tab only appears if you have business transactions in the selected session.

Click the business transaction name to redirect to the transaction flow map.



Charts

The **Charts** page provides you with a set of predefined widgets that offer visualizations of the data set you have created. As with the **Charts** pages of the other Analyze/Session features of the UI, you can delete, re-add, resize, and drag-and-drop to move all of the widgets.



Active Sessions Over Time
Add a graph showing active sessions within the selected time range.
Session Duration Time Distribution
Add a graph showing session duration times within the selected time range.
Sessions By Region
Add a geographical map showing sessions counts as well as the top five locations.
Device Name
Add a bar chart showing sessions by device names.
Device Manufacturer
Add a bar chart showing sessions by device manufacturers.
Application Version
Add a bar chart showing sessions by Application Versions.
Carriers
Add a bar chart showing sessions by Carrier.
OS Versions
Add a bar chart showing sessions by OS Versions.
Connection Types
Add a bar chart showing sessions by connection types.
Crashes By App Version - Top 5
Add a table showing top 5 crashed sessions by app versions.
Crashes By Device Name - Top 5
Add a table showing top crashed sessions by device name.
Crashes By Device Manufacturer - Top 5
Add a table showing top 5 crashed sessions by device manufacturer.
Crashes By Carrier - Top 5
Add a table showing top 5 crashed sessions by carrier.
Crashes By Connection Type - Top 5
Add a table showing top 5 crashed sessions by connection type.
Crashes By OS Version - Top 5
Add a table showing top 5 crashed sessions by OS versions.
Active Users By Region
Add a geographical map showing active users in session counts as well as the top five locations.
Countries By Session Count - Top 5
Add a table showing top 5 countries by session count.
Countries By Active Users - Top 5
Add a table showing top countries by active users.

Mobile Screenshots

Mobile screenshots provide context to the data collected in the Controller UI. They also allow you to better understand the user experience.

Screenshots enable you to:

- **Verify Presentation:** Determine if an app is displaying correctly on different devices.
- **Understand User Behavior**: Determine where users are clicking on the screen.
- **Troubleshoot Bugs:** Analyze bugs and errors by correlating code issues with screenshots. You'll be able to see what the user is doing when issues happen.

AppDynamics Version Requirements

You must use these AppDynamics software versions:

- Controller >= 4.3.2
- iOS/Android Agents >= 4.3.2
- AppDynamics Cordova Plugin >= 1

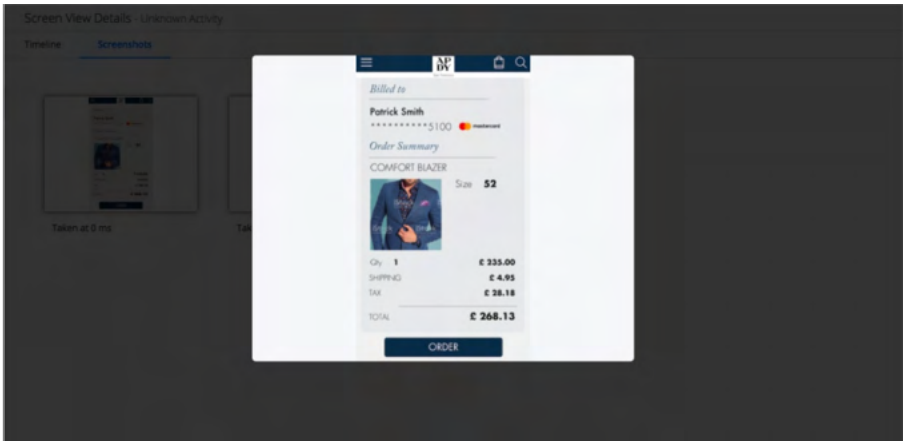
Screenshot Limitations

Mobile screenshots have the following limitations:

- Only iOS/Android/Cordova platforms are supported.
- You can enable or disable screenshots or explicitly exclude screenshots for specific screens/activities.
- You cannot set a minimum/maximum number of screenshots per session.
- Touch points are not collected unless screenshots are in automatic mode.
- The touch points will not be included in screenshots from past sessions.
- The UI Event feature is not related to screenshots or touch points in any way. Thus, the screenshot will not be directly correlated with a UI event in the **Waterfall.**

Types of Screenshots

Mobile RUM captures conventional screenshots and touch-point screenshots that capture user touch events. Both types of screenshots have timestamps, but the latter will also plot "user touches" on the panel.

Conventional Screenshots	Touch Point Screenshots
	


The conventional screenshot will simply show what your users viewing. These screenshots can be taken programmatically or by enabling automatic screenshots in the Controller UI.	The touch point screenshot shows where users tou points are only collected when automatic capture r

When Screenshots Are Taken

Screenshots can only be captured if the Mobile Agent and the Controller UI have enabled screenshots.

Once screenshots have been enabled, screenshots will be only taken if one or more of the following are true:

- The Mobile Agent uses the SDK API to manually take a screenshot.
- You have enabled automatic capture in the Controller UI.

Configure Mobile Screenshots

You have several methods for controlling when screenshots are taken. This page lists the settings for disabling/enabling and taking screenshots.

Screenshot Control Settings

This table lists the different settings for screenshots, the user tasks required for the settings, and a description of what the settings accomplish. Screenshots are enabled by default in the iOS and Android Agents, but disabled in the Controller UI. To use screenshots, you need to enable screenshots in the Controller UI.

Screenshot Setting	User Tasks	Result
Disable Screenshots From Being Taken	Perform one of the following: • Disable screenshots with the iOS /Android SDK. • Disable screenshots in the Controller UI.	**Only Disable Screenshots with the iOS/Android SDK** Screenshots are globally disabled. The Controller UI cannot override the Mobile Agent setting. **Only Disable Screenshots with the Controller UI** The Controller will disable screenshot capture in the Mobile Agent. Because the Controller setting is propagated to the Mobile Agents through the EUM Server, the Mobile Agent may take screenshots before its screenshot setting has been updated. Once the Controller setting has been applied, however, the Mobile Agent will no longer take screenshots.
Enable Screenshots	• Enable screenshots in the Controller UI.	The Mobile Agent can take screenshots, and the Controller UI will display them in the session results.
Enable Screenshots - Manual Screenshots (Wi-Fi)	• Enable screenshots in the Controller UI. • Manually take screenshots using the iOS /Android SDKs.	You call the Mobile SDK to take screenshots. The screenshots are only uploaded to the Controller when the device is using Wi-Fi.
Enable Screenshots - Automatic Screenshots (Wi-Fi)	• Enable screenshots in the Controller UI. • Configure the Controller UI to automatically take screenshots.	Screenshots are automatically taken periodically. The screenshots are only transmitted when the device is using Wi-Fi.

Enable Screenshots - Manual Screenshots (Wi-Fi / Cellular Data)	• Enable screenshots in the Controller UI. • Configure the Controller UI to allow the use of cellular data. • Manually take screenshots using the iOS /Android SDKs.	You call the Mobile SDK to take screenshots.
Enable Screenshots - Automatic Screenshots (Wi-Fi / Cellular Data)	• Enable screenshots in the Controller UI. • Configure the Controller UI to automatically take screenshots. • Configure the Controller UI to allow the use of cellular data.	Screenshots are automatically taken periodically.

Take Mobile Screenshots

Related pages:

- Customize the iOS Instrumentation
- Customize the Android Instrumentation

This page describes how to enable/disable screenshots and take manual/automatic screenshots.

Enable/Disable Screenshots

The following sections show you how to enable or disable screenshots. If you want screenshots taken automatically, see Enable Automatic Screenshots.

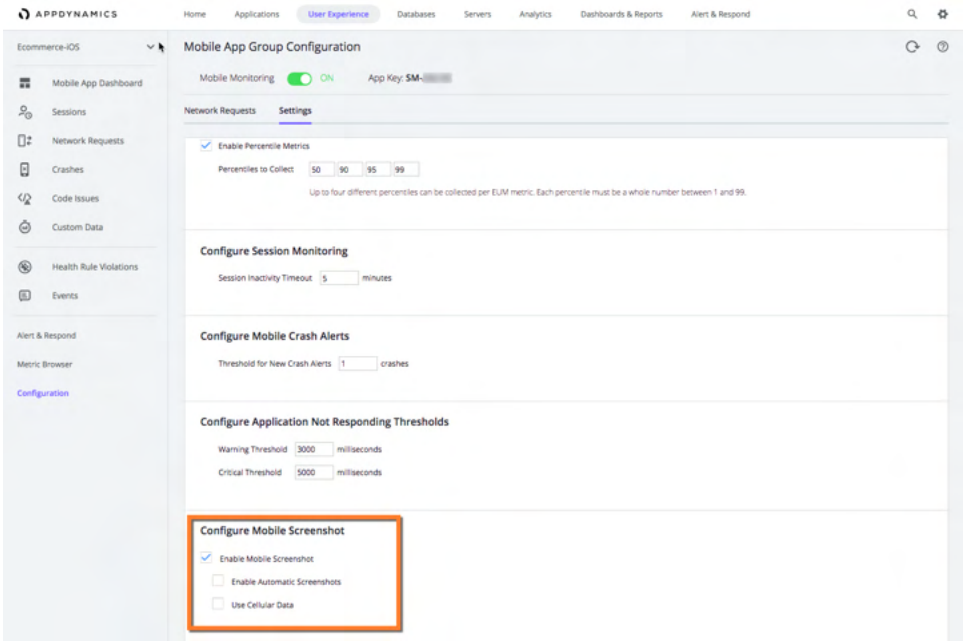
> Mobile screenshots are disabled by default for security and privacy reasons as screenshots may contain sensitive information.

Use the Mobile SDKs to Disable/Enable Screenshots

Mobile screenshots are enabled by default in the iOS and Android Agents. To disable screenshots, see the iOS SDK and Android SDK documentation.

Configure the Controller UI

1. Navigate to one of your mobile apps in the Controller UI.
2. Open the **Configuration** page.
3. Click **Mobile App Group Configuration.**
4. Scroll down to **Configure Mobile Screenshot** and check the **Enable Mobile Screenshot** check box.



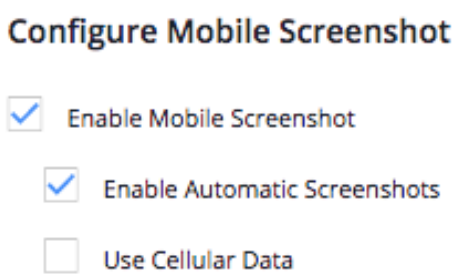
5. (Optional) If you want to allow the application to take screenshots when using cellular data, check the **User Cellular Data** check box.

Enable Automatic Screenshots

Configure the Controller UI to Automatically Take Screenshots

1. Navigate to one of your mobile apps in the Controller UI.
2. Open the **Configuration** page.
3. Click **Mobile App Group Configuration.**
4. Scroll down to **Configure Mobile Screenshot** and confirm that the **Enable Mobile Screenshot** checkbox is checked.

5. Check the **Enable Automatic Screenshots** check box.



6. (Optional) If you want to allow the application to take screenshots when using cellular data, check the **User Cellular Data** check box.

Programmatically Take Screenshots

You can use the Android or iOS SDK to programmatically take screenshots. See:

- Android SDK: Configure and Take Screenshots
- iOS SDK: Configure and Take Screenshots

View Mobile Screenshots

Mobile screenshots are included in the **Session Details**. You can view a timeline of the screenshots and touchpoints that were taken during the user's activity.

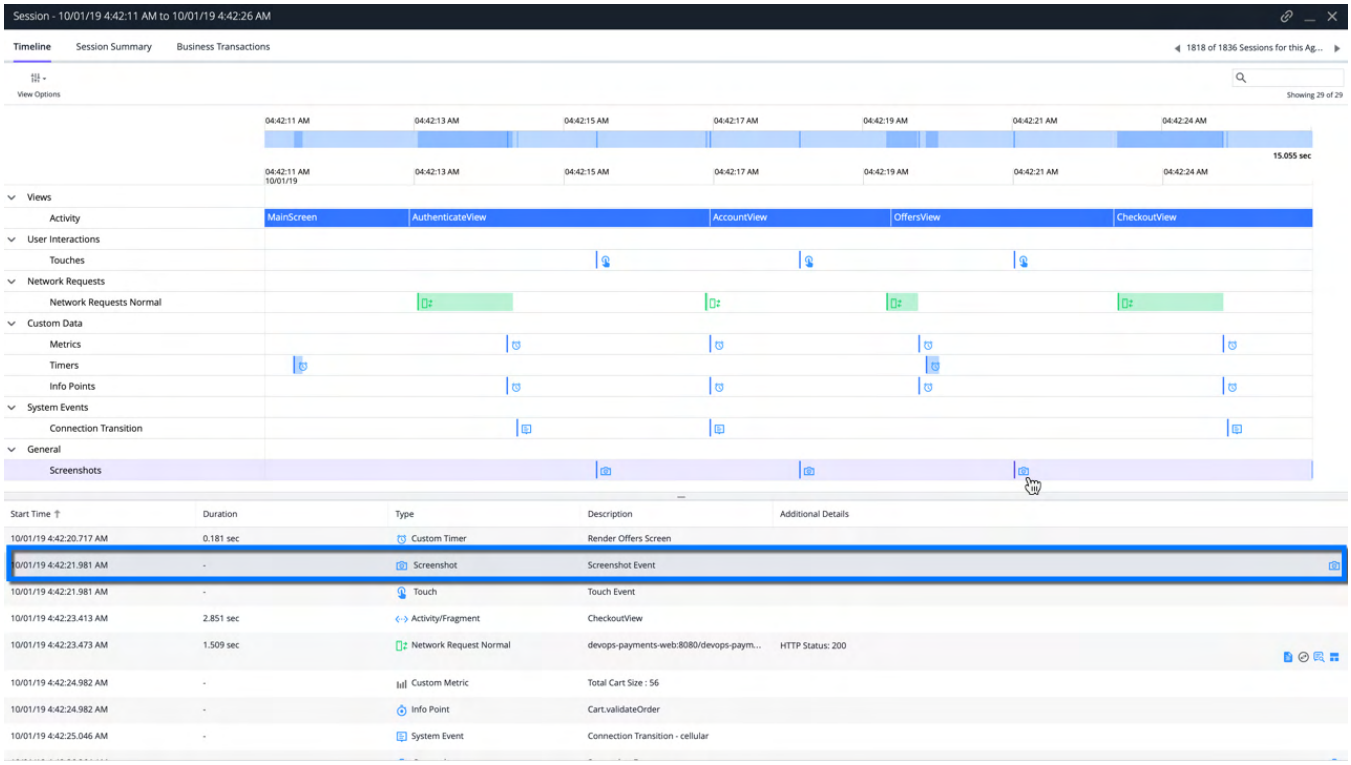
This page describes how to view screenshot and touch events in the timeline of the Timeline tab, and view thumbnails and full-size images of the screenshots and touches in the chronological event list.

Screenshot Events in the Timeline

Both conventional and touch-point screenshot events appear in the Timeline tab at the time that it was taken.

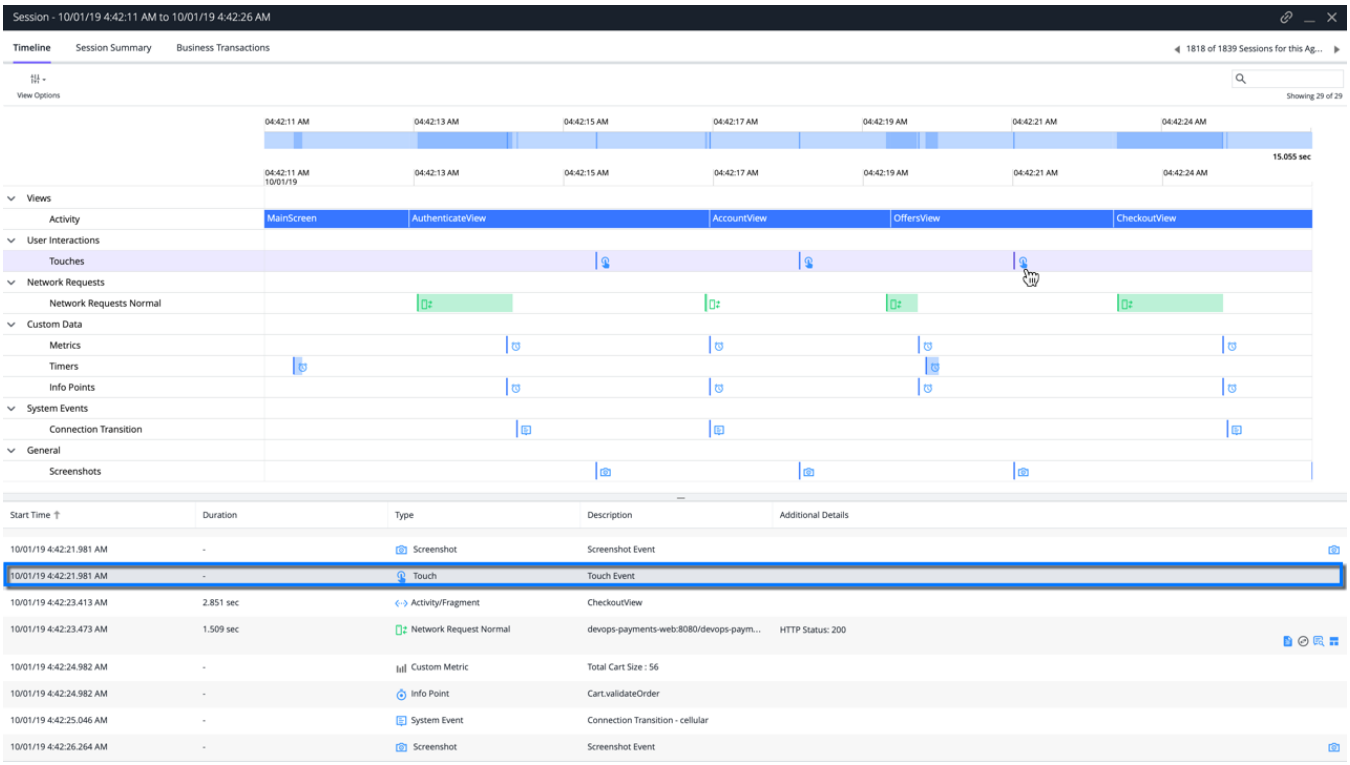
Conventional Screenshots

Conventional screenshots appear in **General > Screenshots**. Click the **camera** icon to view details of the screenshot event in the chronological event list at the bottom.



Screenshots of Touches

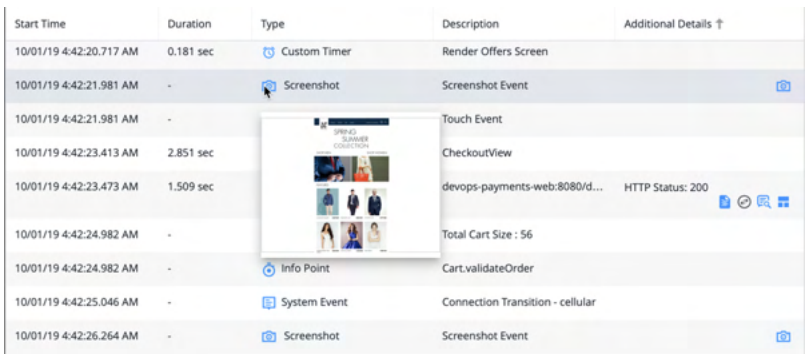
Screenshots of touches appear in **User Interactions > Touches**. Click the **screen touch** icon to view details of the touch event in the chronological event list at the bottom.



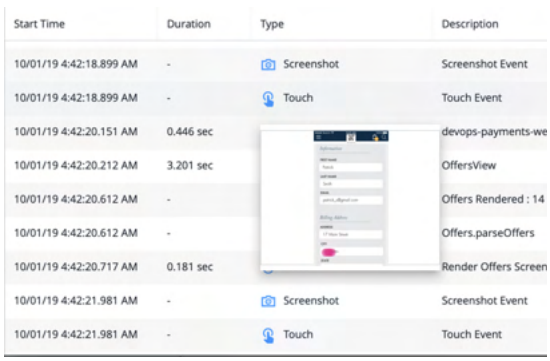
Screenshot Thumbnails

From the chronological list of events at the bottom of the page, you can hover over a screenshot or touch event to view a thumbnail. The screenshot of the touches displays the touch locations in pink.

Conventional Screenshot Thumbnail



Screenshot Thumbnail of Touches



Full-Size Screenshots

To view full-size images of the conventional screenshots, click the **camera** icon on the right of the event details in the chronological list. Full-sized images are not available for screenshots of touches.

Mobile Health Rules

Related pages:

- Policies
- Troubleshoot Health Rule Violations

You can set mobile health rules to trigger actions when certain conditions are met or exceeded based on configured thresholds for mobile application metrics.

To configure alerts and responses, you can use the **Getting Started Wizard** or manually create alerting policies based on mobile health rules. Alerts and responses help you to anticipate and take action for problems with your mobile applications.

This page describes the two types of mobile health rules, how to select mobile health rule types, create new mobile health rules, and how to view the health results of your mobile applications.

Mobile Health Rule Types

When you select the health rule scope for mobile applications, you are given a set of health rules based on the two health rule types: **Mobile Apps** and **Network Requests**. You can create new health rules using the mobile health rule types or use a custom health rule type.

Mobile Apps Health Rule Type

The **Mobile Apps** health rule type can be used to add conditions based on a wide range of mobile application metrics such as application starts, crashes, or network requests for the application. The network request metrics for the **Mobile Apps** health rule type refer to all the network requests of the application. For example, when you configure a threshold for the metric **Slow Network Requests**, the **Mobile App** type health rule will evaluate all the network requests of the mobile application in determining which network requests are slow.

Network Requests Health Rule Type

The **Network Requests** health rule can only be used to add conditions based on network-related metrics such as HTTP errors, network errors, network request time, and network requests per minute. The network request metrics for the **Network Requests** health rule type refers to specific network requests. For example, when you configure a threshold for the metric **Slow Network Requests**, the **Network Requests** type health rule will evaluate one network requests, such as calls to http://google.com in determining which network requests are slow.

Custom Health Rule Type

The **Custom** health rule type allows you to use any metric. This enables you to set health rules that have metrics from different health rule types. For example, you could have a custom health rule that is based on configured thresholds for mobile metrics and business transaction metrics.

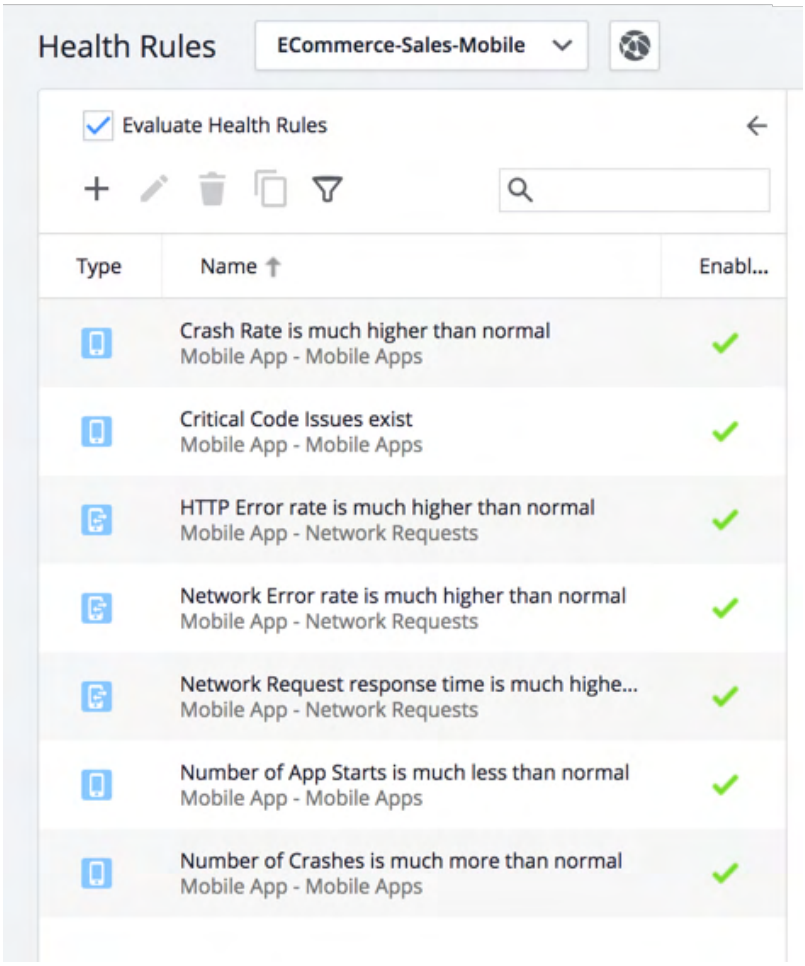
Create Health Rules

The process and user flow for creating health rules for mobile applications are similar to creating health rules for other applications. Thus, if you haven't created policies or health rules before, see Configure Policies and Configure Health Rules for general instructions. The sections below are not going to cover creating policies, but instead focus strictly on the important differences when creating health rules for mobile applications.

The first example will show you how to use the default set of mobile health rules, modify one of the default mobile health rules, and finally, how to create a new health rule using one of the mobile health rule types.

Using Default Health Rules

When you use the health rule scope for mobile applications, you are given a set of default health rules based on mobile health rule types. To enable these default health rules, click **Alert & Respond > Health Rules** to see the list of default health rules for mobile applications. You can use these default health rule types for your mobile applications by checking the **Evaluate Health Rules** checkbox:



Modify Default Health Rules

The default health rules for mobile applications are based on mobile health rule types and have default conditions based on preset values for mobile metrics. You may want to retain the default health rules, but want to customize the conditions for your mobile application. To do this, click the default health rule you want to modify and navigate to either the **Critical Warning** or **Warning Condition** panel. You can then change the parameters of the existing conditions or add new conditions.

Select Mobile Applications for the Health Rules

You can choose whether to apply the health rules for mobile applications. Depending on the mobile health rule type, you have different criteria to choose when to apply the health rules.

For health rules based on the health rule type **Network Requests**, you can apply the health rules for:

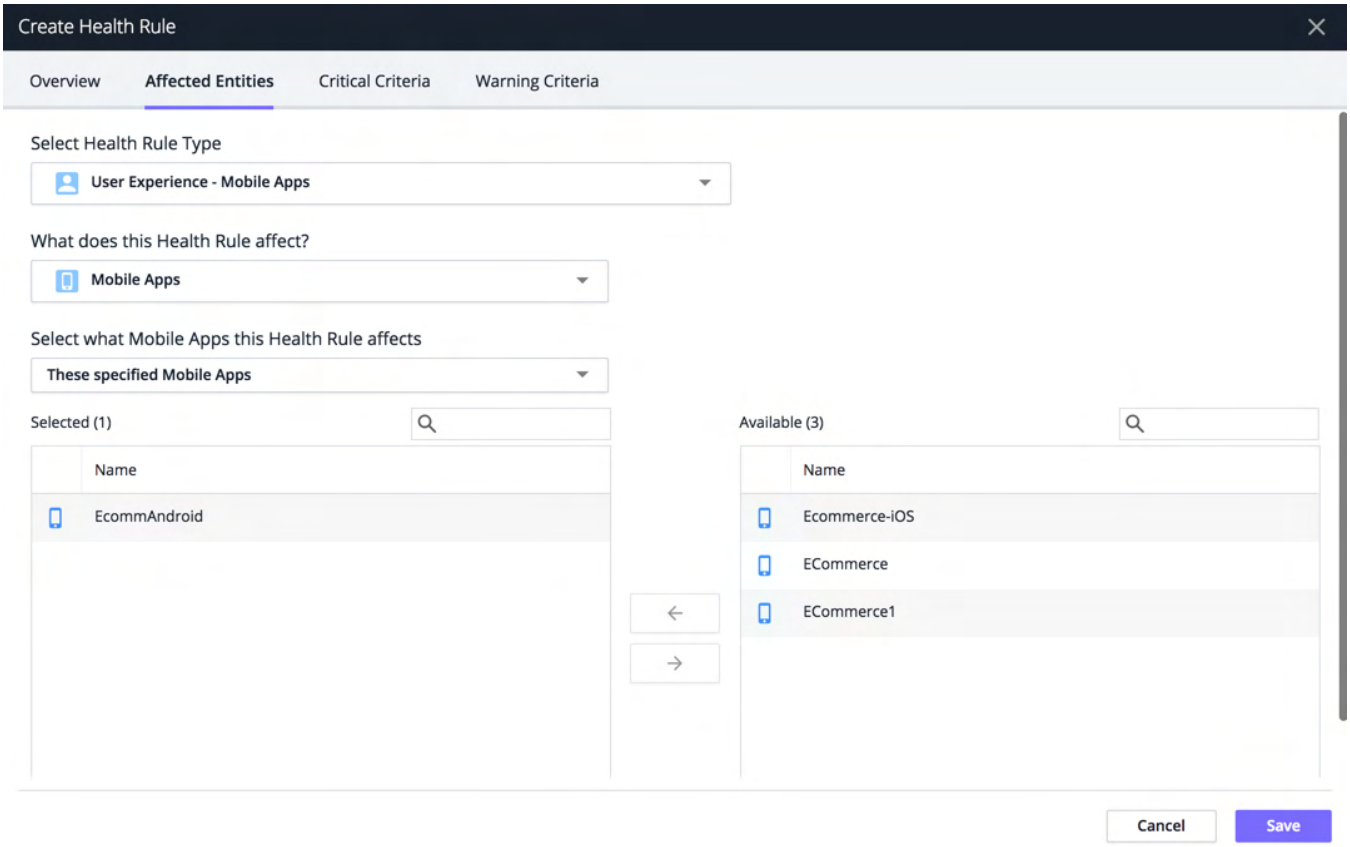
- All network requests in the mobile app group
- Specified network requests
- Network requests matching criteria
- Network requests for specific mobile applications

For health rules based on the health rule type **Mobile Apps**, you can apply the health rules for:

- All mobile applications in a mobile app group
- Specified mobile applications
- Mobile applications matching criteria

Create New Health Rules

You may want to create additional health rules based on one of the mobile health rules or a custom health rule. You do this in the same way you would create any health rule, except from the **Create Health Rule** dialog, you would select either the mobile health rule type **Mobile Apps** or **Network Requests**:



You can choose to apply the new health rule to mobile applications that you select, or those that match given criteria.

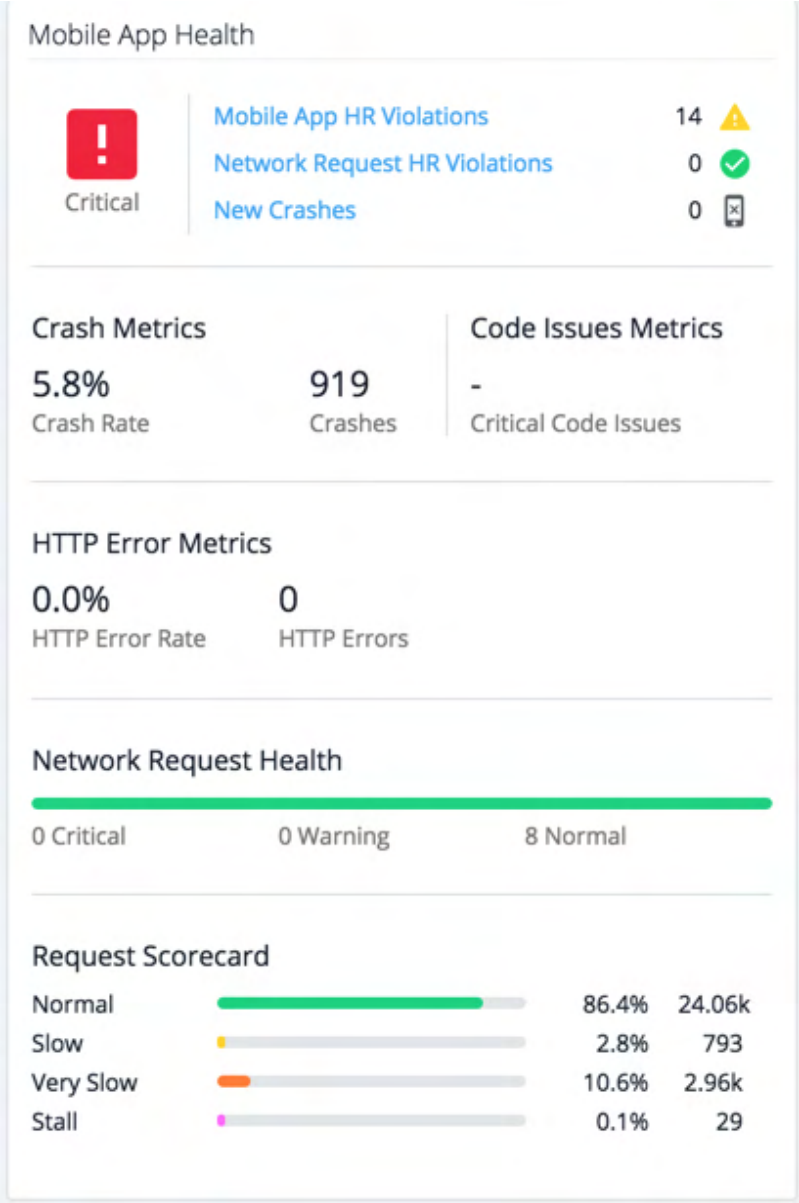
From the **Critical Criteria** and/or **Warning Criteria** panels, you can add conditions and define parameters with mobile metrics.

View Health Results

In addition to getting alerts when mobile applications are unhealthy, you can also view the health of your mobile application from certain widgets the **Mobile App Dashboard** and in the Events and Health Rule Violations tabs.

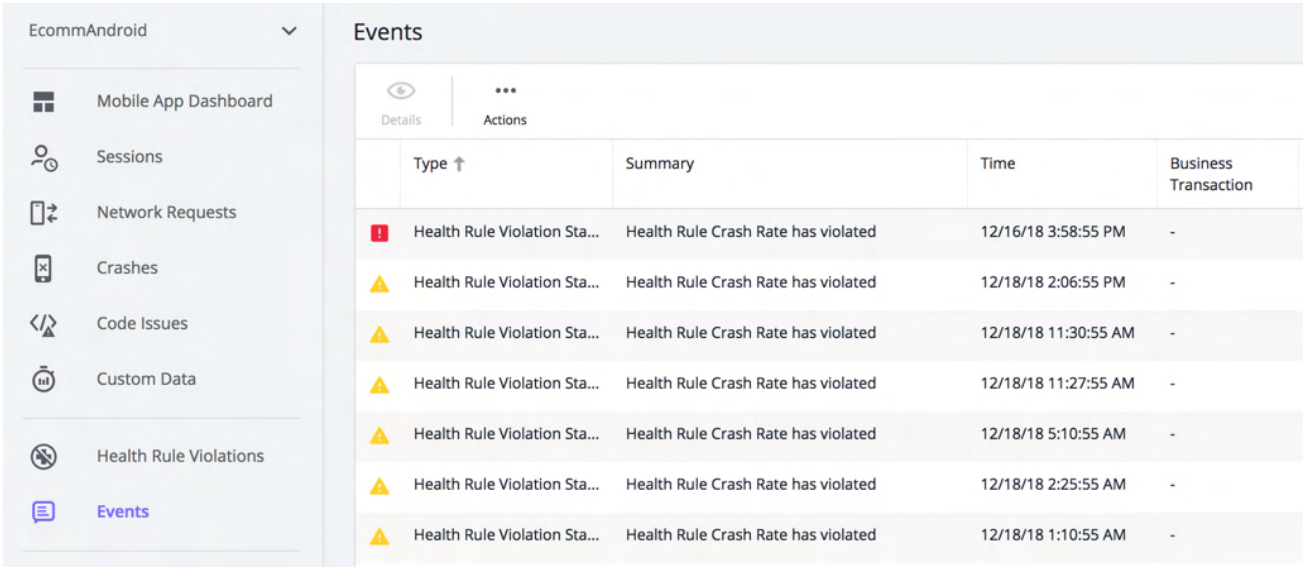
Overview Widgets

From the **Mobile Dashboard**, you should see the **Mobile App Health** widget. The widget displays health rule violations, crash metrics, and the network request health.



Events

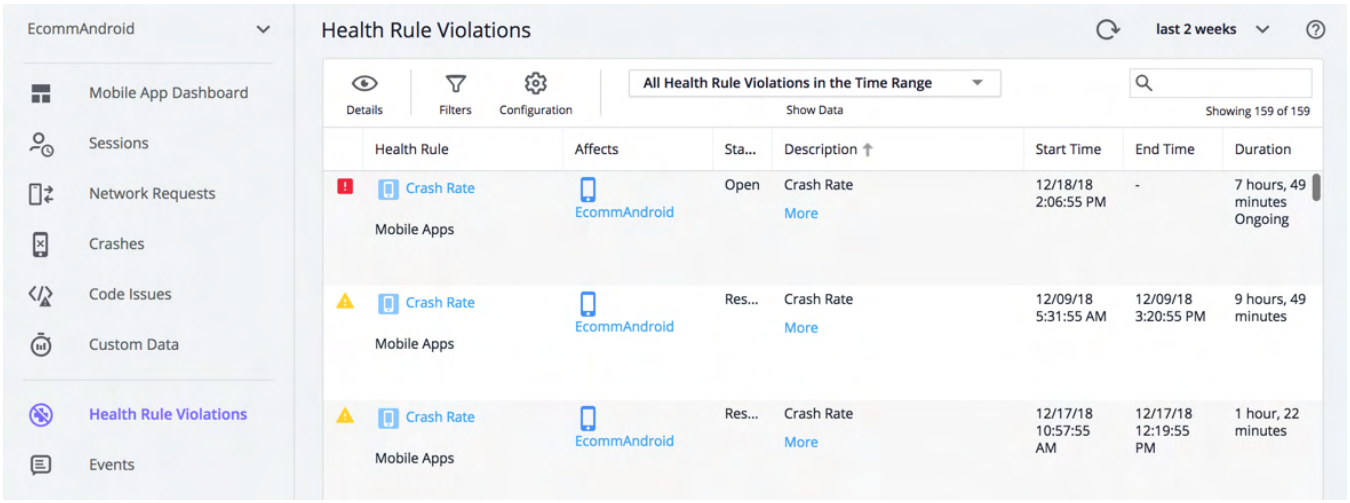
The Events tab displays the health rule violations for your mobile application. See Monitor Events.



You can sort the health rule violations for your mobile application by event types, health rules, or custom events you created.

Health Rule Violations

The Health Rule Violations tab lists the health rule violations that have happened over the specified time or that are still open.



Double-clicking one of the health rule violations in the list opens the **Health Rule Violation Details** dialog showing the type of health rule violation, the timeline, the events, and a description of the violation.

Network Requests

A network request is an HTTP request from your mobile app to a server-side application.

The iOS Agent detects network requests when the underlying implementation is handled by the `NSURLConnection` or `NSURLSession` classes.
The Android Agent detects network requests when the underlying implementation is handled by the `HttpURLConnection`, `HttpsURLConnection`, `HttpClient`, `OkHttp`, or `ch.boye.httpclientandroidlib` classes.

You can use the agent SDK to set up other HTTP classes.

View Network Requests

There are different ways of viewing network request data in the **Network Requests View**:

- The Network Requests list displays current network request types to your applications. You can sort the list according to key metrics such as the slowest response time, highest error rate, highest load, etc. You can view a network request dashboard that summarizes aggregate performance for a specific network request type.
- Network Request Analyze allows you to sort and filter a store of *all* the network request data your agents have collected and to see visualizations based on that data.
- A Network Request Snapshot reports information on an individual instance of a network request. Snapshots are useful for examining the details of the worst-performing requests. Access these snapshots from the network request snapshots list.

Network request data is also displayed in the Mobile App Dashboard.

- The Overview tab has the following widgets showing information about network requests:
  - **Network Request Scorecard:** Displays the number and percentage of normal, slow, very slow, and stalled network requests. Clicking on the widget opens the Network Requests list.
  - **Network Request Health:** Displays the number of network requests evaluated as normal, critical, or warning based on default or configured health rules. Clicking on the widget opens the Network Requests list.
  - **Network Request Time By Country:** Displays a heat map of the world based on the number of network requests. Clicking on the widget opens the geographic view.
  - **Requests Per Minute:** Displays a bar graph showing the number of requests per minute over the specified time period. Clicking on the widget opens the geographic view.
  - **Network Requests Time Distribution:** Displays a bar graph showing the number of requests made at different network request times. In addition, the graph gives the percentage rank of the number of network requests in its frequency distribution of network request time. For example, the **95th percentile (5,419 ms)** indicates that 95% of the network requests had a network request time of 5,419 ms or less. Clicking on the widget opens the Charts tab of Network Request Analyze.
  - **Network Request Time Trend:** Displays a line graph showing the average network response time over a specified time period. Clicking on the widget opens the geographic view.
  - **HTTP Errors:** Displays the number and rate of HTTP errors. Clicking on the widget opens the Network Requests list.
  - **HTTP and Network Errors Trend:** Displays a line graph comparing the number of HTTP and network errors over a specified time period. Clicking on the widget opens the geographic view.
- The geographic view reports aggregated mobile data by geographic location. Monitor the geographic view to learn which countries have the highest number of requests, the longest request times, and the most errors.
- Usage stats display key network request metrics by various criteria: device, carrier, operating system version, connection type, and application. For example, you can see which carriers are the slowest or which devices are producing the most errors.

The Controller processes a maximum of 2000 network requests per mobile app group and 500 network requests per mobile application. See Network Request Limits for suggestions on how to configure network request detection to stay under this limit.

Access the Network Requests View

1. Open the application you want.
2. In the left navigation bar, select **Network Requests**.
3. Click the tab for the view you want to access.

Network Requests List

Related pages:

- Network Request Dashboard
- Network Request Limits

The **Network Requests** list shows all the network requests types from your instrumented mobile application, along with their key performance indicators.

Network Requests List Organization

The **Network Requests** list is a table that displays aggregated metrics for current requests, with one row for each request type. The columns display the name of the network request and the aggregated metrics associated with it. See Mobile RUM Metrics for descriptions of these metrics.

Click a column header to sort the list based on the column's metric. For example, if you want to sort by the slowest requests, click the **Network Request Time (ms)** column header. You can toggle the column to switch between ascending and descending order. Use **View Options** to configure the table. Check **With Load** if you want to show only network request types that have experienced active load, that is, those for which there were one or more measured network requests over the selected time period.

To view a network request dashboard:

1. Select the network request type in the list.
2. Click **Details** or double-click the network request.

More Actions Menu

Use the **More Actions** menu to select one or more requests in the list and perform these actions:

- **Exclude Request(s)**: Use this option to direct AppDynamics to ignore the selected request(s) and stop reporting metrics for them. You can use the **View Excluded Requests** option to see requests that have been excluded and then you can "un-exclude" them.
- **Rename Request**: Use this option to rename one selected request in the AppDynamics console.
- **Delete Request(s)**: Use this option to remove the request(s) from the list. If AppDynamics discovers a deleted request again it will reappear in the list. To prevent it from re-appearing, use **Exclude Request(s)**.

Network Request Dashboard

Related pages:

- Network Requests
- Network Requests List
- Network Request Analyze
- Mobile RUM Metrics

Each network request type has its own dashboard that graphically displays key performance indicators for that type over the selected time range. To select the time range, use the general time range dropdown at the top right of the UI.

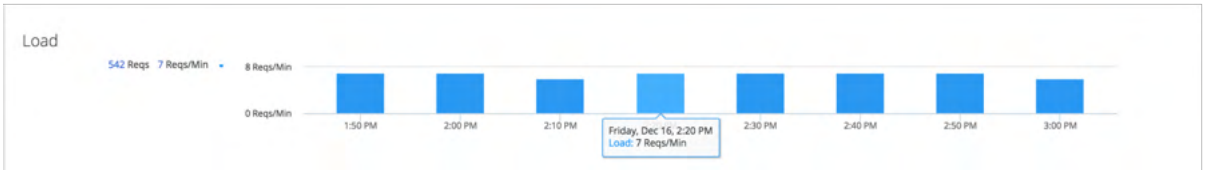
Network Request Dashboard Organization

The **Network Request Dashboard** displays summary key network request metrics for the time selected. To see any particular metric in the metric browser, click the metric value (in link blue).

The trend graphs for the key performance indicators are:

- **Network Request Time**: Average times in milliseconds.
- **Total Server Time:** Displayed only If the mobile request is correlated with a server-side application.
  The total server time is the interval between the time that the server-side application receives the network request to the time that it finishes processing the request. Use this graph to determine, on average, how much time is spent on the network versus how much time is spent on the server to process the user's request.
- **Load**: Total Requests and Requests per Minute.
- **Errors**: Network Errors and HTTP Errors in total and per minute.
- **Related Business Transactions**: If the request is correlated with a server-side application, the dashboard lists business transactions associated with the request below the performance metrics.
  You can click the link to a related business transaction to see its business transaction dashboard.
  If transaction snapshots were taken at the same time as the network request, the dashboard lists the transaction snapshots below the business transactions. See Transaction Snapshots.

You can hover over any data point on any of the trend graphs to see the metric for a precise point:

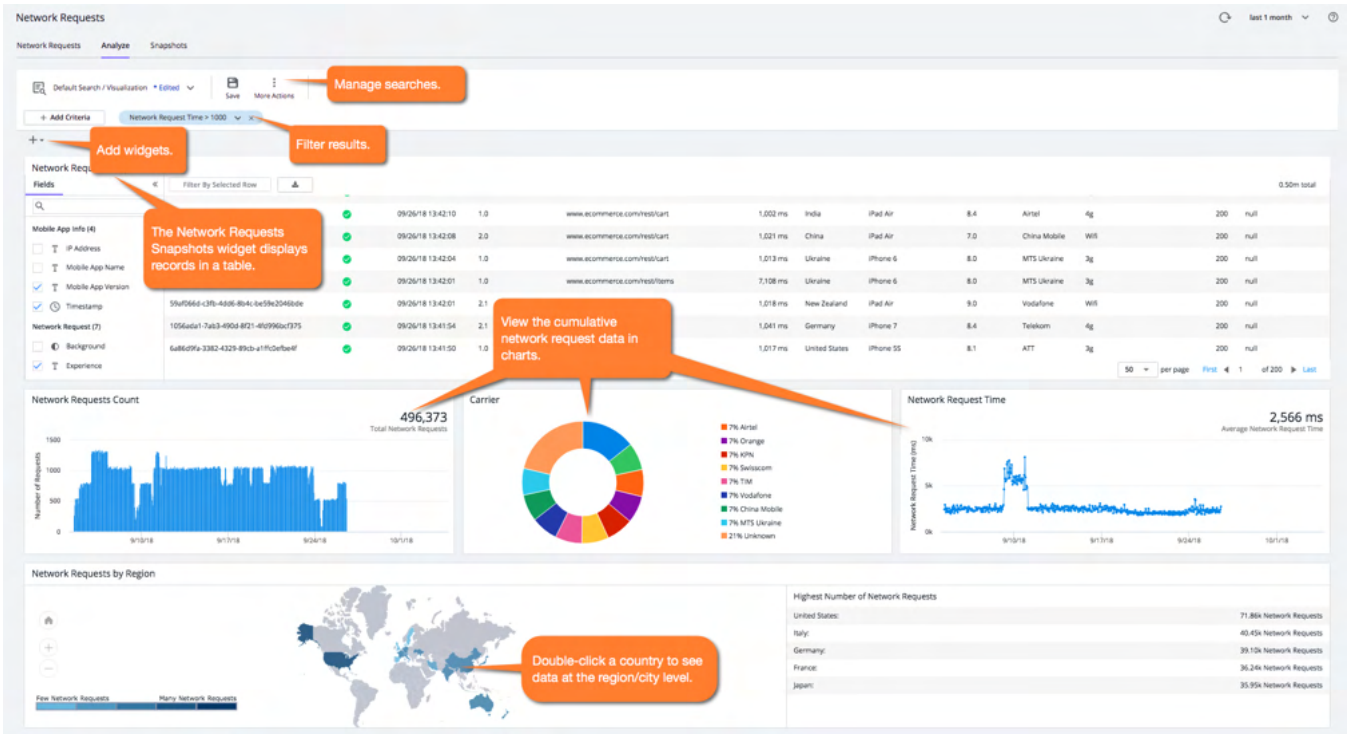


Network Request Analyze

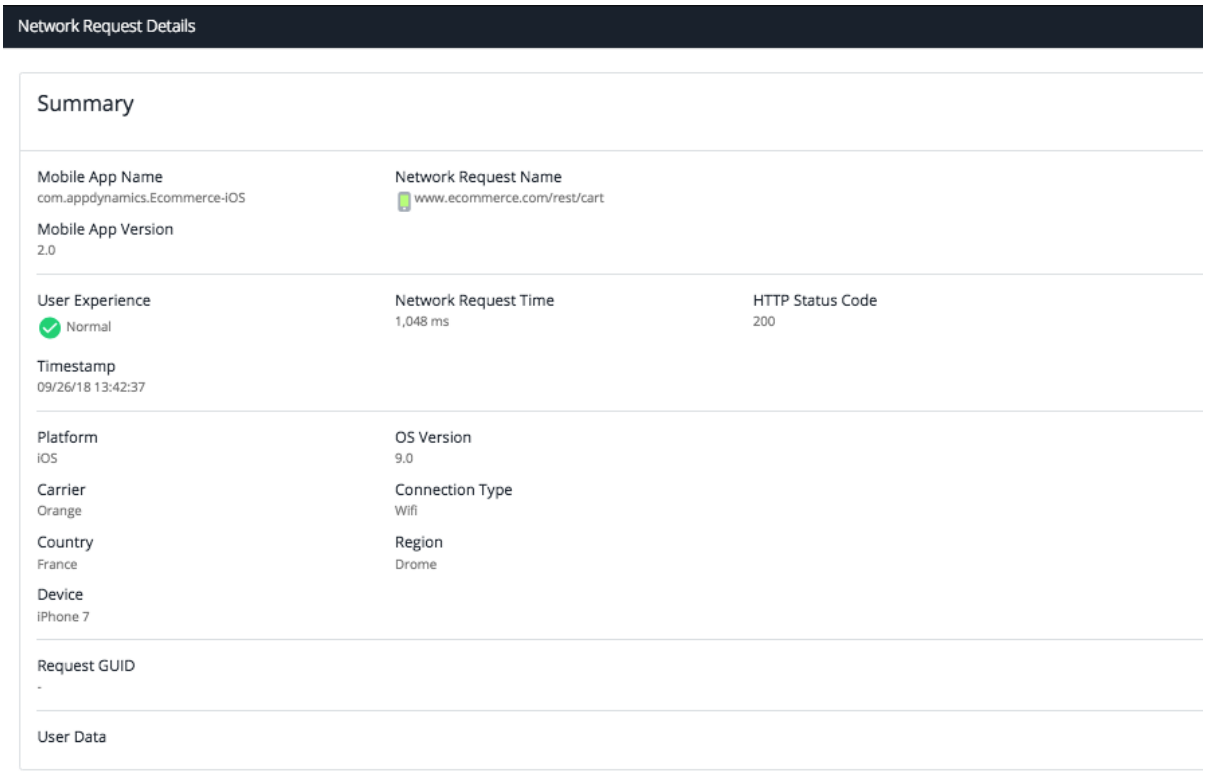
Mobile RUM collects data on every network request that you have instrumented, and it also takes detailed snapshots periodically in case performance issues have been detected.

Based on network request performance data, Mobile RUM calculates metrics which are associated with each network request and with predefined aggregations across network requests. You can focus on certain aspects of the performance data using more specific or flexible criteria, such as all network requests from a specific country *and* originating from a specific carrier.

With **Analyze**, every single network request event is collected and stored by the AppDynamics Events Service. Using **Analyze**, you can see results based on this cumulative data in tabular form or as charts.



Double-click a network request snapshot in the **Network Request Snapshots** widget to see the information for a specific request.



Mobile RUM Network Request Analyze Versus Mobile Requests Analytics

The data shown in the **Analyze** page is processed and stored by the AppDynamics Platform Events Service. **Network Request Analyze** provides a number of widely used visualization types to let you explore your application's performance. A separate product, AppDynamics Mobile Analytics, has components called Mobile Requests and Mobile Crash Reports. These components are based on the same Events Service and use the same data, but offer additional capabilities, including:

- Additional predefined widgets, such as the funnel widget
- ADQL for searching the data
- Creating custom widgets
- Manipulating multiple dashboard types
- Longer retention time for storing data

AppDynamics Mobile Requests Analytics requires a license separate from the Mobile RUM license. See Analytics Mobile Requests Data.

Network Request Snapshots List

A network request snapshot captures the details of one instance of a network request. Examine these details to troubleshoot the causes of slow network request performance. See Network Request Snapshots.

You access the list using the Network Request Snapshots tab. The network request snapshots list is a table that displays a row for each network request snapshot. The columns describe the properties of each snapshot.

To view a network request snapshot:

1. Select the network request snapshot in the list.
2. Click **Details** or double-click the request.

Network Request Snapshots

Related pages:

- Network Request Snapshots List
- Transaction Snapshots

Network request snapshots capture detailed information about individual network request instances by your application. They can help you troubleshoot the causes of poorly performing mobile applications.

When Network Request Snapshots are Captured

Mobile RUM starts capturing snapshots when user experience becomes slow, based on how you have configured the thresholds for slow, very slow, and stalled. See Configure Mobile Network Request Thresholds.

Periodic snapshots of normal user experience are also captured at least once per minute.

Network Request Snapshot Content

A network request snapshot contains summary data about the individual request as well as any business transactions associated with the request if correlation with an instrumented server-side application is available.

The snapshot contains extensive metrics for the request in the Summary data, including:

- **User Experience**: Normal, Slow, Very Slow, or Stalled.
- **Time**: When the request was received by the EUM Cloud or EUM Server collector, in UNIX epoch time.
- **Mobile Network Request**: Link to the network request dashboard for the network request of which this snapshot is an instance. See Network Request Dashboard.

Business Transactions in Network Request Snapshots

When a network request snapshot is associated with one or more business transactions on an instrumented server-side application, the business transactions are listed in the **Business Transactions** panel in the network request snapshot. You can click the link to see the business transaction dashboard for the associated business transaction.

If transaction snapshots for an associated business transaction were captured at the same time as the network request snapshot, they are linked in the **Transaction Snapshots** panel of the network request snapshot. If a call graph icon is displayed for a snapshot in the transaction snapshot list, a full or partial call graph is available for that transaction snapshot. This allows you to examine the cause of performance problems on the server side. Click the link to see the associated transaction snapshot.

Transaction snapshots are triggered on the server when slow or stalled business transactions are identified when a diagnostic session is started or periodically based on a configured interval. In general, slow, very slow, and stalled transactions are more likely to trigger a transaction snapshot on the server than transactions operating within the normal range. For more information about when server-side transaction snapshots are captured, see Transaction Snapshots.

Access Network Request Snapshots from Transaction Snapshots

If a transaction snapshot seen from the server side also has generated a correlated network request snapshot, a mobile snapshot link appears in the top right of the transaction snapshot flow map. Click the link to open the network request snapshot.

Archive Network Request Snapshots

Normally network request snapshots are purged after two weeks. You can archive a snapshot beyond the normal snapshot lifespan to retain it for future analysis.

To archive a snapshot, click the **Archive** button in the upper right corner of the snapshot panel.

You can view archived snapshots by checking **Archived** as a view option in the network request snapshots list.

Customers with on-premises Controllers can modify the default two-week period by configuring the `event.retention.period` property in the **Controller Settings** section of the Administration console.

Crashes

Related pages:

- Crash Analyze
- Crash Snapshots
- Crash Snapshot Properties

Use crashes to get trend and detailed information on mobile application crashes.

A crash snapshot is a detailed report on a particular crash including the code that was executing when the application crashed. Crash snapshots help you understand the causes of crashes.

View Crash Information in Widgets

The **Crash Metrics** and **Events** widgets are on the **Mobile App Dashboard**. The **Crash Metrics** widget displays the crash rate and the number of crashes for your mobile application. The **Events** widget displays new crash events.

1. Open the application you want.
2. From the **Mobile App Dashboard**, both **Events** and **Crash Metrics Scorecard** widgets display.
3. Click **Crash Metrics** or click one of the new crash events in the **Events** widget to access the **Crash Dashboard**.

Access the Crash Dashboard

The Crash Dashboard is where you can view both summary and detailed information about crashes.

1. Open the application you want.
2. On the left navigation bar of your application, select **Crashes**.

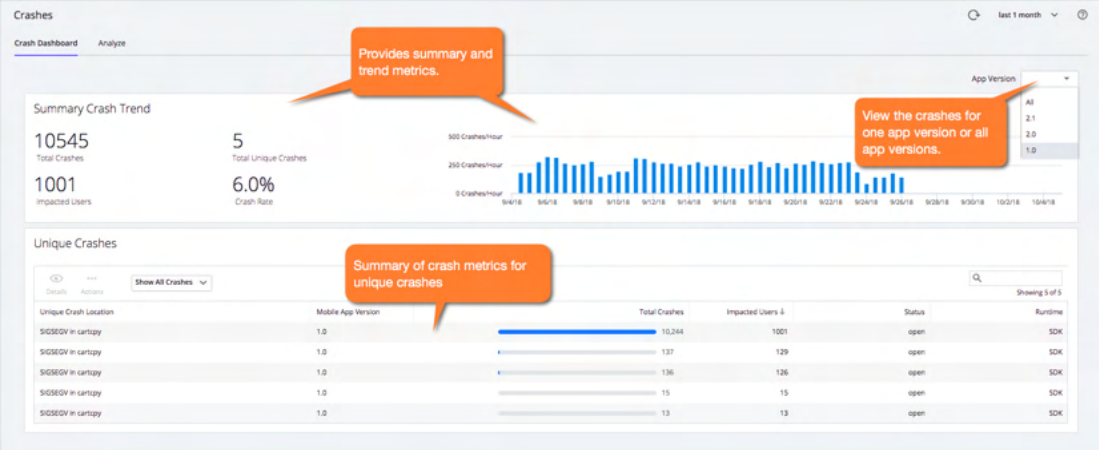
Crash Dashboard

Related pages:

- Crash Snapshots
- Crash Snapshot Properties

The **Crash Dashboard** aggregates mobile application crash data over time, using the Events Service. This service collects and stores *all* the data collected by the mobile agent.

The **Crash Dashboard** is divided into two panels and has the **App Version** dropdown that enables you to view crash data for different versions of your application.

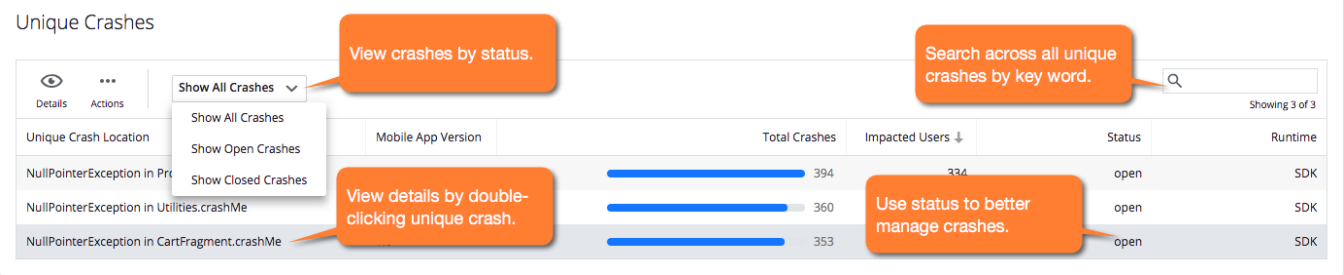


Summary Crash Trend

This panel displays a running total of crashes, unique crashes, impacted users, crash rate, and crash trends. The crash trends is a timeline of crash rates. It also reports any iOS crash reports that were uploaded without the accompanying dSYM file. For more information on how to use dSYM files with crashing reports, see Get Human-Readable Crash Snapshots.

Unique Crashes

Multiple crashes can be caused by the same underlying code issue. The **Unique Crashes** panel displays a list of crashes grouped by common characteristics and displays basic information about the crash. You can view open, closed, or all crashes.

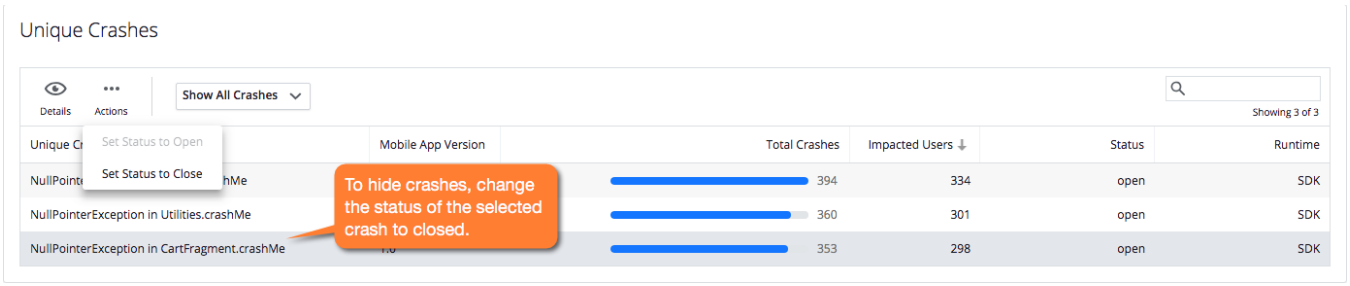


Unique Crash Details

To see more detail per crash, click the crash that interests you, in blue. The dashboard for that crash appears, with a header, trend bar graph, crash distribution charts, and a snapshot of the crucial details common to all the crash snapshots. See the Crash Summary section on the Crash Analyze page.

Crash Status

In addition to viewing crash details, from the **Unique Crashes** panel, you can select a unique crash, click **Actions**, and set the status to either open or closed. You can set the status to mark those unique crashes that you want to ignore or have fixed the root cause of.



When a crash is marked as closed, the crash will no longer trigger a new crash event, so you will not see the crash in the **Events** widget of the **Mobile App Dashboard,** the **Events** page, and it will not be included in alerts for new crashes.

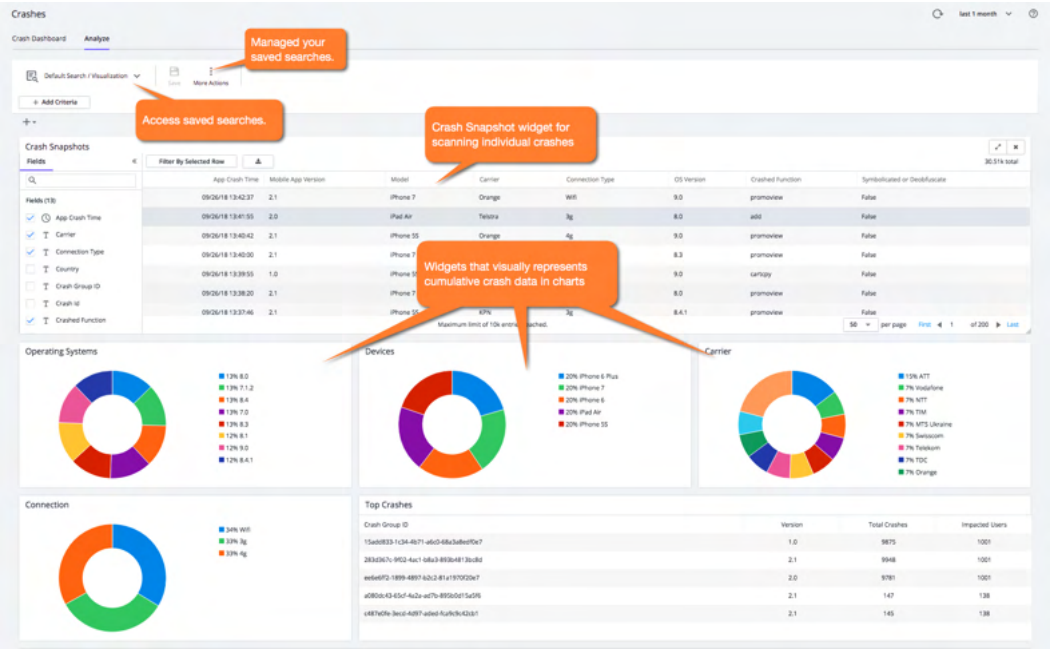
Crash Analyze

Related pages:

- Instrument an iOS Application
- Instrument an Android Application Manually

Crash Analyze lets you view and analyze the results based on the cumulative data. With **Crash Analyze**, every crash event is collected and stored by the AppDynamics Events Service.

The **Crash Analyze** page has the **Crash Snapshots** widget for viewing a list of current crash snapshots, with one row for each snapshot, and a selection of different widgets for visualizing the cumulative data in charts.



Crash Snapshots Widget

The Crash Snapshots tab lets you scan individual crashes and allows you to filter and sort to get exactly the crash set in which you are interested. The columns of the table are fields representing the crash snapshot properties. See Crash Snapshot Properties. Click **View Details** to see information for a specific crash.

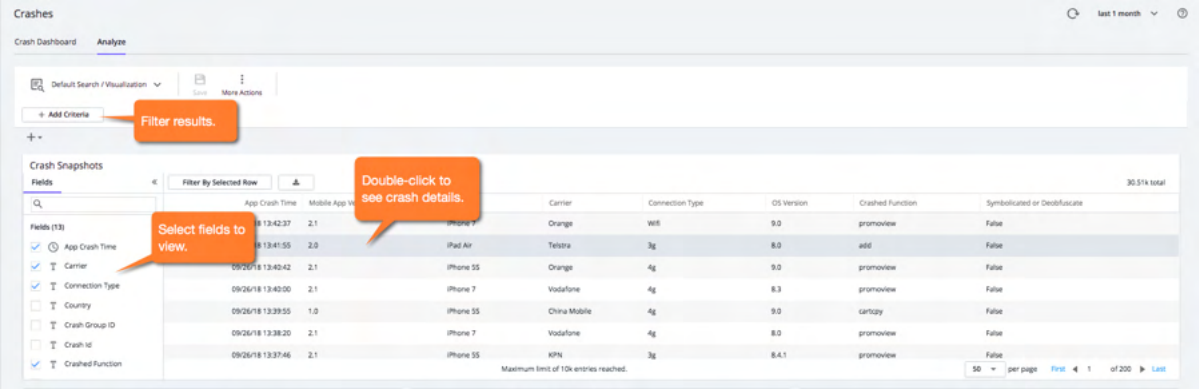


Chart and Tabular Widgets

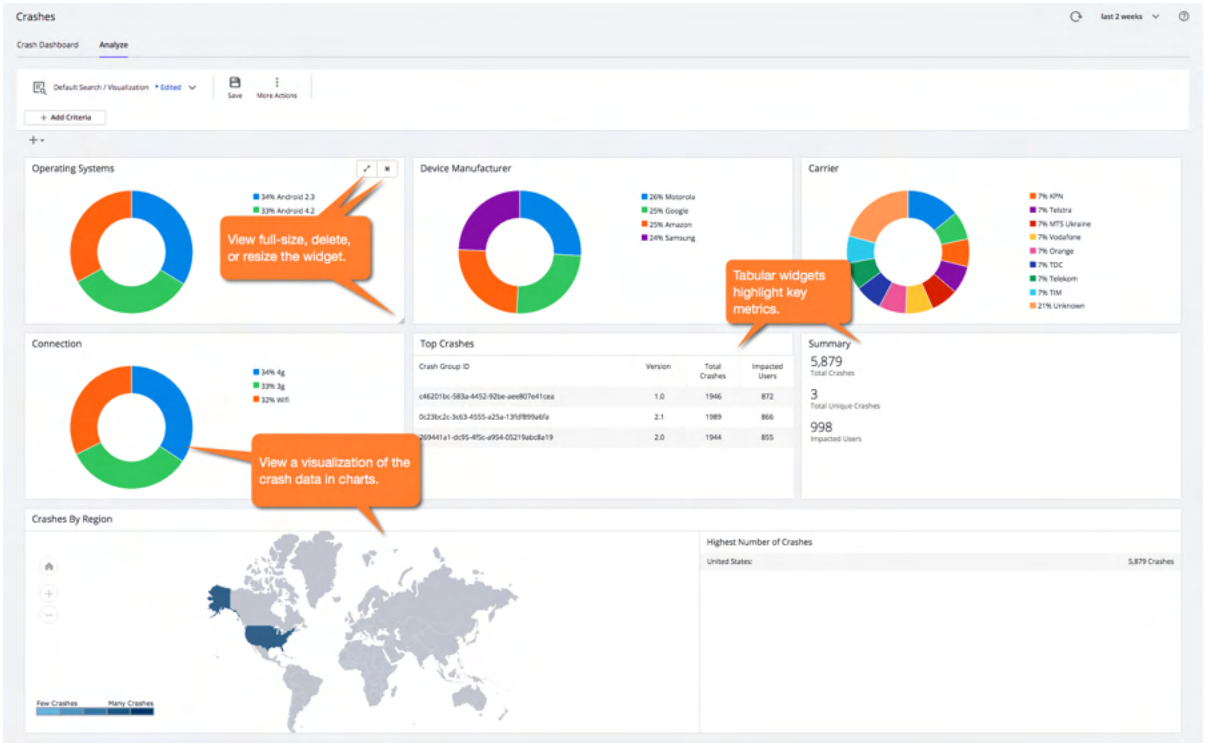
The chart widgets provide you with a set of predefined widgets that offer visualizations of the data set you have created. The tabular widgets highlight key metric points such as top crashes. You can delete, re-add, re-size, and drag-and-drop to move all of the widgets. You can also set criteria to visualize a subset of the data.



You can also view crash snapshots in the context of a separate product, AppDynamics Mobile Analytics. It offers additional mechanisms to analyze and visualize crash patterns, including:

- Additional predefined widgets, such as the funnel widget
- ADQL for searching the data
- Custom widgets
- Manipulating multiple dashboard types
- Longer retention time for storing data

AppDynamics Mobile Crash Report Analytics requires a license separate from the Mobile RUM license.

Crash Snapshots

Related pages:

- Crash Analyze
- Crash Snapshot Properties

Crash snapshots provide detailed information for one application crash. When an instance of an instrumented application crashes, a crash snapshot is created.

The snapshot provides information to help you analyze the cause of the crash, including:

- Crashed function
- Source file containing the crashed function
- Line number in the source file, if available
- Stack trace of the application at the time of the crash

For iOS applications, crash snapshots are based on:

- Fatal signals (SIGSEGV, and so on)
- Unhandled Objective-C exceptions

For Android applications, crash snapshots are based on unhandled Java exceptions.

Crash Snapshot Details

The **Crash Snapshot Details** dialog has the two panels **Crash Summary** and **Crash Distribution**. The **Crash Summary** panel displays basic crash information and the stack trace. The **Crash Distribution** panel displays widgets with distributed crash metrics by the crash group and the stack trace.

To view crash snapshot details:

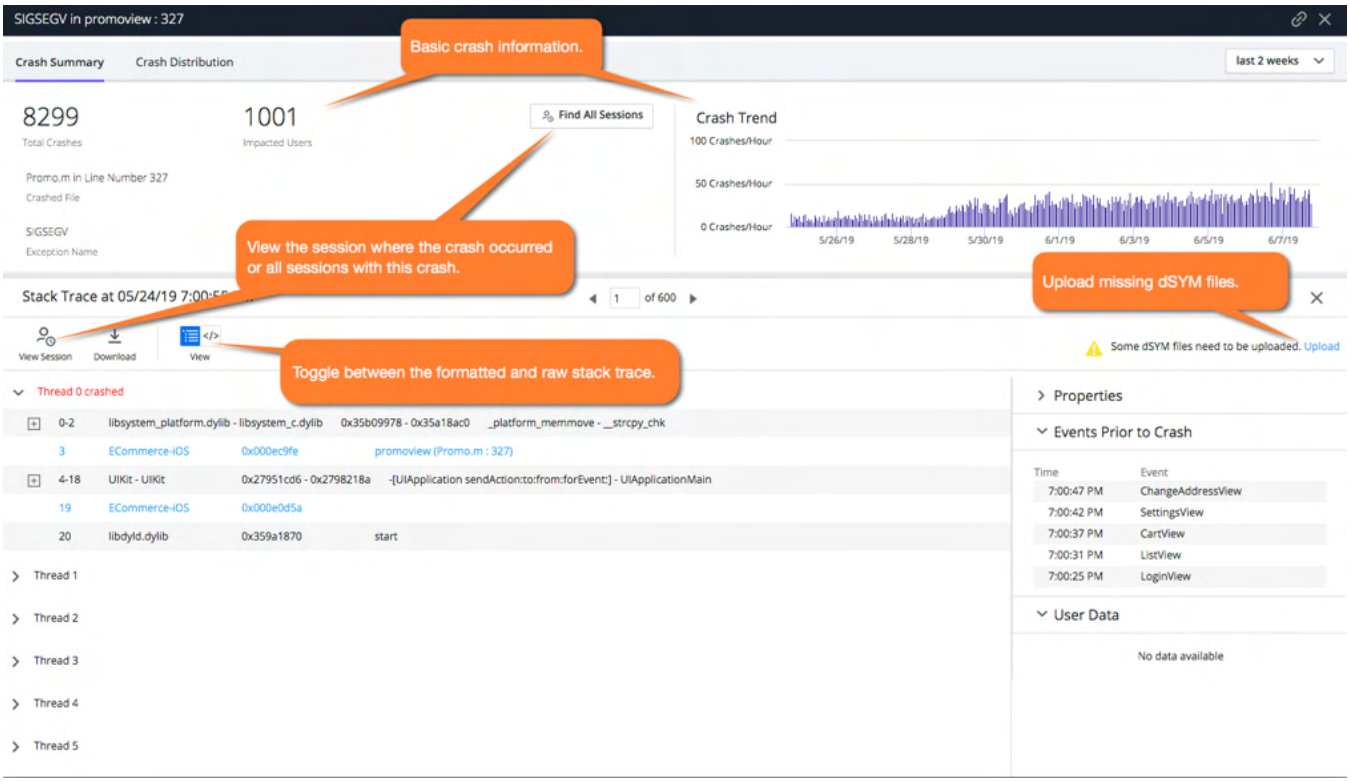
1. From the Records tab, select a crash snapshot in the list.
2. Click **View Details**.

Crash Summary

The **Crash Summary** panel of the snapshot displays the key properties of the snapshot. If you have customized your instrumentation (Android/iOS) to include breadcrumbs, they are displayed in the **Events Prior to Crash** panel. Up to 99 breadcrumbs display, beginning with the most recent. Not all of this information may be available. If you added user data (Android/iOS), it also displays here.

The **Stack Trace** panel displays the call stack of the crashed application, showing the thread in which the crash occurred. This is the full stack trace for this specific crash, not the aggregated stack trace shown in the **Unique Crash Dashboard**. You can view the formatted stack trace that groups threads and parses the output or the raw log output for the stack trace.

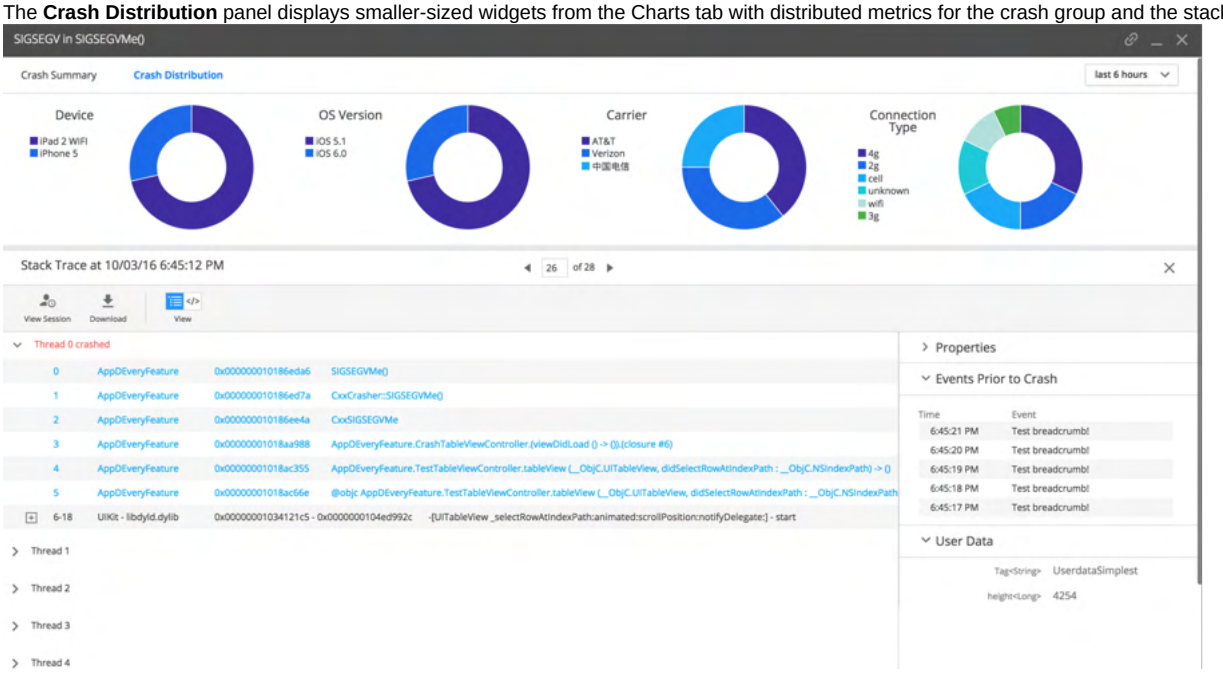
Click **Download** to access the stack trace in a file that you can forward to developers or port to logging platforms. To see the crash in the context of the mobile session, click **View Session**.



If the information in the stack trace is cryptic, it is possible that source code for your iOS app was not symbolicated or the source code for your Android app was obfuscated. See Get Human-Readable Crash Snapshots for information about why this happens and what you can do about it.

Crash Distribution

The **Crash Distribution** panel displays smaller-sized widgets from the Charts tab with distributed metrics for the crash group and the stack trace.



Crash Snapshot Properties

Related pages:

- Network Requests List
- Network Request Analyze
- Network Request Snapshots List
- Network Request Snapshots
- Analytics Mobile Crash Reports Data

This page describes the list of crash snapshot properties. They display in the **Crash Snapshot Details** panel when you open a crash snapshot from **Crash Analyze**.

- **Carrier**: Name of the mobile carrier.
- **Connection Type**: Active connection type at the time of the crash, if known.
- **Crashed File/Line/Function**: Name of the source file containing the crashed function, with the line number, if available. The name of the topmost function on the crashed thread's call stack. If this function is an Objective-C method, this name includes the class name. For Android, this name is the fully qualified name of the topmost method on the uncaught exception's stack trace.
- **Crash Time**: Timestamp when the crash occurred, based on the mobile device's clock.
- **Device/Manufacturer**: Model or manufacturer name of the mobile device on which the crash occurred.
- **Events Prior to Crash**: Any breadcrumbs you might have set up.
- **Exception Name**: Name of the fatal signal (iOS) or uncaught exception (Android) associated with the crash.
- **Memory Usage:** Memory used by the app when the crash occurred.
- **Mobile App**: Name of the app that crashed.
- **OS Version**: Operating system version of the mobile device on which the crash occurred.
- **Platform**: iOS or Android.
- **Request Timestamp**: Time when the beacon arrived at the Collector. Snapshot only.
- **User Data**: Any user data you might have added.
- **Version**: Version string of the crashed application.

Crash Snapshot list only

- **Country: O**riginating country.
- **Crash id: U**nique identifier for the crash.
- **Deobfuscated:** For Android: **true**, if this crash report has been matched with a ProGuard mapping file and deobfuscated; otherwise, **false**.
  See Upload the Proguard Mapping File in Instrument an Android Application Manually and Get Human-Readable Crash Snapshots. A **false** value for this property does necessarily indicate that the crash report will not be human-readable since it is possible that the application in question was not obfuscated.
- **Symbolicated:** For iOS: **true,** if this crash report has been matched with a dSYM file and symbolicated; otherwise, **false**.
  The application must have been compiled with the **Debugging Information Format** set to `DWARF with dSYM File` for a crash report to exist.
  See Upload the dSYM File and Get Human-Readable Crash Snapshots.

Get Human-Readable Crash Snapshots

Related pages:

- Crash Snapshots

The information in most raw crash stack traces is not fully human-readable. To make your crash stack traces more easily understood, you need to provide a platform-specific mapping file that can translate the raw data into human-readable output. Normally, you upload the file at the time that you instrument your mobile application.

- For iOS, see Upload the dSYM File.
- For Android, see Manually Upload Mapping Files.

This page explains the advantages of providing these files.

iOS dSYM File

For iOS applications, the raw data in the stack traces in crash snapshots consists of memory addresses of stack frames that point to executable application code. It also includes symbols and memory offsets for the system library code used by the application. Such a partially symbolicated stack trace looks something like this:

```
Thread 11 Crashed:
0   libobjc.A.dylib                 0x38cb50fc objc_retain + 12
1   SomeApp                         0x003a2204 0xc6000 + 2998788
2   SomeApp                         0x003a0854 0xc6000 + 2992212
3   SomeApp                         0x003a09d4 0xc6000 + 2992596
4   SomeApp                         0x003948e4 0xc6000 + 2943204
5   Foundation                      0x2f3a2dc2 __NSThread__main__ +
1058
6   libsystem_pthread.dylib         0x392cec5a _pthread_body + 138
7   libsystem_pthread.dylib         0x392cebca _pthread_start + 98
8   libsystem_pthread.dylib         0x392ccccc thread_start + 4
```

AppDynamics attempts to display stack traces with the names of functions with offsets into those functions to help you identify the line of code that was executing when the application crashed. To get the symbols that map to the executable code, it needs the dSYM (desymbolication) file for the crashed application.

If the dSYM file for the crashed application has been uploaded, the symbolicated stack trace shows the function name and the offset into the function where the app crashed. It looks something like this:

```
Thread 0 Crashed:
0   libobjc.dylib               objc_release + 0x14
1   CoreFoundation              CFStringCreateWithFormat + 0x4
2   UIKit                       -[UIButton init] + 0x96
3   MyApp                       createUI (MyAppDelegate.m:42)
```

The dSYM file is created when the application source code is compiled with the **Debugging Information Format** set to `DWARF with dSYM file`. AppDynamics recommends that you build all the iOS apps that you want to monitor using this option and then upload the dSYM file to AppDynamics. The best time to do this is when you instrument the app.

If a dSYM has been uploaded for a crashed application, in the crash list the **Symbolicated** column for the associated crash snapshot is true.

If the `symbolicated` property is `false` and you want to see user-friendly stack traces in your crash snapshots for this application, you need to locate and upload the dSYM file for the crashed application.

ProGuard Mapping File for Android

If an Android app was not obfuscated to prevent reverse engineering, you should see human-readable stack traces in your crash snapshots by default.

If the code was obfuscated, however, AppDynamics needs the ProGuard mapping file to be able to deobfuscate the app. The best procedure is to upload this file at the time you build the app.

If a ProGuard mapping file has been uploaded for a crashed application, in the crash list the **Deobfuscated** column for the crash snapshot is `true`.

If the `deobfuscated` property is `false` and the stack traces you see in the crash snapshots are obfuscated, you need to locate and upload the mapping file for the application.

Crash Alerts

You can configure AppDynamics to send you alerts when your mobile application crashes. You can configure email alerts for health rule violates based on some default health rules or by manually creating a policy with a notification action or creating an email digest.

> Crashes that have the status "Closed" do not trigger alerts.

Set Up Alerts for Crashes

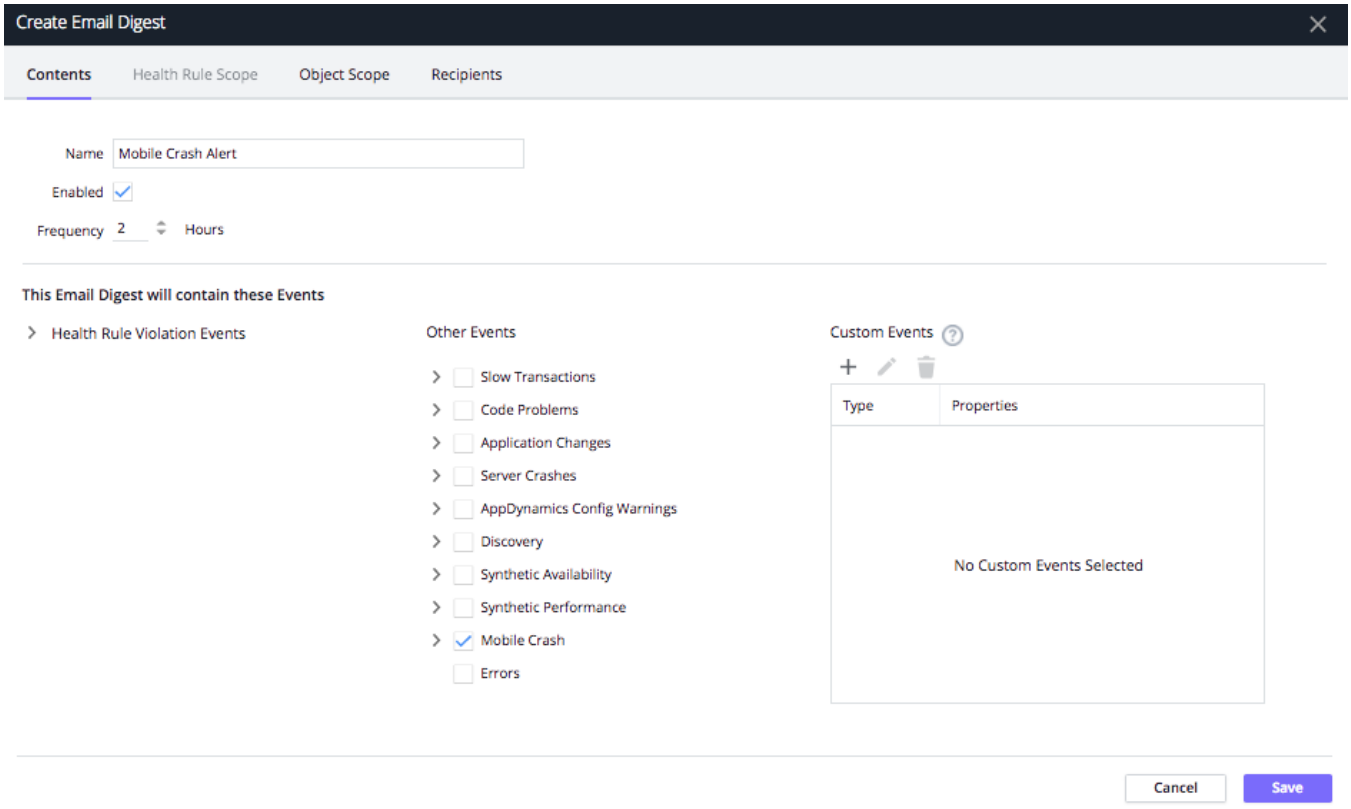
Setting up alerts for crashes is similar to setting up alerts for other health rule violations:

1. Configure Mobile Crash Alerts. This will configure the default number of crashes.
2. If desired, update the **Critical Criteria** and **Warning Criteria** for the health rule **Crash Rate is much higher than normal**. See Configure Health Rules.
3. Create a policy that will be triggered when the health rule for crashes is violated. You'll need to configure an action to be taken when the policy is triggered.
4. After you set up the email alerts, when a health rule is violated, an email will be sent indicating whether there was a warning or critical alert and providing links to view crash and session details.

Create Email Digest for Crashes

You can create the same type of notification for crashes by creating an email digest.

From the **Create Email Digest** dialog, check the **Mobile Crash** checkbox:



You can then use the **Email Digest** wizard to add recipients, a custom message, and schedule the frequency to send emails.

Code Issues

Code issues consist of caught non-fatal exceptions or application not responding (ANR) issues. A code issue snapshot is a detailed report on a particular event including the code that was executing when the exception or ANR occurred.

Code issue snapshots help you understand the causes of these issues. Use **Code Issues** to get trend and detailed information on application non-responsive issues (ANRs) and caught errors and exceptions.

Catch and Report Code Issues

All the Mobile Agents except the iOS Agent will automatically detect and report ANRs. For iOS, you have to enable ANR detection. To catch and report errors and exceptions, you instrument your mobile applications with iOS, Android, and Xamarin SDKs.

See the section "Report Errors and Exceptions" (iOS, Android, Xamarin) to learn how to use the SDKs to manually catch and report errors and exceptions.

Access the Code Issues Dashboard

The Code Issues Dashboard is where you can view both summary and detailed information about code issues.

1. Open the application you want.
2. On the left navigation bar of your application, select **Code Issues**.

View Code Issue Widgets

The **Summary Code Issue Trend** and **Unique Code Issues** widgets are on the **Code Issues Dashboard**. The **Summary Code Issue Trend** widget displ ays the number of code issues, impacted users, and unique code issues as well as graph the code issues on a timeline. The **Unique Code Issues** widget d isplays details about the unique code issues such as the severity, the issue type, runtime, impacted users, and mobile app version.

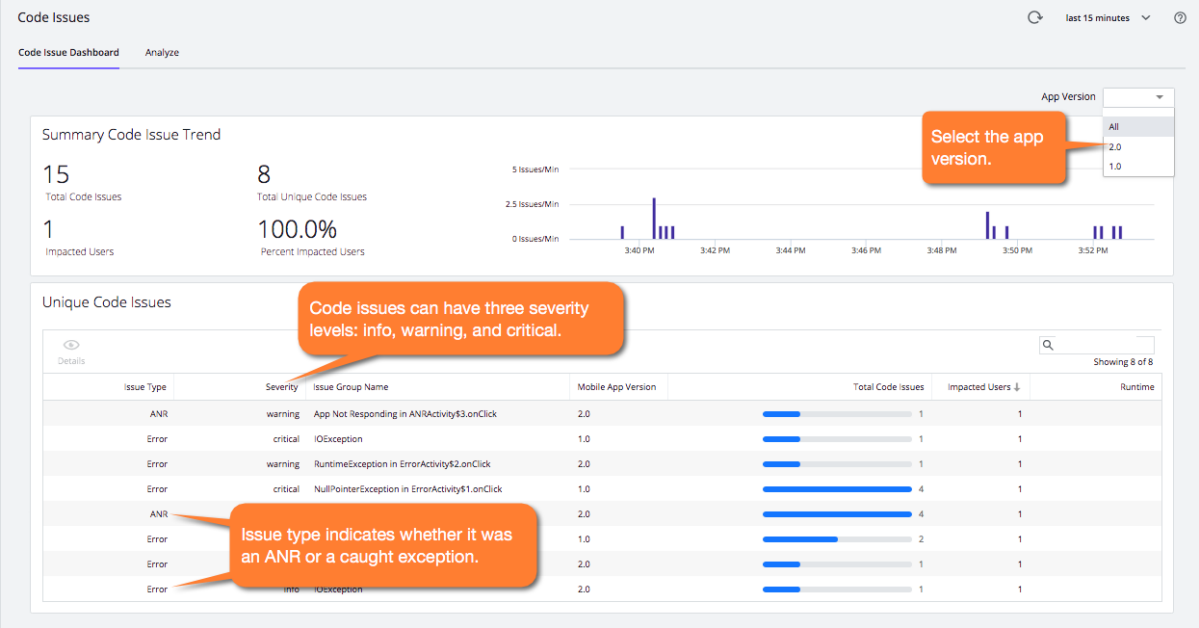
To view code issue information:

1. Open the application you want.
2. From the **Code Issues Dashboard**, both **Summary Code Issue Trend** and **Unique Code Issues** widgets display.
3. You can click one of the unique code issues in the **Unique Code Issues** widget to view the **Code Issues Details** dialog.

