Environment Variable (Application Setting)	Description (Value)	Required
appdynamics.controller.hostName	Host associated with the Controller used by your Azure Function. Do not include http:// or https://	Yes
appdynamics.controller.port	Port associated with your Controller. If the port is left blank or is invalid, defaults to 443.	No
appdynamics.agent.accountName	Account name associated with the Controller used by your Azure Function.	Yes
appdynamics.agent.accountAccessKey	Access key for your Controller. See <a href="#">Agent-to-Controller Connections</a> .	Yes
appdynamics.agent.applicationName	Name of the Azure Function App.	Yes

Environment Variable (Application Setting)	Description (Value)	Required
appdynamics.controller.ssl.enabled	Sets SSL connection to the Controller. Value "True" enables SSL, while value "False" disables SSL.	No

For example:

### Application settings

Application settings are encrypted at rest and transmitted over an encrypted channel. You can choose to display them in plain text in your browser by using the controls below. Application Settings are exposed as environment variables for access by your application at runtime. [Learn more](#)

+ New application setting    Show values    Advanced edit    Filter

Name	Value	Source	Deployment slot setting
appdynamics.agent.accountAccessKey	1234ABC567def\$89	App Config	
appdynamics.agent.accountName	MyAccount	App Config	
appdynamics.agent.applicationName	ECommerceApp	App Config	
appdynamics.controller.hostName	mycompany.saas.appdynamics.com	App Config	
appdynamics.controller.port	8080	App Config	
appdynamics.controller.ssl.enabled	True	App Config

## Install AppDynamics for Azure Service Fabric

The following instructions explain how to deploy the .NET microservices agent for AppDynamics for Azure Service Fabric.

### Before you Install

From [nuget.org](https://www.nuget.org), download the NuGet package `AppDynamics.Agent.Distrib.Micro.Windows` from <https://www.nuget.org/packages/AppDynamics.Agent.Distrib.Micro.Windows/>, then extract it to a folder. Then, use the following instructions to deploy the agent package.

Choose a procedure below to match your environment:

- Deploy the Package using Visual Studio
- [Deploy the Package using another IDE](#)

## Deploy the Package using Visual Studio

1. From your editor, open `ServiceManifest.xml` in *each* folder in the published `application` root.
2. Add the following environment variables in each `CodePackage` :

```
<CodePackage ...>
 <EntryPoint>
 ...
 </EntryPoint>
 <EnvironmentVariables>
 <EnvironmentVariable Name="COR_ENABLE_PROFILING" Value="1" />
 <EnvironmentVariable Name="COR_PROFILER" Value="{39AEABC1-56A5-405F-B8E7-
C3668490DB4A}" />
 <EnvironmentVariable Name="COR_PROFILER_PATH" Value="<PathToDeploymentFolder>/
AppDynamics.Profiler_x64.dll" />
 </EnvironmentVariables>
</CodePackage>
```

3. Make a copy of the `AppDynamicsConfig.json` file and rename it to `<executable_name>.AppDynamicsConfig.json`. For example, `<servicefabricapplicationname>.AppDynamicsConfig.json`.

**i** When you rename the `.json` file to the application name, do not include `.exe` at the end of your application name.

4. Copy `AppDynamics.Agent.dll`, `AppDynamics.Profiler_x64.dll`, `AppDynamicsAgentLog.config`, `AppDynamicsConfig.json` from `<nuget_package> \content\AppDynamics`, then go to your Visual Studio solution "Solution Items" subfolder.
5. Right-click on the AppDynamics related files and select **Copy Always in Properties**.
6. Update `<executable_name>.AppDynamicsConfig.json` with your configuration information:

```
{
 "controller":
 {
 "host": "",
 "port": 0,
 "account": "",
 "password": ""
 },
 "application":
 {
 "name": ""
 }
}
```

Do not specify node; it will be assigned automatically; Specifying tier is optional, it could be assigned automatically.

The next steps are optional and should only be used if you need per service-instance control of the controller/application/tier.

1. Add the following environment variables to each CodePackage:

```
<EnvironmentVariable Name="appdynamics.controller.hostName" Value="< >" />
<EnvironmentVariable Name="appdynamics.controller.port" Value="< >" />
<EnvironmentVariable Name="appdynamics.agent.accountName" Value="< >" />
<EnvironmentVariable Name="appdynamics.agent.accountAccessKey" Value="< >" />
<EnvironmentVariable Name="appdynamics.agent.applicationName" Value="< >" />
<EnvironmentVariable Name="appdynamics_agent_tier_name" Value="< >" />
```

2. Modify `ApplicationManifest.xml`. In each `ServiceManifestImport` and `CodePackage` folder add:

- In `ServiceManifestImport`:

```
<EnvironmentOverrides CodePackageRef="Code">
 <EnvironmentVariable Name="appdynamics.controller.hostName"
Value="<AppD_ControllerHostName>" />
 <EnvironmentVariable Name="appdynamics.controller.port"
Value="<AppD_ControllerPort>" />
 <EnvironmentVariable Name="appdynamics.agent.accountName"
Value="<AppD_AccountName>" />
 <EnvironmentVariable Name="appdynamics.agent.accountAccessKey"
Value="<AppD_AccountAccessKey>" />
 <EnvironmentVariable Name="appdynamics.agent.applicationName"
Value="<AppD_ApplicationName>" />
 <EnvironmentVariable Name="appdynamics_agent_tier_name"
Value="<AppD_Service_Name_TierName>" />
</EnvironmentOverrides>
```

- In `Parameters`:

```
<Parameter Name="AppD_ControllerHostName" DefaultValue="<Your_Controller_Name>" />
<Parameter Name="AppD_ControllerPort" DefaultValue="<Your_Controller_Port>" />
<Parameter Name="AppD_AccountName" DefaultValue="<Your_Controller_Account_Name>" />
<Parameter Name="AppD_AccountAccessKey" DefaultValue="<Your_Controller_Access_Key>" />
<Parameter Name="AppD_ApplicationName" DefaultValue="<Your_Controller_App_Name>" />
```

- For each service: `<Parameter Name="AppD_%SERVICE_NAME%_TierName" DefaultValue="<Tier_Name_For_Service>" />`

3. If you need to provide the AppDynamics configuration during application package deployment, you can now do it using the `- ApplicationParameter` switch of the `New-ServiceFabricApplication` cmdlet.

## Deploy the Package using another IDE

1. From your editor, open `ServiceManifest.xml` in each folder in the published application root.
2. Add the following environment variables in each CodePackage:

```
<CodePackage ...>
 <EntryPoint>
```

```

...
</EntryPoint>
<EnvironmentVariables>
 <EnvironmentVariable Name="COR_ENABLE_PROFILING" Value="1" />
 <EnvironmentVariable Name="COR_PROFILER" Value="{39AEABC1-56A5-405F-B8E7-
C3668490DB4A}" />
 <EnvironmentVariable Name="COR_PROFILER_PATH" Value="AppDynamics/
AppDynamics.Profiler_x64.dll" />
</EnvironmentVariables>
</CodePackage>

```

- Using PowerShell, unpack `AppDynamics.Agent.dll`, `AppDynamics.Profiler_x64.dll`, `AppDynamicsAgentLog.config`, `AppDynamicsConfig.json` from `<nuget_package>\content\AppDynamics` to the code package folder that contains the executable you want to run.
- Make a copy of the `AppDynamicsConfig.json` file and rename it to `<executable_name>.AppDynamicsConfig.json`. For example, `<servicefabricapplicationname>.AppDynamicsConfig.json`.

 When you rename the `.json` file to the application name, do not include `.exe` at the end of your application name.

- Update `<executable_name>.AppDynamicsConfig.json` with your configuration information:

```

{
 "controller":
 {
 "host": "",
 "port": 0,
 "account": "",
 "password": ""
 },
 "application":
 {
 "name": ""
 }
}

```

Do not specify the node; it will be assigned automatically. Specifying the tier is optional; it could be assigned automatically.

The next steps are optional and should only be used if you need per service-instance control of the controller/application/tier.

- Add the following environment variables to each `CodePackage`:

```

<EnvironmentVariable Name="appdynamics.controller.hostName" Value="" />
<EnvironmentVariable Name="appdynamics.controller.port" Value="" />
<EnvironmentVariable Name="appdynamics.agent.accountName" Value="" />

```

```

<EnvironmentVariable Name="appdynamics.agent.accountAccessKey" Value="" />
<EnvironmentVariable Name="appdynamics.agent.applicationName" Value="" />
<EnvironmentVariable Name="appdynamics_agent_tier_name" Value="" />

```

2. Modify `ApplicationManifest.xml`. In each `ServiceManifestImport` and `CodePackage` folder add:

- In `ServiceManifestImport`:

```

<EnvironmentOverrides CodePackageRef="Code">
 <EnvironmentVariable Name="appdynamics.controller.hostName"
 Value="<AppD_ControllerHostName>" />
 <EnvironmentVariable Name="appdynamics.controller.port"
 Value="<AppD_ControllerPort>" />
 <EnvironmentVariable Name="appdynamics.agent.accountName"
 Value="<AppD_AccountName>" />
 <EnvironmentVariable Name="appdynamics.agent.accountAccessKey"
 Value="<AppD_AccountAccessKey>" />
 <EnvironmentVariable Name="appdynamics.agent.applicationName"
 Value="<AppD_ApplicationName>" />
 <EnvironmentVariable Name="appdynamics_agent_tier_name"
 Value="<AppD_Service_Name_TierName>" />
</EnvironmentOverrides>

```

- In `Parameters`:

```

<Parameter Name="AppD_ControllerHostName" DefaultValue="<Your_Controller>" />
<Parameter Name="AppD_ControllerPort" DefaultValue="<Your_ControllerPORT>" />
<Parameter Name="AppD_AccountName" DefaultValue="<Your_Controller_AccountName>" />
<Parameter Name="AppD_AccountAccessKey" DefaultValue="<Your_Controller_AccessKey>" />
<Parameter Name="AppD_ApplicationName" DefaultValue="<Your_Controller_App_Name>" />

```

- For each service: `<Parameter Name="<AppD_Service_Name_TierName>" DefaultValue="<Tier_Name_For_Service>" />`

3. If you need to provide the AppDynamics configuration during application package deployment, you can now do it using the `-ApplicationParameter` switch of the `New-ServiceFabricApplication cmdlet`.

## Install AppDynamics for Azure Cloud Services

You can use Microsoft Visual Studio with the NuGet package `AppDynamics.Agent.Azure.CloudServices` to add the .NET Agent directly to Azure Cloud Services projects: Web Roles and Worker Roles.

## Prepare to Install the NuGet Package

To install the AppDynamics for Windows Azure NuGet package you need:

- Connection information for your [Agent-to-Controller Connections](#) 4.4
- Visual Studio >= 2012
- A Visual Studio solution to monitor

The user account running Visual Studio must have the following permissions to the solution:

- **Read** and **Write** permissions to each **project directory**
- **Read** and **Write** permissions to each **Visual Studio .NET C# Project (\*.csproj)** file

- **Read** and **Write** permissions to the **Service Definition** (ServiceDefinition.csdef) file
- Windows Azure SDK
- Windows Azure account

These instructions assume you are familiar with NuGet package management in Visual Studio and with the Microsoft Azure Portal. You can also try the step-through tutorial on how to instrument an App Service on the [community knowledgebase](#).

If you are upgrading to a new version of the AppDynamics for Windows Azure NuGet Package, see [Upgrade AppDynamics.WindowsAzure NuGet Package](#).

### Add the .NET Agent to Your Azure Solution

Use the NuGet package manager to browse the [nuget.org](#) package source and install the **AppDynamics.Agent.Azure.CloudServices** package to your Azure solution in Visual Studio.

For details about managing NuGet packages, see the [documentation](#) for your version of Visual Studio.

The **AppDynamics.Agent.Azure.CloudServices** package installation prompts you as follows:

- The installer may ask you to verify your changes. If so, click **OK**.
- Click **I accept** to agree to the terms of the license.

The package manager installs the .NET agent into your project.

The configuration file installs to `<project_root>/App_Data/AppDynamics/Config/config.xml`. Enter the connection information for your AppDynamics Controller in the config.xml file. For details about Controller connection settings, see [Agent-to-Controller Connections](#).

```
NuGet - Solution
1 <?xml version="1.0" encoding="utf-8"?>
2 <appdynamics-agent xmlns:xsd="http://www.w3.org/2001/XMLSchema" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
3 <controller host="" port="0" ssl="false" enable_config_deployment="false">
4 <application name="" />
5 <account name="" password="" />
6 </controller>
7 <machine-agent />
8 <app-agents azure="true" azure-role-name="" azure-role-instance-id="">
9 <IIS>
10 <automatic />
11 </IIS>
12 <standalone-applications>
13 <standalone-application executable="WaWorkerHost.exe">
14 <tier name="" />
15 </standalone-application>
16 </standalone-applications>
17 </app-agents>
18 </appdynamics-agent>
19
```

By default the .NET Agent names Azure tiers as role name for Cloud Services.

If you want to customize the tier name, edit config.xml under `<project_root>/App_Data/AppDynamics/Config.xml`. For more information and examples, see "Name IIS Tiers Manually" on [Name .NET Tiers](#).

After you finish any configuration changes, publish your solution to Windows Azure. For Cloud Services solutions, you can put load on your published project and log on to the AppDynamics Controller and begin monitoring your solution.

## Update .NET Agent Configuration for Cloud Services

If you have already published your solution, you can update the .NET Agent configuration for the currently installed version without upgrading the agent.

1. Edit the config.xml file to make configuration changes.
2. Edit the startup.cmd file under `<solution_root>/AppDynamics`.
3. By default, the APPD\_AGENT\_CONFIGUPDATE variable is set to true. If you want to modify the configuration on your Azure Cloud Services machine, and you want to prevent the AppDynamics script from overwriting it, set APPD\_AGENT\_CONFIGUPDATE to false.

## Upgrade AppDynamics.WindowsAzure NuGet Package

If you are currently using the AppDynamics.WindowsAzure NuGet package to monitor your Azure solutions, you must upgrade to one of the newest packages on [nuget.org](https://nuget.org), depending on your platform and the applications that you want to monitor. For a list of packages, see [.NET Microservices Agent](#).

To upgrade your Azure NuGet package:

1. In Visual Studio or other IDE, uninstall the AppDynamics.WindowsAzure NuGet package.

**i** For Azure App Service only: After you uninstall the NuGet package, you *must* delete the AppDynamics folder from the Azure portal and your Visual Studio solution. You may need to stop your application first before deleting this folder. During uninstallation, the webconfig modification that is responsible for filtering user requests against the AppDynamics folder is removed, but this does not remove the AppDynamics folder. You must manually delete this folder. You must also remove the AppDynamics-specific information from `apphostconfig.xdt`.

2. Install one of the new NuGet packages.

## Release Notes and PDFs

Release Notes	Associated PDF
<a href="#">4.4.3 Azure Enhancements and Resolved Issues</a>	<a href="#">4.4.3_AppDynamics_for_Azure_2018-04-02.pdf</a>

### 4.4.3 Azure Enhancements and Resolved Issues

Enhancements:

- Microsoft Orleans is supported on the .NET and .NET microservices agents.
- .NET Core 2.0 for Windows is supported on the .NET microservices agent.
- Support for Azure Service Fabric Remoting v2.

The following NuGet packages are now available. If you have used a previous version of an AppDynamics NuGet package, you will need to upgrade to the new version. See [Upgrade AppDynamics.WindowsAzure NuGet Package](#).

AppDynamics.Agent.Distrib.Micro.Windows	AppDynamics NuGet package for .NET. This package <i>should not</i> be installed directly and is intended for download and file distribution. This package is used for Azure Service Fabric deployments. See <a href="#">Install AppDynamics for Azure Service Fabric</a> for instructions.
AppDynamics.Agent.Windows	AppDynamics .NET Core microservices agent for Windows. Recommended for standalone installations. See <a href="#">Install the .NET Core Microservices Agent for Windows</a> for deployment instructions. NOTE: This package does not support .NET Framework, only .NET Core for Windows.
AppDynamics.Agent.Azure.CloudServices	AppDynamics .NET agent for Azure Cloud Services. See <a href="#">Install AppDynamics for Azure Cloud Services</a> .
AppDynamics.Agent.Azure.AppService.Windows	AppDynamics .NET microservices agent for Azure App Service. This package is intended for applications deployed to Azure App Service (Azure Web Apps and Azure API Apps). See <a href="#">Install the AppDynamics .NET Microservices Agent</a> and <a href="#">Install AppDynamics for Azure App Service</a> for instructions.

## Machine Agents

### Related Pages:

- [SELinux Installation Issues](#)

Machine Agents and Network Agents give you end-to-end visibility into the hardware and networks on which your applications run. These agents can help you identify and troubleshoot problems that can affect application performance such as server failures, JVM crashes, and network packet loss.

You use the [Machine Agent](#) to collect basic hardware metrics. The functionality provided by the Machine Agent includes:

- Reporting basic hardware metrics from the server OS, for example, %CPU and memory utilization, disk and network I/O
- Reporting metrics passed to the Controller by extensions
- Running remediation scripts to automate your runbook procedures. You can optionally configure the remediation action to require human approval before the script is started.
- Running JVM Crash Guard to monitor JVM crashes and optionally run remediation scripts

If you have a [Server Visibility](#) license, the Machine Agent provides the following additional functionality:

- Extended hardware metrics such as machine availability, disk/CPU/virtual-memory utilization, and process page faults
- Group servers together so that health rules can be applied to specific server groups
- Define alerts that trigger when certain conditions are met or exceeded based on monitored server hardware metrics

## SELinux Installation Issues

SELinux is a security mechanism that works on top of the native file and directory read/write/execute permissions within the Linux file system. It is available for most Linux distributions and is installed by default in newer RHEL (Red Hat Enterprise Linux) & Fedora distributions.

As SELinux may prevent the installation and/or operation of any software being executed, ensure that you create appropriate policy file for it.

**i** Ensure that you consult with your security team to determine the correct level of access for the APM.

SELinux allows you to set a finer granularity of restrictions on access and execution. This control is represented by "policy files", typically created and maintained by the SecOps team within your organization. For more details about SELinux, see [https://selinuxproject.org/page/Main\\_Page](https://selinuxproject.org/page/Main_Page).

The policy files are found in `/etc/sestatus.conf` by default. To determine if SELinux exists on your system, run the `getenforce` command which returns the string `Enforcing` if it is active.

Alternatively, you can run this command:

```
sestatus
```

which generates this output:

```
SELinux status: enabled
SELinuxfs mount: /selinux
Current Mode: permissive
Policy version: 16
sestatus
```

If `SELinux status` is `disabled`, it indicates that the system has not installed the package. However, if the status returned is `enabled`, but the `Current Mode` is `permissive`, then SELinux policy files are not enforced. To install and test the APM Agent:

- Set the mode to permissive and then enable it
- Follow the SELinux guidelines to create the appropriate policy statements for the agent in question

**i** For more details on how to customize your policy files, see [https://access.redhat.com/documentation/en-us/red\\_hat\\_enterprise\\_linux/5/html/deployment\\_guide/sec-sel-policy-customizing](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/5/html/deployment_guide/sec-sel-policy-customizing). To enable SELinux, use the command `setenforce 1` to enable enforcing mode; to disable SELinux use `setenforce 0` (set to permissive mode). For more details about enabling/disabling SELinux, see: [https://docs.fedoraproject.org/en-US/Fedora/11/html/Security-Enhanced\\_Linux/sect-Security-Enhanced\\_Linux-Working\\_with\\_SELinux-Enabling\\_and\\_Disabling\\_SELinux.html](https://docs.fedoraproject.org/en-US/Fedora/11/html/Security-Enhanced_Linux/sect-Security-Enhanced_Linux-Working_with_SELinux-Enabling_and_Disabling_SELinux.html)

## Administer App Server Agents

These pages provide general information about [installing App Server agents](#).

For Agent-to-Controller version compatibility information, see [Agent and Controller Tenant Compatibility](#).

## Planning Agent Deployment

When planning your deployment, you should consider whether to install agents manually or automatically.

If deploying a relatively small number of agents, you may choose to install the agent manually.

For larger environments involving hundreds of agents, you should develop an automated deployment strategy.

For specific agents, see these links:

- Java: [Java Agent](#) or [Install the Java Agent](#)
- .NET: [.NET Agent](#) or [Install the .NET Agent for Windows](#)
- Node.js: [Node.js Agent](#) or [Install the Node.js Agent](#)
- PHP: [PHP Agent](#) or [Install the PHP Agent](#)
- Python: [Python Agent](#) or [Install the Python Agent](#)
- Database Agent: [Administer the Database Agent](#)
- Machine Agent: [Install the Machine Agent](#)

For automated deployment guidelines, see [Controller Deployment](#).

## Encrypt Agent Credentials

### Related pages:

- [Encrypt Credentials in .NET Agent Configuration](#)
- [Java Agent Configuration Properties](#)

This page provides an overview of securing agent credentials in AppDynamics.

AppDynamics agents store several types of credential information on disk, including:

- Controller account access key
- Controller keystore/agent truststore password
- Proxy server password

### Secure Credential Store

You can use the Secure Credential Store to encrypt credentials in the agent configuration for environments where security policies require secure credentials on disk.

The Secure Credential Store is comprised of two components:

- `scs-tool.jar`: A utility to create the secure credential store, encrypt credentials, and obfuscate the credential store password.
- Secure credential keystore: A keystore for the secret encryption key.

The Secure Credential Store encrypts plain text using the strongest encryption available according to the system's encryption jurisdiction policy.

For the .NET Agent, see [Encrypt Credentials in .NET Agent Configuration](#).

After you set up the Credential Keystore, you must specify the following settings:

For the Analytics Agent:

- `ad.secure.credential.store.filename`
- `ad.secure.credential.store.password`

See [Analytics Agent Rules](#).

For the Java, Machine, and Database Agents:

- <controller-ssl-enabled>
- <controller-keystore-filename>
- <controller-keystore-password>

See [Java Agent Configuration Properties](#), [Machine Agent Properties](#), and [Database Agent Properties](#).

## Initialize the Secure Credential Store

Before you can encrypt or obfuscate passwords, you must run the Secure Credential Store utility to create the keystore for your secret encryption key. The agent distribution includes the Secure Credential Store utility in the following locations:

- Java Agent: <javaagent\_home>/verX.X.X.X/Utils/scs/scs-tool.jar
- Machine Agent: <machine\_agent\_home>/lib/secure-credential-store-tool-1.3.23.jar
- Database Agent: <database\_agent\_home>/lib/scs-tool.jar
- Analytics Agent: <analytics\_agent\_home>/bin/tool/scs-tool.jar

Run the Secure Credential Store utility `generate_ks` command with the following parameters:

- `filename` : Absolute path where the utility will create the secure credential keystore. Use this path for <credential-store-filename> in agent configuration.
- `storepass` : The secure credential keystore password. Use the obfuscated version of this password as the value for <credential-store-password> in agent configuration.
- `format` (For FIPS-compliant users only): The format of the secure credential keystore.

For example:

### Example

```
/<full path to application JRE>/bin/java -jar ./scs-tool.jar generate_ks -filename '/opt/appdynamics/secretKeyStore' -storepass 'MyCredentialStorePassword'
```

### Example for FIPS-Compliant Users

```
/<full path to application JRE>/bin/java -jar ./scs-tool.jar generate_ks -filename '/opt/appdynamics/secretKeyStore' -storepass 'MyCredentialStorePassword' -format 'FIPS'
```

The Secure Credential Store utility confirms it created and initialized the keystore:

```
Successfully created and initialized new KeyStore file: /opt/appdynamics/secretKeyStore
Verification - New KeyStore file: /opt/appdynamics/secretKeyStore is properly initialized.
```

## Encrypt Passwords

To encrypt passwords using the secure credential store utility, run the `encrypt` command with the following parameters:

- `filename` : Absolute path to the secure credential keystore file.
- `storepass` : Password for the secure credential keystore. You can use either a plain-text password or a password that has been obfuscated as described in the following section.
- `plaintext` : Any plain text to encrypt. For instance, account access key or password.

The following example uses a plain-text password— `storepass` argument—for the secure credential keystore:

```
/<full path to application JRE>/bin/java -jar ./scs-tool.jar encrypt -filename '/opt/appdynamics/secretKeyStore' -storepass 'MyCredentialStorePassword' -plaintext 'MyAccessKeyOrPassword'
```

The same example uses an obfuscated password:

```
/<full path to application JRE>/bin/java -jar ./scs-tool.jar encrypt -filename '/opt/appdynamics/secretKeyStore' -storepass 's_gsnwR6+LDch8JBf1RamiBoWfMvjjiPKrtJMZXAYEkW8=' -plaintext 'MyAccessKeyOrPassword'
```

The Secure Credential Store utility writes out an encrypted password for use in agent configuration files:

```
r9iDWPzHRCNDM1B6KTag4A/cA5B4pouVPkv48ovRm6c=
```

### Obfuscate the Secure Credential Store Password

In order to access the secret key in the secure credential keystore, the agent needs the obfuscated credential store password.

Run the secure credential store utility `obfuscate` command with the following parameter:

- `plaintext` : The plain text secure credential keystore password.

For example:

```
/<full path to application JRE>/bin/java -jar /opt/appdynamics/scs-tool.jar obfuscate -plaintext 'MyCredentialStorePassword'
```

The Secure Credential Store utility writes out an obfuscated password for use in the `<credential-store-password>` in agent configuration.

For example:

```
s_gsnwR6+LDch8JBf1RamiBoWfMvjjiPKrtJMZXAYEkW8=
```

### Encrypt a Plain Text Property

After you obfuscate the Secure Credential Store password, you can encrypt plain text properties.

The following example demonstrates how to encrypt properties in the Analytics Agent:

```
$ /<full path to application JRE>/bin/java -jar scs-tool.jar encrypt -filename /opt/
appdynamics/secretKeyStore -storepass 'Welcome' -plaintext 'MyAccountAccessKey'
```

The property generates an encrypted credential:

```
-001-24-pFoSE/xdPcinkBj9iikVpQ==Rznx8Kt3sPZHqNkFYyubVuhorrBEbYFtDTPm8c/
1kFO+Z2eR2WEHtBRg4vy1GyvJ
```

## Sample Agent Configuration

The following example demonstrates the agent configuration properties for the Secure Credential Store. For more information, see the agent-specific configuration property documentation:

### Java Agent Configuration

```
<?xml version="1.0" encoding="UTF-8"?>
<controller-info>
 ...
 <!-- Encrypted account access key -->
 <account-access-key>r9iDWPzHRCNDM1B6Ktag4A/cA5B4pouVPkv48ovRm6c=</account-access-key>

 <!-- Encrypted Controller keystore / agent trust store password -->
 <controller-keystore-password>Tw49bd0hdCMB0Q5pfMMuYA/cA5B4pouVPkv48ovRm6c=</controller-
keystore-password>

 <!-- Enable the Secure Credential Store -->
 <use-encrypted-credentials>true</use-encrypted-credentials>

 <!-- Path to they secure credential keystore -->
 <credential-store-filename>/opt/appdynamics/secretKeyStore</credential-store-filename>

 <!-- Obfuscated secure credential keystore password -->
 <credential-store-password>n/8GvAZsKk4gM3Z6g+XQ1w==</credential-store-password>
 ...
</controller-info>
```

### Analytics Agent Configuration

#### Example

```
ad.credential.store.filename=/opt/appdynamics/secretKeyStore
ad.credential.store.password=s_gsnwR6+LDch8JBf1RamiBoWfMvjipkrtJMZXAYEkw8=
```

### Example for FIPS-Compliant Users

```
ad.credential.store.filename=/opt/appdynamics/secretKeyStore
ad.credential.store.password=s_gsnwR6+LDch8JBf1RamiBoWfMvjjiPKrtJMZXAYEkW8=
ad.credential.store.format=FIPS
```

## Machine Agent Configuration

```
<?xml version="1.0" encoding="UTF-8"?>
<controller-info>
...
<!-- Encrypted account access key -->
<account-access-key>-001-24-
fr9OWDSaQ2KDpaaHDfXDag==DFiWMukAzjQgj+Ba9XIt0bqn+HIG3F5dYu1IbiQCs1HkJ+6nCIxCQ0QT4w2VP2WG</
account-access-key>
<use-encrypted-credentials>true</use-encrypted-credentials>
<credential-store-filename>/opt/appdynamics/secretKeyStore</credential-store-filename>
<credential-store-format>PKCS12</credential-store-format>
<credential-store-password>s_-001-12-it4fyuDG9hg=hBRnCU+i+o81yG5rIqopog==</credential-store-
password>
...
</controller-info>
```

## Encrypt Data on the Analytics Agent

You can encrypt any data on the Analytics Agent using `secure://<your-encrypted-credentials>`. You can encrypt data in the Analytics Agent properties file or in System Properties.

The following example demonstrates how to encrypt `http.event.accessKey` in the Analytics Agent properties file:

```
http.event.accessKey=secure://-001-24-Dr9FQGC179o4vPnuljnx8A==ZGVw/
P400NvpUIdIhJ2u78FpRVVW8fbgr8J1HBHXwnE=
ad.secure.credential.store.filename=/opt/appdynamics/secretKeyStore
ad.secure.credential.store.password=s_gsnwR6+LDch8JBf1RamiBoWfMvjjiPKrtJMZXAYEkW8=
```

## Manage App Agents

From the AppDynamics Agents page, you can manage, reset, and disable app agents connected to the Controller, and view agent status and information.

### Permissions

To manage app agents, you must belong to a role with the Account level permission:

- Administer users, groups, roles, authentication, and so on
- View license

- View AppDynamics agents
- Use Agent Download Wizard

The predefined Account Owner role includes the required permission.

To access app agent administration settings, click **Settings**  > **AppDynamics Agents** > **App Server Agents**.

### Associate App Agents with a Business Application

If you start an application server with an app agent without specifying the business application, the agent appears in the App Server Agents tab as an unassociated agent. You can associate an agent with an application manually:

1. From the agents list in the App Server Agents tab, select the unassociated app agent from the list.

 In the **View** menu, click **Agents not associated with an Application** to filter the list of App Server Agents.

2. Click **Associate with Application**. This button is enabled only for app agents that are connected to the Controller but not associated with a business application.

### Reset App Agents

 To reset app agents, users need the "Agent Advanced Operation" permission.

Resetting the app agent causes the agent to register itself with the Controller in the same way it does at JVM or application startup, but without restarting the JVM or application. Resetting the app agent purges in-memory data for the agent. It also applies certain configuration changes to the app agent, such as app agent node property changes.

Resetting an app agent causes the Controller to:

- Purge data such as in-memory business transactions and metrics, exit calls, and registration information for the agent
- Reset the business transaction limit counter to zero for the selected agent

Resetting an agent does not re-instrument or remove existing instrumentation. After a reset, the agent re-registers business transactions and backends and it creates new metrics. You may lose a few minutes worth of data between the reset and re-registration operations.

You may need to reset agents after you have reconfigured business transaction or backend detection and the agent is not applying the updated rules:

1. Delete all existing transactions and backends. See information on deleting unwanted business transactions in [Transaction Detection Rules](#), [Monitor Databases](#), and [Remote Services](#).
2. Choose a reset option:
  - To reset all the app agents for a business application, click **Reset Agents**.
  - To disable a individual app agents, select one or more agents and click **Reset Selected App Agent(s)**.

### Enable and Disable App Agents

Disabling an app agent stops the agent from reporting metrics to the Controller. Disabling an agent can help you diagnose agent installation or application issues. It also lets you compare the difference in overhead

between when the agent is capturing data versus when it is not, for example, without removing the agent. Disabling the agent does not require you to shut down or restart the application server.

Disabling an app agent does not stop the agent from operating or remove the bytecode instrumentation added by the agent. To fully remove the agent including remove bytecode instrumentation, follow the steps to uninstall the app agent or fully disable agent instrumentation under the [Install App Server Agents](#) page specific for the agent type. Uninstalling an app agent or fully disabling an app agent in this manner typically requires an application restart.

All agents connected to the Controller count against the agent license limits for that Controller. Even though it only reports minimal app server-related data, a disabled app agent is still connected to the Controller and consumes an app agent license.

To enable or disable all the app agents for a business application, the App Server Agents tab, click **Enable Agents** or **Disable Agents**.

#### Permission:

You must have the application-level permission, *configure agent properties* to enable and disable agents.

You can enable or re-enable individual agents by selecting them and clicking **Enable Selected App Agent** or **Disable Selected App Agent**. Alternatively, enable or disable app agents individually from the Agents tab on the Node Dashboard:

- To disable the agent, click Agent is **Off**.
  - To enable the agent, click Agent is **On**.
- It takes about a minute for the operation to take effect.

By default turning the agent **Off** completely disables monitoring. For Java agents, un-check **Disable all monitoring including JVM and JMX metrics** on the Disable This App Agent pane to continue collecting JVM and JMX metrics such as heap memory, memory pools, garbage collection, and thread count.

## Delete App Agents

Deleting an app agent removes the agent and any associated data from the Controller database. This does not affect the instrumentation of the application server. If the application server is still running with an app agent, or if it is subsequently restarted with an app agent, the agent re-registers and appears again in the Controller.

You can delete an app agent by clicking **Delete Agent from System**.

To completely remove an app agent completely so that it does not register again, uninstall it. See uninstallation instructions for your agent platform under [Install App Server Agents](#).

## Agent Log Files

### Related pages:

- [Java Agent Logging](#)
- [.NET Agent on Windows Logging](#)
- [PHP Agent Logging](#)
- [Node.js Agent Logging](#)
- [Python Agent Debugging and Logging](#)

- [Apache Agent Logging](#)
- [Dynamic Agent Proxy Logging](#)
- [Business Transactions Logging](#)
- [Bytecode Transformer Logging](#)
- [REST Logging](#)
- [Analytics Agent Logging](#)

You can use agent logs to resolve agent configuration and application instrumentation issues. The Controller can generate and archive agent log files that you can submit to AppDynamics Support for troubleshooting assistance. See [Request Agent Log Files](#).

## Agent Log File Information

The beginning of the log file shows the startup of the agent monitoring services and the configuration settings. The agent log also contains the sequence of agent runtime activity and exceptions that are encountered. You can use this information to troubleshoot deployment issues.

Examples of log information:

- Agent version and build date
- JVM runtime version (Java only)
- Configuration changes
- Backend detection
- Exceptions
- Output from logging session requests

## Logging Levels

The logging levels, listed in order from collecting the most information to the least, are:

- ALL: Logs all events.
- TRACE: Reports finer-grained informational events than the debug level that may be useful to debug an application.
- DEBUG: Reports fine-grained informational events that may be useful to debug an application.
- INFO: Default log level. Reports informational messages that highlight the progress of the application at coarse-grained level.
- WARN: Reports on potentially harmful situations.
- ERROR: Reports on error events that may allow the application to continue running.

Not all agents log at all levels.

## Log Structure

This section describes how the agent logs are rolled over for these agents:

- Java Agent
- .NET Agent
- Proxy
- BytecodeTransformer
- Business Transactions
- JMX
- REST
- Machine Agent
- Dynamic Services (used internally)

When the maximum file size is reached, a new log file is created. The first file is named ...0.log, second file is ...1.log, and so on. There is a maximum of five files per set and a maximum of five sets for each instrumented node. If the maximum number of sets is reached, when a new set is created, the oldest set is deleted.

While the agent rotates away old log files, it retains the initial log file. The first log file contains information that reflects the specific context in which the agent was started, along with other information that can be useful for troubleshooting and record keeping. On agent restart, a new set is created and the oldest set is deleted

Each set includes not only the application agent log but also, depending on which logs exist, the `ByteCodeTransformer` log, the `REST` log and the `BusinessTransaction` log. A single set might consist of:

- `agent.<timestamp>.#.log`
- `ByteCodeTransformer.<timestamp>.#.log`
- `REST.<timestamp>.#.log`
- `BusinessTransaction.<timestamp>.#.log`

where `#` is the number of the set.

For example, these logs in the logs directory were created on April 3 or the first set, set 0. The agent is a Java Agent; this is indicated by the prefix `agent`. Other app agents use different naming conventions. See the [agent-specific information](#).

```
agent.2015_04_03__14_49_38.0.log
agent.2015_04_03__14_49_46.0.log
agent.2015_04_03__14_51_04.0.log
BusinessTransactions.2015_04_03__14_49_38.0.log
BusinessTransactions.2015_04_03__14_49_46.0.log
BusinessTransactions.2015_04_03__14_51_04.0.log
ByteCodeTransformer.2015_04_03__14_49_40.0.log
ByteCodeTransformer.2015_04_03__14_49_47.0.log
ByteCodeTransformer.2015_04_03__14_51_04.0.log
REST.2015_04_03__14_49_38.0.log
REST.2015_04_03__14_49_46.0.log
REST.2015_04_03__14_51_04.0.log
```

On the next agent restart a new set is created. The logs in this set, set 1, will have names such as:

```
agent.2015_04_03__14_53_05.1.log
. . .
```

and the next set, set 2,

```
agent.2015_04_04__15_12_06.2.log
. . .
```

and so on through the five potential sets.

---

## Agent-Specific Information

AppDynamics app server agents have different logging locations and different maximum log sizes.

### Bytecode Transformer Logging

#### Related pages:

- [Agent Log Files](#)
- [Java Agent Logging](#)
- [.NET Agent on Windows Logging](#)
- [Dynamics Agent Proxy Logging](#)

The Bytecode Transformer log is generated by the Java Agent, the .NET Agent and the proxy. It contains the information associated with the AppDynamics SaaS bytecode instrumentation (BCI) engine. The BCI engine is used to inject interceptors. The BCI engine logs the classes being loaded in the application.

This log is useful for troubleshooting issues that depend on bytecode instrumentation including entry points, exit points, missing metrics, loggers, errors, exceptions, and asynchronous threads.

This log includes:

- Agent version and build date
- Each Java class that was examined and whether the methods were considered for bytecode instrumentation
- Each method that was instrumented

For the Java Agent and the proxy, the log is named `ByteCodeTransformerYear_mon_day_hr_min.#.log`, where # is the logging set number.

For the .NET Agent, the log is named `ByteCode.txt`.

See [Agent Log Files](#) for details about how the sets are organized that roll over.

### REST Logging

#### Related pages:

- [Agent Log Files](#)
- [Java Agent Logging](#)
- [.NET Agent on Windows Logging](#)
- [Dynamic Agent Proxy Logging](#)

The REST log contains information about the AppDynamics agent and Controller communication. The log contains request and response payload data between the agent and the Controller, and the raw details of communications between the agent and the Controller. By default, the REST log contains INFO level logging for all registration requests up to a limit of one MB every five minutes.

You can use this log to troubleshoot issues with detecting and reporting business transactions, backends, events, and metric reporting.

The communication between the agent and Controller consists of:

- Configuration data
- Node identification
- Machine registration
- Business transaction registration
- Metric registration
- Event registration
- Snapshot capture/upload to controller database
- Metric data upload to controller database
- Event data upload to the Controller database

- Output from Logging Session requests

The naming convention for the REST log is `REST.<timestamp>.#.log` where # is the set.

See [Agent Log Files](#) for information about the structure of the log files into sets that roll over.

Within a set, a REST log file can reach a maximum of 5 MB.

## Metrics Limits

To ensure that metric information that is most relevant to your application displays, agents have limits for the number of metrics they can store. Different limits apply to app agents and machine agents:

- For an app agent, the default maximum number of registered metrics is 5000.
- For the Machine Agent, the default maximum number of registered metrics is 450. This includes both basic hardware metrics and the expanded metrics available with Server Visibility.

If the limit is reached, an error event is generated of type `AGENT_METRIC_REG_LIMIT_REACHED` with a summary of *Metric registration limit of n reached*. No new metrics are created until the agent restarts. If necessary, you can increase the default limit.

### Agent Metric Limits

You can increase or decrease the default metric registration limits for machine agents or app agents.

**!** Changing these limits can affect the resource consumption of your deployment. Before you change this setting verify your application environment and Controller can handle the increased resource requirements.

For the Java agent, modify the limit using the `agent.maxMetrics` system property. For example, to increase the machine agent metric limit, specify the maximum number of metrics as an argument when starting the machine agent in the following format:

```
-Dappdynamics.agent.maxMetrics=<max-number-of-metrics>
```

For example, when starting the machine agent, increase the maximum number of metrics that can be registered to 2000 as follows:

```
nohup java -Dappdynamics.agent.maxMetrics=2000 -jar
machineagent.jar &
```

For the .NET Agent, set the `maxMetrics` property as an environment variable. This setting only affects the app agent. For example:

```
appdynamics.agent.maxMetrics=5500
```

For the .NET Agent for Linux, use the node property below to set agent metric limits. See [App Agent Node Properties \(A\)](#) for more information.

```
appdynamics.agent.metricLimits
```

For the .NET Machine Agent, specify the maximum number of metrics using the Metrics element in the config.xml. See 'Machine Agent Element' on [.NET Agent Configuration Properties](#). See also [Administer the .NET Agent](#).

```
<metrics max-metrics="300"/>
```

## Controller Metric Limits

The Controller applies its own limits on metric registration. For an on-premises Controller, you can view and modify the properties that control the metric registration limit in the Controller settings page in the [Controller Administration Console](#).

The relevant Controller settings are:

- `metric.registration.limit`: The maximum number of metrics that can be registered for an account in the Controller. The default is 2 million.
- `application.metric.registration.limit`: The maximum number of metrics that can be registered for a business application in the Controller. The default is 1 million.

## Historical and Disconnected Nodes

If a node has been out of contact with the Controller for a certain amount of time, the Controller marks the node as a historical node. The Controller suspends certain types of processing activities for the node, such as rule evaluation.

If the node resumes contact with the Controller before the node deletion period expires, the Controller restores it to an active state. Otherwise, the node is permanently removed from the Controller and the node level data is no longer accessible in the UI. Tier and application level historical metric data for the node remains available after the node is deleted.

By default, the Controller considers a node historical after about 20 days of inactivity and deletes the node after 30 days. For a highly dynamic application environment in which nodes are created and destroyed frequently, AppDynamics recommends that you shorten the node activity timeout period to allow recycled nodes to be treated as such in the Controller.

The node activity timeout period is determined by the node retention period or activity settings.

The names of historical nodes can be assigned to new nodes. [Node name reuse](#) is a Java Agent option that, when enabled, directs the Controller to reuse node names so that data generated by multiple, short-lived nodes in a given tier is associated with a single logical node.

## Node Activity and Agent Licensing

For licensing purposes, the Controller releases the license for the agent if the Controller has not received data from the agent in the previous 5 minutes. This license availability behavior is not affected by the historical node status or node deletion timeout settings.

## Configure Node Activity Settings

The node activity settings are account level settings that the root AppDynamics administrator for on-prem customers can modify from the [Administration Console](#). For SaaS customers, you will need to contact your Cisco AppDynamics account representative to change the node activity settings.

- `node.permanent.deletion.period` : Time (in hours) after which a node that has lost contact with the Controller is deleted permanently from the system. The data is removed. If the agent starts reporting again after this period, it will start like a new node. Therefore, no historical data will be available at the node level. You will see historical data at the tier and app level, and cluster roll up will take place as normal.  
The default is 720 hours, the minimum value is 6 hours, and the maximum value for this setting is unlimited.
- `node.retention.period` : Time (in hours) after which a node that has lost contact with the Controller is deleted. In this case, the Controller UI will not display the node, however, the system will continue to retain it.  
If the agent starts reporting again within these hours, it will reappear in the UI and the counter will reset. The data is persisted.

 When entity liveness is enabled in the Administration Console, the historical nodes are displayed in the Controller UI even when the node is deleted (exceeds `node.retention.period`). However, if the nodes are permanently deleted (exceeds `node.permanent.deletion.period`), the Controller UI will not display the node even when entity liveness is enabled.

The default is 500 hours, the minimum value is 1 hour, and the maximum value for this setting is unlimited.

Additional notes about the node retention period:

- A node will be impacted by the node retention period even if a Machine Agent is associated with that node. If a Machine Agent associated with the App Server Agent is running, the node retention period will still be in effect.
- You can have any number of Machine Agents running in background that will never appear in the Controller unless the Machine Agent:
  - runs on a host machine that has been shut down or cannot connect to the Controller.
  - is not instrumented or has been uninstalled.
  - has been stopped.
- If you need a node to be considered for the node retention period, it should be marked as historical on shutdown:

```
-Dappdynamics.jvm.shutdown.mark.node.as.historical=
```

## Configure Nodes as Historical Asynchronous Endpoints

When you mark a node historical using asynchronous processing, it allows the Controller to be more efficient in handling a large number of requests at the same time.

You can use the following parameter to mark a maximum of 25 nodes as historical.

Name	Type	Value	Mandatory
<code>application-component-node-ids</code>	Query	Comma-separated list of node IDs	Yes

The following is an example command that returns the nodes that are validated and queued to be marked as historical.

### Example

```
curl -X POST --user admin@customer1:your_password http://demo.appdynamics.com/controller/
rest/mark-nodes-historical-async?application-component-node-ids=13,27,32a

<application-component-node-id>
<13/>
<27/>
</application-component-node-id>
```

## Agent Behavior When Disconnected from the Controller

If there are network problems or agent errors, the Controller may become unreachable. The Controller server may also be down for a variety of reasons.

If the Controller is unreachable for one minute:

- The agent goes into standby mode during which it does not detect any transactions.
- Any collected snapshots and events are dropped and lost. Snapshots and events are dropped because they consume too much memory to cache.
- All metrics that have not been posted to the Controller are stored in memory. The memory impact of retaining metrics is minimal.
- New business transaction registrations that have not been posted to the Controller are stored in memory.
- The agent attempts to connect to the Controller every minute and resumes normal activity when it can download its full configuration.

If the Controller becomes reachable in the following minute or two:

- All metrics that have been stored in memory are posted to the Controller.
- New business transaction registrations that have been stored in memory are posted to the Controller.
- Snapshots and events collected in the 20 seconds prior to the reconnection are posted to the Controller.

If the Controller is not reachable after three failed attempts that are one minute apart:

- The agent is muted and all business transaction interceptors are disabled. The interceptors are still called when monitored application entry point methods are executed, but they are unproductive. No new business transactions are discovered or registered. Correlation exit points will set a header such as "notxdetect=true", which tells downstream tiers to also ignore the transaction.
- JMX metrics are stored in the application server memory and transmitted to Controller after reconnection; so, there are no gaps in the metric history.
- Periodic metrics for the last three minutes are stored in memory. Metrics older than three minutes are purged from memory.
- The agent configuration channel and the metric channel continue to attempt to connect to the Controller once each minute.

The agent attempts to connect to the Controller in seven one-minute intervals and in five minute intervals afterwards. If the Controller is not able to reconnect after five minutes, the license is freed for another agent to use.

If the connection is successful and the agent is able to download its full configuration and a license:

- All periodic metrics, such as JMX metrics and Windows performance counters for the last three minutes, are posted to the Controller. The Controller drops metrics that were collected too long ago in the past, such as when rollups are already completed.
- The agent is reactivated, business transaction interceptors are re-enabled, business transactions are monitored and possibly snapshotted, new business transactions will be discovered and registered, and downstream correlation is re-enabled.

## Request Agent Log Files

You can use agent logging information to troubleshoot issues that are local to an AppDynamics app agent.

 The Controller cannot access the log files generated by the .NET Microservices Agent.

This page describes how to work with [agent logs](#). To access agent logging operations in the Controller UI, navigate to **Node Dashboard > Agents > App Server Agent > Agent Operations**.

### Permissions

To request agent thread dumps or agent debug logs, users need the *Agent Advanced Operation* permission.

### Get Agent Log Files and Thread Dump Samples

Requesting log files causes the agent to send the contents of its logs directory as a zip file to the Controller. From there, you can download the zip to your local machine.

These agent-specific considerations apply to logging sessions:

- For the Database Agent, Java Agent or PHP Agent, you can get all logs or choose from these alternatives:
  - Output *from a specific logger* at a set level, for a fixed duration. The **Logger Name** field specifies the agent logger names such as `com.singularity`, `com.singularity.tm`, `com.singularity.tm.jdbc`, or as pattern matching the agent logger name. For a list of supported loggers, see [Java Supported Environments](#).
  - *Thread dump samples*. The agent takes a thread dump according to the specified collection interval and specified number to collect. After the interval elapses the thread dumps are uploaded by the agent as a zip file.
- For the Node.js agent, the proxy logs are available.
- For the Python Agent, if you choose *All logs in the logs directory*, you get both the proxy logs and the agent logs. The agent log contains the log messages that it is configured to log in the agent configuration file. See [Python Agent Settings](#).

While the status is PENDING, you can click **Refresh** to update the status field. Once the request succeeds, as indicated by the status, right-click the agent operation name for your request and choose Download Data. Enter a name for your request to prepend the generated zip file with your name. For example, the name of `CurrentTime` produces a zip file named similar to `CurrentTime_Node_8000_1390503141046.zip`.

If SUCCESSFUL doesn't eventually appear in the status for the request, the request may have timed out. A request can timeout due to incorrect request parameters or if the server becomes unavailable. In this case, right-click the request and choose **Delete Data** and retry the request.

### Start an Agent Logging Session

For Java and Database Agents, you can generate log information with the specific type of logging information. For the Node.js and Python agents, the log information generated is from the proxy only.

1. Confirm that you have enough disk space to create the logs before starting a logging session. Log file requests fail if there is not enough disk space available. The disk space required depends on application activity. If you are uncertain about the amount of space required, try conducting an agent logging session with the shortest duration and closely monitor the disk space on the monitored machine.
2. Click **Start Agent Logging Session** in the **Agent Operations** panel.
3. Choose the duration for the logging session and the debug logger types to initiate. The logger type determines the type of information captured with these options:

Logging Session Type	Type of Information
Application Wide Configuration	Application configuration changes
Business Transaction Registration	Transaction, exit identification, self-resolution
Current Time	Requests to synch up the clock skew between the controller and the agent
Events	Changes in application state that are of potential interest
Metric Data	Metric data
Metric Registration	Metric registration
One Way Agent	For system (machine) agent only, information from the capture feature
Request Segment data	Snapshot upload of request segment
System Agent Registration	System (machine) agent registration
System Agent Reregistration	System (machine) agent reregistration
System Agent Polling Handler	System (machine) agent configuration request
Task Execution	Relates to the machine agent where you can create a task to execute on a machine, such as to restart the application server and run a script
Top Summary Stats	Request to upload the 'most expensive backend' summary
Application Configuration	Configuration change requests
Transient Channel	The activity of the transient channel that is used to upload and download instructions for JMX console live data

4. Click **Start Agent Logging Session**. Each selected session type displays in the **Session** panel with a start and end time based on the selected **Duration** of the logging session.

### Submitting Log Files to Support

When submitting log files to AppDynamics Support, ensure you send the entire contents of the agent logs directory available as a zip file for download when you request the agent logs.

---

## App Agent Node Properties

### Related Pages:

- [Monitor JVMs](#)
- [Monitor .NET Nodes](#)

You can register app agent node properties to customize app agent behavior at the application, tier, or node level.

### App Agent Node Properties

App agent node properties control the features and preferences for the Java Agent and .NET Agent. Such agent-specific settings include limits on the number of business transactions, the minimum number of requests to evaluate before triggering a diagnostic session, and so on.

Node properties follow an inheritance model similar to instrumentation detection, so you can set an individual property globally for an application, tier, or node level.

 It is possible to set node properties in the Controller UI for the PHP, Node.js, Python, Web Server Agent, and C/C++ SDK agents, however, doing so may lead to unexpected behavior or agent failure, and is therefore not supported for those agent types.

Even though it is possible to configure node properties in the `app-agent-config.xml` file in the agent home directory, AppDynamics recommends that you use the Controller UI to configure node properties. The Controller UI displays only those node properties that are registered to the agent.

The [App Agent Node Properties Reference](#) reference includes additional properties that do not display in the UI by default. You can register these properties yourself, but unregistered properties are intended for specific application or troubleshooting scenarios and can impact the performance of your deployment. You should register properties or configure properties directly in `app-agent-config.xml` only under the guidance of AppDynamics Support or as specifically instructed by the documentation.

### Permissions

---

 Users need the Configure Agent Properties permission to create, edit, or delete agent configuration.

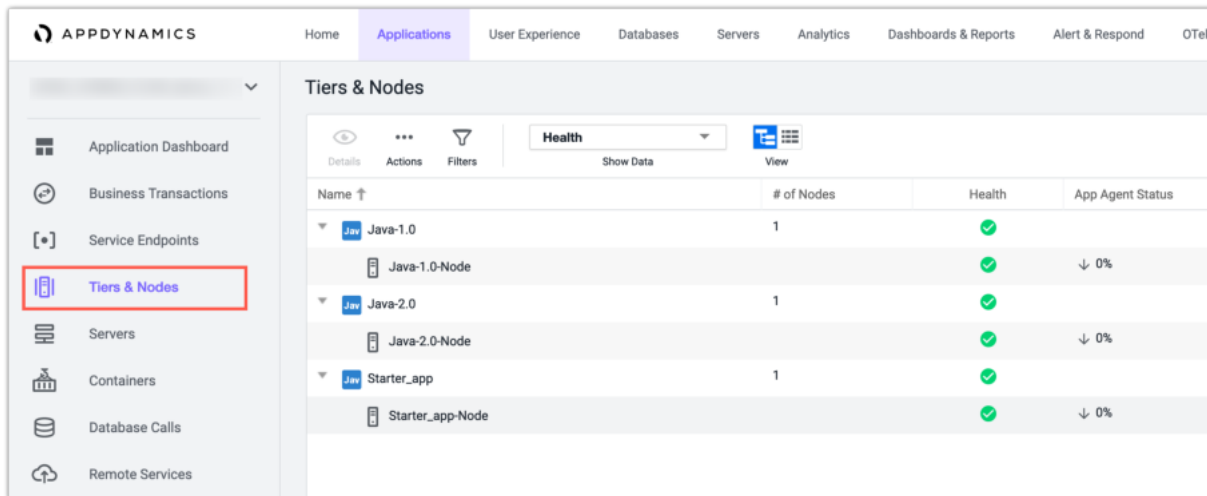

---

### Edit a Registered Node Property

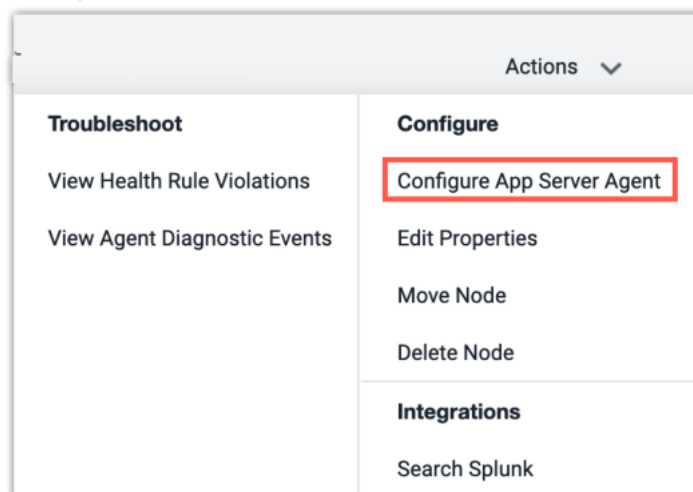

In the Controller UI, you can access node properties for a particular node or for all nodes from the dashboard of any node in the application, as follows:

1. Go to **Applications** and select the application from the list.
2. Select **Tiers & Nodes**. It lists the tiers and nodes of the application. For more information about tiers and nodes, see [Tiers and Nodes](#).

3. Expand the tier and double-click the node that you want to edit.

4. In the node dashboard, click **Actions > Configure App Server Agent**. It displays the **App Server Agent Configuration** panel.

5. In **App Server Agent Configuration**, select the node from the left-hand navigation.

6. Select **Use Custom Configuration**. It lists the agent properties.

7. Select the agent property and click the edit icon.

After customizing a configuration, you can copy the configuration to other nodes, to the tier, or apply it to the entire application.

### Add a Registered Node Property

You can register and configure unregistered [App Agent Node Properties Reference](#) as instructed by AppDynamics Support.

To register a node property, create a custom configuration for the node (see [Edit Registered Node Property](#)). Add properties by clicking the + icon at the top of the list of current node properties.

In the **Create Agent Property** panel, use the values from [App Agent Node Properties Reference](#) to provide values for the name, description, type, and value of the property.

## App Agent Node Properties Reference

This reference page describes the app agent node properties by type. Additionally, the reference includes these pages containing information about the app agent node properties:

- [App Agent Node Properties \(A\)](#)
- [App Agent Node Properties \(B-C\)](#)
- [App Agent Node Properties \(D-E\)](#)
- [App Agent Node Properties \(F-I\)](#)
- [App Agent Node Properties \(J-L\)](#)
- [App Agent Node Properties \(M\)](#)
- [App Agent Node Properties \(N-R\)](#)
- [App Agent Node Properties \(S\)](#)
- [App Agent Node Properties \(T-Z\)](#)

Use caution when modifying the agent default settings. If increasing limits specified for an agent, you must carefully assess and monitor memory consumption by the agent after the change.

### App Agent Node Properties by Type

This table groups the app agent node properties by type to browse properties by functionality and feature area.

Type	Property
Automatic Leak Detection	<a href="#">minimum-age-for-evaluation-in-minutes</a>
	<a href="#">minimum-number-of-elements-in-collection-to-deep-size</a>

## App Agent Node Properties (A)

### adaptive-callgraph-granularity

This property enables adaptive snapshots. The call graph granularity for adaptive snapshots is based on the average response time for the business transaction during the last one minute and is thus adaptive. The following distribution is used:

- Granularity of 10 ms for average response time of <= 10 seconds
- 50 ms for 10 to 60 seconds
- 100 ms for 60 to 600 seconds
- 200 ms for > 600 seconds

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET

### ado-new-resolvers

Enable database detection and naming for ODP.NET backends labeled Unknown0 .

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	.NET

### agentless-analytics-disabled

Disable agentless Transaction Analytics on a particular node or tier.

<b>Type:</b>	Boolean
<b>Default value:</b>	false

<b>Platform(s):</b>	Java, .NET
---------------------	------------

### always-add-eum-metadata-in-http-headers

By default, the Java Agent, .NET Agent, and Node.js Agent set business transaction correlation data in a cookie for HTTP responses, except when the JavaScript Agent has already set an `isAjax:true` header in the request. When it finds the `isAjax:true` header, the agent sets the correlation metadata in the XHR header.

For cross-origin AJAX requests, the JavaScript Agent does not set `isAjax:true` so that the app agent doesn't write correlation data to the header of those responses.

Set `always-add-eum-metadata-in-http-headers` to `true` to configure the app agent to write business transaction metadata to the XHR header and in a cookie even if the request is considered cross-origin.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET, Node.js

### analytics-sql-cpm-limit

This property specifies the per minute upper limit on the number of SQL queries that collect parameter data for analytics. The number is a cumulative total. It is not the number of distinct SQL queries, but the overall number of invocations of the SQL queries that have been configured to collect analytics data.

<b>Type:</b>	Integer
<b>Default value:</b>	10000
<b>Platform(s):</b>	Java, .NET

### api-thread-activity-timeout-in-seconds

This property provides a time-out value that comes into play when you have added global transactions to your application using APIs from the AppDynamics SDK. In the event that the added transaction spawns additional threads that do not return or complete, this property provides a safety valve time-out value. The value is in seconds. The `removeCurrentThread` method is invoked after the specified timeout period.

<b>Type:</b>	Integer
<b>Default value:</b>	300 (seconds)
<b>Range:</b>	Minimum =1; Maximum= 3600
<b>Platform (s):</b>	Java

### api-transaction-timeout-in-seconds

This property provides a time-out value that comes into play when you have added global transactions to your application using APIs from the AppDynamics SDK. In the event that the added transaction does not return or complete, this property provides a safety valve time-out value. The time-out value is in seconds. The `endTransaction` method is invoked after the specified time-out period.

<b>Type:</b>	Integer
<b>Default value:</b>	300 (seconds)
<b>Range:</b>	Minimum =1; Maximum= 3600
<b>Platform (s):</b>	Java

### appagent-export-packages

Use this property to provide the comma-separated list of packages available in the agent module that can be exported to other modules.

<b>Type:</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java

### appdynamics-agent-metricLimits

This property increases the metric limit for the .NET Agent for Linux.

<b>Type:</b>	Integer
<b>Default value:</b>	5000
<b>Platform(s):</b>	.NET Agent for Linux

### apply-reactive-rules

This property provides a switch to flip the entire reactor instrumentation. If you set it to false, all rules pertaining to reactor thread correlation are unapplied.

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	Java

### apply-additional-reactive-rules

This property provides a switch to apply in process correlation rules for prospective thread hand-offs. By default these rules are disabled. These rules can only be applied if 'apply-reactive-rules' node property is set to true. If 'apply-reactive-rules' property is set to false, setting this property to 'true' will not apply any rules.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### aspdotnet-core-legacy-instrumentation

When you set this property, ASP.NET Core entry instrumentation is restored to `RequestServicesContainerMiddleware.Invoke` for .NET Core 2.1 and 2.2 apps. You can use this when Business Transactions are missing from .NET Core apps after you upgrade an agent.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	ASP.NET Core

### aspdotnet-core-naming-controlleraction

If true, causes the agent to identify ASP.NET Core on the full framework business transactions as Controller/Action.

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	ASP.NET Core

### aspdotnet-core-naming-controllerarea

If true, causes the agent to identify ASP.NET Core on the full framework business transactions as Area/Controller/Action.

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	ASP.NET Core

### aspdotnet-mvc-naming-controlleraction

If true, causes the agent to identify ASP.NET MVC business transactions as Controller/Action. See [Name MVC Transactions by Area, Controller, and Action](#).

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	.NET

### aspdotnet-mvc-naming-controllerarea

If true, causes the agent to identify ASP.NET MVC business transactions as Area/Controller. See [Name MVC Transactions by Area, Controller, and Action](#).

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	.NET

### async-tracking

Enable or disable detection of asynchronous exit points. See [Asynchronous Exit Points for .NET](#).

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	.NET

### async-transaction-demarcator

This class name and method name combination marks the end of an asynchronous distributed transaction. Use the format `ClassName/MethodName`. For example, `foo/bar` where `foo` is the class name and `bar` is the method name.

<b>Type:</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java

## App Agent Node Properties (B-C)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

### bci-log-config

Use this property to configure the bytecode transformer log (BCT log). This log shows what AppDynamics instruments and what classes are loaded in the JVM. The initial file (the `0.log`) is saved to preserve the context of the server startup and is not

<b>Type</b>	String
-------------	--------

rolled over. The subsequent files rotate. The format of the file name is ByteCodeTransformer.<timestamp>.<N>.log. The time stamp is represented as YYYY\_MM\_DD\_HH\_mm\_ss . N increments starting from zero.

<b>Default value:</b>	20,5,4
<b>Platform(s):</b>	Java

### Examples

```
ByteCodeTransformer.2012_09_12_20_17_57.0.log
```

Because the file size is checked every 15 seconds, the files may be a bit larger than the specified threshold value before they are rolled over.

The first log file generated is named as follows:

```
ByteCodeTransformer.<timestamp>.0.log
```

The format for this property value is illustrated by the default value, 20,5,4 . The numbered segments have the following meaning:

- 20 is the size, in MB, of the first log file, the .0 version
- 5 is the size in MB for each subsequent rolling file
- 4 is the number of ByteCodeTransformer log files to keep

## bciengine-disable-retransformation

Disable or enable bytecode retransformation. By default, the Sun and JRockit variant of the Java Agent applies configuration changes requiring bytecode retransformation, such as new POJO rules, without a restart to the JVM. Set bciengine-disable-retransformation to true to prevent the agent from performing automatic retransformation to apply such rules.

<b>Type</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### boot-amx

If set to true, enables support for Glassfish AMX MBeans. See [GlassFish Startup Settings](#) for more information about Glassfish server support.

<b>Type</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### callgraph-granularity-in-ms

Specifies the granularity for call graphs for this node. The global configuration is ignored if this property is used. This value is ignored if the adaptive-callgraph-granularity property is set to true. A default value of zero means the global configuration, from **Configuration > Instrumentation > Call Graph Settings** is used. Does not need a restart.

<b>Type</b>	Integer
<b>Default value:</b>	0
<b>Range:</b>	Minimum=0; Maximum=5000
<b>Platform(s):</b>	Java, .NET

### capture-404-urls

This property disables or enables the capture of the URLs causing 404 errors. The URLs are reported as ERROR events every 15 minutes and are viewable through the Event Viewer. The JVM needs a restart if retransformation is not supported for the JVM version.

404 errors usually mean that no application code is executed, resulting in nothing to be captured in a snapshot. You can get insight into the 404 error by setting this property to true. It reports all the URLs which caused 404 error.

The `capture-404-urls` node property is *deprecated* in AppDynamics v. 3.6 and replaced with `capture-error-urls`.

<b>Type</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### capture-error-urls

This property enables or disables the capture of the following HTTP errors:

- 401 - Unauthorized
- 500 - Internal Server Error
- 404 - Page Not Found
- All other error codes are put in a generic HTTP error code bucket.

For these four categories, the agent collects URLs, limited to 25 per category per minute, and sends an event out every 5 minutes.

You can see these URLs when you drill down on an error code by clicking Troubleshoot > Errors > Exceptions tab > HTTP Error Codes.

<b>Type</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	Java

## capture-raw-sql

If `capture-raw-sql` is enabled, SQL calls with dynamic parameters—such as question mark parameters—are captured by the agent and shown in the Controller UI with the dynamic parameters bound to their runtime values.

<b>Type</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET

### Examples

For example, consider Java code that constructs a SQL call as follows:

```
stmt = new PreparedStatement("select * from user where ssn = ?")
stmt.bind(1, "123-123-1234")
stmt.execute()
```

With `capture-raw-sql` enabled, AppDynamics captures the SQL call in the following form:

```
select * from user where ssn = '123-123-1234'
```

If `capture-raw-sql` is disabled, the SQL call appears with question mark parameters not bound to values.

Disabling `capture-raw-sql` and using question mark parameters in SQL prepared statements gives you a mechanism for preventing sensitive data from appearing in the Controller UI.

It is important to note that the sensitive values must be parameterized in the original, prepared statement form of the SQL statement, as shown above. The following statement would result in the potentially sensitive information—the `ssn` value—appearing in the UI whether `capture-raw-sql` is enabled or disabled.

```
stmt = new PreparedStatement("select * from user where ssn = '123-123-1234'")
```

Setting the option as an agent property affects the SQL capture mode for the node. You can configure the behavior for all nodes using the Capture Raw SQL option described in [Call Graph Settings](#).

### capture-set-status

Directs the agent to capture errors where the webservice is using setStatus() to send back an error. By default, only `sendError()` is instrumented by the agent.

<b>Type</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### capture-spring-bean-names

When a class is mapped to multiple Spring bean names, by default only the name of the first Spring bean found displays. This can be misleading. For example, when you see a call graph for web service A that has Spring beans from web service B. Setting this property to false shows only the class name when these conflicts occur and does not show the Spring bean name.

<b>Type</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	Java

### check-bt-excludes-early

Reverses the default order in which Java and .NET agents evaluate rules. If true, exclude rules are evaluated before match rules.

<b>Type</b>	Boolean
-------------	---------

<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET

### collect-user-data-sync

Collect user data from diagnostic POJO data collectors synchronously. Does not require a restart.

<b>Type</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	Java

### collection-capture-period-in-minutes

Total interval in minutes since server restart for which collections are captured for leak evaluation. The property takes effect only after the node restart.

<b>Type</b>	Integer
<b>Default value:</b>	30
<b>Range:</b>	Minimum=5; Maximum=N/A
<b>Platform(s):</b>	Java

### custom-activity-correlation

Use this property to add custom activity correlation rules in the format specified in `custom-activity-correlation.xml`.

<b>Type</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java

### custom-interceptor-rules

Use this property to add custom interceptor rules in the format specified in `custom-interceptors.xml`.

Alternatively, you can set custom interceptors rules directly in `custom-interceptors.xml`. The Java agent considers the latest change.

<b>Type</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java

## App Agent Node Properties (D-E)

### disable-agent

This property enables/disables the agent. When this property is set to true, TransactionEntryPoints will not be monitored. No new BTs or metrics will be registered, metrics, and snapshots will not be reported. Agent background threads will not be stopped. When set to false, the agent becomes active immediately. It does not need a restart.

<b>Type:</b>	Boolean
<b>Default value:</b>	False
<b>Platform(s):</b>	Java

### disable-agent-api

This property disables all calls to the agent-api library. The calls function as no-ops when disabled.

<b>Type:</b>	Boolean
<b>Default value:</b>	False
<b>Platform(s):</b>	Java

### disable-custom-exit-points-for

Disables certain types of automatically detected exit points: SAP, Mail, LDAP, and so on. Type names are case sensitive. Use commas to separate multiple types.

<b>Type:</b>	String
<b>Default value:</b>	none
<b>Supported values:</b>	CASSANDRA, Coherence, DangaMemcache, EHCACHE, LDAP, Memcache, MongoDB, RABBITMQ, REDIS, RMI, SAP, THRIFT
<b>Platform(s):</b>	Java

### disable-dynamic-services

Use this property to disable dynamic services. You can provide a comma-separated string of dynamic service folder names mentioned in the external-services folder. The dynamic services mentioned in this property do not start with the agent.

Example value:

```
netviz,analytics,argentoDynamicService
```

You can edit the property in `app-agent-config.xml`.

**i** For analytics, you can disable the service using this property however, the licenses are consumed for Transactional Analytics. To disable the license consumption, you must disable it as a node property in the Controller UI. See [Disable Transaction Analytics License Consumption](#).

<b>Type:</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	.Net, Java

### disable-exit-call-correlation-for

Disable exit call correlation for a specific type of call. For example, KAFKA, WCF, WEB\_SERVICE, HTTP, JMS, and RMI. By default, all exit call correlations are enabled.

<b>Type:</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java, .NET

### disable-exit-call-metrics-for

Disables exit call monitoring for a specific type of exit call; for example, HTTP, JMS, WEB\_SERVICE. If this property is set, the average data—calls/min, avg response time— for the specific exit call type is not collected. However, for a snapshot, all details are collected. Set this property if the application makes a large number of exit calls per transaction and the avg metrics are not important.

<b>Type:</b>	String
<b>Default value:</b>	By default, all exit call metrics are enabled.
<b>Platform(s):</b>	Java, .NET

### disable-percentile-metrics

App agents that support [percentile metrics](#) enable collection by default. Disable percentile metrics on the Configuration > Slow Transaction Thresholds window or set this node property manually to `true` to disable percentiles.

Changes to this property do not require an agent restart.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET

### disable-service-monitoring-metrics

This property stops the BT-to-BT incoming cross-application metrics to be reported (but normal cross-application metrics continue to be reported, as expected).

<b>Type:</b>	Boolean
<b>Default value:</b>	True

<b>Platform(s):</b>	Java
---------------------	------

### disable-soap-header-correlation-non-http

This property controls correlation with web service transactions. When enabled, it prevents injection of the correlation header into a SOAP message if the WCF transport is not over HTTP or HTTPS.

<b>Type:</b>	Boolean
--------------	---------

<b>Default value:</b>	false
-----------------------	-------

<b>Platform(s):</b>	Java, .NET
---------------------	------------

For more information, see [WCF Entry Points](#)

### disabled-features

Specifies types of data for which agent reporting to suppress. Use this property provides to disable data collection mechanisms at the agent to limit data reported by the agent for security or privacy reasons. This agent configuration overrides any Controller configuration that affects the data.

You can disable

- `LOG_PAYLOAD` : Log payload, such as the node property `log-request-payload`
- `RAW_SQL` : Raw SQL statements
- `CUSTOM_EXIT_SNAP_DATA` : Snapshot data in custom exits
- `METHOD_INV_DATA_COLLECTOR` : Diagnostic data collectors, method invocation
- `HTTP_DATA_COLLECTOR` : Diagnostic data collectors, HTTP requests
- `INFO_POINT` : Information points
- `ALL` : All of the above

<b>Type:</b>	String
--------------	--------

<b>Default value:</b>	none
-----------------------	------

<b>Platform(s):</b>	Java
---------------------	------

- **NONE** : None of the above. This is equivalent to the default agent behavior.

### Examples

Configure disabled features in the app-agent-config.xml in the versioned conf directory for the agent. Specify the data category as the value attribute of the disabled-features property. You can have multiple data categories excluded by listing each separated by commas. For example:

With `capture-raw-sql` enabled, AppDynamics captures the SQL call in the following form:

```
<app-agent-configuration>
 <configuration-properties>

 <property name="disabled-features" value="RAW_SQL,LOG_PAYLOAD"/
 >
 </configuration-properties>

</app-agent-configuration>
```

## disable-ibmbpm-data-collectors

Sets whether data-collectors for IBM-BPM task business transactions should be disabled (value=true) or enabled (value=false).

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### disable-ibmbpm-usertask-bt-in-process-correlation

Sets whether business transactions in-process correlation for IBM-BPM UserTask business transactions should be disabled (value=true) or enabled (value=false).

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### disable-ibmbpm-usertask-bt-naming

Sets whether business transactions naming scheme for IBM-BPM UserTask Business Transactions should be disabled (value=true) or enabled (value=false). When it is set to `true`, the Business Transactions would be named as per the default URL and not the meaningful names.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### dev-mode-suspend-cpm

The maximum number of transactions monitored per minute during development mode before the system switches out of development mode into normal operation mode.

<b>Type:</b>	Integer
<b>Default value:</b>	500

<b>Range:</b>	Minimum= 0; Maximum =N/A
<b>Platform(s):</b>	Java

### dont-show-packages

Do not show these packages / class names in addition to the ones configured in the global call graph configuration, for the call graphs captured on this node. Does not need a restart.

<b>Type:</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java, .NET

### downstream-tx-detection-enabled

If the agent cannot reach the controller for a prolonged period, it turns off most services and notifies the continuing tiers that upstream transaction was detected and is not being monitored. Set this property to `true` to enable the continuing tiers to detect their own transactions in the event of network failure on the upstream tiers.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET

### enable-all-rsd-error-propagation

This property enables the agent to recognize errors that occur in calls outside of or tangential to business transactions.

**false** : All business transaction errors are reported, but errors outside of the business transaction are not reported.

**true** : All business transaction errors are reported. In addition, errors outside of the business transaction are reported. For example, errors generated from tracking analytics for a business transaction are reported.

**full-disable** : No asynchronous errors are recognized.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET

### enable-async-service-endpoints

By default the Java Agent automatically detects service endpoints for worker threads. Set this property to "false" to disable service endpoint detection for worker threads. This has the same effect as the *Automatic Service Endpoint Detection* checkbox for other types of service endpoints on Configuration > Instrumentation > Service Endpoints.

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	Java

### enable-async2-eum-context-lookup

When EUM is enabled on applications implemented using the Servlet3 async dispatch mechanism, it is possible that multiple EUM correlation headers are added to the response.

This node property prevents duplicate ADRUM headers being injected in the HTTP response from Java Agent.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### enable-axon-entry

This node property is used to disable axon entry. By default, it is enabled.

<b>Type:</b>	Boolean
<b>Default value:</b>	true (By default, axon entry is enabled.)
<b>Platform(s):</b>	Java

### enable-boundedcollection-overflow-capture

When set to `true`, the Bounded Collection errors (Agent errors) are reported along with application errors.

You can edit the property in `app-agent-config.xml`.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### enable-axon-exit

This node property is used to disable axon exit. By default, it is enabled.

<b>Type:</b>	Boolean
<b>Default value:</b>	true (By default, axon entry is enabled.)
<b>Platform(s):</b>	Java

### enable-bt-block-wait-time-monitoring

This property controls capture of per BT block and wait time metrics. It is disabled by default.

<b>Type:</b>	Boolean
<b>Default value:</b>	false - (Disabled by default)
<b>Platform(s):</b>	Java

### enable-bt-cpu-time-monitoring

This property controls whether the agent captures the CPU time taken by a business transaction.

<b>Type:</b>	Boolean
--------------	---------

<b>Default value:</b>	true
<b>Platform(s):</b>	Java

### enable-default-http-error-code-reporter

This property disables or enables automatic HTTP error code reporting for error codes between 400 to 505.

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	Java, .NET

### enable-ignore-nested-exception-message

When set to `true`, it ignores the nested exception messages.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET

### enable-info-point-data-in-snapshots

This property disables or enables the capture of information point calls in snapshots. When this property is set to true, information point calls appear in the User Data section of the snapshot.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET

### enable-instance-monitoring

This property enables or disables Instance tracking on this node. Does not need a JVM restart.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### enable-interceptors-for-security

This property enables or disables security interceptors on this node. Set this property to true in environments where the Java 2 Security Manager is enabled. If the Java 2 Security Manager is enabled, and this property is not set to true, then the agent will encounter SecurityExceptions, and will not be able to collect the data that it should. Does not need a JVM restart.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### enable-json-bci-rules

Set this property to true to enable JSON bytecode instrumentation rules. AppDynamics instruments the `get` and `getString` methods within the package/class `org.json.JSONObject` when you set this value to true. Needs a JVM restart.

<b>Type:</b>	Boolean
<b>Default value:</b>	true (This only affects new applications; applications created with a 3.7.x controller will still have this property set by default to false.)
<b>Platform(s):</b>	Java

### enable-kafka-consumer

Set the `enable-kafka-consumer` to `true` to enable Apache Kafka consumer entry points. For more information see 'Apache Kafka Backends' on [Java Backend Detection](#).

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### enable-object-size-monitoring

This property is related to Automatic Leak Detection (ALD) and enables or disables Object Size monitoring on this node. Changing this property does not need a JVM restart. ALD is supported for JVM version 1.6 and up.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### enable-openai-metrics

When set to `true`, this property enables OpenAI API metrics monitoring and reporting on Java Agent. See [Monitor OpenAI API with Java Agent](#).

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### enable-reverse-proxy

When set to `true`, it enables the reverse proxy for Java Agent.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### enable-soap-header-correlation

This property controls correlation with web service transactions. When enabled, a node which receives a web service transaction may correlate that transaction with any downstream transactions. The ability to correlate depends on the particular web services framework. Currently, correlation is supported only by Apache Synapse and CXF frameworks. When disabled, the agent will not perform correlation through any web service tiers.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET

### enable-spring-integration-entry-points

This property disables or enables the default detection of Spring Integration entry points. Set to `false` to disable.

Default detection of Spring Integration entry points is based on MessageHandler. In cases where a lot of application flow happens before the first MessageHandler is executed:

- Set this property to `false`
- Configure suitable [POJO entry points](#)
- Specify the property [spring-integration-receive-marker-classes](#)

See also [Spring Integration Support](#).

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	Java

### enable-spring-rest-client-correlation

This property disables or enables the correlation support for the Spring Rest client.

<b>Type:</b>	Boolean
--------------	---------

<b>Default value:</b>	none
<b>Platform(s):</b>	Java

### enable-spring-ws-dom-parser-rules

This property enables to split web service business transactions on the SOAP XML payload. Set the value to true to enable the property. You can modify namespace context mapping (mapping of the prefix to URI) to parse SOAP message property in the `app-agent-config.xml` file.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### enable-startup-snapshot-policy

This property disables or enables the policy for start-up transaction snapshot. This means snapshots are collected for all BTs for all invocations for the first 15 minutes of application server startup.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET

### enable-transaction-correlation

This property disables or enables transaction correlation. It does not require a restart.

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	Java, .NET

### enable-vertx-http

Enable or disable servlet HTTP entry points and exit points for Vert.x.

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	Java

### enable-vertx-message-entry

Enable or disable Vert.x verticle message entry points for continuing transactions.

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	Java

### enable-xml-bci-rules

This property enables Java XML Binding and DOM Parser bytecode instrumentation rules. Set to `true` to enable. The change takes effect after a JVM restart.

<b>Type:</b>	Boolean
<b>Default value:</b>	true (This only affects new applications; applications created with a 3.7.x Controller will still have this property set by default to false.)
<b>Platform(s):</b>	Java

### end-to-end-message-latency-threshold-millis

Enables end-to-end message latency monitoring for distributed asynchronous systems by setting up a threshold. Any message taking more time than the threshold is viewable through the Event Viewer.

<b>Type:</b>	Integer
<b>Default value:</b>	0
<b>Range:</b>	Minimum=0; Maximum=36000
<b>Platform(s):</b>	Java

## exceptions-to-ignore

By default, configuring an exception to be ignored in the [error detection settings](#) prevents the ignored exception thus marking any Business Transaction that experiences it as in error. However, it does not prevent the occurrences of the exception being tracked in the [Errors and Exceptions dashboard](#).

To completely ignore certain exceptions, provide their fully qualified class names in this node property.

For example, oracle.jdbc.DatabaseException.

Multiple exceptions can be added that are comma-separated.

**i** It is recommended to use this property with caution because it removes all visibility of the impact of exceptions configured in this way.

<b>Type:</b>	String
<b>Default value:</b>	0
<b>Platform(s):</b>	Java

## App Agent Node Properties (F-I)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

## find-entry-points

Set this property to `true` to log all potential entry points that are hitting instrumented exit points or loggers to the Business Transactions log file.

Use this property when you suspect that some traffic is not being detected as business transactions. You should only enable this property for debugging purposes. You should deactivate this property in a production setup.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET

**Tip:** For new applications, you can use the interactive [Live Preview](#) tools to discover entry points.

### heap-storage-monitor-devmode-disable-trigger-pct

The maximum Java heap utilization percentage for development mode. If the heap utilization exceeds this value, development mode is automatically deactivated.

<b>Type:</b>	Integer
<b>Default value:</b>	90
<b>Range:</b>	Minimum=0, Maximum=100
<b>Platform(s):</b>	Java

### ibmbpm-systemtask-bt-naming

Decides BT naming scheme for IBM-BPM System Task POJO business transactions.

The property value is comma-separated identifiers chosen from *project*, *bpd*, *task*, and *implementation*, and is order-sensitive.

<b>Type:</b>	String
<b>Default value:</b>	default
<b>Platform(s):</b>	Java

#### Example

For example:

value = project, task means that the POJO business transactions are named as: <project-name> / <task-name>

value = task, project means that the POJO business transactions are named as: <task-name> / <project-name>

value = none means that the POJO business transactions are not detected, in

other words, deactivated.

value = `default` would mean that all the identifiers are used for BT naming are in the default order, that is, they are named as:

```
<project-name> / <bpd-name> / <task-name> /
<implementation-name>
```

## App Agent Node Properties (J-L)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

### jdbc-callable-statements

Use this property to indicate the implementation classes of the `java.sql.CallableStatement` interface that should be instrumented.

<b>Type:</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java

#### Examples

For example, to instrument calls to Times Ten (an unsupported database), you could set this property to the following:

```
com.timesten.jdbc.JdbcOdbcCallableStatement
```

### jdbc-connections

Use this property to indicate the implementation classes of the `java.sql.Connection` interface that should be instrumented.

<b>Type:</b>	String
--------------	--------

<b>Default value:</b>	none
<b>Platform(s):</b>	Java

### Examples

For example, to instrument calls to Times Ten (an unsupported database), you could set this property to the following:

```
com.timesten.jdbc.JdbcOdbcConnection
```

## jdbc-dbcam-integration-enabled

Use this property to integrate the Java Agent with AppDynamics for Databases and Database Monitoring. Changes to this property do not require a JVM restart for JDK 1.6 and higher. Older 1.5 JVMs do not support class reloading, so for those environments, a restart is required.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### More Info

**AppDynamics for Databases:** When this property is enabled, you can link to AppDynamics for Databases from a Transaction Snapshot Flow Map where an exit call is to an Oracle database, and analyze the SQL statements that were running at the time of the snapshot. This property works in conjunction with the AppDynamics for Databases license and database collector that has been previously set up. Integration must also be set up from the Admin pages of the Controller UI. For more information, see [Integrate and Use AppDynamics for Databases with AppDynamics Pro](#).

**Database Monitoring:** Set this property to enable snapshot correlation between Java applications and Oracle databases. This property configures Globally Unique Identifier (GUID) session tagging between business transactions monitored by the Java Agent and Oracle databases monitored by Database Monitoring. Each snapshot is identified by a GUID which Database Monitoring instrumentation injects into the Oracle session using a standard JDBC API. This enables

AppDynamics to collect the session properties, including the GUID. When the queries are correlated with the GUID, AppDynamics can correlate the backend database activity with the business transaction snapshot.

### jdbc-prepared-statements

Use this property to indicate the implementation classes of the `java.sql.PreparedStatement` interface that should be instrumented.

<b>Type:</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java

#### Examples

For example, to instrument calls to Times Ten (an unsupported database), you could set this property to the following:

```
com.timesten.jdbc.JdbcOdbcPreparedStatement
```

### jdbc-resultsets

Use this property to indicate the implementation classes of the `java.sql.ResultSet` interface that should be instrumented.

<b>Type:</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java

#### Examples

```
com.timesten.jdbc.JdbcStatement
```

### jdbc-statements

Use this property to indicate the implementation classes of the `java.sql.Statement` interface that should be instrumented.

<b>Type:</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java

#### Examples

For example, to instrument calls to Times Ten (an unsupported database), you could set this property to the following:

```
com.timesten.jdbc.JdbcOdbcStatement
```

### jmx-appserver-mbean-finder-delay-in-seconds

When an app server starts up, the associated MBean server starts and the MBeans are discovered. The timing of these activities varies by app server and by configuration. If this activity is not completed in the time that the AppDynamics agent is expecting to discover the MBeans, then the MBean Browser will not show them. Using this node property, you can delay the discovery of MBeans to make sure that agent discovers all the domains after complete startup of the app server. For example, you can set the delay to a time which is 1.5 times of the server startup time. The default delay for the AppDynamics agent is two minutes.

<b>Type:</b>	Integer
<b>Default value:</b>	120
<b>Platform(s):</b>	Java

### jmx-operation-timeout-in-milliseconds

Controls the length of time the Java Agent waits before timing out an MBean operation. If you have MBean operations that run longer than the default of 10 seconds, you can increase the timeout value up to 5 minutes.

<b>Type:</b>	Integer
<b>Default value:</b>	10000 (10 seconds)
<b>Platform(s):</b>	Java

### jmx-rediscover-mbean-servers

When an app server starts up, the associated MBean server starts and the MBeans are discovered. The timing of these activities varies by app server and by configuration. If this activity is not completed in the time that the AppDynamics agent is expecting to discover the MBeans, then the MBean Browser will not show them. Using this node property, you can trigger the rediscovery of MBeans to make sure that the agent discovers all the domains after complete startup of the app server. Set this property to `true` and reset the app agent, as described in [Manage App Agents](#).

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java/td> :

### jmx-rediscover-mbean-servers-periodic-in-min

This property helps to trigger the rediscovery of Mbeans periodically for every "x" mins (x being the value specified by this node property). When enabled, this property causes the agent to refresh its Mbean server cache for every specified amount of time. By

<b>Type:</b>	String
<b>Default value:</b>	0

default, no periodic rediscovery of Mbean servers is done. Set the value of this property to 0 to stop the periodic rediscovery task if enabled.

<b>Platform(s):</b>	Java
---------------------	------

### jmx-query-timeout-limit

This property sets the timeout limit. Setting this property to negative will disable timeout. For example, if you set the property to -1, timeout is disabled.

<b>Type:</b>	Long
<b>Default value:</b>	5
<b>Platform(s):</b>	Java

### jrmp-enable

This property enables or disables AppDynamics support for Sun RMI over Java Remote Protocol (JRMP). You should test Sun RMI JRMP support in a staging environment before using it on production systems. Enable Sun JRMP support by setting this property to true.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java

### leak-diagnostic-interval-in-minutes

The interval at which diagnostic data, content summary and activity trace, is captured for leaking collections.

<b>Type:</b>	Integer
--------------	---------

<b>Default value:</b>	30
<b>Range:</b>	Minimum=2; Maximum=N/A
<b>Platform(s):</b>	Java, .NET

### log-request-payload

Set this property to true to log the request payload— HTTP parameters, cookies, session keys, and so on— as part of a transaction snapshot. The log-request-payload property includes logging of WCF HTTP parameters for .NET.

This property dumps all the HTTP data in the app agent logs. But data collectors "diagnostic data collectors" HTTP type are specific to show only the particular HTTP data and not everything, which is: cookies, header, session. The node property gives a complete HTTP dump.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET

### logbased-visibility-log-check-interval-in-millis

How often the agent checks application log files for information related to garbage collection performance.

<b>Type:</b>	Integer
<b>Default value:</b>	1000 ms

<b>Platform(s):</b>	Java, .NET
---------------------	------------

## App Agent Node Properties (M)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

### maximum-activity-trace-stack-depth

This property determines the depth of the stack trace to capture as part of an activity trace session. By default, the size of the code paths for OIT (Object Instance Tracking), ALD (Automatic Leak Detection) and MIDS (Memory Intensive Data Structures) are set to 10. To increase this limit, use this property.

**Warning:** A larger depth has higher overhead on the system. AppDynamics recommends that you increase the default value of this property only temporarily, and remove it or set it back to 10 once you get the desired output.

<b>Type:</b>	Integer
<b>Default value:</b>	10
<b>Platform(s):</b>	Java

### max-analytics-collectors-allowed

This property sets an upper limit for Analytics collectors in the agent.

<b>Type:</b>	Integer
<b>Default value:</b>	2000
<b>Platform(s):</b>	Java, .NET

### max-async-task-registration-requests-allowed

Adjust this property to increase or decrease the number of asynchronous task registration requests allowed.

<b>Type:</b>	Integer
<b>Default value:</b>	500
<b>Platform(s):</b>	Java

### max-async-task-registrations-allowed

Adjust this property to increase or decrease the number of asynchronous task registrations allowed.

<b>Type:</b>	Integer
<b>Default value:</b>	500
<b>Platform(s):</b>	Java, .NET

### max-business-transactions

Sets a limit on the number of business transactions discovered once an agent is started. The limit helps to ensure that the Controller I/O processing capability and agent memory requirements are appropriate for a production environment. See [Business Transactions](#).

<b>Type:</b>	Integer
<b>Default value:</b>	50

**Warning:** Changing this setting can affect the resource consumption of your deployment. Before you change this setting, verify that your application environment and Controller can handle any increased resource requirements.

<b>Range:</b>	Minimum=N/A; Maximum=300
<b>Platform(s):</b>	Java, .NET, Node.js, SAP/ABAP, C++ SDK (any non-proxied Dynamic Language Agent)

### max-call-elements-per-snapshot

This property represents the maximum number of elements that are collected for any call graph for a snapshot. When the limit is reached, the agent stops collecting more data for this call graph, reports what has been collected to that point, and marks the call graph with a warning that the limit was reached. AppDynamics does not recommend dramatically increasing this number as it may have overhead implications.

<b>Type:</b>	Integer
<b>Default value:</b>	5000
<b>Platform(s):</b>	Java, .NET

### max-concurrent-snapshots

The maximum number of total snapshots that are allowed, including continuing transactions. When the queue goes over the value set, additional snapshots are dropped. This property is ignored in [Development](#) mode.

<b>Type:</b>	Integer
<b>Default value:</b>	20

<b>Range:</b>	Values must be positive integers. No other constraints.
<b>Platform(s):</b>	Java, .NET

### max-correlation-header-size

The maximum size of the correlation header.

<b>Type:</b>	Integer
<b>Default value:</b>	4096
<b>Range:</b>	Values must be positive integers. No other constraints.
<b>Platform(s):</b>	Java

### max-error-snapshots-per-minute

A limit for the number of snapshots per minute due to errors. For example, if too many error snapshots are being seen, then tweak this value to reduce noise in the snapshots.

<b>Type:</b>	Integer
<b>Default value:</b>	5

<b>Platform(s):</b>	Java, .NET
---------------------	------------

### max-jdbc-calls-per-callgraph

The maximum number of JDBC/ADO.NET exit-call stack samples per call graph. Only queries taking more time than the value of `min-duration-for-jdbc-call-in-ms` are reported. Changing the value does not require a restart.

<b>Type:</b>	Integer
<b>Default value:</b>	100
<b>Range:</b>	Minimum=1; Maximum=1000
<b>Platform (s):</b>	Java, .NET

### max-jdbc-calls-per-snapshot

The maximum number of JDBC/ADO.NET exit calls allowed in a snapshot. Calls after the limit are not recorded. Changing the value does not require a restart.

<b>Type:</b>	Integer
<b>Default value:</b>	500
<b>Range:</b>	Minimum=1; Maximum=5000
<b>Platform (s):</b>	Java, .NET

### max-metrics-allowed

This property sets the upper limit to the number of metrics that can be registered by the agent.

**Note:** If the number of metrics—registered + unregistered—is greater than the new node property value, then the new metrics will not be created.

<b>Type:</b>	Integer
<b>Default value:</b>	5000 or as set with <code>-Dappdynamics.agent.maxMetrics=</code>
<b>Platform (s):</b>	Java

### max-prepared-statement-sql-length

Maximum length of the SQL statement for SQL prepared statements. The length of the SQL statement is truncated if it exceeds the value set by this property.

<b>Type:</b>	Integer
<b>Default value:</b>	500
<b>Range:</b>	Minimum=0; Maximum=1000
<b>Platform (s):</b>	Java, .NET

### max-service-end-points-per-async-type

Maximum total number of service endpoints that can be registered for each asynchronous entry point type, such as worker thread. Because a single transaction may spawn many threads, you may expect more asynchronous service endpoint types than for synchronous service endpoint types.

<b>Type:</b>	Integer
<b>Default value:</b>	40
<b>Range:</b>	Minimum=0; Maximum=N/A
<b>Platform(s):</b>	Java

### max-service-end-points-per-entry-point-type

Maximum total number of service endpoints that can be registered for each entry point type, such as servlet, struts action, web service, and so on.

<b>Type:</b>	Integer
<b>Default value:</b>	25
<b>Range:</b>	Minimum=0; Maximum=N/A
<b>Platform(s):</b>	Java, .NET

### max-service-end-points-per-node

Maximum total number of service endpoints that can be detected on a single node. Increasing the value of this property enables more service endpoints to be detected on a particular node.

<b>Type:</b>	Integer
<b>Default value:</b>	100
<b>Range:</b>	Minimum=0; Maximum=N/A
<b>Platform(s):</b>	Java, .NET

### max-service-end-points-per-thread

Maximum number of service endpoints detected on a single thread of transaction execution.

If this property is set to the default value of one and two service endpoints are detected that impact one specific transaction, only one service endpoint will be evaluated at any time. If a second service endpoint is detected in the context of the first one, the second is ignored. But, if the second service endpoint starts after the first one ends, the second service endpoint will be evaluated.

Increase this property to monitor additional service endpoints on a thread. This number ensures a maximum limit on overhead and number of metrics due to service endpoints on each thread execution.

<b>Type:</b>	Integer
<b>Default value:</b>	1
<b>Range:</b>	Minimum=0; Maximum=N/A
<b>Platform(s):</b>	Java, .NET

### max-urls-per-error-code

This property increases the number of URLs the agent can track that produced a certain error. Once the maximum has been reached, all remaining errors are classified as unknown.

<b>Type:</b>	Integer
<b>Default value:</b>	50
<b>Platform(s):</b>	Java

### min-duration-for-jdbc-call-in-ms

A JDBC/ADO.NET call taking more time than the specified time (in milliseconds) is captured in the call graph. The query continues to show up in a transaction snapshot. Setting this value too low (< 10ms) may affect application response times. Changing the value does not require a restart.

<b>Type:</b>	Integer
<b>Default value:</b>	10
<b>Range:</b>	Minimum=0; Maximum=N/A
<b>Platform(s):</b>	Java, .NET

### min-load-per-minute-diagnostic-session-trigger

This property indicates the number of requests per Business Transaction to evaluate before triggering a diagnostic session. This property is useful to prevent diagnostic sessions when there is not enough load.

<b>Type:</b>	Integer
--------------	---------

<b>Default value:</b>	10
<b>Range:</b>	Minimum=0; Maximum=N/A
<b>Platform(s):</b>	Java, .NET

### minimum-age-for-evaluation-in-minutes

Automatic Leak Detection (ALD) tracks all frequently used Collections. For a Collection object to be identified and monitored, it must meet the conditions defined by the ALD properties. This property is the first criteria that needs to be met. The value is the minimum age of the Collection in minutes. This property takes effect after the node restarts.

From the point the collection is captured, it is monitored if it is still available for the specified period without collecting garbage. If it survives, then it is evaluated for size checks. If it meets the criteria, then it is monitored for long term growth in size.

**Warning:** If you reduce the default, there may be a performance hit on the CPU and memory because ALD needs to process more collections.

<b>Type:</b>	Integer
<b>Default value:</b>	30
<b>Range:</b>	Minimum=5; Maximum=N/A
<b>Platform(s):</b>	Java

### minimum-number-of-elements-in-collection-to-deep-size

Automatic Leak Detection (ALD) tracks all frequently used Collections. For a Collection object to be identified and monitored for it must meet the conditions defined by the ALD properties. This property sets the number of elements threshold.

**Warning:** If you reduce the default there may be a performance hit on the CPU and memory because AD is processing more collections.

<b>Type:</b>	Integer
<b>Default value:</b>	1000
<b>Platform(s):</b>	Java

### minimum-size-for-evaluation-in-mb

Automatic Leak Detection (ALD) tracks all frequently used Collections. For a Collection object to be identified and monitored it must meet the conditions defined by the ALD properties. This property sets the minimum initial size in megabytes for a collection to qualify for monitoring. The collection must also survive for the period specified in the minimum-age-for-evaluation-in-minutes property.

**Warning:** If you reduce the default there may be a performance hit on the CPU and memory because AD is processing more collections.

<b>Type:</b>	Integer
<b>Default value:</b>	5
<b>Range:</b>	Minimum=1; Maximum=N/A
<b>Platform(s):</b>	Java

### min-transaction-stall-threshold-in-seconds

For Executor mode only, the asynchronous transactions do not get checked for stall unless they run at least the specified number of seconds.

<b>Type:</b>	Integer
--------------	---------

<b>Default value:</b>	60
<b>Platform(s):</b>	Java

### msmq-correlation-field

By default, the .NET agent disables downstream correlation for MSMQ message queues. Register this node property on both the publishing and receiving tiers to enable downstream correlation for MSMQ and to specify the field where the agent writes correlation data.

The agent supports Extension or Label fields. By default, the agent writes correlation data to the Extension field, however, some frameworks built on MSMQ write data to the Extension field. Only use Label when the Extension field is not available because it is already in use by the framework. The NServiceBus implementation of MSMQ uses the Extension field, so for NServiceBus, use Label. See [MSMQ Backends for .NET](#).

<b>Type:</b>	String
<b>Supported values:</b>	<ul style="list-style-type: none"> <li>• <b>None:</b> Disable downstream correlation for MSMQ</li> <li>• <b>Label:</b> Store correlation information in the label field</li> <li>• <b>Extension:</b> Store correlation information in the extension field</li> </ul>
<b>Default value:</b>	None
<b>Platform(s):</b>	.NET

### msmq-single-threaded

Specify the threading architecture for the MSMQ message queue. The default value is `false`. For multithreaded queue implementations, change the value to `false`. See [MSMQ Backends for .NET](#).

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	.NET

### multi-tenant-agent-enabled

This disables the `multi-tenant` agent, which will disable all services that rely on it, including Cisco Secure Application.

Accepted values:

- `true` - Starts the Cisco Secure Application service.
- `false` - Stops the Cisco Secure Application service.

You can edit the property in `app-agent-config.xml`.

<b>Type:</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java

### multi.tenant.agent.logs.dir

Use this property to set the default log location of `mtagent` and `argentoDynamicService` logs.

Accepted values:

1. `apm` - This default value stores the `mtagent` and `argentoDynamicService` log files in the default APM logging directory along with APM logs.

<b>Type:</b>	String
<b>Default value:</b>	apm
<b>Platform(s):</b>	Java

2. `non-apm` - Use this value to store the `mtagent` and `argentoDynamicService` log files in the `argentoDynamicService` directory in `external-services`.

You can edit the property in `app-agent-config.xml`.

## App Agent Node Properties (N-R)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

### nested-exception-message-depth

It defines the levels to which nested exception messages are ignored.

<b>Type:</b>	Integer
<b>Default value:</b>	10
<b>Platform(s):</b>	Java, .Net

### normalize-prepared-statements

When this flag is set to `true`, any variables in prepared statement SQL would be substituted with '?' before query text is added to any snapshots.

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	Java

### nservicebus-single-threaded

Specify the threading architecture for the NServiceBus message queue. The value defaults to `true`. For multithreaded queue implementations, change the value to `false`. See [NServiceBus Backends for .NET](#).

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	.NET

### osb-ignore-exit-types

This comma-separated property defines which exits protocols (as configured in the Transport Configuration pane) are excluded from detection as uncorrelated custom backends.

Set the property to 'all', if you do not want to detect any exit.

<b>Type:</b>	String
<b>Default value:</b>	http,jms
<b>Platform(s):</b>	Java

### on-demand-snapshots

Collect snapshots for all Business Transactions executed in this node. Does not need a restart. This property is ignored in the [Development](#) mode.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET

## percentile-method-option

You can choose one of two different algorithms to calculate percentiles in AppDynamics:

- **P Square algorithm (default):** This option consumes the least amount of storage and incurs the least amount of CPU overhead. The accuracy of the percentile calculated varies depending on the nature of the distribution of the response times. You should use this option unless you doubt the accuracy of the percentiles presented.
- **Quantile Digest algorithm:** This option consumes slightly more storage and CPU overhead but may offer better percentiles depending on how the response times are distributed.

Changes to this property do not require that you restart the agent.

<b>Type:</b>	Numeric
<b>Supported Values:</b>	<ul style="list-style-type: none"> <li>• 1: P Square</li> <li>• 2: Quantile Digest</li> </ul>
<b>Default value:</b>	1
<b>Platform(s):</b>	Java, .NET

## queue-single-threaded

Specify the threading architecture for the IBM MQ message queue. The value defaults to `false`.

When the IBM MQ `Get()` method is called, the transaction/snapshot is ended prematurely. To prevent this, set the agent node property: `queue-single-threaded=true`.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	Java, .NET

## read-only-environment

By default, the Java agent identifies a read-only environment such as Azure Spring Cloud, and functions accordingly. However, this property allows you to manually specify whether the environment should be treated as read-only or not.

When set to `true/false`, it will override the default detection mechanism and enforce the specified read-only setting. It helps save entries and prevents business transaction loss during the agent restart.

<b>Type:</b>	Boolean
<b>Default value:</b>	none
<b>Platform(s):</b>	Java

## reportingFrequencyInMillis

The agent property specifies the frequency of Request Segment Data (RSD) uploads from the agent.

<b>Type:</b>	Numeric
<b>Default value:</b>	10000 ms
<b>Platform(s):</b>	Java

## rest-num-segments

The property, `rest-num-segments` specifies the  $n$  in the first- $n$ -segments parameter in `rest-uri-segment-scheme`. If this property is 0 or less, then the value of this property is ignored. The value of this property is also ignored if `rest-uri-segment-scheme=full`.

<b>Type:</b>	String
<b>Default value:</b>	2
<b>Platform(s):</b>	Java

## rest-transaction-naming

This node property determines the format in which REST-based business transactions are named. You can use variables to populate the name with values bound at runtime. Any characters in the property value that do not match a variable are treated as literal text in the business transaction name, so you can, for example, separate variables with a colon, slash, or another character.

The agent takes each parameter and fills in the proper value based on the annotations and properties of the Java class:

- `{class-name}` : The app agent will fill in the name of the Java class mapped to the REST resource.
- `{method-name}` : The method being called.
- `{class-annotation}` : Class annotation values.
- `{method-annotation}` : Method annotation applied to the method (not always present).
- `{rest-uri}` : URI of the REST resource. The REST URI is further configured using the following properties:
  - `rest-uri-segment-scheme`
  - `rest-num-segments`
- `{http-method}` : HTTP method of the request, GET, POST, and so on.
- `{param-%d}` : A parameter to the method identified by position. Replace %d with the position of the parameter (ZERO-based).

<b>Type:</b>	String
<b>Default value:</b>	{class-annotation} / {method-annotation}. {http-method}
<b>Platform(s):</b>	Java

### Examples

See [Using Default Settings and Using rest-transaction-naming Properties](#).

## rest-uri-segment-scheme

The property, `rest-uri-segment-scheme` has three valid values: `first-n-segments`, `last-n-segments`, and `full`. This property indicates how many segments of the URI to use for the URI in `{rest-uri}`. This option is case-sensitive. If the value of this property is `full`, then the value of `rest-num-segments` is ignored.

<b>Type:</b>	String
<b>Default value:</b>	first-n-segments
<b>Platform(s):</b>	Java

## rmqsegments

The App Agent for .NET (agent) automatically discovers RabbitMQ remote services. Use the `rmqsegments` node property to refine the queue backend name to include some or all segments of the routing key. You must be familiar with your implementation RabbitMQ exchanges and routing keys. See [RabbitMQ Exchanges and Exchange Types](#).

The RabbitMQ routing key is a string. The agent treats dot-separated (".") substrings of the routing key as segments. Set the value for `rmqsegments` to an integer that represents the number of routing key segments to include in the name. For more details, see information on refining backend naming in [RabbitMQ Backends for .NET](#).

<b>Type:</b>	Numeric
<b>Value:</b>	Integer representing the number of routing key segments to include in the name.
<b>Default value:</b>	0

<b>Platform(s):</b>	.NET
---------------------	------

## App Agent Node Properties (S)

### sensitive-data-filters

Set this property to `true` to hide the sensitive runtime data in the transaction snapshots. Add the filters in the XML format specified in `app-agent-config.xml`. This node property does not override sensitive filter configuration from `app-agent-config.xml`.

<b>Type</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java

#### Example

```
<sensitive-data-filters>
 <sensitive-data-filter applies-to="environment-variables,system-properties,jmx-mbeans"
 match-type="CONTAINS"
 match-pattern="password"/>
</sensitive-data-filters>
```

### sensitive-message-filters

Set this property to `true` to hide the runtime messages containing sensitive data in the transaction snapshots. Add the filters in the XML format specified in `app-agent-config.xml`. This node property does not override other node properties.

<b>Type</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java

### Example

```
<sensitive-message-filters>
 <sensitive-message-filter message-type="throwable,logger-
message,all"
 match-type="EQUALS|CONTAINS|
STARTSWITH|ENDSWITH|REGEX"
 match-pattern="CASESENSITIVE_PATTERN"
 redaction-
regex="SENSITIVE_INFO_REGEX_GROUP"/>
</sensitive-message-filters>
```

## sensitive-url-filters

Set this property to `true` to hide the sensitive URLs in the transaction snapshots. Add the filters in the XML format specified in `app-agent-config.xml`. This node property does not override sensitive filter configuration from `app-agent-config.xml`.

<b>Type</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java

### Example

```
<sensitive-url-filters>
 <sensitive-url-filter delimiter="/"
 segment="2,3"
 match-filter="EQUALS|INLIST|
STARTSWITH|ENDSWITH|CONTAINS|REGEX|NOT_EMPTY"
 match-pattern="pattern"
 param-pattern=""/>
</sensitive-url-filters>
```

### show-packages

For the call graphs captured on this node, show the specified packages or class names in addition to the ones configured in the global call graph configuration. Does not need a restart.

<b>Type:</b>	String
<b>Default value:</b>	none
<b>Platform(s):</b>	Java, .NET

### slow-request-deviation

The value in milliseconds for the deviation from the current average response time. This setting is used for evaluation of slow in-flight transactions. Also, see the `slow-request-threshold` property for more details.

<b>Type:</b>	Integer
<b>Default value:</b>	200
<b>Range:</b>	Minimum=10; Maximum=3600
<b>Platform(s):</b>	Java, .NET

### slow-request-monitor-interval

In-flight requests are checked for slowness in the interval specified by this property. The value is specified in milliseconds.

<b>Type:</b>	Integer
--------------	---------

<b>Default value:</b>	100
<b>Range:</b>	Minimum=0; Maximum=3600
<b>Platform (s):</b>	Java, .NET

### slow-request-threshold

In-flight requests taking more time than this threshold (in ms) with a deviation greater than the `slow-request-deviation` property from the current average response time are monitored to capture hot spots.

<b>Type:</b>	Integer
<b>Default value:</b>	500
<b>Range:</b>	Minimum=0; Maximum=3600
<b>Platform (s):</b>	Java, .NET

### socket-enabled

Use this property to enable NetViz monitoring of .NET and Java applications.

<b>Type:</b>	Boolean
--------------	---------

<b>Default value:</b>	false (.Net) true (Java)
<b>Platform(s):</b>	.NET, Java

### spring-batch-enabled

Use this property to enable or disable OOTB BT Detection for Spring Batch.

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	Java

### spring-integration-receive-marker-classes

Use this property to specify the class and method you have identified as suitable POJO entry points for Spring Integration.

Based on the `MessageHandler` interface, the App Agent for Java by default automatically discovers exits for all channels except `DirectChannel`. In cases where a lot of application flow happens before the first `MessageHandler` is executed,

- Set `enable-spring-integration-entry-points=false`
- Configure suitable [POJO entry points](#),
- Declare each suitable POJO entry point class/method in this property [spring-integration-receive-marker-classes](#)

If the application code polls for messages in a loop, the span of each loop iteration is tracked as a transaction. Tracking begins when the loop begins and end it when the iteration ends. To safeguard against cases where `pollableChannel.receive()` is not called inside a loop, specify this property for each class/method combination that polls messages in a loop.

After setting this property, restart the application server for changes to this property to take effect.

**Type:** Comma-separated string of fully-qualified class / method name, such as `spring-integration-receive-marker-classes = ,<> ....`

**Default value:** none

**Platform(s):** Java

### Examples

For example, to enable tracking for the following:

```
class MessageProcessor
{
void process()
{
while(true)
{
Message message = pollableChannel.receive()
}
}
}
```

set this property as follows:

```
spring-integration-receive-marker-classes = MessageProcessor/process
```

See also [Spring Integration Support](#).

## spring-mvc-naming-scheme

Register this node property to modify the naming scheme for Spring MVC transactions. Bean ID cannot be used as a global naming type. Use the bean ID and method name for global.

<b>Type:</b>	String
<b>Allowed values:</b>	bean-id, simple-class-name, fully-qualified-class-name, business-interface-name, bean-method-name, ben-id-and-method-name, class-and-method-name
<b>Default value:</b>	none
<b>Platform(s):</b>	Java

### App Agent Node Properties (T-Z)

This reference page contains information about app agent node properties. The properties are listed in alphabetical order.

### thread-correlation-classes

For multi-threaded applications, use this property to configure classes to be included in Java thread correlation when simple prefix-matching (matching on `STARTSWITH` ) is sufficient to identify the classes.

The `thread-correlation-classes` property specifies the classes to include for thread correlation. This property can be used together with the `thread-correlation-classes-exclude` property.

The configured correlation takes effect without requiring a restart of the managed application. Also see, [Configure the Thread Correlation in Java Agent](#).

<b>Type:</b>	Comma-separated string of fully-qualified class names or package names
--------------	------------------------------------------------------------------------

<b>Default value:</b>	none
-----------------------	------

<b>Platform(s):</b>	Java
---------------------	------

This property is not recommended for use in the Executor Mode.

### thread-correlation-classes-exclude

For multithreaded applications, use this property to configure classes to be excluded in Java thread correlation when simple prefix-matching (matching on `STARTSWITH` ) is sufficient to identify the classes. This property specifies the classes to exclude from thread correlation. This property can be used in conjunction with the `thread-correlation-classes` node property.

The configured correlation takes effect without requiring a restart of the managed application. See [Configure Multithreaded Transactions \(Java only\)](#)

<b>Type:</b>	Comma-separated string of fully-qualified class names or package names
--------------	------------------------------------------------------------------------

<b>Default value:</b>	none
-----------------------	------

<b>Platform(s):</b>	Java
---------------------	------

This property is not recommended for use in the Executor Mode.

### thread-cpu-capture-overhead-threshold-in-ms

Determines the timeout allotted for collecting and calculating Thread CPU Time for 1000 iterations. If the timeout is exceeded, the Java Agent automatically disables CPU time collection for threads. CPU usage information will then be absent from the BT overview or snapshots in the Controller UI. In addition, an INFO-level log similar to the following appears in the logs:

```
[Thread-0] 22 Oct 2013 14:19:26,346 INFO
JVMThreadCPUtimeCalculator - Disabling BT CPU
Monitoring. Time taken to calculate Thread CPU
Time for [1000] iterations is [15 ms] which is
greater than the allowed budget of [10 ms].
```

This issue may particularly affect JDK 1.6 on Linux due to the issue [getCurrentThreadCpuTime is drastically slower than Windows Linux](#).

<b>Type:</b>	Integer
<b>Default value:</b>	10 ms
<b>Platform(s):</b>	Java

#### Examples

You can increase the `thread-cpu-capture-overhead-threshold-in-ms` property, but it is important to note that this may result in increased overhead on your application. We recommend you use this [Java HotSpot VM option](#) instead to speed up the API call itself:

```
-XX:+UseLinuxPosixThreadCPULocks
```

Restart is needed after changing this value.

## wcf-enable-eum

Enable and disable EUM correlation from a WCF node.

<b>Type:</b>	Boolean
<b>Default value:</b>	false
<b>Platform(s):</b>	.NET

### Examples

The enable EUM correlation, the WCF application must also have the following entry in the `Web.Config`:

```
<serviceHostingEnvironment aspNetCompatibilityEnabled="true" />
```

See [serviceHostingEnvironment](#).

## websocket-entry-calls-enabled

When set to false, no WebSocket entry calls are detected.

<b>Type:</b>	Boolean
<b>Default value:</b>	true
<b>Platform(s):</b>	Java

## Dynamic Language Agent Proxy

Related pages:

- [Configure the Agent for PHP CLI Applications](#)
- [Use a Shared Proxy for PHP Agents](#)
- [Start the PHP Agent Proxy Manually](#)
- [Start the Python Agent Proxy Manually](#)

The AppDynamics proxy is a Java daemon process that handles communication between the Controller and these agents:

- PHP
- Python
- Web Server

The proxy reports data collected by the agent to the Controller, which stores, baselines, and analyzes it.

This page describes information you can use to examine and resolve proxy issues that may prevent an application agent from connecting to the Controller, or reporting data correctly. For detailed information about how the proxy works with a specific agent, see the appropriate *Related pages*.

## Proxy Basics

### Single or Multi-Tenant

For the PHP agents, the proxy can be single-tenant (one proxy per agent) or multi-tenant (multiple agents communicating through a single proxy), depending on the way the agents are configured. The default setup for these agents is single-tenant, but there are circumstances for which a multi-tenant proxy is required or desirable. The Apache Web Server and Python agents always communicate through a multi-tenant proxy when there are multiple agents on a machine.

### Automatic or Manual Startup and Shutdown

Typically the proxy is automatically started when the application agent starts up, but in some cases, you need to launch it manually. These cases vary depending on both the particular agent and the application environment.

After the proxy is started (automatically or manually) it registers with the Controller and requests the agent configuration. The agent must receive the configuration from the Controller via the proxy before it can report metrics.

If the proxy was automatically started, the agent is supposed to shut down the proxy as part of its own cleanup procedures. If the proxy was manually started, it must be shut down manually.

### Proxy Logs

If the proxy is running, you can check the proxy log to examine connection issues.

The proxy log files are named `proxy.<timestamp>.log`.

If the proxy is not running, examine the agent logs for the typical Java startup signature to see if the proxy started.

See the agent-specific documentation for the location of these logs:

- PHP: Default is `<php_agent_install_dir>/logs`. See [Install the PHP Agent](#).
- Python: Default is `/tmp/appd/logs`. See [Python Agent Debugging and Logging](#).
- Web Server: `<webserver_agent_install>/logs/proxy_<date>.log`

### Proxy Not Started Issues

The agent will not work if the proxy did not start.

Determine whether the proxy started by running this command:

```
ps aux|grep java
```

If the proxy is running, you should see `java` and `proxy` in the output, something like this:

```
/usr/lib/appdynamics-php5/proxy/jre/bin/java -server -Xmx120m -classpath /usr/lib/
appdynamics-php5/proxy/conf/logging/*:/usr/lib/appdynamics-php5/proxy/lib/*:/usr/lib/
appdynamics-php5/proxy/lib/tp/*:/usr/lib/appdynamics-php5/proxy/* -Djava.library.path=/usr/
lib/appdynamics-php5/proxy/lib/tp -Dappdynamics.agent.logs.dir=/usr/lib/appdynamics-php5/logs
-Dcomm=/tmp/ad-sij4rp -DagentType=PHP_APP_AGENT -Dappdynamics.agent.runtime.dir=/usr/lib/
appdynamics-php5/proxy com.appdynamics.ee.agent.proxy.kernel.Prox
```

If the proxy did not start, the most common reason is insufficient permissions.

- The agent installation directory, and its proxy control subdirectory, must be readable and executable by all and writable by the directory owner:

```
chmod -R 755 <agent_install_dir>
```

- The agent installation directory must be owned by the instrumented application user. Who this user is depends on the platform. It could be the Apache user, the python container user, the nginx user, etc.

```
chown -R <appuser>:<appsuser> <agent_install_dir>
```

If the proxy did not start, set these permissions and try again.

## Proxy Connection Issues

If the proxy started but you don't have a connection to the Controller, you may be using incorrect Controller information.

Examine the proxy log and verify that there are no typos in the Controller domain name or port and that SSL setting is enabled for an SSL connection. If there are mistakes, edit the Controller/port/SSL values in the configuration. These settings are on the first page of the Agent Download and Install Wizard or the agent settings if you installed the agent manually.

If you have verified that the Controller settings are correct and the proxy still does not connect to the Controller, telnet to the SaaS Controller:

```
telnet <your_account>.saas.appdynamics.com 443
```

If you cannot access the Controller through telnet, examine the agent-registered messages in the logs that indicate why the proxy is unable to connect, such as the existence of a firewall or other obstacle at your site. Work with your administrator to see if you can resolve the issue.

If you can reach the Controller through telnet, there may be a problem on the Controller.

## Dynamic Agent Proxy Logging

Proxy logs are created for app server agents that use the Dynamic Agent Proxy to communicate with the Controller. See [Dynamic Language Agent Proxy](#).

The PHP Agent, Node.js Agent (Java proxy mode), Python Agent, and the Web Server Agent generate logs for the Dynamic Agent Proxy. The logs determine why snapshots are not being taken and diagnose communication issues with the Controller.

The proxy logs consist of a top-level file named `proxyCore Year_mon_day_hr_min.#.log` and files named `proxy Year_mon_day_hr_min.#.log`, where # is the log set. See [Agent Log Files](#) for information about how the logs are organized into sets that roll over.

Other logs associated with each proxy log include:

- Bytecode Transformer log
- REST log
- Dynamic Services (used internally for debugging) log

Each proxy log has a maximum size of five MB.

Allowing for the possibility of several restarts and all the possible logs that could be generated (Proxy, BytecodeTransformer, REST, and Dynamic Services), the maximum number of logs is 20 files (four log files times five sets). The maximum size is 100 MB per set.

## Business Applications

As described in [Overview of Application Monitoring](#), a business application serves as the top-level container in the AppDynamics APM model. Business applications contain a set of related business transactions and service endpoints, along with the infrastructure components and artifacts that interact to provide the services.

### Organize Business Applications

You can model your environment into one or more business applications. When you have multiple business applications within the same AppDynamics account, you can use the [cross application flow map](#) to view relationships between the different applications.

Since access permissions in the Controller UI can be assigned by business application, organizing business application by teams in your organization may make the most sense. Keep in mind that configuration settings such as Health Rules are scoped to a business application, avoid having more business applications than needed to ease configuration.

**i** When you model your environment, be sure to assign unique names to your business applications. Names must be unique among both Application Performance Monitoring and End User Monitoring.

## Permissions

Creating applications requires the *Can Create Applications* permission. Permission to view, edit, or delete applications can be set as part of the default application permissions for a custom role or for specific applications. See [Application Permissions](#).

## View Applications

The Applications page, accessible from the menu bar in the Controller UI, provides a high-level view of the business applications in your environment. At a glance, you can see the performance for the applications.

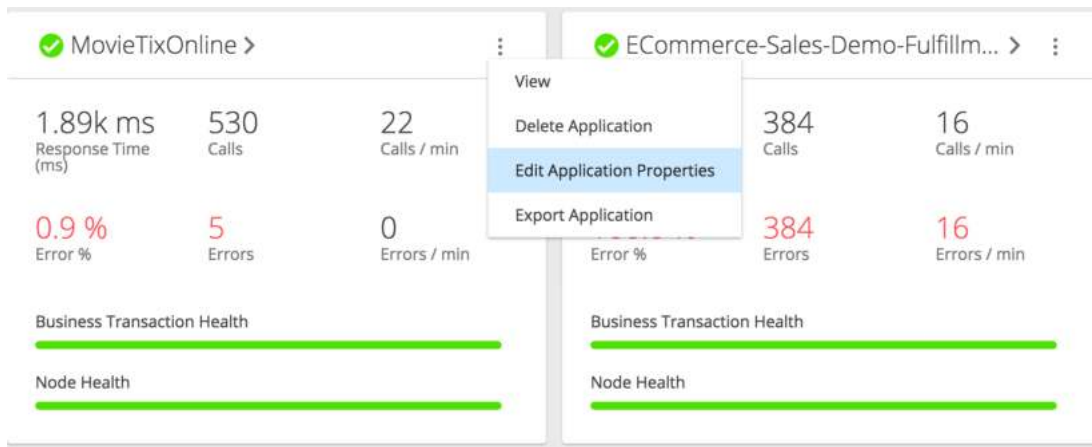

There are several views and sorting options in the page. To view relationships between business application (such as, when a business transaction in one invokes a service in another), select the **Flow View** icon.

## Modify Applications

You can create new business applications from the Applications page, but it's not necessary to create the business application manually. The Controller creates a new business application automatically the first time an app agent registers itself using a new business application name.

## Rename Applications

You can rename applications by selecting **Edit Application Properties** from the drop-down of an application.

**i** If you change the name of an application, you also need to change it in the agent configuration at `controller-info.xml`. If you do not change the `controller-info.xml` application name field, agents will re-create the old application name and report to the old application.

## Deleting Applications

To delete an application:

Select the application in the **Applications** drop-down, and select **Actions > Delete**.

The Controller prompts you to acknowledge a list of related items that will be deleted including:

- 
- Number of tiers and nodes
  - Number of business transactions (see [Business Transactions](#))
  - Browser RUM Apps
  - Mobile Apps

## Application Performance Details

From the Applications page, click a listed application to configure and monitor the business application. In the business application instance Application Dashboard page, you can view:

- **Top Business Transactions:** The key performance indicators for the most expensive business transactions sorted by the various criteria, such as load, response time, errors and so on. Click View All in any of the panels in this tab to see a list displaying all the key performance indicators for the top business transactions in one panel.
- **Transaction Snapshots:** The transaction snapshots for the selected time range. From a transaction snapshot, you can drill down to the root cause of a performance problem.
- **Transaction Analysis:** Application performance over the selected time range as a graph. Use the graph to analyze the impact of different events on the application response time.
- **Machine Snapshots:** When an application has at least one .NET tier, this appears as a list of the machine snapshots for the selected time range. From a machine snapshot, you can drill down to view environmental conditions, such as running processes and memory usage for a particular machine. See [Machine Snapshots for .NET](#).

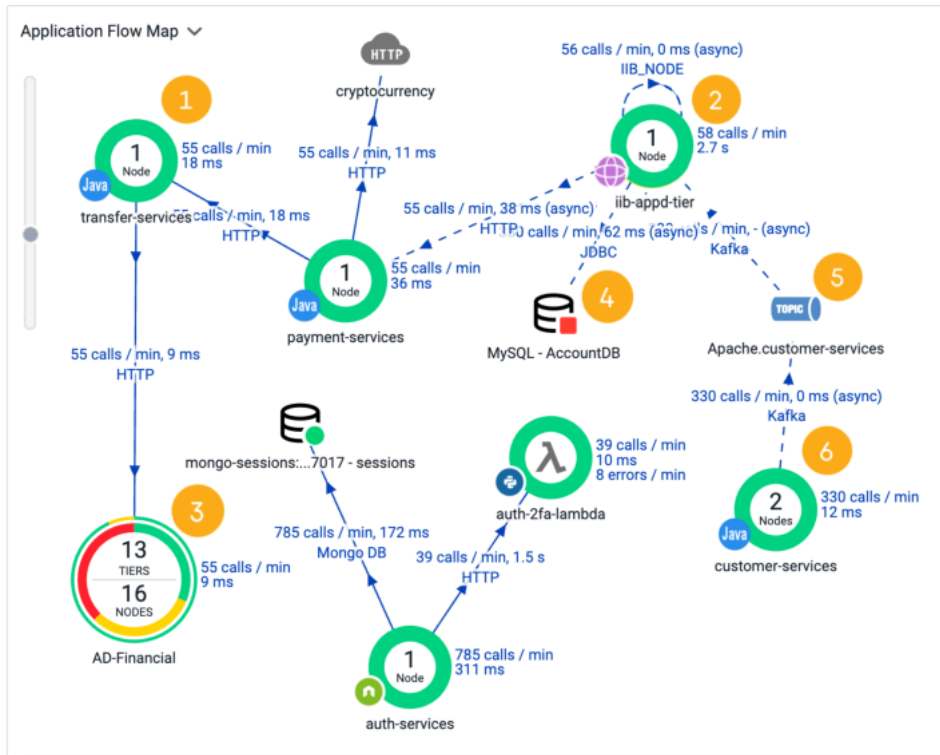

## Flow Maps

This page describes how to view and use flow maps.

Flow maps present a dynamic visual representation of the components and activities of your monitored application environment. See [Overview of Application Monitoring](#).

### Flow Map Overview

Flow maps show the tiers, nodes, message queues, and databases in the environment, and the business transactions that flow through them. This sample shows a basic flow map for an e-commerce application. In the sample, several application server tiers interact with databases, remote services, an Apache message broker, and an IIB node making calls to itself.

- 1 Application server tier with a single node
- 2 Endpoint call to a different endpoint in the same IIB service
- 3 Downstream business application: the inner ring depicts node health and the outer ring depicts Business Transaction (BT) health
- 4 MySQL database service
- 5 Apache messaging service
- 6 Application server tier with two nodes

### Connection Types

Flow lines represent connections between components in the flow map. Solid lines indicate synchronous connections. Dashed lines indicate asynchronous connections.

Many modern frameworks use asynchronous patterns even if you do not explicitly call an asynchronous function or method. For example, your application code may employ a synchronous call to a framework or an Object-relational mapping style API, but the framework itself invokes an asynchronous executor to handle the call. These types of asynchronous segments show up as a dotted line on the flow map. See [Trace Multithreaded Transactions for Java](#) or [Asynchronous Exit Points for .NET](#).

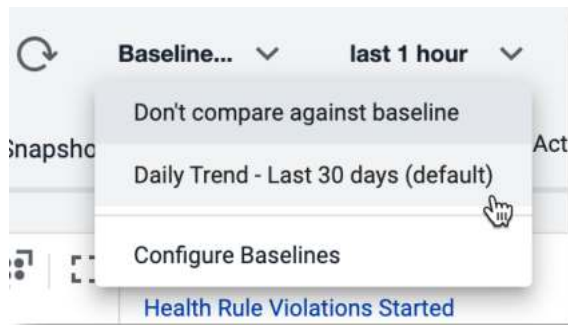

### Request Times

The numbers above the flow lines indicate the calls made per minute to the tier and the average time taken for the request to be serviced; that is, the round-trip time for the request. The round-trip time includes time spent on the network, if applicable to your topology, and the time that the backend server or other process spends processing the request. The calls per minute for a given context, such as a tier, must be one or more for the flow map to display.

### Performance Baselines

AppDynamics automatically calculates the baseline performance for your applications. Once the Controller Tenant establishes prevailing performance characteristics, it can detect anomalous conditions for your application. It calculates baselines by using the underlying hourly data.

The default view for the flow map is set to **Don't compare against baseline**. You can set the flow map to compare against pre-configured or custom baselines using the **Baseline** menu.

If [performance baselines](#) are set for transactions represented in the flow map, the flow lines use a corresponding color to indicate the performance of the service relative to the baseline.

- Green indicates that response times are within range of the baseline.
- Yellow indicates that response times are slower than the baseline.
- Red indicates that response times are critically slow. It can take some time for the Controller Tenant to establish baselines for a new installation.

Click **Legend** to learn more about how flow maps represent data with respect to baselines.

### Live Entity Data

By default, the flow map only shows the nodes receiving performance data. This optimizes rendering and enables a quick view of the active nodes. You can set a filter to view the nodes not receiving performance data to help you troubleshoot node issues.

When an entity is alive, it will affect other associated entities:

- When a business transaction entity is alive, the associated node, tier, and application will be alive.
- When a node is alive, the associated tier and application will be alive.
- When a tier is alive, the associated application will be alive.

**i** If the Controller Tenant detects that a flow map is taking a long time to load, it does not load the flow map automatically. Click **Show Flow Map** to display it.

### Types of Flow Maps

These flow maps appear in several of the built-in dashboards depicting different information according to the data context:

- **Cross-Application**—displays exit calls between applications within the monitored environment. This pattern of calls is known as [cross-application flow](#).
- **Application**—displays the topology and activities within an application. It displays metric values across all [business transactions](#) in the application for the selected time range.
  - For example, the application flow map displays calls per minute; average response time for calls made to databases and remote services; and business transaction errors per minute. These metrics are based on all calls made from a specific tier to a database or remote service across all business transactions.
  - When an application is one of several in a one-app-per-service architecture, business transactions can represent service endpoints. For these applications, the flow map displays a Cross-BT Hovercard that shows calls to upstream and downstream business transactions which represent endpoints of other services.
- **Tier and Node**—displays metric values across all business transactions for the subset of the application flow related to the selected tier or node.

- **Business Transaction**—displays the activity for a BT. The **Start** label indicates the tier where the transaction starts (the originating tier). This flow map shows metrics that are calculated based on all executions of the BT during the selected time range.
- **Snapshot**—displays the metrics associated with a single snapshot specific to a particular execution of the transaction.

AppDynamics shows [cross-application flow](#) in other flow maps where appropriate. For example, a tier flow map shows correlation when there are exit calls from the tier to another instrumented application.

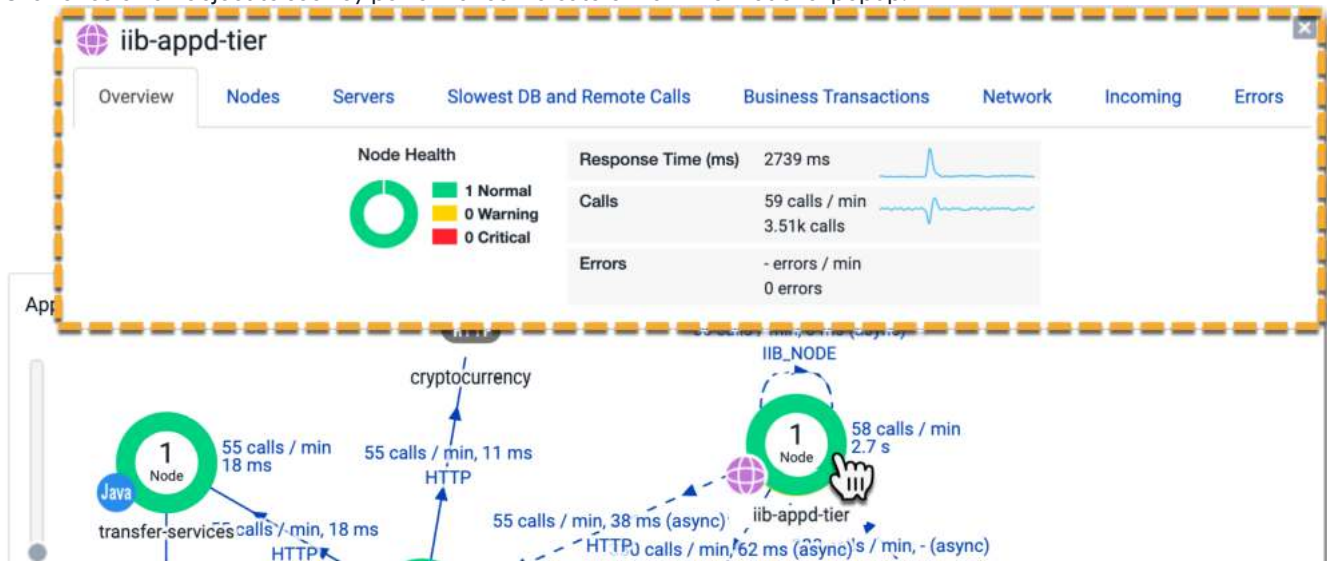

Context can determine the meaning of what flow maps represent. Consider the average response time (ART) for calls to a database.

- In the context of an application, ART averages all calls to the database occurring within the application. Suppose that the application flow map shows that ART for those calls is 20 milliseconds.
- In the context of a BT, ART represents the average execution time for the BT as a whole. Suppose that in a BT within the same application, the database gets called twice each time the BT executes. In the BT flow map, ART represents the average duration of a pair of database calls, meaning that ART is 40 milliseconds.

## Flow Map Interactions

On flow maps you can:

- Click once on an object to see key performance indicators in an informational popup.

- Double click an object to open a detailed flow map of that object.
- Change the **Time Range** setting to have the flow map represent the activity of the system within the selected time frame.
- Click and drag objects to rearrange the flow map layout.
- Use the view and arrangement options at the top right to view as a list, auto-arrange for the fewest crossing flows, or maximize the view.

## The Cross-BT Hovercard in the Application Flow Map

For an application in a one-app-per-service architecture, the application flow map displays a Cross-BT Hovercard showing calls from upstream and downstream business transactions representing endpoints of other services.

This enables you to isolate the service which is the origin of any problem that arises, to one of three possibilities:

1. The service whose endpoint is a BT that you are monitoring (your service).

2. An upstream or downstream service, that your service communicates with through cross-BT calls.
3. Yet another upstream or downstream service, that your service communicates with indirectly through a chain of cross-BT calls between several services.

To access the Cross-BT Hovercard, select the line representing either the incoming or outgoing cross-application call, and then select the Business Transactions tab.

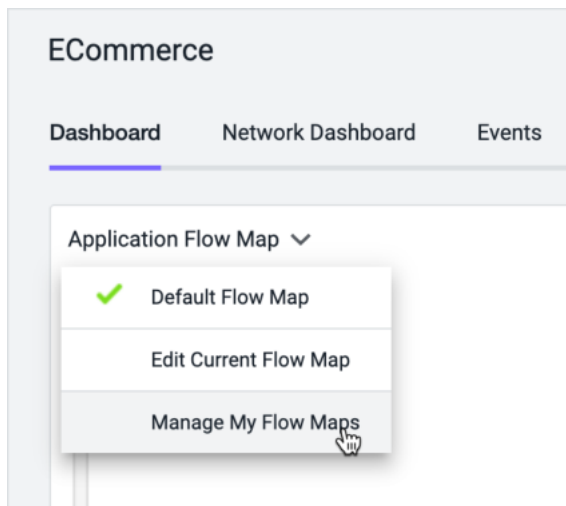

## Manage Flow Maps

In a large-scale deployment, the flow map may show hundreds of monitored nodes. You can create custom flow maps that target specific areas of interest.

You can configure it to show only certain tiers or those based on performance thresholds, for example:

- Only show tiers from where the load exceeds fifty calls per minute and the average response time exceed 10,000 ms.
- Only show backends receiving at least 400 calls per minute and generating more than 10 errors per minute.

To create, copy, or delete a flow map, click **Manage My Flow Maps** in the flow map menu.

When you create a flow map, the new flow map inherits the context of the flow map in which it was created, whether created from an application, business transaction, tier, or node flow map.

## Cross Application Flow

In the AppDynamics model, business applications usually represent a complete application environment. However, it is possible that different business applications share services or infrastructure components.

To view the cross application flow map, the user must have the account-level View Business Flow permission.

## Access the Cross Application Flow Map

The Applications tab in the AppDynamics Controller UI provides several views of the business applications in your account: a card view, list view, and flow view. To access the cross application flow map, click the flow view link in the tab.

## Use the Cross Application Flow Map

Click **View All Applications** on the Controller UI Home page to view the cross application flow.

In the context of a given business application, the call to another application is considered an exit call. If the other application is an AppDynamics-instrumented business application, the call is shown as cross application flow. For an example, see the All Applications Flow Map on [Flow Maps](#).

All users of one application can see correlated applications on the flow map. However, to drill into metrics and snapshots for a correlated application, a user must be a member of a role with view permissions to the correlated application. See [Manage Custom Roles](#).

## Hide Components or Business Application on the Flow Map

You can hide backend components, applications, or queues in the right-clicking menu for the component on the cross application flow map.

For applications monitored with the Java Agent, you can exclude a node from being resolved to a cross application flow by setting the following app agent node property to false:

```
support-cross-app-correlation= false
```

This property must be set in the downstream application and prevents calls from external apps registering as cross application flows.

You may choose to do this, for example, if you wanted the cross application call to be represented as a backend call in the calling applications flow map—and metric scheme—rather than as a call to another application. This ensures that metric data reflecting interactions with the tier in the external business application are retained as backend call metrics.

### Note

The node property `support-cross-app-correlation= false` works only for the Java Agent.

## Export and Import Business Application Settings

This page describes how to export and import the application configuration in the Controller. Application export/import allows you to back up just a single application configuration in the Controller, as opposed to the entire Controller instance, as described in [Controller Data Backup and Restore](#).

For information on exporting other settings from the Controller, see [Configuration Import and Export API](#). For JMX configurations, see [Configure JMX Metrics from MBeans](#).

### What Settings Are Exported?

You can export a business application configuration and import it as a new business application. The two applications can be on the same or different Controllers. If on different Controllers they must be using the same major version of AppDynamics.

The export is an XML file that includes:

- Snapshot collection settings
- Call graph settings
- Error configuration
- Stall configuration and Business Transaction thresholds
- HTTP and SQL Data gatherer settings
- Tier and Node definitions
- Custom entry point configurations for Business Transactions
- Metric baselines
- Information point configurations

The configuration information does not include data such as Events, Health Rule Violations, and metrics. Nor does it include configuration artifacts not related to the business application, such as users, dashboards, policies, database, and remote services, or schedules.

### Export a Business Application

To export the application, from the Applications home page, choose **Export Application** from the action menu for the business application you want to export.

## Applications

The screenshot shows the 'Applications' page in AppDynamics. At the top, there are navigation options: 'Details', 'Create Application', 'Actions', 'View', and 'Sort'. Below this, two application cards are visible. The left card is for 'ECommerce-Demo' and the right is for 'ECommerce-Demo-Fulfillment'. A context menu is open over the 'ECommerce-Demo' card, showing options: 'View', 'Delete Application', 'Edit Application Properties', and 'Export Application' (which is highlighted with a mouse cursor). Each card displays performance metrics: Response Time (ms), Calls, Error %, and Errors / min. Below the metrics are two horizontal bars: 'Business Transaction Health' and 'Node Health', both showing green bars indicating good health.

Your browser downloads the XML-formatted configuration file for the application.

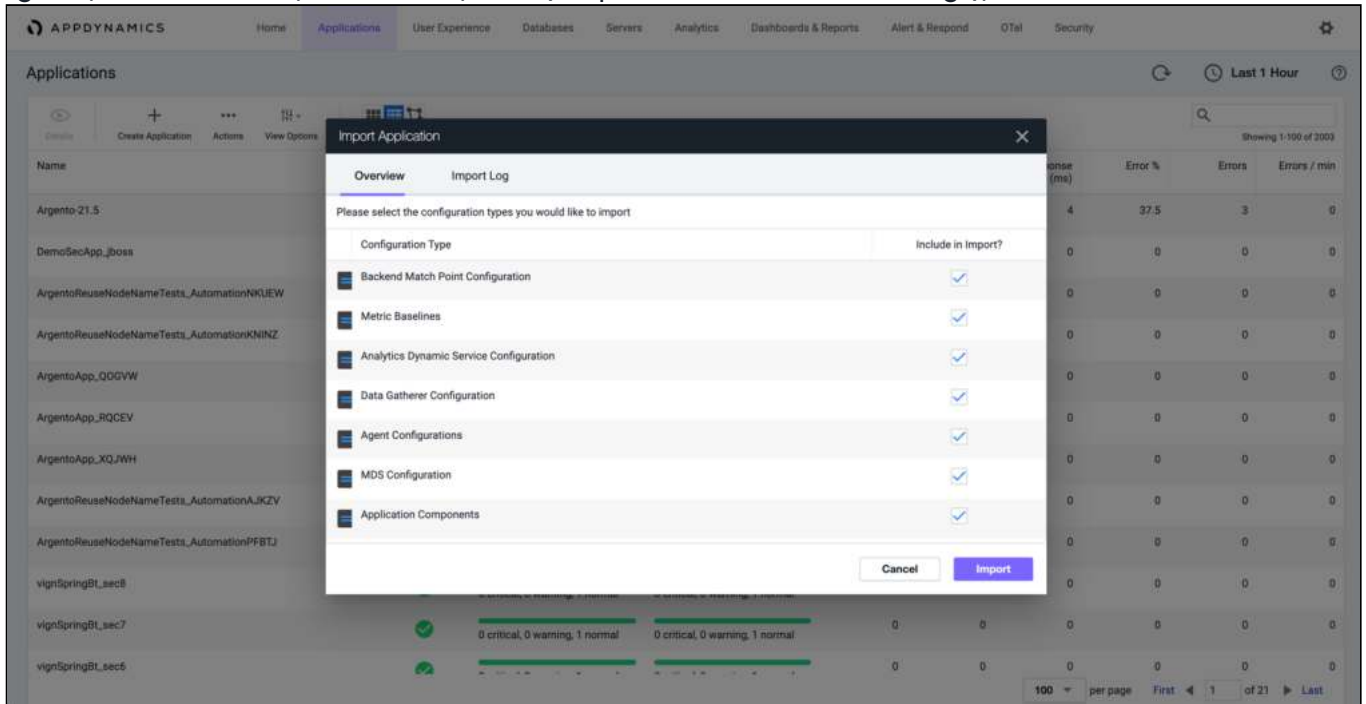

### Import a Business Application

To import an application configuration, you must be logged in as a user with Administrator user role privileges, see [Roles and Permissions](#). You also need access to a previously exported configuration file.

To import the configuration, follow these steps:

1. From the **Applications** page, click **Actions > Import**.
2. Select the XML file that contains the configuration you want to import. You can import it into an existing business application or create a new one.

- Choose the configuration settings you want to import. Options include configuration settings for app agents, data collectors, health rules, MDS (scoped instrumentation settings), and more.

Configuration Type	Description
Backend Match Point Configuration	It is the backend discovery rule configuration. AppDynamics discovers backends from exit point instrumentation placed in the application code. An exit point is a precise location in the code where an outbound call is made from an instrumented node.
Metric Baselines	You can import metric baseline values and then see how data in the Metric Browser compare to baseline values. Monitoring baseline deviation exposes performance metrics that might violate your Service Level Agreements (SLAs).
Analytics Dynamic Service Configuration	The Analytics configuration may include the following: <ul style="list-style-type: none"> <li>◦ <b>Transaction Analytics - Configuration:</b> Enable Analytics for specific applications and business transactions.</li> <li>◦ <b>Transaction Analytics - Manual Data Collection:</b> Analytics supports three types of data collectors: method invocation data collector (MIDC), HTTP, and SQL.</li> <li>◦ <b>Log Analytics:</b> Configure source rules to collect data for log analytics.</li> <li>◦ <b>API Keys:</b> Create API authentication keys for users of the Analytics Events API.</li> </ul>

Configuration Type	Description
Data Gatherer Configuration	<p>It is the data collector configuration. Data collectors supplement business transaction and transaction analytics data with application data. The application data adds context to business transaction performance issues. For example, they may show the values of particular parameters or return values for business transactions affected by poor performance.</p> <p>This data shows the business context affected by performance issues, such as the specific user, order, or product.</p>
Agent Configurations	Agent configurations instrument your applications.
MDS Configuration	Scoped instrumentation settings.
Application Components	Application components such as web services, message queues, and databases.
Entry Match Point Configuration	The entry match point configuration is a custom match rule ( <a href="#">transaction detection rule</a> ) that enables you to define criteria for business transaction discovery and naming for an entry point type.
Health Rules	Health rules let you specify the parameters that represent what you consider normal or expected operations for your environment. The parameters rely on metric values, for example, the average response time for a business transaction or CPU utilization for a node.
EUM Cloud Configuration	AppDynamics End User Monitoring (EUM) provides end-to-end visibility on the performance of your web and mobile applications. EUM helps you troubleshoot problems such as slow web responses, Ajax errors, mobile network requests, and IoT application errors. EUM provides metrics on application performance and user activity.

4. Click **OK** to start importing. The import process first validates the file. As it proceeds, it shows the status for each type of artifact in the **Import Application** dialog.
5. Close the **Import Application** dialog when the import process is complete.

Application import does not work over HTTPS if the Controller uses a self-signed SSL certificate. Use a trusted, CA-signed certificate instead. See [Controller SSL Configuration Properties](#).

---

## Business Transactions

### Related pages:

- [Organize Business Transactions](#)
- [Transaction Detection Rules](#)
- [Service Endpoints](#)

### What is a Business Transaction?

In the AppDynamics application model, a business transaction (BT) represents an end-to-end, cross-tier processing path used to fulfill a request for a service provided by the application.

The business transaction is a key component for effective application monitoring. It consists of all required services within your environment such as login, search, and checkout that are utilized to fulfill and respond to a user-initiated request. These transactions reflect the logical way users interact with your applications. For example, activities such as adding an item to a shopping cart and then checking out various applications, databases, third-party APIs, and web services.

### Business Transaction in AppDynamics

With AppDynamics, you can resolve problems that consume a lot of time and resources, and ensure that your most critical business operations perform optimally. You can drill down in the application to focus on more specific goals and operations. For example, a retail website may choose to focus on its checkout or catalog operation; whereas- a financial services firms may focus on the most-used APIs provided for their mobile clients. By prioritizing your business goals early in the process, BTs are much easier to configure.

AppDynamics automatically discovers and maps business transactions for you. Actions, such as Add to Cart, are tagged and traced across every component of your application and visualized on a topology map, helping you to better understand performance across an entire application.

### Business Transactions and Endpoints

Within the end-to-end context of a business transaction, you must first identify if there is a performance issue with a service endpoint. Is the Edge service at fault? If not, then identify which downstream service may be at fault?

### Business Transactions and Service Triage

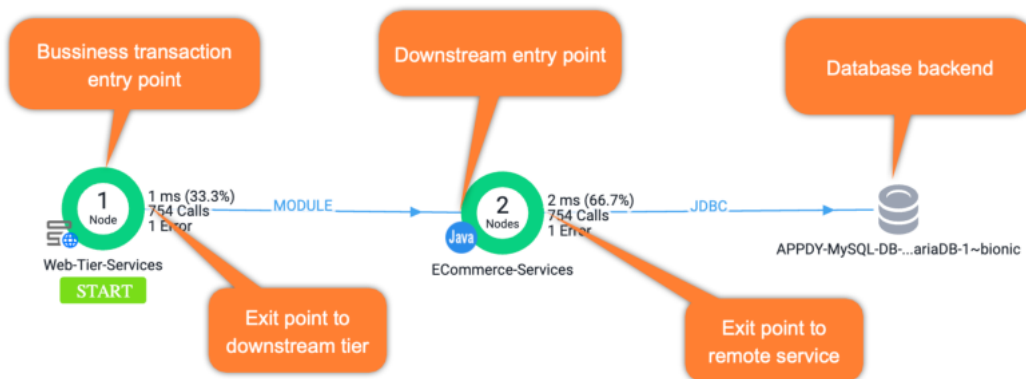

To conduct service triage on performance anomalies, you must first identify the root cause of the problem. To help focus on the cause, you should answer these questions:

- Is the issue my service or in one of its downstream dependencies?
- Is the behavior common across all service endpoint instances, or across a subset?
  - What do the affected instances have in common?
    - Are tags run on service instances, or run on resources?
    - Is shared infrastructure exhibiting a health issue?
    - Is the issue correlated with a release event?
  - Is the issue correlated with an application infrastructure health anomaly?

For recommended AppDynamics best practices for business transactions, see [Best Practices to Create Business Transactions](#).

## Sample Business Transaction

Consider, for example, the fictional ACME online application. The application exposes a checkout service at `http://acmeonline.example.com/checkout`.

A user request to the service triggers these distributed processing flow and actions:

1. The business transaction entry point at the originating tier is `/checkout` URI, which is mapped to a Servlet called `CheckoutServlet`.
2. The request results in the originating tier invoking the `createOrder` method on a downstream tier, the ECommerce-Services server.
3. The inventory tier application calls a backend database, which is an exit point for the business transaction. The request context is maintained across tiers, including calls to backend tiers.
4. Any user request on the entry point is similarly categorized as this business transaction, that is, the Checkout business transaction.

To enable detection of all the components in a distributed business transaction, downstream agents must be at the same AppDynamics release or newer than upstream agents. This is true regardless of whether the tiers are all built on the same platform. For example all Java or multiple platforms, a Node.js tier calling a Java tier, calling a .NET tier, and so on.

## Best Practices to Create Business Transactions

You can apply best practices for the BT configuration to be a smooth and orderly process. This page explains the best practices about how to identify your application's critical business transactions to get the most out of AppDynamics and your application and infrastructure.

- Business Transaction naming and BT limit usage  
The default BT name is based on the first two segments of a URI. More URI or segments may result in the overflow of BTs and some of the useful BTs may fall under `All other traffic - <tier>`.

For example, you want to monitor these URIs for `/eCommerce/login`:

- `/eCommerce/order`
- `/eCommerce/checkout`
- `/eCommerce/feedback`

However, `/order` contains many URI patterns and if it uses more than two segments, then it may reach the 200 BT limit and might result in priority BT such as `/eCommerce/checkout` under `All`

Other traffic - `<tier>` overflow BT. Additionally, `/order` results in many URIs that need to be monitored, (which are not required for the users):

- `/eCommerce/order/1/add`
- `/eCommerce/order/List`
- `/eCommerce/order/2/add`

Therefore, instead of enabling the full URI for servlet naming, it is recommended that you use [Custom Servlet rules](#) for any specific full URI pattern to group the BTs and use the BT space limit more efficiently. Although you can increase the BT limit at the Controller level, you can use the [Service Endpoint feature](#) as another alternative.

- Exclude BTs that are not required- Agent snapshots collection depends on the number of unique BTs in the BT list monitored from the target tier. Therefore, it is recommended to review the **Business transactions** list to check if any BTs listed as part of the auto-discovered transactions are not required. You can use the [Exclude Transactions](#) option to temporarily exclude such BTs. If you do not want to collect the snapshots but want only the KPI metrics, then you can monitor the BTs as [Service Endpoint](#).
- Use BT split and Service Endpoints- If there are too many variant results for BT naming, it is recommended that you do not use the split option for any entry point. If you need to use the split feature, then you should use the [exclude result value](#) in the split option.

Exclude split is only available for some entry points, such as Servlet and POJO.

If you have many outputs for split, then you should use the split feature for Service Endpoint instead of BT.

- Monitor the user transactions using the BT feature and know when to use Service Endpoints- Every BT has an associated snapshot or a call graph collection based on the periodic or slow thresholds, which results in additional data collection (call graph, request details, remote services, and so on). In addition to basic KPI (calls per minute, ART, errors per minute, slow or very slow calls) metrics data collected, if the requirement for any specific API or URI transaction is to only retrieve basic KPI metrics (but not the request details), and call graph is part of BT snapshot collection, then it is recommended that you monitor URI or API using the [Service Endpoint feature](#). For example, when a user wants to know the response time of a particular API.
- Monitor nested transactions with Service Endpoint due to the limitations in BTs- BT includes a snapshot collection feature in which all sub-calls are tracked as part of a single entry point API or URI that is part of the user transactions. For example:

```
CheckoutServletClass => OrderTransaction_WS|SOAP_EndPointAPI => JDBC Exit calls
```

If you need to monitor both `CheckoutServletClass` and `OrderTransaction_WS` API as separate BTs, then the BTs for `OrderTransaction_WS` are treated as a masked or child transaction of entry point `CheckoutServletClass`. The Service Endpoint (SEP) feature is best suited because the SEP does not have nested transaction limitations as in BT. You can monitor all sub-calls as separate endpoints to retrieve basic KPI metrics as in BT.

- Use SEP drill down and BT snapshots - Though SEP does not specifically collect snapshots, you can see snapshots collected as part of the BT when the SEP dashboard for either the API or URI is part of the target snapshot. This provides users the benefit of snapshot level tracking of SEP if monitored SEP is part of the monitored BT sub calls.
- Before you toggle entry points with auto-discovery disabled:
  - You must configure some settings for transaction detection rules for certain entry types (EJB or Spring), in which you must disable auto-discovery
  - If the user application is EJB or Spring based, then it is recommended that you define custom EJB or Spring-based rules instead of enabling the auto-discovery option in the "java auto-discovery rule" UI under the Transaction Detection tab.
- Analyze which API or URI to monitor with the knowledge of the app code flow - You can use Service Endpoint auto-discovery for all entry points instead of the option for BT detection auto-discovery. This helps you capture which APIs are used by your application when the transactions occur. You determine which transactions to monitor as BT and which endpoints to monitor as SEP.

## View Business Transactions

To view business transactions for a business application:

1. Click **Business Transactions** in the application navigation tree. The business transaction list shows key metrics for business transactions for the selected time range.

The screenshot shows the AppDynamics interface with the 'Business Transactions' view selected. The table displays the following data:

Name	Detection Rule Present	Health	Response Time (ms)	Calls / min	Errors / min	% Errors ↑	% Slow Transactions	% Very Slow Transactions	% Stalled Transactions	Tier
FulfillmentConsu...	false	✓	-	-	-	0	0	0	0	Order-Proc...
/appdynamicpil...	false	✓	1,411	5	-	0	0	7	0	Web-Tier-S...
/cart/orderService	false	✓	-	-	-	0	0	0	0	Inventory-S...
/appdynamicpil...	false	✓	6,606	4	-	0	2	9	0	Web-Tier-S...
/appdynamicpil...	false	✓	47	7	-	0	0	0	0	Web-Tier-S...
/appdynamicpil...	false	✓	44	7	-	0	0	0	0	Web-Tier-S...
/appdynamicpil...	false	✓	1,101	6	-	0	5	1	0	Web-Tier-S...
/appdynamicpil...	false	✓	610	26	-	0	2	2	0	Web-Tier-S...
/appdynamicpil...	false	✓	44	6	-	0	0	0	0	Web-Tier-S...
/appdynamicpil...	false	✓	86	6	-	0	0	0	0	Web-Tier-S...
All Other Traffic - ...	false	✓	-	-	-	0	0	0	0	Order-Proc...
All Other Traffic - ...	false	✓	-	-	-	0	0	0	0	ECommerc...
MessageConsum...	false	✓	-	-	-	0	0	0	0	Order-Proc...
All Other Traffic - ...	false	✓	-	-	-	0	0	0	0	Web-Tier-S...

2. To modify the default view, you can :
  - a. choose to display transactions that belong to business transaction groups.
  - b. select transactions that exceed a configurable average response time.
3. Click **View Options** to choose which performance metrics you want to display for business transactions in the list.
4. By default, only business transactions that have performance data in the selected time range appear in the list. You can show inactive business transactions for the time range by modifying the filter view options.
5. To view which actions you can perform on business transactions, click **Actions**. Actions include:
  - View health rule violations
  - [Start a diagnostic session](#) for the transactions
  - Configure thresholds
  - Rename business transactions
  - [View Detection Rule](#)
  - Delete Transaction
  - Exclude Transaction
  - View Excluded Transaction
  - [Set as background task](#)
  - Mark as Permanent
  - Create a business transactions group
  - Delete business transactions group

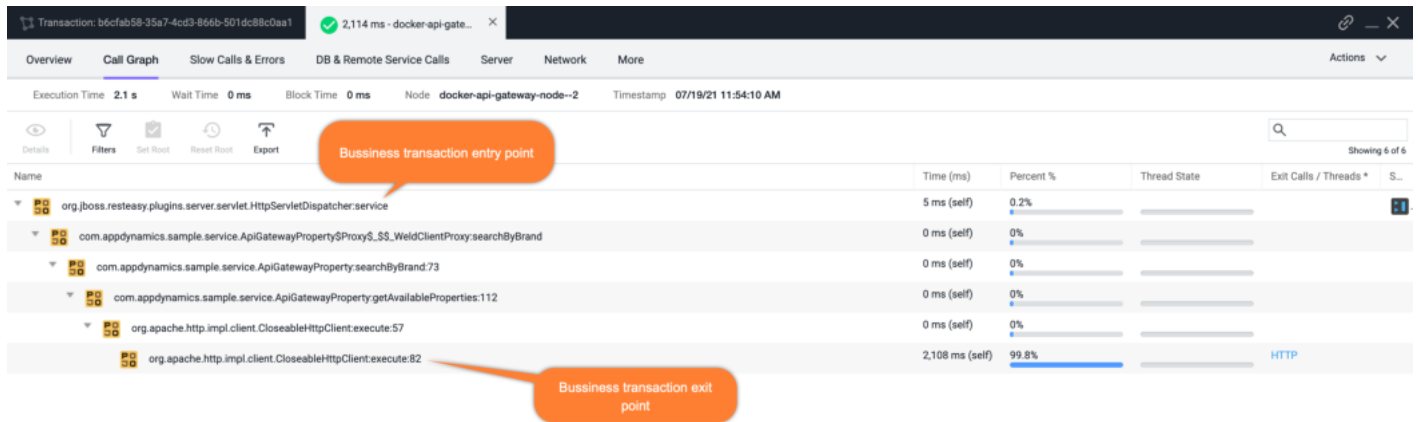

## View and Understand Transaction Entry and Exit Points

When you install an app agent, the agent detects incoming calls and registers transactions based on the default transaction detection rules. Automatic detection rules describe entry points for transactions based on supported frameworks.

Typically, more than one tier participates in the processing of a transaction. A request to the originating tier may invoke services on:

- Another instrumented tier is called a downstream tier.
- Remote services that are not instrumented.

Outbound requests from an instrumented application tier are called exit points. Downstream tiers may, in turn, have exit points that invoke other services or backend requests.

App agents tag exit point calls with metadata describing the existing transaction. When an agent on a downstream tier detects an entry point that includes transaction metadata from another AppDynamics app agent, it treats the entry point as a continuation of the transaction initiated on the upstream tier. This linking of upstream exit points to downstream entry points is called correlation. Correlation maintains the client request context as it is processed by various tiers in your business application.

## View Detection Rule

By default, this feature is disabled in the Controller UI. To enable this feature:

1. Ensure that you are using Java Agent 23.7.0 or later and Controller 23.9.0 or later.
2. Set the `rule.bt.mapping.enabled` flag to `true`. See [Controller Settings for Detection Rule](#).

To view the detection rule enabled for business transactions:

1. Click **Business Transactions** in the application navigation tree.
2. Select transactions for which you want to see the detection rules.
3. Click **Actions > View Detection Rule**. Alternatively, you can right-click on the transaction for which you want to see the detection rule.

It opens the **Rule Editor** window.

**i** If the **View Detection Rule** option is greyed out, either the `rule.bt.mapping.enabled` flag is not enabled or the business transaction is not mapped to the corresponding rule.

---

## Controller Setting for Detection Rule

1. Log in to the Controller administration console using the root user password.  
See [2023-10-19\\_05-04-05\\_Access the Administration Console](#).

```
http://<controller host>:<port>/controller/admin.jsp
```

Use the root user password to access the Admin console when the Controller is installed in single- or multi-tenant mode. See [Update the Root User and Glassfish Admin Passwords](#).

2. Click **Controller Settings > Accounts**.
3. Double-click the account for which you want to enable the detection rule mapping.
4. In the **Account Properties** section, click **+ Add Property**.
5. In the left dialog, enter `rule.bt.mapping.enabled`.
6. In the right dialog, enter `true`. The changes take place after the Agent restarts.

## Configure Business Transactions

Business Transactions (BT) are critical to APM configuration. Before you configure APM, you need to answer these questions:

1. What are my business goals for monitoring?
2. What pain points am I trying to solve with AppDynamics?
3. What are the typical problems that consume my time and resources?
4. What are the most critical business operations that need to perform optimally?

You can use the [Custom Match Rules](#) to configure the BTs.

### Refine the Business Transactions

A business transaction is a set of requests. An important part of implementing AppDynamics is verifying and refining the business transactions used to monitor your application. The business transaction you monitor should reflect those operations that are important to your application and business. You must consider the [limits on business transactions](#), and apply your refinements accordingly.

Refining your business transaction list requires a solid understanding of the important business processes in your environment. You should identify 5 to 20 key operations in the application that must work well for the application to be successful.

Important services can be indicated by the number of calls or calls per minute received by the business transactions generated for the services. You can refine the list of transactions you want to monitor by locking down critical transactions and enabling automatic cleanup of stale transactions. For the Java and .NET environments, you can use interactive [Live Preview](#) tools to help identify important transactions.

To customize the business transaction list, you can use either of these approaches:

- You can modify existing business transactions by grouping, renaming, or removing the business transactions. Most of these operations are available from the business transaction list. Use this approach to apply relatively minor, small scale changes to the current business transaction list. For more information, see [Organize Business Transactions](#).
- You can affect how business transactions are created by modifying the automatic discovery rules. You can modify rules to similarly achieve business transaction grouping and naming, and to exclude transactions. Discovery rules also enable you to define new entry points for business transactions. Discovery rule modification is a powerful mechanism for changing transaction discovery on a larger scale. See [Transaction Detection Rules](#).

## Business Transaction Limits

When reviewing and refining your business transaction limits, you must consider the business transaction limits for the Controller and app server agents. Business transaction limits prevent boundless growth of the business transaction list.

The default limits are:

- Business Application Limits: Each application is limited to 200 registered business transactions.
- App Server Agent Limits: Each agent is limited to 50 registered business transactions.

There is no limit at the tier level.

**i** The App Server Agent limit applies to each app agent, not to the machine. If you have multiple app agents on a single machine, then the business transactions originating from that machine could be up to the number of agents multiplied by 50.

## All Other Traffic Business Transactions

### View All Other Traffic

**All Other Traffic** displays next to other business transactions in the **Business Transactions** list. You can view the dashboard and key performance metrics for **All Other Traffic** in the [Metric Browser](#).

### Controller Limits

As an organizational unit in the AppDynamics model, business transactions are meant to be used for the most important transactions in your environment. The Controller limits the number of business transactions (50 for a node and 200 for a business application). This limit controls resource utilization on the Controller, and also helps you focus on the most important services performed by your application environment.

### Virtual Business Transaction Group

Once the business transaction registration limit is reached or transaction lockdown is enabled, newly detected transactions are not registered as business transactions, but they are monitored and reported by AppDynamics. The transactions are grouped into a virtual business transaction named `All Other Traffic - tier_name`. An *All Other Traffic* group exists for each tier on which the limit is reached.

**i** The All Other Traffic group does not have transaction snapshot for the PHP and the Python Agents.

## Purged Business Transactions

To reduce the number of business transactions and only show relevant ones, AppDynamics periodically runs a purger to move registered business transactions that have not received metrics to **All Other Traffic** as virtual business transactions named `All Other Traffic - tier_name`.

## Promote Business Transactions

When refining business transactions, you may want to move certain transactions from the **All Other Traffic** bucket to make them first-class business transactions. You can keep within the limits by deleting or excluding other business transactions, such as those that have little or no load, by using a custom exclude rule. If the number of business transactions is below the limit and lockdown is enabled, you can promote a transaction from the list of All Other Traffic by registering it from the **Traffic Details** panel.

### View Details for All Other Traffic

To view incoming calls categorized in the **All Other Traffic** transaction:

1. Open the dashboard for the **All Other Traffic** business transaction.
2. Click **View Traffic Details**.

The screenshot shows the AppDynamics dashboard for the 'All Other Traffic - mytier02' transaction. A modal window is open, displaying a table of business transactions. The table has three columns: Business Transaction Name, Count, and Type. The data shown is as follows:

Business Transaction Name	Count	Type
/jboss-helloworld/HelloWorld	1	Servlet
/jboss-kitchensink/rest	1	Servlet

An orange callout bubble points to the modal with the text: "View calls in the 'All Other Traffic' business transaction".

**i** The data available in the traffic details of the **All Other Traffic** transaction is in form of events. This data does not represent metrics and this is why the total count may not match the calls/min count available under the **Load** panel of the dashboard.

The **Traffic Details** panel lists the transaction entry points that are affected by incoming requests after the registration limits are exceeded or after business transaction detection is locked down. The **Business Transaction Name** column contains auto-generated names for the transactions. The **Call** column shows the number of instances of the transaction and the **Type** column shows the entry point type.

If the *Fetch more* link appears, click to view more calls. You can retrieve up to 600 calls each time you click the link. If the *Fetch more* link does not appear, there are no more calls to retrieve for the selected time range.

 Use APPDYNAMICS\_DEFAULT\_TX REST API to fetch All Other Traffic details. For an example, see [Use the AppDynamics REST API](#).

## Add Business Transactions Manually

You can add business transactions manually from a virtual business transaction called *All Other Traffic*, which is populated with transactions once the business transaction registration limits are reached.

## Lock Down Business Transactions

After you determine a set of business transactions to monitor, you may want to *lock down* business transactions. Locking down business transactions prevents application changes, upgrades to the agent software, or other changes from affecting the number or selection of business transactions you monitor as the primary, first-class business transactions in the AppDynamics model of your environment.

A production implementation of AppDynamics involves an initial period of assessing, organizing, and refining business transactions by customizing your default business transaction discovery rules.

With business transaction lockdown enabled, the Controller moves newly discovered transactions into the *All Other Traffic* transaction collection for the tier. You can promote a business transaction from the *All Other Transactions* list by registering it as a first-class business transaction manually.

Business transaction lockdown provides a way to register business transactions individually, by manual selection. In certain scenarios, you may want to enable business transaction lockdown before discovery occurs and register transactions manually. For example, this may be useful if your environment would otherwise generate a large number of business transactions and you only want to monitor a relative few as first class business transactions.

To enable business transaction lockdown:

1. From the left pane, click **Configuration > Instrumentation > Transaction Detection > More**.
2. Under Business Transaction Automatic Cleanup, select **Enable Business Transaction Lock down**.

After locking down business transactions, you can promote a transaction manually by accessing the **Traffic Details** dialog from the **All Other Transactions** dashboard. In the dialog, select the transaction and click **Register** to promote the transaction. If the agent has reached the business transaction registration limit, you will need to delete a registered business transaction before registering one from the *All Other Traffic* list.

**i** If you enable automatic cleanup, business transactions that you lock down but that do not meet the activity threshold are still deleted. To override automatic cleanup for a business transaction, right-click the transaction and select **Mark As Permanent**.

## Optimize Business Transaction Detection

If your system has hundreds of business transactions, you can leverage the rule system to fine-tune which transactions you want to detect and monitor. Creating rules provides you specific transaction visibility. For example, you can create rules to:

- Detect transactions that are not automatically detected.
- Prioritize monitoring some transactions over others.
- Remain under the transaction limit. When you combine multiple transactions in a rule, the individual transactions no longer count towards the transaction limit; the rule is counted as a single transaction.
- Exclude transactions from monitoring.

For example, Val is creating transaction detection rules for an ECommerce application. Val discovers that the most critical transaction, `user-checkout`, is grouped into *All Other Traffic*, which obscures its visibility. To ensure that AppDynamics collects detailed metrics for `user-checkout`, Val creates a rule that detects `user-checkout`, and sets the rule priority to a high value, 50. For less critical transactions, Val creates a rule that detects multiple transactions: `createaccount`, `billing`, and `delivery-options`. Val sets the rule priority to a lower value, 15. Combining multiple transactions into one rule helps Val stay within the transaction limit. See [Transaction Detection Rules](#).

## Organize Business Transactions

Organize and manage registered business transactions on the business transaction list to ensure that you are monitoring the most critical transactions. You can rename transactions, delete transactions, exclude transactions, or create custom transaction detection rules.

Especially for busy applications with lots of transactions, identify the best strategy for maximizing visibility into business-critical operations. Consider these strategies:

- Set transaction detection priorities and delete old transactions to ensure that AppDynamics instruments your most important transactions.
- Combine multiple transactions into rules and exclude unimportant transactions to ensure that you stay within the business transaction limits.
- Rename transactions to informative names and group together similar transactions so that your metrics are easier to read.

## Rename Business Transactions

The default BT name is based on the first two segments of a URI. See [Business Transactions](#).

You can change the name for the business transaction by selecting the business transaction and choosing Rename from the More Actions menu. This change only affects the label for the business transaction in the user interface. You can also modify the default naming scheme for subsequently discovered business transactions, as described in the discussion on naming in [Transaction Detection Rules](#).

**i** By default, AppDynamics uniquely names business transactions according to the tier name and entry point type, along with an internal name. When you rename a business transaction, ensure its new name is unique;

otherwise, there will be multiple business transactions reporting metrics under the same name.

### Group Business Transactions

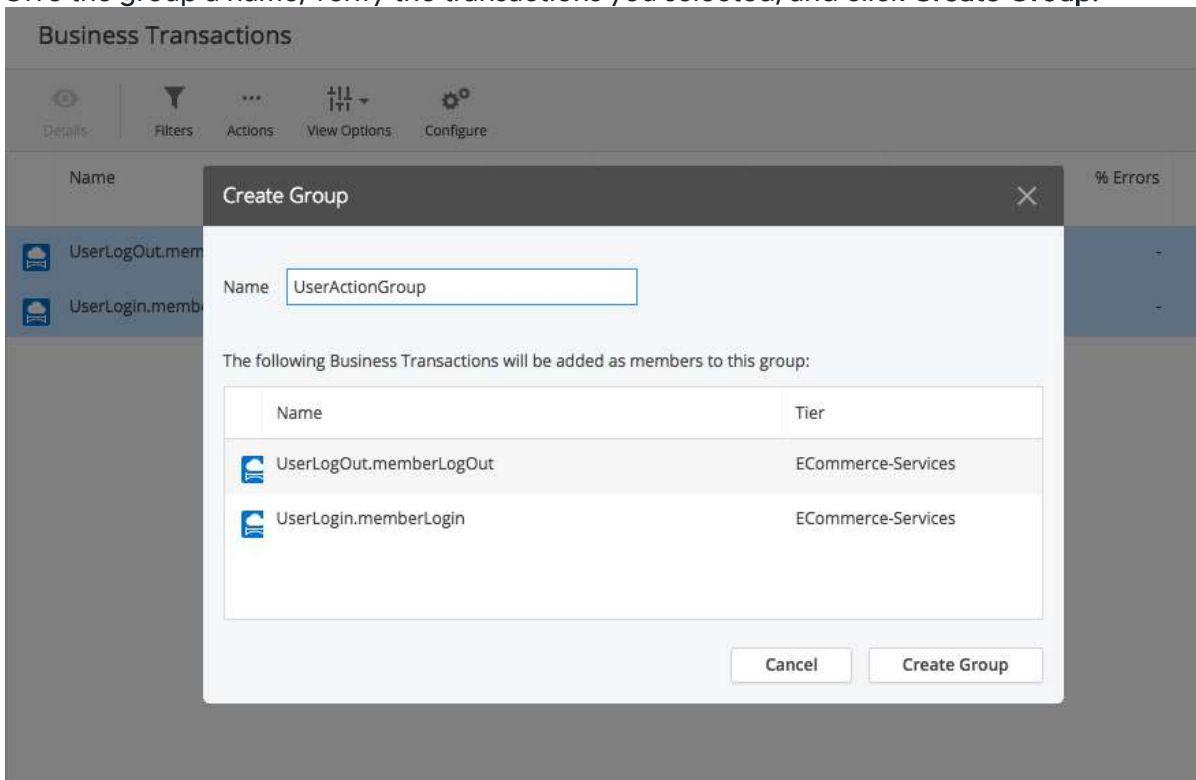

A transaction group lets you collect multiple related transactions into a single organizational unit in the AppDynamics model of your environment. For example, you may wish to group business transactions all of which have entry points in a specific WAR file. Groups could also be used to collect transactions of a specific organization, region, or category.

After grouping transactions, you can see aggregate metrics for the group. Metrics for individual transactions that make up the group remain available.

Grouping transactions does not affect the overall count of registered business transactions. To manage your transaction count, see [Custom Match Rules](#).

To create a business transaction group:

1. Select the transactions you want to group from the Business Transactions list. Use the control or shift keys to multi-select business transactions.
2. Right-click the selected transactions and choose **Create Group**.
3. Give the group a name, verify the transactions you selected, and click **Create Group**.

### Delete or Exclude Business Transactions

Excluding and deleting business transactions reduce the business transaction registration count. You can choose to exclude a short-lived business transaction temporarily or delete a stale business transaction permanently.

---

## Exclude a Business Transaction

In effect, excluding the transaction disables the business transaction for metric processing purposes; it works even if the processing path that the business transaction represents remains active in the monitored application. Both serve to reduce the business transaction count considered against transaction registration limits.

**i** Excluding a business transaction in the business transaction list is not to be confused with using custom exclude rules to control business transaction detection. While the two approaches achieve similar goals, custom exclude rules operate at the transactions detection point and are most useful for preventing discovery and registration of a range or multiple ranges of business transactions at a time. See [Custom Match Rules](#) for more information.

To exclude a business transaction:

1. Select your transaction from the list of business transactions.
2. Right-click the selection and click **Exclude Transactions**.
3. On the Exclude Business Transactions page, select the transaction and click **Exclude Transactions**.

## Restore an Excluded Business Transaction

When you exclude a business transaction, the accumulated metrics for the transaction along with its underlying configuration is retained. You can restore the excluded transaction, if required.

1. From the Business Transactions page, click **Actions > View Excluded Transactions**.
2. From the Excluded Business Transactions page, select your transaction, and click **Unexclude Selected**.

## Delete a Business Transaction

When you delete a business transaction from the list, the accumulated transaction metrics are removed. However, the deleted transaction is rediscovered if the corresponding function in the application is used. To delete a business transaction permanently, modify the discovery rules before deleting a transaction, so that the deleted transaction is not rediscovered.

A business transaction can be considered stale in these scenarios:

- You have decommissioned an application, and you want to delete the historical data associated with business transactions that made up the application.
- You have changed business transaction discovery rules to either eliminate or reorganize business transactions and need to remove unwanted or otherwise obsolete business transactions.

To delete a business transaction:

1. Select your transaction from the list of business transactions.
2. Right-click the selection and click **Delete Transactions**.
3. From the Delete Business Transactions page, select the transaction and click **Delete Business Transactions**.

## Automatic Cleanup of Stale Business Transactions

Automatic cleanup keeps less active transactions from cluttering your business transaction list. Enabling automatic cleanup deletes business transactions that are flagged as stale. You can set the activity threshold for a business transaction after which the transaction is considered stale.

To configure automatic cleanup threshold:

1. From the left pane, click **Configuration > Instrumentation > Transaction Detection > More**.
2. Under Business Transaction Automatic Cleanup, check **Enable Business Transaction Automatic Cleanup**.
3. Update the automatic cleanup threshold that qualifies a business transaction as stale:
  - a. Specify your threshold time in, **Monitor Business transactions for \_\_ minutes since creation**.
  - b. Specify the number of calls in, **Remove Business transactions that have less than or equal to \_\_ calls**.

Since creation, a business transaction is monitored for 15 minutes when automatic cleanup is enabled with default settings. If there are no calls reported within the first 15 minutes since the business transaction is registered, the business transaction is qualified as short-lived and the automatic cleanup deletes that business transaction. Automatic cleanup keeps a business transaction intact if it is reporting data for days.

However, automatic cleanup ignores the business transactions that are:

- Marked as *Permanent*
- Older than three days

### Business Transaction Purger

There are Controller configurations for the business transaction purger:

- `max.bt.to.purge.per.execution`: the number of business transactions that can be purged when the purger executes once. The default is 1000, min is 0, and the max is 100000.
- `max.bt.to.purge.per.transaction`: in order to reduce db lock, the purger tries to purge business transactions in multiple transactions if there are too many business transactions to purge in each execution. This configuration specifies the number of business transactions that can be purged in each transaction. The default is 10, min is 0, and the max is 1000.

## Create Business Transaction Health Rules

You can create health rules to monitor the parameters that represent the normal or expected operations for your business transactions (BT). The parameters rely on metric values, for example, the average response time.

When the performance of a business transaction violates the conditions set by a health rule, a health rule is violated. Alerts notify you of any violation and initiate remediation actions to mitigate the violation event.

It is important that you configure alerts appropriately to ensure that you do not miss any alerts or receive false alerts. You can use Alert Sensitivity Tuning (AST) to configure alerts with appropriate sensitivity. AST provides historical data for the metric or the baseline being configured and helps you visualize the impact of the alerting configuration. See [Alert Sensitivity Tuning Questions and Answers](#).

### Create a BT Health Rule and Fine-Tune Metric Evaluation

You can create a health rule to monitor BT parameters and fine-tune the sensitivity of a BT health rule using AST. See [Create a Health Rule and Fine-tune Metric Evaluation](#) for instructions.

## Monitor the Performance of Business Transactions

After verifying and refining your business transaction scheme, you can focus on monitoring the business transaction performance. The monitoring and troubleshooting tools within the AppDynamics Controller UI provide a business transaction-oriented view of performance. For example, transaction snapshots tie

together all the code call graphs across the monitored tiers that participate in processing a particular instance of a business transaction.

The business transaction list contains a high-level view of business application performance by a transaction. You can click a particular business transaction to access additional information on the business transaction, such as information on slow performing instances of this transaction, errors, and the transaction analysis view.

You can monitor the performance of business transactions with AppDynamics using:

- [Automated Transaction Diagnostics](#)
- [Transaction Thresholds](#)
- [Dynamic Baselines](#)

### View Transaction Scorecard to Monitor the Performance

The transaction scorecard summarizes the performance of a business transaction at the application, tier, or node level within a specified time range. It covers the number and percentage of business transaction instances (calls) that are normal, slow, very slow, stalled or errors based on the configured thresholds for these criteria.

#### Transaction Scorecard

Normal		95.2 %	3.9k
Slow		0.1 %	6
Very Slow		1.7 %	70
Stall		0.0 %	1
Errors		2.9 %	120

The call counts in the scorecards in different dashboards indicate a different meaning:

- In the application dashboard, the business transaction health scorecard aggregates the metrics for all the completed business transactions in the application, including the default business transactions. The number of calls is based on the number of business transactions that are completed. The percentages for those calls are based on the average for all the completed business transactions in the application. For example, if the scorecard displays 3% for very slow transactions, on average 3% of the calls for completed business transactions in the application were slow.
- In a tier dashboard, the transaction scorecard aggregates the metrics for all the nodes in the tier. The number of calls is based on the number of requests that the tier handled, including continuing transactions, threads spawned, and so on.
- A node dashboard is similar to the tier dashboard in that it is based on the number of requests the node handled. The transaction scorecard displays the metrics for the single node.
- In a business transaction dashboard, the transaction scorecard displays the metrics for the entry point of a business transaction.

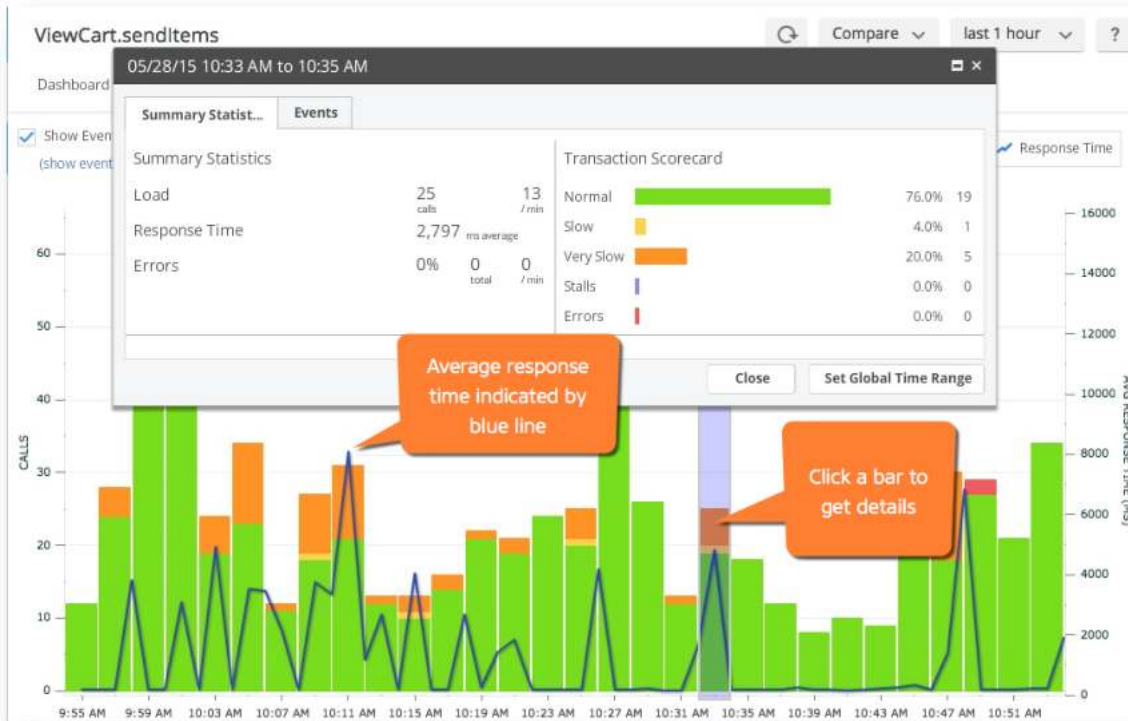

### Transaction Score View

For a more detailed view of the performance of a transaction over time, navigate to the business transaction dashboard and click the Transaction Score tab.

The graph in the tab displays the user experience for the selected business transaction, showing its performance relative to the performance thresholds as a bar chart. For each time slot, the bar reflects the

total calls, while the color segments green, yellow, and so on indicate the relative number of those calls that are normal, slow, very slow, stall, or errors.

The solid blue line in the graph indicates the average response time for the transaction over time, while the dotted line shows the baseline, if available.

## Automated Transaction Diagnostics

### Deployment Support

**i** This capability is available in SaaS >= 20.10.1.

AppDynamics continuously collects [Transaction Snapshots](#) that capture all events in a transaction path for use in performance troubleshooting and root cause analysis. Although [rules and limits](#) exist to prevent excessive resource consumption, you may have hundreds of individual snapshots to sort through as you investigate a particular performance issue.

The Automated Transaction Diagnostics (ATD) capability allows you to be proactive rather than reactive for anomalous transaction behavior. ATD uses machine learning to capitalize on the collected snapshots by automatically recognizing anomalies not yet severe enough to trigger alerts but significant enough to cause future production issues. In seconds you have a prioritized list of causal factor transactions that you can use to manage problematic business transactions before they become visible production slowdowns or outages for your customers.

ATD's guided root-cause analysis clearly exposes the anomalies with the contributing tiers, exit calls, or inter-tier network issues. This allows a broader range of less specialized users to more accurately analyze the behavior and significantly reduce repair time.

## Understand the Diagnostic Process

AppDynamics uses a systematic approach to identify problematic transactions, determine the probable root cause, and provide a list of snapshots used in the diagnosis. The diagnostic process:

- Analyzes business transaction response time data to determine if there was an issue and how long it lasted.
- Analyzes metrics data across the business transaction path to identify the suspected cause and type of issue.
- Uses snapshot data to provide detailed root cause analysis that diagnoses the business transaction anomaly.

## Automated Transaction Diagnostics Workflow

The **Transaction Diagnostics** panel becomes visible after you select a business transaction.

The diagnostic process detects performance issues, automatically identifies the contributing transactions, and provides a report that simplifies root cause analysis allowing you to fix problems before they become production issues.

1. From the Home or Applications tab, choose the application you want to analyze.
  2. Select **Business Transactions**.
  3. Double-click a transaction to investigate.
  4. From the Dashboard tab, review **Transaction Diagnostics** in the right panel.
    - a. The server may take a few seconds to display issues. If the server finds no issues, a message displays that none were identified in that time range. Try selecting a longer time range of up to eight days.
    - b. The performance issues listed may not directly correspond to the business transaction flow map being shown if the health rule was violated in the past.
1. Select a highlighted anomaly to open the **Transaction Diagnostics** details page.
- The interactive graph consists of two charts. The upper graph displays transaction response times that correspond to the time range you choose in the lower navigation bar. The yellow plot bands highlight periods of abnormally slow response times.
1. Use the slider in the lower navigation chart to select a time range from five minutes to eight days.
  2. Click any plot band in the navigation bar to view details for that time range. The chart automatically adapts to display the incidents for your time range choices and includes a baseline for the transaction.
  3. Review the **Details of Performance Issue** section to view the **Suspected cause**. To manually review snapshots from the anomalous period, review the lower **Snapshots of Impacted Transactions** list.
  4. Double-click a snapshot in the list to view the transaction details.

---

## Transaction Thresholds

A threshold is a boundary of acceptable or normal business transaction performance. AppDynamics provides default thresholds against which it compares the performance of every business transaction. Each transaction is classified into a user experience: normal, slow, very slow, stall, or error transaction.

The user experience reflects the performance of a transaction instance relative to the usual performance of the business transaction. This page provides information about refining the criteria by which the classification is applied, based on your requirements.

### Transaction Threshold Values

As soon as a transaction starts, the particular thread representing that transaction is monitored for a stall. Every five seconds, the in-flight transactions are evaluated to determine if they have met or exceeded the stall threshold:

- If a transaction execution finishes before the stall threshold value, the execution time is first compared against the very slow threshold, then the slow threshold, and so on, and marked accordingly.
- If a transaction reaches the stall threshold (greater than 300 deviations above the average for the last two hours) or the set stall threshold, a stall transaction event is generated. Whether the transaction eventually finishes successfully or times out, it is considered a stall for performance monitoring purposes.
- If the standard deviation is large (> 50% of average), the moving average is used to calculate the threshold

Transaction errors are not determined by thresholds. Instead, transactions are marked as errors when the HTTP response status code is in the 400–505 range or when any exception occurs that is not excluded in the custom error configuration.

### Static and Dynamic Thresholds

Thresholds can be based on a static value or dynamic value. By default, a dynamic threshold is based on performance for the previous two hour time period. You can specify a dynamic threshold using either a percentage deviation or a standard deviation measure.

To understand how a transaction is compared to this moving window, consider a two-hour moving average window from 11:00 AM to 1:00 PM. All transactions that arrive in between 1:00 PM and 1:01 PM are measured against the response time and standard deviation of this window. For the next minute, between 1:01 and 1:02 PM, the window moves from 11:01 AM to 1:01 PM. The moving average itself is calculated based on the [exponential moving average formula](#).

- Data for minutes where there is no load is not counted.
- Data is maintained locally on each node for the starting tier for a business transaction. The Controller does not retain any of this data.

### Percentage Deviation Threshold

Percentage deviation defines a threshold based on the moving average of the requests over a certain interval. The default time interval is 2 hours. If the average response time for the last two hours is X milliseconds, and if the request takes the percentage deviation over X ms, then the transaction violates the threshold.

For example, a transaction occurs at 10:00:01 AM. The average of the requests between 8:00:00 and 10:00:00 is 100 ms and the slow threshold is defined as 20% over the threshold. If the transaction takes 120 ms, it is considered a slow transaction.

## Standard Deviation Threshold

Standard deviation defines a threshold based on the moving average over a certain interval. The default time interval is two hours. This means if the average response time for the last two hours is  $X$  milliseconds, and if the request takes the standard deviation over  $X$  ms, the transaction violates the threshold.

To understand how a standard deviation threshold works, consider an example with a moving average that is 1500 ms with a standard deviation of 100 ms. If you set the threshold to 3, it means that the threshold is three times the standard deviation. A transaction that takes more than  $1500 + (3 \times 100)$  or 1800 ms violates the threshold.

Alternatively, you can set the threshold to a static value or use a percentage of the average.

You can also disable stall detection. If you disable stall detection, a transaction that might qualify as a stall is reported as very slow if it completes. If it does not complete, nothing is reported for the incomplete transaction.

## Configure Thresholds

You can configure thresholds in **Configuration > Slow Transaction Thresholds**. You need permissions to [Configure Business Transaction application permissions](#).

Thresholds apply to various levels, by application or business transaction, including background task transactions. You can also configure thresholds for diagnostic sessions.

You can specify thresholds for User Transactions—using the regular business transactions tab—or background transactions tab, depending on the type of entity for which you want to configure thresholds.

Thresholds for Browser Real User Monitoring (RUM) are configured separately. See [Configure Browser RUM Performance Thresholds](#).

You can configure thresholds for slow, very slow, and stalled transactions. When a transaction exceeds a threshold, AppDynamics starts capturing snapshots of it.

Because snapshots are not captured while performance is within the normal range, the snapshots may not contain the full call graph for the transaction.

## Dynamic Baselines

This page describes how AppDynamics automatically calculates the baseline performance for your applications. After it establishes these prevailing performance characteristics, it can detect anomalous conditions for your application. AppDynamics uses baselines to:

- Color the Flow Map.
- Show transaction score dashboards.
- Compare metrics in metric graphs and the metric browser.
- Evaluate health in health rules (see [Health Rules](#)).

## How Baselines Work

AppDynamics calculates baselines by using the underlying hourly data. A baseline can be calculated for every metric. Baselines have two main variables:

- The time over which accumulated data should be considered in calculating the baseline.
- Seasonality of the baseline.

### Use Baselines to Identify Trends

Performance expectations can differ between hours of the day, days of the week, or even months of the year. For example:

- A retail application may experience heavier traffic on the weekend than the rest of the week.
- A payroll application may experience a higher load at the beginning and end of the month compared to the rest of the month.

To account for this variation, you can use a rolling time period as the baseline context. A rolling time period establishes the baseline against data from the current hour taken at a daily, weekly, or monthly interval over the course of the time period.

For example, you can have a baseline that uses a daily trend with a time period configured for 30 days or a weekly trend with a time period of 90 days.

A daily trend calculates the baseline from the data accumulated at the same time each day over the last 30 days.

A weekly trend calculates the baseline from the data accumulated on the same hour and day of the week over the last 90 days. This is one of the available default configurations.

A monthly trend calculates the baseline from data accumulated at the same hour and same day of the month. So, for example, on January 5th at 10:30 AM, the baseline is established based on data accumulated at the same hour on the 5th of each month for the prior 365 days:

Baselines are not available immediately upon startup. It takes time and application load for the AppDynamics SaaS to collect data and create its initial baselines. The amount of time depends on the baseline type being used: daily, weekly, monthly, or none. Using none requires several hours before a baseline is available, daily takes several days, weekly takes several weeks, and so on.

**i** By default, baselines are not computed for metrics if there are fewer than 20 calls per minute. To configure the calls per minute threshold, contact your AppDynamics account representative.

### How are Standard Deviations Calculated

This standard formula is used to calculate the standard deviation:

$$\text{standard deviation} = \sqrt{[(B - A^2/N)/N]}$$

where:

- A = sum of the data values
- B = sum of the squared data values
- N = number of data values

The standard deviation calculations differ based on the type of metric used:

- If the time rollup type = Sum or Average
- If the cluster rollup type = Individual or Collective  
The cluster rollup type is applicable only at the tier or app level (node-level metrics will have the same calculations).

This example shows a standard deviation using metric types of:

- Time rollup type = Average
- Cluster rollup type = Collective

Metric - Calls Per Minute (Average, Collective)

(Hourly Metric Table)

Time	Sum	Count	Weight-Value	Weight-Value-Squared
09:00	180	2	180	300
10:00	300	2	300	780
11:00	150	2	150	195

For these metric values, the baseline of `type = All Data` lasts three hours (at 12:00) using the above values for calculations.

With daily, weekly, or monthly seasonality, the data points considered are values for the same hour for all days, the same day of the week, or the same day of the year, respectively.

In this case, the baseline calculations will be:

$$\text{Value} = (180+300+150)/360 = 1.75$$

$$\text{Standard deviation} = \sqrt{((300+780+195) - (((180+300+150)^2)/360))/360} = 0.69$$

### Configure and View Baselines

A baseline deviation is the standard deviation from a baseline at a point in time, represented as an integer value. You can set health rule conditions based on baseline deviations. For example, you can configure a warning condition as two standard deviations from the baseline and a critical condition as four standard deviations from the baseline.

To configure baselines:

1. Navigate to **Configuration > Baselines**.
  - All available baselines display in the list.
  - The daily trend is the default baseline. This is the baseline used by health rules if another baseline is not specified during health rule creation.
2. Click **Set as Default** to choose another baseline in the baseline list as default.

Changing the default baseline changes the actual baseline for all existing health rules that rely on this default and do not specify another baseline. Be watchful of your existing baselines and health rule definitions before you select this option.

3. Select the trend type to use.
4. Set the trend time period and the trend. The base time period is available in these two ranges:
  - Fixed time range: from some specific date and time to a second specific date and time. For example, if you have a release cycle at a specific time you might limit your data collection to that specific time.
  - Rolling time range: in which the most recent X number of days is used. This is the more common choice.

### End-to-End Latency Performance

Works with:

The response time metric for a business transaction provides performance information about the transaction. However, in asynchronous applications, it may not indicate everything.

Consider a method that spawns other threads, possibly on other tiers, and then immediately returns control to the calling thread. The return of control stops the clock on the transaction in terms of measuring response time, however the logical processing for the transaction continues.

End-to-end latency metrics can reflect the response times for such asynchronous transactions.

## Before You Begin

To monitor end-to-end metrics in AppDynamics, you must first configure the endpoints for your asynchronous transactions. See [Asynchronous Transaction Demarcators](#).

## Monitor End-to-End Performance

After you enable end-to-end latency transaction monitoring, end-to-end metrics appear in the metric browser for individual nodes and the overall application. The business transaction flow map also shows the *End to End Latency Transaction Scorecard*:

The End to End Latency Transaction Scorecard shows health based on the end-to-end asynchronous transaction time. The scorecard criteria—normal, slow, very slow, and stall—for asynchronous transactions are the same as for the standard transaction scorecard. See [Transaction Thresholds](#).

**i** The Transaction Scorecard reflects the data for the originating business transaction only, not end-to-end transactions.

## End-to-End Performance Metrics

You can find the performance metrics for end-to-end message transactions, in the overall application metric tree in the metric browser:

- Average End to End Latency: Average time in milliseconds spent processing end to end message transactions over the selected time frame.
- Number of Slow End to End Messages: Number of end to end transactions that exceeded the slow threshold for the business transaction over the selected time frame. The slow user experience is based on the slow transactions thresholds applicable to the general business transaction. Separate thresholds do not apply to end-to-end latency.
- Number of Very Slow End to End Latency Times: Number of end to end transactions that exceeded the very slow threshold for the business transaction over the selected time frame. The very slow user experience is based on the very slow transactions thresholds applicable to the general business transaction. Separate thresholds do not apply to end to end latency.

If you enable **End to End Latency Time (ms)** view option for the **Business Transactions** list, the waterfall view shows the end-to-end transaction performance for asynchronous transactions.

---

## Monitor Background Tasks

### Related pages:

- [POCO Transaction as a Background Task - .NET](#)

A background task is a processing activity such as an administrative task or internal process that you want to monitor separately from primary business transactions, such as a cron job that backs up a server.

While the process may be important to your environment, it is likely that you do not want to monitor them similarly to primary business transactions. Background task performance metrics do not count toward the average response time of the tier or node.

During business transaction discovery, AppDynamics attempts to identify processes in the environment that are background tasks and classify them accordingly. You can modify the default configuration based on your requirements and manually change business transactions to background tasks.

### View Background Tasks

Although background tasks are monitored separately, they display with other business transactions in the **Business Transactions** list. Background tasks are identified in the list by the background task icon (  ).

This information displays for the background tasks:

- The Business Transactions list shows currently executing background tasks and their statistics.
- The [Metric Browser](#) shows the response time for each background task.
- Transaction snapshots are generated for each execution of a background task. However, if a particular job runs frequently, the snapshot may not capture all details for each execution.

The tier and application-level metrics do not reflect background task activity. In addition, background tasks are not reflected on the application dashboard.

### Reclassify a Business Transaction as a Background Task

To reclassify any of the existing business transactions as a background task:

1. Right-click the business transaction that you want to set as a background task in the business transaction list.
2. Select the **Set as Background Task** option.

Choosing **Set as User Transaction** changes a background task into a primary business transaction.

### Enable Automatic Discovery for Background Tasks

At transaction discovery, a transaction is categorized as a background task based on a setting in a custom match rule that matches the transaction.

AppDynamics includes preconfigured match rules for Java frameworks that are likely to be background tasks, including for JcronTab, JavaTimer, Cron4J and Quartz frameworks. The match rules are disabled by default.

You can enable the match rules, modify them, or create your own custom match rules to have matched transactions categorized as background transactions.

To enable background task detection configuration:

1. From the application or custom tier level configuration, edit an existing match rule or create a new one.

2. Enable the rule, and check the **Background Task** option to business transactions discovered by this rule categorized as background tasks.

### Configure Thresholds for Background Tasks

You can configure performance thresholds for background tasks separately from primary business transactions. From the **Configuration > Slow Transaction Thresholds** page, click the Background Tasks Thresholds tab to access settings specific for background tasks.

AppDynamics recommends that you configure a threshold that is suitable for the background task in your environment. Use static thresholds for slow and very slow background tasks, if they have infrequent load patterns such as once every night. This is because the dynamic moving average-based thresholds are more suitable for production load scenarios and will automatically classify a background process as slow or very slow.

### Monitor the Business Transaction Security

You can use the Cisco Secure Application dashboard to monitor the security of a business transaction. This helps in identifying the risks that are involved with the services included in a transaction.

The Business Transactions page includes the **Security Health** widget that provides a summary of the health status. When you can click the widget, it redirects you to the Cisco Secure Application dashboard. The dashboard displays the security details of that transaction. See [Application Security Monitoring](#).

### Troubleshoot Business Transaction Performance with Transaction Snapshots

This page describes how to view transaction snapshot data to monitor and troubleshoot business transaction performance. To learn about when AppDynamics takes transaction snapshots or how to configure transaction snapshot settings, see [Transaction Snapshot Collection](#).

AppDynamics monitors every execution of a business transaction in the instrumented environment, and the metrics reflect all such executions. For troubleshooting purposes, AppDynamics takes snapshots of specific instances of a transaction. A transaction snapshot gives you a cross-tier view of the processing flow for a single invocation of a transaction.

Call drill downs, where available, detail key information including slowest methods, errors, and remote service calls for the transaction execution on a tier. A drill down may include a partial or complete [call graph](#). Call graphs reflect the code-level view of the processing of the business transaction on a particular tier.

### View Transaction Snapshots

You can access business transaction snapshots from these locations in the AppDynamics Controller:

- **Troubleshooting > Slow Response Times** or **Troubleshooting > Errors** (left navigation tree for a business application)
- Transaction Snapshots tab on the Business Transaction Dashboard

Double-click a business transaction snapshot to display the snapshot viewer. This image and its accompanying table identify the metrics available in the transaction flow map:

Callout	Metric Name	Explanation
1	Tier Response Time (ms)	The total response time for the call as measured at the calling tier. This includes the processing time on the called tier as well as on any tiers and backends it calls in turn.
2	Percentage of Time Spent (%)	The time spent downstream processing at all downstream tiers and backends as measured by the calling tier and represented as a percentage of the entire execution lifespan of a business transaction. This metric does not include the processing time of asynchronous activities, if any.

Callout	Metric Name	Explanation
3	Asynchronous Activity Processing Time (ms)	<p>The processing time of all asynchronous activities at this tier. This metric does not contribute to the overall tier response time because the activity is asynchronous by nature. This metric is calculated by adding the execution times of all asynchronous activities at a tier and the time spent in communication between other tiers and backends as follows:</p> <p><i>Asynchronous Activity Processing Time = Asynchronous-activity-1-processing-time + Asynchronous-activity-2-processing-time + so on.</i></p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p> In the Metric Browser, you can view the Average Async Processing Time metric, which shows the average of the async activity processing time over the selected time range.</p> </div>
4	Execution Time (ms)	<p>Total time spent processing by the business transaction in all affected tiers and communication with other tiers and backends. This metric does not include the processing time of the asynchronous activities. However, in the case of Wait-for-Completion, the originating business transaction will take longer to process the request due to blocking and waiting for all the activities to complete before proceeding.</p> <p>The formula for this metric is calculated by summing up the processing times of a Business Transaction at a particular Tier/communication between Tiers/Backends as follows:</p> <p><i>Execution Time = Time-spent-processing-in-Tier-1 + Time-spent-processing-in-Tier-2 + Time-spent-communicating-with-Tier-2 + so on.</i></p>

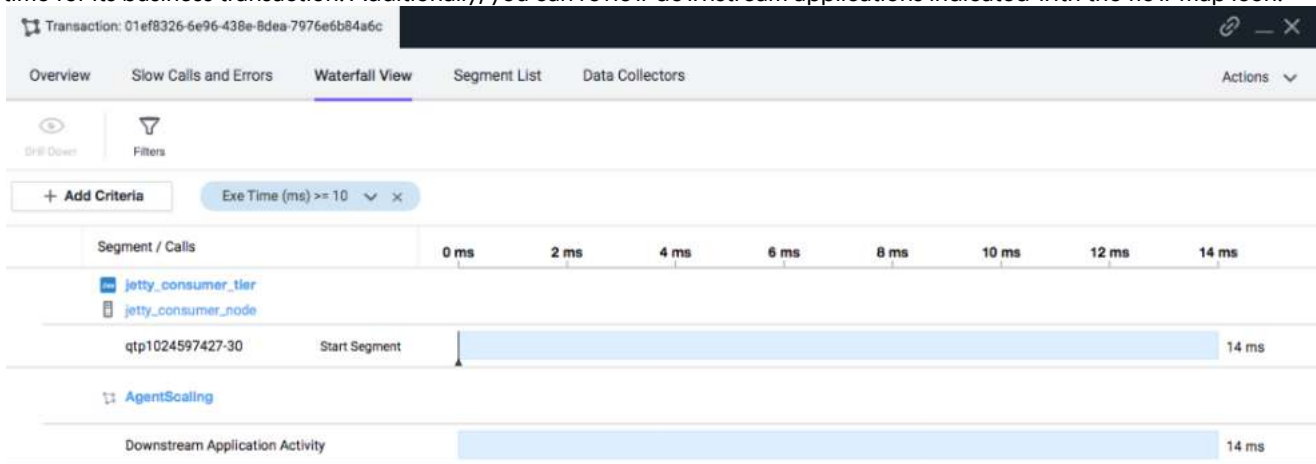

The **Potential Issues** panel highlights slow methods and slow remote service to help you investigate the root causes for performance issues. Click an item in the **Potential Issues** list to view the call in the call graph.

 To drill into a call graph for a correlated application in a transaction with [cross-application flow](#), you need *view* permissions to the destination business application.

If you use the Java Agent and monitor Oracle databases with Database Monitoring and you have configured [snapshot correlation between the Java Agent and the Database Agent](#), the flow map may also include database drill-downs.

The flow map or **Overview** is one of several views of the business transaction in the snapshot viewer. Other views include:

- **Slow Calls and Errors**, which presents information on the slowest database and remote service calls, slowest methods, and errors. You can gain further insight into these slow calls and errors either by viewing their details on by drilling down into their call graphs.
- **Waterfall View**, which shows the execution of an individual business transaction broken into execution segments. Each segment (shown as a blue bar) represents the time spent executing code on a particular thread within an instrumented application runtime, or the time spent waiting for responses from un-instrumented backends. Handoffs between segments are shown as solid lines for synchronous requests, and dotted for asynchronous requests. The waterfall view allows you to quickly determine which calls consumed the transaction time for a given snapshot. You can click a segment to view the resource wait time for its business transaction. Additionally, you can review downstream applications indicated with the flow map icon.

- **Segment List**, which shows the various legs of the transaction in descending order of duration and give access to their snapshots and allows you to drill down into their details.

## Call Drill Downs

A call drill down contains details for that business transaction execution on a particular tier. It provides the code-level information for the transaction.

The contents of a transaction snapshot containing asynchronous segments look slightly different if you access the snapshot through the **Business Transaction** view or through the **App/Tier/Node** views:

- Initially the **Business Transaction** view only displays the originating segments for the transaction. You have the option to drill down into the asynchronous segments as desired.
- The **App/Tier/Node** views surface all the segments that are relative to that specific entity. When you access one of these views, you can see all segments, originating and asynchronous.

## Node Drill Down

The node drill down organizes diagnostic data among these tabs:

- The Overview tab includes a problem summary, execution times, CPU time stamp, tier, node, process ID, thread name, etc.
- The Call Graphs tab lists call graphs showing the execution flow for the transaction on a given tier. For details, see [Call Graphs](#).
- The Slow Calls and Errors tab lists all the slow method calls and calls that resulted in an error. You can use the *Hot Spots* slider to sort calls by execution time with the most expensive calls in the snapshot at the top.
- The Error Details tab exposes exception stack traces and HTTP error codes.

- The DB & Remote Service Calls tab shows all SQL query exit calls to databases and exit calls to other remote services such as web services, message queues, or caching servers. See [Database queries and batching](#) for more information about how AppDynamics handles SQL exit calls.
- The Server tab displays graphs for hardware—CPU Memory, Disk IO, Network IO— Memory—Heap, Garbage Collection, Memory Pools—JMX, and more. If you have [Server Visibility](#), you will have access to full performance details for the server hardware and operating system
- The complete detail is unavailable when you continue with transaction snapshots on the transactions such as, Java POJO business transaction. For example, it may not display example URL, session ID, thread name, and so on.
- For customers using [Network Visibility](#), the Network tab shows charts related to the impact of the network on the transaction and other pertinent data. For information on network KPIs and troubleshooting see [KPI Metrics in Network Dashboard and Application Flow Map](#) and [KPI Metrics in Right-Click Dashboards](#).
- The Data Collectors tab shows pertinent application data for the transaction snapshot. For configuration options, see [Data Collectors](#).

**HTTP Data:** HTTP payloads contain basic data such as the URL and session ID, and additional data for Servlet entry points, Struts, JSF, Web Services, etc. You can use HTTP data collectors to specify which query parameter or cookie values should be captured in the transaction snapshot.

**Cookies:** The snapshot can use cookie values to help identify the user who initiated the slow or error transaction.

**User Data:** User data from any method executed during a transaction, including parameter values and return values, to add context to the transaction. You can use method invocation data collectors to specify the method and parameter index.

In cases where an exit call is made just before a business transaction starts, exit call information can show up in this field, particularly if the transaction is marked as slow or having errors. Please note that sensitive information on the exit call may be shown in this situation.

- The More tab shows how metrics for the node that deviate the most from the established baselines as Node Problems. It also shows all the Service Endpoints invoked during the snapshot and the Servlet URI and Process ID of the transaction.

## Database Queries and Batches

AppDynamics normalizes SQL queries and by default does not display raw/bind values. You can configure SQL capture settings to monitor raw SQL data in the queries. Individual calls that take less than 1 second are not reported.

When returning data to a JDBC client, database management systems often return the results as a batched response. Each batch contains a subset of the total result set, with typically 10 records in each batch. The JDBC client retrieves a batch and iterates through the results. If the query is not satisfied, the JDBC client gets the next batch, and so on.

In the **SQL query** panel, a number followed by an X in the **Query** column means that the query ran the number of times indicated within a batch. The value in the **Count** column indicates the number of times that the batch job executed.

## Database Drill down

Database drill downs provide this transaction information:

- **Queries:** lists the queries consuming the most time in the database as top SQL statements and Stored Procedures. Comparing the query weights to other metrics such as SQL wait times may point you to SQL that requires tuning.
- **Clients:** displays the hostname or IP addresses of the Top N clients using the database. A database client is any host that accesses the database instance.
- **Sessions:** displays the Session ID of the Top N sessions using the database sorted by time spent.
- **Schemas:** shows the names of the Top N busiest schemas on the database server.

## Use the Transaction Snapshot List

You can view transaction snapshots generated in the UI time range from the **Transaction Snapshots** tab of the application, tier, node, or business transaction dashboards. From there you can:

- **Compare Snapshots** shows the performance of calls in two snapshots as a side-by-side comparison.
- Identify the most expensive calls / SQL statements in a group of Snapshots shows the calls that take the most time across the snapshots you have selected. You can select up to 30 snapshots.
- Find snapshots using the filter options.

The Controller purges transaction snapshots after two weeks by default, but you can configure the snapshot retention period. You can archive a snapshot to preserve it beyond the normal snapshot lifespan; for example, to retain a snapshot associated with a particular problem for future analysis. To archive a snapshot, select it from the list and choose **Actions > Archive**.

To archive a snapshot, you need the **Application level - Can create applications** permission.

The file cabinet icon in the far right column indicates that the snapshot is an archive snapshot (  ). To display only archived snapshots in the snapshot list, filter the snapshot list and check **Only Archived**.

## Call Graphs

### Related pages:

- [Call Graph Settings](#)
- [Data Collectors](#)

A call graph in a transaction snapshot shows the business transaction processing information on a particular tier that participated in the business transaction. A call graph lists the methods in a call stack and provides information about each call.

A call graph provides general information about the total execution time, the node name, the time stamp for the start of execution, and the unique identifier for the business transaction instance. You can use call graphs to diagnose performance issues and optimize the flow of a complex business transaction.

Call graphs are also captured by the Node.js Agent in process snapshots, which describe an instance of a CPU process on an instrumented Node.js node. See [Event Loop Blocking in Node.js](#).

## Call Graph Types

A call graph can be one of these types:

- Full call graphs capture the entire call sequence for the business transaction invocation and are shown as blue bars. Call graphs exist for each monitored node involved in the processing of the business transaction. Periodically collected and diagnostic snapshots are always full call graphs.
- Partial call graphs represent the subset of the call sequence for processing a business transaction, typically from the point at which the transaction has been determined to be slow or have errors. Partial call graphs are identified in the transaction snapshot and are shown as gray bars.

## View Call Graphs

To view a call graph:

1. Open the dashboard for the business transaction for which you want to see a call graph and click the Transaction Snapshots tab.

2. In the transaction snapshot list, double-click a snapshot.
3. Click the Drill Down link for the tier on which you want to see a call graph. An asterisk next to the link means that multiple calls are made at this tier for the transaction, which a dialog offers as choices to drill down into.

In the panel, the method execution sequence shows the names of the classes and methods that participated in processing the business transaction on this node, in the order in which the flow of control proceeded.

For each method, you can see the time spent processing and the line number in the source code, enabling you to pinpoint the location in the code that could be affecting the performance of the transaction.

The call graph panel includes UI controls for navigating large call graphs. For example, you can use the filter field to display only a particular method or types of methods. When you find a method of interest, you can set it as the root method in the tree to view only the portion of the call graph that occurs from that point forward.

The screenshot shows the 'Partial Call Graph' interface for a transaction. The top navigation bar includes 'Overview', 'Partial Call Graph', 'Slow Calls & Errors', 'DB & Remote Service Calls', 'Server', 'Data Collectors', and 'More'. Below the navigation, a summary bar displays 'Execution Time: 34.4 s', 'Wait Time: 0 ms', 'Block Time: 0 ms', 'Node: ECommerce-E2E-Demo\_WEB2\_NODE', and 'Timestamp: 07/26/17 10:15:08 AM'. The main area is a tree view of method calls. Callouts highlight: 'Transaction Globally Unique Identifier (GUID)' pointing to the transaction ID; 'Business transaction details' pointing to the top right; 'Execution time per method' pointing to the 'Time (ms)' column; 'Method details: type, class name, method name and line number' pointing to a method entry; and 'Exit calls to remote services' pointing to 'HTTP' and 'Web Service (2)' links.

Name	Time (ms)	Percent %	Thread State	Exit Calls / Threads...
java.lang.Thread:run:745	0 ms (self)	0%		
com.appdynamics.pilot.servlet.EntityManagerFilter:doFilter:64	0 ms (self)	0%		
StrutsActionProxy:execute:54	0 ms (self)	0%		
Struts Action - ViewCart:sendItems:243	51 ms (self)	0.1%		HTTP
com.appdynamics.pilot.service.CartService:checkOut:134	0 ms (self)	0%		
Spring Bean - soapUtil:raisePO:57	8,512 ms (se...)	24.6%		Web Service (2)
Spring Bean - fulfillmentProducer:sendFulfillment:36	0 ms (self)	0%		
org.springframework.jms.core.JmsTemplate:send:5...	0 ms (self)	0%		
org.springframework.jms.core.JmsTemplate:send:534	0 ms (self)	0%		

The call graph displays exit call links for methods that make calls to outside applications and services such as database queries and web service calls. Exit calls that do not exceed a minimum time threshold may not be represented.

### SQL Query Exit Calls in Call Graphs

Often times application code executes database calls in multiple phases. For example:

- Construct and execute a SQL query
- Iterate over the result set

For example:

```

stmt = con.createStatement();
Execute the query
ResultSet rs = stmt.executeQuery(query);
Iterate through the results
while (rs.next()) {
 String PizzaType = rs.getString("PIZZA_TYPE");
 float price = rs.getFloat("PRICE");
}

```

The Java Agent represents JDBC SQL query executions and the iterations over the result set display separately in the call graph:

- For the execute call, the call graph shows the SQL query and the execution time. You can access the exit call details through a database link in the **External Call** column.
- For the iteration over the result set, it shows a count for the number of iterations and the total time. You can access the exit call details through a result set iteration link in the **External Call** column.

The .NET Agent does not separate ADO.NET SQL query execution exit calls from iteration over the result set in the call graph.

The Python Agent and the Node.js Agent sometimes separate out iterations as separate exit calls based upon the database driver used to make the call.

**i** AppDynamics does not always represent every database call as a separate exit call. Therefore you may see a greater number of database calls than the actual number of exit calls in the call graph.

### Minimum Capture Threshold Times for SQL Calls

The query and result set iteration are both subject to the minimum capture threshold times for SQL calls (which is 10 ms by default). If the execution time for a query or result set iteration does not exceed the threshold, then it does not appear in the call graph. This means that a given database interaction may be represented in a call graph in one of three ways depending on which parts of the operation took longer than 10 ms, if any:

1. Only the query appears (Callout 1)
2. Only the ResultSet iteration appears (Callout 2)
3. Both appear (Callout 3)

Time (ms)	Percent %	Exit Calls / Threads...
12 ms (self)	42.9%	<a href="#">JDBC ResultSet Iteration</a> <a href="#">JDBC</a>
0 ms (self)	0%	
5 ms (self)	17.9%	<a href="#">JDBC</a>
0 ms (self)	0%	
0 ms (self)	0%	<a href="#">JDBC ResultSet Iteration</a>

---

Click the link to view more details for the SQL exit call, or the result set iteration.

### Maximum Number of SQL Queries in Snapshots

By default, the maximum number of SQL queries in snapshots is set to 500. For Java Agents, you can increase the value of the `max-jdbc-calls-per-snapshot` node property if you do not see expected SQL queries in a call graph.

### Request Root Node

The call graphs in transaction snapshots of the Node.js, PHP, and Python agents have an artificial root node named `{request}`.

For Python and PHP, the purpose of this node is to reconcile time differences between the total business transaction time and the sum of the observed call graph nodes, to act as a single entry point for the call graph, and to contain any exit calls which could not be attributed to any other nodes.

For Node.js, the `{request}` node in a business transaction call graph signals the availability of a process snapshot call graph that intersects with the transaction snapshot. If there is no `{request}` node, no process snapshot is available. See [Process Snapshots and Business Transaction Snapshots](#).

### Node.js Call Graphs

When the Node.js agent captures a complete call graph, the call graph tab of the transaction snapshot displays the total execution total time of the transaction, including wait times, at the top the call graph.

The execution time shown in the call graph pane is the sum of the times of the individual method calls inside the call graph. This value may be less than the total execution time because it does not include wait times between calls.

### Display Excluded Classes in Call Graphs

The sequence of method invocations in a call graph may involve hundreds of classes. These classes include user application classes, framework classes (such as Tomcat or Websphere runtime classes), Java/J2EE core libraries, .NET Framework classes, and more.

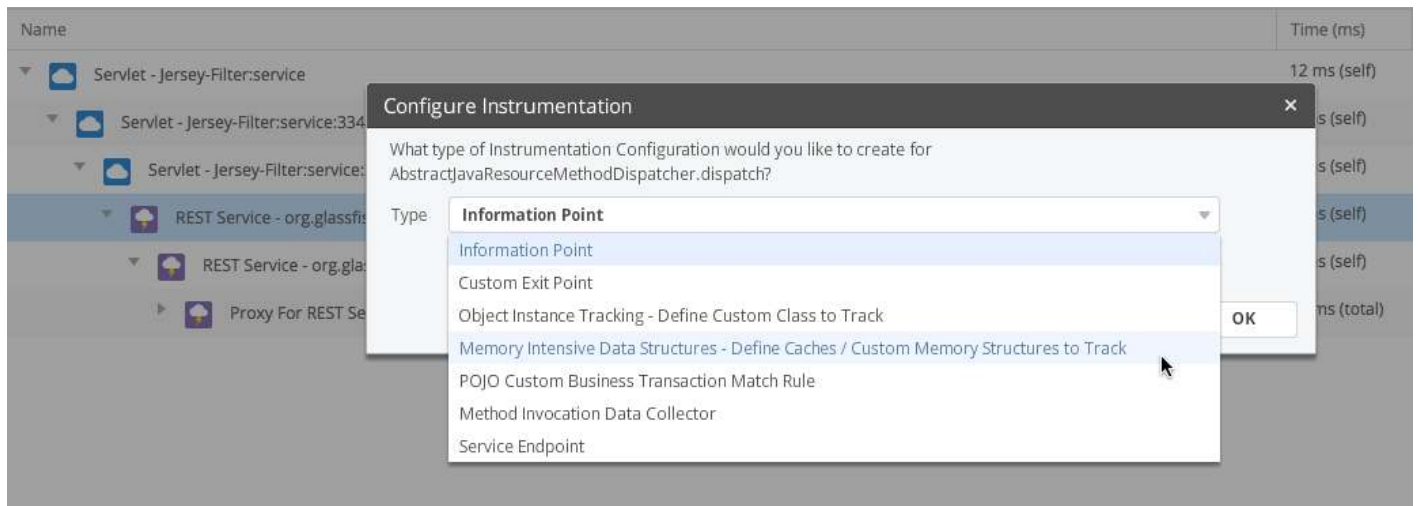

Not all of those classes may be relevant to the type of troubleshooting you normally do. In most cases, your primary interests are the custom application classes you have built on top of the framework or language platform. Other classes may be needed, but only on rare occasions.

To make the call graph more readable and to avoid the overhead of processing the timing information for non-user-application classes, other classes are not shown in the call graph.

If packages (Java) or namespaces (.NET) have been excluded, you can click the *packages/namespaces have been excluded* link to view the packages, and optionally configure the classes to be included in call graphs.

### Configure Instrumentation

You can right-click any item in a call graph and select **Configure Instrumentation for this Class/Method**.

The Configure Instrumentation panel presents a drop-down from which you can select the type of configuration that you want to create for the method.

## Diagnostic Sessions

By default, AppDynamics retains transaction snapshots that it captures at regular intervals and when a transaction is detected to be performing abnormally. The snapshots may have full, partial, or no call graphs. See [Troubleshoot Business Transaction Performance with Transaction Snapshots](#).

Diagnostic sessions let you trigger a timed session in which AppDynamics captures transaction snapshots for a business transaction at a more frequent interval that you set. In the session, AppDynamics captures full call graphs for the transactions.

Diagnostics sessions can also be triggered automatically by a health rule violation or in response to an abnormal amount of slow or error transactions. By default, if more than 10% of the requests in a minute are slow, AppDynamics starts a diagnostic session.

If the diagnostic session is triggered manually, the diagnostic session collects snapshots on all the nodes that the selected business transaction passes through. If the diagnostic session is triggered to start automatically, the diagnostics session collects snapshots on the triggering node.

## Trigger a Diagnostic Session Manually

---

 To start a diagnostic session manually, you need the **Start Diagnostic Sessions** permission.

---

You can start a diagnostic session from the business transaction list. In the list, select the transactions and start the session from the **More Actions** menu.

To view the transaction snapshots gathered in the session, in the business transaction dashboard, choose **Transaction Snapshots > Diagnostic Sessions**.

## Configure Automatic Diagnostic Sessions for Slow and Error Transactions

You configure settings that trigger automatic diagnostic sessions from the [transaction threshold configuration page](#). You can configure the threshold settings that trigger a diagnostic session as well as the snapshot collection frequency and duration once the session is triggered.

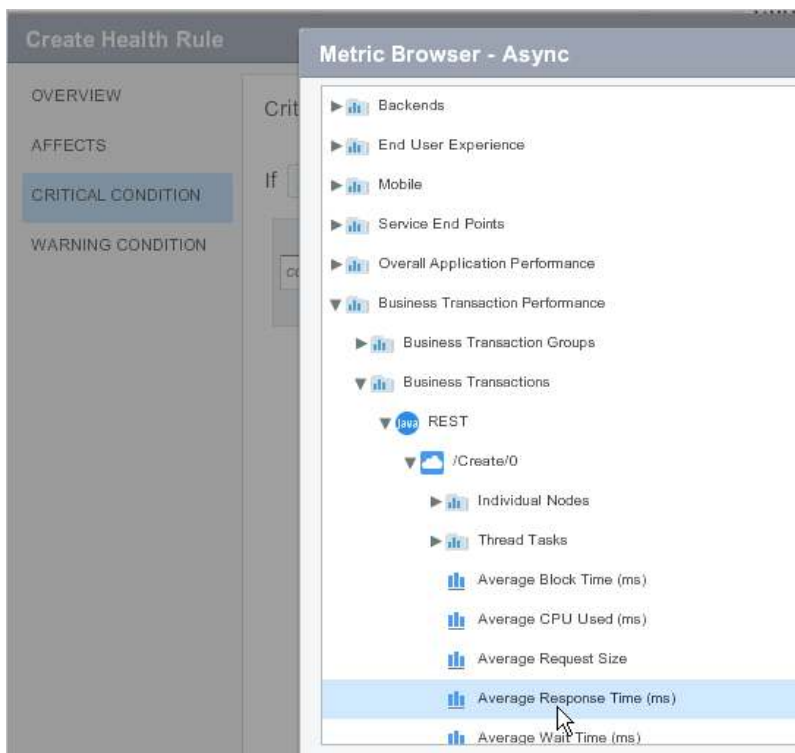

For performance reasons, you want to limit the duration and frequency of diagnostic sessions to the minimum required time to obtain the maximum amount of information for troubleshooting purposes. To avoid continuous collection when there are ongoing performance problems, configure the wait period between sessions and increase the time as needed.

## Use Diagnostic Sessions for Asynchronous Activity

Diagnostic sessions are usually triggered based on the overall performance of a business transaction. However, the overall performance of the business transaction may not reflect the execution time of asynchronous activity. It's possible that the originating transaction executes within normal bounds, while the asynchronous activity takes much longer.

To initiate diagnostic sessions for these scenarios, you can use health rules based on a performance metric (such as response time) of the asynchronous activity. Then, create a policy that triggers a diagnostic session when the health rule violates:

1. [Create a custom health rule](#) based on the asynchronous metric, such as average response time. The metrics for thread tasks are visible in the metric browser under the **Thread Tasks** node for transactions with asynchronous activity. Each thread task has an individual node (usually its simple class name). Select **Custom** as the type for the health rule.

2. [Create a policy](#) that is based on the baseline of the asynchronous metric of interest, for example, the average response time.

3. Configure the policy to trigger a diagnostic session on the affected business transaction. See [Business Transactions](#).

## Transaction Snapshot Collection

This page describes the scenarios that trigger AppDynamics to capture a transaction snapshot and how to configure transaction snapshot settings.

AppDynamics captures transaction snapshots of select instances of a transaction and provides a cross-tier view of the processing flow for a single invocation of a transaction. See [Troubleshoot Business Transaction Performance with Transaction Snapshots](#).

Subject to the guidelines and limits described on this page, snapshots are captured when:

- The app agent determines the user experience for the business transaction to be slow or the transaction incurred an error.
- The app agent collects snapshots during periodic snapshot collection.
- The app agent collects snapshots during a diagnostic session.

## Snapshot and Call Graph Retention Rules

For a given transaction instance, a call graph may be available for some tiers but not all. These guidelines describe the rules for when the app agent captures transaction snapshots for the originating and downstream tiers in a transaction. They also describe the type of call graphs a snapshot might include depending on the cause for the snapshot. The guidelines apply to business transaction correlation as well as cross-application flow.

- Any tier (originating or continuing) takes a snapshot when it recognizes that it is experiencing slow, very slow, or stalled response times or has errors.
- An originating tier takes a transaction snapshot:
  - When the agent starts a diagnostic session on the originating tier because it has detected a pattern of performance problems. You can also manually start a diagnostic session from the **Business Transaction Dashboard**. See [Diagnostic Sessions](#).
  - When the agent identifies slow, very slow, or stalled response times, or errors on the originating tier. These snapshots may have partial call graph information because they start at the time when the transaction slowed or experienced an error.
  - Based on the periodic collection schedule. By default, the agent captures one snapshot every 10 minutes.
- The downstream tier captures snapshots when the tier immediately upstream to it tells it to take a snapshot. An upstream tier might direct its downstream tier to take a snapshot under these circumstances:
  - The upstream tier is taking a snapshot for a diagnostic session.
  - The upstream tier is taking a snapshot based on the periodic collection schedule.

## Transaction Snapshot Limits

Within the guidelines, snapshot retention is also subject to snapshot retention limits. Snapshot retention limits prevent excessive resource consumption at the node level:

- Originating transaction snapshots are limited to a maximum of 20 originating—5 concurrent—snapshots per node per minute.
- Continuing transaction snapshots are limited to a maximum of 200—100 concurrent—snapshots per node per minute.

AppDynamics applies snapshot retention limits to error transactions. As a result, not every error occurrence that is represented in an error count metric, for example, will have a corresponding snapshot. For error transactions, these limits apply:

- For a single transaction, there is a maximum of two snapshots per minute.
- Across transactions, the maximum is limited to five snapshots per minute (specified by the node property `max-error-snapshots-per-minute`).

## Configure Snapshot Periodic Collection Frequency

By default, AppDynamics collects a snapshot every 10 minutes.

---

Navigate to **Configuration > Slow Transaction Thresholds**. You can modify this default in the **Slow Transaction Thresholds** configuration page.

The value will apply to subsequently created business transactions, but if you check **Apply to all Existing Business Transactions**, all existing business transactions are affected by the change.

If you have a high load production environment, do not use low values for snapshot collection. You must configure the collection on a very frequent basis. When there are thousands or millions of requests per minute, collecting snapshots too frequently may result in many extra and useless snapshots. Either turn off the periodic snapshots and apply to all Business Transactions, or choose a very conservative (high) rate depending on the expected load. For example, if you have a high load on the application, choose every 1000th executions or every 20 minutes, depending on the load pattern.

## Business Transactions Logging

### Related pages:

- [Agent Log Files](#)
- [Java Agent Logging](#)
- [.NET Agent on Windows Logging](#)
- [Dynamic Agent Proxy Logging](#)

The Business Transactions log contains this information:

- Discovered business transactions
- Discovery stack trace for each entry point
- Dropped business transactions, which show up in the "All Other Traffic" business transaction when there is business transaction overflow. Only executed methods show up in the business transaction log. If the business functionality is not exercised by the application, the code is not executed, and the methods are not examined as potential entry points.

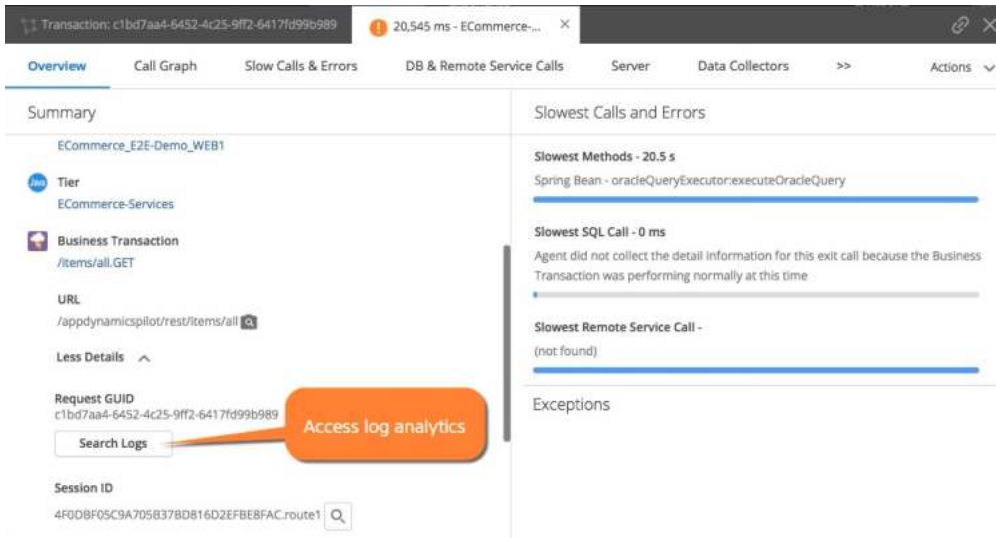

For the Java Agent and the proxy, the name of the Business Transactions log is `BusinessTransactions Year_mon_day_hr_min.#.log` where # is the log set.

For the .NET Agent, the name of the Business Transactions log is `BusinessTransactionsLog.#.txt` where # is the log set.

See [Agent Log Files](#) for information about how the logs are organized into sets that roll over. Within a set, the Business Transactions log file can reach a maximum of five MB.

## Correlate Business Transaction Logs

When the tracing application code does not provide enough clues to track down the cause of a problem, AppDynamics provides visibility into the transaction logs that you can correlate to specific business transaction requests. Log correlation visibility requires a license for both [Transaction Analytics and Log Analytics](#). See [Business Transaction and Log Correlation](#).

## Service Endpoints

Works with:

In complex, large-scale applications, you (as an owner of specific application services spanning one or more logical tiers) may need metrics on your specific service instead of metrics across an entire business transaction or entire tier. You can use service endpoints to obtain a subset of metrics and associated snapshots for your service so you can focus on information important to you. Using service endpoints, you can define a set of entry points into your specific service to create a customized view in the AppDynamics UI and display key performance indicators, associated snapshots, and metrics that affect only those services. You can understand the performance of your service and quickly drill down to snapshots that affect your service, instead of sifting through snapshots for the entire tier or business transaction.

### Difference Between Service Endpoints and Business Transactions

	Business Transactions	Service Endpoints
Metrics Reporting/ Tracking	Business transactions report metrics both at the entry and exit points	Service endpoints are similar to business transactions except that they report metrics only at the entry point, and do not track metrics for any downstream segments.
Entry Points	Business transactions are automatically detected	Service endpoints are not automatically detected; you must specify the entry points for service endpoints. Service endpoints support the same entry point types as business transactions and you configure them similarly.

	Business Transactions	Service Endpoints
Performance Metrics	Business transactions provide both performance metrics and full code visibility with call graphs	Service endpoints provide performance metrics only.
Calls	Business transactions are Checkout, Landing Page, Add to Cart, and so on, and are known by every end-user of the application. These business transactions cover all method executions, database calls, web service calls.	Service endpoints are the sub-calls (method call or web service call), which are executed inside the business transactions. For example, the Check Inventory service, is executed in both Checkout and Add to Cart transactions.

## Customize Service Endpoints

For Java applications, AppDynamics automatically detects and registers service endpoints. For either Java or .NET applications, you can configure custom service endpoint detection rules. See [Service Endpoint Detection](#).

## Service Endpoint Health Rules

You can create health rules to monitor the parameters that represent the normal or expected operations for your service endpoints. The parameters rely on metric values, for example, the average response time. When the performance of a service endpoint violates the conditions set by a health rule, a health rule is violated. Alerts notify you of any violation and initiate remediation actions to mitigate the violation event. It is important that you configure alerts appropriately to ensure that you do not miss any alerts or receive false alerts. 'Alert Sensitivity Tuning' (AST) helps you configure alerts with appropriate sensitivity. AST provides historical data for the metric or the baseline being configured, and helps you visualize the impact of the alerting configuration. To create a health rule to monitor service endpoint parameters and fine-tune the sensitivity of the health rule using AST, see [Create a Health Rule and Fine-tune Metric Evaluation](#).

## Monitor Service Endpoints

From the **Applications** navigation menu in the Controller, select **Service Endpoints** to view a list of service endpoints with key performance metrics.

Service Endpoints 🔄 ⌚ Last 1 Hour

Exclude  View Excluded  Configure 🔍 Search...

	Name	Response ...	Calls	Calls / Min	Errors	Errors / Min	Type	Tier
<input type="checkbox"/>	/app5-s12-bt1	293	3,148	52	2	0	Servlet	app5-s12
<input type="checkbox"/>	/app5-s12-bt2	304	3,148	52	2	0	Servlet	app5-s12

<input type="checkbox"/>	/app5-s14-bt2	100	6,297	105	0	0	Servlet	app5-s14
<input type="checkbox"/>	BackendServi...	61	25,184	420	12,592	210	Async	app5-s12

Service endpoints that contain performance data within the selected time range display in the list.

Select the **Filter** icon (on the top right of the page) to set various filtering options for active and inactive service endpoints within the designated time range. Other view options include showing transactions of certain types or ones that exceed a configurable average response time. After you set the desired filters, select **Apply**.

The screenshot shows the 'Service Endpoints' dashboard. At the top right, there is a refresh icon and a clock icon labeled 'Last 1 Hour'. Below this is a top menu bar with icons for 'Exclude' (trash), 'View Excluded' (eye), and 'Configure' (gear), along with a search bar. The main area contains a table with columns: 'Calls / ...', 'Errors', 'Errors / ...', 'Type', and 'Tier'. A 'Filters' sidebar is open on the left, showing search and filter options for 'Response Time (ms)', 'Calls / Min', 'Type', 'Name', and 'Tier'. At the bottom of the sidebar are 'Cancel' and 'Apply' buttons.

Filters	Calls / ...	Errors	Errors / ...	Type	Tier
Search...	3,148	52	2	Servlet	app5-s12
<input checked="" type="checkbox"/> Service Endpoints with Performance D...	3,148	52	2	Servlet	app5-s12
<input checked="" type="checkbox"/> Response Time (ms) > 0	6,297	105	0	Servlet	app5-s13
<input checked="" type="checkbox"/> Calls / Min > 0	6,297	105	0	Servlet	app5-s13
<input type="checkbox"/> Type <input type="checkbox"/> Async <input type="checkbox"/> Servlet	6,296	105	0	Servlet	app5-s14
<input checked="" type="checkbox"/> Name Matches	6,297	105	0	Servlet	app5-s14
<input checked="" type="checkbox"/> Tier Matches	5,184	420	12,592	Async	app5-s12

Additionally, you can view, delete, and exclude selected service endpoints by selecting the options from the top menu bar. Select **Exclude** to hide the service endpoint from the list.

To completely disable metric collection for the service endpoint, you can create an exclude rule by selecting **Configure**. See [Service Endpoint Detection](#).

Diagnostic sessions are not intended to run in the context of a service endpoint alone. As a result, you cannot directly start a diagnostic session from a service endpoint. If you run a diagnostic session on the business transactions that include calls to the service endpoint, the transaction snapshots from these diagnostic sessions display in the service endpoint dashboard.

## Service Endpoint Limits

A service endpoint adds a small amount of system overhead. Agents capture approximately three metrics per service endpoint, so monitoring each service endpoint results in additional metric traffic.

To prevent the possibility of a boundless expansion of service endpoints, the Controller and agent configurations apply these limits:

Element	Limit	For more information
Application Agent	25 service endpoints per entry point type	See <code>max-service-end-points-per-entry-point-type</code> on <a href="#">App Agent Node Properties Reference</a> .
Java Agent	40 asynchronous worker thread service endpoints	See <code>max-service-end-points-per-async-type</code> on <a href="#">App Agent Node Properties Reference</a> .
Node	100 service endpoints	See <code>max-service-end-points-per-node</code> on <a href="#">App Agent Node Properties Reference</a> .
Controller account	4000 service endpoints	For an on-premises Controller, the limit is configurable using the <code>sep.ADD.registration.limit</code> configuration property accessible in the Administration Console.
Execution thread	1 endpoint	See <code>max-service-end-points-per-thread</code> on <a href="#">App Agent Node Properties Reference</a> .

## Service Endpoint Metrics

Service endpoint metrics display under **Service Endpoints** in the metric browser. Service endpoint metrics are subject to the same operations as other metrics, including those around metric registration, metric rollups for tiers, and limits on the number of metrics. Custom metrics are not available for service endpoints.

## Tiers and Nodes

### Related pages:

- [Monitor Windows Hardware Resources](#)
- [Troubleshooting Machine Agent Installation](#)
- [Java Agent Configuration Properties](#)
- [Configure the .NET Machine Agent](#)

- [Node.js Setting Reference](#)
- [Node Naming in a PHP Environment](#)

This page describes to view, create, and name tiers and nodes. In the Controller UI, you can use **Tiers & Nodes** to view and organize tiers, and the monitored nodes within each tier.

## View All Tiers and Nodes

To view the list of tiers and nodes, click **Tiers & Nodes** in the left application panel. The tier list shows all tiers and health data for each tier.

In the tiers list, the **Machine Agent** column indicates whether the Machine Agent is reporting to the Controller. If the Machine Agent is not reporting, the column is empty. In this case, either an agent is not installed or it is not reporting.

You can change descending and ascending order of the list by clicking on any of the columns.

## View Tier and Node Dashboards

In **Tiers & Nodes**, select a tier or node and click **Details**. The tier and node dashboards contain a flow map view at the tier or node level, including widgets for health statuses, load time, response time, and errors. The Memory tab shows memory information relevant to your application environment. Note that the specific information shown for each environment can vary, depending on the environment. PHP memory management is different than other languages. The relevant memory metrics supplied by the App Agent for PHP are in the [Metric Browser](#).

## Create a Tier

You can create a tier in the AppDynamics model of your environment by specifying the new tier in the agent configuration of your instrumented application (recommended method). However, you can also create tiers manually by navigating to **Tiers & Nodes > Actions > Create App Server Tier**.

After creating a tier, you can add nodes to the tier through the app agent configuration, or by reassigning an existing node to the new tier.

## Rename Node, Tier, or Business Application in the UI

To rename a node, tier, or business application, see [interacting with flow maps](#).

The UI prevents you from using certain special characters for nodes, tiers, and business applications names. Besides numbers, and upper and lower case characters, you can use these special characters in the names :

: ~ ! @ # \$ % ^ \* ( ) - \_ + = / \ \ , . [ ] { } | ? .

## Move and Rename Nodes

This page describes how to move and rename nodes. In the Controller UI, you can move and rename nodes between business applications or tiers to reflect changes in your environment model. See [Overview of Application Monitoring](#).

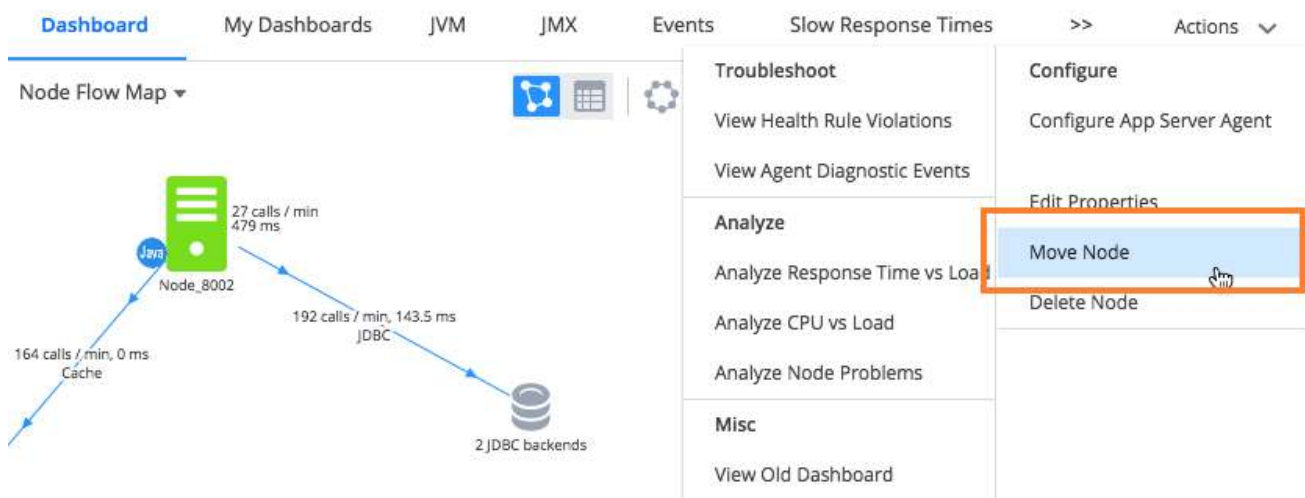

## Move a Node

When you move a node to another tier or application in the Controller UI:

- All historical data is removed for that node, with no possibility for data recovery. Moving nodes in the UI is primarily intended for refining the AppDynamics application model of your environment, or other non-production scenarios. To retain historical data for the node, you can either change the tier name (without changing the application or node name) in the agent's `controller-info.xml` file or move the node to a different tier of the same application without data loss.
- The tier or application association in the agent's configuration file no longer reflects the actual tier or application association. The UI association is maintained unless the `force-agent-registration` flag is set to true in the agent's `controller-info.xml`.

You can move a node to a new application or tier with two methods:

- Controller UI: In the node dashboard, click **Actions > Move Node**. You do not need to restart the JVM using this method.

- `controller-info.xml`: Update the tier or application setting in the agent's `controller-info.xml` configuration file and restart the JVM.

## Force Node Registration

If you moved a node in the UI and you want to move it again elsewhere using `controller-info.xml`, set the `force-agent-registration` property in the configuration file to `true` and restart the JVM. See [Force Agent Registration Property](#).

## Data Retention

When you move a node to another tier or application, all node-level historical data (metrics, events, and snapshots) is lost. The historical data is not recoverable. If retaining historical data for the node is important to you, you can change the tier, application or node name in the agent's `controller-info.xml` file.

Any tier-level data that was generated by the moved node is retained in the former tier. Similarly, when moving nodes between tiers in the same application, the tier-level data generated by the node is retained in the former tier.

## Moving a Java Node and Machine Agent

If your JVM machine has both a Java Agent and a Machine Agent, you cannot change the associations in the Machine Agent `controller-info.xml` file. You can only change these associations either through the

---

UI or by modifying the Java Agent `controller-info.xml` file described in [Java Agent Configuration Properties](#).

### Rename a Node

To rename a node, change the name in Controller UI and then in the app agent configuration file. Changing the node name in the configuration file ensures that the new name is retained through the next agent restart.

If you rename a node from the app agent configuration file only, the effect is that a new node is created with the restarted agent reporting data as that node. AppDynamics retains the historical data previously collected for the node, but the data is associated with the old node name. For most purposes, renaming the node involves changing it in the UI first, and then in the configuration file.

To change the name in the UI, follow the instructions for moving the node, but choose **Edit Properties** from the **Actions** menu, and enter the new name in the **Node Properties** dialog.

For information on changing the node name in the configuration files, see the agent installation or configuration documentation for your agent under [Install App Server Agents](#).

For information on renaming a business application, see [Business Applications](#).

### Troubleshoot Node Problems

The page describes how to use the **Node Problem** viewer to troubleshoot node problems.

AppDynamics categorizes the ten items that deviate the most from the baseline performance as node problems. The Machine Agent must be installed on the machine hosting the node that you are troubleshooting.

#### Use the Node Problem Viewer

If accessed from the **Snapshot** viewer, the **Node Problem** viewer displays node problems for the time range of the snapshot. If accessed from the Node dashboard, the **Node Problem** viewer uses the time range set in the Node dashboard. You can edit the time range in the **Node Problem** viewer and then apply the new time range. You can also define and save a custom time range.

The right panel of the **Node Problem** viewer displays the metrics that deviate the most from their baselines for the specified time range.

On the left, you can set filters on what data appears. Options include:

- The baseline to use to define node problems.
- The type of metrics, whether custom, hardware metrics, JVM, and so on.
- Specify whether to display problems with values that are:
  - Higher than baseline
  - Lower than the baseline
  - Higher and lower than baseline

For example, if you are only interested in CPU that is too high, set the **Analysis Type** to **Higher for Hardware Resources**.

However, if you want to monitor the load on your machine continuously because low CPU usage would also be a problem, set the **Analysis Type** to **Higher and Lower**. The right panel shows the ten items that deviate the most from the baseline.

After changing an option, click **Analyze Node Problems** to apply the change.

---

## Monitor JVMs

This page provides an overview of some of the tools AppDynamics provides for monitoring Java applications and troubleshooting common issues.

### JVM Key Performance Indicators

A typical JVM may have thousands of attributes that reflect various aspects of the JVM's activities and state. The key performance indicators that AppDynamics focuses on as most useful for evaluating performance include:

- Total classes loaded and how many are currently loaded
- Thread usage
- Percent CPU process usage

On a per-node basis, AppDynamics reports:

- Heap usage
- Garbage collection
- Memory pools and caching
- Java object instances

You can configure additional monitoring for:

- Automatic leak detection
- Custom memory structures

### View JVM Performance

You can view JVM performance information from the Tiers & Nodes dashboard or from the Metric Browser.

In the Tiers & Nodes dashboard, see the following tabs for JVM-specific information:

- The Memory subtab of the Tiers & Nodes dashboard allows you to view various types of JVM performance information: Heap and Garbage Collection, Automatic Leak Detection, Object Instance Tracking, and Custom Memory Structures.
- The JMX subtab of the Tiers & Nodes dashboard allows you to view information about JVM classes, garbage collection, memory, threads, and process CPU. In the JMX Metrics subtab metric tree, click an item and drag it to the line graph to plot current metric data.

In the Metric Browser, click **Application Infrastructure Performance** and expand the JVM folder for a given node to access information about Garbage Collection, Classes, Process CPU, Memory, and Thread use.

### Alert for JVM Health

You can set up health rules based on JVM or JMX metrics. Once you have a health rule, you can create specific [policies](#) based on health rule violations. One type of response to a health rule violation is an alert. See [Alert and Respond](#) for how to use health rules, alerts, and policies.

You can also create additional persistent JMX metrics from MBean attributes. See [Configure JMX Metrics from MBeans](#).

### JVM Crash Guard

Using the [Machine Agent](#), when a JVM crash occurs on a machine or node, you can be notified almost immediately and take [remediation actions](#). A JVM crash is because it may be a sign of a severe runtime problem in an application. Implemented as part of [JVM Crash Guard](#), JVM crash is an event type that you can activate to provide the critical information you need to expeditiously handle JVM crashes.

---

## Memory Management

Memory management includes managing the heap, certain memory pools, and garbage collection. This section focuses on managing the heap. You can view heap information in the metric browser or in the Memory tab for a given node as directed in **Monitoring JVM Information**.

The size of the JVM heap can affect performance and should be adjusted if needed:

- A heap that is too small will cause excess garbage collections and increases the chances of `OutOfMemory` exceptions.
- A heap that is too big will delay garbage collection and stress the operating system when needing to page the JVM process to cope with large amounts of live data.

See [Garbage Collection](#).

### Detect Memory Leaks

By monitoring the JVM heap and memory pool, you can identify potential memory leaks. Consistently increasing heap valleys might indicate either an improper heap configuration or a memory leak. You can identify potential memory leaks by analyzing the usage pattern of either the survivor space or the old generation. To troubleshoot memory leaks, see [Java Memory Leaks](#).

### Detect Memory Thrash

Memory thrash is caused when a large number of temporary objects are created in very short intervals. Although these objects are temporary and are eventually cleaned up, the garbage collection mechanism might struggle to keep up with the rate of object creation. This might cause application performance problems. Monitoring the time spent in garbage collection can provide insight into performance issues, including memory thrash. For example, an increase in the number of spikes for major collections affects the JVM's ability to serve Business Transaction traffic and might indicate potential memory thrash.

The **Tiers & Nodes > Memory > Object Instance Tracking** subtab helps you isolate the root cause of possible memory thrash. To troubleshoot memory thrash, see [Java Memory Thrash](#).

### Monitor Long-lived Collections

AppDynamics automatically tracks long-lived Java collections (HashMap, ArrayList, and so on) with Automatic Leak Detection. [Custom Memory Structures](#) that you have configured, display in **Tiers & Nodes > Memory > Custom Memory Structures**.

AppDynamics provides visibility into:

- Cache access for slow, very slow, and stalled business transactions
- Usage statistics (rolled up to Business Transaction level)
- Accessed keys
- Deep size of the internal cache structure

### Automatic Leak Detection for Java

This page describes how to view the Automatic Memory Leak dashboard and enable automatic leak detection. See [Java Memory Leaks](#).

### JVM Requirements

- Oracle JVM  $\geq 1.5$
- JRockit JVM  $\geq 1.5$

- IBM JVM >= 1.6

## Automatic Memory Leak Dashboard

The Automatic Memory Leak dashboard shows:

- **Collection Size:** The number of elements in a collection.
- **Potentially Leaking:** Potentially leaking collections are marked as red. You should start diagnostic sessions on potentially leaking objects.
- **Status:** Indicates if a diagnostic session has been started on an object.
- **Collection Size Trend:** A positive and steep growth slope indicates a potential memory leak.

You must have the **Configure Agent Properties** permission to activate or deactivate automatic leak detection. See [Manage Custom Roles](#).

## Enable Automatic Leak Detection

1. In the left navigation pane, click **Tiers & Nodes**.
2. In the right pane, expand the tier of the node you want to configure.
3. Select the node and click **View Dashboard**.
4. Click **Memory > Automatic Leak Detection**.
5. Click **On**.
6. Click **Start On Demand Capture Session** to detect leaking collections.

### Test before implementing

Leak Detection may affect performance, so test this functionality in a preproduction environment or on a single node first.

AppDynamics begins to automatically track the top 20 application classes and the top 20 system (core Java) classes in the heap.

## Troubleshoot Leak Detection

If you cannot see any captured collections, ensure that you have the correct configuration for detecting potential memory leaks. As described in the on-screen instructions you may need to lower the minimum collection size from the default, 5 MB:

To configure the agent of a specific node to capture smaller collections:

1. On the **Tiers & Nodes** list, expand a tier and double-click the node you want to configure.
2. Ensure the **App Server Agent** tab is active and click **Configure**.
3. Select the Application, Tier, and Node and then click **Use Custom Configuration**.
4. Search for `minimum-size-for-evaluation-in- mb` in the node properties list. Set the value to a smaller size.
5. Choose to overwrite the node configuration.