Code Issues Dashboard

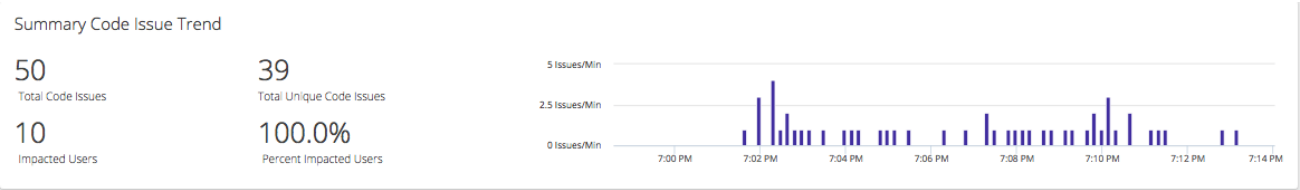
The **Code Issues Dashboard** aggregates mobile application caught exceptions and ANRs over time, using the Events Service. This service collects and stores *all* the data collected by the mobile agent.

The **Code Issues Dashboard** is divided into two panels and has the dropdown **App Version** to view code issues for different versions of your application.



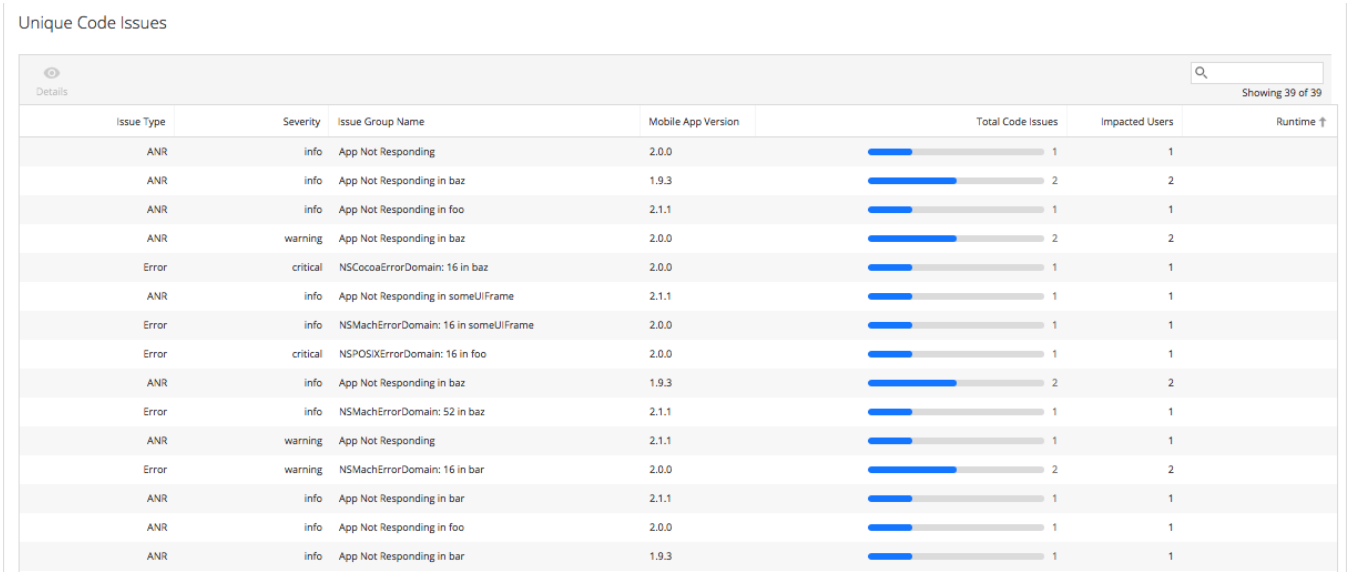
Summary Code Issue Trend

This panel displays a running total of code issues, unique code issues, impacted users, the percent of impacted users, and code issue trends. The code issues trends is a timeline of code issues.



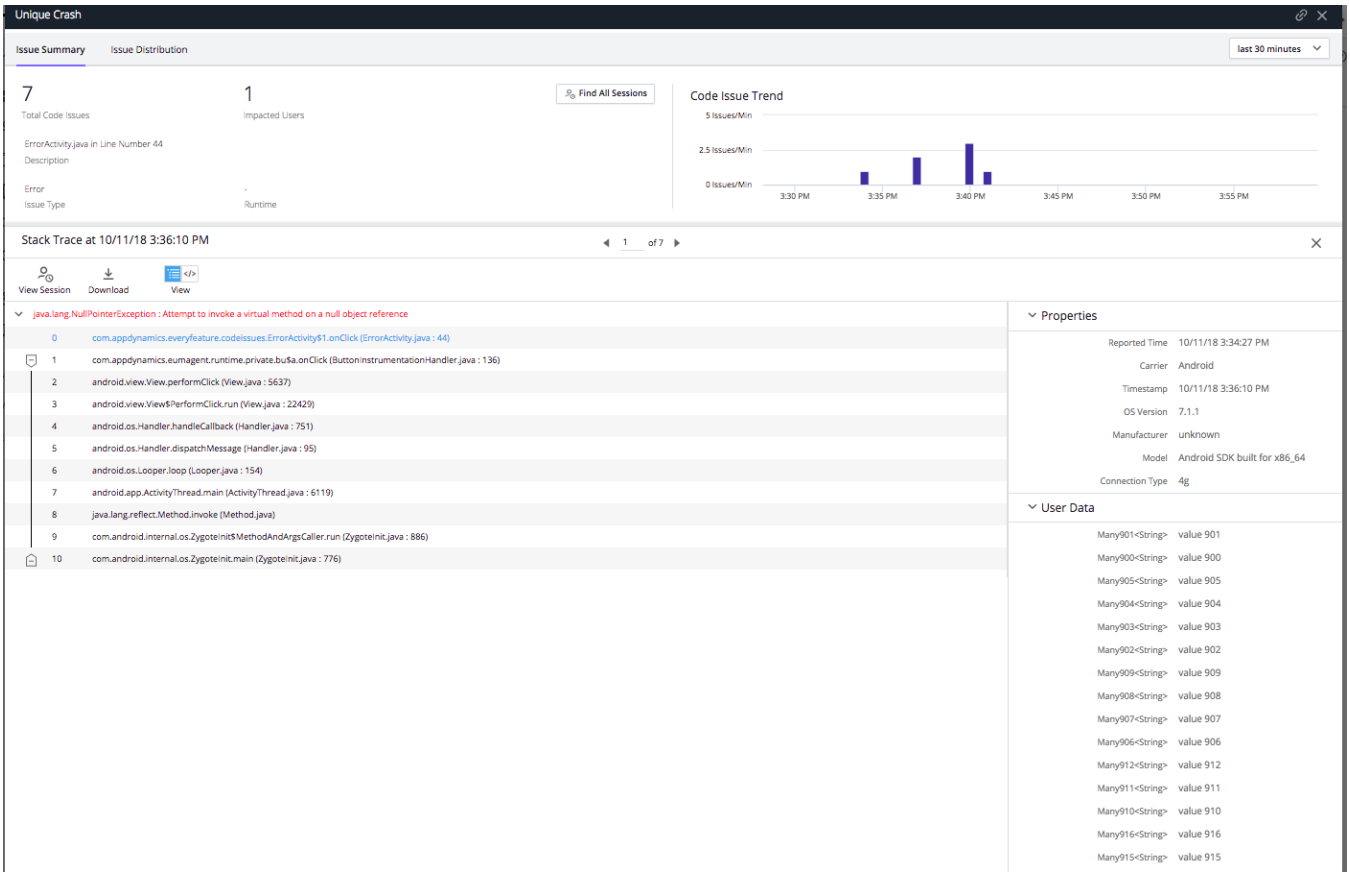
Unique Code Issues

Multiple code issues can be caused by the same underlying issue. The **Unique Code Issues** panel displays a list of code issues grouped by common characteristics and displays basic information about the issue.



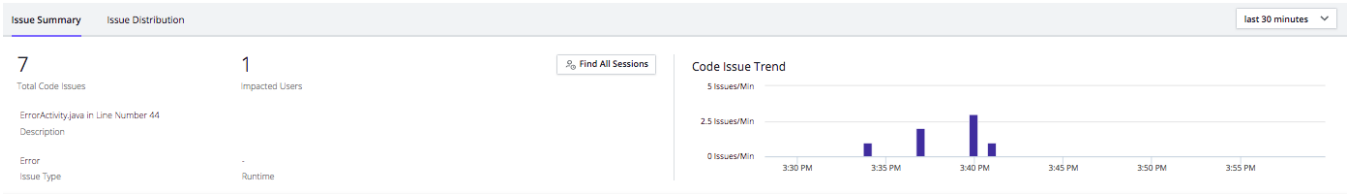
Unique Issue Details

To see more detail per code issue, select the unique code issue that interests you and click **Details**. The **Unique Issue** dialog has the two tabs Issue Summary and Issue Distribution.



Issue Summary

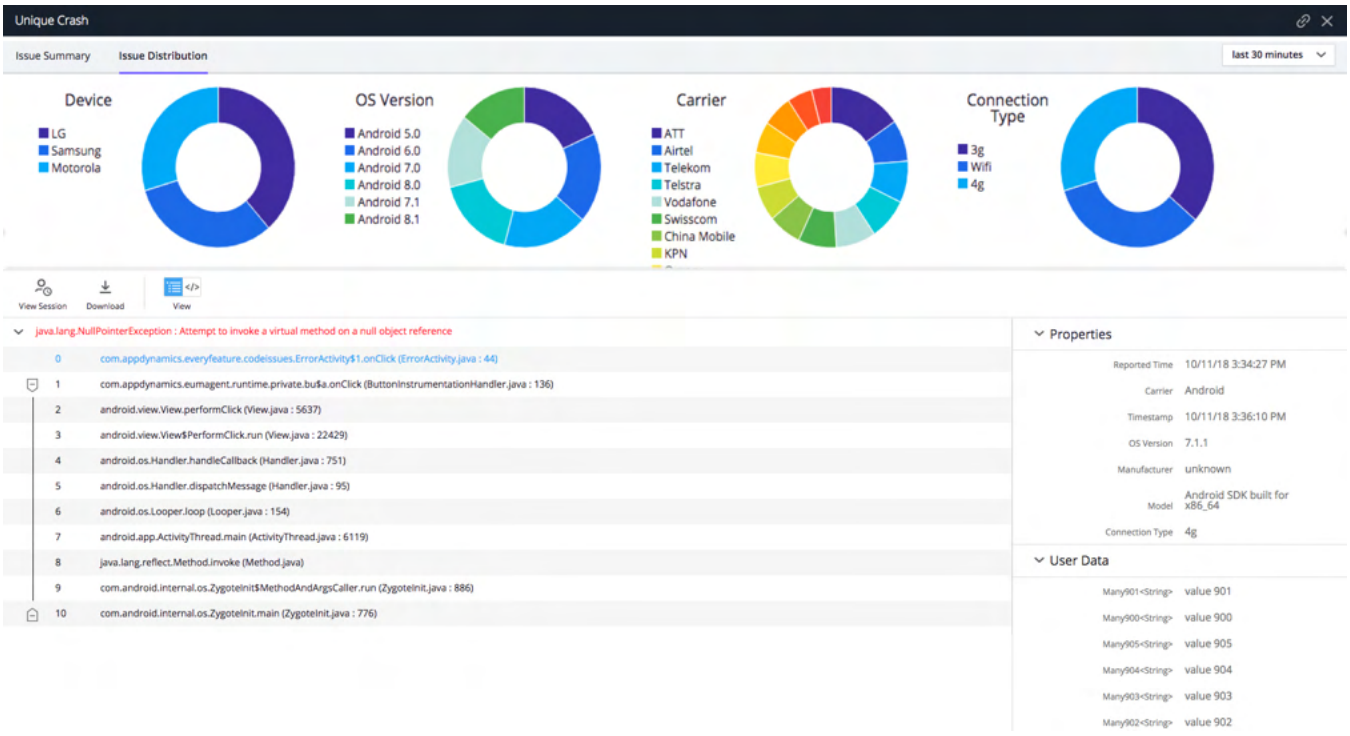
The Issue Summary tab has two main panels. The top panel shows summary information such as the total code issues, the issue type, impacted users, the runtime, and a code issue trend bar graph.



The bottom panel shows a sequence of threads in the stack trace that you can expand for more information, a **Properties** section with general information about the device, and a **User Data** section with any set user data.

Issue Distribution

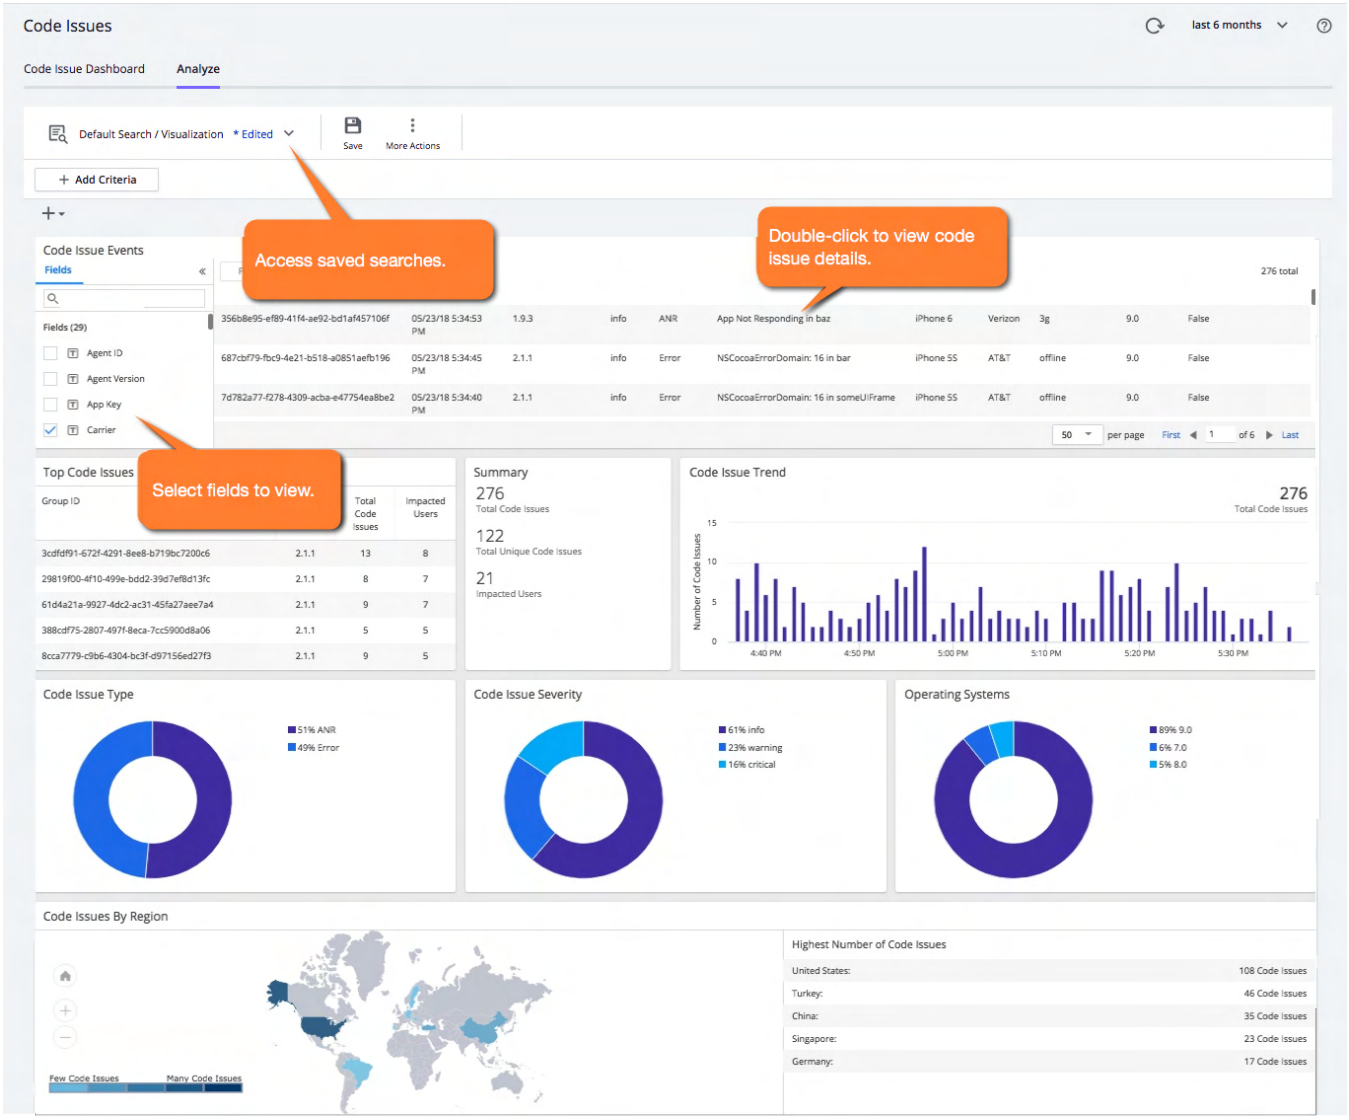
The Issue Distribution tab displays the same stack trace panel, but the top panel dashboard instead displays the distribution charts for the code issue.



Code Issues Analyze

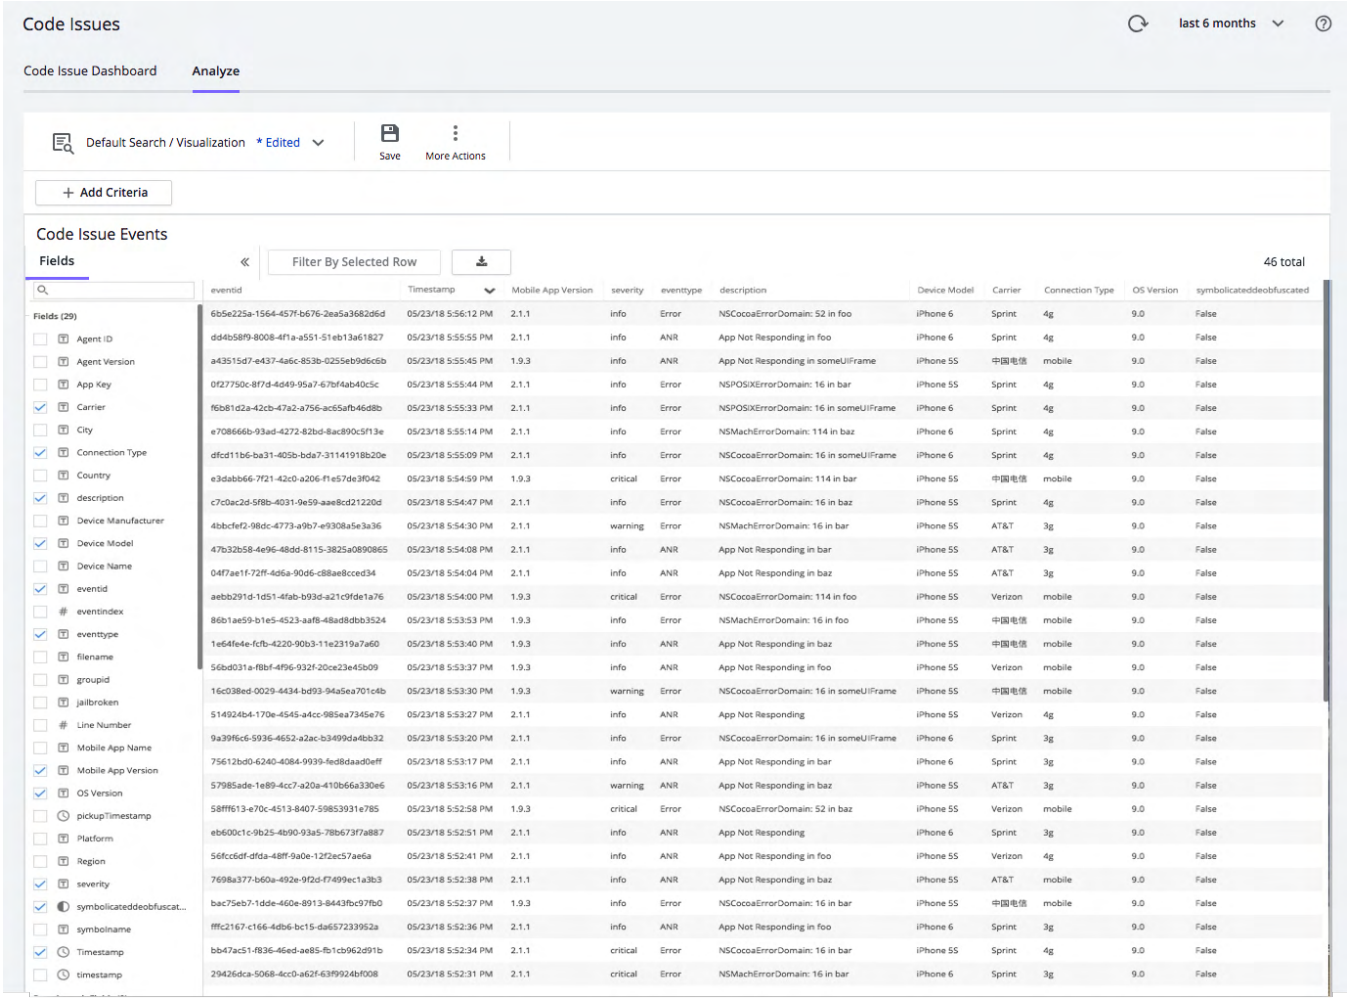
The **Code Issues Analyze** page has the **Code Issue Events** widget for viewing a list of current code issue snapshots, with one row for each snapshot, widgets for visualizing code issues data, and widgets for highlighting key data points.

Code Issues Analyze enables you to view and analyze the results based on cumulative data based on configured criteria. You can delete, re-add, re-size, and drag-and-drop to move all of the widgets. You can set criteria to visualize a subset of the data. Every code issue event in **Code Issues Analyze** is collected and stored by the AppDynamics Events Service.



Code Issue Events Widget

The **Code Issue Events** widget enables you to scan individual code issues, filter, and sort to get exactly the code issue in which you are interested. The columns of the table are fields representing the code issue properties. See Code Issue Snapshot Properties.



Other Code Issue Widgets

The other widgets fall into the following three categories: tables, charts, a summary, and a hybrid.

Table Widgets

The table widgets display rows of code issues in tabular form. The **Code Issue Events** widget lists the code issue snapshots.

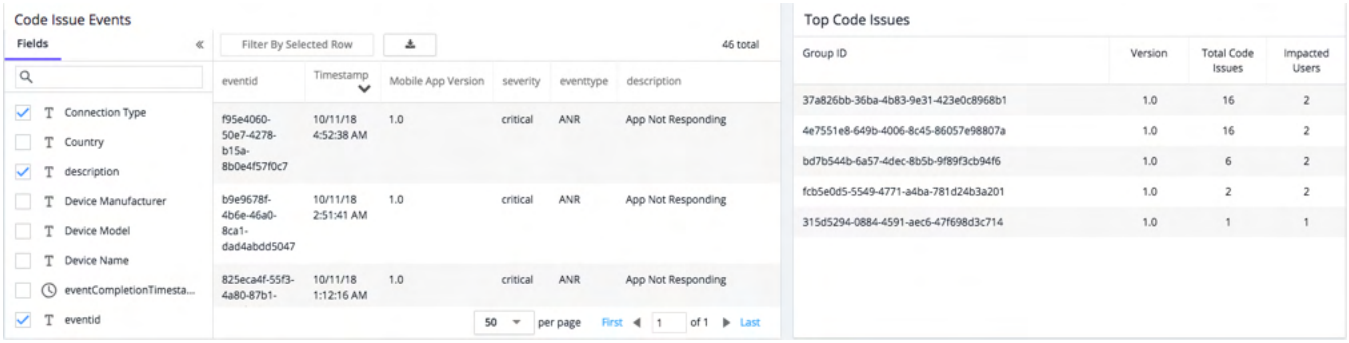


Chart Widgets

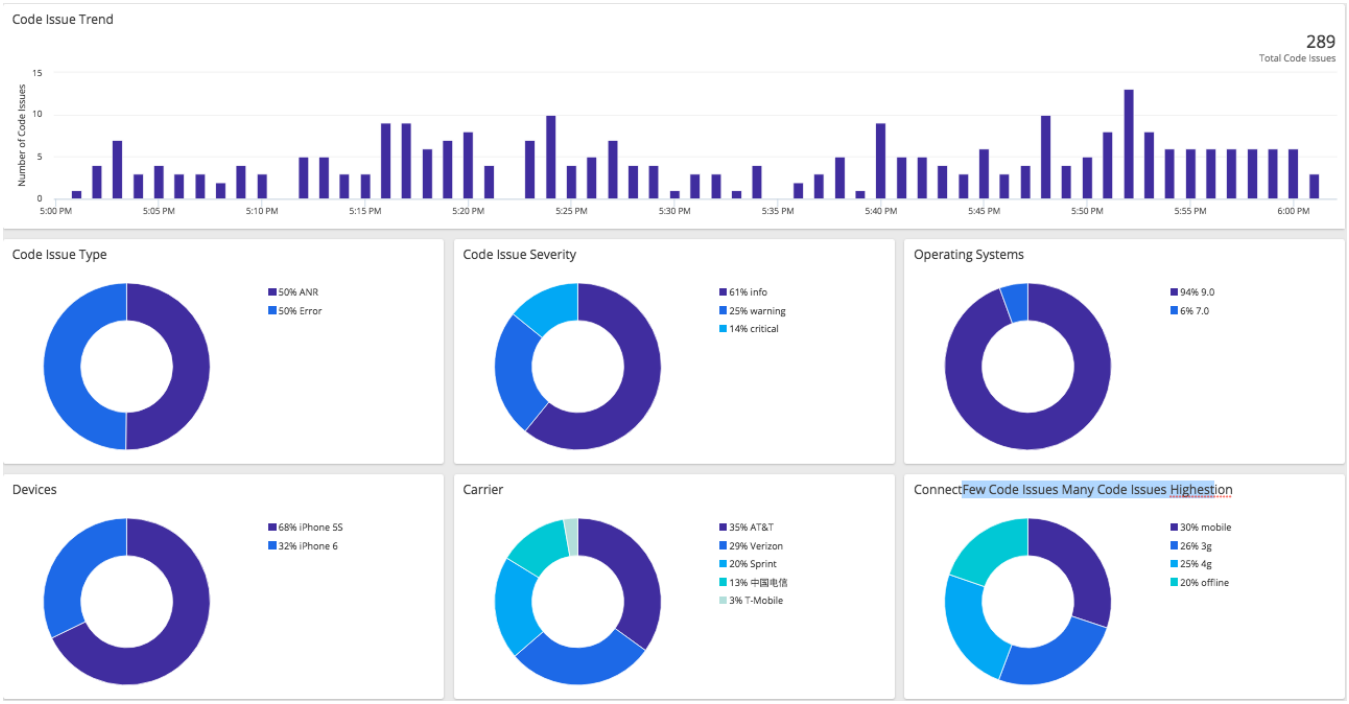
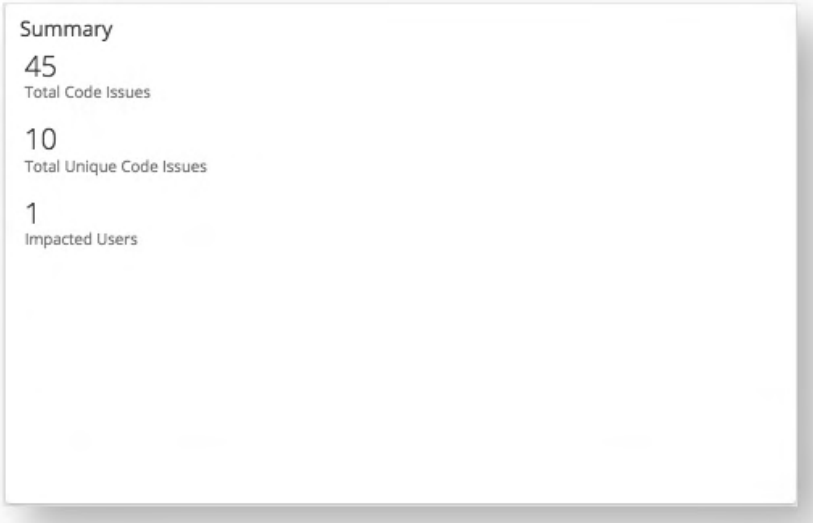
The chart widgets visualize the code issue data. For example, you can view the code issues data in pie charts showing the ratio of ANRs to caught errors /exceptions, severity levels, operating systems, and so on.



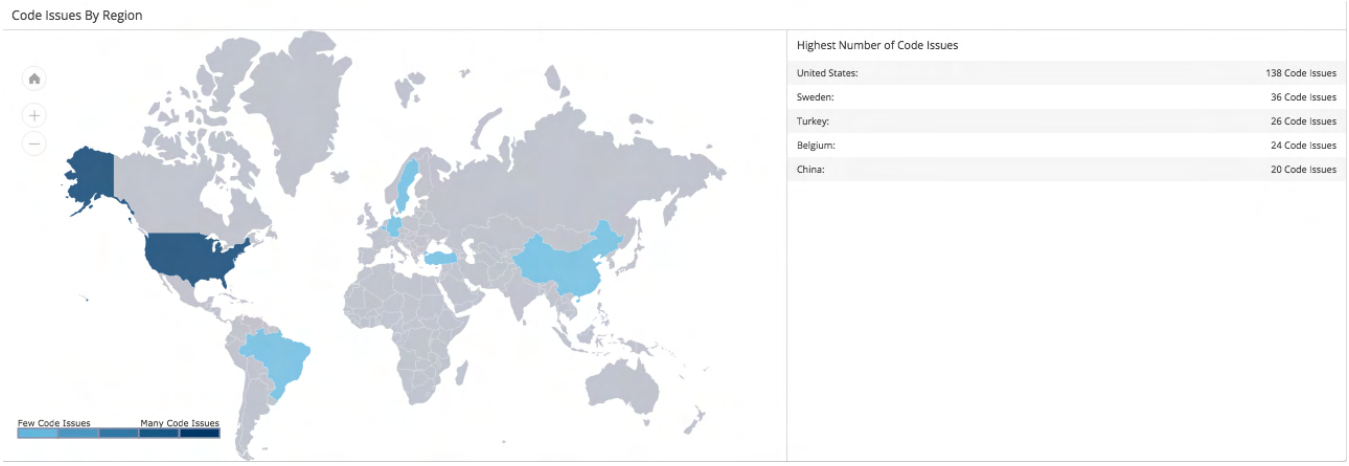
Summary Widget

The **Summary** widget lists totals for key statistics.



Hybrid Widget

The **Code Issues By Region** widget is a hybrid, displaying geographic data in a map and listing the data points in a table.



Code Issues in Mobile Analytics

Code issue snapshots can also be viewed in the context of a separate product, AppDynamics Mobile Analytics. It offers additional mechanisms to analyze and visualize code issue patterns, including:

- Additional predefined widgets, such as the funnel widget
- ADQL for searching the data
- Custom widgets
- Manipulating multiple dashboard types
- Longer retention time for storing data

AppDynamics Analytics Mobile Non-Fatal Issues Data requires a license separate from the Mobile RUM license.

Code Issue Snapshots

Code issue snapshots provide the detailed information for one code issue. A code issue snapshot is created when an instance of an instrumented application experiences an ANR, slow UI, or manually reports a caught exception. To manually report caught exceptions, you use either the iOS SDK or the Android SDK.

- Thread that contains a function that is not responding or has a caught exception
- Source file containing the function that is not responding or has the caught exception
- Line number in the source file, if available
- Stack trace of the application at the time of the code issue

For iOS applications, code issue snapshots are based on:

- ANRs
- Handled Objective-C exceptions
- Slow UI

For Android applications, crash snapshots are based on:

- ANRs
- Handled Java exceptions
- Slow UI

Code Issue Snapshot Details

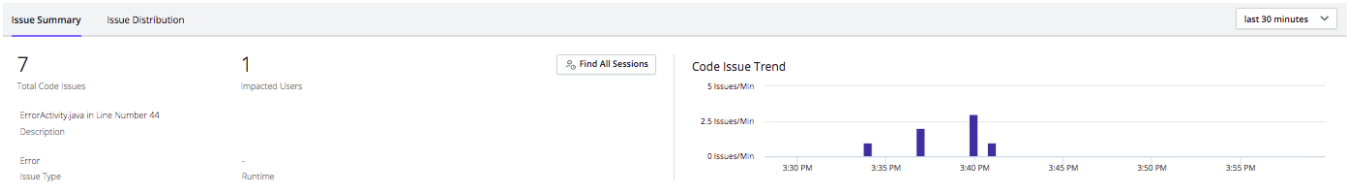
The **Issue Snapshot Details** dialog has the two panels **Issue Summary** and **Issue Distribution**. The **Issue Summary** panel displays basic information about the code issue and the stack trace. The **Issue Distribution** panel displays widgets with distributed issue metrics by code issue group as well as the stack trace.

View Code Issue Snapshot Details

1. Navigate to **Code Issues > Analyze**.
2. From the **Code Issue Events** widget, double-click one of the code issue snapshots.

Issue Summary

The **Issues Summary** panel of the snapshot displays the key properties of the snapshot. Unlike with crashes, code issues do not include breadcrumbs.

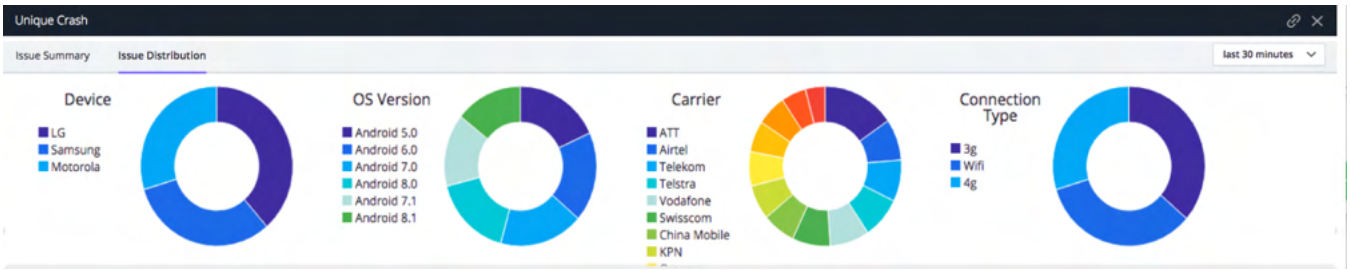


The **Stack Trace** panel displays the call stack of the code issue, showing the thread in which the caught exception or ANR occurred. This is the full stack trace for this specific code issue, not the aggregated stack trace shown in the **Unique Issue Dashboard**. You can view the formatted stack trace that groups threads and parses the output or the raw log output for the stack trace.

Click **Download** to grab the stack trace in a file that you can forward to developers or port to logging platforms. To see the code issue in the context of the mobile session, click **View Session**.

Issue Distribution

The **Issue Distribution** panel displays smaller-sized widgets from the **Analyze** tab with distributed metrics for the code issue group.



Code Issue Snapshot Properties

This page lists the code issue snapshot properties. They appear in the **Code Issue Snapshot Details** panel when you open a code issue snapshot from **Code Issue Analyze**.

- **Agent ID:** The ID of the Mobile Agent reporting the code issue.
- **Agent Version:** The version of the Mobile Agent reporting the code issue.
- **Application Key:** The application key.
- **Carrier**: The name of the mobile carrier.
- **City:** The originating city.
- **Client Time:** The timestamp of a device when the beacon was made.
- **Connection Type**: The active connection type at the time of the code issue, if known.
- **Country:** The originating country.
- **Description:** The type of code issue, such as an application not responding (ANR) or a caught non-fatal exception.
- **Device/Manufacturer/Model**: The model or manufacturer name of the mobile device on which the code issue occurred.
- **Event Type:** Type of code issue (for example, ANR, Caught Exception)
- **Jailbroken:** Flag indicating whether the mobile device has been jailbroken.
- **Group ID:** The event group id after grouping.
- **Mobile App**: The name of the app that had the code issue.
- **OS Version**: The operating system version of the mobile device on which the code issue occurred.
- **Platform**: iOS or Android.
- **Region:** The originating region, such as the province or state.
- **Request Timestamp**: When the beacon arrived at the Collector. Snapshot only.
- **Severity:** The severity level set for the code issue.
- **Symbolication/Obfuscation:** Flag indicating whether the application code has been symbolicated/obfuscated.
- **User Data**: Any user data you might have added.
- **Version**: The version string of the application that had the code issue.

Code Issue Alerts

You can configure AppDynamics to send you alerts when your mobile application has code issues. You can configure email alerts for health rule violates based on the default health rule or by manually creating a policy with a notification action.

Set Up Alerts for Code Issues

This basic workflow describes how to set up alerts for code issues:

1. Report Errors: In your application code, use the iOS, Android, or Xamarin SDK to report errors. Set the severity to either `INFO`, `WARNING`, or `CRITICAL`. Only errors with the severity of `CRITICAL` trigger alerts with the default health rule.
2. Configure Thresholds: Set the warning and critical thresholds for application not responding issues:
    a. Navigate to **Configuration > Mobile App Group Configuration > Settings**.
    b. From **Configure Application Not Responding Thresholds**, set the values for **Warning Threshold** and **Critical Threshold**. Any value that is less than the warning threshold will be labeled as **Info**.
3. View alerts for code issues.

Report Errors with the Mobile SDKs

See "Report Errors and Exceptions" (iOS/Android/Xamarin) to report errors and set the severity for iOS, Android, or Xamarin applications.

Configure Threshold for Code Issue Alerts

You can configure the thresholds for ANRs that must be reached before you are alerted. See Configure Application Not Responding Thresholds.

View Code Issue Alerts

The health rule **Critical Code Issues exist** is used to send alerts when one if the following occurs:

- You have used the Android or iOS SDK to report an error with the severity of `CRITICAL`.
- The time that your application has not responded exceeded the critical threshold.

After you set up the email alerts, when a health rule is violated, an email will be sent indicating whether there was a warning or critical alert and providing links to view code issue and session details.

Custom Data

Mobile RUM provides substantial information on crashes and network and server-related performance. You may want, however, to customize the Mobile Agent to collect other metrics and data to understand how your application is performing for your users.

For information on customizing the agent, including sample code, see:

- Customize the iOS Instrumentation
- Customize the Android Instrumentation

To see the results of your data collection, you use the **Custom Data** view.

Custom Data Types

There are three kinds of custom data that you can collect:

- Info Points
- Custom Timers
- Custom Metrics

> There are two other types of custom data: the breadcrumb and user data. Breadcrumbs display only in Crash Snapshots. User data is available in **Crash Analyze** and **Network Request Analyze**. See the agent SDK docs for more information.

Info Points

An information point allows you to collect information on how a specific method in your code is performing. How many times was a particular method executed? Was an exception thrown? If you need to monitor multiple methods, you can create multiple info points.

If you know there are important methods you always want to monitor, create static info points as described in Customize the iOS Instrumentation and Customize the Android Instrumentation.

Custom Timers

Custom timers allow you to time how long something takes between any arbitrary start point and end point, even if they span multiple methods. For example, how long did it take to repaint a frame buffer? How long did the app take to start up?

Custom Metrics

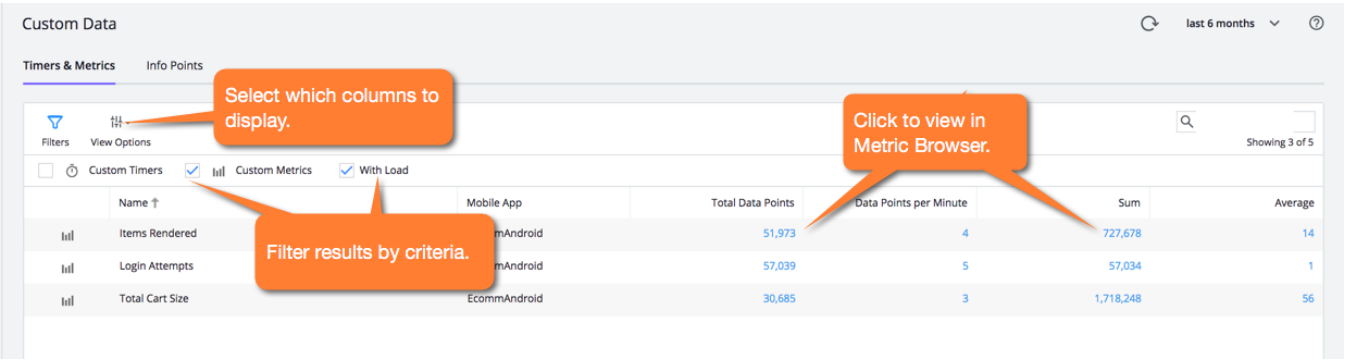
Custom metrics allow you to collect data on any metric you define in your application. Metrics can be any integer-based data. Over the specified time frame, Mobile RUM calculates the minimum, maximum, average, sum, and count of these values.

View Custom Data

Your data is shown in tabular format in two tabs.

Custom Timers & Metrics

Click on any value (in blue) to display the same metric in the Metric Browser.



Info Points

The Info Points tab shows any current info points.

Configure the Controller UI for Mobile RUM

Using the Controller UI, you can configure:

- How to rename mobile requests
- Thresholds that cause network request snapshots to be considered slow, very slow or stalled
- Percentile levels to display, if any
- Which network requests are sent to the Event Service
- If the IP address from which the request comes should be stored

To configure Mobile RUM from the Controller UI, your user account must belong to a role that has the **Configure EUM** permission. See End User Monitoring Permissions.

Access the Mobile Container Configuration

To access mobile request configuration:

1. Open the mobile application in which you are interested.
2. From the left-hand navigation menu, click **Configuration**.
3. From the **Configuration** page, click **Mobile App Group Configuration >**.

Configure Mobile Network Request Naming

This page describes how to modify the default naming configuration for network requests and create include/exclude naming rules for network requests.

> If you create a rule for capturing mobile network requests and later disable the rule, the URLs that were formerly captured by the rule will be displayed with the network request name "/" unless you have another rule that captures the URL. To avoid this from occurring, you can create a custom rule that serves as a catch-all for URLs that are not captured by custom rules. See Network Request Limits.

Default Network Request Naming Configuration

By default, AppDynamics names network requests using:

- Hostname
- First two segments of the URL

For example, if an application makes this HTTP request:

```
http://myapp.com/friends/profiles/12345
```

The default name that is displayed in the Controller UI for that request is:

```
myapp.com/friends/profiles
```

If this is adequate for your needs, you can leave the default setting.

> The naming rules you configure here apply to all the mobile applications that are in the same Mobile App Group.

Modify the Default Naming Configuration Rule

You may want to configure a different default rule for naming your network requests to help you visualize the parts of your application more clearly. The task is similar to configuring naming rules for business transactions on the server side. Try to group logically related requests together while keeping unrelated requests in separate groups.

- If the default hostname and first two segments of the URL for all your requests are identical, you might want to name the requests based on the last segments or a selection of non-contiguous segments of the URL to distinguish among requests in the network requests list.
- You can also name the requests based on query parameters. For example, if the request passes an order number, you could specify that the value of the `order-number` query parameter is used in the network request name.
- You can also base the name on a regular expression run on the URL. AppDynamics uses the Java libraries for regular expressions. See:
  - Tutorial: http://download.oracle.com/javase/tutorial/essential/regex/index.html
  - Javadoc: http://download.oracle.com/javase/1.5.0/docs/api/java/util/regex/Pattern.html

Modify the Default Network Request Naming Rule

The default configuration covers how all your requests are named if you do not customize them further.

1. From the **Network Request** tab, scroll down to the **Include Rules** section.
2. Double-click **Default Naming Configuration**.
3. In the **Include Rule** dialog, select the elements you want to use for your default network request naming.
4. Click **OK**.
5. Click **Save**.

Create Mobile Include Rules

By default, the same request naming rule is applied to every URL that your application requests. If you want to apply different naming rules to different URLs, create include rules.

For example, if some requests call your own in-house server and others call out to a third-party API, you may want to see all the third-party API calls as one network request and use the default naming rules for the calls to your own server. You would create a custom naming rule that matches the third party calls and uses only the host in the default rule name or perhaps also include certain query parameters.

Create an Include Rule

1. From the **Network Request** tab, scroll down to the **Include Rules** section.
2. Click **Add**.

3. In the **Include Rule** dialog, enter a name for the custom rule that you are creating.
4. Check the **Enabled** check box to enable the rule.
5. Select the check boxes and radio buttons and enter the match criteria for AppDynamics to use to name network requests.
6. Click **OK**.

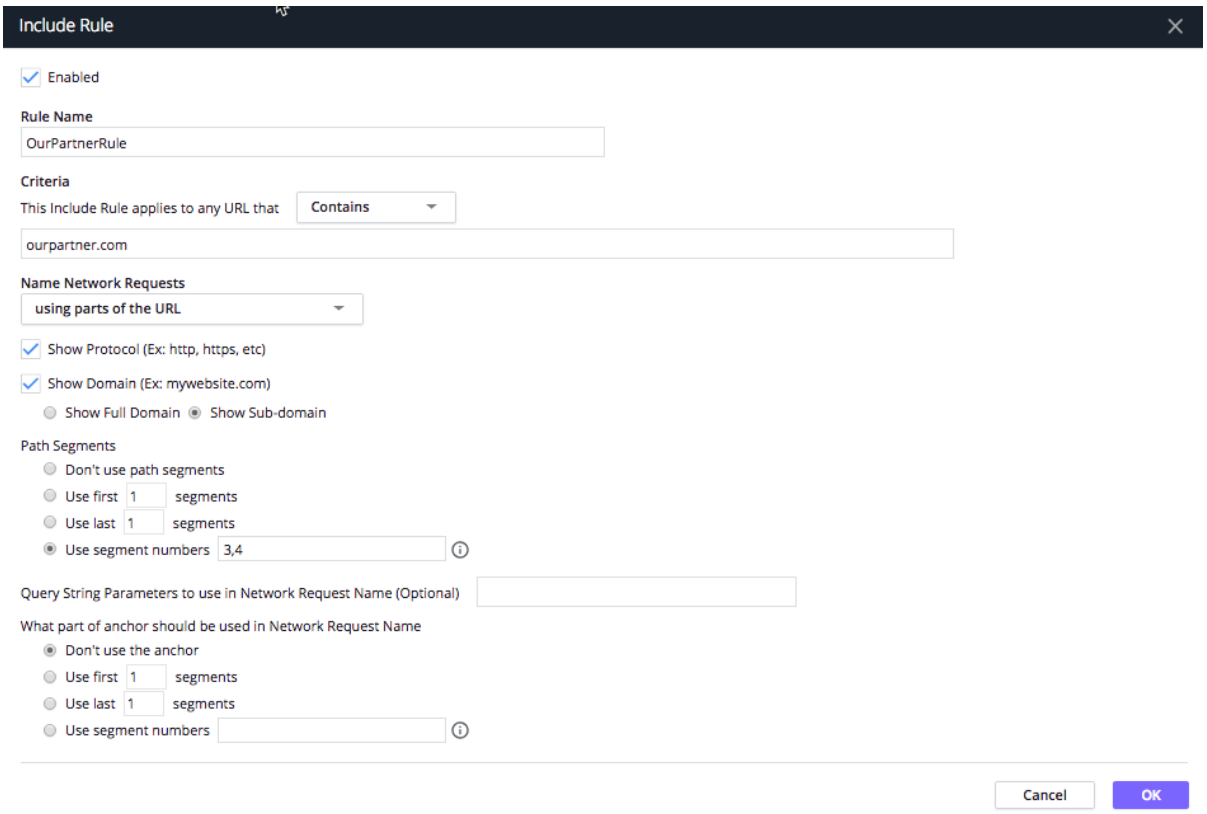
Guidelines for Using Regular Expressions in Mobile Include Rules

When using regular expressions to match URLs in your include rules, you should note the following:

- URL strings are case-sensitive. So, although the page names displayed in the Network Request Dashboard are converted to lowercase, your regular expressions still need to match the case used in URLs that your include rule are trying to capture.
- Your regular expression should match the entire URL, from beginning to end, not just a section; otherwise, the rule will not match. This differs from using regular expressions in custom match rules for naming transactions, which only need to match sections of the URL.

Sample Include Rule

The following rule creates a custom match rule for requests in which the URL contains "ourpartner.com". This rule uses the protocol, the subdomain and the third and fourth segments of the URL in the network request name.



You can temporarily cancel the application of a custom naming rule by clearing the **Enabled** checkbox in the custom rule configuration. In this case, the default naming rule is applied to requests that would have been named by the disabled custom rule. To remove the rule permanently, select the custom rule in the **Custom Naming Rules** list and click the **Delete** icon.

Create Mobile Exclude Rules

If there are certain types of requests that you do not want to monitor, create custom exclude rules for them based on the URL and/or the application name. Excluded network requests are not reported or counted toward the network request limit of 500 requests per controller application.

Create an Exclude Rule

1. From the Network Request tab, scroll down to the **Exclude Rules** section.
2. Click **Add**.
3. In the **Exclude Rule** dialog, enter a name for the exclude rule that you are creating.
4. Check the **Enabled** check box to enable the rule.
5. Select the check boxes and radio buttons and enter the match criteria for AppDynamics to use to name network requests.
6. Click **OK**.

You can temporarily cancel the application of an exclude rule by clearing the **Enabled** checkbox in the exclude rule configuration. To remove the rule permanently, select the exclude rule in the **Exclude Rules** list and click the **Delete** icon.

Change Priority of Rules

Rules are evaluated in the order that they appear in the include or exclude list. You can change the priority of the rules by dragging and dropping rules towards the top (higher priority) or towards the bottom of the list (lower priority). Custom rules are always evaluated before the default naming rule, beginning with the custom rule that has the highest priority.

Configure Mobile Network Request Thresholds

Related pages:

- Network Request Limits
- Network Requests

The Mobile Agent uses configurable thresholds to determine whether network request time is normal, slow, very slow or stalled. It uses these thresholds:

- To decide whether to create a mobile request snapshot
- For labeling network request experience in a network request snapshot

Default Network Request Thresholds

By default, the Mobile Agent uses these default values to determine whether a request is slow or stalled:

- **Slow:** Greater than 3 standard deviations
- **Very slow:** Greater than 4 standard deviations
- **Stall:** Greater than 45000 ms

You should configure these defaults to conform to your own criteria for your mobile applications. An absolute threshold rather than one based on the standard deviation is often more appropriate for mobile applications.

Configure Network Request Thresholds

1. From the **Mobile App Group Configuration** page, click the Settings tab.
2. In the **Thresholds for Slow End User Experience** section, set the thresholds for slow, very slow, and stalled in milliseconds or by standard deviations.
3. Click **Save**.

Configure Mobile Percentile Metrics

Parts of the Controller UI for Mobile RUM rely on the processing done by the Events Service, including some of the widgets in the **Mobile App Dashboard Overview**, **Network Requests Analyze**, and **Crash Analyze**.

For the Mobile App Dashboard, **Network Requests Analyze**, and **Crash Analyze**, you can choose widgets to display the metrics collected using either averages or percentiles.

A *percentile* is a measure that indicates a value below which a given percentage of values in a set falls: for example, the 99th percentile means that 99% of all values are below this level.

Using percentiles can be a good way to reduce the impact of extreme outliers in performance metrics, which can be useful in the often noisy environments of end-user experience monitoring. Percentiles also display in the **Metric Browser**.

You can:

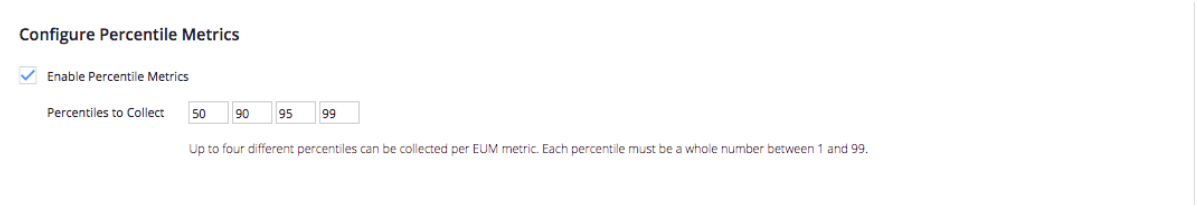
- Enable or disable percentile display of metrics.
- Set up to four different percentile levels to be applied to metrics.

Access Configure Percentile Metrics

From the **Configuration > Mobile App Group Configuration**, click the Settings tab and navigate to the **Configure Percentile Metrics** section.

Configure Percentile Metrics

You can change the percentiles which are used to evaluate data via the Events Service.



1. Check the box to enable percentile metric display.
2. Add up to four percentile levels to collect. Each value must be a whole number between 1 and 99.

If you change the percentiles to collect new values, it takes time for the recalculation to occur. If you review the **Metric Browser,** you will see metrics based on the old percentiles until the moment that you update the values, when they change to reflect the change.

Configure Which Network Requests Are Sent to the Event Service

Related pages:

- Network Request Limits

Your mobile app may make various kinds of network requests, and not all of them may be equally important to monitor in detail. For example, any requests to Google Analytics that your app may make are useful but probably aren't as important to analyze as the requests it makes to your backend.

To manage the impact on your overall Event Service usage, you can create rules which specify which of these network requests should be sent on to the Event Service, either by excluding a request entirely, including a particular request or a sample of that request types by percentage, or by simply allowing the request to be sent on.

The behavior follows this pattern:

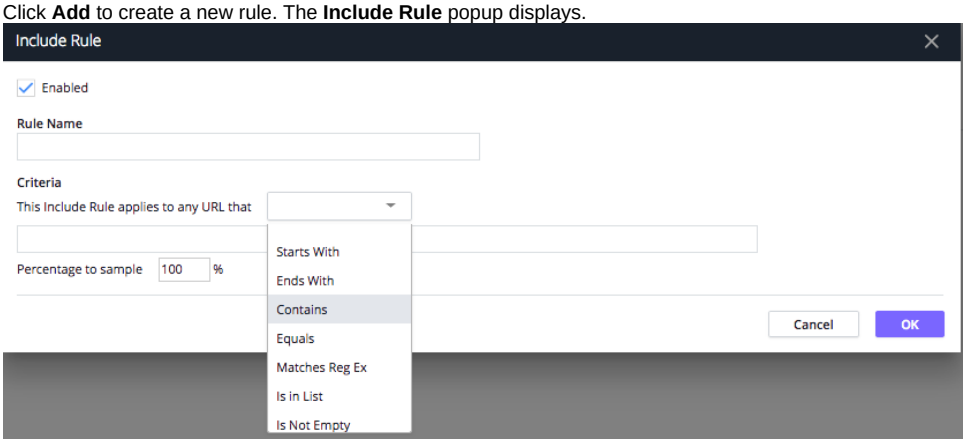
- If no rules are specified, data on all network requests are sent on.
- If exclude rules are specified, and a network request satisfies a rule, that data is *not* sent on.
- If include rules are specified, any network request that satisfies a rule is sent on, based on sampling defined by the percentage indicated in the rule.
- If both include and exclude rules are specified, a network request that satisfies an include rule but does *not* satisfy an exclude rule is sent on.

Access Network Requests Rules

From the **Mobile App Group Configuration** page, select the Event Service tab.

Configure Include Rules

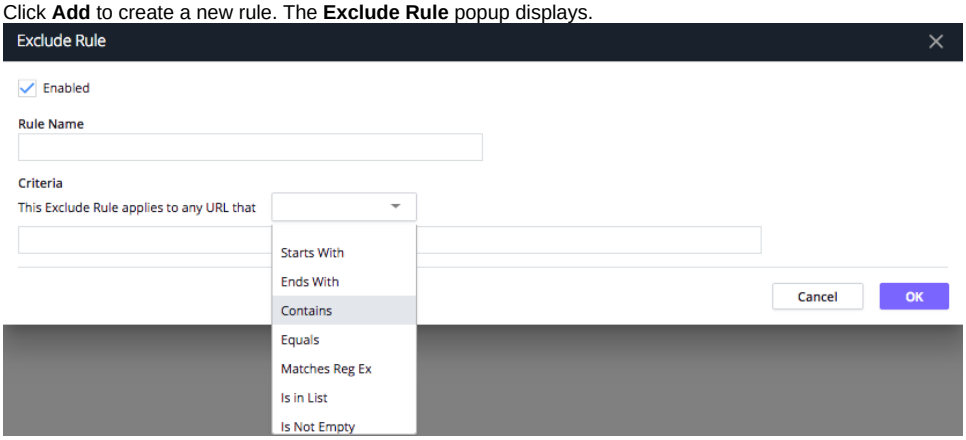
1. Click **Add** to create a new rule. The **Include Rule** popup displays.



2. Give your rule a display name.
3. Check **Enabled** to place the rule in force.
4. Specify the Network Request **URL** using any of the options in the dropdown.
5. If you want to sample this request type, select a percentage for sampling.
6. Click **OK**.

Configure Exclude Rules

1. Click **Add** to create a new rule. The **Exclude Rule** popup displays.



2. Specify a display name for the rule.
3. Check **Enabled** to place the rule in force.
4. Specify the Network Request **URL** using any of the options in the dropdown.
5. Specify the percentage of URLs to sample.
6. Click **OK**.

Change Priority of Rules

Rules are evaluated in the order that they appear in the include or exclude list. You can change the priority of the rules by dragging and dropping rules towards the top (higher priority) or towards the bottom of the list (lower priority). Custom rules are always evaluated before the default naming rule, beginning with the custom rule that has the highest priority.

Configure Request IP Address Storage - Mobile

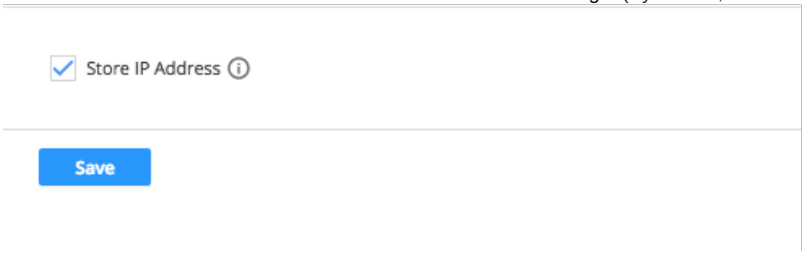
Related pages:

- Network Request Limits
- Network Requests

For security and privacy reasons, Mobile RUM does not store source IP addresses associated with network requests.

To have Mobile RUM store source IP addresses associated with network requests, following the instructions below.

1. From the **Mobile App Group Configuration** page, select the Settings tab.
2. Click the **Mobile Network Request Naming,** Thresholds & Percentiles tab.
3. Check the **Store IP Address** checkbox to enable IP address storage. (By default, the box is not checked.)



4. Click **Save**.

Configure Session Monitoring

Sessions begin when a user starts using your application and ends after a configurable period of user inactivity. Increasing the period of user inactivity enables sessions to capture more user events, but this could impact the session limits of your account. See Mobile Sessions.

Access Session Monitoring

1. Open the mobile application in which you are interested.
2. From the left-hand navigation menu, select **Configuration**.
3. Click **Mobile App Group Configuration >**.
4. Select the Settings tab.
5. Find the **Configure Session Monitoring** section.

Set Inactivity Timeout

From **Configure Session Monitoring:**

1. Set the number of minutes for the **Session Inactivity Timeout** field.
2. Click **Save**.

Configure Mobile Crash Alerts

New crashes are shown in the **Events** widget, and you can configure Mobile RUM to send you alerts when new crashes occur. See Crash Alerts.

To restrict the number of alerts for new crashes, follow these instructions configure the number of crashes that must occur before you are alerted.

Access Configure Mobile Crash Alerts

1. Open the mobile application in which you are interested.
2. On the left navigation bar, select **Configuration**.
3. Click **Mobile App Group Configuration >**.
4. Select the Settings tab.
5. Navigate to the **Configure Mobile Crash Alerts** section.

Set Threshold for New Crash Alerts

From **Configure Mobile Crash Alerts:**

1. Set the threshold for new crash alerts. The default value is 1.
2. Click **Save**.

Configure Application Not Responding Thresholds

The Mobile Agent uses configurable thresholds to set the severity level for application-not-responding (ANR) errors. The severity levels for ANRs are **warni ng** and **critical,** and these levels can be used to set health rules and receive alerts for health rule violations.

You can use Controller UI to configure thresholds for warning and critical severity levels. These thresholds will be propagated to the Mobile Agents without the need to redeploy the application.

Default Network Request Thresholds

The Mobile Agent uses the following default values to determine the severity level:

- **Warning:** greater than 3000 ms
- **Critical:** greater than 5000 ms

You should set custom thresholds best suited for your mobile applications.

Configure Application Not Responding Thresholds

1. From the **Mobile App Group Configuration** page, click the Settings tab.
2. In the **Configure Application Not Responding Thresholds** section, set the thresholds for **Warning Threshold** and **Critical Threshold** in milliseconds.
3. Click **Save**.

Instrument iOS Applications

With the iOS 14 release (supported by iOS Agent 20.10.0), Apple introduced a new data collection policy. See iOS Data Collection Disclosure.

Before you can monitor your iOS application, you will need to instrument your application to enable the iOS Agent to collect mobile metrics.

After you have set up and accessed Mobile RUM, follow these instructions:

1. Install the iOS SDK
2. Instrument an iOS Application
3. Customize the iOS Instrumentation (Optional)
4. Troubleshoot the iOS Instrumentation (Optional)

Install the iOS SDK

Related pages:

- Instrument an iOS Application
- Customize the iOS Instrumentation
- Troubleshoot the iOS Instrumentation

With the iOS 14 release (supported by iOS Agent 20.10.0), Apple introduced a new data collection policy. See iOS Data Collection Disclosure for details.

You can install the iOS SDK using CocoaPods or by manually downloading and installing it. We recommended that you use CocoaPods to install the iOS SDK because it handles the dependencies, the build settings, and simplifies upgrading.

Follow the instructions for your preferred installation method:

- CocoaPods Install
- Manual Install

iOS SDK Install Requirements

To install the iOS SDK, you must be running Xcode >= 7.

CocoaPods Install

1. Add the line below to a `target` block in your Podfile:

   ```
   pod 'AppDynamicsAgent'
   ```

   For example:

   ```
   platform :ios, '8.0'
   use_frameworks!

   target 'YourApp' do
     pod 'AppDynamicsAgent'
   end
   ```

2. In your project directory, run this command:

   ```
   pod install
   ```

Manual Install

To manually install the iOS SDK, follow these steps:

Download the iOS SDK

1. Navigate to the AppDynamics Download page.
2. From the **APP AGENT** list, check the **Mobile RUM Agent - iOS** checkbox.
3. Click **Download** for the latest iOS Agent that will appear in the **Releases** results. This downloads a file named `iOSAgent-<version>.zip`.

Add the Framework to the App

You can only use a Swift framework if that framework was built with the exact same version of Swift as the Xcode compiling your app.

1. Unzip `iOSAgent-<version>.zip`.
2. Import the `ADEUMInstrumentation.framework` folder into your project Xcode.

If you don't see that Xcode has automatically added the correct path(s), add a project-relative path to your frameworks.

Add Required Libraries

The AppDynamics iOS Agent requires these libraries:

- `SystemConfiguration.framework`
- `CoreTelephony.framework`
- `libz.dylib` or `.tbd`

To add the libraries:

1. Select the target that builds your app in Xcode.
2. Select the Build Phases tab.
3. Expand the **Link Binary With Libraries** section.
4. If any of the above libraries are not listed:
    - Click the **+** button.
    - Locate the missing library in the list.
    - Click **Add**.

    Repeat this step for each missing library.

Set the -ObjC Flag

You also need to add the `-ObjC` flag to Other Linker Flags.

1. Select your project in the **Project Navigator**.
2. In the target list, select the target that builds your application.
3. Select the Build Settings tab.
4. Scroll to **Linking** and open.
5. Go to **Other Linker Flags** and double-click to open the popup.
6. If the `-ObjC` flag is not in your list, click **+** and add it.

The `-ObjC` flag is necessary because the iOS Agent defines categories with methods that can be called at runtime, and by default, these methods are not loaded by the linker. As a result, you'll get an "unrecognized selector" runtime exception. The use of `-ObjC` ensures the methods will be loaded.

Upgrade the iOS SDK

Upgrade with CocoaPods

1. In your project directory, run this command: `$ pod update`
2. Rebuild.

Upgrade Manually

To pick up new features or to get crucial bug fixes you want to upgrade the iOS SDK in your app.

1. Download the updated SDK.
2. Replace the `.framework` file using the updated SDK.
3. Rebuild your app.

Instrument an iOS Application

Follow these steps to get your EUM App Key and instrument your iOS apps.

Get Your Application Key

After you completed the **Getting Started Wizard**, you were given an EUM App Key. You will need this key when you modify the source code. In some cases, multiple mobile applications can share the same key.

If you have completed the **Getting Started Wizard**, but don't have your EUM App Key, see Get Your Application Key.

Initialize the Agent

Generate a dSYM File

To enable the agent to provide human-readable information in the crash snapshots that are produced if the application crashes, compile with the `DWARF with dSYM` file option to generate a debug symbols (dSYM) file for the application. For more details about why you would want to do this, see Get Human-Readable Crash Snapshots.

1. In Xcode, select your project in the **Project Navigator**.
2. In the target list, select the target that builds your application.
3. Select the **Build Settings** tab.
4. In the **Build Options** section, make sure that the **Debug Information Format** is set to `DWARF with dSYM File`.
5. Rebuild the Xcode project.

Monitor Crashes with the dSYM File

This step is optional but highly recommended if you plan to monitor crashes. AppDynamics needs the dSYM file for the application to produce human-readable stack traces for crash snapshots.

For instructions, see Upload the dSYM File.

Customize the Instrumentation (Optional)

The `ADEumInstrumentation` class has additional methods to allow you to extend the kinds of data you can collect and aggregate using AppDynamics. There are five basic kinds of extensions that you can create:

- Custom timers: any arbitrary sequence of events within your code timed, even spanning multiple methods
- Custom metrics: any integer-based data you wish to collect
- User data: any string key/value pair you think might be useful
- Information points: how often a single method is invoked, and how long it takes to run
- Breadcrumbs: context for a crash

See Customize the iOS Instrumentation.

Configure the iOS Agent for On-Premises Deployments (Optional)

By default, the agent is configured to send its beacons to the EUM Cloud, which is an instance of the EUM Server running on AWS. If you wish to instrument your app in an environment that is using an on-premises version of the EUM Server, you need to modify the URL to which the agent sends its beacons. You do this using the `ADEumAgentConfiguration` object to set the Collector URL and the Screenshot Service URL to your on-premises EUM Server URL.

> The iOS Agent knows which path to use to make calls to different services (Collector/Screenshot Service). For example, if the EUM Server URL is `https://myEUMServerURL.com:7001`, the iOS Agent will know to use `https://myEUMServerURL.com:7001/eumcollector` to make requests to the EUM Collector. By specifying the Collector URL, you will *not* be able to use the SaaS deployment of the EUM Cloud for the Screenshot Service.

To get the EUM Server URL:

1. Open the Administration Console.
2. From the left navigation bar, click **Controller Settings**.

3. In the search field, enter **eum.beacon.host** or **eum.beacon.https.host** if you're using HTTPS.
4. Copy the value for the configuration. This is your EUM Server URL.

The code examples below show how to set the Collector URL and Screenshot Service URL using Objective-C and Swift.

Enable HTTP to Send Beacons to On-Premises EUM Servers

If you use an on-premises EUM Server and you wish to use HTTP to dispatch your beacons to the EUM Server, starting with iOS 9 you need to set a flag in your app's `info.plist` file to allow it to use the unsecured connection. By default, HTTPS is enforced in all iOS 9 applications by App Transport Security (ATS), and the iOS Agent complies with ATS when used with the EUM Cloud.

Customize the iOS Instrumentation

Related pages:

- Install the iOS SDK
- Instrument an iOS Application
- iOS SDK Documentation

Once you have instrumented your iOS application with the Mobile iOS SDK, you can also use the APIs exposed by the SDK to customize the data for your app that appears in the Controller UI.

The following sections show you how to use the iOS SDK to customize your instrumentation.

Because the agent stores data about events in a local buffer before reporting the information, you are recommended to use the APIs with discretion.

Collect Additional Types of Data

You can use methods available in the ADEUMInstrumentation class to collect six additional types of data:

Type of Data	Description	Specifications	Where Data is Displayed
Info points	How often a method is invoked, and how long it takes to run.	• Data is numeric • Names must consist of alphanumeric characters and/or spaces	• Metric Browser • Custom Data • Network Request Snapshots • Mobile Sessions • Network Request Analyze
Custom timers	Any arbitrary sequence of events within your code timed, even spanning multiple methods.	• Data is numeric • Metric names must consist of alphanumeric characters and/or spaces	• Metric Browser • Custom Data
Custom metrics	Any integer-based data you wish to collect.	• Data is numeric • Metric names must consist of alphanumeric characters and/or spaces	• Metric Browser • Custom Data
User data	Any string key/value pair you think might be useful.	• Data can be any type • Metric names have no restrictions	• Network Request Snapshots • Mobile Sessions • Network Request Analyze • Crash Snapshots
Breadcrumbs	The context for a crash.	• Data can be any data type • Metric names have no restrictions	• Network Request Snapshots • Mobile Sessions • Network Request Analyze • Crash Snapshots

User interaction	Capture when users press buttons, click on lists, and select text.	• Data can be any data type • Metric names have no restrictions	• Network Request Snapshots • Mobile Sessions • Network Request Analyze

When you have set up additional data types, the Mobile Agent packages that data in a mobile beacon. Normally, the beacon is transmitted when the instrumented app sends an HTTP request or when the app is restarted following a crash, but if custom data has been collected and neither of those events has occurred for at least five minutes, the custom data is sent at that time.

Info Points

Information points allow you to track how your own code is running. You can see how often a method is invoked, and how long it takes to run, by using `beginCall` and `endCall`, something like the following:

If an exception is thrown, it is also reported. This information appears in the **Custom Data** view in the Controller UI.

Custom Timers

Custom timers allow you to time any arbitrary sequence of events within your code, even spanning multiple methods, by using `startTimer` and `stopTimer`. For example, to track the time a user spends viewing a screen, the instrumentation could look like this:

This information appears in the **Custom Data** view of the Controller UI.

Calling `startTimerWithName` again with the same name value resets a named timer.

Custom Metrics

Any integer-based data can be passed to the agent. The first parameter to the `report.MetricWithName` call is the name you want the metric to appear under in the Controller UI. The metric name should only contain alphanumeric characters and spaces. Illegal characters are replaced by their ASCII hex value.

Reporting a metric called "My custom metric", for example, would look something like this:

```
[ADEumInstrumentation reportMetricWithName:@"My custom metric" value:<#VALUE HERE#>];
```

This information appears in the **Custom Data** view of the Controller UI.

User Data

You can set any string key/value pair you think might be useful. The first parameter to the `setUserData` call is the key you want to use, which must be unique across your application. The second is the value that you want to be assigned to the key.

For example:

This information is available in **Network Request Analyze** and is added to any crash snapshots that may be taken. Keys and values are limited to 2048 characters each.

You can also set user data with values of other types (Long, Boolean, Double, Date) using the following methods:

- `setUserDataLong:value`
- `setUserDataBoolean:value:`
- `setUserDataDouble:value:`
- `setUserDataDate:value:`

Breadcrumbs

Breadcrumbs allow you to situate a crash in the context of your user's experience. Set a breadcrumb when something interesting happens. If your application crashes at some point in the future, the breadcrumb will be displayed along with the crash report.

There are two ways of leaving breadcrumbs:

- Crash Reports Only
- Modal

Using this method means that breadcrumbs are reported in crash reports only.

```
+ (void)leaveBreadcrumb:(NSString *)breadcrumb
```

Using this method lets you fine tune where the breadcrumbs are reported, either only in crash reports or in crash reports *and* sessions.

```
+ (void)leaveBreadcrumb:(NSString *)breadcrumb mode:(ADEumBreadcrumbVisibility)mode
```

Where `mode` is either:

- `ADEumBreadcrumbVisibilityCrashesOnly`
- `ADEumBreadcrumbVisibilityCrashesAndSessions`

If the `breadcrumb` is over 2048 characters, it is truncated. If it is empty or `nil`, no breadcrumb is recorded. Each crash report displays the *most recent* 99 breadcrumbs.

Capture User Interactions

You can enable the iOS Agent to track certain UI events triggered by user interactions. Once user interactions have been captured, you can sort sessions by UI event and view UI events in the timeline of the session waterfall.

You can capture when users do one or all of the following:

- press buttons
- select table cells
- select text fields
- select text views

Security and Privacy Concerns

The interaction capture mode is disabled by default for security and privacy reasons as user interactions may contain sensitive information. Moreover, this potential security and privacy issue may be compounded if you enable both the capturing of UI interactions and screenshots.

Enable User Interaction Capture Mode

To enable user interaction capture mode, you assign the capture mode to the property `interactionCaptureMode` of the `ADEumAgentConfiguration` object. The instrumentation code example below configures the iOS Agent to capture all the supported types of user interactions.

```
ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc] initWithAppKey: <#EUM_APP_KEY#>];
config.interactionCaptureMode = ADEumInteractionCaptureModeAll;
[ADEumInstrumentation initWithConfiguration:config];
```

You can also configure the iOS Agent to only capture one type of user interaction:

```
ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc] initWithAppKey: <#EUM_APP_KEY#>];
config.interactionCaptureMode = ADEumInteractionCaptureModeButtonPressed;
[ADEumInstrumentation initWithConfiguration:config];
```

Configure and Take Screenshots

Mobile screenshots are enabled by default. The `takeScreenshot()` function limits screenshots to a maximum of 1 per 10s.

You can configure the Controller UI to automatically take screenshots or use the iOS SDK to manually take a screenshot as shown below:

Disable Screenshots

You can disable screenshots from the Controller UI or with the iOS SDK. To disable screenshots with the iOS SDK, set the property `screenshotsEnable` of the `ADEumAgentConfiguration` object to `NO` for Objective-C and `false` for Swift as shown below.

Block and Unblock Screenshots

You can also use the iOS SDK to block screenshots from being taken during the execution of a code block. This just temporarily blocks screenshots from being taken until you unblock screenshots. This enables you to stop taking screenshots in situations where users are entering personal data, such as on login and account screens.

The `ADEumInstrumentation` class provides the methods `blockScreenshots` and `unblockScreenshots` to block and unblock screenshots. If screenshots are disabled through the property `screenshotsEnabled` of the `ADEumAgentConfiguration` object or through the Controller UI, these methods have no effect. You can also call `screenshotsBlocked` to check if screenshots are being blocked.

The following example demonstrates how you could use the API to block and unblock screenshots for a user login.

Disable the Agent to Stop Sending User Data to the Collector

You can disable the agent to stop sending all data to the collector while the agent is initialized and running. For example, you can disable the agent if your app has an option for users to opt-out of monitoring for privacy reasons.

`shutdownAgent`

The `shutdownAgent` call stops outgoing data to the collector, and does not persist data on the device.

- The call only stops the traffic out of the agent.
- Once the agent has been initialized, the call cannot be removed, and a license will have been consumed.
- If you want to make this state permanent for a device, add code in UserDefaults to save the state and use that flag to conditionally initialize the agent in your code.

`restartAgent`

To re-enable the agent and reverse `shutdownAgent`, use `restartAgent`.

- This call will respect the server side calls that can remotely shutdown the agent in a similar way.
- The call is only in effect while the app is running.
- The call will be ignored if the agent has been remotely disabled.
- If the call is removed from memory and the app restarts, or the device is rebooted, the agent will be initialized as normal.

Add a Crash Reporting Callback

You may want to make crash report information that Mobile RUM collects available to other parts of your code, for example, to Google Analytics, if you are using it. To enable you to pass on summary crash information, you can set up a crash report runtime callback. To get a callback when the iOS Agent detects and then reports a crash, you need to implement the following protocol in your code:

```
@protocol ADEumCrashReportCallback <NSObject>

- (void)onCrashesReported:(NSArray<ADEumCrashReportSummary *> *)crashReportSummaries;

@end
```

This callback is invoked on your app's UI thread, so any significant work should be done on a separate work thread.

Each `ADEumCrashReportSummary` passed in has the following properties:

```
@interface ADEumCrashReportSummary : NSObject

/** Uniquely defines the crash, can be used as key to find full crash report. */
@property (nonatomic, readonly) NSString *crashId;

/** The exception name, may be `nil` if no `NSException` occured. */
@property (nonatomic, readonly) NSString * ADEUM_NULLABLE exceptionName;

/** The exception reason, may be `nil` if no `NSException` occured. */
@property (nonatomic, readonly) NSString * ADEUM_NULLABLE exceptionReason;

/** The Mach exception signal name */
@property (nonatomic, readonly) NSString *signalName;

/** The Mach exception signal code */
@property (nonatomic, readonly) NSString *signalCode;

@end
```

If you are sending the information to another analytics tool, such as Google Analytics, it is best to include all five properties:

- `exceptionName` and `exceptionReason` are optional and useful for a quick identification of what the crash is. These are only present if the crash cause occurred within an exception reporting runtime, such as Objective-C.
- `signalName` and `signalCode` are useful for quick identification of the crash. These are from the system and are independent of the runtime.
- For additional information, `crashId` can be used to look up the crash in the AppDynamics Controller UI.

For example, to print the crash information to iOS's logger, you could implement an `ADEumCrashReportCallback` class like this:

```
// assumes the containing object has "adopted" the protocol
- (void)onCrashesReported:(NSArray<ADEumCrashReportSummary *> *)summaries {
    for (ADEumCrashReportSummary *summary in summaries) {
        NSLog(@"Crash ID: %@", summary.crashId);
        NSLog(@"Signal: %@ (%@)", summary.signalName, summary.signalCode);
        NSLog(@"Exception Name:\n%@", summary.exceptionName);
        NSLog(@"Exception Reason:\n%@", summary.exceptionReason);
    }
}
```

You set the object that implements the `ADEumCrashReportCallback` protocol during agent configuration:

```
ADEumAgentConfiguration *config = [ADEumAgentConfiguration new];
config.crashReportCallback = myCrashReportCallback;
```

Your callback is invoked, on the main/UI thread, if a crash from a previous run is detected and collected. See the latest iOS SDK documentation for more information.

Disable Crash Reporting

Crash reporting is enabled by default, but you can manually disable crash reporting through the instrumentation configuration. If you are using other crash reporting tools, you might disable crash reporting to minimize conflicts and optimize the crash report results.

You can disable crash reporting by configuring the instrumentation with the `crashReportingEnabled` property as shown in the following code example.

Report Errors and Exceptions

You can report exceptions using the method `reportError` from the `ADEumInstrumentation` class. Reported exceptions will appear in session details.

The method can have the following two signatures:

Objective-C Function Signature	Description

`(void)reportError:(NSError *)error withSeverity (ADEumErrorSeverityLevel) severity;`	Use this signature to report errors, set the severity level of the issue, and send the stack trace. This function signature sends the stack trace by default. If you don't want to send the stack trace, use the function signature below with the additional argument `andStackTrace` and set its value to `NO`.
`(void)reportError:(NSError *)error withSeverity:(ADEumErrorSeverityLevel) severity andStackTrace:(BOOL)stacktrace;`	Use this signature to report errors, set the severity level of the issue, and explicitly specify whether the stack trace should be included. If you include the stack trace with the reported error by setting `stacktrace` to `YES`, you can view the stack trace in the **Code Issues Details** dialog. To report the error without the stack trace, set `stacktrace` to `NO`.

Severity Levels

You can also set one of the following severity levels for an issue. With the severity level, you can filter errors in the **Code Issues Dashboard** or **Code Issues Analyze**.

- `ADEumErrorSeverityLevelInfo`
- `ADEumErrorSeverityLevelWarning`
- `ADEumErrorSeverityLevelCritical`

Examples of Reporting Errors

The example below uses the API to report possible exceptions and set the severity level to `ADEumErrorSeverityLevelCritical` for a failed attempt to perform a file operation.

You can also create and report custom errors with the following. Note that because `reportError` is not passed the argument `andStackTrace`, by default, the stack trace is automatically included with the error.

Configure Application-Not-Responding (ANR) Detection

By default, the iOS Agent does not detect ANR issues, and when ANR detection is enabled, the ANR issues are reported without stack traces. You must manually enable ANR detection and set a flag to include stack traces through the iOS Agent configuration. For more information about ANR monitoring, see Code Issues. To specify thresholds for ANR issues, see Configure Application Not Responding Thresholds.

Enable ANR Detection

You enable the detection of ANR issues by configuring the instrumentation with the `anrDetectionEnabled` property as shown below.

Report Stack Traces with ANRs

In addition to enabling ANR detection, you set the property `anrStackTraceEnabled` to `YES` (Objective-C) or `true` (Swift) to report stack traces with the ANRs.

Configure Hybrid Application Support

By default, the iOS Agent instruments iOS WKWebViews, but does not collect and report Ajax calls. See Hybrid Application Support for an overview and an explanation of how it works.

You can configure the static or runtime configuration to disable hybrid application support or modify its behavior. The sections below show you how to change the defaults for hybrid support through either runtime or static configuration.

Runtime Configuration for Hybrid Application Support

The code example below disables the injection of the JavaScript Agent. By disabling the injection, the WKWebViews in your application will not be instrumented and Ajax calls will not be reported.

```
ADEumAgentConfiguration *adeumAgentConfig = [[ADEumAgentConfiguration alloc] initWithAppKey: <#EUM_APP_KEY#>];
// Disable the JavaScript Agent Injection
adeumAgentConfig.jsAgentEnabled = NO;
[ADEumInstrumentation initWithConfiguration:adeumAgentConfig];
```

The JavaScript Agent injection is enabled by default. To also enable the collection and reporting of Ajax calls:

```
ADEumAgentConfiguration *adeumAgentConfig = [[ADEumAgentConfiguration alloc] initWithAppKey: <#EUM_APP_KEY#>];
// Enable the collection and reporting of Ajax calls
adeumAgentConfig.jsAgentAjaxEnabled  = YES;
[ADEumInstrumentation initWithConfiguration:adeumAgentConfig];
```

Static Configuration for Hybrid Application Support

You should use static configuration for the following reasons:

- force the instrumentation of WKWebViews and/or Ajax calls (override the runtime configuration)
- disable hybrid support and override the runtime configuration
- set the URL to your self-hosted JavaScript Extension file

The table below describes the supported properties and provides the default value for the `info.plist` file.

Property	Default Value	Description
`serverJsAgentEnabled`	true	If the client receives a `false` for this flag, then the JavaScript Agent will be disabled. Thus, the WKWebViews and Ajax requests will not be monitored. The injection occurs during the creation of a new WKWebView. So, if a WKWebView is created when this flag is set to `false`, that particular WKWebView won't be instrumented even if the flag is subsequently set to `true`.
`ForceWebviewInstrumentation`	false	When set to `true`, the iOS Agent will inject the JavaScript Agent into the WKWebViews regardless of the runtime configuration.
`ForceAjaxInstrumentation`	`true`	When set to `true`, Ajax operations will always be collected and reported regardless of the runtime configuration.
`ADRUMExtUrlHttp`	http://cdn.appdynamics.com	The JavaScript Agent consists of two components: the base JavaScript Agent and the JavaScript Agent extension. The base JavaScript Agent is built into the Mobile Agent binary and injected according to the rules above. After initialization, the JavaScript Agent fetches the JavaScript Agent extension from the URLs specified by these properties.
`ADRUMExtUrlHttps`	https://cdn.appdynamics.com/	

Example Configuration

The example `info.plist` below forces the instrumentation of WKWebViews (overriding the runtime configuration), but does not force the collection and reporting of Ajax requests. The configuration also sets the URL where the JavaScript Extension file is obtained.

```
<plist>
  <dict>
    ...
    <key>ADEUM_Settings</key>
    <dict>
      <key>ForceWebviewInstrumentation</key>
      <true/>
      <key>ForceAjaxInstrumentation</key>
      <false/>
      <key>ADRUMExtUrlHttp</key>
      <string>http://<your-domain>/adrum.cdn</string>
      <key>ADRUMExtUrlHttps</key>
      <string>https://<your-domain>/adrum.cdn</string>
    </dict>
    ...
 </dict>
</plist>
```

Programmatically Control Sessions

By default, a mobile session ends after a period of user inactivity. For example, when a user opens your application, the session begins and only ends after the user stops using the app for a set period of time. When the user begins to use the application again, a new session begins.

Instead of having a period of inactivity to define the duration of a session, however, you can use the following API to programmatically control when sessions begin and end:

```
- (void)startNextSession
```

When you call the method `startNextSession` from the `ADEumInstrumentation` class, the current session ends and a new session begins. The API enables you to define and frame your sessions so that they align more closely with business goals and expected user flows. For example, you could use the API to define a session that tracks a purchase of a product or registers a new user.

Excessive use of this API will cause sessions to be throttled (excessive use is >10 calls per minute per iOS Agent, but is subject to change). When not using the API, sessions will fall back to the default of ending after a period of user inactivity.

Example of a Programmatically Controlled Session

In the example below, the current session ends and a new one begins when the check out is made.

Start and End Session Frames

You can use the `SessionFrame` API to create session frames that will appear in the session activity. Session frames provide context for what the user is doing during a session. With the API, you can improve the names of user screens and chronicle user flows within a business context.

Use Cases

The following are common use cases for the `SessionFrame` API:

- One `ViewController` performs multiple functions and you want more granular tracking of the individual functions.
- A user flow spans multiple ViewController or user interactions. For example, you could use the API to create the session frames "Login", "Product Selection", and "Purchase" to chronicle the user flow for purchases.
- You want to capture dynamic information based on user interactions to name session frames, such as an order ID.

SessionFrame API

The table below lists the three methods you can use with session frames. In short, you start a session frame with `startSessionFrame` and then use the returned `ADeumSessionFrame` object to rename and end the session frame.

Session Frame Example

In the following example, the `SessionFrame` API is used to track user activity during the checkout process.

Configure the Agent for Custom App Names

By default, AppDynamics automatically detects the name of your application. The application name is a string form of the bundle ID. Thus, if the bundle ID is `com.example.appdynamics.HelloWorld`, the application name will be "com.example.appdynamics.HelloWorld".

There may be cases, however, where you deploy essentially the same app binary with different bundle IDs to various regional app stores. To make sure all the data belonging to one app is collected and displayed together, despite varying bundle IDs, you can set a common name by giving the apps a custom name. To do this, set the application name property in the `ADEumAgentConfiguration` instance that you use to set up `ADEumInstrumentation`. See the latest iOS SDK documentation for more information.

```
@property (nonatomic, strong) NSString *applicationName;
```

Configure the Agent for Ignoring Some HTTP Requests

In some cases, HTTP requests using NSURL are used for internal purposes in an application and do not represent actual network requests. Metrics created based on these requests are not normally useful in tracking down issues, so preventing data on them from being collected can be useful. To ignore specific NSURL requests, set the excluded URL patterns property in the `ADEumAgentConfiguration` instance that you use to set up `ADEumInstrumentation`. Use the simplest regex possible. See the latest iOS SDK documentation for more information.

```
@property (nonatomic, strong) NSSet * excludedUrlPatterns;
```

Use the Agent with a Custom HTTP Library

The iOS Agent automatically detects network requests when the underlying implementation is handled by either by the `NSURLConnection` or the `NSURLSession` classes. This covers the great majority of iOS network requests. In some cases, however, mobile applications use custom HTTP libraries.

- To have the iOS Agent detect requests from a custom library, add request tracking code to your application manually, using the `ADEumHTTPRequestTracker` class.
- To set headers to allow correlation with server-side processing, use the `ADEumServerCorrelationHeaders` class.
- To configure the agent *to use your custom library* to deliver its beacons over HTTP, use the `ADEumCollectorChannel` protocol and the `ADEumAgentConfiguration` class.

Add Request Tracking

To add request tracking manually, you tell the agent when the request begins and when it ends. You also set properties to tell the agent the status of the response.

Start and complete tracking a request

To begin tracking an HTTP request, call the following method immediately before sending the request.

> ⚠ You must initialize the agent using one of the `ADEumInstrumentation`'s `initWithKey` methods before using this method.

```
@interface ADEumHTTPRequestTracker : NSObject
...
+ (ADEumHTTPRequestTracker *)requestTrackerWithURL:(NSURL *)url;
```

Where `url` is the URL being requested. This parameter must not be `nil`.

To complete tracking an HTTP request, immediately after receiving a response or an error, set the appropriate properties on the tracker object and call the following method to report the outcome of the request back to the agent. You should not continue to use this object after calling this method. To track another request, call `requestTrackerWithURL` again.

```
- (void)reportDone;
```

Properties to be set

The following properties should be set on the `requestTrackerWithURL` object to describe to the agent the results of the call.

```
@property (copy, nonatomic) NSError *error;
```

Indicates the failure to receive a response, if this occurred. If the request was successful, this should be `nil`.

```
@property (copy, nonatomic) NSNumber *statusCode;
```

Reports the HTTP status code of the response, if one was received.

- If a response was received, this should be an integer.
- If an error occurred and a response was not received, this should be `nil`.

```
@property (copy, nonatomic) NSDictionary *allHeaderFields;
```

Provides a dictionary representing the keys and values from the server's response header. The format of this dictionary should be identical to the `allHTTPHeadersFields` property of `NSURLRequest`. The dictionary elements consist of key/value pairs, where the key is the header key name and the value is the header value.

If an error occurred and a response was not received, this should be `nil`.

Example:

Given a request snippet like this:

```
- (NSData *)sendRequest:(NSURL *) url error:(NSError **)error {
      // implementation omitted
      NSData *result = nil;
      if (errorOccurred) {
          *error = theError;
      } else {
          result = responseBody;
      }
      return result;
  }
```

Adding the tracker could look something like this:

```
- (NSData *)sendRequest:(NSURL *)url error:(NSError **)error {
      ADEumHTTPRequestTracker *tracker = [ADEumHTTPRequestTracker requestTrackerWithURL:url];
      // implementation omitted
      NSData *result = nil;
      if (errorOccurred) {
          *error = theError;
          tracker.error = theError;
      } else {
          tracker.statusCode = theStatusCode;
          tracker.allHeaderFields = theResponseHeaders;
          result = responseBody;
      }
      [tracker reportDone];
      return result;
  }
```

Enable Server-Side Correlation

To enable correlation between your request and server-side processing, add specific headers to outgoing requests that the server-side agent can detect and return the headers obtained from the server-side agent in the response to make them available to the iOS Agent.

This is done automatically for standard HTTP libraries.

```
@interface ADEumServerCorrelationHeaders : NSObject
+ (NSDictionary *)generate;
@end
```

You must:

1. Call the `generate` method and set the generated headers *before* sending a request to the backend.
2. Report back the response headers, using the allHeaderFields property shown above.

Configure Agent to Use Custom HTTP Library

The iOS Agent uses HTTP to deliver its beacons. To have the agent use your custom HTTP library for this purpose, do the following.

1. Implement a class that conforms to this protocol:

```
/**
* Protocol for customizing the connection between the agent SDK and the collector.
*/
@protocol ADEumCollectorChannel <NSObject>

/**
* Sends a request synchronously and returns the response received, or an error.
*
* The semantics of this method are exactly equivalent to NSURLConnection's
* sendSynchronousRequest:returningResponse:error: method.
*
* @param request The URL request to load.
* @param response Out parameter for the URL response returned by the server.
* @param error Out parameter used if an error occurs while processing the request. May be NULL.
*/
- (NSData *)sendSynchronousRequest:(NSURLRequest *)request returningResponse:(NSURLResponse **)response
error:(NSError **)error;
@end
```

2. Set the `collectorChannel` property in `ADEumAgentConfiguration` before initializing `ADEumInstrumentation`, passing in an instance of your class that implements `ADEumCollectorChannel`. See the latest iOS SDK documentation for more information.

```
@property (nonatomic, strong) id<ADEumCollectorChannel> collectorChannel;
```

Transform URLs for Network Requests

When your application makes network requests, you may not want to report URLs containing sensitive information to the EUM Server. You can instead transform the network request URL before reporting it or ignore it altogether.

To do so:

1. Implement a network request callback that modifies or ignores specific URLs.
2. Register the network request callback in the initialization code.

Implement the Network Request Callback

The callback that modifies or ignore specific URLs is an implementation of the protocol below. The callback method networkRequestCallback is synchronous, so it is recommended that you return from the function quickly.

```
- (BOOL)networkRequestCallback:(ADEumHTTPRequestTracker *)networkRequest
```

Transforming URLs

The `networkRequestCallback` method, in general, should follow the steps below to transform URLs:

1. Identify specific URLs using techniques such as regex or pattern matching.
2. Modify the `url` property of the `ADEumHTTPRequestTracker` object. (Modifying other properties of the `ADEumHTTPRequestTracker` object will be ignored.)
3. Assign a valid URL to the `url` property.
4. Return `YES` (Objective-C) or `true` (Swift).

The first step is optional as you could choose to transform the URLs of all network requests.

In general, however, you would want to identify and transform URLs that contain sensitive information as implied in the example below.

Ignoring URLs

If the `networkRequestCallback` method returns false, the beacon is dropped. The general process for ignoring beacons is as follows:

1. Identify specific URLs using techniques such as regex or pattern matching.
2. Return `false`.

You could theoretically ignore all network requests by having the callback `networkRequestCallback` always return `NO` (Objective-C) or `false` (Swift):

In general, though, you would identify network requests that you didn't want to monitor and return `NO` (Objective-C) or `false` (Swift) to ignore the network request as implied by this example.

Register the Callback

After implementing the callback, you register the object implementing the protocol method in the initialization code as shown below. When the iOS Agent is ready to create a network request beacon, it will first call the callback with an `ADEumHTTPRequestTracker` object.

Enable Logging and Set Logging Level

You use the method `loggingLevel` to enable and set the logging level. You can set logging to one of the following levels:

- `ADEumLoggingLevelOff`
- `ADEumLoggingLevelAll`
- `ADEumLoggingLevelVerbose`
- `ADEumLoggingLevelDebug`
- `ADEumLoggingLevelInfo`
- `ADEumLoggingLevelWarn`
- `ADEumLoggingLevelError`

Use verbose, all, and debug levels of logging only for troubleshooting and be sure to turn off for production.

Examples:

iOS SDK Documentation

See the latest iOS SDK documentation or the previous versions listed below:

- https://sdkdocs.appdynamics.com/ios-sdk/21.5/html/
- https://sdkdocs.appdynamics.com/ios-sdk/21.2/html/
- https://sdkdocs.appdynamics.com/ios-sdk/20.12/html/
- https://sdkdocs.appdynamics.com/ios-sdk/20.10/html/
- https://sdkdocs.appdynamics.com/ios-sdk/20.8/html

- https://sdkdocs.appdynamics.com/ios-sdk/2020.3/html

Upload the dSYM File

Related pages:

- Manage the dSYM Files with Bitcode Enabled
- Troubleshoot the iOS Instrumentation

AppDynamics needs the dSYM file for the application to produce human-readable stack traces for crash snapshots. For details about why you should do this, see Get Human-Readable Crash Snapshots.

If you update the application, you need to provide the new dSYM file for the new application version. The dSYM file contains a UUID that links it to a specific Xcode build, so AppDynamics can unambiguously match the correct dSYM file with an incoming crash report with no additional information.

To upload the dSYM file:

- Enable the dSYM file
- Set up your environment to upload the file automatically each time you build or upload the file manually

Enable the dSYM File

To enable the agent to provide human-readable information in the crash snapshots that are produced if the application crashes, compile with the `DWARF with dSYM` file option to create a debug symbols file for the application.

To enable dSYM:

1. In Xcode, select your project in the **Project Navigator**.
2. In the target list, select the target that builds your application.
3. Select the Build Settings tab.
4. In the **Build Options** section, make sure that the **Debugging Information Format** is set to `DWARF with dSYM File`.

Upload the dSYM File to AppDynamics Automatically with Each Build

Automating the upload of your dSYM file reduces the number of manual steps required for each build and ensures that all builds have appropriate dSYM files available for AppDynamics to use.

1. In Xcode, select your project from the **Project Navigator**.
2. Click on the application target.
3. Select the **Build Phase** tab in the **Settings** editor.
4. Click the **+** icon in the upper left corner of the main panel.
5. Select **New Run Script Phase** from the dropdown.
6. In the script box, add these lines:

```
export ADRUM_ACCOUNT_NAME="<Account_Name_HERE>" // From the View License - End User Monitoring section
of the License Page
export ADRUM_LICENSE_KEY="<License_Key_HERE>"  // From the View License - End User Monitoring section of
the License Page
SCRIPT=$(/usr/bin/find "${SRCROOT}" -name xcode_build_dsym_upload.sh | head -n 1)
/bin/sh "${SCRIPT}"
```

7. There are also some optional parameters you can set if desired. To set them, add the following line(s) after the second `export` statement above. Set to `1` to enable.

```
export ADRUM_UPLOAD_WHEN_BUILT_FOR_SIMULATOR=0
export ADRUM_TREAT_UPLOAD_FAILURES_AS_ERRORS=0
export ADRUM_EUM_PROCESSOR="<EUM_SERVER_URL>"
```

   The last statement should be used to set the URL for an on-prem version of the EUM Server.

Upload the dSYM File to AppDynamics Manually

To upload the file manually:

1. Get the dSYM file from Xcode
2. Upload the dSYM file to AppDynamics using the UI
   or
   Upload the dSYM File to AppDynamics Using the API
3. Check Uploaded dSYMs Using the REST API

Get the dSYM file from Xcode

1. In Xcode, run the Xcode build: **Product > Build**.
2. View the log navigator: **View > Navigators > Show Report Navigator**.

   > Older versions of Xcode used **Show Log Navigator**.

3. Click the log entry for the most recent build.
4. Near the end of the log, find and mouse over the log entry named `Generate <Your_App_Name>.app.dSYM`.
5. Click the button on the right side of the entry to expand it.
   The end of the displayed command is the path to the dSYM file.
6. Navigate to this dSYM file in the Finder.
7. Right-click on the dSYM file and choose **Compress**.
8. Upload to AppDynamics the `.zip` file that **Finder** generates.

Upload the dSYM File to AppDynamics Using the UI

1. From the Mobile App menu, click **Configuration**.
2. Click **Mobile App Configuration >**.
3. From **dSYM Mappings**, click **Upload dSYM package file for iOS crashes**.
4. From the **XCode dSYM package upload** dialog, click **Choose File**.
   The uploader expects a file with a `.zip` extension.
5. In the file browser locate the zipped dSYM file for the application that you are instrumenting and click **Open**.
6. Click **Upload**.

Upload the dSYM File to AppDynamics Using the REST API

The API uses HTTP basic authentication. The username is your EUM account name and the password is your EUM license key.

Set up your HTTP basic authentication credentials

1. In the upper-right corner of the Controller UI, click the gear icon ( ) and choose **License**.
2. From the Account Usage tab, scroll down to the **User Experience** section.
3. Click **Show** next to License Key to display the EUM license key. This is your password for authentication.

4. URL-encode the EUM account name and the EUM license key.

Send the dSYM File

Send the dSYM as a zip archive in the body of a `PUT` request to the following URI:

```
https://api.eum-appdynamics.com/v2/account/<EUM_Account_Name>/ios-dsym
```

You must set a Content-Type header, `-H Content-Type:application/octet-stream`, and your URL-encoded account name (the username) and license key (the password) to the call.

Sample Request and Response

This is a sample request and response using the REST API.

Upload Request

The following example uses `curl` to send a dSYMm file named `UISampleApp.app.dSYM.zip`. The EUM account name is "Example account" and the password is "Example-License-Key-4e8ec2ae6cfe", the EUM License Key. The plus signs replace spaces in the account name when the account name is URL-encoded.

```
curl -v -H Content-Type:application/octet-stream --upload-file UISampleApp.app.dSYM.zip --user Example account:
Example-License-Key-4e8ec2ae6cfe https://api.eum-appdynamics.com/v2/account/Example+account/ios-dsym
```

Upload Response

The successful output of the sample request looks like this:

```
* About to connect() to api.eum-appdynamics.com port 443 (#0)*   Trying ::1...
* connected
* Connected to api.eum-appdynamics.com (::1) port 443 (#0)
* Server auth using Basic with user 'Example+account'
> PUT /v2/account/Example+Account/ios-dsym  HTTP/1.1
> Authorization: Basic SW50ZXJuYWwrdGVzdCthY2NvdW50OlRlc3RBY2N0LTFlMzktNDVkMy05MzAzLTRlOGVjMmFlNmNmZQ==
> User-Agent: curl/7.24.0 (x86_64-apple-darwin12.0) libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.5
> Host: localhost:7001
> Accept: */*
> Content-Length: 0
> Expect: 100-continue
>
< HTTP/1.1 100 Continue

Check Uploaded dSYMs Using the REST API

You can check to make sure that your dSYMs have successfully uploaded using two REST APIs.

1. Get a list of the UUIDs for the last 50 dSYMs you have uploaded
2. Check if a specific dSYM has been uploaded

List of the Last 50 dSYMs Uploaded

The `dsymQuery` method allows you to retrieve a list of UUIDs for up to the last 50 dSYM files that have been uploaded to your account, along with the time they were uploaded. The response is displayed as JSON, by upload time, with the most recent first.

1. Set up your authentication as described in Upload the dSYM File to AppDynamics Using the REST API.
2. Create a GET request of the form:

   ```
   curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://<EUM_Cloud/Server_Host:Port>/v2
   /account/Example+account/crash-symbol-file-query/dsym
   ```

   where the value for `--user` is the authentication string you created in Upload the dSYM File to AppDynamics Using the REST API, `EUM_Cloud/Server` is `api.eum-appdynamics.com:443` for SaaS-based EUM Cloud accounts or as configured for on-premises EUM Servers.

Sample Request

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe  https://api.eum-appdynamics.com:443/v2/account
/Example+account/crash-symbol-file-query/dsym
```

Sample Response

```
{"dSymFiles":[
{"uploadTime":"mm/dd/yyyy 14:15:32","UUID2":"my_uuid2"},
{"uploadTime":"mm/dd/yyyy 14:15:32","UUID":"my_uuid"}
]}
```

Check for Specific dSYM by UUID

The `checkForDSymFile` method allows you to check if a specific dSYM by UUID has been uploaded. The upload time is returned in the response.

1. Set up your authentication as described in Upload the dSYM File to AppDynamics Using the REST API.
2. Create a GET request of the form:

   ```
   curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://<EUM_Cloud/Server_Host:Port>/v2
   /account/Example+account/crash-symbol-file-query/dsym/uuid/<UUID_to_Check>
   ```

where the value for `--user` is the authentication string you created in Upload the dSYM File to AppDynamics Using the REST API, `EUM_Cloud/Server` is `api.eum-appdynamics.com:443` for SaaS-based EUM Cloud accounts or as configured for on-prem EUM Servers, and `UUID_to_Check` is the UUID of the dSYM in which you are interested.

Sample Request

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe  https://<EUM_Cloud/Server_Host:Port>/v2
/account/Example+account/crash-symbol-file-query/dsym/uuid/<UUID_to_Check>
```

Sample Response

```
{"uploadTime":"mm/dd/yyyy 14:15:32","UUID":"my_uuid"}
```

Manage the dSYM Files with Bitcode Enabled

Related pages:

- Upload the dSYM File

With iOS 9, Apple introduced a new mode of building and distributing iOS apps called App Thinning. As part of this initiative, apps containing bitcode are delivered.

If you choose to create your app containing bitcode, the process of acquiring your dSYM files for upload while you are in local development, debugging, and testing mode (Xcode on simulators or Devices) is exactly the same as in earlier versions.

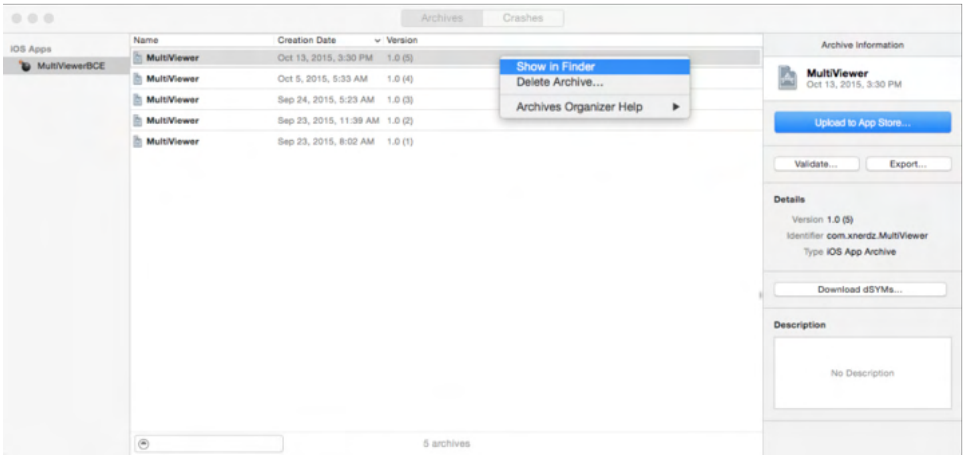
It also works if you are using Ad Hoc Provisioning. But once you have used iTunes Connect to upload your application to Apple, for either TestFlight beta testing or application release, you have to take a few additional steps to get your dSYM files for use with AppDynamics.

Get and Upload the Correct dSYM File

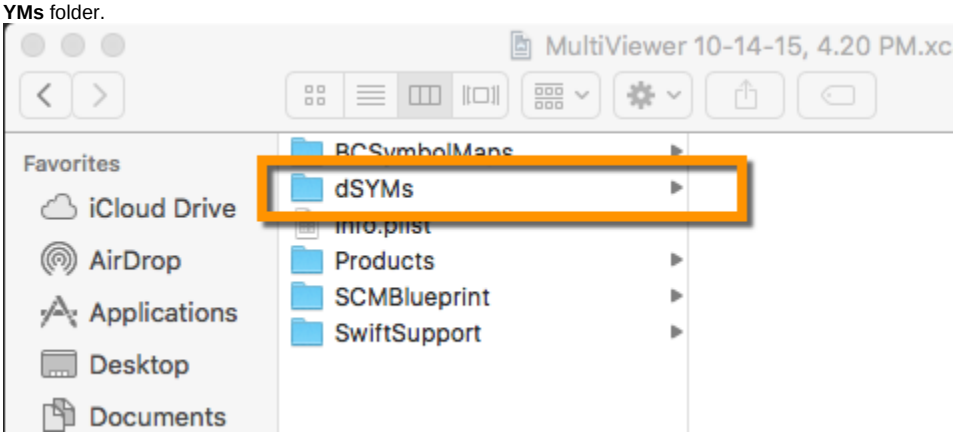
As part of the process of preparing to upload your application using iTunes Connect, you create an archive. After the app is uploaded to iTunes Connect, it is processed by Apple. To have the correct version of the dSYM for AppDynamics, you must download this processed version to your local archive.

To download the processed dSYM file, in the Xcode **Archives Organizer**:

1. Make sure this version of the application is available for download (either TestFlight or the iTunes store).
2. In the **Archives** organizer, select the archive for this version.
3. Click the **Download dSYMs** button.



4. Right-click the `.xcarchive` file you receive and select **Show in Finder**. Right-click again and select **Show Package Contents**, and select the **dSYMs** folder.

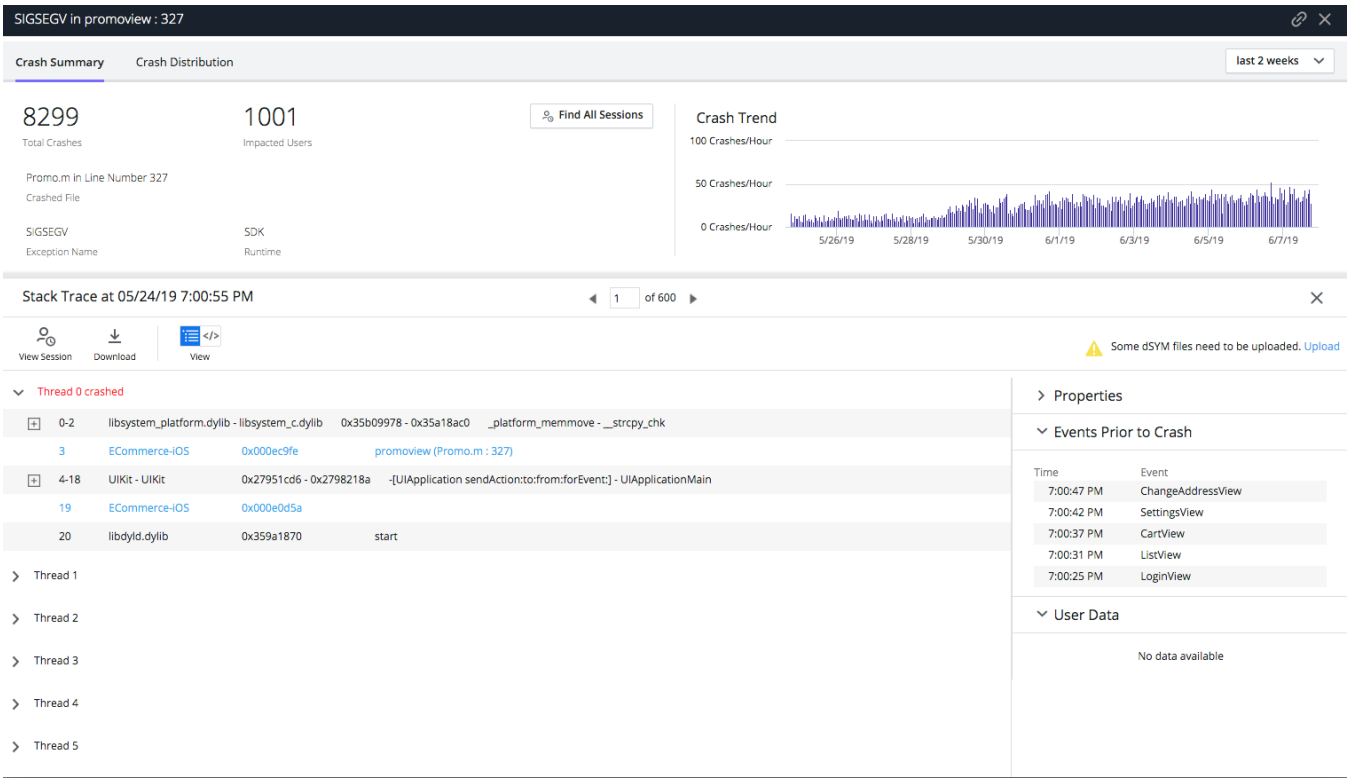


5. Zip this directory and upload.

See the Apple Developer docs.

Upload Missing dSYM Files

If you have crashes that AppDynamics could not symbolicate because it did not have a correct dSYM file, you get an error message in the **Crashes Details** dialog.



If you click **Upload missing dSYM files in Instrumentation**, a list of dSYM hashes appears. Match the missing files with the dSYMs in your archives, as shown above. If necessary, click **Download dSYMs** to update the archive. Upload the necessary files to AppDynamics.

> ⚠ Some of the missing dSYM files that AppDynamics reports may belong to simulation/debug builds that have crashed. In this case, the dSYMs may no longer be available.

Troubleshoot the iOS Instrumentation

Related pages:

- Install the iOS SDK
- Instrument an iOS Application
- Customize Your Instrumentation With the iOS SDK

This page provides instructions and tips for solving some common iOS instrumentation issues.

Agent Not Detecting Requests

First, confirm that you are using either the `NSURLConnection` or the `USURLSession` class. By default, you are required to make network requests. If you are using a custom HTTP library, make sure you follow the instructions given in Use the Agent with a Custom HTTP Library.

If you are using `NSURLSession`, be sure to create an instance of `NSURLSession` *after* initializing the iOS agent. This is because the agent may not be aware of objects created before the instrumentation is initialized.

Unrecognized Selector Error

If you are instrumenting your app using the manual method and you see this error message:

```
+[NSURLConnection ADEumInsertHooks]: unrecognized selector sent to class <hex value>
```

Then, you did not add `-ObjC` to your link flags. See Set the -ObjC Flag for instructions.

Instrument Android Applications

Before you can monitor your Android application, you need to build and instrument your application to enable the Android Agent to collect mobile metrics. The Android Agent supports monitoring for Android applications written in Java or any JVM-based language such as Kotlin.

After you have set up and accessed Mobile RUM, use one of the following ways to build and instrument your application:

- Instrument an Application with the Android Agent Installer - The Android Agent Installer is an Android Studio plugin that will configure the build and insert the instrumentation code for you.
- Instrument an Android Application Manually - If you are unable to use the Android Studio plugin, follow these instructions to configure your build and instrument your application.

For further customization, see Customize the Android Build and Customize the Android Instrumentation.

Instrument an Application with the Android Agent Installer

This page describes how to use the AppDynamics Android Agent Installer plugin to instrument an app with the AppDynamics Android SDK. The instructions will include how to get the EUM App Key, install the plugin, and use the plugin to instrument the application.

Follow the steps below to get your EUM App Key and instrument your Android applications:

> The plugin is recommended for initial basic instrumentation. If your app requires custom initialization or more advanced configuration, see Customize the Android Build and Customize the Android Instrumentation.

Check the Prerequisites

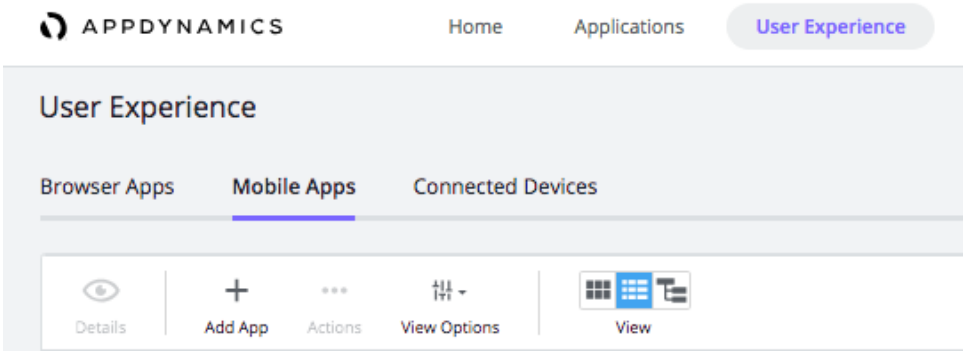
To use the plugin, you need the following:

- An AppDynamics account - If you do not have an account, sign up for a free account.
- Android Studio 2.1.0 - 2.9.9, and 3.2.1 - 3.9.9 (Not supported: 3.0.0 - 3.2.0, and 4.0)
- Java >= 7

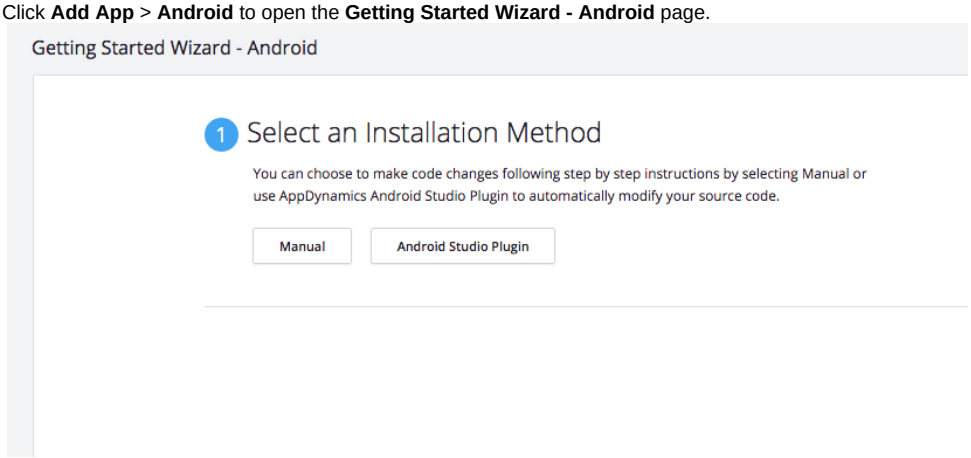
If you are running an on-premises deployment, you also need the URL to your EUM Server.

Get the EUM App Key

1. From the top navigation bar of your Controller UI, go to **User Experience** > **Mobile Apps**.

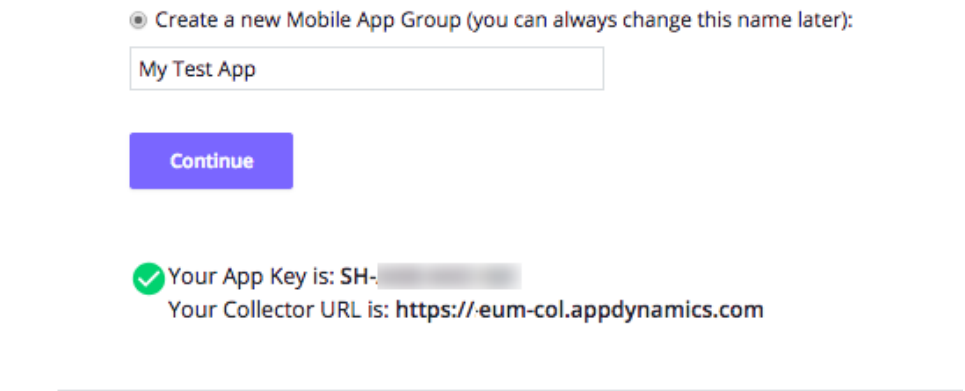


2. Click **Add App** > **Android** to open the **Getting Started Wizard - Android** page.

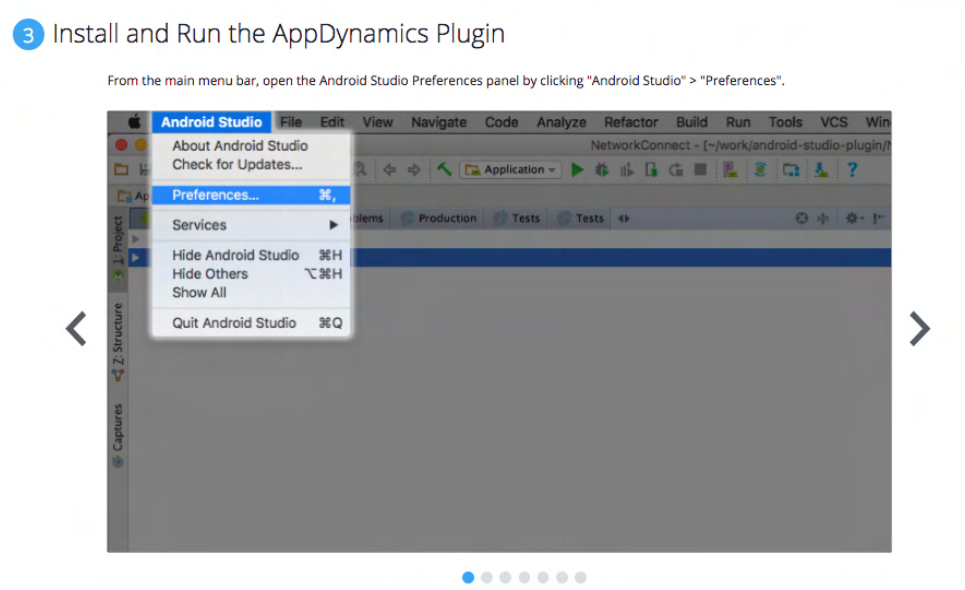


3. Click **Android Studio Plugin**.
4. Select the **Create a new Mobile App Group** radio button, enter an application name, and click **Continue**.

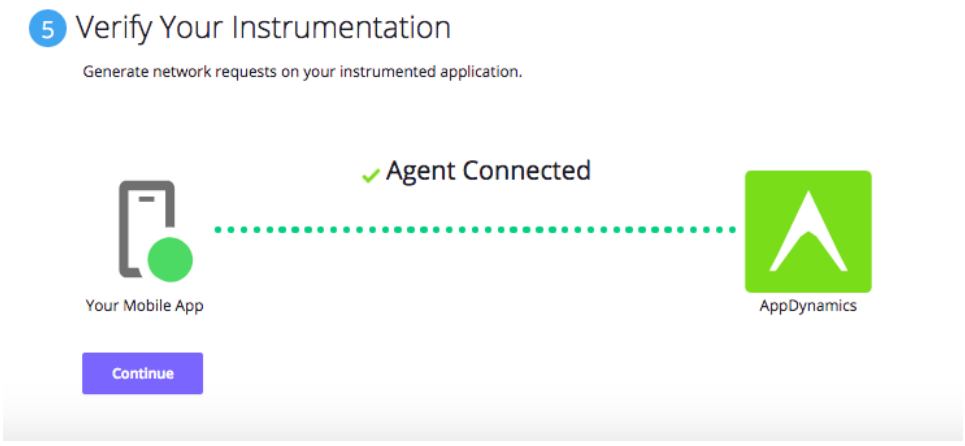
5. Copy the displayed App Key and the Collector URL.



6. Follow the instructions in 3 Install and Run the AppDynamics Plugin.



7. Keep the wizard open until the instrumentation has been verified in the wizard.



Instrument an Android Application Manually

Related pages:

- Verify the Android Instrumentation
- Confirm the Mobile Agent Connected to the Controller
- Customize the Android Build
- Customize the Android Instrumentation

To instrument Android Applications, you need to first build the application for the platform you are using and then add the instrumentation code.

To get started, follow the instructions below:

1. Build the Android Application
2. Instrument the Android Application

Build the Android Application

To build your application, follow the instructions for your platform:

- Gradle/Android Studio
- Maven
- Ant

If you are fetching the AppDynamics Android SDK from the AppDynamics Download page, see Download Manually.

Gradle/Android Studio

Complete the following steps to configure the build for your Android application:

1. Confirm the compatibility of your Gradle, Android Tools with the AppDynamics plugin versions.
2. Install the Android Agent.
3. Activate the plugin.

Install the Android Agent

Use the native package system to install the Android Agent. In the app module `build.gradle`, add the class path of the AppDynamics Gradle Plugin to the build path dependencies clause. Use `com.appdynamics:appdynamics-gradle-plugin:21.4.0` unless you need to use another version of the AppDynamics plugin for compatibility between your Gradle and Android Tools.

```
buildscript {
    repositories {
        jcenter()
    }
    dependencies {
        classpath 'com.android.tools.build:gradle:1.1.0'
        classpath 'com.android.tools.build:gradle:3.4.1' // >=3.4.1
        classpath 'com.appdynamics:appdynamics-gradle-plugin:21.4.0' // this line added for AppDynamics
    }
}
allprojects {
    repositories {
        jcenter()
    }
}
```

If you are unable to use the Android Gradle plugin >=3.4.1, you will have to use the Android Agent <=20.4.0.

Activate the Plugin

In your module-level `build.gradle`, add the `adeum` plugin immediately after the `com.android.application` plugin, so that it looks similar to the example below:

```
apply plugin: 'com.android.application'
apply plugin: 'adeum' // this line added for AppDynamics
```

Apache Maven Project

If your application is a Maven Project:

1. Add the following code to the `<dependencies>` section:

```
<dependency>
   <groupId>com.appdynamics</groupId>
   <artifactId>appdynamics-runtime</artifactId>
   <version>1.0</version>
</dependency>
```

2. Add the following code to the `<plugins>` section:

```
<plugin>
    <groupId>com.appdynamics</groupId>
    <artifactId>appdynamics-maven-plugin</artifactId>
    <version>1.0</version>
    <executions>
        <execution>
            <phase>compile</phase>
            <goals>
                <goal>adinject</goal>
            </goals>
        </execution>
    </executions>
</plugin>
```

Ant/Eclipse

See the Knowledge Base article Use Ant to Build Android Apps with the AppDynamics Android SDK for instructions.

Instrument the Android Application

After you have completed building your application, follow the steps below:

1. Get the Application Key
2. Add the Required Permissions
3. Modify the Source
4. Run the Build

Get Application Key

After you completed the **Getting Started Wizard**, you were given an EUM App Key. You will need this key when you modify the source code. In some cases, multiple mobile applications can share the same key.

If you have completed the **Getting Started Wizard**, but don't have your EUM App Key, see Get Your Application Key.

Add the Required Permissions

Open your application's `AndroidManifest.xml` file and verify that it has these permissions:

```
<uses-permission android:name="android.permission.INTERNET"></uses-permission>
<uses-permission android:name="android.permission.ACCESS_NETWORK_STATE"></uses-permission>
```

If both of these permissions are not present, add them.

Modify the Source

1. In the source file that defines your application's primary Activity, add the following import:

```
import com.appdynamics.eumagent.runtime.Instrumentation;
```

2. In your primary Activity's `onCreate()` method, add the following lines, passing in the EUM App Key from step 2 above:

```
Instrumentation.start(<EUM_APP_KEY>, getApplicationContext());
```

3. Save the file.
   Your code should look something like this.

```
import com.appdynamics.eumagent.runtime.Instrumentation;
...
@Override public void onCreate(Bundle savedInstanceState) {
  Instrumentation.start(<EUM_APP_KEY>, getApplicationContext());
  ...
}
```

4. Configure the Android Agent to report metrics and screenshots to the SaaS EUM Server and Screenshot Service in your region when initializing the agent with the methods `withCollectorURL` and `withScreenshotURL`. (If you are using an on-premises EUM Server, see Customize the Agent Configuration for implementation details.)

Verify the Instrumentation

See Verify the Android Instrumentation for build and verification instructions.

Upgrade the Android Mobile Agent

As new features are added to the agent, you will need to upgrade the Android SDK in your app.

To upgrade, you simply update the build file for your platform:

- Gradle/Android Studio
- Maven

The process of installing and updating the latest Android SDK is the same.

Verify the Android Instrumentation

To verify your Android instrumentation:

1. Run the build.
2. Verify the instrumentation.
3. Confirm the agent connected to the Controller.

Run the Build

Build your Android app following the instructions for your build system:

- Android Studio
- Gradle
- Maven

In the console, you should see something like this:

```
[injector]                                /=======================================\
[injector]                                | AppDynamics BCI Instrumentation summary  |
[injector]                                \=======================================/
[injector]
[injector]
[injector]                 - Total number of classes visited (#720 classes)
[injector]                 - Total number of classes instrumented (#1 classes)
[injector]                 - Total number of classes failed to instrument (#2 classes)
[injector]                 - Total number of features discovered (#3)
[injector]
```

Verify the Instrumentation

Based on the build system you used, verify that the instrumentation was successful:

- Gradle/Android Agent Installer Plugin
- Maven
- Ant

Gradle/Android Agent Installer Plugin

If you didn't use the `-i` flag, check to make sure there is a line in your console output that contains "`inject`". If you don't see this information printed in your console, either your project is incorrectly configured or the injector failed to run completely. There is a very detailed log of this process either at `<project>/target/appdynamics_eum_android_bci.log` or `<module>/target/appdynamics_eum_android_bci.log`.

Maven

If you don't see this information printed in your console, either your project is incorrectly configured or the injector failed to run completely. There is a very detailed log of this process either at `<project>/target/appdynamics_eum_android_bci.log` or `<module>/target/appdynamics_eum_android_bci.log`.

Ant

If you don't see this information printed in your console, either your project is incorrectly configured or the injector failed to run completely. There is a very detailed log of this process either at `<project>/target/appdynamics_eum_android_bci.log` or `<module>/target/appdynamics_eum_android_bci.log`.

Customize the Android Build

Related pages:

- Instrument an Android Application Manually
- Customize the Android Instrumentation

Build the Android Application showed you how to use the bare minimum configuration to build your application.

The following pages show you how to add additional configuration to customize your build:

- Automatically Upload Mapping Files
- Configure ProGuard to Prevent Obfuscation and Class Removal
- Exclude Classes from Being Instrumented
- Enable/Disable Instrumentation for Build Types
- Enable/Disable Native Crash Reporting

Automatically Upload Mapping Files

You can configure the build to add your EUM account information so that you can automatically upload your ProGuard or DexGuard mapping files for crash reports with each build.

This is the recommended way of managing these types of mapping files, although manual modes are available for uploading mapping files. If you do not use ProGuard or DexGuard to obfuscate your files you can ignore this section. See Configure ProGuard to Prevent Obfuscation and Class Removal.

> **DexGuard Limitation**
>
> DexGuard mapping files must be in the default location. This means that their dexguard configurations should not specify `--printMapping`, which changes where to print the mapping file.

Upload to the SaaS EUM Server

If you are using the SaaS EUM Server, you just need to provide your account name and license key to automate uploading as shown below.

```
adeum {
        url COLLECTOR_URL // Only needed for on-prem. This is used to upload the proguard mapping file by the
buildscript. For on-prem it should be the public collector url.
        account {
                licenseKey EUM_LICENSE_KEY name EUM_ACCOUNT_NAME
                }
        proguardMappingFileUpload {
                failBuildOnUploadFailure false enabled true // This specifies whether the entire build should
fail if mapping file upload fails. Enabled refers to whether auto-uploading of mapping file is enabled.
                }
        excludeClasses = ['android.support.multidex.*', 'okio.**'] // This specifies any classes customers
would like to exclude from auto-instrumentation. The notation is standard java package/class specification used
in Gradle.
        enabledForDebugBuilds = true // Whether auto-instrumentation is enabled for debug builds, true by
default.
        enabledForReleaseBuilds = true // Whether auto-instrumentation is enabled for release builds, true by
default.
        webViewCallbackCrashReportingEnabled = false // Auto-instrumentation is enabled for WebChromeClient and
WebViewClient
...

// This block specifies how to handle native crashes. By default, this is not enabled.
        nativeCrashHandling {
                if (BUILD_NDKLIB) {
                        enabled = true
                        symbolUpload {
                                variantLibraryPaths = ["appRelease": "ndkLib/obj/local"]
                        }
                }
        }
}
```

Upload to the On-Premises EUM Server

If you are using an on-premises deployment, in addition to supplying your account name and license, you must also assign the URL to your on-premises EUM Server to the `url` property as shown:

```
adeum{
    // The account information is also needed for on-prem deployments.
    account {
      name "The EUM Account Name from the License screen"
      licenseKey "The EUM License Key from the License screen"
    }
    ...
    // Add this information to point to the on-prem EUM Server.
    url "https://<your-on-prem-eum-server>:7001"
}
```

Modify the Default Upload Behavior

You can also modify the default upload behavior for both on-premises and SaaS deployments. For on-premises deployments, you will need to provide the URL to your on-premises EUM Server with the `url` property.

The configuration example below sets `failBuildOnUploadFailure` to `true`, so that the build will fail if the upload to the URL specified by `url` is unrea chable. The object `proguardMappingFileUpload` is used for both Proguard and DexGuard mapping files. If you don't want your build to fail because the ProGuard or DexGuard mapping file couldn't be uploaded, do *not* modify the default setting.

```
adeum{
    ...
    // Add this information to point to the on-prem EUM Server.
    url "https://<your-on-prem-eum-server>:7001"

   // Add this information if you want to modify upload behavior.
    proguardMappingFileUpload {
      failBuildOnUploadFailure true // If true, will fail build. Defaults to false.
      enabled true //enables automatic uploads.  Defaults to true
    }
}
```

Configure Proguard to Prevent Obfuscation and Class Removal

If you use ProGuard to verify or optimize your code, add the following lines to the ProGuard configuration file `proguard-rules.pro` under Gradle Scripts to prevent ProGuard from obfuscating or removing classes needed for proper instrumentation.

```
-keep class com.appdynamics.eumagent.runtime.DontObfuscate
-keep @com.appdynamics.eumagent.runtime.DontObfuscate class * { *; }
```

Configure ProGuard to Prevent Obfuscation and Class Removal

Related pages:

- Automatically Upload Mapping Files

If you use ProGuard to verify or optimize your code, add the following lines to the ProGuard configuration file `proguard-rules.pro` under Gradle Scripts to prevent ProGuard from obfuscating or removing classes needed for proper instrumentation.

```
-keep class com.appdynamics.eumagent.runtime.DontObfuscate
-keep @com.appdynamics.eumagent.runtime.DontObfuscate class * { *; }
```

Exclude Classes from Being Instrumented

You can exclude one or more class names from being instrumented, using the "adeum" `excludeClasses` snippet.

Class names can contain wildcards:

- '?' for a single character
- '*' for any number of characters, but *not* the package separator
- '**' for any number of (any) characters
- '$' prefix for an inner class name

To exclude named classes from instrumentation, add the class names to the `excludeClasses` array, using matching patterns where needed:

```
...
adeum {
    // Excludes all the classes in the android.support.multidex and okio packages.
    excludeClasses = ['android.support.multidex.*', 'okio.**']
}
...
```

Enable and Disable Instrumentation for Build Types

This page describes how to enable and disable instrumentation for Android build types.

Default Instrumentation for Build Types

For `release` builds, auto-instrumentation is enabled by default.

```
adeum {
...
enabledForDebugBuilds = true // Whether auto-instrumentation is enabled for debug builds, true by default.
        enabledForReleaseBuilds = true // Whether auto-instrumentation is enabled for release builds, true by
default.
        webViewCallbackCrashReportingEnabled = false // Auto-instrumentation is enabled for WebChromeClient and
WebViewClient
...
}
```

Verify the Instrumentation State at Runtime

If one or more of your builds have disabled instrumentation, you need to disable the instrumentation check at runtime. You can set boolean fields in the build configuration to disable the runtime verification of instrumentation. The runtime verification of instrumentation is on by default. You can turn it off using the method `withAutoInstrument`.

In the build configuration, you can set a boolean value for the `CHECK_ENABLED` field for build types. The table below shows the config value, the instrumentation state, and then describes the runtime behavior of your applications.

Config Value	Instrumentation State	Runtime Behavior
`true`	Enabled	The agent will verify that instrumentation has been enabled before initializing.
	Disabled	The agent will verify that the instrumentation has not been enabled and then thrown an `IllegalState` exception.
`false`	Enabled	The agent will initialize without checking whether instrumentation has been enabled.
	Disabled	

For example, in the build configuration below, the field `CHECK_ENABLED` is set to `true` for the release build and `false` for the debug build.

The agent for the `debug` build will not verify if instrumentation has been enabled before executing instrumentation code, whereas, the application code for the `release` build will check before executing the instrumentation code.

```
...
android {
    // usual stuff
    buildTypes {
    // usual stuff
        release {//these lines added for AppDynamics
            //release based configuration
            // The release build by default is not "debuggable".
            // The build config "CHECK_ENABLED" will be accessible in the runtime environment.
            // This enables the Android Agent to verify that the instrumentation has been enabled before
running the initialization code.
            // If instrumentation has not been enabled, an "IllegalState" exception is thrown.
            buildConfigField "boolean", "CHECK_ENABLED", "true"
        }
        debug {
            // Setting 'CHECKED_ENABLED' to "false" means the Android Agent will run the initialization code
without confirming that
            // instrumentation has been enabled. No exception will be thrown.
            buildConfigField "boolean", "CHECK_ENABLED", "false"
        }
    }
}
...
```

If the value of `CHECK_ENABLED` is `true`, the Android Agent will confirm that instrumentation has been enabled before executing the initialization code. If the value is `false`, the Android Agent executes the initialization code regardless of whether instrumentation has been enabled.

The following instrumentation initialization code shows you how to check the value of the build config `CHECK_ENABLED` with the method `withCompileTimeInstrumentationCheck`.

```
import com.appdynamics.eumagent.runtime.Instrumentation;
...
Instrumentation.start(
        AgentConfiguration config = AgentConfiguration.builder()
            .withAppKey(<EUM_APP_KEY>)
            .withContext(this)
            .withCompileTimeInstrumentationCheck(BuildConfig.CHECK_ENABLED)
            .build();
);
...
```

Enable and Disable Native Crash Reporting

You can report native crashes caused by native libraries. This feature is available for all architectures supporting the Android Native Development Kit (NDK) .

Native Crash Handler

When instrumentation is initialized, the native crash handler loads the AppDynamics library `libadeum`. At entry points of your code, a signal handler is injected into the running process. After a signal is handled, `libadeum` restores the previous signal handler. (This enables you to use different methods to handle signals.)

The handler collects and writes the information about the native crash into a temporary file. When the application is restarted, the temporary file is read, processed, and the crash information is displayed in the Controller UI.

Configuration for Native Crash Reporting

By default, however, this feature is turned off, so you need to add the section `nativeCrashHandling` and set `enabled` to true. In addition, you point the library paths in the `variantLibraryPaths` array for each build variant to write the symbol files locally and transmit the symbol files to the EUM Server. You can also specify a build ID for a project build. After you build the project, the build ID can be found in `build/appDynamics /ndkSym<VariantName>/<AppBuildID>`. If not specified, the build ID of the most recently built project will be used.

```
adeum {
    // Other configuration if needed.

    // Enable native crash handling; the default is false.
    nativeCrashHandling {
        enabled = true
        symbolUpload {
            buildId = "<your_custom_build_id>"
            variantLibraryPaths = ["release": "ndkLib/obj/local", "debug": "ndkLib/obj/debug", ...]
        }
    }
}
```

Configuration for the Android App Bundle

If you using Android App Bundle, you need to add the following line to your app module `build.gradle` for crashes to symbolicate correctly.

```
android.bundle.enableUncompressedNativeLibs=false
```

View Source Code Information in the Stack Trace

You have two different ways to view symbol information in the stack trace:

1. From the **Crash Details** dialog, download the crash report and use a utility like `ndk-stack` to view the crash report with source code level symbolications.
2. Upload the symbol files and then view the stack trace in the **Crash Details** dialog.

Download the Crash Report and Use ndk-stack

1. From the **Crash Dashboard**, double-click one of the crashes listed in the **Unique Crashes** widget.
2. From the **Crash Details** dialog, click **Download** to download the crash report.
3. Run ndk-stack (or a similar utility) on the downloaded crash report as the input file to generate a crash report with source code level symbolications.

Upload the Symbol File and View the Stack Trace

You are recommended to automatically generate and upload symbol files, but you can also manually generate and upload the symbol files, too. After you upload the symbol files, when the app with the same build ID as the UUID of the uploaded `ndkSYM` file crashes, you will see the file name and the line number next to the C/C++ function name for each frame of the stack trace shown in the **Crash Details** dialog.

Automatically Generate and Upload Symbol Files

You can run the following `gradle` command to generate and upload the symbol files to the EUM Server. Replace `<VariantName>` with the build variant names you defined in the configuration. For example, in the configuration above, the `<VariantName>` could be release or debug.

```
$ gradle appDynamicsUploadNDKSymbolFile<VariantName>
```

Manually Generate and Upload Symbol Files

To generate symbol files, run the following gradle command, where `<VariantName>` is the build variant names. The generated symbol file will be written to `build/appDynamics/ndkSym<VariantName>/<AppBuildID>/<AppBuildID>.ndkSYM.zip`.

```
$ gradle appDynamicsGenerateNDKSymbolFile<VariantName>
```

To manually upload the generated symbol file, use the following cURL command, replacing the `<ndkSymZipFile>` with your generated symbol file, `<Account Name>` with your EUM Account name, and `<License Key>` with your EUM License Key.

```
$ curl -v -H Content-Type:application/octet-stream --upload-file <ndkSymZipFile> --user <Account Name>:<License Key> https://api.eum-appdynamics.com/v2/account/<Account Name>/android-ndksym
```

Customize the Android Instrumentation

Related pages:

- Instrument an Android Application
- Android SDK Documentation

Once you have instrumented your Android application with the Android SDK, you can also use the APIs exposed by the SDK to customize the data for your application that appears in the Controller UI. The following sections show you how to use the Android API to customize your instrumentation:

Because the Android Agent stores data about events in a local buffer before reporting the information, we recommend you use the APIs with discretion.

Collect Additional Types of Data

The `Instrumentation` class has additional methods to allow you to extend the kinds of application data you can collect and aggregate using Mobile RUM. There are six basic kinds of extensions that you can create:

Extension	Description	Specification	Where Data is Displayed in the Controller UI
Info points	How often a method is invoked, and how long it takes to run	• Data is numeric • Names must consist of alphanumeric characters and/or spaces	• Metric Browser • Custom Data • Network Request Snapshots • Mobile Sessions • Network Request Analyze
Custom timers	Any arbitrary sequence of events within your code timed, even spanning multiple methods	• Data is numeric • Metric names must consist of alphanumeric characters and/or spaces	• Metric Browser • Custom Data
Custom metrics	Any integer-based data you wish to collect	• Data is numeric • Metric names must consist of alphanumeric characters and/or spaces	• Metric Browser • Custom Data
User data	Any string key/value pair you might find useful	• Any data type • Metric names have no restrictions	• Network Request Snapshots • Mobile Sessions • Network Request Analyze • Crash Snapshots
Breadcrumbs	The context of a crash	• Any data type • Metric names have no restrictions	• Network Request Snapshots • Mobile Sessions • Network Request Analyze • Crash Snapshots

User interactions	Captured when users press buttons, click on lists, and select text	• Any data type • Metric names have no restrictions	• Network Request Snapshots • Mobile Sessions • Network Request Analyze

When you have set up info points, custom timers, custom metrics, and/or user data, the Mobile Agent packages that data in a mobile beacon. Normally, the beacon is transmitted when the instrumented application sends an HTTP request or when the application starts after a crash, but if custom data has been collected and neither of those events has occurred for at least 5 minutes, the custom data is sent at that time.

Info Points

Information points allow you to track how your own code is running. You can see how often a method is invoked, how long it takes to run, and if an exception is thrown. The simplest way to set up an information point is to use the `@InfoPoint` annotation. For example:

```
@InfoPoint
 public void infoPointMethod(String arg1, int arg2, long value) {
   System.out.println("Executing infoPointMethod!");
 }
```

You can also do this manually, using the `CallTracker` interface. For example, to collect information on the `downloadImage` method, you could use code similar to this:

```
private void downloadImage(URL url) {
     CallTracker tracker =
          Instrumentation.beginCall("com.example.android.awesomeapp.ImageDownloader", "downloadImage")
              .withArguments(url);
     try {
          //download image.
          tracker.reportCallEnded()
     } catch(Exception e) {
         //handle exception thrown
         tracker.reportCallEndedWithException(e);
     }
 }
```

This information appears in the **Custom Data** view of the Controller UI.

Custom Timers

Custom timers allow you to time any arbitrary sequence of events within your code, even spanning multiple methods, by using `startTimer` and `stopTimer`.

```
public class MyActivity extends Activity {
   @Override
   protected void onStart(){
       Instrumentation.startTimer("Time Spent on MyActivity");
       //your code here.
   }

   @Override
   protected void onStop(){
       Instrumentation.stopTimer("Time Spent on MyActivity");
       //your code here.
   }
 }
```

The methods `startTimer(String)` and `stopTime(String)` can be called from different threads. Calling `startTimer` again with the same name value resets a named timer.

This information appears in the **Custom Data** view of the Controller UI.

Custom Metrics

Any integer-based data can be passed to the Android Agent. The first parameter to the `reportMetric` call is the name you want the metric to appear under in the Controller UI. The metric name should only contain alphanumeric characters and spaces. Illegal characters are replaced by their ASCII hex value.

For example, to track the number of times your users click the checkout button in your UI, you could use code similar to this.

```
findViewById(R.id.checkout_button).setOnClickListener(new View.OnClickListener(){
      @Override
      public void onClick(View view){
          //run your checkout routine.
          Instrumentation.reportMetric("Checkout Count", 1);
      }
 });
```

This information appears in the **Custom Data** view of the Controller UI.

User Data

You can set any string key/value pair you think might be useful. The first parameter to the `setUserData` call is the key you want to use, which must be unique across your application. The second is the value you want assign to the key.

For example:

```
void onUserLoggedIn(String userid) {
    Instrumentation.setUserData("User ID", userid);
    ...
}
```

This information is available in **Network Request Analyze** and is added to any crash snapshot. Keys and values are limited to 2048 characters each.

You can also set user data with values of other types (Long, Boolean, Double, Date) using the following methods:

- `setUserDataLong`
- `setUserDataBoolean`
- `setUserDataDouble`
- `setUserDataDate`

Breadcrumbs

Breadcrumbs allow you to situate a crash in the context of your user's experience. Set a breadcrumb when you want to capture a series of events. If your application crashes at some point in the future, the breadcrumb will be displayed along with the crash report.

There are two ways of leaving breadcrumbs:

- Crash Reports Only
- Modal

Crash Reports Only

Using this method means that breadcrumbs are reported in crash reports only.

```
public static void leaveBreadcrumb(java.lang.String breadcrumb)
```

Modal

Using this method lets you fine tune where the breadcrumbs are reported, either only in crash reports or in crash reports *and* sessions.

```
public static void leaveBreadcrumb(java.lang.String breadcrumb, int mode)
```

Where `mode` is either:

- `CRASHES_ONLY`
- `CRASHES_AND_SESSIONS`

If the `breadcrumb` is over 2048 characters, it is truncated. If it is empty, no breadcrumb is recorded. Each crash report displays the most recent 99 breadcrumbs.

Add a Crash Reporting Callback

You may want to make crash report information (that the Android Agent collects) available to other parts of your code, for example, to Google Analytics. To enable passing on summary crash information, you can set up a crash report runtime callback. To get a callback when the Android Agent detects and then reports a crash, implement the following interface in your code:

```
public interface CrashReportCallback {
    void onCrashesReported(Collection<CrashReportSummary> summaries);
}
```

The Android Agent sends a collection of crash report summaries instead of an individual callback in the event that there is more than one crash, producing multiple crash report summaries.

The method `onCrashesReported` is invoked during the next initialization of the Android Agent after a crash has occurred.

This callback is invoked on your app's UI thread, so any work should be done on a separate work thread.

Each `CrashReportSummary` has the following properties:

```
public class CrashReportSummary {
    public final String crashId;
    public final String exceptionClass;
    public final String exceptionMessage;
}
```

If you are sending the information to another analytics tool, such as Google Analytics, we recommend to include all three properties: `exceptionClass` an d `exceptionMessage` are useful for quick identification of the crash, and `crashId` is useful to look up the crash in the Controller UI.

For example, to print the crash information to Android's logger, you could implement a `CrashReportCallback` class like this:

```
public static class MyCrashReportCallback implements CrashReportCallback {
    @Override
    public void onCrashesReported(Collection<CrashReportSummary> summaries) {
        for (CrashReportSummary crash : summaries) {
            Log.e("MyApp", "Crash Detected: " + crash.exceptionClass + " : " + crash.exceptionMessage + " (" +
crash.crashId + ")");
        }
    }
}
```

You set your callback as using the AgentConfiguration object:

```
final AgentConfiguration config = AgentConfiguration.builder()
        .withAppKey(appKey)
        .withContext(context)
        .withCrashCallback(new MyCrashReportCallback())
        .build();
```

Your callback is invoked after a crash, during the next initialization, on the main thread. For more information, see the latest JavaDocs for the complete Android SDK API.

Disable Crash Reporting

Crash reporting is enabled by default, but you can manually disable crash reporting through the instrumentation configuration. If you are using other crash reporting tools, you might disable crash reporting to minimize conflicts and optimize the crash report results.

You can disable crash reporting by configuring the instrumentation with the `crashReportingEnabled` property as shown in the following:

```
let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>);
config.crashReportingEnabled = false;
ADEumInstrumentation.initWith(config);
```

Report Errors and Exceptions

You can report exceptions using the method `reportError` from the `Instrumentation` class. Reported exceptions will appear in session details.

You can also set one of the severity levels below for an issue. With the severity level, you can filter errors in the **Code Issues Dashboard** or **Code Issues Analyze**.

- `ErrorSeverityLevel.INFO`
- `ErrorSeverityLevel.WARNING`
- `ErrorSeverityLevel.CRITICAL`

The example below uses the API to report possible exceptions and sets the severity level to `ErrorSeverityLevel.CRITICAL` (critical) when writing to a file.

```
private void writeToFile(String filePath, String data) {
    try {
        OutputStream outputStream = new FileOutputStream(filePath);
        Writer outputStreamWriter = new OutputStreamWriter(outputStream);
        outputStreamWriter.write(data);
        outputStreamWriter.close();
    } catch (IOException e) {
        Log.e("Exception", "File write failed: " + e.toString());
        Instrumentation.reportError(e, ErrorSeverityLevel.CRITICAL);
    }
}
```

Disable the Agent to Stop Sending User Data to the Collector

You can disable the agent to stop sending all data to the collector while the agent is initialized and running. For example, you can disable the agent if your app has an option for users to opt-out of monitoring for privacy reasons.

`shutdownAgent`

The `shutdownAgent` call stops outgoing data to the collector, and does not persist data on the device.

```
Instrumentation.shutdownAgent();
```

- The call only stops the traffic out of the agent.
- Once the agent has been initialized, the call cannot be removed, and a license will have been consumed.
- If you want to make this state permanent for a device, add code in UserDefaults to save the state and use that flag to conditionally initialize the agent in your code.

`restartAgent`

To re-enable the agent and reverse `shutdownAgent`, use `restartAgent`.

```
Instrumentation.restartAgent();
```

- This call will respect the server side calls that can remotely shutdown the agent in a similar way.
- The call is only in effect while the app is running.
- The call will be ignored if the agent has been remotely disabled.
- If the call is removed from memory and the app restarts, or the device is rebooted, the agent will be initialized as normal.

Configure Hybrid Support

By default, the Android Agent instruments Android WebViews by injecting the JavaScript Agent into WebViews. See Hybrid Application Support for an overview and an explanation of how it works.

Runtime Configuration for Hybrid Support

The code example below disables the injection of the JavaScript Agent. If the client receives a `false` for this flag, then the JavaScript Agent will be disabled. Thus, WebViews will not be instrumented, and Ajax requests will not be monitored.

```
Instrumentation.start(
    AgentConfiguration.builder()
        .withAppKey(getString(R.string.app_key))
        .withContext(applicationContext)
        .withJSAgentInjectionEnabled(false)
        .build())
```

The injection occurs during the creation of a new WKWebView. So, if a WKWebView is created when this flag is set to `false`, that particular WKWebView won't be instrumented even if the flag is subsequently set to `true`.

The collection and reporting of Ajax calls are disabled by default. To enable the injection and the collection and reporting of Ajax calls, pass `true` to the method `jsAgentEnabled` in the instrumentation configuration as shown below.

```
Instrumentation.start(
    AgentConfiguration.builder()
    .withAppKey(getString(R.string.app_key))
    .withContext(applicationContext)
    .withJSAgentAjaxEnabled(true)
    .build())
```

Programmatically Control Sessions

By default, a mobile session ends after a period of user inactivity. For example, when a user opens your application, the session begins and only ends after the user stops using the application for a set period of time. When the user begins to use the application again, a new session begins.

Instead of having a period of inactivity to define the duration of a session, however, you can use the following API to programmatically control when sessions begin and end:

```
void startNextSession()
```

When you call the method `startNextSession` from the Instrumentation class, the current session ends and a new session begins. The API enables you to define and frame your sessions so that they align more closely with business goals and expected user flows. For example, you could use the API to define a session that tracks a purchase of a product or registers a new user.

Excessive use of this API will cause sessions to be throttled (excessive use is >10 calls per minute per Android Agent, but is subject to change). When not using the API, sessions will fall back to the default of ending after a period of user inactivity.

Example of a Programmatically Controlled Session

In the code example below, the current session ends and a new one begins when the check out is made.

```
public void checkoutCart(){
    if (currentCartItems!=null && currentCartItems.size()>0){
        CheckoutTask checkoutReq = new CheckoutTask();
        checkoutReq.execute(getEndpoint() + "cart/co");
        currentCartItemsMap.clear();
        convertItemsMaptoList();
        Instrumentation.startNextSession();
    } else {
        displayToast("There are no items in the cart");
    }
}
```

Start and End Session Frames

You can use the `SessionFrame` API to create session frames that will appear in the session activity. Session frames provide context for what the user is doing during a session. With the API, you can improve the names of user screens and chronicle user flows within a business context.

Use Cases

The following are common use cases for using the `SessionFrame` API:

- One Activity performs multiple functions and you want more granular tracking of the individual functions.
- A user flow spans multiple activities or user interactions. For example, you could use the API to create the session frames "Login", "Product Selection", and "Purchase" to chronicle the user flow for purchases.
- You want to capture dynamic information based on user interactions to name session frames, such as an order ID.

SessionFrame API

The table below lists the three methods you can use with session frames.

Class	Method	Description
`Instrumentation`	`static SessionFrame startSessionFrame (String sessionFrameName)`	Use this to start and name your session frame. Naming session frames enable you to easily identify and track the frames in the **Sessions Dialog.**
`SessionFrame`	`static void updateName(String updatedSessionFrameName)`	Use this to start and name your session frame. Naming session frames enable you to easily identify and track the frames in the **Sessions Dialog.**

`SessionFrame`	`static void end()`	End the session frame. You call this method from the `SessionFrame` object returned from `startSessionFrame`.

Session Frame Example

In the following example, the `ShoppingCartActivity` class uses the `SessionFrame` API to track user activity during the checkout process.

```
public class ShoppingCartActivity extends Activity {

  SessionFrame checkoutSessionFrame;

  public void onCheckoutCartButtonClicked() {
    // The user starts the checkout by clicking the checkout button.
    // This may be after they have updated the quantities of items in the cart, etc.
    checkoutSessionFrame = Instrumentation.startSessionFrame("Checkout");
  }

  public void onConfirmOrderButtonClicked() {
    // Once they have confirmed payment info and shipping information, and they
    // are clicking the "Confirm" button to start the backend process of checking out,
    // we may know more information about the order itself, such as an order ID.
    checkoutSessionFrame.updateName("Checkout: Order ID " + orderId);
  }

  public void onProcessOrderCompleted() {
    // Once the order is processed, the user is done "checking out", so we end the session frame.
    checkoutSessionFrame.end();
    checkoutSessionFrame = null;
  }

  public void onCheckoutCanceled() {
    // If the user cancels or returns to the cart, you'll want to end the session frame also, or else it will be
    // left open and appear to have never ended.
    checkoutSessionFrame.end();
    checkoutSessionFrame = null;
  }
}
```

Use a Custom HTTP Library

The Android Agent automatically detects network requests when the underlying implementation is handled by any one of the supported network libraries. To have the Android Agent detect requests from a custom library, add request tracking code to your application manually, using the `HttpRequestTracker` interface.

Supported Network Libraries

The libraries below cover the great majority of Android network requests. In some cases, however, mobile applications use custom HTTP libraries.

- `HttpURLConnection`
- `HttpsURLConnection`
- `HttpClient` classes
- `OkHttp`
- `OkHttp3`
- `ch.boye.httpclientandroidlib`

To set headers to allow correlation with server-side processing, use the `ServerCorrelationHeaders` class.

Add Request Tracking

To add request tracking manually, you use an `HttpRequestTracker` object to tell the agent when the request begins and when it ends and to report fields of the response to the agent.

Tracking a request

To begin tracking an HTTP request, use an instance of the following interface.

You must initialize the agent using the `Instrumentation.start` method before using this interface.

```
public interface HttpRequestTracker {
    public Exception getException();
    public HttpRequestTracker withException(Exception e);

    public String getError();
    public HttpRequestTracker withError(String error);

    public int getResponseCode();
    public HttpRequestTracker withResponseCode(int responseCode);

    public Map<String, List<String>> getResponseHeaderFields();
    public HttpRequestTracker withResponseHeaderFields(Map<String, List<String>> responseHeaderFields);

   /**
    * Stops tracking an HTTP request.
    *
    * Immediately after receiving a response or an error, set the appropriate fields and call this method to
    * report the outcome of the HTTP request. You should not continue to use this object after calling this
    * method -- if you need to track another request, obtain a new instance.
    */
    public void reportDone();
}
```

Example

Given a request snippet like this:

```
public byte[] sendRequest(URL url) throws HttpException {
    try {
        // implementation omitted
        return responseBody;
    } catch (UnderlyingException e) {
        throw new HttpException(e);
    }
}
```

Adding the tracker could look like this:

```
public byte[] sendRequest(URL url) throws HttpException {
    HttpRequestTracker tracker = Instrumentation.beginHttpRequest(url);
    try {
        // implementation omitted
        tracker.withResponseCode(theResponseCode)
               .withResponseHeaderFields(theResponseHeaderFields)
               .reportDone();
        return responseBody;
    } catch (UnderlyingException e) {
        tracker.withException(e)
               .reportDone();
        throw new HttpException(e);
    }
}
```

Attach a custom user data property to a network request

You can attach a custom user data property to a network request by adding `withUserData` to `HttpRequestTracker`:

```
public HttpRequestTracker withUserData(String key, String value)
```

Enable Server-Side Correlation

To enable correlation between your request and server-side processing, add specific headers to outgoing requests that the server-side agent can detect.

This is done automatically for standard HTTP libraries.

```
public class ServerCorreleationHeaders {
    public static Map<String, List<String>> generate();
}
```

You must:

1. Call the `generate` method and set the generated headers *before* sending a request to the backend.
2. Report back the response headers, using data from the `withResponseHeaderFields` field.

Override the Request/Response Content-Length

- You can generally obtain the content lengths of the network request and response by passing the headers with `HttpRequestTracker.withRequestHeaderFields()` and `HttpRequestTracker.withResponseHeaderFields()`.
- If for some reason this does not work for your custom HTTP tracking (i.e. the network library doesn't populate those fields until its being transmitted), then you can still report the request and response content lengths using `HttpRequestTracker.withRequestContentLength(Long length)` and `HttpRequestTracker.withResponseContentLength(Long length)`.
- For example, you want to track a request that has a `byte` array of content. You can report the request content length by passing the size of the byte array:

```
byte[] requestContent;
HttpRequestTracker tracker;
tracker.withRequestContentLength(requestContent.size());
```

Customize the Agent Configuration

To customize the behavior of the agent itself, you pass the `AgentConfiguration` object to the `Instrumentation.start` method. The `AgentConfiguration` object allows you to:

- Point to an on-premises EUM Server
- Enable logging
- Custom-set the application name, which is useful if you deploy the same application binary with different package names to different geographic areas. This ensures that all the data ends up being processed under the same name.
- Ignore HTTP requests internal to your application that are not used for network requests
- Configure the agent to use your custom HTTP library to send its beacons

Syntax

See the latest JavaDocs for more information.

```
Instrumentation.start(AgentConfiguration.builder()
      .withAppKey("<EUM_APP_KEY>")
      .withContext(getApplicationContext())
      .withCollectorURL(collectorURL*) // The URL of the EUM Server(on-prem)
      .withCompileTimeInstrumentationCheck(true) // Set to false if you are using features of the SDK only,
like custom HTTP support, but not to instrument your app.
      .withLoggingEnabled(true)//set default INFO logging. Tagged "AppDynamics".
      .withApplicationName(applicationName)//set a custom app name
      .withExcludedUrlPatterns(excludedUrlPatterns) // Set excluded url regex patterns for http tracking
      .withCollectorChannelFactory(collectorChannelFactory()) // The custom HTTP implementation to use
      .build());
```

*For a list of URLs of EUM servers, see External Access Locations.

Configure the Agent to Use Custom HTTP Library

The Android Agent uses HTTP to deliver beacons. If you want the agent use your custom HTTP library to deliver beacons:

1. Implement a class that extends the following abstract class:

```
public abstract class CollectorChannel {
    private URL url;
    private int connectTimeout;
    private int readTimeout;
    private Map<String, List<String>> requestProperties = new HashMap<String, List<String>>();
    private String requestMethod;

    public void setURL(URL url) {
        this.url = url;
    }

    public URL getURL() {
        return url;
    }

    public void setConnectTimeout(int connectTimeout) {
        this.connectTimeout = connectTimeout;
    }

    public int getConnectTimeout() {
        return connectTimeout;
    }

    public void setReadTimeout(int readTimeout) {
        this.readTimeout = readTimeout;
    }

    public int getReadTimeout() {
        return readTimeout;
    }

    public void addRequestProperty(String property, String value) {
        if (!requestProperties.containsKey(property)) {
            requestProperties.put(property, new ArrayList<String>());
        }
        requestProperties.get(property).add(value);
    }

    public Map<String, List<String>> getRequestProperties() {
        return Collections.unmodifiableMap(requestProperties);
    }

    public void setRequestMethod(String requestMethod) {
        this.requestMethod = requestMethod;
    }

    public String getRequestMethod() {
        return requestMethod;
    }

    public abstract OutputStream getOutputStream() throws IOException;

    public abstract InputStream getInputStream() throws IOException;

    public abstract int getResponseCode() throws IOException;

    public abstract Map<String,List<String>> getHeaderFields() throws IOException;
}
```

This interface is loosely based on `HttpURLConnection`.

2. Implement a version of the `CollectorChannelFactory` interface:

```
public interface CollectorChannelFactory {

    /**
     * Returns a new instance of CollectorChannel.
     *
     * If you want to supply a custom CollectorChannel, implement this interface, and return
     * an instance of your concrete implementation of CollectorChannel from this method.
     */
    public CollectorChannel newCollectorChannel();
}
```

The implementation of `newCollectorChannel` should return a new instance of your implementation of `CollectorChannel`.

3. Pass the `CollectorChannelFactory` to the `AgentConfiguration` object.

Capture User Interactions

You can enable the agent to track certain user interactions. Once user interactions have been captured, you can sort sessions by UI event and view the UI event in the timeline of the session waterfall.

You can capture when users do one or all of the following:

- Press buttons
- Select a text field
- Click a list item

Security and Privacy Concerns

The interaction capture mode is disabled by default for security and privacy reasons as user interactions may contain sensitive information. This potential security and privacy issue may be compounded if you enable both the capturing of UI interactions and screenshots.

Enable User Interaction Capture Mode

To enable user interaction capture mode, pass the capture mode to the method `withInteractionCaptureMode()` from an `AgentConfiguration` obj ect. The instrumentation code example below configures the Android Agent to capture all the supported types of user interactions.

```
Instrumentation.start(AgentConfiguration.builder()
      .withAppKey("<EUM_APP_KEY>")
      .withContext(getApplicationContext())
      .withInteractionCaptureMode(InteractionCaptureMode.All)
      .build());
```

You can also configure the Android Agent to only capture one type of user interaction:

```
Instrumentation.start(AgentConfiguration.builder()
      .withAppKey("<EUM_APP_KEY>")
      .withContext(getApplicationContext())
      .withInteractionCaptureMode(InteractionCaptureMode.ButtonPressed)
      .build());
```

Configure and Take Screenshots

Mobile screenshots are enabled by default in the agent. You can configure the Controller UI to automatically take screenshots or use the Android SDK to manually take a screenshot:

```
Instrumentation.takeScreenshot();
```

For example, you might want to take a screenshot after you load a UI element to view how the element is displayed to customers:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
   super.onCreate(savedInstanceState);
   setContentView(R.layout.activity_spinner_with_toast);
   spinner = (Spinner) findViewById(R.id.spnOptions);
   btnSpinnerVal = (Button) findViewById(R.id.btnSpinnerValue);
   loadSpinner();
   Instrumentation.takeScreenshot();
}
```

Disable Screenshots

You can disable screenshots from the Controller UI or with the Android SDK. To disable screenshots with the Android SDK, use the method `withScreens hotsEnabled(false)` from the `AgentConfiguration` class:

```
Instrumentation.start(AgentConfiguration.builder()
     .withAppKey("<EUM_APP_KEY>")
     .withContext(getApplicationContext())
     .withScreenshotsEnabled(false)
     .build());
}
```

Block/Unblock Screenshots

You can also use the Android SDK to block screenshots from being taken during the execution of a code block. This just temporarily blocks screenshots from being taken until you unblock screenshots. This enables you to stop taking screenshots in situations where users are entering personal data, such as on login and account screens.

You use the methods `Instrumentation.blockScreenshots()` and `Instrumentation.unblockScreenshots()` to block and unblock screenshots. If screenshots are disabled through `AgentConfiguration.Builder.withScreenshotsEnabled(true)` or through the Controller UI, these methods have no effect. You can call `Instrumentation.screenshotsBlocked()` to check if screenshots are being blocked.

The following example demonstrates how you could use the API to block and unblock screenshots when displaying user information.

```
public class UserAccountActivity extends Activity {
  ...
  public void displayCustomerAccount() {
    // Check to see if screenshots are blocked
    if (! Instrumentation.screenshotsBlocked()) {
        // If screenshots aren't blocked, block them before showing customer details
        Instrumentation.blockScreenshots();
    }
    // Code to display customer details
    displayAccount(this.user);
    // After you're done, unblock screenshots
    Instrumentation.unblockScreenshots();
  }
  ...
}
```

Transform URLs for Network Requests

When your application makes network requests, you may not want to report URLs containing sensitive information to the EUM Server. You can instead transform the network request URL before reporting it or ignore it altogether:

1. Implement a network request callback that modifies or ignores specific URLs.
2. Register the network request callback in the initialization code.

Implement the Network Request Callback

The callback that modifies or ignores specific URLs is an implementation of the interface below. The method `onNetworkRequest` is synchronous, we recommend that you return from the function quickly.

```
public interface com.appdynamics.eumagent.runtime.NetworkRequestCallback  {
    boolean onNetworkRequest(HttpRequestTracker httpRequestTracker);
}
```

Transforming URLs

The `onNetworkRequest` method, in general, should follow the steps below to transform URLs:

1. Identify specific URLs using techniques such as regex or pattern matching.
2. Modify the `url` property of the `HttpRequestTracker` object.
3. Assign a valid URL to the `url` property. Modifying other properties of the `HttpRequestTracker` object will be ignored.
4. Return `true`.

The first step is optional as you could choose to transform the URLs of all network requests.

```
private static class myNetworkRequestCallback implements com.appdynamics.eumagent.runtime.
NetworkRequestCallback  {
    @Override
    public boolean onNetworkRequest(HttpRequestTracker httpRequestTracker) {
        URL urlMask = new URL("http://networkrequest-mask.com/");
        httpRequestTracker.withURL(urlMask);
        return true;
    }
}
```

In general, however, you would want to identify and transform URLs that contain sensitive information. For example:

```
private static class myNetworkRequestCallback implements com.appdynamics.eumagent.runtime.
NetworkRequestCallback  {
    @Override
    public boolean onNetworkRequest(HttpRequestTracker httpRequestTracker) {
        String urlString = httpRequestTracker.getURL().toString();
        try {
            URL url = new URL("http://customer-account.com/");
            if (urlString.contains("accountInfo")) {
                // Change the URL for calls to Facebook
                httpRequestTracker.withURL(url);
                return true;
            }
        } catch (MalformedURLException e) {
            return false;
        }
        return true;
    }
}
```

Ignoring URLs

If the `onNetworkRequest` method returns `false`, the beacon is dropped. The general process for ignoring beacons is:

1. Identify specific URLs using techniques such as regex or pattern matching.
2. Return `false`.

You could also ignore all network requests with the following implementation of `onNetworkRequest:`

```
private static class myNetworkRequestCallback implements com.appdynamics.eumagent.runtime.
NetworkRequestCallback  {
    @Override
    public boolean onNetworkRequest(HttpRequestTracker httpRequestTracker) {
        return false;
    }
}
```

In general, you would identify network requests that you didn't want to monitor and return `false` to ignore the network request. For example:

```
private static class myNetworkRequestCallback implements com.appdynamics.eumagent.runtime.
NetworkRequestCallback  {
    @Override
    public boolean onNetworkRequest(HttpRequestTracker httpRequestTracker) {
        String urlString = httpRequestTracker.getURL().toString();
        try {
            URL url = new URL("http://socialnetworksite.com/");
            if (urlString.contains("avatar")) {
                // Ignore calls for avatars
                return false;
            }
        } catch (MalformedURLException e) {
            return false;
        }
        return true;
    }
}
```

Register the Network Request Callback

After implementing the callback, you register it in the initialization code. When the Android Agent is ready to create a network request beacon, it will first call the callback with an `HttpRequestTracker` object.

To register the callback in the initialization code:

```
Instrumentation.start(AgentConfiguration.builder()
        .withContext(getApplicationContext())
        .withAppKey("<EUM_APP_KEY>")
        .withNetworkRequestCallback(new myNetworkRequestCallback())
        .build());
```

Enable Logging and Set Logging Level

You use the method `withLoggingLevel` of the class `AgentConfiguration` to enable logging and set the logging level. You can set logging to one of the following levels:

- `LOGGING_LEVEL_NONE`
- `LOGGING_LEVEL_INFO`
- `LOGGING_LEVEL_VERBOSE`

Use verbose logging only for troubleshooting. Make sure to disable for production.

Example:

```
AgentConfiguration config = AgentConfiguration.builder()
config.withAppKey(appKey)
config.withContext(context)
 .withLoggingLevel(Instrumentation.LOGGING_LEVEL_VERBOSE)
        .build();
    Instrumentation.start(config);
```

Android SDK Documentation

For the complete SDK API documentation, see the latest JavaDocs or the previous versions listed below:

- https://sdkdocs.appdynamics.com/android-sdk/20.3/

Manually Upload Mapping Files

Related pages:

- Automatically Upload Mapping Files

If you have obfuscated your code and want to monitor crashes, you will need to upload the ProGuard or DexGuard mapping files. AppDynamics needs the mapping file for the application to produce human-readable stack traces for crash snapshots. For details about why you should do this, see Get Human-Readable Crash Snapshots.

DexGuard is built on ProGuard, so the Controller UI and some of the REST API for uploading mapping files will refer to ProGuard for both ProGuard and DexGuard files.

This page describes the requirements, the available methods, and instructions to manually upload the mapping files.

It is highly recommended to set up automatic uploading of the ProGuard or DexGuard mapping files using Gradle and your `build.gradle` file.

Requirements

To manually upload the mapping files, you need to associate the mapping file with the correct version of the application by providing the following:

- the package name of the Android package for the application
- the version code for that application specified in either the `AndroidManifest.xml` file or the `build.gradle` file

Upload Methods

You can then either upload the mapping file using the **Upload missing ProGuard Mappings** dialog in the Controller UI or use a special REST API. Perform the upload separately for each ProGuard mapping file that you are providing. You can also check your uploads with a separate REST API.

If you update your application, you need to upload the new version of the mapping file.

Upload with the Controller UI

1. From the Mobile App menu, click **Configuration**.
2. Click **ProGuard Mappings >**.
3. From the **Upload missing ProGuard Mapping** dialog:
    a. Enter the version code (a number) for the package. This is the `versionCode` property specified in either the `AndroidManifest.xml` file or the `build.gradle` file of the application for which this mapping file was generated.
    b. Click **Choose File.**
    The uploader expects a file with the `.txt` extension. The file is named `mapping.txt`.
    c. In the file browser, locate and select the mapping file and click **Open**.
    d. Click **Upload**.

Upload with the REST API

The API uses HTTP basic authentication. The username is your AppDynamics EUM account name and the password is your EUM license key.

Send the mapping file

Send the mapping file as a text file in the body of the PUT request to the following URL:

```
https://api.eum-appdynamics.com/v2/account/<MyAccountName>/<androidPackageName>/<versionCode>/proguard-mapping
```

These parameters are required:

- `MyAccountName`: the URL-encoded version of your account name.
- `androidPackagename`: the name of the Android package for which this mapping file was generated.
- `versionCode`: the string representation of the "versionCode" property specified in either the `AndroidManifest.xml` file or the `build.gradle` file of the application for which this mapping file was generated.

The request body contains the mapping file. You need to add a `Content-Type` header, `-H Content-Type:text/plain,` and your account name and license key/password to the call.

Sample Request and Response Using the REST API

This is a sample request and response using the REST API.

Upload Request

The following example uses curl to send a ProGuard mapping file. You would use a similar command to send a DexGuard mapping file. The account name is "Example account" and the license key/password is "Example-License-Key-4e8ec2ae6cfe". The plus signs replace spaces in the account name when the account name is URL-encoded. The package name of the Android application is "com.example.networklogger". The mapping file corresponds to the version with `versionCode`.

```
curl -v -H Content-Type:text/plain --upload-file mapping.txt --user Example+account:Example-License-Key-
4e8ec2ae6cfe https://api.eum-appdynamics.com/v2/account/Example+account/com.example.networklogger/1/proguard-
mapping
```

Upload Response

The successful output of the example request looks like this:

```
* About to connect() to api.eum-appdynamics.com port 443 (#0)
*   Trying ::1...
* connected
* Connected to api.eum-appdynamics.com  (::1) port 443 (#0)
* Server auth using Basic with user 'Example+account'
> PUT /v2/account/Example+account/com.example.networklogger/1/proguard-mapping HTTP/1.1
> Authorization: Basic SW50ZXJuYWwrdGVzdCthY2NvdW50OlRlc3RBY2N0LTFlMzktNDVkMy05MzAzLTRlOGVjMmFlNmNmZQ==
> User-Agent: curl/7.24.0 (x86_64-apple-darwin12.0) libcurl/7.24.0 OpenSSL/0.9.8y zlib/1.2.5
> Host: app.eum-appdynamics.com
> Accept: */*
> Content-Length: 4
> Expect: 100-continue
>
< HTTP/1.1 100 Continue
* We are completely uploaded and fine
< HTTP/1.1 200 OK
< Content-Length: 0
< Server: Jetty(8.1.4.v20120524)
<
* Connection #0 to host app.eum-appdynamics.com left intact
* Closing connection #0
```

Check Uploaded Mapping Files Using the REST API

You can check to make sure that your mapping files have successfully uploaded using two REST APIs.

1. Get a list of the GUIDs for the last 50 mapping files you have uploaded.
2. Check if a specific mapping file has been uploaded.

List of the Last 50 Mapping Files Uploaded

The `proguardQuery` method allows you to retrieve a list of GUIDs for up to the last 50 mapping files (ProGuard or DexGuard) that have been uploaded to your account, along with the time they were uploaded. The response is displayed as JSON, by upload time, with the most recent first.

1. Set up your authentication as described in Upload with the API.
2. Create a GET request of the form:

   ```
   curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://<EUM_Cloud/EUM_Server_Host:port>/v2
   /account/<EUM_Account_Name>/crash-symbol-file-query/proguard
   ```

   where the value for `--user` is the authentication string you created in step 1, **`EUM_Cloud`** refers to `api.eum-appdynamics.com:443` for SaaS-based EUM Cloud accounts or **EUM_Server_Host**, which refers to the URL where your on-premises EUM Server is hosted, and **`EUM_Account_Name`** is your EUM account name.

Sample Request

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe  https://api.eum-appdynamics.com:443/v2/account
/<EUM_Account_Name>/crash-symbol-file-query/proguard
```

Sample Response

```
{"proguardFiles": [
{"packageName":"my_package_name1", "version":"1", "uploadTime":"mm/dd/yyyy 16:09:23","GUID":"my_build_id1"},
{"packageName":"my_package_name2", "version":"1", "uploadTime":"mm/dd/yyyy 16:09:23","GUID":"my_build_id2"}
]}
```

Check for Specific Mapping File by GUID

The `checkForProguardFile` method allows you to check if a specific ProGuard or DexGuard file by GUID has been uploaded. The upload time is returned in the response.

a. Set up your authentication as described in Upload with the REST API.
b. Create a GET request of the form:

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://<EUM_Cloud/EUM_Server_Host:
port>/v2/account/<EUM_Account_Name>/crash-symbol-file-query/proguard/guid/<GUID_To_Check>
```

where the value for `--user` is the authentication string you created in step 1, **`EUM_Cloud`** `refers` to `api.eum-appdynamics.com:443` for SaaS-based EUM Cloud accounts or **EUM_Server_Host** refers to the URL pointing to your on-premises EUM Server, **`EUM_Account_Name`** is your EUM account name and **`GUID_To_Check`** is the GUID of the ProGuard file in which you are interested.

Sample Request

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe  https://api.eum-appdynamics.com:443
/v2/account/<EUM_Account_Name>/crash-symbol-file-query/proguard/guid/my_build_id1
```

Sample Response

```
{"packageName":"mypackagename","version":"1","uploadTime":"mm/dd/yyyy 16:09:23","GUID":"
my_build_id1"}
```

Troubleshoot the Android Instrumentation

Related pages:

- Instrument Android Applications
- Customize the Android Build
- Customize the Android Instrumentation

This page provide instructions and tips for solving some common Android instrumentation issues.

Dex Failure After Upgrading Agent

If you build your application with Gradle and you get a dex failure after upgrading the Mobile Agent, you likely need to clear the Gradle cache.

Use Android Studio

To clear the cache using Android Studio:

1. Select **Build** > **Clean Project.**
2. Select **File** > **Invalidate Caches.**

Sometimes a restart is also necessary.

Using the Command Line

To clear the cache using the command line:

1. Stop Gradle.

```
$ gradlew --stop
```

2. You may also need to refresh dependencies.

```
$ gradlew --refresh-dependencies
```

You can also try removing the AppDynamics cached images.

1. Find the images.

```
$ find ~/.gradle/caches -name com.appdynamics
```

2. Delete them.

```
$ find ~/.gradle/caches -name com.appdynamics -print0 | xargs -0 rm -r
```

Instrumentation Appears to Be Running After Being Disabled

If you disabled the instrumentation in Android using the Gradle flag `enabledForDebugBuilds`, but the instrumentation task still runs, this is because of the Transform API.

Android Gradle Plugin 1.5.0 introduced the Transform API that the Android Agent uses to do the bytecode injection. Due to the limitations of the Transform API, even when instrumentation is disabled, the `transformClassesWithAppDynamicsForDebug` task will still appear in the Gradle task log. To ensure that it is not actually instrumenting, run `gradle` with `--info` flag to show the info logs.

You should see the following log:

```
Instrumentation is disabled for this build variant. Just copying the input files to fulfill Transform contract.
```

Crashes Are Not Reported After Using Custom Default Uncaught Exception Handler

Install your exception handler before you start the Android Agent. When an uncaught exception is handled by the agent, it will first store the crash report, and then call your exception handler.

Network Requests Are Not Being Reported

Please see the list of supported networking libraries. If your library is not on the list, you can always report these network requests manually.

For builds with the `debuggable` attribute, auto-instrumentation (the `enableInstrumentation` build attribute) is disabled to improve build speeds, and you cannot enable auto-instrumentation for those builds. Debuggable builds using Android Agent 20.5.0-20.7.0 do not auto-instrument network requests.

Exclude Classes from Being Instrumented

- `excludeClasses`

Enforce a Different Runtime Version from the Plugin Version

- ```
  dependencies.compile 'com.appdynamics:appdynamics-runtime:4.5.+'
  adeum.dependencyInjection.enabled = false
  ```
  ```

Instrument Xamarin Applications

Before you can monitor your Xamarin application, you will need to instrument your application to enable the Xamarin Agent to collect mobile metrics.

After you have set up and accessed Mobile RUM, follow these instructions:

1. Confirm that the Xamarin Agent supports your platform
2. Understand the limitations of the Xamarin Agent
3. Instrument a Xamarin Application
4. Customize the Xamarin Instrumentation (Optional)

Xamarin Agent Support

Supported Platforms

- iOS and Android platforms

> All other platforms will build and run without errors, but no monitoring will occur.

Supported Libraries

- .Net Standard 2.0 (with Xamarin Agent >= 20.10.0)

> **Recommendations**
>
> Xamarin <= 50.2 only supported the instrumentation of applications that reference the Portable Class Libraries (PCL). From Xamarin >= 50.3, the Xamarin Agent only supports the .NET Standard library and the instrumentation of applications that reference the .NET Standard library. If you still need PCL support, you are recommended to use Xamarin <= 50.2.

Limitations

The Xamarin Agent has these limitations:

- Automatic instrumentation is not supported, so you will need to manually report events and metrics.
- Symbolication is not supported, although the Xamarin Agent *does* report uncaught exceptions and native application crashes.

Instrument Xamarin Applications

Follow the steps below to manually instrument your Xamarin iOS, Android, and Forms apps.

Add the Xamarin Agent Package

1. Get the Xamarin Agent from the NuGet Gallery. Follow the instructions given in Adding a Package to add the package `AppDynamics Xamarin Agent` from nuget.org.
2. In the `Xamarin.Android` project, add the following to `MainActivity.cs` under `OnCreate`:

```
AppDynamics.Droid.Agent.Init(this, bundle);
```

Example

```
public class MainActivity : global::Xamarin.Forms.Platform.Android.FormsAppCompatActivity {
    protected override void OnCreate(Bundle bundle) {
        base.OnCreate(bundle);  //existing code
        global::Xamarin.Forms.Forms.Init(this, bundle);

        AppDynamics.Droid.Agent.Init(this, bundle); //initialize the agent on the Android Platform

        LoadApplication(new App());
    }
}
```

Get Your Application Key

Complete the **Getting Started Wizard** to get an EUM App Key. You will need this key when you modify the source code. In some cases, multiple mobile applications can share the same key.

Because there is no Xamarin platform option, you will need to choose either Android or iOS. For Android, you will need to select **Manual**.

If you have completed the **Getting Started Wizard**, but don't have your EUM App Key, see Get Your Application Key.

Add the Required Permissions (Android Deployments Only)

Open the file `Properties/AndroidManifest.xml` and verify that it has these permissions:

```
<uses-permission android:name="android.permission.INTERNET"></uses-permission>
<uses-permission android:name="android.permission.ACCESS_NETWORK_STATE"></uses-permission>
```

If these permissions are not present, add them.

Link the AppDynamics Agent Assembly

Forms Solution

Xamarin Forms is the unified development environment for running all platforms. If you try to run something on an unsupported platform, linking our agent won't allow you to monitor the application, but it also will not cause any errors.

To use the Xamarin Agent for your iOS/Android apps, add the `using` directive at the top of the `App.xaml.cs` file:

```
using Xamarin.Forms;
using AppDynamics.Agent;

namespace <AppName>
{
    public partial class App : Application
    {
        ...
    }
}
```

iOS Solution

To use the Xamarin Agent in iOS apps, add the `using` directive at the top of the `AppDelegate.cs` file:

```
using Foundation;
using UIKit;
using AppDynamics.Agent;

public class AppDelegate : UIApplicationDelegate
{
    ...
}
```

Android Solution

To use the Xamarin Agent in Android apps, add the using directive at the top of the `MainActivity.cs` file:

```
using Android.App;
using Android.Widget;
using Android.OS;
using System;
using Android.Content;
using AppDynamics.Agent;

namespace <AppName>
{
    [Activity(Label = "Phoneword", MainLauncher = true, Icon = "@mipmap/icon")]
    public class MainActivity : Activity
    {
       ...
    }
    ...
}
```

Initialize the Agent

To initialize the Xamarin Agent, you use the code below for iOS and Android. Use the EUM app key (enter as a string) that you received after completing step 2.

```
var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
```

If you are running an on-premises EUM Server, you need to specify the URL to the EUM Server. See Point to an On-Premises EUM Server (Optional) to learn how.