## Object Instance Tracking for Java

This page describes how to configure and use object instance tracking for Java applications. For more information about why you may need to configure this, see [Java Memory Thrash](#).

When object instance tracking is enabled, AppDynamics tracks the top 20 application and top 20 system (core Java) classes in the heap by default. You can also [track specific classes](#).

**i** AppDynamics does not perform allocation tracking for core Java classes by default since doing so would add significant system overhead. However, it is possible to track core classes on a short-term basis (for example, while troubleshooting) or in pre-production environments. For more information, see [Enabling Allocation Tracking for Core Java Classes](#).

**🔒** You need the **Configure Agent Properties** permission to set object instance tracking. You need the **Configure Memory Monitoring** permission to configure the custom classes to track. See [Manage Custom Roles](#).

### Prerequisites for Object Instance Tracking

- Review [Java Supported Environments](#) for information about platform support for object instance tracking.
- For JVMs prior to Java 9, object instance tracking uses tools.jar. If your application runs with the JDK, tools.jar should be already available. If you are running with the JRE, you must add tools.jar to `<JRE_HOME>/lib/ext` and restart the JVM. You can find `tools.jar` in `<JAVA_HOME>/lib/tools.jar`. For Java 9 onwards JEP220 moved the capabilities needed by OIT to the Core Java runtime, therefore `tools.jar` is no longer necessary.
- In some cases, you might also need to copy `libattach.so` (Linux) or `attach.dll` (Windows) from your JDK to your JRE.
- Depending on the JDK version, you may also need to specify the classpath as shown below (along with other `-jar` options).

**i** `jdk.jcmd` is no longer a required module for the custom runtime. However, it is required for the proper functioning of object instance tracking.

### Specify the Classpath

When using the JDK runtime environment, set the classpath using the `-classpath` option for the application. For example:

- On Windows:  

```
java -classpath <complete-path-to-tools.jar>;%CLASSPATH% -jar myApp.jar
```
- On Unix:  

```
java -Xbootclasspath/a:<complete-path-to-tools.jar> -jar myApp.jar
```

### Enable Object Instance Tracking

To start an object instance tracking session, follow these steps:

1. In the left navigation pane, click **Tiers & Nodes**.
2. In the right pane, expand the tier node and open the Node Dashboard for the node on which you want to enable object instance tracking.
3. Click the Memory tab.
4. Click the Object Instance Tracking subtab.
5. Click **ON**.

Tracked classes now appear in the Object Instance Tracking table. You can drill down to the tracked classes to see details.

## Track Specific Classes

For performance reasons, only the top 20 application classes and the top 20 system (core Java) classes in the heap are tracked automatically.

Use the Configure Custom Classes to Track option on the Object Instance Tracking subtab to specify instances of specific classes to track. Note that the classes you configure here are tracked only if their instance count is among the top 1000 instance counts in the JVM.

To track instances of custom classes:

1. On the Object Instance Tracking tab, click **Configure Custom Classes to Track**.
2. On the Instrumentation page that displays, click the tier you want to customize.
3. In the Object Instance Tracking section for the tier, click **Add**.
4. Enter the fully-qualified class name of the class to track and click **Save**.

The class you added is now tracked during object instance tracking sessions.

## Custom Memory Structures for Java

This page describes how to monitor custom memory structures for Java.

AppDynamics automatically tracks long-lived Java collections (HashMap, ArrayList, and so on) with Automatic Leak Detection. To track specific classes, you can use the Custom Memory Structures capability in the Controller UI.

You can use this capability to monitor a custom cache or other structure that is not a Java collection. For example, you may have a custom cache or a third-party cache such as Ehcache. In a distributed environment, caching can easily become a prime source of memory leaks. In addition, custom memory structures may or may not contain collections of objects that would be tracked using automatic leak detection.

 Monitoring custom memory structures with the Java Agent can result in increased CPU utilization. AppDynamics recommends you enable memory structure monitoring on a short-term basis only while troubleshooting or in pre-production environments.

To configure custom memory structures, ensure custom memory structures are supported in your JVM environment. See [JVM Support](#).

- To activate or deactivate object instance tracking, you need the Configure Agent Properties permission.
- To configure the custom classes to track, you need the Configure Memory Monitoring permission. See [Manage Custom Roles](#).

## Custom Memory Structures and Memory Leaks

Typically custom memory structures are used as caching solutions. In a distributed environment, caching can easily become a source of memory leaks. AppDynamics helps you to manage and track memory statistics for these memory structures.

AppDynamics provide visibility into:

- Cache access for slow, very slow, and stalled business transactions.

- Usage statistics rolled up to the Business Transaction level.
- Keys being accessed.
- Deep size of internal cache structures.

## Automatic Leak Detection Versus Monitoring Custom Memory Structures

Automatic leak detection captures memory usage data for all map and collection libraries in a JVM session. However, custom memory structures may not contain all collection objects. For example, you may have a custom cache or a third-party cache such as Ehcache for which you want to collect memory usage statistics.

Using custom memory structures, you can monitor any custom object created by the app and the size data can be traced across JVM restarts. Automatic leak detection is typically used to identify leaks, while custom memory structures are used to monitor large coarse-grained custom cache objects.

The following provides the workflow for configuring, monitoring, and troubleshooting custom memory structures. You must configure custom memory structures manually.

1. On the **Tiers & Nodes** dashboard, use the **Automatic Leak Detection, On Demand Capture Session** feature to determine which classes aren't being monitored, for example, custom or third-party caches such as EhCache.
2. Configure **Custom Memory Structures** and then restart the JVM if necessary.
3. Enter the fully-qualified classname on the Create New Instance Tracker window and click **Save**. AppDynamics automatically tracks long-lived Java collections (HashMap, ArrayList, and so on) with Automatic Leak Detection.
4. Turn on **Custom Memory Structures** monitoring to detect potential memory leaks in the custom memory structures you have configured.
5. Drill down into leaking memory structures for details that will help you determine where the leak is.

To identify custom memory structures:

1. Navigate to **Memory > Automatic Leak Detection** and click **On**.
2. Click **Start On Demand Capture Session** to capture information on which classes are accessing which collections objects. Use this information to identify custom memory structures.

AppDynamics captures the top 1000 classes, by instance count.

## Identify Potential Memory Leaks

Start monitoring memory usage patterns for custom memory structures. An object is automatically marked as a potentially leaking object when it shows a positive and steep growth slope. The **Memory Leak** dashboard provides the following information:

- **Heap & Garbage Collection**—Provides heap and garbage collection metrics.
- **Automatic Leak Detection**—Provides memory usage data for all map and collection libraries in a JVM session.
- **Object Instance Tracking**—Provides tracking data for the top 20 application and top 20 system (core Java) classes in the heap.
- **Custom Memory Structures**—Allows you to track specific classes and monitor a custom cache or other structure that is not a Java collection.

The **Custom Memory Structures** dashboard provides the following information:

- **Class**—The name of the class or collection being monitored.
- **Deep Size (bytes)**—The upper boundary of memory available to the structure. The deep size is traced across JVM restarts
- **% of Current Used Heap**—The percentage of memory available for dynamic allocation.
- **Potentially Leaking**—Potentially leaking collections are marked as red. We recommend that you [start a diagnostic session](#) on potentially leaking objects.
- **JVM Start Time**—Custom Memory Structures are tracked across JVM restarts.

- **Status**—Indicates if a diagnostic session has been started on an object.
- **Deep Size**—A positive and steep growth slope indicates a potential memory leak.

After the potentially leaking collections are identified, start the diagnostic session.

## Diagnose Memory Leaks

On the **Custom Memory Structures** dashboard, select the class name to monitor and click **Drill Down**.

## Isolate Leaking Collections

Use **Content Inspection** to identify to which part of the application the collection belongs. It allows monitoring histograms of all the elements in a particular memory structure. Start a diagnostic session on the object and then follow these steps:

1. Select the Content Inspection tab.
2. Click **Start Content Summary Capture Session**.
3. Enter the session duration. Allow at least 1-2 minutes for the data to generate.
4. Click **Refresh** to retrieve the session data.
5. Click a snapshot to view the details about that specific content summary capture session.

## Access Tracking

Use **Access Tracking** to view the actual code paths and business transactions accessing the memory structure. Start a diagnostic session on the object and then follow these steps:

1. Select the Access Tracking tab.
2. Select **Start Access Tracking Session**.
3. Enter the session duration. Allow at least 1-2 minutes for data generation.
4. Click **Refresh** to retrieve the session data.
5. Click a snapshot to view the details about that specific content summary capture session.

## JVM Crash Guard

This page describes how to view and monitor JVM crashes with JVM Crash Guard. When a JVM crash occurs, you need to know as soon as possible. A JVM crash may be a sign of a severe runtime problem in an application and often calls for immediate remediation steps.

## View JVM Crash Information

When a JVM crash occurs, a corresponding event type is generated in the Controller UI.

To analyze and troubleshoot the crash:

1. In the **Events** panel, double-click the JVM Crash of interest.
2. Examine any logs associated with the JVM Crash event. (The local log folder is determined by the type of JVM and how it is configured. For more information, refer to the documentation for the specific JVM.)

The JVM Crash panel also displays information about actions executed as a result of the crash. These are actions that you specify when creating a policy that is triggered by a JVM crash event. See [Policies](#).

The JVM Crash event details include this information:

- Timestamp
- Crash reason

- Hostname IP address
- Process ID
- Application name
- Node name
- Tier name

In the JVM Crash Details tab, the **Crash Reason** details field (if available) indicates the root cause of the crash. For example, the field could contain `java.lang.OutOfMemoryError` or Segmentation Fault.

To facilitate the discovery and display of the reason for the JVM crash, JVM Crash Guard supports:

- Hotspot JVM error log analysis
- IBM JVM system dump log analysis
- Jrockit JVM error log analysis

### Enable Monitoring for JVM Crashes

Before you can monitor JVM crashes, you must:

- Install and enable a Machine Agent on the machine you want to monitor for JVM crashes. JVM Crash Guard works with the [Machine Agent](#) to trigger a policy when a JVM Crash event occurs.
- Ensure that the Machine Agent is running with the required privileges:
  - On Windows, the Machine Agent must run in Administrator root mode.
  - On Linux, JVM Crash Guard requires that the Machine Agent user be able to read all the processes in `/proc/*`. This may be the root user or another user with this privilege.
- Enable the JVM Crash Guard (it is disabled by default). Navigate to `extensions/CrashGuard/conf/crashGuardConfig.yml` and open the `crashGuardConfig.yml` file. Set `enabled` to `true`.

Once you have verified the requirements, follow these steps to create a policy for JVM crash events:

1. From the left-hand navigation menu, click **Alert & Respond > Policies > Create a Policy**.

The screenshot shows the 'Create Policy' dialog box with the following details:

- Name:** [Empty text field]
- Enabled:**
- Execute actions in batch:**
- Trigger:**
  - Health Rule Violation Events:**
    - Health Rule Violation Started - Warning
    - Health Rule Violation Started - Critical
    - Health Rule Violation Continues - Warning
    - Health Rule Violation Continues - Critical
    - Health Rule Violation Upgraded - Warning to Critical
    - Health Rule Violation Downgraded - Critical to Warning
    - Health Rule Violation Ended - Warning
    - Health Rule Violation Ended - Critical
    - Health Rule Violation Canceled - Warning
    - Health Rule Violation Canceled - Critical
  - Other Events:**
    - Slow Transactions
    - Code Problems
    - Application Changes
    - Server Crashes
      - JVM Crash
      - CLR Crash
    - AppDynamics Config Warnings
    - Discovery
    - Synthetic Availability
    - Synthetic Performance
  - Custom Events:** No Custom Events Selected

2. In the **Other Events** section, expand the **Server Crashes** option and click **JVM Crash**. The JVM Crash event then becomes a trigger to fire a policy.
3. Proceed as usual to create the policy. See [Policies](#).

**i** If an uninstrumented JVM crash occurs within less than a minute of a previous crash, it will not be reported by the Machine Agent. In some circumstances, the JVM may crash and then be restarted only to crash again within one minute. For this repetitive cycle crash and restart scenario, only the first JVM crash is reported by the agent.

## Garbage Collection

This page describes how to monitor Garbage Collection for Java applications.

AppDynamics gathers Garbage Collection metrics and lets you analyze how periodic Garbage Collections affect the performance of your application. It is important to identify the impact of excessive Garbage Collection or memory-caused instability on the application. A typical Java application which runs on the Java Virtual Machine (JVM) creates objects such as strings, files, and arrays of primitives on the heap. The Java Garbage Collection is an automatic memory management process which finds and gets rid of the objects which are no longer used by the application.

The JVM periodically performs [Garbage Collection](#) to maximize available memory and the programmer need not explicitly mark the objects to be deleted. Garbage Collection requires a stop-the-world suspension of all application threads. This process affects the performance, especially for applications with large amounts of data, multiple threads, and high transaction rates.

See [How to Master Your Java Memory](#) for a review of how generational Garbage Collection works.

### Before You Begin

If your application runs under JDK version 1.6.0\_26-b03 and you have configured the monitored application to use G1GC, the Java Agent cannot capture memory statistics. To capture memory statistics, you can do any one of the following:

- Remove G1GC ( `-XX:+UseG1GC` ) from the application startup options, or
- Upgrade the JDK to `>= 1.6.0_32`.

In JVM `>= 1.7`, the agent attaches listeners to the Java event notification service to generate Garbage Collection metrics. In JVM `< 1.7`, the agent parses certain JVM log files to generate metrics, so you must verify that your JVM is generating the required logs. See [Enable Log-based Garbage Collection](#).

**i** The Z Garbage Collector cycles are not categorized into minor or major collections. The agent reports all the Z Garbage Collector metrics as a minor collection.

## Monitor Garbage Collection

The Java Agent reports certain Garbage Collection metrics at one-minute intervals. You can view these metrics on the Heap & Garbage Collection sub-tab of the Memory tab on the Node dashboard:

- **Heap utilization:** free, used, committed, and available.  
This is the most coarse-grained view of memory use.
- **Garbage Collection:** minor, major, and total on one timeline.  
This should give you some notion of the ratio of minor to major collections.
- **Minor Garbage Collection** on a timeline.
- **Major Garbage Collection** on a timeline.
- **Memory pool use**, including the use of all memory spaces: Young Generation, Old Generation, and PermGen.

For a finer-grained view of the impact of Garbage Collection on application performance, you can view Garbage Collection metrics in the Metric Browser. Navigate to **Application Infrastructure Performance > tier > JVM > Garbage Collection**.

In addition to the periodically-collected metrics, the Metric Browser shows the following metrics triggered by minor or major Garbage Collection events:

Metric	Triggering Event	Description
Allocated-Objects	Minor collection	<p>The amount of memory allocated to the Young Generation.</p> <p>A high growth rate might indicate memory thrash. The allocation rate affects the frequency of minor collection events, which can impact application performance over time.</p> <p>The value for <b>Count</b> indicates how many collections were made.</p>
Promoted-Objects	Major collection	<p>The amount of memory in use for objects promoted from Young Gen space to Old Gen space.</p> <p>A high promotion rate is related to major collection events, which can have a significant impact on application performance due to the duration of a full major collection cycle.</p> <p>If the promotion rate is close to the allocation rate, this might indicate premature promotion. In this case, you might want to allocate more memory to Young Gen space.</p> <p>The value for <b>Count</b> indicates how many collections were made.</p>

Metric	Triggering Event	Description
Freed Objects	Minor or Major collection	The amount of memory in use for objects being reclaimed in Young and Old space.  In a normal system, the number of objects allocated and the free rate metrics should be roughly equal.  The value for <b>Count</b> indicates how many collections were made.
LiveData	Major collection	The amount of memory in use that persists after major Garbage Collections.  An upward slope in the size of live data indicates a possible memory leak.

### Tune Garbage Collection in the JVM

After reviewing Garbage Collection diagnostic metrics, you can use these JVM arguments to tune space allocation in the JVM Garbage Collection memory pool. For example, you might want to increase the size of tenured space if your application needs to store many objects long term.

JVM Arguments	Meaning
<code>-Xms</code>	The amount of total memory allocated to young and old generation space.
<code>-XX:NewSize</code>	The amount of memory allocated to the young generation space.
<code>-XX:PermSize</code>	The amount of memory allocated to the permanent generation

### Enable Log-based Garbage Collection

For applications running in JVMs < 1.7, Garbage Collection monitoring is based on periodically parsing certain Garbage Collection logs.

To set up Garbage Collection logging for your application, use these arguments:

```
-Xloggc:log-file-path
-XX:+Usecollector-type
-XX:+PrintGCDetails
```

The `log-file-path` option specifies where the log file is located. This table describes the possible values for collector types for the `-XX:+Usecollector-type` option:

Collector Type	Effect
CMS Collector <code>-XX:+UseConcMarkSweepGC</code>	Good for applications that require low pause times and that can share resources with the garbage collector.  Use the <code>-XX:ParallelCMSThreads=&lt;n&gt;</code> to set the number of threads to use.
Throughput or Parallel Collector <code>-XX:+UseParallelGC</code> <code>-XX:+UseParallelOldGC</code>	Can use multiple CPUs to speed up application throughput; good to use for work-intensive apps that can accept long pauses.
G1 Collector <code>-XX:+UseG1GC</code>	Available in Java 7 and designed to be a long term replacement for the CMS collector. This is a parallel, concurrent, and incrementally compacting low-pause collector.

To direct the Controller to display logged information, [register the following node properties](#) in the Controller UI:

```
enable-jmx-visibility=true
enable-log-based-gc=visibility=true
```

To change the default log check interval, register the following node property:

```
logbased-visibility-log-check-interval-in-mills=1000
```

### Specify Regular Expressions for Parsing Garbage Collection Logs

When you enable log-based Garbage Collection metrics, the agent uses built-in regular expressions to accommodate different JDK and Garbage Collection type combinations. If the built-in regular expressions don't return the Garbage Collection metrics for your system, you can register the following node properties to specify custom regular expressions for parsing the logs:

- `young-gc-custom-regex-1`
- `young-gc-custom-regex-2`
- `young-gc-custom-regex-3`
- `full-gc-custom-regex-1`
- `full-gc-custom-regex-2`
- `full-gc-custom-regex-3`

After you set a custom regular expression using a node property, the agent no longer uses any of the built-in regular expressions to parse the logs.

---

## Monitor JMX

This page covers monitoring for Java Management Extensions (JMX). Java application environments usually support JMX or IBM Performance Monitoring Infrastructure (PMI). AppDynamics automatically discovers JMX and PMI attributes.

### About JMX Monitoring Support

JMX uses objects called MBeans (Managed Beans) to expose data and resources from your application. In a typical application environment, there are three main layers that use JMX:

- JVMs provide built-in JMX instrumentation or platform-level MBeans that supply important metrics about the JVM.
- Application servers provide server or container-level MBeans that reveal metrics about the server.
- Applications often define custom MBeans that monitor application-level activity.

MBeans are typically grouped into domains to indicate where resources belong. Usually, in a JVM there are multiple domains. For example, for an application running on Apache Tomcat, there are *Catalina* and *Java.lang* domains. *Catalina* represents resources and MBeans relating to the Tomcat container, and *Java.lang* represents the same for the JVM Hotspot runtime. The application may have its own custom domains.

You can use MBean attributes to create persistent JMX metrics in AppDynamics as described here. In addition, you can import and export JMX metric configurations from one version or instance of AppDynamics to another.

See [Writing PMI Applications Using the JMX Interface](#).

### Requirements for JMX Monitoring

AppDynamics can capture MBean data if:

- The monitored system runs on Java  $\geq 1.5$ .
- Each monitored Java process has JMX enabled. See [JMX documentation](#).

### MBean-Based Metrics

AppDynamics creates long-term metrics of the key MBean attributes that represent the health of the Java container. Depending on your application configuration, metrics may include:

- Session information such as the number of active and expired sessions, maximum active sessions, processing time, average and maximum alive times, and a session counter.
- Web container runtime metrics that represent the thread pool that services user requests. The metrics include pending requests and the number of current threads servicing requests. These metrics are related to Business Transaction metrics such as response time.
- Messaging metrics related to JMS destinations, including the number of current consumers and the number of current messages.
- JDBC connection pool metrics including current pool size and maximum pool size.

To view the JMX metrics discovered in a node, see the JMX tab on the Node Dashboard. For additional metrics not discovered automatically, you can configure JMX Metrics from MBeans yourself.

You can mask sensitive JMX and MBean data by setting the sensitive-data-filters property in the `app-agent-config.xml`. See [Filter Sensitive Data](#).

### View JMX Metric Data

You can view MBean-based metrics using the Node Dashboard and the Metric Browser. In addition, the MBean Browser enables you to view all the MBeans defined in the system.

To view JMX metrics in the Metrics Browser, click the **JMX** tab in the Node Dashboard. The JMX Metrics browser opens and displays the MBeans in a Metric Tree.

You can perform all the operations that are provided by the Metric Browser. See [Metric Browser](#).

### View Trending MBeans with Live Graphs

You can monitor the trend of a particular MBean attribute over time using the **Live Graph**.

To view live graphs:

1. In the Node Dashboard, click the JMX tab and then the MBean Browser sub-tab.
2. Select the domain for which you want to monitor MBeans.
3. In the domain tree, expand the domains to find and then select a MBean.
4. Expand the **Attributes** section and then choose an attribute of the MBean.
5. Click **Start Live Graph for Attribute** and then click **Start Live Graph**. The runtime values appear.
6. Select an attribute and click **Live Graph for Attribute** to see a larger view of a particular graph.

### Working with MBean Values

When troubleshooting or monitoring a Java-based system, you may want to change the values of composite MBeans and execute MBean methods.

---

 To change the value of an MBean attribute or invoke operation, you need the **Set JMX MBean Attributes and Invoke Operations** permission for the application. See [Application Permissions](#).

---

To view and edit MBean attribute values:

1. From the **JMX** panel, select **MBean Browser**.
2. In the Domain tree, locate the MBean that interests you.
3. Select an editable attribute, one that has **Yes** in the **Editable** column, and then click **View/Edit Attribute**.
4. In the **MBean Attribute** panel that displays, you see the current value of the MBean Attribute.
5. You can change the value of an editable MBean Attribute by entering a new value in the **Value** field.

### Invoke MBean Operations

---

 To perform this action, a user must have the **Set JMX MBean Attributes and Invoke Operations** permission for the application

---

To invoke MBean operations:

1. Open the **MBean Browser**.
2. In the Domain tree, locate the MBean that interests you.
3. Open the **Operations** pane, scroll to find the operation that interests you, and double-click **Invoke Action**.
4. Enter the parameter values for the operation and then click **Invoke**. Scalar values for constructors of complex types, such as `getMBeanInfo(java.util.Locale)` allow you to enter "en-us".

A message appears indicating that the operation is in progress and the number of seconds elapsed. When the operation completes, the results display. The method return result from an invocation can also be a complex attribute. In this case, the name, description, type, and editable attributes of the method are also displayed in the MBean Operation Result area.

## Available JMX Metrics

Java Management Extensions (JMX) is a public specification for monitoring and managing Java applications. Through JMX, AppDynamics can access Java class properties that collect management data, such as the resources your application is consuming.

For information on the specific metrics available for your environment, see the documentation provided by your vendor:

- Apache ActiveMQ, see [ActiveMQ MBeans Reference, in the ActiveMQ Features documentation](#)
- Apache Kafka, see [Default JMX Metrics for Apache Kafka Backends](#)
- Apache Solr, see [Quick Demo](#) in the Solr JMX documentation
- Apache Tomcat, see the descriptions of [JMX MBeans for Catalina](#) in the `mbeans-descriptor.xml` file for each package
- Cassandra, see [Cassandra Metrics](#)
- Coherence, see the Coherence MBeans Reference in Appendix A of the [Coherence Management Guide](#)
- GlassFish, see the Oracle Sun Glassfish Administration Guide where you can find a [Metrics Information Reference](#)
- HornetQ, see [Using Management Via JMX](#)
- JBoss, see [An Introduction to JMX Technology](#)
- Kafka Broker, see [Monitoring Kafka](#)
- Oracle WebLogic Server, see [Understanding JMX](#)
- WebSphere PMI, see [PMI data organization](#) in the IBM Websphere Application documentation

## Adding JMX Metrics

In addition to the preconfigured metrics, you can define a new persistent metric using a JMX Metric Rule that maps a set of attributes from one or more MBeans. See [Configure JMX Metrics from MBeans](#).

## Extending Monitoring with the Agent API

The Application Server Agent API lets you access metrics that are not supported by default or by MBeans. You can use the API to:

- Inject custom events and report on them
- Create and report on new metrics
- Correlate distributed transactions when using protocols that AppDynamics does not support

To learn more about the Application Server Agent API, see the Javadoc included with the Java Agent software at this location:

```
<agent_home>/sdk/docs/index.html
```

## Default JMX Metrics for Apache Kafka Backends

This page describes default metrics for Apache Kafka Backends. The Java Agent includes rules for key metrics exposed by Apache Kafka producers and consumers. To monitor JMX metrics not collected by default, you can use the MBean browser to select the Kafka JMX metric and create a rule for it.

### Kafka Producer JMX Metrics

- Response rate: the rate at which the producer receives responses from brokers
- Request rate: the rate at which producers send request data to brokers
- Request latency average: average time between the producer's execution of `KafkaProducer.send()` and when it receives a response from the broker

- Outgoing byte rate: producer network throughput
- IO wait time: percentage of time the CPU is idle and there is at least one I/O operation in progress
- Record error rate: average record sends per second that result in errors
- Waiting threads: number of user threads blocked waiting for buffer memory to enqueue their records
- Requests in flight: current number of outstanding requests awaiting a response
- Network IO rate: average number per second of network operations, reads or writes, on all connections

## Kafka Consumer JMX Metrics

- Records lag max: maximum lag in terms of number of records for any partition within the timeframe
- Bytes consumed rate: average number of bytes consumed per second
- Fetch rate: number of fetch requests per second
- Records consumed rate: average number of records consumed per second
- Fetch latency max: maximum time this is taken for any fetch request

## Kafka Server JMX Metrics

- `broker-request-total-time-ms` : Total end-to-end time in milliseconds.
- `broker-request-send-response-ms` : Responses dequeued are sent remotely through a non-blocking IO. The time between dequeuing the response and completing send is indicated by this metric.
- `broker-request-response-queue-ms` : Responses too are added to a queue. There is one queue per network processor. Network processor dequeues this response and sends it back. Time spent waiting in this queue is indicated by this metric.
- `broker-request-remote-time-ms` : If the request needs remote processing, the time spent in remote processing is indicated by this metric. For example, for the producer request, if acks is set to -1, the request is not completed until the acknowledgment is received from the followers. Time spent waiting for the followers is indicated by this metric. A fetch request can also be delayed if there is not enough data to fetch. That time too is accounted for by this metric.
- `broker-request-processing-ms` : The request is then processed by the KafkaAPI. The time spent in the processing is indicated by this metric. If this metric is high, debug the relevant request handler.
- `broker-request-queue-time-ms` : The request is added to a common queue. The items in the queue are processed by the request handler threads. The number of these handler threads can be configured through `num.io.threads` parameter. The average time, a request spends in this queue, is indicated by this metric. If this metric is high, increase the handler threads.

## Monitor .NET Nodes

This page describes specific considerations for monitoring .NET applications and how to fine-tune the configuration for .NET frameworks and technologies. These include, for example, monitoring and configuration pages for your IIS applications, Windows services, and standalone applications.

Once you instrument your .NET application environment with the AppDynamics .NET Agent, you can start monitoring .NET application performance. See [AppDynamics Essentials](#).

## End-to-End APM for .NET

- [Getting Started](#)
- [.NET Supported Environments](#)
- [.NET Agent](#)
- [Monitor CLR](#)s
- [Monitor Windows Hardware Resources](#)

## Monitor Windows Hardware Resources

This page describes how to monitor Windows hardware resources with the .NET Machine Agent. The AppDynamics .NET Agent includes an embedded .NET Machine Agent that runs as part of the `AppDynamics.Agent.Coordinator` service. The .NET Machine Agent regularly gathers system performance data metrics such as:

- CPU activity

- Memory usage
- Disk reads and writes
- Network traffic
- Percent free disk space and megabytes free

You can view Windows Hardware Resource metrics in the [Metric Browser](#). When IIS is installed on the machine, the .NET Machine Agent also reports IIS, ASP.NET, and ASP.NET Application metrics. See [Monitor IIS](#). The .NET Machine Agent also reports CLR metrics, which are based on performance counters. See [Monitor CLR](#)s.

For applications running on the Windows Azure platform, AppDynamics disables these hardware resource monitoring and machine agent features:

- CLR crash reporting
- Machine snapshots
- Performance counter metrics

## Manage the .NET Machine Agent

You can manage the .NET Machine Agent in the Controller under **Settings > AppDynamics Agents** on the Machine Agents tab.

- To enable or disable all the machine agents, including the Machine Agent, for a business application, click **Enable Agents** or **Disable Agents**.
- To enable or disable an individual .NET Machine Agent, right-click the agent and click **Enable Selected Machine Agent** or **Disable Selected Machine Agent**.

Disabled agents maintain a 'heartbeat' connection to the Controller so you can enable it again. The agent persists its enabled/disabled state even after a restarted.

- To reset a .NET Machine Agent, right-click the agent and click **Reset Selected Machine Agent**. The reset operation purges all existing metrics for the agent. The agent restarts and begins gathering metrics again.

## Machine Agent Tier

Immediately after you install and configure the .NET Agent, the .NET Machine Agent registers with the Controller and starts reporting performance data.

Frequently the machine agent metrics reach the Controller before the app agent has had time to instrument and register IIS applications, Windows services, or standalone applications. If there are no application tiers, then the machine agent registers as the Machine Agent tier.

Once the app agent begins reporting metrics for configured application tiers, the .NET Machine Agent reports to the application tiers and stops sending data to the Machine Agent tier. If you do not instrument any IIS applications, Windows services, or standalone applications on the server, the .NET Machine Agent always reports to the Machine Agent tier.

If you install the Machine Agent, a Java application, in a .NET environment, then you can add custom monitors and extensions such as the HTTP listener. See [Configure the .NET Machine Agent](#).

## Machine Snapshots for .NET

Sometimes environmental conditions cause trouble on the machines where your application runs. Issues that occur outside monitored application code don't show up on [transaction snapshots](#). Machine snapshots

provide critical details about CPU usage, memory usage, and the IIS queue on a server at a specific moment in time. Use the data in machine snapshots to uncover and resolve environmental problems.

AppDynamics generates machine snapshots to capture the state of a server at a specific moment in time. The machine snapshots show the processes running on the machine, the IIS application pool activity, and any related transaction snapshots. By default the .NET Machine Agent takes machine snapshots under these conditions:

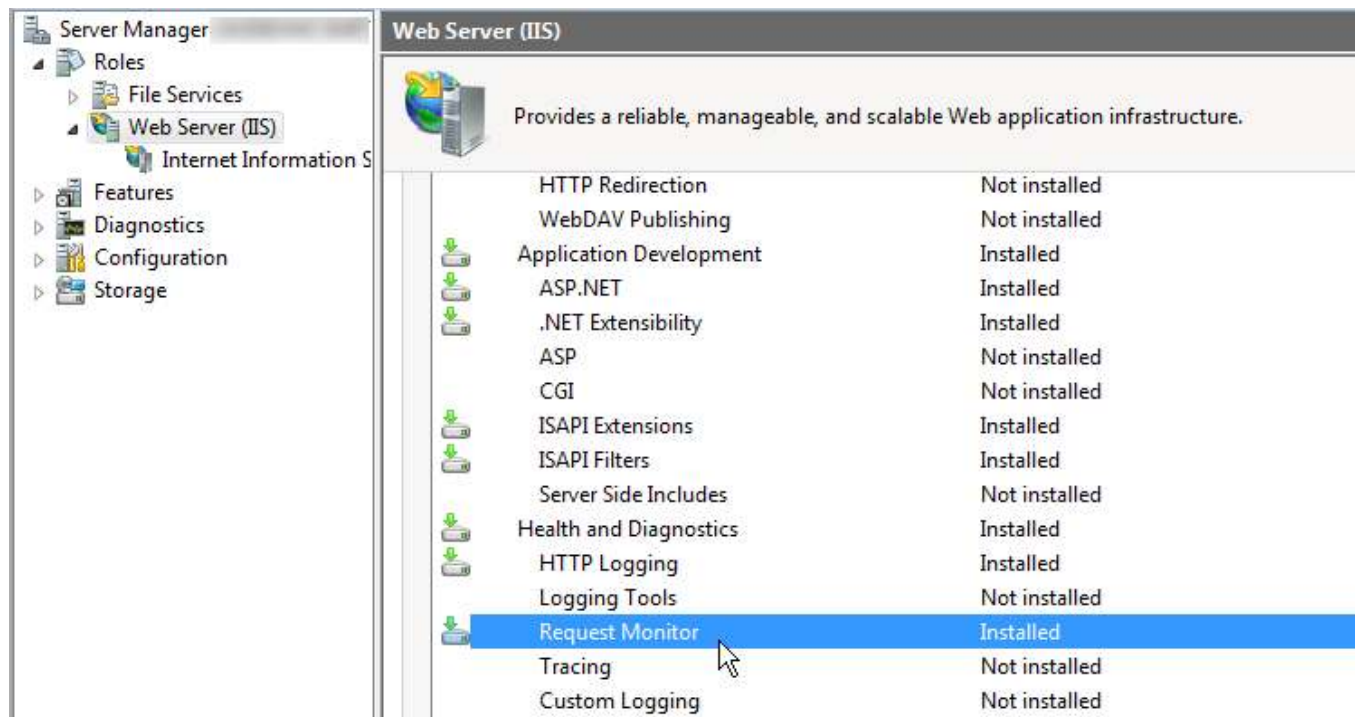

- Periodic collection: The agent takes one snapshot every 10 minutes.
- Breached thresholds: The .NET Machine Agent takes samples of machine statistics every 10 seconds within a 10-minute window. For each sample, the agent checks the CPU percent usage, the memory percent usage, and the oldest item in the IIS application pool queue. The agent flags a sample as a violation when the current usage meets or exceeds one of these thresholds:
  - CPU at 80% or higher
  - Memory at 80% or higher
  - IIS application pool queue item older than 100 milliseconds

The agent takes a snapshot when it identifies 6 violations of a single type, such as CPU usage, within the window. The agent only takes one snapshot per window for breached thresholds.

To customize the periodic collection or threshold settings, see [Configure Machine Snapshots for .NET](#).

### Before Starting

The .NET Machine Agent requires  $\geq$  IIS 7 to return machine snapshot data for IIS application pools. Additionally, you must enable the **Request Monitor** for the **IIS Health Monitoring** feature.

To enable Request Monitor from the Windows PowerShell command line, launch PowerShell as an administrator and run this command:

Install-WindowsFeature Web-Request-Monitor

## Work With Machine Snapshots

The Machine Snapshot tab on the Application dashboard lists all the snapshots for the selected time range. Entries for individual snapshots show:

- Time the .NET Machine Agent took the snapshot
- Machine name for the snapshot
- Snapshot trigger, either periodic snapshot collection or threshold exceeded
- Percent CPU usage
- Percent memory usage

Use **Filters** to limit the snapshot list to a specific snapshot trigger:

- Periodic collection
- Memory events
- CPU events
- IIS events
- Machines where the agent took snapshots
- Archived snapshots

Double-click a snapshot to open the Machine Snapshot panel:

- The Processes tab shows information similar to that from the Windows Task Manager, including:
  - Process ID
  - Process name
  - Process description
  - Percent CPU used by the process
  - Percent memory used by the process

Click a column heading to sort by the column. For example, click **CPU %** and sort descending to identify processes using the most CPU.

The screenshot shows the 'Machine Snapshot' panel with the following details:

- Snapshot Summary:**

SNAPSHOT TYPE	TIMESTAMP	MACHINE	CPU %	MEMORY %
CPU	07/23/2014 04:33:07 PM	W2K8VMCSMITH	100	72
- Navigation:** Processes (selected), IIS App Pools, Transaction Snapshots
- Text:** The following processes were executing on the machine when this machine snapshot was taken:
- Process List Table:**

Process ID	Process Name	Process Description	CPU %	Memory (in MB)
5232	consume	XXX program	96	13
1596	erl	erl	1	44
2036	dllhost#1	COM Surrogate	1	121
4	System	System	0	0
256	smss	Windows Session Manager	0	0
344	csrss	Client Server Runtime Process	0	2
396	wininit	Windows Start-Up Application	0	1

- The IIS App Pools tab shows information on the active IIS application pools:
  - Application pool name

- Arrivals to the queue per second
- Queue requests processed per second
- Age of the oldest item in the queue
- The Transaction Snapshots tab displays all [transaction snapshots](#) involving the current machine for five minutes prior to and five minutes after the machine snapshot. This demonstrates how current environmental factors are affecting your business transaction performance. For example, when CPU usage is high, you may discover slow and stalled transactions. Double-click a transaction snapshot to open it.

## Monitor CLR's

This page describes how to monitor CLR's with the .NET Machine Agent. The AppDynamics .NET Agent includes the .NET Machine Agent that runs as part of the AppDynamics.Agent.Coordinator service. The .NET Machine Agent regularly gathers CLR performance data and reports it back to the Controller.

### CLR Events

The .NET Machine Agent monitors for CLR shutdown and restart events:

- The agent reports an App Server Restart event and indicates if the restart was graceful or not.
- For non-graceful shutdown, the agent reports a [CLR Crash](#) if it detects one.

The default exit code for a graceful shutdown is "0". If your Windows service or standalone application uses a different exit code, see "Profiler - Successful Exit Code Element" on [.NET Agent Configuration Properties](#).

### CLR Metrics

CLR metrics provide insight into how the .NET runtime is performing. There metrics are collected from [Windows Performance counters](#). The AppDynamics preconfigured CLR metrics include:

- .NET CLR memory usage
- Total classes loaded and how many are currently loaded
- Garbage collection time spent, and detailed metrics about GC memory pools and caching
- Locks and thread usage
- Memory heap and non-heap usage, including the large object heap
- Percent CPU process usage

### .NET Core CLR Metrics

.NET Core metrics are collected from [.NET EventCounters](#) within the running process. The following EventCounters collected for .NET Core:

- Percent CPU process usage
- Memory heap and non-heap usage, including the large object heap
- Garbage collection time spent, and detailed metrics about GC memory pools and caching

 This is supported in .NET Core 3.1 and above with all .NET Agents (Azure, MSI, Microservices, etc.) when instrumenting .NET Core applications.

### CLR Health Alerts

You can set up health rules based on infrastructure metrics. Once you have a health rule, you can create specific policies based on health rule violations. One type of response to a health rule violation is an alert.

In addition to the default metrics, you may be interested in additional metrics. You can specify additional performance counters to be reported by the .NET Machine Agent. See [Manage Windows Performance Metrics](#).

## Monitor CLR Crashes

This page describes monitoring for CLR crash events. The .NET Machine Agent monitors Windows for non-graceful CLR shutdowns on IIS, Windows services, and standalone applications. The agent raises [CLR crash events](#) in the Controller when such crashes occur. Use a policy to alert responsible parties when the agent reports a CLR crash.

### Monitor for CLR Crash Events

Create a policy that sends notifications when a CLR crash event occurs.

1. Verify your **Email / SMS Configuration**. See [Enable an Email Server](#).
2. Create a notification action configured to alert the parties who respond to CLR crashes. See [Notification Actions](#).
3. Create a policy to trigger on **CLR Crash** under **Other Events** on the Create Policy panel. For the action, choose the notification action you created in step 2. See [Configure Policies](#).

After you create the policy, the Controller sends a notification when the .NET Machine Agent raises CLR crash events.

### Analyze and Respond to CLR Crashes

When a CLR crashes, the .NET Machine Agent raises an event in the Controller. The events page on the application dashboard displays the number of server crash events, including CLR crashes, during the selected time range.

1. Click the **Server Crashes** link in the application dashboard to display a list of all server crash events during the selected time range.
2. Optionally filter on the **CLR Crash** event type.  
Entries for individual CLR crashes display information about the crash event, including the process ID and the Windows event log ID.

**i** After a CLR crash, IIS automatically tries to restart the CLR, so one issue frequently causes multiple CLR crash events.

3. Double-click a CLR Crash type event to display more information in the **CLR Crash** panel:
  - The Summary tab shows the Windows process ID of the w3wp process that crashed and the Windows event log ID for the crash. The summary also includes the affected tier and node names.

**i** If multiple tiers have nodes on the same machine, you may see more than one tier in the CLR Crash window.

- The Details tab displays essential information about the crash.
- The Actions Executed tab shows any actions the event triggers. See [Monitor for CLR crash events](#).
- Read and add new comments on the Comments tab. For example, you can add a comment to the CLR crash event to notify colleagues that of the issue.

### Disable CLR Crash Event Reporting

The .NET Machine Agent enables CLR crash event reporting by default. To disable it:

1. Edit the agent `config.xml` as an administrator. See [Where to Configure App Agent Properties](#).
2. Set `enabled="false"` for the CLR Crash Reporting element. See [CLR Crash Reporting Element](#).
3. Restart the `AppDynamics.Agent.Coordinator` service.

## Crash Events Monitored by the .NET Machine Agent

The .NET Machine Agent listens on these Windows event logs for crash events:

- Application Log
- System Log

The agent listens for events logged at event-level `Warning` and higher on these sources:

- Application Error
- .NET Runtime
- WAS (Windows Process Activation Service)

The agent listens for events logged at event-level `Information` and higher on this source:

- Windows Error Reporting

The agent reports CLR crashes as events to the Controller:

- All `w3wp` process crashes
- Instrumented Windows service crashes
- Instrumented standalone application crashes

The Controller treats all events as `Warning` severity, which is not directly related to the Windows event level.

## Object Instance Tracking for .NET

This page describes how to enable object instance tracking on a node. When you enable object instance tracking on a node, AppDynamics analyzes the heap to identify classes with the most instances on the heap. AppDynamics tracks the top 20 .NET framework classes and the top 20 application classes based on the number of instances. Use object instance tracking to identify memory usage trends in classes with a large number of instances.

### Permissions

To enable object instance tracking, you need one of these permissions:

- Configure Memory Monitoring
- Configure Agent Properties

See [Manage Custom Roles](#).

### Limitations

Object Instance Tracking is not supported on Windows Nano.

### Prerequisites

- If you are not using MSI for the agent installation, make sure you copy the following files.
  - On Linux: `AppDynamics.HeapDump.Library.dll`
  - On Windows: `AppDynamics.HeapDump_x86.dll` and `AppDynamics.HeapDump_x64.dll`
- On Linux, ensure that applications have the required permission to perform `ptrace` calls. In Docker Linux containers, the following command argument will enable the `SYS_PTRACE` capability.

```
--cap-add SYS_PTRACE
```

## Enable Object Instance Tracking on a Node

1. From the [node dashboard](#), click the **Memory** tab.
2. Click the **Object Instance Tracking** tab.
3. Click **ON**.

When the agent completes the heap analysis, AppDynamics begins to track the top 20 application classes and the top 20 system (Core .NET) classes in the heap.

When you enable object instance tracking, the .NET application pauses during heap analysis and cannot process requests. Enable object instance tracking while you diagnose memory issues, and turn it off when you finish troubleshooting.

## Identify Memory Usage Problems

Use these guidelines to identify memory usage problems:

- The Controller resolution for object instances is one minute, but the .NET Agent only sends data every ten minutes, so .NET memory appears as a series of peaks over time.
- It is normal for the Controller to display 0 for the **Current Instance Count** and **Shallow Size** in between instance count collection times.
- Hover over a peak to display information about the instance count.
- Look for trends where the peaks increase in size from left to right which may indicate a memory leak.

## Track Object Instances for Custom Classes

If you want to track a class that does not appear in the top 20 on the **Object Instance Tracking** tab, you can configure a specific class to track.

1. Navigate to **Object Instance Tracking > Configure Custom Classes to Track > Configure Instrumentation > Memory Monitoring**.
2. Click **Add**. The Create New Instance Tracker panel opens.
3. Leave **Enabled** checked.
4. Enter the fully qualified class name for the instance to track.
5. Click **Save**.

## Monitor IIS

This page describes how AppDynamics monitors Internet Information Services (IIS). The AppDynamics .NET Agent includes the .NET Machine Agent that runs as part of the AppDynamics.Agent.Coordinator service. The .NET Machine Agent regularly gathers IIS performance data and reports it back to the Controller as metrics.

### IIS Events

The .NET Machine Agent monitors IIS for shutdown and restart events:

- The agent reports an App Server Restart event and indicates if the restart was graceful or not.
- For non-graceful shutdown, the agent reports a [CLR Crash](#) if it detects one.

---

## Default IIS Metrics for .NET

You must install IIS on the machine to view the metrics for IIS, ASP.NET, and ASP.NET applications. The .NET Machine Agent uses [Microsoft Windows Performance Counters](#) to gather IIS metrics. In the Controller, you can view preconfigured metrics for IIS in the Metric Browser.

### IIS Metrics

From the [Metric Browser](#):

- To view the IIS metrics for a tier, expand **Application Infrastructure Performance** > <Tier> > **IIS**.
- To View the IIS metrics for a node, expand **Application Infrastructure Performance** > <Tier> > **Individual Nodes** > <Node> > **IIS**.

AppDynamics reports each metric for the entire tier, each individual application pool, and each individual node as follows:

- **Application Infrastructure Performance** > <Tier> > **IIS** = combined for all IIS processes in all Application Pools for this tier
- **Application Infrastructure Performance** > <Tier> > **Application Pools** > <application pool name> = combined for all processes in this specific Application Pool
- **Application Infrastructure Performance** > <Tier> > **Individual Nodes** > <Node> = metrics for the specific node

### ASP.NET Metrics

To view the ASP.NET metrics in the [Metric Browser](#), expand **Application Infrastructure Performance** > <Node> > **ASP.NET**.

AppDynamics reports these ASP.NET metrics:

- Application Restarts
- Applications Running
- Requests Disconnected
- Requests Queued
- Requests Rejected
- Request Wait Time
- Worker Process Restarts

### ASP.NET Application Metrics

To view the ASP.NET Application metrics in the [Metric Browser](#), expand **Application Infrastructure Performance** > <Node> > **ASP.NET Applications**.

AppDynamics reports these ASP.NET Application metrics:

- Anonymous Requests
- Anonymous Requests/sec
- Cache Total Entries
- Cache Total Hit Ratio
- Cache Total Turnover Rate
- Cache API Entries
- Cache API Hit Ratio
- Cache API Turnover Rate
- Errors Unhandled During Execution/sec
- Errors Total/sec
- Errors During Preprocessing
- Errors During Compilation
- Errors During Execution
- Errors Unhandled During Execution
- Errors Unhandled During Execution/sec
- Errors Total

- Errors Total/sec
- Output Cache Entries
- Output Cache Hit Ratio
- Output Cache Turnover Rate
- Pipeline Instance Count
- Requests Executing
- Requests Failed
- Requests In Application Queue
- Requests Not Found
- Requests Not Authorized
- Requests Succeeded
- Requests Timed Out
- Requests Total
- Requests/sec
- Session State Server Connections Total
- Session SQL Server Connections Total
- Sessions Active
- Sessions Abandoned
- Sessions Timed Out
- Sessions Total
- Transactions Aborted
- Transactions Committed
- Transactions Pending
- Transactions Total
- Transactions/sec

## Monitor IIS Application Pools

You can monitor the health of IIS application pools for the instrumented .NET nodes in a tier. You can view the information by application pool, machine, and process IDs.

This view enables you to visualize key performance indicators for your infrastructure, such as node health and last CLR restart time.

To view the IIS application pools:

1. In the left navigation pane, click **Tiers & Nodes > Tier dashboard > Nodes** tab.
2. In the Show Data dropdown, select **IIS App Pools**.

 If a machine or application pool name is not available for a .NET node, the .NET Agent creates the "Unknown App Pool" / "Unknown Machine" grouping.

## Monitor Node.js Processes

This page describes how to monitor Node.js processes. The AppDynamics [Node.js Agent](#) helps you monitor Node.js applications in production to determine which applications are slower than normal or producing errors. It also provides tools for troubleshooting application problems so that you can take action before your users experience poor performance.

To access the data, log in to the Controller from a Web browser using your AppDynamics credentials. You can also access the data programmatically using the [AppDynamics REST API](#).

---

## Process Snapshots

The node dashboard for Node.js is similar to the node dashboards for other app agents except that it also includes a Process Snapshots tab, which you use to access [process snapshots](#) for the Node.js process.

In a single-threaded model, such as Node.js, one slow function forces other functions to wait. You can [monitor Node.js processes](#) using lists of process snapshots to identify which functions have high CPU times and which consume a lot of memory. From the list, you can select and examine process snapshots to identify exactly which functions in your code are blocking the CPU or leaking memory.

A process snapshot describes an instance of a CPU process on an instrumented Node.js node. It generates a process-wide call graph for a CPU process over a configurable time range. Process snapshots are independent of any running business transactions.

You can monitor process snapshots at the tier level or the node level.

## Customizations

The Node.js Agent collects several metrics that do not appear in standard dashboards. You can see all the metrics in the [Metric Browser](#), including special metrics related to Node.js processes in **Application Infrastructure Performance > Tier > Node.js**.

You can create custom dashboards that display any of these metrics using a variety of widgets to create a visual display of information customized for specific types of users in your organization: executives, ops, developers, QA and so forth.

You can also create health rules that stipulate certain levels of acceptable performance and then create policies that automatically send an alert or take an automated action when those rules are violated.

## Object Instance Tracking for Node.js

This page describes how to enable object instance tracking for Node.js. The Node.js Agent provides object instance tracking (OIT) for monitoring memory usage. When you enable object instance tracking for a node, the Node.js Agent attempts to identify the object types with the most instances on the heap. The agent tracks the top 20 object types based upon the number of instances. Use object instance tracking to identify memory usage trends in objects with large numbers of instances.

### Enable Object Instance Tracking on a Node

1. In the left navigation pane, click **Tiers & Nodes**.
2. In the **Tiers & Nodes** panel navigate to and select the node that you want to track.
3. Double-click or click **View Dashboard**.
4. In the node dashboard, click the Memory tab.
5. Click the **Object Instance Tracking** subtab.
6. Click **On** to start tracking. After completing the heap analysis, the agent begins tracking the top 20 object types in the heap.
7. When you are finished tracking, click **Off** because tracking can slow down the Node.js process. Use OIT for only for brief periods.

Although the Node.js OIT UI displays "Class" and "Classes" throughout, the Node.js Agent tracks object types, not classes. Substitute "object" for "class" wherever you see "class" for this feature.

## Identify Memory Usage Problems

Use these guidelines to identify memory usage problems:

- The Node.js Agent attempts to report once per minute, but on a heavily loaded, memory-saturated application it could be less often.
- It is normal for the controller to display 0 for the Current Instance Count and Shallow Size between instance count collection times.
- Hover over a peak in the graph to display information about the instance count.
- Look for trends where the peaks increase in size from left to right. These may indicate a memory leak.

## Track Object Instances for Custom Object Types

If you want to track an object that does not appear in the top 20 on the Object Instance Tracking tab, you can configure a specific object to track.

1. In the Object Instance Tracking tab, click **Configure Custom Classes to Track**.
2. In the **Define Custom Classes to Track** panel, click **Add**. The **Create New Instance Tracker** panel opens.
3. Leave **Enabled** checked.
4. Enter the object for the instance to track.
5. Click **Save**. The configured object is added to the objects to track when OIT is on.

## Examine OIT Metrics in the Metric Browser

When enabled, OIT metrics are also reported under the **Application Infrastructure Performance > <tier> > Individual Nodes > <node> > Object Instance Tracking** branch in the Metric Browser.

## Node.js Metrics

This page describes Node.js process metrics that are specific to the Node.js Agent.

You can view the metrics under these paths in the [Metric Browser](#) navigation tree:

- By tier at **Application Infrastructure Performance > <TierName> > Node.js**
- By node at **Application Infrastructure Performance > <TierName> > Individual Nodes > Nodejs\_<NodeName> > Node.js**

## CPU Usage Metric

- CPU Usage: % busy

## Memory Metrics

### Garbage Collection

- Full GC Per Min: Number of full garbage collection cycles per minute that the V8 JavaScript runtime has performed in the selected time range.
- Incremental GC Per Min: Number of incremental garbage collection cycles per minute that the V8 JavaScript runtime has performed in the selected time range.

## Memory

- Heap size changed: Total amount of memory reclaimed by the full and incremental garbage collection cycles (as a percentage) in the selected time range.
- Current usage (V8 heap used in MB): Total size of the heap at the current time point. This reports how much memory the node process is using for data storage.
- RSS: Resident Set Size of the Node process. This reports the amount of memory (heap and stack) allocated for the process and in RAM, not swapped out.

---

## I/O Metrics

### Disk

- KB read per second: KB read from disk per second for the selected time range.
- KB written per second: KB written to disk per second for the selected time range.

### Network

- Incoming: KB/sec received for the selected time range.
- Outgoing: KB/sec sent for the selected time range.

### Socket.io Metrics

- Number of Connections: Number of currently open Socket.IO connections.
- Total Number of Connections: Number of connections that have been opened since the application started.
- Number of Messages Sent/Received: Number of messages that have been exchanged between the application and all connected Socket.IO clients.
- Size of Messages Sent/Received: Average size, in characters, of the messages exchanged. The underlying transport is text only, so non-string messages are JSON.serialized to determine their size.

### Event Loop Metrics

- Average IO Time: Average number of milliseconds per event loop tick spent processing IO callbacks.
- Average Tick Length: Average amount of milliseconds between event loop ticks.
- Maximum Tick Length: Shortest amount of milliseconds between event loop ticks.
- Minimum Tick Length: Longest amount of milliseconds between event loop ticks.
- Tick Count: Number of times the event loop was ticked.

## N|Solid Monitoring Data

This page describes available metrics and data for N|Solid monitoring. N|Solid is an enterprise-grade Node.js runtime produced by Nodesource that provides additional performance metrics about Node.js processes.

### Metrics

When the Node.js Agent is installed on an N|Solid runtime, it collects these additional metrics and makes them available in the Controller so you can use them to diagnose latency issues and memory leaks.

You can view the metrics under these paths in the metric browser navigation tree, by node at **Application Infrastructure Performance > <TierName> > Individual Nodes > Nodejs\_<NodeName> > Node.js**.

- NSolid -> 1-minute, 5-minute, and 15-minute load average
- NSolid -> System Uptime & Process uptime (ms)
- NSolid -> Memory -> JS heap -> Total Usage (MB)
  - The amount of the heap that is being used by JavaScript.
- NSolid -> Memory -> V8 heap -> Total Available (MB)
  - Total memory available to the V8 heap.
- NSolid -> Memory -> Total Available (MB)
  - Total memory available to the process.
- NSolid -> Memory -> Total Size (MB)
  - Total memory used by the process.
- NSolid -> Event Loop -> Active Handles:
  - The number of active handles the event loop will process. Handles tend to be longer-lived larger-scale asynchronous operations, such as open sockets or timers. An uptick in this metric could indicate a possible memory leak.
- NSolid -> Event Loop -> Active Requests:
  - The number of active requests the event loop will process. Requests tend to be shorter-lived smaller-scale operations such as writing to file handles and other file-related operations. This metric provides additional insight into load characteristics.

- NSolid -> Idle Percent:
  - Time spent waiting for I/O and not running Javascript.
- NSolid -> Estimated Lag
  - Average amount of time a I/O response may have to wait before being processed.
- NSolid -> Loops Per Second
  - Number of executions per second of the libuv event loop.
- NSolid -> Average Tasks:
  - Number of asynchronous Javascript tasks per turn of the loop.
- NSolid -> Total Count:
  - Total number of event loop turns.

## Process Snapshots Data

You can view details on asynchronous activities in the Node.js event loop for N|Solid processes in **Process Snapshots > Async Activity**. These event loop activity categories display in Async Activity:

- Active Handles: active handles that the event loop will process
- Active Requests: the number of active requests the event loop will process
- Pending: lower level asynchronous activity

This information displays for each property:

- Type: The property type (e.g., TCP socket connection, setTimeout)
- Location: The source location associated with the activity, when available

## Remote Services

This page describes the monitoring information available for remote services, also known as backends.

### What is a Remote Service?

A remote service is a process that resides outside of the application server and provides a service to the application. An example of a remote service is a web service, message queue, or caching server.

AppDynamics automatically detects many common types of remote services when instrumented nodes make outbound requests. For more details on backend support by app agent type, refer to the supported environments page for your agent type under [Install App Server Agents](#), such as [Java Supported Environments](#).

To monitor call performance to a service, first make sure it shows up in the remote services list, which you can access by clicking the **Remote Services** link in the Applications menu. If a service you expect to see listed does not appear in the list, make sure the backend detection configuration is configured appropriately for your environment, as described in [Backend Detection Rules](#).

### Monitoring Information for Remote Services

AppDynamics monitors the overall performance of calls to a remote service, as well as the performance of those calls from within specific business transactions.

Metrics for remote services are presented in the Controller UI in the following locations:

- Business transaction metrics: The Transaction flow map shows the metrics for a specific business transaction for a specific service
- Tier metrics: The Tier flow map shows the metrics for all calls from a tier to the specified service

- Remote service metrics: The Application flow map and the Remote Services Dashboard show the overall remote service metrics across the application (all business transactions)

## Remote Services Health Rules

You can create health rules to monitor the parameters that represent the normal or expected operations for your remote service. The parameters rely on metric values, for example, the average response time. When the performance of a remote service violates the conditions set by a health rule, a health rule is violated. Alerts notify you of any violation and initiate remediation actions to mitigate the violation event. It is important that you configure alerts appropriately to ensure that you do not miss any alerts or receive false alerts. Alert Sensitivity Tuning (AST) helps you configure alerts with appropriate sensitivity. AST provides historical data for the metric or the baseline being configured and hence helps you visualize the impact of the alerting configuration. To create a health rule to monitor remote service parameters and fine-tune the sensitivity of the health rule using AST, see [Create a Health Rule and Fine-tune Metric Evaluation](#).

## View Remote Service Performance on Flow Maps

Remote services detected during the specified time window appear on the Application Dashboard flow map. You can view the detected services in the context of the entire application's transaction flow. The application flow map displays calls per minute and average response time for calls made to remote services. These metrics include all calls made from a specific tier to a service across all business transactions. The tier and node flow maps display the same metric in their respective contexts.

The detected remote services show up on the Tier dashboard flow map. You can view the detected services in the context of the traffic on this specific tier.

For business transactions involving calls to remote services, the services appear on the Business Transaction dashboard flow map. You can view the detected services in the context of the traffic for this specific business transaction. The transaction flow map shows the average time spent in remote service calls for the business transaction. See [Flow Maps](#).

## View Discovered Remote Services

The Remote Services list shows all detected remote services along with key performance indicators. Services that are not active are removed after a configurable time period. See [Stale Remote Service Removal](#).

From the Remote Services list, you can select a service and click **View Dashboard** to see the Remote Service Dashboard. The dashboard displays a Database Flow Map, backend properties, and graphs of the key performance indicators (KPIs). The properties indicate how the service is identified and determine how it shows in the flow map and how the metrics are aggregated. For a discussion of baselines and how they are used and configured, see [Dynamic Baselines](#).

The Remote Services Dashboard has two tabs and an action option menu:

- Dashboard: Displays the flow map showing traffic from the calling tier to the remote service, the backend properties used for auto-detection and naming, and key performance indicators.
- Slowest Remote Services Calls: Lists up to ten calls to the service with the longest execution time, by tier and for all tiers.
- From the Action menu, you can also rename a backend, delete a backend, or [resolve a backend to a tier](#).

## Slow Remote Service Calls

AppDynamics displays a list of the slowest remote service calls with call details. Click **Troubleshoot > Slow Response Times > Slowest DB & Remote Service Calls** tab to view specific call details and related business transaction snapshots that can help you to troubleshoot.

The Slowest DB & Remote Service Calls tab lists up to ten calls to a remote service with the longest execution time over the selected time frame, by tier and for all tiers, and relevant metrics.

**Max Time** determines which calls are displayed in the **Slowest DB & Remote Service Calls** list. **Max Time** must exceed 50 ms before AppDynamics tracks the call as a potential candidate for this list. App agents aggregate and report call data to the Controller every 15 minutes.

**i** If Query, Queue, or URL are not specified in the custom exit call, the details for the slowest service call will not be displayed.

## Data Resolution and Retention

Depending on the period of time you're viewing in graphs, how old the data is, and the resolution of the data for slow remote service calls, graphs may display data at a granularity of 5 minutes, 1 hour, and 12 hours. The table below shows the data retention for each data resolution period.

**i** For each day, there are two 12-hour data intervals [00:00 GMT, 12:00 GMT] and [12:00 GMT, 00:00 GMT].

Data Resolution	Data Retention
5 minute	6 hours
1 hour	3 days
12 hours	14 days

For the data resolution and retention for other metrics in the Controller, see [Metric Data Resolution over Time](#).

## Stale Remote Service Removal

A stale remote service is a service for which AppDynamics has previously captured metrics, but which has experienced no metric activity for a certain time period. If a backend is not called for 30 days (in other words, the call per minute metric is zero for 30 days) AppDynamics considers it a stale backend and removes it as a monitored artifact.

After a backend is removed, its metrics no longer appear in the Metric Browser and health rules that reference those metrics do not fire. You should remove any health rules conditions that reference metrics in stale backends.

For an on-premises Controller, you can configure the interval by setting the `backend.permanent.deletion.period` property in the [Administration Console](#). Reducing the period may be advisable for large installations, since the maximum number of backends removed in one pass is 50. The minimum interval is one week. Alternatively, you can disable automatic removal by setting the interval to 0.

## Group Remote Services on Flow Maps

You can group remote services—or backends—in the flow map configuration to have two or more services of the same type to appear as a single icon in the flow map.

Backend grouping can improve readability and the focus of the flow map, for example, if individual databases or remote service instances are not important to the flow map users.

The following screenshot shows grouped databases on a flow map:

If you want to ungroup backends on a flow map, right-click the backend group and choose **Ungroup Backends**.

Grouped backend services must meet the following conditions:

- All backends must be of the same type
- All backends are called by the same tiers
- No backend in the group calls other backends or calls into other tiers

The following example shows the scenarios in which a set of backends could be grouped.

You can configure backend grouping in the Databases & Remote Services tab of the [Configure Flow Map](#) dialog.

You can set a few parameters around grouping, such as the minimum number of backends must be present before they are grouped. For example, if you set the minimum to 4 and only three backends are detected, they are not grouped.

You can exclude a specific backend server from ever being grouped by the flow map, regardless of the grouping configuration, by checking the **Ungroupable** checkbox for that backend in the Visibility and Grouping list.

If there are specific database or remote services that you do not want to see or group in the flow map, check the **Hidden** or **Ungroupable** check box.

## Monitor Databases

AppDynamics can monitor the performance of database calls made by instrumented applications.

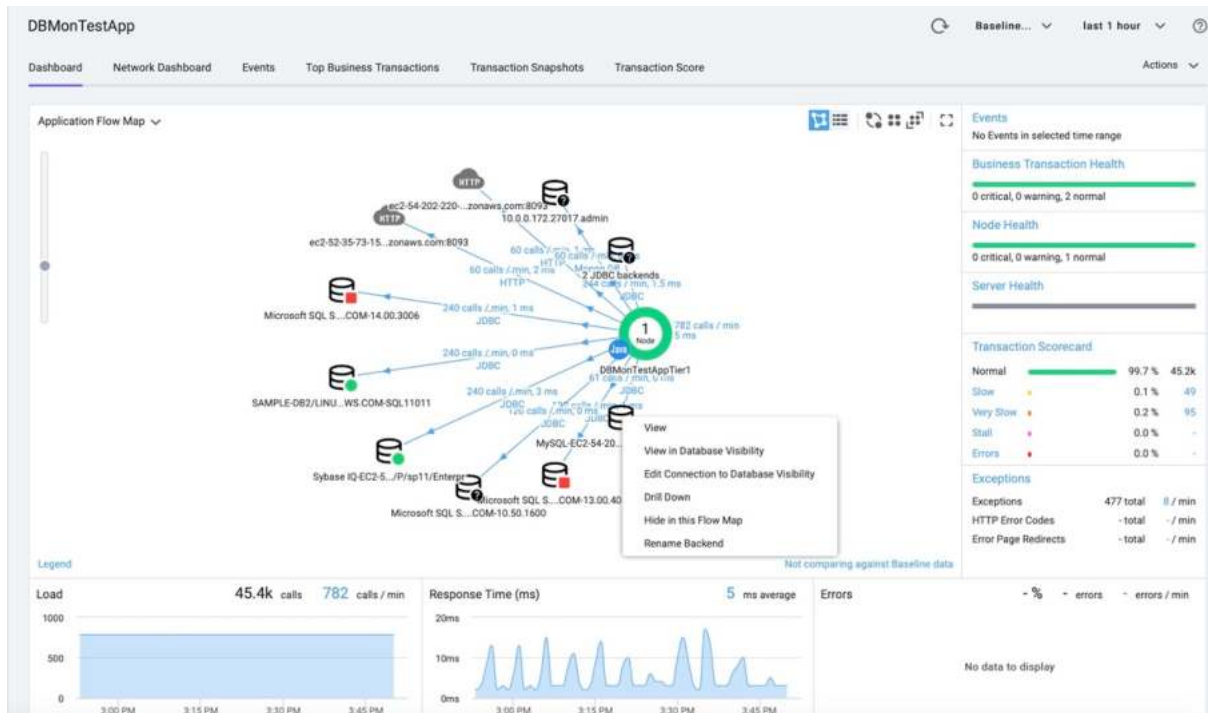

### Measure Database Performance

AppDynamics collects metrics for database calls and response times at the following levels:

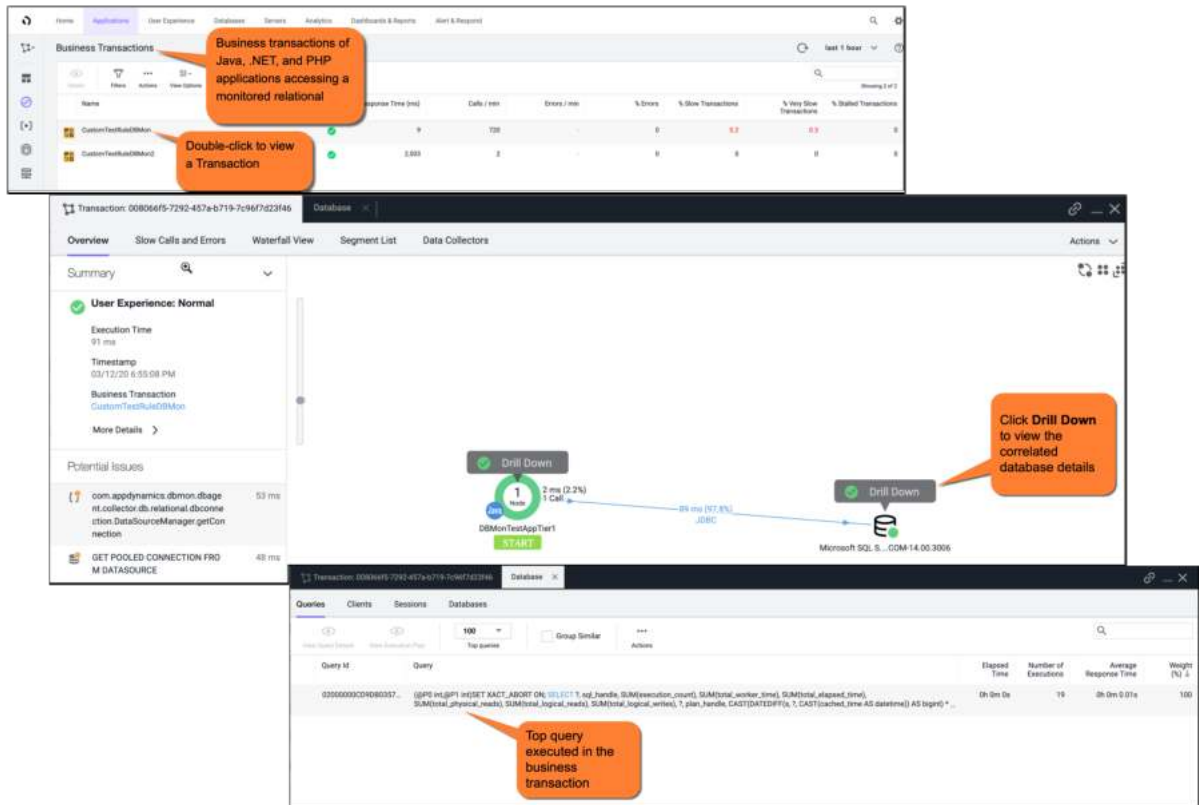

- Business transaction metrics: The metrics for a specific business transaction for a specific database are visible on the transaction flow map.
- Tier metrics: The metrics for all calls from a tier to the specified database are visible on the tier flow map.

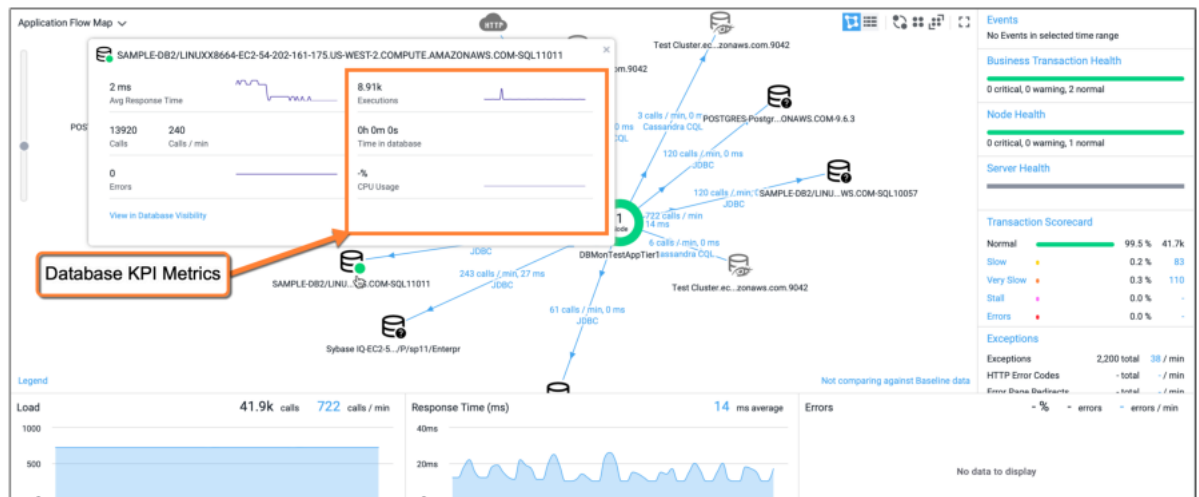

- Database call metrics: The overall database access metrics across the application (all business transactions) are visible on the application flow map and the Database Calls dashboard.
- Integrated database metrics with **Database Visibility**:
  - When a database Collector has been set up in AppDynamics **Database Visibility**, you can link to that product from the Application and Database Calls dashboards. If you have already associated the database server with a Database Collector in Database Visibility, you can view the **Database Visibility** UI. If not, the disconnected database icon is displayed and you are prompted to link the database to an already configured server or cluster in **Database Visibility**. Also, you must have view permission to the corresponding collector configured in **Database Visibility**, to map/un-map it with the database server or cluster.

- A relational database backend of a Java application has the same hostname, port number, and database type as a database server already configured in a database Collector. The Oracle backend is automatically matched with the corresponding **Database Visibility** Collector. The Snapshot correlation view, which is available for relational database backends, shows the details of queries, clients, sessions, and schemas when the snapshot was captured.

- When a backend database is linked to a server or a cluster in **Database Visibility**, clicking the database icon displays basic details with a link to **Database Visibility** UI. You can also view the database KPI metrics.

By default, many databases and data stores are automatically detected when calls are made from nodes instrumented with AppDynamics app agents. See [Access Database Visibility from Application Monitoring Views](#).

To monitor call performance to a database, confirm that it appears in the Databases Calls list and has its own Database Calls dashboard. If a database is not appearing, check the configuration.

The database icons on the flow maps help you identify the status of the database. The following table lists the different database icons:

Database Icon	Status
	The database is healthy. No active health rule violations
	Health Rule Violation - Critical Condition
	Health Rule Violation - Warning Condition
	The database is either not linked to the appropriate server or cluster node. This icon also appears when the database is in the process of changing the state.
	The database is not connected to the server or cluster in <b>Database Visibility</b> . Click the database icon, then the <b>Connect</b> link to link the database backend to the appropriate server or cluster.

### View Database Performance on Flow Maps

Databases detected during the specified time window show up on the Application Dashboard flow map, where you can view them in the context of the entire application's transaction flow. The application flow map displays calls per minute and average response time for calls made to databases. These metrics include all calls made from a specific tier to a database across all business transactions. The tier and node flow maps display a similar metric aggregating data from calls across all business transactions by tier or node respectively.

The detected databases appear on the Tier Flow Map, where you can view them in the context of the traffic on this specific tier.

For business transactions involving calls to databases, the databases appear on the Transaction Flow Map, where you can view them in the context of the traffic for this specific business transaction. The transaction flow map shows the average time spent in database calls for the business transaction.

### Drill Down on Database Performance

In addition to seeing monitored databases in the flow map, you can view:

- Business transactions that make the most database calls. To see this, navigate to Database Business Transactions panel.
- Queries executed the most number of times by business transactions. To see this, double click on the business transaction and open the DB Queries tab.

## Resolving Unexpected Databases on the Flow Map

AppDynamics can sometimes reveal unexpected connections from an application to a database on the flow map. If this occurs for you, try the following to determine why this database appears:

- From the left navigation menu, select **Tiers & Nodes > Databases**. Select the Slowest Database Calls tab and drill down into the snapshots to see the code that is calling the database. See [To troubleshoot slow database and remote service calls](#).
- Run a diagnostic session to capture some transaction snapshots and look for calls to the database. See [Diagnostic Sessions and Transaction Snapshots](#). If you have integrated AppDynamics for Databases, you can select a transaction snapshot that involves running SQL on an Oracle database and from the Transaction Flow Map you can link to AppDynamics for Database to see all queries executed in the SQL session that are associated with that transaction snapshot. See [Use AppDynamics Pro with AppDynamics for Databases](#).
- Are any exceptions thrown when the database is seen? If so, look for error snapshots that point to the exception trace.

## View Discovered Databases

The database list shows all detected databases along with key performance indicators. Stale databases can be configured to be automatically removed.

From the database list, you can select a database and click **View** to see the Database Calls dashboard. The dashboard displays a Database Flow Map, database properties, and graphs of the key performance indicators (KPIs). The database properties indicate how the agent identifies the database and control how it shows in the display map and how the metrics are aggregated. For a discussion of baselines and how they are used and configured, see [Dynamic Baselines](#).

The database dashboard has two tabs and an action options menu:

- **Dashboard**: Displays the flow map showing traffic from the calling tier to the database, the backend properties used for auto-detection and naming, and key performance indicators.
- **Slowest Database Calls**: Lists up to ten calls to the database with the longest execution time, by tier and for all tiers. See [Slow Database Calls](#).
- The Action menu provides additional actions:
  - **Rename Backend**: Renames the database.
  - **Resolve Backend to Tier**: Associates the database with the tier that you select so that the backend appears in the grid view of the tier and not as an independent component ("unresolved backend") on the application dashboard flow map. You can reverse this operation from the **Configure Backends resolving to this Tier** item in Actions menu in the Tier dashboard.
  - **Delete Backends**: Removes instances of the database from the controller and all agents. An agent can re-discover the database and register it with the controller.

You can access the Database Server List by clicking **Servers > Databases**. See [Backend Detection Rules](#).

## Slow Database Calls

AppDynamics displays a list of the slowest database calls. For each call, you can view specific call details and related business transaction snapshots. The list shows up to ten database calls with the longest execution time over the selected time frame, by tier and for all tiers. Each call shows:

- **Call**: SQL Query
- **Avg. Time per Call (ms)**: the average time per call in milliseconds
- **Number of Calls**: the number of calls executed during the time range
- **Max Time (ms)**: the maximum execution time in milliseconds
- **View snapshots**: a link to view existing transaction snapshots

App agents aggregate and report call data to the Controller every 15 minutes. **Max Time** determines which calls are displayed in the **Slowest Database Calls** list. For example for JDBC calls, **Max Time** must exceed 10 ms before AppDynamics tracks the call as a potential candidate for this list.

Slowest database calls are defined as:

- Max Time greater than 10 ms
- Top ten slowest
- Reported every 15 minutes

## View Slowest Database Calls

To view slowest database calls, click **Troubleshoot > Slow Response Times > Slowest DB and Remote Service Calls**.

On this page, you can do the following:

- If transaction snapshots are available for a call, you can click the **View Snapshots** link in the **Snapshots** column to select a snapshot and drill down to the root cause of the slowness.
- You can view explain plans by selecting a call and clicking **View Details**. In the dialog box, click **Explain Plans**. If parameter values are filtered out from the captured SQL, the Explain Plan feature is disabled.

### NoSQL

AppDynamics displays NoSQL databases as Remote Services. See [Remote Services](#).

## Resolve Remote Services to Tiers

Resolving remote services to a tier can put the metrics for the services into an element of the AppDynamics application model that may provide a more useful view of the activities of the services in flow maps.

The tier may already exist in the business application model or you can create a new one. If it exists, after you resolve the backend to a tier it no longer appears as a backend icon in the flow maps.

AppDynamics automatically resolves some backends to tiers. In general, these are custom backends or HTTP, RMI, Thrift or web services, which are usually logically linked to a tier. If you want to see the backend on its own, you can unresolve it to display it on the flow map.

### When to Resolve Backends to a Tier

You may want to resolve a backend to a tier if it represents a more logical view of your environment, for example, if a database runs on the same machine as an application server. Another reason to resolve backends to a tier is to combine similar backends.

For example, if there appear to be multiple databases that are actually the same database using different namespaces, the default flow map is likely to display the databases separately. You can resolve the database backends to a new tier of type "Database Server" so they display as one and the tier metrics are together. If a backend is taken out, the historical data for the backend is retained at the tier level.

### Resolving Backends to Tiers

You can resolve a backend to a tier from the backend's dashboard page, either its Remote Service Dashboard or Database Dashboard. In the database dashboard, from the **Actions** menu, click **Resolve**

---

**Backend to Tier** and select an existing tier or create a new one. Similarly, you can see backends that are associated with a tier and unresolve a backend from the action menu for the Tier dashboard.

Deleting the backend from the tier causes it to re-appear as an unresolved backend in the flow map or resolve it to a different tier.

## Information Points

This page describes information points in AppDynamics. You can use information points to define custom metrics based on methods you configure. Information points are similar to data collectors; while data collectors show application data in the context of a business transaction, information points reflect data state across all invocations of a method, independent of business transactions. You can also apply computations to the values, for example, representing the sum or average for a method return value or input parameter.

To create, edit, or delete information points, you need the **Configure Information Points** permission.

---

### Information Point Data: Code Metrics and Business Metrics

When you configure an information point, you automatically receive the KPI metrics (called *code metrics*) for the information point method.

The code metrics are:

- Total call count
- Calls per minute count
- Errors per minute
- Average response time

You can supplement the KPI metrics with custom business metrics for the information point.

Business metrics reflect the value of runtime data, such as the method parameter, return value, or a value captured by getter chain on the object on which the identified method was invoked. The business metric value represents either the sum or average of the values of the code point you identify as the information point.

Information points can give you significant insight into how the performance of an application corresponds to business performance. For example, depending on the nature of your application, you could use it to resolve business questions such as:

- What is the average value of the credit card total?
- How many credit cards did my application process in a certain time period, regardless of the business transaction?
- What was the average time spent processing a credit card transaction?

A example of a practical use of an information point is ignored exceptions. Exceptions, especially one that occurs frequently, can contribute to CPU spikes in a JVM. If you configure the exception to be ignored in AppDynamics, for example, if it is generated in the underlying application framework and does not have a direct bearing on your application performance, it may not be readily evident to you when the exception is affecting your application. An information point that counts the exception occurrence can help you identify the additional overhead.

## Creating Information Points

To create information points, see [Java and .NET Information Points](#) and [PHP Information Points](#).

## Viewing Information Point Data

You can view information point values in various places in the Controller UI, including the following:

- Information Points page: The primary page for viewing and administering information points is the **Information Points** page. From there, click on an information point to view a histogram of the metrics for the information point for the selected time period.
- Metric Browser: The metrics also appear in the Metric Browser under the Information Points folder.
- REST API: Business metrics can be accessed from the [AppDynamics REST API](#).
- Business Transaction Snapshots: Information point data does not appear in transaction snapshots by default, but you can configure it to appear by setting the `enable-info-point-data-in-snapshots` node property to `true`. When the `enable-info-point-data-in-snapshots` node property is set, information point calls appear in the User Data section of the snapshot. See [App Agent Node Properties](#).

## Java and .NET Information Points

Applies to:

This page describes how to create information points for Java and .NET applications. For PHP-based information points, see [PHP Information Points](#).

### Before Starting

You must be logged in to the Controller as a user with Configure Information Points permissions. See [Create and Manage Custom Roles](#).

### Create an Information Point from a Transaction Snapshot

You can create an information point from the call graph of a transaction snapshot that includes the method.

When you locate an invocation of the method in the call graph, right-click it and select the option to configure instrumentation on this class or method. Your selection creates an information point

### Create and Manage Information Points Manually

You can create, view, and modify information points on the **More > Information Points** page.

To create an information point, you must specify the class and method for which you want to collect information, along with other identifying information. For details on using the UI to configure code matching for an information point, see [Data Collectors](#).

Information points are evaluated based on the execution of the method on which they are placed. Any match conditions apply to the state of the data at that time.

To collect business metrics from the method, from the **Edit Information Point** page, select **Add** to add a custom metric for the information point. You can configure and customize the type of data you want to collect for business metrics. Select **Save** when you are finished.

## PHP Information Points

This page describes how to define information points for PHP applications.

[Information points](#) reflect key performance metrics and custom metrics for methods and code data points that you configure.

### About PHP Information Points

To create an information point for PHP:

1. Define the information point using JSON notation.
2. In the definition, specify the method for the information point
3. Optionally, specify a point in the code that you want to capture as a custom metric, such as a parameter value or return value.
4. Navigate to **More > Information Points** and add an information point.
5. Choose **PHP** as the agent type and then paste the definition into the information point text box.

The elements of the definition correspond to configuration options available in the **Add Information Point** dialog for Java or .NET applications.

However, for PHP, the information point is defined in JSON syntax, and there are a few limits on configuration options. For one, class matching is limited to classname-based matches only. (Superclass matching or annotation matching are not available.) Also, you can only define a single match condition on a matched method. (A match condition refines the match of a method by testing a parameter or return value.)

If you do not configure a custom metric, the information point captures the generic KPIs for a matched method (response time, calls and calls per minute, errors and errors per minute). Custom metrics extend the information point by capturing the return or parameter value of a method, or the value of an invoked object.

### Before Starting

To create information points in the Controller UI, you need to be logged in as a user with **Configure Information Points** permissions. See [Manage Custom Roles](#).

### Method Match Conditions

A match definition specifies the method associated with the value you want to capture as an information point. The match definition must specify the method, but it may also specify the containing class and a refining match condition. The match condition can test the value of a method parameter, return value, or the return value of an invoked object.

Use this template to create a match definition:

```
{
 "probe": {
 "phpDefinition": {
 "classMatch": {
 "type": "MATCHES_CLASS",
 "classNameCondition": {
 "type": "EQUALS",
 "matchStrings": [
 "<class name>"
]
 }
 }
 }
 }
}
```

```

]
 },
 "methodMatch": {
 "methodNameCondition": {
 "type": "EQUALS",
 "matchStrings": [
 "<method name>"
]
 }
 }
}
}
}

```

Edit the JSON objects in the following way:

- `classMatch` is optional. If you do not want to specify a class to match, delete the `classMatch` object from the `phpDefinition` object.
- If you are using the class match, set the value for the `classNameCondition` match string to the class name.
  - The class must be defined as a separate file from the file in which it is instantiated and invoked.
  - If your class names are defined in a namespace, escape the backslashes in the namespace with an escape backslash.
- `methodMatch` is required. Set the value for the `methodNameCondition` match string to the method name.

The following values are required for PHP information points:

- `classMatch` type: `MATCHES_CLASS`
- `classNameCondition` type: `EQUALS`
- `methodNameCondition` type: `EQUALS`

For example, the following JSON creates an information point on a class for which the class name equals `CheckoutManager` and the method name `processPayment` :

```

{
 "probe": {
 "phpDefinition": {
 "classMatch": {
 "type": "MATCHES_CLASS",
 "classNameCondition": {
 "type": "EQUALS",
 "matchStrings": [
 "Bundy\\ShoesBundle\\Entity\\CheckoutManager"
]
 }
 },
 "methodMatch": {
 "methodNameCondition": {
 "type": "EQUALS",
 "matchStrings": [
 "processPayment"
]
 }
 }
 }
 }
}

```

```
}
}
```

If creating an information point primarily to capture KPI metrics for the method, it is likely you will define the class for the method. However, if you are creating an information point to implement a code metric, you may only need to specify method name matching.

This example shows a method match that tracks how many times a method is called:

```
{
 "probe": {
 "phpDefinition": {
 "methodMatch": {
 "methodNameCondition": {
 "type": "EQUALS",
 "matchStrings": [
 "deleteCartItems"
]
 }
 }
 }
 }
}
```

## Match Conditions

A match condition (defined by a `matchConditions` object) lets you refine the method matching criteria by specifying a match condition based on a parameter or return value or the value returned by an invoked object.

A match condition is optional, but there can be at most one for the information point. If you do not supply a match condition, the information point includes all invocations of the matched method.

The condition consists of a match type and the comparison operator that defines the data to be compared. The match types are:

- EQUALS
- NOT\_EQUALS
- LT
- GT
- LE
- GE
- NOT
- AND
- OR

The comparison operator is an expression node that defines a left side (`lhs`) and a right side (`rhs`) of the operation. It contains:

- a type: `ENTITY`, `STRING`, or `INTEGER`
- a value, which is an `entityValue`, `stringValue`, or `integerValue`

If the type is `ENTITY`, the `entityValue` has one of the following types: `INVOKED_OBJECT`, `RETURN_VALUE`, or `PARAMETER`. If the type of the `entityValue` is `PARAMETER`, the `parameterIndex` indicates the 0-

based numeric index of the parameter on which to match. So if the method takes two parameters, for example, the first being a string and second an integer, a `parameterIndex` of 0 matches against the string and a `parameterIndex` of 1 matches the integer value.

The information point in the following example only matches invocations of the `processPayment` method in which the second parameter (at parameter index 1) equals `VISA`.

```
{
 "probe": {
 "phpDefinition": {
 "methodMatch": {
 "methodNameCondition": {
 "type": "EQUALS",
 "matchStrings": [
 "processPayment"
]
 },
 "matchCondition": {
 "type": "EQUALS",
 "comparisonOp": {
 "lhs": {
 "type": "ENTITY",
 "entityValue": {
 "type": "PARAMETER",
 "parameterIndex": 1
 }
 },
 "rhs": {
 "type": "STRING",
 "stringValue": "VISA"
 }
 }
 }
 }
 }
 }
}
```

## Metric Definitions

You can define custom metrics for data captured by an information point using the `metricDefinitions` object in your information point definition. Custom metrics appear in the Metric Browser and in the dashboard for the information point. You can create health rules based on a custom metric and retrieve custom metric values using the AppDynamics REST API.

There can be multiple custom metrics for a single information point. For example, one metric might be based on the average and one on the accumulated (sum) of the information point's values.

A `metricDefinitions` object consists of one or more definitions, each having the following structure:

- a name
- a rollup type ( `AVERAGE` or `SUM` )

- data, which consists of a type, ( ENTITY , STRING , or INTEGER ) and a value ( entityValue , stringValue , or integerValue )

If the type is ENTITY , the entityValue has a type, which is INVOKED\_OBJECT , RETURN\_VALUE , or PARAMETER . If the type of the entityValue is PARAMETER , the zero-based parameterIndex indicates the parameter on which to base the match. A return value or parameter metric cannot be an array.

For example, the following metricDefinitions object defines two custom metrics: VisaTotal , which reports the sum of the Visa payments processed and VisaAverage , which reports the average value of the Visa payments processed.

```
"metricDefinitions": [
 {
 "name": "VisaTotal",
 "rollup": "SUM",
 "data": {
 "type": "ENTITY",
 "entityValue": {
 "type": "RETURN_VALUE"
 }
 }
 },
 {
 "name": "VisaAverage",
 "rollup": "AVERAGE",
 "data": {
 "type": "ENTITY",
 "entityValue": {
 "type": "RETURN_VALUE"
 }
 }
 }
]
```

### Sample JSON Information Point Configuration

This is an example that you can copy and paste into the JSON text field in the PHP information point window. It produces two metrics, named VisaTotal and VisaAverage .

```
{
 "probe": {
 "phpDefinition": {
 "classMatch": {
 "type": "MATCHES_CLASS",
 "classNameCondition": {
 "type": "EQUALS",
 "matchStrings": [
 "CheckoutManager"
]
 }
 }
 }
 }
}
```

```

 }
 },
 "methodMatch": {
 "methodNameCondition": {
 "type": "EQUALS",
 "matchStrings": [
 "processPayment"
]
 },
 "matchCondition": {
 "type": "EQUALS",
 "comparisonOp": {
 "lhs": {
 "type": "ENTITY",
 "entityValue": {
 "parameterIndex": 1,
 "type": "PARAMETER"
 },
 },
 "rhs": {
 "type": "STRING",
 "stringValue": "VISA"
 }
 }
 }
 }
},
"metricDefinitions": [
 {
 "name": "VisaTotal",
 "rollup": "SUM",
 "data": {
 "entityValue": {
 "type": "RETURN_VALUE"
 },
 "type": "ENTITY"
 }
 },
 {
 "name": "VisaAverage",
 "rollup": "AVERAGE",
 "data": {
 "type": "ENTITY",
 "entityValue": {
 "type": "RETURN_VALUE"
 }
 }
 }
]
}

```

## AppDynamics for OpenTelemetry™

[OpenTelemetry](#) is a collection of tools, APIs, and SDKs used to instrument, generate, collect, and export telemetry data (metrics, logs, and traces) to help you analyze software performance and behavior.

AppDynamics provides an OpenTelemetry-compatible backend to ingest OpenTelemetry trace data using OpenTelemetry components. The ingested data is processed by the AppDynamics backend and displayed in the Controller UI. This service is referred to as AppDynamics for OpenTelemetry.

### Getting Started

To get started with AppDynamics for OpenTelemetry:

1. Deploy the [OpenTelemetry Collector](#) version  $\geq 0.36.0$  in your computing environment.
2. In the Controller top navigation panel, click **OTel > Get Started**.
3. Click **Generate Access Key**. It may take up to 30 seconds to generate the key.  
If you have already completed onboarding, you can retrieve the API Key in the Controller:
  - a. In the top navigation panel, click **OTel**.
  - b. Under the **Access Key** section, click **Show**.

### Next Steps

1. [Configure Collector](#)
2. [Configure Resource Attributes](#)
3. [Instrument Applications with AppDynamics for OpenTelemetry™](#)
4. [View OpenTelemetry Data in the Controller UI](#)

OpenTelemetry™ is a trademark of The Linux Foundation®.

### Configure Collector

The collector acts as the service pipeline by gathering telemetry data from your applications and exporting it to a backend. With AppDynamics for OpenTelemetry™, the collector collects and sends distributed traces to the AppDynamics backend.

You can use one of the following two collectors:

1. AppDynamics Distribution for OpenTelemetry Collector
2. AppDynamics Distribution for OpenTelemetry Collector MSI
3. [OpenTelemetry Collector](#)

**i** It is recommended to use AppDynamics Distribution for OpenTelemetry Collector for seamless integration with the AppDynamics backend.

The collector consists of these components:

- **Receivers:** Receives data from OpenTelemetry sources (tracers and SDKs).
- **Processors:** Allows additional processing of data, such as data enrichment and batching.
- **Exporters:** Converts the data into a specified format and sends the converted data to a chosen destination.
- **Extensions:** Extensions provide additional functionalities such as health monitoring, service discovery, and data forwarding. This does not involve processing telemetry data.

See the following sections to configure these components in your OpenTelemetry `otel-config.yaml` file. Once configured, the components must be enabled via pipelines in the [service](#) section.

### Before You Begin

To get started with AppDynamics for OpenTelemetry:

1. Download the collector of your choice and deploy it in your computing environment.

[AppDynamics Distribution for OpenTelemetry Collector](#) AppDynamics Distribution for OpenTelemetry Collector MSI  
OpenTelemetry Collector

- a. Go to [Downloads](#) and search for `Collector for OpenTelemetry`.
- b. Based on your environment, download any of the following AppDynamics Distribution for OpenTelemetry Collector `>= 22.8.0`.
  - OpenTelemetry Collector Linux ARM64
  - OpenTelemetry Collector Darwin ARM64
  - OpenTelemetry Collector Windows AMD64
  - OpenTelemetry Collector Linux AMD64
  - OpenTelemetry Collector Darwin AMD64

AppDynamics Distribution for OpenTelemetry Collector [AppDynamics Distribution for OpenTelemetry Collector MSI](#)  
OpenTelemetry Collector

- a. Go to [JFrog](#) and download the applicable collector MSI. For example, `appdotelcol-  
amd64-23.3.0765.msi`.
- b. Run the following command to install the MSI.

```
msiexec.exe /i "<msi-file-name>.msi"
```

- c. See the following sections to prepare a working configuration for the collector.
  - [Configure Receivers](#)
  - [Configure Processors](#)
  - [Configure Exporters](#)

- [Configure the Service Pipeline](#)
  - [Collector Configuration Sample](#)
- a. Go to the following file and replace the existing configurations with your configuration.  
C:\Program Files\AppDynamics\AppDynamics Distribution of OpenTelemetry Collector\otel-config.yaml
  - b. Run the following command to restart the Windows service.

```
net stop appdotelcol
net start appdotelcol
```

AppDynamics Distribution for OpenTelemetry Collector    AppDynamics Distribution for OpenTelemetry Collector MSI  
[OpenTelemetry Collector](#)

- a. Go to [GitHub](#) and download `otelcol-contrib` version  $\geq 0.36.0$ .
- b. Deploy the [OpenTelemetry Collector](#) in your computing environment.

**i** We recommend using [OpenTelemetry Protocol \(OTLP\)](#) version  $\geq 0.9.0$  as the specified trace receiver. For a list of verified OTLP open-source versions, see [Verified Open Source Versions](#).

2. In the Controller top navigation panel, click **OTel > Get Started**.
3. Click **Generate Access Key**.  
If you have already completed onboarding, you can retrieve the API Key in the Controller:
  - a. In the top navigation panel, click **OTel**.
  - b. Under the **Access Key** section, click **Show**.
  - c. Copy the key to use in the [Configure Exporters](#) section below.

### Configure Receivers

[Receivers](#) specify how data gets into the OpenTelemetry Collector. Receivers use OTLP to support transaction-oriented application data processing.

We recommend you use [OpenTelemetry Protocol \(OTLP\)](#) version  $\geq 0.9.0$  as the specified trace receiver. For a list of verified OTLP open-source versions, see [Verified Open Source Versions](#).

In the `receivers: OTLP:` section, specify the Collector endpoints:

```
receivers:
 otlp:
 protocols:
 grpc:
 endpoint:
 http:
 endpoint:
```

## Configure Processors

**Processors** allow additional processing of data, such as data enrichment and batching.

You must configure the `processors` section to add AppDynamics Controller information and (optional) custom data collection.

### Resource Processor

Add the AppDynamics Controller account, host, and port to the resource processor:

In the `resource: attributes:` section, add the following:

- `appdynamics.controller.account` : Your AppDynamics Controller account name
- `appdynamics.controller.host` : Your AppDynamics Controller hostname
- `appdynamics.controller.port` : Your AppDynamics Controller port number

You also must add `service.name` and `service.namespace` resource attributes, but you have three options for how to add them:

- Set the `service.name` and `service.namespace` from inside your application code.
- Set `service.name` in your OpenTelemetry `otel-config.yaml` file.
- Set `service.name` and `service.namespace` in the `OTEL_RESOURCE_ATTRIBUTES` environment variable.

See [Configure Resource Attributes](#) for more information.

### Resource Processor

```
processors:
 resource:
 attributes:
 - key: appdynamics.controller.account
 action: upsert
 value: "acme"
 - key: appdynamics.controller.host
 action: upsert
 value: "acme.saas.appdynamics.com"
 - key: appdynamics.controller.port
 action: upsert
 value: 443 # can be an integer or string.
```

### Batch Processor

The **batch processor** accepts spans, metrics, or logs and places them into batches in the OpenTelemetry Collector pipeline.

Configure the following `batch:` attributes to help improve performance:

- `timeout` : Time after which a batch is sent, regardless of size. The default is 30 seconds.
- `send_batch_size` : Number of spans or metrics after which a batch is sent. The default is 8,192.

We recommend batching 90 spans or less per request for optimal results.

## Batch Processor

```
processors:
 batch:
 timeout: 30s
 send_batch_size: 90
```

## Configure Exporters

The [exporter](#) is how data is sent to the AppDynamics backend. For AppDynamics for OpenTelemetry, only HTTP is supported to transmit OTLP trace export calls. Your tracer/SDKs exporter should be based on OTLP version  $\geq 0.9.0$ .

In the `exporters: otelhttp:` section, you must configure the following attributes with the AppDynamics endpoint and API key:

```
exporters:
 otelhttp:
 endpoint: "<appd-endpoint>"
 headers: {"x-api-key": "<x-api-key>"}
```

For more details on `<x-api-key>` and `<appd-endpoint>` see [Resource Attribute Descriptions](#).

For more details on `<appd-endpoint>` see [Regions and Endpoints](#).

## Configure the Service Pipeline

The [service pipeline](#) is what enables the configurations set in the `receivers:`, `processors:`, and `exporters:` sections.

You must verify that all previously noted exporters, receivers, and processors are included in the `service: pipelines:` section:

```
service:
 pipelines:
 traces:
 receivers: [otel]
 processors: [resource, batch]
 exporters: [otelhttp]
```

## Regions and Endpoints

Please note that your OpenTelemetry data may transit through regions different from where your Controller is hosted if you configure your OpenTelemetry Collector using an AppDynamics endpoint located outside of the region where your Controller is hosted.

Region	City	Endpoint
Americas	Oregon	See <a href="#">SaaS Domains and IP Ranges</a> for OpenTelemetry endpoints.
	Sao Paulo	
EMEA	Frankfurt	
	London (Coming soon)	
	Capetown (Coming soon)	
APAC	Hong Kong (Coming soon)	
	Mumbai	
	Singapore	
	Sydney	

### Attribute Descriptions

Key	Location	Type	Example	Required	Description
<code>appd-endpoint</code>	otlphttp exporter	string	See <a href="#">Supported Regions</a> .	Yes	Your AppDynamics endpoint for your region where the OpenTelemetry Collector sends the ingested traces.
<code>x-api-key</code>	otlphttp exporter	string	<alpha numeric key>	Yes	Your AppDynamics API key must be defined as an HTTP header.  To obtain your unique <code>x-api-key</code> , you should work closely with your AppDynamics account team.
<code>appdynamics.controller.account</code>	resource attribute	string	<code>acme</code>	Yes	AppDynamics Controller account name.

Key	Location	Type	Example	Required	Description
<code>appdynamics.controller.host</code>	resource attribute	string	<code>acme.saas.appdynamics.com</code>	Yes	AppDynamics Controller host used by OpenTelemetry.   Do not include <code>http://</code> or <code>https://</code> .
<code>appdynamics.controller.port</code>	resource attribute	string	<code>443</code>	Yes	AppDynamics Controller port number.
<code>service.name</code>	resource attribute	string	<code>shoppingcart</code>	Yes	Logical name of the service; equivalent to your AppDynamics tier name. Set the corresponding <code>service.name</code> resource attribute for every service being monitored using either the SDK, or by setting the <code>OTEL_RESOURCE_ATTRIBUTES</code> environment variable.  Must be the same for all instances of horizontally scaled services.
<code>service.namespace</code>	resource attribute	string	<code>Shop</code>	Yes	A namespace for the <code>service.name</code> ; equivalent to your AppDynamics application name. Set the corresponding <code>service.namespace</code> resource attribute for every service being monitored using either the SDK, or by setting the <code>OTEL_RESOURCE_ATTRIBUTES</code> environment variable.  A non-null, non-empty string value for <code>service.namespace</code> is required.

### Collector Configuration Sample

This example includes configuration for the processors, receivers, exporters, service, and attributes:

```
processors:
 resource:
```

```

attributes:
- key: appdynamics.controller.account
 action: upsert
 value: "acme"
- key: appdynamics.controller.host
 action: upsert
 value: "acme.saas.appdynamics.com"
- key: appdynamics.controller.port
 action: upsert
 value: 443
- key: service.namespace
 action: upsert
 value: shop
batch:
 timeout: 30s
 send_batch_size: 90
receivers:
 otlp:
 protocols:
 grpc:
 endpoint:
 http:
 endpoint:
exporters:
 otlphttp:
 endpoint: "https://<your region>-sls-agent-api.saas.appdynamics.com" // See the Supported
Regions section above.
 headers: {"x-api-key": "*****"}
service:
 pipelines:
 traces:
 receivers: [otlp]
 processors: [resource, batch]
 exporters: [otlphttp]

```

## Start the Collector

1. Ensure that the downloaded collector binary has execution privileges.
2. Run the following commands to start sending data to the common ingestion stream.

```
./appdotelcol_* --config otel-config.yaml
```

To validate that your configuration is working properly, review your OpenTelemetry Collector logs. The output from the console log should not have any errors.

You can also set up a logging exporter to monitor the Collector. See [Logging Exporter](#) for more information.

## Next Steps

After deploying and configuring the OpenTelemetry Collector, you must [Configure Resource Attributes](#).

OpenTelemetry™ is a trademark of The Linux Foundation®.

## Configure Resource Attributes

Once the OpenTelemetry™ Collector is deployed and configured, you must set the **resource attributes** to your AppDynamics-monitored application and tier names, and verify that the `telemetry.sdk.language` attribute is set to your application's language. This will map OpenTelemetry services from your application to AppDynamics.

### Before You Begin

Make sure you have [deployed and configured the OpenTelemetry™ Collector](#) before configuring the attributes in the sections below.

### Set `service.name` and `service.namespace` to Your Application and Tier Names

**i** For applications monitored by OpenTelemetry tracers/SDKs, make sure the `service.name` and `service.namespace` are configured to map to the tier and application names in the AppDynamics Controller UI. See [Attributes with Special Handling](#).

You have three options to set `service.name` and `service.namespace` resource attributes:

- (Recommended option) Set `service.name` and `service.namespace` inside your application code:
  - For Node.js applications monitored by AppDynamics, the OpenTelemetry `ApplicationName` and `TierName` is derived from the `ApplicationName` and `TierName` in the Node.js `require` statement:
  - For Java applications monitored by AppDynamics, set the tier name (in `service.name`) and application name (in `service.namespace`) for the JVM:

```
-Dotel.resource.attributes="service.name=Shop,service.namespace=Shopping"
```

- Set `service.name` in your OpenTelemetry `otel-config.yml` file (see [Collector Configuration Sample](#)) to your AppDynamics-monitored tier name(s):

```
service.name: shopping cart
```

- Set `service.name` and `service.namespace` in the `OTEL_RESOURCE_ATTRIBUTES` [environment variable](#). See [OpenTelemetry Instrumentation](#) for language-specific instructions.

### Set `telemetry.sdk.language` to Your Application Language

Most language SDKs populate the attribute `telemetry.sdk.language` automatically. If this attribute is not set, the AppDynamics Controller may not be able to determine the language of your application. To set this language attribute, see [OpenTelemetry Telemetry SDK](#).

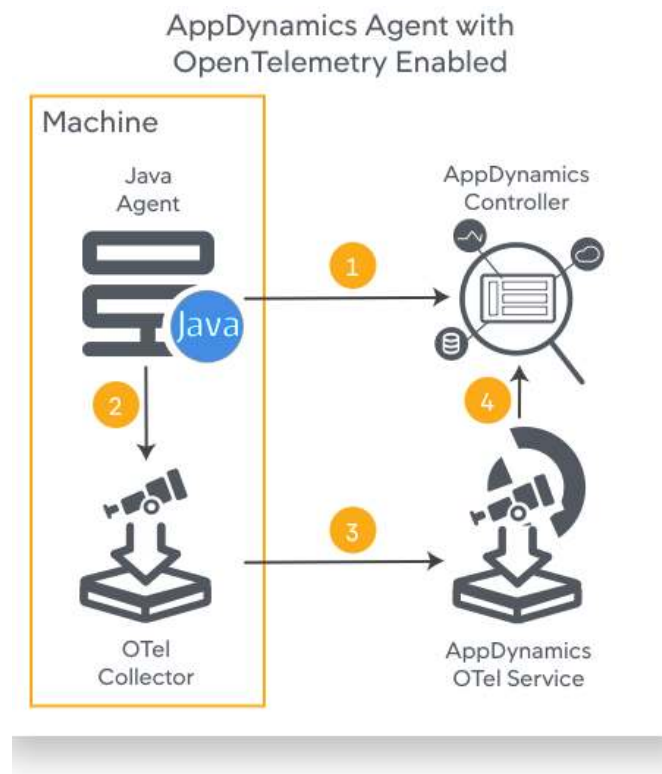

### Next Steps

Once you have configured the resource attributes, see [Instrument Applications with AppDynamics for OpenTelemetry™](#).

OpenTelemetry™ is a trademark of The Linux Foundation®.

## Instrument Applications with AppDynamics for OpenTelemetry™

If you have an application that is monitored with AppDynamics Java, .NET, or Node.js Agents, you can instrument AppDynamics agents in your application to report both OpenTelemetry span data and AppDynamics SaaS data. When instrumented, the agents will generate OpenTelemetry span data from HTTP entry and exit requests. The AppDynamics correlation header is injected inside the [OpenTelemetry baggage header](#), which results in the correlation with Business Transactions through intersecting OpenTelemetry nodes.

For example, the diagram above demonstrates how OpenTelemetry data is reported when an AppDynamics Java Agent is enabled for OpenTelemetry. The Java Agent sends AppDynamics SaaS data to the AppDynamics Controller and OpenTelemetry spans to the OpenTelemetry Collector. The Collector then sends the received spans to the AppDynamics OpenTelemetry Service via OTLP/HTTP(s). The AppDynamics OpenTelemetry Service consolidates the spans into traces and maps traces to Business Transactions that are registered with the Controller. The Controller UI displays both the AppDynamics SaaS data from the AppDynamics Agent and the OpenTelemetry data from the AppDynamics OpenTelemetry Service.

### Before You Begin

Make sure you have [deployed and configured the OpenTelemetry™ Collector](#) and [configured the resource attributes](#).

## Enable OpenTelemetry in the Java Agent

To enable the Java Agent for OpenTelemetry, you need Java Agent version  $\geq 21.11.4$  (we recommend using Java Agent version  $\geq 22.3.0$ ). For a list of Java frameworks supported for OpenTelemetry, see [Supported Java Agent Frameworks for OpenTelemetry](#).

Add the following system properties in your JVM system properties:

1. Enable OpenTelemetry:

```
-Dappdynamics.opentelemetry.enabled=true
```

2. Set the traces exporter to OTLP (the OpenTelemetry-enabled Java Agent will send OpenTelemetry spans in the OTLP format):

```
-Dotel.traces.exporter=otlp
```

3. Set the tier name (in `service.name`) and application name (in `service.namespace`) for the JVM:

 If you do not set the tier name in `service.name`, the value defaults to the tier name originally registered by the .NET Agent (when the tier was first instrumented by AppDynamics).

```
-Dotel.resource.attributes="service.name=myServiceName,service.namespace=myServiceNameSpace"
```

You also have the option to set tier and application names in your OpenTelemetry `otel-config.yml` file or in the `OTEL_RESOURCE_ATTRIBUTES` environment variable. See [Set service.name and service.namespace to Your Application and Tier Names](#).

### (Optional) Configure the Collector Endpoint

By default, the collector endpoint points to `http://localhost:4317` but can be optionally configured in property `Dotel.exporter.otlp.traces.endpoint`:

```
-Dotel.exporter.otlp.traces.endpoint=http://localhost:8080
```

### (Optional) Configure the Batching Timing

The default exporter span batching schedule is 5000 milliseconds. The batching schedule can be configured with the OpenTelemetry environment variable `OTEL_BSP_SCHEDULE_DELAY`:

```
-Dotel.bsp.schedule.delay=90000
```

### Java Instrumentation Sample

```
-Dotel.traces.exporter=otlp
```

```
-Dotel.resource.attributes="service.name=myServiceName,service.namespace=myServiceNameSpace"
-Dappdynamics.opentelemetry.enabled=true
-Dappdynamics.controller.hostname=sample-controller.e2e.appd-test.com
-Dappdynamics.controller.port=443
-Dappdynamics.agent.accountName=OTEL-account
-Dappdynamics.agent.accountAccessKey=3ea55405-61b2-43bb-a8e0-58aff761a028
-Dappdynamics.controller.ssl.enabled=true
-Dappdynamics.agent.applicationName=ecommerce_OT
-Dappdynamics.agent.uniqueHostId=ecommerce_OT_1
-Dappdynamics.agent.tierName=DownTier
-Dappdynamics.agent.nodeName=DownNode
-javaagent:./<Java Agent Jar Path>/javaagent.jar
```

## Enable OpenTelemetry in the .NET Agent

To enable the .NET Agent for OpenTelemetry, you need:

- .NET Agent version `>= 22.6.0`
- Applications using .NET version `>= 6.0`
- For a list of .NET frameworks supported for OpenTelemetry, see [.NET Agent Frameworks for OpenTelemetry](#).

Add the following environment variable in the process that executes your .NET application:

### 1. Enable OpenTelemetry:

```
APPDYNAMICS_OPENTELEMETRY_ENABLED=true
```

### 2. Set the trace exporter to OTLP (the OpenTelemetry-enabled .NET Agent will send OpenTelemetry spans in the OTLP format):

```
OTEL_TRACES_EXPORTER=otlp
```

### 3. Set the tier name (in `service.name`) and application name (in `service.namespace`) for the application:

If you do not set the tier name in `service.name`, the value defaults to the tier name originally registered by the .NET Agent (when the tier was first instrumented by AppDynamics).

```
OTEL_RESOURCE_ATTRIBUTES=service.name=myServiceName,service.namespace=myServiceNameSpace
```

You also have the option to set tier and application names in your OpenTelemetry `otel-config.yml` file. See [Set `service.name` and `service.namespace` to Your Application and Tier Names](#).

## (Optional) Configure the Collector Endpoint

By default, the collector endpoint is set to `http://localhost:4318` and sends metrics via HTTP using OTLP format. The .NET Agent for OpenTelemetry does not support sending metrics via gRPC.

The endpoint can be configured with the environment variable `OTEL_EXPORTER_OTLP_ENDPOINT`:

```
OTEL_EXPORTER_OTLP_ENDPOINT=http://otel-collector:8080
```

### (Optional) Configure Batching timing

The default exporter span batching schedule is 5000 milliseconds. The batching schedule can be configured with the environment variable `OTEL_BSP_SCHEDULE_DELAY` :

```
OTEL_BSP_SCHEDULE_DELAY=90000
```

### .NET Instrumentation Sample

```
...
APPDYNAMICS_OPENTELEMETRY_ENABLED=true
OTEL_TRACES_EXPORTER=otlp
OTEL_EXPORTER_OTLP_ENDPOINT=http://otel-collector:4318
OTEL_RESOURCE_ATTRIBUTES=service.name=myServiceName,service.namespace=myServiceNameSpace
...
```

### Enable OpenTelemetry in the Node.js Agent

To enable OpenTelemetry in the Node.js Agent, you need Node.js Agent version  $\geq 22.3.0$ .

Add the following OpenTelemetry configurations in your Node.js application code:

1. Enable OpenTelemetry in the `require` statement:

**i** For Node.js applications, OpenTelemetry AppName and TierName is derived from the AppName and TierName in the Node.js `require` statement. If your AppDynamics application/tier is named `MY_APP/MY_TIER` , your OpenTelemetry application/tier will be `MY_APP_OTEL/MY_TIER_OTEL` .

```
require("appdynamics").profile(
{
 ...
 openTelemetry: {
 enabled: <True:False> // openTelemetry is enabled or disabled
 }
 ...
}
)
```

2. Allow additional logging of span data:

```
require("appdynamics").profile(
```

```

{
 ...
 openTelemetry: {
 debug: <True:False> // Additional logging, console dump of span data
 ...
 }
 ...
}
)

```

### 3. Add the OpenTelemetry Collector URL:

```

require("appdynamics").profile(
{
 ...
 openTelemetry: {
 collector: {
 url: <url> <http://host:port/v1/traces> // The default value is http://
localhost:55680/v1/traces
 }
 ...
 }
}
)

```

### (Optional) Configure the Batching Timing

```

require("appdynamics").profile(
{
 ...
 openTelemetry: {
 exporter: {
 maxQueueSize: size_in_byte the maximum queue size. After the size is reached spans are
dropped. The default value is 2048.
 scheduledDelayMillis: time_in_ms the delay interval in milliseconds between two
consecutive exports. The default value is 5000.
 }
 ...
 }
}
)

```

### Node.js Instrumentation Sample

```

require("appdynamics").profile(
{
 ...
 openTelemetry: {

```

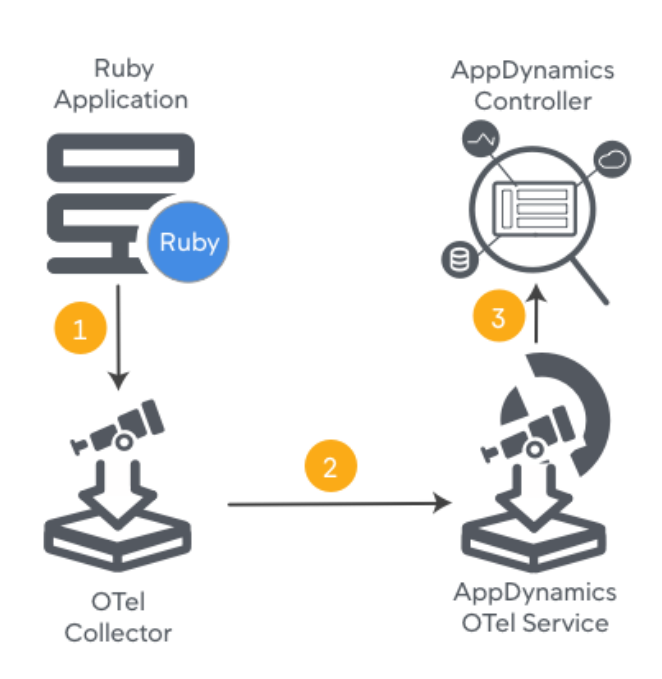

```

enabled: <True:False> // OpenTelemetry enabled or disabled
debug: <True:False> // Additional logging, console dump of span data
collector: {
 url: <url> <http://host:port/v1/traces> // The default value is http://
localhost:55680/v1/traces
}
}
...
}
)

```

### Instrument Ruby Application Using OpenTelemetry

The following diagram demonstrates how OpenTelemetry data of a Ruby application is ingested into AppDynamics:

The Ruby application sends the OpenTelemetry spans to the OpenTelemetry Collector. The Collector then sends the spans to the AppDynamics OpenTelemetry Service via OTLP/HTTP(s). The AppDynamics OpenTelemetry Service consolidates the spans into traces and maps traces to Business Transactions that are registered with the Controller. The Controller UI displays the OpenTelemetry data from the AppDynamics OpenTelemetry Service.

### Configure Ruby Application

**i** The following procedures provide brief instructions to configure a Ruby application. For more details, see [OpenTelemetry for Ruby](#).

You can instrument the Ruby application using OpenTelemetry in one of the following ways:

- [Automatic Instrumentation](#)
- [Manual Instrumentation](#)

Automatic Instrumentation is the recommended instrumentation method.

## Automatic Instrumentation

The `opentelemetry-sdk` and `opentelemetry-instrumentation-all` packages populate the traces/spans automatically with minimal manual effort.

For the list of supported frameworks, see [Supported Framework](#).

The following procedure is an example of instrumenting a simple Ruby On Rails application:

1. Add the following packages to the existing Gemfile.

### Gemfile

```
gem 'opentelemetry-sdk'
gem 'opentelemetry-exporter-otlp'
gem 'opentelemetry-instrumentation-all'
```

2. Configure the Ruby application to initialize OpenTelemetry. Create a `<project>/config/initializers/opentelemetry.rb` file.

### config/initializers/opentelemetry.rb

```
config/initializers/opentelemetry.rb
require 'opentelemetry/sdk'
require 'opentelemetry/exporter/otlp'
require 'opentelemetry/instrumentation/all'

OpenTelemetry::SDK.configure do |c|
 c.resource = OpenTelemetry::SDK::Resources::Resource.create({
 OpenTelemetry::SemanticConventions::Resource::SERVICE_NAMESPACE =>
 '<YOUR_SERVICE_NAMESPACE>', # corresponds to Appd controller Application name
 OpenTelemetry::SemanticConventions::Resource::SERVICE_NAME => '<YOUR_SERVICE_NAME>' #
 corresponds to Appd controller Tier name
 })
 c.use_all() # enables all instrumentation!
end
```

3. Configure the application to report traces to the OpenTelemetry Collector. Set up the `OTEL_EXPORTER_OTLP_ENDPOINT` environment variable on which the OpenTelemetry Collector listens to:

**env**

```
export OTEL_EXPORTER_OTLP_ENDPOINT=http://0.0.0.0:4318
```

 0.0.0.0 is the OpenTelemetry collector HOST and 4318 is the OpenTelemetry Collector PORT. For more information about available exporters, see [Ruby Exporter](#).

4. Install the newly added Gems to Gemfile.

```
bundle install
```

5. Start the Ruby application.

## Manual Instrumentation

Use the manual instrumentation method only if there is no framework support.

1. Add the following packages to the existing Gemfile.

**Gemfile**

```
gem 'opentelemetry-sdk'
gem 'opentelemetry-exporter-otlp'
```

2. Add the following lines to create spans manually. For example, you can create spans to instrument a Ruby script or an unsupported framework.

**code snippet**

```
require 'opentelemetry/sdk'
require 'opentelemetry/exporter/otlp'

OpenTelemetry::SDK.configure

def hello_world
 tracer_provider = OpenTelemetry.tracer_provider
 tracer = tracer_provider.tracer('hello world')
 tracer.in_span("hello_world", kind: :server) do |span|
 puts "Hello all"
 # Do something... expensive/simple task that you want to instrument
 end
 tracer_provider.shutdown
end
```

```
end
hello_world
```

3. Set up the `OTEL_EXPORTER_OTLP_ENDPOINT` environment variable on which the OpenTelemetry Collector listens to:

**env**

```
export OTEL_EXPORTER_OTLP_ENDPOINT=http://0.0.0.0:4318
```

**i** `0.0.0.0` is the OpenTelemetry collector HOST and `4318` is the OpenTelemetry Collector PORT. For more information about available exporters, see [Ruby Exporter](#).

4. Install the newly added Gems to Gemfile.

```
bundle install
```

5. Start the Ruby application.

## OpenTelemetry Collector

Add the AppDynamics configuration to the OpenTelemetry Collector service.

**i** The following snippet is a sample configuration file. See [Configure Collector](#) for more details about OpenTelemetry Collector.

**otel-config.yaml**

```
otel-config.yaml
processors:
 batch:
 memory_limiter:
 resource:
 attributes:
 - key: service.namespace
 action: upsert
 value: "xxx"
 - key: appdynamics.controller.host
 action: upsert
 value: "xxx"
 - key: appdynamics.controller.port
 value: xxx
 action: upsert
```

```

- key: telemetry.sdk.name
 value: "xxx"
 action: upsert
- key: appdynamics.controller.account
 value: "xxx"
 action: upsert

receivers:
 otlp:
 protocols:
 grpc:
 http:
 cors_allowed_origins:
 - http://*
 - https://*

exporters:
 otlphttp:
 endpoint: "https://<your-region>-sls-agent-api.saas.appdynamics.com"
 headers: { "x-api-key": "xxxxxx" }

logging:
 loglevel: debug

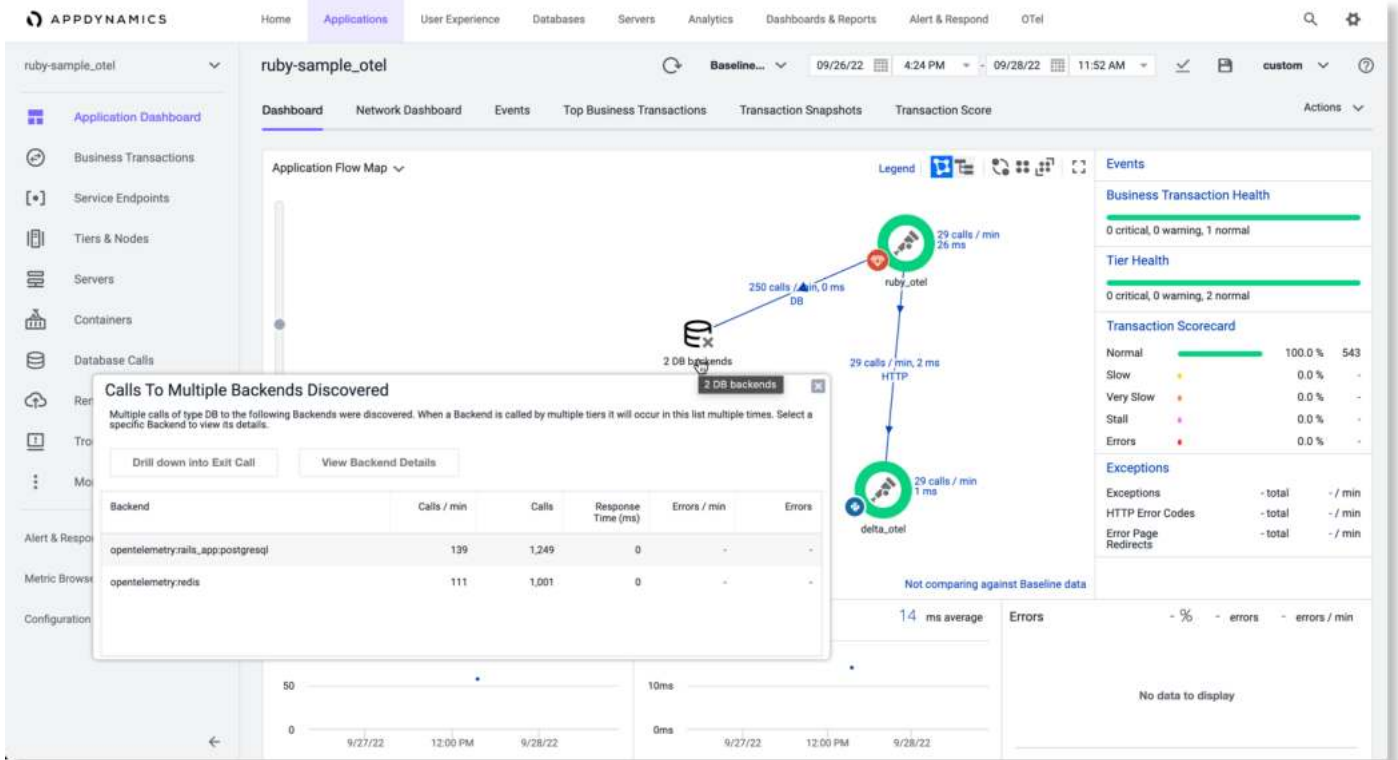

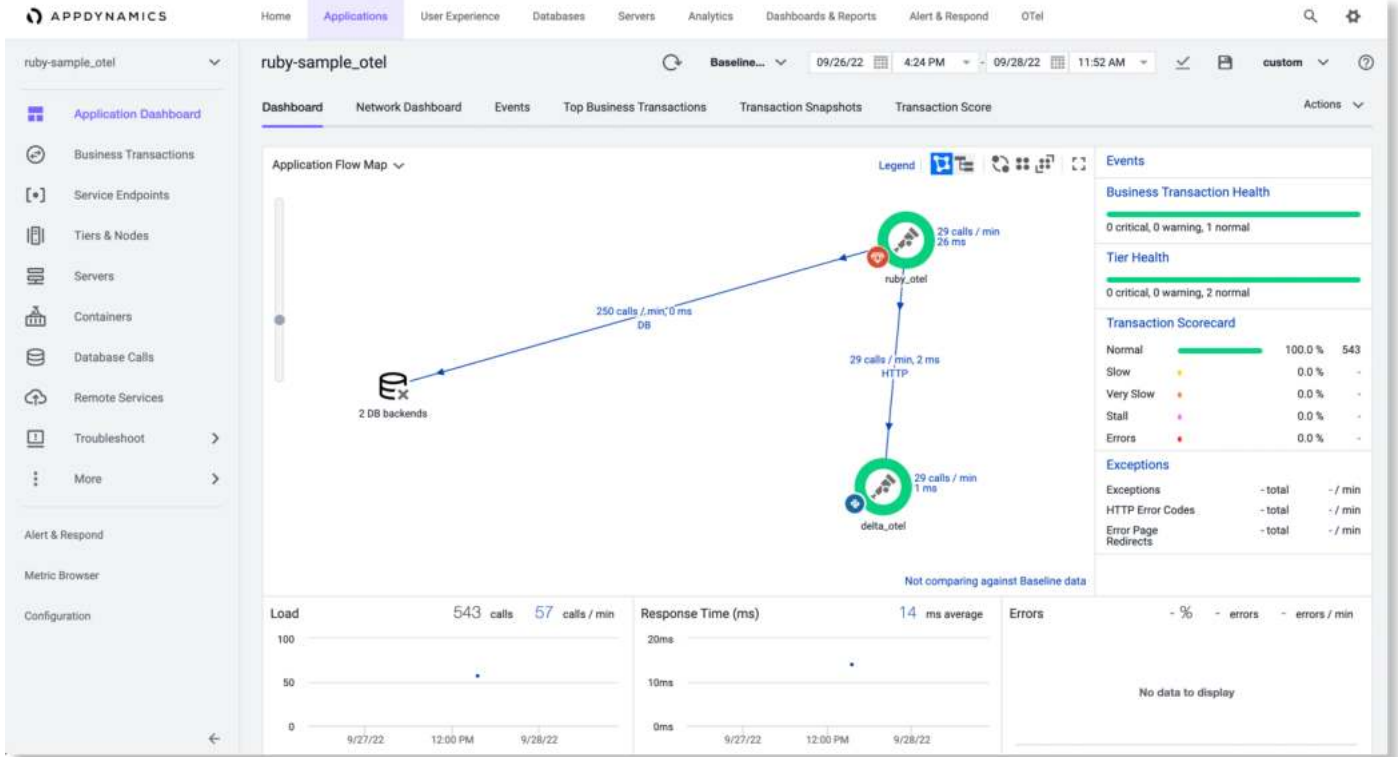

service:
 pipelines:
 traces:
 receivers: [otlp]
 processors: [batch, resource]
 exporters: [otlphttp, logging]

```

## AppDynamics Controller

The following screenshots show the Ruby application dashboard on the AppDynamics Controller:

**i** For applications that use OTel SDK only or OTel SDK and updated agents (Java >=21.11, .NET >=22.6, and Node.js >=22.3), you can view the end-to-end flow in the **OTel** flow map view. For mixed environments or older agents, you may need to use the **All Sources** flow map view, which includes flows discovered using both traditional AppDynamics SaaS and OTel. For more details, see [View OpenTelemetry™ Data in the Controller UI](#).