Forms Solution

For Forms Solutions, you only need to place the initialize code in the constructor of the `App.xaml.cs` file for the Xamarin Agent to instrument both Android and iOS applications.

```
public App()
{
    InitializeComponent();
    // This initialization code is used by both iOS and Android apps.
    var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
    AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
    MainPage = new FormsExamplePage();
}
```

If you have application code in the `MainActivity.cs` file for Android or `AppDelegate.cs` for iOS that you want to instrument, however, you should initialize the Xamarin Agent in those files as you would do for iOS Solutions and Android Solutions.

iOS Solution

For iOS apps, you place the initialize code In the `AppDelegate.cs` file in the method `FinishedLaunching` of the class `AppDelegate` as shown below.

```
public class AppDelegate : UIApplicationDelegate
{
   // class-level declarations
   public override UIWindow Window
   {
      get;
      set;
   }
   public override bool FinishedLaunching(UIApplication application, NSDictionary launchOptions)
   {
       // The two lines below initialize the AppDynamics instrumentation.
       var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
       AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
       ...
       return true;
    }
    ...
}
```

You may also consider placing it in the `Main.cs` int the method `Main`.

Android Solution

In the `MainActivity.cs` file, place the initialization code in the method `OnCreate`:

```
class MainActivity {

  protected override void OnCreate(Bundle savedInstanceState) {
    // The two lines below initialize the AppDynamics instrumentation.
    var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
    AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
    ...
  }
}
```

Build the Application

Run and build your application from Visual Studio. From the **Getting Started Wizard**, you should see that the application has connected and the instrumentation has been verified.

For iOS projects with Xamarin Agent 20.10.0 - 21.4.0, you must add the additional `MtouchExtraArgs` argument `--gcc_flags "-ObjC -lz"` for each build configuration, such as the `debug` and `release` builds. If the iOS project file is edited directly, the build configuration should contain the `MtouchExtraArgs` element:

```
<PropertyGroup Condition=" '$(Configuration)|$(Platform)' == 'Debug|iPhoneSimulator' ">
    <DebugSymbols>true</DebugSymbols>
    <DebugType>full</DebugType>
    <Optimize>false</Optimize>
    <OutputPath>bin\iPhoneSimulator\Debug</OutputPath>
    <DefineConstants>DEBUG;ENABLE_TEST_CLOUD;</DefineConstants>
    <ErrorReport>prompt</ErrorReport>
    <WarningLevel>4</WarningLevel>
    <CodesignKey>iPhone Developer</CodesignKey>
    <MtouchDebug>true</MtouchDebug>
    <MtouchFastDev>true</MtouchFastDev>
    <MtouchLink>SdkOnly</MtouchLink>
    <MtouchArch>x86_64</MtouchArch>
    <MtouchHttpClientHandler>HttpClientHandler</MtouchHttpClientHandler>
    <MtouchTlsProvider>Default</MtouchTlsProvider>
    <DeviceSpecificBuild>false</DeviceSpecificBuild>
    <MtouchExtraArgs>--gcc_flags "-ObjC -lz"</MtouchExtraArgs>
  </PropertyGroup>
```

Customize Your Instrumentation (Optional)

The Xamarin SDK has additional classes to allow you to extend the kinds of application data you can collect and aggregate using Mobile RUM. See Customize the Xamarin Instrumentation.

Point to an On-Premises EUM Server (Optional)

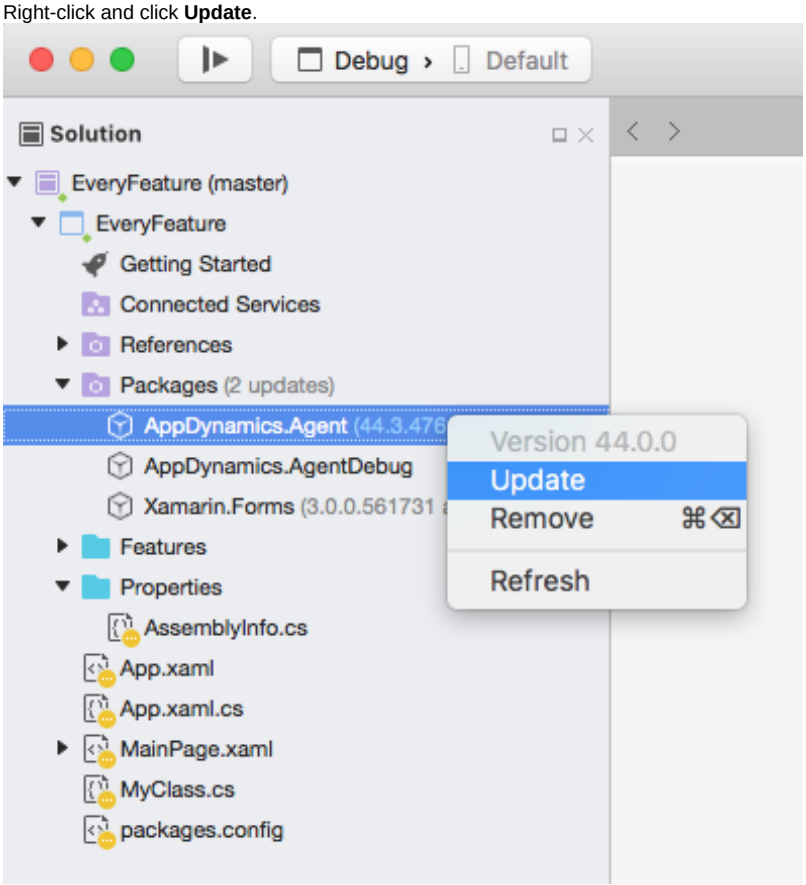
To use an on-premises EUM Server, you pass the URL to the on-premises EUM Server when you initialize the instrumentation with the EUM App Key from Get Your Application Key:

```
var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
config.CollectorURL = <COLLECTOR_URL:PORT>;
AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
```

Upgrade the Xamarin Agent

As new features are added to the agent, you will need to upgrade the Xamarin Agent package in your app.

1. From Visual Studio, open the Xamarin application that has the AppDynamics Agent package.
2. From the **Packages** folder, select the AppDynamics Agent.
3. Right-click and click **Update**.



Customize the Xamarin Instrumentation

Related pages:

- Instrument Xamarin Applications
- Xamarin SDK Documentation

The following sections show you how to use the Xamarin SDK to customize your instrumentation.

Because the agent stores data about events in a local buffer before reporting the information, you are recommended to use the APIs with discretion.

Track Calls

You can instrument methods to see how often the instrumented a method is invoked and how long it takes to run. To do this, add a call at the beginning and end of the method you'd like to instrument.

In the example below, the code executed in the constructor for the class `ShoppingCart` will be tracked and reported. In your own code, start tracking calls by specifying the class and method in `BeginCall` and then complete the tracking and report the data by calling `ReportCallEnded`.

```
using AppDynamics.Agent;
...
public class ShoppingCart {
    public ShoppingCart() {

        // Code to create the shopping cart
    }
    void CheckOut(int custId, int transactionId) {
      var tracker = Instrumentation.BeginCall("ShoppingCart", "CheckOut", custId, transactionId);
       // The code placed here will be tracked and reported.
       tracker.ReportCallEnded();
    }
}
```

Timing Events

Sometimes you want to time an event in your application that spans multiple methods. You can do this by calling `StartTimerWithName` when the event starts, and then `StopTimerWithName` when it ends. For example, to track the time a user spends viewing a screen, the instrumentation might look something like the following:

```
using AppDynamics.Agent;
...
async private void StartCapturePreview_Click(object sender, RoutedEventArgs e) {
    capturePreview.Source = captureManager;
    Instrumentation.StartTimerWithName("CapturePreview");
    await captureManager.StartPreviewAsync();
}
async private void StopCapturePreview_Click(object sender, RoutedEventArgs e) {
    await captureManager.StopPreviewAsync();
    Instrumentation.StopTimerWithName("CapturePreview");
}
```

Report Metrics

To report other types of data, you can use a metric. The metric name should only contain alphanumeric characters and spaces. Illegal characters are replaced by their ASCII hex value. The metric value must be a long integer.

The snippet below shows how you might report a metric.

```
using AppDynamics.Agent;
...
Instrumentation.ReportMetricWithName("Database Rows", 5123);
```

Add Tracking to HTTP Requests

Semi-automatic HTTP Tracking

The `HttpMessageHandler` handles all the tracking and error handling. It can also include other inner handlers if you are already using a custom `HttpMessageHandler` for other purposes, such as for logging.

To add semi-automatic tracking, instantiate a `HttpClient` and pass the `HttpRequestTrackerHandler`:

```
var client = new HttpClient(new HttpRequestTrackerHandler());
```

Then, all the requests sent using the client will be already instrumented:

```
 response = await client.GetAsync(uri);
```

If you already have `HttpMessageHandler` passed to the `HttpClient` (for example, adding a logging handler), you must instantiate `HttpRequestTrackerHandler` and pass the existing handler to the constructor:

```
var loggingHandler = new MyLoggingHandler();
var client = new HttpClient(new HttpRequestTrackerHandler(loggingHandler));
```

Manual HTTP Tracking

You can manually report a network request using the `AppDynamics.Agent.HTTPRequestTracker` class.

The example below uses `HTTPRequestTracker` with the `System.Net.Http.HttpClient` class. The `tracker` object synchronously captures and reports the network request as well as any network errors.

```
using AppDynamics.Agent;
...
public async Task<string> Fetch(Uri uri) {
  var client = new HttpClient();
  // Create AppDynamics Tracker
  var tracker = HTTPRequestTracker.Create(uri);
  // Add AppDynamics Server Correlation Headers
  foreach (var header in ServerCorrelationHeaders.Generate) {
      // Each header could have multiple values
      foreach (var value in header.Value) {
          client.DefaultRequestHeaders.Add(header.Key, value);
      }
  }
  HttpResponseMessage response = null;
  try {
      response = await client.GetAsync(uri);
  } catch (Exception ex) {
      // Capture any network errors.
      tracker.Exception = ex;
      tracker.ReportDone();
      throw ex; //you decide to throw it or not
  }
  if (!response.Equals(null)) {
      // Capture request information such as the
      // status code, status message, and headers.
      tracker.ResponseCode = (int)response.StatusCode;
      tracker.StatusLine = response.ReasonPhrase;
      tracker.ResponseHeaderFields = response.Headers;
      tracker.ReportDone();
      return await response.Content.ReadAsStringAsync();
   }
   return null;
}
```

Leave Breadcrumbs

You can leave breadcrumbs to mark interesting events. For example, if your application crashes, the breadcrumbs you left with be displayed in the crash report and could provide context. You can also configure the breadcrumb to appear in sessions.

The following is the method signature for leaving breadcrumbs:

```
static void AppDynamics.Agent.Instrumentation.LeaveBreadcrumb(string breadcrumb, BreadcrumbVisibility mode)
```

You use the mode to set the visibility of the breadcrumb. The visibility defines where you will see the breadcrumb in the Controller UI. The value of `mode` can be one of the following:

- `BreadcrumbVisibility.CrashesOnly` – The breadcrumb will only appear in crash snapshots.
- `BreadcrumbVisibility.CrashesAndSessions` – The breadcrumb will appear in crash snapshots and sessions.

Thus, you would use the method below to set breadcrumbs that are only reported in crash reports:

```
using AppDynamics.Agent;
...
Instrumentation.LeaveBreadcrumb("GetUserInfo", BreadcrumbVisibility.CrashesOnly);
```

If you would like to see the breadcrumb in crash reports and sessions:

```
using AppDynamics.Agent;
...
Instrumentation.LeaveBreadcrumb("GetUserInfo", BreadcrumbVisibility.CrashesAndSessions);
```

Disable the Agent to Stop Sending User Data to the Collector

You can disable the agent to stop sending all data to the collector while the agent is initialized and running. For example, you can disable the agent if your app has an option for users to opt-out of monitoring for privacy reasons.

`shutdownAgent`

The `shutdownAgent` call stops outgoing data to the collector, and does not persist data on the device.

```
using AppDynamics.Agent;
...
Instrumentation.shutdownAgent();
```

- The call only stops the traffic out of the agent.
- Once the agent has been initialized, the call cannot be removed, and a license will have been consumed.
- If you want to make this state permanent for a device, add code in UserDefaults to save the state and use that flag to conditionally initialize the agent in your code.

`restartAgent`

To re-enable the agent and reverse `shutdownAgent`, use `restartAgent`.

```
using AppDynamics.Agent;
...
Instrumentation.restartAgent();
```

- This call will respect the server side calls that can remotely shutdown the agent in a similar way.
- The call is only in effect while the app is running.
- The call will be ignored if the agent has been remotely disabled.
- If the call is removed from memory and the app restarts, or the device is rebooted, the agent will be initialized as

Report Errors and Exceptions

You can report exceptions using the method `reportError` from the `Instrumentation` class. Reported exceptions will appear in session details.

You can also set one of the severity levels below for an issue. With the severity level, you can filter errors in the **Code Issues Dashboard** or **Code Issues Analyze**.

- `ErrorSeverityLevel.INFO`
- `ErrorSeverityLevel.WARNING`
- `ErrorSeverityLevel.CRITICAL`

The example below uses the API to report possible exceptions and sets the severity level to `ErrorSeverityLevel.CRITICAL` (critical) when writing to a file

```
using AppDynamics.Agent;
...
try {
    // possible exception //
}
catch (Exception e){
    Instrumentation.ReportError(exception, ErrorSeverityLevel.CRITICAL);
}
```

Disable the Reporting of Exceptions as Crashes

By default, the Xamarin Agent reports exceptions as a crash. You can enable or disable the all exceptions as crashes with the boolean property `enableExceptionReporting`. The default value is `true`.

```
using AppDynamics.Agent;
...
var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
AppDynamics.Agent.Instrumentation.enableExceptionReporting = false;
AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
...
```

Report Aggregate Exceptions as Crashes

You can configure the Xamarin Agent to report aggregate exceptions (handled and unhandled) as crashes by setting the boolean property `EnableAggregateExceptionHandling` to `true`. When the property is set to `false`, only unhandled exceptions are reported. The default value is `false`.

The following code example configures the Xamarin Agent to report aggregate exceptions (handled and unhandled) as crashes.

```
using AppDynamics.Agent;
...
var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
AppDynamics.Agent.Instrumentation.EnableAggregateExceptionHandling = true;
AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
...
```

Disable Crash Reporting

Crash reporting is enabled by default, but you can manually disable crash reporting through the instrumentation configuration. If you are using other crash reporting tools, you might disable crash reporting to minimize conflicts and optimize the crash report results.

You can disable crash reporting by configuring the instrumentation with the `crashReportingEnabled` property as shown in the following:

```
var config = AgentConfiguration.Create(<EUM_APP_KEY>);
config.CrashReportingEnabled = false;
Instrumentation.InitWithConfiguration(config);
```

Programmatically Control Sessions

By default, a mobile session ends after a period of user inactivity. For example, when a user opens your application, the session begins and only ends after the user stops using the app for a set period of time. When the user begins to use the application again, a new session begins.

Instead of having a period of inactivity to define the duration of a session, however, you can use the following API to programmatically control when sessions begin and end:

```
static void AppDynamics.Agent.Instrumentation.StartNextSession()
```

When you call the method `StartNextSession`, the current session ends and a new session begins. The API enables you to define and frame your sessions so that they align more closely with business goals and expected user flows. For example, you could use the API to define a session that tracks a purchase of a product or registers a new user.

Excessive use of this API will cause sessions to be throttled (excessive use is > 10 calls per minute per Xamarin Agent, but is subject to change). When not using the API, sessions will fall back to the default of ending after a period of user inactivity.

Example of a Programmatically Controlled Session

In the example below, the current session ends and a new one begins when an item is bought.

```
using AppDynamics.Agent;
...
public async Task BuySaleItemAsync(SaleItem item)
{
    try
    {
        bool buySucceeded = await this.MobileService.InvokeApiAsync<SaleItem, bool>("buy", item);
        if (buySucceeded)
        {
            await UserDialogs.Instance.AlertAsync("Thanks for buying this item");
            Instrumentation.StartNextSession();
        }
    }
    catch (Exception e)
    {
        Debug.WriteLine(@"Unexpected error {0}", e.Message);
    }
}
```

Start and End Session Frames

You can use the `ISessionFrame` API to create session frames that will appear in the session activity. Session frames provide context for what the user is doing during a session. With the API, you can improve the names of user screens and chronicle user flows within a business context.

Use Cases

The following are common use cases for the `ISessionFrame` API:

- One screen performs multiple functions and you want more granular tracking of the individual functions.
- A user flow spans multiple screens or user interactions. For example, you could use the API to create the session frames "Login", "Product Selection", and "Purchase" to chronicle the user flow for purchases.
- You want to capture dynamic information based on user interactions to name session frames, such as an order ID.

ISessionFrame API

The table below lists the two methods and one property you can use with session frames. In short, you start a session frame with `StartSessionFrame` an d then use the returned `ISessionFrame` object to rename and end the session frame.

Class	Method/Property	Description
`Instrument`	Method: `static ISessionFrame StartSessionFrame(string sessionFrameName)`	Use this to start and name your session frame. Naming session frames enables you to easily identify
`ISessionFra me`	Property: `string Name`	Rename the session frame name. You assign the updated session frame name with this `sionFrame`.
`ISessionFra me`	Method: `static void End()`	End the session frame. You call this method from the `ISessionFrame` objec

Session Frame Example

In the following example, the `ISessionFrame` API is used to track user activity during the checkout process.

```
using AppDynamics.Agent;
...

namespace ShoppingApp {
    public partial class ShoppingCart : ContentPage {
        private ISessionFrame sessionFrame;
        private string orderId;
        ...
        void checkoutCartButtonClicked(object sender, EventArgs e) {
            // The checkout starts when the user clicks the checkout button.
            // This may be after they have updated quantities of items in their cart, etc.
            sessionFrame = Instrumentation.StartSessionFrame("Checkout");
        }
        void confirmOrderButtonClicked(object sender, EventArgs e) {
            // Once they have confirmed payment info and shipping information, and they
            // are clicking the "Confirm" button to start the backend process of checking out,
            // we may know more information about the order itself, such as an order ID.
            sessionFrame.Name = $"Checkout: Order ID {this.orderId}";
        }
        void processOrderCompleted(object sender, EventArgs e) {
            // Once the order is processed, the user is done "checking out" so we end
            // the session frame.
            sessionFrame.End();
        }
        void checkoutCancelled(object sender, EventArgs e) {
            // If they cancel or go back, you'll want to end the session frame also, or else
            // it will be left open and appear to have never ended.
            sessionFrame.End();
        }
    }
}
```

Add User Data

You can set a key/value pair of strings to record important events or information. Below is the method signature for setting user data:

```
static void AppDynamics.Agent.Instrumentation.SetUserData(string key, string value)
```

For example, you might want to log the user ID when the method for logging in the user is called:

```
using AppDynamics.Agent;
...
void LogInUser(UserCredentials) {
   // Log in user
   ...
   // Set user data with the user name.
   Instrumentation.SetUserData("user_id", UserCredentials.ID);
}
```

This information is available in **Network Request Analyze** and is added to any crash snapshots that may be taken. Keys and values are limited to 2048 characters each.

You can also set user data with values of other types (long, boolean, double, DateTime) using the following methods:

- SetUserDataBoolean
- SetUserDataDate
- SetUserDataDouble
- SetUserDataLong

To remove user data, use the following methods:

- RemoveUserData
- RemoveUserDataBoolean
- RemoveUserDataDate
- RemoveUserDataDouble

- RemoveUserDataLong

Set the Logging Level (Optional)

You can set the logging level with the configuration `LoggingLevel` as part of the class AgentConfiguration.

You can set `LoggingLevel` to one of the levels listed in the table below.

Level	Description
`Off`	Agent will emit no messages at all.
`Error`	Only show errors and initial banner. This is the default.
`Warn`	Warning level messages and above.
`Info`	Information level messages and above May be useful to the developer.
`Debug`	Debug level messages and above. Useful for support personnel and developers.
`Verbose`	Verbose level messages and above. Use verbose logging only for troubleshooting. Be sure to disable for production.
`All`	All messages.

For example:

```
var config = AppDynamics.Agent.AgentConfiguration.Create("<#Your App Key#>");
config.LoggingLevel = AppDynamics.Agent.LoggingLevel.All;
AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
```

Transform URLs for Network Requests

Implement the Network Request Callback

The callback that modifies or ignore specific URLs should be assigned to the `Func` delegate below.

> The callback method `OnNetworkRequest` is synchronous, so we recommend that you return from the function quickly.

```
public Func<IHttpRequestTracker, bool> OnNetworkRequest { get; set; }
```

Transforming URLs

To transform URLs, the `OnNetworkRequest` method should:

1. Identify specific URLs using techniques such as regex or pattern matching.

   > This first step is optional because you can choose to transform the URLs of all network requests.

2. Modify the URL property of the `IHttpRequestTracker` object.
3. Assign a valid URL to the `url` property. Modifying other properties of the `IHttpRequestTracker` object will be ignored.
4. Return `true`.

For example:

```
public static bool NetworkRequestCallback(IHttpRequestTracker tracker)
{
    var maskUrl = new Uri("http://networkrequest-mask.com/");
    tracker.Uri = maskUrl;
    return true;
}
```

Transforming Sensitive URLs

You may want to identify and transform URLs that contain sensitive information.

For example:

```
public static bool NetworkRequestCallback(IHttpRequestTracker tracker)
{
    var urlString = tracker.Uri.ToString();
    if (urlString.Contains("accountInfo"))
    {
        tracker.Uri = new Uri("http://customer-account.com/");
    }
    return true;
}
```

Ignoring URLs

If the `onNetworkRequest` method returns `false`, the beacon is dropped. Generally, the process for ignoring beacons is:

1. Identify specific URLs using techniques such as regex or pattern matching.
2. Return `false`.

To ignore specific URLs, you would identify network requests that you didn't want to monitor and return `false` to ignore the network request.

For example:

```
public static bool NetworkRequestCallback(IHttpRequestTracker tracker)
{
    if (tracker.Uri.ToString().Contains("avatar"))
    {
        //ignore calls for avatars
        return false;
    }
    return true;
}
```

To ignore all network requests, implement the following:

```
public static bool NetworkRequestCallback(IHttpRequestTracker tracker)
{
    return false;
}
```

Register a Network Request Callback

To register a network request callback:

1. Define your own method to handle the callback:

   ```
   public static bool NetworkRequestCallback(IHttpRequestTracker tracker)
   {
       return true;
   }
   ```

2. Pass it during the `AgentConfiguration` initialization phase:

```
IAgentConfiguration config = AgentConfiguration.Create(appKey);
config.OnNetworkRequest += NetworkRequestCallback; //Register the Callback
Instrumentation.InitWithConfiguration(config);
```

3. Or you can use an anonymous function:

```
IAgentConfiguration config = AgentConfiguration.Create(appKey);
config.OnNetworkRequest += (IHttpRequestTracker tracker) =>
{
    return true;
};
Instrumentation.InitWithConfiguration(config);
```

Configure and Take Screenshots

Mobile screenshots are enabled by default, but you can configure the Controller UI to automatically take screenshots or use the Xamarin SDK to manually take a screenshot:

```
Instrumentation.TakeScreenshot();Disable Screenshots
```

The `takeScreenshot()` function limits screenshots to a maximum of 1 screenshot per 10 seconds.

Disable Screenshots

You can disable screenshots from the Controller UI or with the Xamarin SDK. To disable screenshots with the Xamarin SDK, set the property `ScreenshotsEnabled` of the `IAgentConfiguration` object to `false`:

```
IAgentConfiguration config = AgentConfiguration.Create(appKey); config.ScreenshotsEnabled = false;
Instrumentation.InitWithConfiguration(config);
```

Block and Unblock Screenshots

You can also use the Xamarin SDK to block screenshots from being taken during the execution of a code block. This just temporarily blocks screenshots from being taken until you unblock screenshots. This enables you to stop taking screenshots in situations where users are entering personal data, such as on login and account screens.

The Instrumentation class provides the methods `blockScreenshots()` and `unblockScreenshots()` to block and unblock screenshots.

If screenshots are disabled through the property `ScreenshotsEnabled` of the `IAgentConfiguration` object or through the Controller UI, these methods have no effect. You can also check the `Instrumentation.ScreenshotsBlocked` property to check if screenshots are being blocked.

```
public void LoginUser()
{
        if (!Instrumentation.ScreenshotsBlocked)
        {
                Instrumentation.BlockScreenshots();
        }
        LoginCredentials credentials = UserLogin.GetCredentials();

        if (credentials.Authorized)
        {
                RedirectToProfile(credentials.user);
                Instrumentation.UnblockScreenshots();
        }
}
```

Xamarin SDK Documentation

For the complete SDK API documentation, see the latest Xamarin SDK documentation or the previous versions listed below:

- https://sdkdocs.appdynamics.com/xamarin-sdk/21.5/html/

Instrument Cordova Applications

Related pages:

- Hybrid Application Support
- Customize the Cordova Instrumentation
- Update Cordova Agent Configurations

Follow the steps below to get your EUM App Key and instrument your Cordova-based apps.

For native mobile applications, follow either the iOS Instrumentation or Android Instrumentation instructions. The mobile agents will inject the JavaScript Agent and auto-instrument your mobile application including the auto-instrumentation of the WKWebView.

Check Requirements

To use the AppDynamics Cordova plugin, your hybrid application must be using the following:

- Cordova >= 8.0.0
- npm >= 3.10.10
- Node.js >= 6.11.3
- WKWebView for iOS applications

WkWebView Requirements

By default, the Cordova iOS platform command adds a version of `cordova-ios` that supports UIWebView. AppDynamics does not support UIWebView, so you must manually change this to WkWebView.

1. Run the following command:

   ```
   (ionic) cordova platform add ios
   ```

2. Verify the log output returns:

   ```
   Using WkWebView
   ```

3. If the log output returns `Using UIWebView`, you must manually change it to `Using UIWebView`.

Get Your Application Key

After you completed the **Getting Started Wizard**, you were given an EUM App Key. You will need this key when you modify the source code. In some cases, multiple mobile applications can share the same key.

If you have completed the **Getting Started Wizard**, but don't have your EUM App Key, see Get Your Application Key.

Install and Initialize the Cordova Plugin

The AppDynamics Cordova plugin is certified to work with the Ionic and PhoneGap frameworks. Thus, the installation instructions below are for Ionic and PhoneGap applications. See the plugin installation instructions for your Cordova-based framework.

Customize the Cordova Application Instrumentation

See Customize the Cordova Application showing how to use the Cordova SDK through examples and brief explanations.

Update Cordova Agent Configurations

To update the configurations set when you first added the Cordova plugin to your application, the suggested practice is to remove the values for configuration values and then add new configuration values.

See the following examples:

Change the App Key

To change the app key for your Ionic or PhoneGap applications:

1. Remove the old value for the variable `APP_KEY` with the `remove` command:

```
cordova plugin remove --variable APP_KEY="old-app-key" appd-plugin-eum-mobile
```

2. Add new value for the variable `APP_KEY` with the `add` command. Be sure to include the variables that you set when you first added the plugin (represented by `<variable_list>` below). For example, if you set `REACHABILITY_HOST=http://example.com` when you first added the plugin, you will need to reset the variable when running the `add` command again.

```
cordova plugin add --variable APP_KEY="new-app-key" <variable_list> appd-plugin-eum-mobile
```

Change the App Name

To change the name of your Ionic or PhoneGap applications:

1. Remove the old value for the variable `APP_NAME` with the `remove` command:

```
cordova plugin remove --variable APP_NAME="old-app-name" appd-plugin-eum-mobile
```

2. Add new value for the variable `APP_NAME` with the `add` command. Be sure to include the variables that you set when you first added the plugin (represented by `<variable_list>` below). For example, if you set `REACHABILITY_HOST=http://example.com/` when you first added the plugin, you will need to reset the variable when running the `add` command again.

```
cordova plugin add --variable APP_NAME="new-app-name" <variable_list> appd-plugin-eum-mobile
```

Customize the Cordova Instrumentation

Related pages:

- Instrument Cordova Applications
- Cordova SDK Documentation

Once you have instrumented your Cordova-based application with the Cordova Plugin, you can also use the APIs to customize the data for your app that appears in the Controller UI. The following sections show you how to use the Cordova Plugin SDK API to customize your instrumentation:

Using the Cordova Plugin SDK API

Syntax

To call SDK API methods, use the following syntax: `window.plugins.ADEUMMobilePlugin.<method>`

Arguments

The last two arguments for all of the SDK API methods should always be two functions. The first function should handle successful cases and the last method should handle failures.

For example:

```
window.plugins.ADEUMMobilePlugin.changeAppKey("<EUM_APP_KEY>",
    (success) => {
        this.showAlert("changeAppKey return: success");
    },
    (error) => {
        this.showAlert("changeAppKey error:" + error);
    }
);
```

Add Methods to Call SDK APIs

To use the SDK APIs, you are recommended to create class methods that call the SDK APIs as shown below.

```
export class HomePage {
    ...
    someMethod(event) {
         window.plugins.ADEUMMobilePlugin.<method>(<arg1>, <success_function>, <failure_function>);
    }
    ...
}
```

Example

Thus, for the `HomePage.js` file, your `HomePage` class could have the method `takeScreenshot` that calls the SDK API method `screenshot` as shown here.

```
export class HomePage {
    ...
    takeScreenshot(event) {
      // Call the Cordova plugin SDK methods
      window.plugins.ADEUMMobilePlugin.screenshot(
       (success) => {
        this.showAlert("crash return: success");
       },
      (error) => {
        this.showAlert("crash error:" + error);
      });
    }
    ...
}
```

Change the App Key

To change the EUM application key, you use the method `changeAppKey` with the parameters below.

Parameter Name	Data Type	Description
`appKey`	string	The EUM application key.
`success`	function	A user-defined function that is called when `changeAppKey` is successful.
`error`	function	A user-defined function that is called when `changeAppKey` fails.

For example, you could create a new method that takes a new app key and passed it to the SDK API method `changeAppKey`.

```
changeAppKey(event, newAppKey) {
    window.plugins.ADEUMMobilePlugin.changeAppKey(newAppKey,
        (success) => {
            this.showAlert("changeAppKey return: success");
        },
        (error) => {
            this.showAlert("changeAppKey error:" + error);
        }
    );
}
```

Collect Additional Types of Data

You can use methods available in the `ADEUMMobilePlugin` class to collect five additional types of data:

- Info points
- Custom timers
- Custom metrics
- User data
- Breadcrumbs

Info Points

Information points allow you to track how your own code is running. You can see how often a method is invoked, and how long it takes to run by calling `beginCall`. When the callbacks `success` or `error` are called, the call to track the info point ends.

- `beginCall(name, functionName, args, success, error)`

Parameters

The table below describes the parameters for the two methods:

Name	Type	Description
`name`	string	The name of the file or module where the info point is being recorded.
`functionName`	string	The function that is invoking `beginCall` to track an info point.

`success`	function	The user-defined callback for successful cases.
`error`	function	The user-defined callback for failed cases.

Example

For example, you can use create info points with something like the code below to determine how a method is invoked, and how long it takes to run:

```
beginCall(event) {
    window.plugins.ADEUMMobilePlugin.beginCall("home.ts", "callTrackerFunction", "event",
        (tracker) => {
            tracker.reportCallEndedWithReturnValue("Return from home.ts",
                (success) => { console.log("End call with return value success:" + success);},
                (error) => { console.log("End call with return value error:" + error); });
            },
            (error) => {
                console.log("Begin call error:" + error);
        }
    );
}
```

Custom Timers

You can create custom timers to time any arbitrary sequence of events within your code, even spanning multiple methods. You create the custom timers using the SDK API methods `startTimer` and `stopTimer`.

- `startTimerWithName(name, success, error)`
- `stopTimerWithName(name, success, error)`

Parameters

The two methods take the following parameters:

Name	Type	Description
`name`	string	The name of the custom timer. Allowed characters are [A-Za-z\s0-9]. Illegal characters are replaced by their ASCII hex value.
`success`	function	The user-defined callback for successful cases.
`error`	function	The user-defined callback for failed cases.

Example

For example, to track the time a user spends viewing a screen, the instrumentation could look like this:

```
startTimer(event) {
    window.plugins.ADEUMMobilePlugin.startTimerWithName(data.name,
        (success) => {
            this.showAlert("startTimerWithName return: success");
        },
        (error) => {
            this.showAlert("startTimerWithName error:" + error);
        }
    );
}
stopTimer(event) {
    window.plugins.ADEUMMobilePlugin.stopTimerWithName(data.name,
        (success) => {
            this.showAlert("stopTimerWithName return: success");
        },
        (error) => {
            this.showAlert("stopTimerWithName error:" + error);
        }
    );
}
```

Custom Metrics

You can also report custom metrics.

You create custom metrics with the `reportMetricWithName`:

- `reportMetricWithName(name, value, success, error)`

Parameters

The `reportMetricWithName` method takes the following parameters:

Name	Type	Description
`name`	string	The name of the custom metric. The metric names must consist of alphanumeric characters. Illegal characters are replaced by their ASCII hex value.
`value`	number	if value is not a whole number an error will be returned.
`success`	function	User-defined success callback.
`error`	function	User-defined error callback.

Example

For example, the following method could be used to report custom metrics:

```
reportMetric(event, data) {
    window.plugins.ADEUMMobilePlugin.reportMetricWithName(data.name, parseInt(data.value),
        (success) => {
            this.showAlert("reportMetricWithName : success");
        },
        (error) => {
            this.showAlert("reportMetricWithName error:" + error);
        }
    );
};
```

Breadcrumbs

Breadcrumbs allow you to situate a crash in the context of your user's experience. Set a breadcrumb when something interesting happens. If your application crashes at some point in the future, the breadcrumb will be displayed along with the crash report. Each crash report displays the most recent 99 breadcrumbs.

You create and leave breadcrumbs with the following SDK API method:

- `leaveBreadcrumb(breadcrumb, mode, success, error)`

Parameters

The method `leaveBreadcrumb` takes the following parameters:

Name	Type	Description
`breadcrumb`	string	The string to include in the crash report and sessions. Truncated at 2048 characters; empty values are ignored.
`mode`	number	The mode determining where the breadcrumb will be displayed: • 0 - for crashes only • 1 - for crashes and sessions. The mode defaults to crashes if the value is not parseable.
`success`	function	The user-defined callback for successful cases.
`error`	function	The user-defined callback for failed cases.

Example

This code example shows how to use the SDK API to leave a breadcrumb:

```
breadcrumb(mode) {
      window.plugins.ADEUMMobilePlugin.leaveBreadcrumb( "breadcrumb1", mode,
     (success) => {
        this.showAlert("leaveBreadcrumb return: success");
      },
      (error) => {
        this.showAlert("leaveBreadcrumb error:" + error);
    }
)
```

Add Custom User Data

You can set and later remove any string key/value pair you think might be useful with the following methods:

- `setUserData(key, value, success, error)`
- `removeUserData(key, success, error)`

Parameters

The following table describes the parameters:

Name	Type	Description
`key`	string	The key identifying the key-value pair.
`value`	string	The value associated with the key.
`success`	function	The user-defined callback for successful cases.
`error`	function	The user-defined callback for failed cases.

Example

The code example below shows how to set and remove user data with the SDK API:

```
setCustomData(event, data) {
    window.plugins.ADEUMMobilePlugin.setUserData(data.name, data.value,
        (success) => {
            this.showAlert("setUserData return: success");
        },
        (error) => {
            this.showAlert("setUserData error:" + error);
        }
    );
};
removeUserData(event, key) {
    window.plugins.ADEUMMobilePlugin.removeUserData(key,
        (success) => {
            this.showAlert("removeUserData return: success");
        },
        (error) => {
            this.showAlert("removeUserData error:" + error);
        }
    );
}
```

Programmatically Control Sessions

By default, a mobile session ends after a period of user inactivity. For example, when a user opens your application, the session begins and only ends after the user stops using the app for a set period of time. When the user begins to use the application again, a new session begins.

Instead of having a period of inactivity to define the duration of a session, however, you can use the following API to programmatically control when sessions begin and end.

```
startNextSession(success, error)
```

When you call the method `startNextSession` from `ADEUMMobilePlugin`, the current session ends and a new session begins. The API enables you to define and frame your sessions so that they align more closely with business goals and expected user flows. For example, you could use the API to define a session that tracks a purchase of a product or registers a new user.

Excessive use of this API will cause sessions to be throttled (excessive use is >10 calls per minute, but is subject to change). When not using the API, sessions will fall back to the default of ending after a period of user inactivity.

Example of a Programmatically Controlled Session

In the example below, the current session ends and a new one begins when the checkout is made.

```
completeCheckout() {
    if (this.validateAddress() && this.validatePayment()){
        let loader = this.loader.create({
            content: "Completing the checkout..."
        });
        loader.present();
        return this.order.create({
          shipping_address: this.address,
          billing_address: this.address,
          cart_id: Number(this.configuration.get('cart_id'))
        })
        ...
        window.plugins.ADEUMMobilePlugin.startNextSession(
           (success) => {
                          console.log("startNextSession return: success");
                        },
           (error) => {
                          console.log("startNextSession error:" + error);
                      }
       );
}
```

Start and End Session Frames

You can use Cordova Plugin to create session frames that will appear in the session activity. Session frames provide context for what the user is doing during a session. With the API, you can improve the names of user screens and chronicle user flows within a business context.

Use Cases

The following are common using session frames:

- One page performs multiple functions and you want more granular tracking of the individual functions.
- A user flow spans multiple pages or user interactions. For example, you could use the API to create the session frames "Login", "Product Selection", and "Purchase" to chronicle the user flow for purchases.
- You want to capture dynamic information based on user interactions to name session frames, such as an order ID.

SessionFrame API

The table below lists the three methods you can use with session frames. In short, you start a session frame with `startSessionFrame` and then use `updateName` and `end` to rename and end the session frame.

Method	Parameters	Description
`startSessionFrame(name, success, error)`	• `name` (string) - The name of the session frame. • `success` (function) - The user-defined success callback. • `error` (function) - The user-defined error callback.	Use this to start and name your session frame. You call this method from `window.plugins.ADEUMMobilePlugin`.

`updateName(name, success, error)`	• `name` (string) - The name of the session frame. • `success` (function) - The user-defined success callback. • `error` (function) - The user-defined error callback.	Rename the session frame name. You call this method from the `ADEUMMobilePlugin` object.
`end(success, error)`	• `success` (function) - The user-defined success callback. • `error` (function) - The user-defined error callback.	End the session frame. You call this method from the `ADEUMMobilePlugin` object.

Session Frame Example

In the following example, session frames are used to track user activity during the checkout process.

```
declare var window: any;
@Component({
    ...
})
export class OrderPage {
    sessionFrame: any;
    ...

    checkoutCartButtonClicked() {
        // The user starting to check out starts when the user clicks the checkout button
        // this may be after they have updated quantities of items in their cart, etc.
        window.plugins.ADEUMMobilePlugin.startSessionFrame("Checkout",
            (sessionFrame) => {
                // The returned object is saved to the class property 'sessionFrame' so
                // the SessionFrame API methods 'updateName' and 'end' can be called from it later.
                this.sessionFrame = sessionFrame;
            },
            (error) => {
                console.log("startSessionFrame call error:" + error);
             }
        );
    }
    confirmOrderButtonClicked() {
        // Once they have confirmed payment info and shipping information, and they
        // are clicking the "Confirm" button to start the backend process of checking out
        // we may know more information about the order itself, such as an Order ID.
        this.sessionFrame.updateName("Checkout: Order ID " + this.orderId,
            (success) => {
                console.log("Order has been placed and sessionFrame updated:" + this.orderId);
            },
            (error) => {
                console.log("Order has been placed but sessionFrame couldn't be updated because of the error "
+ error);
            }
        );
    }
    processOrderCompleted() {
        // Once the order is processed, the user is done "checking out" so we end
        // the session frame.
        this.sessionFrame.end(
            (success) => {
                console.log("Order was completed and sessionFrame ended: " + success);
            },
            (error) => {
                console.log("Order was completed but sessionFrame couldn't be ended because of: " + error);
            }
        );
    }
    checkoutCancelled() {
        // If they cancel or go back, you'll want to end the session frame also, or else
        // it will be left open and appear to have never ended.
        this.sessionFrame.end(
            (success) => {
                console.log("Order was cancelled and sessionFrame ended: " + success);
            },
            (error) => {
                console.log("Order was cancelled but sessionFrame couldn't be ended because of: " + error);
            }
        );
    }
} // end of export class OrderPage
```

Configure and Take Screenshots

Mobile screenshots are enabled by default. These screenshots will show up in the **Sessions Details** dialog.

You can configure the Controller UI to automatically take screenshots or use the Cordova plugin to manually take a screenshot as shown below:

```
screenshot(event) {
     // make a call to plugin
     console.log("screenshot click handler");
      window.plugins.ADEUMMobilePlugin.takeScreenshot(

     (success) => {
        this.showAlert("screenshot return: success");
      },
      (error) => {
        this.showAlert("screenshot error:" + error);
      });
}
```

This will capture everything, including personal information, so you must be cautious of when to take the screenshot.

Block and Unblock Screenshots

You can also block screenshots from being taken during the execution of a code block. This just temporarily blocks screenshots from being taken until you unblock screenshots. This enables you to stop taking screenshots in situations where users are entering personal data, such as on login and account screens.

```
logInScreen(event) {
    // Block Screen while getting user input
    window.plugins.ADEUMMobilePlugin.blockScreenshots(
        (success) => {
            console.log("blockScreenshots return: success");
            this.getUserInput();
            this.submitUserInput();
        },
        (error) => {
            console.log("blockScreenshots error:" + error);
         }
    );
    // Unblock screen and return to home page
    window.plugins.ADEUMMobilePlugin.unblockScreenshots(
        (success) => {
            console.log("unblockScreenshots return: success");
            this.homePage()
        },
        (error) => {
            console.log("unblockScreenshots error:" + error);
        }
    );
}
```

Enable Logging and Set Logging Level

You use the method `loggingLevel` to enable and set the logging level. You can set logging to one of the following levels:

Value	Logging Level	Description
0	None	No logs are displayed. **This level disables logging.**
1	Error	Only error messages are displayed. **This is the default logging level.**
2	Warn	Warning and error messages are displayed.
3	Info	Warning, errors, and developer-focused messages are displayed.
4	Debug	Errors, warnings, developer information, and debugging messages are displayed.
5	Verbose	Errors, warnings, developer information, debugging, and troubleshooting messages are displayed.

6	All	All the supported log messages are displayed.

You enable logging by setting the logging level in the instrumentation configuration. For example, in this example, you are enabling logging and setting the logging level to `Info`:

```
window.plugins.ADEUMMobilePlugin.initWithConfiguration(
    {
        "appKey": "<EUM_APP_KEY>",
        "loggingLevel": 3
     },
     (success) => {
        this.showAlert("initWithConfiguration return: success");
     },
     (error) => {
        this.showAlert("initWithConfiguration error:" + error);
     }
);
```

Cordova SDK Documentation

For the Cordova SDK API reference documentation, see the latest JSDoc documentation or the previous versions listed below:

Instrument React Native Applications

Related pages:

- Hybrid Application Support
- Manually install the React Native Package
- Point to an On-Premises EUM Server (Optional)
- Customize the React Native Instrumentation

Follow these steps to get your EUM App Key and instrument your React Native application.

Requirements

- React Native >=0.60

  > The React Native Agent has been tested and certified to work with React Native >=0.60. React Native is in rapid development; thereby any minor update to React Native could potentially affect the functionality of the React Native Agent.

- (iOS only): Pod target and Xcode deployment target must both be >=11. Find the pod target version in the `podfile` located in `<your_react_native_app>/ios/`.

Get Your Application Key

From the Controller's **Getting Started Wizard**, create either an iOS or an Android application. You will be given an EUM App Key that you will use to instrument your application. In some cases, multiple mobile applications can share the same key.

If you have completed the **Getting Started Wizard**, but don't have your EUM App Key, see Get Your Application Key.

Eject Your React Native Application

If you created your React Native application with one of the commands in the following table, you will need to eject the application:

Command	Why Ejection Is Needed
`create-react-native-app`	This command enables you to quickly set up and run a Native React application with no configuration but does *not* provide the full development environment required by the React Native Agent.
`expo init`	Expo projects do not currently support the React Native Agent module.

If you created your app with `create-react-native-app`, use `npm` to eject the app. If you used `expo`, run the `expo` command below to eject the app.

From your project directory, run the command appropriate for your use case:

Install the React Native Agent

This module injects the native AppDynamics agents into your application and offers a JavaScript bridge to the `Instrumentation` management interface.

1. Install the React Native Agent:

   ```
   npm install --save @appdynamics/react-native-agent
   ```

2. Build the configuration to enable the build-time instrumentation of your application:

   ```
   node node_modules/@appdynamics/react-native-agent/bin/cli.js install
   ```

> The React Native Agent CLI assumes you've kept the default project structure created with the `react-native` CLI tools.

3. If the above commands failed, see manually install the React Native package. Otherwise, proceed to Add Required Libraries (iOS Only) and/or Add Permissions (Android Only).

Manually Install the React Native Package (Only If Required)

Most users do not have to manually install the package, but the command above may fail if you heavily modified your iOS and Android projects.

Follow these steps to manually install the React Native package:

Add Permissions (Android Only)

Add the following permissions to your app's `AndroidManifest.xml` (which should be located under `android/app/src/main/`).

```
  <manifest xmlns:android="http://schemas.android.com/apk/res/android"
    package="com.your.application">

    // Add the following:
    <uses-permission android:name="android.permission.ACCESS_NETWORK_STATE"/>

    // ...
</manifest>
```

> The React Native Agent tries to minimize its network footprint. Without this permission, the agent always assumes poor network conditions and some metrics may not get reported.

Instrument Your Application Code

In the `index.js` file of your React application:

1. At the top of the file near the other `import` statements, add the following line of code to import the Native React Agent:

   ```
   import { Instrumentation } from '@appdynamics/react-native-agent';
   ```

2. In the same file and in the global scope, initialize the instrumentation with the following, making sure to replace <EUM_APP_KEY> with a string containing your EUM App Key.

   ```
   Instrumentation.start({
       appKey: <EUM_APP_KEY>,
   });
   ```

3. Verify that your `index.js` file looks similar to the following:

```
import {AppRegistry} from 'react-native';
import App from './App';
// === Add the following to import the React Native Agent
import { Instrumentation } from '@appdynamics/react-native-agent';

// Initialize the instrumentation
Instrumentation.start({
    appKey: 'YOUR-APP-KEY',
});

// Create a component
const App = () => (
  // Other components
);

// Register the App component
AppRegistry.registerComponent('my-application', () => App);
```

4. (For older React Native setup builds) If you have `use_frameworks!` defined in your `ios/Podfile`, we recommend adding the following:

```
$ toggleADEUMRNStaticFramework = true
```

Build and Run Your React Native Applications (Optional)

1. Run the command to build and run the app for your platform.
2. From the Controller UI, verify that the instrumentation was successful.

Point to an On-Premises EUM Server (Optional)

To use an on-premises EUM Server, pass the URL to the on-premises EUM Server when you initialize the instrumentation with the EUM App Key from Get Your Application Key.

```
Instrumentation.start({
     appKey: <EUM_APP_KEY>,
     collectorURL: <COLLECTOR_URL>
});
```

Customize the React Native Instrumentation

The sections below describe how to use the React Native APIs to customize your instrumentation.

Using the React Native Agent APIs

After you have installed and initialized the React Native Agent, you instrument your application code by importing the class, interface, or enumeration and then calling API methods.

Import Syntax

To access the React Native Agent APIs, use an import statement at the top of the file. The following line imports the class `Instrumentation`:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

API Method Syntax

Once the class, interface, or enumeration has been imported, call the API methods from the imported component. In this example, you set custom user data with `setUserDataBoolean` from the `Instrumentation` class.

```
Instrumentation.setUserDataBoolean("Boolean Key", true);
```

Change the App Key

You can use the Native React Agent API to dynamically change the EUM app key. You receive the EUM App Key when creating a mobile app in the Controller UI. See Set Up and Access Mobile RUM for information about getting the EUM App Key.

Class

The API to change app keys is available through the `Instrumentation` class.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

Methods

The API consists of the following method:

- `changeAppKey(appKey)`

Method Parameters

The `changeAppKey` method takes the following parameter:

Parameter Name	Data Type	Description
`appKey`	string	The EUM App Key.

Examples

In this example, you create a method that takes a new app key and passes it to the API method `changeAppKey`.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
private updateAppKey(newAppKey) {
    Instrumentation.changeAppKey(newAppKey);
}
```

Collect Additional Types of Data

The React Native APIs have methods that extend the application data types you can collect and aggregate with Mobile RUM. There are six basic kinds of extensions that you can create:

Type of Data	Description	Specifications	Where Data is Displayed
Info points	How often a method is invoked, and how long it takes to run.	• Data is numeric • Names must consist of alphanumeric characters and/or spaces	• Metric Browser • Custom Data • Network Request Snapshots • Mobile Sessions • Network Request Analyze
Custom timers	Any arbitrary sequence of events within your code timed, even spanning multiple methods.	• Data is numeric • Metric names must consist of alphanumeric characters and/or spaces	• Metric Browser • Custom Data
Custom metrics	Any integer-based data you wish to collect.	• Data is numeric • Metric names must consist of alphanumeric characters and/or spaces	• Metric Browser • Custom Data
User data	Any string key/value pair you think might be useful.	• Data can be any type • Metric names have no restrictions	• Network Request Snapshots • Mobile Sessions • Network Request Analyze • Crash Snapshots
Breadcrumbs	The context for a crash.	• Data can be any data type • Metric names have no restrictions	• Network Request Snapshots • Mobile Sessions • Network Request Analyze • Crash Snapshots
User interactions	Capture when users press buttons, click on lists, and select text.	• Data can be any data type • Metric names have no restrictions	• Network Request Snapshots • Mobile Sessions • Network Request Analyze

Report Info Points

Information points allow you to track how your own code is running. Unlike the other React Native APIs that require importing a module and using a method from that module, you add annotations to your code to report info points.

Class/Interface

The API is available through the `InfoPoint` function.

```
import { InfoPoint } from '@appdynamics/react-native-agent';
```

Methods

With the `@InfoPoint` annotation, you only need to provide a function to report info points. The `@InfoPoint` annotation has two signatures:

- `@InfoPoint`
- `@InfoPoint({className: string, fnName: string})`

Method Signatures

Methods	Parameters	Description
`@InfoPoint`	None	Automatically reports the info points of the method that is being annotated.
`@InfoPoint({className: string, fnName: string})`	Object • `className` - The name of the file or module where the info point is recorded. • `fnName` - The function that invokes `beginCall` to track an info point.	Manually specify the class and function names to annotate. For example: `@InfoPoint({ className: 'Automobiles', fnName: 'checkInventory' })`

Examples

The following examples show you how to use automatic and manual reporting of info points.

We recommended you use automatic reporting if your code will not be minified: it's simpler and reports the same information. If your code will be minified, however, you should manually report the class and function names to avoid reporting the useless class and function names created by minification.

Automatic Reporting

Add the annotation `@InfoPoint` to automatically create an info point for the method below it. Info point reports how the method is invoked and how long it takes to run.

```
import { InfoPoint } from '@appdynamics/react-native-agent';

class InfoPointsScreen extends Component {

  @InfoPoint
  public infoPointMethod(arg1, arg2, value) {
    console.log("Executing infoPointMethod!");
  }
}
```

Manually Reporting

To create an info point for a specific method in a class (the symbol names), pass an object to the `@InfoPoint` annotation that specifies the class and method name as shown below.

```
import { InfoPoint } from '@appdynamics/react-native-agent';

class InfoPointsScreen extends Component {

  @InfoPoint({ className: 'MyClass', fnName: 'infoPointMethod' })
  public infoPointMethod(arg1, arg2, value) {
    console.log("Executing infoPointMethod!");
  }
}
```

Set Custom Timers

You create custom timers to time any arbitrary sequence of events within your code, even spanning multiple methods.

Class/Interface

The Custom Timers API is accessible through the `Instrumentation` class:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

Methods

You create the custom timers using the following React Native Agent API methods:

- `startTimerWithName(name)`
- `stopTimerWithName(name)`

Method Parameters

Both methods take the following parameter:

Name	Type	Description
`name`	string	The name of the custom timer. Allowed characters are [A-Za-z\s0-9]. Illegal characters are replaced by their ASCII hex value.

Examples

For example, to track the time a user spends viewing a screen, the instrumentation could look like this:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
private startCustomTimer() {
  Instrumentation.startTimer("My timer");
}
private stopCustomTimer() {
   Instrumentation.stopTimer("My timer");
}
```

Create Custom Metrics

The React Native API enables you to report custom metrics. You specify the name of the custom metric that will appear in the Controller UI.

Class

The Custom Metrics API is accessible through the `Instrumentation` class:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

Methods

You create custom metrics with the `reportMetric`:

- `reportMetric(name, value)`

Method Parameters

The `reportMetric` method takes the following parameters:

Name	Type	Requirements	Description
`name`	string	The metric names must consist of alphanumeric characters. Illegal characters are replaced by their ASCII hex value.	The name of the custom metric.
`value`	number	The value must be a whole number, otherwise, an error will be returned.	The numeric value associated with the custom metric.

Examples

For example, the following method could be used to report custom metrics:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
private reportMetrics() {
    Instrumentation.reportMetric("Normal metric", 23);
    Instrumentation.reportMetric("Large metric", Number.MAX_SAFE_INTEGER + 1);
    Instrumentation.reportMetric("Small metric", Number.MIN_SAFE_INTEGER - 1);
}
```

Add Custom User Data

Use the Custom User Data API to set and remove key/value pairs of different data types. The key must be unique across your application.

Class

The Custom User Data API is accessible through the `Instrumentation` class:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

Methods

The API provides the following methods for setting and removing custom user data:

Methods for Setting Custom User Data

- `setUserData(key, value)`
- `setUserDataBoolean(key, value)`
- `setUserDataDate(key, value)`
- `setUserDataDouble(key, value)`
- `setUserDataInteger(key, value)`

Methods for Removing Custom User Data

- `removeUserData(key)`
- `setUserDataBoolean(key)`
- `setUserDataDate(key)`
- `setUserDataDouble(key)`
- `setUserDataInteger(key)`

Method Parameters

The following table lists the parameters for the methods for setting custom user data.

Methods for Setting Custom User Data	Parameters	Data Type
`setUserData`	key	string
	value	string || null
`setUserDataBoolean`	key	string
	value	boolean
`setUserDataDate`	key	string
	value	Date object
`setUserDataDouble`	key	string
	value	number
`setUserDataInteger`	key	string
	value	number

The following table lists the parameters for the methods for removing custom user data.

Methods for Removing Custom User Data	Parameters	Data Type

`removeUserData`	key	string
`removeUserDataBoolean`		
`removeUserDataDate`		
`removeUserDataDouble`		
`removeUserDataInteger`		

The method `removeUserData` is called when setting custom data to the value `null`. For example, the method `Instrumentation.setUserData("name", null)` will call `Instrumentation.removeUserData("name")`.

Examples

The following code example shows how to set and remove user data with the Custom User Data API:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
private setUserData() {
    Instrumentation.setUserData("userId", "AISJ1723871");
    Instrumentation.setUserDataBoolean("isVip", true);
    Instrumentation.setUserDataDate("purchaseDate", new Date(1234567890));
    Instrumentation.setUserDataDouble("monthlyVisits", 1.2345);
    Instrumentation.setUserDataInteger("totalPurchasedItems", 42);
}
private clearUserData() {
    Instrumentation.removeUserData("userId", null);
    Instrumentation.removeUserDataBoolean("isVip", null);
    Instrumentation.removeUserDataDate("purchaseDate", null);
    Instrumentation.removeUserDataDouble("monthlyVisits", null);
    Instrumentation.removeUserDataInteger("totalPurchasedItems", null);
}
```

Leave Breadcrumbs

Breadcrumbs enable you to situate a crash in the context of your user's experience. Set a breadcrumb when something interesting happens. If your application crashes at some point in the future, the breadcrumb will be displayed along with the crash report. Each crash report displays the most recent 99 breadcrumbs.

Class

The Breadcrumb API is accessible through the `Instrumentation` class:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

Methods

You create and leave breadcrumbs with the following API method:

- `leaveBreadcrumb(breadcrumb, mode)`

Method Parameters

The method `leaveBreadcrumb` takes the following parameters:

Name	Type	Description
`breadcrumb`	string	The string to include in the crash report and sessions. Truncated at 2048 characters; empty values are ignored.

`mode`	Enumeration	The mode determining where the breadcrumb will be displayed. You can report crashes only or crashes and sessions with the following modes: • `BreadcrumbVisibility.CRASHES_ONLY` • `BreadcrumbVisibility.CRASHES_AND_SESSIONS` The default mode is `BreadcrumbVisibility.CRASHES_ONLY`. If the value is invalid, the default mode will be applied.

Examples

Basic Usage

The following example shows the syntax and usage of the Breadcrumb API.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
private leaveBreadcrumb() {
    Instrumentation.leaveBreadcrumb("Drop a breadcrumb button implementation", BreadcrumbVisibility.
CRASHES_AND_SESSIONS);
}
```

Extended Use Case

Supposed your React Native app has a wizard that shows different steps of a process sequentially on the same screen. In the case of a crash or an "Application Not Responding" (ANR) error, you would want to know what step of the wizard caused the crash or ANR.

If your app had a wizard engine similar to the one below, you could leave a breadcrumb for each screen to track events and issues.

```
async function wizard(...screens) {
    let currentScreen = 0;
    while (true) {
        const screen = screens[currentScreen];
        if (screen == null) return;
        // Report the current screen with AppDynamics instrumentation
        Instrumentation.leaveBreadcrumb('wizard screen ' + screen.name);
        currentScreen += await screen.action();
    }
}
```

The wizard engine could be used for a checkout:

```
wizard(
    { name: 'review cart', action:reviewCartAction },
    { name: 'chose payment', action:chosePaymentAction },
    { name: 'chose address', action:choseAddressAction },
    { name: 'review order', action:reviewOrderAction },
    { name: 'checkout', action:checkoutAction }
)
```

If you receive an alert that your app is triggering a lot of ANRs, you can diagnose the problem through the mobile sessions where the ANRs occur. In the session, you will see the breadcrumbs associated with the ANRs. For example, you may discover that the breadcrumbs "review cart" and "chose payment" are associated with ANRs, but "chose address" is not. Further investigation of the payment screen could lead to the discovery that the process that is encrypting credit card numbers is running on the main thread and freezing the app.

Capture User Interaction

The React Native Agent can track certain UI events triggered by user interactions. Once user interactions have been captured, you can sort sessions by UI event and view UI events in the timeline of the session waterfall.

Supported User Interactions

You can capture when users do one or all of the following:

- press buttons
- select table cells
- select text fields

- select text views

Security and Privacy Concerns

The interaction capture mode is disabled by default for security and privacy reasons, as user interactions may contain sensitive information. Moreover, this potential security and privacy issue may be compounded if you enable both the capturing of UI interactions and screenshots.

Class

The Interaction Capture Mode API is accessible through the `InteractionCaptureMode` class, but you also need the `Instrumentation` class to start instrumentation with the configured user capture mode.

```
import { Instrumentation, InteractionCaptureMode } from '@appdynamics/react-native-agent';
```

Properties

The following properties are accessed through the `InteractionCaptureMode` class and used to configure the user interaction capture. For example: `InteractionCaptureMode.All`

Property	Description	Platform Support
`All`	Track all the user interactions.	iOS, Android
`ButtonPressed`	Track button presses.	iOS, Android
`ListViewItemsSelected`	Track "List Item" clicks and focus changes for `android.widget.AbsListView` and its subclasses.	Android
`None`	Disables the tracking of any user interactions.	iOS, Android
`TableCellSelected`	Track table cell selection.	iOS
`TextFieldSelected`	Track text field selection.	iOS, Android
`TextViewSelected`	Track text view selection.	iOS

Methods

The API methods take an array of user interaction capture modes and return an `InteractionCaptureMode` object that determines which user interactions will be captured. The methods do not mutate the object.

Method	Description
`with`	Combines the multiple user interaction capture modes.
`without`	Excludes the specified user interaction modes from being captured.

Examples

Set User Interaction Mode with API Properties

The following example configures the React Native Agent to capture all user interactions.

```
import { Instrumentation, InteractionCaptureMode } from '@appdynamics/react-native-agent';
...
Instrumentation.start({
     appKey: <EUM_APP_KEY>,
     // ...your other configurations

     // Capture all user interactions
     interactionCaptureMode: InteractionCaptureMode.All
 })
```

Combine User Interaction Modes

In the following example, the `with` method combines the `ButtonPressed` (button presses) and `TextFieldSelected` (text field selected) modes with the `None` mode, effectively just enabling those two user interaction modes.

```
import { Instrumentation, InteractionCaptureMode } from '@appdynamics/react-native-agent';
...
Instrumentation.start({
    appKey: <EUM_APP_KEY>,
    // ...your other configurations

    // Only enable "ButtonPressed" and "TextFieldSelected" interaction modes, and disable the rest.
    interactionCaptureMode: InteractionCaptureMode.None.with(
        InteractionCaptureMode.ButtonPressed,
        InteractionCaptureMode.TextFieldSelected
    )
})
```

Exclude User Interaction Modes

The following example excludes the user interaction modes `ButtonPressed` (button presses) and `TextFieldSelected` (text field selected) from the mode `InteractionCaptureMode.All` (all user interactions). Effectively, the React Native Agent would be configured to only capture `ListViewItemSelected` ("List Item" clicks), `TableCellSelected` (table cell selection), and `TextViewSelected` (text view selected) modes.

```
import { Instrumentation, InteractionCaptureMode } from '@appdynamics/react-native-agent';
...
Instrumentation.start({
    appKey: <EUM_APP_KEY>,
    // ...your other configurations

    // Include all capture modes except "ButtonPressed" and "TextFieldSelected".
    interactionCaptureMode: InteractionCaptureMode.All.without(
        InteractionCaptureMode.ButtonPressed,
        InteractionCaptureMode.TextFieldSelected
    )
})
```

Disable the Agent to Stop Sending User Data to the Collector

You can disable the agent to stop sending all data to the collector while the agent is initialized and running. For example, you can disable the agent if your app has an option for users to opt-out of monitoring for privacy reasons.

`shutdownAgent`

The `shutdownAgent` call stops outgoing data to the collector, and does not persist data on the device.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
Instrumentation.shutdownAgent();
```

- The call only stops the traffic out of the agent.
- Once the agent has been initialized, the call cannot be removed, and a license will have been consumed.

`restartAgent`

To re-enable the agent and reverse `shutdownAgent`, use `restartAgent`.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
Instrumentation.restartAgent();
```

- This call will respect the server side calls that can remotely shutdown the agent in a similar way.
- The call is only in effect while the app is running.
- The call will be ignored if the agent has been remotely disabled.
- If the call is removed from memory and the app restarts, or the device is rebooted, the agent will be initialized as normal.

Programmatically Control Sessions

By default, a mobile session ends after a period of user inactivity. For example, when a user opens your application, the session begins and only ends after the user stops using the app for a set period of time. When the user begins to use the application again, a new session begins. Instead of having a period of inactivity to define the duration of a session, however, you can use this API to programmatically control when sessions begin and end.

Class

The API is accessible through the `Instrumentation` class:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

Methods

The API provides the following method for ending the current session and starting a new session:

Method	Description
`startNextSession()`	When you call the method `startNextSession` from `Instrumentation`, the current session ends and a new session begins. The API enables you to define and frame your sessions so that they align more closely with business goals and expected user flows. For example, you could use the API to define a session that tracks a purchase of a product or registers a new user.

Excessive use of this API will cause sessions to be throttled (excessive use is >10 calls per minute, but is subject to change). When not using the API, sessions will fall back to the default of ending after a period of user inactivity.

Examples

In the following example, the current session ends and a new one begins when the check out is made.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
private checkoutCart(){
    if (currentCartItems!=null && currentCartItems.size()>0){
            CheckoutTask checkoutReq = new CheckoutTask();
                checkoutReq.execute(getEndpoint() + "cart/co");
                currentCartItemsMap.clear();
                convertItemsMaptoList();
        Instrumentation.startNextSession();
        } else {
            displayToast("There are no items in the cart");
        }
}
```

Start and End Session Frames

You can use the React Native Agent API to create session frames that appear in the session activity. Session frames provide context for what the user is doing during a session. With the API, you can improve the names of user screens and chronicle user flows within a business context.

Use Cases

The following are common use cases for session frames:

- One page performs multiple functions and you want more granular tracking of the individual functions.
- A user flow spans multiple pages or user interactions. For example, you could use the API to create the session frames "Login", "Product Selection", and "Purchase" to chronicle the user flow for purchases.
- You want to capture dynamic information based on user interactions to name session frames, such as an order ID.

Class/Interface

The SessionFrame API is accessible through the `Instrumentation` class.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

To update the name and end a session frame, you would use the `SessionFrame` interface.

Methods

The following table lists the three methods you can use with session frames. In short, you start a session frame with `startSessionFrame` and then use `updateName` and `end` to rename and end the session frame.

Method	Description
`startSessionFrame(name)`	Starts the session frame. You call this method from `Instrumentation`, and it returns `SessionFrame` object.
`updateName(name)`	Updates the name of the session frame. You call this method from the `SessionFrame` object.

Method Parameters

The methods `startSessionFrame` and `updateName` takes the following parameter:

Parameters	Data Type	Description
name	string	The name of the session frame.

Session Frame Example

In the following example, session frames are used to track user activity during the checkout process.

```
let sessionFrame: SessionFrame | undefined;

private onCheckoutCartButtonClicked() {
    // The user starts the checkout by clicking the checkout button.
    // This may be after they have updated the quantities of items in the cart, etc.
    sessionFrame = Instrumentation.startSessionFrame("Checkout");
}
private onConfirmOrderButtonClicked() {
    // Once they have confirmed payment info and shipping information, and they
    // are clicking the "Confirm" button to start the backend process of checking out,
    // we may know more information about the order itself, such as an order ID.
    if (sessionFrame) {
        sessionFrame.updateName("Checkout: Order ID " + orderId);
    }
}
private onProcessOrderCompleted() {
    // Once the order is processed, the user is done "checking out", so we end the session frame.
    if (sessionFrame) {
            sessionFrame.end();
            sessionFrame = null;
    }
}
private onCheckoutCancled() {
  // If the user cancels or returns to the cart, you'll want to end the session frame also, or else it will be
    // left open and appear to have never ended.
    sessionFrame.end();
    sessionFrame = null;
  }
}
```

Configure and Take Screenshots

Mobile screenshots are enabled by default. These screenshots appear in the **Sessions Details** dialog.

Class

The Screenshots API is accessible through the `Instrumentation` class:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

Methods

The Screenshot API provides the following methods:

Method	Return Value	Description
`takeScreenshot()`	None	Asynchronously takes a screenshot of the current screen. This will capture everything, including personal information, so you must be cautious of when to take the screenshot. These screenshots will show up in the Sessions screen for this user. The screenshots are taken on a background thread, compressed, and only non-redundant parts are uploaded, so it is safe to take many of these without impacting the performance of your application.
`screenshotsBlocked()`	Promise<boolean>	Returns a Boolean indicating whether screenshot capture is blocked.
`blockScreenshots()`	Promise<void>	Blocks screenshot capture and returns a Promise that resolves when screenshots are effectively blocked.
`unblockScreenshots()`	Promise<void>	Unblocks screenshot capture if it is currently blocked. Otherwise, this has no effect. If screenshots are disabled through `AgentConfiguration.screenshotsEnabled` or through the Controller UI, this method has no effect. If screenshots are set to manual mode in the Controller UI, this method unblocks for manual mode only.

Configure Screenshots

Disable Screenshots

You can disable screenshots from the Controller UI or with the React Native API. To disable screenshots, set the property `screenshotsEnabled` to `false` when initializing the Native React Agent.

```
Instrumentation.start({
    appKey: <EUM_APP_KEY>,
    screenshotsEnabled: false,
    ...
});
```

Set On-Prem Screenshot Service

If you have deployed an on-prem EUM Server, you will need to specify the URL to the EUM Server with the property `screenshotURL`.

```
Instrumentation.start({
    appKey: <EUM_APP_KEY>,
    screenshotURL: "https://<COLLECTOR_URL>:<PORT>",
    ...
});
```

Examples

Take Screenshots

You can configure the Controller UI to automatically take screenshots or use the React Native API to manually take a screenshot as shown below:

```
private loadShoppingCart() {
  // Load shopping cart
  this.setState({
      shoppingCart: this.state.cart
  });
  // Manually take screenshot
  Instrumentation.takeScreenshot();
}
```

This will capture everything, including personal information, so precaution is necessary when taking screenshots

Block and Unblock Screenshots

You can also block screenshots from being taken during the execution of a code block. This just temporarily blocks screenshots from being taken until you unblock screenshots. This enables you to stop taking screenshots in situations where users are entering personal data, such as on login and account screens.

```
private displayCustomerAccount() {
    // Check to see if screenshots are blocked
    if (! Instrumentation.screenshotsBlocked()) {
        // If screenshots aren't blocked, block them before showing customer details
        Instrumentation.blockScreenshots();
    }
    // Code to display customer details

    // After you're done, unblock screenshots
    Instrumentation.unblockScreenshots();
}
```

Enable Logging and Set Logging Level

You enable logging by setting the logging level in the instrumentation configuration. You are recommended to disable logging for production.

Class

The Logging Level API is accessible through the `LoggingLevel` class:

```
import { LoggingLevel } from '@appdynamics/react-native-agent';
```

Configuration Properties

You enable and set the logging level with the following configuration property:

- `loggingLevel`

Logging Levels

You can set logging to one of the following levels:

Enumeration	Logging Level	Description
`LoggingLevel.NONE`	None	No logs are displayed. **This level disables logging.**
`LoggingLevel.INFO`	Info	Warning, errors, and developer-focused messages are displayed.
`LoggingLevel.VERBOSE`	Verbose	Errors, warnings, developer information, debugging, and troubleshooting messages are displayed.

Examples

In the following example, logging is enabled and the logging level is set to `VERBOSE`:

```
private async start() {
        try {
            await Instrumentation.start({
                appKey: this.state.appKey,
                loggingLevel: LoggingLevel.VERBOSE,
                anrDetectionEnabled: true,
                interactionCaptureMode: InteractionCaptureMode.None.with(
                    InteractionCaptureMode.ButtonPressed,
                    InteractionCaptureMode.ListViewItemSelected,
                    InteractionCaptureMode.TableCellSelected,
                    InteractionCaptureMode.TextFieldSelected,
                    InteractionCaptureMode.TextViewSelected
                )
            }
        )
    }
}
```

Receive a Crash Report Summary for Native Crashes

You can use `CrashReportCallback` to receive a report for native crashes.

Class

The `CrashReportCallback` API is accessible through the `Instrumentation` class:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

How to Use

1. Submit the `CrashReportCallback` object as the `crashReportCallback` native agent configuration option.

   ```
   Instrumentation.start({
         crashReportCallback: (summaries: CrashReportSummary[]) => {
             console.log(summaries);
         },
    });
   ```

2. On application restart, you will receive a `CrashReportSummary` for each crash.

   ```
   export type CrashReportSummary = {
     crashId: string;
     exceptionName: string;
     exceptionReason: string;
     signalName: string;
     signalCode: string;
   };
   ```

`CrashReportSummary` Properties

`CrashReportSummary` has the following properties:

Name	Type	Description
`crashId`	string	Uniquely defines the crash. Can be used as key to find the full crash report or look up the crash in the Controller UI.
`exceptionName`	string	The exception name, may be `null` if no exception occured.
`exceptionReason`	string	The exception reason, may be `null` if no exception occurred.
`signalName`	string	The exception signal name.

`signalCode`	string	The exception signal code.

Disable Crash Reporting

Crash reporting is enabled by default, but you can manually disable crash reporting through the instrumentation configuration. If you are using other crash reporting tools, you might disable crash reporting to minimize conflicts and optimize the crash report results.

You can disable crash reporting by configuring the instrumentation with the `crashReportingEnabled` property as shown in the following:

```
import { Instrumentation } from '@appdynamics/react-native-agent';

Instrumentation.start({
        appKey: <#EUM_APP_KEY#>,
        crashReportingEnabled: false
})
```

Log Silenced Errors

If you use React Native's `ErrorBoundary`, the errors are silently caught, but the agent will not receive and log them. If you want silenced crashes to be logged, we recommend you use `ErrorBoundary` provided in the AppDynamics React Native package:

```
import { ErrorBoundary } from '@appdynamics/react-native-agent'
```

Use the Agent with a Custom HTTP Library

The agent automatically detects network requests when the underlying implementation is handled by `NSURLConnection`/`NSURLSession` classes (iOS) or `HttpURLConnection`/`OkHttp` (Android). This covers most network requests, but in some cases, mobile applications use custom HTTP libraries.

To enable the agent to detect requests from a custom library, add request tracking code to your application manually with the `RequestTracker` class.

You must initialize the agent with a valid key using the `Instrumentation.start()` interface before using this method.

`RequestTracker` Properties

The following properties should be set on the RequestTracker object to describe the parameters of the custom call.

Property	Description	Code
`error`	Javascript error or `null` An error describing the failure to receive a response, if one occurred. If the request was successful, this should be left `null`.	`tracker.setError(e);`
`statusCode`	Number or `null` The status code of response, if one was received. If a response was received, this should be an an integer. If an error occurred and a response was not received, this should remain `null`.	`tracker.setResponseStatusCode(response.statusCode);`
`requestHeaders`	Dictionary or `null` A dictionary representing the keys and values from the client's request header.	`tracker.setRequestHeaders(headers);`
`responseHeaders`	Dictionary or `null` A dictionary representing the keys and values from the server's response header. If an error occurred and a response was not received, this should be `null`.	`tracker.setResponseHeaders(headers);`

Track a Custom HTTP Request

To add manual request tracking, you must specify when the request begins, when it ends and what the status of the response is.

1. Create a `RequestTracker` object immediately before sending the request:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
const tracker = new RequestTracker({ "My_URL" });
```

"`MY_URL`" is the URL being called. This parameter must not be `null`.

2. (Optional) Add your custom headers to the tracker before sending the request:

```
 const headers = {
  'Content-Length': '5000',
         };
 tracker.setRequestHeaders(headers);
```

`requestHeaders`: A dictionary (or `null`) representing the keys and values from the request headers.

3. (Optional) Enable correlation between your request and server-side processing. Add specific headers to outgoing requests that the server-side agent can detect and return the headers obtained from the server-side agent in the response to make them available to the agent:

```
tracker.addServerCorrelationHeaders()
```

4. Immediately after receiving a response or an error, set properties on the tracker object based on whether the request finished successfully or ended in error:

```
try {
    const response = await customRequest(url);
    tracker.setResponseStatusCode(response.statusCode);
    tracker.setResponseHeaders(response.headers);
} catch (e) {
    tracker.setError(e);
}
```

6. Call `reportDone()`:

```
tracker.reportDone();
```

To track another request, instantiate a new tracker object again.

Complete example

```
const tracker = new requestTracker({
  url: <MY_URL>
});
```

```
const headers = {
  'Content-Length': '5000',
};
tracker.setRequestHeaders(headers);
tracker.addServerCorrelationHeaders();

try {
  const response = await customRequest(url);
  tracker.setResponseStatusCode(response.statusCode);
  tracker.setResponseHeaders(response.headers);
} catch (e) {
  tracker.setError(e);
} finally {
  tracker.reportDone();
}
```

Troubleshoot Mobile Applications

You can use Mobile RUM to investigate two different kinds of problems that can arise with your mobile applications:

- Slow network requests
- Mobile application crashes

Identify Your Slowest Network Request Types

To identify slow network requests:

1. Open the application in which you are interested.
2. In the left navigation bar, click **Network Requests**.
3. Select the Network Requests tab.
4. Click the top of the **Network Request Time (ms)** column, then toggle it to sort the network requests with the slowest ones at the top.
5. Skip over network requests that you expect to run for a long time or that have very little load (low Requests per Minute).
6. Select and double-click one of the slow network requests that you want to investigate.
7. In the network request dashboard, view the **Key Performance Indicators** at the top of the **Network Request Dashboard**. For example:

    - If the value for Network Request Time is large, the request or response body may be too large and is taking a while to transmit, or the data connection might be slow.
    - If the backend server is instrumented and the value for Total Server Time makes up a significant amount of the delay, scroll down to the **Related Business Transactions** section to investigate related business transactions on the server side.

Access Details of Individual Instances of Slow Requests

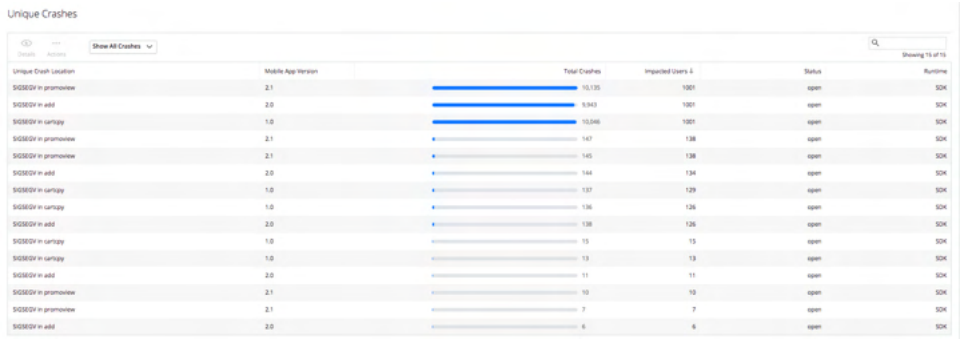
To investigate the cause of slow requests:

1. Select the Snapshots tab. The **Snapshots List** opens.
2. Click **Filters**.
3. In the **Network Request Names** dropdown under **Network in the Filters** panel, check the check box for the network request that you identified in Identify your slow network requests, then click **Search**.
   This restricts the list to snapshots for that network request only.
4. Click **Filters** again to close the filters panel.
5. In the list, click the top of the **Network Request Time (ms)** column, then toggle it to sort the network request snapshots with the slowest requests at the top.
6. Select and double-click one of the slow network requests.
   The network request snapshot displays the details of the slow request.
7. If this request is associated with a server-side application that is also instrumented, scroll down to see if transaction snapshots for this request are available on the server side.
   If transaction snapshots are available and if most of the time for this network request is spent on the server, click through to the related transaction snapshots to understand what is causing the slow performance on the server. See Transaction Snapshots.

Identify Applications that Crash the Most or Affect the Most Users

To troubleshoot mobile application crashes with crash dashboards and crash snapshots:

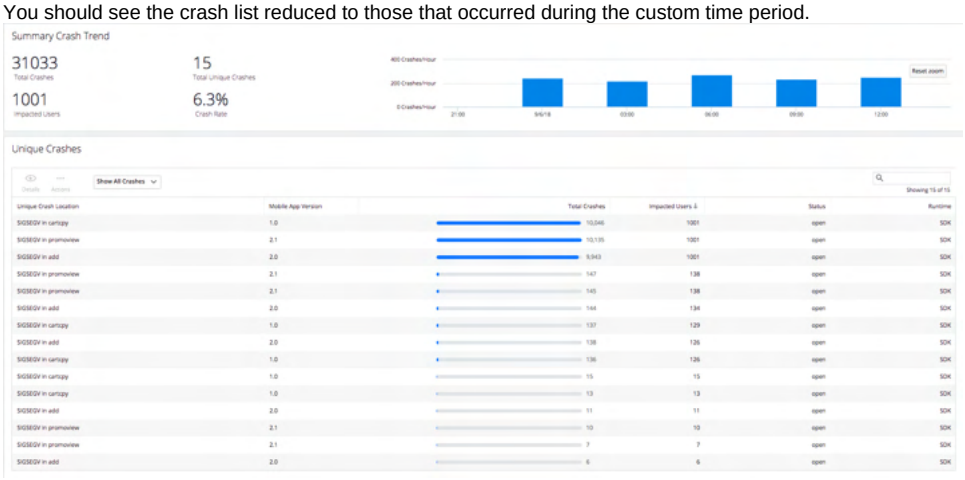
1. Open the application in which you are interested.
2. On the left navigation bar, click **Crashes**.
3. Select the Crash Dashboard tab.
4. Check the **Unique Crashes** list.
5. Sort either by **Total Crashes** or **Impacted Users**, depending on what you want to know. In the screenshot below, the list is sorted by impacted users.



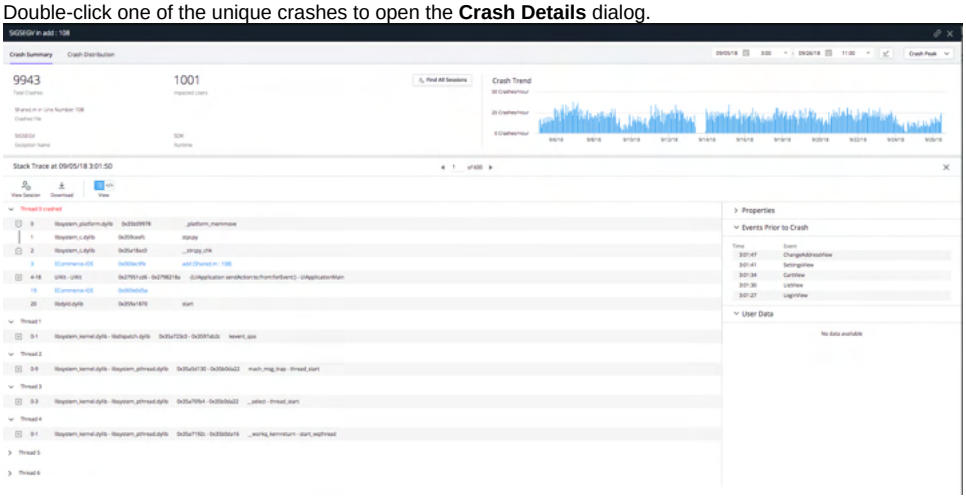
6. View the **Summary Crash Trend** graph to discover particularly problematic time periods.

7. To find crashes in the problematic timeframe, click **Analyze** and drag up on the timeline where the most crashes occurred.

8. You should see the crash list reduced to those that occurred during the custom time period.



9. Double-click one of the unique crashes to open the **Crash Details** dialog.



10. From here, you can view the stack trace of the crash snapshot, note the thread and function in which the crash occurred. For some crashes, the crashed line number is also available. Optional: Click **Download** to get a text version of the stack trace to send to your application development team.
11. To access a complete data set for crashes that belong to this crash group, click **Find Sessions**. This opens the Mobile Sessions view with a filter for this **Crash Group** already selected.

Get More Information about Mobile RUM

Use the following to find out more about Mobile RUM.

- Mobile RUM Metrics
- Mobile RUM Supported Environments
- Real User Monitoring Licenses
- Network Request Limits

Mobile RUM Metrics

AppDynamics displays key metrics for Mobile RUM on the various dashboards in the Mobile UI and in the **Metric Browser**.

> With the exception of App Crashes per Minute, the crash information displayed in the Controller UI is based on data stored in the Events Store and does not display in the **Metric Browser**.

Crashes

Crash measurements are created using the Analyze event store, and display in the **Crash Dashboard**.

- **Total Crashes:** total number of crashes over the selected time range
- **Total Unique Crashes:** total number of unique crash types over the selected time range
- **Impacted Users**: total number of unique users affected by a crash
- **Crashes by Usage Stats:** percentage of crashes based on device, OS version, carrier, and connection type
- **Crashes by Geo Location:** total number of crashes by origin over the selected time range

Crash Metrics

- **App Crashes per Minute:** arithmetic average number of crashes

HTTP Errors

An HTTP error occurs when an HTTP request is sent and a response is received, but the response status code indicates that an error occurred. These errors suggest that the network is working correctly, but a problem exists on the client side (4xx status codes) or the server side (5xx status codes) that prevented normal handling of the request.

- **HTTP Errors Per Minute**: arithmetic average of errors per minute for errors that return an HTTP response code between 400 and 599
- **HTTP Errors (total):** total number of HTTP errors over the selected time range (shown in the **Geo Dashboard**)

Mobile Device Metrics

See Mobile Device Metric Collection for more information.

Network Errors

A network error is any occurrence that prevents the HTTP request from being sent or the HTTP response from being received successfully.

- **Network Errors per Minute**: arithmetic average of network errors per minute
- **Network Errors (total)**: total number of network errors over the selected time range (shown in the **Geo Dashboard**)

Typical causes of network errors include:

- Host cannot be resolved
- Host refused connection
- Connection timed out
- Device is offline
- General connectivity problems

Network Requests

Network request metrics are reported for each platform and instrumented mobile application.

- **Network Request Time**: arithmetic average interval in milliseconds between the time that a mobile application initiates a request by calling the system API and the time that the system returns the response to the application
- **Requests per Minute**: arithmetic average number of HTTP requests per minute
- **Total Requests**: total of HTTP requests per minute over the selected time range (shown in the **Geo Dashboard**)
- **Request Content Length:** total number of bytes of data in the body of the request. The body is the part that comes after the blank line below the headers
- **Response Content Length:** total number of bytes of data in the body of the response

Mobile RUM Supported Environments

See the following for the list the supported environments for Android, iOS, Xamarin, and Cordova:

- Android Agent
- iOS Agent
- Xamarin Agent
- Cordova Plugin
- React Native Agent

Mobile RUM Support

Android Agent

Supported Environments	Name	Supported Version(s)
Operating System	Android	>= 2.3.3
Architecture	arm64-v8a, armeabi, armeabi-v7a, mips, mips64, x86, and x86_64	-
Frameworks	Ant	-
	Gradle	>= 0.6.3
	Maven	3.1.1
Crash Reporters	Mobile RUM does not officially support 3rd-party crash reporters.	N/A
HTTP Libraries	`HttpURLConnection/HttpsURLConnection`	-
	`HttpClient`	-
	`OkHttp`	2.2.0 - 3.9.0
	`ch.boye.httpclientandroidlib`	-
	`retrofit`	-
	`retrofit2`	-
	Other HTTP libraries can be added by using the agent SDK. See Customize the Android Instrumentation for more information.	-

Android Gradle Plugin Version	Minimum Android Agent Version
0.6.3	3.8.2.0
0.7.3 - 0.9.2	3.8.3.0
0.10.0 - 0.12.0	3.9.0.0
1.1.2 - 1.1.3	4.0.3.3
1.3.0 - 1.4.0	4.0.7
1.5.0 - 2.2.0	4.2.0*
2.3.0 - 3.4.0 (forces Build Tools 25.0.0 or higher)	4.2.9
>= 3.4.1	>= 20.7.1

Recommendations for Android Agent Versions

- If your project uses Android Gradle Plugin version < 3.4.1, use Android Agent 20.4.0.
- If your project uses Android Gradle Plugin version >= 3.4.1, use Android Agent >= 20.7.1.

*Android Agent Plugin versions before 4.2.9 are not compatible with Android Build Tools versions >=24 because of the Java 8 bytecode generated in class files.

iOS Agent

Supported Environments	Name	Supported Version(s)
Operating System	iOS	>= 9
Architecture	Apple 32-bit ARM, Apple 64-bit A7	-
Framework	XCode	>= 8
Crash Reporters	Mobile RUM does not officially support 3rd-party crash reporters.	N/A
Apple WatchKit Extension Environments	watchOS	1
HTTP Libraries	`NSURLConnection`	-
	`NSURLSession`	-
	Alamofire - Initialize the iOS Agent before initializing Alamofire to ensure that network requests are monitored. If you need to make a network request(s) prior to iOS Agent initialization, see Alamofire Guidelines.	-
	Other HTTP libraries can be added by using the agent SDK. See Customize the iOS Instrumentation for more information.	-

Xamarin Agent

Supported Environments	Name	Supported Version(s)
Operating System	Android	>= 2.3.3
	iOS	>= 9
Architecture	Xamarin.Android Supported CPU Architectures	-
	Apple 32-bit ARM, Apple 64-bit A7 - See 32/64-bit platform considerations for information regarding the correct architecture for your iOS version.	-
Framework	.NET - Mono	>= 4.8
Crash Reporters	Mobile RUM does not officially support 3rd-party crash reporters.	N/A
Apple WatchKit Extension Environments	Not supported	-
HTTP Libraries	N/A - The Xamarin Agent does not support automatic instrumentation for network requests made with any library. You will need to manually instrument HTTP network requests regardless of what library is used.	-

Cordova Plugin

Supported Environments	Name	Supported Version(s)
Operating System	Android	4.4 - 8.1
	iOS	>= 9
Architecture	Android: arm64-v8a, armeabi, armeabi-v7a, mips, mips64, x86, and x86_64	-
	iOS: Apple 32-bit ARM, Apple 64-bit A7	-
Framework	Apache Cordova	>= 7
Crash Reporters	Mobile RUM does not officially support 3rd-party crash reporters.	N/A
Apple WatchKit Extension Environments	Not supported	-

HTTP Libraries	Android: • `HttpURLConnection/HttpsURLConnection` • `HttpClient` • `OkHttp` • `ch.boye.httpclientandroidlib`	-
	iOS: • `NSURLConnection` • `NSURLSession`	-

React Native Agent

Supported Environments	Name	Supported Version(s)
Operating System	Android	>= 4.1 (with React Native Agent >= 20.10.1)
	iOS	>= 11 (with React Native Agent >= 20.10.1)
Architecture	Android: arm64-v8a, armeabi, armeabi-v7a, mips, mips64, x86, and x86_64	-
	iOS: Apple 64-bit A7 (with React Native Agent >= 20.10.1)	-
Framework	React Native	>= 0.60 (with React Native Agent >= 20.10.1) < 0.60 (with React Native Agent 20.7.0)
Crash Reporters	Mobile RUM does not officially support 3rd-party crash reporters.	N/A
Apple WatchKit Extension Environments	Not supported	-
HTTP Libraries	Android: • `HttpURLConnection/HttpsURLConnection` • `HttpClient` • `OkHttp` • `ch.boye.httpclientandroidlib`	-
	iOS: • `NSURLConnection` • `NSURLSession`	-

Alamofire Guidelines

If you need to use Alamofire to make a network request(s) prior to initializing the iOS Agent, you can use the following sample code as a guideline for making the necessary changes.

To ensure that Alamofire network requests made after iOS agent initialization will be instrumented, you can initialize a custom instance of `Session` (the principle class defined in Alamofire 5, renamed from previous Alamofire versions). This will create a new instance of `URLSession`, which can be instrumented by the iOS Agent. Any Alamofire network requests made prior to the agent initialization and creation of the Session instance cannot be instrumented by the agent.

- The order of operations in this code is very important. See the inline comments.
- This code assumes you are initially creating a customized instance of `Session` (which is common practice). If not, you can eliminate the first usage of customized `Session` and defer its creation until after the iOS agent initialization.
- You can test this code by going to https://www.google.com/?q=request%202, which is instrumented because it occurs after the replacement of `mySession` with `instrumentedSession`. The other two requests are not instrumented.

```
import UIKit
import Alamofire
import ADEUMInstrumentation

var mySession:Session?                                          // customized Session singleton

@UIApplicationMain
class AppDelegate: UIResponder, UIApplicationDelegate {

        func application(_ application: UIApplication, didFinishLaunchingWithOptions launchOptions:
[UIApplication.LaunchOptionsKey: Any]?) -> Bool {
                // Override point for customization after application launch.