## Next Steps

Once you have instrumented your applications with AppDynamics for OpenTelemetry, you can [view OpenTelemetry data in the Controller](#).

OpenTelemetry™ is a trademark of The Linux Foundation®.

## View OpenTelemetry™ Data in the Controller UI

AppDynamics for OpenTelemetry™ ingests and aggregates traces into Business Transaction flow metrics in the Controller UI. A trace represents an end-to-end request which can be made up of one or multiple spans. Each span represents one event within a component in the application triggered in the trace. The Business Transaction represents the entire graph of all traces sharing the same root span and visualizes how traces flow between services.

### Before You Begin

To view OpenTelemetry data in the Controller UI, you need the following:

- AppDynamics SaaS Controller >= 22.3.0
- Paid or trial AppDynamics license

For information on data limits for AppDynamics for OpenTelemetry, see [License Entitlements and Restrictions](#).

### View OpenTelemetry Data in the Controller UI

#### Application Dashboard

The **Application Flow Map** is a dynamic visual representation of your monitored environment's components and activities. Monitored services using OpenTelemetry are represented by the OpenTelemetry telescope icon. For a list of supported language in the flow map, see [Supported Languages](#).

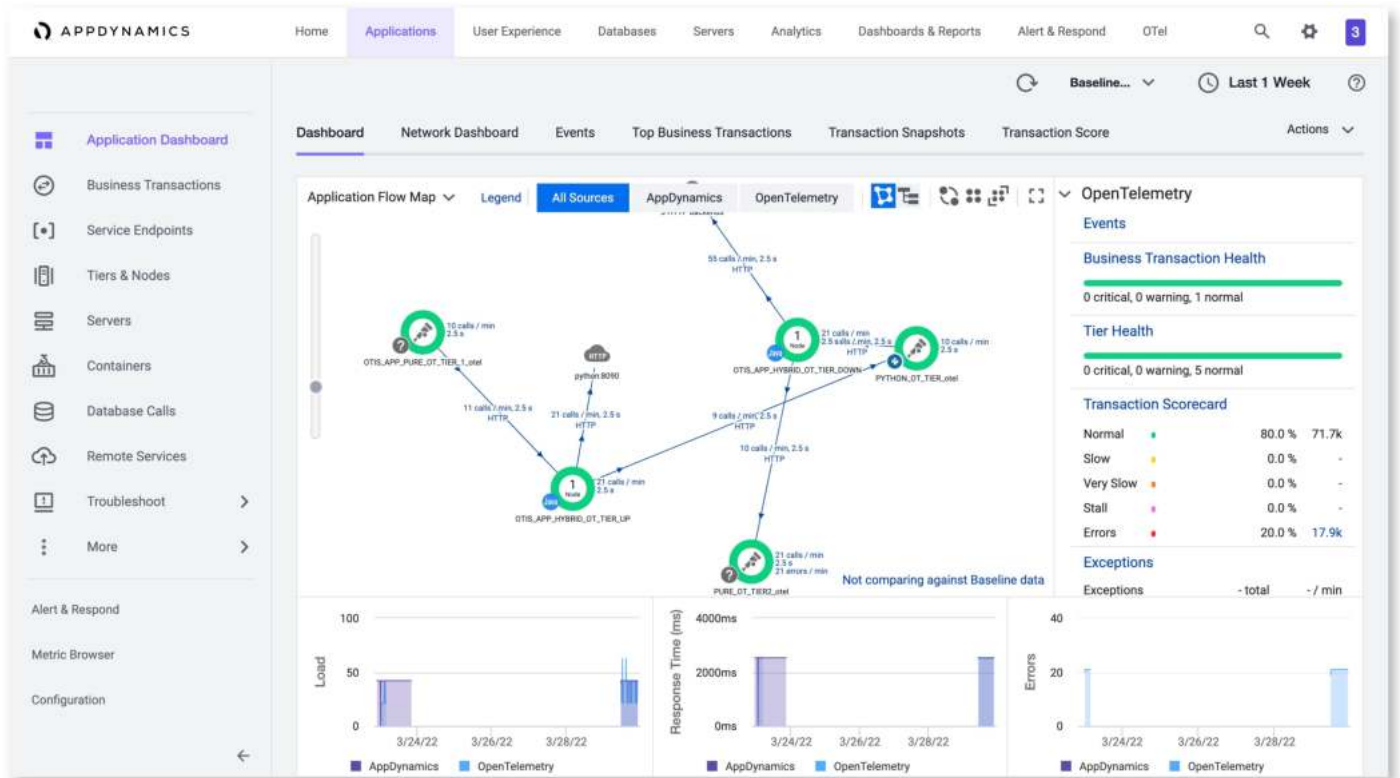

To view OpenTelemetry data on your **Application Dashboard**:

1. Go to your OpenTelemetry-enabled application.
2. Click **Application Dashboard > Dashboard**.

After instrumentation, it may take up to five minutes for data to populate in the Controller UI.

**i** **Known Issue**

For OpenTelemetry flow maps, Business Transactions (BTs) can lose the upstream context and appear as new BTs rather than continuations. This causes BTs to appear split up in the BT dashboard, resulting in BT Metrics to be split up as well.

The **All Sources** view shows a blend OpenTelemetry and AppDynamics source data.

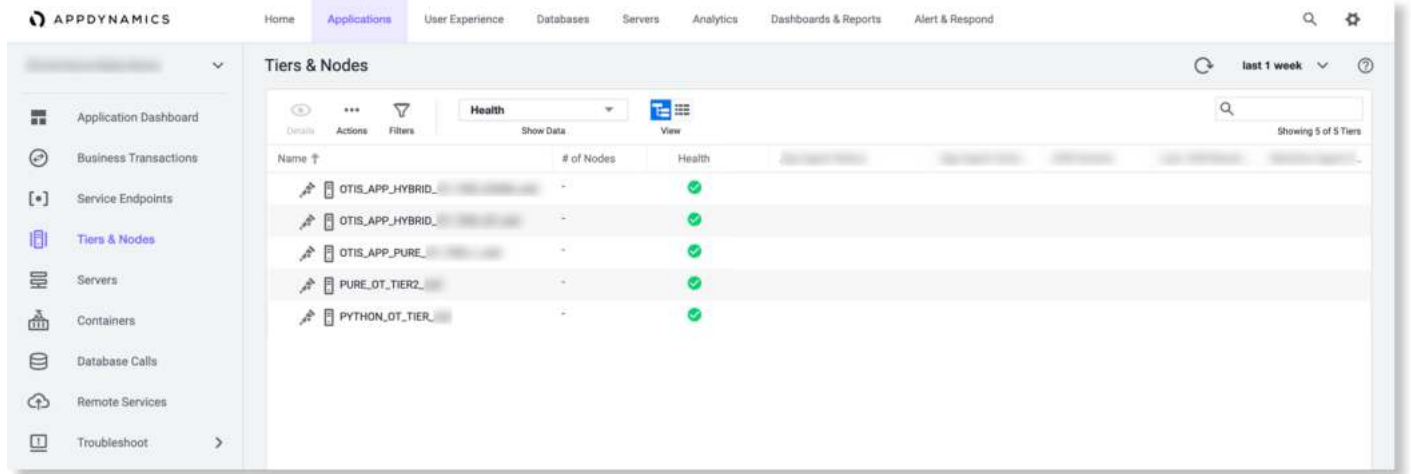

In the **OpenTelemetry** source view, the **Flow Map** displays data and activity between tiers. Only tiers are displayed in the **OpenTelemetry** source view; no node-level details are available.

If you want to look at data from just one tier, click on a tier in the **Flow Map**. You'll be redirected to the **Tiers & Nodes Flow Map** which will populate with data for that OpenTelemetry tier.

See [Learn how to navigate and customize flow maps](#).

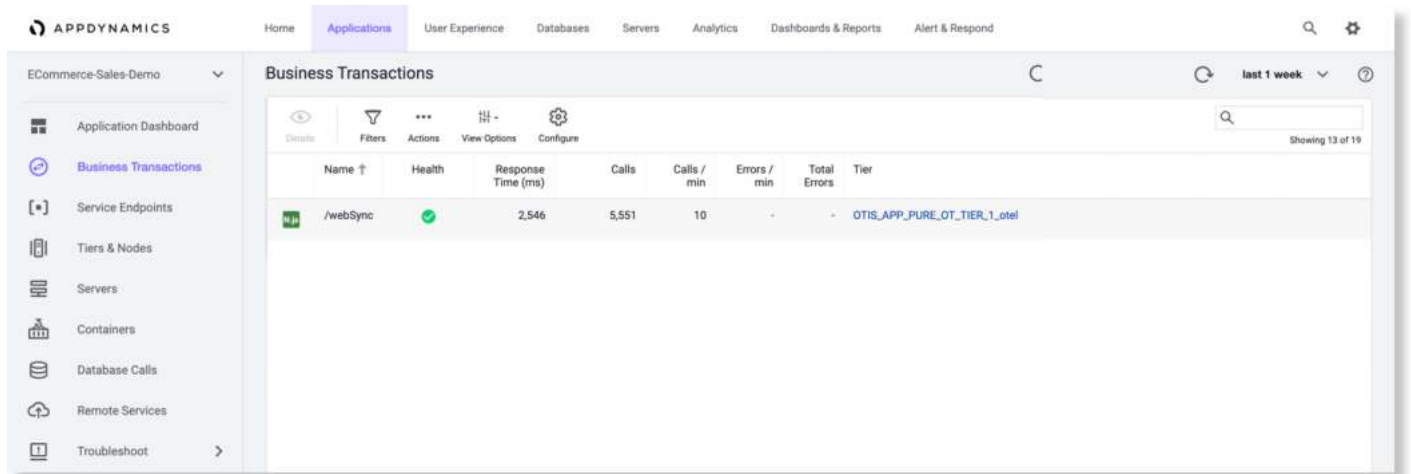

## Tiers & Nodes

On **Tiers & Nodes**, you can view a list of all tiers in an application. The tiers represent the services (defined by `service.name`) that were encountered by the ingested traces. To investigate specific tiers, double-click on a tier name and see a new flow map that is updated with tier-specific data.

## Business Transactions

On **Business Transactions**, the names of the Business Transactions are derived from the name of the first span of each trace (also known as the root span). The health status, response time, number of calls, and other metrics are reported for the Business Transaction.

## Transaction Snapshots

AppDynamics monitors every execution of a business transaction in the instrumented environment, and the metrics reflect all such executions. For troubleshooting purposes, AppDynamics takes snapshots of specific instances of a transaction.

A transaction snapshot gives you a cross-tier view of the processing flow for a single invocation of a transaction.

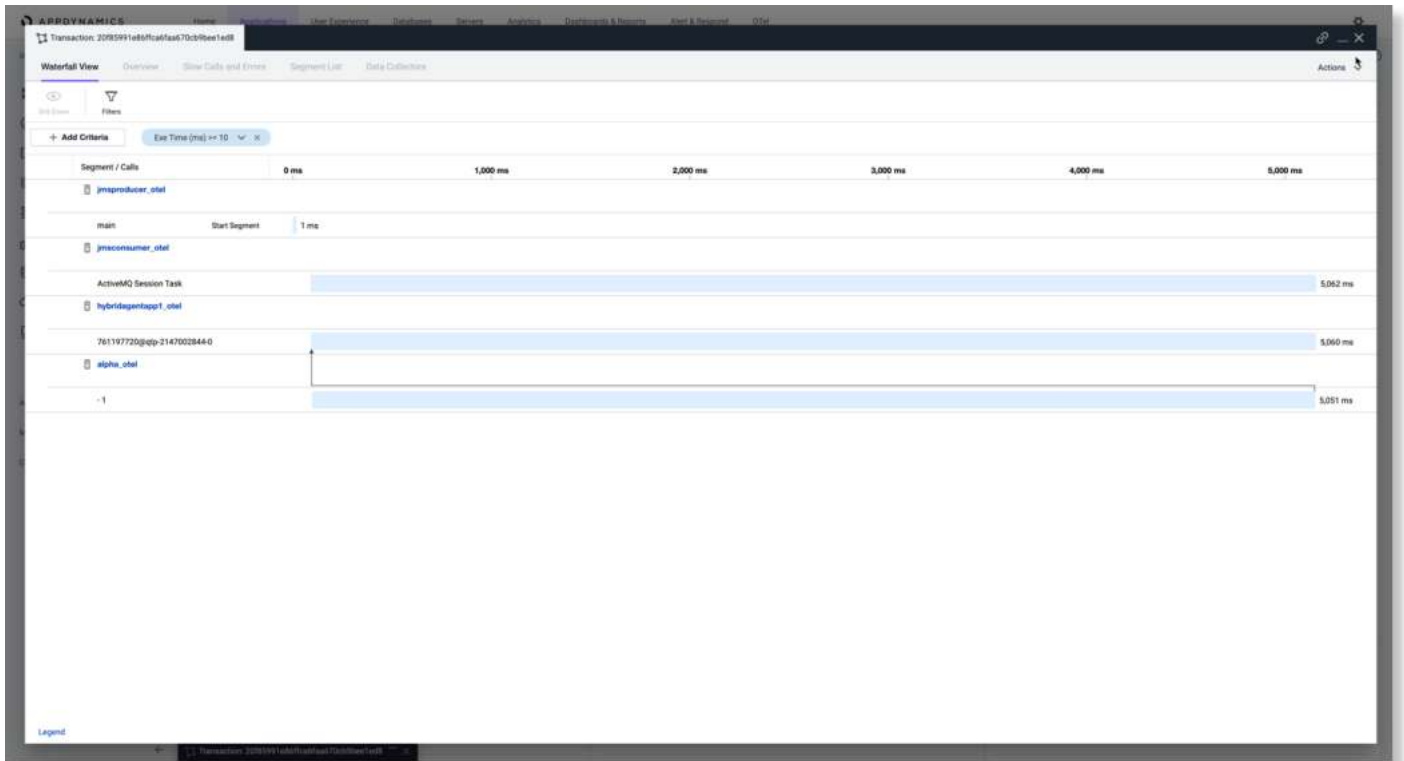

To know more about scenarios that trigger AppDynamics to capture a transaction snapshot and how to configure transaction snapshot settings, see [Transaction Snapshot Collection](#).

To know more about how to view transaction snapshot data to monitor and troubleshoot business transaction performance, see [Troubleshoot Business Transaction Performance with Transaction Snapshots](#).

In a **Transaction Snapshot**, the following information is available.

Field	Description
<b>Waterfall View</b>	Shows the execution of an individual business transaction broken into execution segments. Each segment (shown as a blue bar) represents the time spent executing code on a particular thread within an instrumented application runtime, or the time spent waiting for responses from un-instrumented backends. Handoffs between segments are shown as solid lines for synchronous requests, and dotted for asynchronous requests. The waterfall view allows you to quickly determine which calls consumed the transaction time for a given snapshot. You can click a segment to view the resource wait time for its business transaction. Additionally, you can review downstream applications indicated with the flow map icon.

## Support for AppDynamics for OpenTelemetry™

This page covers support for AppDynamics for OpenTelemetry.

- [Regions and Endpoints](#)
- [Backend Languages](#)
- [Java Agent Frameworks for OpenTelemetry](#)
- [Verified OTLP Open Source Versions](#)
- [Data Limits](#)

### Regions and Endpoints

Please note that your OpenTelemetry data may transit through regions different from where your Controller is hosted if you configure your OpenTelemetry Collector using an AppDynamics endpoint located outside of the region where your Controller is hosted.

Region	City	Endpoint
Americas	Oregon	See <a href="#">SaaS Domains and IP Ranges</a> for OpenTelemetry endpoints.
	Sao Paulo	
EMEA	Frankfurt	

Region	City	Endpoint
	London (Coming soon)	
	Capetown (Coming soon)	
APAC	Hong Kong (Coming soon)	
	Mumbai	
	Singapore	
	Sydney	

### Backend Languages

**i** If the Flow Map displays an **Unknown** language icon, you may need to set the `telemetry.sdk.language` resource attribute to your application's language. See [Set Resource Attributes to Your Application Language SDKs](#).

The following languages are supported for AppDynamics for OpenTelemetry:

- \*C++
- \*C#
- Elixir
- Erlang
- Go
- Java
- JavaScript
- Python
- Ruby
- Rust

\*C++ and C# programming languages default to a .NET icon in the Controller UI Flow Map.

### Java Agent Frameworks for OpenTelemetry

Vendor	Framework	Version	Entry Points	Exit Points	Configuration Notes
Open Source	Java Servlet API	2.x, 3.0	Yes	-	-
Apache	ActiveMQ	5.x	Yes	Yes	-

Vendor	Framework	Version	Entry Points	Exit Points	Configuration Notes
Apache	Apache HTTP Client	-	Yes	Yes	See "HTTP Backends" on <a href="#">Java Backend Detection</a> .
Open Source	Http4s Blaze Client	Blaze versions: 0.21.1, 0.21.0, 0.20.23, 0.20.5 scala 2.11, 2.12	No	Yes	-
Apache	Kafka	0.9.0.0 to 3.0.0	-	Yes	Kafka consumer entry points are disabled by default. Correlation is supported. See <a href="#">Apache Kafka Consumer Backends</a> .
Apache	Kafka Streams	<=3.5.1	Yes	Yes	-
Open Source	Micronaut	3.3.3	Yes	Yes	-
Apache	Struts	1.x, 2.x	Yes	-	See <a href="#">Struts Entry Points</a> .
Apache	Tomcat	5.x, 6.x, 7.x, 8.x, 9, 10	Yes	-	See <a href="#">Apache Tomcat Startup Settings</a> .
Open Source	Spring Boot	2.x, 3.x	Yes	-	-
Open Source	Play for Java Play for Scala	2.3, 2.4, 2.5, 2.6, 2.7, 2.8	Yes	-	Play EUM-APM correlation supported
Open Source	Scala	2.11.6	-	-	-
Open Source	Spring REST	-	-	Yes	-
Open Source	Spring RMI	-	Yes	Yes	-

Vendor	Framework	Version	Entry Points	Exit Points	Configuration Notes
Open Source	Akka HTTP Name: akka-http-stream-entry-enabled Type: Boolean Default: False	Akka Actor 2.6 Akka HTTP up to 10.2.6 Scala 2.11, 2.12	Yes	Yes	EUM is supported Support for Non-Route DSL
Oracle	WebLogic RMI	9.x+	Yes	Yes	See <a href="#">Oracle WebLogic Startup Settings</a> .
Oracle and BEA	WebLogic Server	9.x+	Yes	Yes	See <a href="#">Oracle WebLogic Startup Settings</a> .
Oracle	OSB deployed on WebLogic	12.2.1	Yes	Yes	See <a href="#">OSB Support</a> .
Open Source	HTTP Client	0.3-3	Correlation: Yes; Entry: No	Yes	See <a href="#">Oracle WebLogic Startup Settings</a> and <a href="#">Default configuration</a> excludes WebLogic classes.
Open Source	Java Server Pages	2.x, 3.1	-	-	-
Open Source	JBoss EAP	7.1.5, 7.2.0, 7.3.0	Yes	Yes	See <a href="#">JBoss and Wildfly Startup Settings</a> .
Open Source	JBoss Wildfly (formerly JBoss Application Server)	12.x+	Yes	Yes	See <a href="#">JBoss and Wildfly Startup Settings</a> .

Vendor	Framework	Version	Entry Points	Exit Points	Configuration Notes
Spring	Spring Integration	2.2.0+, 4.0+, 5.2, 5.3	Yes	Yes	See <a href="#">Spring Integration Support</a> .  See also "Java Message Service Backends" on <a href="#">Java Backend Detection</a> .
Spring WS	Web Services (HTTP and SOAP)	3.x, 4.x, 5.x	To enable correlation using a header transported in the SOAP:Envelope set node property enable-soap-header-correlation=true	-	Web Service naming
Open Source	Spring WebFlux	5.0, 5.1, 5.2, 5.3	Spring Boot (Netty, Jetty, Tomcat, Undertow)	WebClient (Reactor Netty, Reactive Jetty)	The node property <code>enable-webclient</code> , disables the Netty instrumentation and enables WebClient configuration.  This node property should not be enabled unless there is some issue or loss of visibility with the OOTB support. By default, the value of this property is false.
Open Source	WebSocket	1.0 (Java EE 7, JSR-356)	Yes, correlation not supported	Yes	Node property: <a href="#">websocket-entry-calls-enabled</a>

## Verified OTLP Open Source Versions

Though all OTLP sources are supported, AppDynamics for OpenTelemetry has been verified to work with the following open source versions for each language:

Language	OTLP Open Source Version
.Net, C#	<ul style="list-style-type: none"> <li>• OpenTelemetry.Exporter.OpenTelemetryProtocol: 1.2.0-rc2</li> <li>• OpenTelemetry: 1.2.0-rc2</li> <li>• Grpc.Net.Client: 2.32.0</li> </ul>
Python	<ul style="list-style-type: none"> <li>• Python: 3.8.3</li> <li>• opentelemetry-api: 1.8.0</li> <li>• opentelemetry-exporter-otlp: 1.8.0</li> <li>• opentelemetry-exporter-otlp-proto-grpc: 1.8.0</li> <li>• opentelemetry-exporter-otlp-proto-http: 1.8.0</li> <li>• opentelemetry-instrumentation: 0.27b0</li> <li>• opentelemetry-proto: 1.8.0</li> <li>• opentelemetry-sdk: 1.8.0</li> <li>• opentelemetry-semantic-conventions: 0.27b0</li> </ul>
Go	<ul style="list-style-type: none"> <li>• OS_NAME: Debian GNU/Linux 11 (bullseye)</li> <li>• Golang: 1.17</li> <li>• OTel: v1.4.1</li> </ul>
C++	<ul style="list-style-type: none"> <li>• opentelemetry-cpp sdk: 1.2.0</li> </ul>
Ruby	<ul style="list-style-type: none"> <li>• OS_NAME: "Debian GNU/Linux 10 (buster)"</li> <li>• Ruby Version: ruby 2.6.3p62 (2019-04-16 revision 67580) [x86_64-linux]</li> <li>• OTel API: 1.0.1</li> <li>• OTel SDK: 1.0.2</li> <li>• OTel OTLP Exporter: 0.21.0</li> </ul>
Java	<ul style="list-style-type: none"> <li>• OTel Java Auto-Instrumentation: <a href="#">1.29.0</a></li> </ul>
JavaScript (Browser and Nodejs)	<ul style="list-style-type: none"> <li>• "@opentelemetry/api": "1.0.4"</li> <li>• "@opentelemetry/core": "1.0.1"</li> <li>• "@opentelemetry/sdk-trace-base": "1.0.1"</li> <li>• "@opentelemetry/exporter-trace-otlp-proto": "0.27.0", (export to collector)</li> <li>• "@opentelemetry/auto-instrumentations-node": "0.28.0"</li> <li>• "@opentelemetry/instrumentation": "0.27.0"</li> </ul>

## Data Limits

See [License Entitlements and Restrictions](#).

OpenTelemetry™ is a trademark of The Linux Foundation®.

## Filter Sensitive Data Using the Collector

**i** This document contains references to OpenTelemetry™ documentation. AppDynamics does not own any rights and assumes no responsibility for the accuracy or completeness of such third-party documentation.

While sensitive data can be helpful for diagnosis and troubleshooting, security considerations may require filtering certain information. Data filtering can be done at the agent level or the Collector level. This page includes the recommended configurations to filter the sensitive data at the Collector level. Sensitive data such as identity, credit card information, or email addresses require special data management to ensure data protection and compliance with industry standards.

Sensitive data sent to AppDynamics can be removed using the AppDynamics Distribution for OpenTelemetry Collector or the OpenTelemetry Collector. To filter the sensitive data using the Collector, perform the following steps:

1. Add the required processors to the Collector's configuration file. The processors allow you to delete, redact, or hash specific attributes.
2. Activate the processor functionality by modifying the appropriate `service | pipelines`.

The processors available for filtering sensitive data are:

- `attributes`
- `redaction`
- `transform`

## Common Filtering Scenarios

### Attributes

Use the attributes processor to remove specific keys such as credit card information, passwords, and other sensitive values. See [Attributes Processor](#) and [General Identity Attributes](#).

### Credit Card Information

You can redact values that appear in the `credit_card_number` attribute:

```
...
processors:
 attributes/update:
 actions:
 - key: credit_card_number
 value: redacted
 action: update
...
service:
 pipelines:
 traces:
```

```

 processors: [..., attributes/update, ...]
 metrics:
 processors: [..., attributes/update, ...]
 logs:
 processors: [..., attributes/update, ...]
 ...

```

## Passwords

You can delete a `user.password`:

```

...
processors:
 attributes/update:
 actions:
 - key: user.password
 action: delete
...
service:
 pipelines:
 traces:
 processors: [..., attributes/update, ...]
 metrics:
 processors: [..., attributes/update, ...]
 logs:
 processors: [..., attributes/update, ...]
...

```

## Redaction

Use the redaction processor to remove all attributes except `description`, `group`, `id`, and `name`. See [Redaction Processor](#).

```

...
processors:
 redaction/update:
 allow_all_keys: false
 allowed_keys:
 - description
 - group
 - id
 - name
...
service:
 pipelines:
 traces:
 processors: [..., redaction/update, ...]
 metrics:
 processors: [..., redaction/update, ...]

```

```

 logs:
 processors: [..., redaction/update, ...]
 ...

```

**i** The redaction processor includes a summary configuration that provides details on what is filtered.

Use the `redaction` processor to block the card numbers using regular expression filters for Visa and Master card formats.

```

...
processors:
 redaction/update:
 allow_all_keys: true
 blocked_values:
 - "4[0-9]{12}(?:[0-9]{3})?" ## Visa credit card number
 - "(5[1-5][0-9]{14})" ## MasterCard number
 summary: debug
...
service:
 pipelines:
 traces:
 processors: [..., redaction/update, ...]
 metrics:
 processors: [..., redaction/update, ...]
 logs:
 processors: [..., redaction/update, ...]
...

```

## Transform

Use the transform processor to mask specific values. See [Transform Processor](#).

### Create Allowlist for Specific Keys

Use the transform processor to remove all attributes except `service.name`, `service.namespace`, `cloud.region`, `process.command_line`:

```

...
processors:
 transform/update:
 traces:
 queries:
 - keep_keys(resource.attributes, "service.name", "service.namespace",
"cloud.region", "process.command_line")
 metrics:
 queries:
 - keep_keys(resource.attributes, "service.name", "service.namespace",
"cloud.region", "process.command_line")

```

```

 logs:
 queries:
 - keep_keys(resource.attributes, "service.name", "service.namespace",
"cloud.region", "process.command_line")

 ...
 service:
 pipelines:
 traces:
 processors: [..., transform/update, ...]
 metrics:
 processors: [..., transform/update, ...]
 logs:
 processors: [..., transform/update, ...]
 ...

```

### Mask a Partial Value for a Specific Key

Use the transform processor to redact a password that appears on the command line. For example, `$env password=mysecret username=myusername python run-my-app.py`.

```

...
processors:
 transform/update:
 traces:
 queries:
 - replace_pattern(resource.attributes["process.command_line"], "password\\=[^\\
\\s]*(\\s?)", "password=***")
 metrics:
 queries:
 - replace_pattern(resource.attributes["process.command_line"], "password\\=[^\\
\\s]*(\\s?)", "password=***")
 logs:
 queries:
 - replace_pattern(resource.attributes["process.command_line"], "password\\=[^\\
\\s]*(\\s?)", "password=***")
 ...
 service:
 pipelines:
 traces:
 processors: [..., transform/update, ...]
 metrics:
 processors: [..., transform/update, ...]
 logs:
 processors: [..., transform/update, ...]
 ...

```

## View OpenTelemetry™ Ingestion Data in the Controller UI

The **Ingestion Data Usage** is a dynamic visual representation of data (traces) that AppDynamics for OpenTelemetry™ ingest in your monitored environment.

A trace represents an end-to-end request which can be made up of one or multiple spans. Each span represents one event within a component in the application triggered in the trace.

AppDynamics for OpenTelemetry™ ingests and aggregates traces into Business Transaction flow metrics in the Controller UI.

### Data Metering Indicators

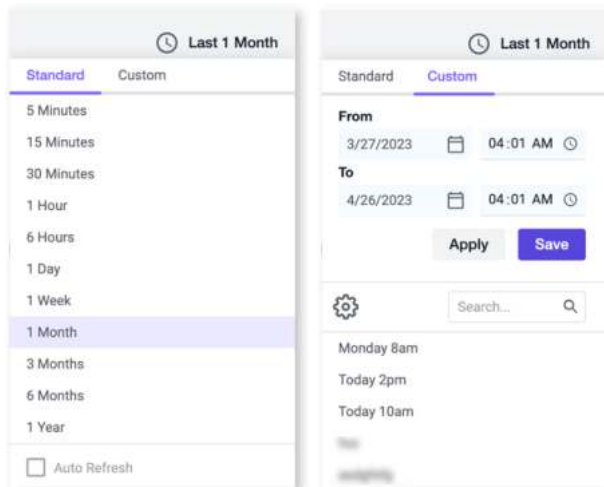

Clicking **OTel > Ingestion Data Usage** displays the current data usage. The **Ingestion Data Usage** page displays the following metrics and data metering indicators.

Display Name	Description
Daily Request Usage	The number of OTel data requests ingested by the account in one day. The daily limit is 270 000 requests.
Monthly Request Usage	The number of OTel data requests ingested by the account in one month. The monthly limit is 8 million requests.
Spans Ingested Today	The number of spans ingested in the last 24 hours. There is no limit for spans.

Display Name	Description
Average Spans Ingested Daily	The average number of spans ingested daily. The average is calculated based on the last 30 days of data.
Average Requests Sent Daily	The average number of OTel data requests sent daily. The average is calculated based on the last 30 days of requests.
Average Request Sent Monthly	The average number of OTel data requests sent monthly. The average is calculated based on the last 90 days of requests.

If you do not see any data, adjust the time range accordingly. For example, if the time range is set to Last 1 Hour, change the time range to Last 1 Week or select a custom time range. It will show all spans and requests from the previous seven days.

OpenTelemetry™ is a trademark of The Linux Foundation®.

## Troubleshooting AppDynamics for OpenTelemetry

The sections below cover some common issues and troubleshooting for AppDynamics for OpenTelemetry.

### Spans Not Being Processed

If some spans are not being processed by AppDynamics, try the following:

- [Verify the required attributes for outgoing calls](#)
- [Change the default SpanKind](#)

### Verify the required attributes for outgoing calls

For spans instrumenting an outgoing call, AppDynamics requires unique attributes appended to the Span Object or else the Span will get dropped from the AppDynamics pipeline. See the tables below for both required and recommended attributes for spans.

Some attributes are not required but are still highly recommended in order to get a more accurate depiction in the Flow Map.

## HTTP

Attribute	Type	Description	Example(s)	Requirement
<code>http.method</code>	string	HTTP request method	GET, POST, HEAD	Required
<code>http.url</code>	string	Full HTTP request URL	<code>https://www.foo.bar/search?q=OpenTelemetry#SemConv</code>	*Conditional Requirement
<code>http.host</code>	string	value of HTTP host header	<code>www.example.org</code>	*Conditional Requirement
<code>http.target</code>	string	The full request target as passed in a HTTP request line or equivalent.	<code>/path/12314/?q=ddd#123</code>	*Conditional Requirement
<code>http.scheme</code>	string	Scheme identifying the used protocol	<code>http, https</code>	*Conditional Requirement
<code>net.peer.ip</code>	string	Remote address of the peer	<code>127.0.0.1</code>	*Conditional Requirement
<code>net.peer.port</code>	int	Remote port number	<code>80, 8080, 443</code>	*Conditional Requirement
<code>net.peer.name</code>	string	Remote hostname or similar	<code>example.com</code>	Required

\*Conditional Requirement - One of the following *must be included* at span creation time:

- `http.url`
- `http.scheme`, `http.host`, `http.target`
- `http.scheme`, `net.peer.name`, `net.peer.port`, `http.target`
- `http.scheme`, `net.peer.ip`, `net.peer.port`, `http.target`

## Database

Attribute	Type	Description	Example(s)	Requirement
<code>db.system</code>	string	An identifier for the database management system (DBMS) product being used	<code>other_sql</code>	Required
<code>net.peer.ip</code>	string	Remote address of the peer (dotted decimal for IPv4 or <a href="#">RFC5952</a> for IPv6)	<code>127.0.0.1</code>	*Conditional Requirement
<code>net.peer.name</code>	string	Remote Hostname	<code>example.com</code>	*Conditional Requirement

\*Conditional Requirement- You need to use either `net.peer.ip` or `net.peer.name`.

## Messaging Queues

Attribute	Type	Description	Example(s)	Requirement
<code>messaging.system</code>	string	A string identifying the Messaging System	<code>kafka, rabbitmq, rocketmq, activemq</code>	Required
<code>messaging.destination</code>	string	The message destination name. This might be equal to the span name but is required nevertheless.	<code>MyQueue, MyTopic</code>	Required

## Change the default SpanKind

AppDynamics does not process the default `span kind INTERNAL`. If your implementation is sending `INTERNAL` spans, those spans will not be reflected in the Controller UI Flow Maps. You must set `SpanKind` to any of the following alternative span kinds:

- `SERVER` - Indicates that the span covers server-side handling of a synchronous RPC or other remote request. This span is often the child of a remote `CLIENT` span that was expected to wait for a response.
- `CLIENT` - Indicates that the span describes a request to some remote service. This span is usually the parent of a remote `SERVER` span and does not end until the response is received.
- `PRODUCER` - Indicates that the span describes the initiators of an asynchronous request. This parent span will often end before the corresponding child `CONSUMER` span, possibly even before the child span starts. In messaging scenarios with batching, tracing individual messages requires a new `PRODUCER` span per message to be created.
- `CONSUMER` - Indicates that the span describes a child of an asynchronous `PRODUCER` request.

`SERVER` and `CONSUMER` spans are entry spans, whereas `CLIENT` and `PRODUCER` spans are exit spans. An entry span must precede an exit span to make the exit calls discoverable. Also, one or more `INTERNAL` spans can be present between an entry and exit span as long as the entry span precedes the exit span.

See [OpenTelemetry Specifications](#) for more information.

Here is an example from [OpenTelemetry documentation](#) to set `SpanKind` to `SERVER` using the OpenTelemetry SDK (Java):

```
Span span = tracer.spanBuilder("/resource/path").setSpanKind(SpanKind.SERVER).startSpan();
span.setAttribute("http.method", "GET");
span.setAttribute("http.url", url.toString());
```

### Unknown Language Icon in Flow Map

If the Flow Map displays an **Unknown** language icon, you may need to set the `telemetry.sdk.language` resource attribute to your application's language. See [Set Resource Attributes to Your Application Language SDKs](#) for more information.

## Development Level Monitoring

Works with:

### Development Level Monitoring and AppDynamics

AppDynamics monitors your production applications in a way that is designed to provide maximum visibility with the least amount of overhead. Development level monitoring is a mode in which certain default limits on the data that AppDynamics collects are turned off, giving you additional visibility on application activities.

This default mode is production-level monitoring and applies limits to the retention of certain types of information. In a testing environment or other environments where overhead is not an issue, you can enable development level monitoring. Development mode is intended for temporary use while setting up AppDynamics or for occasional application troubleshooting.

You apply development monitoring to a specific business transaction and originating node combination. An *originating node* is one or more of the nodes that serve as the entry points for the transaction.

Transactions originating on an enabled node are subject to development level monitoring on downstream nodes that participate in processing that business transaction. Note that this applies for that business application only, however. Processing for a continuing transaction in another business application is not monitored at the development level unless you have enabled development level monitoring at the continuing business application as well.

While development monitoring increases the retention of call graphs and SQL statement capture, certain limits still apply. The limits specify maximum thresholds for calls per minute, Java heap utilization, and snapshot segments generated across the Controller. If the thresholds are exceeded, development level monitoring is turned off. See [Development Level Monitoring Limits](#).

### Effects of Development Mode

Enabling development level monitoring affects the capture of the following information:

- **Exit Calls**—AppDynamics increases information collected for exit calls to backend systems. For database backends, the agent collects all SQL statements without per-transaction limits. The agent also collects all JDBC and ADO.NET calls attached to methods, even when the call duration is less than 10 ms.
- **Snapshots**—The agent attempts to take a snapshot for every transaction, ignoring the values for these agent node properties:
  - [max-concurrent-snapshots](#)
  - [on-demand-snapshots](#)

 Development mode does not guarantee snapshots for every transaction since it was not designed to capture data on every request.

- **Call Graphs**—The agent captures full call graphs in development mode.

 Users must belong to a role with the Configure Monitoring Level (Production/Development) permission for the application to set development level monitoring. See [Manage Custom Roles](#).

## Enable Development Level Monitoring

You enable development level monitoring in the context of a particular business transaction/originating node combination. To avoid exceeding development mode limits described in [Development Level Monitoring Limits](#), it is recommended that you enable development monitoring at the smallest scope possible.

To enable development level monitoring:

1. In the business application for which you want to enable monitoring, click **Configuration > Development Level Monitoring**.
2. Enable the **Development Level Monitoring** switch at the top of the page.  
For agents  $\leq$  4.3, enabling development level monitoring applies globally, rather than for a particular business transaction. For agents  $>$  4.3, you need to configure the business transaction and node to which the configuration applies, as described in the following step.
3. Select the Business Transaction for which you want to enable development monitoring.
4. Click the **Enabled** checkbox next to the originating nodes on which you want to enable development level monitoring.

## Turn Off Development Level Monitoring

Even in pre-production environments, enabling development level monitoring would normally be a temporary measure done in select cases. When finished, turn off development level monitoring for the business application, as described here.

To turn off development level monitoring:

1. In the business application for which you want to turn off development level monitoring, click **Configuration > Development Level Monitoring**.
2. Use the **Development Level Monitoring** switch at the top of the page to turn off development level monitoring. The switch turns off such monitoring for all business transactions in the business application.

Development mode may also be turned off automatically.

---

## Development Level Monitoring Limits

The following agent-applied and Controller-applied limits prevent excessive resource consumption during development mode.

### App Agent Limits

These limits apply for an App Agent:

- For each node, a maximum of 500 calls per minute. (See [dev-mode-suspend-cpm](#).)
- For each JVM, the maximum heap utilization percentage of 90%. (See [heap-storage-monitor-devmode-disable-trigger-pct](#).)

If a limit is exceeded, an agent log event is generated indicating that the development mode has been turned off because limits were exceeded

### Controller Limits

The Controller monitors the number of snapshot segments collected during development monitoring across business transactions. A snapshot segment corresponds to the processing activities for a business transaction on a particular tier. A single business transaction that traverses many tiers can generate more data than several business transactions that only traverse a few tiers.

When the threshold of 5000 snapshot segments per minute is exceeded, the Controller turns off development mode for the top contributing business transactions. The Controller turns off development mode on as many business transactions as are needed to reduce the snapshot segment contribution by 20%.

For example, if a single business transaction is accountable for 25% of the snapshot segments when the threshold is exceeded, only it is turned off. As another example, given the following business transactions and the percentage of snapshot segments, they each contributed when the threshold was exceeded, the first two are turned off:

1. BT1: 17%
2. BT2: 16%
3. BT3: 15%
4. BT4: 15%
5. BT5: 13%
6. BT6: 12%
7. BT7: 12%

You cannot configure this Controller limit.

## Configure Instrumentation

In AppDynamics, instrumentation refers to how app agents interact with your application software to gather performance data and report it back to the AppDynamics Controller. The first step to instrumenting your application is [installing the app agents](#) on the servers where the code runs.

App agents ship with default instrumentation settings that cover the most common types of application frameworks and programming patterns. If your requirements are more complex, you can customize the instrumentation behavior to suit your environment.

See [Configure Instrumentation Overview](#) for information on how AppDynamics applies instrumentation settings across your business application.

---

## Access Instrumentation Settings

Navigate to **Configuration > Instrumentation** to customize:

- [Transaction detection rules](#) that define entry points for [business transactions](#).
- [Backend detection rules](#) that define exit points for your [business transactions](#).
- [Error detection](#) settings that define which transactions qualify as [error transactions](#).
- [Service endpoints](#) to view metrics specific to services and transaction segments outside the context of a single business transaction.
- [Diagnostic data collectors](#) for an app agent to extract additional context about a specific transaction at transaction snapshot time. You can also configure data collectors for [Application Analytics](#).
- [Call Graph Settings](#) to tune the amount of data the app agent collects for call graphs.
- JMX metrics that the Java agent collects for specific products and frameworks. See "Configure JMX Metric Rules" on [Configure JMX Metrics from MBeans](#).
- Memory monitoring settings for agents that collect instance tracking data for specific classes or objects. See the following topics:
  - [Object Instance Tracking for Java](#)
  - [Object Instance Tracking for .NET](#)
  - [Object Instance Tracking for Node.js](#)
- [Asynchronous transaction demarcators](#) to set endpoints for asynchronous transactions.

## Configuration Page Items

In addition to the instrumentation configuration options described on this page, there are many other ways to customize AppDynamics for your environment. For more information on the items on the **Configuration** page, review these pages:

- "Configure Thresholds" on [Transaction Thresholds](#).
- "View Baselines" on [Dynamic Baselines](#).
- [Information Points](#)
- [Development Level Monitoring](#)

If you have an End-User monitoring license, review these pages on **User Experience App Integration**:

- [Correlate Business Transactions for Browser RUM](#)
- [Automatic Injection of the JavaScript Agent](#)
- [Assisted Injection](#)

## Configure Instrumentation Overview

The scope configuration model reduces the number of steps it takes to apply transaction detection rules to multiple tiers.

Under the [scope configuration model](#), you can apply settings to groups of tiers, in addition to individual tiers and nodes. Groups of tiers are called scopes. Only transaction detection settings for applications created in AppDynamics >= 4.3 adhere to the scope model.

### Live Preview Mode

You can interactively experiment with transaction detection rule configurations using Live Preview. Live Preview streams data from an active node, providing real-time data for the following configurations:

- All transaction detection rules that apply to a node. See [Business Transaction Discovery Sessions](#).
- A single custom match rule applied to a node. See [Custom Match Rule Live Preview](#).

The following limits apply to Live Preview:

- 100 sessions on the Controller
- 20 sessions on an account

- 10 sessions on a business application

## Programmatic Expressions

You can specify the following types of programmatic expressions when configuring detection rules:

- Regular expression: A string or character search pattern
- Getter chains: Enable you to access data returned by methods in your application

## Scope Configuration Model

The scope configuration model allows you to bundle multiple tiers into a scope, and apply transaction detection rules to that scope.

You can apply a rule to select tiers all at once. The Default Scope consists of all the tiers in the application.

In the diagram, you want to apply a rule to three of the six tiers in an application. Rather than manually applying the rule to each of the three tiers, you can bundle the tiers into a scope (Scope A) and apply the rule to the scope.

## Creating a Custom Scope

You can create a custom scope by navigating to **Configuration > Instrumentation > Scopes**.

1. Click **Add**.
2. Enter a name for your scope.
3. In the **Include the following Tiers** dropdown, select one of these options:
  - a. **All Tiers in the Application**: creates a scope that includes all the tiers in the application, except tiers that you specify. You can select tiers to exclude from the scope in the **Available Tiers** box and clicking the left-pointing arrow.
  - b. **These Specific Tiers**: creates a scope that includes only tiers that you specify. You can select tiers to include in the scope in the **Available Tiers** box and clicking the left-pointing arrow.
4. Click **Save**.

---

To view the rules that are applied to a scope, select the scope in the Scopes tab. The rules applied to that scope display in the panel on the right.

### Set the Scope for a Rule

When you create a new application, all rules for the application use the default scope. You can create additional scopes for that application, and choose which rules to apply to that scope. Each rule can only apply to one scope.

1. Click the Rules sub-tab.
2. Select the rule that you want to apply to a scope. The tiers that the rule is applied to are displayed in the panel on the right.
3. Click **Edit**.
4. Click **Change Scope**.
5. Select the scope that you want to apply this rule to.
6. Click **OK**.
7. Click **Save**.

To apply a rule to a scope, you need permissions to all the tiers in the scope. To apply a rule to the default scope, you need application-level permission.

### Using Regular Expressions

#### Related pages:

- [Transaction Detection Rules](#)
- [Custom Match Rules](#)

Regular expressions display in various places in the AppDynamics configuration. These places include, for example, transaction detection rules, data collectors, EUM injection settings, health rules, and more. This page describes the use of regular expressions in AppDynamics.

#### Matching Guidelines

A match condition consists of a named property to match (such as a method name, Servlet name, URI, parameter, or hostname), a comparison operator, and a matching value. For complex match conditions, you can use a regular expression (often abbreviated to just regex).

Match rules are case sensitive. Also, matching is based on subsequence pattern matching. To match a complete string instead, you need to include "^" to match the start of the string and "\$" to match the end of the string in your regular expression.

In the context of business transaction matching, the pattern does not include the protocol (e.g., "http://"), host, port, or query parameters in the URL. So for example, a URI of `http://www.mysite.com:8000/account/settings.html?action=update` would be matched by a business transaction regular expression with only `"/account/settings.html"`.

#### Regular Expression Engines

The Java Agent uses Java libraries for regular expressions. See:

- Tutorial: <http://download.oracle.com/javase/tutorial/essential/regex/index.html>
- Javadoc: <http://download.oracle.com/javase/1.5.0/docs/api/java/util/regex/Pattern.html>

The .NET Agent uses the built in .NET regular expressions engine. See:

- MSDN: [.NET Framework Regular Expressions](#)

The Node.js Agent uses JavaScript regular expressions. See:

- [https://developer.mozilla.org/en-US/docs/Web/JavaScript/Reference/Global\\_Objects/RegExp](https://developer.mozilla.org/en-US/docs/Web/JavaScript/Reference/Global_Objects/RegExp)

The PHP Agent uses PHP's built-in PCRE regular expression engine and requires the same syntax, including delimiters (for example: `/^Foo/`). See:

- [PCRE Manual](#)

The Python Agent uses Python's regular expression syntax. See:

- <https://docs.python.org/2/library/re.html>

The Web Server Agent uses Perl regular expression syntax. See:

- [http://www.boost.org/doc/libs/1\\_57\\_0/libs/regex/doc/html/boost\\_regex/syntax/perl\\_syntax.html](http://www.boost.org/doc/libs/1_57_0/libs/regex/doc/html/boost_regex/syntax/perl_syntax.html)

## Regular Expression Examples

These examples show how to construct regular expressions to achieve different results.

### Matching Non-Adjacent URL Segments

A typical use of regular expressions in the AppDynamics configuration is for business transaction custom match rules in which the expression is matched to a requested URI. In this context, it's common for an application's URI pattern to put information that would be useful for business transaction identification in different segments of the URI.

For example, given an example URL of `http://retailstore.example.com/store/jump/category/shoes/departments/view-all/cat630006p`, a business transaction might need to match on `/store/jump` and `all` to group user requests to view all of an available category.

A regular expression to match this case could be:

```
/store/jump.*\b?all\b
```

### Matching Any Digit

Say you want to ignore numbers contained within a pattern. For example, consider the following URL examples:

- `/group/1/session/`
- `/group/1/session/`
- `/group/31/session/`
- `/group/2/session/`

Examples of matching regular expressions would be:

- `^/group/\d*/session/?$`
- `session`
- `/\d*/session/?$`

### Requiring a Digit

To group URLs that contain letters then numbers into one business transaction, such as the following:

- `/aaa123.aspx`
- `/b1.aspx`

You could use an expression such as the following:

```
/[a-z]+?[0-9]+?
```

Not matched would be a URL that does not have digits after the letters, for example: `/z.aspx`

### Handling Letter Casing

Regular expression matching is performed in a case-sensitive manner. To match any case letters, you can use something similar to the following:

```
/[a-zA-Z]+?[0-9]+?
```

Or match in a case-insensitive manner using the *i* modifier. For example:

```
(?i)\w*cart\w*
```

Would match `addToCart` as well as `addTocart`.

### Backend Discovery Rules

For an example of a JDBC backend regular expression, see the section [JDBC with complex URLs](#) in [Example JDBC Backend Configuration](#).

**i** You can find resources for testing your own regular expressions at <http://www.regexplanet.com/advanced/java/index.html>. There you can find regular expression test pages for many language engines, including Java, JS, .NET, PHP and more.

### Performance Considerations

Although regular expressions are a powerful way to set AppDynamics configurations, you should consider the following to avoid performance issues:

- Do not use wildcard expressions unless absolutely needed. You do *not* need to use wildcard expressions (*.\**) before or after a match, and each wildcard regular expression results in approximately an order of magnitude performance impact.
- The number of configurations, the frequency the configuration is applied, and the content length of the target string: For example, if the configuration using a regular expression is applied in many places at high frequency for longer target strings, you might consider reducing the usage of the configuration or decrease the frequency of its application.

### Using Getter Chains

#### Related pages:

- [Transaction Detection Rules](#)

Getter chains let you access method data in various contexts of the AppDynamics configuration. For example, getter chains enable you to name business transactions based on return values. This page describes how to use getter chains.

## Getter Chains

You can use getter chains to:

- Create a new JMX Metric Rule and define metrics from MBean attributes. See [Configure JMX Metrics from MBeans](#).
- Configure method invocation data collectors. See the Configuration Notes in [Data Collectors](#).
- Define a new business transaction custom match rule that uses a POJO object instance as the mechanism to name the transaction. See [POJO Entry Points](#).
- Configure a custom match rule for servlet entry points and name the transaction by defining methods in a getter chain. See "Split by POJO Method Call" on [Split Servlet Transaction by Payload Examples](#).

As a best practice, you should use getter chains with simple getter methods only. Getter chains on processing-intensive methods, such as one that make numerous SQL calls, can result in degraded performance for the application and agent.

For example, the following shows a simple get method that returns a property for a class, such as `MyUser.Name` :

```
public class MyUser
{
 private String Name {get; set;}
 private String Url;
 public String GetUrl() {
 return this.Url;
 }
}
```

## Special Characters in Getter Chains

Use the following special characters as indicated:

- Parentheses `()` to enclose parameters
- Commas `,` to separate parameters
- Forward slashes `/` to separate type declarations from a value in a parameter
- Backslashes `\` to escape characters.
  - To search for a backslash `\`, escape the backslash with a backslash:

```
GetString().Find(\\)
```

- To split a string by a backslash `\`, escape the backslash in Java and within the Getter Chain:

```
GetString.split(\\).[0]
```

- Dots `.` to separate methods and properties in the getter chain
- Dot `.` to represent "anything" must be escaped
- Curly braces `{ }` to delineate getter chains from static elements in custom expressions on `HttpRequest` objects (including in the Java Servlet Transaction Naming Configuration window and in the Split Transactions Using Request Data tab of the servlet custom match and exclude rules)

Getter chains also treat spaces at the beginning or end of a string as special characters.

## Escape Literal Characters

If the getter chain should treat a special character literally, escape it using a backslash. For parentheses, you only need to escape the closing parenthesis in a string.

- The following example shows the how to escape the dot in the string parameter.

```
GetAddress().GetParam(a\.b\.c\.)
```

The agent executes `GetParam("a.b.c.")` on the result of `GetAddress()` and returns the value of the parameter.

- In the following example, the first dot is part of the string method parameter, which requires an escape character. The second and third dots don't require an escape character because they are used as method separators.

```
GetUser(suze\.smith).GetGroup().GetId()
```

- The following example shows how to escape the opening and closing parenthesis in a search for "(" within a string.

```
GetString.Find(\(\))
```

## .NET Notes and Examples

These sections apply to getter chains used in .NET Agent configurations.

**i** Escape backslashes within a getter chain for .NET with the double backslash.

## Declare Parameter Types

The .NET Agent identifies parameter types as follows:

- Dictionaries, anything with property accessors, use a normal parameter set, which defaults to string.
- Arrays use single integers as parameters.

Therefore `@` means `string/@` if you have a hash, or anything that translates to `get_Item` (any kind of property). `@` means `int/@` if you have an array.

When your getter chain uses a method with parameters other than the default type, you need to declare the parameter type.

- The following example demonstrates how to declare the parameter types to resolve the overloaded `Substring()` method. The forward slash serves as the type separator.

```
GetAddress(appdynamics, sf).Substring(int/@, int/10)
```

For instance, if `GetAddress(appdynamics, sf)` returns "303 2nd St, San Francisco, CA 94107", the full getter chain expression returns "303 2nd St".

- The following example shows how to declare the parameter types for a user-defined method that takes a float parameter, a boolean parameter, and an integer parameter. The forward slash serves as the type separator.

```
GetAddress(appdynamics, sf).MyMethod(float/0\\.2, boolean/true, boolean/false, int/5)
```

## Access Indexed Properties and Dictionary Values

If your getter chain accesses a dictionary object, you can access the values using the following syntax:

- The following example returns the value for the key `suze.smith`.

```
UserDictionary.[string/suze\\.smith]
```

- The following example returns the value for the key `suze.smith` using the implied getter.

```
UserDictionary.get_Item(suze\\.smith)
```

## Split by Character or Regular Expression Match in .NET Getter Chains

You can split values matched by character or as a string by matching a regular expression pattern. The result of a split operation is a string or character array that you can reference in your getter chain by an array index value.

The following examples illustrate how to use the character and string regular expression split operations in getter chains.

### Split by Character

- The following chain splits a URL on the forward slash character. In this case, the first slash acts as a type separator. The getter chain returns the fourth item in the array.

```
GetUrl().Split(char[]//).[3]
```

The agent returns "Search" when it applies the getter chain to the following URL: `http://howdyworld.example.com/Search/Airfare`

- In the following example, the split occurs on the forward slash character, and the result is the length of the resulting array.

```
GetUrl().Split(char[]//).Length
```

- This example illustrates a transaction splitting rule for URIs that use a semicolon delimiter. The getter chain splits on the forward slash, then splits the fourth element on the semicolon.

```
GetUri().Split(char[]//).[3].Split(char[]/;).[0]
```

The agent returns `create-user` when it applies the getter chain to the following URL:

```
http://HowdyWorld.example.com/create-user;sessionId=BE7F31CC0235C796BF8C6DF3766A1D00?act=Add&uid=c42ab7ad-48a7-4353-bb11-0dfeabb798b5
```

## Split by Regular Expression

For more control, you can split values by string-based pattern matching. Pattern matching is particularly useful for situations that require complex matching, such as matching content within a request body.

The following example shows a getter chain that splits the value returned by `GetAddress()` and selects the seventh element in the resultant array:

```
GetAddress().Split(string/\\W+).[6]
```

Given an address such as `303 2nd St, San Francisco, CA 94107`, the example splits the value by word and references the sixth word in the array, `CA` in this case.

## Compose Getter Chains for HTTP Requests

The .NET Agent requires special syntax for getter chains for HTTP Requests:

- For ASP.NET WebForms, MVC, and MVC WebAPI applications create getter chains based upon the `System.Web.HttpRequest` objects.
- For ASP.NET Core on the full framework, create getter chains based upon `Microsoft.AspNetCore.Http.Internal.DefaultHttpRequest` objects.

**i** If you have both ASP.NET and ASP.NET Core on the full framework apps in the same tier, you cannot use a getter chain to apply to both because the two frameworks use different objects to handle HTTP requests.

- Use the following syntax to delineate the boundaries of the getter chain:

```
`${myobject.myproperty}`
```

- The following example determines the user principal:

```
`${Context.User.Identity.Name}`
```

Places to use this syntax include:

- HTTP Request Data Collectors
- ASP.NET Transaction Detection custom expressions

## Java Notes and Examples

The following sections apply to getter chains used in Java Agent configurations.

### Values Passed in a Getter Chain

The value passed in a getter chain is always a string unless cast to another type.

The following cast types are supported:

- `int`
- `float`
- `bool` (the primitive Boolean value)
- `boolean` (a boxed boolean value; i.e. an object type that wraps a boolean)

- long
- object

The following section shows examples of how to refer to the types in parameters to getter chain methods. Notice that letter case is not important for the names of the types. Type casting is performed in a case-insensitive manner.

### Java Getter Chain Examples

- Getter chain with integer parameters in the substring method using the forward slash as the type separator:

```
getAddress(appdynamics, sf).substring(int/0, int/10)
```

- Getter chain with various non-string parameter types:

```
getAddress(appdynamics, sf).myMethod(float/0.2, boolean/true, boolean/false, int/5)
```

- Getter chain with forward slash escaped; escape character needed here for the string parameter:

```
getUrl().split(\\) # node slash is escaped by a backward slash
```

- Getter chain with an array element:

```
getUrl().split(\\).[4]
```

- Getter chains that return Hashmap values:

```
get(object/myvalue).substring(int/0,int/10)
get(object/ACTION)
```

- Getter chain with multiple array elements separated by commas:

```
getUrl().split(\\).[1,3]
```

- Getter chain retrieves property values, such as the length of an array:

```
getUrl().split(\\.).length
```

- Getter chain using backslash to escape the dot in the string parameter; the call is getParam (a.b.c).

```
getAddress.getParam(a\\.b\\.c\\.)
```

- In the following getter chain, the first dot requires an escape character because it is in a string method parameter (inside the parentheses). The second dot does not require an escape character because it is not in a method parameter (it is outside the parentheses).

```
getName(suze\.smith).getClass().getSimpleName()
```

The following getter chain is from a transaction splitting rule on URIs that use a semicolon as a delimiter.

```
getRequestURI().split(\/).[2].split(;).[0]
```

The call gets the URI using `getRequestURI()` and then splits it using the escaped forward slash. From the resulting array, it takes the third entry (as the split treats the first slash as a separator) and inserts what before the slash (in this case, nothing) into the first entry. Then it splits this result using the semicolon, getting the first entry of the resulting array, which in this case contains the API name.

For example, given the following URI:

```
/my-webapp/xyz;jsessionId=BE7F31CC0235C796BF8C6DF3766A1D00?
act=Add&uid=c42ab7ad-48a7-4353-bb11-0dfeabb798b5
```

The getter chain splits on the API name, so the resulting split transactions are "API.abc", "API.xyz" and so on.

**Tip:** When using `string.split()`, remember that it takes a regex and you have to escape any special regex characters.

For example, if you want to split on the left square bracket ([):

```
Java syntax: split("\[")
Getter chain syntax: split(\\\[)
```

**i** A Vertical Bar or Pipe (|) is a reserved character in Getter strings. For methods with a regular expression parameter, use Unicode as an alternative.

For example:

```
split(string/\\u007C).[0] // return the first element of an string split by a Vertical Bar.
```

## Blocklisted Classes or Packages and Methods of the Java Getter Chain

Certain packages and classes have been blocklisted from being accessed within getter chains.

The following methods and classes or packages have been blocklisted by the Java Agent for Getter Chains:

---

## Methods:

- `getClassLoader`
- `loadClass`
- `invoke`

## Classes or packages:

- `reflect`
- `nio.file`
- `ClassLoader`
- `io.File`
- `io.Socket`
- `net.Socket`
- `ProcessBuilder`
- `Runtime`

## Transaction Detection Rules

### Related pages:

- [.NET Business Transaction Detection](#)
- [PHP Business Transaction Detection](#)

AppDynamics uses different types of transaction detection rules to define entry points and name **business transactions**:

- [Automatic transaction discovery rules](#) include the default entry point types and naming configuration for each app agent type.
- [Custom match rules](#) offer finer control over transaction discovery and naming for a single entry point type.

In many cases, the built-in rules yield a useful set of business transactions. If not, you can create new rules or edit the existing rules to optimize the transaction detection for your environment.

### Permissions

The *Configure Transaction Detection* permission is needed to customize transaction detection rules.

The *View Sensitive Data permission*, In combination with the *Configure Transaction Detection* permission, enables the use of [Live Preview](#) and [Business Transaction Discovery](#) features to stream live data from your application.

### Live Preview

For Java and .NET environments, you can use interactive live preview tools to find business transaction entry points:

- [Business transaction discovery sessions](#) stream live data from the node to the Controller UI to help you make instrumentation decisions. These sessions display transactions based on all transaction detection rules active for the node.
- For certain types of entry points, [custom match rule live preview](#) enables you to preview transactions based on applying a single transaction detection rule on a node.

Business transactions within the context of the Live Preview, called transient transactions, do not persist after the Live Preview ends. Business transaction discovery sessions let you apply or discard rule changes when you end the session. Custom match live preview rules apply after you save the rule.

Some transient transactions may invoke exit calls to the same node where the Live Preview session is running. In certain cases, the agent may discover additional transient transactions and uninstrumented code on the downstream segment:

- The exit call and corresponding entry point are automatically discovered exit and entry points like HTTP or Web Service.

- Rare cases of custom activity in-process calls.

## Manage Transaction Detection Rules

To customize transaction detection rules in the Controller UI, go to **Configuration > Instrumentation**. From the [Business Transactions](#) list, you can also click **Configure** to quickly access Transaction Detection settings.

You apply transaction detection rules to tiers using the flexible [scope configuration model](#). From the Transaction Detection tab, you can manage rules as follows:

- Manage rules for individual scopes on the Transaction Detection tab.
- Manage rules application-wide on the Rules sub-tab. The Rules sub-tab also shows you the tiers where rules are applied and according to which scope.
- View or modify the rules for specific tiers on the Tiers sub-tab.

To modify an existing rule, you can double-click it to display the **Rule Editor**. Click **+/Add** to define a new rule.

Use **Live Preview** button to start a [Business Transaction Discovery](#) session for nodes running the Java and .NET Agent.

## Transaction Detection Rule Priorities

AppDynamics app agents apply transaction detection rules of the same type in the following order of precedence:

1. Rule priority from highest to lowest. A priority of 0 is the lowest priority possible.
2. Creation date from oldest to newest. This is applicable to custom rules only.

For example, consider an HTTP request that matches a priority 2 custom match rule and a priority 6 custom match rule. The agent applies the priority 6 rule.

When an incoming request matches more than one type of detection rule, AppDynamics applies the detection rules in the following order of precedence:

1. Custom match *include* rules according to the include rule priority. If the request matches an include rule, the agent names the business transaction based on the rule.
2. Custom match *exclude* rules according to the exclude rule priority. If the request matches an exclude rule, the app agent excludes the transaction from discovery.
3. Default automatic detection rules. If the request matches a default automatic detection rule, it names the transaction according to the auto-detection naming scheme.

If two entry point types have the same priority where either can be used to define or register an entry point, then there is some precedence between them.

For example: If in Java just the Java Automatic Discovery Rule with all types is enabled, and there are entry points which can be considered as Web Services or Servlets - then the Servlets will take priority - a higher priority rule is needed if Web Services are the desired default.

To view the default order of transaction detection rules for a tier:

1. Navigate to **Configuration > Instrumentation > Transaction Detection > Tiers**.
2. Click a tier to see the rules ordered by precedence and priority.

For Java and .NET, you can set the `check-bt-excludes-early` node property to "true" to configure the app agent to evaluate custom match exclude rules before custom match include rules. This is a node-based configuration and does not affect the display order of rules in the Controller UI.

## Export Detection Rules

You can migrate the rules between applications and tiers using the Controller API. See [Configuration Import and Export API](#).

## Automatic Transaction Discovery Rules

Each AppDynamics app agent type has a default automatic transaction discovery rule that applies to all the [entry points](#) for that agent. When an agent identifies a business transaction that matches an automatic transaction discovery rule, it names the business transaction based on naming rules for the entry point type.

### Automatic Transaction Naming

The naming logic varies depending on the application technology. For example:

- For web-oriented technologies that have URI entry points such as Java Servlets, detection rules name the transaction using the first two segments of the URI by default. See [URI Based Entry Points](#).
- For message-oriented technologies such as an asynchronous message listener or message-driven bean (JMS), the agent names the business transaction for the destination name (the queue name) or the listener class name (if the destination name is not available.)
- For Web services, the agent names the business transaction for the Web service name plus the operation name.

### Customize Automatic Transaction Discovery Rules

You can customize automatic transaction discovery rules as follows:

- Add an automatic transaction discovery rule for an agent type.
- Enable or disable different types of automatically discovered entry points.
- Customize transaction naming for some entry points, such as most URI-based entry points.

To access the Rule Editor, double-click an Automatic Transaction Discovery rule for an app agent. Alternatively, you can create a new automatic transaction discovery rule for the agent type by clicking **Add**. Clicking the Rule Configuration tab displays the entry points for the automatic discovery rule.

When you edit, delete, or change the scope for an automatic transaction discovery rule, the Controller UI performs [validation](#) to ensure each tier has the correct automatic discovery rule available for its agent type.

If you are using the Java Agent you can preview the effects of your customizations before you apply them in production. See "Edit and Preview Transaction Discovery Rules" on [Business Transaction Discovery Sessions](#).

### Disable Transaction Monitoring for Entry Points

Automatic transaction detection rules have a **Transaction Monitoring Enabled** checkbox for each entry point type to control automatic discovery. By default, all entry point types are enabled. When you disable discovery for an entry point type, the agent stops counting, measuring, and recording all activity for that entry point type for the scope where the rule is applied.

 The **Transaction Monitoring Enabled** configuration affects custom match rules in the same scope for the entry point type. For example, if you disable POJO monitoring in the Java Default Automatic Transaction Discovery Rule for a scope, the Java Agent will not discover any POJO transactions for the scope.

Following are the cases when you might want to disable monitoring:

- You know that you don't want to monitor any business transactions of a specific entry point type.
- You want to monitor transactions from a downstream call.

For example, consider an application where Servlets implement Spring Beans and you are interested in monitoring the transaction starting at the Spring Bean level. Disable Servlet monitoring and the auto-detection rule for Spring Beans will be the entry point for the transaction.

### Disable Automatic Transaction Detection for an Entry Point Type

If you want to continue monitoring custom match rules, you can disable **Discover transactions automatically for <entry point type>**. When you disable automatic transaction discovery, the app agent stops reporting metrics for previously-detected transactions for the now disabled entry point type. The agent only detects transactions based on custom match rules. However, disabled transactions are not deleted or excluded. See [Organize Business Transactions](#) for information on deleting transactions.

- The agent does not discover any new transactions based on the Default Automatic Transaction Discovery Rule for the disabled type.
- The agent no longer auto-detects calls to methods and operations of the disabled entry point type.
- Custom match rules for the entry point type remain active and the agent reports metrics for transactions resulting from custom matches.
- Exit point detection remains enabled.

The *Discover Transactions automatically* configuration does not apply to [POJO entry points](#) or [POCO entry points](#).

### Customize Transaction Naming for an Entry Point

To view and edit the business transaction automatic discovery rules, go to **Configuration > Instrumentation > Transaction Detection**.

Instrumentation

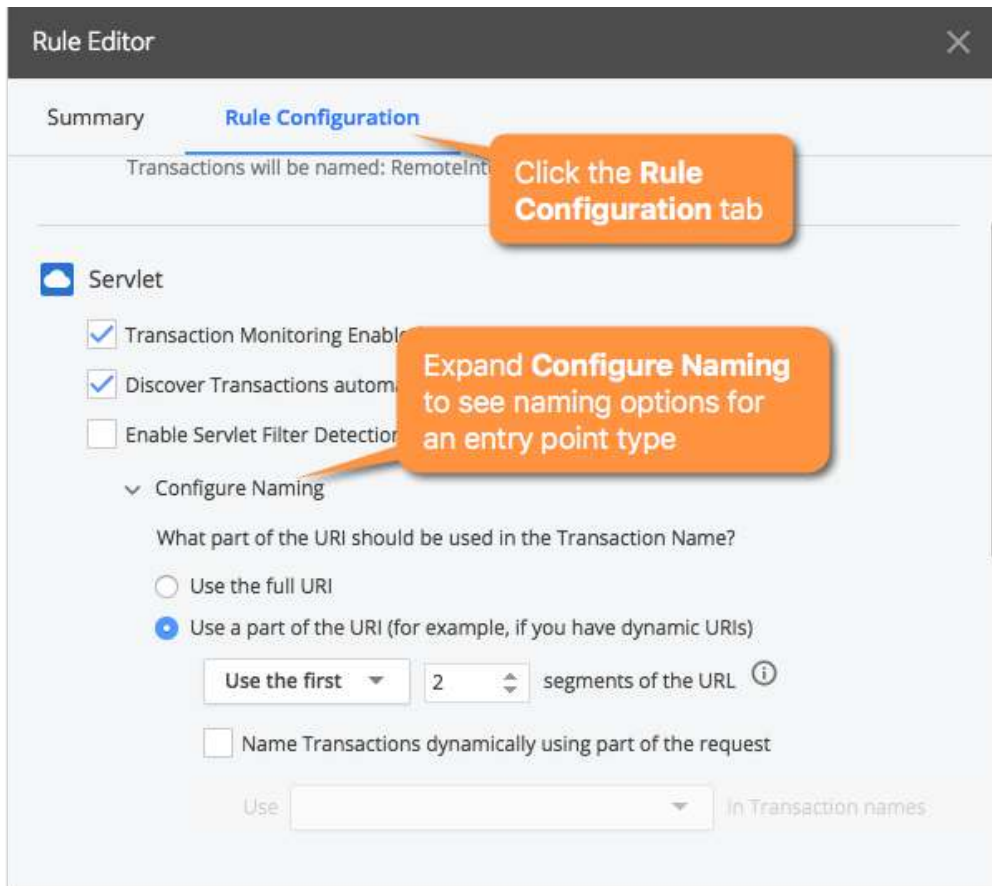

Transaction Detection Service End

Scopes **Rules** Tiers More

Filters Add Edit Delete Copy  Showing 35 of 35

↑	Agent Type	Name	Scope	Enabled	Prio...
	Java	Java Auto Discovery Rule	Default Scope	✓	0
	C/C++ SDK	C/C++ SDK Auto Discove	Default Scope	✓	0
		default Scope	default Scope	✓	0

To customize transaction naming for an entry point type, double-click a Default Automatic Transaction Discovery rule for specific agent type. Click the Rule Configuration tab to see entry points for the rule. Entry point types that have customizable naming options have the **Configure Naming** expander, as shown below.

For more information specific to customizing naming for URI-based transactions, see [URI Based Entry Points](#).

You can also customize transaction naming using a [Custom Match Rule](#).

### Transaction Detection for Apache Web Servers

The AppDynamics Apache Agent monitors web server entry points and names business transactions originating on Apache web server tiers based on the request URI. You can modify the default business transaction naming scheme if needed.

### Default Automatic Naming for Web Transactions

By default, the AppDynamics auto-detection naming scheme identifies all web server transactions using the full URI before the query string. For example, the following URI represents a funds transfer operation for an online bank:

```
http://bank.example.com/Account/Transferfunds/California
```

Based on the default scheme, the business transaction would be named /Account/Transferfunds/California.

You can customize the auto-detected naming scheme by configuring identification based on:

- URI segments
- Headers, cookies, and other parts of HTTP requests

To customize auto-detected naming:

1. On the **Transaction Detection** page, select the application or tier to configure and click the **Web Server** tab.
2. Verify that **Transaction Monitoring** is enabled and click **Discover Transactions automatically for http web requests**.  
 If you disable **Discover Transactions automatically for WEB requests**, the agent doesn't discover WEB transactions even if you configure custom naming.
3. Click **Configure Naming** for the **Web** type in the **Entry Points** panel.

### Identify Transactions Using URI Segments

AppDynamics offers several options to automatically name web transactions based on the URI. Consider the following URL representing a checkout operation in an online store:

```
http://onlinestore.example.com/Web/Store/Checkout
```

You can configure AppDynamics to identify a more meaningful name using one of the following options:

- Click **Use the first** or **Use the last** to use the selected number of contiguous segments at the beginning or end of the URI. For example, to identify the checkout transaction using the last two segments of the URI: `/Store/Checkout`.
- If you need more flexibility, such as using non-contiguous segments in the name, click **Name Transactions dynamically using part of the requests** and specify the segments with the **Use URI segments in Transaction names** option.
- To name the transaction for specific URI segments, click **Use URI segment(s) in Transaction names**. This enables you to skip URI segments or use non-contiguous segments in the naming scheme.  
 Enter the segment numbers separated by commas: `1, 3`. For example, the following URL represents the checkout transaction requested by a customer with ID 1234:  

```
http://onlinestore.example.com/Store/cust1234/Checkout
```

 The checkout transaction is the same regardless of the customer, so it makes sense to omit the customer ID and name the transaction based on the first and third segments of the URI: `/Store/Checkout`.

### Identify Transactions Using Headers, Cookies, and Other Parts of HTTP Requests

To identify business transactions using particular parts of the HTTP request, click **Name Transactions dynamically using part of the request** and configure the option that makes sense for your application.

Carefully consider your naming configuration choices. If you use a value such as the request originating address and you have many clients accessing your application, it's likely that you would quickly reach the maximum number of registered business transactions. See "About the "All Other Traffic" Business Transaction" in [Business Transactions](#) for information about this event.

The following provides sample results based on the configuration options:

- To name transactions based upon the parameter name, click **Use a parameter value in Transaction names** and enter the **Parameter Name**.  
 For example, when you name the following transaction using the parameter name "category": `http://example.com/Store/Inventory?category=electronics`, AppDynamics names the transaction to include the category parameter value: `/Store/Inventory.electronics`.
- To use a header value in transaction names, click **Use header value in transaction names** and enter a **Header Name**.  
 For example, if you name the transaction using a header such as "Version", AppDynamics names transactions with the header value as follows: `/Store/Inventory.v2.5`.
- To use a cookie value in transaction names, click **Use a cookie value in Transaction names** and enter the **Cookie Name**.  
 For example, for a website that tracks a user's loyalty status in a cookie. Set the Cookie Name to "loyalty". AppDynamics names transactions for the loyalty cookie value: `/Store/Inventory.Status=Gold`.
- To Use a session attribute value in transaction names, Click **Use a session attribute in Transaction names** and enter the **Session Attribute Key**.  
 For example, a website stores a customer's region in the session property. Set the Session Attribute name to "region". AppDynamics names transactions for the region session attribute value: `/Store/Inventory.NorthAmerica`.

- To use the request method in Transaction names, click **Use the request method (GET/POST/PUT)** in Transaction names. For example: `/Store/Inventory.GET`.
- To use the request host in Transaction names, click **Use the request host in Transaction names**. For example: `/Store/Inventory.192.0.2.0`
- To use the request originating address in Transaction names, click **Use the request originating address in Transaction names**. AppDynamics names transactions for the IP address of the request client. For example: `/Store/Inventory.192.0.2.10`.
- To use a regular expression on the URI to name the transaction, click **Apply a custom regular expression on the transaction name**. AppDynamics uses the following rules to name the transaction:
  - The Apache Agent uses [Perl style regular expressions](#).
  - AppDynamics tests the regular expression against the segments specified in the configuration.
  - AppDynamics names the business transaction for the substring match.
  - If the regular expression pattern isn't found, the business transaction name follows the URI rules.
  - If you use groups in the regular expression, AppDynamics names the business transaction for the first matching group. If no matching groups are found in the pattern match, AppDynamics names the transaction for the fully matched substring. For example consider the following URL: `http://mywebapp.example.com/abc/;jsessionid=12345008;mykey=mytransaction;anotherkey=foo`. Use the first two segments of the URI with the following regular expression to name the transaction for the value of *mykey*: `.*mykey.(\w+).*`. In this instance AppDynamics names the transaction *mytransaction*.

## Custom Match Rules and Exclude Rules

You can create custom match rules and exclude rules for Web type entry points for Apache Agent. The configuration parameters work the same as those for custom naming in this page. If an excluded request on the Web Server tier passes to another instrumented tier such as Java, PHP, or Python, the downstream agent will detect the transaction. See [Custom Match Rules](#).

## Validation for Automatic Transaction Discovery Rules

When you first create a business application in AppDynamics, the Default Scope ensures that all tiers for the application have a default automatic discovery rule for every agent type. Because the scope configuration model is highly configurable, the Controller UI enforces validations in the following cases:

- When you change the automatic discovery rules for a scope.
- When you assign or reassign tiers to a scope.

When you attempt to make an invalid change, the Controller prevents the change and displays a message in the Controller UI.

These validations ensure that after configuration updates every tier in your business application has the default automatic discovery rule for its agent type. They also ensure that there is an automatic discovery rule for all agent types to handle any prospective tiers you add to your application.

## Existing Tiers

Every existing tier must belong to a scope that includes an automatic transaction detection rule for the tier's agent type. For example, a Java tier must belong to a scope with a Java automatic transaction detection rule.

The following rules apply:

- You can remove a tier from scope only when the tier has an auto-discovery rule from another scope.
- You can remove an automatic transaction detection rule from a scope only when tiers have auto-discovery rule from another scope.

## Prospective Tiers

To ensure that any new tier you add to your application has an automatic transaction detection rule available, there must be at least one automatic transaction detection rule for each agent type in a scope of the following types:

- A scope that contains all tiers.  
OR
- A scope that contains all tiers excluding specific existing tiers.

## Custom Match Rules

### Related pages:

- [Using Regular Expressions](#)
- [Custom Exclude Rule Examples](#)
- [.NET Agent for Linux Business Transaction Configuration](#)

A custom match rule is a type of [transaction detection rule](#) that enables you to define criteria for business transaction discovery, and naming for an entry point type.

There are two types of custom match rules:

- A custom include rule defines an entry point to use in a new transaction.
- A custom exclude rule lets you prevent AppDynamics from detecting business transactions you are not interested in tracking. For example, application framework services, administrative console requests, or heartbeat pings, and so on.

Use [Live Preview](#) to experiment with certain custom match rule configurations and identify potential business transaction entry points:

- During a [Business Transaction Discovery Session](#), you can use the Classes/Methods browser or Uninstrumented Code to create [POJO](#) and [POCO](#) custom match rules.
- When you create or edit a [POJO](#) or [Servlet](#) entry point, you can use [Live Preview](#) for the individual rule you are creating.

## Transaction Naming

When an app agent detects a request that matches a custom include rule, it names the business transaction based on the rule name. You can further refine the transaction name using transaction splitting for [URI based rules](#), for [POJOs](#), or for [POCOs](#).

If a request matches more than one custom include rule, it applies the rule with the highest number priority. See [Transaction Detection Rules](#).

## Create a Custom Match Rule

1. Navigate to **Configuration > Instrumentation** and select the **Transaction Detection** subtab.
2. Select the Rules subtab.

 You can also add a rule within a specific scope on the Transaction Detection tab.

3. Select **Add** to open the Add Rule page with *Custom Match Rule* selected.
4. Select the **Agent Type** and the **Entry Point Type** and select **Next**.
5. On the Summary tab, make general rule configurations:
  - If you are creating a custom match exclude rule, click **Exclude Transactions discovered by this rule**.
  - Enter the rule *Name*. The app agent names requests that match the rule for the rule name.

**i** To avoid errors, do not include these special characters in the rule name: less than sign (<) and greater than sign (>).

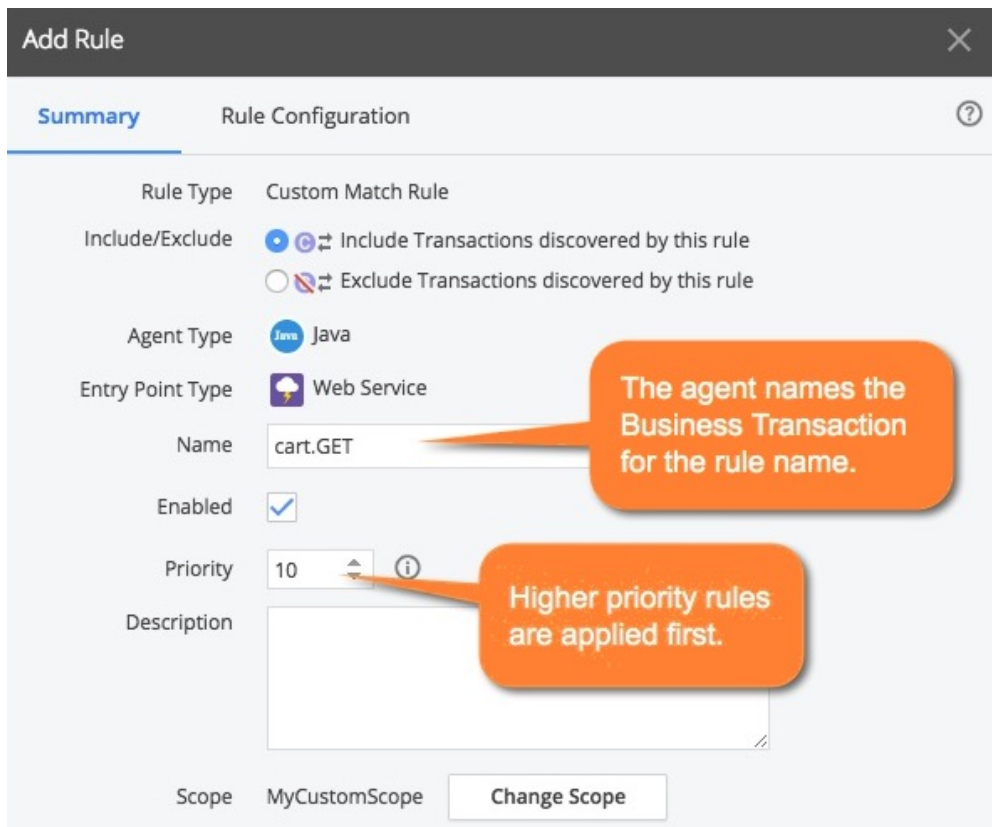

- Optionally disable the rule, set the rule *Priority* and assign the rule to a *Scope*.  
For information on rule priorities, see [Transaction Detection Rules](#).  
For information on scopes, see [Scope Configuration Model](#).

6. On the Rule Configuration tab, configure the match criteria based upon the entry point type. The PHP web choices, for example, let you specify HTTP-oriented match criteria, such as those for HTTP method, URI, and query parameters.

**✓** Servlet and POJO entry point types feature a *Live Preview* button to launch [custom match rule live preview](#) session. A live preview streams data from an active node so you can interactively experiment with rule configuration in the Add Rule window.

### Custom Match Include Rule Example

This example shows a custom match include rule named *cart.GET* in a scope named MyCustomScope.

**Add Rule**

**Summary** | Rule Configuration

Rule Type: Custom Match Rule

Include/Exclude:  Include Transactions discovered by this rule  
 Exclude Transactions discovered by this rule

Agent Type: Java

Entry Point Type: Web Service

Name:

Enabled:

Priority:  **i**

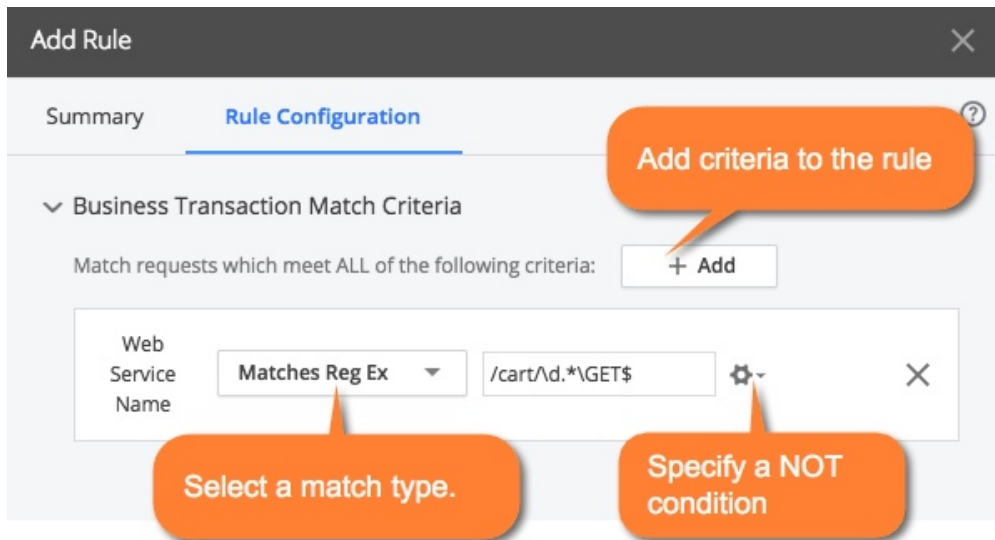

Description:

Scope: MyCustomScope

**The agent names the Business Transaction for the rule name.**

**Higher priority rules are applied first.**

The "cart.GET" rule generates business transactions for Web Service GET requests where the URI begins with `/cart/` followed by a number. AppDynamics names the resulting business transaction `cart.GET` :

You can add conditions to the rule to match based on specific HTTP parameters or hostnames.

For certain HTTP-based request types, such as Servlets or ASP.NET, a match rule can have more than one HTTP Parameter match condition. A request must match all HTTP Parameter conditions to match this rule. There is an implicit AND operator between the parameters rather than an OR operator.

You can use more complex regular expression matching. For example, the following request URLs:

- `example.com/aaa123.aspx`
- `example.com/b1.aspx`

To match any incoming request URL to this business transaction, use:

```
example\.com/[a-zA-Z]]+?[0-9]]+?
```

Any request to a URL that includes `example.com` followed by uppercase or lowercase letters and numbers would match this business transaction detection rule. A URL that has no digits after the letters, such as `example.com/z.aspx` does not match.

See [Using Regular Expressions](#) for more information on using regular expressions in the UI.

### Transaction Splitting for URI Based Entry Points

You can configure business transaction splitting for these types of URI based entry points:

- Java Servlet
- ASP.NET
- PHP Web
- Node.js Web
- Python Web
- Web Server

When you enable transaction splitting, the agent resolves a subset of requests that match the custom include rule into a separate business transaction based on a dynamic part of a request. The app agent names the transaction:

<custom match rule name>.<name derived from the split configuration>.

Consider an application with incoming requests:

- `http://nwtrader.com/checkout?category=electronics`
- `http://nwtrader.com/checkout?category=clothing`

This example shows how to configure transaction splitting to resolve two requests into two different business transactions, named:

- Checkout.electronics
- Checkout.clothing

You can split servlet transactions based upon the payload. See [Split Servlet Transaction by Payload Examples](#).

---

## Default Custom Exclude Rules

AppDynamics includes default exclude rules for the entry points for frameworks that are not usually of interest. Navigate to **Configuration > Instrumentation > Transaction Detection > Rules** and filter on **Rule Type: Custom Exclude** to view or modify the default custom match exclude rules. See [Custom Exclude Rule Examples](#).

To configure exclude rules for Service Endpoints, see [Service Endpoints](#).

## Java Business Transaction Detection

This page lists different types of Java entry points for business transactions.

A tier can have multiple entry points. For example, a Java framework implementation may have a combination of pure Servlets or JSPs, Struts, Web services, and Servlet filters, all co-existing as monitored entry points on the same JVM.

The middle-tier components like EJBs and Spring beans are usually not considered entry points because they are normally accessed using either the front-end layers such as Servlets or from classes that invoke background processes.

For details on types of Java entry points and how to set up custom match rules, see:

- [Servlet Entry Points](#)
- [Struts Entry Points](#)
- [Spring Bean Entry Points](#)
- [EJB Entry Points](#)
- [POJO Entry Points](#)
- [Web Service Entry Points](#)
- [Binary Remoting Entry Points for Apache Thrift](#)
- [CometD Support](#)
- [JAX-RS Support](#)
- [Spring Integration Support](#)

## Servlet Entry Points

AppDynamics automatically detects requests to servlet-based entry points and generates business transactions based on the requests. For general information on how to customize automatic transaction detection, see [URI Based Entry Points](#).

### Frameworks Supported as Servlets or Servlets Filter

AppDynamics supports many web frameworks based on servlets or servlet filters. The servlet configuration settings in AppDynamics apply to these frameworks as well as to plain servlets. Frameworks include:

- Spring MVC
- Wicket
- Java Server Faces (JSF)
- JRuby
- Grails
- Groovy
- Tapestry
- ColdFusion

## Custom Match Rules for Servlet Transactions

Custom match rule let you control how business transactions are generated for Servlet-based requests.

### Match Conditions

---

Match conditions can be based upon the URI, HTTP method, hostname, servlet name, or other characteristics of the request.

For HTTP Parameter conditions, you can add more than one. If you configure more than one HTTP Parameter match criteria, they must all be met by a request to be subject to this business transaction identification and naming rule, as must all conditions you configure for the rule.

Some of the options have NOT conditions that you can choose to negate the configured condition. Choose this option in the gear icon next to the condition.

### Splitting Transactions using Request Data or Payload

If you match by URI, you can have the transaction identified (or split) based on values from the request, such as URI patterns, request data, or payload. See [URI Based Entry Points](#) for information on naming or splitting transactions by the request elements.

When you create the rule, it appears in the Custom Match Rule list, where you can enable, disable, edit or remove the rule.

See [Split Servlet Transaction by Payload Examples](#) for use case examples.

### POST Request Body Parameter Matching Considerations

You can configure Servlet-based custom match that match POST requests based on HTTP body parameter values. To avoid interfering with the operation of the application, the Java Agent applies some special processing measures and limits on how it accesses the body parameters. This behavior can affect whether requests can be matched by POST body parameters for your particular application. If you are having trouble configuring matching by HTTP parameter in POST requests, you should understand this behavior.

### Transaction Naming Match Criteria

For transaction match criteria, match conditions for HTTP parameters work under these conditions:

- If the parameter is a query string in the URL of the POST request, as opposed to the request body.
- If the Servlet Request body parameters have already been read and parsed by the application prior to the invocation of the servlet. A Servlet Filter, for example, may do this.

Otherwise, custom servlet match rules do not match HTTP parameter values in POST requests.

### Transaction Splitting

For transaction split rules based on parameter matching in POST requests, the Java Agent defers transaction naming for incoming requests until the application servlet has accessed the request parameters.

The Java Agent considers the parameters "accessed" once the application invokes `getParameterMap()`, `getParameter()`, `getParameterNames()`, or `getParameterValues()` on the `ServletRequest` object. If the servlet does not call one of these methods, the agent will not apply the split rule and the transaction will not be named.

### Exclude Rules for Servlets

To prevent specific Servlet methods from being monitored, add a custom [exclude rule](#). The controls for selecting Servlets to exclude are the same as those for custom match rules.

### Split Servlet Transaction by Payload Examples

AppDynamics lets you split [servlet custom match rules](#) according to the request payload. For each of these examples, you must create a servlet custom match rule and enable the URI option on the Rule Configuration tab.

### Split by POJO Method Call

Using a Java method to name a transaction is useful when:

- You might not have a clear URI pattern, or
- You are using an XML/JSON framework not otherwise supported

For example, consider the `processOrder()` method in the `doPost()` method of the servlet at the following URL: `http://acmeonline.com/store`.

```
public void doPost(HttpServletRequest req, HttpServletResponse resp) {
 //process the data from the sevlet request and get the orderType and the items
 processOrder(orderType,item)
 ...
}
public void processOrder(String orderType,String item) {
 //process order
}
```

You want to derive transaction naming from the first parameter to the `processOrder()` method, `orderType`.

1. On the Rule Configuration tab for the custom match rule, enable the **Split Transactions using the XML/JSON payload or Java method invocation**.
2. Select **POJO Method Call** as the splitting mechanism.
3. For the method, choose the `processOrder`, and specify the parameter to use by numeric position in the parameter (0 index). The following screenshot displays the configuration of a custom match rule which

will name all the qualifying requests into a `Store.order.creditcard` transaction:

The screenshot shows the 'Add Rule' dialog box with the 'Rule Configuration' tab selected. The 'URI' field is set to 'Is Not Empty'. Under the 'Split Transactions Using Payload' section, the checkbox for 'Split Transactions using XML/JSON Payload or a Java method invocation' is checked. The 'Split Mechanism' is set to 'POJO Method Call'. The 'Class Name' is 'com.acme.Order', the 'Method Name' is 'processOrder()', the 'Return Type' checkbox is unchecked, the 'Number of Arguments' is '2', and the 'Argument Index' is '0'.

In addition to the parameter, you can also specify either the return type or a recursive getter chain on the object to name the transaction. For example, if the method parameter points to a complex object like `PurchaseOrder`, you can use something like `getOrderDetails().getType()` to correctly name the transaction.

### Split Transaction by JSP Name

You can identify transactions by JSP name, as follows:

1. On the Rule Configuration tab, enable the **Split Transactions using the XML/JSON payload or Java method invocation**.
2. Select **POJO Method Call** as the splitting mechanism.
3. Set the name of the class to `com.sun.faces.application.ViewHandlerImpl`.
4. Set the name of the method to `renderView()`.
5. Set the argument index to 1.
6. Define the Method Call Chain or getter as `getViewId()`. The agent appends the value to the name of the transaction as follows: `<Name of the Custom Rule>.<path to jsp>`.

You can later rename these business transactions to a more user-friendly name if you like.

### Split Transactions on XPath Expression

You can access values in an XML payload for business transaction naming or splitting using an XPath expression. Consider the following example from an Ecommerce order transaction where the XML represents an order for three items. The order uses credit card processing, which is the distinguishing element for this body:

```
<acme>
 <order>
 <type>creditcard</type>
 <item>Item1</item>
 <item>Item2</item>
 <item>Item3</item>
 </order>
</acme>
```

The URL is:

```
http://acmeonline.com/store
```

The `doPost()` method of the Servlet is:

```
public void doPost(HttpServletRequest req, HttpServletResponse resp) {
 DocumentBuilderFactory docFactory =
 DocumentBuilderFactory.newInstance();
 DocumentBuilder docBuilder = docFactory.newDocumentBuilder();
 Document doc = docBuilder.parse(req.getInputStream());
 Element element = doc.getDocumentElement();
 //read the type of order
 //read all the items
 processOrder(orderType, items)
 ...
}
```

Imagine you want to differentiate "Order" transactions based upon the type of order. You can use the XPath expression `//order/type` on this XML payload, which in this example evaluates to `creditcard`.

1. On the Rule Configuration tab, click **Split transactions using XML/JSON Payload or a Java method invocation**.
2. Choose **XPath Expressions** for the Split Mechanism.
3. Enter the XPath expression that points to the value of the XML element to use for naming. In this example, `//order/type`

The agent appends the value of the XPath expression to the name of the business transaction, for example, `Store.order.creditcard`. Even though the agent doesn't name the transaction until after XML parsing, AppDynamics measures the duration of the business transaction to include the execution of the `doPost()` method.

You can use one or more XPath expressions to chain the names generated for the Business Transaction.

You can specify whether the request results in transaction splitting when the expression does not evaluate to a value.

### Split Transactions on Java XML Binding

You can identify transactions for Java XML data binding frameworks for these types of frameworks:

- Castor
- JAXB
- JibX
- XMLBeans
- XStream

In the following example, the posted XML is unmarshalled to the `PurchaseOrderDocument` object, and the `getOrderType()` method should be used to identify the type of the order:

```
<acme>
 <order>
 <type>creditcard</type>
 <item>Item1</item>
 <item>Item2</item>
 <item>Item3</item>
 </order>
</acme>
```

The following snippet shows the `doPost()` method for the Servlet:

```
public void doPost(HttpServletRequest req, HttpServletResponse resp) {
 PurchaseOrderDocument poDoc = PurchaseOrderDocument.Factory.parse(po);
 PurchaseOrder po = poDoc.getPurchaseOrder();
 String orderType = po.getOrderType();

 //read all the items
 processOrder(orderType, items)
 ...
}
```

To split the transaction based upon the XML Binding:

1. On the Rule Configuration tab, check **Split transactions using XML/JSON Payload or a Java method invocation**.
2. Select **Java XML Binding** as the split mechanism.
3. Enter these values for the match criteria:
  - Unmarshaled Class Name: `PurchaseOrderDocument`
  - Method name: `getOrderType()`

The agent identifies the business transaction for this example as `Store.order.creditcard`:

This custom rule ensures that the Java agent intercepts the method in XMLBeans (which unmarshalls XML to Java objects). If the name of the transaction is not on a first level getter on the unmarshalled object, you can also use a recursive getter chain such as `getOrderType().getOrder()` to get the name.

Although the transaction name is not obtained until the XML is unmarshalled, the response time for the transaction is calculated from the `doGet()` method invocation.

## Split Transactions on JSON Payload

You can access JSON payload for transaction identification purposes using the method where the Servlet unmarshalls the payload.

For example, the following JSON payload posts an `order` for an item `car` and uses `creditcard` for processing the order. The URL is `http://acmeonline.com/store`:

```
order :{
 type:creditcard,
 id:123,
 name:Car,
 price:23
}}
```

The following code snippet shows the `doPost` method of the Servlet:

```
public void doPost(HttpServletRequest req, HttpServletResponse resp) {
 //create JSONObject from servlet input stream
 String orderType = jsonObject.get("type");
 //read the item for the order
 processOrder(orderType, item)
 ...
}
```

After the application unmarshalls the posted JSON payload to the JSON object, the `type` key is available to identify the type of the order. In this case, this key uniquely identifies the business transaction.

To use the JSON payload for transaction identification you must set the `enable-json-bci-rules` node property to `true` on each node to enable this rule. To configure the rule:

1. On the Rule Configuration tab, check **Split transactions using XML/JSON Payload or a Java method invocation**.
2. For the JSON object key, enter the name of the JSON object. For example, `type`.

The agent automatically intercepts the `JSONObject.get("$JSON_Object_Key")` method to name the transaction. Although the agent doesn't obtain the transaction name until the JSON object is unmarshalled, the response time for the transaction will be calculated from the `doGet()` method.

## Struts Entry Points

When your application uses Struts to service user requests, AppDynamics intercepts individual Struts Action invocations and names the user requests based on the Struts action names. A Struts entry point is a Struts Action that is being invoked.

AppDynamics supports the following versions of Struts:

- Struts 1.x
- Struts 2.x

Struts Action invocations are typically preceded by a dispatcher Servlet, but identification is deferred to the Struts Action. This ensures that the user requests are identified based on the Struts Action and not from the generic URL for Dispatcher Servlet.

---

The response time for the Struts-based transaction is measured when the Struts entry point is invoked.

### Struts Request Names

When a Struts Action is invoked, by default AppDynamics identifies the request using the name of Struts Action and the name of the method. All automatically discovered Struts-based transactions are thus named using the convention `<Action Name>.<Method Name>`.

For example, if an action called ViewCart is invoked with the SendItems(), the transaction is named `ViewCart.SendItems`.

For Struts 1.x the method name is always `execute`.

You can rename or exclude auto-discovered transactions. See [Organize Business Transactions](#).

### Custom Match Rules for Struts Transactions

For finer control over the naming of Struts-based transactions, use custom match rules.

A custom match rule lets you specify customized names for your Struts-based requests. You can also group multiple Struts invocations into a single business transaction using custom match rules. See [Custom Match Rules](#) for information about accessing the configuration screens.

The matching criteria for Struts transactions are: Struts Action class names, Struts Action names, and Struts Action method names.

### Exclude Rules for Struts Actions or Methods

To prevent specific Struts Actions and methods from being monitored, add a [custom exclude rule](#). The criteria for Struts exclude rules are the same as those for custom match rules. In particular, you may need to exclude custom-built dispatch servlets, as described next.

### Exclude Custom-built Dispatch Servlet

When a Struts action is called, it can demarcate a transaction as an entry point. AppDynamics instruments the Struts invocation handler to get the action name because the Struts action is not an interface. The invocation handler provides the Java Agent with the name of the action being invoked. If the dispatcher Servlet is custom-built and has not been excluded from instrumentation, the wrong entry point could be instrumented and the business transaction could be misidentified.

To address this issue, add a custom exclude rule for the dispatcher servlet or add a BCI exclude for it.

## Spring Bean Entry Points

This page describes how to configure transaction entry points for Spring Bean requests.

### Spring Bean-based Transactions

AppDynamics allows you to configure a transaction entry point for a particular method for a particular bean in your environment. The response time is measured from when the Spring Bean entry point is invoked (after receipt at a dispatcher servlet).

### Default Naming for Spring Bean Requests

When you enable automatic discovery for Spring Bean based requests, AppDynamics automatically identifies all the Spring Beans based transactions and names these transactions using the following format:

BeanName.MethodName

By default, the transaction discovery for Spring Bean-based requests is turned off. You can enable it in any Automatic Transaction Discovery rule for Java. Select **Discover Transactions automatically for all Spring Bean invocations** on the Rule Configuration tab.

When a class is mapped to multiple Spring bean names, by default only the name of the first Spring bean found is used. This may not be ideal for your application such as cases where a call graph for web service A that has Spring beans from web service B. To contend with this scenario, you can remove the Bean name from the transaction name using the `capture-spring-bean-names` node property, as described on [App Agent Node Properties \(B-C\)](#).

### Custom Match Rules for Spring Bean Requests

If you are not getting the required visibility with the auto-discovered transactions, you can create a [custom match rule](#) for a Spring Bean based transaction. You can match based on one or more of the following criteria:

- Bean ID
- Method Name
- Class Name
- Extends
- Implements

The following example creates a custom match rule for the `placeOrder` method in the `orderManager` bean.

The screenshot shows the 'Rule Configuration' tab of a rule configuration interface. Under the 'Business Transaction Match Criteria' section, there is a text label 'Match requests which meet ALL of the following criteria:' followed by a '+' button. Below this, two criteria are listed in a table-like structure:

Criteria	Operator	Value	Settings	Action
Bean ID	Equals	orderManager	⚙️	✕
Method Name	Equals	placeOrder	⚙️	✕

### Exclude Rules Spring Bean Transactions

To exclude specific Spring Bean transactions from detection, add a [custom exclude rule](#).

The criteria for Spring Bean exclude rules are the same as those for custom match rules.

## EJB Entry Points

AppDynamics allows you to configure an EJB-based transaction entry point on either the bean name or method name. The response time for the EJB transaction is measured when the EJB entry point is invoked.

### Default Naming for EJB Entry Points

AppDynamics automatically names all the EJB transactions `<EJBName>.<MethodName>`.

### Enabling EJB Transaction Detection

By default, automatic transaction discovery for EJB transactions is turned off. To get visibility into these transactions, enable the auto-discovery for EJB based transactions explicitly.

Before you enable auto-discovery for EJB based transactions, note that:

- If the EJBs use Spring Beans on the front-end, the transaction is discovered at the Spring layer and the response time is measured from the Spring Bean entry point.
- AppDynamics groups all the participating EJB-based transactions (with remote calls) in the same business transaction. However, if your EJBs are invoked from a remote client where the App Server Agent is not deployed, these EJBs are discovered as new business transactions.

You can enable auto-discovery for EJB transactions in any Automatic Transaction Discovery rule for Java. Check **Discover Transactions automatically for all EJB invocations** on the **Rule Configuration** tab.

### Custom Match Rules for EJB based Transactions

If you are not getting the required visibility with auto-discovered transactions, create a [custom match rule](#) for an EJB based transaction.

The following example creates a custom match rule for the receiveOrder method in the `TrackOrder` bean.

The screenshot shows the 'Rule Configuration' tab for a business transaction rule. Under 'Business Transaction Match Criteria', it states 'Match requests which meet ALL of the following criteria:'. There are two criteria listed:

- EJB Name**: Equals `TrackOrder`
- Method Name**: Equals `recieveOrder`

Each criterion has a gear icon for settings and an 'X' icon for removal. There is also a '+ Add' button to add more criteria.

In addition to the bean and method names, other match criteria that could be used to define the transaction are the EJB type, class name, superclass name, and interface name.

### Exclude Rules for EJB Transactions

To exclude specific EJB transactions from detection add a [custom exclude rule](#). The criteria for EJB exclude rules are the same as those for custom match rules.

## POJO Entry Points

This page describes how to create custom match rules for POJO (Plain Old Java Object) applications. See [Custom Match Rule Live Preview](#) for instructions about interactively working with live data to create a POJO.

### About POJO Custom Match Rules

[Custom match rules](#) for POJOs let you configure business transaction detection in application environments that run pure Java applications or that use frameworks with entry points that are not automatically detected.

Unlike common frameworks, which are characterized by well-known entry points for applications, the logical entry point for a business transaction for a POJO entry point could be any method in the application.

To configure a custom POJO entry point, therefore, you need to identify the method that AppDynamics should consider the business transaction entry point. Keep in mind that the start and end of the execution of the method will correspond to the start and end of the business transaction, so the method should encapsulate the complete execution of the business transaction.

For example, consider the method execution sequence:

```
com.foo.threadpool.WorkerThread.run()
 calls com.foo.threadpool.WorkerThread.runInternal()
 calls com.foo.Job.run()
```

The first two calls to `run()` method are the blocking methods that accept a job and invoke it. The `Job.run()` method is the actual unit of work, because `Job` is executed every time the business transaction is invoked and finishes when the business transaction finishes.

Methods like these are the best candidates for POJO entry points. The response time for POJO transactions is measured from this entry point, and remote calls are tracked the same way as are remote calls for a Servlet's Service method.

### Creating POJO Custom Match Rules

You can create a POJO entry point by adding a [custom match rule](#) with *POJO* as the Entry Point Type. The agent names business transactions for the custom match rule.

**i** In order for the agent to discover POJO transactions, your custom match rule must belong to a scope that also includes a Default Java Automatic Transaction Discovery rule with POJO transaction monitoring enabled.

You can classify matching transactions as background tasks by enabling the **Background Task** check box. When a request runs as a background task, AppDynamics reports only Business Transaction metrics for the request. It does not aggregate response time and calls metrics at the tier and application levels for background tasks. This ensures that background tasks do not distort the baselines for the business

application. Also, you can set a separate set of thresholds for background tasks. For more information, see [Monitor Background Tasks](#).

The custom match rule configuration offers several options for matching method invocations and splitting matched calls into separate business transactions, as described below.

**i** If you are running on IBM JVM v1.5 or v1.6, you must restart the JVM after defining the custom match rules.

### Matching by Class and Method

You can specify matching criteria for the custom rule based on various forms of a method or class to which the method belongs.

When specifying the method name matching criteria, use parameter matching to match against a particular method signature. For example, say you want to instrument one of more methods in the following class:

```
class A
{
 public void m1();
 public void m1(String a);
 public void m1(String a, com.mycompany.MyObject b);
}
```

Configure instrumentation for each method based on its signature as follows:

- To instrument the first method signature (with no parameters), create a POJO-based business transaction match rule as follows:
  - Match Classes: with a Class Name that Equals A
  - Method Name: Equals m1()
- To instrument the second method, create a match rule as follows:
  - Match Classes: with a Class Name that Equals A
  - Method Name: Equals m1(java.lang.String)
- To instrument the third method, create a match rule as follows:
  - Match Classes: with a Class Name that Equals A
  - Method Name: Equals m1(java.lang.String, com.mycompany.MyObject)

You can also match methods that belong to classes with certain annotations. For example, say you want to match all classes that are annotated with `@com.acme.Processor`. The custom rule configuration can define the annotation as follows:

When calls to the `process()` method match, the result is a business transaction named for the custom match rule name.

#### Matching on Inner Classes and Inner Interfaces

You can match on inner classes and inner interfaces by adding a \$ sign after the class name. For example, you could specify the following for the class name:

```
com.my.package.OuterClass$InnerClass
```

#### Splitting Matches into Separate Business Transactions

With only transaction matching configured, all requests matched by the match rule belong to the custom business transaction. Alternatively, you can create a match rule that generates multiple named business transaction based on criteria in the request.

For example, the following configuration defines a custom match rule that matches by superclass. In the example, the entry point matches the `process()` method defined in classes that extend the `com.acme.AbstractProcessor` superclass. In our example, the superclass is extended by the subclasses `SalesProcessor`, `InventoryProcessor`, `BacklogProcessor`.

1. Create A custom rule that matches the superclass matches all of those subclasses:
2. Split the transaction on class name, you can have separate business transactions created for the respective subclasses. AppDynamics names the transactions with the class name, prepending the match rule name to the class name. For example, `Process.SalesProcessor`, `Process.InventoryProcessor`, and `Process.BacklogProcessor`.

▼ Transaction Splitting

Split POJO Transactions

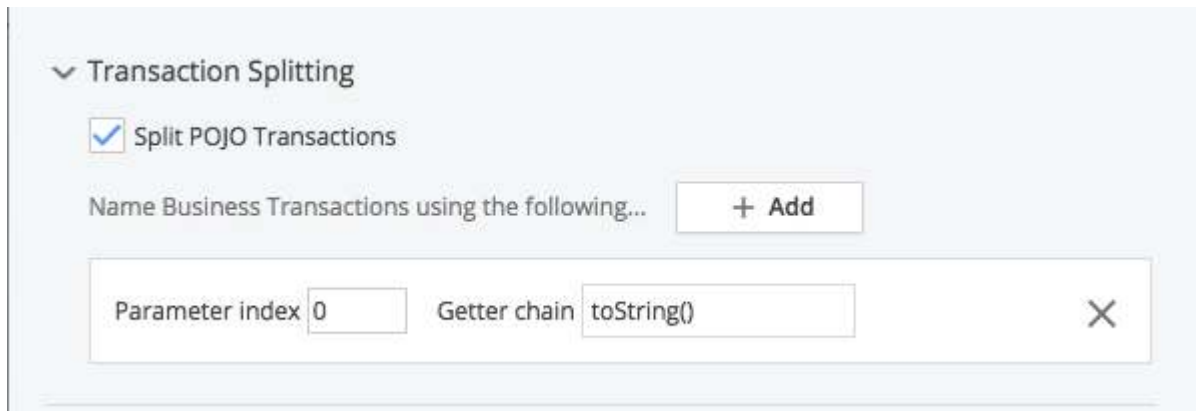

Name Business Transactions using the following... + Add

Simple Class Name and Method Name
×

It's possible that parameter values carry what would be meaningful identifiers for business transactions in your application. For example, say the `jobType` parameter in the following method may have the values of `Sales`, `Inventory` or `Backlog`.

```
public void process(String jobType,String otherParameters...)
```

You can split the transaction based on parameter value by indicating the zero-based position of the parameter in the method signature, `0` in the example:

The `toString()` method indicates how the value of the parameter should be rendered. See [Using Getter Chains](#) for more information. As indicated in the dialog, you can use other transaction splitting criteria as well, including thread ID, method name, class name, and so on.

The name of the rule is prepended to the dynamically-generated name to form the business transaction name.

#### Exclude Matches from Transaction Splitting

An exclude rule defines criteria which, when matched by a transaction instance, prevents transaction splitting from occurring as otherwise configured. In effect, this nullifies the effects of transaction splitting for the subset of transactions matched by the exclude condition.

#### Monitor Java Interface Static and Default Methods

As of Java 8, Java interfaces can include static and default methods. This page describes how to monitor these types of interface methods.

**i** Note that another Java language feature introduced in Java 8, lambda method interfaces, are not supported by the AppDynamics Java Agent.

#### Interface Static Methods

The following code snippet shows an example static interface method:

```
package jdk8;

interface InterfaceForStaticMethod
{
 static int sum(int acc, int x)
 {
 return acc + x;
 }
}
```

The actual bytecode for the method would reside in the compiled class file, so a class match against the

interface class in the AppDynamics configuration would result in the instrumentation of that class for a business transaction.

To instrument such methods, create a POJO business transaction match rule for the `interfaceForStaticMethod`, such as:

In this case, the rule would match classes with a Class Name of `jdk8.InterfaceForStaticMethod`.

### Interface Default Methods

Interfaces can also define default methods. As with interface static methods, the bytecode for default methods resides in the compiled class files.

When configuring instrumentation for a default method:

- If the targets are classes that do *not* override the default method, target the interface via a class match
- If the targets are classes that do override the default method, target the interface via an interface match

### Instrument an Interface Default Method Directly

Given the following interface:

```
package jdk8;

interface InterfaceForConcreteClassDefaultMethod
{
 default int sum(int acc, int x)
 {
 return acc + x;
 }
}
```

And its implementing class:

```
package jdk8;

class ClassForDefaultMethod implements InterfaceForConcreteClassDefaultMethod
{
}
```

In this example, the `ClassForDefaultMethod` does *not* override the default method. Therefore, you can use a class match against the interface such as:

### Instrument an Overridden Default Method

Given the following interface:

```
package jdk8;

interface InterfaceForAnonymousClassDefaultMethod
{
 default int sum(int acc, int x)
 {
 return acc + x;
 }
}
```

And:

```
InterfaceForAnonymousClassDefaultMethod i = new InterfaceForAnonymousClassDefaultMethod()
{
 @Override
 public int sum(int acc, int x)
```

```
{
 return acc + x;
};
```

Because the method is overridden, the target `bytecode` resides in the anonymous class, `InterfaceForAnonymousClassDefaultMethod`. So you need to create an interface match POJO business transaction match rule such as:

The screenshot shows the 'Rule Configuration' tab of a configuration page. Under the 'Match Class & Method' section, there are two main fields: 'Match Classes' and 'Method Name'. Each field has a dropdown menu set to 'Equals'. The 'Match Classes' field contains the value 'jdk8.InterfaceForAnonymousClass'. The 'Method Name' field contains the value 'sum'. Below these fields is a blue link that says 'Browse classes and methods'. There is also a gear icon next to the 'Method Name' field.

### Instrument Java Lambda Expressions

This page describes [Lambda](#) expressions, a Java language feature introduced in Java 8 that enables a functional style of programming in Java.

#### Java Lambda

Here's a short example:

```
LambdaMethodInterface i = (acc, x) -> acc + x;
```

In the JVM, this creates an anonymous instance of the associated `FunctionalInterface`, as shown below:

```
package jdk8;

@java.lang.FunctionalInterface
interface LambdaMethodInterface
{
 int sum(int acc, int x);
}
```

## Instrument Java Lambda Instances

To instrument lambda instances, create a POJO business transaction match rule for the `LambdaMethodInterface`, for example:

Business Transaction Match Rule - POJO

Name: (3) Lambda method ref

Enabled:

Background Task:

Transaction Match Cri... | Transaction Splitting | Exclude Rule

Define match criteria for a POJO method which be will an entry point for a Business Transaction

<input checked="" type="checkbox"/>	Match Classes *	that implements an interface which	Equals	jdk8.LambdaMethodInterface
<input checked="" type="checkbox"/>	Method Name *	sum	Equals	

Cancel Save

This sample rule matches classes that implement the interface name `jdk8.LambdaMethodInterface`.

## Web Service Entry Points

When your application uses Web Services to service user requests, AppDynamics intercepts the Web Service invocations and names requests based on the Web Service action names and operation name. A Web Service entry point is a Web Service endpoint that is being invoked.

This is relevant only when the Web Service invocation is part of the entry point tier or in cases where the transaction should be continued in a downstream tier using a correlation header transported in the SOAP Envelope.

Web Service invocations are usually preceded by a dispatcher Servlet, but identification is deferred to the Web Service endpoints. This configuration ensures that the requests are identified or correlated based on the Web Service or its payload and not based on the generic URL for the dispatcher Servlet.

### Default Naming

When the Web Service endpoint is invoked, the request is named after the Web Service name and the operation name.

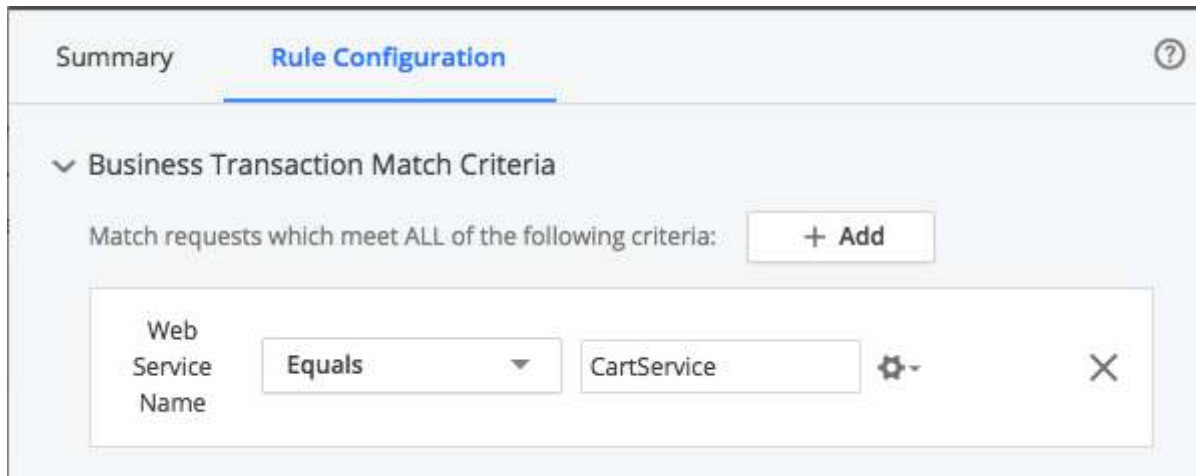

For example, if a service called `CartService` is invoked with the `Checkout` operation, the is named `CartService.Checkout`.

You can rename or exclude these automatically discovered transactions. See [Organize Business Transactions](#).

### Custom Match Rules for Web Services

You can aggregate different Web Service requests into a single business transaction using the web service name or the operation name. You do this by creating custom match rules for Web Services. See [Custom Match Rules](#) for information about accessing the configuration screens.

This example names all operations for the Web Service named `CartService` :

### Exclude Rules

To exclude specific Web Services or operation names from detection, add an exclude rule. See [Custom Match Rules](#). The criteria for Web Service exclude rules are the same as those for custom match rules.

### Transaction Splitting for Web Services Based on Payload

1. Disable the Web Service automatic transaction discovery.
2. Disable the following default exclude rules:
  - Apache Axis Servlet
  - Apache Axis2 Servlet
  - Apache Axis2 Admin Servlet
3. Add the custom match rule for Axis or Axis2 Servlet (based on the version being used) and split the transaction using payload or request depending on the pattern in your scenario.

### Exclude Rule for JBoss Correlation

To detect Web Service entry and to support correlation in JBoss SOAP Web Service, you must create a Servlet exclude rule by excluding the class name, `org.jboss.wsf.stack.cxf.CXFServletExt` as follows:

1. In **Add Rule**, select **Custom Match Rule**.
2. Select **Servlet** as the **Entry Point Type**.
3. Select **Exclude Transactions discovered by this rule**.

The screenshot shows the 'Add Rule' dialog box with the following configuration:

- Rule Type:** Custom Match Rule
- Include/Exclude:**
  - Include Transactions discovered by this rule
  - Exclude Transactions discovered by this rule
- Agent Type:** Java
- Entry Point Type:** Servlet
- Name:** (Empty text field)
- Enabled:**
- Priority:** 0
- Description:** (Empty text area)
- Scope:** Select Scope

4. Click **Save**.
5. In the Rule Configuration tab, specify the class name as `org.jboss.wsf.stack.cxf.CXFServletExt`.
6. Click **Save**.

### Binary Remoting Entry Points for Apache Thrift

Apache Thrift is a binary remoting protocol. Cassandra uses the Thrift protocol to achieve portability across programming languages. Applications written in many different languages can make calls to the Cassandra database using the Thrift protocol.

AppDynamics is preconfigured to detect business transaction entry points for Cassandra with Thrift framework applications. Note that Binary Remoting entry points are not available as [Service Endpoints](#).

AppDynamics measures performance data for Thrift transactions as for any other transaction. Thrift entry points are POJO-based. The response time for the transaction is measured from the POJO entry point, and the remote calls are tracked the same way as remote calls for a Servlet's Service method.

#### Default Naming for Binary Remoting (Thrift) Entry Points

When the automatic discovery for a request using Binary Remoting (Thrift) protocol is enabled, AppDynamics automatically identifies all the transactions and names them using the following format:

```
RemoteInterfaceClassName:MethodName
```

### Enabling Detection for Binary Remoting (Thrift) Entry Points

Binary Remoting (Thrift) entry points are enabled by default, but if you are not seeing them in the Tier Flow Map, verify that they have been enabled in the Java automatic transaction detection rule. For more information, see [Transaction Detection Rules](#).

When enabled, you can see Thrift calls from calling tiers to the Cassandra database in the List View of the Tier Dashboard. Since the transactions using the Thrift protocol are POJO-based, they appear as POJO in the Type column.

### Creating Custom Match Rules for Binary Remoting (Thrift) Requests

If you are not getting the required visibility with the auto-discovered transactions, you can configure [custom match rules](#) and transaction splitting for specific classes and methods.

When creating the custom match rule, choose POJO as the rule type. The rule should be defined on the class and method you want to use as the entry point. Someone who is familiar with your application code may need to help you make this determination.

For information about and examples of the various POJO-based business transaction match rules you can create for Binary Remoting (Thrift), see [POJO Entry Points](#). The rules for Binary Remoting (Thrift) entry points are the same as those for POJO entry points.

## CometD Support

### Related pages:

- [Jetty Startup Settings](#)
- [Exclude Rules](#)

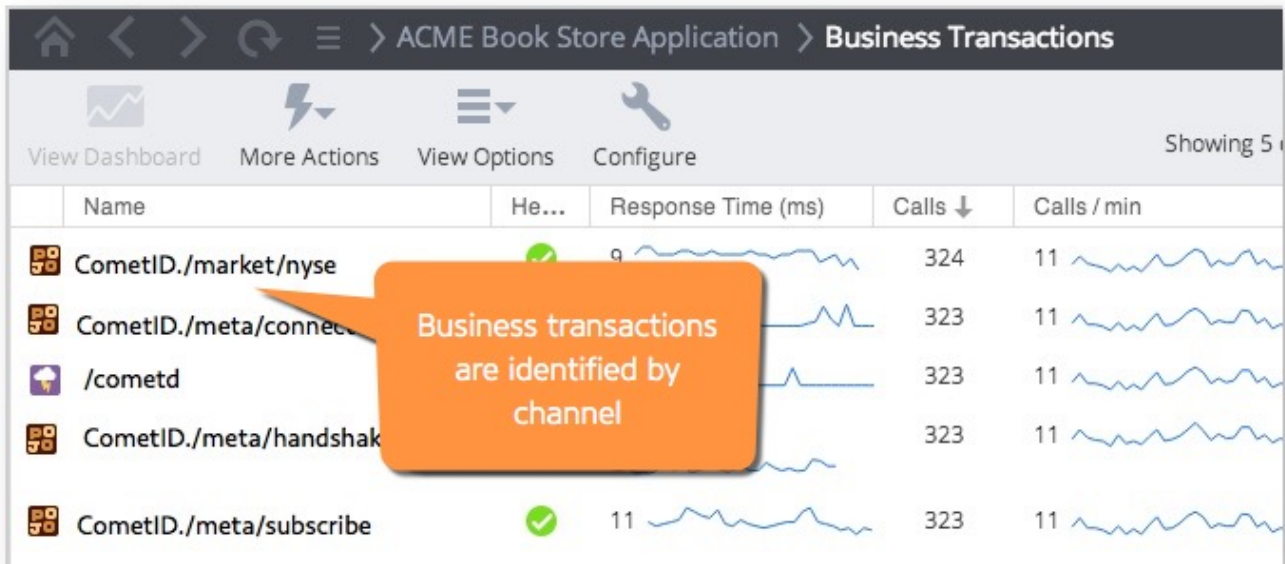

CometD is an HTTP-based event routing bus for transporting asynchronous messages over HTTP. CometD provides both a JavaScript API and a Java API and is often used for real-time interactive applications such as multi-player games and chat rooms.

CometD is distributed as a WAR file. When you instrument the CometD application container that runs the WAR (typically a Jetty server) with the Java agent, AppDynamics automatically detects and tracks CometD activity, as described in the following section.

### About the Built-in Support

AppDynamics supports both the WebSocket and the HTTP long-polling client transports in CometD. It tracks CometD messages as they traverse channels using POJO rules that split business transactions based on channel name.