                // create customized instance of AF Session
                let myConfiguration = URLSessionConfiguration.af.default
                mySession = Session(configuration: myConfiguration)

                let myUrl1 = URL(string: "https://www.google.com/?q=request%201")!
                let urlRequest1 = URLRequest(url: myUrl1)

                // the first network request prior to ADEumInstrumentation.initWith will not be instrumented
                mySession?.request(urlRequest1 as URLRequestConvertible).response {
                        response in debugPrint(response)

                        // initialize iOS agent
                        let config = ADEumAgentConfiguration(appKey: "XX-XXX-XXX-XXX")
                        config.loggingLevel = .all
                        ADEumInstrumentation.initWith(config)

                        // update our Session instance singleton, instrumentedSession, so that URLSession will
be instrumented
                        let myConfiguration = URLSessionConfiguration.af.default
                        let instrumentedSession = Session(configuration: myConfiguration)
                        // replace mySession with instrumentedSession
                        mySession = instrumentedSession

                        // subsequent requests use updated mySession from instrumentedSession, so should be
instrumented
                        let myUrl2 = URL(string: "https://www.google.com/?q=request%202")!
                        let urlRequest2 = URLRequest(url: myUrl2)
                        mySession?.request(urlRequest2 as URLRequestConvertible).response {
                                response in debugPrint(response)
                        }
                }
                // has instrumentedSession been created yet? Indeterminate. If not, this request won't be
instrumented
                let myUrl3 = URL(string: "https://www.google.com/?q=request%203")!
                let urlRequest3 = URLRequest(url: myUrl3)
                mySession?.request(urlRequest3 as URLRequestConvertible).response {
                        response in debugPrint(response)
                }
                return true
        }

}
```

Network Request Limits

The EUM Server (on-premises/SaaS) can process a maximum of 2000 network request types per mobile app group and 500 network requests per mobile application.

If the number of network requests for an application exceeds one of these limits, AppDynamics continues to monitor network requests that have already been discovered, but new network requests will not be discovered. Should a limit be exceeded, a warning appears on the network request list.

You can use these techniques to keep your usage under the two network request limits.

Remove Network Requests Without Load

Removing network request types that have been discovered but are not receiving any load is a good place to start to reduce the number of your registered requests.

> Deleting network requests does not prevent them from being re-discovered in the future if the request once again comes under load. To prevent specific network requests from ever being discovered, you must create exclude rules. See the section "Creating Mobile Exclude Rules" in Configure Mobile Network Request Naming.

Delete network requests with no load

1. In the **Network Requests** list, uncheck the **With Load** checkbox.
2. Refresh the list.
3. Find the requests that have no load. They are candidates for removal.
4. Select the requests that you want to delete.
5. In the **More Actions** dropdown, click **Delete Request(s)**.

Exclude Requests That Do Not Need to Be Monitored

The Mobile Agent may be detecting network requests types that are not interesting for you to monitor. You have two methods to exclude these types of network requests.

The first method is to add custom exclude rules from **Configuration > Mobile Request Naming, Thresholds, & Percentiles.** See Creating Mobile Exclude in Rules for explicit instructions.

Using custom exclude rules, network requests for new data that match the exclude rules will not be registered. The load on the existing network requests that match the exclude rule will drop to zero. To delete any network requests of the excluded type that have already been registered from the network request list, follow the procedure described in Delete network requests with no load.

The second method is to select an existing network request from the **Network Requests** list and then exclude it. This will change the app's exclude rules so that incoming data matching that request will not be tracked. In addition, the historical data for that request will be deleted.

To use the second method for the exclude rules that prevent a network request from being tracked and remove historical data for that network request:

1. From **Network Requests**, select the network request you want to exclude.
2. Click **Actions > Exclude Requests** to open the **Exclude Requests** dialog.
3. Click **Exclude**.

Group Network Requests of Similar Type

Review the default network request naming rule described in Configure Mobile Network Request Naming. It is possible that the default rule is generating many more network requests types than are desirable.

For example, perhaps your application loads images dynamically and stores them on your server with URLs like `http://myapp.com/image/image1234.jpg`. This would cause a separate network request to be generated for each image, which is probably not what you want. You could create a custom naming rule to group all the image URLs as a single network request. See Configure Mobile Network Request Naming.

After you have created custom rules to reduce the number of network requests detected, unregister the network requests for those are now covered by the custom rule, following the procedure described in Delete network requests with no load.

Mobile Agent Version and Deployment Support Matrix

Related pages:

- Mobile RUM Supported Environments

Using the AppDynamics Mobile Agents with the following recommended minimum Controller/EUM Server versions will ensure that all features for the specified releases will function correctly and that there will be no unexpected side effects.

Mobile Agent	Agent Version(s)	Minimum Controller/EUM Server Version
React Native Agent	1.0.x	4.5.8
iOS Agent	50.0.x	4.5.0
	50.1.x	4.5.8
Android Agent	5.0.x	4.5.0
	5.1.x	4.5.8
Xamarin Agent	>= 50.0.x	4.5.0
	50.1.x	4.5.8
Cordova Plugin	1.1.x – 1.7.x	4.5.0
	1.8.x	4.5.8

Post-release Support for the Mobile Agents

Although Mobile Agents may be compatible with future releases of the Controller and EUM Server, AppDynamics only provides support for Mobile Agent versions with the Controller and EUM Server for two years after the release of the agent.

Deployment Support for Mobile Agent Features

For deployment support for individual mobile features, see:

- iOS SDK Documentation
- Android SDK Documentation
- Xamarin SDK Documentation
- Cordova SDK Documentation
- React Native Agent Documentation

Mobile Agent Feature Support

This table lists the feature support for the Mobile Agents:

- Native Mobile Agents
- Hybrid Agents

For instrumentation instructions, see the custom instrumentation pages (Android, iOS, Xamarin, Cordova, React Native).

Hybrid Application Support

AppDynamics supports monitoring for hybrid applications based on the iOS/Android native SDK or any Cordova-based framework.

Hybrid Applications

Hybrid applications are web applications running inside an Android or iOS native shell. The web application can be in the form of an Android WebView, an iOS WKWebViews, or a Cordova web application that consists of HTML, CSS, JavaScript, and other resources just like a conventional web application.

Hybrid Use Cases

Mobile RUM supports these two use cases.

- Native Mobile applications that run web applications or web views. Examples of this are Android WebViews and iOS WKWebView.
- Applications written in Cordova-based frameworks, such as Ionic, that provide a native shell for running a web application and an interface for native mobile APIs.

Hybrid Application Instrumentation Requirements

For instrumenting hybrid apps, you are required to:

- Manually instrument the iFrames with the JavaScript Agent. For mobile native applications, the JavaScript Agent is injected into the top-level WebView or WKWebView instance, not in embedded web pages (iFrames).
- Manually report events for Cordova-based applications using the plugin JavaScript API.
- Use Android WebViews or iOS WKWebView for hybrid applications with embedded web views. See Instrument Cordova Applications.

Instrumentation Steps

To monitor your hybrid applications, you will need to set up and access Mobile RUM and follow the steps below based on your hybrid use case:

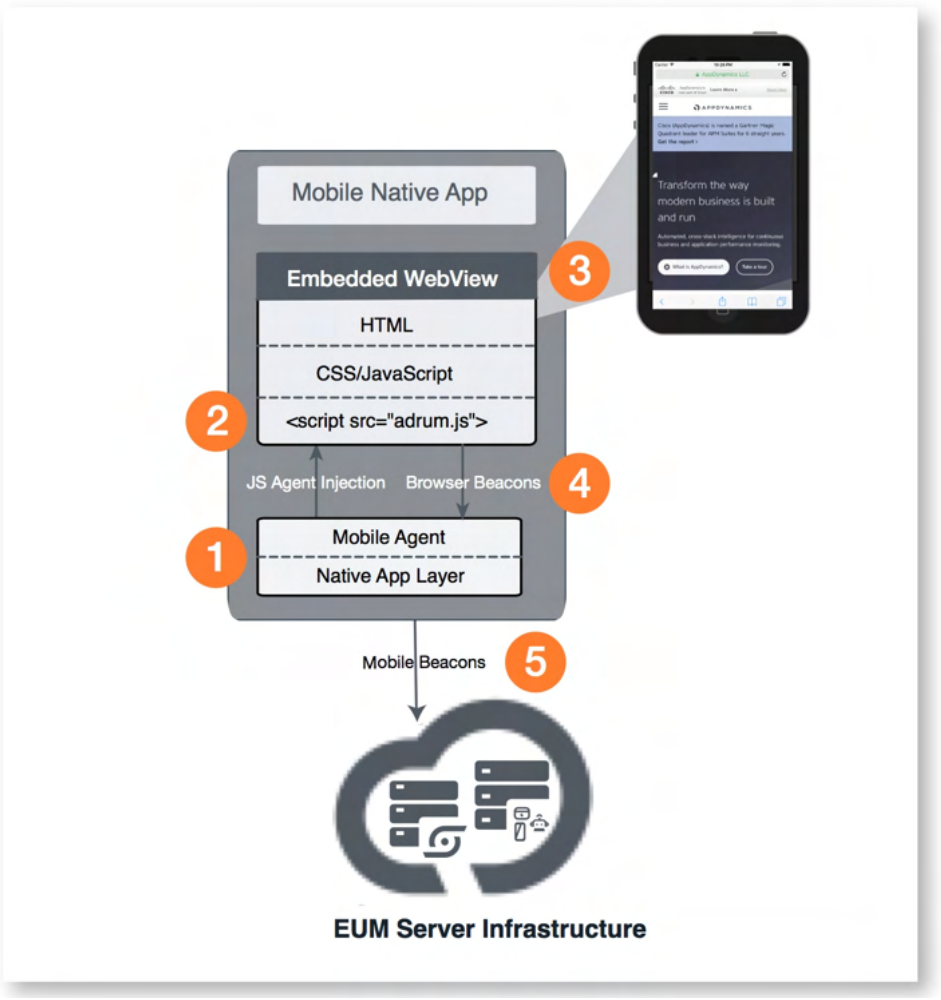
Native iOS Application	Native Android Application	Cordova-Based Applications
1. Instrument an iOS Application 2. Configure Hybrid Support for the iOS Application	1. Customize the Android Build 2. Instrument an Android Application 3. Configure Hybrid Support for Android Applications	1. Instrument a Cordova Application 2. Customize the Cordova Instrumentation

How it Works

For native Android/iOS applications, the Android Agent or iOS Agent will inject the JavaScript Agent into an Android WebView or iOS WKWebView. For Cordova-based applications, the AppDynamics plugin will inject the JavaScript Agent into the web application.

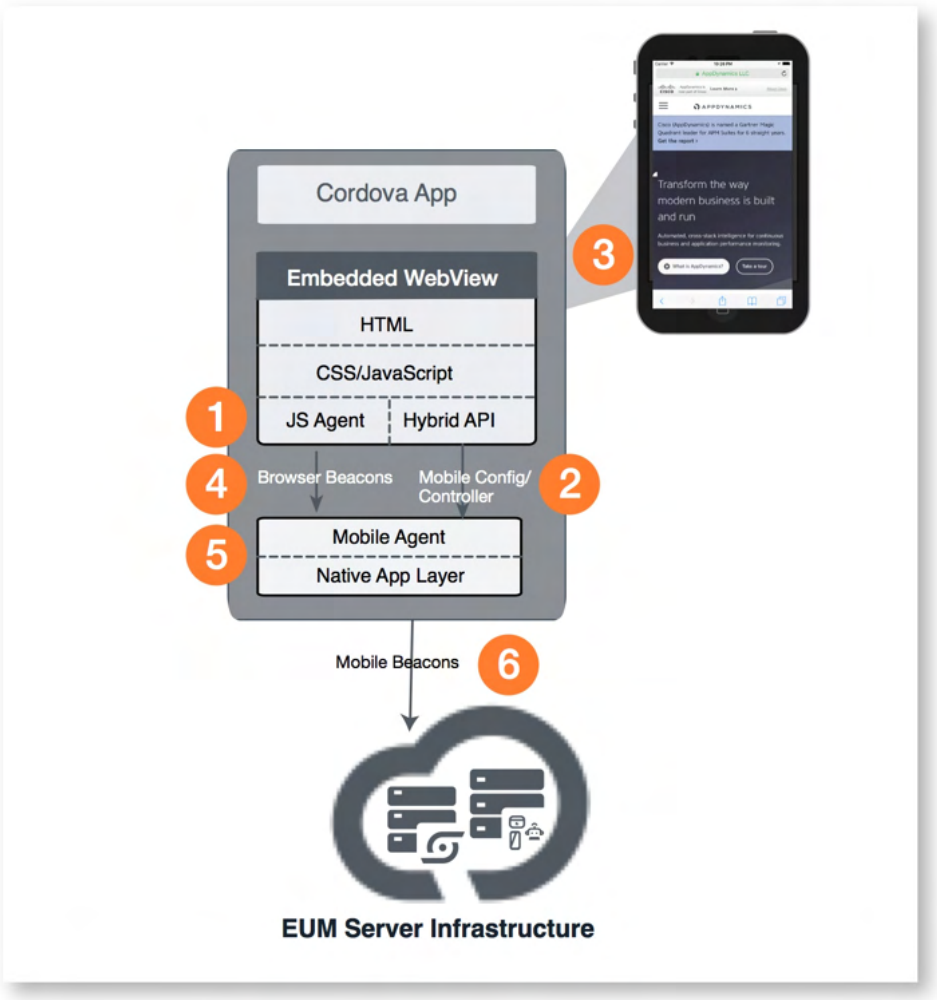
The diagrams below provide an overview of how Mobile RUM is used to monitor mobile native applications and Cordova-based applications.

Mobile Native Application Architecture



1. You instrument your mobile application with either the Android /iOS Agent.
2. When your mobile application instantiates a WebView or WKWebView instance, the Mobile Agent injects the JavaScript Agent into it.
3. The JavaScript Agent monitors the performance and WebView usage.
4. The JavaScript Agent reports the application activity by sending beacons to the Mobile Agent.
5. The Mobile Agent repackages the browser beacons into mobile beacons and sends the beacons to the EUM Server.

Cordova-Based Application Architecture



1. The AppDynamics Cordova plugin injects the JavaScript Agent into the Cordova WebView.
2. The Cordova-based application uses the plugin's JavaScript binding to configure the Mobile Agent.
3. The JavaScript Agent injected into the WebView monitors the application activity and performance.
4. The JavaScript Agent sends browser beacons to the Mobile Agent.
5. The Mobile Agent parses and converts the browser beacons into mobile beacons.
6. The Mobile Agent sends the mobile beacons to the EUM Server.

Mobile Agent and JavaScript Agent Compatibility

When hybrid app support is enabled, the Mobile Agents use an embedded JavaScript Agent to monitor mobile web pages. If you are already monitoring the same mobile web pages with a browser application, the JavaScript Agent version used to instrument the browser application may be different than the JavaScript Agent version used by the Mobile Agent. If the two versions of the JavaScript Agent are incompatible, the Mobile Agent will not be able to instrument web views or access event notifications from web views.

How to Ensure Compatibility

To ensure compatibility, browser applications should use JavaScript Agent version >= 4.5.4 and mobile applications should use Mobile Agent versions >= 4.5.5. When using compatible versions of the JavaScript Agents, the JavaScript Agent of the browser app will report beacons for a web page, and the embedded JavaScript Agent of the mobile app will be ignored and not report beacons because a web page cannot be instrumented with the JavaScript Agent multiple times.

> If you have disabled the Mobile Agent's hybrid app support, there will be no compatibility issues regardless of the JavaScript Agent version used by the browser application.

Troubleshooting Incompatible JavaScript Agent Versions

If you are using incompatible versions of the JavaScript Agents, do one of the following to correct the problem:

- Upgrade the JavaScript Agent that you are using to instrument the browser application.
- In the mobile instrumentation, disable the hybrid support (iOS/Android), so that the mobile web pages are only instrumented by the browser application instrumented with the older version of the JavaScript Agent.

Hybrid Application Network Requests

Network calls made in the context of the WebView for Cordova-based applications show up as Ajax calls from the JavaScript Agent.

iOS Data Collection Disclosure

With the iOS 14 release, Apple introduced a new data collection policy, available at https://developer.apple.com/app-store/user-privacy-and-data-use/ (the "Apple iOS 14 User Privacy and Data Use Policy"). This page describes how Apple's iOS 14 data use policy applies to AppDynamics.

Data Collection with Screenshots

When you use the Mobile Screenshots feature, the iOS Agent captures an image of the your user's screen and may send a copy of the image to AppDynamics' server for the Controller to visualize app usage. Such screenshots may capture anything your application displays, including any user data your user submits. It is your responsibility to review the data captured in the screenshots and determine where such captured data falls in Apple's categorization of types of disclosable data. See Data Collection Details.

Disable Mobile Screenshots

You can use `blockScreenshots()` to temporarily disable screenshots for any screen which may display such data. See Customize the iOS Instrumentation.

Data Collection Details

AppDynamics does not enable any targeted advertisements, data broker, or data combination as described in the Apple iOS 14 User Privacy and Data Use Policy. In addition, ID for Vendors (IDFV) as defined under such guidelines is not currently used in any AppDynamics Mobile features.

This table references https://developer.apple.com/app-store/app-privacy-details/ and describes how AppDynamics does, or does not collect data.

Apple Data Category	Apple Data Description	AppDynamics Data Collection
Contact Info	**Name** Such as first or last name	Subject to screen capture functionality
	Email Address Including but not limited to a hashed email address	
	Phone Number Including but not limited to a hashed phone number	
	Physical Address Such as home address, physical address, or mailing address	
	Other User Contact Info Any other information that can be used to contact the user outside the app	
Health and Fitness	**Health** Health and medical data, including but not limited to from the Clinical Health Records API, HealthKit API, MovementDisorderAPIs, or health-related human subject research or any other user provided health or medical data	Does not collect data
	Fitness Fitness and exercise data, including but not limited to the Motion and Fitness API	
Financial Info	**Payment Info** Such as form of payment, payment card number, or bank account number. If your app uses a payment service, the payment information is entered outside your app, and you as the developer never have access to the payment information, it is not collected and does not need to be disclosed.	Does not collect data
	Credit Info Such as credit score	
	Other Financial Info Such as salary, income, assets, debts, or any other financial information	
Location	**Precise Location** Information that describes the location of a user or device with the same or greater resolution as a latitude and longitude with three or more decimal places	Does not collect data
	Coarse Location Information that describes the location of a user or device with lower resolution than a latitude and longitude with three or more decimal places, such as approximate location services	

Sensitive Info	**Sensitive Info** Such as racial or ethnic data, sexual orientation, pregnancy or childbirth information, disability, religious or philosophical beliefs, trade union membership, political opinion, genetic information, or biometric data	Does not collect data
Contacts	**Contacts** Such as a list of contacts in the user's phone, address book, or social graph	Does not collect data
User Content	**Photos or Videos** The user's photos or videos	Subject to screen capture functionality
	Audio Data The user's voice or sound recordings	
	Gameplay Content Such as user-generated content in-game	
	Customer Support Data generated by the user during a customer support request	
	Other User Content Any other user-generated content	
Browsing History	**Browsing History** Information about content the user has viewed that is not part of the app, such as websites	Does not collect data
Search History	**Search History** Information about searches performed in the app	Does not collect data
Identifiers	**User ID** Such as screen name, handle, account ID, assigned user ID, customer number, or other user- or account-level ID that can be used to identify a particular user or account	Subject to screen capture functionality
	Device ID Such as the device's advertising identifier, or other device-level ID	Does not collect data
Purchases	**Purchase History** An account's or individual's purchases or purchase tendencies	Does not collect data
Usage Data	**Product Interaction** Such as app launches, taps, clicks, scrolling information, music listening data, video views, saved place in a game, video, or song, or other information about how the user interacts with the app	• Application life cycle events (start, relaunch, crash) • Views of transition events • Tabs • Clicks • Scrolling information • Activation/deactivation of text input fields
	Advertising Data Such as information about the advertisements the user has seen	Does not collect data
	Other Usage Data Any other data about user activity in the app	• Developer-specified breadcrumbs to track custom milestones
Diagnostics	**Crash Data** Such as crash logs	• Crash time • Crash stack traces
	Performance Data Such as launch time, hang rate, or energy use	• ANR (Application not Responding) with associated stack trace • Remaining storage, memory, and battery use
	Other Diagnostic Data Any other data collected for the purposes of measuring technical diagnostics related to the app	• Device type • OS version

Other Data	**Other Data Types** Any other data types not mentioned	• Network calls: duration, type (POST, GET, and so on), URL (parameters are stripped from URL prior to capture), content length, response content length, status codes.

Mobile Device Metric Collection

This page explains what mobile device metrics are collected, and how to enable collection and view device metrics in the Controller UI. To learn how Apple's iOS 14 data use policy applies to AppDynamics mobile device metric collection, see iOS Data Collection Disclosure.

Mobile agents can capture the following mobile device metrics:

- **Memory (RAM):** total memory of the device (i.e. 8GB total memory) and the resource consumption (i.e. 34% of device memory has been consumed)
- **Disk Space:** total storage capacity of the device (i.e. 64GB total storage capacity) and storage usage (i.e. 65% of device storage has been consumed)
- **Battery:** battery level of the device (i.e. include charging and lower power mode statuses)

For Android devices, the metrics reported in the UI might not exactly match the Android device metrics. Due to API limitations, the memory value that the Android Agent returns might not include segments on the device's reserved memory. For example, a device might have 64GB storage and 8GB memory, but the agent might report only 53GB storage and 6.5GB memory. This also varies based on device type and manufacturer.

Support

- Available for both SaaS and on-prem
- Controller 20.11.0 and later
- Android Agent 20.10.0 and later
- iOS Agent 20.10.0 and later

Enable and Configure Device Metric Collection

To configure device metric data collection in the Controller:

1. Go to a browser application.
2. In the left-hand panel, go to **Configuration** > **Mobile App Group Configuration** > **Settings**.
3. Under **Configure Mobile Device Metrics**, enable each option. It may take a few minutes for data to appear on the **Mobile App Dashboard**.
4. Set **Frequency of data collection** to how often device data is collected for the options you enabled. For example, if the frequency is set to 2, every 2 minutes the enabled device data is collected and shown in the dashboard widgets.

Warning

The maximum frequency is 2 minutes and collects the most data. However, sessions under 2 minutes or temporary metric spikes will not be captured.

Add Device Metric Widgets to the Mobile App Dashboard

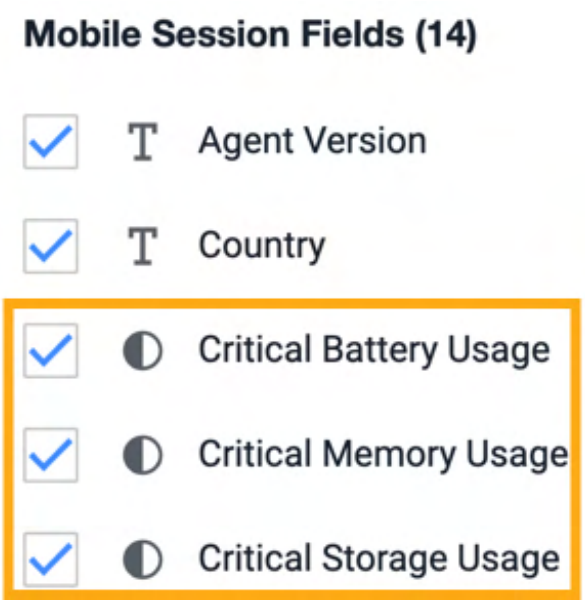
You can view device metric widgets on the **Mobile App Dashboard**. To add device metric widgets:

1. Go to the **Mobile App Dashboard**.
2. In the top-left corner, click **+**.
3. Add the widgets **Device Memory Capacity**, **Device Storage Capacity**, and **Device Battery Capacity**.
4. Click on a widget and view performance and sessions by battery, memory, and storage.

View Sessions with Device Metrics

On the **Sessions** dashboard, you can add columns to sort sessions for each device metric. To add device metric columns:

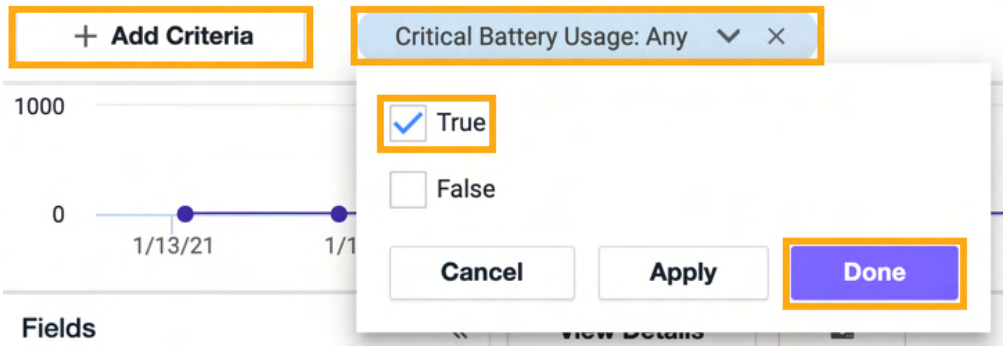
1. Go to **Mobile Session Fields**.
2. Check the fields **Critical Battery Usage**, **Critical Memory Usage**, and **Critical Storage Usage**.



Filter Sessions by Device Metric Values

You can filter sessions by critical device states you configured. For example, if you want to look at sessions with over 90% device storage used:

1. Go to **Sessions**.
2. Click **+ Add Criteria**.
3. Select "Critical Battery Usage: Any".
4. Check "True."



Set Critical Usage Thresholds

You can set the usage threshold to trigger a critical event. To configure what usage percentage triggers a critical event:

1. Go to **Configuration** > **Mobile App Group Configuration** > **Settings**.
2. Under **Configure Mobile Device Metrics**, enter a value for each device metric threshold. For example, if you want to capture battery usage below 50%, set **Enable Battery Usage and Capacity Metrics** to 50%. When that configured threshold is reached, the resource consumption (percentage value) is captured by the agent and shown in session data.

When you look at a mobile session, you can see the critical events you configured.

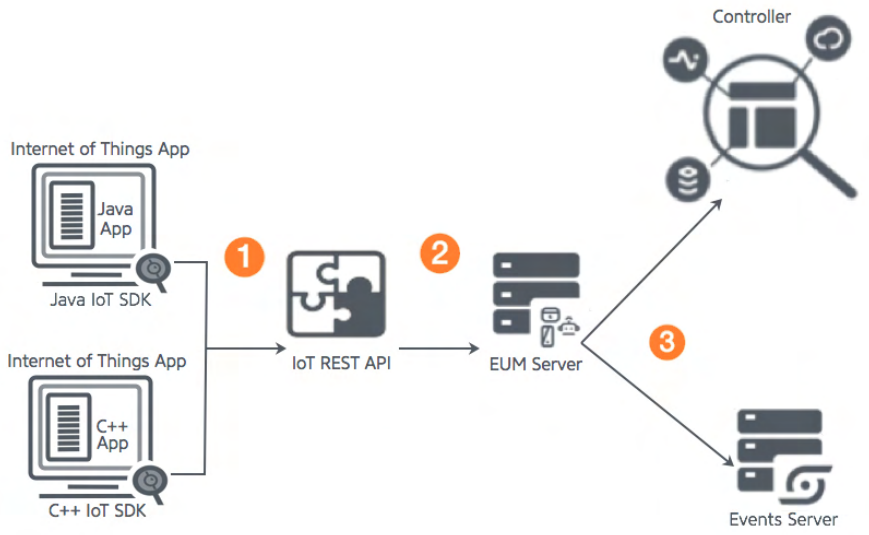
IoT Monitoring

Deployment Support

SaaS

AppDynamics IoT Monitoring enables you to track and understand the transactions of your IoT applications. Because IoT devices are diverse, both in terms of the platforms they use and their business function, AppDynamics has developed a REST API in addition to language SDKs to provide the maximum flexibility for reporting IoT data. This API can be used from any device that supports HTTPS and is connected to the Internet.

IoT Monitoring requires application developers to instrument their code. To make this process easier, AppDynamics has developed C/C++ and Java SDKs, so that developers using the platforms supporting these languages can leverage the features of the SDK instead of using the REST API. The IoT SDKs (1) use the REST APIs to report IoT Data to the EUM Server (2), where the data is aggregated and made available to the AppDynamics Controller and the Events Service (3) as shown in this diagram:



Benefits of IoT Monitoring

IoT Monitoring enables you to capture and diagnose network requests, errors, and custom application and domain-specific events for applications running on devices that impact business objectives.

With IoT Monitoring, you can monitor the following for devices:

- Availability
- Network Performance:
  - Slow interaction
  - Latency between the device and backend services
- Usage: User and system behavior and patterns
- Errors and Exceptions

IoT Monitoring Use Cases

IoT applications are typically embedded applications running on connected devices. This section focuses on how IoT Monitoring can collect and report data for the most common categories of IoT applications.

In the tabs below, you can view these IoT app categories and see how a typical example of each would use the three supported IoT Monitoring events to report data.

IoT SDKs

IoT Monitoring provides SDKs for C/C++ and Java languages. Some of the features of IoT SDKs are:

- APIs for reporting instrumentation data through custom events, error events, and network requests.
- Serialization of all events into JSON format before sending them to EUM Server
- API to plugin application HTTPS stack into SDK which will be used to communicate with EUM Server
- Business Transaction (BT) correlation
- Auto-disable when monitoring is turned off from the Controller UI

For languages other than C++ and Java, you can use the REST API to send custom events, error events, and network requests.

IoT Monitoring UI

IoT Monitoring also provides the following features through the Controller UI:

- Dashboards for monitoring devices, network requests, as well as errors and exceptions
- Predefined and custom widgets to visualize reported application data
- Analytics for device application data through AppDynamics Application Analytics
- Configuration for naming and excluding network requests

IoT Monitoring Workflow

The IoT SDKs and REST API enable you to report application data for a large number of different kinds of devices. This flexibility allows for a great deal of customization in the kind of the data you report, the quantity of data you report, and the timing of when the data is sent to the EUM Server.

To monitor customized data, you will need to better understand the data generated by your application and your device instrumentation. The goal of this page is to guide you through the process of understanding your application data, instrumenting your device application, and creating custom dashboards, so you can monitor device performance and activity.

We recommend that you follow this procedure as a guideline to monitor your devices:

1. Define your monitoring goals.
2. Identify what data needs to be captured.
3. Determine which events to use to report the data.
4. Obtain an EUM App Key.
5. Report events.
6. Monitor the availability, usage, and performance of your devices.
7. Build widgets.
8. Diagnose problems through filters.
9. Improve monitoring and troubleshoot.

Define Monitoring Goals

AppDynamics IoT Monitoring enables you to monitor the availability, performance, and usage of your device. You should devise a plan that prioritizes your monitoring goals, considering the needs of all stakeholders (developers, DevOps, business units), and lists the resources that need to be monitored. Also, you should consider who will be instrumenting the device application, who will be performing the monitoring, and the parties who should be notified when something goes wrong.

Identify Data to Capture

Next, you will need to analyze your device to identify what application data can be used to meet your monitoring goals. For example, if your device is a car, you would want to look at network requests to check device availability or report custom data for the wear and tear on its components or road conditions.

Determine Which Event Types to Use to Report Data

You report app data through the three types of events shown in the table below. Based on this information, map the most suitable event types to the data you identified and your monitoring goals.

Event Type	Monitoring Objective
Custom	Usage
	Business
Network Request	Availability
	Performance
	Usage

Error	Performance

Obtain an EUM App Key

Follow the instructions provided in Get an EUM App Key.

Report Events

You can use the IoT SDKs or REST API to capture and report key data points using one of the event types. If you are using a language other than C/C++ or Java, use the IoT REST API, which gives you the flexibility to report data from any platform.

Follow the getting started instructions to learn how to install the SDK and instrument your IoT application:

- Instrument Applications with the IoT C/C++ SDK
- Instrument Applications with the IoT Java SDK

Monitor Your IoT Application

To monitor your IoT applications, you will need to understand the function and purpose of the three IoT dashboards. See Monitor Applications with the IoT Dashboards for a brief introduction of each dashboard and usage instructions.

Build Widgets Based on Your Data Models

Each dashboard has a set of predefined widgets for basic performance and activity monitoring. You will need to create your own widgets, however, to optimize the monitoring capabilities of **IoT Monitoring**. Based on the events you reported, create custom widgets to monitor device activity and performance. See the section Build Custom Dashboard Widgets to learn how to build widgets with the **IoT Widget Builder Wizard**.

Diagnose Problems

When you do discover deviations from expected behavior, you can then add criteria to filter results. This enables you to narrow the results to certain devices or possible causes.

Troubleshoot Issues and Improve Monitoring

For performance issues, you can open the device details to analyze errors and slow network requests. The device details allow you to trace the error event you are interested in and even download the stack trace. The developer can then use this information to determine the root cause of the problem and devise a possible solution. Going back to our point-to-sale device example, you might discover that most of the failed payments were due to network request errors.

You can use the usage information to improve your monitoring or the devices themselves. For example, an inventory management application indicates that several stores sell a smaller quantity of a certain product. It turns out that this product is often out of stock at these stores. You could improve the monitoring of your IoT app by using custom events to report when a product is sold out and then creating custom widgets to let you know which stores need to restock.

IoT Analytics

All IoT data is processed and stored by the AppDynamics Platform Events Service. A separate product component, AppDynamics Analytics, has an event type called Connected Device Data. This event type is based on the same Events Service and uses the same data. Viewing this event type from the Analytics UI offers additional capabilities, including:

- Additional predefined widgets, such as the funnel widget
- ADQL for searching the data
- Creating custom widgets
- Manipulating multiple dashboard types
- Longer retention time for data storage

IoT Analytics does *not* require a license separate from the IoT Monitoring license.

To view Analytics data for connected devices, users need **Connected Devices Permissions** for the application (identified by a specific App Key).

IoT Licenses and Limits

Currently, AppDynamics only offers the **IoT PRO** license. To learn about the license entitlements and restrictions, contact your AppDynamics account representative.

Set Up and Access IoT Monitoring

This describes when you should use an IoT SDK or the IoT REST API, get an EUM App Key, and direct you to instructions for capturing and reporting data.

SDKs Versus REST API

The IoT SDKs use the REST API to transmit data to the EUM Server. By handling HTTP requests, serializing JSON, and managing events in memory, the SDKs make it easier to capture and report data, so you can focus on instrumenting your application. For platforms other than C++ or Java, you can take advantage of the wide variety of HTTP(S) and JSON libraries to use the IoT REST API to report data.

Get an EUM App Key

To get an EUM App Key, you need to either create an IoT app manually or use the **Getting Started Wizard**, which is recommended if you are a new user. You will need the EUM App Key to use the IoT REST API or IoT SDKs to report device information and events to the EUM Server. Multiple IoT applications can share the same key.

Create an IoT Application with the Getting Started Wizard

From the Controller:

> IoT applications created from existing applications cannot be deleted. You would need to delete the existing IoT application that was used to create the application.

Manually Create an IoT Application

From your Controller:

1. Click **User Experience** from the top navigation bar.
2. Select the Connected Devices tab.
3. Click **Get Started.**
4. From the **Create Application** dialog, select **Create an Application manually**.
5. Enter a name for your IoT app.
6. Click **OK**.
7. From the **Connected Devices** tab, select IoT app and click  to copy the App Key to your clipboard.

Report IoT Data

Based on the method you plan on reporting data, use your App Key and follow the instructions for one of these tutorials:

- Instrument Applications with the IoT C/C++ SDK
- Instrument Applications with the IoT Java SDK
- Instrument Applications with the IoT REST APIs

Correlate Business Transactions for IoT Monitoring

Related pages:

- Correlate Business Transactions for EUM Monitoring
- Business Transactions

You can correlate IoT network request events with business transactions. The correlation is made between beacons containing network request event information and instances of business transactions (transaction snapshots).

IoT Network Requests Correlation

This procedure outlines how IoT applications correlate network requests with business transactions:

1. The IoT application attaches AppDynamics HTTP headers to a network request to the app server agent. These AppDynamics HTTP headers instruct the app server agent to send back correlation headers.
2. The app server agent:
    - Sends HTTP response headers identifying the business transaction to the IoT application.
    - Aggregates backend metrics and sends them along with the business transaction identifiers to the Controller. This serves as the content for the transaction snapshot.
3. The IoT Agent sends business transaction identifiers (from the HTTP response headers) as part of IoT network request event to the EUM Server. This serves as the content for the network request.
4. The Controller fetches the events and business transaction identifiers from the EUM Server. These business transaction identifiers are used to correlate the network request with the transaction snapshots.

Correlate IoT Network Request Events with Business Transactions

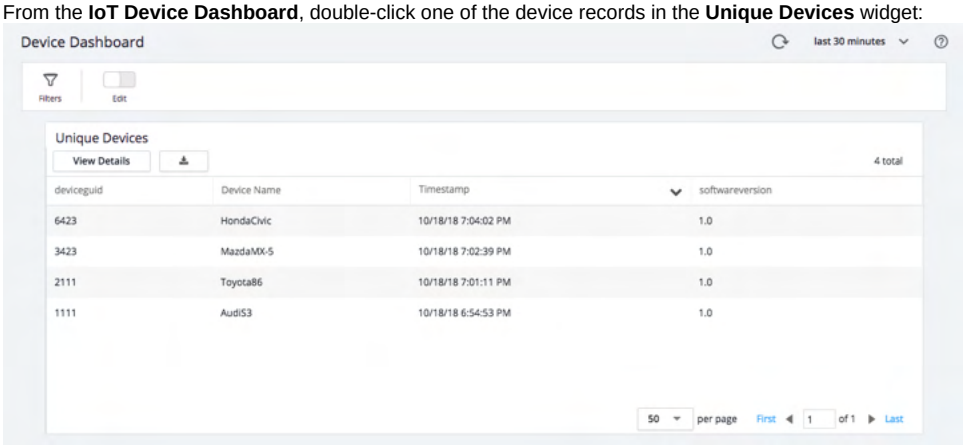
Use the IoT SDKs or the IoT REST API to send the returned response headers from the business application with beacons to report IoT network request events and correlate those events with the business transaction.

For correlation instructions, see "Correlate Business Transactions with Network Requests" for either the IoT C/C++ SDK, IoT Java SDK, or the IoT REST API.

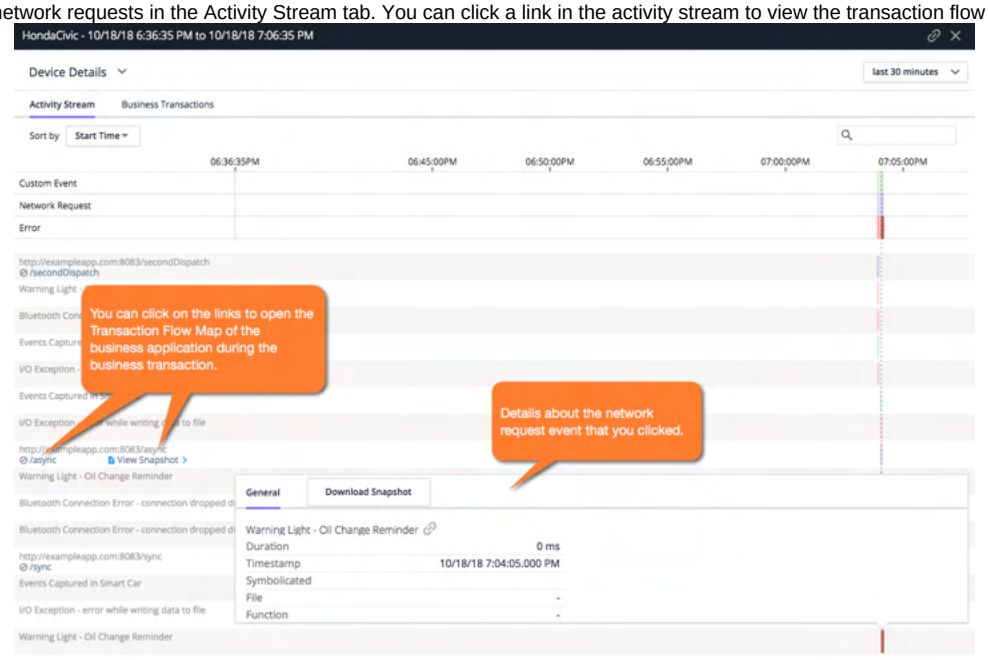
View Business Transactions Correlated with IoT Applications

There are several ways to navigate from a network request snapshot to its correlated business transaction. The following steps show you one possible way.

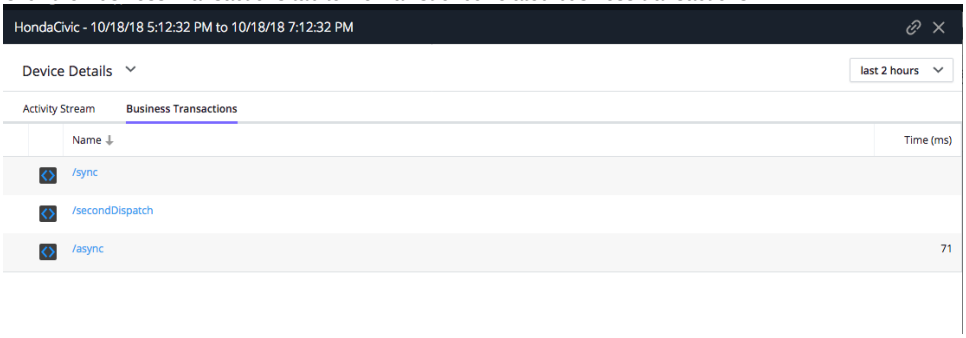
1. From the **IoT Device Dashboard**, double-click one of the device records in the **Unique Devices** widget:



2. You should now see a list of network requests in the Activity Stream tab. You can click a link in the activity stream to view the transaction flow map for a business transaction.



3. Click the Business Transactions tab to view a list of correlated business transactions.



4. You can then click a business transaction to view the **Transaction Flow Map** shown below**,** which provides a visual representation of the components and activities of the business application during the correlated business transaction.

Instrument Applications with the IoT C and C++ SDK

The IoT C++ SDK provides APIs to instrument C++ applications running on connected devices such as industrial or home gateways, points of sale, smart TVs or car infotainment systems. This getting started will show you how to install the C++ SDK and instrument your IoT application.

Follow these steps to get your EUM App Key and instrument your IoT C/C++ apps.

> If you have ANSI-C application or if your platform is not Linux x86, please contact your AppDynamics account representative.

Learn About the C/C++ SDK

You should know that the C++ SDK:

- Operates within the application thread and doesn't spawn any new threads.
- Keeps all the event data in memory and doesn't persist on disk.
- Provides an API to register for the network interface.
- Uses application's HTTPS stack to communicate with the EUM Server.
- Provides an API to fetch SDK log messages. Application developers have to manage logs by writing the log messages to `stderr` or to a log file.
- Uses the open-source json-c library that is statically linked.
- Makes synchronous blocking API calls that are not thread-safe. Application developers are responsible for making thread-safe calls.

Review the Requirements

Before you begin, make sure you meet these requirements:

- GNU C++ Compiler (g++) version 4.2 for 32/64-bit architectures
- Any Linux distribution based on glibc >= 2.20
- HTTPS stack for sending beacons to the EUM Cloud
- EUM App Key

Get the IoT C++ SDK

You can get the C++ SDK by cloning or downloading the IoT C++ SDK from GitHub. Follow the instructions given in Installation to build the IoT C++ SDK.

Upgrade the IoT C++ SDK

From the root directory of your clone of the IoT C++ SDK from GitHub:

- Update the repository: `$ git pull origin master`
- Follow the instructions given in Installation to rebuild the IoT C++ SDK.

Install the C++ SDK in Your Application

The C++ SDK is packaged as a tar zip file and contains the following:

- `include` - directory containing headers for the public API for use with the C++ SDK
- `lib` - the directory containing the shared object files for the C++ SDK

Add the SDK Headers

Copy or move the `include` directory, which contains the SDK header files into your application directory, and include it in your code to access the SDK APIs.

```
#include "appd_iot_interface.h"
  ....
{
```

Initialize the SDK

You must initialize the C++ SDK by providing the SDK and device configuration as input parameters and then calling the function `appd_iot_init_sdk` as shown below. The SDK configuration takes in parameters for the app key, log level, and the EUM Collector URL. The SDK uses the EUM Collector URL to send data to the EUM Server. The device configuration contains information to identify a unique device.

```
#include "appd_iot_interface.h"
  ....
{
  // Declare config variables for the SDK and device.
  appd_iot_sdk_config_t sdkcfg;
  appd_iot_device_config_t devcfg;
  appd_iot_init_to_zero(&sdkcfg, sizeof(sdkcfg));
  appd_iot_init_to_zero(&devcfg, sizeof(devcfg));

  // Set the initialization configurations for the SDK
  sdkcfg.appkey = "<EUM_APP_KEY>";

  // Set the device configurations
  devcfg.device_id = "1111";
  devcfg.device_type = "SmartCar";
  devcfg.device_name = "AudiS3";

  // Initialize the instrumentation
  appd_iot_init_sdk(sdkcfg, devcfg);
}
```

Register Network Interface

The SDK needs an HTTPS interface to send events to the EUM Server. The application developer has to provide callback functions for the SDK to execute the HTTPS request. Refer to Run the Sample Application for a sample network interface implementation using `libcurl`.

```
#include "appd_iot_interface.h"
  ....
{
  appd_iot_http_cb_t http_cb;

  //Callback function triggered by SDK to send http request and receive http response
  http_cb.http_req_send_cb = &your_network_interface_send_cb;

  //Callback function triggered by SDK to indicate completion of http response processing
  http_cb.http_resp_done_cb = &your_network_interface_resp_done_cb;

  //register http interface callbacks
  appd_iot_register_network_interface(http_cb);

  ...
}
```

Add and Send Events

To understand the different types of events, you will work with the sample smart car IoT application given in the sections below.

Custom Events

Custom event to capture technical stats of a "SmartCar".

```
#include "appd_iot_interface.h"
  ....

{
  appd_iot_custom_event_t custom_event;
  appd_iot_init_to_zero(&custom_event, sizeof(custom_event));

  custom_event.type = "SmartCar Stats";
  custom_event.summary = "Technical Stats of SmartCar";
  custom_event.timestamp_ms = ((int64_t)time(NULL) * 1000);
  custom_event.data = (appd_iot_data_t*)calloc(2, sizeof(appd_iot_data_t));
  appd_iot_data_set_integer(&custom_event.data[0], "Speed mph", 65);
  appd_iot_data_set_double(&custom_event.data[1], "Oil Temperature", 220);

  appd_iot_add_custom_event(custom_event);
  free(custom_event.data);

  ....

  appd_iot_send_all_events();
}
```

Network Request Events

Network Request event to capture the performance of an HTTPS call to get weather information.

```
#include "appd_iot_interface.h"
  ....

{

  appd_iot_network_request_event_t network_event;
  appd_iot_init_to_zero(&network_event, sizeof(network_event));

  network_event.url = "https://apdy.api/weather";
  network_event.resp_code = 202;
  network_event.duration_ms = 10;
  network_event.req_content_length = 300;
  network_event.req_content_length = 100;
  network_event.timestamp_ms = ((int64_t)time(NULL) * 1000);
  network_event.data = (appd_iot_data_t*)calloc(1, sizeof(appd_iot_data_t));
  appd_iot_data_set_string(&network_event.data[0], "city", "San Francisco");

  appd_iot_add_network_request_event(network_event);
  free(network_event.data);

  ....
  appd_iot_send_all_events();
}
```

Error Events

The Error event below is used to capture Bluetooth errors in the SmartCar app.

```
#include "appd_iot_interface.h"
  ....
{

  appd_iot_error_event_t error_event;
  appd_iot_init_to_zero(&error_event, sizeof(error_event));

  error_event.name = "Bluetooth Connection Error";
  error_event.message = "connection dropped due to bluetooth exception";
  error_event.severity = APPD_IOT_ERR_SEVERITY_CRITICAL;
  error_event.timestamp_ms = ((int64_t)time(NULL) * 1000);
  error_event.data = (appd_iot_data_t*)calloc(1, sizeof(appd_iot_data_t));
  appd_iot_data_set_integer(&error_event.data[0], "Bluetooth Error Code", 43);

  appd_iot_add_error_event(error_event);
  free(error_event.data);

  ....

  appd_iot_send_all_events();
}
```

Correlate Business Transactions with Network Requests (Optional)

To correlate business transactions (BTs) with network requests, you need to instrument a business application and enabled business transactions in the Controller UI. See Correlate Business Transactions for IoT Monitoring to learn more.

The steps below show you how to get the BT response headers and use them to correlate the BT with an IoT Network Request event.

1. Set the AppDynamics HTTP headers `ADRUM` and `ADRUM_1` as part of a network request to your business application.

```
/* Initialize all the data structures for the request and response. */
appd_iot_http_req_t http_req;
appd_iot_http_req_t http_resp;

/* Initialize the request and response. */
appd_iot_init_to_zero(&http_req, sizeof(http_req));
appd_iot_init_to_zero(&http_resp, sizeof(http_resp));

/* Provide the URL to your instrumented business app that is enabled for business transaction
correlation. */
http_req.url = "<url-to-your-business-app-enabled-for-bt>";

/* Add your other HTTP request parameters here:
...
*/
/* Call the SDK method to get the headers for ADRUM and ADRUM_1. */
const appd_iot_data_t* correlation_headers = appd_iot_get_server_correlation_headers();

for (size_t i = 0; i < APPD_IOT_NUM_SERVER_CORRELATION_HEADERS; i++)
{
  appd_iot_data_set_string(&http_req.headers[i], correlation_headers[i].key, correlation_headers[i].
strval);
}

/* Make the request, and assign the response to a variable. */
http_resp = http_curl_req_send_cb(&http_req);
```

2. The call will return response headers (i.e., `ADRUM_*`) that contain information for correlating the business transaction. If you were to print these BT response headers, you would see something like the following:

```
ADRUM_0: clientRequestGUID:0f5c7602-9b69-4e40-85a6-e0abf288accf
ADRUM_1: globalAccountName:eum-mobile_4debdbad-3f8e-4f6d-8faf-e5f5781ec0d7
ADRUM_2: btId:3867
ADRUM_3: serverSnapshotType:f
ADRUM_4: btDuration:829
```

3. Add these BT response headers to the network event that you send to the EUM Server:

```
/* Create a network event to report to the EUM Server. */
appd_iot_network_request_event_t network_event;
appd_iot_init_to_zero(&network_event, sizeof(appd_iot_network_request_event_t));

/* Add information about the network event that you want to report. */
network_event.url = "<url-to-your-business-app-enabled-for-bts>";
network_event.resp_code = http_resp->resp_code;

/* Assign the returned BT response headers from the call to the business app to the headers of the
request. */
network_event.resp_headers = http_resp->headers;

// Add the network event to beacon to send to the EUM Server. */
appd_iot_add_network_request_event(network_event);
appd_iot_send_all_events();
```

4. In the Controller UI, you should be able to view the correlated business transaction in the **Device Details** dialog.

Compile and Run Your App with the SDK Library File

1. Compile your program. For example, if the driver file is `main.cpp`:

```
$ g++ -c main.cpp -I<appd_iot_sdk_dir>/include
```

2. Create the binary with the object code of your application and linking AppDynamics IoT C++ SDK library.

   You can combine steps 1 and 2 into one step as below:

```
$ g++ main.cpp -o main -I<appd_iot_cpp_sdk_dir>/include -L<appd_iot_cpp_sdk_dir>/lib -lappdynamics_iot
```

3. Set the environment variable `DYLD_LIBRARY_PATH` to the `PATH` where the SDK library is installed. This will let dynamic linker know the directory to search for shared libraries.
4. Run your program. For example:

```
$ ./main
```

Verify the Instrumentation in the Controller UI

See Confirm the IoT Application Reported Data to the Controller to verify the instrumentation.

Customize the IoT C++ Instrumentation (Optional)

You can further customize the IoT C++ instrumentation using the IoT C++ SDK. See the latest IoT C++ SDK documentation or the previous versions listed below:

- https://sdkdocs.appdynamics.com/javadocs/iot-cpp-sdk/4.5/4.5.0/
- https://sdkdocs.appdynamics.com/javadocs/iot-cpp-sdk/4.5/4.5.1/
- https://sdkdocs.appdynamics.com/javadocs/iot-cpp-sdk/4.5/4.5.2/
- https://sdkdocs.appdynamics.com/javadocs/iot-cpp-sdk/4.5/4.5.4/

Run the Sample C++ Application

The sample C++ application sends sample data for Custom, Network Request, and Error events. The data mocks a smart car application, capturing usage information, network performance, and errors.

To run the sample app, follow the instructions given in Sample Application using IoT C++ SDK.

Instrument Applications with the IoT Java SDK

The IoT Java SDK can be included in IoT Java applications running on an edge device like gateways, points of sale, car infotainment centers. This getting started will show you how to install the Java SDK and instrument your IoT application.

Follow these steps to get your EUM App Key and instrument your IoT C/C++ apps.

This Java SDK differs from the AppDynamics Java Agent in that it is a very lightweight library specially designed for lower-end devices. A lot of flexibility is also built into the way event information can be extended and the instrumentation code configured as well as controlled.

Review the Requirements

Before you begin, make sure you meet these requirements:

- A device running one of the following version of Java Runtime:
    - Java SE 7
    - Java SE Embedded 7
    - Java SE 8
    - Java SE Embedded 8
- HTTPS interface to send beacons to the EUM Server
- EUM App Key

Get the IoT Java SDK

You can get the Java SDK by cloning or downloading the IoT Java SDK from GitHub. Follow the instructions given in Build the SDK to build the IoT Java SDK.

If you're using the IntelliJ IDE, add the file `lib/appd-iot-sdk.jar` to your project by following the instructions given in Working with module dependencies. Confirm that the JAR file shows up under **External Projects** in your IntelliJ project.

Upgrade the IoT Java SDK

From the root directory of your clone of the IoT Java SDK from GitHub:

- Update the repository: `$ git pull origin master`
- Follow the instructions given in Build the SDK to rebuild the IoT Java SDK.

Add the SDK Dependencies to the Gradle Configuration

Add the following to your `build.gradle` file:

```
dependencies {
   runtime group: 'org.slf4j', name: 'slf4j-api', version: '1.7.25'
   runtime group: 'com.google.guava', name:'guava', version:'18.0'
   runtime group: 'com.google.code.gson', name: 'gson', version: '2.8.0'
 }
```

Add the Instrumentation Code

Import the IoT SDK

In your application file, add the `import` statement that includes the Java IoT SDK:

```
import com.appdynamics.iot.Instrumentation;
```

Configure the IoT Java Agent

Configure the instrumentation by providing the EUM App Key and the URL to the EUM Collector. If the EUM Collector URL is not specified, the default SaaS Collector URL is used.

```
import com.appdynamics.iot.AgentConfiguration;
AgentConfiguration.Builder agentConfigBuilder = AgentConfiguration.builder();
AgentConfiguration agentConfig = agentConfigBuilder
        .withAppKey(<EUM_APP_KEY>)
        .build();
```

Set Device Info

You are required to set the name and ID for devices. The name should consist of a short string that identifies the type and model of the device, such as "EV Model 3" or "Thermostat Model Star7". The device ID must be a unique identifier for the device, such as a UUID, the VIN number of a car, or the MAC address of the device.

The example code below sets the device ID to a random UUID and the name to "Smart Shelf".

```
import java.util.UUID;
import com.appdynamics.iot.DeviceInfo;
...
DeviceInfo.Builder deviceInfoBuilder = DeviceInfo.builder("Smart Shelf P1", UUID.randomUUID().toString());
DeviceInfo deviceInfo = deviceInfoBuilder.withDeviceName("Smart Shelf").build();
```

Set Version Info

You can set the versions for the firmware, hardware, OS, and software as shown below.

```
import com.appdynamics.iot.VersionInfo;
...
VersionInfo.Builder versionInfoBuilder = VersionInfo.builder();
VersionInfo versionInfo = versionInfoBuilder
 .withFirmwareVersion("2.3.4")
 .withHardwareVersion("1.6.7")
 .withOsVersion("8.9.9")
 .withSoftwareVersion("3.1.1").build();
```

Initialize the Agent

To initialize the agent, pass the `AgentConfiguration` object, the `DeviceInfo` object, and the `VersionInfo` object to the `start` method:

```
Instrumentation.start(agentConfig, deviceInfo, versionInfo);
```

Build and Run the Application

Use your favorite Java IDE or CLI environment to build and run the application. Note that the AppDynamics IoT Java SDK needs to be the in build and runtime classpath.

For instructions on adding libraries to the classpath:

- IntelliJ IDE: Creating a library
- Eclipse: Classpath Variables
- Linux/Mac/Windows: PATH and CLASSPATH

For instructions to build and run the app:

- IntelliJ: Building and Running the Application
- Eclipse: Running your programs
- Gradle: Building Java Projects with Gradle

Add and Send Events

The following sections will show you how to create and send the supported events: Custom, Network Request, and Error.

Create a Basic Custom Event

A Custom event can be used to report any performance, device, or business logic data. It is the most general, configurable and flexible data type available.

The Custom event builder takes two required parameters.

- Event Type: A short human-readable description of the event, such as "FL Pressure Drop".
- Description: A string describing the event, such as "Front Left Tire Pressure Drop".

To make reporting this event meaningful, it is recommended that you provide a timestamp and at least one kind of datatype.

1. Create a basic custom event.

```
import com.appdynamics.iot.events.CustomEvent;
...
CustomEvent.Builder builder = CustomEvent.builder("FL Pressure Drop", "Front Left Tire Pressure Drop");
long eventStartTime = System.currentTimeMillis();
long duration = 6000;
builder.withTimestamp(eventStartTime).withDuration(duration);
builder.addLongProperty("PSI Drop", 37);
CustomEvent customEvent = builder.build();
```

   Additional information can be added to the `CustomEvent`. For details, see the `CustomEvent` class in the latest Java IoT SDK documentation.
2. Add the custom event to the instrumentation (this adds it to the in-memory buffer).

```
Instrumentation.addEvent(customEvent);
```

3. Send all the events to the EUM Server. This is a blocking call, so the application can send it on a separate thread as shown above.

```
Instrumentation.sendAllEvents();
```

Send a Network Event

1. Report a Network Request Event using the `HttpRequestTracker` class. This call automatically adds an event to the in-memory buffer, so you need to explicitly import the class.

```
import com.appdynamics.iot.HttpRequestTracker;
...
String url = "http://ip.jsontest.com/?callback=showMyIP";
// Add a Network Event
try {
    URL thisUrl = new URL(url);
    // [AppDynamics Instrumentation] Get a Tracker
    HttpURLConnection con = (HttpURLConnection) thisUrl.openConnection();
    final HttpRequestTracker tracker = Instrumentation.beginHttpRequest(thisUrl);
    con.setRequestMethod("POST");
    con.setRequestProperty("Accept-Language", "en-US,en;q=0.5");
    int responseCode = con.getResponseCode();
    con.setDoInput(true);
    con.setDoOutput(true);
    DataOutputStream wr = new DataOutputStream(con.getOutputStream());
    wr.flush();
    wr.close();
    System.out.println("Response Code :" + responseCode);
    // [AppDynamics Instrumentation] Retrieve the headers from the response
    Map<String, List<String>> headerFields = null;
    System.out.println("Sending 'POST' request to URL :" + url);
    BufferedReader in;
    String inputLine;
    new InputStreamReader(con.getErrorStream()));
    if (responseCode >= 200 && responseCode < 300) {
        in = new BufferedReader(new InputStreamReader(con.getInputStream()));
    } else {
        in = new BufferedReader(
    }
    StringBuffer response = new StringBuffer();
    if (headerFields != null && headerFields.size() > 0){
        while ((inputLine = in.readLine()) != null) {
           response.append(inputLine);
        }
        in.close();
        // [AppDynamics Instrumentation] Initiate adding NetworkRequestEvent
        if (responseCode >= 200 && responseCode < 300) {
            tracker.withResponseCode(responseCode).withError(response.toString()).reportDone();
                   .withResponseHeaderFields(headerFields)
                   .reportDone();
        } else {
            tracker.withResponseCode(responseCode).reportDone();
        }
    } else {
        tracker.withResponseCode(responseCode)
    }
// End: Add for AppDynamics Instrumentation - Initiate adding NetworkRequestEvent
} catch (MalformedURLException e) {
    e.printStackTrace();
} catch (Exception ex) {
    ex.printStackTrace();
}
```

2. Send all the events to the EUM Server. This is a blocking call. The application can send it on a separate thread. The recommendation is to batch a number of events together before calling the `sendAllEvents` method.

```
Instrumentation.sendAllEvents();
```

Send an Error Event

1. Report an Error Event using the API.

```
try {
    //Force creating an exception
    float f = (5 / 0);
} catch (Throwable t) {
    Instrumentation.addErrorEvent(t, Instrumentation.Severity.ALERT);
}
```

2. Send all the events to the EUM Server. This is a blocking call. The application can send it on a separate thread.

```
Instrumentation.sendAllEvents();
```

Verify the Instrumentation in the Controller UI

See Confirm the IoT Application Reported Data to the Controller to verify the instrumentation.

Correlate Business Transactions with Network Requests (Optional)

To correlate business transactions (BTs) with network requests, you need to have instrumented a business application and enabled business transactions in the Controller UI. See Correlate Business Transactions for IoT Monitoring to learn more.

The steps below show you how to get the BT response headers and use them to correlate the BT with an IoT Network Request event.

1. Make a network request that includes the AppDynamics HTTP request headers `ADRUM` and `ADRUM_1` to one of your business applications:

```
import com.appdynamics.iot.HttpRequestTracker;
...
// Create a network request to the business app.
String url = "<url_to_business_application>";
URL thisUrl = new URL(url);
[AppDynamics Instrumentation] Get a Tracker
HttpURLConnection con = (HttpURLConnection) thisUrl.openConnection();
final HttpRequestTracker tracker = Instrumentation.beginHttpRequest(thisUrl);
con.setRequestMethod("POST"); // Some HTTP method: GET, POST, PUT...

// Add the AppDynamics HTTP headers ADRUM and ADRUM_1 to the request.
con.setRequestProperty("ADRUM", "isAjax:true");
con.setRequestProperty("ADRUM_1", "isMobile:true");

// Make the request to your business app.
con.setDoInput(true);
```

2. The call will return response headers that contain information for correlating business transactions. If you were to print these BT response headers, you would see something like the following:

```
{
  ADRUM_1=[globalAccountName:customer1_78203698-278e-428f-8726-bb381219c6cb],
  null=[HTTP/1.1 200 OK],
  ADRUM_0=[clientRequestGUID:2ff45113-6746-4c94-b6d0-4af26055613c],
  ADRUM_3=[btERT:269],
  ADRUM_2=[btId:4423],
  Server=[Jetty(9.4.z-SNAPSHOT)],
  ADRUM_5=[btDuration:327],
  ADRUM_4=[serverSnapshotType:f],
  Content-Length=[514],
}
```

3. Send a beacon containing the BT response headers to the EUM Server:

```
// Fetch the response headers, which will include the BT headers (ADRUM_0, ADRUM_1, ...).
Map<String, List<String>> headerFields = con.getHeaderFields();

// Add the BT response headers to the request body of the Network Request event.
// that you're reporting.
tracker.withResponseCode(responseCode).withError(response.toString()).reportDone();
                   .withResponseHeaderFields(headerFields)
                   .reportDone();

// Report the Network Request event to the EUM Server.
Instrumentation.sendAllEvents();
```

4. In the Controller UI, you should be able to view the correlated business transaction in the **Device Details** dialog.

Enable Logging for the SDK (Optional)

The IoT Java SDK uses the Simple Logging Facade for Java (SLF4J) as the logging framework. You can use your favorite logging engine that is compatible with SLF4J.

If no binding is found on the classpath, then SLF4J will default to a no-operation implementation and display console messages like the following:

```
SLF4J: Failed to load class "org.slf4j.impl.StaticLoggerBinder".
SLF4J: Defaulting to no-operation (NOP) logger implementation //
SLF4J: See http://www.slf4j.org/codes.html#StaticLoggerBinder for further details.
```

To use the `java.util.logging` engine, add the following line to the `build.gradle` file:

```
dependencies {
   ....
   runtime group: 'org.slf4j', name: 'slf4j-jdk14', version: '1.7.25'
   ....
 }
```

To see all the debug messages from the library, append the following line to the bottom of the file `/Library/Java/JavaVirtualMachines/<your-jdk-version>/Contents/Home/jre/lib/logging.properties`:

```
com.appdynamics.iot.level = FINEST
```

Customize the IoT Java Instrumentation (Optional)

You can further customize the IoT Java instrumentation using the IoT Java SDK. See the latest IoT Java SDK documentation or the previous versions listed below:

- https://sdkdocs.appdynamics.com/javadocs/iot-java-sdk/4.5/4.5.0/
- https://sdkdocs.appdynamics.com/javadocs/iot-java-sdk/4.5/4.5.1/
- https://sdkdocs.appdynamics.com/javadocs/iot-java-sdk/4.5/4.5.2/
- https://sdkdocs.appdynamics.com/javadocs/iot-java-sdk/4.5/4.5.4/

Run the Sample Java Application

The sample Java application sends sample data for Custom, Network Request, and Error events. The data mocks a smart car application, capturing usage information, network performance, and errors.

To run the sample app, follow the Getting Started instruction given in the iot-java-sdk GitHub repository.

Troubleshooting the IoT Java SDK

This section provides instructions for debugging common issues.

Unable to Link the IoT Java Agent

If you are getting the following error when trying to link the IoT Java Agent, it's because of a dependency on `log4j`.

```
loader constraint violation: when resolving method "org.slf4j.impl.StaticLoggerBinder.getLoggerFactory()Lorg
/slf4j/ILoggerFactory;" the class loader (instance of com/intellij/ide/plugins/cl/PluginClassLoader) of the
current class, org/slf4j/LoggerFactory, and the class loader (instance of com/intellij/util/lang
/UrlClassLoader) for the method's defining class, org/slf4j/impl/StaticLoggerBinder, have different Class
objects for the type org/slf4j/ILoggerFactory used in the signature
java.lang.LinkageError: loader constraint violation: when resolving method "org.slf4j.impl.StaticLoggerBinder.
getLoggerFactory()Lorg/slf4j/ILoggerFactory;" the class loader (instance of com/intellij/ide/plugins/cl
/PluginClassLoader) of the current class, org/slf4j/LoggerFactory, and the class loader (instance of com
/intellij/util/lang/UrlClassLoader) for the method's defining class, org/slf4j/impl/StaticLoggerBinder, have
different Class objects for the type org/slf4j/ILoggerFactory used in the signature
        at org.slf4j.LoggerFactory.getILoggerFactory(LoggerFactory.java:273)
        at org.slf4j.LoggerFactory.getLogger(LoggerFactory.java:241)
        at org.slf4j.LoggerFactory.getLogger(LoggerFactory.java:254)
        at com.appdynamics.iot.Instrumentation.<clinit>(Instrumentation.java:39)
        ...
```

To correct the problem, you need to remove the dependency that you added to enable logging. Thus, *remove* the line specifying the group `org.slf4j` shown below from `dependencies`:

```
dependencies {
   ....
   runtime group: 'org.slf4j', name: 'slf4j-jdk14', version: '1.7.25'
   ....
}
```

Instrument Applications with the IoT REST APIs

The IoT REST APIs enable you to report instrumentation data directly to the EUM Server. You can use any platform or language that has support for HTTPS requests and JSON.

This page describes how to create a JSON request body, form the resource URI, and make an HTTPS request to the IoT REST APIs to report instrumentation data for the three supported events.

Follow these steps to get your EUM App Key and use the IoT REST API:

Review the Requirements

Before you begin, make sure you meet these requirements:

- Get an EUM App Key
- Platform/language that supports HTTPS requests
- JSON support

Form the IoT REST URLs

To form the IoT Monitoring REST resource URL, you will need to know the IoT REST API base URL and port as well as your App Key.

IoT REST API Base URL

The IoT REST API base URL depends on your Controller location. See the IoT REST API row on SaaS Domains and IP Ranges. For example, the IoT base URL for the Americas region would be:

```
https://iot-col.eum-appdynamics.com/eumcollector/iot/v1
```

After creating your IoT Application, use your App Key to test your IoT endpoint and look for a HTTP 200 response. For example, for the Americas region, run the following command:

```
curl -I https://iot-col.eum-appdynamics.com/eumcollector/iot/v1/application/<APPKEY>/enabled
```

IoT Endpoints

With your App Key, you can form the IoT resource endpoints. See the Summary of the IoT endpoints for the list of supported resource endpoints and their descriptions.

Create the JSON Request Body

You report device information and events in a JSON request body. The JSON includes an array of beacon objects, with each beacon object containing device data and events. The array enables you to transmit data from multiple devices in one request to the EUM Server. You can transmit up to 200 beacons per request.

Save the JSON below to a file (e.g., `testBeacon.json`) and replace the values for the timestamp properties with integers representing the UNIX Epoch time in milliseconds. The JSON contains the three supported events `customEvents`, `networkRequestEvents`, and `errorEvents` for a smart thermostat. In the next two steps, you will validate and send the JSON as a beacon to the IoT REST API.

Make sure you save timestamps in milliseconds, and not seconds.

```
[
 {
  "deviceInfo": {
   "deviceType": "Thermostat",
   "deviceId": "4e75d70d-a3f9-474b-bacf-0f4a57fa944c"
  },
  "versionInfo": {
    "hardwareVersion": "Board Rev. 13A",
    "firmwareVersion": "123.5.31",
    "softwareVersion": "9.1.3",
    "operatingSystemVersion": "Linux 13.4"
  },
  "customEvents": [
    {
      "timestamp": <UNIX_Epoch_time_in_milliseconds>,
      "eventType": "Temperature Reading",
      "eventSummary": "Temperature: 25° c",
      "doubleProperties": {
        "celsius": 25.0
      }
    }
  ],
  "networkRequestEvents": [
   {
    "timestamp": <UNIX_Epoch_time_in_milliseconds>,
    "duration": 245,
    "url": "https://api.company.com/v1/temperature",
    "statusCode": 200,
    "requestContentLength": 32,
    "responseContentLength": 0,
    "doubleProperties": {
     "reportedTemperature": 25.0
    }
   }
  ],
  "errorEvents": [
   {
    "timestamp": <UNIX_Epoch_time_in_milliseconds>,
    "name": "SQLException",
    "message": "open() failed because db is locked"
   }
  ]
 }
]
```

Transmit the Beacon Data

To send the beacon, you post the JSON request body to the `/beacons` endpoint. Again, in this cURL example, use the JSON you saved to the file `testBeacon.json` and replace <appKey> with your EUM App Key:

```
curl -v -X POST -d '@testBeacon.json' https://iot-col.eum-appdynamics.com/eumcollector/iot/v1/application
/<appKey>/beacons
```

If the beacons were transmitted successfully, the IoT REST API will return the HTTP Status Code 202:

```
< HTTP/1.1 202 Accepted
```

Verify the Instrumentation in the Controller UI

See Confirm the IoT Application Reported Data to the Controller to verify the instrumentation.

Correlate Business Transactions with Network Requests (Optional)

To correlate business transactions (BTs) with network requests, you need to have instrumented a business application and enabled business transactions in the Controller UI. See Correlate Business Transactions for IoT Monitoring to learn more.

The steps below show you how to get the BT response headers and use them to correlate the BT with an IoT Network Request event.

1. Make a network request that includes the AppDynamics HTTP request headers `ADRUM` and `ADRUM_1` to one of your business applications:

```
curl -H "ADRUM: isAjax:true" -H "ADRUM_1: isMobile:true" -H "Accept: application/json" -H "Content-Type:
application/xml" -H "Content-Length: 0" -X GET http://<url_to_business_app>
```

2. The business application will return response headers that contain information for correlating business transactions. If you were to print these BT response headers, you would see something like the following:

```
ADRUM_0: clientRequestGUID:a27ce4da-d4e6-4bf5-bbca-9b1751aa44a4
ADRUM_1: globalAccountName:customer1_78203698-278e-428f-8726-bb381219c6cb
ADRUM_2: btId:4423
ADRUM_3: btERT:267
ADRUM_4: btDuration:368
Content-Length: 469
Server: Jetty(9.4.z-SNAPSHOT)
```

3. Create a beacon file `btCorrelation.json` with the returned BT response headers (only those headers that include `ADRUM_*`). You assign the returned `ADRUM_*` response headers from the network event request to the business application to the object `responseHeaders` in the beacon as shown below.

```
[
      {
         'deviceInfo':{
            'deviceId':'1111',
            'deviceName':'AudiS3',
            'deviceType':'SmartCar'
         },
         'versionInfo':{
            'hardwareVersion':'1.0',
            'firmwareVersion':'1.0',
            'softwareVersion':'1.0',
            'operatingSystemVersion':'1.0'
         },
         'networkRequestEvents':[
            {
               'url':'<url_to_business_app>',
               'statusCode':200,
               'responseHeaders':{
                  'ADRUM_0':[
                     '<value_returned_from_business_app>'
                  ],
                  'ADRUM_1':[
                     '<value_returned_from_business_app>'
                  ],
                  'ADRUM_2':[
                     '<value_returned_from_business_app>'
                  ],
                  'ADRUM_3':[
                     '<value_returned_from_business_app>'
                  ]
               },
               'timestamp':1525226857000,
               'duration':0,
               'requestContentLength':0,
               'responseContentLength':457
            }
         ]
      }
]
```

4. Send the beacon containing the BT headers to the EUM Server with a cURL command similar to the one here:

```
curl -I -H "Content-Type: application/json" -H "Accept: application/json" -X POST -d @btCorrelation.json
-H https://iot-col.eum-appdynamics.com/eumcollector/iot/v1/application/<appKey>/beacons
```

5. For a successful call, the response headers should be similar to the following:

```
HTTP/1.1 202 Accepted
Cache-Control: private, no-cache, no-store, must-revalidate, max-age=0, proxy-revalidate, s-maxage=0
Expires: 0
Pragma: no-cache
Vary: *
Transfer-Encoding: chunked
Via: 1.1 sjc12-dmz-wsa-5.cisco.com:80 (Cisco-WSA/X)
Connection: keep-alive
```

6. In the Controller UI, you should be able to view the correlated business transaction in the **Device Details** dialog.

Customize the IoT REST API Instrumentation (Optional)

You can further customize the IoT instrumentation using the IoT REST API. See the latest IoT REST API documentation or the previous versions listed below:

- https://sdkdocs.appdynamics.com/javadocs/iot-rest-api/4.5/4.5.0/
- https://sdkdocs.appdynamics.com/javadocs/iot-rest-api/4.5/4.5.1/
- https://sdkdocs.appdynamics.com/javadocs/iot-rest-api/4.5/4.5.2/
- https://sdkdocs.appdynamics.com/javadocs/iot-rest-api/4.5/4.5.4/

Run the Sample Python Application

The sample Python application uses the IoT REST API to send sample data for Custom, Network Request, and Error events. The Network Request events include correlated business transactions. The data mocks a smart car application, capturing usage information, network performance, and errors.

To run the sample app, follow the instructions given in the GitHub repository iot-rest-api-sample-apps.

Troubleshoot the IoT REST API Instrumentation

The sections below provide instructions for troubleshooting your IoT REST API Instrumentation.

Verify Your IoT App Has Been Enabled

Using your App Key, verify that your IoT app has been enabled:

```
curl -v -X GET https://iot-col.eum-appdynamics.com/eumcollector/iot/v1/application/<appKey>/enabled
```

If your App Key has been enabled, you should get the following response:

```
< HTTP/1.1 200 OK
< Cache-Control: private, no-cache, no-store, must-revalidate, max-age=0, proxy-revalidate, s-maxage=0
< Date: Sat, 19 Aug 2017 01:20:39 GMT
< Expires: 0
< Pragma: no-cache
< Vary: *
< Content-Length: 0
< Connection: keep-alive
```

If the App Key does not exist:

```
< HTTP/1.1 403 Forbidden
```

Validate Beacons

You can use the validate beacon endpoint (`/validate-beacons`) to verify that the beacon's JSON request body complies with the REST API schema.

> You are not required or recommended to validate beacons before transmitting them. You should only use this endpoint in development for testing and troubleshooting.

In this cURL example, you are verifying that the JSON given in the file `testBeacon.json` is valid. Replace `<appKey>` with your EUM App Key.

```
curl -v -X POST -d '@testBeacon.json' https://iot-col.eum-appdynamics.com/eumcollector/iot/v1/application
/<appKey>/validate-beacons
```

If the JSON request body containing the beacon data is valid, the IoT Monitoring REST API will return the HTTP Status 200:

```
HTTP/1.1 200 OK
```

If the JSON request body is invalid, the IoT REST API will return the HTTP Status 422 and a response body with the description of the error message.