Accordingly, business transactions in AppDynamics correspond to CometD channels. The following screenshot shows a business transaction generated for the `/market/nyse` channel:

AppDynamics provides built-in exclude rules for the servlets that implement CometD transport functions, `org.cometd.annotation.AnnotationComet` and `org.cometd.server.CometdServlet`. For best results, you should exclude tracking for the container servlet as well, as described in the next section.

### Create Container Transport Servlet Exclude Rules

CometD is implemented as a servlet. Since the servlet implements transport activity, you should create exclude rules for the servlets that perform the CometD transport function. This ensures that the results of business transaction discovery do not obscure the POJO-based BTs corresponding to CometD channels.

CometD is generally contained within a Jetty container, so the rules should exclude the Jetty container tracking in most cases. For Jetty, you should configure exclude rules for these Jetty servlets:

- EQUALS, `org.eclipse.jetty.server.handler.ContextHandler`
- EQUALS, `org.eclipse.jetty.servlet.ServletContextHandler`
- ENDSWITH, `jetty.plugin.JettyWebAppContext`

If using another type of container, you should create similar exclude rules for the equivalent supporting classes.

### JAX-RS Support

The Java Agent supports Jersey 1.x and 2.x by default.

Business transaction entry points are named using the following app agent node properties:

- [rest-num-segments](#)
- [rest-transaction-naming](#)
- [rest-uri-segment-scheme](#)

### Business Transaction Naming Scheme

By default, the Java Agent makes a best-effort basis to name JAX-RS-based transactions using the class annotation, method annotation, and HTTP method of the detected entry point, in the following form:

```
{class-annotation}/{method-annotation}.{http-method}
```

In some situations where the annotation values are not available, the agent may name the transaction as follows:

```
{fully qualified class name}.{method}
```

For example, when the JAX RS service endpoints don't have the class and method names in them explicitly, but the annotations are inferred in some other way.

For annotation inheritance cases, the agent attempts to fetch the annotations from the superclasses and interfaces as described by the [JAX RS specification](#). The specification makes the following recommendation:

For consistency with other Java EE specifications, it is recommended to always repeat annotations instead of relying on annotation inheritance.

Repeating annotations on the endpoint methods enables the Java Agent to name business transaction according to the default scheme.

#### rest-transaction-naming Variables

The `rest-transaction-naming` node agent property enables you to control naming for JAX-RS-based business transactions. You can use variables to have the transactions named with runtime values, for example, based on the method name, class name, parameter values, and more. For a full list of variables, see [App Agent Node Properties Reference](#).

You can add a getter chain after any of the parameters to operate on the parameter values. To do so, add ':' followed by the getter chain. Standard getter chain escape requirements and rules apply.

#### Naming Examples

The following example shows naming based on a part of the value of the sixth parameter:

```
rest-transaction-naming={param-5:toString().toLowerCase().substring(5,20)}
```

The characters '{' and '}' are reserved. If used in getter chains or as text in the name the characters must be escaped with '\'. E.g. `{{ class-name }}` would display as `{ com.singularity.RestObject }`.

You can use characters in addition to parameters. For example, in the following example, the class name and method name are separated by a slash:

```
rest-transaction-naming={class-name}/{method-name}
```

Based on this example, when the Java Agent sees a REST resource with a class name of `com.company.rest.resources.Employees` with a `CreateNewEmployee` method, it names the business transaction `com.company.rest.resources.Employees/CreateNewEmployee`.

## Spring Integration Support

In Spring-based applications, [Spring Integration](#) enables lightweight messaging and supports integration with external systems via declarative adapters.

The Java Agent automatically discovers entry points based on the `MessageHandler` interface. The Java Agent automatically discovers exit points for all Spring Integration Release 2.2.0 channels except `DirectChannel`.

The Java Agent supports tracking application flow through Spring Integration [messaging channels](#). For pollable channels:

- A continuing transaction is tracked if the Spring Integration framework is polling for messages.
- If the application code polls for messages in a loop, the span of each loop iteration is tracked as a transaction. Tracking begins when the loop begins and ends when the iteration ends.

### Entry Points

Originating transactions begin with `MessageHandler.handleMessage()` implementations. If the incoming message is already recognized by the Java Agent then a continuing transaction is started.

### Exit Points

Exit points are based on `MessageChannel.send()`.

Most message channels exist inside the JVM. To represent this arrangement in a flow map, the Controller UI shows a link from the tier to the message channel component name (bean name) and then back to the tier.

## Spring Integration Support Customizations

The following sections describe typical scenarios for tuning the default Spring Integration monitoring.

### Track Application Flow Before Message Handler is Executed

In cases where a lot of application flow happens before the first `MessageHandler` gets executed, you should enable tracking the application flow as follows:

- Find a suitable POJO entry point and [configure it](#).
- Set the `enable-spring-integration-entry-points` node property to `false`. This property is set to `true` by default.
- Restart the application server

### Limit Tracking of Looping Pollable Channels

To safeguard against cases where `pollableChannel.receive()` is not called inside a loop, you can ensure that the Java Agent tracks a pollable channel loop only if it happens inside a class/method combination similar to that defined in the following example.

You can configure the `spring-integration-receive-marker-classes` node property for each class/method combination that polls messages in a loop, in which case only those class/methods identified in this node property are tracked.

```
class MessageProcessor {
```

```

void process() {
 while(true) {
 Message message = pollableChannel.receive()
 }
}

```

For example, for the loop above, set the `spring-integration-receive-marker-classes` node property as follows and restart the application server:

```
spring-integration-receive-marker-classes=MessageProcessor/process
```

**i** The `spring-integration-receive-marker-classes` node property must be configured before the method `process()` gets executed for any changes to take effect. Restart the application server after setting this property.

## .NET Business Transaction Detection

### Related pages:

- [Transaction Detection Rules](#)
- [Organize Business Transactions](#)
- [Configuration Import and Export API](#)
- [.NET Agent for Linux Business Transaction Configuration](#)

The page lists different types of ASP.NET entry points for business transactions:

- [POCO Entry Points](#)
- [ASP.NET Entry Points](#)
- [WCF Entry Points](#)
- [ASP.NET Web Service Entry Points](#)
- [ASP.NET Core Instrumentation Options](#)
- [Name MVC Transactions by Area, Controller, and Action](#)

### POCO Entry Points

Certain types of applications, such as Windows Services or standalone applications, may not have entry points that are automatically detected by the .NET Agent.

For these cases, you can create custom match rules for Plain Old CLR Objects (POCOs).

#### POCO Custom Match Rules Overview

To create a POCO custom match rule, define the custom match rule on the .NET class/method that is the most appropriate entry point for the business transaction. Someone who is familiar with your application code can help make this determination. You can also refer to the [Custom Match Rules](#) page.

You can optionally enable the Background Task option to have the transaction monitored as a background task. AppDynamics reports only Business Transaction metrics for background task transactions. It does not aggregate response time and call metrics at the tier and application levels for background tasks.

See [Monitor Background Tasks](#) for more information.

After you create the rule, AppDynamics detects traffic on the matched entry point method and registers a business transaction for it, naming the transaction with the name of the custom match rule.

**i** By default, you have to wait one minute and then restart the application to apply instrumentation changes required for new POCO entry points. If you create an application-level POCO that applies to a tier that has not yet registered with the Controller, you may need to restart the application after the tier registers in order to see the business transaction. You can [enable Runtime Reinstrumentation](#) for the .NET Agent so that you don't need to restart your application after instrumentation changes.

As an alternative to defining POCO entry points as described here, you can use the transaction discovery tool to create match rules based on discovered transactions. See [Business Transaction Discovery Sessions](#).

**i** The .NET Agent for Linux supports the configuration of simple POCO business transactions through the Controller UI. See [.NET Agent for Linux Business Transaction Configuration](#)

### Define a POCO Entry Point

On an originating tier, a POCO entry point is the method that starts the business transaction. If the POCO entry point is on a downstream tier, it may correlate to an upstream exit point. When defining a POCO entry point, it is important to choose a method that begins and ends every time the business transaction executes. See [Business Transactions](#).

Good candidates for POCO entry points include the following:

- A method in a socket application that executes every time a client connects.
- A loop in a standalone application that batch processes records via a web service call. For example, an expense reporting system that loops through approved expenses to submit them for reimbursement.
- A Windows service that regularly executes a database call to check for new jobs to process. In this example, the POCO entry point would be defined on the namespace JobProcessor, class JobProcessorCore and method ProcessJobs:

#### .NET

```
using System.Threading;
using System;
using System.Threading.Tasks;
using System.Configuration;
using System.Collections.Generic;

namespace JobProcessor {
 class JobProcessorCore {
 public void Process() {
 while(running) {
 ProcessJobs ();

 // run jobs again after 1 minute
 }
 }
 }
}
```

```

 Thread.Sleep(60000);
 }
}

private void ProcessJobs() {
 var logic = new JobManagement ();
 var jobs = logic.GetJobs(); // Query Database for a list of jobs to process

 foreach (var job in jobs) {
 logic.ExecuteJob(job); // logic for executing a job
 }
}
}
}

```

### Task-Based POCO Entry Point Methods

AppDynamics automatically tracks POCO transactions for asynchronous, Task-based method entry points as end-to-end transactions. End-to-end latency metrics reflect the time it takes to complete the asynchronous actions associated with such methods.

To be tracked as an end-to-end transaction, the method you define as the POCO entry point must return a `Task` object and use the `async` modifier. In other words, the method signature should look similar to the following:

```

public async Task<int> SearchBestPrice()
{
 ...
}

```

AppDynamics records the response times for such methods as it does for other types of methods—the response time reflects the time from when the method is called to when it returns control to the calling thread. However, for asynchronous task-based methods, AppDynamics records the time it takes for the asynchronous task to be fulfilled as an end-to-end transaction latency metric.

**i** For .NET Agents  $\geq 20.3.0$ , time spent on asynchronous tasks is reported in average response time (ART) but not reported in the end-to-end latency metric.

See [End-to-End Latency Performance](#).

### ASP.NET Entry Points

#### Related pages:

- [Transaction Detection Rules](#)
- [Business Transactions](#)

AppDynamics automatically detects entry points for client requests to ASP.NET applications. If the request occurs on an [originating tier](#), the method or operation marks the beginning of a business transaction and defines the transaction name. In most cases, this type of entry point maps to a user request or action such as "Cart/Checkout". AppDynamics allows you to configure transaction naming based upon the ASP.NET request.

For information on how to configure default ASP.NET transaction detection, see [URI Based Entry Points](#).

### Custom Match Rules for ASP.NET Transactions

Custom match rules provide greater flexibility for transaction naming. When you define a match rule, AppDynamics uses the rule name for the business transaction name.

See [Custom Match Rules](#) for general information on how to create custom match rule.

 The .NET Agent for Linux supports the configuration of simple ASP.NET business transactions through the Controller UI. See [.NET Agent for Linux Business Transaction Configuration](#).

When AppDynamics detects a request matching your specified criteria, it identifies the request using your custom name. You can use the following criteria to match transactions:

**Method:** Match on the HTTP request method, GET, POST, PUT or DELETE.

 With automatic discovery for ASP.NET transactions enabled, configuring the match on `GET` or `POST` causes the agent to discover both GET and POST requests. If you only want either `GET` or `POST` requests for the transaction, consider the following options:

- Disable automatic discovery for ASP.NET transactions.
- Create an exclude rule for the method you don't want: `GET` or `POST`.

**URI:** Set the conditions to match for the URI.

- For rules on regular expressions for .NET, see [.NET Framework Regular Expressions](#).
- Optionally click the gear icon to set a NOT condition.
- You must set a URI match condition in order to use transaction splitting.

**HTTP Parameter:** Match on HTTP parameter existence or a specific HTTP parameter value.

**Header:** Match on a specific HTTP header's (parameter's) existence or a specific HTTP header value.

- **Hostname:** Match on the server hostname. Optionally click the gear icon to set a NOT condition.
- **Port:** Match on the server port number. Optionally click the gear icon to set a NOT condition.
- **Class Name:** Match on the ASP.NET class name. Optionally click the gear icon to set a NOT condition.
- **Cookie:** Match on cookie existence or specific cookie value.
- Hostname, Port, and Class Name options are non-functional in the .NET Agent 4.5.9 for Linux.

### Split Custom ASP.NET Transactions

AppDynamics lets you further refine ASP.NET custom transaction names using transaction splitting.

- To use transaction splitting, you must specify URI match criteria for the custom match rule.
- The *Split Transactions Using Request Data* options work the like the automatic transaction detection configuration options described in [URI Based Entry Points](#).

For example, you have a custom match rule named `MyTransaction` that matches the following URL: `http://example.com/Store/Inventory?category=electronics`. You can split the transaction on the parameter value as follows:

The screenshot shows the 'Rule Configuration' interface. It has two main sections:

- HTTP Request Match Criteria:** A section with a '+ Add' button. Below it, a criteria entry is shown: 'URI' with a dropdown set to 'Contains' and a text field containing 'Inventory'. There are also icons for settings and deletion.
- Split Transactions Using Request Data:** A section with a checked checkbox 'Split Transactions Using Request Data'. Below it, a dropdown menu is set to 'a parameter value' with the text 'in Transaction names'. Below that, a text field 'Parameter Name' contains the value 'category'.

The .NET Agent names the resulting transaction `MyTransaction.electronics`.

### IIS Integrated Pipeline Instrumentation

Full IIS pipeline instrumentation can be enabled by setting the node property: `aspdotnet-full-iis-pipeline` to `true` for the executing node. With this property enabled, regular **ASP.NET** instrumentation is disabled. When this mode is enabled, all managed HTTP modules, and handlers can be monitored by the .NET Agent. The `aspdotnet-full-iis-pipeline` mode is designed to work only for application pools configured to use **IIS Integrated Pipeline**.

When IIS pipeline instrumentation, as well as MVC area, or Controller naming is enabled, MVC naming will not be applied as it is a function of ASP.NET instrumentation. Also, with IIS pipeline instrumentation, each web request is tracked from the execution of the first HTTP module, or handler through to the end of the last, not only the ASP.NET application portion of the request.

### WCF Entry Points

#### Related pages:

- [Configure Business Transaction Detection for .NET](#)
- [Windows Communication Foundation \(Microsoft Windows Reference\)](#)

AppDynamics automatically detects entry points for client requests to Windows Communication Foundation (WCF) services. If the request occurs on an originating tier, the method or operation marks the beginning of a business transaction and defines the transaction name. For information on originating tiers, see [Business Transactions](#).

The .NET Agent detects async entry points for the following patterns:

- Task-based asynchronous operations
- IAsyncResult Begin-End Asynchronous pattern

### Controlling Correlation Header Location

In 4.4 and earlier, when WCF calls execute on a downstream tier, AppDynamics includes them as part of the business transaction from the originating tier. If the downstream WCF service uses the NetTcpBinding in WCF, you must register the app agent node property `enable-soap-header-correlation` with a value of `true`. See 'enable-soap-header-correlation' on [App Agent Node Properties Reference](#). Otherwise, the .NET Agent will detect the WCF call as the entry point for a new business transaction.

In the following table, when the node property is set to the default (false), the correlation message with header will only successfully deliver when sent over HTTP, not over SOAP with an HTTP wrapper or other protocol. When the node property is set to true, the correlation message with header will succeed in all scenarios.

	<code>enable-soap-header-correlation</code>	HTTP	SOAP (HTTP)	SOAP (other)
4.4 default	false	X	-	-
4.4	true	X	X	X

In 4.4.1 and later, the `enable-soap-header-correlation` node property and the default behavior for SOAP calls over non-HTTP protocols in WCF have changed. In addition, a new property, `disable-soap-header-correlation-non-http`, has been added. See `disable-soap-header-correlation-non-http` on [App Agent Node Properties Reference](#). With the new default AppDynamics will, by default, include downstream WCF services using NetTcpBinding as part of business transactions.

The following table captures the changes and additions of the correlation data for the following use cases:

- When the node properties for both `enable-soap-header-correlation` and `disable-soap-header-correlation-non-http` are set to the default (false), the correlation message with header will only successfully deliver when sent over HTTP or SOAP wrapped in a protocol other than HTTP.
- When the node property for `enable-soap-header-correlation` is set to `true`, and the `disable-soap-header-correlation-non-http` node property is set to the default ( false ), the correlation message with header will succeed in all scenarios.
- When the node property for `enable-soap-header-correlation` is set to the default ( false ), and the `disable-soap-header-correlation-non-http` node property is set to `true`, the correlation message with header will only successfully deliver when sent over HTTP, not over SOAP with an HTTP wrapper or other protocol.
- When the node properties for both `enable-soap-header-correlation` and `disable-soap-header-correlation-non-http` are set to `true`, the correlation message with header will only successfully deliver when sent over HTTP or SOAP with an HTTP wrapper, not over SOAP with another protocol.

**i** When upgrading from 4.4.0 to 4.4.1 or later, the `enable-soap-header-correlation` property retains its previous value and `disable-soap-header-correlation-non-http` defaults to `false`.

	<code>enable-soap-header-correlation</code>	<code>disable-soap-header-correlation-non-http</code>	HTTP	SOAP (HTTP)	SOAP (other)
4.5 default	<code>false</code>	<code>false</code>	X	-	X
4.5	<code>true</code>	<code>false</code>	X	X	X
4.5	<code>false</code>	<code>true</code>	X	-	-
4.5	<code>true</code>	<code>true</code>	X	X	-

By default, the .NET Agent does not correlate EUM transactions for WCF entry points. You can enable EUM correlation for WCF using the `wcf-enable-eum` node property. This feature is useful when an instrumented mobile application calls directly into a WCF entry point. See 'wcf-enable-eum' on [App Agent Node Properties Reference](#).

#### Automatic Naming for WCF Transactions

By default, the AppDynamics auto-detection naming scheme identifies all WCF transactions using the service name and operation name:

```
ServiceName.OperationName
```

For example, a web service for a travel website books reservations from client front ends: `TravelService.BookTravel`. You can rename or exclude automatically discovered transactions from the Business Transactions List.

#### Custom Match Rules for WCF Transactions

Custom match rules provide flexibility for WCF transaction naming. When you define a match rule, AppDynamics uses the rule name for the business transaction name. See [Custom Match Rules](#) for more information.

When AppDynamics detects a request matching your specified criteria, it identifies the request using your custom name. You can match based upon:

##### Web Service Name

- For rules on regular expressions for .NET, see [.NET Framework Regular Expressions](#).
- Optionally use the gear dropdown to set a NOT condition.

##### Operation Name

- For rules on regular expressions for .NET, see [.NET Framework Regular Expressions](#).

- Optionally use the gear dropdown to set a NOT condition.

For example, you could report all operations for a TravelService, such as `SearchTravel` and `BookTravel`, as one business transaction.

## ASP.NET Web Service Entry Points

AppDynamics automatically detects entry points for client requests to ASP.NET web services. If the request occurs on an originating tier, the method or operation marks the beginning of a business transaction and defines the transaction name. For more information on originating tiers, see [Configure Business Transaction Detection for .NET](#).

When web service calls execute on a downstream tier, AppDynamics includes them as part of the business transaction from the originating tier.

### Automatic Naming for Web Service Transactions

By default, the AppDynamics auto-detection naming scheme identifies all web service transactions using the service name and operation name:

```
ServiceName.OperationName
```

For example, a web service for a travel website books reservations from client front ends.

Name	Health	Response Time (ms)	Calls	Calls / min	Errors
TravelService.BookTravel	✓	44	1	< 1	0

You can rename or exclude automatically discovered transactions from the business transaction list.

### Custom Match Rules for ASP.NET Web Service Transactions

Custom match rules provide flexibility for ASP.NET web service transaction naming. When you define a match rule, AppDynamics uses the rule name for the business transaction name.

To access the Custom Match Rules pane, see 'To create custom match rules for .NET entry points' on [.NET Business Transaction Detection](#).

To create an ASP.NET web service custom match rule

1. In the **Custom Match Rules** pane, click the plus symbol (+) to add an entry point.
2. Click **Web Service** in the dropdown. Click **Next**.
3. Name the **New Business Transaction Match Rule**.
  - AppDynamics uses the rule **Name** to name the BT.
  - The Controller enables the rule by default. Disable it later if needed.
  - Set the **Priority** for the match rule. AppDynamics applies higher priority rules first.
4. Set one or more of the following match criteria. When AppDynamics detects a request matching your specified criteria, it identifies the request using your custom name.

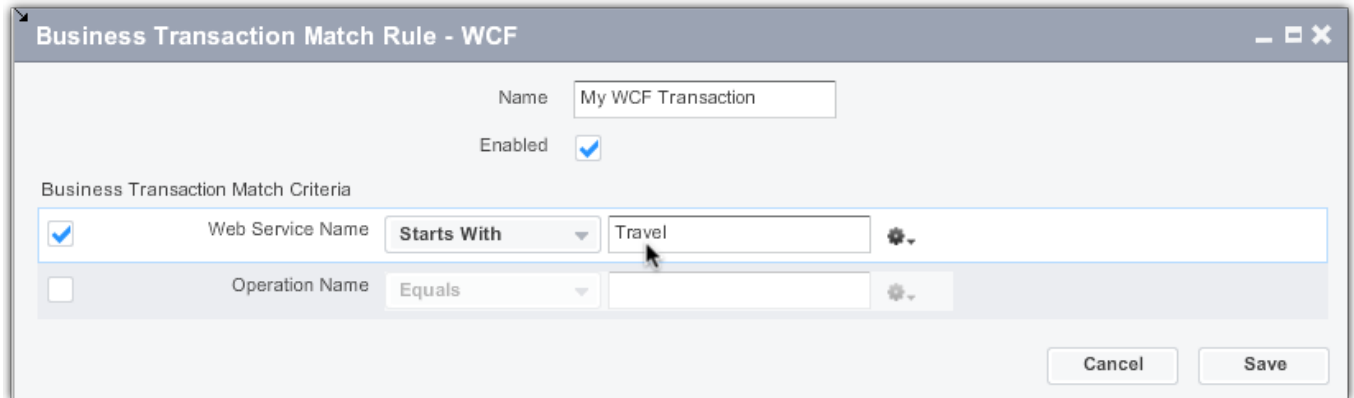

### Web Service Name

- For rules on regular expressions for .NET, see [.NET Framework Regular Expressions](#).
- Optionally use the gear dropdown to set a NOT condition.

### Operation Name

- For rules on regular expressions for .NET, see [.NET Framework Regular Expressions](#).
- Optionally use the gear dropdown to set a NOT condition.

For example, to report all operations for a TravelService, such as `SearchTravel` and `BookTravel`, as one business transaction:

#### 5. Click **Create Custom Match Rule**.

The rule appears in the **Custom Match Rule** list. The business application or tier you customized displays a green check in the **Select Application or Tier** pane.

After the agent receives the updated configuration, it discovers the new business transaction and displays it in the Business Transactions list.

### ASP.NET Core Instrumentation Options

When you develop an ASP.NET Core application, a pipeline is built by connecting the configured middleware components together.

By default (for example, when you re-use the standard template application startup code), you do not have to define how to build the pipeline or the sequence of middleware components in this pipeline. Everything works as defined. For applications with more complex processing demands, you would typically modify the middleware pipeline and consider how the .NET Agent instruments ASP.NET Core applications. [See middleware pipeline information from the Microsoft site.](#)

The .NET Agent can instrument this middleware pipeline at different points along the pipeline. Each instrumentation option provides advantages and disadvantages:

- Resource invoker instrumentation
- Endpoint instrumentation
- HTTP instrumentation
- MVC routing instrumentation

#### Resource Invoker Instrumentation

- Default setting for ASP.NET Core 2.x.
- For ASP.NET Core 3.x and 5.0, set the node property `aspdotnet-core-instrumentation (string) = "ResourceInvoker"` to enable it.

---

This instrumentation occurs at the end of the pipeline just before it calls the controller action or page handler. This applies to Razor Page handlers, and MVC and Web API controller actions.

The advantage is that only actual action code is instrumented, and the .NET Agent instrumentation does not execute for any other web requests such as: static files and not found paths ( `Error Code 404` ).

This is the most lightweight instrumentation option. It is the optimal choice for most ASP.NET Core applications, especially where minimal or no customization was applied to the middleware pipeline from the default application code.

### Endpoint Instrumentation

- Default setting for ASP.NET Core 3.x and 5.0 (as of .NET Agent 21.3).
- Not available for ASP.NET Core 2.x.

With the improved endpoint routing introduced in ASP.NET Core 2.2, all routing for Web API, MVC, and Razor Pages was merged into a new architecture enabling the .NET Agent to perform instrumentation just after the `EndpointRoutingMiddleware` .

The advantage of using Endpoint instrumentation (instead of Resource Invoker instrumentation) is that the Business Transaction is tracked through the execution of all middleware after the `EndpointRoutingMiddleware` . This provides more visibility into operations performed before the controller action is executed. This includes only middleware that participates in the routing process such as authentication and authorization, but excludes middleware such as health checks, serving up static files, and so on.

Endpoint instrumentation balances full pipeline visibility (which may introduce too much noise and overhead) with no visibility (using Resource Invoker instrumentation).

### HTTP Instrumentation

- This setting is available for ASP.NET Core 2.x, 3.x, and 5.0 (as of .NET Agent 21.3).
- Set the node property `aspdotnet-core-instrumentation (string) = "HTTP"` to enable it.

This instrumentation option instruments the full middleware pipeline by instrumenting every single web request. It provides the most visibility of all options. However, when enabling this option, you must consider:

- MVC naming is not possible because the request URL has not been decoded by the routing middleware. It may not be an MVC request; if it is, then controller and action names have not been resolved. All business transactions will use the URL path as its name.
- Because the .NET Agent instrumentation runs and inspects every web request (even requests that result with `404 Errors` , and so on), it has a greater performance impact on the application. To understand the performance impact, you should test this option either in a pre-production environment, or on a limited node count before you enable the option for the entire tier or application.

### MVC Routing Instrumentation

- This is the original instrumentation option introduced for ASP.NET Core 1.x. It is the default setting for ASP.NET Core 1.x, and a configurable option for 2.x.
- Set the node property `aspdotnet-core-instrumentation (string) = "Legacy"` to enable this for ASP.NET Core 2.x.

The MVC Routing instrumentation functionality has been deprecated with ASP.NET Core 3.0. It provides full pipeline visibility by instrumenting from the first middleware in the pipeline. However, when attempting to do MVC naming of incoming web requests, it may cause issues. It assumes that you built the middleware pipeline in a specific way, and contains very specific middleware request delegates.

If you are using ASP.NET Core 2.x, and need full pipeline visibility with MVC naming, then this is the only available option for you.

### Name MVC Transactions by Area, Controller, and Action

#### Related pages:

- [Business Transactions](#)
- [Transaction Detection Rules](#)

By default, the AppDynamics .NET Agent names ASP.NET transactions based upon the [URI](#). For ASP.NET Core on the full framework, the agent uses MVC area, Controller, and action naming by default, and can also be configured to use the URI. This page describes the MVC transaction naming configuration options for both ASP.NET and ASP.NET Core on the full framework.

**i** For transactions using the MVC naming conventions, the automatic transaction detection configuration settings apply to the MVC segments, not to the URI.

#### MVC Transaction Naming

For some MVC applications, URI-based naming may not produce meaningful business transaction names. Depending on the URI scheme, it might create many business transactions, pushing you quickly over your business transaction limit and causing most traffic to fall into the *All other traffic* business transaction.

For example, consider an MVC application that indicates store locations in the URL as the result of a city location search, such as the following sample URL:

`http://myapp.mycompany.com/Bellevue`

Based on this URL, AppDynamics registers a business transaction named `/Bellevue`. Each search result with a unique city would similarly generate a unique business transaction.

Name	Health	Server Time (ms)	Calls	Calls / min
/Bellevue	✓			4
/Mountain View	✓			14
/San Francisco	✓			9
/San Jose	✓	1	11	11
/Seattle	✓	1	21	21

Alternatively, you can configure the agent to identify transactions by the area, Controller, or action name. After you configure the agent to name transactions by Controller and action, the agent identifies the business transaction based on the Controller and action name, in this case, `Search/Results`.

 View Dashboard  More Actions  View Options  Configure					
Name	Health	Server Time (ms)	Calls	Calls / min	
 /Search/Results		1	166	55	

In this example, the new business transaction combines search requests for all cities into one transaction, resulting in a more logical unit for measuring application performance.

Similarly, if your application uses areas to logically group Controllers, you can configure the use of area name in the business transaction.

For background information on ASP.NET Routing, see this Microsoft Developer Network article: [msdn.microsoft.com/en-us/library/cc668201.aspx](https://msdn.microsoft.com/en-us/library/cc668201.aspx)

#### Configure Node Properties for MVC Transactions

You can configure custom MVC transaction naming using node properties. This table describes how to configure node properties for MVC transactions based on the type of entry point.

 The node property supports: MVC 3, MVC 4, and WebAPI transactions.

Type of Entry Point	Name Business Transactions	Transaction Naming Configuration
ASP.NET hosted in IIS ( <code>aspdotnet-mvc-</code> )	To name business transactions using the Controller and Action values	Register the <code>aspdotnet-mvc-naming-controlleraction</code> node property with a value = <code>true</code>
	To name business transactions using the Area and Controller values	Register the <code>aspdotnet-mvc-naming-controllerarea</code> node property with a value = <code>true</code>
	To include all three component values (Controller, Action, and Area) in business transaction names	<ol style="list-style-type: none"> <li>1. Register both node properties</li> <li>2. Configure the ASP.NET transaction naming to use three URI segments instead of two (default)</li> </ol> See <a href="#">Automatic Transaction Discovery Rules</a> .

Type of Entry Point	Name Business Transactions	Transaction Naming Configuration
ASP.NET Core on the Full Framework ( <code>aspdotnet-core-</code> )	To name business transactions using the URI	Register both of these node properties with a value = <code>false</code> <ul style="list-style-type: none"> <li><code>aspdotnet-core-naming-controllerarea **</code></li> <li><code>aspdotnet-core-naming-controlleraction</code></li> </ul>
	To omit the Area value from your transaction names	Register the <code>aspdotnet-core-naming-controllerarea</code> node property with a value = <code>false</code>
.NET Agent for Linux	To use MVC Area, Controller, URI, and Action in business transactions name	Register the <code>aspdotnet-mvc-naming-controlleraction</code> node property with a value = <code>true</code>

To register a new node property, see [App Agent Node Properties](#).

After you modify any transaction naming configuration, and traffic to the previously registered business transactions terminates, you can delete the old business transactions.

## Node.js Business Transaction Detection

### Related pages:

- [Transaction Detection Rules](#)

This page provides instructions about transaction detection and configuration for the Node.js Agent.

## GraphQL Business Transactions

GraphQL is a query and schema definition language that allows servers to expose an API over a HTTP endpoint. You specify the required data in the request payload and send all the requests from the client to a server endpoint.

AppDynamics supports GraphQL when used with the `graphql-http` module, view [GraphQL HTTP Server Middleware](#).

1. On the server side, you define a schema that describes the data and available operations on said data.
2. Then, you invoke operations defined by the schema to retrieve data (through URL requests that receive GraphQL queries) and mutate it.

In the current model, the Node.js Agent identifies an individual Business Transaction from the various requests coming to the server, but the agent does not capture the request payload.

GraphQL Business Transactions determines the business transaction through the incoming endpoint and incoming GraphQL payload, allowing further visibility into the GraphQL Node.js applications. Every GraphQL query that matches this URL is aggregated into one Business Transaction. With GraphQL Business Transactions, the Node.js Agent can be configured in the Controller to identify if an incoming

---

business transaction matches a specific URI (for example, starting with `/QL`) and split that transaction with an operation into multiple transactions.

By default, GraphQL Business Transactions is disabled. To configure the Node.js Agent to enable GraphQL Business Transactions, set `enableGraphQL` to `true` in the call to `profile()`:

```
enableGraphQL: true,
```

Once GraphQL Business Transactions is enabled, you can configure a GraphQL custom match rule for a Node.js application:

1. In the Controller, select **Configuration > Instrumentation > Transaction Detection**.
2. Click **Add Rule > Summary > Custom Match Rule**.
3. Select Node.js in the **Agent Type** dropdown. Click **Next**.
4. Enter a name for the match rule and ensure that the enabled checkbox is checked.
5. Click **Select Scope** and select the desired scope for the rule. Click **OK**.
6. Next, navigate to **Rule Configuration > HTTP Request Match Criteria** and click **Add**.
7. Select URI as the criteria and choose the desired operation from the dropdown list. Then, enter the desired value for the GraphQL incantation (for example, the URL prefix).
8. Navigate to **Split Transactions Using Request Data** and click the **Split Transactions Using Request Data** checkbox.

9. Select the **graphql** operation name from the dropdown and select **Save**.

Upon configuring the rule and sending a GraphQL queries in your application, the **Business Transactions** page displays separate transactions.

## PHP Business Transaction Detection

### Related pages:

- [Configuration Import and Export API](#)
- [Configure PHP Custom Match and Exclude Rules](#)

This page describes transaction detection and configuration procedures that related specifically to the PHP Agent. See [Transaction Detection Rules](#).

## PHP Entry Points

The entry point is where the business transaction begins, typically a URI or a page callback name, MVC controller action, page template name, or page template. The PHP Agent automatically detects and monitors the entry point types listed under PHP Frameworks and Protocols in [PHP Supported Environments](#).

If the agent cannot detect the framework, the entry point type defaults to PHP Web. PHP Web automatically detects all HTTP requests to the application.

## Enable Monitoring by Entry Point

You can enable and disable transaction monitoring for each entry point type.

When monitoring is disabled, the agent stops counting, measuring, and recording all activity on servers of that type.

Enable or disable monitoring by checking or clearing the **Transaction Monitoring** checkbox in the **Transaction Detection** panel for the PHP entry point type.

## Transaction Naming

By default, PHP Agent names transactions are named after the first two segments in the service request URL. You can modify the default naming scheme in the same manner as for any web-based business transaction entry point.

For PHP-based entry point tiers that use a multi-layered framework architecture, the last framework that processes the transaction determines the name of the PHP business transaction. For example, for an incoming request processing path of PHP Web > MVC > Drupal 8, a new business transaction would be named based on the Drupal 8 invocation rather than the preceding layers in the request processing flow.

### Virtual Host Naming by Entry Point

If you have multiple virtual hosts configured on a single web server, you can differentiate among the business transactions by adding the virtual host name as a prefix to the default business transaction name. Enable use of the prefix by checking the **Use Virtual Host in Business Transaction names** checkbox in the **Transaction Detection** panel for the PHP entry point type. Transactions discovered and named subsequent to this configuration will use the virtual host name as a prefix to the default name.

For example, an application has two `exit.php` actions running on the same physical host. One action runs on a virtual host named `phpagent1` and the other runs on a virtual host named `phpagent2`. Transaction naming will occur as follows:

- virtual host name is not used: agent identifies all requests to `exit.php` as a single business transaction named `exit.php`
- virtual host name is used: agent identifies requests as two different business transactions named `phpagent1 : exit.php` and `phpagent2 : exit.php`

### Customize Transaction Detection and Naming

If the default contentions do not produce transactions to fit your needs, you can change the transaction configuration as follows:

- Create exclude rules to eliminate entry points that you do not need to monitor.
- Create custom match rules that specify matching rules for identifying and naming transactions.
- For PHP Web entry points, you can also configure transaction naming.

To access the transaction detection panes, select **Configuration > Instrumentation > Transaction Detection > PHP-Transaction Detection**.

### Configure PHP Custom Match and Exclude Rules

#### Related pages:

- [Transaction Detection Rules](#)
- [Using Regular Expressions](#)

This page summarizes the criteria that you can use for creating custom match and exclude rules for each entry point type.

The criteria are the same for custom match and exclude rules.

If you disable automatic detection for an entry point type and then apply custom match rules, the agent discovers only requests defined by those match rules. For example, if you have a PHP MVC custom match rule that matches on "Action contains search", and another rule that matches on "Action contains view", requests that contain "search" or "view" are the only MVC transactions that the agent detects.

On the other hand, if you do not disable automatic detection and you apply a custom match rule "Action contains search", all the requests that match that criterion are grouped together as a single "search" transaction and then any other requests (those that do not contain "search") are discovered using automatic detection.

### Accessing Custom Rule Configuration

1. Click **Configuration Instrumentation > Transaction Detection > PHP-Transaction Detection**.

2. Scroll down to either the **Custom Match Rule** section or the **Exclude Rule** section.
3. Click **+** to create a new rule, then select from the dropdown the entry point type to which the rule applies.

## PHP Web

Matching criteria can include one or more of the following:

- HTTP method
- URI segments
- HTTP parameter (value or existence)
- HTTP header (value or existence)
- Port
- Cookie (value or existence)

See [Set Priority When Multiple Rules Apply in Custom Match Rules](#).

## Transaction Splitting

For PHP Web, if a transaction is configured to identify the entry point based on the URI, you can optionally split the transaction into multiple transactions. For example, a login request may be automatically detected as a single transaction, but you want to split it into two transactions based on whether the request branches to a new-user or existing-user operation.

You can split a PHP Web transaction using request data from the transaction names such as URI segments, parameter values, header values, and cookie values.

## PHP Web Splitting Example

For example, to split a custom match rule transaction "mobile checkout" by the mobile carrier parameter, so the agent detects separate transactions as follows:

- products/mobile/checkout?carrier=verizon
- products/mobile/checkout?carrier=sprint
- products/mobile/checkout?carrier=att

To split transactions based upon the carrier parameter:

1. On the Rule Configuration tab, set a URI match option.
2. Check **Split Transactions Using RequestData**.
3. Select **Use a parameter value in Transaction names**.
4. Enter "carrier" for the **Parameter Name**.

The agent creates the following transactions: "mobile checkout.verizon", "mobile checkout.sprint", and "mobile checkout.att".

## PHP Web Custom Match Rules vs Auto-Detection Rules of Other Types

If a custom match rule configured for PHP Web matches the same criteria as an auto-detection rule for a business transaction of a different transaction type in the same application, the PHP Web custom match rule takes precedence and the business transaction appears as a PHP Web transaction type.

However, if a custom match rule for PHP Web and a custom match rule for another transaction type match the same criteria, precedence depends on the values of the rules' priorities. See [Setting Match Rule Priority](#) for information on rule priorities.

## PHP MVC

---

By default, for most MVC frameworks, the business transaction is named using the controller:action. For modular MVC frameworks, the business transaction is named using the module:controller:action.

You can modify detection to match only a portion of the module, controller or view name (such as "Begins with" or "Contains") or on a regular expression, rather than the default which matches the entire name using "Equals" for the match condition.

You cannot configure a single match rule that matches on both the controller and the action. You can create MVC custom match rules using any of the following:

- controller name only
- action name only
- module name and action
- module and controller name

### PHP Web Service

By default, for Web Services frameworks, the business transaction is named for the entire web service name and the entire operation name using "Equals" for the match condition.

You can modify detection with a custom rule that matches on only the web service name or only the operation name. You can match on a portion of either name or use a regular expression.

### PHP Drupal

By default, AppDynamics automatically names Drupal transactions based on the entire page callback name of the Drupal module using "Equals" for the match condition.

You can modify detection with a custom match rule that uses just a portion of the page callback name or use a regular expression.

### PHP Wordpress

By default, AppDynamics automatically names Wordpress transactions based on the entire Wordpress template name using "Equals" for the match condition.

You can modify detection with a custom match rule that uses just a portion of the template name, or use a regular expression.

### PHP CLI

By default, AppDynamics automatically names PHP CLI transactions based on the last two segments of the script's directory path plus the name of the script.

The agent creates a business transaction instance every time the script is run.

You can modify detection with a custom match rule that matches on a different portion of the script path and name or uses a regular expression.

### Custom Exclude Rule Examples

Custom exclude rules prevent detection of business transactions that match certain criteria. You might want to use exclude rules in the following situations:

- AppDynamics detects business transactions that you do not want to monitor.
- To stay within agent and controller limits, you want to reduce the total number of business transactions.
- You need to suppress a default entry point to allow for the detection of a more precise entry point defined by a custom match rule.

You can customize existing rules or set up new rules. See [Custom Match Rules](#).

### Change the Default Exclude Rule Settings

AppDynamics has a default set of custom exclude rules for various agent types. Sometimes you need to disable a default rule or add a new custom exclude rule. Different entry point types include different match criteria that you can use to exclude transactions.

You can view the default rules on the **Transaction Detection > Rules** tab:

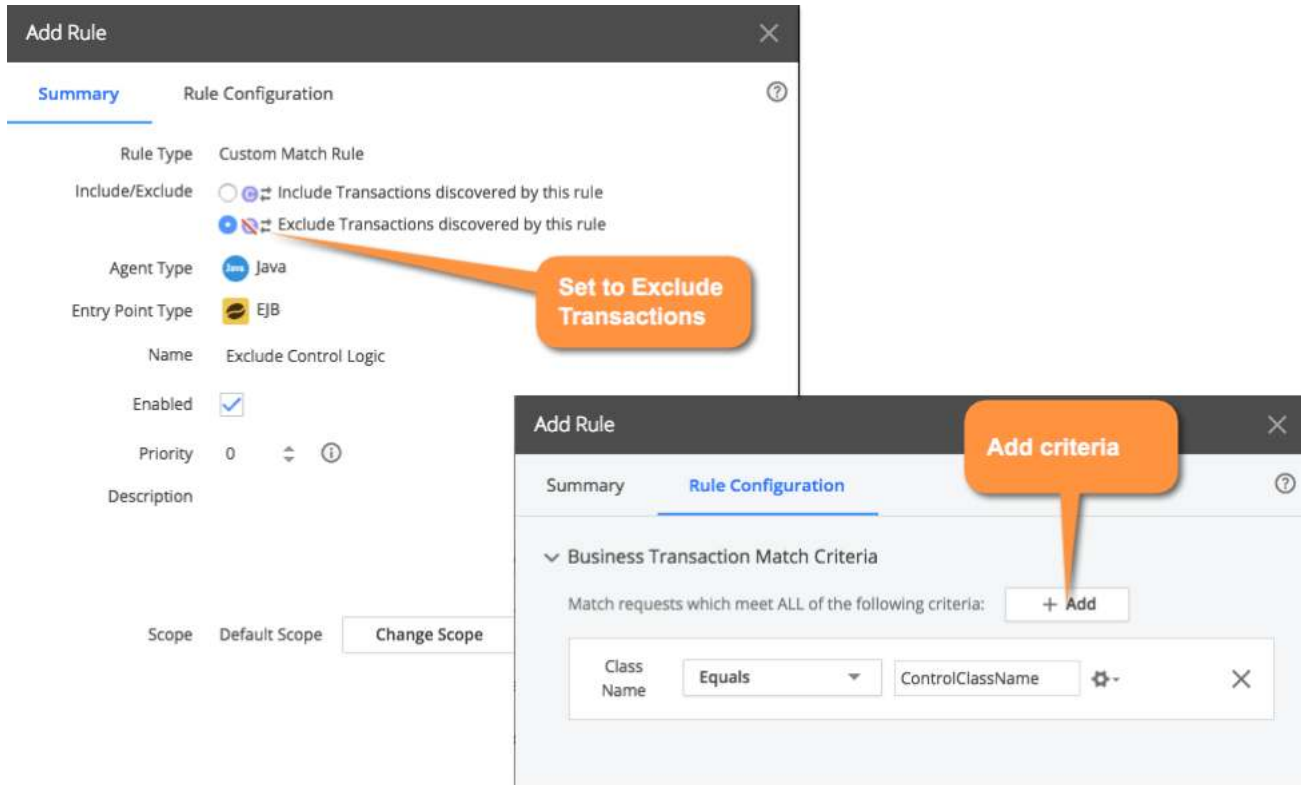

The screenshot shows the 'Transaction Detection > Rules' interface. The 'Rules' tab is selected, and the 'Rule Type' is set to 'Custom Exclude'. An orange callout bubble points to the 'Rule Type' dropdown with the text 'Filter to view exclude rules'. Below the filters is a table of rules with columns for Agent Type, Name, Scope, Enabled, and Priority.

Agent Type	Name	Scope	Enabled	Prior...
Java	Spring WS - Base servlet for...	Default Scope	✓	0
Java	Spring WS - dispatching of ...	Default Scope	✓	0
Java	Websphere web-services Se...	Default Scope	✓	0
Java	JBoss 6.x web-services Servl...	Default Scope	✓	0
.NET	ASP.NET WebService Sessio...	Default Scope	✓	0
.NET	ASP.NET WCF Activation Ha...	Default Scope	✓	0
.NET	ASP.NET WebService Script ...	Default Scope	✓	0
.NET	ASP.NET MVC5 Resource Ha...	Default Scope	✓	0
Node.js	NodeJS Static Content Filter	Default Scope	✓	0
Python	Python Static Content Filter	Default Scope	✓	0

### Define Transaction Names Using Downstream Application Logic

Sometimes an incoming request invokes control logic in your code that uses payload data to execute different business logic. In such cases, it makes sense to name your business transactions for the business logic class and method. You can use a custom exclude rule to prevent AppDynamics from naming the business transaction for control logic. Then you can identify the transaction by the business logic instead.

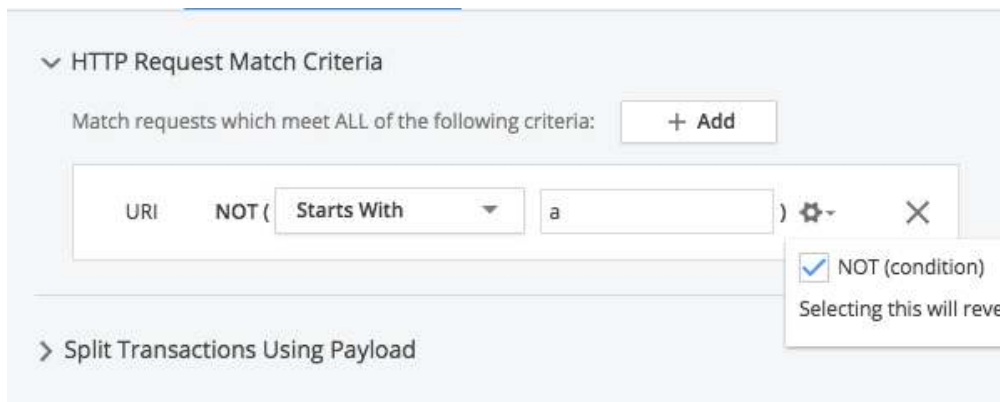

Consider an example where you have implemented both the control logic and business logic as EJBs. With **EJB** discovery enabled, AppDynamics discovers and names business transactions based on the control class and method. You can create an EJB exclude rule for the control class name using the **Class Name Equals** match criteria. After you create the rule AppDynamics discovers and names the business transactions for your business logic APIs:

### Use an Exclude Rule as a Filter

Custom exclude rules filter out unwanted requests from transaction discovery. You can specify match criteria that allow eligible requests but ignore everything else.

For example, you want to use default discovery rules. Your application receives URI ranges that start with : / a, /b ... /z. However, you only want to monitor URIs only when they start with /a . You can create a custom exclude rule that does a "Match : Doesn't Start With /a" as shown here:

In another example, imagine a specific an application that implements Spring Beans of the classes `java.lang.String` and `java.util.ArrayList`. This means that AppDynamics identifies all instances of these classes as Spring Beans with the same IDs. To fix the problem, you can define a custom exclude rule specific Spring Bean IDs:

The screenshot displays the 'Add Rule' configuration interface in AppDynamics. The main window is titled 'Add Rule' and has two tabs: 'Summary' and 'Rule Configuration'. The 'Rule Configuration' tab is active, showing the following settings:

- Rule Type:** Custom Match Rule
- Include/Exclude:** Exclude Transactions discovered by this rule (selected)
- Agent Type:** Java
- Entry Point Type:** Spring Bean
- Name:** (empty text field)
- Enabled:**
- Priority:** 0
- Description:** (empty text area)
- Scope:** Default Scope

An overlapping 'Add Rule' window is shown in the foreground, also with 'Rule Configuration' selected. It displays the 'Business Transaction Match Criteria' section, which includes a plus sign to add criteria and a list of criteria. One criterion is visible: 'Bean ID' with a dropdown menu set to 'Equals' and a text input field containing 'MyBean'.

## Custom Match Rule Live Preview

 You must have Configure Transaction Detection and View Sensitive Data permissions to use Live Preview. See [Manage Custom Roles](#).

When you create or edit servlet or POJO custom match rules in AppDynamics, you can click **Live Preview** to inspect pertinent transaction data from a node.

Custom transaction detection rule Live Preview session lets you interactively preview the effect of rule updates on your business transactions. Live Preview also provides tools for the different rule types to let you inspect the live data streaming from your application.

When you launch Live Preview, select the node where you want to preview transactions. Nodes are organized by tier. You can see which nodes have active agents and if there is a live preview session already running on a node.

## Preview Business Transactions

When you initiate a custom match rule live preview session, the Controller shows the rule configuration in the left pane. Click **Preview Business Transactions** in the right pane to see the resulting transactions. You can edit the rule and click **Apply** to update the changes within the session.

When the agent discovers an entry point for a rule but the transaction payload contains correlation data from an existing transaction, Live Preview displays a [masked transaction](#).

## POJO Match Rule Tools

You can use these tools to inspect data and configure the entry point for a POJO custom match rule:

- **Classes/Methods browser**—lets you search for classes.
  - You can right-click a class or method in the result to set the class and method match criteria for the POJO.
  - You can view method invocations for a selected method.

In live preview mode, the number of methods and classes that can be returned by an agent is now limit-bounded. The limits are:

- Maximum number of classes: 1000
- Maximum number of methods: 300

You can change limits by modifying the node properties

`classmethodservice.max.no.of.classes.reported` and  
`classmethodservice.max.no.of.methods.reported`, respectively

- **Method Invocations**—lets you inspect live data from the server for the specified method.
  - a. Expand a method invocation to see detailed information including invoked objects, parameters, and return values.
  - b. Right-click on a data point to use it in transaction splitting.
    - AppDynamics automatically creates a splitting rule following the `get<field>()` syntax.
    - If your code follows another convention, you need to manually specify the getter method for the data point.

- c. You can also copy a [getter chain](#) to the clipboard.  
The example below shows the data for a method, `Order.setQuantity()` :

End Live Preview | Connected 00:22:09 | ECommerce-E2E-Demo\_WS\_NODE

Preview Business Transactions | Tools | Method Invocations

Filter | Refresh | Stop Streaming

Match Classes with a Class Name that Equals com.a... | Method Name: Equals setQuantity

Operation stopped.

- Copy Name to Clipboard
- Copy Details to Clipboard

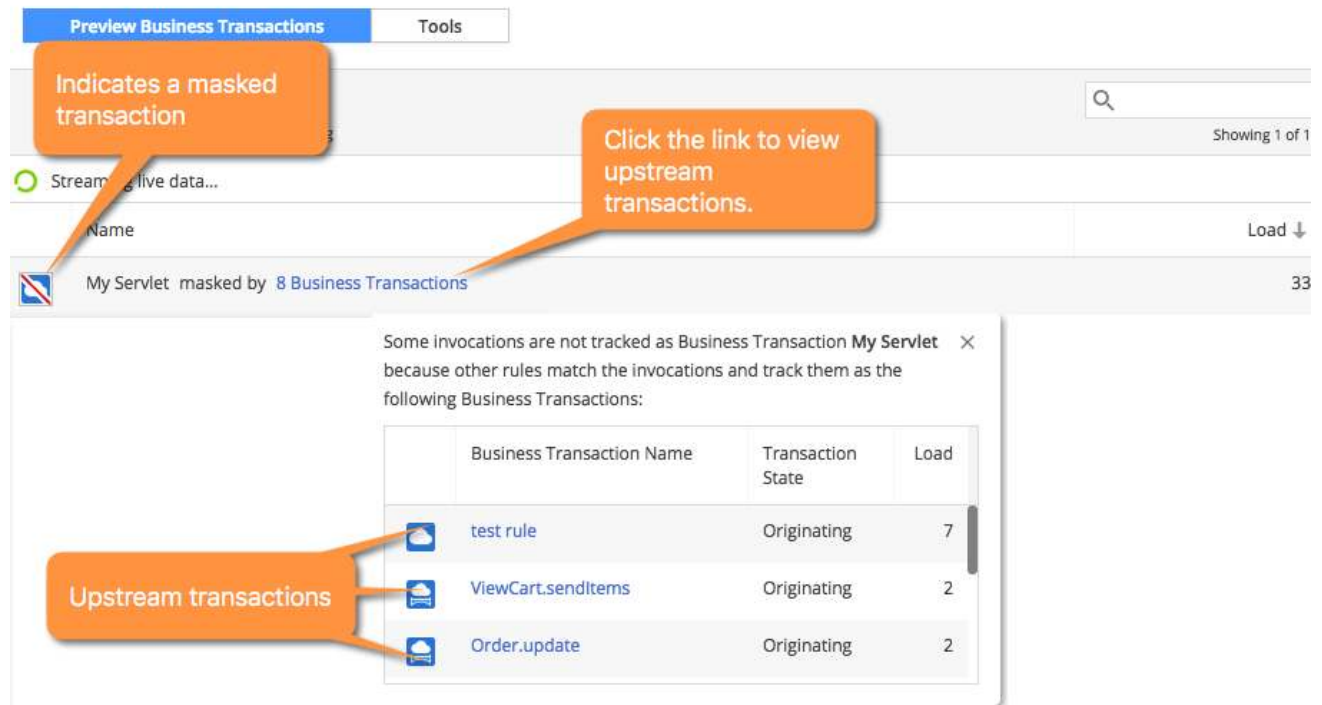

### Servlet Match Rule Tools

When you use Live Preview to inspect data for a servlet custom match rule, AppDynamics shows live HTTP Requests that meet the rule criteria. You can click an individual Request URL to view detailed request data: headers, cookies, and parameters.

1. Right-click an individual data point, such as a header, to add the value to the match criteria or to set it as a transaction splitting option.
2. You can group the incoming HTTP requests by various parts of the request and its payload, such as the URI, an HTTP parameter, a header, etc. You can right-click a result from the **Values** column and add the value to the **HTTP Request Match** criteria.

### Masked Transactions

Live Preview flags transactions that are downstream from another existing business transaction as masked transactions. To view the originating business transactions masking the current transaction, click the link indicating the number of transactions.

Click a business transaction name to view the business transaction dashboard for the masking transaction.

If you want to view metrics for the current entry point outside of a masking transaction or transactions, you can either:

- Deactivate the business transaction detection rules that created the upstream transactions, or
- Create a [service endpoint](#) for the entry point.

Otherwise, you can continue to track the performance of the masked entry point as a segment of the business transaction it currently belongs to.

### URI Based Entry Points

For almost every web-based framework or platform, there is a URI based business transaction entry point for user requests. AppDynamics App Agents automatically discover the following URI-based entry points:

- Java Agent: Servlet entry points
- .NET Agent: ASP.NET entry points
- Node.js Agent: Node.js web entry points
- Python Agent: Python web entry points

The Web server Agent can detect Web request entry points, but automatic discovery is turned off by default so an agent on a downstream node can name the transaction.

URI based entry points all have similar configuration options for [Automatic Transaction Discovery](#) and [Custom Match](#) rules.

For additional functionality that applies to servlets, see [Servlet Entry Points](#).

## Default Naming

By default, when an app agent detects a URI request, it names the business transactions using the first two segments of the URI. For example, consider the following URI for a checkout operation in an online store: `http://acmeonline.com/store/checkout`.

The agent names the business transaction `"/store/checkout"` and assigns all requests that match that URI to the `"store/checkout"` business transaction.

If the first two segments of the URI do not contain enough information to effectively identify the business transaction in your environment, you can edit the [automatic discovery rule](#) to name the transaction based upon the URI and its context. Alternatively, you can create a [custom match rule](#) to specify a name.

 For ASP.NET Core on the full framework, the default naming convention uses the Controller, action, and area. See [Name MVC Transactions by Area, Controller, and Action](#) for more information and configuration options.

## Customize Automatic Naming Rules

When you edit or create a new Default Automatic Discovery Rule for URI based entry points, you can adjust naming to:

- Use the full URI to name transactions.
- Use part of the URI to dynamically name transactions.

Expand the **Configure Naming** option on the **Rule Configuration** tab to display the configuration options.

When you configure the rule to **Use the full URI**, the agent creates a business transaction name for the full request URI. There are no dynamic naming options. For example, for the URI `http://acmeonline.com/store/coats/men`, the agent names the transaction `"/store/coats/men"`.

 **Use the full URI** works well for Grails servlet transactions because the default naming scheme often doesn't differentiate between multiple transactions.

When you use parts of the URI to name transactions, you have several options to configure transaction naming:

- [Use a Part of the URI](#)
- [Use Headers, Cookies, and Other Parts of HTTP Requests](#)
- [Use a Custom Expression](#)

### Use a Part of the URI

AppDynamics offers the following options to automatically name URI based transactions based upon the URI:

- Use the first or last URI segments
- Use specific URI segments

For the following URL the first two segments of the URI don't provide a significant name for the business transaction:

`http://example.com/Web/Store/Checkout` yields a default transaction name of "Web/Store".

You can use one of the following options to identify more meaningful transaction names:

- Click **Use the first** or **Use the last n** segments to use two contiguous segments at the beginning or end of the URI, where **n** is the number of segments. For example, if identify the checkout transaction using the last two segments of the URI, the agent names the transaction `"/Store/Checkout"`.
- If you need more flexibility, such as using non-contiguous segments in the name, click **Name Transactions dynamically using part of the request**. Select **Use URI segments in Transaction names** option. To specify multiple segments, enter a comma-separated list of segment numbers.

For example, the following URL represents the checkout transaction requested by a customer with ID 1234: `http://example.com/Store/cust1234/Checkout`

The checkout transaction is the same regardless of the customer, so it makes sense to name the transaction based upon the first and third segments of the URI. AppDynamics names the transaction: "StoreCheckout".

Configure Naming

What part of the URI should be used in the Transaction Name?

Use the full URI

Use a part of the URI (for example, if you have dynamic URIs)

Use the first 2 segments of the URL

Name Transactions dynamically using part of the request

Use specific URI segment(s) in Transaction names

Segment Numbers 1, 3

Enter a comma separated list of segment numbers (e.g. 1, 3, 4)

## Use Headers, Cookies, and Other Parts of HTTP Requests

When you use the **Name Transactions dynamically using part of the request** option, you can choose to identify your URI based transactions using particular parts of the HTTP request. Note that not all agents offer all the naming options below.

**i** Carefully consider your naming configuration choices. If you use a value such as the request originating address and you have many clients accessing your application, you may see the all other traffic business transaction.

- To use HTTP parameter values in transaction names, select **Use a parameter value in Transaction names** and enter the **Parameter Name**.

For example, consider the following URL: `http://example.com/Store/Inventory?category=electronics`

What part of the URI should be used in the Transaction Name?

Use the full URI

Use a part of the URI (for example, if you have dynamic URIs)

Use the first  segments of the URL ?

Name Transactions dynamically using part of the request

Use  in Transaction names

Parameter Name

AppDynamics names the transaction to include the category parameter value "/Store/Inventory.electronics".

- To use a header value in transaction names, select **Use header value in Transaction names** and enter a **Header Name**. For example, consider a site that uses the custom header "Version", AppDynamics names transactions with the header value "/Store/Inventory.v2.5".
- To use a cookie value in transaction names, select **Use a cookie value in Transaction names** and enter the **Cookie Name**. For example, a website tracks a user's loyalty status in a cookie. Set the Cookie Name to "loyalty". AppDynamics names transactions for the loyalty cookie value "/Store/Inventory.Status=Gold"
- To Use a session attribute value in transaction names, Click **Use a session attribute in Transaction names** and enter the **Session Attribute Key**. For example, a website stores a customer's region in the session property. Set the Session Attribute name to "region". AppDynamics names transactions for the region session attribute value "/Store/Inventory.NorthAmerica".
- To use the request method in Transaction names, click **Use the request method (GET/POST/PUT) in Transaction names**. For example AppDynamics names the transaction "/Store/Inventory.GET".
- To use the request host in Transaction names, click **Use the request host in Transaction names**. For example AppDynamics includes the request host id in the transaction name "/Store/Inventory.192.0.2.0".
- To use the request originating address in Transaction names, click **Use the request originating address in Transaction names**. AppDynamics names transactions for the IP address of the request client "/Store/Inventory.192.0.2.10".

## Use a Custom Expression

You can use a custom expression on the URI to name:

- Java servlet transactions
- .NET ASP.NET transactions

Select **Name Transactions dynamically using part of the request** and choose **Use a custom expression in Transaction names**. Enter your custom expression getter chain as follows:

For Java, you can use getter chains to access values from the `HttpServletRequest` object. For example, suppose you want to use a combination of the authenticated user and the value of an `HttpServletRequest` :

```
${getParameter(myParam)}-${getUserPrincipal().getName() }
```

The equivalent code expression would evaluate to:

```
request.getParameter("myParam")+"-"+request.getUserPrincipal()
```

You can create a custom expression on the `HttpServletRequest` to identify all Servlet based requests (modify global discovery at the transaction naming level) or for a specific set of requests (custom rule).

A custom expression for a servlet transaction can have a combination of any of the following getter methods on request attributes:

Getters on Request Attributes	Transaction Identification
<code>getAuthType()</code>	Use this option to monitor secure (or insecure) communications.
<code>getContextPath()</code>	Identify the user requests based on the portion of the URI.
<code>getHeader()</code>	Identify the requests based on request headers.
<code>getMethod()</code>	Identify user requests invoked by a particular method.
<code>getPathInfo()</code>	Identify user requests based on the extra path information associated with the URL (sent by the client when the request was made).
<code>getQueryString()</code>	Identify the requests based on the query string contained in the request URL after the path.
<code>getRemoteUser()</code>	Identify the user requests based on the login of the user making this request.
<code>getRequestedSessionId()</code>	Identify user requests based on the session id specified by the client.
<code>getUserPrincipal()</code>	Identify user requests based on the current authenticated user.

For .NET, you can use [getter chains](#) to access properties and methods for the `HttpRequest` object for ASP.NET or `Microsoft.AspNetCore.Http.Internal.DefaultHttpRequest` for ASP.NET Core on the full framework.

- Enclose getter chains inside braces: `${}` . The custom expression may contain multiple getter chains.
- Use [getter chain](#) syntax.
- Use any `HttpRequest` request attributes or methods.

For example, consider the URL `http://mystore.example.com/Store/Inventory-Furniture` .The following custom expression uses two getter chains to access properties of the `HttpRequest` object:

```
${Url.ToString().Split(Char[]/-).[2]}-${UserAgent}
```

- The first getter chain fetches the URL, splits it on the dash character ("-"), and uses the second string in the array.
- The second getter chain fetches the `HttpRequest.UserAgent` property.
- The literal dash character "-" separates the two getter chains.

The result is the following business transaction name:

Furniture-Mozilla/5.0 (Windows NT 6.3; Trident/7.0; rv:11.0) like Gecko

## Message Queue Entry Points

Most frequently an instrumented application calls to a message queue as a [remote service](#) or backend. However, in cases when an application uses asynchronous message listeners or message-driven beans as the primary trigger for business processing on an originating tier, AppDynamics can intercept the message listener invocations and track them as business transactions.

AppDynamics discovers the following types of business transaction entry points:

- Java JMS entry points.
- .NET Message Queue entry points

Message queue entry points all have similar naming configuration options for [Automatic Transaction Discovery](#) and [Custom Match Rules](#).

## Default Naming

By default, the AppDynamics auto-detection naming scheme identifies all message queue transactions using the destination name. Otherwise, if the destination name is not available, AppDynamics uses the listener class name.

## Custom Match Rule Options

When you create a JMS or Message Queue custom match rule, the agent names matching transactions for the custom match rule name. See [Custom Match Rules](#).

You have the option to specify the following match criteria as a combination of the following entry point properties:

- The **Message Destination** as **Queue**, **Topic** or **Unknown**.
- **Message Property**. You can match against a property's existence or against a property's value.
- **Message Content**.

## Business Transaction Discovery Sessions

Business Transaction Discovery Sessions provide interactive tools to help you create the optimal set of transaction detection rules and discover crucial business transactions.

During a discovery session, you can preview the effects of all the transaction detection rules on a node. This way you can create rules that capture the precise business transactions that impact your business and avoid rules that generate too many transactions.

Within the context of the discovery session, you can:

- Edit Java Agent transaction detection rules and Preview Business Transactions. (Java only)
- Identify entry points from Uninstrumented Code.
- Browse Classes/Methods to identify entry points.

During the business transaction discovery session, you can test out various transaction detection rule configurations without impacting your production environment.

Any business transactions discovered within the context of the discovery session, called transient transactions, do not persist after the session ends. When you end the session you have the opportunity to discard the rule changes or to apply them to your production configuration.

## Permissions

 You need the following permissions to launch a Business Transaction Discovery Session:

- Configure Transaction Detection
- View Sensitive Data

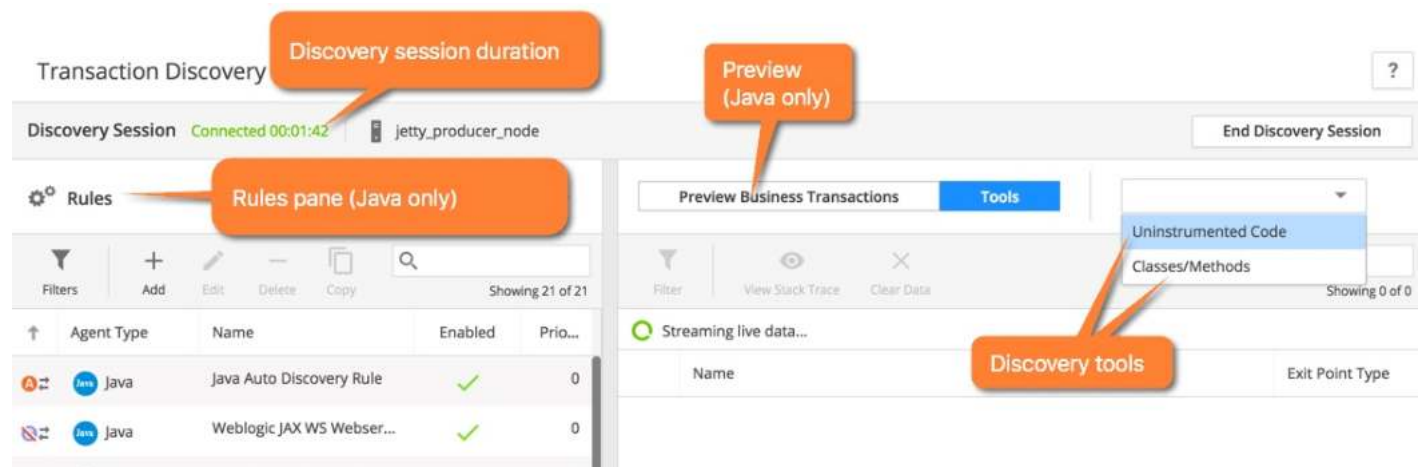

For information on AppDynamics Role Based Access Control, see [Manage Custom Roles](#).

## Launch a Business Transaction Discovery Session

1. Navigate to **Configuration > Instrumentation** and click the Transaction Detection tab.
2. Click **Live Preview**.
3. Click **Start Discovery Session** to start a Business Transaction Discovery session.
4. Select the node to act as the source of the live data stream.

Nodes are organized by tier. You can see which nodes have active agents and if there is a discovery session already running on a node.

The Transaction Discovery page displays information about the discovery session lets you navigate among the available interactive transaction discovery tools:

The screenshot shows the 'Transaction Discovery' interface. At the top, it displays 'Discovery Session Connected 00:01:42' for the node 'jetty\_producer\_node'. Below this is a 'Rules' pane with a table of active rules. To the right, there are 'Preview Business Transactions' and 'Tools' buttons. A dropdown menu is open under 'Tools', showing 'Uninstrumented Code' and 'Classes/Methods'. A 'Streaming live data...' indicator is visible below the tools. Callouts point to the session duration, the preview button, the rules pane, and the tools section.

Agent Type	Name	Enabled	Prio...
Java	Java Auto Discovery Rule	✓	0
Java	Weblogic JAX WS Webser...	✓	0

 The transaction discovery tool works as it did in previous versions for upgraded business applications. See [Business Transaction Discovery Sessions](#).

When you initiate a transaction discovery session on a Java node, the Rules pane displays the active transaction discovery rules that apply to the node. The right-hand pane lets you **Preview Business Transactions** or use the available interactive **Tools**: Uninstrumented Code detection and the Classes/Methods Browser.

When you launch a discovery session on a .NET node, you see the available tools: Uninstrumented Code detection and the Classes/Methods Browser.

During a discovery session, you can use other features of AppDynamics while the discovery process continues in the background. This is useful for busy environments with many active transactions. You can give AppDynamics a few minutes to complete the discovery. When you are ready to return to the Transaction Discovery page click **Configuration > Instrumentation** and click the **Live Preview** button to resume your discovery session.

### Edit and Preview Transaction Discovery Rules

You can add, edit, or delete any type of [transaction detection rule](#) for the Java Agent in the Rules pane. Click **Apply** to update the rule within the context of the discovery session.

To see the effects of your changes, click **Preview Business Transactions**. As the app agent discovers business transactions based on the rule configuration, the transactions show up in a list in the right-hand pane:

The screenshot shows the AppDynamics interface with two main panes. The left pane is titled 'Rules' and contains a table of transaction detection rules. The right pane is titled 'Preview Business Transactions' and displays a list of discovered transactions. Callouts provide the following information:

- Add or edit transaction detection rules that apply to the currently selected nodes within the discovery session:** Points to the 'Add' button in the Rules pane.
- Displays transactions:** Points to the 'Preview Business Transactions' button.
- Clears the list of discovered business transactions:** Points to the 'Clear Data' button.
- Transactions discovered based upon the detection rules in the discovery session:** Points to the list of transactions in the right pane.

Agent Type	Name	Status	Count
Java	Java Auto Discovery Rule	✓	0
Java	Jersey Servlet	✓	0
Java	Websphere web-services ...	✓	0
Java	Weblogic JAX WS Servlet	✓	0

Name	Load
/DockerServletApp/frompython27flask.http	31
/DockerServletApp/fromnodejs.http	31
/DockerServletApp/fromapache.http	31

You can select a transaction and click **Capture Snapshots** to collect transaction snapshots.

**⚠** The Capture Snapshots feature is only available for Servlets.

Click a specific snapshot to display the payload data for the business transaction in the Snapshot Details:

Capturing Snapshots for Transaction: /appdynamicspilot/ ...

**Cookies**  
No data available

When you create [custom match rules](#) for servlets or for [POJOs](#) you can start a [Live Preview](#) session limited to the specific rule.

### Inspect Uninstrumented Code to Discover Entry Points

When the app agent doesn't automatically discover an entry point for a framework in your application, you can use Uninstrumented Code detection to find entry points for the framework. After you identify an entry point you want to track as a business transaction, you can create a [custom match rule](#).

Uninstrumented Code detection identifies the support exit calls for an app agent on the node when the entry point is undetected. In the following example the Java Agent discovers some uninstrumented JDBC exit points:

Preview Business Transactions **Tools** Uninstrumented Code ▾

Filter  View Stack Trace  Clear Data  Showing 9 of 9

Streaming live data...

	Load	Timestamp	Exit Point Type
org.apache.tomcat.dbcp.dbcp2.PoolingDataSource:ge...	2	12/09/16 2:15:28 PM	JDBC
org.apache.tomcat.dbcp.dbcp2.PoolingDataSource:ge...	2	12/09/16 2:15:28 PM	JDBC
org.apache.tomcat.dbcp.dbcp2.BasicDataSource:ge...			JDBC
org.apache.tomcat.dbcp.dbcp2.PoolingDataSource:ge...	2	12/09/16 2:15:28 PM	JDBC
com.mysql.jdbc.PreparedStatement:executeQuery	2	12/09/16 2:15:28 PM	JDBC

You can select an exit point and click **View Stack Trace** to display the call stack for the exit point. Select any call in the stack trace and click **Monitor** to show interactive data for that specific call. When the agent returns the monitoring result, you can inspect the values for a specific method invocation including the **Invoked Object**, **Return Value**, **Parameters**, and more.

The example below shows the upstream stack trace for the `com.mysql.jdbc.PreparedStatement:executeQuery` JDBC exit call:

**Uninstrumented Code Stack Trace**

Monitor + Add POJO Rule

com.mysql.jdbc.PreparedStatement:executeQuery

notes	[null, org.apache.catalina.connector.Response@4fd57219, null, null, null, null, null, null, null, null, null, ...

When you identify the method you want to instrument, you can click to add a POJO or POCO. The Controller UI automatically populates the Rule Configuration in the Add Rule editor with the class and method you want to instrument. Complete the custom match rule for the [POJO](#) or [POCO](#) as normal.

### Search for Classes and Methods to Instrument

If you are familiar with your application code, you can use the Classes/Methods browser to search the running code for specific classes and methods to instrument. The example below illustrates how a search for `jetty.server` in a sample application returns both instrumented and uninstrumented classes and methods:

When you identify a method you want to instrument, right-click the method to open the Add Rule editor. AppDynamics automatically populates the class and method configuration based upon your search criteria from the Class/Method browser. You can right-click a class to instrument it, but you must add the method before you can save the POJO or POCO. Complete the custom match rule for the [POJO](#) or [POCO](#) as normal.

## Backend Detection Rules

### Related pages:

- [Java Backend Detection](#)
- [.NET Backend Detection](#)

In AppDynamics, databases and remote services (and in fact, any detected out of process components that are involved in Business Transaction processing) are collectively known as backends.

AppDynamics discovers backends from exit point instrumentation placed in the application code. An exit point is the precise location in the code where an outbound call is made from an instrumented node. AppDynamics automatically discovers a wide range of backends.

### Default Automatic Backend Discovery

A discoverable backend is identified by its type and associated properties. The precise set of properties used to identify any given backend is dependent on its type. The type itself is defined in the built-in backend discovery rules for backend types supported out of the box. For exit calls to backends that are not instrumented with APM agents, AppDynamics uses the backend properties to identify and name the backend. Where a backend call is actually processed by a downstream tier also instrumented with AppDynamics, ensure that any given backend that is identified will always result in calls that will be processed by just one downstream tier.

This means, for example, that if tier A makes an HTTP call to an HTTP router on localhost:4040 which will forward the call to tier B or tier C depending on the URL, custom backend naming rules will be required to include enough segments of the request URL - as well as the host and port - such that requests destined for tier B will be associated with a backend with a different set of backend properties than those associated with tier C.

---

The **Automatic Backend Discovery** list in the **Configuration > Instrumentation > Backend Detection** tab shows the configurable backend discovery rules.

The automatic discovery rules vary according to the type of backend being identified, but generally include settings for enabling automatic discovery of the backend type, enabling correlation, and properties used to identify and name the backend. AppDynamics uses transaction correlation to track request processing across distributed tiers. Certain types of backends are automatically discovered as *high volume* exit points (sometimes called turbo exit points). These backend types include cache servers, EhCache, Danga Memcache, Memcached, and Oracle Coherence. For more about high volume exit points, see [Exit Point Detection Rules](#).

When an exit point is identified for the first time, the exit call results in a backend discovery event.

## Permissions

To modify backend detection, you need the **Configure Backend Detection** permission.

### Modify Automatic Discovery

If you know that the application flow map should be showing a specific backend and you are not seeing it, you can modify the configuration to detect backends. You can:

- Edit the default backend discovery rules.
- Create new custom backend discovery rules.
- Create new custom exit points to provide visibility for backend types that are not automatically discovered.
- Disable automatic discovery of backends that are not of interest.
- Disable correlation for the backend.

In many cases, you can achieve the level of customization that you need by editing the default rules rather than creating new rules.

To edit a rule, in the Backend Detection tab, select the application and click **Edit Automatic Discovery**.

For certain backend types—particularly those named by URL—the name of the discovered backend instances include a port number. If the app agent is unable to discover the port number for some reason, the port number is displayed in the UI as "-1". This can happen, for example, when a port is not a public port or the API for discovering the port is not available on the application environment (often the case for an RMI backend type). Despite having an unknown port number, the backends are nonetheless uniquely identified.

### Configurable Properties and Naming

For many of the automatically discovered backend types, AppDynamics uses a set of configurable properties to identify and name the backend. For example, the properties for a JMS messaging queue are something like this:

- DestinationType (for example, QUEUE)
- Destination (for example, OrderQueue)
- Vendor (for example, Active MQ)

The following informational popup shows how the values are used to identify a discovered backend. In the following example, callout 1 shows the value that corresponds to the destination type, callout 2 to the vendor name, and callout 3 to the destination queue name:

### Aggregate or Split Backends

You can change the default configuration for the backend types shown in the UI to aggregate or split the backends. For example, you could disable the Vendor property for JMS backend detection to aggregate (join) all JMS backends with the same destination and destination type. The metrics for all JMS backends with the same destination and destination type would be aggregated as one backend.

For properties that you want to use, you can also configure how AppDynamics uses the property. For example, if the URL property is used to identify a backend and your URLs include a file name, the default configuration results in a separate backend for every file.

To reduce the number of backends identified using the URL property, configure which parts of the URL to use. For example, run a regular expression on the URL to discard the file name or any other parts of the URL that you do not want used for identification.

### Add Custom Backend Discovery Rules

AppDynamics provides the additional flexibility to create new custom discovery rules for the automatically discovered backend types.

To create a custom discovery rule for an automatically discovered backend type, select the backend type in the **Automatic Backend Discovery** list. Click **Add** (the + icon) to create a new rule. Specify the following:

- **Name** for the custom rule.
- **Enabled** to enable or disable the rule.
- **Correlation Enabled** to specify whether or not to send business transaction correlation data to the backend.
- **Priority** for this custom rule compared to other custom rules for this backend type. The higher the number, the higher the priority. A value of 0 (zero) indicates that the default rule should be used.
- **Match Conditions** used to identify which backends are subject to the custom naming rules. AppDynamics applies the default rules to backends that do not meet all the defined match conditions.
- **Backend Naming Configuration** used to name the backends matching the match conditions. The naming configuration must include the property used by the match condition.

See specific exit points for examples.

### Backend Detection Rule Priorities

When a request matches more than one type of backend detection rule, AppDynamics agents apply backend detection rules in the following order:

[Custom Exit Points](#) > [Custom Discovery Rules](#) > [Automatic Backend Discovery](#).

If detection rules are of the same type, AppDynamics agents apply backend detection rules based on rule priority from highest to lowest. A priority of 0 is the lowest priority possible.

For example, consider an HTTP request that matches a priority 2 custom discovery rule and a priority 6 custom discovery rule. The agent applies the priority 6 rule.

To configure exit point detection:

1. Go to the **Configuration > Instrumentation** page.
2. Select the **Backend Detection** tab.
3. Select the application or tier on which you want to configure an exit point and the application type of the exit point, Java, .NET, and so on. From there you can add new exit points or modify existing ones.

### All Other Traffic Backends

AppDynamics limits the number of backend systems that can be registered and tracked. Once the limit is reached (databases and remote services combined), additional backend are put in the "All other traffic for <type>" category.

The "type" is the backend type such as HTTP or Web Service. HTTP calls and JMS queues are the most common types that may reach the limit with the default configuration rules.

On a flow map, the category appears as follows:

Metrics for the backend calls grouped in the "All other traffic" category are aggregated. If the group includes backend instances that you want to be individually tracked, you can manage backend detection, as described in [Manage Backend Discovery](#).

### Backend Registration Limits

The limits on the number of backends that can be registered:

- The Controller enforces a limit of 1000 backend registrations in the business application for each type of backend (that is, 1000 HTTP backends, 1000 JMS backends, and so on). This setting is controlled by the `backend.registration.limit` Controller Setting. This limit applies whether the backends are resolved to a tier or unresolved.
- Agents apply a limit of 300 unresolved backends per application, regardless of the type. When determining if the limit has been reached, it's important to include all types. For example, agents, databases, remote services, etc., should all be included when totaling unregistered backends if it appears that the limit has not been reached but the logs have reported it has. To safeguard against reaching the limit, we recommend that you [delete unnecessary backends](#).

When the backend count exceeds the limit, the "All Other Traffic" category is automatically created. The logs indicate that a limit has been reached by a log entry such as the following:

```
[pool-1-thread-2] 21 Mar 2013 11:28:01,702 DEBUG AFastBackendResolver - Not discovering
backend call [Exit Point Type [WEB_SERVICE] Properties
[{{SERVICE_NAME=ZipCodeService002.wsdl}} Display Name [ZipCodeService002.wsdl]] because
maximum limit of discovered backends [300] reached.
```

## Manage Backend Discovery

After reaching the backend registration limit, you should make sure that the systems being tracked as first-class registered backends are the ones that are important to you relative to those in the "All Other Traffic" category.

Also make sure that application environmental conditions are not causing an excess number of backends to be registered. These conditions may include:

- JMS queues that use the session ID in the destination. This causes each session to be identified as a separate backend.
- Calls to message queues hosted on the same server. In this case, you might not be interested in seeing each queue separately, and instead, want to aggregate everything for the same host and port to the same backend.
- Dynamic generation of IP addresses, such as when you host a service on Amazon Elastic Compute Cloud (Amazon EC2).
- Different JDBC drivers connecting to the same database may cause many backends. This can happen when there are slight variations in the driver metadata that AppDynamics uses to identify the database. For example, if two different JDBC drivers are used to access the same database, something as simple as a different spelling or format of the database name (ORACLE, oracle, or ORACL) can generate multiple database names when they are the actually the same physical database.

To manage backend registrations, you can change the configuration of the backend detection rules. For example, if a property causes excessive unique identification, consider removing the property or modifying its use in the detection and naming rule. If you created custom exit points, consider refining or removing them.

## Delete Unnecessary Backends

Some backends may no longer have traffic. You can delete unused backends from the Remote Services List, any Remote Service dashboard, the Databases List, and any Database dashboard. If the backend has new traffic in the future, the app agent rediscovers it and reregisters it with the Controller.

You can also configure the Controller to automatically remove stale backends. See [Stale Remote Service Removal](#).

## Organize Backends in Flow Maps

Once you have configured detection for all the backends you require, you may need to organize the way they appear in the UI. See [Group Remote Services on Flow Maps](#).

## Exit Point Detection Rules

Custom exit points enable you to identify backend types that are not automatically detected. For example, you can define a custom exit point to monitor code calls to a file system read method.

After you have defined a custom exit point, the backend appears on the flow map with the type-associated icon you selected when you configured the custom exit point. See [Custom Exit Points for Java](#).

## Configuration Notes

You configure exit point detection in the **Configuration > Instrumentation** page. Select the Backend Detection tab and choose the application or tier on which to configure an exit point and the application type of the exit point, Java, .NET, and so on. From there you can add new exit points or modify existing ones.

The specific configuration options available differ based on the application type, but in general, you identify the exit point and specify the mechanism for it to be detected, such as a class and method name. These additional notes apply to exit point configuration:

- If the method you are using to identify the exit point is overloaded, you need to add the parameters that identify the signature for this form of the method.
- Match conditions let you restrict the method invocations for which you want AppDynamics to collect metrics based on runtime values tested by the condition. Match conditions can test parameter values or any value accessible by getter chain from the invoked object.
- Optionally, you can split an exit point based on a method parameter, the return value, or the invoked object.
- You can configure custom metrics and transaction snapshot data to collect for the backend.
- If you configure a custom backend for a method that encapsulates an automatically detected backend, such as an HTTP client call, you may lose correlation from the automatically detected exit call.
- Splitting a backend on return value may break correlation.

You are limited to 50 characters for the exit point value when adding a custom exit point or splitting/grouping exit points.

## Adding a Custom Exit Point

When adding a custom exit point, you specify the class and method that identify an external call to the exit point. You can refine the call by specifying a return value, parameter, or getter chain match value.

The type you choose determines the icon that appears in the flow map for the custom exit point. If the type is not listed, select **Use Custom** and enter a string in the **Type** field to identify the exit point calls in the UI.

Note that you can also split the exit point based on these values. If you add a split condition for an exit point, it means that any exit point that matches the overall match condition for the custom exit point is further evaluated against the split condition. If its call matches the split condition, it is given the more specific name you configure in the split exit point configuration.

## High Volume Exit Points

The **Is High Volume** option for custom exit points lets you create an optimized exit point configuration for backend systems with high-performance requirements, such as caching servers or in-memory databases.

A "high volume" exit point keeps the overhead associated with the exit point to a negligible amount by bypassing certain processing operations on calls to this exit point. As a result, transaction correlation and error detail reporting are not available for the exit point, nor are match conditions in the exit point configuration.

With a high volume exit point, you do get the number of calls, number of errors, and average response time for calls.

## Split and Group Exit Points

By splitting an exit point, you can use dynamic application values to identify an exit point. Specifically, you can use the value of either a method parameter, the method return value, or a value returned by a specified

getter chain on the invoked object of the identified method. The configuration settings you use to configure exit point splitting are the same as used for Data Collectors. See [Data Collectors](#) for information on how to use the configuration UI.

A simple example of how you would use exit point splitting is for a cache exit point. In this example, say you configure splitting for an exit point that identifies a method for writing to the cache. The object on which the method for writing to the cache offers a method to get the current cache name, the `getCacheName()` method. By configuring a split on this method (as a getter chain on the invoked object), you can have the exit point named with the name of the cache node, as dynamically determined:

The screenshot shows the 'Create Custom Exit Point' dialog. At the top, 'Name' is 'CoherenceCacheAccess' and 'Type' is 'Cache'. There are tabs for 'Identificat...', 'Custom Metrics', and 'Snapshot Data'. The main section is titled 'Define the class and method name which, when called, will be identified as a Custom Exit Point:'. It includes a 'Class' dropdown set to 'with a Class Name that' and a text field containing 'com.tangosol.net.NamedCache'. Below that is a 'Method Name' field with 'entrySet' and a checkbox for 'Is this Method Overloaded?'. There are also fields for 'Method Parameters (optional)' and 'Match Conditions (optional)', each with an 'Add' button. At the bottom, a section titled 'Calls to the specified class and method name can be further split based by a combination of method parameters and return value:' contains a table with one entry: 'CacheName' with the description 'Collect data from the invoked object and capture the result of getCacheName()'. Buttons for 'Add', 'Edit', 'Delete', 'Cancel', and 'Save' are visible.

Splitting also lets you group exit points. Given an exit point for `NamedCache.entrySet()`, as shown in the example above, suppose we created another exit point. This one uses the `getAll()` method on the same class, `NamedCache`. It also has a split configuration that uses the `getCacheName()` method of the invoked object.

If the `getCacheName()` getter chain points to the same cache name when the `getAll()` and the `entrySet()` methods are invoked, they will be shown as calls to the same backend.

## Java Backend Detection

### Related pages:

- [Exit Point Detection Rules](#)
- [Monitor Databases](#)
- [Remote Services](#)

The AppDynamics Java Agent automatically discovers common types of remote services as backend systems based on the exit point associated with the backend. If AppDynamics does not automatically discover a backend system used in your environment, check whether it's an automatically discovered type

(based on the list below) and compare the default exit points for the type to that used in your application environment.

Each automatically discovered backend type has a default discovery rule. Many backend types have a set of backend naming properties. Where individual properties are configurable, you can configure the property as follows:

- Use the property as is.
- Use segments of the property.
- Run a regular expression on the property. See [Using Regular Expressions](#).
- Execute methods on the property. See [Using Getter Chains](#).

For instructions to revise backend discovery rules, see [Backend Detection Rules](#).

### Amazon Simple Notification Service Backends

AppDynamics detects exit calls to the Amazon SNS messaging service using the Amazon SNS Client: `AmazonSNSClient.publish`.

#### Amazon SNS Naming Properties

You can enable or disable the use of the following properties for Amazon S3 backend identification:

Configurable Properties	Default Automatic Amazon SNS Backend Discovery/Naming
Vendor	Yes
Topic ARN	Yes

### Amazon Simple Queue Service Backends

AppDynamics can detect the following types of Amazon Web Services SQS message queue actions:

- Basic send/receive
- Batched send/receive
- Asynchronous send/receive

Correlating SQS traffic requires you to configure the continuation entry point for the SQS message.

### Amazon Simple Storage Service Backends

AppDynamics automatically detects the following exit points for Amazon Web Services S3 backends:

- `AmazonS3Client.deleteObject`
- `AmazonS3Client.getObject`
- `AmazonS3Client.getObjectMetadata`
- `AmazonS3Client.listObjects`
- `AmazonS3Client.putObject`

#### Amazon S3 Naming Properties

You can enable or disable the use of the following properties for Amazon S3 backend identification:

Configurable Properties	Default Automatic Amazon S3 Discovery/ Naming
Bucket Name	Yes
Vendor	Yes
Object Key	No

### Amazon Web Services Backends

AppDynamics detects the following exit calls to the following Amazon Web Services:

- DynamoDB requests using the `AmazonDynamoDBClient` create, read, update, and delete (CRUD) methods using the Amazon low-level DynamoDB API. The agent discovers the Document API calls as the underlying low-level API call.

### Amazon Web Service Naming Properties

For Amazon Web Services, you can enable or disable the use of the following naming properties for backend identification:

Configurable Properties	Default Automatic Amazon Web Service Backend Discovery/Naming
Vendor	Yes
Service	Yes
Endpoint	Yes

### Apache Cassandra CQL Backends

By default, AppDynamics automatically detects and identifies exit calls to Apache Cassandra using Thrift and DataStax drivers.

- i** Exceptions returned from Cassandra backends show up as separate exit calls. For the DataStax 1.0 driver, the Java Agent detects an "unknown" Cassandra backend in order to capture the error details.

### Cassandra Backend Naming Properties

You can enable or disable the use of the properties below for Cassandra backend identification:

- i** When you configure Cassandra backend naming, consider the following:
  - For DataStax clients, AppDynamics does not recommend using the `keyspace` property. Due to driver limitations, the `keyspace` property is only available when

Statement `.setKeyspace` is called explicitly in Cassandra. This can lead to the discovery of multiple backends.

- Thrift clients don't support Cluster Name, Rack or Data Center properties, so those properties return null for Thrift.

Configurable Properties	Default Automatic Cassandra CQL Backend Discovery/Naming
Cluster Name	Yes
Keyspace	No
Host	Yes
Port	Yes
Data Center	No
Rack	No

### Apache Kafka Backends

By default, the Java Agent detects publish activity to Apache Kafka as an exit point from a Java node. You can configure the Java Agent to detect Kafka consumer activity as an entry point, see [Apache Kafka Consumer Backends](#).

### Kafka Backend Naming Properties

You can enable or disable the use of the following properties for Kafka backend identification:

Configurable Properties	Default Automatic IBM MQ Backend Discovery/Naming
Vendor	Yes
Topic Name	Yes
Broker URL	No

### Default Kafka JMX Metrics

Kafka Producer and Consumer expose many JMX metrics. By default, we provide rules for some of these metrics. See [Default JMX Metrics for Apache Kafka Backends](#). If you need to create a new rule, see [Configure JMX Metrics from MBeans](#).

## Couchbase Backends

By default, AppDynamics automatically detects and identifies exit calls made to the Couchbase cluster node.

### Couchbase Backend Naming Properties

You can enable or disable the use of the following properties for Couchbase exit backend identification:

Configurable Properties	Default Automatic Couchbase Backend Discovery/Naming
Server Pool	Yes
Vendor	Yes
Bucket Name	Yes

## HTTP Backends

HTTP exit point activity includes all HTTP calls done outside of a web service call. Web service calls are not considered an HTTP exit point. By default, the Java Agent names the HTTP backend for the Host and Port properties. For instance, "myHTTPHost:5000".

### HTTP Backend Naming Properties

You can enable or disable the use of the following properties for HTTP backend identification:

Configurable Properties	Default Automatic HTTP Backend Discovery/Naming
Host	Yes
Port	Yes
URL	No
Query String	No

For examples of common HTTP backend configurations, see [HTTP Backend Detection](#).

For sample JDBC backend configurations, see [Example JDBC Backend Configuration](#).

## IBM Websphere Message Queue Backends

IBM MQ, also known as IBM WebSphere MQ and IBM MQSeries, is IBM's message-oriented middleware similar to JMS. Several additional properties are configurable, such as host and port. This is useful where you have lots of queues and you want to monitor them based on a subset of the properties.

## IBM MQ Backend Naming Properties

You can enable or disable the use of the following properties for IBM MQ backend identification:

Configurable Properties	Default Automatic IBM MQ Backend Discovery/ Naming
Destination	Yes
Destination Type	Yes
Host	Yes
Port	Yes
Major Version	Yes
Vendor	Yes

For examples of common message queue configuration scenarios, see [Example Message Queue Backend Configuration](#).

## Java Message Service Backends

JMS backend activity includes all JMS message send and publish activity. By default, AppDynamics identifies JMS back ends using the properties of the JMS server such as: vendor, destination name, and destination type. The default configuration uses all three properties of the JMS queue.

## JMS Backend Naming Properties

You can enable or disable the use of the following properties for JMS backend identification:

Configurable Properties	Default Automatic JMS Backend Discovery/ Naming
Destination	Yes
Destination Type	Yes
Vendor	Yes

Transaction names are derived from the enabled properties, for example, "ActiveMQ-OrderQueue".

For examples of common message queue configuration scenarios, see [Example Message Queue Backend Configuration](#).

## JDBC Backends

JDBC backend activity consists of all JDBC calls including inserts, queries, updates, getting connections from connection pools, and so on.

Expand to show exit calls the agent captures for the Oracle JDBC driver as an example...

Class	Method
<code>oracle.jdbc.driver.PhysicalConnection</code>	<ul style="list-style-type: none"> <li><code>prepareStatement</code></li> <li><code>prepareCall</code></li> <li><code>commit</code></li> <li><code>rollback</code></li> </ul>
<code>oracle.jdbc.driver.OracleStatement</code>	<ul style="list-style-type: none"> <li><code>executeQuery</code></li> <li><code>executeUpdate</code></li> <li><code>execute</code></li> </ul>
<code>oracle.jdbc.driver.OracleDataSource</code>	<ul style="list-style-type: none"> <li><code>getConnection</code></li> </ul>
<code>oracle.jdbc.driver.OraclePreparedStatement</code>	<ul style="list-style-type: none"> <li><code>executeQuery</code></li> <li><code>addBatch</code></li> <li><code>execute</code></li> <li><code>executeUpdate</code></li> </ul>
<code>oracle.jdbc.driver.OraclePreparedStatementWrapper</code>	<ul style="list-style-type: none"> <li><code>execute</code></li> <li><code>executeQuery</code></li> <li><code>executeUpdate</code></li> </ul>

The Java Agent measures the response time for a database call as the round trip time it takes for a JDBC call to return. The response time for a database call includes network round trip time + database connection time + SQL query time or any other time spent in the database.

By default, the agent identifies JDBC backends using the following logical properties of the database:

- URL
- Host name
- Port number
- Database schema
- Version
- Vendor

If a database backend has the same hostname, port number, and database type as a database server already configured in a database Collector, the database backend is automatically matched with the Collector, and drill-downs from the Application Flow Map, Tier Flow Map or Node Flow Map to Database Monitoring are enabled.

## JDBC Backend Naming Properties

You can enable or disable the use of the following properties for JDBC backend identification:

Configurable Properties	Default Automatic JDBC Backend Discovery/Naming	Description
URL	Yes	JDBC URL provided to the driver
Host	Yes	Database host
Port	Yes	Database port
Database	Yes	Database schema
Version	Yes	Database version as reported by JDBC driver
Vendor	Yes	Database vendor as reported by JDBC driver

### Jolt Backends

AppDynamics detects exit calls to Tuxedo services from the JoltRemoteService class in the Jolt Class Library.

### Jolt Naming Properties

You can enable or disable the use of the following naming properties for Jolt backend identification.

Configurable Properties	Default Automatic Jolt Backend Discovery/Naming
Host	Yes
Port	Yes
Service	Yes

### MongoDB Backends

By default, the Java Agent detects exit calls to MongoDB using the Mongo Java Driver over the MongoDB Wire Protocol. The agent detects the exit point on the Wire Protocol methods and excludes the methods between the external API and the Wire Protocol.

## MongoDB Backend Naming Properties

Configurable Properties	Default Automatic MongoDB Backend Discovery/Naming
Host	Yes
Port	Yes
Database	Yes

## RabbitMQ Backends

RabbitMQ is open source, commercially supported, messaging middleware that runs on many different operating systems. The Java Agent discovers exit points using the RabbitMQ Java API, `amqp-client.jar` in most distributions. By default, RabbitMQ backends are identified by Host, Port, Routing Key, and Exchange. For instance: "amqp://guest@127.0.0.1:5672/exchange/task\_queue".

## RabbitMQ Backend Naming Properties

You can enable or disable the use of the following properties for RabbitMQ backend identification:

Configurable Properties	Default Automatic RabbitMQ Backend Discovery/Naming
Host	Yes
Port	Yes
Routing Key	Yes
Exchange	Yes

For examples of common message queue configuration scenarios, see [Example Message Queue Backend Configuration](#).

## RMI Backends

The Java Agent automatically discovers backends called using the standard Java RMI API. For a list of supported RMI frameworks, see 'RPC/Web Services API/HTTP Client Support' on [Java Supported Environments](#).

## RMI Backend Naming Property

The JAVA Agent names the RMI backend for the URL. You can configure how the agent uses the URL to name the RMI backend.

## Thrift Backends

By default, AppDynamics automatically detects and identifies Apache Thrift exit points (backends). See [Apache Thrift](#) for details.

### Thrift Backend Naming Properties

You can enable or disable the use of the following properties for Thrift exit backend identification:

Configurable Properties	Default Automatic Thrift Backend Discovery/ Naming
Host	Yes
Port	Yes
transport	Yes

## Web Services Backends

Web service backend activity includes all web service invocations. Web service backends are identified using the web service name.

### Web Services Backend Naming Properties

Configurable Properties	Default Automatic Web Service Backend Discovery/Naming
Service	Yes
URL	No
Operation	No
Soap Action	No
Vendor	No

**i** By default, the gRPC backend is identified as `ServiceName-gRPC`. This is also configurable under web services backend.

## Custom Exit Points for Java

This page describes settings you can use to create custom exit point configurations for specific backends in Java environments.

In general, custom exit rules match calls to custom backends by class and method name. In some cases, you need to configure splitting as well. The following tables give you the class and method names to use for the various types.

Enter the configuration settings in the corresponding fields in the custom exit point UI. The following screenshot illustrates a sample configuration for an EhCache custom match rule:

For more about creating custom exit points, see [create a custom exit point](#).

**i** Oracle Coherence, EhCache, and Memcached backends are detected automatically as **high volume exit points**. You can create custom exit points for the backends as described here for particular backend splitting and naming results.

### Coherence Exit Points

Name of the Exit Point	Type	Method Name	Class Match Criteria	Class/Interface/Superclass/Annotation Name	Method Name	Splitting Configuration
Coherence.Put	Cache		that implements an interface which	com.tangosol.net.NamedCache	put	getCacheName()
Coherence.PutAll	Cache		that implements an interface which	com.tangosol.net.NamedCache	putAll	getCacheName()
Coherence.EntrySet	Cache		that implements an interface which	com.tangosol.net.NamedCache	entrySet	getCacheName()
Coherence.KeySet	Cache		that implements an interface which	com.tangosol.net.NamedCache	keySet	getCacheName()
Coherence.Get	Cache		that implements an interface which	com.tangosol.net.NamedCache	get	getCacheName()
Coherence.Remove	Cache		that implements an interface which	com.tangosol.net.NamedCache	remove	getCacheName()

### EhCache Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/Superclass/Annotation Name	Method Name	Splitting Configuration
EhCache.Get	Cache	With a class name that	net.sf.ehcache.Cache	get	getName()
EhCache.Put	Cache	With a class name that	net.sf.ehcache.Cache	put	getName()

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/ Superclass/ Annotation Name	Method Name	Splitting Configuration
EhCache.PutIfAbsent	Cache	With a class name that	net.sf.ehcache.Cache	putIfAbsent	getName()
EhCache.PutQuiet	Cache	With a class name that	net.sf.ehcache.Cache	putQuiet	getName()
EhCache.Remove	Cache	With a class name that	net.sf.ehcache.Cache	remove	getName()
EhCache.RemoveAll	Cache	With a class name that	net.sf.ehcache.Cache	removeAll	getName()
EhCache.RemoveQuiet	Cache	With a class name that	net.sf.ehcache.Cache	removeQuiet	getName()
EhCache.Replace	Cache	With a class name that	net.sf.ehcache.Cache	replace	getName()

### LDAP Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/ Superclass/ Annotation Name	Method Name
LDAPExitPoint.Bind	LDAP	With a class name that	javax.naming.directory.InitialDirContext	bind
LDAPExitPoint.Rebind	LDAP	With a class name that	javax.naming.directory.InitialDirContext	rebind
LDAPExitPoint.Search	LDAP	With a class name that	javax.naming.directory.InitialDirContext	search
LDAPExitPoint.ModifyAttributes	LDAP	With a class name that	javax.naming.directory.InitialDirContext	modifyAttributes
LDAPExitPoint.GetNextBatch	LDAP	With a class name that	com.sun.jndi.ldap.LdapNamingEnumeration	getNextBatch

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/ Superclass/ Annotation Name	Method Name
LDAPExitPoint.NextAux	LDAP	With a class name that	com.sun.jndi.ldap.Ldap NamingEnumeration	nextAux
LDAPExitPoint.CreatePooledConnection	LDAP	With a class name that	com.sun.jndi.ldap.Ldap ClientFactory	createPooledConnection
LDAPExitPoint.Search	LDAP	With a class name that	com.sun.jndi.ldap.Ldap ClientFactory	search
LDAPExitPoint.Modify	LDAP	With a class name that	com.sun.jndi.ldap.Ldap ClientFactory	modify

#### Mail Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/ Superclass/ Annotation Name	Method Name
MailExitPoint.Send	Mail Server	With a class name that	javax.mail.Transport	send
MailExitPoint.SendMessage	Mail Server	With a class name that	javax.mail.Transport	sendMessage

#### Memcached Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/ Superclass/ Annotation Name	Method Name
Memcached.Add	Cache	With a class name that	net.spy.memcached.MemcachedClient	add
Memcached.Set	Cache	With a class name that	net.spy.memcached.MemcachedClient	set
Memcached.Replace	Cache	With a class name that	net.spy.memcached.MemcachedClient	replace

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/ Superclass/ Annotation Name	Method Name
Memcached.CompareAndSwap	Cache	With a class name that	net.spy.memcached.MemcachedClient	cas
Memcached.Get	Cache	With a class name that	net.spy.memcached.MemcachedClient	get
Memcached.Remove	Cache	With a class name that	net.spy.memcached.MemcachedClient	remove

### MongoDB Exit Points

Name of Exit Point	Type	Class Match Criteria	Class/ Interface/ Superclass/ Annotation Name	Method Name	Splitting Config/ Custom Exit Point Identifier		Snapshot Data Operation on Invoked Object
					Collect Data From	Getter Chain Operation on Invoked Object	
MongoDB.Insert	JDBC	With a class name that	com.mongodb.DBCollection	insert	Invoked Object	getDB().getName()	Parameter_0.toString()
MongoDB.Find	JDBC	With a class name that	com.mongodb.DBCollection	find	Invoked Object	getDB().getName()	Parameter_0.toString()
MongoDB.Update	JDBC	With a class name that	com.mongodb.DBCollection	update	Invoked Object	getDB().getName()	Parameter_0.toString()
MongoDB.Remove	JDBC	With a class name that	com.mongodb.DBCollection	remove	Invoked Object	getDB().getName()	Parameter_0.toString()
MongoDB.Apply	JDBC	With a class name that	com.mongodb.DBCollection	apply	Invoked Object	getDB().getName()	Parameter_0.toString()

### **i** Avoiding high overhead

AppDynamics recommends that you avoid instrumenting highly-used methods, such as the find() method, because the activity around these methods can cause an undesired amount of overhead on the system.

### Sample MongoDB Exit Point Configuration

The screenshot shows the 'Create Custom Exit Point' configuration window in AppDynamics. The main window has a 'Name' field containing 'EhCache.Get' and a 'Type' dropdown set to 'Cache'. Below this are tabs for 'Identification', 'Custom Metrics', and 'Snapshot Data'. The 'Identification' tab is active, showing a 'Class' field with 'with a Class Name that equals' and a 'Method Name' field with 'get'. A 'Match Criteria for the class' callout points to the 'Class' field. A 'Method' callout points to the 'Method Name' field. A 'Splitting configuration' callout points to the 'Collect Data From' and 'Operation on Method Parameter' sections. An 'Add' button is visible at the bottom left. Two modal windows are open: 'Add Custom Exit Point Identification' and 'Add Snapshot Data'. The 'Add Custom Exit Point Identification' modal has a 'Display Name' field, a 'Collect Data From' section with radio buttons for 'Method Parameter @ Index: 0', 'Return Value', and 'Invoked Object', and an 'Operation on Method Parameter' section with radio buttons for 'Use toString()' and 'Use Getter Chain'. The 'Use Getter Chain' option is selected, and a text box contains 'getName()'. The 'Add Snapshot Data' modal has a 'Display Name' field with 'insertValue', a 'Collect Data From' section with radio buttons for 'Method Parameter @ Index: 0', 'Return Value', and 'Invoked Object', and an 'Operation on Method Parameter' section with radio buttons for 'Use toString()' and 'Use Getter Chain'. The 'Use toString()' option is selected.

## SAP Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/ Superclass/Annotation Name	Method Name
SAP.Execute	SAP	With a class name that	com.sap.mw.jco.rfc.Middle wareRFC\$Client	execute
SAP.Connect	SAP	With a class name that	com.sap.mw.jco.rfc.Middle wareRFC\$Client	connect
SAP.Disconnect	SAP	With a class name that	com.sap.mw.jco.rfc.Middle wareRFC\$Client	disconnect
SAP.Reset	SAP	With a class name that	com.sap.mw.jco.rfc.Middle wareRFC\$Client	reset
SAP.CreateTID	SAP	With a class name that	com.sap.mw.jco.rfc.Middle wareRFC\$Client	createTID
SAP.ConfirmTID	SAP	With a class name that	com.sap.mw.jco.rfc.Middle wareRFC\$Client	confirmTID

## Example Message Queue Backend Configuration

### Monitor the Server by Ignoring the Queue Name

In JMS example, the application is making calls to a message server that handles several queues. The sample destination names look like this:

- AccountQ
- AccountReplyQ
- AccountRecQ
- AccountDebitQ

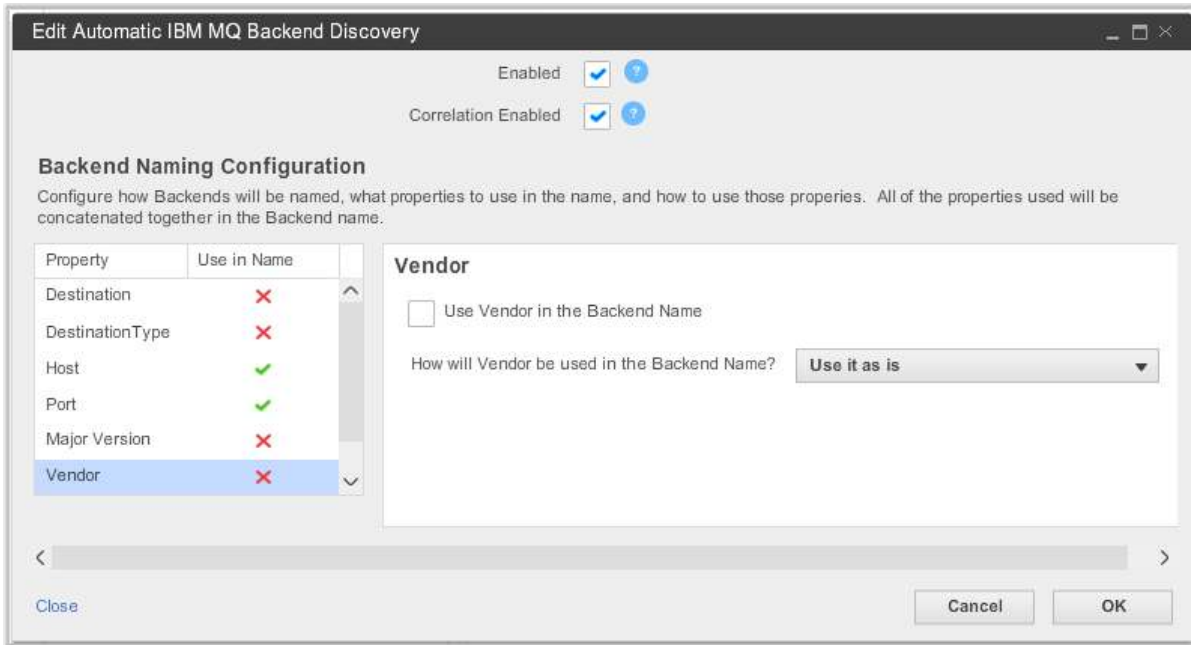

The default automatic discovery rule detects one backend for each unique destination and so the flow map shows one queue backend for each different queue name. In this example, each of the above would show as a separate backend on the application flow map. If you are interested in monitoring the performance of the server and not each queue name, you can modify the configuration to ignore the Destination property and use just the Type and Vendor.

To achieve this result, you create a new custom JMS Discovery Rule.

Taking IBM MQ for another example, the application is making calls to a message server that handles several queues. The sample destination names look like this:

- MQhostwest-US:1521
- MQhosteast-US:1521
- MQhostsouth-US:1521

The default automatic discovery rule detects one backend for each unique destination and so the flow map shows one queue backend for each different queue name. In this example, each of the above would show as a separate backend on the application flow map. If you are interested in monitoring the performance of the server and not each queue name, you can create a discovery rule that just uses the Host and Port, as follows:

## Temporary Queues

In this example an application creates many temporary JMS response queues that are deleted after the message is received. By default, AppDynamics discovers these queues separately and lists each one as a unique remote service. This default behavior probably does not enable effective monitoring. Instead, you can create a custom JMS discovery rule stating that if the destination name contains "TemporaryQueue", list it as "WeblogicTempQueue", or whatever name makes sense in your monitoring environment. In this way, you can monitor the performance that matters. The configuration to accomplish this is shown in the following screen shot:

Create Custom JMS Backend Discovery Rule
\_ □ ×

Name:

Enabled:  ?

Correlation Enabled:  ?

Priority:  ?

**Match Conditions**

Backends that match ALL of the enabled match conditions below will be discovered and named according to the 'Backend Naming Configuration' below. You must configure at least one condition.

<input type="checkbox"/>		Destination	Equals	<input type="text"/>	⚙
<input type="checkbox"/>		DestinationType	Equals	<input type="text"/>	⚙
<input type="checkbox"/>		Vendor	Equals	<input type="text"/>	⚙

**Backend Naming Configuration**

Configure how Backends will be named, what properties to use in the name, and how to use those properties. All of the properties used will be concatenated together in the Backend name.

Property	Use in Name
Destination	<input checked="" type="checkbox"/>
DestinationType	<input checked="" type="checkbox"/>
Vendor	<input checked="" type="checkbox"/>

**Destination**

Use Destination in the Backend Name

How will Destination be used in the Backend Name? Run a Regular Expression on it

Regular Expression:

Regular Expression Groups:  (Comma Separated List of list)

Close
Cancel
OK

## Session ID in the Queue Name

If your JMS queues use the session ID in the destination, this causes each session to be identified as a separate backend. In this case, you might not be interested in seeing each queue separately, and instead want to aggregate everything for the same host and port to the same backend. You can generate the right name and the correct number of backends to monitor by editing the automatic discovery rule. Doing this enables you to monitor the key performance indicators (KPIs) that are of most interest to you.

## Example JDBC Backend Configuration

### Related pages:

- [Java Backend Detection](#)
- [Using Regular Expressions](#)

Depending on exactly what you need to monitor, you may want to change the default JDBC configuration. When you see the same physical database represented as multiple JDBC databases, you may need to [revise the automatic discovery rule](#). Doing this enables you to more effectively monitor the key performance indicators (KPIs) that are of most value to you.

## Multiple Databases from Same Vendor

JDBC connections to the same physical Oracle database (with the same URI) may appear as multiple backends. In some circumstances, the Vendor property captured for the database is different. This can

happen when different drivers are used to access the database. For example, you might see JDBC backends with the following vendor names:

- Oracle DB
- Oracle

If the database driver package name matches the standard Oracle database driver, then the vendor name used is "Oracle DB". If it doesn't match, then the product name from the database metadata (using the `java.sql.DatabaseMetaData` class) is used as a vendor name. So database calls that use different drivers to reach the same physical database may be detected as separate databases. You can fix this by disabling the use of the Vendor property in the discovery rule.

### JDBC with Complex URLs

In this example, the database URL is configured for high availability, so it is quite long and complex. Choosing the **Run a regular expression on it URL** option is the way to go. Disable the use of the Host and Port properties for JDBC automatic discovery. Instead enable the use of the URL that appears in the JDBC call, along with a regular expression to get the correct database naming and discovery.

For example, to extract all the hosts and all the ports from the following URL:

```
jdbc:oracle:thin:@(DESCRIPTION_LIST=(LOAD_BALANCE=OFF)(FAILOVER=ON)
(DESCRIPTION=(ADDRESS_LIST=(LOAD_BALANCE=ON)(ADDRESS=(PROTOCOL=TCP)(HOST=titanpfmcl01)
(PORT=1521)))(CONNECT_DATA=(SERVICE_NAME=trafrefpfm01.global.trafigura.com)))
(DESCRIPTION=(ADDRESS_LIST=(LOAD_BALANCE=ON)(ADDRESS=(PROTOCOL=TCP)(HOST=titanpfmcl02)(PORT =
1521)))(CONNECT_DATA=(SERVICE_NAME=trafrefpfm01.global.trafigura.com)))
```

This sample is for a string that contains the host and service name twice. You can also use port in your regular expression if needed by your requirements.

The following regular expression applied to the previous high availability URL results in a backend name similar to this: `titanpfmcl01-trafrefpfm01.global.trafigura.com-titanpfmcl02-trafrefpfm01.global.trafigura.com`.

```
.*HOST=([\^\\])*.*SERVICE_NAME=([\^\\])*.*HOST=([\^\\])*.*SERVICE_NAME=([\^\\])*.*
```

Note: the expression starts and end with "." Set **Regular Expression Groups** to **1,2,3,4**. Set the **Merge Delimiter** to "-".

This configuration looks like this in the UI:

**Edit Automatic HTTP Backend Discovery**

Enabled  ?

Correlation Enabled  ?

**Backend Naming Configuration**

Configure how Backends will be named, what properties to use in the name, and how to use those properties. All of the properties used will be concatenated together in the Backend name.

Property	Use in Name
Host	<input type="checkbox"/>
Port	<input type="checkbox"/>
URL	<input checked="" type="checkbox"/>
Query String	<input type="checkbox"/>

**URL**

Use URL in the Backend Name

How will URL be used in the Backend Name? **Run a Regular Expression on it**

Regular Expression `.*HOST=([^\s]*)*.SERVICE_NAME=([^\s]*)*.HOST=([^\s]*)*.SERVICE_NAME=([^\s]*)*`

Regular Expression Groups  (Comma Separated List of list)

Merge Delimiter

## EC2 Hosted Databases

AppDynamics automatically discovers JDBC backends based on host, port, URL, database, version and vendor values. To monitor all JDBC databases that contain "EC2" in their host names as a single database, create a JDBC custom discovery rule and use the following match condition: Host Contains "EC2" as shown in the following screen shot.

**Create Custom JDBC Backend Discovery Rule**

Name

Enabled  ?

Correlation Enabled  Correlation is not supported for JDBC Backends. ?

Priority

**Match Conditions**

Backends that match ALL of the enabled match conditions below will be discovered and named according to the 'Backend Naming Configuration' below. You must configure at least one condition.

<input type="checkbox"/>	URL	Equals	<input type="text"/>	<input type="checkbox"/>
<input checked="" type="checkbox"/>	Host	Contains	<input type="text" value="EC2"/>	<input type="checkbox"/>
<input type="checkbox"/>	Port	Equals	<input type="text"/>	<input type="checkbox"/>
<input type="checkbox"/>	Database	Equals	<input type="text"/>	<input type="checkbox"/>
<input type="checkbox"/>	Version	Equals	<input type="text"/>	<input type="checkbox"/>
<input type="checkbox"/>	Vendor	Equals	<input type="text"/>	<input type="checkbox"/>

Assuming host names of the format "EC2-segment2-segment3", use the following naming configuration:

### Backend Naming Configuration

Configure how Backends will be named, what properties to use in the name, and how to use those properties. All of the properties used will be concatenated together in the Backend name.

Property	Use in Name
URL	✗
Host	✔
Port	✗
Database	✗
Version	✗
Vendor	✗

#### Host

Use Host in the Backend Name

How will Host be used in the Backend Name? Use a segment of it

Use the First N Segments: 1 (Number of Segments)

Split Delimiter -

Merge Delimiter

Close
Cancel
OK

This configuration results in a single database icon on the flow map named "EC2".

## Apache Kafka Consumer Backends

You can configure the AppDynamics Java Agent to detect entry points for Apache Kafka consumer activity using `KafkaConsumer.poll()` (introduced in Kafka v0.10) and `Kafka SimpleConsumer.fetch()` (introduced in Kafka v0.9). Prior to version 0.11, the Kafka payload did not include a location to store correlation data, so end-to-end Business Transaction correlation is only possible with the Kafka client and broker  $\geq 0.11$ .

### KafkaConsumer.poll

To instrument Kafka consumer entry points using `KafkaConsumer.poll()`, identify the method in which the consumer reads messages in a loop with a custom interceptor definition. We instrument the iterator's next method to start and end the Business Transaction for each message. There could be many iterators used for iterating messages but we only support iterators of the following types:

- `kafka.consumer.ConsumerIterator`
- `org.apache.kafka.clients.consumer.ConsumerRecords$ConcatenatedIterable$1`

1. Identify the class and method of the loop that processes messages from Kafka. Consider, for example, a class `MyConsumer` that employs the following loop to poll and process messages from Kafka:

```

ConsumerRecords<String, String> records = kafkaConsumer.poll(1000);
pollMessages(records);
private void pollMessages(ConsumerRecords<String, String>records) throws Exception {
 //AppDynamics instrumentation gets applied here
 for (ConsumerRecord<String, String> record : records) {
 //Processing of the records
 System.out.println(record.value());
 }
}

```

For this case, you want to intercept:

- Class: `MyConsumer`
- Method: `pollMessages`

The interceptor can also be applied to a method that processes individual records, not just a loop. For example:

```
ConsumerRecords<String, String> records = kafkaConsumer.poll(1000);
pollMessages(records);
private void pollMessages(ConsumerRecords<String, String>records) throws Exception {
 //AppDynamics instrumentation gets applied here
 for (ConsumerRecord<String, String> record : records) {
 processRecord(record)
 }
}
```

2. Use your preferred text editor to create and edit a file named `custom-interceptors.xml` at the following path:

```
<agent_home>/<version_number>/conf
```

For example:

```
/usr/home/appdynamics/appagent/ver4.3.1.0/conf/custom-interceptors.xml
```

3. Copy the following XML to `custom-interceptors.xml`:

```
<custom-interceptors>
 <custom-interceptor>
 <interceptor-class-name>com.singularity.KafkaMarkerMethodInterceptor</interceptor-
class-name>
 <match-class type="matches-class">
 <name filter-type="equals">my-fully-qualified-class-name</name>
 </match-class>
 <match-method>
 <name>my-method-name</name>
 </match-method>
 </custom-interceptor>
</custom-interceptors>
```

4. Set the value of the class name to the name of your consumer class. For instance, to specify the `MyConsumer` class:

```
<match-class type="matches-class">
 <name filter-type="equals">com.mycompany.mypackage.MyConsumer</name>
</match-class>
```

5. Set the value of the method name to the name of your message processing loop method. For instance, to specify the `pollMessages` method:

```
<match-method>
 <name>pollMessages</name>
</match-method>
```

After the Java Agent reads the updated configuration, it detects consumer activity and upstream Kafka queue. The application flow map shows the tier receiving data from the Kafka queue.

### Kafka SimpleConsumer Entry Points

To enable consumer entry points for Kafka clients that retrieve messages using `SimpleConsumer.fetch()`, register the `enable-kafka-consumer` node property with a value of "true."

**i** Kafka consumer activity shows up as an exit call in this case.

### .NET Backend Detection

The .NET Agent automatically detects many common backend types. Most backend types have a default discovery rule and a set of configurable properties. To revise backend discovery rules, see [Backend Detection Rules](#) and [Exit Point Detection Rules](#).

For all other traffic transactions, see [Business Transactions](#).

### ADO.NET Backends

The .NET Agent automatically discovers ADO.NET data providers implementing standard Microsoft interfaces as database backends. See [.NET Supported Environments](#).

Because the ADO.NET API is interface-based, AppDynamics instruments all ADO.NET database providers that implement these interfaces by default.

AppDynamics uses database identification information from the ADO.NET connection string. The connection string specifies the server address and schema, or the local file name. Most connection strings are formatted based on common rules that you can parse and distill to a database name. However because no standards exist for the connection string, the ADO.NET provider implementer determines the format.

For some providers, AppDynamics may fail to parse the connection string. In these cases, the .NET Agent uses the complete connection string minus any user password. The property is labeled ADO.NET connection string, and the value shows the connection string minus any user password.

For example, the .NET Agent names this database backend using the connection string pattern `<datasource name>-<database name>`

```
.\SQLEXPRESS-HowdyWorldDB
```

### ADO.NET Configurable Properties

You can enable or disable the use of these properties for ADO.NET exit points:

Configurable Properties	Default Detection and Naming Property?	Description
Host	Yes	Data source or database server
Database	Yes	Database name

Configurable Properties	Default Detection and Naming Property?	Description
Vendor	No	Type of client-side ADO.NET library
Connection String	No	Full connection string with password filtered out
Port	No	Port number

### Directory Service Backends

The .NET Agent automatically discovers exit calls to directory services that use the `System.DirectoryServices.Protocols (S.DS.P)` libraries.

The agent names the backend for the server name. If the agent cannot derive the server name from the request, it then constructs a name using Domain Component (DC) values.

For example: `activedirectory.example.com`

### HTTP Backends

AppDynamics automatically detects HTTP exit points (backends). See HTTP Backend Detection.

### .NET Agent for Windows

For the .NET Agent for Windows, the default HTTP automatic discovery rule uses the URL property. From the enabled properties, AppDynamics derives a display name using the URL.

For example: `http://api.example.com:8989/searchfares`

### .NET Agent for Linux

For the .NET Agent for Linux, the default HTTP automatic discovery rule for backends uses the host name and port number.

For example: `http://api.example.com:8989/`

### HTTP Configurable Properties

For both Windows and Linux versions of the .NET Agent, you can enable or disable the use of these properties for HTTP exit points:

Configurable Properties	Default Detection and Naming Property?		Description
	.NET Agent for Windows	.NET Agent for Linux	
Host	No	Yes	HTTP host
Port	No	Yes	HTTP port number
URL	Yes	No	Full URL
Query String	No	Yes	HTTP parameters/query string

### Message Queue Backends

By default, AppDynamics automatically detects and identifies many message queue exit points. For a list of the supported message-oriented middleware products, see [Supported Remote Service Detection for .NET](#).

The default queue automatic discovery rule uses the destination property to name the message queue backend.

For example: `HowdyWorldQueue$\HWT_MQ_Server1_MsgQ`

### Message Queue Configurable Properties

This table lists the properties used for queue exit points. However, each message-oriented product is different and there may be variations in the properties, or their names.

Configurable Properties	Default Detection and Naming Property?	Description
Host	No	Queue server name
Destination	Yes	Name of topic or queue
Destination Type	No	Queue or topic
Vendor	No	Vendor from the client library

For specific queue types, see:

- [MSMQ Backends for .NET](#)
- [NServiceBus Backends for .NET](#)
- [RabbitMQ Backends for .NET](#)

## MongoDB Backends

By default, the .NET Agent detects MongoDB exit calls for create, read, update, and delete (CRUD) operations using the C# and .NET MongoDB Driver versions: 1.10, 2.0, 2.2, and 2.4.

The default MongoDB automatic discovery rule uses the host, port, and database name to name the MongoDB backend.

For example: `mymongohost.27017.mymongodb`

## MongoDB Configurable Properties

You can configure the use of these properties for MongoDB exit points:

Configurable Properties	Default Detection and Naming Property?	Description
Host	Yes	MongoDB host
Port	Yes	MongoDB port
Database	Yes	MongoDB database name

## .NET Remoting

When an application uses .NET remoting, AppDynamics automatically detects and identifies remoting exit points (backends). See [Enable Correlation for .NET Remoting](#) to configure downstream correlation.

The default remoting automatic discovery rule uses the URL property.

For example: `tcp://remoting.example.com:8648/MovieTicketBooking`

## .NET Remoting Configurable Properties

You can configure the use of this property for .NET Remoting exit points:

Configurable Properties	Default Detection and Naming Property?	Description
URL	Yes	Full URL

## WCF Backends

AppDynamics automatically detects and identifies WCF exit points (backends) when an application uses the WCF client library. The default WCF automatic discovery rule uses the remote address property. The agent uses the enabled properties to derive a display name using the remote address.