```
< HTTP/1.1 422 Unprocessable Entity
```

Verify Timestamps

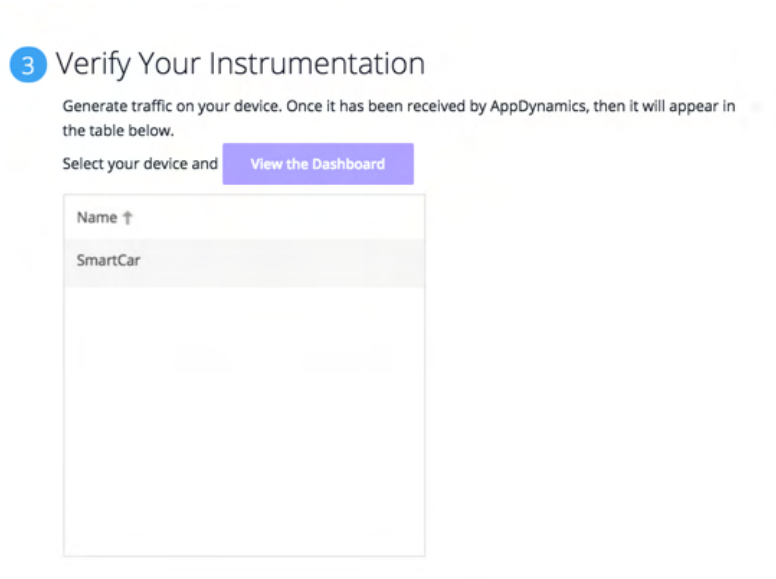
When you create the JSON body and replace the values for the timestamp properties, make sure the timestamps are in milliseconds, not seconds.

Confirm the IoT Application Reported Data to the Controller

Related pages:

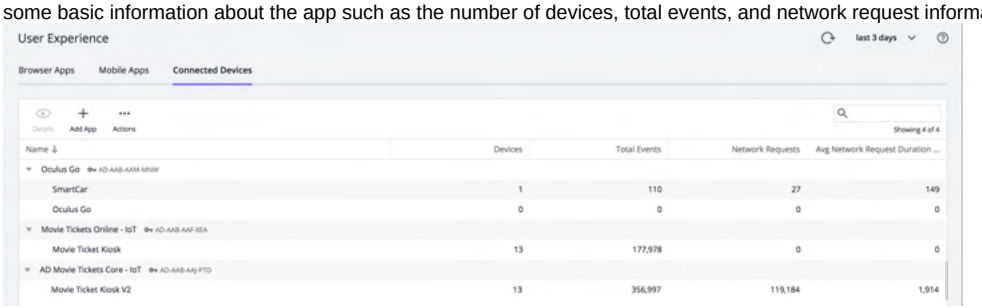
- Instrument Applications with the IoT C/C++ SDK
- Instrument Applications with the IoT Java SDK
- Instrument Applications with the IoT REST APIs

From the **Getting Started Wizard**, you will see your device listed in the table after the IoT application has reported data to the Controller.



If you left the **Getting Started Wizard**, you can always verify the IoT application has been enabled and reported data by doing the following:

1. In the Controller UI, open **User Experience > Connected Devices**.
2. Check the list of registered connected device applications to verify that the application is registered with the Controller. You can also use view some basic information about the app such as the number of devices, total events, and network request information.



3. Start monitoring your application. See Configure IoT Application Monitoring.

Monitor Applications with the IoT Dashboards

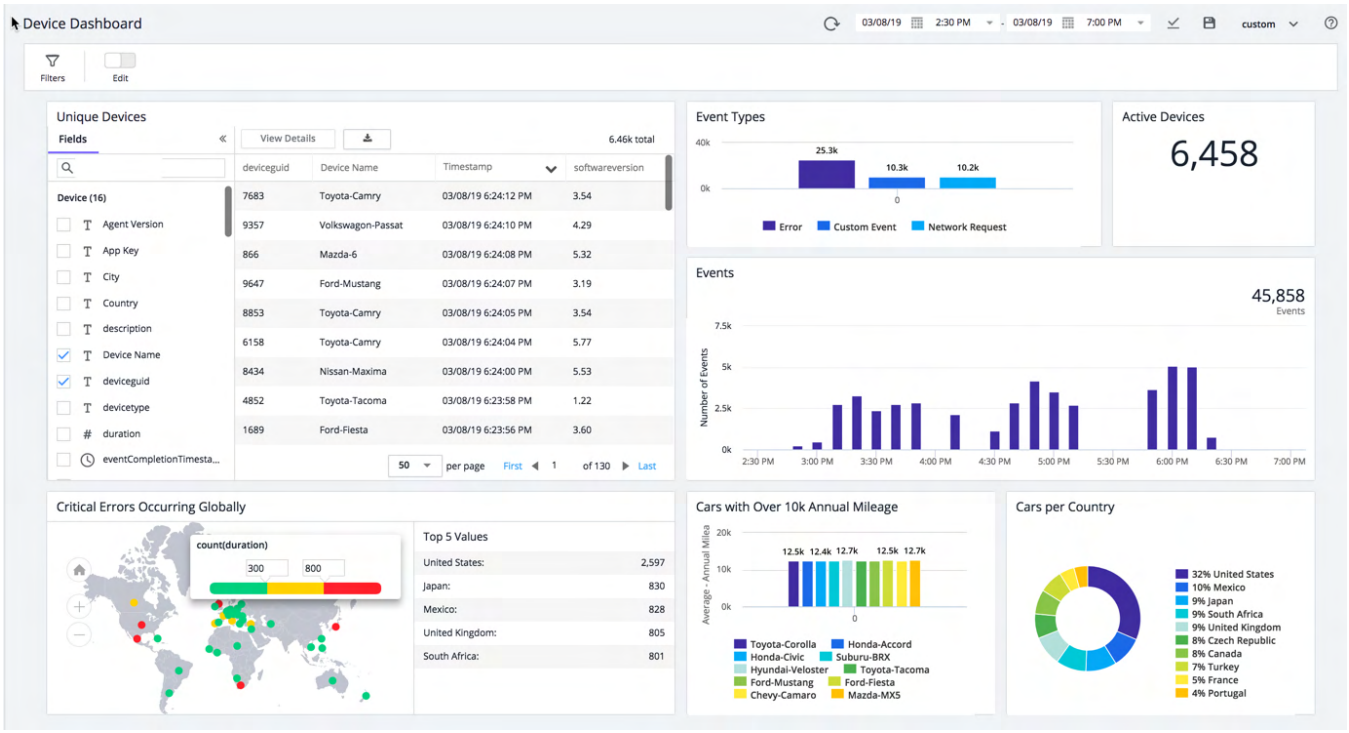
IoT Monitoring provides you with three dashboards to view and analyze the performance and usage of your application. Each dashboard provides you with a different aspect of your application's performance. Within each dashboard, you can view data visualized as widgets or detailed records or create custom widgets based on your chosen parameters.

The page introduces the features, functionality, and goal of each of these dashboards:

Device Dashboard

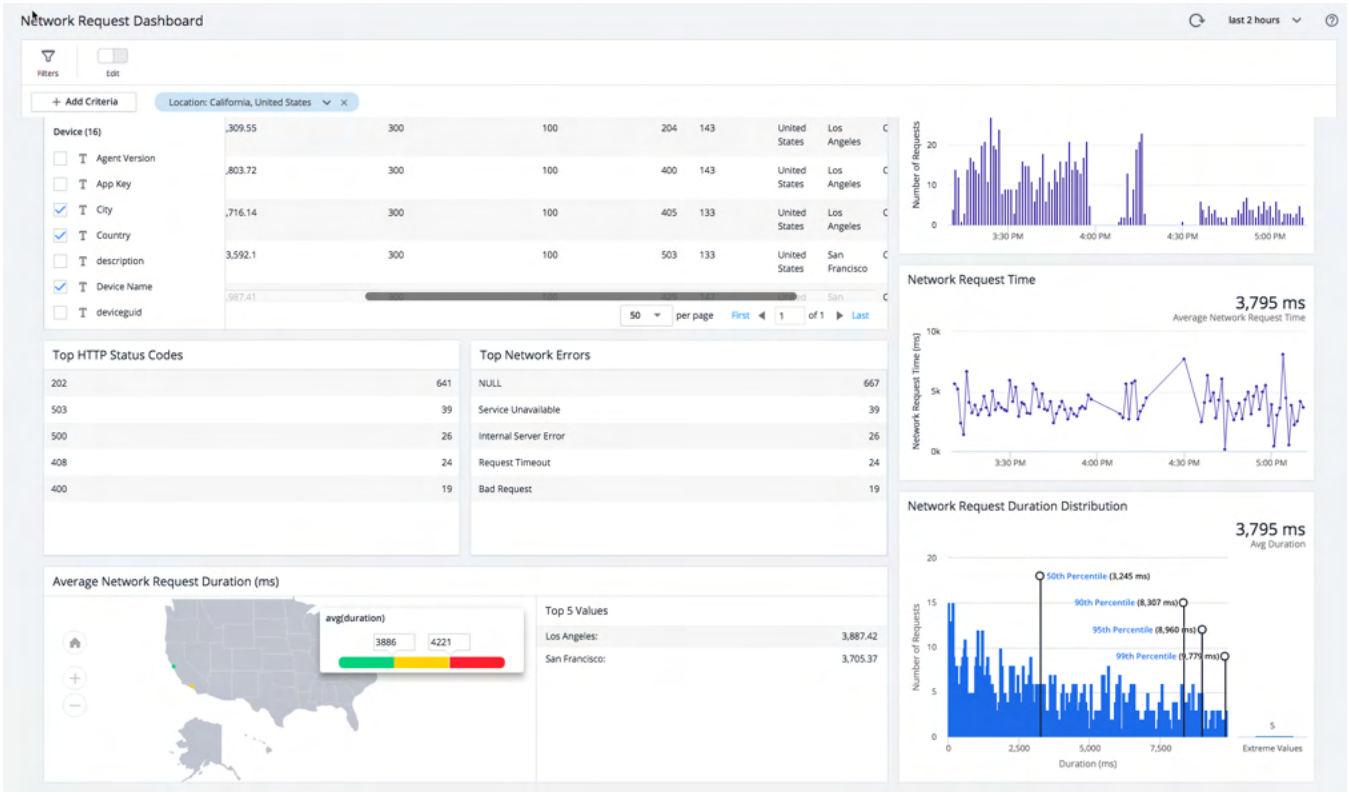
The **Device Dashboard** enables you to monitor your device status, custom information, and custom device application information. You can view summary activity or use filters to drill down to view metrics for a specific device.

Using the **Device Dashboard**, DevOps can ensure that devices are up and running, product managers and business stakeholders can examine device activity and trends, and developers can drill down into results to identify issues affecting single or multiple devices.



Network Request Dashboard

The **Network Request Dashboard** enables you to view outgoing network requests, network request details, and analyze network requests.

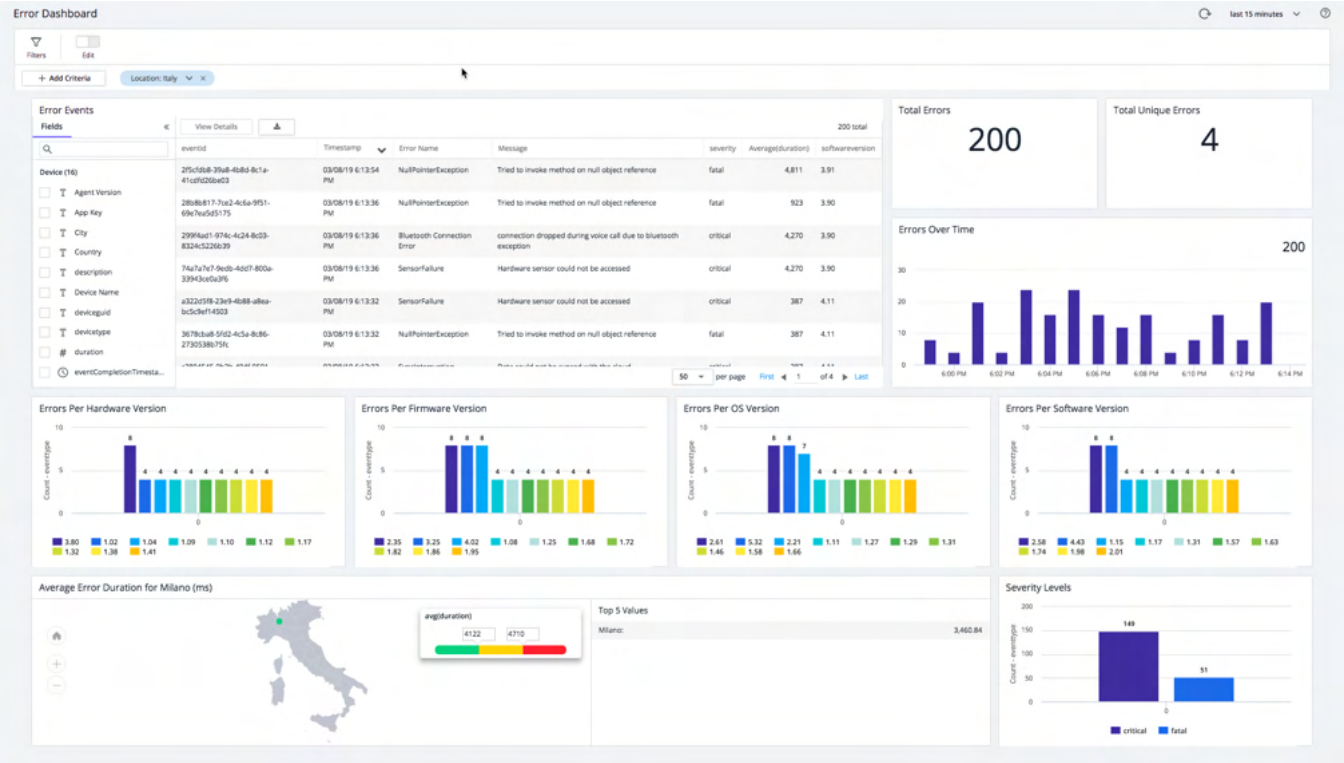


With the **Network Requests Dashboard**, you can:

- Check the availability of a device or service
- Discover slow network requests
- View failed network requests
- Analyze and sort network requests by criteria such as status code, app version, and so on
- Monitor network traffic over time

Error Dashboard

The **Error Dashboard** enables you to view crashes, exceptions, and custom errors, both fatal and non-fatal. DevOps can monitor activity list and notify developers of error events. The developers can select the error event to view details and download the stack trace for debugging.



The stack trace will only be available if it is reported with the IoT SDKs or through the IoT REST API.

With the **Error Dashboard**, you can:

- Discover new errors
- Assess the scope and impact of errors, such as how many devices are affected, what type of devices are affected, and how seriously affected are the devices.
- Monitor error patterns
- Download stack traces of errors to debug code
- Discover broken devices (failed hardware)

How to Use IoT Dashboards

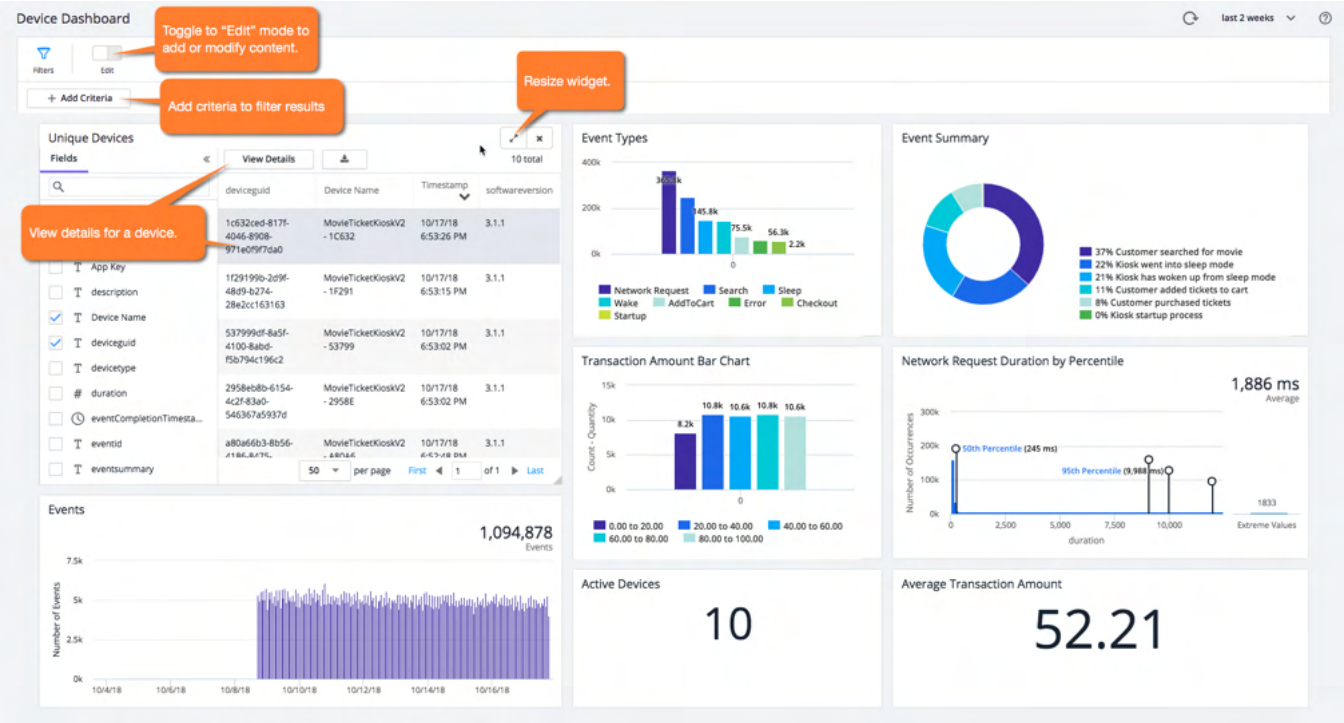
Although each dashboard presents different information, they all have the same UI functionality and features. This page provides an overview of the dashboard functionality to help you get started monitoring your devices.

Access the IoT Dashboards

1. Open the application you want.
2. Select one of the dashboards to view:
    - **Devices**
    - **Network Requests**
    - **Errors**

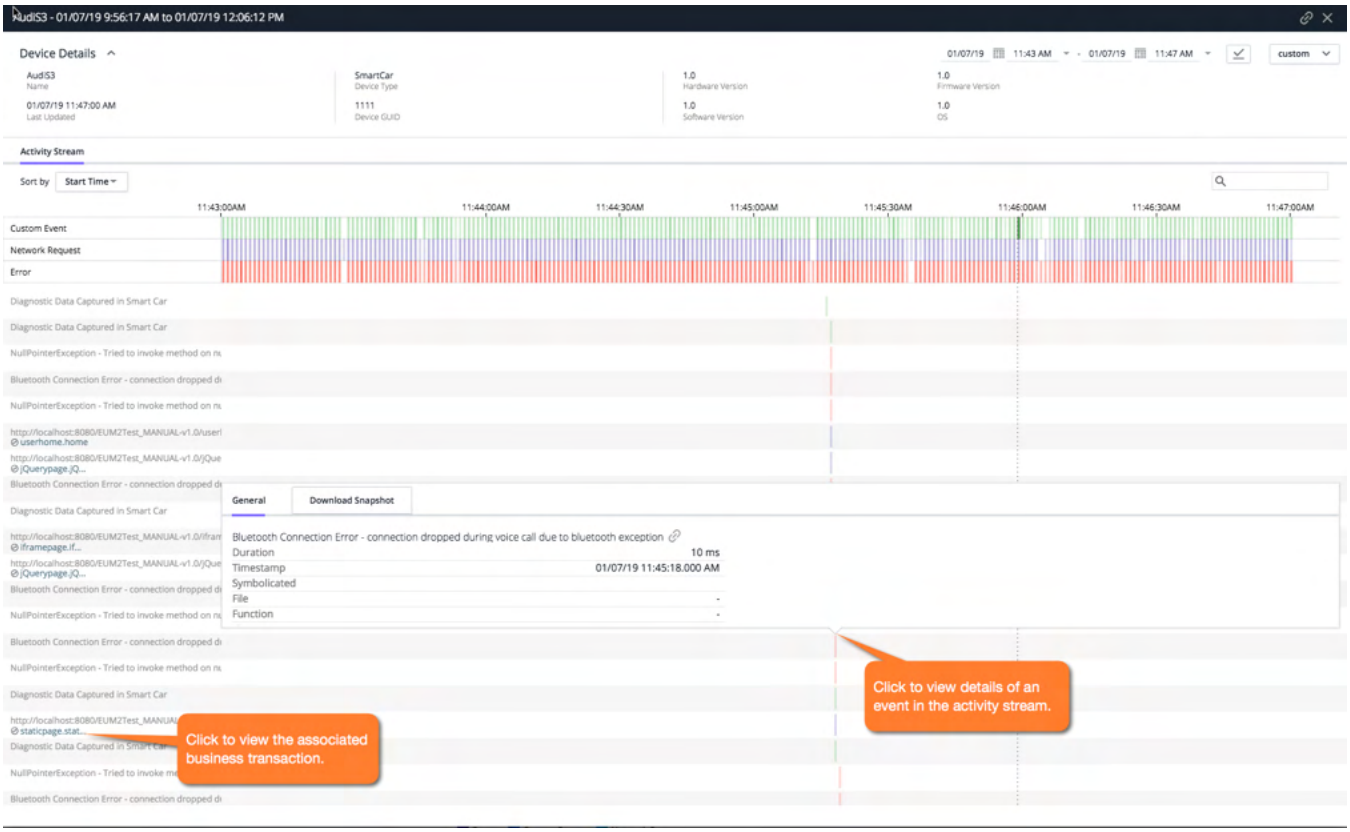
View Dashboard Summaries

From each dashboard, you can view aggregated data in predefined and custom widgets. Each dashboard is in view mode by default, so data is read-only, although you can set filters, view details, and resize widgets.



View Details

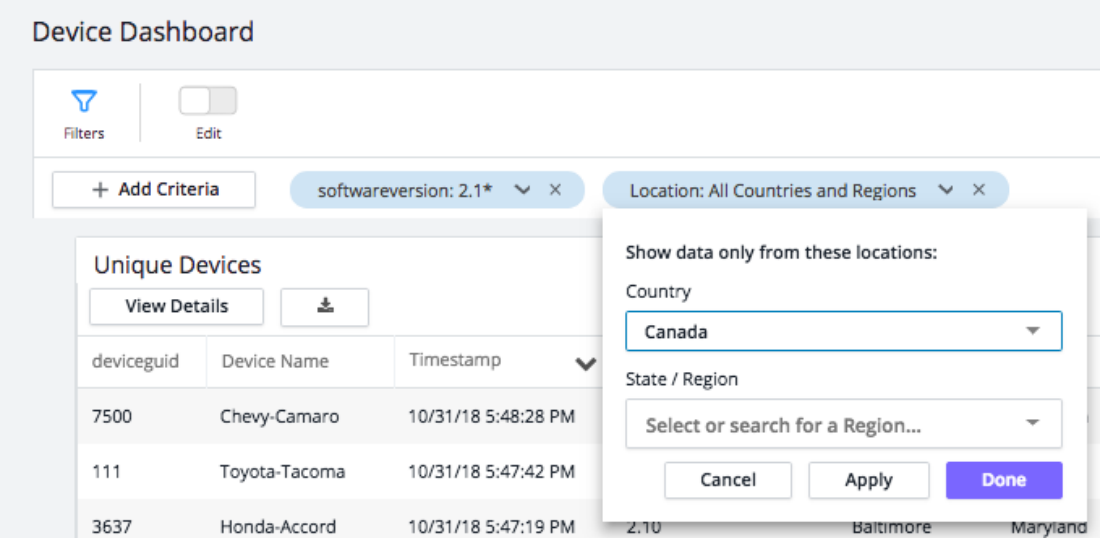
To view details, you select a row in one of the tables and click the **Details** icon. The **Device Details** dialog displays. You can view when the three types of events (Custom Event, Network Request, and Error) occurred on the timeline, or by duration. You can also click on the event bar in the waterfall for more details.



Filter Results

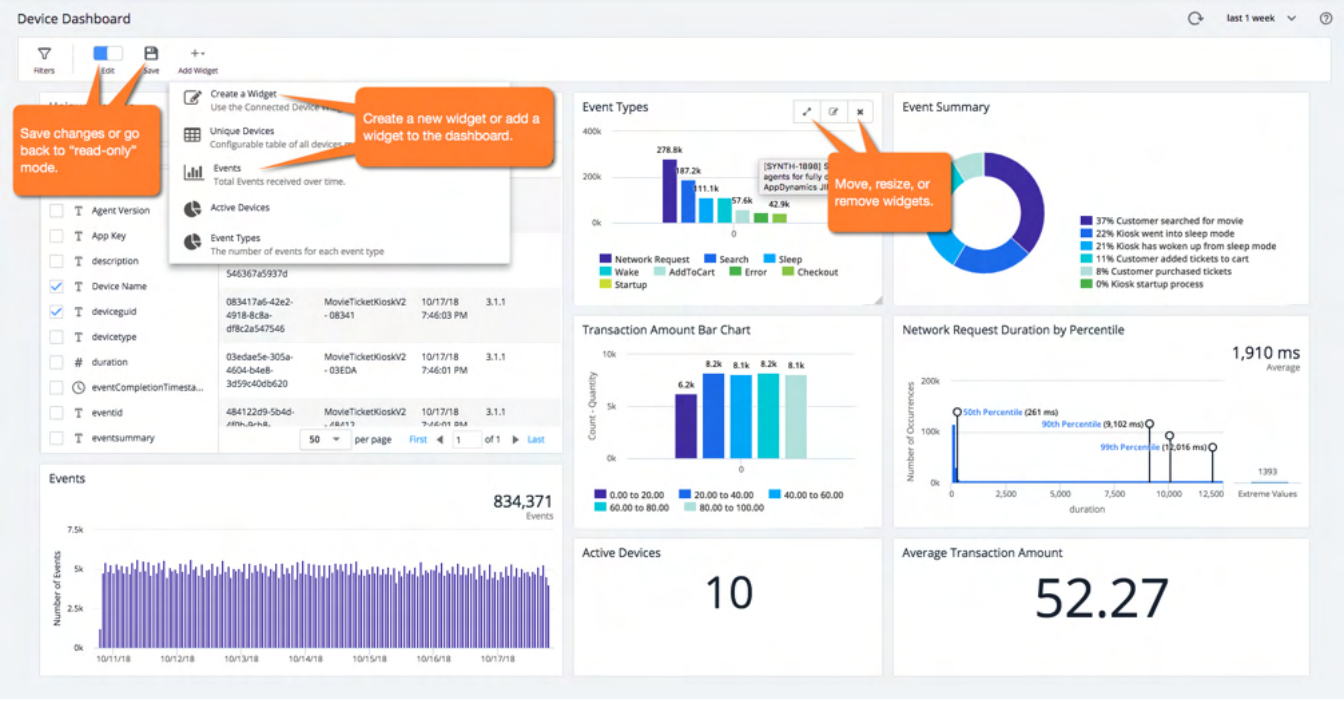
You can filter results by adding criteria. This enables you to focus on factors affecting availability, usage, and performance.

In this screenshot, the criteria **softwareversion** and **Country** are added, which could potentially home in on performance issues caused by a particular software version in a particular country.



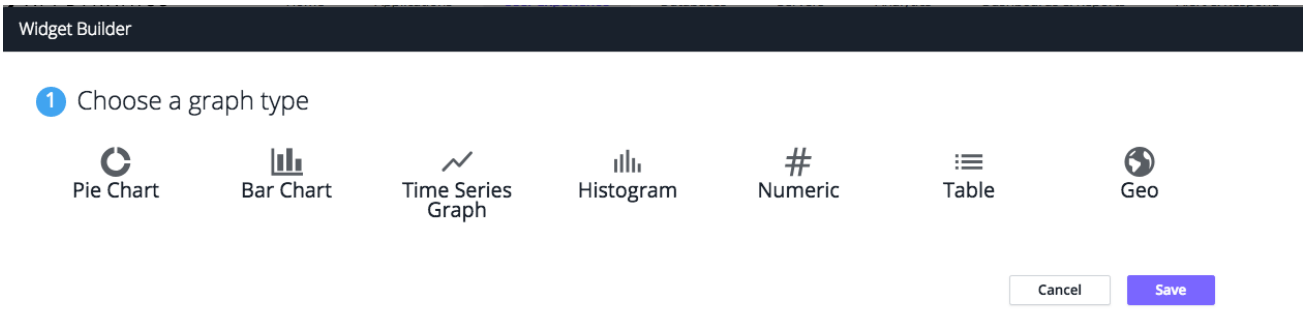
Modify Content and Presentation

To modify the dashboard, you need to be in **Edit** mode. You simply change the toggle to **Edit**, and then you'll be able to add, move, resize, remove, and even create widgets.



Build Custom Dashboard Widgets

Each dashboard has predefined widgets for basic monitoring, but because there are so many different devices and platforms, you will need to create custom widgets with the **Widget Builder**, which guides you through the creation of a widget. This page provides guidance for selecting graph types and using filters when you create widgets.



How to Access the Widget Builder

1. Select a dashboard.
2. Change to **Edit** mode.
3. From the toolbar, click **Add Widget**.
4. From the dropdown, click **Create a Widget**.

Choose the Best Graph Type

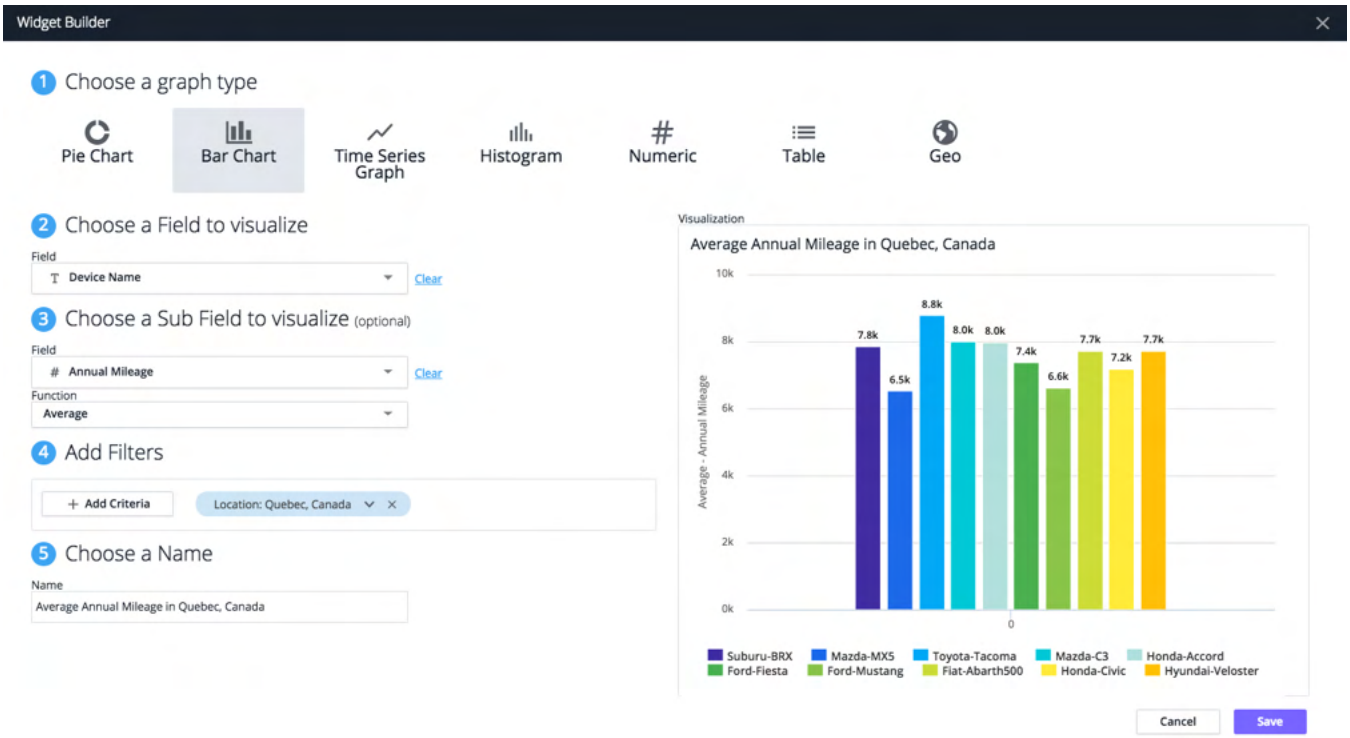
The **Widget Builder** allows you to choose from one of six types of graphs, you should try to use the best graph for your data set. The following is a guideline for choosing the graph type:

Graph Type	Graph Properties	Use Case(s)
Pie Chart	• Field • Subfield • Filters • Name	Use pie charts to compare parts of a whole. Examples: • For a retail device, the percentage of sales for each store. • For a fitness device, the percentage of different types of activities such as running, bicycling, walking.
Bar Chart	• Field • Subfield • Filters • Name	Use bar charts to compare different items within the same category. Examples: • For an inventory device, the number of items per store. • For a smart car, the mileage of different cars.
Time Series	• Field • Filters • Name	Use a time series to measure events over time. Examples: • network errors • sales
Histogram	• Field • Filters • Name	Use histograms to analyze and understand the distribution of large sets of numerical data. Examples: • The distribution of network request duration. • For a smart home device, the distribution of temperatures.
Number	• Field • Filters • Name	Use a number graph to highlight an important data point. Examples: • active devices • sales total • network errors

Table	• Field • Filters • Name	Use a table to view detailed data for a list of similar items. Examples: • customers • network requests • devices
Geo	• Field • Filters • Name	Use the Geo widget to analyze and understand performance across geographic areas. Examples: • Sales in different countries, regions, and cities • Network request durations across countries, regions, and cities • Device errors in different countries, regions, and cities

How to Use Filters

Filters enable you to narrow your results to meaningful information. For example, suppose you wanted to see the total number of items sold at each store, but you were particularly interested in those more expensive items. You could choose a bar graph and use the field **Device Name** and the subfield **Annual Mileage** with the filter **Location: Quebec, Canada** to view the average annual mileage of cars in Quebec, Canada, as shown in the example widget:



Configure IoT Application Monitoring

In addition to enabling and disabling **IoT Monitoring**, you can also configure the display names of network requests and exclude network requests matching given criteria from being monitored.

You can:

- Use the AppDynamics default naming rule, which you can leave as is or modify.
- Disable/modify the default naming configuration.
- Create custom include rules to override the default convention.
- Create custom exclude rules to exclude from monitoring network requests that meet certain criteria.

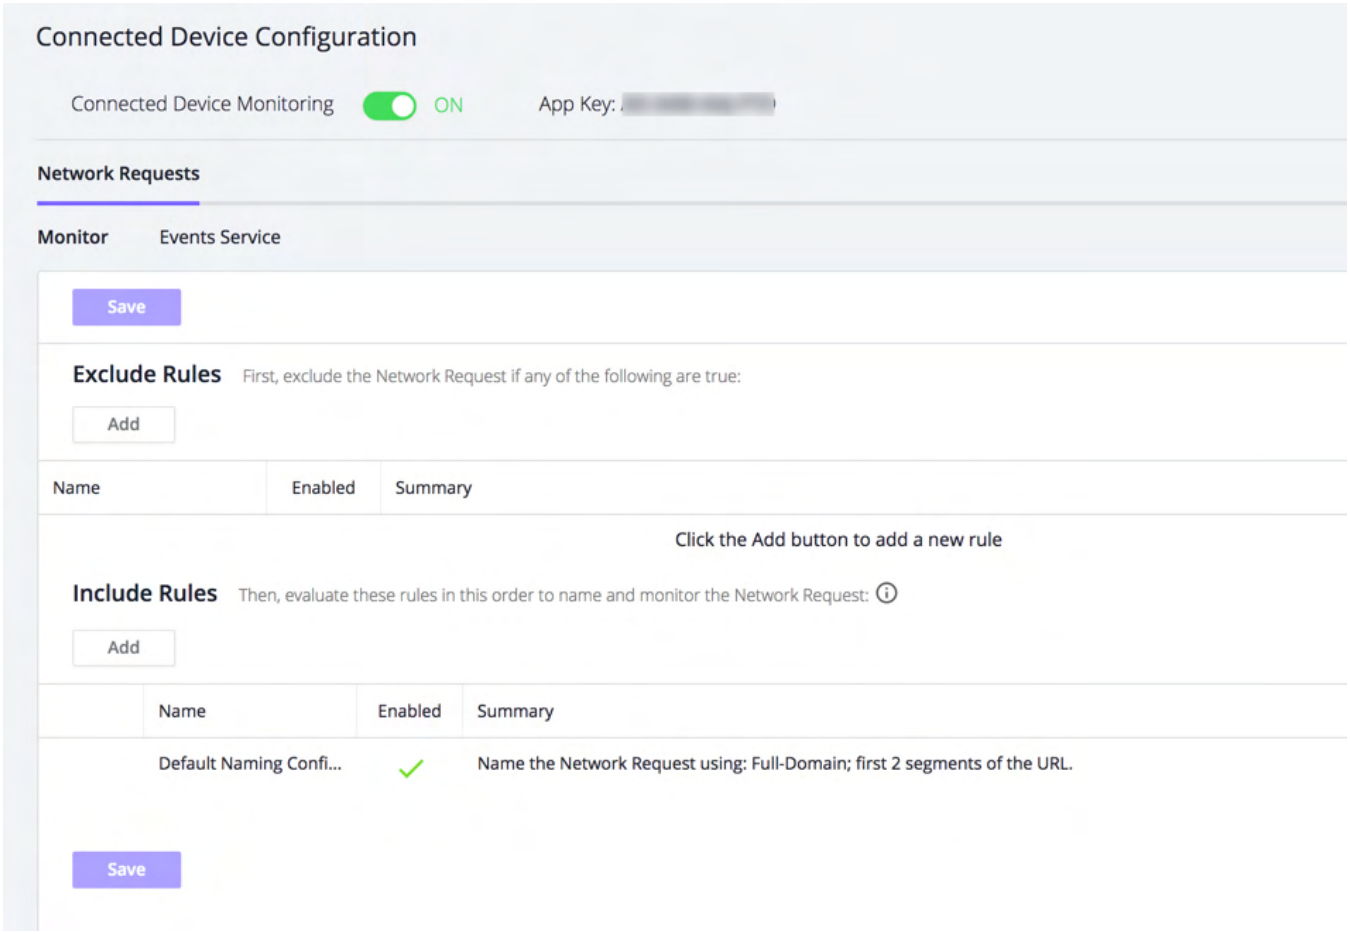
Access the IoT App Configuration

To access connected device configuration:

1. Open the IoT application you want.
2. From the left-hand navigation menu, click **Configuration**.

Enable/Disable IoT Monitoring

From the **Configuration** page, toggle the **Connected Device Monitoring** switch to **ON** to enable monitoring or **OFF** to disable monitoring.



Name IoT Network Requests

The following sections show you how to modify the default naming configuration for network requests and create include naming rules for network requests.

Access Network Requests Rules

From the **Configuration** page, click the Monitor tab if it's not selected already.

Default Network Request Naming Configuration

By default, AppDynamics names network requests using:

- Hostname
- First two segments of the URL

For example, if an application makes this HTTP request: `http://myapp.com/friends/profiles/12345`

The default name that is displayed in the Controller UI for that request is: `myapp.com/friends/profiles`

If this is adequate for your needs, you can leave the default as is. The naming rules you configure here apply to all the IoT applications that are in the same IoT App Group.

Modify the Default Naming Configuration Rule

You may want to configure a different default rule for naming your network requests to help you visualize the parts of your application more clearly. The task is similar to configuring naming rules for business transactions on the server side. Try to group logically related requests together while keeping unrelated requests in separate groups.

- If the default hostname and first two segments of the URL for all your requests are identical, you might want to name the requests based on the last segments or a selection of non-contiguous segments of the URL to distinguish among requests in the network requests list.
- You can also name the requests based on query parameters. For example, if the request passes an order number, you could specify that the value of the `order-number` query parameter is used in the network request name.
- You can also base the name on a regular expression run on the URL. AppDynamics uses the Java libraries for regular expressions. See:
  - Tutorial: http://download.oracle.com/javase/tutorial/essential/regex/index.html
  - Javadoc: http://download.oracle.com/javase/1.5.0/docs/api/java/util/regex/Pattern.html

Modify the Default Network Request Naming Rule

The default configuration covers how all your requests are named if you do not customize them further.

1. From the Network Request tab, scroll down to the **Include Rules** section.
2. Double-click **Default Naming Configuration**.
3. In the **Include Rule** dialog, select the elements you want to use for your default network request naming.
4. Click **OK**.
5. Click **Save**.

Create IoT Network Request Include Rules

By default, the same request naming rule is applied to every URL that your application requests. If you want to apply different naming rules to different URLs, create include rules.

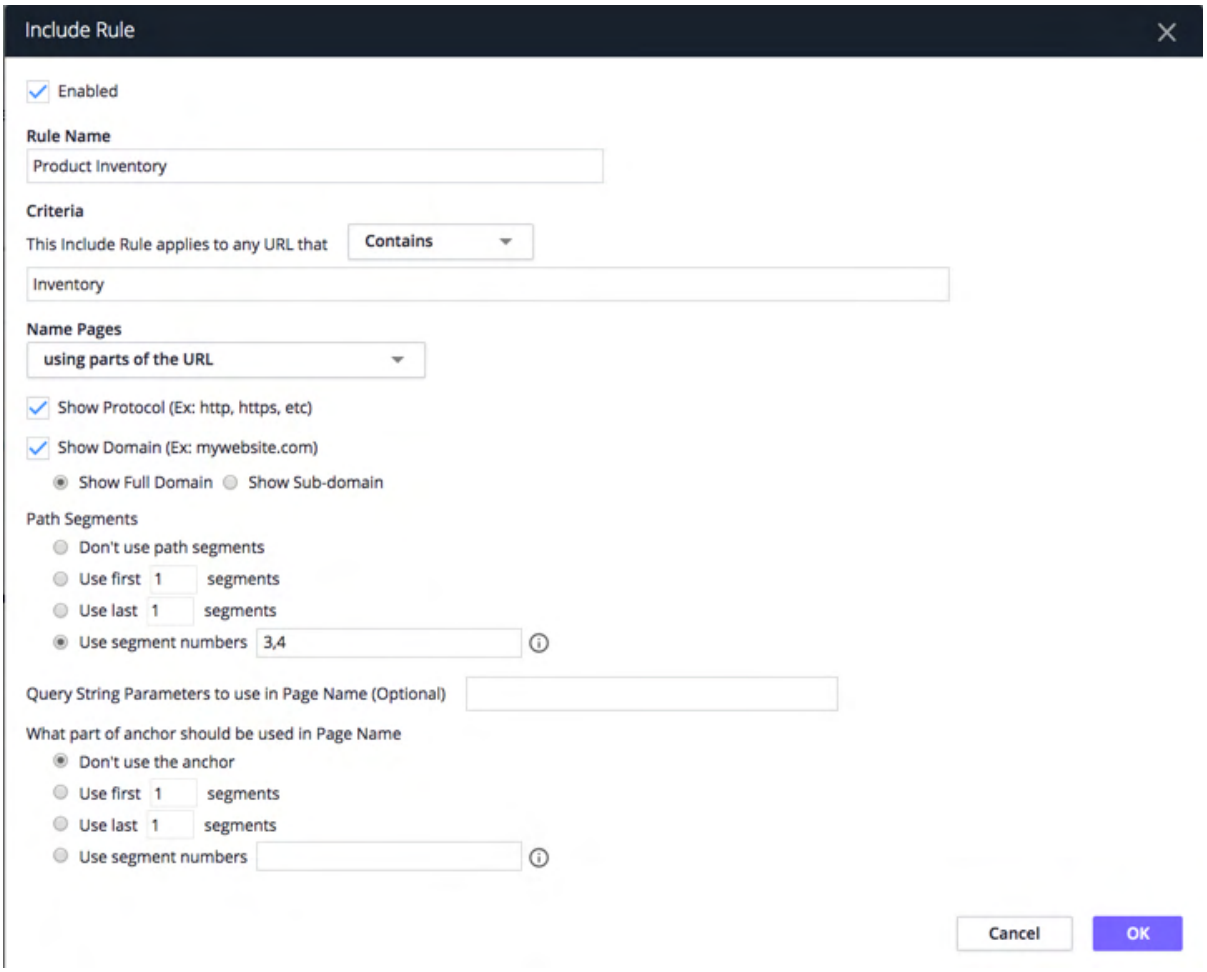
For example, if some requests call your own in-house server and others call out to a third-party API, you may want to see all the third-party API calls as one network request and use the default naming rules for the calls to your own server. You would create a custom naming rule that matches the third party calls and uses only the host in the default rule name or perhaps also include certain query parameters.

Creating an Include Rule

1. From the **Network Request** tab, scroll down to the **Include Rules** section.
2. Click **Add**.
3. In the **Include Rule** dialog, enter a name for the custom rule that you are creating.
4. Check the **Enabled** checkbox to enable the rule.
5. Select the checkboxes and radio buttons and enter the match criteria for AppDynamics to use to name network requests.
6. Click **OK.**

Sample Include Rule

The following rule creates a custom match rule for requests in which the URL contains "inventory". This rule uses the protocol, the subdomain and the third and fourth segments of the URL in the network request name.



You can temporarily cancel the application of a custom naming rule by clearing the **Enabled** checkbox in the custom rule configuration. In this case, the default naming rule is applied to requests that would have been named by the disabled custom rule. To remove the rule permanently, select the custom rule in the **Custom Naming Rules** list and click the **Delete** icon.

Exclude IoT Network Requests

If there are certain types of requests that you do not want to monitor, create custom exclude rules for them based on the URL and/or the application name. Excluded network requests are not reported or counted toward the network request limit of 500 requests per controller application.

Create an Exclude Rule

1. From the Network Request tab, scroll down to the **Exclude Rules** section.
2. Click **Add**.
3. In the **Exclude Rule** dialog, enter a name for the exclude rule that you are creating.
4. Check the **Enabled** checkbox to enable the rule.
5. Select the check boxes and radio buttons and enter the match criteria for AppDynamics to use to name network requests.
6. Click **OK.**

You can temporarily cancel the application of an exclude rule by clearing the **Enabled** checkbox in the exclude rule configuration. To remove the rule permanently, select the exclude rule in the **Exclude Rules** list and click the **Delete** icon.

Change Priority of Rules

Rules are evaluated in the order that they appear in the include or exclude list. You can change the priority of the rules by dragging and dropping rules towards the top (higher priority) or towards the bottom of the list (lower priority). Custom rules are always evaluated before the default naming rule, beginning with the custom rule that has the highest priority.

Your IoT app may make various kinds of network requests, and not all of them may be equally important to monitor in detail. For example, any requests to Google Analytics that your app may make are useful but probably aren't as important to analyze as the requests it makes to your backend.

To manage the impact on your overall Events Service usage, you can create rules which specify which of these network requests should be sent on to the Event Service, either by excluding a request entirely, including a particular request or a sample of that request types by percentage, or by simply allowing the request to be sent on.

In general, the behavior follows this pattern:

- If no rules are specified, data on all network requests are sent on.
- If exclude rules are specified, and a network request satisfies a rule, that data is *not* sent on.
- If include rules are specified, any network request that satisfies a rule is sent on, based on sampling defined by the percentage indicated in the rule.
- If both include and exclude rules are specified, a network request that satisfies an include rule but does *not* satisfy an exclude rule is sent on.

IoT Custom Geo Mapping

By default, IoT Monitoring uses public geographic databases to resolve external IP addresses to geolocations. You can instead use IoT custom geo mapping to map internal IP addresses to geolocations for your IoT applications.

With custom geo mapping, you can monitor the performance of devices running in Virtual Private Clouds (VPCs) with internal addresses distributed across different geographies.

Methods to Map IP Addresses

You can map one IP address, a range of IP addresses, or multiple IP addresses with a subnet mask to one geolocation, giving you a wide range of control over how to map internal IP addresses to geographic locations.

Scope of Custom Geo Mapping

You can only use custom geo mapping in SaaS Controllers. You can provide one custom geo mapping for each app key. Each app key can include multiple applications, enabling them to use the custom geo mapping.

Geo Mapping File

The geo-mapping file is an XML file used to map IP addresses to geolocations. You upload this file to the Controller for your IoT application.

File Specification

The geo-mapping file size is limited to 1 GB, but there is no limit to the number of mapped IP addresses.

Default Mapping

If you upload a custom geo-mapping file, IoT Monitoring will only resolve the IP addresses based on your mapped IP addresses and locations. Thus, if you are going to use a custom geo-mapping file, you should configure the default to cover the entire IP range.

IP Addresses and Ranges

You can only specify IPv4 addresses in the custom geo-mapping file.

When using IP address ranges, you must list the addresses in ascending order. For example, if your geo-mapping file specifies the two ranges 1.1.1.1–2.2.2.2 and 2.2.2.2–3.3.3.3, you must list the first range before the second so that they are in ascending order.

Example Geo Mapping Files

The example geo-mapping files below show you the scope of mapping geolocations and provide a general use case for each.

Geo Mapping File XML Schema

You can download the XML schema file `custom-geo-mapping.xsd` below to validate your geo-mapping XML file.

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<xs:schema version="1.0" xmlns:xs="http://www.w3.org/2001/XMLSchema">
  <xs:element name="mappings" type="config"/>
  <xs:element name="ip-range" type="explicitIpAddressRange"/>
  <xs:element name="subnet" type="subnetIpAddressRange"/>
  <xs:complexType name="config">
    <xs:sequence>
      <xs:element name="mapping" type="mapping" minOccurs="0" maxOccurs="unbounded"/>
      <xs:element name="default" type="geoLocation" minOccurs="0" maxOccurs="1"/>
    </xs:sequence>
  </xs:complexType>
  <xs:complexType name="mapping">
    <xs:sequence>
      <xs:choice>
        <xs:element ref="ip-range"/>
        <xs:element ref="subnet"/>
      </xs:choice>
      <xs:element name="location" type="geoLocation" minOccurs="1"/>
    </xs:sequence>
  </xs:complexType>
  <xs:complexType name="geoLocation">
    <xs:attribute name="country" type="xs:string" use="required"/>
    <xs:attribute name="region" type="xs:string" use="required"/>
    <xs:attribute name="city" type="xs:string" use="required"/>
  </xs:complexType>
  <xs:complexType name="explicitIpAddressRange">
      <xs:attribute name="from" type="xs:string" use="required"/>
      <xs:attribute name="to" type="xs:string" use="required"/>
  </xs:complexType>
  <xs:complexType name="subnetIpAddressRange">
      <xs:attribute name="from" type="xs:string" use="required"/>
      <xs:attribute name="mask" type="xs:string" use="required"/>
  </xs:complexType>
</xs:schema>
```

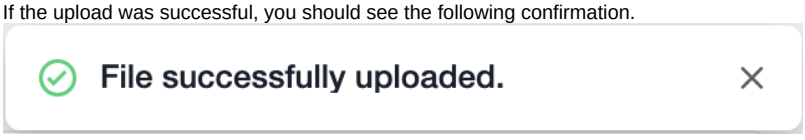
Upload Geo Mapping Files

From your SaaS Controller, you can perform the following actions with your custom geo-mapping file:

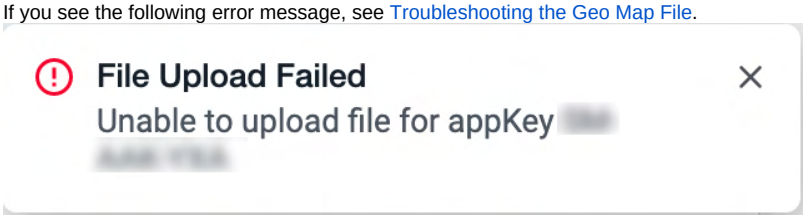
- Upload New Geo Mapping File
- Overwrite Existing Geo Map File
- Reset Geo Map File

Upload New Geo Mapping File

1. Navigate to the **Configuration > Custom GeoMap**.
2. From the **Upload Custom GeoMap file** dialog, click **Choose File**.
3. Select a geo-mapping XML file.
4. Click **Upload**.
5. If the upload was successful, you should see the following confirmation.



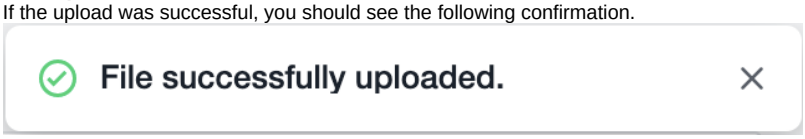
6. If you see the following error message, see Troubleshooting the Geo Map File.



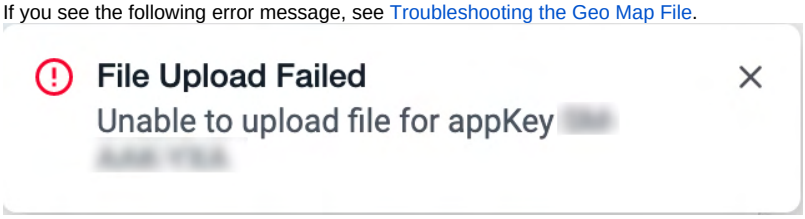
After you have uploaded the geo-mapping file, it may take some time for IoT Monitoring to apply the new custom mapping to your applications.

Overwrite Existing Geo Map File

1. Navigate to the **Configuration > Custom GeoMap**.
2. From the **Upload Custom GeoMap file** dialog, click **Overwrite Current Mapping**.
3. Select a geo-mapping XML file.
4. Click **Upload**.
5. If the upload was successful, you should see the following confirmation.



6. If you see the following error message, see Troubleshooting the Geo Map File.



Reset Geo Map File

1. Navigate to the **Configuration > Custom GeoMap**.
2. From the **Upload Custom GeoMap file** dialog, click **Reset to Default**.
3. From the **Reset Confirmation** dialog, click **Reset**.

View Custom Geo Locations

You can add the **Geo** widget to one or more of the available dashboards to view the geolocation information of your devices. The Geo widget will display geo locations resolved with the public geographic databases or a custom IP address mapping. To view the geolocations from the **Device Dashboard**:

1. From your IoT application, navigate to **Devices**.
2. Scroll down to the **Geo** widget.
3. (Optional) Build a custom **Geo** widget. You can filter the devices by geodata such as city, region, or country.

In addition, you can filter data in the other widgets by geodata based on your geo-mapping file.

Troubleshooting the Geo Map File

Upload Issues

If you get an error message trying to upload the custom geo-mapping file, check the following:

- XML validity: Use an XML validation tool to determine if your XML of your geo-mapping file is valid.
- XML schema: Confirm that your custom geo-mapping file conforms to the XML schema.
- Invalid IP addresses: Confirm your IP addresses are valid.
- File size: Confirm that the custom geo-mapping file is less than 1 GB.

Incorrect Geo Mapping

If IP addresses are not being resolved to the correct geolocations, confirm that the IP addresses and geo-locations in your geo-mapping file are correct.

Database Visibility

Database Visibility in AppDynamics provides end-to-end visibility on the performance of your database, helps you troubleshoot problems such as slow response times and excessive load, and provides metrics on database activities, such as:

- SQL statements or stored procedures that are consuming most of the system resources
- Statistics on procedures, SQL statements, and SQL query plans
- Time spent on fetching, sorting, or waiting on a lock
- Activity from the previous day, week, or month

Installation and Administration

- Install the Database Agent
- Start and Stop the Database Agent
- Upgrade the Database Agent

Configuration

- Configure the Database Agent
- Add Database Collectors

Using Database Visibility

- Overview of Database Visibility
- Monitor Database Performance
- Monitor Database Server Hardware

Reference

Overview of Database Visibility

Related pages:

- Add Database Collectors
- Database Visibility

Database Visibility provides metrics on the performance of your database and helps troubleshoot performance-related issues.

Components of Database Visibility

AppDynamics Database Visibility consists of four main components:

- Database Agent
- Collector
- Controller
- Events Service (on-premises only)

Database Agent

The AppDynamics Database Agent is a standalone Java program that collects performance metrics about your database instances and database servers. You can deploy the Database Agent on any machine running Java 1.8 or higher. The machine must have network access to the AppDynamics Controller and the database instance that you want to be monitored.

A database agent running on a typical machine with 16 GB of memory can monitor about 25 databases. On larger machines, a database agent can monitor up to 200 databases. To monitor more than 100 databases, increase the initially allocated heap size for the Database Agent JVM. See Database Visibility Supported Environments

Collector

The Database Agent Collector is the process that runs within the Database Agent to collect performance metrics about your database instances and database servers. One collector collects metrics for one database instance. Multiple collectors can run in one Database Agent.

AppDynamics Database Visibility detects when a database back end has matching credentials with a database server being monitored by a collector. Database Visibility automatically associates the back end with the collector, so you can view its performance with the Application Flow Map, Tier Flow Map, or Node Flow Map.

Controller

The Controller is the central interface where you can see all your database instances and database server performance metrics.

The following types of information are sent to the Controller:

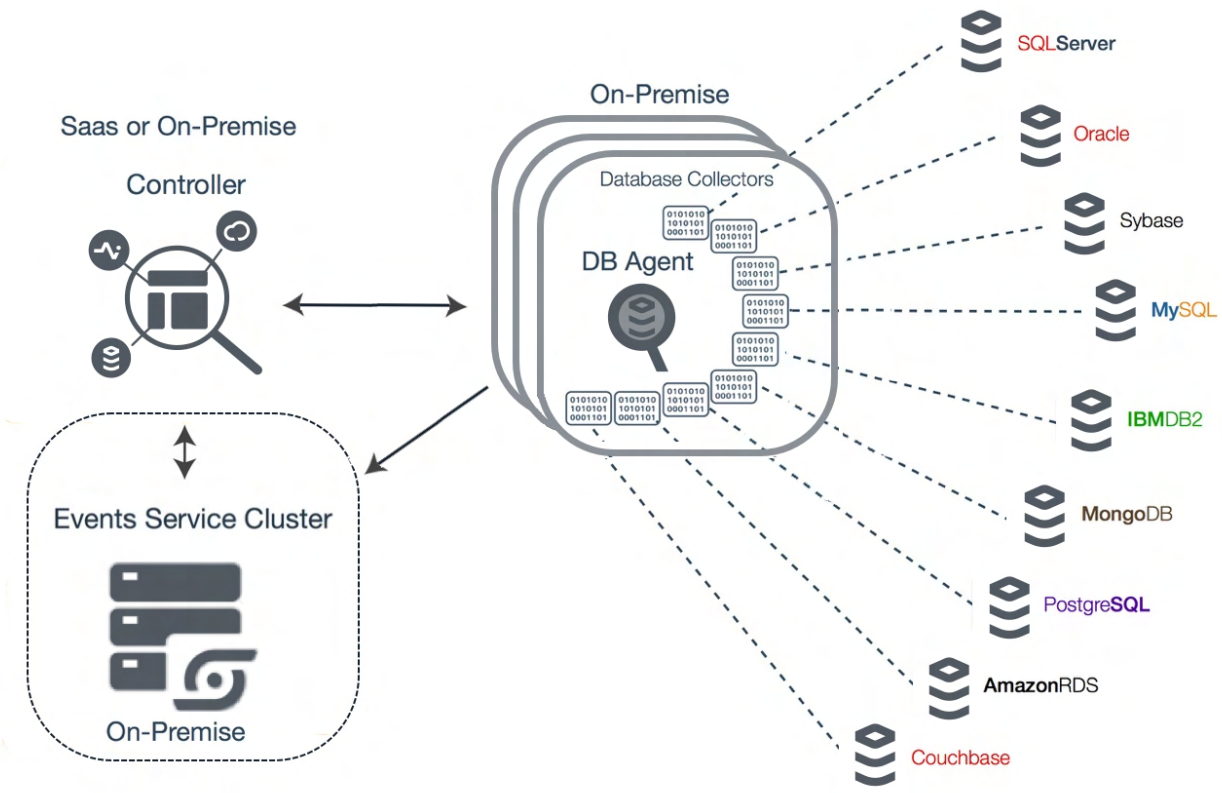
- Database-level metrics, such as the number of queries processed and other database statistics
- Names and attributes of all sessions, clients, queries, and other objects on the monitored system

Events Service

Event service stores high volumes of metric data. If you are using the on-premises version of Database Visibility, you must install the Events Service.

The following types of information are sent to the Events Service:

- Time that each query spends at each wait state
- Individual query statistics for databases that support it
- Information about individual execution plans in databases that support it



Saas or On-Premise
Controller

Database Visibility Supported Environments

Related pages:

- Add Database Collectors
- Database Visibility

This page describes the application environments and versions supported by the Database Visibility Agent.

Database Visibility Support

Once Database Visibility is available, you can create collectors that run on the Database Agent to monitor any of these systems:

Database	Supported through Amazon RDS	Version
Apache Cassandra		>= 3.11.4
Datastax Enterprise (DSE) Cassandra		>= 6.7.3
Couchbase		>= 4.5
IBM DB2 LUW		9.x, 10.x, 11.x
MongoDB, MongoDB cluster		>= 2.6
MySQL	Yes	All versions including MySQL Version 8.0, Percona, MariaDB, and Aurora
Microsoft SQL Server	Yes	2005, 2008, 2012, 2014, 2016, 2017, 2019, and SQL Azure
Microsoft SQL Server on Linux		SQL Server on Linux is currently available as a public preview and is not recommended for production use. Database Visibility works well with this preview release, but monitoring results may vary until a stable version of SQL Server on Linux is available.
Oracle, Oracle RAC	Yes	10g (>= 10.2), 11g, 12c, 18c, and 19c
PostgreSQL	Yes	All the versions including Azure Database for PostgreSQL
Sybase ASE		>= 15
Sybase IQ		All versions

Operating System	Version
Windows	64-bit From 20.5 release, 32-bit is unsupported.
Linux	32-bit and 64-bit
Solaris	All versions
AIX	>= 6.1
Amazon RDS	All versions

To avoid metric value errors, use a 64-bit JRE with the 64-bit operating system.

Recommended

If you use a third-party application along with Database Visibility to monitor Sybase, the data displayed in the controller may not display correctly. For accurate metrics, do not use both a third-party application and Database Visibility to monitor Sybase.

Database Visibility System Requirements

This page describes the hardware and software requirements using Database Visibility.

Hardware Requirements

Hardware requirements vary depending on database activity. If your database activity increases, you may need to adjust your hardware configuration.

The machine running the Database Agent should meet the following hardware requirements:

- 1 GB of heap space and an additional 512 MB of heap space for each monitored database instance. For less busy databases, you may reduce the heap space to 256 MB per monitored database instance.
- 2 GHz or higher CPU.

> **Database Instance**
>
> A Database instance can be a node in the Oracle RAC, MongoDB, Couchbase cluster, standalone-collector, or a sub-collector.

This table shows sample calculations for heap space allocation:

Number of Database Instances Monitored	Heap Space Allocation
5	(5 x 512 MB) + 1024 MB = 3,584 MB
20	(20 x 512 MB) + 1024 MB = 11,264 MB
100	(100 x 512 MB) + 1024 MB = 52,224 MB

AppDynamics Controller Sizing Requirements

The Controller database should meet the following hardware requirements:

- 500 MB of disk space per collector per day
- 500 MB of disk space for the Events Service per day. By default, the Events Service retains data for 10 days.

See Controller System Requirements.

> **Note**
>
> The Database Agent requires the Events Service. Start Event Service before you start the Database Agent.

Software Requirements

- The Database Agent runs on a Java Virtual Machine. You must have Java >= 1.8.
- The operating systems Linux and Windows are supported.

Network Requirements

- The machine on which the database is running or the machine you want to monitor must be accessible from the machine where the Database Agent is installed and running. This machine must have a network connection, internet, or intranet.
- If your databases are behind a firewall, you must configure the firewall to permit the machine running the Database Agent program access to the databases. The database listener port (and optionally the SSH or WMI port) must be open.
- The network bandwidth used between the agent and the controller is approximately 300 KB per minute per collector for a large database with 200 clients using 50 schemas, processing about 10,000 queries a minute. The actual numbers depend on the type of database server, the number of individual schemas on the server, and the number of unique queries executed daily, and therefore varies.

Administer the Database Agent

Related pages:

- Database Visibility
- Database Agent Configuration Properties
- Add Database Collectors
- Start the Database Agent Automatically on Linux
- Start the Database Agent Automatically on Windows

The Database Agent is a standalone Java program that collects performance metrics about your database instances and database servers. You can view these performance metrics in the Metric Browser of the AppDynamics Controller UI.

To start monitoring your database, you must first install the Database Agent. You may want to install multiple agents for the following reasons:

- You have databases on multiple networks that are not accessible by one machine.
- You have multiple SQL Server instances that each require different credentials, and you want to connect to them through Windows Authentication.
- You want one or more agents to back up a primary agent. Backup agents ensure that your database instances are continually monitored during agent failure or machine downtime.

Prepare to Install the Database Agent

Related pages:

- Database Visibility
- Database Agent Configuration Properties
- Add Database Collectors
- Start the Database Agent Automatically on Linux
- Start the Database Agent Automatically on Windows

Database Agent Installation Requirements

Ensure that your environment meets these requirements:

- Java >= 1.8
- The machine that you install the agent on has network access to the databases that you want to monitor.

Controller Communication Information

If you are installing using the Database Agent downloaded from the **Getting Started Wizard**, the Controller communications information is already configured for you in the agent `controller-info.xml` file.

To complete the **Getting Started Wizard - Databases**, you need:

- Controller Host Name
- Controller Port Number

If you are installing using the agent installation zip file downloaded from the AppDynamics portal, you need:

- Controller Host Name
- Controller Port Number
- Account Access Key

See Agent-to-Controller Connections.

Install the Database Agent

Related pages:

- Database Visibility
- Database Agent Configuration Properties
- Add Database Collectors
- Enable SSL and SSH for Database Agent Communications
- Start the Database Agent Automatically on Linux
- Start the Database Agent Automatically on Windows

This page describes how to manually install the Database Agent. You can alternatively follow the steps in the **Download & Install Wizard**, which you can access from the Home page in the Controller UI. The wizard simplifies the install process.

To avoid permission issues, you should install the Database Agent as the same user who will run the agent, or as an administrator on the host machine. To run the Database Agent, you must have write privileges to the logging output directory and to the `conf` directory, which are located in the agent installation directory.

Install the Agent Software

1. Download the version of the installation package that is appropriate for your OS environment from the AppDynamics Download Center (http://download.appdynamics.com).
2. Extract the zip file to the destination directory. Do not use spaces in the agent installation destination directory.
3. Log on as an administrator to the machine where you will be installing the Database Agent.

Windows

Double-click the `dbagent-x.x.x.zip` file and extract the files to `<db_agent_home>`. If necessary, you can unblock the zip file before you extract it as follows: Right-click on the zip file, select **Properties** and choose **unblock**.

There are two versions of the database agent: one that is 32-bit and one that is 64-bit *(as of 4.5.2)*. Choose a version based on your OS requirements.

Linux

Enter the following on the command line:

```
unzip dbagent-x.x.x.zip -d <db_agent_home>
```

Running Multiple Database Agents

You can have multiple Database Agents concurrently running the agent jar in the `<db_agent_home>` directory on the same machine. Some system properties may be required depending on how you'll be using the agents.

Database Agent Licensing (On-premises Only)

Obtain a `license.lic` file with Database Monitoring licensing from your sales or support representative and put the license file in the directory where you installed the Controller. After placing the license in the directory, the Controller may take a minute or two to detect the new license. Restarting the Controller forces it to detect new licenses.

Configure the Agent

You can configure properties for the Controller host name, port number, and account access key using either the `<db_agent_home>/conf/controller-info.xml` file or by adding system properties to the Database Agent startup script.

Controller Host Name

Configure using controller-info.xml: `<controller_host>`
Configure using System Properties: `-Dappdynamics.controller.hostName`
Required: Yes
Default: None

Controller Port

Configure using controller-info.xml: `<controller_port>`
Configure using System Properties: `-Dappdynamics.controller.port`
Required: Yes
Default: For On-premises Controller installations: Port 8090 for HTTP and 8181 for HTTPS communication.
For SaaS Controller service: Port 80 for HTTP and port 443 for HTTPS communication.

Account Access Key

Configure using controller-info.xml: `<account_access_key>`
Configure using System Properties: `-Dappdynamics.agent.accountAccessKey`
Required: Yes
Default: None

Optional Configurations:

- Configure the agent to use SSL, see Enable SSL for Communicating with the Controller.
- Configure the agent to use Proxy Settings, see Proxy Settings for the Controller.
- Configure the agent to run automatically when the Machine starts on Linux or Windows.
- Configure the agent to uniquely identify itself to the Controller, such as when you require multiple agents. See Multiple Agent Environment Properties.
- Configure the agent to act as a backup to another Database Agent. See Multiple Agent Environment Properties.
- Configure the logging level of the Database Agent running on the agent JVM. The attached log file shows an example of the agent log file when the agent logging is set to INFO level. This is the default. The log files are in `<db_agent_home>\logs`.

Start the Controller Events Service (On-premises Only)

In an on-premises environment, for monitoring the database you must start the controller events service before starting Database Agent.

Linux

```
bin/platform-admin.sh start-events-service
```

Windows

```
bin\platform-admin.exe start-events-service
```

Launch the Database Agent using System Properties

The following assumes that all the necessary parameters have been specified in the `controller-info.xml`.

Method 1: Launch Agent with Start Script

You can use a script to start the agent. This is the recommended method.

Linux

```
./start-dbagent -Xms<min_heap_size> -Xmx<max_heap_size> &
```

Windows

```
start-dbagent.bat -Xms<min_heap_size> -Xmx<max_heap_size>
```

Alternatively, you can launch the agent as a Windows Service *(as of 4.5.4)*. See Install the Database Agent as a Windows Service.

Method 2: Launch Agent with Java Command

Alternatively, you can launch the agent with these Java commands:

Linux

```
java -XX:+HeapDumpOnOutOfMemoryError -XX:OnOutOfMemoryError="kill -9 %p" -jar db-agent.jar
```

Windows

```
C:\java -Djava.library.path="<db_agent_home>\auth\x64" -Ddbagent.name="Scarborough Network Database Agent" -jar
<db_agent_home>\db-agent.jar
```

System Properties

Database Agent Name

Configure using System Properties: `-Ddbagent.name=<db_agent_name>`
Type: ASCII string, including spaces. If `<db_agent_name>` contains spaces, you must enclose the entire name in double quotes (" ").
Required: Yes, when you have multiple agents reporting to the same Controller.
Default: Default Database Agent

Java Library Path

Configure using System Properties: `-Djava.library.path=<db_agent_home>\auth\x64`
Type: ASCII string, including spaces. If `<db_agent_home>` contains spaces, you must enclose the entire name in double quotes (" ").
Required: Yes, for Windows only
Specify:
For 64-bit systems: <db_agent_home>\auth\x64
For 32-bit systems: <db_agent_home>\auth\x86

Increase the JVM Memory

To monitor multiple databases, you may need to increase the JVM memory allocation size. Increased activity on the databases you are monitoring results in increased memory usage.

Use one of the following commands to start the agent, and to initially allocate 1536 MB to the agent instead of the default of 64 MB.

For Windows 64-bit

```
C:\java -Xmx1536m -Djava.library.path="<db_agent_home>\auth\x64" -jar <db_agent_home>\db-agent.jar
```

For Linux

```
% java -Xmx1536m -jar <db_agent_home>/db-agent.jar
```

Verify the Database Agent Installation

Related pages:

- Database Agent Configuration Properties
- Agent and Controller Compatibility

Review the Agent Logs

After a successful install, your agent logs, located at `<db_agent_home>/logs`, should contain this message:

```
Started AppDynamics Database Agent Successfully
```

If the agent log file is not present, the Database Agent may not be accessing the Database Agent command properties. To troubleshoot, check the application server log file where STDOUT is logged. It will have the fallback log messages, useful for troubleshooting the agent.

Verify that the Agent is Reporting to the Controller

1. Click **Settings > AppDynamics Agents**.
2. Click the Database Agents tab.

A list for each Database Agent reporting to the Controller should display. An agent can have one of the following statuses:

- Active: The agent is running
- Passive: The agent is used as a backup for active agents

If you don't see the Database Agent, check your `controller-info.xml` properties to ensure they have specified the correct host properties.

Verify that the Agent is Running

Use the following command to verify that the agent process is running:

Linux:

```
ps -ef | grep db-agent
```

Windows:

1. Open a command-line console.
2. Start the **Task Manager** and click the Processes tab.
3. The agent process should be running. If it is not running, then stop and restart the agent.

Upgrade the Database Agent

Related pages:

- Database Agent Configuration Properties
- Agent and Controller Compatibility

Important Upgrade Notes

- Before upgrading, ensure that you have all the required user permissions as mentioned in each database collector configuration.
- If you are upgrading the Controller and agents, first upgrade the Controller and then upgrade the Database Agents.
- Shut down the Database Agent process before you install the new agent. All Database Agents that are running from the same install location need to be shut down when updating that install location.
- Download the installation package that is appropriate for your OS environment from the AppDynamics Download Center (https://download.appdynamics.com/download/).
- Back up the `<db_agent_home>` directory so you can revert to the previous installation if required. To maintain the same configuration information, you will also need the `<db_agent_home>\conf\controller-info.xml` file.
- If both the old and new agents are >= 4.2, you can keep the old agent running while installing the new agent, allowing you to upgrade the agent with no downtime. Once you see the new agent showing up as "ACTIVE" in the agents page in the Controller, stop the old agent.

Stop the Agent

Stop the agent as described for your specific installation in Start and Stop the Database Agent.

Back up the Existing Agent Directory

Make a copy of the existing agent directory, `<db_agent_home>`. Backing up allows you to revert to the previous agent installation if you need to. You can also copy over the `controller-info.xml` configuration file to the new installation to ensure the agent configuration is maintained.

Install the Agent

Install the Database Agent as described for your specific installation in Administer the Database Agent.

Copy the controller-info.xml File

To ensure the agent configuration is maintained, copy the `<backup_db_agent_home>\conf\controller-info.xml` file to the new installation directory, `<db_agent_home>\conf`.

Start the New Agent

See Start and Stop the Database Agent.

Verify the Database Agent Installation

See Verify the Database Agent Installation.

Uninstall the Database Agent

Related pages:

- Administer the Database Agent
- Database Agent Configuration Properties
- Manage App Agents

To uninstall the database agent:

1. Shut down the JVM that the database agent runs on.
2. Delete the installation directory.

If you have the agent installed the agent as a service, you must also stop the Database Agent service.

To prevent a Database Agent from connecting to the Controller, ensure that it doesn't start up. This frees the license associated with the agent in the Controller and makes it available for use by another Database Agent.

Configure the Database Agent

Once you have installed and launched the Database Agent, you can further customize the agent.

- Database Agent Configuration Properties
- Enable SSL and SSH for Database Agent Communications
- Enable Snapshot Correlation for Oracle
- Increasing JVM Memory
- Database Agent Logging

Database Agent Configuration Properties

This page describes how configure a Database Agent.

Related pages:

- Administer the Database Agent

Where to Configure Database Agent Properties

You can configure agent properties in the following locations:

- The `controller-info.xml` file located in the `<db_agent_home>/conf` directory
- The system properties (`-D options`) section in the JVM start-up command. The system properties override the settings in the `controller-info.xml` file. System properties are case-sensitive.

  ```
  java -XX:+HeapDumpOnOutOfMemoryError -XX:OnOutOfMemoryError="kill -9 %p" -jar db-agent.jar
  ```

  Alternatively, you can use a script to start the agent.

Windows	`start-dbagent.bat -Xms<min_heap_size> -Xmx<max_heap_size>`
Linux	`./start-dbagent -Xms<min_heap_size> -Xmx<max_heap_size> &`

Example Database Agent controller-info.xml File

```
        <?xml version="1.0" encoding="UTF-8"?>
<controller-info>

        <controller-host>192.10.10.10</controller-host>
        <controller-port>8090</controller-port>
    <account-access-key>165e65645-95c1-40e3-9576-6a1424de9625</account-access-key>
        <!-- The following attribute enables or disables SSL communications between the agent and the
Controller.-->
        <controller-ssl-enabled>false</controller-ssl-enabled>

        <!-- The following account-related parameters are necessary only for SaaS installations-->
        <!--account-name></account-name-->

</controller-info>
```

Example Startup Configuration Using System Properties

A bash example. Note that the system properties are case-sensitive.

```
-Dappdynamics.controller.hostName=192.168.1.20 -Dappdynamics.controller.port=8090
```

Database Agent Properties

This section describes the Database Agent configuration properties, including their `controller-info-xml` elements and their system property options.

Required System Properties

Path to the Agent jar File

Description: Provides the absolute path to the jar file.

System Property: `-jar`

Value: `<db_agent_home>db-agent-jar`

Type: ASCII string, including spaces. If `<db_agent_name>` contains spaces, you must enclose the entire name in double quotes (" ").

Required: Yes

Example: `-jar="D:\AppDynamics\Database Agent\db-agent.jar"`

Path to the Java Library

Description: Provides the absolute path to `sqlijdbc_auth.dll`.

System Property: `-Djava.library.path`

Value:

- For 64-bit systems: `<db_agent_home>\auth\x64`
- For 32-bit systems: `<db_agent_home>\auth\x32`

Type: ASCII string, including spaces. If `<db_agent_home>` contains spaces, you must enclose the entire name in double quotes (" ").

Required: Recommended. Required for SQL Server Windows Authentication on Windows 64-bit systems.

Example: `-Djava.library.path="D:\AppDynamics\Database Agent\auth\x64"`

Optional System Properties

Disable Retry on Auth Failure

Description: Stops retrying to establish JDBC connection when JDBC authentication fails.

System Property: `-Dretry.on.auth.failure=false`

Default: The system property is set to true.

Type: String

Supported Locales for Parsing Numbers

Description: Specifies which locale to use for parsing numbers. See Java 7 Supported Locales or Java 8 Supported Locales for valid values. Use the values for the Java version that you are running in your environment.

System Property: `-Ddbagent.language`

Default: The system property is set to `en-US` or `en_US`.

Type: String

Agent-Controller Communication Properties

Controller Host Property

Description: This is the host name or the IP address of the AppDynamics Controller, for example, 192.168.1.22 or myhost or myhost.abc.com. This is the same host that you use to access the AppDynamics Controller UI.

Element in controller-info.xml: `<controller-host>`

System Property: `-Dappdynamics.controller.hostName`

Environment Variable: `APPDYNAMICS_CONTROLLER_HOST_NAME`

Type: String

Default: None

Required: Yes

Controller Port Property

Description: This is the HTTP(S) port of the AppDynamics Controller. This is the same port that you use to access the AppDynamics browser-based user interface. If the Controller SSL Enabled property is set to true, specify the HTTPS port of the Controller; otherwise, specify the HTTP port. See **Controller SSL Enabled Property**.

Element in controller-info.xml: `<controller-port>`

System Property: `-Dappdynamics.controller.port`

Environment Variable: `APPDYNAMICS_CONTROLLER_PORT`

Type: Positive Integer

Default: For on premises installations, port 8090 for HTTP and port 8181 for HTTPS are the default ports the Controller listens to.
For the SaaS Controller Service, port 80 for HTTP and port 443 for HTTPS are the default ports the Controller listens to.

Required: Yes

Account Access Key Property

Description: This is the account access key used to authenticate with the Controller.

Element in controller-info.xml: `<account-access-key>`

System Property: `-Dappdynamics.agent.accountAccessKey`

Environment Variable: `APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY`

Type: String

Default: None

Required: Yes. Earlier than 4.1, this property was required only for SaaS and multi-tenant Controllers. The account access key property is now required to authenticate all agent to Controller communications.

Example: `-Dappdynamics.agent.accountAccessKey=165e65645-95c1-40e3-9576-6a1424de9625`

Multiple Agent Environment Properties

The following properties are useful when you are configuring your system to include more than one Database Agent.

Database Agent Name Property

Description: This property uniquely identifies the Database Agent to the Controller.

System Property: `-Ddbagent.name=<db_agent_name>`

Type: ASCII string, including spaces. If `<agent_name>` contains spaces, you must enclose the entire name in double quotes (" ").

Default: Default Database Agent

Required: Required when you have more than one Database Agent reporting to the Controller.

You may want to run multiple **Database Agents** under the following conditions:

- When you have databases spread across multiple networks, and one machine cannot access all the databases on all the networks. In this case, you can have a uniquely named Database Agent in each network that monitors the databases only visible on that network.
- If you have multiple SQL Server instances that each require different credentials, and you want to connect to them via Windows Authentication. When using Windows Authentication, the Database Agent will use the credentials of the currently logged in user.
- When you want one or more agents to back up a primary agent. The database agent names for your backup agents must match the database agent name of your primary agent. The last agent you launch will be the primary agent.

Example: `-Ddbagent.name="Scarborough Network Database Agent"`

Unique Host ID

Description: The Unique Host ID logically partitions a single physical host or virtual machine such that it appears to the Controller that the application is running on different machines. Set the value to a string that is unique across the entire managed infrastructure. The string must not contain any spaces. If you have a machine agent that is running on the same host as that of the database agent, then this property value must be different than that of the machine agent. If you are running multiple database agents from the same host with the same name, then this property value must be different for those agents.

System Property: `-Dappdynamics.agent.uniqueHostId`

Type: String

Default: None

Environment Variable: `APPDYNAMICS_AGENT_UNIQUE_HOST_ID`

Multi-Tenant Mode Properties

If the AppDynamics Controller is running in multi-tenant mode or if you are using the AppDynamics SaaS Controller, specify the account name and account access key for this agent to authenticate with the Controller.

If the Controller is running in single-tenant mode (the default) there is no need to configure these values.

Account Name Property

Description: This is the account name used to authenticate with the Controller.
If you are using the AppDynamics SaaS Controller, the Account Name is in the Welcome email AppDynamics sent to you.

Element in controller-info.xml: `<account-name>`

System Property: `-Dappdynamics.agent.accountName`

Environment Variable: `APPDYNAMICS_AGENT_ACCOUNT_NAME`

Type: String

Default: None

Required:

Yes for AppDynamics SaaS Controller and other multi-tenant users

No for single-tenant users

Proxy Properties for the Controller

These properties route data to the Controller through a proxy.

Proxy Host Property

Description: This is the proxy host name or IP address.

Element in controller-info.xml: Not applicable

System Property: `-Dappdynamics.http.proxyHost`

Type: String

Default: None

Required No

Proxy Port Property

Description: This is the proxy HTTP(S) port.

Element in controller-info.xml: Not applicable

System Property: `-Dappdynamics.http.proxyPort`

Type: Positive Integer

Default: None

Required: No

Proxy User Name

Description: The name of the user that is authenticated by the proxy host.

Element in controller-info.xml: Not applicable

System Property: `-Dappdynamics.http.proxyUser`

Type: String

Default: None

Required: No

Proxy Password

Description: The absolute path to the file containing the password of the user that is authenticated by the proxy host. The password must be the first line of the file.

If Use Encrypted Credentials is false, enter the password in plain text. If Use Encrypted Credentials is true, encrypt the password. See Encrypt Agent Credentials.

Element in controller-info.xml: Not applicable

System Property: `-Dappdynamics.http.proxyPasswordFile`

Type: `String`

Default: None

Required: No

Other Properties

Controller SSL Enabled Property

Description: This property specifies whether the agent should use SSL (HTTPS) to connect to the Controller. If SSL Enabled is true, set the Controller Port property to the HTTPS port of the Controller. See **Controller Port Property**.

Element in controller-info.xml: `<controller-ssl-enabled>`

System Property: `-Dappdynamics.controller.ssl.enabled`

Environment Variable: `APPDYNAMICS_CONTROLLER_SSL_ENABLED`

Type: Boolean

Default: False

Required: No

Enable SSL and SSH for Database Agent Communications

Enable SSL for the Database Agent

This page describes how to configure the Database Agent to connect to the Controller using SSL. It assumes that you use a SaaS Controller or have configured the on-premises Controller to use SSL.

The Database Agent supports extending and enforcing the SSL trust chain when in SSL mode.

Requirements

Gather this information:

- The Controller SSL port.
  - For SaaS Controllers the SSL port is 443.
  - For on-premises Controllers the default SSL port is 8181, but you may configure the Controller to listen for SSL on another port.
- The signature method for the Controller's SSL certificate:
  - A publicly known certificate authority (CA) signed the certificate. This applies for DigiCert, Verisign, Thawte, and other commercial CAs.
  - A CA internal to your organization signed the certificate. Some companies maintain internal certificate authorities to manage trust and encryption within their domain.
  - The Controller uses a self-signed certificate.

Establish Trust for the Controller's SSL Certificate

To establish trust between the Database Agent and the AppDynamics Controller, you must create an agent truststore that contains the root certificate for the authority that signed the Controller's certificate.

> If you secured your on-premises Controller with a self-signed certificate, see Keystore Certificate Extractor Utility for instructions to create the agent keystore.

1. Obtain one of the following root certificates:
   - DigiCert Global Root CA for the AppDynamics SaaS Controller
   - Root certificate for the publicly known certificate authority (CA) that signed the certificate for your on-premises Controller
   - Root certificate for the internal CA that signed the Controller certificate for your on-premises Controller
2. Run the Java keytool command to create the Database Agent truststore:

   ```
   keytool -import -alias rootCA -file <root_certificate_file_name> -keystore cacerts.jks -storepass
   <truststore_password>
   ```

   For example:

   ```
   keytool -import -alias rootCA -file /usr/home/appdynamics/DigicertGlobalRootCA.pem -keystore cacerts.jks
   -storepass MySecurePassword
   ```

   > Make note of the truststore password, you need it to configure the Database Agent.

3. Install the agent truststore to the Database Agent configuration directory:

   ```
   <db_agent_home>/conf/
   ```

Secure the Database Agent Truststore

AppDynamics recommends you take the following security measures to prevent tampering with the Database Agent truststore:

- Secure the truststore file through file system permissions:
  - Make the Database Agent truststore readable by any user.
  - Make the truststore owned by a privileged user.
  - Make the truststore writable only by the specified privileged user.
- Secure the Database Agent configuration files so that they are only readable by the agent runtime user and only writable by a privileged user:
  - Global configuration file: `<db_agent_home>/conf/controller-info.xml`.

Configure SSL System Properties for the Database Agent

1. Configure the following system properties in the versioned `controller-info.xml`: `<db_agent_home>/<version_number>/conf/controller-info.xml`. See "SSL Configuration Properties" on Database Agent Configuration Properties for full details on each property.
    - **Controller Port**: the SSL port for the Controller. 443 for AppDynamics SaaS.

      ```
      <controller-port>443</controller-port>
      ```
    - **Controller SSL Enabled:** true.

      ```
      <controller-ssl-enabled>true</controller-ssl-enabled>
      ```
    - **Controller Keystore Password:** the plain text password for the Database Agent truststore.

      ```
      <controller-keystore-password>MySecurePassword</controller-keystore-password>
      ```
    - **Controller Keystore Filename:** path of the Database Agent truststore relative to `<db_agent_home>/<version>/conf`. Required if you use a truststore other than the default `<db_agent_home>/<version_number>/conf/cacerts.jks`.

      ```
      <controller-keystore-filename>../../conf/cacerts.jks</controller-keystore-filename>
      ```

      > You can specify the Controller port and enable SSL for the Controller in the JVM startup script, but you must specify the truststore password and filename in the `controller-info.xml` file.

2. Save your change to the `controller-info.xml` file and restart the Database Agent.

Sample SSL `controller-info.xml` Configuration

```
<?xml version="1.0" encoding="UTF-8"?>
<controller-info>
        <controller-host>mycompany.saas.appdynamics.com</controller-host>
        <controller-port>443</controller-port>
        <controller-ssl-enabled>true</controller-ssl-enabled>
        <controller-keystore-password>MySecurePassword</controller-keystore-password>
        <controller-keystore-filename>../../conf/cacerts.jks</controller-keystore-filename>
        ...
</controller-info>
```

Keystore Certificate Extractor Utility

The Keystore Certificate Extractor Utility exports certificates from the Controller's Java keystore for the Database Agent truststore. It installs to the following location:

```
<agent_home>/utils/keystorereader/kr.jar
```

To avoid copying the Controller keystore to a Database Agent machine, you can run this utility from the Controller server. Access the agent distribution on the Controller at the following location:

1. Run the Keystore Certificate Extractor Utility from the Controller:

   ```
   % /<full path to application JRE>/bin/java -jar <controller_home>/appserver/glassfish/domains/domain1/appagent/<controller_version>/utils/keystorereader/kr.jar
   ```

2. Enter the following when prompted:
    - The full path to the Controller's keystore:

      ```
      Enter input keystore: <controller_home>/appserver/glassfish/domains/domain1/config/keystore.jks
      ```

    - The truststore output file name. By default the Database Agent looks for `cacerts.jks`.

      ```
      Enter output agent truststore file name: <controller_home>/appserver/glassfish/domains/domain1/config/keystore.jks
      ```

      The password for the Controller's certificate, which defaults to "changeit". If you don't include a password, the extractor applies the password "changeit" to the output truststore.

- **Example command to execute kr.jar**

```
/<full path to application JRE>/bin/java -jar kr.jar <controller_home>/appserver/glassfish/domains
/domain1/config/keystore.jks cacerts.jks <controller_certificate_password>
```

3. Install the agent trust store to the agent configuration directory:

```
<db_agent_home>/conf/
```

Enable SSH for the Database Agent

> **For Linux hosts only**
>
> Applies only when Database Agent is running on a Linux host.

When the Database Agent is running on Linux and you want to monitor hardware, except to monitor the local host, authentication is required and a password is passed between the Database Agent and the database server.

> **SSH port option**
>
> The SSH port option does not appear unless the Database Agent is running on Linux.

1. On the agent machine, generate the rsa or dsa key as follows:

Generate rsa key

```
% ssh-keygen -b 1024 -f id_rsa -t rsa
```

or

Generate dsa key

```
% ssh-keygen -b 1024 -f id_dsa -t dsa
```

This will create a rsa or dsa 1024-bit key and put the keys into `/home/<user_name>/.ssh/id_rsa` and `/home/<user_name>/.ssh/id_rsa.pub` or `/home/<user_name>/.ssh/id_dsa'` and `/home/<user_name>/.ssh/ida_dsa.pub'` files. Do not change the names of these files.

2. Copy the private key, `/home/<user_name>/.ssh/id_rsa` or `/home/<user_name>/.ssh/id_id_dsa` into the `<db-agent_home>/keys` directory.
3. On both the monitored machine and the agent machine, verify that you have the correct permissions on the `.ssh` directory, or set them as follows:

.ssh directory permissions

```
% cd /home/<user_name>
% chmod 755 .ssh
```

4. On the monitored machine, verify that you have a `/home/<user_name>/.ssh/authorized_keys` file. If you do not have this file, create the a `uthorized_keys` file on the monitored machine as follows:

Create authorized_keys file

```
% cd /home/<user_name>/.ssh
% touch .ssh/authorized_keys
```

5. Verify that you have the correct permissions to the `/home/<user_name>/.ssh/authorized_keys` file, or change the permissions as follows:

authorized_keys file permissions

```
% cd /home/<user_name>/.ssh
% chmod 644 authorized_keys
```

6. Append (do not copy) the file 'id_rsa.pub' or the file 'id_dsa.pub' to the file, /home/<user_name>/.ssh/authorized_keys, such as follows:

Append rsa public key to authorized key

```
% echo /home/<user_name>/.ssh/id_rsa.pub >> /home/<user_name>/.ssh/authorized_keys
```

or

Append dsa public key to authorized key

```
% echo /home/<user_name>/.ssh/id_dsa.pub >> /home/<user_name>/.ssh/authorized_keys
```

7. The SSH port of the database Collector is set to 22 by default. You can change it by navigating to the Monitoring Hardware section of the Collector configuration dialog. In the dialog, set the SSH port to the port your require.
8. Save your change to the Collector configuration and restart the Database Agent.

Enable SSH via PEM certificate

For Linux, AppDynamics also supports certificate-based authentication via Privacy Enhanced Mail (PEM). To implement certificate-based authentication:

1. Enable the **Use certificate** option in the Monitoring hardware section of the Collector configuration dialog.
2. Copy the PEM file to the <db_agent_home>/keys directory. Note, if the home/<user_home>/.ssh directory exists, the agent will use the certificate found there.
3. Restart the agent.

Monitor SSL-enabled PostgreSQL on Amazon RDS

To monitor a PostgreSQL instance that uses SSL connections, complete the following steps.

1. Create the `.postgresql` directory under the system home folder, then create a file, `root.crt` in the directory.
   `/home/<name>/.postgresql/root.crt`
2. Download PEM file from Amazon and copy to a local directory.
3. Convert the PEM file to a DER file using the following `openssl` command:

   ```
   openssl x509 -outform der -in rds-combined-ca-bundle.pem -out rds-combined-ca-bundle.der
   ```

4. Add the certificate to the Java keystore using the following command:

   ```
   sudo keytool -import -noprompt -trustcacerts -alias AmazonRDS -file rds-combined-ca-bundle.der -keystore
   $JAVA_HOME/jre/lib/security/cacerts -storepass changeit
   ```

   You can verify that the certificate was added by running the following command:

   ```
   keytool -list -keystore $JAVA_HOME/jre/lib/security/cacerts -storepass changeit
   ```

5. Re-start the dbagent process to register the certificate you added.
6. In the Controller, create a new collector for PostgreSQL.
   a. In the **Custom JDBC Connection String** field, enter the following JDBC string:
      `jdbc:postgresql://<RDS-Hostname>:<RDS-Port>/postgres?ssl=true`
   b. In the **ADVANCED OPTIONS** section, select **Connection Properties** and then specify these property details:

Property Name	Property Value
`sslrootcert`	The location of the downloaded PEM file
`sslmode`	`verify-full`

Monitor SSL-enabled MySQL on Amazon RDS

To monitor a MySQL instance that uses SSL connections, enable MySQL in SSL mode, consulting the online documentation appropriate to your deployment.

Download the files shown below as they are required to complete this procedure:

- `ca.pem`
- `server-cert.pem`
- `server-key.pem`
- `client-cert.pem`
- `client-cert.key`

Run the following commands at the command line. Substitute URLs and other information from your deployment for the placeholders in the examples.

1. Test your local SSL connection:

```
mysql -h ec2-11-111-111-11.us-west-2.compute.amazonaws.com -u Testssl --ssl-ca=/etc/certs/ca.pem --ssl-
cert=/etc/certs/server-cert.pem --ssl-key=/etc/certs/server-key.pem -p
```

2. Verify the remote connection:

```
mysql -h ec2-11-111-111-11.us-west-2.compute.amazonaws.com -u Testssl --ssl-ca=/home/appdynamics/cert/ca.
pem --ssl-cert=/home/appdynamics/cert/client-cert.pem --ssl-key=/home/appdynamics/cert/client-key.pem -p
```

3. Import the `ca.pem` file to the default truststore:

```
sudo keytool -importcert -alias MySQLCACert -file ca.pem -keystore $JAVA_HOME/jre/lib/security/cacerts -
storepass changeit
```

   - Do not forget the password, as you need it in step 7

4. Convert the client key and certificate files to a PKCS #12 archive:

```
openssl pkcs12 -export -in client-cert.pem -inkey client-key.pem -name "mysqlclient" -passout pass:
changeit -out client-keystore.p12
```

5. Import the client key and certificate into a Java keystore:

```
sudo keytool -importkeystore -srckeystore client-keystore.p12 -srcstoretype pkcs12 -srcstorepass
changeit -destkeystore $JAVA_HOME/jre/lib/security/cacerts -deststoretype JKS -deststorepass changeit
```

6. Verify that the certificate was added:

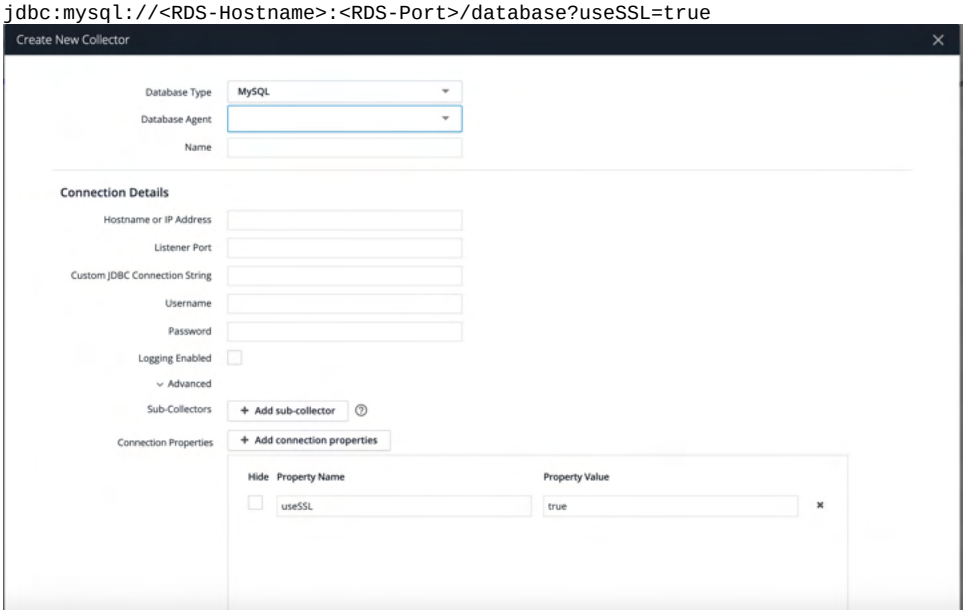
```
keytool -list -keystore $JAVA_HOME/jre/lib/security/cacerts -storepass mypassword
```

7. Start the db-agent after ensuring that the following properties are added:

```
/<full path to application JRE>/bin/java -jar -Djavax.net.ssl.trustStore=$JAVA_HOME/jre/lib/security
/cacerts -Djavax.net.ssl.trustStorePassword=changeit -Djavax.net.ssl.keyStore=$JAVA_HOME/jre/lib/security
/cacerts -Djavax.net.ssl.keyStorePassword=changeit db-agent.jar
```

8. In the Controller, create a new collector for MySQL
   - In the Configuration panel, add the connection property with Property Name "*useSSL*" and Property Value "*true*"
   - Alternatively, you can also use the following custom connection string:

```
jdbc:mysql://<RDS-Hostname>:<RDS-Port>/database?useSSL=true
```



Monitor SSL-enabled MongoDB

You can configure your MongoDB instance to use SSL connections.

1. Create a keystore on the database agent host.
2. Import the SSL certificates to this keystore using the following command:

```
keytool -importcert -trustcacerts -file <mongodb certificate location> -keystore <keystore e.g. path
/mongo.jks> -storepass <keystore password> -alias <alias>
```

3. Start the database agent with the following flags:

```
java -Ddbagent.name=<DBAgent Name> -Djavax.net.ssl.trustStore=<keystore e.g. path/mongo.jks> -Djavax.net.
ssl.trustStorePassword=<keystore password> -jar db-agent.jar
```

4. Create the mongodb collector with custom URL:

```
mongodb://<mongodb-host>:27017/?ssl=true
```

Enable Snapshot Correlation for Oracle

For the Oracle Collector AppDynamics Database Visibility to collect database queries, sessions, clients, and schemas information that occurred during snapshots captured by the Java Agent, you need to set the `jdbc-dbcam-integration-enabled` App Agent property for the Java Agent.

For information on the `jdbc-dbcam-integration-enabled` property, see App Agent Node Properties.

For information on snapshot correlation between the Oracle database Collector and a Java business transaction, see Access Database Visibility from Application Monitoring Views

Increasing JVM Memory

To monitor multiple databases, you may need to increase the JVM memory allocation size. Increased activity on the databases you are monitoring results in increased memory usage.

Use one of the following commands to start the agent, and to initially allocate 1536 MB to the agent instead of the default of 64 MB.

For Windows 64-bit

```
C:\java -Xmx1536m -Djava.library.path="<db_agent_home>\auth\x64" -jar <db_agent_home>\db-agent.jar
```

For Linux

```
% java -Xmx1536m -jar <db_agent_home>/db-agent.jar
```

Database Agent Logging

By default, the Database Agent writes log files to the */log* directory.

Configure Agent Logging

You can configure the agent to generate log files.

1. From the agent home directory, navigate to log directory.
2. Open `log4j.xml`.
3. Find `logger name="com"`. Inside this tag, set `level value` to `debug`, as shown below:

```
<logger name="com">
   <level value="debug"/>
</logger>
```

4. Let the agent run for 10 minutes to generate some logs.
5. From the agent home directory, navigate to the */log* directory to view your logs.

Start and Stop the Database Agent

Start the Agent

If you are using an on-premises version of Database Visibility, you must start the Events Service before you start the Database Agent. Before starting the agent, you must configure the properties in this file. You must specify these properties:

- Controller Host Property
- Controller Port Property
- Account Access Key Property

Start the Agent in a Command Shell

The following assumes that all the necessary parameters have been specified in the `controller-info.xml`. The `controller-info.xml` file describes the properties of agent to Controller communications. Note that `<db_agent_home>` is the absolute path to the location where the Database Agent is installed. Setting the heap size is recommended as shown below. See Database Visibility System Requirements.

Windows

```
cd <db_agent_home>
start-dbagent.bat -Xms<min_heap_size> -Xmx<max_heap_size>
```

Linux

```
cd <db_agent_home>
./start-dbagent -Xms<min_heap_size> -Xmx<max_heap_size> &
```

Start the Agent as a Service

See Install the Database Agent as a Windows Service, Start the Database Agent Automatically on Windows, and Start the Database Agent Automatically on Linux.

Stop the Agent

Stop the Agent in a Command Shell

If the Database Agent process is running in the background, you can stop it by simply entering the kill command with the process ID as the argument. If it is running in the foreground in a console, you can press Ctrl+C to shut down the agent.

Stop the Agent Service in Windows

In the Windows Services application, select **AppDynamics Database Agent** and click **Stop**.

Start the Database Agent Automatically on Linux

Related pages:

- Install the Database Agent
- Database Agent Configuration Properties

To enable the Database Agent to start automatically whenever the machine starts up:

1. Create an initialization script that starts the agent, as in the sample initialization script that is an attachment to this page.

   In your script, set the `JAVA` and `AGENT_HOME` values to the paths for your system. Also, configure agent options and heap size, as needed.

2. Enable execution permissions for the script. For example, given an initialization script named `db-agent`, enter:

   ```
   sudo chmod 775 db-agent
   ```

3. Place the script in the initialization directory on your system, typically `/etc/init.d`. Alternatively, create a symbolic link to the script from the `init.d` directory to the script if you want to keep it in another location.
4. Add the script as a service as follows:

   - For Red Hat and most Linux Operating Systems, run these commands, replacing `db-agent` with the name of your file or symbolic link:

     ```
     chkconfig --add db-agent
     chkconfig --level 2345 db-agent on
     ```

   - For Ubuntu and Debian Operating Systems, run this command, replacing `db-agent` with the name of your file or symbolic link:

     ```
     update-rc.d -f db-agent start 99 2 3 4 5 .
     ```

     In the command:

     - `start` is the argument given to the script (start, stop).
     - 99 is the start order of the script (1 = first one, 99 = last one)
     - 2 3 4 5 are the runlevels to start
     - Be sure to include the dot (.) at the end of the command.

The Database Agent now starts automatically upon machine startup. When setting the agent to automatically start up using Task Scheduler when the machine starts or restarts, ensure the agent runs with the highest privileges available.

Start the Database Agent Automatically on Windows

Related pages:

- Administer the Database Agent
- Database Agent Configuration Properties
- Database Visibility

Most Windows server software runs as a service when the machine boots up. You can create a Windows service to run the Database Agent by executing a script bundled with the product.

Install the Database Agent as a Windows Service

To create the Database Agent as a Windows service, run the following command as an administrator:

```
cscript <db_agent_home>\InstallService.vbs <jvm_options>
```

<db_agent_home> is the path to the install directory.

A Windows service named `Appdynamics Database Agent` is created.

`SilentInstall` and `serviceName` are optional parameters, which can be used along with the preceding command. The following syntax shows how to add these parameters:

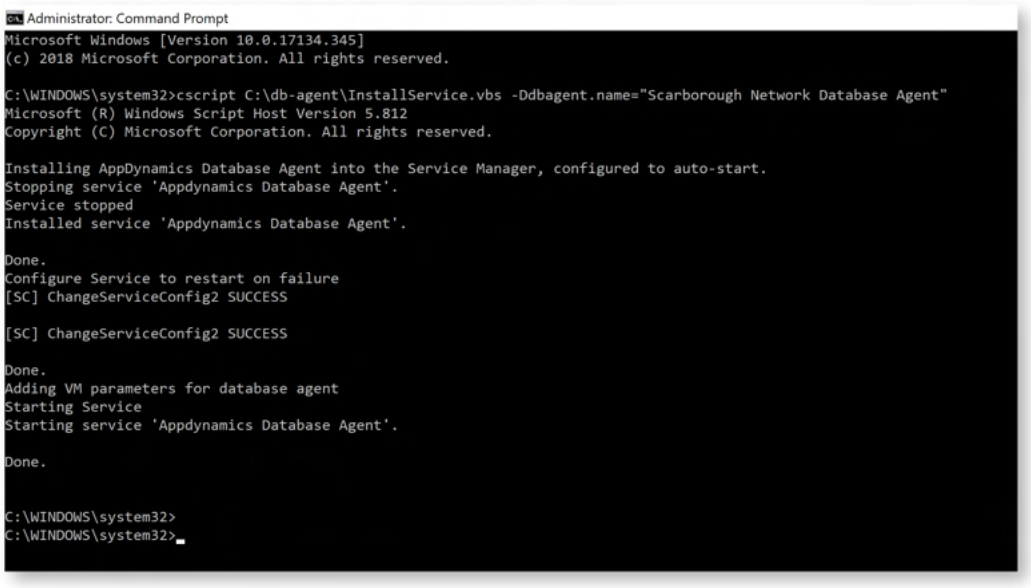
```
cscript <db_agent_home>\InstallService.vbs SilentInstall serviceName=<name_of_the_service> <jvm_options>
```

<db_agent_home> is the path to install directory, and <name_of_service> is the name that you want to use for renaming the service.

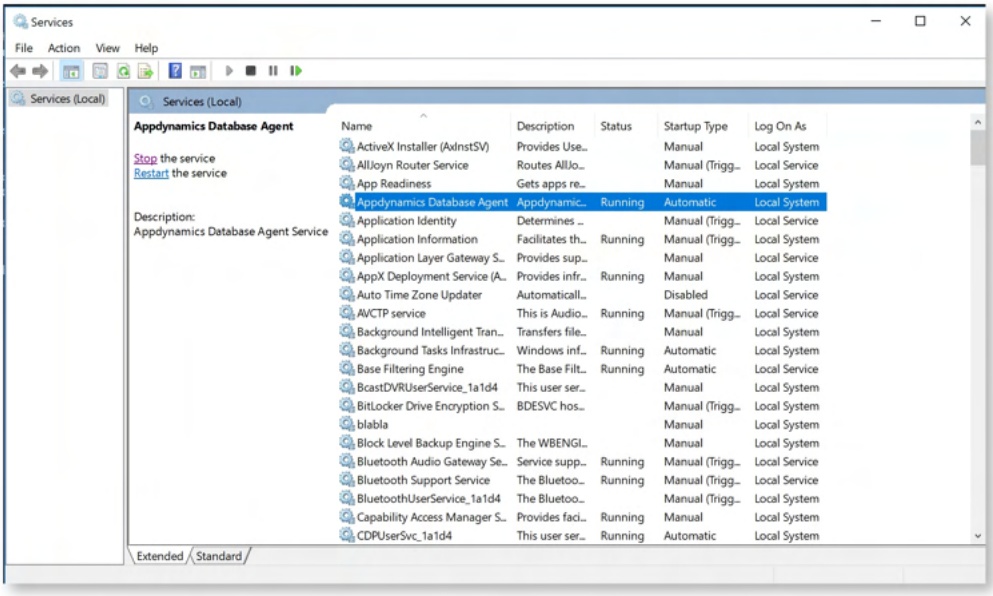
You can use `SilentInstall` to create the Database Agent as a Windows service in the silent mode where the script skips user input for installation.

For database Agent>= 20.5, you can add a service with a different name or change the name of the service by using the `serviceName` parameter. If you do not specify any value for this parameter, the service name is set to `Appdynamics Database Agent` by default.

> To use different Windows service name for different Database Agents, ensure that you run each Database Agent as a service from different install directories.



The screenshot below shows the Windows Service Control Manager.

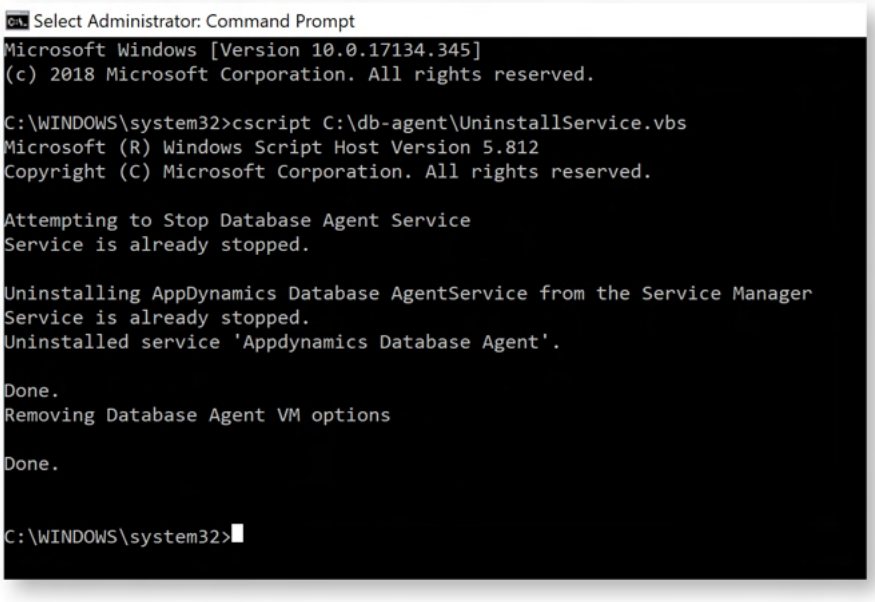


If you choose to use Windows authentication for Microsoft SQL Server, you must change your login credentials and restart the database agent service.

Uninstall the Database Agent as a Service

To uninstall the database agent service, run the following command as an administrator:

```
cscript <db_agent_home>\UninstallService.vbs
```



Running the Agent on Windows Using the Task Scheduler

It is recommended to run the Database Agent as a Windows service. However, if you choose to run the agent using Task Scheduler, ensure the agent runs with the highest privileges available. When using Task Scheduler, if the host is restarted, the agent will not start automatically.

Add Database Licenses

Related pages:

- Add Database Collectors
- License Management in the Controller

The Controller requires a license for the total number of databases to monitor concurrently. For Database Agent license details, see License Entitlements and Restrictions.

Add New Licenses

To add a new license, see Apply or Update a License File.

Manage Licenses in the Controller

To view and manage license consumption in the Controller, see License Management in the Controller.

Transfer a License Between Databases

A database license is allocated to the first agents that register with the Controller up to the licensed limit.

To transfer a license for the Database Agent to another database, you simply remove the Collector for the old database and then add a new Collector for the database you want to monitor instead. See Add Database Collectors.

If you disable a collector, it still consumes a license.

Configure Controller Settings for Monitoring Database

You can configure parameters for the controller, such as the number of events sent to the Events Service at a given time.

To change the Controller settings for Database Agents:

1. Log in to the Administration Console.
2. Click **Controller Settings**.
3. Change the settings as needed and **Save**.

Controller Settings

Property Name	Property Overview	Default	Minimum Value
`dbmon.event.publisher.esclient.batch.size`	Batch size for each Event Service client used by Database Monitoring.	1500	200
`dbmon.event.publisher.queue.size`	Maximum measurement queue size maintained by Database Monitoring.	100000	100000
`dbmon.config.data.retentionperiod`	Number of days to retain database monitoring data (queries, clients, users, sessions, schemas) excluding the current day. Data reported before the retention period might be unrecoverable, even for a momentary update of this property.	10	1
`dbmon.config.max.custommetric`	Number of custom metrics that can be created per collector.	40	0

Configure the Agent Settings for Monitoring Database

This page provides information about the different agent properties that are used for database monitoring. For configuring the basic agent properties, see Database Agent Configuration Properties.

You can update the following properties using the `controller-info.xml` file located in the `<db_agent_home>/conf` directory.

The following table includes the property names that can be used for any specific database or for all the databases along with the purpose of the properties.

Agent Properties for Monitoring Relational Databases

Property Name	Database	Purpose	Default Value
`-Ddbagent.disable.sybase.ase.system.monitoring`	Sybase	This property specifies whether the agent should disable Sybase. You may want to disable Sybase monitoring with Database Visibility if you are already using other tools to monitor Sybase. Refer to Sybase Database Permissions for information on configuring Sybase permissions. If an agent is run with the `-Ddbagent.disable.sybase.ase.system.monitoring` flag, Database Visibility will stop executing `sp_sysmon` for Sybase databases. As a result, the following metrics might not show reliable data: • Calls per Minute (KPI) • All metrics under Server Statistic in the Metric Browser • The Load value on the Sybase dashboard	false
`-Ddbagent.sampling.interval`	All relational database ⓘ This property can be used for MongoDB and Couchbase.	This is the interval at which queries are sampled. The interval can be 1s, 2s, 5s, 10s, 20s, or 30s. For example, if you have configured the property value as 2, **Elapsed Time** is displayed for 2s, 4s, 6s, and so on (in the multiples of 2).	1

Agent properties for monitoring Cassandra

Property Name	Purpose	Default Value
`dbagent.cassandra.sampling.interval.seconds`	The interval at which queries are sampled. According to the sampling interval (between 1 and 60), the sampling threshold is set (between 300 ms and 1000 ms).	10
`dbagent.cassandra.max.query.execution.time.seconds`	Maximum query execution time. Queries executing for more than this duration are not be sampled.	300
`dbagent.cassandra.query.sampling.limit`	The maximum number of queries to sample in a single sampling period. If this value is 0, query sampling is disabled.	100,000
`dbagent.cassandra.dse.skip.slow.query.table.for.sampling`	Whether to use sampling from query traces instead of the node_slow_log table for DSE Cassandra.	false
`dbagent.cassandra.apache.sampling.threshold.in.milliseconds`	Defines the sampling threshold for Apache Cassandra. In other words, queries taking more than this threshold to execute, are sampled by the database agent. ⓘ This property sets a fixed sampling threshold. To use a dynamic sampling threshold based on the sampling interval set a negative value to this property.	-1

Add Database Collectors

To enable the Database Agent to collect data, you must add and configure a Database Collector for each database that you want to monitor. The Database Collector is the process that runs within the Database Agent to collect performance metrics about your database instances and database servers.

Required Database Permissions

You must have the required permissions to monitor your databases. See Database Visibility Supported Environments.

AppDynamics Permissions

To add, edit, and create collectors, users need a role with the proper permissions:

- Can Create Collectors
- Can Edit All Collectors
- Can Delete All Collectors

See Database Permissions.

Add a Database Collector

1. Click the Configuration tab in the left panel menu.
2. Click the **Collectors** option.
3. In the Collectors panel, click **Add** (**+**).
4. Complete each field of the **Create New Collector** dialog
5. If you want to add a sub-collector to be monitored, click **Advanced** >> **+Add sub-collector** to enter host and port details.

   > Sub-collectors are applicable only to relational database types.

6. Click **OK**. Your database administrator can provide you with the necessary details.

After you have added a collector, you can configure the collector for your database. You can also link a database on the application flow maps to a database instance monitored by Database Visibility.

Hardware Monitoring

For information on the fields to complete in order for the Database Agent to monitor the server hardware in addition to the database, see Configure the Database Agent to Monitor Server Hardware.

Verify Collector Setup

Once the Collector is up and running, in just a short time you can start viewing the historical activity data.

The Collector configuration window now has a collector icon you can click to edit the details of the collector if required. The Collector will also appear in the list of Databases shown in the left navigation menu. It might take a few minutes before the Collector and its metrics are reported.

From the left navigation menu, click **Databases** to see a high-level view of the activity of all the configured Collectors.

Click the name of the database to see more details of the metrics AppDynamics Database Monitoring has captured.

For information on using and interpreting the Collector windows, see Monitor Databases and Database Servers.

Edit a Database Collector

From the Collectors panel, you can edit any of the details of the collector except the type of database platform to monitor.

For more information on collector fields, see the collector configuration page for your database.

- Configure IBM DB2 Collectors
- Configure Microsoft SQL Server Collectors
- Configure Microsoft Azure Collectors
- Configure MongoDB Collectors
- Configure MySQL Collectors
- Configure Oracle Collectors
- Configure PostgreSQL Collectors
- Configure Sybase Collectors
- Configure Sybase IQ Collectors

Delete a Database Collector

From the Collectors panel, you can delete a database Collector.

Export Database Collector Data

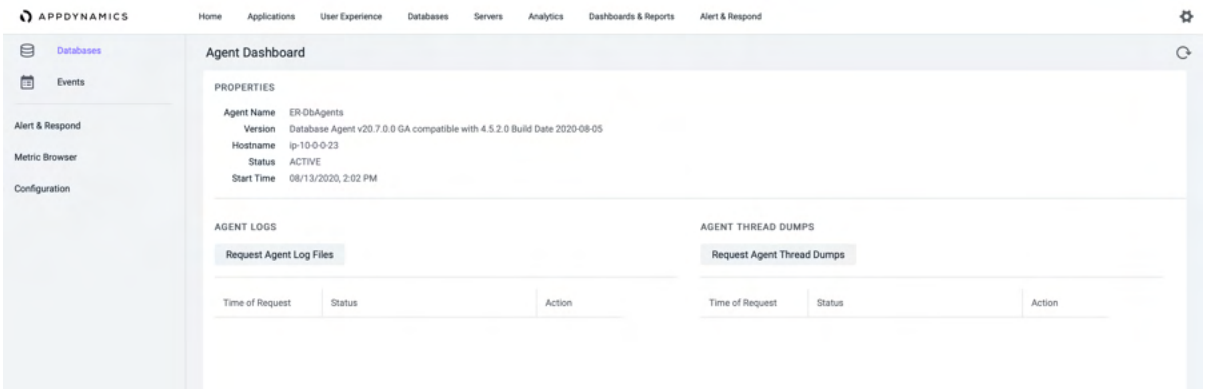
From the Collectors panel, you can click on **Actions** > **Export Data** to generate a CSV file containing the following data for each collector:

- Collector name
- Host name
- Port number
- Username
- Database type
- Agent name

View Database Agent Properties and Logs

You can view the database agent properties along with the agent logs and thread dumps by accessing **Agent Dashboard**. These logs are required for deb ugging and troubleshooting the issues.

To access **Agent Dashboard**, click the agent name under **Agent Name** on the **Collectors** page.



You can click **Request Agent Log files** to either download logs from a specific logger by setting a specific log level for a specific duration or download all logs.

You can click **Request Agent Thread Dumps** to download the required number of thread dumps.

See Agent Log Files and Request Agent Log Files.

Troubleshooting Collector Problems

Collectors that have not been configured correctly, or that cannot connect to the database for any reason, will show an error on the **Databases** overview page and individual database dashboards. Hovering over the error icon displays the potential reason for the error.

If your Collector isn't reporting any metrics after a few minutes, and you know the database is up and running with activity, check the **Events** panel. Agent Diagnostic Events can appear if the password is incorrect or communication errors have occurred. The message summaries on the **Events** panel can help you diagnose and troubleshoot Collector problems.

Check the collector configuration to ensure all the values you entered are correct.

Ensure that your Database Agent has network connection to the databases you want to monitor along with the required permissions. See Database Monitoring Requirements and Supported Environments.

Configure Cassandra Collectors

This page provides configuration details for Cassandra collectors.

Prerequisites

To monitor Cassandra with Database Visibility, you must be running version:

- Apache Cassandra >= 3.11.4
- Datastax Enterprise (DSE) Cassandra >= 6.7.3

Connection Details

	Field	Description
Create New Collector	Database Type	The Database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent.
	JMX Port	The port to remotely connect through JMX (optional for DSE Cassandra). See JMX Configurations.
	JMX Username	The name of the JMX user who is connecting to and monitoring the database using the Database Agent. See JMX configurations.
	JMX Password	The password of the JMX user who is connecting to and monitoring the database through the Database Agent.
Username and Password	Username	The name of the user who is connecting to and monitoring the database using the Database Agent. The user must have the permissions described in: • User Permissions for Apache Cassandra • User Permissions for DSE Cassandra
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
Advanced Options	SSL Connection	Click to enable SSL Connection: • Truststore Location: Location of the certificate on the DB Agent host. • Truststore Type: Type of SSL Connection. There are two `truststore` types: **PKCS12** (default) **SSO**: Enables auto-login. If you use SSO, you only need to provide the `truststore` location and `truststore` type • Truststore Password: Password for SSL Connection. If you also use client certificate authentication, then click the **Enable SSL Client Authentication** box. • Keystore Location: location of the certificate on the DB Agent host • Keystore Type: type of SSL Connection • Keystore Password: password for SSL Connection
	Monitor Operating Systems	See Configure the Database Agent to Monitor Server Hardware.

Cassandra Configurations

These are the required configurations:

- **Query Capture Configurations**
  - Apache Cassandra
  - DSE Cassandra
- **JMX Configurations for Apache/DSE Cassandra**

a. Open `cassandra-env.sh` file.
b. To enable JMX for:
    i. local connection, under the if *["$LOCAL_JMX" = "yes"];* then statement, set:

```
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.authenticate=true"
```

    ii. for remote connection, under the corresponding else statement, set:

```
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.authenticate=true"
```

c. Set the path to the credentials file, `jmxremote.password`:

```
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.password.file=PATH TO FILE"
```

d. In the `jmxremote.password` file, set JMX credentials to be the same as that of the database user credentials to be specified in the collector configuration:

```
username password
```

You may choose to give ReadOnly JMX access to the database monitoring user by defining in the `jmxremote.access` file as mentioned in Enabling JMX authentication and authorization.

Database Column Families Panel

To see the Top N Queries run on a column family, double-click or single-click the column family, and then click **View Top Queries**. For more details about a query, double-click a query to open the **Query Details** panel.

Access the Column Lists Panel

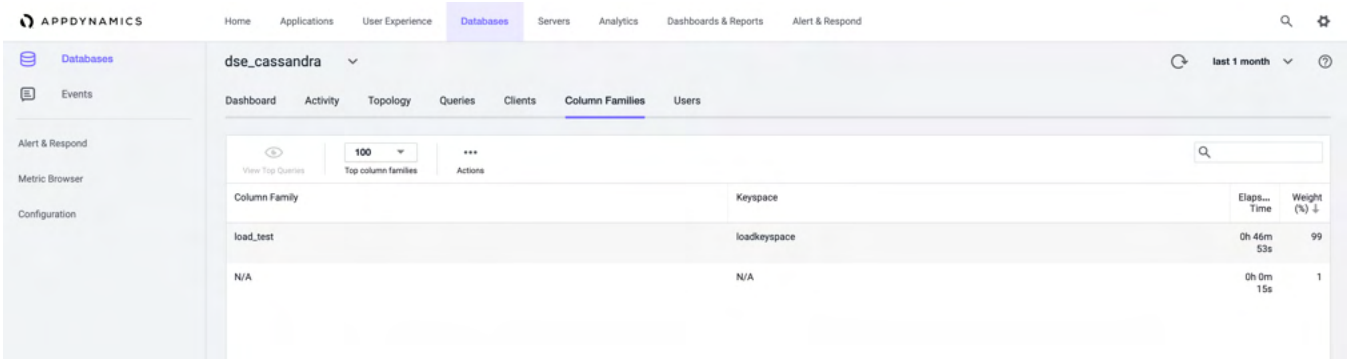
To access the **Column Lists** panel:

1. Click the name of the database from the list.
2. Click the Column Families tab. You may have to click the expand button (**>>**) to see the tab. Use the **Top column families** dropdown to view information for the top 10, 50, 100 or 200 column families sorted by total time spent in the database.

Features of the Column Families Panel

On the **Database Column Families** panel, you can see this information:

- **Column Family**: The names of the column families on which queries have been executed in this database.
- **Keyspace**: The names of the keyspaces on which queries have been executed in this database.
- **Elapsed Time**: Duration of time queries executed in the column family.
- **Weight (%)**: Time spent on executing queries on column families as a percentage of the total time spent by all column families.



Click **Actions** to export the data on this panel in a `.csv` formatted file that is automatically downloaded to your specified downloads directory.

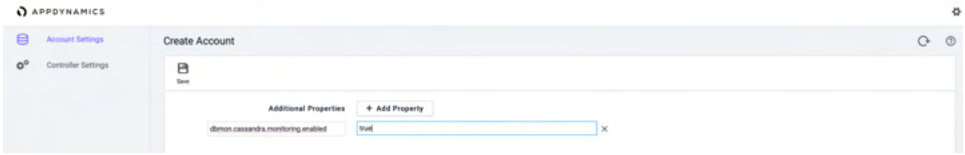
Enable Cassandra Monitoring

Before you can enable Cassandra monitoring, you must meet these requirements:

- Controller >= 4.5.17
- Database Agent >= 4.5.16
- Set the account level property to "`dbmon.cassandra.monitoring.enabled`":

To enable Cassandra monitoring :

1. Go to `<controller_url>/admin.jsp`, then click **Account Settings**. A list of accounts display.
2. Select an account from the list of options to enable Cassandra monitoring, then click **Edit**.
3. Click **+ Add Property**. Two blank fields display.
4. Enter `dbmon.cassandra.monitoring.enabled` and `true` in the first and second blank fields, respectively.



5. Select **Save**.

Query Capture Configurations for Apache Cassandra

The Database Agent captures only traced queries. To enable query tracing:

1. Turn on tracing in the CQLSH prompt
2. Enable tracing for the statement/prepared statement in the client application
3. Enable probabilistic tracing

Add this configuration to the `cassandra.yaml` file:

```
# TTL for different trace types used during logging of the repair process.
tracetype_query_ttl: 300
```

This reduces the persistence of entries in `system_traces keyspace` (sessions and events) from 24 hours to 30 minutes. You may allow longer retention based on the number of queries being traced.

User Permissions for Cassandra

These are the user permissions to configure Cassandra:

```
CREATE ROLE appdynamics_role;
GRANT SELECT ON KEYSPACE system_traces TO appdynamics_role;
GRANT appdynamics_role TO appdynamics;
```

Query Capture Configurations for DSE Cassandra

In the `dse.yaml` file, configure (or uncomment and edit) these parameters:

```
cql_slow_log_options:
    enabled: true
    #  When t > 1, log queries taking longer than t milliseconds.
    #      0 <= t <= 1,  log queries above t percentile
    threshold: 2000
    # Initial number of queries before percentile filter becomes active
    minimum_samples: 100
    ttl_seconds: 259200
     # Keeps slow queries in-memory only and doesn't write data to the database.
    # WARNING - if this is set to 'false' then set threshold >= 2000, otherwise there will be a
    # high load on the database.
    skip_writing_to_db: false
    # The number of slow queries to keep in-memory
    num_slowest_queries: 5
```

You can adjust all of these parameters, except "`enabled`" and "`skip_writing_to_db`", per the monitoring requirements.

User Permissions for DSE Cassandra

```
CREATE ROLE appdynamics_role;
GRANT SELECT ON KEYSPACE system_traces TO appdynamics_role;
GRANT SELECT ON TABLE dse_perf.node_slow_log TO appdynamics_role;
GRANT appdynamics_role TO appdynamics;
```

Configure Couchbase Collectors

To monitor Couchbase with Database Visibility, you must have:

- Couchbase >= 4.5
- Database Agent >= 4.5

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for Couchbase.
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
Advanced Options	Exclude Databases	The databases that you want to exclude, separated by commas.
	Monitor Operating Systems	See this page for more details, Configure the Database Agent to Monitor Server Hardware.

User Permissions for Couchbase

The monitoring user must have Full Administrator or Read-only Administrator privileges. Alternatively, if you do not want the monitoring user to have Administrator privileges, you can assign a combination of Data Monitoring and Query System Catalog privileges (available for Couchbase >= 5).

Configure IBM DB2 Collectors

This page describes configuration details for IBM DB2 collectors.

> **Prerequisites**
>
> To monitor IBM DB2 with Database Visibility, you must be running DB2 >= 9.x.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Database	The name of the database instance that you want to monitor. If the database instance hosts multiple databases, ensure to create separate collector for each database.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent.
	Custom JDBC Connection String	The JDBC connection string generated by the database agent, for example, `jdbc:db2://`. You can also specify a custom connection string, which is useful for setting custom authentication options. If you are using the connection string for Kerberos authentication, ensure to select the **Kerberos** option under **Advanced Options**.
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for IBM DB2 LUW.
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
	Cyberark	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the `JavaPasswordSDK.jar` file from the CyberArk web site and rename the file to `cyberark-sdk-9.5.jar`. Then, you must copy the JAR file to the lib directory of the database agent zip file.
Advanced Options	Sub-Collectors	Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. To monitor a custom cluster, you can add additional hostname or IP address, and port details for each sub-collector. You can add up to a total of 29 sub-collectors. Thereby, 30 databases can be monitored in a custom cluster. In addition to the licenses consumed by the main collector, each sub-collector consumes one or more licenses, depending on the database type. **Note** • All connection parameters other than the hostname or IP address, and port details of the sub-collector are the same as the main collector. If you want to specify different parameters for the sub–collectors, while creating or editing the collector configuration, you can do that only through the Create Collector API. • You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data.

	Connection Properties	Click to add a new JDBC connection property or edit an existing property for relational databases. For monitoring the database using Kerberos authentication, follow the instructions mentioned at Monitor IBM DB2 Databases Using Kerberos Authentication.
	Kerberos	Click to use Kerberos authentication to manage the database user and host user passwords.
	Monitor Operating System	See Configure the Database Agent to Monitor Server Hardware.

User Permissions for IBM DB2 LUW

The monitoring user needs SYSMON authority and connection privileges to monitor. This user must be a part of the sysmon_group.

To generate an execution plan, you must create the associated EXPLAIN tables in the schema.

DB2 >= 9.7

For complete Database Visibility functionality, the following monitoring switches of the DB2 server need to be enabled: "TIMESTAMP".

To enable the "TIMESTAMP" monitoring switch, enter:

```
update dbm cfg using dft_mon_timestamp on;
update db cfg using mon_act_metrics BASE
```

Privileges

```
grant select on SYSIBMADM.MON_CURRENT_SQL to user DBMon_Agent_User
grant select on SYSIBMADM.MON_LOCKWAITS to user DBMon_Agent_User
grant execute on function SYSPROC.MON_GET_CONNECTION to user DBMon_Agent_User
grant execute on function SYSPROC.MON_GET_PKG_CACHE_STMT to user DBMon_Agent_User
(version 10.5 and above) grant execute on function SYSPROC.MON_GET_TRANSACTION_LOG to DBAgent_User
(version 10.5 and above) grant execute on function SYSPROC.MON_GET_DATABASE to DBAgent_User
```

Replace `DBMon_Agent_User` with the user name under which you run the Database Visibility Agent.

DB2 9.5

For complete Database Visibility functionality, the following monitoring switches of the DB2 server need to be enabled: "STATEMENT", and "TIMESTAMP".

To enable these monitoring switches, enter:

```
update dbm cfg using dft_mon_stmt on;
update dbm cfg using dft_mon_timestamp on;
```

Privileges

```
grant select on SYSIBMADM.SNAPSTMT to user DBMon_Agent_User
grant select on SYSIBMADM.SNAPAPPL_INFO to user DBMon_Agent_User
grant select on table SYSIBMADM.ENV_PROD_INFO to user DBMon_Agent_User
```

where `DBMon_Agent_User` is the user name under which you run the Database Visibility Agent.

User Permissions When restrict_access is Set to YES

If your database has the `restrict_access` parameter set to YES, you must grant these privileges:

```
grant select on SYSIBMADM.MON_CURRENT_SQL to user DBMon_Agent_User;
grant select on SYSIBMADM.MON_LOCKWAITS to user DBMon_Agent_User;
grant execute on function SYSPROC.MON_GET_CONNECTION to user DBMon_Agent_User;
grant select on SYSIBMADM.SNAPAPPL_INFO to user DBMon_Agent_User;
grant EXECUTE on function SYSPROC.MON_GET_PKG_CACHE_STMT to user DBMon_Agent_User;
grant execute on function SYSPROC.MON_GET_TRANSACTION_LOG to user DBMon_Agent_User;
grant EXECUTE on package NULLID.SQLC2K26 to user DBMon_Agent_User;
grant select on SYSIBM.SYSDUMMY1 to user DBMon_Agent_User;
grant select on SYSIBMADM.ENV_PROD_INFO to user DBMon_Agent_User;
grant select on SYSIBMADM.ENV_SYS_RESOURCES to user DBMon_Agent_User;
grant execute on function SYSPROC.SNAP_GET_STMT(varchar(),Integer) to user DBMon_Agent_User;
grant select on SYSCAT.STATEMENTS to user DBMon_Agent_User;
grant select on SYSIBMADM.DBCFG to user DBMon_Agent_User;
grant execute on function SYSPROC.SNAP_GET_DB(varchar(),Integer) to user DBMon_Agent_User;
grant EXECUTE on package NULLID.SYSSH200 to user DBMon_Agent_User;
grant select on SYSIBMADM.ENV_SYS_RESOURCESto user DBMon_Agent_User;
grant select on SYSCAT.DBAUTH to user DBMon_Agent_User;
grant execute on function SYSPROC.SNAP_GET_DBM(Integer) to user DBMon_Agent_User;
grant select on syscat.schemata to user DBMon_Agent_User;
```

Replace `DBMon_Agent_User` with the user name under which you run the Database Visibility Agent.

Generate Execution Plans

To generate an execution plan in DB2, the monitoring user ID must have access to the explain_* tables.

1. Create the explain tables one of theses methods:

    - Call the `SYSPROC.SYSINSTALLOBJECTS procedure:{{}}`

      ```
      {{db2 CONNECT TO database-name
      db2 }}

      {{CALL SYSPROC.SYSINSTALLOBJECTS('EXPLAIN', 'C',
      CAST (NULL AS VARCHAR(128)), CAST (NULL AS VARCHAR(128)))}}
      ```

This call creates the explain tables under SYSTOOLS schema. To create them under a different schema, specify a schema name as the last parameter in the call.

    - Run the `EXPLAIN.DDL command file:{{}}`

      ```
      {{db2 CONNECT TO database-name
      db2 -tf EXPLAIN.DDL}}

      {{}}
      ```

Explain plans will not function properly unless the monitoring user ID is granted SELECT privilege on every table being accessed in the SQL as well as the necessary explain_* tables.

Monitor IBM DB2 Databases Using Kerberos Authentication

For the Database Agent to connect to and monitor the DB2 databases using Kerberos authentication, these settings are required:

- Start the Database Agent using the `Djava.security.krb5.conf="<path of the Kerberos configuration file>"`:

  ```
  nohup java -Djavax.security.krb5.conf="<path to Kerberos configuration file>"
  ```

- In the **CONNECTION DETAILS** section of the Collector configuration dialog, specify **Hostname or IP Address**, **Database**, **Listener Port**, and **Custom JDBC Connection String** with Kerberos details:

  ```
  jdbc:DB2:Tds:<hostname>:<portnum>?<Kerberos connection details>
  ```

- In the **ADVANCED OPTIONS** section of the Collector configuration dialog, ensure to provide these details:

  - Select **Kerberos**.
  - Select **Connection Properties**, then specify these JDBC connection properties:

Property Name	Property Value
securityMechanism	11
kerberosServerPrincipal	<Specify the name of the Kerberos Principal>

Configure Microsoft SQL Server Collectors

This page provides configuration details for Microsoft SQL Server collectors.

Prerequisites

To monitor Microsoft SQL Server with Database Visibility, you must be running the 2005 version or newer.

To configure an Azure SQL Managed instance, follow the configuration procedures of a Microsoft SQL Server Collector described in this topic.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on. To monitor a cluster, specify the hostname or IP address of the listener of the cluster. See Monitor the Microsoft SQL Server Cluster to enable monitoring the MSSQL cluster.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent. If you are using a Microsoft SQL Server cluster, specify the listener port of the cluster. To enable monitoring of all the nodes in a cluster, you must enable the monitoring of the cluster. This allows the agent to automatically discover all the nodes present in a cluster. See Monitor the Microsoft SQL Server Cluster
	Windows Authentication	Click to enable Windows authentication when connecting to the database.
	Custom JDBC Connection String	The JDBC connection string generated by the database agent, for example, `jdbc:sqlserver://`. You can also specify a custom connection string, which is useful for setting custom authentication options.
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for Microsoft SQL Server.
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
	CyberArk	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the `JavaPasswordSDK.jar` file from the CyberArk web site and rename the file to `cyberark-sdk-9.5.jar`. Then, you must copy the JAR file to the `lib` directory of the database agent zip file.

Advanced Options	Sub-Collectors	Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. To monitor a custom cluster, you can add additional hostname or IP address, and port details for each sub-collector. You can add up to a total of 29 sub-collectors. Thereby, 30 databases can be monitored in a custom cluster. In addition to the licenses consumed by the main collector, each sub-collector consumes one or more licenses, depending on the database type. **Note** • All connection parameters other than the hostname or IP address, and port details of the sub-collector are the same as the main collector. If you want to specify different parameters for the sub–collectors, while creating or editing the collector configuration, you can do that only via the Create Collector API. • You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data.
	Connection Properties	Click to add a new JDBC connection property or edit an existing property for relational databases.
	Exclude Databases	The databases that you want to exclude, separated by commas.
	Monitor Operating System	See this page for more details, Configure the Database Agent to Monitor Server Hardware.

Note

To handle High Availability (Multi-AZ) for Amazon RDS, set the databaseName JDBC connection string property to a user database.

Monitor Microsoft SQL Server

You can monitor the SQL Server either using an existing user account or by creating a new user account, with relevant privileges.

Monitor the Microsoft SQL Server Cluster

You can monitor all the nodes in the availability group of an MSSQL database server 2012 or later.

To enable monitoring of all the nodes, you must enable the `dbagent.mssql.cluster.discovery.enabled` property either at the Controller level or at the agent level.

This property is disabled by default.

Authentication Methods

You can monitor the SQL server using either of the following authentication methods:

- Windows authenticated account (if the Database Agent is running on Windows)
- SQL Server authenticated account (if the Database Agent is running on Windows or Linux)

Before you Begin

To connect to the SQL Server database using a Windows authenticated account, perform the following:

Select **Windows Authentication** checkbox when creating the collector using "Create New Collector" dialog.

Note

Do not specify the username and password when updating database connection details.

Specify the path to the Database Agent authentication library as follows:

Version Details	Path

Windows 64-bit	`java -Djava.library.path="C:\dbagent_install_dir\auth\x64" -jar db-agent.jar`
Windows 32-bit	`java -Djava.library.path="C:\dbagent_install_dir\auth\x86" -jar db-agent.jar`

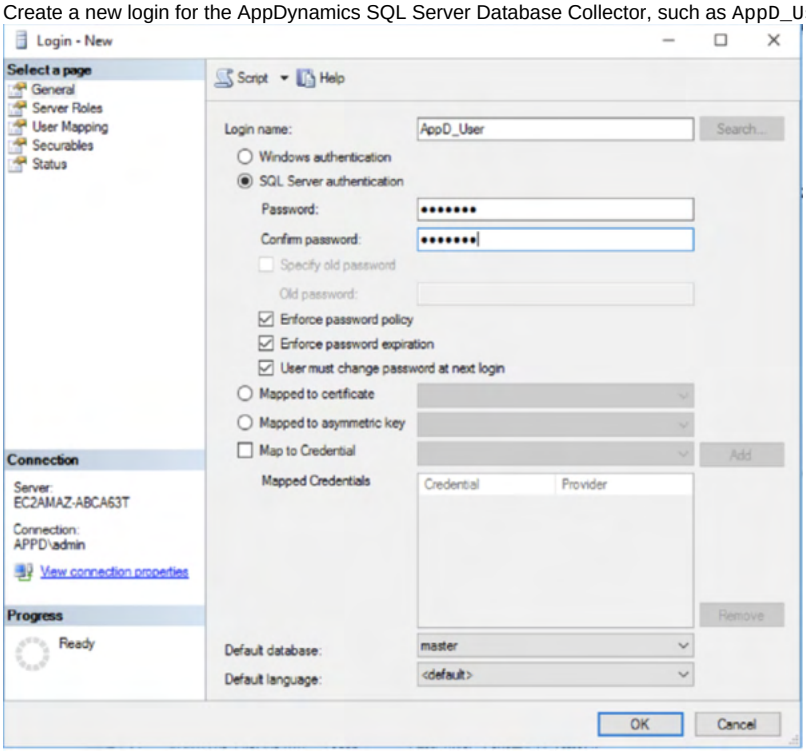
Ensure that the Windows account user has appropriate privileges to authenticate the database server and can start the database agent.

Change the logon credentials of the service to the Windows account with SQL Server access, if using a Windows service to run the Database Agent.

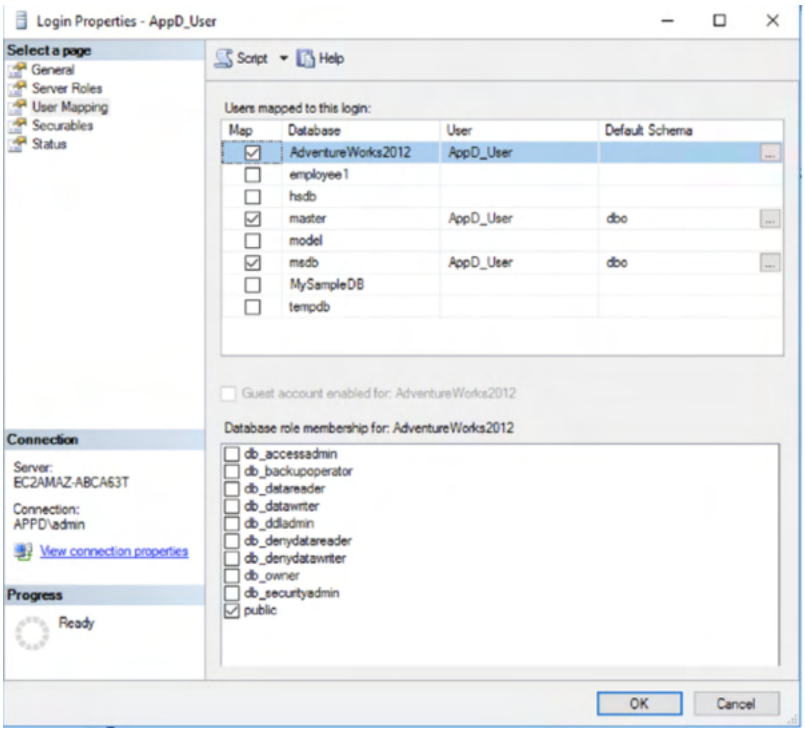
Server Level Permissions for SQL Server Logon

To create a new SQL Server user (with minimum permissions required to monitor), perform the following steps:

1. Create a new login for the AppDynamics SQL Server Database Collector, such as `AppD_User`, using SQL Server Management Studio (SSMS).



2. To map the new user to "master" and "msdb" databases, click "master" and "msdb" under **Users mapped to this login**.



> User mapping to "master" and "msdb" are mandatory for monitoring. To view object information in the Object Browser screens, additional mapping to other databases is required.

3. After creating the login, grant the following privileges to the user by substituting `AppD_User` with the name you specified on the Login - New window:

```
use master
GRANT VIEW ANY DATABASE TO AppD_User;
GRANT VIEW ANY definition to AppD_User;
GRANT VIEW server state to AppD_User;
GRANT SELECT ON [sys].[master_files] TO AppD_User;
```

Optional Object Permissions for SQL Server

The following object permissions are required for optional screens within the Database (DB) Visibility user interface:

Screen	Object Permissions
Object Browser > Users	`GRANT execute on sp_helplogins to AppD_User;` **Note** securityAdmin role is required
Object Browser > Storage	To view object storage metadata, user mapping to other databases of interest is required. **Note** public role is required

Object Browser > Job Status	``` use msdb GRANT SELECT on dbo.sysjobsteps TO AppD_User; GRANT SELECT on dbo.sysjobs TO AppD_User; GRANT SELECT on dbo.sysjobhistory TO AppD_User; ```
Object Browser > Error Log	``` GRANT execute on sp_readErrorLog to AppD_User; ``` **Note** securityAdmin role required
Object Browser > Database	To view object storage metadata, user mapping to other databases of interest is required e.g. Table/View metadata. **Note** public role required. Following image shows how users are mapped to AdventureWorks2012 database: 
Microsoft SQL Server on AWS RDS Permissions

The user account used for monitoring can be a Windows authenticated account (if the Database Agent is running on Windows) or SQL Server authenticated (if AppDynamics Database Visibility is running on Windows or Linux).

Minimum Permissions Required for SQL Server Logon

You can use the procedure to create a SQL Server user with the minimum permissions required.

Use the following to create a SQL Server logon user that provides the minimal level of permissions required in order to gain full AppDynamics Database Visibility/SQL Server functionality.

1. Using SQL Server Management Studio, create a new login for the AppDynamics SQL Server Database Collector, such as `DBMon_Agent_User`.
2. From the User Mapping tab, map the new user to the master and msdb databases.

   Viewing Object Information

   To view object information on the **Database > Objects Browser**, map the monitoring user to the databases of interest.

3. Once you have created the login, give the following privileges to the user, substituting `DBMon_Agent_User` with the name you specified on the **Login - New** panel:

You can execute the following as a batch from a query window in Management Studio. The example shows grants to `DBMon_Agent_User`; remember to change this if you have set up a different login.

```
use master
ALTER SERVER ROLE processadmin ADD MEMBER DBMon_Agent_User;
GRANT VIEW ANY DATABASE TO DBMon_Agent_User;
GRANT VIEW ANY definition to DBMon_Agent_User;
GRANT VIEW server state to DBMon_Agent_User;
```

where `DBMon_Agent_User` is the name of the SQL Server user account specified in **Create New Collector, Connection Details, Username** field.
To generate an execution plan on AWS RDS, you need additional permissions. The SHOWPLAN permission must be provided explicitly for each database:

```
USE <DB NAME>
go
GRANT SHOWPLAN to DBMon_Agent_User;
go
```

Configure Microsoft Azure Collectors

To monitor Microsoft Azure with Database Visibility, you must run Microsoft Azure >= 2008.

> To configure an Azure SQL Managed Instance, follow the configuration procedures of a Microsoft SQL Server Collector. See Configure Microsoft SQL Server Collectors.
>
> Procedures in this page are specific to an Azure SQL Database collector and **not** applicable for an Azure SQL Managed Instance.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Database	The name of the database instance that you want to monitor.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent
	Custom JDBC Connection String	The JDBC connection string generated by the database agent. You can also specify a custom connection string, which is useful for setting custom authentication options.
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for Microsoft Azure.
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
	CyberArk	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the `JavaPasswordSDK.jar` file from the CyberArk web site and rename the file to `cyberark-sdk-9.5.jar`. Then, you must copy the JAR file to the `lib` directory of the database agent zip file.
Advanced Options	Sub-Collectors	Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. To monitor a custom cluster, you can add additional hostname or IP address, and port details for each sub-collector. You can add up to a total of 29 sub-collectors. Thereby, 30 databases can be monitored in a custom cluster. In addition to the licenses consumed by the main collector, each sub-collector consumes one or more licenses, depending on the database type. **Note** • All connection parameters other than the hostname or IP address, and port details of the sub-collector are the same as the main collector. If you want to specify different parameters for the sub–collectors, while creating or editing the collector configuration, you can do that only via the Create Collector API. • You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data.
	Connection Properties	Click to add a new JDBC connection property or edit an existing property for relational databases.

	Monitor Operating System	See this page for more details, Configure the Database Agent to Monitor Server Hardware.

User Permissions for Microsoft Azure

The user account used for monitoring can be a Windows authenticated account (if the Database Agent is running on Windows) or an SQL Server authenticated account (if AppDynamics Database Visibility is running on Windows or Linux).

Minimum Permissions Required for SQL Server Logon

You can create an SQL Server authenticated login or user with minimal level of permissions. To create a SQL Server login, you must be connected to the primary database from an admin account through SQL Server Management Studio (SSMS) or SQL Editor.

1. Run the command given below to create a login. Specify a secure password in the command.

   ```
   CREATE LOGIN DBMon_Agent_User WITH PASSWORD = 'Password123'
   ```

2. Run the following command in your Azure SQL database to create a user account for the newly created login:

   ```
   CREATE USER DBMon_Agent_User FOR LOGIN DBMon_Agent_User WITH DEFAULT_SCHEMA = dbo
   ```

3. While connected to your Azure SQL database, run the command given below to grant the pre-requisite roles and privileges:

   ```
   grant VIEW DATABASE STATE to DBMon_Agent_User
   ```

Configure MongoDB Collectors

To monitor MongoDB with Database Visibility, you must run MongoDB >= 2.2.

If you are configuring a collector for a MongoDB cluster, you only need to configure one collector for the entire cluster. You can choose any node in the cluster to connect to, and the entire cluster will automatically be detected.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent
	Custom Connection String	The connection string generated by the database agent. You can also specify a custom connection string, which is useful for setting custom authentication options. Ensure that you do not specify the username and password in the custom connection string because it can cause a security risk.
	SRV Record	Enable this field to use the SRV record, where the connection string includes `mongodb+srv`.
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for MongoDB.
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
	CyberArk	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the `JavaPasswordSDK.jar` file from the CyberArk web site and rename the file to `cyberark-sdk-9.5.jar`. Then, you must copy the JAR file to the `lib` directory of the database agent zip file.
Advanced Options	Exclude Databases	The databases that you want to exclude, separated by commas.
	Monitor Operating System	See Configure the Database Agent to Monitor Server Hardware.

When configuring the collector, ensure that you encode the username and password that uses special characters.

User Permissions for MongoDB

For MongoDB < 2.6.*x*, the readAnyDatabase and ClusterMonitor built-in roles are required to monitor using AppDynamics Database Visibility. For MongoDB shared clusters, the monitoring user must have access to all shards.

For MongoDB >= 2.6, the `clusterMonitor` built-in role in addition to read is required.

If you choose to create a new user to monitor MongoDB, the user must be created in the admin database.

You can configure user roles as shown in the sample query below:

```
use admin
db.createUser({ user: "tanujaAdmin",
pwd: "tanuja123",
    roles: [
        { role: "clusterMonitor", db: "admin" },
          { role: "read", db: "admin" },
    ]
})
```

Configure MySQL Collectors

To monitor MySQL with Database Visibility, you must run MySQL >= 2.2.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent
	Custom JDBC Connection String	The JDBC connection string generated by the database agent, for example, `jdbc:mysql://`. You can also specify a custom connection string, which is useful for setting custom authentication options.
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for MySQL.
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
	CyberArk	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the JavaPasswordSDK.jar file from the CyberArk web site and rename the file to cyberark-sdk-9.5.jar. Then, you must copy the JAR file to the lib directory of the database agent zip file.
Advanced Options	Sub-Collectors	Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. To monitor a custom cluster, you can add the additional hostname or IP address, and port details for each sub-collector. You can add up to a total of 29 sub-collectors. Thereby, 30 databases can be monitored in a custom cluster. In addition to the licenses consumed by the main collector, each sub-collector consumes one or more licenses, depending on the database type. **Note** • All connection parameters other than the hostname or IP address, and port details of the sub-collector are the same as the main collector. If you want to specify different parameters for the sub–collectors, while creating or editing the collector configuration, you can do that only via the Create Collector API. • You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data.
	Connection Properties	Click to add a new JDBC connection property or edit an existing property for relational databases.
	Exclude Databases	The databases that you want to exclude, separated by commas.
	Monitor Operating System	See Configure the Database Agent to Monitor Server Hardware.

User Permissions for MySQL

The MySQL user the Database Agent uses to monitor the MySQL database must have "SELECT", "PROCESS", and "SHOW DATABASES" privileges on all databases.

The user must also have the "REPLICATION CLIENT" privilege to collect these metrics:

- Slave_io_running
- Slave_sql_running
- Seconds_behind_master
- SQL_Delay

If you do not have a suitable existing user, you can use the command below to create a new user.

```
GRANT SELECT,PROCESS,SHOW DATABASES on *.* to 'DBMon_Agent_User'@'host' identified by 'password';
GRANT REPLICATION CLIENT ON *.* to 'DBMon_Agent_User'@'host';
FLUSH privileges;
```

Substitute `DBMon_Agent_User` with the username under which you run the Database Visibility Agent. Substitute `host` with the hostname or IP address of the machine running the AppDynamics Database Agent, and substitute `password` with a secure password.

Set the `max_allowed_packet` parameter to 1073741824 on the server.

Troubleshooting MySQL Permissions

View MySQL Error Logs

To view the error log file, these conditions must be met:

- `secure_file_priv` is either empty or the name of the folder containing the error log file. You must restart MySQL for changes in the `secure_file_priv` variable to take effect.
- The error log file is readable to all users.
- `max_allowed_packet` is larger than the error log file size.
- The user has FILE privileges.

Configure Oracle Collectors

To monitor Oracle with Database Visibility, you must be running Oracle 10g or newer.

If you are configuring a collector for Oracle RAC, you only need to configure one collector for the entire cluster. You can choose any node in the cluster to connect to, and the entire cluster will automatically be detected.

If you are using Oracle 12c as PDB, the query for system metrics is available from Oracle Database 12c Release 2 (12.2.0.1) onwards. See the Oracle documentation for more information.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent
	SID or Service Name	The SID or service name of the Oracle instance you want to monitor. For CDB (container database) monitoring, provide the CDB service name and for PDB (pluggable database) monitoring, provide the PDB service name. For PDB (pluggable database) monitoring, the service name must be present in all the nodes that have PDB so that all the nodes get monitored.
	Custom JDBC Connection String	The JDBC connection string generated by the database agent, for example, `jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=`. You can also specify a custom connection string, which is useful for setting custom authentication options. When using connection string for Kerberos, ensure that you select the **LDAP/Kerberos** option under **Advanced Options**.
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for Oracle.
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
	Cyberark	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the JavaPasswordSDK.jar file from the CyberArk web site and rename the file to cyberark-sdk-9.5.jar. Then, you must copy the JAR file to the lib directory of the database agent zip file.
Advanced Options	Sub-Collectors	Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. To monitor a custom cluster, you can add additional hostname or IP address, and port details for each sub-collector. You can add up to a total of 29 sub-collectors. Thereby, 30 databases can be monitored in a custom cluster. In addition to the licenses consumed by the main collector, each sub-collector consumes one or more licenses, depending on the database type. **Note** • All connection parameters other than the hostname or IP address, and port details of the sub-collector are the same as the main collector. If you want to specify different parameters for the sub–collectors, while creating or editing the collector configuration, you can do that only via the Create Collector API. • You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data.

Connection Properties	Click to add a new JDBC connection property or edit an existing property for relational databases. For monitoring the database using Kerberos authentication, follow the instructions mentioned at Monitor Oracle Databases Using Kerberos Authentication.
Exclude Schemas	The schemas that you want to exclude, separated by commas.
SSL Connection	Click to enable the SSL connection. You can use SSL Connection for authentication and signing credentials. • Truststore Location: location of the SSL certificate that is stored on the DB Agent host • Truststore Type: type of truststore used for SSL certificate. There are two truststore types: **PKCS12** (default) **SSO**: enables auto-login. If you use SSO, you only need to provide the truststore location and truststore type. • Truststore Password: password for SSL certificate. If the SSL_CLIENT_AUTHENTICATION parameter is set to true in listener.ora and sqlnet.ora, then click the Enable SSL Client Authentication box. • Keystore Location: location of the SSL certificate on the DB Agent host • Keystore Type: type of SSL certificate • Keystore Password: password of SSL certificate
LDAP/Kerberos	Use LDAP/Kerberos authentication to manage the database user and the host user passwords.
Monitor Operating System	See this page for more details, Configure the Database Agent to Monitor Server Hardware.

User Permissions for Oracle

For versions of Oracle 10g and later

The following permissions are required for the Oracle user:

- CREATE SESSION
- SELECT_CATALOG_ROLE

To create a user with these permissions, you can run the following SQL. In this SQL, change "password" to a safe and secure password, and change the tablespace names, "users" and "temp" to those available in your Oracle instance.

```
CREATE USER DBMon_Agent_User IDENTIFIED BY password
default tablespace users
temporary tablespace temp;

GRANT CREATE SESSION, SELECT_CATALOG_ROLE TO DBMon_Agent_User;
```

where DBMon_Agent_User is the user name under which you run the Database Visibility Agent.

For versions of Oracle 12c and later with Multitenant Container Database Option enabled

The following permissions are required for the Oracle user:

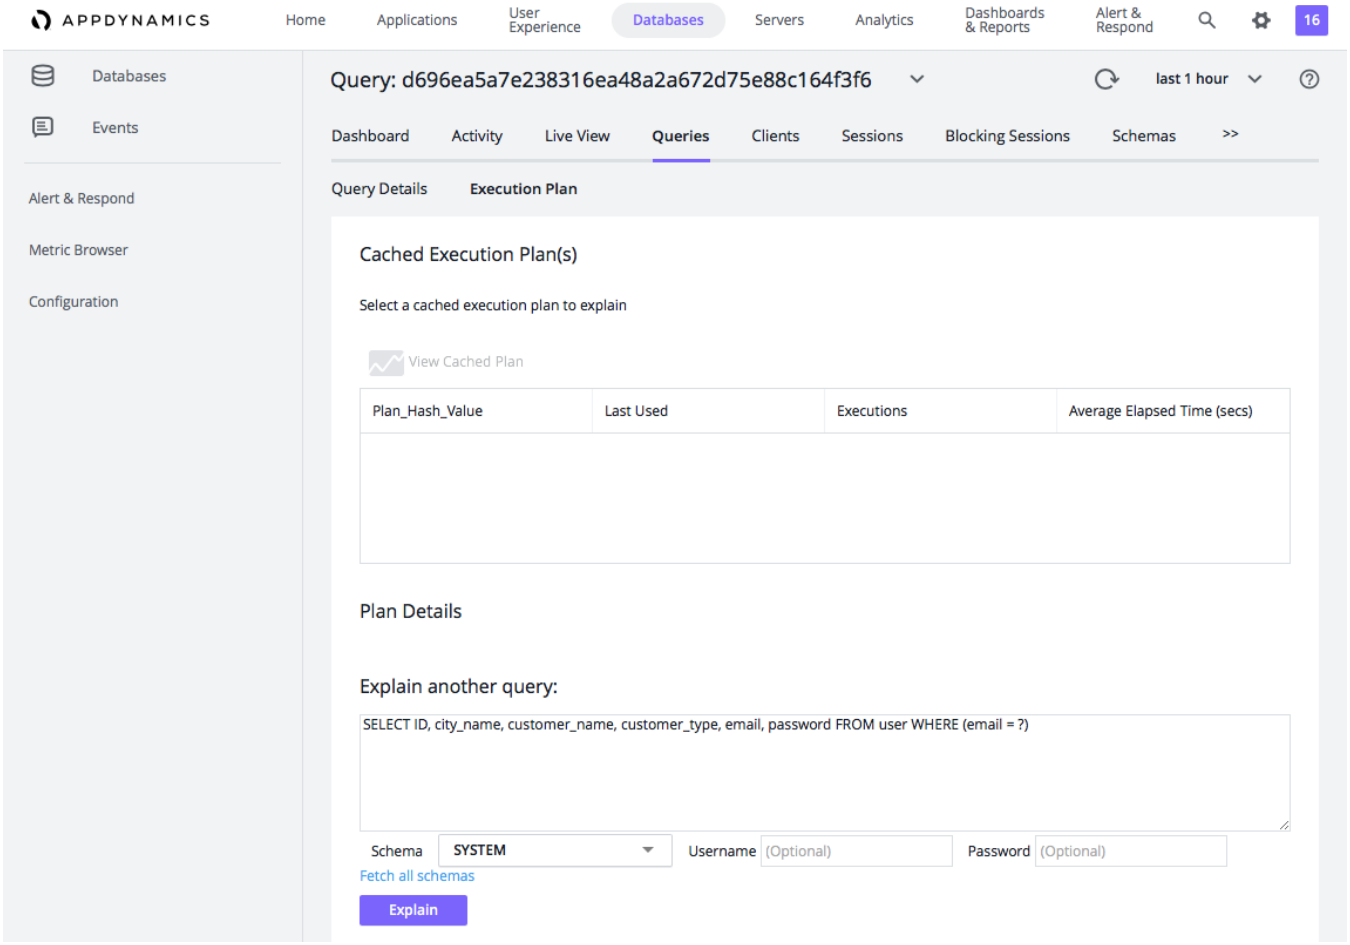
- CREATE SESSION
- SELECT_CATALOG_ROLE

To create a user with these permissions, you can run the following SQL. In this SQL, change "password" to a safe and secure password, and change the tablespace names, "users" and "temp" to those available in your Oracle instance.

```
CREATE USER C##DBMon_Agent_User IDENTIFIED BY password default tablespace users temporary tablespace temp
CONTAINER=ALL;
GRANT CREATE SESSION, SELECT_CATALOG_ROLE TO C##DBMon_Agent_User CONTAINER=ALL;
ALTER USER C##DBMon_Agent_User QUOTA 100M ON USERS;
alter user C##DBMON_AGENT_USER set container_data=all container=current;
```

Permissions Required for Oracle Explain Plans

To generate an execution plan for a specified query, paste the query text into the **Explain another query** boxy. You must provide a plan table in the AppDynamics monitoring user's schema. You can find a sample output table named PLAN_TABLE in the UTLXPLAN.SQL script. To update or view the plan table, you need INSERT and SELECT privileges. To explain a query, you need access privileges for the tables and views included in that query.



AppDynamics Database Visibility can generate explain plans within its SQL drill-down window. To enable this functionality, you must have a plan table accessible to the AppDynamics Database Visibility schema user. You can create this plan table with the following command from sqlplus when logged on as the AppDynamics Database Visibility user:

Windows:

```
@?\rdbms\admin\utlxplan.sql
```

Linux:

```
@?/rdbms/admin/utlxplan.sql
```

Permissions for individual views and tables

You can grant permission to individual views and tables even if the SELECT_CATALOG_ROLE permission is not available to your organization.

1. Execute permissions on dbms_application_info.set_module.
2. Select permissions on the following privileges:
   `dba_data_files`
   `dba_ind_columns`
   `dba_indexes`
   `dba_objects`
   `dba_procedures`
   `dba_segments`
   `dba_sequences`

```
dba_synonyms
dba_tab_columns
dba_tables
dba_users
dba_views
gv$instance
gv$containers
gv$parameter
v$archive_dest
v$archive_dest_status
v$database
v$datafile
v$event_name
v$instance
v$license
v$log
v$osstat
v$parameter
v$process
v$session
v$sesstat
v$session_wait
v$sga
v$sql
v$sql_plan
v$sqlstats
v$sqltext
v$statname
v$sysmetric
v$sysstat
v$system_event
```

When you are granting access to v$ views, you must grant SELECT on the underlying objects, which are named using the v_$ format, e.g. `GRANT SELECT on v_$archive_dest`.

Configure Oracle RAC

Related pages:

- Database Topology Window

If you are configuring a collector for Oracle RAC, you only need to configure one collector for the entire cluster. You can choose any node in the cluster to connect to, and the entire cluster is automatically detected.

If you have sub-collectors, it will disable automatic cluster discovery.

When the Database Visibility collecter connects to the hostname or IP address defined in the collector configuration, it auto-discovers the RAC instance. Once a successful connection is made to a node within the RAC, then a query on GV$INSTANCE will be used to return the details of the other member nodes and to populate the Topology Window.

When monitoring Oracle RAC, the Controller displays the aggregate data for the entire cluster.

User Permissions for Oracle RAC

When you upgrade to 4.3, you may encounter the following error: Network access denied by access control list (ACL). You can resolve the error by enabling ACLs for the monitoring user.

```
begin
dbms_network_acl_admin.create_acl (
acl             => 'Resolve_Access.xml',
description     => 'Resolve Network Access using UTL_INADDR',
principal       => '<DBMON USER>',
is_grant        => TRUE,
privilege       => 'resolve',
start_date      => null,
end_date        => null
);
commit;
end;
/

begin
dbms_network_acl_admin.assign_acl (
acl           => 'Resolve_Access.xml',
host          => '*',
lower_port    => null,
upper_port    => null);
commit;
end;
/
```

Monitor Oracle Databases Using Kerberos Authentication

For the Database Agent to connect to and monitor the Oracle databases using Kerberos authentication, these settings are required:

- Start the Database Agent using the property, `java.security.krb5.conf`:

  ```
  nohup java -Djavax.security.krb5.conf="<path to Kerberos configuration file>"
  ```

- In the **CONNECTION DETAILS** section of the Collector configuration dialog, specify the JDBC connection string:

  ```
  jdbc:Oracle:Tds:<hostname>:<portnum>?<Kerberos connection details>
  ```

- In the **ADVANCED OPTIONS** section of the Collector configuration dialog, ensure to provide these details:

  - Select **LDAP/Kerberos**.
  - Select **Connection Properties**, then specify these JDBC connection properties:

Property Name	Property Value
oracle.net.authentication_services	(KERBEROS5)
oracle.net.kerberos5_mutual_authentication	true
oracle.net.kerberos5_cc_name	"<*cache_file_path*>" For example: `"I:\\Kerberos\\krb5ccFile"`

Configure PostgreSQL Collectors

You can monitor any version of PostgreSQL with Database Visibility.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent.
	Custom JDBC Connection String	The JDBC connection string generated by the database agent, for example, `dbc:postgresql://`. You can also specify a custom connection string, which is useful for setting custom authentication options.
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for PostgreSQL.
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
	CyberArk	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the `JavaPasswordSDK.jar` file from the CyberArk web site and rename the file to cyberark-sdk-9.5.jar. Then, you must copy the JAR file to the lib directory of the database agent zip file.
Advanced Options	Sub-Collectors	Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. To monitor a custom cluster, you can add additional hostname or IP address, and port details for each sub-collector. You can add up to a total of 29 sub-collectors. Thereby, 30 databases can be monitored in a custom cluster. In addition to the licenses consumed by the main collector, each sub-collector consumes one or more licenses, depending on the database type. • All connection parameters other than the hostname or IP address, and port details of the sub-collector are the same as the main collector. If you want to specify different parameters for the sub–collectors, while creating or editing the collector configuration, you can do that only via the Create Collector API. • You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data.
	Connection Properties	Click to add a new JDBC connection property or edit an existing property for relational databases.
	EnterpriseDB	Click if your PostrgreSQL database installation is an EnterpriseDB distribution.
	Exclude Databases	The databases that you want to exclude, separated by commas.

	Monitor Operating System	See Configure the Database Agent to Monitor Server Hardware.

User Permissions for PostgreSQL

The monitoring user must either have a role of superuser or be granted access to the pg_stat_activity table using the technique described below.

The following script allows you to create a SECURITY DEFINER function that is owned by the superuser, and runs the query you want, thus allowing non-superusers to see the contents of `pg_stat_activity` by calling the `get_sa()` function and pg_stat_statements by calling the get_querystats( ) function respectively. The script must be executed by the superuser.

> Ensure that you create the `pg_stat_statements` extension by using the command, `create extension pg_stat_statements`.

```
CREATE FUNCTION get_sa()
RETURNS SETOF pg_stat_activity LANGUAGE sql AS
$$ SELECT * FROM pg_catalog.pg_stat_activity; $$
VOLATILE
SECURITY DEFINER;

CREATE VIEW pg_stat_activity_allusers AS SELECT * FROM get_sa();
GRANT SELECT ON pg_stat_activity_allusers TO public;
```

```
CREATE FUNCTION get_querystats()
RETURNS SETOF pg_stat_statements LANGUAGE sql         AS
$$ SELECT * FROM pg_stat_statements; $$
VOLATILE
SECURITY DEFINER;
CREATE VIEW pg_stat_statements_allusers AS SELECT * FROM get_querystats();
GRANT SELECT ON pg_stat_statements_allusers TO public;
```

The monitoring user must also be able to connect remotely to the PostgreSQL instance from the AppDynamics for Databases machine.

Configure Sybase Collectors

To monitor Sybase with Database Visibility, you must run Sybase >= 15.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent.
	Custom JDBC Connection String	The JDBC connection string generated by the database agent, for example, `jdbc:sybase:`. You can also specify a custom connection string, which is useful for setting custom authentication options.
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for Sybase.
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
	CyberArk	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the JavaPasswordSDK.jar file from the CyberArk web site and rename the file to cyberark-sdk-9.5.jar. Then, you must copy the JAR file to the lib directory of the database agent zip file.
Advanced Options	Sub-Collectors	Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. To monitor a custom cluster, you can add additional hostname or IP address, and port details for each sub-collector. You can add up to a total of 29 sub-collectors. Thereby, 30 databases can be monitored in a custom cluster. In addition to the licenses consumed by the main collector, each sub-collector consumes one or more licenses, depending on the database type. • All connection parameters other than the hostname or IP address, and port details of the sub-collector are the same as the main collector. If you want to specify different parameters for the sub–collectors, while creating or editing the collector configuration, you can do that only via the Create Collector API. • You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data.
	Connection Properties	Click to add a new JDBC connection property or edit an existing property for relational databases.
	Exclude Databases	The databases that you want to exclude, separated by commas.
	Monitor Operating System	See Configure the Database Agent to Monitor Server Hardware.

User Permissions for Sybase

For complete AppDynamics Database Visibility functionality, the monitoring user requires the permissions listed in the table below.

Permission type	Permission
Role permission	• sa_role • mon_role
Select permission	• master.dbo.monWaitEventInfo • master.dbo.sysconfigures • master.dbo.sysmonitors • master.dbo.monProcess • master.dbo.monProcessLookup • master.dbo.monProcessSQLText • master.dbo.monProcessProcedures
Execute permission	• sp_sysmon

To create a new dedicated user for AppDynamics Database Visibility, you can use following sample user creation script. Before running the script, change "password" to a more secure value.

```
exec  sp_addlogin  'DBMon_Agent_User', 'password', @defdb='master', @deflanguage='us_english',
@fullname='DBMon_Agent_User monitoring account', @auth_mech = 'ANY'
go
exec  sp_locklogin  'DBMon_Agent_User', 'unlock'
go
exec  sp_role 'grant', 'mon_role', 'DBMon_Agent_User'
go
```

where DBMon_Agent_User is the user name under which you run the Database Visibility Agent.

Also, the following configuration parameters must be set to 1 (true) to monitor the Sybase ASE database with AppDynamics Database Visibility: "enable monitoring", "wait event timing", "SQL batch capture", and "object lockwait timing". You should also set "max SQL text monitored" to at least 8192 (8kB).

Here is an example of the commands required to configure these settings:

```
sp_configure "enable monitoring", 1
go
sp_configure "wait event timing", 1
go
sp_configure "SQL batch capture", 1
go
sp_configure "object lockwait timing", 1
go
sp_configure "max SQL text monitored", 8192
go
```

If the value for "max SQL text monitored" was previously less than 4096, then increasing this setting will require that you restart the Sybase ASE instance.

To monitor Sybase >= 15.7 without the sa_role permission, run these commands:

```
use sybsystemprocs
grant execute on sp_sysmon to mon_role
```

If you choose to monitor Sybase using sp_sysmon, you may encounter the following errors:

- Thread utilization is incorrectly reported. View the official report here.
- Timeslice error in mmap64 or mda_flush_iostats. View the official report here.

Configure Sybase IQ Collectors

You can monitor any version of Sybase IQ with Database Visibility.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent.
	Custom JDBC Connection String	The JDBC connection string generated by the database agent, for example, `jdbc/sybaseiq:`. You can also specify a custom connection string, which is useful for setting custom authentication options.
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for Sybase IQ.
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
	CyberArk	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the JavaPasswordSDK.jar file from the CyberArk web site and rename the file to cyberark-sdk-9.5.jar. Then, you must copy the JAR file to the lib directory of the database agent zip file.
Advanced Options	Sub-Collectors	Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. To monitor a custom cluster, you can add additional hostname or IP address, and port details for each sub-collector. You can add up to a total of 29 sub-collectors. Thereby, 30 databases can be monitored in a custom cluster. In addition to the licenses consumed by the main collector, each sub-collector consumes one or more licenses, depending on the database type. • All connection parameters other than the hostname or IP address, and port details of the sub-collector are the same as the main collector. If you want to specify different parameters for the sub–collectors, while creating or editing the collector configuration, you can do that only via the Create Collector API. • You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data.
	Connection Properties	Click to add a new JDBC connection property or edit an existing property for relational databases.
	Exclude Databases	The databases that you want to exclude, separated by commas.
	Monitor Operating System	See Configure the Database Agent to Monitor Server Hardware.

User Permissions for Sybase IQ

To monitor with a non-DBA account, you need:

- User account with SERVER OPERATOR system privilege.
- Execution privileges on several procedures which can be granted as follows:

```
grant execute on sp_iqconnection to DBMon_Agent_User
grant execute on sp_iqtransaction to DBMon_Agent_User
grant execute on sp_iqcontext to DBMon_Agent_User
grant execute on sp_iqstatus to DBMon_Agent_User
grant execute on sp_iqcolumn to DBMon_Agent_User
grant execute on sp_iqindex to DBMon_Agent_User
```

  where DBMon_Agent_User is the user name under which you run the Database Visibility Agent.
- Grant DBA authority to DBMon_Agent_User:

```
grant DBA to DBMon_Agent_User
```

Monitor Sybase Databases Using Kerberos Authentication

For the Database Agent to connect to and monitor Sybase databases using Kerberos authentication, these settings are required:

- In the Connection Details section of the **Collector** configuration dialog, specify the JDBC connection string:

```
jdbc:sybase:Tds:<hostname>:<portnum>?REQUEST_KERBEROS_SESSION=true&SERVICE_PRINCIPAL_NAME=<myserver>
```

- Start the Database Agent using the `-Djavax.security.auth.useSubjectCredsOnly=false` option:

```
nohup java -Djavax.security.auth.useSubjectCredsOnly=false /<db_agent_home>/db-agent.jar &
```

Configure the Database Agent to Monitor Server Hardware

Related pages:

- Monitor Database Server Hardware

In addition to monitoring the database server, the Database Agent can also monitor the hardware that hosts the database server. To configure the Database Agent to monitor the database server hardware, complete the **Hardware Monitoring** section of the Collector configuration dialog.

Click **Databases > Configuration > Collectors** and then choose an existing collector to monitor the hardware for that database server and click **Edit**, or click **Add** to set up a new collector to monitor a different database server and the hardware hosting that server.

Complete the Hardware Monitoring Section

The following describes the fields in the **Collector Configuration** dialog that you must complete if you want to monitor the database server host hardware, in addition to the database server.

> For Oracle database, the **CPU** and the **Memory** metrics are monitored even when hardware monitoring is disabled.

Monitor Operating System: Select if you want CPU consumption metrics collected from the monitored host.

Operating System: Specify the operating system of the monitored host: Windows, Linux, Solaris, AIX, or RDS.

Use Local WMI: Check this box if you want to monitor the machine the Database agent is running on, i.e. localhost. When selected, the authorization fields are not used because no authorization is required.

Domain: For Windows only, specify the name of the domain in which the hardware resides.

SSH Port: For Linux, AIX, and Solaris only, specify the Secure Shell (SSH) port number the Controller should use for encrypted communications with the monitored host. The default port number of 22 will be used if you do not specify a different port number here.

Use certificate: For Linux, AIX, and Solaris only, AppDynamics also supports certificate-based authentication through Privacy Enhanced Mail (PEM). To implement certificate-based authentication, enable the **Use certificate** option and copy the PEM file to the `<db_agent_home>\keys` directory. Note, if the `$HOME/.ssh` directory exists, the agent will use the certificate found there. This option appears only if the agent is running on a machine running Linux, AIX or Solaris.

Username: Specify the name of the user the Database Agent uses to log on to the monitored host. To collect OS metrics from a Windows host, the configured user (or Collector Service user if using Windows Authentication) must be able to establish a WMI connection to the target host and collect Windows Performance Counters.

Password: Specify the password of the user the Database Agent uses to log on to the monitored host. The number of echo characters shown in the password text field should not be interpreted to imply the number of characters stored for the (encrypted) user password.

> Windows hardware monitoring is not supported by Database Agent installed on a Linux system. However, Database Visibility can support hardware metrics for SQL server through SQL query collection.

Resolve Metric Reporter Type Mismatch Problem

Switch from the Java Hardware Monitor to the Hardware Monitor if you see messages similar to the following in the logs:

```
[Worker-7] 12 Sep 2014 07:27:49,449 WARN MonitorOutputHandler - Metric Reporter type mismatch for metric
[Hardware Resources|Network|Incoming packets/sec]
com.singularity.ee.agent.commonservices.metricgeneration.metrics.MetricReporterTypeMismatchException:
Aggregator of OBSERVATION already exists for metric Metric Identifier[Hardware Resources|Network|Incoming
packets/sec] ID[0]
```

Required Monitored Host Permissions

Database Agent User Permissions

Database Visibility collects the stats from common commands like `vmstat/iostat` or gathering metrics from the file system such as `/proc` and as such the user that runs the Database Agent requires no special permissions, just the ability to run those common commands and write to files in the Database Agent directory.

Database Agent Collector Authentication

When monitoring the database host, Database Visibility must log in to the host system to gather system information. There are three ways to authenticate the Database Collector to access the monitored host:

- Specify a username and password in the Collector configuration dialog
- Place a PEM file or an id_rsa file in the `<agent home>/keys` directory
- If the Database Agent is running on LINUX, Solaris or AIX, place SSH keys in the `<home>.ssh` directory of the user running the agent. You can create an SSH key using the same procedure as described for the Controller. See Configure a Controller SSH Key.

Required SSH Permissions

When monitoring the database host, Database Visibility uses SSH on Linux and Windows systems to gather system information. SSH access can be through either an authenticated username/password or a private key.

You can create an SSH key using the same procedure as described for the Controller. See Configure a Controller SSH Key.

Configure WMI Permissions and Security

Related pages:

- WMI and the Database Agent on the AppDynamics Community

To monitor Windows-based machine hardware with AppDynamics Database Visibility, AppDynamics uses Windows Management Instrumentation (WMI) to remotely gather the metrics. WMI is often complicated to troubleshoot when the Database Agent is running on a Linux or Unix-like machine.

This page describes requirements for the target machine configuration that can help you avoid some problems and pitfalls. It also provides some additional considerations regarding using WMI to monitor a SQL Server database agent and preventing unauthorized remote access to WMI.

> **Named Windows Account:**
>
> The user specified in the collector configuration that the AppDynamics Database Agent uses to connect to the target machine is referred to as <named Windows account>.

The following are required when the Database Agent is hosted on AIX, Linux or Solaris platforms to monitor Windows >= 7 systems.

- Ensure that the named Windows account is a member of the local Administrators group.
- Ensure User Account Meets Minimum Security Requirements When Using WMI
- Enable Remote Registry Access
- Grant access to WBEM scripting locator

The following are required when the Database Agent is hosted on AIX, Linux, or Solaris platforms to monitor Windows >= 2012 systems.

- Grant full control permissions to select registry keys

The following is required when the Database Agent is hosted on Windows.

- Ensure that the named Windows account is a member of the local Administrators group.

Requirements to Monitor Windows >= 7 Systems (Agent Running on Unix-like Platform)

The following are required when the Database Agent is hosted on AIX, Linux, or Solaris platforms to monitor Windows >= 7 systems.

Ensure User Account Meets Minimum Security Requirements When Using WMI

Enable Security Options for Windows Systems are Part of a Domain

Ensure the named Windows account has the correct permissions for WMI Control.

1. Run the `wmimgmt.msc` program.
2. Right-click the **WMI Control** icon on the left and click **Properties**.
3. Click **Security.**
4. Click the root node of the tree, and click **Security**.
5. Ensure that the named user account running the Database Agent has the relevant permissions.

> The minimum permissions that your remote Windows account needs for the Database Agent are:
>
> - Execute Methods
> - Enable Account
> - Remote Enable
>
> If the named Windows account does not have all of these permissions, you may receive an access denied error or the following errors:
>
> ```
> Error=800706BA The RPC server is unavailable. SWbemLocator
> ```
>
> or
>
> ```
> Error=80070005 Access is denied SWbemLocator
> ```

Enable Classic Security Options for Local (Non-Domain) Windows Systems

Applies to Windows computers that are not part of a domain.

1. Open the **Control** panel, and go to **Administrative Tools** > **Local Security Policy**. The **Local Security Settings** panel appears.
2. Go to **Local Policies** > **Security Options.**
3. Change the value of **Network access: Sharing and security model for local accounts** to **Classic**.

Enable Remote Registry Access

The Remote Registry service must be running on the target machine. If the Remote register service is off, you will receive the following error:

```
Message not found for errorCode: 0xC0000034
```

or

```
Access is denied
```

By default Windows >= 7 systems will still deny remote access to the registry, even if the Remote Registry service is started.

To test this:

1. Attempt to access the replica registry using Regedit on another machine.
2. If you get an error similar to `Access is denied`, run PowerShell as an administrator on the replica, and execute `Enable-PSRemoting`.
3. Restart the machine and try launching the replica again.

Grant Access to WBEM Scripting Locator

The Database Agent requires full access to the WBEM Scripting Locator. On the target system, allow full access to the WBEM Scripting Locator as follows:

1. As an Administrator on the target machine, launch Regedit.
2. Locate the registry key:
   `76A64158-CB41-11D1-8B02-00600806D9B6` in `HKEY_CLASSES_ROOT\CLSID`
3. Right-click the key and click **Permissions**.
4. Click **Advanced**.
5. Click **Owner** and change the owner to the Administrators group. Click **Apply**.
6. Click **Permissions** and change the permissions for the Administrators group to **Full Control**. Click **Apply**.
7. Close Regedit.
8. Restart the Remote Registry Service, using **Administrative Tools** > **Services**.

Configure the Firewall

WMI uses RPC which listens on port 135 but then allocates a dynamic port for subsequent communication. Configure your Firewall to always allow the TCP port 135 exception and follow the dynamic RPC ports. If there is a problem with the firewall, port 135 then you will probably see this error:

```
ERROR: Message not found for errorCode: 0xC0000001
```

See How to configure RPC dynamic port allocation to work with firewalls.

Additional Requirements to Monitor Windows >= 2012 Systems (Agent Running on Unix-like Platform)

In addition to the requirements described in Requirements to Monitor Windows >=7 Systems, the following are also required when the Database Agent is hosted on AIX, Linux, or Solaris platforms to monitor Windows >= 2012 systems.

Grant Full Control Permissions to Select Registry Keys

For the Database Agent running on AIX, Linux, or Solaris to monitor Windows >= 2012 (64-bit) systems, complete the following changes on the target system.

1. As an Administrator on the target machine, launch Regedit.
2. Change the permissions for both of these registry keys to **Full Control**:
   `72C24DD5-D70A-438B-8A42-98424B88AFB8` in `HKEY_LOCAL_MACHINE\SOFTWARE\Classes\Wow6432Node\CLSID`
   `76A64158-CB41-11D1-8B02-00600806D9B6` in `HKEY_CLASSES_ROOT\CLSID`
3. Find this registry key:
   `72C24DD5-D70A-438B-8A42-98424B88AFB8` in `HKEY_LOCAL_MACHINE\SOFTWARE\Classes\Wow6432Node\CLSID`
4. Right-click and click **Permissions**.
5. Change the owner to the Administrators group.
6. Change the permissions for the Administrators group to **Full Control**.
7. Change owner back to **TrustedInstaller**. User is <NT Service\Trusted Installer> on the local machine.
8. Repeat steps 4 to 6 above for this registry key:
   `76A64158-CB41-11D1-8B02-00600806D9B6` in `HKEY_CLASSES_ROOT\CLSID`.
9. Close Regedit.
10. Restart the Remote Registry service, using **Administrative Tools** > **Services**.

General Considerations for all Platforms

This information applies to the Database Agent running on Windows systems.

Use Windows Authentication for Microsoft SQL Server

To use Windows Authentication for the Database Agent to connect to a Microsoft SQL Server database instance, you must use a command similar to the following to start the Database Agent; specifying the path to the Database Agent authentication library.

Windows 64-bit

```
java -Djava.library.path="C:\dbagent404\auth\x64" -jar db-agent.jar
```

Windows 32-bit

```
java -Djava.library.path="C:\dbagent404\auth\x86" -jar db-agent.jar
```

The Windows account used to start the Database Agent must be a Windows user who can authenticate with the database server.

Monitor Databases and Database Servers

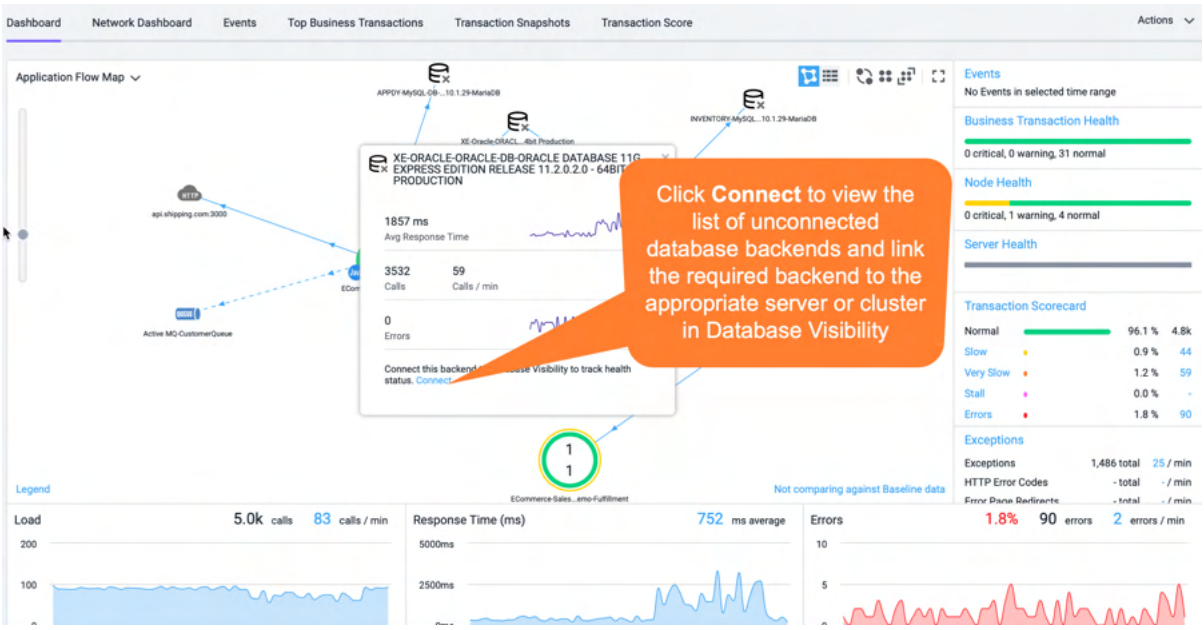
Access Database Visibility from Application Monitoring Views

Related pages:

- Monitor Database Performance
- App Agent Node Properties

To view the application dashboard of a specific application, click the application on the **Home** page. On the application dashboard, you can view the following:

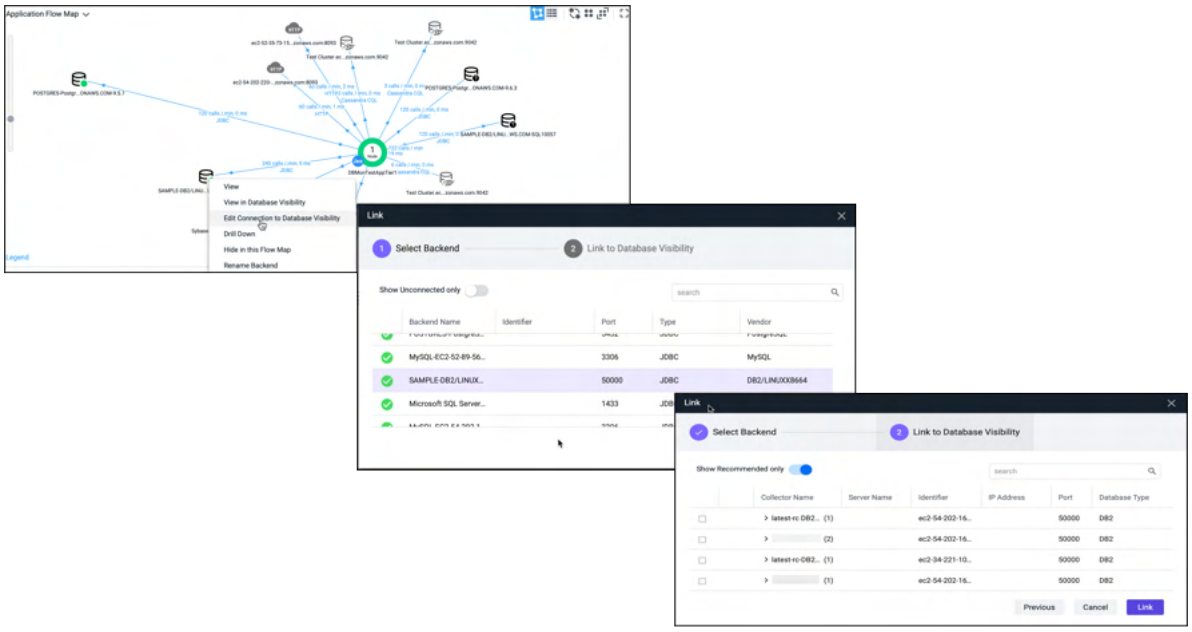
- Unconnected Backends: If there are any unconnected backend database servers, the flowmap displays the unconnected database server icon. You can click the icon, then click **Connect** to connect the backend database to the appropriate server or cluster in **Database Visibility**.
- Status of the Database: There are different icons to display different states of the database based on the health rule violation. For information about the different icons, see Database Icons.
- Quick View of **Database Visibility**: If you require to view some of the main metrics without going to the **Database Visibility** UI, you can click the database icon and the quick view of the metrics is displayed. For detailed information, click **View in Database Visibility.**



View Database Activity in Database Visibility

Once you have configured a database Collector in AppDynamics Monitoring, you can access Database Visibility either from the AppDynamics Home page or you can link to the Database Visibility database instance Dashboard by right-clicking the database and selecting **View in Database Visibility** on the Application Flow Map, Tier Flow Map or Node Flow Map.

Database backends with the same hostname, port number, and database type as a database server already configured in a database Collector are automatically matched with the Collector, and drilldowns from the Application Flow Map, Tier Flow Map or Node Flow Map to Database Visibility are enabled.



The AppDynamics Database Visibility section in the Application Database Dashboard displays which database Collector is associated with the database. If you require to change this association, right-click the database and then click **Edit Connection to Database Visibility** and choose the appropriate server or cluster that is configured in **Database Visibility**.

View Business Transaction Snapshot Correlated Database Details

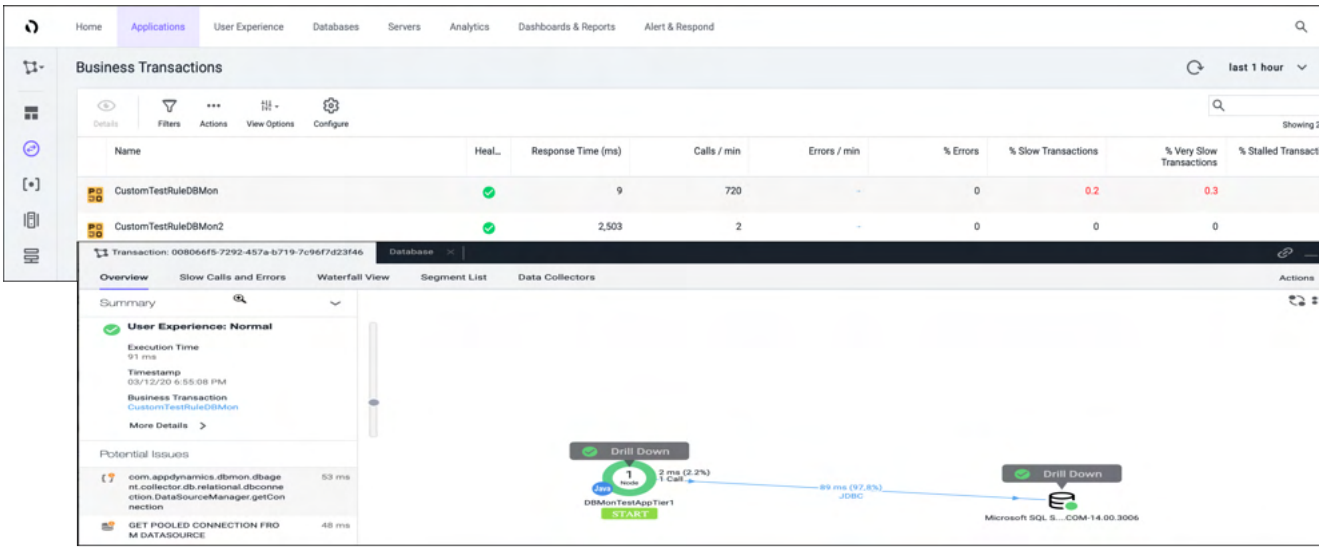
Available for Java, .NET, and PHP applications and their relational database backends, snapshot correlation shows the details of queries executed by the business transaction. It also shows the clients, sessions, and schemas in which those queries were executed.

View Database Details

1. On the Business Transactions page, double click any business transaction to view the queries that are executed in that transaction.
2. Click the DB Queries tab. On this tab, you can view the queries that were issued by this business transaction.

View Correlated Database Details

1. From a list of business transactions with snapshots, choose a long-running business transaction that accesses the database, one that takes a few seconds or more. These are more likely to have captured database details.
2. Double-click **Drill Down** above the database icon. The correlated database details window appears.
3. Click the Queries, Clients, Sessions, and Schema tabs to view details of database activity that occurred around the time when the snapshot was captured. For relational databases, these details reflect the database activity from the transaction snapshot. For non-relational databases, these details reflect the database activity that occurred around the time of the transaction snapshot.



For Oracle backends only: If you want to list only the queries executed by the Transaction Snapshot in the Transaction Snapshot window, you can enable the `jdbc-dbcam-integration-enabled` node property for the Java Agent.

Discover Normal Database and Server Activity

Related pages:

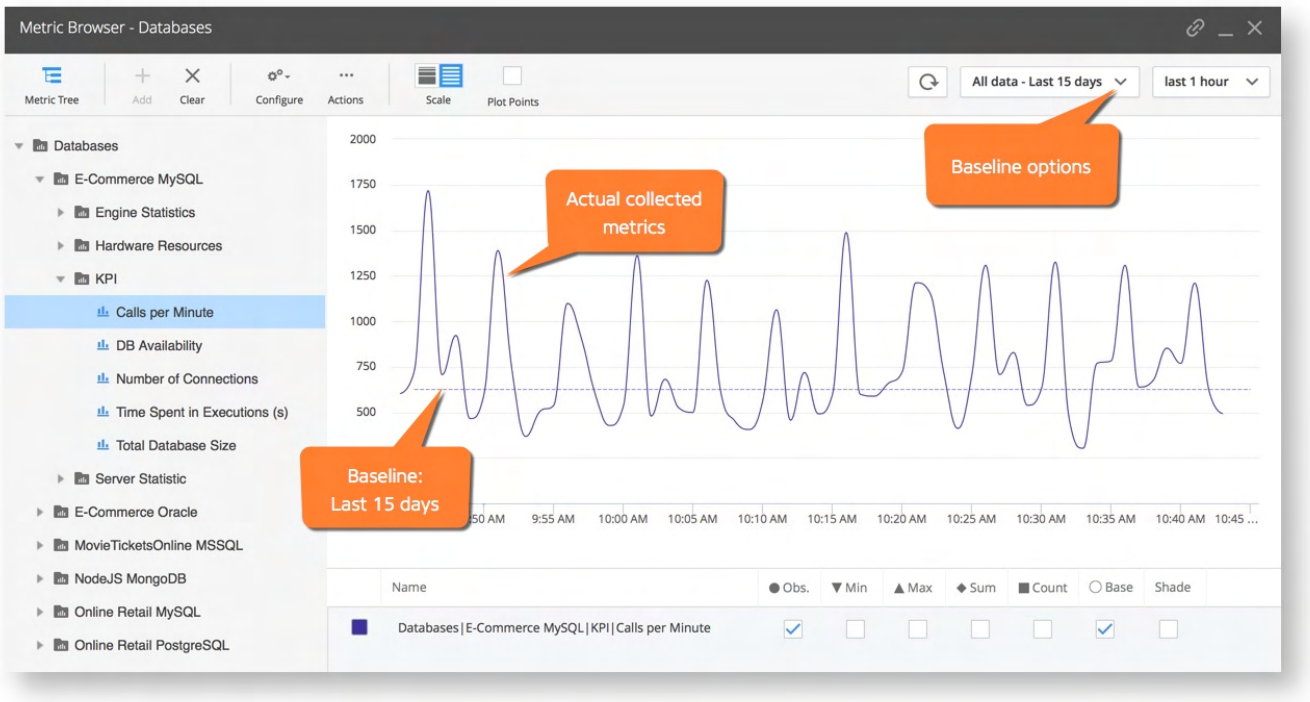
- Dynamic Baselines
- Health Rules

AppDynamics Database Visibility automatically learns to detect performance anomalies using baselines that are specific to your database and database server environments.