For example: `http://wcf.example.com:8205/Services/Service1.svc`

## Agent Compatibility

This table describes the WCF backend detection support for each variant of the .NET Agent:

Agent and Version	WCF Backend Detection Support
.NET Agent for Windows (.NET Framework)	Fully supported
.NET Agent for Linux >= 20.7.0	Partially supported <ul style="list-style-type: none"> <li>• Works with .NET Core &gt;= 3.1</li> <li>• Compatible with asynchronous calls over HTTP</li> <li>• Does not support the <code>Operation Contract</code>, <code>Service Contract</code>, and <code>SOAP Action</code> properties.</li> </ul>
.NET Agent for Windows (.NET Core) >= 21.3.0	

### WCF Configurable Properties

You can enable or disable the use of these properties for WCF exit points:

Configurable Properties	Default Detection and Naming Property?	Description
Remote Address	Yes	URL minus the query, fragment, and user information (name and password)
Operation Contract	No	WCF operation contract name
Service Contract	No	WCF service contract name
URL	No	Full URL
Host	No	Host portion of URL
Port	No	Port number if present in the URL; otherwise, protocol default
SOAP Action	No	For web service calls, the SOAP action

### .NET Web Services Backends

When an application uses the Microsoft Web Services client library, AppDynamics automatically detects and identifies web services exit points (backends) by default. The default web services automatic discovery rule uses the URL property. From the enabled properties, AppDynamics derives a display name using the URL.

For example: `http://webservice.example.com:8105/Services/Service1.asmx`

### Web Services Configurable Properties

You can enable or disable the use of these properties for Web Services exit points:

Configurable Properties	Default Detection and Naming Property?	Description
Service	No	Web service name
URL	Yes	Full URL
Operation	No	Web service operation name
Soap Action	No	SOAP action

### Custom Exit Points

To monitor a backend that is not included in [.NET Supported Environments](#), you can [configure a custom exit point](#).

**i** By default, you have to restart the instrumented application for instrumentation changes to take effect. You can [enable Runtime Reinstrumentation](#) for the .NET Agent to avoid having to restart your application and the `AppDynamics.Agent.Coordinator` after instrumentation changes.

### Asynchronous Exit Points for .NET

#### Related pages:

- [.NET Backend Detection](#)
- [Using Asynchronous Methods in ASP.NET 4.5](#)

Asynchronous programming patterns can enhance the scalability and performance of applications. Microsoft .NET lets you designate methods as asynchronous tasks.

The .NET runtime releases resources for asynchronous methods while tasks complete. When task processing finishes, the runtime calls back to the originating asynchronous method so the method may continue processing.

The .NET Agent detects certain asynchronous programming patterns as exit points. Because tasks may execute in parallel, AppDynamics sometimes represents asynchronous activity differently from synchronous activity in the Controller.

AppDynamics differentiates .NET async backend tracking from thread correlation. To configure thread correlation, see [Thread Correlation for .NET](#).

#### Supported Asynchronous Exit Point Patterns

The agent discovers exit points for Microsoft .NET 4.5 `async` and `await` keywords. See [Asynchronous Programming with Async and Await](#).

The agent detects asynchronous exit points for the following backend types:

- ADO.NET

- Azure Blob Storage, Azure File Storage, and Azure Table Storage
- CosmosDB
- HTTP
- MongoDB
- WCF
- Web Service

Flow maps in the Controller UI represent asynchronous exit points as dotted lines labeled "async". Because calls in an asynchronous transaction may execute simultaneously, the Controller doesn't display end-to-end percentage times for individual asynchronous calls.

## Troubleshoot Asynchronous Calls in Transaction Snapshots

Transaction snapshots include several features to help you discover problem areas in business transactions that use asynchronous methods. For an overview of transaction snapshots, see [Troubleshoot Business Transaction Performance with Transaction Snapshots](#).

### Transaction Snapshot Flow Map

The Transaction Snapshot Flow Map graphically represents the business transaction. It displays the user experience, execution time, and timestamp of the transaction. The flow map also provides details of the overall time that is spent in a particular tier and in database and remote service calls. The *async* label indicates asynchronous calls.

### Snapshot Execution Waterfall View

The transaction Snapshot Execution Waterfall View shows a timeline representation of the end-to-end execution of the business transaction. Synchronous and asynchronous processes appear on a bar diagram illustrating their relative execution time arranged in chronological order. Synchronous calls are represented by solid line arrows, and asynchronous calls are represented by dotted line arrows.

The waterfall view enables you to visually identify which processes are running the longest. Double-click a bar to drill down to a call graph and investigate problematic code.

### Analyze Asynchronous Activity in the Metric Browser

The Metric Browser displays asynchronous activity in the following places:

- **Business Transaction Performance > Business Transactions > tier > business transaction > Thread Tasks > Asynchronous Operation > External Calls**
- **Overall Application Performance > tier > Thread Tasks > Asynchronous Operation > External Calls**
- **Overall Application Performance > tier > Individual Nodes > node name > Thread Tasks > Asynchronous Operation > External Calls**

## MSMQ Backends for .NET

### Related pages:

- [.NET Backend Detection](#)
- [App Agent Node Properties](#)

The AppDynamics .NET Agent (agent) automatically detects MSMQ backends when an instrumented tier makes a call to MSMQ. MSMQ exit points are methods that publish or push messages to a queue. If you are using NServiceBus over the MSMQ transport, see [NServiceBus Backends for .NET](#).

MSMQ entry points are methods that listen or poll for new messages in the queue. Before the agent can detect entry points or perform downstream correlation for MSMQ you must define the correlation field and, for multithreaded architectures, specify threading architecture.

## Exit Points and Backend Naming

The agent names the queue for the queue name returned from the system.

## Entry Points

To enable downstream correlation for MSMQ, you must configure the agent.

### Define the MSMQ Correlation Field

Register the *msmq-correlation-field* app agent node property on both the publishing tier and on the receiving tier. Specify the field where the agent will write and read correlation information.

The agent supports the following fields:

- Extension, the default field
- Label

By default, the .NET Agent writes to the Extension field. However, some frameworks built on MSMQ write data to the Extension field. In this case, the Extension field does not work because it is already in use, so you must configure the .NET Agent to write correlation data to the Label field.

**i** Choose a field not in use by your queue implementation. If your implementation uses both the "Label" and "Extension" fields, downstream correlation is not currently possible.

See "msmq-correlation-field" on [App Agent Node Properties Reference](#). For instructions to register a node property, see [App Agent Node Properties](#).

### Specify the threading architecture

If your queue implementation uses a multithreaded architecture, you must register the *msmq-single-threaded* app agent node property to specify the threading architecture. Set *msmq-single-threaded* to "False" for multithreaded implementations of MSMQ. See "msmq-single-threaded" on [App Agent Node Properties Reference](#). For instructions to register a node property, see [App Agent Node Properties](#).

The threading architecture dictates how the agent calculates the call timing for the message queue:

- For single-threaded queues, the agent calculates the call time between receive requests. The call time begins at the end of the first receive method and ends when the next receive method starts.  
In the following example, the length of the `ProcessMessage()` method:

```
MessageQueue messageQueue;
for(;;)
{
 var message = messageQueue.Receive();
 ProcessMessage(message);
}
```

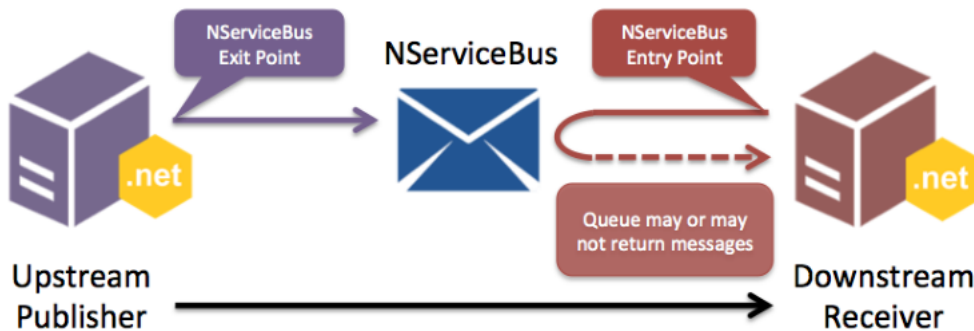

- For multithreaded queues, the agent does not capture timing.

## NServiceBus Backends for .NET

### Related pages:

- [.NET Backend Detection](#)

The AppDynamics .NET Agent automatically discovers exit points to NServiceBus backends when an instrumented tier makes a call to NServiceBus over MSMQ or RabbitMQ transports. The agent discovers NServiceBus entry points for downstream correlation from NServiceBus version 5. AppDynamics supports NServiceBus version 5 and versions that are backward compatible with version 5.

### Exit Points and Backend Naming

NServiceBus exit points are methods that publish or push messages to a queue from an upstream tier. The agent detects exit points regardless of the NServiceBus version or threading architecture. The agent names the queue for the queue name returned from the system.

### Entry Points in a Single-threaded Architecture

NServiceBus entry points are methods that listen or poll for new messages in the queue. When the message receiver uses a single-threaded architecture, the .NET Agent automatically discovers entry points and correlates downstream activity without additional configuration.

The agent measures the call time from the end of the first receive method to the start of the subsequent receive method. In the following example loop, the length of the `ProcessMessage()` method:

```
MessageQueue messageQueue;
for(;;)
{
 // Call timing for previous iteration ends.
 var message = messageQueue.Receive();
 // Call timing begins.
 ProcessMessage(message);
}
```

### Entry Points in a Multithreaded Architecture

For the .NET Agent to automatically detect NServiceBus entry points when the receiver is running a multithreaded architecture, set the `nservicebus-single-threaded` app agent node property to "false" on the

receiver. See "nservicebus-single-threaded" on [App Agent Node Properties Reference](#). For instructions to register a node property, see [App Agent Node Properties](#).

For multi-threaded message receivers, the agent does not capture timing.

## Resolve Issues with NServiceBus Backends

- If you have NServiceBus version 5 and are not seeing downstream correlation on the receiver, verify the threading architecture on the receiver. Set the *nservicebus-single-threaded* app agent node property to "false" on the multithreaded receivers.
- Only use the node properties for MSMQ, *msmq-single-threaded* and *msmq-correlation-field*, if you are using MSMQ independently of NServiceBus. The .NET Agent does not use MSMQ node properties when discovering and instrumenting NServiceBus over MSMQ transport.
- If you are using NServiceBus version 4, you can disable NServiceBus instrumentation on both the publisher and the receiver:
  - Copy the following Instrumentation element to a child of the Machine Agent element:

```
<!--Disable NServiceBus instrumentation-->
 <instrumentation>
 <instrumentor name="NServiceBusReceiveContextInstrumentor"
enabled="false" />
 <instrumentor name="NServiceBusPublishExitInstrumentor"
enabled="false" />
 <instrumentor name="NServiceBusEntryInstrumentor" enabled="false" /
>
 <instrumentor name="NServiceBusExitInstrumentor" enabled="false" />
 </instrumentation>
```

For more information, see "Instrumentation Element" on [.NET Agent Configuration Properties](#).

- Configure the publisher and receiver as you would for [MSMQ](#) or [RabbitMQ](#).

## RabbitMQ Backends for .NET

### Related pages:

- [.NET Backend Detection](#)
- [RabbitMQ Monitoring Extension](#)

The AppDynamics .NET Agent automatically detects RabbitMQ backends based upon calls from instrumented tiers. RabbitMQ exit points are methods that publish or push messages to a queue. RabbitMQ entry points are methods that listen or poll for new messages in the queue.

 .NET extends support for `BasicPublish` and `BasicConsume` in the RabbitMQ client `>= 6.0.0`.

If you are using NServiceBus over the RabbitMQ transport, see [NServiceBus Backends for .NET](#).

## Exit Points and Backend Naming

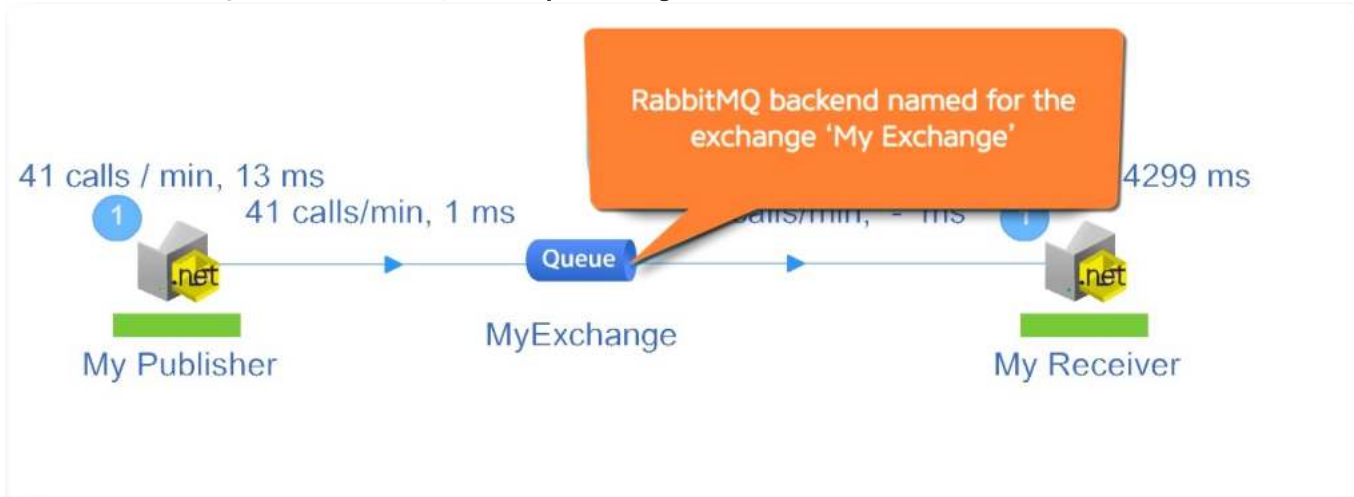

The agent discovers a RabbitMQ backend exit point when your application sends a message to the queue using the `BasicPublish()` method.

By default, the agent names the RabbitMQ backend for the exchange parameter of the `BasicPublish()` method.

For example:

```
model.BasicPublish("MyExchange", "", false, false,
 basicProperties, Encoding.UTF8.GetBytes(message));
```

In this case the agent names the queue **MyExchange**.

You can refine the backend name to include some or all segments of the routing key. To configure RabbitMQ naming you must be familiar with your implementation RabbitMQ exchanges and routing keys. See [RabbitMQ Exchanges and Exchange Types](#).

Refine backend naming

Register the *rmqsegments* node property. For instructions on how to set a node property, see [App Agent Node Properties](#).

Name: *rmqsegments*

Description: "Configure RabbitMQ naming to include routing key segments."

Type: Integer

Value: <integer>

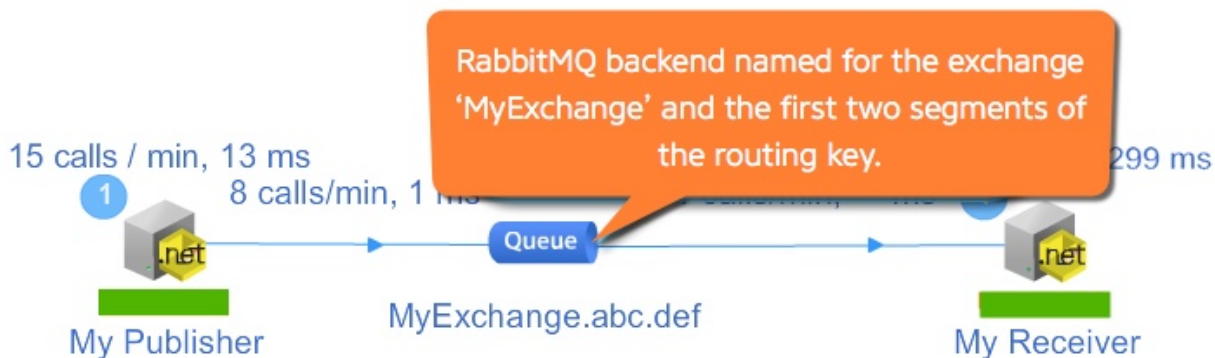

The routing key is a string. The agent treats dot-separated (".") substrings of the routing key as segments. Set the value to an integer that represents the number of routing key segments to include in the name.

In the following example the routing key is "abc.def.ghi". Set the *rmqsegments* value to "2" to name the queue "MyExchange.abc.def".

```
model.BasicPublish("MyExchange", "abc.def.ghi", false, false,
 basicProperties, Encoding.UTF8.GetBytes(message));
```

After you save the node property, the Controller sends the configuration to the agent. After some time the RabbitMQ backend shows up with the new name.

### Entry Points

The agent discovers RabbitMQ backend entry point when your application polls the queue. AppDynamics auto-detects RabbitMQ based upon the following patterns:

- [BasicGet](#)
- [HandleBasicDeliver](#)

### BasicGet Method

The agent detects the pattern below where the application periodically polls the message queue using the `BasicGet()` method. The call timing is limited to the time spent inside the `while` loop. The timer only starts when the `BasicGet` result returns a value at line 4. The timer ends when the next `BasicGet` executes. In this example, the application polls every five seconds, so the execution time equals the time in the `if` loop plus five seconds.

RabbitMQ Client before version 6.x:

```

1 while (true)
2 {
3 var result = channel.BasicGet("MyExchange", true);
4 if (result != null)
5 {
6 var body = result.Body;
7 var message = Encoding.UTF8.GetString(body);
8 Console.WriteLine("Received: {0}.", message);
9 }
10
11 Thread.Sleep(5000);
12 }

```

RabbitMQ Client version 6.x:

```

1 while (true)
2 {
3 var result = channel.BasicGet("MyExchange", true);
4 if (result != null)

```

```

5 {
6 var body = result.Body.ToArray()
7 var message = Encoding.UTF8.GetString(body);
8 Console.WriteLine("Received: {0}.", message);
9 }
10
11 Thread.Sleep(5000);
12 }
```

### HandleBasicDeliver Method

The agent detects the `HandleBasicDeliver()` method for custom implementations of the `IBasicConsumer` interface. In this case, the call timing reflects the execution time for the `HandleBasicDeliver` method.

### Correlation Over Microsoft BizTalk

When you install the .NET Agent on a Microsoft BizTalk Server, the agent automatically discovers BizTalk entry points and exit points so you can monitor your BizTalk integration.

### Requirements

- Microsoft BizTalk 2010, 2013
- BizTalk must be a downstream tier from an originating tier for a business transaction. The agent doesn't discover BizTalk as the originating tier of a transaction.

### Entry Points

The .NET Agent detects incoming BizTalk requests using the WCF Send Adapter or the SOAP Send Adapter.

### Instrument the BizTalk Service

1. Install the .NET Agent on the BizTalk server. See [Install the .NET Agent for Windows](#).
2. Register the "enable-soap-header-correlation" app agent node property with a value of "true" for the nodes upstream from the BizTalk tier. See [App Agent Node Properties](#).
3. Instrument the BizTalk service executables: `BTSNTSvc.exe` and `BTSNTSvc64.exe`. See [Configure the .NET Agent for Windows Services and Standalone Applications](#). For instance:

```

<standalone-applications>
 <standalone-application executable="BTSNTSvc">
 <tier name="BizTalk Service"/>
 </standalone-application>
</standalone-applications>
```

If you run multiple instances of BizTalk on the same Windows server, you can assign the different instances to unique nodes using command line options. For example, to differentiate nodes within the same tier, specify the BizTalk Service command "name" parameter in the standalone application `command-line` attribute:

```

<standalone-applications>
 <standalone-application executable="BTSNTSvc" command-
line="-name "BizTalk1"">
 <tier name="BizTalk Service"/>
 <node name="BizTalk1"/>
 </standalone-application>
 <standalone-application executable="BTSNTSvc" command-
line="-name "BizTalk2"">
 <tier name="BizTalk Service"/>
 <node name="BizTalk2"/>
 </standalone-application>
</standalone-applications>

```

Notice the use of quotes to enclose the name command-line parameter.

4. Optionally enable BizTalk performance counters. For more information, see [Manage Windows Performance Metrics](#). Refer to the Microsoft BizTalk Server documentation for descriptions of individual performance counters.

```

<machine-agent>
 <!-- BizTalk Performance Counters -->
 <perf-counters>
 <perf-counter cat="BizTalk:Message Agent" name="High
database session" instance="*"/>
 <perf-counter cat="BizTalk:Message Agent" name="High
database size" instance="*"/>
 <perf-counter cat="BizTalk:Message Agent" name="High in-
process message count" instance="*"/>
 <perf-counter cat="BizTalk:Message Agent" name="High
message delivery rate" instance="*"/>
 <perf-counter cat="BizTalk:Message Agent" name="High

 </perf-counters>
</machine-agent>

```

Once you've completed instrumentation, the .NET Agent correlates traffic through your BizTalk server:

If you enabled Performance Counter metrics, they appear under the Custom Metrics tree in the Metric Browser.

### Apache Web Server Backend Detection

The Apache Agent discovers Apache Modules as backends. To review general information about monitoring backends, see [Backend Detection Rules](#).

### Apache Modules

The Apache Agent automatically detects loaded Apache modules as remote services:

- Modules must be in the handler stage.
- The agent excludes a list of common modules from discovery, see "Remote Service Detection" on [Supported Apache Web Servers](#).

By default, the Apache Agent includes metrics for module backends with the downstream backend or tier. The Controller doesn't display the module on flow maps. For example, if Apache calls `mod_jk.c`, the module backend doesn't show on flow maps and metrics are included with the downstream Tomcat backend or tier.

To view Apache modules on the flow map and to see separate metrics for Apache modules, set `AppDynamicsResolveBackends` to "OFF" in the `appdynamics_agent.conf` file. See [Install the Apache Agent](#).

The agent names the Apache modules backend for the module name and the server: `<module>-<host>:<port>`. For example, `mod_jk.c-myapache.example.com:80`.

Previously, the backend name for requests routed through the reverse proxy was `mod_proxy.c-<ip and port of server >`. It is now resolved to the actual URL where the request is transferred to.

To add end segments that are displayed in the backend naming, set `AppDynamicsBackendNameSegments` with the required end segments. See [Install the Apache Agent](#).

---

## HTTP Backend Detection

### Related pages:

- [Java Backend Detection](#)
- [.NET Backend Detection](#)

AppDynamics automatically detects HTTP backends when outbound calls are made through supported HTTP clients, and by default names them according to their host and port. If the default configuration results in names that are not meaningful for your application (such as EC2 host names, file paths, and ports in the name) you can change the default discovery rule.

Additionally, if an HTTP call is destined for an http router which could route the request to one of several instrumented downstream tiers then the default naming rules will need to be modified such that the name includes enough segments of the target URL such that each destination tier is associated with a differently named backend.

### HTTP Backend Naming

To ensure that the HTTP backends detected in your application have meaningful names, and that Business Transaction correlation functions correctly, your custom configuration will need to take into account the specific format used in your environment.

The format can vary even within a single environment. For example, some backend systems may have hostnames prefixed with `ec2storage`, which may not be meaningful in naming, while others may use hostnames such as `salesforce.com`, which may be meaningful.

To account for different formats, you should create a custom rule rather than changing the automatic discovery rule. This lets you apply different rules for different URL formats.

You can then apply a specialized approach for each case, as in the following examples:

- For format `"ec2storage/servicename"`, you would use the URL
- For format `"salesforce.com"`, use the host name
- For the other backends, you may use a query string
- For calls that could hit one of several downstream tiers via an HTTP router, you should use sufficient segments of the target URL in the name such that each downstream tier that could process the request is associated with a differently named backend

In some cases, your HTTP backend discovery configuration might consist of a combination of the default rule and custom rules. The following section walks you through a specific example:

### Use the URL Path in a Detection Rule

For example, when all the HTTP backends for a tier or application have a similar format, such as a prefix like `"ec2storage"`, you can generate the right name and the correct number of backends to monitor by editing the automatic discovery rule. This enables you to monitor the KPIs that are interested in.

Consider an application with the following HTTP URLs:

```
http://ec2-17:5400/service1
http://ec2-17:5450/service2
http://ec2-18:5400/service1
http://ec2-18:5450/service2
```

In this case, measuring performance based on host name would not be useful, since the IP addresses are transient and all performance numbers would be irrelevant after the IP addresses recycle. Instead, you can

monitor by service name by avoiding the use of Host and Port properties and using only the URL property, as follows:

1. Edit the **Automatic Backend Discovery** rule for HTTP for your agent type. See [Backend Detection Rules](#) for details on accessing this pane.
2. First, select and disable the use of **Host** and **Port**.
3. Then select and enable the property you want to use to uniquely identify the backend. In this case, select **URL** and check **Use URL in the Backend Name**.
4. For the field **How will URL be used in the Backend name?**, select **Use a segment of it**.
5. From the segment options dropdown, select **Use the first N Segments**.  
The important URL segment is for the "create" service, so your configuration is the same as in the previous screenshot.
6. Enter "/" slash for the **Split Delimiter**.  
Use a similar technique to strip out some segment of the URL, such as a user name as in the following URLs:  
[http://host:34/create/username1]  
[http://host:34/create/username2]
7. Once you change the configuration, delete all HTTP backends. When the agent rediscovers the backends with the new configuration, the flow map shows only the service backends.

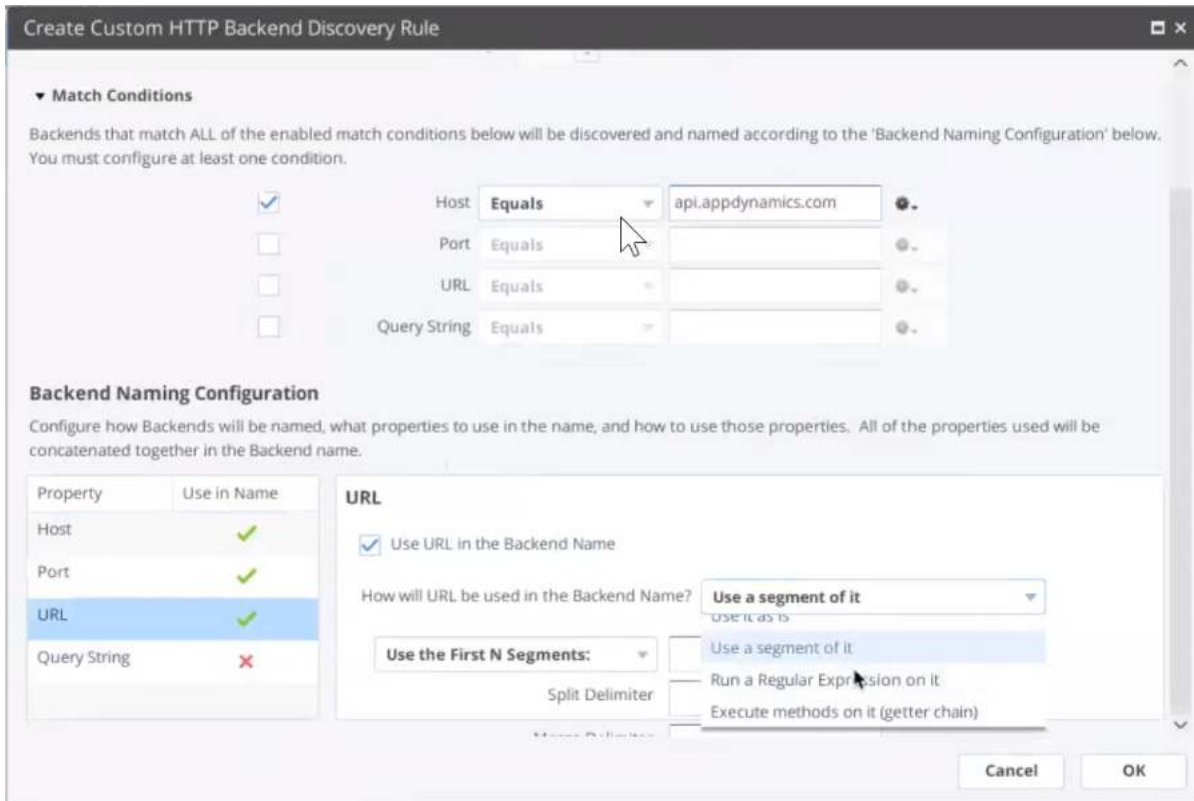

### Custom HTTP Backend Detection and Naming Configuration

**i** You can now customize HTTP backend detection and naming for the .NET Agent for Linux through the Controller UI.

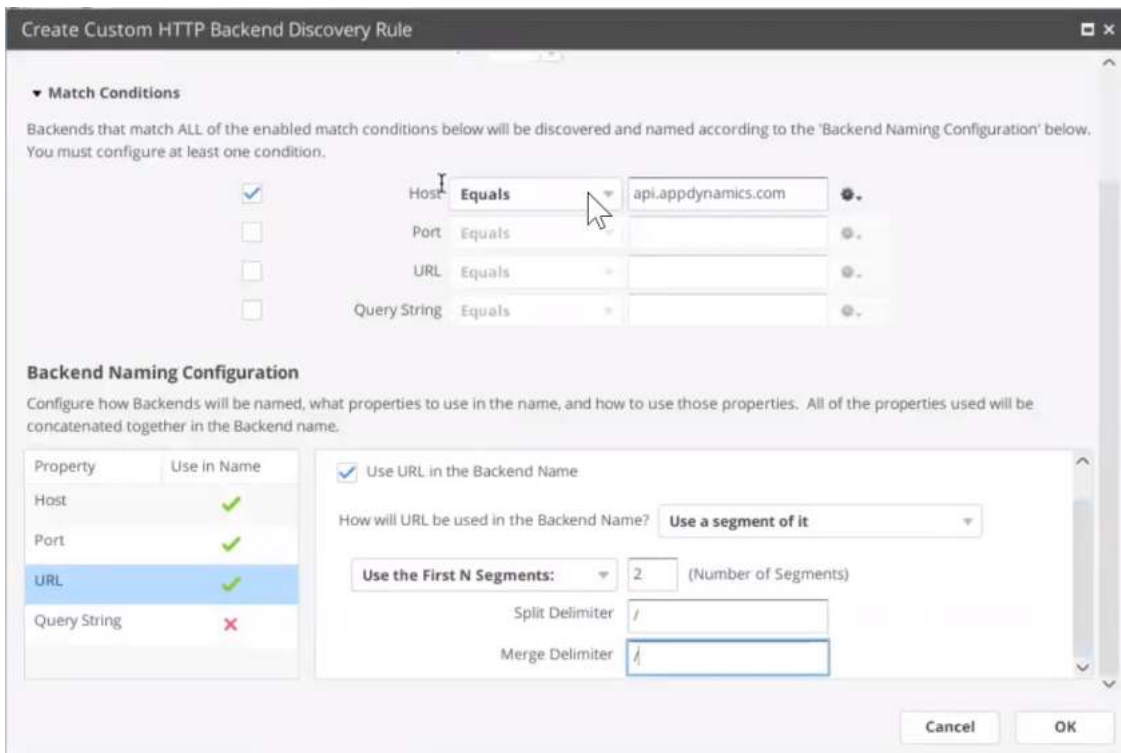

By default, AppDynamics uses the host name and port number to detect and name HTTP backends. This may be suitable in many cases, however, when your microservices, containers or serverlets are managed by an API gateway or portal, backend services communicating with a client or with each other cannot be correctly mapped to the proper tiers unless you edit automatic discovery to use a portion of the query string or use HTTP custom discovery rules to uniquely name them. AppDynamics recommends you create a custom HTTP backend discovery rule in this case.

The following screenshots provide an example configuration.

Here we choose Match Conditions to describe the API gateway host, in this case, [api.appdynamics.com](https://api.appdynamics.com).

This screenshot shows where we choose to use the First 3 segments, using '/' as both the split and merge delimiters.

Configuring the HTTP Backend Discovery Rule as above detects backend metrics and reports them under a business transaction name that begins with [api.appdynamics.com](https://api.appdynamics.com) followed by the first three segments of the URL of the transaction, such as [api.appdynamics.com/api/catalog](https://api.appdynamics.com/api/catalog) or [api.appdynamics.com/api/payment](https://api.appdynamics.com/api/payment). Transactions matching the configured HTTP discovery rule are recognized as individual backends even when they share the same host name and port number. These transactions can be mapped to different tiers so you can analyze the metrics of the transactions that occur behind the API gateway.

There is a known issue in HTTP backend detection configuration in the current preview. When defining HTTP backend using URL segments, segment enumeration starts with number 2 instead of number 1, and segment 1 always returns empty. For example, to define unique backends using the first two segments of the URL, you would need to configure HTTP backend detection to use the first 3 segments or segment 2 and 3.

## Error Detection

You can customize how AppDynamics associates code events with business transaction errors by adding or removing the methods, log messages, HTTP codes, or redirect pages that are configured to indicate business transaction errors.

### Permissions

To configure error detection, you need the "Configure Error Detection" permission.

### Error Detection Configuration

You can view or modify error detection configuration in the Error Detection tab. In the Controller UI, open an application and navigate to **Configuration > Instrumentation > Error Detection**.

The Error Detection tab takes you to the configurable options for each programming language or platform. You configure settings individually for each language or platform. Some settings are platform-specific. For example, custom loggers and error detection using redirect pages are available for Java and .NET only. Configuration changes made in the Error Detection tab apply to all business transactions for the selected application. You cannot make changes to individual transactions.

To prevent marking transactions as errors, uncheck the **Mark Business Transaction as error** for each applicable language or platform. If unchecked, the transactions are not added to the error count metric and are considered in other metrics, such as response time, despite the occurrence of the error.

The checkboxes for NLog and Log4Net are checked by default, no additional configurations are needed.

▼ Define where AppDynamics will look for log messages or exceptions to detect errors

- Detect errors logged using NLog
- Detect errors logged using Log4Net
- Disable System Trace
- Disable Event Log
- Detect errors by looking at messages logged with ERROR or higher severity
- Mark Business Transaction as error

### Supplement Error Detection

For Java and .NET, you can supplement the methods that AppDynamics considers error methods from common error handling frameworks with your own, custom-defined error methods by defining a custom logger. When the application invokes the method in a business transaction, AppDynamics considers the transaction to be an error transaction for metric purposes.

In the custom logger configuration, you can specify the parameter that contains the exception or error information passed to the method. This information will appear as the error message in AppDynamics, which invokes `toString()` on the parameter to extract the message.

To configure a custom logger:

1. In the Controller UI, on the Error Detection configuration tab, click **Add Custom Logger Definition** in the error configuration panel.
2. Enter a descriptive name for the custom logger definition and use the settings to identify the class name and method for the custom logger. For more information on how to use the AppDynamics UI to identify classes and methods, see [Data Collectors](#).
3. For the **Method Parameter** field, add a parameter definition for each parameter in the signature of the method.  
If the method is overloaded, create a logger definition for each form of the overloaded method where you want to detect errors. Your custom method must accept at least one parameter, which should be the parameter that conveys the logged error or exception information.
4. For the **Exception Parameter** field, identify the parameter in the method signature that contains the exception object by index number (0-based).  
This parameter, identified by an index, can be any type of object, including Arrays. If the object is not null, AppDynamics converts the object to a string, the result of which constitutes the error details. A business transaction is considered to be an error only if a non-null exception object is passed to the logger method.

Consider the following custom logger class and methods in a .NET application:

- Namespace and class = `Logging.MyLogger`
- `logger.Error(string message, int param1)`
- `logger.Error(string message, int param1, int param2)`

Notice that the Error method is overloaded. To capture errors logged in the second form of the method using the first parameter as the error to log. This screenshot illustrates the configuration:

**Custom Logger Definition**

A custom logger definition needs the method signature with the fully qualified class/interface/super-class/annotation name and the method name. If the method is overloaded, it is recommended that you also specify the fully qualified parameter types.

Name:

Enabled:

**Define the Class and Method Signature**

Class:  equals

Method Name:

Method Parameters:

Param Index 0	<input type="text" value="System.String"/>	<input type="text"/>	<input type="text"/>
Param Index 1	<input type="text" value="System.Int32"/>	<input type="text"/>	<input type="text"/>
Param Index 2	<input type="text" value="System.Int32"/>	<input type="text"/>	<input type="text"/>

**Specify the parameter index for the exception object**

Exception Parameter:

Notice that the exception parameter is set to 0, identifying the `string message` method parameter as the error message. When enabled, AppDynamics detects and reports the custom logger.

### Detect HTTP Responses or Redirect Pages as Errors

In Java, .NET, Node.js, and Python you can configure errors based on HTTP response codes. If the error code is set as part of business transaction processing, the transaction is marked as an error. For PHP, it is possible to classify transactions as in error based on 4xx HTTP return codes using the [PHP Agent Configuration Settings](#).

By default, AppDynamics captures HTTP error codes from 400 to 505. HTTP response codes may convey errors that occur at the business level of an application. For example, in an e-commerce application, a 522 error might indicate that an item is out of stock. For this case, you may want to include the error as a default transaction error indicator.

To exclude a return code add them to the error detection list by creating a custom error code range and then disabling that error code by clearing its **Enabled** checkbox. This in effect excludes the error code as an error indicator.

**Error Detection Using HTTP Return Codes**

**Detect Errors based on HTTP Return Codes** ?

To identify certain HTTP error code(s) as errors and define them as custom error types, add a code or a range of codes against a custom error name. This name would be used in the application error list, and these codes will be used to identify errors in Business Transactions.

Description	Lower Bound (inclusive)	Upper Bound (inclusive)	Enabled
InventoryEmpty Error	522	522	<input checked="" type="checkbox"/>
Do Not Report Error Code	512	520	<input type="checkbox"/>

**Add Code**   **Delete**

For Java and .NET agents, you can specify custom redirect target error pages as error indicators. To specify a redirect page, click **Add Error Redirect Page** and add a name for the configuration and a regular expression to match the URL of the page, such as `AcmeErrorPage.jsp`.

### Ignore Exceptions and Log Messages as Error Indicators

Certain types of exceptions, loggers or log messages as transaction error indicators may not reflect events that should be counted as transaction errors in your environment. They may include exceptions raised by application framework code or by user login failures.

When you configure an exception to be ignored, the agent detects the exception, increments the exception count, and displays the exception in Exceptions lists in the UI, but the business transaction in which the error is thrown is not considered an "error transaction" for monitoring purposes. The transaction snapshot would not show the exception in the Summary or Error Details section and the user experience for the transaction instance would be unaffected by the exception.

To configure exceptions for the agent to ignore, click the **Add New Exception to Ignore** button in the error configuration window.

Enter the name of the exception to be ignored. The name must be the same as the name displayed in **Name** column given in **Troubleshoot > Errors > Exceptions**. For example, in the screenshot below, you would enter **IOException** to ignore this exception.

The screenshot shows the 'Errors' section in the AppDynamics interface. It includes a sidebar with navigation options like 'Application Dashboard', 'Business Transactions', and 'Errors'. The main content area displays 'Error Transactions' and 'Exceptions'. A line graph shows 'Exceptions' over time, with a peak at 6:15 PM. Below the graph is a table of exceptions:

Name	Summary	Exception
IOException	java.io.IOException	
AppdynamicsDemoException	com.acme.lambda.demo.AppdynamicsDemoException Resource Access Err...	
AppdynamicsDemoException	com.acme.lambda.demo.AppdynamicsDemoException Resource Access Err...	
AppdynamicsDemoException	com.acme.lambda.demo.AppdynamicsDemoException Resource Access Err...	
AppdynamicsDemoException	com.acme.lambda.demo.AppdynamicsDemoException Resource Access Err...	

**i** The text field for **Match Condition for Exception Message** cannot contain the characters " , < , > , and & .

The following example directs the agent to ignore `java.lang.RuntimeExceptions` that wrap a `javax.sql.SQLException` only when the `exception.getMessage()` call in the root exception contains the string "format". (Other types of `java.lang.Runtime` exceptions will not be ignored.)

**Configure an Exception to Ignore when Detecting Errors** ✕

**Exception, or Exception Chain**

Enter fully qualified Class Names for Exceptions separated by :

 ?

**Match Condition for Exception Message**

This condition will be used to match against `exception.getMessage()`. If it matches, for the exception configured above, the exception will not be detected as an Error

Exception Message Contains  ⚙️

---

When you define the class of an exception to ignore by an exception chain, the exception message against which the match condition is applied must be in the root exception of the chain. The match is not applied to any nested exceptions.

In .NET and Java, you can specify that errors logged with certain loggers or logger categories be ignored. Click **Add New Category/Logger to Ignore**.

### Error Detection Notes by Platform

The following sections list error detection configuration and error monitoring considerations, if any, by application platform.

#### Error Configuration for .NET

By default, the Windows .NET Agents can instrument calls using NLog and Log4Net. They can also gather information from System Trace and the Event Log. Beginning with Agents  $\geq 4.5.19$  on Linux, and  $\geq 21.2.0$  on Windows, Agents running on .NET Core can also instrument calls using loggers that implement the Microsoft.Extensions.Logging.ILogger API. To instrument calls using other loggers, add a custom logger definition. See [Supplement Error Detection](#).

Messages logged as higher than ERROR include severe levels such as CRITICAL or FATAL.

If you do *not* want system trace or event log errors to be monitored, disable them by checking the appropriate box. System trace errors are anything written as an error message to the Listeners collection via TraceError.

Event log errors are anything written to the EventLog when the type is set to error. For example:

```
myEventLog.WriteEntry(myMessage, EventLogEntryType.Error, myID);
```

#### Error Configuration for PHP

The PHP Agent instruments the PHP reporting facility. PHP applications can use trigger\_error to report errors through that facility. PHP extensions and PHP itself can also use the PHP facility for reporting errors.

By default, the agent can check for PHP errors using multiple thresholds:

- If you select Error, the agent reports only messages and exceptions marked Error.
- If you select Warning, the agent reports only messages and exceptions marked Error and Warning.
- If you select Notice, the agent reports messages and exceptions marked Error, Warning and Notice.

#### Error Configuration for Node.js

The Node.js Agent reports exceptions thrown by the Node.js application or by Node.js itself.

You can configure certain exceptions or logged messages not to cause transactions to be reported as errors using the 'Ignored Exceptions' and 'Ignored Messages' lists. See [Ignoring Exceptions and Log Messages as Error Indicators](#).

#### Error Configuration for Python Notes

By default, the Python Agent reports error transactions for unhandled exceptions, HTTP status codes greater than or equal to 400, and messages logged at ERROR or higher by the Python logging module.

---

If you do not want any logged errors to cause transactions to be reported as errors, clear the "Mark Business Transaction as error" checkbox. If you do not want to capture logged messages at all, clear the "Detect Errors" checkbox.

You can configure certain exceptions or logged messages not to cause transactions to be reported as errors using the 'Ignored Exceptions' and 'Ignored Messages' lists. See [Ignoring Exceptions and Log Messages as Error Indicators](#).

## Service Endpoint Detection

AppDynamics automatically detects [service endpoints](#) for Java applications. You can configure custom service endpoints for Java or .NET to monitor the performance of services.

You can also configure exclude rules for service endpoints, which prevent agents from registering service endpoints for methods that match the exclude rules. The order of precedence for match, exclude and automatic rules are:

1. Exclude rules
2. Custom service endpoint rules
3. Automatic discovery

### Permissions

To configure service endpoints your user account must have the Configure Service Endpoints permission for the business application. For information on AppDynamics Role Based Access Control, see [Application Permissions](#).

### Configure Custom Service Endpoints

You configure custom service endpoints like you configure custom match rules for business transactions:

1. From the **Service Endpoints** pane, click **Configure**.
2. Click the Custom Service Endpoint tab.
3. Choose the tier on which the service runs and click the plus icon to add a service endpoint configuration. The configuration settings are similar to business transaction entry point configuration settings. See [Custom Match Rules](#).

As you choose a method for a service endpoint, avoid methods that occur within the following programming patterns:

- High-frequency loops, such as a for or while loop.
- Recursive functions.

Service endpoints inside such structures may cause performance overhead. Instead, consider adding a service endpoint at a point in the code upstream from a high-frequency loop or recursive function.

Configure service endpoint exclude rules in the same pane as the custom service endpoints. Click **Is Exclude Rule** on the **New Service Endpoint Definition** pane.

### Automatic Discovery for Java

The Java Agent automatically discovers service endpoints. To configure service endpoint automatic detection settings, click to **Configure** on the **Service Endpoints** pane. You can configure the following settings:

- For existing service endpoint detection rules, you can enable or disable the detection rule.

- For servlet service endpoints, you can modify automatic naming as you would with servlet business transactions.

**i** The maximum limit for naming the service endpoints through automatic discovery is 99 characters.

## POJO Service Endpoints

For the Java Agent to detect Plain Old Java Objects (POJO) service endpoints, you must do the following:

- Create at least one POJO custom service endpoint definition and enable it. The agent only detects POJO service endpoints for enabled custom service endpoint definitions.
- Verify automatic discovery for POJO service endpoints is enabled. It is enabled by default.

**i** When you disable automatic discovery for POJO service endpoints, the agent doesn't detect custom service endpoints.

## Asynchronous Worker Thread Service Endpoints

The Java Agent automatically detects asynchronous worker threads spawned within a transaction as service endpoints. The agent names worker thread service endpoints for the class name, for example, "worker1". There is no end-to-end latency metric for worker thread service endpoints.

To disable worker thread service endpoints, register the `enable-async-service-endpoints` app agent node property with a value of "false". See [App Agent Node Properties](#).

## Configure Service Endpoints for .NET

The .NET Agent doesn't automatically discover service endpoints. To define a custom service endpoint for .NET, navigate to **Configuration > Instrumentation > Service Endpoints > Custom Service Endpoints**. Define the service endpoint as you would a custom match rule for a business transaction. See [Service Endpoints](#) and [Transaction Detection Rules](#).

You can create service endpoints for the following entry point types:

- ASP.NET
- Message Queues
- POCO
- WCF
- Web Service

**i** The .NET Agent doesn't support service endpoints for MSMQ.

By default, you need to restart the instrumented application for instrumentation changes such as adding a POCO service endpoint to take effect. You can [enable Runtime Reinstrumentation](#) for the .NET Agent so that you don't need to restart your application and the `AppDynamics.Agent.Coordinator` after instrumentation changes.

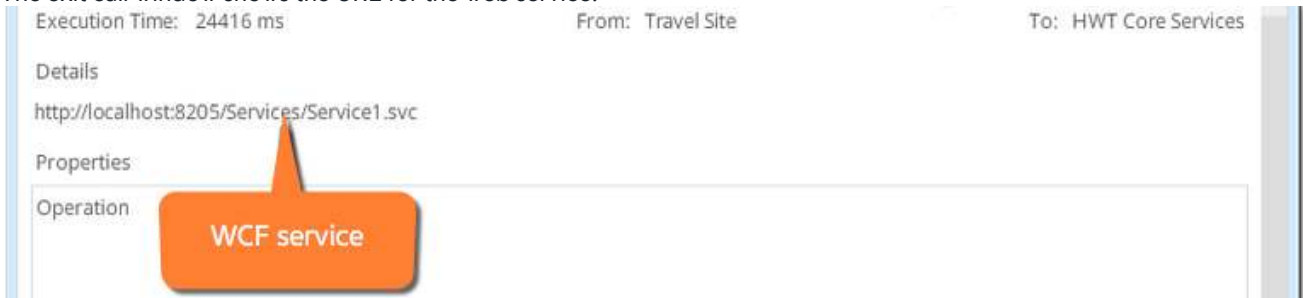

After you configure a custom service endpoint, you can monitor it on the service endpoint dashboard that shows KPIs and transaction snapshots where the service endpoint executed. You can also use the metric browser to analyze service endpoint performance. See [Service Endpoints](#).

## Tips for Defining .NET Service Endpoints

The methods that serve as the entry points for business transactions are often the same methods that you want to monitor as service endpoints as well. You can create service endpoints on the originating entry point for a business transaction.

- For ASP.NET service endpoints, you can use the URL to define the service endpoint. For example, in the Travel Site tier above, set a URL match to " /Travel/Search "
- For WCF and ASP.NET web service entry points, you can use an existing transaction snapshot to find the URL for the service.
  - a. Open a full transaction snapshot for the business transaction.
  - b. From the upstream tier, click the exit call link, either **WCF** or **Web Service**.  
The exit call window shows the URL for the web service.

- c. Open the service URL in a browser.
- d. On the service page, use the URL to access the WSDL file.

## Service1 Service

You have created a service.

To test this service, you will need to create a client and use it to call the service. You can do this using syntax:

```
svcutil.exe http://localhost:8205/Services/Service1.svc?wsdl
```

You can also access the service description as a single file:

```
http://localhost:8205/Services/Service1.svc?singleWsdL
```

This will generate a configuration file and a code file that contains the client class. Add the two files to the Service. For example:

- e. The service name element shows the service name.

```
<wsdl:service name="Service1">
```

- Define POCO service endpoints exactly as you would a POCO custom match rule for a business transaction.

## Data Collectors

Works with:

You can use data collectors to supplement business transaction and transaction analytics data with application data. The application data adds context to business transaction performance issues. For example, they may show the values of particular parameters or return values for business transactions affected by poor performance.

This data shows the business context affected by performance issues, such as the specific user, order, or product.

## Types of Data Collectors

There are two types of data collectors:

- Method invocation data collectors - Capture code data, such as method arguments, variables, and return values.
- HTTP data collectors - Capture the URLs, parameter values, headers, and cookies of HTTP messages exchanged in a business transaction.

See [Collect Transaction Analytics Data](#).

## View Collected Data

When applied to business transactions, the data collectors supplement the information shown in transaction snapshots. The information captured by HTTP data collectors appears in the HTTP DATA and COOKIES sections, while method invocation data appears in the Business Data section.

To view collected data:

1. Navigate to the **Transaction Snapshots** pane.
2. Double-click the transaction for which you want to view data.
3. Click **Data Collector** to view collected data.

## Configure a Data Collector

To configure data collectors, you need the Configure Diagnostic Data Collectors permission. Follow these steps to configure a data collector:

1. Identify the method on which to capture data. To do this, define the method signature and (optionally) filters based on the value of a code point in the method (such as, return value or argument).
2. Specify the actual code point that serves as the source of the data.
3. If the data collector applies to business transactions, then select the applicable business transactions.

When creating a data collector, you typically need to know the code on which you are setting up the collector, and whether it is based on access to the source code for the application, or its documentation. For the JVM 1.5 and .NET application environments, you must restart the JVM or application server if your method invocation data collector results in modifications to instrumentation configuration (class name, method name, method parameters, and so on).

These platform-specific considerations apply to data collectors:

- For C/C++ SDK: Create a method data collector using the `appd_bt_add_user_data function()`, not the Controller UI as described here. See [C/C++ SDK Reference](#).
- For Node.js Agent: Create a method data collector using only the `addSnapshotData()` Node.js API, not the Controller UI as described here. See [Node.js Agent API Reference](#).
- For Python Agent, you can create data collectors by using:
  - Python Agent API: Create a method data collector using the `add_snapshot_data()` Python Agent API. See [Python Agent API Reference](#).Or,

- Controller UI: Only the **with a Class Name that** option is valid. You cannot add a method data collector to a standalone Python function. Getter chains support the `access(user.name)` attribute, `access(user['name'])` key-value, and `calling(user.getName())` method.
- For PHP method data collectors, only the **with a Class Name that** option is valid. You cannot add a method data collector to a standalone PHP function.

## Configure a Data Collector Automatically

You can add a data collector directly from a transaction snapshot through the call graph. This automatically adds the class and method for you.

1. Double-click a call graph.
2. Drill down to the node you want.
3. Right-click the method you want.
4. Click **Configure Instrumentation for this Class/Method**.
5. Complete the wizard.

## Configure a Data Collector Manually

Data collectors can be manually configured in at least two ways.

From the left pane:

1. Click **Configuration** in the left pane.
2. Click **Instrumentation**.
3. Click the Data Collectors tab, and click **Add** below the data collector box for the type of data collector you want to add. The data collector configuration panel displays.

From a call graph:

1. Double-click a call graph.
2. Click **Data Collectors** in the menu bar.
3. Click **Actions**.
4. Click **Configure Data Collectors**.
5. Click **Add** at the bottom of the data collector box for the type of data collector you want to add. The data collector configuration panel displays.

Note the following platform-specific considerations applicable to data collectors:

- C/C++ SDK - Create a method data collector using the `appd_bt_add_user_data function()`, not the Controller UI as described here. See [C/C++ SDK Reference](#).
- Node.js Agent - Create a method data collector only using the `addSnapshotData()` Node.js API, not the Controller UI as described here. See [Node.js Agent API Reference](#).
- Python Agent - Create a method data collector using the `add_snapshot_data()` Python Agent API, not the Controller UI. See [Python Agent API Reference](#).
- PHP method data collectors - Only the "with a Class Name that" option is valid. Also, you cannot add a method data collector to a standalone PHP function.

The general steps for configuring a data collector are:

1. Identify the method on which to capture data. To do this, define the method signature and (optionally) filters based on the value of a code point in the method (such as return value or argument).
2. Specify the actual code point that serves as the source of the data.
3. If the data collector applies to business transactions, choose the applicable business transactions.

Typically, creating a data collector requires knowledge of the code on which you are setting up the collector, whether based on access to the source code for the application or its documentation. For some application environments, including JVM 1.5 and .NET, you will need to restart the JVM or application server if your method invocation data collector results in modifications to instrumentation configuration (class name, method name, method parameters, and so on).

## Configuration Notes

- The **Apply to new Business Transactions** option applies the collector to business transactions created after you have configured the data collector. Otherwise, the data collector applies only to the business transactions you select in the subsequent data collector configuration pane.
- For **Class**, select the match condition that the data collector can use to identify the class, such as class name, implemented interface name, and so on. If matching by class name, then use the fully qualified name of the class, as appropriate for the application platform. For example, the form of the equals field value would be:
  - In Java: `com.appdynamics.model.Item`
  - In .NET: `Bookstore.Item`
  - In PHP: `book`
- **Is this Method Overloaded:** If this is an overloaded method, then add parameters that identify the signature. You must create a data collector definition for each form of the method for which you want to capture data. For example, given the overloaded method in this table, to capture data for only the second two forms, you would need to create two data collectors. The parameters to configure are shown:

Signature	Parameters to Configure
<code>getName()</code>	<ul style="list-style-type: none"> <li>◦ None</li> </ul>
<code>getName(int studentId)</code>	<ul style="list-style-type: none"> <li>◦ Param Index 0: java.lang.int</li> </ul>
<code>getName(int studentId, string name)</code>	<ul style="list-style-type: none"> <li>◦ Param Index 0: java.lang.int</li> <li>◦ Param Index 1: java.lang.String</li> </ul>

- You can refine the method selection to meet specific conditions. If you configure more than one match condition, then all match conditions must be satisfied by the request for the data collector to be applied to the request.
- Once you identify the method, specify the code point from which you want to capture data, such as the method return value, argument, or a value captured by the getter chain on the invoked object. Configure this code point in the **Specify the Data to Collect from this Method Invocation** section of the configuration settings.
- HTTP data collector can capture data from HTTP parameters, request attributes, cookies, and other data. The names of these properties need to match exactly: no wildcards are supported. Notice that the Content-Length HTTP header is already captured in AppDynamics as the Average Request Size metric. However, you may choose to configure a data collector for this header to have the value appear in transaction snapshots, providing you insight into, for example, whether message size corresponds to slow performance.
- You can configure multiple data collectors. The effect of multiple data collectors is cumulative. For example, if you add a custom data collector that does not include the collection of the URL HTTP request attribute, but keep the Default HTTP Request Data Collector configuration in which the URL is configured to be collected, then the URL is collected.

## Method Invocation Data Collector Example

Method invocation data collectors are applicable to Java and .NET.

In this example of a manual setup (not using the wizard), we'll set up a method invocation data collector on a Java application. We want to create a data collector on the method `getCartTotal()`, which is shown in this code snippet with the method `getUser()` and which we will use later as a data source.

```

package com.appdynamicspilot.model;
...
public class Cart implements java.io.Serializable {
 ...
 private Double fakeAmount = 0.0;
 ...
 private User user;
 ...
 public User getUser() {
 return user;
 }
 ...
 public Double getCartTotal() {
 if (fakeAmount == 0.0) {
 double total = 0;
 if (items != null) {
 for (Item item : items) {
 total += item.getPrice();
 }
 }
 return total;
 }
 return fakeAmount;
 }
 ...
}

```

To configure a data collector for an application, add a data collector and then configure it:

1. When you add your data collector, make your selections as appropriate for your configuration.
2. Add a class and a method, if not already filled in. Class and Method Name are used to identify the method.
3. At the **Enable Data Collector** for checkboxes, select **Transactions Snapshots** to add metadata for troubleshooting purposes and for APM snapshots, or select **Transaction Analytics** to collect metadata about every execution of the transaction to use later in the analytics platform. It is recommended that you start with **ONLY Transactions Snapshots**. Enable **Transactions Analytics** after the targeted data collection is confirmed.
4. Click **Add Parameter** or **Add Match Condition** to select the correct parameter from the popup.
  - a. Method Parameters are added if the method is overloaded. Clicking **Add Parameter** adds the Param Index 0. Add the fully qualified class name for the parameter.
  - b. Match Conditions allow you to pick specific data when a method or line of code is called multiple times. Match Conditions engage method parameters or return values. Selecting **Add Match Condition** opens the Create Match Condition popup. Make your selections, and then click **Save**.
  - c. When setting up your data collector, note the checkbox beside **Apply to new Business Transactions**.
    - i. Checking this box automatically applies the rule to new business transactions.
    - ii. Not checking this box requires you to manually apply the rule to business transactions by navigating to **Configuration > Instrumentation > Data Collectors**.

- d. To add multiple collection types, click **Add** beneath Specify the Data to Collect from this Method Invocation to configure the source of data. For this section of code, use an invoked object and a getter chain of `user.getCustomerName`. This code snippet is an example of how to capture the user name on the invoked object. The `Cart` class instantiates a `User` object based on the following class in the same package as `Cart`. Note that the `User` class includes a method for returning the name of the user, `getCustomerName()`.

```
package com.appdynamicspilot.model;
...
public class User implements java.io.Serializable {
 ...
 private String customerName = null;
 ...

 public String getCustomerName() {
 return customerName;
 }
 public void setCustomerName(String customerName) {
 this.customerName = customerName;
 }
 ...
}
```

Using a getter chain, you can identify this method as another data source in the same data collector. For example, you could select **Invoked Object** as the source of the data. The getter chain `getUser().getCustomerName()` is the operation on the invoked object.

For the PHP agent, if a method return value collected by MIDC is not stored in any variable, it is seen as null in both snapshot and Analytics data.

5. When finished, click **Save**.

After you configure the method invocation data collectors, you can click **Configure Transactions using this Data Collector** on the Instrumentation pane to drag and drop (or highlight and move) the transactions to a given data collector.

When complete, transaction snapshots for slow, very slow, and stalled transactions, the transaction snapshots will include the specified user data.

### HTTP Data Collector Example

In the HTTP Data Collector configuration, specify the request data that you want to display in the snapshot.

To configure a data collector, add a data collector and then configure it:

1. Make your selections as appropriate for your configuration.
2. Determine if you are collecting parameters, cookies, session keys, or header data.
3. Click **+Add** beneath a data type to specify the request data that you want to display in the snapshot, and fill in as appropriate.

When setting up your data collector, note the checkbox beside **Apply to new Business Transactions**.

- a. Checking this box will automatically apply the rule to new business transactions.
- b. Not checking this box requires you to manually apply the rule to business transactions by navigating to **Configuration > Instrumentation > Data Collectors**.

4. When finished, click **Save**.

## Call Graph Settings

### Related pages:

- [Transaction Thresholds](#)
- [Transaction Snapshot Collection](#)

### Works with:

You can control the data captured in call graphs with the **Call Graph Settings** panel.

### Permissions

To configure call graph settings, you need the **Configure Call Graph Settings** permission.

### Call Graph Granularity

To control the granularity for call graphs, use the following settings:

- **Control granularity for Methods:** To ensure low-performance overhead, choose a threshold in milliseconds for method execution time. Methods taking less than the time specified here are filtered out of the call graphs.
- **Control granularity for SQL calls:** You can specify a threshold for SQL queries. SQL queries taking less than the specified time in milliseconds are filtered out of the call graphs. See [Tune Java Agent Performance](#).

**i** Only SQL Capture Settings apply to call graph configuration for the Node.js agent.

To access call graph configuration, click **Configuration > Instrumentation** and choose the Call Graph Settings tab. There are subtabs for each application type.

### Exclude Packages or Namespaces from Call Graphs

A call graph can potentially contain hundreds of methods. You can exclude packages (Java) or namespaces (.NET) with classes that you do not want to monitor.

For Java, some packages are excluded by default. These are visible in the Excluded Packages list. The packages that are excluded by default cannot be removed. However, you can include a particular sub-package from an excluded package.

You can customize call graph instrumentation from the call graph instrumentation page. From there, choose from these configuration options:

- Use the **Add Custom Package Exclude** (Java) or **Add Custom Namespace Exclude** (.NET) configuration options to exclude specific packages or namespaces from call graphs.
- Use the **Add Always Show Package/Class** (Java) or **Add Always Show Namespace/Class** (.NET) configuration options to have a package or namespace always shown in call graphs.

When the Controller constructs a call graph it uses excluded packages and included sub packages to determine which calls to include. However, the Controller includes some calls even if they are listed among the excluded packages. For example, web service calls.

## SQL Capture Settings

The SQL capture settings control whether SQL statements are captured and presented in the Controller UI with dynamic parameters bound to their runtime values. For example, consider Java code that constructs a SQL call as follows:

```
stmt = new PreparedStatement("select * from user where ssn = ?")
stmt.bind(1, "123-123-1234")
stmt.execute()
```

With the capture raw SQL option enabled, AppDynamics captures and presents the SQL call in the following form:

```
select * from user where ssn = '123-123-1234'
```

If capture raw SQL is disabled, the SQL call appears in its original form, with question mark parameters not bound to values. Disabling capture-raw-sql and using question mark parameters in SQL prepared statements gives you a mechanism for preventing sensitive data from appearing in the Controller UI.

It is important to note that the sensitive values must be parameterized in the original, prepared statement form of the SQL statement, as shown above. The following statement results in the potentially sensitive information (social security number) appearing in the Controller UI whether capture raw SQL is enabled or disabled since the sensitive data is not parameterized.

```
stmt = new PreparedStatement("select * from user where ssn ='123-123-1234'")
```

To configure SQL capture settings, in the Call Graph Settings tab, scroll down to the **SQL Capture Settings** section and choose one of the following options:

- **Capture Raw SQL:** Select this option to have SQL statements that are composed as prepared statements captured with dynamic parameters bound to runtime values. By default, private SQL data and queries that take less than 10 ms are not captured.

### Important

You can select this option to capture raw query details for NoSQL databases such as MongoDB, DynamoDB, and CassandraDB and the relational queries will not be scrubbed.

When you enable Capture Raw SQL in .NET environments, the agent captures the parameters for ADO.NET stored procedure calls even though the parameters are not represented by question marks. It does not capture stored procedure local variables that are not available to the CLR.

- **Filter Parameter values:** Select this option to have SQL statements that are composed as prepared statements captured without dynamic parameters bound to runtime values.

## Configure JMX Metrics from MBeans

### Related pages:

- [Exclude JMX Metrics](#)

This page describes how to create persistent JMX metrics from MBean attributes. See [Monitor JMX](#).

There are many helpful [JMX topics](#) on the AppDynamics community to help you with platform-specific troubleshooting tips.

### JMX Metric Rules and Metrics

You can add persistent JMX-based metrics to AppDynamics using metric rules. Once you create a persistent JMX metric, you can:

- View it in the Metric Browser.
- Add it to a Custom Dashboard.
- Create a health rule for it so that you can receive alerts.

You must have Configure JMX permissions for the application to configure new JMX Metrics your user account. See [Manage Custom Roles](#).

### Access the MBean Browser

If the MBean is already monitored and you want to create a metric from one of its attributes, you can do so from the MBean Browser.

To create a metric from an existing MBean attribute:

1. Open the Node Dashboard of the node that hosts the MBean, and navigate to **MBean Browser > JMX**.
2. Expand the domains listed in the left panel and select the MBean that contains the attribute of interest.
3. Expand the **Attributes** section, select the attribute, and click **Create Metric**.

### Configure JMX Metric Rules

1. Navigate to **Configuration > Instrumentation > JMX** to add an MBean and attributes, possibly based on complex matching patterns.
2. From the JMX Metric Configurations panel, click the Java platform to add the metric to a platform group.
3. Alternatively, create a new group and add your metric to the group.  
Groups allow you to organize metrics to meet your needs. For example, you may choose to keep custom metrics with their Java platform, or put all metrics you add into a Custom group to differentiate them from out-of-the-box metrics.

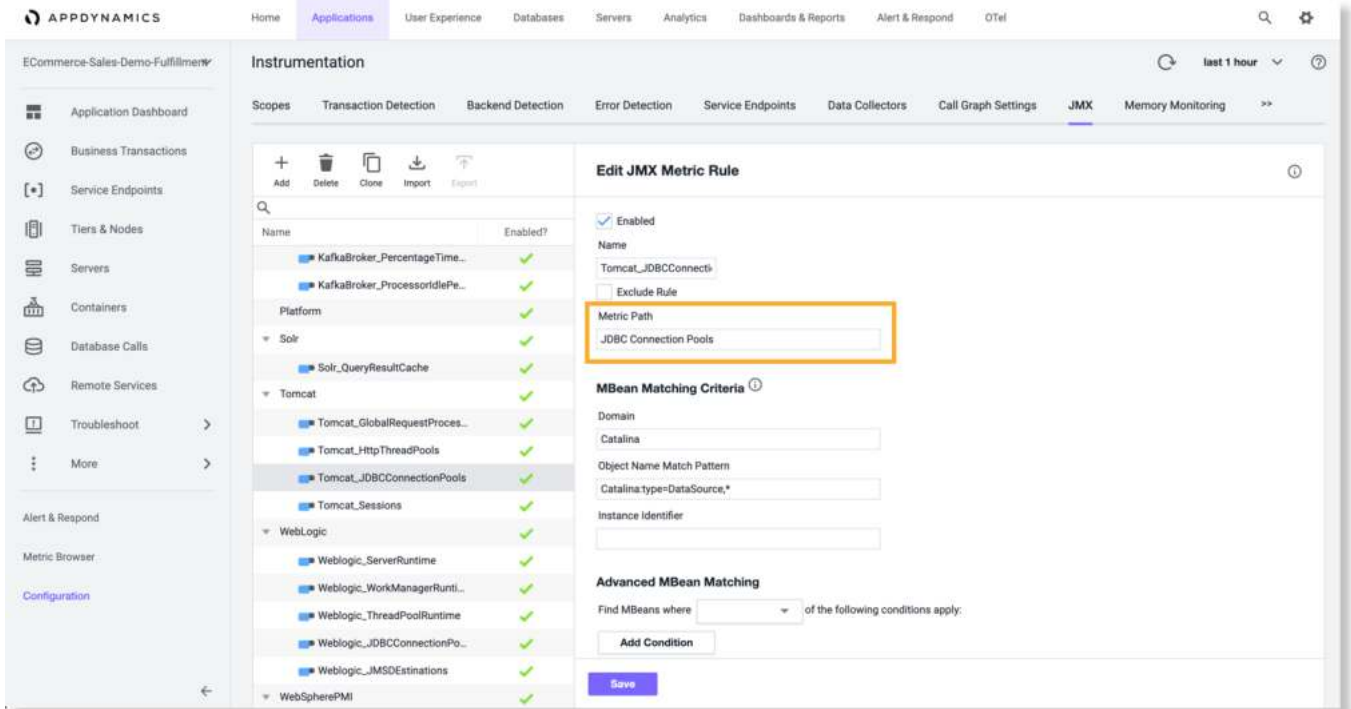

### JMX Metric Settings

The general settings for adding instrumentation for an MBean are:

- The **Name** is the identifier you want to display in the UI for the MBean.
- An **Exclude Rule** excludes matched MBeans that would otherwise be included by other rules. See [Exclude MBean Attributes](#).
- **Enabled** means that you want this rule to be applied.
- The **Metric Path** determines where the metric appears in the metric browser. For example, in the screenshot below, the metric path is "JDBC Connection Pools" for JMX metric "Tomcat\_JDBCConnectionPools".

Make sure that you do not use the full path in **Metric Path**. For example, use `Web Container Runtime` instead of `Application Infrastructure Performance|account-services|JMX|Web Container Runtime`.

In the MBeans subpanel, add matching criteria to identify the MBeans that you want to monitor.

- The **Domain name** is the Java domain. This property must be the exact name; no wildcard characters are supported.
- The **Object Name Match Pattern** is the full object name pattern. The property may contain wildcard characters, such as the asterisk for matching all the name/value pairs. For example, specifying `jmx:type=Hello,*` matches a JMX MBean `ObjectName, jmx:type=Hello,name=hello1,key1=value1`.
- The **Instance Identifier** is the MBean ID.  
Instance Identifier is a field in the JMX Object pattern that can be used to categorize the runtime context of MBean category that has the same set of attributes. For example, the user category has two HTTP ports: 8090 and 8181. But attributes such as `currentThreadsBusy` and `maxThreads` are the same. If a JMX pattern has both HTTP and AJP, but the user is interested in monitoring only HTTP and not AJP thread pool, then the user uses an identifier, a name that matches HTTP so that only HTTP ports related MBean data is collected.
- **Advanced MBean Matching Criteria** is an optional control for matching against attribute values. Identify the attribute name and value to test, along with matching criteria, such as a substring match.

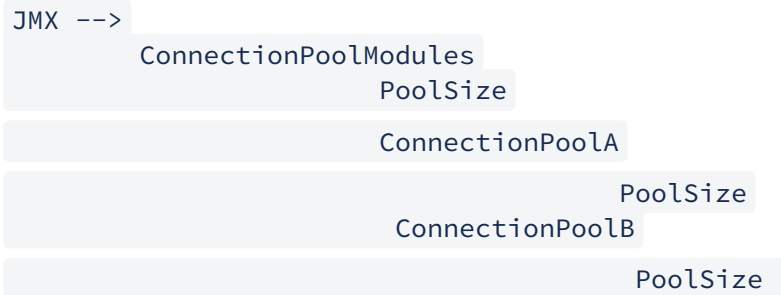

Without any instance identifier specified, a tree of resources or attributes is shown on the JMX Metric browser that matches the Object Name Match Pattern.

### Example1

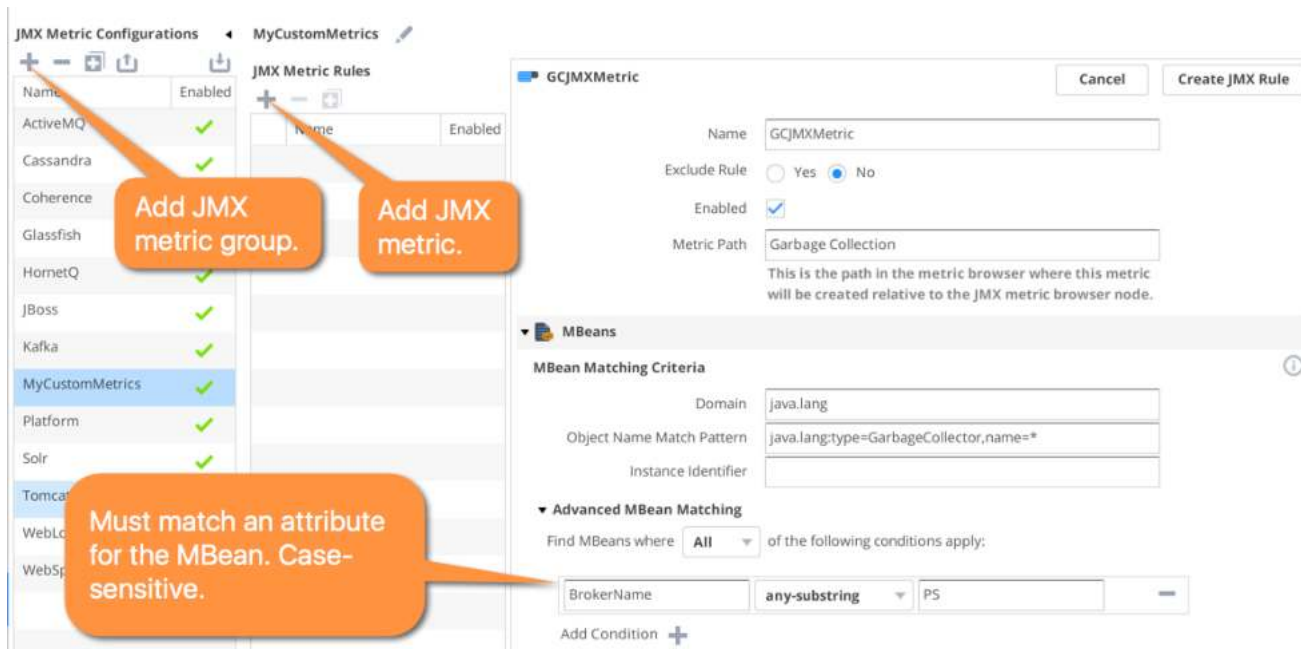

```
JMX -->
 ConnectionPoolModules
 ConnectionPoolA
 PoolSize
 ConnectionPoolB
 PoolSize
```

If you specify an `instanceIdentifier` like `instance identifier = path2`, it will show the second level attributes on the top level also.

The above tree will be shown as in the following example. The PoolSize, which is in the second level, also appears in the top level.

For example, this screenshot displays the MBean matching criteria for the GCJMXMetric rule.

For all matched MBeans, you can define one or more metrics for the attributes of those MBeans:

- **Metric Getter Chain**—Expressions can be executed against any value. In addition, getter chains for Strings and Booleans are supported using implicit conversion. See [MBean Getter Chains](#).
- **Metric Time Rollup**—Determines how the metric will be aggregated over a period of time. You can choose to either average or sum the data points, or use the latest data point in the time interval.
- **Metric Cluster Rollup**—Defines how the metric will be aggregated for a tier, using the performance data for all the nodes in that tier. You can either average or sum the data.
- **Metric Aggregator Rollup**—Defines how the Agent rolls up multiple individual measurements (observations) into the observation that it reports once a one minute. For performance reasons, Agents report data to the Controller at one-minute intervals. Some metrics, such as Average Response Time, are measured (observed) many times in a minute. The Metric Aggregator Rollup setting determines how the Agent aggregates these metrics. You can average or sum observations on the data points or use the current observation. Alternatively, you can use the delta between the current and previous observation.

For example, the maxThreads MBean attribute is mapped to the Maximum Threads metric in the JMX metrics browser as shown here:

MBean Attribute	<input type="text" value="maxThreads"/>
Metric Name	<input type="text" value="Maximum Threads"/>
▶ <b>Advanced</b>	
MBean Attribute	<input type="text" value="currentThreadCount"/>
Metric Name	<input type="text" value="Current Threads in Pool"/>
▶ <b>Advanced</b>	

Add Attribute 

### Example2

For instance, in a JBoss you get the active count property from the following mbean:

```
jboss.as:subsystem=datasources,data-source=MyDatasource_01,statistics=pool
```

Define the metric rule:

**Object name Match Pattern:** jboss.as:subsystem=datasources,\*,statistics=pool

**Instance identifier:** data-source

**Attribute:** ActiveCount

In the Object Name Match Pattern, you can even use the wildcard to replace several branches, which is, if it were "jboss.as:subsystem=datasources,whatever=another\_level,whatever=another\_level,data-source=MyDatasource\_01,statistics=pool" you can use "jboss.as:subsystem=datasources,\*,statistics=pool".

The Instance Identifier is the instanced element that is separated:

```
jboss.as:subsystem=datasources,data-source=MyDatasource_01,statistics=pool
```

```
jboss.as:subsystem=datasources,data-source=MyDatasource_02,statistics=pool
```

...

```
jboss.as:subsystem=datasources,data-source=MyDatasource_07,statistics=pool
```

Therefore, you must use data-source as the instance identifier.

### Export and Import JMX Configuration

After you modify the JMX configuration, you can backup or transfer the configuration using the JMX Configurations export and import icons at the top of the JMX Metric Configuration panel on the JMX instrumentation page. The configuration exports as an XML file.

### Deactivate Transaction Monitoring for JMX Monitored Nodes

In some circumstances, such as for monitoring caches and message buses, you want to collect JMX metrics without the overhead of transaction monitoring.

You can do so by turning off transaction detection at the entry point. See [Transaction Detection Rules](#).

## MBean Getter Chains

Getter chains in custom MBean configuration specify the method that retrieves the value of interest.

Expressions can be executed against any value. In addition to getter chain support for numeric boxed primitives (Short, Integer, Long, and so on), Strings and Booleans are supported using implicit conversion.

Boolean and String are implicitly converted to an Integer:

- Booleans are automatically converted to 0 (false) and 1 (true).
- Strings are converted to numeric values.

This example illustrates how to use a getter chain, given the class with a `getSomething()` method that returns the time:

```

1 package com.appdynamics.flexibleapp.mbean;
2
3 public class MyComplexObject
4 {
5 public long getSomething()
6 {
7 return System.currentTimeMillis();
8 }
9 }

```

In this example the metric getter chain configuration would be:

The screenshot shows the AppDynamics configuration interface for MBeans. On the left is a sidebar with a list of monitored components: HornetQ, JBoss, MyCustom, MyCustomMetrics (highlighted), Platform, Solr, Tomcat, WebLogic, and WebSpherePMI. The main panel is titled 'MBeans' and contains the following configuration sections:

- MBean Matching Criteria:**
  - Domain: `com.appdynamics.flexibleapp`
  - Object Name Match Pattern: `com.appdynamics.flexibleapp:type=Information`
  - Instance Identifier: (empty)
- Advanced MBean Matching:**
  - Find MBeans where: **All** of the following conditions apply:
  - Add Condition: +
- Attributes:**
  - Define Metrics from MBean Attribute(s):
    - MBean Attribute: `MyComplexObject`
    - Metric Name: `MyComplexObject`
  - Advanced:**
    - Metric Getter Chain: `getSomething()`
    - Metric Time Rollup: **Average the data points**

## Exclude JMX Metrics

This page describes how to exclude MBean attributes from being monitored as JMX metrics. For background information about JMX metrics, see [Monitor JMX](#).

## Customize Metrics To Gather

AppDynamics provides a default configuration for certain JMX metrics. However, in situations where an environment has many resources, there may be too many metrics gathered. AppDynamics lets you exclude resources and particular operations on resources.

### Exclude a Metric

For example, suppose you want to exclude monitoring for HTTP Thread Pools. Follow the procedure described in [Create a new JMX Metrics Rule](#), using the following criteria:

1. Set the **Exclude Rule** option to **Yes**.
2. Provide the **Object Name Match Pattern**:

```
Catalina:type=ThreadPool, *
```

3. Provide the **Advanced MBean Matching** value:

```
http
```

This configuration directs AppDynamics to stop monitoring metrics for HTTP Thread Pools. You can clear the **Enabled** checkbox to disable the rule.

### Exclude MBean Attributes

Some MBean attributes contain sensitive information that you do not want the Java Agent to report. You can configure the Java Agent to exclude these attributes using the `<exclude object-name>` setting in the `app-agent-config.xml` file.

To exclude an MBean attribute:

1. Open the `AppServerAgent/conf/app-agent-config.xml` file.
2. The new configuration takes effect immediately if the `agent-overwrite` property is set to `true` in the `app-agent-config.xml`. If `agent-overwrite` is `false`, which is the default, then the new configuration will be ignored and you have to restart the agent. Set the property to `true`.

```
<property name="agent-overwrite" value="true"/>
```

3. Locate the `JMXService` section. It looks like this:

```
<agent-service name="JMXService" enabled="true">
```

4. In the `JMXService <configuration>` section add the `<jmx-mbean-browser-excludes>` section and the `<exclude object-name>` property as per the instructions in the comment.

```
<configuration>
 <!--
 Use the below configuration sample to create rules to
 exclude MBean attributes from MBean Browser.
 <exclude object-name=<MBean name pattern> attributes=<
* |comma separated list of attribute names> >
 The example below will exclude all attributes of
 MBeans that match "Catalina:*".
 <jmx-mbean-browser-excludes>
 <exclude object-name="Catalina:*" attributes="*" />
 </jmx-mbean-browser-excludes>
 -->
</configuration>
```

5. Save the file.

## JMX Logging

JMX logs contain information about JMX interactions between AppDynamics agents and the monitored server's JMX domains.

JMX log entries are useful for diagnosing problems associated with JMX metrics or with JVM metrics that rely on JMX. For example, they can help you determine why MBeans or metrics created from MBeans do not appear in the Controller UI.

The name of the log is `JMXYear_mon_day_hr_min.#.log`, where # is the log set. See [Agent Log Files](#) for information about the structure of the log files into sets.

The JMX log file can reach a maximum of 5MB within a set.

Collecting JMX log (sample):

```
<ADRRAFAppender name="JMXLogger" fileName="JMX.log">
 <PatternLayout pattern="[%t] %d{DATE} %5p - %m%n" />
 <SizeBasedTriggeringPolicy size="20 MB" />
 <ADRRolloverStrategy max="5" />
</ADRRAFAppender>
```

```
<AsyncLogger name="com.singularity.JMX" level="info"
additivity="false">
```

```
<AppenderRef ref="JMXLogger" />
</AsyncLogger>
```

These configurations can be used in log4j2.xml file.

## Asynchronous Transaction Demarcators

To monitor end-to-end transaction performance for an asynchronous transaction, you must identify the demarcator for the transaction's logical endpoint. There are two ways you can define a transaction demarcator:

- For Java applications, you can specify a tier on which the end to end transaction processing is completed. This lets you determine the logical transaction response time for transactions that perform asynchronous backend calls (such as JMS calls or web service calls). When the last of the threads spawned by the transaction terminates on that tier, the agent considers the transaction complete.

**i** The Java Agent uses patent-pending heuristics to determine when the last thread associated with the Business Transaction has run. These heuristics are successful for many common cases. In complex environments with many thread handoffs unconstrained by frameworks, these heuristics may be inaccurate. For example Reactive Java, AKKA, or Scala environments. You should validate that the last thread on tier mechanism returns an end to end time consistent with the end to end latency shown within full transaction snapshots.

- For Java or .NET applications, you can identify the method that acts as the logical endpoint for the transaction processing sequence. For a response handler, this could be a method that watches for spawned threads to complete and when done, assembles the response and sends it back to the client.

You may specify more than one endpoint demarcator for a particular business transaction. In this case, the first match ends the transaction for purposes of end-to-end latency monitoring. Be careful not to configure multiple demarcators that could be satisfied on different tiers for a given transaction.

For the last thread on tier demarcator type, the transaction endpoint is considered to be the time when the thread that receives the traced transaction terminates or the latest points at which any descendant threads terminate.

For the method-based transaction demarcator option, you can configure the demarcator to consider runtime state, such as the values of parameters passed to the method. This allows you to account for an application design in which the completion of a logical business transaction is signaled by the value of a method parameter or return value.

**i** For .NET POCO entry point on methods that return a `Task` class, AppDynamics tracks the return of the task object as an end to end latency transaction automatically. You can configure your own transactions as end to end transactions for Java and .NET applications as described here. See [POCO Entry Points](#) for information on `Task`-based POCO entry points.

To create the configuration:

1. Open the **Configuration > Instrumentation** page and choose **Asynchronous Transactions** from the top menu. You likely need to expand the menu list (>>) to view the **Asynchronous Transactions** item.
2. Click **Add** and choose the demarcator method:
  - Java only: **Transaction is complete when last thread on specified Tier is finished running.**
  - Java or .NET: **Transaction is complete when specified class/method is invoked.** However, the end-to-end transaction time includes the time it takes for this configured method to finish processing, not when the method is invoked.
3. Follow the instructions that display for the option you choose. Note the following points:
  - You configure the class/method option using the standard method selector. See [Configure Instrumentation](#) for more information about identifying classes and methods in the AppDynamics configuration.
  - For the last thread on the tier approach, first, give a name for the transaction configuration and choose the tier.
4. Choose the business transaction where the configuration applies.

The threads in the logical transaction processing flow must be traceable by AppDynamics, including the thread that contains the end-point method. If needed, configure custom thread correlation to ensure that all threads are properly traced. For more information on thread correlation, see [Configure the Thread Correlation in Java Agent](#) and [Thread Correlation for .NET](#).

## Automatic Instrumentation of Specialist Packages/Frameworks

### Related pages:

- [Transaction Detection Rules](#)
- [Backend Detection Rules](#)

One of the goals of the AppDynamics Application Performance Management (APM) Platform is to provide maximum visibility into Enterprise IT systems for the minimum of set-up effort.

To achieve this, AppDynamics configures its agents to place instrumentation on entry points, exit points, and thread hand-offs right out of the box. The user interface facilitates configuring naming rules for transactions and backends.

Within this documentation, you can find pages about Supported Environments, Transaction Detection, and Backend Detection for many common frameworks (including servlet, JAX-RS, and JDBC) and many HTTP clients.

In addition, the following pages describe the specialized out-of-the-box configuration for instrumenting off-the-shelf products, packages, or frameworks whose entry and exit points are too complex for the more general documentation:

- [IBM-BPM Support](#)
- [Spring Batch Support](#)
- [OSB Support](#)
- [Open Tracing Support](#)

### IBM-BPM Support

IBM® Business Process Manager (IBM BPM) is a comprehensive business process management platform. It provides tools to enable authoring, testing, and deployment of business processes, as well as management capabilities. See [IBM documentation](#).

IBM BPM 8.5.7 is used to define and execute Business Process Definitions (BPDs) which combine elements of human interaction Client-Side Human Services (CSHS) or 'user tasks' for example, manual loan approvals and so on with elements of system integration system tasks, for example, registering a loan approval in a CRM system and so on. These processes are critically important and it is, therefore, natural to use

---

AppDynamics Business Transactions to monitor the system integration elements of the processes to ensure the performance and reliability of these technical integrations. You can also use the AppDynamics Business Journeys capability to monitor the end-to-end progress of the processes, including the elements of human interaction.

### **AppDynamics Instrumentation Use Cases**

To facilitate these monitoring use cases, the AppDynamics agent provides out-of-the-box configuration necessary to:

- Appropriately start and name Business Transactions originated within IBM BPM to allow management of system tasks with App iQ APM
- Correlate the processing within IBM BPM to facilitate end-to-end tracing of these Business Transactions
- Collect sufficient process metadata to allow these Business Transactions to be used within Business Journeys to provide visibility into the progress of processes including the human interactions

### **Agent Installation and Setup**

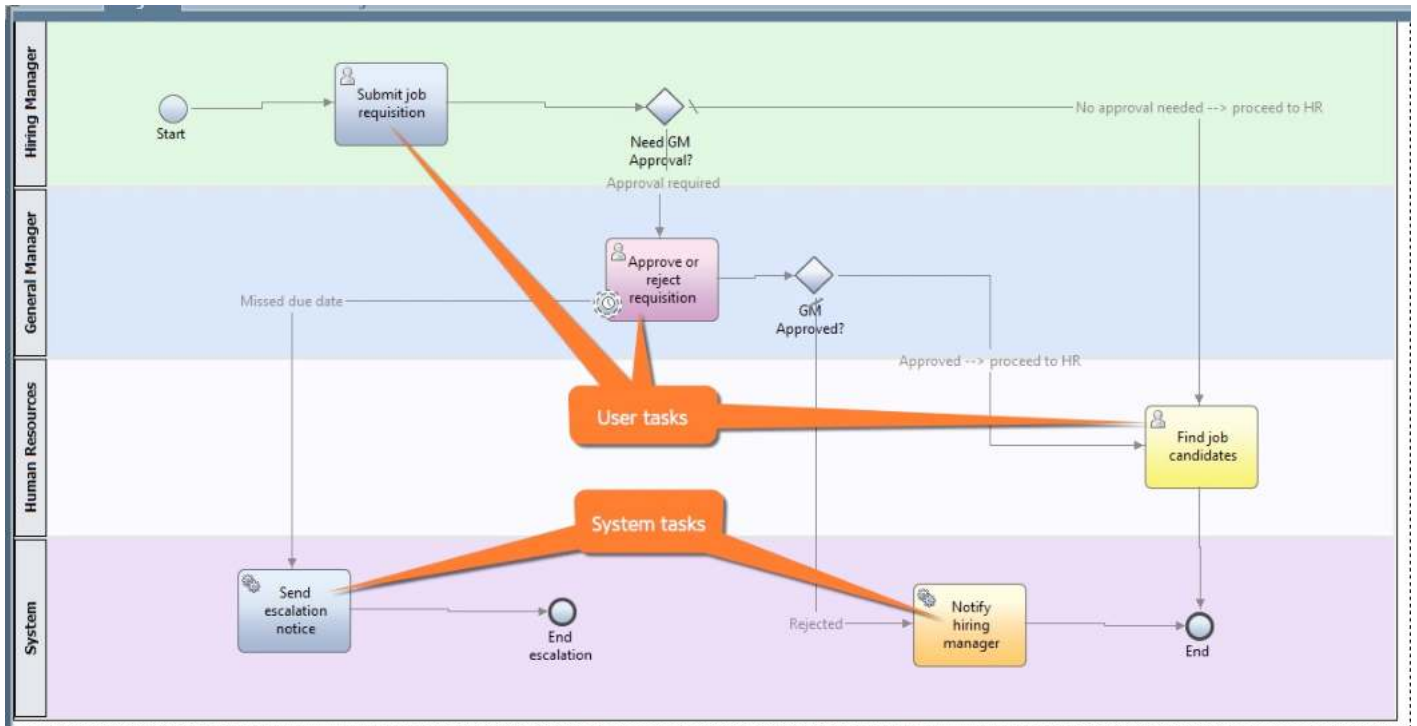

IBM BPM runs in WebSphere. See [IBM WebSphere and InfoSphere Startup Settings](#) for more details.

### **Business Process Definitions: System and User Tasks**

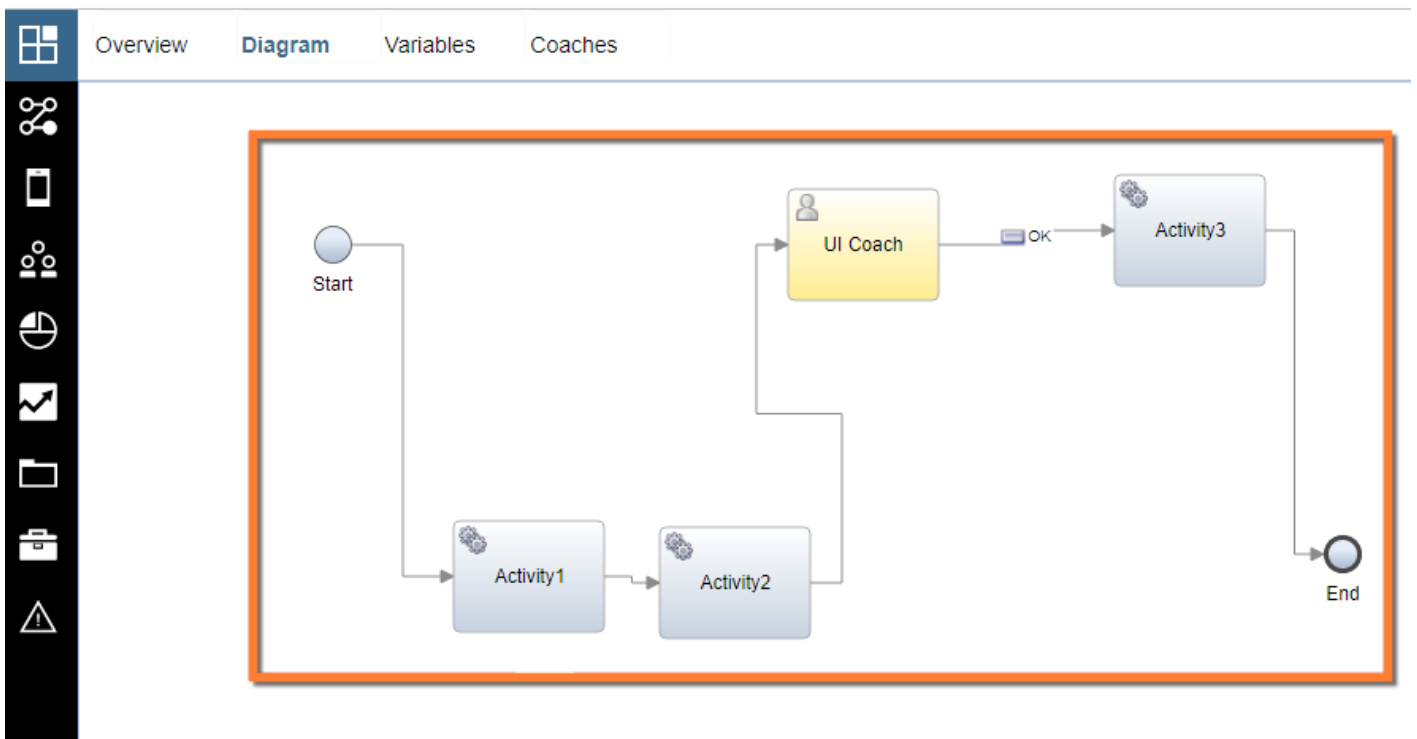

A BPD process consists of the flow of a business process which may involve user interactions. It consists of User Tasks, System Tasks, and other logic.

The screenshot displays a sample process within the BPD designer:

User tasks, in turn, break down into one or more user interactions, such as submit a form and approve a decision. They can be implemented as a CSHS, one of which is shown below:

Client-Side Http Service ▾ ⊗ ⓘ ⚠

A CSHS always starts with a start event and consists of one or more activities each of which uses a system service as the underlying implementation, and one or more Coaches, which define the user interactions.

## Business Transaction Support

### Business Transaction Support for Client Side Human Services

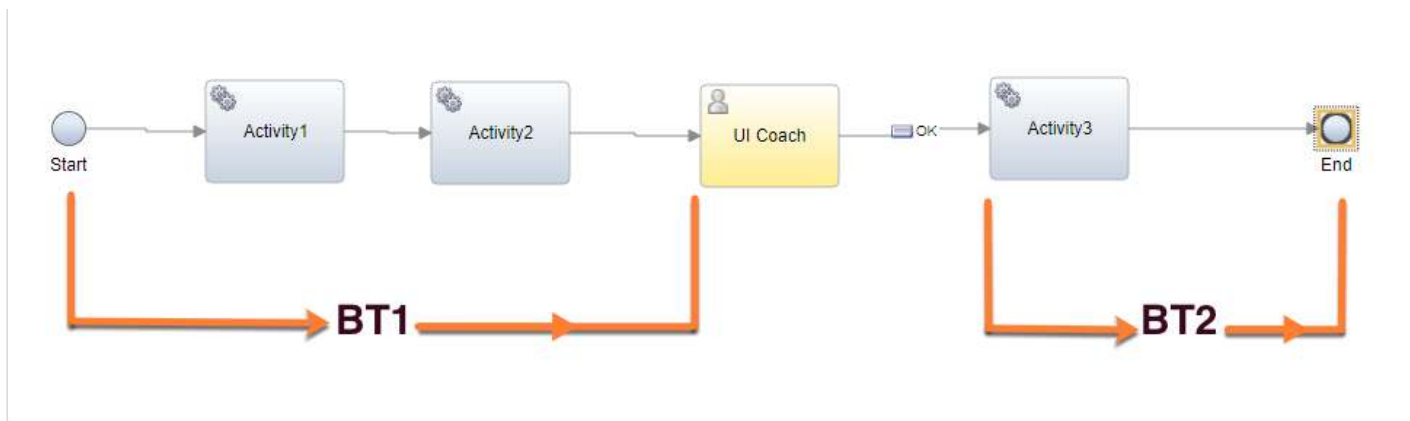

#### CSHS Transaction naming

All Business Transactions detected within a CSHS are detected as servlet type transactions, and their naming can be configured using custom servlet naming rules. The default servlet naming rule uses only the first two segments of the URL for naming, hence, without custom naming configuration the Business Transactions will be detected as –  
/`<Project Name>` /`<BPD Name>`

#### CSHS Transaction naming control

To disable the IBM BPM specific naming for CSHS Business Transactions use the `disable-ibmbpm-usertask-bt-naming` node property.

Since the Business Transaction is designed to monitor technical activity only, one CSHS may spawn multiple Business Transactions:

Any element inside a CSHS is associated with the following identifiers:

- Project Name
- BPD Process Name
- User Task Name
- CSHS Process Name
- Activity Name or Coach Name

Additionally, for Activity (Service), the activity has a service as its implementation which has its own identifier (Service Name).

These are annotated on screenshots of the IBM design tools:

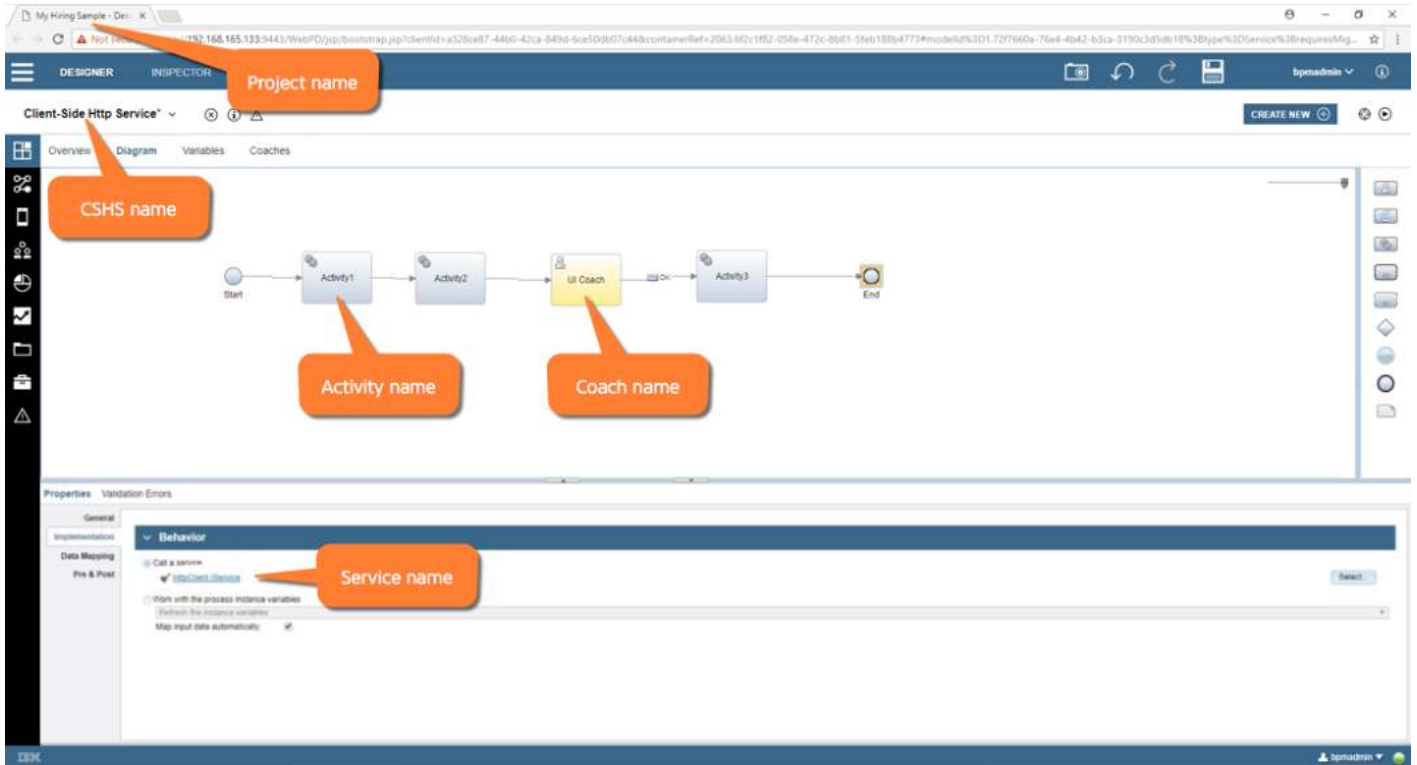

## BPD Screen

The screenshot displays the IBM Process Designer interface for a project named "MY HIRING SAMPLE". The main workspace shows a BPMN diagram for the process "Standard HR Open New Position". The diagram is divided into swimlanes: "Hiring Manager", "General Manager", and "System". Key tasks include "Submit job requisition" (a user task), "Approve or reject requisition" (a system task), "Send escalation notice", "End escalation", and "Notify hiring manager". A decision diamond labeled "GH? Approved?" follows the approval task. The "Properties" panel at the bottom is open to the "Implementation" tab, showing the task type as "User Task" and the implementation as "Client-Side Http Service".

Callouts in the image identify the following elements:

- Project name:** Points to the "MY HIRING SAMPLE" label in the top-left sidebar.
- BPD process:** Points to the "Standard HR Open New Position" title bar.
- User task name:** Points to the "Submit job requisition" task in the Hiring Manager swimlane.
- Client-Side Human Service (CSHS):** Points to the "Client-Side Http Service" implementation in the Properties panel.

## CSHS Screen

### Business Transaction Detection and Naming at the Start and End Points within a CSHS

Within a CSHS, there can be one or more activity-services involved in the flow. Each of this hits a specific REST URL. Hence, an HTTP entry point is defined for each of these services.

- For example, the default URL for the **Start** BT – `/teamworks/process.lsw`
- For example, the default URL for the **End** BT – `/teamworks/cfecontroller`

Business Transactions originating from the start of a user task are detected as servlet Business Transactions and are named according to the following scheme:

```
<Project Name>/<BPD Name>/<Task Name>/<CSHS Name>/Start:Event
```

For example (corresponding to the images shown above, BPD image and CSHS image), the Business Transactions would be named –

```
/My Hiring Sample/Standard HR Open New Position/Step: Submit job requisition/Client-Side Http Service/Start:Event
```

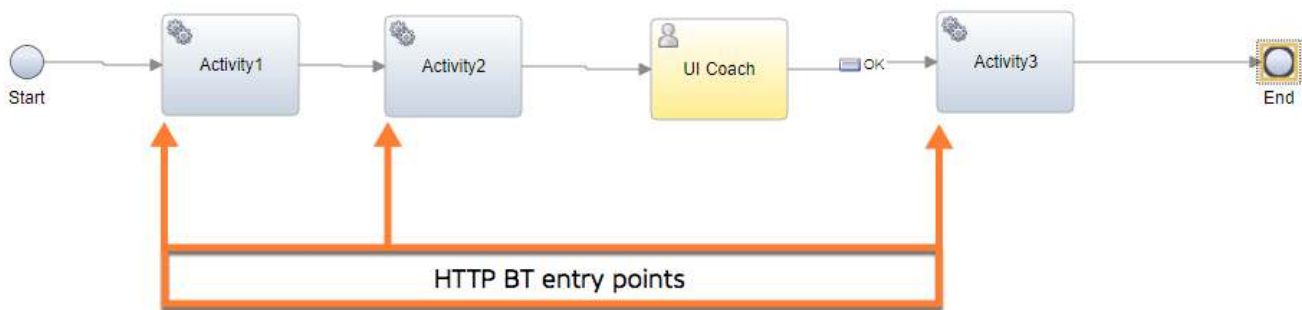

```
/My Hiring Sample/Standard HR Open New Position/Step: Submit job requisition/Client-Side Http Service/End:Event
```

### Business Transaction Detection and Naming at an Activity (Service) Node Within a CSHS

Each user task in the BPD process has a CSHS as its implementation. Within a CSHS, there can be one or more activity-services involved in the flow. Each of them hits a specific REST URL. Hence, HTTP entry point is defined for each of these services.

For example, the default URL is –

```
/rest/bpm/wle/v1/coachflow/service/1.a22ce595-1573-4fdd-90f6-734884753610
```

Business Transactions originating within a CSHS activity service are detected as servlet Business Transactions and are named according to the following scheme:

```
<Project Name>/<BPD Name>/<Task Name>/ <CSHS Name>/ <Activity Name>/<Implementation Service Name>:Service
```

For example (corresponding to the images BPD image and CSHS image), the Business Transactions would be named:

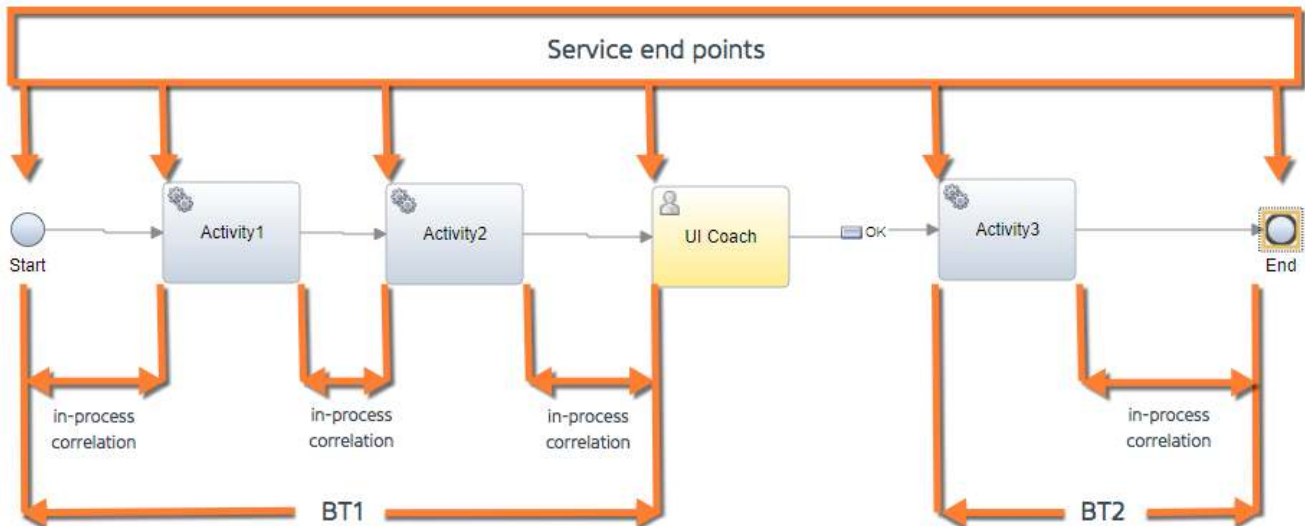

```
/My Hiring Sample/Standard HR Open New Position/Step: Submit job requisition/Client-Side Http Service/Activity1/HttpClient IService:Service
```

### Business Transaction Detection at the CSHS Coach

A User Task in a BPD process has a CSHS as its implementation. Within a CSHS, there can be one or more UI Coach(es) involved in the flow. Each UI Coach represents the UI page(s) which opens up for the user to perform some actions (like completing a form, approving something, and so on). Each of these hits a specific REST-URL. Hence, the servlet entry point is used for the naming of the UI Coach.

For example, the default URL for this Business Transactions is –

`/teamworks/generatecoachng`

### Business Transaction Naming Scheme at Coach of CSWS

The Business Transactions originating on entry to a UI coach are detected as Servlet Business Transactions –

`/<Project Name>/<BPD Name>/<Task Name>/<CSWS Name>/<Coach Name>:Coach`

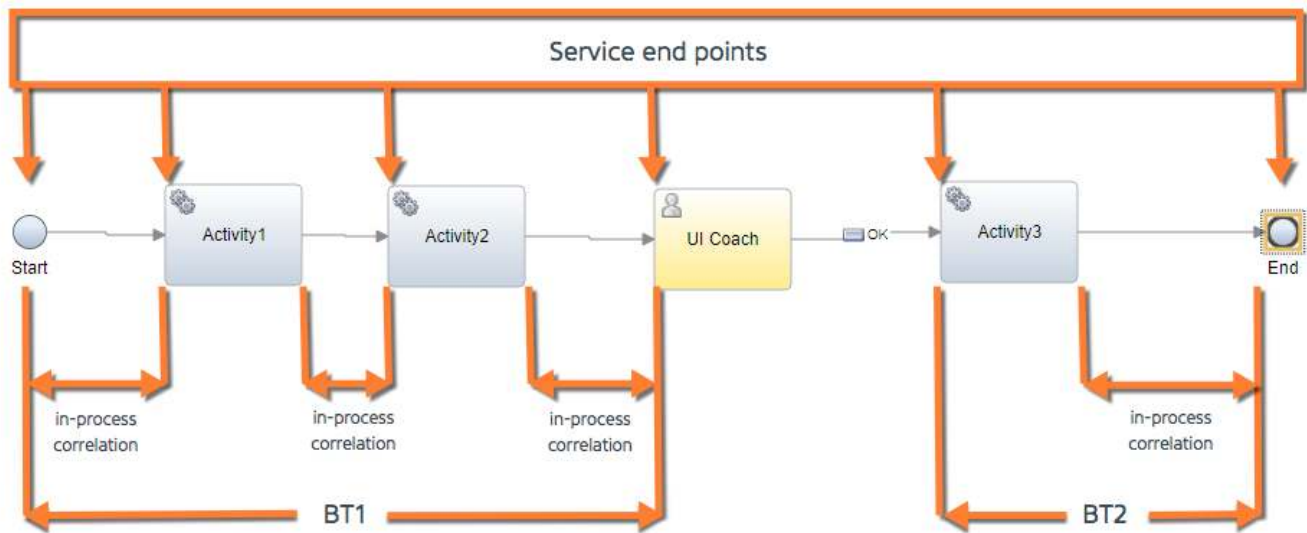

For example (corresponding to the images BPD image and CSWS image), the business transaction would be named:

`/My Hiring Sample/Standard HR Open New Position/Step:Submit job requisition/Client-Side Http Service/UI Coach:Coach`

### In-Process Correlation Between Elements within a CSWS

There can be more than one element involved within a User Task (CSWS) with no user interaction in between them. These form a part of the same business transaction. Service Endpoints give visibility of the individual steps within the resulting business transaction as illustrated below:

### Business Transaction Support for System Tasks within a BPD Process

POJO business transactions are generated for System Tasks within a BPD process.

The POJO business transactions are named using four identifiers:

1. Project Name (<project-name>)
2. BPD Process Name (<bpd-name>)
3. System Task Name (<task-name>)
4. Implementation Process Name (<implementation-name>)

If any identifier's value is not available, it is replaced with <UNKNOWN> in the resulting transaction name.

For example, a business transaction detected for default configuration (<project-name> / <bpd-name> / <task-name> / <implementation-name>) is:

APPDYNAMICS				
Home Applications User Experience Databases Servers Analytics Dashboards & Reports Alert & Respond				
Business Transactions				
Details Filters Actions View Options Configure				
Name ↓	Health	Response Time (ms)	Calls	
My Hiring Sample / Standard HR Open New Position / Step: Send escalation notice / HttpClient (Service)	✓	187	29	
InterServerMessageListener:TWServerTopic	✓	3	1,074	
Internal Order Approval App / IOA_BPD / Step: IOA_Outbound_Integration Service / IOA_Outbound_Int...	✓	135	5	
DataDefLoaderBean:DataDefLoaderQueueDestinationSingleCluster	✓	80	542	
CacheRequestListener:Bean:cacheTopic	✓	6	250	
/WebPD/jsp/registryReader.jsp	✓	16	2	
/teamworks/redirect-login.jsp	✓	48	6	

The default naming scheme can be customized using the `ibmbpm-systemtask-bt-naming` node property.

The property value is comma-separated identifiers chosen from project, bpd, task, implementation, and is order sensitive.

For example if,

value = "project, task" means POJO Business Transactions are named as: `<project-name>/<task-name>`

value = "task, project" means POJO Business Transactions are named as: `<task-name>/<project-name>`

value = "none" means POJO Business Transactions are not detected (disabled)

value = "default" means all the identifiers are used for Business Transactions naming in a default order, that is, they are named as `<project-name>/<bpd-name>/<task-name>/<implementation-name>`

Set `ibmbpm-systemtask-bt-naming` property to "none" to disable detection of Business Transactions for system tasks.

## Built-in Data Collectors

### Controlling the Built in Data Collectors

To disable the out of the box data collectors use the `disable-ibmbpm-data-collectors` node property.

For a System Task or a User Task, the following data collectors are available:

- PROCESS NAME
- TASK ID
- TASK NAME
- BPD INSTANCE ID
- BPD NAME
- PROJECT NAME

In addition to these, for a CSHS implementation of a User Task, if the IBM BPM specific naming Business Transactions naming scheme is enabled, an additional data collector, **ACTUAL URL**, will also be present, populated with the actual URL hit when the business transaction is initiated.

Additional data collectors defined for a User Task depending upon the element of the CSHS being called can be:

- COACH NAME for Coach
- EVENT TYPE for Start and End (value is either **Start** or **End** depending upon on the event)
- ACTIVITY NAME for Activity (Service)
- SERVICE NAME for Activity (Service – denoting the implementation service of the activity)

## Sample Data Collectors

You can view the snapshot data collectors as:

## Configuration Notes

There are some other configuration settings that may be helpful when implementing AppDynamics for IBM BPM monitoring:

- Increase the value of the node-property `max-business-transactions` if necessary, to accommodate the number of tasks involved in the BPD process (the default = 50).
- Add a node property `framework-support` with a value of "none" to disable CometD and GWT POJO Business Transactions a large number of which otherwise get detected. These correspond to activity within the IBM tooling and are not valuable for BPM monitoring.
- Exclude Servlet Business Transactions like `/portal/login`, `/webasset/..`, which are not valuable for BPM monitoring.

## Node Properties That Control IBM BPM Instrumentation

Node Properties available when using IBM-BPM support:

- `disable-ibmbpm-usertask-bt-naming`: Sets whether Business Transactions naming scheme for IBM-BPM UserTask Business Transactions should be disabled (value = true) or enabled (value = false). When it is set to "true", the Business Transactions would be named as per the default URL and not the meaningful names.
- `disable-ibmbpm-usertask-bt-in-process-correlation`: Sets whether Business Transactions in-process correlation for IBM-BPM UserTask Business Transactions should be disabled (value = true) or enabled (value = false).
- `ibmbpm-systemtask-bt-naming`: Decides Business Transactions naming scheme for IBM-BPM System Task POJO Business Transactions.
- `disable-ibmbpm-data-collectors`: Sets whether data-collectors for IBM-BPM task Business Transactions should be disabled (value = true) or enabled (value = false).

## Spring Batch Support

Spring Batch is an open-source project for batch processing (execution of a series of jobs).

A Batch Job is composed of one or more Steps. Each step consists of a Tasklet (explicitly or implicitly using ItemReader and ItemWriter). Each level (Job, Step and Tasklet) has an execute method.

Step execution can be parallelized using multiple threads. Remote Chunking (processing of part of Step, chunk on a remote JVM) can also be done with the help of JMS. Different steps in a job can be executed in separate threads use-case permitting.

From an APM perspective, tracking batch workloads at the Job level brings limited value, since batch Jobs are usually very long-running and an alert that the Job overran would come too late for remedial action to be taken. For this reason, the AppDynamics Business Transactions should be placed at the Tasklet level, meaning one batch Job will be composed of many Tasklet Business Transaction executions.

You can turn off spring batch instrumentation using the [spring-batch-enabled](#) node property.

Alerting on the response times of these Business transactions allows AppDynamics users to:

- Proactively detect that a Batch Job is progressing more slowly than usual, and thus predict if it will overrun any batch window
- Troubleshoot the root-cause of any unusual slow-downs in the progress of batch jobs in order that the issue can be remediated before the Job overruns

To achieve this, from Java Agent 4.5:

- Creates BTs at Tasklet.execute, named after the Job, Step, and Tasklet
- Correlates chunks across thread boundaries or process boundaries through JMS

## OSB Support

Oracle Service Bus (OSB) is Oracle's Enterprise Service Bus (ESB) implementation. It is configuration-based and policy-driven and provides reliable service-oriented integration, service management, and traditional message brokering across heterogeneous IT environments.

This service-infrastructure software adheres to the SOA principles of building coarse-grained, loosely coupled, and standards-based services. Additionally, OSB acts as a message brokering, service monitoring, administration, dynamic routing, and message transformation layer to infrastructure.

OSB relies on Oracle WebLogic Server run-time facilities. OSB supports various service types and transports.

From agent release 4.5.8, AppDynamics supports Business Transaction entries and exits for the HTTP and JMS transports and correlates activity through the broker to give end-to-end transaction visibility. Outbound flows using other transports will be shown as uncorrelated custom backends on the flowmap.

If you want to use custom configuration to influence how the agent instruments non-http and jms outbound transportation, you can use the `ignore-exit-types` node property to disable the default behavior.

For Business Transactions originating in OSB itself, the transaction naming scheme that will be used is dependent on the OSB Proxy Service Type.

Service Type	Naming Scheme
REST, WSDL, SOAP	<a href="#">WebService Entry</a>
Messaging, XML	<a href="#">Servlet Entry</a>

For more details on proxy service types and transports in OSB, see [Oracle documentation](#).

## Open Tracing Support

OpenTracing is an open standard for Tracing in-process and out-of-process distributed transactions. At a high level, it performs shallow stitching of method executions involved in a business flow, and hence enables measuring it end to end.

AppDynamics Tracer is an implementation based on OpenTracing 0.31.0 standards.

### Prerequisite

For the OpenTracer to work correctly, use the [Executor strategy](#) in the Java agent. You can specify it in `app-agent-config.xml` or as node property:

```

<!--As part of app-agent.config.xml-->
<property name="async-instrumentation-strategy" value="executor"/>

```

Or, just specify the following node property in the Controller:

```
async-instrumentation-strategy = "executor"
```

## Obtain the AppDynamics OpenTracer

### Install the Dependency

The OpenTracer jar can be accessed directly, or downloaded from Maven Central, or it can be downloaded from the AppDynamics portal. The library version changes with each new OpenTracer release, and is not tightly coupled to the version of the underlying agent, which must be at least = 4.5.13.

[Gradle](#) [Maven](#) [SBT](#)

```

dependencies {
 compile group: 'com.appdynamics.agent', name: 'opentracer', version: '4.5.13.27526'
}

```

[Gradle](#) [Maven](#) [SBT](#)

```

<dependency>
 <groupId>com.appdynamics.agent</groupId>
 <artifactId>opentracer</artifactId>
 <version>4.5.13.27526</version>
</dependency>

```

[Gradle](#) [Maven](#) [SBT](#)

```
libraryDependencies += "com.appdynamics.agent" % "opentracer" % "4.5.13.27526"
```

## Enable or Disable the Tracer

By default when plugged in, OpenTracer is enabled. There are two ways to disable it:

- Programmatically you can enable and/or disable using:

```
AppdynamicsTracerConfiguration.appdTracingConfiguration().setTracingEnabled();
```

Optionally,

- At startup, you can specify the system property to enable and/or disable using:

```
-Dappdynamics.opentracing.enabled=false
```

## Plug the Tracer into Lightbend Telemetry

The first OpenTracing use case validated by AppDynamics is its use with Lightbend telemetry (also known as the Cinnamon agent), which allows transaction tracing through applications built on the Lightbend reactive platform, for example those built on Akka HTTP. For more details, refer to the [Lightbend documentation](#), in particular as it relates to [OpenTracing integration](#).

Full instructions as to how to set up Lightbend Telemetry are beyond the scope of the AppDynamics documentation. At a high level, the necessary steps for configuration are:

1. Configure the Lightbend telemetry agent. For Lightbend instructions, see [Instructions](#).
2. Enable tracing for the Akka HTTP endpoints you want the AppDynamics agent to trace. For Lightbend instructions, see [OpenTracing Configuration](#).

**i** Ensure the active sampler is set to `const-sampler` in your `cinnamon.opentracing` file. (The low-overhead nature of the AppDynamics Java agent means that you can safely ignore the comment in the sample configuration file that states this should only be used for non-production).

3. Plug the AppDynamics OpenTracing implementation in to Lightbend Telemetry as a custom OpenTracing tracer using the `AppdynamicsTracerFactory` as described in the [Lightbend documentation](#). A sample AppDynamics tracer factory is provided below:

```
import com.appdynamics.opentracing.core.AppdynamicsTracerFactory;
import com.lightbend.cinnamon.opentracing.TracerFactory;
import io.opentracing.Tracer;

public class AppdynamicsTracerPlugin implements TracerFactory {
 @Override
```

```

public Tracer create() {
 return AppdynamicsTracerFactory.getTracer();
}
}

```

## Troubleshooting Applications

### Related pages:

- [Garbage Collection](#)
- [Error Detection](#)

AppDynamics includes many tools and views designed to help you diagnose application-related problems.

### Access Troubleshooting

When starting to troubleshoot an application problem, you should begin in the **Troubleshoot** section of the UI. You can access from the left-hand navigation pane of the Controller UI in an application context.

The area includes pages for analyzing slow response times, errors and exceptions, and health rule violations. It also provides access to war rooms, an area of the UI dedicated to troubleshooting a specific problem.

### Restricting Memory Amounts

Agent	Functionality

PHP Agent	This functionality is not configurable.
Python Agent	This functionality is not configurable.

## Additional Help

If slow response time persists even after you've completed the steps outlined above, you may need to perform deeper diagnostics. If you cannot find the information you need in the AppDynamics documentation, consider posting a note about your problem in the [Community Discussion Boards](#). These discussions are monitored by customers, partners, and AppDynamics staff.

## Slow Response Times

You may receive a notification based on a health rule violation, see performance indicators in flow maps or transaction scorecards that indicate slow response times. When you do, the following guidelines provide a strategy for troubleshooting and diagnosis.

The Slow Response Times Dashboard in the Troubleshoot menu lists the Business Transactions most responsible for slow Average Response Time (ART). From that dashboard, you can select a time range centered around a spike in ART that also captures more normal-looking time spans. This information is also available through the **Top Business Transactions** tab on the **By Contribution to App Average Response Time** tile.

### Step 1: Check for slow or stalled business transactions.

AppDynamics uses [transaction thresholds](#) to detect slow, very slow, and stalled transactions. Follow these steps to determine if you complete Step 2 or move on to Step 3.

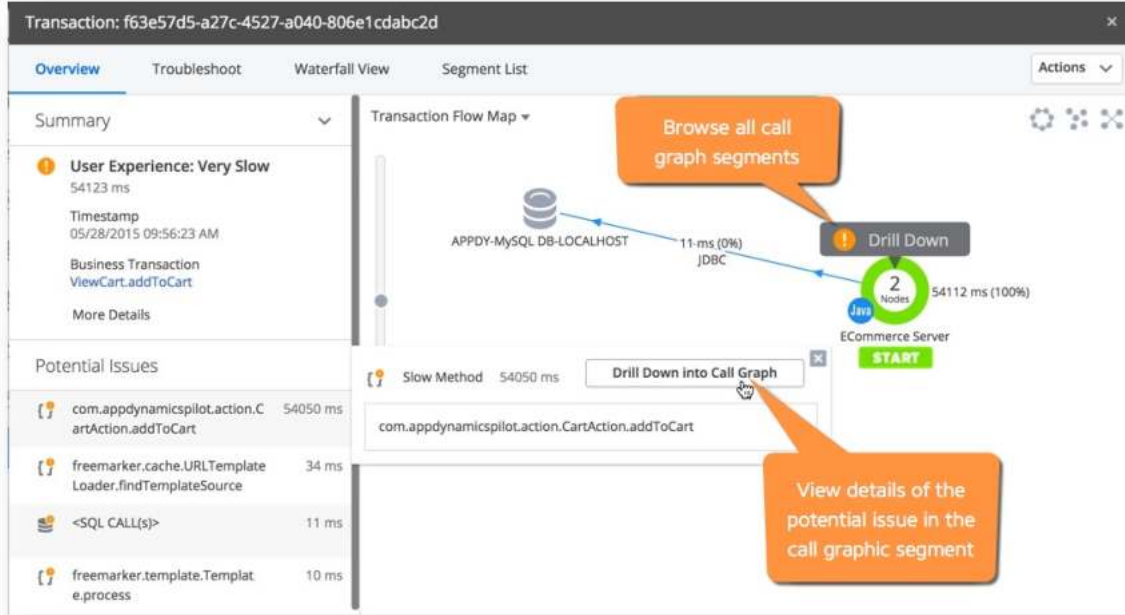

Do you have slow or stalled transactions?

1. Make sure that the time frame selected in the Controller UI encompasses the time when the performance issue occurred. If it's a continuing condition, you can keep the time frame relatively brief. Use the **Time Range** dropdown.
2. Click **Troubleshoot > Slow Response Times**.
3. Click the **Slow Transactions** tab if it is not already selected.
4. Do you see one or more slow transaction snapshots on this page?
  - If **Yes** – Go to [Step 2](#) to drill down to find the root cause.
  - If **No** – Go to [Step 3](#) and check for slow backends.

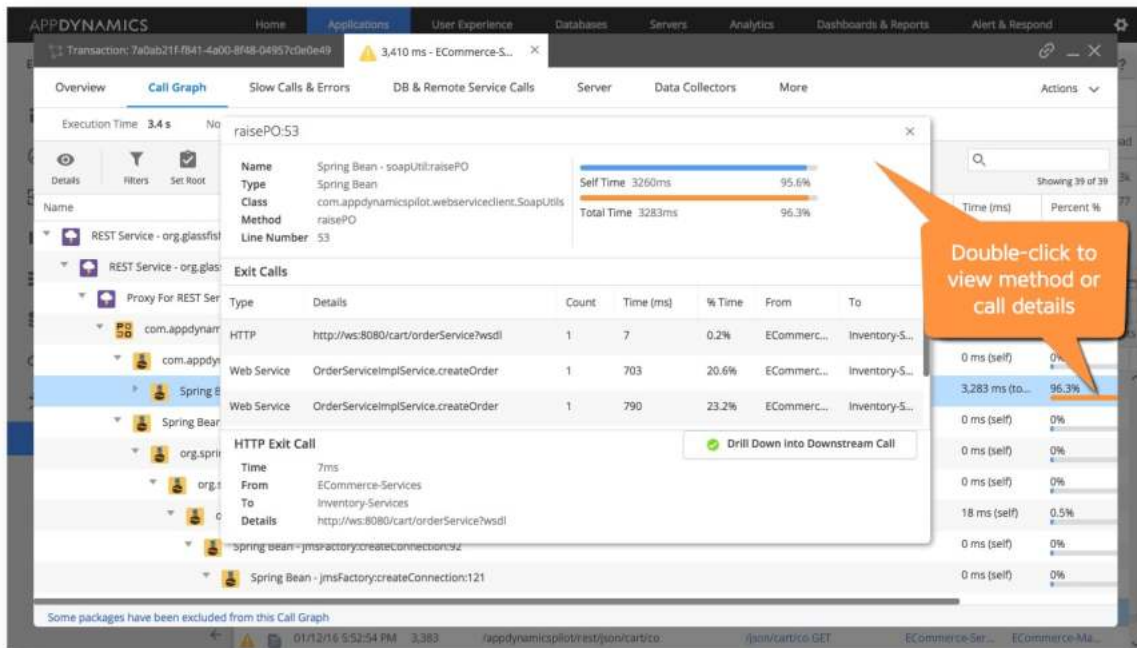

### Step 2: Drill into slow or stalled transactions to determine the root cause.

1. From the left menu, navigate to **Troubleshoot > Slow Response Times**.
2. In the lower pane of the **Slow Transactions** tab, click the **Exe Time (ms)** ↓ column to sort the transactions from slowest to fastest.
3. Select a snapshot from the list and click **Details** .

4. Review the **Potential Issues** list to see the longest-running method and SQL calls in the transaction.
5. Click a potential issue and select **Drill Down into Call Graph** to go directly to that point in the call graph, or click **Drill Down** in the transaction flow map pane to see the complete set of call graph segments retained for this transaction.

6. View the **Time (ms)** column to see how long this method execution takes relative to the transaction execution time.
7. Click the **HTTP** link in the last column on the right to display the information details pain. In this example, the selected method is taking 96.3% of the transaction execution time.

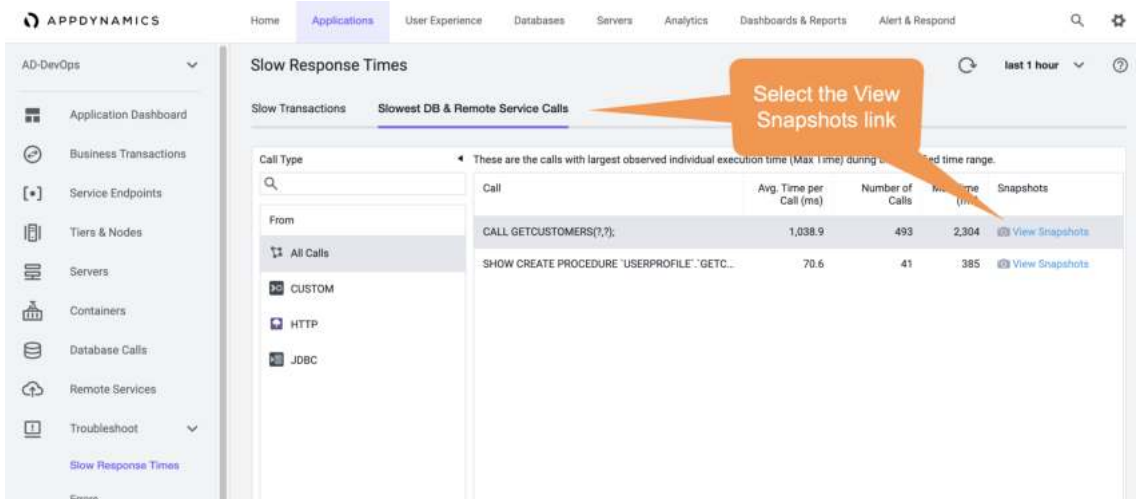

- Note the *Class*, *Method*, and *Line Number* (if available) represented by the execution segment. This information provides a starting point for troubleshooting this code issue.

If there are multiple slow or stalled transactions, repeat this step until you have resolved them all and then continue to [Step 3](#).

### Step 3: Check for slow database or remote service calls on the backend.

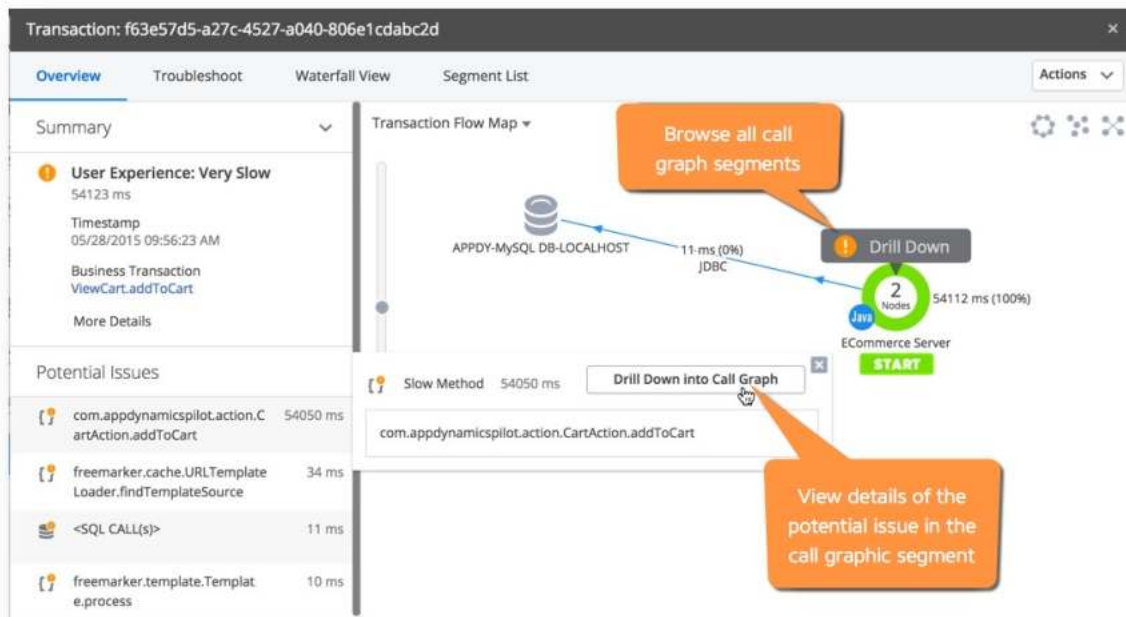

AppDynamics collects metrics about the performance of business transaction calls to the databases and remote servers from the instrumented app servers. You can drill down to the root cause of slow database and remote service calls.

- Click **Troubleshoot > Slow Response Times**, then click the Slowest DB & Remote Service Calls tab.
- Select a call from the list and click the **View Snapshots** link to show a list of Correlated Snapshots.

- Click the **Exe Time (ms)** column to sort the transactions from slowest to fastest.
- Select a transaction and click **Drill Down**.
- Select a potential issue from the **Potential Issues** list

- Click **Drill Down into Call Graph** to go directly to that point in the call graph, or click **Drill Down** in the flow map pane to see the complete set of call graph segments retained for this transaction.

- Review the **Time (ms)** column and select the transaction with the longest execution time for this method relative to the transaction execution time.
- Select the **DB & Remote Service Calls** tab.
- Do you see one or more slow calls on the **SQL Calls** or **Remote Service Calls** tabs?
  - If **Yes** – Go to [Step 4](#) to drill down and find the root cause.
  - If **No** – Go to [Step 5](#) to determine if the problem is affecting all nodes in the slow tier.

#### Step 4: Drill into SQL or Remote Service Calls to determine the root cause.

- On the **SQL Calls** tab of the transaction snapshot, sort the SQL Calls by Avg. Time (ms).
  - Slow database call**– click the database call to gain information about the call.
  - If you have **Correlated snapshots** between Java applications and Oracle databases – drill down into the Oracle database on the Transaction Snapshot to view database details captured during the snapshot.
  - If you have **AppDynamics for Databases** – right-click the database on the Application, Tier, Node or Backend Flow Map, and choose **Link to AppDynamics for Databases**. You can use AppDynamics for Databases to diagnose database issues.
  - If you have **Database Monitoring** – right-click the database on the Application, Tier, Node or Backend Flow Map, and choose **View** to review database problems.

Query Type	Query	Avg. Time...	Count	Total Time...	% Time	From Tier	To Tier	Error
COMMIT	DB Transaction Commit	4	2	8	0		APPD...	
Delete	DELETE FROM cart WHERE (user_id = 7)	0	1	0	N/A		APPD...	
Query	SELECT id, city_name, customer_name, customer_type, email, password FROM user WHERE (email = 7)	1	1	1	0		APPD...	
Delete	DELETE FROM cart_item WHERE EXISTS(SELECT ID FROM cart WHERE (user_id = 7) AND ID = cart_item.Ca...	1	1	1	0		APPD...	
Query	SELECT id, user_id FROM cart WHERE (user_id = 7)	0	1	0	N/A		APPD...	
Datasource.Get...	Get Pooled Connection From Datasource	4	4	16	0		APPD...	

**Business transactions of a Java application accessing a monitored Oracle database.**

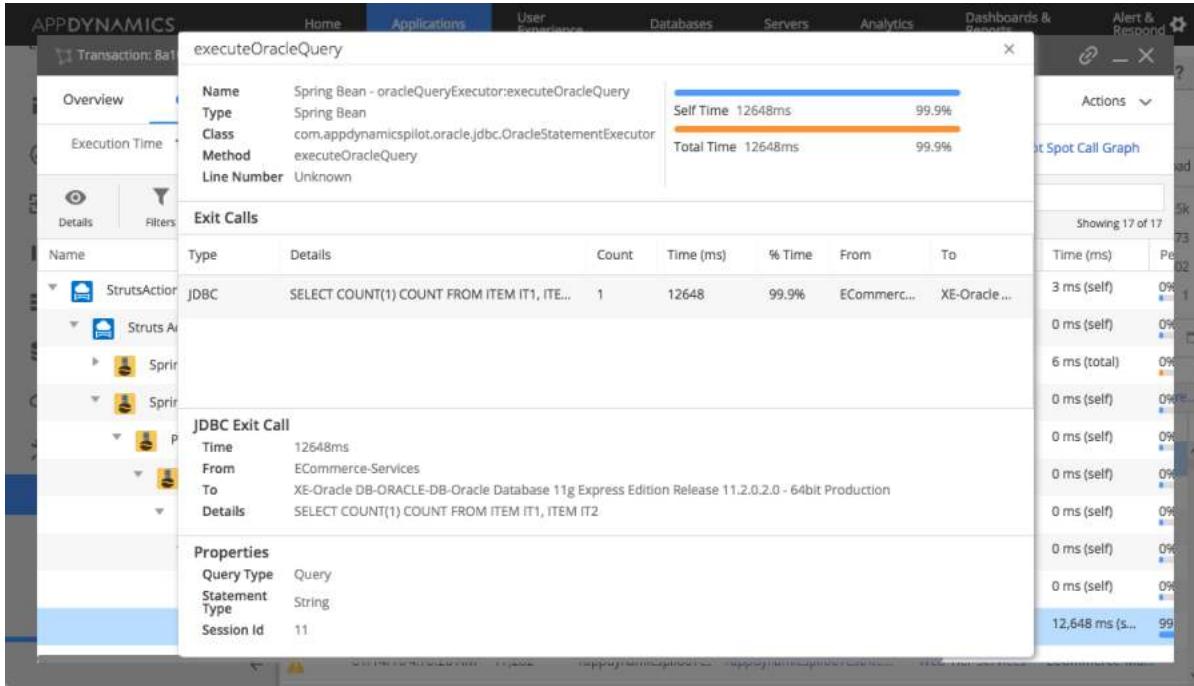

**1. Double-click to view a Transaction Snapshot.**

**2. Double-click database "Drill Down" to see correlated database details.**

**3. View database details captured during the business transaction snapshot.**

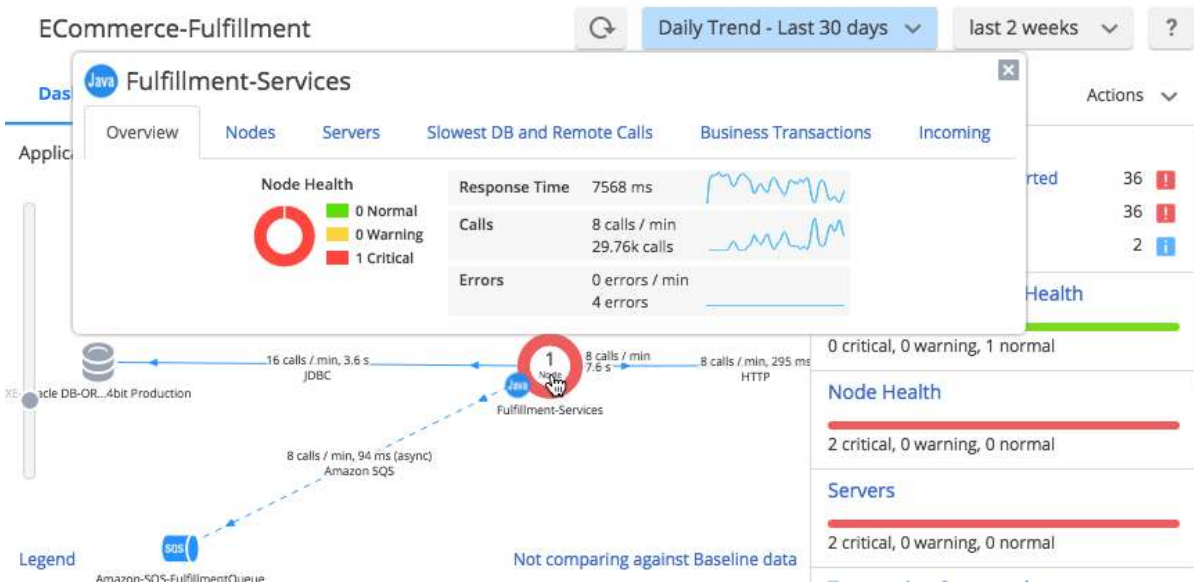

2. On the Remote Service Calls tab, sort the queries by Avg. Time (ms) ↓.
3. Select the slow call.
4. Click **Drill Down into Downstream Call** to gain further insight into the methods of the service call.
5. Sort the methods by the **Time (ms)** column.
6. Select a slow method.

7. Click **Details** 

**Step 5: Does the problem affect all nodes in the slow tier.**

1. In the Application or Tier Flow Map, click the **tier** or **node** icon to see a quick overview of the health of each node in the tier.

2. Is the problem affecting all nodes in the slow tier? If all the nodes are yellow or red, the answer to this question is Yes. Otherwise, the answer is No.

- If **Yes** – Go to [Step 6](#).
- If **No** – The problem is either in the node's hardware or in the way the software is configured on the node. If only one node in a tier is affected, the problem is probably not related to the application code. Follow these steps to determine a hardware related problem.

- i. In the left navigation pane, click **Tiers & Nodes**.
- ii. Expand the Tier in the right pane and double-click the affected node to open its Node Dashboard.
- iii. Click the Memory tab
  1. Explore each of the available tabs to determine if you need to add memory to the node, configure additional memory for the application, or take some other corrective action.
- iv. Click the **Server** tab.
  1. If the Hardware tab indicates a hardware related problem, contact your IT department.

You have isolated the problem.

### Step 6: Check to see whether the problem affects most business transactions

1. On the **Application Dashboard**, look at the *Business Transaction Health* pane on the right side of the screen.

2. Is the bar representing Business Transaction Health is primarily yellow or red? Yes or No?
  - If **No** – Then:
    - i. Click **Business Transactions** in the left navigation pane.
    - ii. Sort by Health, Transaction Score or other column headings to find the business transaction that is experiencing issues.
    - iii. Double-click the problematic business transaction to see its dashboard, then use the tabs to diagnose the problem.

You have isolated the problem.

### Additional Help

If you've tried to diagnose the problem using the previous steps and haven't found the problem, see additional information for your specific agent:

- [Troubleshooting Applications](#)
- [Monitor Databases](#)
- [Troubleshoot Mobile Applications](#)
- [Slow Response Times for .NET](#)

## Errors and Exceptions

AppDynamics Application Intelligence Platform captures and presents information on business transaction errors in the monitored environment.

At a high-level, a business transaction is considered to have an error if its normal processing has been affected by a code-level exception or error event, including custom error events based on methods you specify.

### View Error and Exception Information

The Controller UI presents information on errors and exceptions in various places in the UI, including in transaction snapshots, metrics, and dashboards.

The informational popups for tiers in flow maps have an error tab that displays error rate metrics for the tier:

Name	Count	Errors / min
RuntimeException	2	11
Internal Server Error : 500	4	22
Log4j	6	33

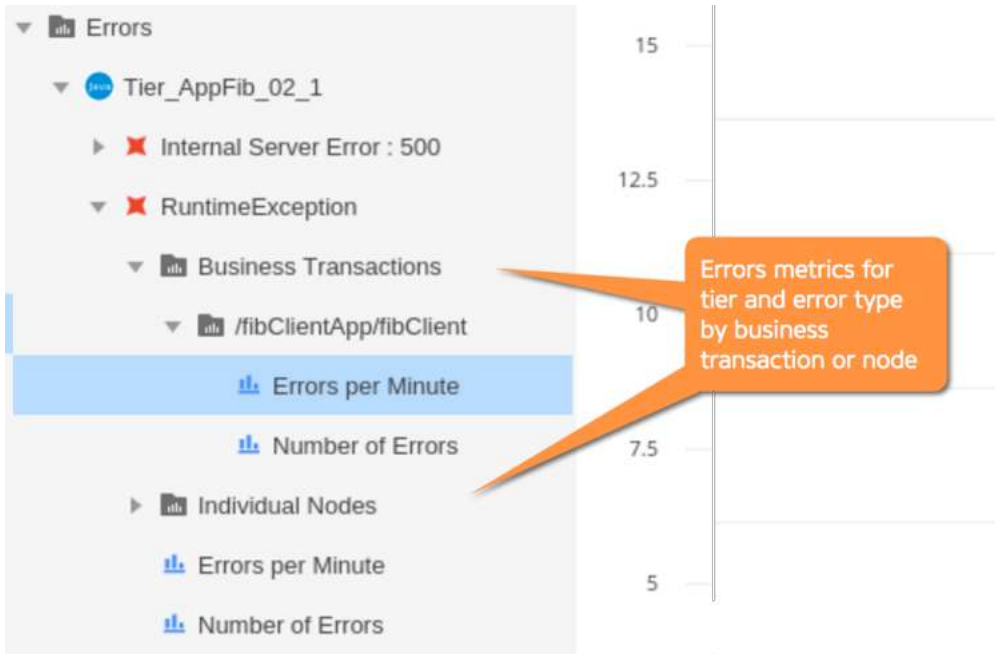

Click to display error rates

Click to display the informational popup

Java Node  
3 calls / min  
6 ms  
3 errors / min

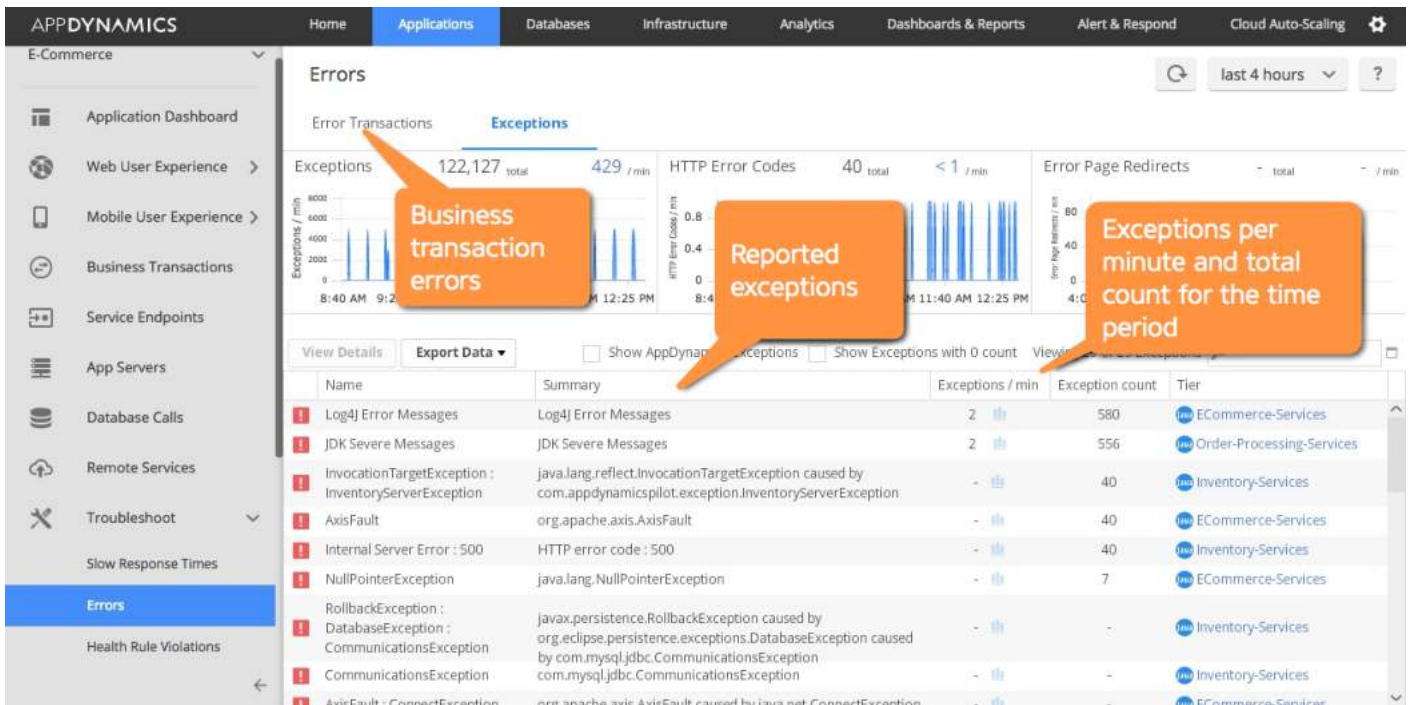

On the application and tier flow maps, the error rate is for all business transactions. On the business transaction flow map, errors apply only to the current business transaction.

The Metric Browser includes Error metrics:

The **Troubleshoot > Errors** page shows all error transactions. The page contains two tabs, one for transaction errors and one for Exceptions.

The tabs show information on the rate of errors or exceptions, and lets you drill down to the error or exception for more information, as shown:

---

## Business Transaction Error

All transaction errors that have been detected according to the configured error detection rules in the selected time frame of the Controller UI appear in the Error Transactions tabs of the **Errors** page.

By default, AppDynamics considers a business transaction to be in error if it detects one of the following types of events in the context of the transaction:

- An unhandled exception or error. An exception that is thrown and never caught or caught after the business transaction terminates results in a transaction error, and the exception is presented in AppDynamics. An exception that is thrown and caught within the context of the business transaction is not considered a transaction error and the exception is not captured in AppDynamics.
- An exception caught in an exit call, such as a web service or database call.
- An HTTP error response, such as a status code 404 or 500 response.
- A custom-configured error method and error message.

Error detection configuration is described in [Error Detection](#).

Errors that occur on a downstream tier that are not propagated to the originating tier do not result in a business transaction error. If the originating client receives a 200 success response, for example, the business transaction is not considered an error. The error contained within the downstream tier does count against the Error Per Minute metric for the continuing segment.

When a business transaction experiences an error, it is counted only as an error transaction. It is not also counted as a slow, very slow or stalled transaction, even if the transaction was also slow or stalled.

## Code Exceptions in AppDynamics

Code exceptions are a common cause of business transaction errors. The Exceptions tab in the **Errors** page shows an aggregated view of the exceptions across all transactions. For purposes of this view, AppDynamics considers the following types of incidents to be exceptions:

- Any exception logged with a severity of Error or Fatal (using Log4j, java.util.logging, Log4Net/NLog, or another supported logger). This applies even if the exception occurs outside the context of a business transaction, in which case the exception type is specified as *Application Server*.
- HTTP errors that do not occur in the context of a Business Transaction.
- Error page redirects.

Exceptions that are thrown and handled within a business transaction are not captured by AppDynamics and do not appear in the Exceptions tab.

When troubleshooting errors, notice that the number of business transaction errors does not necessarily correspond to the number of exceptions in a given time frame. A single transaction that counts as an error transaction can correspond to multiple exceptions. For example, as the transaction traverses tiers, it can generate an exception on each one. Troubleshooting an error typically involves finding the exception closest to the originating point of the error.

If a stack trace for the exception is available, you can access it from the Exception tab in the Controller UI. A stack trace is available for a given exception if the exception was passed in the log call. For example, a logging call in the form of `logger.log(Level.ERROR, String msg, Throwable e)` would include a stack trace, whereas a call in the form of `logger.log(Level.ERROR, String msg)` would not.

---

## Agent Errors

The Java Agent differentiates between agent internal errors and application errors. By default, agent internal errors no longer set off health rule violations. You can view agent internal errors in the following Metric Browser path: **Application Infrastructure Performance > <tier> > Agent > Internal Errors**.

### Error and Exception Limits

AppDynamics limits the number of registered error types (based on error-logging events, exception chains, and so on) to 4000. It maintains statistics only for registered error types.

Reaching the limit generates the `CONTROLLER_ERROR_ADD_REG_LIMIT_REACHED` event. While it is possible to increase the limit, we recommend refining the default error detection rules to reduce the number of error registrations to have the error you are not interested in capturing ignored.

For more information, see information on configuring log errors and exceptions to ignore in [Error Detection](#).

### Configure Errors and Exceptions

AppDynamics automatically recognizes errors and exceptions for many common frameworks. You can customize the default error detection behavior as needed, for example, if you use your own custom error framework. See [Error Detection](#).

## Slow Response Times for .NET

You may notice that your application's response time is slow from these methods:

- You receive an alert: If you have received an email alert from AppDynamics that was configured through the use of health rules and policies, the email message provides a number of details about the problem that triggered the alert. See information about Email Notifications in [Notification Actions](#). If the problem is related to slow response time, see [Initial Troubleshooting Steps](#).
- You view the Application Dashboard for a business application and see slow response times.
- A user reported slow response time that relates to a particular business transaction, for example, an internal tester reports "Searching for a hotel is slow".

### Initial Troubleshooting Steps

In some cases, the source of your problem might be easily diagnosed by choosing **Troubleshoot > Slow Response Times** in the left navigation pane. See [Slow Response Times](#).

### .NET Resource Troubleshooting

If you've tried to diagnose the problem using those techniques and haven't found the problem, use the following troubleshooting approaches to find other ways to determine the root cause of the issue.

#### Step 1 - CPU saturated?

Is the CPU of the CLR saturated?

#### How do I know?

1. Display the Tier Flow Map.
2. Click the Nodes tab, and then click the Hardware tab.
3. Sort by CPU % (current).

If the CPU % is 90 or higher, the answer to the question in Step 4 is Yes. Otherwise, the answer is No.

---

Yes – Go to [Step 2](#)

No – Review various metrics in the Metric Browser to pinpoint the problem.

In the left navigation pane, click **Servers > Tiers & Nodes > *slow tier***. Review these metrics in particular:

- ASP.NET -> Application Restarts
- ASP.NET -> Request Wait Time
- ASP.NET -> Requests Queued
  
- CLR -> Locks and Threads -> Current Logical Threads
- CLR -> Locks and Threads -> Current Physical Threads
  
- IIS -> Number of working processes
- IIS -> Application pools -> <Business application name> -> CPU%
- IIS -> Application pools -> <Business application name> -> Number of working processes
- IIS -> Application pools -> <Business application name> -> Working Set

You have isolated the problem and don't need to continue with the rest of the steps below.

### Step 2 - Significant garbage collection activity?

#### How do I know?

1. Display the Tier Flow Map.
2. Click the Nodes tab, and then click the Memory tab.
3. Sort by Time Spent on Collections (%) to see what percentage of processing time is being taken up with garbage collection activity.

If Time Spent on Collections (%) is higher than acceptable (say, over 40%), the answer to the question in Step 5 is Yes. Otherwise, the answer is No.

Is there significant garbage collection activity?

Yes – Go to [Step 3](#).

No – Use your standard tools to produce memory dumps; review these to locate the source of the problem.

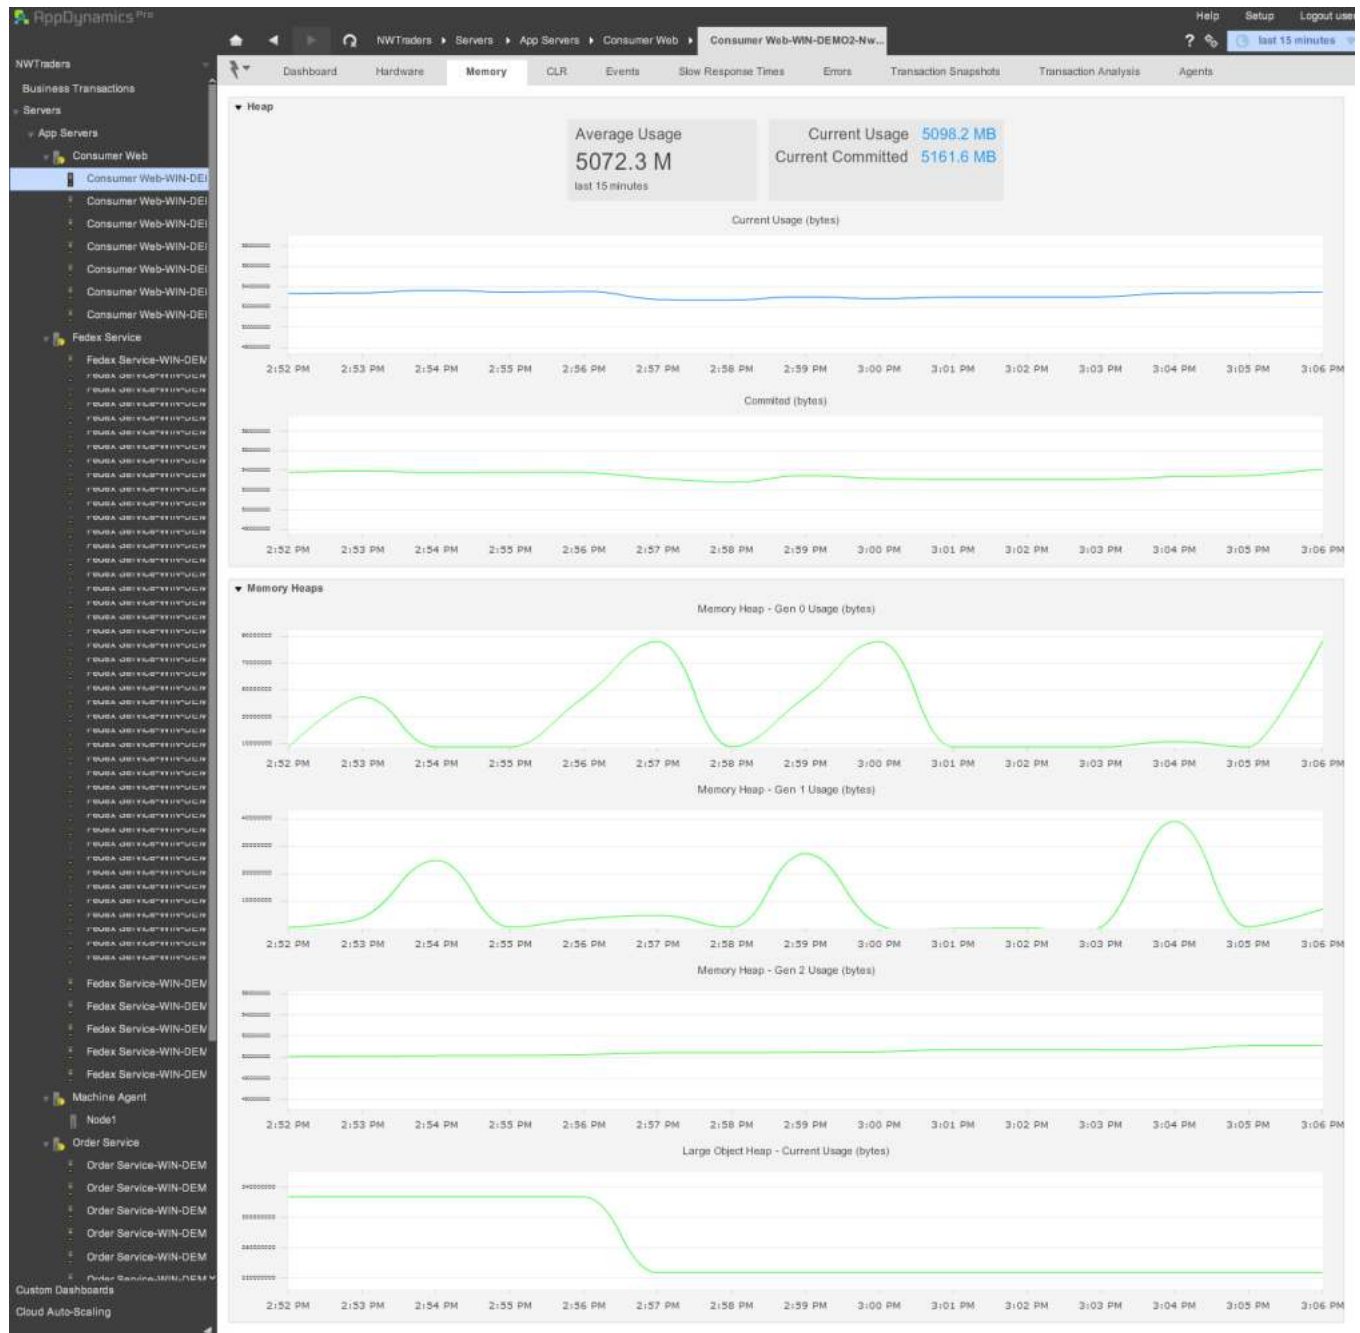

You have isolated the problem and don't need to continue with the rest of the steps below.

### Step 3 - Memory leak?

Is there a memory leak?

#### How do I know?

1. From the list of nodes displayed in the previous step (when you were checking for garbage collecting activity), double-click a node that is experiencing significant GC activity.
2. Click the Memory tab, then review the committed bytes counter and the size of the Gen0, Gen1, Gen2 and large heaps.

If memory is not being released (one or more of the above indicators is trending upward), the answer to the question in Step 6 is Yes. Otherwise, the answer is No.

Yes – Use your standard tools for troubleshooting memory problems. You can also review ASP.NET metrics; click **Tiers & Nodes > slow tier > ASP.NET**.

No – Use your standard tools to produce memory dumps; review these to locate the source of the problem. Whether you answered Yes or No, you have isolated the problem.

## Java Resource Issues

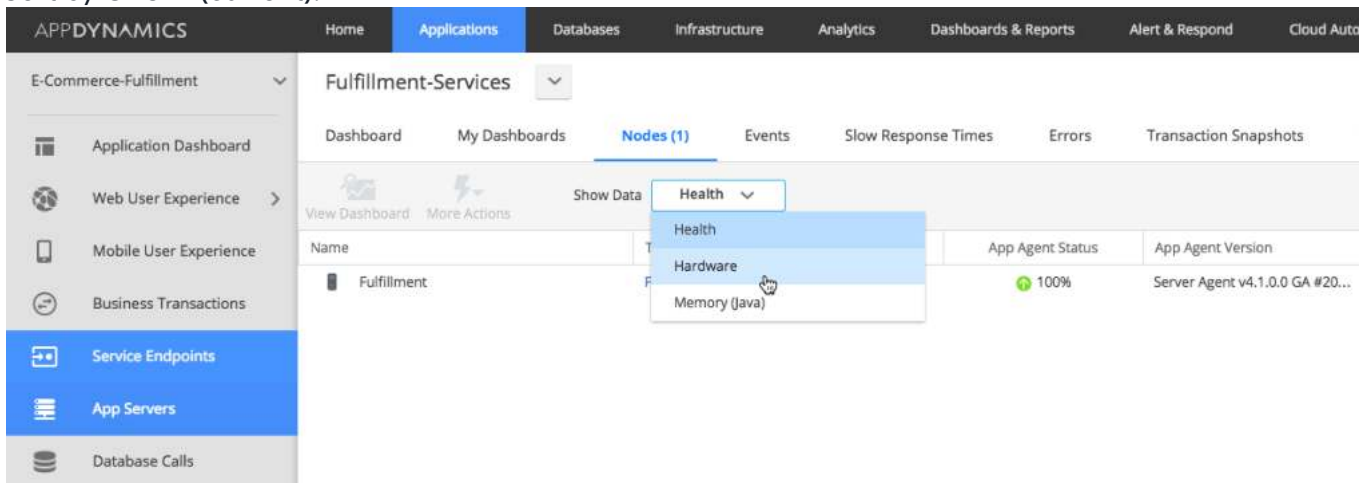

These troubleshooting guidelines may help you determine the root cause of many Java-related issues.

### Step 1. CPU saturated?

Is the CPU of the JVM saturated?

#### How do I know?

1. Display the Tier Flow Map.
2. Click the Nodes tab, and then show **Hardware** data.
3. Sort by CPU % (current).

If the CPU % is 90 or higher, the answer to this question is Yes. Otherwise, the answer is No.

Yes – Go to [Step 2](#).

No – The issue is probably related to a custom implementation your organization has developed. Take snapshots of the affected tier or node(s) and work with internal developers to resolve the issue.

### Step 2. Significant garbage collection activity?

Is there significant garbage collection activity?

#### How do I know?

1. Display the Tier Flow Map.
2. Click the Nodes tab, and then click the Memory tab.
3. Sort by **GC Time Spent** to see how many milliseconds per minute is being spent on GC; 60,000 indicates 100%.
4. If GC Time Spent is higher than 500 ms, the answer to the question in Step 5 is Yes. Otherwise, the answer is No.

#### Result

Yes – Go to [Step 3](#).

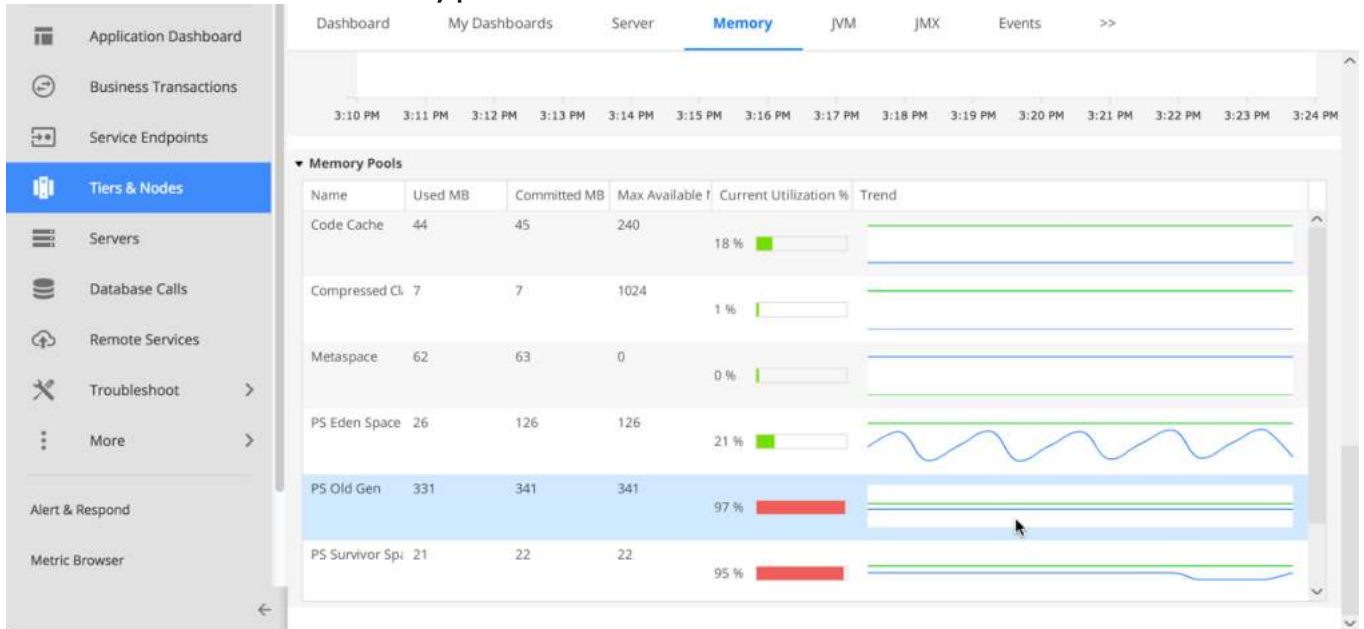

No – Go to [Step 4](#).

### Step 3. Memory leak?

Is there a memory leak?

How do I know?

1. From the list of nodes displayed in the previous step (when you were checking for Garbage Collecting activity), double-click a node that is experiencing significant GC activity.
2. Click the Memory tab, then scroll down to display the Memory Pool graphs at the bottom of the panel.
3. Double-click the **Old Gen memory pools** chart.

If memory is not being released (use is trending upward), the answer to this question is Yes. Otherwise, the answer is No.

### Result

Yes – Use various AppDynamics features to track down the leak. One useful tool for diagnosing a memory leak is object instance tracking, which lets you track objects you are creating and determine why they aren't being released as needed. Using object instance tracking, you can pinpoint exactly where in the code the leak is occurring. For instructions on configuring object instance tracking, as well as links to other tools for finding and fixing memory leaks, see [Need more help?](#)

No – Increase the size of the JVM. If there is significant GC activity but there isn't a memory leak, then you probably aren't configuring a large enough heap size for the activities the code is performing. Increasing the available memory should resolve your problem.

Whether you answered Yes or No, you have isolated the problem.

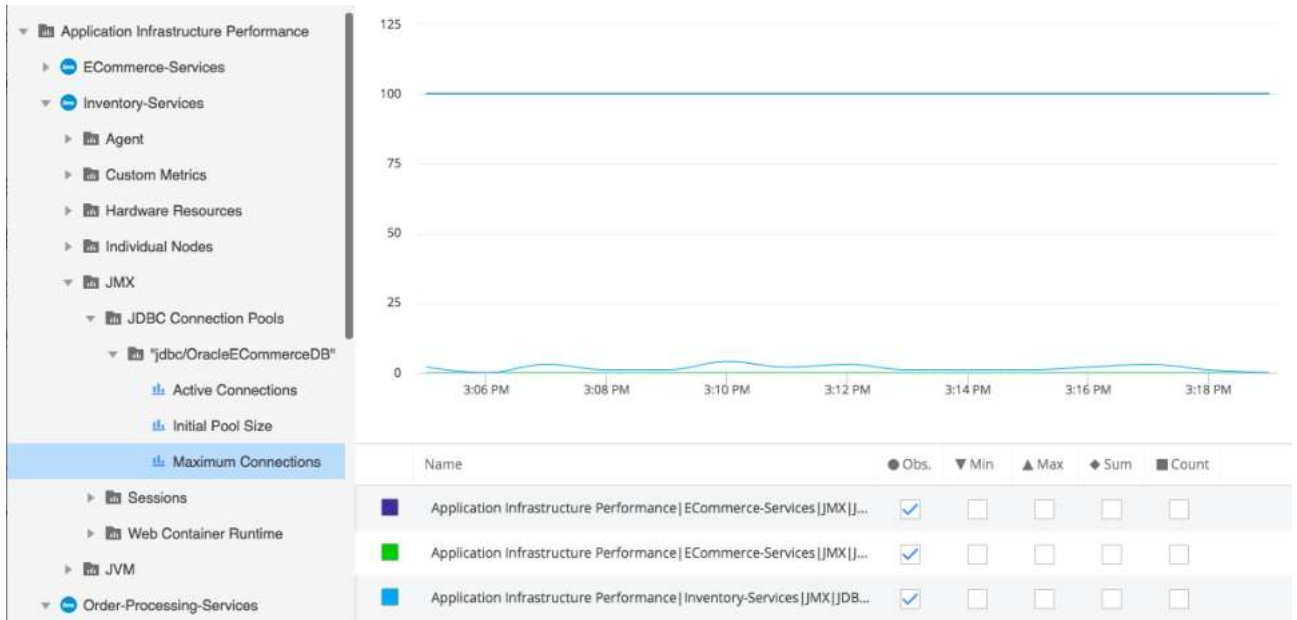

### Step 4. Resource leak?

Is there a resource leak?

## How do I know?

1. In the left Navigation pane, go to (for example) **Metric Browser > Application Infrastructure Performance > TierName > Individual Nodes > NodeName > JMX > JDBC Connection Pools > PoolName.**
2. Add the **Active Connections** and **Maximum Connections** metrics to the graph.
3. Repeat as needed for various pools your application is using.

If connections are not being released (use is trending upward), the answer to the question in Step 7 is Yes. Otherwise, the answer is No.

## Result

Yes – To determine where in your code resources are being created but not being released as needed, take a few thread dumps using standard commands on the problematic node. You can also create a diagnostic action within AppDynamics to create a thread dump; see *Thread Dump Actions* in [Diagnostic Actions](#).

No – Restart the JVM. If none of the above diagnostic steps addressed your issue, it's possible you're simply seeing a one-time unusual circumstance, which restarting the JVM can resolve.

## Java Memory Leaks

This page describes how to detect and troubleshoot Java memory leaks.

- To activate Automatic Leak Detection, you need the Configure Agent Properties permission.
- To start an On Demand Capture Session, you need the Advanced Agent Operation permission. See [Manage Custom Roles](#).

The garbage collection feature of the JVM greatly reduces the opportunities to introduce memory leaks into a codebase. However, because garbage collection does not eliminate memory leaks completely, AppDynamics includes Automatic Leak Detection for supported JVMs.

## Automatic Leak Detection

You can access **Automatic Leak Detection** on the Memory tab of the Node Dashboard. **Automatic Leak Detection** is disabled by default because it increases overhead on the JVM. You should enable leak detection mode only when you suspect a memory leak problem. Turn off **Automatic Leak Detection** after you identify the cause for the leak.

Automatic Leak Detection uses **On Demand Capture Sessions** to capture actively used collections, any class that implements JDK Map or Collection interface during the capture period. The default capture period is 10 minutes.

AppDynamics tracks every Java collection that meets the following criteria:

- The collection has been alive for at least 30 minutes.
- The collection has at least 1000 elements.
- The collection Deep Size is at least 5 MB. The agent calculates Deep Size by traversing recursive object graphs of all the objects in the collection.

The following node properties define the defaults for leak detection criteria:

- `minimum-age-for-evaluation-in-minutes`
- `minimum-number-of-elements-in-collection-to-deep-size`
- `minimum-size-for-evaluation-in-mb`

See [App Agent Node Properties](#).

The Java Agent tracks the collection and identifies potential leaks using a linear regression model. You can identify the root cause of the leak by tracking frequent access to the collection over a period of time.

After it qualifies a collection, AppDynamics monitors the collection size for a long-term growth trend. Positive growth indicates the collection is the potential source of a memory leak.

After AppDynamics identifies a leaking collection, the Java Agent automatically triggers diagnostics every 30 minutes. The diagnostics capture a shallow content dump and activity traces of the code path and business transactions that access the collection. You can drill down into any leaking collection monitored by the agent, to manually trigger Content Summary Capture and Access Tracking sessions.

You can also monitor memory leaks for custom memory structures. Typically custom memory structures are used as caching solutions. In a distributed environment, caching can easily become a prime source of memory leaks. It is therefore important to manage and track memory statistics for these memory structures. To do this, you must first configure custom memory structures. See [Custom Memory Structures for Java](#).

## Workflow to Troubleshoot Memory Leaks

You can use this workflow to troubleshoot memory leaks on JVMs that have been identified with a potential memory leak problem:

1. Monitor memory for potential JVM memory leaks.
2. Enable automatic leak detection.
3. Start an on demand capture session.
4. Detect and troubleshoot leaking conditions.

## Monitor Memory for Potential JVM Leaks

Use the **Node** dashboard to identify the memory leak. A possible memory leak is indicated by a growing trend in the heap as well as the old/tenured generation memory pool.

An object is automatically marked as a potentially leaking object when it shows a positive and steep growth slope.

The **Automatic Memory Leak** dashboard shows:

- **Collection Size**—The number of elements in a collection.
- **Potentially Leaking**—Potentially leaking collections display as red. You should start diagnostic sessions on potentially leaking objects.
- **Status**—Indicates if a diagnostic session has been started on an object.
- **Collection Size Trend**—A positive and steep growth slope indicates a potential memory leak.

To identify long-lived collections, compare the JVM start time and Object Creation Time.

If no captured collections display, ensure that you have the correct configuration for detecting potential memory leaks.

### Enable Memory Leak Detection

Memory leak detection is available through the **Automatic Leak Detection** feature. Once the **Automatic Leak Detection** feature is turned on and a capture session has been started, AppDynamics tracks all frequently used collections. Therefore, using this mode results in higher overhead.

1. Turn on **Automatic Leak Detection** mode only when a memory leak problem is identified
2. Click **Start On Demand Capture Session** to start monitoring frequently used collections and detect leaking collections.
3. After you identify and resolve the leak, turn the capture session and the leak detection modes off.
4. Start diagnosis on one individual collection at a time to achieve optimum performance.

### Troubleshoot Memory Leaks

After detecting a potential memory leak, troubleshooting the leak involves performing these three actions:

- [Select the Collection Object that you want to monitor](#)
- [Use Content Inspection](#)
- [Use Access Tracking](#)

### Select the Collection Object to Monitor

On the Automatic Leak Detection dashboard, right-click the class name and click **Drill Down**.

For performance reasons, start the troubleshooting session on a single collection object at a time.

### Use Content Inspection

Content Inspection identifies which part of the application the collection belongs to so that you can start troubleshooting. It allows monitoring histograms of all the elements in a particular collection.

Enable Automatic Leak Detection by starting an On Demand Capture Session, select the object you want to troubleshoot, and then follow the steps listed below:

1. Click the Content Inspection tab.
2. Click **Start Content Summary Capture Session** to start the content inspection session.
3. Enter the session duration. Allow at least 1 – 2 minutes for data generation.
4. Click **Refresh** to retrieve the session data.
5. Click on the snapshot to view details about an individual session.

## Use Access Tracking

Use Access Tracking to view the actual code paths and business transactions accessing the collections object.

As described above in [Workflow to Troubleshoot Memory Leaks](#), enable Automatic Leak Detection, start an On Demand Capture Session, select the object you want to troubleshoot, and then follow the steps listed below:

1. Select the Access Tracking tab
2. Click **Start Access Tracking Session** to start the tracking session.
3. Enter the session duration. Allow at least 1-2 minutes for data generation.
4. Click **Refresh** to retrieve session data.
5. Click the snapshot to view details about an individual session.

The troubleshooting information pane shows the Java stack trace associated with the session. By default, the stack trace is shown to a depth of 10 lines. If you would like to temporarily increase the number of lines captures, you can use the `maximum-activity-trace-stack-depth` Java Agent property described on [App Agent Node Properties Reference](#).

Increasing the stack trace depth can consume a significant amount of system resources. You must remove the property or set it back to the default value of 10 after you have captured the desired information.

## Java Memory Thrash

Memory thrash is caused when a large number of temporary objects are created in very short intervals. Although these objects are temporary and are eventually cleaned up, the garbage collection mechanism may struggle to keep up with the rate of object creation. This may cause application performance problems. Monitoring the time spent in garbage collection can provide insight into performance issues, including memory thrash.

For example, an increase in the number of spikes for major collections either slows down a JVM or indicates potential memory thrash. Use object instance tracking to isolate the root cause of the memory thrash. To configure and enable object instance tracking, see [Object Instance Tracking for Java](#).

AppDynamics automatically tracks object instances for the top 20 core Java (system) classes and the top 20 application classes.

The Object Instance Tracking subtab provides the number of instances for a particular class and graphs the count trend of those object in the JVM. It provides the shallow memory size (the memory footprint of the object and the primitives it contains) used by all the instances.

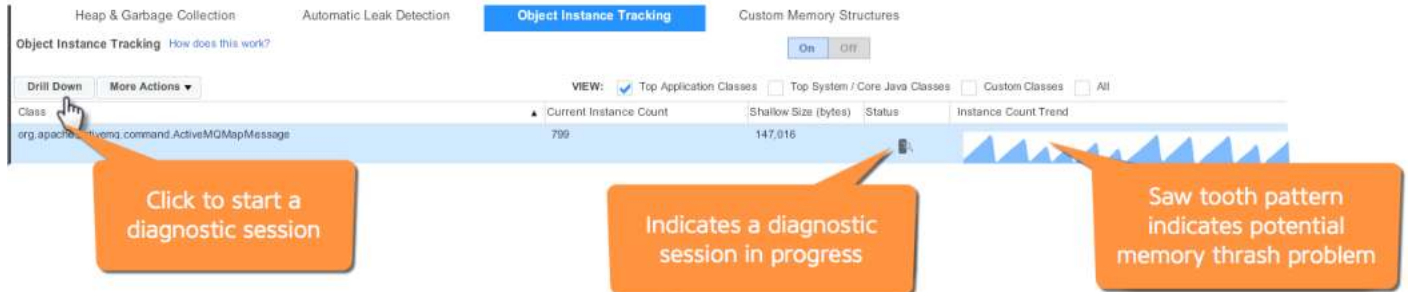

## Analyze Memory Thrash

Once a memory thrash problem is identified in a particular collection, start the diagnostic session by drilling down into the suspected problematic class.

Select the class name to monitor and click **Drill Down** at the top of the Object Instance Tracking dashboard or right-click the class name and select the **Drill Down** option.

 For optimal performance, trigger a drill-down action on a single instance or class name at a time.

After the drill down action is triggered, data collection for object instances is performed every minute. This data collection is considered to be a diagnostic session and the Object Instance Tracking dashboard for that class is updated with this icon , to indicate that a diagnostic session is in progress.

The Object Instance Tracking dashboard indicates possible cases of memory thrash. Prime indicators of memory thrash problems indicated on the Object Instance Tracking dashboard are:

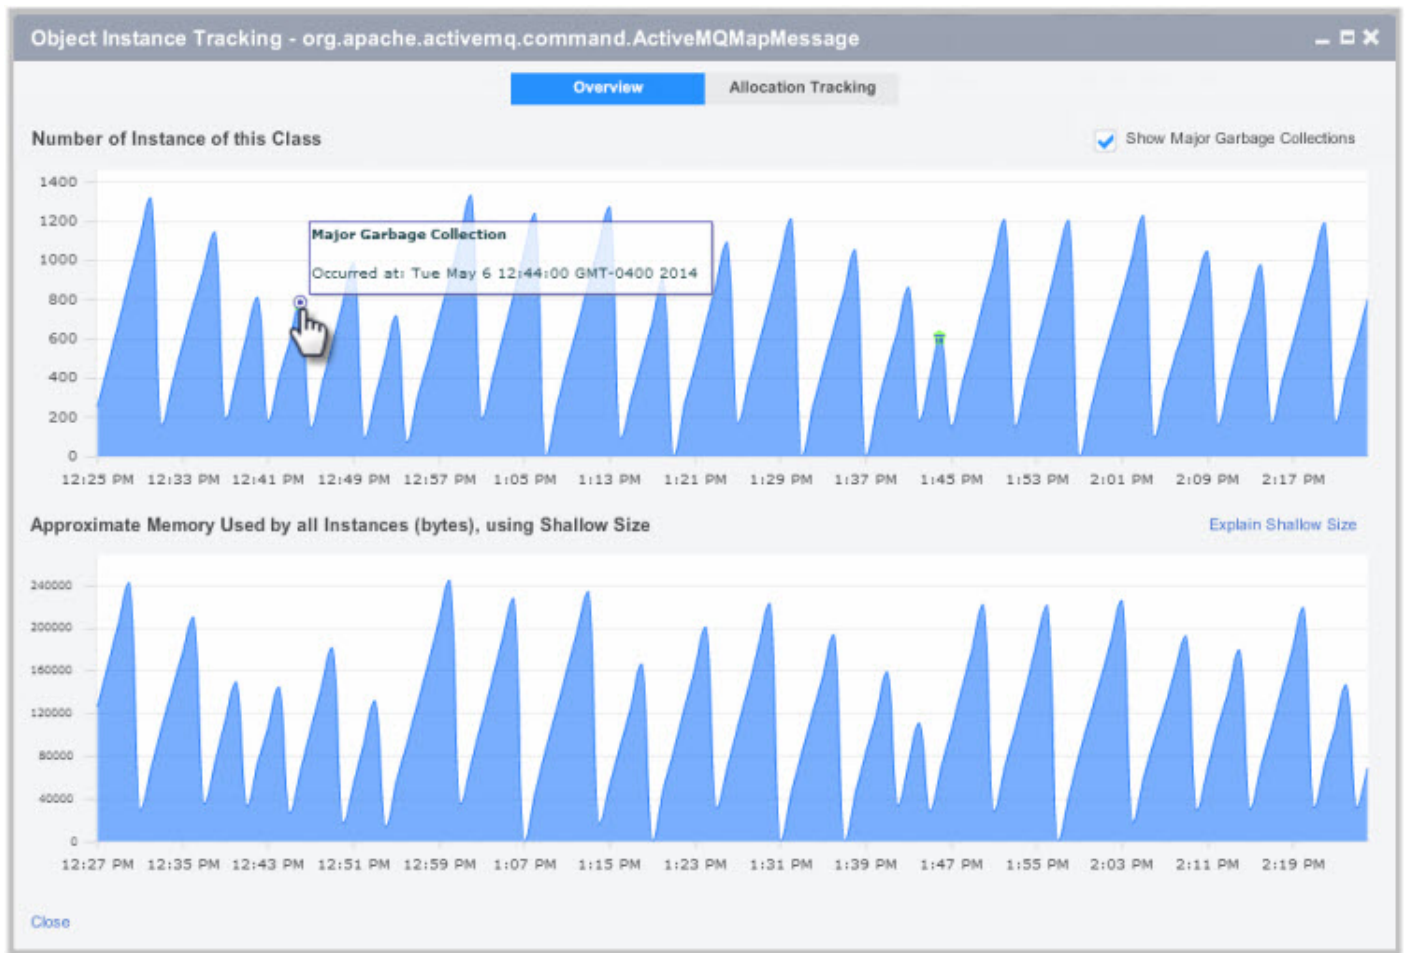

- **Current Instance Count:** A high number indicates the possible allocation of a large number of temporary objects.
- **Shallow Size:** Is the approximate memory used by all instances in a class. A large number for shallow size signals potential memory thrash.
- **Instance Count Trend:** A saw wave is an instant indication of memory thrash.

If you suspect you have a memory thrash problem at this point, then you should verify that this is the case. See [To verify memory thrash](#).

### Verify Memory Thrash

Select the class name to monitor and click **Drill Down** at the top of the Object Instance Tracking dashboard. On the Object Instance Tracking window, click **Show Major Garbage Collections**.

The following Object Instance Tracking Overview provides further evidence of a memory thrash problem.

If the instance count doesn't vary with the garbage collection cycle, it is an indication of a potential leak and not a memory thrash problem. See [Java Memory Leaks](#).

### Troubleshoot Java Memory Thrash Using Allocation Tracking

Allocation Tracking tracks all the code paths and those business transactions that are allocating instances of a particular class. It detects those code path/business transactions that are creating and throwing away instances.

To use allocation tracking:

1. Using the **Drill Down** option, trigger a diagnostic session.
2. Click the Allocation Tracking tab.
3. Click **Start Allocation Tracking Session** to start tracking code paths and business transactions.
4. Enter the session duration and allow at least 1 to 2 minutes for data generation.
5. Click **Refresh** to retrieve the session data.
6. Click a session to view its details.
7. Use the Information presented in the Code Paths and Business Transaction panels to identify the origin of the memory thrash problem.

## Monitor Java Object Instances

If the application uses a JRE (rather than a JDK), use these steps to enable object instance tracking:

1. Ensure the tools.jar file is in the `jre/lib/ext` directory.
2. On the Node Dashboard, click the Memory tab.
3. On the Memory tab, click the Object Instance Tracking subtab.
4. Click **On** and then **OK**.

See [Object Instance Tracking for Java](#).

## Code Deadlocks for Java

By default, the Java Agent detects code deadlocks. You can find deadlocks and see their details using the Events list or the REST API.

### Code Deadlocks and Their Causes

In multi-threaded development environments, it is common to use more than a single lock. However, sometimes deadlocks will occur. Here are some possible causes:

- The order of the locks is not optimal
- The context in which they are being called (for example, from within a callback) is not correct
- Two threads may wait for each other to signal an event

### Finding Deadlocks Using the Events List

Select **Code Problems** (or just **Code Deadlock**) in the Filter By Event Type list to see code deadlocks in the Events list. The following list shows two deadlocks in the ECommerce tier.

Type	Summary	Time	Business T	Tier	Node	Policy
Code Deadlock	JVM de...	09/19/12 4:		EComm...		
Code Deadlock	JVM de...	09/19/12 4:		EComm...		

To examine a code deadlock, double-click the deadlock event in the events list and then click the Code Deadlock Summary tab. Details about the deadlock are in the Details tab. See [Monitor Events](#).

---

## Find Deadlocks Using the REST API

You can detect a DEADLOCK event-type using the AppDynamics REST API. For details, see the example [Retrieve event data](#).

## Thread Contention

Works with:

Thread contention arises when two or more threads attempt to access the same resource at the same time. This page describes how AppDynamics helps you diagnose and resolve thread contention issues.

### Performance Issues Resulting from Thread Contention

Multithreaded programming techniques are common in applications that require asynchronous processing. Although each thread has its own call stack in such applications, threads may need to access shared resources, such as a lock, cache, or counter. See [Enabling Thread Correlation](#).

While synchronization techniques can help to prevent interference between threads in such scenarios, they may nevertheless compete for access to shared resources. This can result in application performance degradation or even data integrity issues.

AppDynamics can help you identify and resolve problems relating to thread contention in business transactions and service endpoints. See [Trace Multithreaded Transactions for Java](#).

### Thread Contention Detection

AppDynamics detects thread contention based on the thread state of the instrumented application.

It identifies these block or waiting states in the JVM:

- Acquiring a lock ( `MONITOR_WAIT` )
- Waiting for a condition ( `CONDOR_WAIT` )
- Sleeping ( `OBJECT_WAIT` )
- A blocking I/O operation

The `OBJECT_WAIT` state is triggered when the application makes one of the following calls:

- `Thread.sleep`
- `Object.wait`
- `Thread.join`
- `LockSupport.parkNanos`
- `LockSupport.parkUntil`
- `LockSupport.park`

The Controller alerts you to possible thread contention problems in the **Potential Issues** pane of the Business Transaction Flow Map. From there, you can use the browser to access additional information about blocked and waiting threads in business transactions or service endpoints, and determine the cause of the performance problem.

The following sections explain how you use the browser to surface contention information for business transaction and service endpoints.

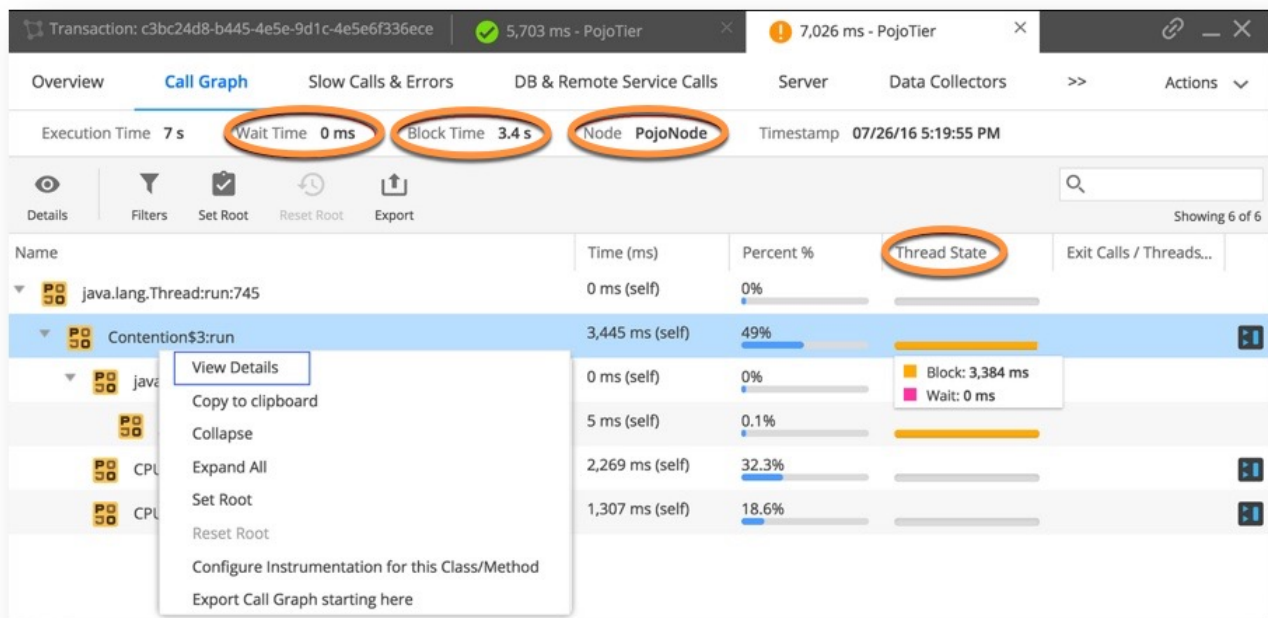

## Thread Contention in Transaction Snapshots

To view information about thread contention:

1. In the transaction snapshot navigation page, look for items labeled as *Thread Contention* issues in the **Potential Issues** pane. The time column indicates blocked or wait time:

Potential Issues		
	com.pcappd.threadcontention.CPUBurnerUtil.findPrimes	18.8 s
	java.lang.Object.wait	12 s
	com.pcappd.threadcontention.MultiLock\$4.run	6.4 s
	Thread Contention - Blocked on java.lang.Object@246ae04d	6.4 s

2. To display more information about the blocked method, click the thread contention item and select **Drill Down into Call Graph**:

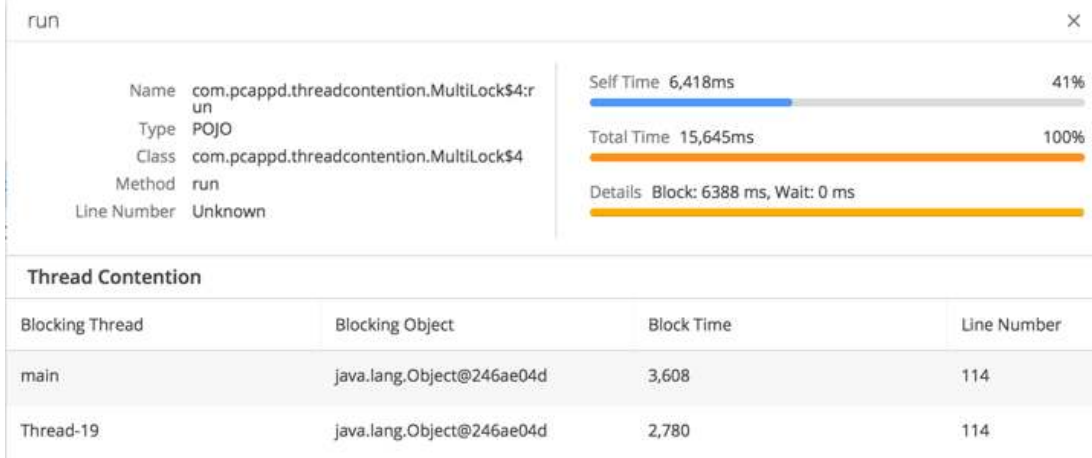

The call graph shows the following information relevant to thread contention:

- In the **Call Graph** header, **Wait Time** and **Block Time** indicate aggregate measures for the thread in one segment of the business transaction.
- In the **Call Graph** header, **Node** specifies the name of the node hosting the contending threads, `PojoNode` in the example above.
- The **Time** column indicates the total self time for the method.
- The **Percent%** column shows the amount of time spent in the method as a percentage of overall time for the thread.
- The **Thread State** Column indicates the degree of thread contention issues for the method. Gray means no problems; yellow to red shading signals the severity of contention problems.

(When you hover over the bar, a breakdown of the elements that make up the thread state is shown: This includes Block time and Wait time by default. To include Cpu Time in the Thread State detail, Dev mode must be enabled.)

- Right-click on any method with a thread state that indicates block or wait times and select **View Details**. The Thread Contention details pane appears:

The Thread Contention details pane displays the name of the blocked method in the top left corner and adds the following information in the Thread Contention table:

Element	Meaning
Blocking Thread	The thread holding a lock on the blocking object.
Blocking Object	The object that the blocked thread is waiting to access.
Block Time	The amount of time waiting to access the object.
Line Number	The line number in the blocked method where the blocking object is being accessed. With respect to the example above, <code>run</code> is attempting to access a locked object at line 114.

The order in which blocking threads are shown in the table is not significant; it does not imply a call order or time sequence.

**i** In **development mode**, AppDynamics reports explicit locks such as `java.util.concurrent.locks.ReentrantLock` as **Wait Time** instead of **Block Time** in the Thread Details Call Graph view. Take this into consideration when monitoring business transactions and analyzing performance related to lock contentions.

### Thread Contention in Service Endpoints

You can view thread contention information for service endpoint methods in AppDynamics. Call graphs identify service endpoint methods with this icon: .

Select **More > Service Endpoints** from the menu bar to view thread contention information by service endpoint.

### Export Contention Information

When you export the Call Graph for a Business Transaction, AppDynamics includes Transaction Contention information.

- The Summary pane includes **Block Time** data: the block time specified is the sum of all block times for the blocked methods shown in the CallGraph pane.

Summary	
User Experience	VERY_SLOW
Execution Time	7026 ms
CPU Time	2158 ms (30.71%)
<b>Block Time</b>	<b>3389 ms (48.24%)</b>
Transaction Timestamp	07/26/16 5:19:55 PM (server) 07/26/16 5:10:26 PM (agent)
Summary	[Continuing] Request was slower than the Standard Deviation threshold: 4.0
Tier	PojoTier
Node	PojoNode
Business Transaction	MultiObjLockBT

- The Call Graph pane lists block time by method:

### Call Graph

```

java.lang.Thread:run: 745(execution time: 0 ms of 7026 ms total, block time: 0 ms of 3389 ms total)
Contention$3:run: Unknown (execution time: 3445 ms of 7026 ms total, block time: 3384 ms of 3389 ms total)
java.util.concurrent.locks.ReentrantLock:lock: 285(execution time: 0 ms of 5 ms total, block time: 0 ms of 5 ms total)
java.util.concurrent.locks.LockSupport:park: 175(execution time: 5 ms of 5 ms total, block time: 5 ms of 5 ms total)
CPUBurnerUtil:findPrimes: Unknown (execution time: 2269 ms of 2269 ms total)
CPUBurnerUtil:findPrimes: Unknown (execution time: 1307 ms of 1307 ms total)

```

## Event Loop Blocking in Node.js

You can use process snapshots to examine Node.js event loop activity and identify functions with high CPU times that are blocking the event loop.

### Latency in Node.js Event Loops

The event loop of a Node.js process is a single thread that polls for incoming connections and executes all application code. When a Node.js request makes a call to an external database, remote service or the filesystem, the event loop automatically directs the application's control flow to some other task, including other connections or callbacks.

---

CPU-intensive operations block the event loop, preventing it from handling incoming requests or finishing existing requests. A CPU-intensive operation in one business transaction may cause slowness in other business transactions.

## Process Snapshots In AppDynamics

A process snapshot describes an instance of a CPU process on an instrumented Node.js node. It generates a process-wide flame graph for a Node.js process over a configurable time range.

Process snapshots provide visibility into the Node.js event loop across all business transactions for the duration of the process snapshot. Process snapshots are useful when the main troubleshooting tools (such as, business transaction snapshots) are inconclusive because the source of latency is a CPU-intensive operation in another business transaction. You can use lists of process snapshots to identify which functions have high CPU times. From the list, you can select and examine process snapshots to identify exactly which functions in your code are blocking the CPU.

For a given Node.js node or tier, you can access the list of process snapshots from the Process Snapshots tab of the node or tier dashboard. You can filter the process snapshot list to display only the snapshots that you are interested in. You can filter by execution time, whether the snapshot is archived, and the GUID of the request. If you access the list from the tier dashboard, you can also filter by node.

For more information on how process snapshots are generated and how to configure them, see [Manage Node.js Process Snapshots](#).

To learn how process snapshots and business transaction snapshots are created, see [Process Snapshots and Business Transaction Snapshots](#).

Process snapshots persist for 14 days, unless you archive them, in which case they are available forever.

A process snapshot contains these tabs:

- Overview
- Flame Graph
- Call Graph
- Allocation Call Graphs
- Hot Spots

### Overview

Summarizes the snapshot. Contents vary based on the available information.

Usually contains at least the total execution time, tier and node of the process, timestamp, slowest method and request GUID.

### Flame Graph

Provides a visualization of each stack frame's frequency on the CPU over the duration of a process snapshot. The frame's position relative to the bottom-most stack depicts the call-stack depth.

The flame graph contains the same information as the call graph, but allows you to quickly spot methods that are consuming more CPU resources relative to others.

The method corresponding to the stack frame on the top edge of the flame graph represents the method's CPU resource consumption frequency.

To identify long-running CPU executions, look for long horizontal cells on the top edge of the flame graph.

A healthy Node.js process has minimal CPU-blocking activity; correspondingly, a flame graph for a healthy Node.js process has minimal long, horizontal cells along the top edge of its flame graph. See [The Flame Graph](#).

### Call Graph

Shows the total execution time and the percentage of the total execution time of each method on the process's call stack. The numbers at the ends of the methods are the line numbers in the source code. You can filter out methods below a certain time to simplify the graph and isolate the trouble spots.

The **Time** and **Percentage** columns identify which calls take the longest time to execute.

To see more information about a call, select the call and click **Details**.

### Allocation Call Graph

Available only for process snapshots that are collected manually. See [Manage Node.js Process Snapshots](#).

Shows the amount and percentage of the memory allocated and not freed by each method on the process's call stack during the process snapshot. You can use the **Method Size** slider to configure how much memory a method must allocate to be displayed in the allocation call graph. You can also filter out methods that consume less than a certain amount of memory to simplify the graph and isolate the trouble spots.

The **Size** and **Percentage** columns identify which calls consume the most memory.

The agent cannot report allocations made prior to the beginning of the allocation snapshot.

The allocation reported in the snapshot is the memory that is still referenced when the snapshot ends: memory allocated during the snapshot period minus memory freed during the snapshot period.

For more information about a call, select the call and click **Details**.

### Hot Spots

This tab displays the calls by execution time, with the most expensive calls at the top. To see the invocation trace of a single call in the lower panel, select the call in the upper panel.

Use the **Method Time** slider in the upper right corner to configure how slow a call must be to be considered a hot spot.

### Manage Node.js Process Snapshots

#### Related pages:

- [Event Loop Blocking in Node.js](#)
- [Node.js Metrics](#)
- [Process Snapshots and Business Transaction Snapshots](#)

This page describes how process snapshots are generated and viewed.

### Automatic Process Snapshot Generation

When a business transaction snapshot is triggered by periodic collection or by a diagnostic session, a ten-second process snapshot is automatically started. By default, the agent starts no more than two process snapshots per minute automatically, but this behavior is configurable.

You can also start process snapshots manually on demand. See [Collect Process Snapshots Manually](#).

---

## Configure Automatic Collection

You can configure automatic process snapshot collection using these settings:

- `processSnapshotCountResetPeriodSeconds` : Frequency, in seconds, at which the automatic process snapshot count is reset to 0; default is 60 seconds.
- `maxProcessSnapshotsPerPeriod` : Number of automatic process snapshots allowed in `processSnapshotCountResetPeriodSeconds` seconds; default is 2 snapshots.
- `autoSnapshotDurationSeconds` : Duration of an automatically-generated process snapshot; default is 10 seconds.

To configure these settings, add them to the `require` statement in your application source code as described in [Install the Node.js Agent](#). Then stop and restart the application.

## Collect Process Snapshots Manually

If you want to generate some process snapshots now, you can start them manually.

1. Navigate to the dashboard for the tier or node for which you want to collect process snapshots.
2. Click the Process Snapshots tab.
3. Click **Collect Process Snapshots**.
4. If you are in the **Tier** dashboard, select the node for which you want to collect snapshots from the **Node** dropdown. If you are in the **Node** dashboard, you can only set up snapshot collection for that node.
5. Enter how many seconds you want to collect process snapshots for this node. The maximum is 60 seconds.
6. Click **Create**.

The agent collects process snapshots for the configured duration. Process snapshots that are started manually include an allocation call graph that shows how much memory has been allocated and not freed during the period recorded by the snapshot.

## Process Snapshots and Business Transaction Snapshots

### Related pages:

- [Troubleshoot Business Transaction Performance with Transaction Snapshots](#)
- [Manage Node.js Process Snapshots](#)

This page explains the relationship between transaction snapshots and process snapshots created by the Node.js Agent.

## V8 Sampler

Node.js is built on the V8 JavaScript engine, which includes a code sampler.

The Node.js Agent uses the V8 sampler to create process-wide [process snapshots](#), which contain call graphs of the methods on the Node.js process's call stack.

## Call Graph Data in Snapshots

Call graph data displays in business transaction snapshots as well as process snapshots.

When you view a business transaction snapshot, the displayed call graph specific to the transaction instance is derived from the concurrent process snapshot call graph.

When you view a process snapshot, the complete call graph of all the business transactions executed while the process snapshot was captured is displayed.

The call graph in a business transaction snapshot displays a view of the data from a concurrent process snapshot that is filtered to display only time in methods attributable to the specific business transaction. It is a subset of the concurrent process snapshot call graph.

For this reason, you might see an execution time for a method in a business transaction call graph that is less than the execution time for the same method in the concurrent process snapshot call graph. This would indicate that some calls to that method were made outside the context of the business transaction instance captured by the transaction snapshot.

The summary tab of a transaction snapshot includes a link to the process snapshot that was taken during the time covered by the transaction snapshot.

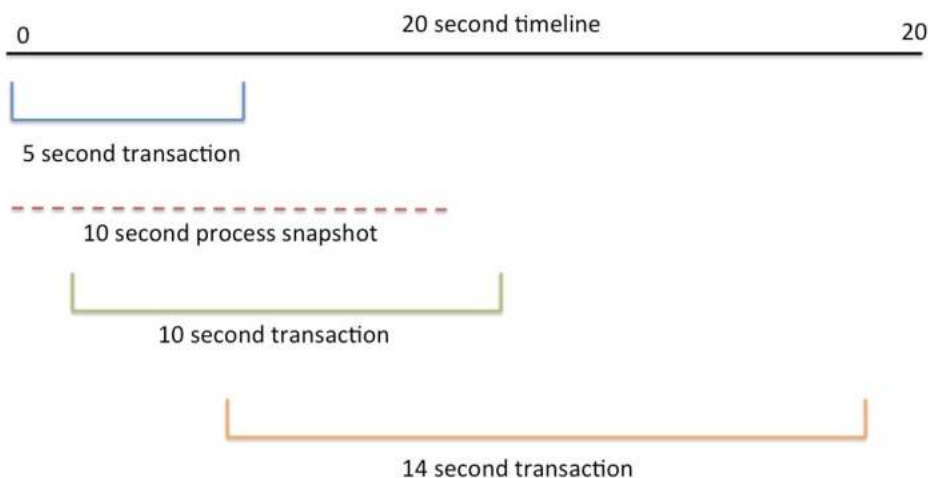

### Business Transaction Snapshots Trigger Process Snapshots

To provide call graph data associated with business transaction snapshots, the agent starts a ten-second process snapshot whenever it starts a business transaction snapshot that is triggered by periodic collection or a diagnostic session if there is no existing process snapshot in progress for the current process. Process snapshots do not overlap. Periodic collection means that a business transaction is collected at periodic intervals, by default every ten minutes, but configurable. Diagnostic session means that either the agent has detected a pattern of possible performance issues and automatically started capturing transaction snapshots or a human has manually started a diagnostic session for the same reason.

### Concurrent Business Transaction and Process Snapshots

The result presented is a process snapshot that ran concurrently with a business transaction. How well the two snapshots line up depends on the relative durations and start times of the transaction and the process snapshots.

In the scenario sketched below, all of the five-second blue transaction's calls, and most of the 10-second green transaction's calls are captured by a 10-second process snapshot, but only the about half of the 14-second orange transaction snapshot's calls.

If you find that your business transactions are running longer than your process snapshots, you can increase the default length of a process snapshot in the `autoSnapshotDurationSeconds` setting in the `require` statement.

## App Server Agents Supported Environments

This page provides an aggregated view of the supported environments for the App Server agents.

**i** App Server agents have been tested successfully on AWS Outposts using these instructions: [Install App Server Agents](#)

### Java Agent

This page lists the application environments and versions supported by the AppDynamics Java Agent.

**i** If your application environment is unavailable in the Supported Environments list, suggest it as an idea in the [AppDynamics Idea Exchange](#) portal.

### Java Agent Supported Platforms

In the following tables, note that:

- A dash ("-") in a table cell indicates that this column is not relevant or not supported for that particular environment.
- In cases where no version is provided, assume that all versions are supported. Contact AppDynamics Sales for confirmation.
- For environments that require additional configuration, a separate table describing or linking to configuration information follows the support matrix.
- For environments supported by AppDynamics End User Monitoring, see [Supported Environments and Versions - Web EUM](#).
- For environments supported by AppDynamics Server Visibility, [Machine Agent Requirements and Supported Environments](#).

### JVM Support

The AppDynamics Java Agent uses the standard JVM Tool Interface (JVMTI) mechanism allowing it to instrument any software running on a JVM supporting this mechanism.

AppDynamics certifies the successful operation of the basic mechanisms of instrumentation used by the agent on the following Java runtimes. These capabilities are supported on both JRE or full JDK installations.

Where the agent supports the following advanced memory monitoring features, they are listed for the JVM: Object Instance Tracking (OIT), Automatic Leak Detection (ALD), Content Inspection (CI), and Access Tracking (AT).

**i** Unless listed on this page, builds downloaded from other sources are not officially supported.

JVM	OS	Memory Monitoring Features
Eclipse Adoptium 17, 18, 19, and 20	Linux, Windows, MacOS	OIT (supported only for Hotspot JVM), ALD, CI, AT

JVM	OS	Memory Monitoring Features
Amazon Corretto 8, 11, 17, 18, 19, and 20	Linux, Windows	OIT, ALD, CI, AT
Azul Zing 15.x.	Linux x64	OIT, ALD
Azul Zulu OpenJDK 8, 9, 10, 11, 13, 14, 15, 16, 17, 18, and 19  JDK11 is supported from 4.5.6 onwards  JDK13 is supported from 4.5.15 onwards  JDK14 is supported from 20.4.0 onwards  JDK15 is supported from 20.10.0 onwards  JDK16 is supported from 21.4.0 onwards  JDK17 is supported from 21.11.0 onwards  JDK18 is supported from 22.7.0 onwards  JDK19 is supported from 23.1.0 onwards	Linux, Windows	OIT, ALD, CI, AT
JVM - BellSoft Liberica JDK 8, 11, 16, 17, 18, and 19	Linux, Windows, MacOS	OIT, ALD
GraalVM 20.0.0, 20.2.0, 21.1.0, 21.3.0	Linux, Windows, MacOS	OIT, ALD, CI, AT
HP OpenVMS		

JVM	OS	Memory Monitoring Features
IBM JVM 1.8.x	AIX, HP-UX, Linux, Solaris, Windows, z/OS	<p>ALD, CI</p> <p>Object instance tracking, automatic leak detection, and custom memory structure monitoring are not supported with the AppDynamics IBM Java Agent. IBM JVMs can be instrumented with the AppDynamics Sun Java Agent to work around this limitation; however, this only enables automatic leak detection and custom memory structure monitoring.</p> <p>Object instance tracking is not available. Working around this limitation can result in negative performance impact and is not recommended. In such cases, the IBM JVM needs to be restarted to enable custom memory structure monitoring.</p>
Oracle Rockit JVM 28.1+	Linux Intel 64, Windows	

JVM	OS	Memory Monitoring Features

## JVM Application Server and Framework Support

AppDynamics supports the use of the Java Agent to instrument any application component running on a supported JVM, irrespective of how that component is built. It can automatically discover the topology and behavior of complex enterprise applications without requiring deep technical knowledge of the application's underlying code.

Frequently, Java-based systems employ standard framework code to implement business logic. Automatic instrumentation of framework code relies on knowledge of the business logic and programming patterns employed by the framework. AppDynamics instrumentation targets processing hand-offs between components, called [entry points and exit points](#), either within the JVM or between JVMs. This includes hand-offs between frameworks in cases where multiple frameworks are being used together. This section covers the capabilities for frameworks for which AppDynamics provides automatic detection rules.

Monitoring application components built using frameworks not listed here may require custom configuration. The custom configuration may involve, for example, custom [POJO entry](#) or [exit points](#). If you understand how the application behaves internally, you can easily configure this type of instrumentation. For more complex configuration tasks, contact your account representative to discuss how to engage the AppDynamics customer success organization.

## JVM Language Frameworks Support

No additional configuration is required for these frameworks.

Vendor	JVM Language Framework	Version	Correlation/Entry Points	Exit Points	Transports	Notes
Open Source	Akka Actor	2.1 – 2.5.x	Yes	Yes	Netty	4.3.1 required for 2.4.x 2.5x support includes Persistence Remoting exit/entry supported

Vendor	JVM Language Framework	Version	Correlation/Entry Points	Exit Points	Transports	Notes
Open Source	Akka HTTP Name: akka-http-stream-entry - enabled Type: Boolean Default: False	Akka Actor 2.6 Akka HTTP upto 10.2.6 Scala 2.11, 2.12	Yes	Yes	HTTP	EUM is supported Support for Non-Route DSL
Open Source	Http4s Blaze Client	Blaze versions: 0.21.1, 0.21.0, 0.20.23, 0.20.5 scala 2.11, 2.12	No	Yes	HTTP	-
Open Source	Groovy	-	Yes	Yes		
Open Source	Ktor	1.0.x -1.6.x	Yes (Netty Engine)	-	HTTP	EUM is supported
Open Source	Play for Scala Play for Java	2.1 – 2.8 Scala 2.11, 2.12	Yes	-	HTTP over Netty server Akka HTTP server	Includes framework specific entry and exit points Play EUM-APM correlation supported
Open Source	Scala	2.11.6				

Vendor	JVM Language Framework	Version	Correlation/Entry Points	Exit Points	Transports	Notes
Open Source	Spray toolkit ( <a href="#">Spray.io</a> )	1.1.x 1.1.3	Yes	Yes	HTTP	Entry points are detected and configurable as <a href="#">servlet entry point</a> and exit points as HTTP exits
Pivotal	Grails	-	-	-	-	

### Java Framework Support

The Java Agent supports these Java frameworks. Some require additional configuration as indicated in the Configuration Notes column.

Vendor	Framework	Version	SOA protocol (WebServices)	Auto Naming	Entry Points	Exit Points	Detection	Configuration Notes
Adobe	BlazeDS	-	HTTP and JMS adaptor	-	Yes		-	See <a href="#">Example Message Queue Backend Configuration</a> .
Adobe	ColdFusion	8.x, 9.x	-	-	Yes	-	Configuration required for transaction discovery	Configuration is required for transaction discovery. See: <ul style="list-style-type: none"> <li>• <a href="#">Java Business Transaction Detection</a></li> <li>• <a href="#">Servlet Entry Points</a></li> </ul>

Vendor	Framework	Version	SOA protocol (WebServices)	Auto Naming	Entry Points	Exit Points	Detection	Configuration Notes
Apache	Cassandra with Thrift framework	-	-	-	Yes	Yes	Apache Thrift Entry and Exit points are detected

By default, the value of this property is false.</p>
Open Source	WebSocket	1.0 (Java EE 7, JSR-356)	Yes, correlation not supported	Yes	Node property: <a href="#">websocket-entry-calls-enabled</a>

## Application Servers

The Java Agent supports the following application servers. Some require additional configuration. Click the link on the server or OSGi Runtime for information about additional requirements or related configuration topics. The agent usually discovers application servers as an entry point.

Vendor	Application Server / OSGi Runtime	Version	SOA Protocol	RMI Supported	JMX	Entry Points	Configuration Notes
Adobe	Cold Fusion	8.x, 9.x	-	No	-	Yes	Requires configuration for transaction discovery; see <a href="#">Servlet Entry Points</a> .
	Equinox	-	-	-	-	Yes	See <a href="#">OSGi Infrastructure Configuration</a> .
Apache	Felix	-	-	-	-	Yes	See <a href="#">OSGi Infrastructure Configuration</a> .
Apache	Sling	-	-	-	-	Yes	See <a href="#">OSGi Infrastructure Configuration</a> .
Apache	Tomcat	5.x, 6.x, 7.x, 8.x, 9, 10	-	-	Yes	Yes	See <a href="#">Apache Tomcat Startup Settings</a> .
Apache	Resin	1.x - 4.x	-	-	-	-	See <a href="#">Resin Startup Settings</a> .
Eclipse	Jetty	6.x, 7.x, 8x, 9x	-	-	-	-	See <a href="#">Jetty Startup Settings</a> .

Vendor	Application Server / OSGi Runtime	Version	SOA Protocol	RMI Supported	JMX	Entry Points	Configuration Notes
IBM	InfoSphere	8.x	-	-	-	Yes	See <a href="#">IBM WebSphere and InfoSphere Startup Settings</a> .
IBM	WebSphere	6.1, 7.x, 8.x, 9.x	JAX-WS	Yes, detect and correlate	Yes for WebSphere PMI	Yes	See <a href="#">IBM WebSphere and InfoSphere Startup Settings</a> .
Open Source	Liferay Portal	-	-	-	-	-	
Open Source	JBoss EAP	7.1.5, 7.2.0, 7.3.0		Yes		Yes	See <a href="#">JBoss and Wildfly Startup Settings</a> .
Open Source	JBoss Wildfly (formerly JBoss Application Server)	4.x to 26.x		Yes		Yes	See <a href="#">JBoss and Wildfly Startup Settings</a> .
Sun/Oracle	GlassFish Enterprise Server	2.x	-	-	Yes	Yes	See <a href="#">GlassFish Startup Settings</a> .
Oracle	GlassFish Server and GlassFish Server Open Source Edition	3.x, 4.x	-	-	Yes for AMX	Yes	See <a href="#">GlassFish Startup Settings</a> .

Vendor	Application Server / OSGi Runtime	Version	SOA Protocol	RMI Supported	JMX	Entry Points	Configuration Notes
Oracle and BEA	WebLogic Server	9.x+	JAX-WS	Yes, detect and correlate for 10.x  To enable correlation using a header transported in the <code>SOAP:Envelope</code> set node property <code>enable-soap-header-correlation=true</code>	Yes	Yes	See <a href="#">Oracle WebLogic Startup Settings</a> .
Software AG	webMethods	9.5, 9.6, 10.x	-	-	-	Yes	See <a href="#">webMethods Startup Settings</a> .
Tibco	ActiveMatrix BusinessWorks Service Engine	5.x, 6.x	-	To enable correlation using a header transported in the <code>SOAP:Envelope</code> set node property <code>enable-soap-header-correlation=true</code>	-	Yes	See <a href="#">Tibco ActiveMatrix BusinessWorks Service Engine Settings</a> .
	Application Server (OC4J)	-	-	Yes, detect and correlate for 10.x	-	Yes	

Vendor	Application Server / OSGi Runtime	Version	SOA Protocol	RMI Supported	JMX	Entry Points	Configuration Notes
-	Grails, with Tomcat 7.x, Glassfish v3, Weblogic 12.1.1 (12c)	-	-	-	-		

Servlet 3.x detection is not supported.

### PaaS Providers

PaaS Provider	Buildpack
Pivotal Cloud Foundry	See <a href="#">Java Buildpack 3.4 and higher</a> . See <a href="#">Using AppDynamics with Java Applications on Pivotal Cloud</a> .
Red Hat Openshift 3	JBoss EAP 6.4 and 7.x WildFly 8.1 Docker images For documentation and download information, see the <a href="#">AppDynamics Java APM Agent page</a> on the Red Hat Customer Portal.

### Message Oriented Middleware Support

The Java Agent supports the following message oriented middleware environments. Some require additional configuration as indicated in the Configuration Notes column. Message oriented middleware servers are usually found by the Java Agent as an entry point.

Vendor	Messaging Server	Version	Protocol	Correlation/Entry Points	Exit Points	JMX	Configuration Notes
Amazon	Simple Queue Service (SQS)	-	-	Yes (correlation only)	Yes	-	See "Amazon Simple Queue Service Backends" on <a href="#">Java Backend Detection</a> .

Vendor	Messaging Server	Version	Protocol	Correlation/Entry Points	Exit Points	JMX	Configuration Notes
Amazon	Simple Notification Service (SNS)	-	-	No	Yes	-	See "Amazon Simple Notification Service Backends" on <a href="#">Java Backend Detection</a> .
Apache	ActiveMQ	5.x+	JMS 1.x	Yes	Yes	Yes	
Apache	ActiveMQ	5.x+	STOMP	No	-	Yes	
Apache	ActiveMQ	5.8.x+	AMQP 1.0	No	-	Yes	See <a href="#">Example Message Queue Backend Configuration</a> .
Apache	Axis	1.x, 2.x	JAX-WS	Yes	Yes	-	Default exclude rules exist for Apache Axis, Axis2, and Axis Admin Servlets. See also "Web Service Entry Points" on <a href="#">Java Backend Detection</a> .
Apache	Apache CXF	2.1	JAX-WS	Yes	Yes	-	To enable correlation, set node property <code>enable-soap-header-correlation=true</code> .

Vendor	Messaging Server	Version	Protocol	Correlation/Entry Points	Exit Points	J M X	Configuration Notes
Apache	Kafka	0.9.0.0 to 3.0.0	-	Yes	Yes	Yes	Kafka consumer entry points are disabled by default. Correlation is supported. See <a href="#">Apache Kafka Consumer Backends</a> .
Apache	Kafka Streams	<=3.5.1	-	Yes	Yes	-	-
Apache	Synapse	2.1	HTTP	Yes	Yes	-	To enable correlation, set node property <code>enable-soap-header-correlation=true</code>
Fiorano	Fiorano MQ		-	-	-	-

### JDBC Drivers and Database Servers Support

The Java Agent supports these JDBC driver and database server environments. AppDynamics can follow transactions using these drivers to the designated database.

JDBC Vendor	Driver Version	Driver Type	Database Server	Database Version
Apache	10.9.1.0	Embedded or client	Derby	-
Apache	-	-	Cassandra	-

JDBC Vendor	Driver Version	Driver Type	Database Server	Database Version
Progress	DataDirect	data connectivity for ODBC and JDBC driver access, data integration, and SaaS and cloud computing solutions	-	-
IBM	JDBC 3.0 version 3.57.82 or JDBC 4.0 version 4.7.85	DB2 Universal JDBC driver	DB2	9.x
IBM	JDBC 3.0 version 3.66.46 or JDBC 4.0 version 4.16.53	DB2 Universal JDBC driver	DB2	10.1
IBM	-	DB2 Universal JDBC driver	DB2	11.x
IBM	-	Type IV	Informix	-
Maria				1.4.x - 2.6.x
Microsoft	4	Type II	MS SQL Server	2012
Oracle MySQL, MySQL Community	5.x, 6.x, 8.x	Type II, Type IV	MySQL	5.x
Oracle	RAC			
Oracle	9i, 10g 11g, 12c, 18c, 19c	Type II, Type IV	Oracle Database	8i+
Open Source PostgreSQL	42.2.5	Type IV	Postgres	8.x, 9.x, 11x
Sybase	jConnect	Type IV	Sybase	-
Teradata			Teradata	-

**Notes:**

- Type II is a C or OCI driver
- Type IV is a thin database client and is a pure Java driver

## NoSQL/Data Grids/Cache Servers Support

The Java Agent supports these NoSQL, data grids and cache server environments. Some require additional configuration.

Vendor	Database/Data Grid/Cache	Version	Correlation/Entry Points	JM X	Configuration Notes
Amazon	DynamoDB	-	Exit Points	-	See <a href="#">Amazon Web Services</a> .
Amazon	Simple Storage Service (S3)	-	-	-	"Amazon Simple Storage Service Backends" on <a href="#">Java Backend Detection</a> .

### Business Transaction Error Detection

The Java Agent supports the following logging frameworks for business transaction error detection:

- Apache `Log4j` and `Log4j 2`
- `java.util.logging`
- Simple Logging Facade for Java (SLF4J)  
Support for the following method has been added: `public void error(String format, Object... argArray)`
- Logback

To instrument other types of loggers, see [Error Detection](#).

## .NET Agent

### Supported Runtime Environments

This section lists the environments where the .NET Agent does some automatic discovery after little or no configuration. See [Browser RUM Supported Environments](#) for additional supported environments.

**i** Out-of-process IIS applications should be instrumented as standalone applications.

### OS Versions

All versions of Windows (x86/x64) and Linux (x64) operating systems (OS) are supported by the target runtime and operating system vendor.

## Runtimes

**i** AppDynamics only supports versions of .NET Framework that Microsoft currently supports. Previous versions not listed are not supported by Microsoft, or by AppDynamics. See [Microsoft .NET Framework Supported Versions](#).  
However, AppDynamics supports all .NET applications running on the below-mentioned runtimes. For example, when .NET Framework 3.5 SP1 is installed on the server, the .NET Framework 2.0 applications are also supported.

- Microsoft .NET Framework: 3.5 SP1, 4.6.2, 4.7.x, 4.8.x
- Microsoft .NET: 6, 7, 8

## Hosts

- Managed Standalone Applications
- Managed Windows Services
- Microsoft IIS
- Microsoft SharePoint 2010, 2013 as services running inside IIS

## Microsoft Windows Azure

- Azure App Services on Windows in the Azure Portal
  - Web Apps
  - Web Jobs
  - API Apps
  - Container Services

For Azure App Services, certain infrastructure monitoring features are not supported, those include: CLR crash reporting, machine snapshots, and Windows performance counter monitoring.

- Azure Cloud Services
  - Web Roles
  - Worker Roles

## Automatically Discovered Business Transactions

The .NET Agent discovers business transactions for the following frameworks by default. The agent enables detection without additional configuration.

Type	Custom Configuration Options?	Downstream Correlation?
ASP.NET*	Yes	Yes
ASP.NET MVC 2 ASP.NET MVC 3 ASP.NET MVC 4 ASP.NET MVC 5	Yes	Yes
ASP.NET Core	Yes	Yes

Open Web Interface for .NET (OWIN) web API	Yes	Yes
.NET Remoting	No	See <a href="#">Enable Correlation for .NET Remoting</a> .
Windows Communication Foundation (WCF)	No	Yes
Web Services including SOAP	No	Yes
<b>Message Queues</b>		
Apache ActiveMQ NMS framework and related MQs	No	Yes
IBM WebSphere MQ	No	Yes
Microsoft Message Queuing (MSMQ)	No	Yes
Microsoft Service Bus / Windows Azure Service Bus	No	Yes
NServiceBus over MSMQ or RabbitMQ transport	No	Yes
RabbitMQ	Yes	Yes
TIBCO Enterprise Message Service	No	Yes
TIBCO Rendezvous	No	Yes
Windows Azure Queue	No	No

\* The .NET Agent automatically discovers entry points for ASP.NET web forms with the Async property set to "true" in the [Page directive](#).

## Supported Loggers for the .NET Agent

- Log4Net
- NLog
- System Trace
- Windows Event Log
- Loggers on .NET Core that implement the Microsoft.Extensions.Logging.ILogger API

If you are using a different logger, see [Error Detection](#).

## Remote Service Detection

The .NET Agent automatically detects these remote service types. The agent enables detection by default. You do not need to perform extra configuration.

Type	Custom Configuration Options?	Async Detection?*	Downstream Correlation?
CosmosDB: <ul style="list-style-type: none"> <li>v2.x (Microsoft.Azure.DocumentDB.Core)</li> <li>v3.x (Microsoft.Azure.Cosmos)</li> </ul>	No	See <a href="#">Asynchronous Exit Points for .NET</a> .	N/A
Directory Services, including LDAP	No	No	N/A
HTTP	Yes	See <a href="#">Asynchronous Exit Points for .NET</a> .	Yes
MongoDB: C# and .NET MongoDB Driver version 1.10, 2.0	No	See <a href="#">Asynchronous Exit Points for .NET</a> .	N/A
.NET Remoting	Yes	No	See <a href="#">Enable Correlation for .NET Remoting</a> .
WCF	Yes	See <a href="#">Asynchronous Exit Points for .NET</a> .	Yes
WCF Data Services	Yes	No	No
Web Services, including SOAP	Yes	See <a href="#">Asynchronous Exit Points for .NET</a> .	Yes
Azure Service Fabric Remoting v1 and v2—for the .NET Microservices Agent	-	-	-
<b>Data Integration</b>			
Microsoft BizTalk Server 2010, 2013	No	Yes	See <a href="#">Correlation Over Microsoft BizTalk</a> .

Message Queues			
Apache ActiveMQ NMS framework and related MQs	Yes	No	Yes
IBM WebSphere MQ (IBM XMS)	Yes	No	Yes
Microsoft Message Queuing (MSMQ)	Yes	See <a href="#">MSMQ Backends for .NET</a>	See <a href="#">MSMQ Backends for .NET</a>
Microsoft Service Bus / Windows Azure Service Bus	No	Async exit points only	Yes
NServiceBus over MSMQ or RabbitMQ transport	No	See <a href="#">NServiceBus Backends for .NET</a>	Yes
RabbitMQ	See <a href="#">RabbitMQ Backends for .NET</a>	No	Yes
TIBCO Enterprise Message Service	Yes	No	Yes
TIBCO Rendezvous	Yes	No	Yes
Windows Azure Queue	No	No	No

\* The agent discovers asynchronous transactions for the Microsoft .NET 4.5 framework. See [Asynchronous Exit Points for .NET](#).

### Supported Windows Azure Remote Services

Type	Customizable Configuration?	Downstream Correlation?
Azure Blob	No	No
Azure Queue	No	No
Microsoft Service Bus	No	Yes

## Cache Clients

Type	Customizable Configuration?	Async Detection?*	AppD for Databases?
StackExchange.Redis	No	Yes	No

## Data Storage Detection

The .NET Agent automatically detects the following data storage types. The agent enables detection by default. You do not need to perform extra configuration.

Type	Customizable Configuration?	Async Detection?*	AppD for Databases?
ADO.NET (see supported clients below)	Yes	Yes	No
Windows Azure Blob Storage	No	Yes	No
Windows Azure File Storage	No	Yes	No
Windows Azure Table Storage	No	Yes	No

\* The agent discovers asynchronous transactions for the Microsoft .NET 4.5 framework. See [Asynchronous Exit Points for .NET](#).

## Supported ADO.NET Clients

AppDynamics can monitor any ADO.NET client version and type. Clients we've tested include the following:

Database Name	Database Version	Client Type
Oracle	10, 11, 12	ODP.NET
Oracle	10, 11, 12	Microsoft Provider for Oracle
MySQL	5.x	Connector/Net and ADO.NET
Microsoft SQL Server*	2005, 2008, 2012	ADO.NET

\*Microsoft, SQL Server, and Windows are registered trademarks of Microsoft Corporation in the United States and other countries.

## Other Backends

- ADO.NET backend calls (SqlClient, MySql, SQLite, PostgreSQL)
- EntityFramework

## .NET Agent Frameworks for OpenTelemetry

Vendor	Framework	Version(s)	Entry Points	Exit Points
Microsoft	ASP.NET Core	6.0	Yes	-
Microsoft	Web Services (HttpClient)	6.0	-	Yes

## Limitations

- Tier network dashboard is not supported on .NET Core / .NET runtime.
- Node memory is not supported on Linux.
- Cisco Secure Application does not support single file deployment.
- For .NET Framework, AppDynamics reports vulnerable assemblies. To see if an agent is reporting correctly, navigate to the Cisco Secure Application dashboard, go to **Application**, click the desired **Tier**, then click the desired **Node** name. After selecting the **Node**, you can view the **Last Dependency Reported** column.

## Unsupported .NET Features

- [Assembly trimming](#)
- [Assembly unloadability](#)
- [Trim self-contained deployments, and executables](#)

## Node.js Agent

This page provides an overview of supported environments for the Node.js Agent.

 The Node.js Agent is supported on [RedHat](#), and [Docker Hub](#).

## Node.js Agent Versions

Agent Versions	Node.js Versions
23.7.0 - 23.10.0	14, 15, 16, 17, 18, 19, 20
23.5.0	12, 13, 14, 15, 16, 17, 18, 19
23.3.0	12, 13, 14, 15, 16, 17, 18
22.9.0 - 23.2.0	12, 13, 14, 15, 16, 17
21.8.0 - 22.8.0	12, 13, 14, 15, 16

## Operating Systems

- Docker images for Node 18 are only available for Alpine Linux in versions  $\geq 22.11.0$ .
- Alpine Linux Docker  $\geq 3.7$  on 64-bit platform
- Linux distribution based on glibc 2.5 and later and the x86/x86-64 architecture
- Mac OS X  $\geq 10.8$ , x86/x86-64 architecture
- Windows Server 2012 R2 and later on 64-bit platform with Node.js  $\geq 0.12.0$

## Transaction Naming

Entry Type	Default Transaction Naming
Node.js Web	URI

## HTTP Exit Points

Supported HTTP Exit Points
Node.js HTTP client library

See [Node.js Documentation](#) for the Node.js HTTP client library.

## Database Exit Points

Supported Database Exit Points
Cassandra
Couchbase
DynamoDB (using AWS SDK Driver)
Redis (up to 3.x driver only)
Memcached
MongoDB
MSSQL
MySQL
PostgreSQL

- NoSQL  
AppDynamics displays NoSQL databases as Remote Services.

## PHP Agent

### Related pages:

- [PHP Business Transaction Detection](#)

---

## PHP Agent Support

### PHP Versions

PHP Agent supports these versions of PHP:

- 7.4
- 8.0
- 8.1
- 8.2

PHP ZTS Agent supports these versions of PHP:

- 7.4
- 8.0
- 8.1
- 8.2

### PHP Web Servers

Apache 2.2 and 2.4 in these modes:

- `prefork` mode using `mod_php`
- worker MPM mode using `mod_fastcgi` with `php -fpm` or `mod_fcgid` with `php -cgi`

Any web server compatible with `php -fpm`.

### Operating Systems

- Any Linux distribution based on `glibc>=2.17` or `GLIBCXX_>=3.4.19` and the x86 64-bit architecture.
- Alpine Linux `>=3.18`.

 For Alpine Linux, we recommend that you use the latest release of the supported PHP Versions.

 The PHP agent does not support Power Architecture.

**PHP Frameworks and Protocols**

Framework/Protocol	Version < PHP 8	Version = PHP 8	Version = PHP 8.1, 8.2	Entry Point Type
Drupal	7	-	-	Drupal
Drupal	8	9.1+	9.1+	PHP MVC
WordPress	3.4+, 4.x, 5.x	5.6+	*	Wordpress
Zend	1, 2, 3	3+	3+	PHP MVC
CodeIgniter	2.x, 3.x, 4.x	3+	3+	PHP MVC
FuelPHP	1.5x, 1.6x, 1.8x	1.8.2	1.8.2	PHP MVC
Magento	1.5, 1.6, 1.7, 2.3			PHP MVC
Symfony	1, 2, 3, 4	5.2+	5.2+	PHP MVC
CakePHP	2.x, 3.x, 4.x	4+	4+	PHP MVC

Framework/Protocol	Version < PHP 8	Version = PHP 8	Version = PHP 8.1, 8.2	Entry Point Type
Laravel	5.7, 6, 8, 9.x	6.20.+	6.20.+	PHP MVC
HTTP	-	-	-	PHP Web
CLI	-	-	-	PHP CLI

\*For PHP 8.1, the WordPress 5.9+ versions will be supported in upcoming releases. You can still use WordPress, but the agent might not collect the data properly.

**i** PHP 8.x supports the framework versions only from the mentioned versions. The versions below these are not supported.

If your PHP framework is not listed here, the agent detects your entry points as PHP Web and names the business transactions based on the first two segments of the URI — the default naming convention for PHP Web transactions. So it is still possible to monitor applications on *unsupported* frameworks. Laravel BTs are detected as symfony, as laravel itself is built on top of symfony.

**i** There are few limitations of the PHP Agent. The PHP Agent does not:

- Support Zend Monitor
- Officially support plug-ins that encrypt and, or obfuscate PHP code such as Zend Guard or ionCUBE Loader
- Support compatibility with the Xdebug module
- Support the `pcntl_fork` function which forks the child/sub-processes

## Transaction Naming

Framework/Environment	Default Transaction Naming
Drupal	page callback name
Wordpress	template name
PHP MVC Frameworks	controller:action
PHP Modular MVC Frameworks	module:controller:action
PHP Web	URI
PHP Web Service	service name.operation name
PHP CLI	last two segments of the script's directory path plus the name of the script

Virtual host prefixing is available for all supported entry point types except PHP CLI.

## PaaS Providers

PaaS Provider	Buildpack
Pivotal Cloud Foundry	<a href="https://github.com/Appdynamics/php-buildpack">https://github.com/Appdynamics/php-buildpack</a> See <a href="http://docs.pivotal.io/appdynamics/index.html">http://docs.pivotal.io/appdynamics/index.html</a> for information about integration with PCF.

## Exit Points

Supported HTTP Exit Points
<code>curl/curl-multi*</code>
<code>drupal_http_request()</code>
<code>fopen()</code> , <code>file_get_contents()</code>
<code>Zend_HTTP_Client::request()</code>

\*The total time reported for a `curl/multi_curl` request in the Controller is the same as reported by the function `curl_getinfo`. Also, we report the the following execution metrics in the exit call details for the `curl/multi_curl` request which are included in the total time:

- `namelookup_time`

- `connect_time`
- `pretransfer_time`
- `redirect_time`

### Supported Database Exit Points

MySQL old native driver (removed for PHP 7)

MySQLi Extension\*

OCI8

PDO

PostgreSQL accessed via PDO and pgsql extensions

\* `mysqli_multi_query` is not supported.

### Supported Cache Exit Points

Memcache

Memcached

Predis 0.8.5 and 1.1.1, on PHP versions 7.0 and higher

Phredis 4.1

Although Predis is a full PHP client library, the PHP Agent supports Predis as an exit point only, not as an entry point.

### Supported Web Service Exit Points

PHP SOAPClient

NuSOAP 0.9.5

### Supported Message Queue Exit Points

RabbitMQ

RabbitMQ support requires the [amqp extension](#).

RabbitMQ is not supported on PHP 8.2 because amqp extension is not compatible with PHP 8.2.

## Opcode Cache Compatibility

Alternative PHP Cache (APC)	
-----------------------------	--

## Python Agent

### Related pages:

- [Python Agent](#)

## Python Agent Support

### Python Versions

The Python agent supports these Python versions:

- **Linux:** Python 3.7, 3.8, 3.9, 3.10, and 3.11
- **Alpine Linux:** Python 3.7, 3.8, 3.9, 3.10, and 3.11

### Operating Systems

The Python agent operates on:

- Linux distribution based on glibc 2.12+ and x86 64-bit architecture
- Alpine Linux (3.13+) distribution based on musl 1.2.2+ and x86 64-bit architecture

 The Python agent does not support Power Architecture.

### Python Frameworks and Protocols

Python Agent supports:

- ASGI supported frameworks such as FastAPI
- WSGI supported frameworks such as Django, Flask, CherryPy, Bottle, and Pyramid
- Tornado

You can configure the agent to instrument any WSGI-based and ASGI-based application or framework as Python Web, including but not limited to those listed in the following tables.

At present, the Python agent fully supports exception detection in Django, Flask, CherryPy, Bottle, Pyramid, Tornado, and FastAPI frameworks. Other frameworks and custom applications may install exception handlers that effectively hide some exceptions from the agent. In such cases, the agent will only detect exceptions during exit calls, missed exceptions that are propagated to the WSGI or ASGI middleware, and exceptions reported via the custom business transaction API.

ASGI-Based Framework	Version	Notes
FastAPI	0.72.0 - 0.95.0	Only HTTP endpoints are supported

WSGI-Based Frameworks	Version	Notes
WSGI	1.0	<b>Entry point type:</b> Python web <b>Default transaction naming:</b> the first two segments of the URI
Bottle	0.12.19	
CherryPy	18.6.1	
Django	3.1.6	
Flask	1.1.2	
PasteDeploy	2.1.0	
Pyramid	2.0	
mod_wsgi	4.7.1	

Miscellaneous Frameworks	Version	Notes
Tornado	3.2 - 4.5, 5.x (without asyncio), and 6.0	<b>Entry point type:</b> Python web <b>Default transaction naming:</b> the first two segments of the URI

#### Database Exit Points

Supported Database Exit Points	Version
cx_Oracle <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;">  Both <code>Connect()</code> and <code>SessionPool()</code> connection handlers are supported.           </div>	8.x.x
MongoDB	3.1+
MySQL-Python	
mysqlclient	

Supported Database Exit Points	Version
MySQL Connector/Python	
Psycopg 2	
PyMySQL	
TorMySQL	

### HTTP Exit Points

Supported HTTP Exit Points
httplib*
httplib2
requests
urllib
urllib2
urllib3
tornado.httpclient

\* The agent detects calls to any external library built on top of `httplib`. Therefore, backend calls to such services, such as, boto, dropbox, python-twitter are detected and displayed as HTTP exit calls.

### Cache Exit Points

Supported Cache Exit Points
Memcache
Redis-py

## Apache Web Server Agent

### Related pages:

- [Browser RUM Supported Environments](#)

## Apache Server Agent Support

### Apache Web Servers

#### Supported Apache Web Server Version

- Apache HTTP Server 2.2.x
- Apache HTTP Server 2.4.x
- IBM HTTP Server >= 7.0
- Oracle HTTP Server >= 11g

### Operating Systems

- Any Linux distribution x86 64-bit architecture based on `glibc >= 2.34`.
- AIX (Advanced Interactive eXecutive) 7.2 (7200-05-03-2148 or later) running on PowerPC Architecture

Apache Agent on AIX supports only 64-bit architecture and Apache 2.4.

- Alpine Linux >= 3.18.3

Apache Agent on Alpine supports only 64-bit architecture and Apache 2.4.

- RHEL9 or later is supported from Apache Agent 23.8.x onwards.

If you encounter an ELF warning message, it may be related to the incorrect version of `glibc`. Verify that your operating system has a suitable `glibc` version.

### Automatically Discovered Business Transactions

The Apache Agent automatically discovers the following business transactions:

Type	Custom Configuration Options	Downstream Correlation
Web (HTTP)	Yes	Yes

By default, the agent excludes requests for the following static file types:

```

bm jar png
p jpe pps
ca g properties
b jpg swf
cla js tif
ss mo txt
co v zip

```

nf mp  
 css 3  
 do mp  
 c 4  
 gif pdf  
 ico

## Remote Service Detection

### Apache Modules

The Apache Agent automatically detects loaded Apache modules as remote services. The agent excludes a list of common modules from detection.

Show the list of excluded modules...

core.c	mod_cgi.c	mod_negotiation.c
http_core.c	mod_data.c	mod_perl.c
mod_access_co mpat.c	mod_dbd.c	mod_python.c
mod_actions.c	mod_deflate.c	mod_remoteip.c
mod_alias.c	mod_dir.c	mod_reqtimeout.c
mod_allowmeth ods.c	mod_disk_cache .c	mod_rewrite.c
mod_appdynami cs.cpp	mod_dumpio.c	mod_setenvif.c
mod_auth_basic .c	mod_echo.c	mod_slotmem_plain.c
mod_auth_diges t.c	mod_env.c	mod_slotmem_shm.c
mod_authn_alias .c	mod_expires.c	mod_so.c
mod_authn_ano n.c	mod_ext_filter.c	mod_socache_dbm.c
mod_authn_cor e.c	mod_file_cache. c	mod_socache_memcache.c
mod_authn_dbd .c	mod_filter.c	mod_socache_shmcb.c
mod_authn_db m.c	mod_headers.c	mod_speling.c
mod_authn_def ault.c	mod_include.c	mod_ssl.c
	mod_info.c	mod_status.c
	mod_lbmethod_ bybusyness.c	mod_substitute.c
	mod_lbmethod_ byrequests.c	mod_suexec.c
	mod_lbmethod_ bytraffic.c	mod_systemd.c
		mod_unique_id.c
		mod_unixd.c
		mod_userdir.c

---

mod_authn_file.c	mod_lbmethod_heartbeat.c	mod_usertrack.c
mod_authn_socache.c	mod_log_config.c	mod_version.c
mod_authnz_ldap.c	mod_logio.c	mod_vhost_alias.c
mod_authz_core.c	mod_lua.c	prefork.c
mod_authz_dbd.c	mod_mem_cache.c	util_ldap.c
mod_authz_dbm.c	mod_mime.c	
mod_authz_default.c	mod_mime_magic.c	
mod_authz_groupfile.c		
mod_authz_host.c		
mod_authz_owner.c		
mod_authz_user.c		
mod_autoindex.c		
mod_cache.c		
mod_cache_disk.c		

 For End User Monitoring, the Apache Agent does not support automatic injection of the Javascript `adrum` header and footer to instrument web pages.

### Third-Party Modules

The Apache Agent  $\geq 20.5$  requires the use of the latest version of SiteMinder 12.52 SP1 to eliminate a known bug in SiteMinder.

---

## C++ Agent

### C/C++ Supported Platforms

#### Operating Systems

- Any Linux distribution based on glibc  $\geq$  2.5 and the x86 32-bit or x86 64-bit architecture
- Windows Server  $\geq$  2012 R2
  - Visual Studio  $\geq$  2015

**i** To develop with the C++ SDK, you need Visual Studio  $\geq$  2015 . However, the SAP ABAP Agent on Windows leverages the same SDK and does not require development work. You must install the Visual Studio C++ Redistributable; the full development environment is not required.

## Go Language Agent

### Go Supported Platforms

#### Language Support

All Go language versions are currently supported.

#### Operating Systems

- Any Linux distribution based on glibc  $\geq$  2.5, and the x86 32-bit or x86 64-bit architecture
- Mac OS X  $\geq$  10.8 on x86/x86-64 architecture

**i** AppDynamics does not currently support Mac on Apple silicon (Apple M1 chip, ARM-based architecture).

## IIB Agent

### IIB Agent Support

This page provides the supported versions, operating systems, and node types of the IIB agent. The AppDynamics IIB agent supports the Linux and AIX operating systems.

#### Operating Systems

The IIB agent supports these operating systems:

- Linux x86-64
- AIX v7.1 and v7.2

#### IIB Versions

The IIB Agent supports these versions of IIB for the Linux and AIX operating systems:

Operating System	IIB Version
Linux (Any Linux distribution based on glibc >= 2.17)	<ul style="list-style-type: none"> <li>• IIB v10</li> <li>• ACE v11</li> <li>• ACE v12</li> </ul>
AIX 7.1 (minimum patch level 7100-03-09-1717 or 7100-04-04-1717)	<ul style="list-style-type: none"> <li>• IIB v10</li> </ul>
AIX 7.2	<ul style="list-style-type: none"> <li>• IIB v10</li> <li>• ACE v11 (requires ACE Fix Pack &gt;= v11.0.0.9)</li> <li>• ACE v12</li> </ul>

### IIB Node Types

The agent can continue business transactions detected upstream at these node types:

- SOAPInput
- HTTPInput
- JMSInput
- MQInput

The agent can detect and tag exit calls for downstream correlation at these node types:

- SOAPRequest
- HTTPRequest
- JMSOutput, JMSReply
- MQOutput, MQReply

For MQ, we use the MQRFH2 message header to provide correlation. Any applications consuming MQ messages from IIB with the IIB agent must support the MQRFH2 header.

The agent can detect database backend calls for these node types:

- DatabaseRetrieve
- DatabaseRoute

All nodes are represented within AppDynamics Business Transactions as Threads. You can view the per node timings in the tree view of the Business Transaction dashboard and in the transaction snapshots.

## Application Security Monitoring

 Cisco Secure Application is available for the SaaS environment only.

AppDynamics with Cisco Secure Application reduces the risk of security exposure without compromising the delivery speed for an APM-managed application. Normally, the traditional vulnerability scanning occurs before the application is launched to production, and then continues on a monthly, or quarterly cadence. As soon as the app is deployed to production, new security gaps, and zero-day exploits make the application vulnerable despite pre-production testing. Cisco Secure Application enables continuous vulnerability assessment and protection by scanning code execution to prevent possible exploits.

Cisco Secure Application enables:

- The IT Operations team responsible for performance monitoring to gain real-time access to all security events.
- Application security (AppSec) developers and application developers to gain insights into violations of best practices and to collaborate on a solution without friction.
- AppSec and DevOps to add security into the existing automation, which benefits the DevSecOps environment.
- Businesses to operate at a faster pace with a lower risk profile due to constant run-time protection, real-time remediation, and security automation.

To monitor the application security, you must enable the security for the application using the Cisco Secure Application dashboard. Use the **Security Events** widget on the AppDynamics Application dashboard to navigate to the Cisco Secure Application dashboard. To view the **Security Events** widget within AppDynamics, enable your SaaS account with the subscription license for Secure Application. See [License Entitlements and Restrictions](#).

## Supported APM Agents

The Cisco Secure Application features are built into these AppDynamics APM Agents:

- Java Agent
- .NET Core
- Node.js Agent

## Cisco Secure Application Components

Cisco Secure Application uses the combination of the supported APM Agent, Controller, and Cisco Secure Application dashboard to monitor the security of the applications.

- **APM Agent:** Cisco Secure Application library is bundled with the Java and .NET Agents. The agent communicates with the Cisco Secure Application service within the Controller, which is maintained in the cloud.
- **AppDynamics Controller:** The Cisco Secure Application service is maintained in the cloud by AppDynamics. The APM Agent sends data to the service within the Controller. The service analyzes the data to protect against different types of attacks and vulnerabilities and then the service provides the analysis to the dashboard. For information about the attacks and vulnerabilities that Cisco Secure Application detects, see [Cisco Secure Application Policies](#). It uses external feeds along with internal data to analyze the behavior of the application. It analyzes the CVEs (Common Vulnerabilities and Exposures) against a curated vulnerability feed.

The service can detect:

- A vulnerability when it is enabled in the policy and when the associated behavior and the library used are considered vulnerable.
- An attack when it is enabled in the policy and abnormal behavior is detected.

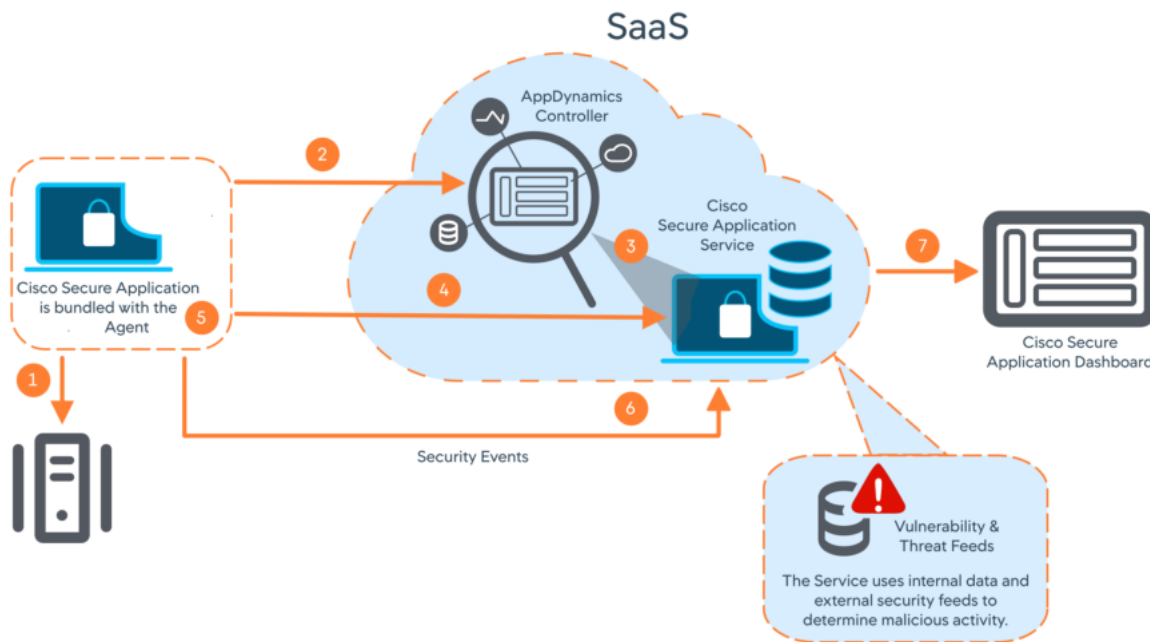

Currently, attacks are not captured for .NET Agents.

- **Cisco Secure Application Dashboard:** A graphical representation of all the analyzed data. You can view this dashboard based on the role defined in the AppDynamics Controller. The data is updated on the dashboard when the service within the Controller sends the analyzed data to the dashboard.

## Cisco Secure Application Architecture

This is a high-level architecture of Cisco Secure Application.

**i** The APM Agent (Java Agent) communicates to the Cisco Secure Application service through the AppDynamics Controller.

1. You install the supported APM Agent and then add the Cisco Secure Application license.
2. The APM-managed application runs and the APM Agent retrieves the data to send to the Controller.
3. The Cisco Secure Application service retrieves the application, tiers, and nodes data from the Controller.
4. The APM Agent communicates with the Cisco Secure Application service to check if the security is enabled for the application.
5. If the security is enabled, then the agent downloads the configuration along with the policies from the Cisco Secure Application service.
6. Based on the configured policies, the agent sends the security events to the Cisco Secure Application service.
7. The service collects all the data, analyzes the application behavior, and then provides the analyzed data to the Cisco Secure Application dashboard.