AppDynamics creates baselines by collecting metrics from your monitored databases and servers over defined periods of time. This establishes what is normal for your environment. You can also create your own baselines.

View Performance Metrics on the Metric Browser

On the Metric Browser for Database Visibility, you can visualize performance metrics and see how they deviate from expected behaviors established by the baseline.



Monitor Database Performance

Important information

Garbage collection affects all monitored entities, including database queries, sessions, clients, and schemas. Entities that are garbage collected will be displayed as unavailable.

View Overall Database and Server Performance

Related pages:

- Access Database Visibility from Application Monitoring Views

Database Visibility provides overall views of your databases that show key performance indicators.

Access the Databases Window

From AppDynamics Home, click **Databases**.

Features of the Databases Window

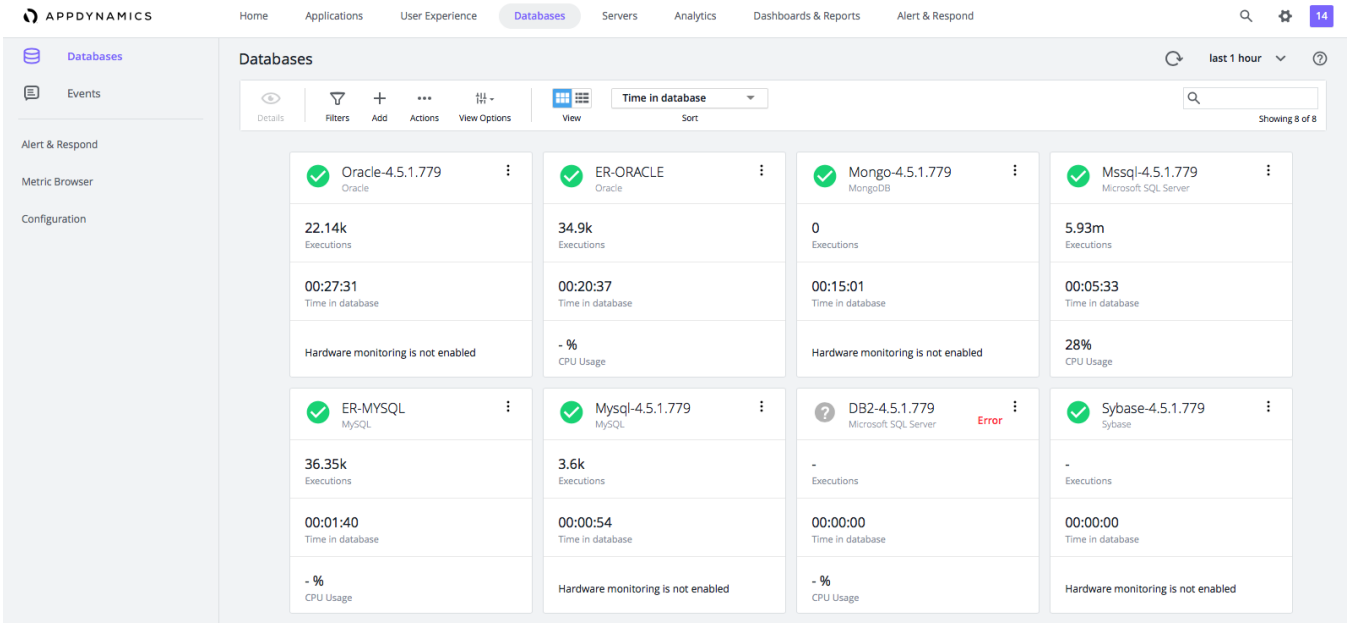
On the views of the Databases window you can:

- Show only databases meeting certain criteria by entering search criteria in the search box on the top right of the page.
- Click **Filters** to show only databases meeting certain search criteria, such as criteria that describes Health, Load, Time in database or Type.
- Click **+** to add a new database Collector.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.
- Click **View** to switch between card and list view.
- See the overall performance of your databases and if there are any critical issues with them. The server health or status indicates whether criteria has been met for normal, warning or critical health rules. The green checkmark indicates that the database is operating within normal conditions, the red exclamation mark indicates that at least one critical health rule has been violated.
- Click the name of the database to switch to the Database Dashboard for that specific database.

Databases Card View

From the Databases card view, you can view:

- The configured collectors along with the database type and the number of nodes used in the database cluster.
- The **Total Executions** graph that provides insight into the total number of calls (transactions for PostgreSQL databases) monitored for the database over the selected time period.
- The **Time in Database** graph that indicates the total time spent executing those calls during the selected time period. This metric is expressed in hours, minutes, and seconds.
- **CPU Usage** metrics that when enabled shows the percentage of CPU capacity consumed by the database.



Databases List View

From the Databases list view, you can:

- View the number of database nodes under the **Nodes** column.
- Click **View Options** to turn the spark charts on and off.
- Get to the databases you want to see quickly if you are monitoring many databases.
- Click on any point in the spark charts to see a metric for that point in time. For example, clicking on a point in the calls Trend shows how many calls were monitored at that time.
- Click on a column name to sort the list on that key.

Database Dashboard

Related pages:

- Access Database Visibility from Application Monitoring Views
- View Overall Database and Server Performance
- Discover Normal Database and Server Activity
- Database Health Rules and Alerts
- Monitor Database Performance

The dashboard for each individual database provides detailed information about your database.

Permissions

To view database collectors, users need a role with the **Can View All Collectors** permission.

Access the Database Dashboard

You can access the Database Dashboard in one of these ways:

- In AppDynamics Home, on the **Databases** card, click the name of the database for which you want to see the Database Dashboard.
- In the Databases overview panel, click the name of the database for which you want to see the Database Dashboard.

Features of the Database Dashboard

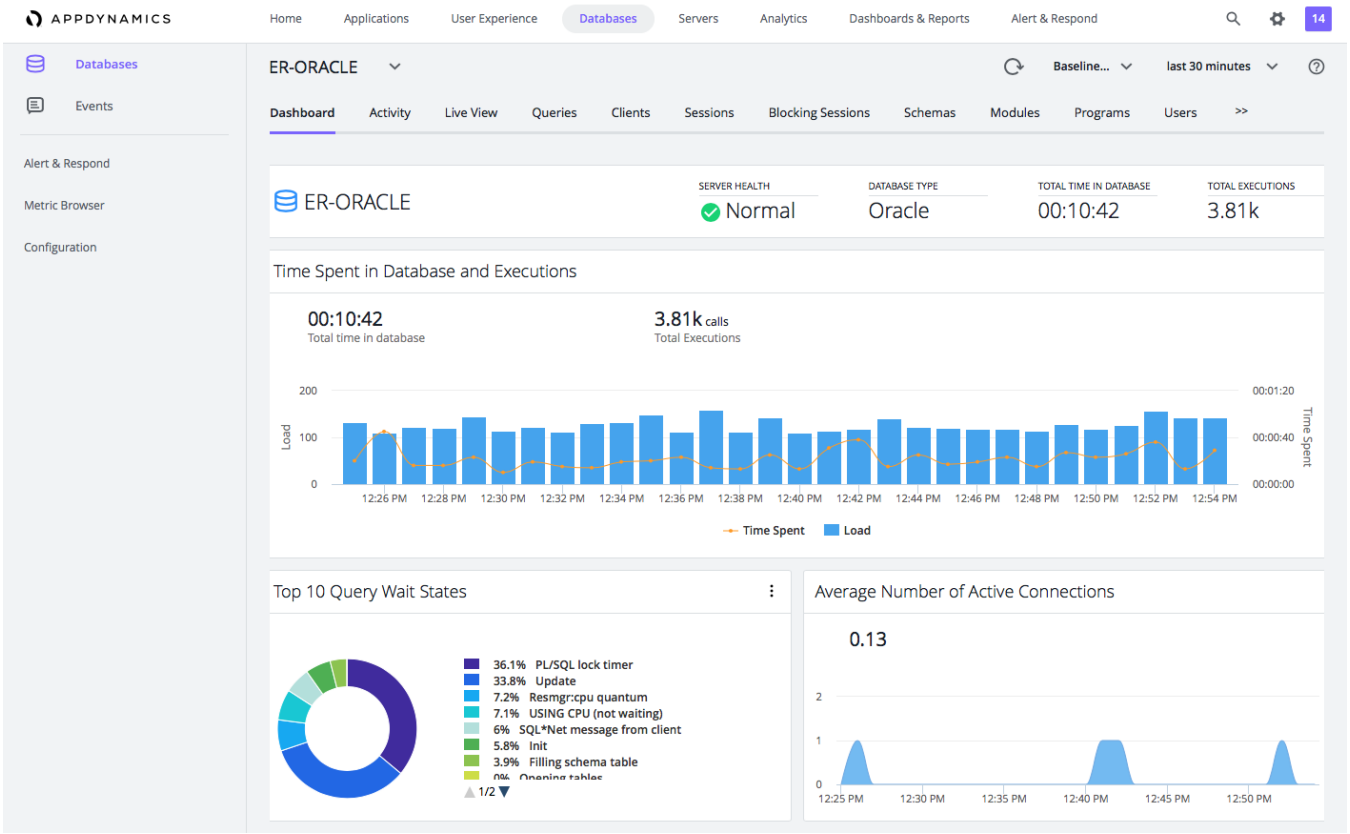
On the Database Dashboard you can:

- Click the dropdown arrow next to the database Collector name at the top of the page to choose a database that you want to see the dashboard for.
- (From 21.5 onwards) For a clustered database, click the down-arrow below the collector name to navigate between different nodes of the cluster. By default, **All Nodes** is selected.
- Click the down-arrow next to the clustered database Collector name to navigate between different nodes of the cluster.
- Click the status icon below **SERVERS** in the top section of the dashboard to go directly to **Events** where you can see any recent events.

On the Database Dashboard, you can view:

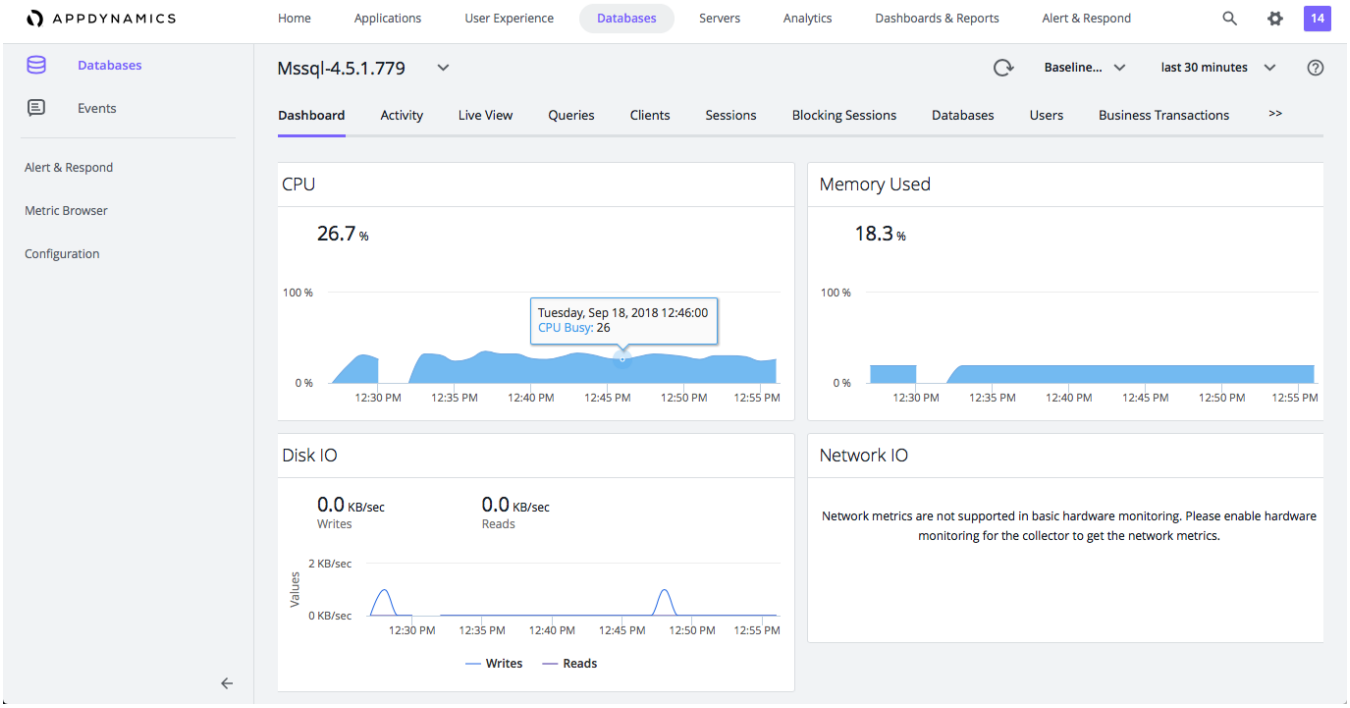
- **Server Health**: Server Health at the top of this panel indicates the extent to which health rules are being violated:
  - Green - Healthy server
  - Yellow/orange - server with warning-level violations
  - Red - server with critical-level violations
- **Type**: The database type.
- **Time Spent in Database and Executions**:
  - Load - At a glance, you can see the total number of calls (transactions for PostgreSQL databases) during the specified time period and the number of calls for any point in time.
  - Time spent in Database - The total time spent executing SQL statements during the specified time period.
  - Changes - Changes made to the database configuration parameters.
  - Max CPU - It displays the CPU cores present in the database server and is disabled by default. The CPU core count is collected using SQL (for Oracle, DB2, and MSSQL) and Hardware monitoring (if enabled for MySQL, PostgreSQL and Sybase).
- **Top 10 SQL Wait States (not available for Couchbase)**: Activities that contribute to the time it takes the database to service the request. The wait states consuming the most time may point to performance bottlenecks. For example, a db file sequential read wait state may be caused by segment header contention on indexes or by disk contention. See your database platform documentation for descriptions of the SQL wait states. For example:
  - Wait State - CHECKPOINT_QUEUE
  - Description - Used by background worker that waits on events on queue to process checkpoint requests.
  - Recommended Action - You should be able to safely ignore this action because it indicates that the checkpoint background worker is waiting for work to do. If you thought you had issues with checkpoints not working or log truncation, you might see if this worker ever "wakes up". Expect higher wait times as this will only wake up when there is work to do.
- **Top 10 Phases (Couchbase only)**: The phases that have processed the most documents.
- **Average number of active connections**: The average number of sessions that are actively running a query during the selected time period.

> **Accessing the Comparison Report**
>
> Click on any data point to view the time comparison report, which shows query run times and wait states 15 minutes before, and 15 minutes after the selected time.



The **CPU**, **Memory**, **Disk I/O**, and **Network I/O** graphs display when the Database Agent has been configured to also monitor the database host hardware. See, "Configure the Database Agent to Monitor Server Hardware" on Add Database Collectors.

- **CPU**: The CPU graph shows the relative percentages of CPU processing time used for handling system and users processes.
- **Memory**: The Memory graph shows the percentage of total memory in use at any point in time.
- **Disk I/O**: The Disk I/O graph shows disk usage, the volume of data read and written.
- **Network I/O**: The Network I/O graph shows network activity, the volume of data sent and received.



Accessing the Metric Browser

To see more information about a specific metric, double click any point on the graph and the Metric Browser opens displaying that metric. You can then hover over a point on the graph in the Metric Browser for more information about the metric. This feature is available for all the graphs except the SQL wait states graph.

Database Activity Window

Related pages:

- Access Database Visibility from Application Monitoring Views
- Database Visibility
- Monitor Databases and Database Servers
- Monitor Database Performance

The following describes the reports available in Database Visibility on the Database Activity Window. The reports available depend on the database platform being monitored. The reports are listed in alphabetical order and indicate which database platform supports them.

Access the Database Activity Window

To access the Database Activity window

1. To view a database's activity, click the name of the database.
2. Click the **Activity** tab.

Features of the Database Activity Windows

To view the database reports of different databases, click the down arrow next to the database name at the top of the page. From the list, select the database you want to view or search for the database in the search bar. Click the refresh icon to show only databases that meet that search criterion.

The activity reports available are described below. The reports available are database-dependent. The reports are listed in alphabetical order and indicate which database platform supports them. The reports will only show 10 days of data, which is the Events Service limit.

Wait State

Description: This report displays time-series data on Wait Events (states) within the database. Each distinct wait is color-coded, and the Y-axis displays time in seconds. This report also displays data in a table and highlights the time spent in each wait state for each SQL statement.

Relevance: The wait states consuming the most time may point to performance bottlenecks. For example, db file sequential reads may be caused by segment header contention on indexes or by disk contention.

Platform: IBM DB2, Microsoft SQL Server, MySQL, Oracle, PostgreSQL, Sybase, and Sybase IQ

Max CPU - It displays the CPU cores present in the database server and is disabled by default. The CPU core count is collected using SQL (for Oracle, DB2, and MSSQL) and Hardware monitoring (if enabled for MySQL, PostgreSQL and Sybase).

Phase

Description: This report displays the number of documents processed during a phase of query execution.

Relevance: The phase processing the most documents may point to performance bottlenecks.

Platform: Couchbase

Top Activity

Description: Display the top time in database SQL statements in a time-series view. This report also displays data in a table and highlights the time spent in the database for each of 10 top SQL statements. Only queries reported by newer agents are grouped; the queries reported by older agents may not appear upon grouping.

Relevance: Use this report to see which SQL statements are using the most database time. This helps to determine the impact of specific SQL statements on overall system performance allowing you to focus your tuning efforts on the statements that have the most impact on database performance.

Platform: IBM DB2, Microsoft SQL Server, MySQL, Oracle, PostgreSQL, Sybase, Sybase IQ, and Couchbase

Time Comparison

Description: This report allows compares the performance of two databases during the same time period based on a specific statistic type. You can click Group Similar to group together queries with the same number of parameters. Only queries reported by newer agents are grouped; the queries reported by older agents may not appear upon grouping.

Relevance: You may want to compare the performance of your development and production databases before and after you tune the SQL queries or add an index or join. This report can help you determine the effectiveness of any performance tuning procedures you have implemented.

Platform: IBM DB2, Microsoft SQL Server, MySQL, Oracle, PostgreSQL, Sybase, and Sybase IQ

I/O

Description: This report gives information on physical I/O performed by the database instance.

The SQL Server and PostgreSQL I/O reports include the following metrics:

- Time spent in the database
- Query throughput
- CPU usage (if hardware monitoring is enabled)
- Read and Write I/O. This metric is only available for SQL Server.
- Per file statistics (if the agent is run with the `dbagent.mssql.datafile.statistics` property). This metric is only available for SQL Server.
- Per database statistics. This metric is only available for PostgreSQL.

Relevance: Your physical disk I/O may be affecting database performance.
Poor response times may mean one of the following:

- You're doing too much physical I/O and need to adjust your I/O capacity
- You're scanning tables or indexes when you should be doing seeks
- Your database tables are missing indexes
- Your SQL needs to be tuned

Platform: Microsoft SQL Server, Oracle, PostgreSQL

Top Query

Description: This report displays the top 10 SQL statements for the specified statistic in a time-series view.

You can filter queries by command type using the **Command Type** dropdown menu and by statistic type using the **Statistic Type** dropdown menu.

With the Controller version 21.2.0 and later, some of the unused statistic types under the **Statistic Type** dropdown menu are removed from the list. You can filter queries using the most common statistic types.

Relevance: Use this report to see which SQL statements are using the most database resources. This helps to determine the impact of specific SQL statements on overall system performance allowing you to focus your tuning efforts on the statements that have the most impact on database performance. You can choose one of many statistics to base the report on.

Platform: IBM DB2, Microsoft SQL Server, Oracle

Query Wait State

Description: This report displays the wait times for all queries.

Relevance: Use this report to see how much time queries are spending in different wait states.

Platform: IBM DB2, Microsoft SQL Server, MongoDB, MySQL, Oracle, PostgreSQL, Sybase, and Sybase IQ

Parameter Changes

Description: This report displays changes to the database configuration parameters. You can select a parameter change and click one of the following options:

- **View Event Details**: Displays the parameter change event details, such as comments associated with the parameter change.
- **View Comparison Report**: Compares the query run times and wait states 15 minutes before and 15 minutes after the database parameter was changed. The comparison report is not available for clusters.

Relevance: Use this report to keep track of the changes you make to the database configuration parameters.

Platform: IBM DB2, Microsoft SQL Server, Microsoft Azure, MySQL, Oracle, PostgreSQL, Sybase ASE, and Sybase IQ

BT Activity

Description: This report displays the top (Java or PHP) business transactions that make calls to the database.

Relevance: Use this report to see which business transactions are affected by the database.

Platform: IBM DB2, Microsoft SQL Server, Microsoft Azure, MySQL, Oracle, PostgreSQL, Sybase ASE, and Sybase IQ

Database Topology Window

The Topology view displays current activity for the routing service and shards of a MongoDB database, Oracle RAC server or a custom cluster. The Topology view shows key performance metrics for the routing service and shards or nodes of the database.

Access the Database Topology Window

To access the Database Topology window:

1. To view a database's topology, click the name of the database.
2. Click the Topology tab.

Database Topology Window Features

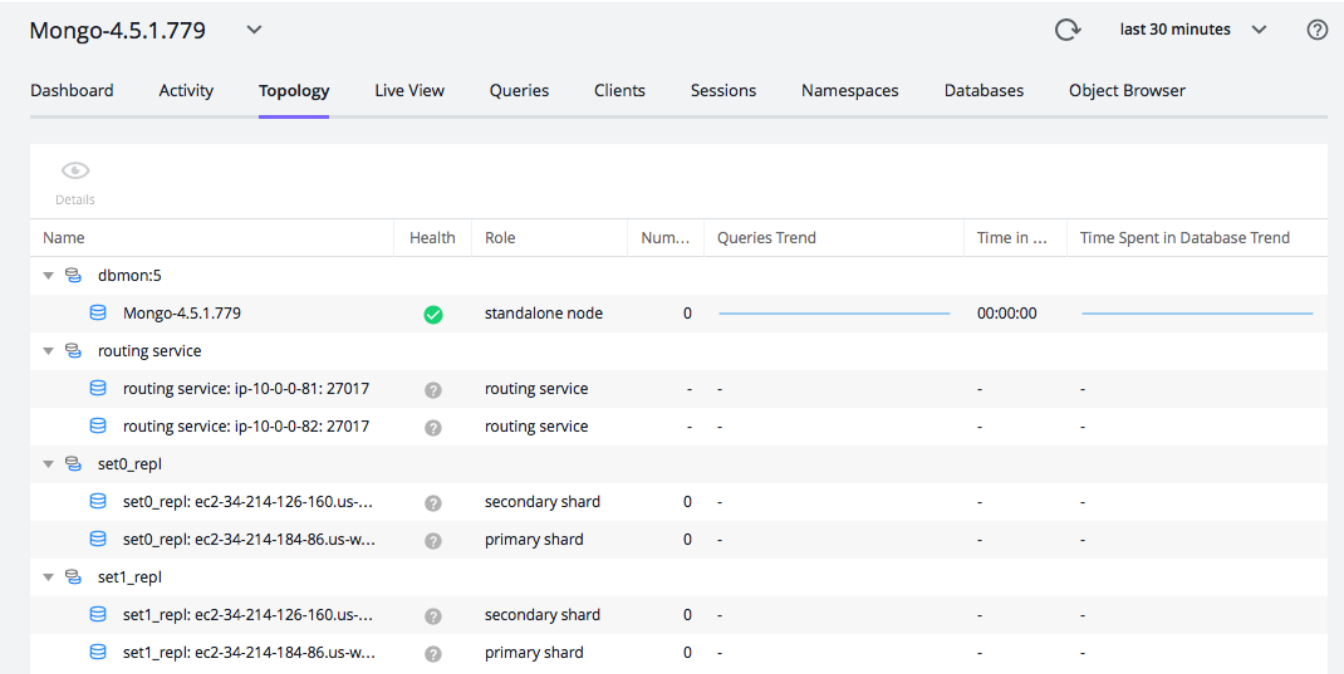
From the Database Topology window, you can:

- Select the **Auto Refresh** box. From the **Every** list, you can choose how often the system updates the live view.
- Click the dropdown arrow next to the database Collector name at the top of the page to choose a node or cluster that you want to see the metric views for. You can either select the database Collector name from the list or search for the database Collector by entering text in the search bar and then clicking the refresh icon to show only database Collectors that meet those search criteria.
- Hover over the sections of the trends to see their details.
- Click a column title on the **Topology** name list to sort the topologies using that column as the sort key.

From the Topology window, you can view:

- **Health**: Indicates whether any health rules for the routing service or shards of the replica set or nodes have been violated.
- **Role**: The role performed by the shard. The routing service routes the queries to the shards to balance the load. The members or shards of the replica sets can have either primary or secondary shard role.
- **Num Queries**: The number of queries handled.
- **Queries Trend**: The trend of queries handled over time.
- **Time in Database**: The time required for the database to respond to the queries.
- **Time Spent in Database Trend**: The trend of time spent in the database over time.

> If you change the port number for a monitored database node, the Topology window shows a new node with the new port number, as well as the original node with the old port number. The original node remains in the Topology window for the duration of the retention period that you specify in Controller Settings.



Database Live View Window

Related pages:

- Access Database Visibility from Application Monitoring Views
- Database Visibility
- Monitor Databases and Database Servers
- Monitor Database Performance

The Live View displays current activity for the database server. The live view shows key performance metrics for the last time period, which can be refreshed in a specified time interval between 10 seconds and 5 minutes.

Access the Database Live Window

To access the Database Live window:

1. To view a database's current performance, click the name of the database.
2. Click the **Live View t**ab.
3. For clustered databases, select the node to view its details.

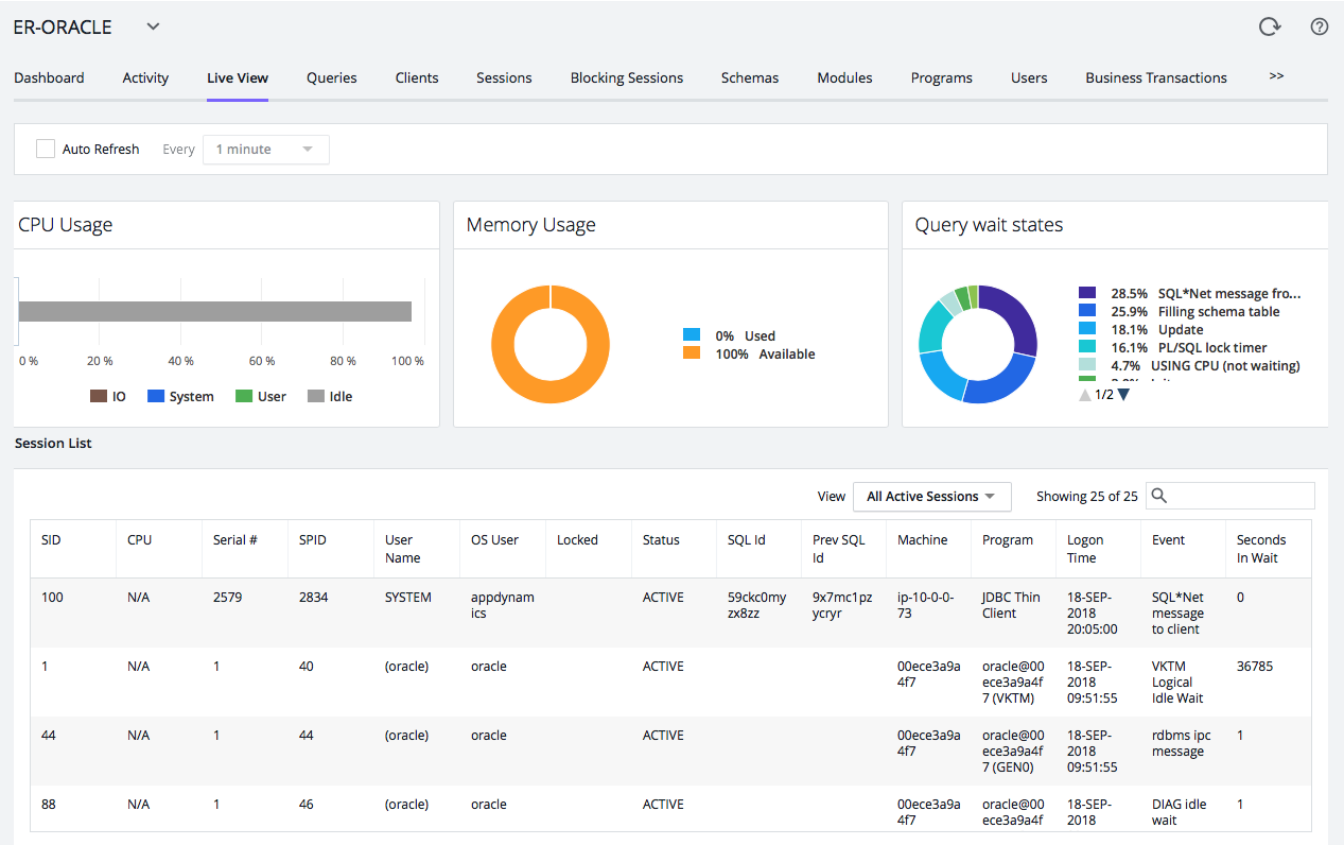
Database Live Window Features

From the Database Live window, you can:

- Select the **Auto Refresh** box and then from the **Every** list, choose how often you want the system to update the live view.
- Click the down arrow next to the database collector name at the top of the page to choose to view the live view of a different database Collector by either selecting the database Collector name from the list or by searching for the database collector by entering text in the search bar and then clicking the refresh icon to show only database collectors that meet that search criteria.
- Hover over the sections of the charts to see their details.
- Click the **View** list to view **All Active Sessions** or **All Sessions**.
- Click a column title on the **Session List** to sort the Session List using the clicked column as the sort key.

From the Database Live window, you can view:

- **CPU Usage**: If you have enabled Hardware Monitoring for the server the chart shows the percentage of available CPU resources consumed by users and the system and a break down of how the CPU is being used.
    - IO - Disk input and output.
    - System - Database operating system activities.
    - User - User interaction with the database.
- **Memory Usage**: Displays how much memory is in use and how much is available.
- **Query wait states**: Activities that contribute to the time it takes the database to service the request. The wait states consuming the most time may point to performance bottlenecks. For example, database file sequential reads may be caused by segment header contention on indexes or by disk contention.
- **Session List**: A table describing database usage instances and their properties. The database session is the application interaction with the database, a new session is started for each request. The columns displayed are database dependent.
- **Blocking Tree**: A tree showing all the sessions causing blocks. Nested under each blocking session are the sessions being blocked and the corresponding queries and blocked objects.



For SQL Server, the **CPU Usage** and **Memory Usage** statistics are displayed in Live View even when hardware monitoring is disabled.

In the Live View for database clusters, you must select a node from the dropdown menu to view that node's activity.

Database Queries Window

Related pages:

- Access Database Visibility from Application Monitoring Views
- Add Database Collectors
- Database Visibility
- Monitor Databases and Database Servers
- Monitor Database Performance

The Queries window displays the SQL statements and stored procedures that consume the most time in the database. You can compare the query weights to other metrics such as SQL wait times to determine SQL that requires tuning.

Access the Database Queries Window

To access the Database Queries window:

1. To view database queries, click the name of the database.
2. Click the Queries tab.

Database Queries Window Features

From the Database Queries window, you can:

- View the top N queries. These are the queries that consumed the greatest amount of database time to complete.
- Choose to display the top 5, 10, 100 or 200 queries.
- Click the name of a column to sort the **Query** list using that key.
- Click **Filter by Wait States** to choose wait states to filter the **Query** list by. The filtered list only displays queries that caused the selected wait states.
- Check the **Group Similar** box to group together queries with the same syntax. Queries that share the same syntax but different 'IN' clause parameters are still grouped together. Query grouping is case-insensitive. Double-click a query group to dive into the Group Details for more information about that query group. Only queries reported by newer agents are grouped; the queries reported by older agents may not appear upon grouping.
- Search for a specific query, by entering text in the search bar that may appear in the Query. This is useful if you found a slow query in the Slow Database calls window of AppDynamics Application monitoring.
- Double-click a query or select a query and click **View Query Details** to dive into the **Query Details** for more detailed information about that specific query. If you see a message saying that query details are unavailable, you may need to update your permissions or extend your query retention period.
- Click the down arrow next to the database Collector name at the top of the page to choose to view the database queries of a different database Collector by either selecting the database Collector from the list or by searching for the database Collector by entering text in the search bar and then clicking the refresh icon to show only database Collectors that meet that search criteria.
- Click **Actions** to:
    - Export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.
    - Rename the selected query so that it is easier to identify. Note that the query name is associated with the query itself. Thus, when a query's retention period expires, both the query and the query name disappear.

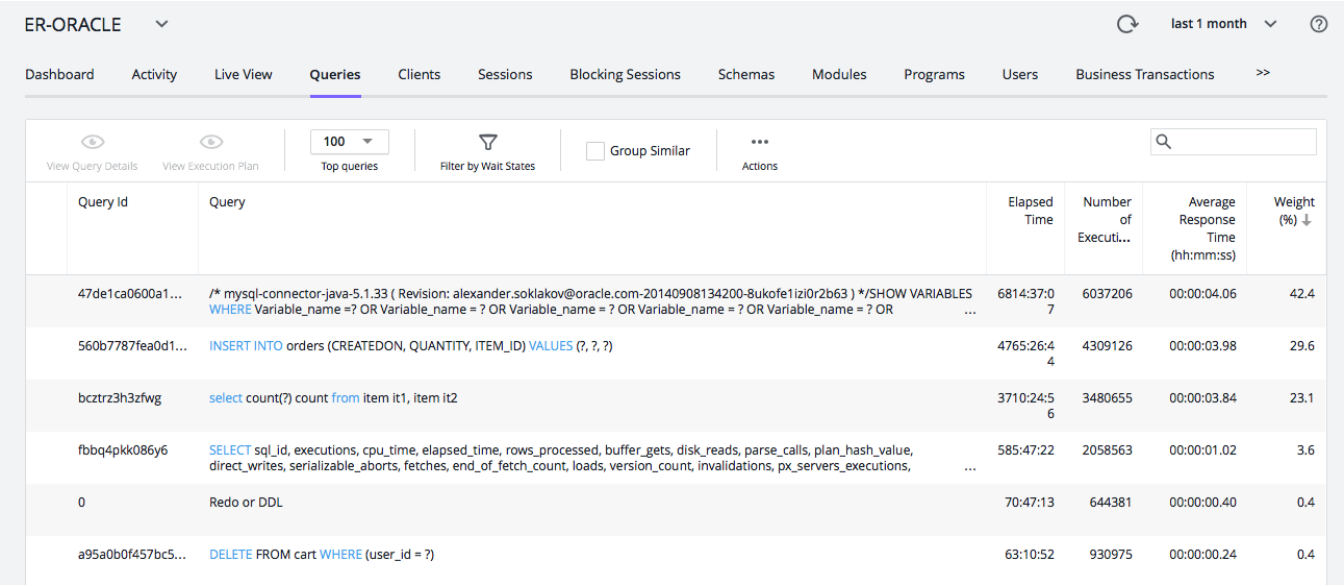
From the Database Queries window, you can view:

- **Query Id**: This is the unique ID assigned to the query internally by the database.
- **Query**: The text of the query, custom query name, or, in the case of a stored procedure invocation, the name of the stored procedure. If the user does not have the ANY permission to view the stored procedure name, the definition of the stored procedure is shown instead of the stored procedure name.

For SQL Server, Azure, Oracle, PostgreSQL and DB2 the metrics Number of Executions, Average Response TIme and Elapsed Time are inferred from the query index. When you are viewing the queries with Group Similar checked, the statistics reflect only the queries that have captured query statistics. Queries that do not have query statistics are excluded from the statistic values.

For databases such as MySQL and MongoDB which do not have a query index, no data will appear in the Number of Executions and Average Response Time columns. However, Elapsed Time can be inferred for MySQL and MongoDB databases using the wait state index. Elapsed Time can also be inferred using the wait state index when query statistics for a query run on an SQL Server, Azure, Oracle, PostgreSQL or DB2 database are otherwise not available. When query statistics are not available for a query run on an SQL Server, Azure, Oracle, PostgreSQL or DB2 database, the Number of Executions and Average Response Time statistics cannot be reported and are marked with a hyphen (-). This means that the database did not provide statistics for this query in the selected time range.

- **Elapsed Time**: The total time consumed by all executions of this query. Query statistics such as Number of Executions, Average Response Time and Elapsed time are available for databases supporting the query index, such as SQL Server, Azure, Oracle, PostgreSQL and DB2. For databases where the query index is not available, the elapsed time is inferred from the wait state index.
  By default, the query sampling frequency is once every second. If a query takes less than one second and happens to occur in the time between sampling instances, its elapsed time is reported as 0 seconds.
  You can configure the sampling frequency by adding the `-Ddbagent.sampling.interval= <value>` property for Database Agent. For information about adding the system properties, see Database Agent Configuration Properties.
- **Number of Executions**: (supported for SQL Server, Azure, Oracle, DB2, PostgreSQL) The number of times the query ran during the specified time period. If you are monitoring Greenplum, the number of executions appears as 0.
- **Average Response Time (hh:mm:ss)**: (supported for SQL Server, Azure, Oracle, DB2, PostgreSQL) The average time required during the specified time period to respond to the query.
- **Weight (%)**: The percentage of the total time consumed by the query.



Once you have identified the statements that are consuming the most resources, you can dig down deeper for details that can help you tune the SQL statement. For in-depth query details, click a SQL statement and then click **View Query Details**. See Database Query Details Window.

Database Query Details Window

Related pages:

- Access Database Visibility from Application Monitoring Views
- Add Database Collectors
- Database Visibility
- Monitor Databases and Database Servers
- Monitor Database Performance

Once you have identified the statements on the Database Queries window that are spending the most amount of time in the database, you can dig down deeper for details that can help you tune those SQL statements. The database instance Query Details window displays details about the query selected on the Database Queries window.

Access the Database Query Details Window

To access the Database Query Details window:

1. To view a database's query details, click the name of the database.
2. Click the Queries tab.
3. Select a query and click **View Query Details**.

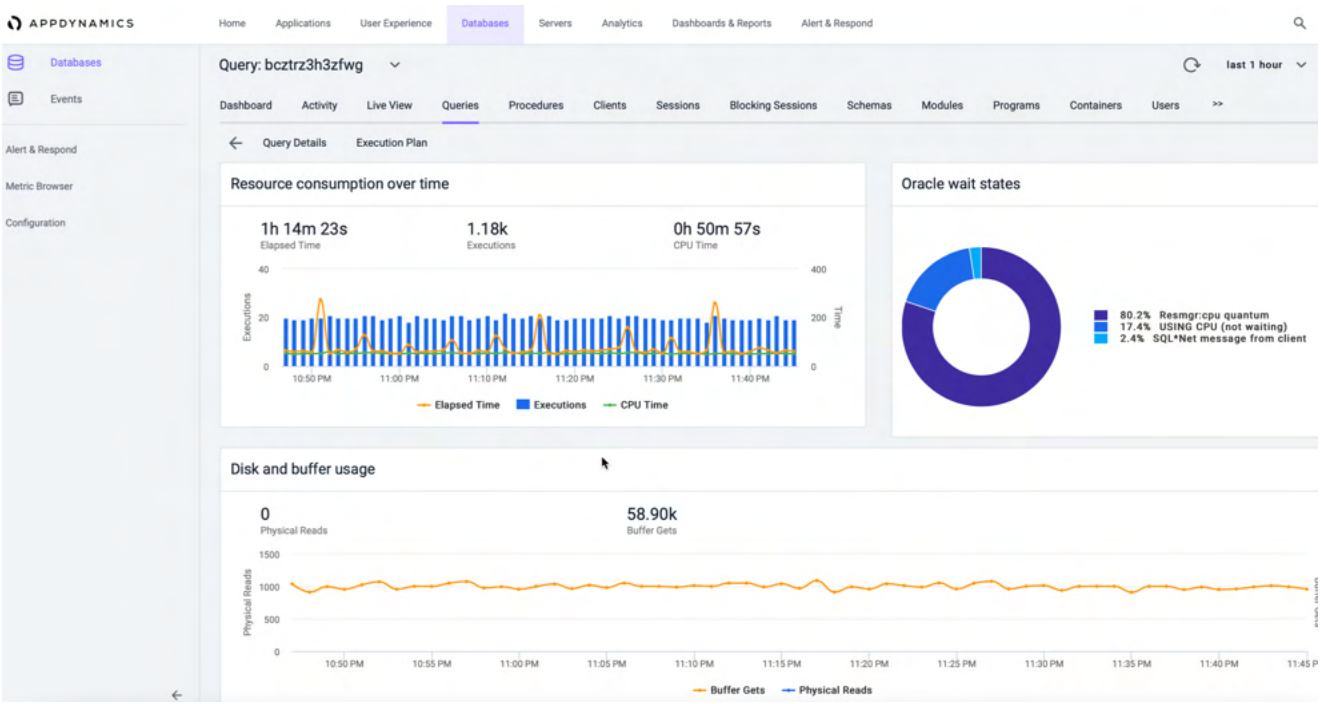
Database Query Details Window Features

From the Database Query Details window, you can:

- Click **Execution Plan** to view an explanation plan for the query you selected on the Queries window if it was a SELECT query.
- Click on the graphs to see metrics for that specific point in time.
- Click the down arrow next to the database Collector name at the top of the page to choose to view the query details of a different database Collector.
- (From 21.5 onwards) Click the back arrow () icon to return to the top queries view in the **Database Queries** window.

From the **Database Query Details** window, you can view:

- **Resource consumption over time**: For SQL Server, Azure, Oracle, and DB2, shows the amount of time the query spent in the database using resources, the number of executions, and the amount of CPU time consumed. Query statistics are only available for the aforementioned database platforms.
  The resource consumption card is also available for query groups. If all queries in the group have query metrics (for example, elapsed time and number of executions), then the aggregate of the group's metrics are shown. If none of the queries in the group have query metrics, then the aggregate elapsed time of the queries in the group, taken from the wait state index, is shown. If some queries in the group have query metrics and others do not, then the aggregate value of the available query metrics is shown.
- **Business Transactions Executing Similar Queries**: Displays the Java or PHP business transactions that execute queries similar to this query.
- **Disk and buffer usage**: Displays data when hardware monitoring is enabled for this database collector. This graph shows at a glance how effectively the database buffer is used. SQL that runs frequently is best kept in the buffer as physical disk reads are much more time-consuming. You may need to optimize your buffer manager if you see that the ratio of physical reads to buffer gets is too high.
- **Clients**: Shows the machines that executed the selected SQL statement and the percentage of the total time required to execute the statement performed by each machine. The table also shows the applications, nodes, and tiers of the machines.
- **<database_type> wait states**: Activities that contribute to the time it takes the database to service the selected SQL statement. The wait states consuming the most time may point to performance bottlenecks. For example, a db file sequential read wait state may be caused by segment header contention on indexes or by disk contention. See your database platform documentation for descriptions of the SQL wait states and recommended actions.
- **Query Active in Database/Schema**: Shows the schemas that have been accessed by this SQL.
- **Query ID (Oracle) SQL Handle (SQL Server)**: A unique ID that allows the database server to more quickly locate this SQL statement in the cache.
- **Query**: The entire syntax of the selected SQL statement. You can click the pencil icon in the top right corner of the Query card to edit the query name so that it is easy to identify.
- **Queries in Group (only in Group Details view)**: The top 100 queries in the query group
- **Users**: The users that executed this query.
- **Programs/Applications**: The program/application from which this query was executed.
- **Procedures**: The list of procedures for the queries that you monitor.
- **Containers:** The containers on which the query runs.



To see how the SQL was executed internally within the database, click the Execution Plan tab. The statement execution plan is the sequence of operations the database performs to run the statement.

Oracle Explain Plan Limitations

For Oracle, AppDynamics Database Visibility displays execution plans for only SELECT, UPDATE, INSERT, and DELETE statements because Database Visibility relies on the Oracle EXPLAIN PLAN statement to obtain the execution plans and the Oracle EXPLAIN PLAN statement only provides the Oracle optimizer's execution plans for SELECT, UPDATE, INSERT, and DELETE statements. See also, User Permissions for Oracle.

If you have a poorly performing piece of SQL that you are trying to tune, the obvious place to start is to look at the most costly step of the execution plan.

Tuning SQL is a vast topic, but a couple of things to look out for include:

- Index or table scans: May indicate a need for better or additional indexes.
- Bookmark Lookups: Consider changing the current clustered index, using a covering index and limiting the number of columns in the SELECT statement.
- Filter: Remove any functions in the WHERE clause, don't include views in your Transact-SQL code, may need additional indexes.
- Sort: Does the data really need to be sorted? Can an index be used to avoid sorting? Can sorting be done at the client more efficiently?

Database Query Execution Plan Window

Related pages:

- Access Database Visibility from Application Monitoring Views
- Add Database Collectors
- Database Visibility
- Monitor Databases and Database Servers
- Monitor Database Performance

The Database Query Execution Plan window can help you to determine the most efficient execution plan for your queries. Once you've discovered a potentially problematic query, you can run the EXPLAIN PLAN statement to check the execution plan that the database created. A query's execution plan reveals whether the query is optimizing its use of indexes and executing efficiently. This information is useful for troubleshooting queries that are executing slowly.

Access the Database Query Execution Plan Window

To access the Database Query Execution Plan window:

1. To view a query execution plan, click the name of the database.
2. Click the Queries tab.
3. Click a **SELECT** statement to examine and click **View Query Details**.
4. Click the Execution Plan tab.

Database Query Execution Plan Window Features

From the Database Query Execution Plan window, you can:

- Click **Explain** to view the execution plan for a query.
- Click **Schema** to choose a different schema and then explain the execution plan based on that schema. If you want to view the execution plan for a query that belongs to a schema outside the scope of your database account permissions, you can enter a username and password for a different database account that has access to the schema.
- If you want to improve a suboptimal query, you can modify the query and paste it into the **Explain another query** box. Click the **Explain** button to generate the execution plan for your modified query and determine whether the modified query is more efficient.
- Click the down arrow next to the query name at the top of the page to choose to view queries and query execution plans of a different database Collector. You can either select the database Collector name from the list or search for the database Collector in the search bar. Click the refresh icon to show only database Collectors that meet your search criteria.

If you are using MSSQL, you can perform these steps to view the costly operations (the amount of work such as CPU usage, I/O, and memory required to complete the operation) in the execution plan along with the warnings (if any) in the plan:

1. Under **Query Plan Handle(s)**, select a cached execution plan.
2. Click **View Cached Plan.**
   You can view the following details:
   Top Plan Operations:

Field Name	Description
Operation	The object scan (table or index) operation in the execution plan
Database	The database name of the object
Schema	The schema of the object in the database
Object Name	The name of the object (table or index) that is scanned in the operation
Estimated I/O Cost	The estimated cost of the input/output (`I/O`) to perform the operation
Estimated CPU Cost	The estimated CPU cost to perform the operation
Estimated number of rows	The estimated number of rows in the object

Warnings: This table includes the warnings in the execution plan related to any issue such as Typecast. This table helps you in understanding the potential performance-degrading activities that happen during the query execution. This table includes these fields:

Issue: The issue description for the warning.

Expression: The query expression used in the execution plan that correlates to the issue.

If you are using Oracle, SQL Server or Azure you can view the execution plan in one of the following ways:

- Select a cached execution plan and click **View Cached Plan** to view the plan details.

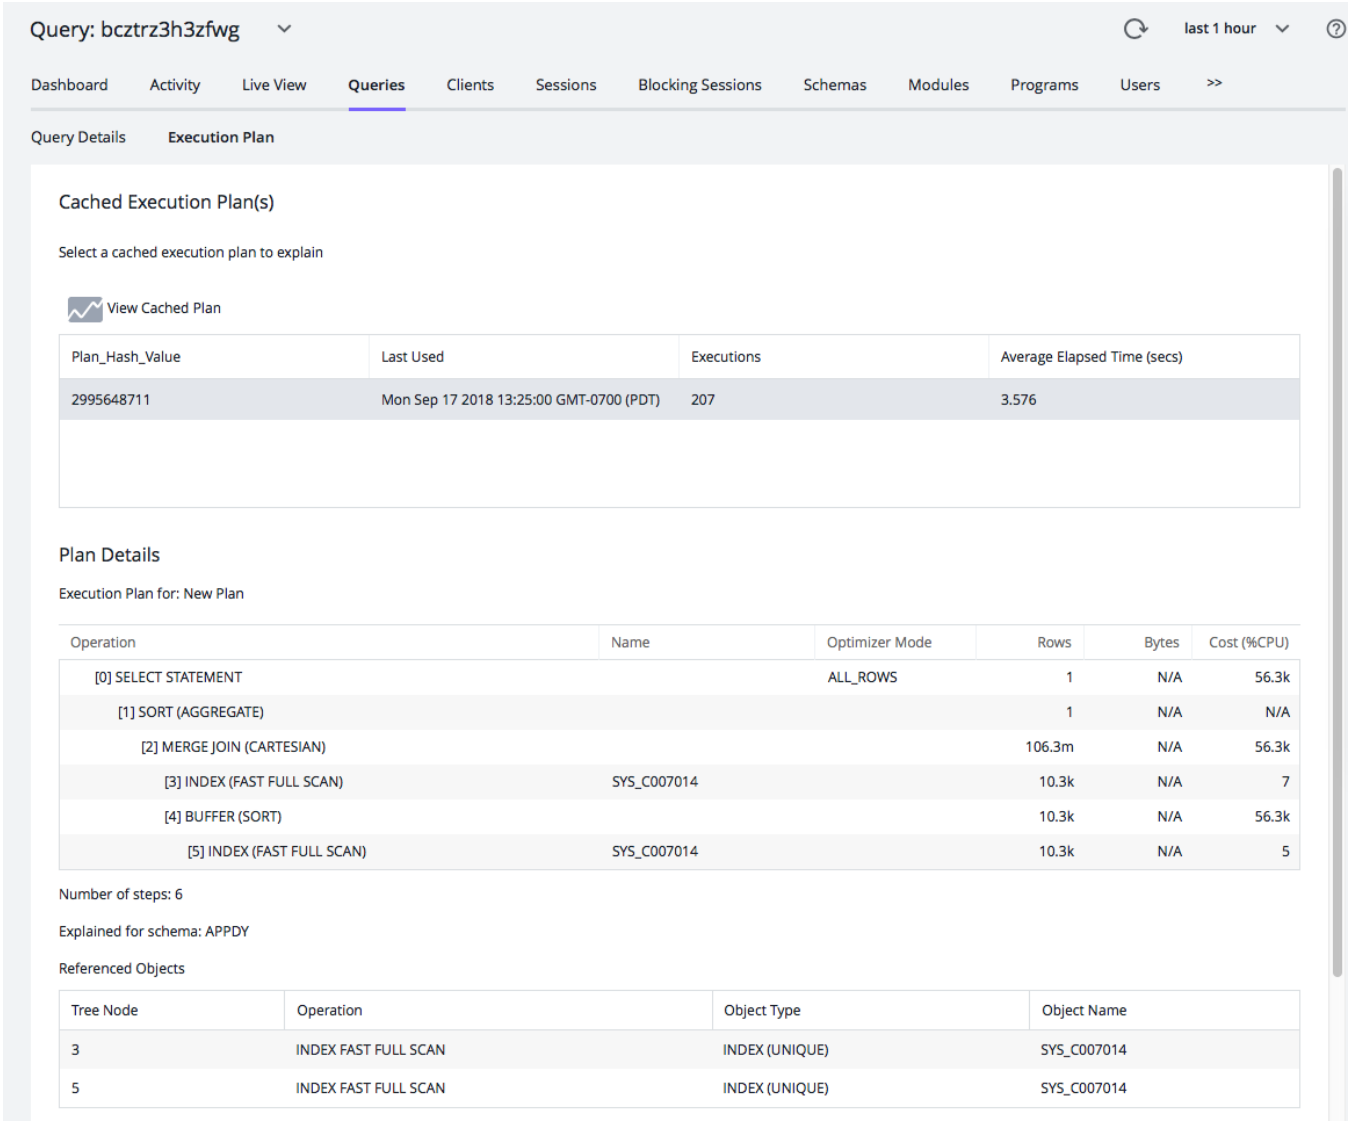
- Double-click a cached execution plan.

If you are using MySQL, you can also:

- Choose to explain the query on another schema. In **Plan Details**, from the list on the right, choose the schema name and then click **Explain**.
- Copy the text in the Parsed SQL output box and paste it into the **Explain another query** box where you can edit it and then explain the edited version of the query.

From the Database Query Execution Plan window, you can view:

- **Cached Execution Plan(s)**: identifying details of the cached execution plan, which vary from one database to another. For SQL Server, the execution plan is rendered as a diagram.
- **Plan Details**: execution plan details, showing the step by step procedure the database followed to process the selected query.
- **Referenced Objects**: the database objects accessed by the execution plan.



Database Procedures Window

The Database **Procedures** window is available for Oracle Server.

The Database **Procedures** window shows you the names of the Top N procedures on the database instance based on time. To see the Top N Queries that are executed in a procedure, click a procedure name and then click **View Top Queries**. From the **Procedures** top queries page, to see more details about a query you can double-click a query to open the Query Details window.

Access the Database Procedures Window

To access the Database Procedures window:

1. To view a database's procedure, click the name of the database.
2. Click the Procedures tab.

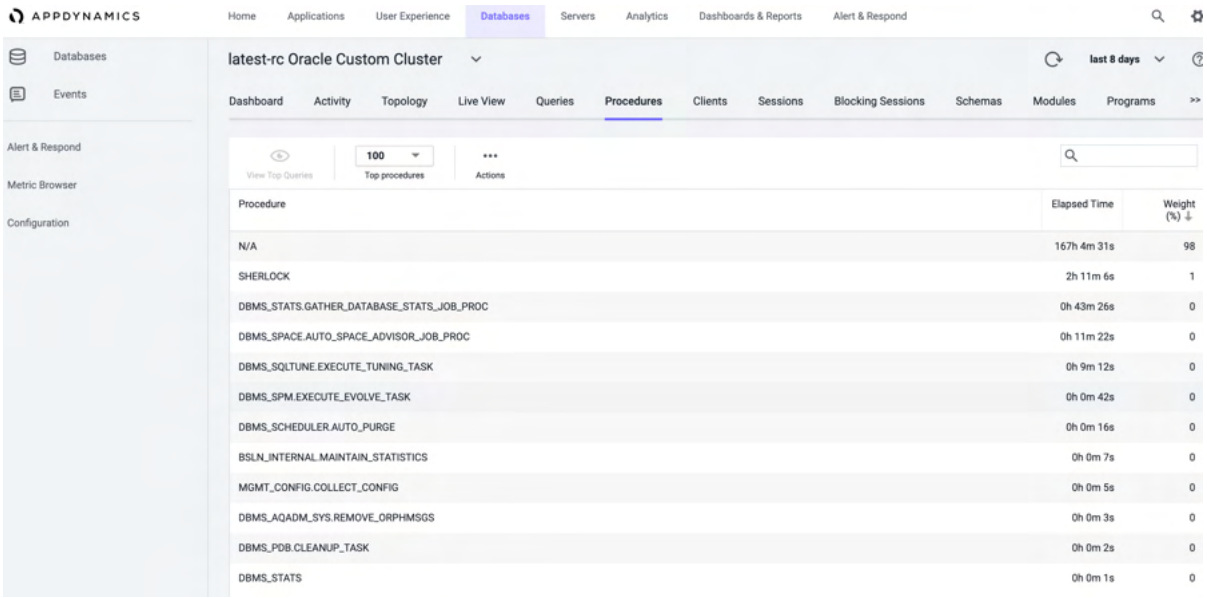
Database Procedures Window Features

From the Database Procedures window, you can:

- Choose to view information for the top 10, 50, 100 or 200 procedures that most frequently access the database server.
- Double click the name of a procedure to view the top queries for one procedure in particular, or select the procedure and then click **View Top Queries**.
- Click the down arrow next to the database collector name at the top of the page to choose to view the procedures of a different Oracle database collector by either selecting the database collector from the list or by searching for the database collector by entering text in the search bar and then clicking the refresh icon to show only database collectors that meet that search criteria.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database **Procedures** window, you can view:

- **Procedure**: The name of the procedure run by an active session in the database.
- **Elapsed Time**: The time taken by the procedure.
- **Weight (%)**: The percentage of time the procedure was consuming the database resources in comparison with the usage percentage of other procedures.



Database Clients Window

Related pages:

- Access Database Visibility from Application Monitoring Views
- Database Queries Window
- Database Visibility
- Monitor Databases and Database Servers
- Monitor Database Performance

The Database Clients window shows you the hostname or IP addresses of the Top N clients using the database. A database client is any host that accesses the database instance. To see the Top N Queries run by the client, click a client name and then click **View Top Queries**. From the client top queries page, to see more details about a query you can double-click a query to open the Query Details window.

Access the Database Clients Window

To access the Database Clients window:

1. To view a database's clients, click the name of the database.
2. Click the Clients tab.

Database Clients Window Features

From the Database Clients window, you can:

- Choose to view information for the top 10, 50, 100 or 200 clients sorted by total time spent in the database.
- Choose to view information for one client in particular.
- Click the down arrow next to the database name at the top of the page to choose to view the database clients of a different database by either selecting the database from the list or by searching for the database by entering text in the search bar and then clicking the refresh icon to show only databases that meet that search criteria.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database Clients window, you can view:

- **Client**: The names of the machines that have connected to the database.
- **Elapsed Time**: The total time spent by the client executing queries.
- **Weight (%)**: The percentage of time the client was connected to the database in comparison with connection times of other clients.

Database Sessions Window

Related pages:

- Access Database Visibility from Application Monitoring Views
- Database Visibility
- Monitor Databases and Database Servers
- Monitor Database Performance

The **Sessions** window shows you the Session ID of the Top N sessions using the database sorted by time spent. To see the Top N SQL run by a session, click the **Session ID** and then click **View Top Queries**. From the Client top queries page, to see more details about a query, double-click a query to open the Query Details window and from there see the Execution Plan of the query.

Access the Database Sessions Window

To access the Database Sessions window:

1. To view a database's sessions, click the name of the database.
2. Click the Sessions tab.

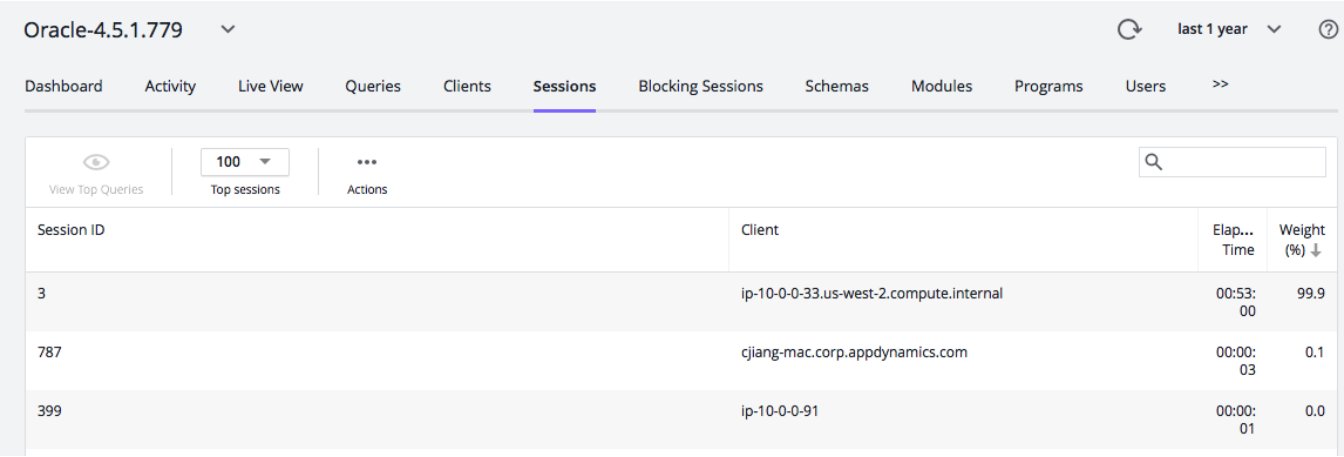
Database Sessions Window Features

From the Database Sessions window, you can:

- Choose to view information for the top 10, 50, 100 or 200 sessions consuming database resources.
- Double click a **Session ID** to view the queries run in that particular session.
- Click the down arrow next to the database name at the top of the page to choose to view the database sessions of a different database by either selecting the database from the list or by searching for the database by entering text in the search bar and then clicking the refresh icon to show only databases that meet that search criteria.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database Sessions window, you can view:

- **Session ID**: the Session ID of each database instance usage.
- **Weight (%)**: the percentage of time that instance was using the database in comparison with the database usage of other sessions.



Database Blocking Sessions Window

The blocking tree displays a tree view of sessions that are blocking other sessions for Oracle, SQL Server, Sybase ASE, and DB2. You can use the blocking tree to determine the cause of deadlocks.

Access the Database Blocking Sessions Window

To access the Database Topology window:

1. To view a database's blocking sessions, click the name of the database.
2. Click the Blocking Sessions tab.

Database Blocking Tree Window Features

From the Database Blocking Tree window you can expand the tree of a blocking session to see the sessions it is blocking.

From the Database Sessions window, you can view:

- **Session ID**: the Session ID of the sessions causing the block, and the sessions being blocked
- **Client**: the names of the machines where the session is blocked
- **User**: the user of the blocked session
- **Query**: the query that is blocked or causing the block
- **Blocked Object**: the object that is blocked
- **First occurrence of block**: the time that the block first occurred in the specified time range
- **Block Duration**: the amount of time that the session was blocked or causing the block

Database Schemas and Databases Windows

The Database Schemas window is available only for Oracle database servers.

The Database Databases window is available for other database servers.

The database Schemas or Databases window shows you the names of the Top N busiest schemas or databases on the database server. To see the Top N Queries run on a specific Database or Schema, click a name and then click **View Top Queries**. From the Schema or Database top queries page, to see more details about a query you can double-click a query to open the Query Details window.

Access the Database Schemas or Databases Window

To access the Database Schemas or Database window:

1. From the AppDynamics Home page, on the **Databases** card, click the name of the database that you want to view the schemas or databases for.
2. Depending on the platform, click either the Schemas or Databases tab.

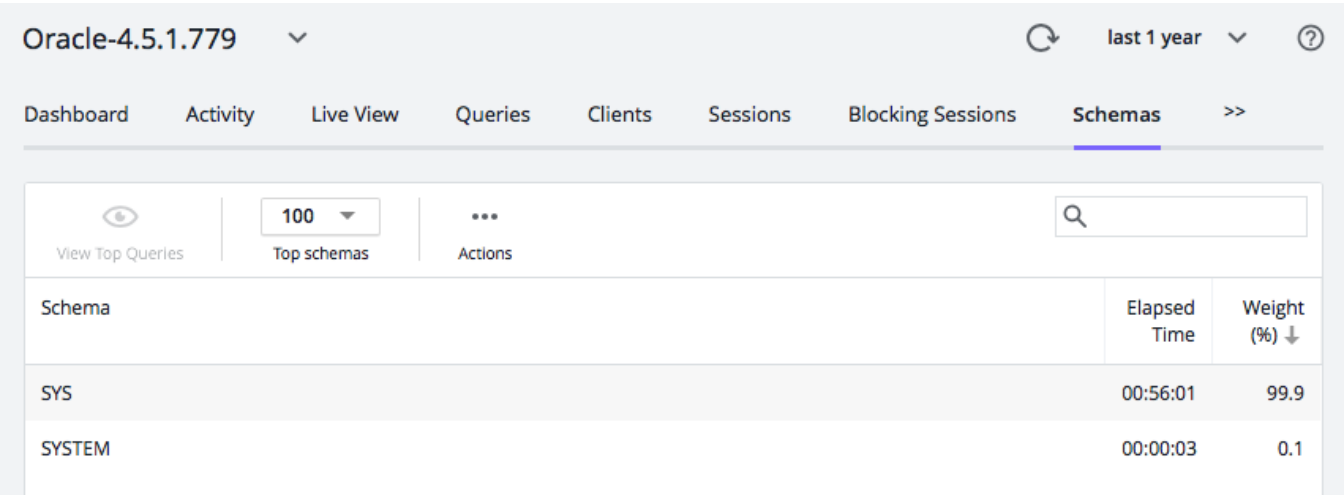
Database Schemas or Databases Window Features

From the Database Schemas and Databases window you can:

- Choose to view information for the top 10, 50, 100 or 200 schemas or databases containing the most time spent executing queries by the database server.
- Double click the name of a schema or database to view the top queries for one schema database in particular, or select the schema or database and click **View Top Queries**.
- Click the down arrow next to the Database Collector name at the top of the page to choose to view the database schemas or databases of a different database Collector by either selecting the database Collector from the list or by searching for the database Collector by entering text in the search bar and then clicking the refresh icon to show only database Collectors that meet that search criteria.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database Schemas or Databases window, you can view:

- **Schema or database**: The names of the schemas or database on the database server.
- **Weight (%)**: The percentage of time the schema or database was used by the database server in comparison with the usage percentage of other schemas or databases.



Database Modules Window

The Database Modules window is available only for Oracle database servers. The **Module** field is often identical to the **Program** field unless it has been programmatically set with a call to DBMS_APPLICATION_INFO. Some packaged applications, such as Oracle E-Business Suite, automatically set the **Module** field with relevant identifiers.

The Database Modules window shows you the names of the Top N busiest modules on the Oracle database server. To see the Top N Queries run on the database by a module, click a module name and then click **View Top Queries**. From the Modules top queries page, to see more details about a query you can double-click a query to open the Query Details window.

Access the Database Modules Window

To access the Database Modules window:

1. To view a database's modules, click the name of the database.
2. Click the Modules tab.

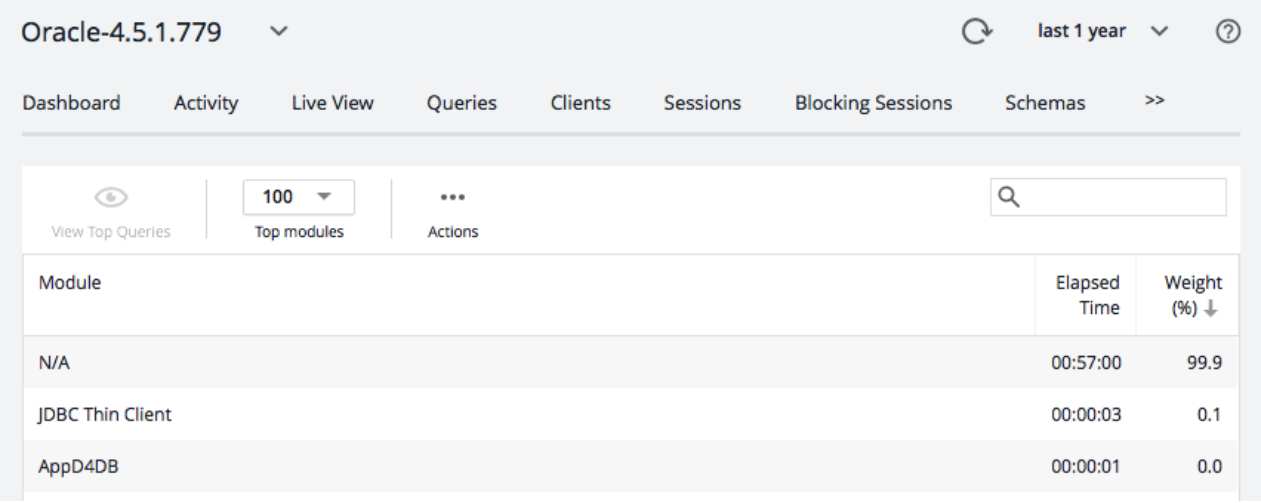
Database Modules Window Features

From the Database Modules window, you can:

- Choose to view information for the top 10, 50, 100 or 200 modules most frequently accessing the database server.
- Double click the name of a module to view the top queries for one module in particular, or select the module and click **View Top Queries**.
- Click the down arrow next to the database collector name at the top of the page to choose to view the modules of a different Oracle database collector by either selecting the database collector from the list or by searching for the database collector by entering text in the search bar and then clicking the refresh icon to show only database collectors that meet that search criteria.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database Modules window, you can view:

- **Module**: The name of the module run by the active sessions in the database.
- **Weight (%)**: The percentage of time the module was consuming the database resources in comparison with the usage percentage of other modules.



Database Programs Window

The Database Programs window is available for Oracle and SQL Server.

The Database Programs window shows you the names of the Top N programs on the database instance based on time. To see the Top N Queries run on the database by a program, click a program name and then click **View Top Queries**. From the Programs top queries page, to see more details about a query you can double-click a query to open the Query Details window.

Access the Database Programs Window

To access the Database Programs window:

1. To view a database's programs, click the name of the database.
2. Click the Programs tab.

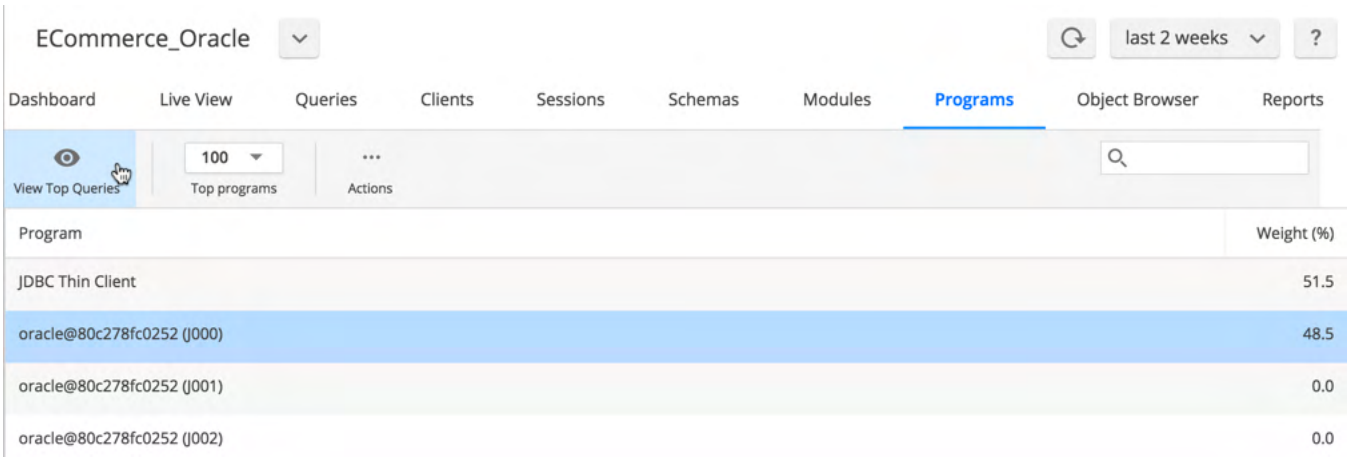
Database Programs Window Features

From the Database Programs window, you can:

- Choose to view information for the top 10, 50, 100 or 200 programs most frequently accessing the database server.
- Double click the name of a program to view the top queries for one program in particular, or select the program and click **View Top Queries**.
- Click the down arrow next to the database collector name at the top of the page to choose to view the programs of a different Oracle database collector by either selecting the database collector from the list or by searching for the database collector by entering text in the search bar and then clicking the refresh icon to show only database collectors that meet that search criteria.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database Programs window, you can view:

- **Program**: The name of the program run by an active session in the database.
- **Weight (%)**: The percentage of time the program was consuming the database resources in comparison with the usage percentage of other programs.



Database Containers Window

The Database **Containers** window is available for Oracle Server.

The **Containers** window displays the names of the Top N containers on the database instance based on time. To see the top N queries run on the container, click a container name and then click **View Top Queries**. From the **Containers** top queries page, to see more details about a query you can double-click a query to open the Query Details window.

Access the Database Containers Window

To access the Database Containers window:

1. To view a database's containers, click the name of the database.
2. Click the Containers tab.

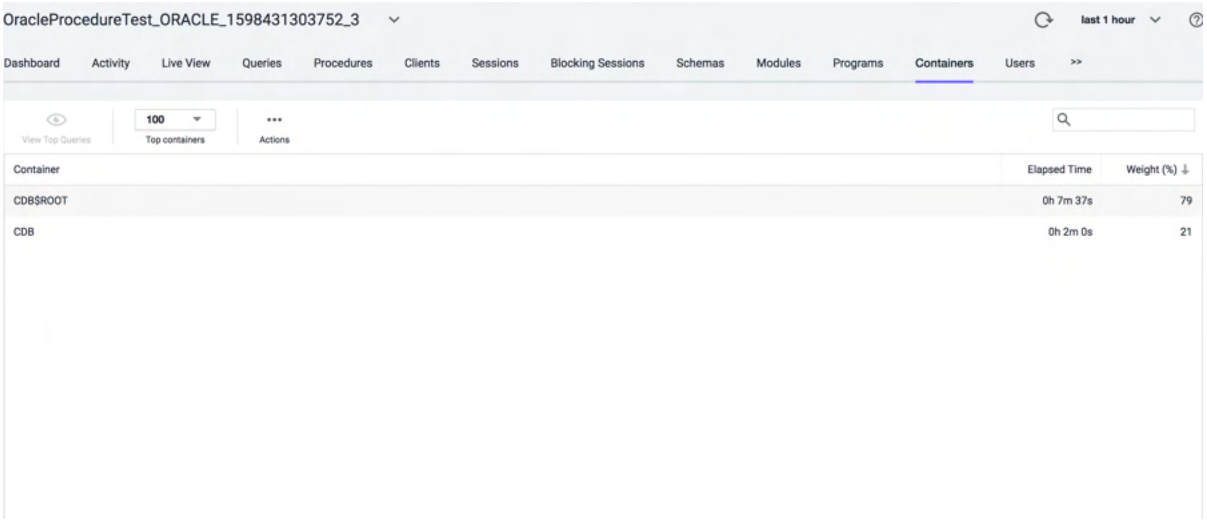
Database Containers Window Features

From the Database Containers window, you can:

- Choose to view information for the top 10, 50, 100 or 200 containers most frequently accessing the database server.
- Double click the name of a container to view the top queries for one container in particular, or select the container and click **View Top Queries**.
- Click the down arrow next to the database collector name at the top of the page to choose to view the containers of a different Oracle database collector by either selecting the database collector from the list or by searching for the database collector by entering text in the search bar and then clicking the refresh icon to show only database collectors that meet that search criteria.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database Containers window, you can view:

- **Container**: The name of the container where queries run in the database.
- **Elapsed Time**: The time taken by the queries to run on the container.
- **Weight (%)**: The percentage of time the Container was consuming the database resources in comparison with the usage percentage of other Containers.



Database Users Window

The Database **Users** window shows you the users using the database. To see the Top N Queries run by a user, double-click the User name, or single-click the User name and then click **View Top Queries**. From the User top queries page, to see more details about a query you can double-click a query to open the Query Details window.

Access the Database Users Window

To access the Database Users window:

1. To view a database's users, click the name of the database.
2. Click the Users tab. You may need to click the expand button (**>>**) to see the Users tab.

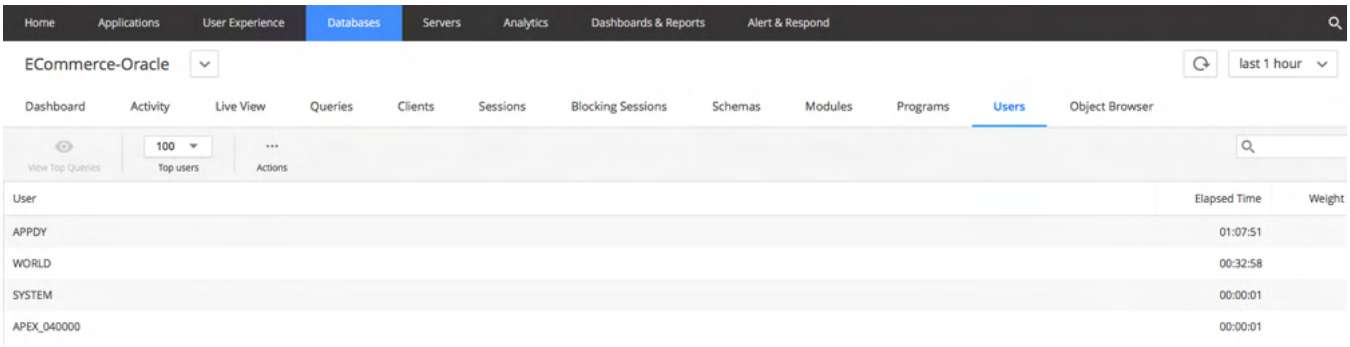
Database Users Window Features

From the Database Users window, you can:

- Use the **Top users** dropdown menu to view information for the top 10, 50, 100 or 200 users sorted by total time spent in the database.
- Click a user to view information for about that user.
- Click the down arrow next to the database name at the top of the page to choose to view the database users of a different database. You can either select the database from the list or search for the database by entering text in the search bar and clicking the refresh icon to show only databases that meet that search criterion.
- Search for the database by entering text in the search bar and then clicking the refresh icon to show only databases that meet that search criterion.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database Users window, you can view:

- **User**: The names of the user accounts that have connected to the database.
- **Elapsed Time**: Duration of time that the user spent executing queries.
- **Weight (%)**: Time the user spent executing queries as a percentage of the total time spent by all users.



Database Buckets Window

The **Buckets** window is available only for Couchbase collector.

The **Buckets** window shows you the names of the top 200 buckets sorted in descending order based on operations. To see the details of a specific bucket, click a bucket name, and then click **View Bucket Details**.

Access the Buckets Window

1. From the AppDynamics Home page, on the **Databases** card, click the name of the Couchbase collector that you want to view the buckets for.
2. Click the Buckets tab.

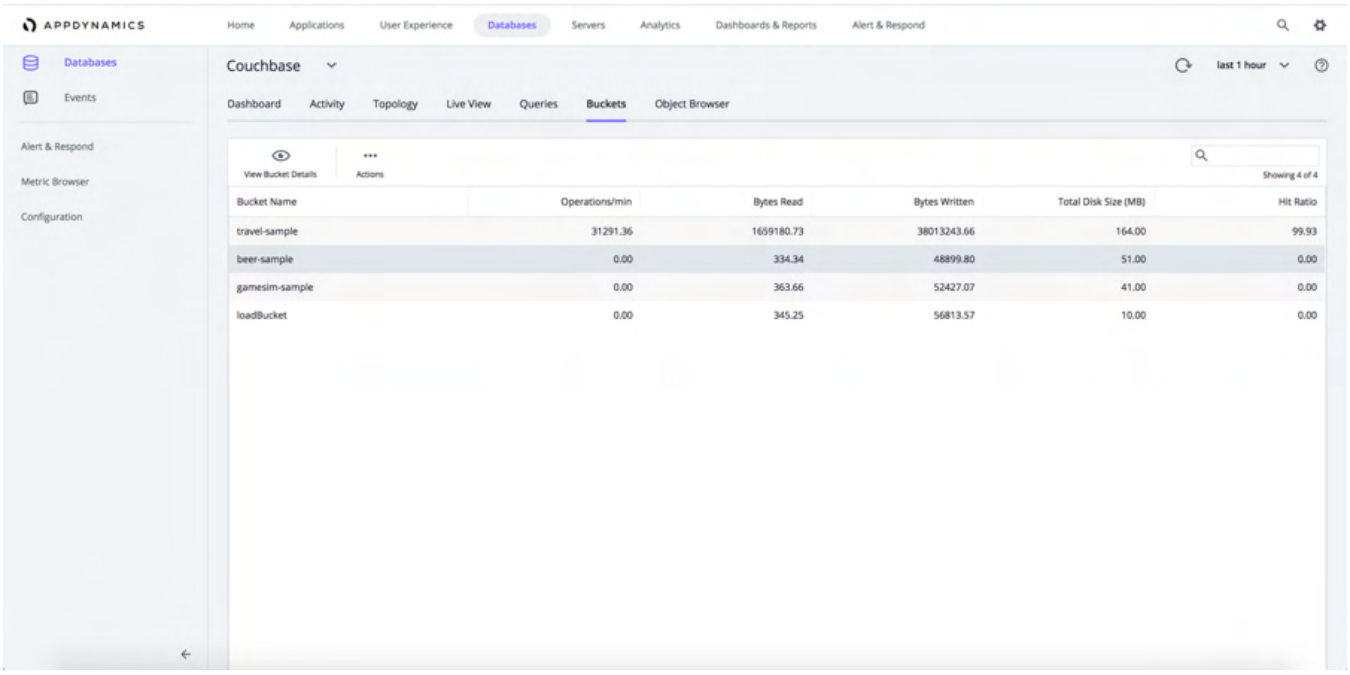
Buckets Window Features

From the Buckets window, you can:

- Double click the name of the bucket to view the bucket statistics for the selected time range.
- Click the down arrow next to the Couchbase collector name at the top of the page to choose to view the buckets of a different Couchbase collector by either selecting the Couchbase collector from the list or by searching for the Couchbase collector by entering text in the search bar and then clicking the refresh icon to show only database collectors that meet that search criteria.
- Click **Actions** to export the data on this window in a `.csv` formatted file that is automatically downloaded to your specified downloads directory.

From the Buckets window, you can view statistics for a bucket:

Operations (`ops`), Bytes Read (`bytes_read`), Bytes Written (`bytes_written`), Total Disk Size, in MB (`couch_total_disk_size`), Hit Ratio (`hit_ratio`)



Database Business Transactions Window

The Database **Business Transactions** window shows you the top Java or PHP business transactions, ranked by their cumulative execution time on the database. To see the Top N SQL run by a business transaction, click the business transaction and then click **View Top Queries**. From the Business Transaction top queries page, you can double-click a query to open the Query Details window.

Supported Platforms

AppDynamics supports Java as an application framework. Relational databases are supported as backends that need to be mapped on the Java APM to a monitored instance in database visibility. For more information, see Linking Database with application backend.

Access the Database Business Transactions Window

To access the Top Business Transactions window:

1. To view a database's business transactions, click the name of the database.
2. Click the Business Transactions tab.

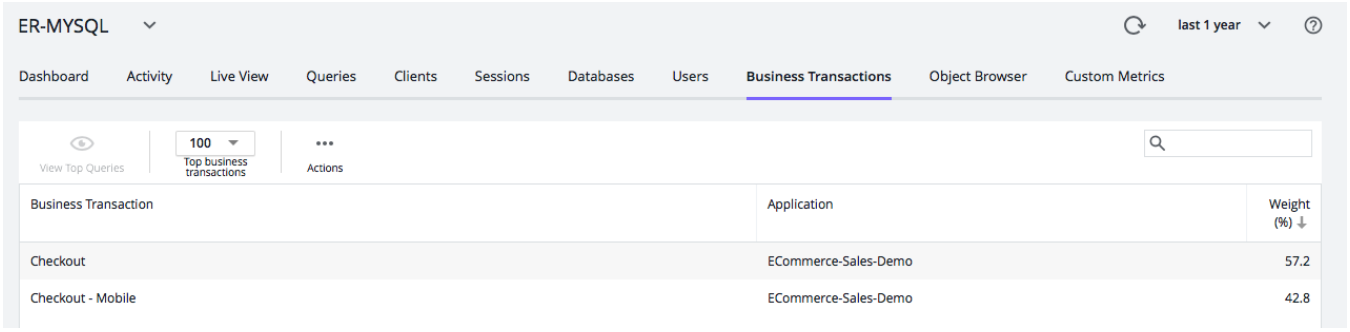
Database Business Transactions Window Features

From the Database Business Transactions window, you can:

- Choose to view information for the top 10, 50, 100 or 200 business transactions executing queries on the database.
- Double-click a business transaction to view the queries run in that particular transaction.
- Click the down arrow next to the database name at the top of the page to choose to view the business transactions that access a different database by either selecting the database from the list or by searching for the database by entering text in the search bar and then clicking the refresh icon to show only databases that meet that search criteria.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database Business Transactions window, you can view:

- **Business Transaction**: the business transactions that run the most number of queries on the database.
- **Application**: the application that each business transaction is executing in.
- **Weight (%)**: the percentage of time that business transaction took to execute compared to other business transactions.



Database Applications Window

The Database **Applications** window is available for Postgres, Sybase ASE, Sybase IQ, and DB2.

The **Applications** window shows you the names of the Top N Applications on the database instance based on time. To see the Top N Queries run on the database by an application, click the name of an application and then click **View Top Queries**. From the Applications top queries page, to see more details about a query you can double-click a query to open the Query Details window.

Access the Database Applications Window

To access the Database Applications window:

1. To view a database's applications, click the name of the database.
2. Click the Applications tab.

Database Applications Window Features

From the Database Applications window, you can:

- Choose to view information for the top 10, 50, 100 or 200 applications most frequently accessing the database server.
- Double click the name of an application to view the top queries for one application in particular, or select the application and click **View Top Queries**.
- Click the down arrow next to the database collector name at the top of the page to choose to view the applications of a different MongoDB database collector by either selecting the database collector from the list or by searching for the database collector by entering text in the search bar and then clicking the refresh icon to show only database collectors that meet that search criteria.
- Click **Actions** to export the data on this window in a `.csv` formatted file that is automatically downloaded to your specified downloads directory.

From the Database Applications window, you can view:

- **Applications**: The name of the application run by an active session in the database.
- **Weight (%)**: The percentage of time the application was consuming the database resources in comparison with the usage percentage of other applications.

Database Object Browser Window

Related pages:

- Access Database Visibility from Application Monitoring Views
- Database Visibility
- Monitor Databases and Database Servers
- Monitor Database Performance

When you detect a problem with database performance, you may be able to correct the problem by adding an index, refusing access to certain users, or creating a new index on a table. You can browse through the database objects to find ways to tune the database, including the indexes that are currently available on the various tables. The contents of the **Database Object Browser** are updated when you access them or click **Refresh**.

> The objects available for browsing are database dependent. For clustered databases, select the node to browse its objects.

Access the Database Objects Window

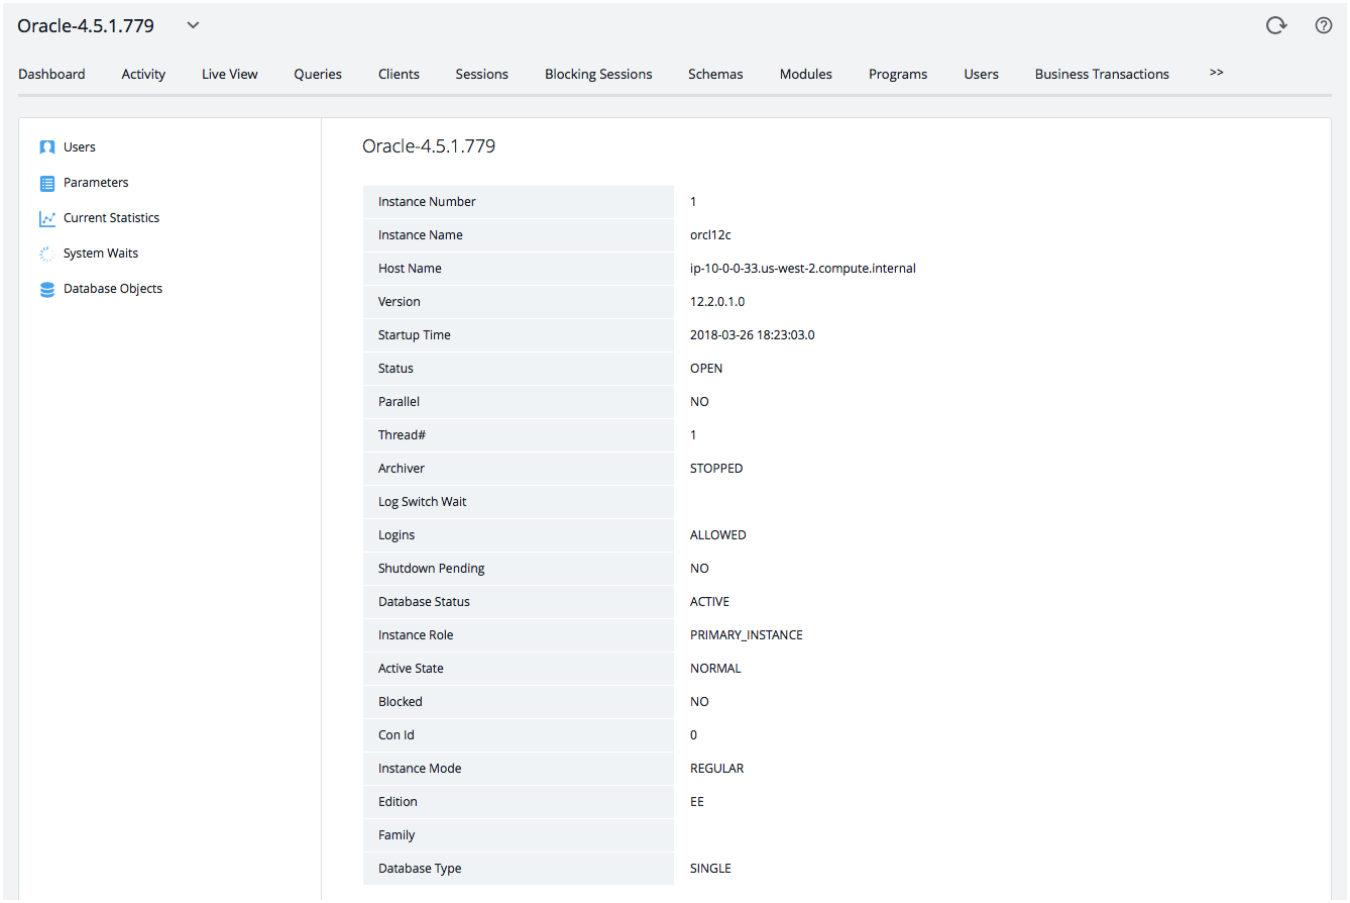
To access the Database Objects window:

1. To view a database's objects, click the name of the database.
2. Click the Objects tab.

Database Objects Window Features

From the **Database Objects** window you can:

- Click an object type in the tree to see more information about it.
- For Oracle, search for a specific database item.
- Click the down arrow next to the database name at the top of the page to choose to view the database objects of a different database by either selecting the database from the list or by searching for the database by entering text in the search bar and then clicking the refresh icon to show only databases that meet that search criteria.



The following are some examples of browsable content.

- Database uptime and version for all platforms
- **Users**: who has access to the database for all platforms (supported for Oracle, MySQL)
- **Job Status**: status of SQL agent job (supported for SQL Server)
- **Parameters**: database initialization parameters (supported for Oracle)
- **Variables**: system variables indicating how the database was configured.
- **Current Statistics**: the current value of statistics collected. The various statistics available are database dependent and are a superset of those shown in the **Database Monitoring - Metric Browser** page.
- **System Waits**: SQL waits experienced by the database