## Cisco Secure Application Requirements

This page describes the requirements, supported environments, and versions supported by the Cisco Secure Application.

**i** Cisco and AppDynamics and its products are not affiliated with Google or Google products. All references to Google products herein are for informational purposes only and Google retains all rights in all Google product names, logos, marks, and other trademarks.

## Software Requirements

The Cisco Secure Application capabilities are integrated with these APM Agents:

### Java APM Agent

The Java APM Agent with Cisco Secure Application works on the following platforms:

- Operating Systems - AIX, Linux, and Windows
- Containers - All major container systems
- Languages - Java versions 8 to 16, inclusive, Oracle, OpenJDK, Azul, and IBM
- Application Framework Support - All major frameworks such as Spring (see [Java Supported Environments](#))
- Application Server Platform Support - All major Application Servers (see [Java Supported Environments](#))
- User Permissions - The user under which the JVM runs must have write privileges to the Cisco Secure Application extension directory ( `<JAVA_AGENT_HOME>/ver<VERSION>/external-services/argentoDynamicService/` ). For more information on Java Agent installation requirements, see [Install the Java Agent](#).

Review [Install App Server Agents](#) for instructions and guidance. AppDynamics provides an [Agent Installer](#) that simplifies the agent installation process and streamlines the deployment of Java and Machine Agents.

**i** The Cisco Secure Application capabilities are integrated only with Java Agent JDK8+. The Java Agent Legacy does not support Cisco Secure Application. Ensure the following points to check if you have installed the correct agent:

- The Java Agent JDK8+ install directory includes `1.8` in the directory name, for example, `AppServerAgent-1.8-22.6.0`.
- The `argentoDynamicService` folder is listed under `external-services`.

### .NET APM Agent

The .NET Agent with Cisco Secure Application works on all frameworks that the .NET Agent instruments. To view the full list, see [.NET Supported Environments](#) and its [Limitations](#).

Supported:

- Reporting of vulnerability for .NET, and beta support for .NET Framework.
- Reporting of Command Execution events.
  - Only process filtering policies are supported for this feature.
- Azure Site Extension for Reporting of Command Execution events, and Vulnerability Reporting.

Not supported:

- Single file deployment for Vulnerability Reporting. This exception does not apply to Reporting Command Execution events.
- Stack filtering for Command Execution events feature.

### Node.js Agent

See [Vulnerability Reporting on Node.js Agent](#).

## Resource Utilization and Performance Impact

Within the Java Agent, the Cisco Secure Application capabilities require:

- Disk - 4 MB (install) and <15 mb (daily usage)
- Memory - consistently heap/mem usage should be 4-6 MB
- CPU - consistently < 1% - spikes < 5%
- Latency - consistently < 4-6 ms per transaction (average is lower) - spikes < 10ms
- Classes Instrumented: rules (12) classes (generally < 30 - based on implementations of some of the interface rules)

 There is a negligible resource utilization with the .NET Agent. However, this may change based on the application usage.

## Browser Requirements

Currently, Google Chrome is the supported browser for accessing Cisco Secure Application dashboard.

## Before You Begin

To use Cisco Secure Application within the supported APM Agent, ensure:

- That you have met the preceding Cisco Secure Application Requirements.
- You have enough Cisco Secure Application licenses to cover the supported APM agent usage within the applications you plan on securing. To get a Cisco Secure Application license, contact the AppDynamics sales representative, or email [salesops@appdynamics.com](mailto:salesops@appdynamics.com).
- Controller  $\geq$  22.8.

### Tip:

These versions reflect recommended minimum versions. We continually update our technology, so it's optimal to use the most recent agent version when possible.

- Java Agent: Ensure that Java APM Agent  $\geq$  22.8 is installed and licensed. If you are using reverse proxy, ensure you configure properties to communicate from the APM Agent to the Controller. See [Configure Properties to Use Reverse Proxy](#).
- .NET Core: Ensure that the .NET APM Agent  $\geq$  22.8 is installed and licensed.
- .NET Framework Agent: Ensure that the .NET APM Agent  $\geq$  22.11.0 is installed and licensed.
- You have successfully configured the supported APM Agent in your application environment.

## Configure Properties to Use Reverse Proxy

Cisco Secure Application automatically interprets the APM agent setting for an HTTP Proxy server and uses the same server for communication between the agent and Controller. However, you must configure these settings for the APM agent to communicate with Controller through a reverse proxy:

- The reverse proxy configuration may change based on the reverse proxy solution that you use. Ensure that you use a pass-through reverse proxy to forward any requests containing `/argento-agent/v1` or `auth/v1/oauth` to `<tenant-name>.saas.appdynamics.com`.
- These steps are not applicable for the .NET Agent because the .NET Agent does not support reverse proxy.

1. In the JVM, configure the reverse proxy details for Cisco Secure Application:
  - a. Specify the reverse proxy URL:

```
-Dargento.management.server.reverse.proxy.url=http://<reverse-proxy-host>:<reverse-proxy-port>/
```

Here, *reverse-proxy-host* and *reverse-proxy-port* are the hostname and port of the reverse proxy that will direct communications to the Controller.

- b. Specify the domain:

```
-Dargento.management.server.add.headers=Host:<tenant-name>.saas.appdynamics.com
```

Here, *tenant-name* is the tenant name of the Controller.

2. In the JVM, configure these Cisco Secure Application system properties to use the reverse proxy:

- a. `Dargento.management.server.authentication.access.key`

```
-Dargento.management.server.authentication.access.key=<access-key>
```

Here, *access-key* is the access key specific to the tenant.

- b. `Dargento.management.server.authentication.user`

```
-Dargento.management.server.authentication.user=singularity-agent@<tenant-name>
```

Here, *tenant-name* is the tenant name of the Controller.

## Getting Started with Cisco Secure Application

This page provides a step-by-step procedure on how to get started with Cisco Secure Application.

Step	Task	Reference
Step 1: Ensure that all requirements are met, and that the licensed version of supported APM Agent is installed.	Check the required version of the Controller and APM Agent. <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;">  Cisco Secure Application is supported on a SaaS Controller only.           </div>	<ul style="list-style-type: none"> <li>• <a href="#">Cisco Secure Application Requirements</a></li> <li>• <a href="#">Install the Java Agent</a></li> <li>• <a href="#">Install the .NET Agent for Linux</a></li> </ul>
Step 2: Obtain the Cisco Secure Application license.	Contact the AppDynamics sales representative or email <a href="mailto:salesops@appdynamics.com">salesops@appdynamics.com</a> .	<a href="#">Cisco Secure Application Requirements</a>

Step	Task	Reference
<p>Step 3: Assign roles using the AppDynamics Administration Console.</p>	<p>Assign the <b>Configure Cisco Secure Application</b> account permission to the users who are required to modify configurable fields on the Cisco Secure Application dashboard.</p> <p>Assign <b>View Cisco Secure Application</b> account permissions to users who are required to only monitor the dashboard.</p>	<p><a href="#">Account Permissions</a></p>
<p>Step 4: Click the <b>Security Events</b> widget on an application flowmap.</p>	<p>Launch the required AppDynamics Application dashboard using your account, and then click <b>Security Events</b> on the right pane.</p> <p>This redirects you to the Cisco Secure Application dashboard.</p>	<p><a href="#">Monitor Application Security Using Cisco Secure Application</a></p>
<p>Step 5: From the Cisco Secure Application Dashboard navigate to the <b>Applications</b> page, and then set <b>Security Setting</b> as <b>Enabled</b> for the target application.</p> <p>Or</p> <p>Click the <b>gear icon</b>  that displays the <b>Administration</b> option. Navigate to the <b>Settings</b> tab. Here you can enable security for all applications by default.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p> This is applicable for all users with the <b>Configure</b> permission for Cisco Secure Application.</p> </div>	<p>The <b>Security Setting</b> value is set to <b>Inherit</b> by default for all applications that inherit the non-configurable tenant setting of <b>Disabled</b>. To enable security for an application, you must set <b>Security Setting</b> to <b>Enabled</b>.</p>	<p><a href="#">Monitor Security Status of Applications</a></p>
<p>Step 6: From the <b>Applications</b> page, verify that the application nodes are registered and active.</p>	<p>From the <b>Applications</b> page, check the <b>Active Nodes</b> and <b>Registered Nodes</b> fields for the specific application. Ensure that the application nodes are active. If the nodes are not active, then the application security data is not displayed on the dashboard.</p>	<p><a href="#">Monitor Security Status of Applications</a></p>

Step	Task	Reference
Step 7: From the <b>Libraries</b> page view the risk-sorted libraries of secured applications.	The <b>Libraries</b> page displays all the existing libraries of application(s) based on the selected application scope. You can use the risk score to prioritize the remediation task.	<a href="#">Monitor Libraries</a>

Based on your analysis from the dashboard, you can create or modify policies, then view the different pages on the dashboard to monitor the security of APM-managed applications. See [Cisco Secure Application Policies](#).

## Next Steps

- [Monitor Application Security Using Cisco Secure Application](#)
- [Monitor the Home Page of Cisco Secure Application](#)
- [Monitor Security Status of Applications](#)
- [Monitor Libraries](#)
- [Monitor Vulnerabilities](#)
- [Monitor Attacks](#)

## Cisco Secure Application Policies

Cisco Secure Application **Runtime** policies define what runtime behaviors to ignore, detect, or block. The runtime events identify all the attacks and vulnerabilities and the action is taken based on the defined runtime policy. You can create and configure runtime policies to specify an action to mitigate the attacks and vulnerabilities.

To monitor the security of the application, you must create policies. To create policies, you require the Configure permission for Cisco Secure Application. By default, Cisco Secure Application includes a runtime policy that provides the best detection of all the attacks and vulnerabilities, reducing the false positives.

### Supported Runtime Policies

Cisco Secure Application scans attacks and vulnerabilities for the following runtime behaviors:

- [Command Execution \(PROCESS\)](#)
- [Filesystem Access \(FILE\)](#)
- [Headers in HTTP Transactions \(HTTP\\_RESPONSE\\_HEADER\)](#)
- [Web Transaction \(TRANSACTION\)](#)
- [Network or Socket Access \(NETWORK\)](#)

### Command Execution (PROCESS)

This policy detects or blocks the creation of new application processes. You can block a process at the tier level, but not at the application or the global level.

The action can be limited to specific processes by name. For example, you can detect the creation of any process that executes the `ps` command or block the creation of any process that executes the `cat` command.

You can create rules for processes and stack traces. Meaning, that you can **Detect**, **Block**, or **Ignore** any command execution if a process starts with the following: **equals**, **contains**, or **matches regex** for a specific

value. You can also **Detect**, **Block**, or **Ignore** any command execution if the stack trace **contains**, or **matches regex** of a specific value.

### Filesystem Access (FILE)

This policy detects or blocks the access to the local files. You can block the access to local files at tier level, but not at the application or the global level.

The action can be limited to specific files by name. For example, you can detect the access to any file that contains `/etc` or block the access to any file that contains `passwd`.

### Headers in HTTP Transactions (HTTP\_RESPONSE\_HEADER)

This policy adds or detects a specific HTTP header to each HTTP response. The default action is detect.

You can specify which headers to add with the `patch` option. You can specify this at the tier level, not at the application or the global level.

You can set the action for any of the following headers:

- Strict-Transport-Security
- X-Frame-Options
- X-XSS-Protection
- X-Content-Type-Options

 You must specify **Application** and **Tier** to set an action for each header.

### Web Transaction (TRANSACTION)

This policy detects or block certain web requests. The default action for this type of policy is `detect`.

The transaction policy has two special options, to block non-encrypted HTTP requests and to block requests from unauthenticated users.

You can specify rules to block requests based on originating IP or based on the URL.

### Network or Socket Access (NETWORK)

This policy detects or blocks network connections to specific hosts. You can block the network connections at the tier level, not at the application or the global level.

A specific rule can either block connections to and from a specific host, or connections that originate from a specific stack trace within the application.

## Create a Runtime Policy

To create a policy for an attack or vulnerability at runtime, perform the following steps:

1. Click **Policies > Create New Policy**.
2. From the **Add Policy** dialog, select the required criteria for the runtime in these fields:

Field Name	Details	
Name	Select the required runtime activity. See <a href="#">Supported Runtime Policies</a> .	
Application	Select the application that includes the tiers or services on which you require to apply the policy. AppDynamics recommends to select a specific application for the policy. However, you can select <b>All</b> to apply the policy on all the applications.	
Tier	Select the required application-specific tier or service to apply the policy. AppDynamics recommends to select a specific tier for the policy. However, you can select <b>All</b> to apply the policy on all the tiers or services. Also, review the default policy and if needed create a policy for specific applications and tiers.	
Default Action	<p>Select the default action for this policy.</p> <ul style="list-style-type: none"> <li>You can select <b>Ignore</b> for no notifications for the runtime activity; select <b>Detect</b> to detect the runtime activity and display the details on the <b>Attacks</b> or <b>Vulnerabilities</b> page; or select <b>Block</b> to block a specific runtime activity and to display it as <b>Blocked</b> on the <b>Attacks</b> and <b>Vulnerabilities</b> page.</li> <li>In case of headers the <b>Default Action</b> is always set to <b>Detect</b>.</li> </ul> <div style="border: 1px solid #00aaff; padding: 10px; margin-top: 10px;"> <p><b>i</b> Block is unavailable for some of the supported runtime policies. For policies such as <b>Headers in http transactions</b> policy, you need to specify the <b>Application</b> and <b>Tier</b> to block a runtime activity.</p> </div>	

Field Name	Details	
Rules	<p>Add the rules based on your requirement. The action that you specify within the rule supersedes the default action specified in <b>Default Action</b>.</p> <p>You can select <b>Ignore</b> for no notifications for the runtime activity; select <b>Detect</b> to detect the runtime activity and display the details on the <b>Attacks</b> or <b>Vulnerabilities</b> page; or select <b>Patch</b> to add the header and value to the HTTP response.</p> <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> <p> <b>Block</b> is unavailable for some of the supported runtime policies.</p> </div>	
Enable Policy	<p>Select <b>Yes</b> to enable the runtime policy.</p> <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> <p> If <b>Application</b> and <b>Tier</b> are set to <b>All</b>, you cannot select this option.</p> </div>	

3. Click **Save**.

## Modify a Security Policy

To view or modify a policy, perform the following steps:

 You can use the **Search** filter to search based on the values of the **Name**, **Tier** or **Application** fields. Here, **Name** is the name of the runtime policy.

1. Click **Policies > Runtime**.  
You can view 5, 10, 20, or 50 policies based on the number that you select at the bottom right corner of the page in the **Show<number of policies>** dropdown.
2. Click the **Modify** icon next to the required policy.
3. Modify the required fields.
4. Click **Update** or click **Delete Policy** based on the requirement.

## Alerts Using Cisco Secure Application

This page focuses on the **Alerts** feature using Cisco Secure Application. The **Alerts** tab allows you to configure email and HTTP based alerts. You can set up **Actions** to get alerted when new vulnerabilities or business risks are detected.

 Only users with the **Edit** permission can access **Alerts**.

---

## Create an HTTP Alert

1. Click the **gear icon**  that displays in the top-right corner.
2. Click **Alerts**.
3. From the **HTTP** tab, click **+ Add Action**.
4. Enter the **Action Name**.  
Do not use special characters in the **Action Name**.
5. Select the **Event Type: Vulnerability, Business Risk, or Attack**.
6. Click **Next**.
7. Enter following **Action Details**:
  - a. **Method Type**: POST
  - b. **Encoding**: UTF-8
  - c. **Raw URL**: Enter the Raw URL of your HTTP request.
8. Click **Next**.
9. Select **None** or **Basic** as the **Authentication Type**.

 If the communication is not encrypted, we recommend that you do not use any authentication.

10. Click **Next**.
11. (Optional) Specify custom headers for the request.
12. Click **Next**.
13. **Add Payload**. The payload must be in JSON format.  
You can copy **Predefined Variables**, and paste the variables in the **Editor**. For example, if you select **Business Risk** as the **Event Type**, then you can view business transaction variables when you **Add Payload**.
14. Confirm and review the following information: **cURL, General Information, Actions, Security, Custom Headers, and Payload**.  
Example payload for ServiceNow:

View Action - ServiceNow - Business Risk

**cURL**

**Request**

```
curl http://servicenow.com/endpoint --request POST --header 'Accept: application/json' --header 'Content-Type: application/json' --header 'Content-Type: application/json' --data '{
 "consumer": "cd97ef1dd8bc7006b7a9646db9619ac",
 "description": "Consumer Test Case"
}'
```

---

**General Information**

Name	Action Type	Event Type
ServiceNow - Business Risk	HTTP	Business Risk

---

**Actions**

Method Type	Encoding	Raw URL
POST	UTF-8	http://servicenow.com/endpoint

---

**Security**

**Authentication Type**  
None

---

**Custom Headers**

Header Key	Header Value
Content-Type	application/json

---

**Payload**

**Data**

```
{
 "consumer": "cd97ef1dd8bc7006b7a9646db9619ac",
 "description": "Consumer Test Case"
}
```

15. Click **Save**.  
Once you click **Save**, default **Rules** are automatically generated.

## Create an Email Alert

You can also view  $\leq 100$  vulnerabilities, business risks, or attacks per email notification. To view  $> 100$  vulnerabilities, business risks, or attacks, sign in to the UI.

1. Click the **gear icon** that displays in the top-right corner.
2. Click **Alerts**.
3. From the **Email** tab, click **+ Add Action**.
4. Enter the **Action Name**.  
Do not use special characters in the **Action Name**.
5. Select the **Event Type: Vulnerability, Business Risk, or Attack**.
6. Click **Next**.
7. Enter following **Action Details**:
  - a. (Optional) Select **Notify directly in case of an exploited attack**, if you would like to receive email alerts for exploited attacks.
  - b. **Email**
  - c. **Email Digest**
8. Click **Next**.
9. Select fields to report and click **Next**.
10. Confirm and review the following information: **General Information, Actions, Fields**.

11. Click **Save**.

Once you click **Save**, default **Rules** are automatically generated.

## Integrate Cisco Secure Application with Splunk

You can send Cisco Secure Application security events to a Splunk deployment over the HTTP and Secure HTTP (HTTPS) protocols. When you enable a new connection with the details of the Splunk server, the vulnerability, the attack, and the observation events are sent from Cisco Secure Application to the specified Splunk instance.

The **gear icon**  displays the **Settings** option. From this option you can use the **Connections** option to connect to a third-party server for advanced security.

Currently, Cisco Secure Application supports integration with Splunk only.

To create a new connection, click **New Connection** and specify the following in the **New Connection** dialog box:

- **Name:** Any name to identify the connection.
- **Service Type:** **Splunk HTTP Event Collector**.  
Currently, Cisco Secure Application supports the HTTP event collector only.
- **Endpoint:** The Splunk host endpoint.
- **Token:** The token generated through Splunk.  
The value is hidden after you save the connection.

The **Connections** page displays the Splunk connection details with its status. You can modify the connection by using the **modify icon** .

After the connection is successful, Cisco Secure Application sends the events every one minute.

Currently, this connection supports **Vulnerabilities**. The support will extend to **Attacks** and **Observations** in later releases.

## AppDynamics IP Addresses

If your Splunk instance is blocking public IPs, ensure that you unlock the following list of IPs. All traffic originating from the Oregon environment will have one of the following source IP addresses:

- 34.218.183.67
- 52.88.49.75
- 34.218.135.55
- 44.224.91.190
- 44.224.93.208
- 100.21.44.47
- 35.163.240.75
- 100.21.168.150
- 44.224.41.204

To view all IPs and their regions, see [SaaS Domains and IP Ranges](#).

## Security Events

The supported agents send the security events to Cisco Secure Application to display the attacks and vulnerabilities on the UI. To use these events within Splunk, Cisco Secure Application sends the event attributes to Splunk in the required format. These are the event details:

## Vulnerabilities

Attribute	Type	Description
tenantId	int32	The Tenant ID of the server where the AppDynamics Controller is installed.
tenantName	String	The name of the server on which AppDynamics Controller is installed.
applicationId	int32	The ID of the application that is vulnerable.
applicationname	String	The name of the vulnerable application.
applicationUuid	String	The unique ID of the server on which the application is running.
tierId	int32	The tier ID of the application that is vulnerable.
tiername	String	The name of the application tier that is vulnerable.
tierUuid	String	The unique ID of the server on which the tier is running.
timestamp	String	The time the vulnerability is first detected.
severity	String	The CVSS3 environmental severity description.
severityNumber	Float32	The risk score of the vulnerability. The higher the number, the higher the risk.
resource	String	The source of the security events. This will show the value as Secure App, which means that the security events are sent from Cisco Secure Application.
createdAt	String	The time when the vulnerability was first detected. This value is same as the timestamp value.
lastSeenAt	String	The time when the vulnerability was last detected.
fixedAt	String	The date of CVE remediation. This value is available only if the CVE is fixed.
cveId	String	The common vulnerability and exposure ID.

Attributes	Type	Description
packageName	String	The name of the library that the vulnerability has been detected in.
packageVersion	String	The version of the package with the vulnerability.
fixedVersion	String	The version of the package that fixes the vulnerability. This is the remediation version.

### Attacks

Attributes	Type	Description
TenantId	int32	The Tenant ID of the server where the AppDynamics Controller is installed.
TenantName	String	The name of the server on which AppDynamics Controller is installed.
ApplicationId	int32	The ID of the application that is affected by the attack.
ApplicationName	String	The name of the application that is affected by the attack.
ApplicationUuid	String	The unique ID of the application that is affected by the attack.
Timestamp	String	The time when the attack is detected.
SeverityNumber	float32	The risk score of the attack. The higher the number, the higher the risk.
Name	String	The name of the attack event.

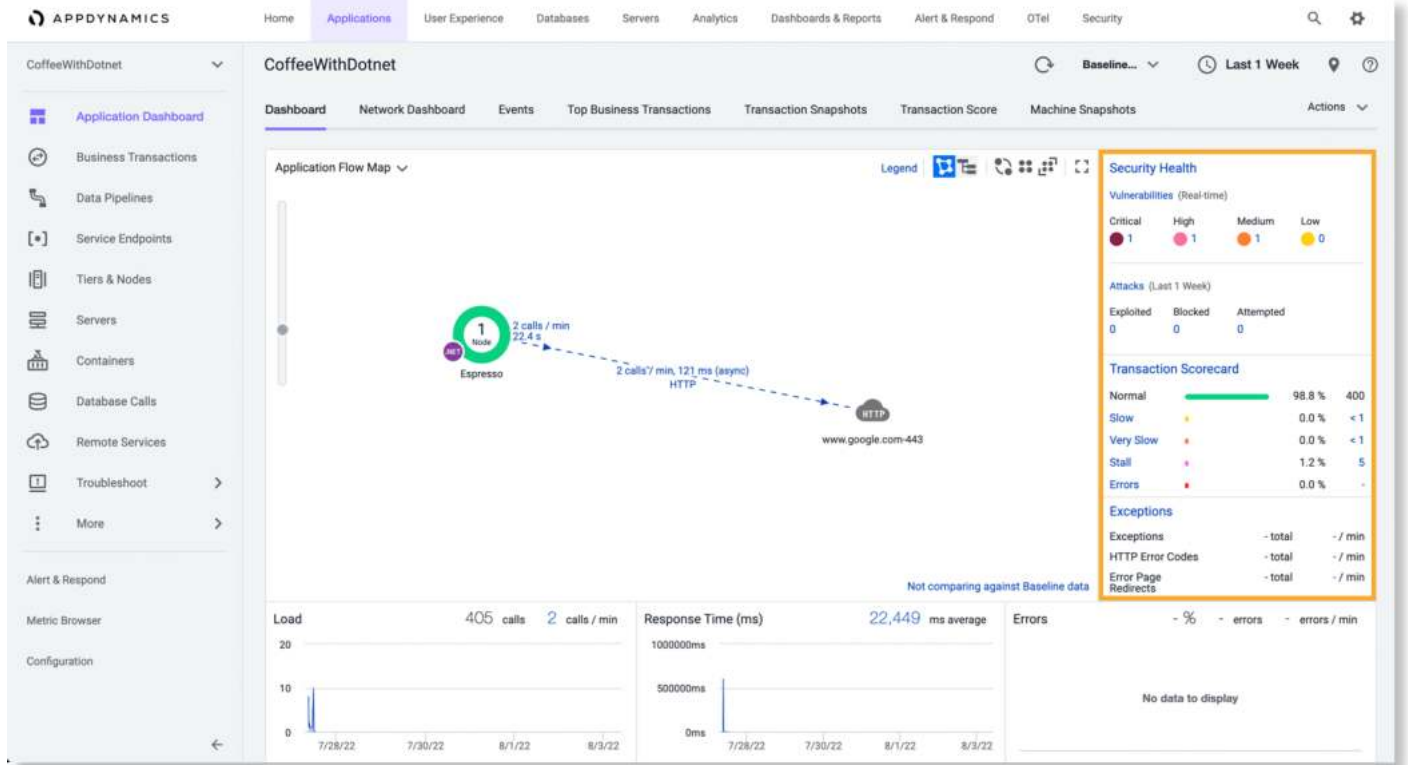

Attributes	Type	Description
Resource	String	The entry point of the attack. It is the webserver URL accessed by the client in the transaction that triggered the event. Based on the event type, this field may not be displayed.
Created At	String	The timestamp when the attack was first detected. This is same as timestamp.
LastSeenAt	String	The time when the attack was last detected.
MaliciousIpAddress	String	The name of the malicious IP list. This is available if the attack is from a client IP address that is on a known malicious IP list.  Currently, the Talos malicious IP list is supported. Therefore, this attribute displays the value Talos when the attack is from a client IP on the Talos list.

## Monitor Application Security Using Cisco Secure Application

Cisco Secure Application provides a real-time dashboard that provides visibility on the security health of your applications. This dashboard is available when an application is registered with an APM agent and has the appropriate licensing. The agent sends the security events to Cisco Secure Application through the Controller.

The **Security Health** widget on the AppDynamics Application Dashboard provides high-level information about the security of a registered application. This widget displays the number of critical, warning, and normal security events. To view the details of security for the selected application on Cisco Secure Application, click the **Security Health** widget.

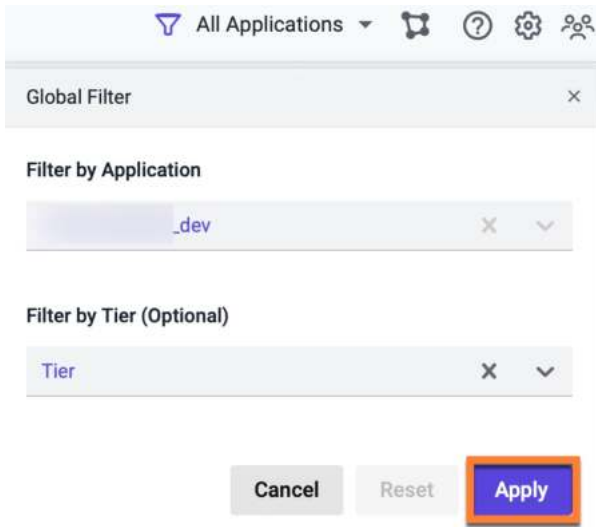

## Select Scope for the Dashboard

Cisco Secure Application dashboard provides a **Global Filter** to select the required application and tier scope that is applied across all views within this dashboard except Policies. By default, the application scope is the selected application on the AppDynamics dashboard prior to navigating to Cisco Secure Application.

To view the data on the dashboard for a specific application:

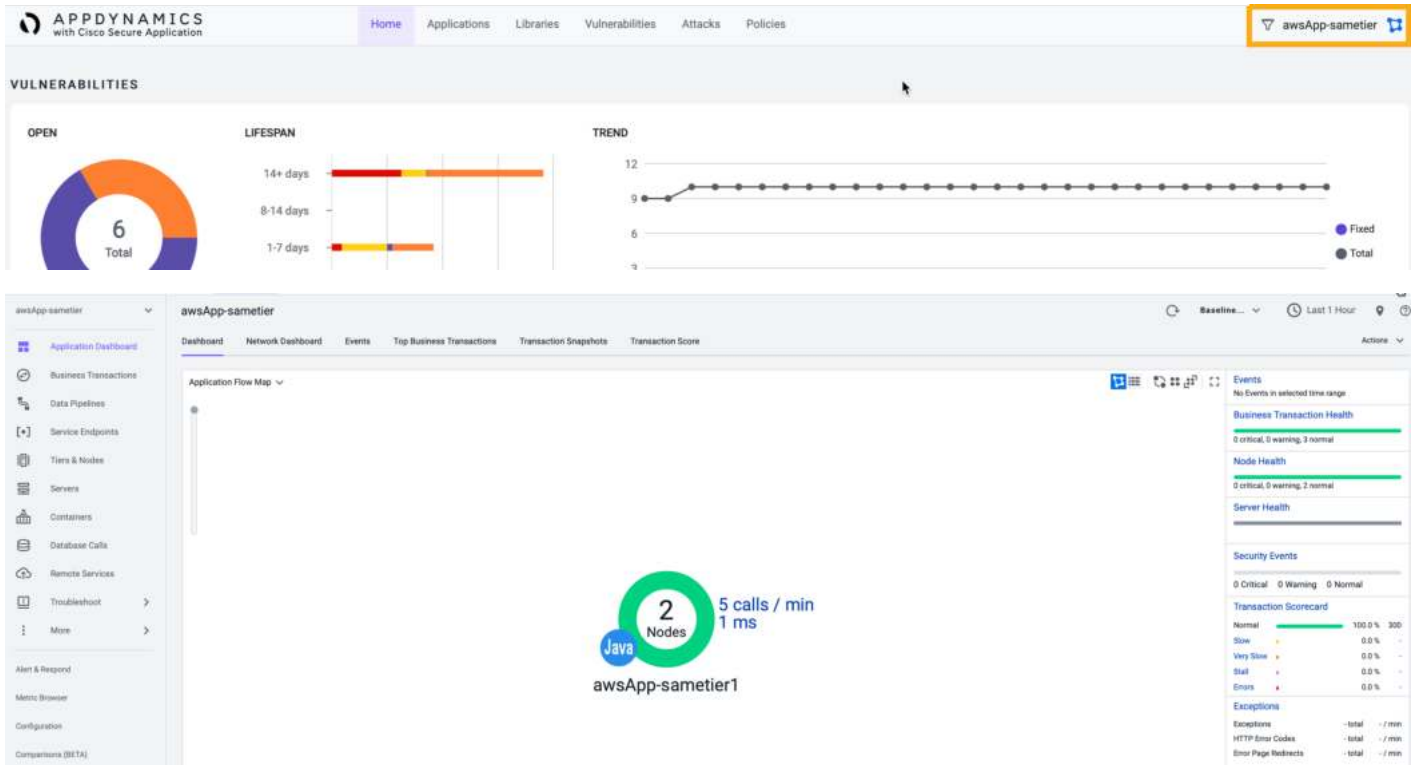

1. Click the filter icon (  ) on the top right corner of the dashboard.
2. In the **Filter by Application** tab, search for the specific application.
3. Select the application.
4. (Optional) In the **Filter by Tier** tab, search for the required tier.  
If you do not select any specific tier, then data is displayed for all the tiers.
5. Click **Apply**.

## Navigate to AppDynamics Application or Tier Flowmap

To navigate from the Cisco Secure Application dashboard to the AppDynamics flowmap, click the flowmap icon (  ) at the top right corner of the Cisco Secure Application dashboard. The flowmap icon is associated with the selected scope for the Cisco Secure Application dashboard. See [Select Scope for the Dashboard](#).

For example, in this image the tier scope is **awsApp-sametier1**. You can click the flowmap icon (  ) to launch the **awsApp-sametier1** flowmap on the AppDynamics dashboard.

## View Data Using Search Filter

The Cisco Secure Application provides a **Search** filter on various pages in the dashboard. The search filter allows you to search based on a selected category.

For example, on the **Business Transaction** page, you can search by **Business Transaction**, **Application**, and **Entry Tier**.

You can select the required search category from the dropdown list, then click the **Search** field to view the list of values corresponding to the category. You can also find the required value as you type.

If you do not require the exact match, you can enter the required generic value in the **Search** field.

For example, consider that you want to search for all applications that start with a specific prefix, **AD**. You can select the search category as **Application** and enter **AD** in the **Search** field.

**i** You can search using one or all the categories, but each category can have a single search value. A category is disabled when you specify a search value for that category, but you can continue to select another available category and specify its search value. These search values act as filters. You can remove the search values to remove the search filter.

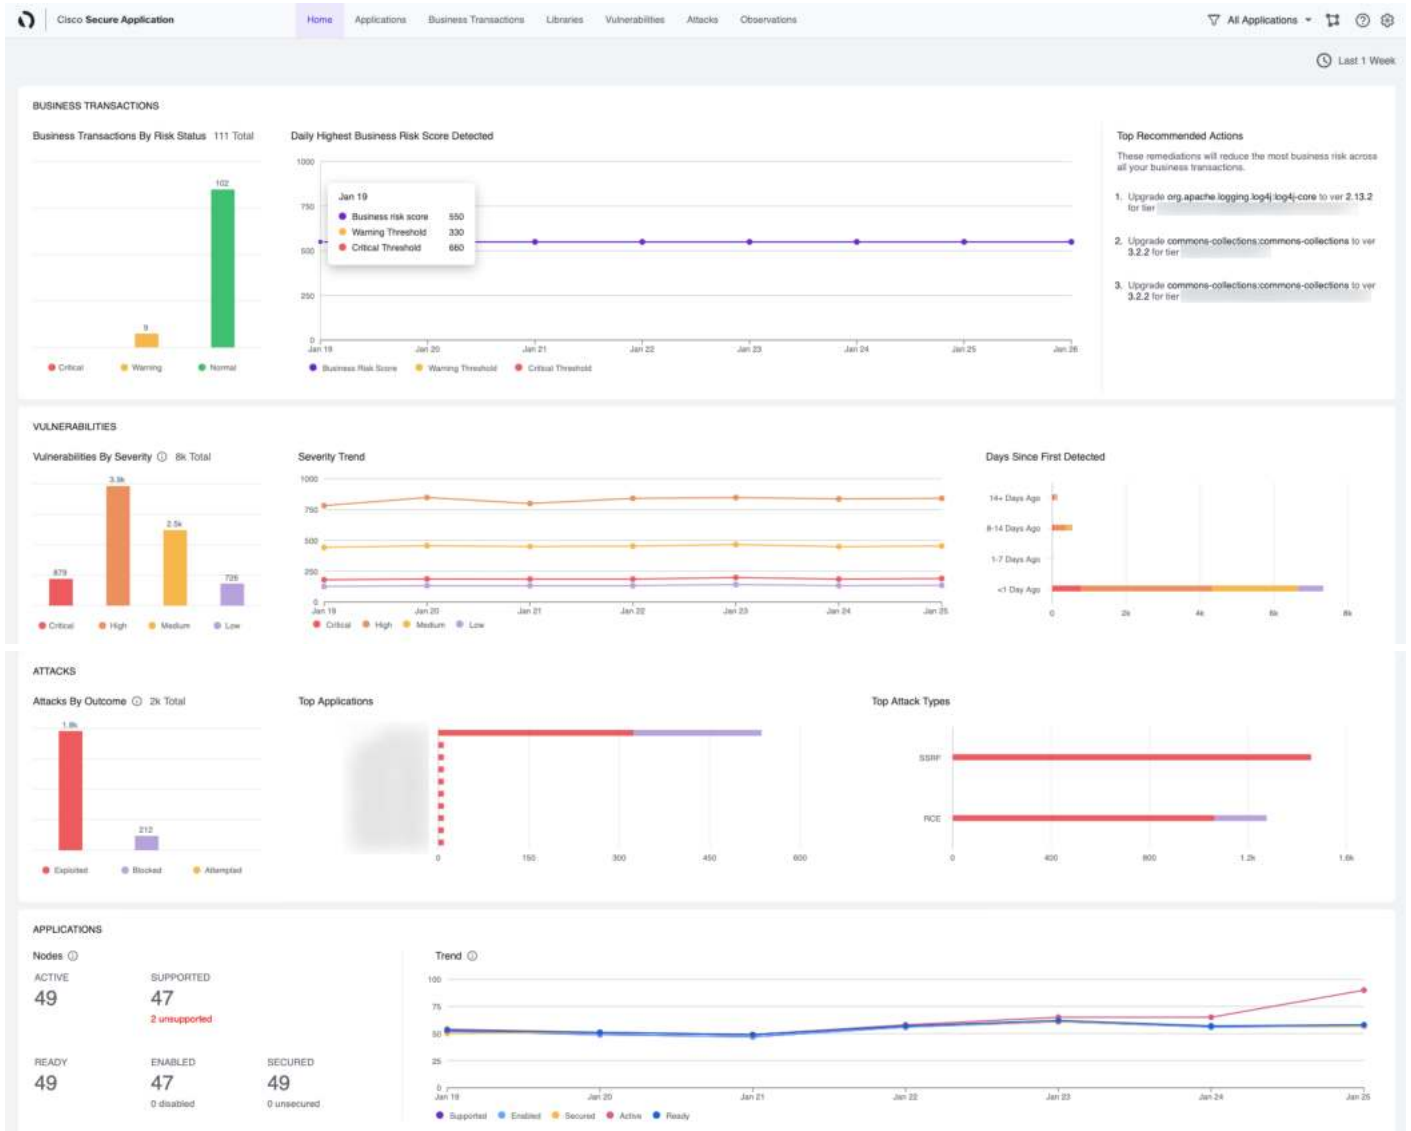

Cisco Secure Application provides a real-time dashboard that displays these pages:

- **Home:** This page provides an overall overview of attacks and vulnerabilities of monitored applications. See [Monitor the Home Page of Cisco Secure Application](#).
- **Applications:** This page provides the details of monitored nodes that are registered with Cisco Secure Application for the managed applications. See [Monitor Security Status of Applications](#).
- **Libraries:** This page provides details of the existing libraries that require remediation. See [Monitor Libraries](#).
- **Vulnerabilities:** This page provides information about all discovered vulnerabilities. See [Monitor Vulnerabilities](#).
- **Attacks:** This page provides information about all detected attacks. See [Monitor Attacks](#).
- **Policies:** This page allows you to create or customize the policies for vulnerabilities and attacks. See [Cisco Secure Application Policies](#).

## Monitor the Home Page of Cisco Secure Application

The **Home** page is the landing page for Cisco Secure Application. This page provides a quick view of the security of the selected application.

**i** By default, this page displays an overview of the selected application. For information about selecting a specific application or service, see [Select Application Scope at Monitor Application Security Using Cisco Secure Application](#).

## Business Transactions

The Business Transactions pane includes details to monitor the vulnerability risk of a Business Transaction.

Field Name	Description
Business Transaction	The name of the business transaction. To view the business transaction on the AppDynamics Controller, click the icon next to the name.

Field Name	Description
<b>Business Transactions By Risk</b>	The risk score. The higher the value, the higher the risk for the application vulnerability. Business risk is calculated based on the likelihood of vulnerability exploitation, and the impact of the potential exploitation in a business transaction. These are the three statuses: <b>Normal</b> 0-330, <b>Warning</b> 340-660, and <b>Critical</b> 670-1000.
<b>Daily Highest Business Risk Score Detected</b>	The highest business risk score detected by <b>Business Risk Score</b> , <b>Warning Threshold</b> , and <b>Critical Threshold</b> .
<b>Top Recommended Actions</b>	The top remediations that will reduce the most business risk across all of your business transactions.

### Vulnerabilities

The **Vulnerabilities** pane includes a real-time trend graph that shows the number of both fixed and open vulnerabilities.

Chart	Description
<b>Vulnerabilities By Severity</b>	This chart displays visualization for the number of vulnerabilities based on these severity levels: <b>Critical</b> , <b>High</b> , <b>Medium</b> , and <b>Low</b> .
<b>Severity Trend</b>	This chart displays the number of open tickets versus the number of fixed tickets. This shows the trend of fixing the open vulnerabilities.
<b>Days Since First Detected</b>	This chart displays the number of days the vulnerability is open versus the severity of the vulnerability (critical, high, medium, or low).

### Attacks

The **Attacks** pane includes the visualization for the number of attacks.

Chart	Description
<b>Attacks By Outcome</b>	This chart represents the total number of attacks. This chart displays the number of attacks based on these states: <b>Exploited</b> , <b>Blocked</b> , and <b>Attempted</b> .

Chart	Description
<b>Top Applications</b>	This chart displays the top 10 applications based on attacks per application. For more information about changing the scope of the application, see <a href="#">Monitor Application Security Using Cisco Secure Application</a> . These applications are in either an <b>Exploited</b> , <b>Blocked</b> , or <b>Attempted</b> state. You can hover over each state to view the total number.
<b>Top Attack Types</b>	This chart displays the top attack types. Attack Types include: <ul style="list-style-type: none"> <li>• <b>DESERIAL</b>: The agent detected a Java class deserialization event.</li> <li>• <b>SQL</b>: The agent detected a known SQL injection signature event.</li> <li>• <b>RCE</b>: The agent detected a remote code execution event.</li> <li>• <b>LOG4J</b>: The agent detected a Log4Shell attack.</li> <li>• <b>SSRF</b>: The agent detected a server side request forgery event.</li> <li>• <b>MALIP</b>: The agent detected either an inbound, or outbound socket connection to a known malicious IP address.</li> </ul>

## Applications

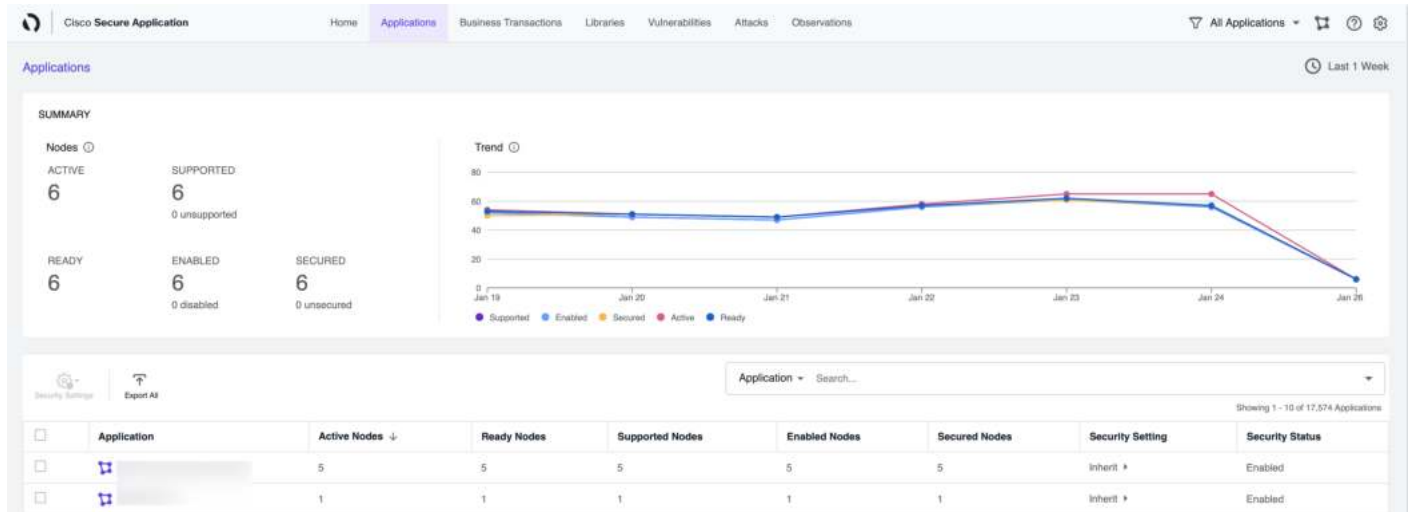

The **Applications** pane includes the number of nodes of the managed applications.

Chart	Description
<b>ACTIVE</b>	The number highlights the number of nodes that are actively communicating with the AppDynamics Controller.
<b>SUPPORTED</b>	The number highlights the number of nodes registered with the Cisco Secure Application. This also displays the number of unregistered nodes.
<b>READY</b>	The number highlights the number of nodes that can be successfully registered.
<b>ENABLED</b>	The number highlights the total number of nodes that have security enabled for the applications. This also displays the number of nodes on which the security setting is disabled.
<b>SECURED</b>	The number highlights the number of secured nodes. This also displays the number of unsecured nodes.
<b>TREND</b>	This displays the number of supported, enabled, secured, active, and ready nodes against the day of the month.

You can click the **Export** button to download the table data. It downloads all of the rows, columns, and related data in a `.csv` file. A separate `.json` file includes the following: link to the Cisco Secure Application website where the table is exported from, global filters (if any) applied to the pages, and search filters applied to the columns. These two files are compressed into a `.zip` file for downloading. The maximum number of rows that can be exported is 10,000. If table data exceeds 10,000 rows you may apply filters to narrow your search, or export the first 10,000 results.

## Monitor Security Status of Applications

The **Applications** page focuses on the current state of security capabilities across applications, tiers, and nodes. You can control the security setting (with the configure permission) and identify the issues with the agents that are not registered or are inactive.

### Top Pane

The top pane chart displays **Node** counts and their trends. The top pane also includes the visualization of the number of enabled, registered, and active nodes for all applications.

- **ACTIVE** - nodes that are active for the corresponding application.
- **SUPPORTED** - nodes with APM agents that are registered with Cisco Secure Application.
- **ENABLED** - nodes with security enabled.
- **SECURED** - nodes that are secured with the Cisco Secure Application policy.
- **TOTAL ACTIVE NODES** - nodes with currently active registered APM agents.
- **READY** - nodes that can be successfully registered.

**i** Use the filter to select the application or the tier scope. In the **Applications** table, you can click the application row to drill down to all the tiers for that application. Also, you can click a tier row to drill down to the corresponding nodes. See [View Data Using Search Filter](#) in [Monitor Application Security Using Cisco Secure Application](#).

### Bottom Pane

The bottom pane provides the following:

**!** The total number of applications is mentioned in parenthesis.

Field Name	Description
<b>Application</b>	This field displays the list of all applications. Click the flowmap icon (  ) next to an application to view the application flow map in the AppDynamics dashboard. Click this field to sort in alphabetical order. This field changes when you click to drill down to the tier list, then the node list. You can use the respective <b>Search</b> filter for each list view to quickly search the application, tier, or node.
<b>Active Nodes</b>	<p>This field displays the number of nodes that are active for the corresponding application. You can drill down to tiers to view the number of active nodes in a tier. When you drill down to the nodes list, this field indicates if the node is active or not. The info icon (  ) indicates a difference in the number of enabled nodes compared to active nodes.</p> <p>(For application and tiers) Click this field to sort the number of active nodes in increasing or decreasing order.</p> <p>(For nodes) Click this field to sort based on the values <b>Yes</b> or <b>No</b>.</p> <p>When you drill down to nodes, this field indicates if the node is active.</p>
<b>Ready Nodes</b>	This field displays the total number of nodes that can be successfully registered.
<b>Supported Nodes</b>	<p>This field displays the number of nodes that are registered with the Cisco Secure Application for the corresponding application. You can drill down to tiers or nodes list to view the number of registered nodes in a tier, or a node respectively. The info icon (  ) indicates that there are security-enabled nodes that are not registered with the agent.</p> <p>Click this field to sort the number of registered nodes in increasing or decreasing order. When you drill down to nodes, this field indicates if the node is registered.</p>
<b>Enabled Nodes</b>	This field displays the total number of nodes that have Cisco Secure Application security setting enabled in the corresponding application. You can drill down to tiers or nodes list to view the total number of nodes in a tier, or a node respectively. Click this field to sort the number of nodes in increasing or decreasing order.
<b>Secured Nodes</b>	This field displays the total number of nodes that exist in the corresponding application and are secured. You can drill down to tiers or nodes list to view the total number of nodes in a tier, or a node respectively. Click this field to sort the number of nodes in increasing or decreasing order.

Field Name	Description
<b>Security Setting</b>	<p>The security setting is disabled by default. If you require to enable the security, select <b>Enable</b>. This field displays these security settings for the corresponding application:</p> <ul style="list-style-type: none"> <li>• <b>Enable</b>: When the security setting is enabled for the nodes.</li> <li>• <b>Disable</b>: When the security setting is disabled for the nodes.</li> <li>• <b>Inherit</b>: When the security setting is inherited from the Controller. By default, the security setting is <b>Disabled</b>. Therefore, <b>Security Status</b> is <b>Disabled</b> for the application. For tiers and nodes, the security setting is inherited from the parent application and tier respectively.</li> </ul> <p>You can drill down to tiers or nodes list to view the security settings of a tier, or a node respectively. You can also update these settings if you have the Configure Cisco Secure Application permission.</p> <div style="border: 1px solid #00aaff; padding: 5px; margin: 10px 0;"> <p><b>i</b> Be aware that changing security settings at one level affect other levels. When you update <b>Security Setting</b> for any object (application, tier, or node), it can affect all the nodes in the object hierarchy (<b>Application&gt;Tier&gt;Node</b>). This happens when <b>Security Setting</b> is set to <b>Inherit</b> for either the object or its parent object.</p> </div> <p>Click this field to sort the security setting in alphabetical order.</p>
<b>Security Status</b>	<p>This field displays if the security status is enabled, or disabled for the corresponding application based on the security setting. You can drill down to tiers or nodes list to view the security status of a tier, or a node respectively. Click this field to sort the status based on whether the status is enabled or disabled. If you have the Configure permission, you can change the security status using the <b>Set Status</b> option.</p>

You can click the **Export** button to download the table data. It downloads all of the rows, columns, and related data in a `.csv` file. A separate `.json` file includes the following: link to the Cisco Secure Application website where the table is exported from, global filters (if any) applied to the pages, and search filters applied to the columns. These two files are compressed into a `.zip` file for downloading. The maximum number of rows that can be exported is 10,000. If table data exceeds 10,000 rows you may apply filters to narrow your search, or export the first 10,000 results.

### Node Table

The Nodes page includes the following information about nodes:

Field Name	Description
<b>Node</b>	Identifies the node name.

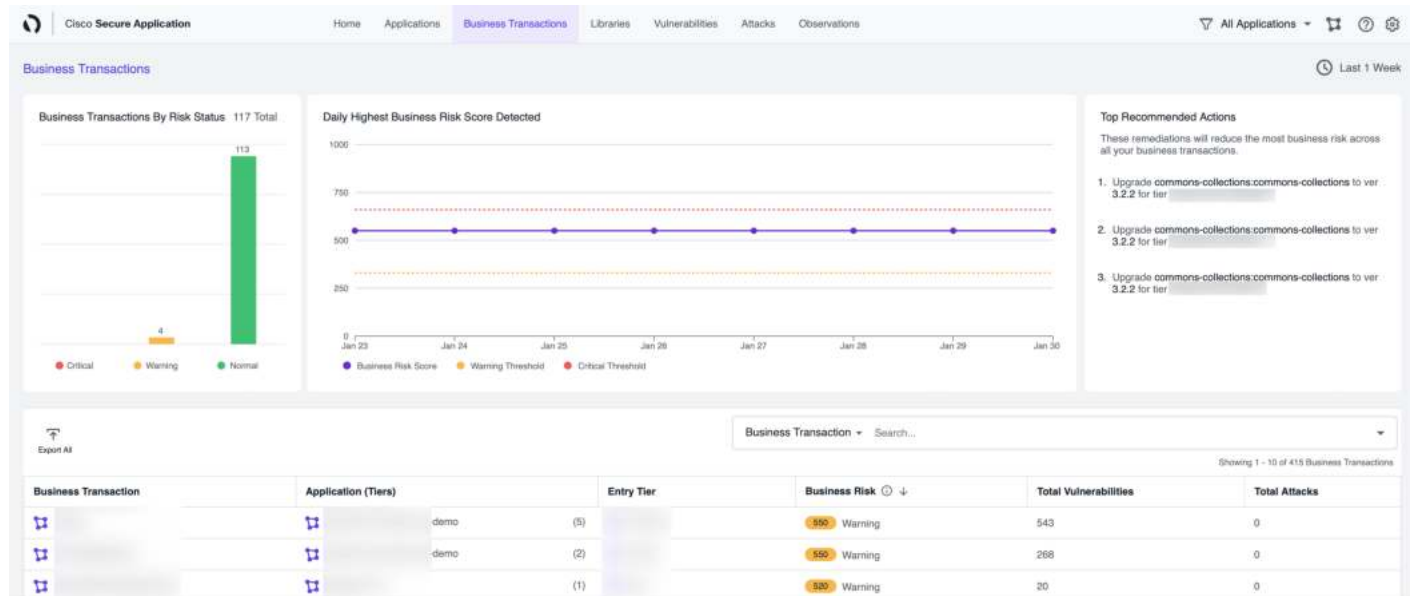

Field Name	Description
Agent Type	The technical stack of the agent matching the application stack that is monitored.
Agent Version	Identifies the version of the APM Agent.
Is Active	Displays whether or not the total number of APM nodes are registered and active. Value is either <b>Yes</b> or <b>No</b> .
Is Ready	Displays whether or not the number of <b>Supported</b> nodes that are sending heartbeats to the Secure Application service are ready. Value is either <b>Yes</b> or <b>No</b> .
Is Supported	Displays whether or not the number of <b>Active</b> nodes that are running a Secure Application are supported. Value is either <b>Yes</b> or <b>No</b> .
Is Enabled	Displays whether or not the number of <b>Ready</b> nodes have a Security Setting value of <b>Enabled</b> . Value is either <b>Yes</b> or <b>No</b> .
Is Secured	Displays whether or not the number of <b>Enabled</b> nodes are sending security insights to the Secure Application service. Value is either <b>Yes</b> or <b>No</b> .
Security Setting	<p>The security setting is disabled by default. If you require to enable the security, select <b>Enable</b>. This field displays these security settings for the corresponding application:</p> <ul style="list-style-type: none"> <li>• <b>Enable</b>: When the security setting is enabled for the nodes.</li> <li>• <b>Disable</b>: When the security setting is disabled for the nodes.</li> <li>• <b>Inherit</b>: When the security setting is inherited from the Controller. By default, the security setting is <b>Disabled</b>. Therefore, <b>Security Status</b> is <b>Disabled</b> for the application. For tiers and nodes, the security setting is inherited from the parent application and tier respectively.</li> </ul>
Security Status	This field displays the security status for the corresponding application based on the security setting. If you have the Configure permission, you can change the security status using the <b>Set Status</b> option.
Last Activity	<p>Identifies when the last activity was detected. Secured nodes send heartbeats every minute.</p> <ul style="list-style-type: none"> <li>• Orange warning icon: indicates dependency report for a node could not be processed for more than 24 hours.</li> <li>• Red error icon: indicates that the node could not be processed for more than 25 hours.</li> </ul>

Field Name	Description
Last Dependency Reported	<p>Identifies when the last dependency was detected. This reports secure and active nodes that are processed every 24 hours.</p> <ul style="list-style-type: none"> <li>Orange warning icon: indicates that the agent heartbeats were unable to reach the service for more than 3 minutes.</li> <li>Red error icon: indicates that the nodes were unable to be reached for more than 5 minutes.</li> </ul>

## Monitor Business Transactions

This page includes details to monitor the vulnerability risk of a [Business Transaction](#). Cisco Secure Application evaluates the risk of a business transaction using an algorithm that factors in exposure to the internet, access to potentially sensitive data, usage of vulnerable libraries, reached vulnerable code, prediction of vulnerability exploitation, unsafe external APIs, and runtime threat activity. These factors enable you to prioritize what is required to triage, mitigate, and remediate, which reduces risk exposure to the business.

**i** You can use the **Search** filter for the **Business Transaction, Application, and Entry Tier** categories. For more information about the **Search** filter, see [View Data Using Search Filter in Monitor Application Security Using Cisco Secure Application](#).

This page includes the following details:

Field Name	Description
<b>Business Transaction</b>	The name of the business transaction. To view the business transaction on the AppDynamics Controller, click the icon next to the name.
<b>Application (Tiers)</b>	The application name and the number of tiers that are part of the business transaction for the application. To view the application on the AppDynamics Controller, click the icon next to the name.
<b>Entry Tier</b>	The tier from which the transaction originates. To view the tier on the AppDynamics Controller, click the icon next to the name.
<b>Business Risk</b>	The Business Risk algorithm is calculated based on the likelihood of vulnerability exploitation, and the impact of the potential exploitation in a business transaction. These are the three statuses for a Business Risk: <b>Normal 0-330</b> , <b>Warning 340-660</b> , and <b>Critical 670-1000</b> . The higher the value, the higher the risk for the application vulnerability.
<b>Total Vulnerabilities</b>	<p>The number of vulnerabilities detected is based on their severity.</p> <ul style="list-style-type: none"> <li>• Critical</li> <li>• High</li> <li>• Medium</li> <li>• Low</li> </ul> <p>The color-coded icons represent these severities.</p>
<b>Total Attacks</b>	The number of attacks based on their status: <b>Exploited, Blocked, Attempted</b> .

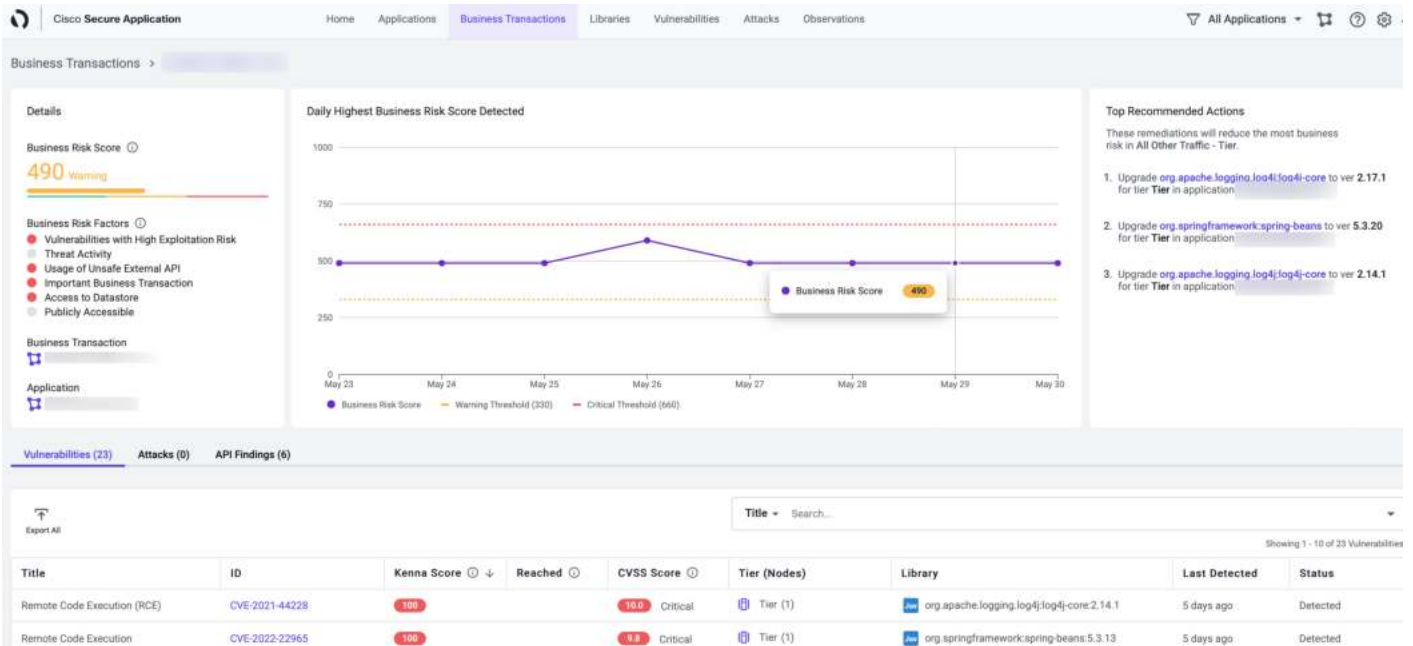

You can click the **Export** button to download the table data. It downloads all of the rows, columns, and related data in a `.csv` file. A separate `.json` file includes the following: link to the Cisco Secure Application website where the table is exported from, global filters (if any) applied to the pages, and search filters applied to the columns. These two files are compressed into a `.zip` file for downloading. The maximum number of rows that can be exported is 10,000. If table data exceeds 10,000 rows you may apply filters to narrow your search, or export the first 10,000 results.

## View Business Transaction Details

To view details for a specific business transaction, click any business transaction on the **Business Transactions** page. The top pane is split into the following sections:

- **Business Risk Score**, which includes six **Business Risk Factors**:
  - **Vulnerabilities with High Exploitation Risk**: Identifies business transaction vulnerabilities with Kenna score > 66.
  - **Threat Activity**: Identifies business transaction security events that match known attack types see [Monitor Attacks](#), or can impact the security but any malicious intent is not determined, see [Monitor Observations](#).
  - **Usage of Unsafe External API**: Identifies uses of external APIs that are unsafe.
  - **Important Business Transaction**: Identifies a business transaction that has a custom name.
  - **Access to Datastore**: Identifies a business transaction that has access to a datastore.

- **Publicly Accessible:** Identifies a business transaction that is accessible from the internet.
- **Business Transaction**
- **Application**
- **Entry Tier**
- **Daily Highest Business Risk Score Detected**
- **Top Recommended Actions**

### Vulnerabilities Tab

The bottom pane displays the vulnerabilities found in the selected business transaction.

Field Name	Description
<b>Title</b>	The vulnerability type involved in the business transaction.
<b>ID</b>	The Common Vulnerabilities and Exposure (CVE) identifier. You can click the name to view the details specific to that CVE.
<b>Kenna Score</b>	Kenna score provides an estimate of exploitation based on real-time events. These are the three statuses: Green 0-33, Amber 34-66, Red 67-100.
<b>Reached</b>	If there is an exclamation mark in this column, it means this vulnerable code has been reached.
<b>CVSS Score</b>	This score is based on the Common Vulnerability Scoring System (CVSS) with five severities: <b>None</b> 0-0, <b>Low</b> 0.1-3.9, <b>Medium</b> 4.0-6.9, <b>High</b> 7.0-8.9, <b>Critical</b> 9.0-10.0.

Field Name	Description
Tier (Nodes)	The services or the tiers that are affected because of the selected vulnerability. The number indicates the number of affected nodes. The tier icon directs to the AppDynamics flow map for that tier.
Library	The library affected because of the vulnerability. You can click the library to view the details of the library. See <a href="#">Monitor Libraries</a> .
Last Detected	The time duration since the vulnerability was last seen on the tier.
Status	<p>The status of the selected vulnerability. The status value can be:</p> <ul style="list-style-type: none"> <li>• <b>Detected</b> (at least one vulnerability is detected in the library)</li> <li>• <b>Confirmed</b> (manually set by user after review)</li> <li>• <b>Fixed</b> (vulnerability is fixed)</li> <li>• <b>Ignored</b> (manually set by user after review)</li> <li>• <b>Not Vulnerable</b> (no vulnerabilities are found in the library)</li> </ul> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p> The <b>Detected</b> and <b>Fixed</b> statuses are automatically detected based on the libraries used in the application.</p> </div>

### Attacks Tab

Name	Description
ID	<p>The ID of the corresponding Attack. Cisco Secure Application generates this ID. You can modify this ID on the attacks details page. To view the attack details page, click the desired row.</p> <p>Click this field to sort the ID alphabetically.</p>
Outcome	<p>The outcome of the corresponding attack. This provides information on these state of the attack:</p> <ul style="list-style-type: none"> <li>• <b>Observed:</b> When the events may impact the security, but any malicious intent is not determined. For example, an application opening a file outside the application directory causes <b>Observed</b> state.</li> <li>• <b>Blocked:</b> When the events are blocked based on the attack policy.</li> <li>• <b>Exploited:</b> When malicious activity is performed to impact the application's security.</li> <li>• <b>Attempted:</b> When the malicious activity is determined but not exploited.</li> </ul> <p>Click this field to sort the values alphabetically.</p>
Attack Type (Events)	The type of the attack and count of that attack type.

Name	Description
<b>Attack Trigger</b>	Relevant information from the runtime behavior resulting from the event where Secure Application determined a potential attack.
<b>Tier</b>	The tier name and the number of nodes. You can click  to launch the application flowmap in the Appdynamics Dashboard. The info icon (  ) next to an affected tier indicates that the attacked nodes in the tier include critical or medium vulnerability.
<b>Last Detected</b>	The time that is elapsed since the last event within the attack. Click this field to sort the values in ascending or descending order.
<b>Status</b>	The status of the attack is defined as either <b>open</b> or <b>closed</b> . If you have Configure permissions, click the checkboxes for the required rows and then click the <b>Set Status</b> option to set the appropriate status. Click this field to sort based on the <b>Open</b> or <b>Closed</b> state.

### API Findings Tab

Name	Description
<b>Panoptica Findings</b>	These findings are the vulnerabilities associated with the API.
<b>Category</b>	The category that the enlisted weakness, or vulnerability belongs to. For example, DNS, Network, etc.
<b>Severity</b>	The severity level of the API Security Findings, which can have a status of <b>Critical, High, Medium, Low, or Unclassified</b> .
<b>API Name</b>	The API name, usually a fully qualified domain name (FQDN). This can be logical, or can correspond to one of the endpoints where the API is reachable. For example, api.webex.com.
<b>Tier</b>	The tier name from in the business transaction chain that is making the API calls.

You can click the **Export** button to download the table data. It downloads all of the rows, columns, and related data in a `.csv` file. A separate `.json` file includes the following: link to the Cisco Secure Application website where the table is exported from, global filters (if any) applied to the pages, and search filters applied to the columns. These two files are compressed into a `.zip` file for downloading. The maximum number of rows that can be exported is 10,000. If table data exceeds 10,000 rows you may apply filters to narrow your search, or export the first 10,000 results.

## Monitor Libraries

The **Libraries** page provides a list of all libraries that are in use by the corresponding applications. The page highlights the vulnerabilities and associated risks introduced by the use of those libraries.

- You can use the **Search** filter for the **Application**, **Package Language**, **Tiers**, **Status**, and **Libraries** categories. For information about the **Search** filter, see [View Data Using Search Filter in Monitor Application Security Using Cisco Secure Application](#).
- The **Set Status** and **Edit Note** bulk edit options are available if you have the **Configure Cisco Secure Application** permission.

Library	Application	Tier (Nodes)	Highest Kenna Score	Highest CVSS Score	Total Vulnerabilities	Remediation	Status
commons-collections.com...			100	9.8 Critical	3	3.2.2	Confirmed
commons-collections.com...			100	9.8 Critical	3	3.2.2	Detected
commons-collections.com...			100	9.8 Critical	3	3.2.2	Detected
commons-collections.com...			100	9.8 Critical	3	3.2.2	Detected
commons-collections.com...			100	9.8 Critical	3	3.2.2	Detected
org.apache.logging.log4j...			100	10.0 Critical	6	2.13.2	Detected
commons-collections.com...			100	9.8 Critical	3	3.2.2	Detected
commons-collections.com...			100	9.8 Critical	3	3.2.2	Detected
org.apache.tomcat.embed...			100	9.8 Critical	31	8.5.78	Detected
commons-collections.com...			100	9.8 Critical	3	3.2.2	Detected

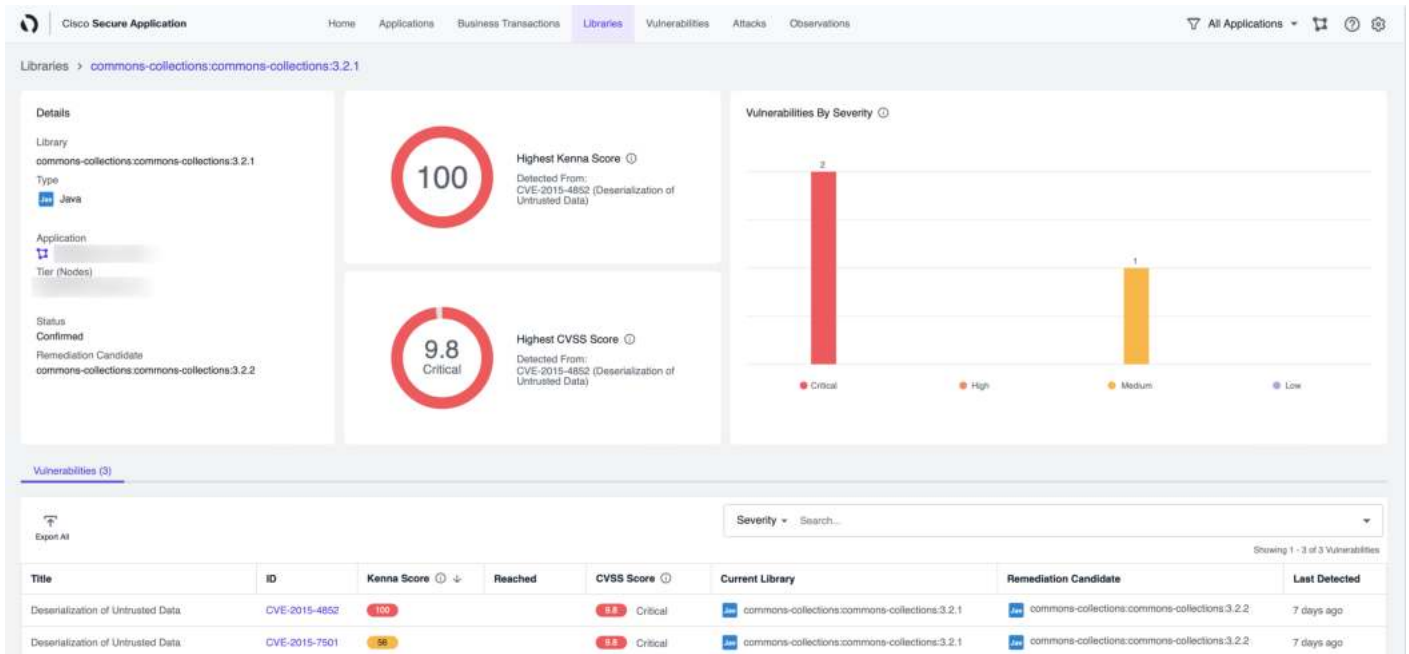

Field Name	Description
<b>Library</b>	Libraries in the selected application. You can click on the row to view the details of the library. See <a href="#">View Vulnerabilities for a Library</a> .
<b>Application</b>	The application name that uses the corresponding library.
<b>Tier (Nodes)</b>	The application tier that is vulnerable because of its relationship to the corresponding library. Click the flow map icon (  ) next to an application to view the application flow map in the AppDynamics dashboard.
<b>Highest Kenna Score</b>	Kenna score provides an estimate of exploitation based on real-time events. These are the three statuses: Green 0-33, Amber 34-66, Red 67-100.
<b>Highest CVSS Score</b>	This score is based on the Common Vulnerability Scoring System (CVSS) with five severities: <b>None</b> 0-0, <b>Low</b> 0.1-3.9, <b>Medium</b> 4.0-6.9, <b>High</b> 7.0-8.9, <b>Critical</b> 9.0-10.0.

Field Name	Description
<b>Total Vulnerabilities</b>	<p>The number of vulnerabilities based on severity:</p> <ul style="list-style-type: none"> <li>• Critical</li> <li>• High</li> <li>• Medium</li> <li>• Low</li> </ul> <p>Hover on the required color to know the severity. Click this field to sort in increasing or decreasing order based on the number of vulnerabilities.</p>
<b>Remediation</b>	<p>The recommended version of the library that can be used for remediation.</p>
<b>Status</b>	<p>The status of the vulnerable libraries. By default, when a vulnerability is detected the value is <b>Detected</b>. The status value can be:</p> <ul style="list-style-type: none"> <li>• <b>Detected</b> (at least one vulnerability is detected in the library)</li> <li>• <b>Confirmed</b> (Library is reviewed)</li> <li>• <b>Upgraded</b> (Library is upgraded to fix the issue)</li> <li>• <b>Downgraded</b> (Library is downgraded to fix the issue)</li> <li>• <b>Removed</b> (Library is removed to fix the issue)</li> <li>• <b>Ignored</b> (the library does not require to be considered when remediating vulnerability libraries because of some mitigations or exception)</li> <li>• <b>Not Vulnerable</b> (no vulnerabilities are found in the library)</li> </ul> <p>The <b>Detected</b>, <b>Downgraded</b>, and <b>Upgraded</b> status are auto-populated. If you have the <b>Configure Cisco Secure Application</b> permission, you can change the <b>Status</b> by selecting the required libraries and using the <b>Set Status</b> option.</p> <div style="border: 1px solid #00aaff; padding: 5px; margin: 10px 0;"> <p> You must have the configure permission to view and use the <b>Set Status</b> option.</p> </div> <p>Click this field to sort based on the status of the vulnerable library.</p>

You can click the **Export** button to download the table data. It downloads all of the rows, columns, and related data in a `.csv` file. A separate `.json` file includes the following: link to the Cisco Secure Application website where the table is exported from, global filters (if any) applied to the pages, and search filters applied to the columns. These two files are compressed into a `.zip` file for downloading. The maximum number of rows that can be exported is 10,000. If table data exceeds 10,000 rows you may apply filters to narrow your search, or export the first 10,000 results.

### View Vulnerabilities for a Library

To view all the vulnerabilities within a specific library, click the row on the **Libraries** page.

The top, and bottom pane displays the details about the vulnerable library, which includes these fields:

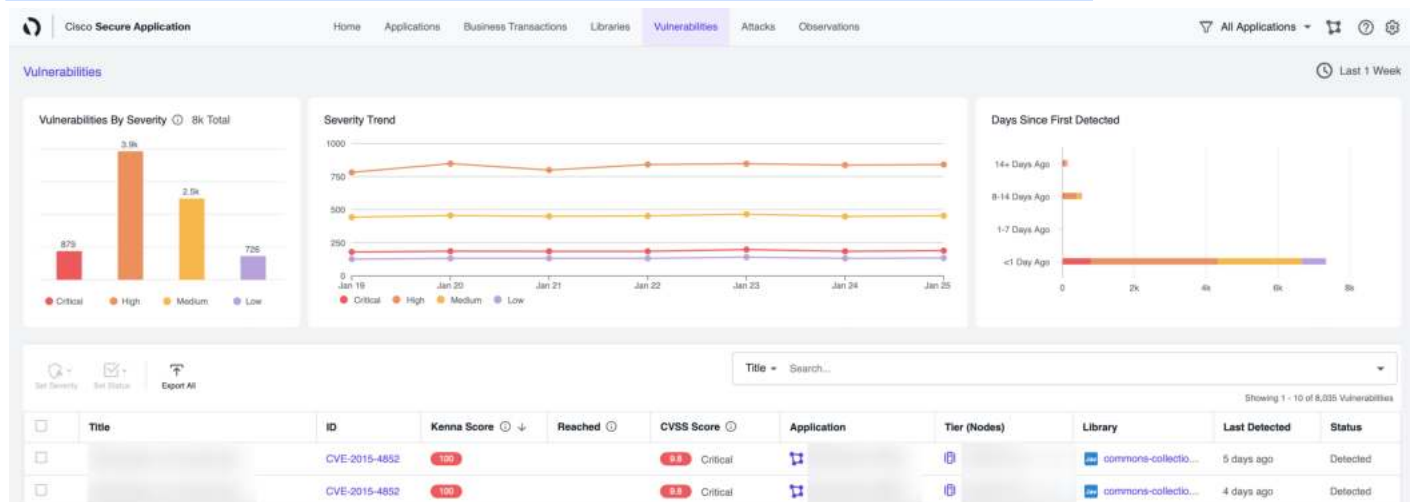

Field Name	Description
<b>Library</b>	Libraries in the selected application. You can click on the row to view the details of the library. See <a href="#">View Vulnerabilities for a Library</a> .
<b>Type</b>	The language used for the corresponding library. Currently, Cisco Secure Application supports Java and .NET.
<b>Application</b>	The name of the application that uses the selected library.
<b>Tier (Nodes)</b>	Name of the affected tier. You can click the flowmap icon (  ) next to the tier name to view the flowmap on the AppDynamics dashboard. The number in the parenthesis ( ) indicates the number of affected nodes.
<b>Status</b>	The status of the library.
<b>Remediation Candidate</b>	The version of the library that should be used to remediate the vulnerability.
<b>Highest Kenna Score</b>	Kenna score provides an estimate of exploitation based on real-time events. These are the three statuses: Green 0-33, Amber 34-66, Red 67-100.
<b>Highest CVSS Score</b>	This score is based on the Common Vulnerability Scoring System (CVSS) with five severities: <b>None</b> 0-0, <b>Low</b> 0.1-3.9, <b>Medium</b> 4.0-6.9, <b>High</b> 7.0-8.9, <b>Critical</b> 9.0-10.0.

Field Name	Description
<b>Vulnerabilities By Severity</b>	The number of vulnerabilities based on severity: <ul style="list-style-type: none"> <li>• Critical</li> <li>• High</li> <li>• Medium</li> <li>• Low</li> </ul>
<b>Reached</b>	A yellow icon is displayed in this column to indicate that a vulnerability method is matched.
<b>ID</b>	The Common Vulnerabilities and Exposure (CVE) identifier. Click the CVEs to view the vulnerability details. For information about Vulnerabilities, see <a href="#">Monitor Vulnerabilities</a> .
<b>Current Library</b>	The library that introduced the vulnerability to the application.

## Monitor Vulnerabilities

An application registered with Cisco Secure Application is scanned, and continuously monitored for vulnerabilities. The **Vulnerabilities** page displays the list of all the scanned vulnerabilities. When vulnerabilities are detected, a user with Configure permission can prioritize the vulnerabilities. There are few options such as **Set Status**, and **Set Severity** that are available only if you have the Configure permissions.

**i** By default, this page displays an overview of the selected application. For information about selecting a specific application or service, see [Select Application Scope at Monitor Application Security Using Cisco Secure Application](#). You can also use the **Search** filter to search based on the **Vulnerability, Package Language, CWE, Severity, Application, Tiers, Libraries** and **Status** values.

**Vulnerabilities** includes **Last 1 Week**, which displays data for last seven days.

The top, and bottom pane of the **Vulnerabilities** includes:

Chart	Description
<b>Vulnerabilities By Severity</b>	<p>This chart represents the total number of vulnerabilities. The number of vulnerabilities based on the following severity: <b>Critical, High, Medium, and Low</b>.</p> <p>Hover on the required severity to view the number of open vulnerabilities with that severity. If you require all the charts in the pane to display based on a specific severity, click the severity on the pie chart. To return back to the complete chart, click the same severity again.</p>
<b>Severity Trend</b>	<p>This chart displays the number of open tickets versus the number of fixed tickets from the last 7 days. This shows the trend of fixing open vulnerabilities.</p>
<b>Days Since First Detected</b>	<p>This chart displays the number of days the vulnerability is open versus the severity of the vulnerability (critical, high, medium, or low).</p>
<b>Title</b>	<p>The name of the vulnerability.</p>
<b>ID</b>	<p>The Common Vulnerabilities and Exposure (CVE) identifier. You can click the name to view the details specific to that CVE.</p>
<b>Kenna Score</b>	<p>Kenna score provides an estimate of exploitation based on real-time events. These are the three statuses: Green 0-33, Amber 34-66, Red 67-100.</p>
<b>Reached</b>	<p>The application uses the vulnerable method as part of its code flow. A yellow icon is displayed in this column to indicate that a vulnerability method is matched.</p>
<b>CVSS Score</b>	<p>This score is based on the Common Vulnerability Scoring System (CVSS) with five severities: <b>None</b> 0-0, <b>Low</b> 0.1-3.9, <b>Medium</b> 4.0-6.9, <b>High</b> 7.0-8.9, <b>Critical</b> 9.0-10.0.</p>
<b>Application</b>	<p>Name of the affected application.</p>

Chart	Description
Tier (Nodes)	<p>The services or the tiers affected because of the corresponding vulnerability. The number in parenthesis indicates the number of nodes. Click the flow map icon(  ) to view the AppDynamics flow map for that tier.</p> <p>Note that a node count of zero (0) means that a vulnerability isn't present in any of your active nodes. AppDynamics does not change the state of a fixed vulnerability to a confirmed vulnerability because that is a user-defined state.</p>
Library	<p>The library that exists in the corresponding application and tier. You can click the value in this field to view the list of all the vulnerabilities that impacts this library.</p>
Last Detected	<p>The time elapsed after the vulnerability was last detected.</p>
Status	<p>The status of the corresponding vulnerability. The status value can be:</p> <ul style="list-style-type: none"> <li>◦ <b>Detected</b> (at least one vulnerability is detected in the library)</li> <li>◦ <b>Confirmed</b> (Library is reviewed)</li> <li>◦ <b>Fixed</b> (Library is fixed)</li> <li>◦ <b>Ignored</b> (not a library)</li> <li>◦ <b>Not Vulnerable</b> (no vulnerabilities are found in the library)</li> </ul> <p>The status Ignored can be updated by the developer with Configure permission for Cisco Secure Application. If you have Configure permissions, you can select the vulnerabilities using the checkbox, and then set the status by using the <b>Set Status</b> option. Without Configure permission, the <b>Set Status</b> option is unavailable.</p>

### View Vulnerability Details

To prioritize vulnerabilities, you may require additional information. Click a vulnerability row to view detailed information about a vulnerability.

The screenshot displays the vulnerability details view in AppDynamics. At the top, the navigation bar includes 'Cisco Secure Application', 'Home', 'Applications', 'Business Transactions', 'Libraries', 'Vulnerabilities', 'Attacks', and 'Observations'. The main content area is titled 'Vulnerabilities > Deserialization of Untrusted Data (CVE-2015-4852)'. It features two score cards: 'Kenna Score' with a value of 100 and 'CVSS Score' with a value of 9.8 (Critical). A 'Details' pane on the right lists the title, ID (CVE-2015-4852), CWE (CWE-502), publish date (11-06-2015), first/last seen (5 days ago), type (commons-collections:commons-collections:3.2.1), and remediation (commons-collections:commons-collections:3.2.2). An 'Overview' pane provides a description of the vulnerability and a note about the affected library. At the bottom, a table titled 'Affected Tiers (1)' shows one entry with application 'commons-collections:commons-collections:3.2.1', tier '(1)', reached status, and last detected 5 days ago.

The top, and bottom pane of the vulnerability details view displays the following details:

Field Name	Description
Kenna Score	Kenna score provides an estimate of exploitation based on real-time events. These are the three statuses: Green 0-33, Amber 34-66, Red 67-100.
CVSS Score	This score is based on the Common Vulnerability Scoring System (CVSS) with five severities: <b>None</b> 0-0, <b>Low</b> 0.1-3.9, <b>Medium</b> 4.0-6.9, <b>High</b> 7.0-8.9, <b>Critical</b> 9.0-10.0.
Title	The name of the vulnerability.
ID	The Common Vulnerabilities and Exposure (CVE) identifier. You can click the name to view the details specific to that CVE.
CWE	The Common Weakness Enumeration ID for the corresponding vulnerability.
Publish Date	The date in which the details were published.
First / Last Seen	The timeframe when the vulnerability was first detected and when the vulnerability was last detected.
Type	The vulnerability type.

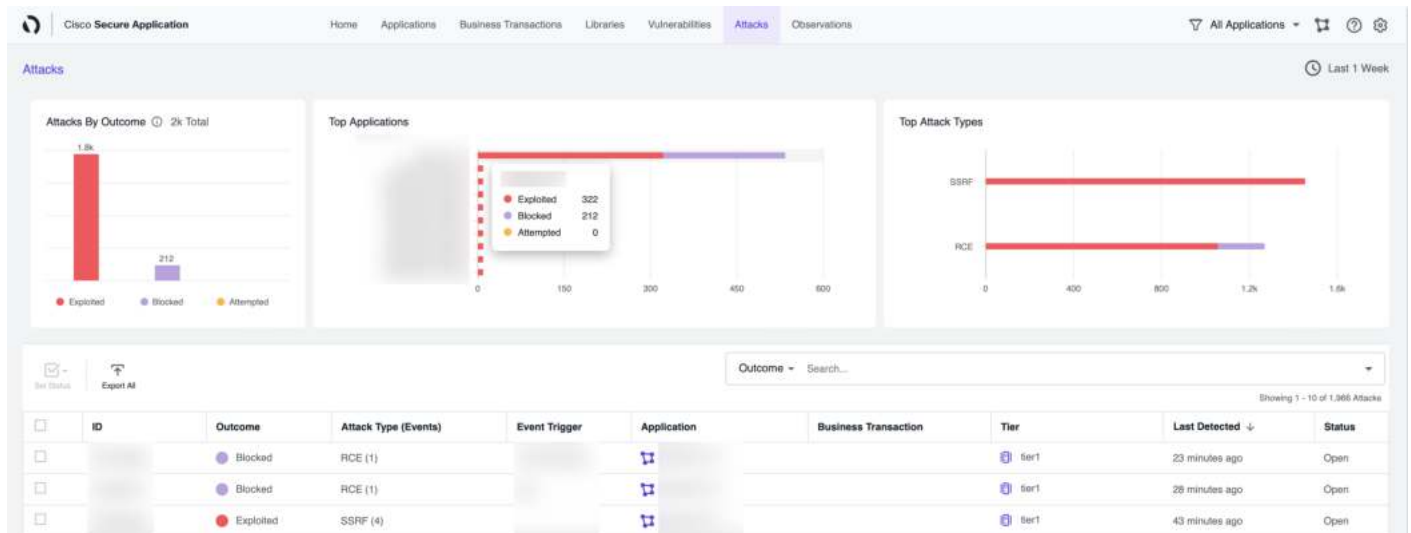

Field Name	Description
Remediation	The recommended remediation action. In the case of a vulnerable library, the version(s) to upgrade the library for remediation. Click on <b>show all &lt;count of versions&gt;</b> to view all the recommended remediation versions.
Overview	The overview of the vulnerability.
Application	Name of the affected application.
Tier (Nodes)	The services or the tiers affected because of the corresponding vulnerability. The number in parenthesis indicates the number of nodes. Click the flow map icon(  ) to view the AppDynamics flow map for that tier.  Note that a node count of zero (0) means that a vulnerability isn't present in any of your active nodes.
Library	The library that exists in the corresponding application and tier. You can click the value in this field to view the list of all the vulnerabilities that impacts this library.
Reached	The application uses the vulnerable method as part of its code flow. A yellow icon is displayed in this column to indicate that a vulnerability method is matched.
Last Detected	The time elapsed since the vulnerability is detected.
Status	<p>The status of the selected vulnerability. The status value can be:</p> <ul style="list-style-type: none"> <li>• <b>Detected</b> (at least one vulnerability is detected in the library)</li> <li>• <b>Confirmed</b> (vulnerability is reviewed)</li> <li>• <b>Fixed</b> (vulnerability is fixed)</li> <li>• <b>Ignored</b> (not a vulnerability)</li> <li>• <b>Not Vulnerable</b> (no vulnerabilities are found in the library)</li> </ul> <p>If you have Configure permissions, you can select the rows using the checkbox, and then set the status by using the <b>Set Status</b> option. Without Configure permission, the <b>Set Status</b> option is unavailable.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p> The <b>Detected</b> and <b>Fixed</b> status are automatically detected based on the libraries used in the application.</p> </div>

You can click the **Export** button to download the table data. It downloads all of the rows, columns, and related data in a `.csv` file. A separate `.json` file includes the following: link to the Cisco Secure Application website where the table is exported from, global filters (if any) applied to the pages, and search filters applied to the columns. These two files are compressed into a `.zip` file for downloading. The maximum number of rows that can be exported is `10,000`. If table data exceeds `10,000` rows you may apply filters to narrow your search, or export the first `10,000` results.

## Monitor Attacks

The **Attacks** page includes details of all the open and closed attacks on the managed applications.

**i** By default, this page displays an overview of the selected application. For information about selecting a specific application or service, see **Select Scope for the Dashboard** at [Monitor Application Security Using Cisco Secure Application](#).

### Attacks - Top Pane

The top pane includes these details:

Chart	Description
<b>Attacks By Outcome</b>	This provides information on these state of the attack: <ul style="list-style-type: none"> <li>• <b>Exploited:</b> When malicious activity is performed to impact the application's security.</li> <li>• <b>Blocked:</b> When the events are blocked based on the attack policy.</li> <li>• <b>Attempted:</b> When the malicious activity is determined but not exploited.</li> </ul>

Chart	Description
Top Applications	<p>This chart displays the top 10 applications based on open attacks per application. If you select a specific application scope, then only that application is displayed. To view all the applications, reset the application scope. See <a href="#">Monitor Application Security Using Cisco Secure Application</a>. These applications are in either an <b>exploited</b>, <b>blocked</b>, <b>attempted</b>, or state versus the total number of open attacks on the application.</p> <p>Hover on each state to view the number of blocked, exploited, and open attacks.</p>
Top Attack Types	<p>This chart displays the top 10 attack events that are in an <b>exploited</b>, <b>blocked</b>, or <b>attempted</b> state versus the total number of open attacks on the events. Hover on each state to view the number of blocked, exploited, attempted, and open attacks. Attack Types include:</p> <ul style="list-style-type: none"> <li>• <b>DESERIAL</b>: The agent detected a Java class deserialization event.</li> <li>• <b>SQL</b>: The agent detected a known SQL injection signature event.</li> <li>• <b>RCE</b>: The agent detected a remote code execution event.</li> <li>• <b>LOG4J</b>: The agent detected a Log4Shell attack.</li> <li>• <b>SSRF</b>: The agent detected a server side request forgery event.</li> <li>• <b>MALIP</b>: The agent detected either an inbound, or outbound socket connection to a known malicious IP address.</li> </ul>

### Attacks - Bottom Pane

The bottom pane displays these details:

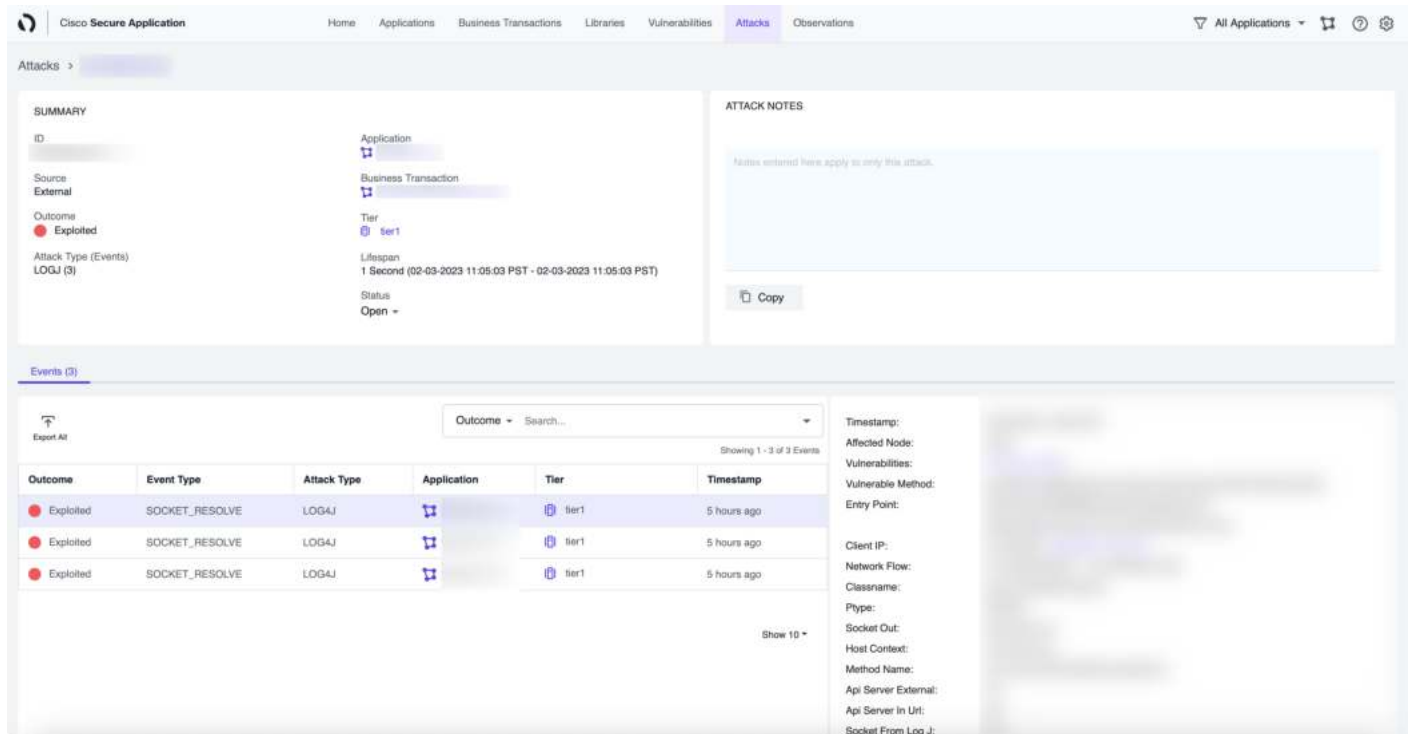

Name	Description
ID	The ID of the corresponding Attack. Cisco Secure Application generates this ID. You can modify this ID on the attacks details page. To view the attack details page, click the desired row. Click this field to sort the ID numerically.
Outcome	<p>The outcome of the corresponding attack. This provides information on these state of the attack:</p> <ul style="list-style-type: none"> <li>• <b>Exploited</b>: When malicious activity is performed to impact the application's security.</li> <li>• <b>Blocked</b>: When the events are blocked based on the attack policy.</li> <li>• <b>Attempted</b>: When the malicious activity is determined but not exploited.</li> </ul> <p>Click this field to sort the values alphabetically.</p>
Attack Type (Events)	The type of the attack and count of that attack type.

Name	Description
<b>Event Trigger</b>	Relevant information from the runtime behavior resulting from the event where Secure Application determined a potential attack.
<b>Application</b>	The application affected by the attack.
<b>Business Transaction</b>	When you click an <b>Attack ID</b> , you receive a summary for each <b>Attack</b> , and a <b>Business Transition</b> type, if you have a <b>Business Transaction</b> enabled. See <a href="#">Monitor Business Transactions</a> .
<b>Tier</b>	The tier name and the number of nodes. You can click  to launch the application flowmap in the AppDynamics Dashboard. The info icon (  ) next to an affected tier indicates that the attacked nodes in the tier include critical or medium vulnerability.
<b>Last Detected</b>	The time that is elapsed since the last event within the attack. Click this field to sort the values in ascending or descending order.
<b>Status</b>	The status of the attack is defined as either <b>open</b> or <b>closed</b> . If you have Configure permissions, click the checkboxes for the required rows and then click the <b>Set Status</b> option to set the appropriate status. Click this field to sort based on the <b>Open</b> or <b>Closed</b> state.

You can click the **Export** button to download the table data. It downloads all of the rows, columns, and related data in a `.csv` file. A separate `.json` file includes the following: link to the Cisco Secure Application website where the table is exported from, global filters (if any) applied to the pages, and search filters applied to the columns. These two files are compressed into a `.zip` file for downloading. The maximum number of rows that can be exported is 10,000. If table data exceeds 10,000 rows you may apply filters to narrow your search, or export the first 10,000 results.

### View Attack Details

The attack details page provides information of the attack. Click any attack to view the attack details page.

### Attack Details - Top Pane

The top pane provides a summary of the attack. To view the application flowmap, you can click the flowmap icon (  ) next to the application name. A user (with Configure permission) can add notes under **Attack Notes** if desired. This note is visible to all users when monitoring attack details.

### Attack Details - Bottom Left and Bottom Right Pane

The bottom pane is split into left pane (a list of events correlated to the attack automatically) and right pane (the details of a selected event).

 You can use the **Search** filter to filter based on the following categories:

- Outcome
- Event Type
- Attack Type
- Affected Tiers

For more information about the **Search** filter, see **View Data Using Search Filter** in [Monitor Application Security Using Cisco Secure Application](#).

### Left Pane

The left pane displays these details:

Field Name	Description
Outcome	The outcome of the event. This provides information on whether the selected event is <b>Exploited</b> , <b>Blocked</b> , or <b>Attempted</b> .
Event Type	The type of the attack event or the vulnerability name.
Attack Type	The type of the attack such as RCE and so on.
Application	The affected application.
Tier	The affected tier.
Timestamp	The time the event is detected.

You can click the **Export** button to download the table data. It downloads all of the rows, columns, and related data in a `.csv` file. A separate `.json` file includes the following: link to the Cisco Secure Application website where the table is exported from, global filters (if any) applied to the pages, and search filters applied to the columns. These two files are compressed into a `.zip` file for downloading. The maximum number of rows that can be exported is 10,000. If table data exceeds 10,000 rows you may apply filters to narrow your search, or export the first 10,000 results.

### Right Pane

The right pane displays the following details based on the selected event:

 These fields are displayed when the events are triggered during a web transaction.

Field Name	Description
Timestamp	The date and time when the event is detected.
Affected Node	The name of the affected node. You can click the flowmap icon (  ) to view the <b>Tiers and Nodes</b> flowmap on the AppDynamics dashboard.
Event Trigger	It displays the attack target. It can be a file, host, command, etc.
Vulnerabilities	The type of vulnerability used for the attack. Based on the event type, this field may not be displayed.  If the value is displayed, click the value to view the vulnerability details. For information about Vulnerabilities, see <a href="#">Monitor Vulnerabilities</a> .

Field Name	Description
<b>Entry Point</b>	The webserver URL accessed by the client in the transaction that triggered the event. Based on the event type, this field may not be displayed.
<b>Client IP</b>	<p>The IP address of the remote endpoint of the connection in the transaction. This IP address can be the IP address of client machine, load balancer or proxy in a client network.</p> <p>The warning icon (  ) next to IP address indicates that a known malicious IP is detected.</p> <p>This is available if the attack is from a client IP address that is on a known malicious IP list.</p> <p>Currently, the Talos malicious IP list is supported. Therefore, this attribute displays the value Talos when the attack is from a client IP on the Talos list.</p>
<b>Network Flow</b>	The network flow as observed from the node that includes the source and the destination IP address.
<b>Details</b>	<p>The details about the resulting behavior of the node triggered by an inbound request. The details may change based on the event and attack type. Click <b>Show More</b> to view the <b>Details</b> dialog box.</p> <p>You can copy the details as per your requirement.</p>
<b>Stack Trace</b>	<p>Details of the stack trace for the corresponding event. Click <b>Show More</b> to view the <b>Stack Trace</b> dialog box.</p> <p>You can use this information to guide developers to the lines of code that were used to achieve the result of the event. You can copy the details as per your requirement.</p>
<b>Socket Address</b>	<p>The destination IP address. It can be a host, network, subnetwork, etc. The warning icon (  ) next to IP address indicates that a known malicious IP is detected.</p> <p>This is available if the attack is from a client IP address that is on a known malicious IP list.</p> <p>Currently, the Talos malicious IP list is supported. Therefore, this attribute displays the value Talos when the attack is from a client IP on the Talos list.</p>

Field Name	Description
Policy	<p>The action that is used for this event based on the existing policy when the event is detected.</p> <p>If you have the Configure permission, you can change the policy by clicking this value. See <a href="#">Cisco Secure Application Policies</a>.</p>

## Monitor Observations

Observations are runtime events that do not violate a policy or that are not considered to be an attack. These can be normal runtime behavior where the events may impact the security, but any malicious intent is not determined. For example, an application opening a file outside the application directory causes **Observed** state.

You can use this information in investigating incidents to understand the historical behavior of an application and in defining the runtime policy.

The top pane includes the observed top 10 applications and top 5 event types.

The bottom pane includes these details:

Name	Description
ID	<p>The ID of the corresponding Observation. Cisco Secure Application generates this ID.</p> <p>You can modify this ID on the Observation details page. To view the Observation details page, click the desired row.</p> <p>Click this field to sort the ID alphabetically.</p>
Source	<p>The source of the corresponding Observation. This provides information on these types of the observation:</p> <ul style="list-style-type: none"> <li>• <b>Internal:</b> When the events are detected from an internal source.</li> <li>• <b>External:</b> When the events are detected from an external source.</li> <li>• <b>Unknown:</b> When the source of the runtime behaviour is not known.</li> </ul> <p>Click this field to sort the values alphabetically.</p>
Events	<p>The type of the observation and count of that observation type.</p>

Name	Description
<b>Observation Type</b>	<b>Observation types include:</b> <ul style="list-style-type: none"> <li>• <b>API:</b> The agent detected an outgoing socket connection from the application stack.</li> <li>• <b>COMMAND:</b> The agent detected a local command was forked by the application stack.</li> <li>• <b>DESERIAL:</b> The agent detected a Java class deserialization event.</li> <li>• <b>LFI:</b> The agent detected a file read, file write, or file delete event.</li> <li>• <b>NETWORK:</b> This agent detects network connections to specific hosts.</li> <li>• <b>PATH:</b> The agent detected a path traversal event in the application stack.</li> <li>• <b>SQL:</b> The agent detected a non-parameterized SQL command.</li> <li>• <b>VULN:</b> The agent detected and unsafe cookie, unauthenticated access, or clear text HTTP event.</li> </ul>
<b>Application</b>	The application affected by the observation.
<b>Tier (Nodes)</b>	The tier name and the number of nodes. You can click  to launch the application flowmap in the Appdynamics Dashboard. The info icon (  ) next to an affected tier indicates that the observed nodes in the tier include critical or medium vulnerability.
<b>Last Detected</b>	The time that is elapsed since the last event within the observation.  Click this field to sort the values in ascending or descending order.

You can click the **Export** button to download the table data. It downloads all of the rows, columns, and related data in a `.csv` file. A separate `.json` file includes the following: link to the Cisco Secure Application website where the table is exported from, global filters (if any) applied to the pages, and search filters applied to the columns. These two files are compressed into a `.zip` file for downloading. The maximum number of rows that can be exported is 10,000. If table data exceeds 10,000 rows you may apply filters to narrow your search, or export the first 10,000 results.

## Cisco Secure Application for OpenTelemetry

Cisco Secure Application is available for OpenTelemetry Java. If you have an application monitored by the OpenTelemetry Java Agent, you can deploy the Cisco Secure Application extension for OpenTelemetry Java to monitor the application security. See [Cisco Secure Application Requirements](#).

### Before You Begin

To use Cisco Secure Application, ensure:

- You have met the preceding Cisco Secure Application Requirements.

- You have enough Cisco Secure Application licenses to cover the supported Cisco Secure Application extension usage within the applications you plan on securing. To get a Cisco Secure Application license, contact the AppDynamics sales representative, or email [salesops@appdynamics.com](mailto:salesops@appdynamics.com).
- You have the Controller version  $\geq 23.11.0$ . These versions reflect recommended minimum versions. We continually update our technology, so it's optimal to use the most recent agent version when possible.
- For OpenTelemetry Java, you have the OpenTelemetry Java version  $\geq 1.28.0$ . See [OpenTelemetry Java releases](#).
- You have Cisco Secure Application Extension version  $\geq 23.11.0$ .
- You have configured the traces to be sent to AppDynamics for OpenTelemetry. See [AppDynamics for OpenTelemetry™](#). This is required to in order to have Cisco Secure Application registered and active.

- The `service.namespace` resource attribute is required and maps to Application name in the Controller. See [Configure Resource Attributes](#).
- The `service.name` resource attribute is required and maps to the tier name. See [Configure Resource Attributes](#).
- Traces can be sampled if the only requirement allows registration of the Cisco Secure Application extension. See [OpenTelemetry Tail Sampling Processor](#).

## Configure the OpenTelemetry Java

You must configure the OpenTelemetry Java Agent in order to launch the Cisco Secure Application extension. To add the extension to the OpenTelemetry Java Agent:

1. Download the Cisco Secure Application extension zip from [AppDynamics Downloads Portal](#) under **AppDynamics OpenTelemetry Extensions**. If your application is deployed in a container environment, then you can download the Cisco Secure Application extension docker image from [Docker Hub](#) into a shared volume utilizing an init container.
2. Extract the Cisco Secure Application extension zip file and copy it to the host that is running the application to the OpenTelemetry Java Agent.
3. Set the `otel.javaagent.extensions` system property or the `OTEL_JAVAAGENT_EXTENSIONS` environment variable to the full path of the extension JAR or folder. See [OpenTelemetry Extensions Config](#).

```
-Dotel.javaagent.extensions=/opt/appdynamics/otel-java-extensions
```

The following resource attributes are determined through `otel.resource.attributes` system property or `OTEL_RESOURCE_ATTRIBUTES` environment variable in the OpenTelemetry Java Agent:

- `service.name` = tier name
- `service.namespace` = application name
- Cisco Secure Application automatically sets the `node.name` using one of these three attributes: `service.node`, `service.instance.id`, or Container ID.

## Configure the Cisco Secure Application Extension

You must configure the Controller access for the Cisco Secure Application extension. To do that, use one of the following options:

1. Use these system properties:

```
-Dappdynamics.controller.hostName=name.saas.appd-test.com
-Dappdynamics.controller.port=443
```

```
-Dappdynamics.controller.ssl.enabled=true
-Dappdynamics.agent.accountName=name
-Dappdynamics.agent.accountAccessKey=key
```

2. Use these environment variables:

Environment Variable	Equivalent property
APPDYNAMICS_CONTROLLER_HOST_NAME	<controller-host>
APPDYNAMICS_CONTROLLER_PORT	<controller-port>
APPDYNAMICS_CONTROLLER_SSL_ENABLED	<controller-ssl-enabled>
APPDYNAMICS_AGENT_ACCOUNT_NAME	<account-name>
APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY	<account-access-key>

## Troubleshooting

For common troubleshooting actions that you can take to solve Cisco Secure Application issues, see [Troubleshooting Cisco Secure Application Issues](#).

## Troubleshooting Cisco Secure Application Issues

This page provides common troubleshooting actions that you can take to solve Cisco Secure Application issues.

### Cisco Secure Application Does Not Start

- Cisco Secure Application runs with monitored application processes. At startup, Cisco Secure Application attempts to create its own log directory. An OS user, under which monitored application processes run, must have **Read**, and **Write** access to all AppDynamics, and Cisco Secure Application related directories, libraries, and installed components. Otherwise, Cisco Secure Application will not start.
- Ensure that you update OS permissions. To do this, grant **Read**, and **Write** access to the existing owner of the Cisco Secure Application directories by issuing the command from a terminal (on Linux platforms):

```
find external-services/argentoDynamicService -type d -exec chmod g+w {}
```

### Cisco Secure Application Permissions Are Unavailable in the Role Configuration

- Check if the Controller version meets the requirements. See [Cisco Secure Application Requirements](#).
- If the permissions are unavailable even when the Controller version is supported, ensure that you have activated the Cisco Secure Application license for the Controller. To get a Cisco Secure Application license, contact the AppDynamics sales representative, or email [salesops@appdynamics.com](mailto:salesops@appdynamics.com).

## Cisco Secure Application for OpenTelemetry Is Not Loading

Cisco Secure Application for OpenTelemetry may take 20+ minutes for the initial application and security findings to appear in the Controller.

### Disable Cisco Secure Application at Agent Start-up

The dynamic service for bootstrapping Cisco Secure Application within the Java Agent is enabled by default. However, if you need to disable the Cisco Secure Application dynamic service, you can use any of the following ways.

- The properties below disable Cisco Secure Application within an agent only while launching the monitored application process. The properties can't stop an already running instance of the Cisco Secure Application service.
- The properties `multi-tenant-agent-enabled` and `multi.tenant.agent.no.service.startup` impact not only Cisco Secure Application, but other multi-tenant agent services. To disable just the Cisco Secure Application dynamic service, see [disable-dynamic-services](#).

- Apply the node property from the Controller UI. You can use any one of the following node properties:

Property Name	Value
<code>multi-tenant-agent-enabled</code>	<code>false</code>
<code>disable-dynamic-services</code>	<code>argentoDynamicService</code>

- Add the System Property `-Dmulti.tenant.agent.no.service.startup=true` in JVM arguments.

## Security Events Widget Is Not Displayed in an Application Flow Map

- You can view the **Security Events** widget after the license activation. Ensure that you have the Cisco Secure Application license. To get a Cisco Secure Application license, contact the AppDynamics sales representative, or email [salesops@appdynamics.com](mailto:salesops@appdynamics.com).
- If the widget is not displayed even when the license is activated, then confirm with the administrator that the account has the necessary permissions to view or configure Cisco Secure Application. See [Account Permissions](#).

## Number of Registered Nodes and Active Nodes Does Not Match

On the **Applications** page, drilldown in the application to identify the inactive node. Check the APM agent logs on the inactive node(s). See [Troubleshooting Java Agent Issues](#).

## Vulnerabilities or Attacks Are Not Displayed on the Home, Vulnerabilities, or Attacks Page

- Ensure that the **Security Setting** is set to **Enabled** on at least one of the applications, tiers, or nodes within the **Applications** page. Also, that the agents are registered and active. See [Monitor Security Status of Applications](#).
- If the vulnerabilities and attacks are not displayed even when the **Security Setting** is enabled, review the following troubleshooting scenarios to identify other potential issues.

## Number of Enabled Nodes and Registered Nodes Does Not Match

- Check if the nodes that have **Security Status** set to **Enabled** use the APM Agent version that meets the requirements. See [Cisco Secure Application Requirements](#).

- If the agent version is supported, then drilldown in the **Application** view to identify the unregistered node(s). Check the APM agent logs on the unregistered node(s). See [Troubleshooting Java Agent Issues](#).

### Security Setting is Enabled and No Libraries Are Listed

- Confirm that there are active nodes in the **Application** view. See [Monitor Security Status of Applications](#).
- It is also possible that there are no third-party libraries used in the monitored applications.

### Security Setting is Enabled and No Vulnerabilities Are Listed

- Confirm that there are active nodes in the **Application** view. See [Monitor Security Status of Applications](#).
- Verify that there is a vulnerability policy enabled, and that it has an action of **Detect** or **Patch** for a monitored application with active nodes. See [Cisco Secure Application Policies](#).
- It is also possible that there are no vulnerabilities within the third-party libraries used within the monitored applications or observed in the application behavior.

### Security Setting is Enabled and No Attacks Are Listed

- Confirm that there are active nodes in the **Application** view. See [Monitor Security Status of Applications](#).
- Verify that there is an attack policy enabled, and that it has an action of **Detect** or **Block** for a monitored application with active nodes. See [Cisco Secure Application Policies](#).
- It is also possible that there are no attacks detected in the monitored applications.

## The Applications Page Display the Node Not Active Message for an Active Node

The AppDynamics dashboard displays the node data even when the node is displaying as not active in the Cisco Secure Application Dashboard.

This issue may occur when there are multiple versioned Java Agent directories. The Java Agent can use the configuration from any one of the versioned directories while keeping the Jar file in the top-level (global) directory.

In this scenario, Cisco Secure Application may not consider the configuration from the same versioned directory. Therefore, to ensure that Cisco Secure Application library uses the configuration from the same versioned directory, update the version of the directory using this property:

- For updating as system property:

```
-Dmulti.tenant.agent.use.apm.config.version=<version-folder-name>
```

Here, the *version-folder-name* is the required versioned directory name.

For example: `-Dmulti.tenant.agent.use.apm.config.version=ver21.6.0.32672`

- For updating as an environment variable:

```
MT_AGENT_USE_APM_VERSION_PROPERTY=<version-folder-name>
```

Here, the *version-folder-name* is the required versioned directory name.

For example: `MT_AGENT_USE_APM_VERSION_PROPERTY=ver21.6.0.32672`

## Splunk Integration - Connection Issue

All traffic originating from the Oregon Datacenter environment will have one of the following source IP addresses:

- 34.218.183.67
- 52.88.49.75
- 34.218.135.55
- 44.224.91.190
- 44.224.93.208
- 100.21.44.47
- 35.163.240.75
- 100.21.168.150
- 44.224.41.204

To view the of lists current AppDynamics SaaS IP ranges and domains for each region, see [SaaS Domains and IP Ranges](#).

## End User Monitoring

AppDynamics End User Monitoring (EUM) provides end-to-end visibility on the performance of your web and mobile applications. EUM helps you troubleshoot problems such as slow web responses, Ajax errors, mobile network requests, and IoT application errors. EUM provides metrics on application performance and user activity, such as:

- How server performance impacts your web, mobile, and device performance
- How third-party APIs impact your web, mobile, and device performance
- Where your heaviest loads originate
- How your users connect to and navigate your application

### Installation

## Overview of End User Monitoring

 Custom metrics for EUM Analytics are not supported in on-premises environments.

AppDynamics End User Monitoring (EUM) gives you visibility on the performance of your application from the viewpoint of the end user.

While Application Performance Monitoring (APM) measures user interaction starting at the web server or application server entry point, EUM extends that visibility all the way to the web browser, mobile, or IoT application. As a result, EUM reveals the impact the network and browser rendering time have on the user experience of your application.

The diagram below provides an overview of the different components, deployment models (SaaS/on-premise), and the Controller UI as seen by AppDynamics end users. The SaaS deployment employs services (Controller Service, Events Service, EUM Service, EUM Synthetic Monitoring Service) to collect, store, and process data, whereas, the on-premise deployment requires customers to install discrete components such as the Controller and servers (Events Server, EUM Server) that run processes to collect, store, and process data.

Annotations are provided for each label below the diagram.

Step	Description	Component(s)
1	The Browser, Mobile, and IoT Agents run in web/mobile/IoT applications, collect metrics, and then transmit that data to either a SaaS or an on-premise deployment of AppDynamics.	<ul style="list-style-type: none"> <li>• Browser/Mobile/IoT Apps</li> <li>• EUM Agents</li> </ul>

Step	Description	Component(s)								
2	The AppDynamics SaaS Cloud, consisting of the components listed to the right, stores, processes, and analyzes data, and then delivers RUM metrics to the Controller UI.	<table border="1"> <tr> <td data-bbox="974 331 1105 541">A</td> <td data-bbox="1105 331 1498 541">Controller Service - stores data and metadata, makes calls to the EUM Server for raw data and the Events Service for analytic data.</td> </tr> <tr> <td data-bbox="974 541 1105 751">B</td> <td data-bbox="1105 541 1498 751">Events Service - stores short-term RUM data (such as sessions, network requests, snapshots) for heavier analysis.</td> </tr> <tr> <td data-bbox="974 751 1105 940">C</td> <td data-bbox="1105 751 1498 940">EUM Service - verifies, aggregates, and packages raw browser/mobile app metrics.</td> </tr> <tr> <td data-bbox="974 940 1105 1150">D</td> <td data-bbox="1105 940 1498 1150">EUM Synthetic Monitoring Service - schedules and executes Browser Synthetic jobs and returns session data to the Controller.</td> </tr> </table>	A	Controller Service - stores data and metadata, makes calls to the EUM Server for raw data and the Events Service for analytic data.	B	Events Service - stores short-term RUM data (such as sessions, network requests, snapshots) for heavier analysis.	C	EUM Service - verifies, aggregates, and packages raw browser/mobile app metrics.	D	EUM Synthetic Monitoring Service - schedules and executes Browser Synthetic jobs and returns session data to the Controller.
A	Controller Service - stores data and metadata, makes calls to the EUM Server for raw data and the Events Service for analytic data.									
B	Events Service - stores short-term RUM data (such as sessions, network requests, snapshots) for heavier analysis.									
C	EUM Service - verifies, aggregates, and packages raw browser/mobile app metrics.									
D	EUM Synthetic Monitoring Service - schedules and executes Browser Synthetic jobs and returns session data to the Controller.									
3	The on-premise deployment of AppDynamics has most of the same components and data as the SaaS model. In this model, DevOps install and administer their own Controller, Events Service, and EUM Server. The EUM Synthetic Monitoring Service and sessions data, however, are not available in the on-premise deployment.	<ul style="list-style-type: none"> <li>• Controller</li> <li>• Events Server</li> <li>• EUM Server</li> </ul> <div data-bbox="974 1276 1474 1501" style="border: 1px solid #add8e6; padding: 5px;"> <p><b>i</b> See the descriptions for each component above in step 2. The EUM Server performs the same functions as the EUM Service.</p> </div>								
4	AppDynamics users can go to the AppDynamics Controller UI to view and analyze RUM metrics as snapshots, pages, Ajax requests, sessions, network requests, or in the form of charts and graphs.	<p>Controller UI</p> <div data-bbox="974 1585 1474 1705" style="border: 1px solid #add8e6; padding: 5px;"> <p><b>i</b> See the description for the Controller UI in step 2.</p> </div>								

## Understand End User Activity

Using EUM, you can determine:

- Where geographically your heaviest application load is originated.

- Where geographically your slowest End User response times occur.
- How performance varies by
  - location.
  - client type, device, browser and browser version, and network connection for web requests.
  - application and application version, operating system version, device, and carrier for mobile requests.
- What your slowest web/Ajax requests are, and where the problem may lie.
- What your slowest mobile and IoT network requests are, and where the problem may lie.
- How application server performance impacts the performance of your web and mobile traffic.
- Whether your mobile or IoT applications are experiencing errors or crashes and the root cause of the issues. For example, for mobile applications, EUM provides stack traces and event trails for the crash or error, helping you troubleshoot and optimize mobile applications.

## View EUM Data

The performance information generated by EUM is distinct from the application monitoring data generated by app server agents.

EUM data appears in various locations in the Controller UI, including in the **User Experience** dashboard, **Metric Browser**, and AppDynamics **Analytics** pages.

When linked to application business transactions, EUM data gives you a complete view of your end users' experience from the client request, through the application environment, and back to the client as the user response.

You can view EUM performance data in the Controller UI in the **User Experience** tab. From there, you can access information specific to browser applications, mobile applications, or connected devices (IoT applications).

## On-Premise EUM Deployments

By default, EUM is configured to use an AppDynamics-hosted component called the EUM Cloud. For a fully on-premiseS installation, the EUM Server provides the functionality of the EUM Cloud. For information, see [EUM Server Deployment](#).

Some functionality for EUM depends on the AppDynamics Platform Events Service. In a SaaS environment, this is managed by AppDynamics, but it is also possible to use this functionality in an on-premise form.

To host the Events Service on premises, see:

- [Install a Production EUM Server](#)

If you are adding EUM to an existing on-premiseS Controller installation, you should evaluate your current configuration's ability to handle the additional load imposed by EUM. For more information, see [Controller Sizing](#).

## Access the SaaS EUM Server

The SaaS EUM Server consists of the components listed below. Each component may have different endpoints depending on the region of your Controller.

- EUM Services - The Mobile Agents, JavaScript Agent, and IoT SDKs send data to the EUM Services. The Controller fetches data from the EUM Server.
- Events Service - The EUM Server sends analytics data to the Events Service. The Controller also queries the Events Service.
- Synthetic Services - The Synthetic Private Agent and Synthetic Hosted Agent send data to the Synthetic Services.

---

If your SaaS or on-premise deployment requires access to any of these components on the Internet, make sure the URLs given in [SaaS Domains and IP Ranges](#) are accessible from your network.

**i** For on-premise deployments, however, the EUM Server can either be located on the Internet or hosted inside your own data center/network. On-premise access points are configured at installation or through the UI. See [EUM Server Deployment](#) for more information.

## How EUM Works with other AppDynamics Products

This section describes how other App iQ Platform products work with EUM to provide complete, full visibility on application health and user experience.

### EUM and Application Performance Monitoring

Using APM with EUM provides you with greater insight into how the performance of your business application affects the end-user experience. To integrate APM with EUM, you correlate business transactions with browser snapshots. This enables you to trace bad user experiences to issues with your backends such as an unresponsive web service, bad database query or slow server response. To learn how to integrate APM with EUM, see [Correlate Business Transactions for Browser RUM](#).

You can also use the app server agents running on business applications that serve your browser applications to inject JavaScript agent into the code that runs on the browser. This obviates the need to manually inject the JavaScript agent. For more information, see [Automatic Injection](#) and [Assisted Injection](#).

**i** You must assign unique names to EUM applications and business applications. For example, if you created the business application "E-Commerce", you cannot create a browser, mobile, or IoT application with that same name or vice versa.

### EUM and Application Analytics

[AppDynamics Application Analytics](#) enables you to use the powerful [AppDynamics Query Language \(ADQL\)](#) to analyze different types of EUM data through complex queries. The Analytics components are based on the Events Service, which is also the source of data for [Browser Analyze](#), [Crash Analyze](#), [Network Requests Analyze](#), and all IoT data. Analytics requires a license separate from the EUM licenses except for IoT Monitoring.

## Learn More

For more information on the type of user monitoring you interested in, see:

- [Browser Real User Monitoring](#)
- [Browser Synthetic Monitoring](#)
- [Mobile Real User Monitoring](#)

---

## Experience Journey Map

Experience Journey Map provides real-time insights into business and application performance, visualizing key user journeys and the correlation between performance and traffic. This perspective unifies the primary application stakeholders: application owners, developers, and IT operations.

See [Use Cases for Experience Journey Map](#).

### Requirements

To use Experience Journey Map you need:

- SaaS: Controller  $\geq$  20.6.0
- On-premise: Controller  $\geq$  20.7.0
- [EUM Peak license](#) (RUM Peak, Browser RUM Peak, or Mobile RUM Peak)
- Instrumented browser or mobile application

### Access Experience Journey Map

To access Experience Journey Map:

1. Under the **User Experience** tab, go to a browser or mobile app.
2. In the left application panel, click **Experience Journey Map**.

### Experience Journey Map UI

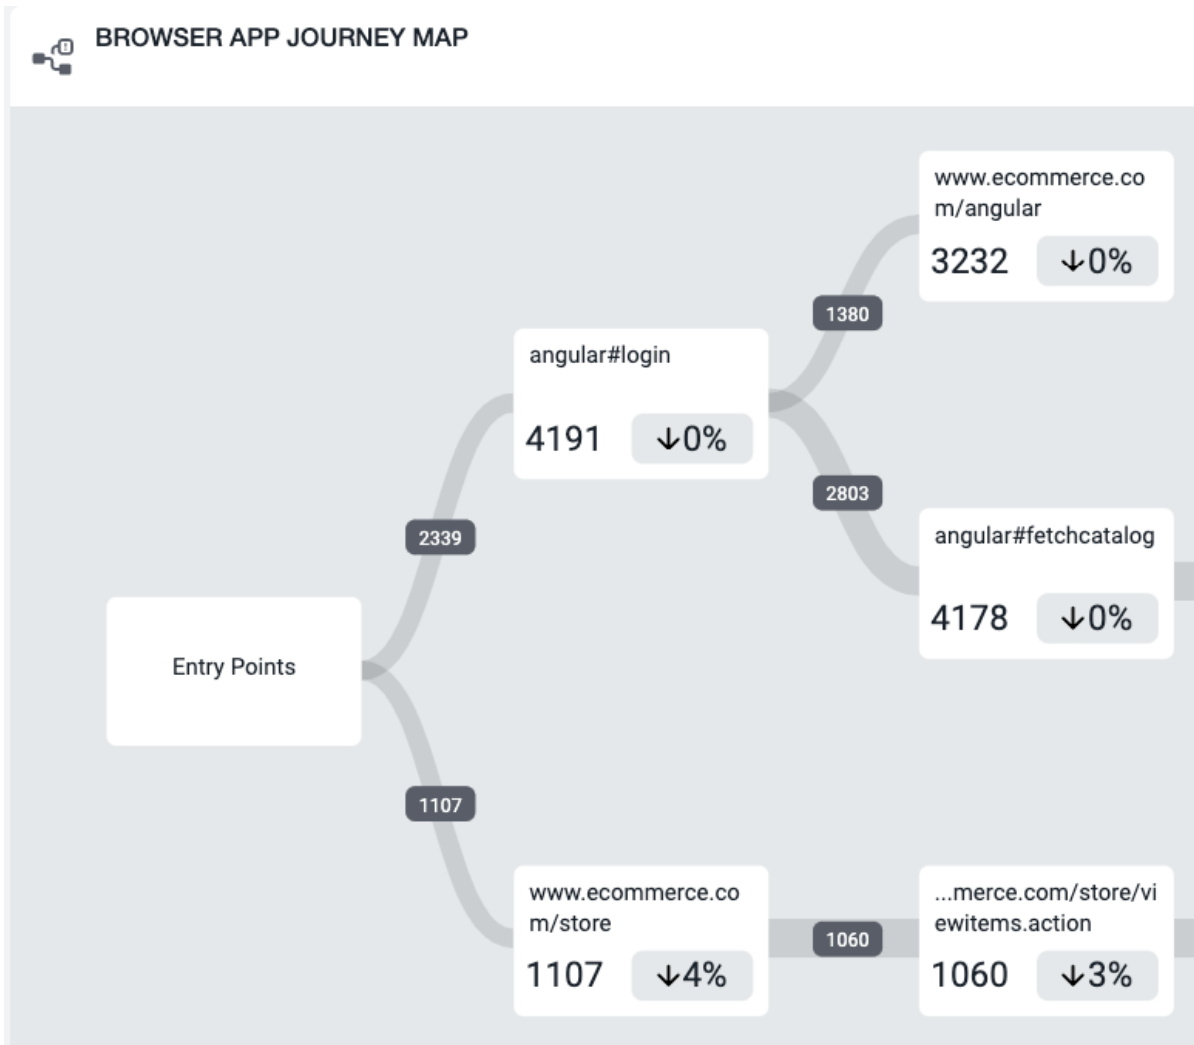

The sections below provide an overview of the Experience Journey Map UI. In the Controller, click on the **Legend**  for key terms.

#### Experience Journey Map Dashboard

The Experience Journey Map dashboard displays the top user journeys, or the most trafficked parts of an app. The default time frame is set to one hour, but you can adjust the time and the dashboard automatically updates the user journeys and data for that time frame.

[Browser App](#)   Mobile App

MOBILE APP JOURNEY MAP  
Ecommerce-iOS

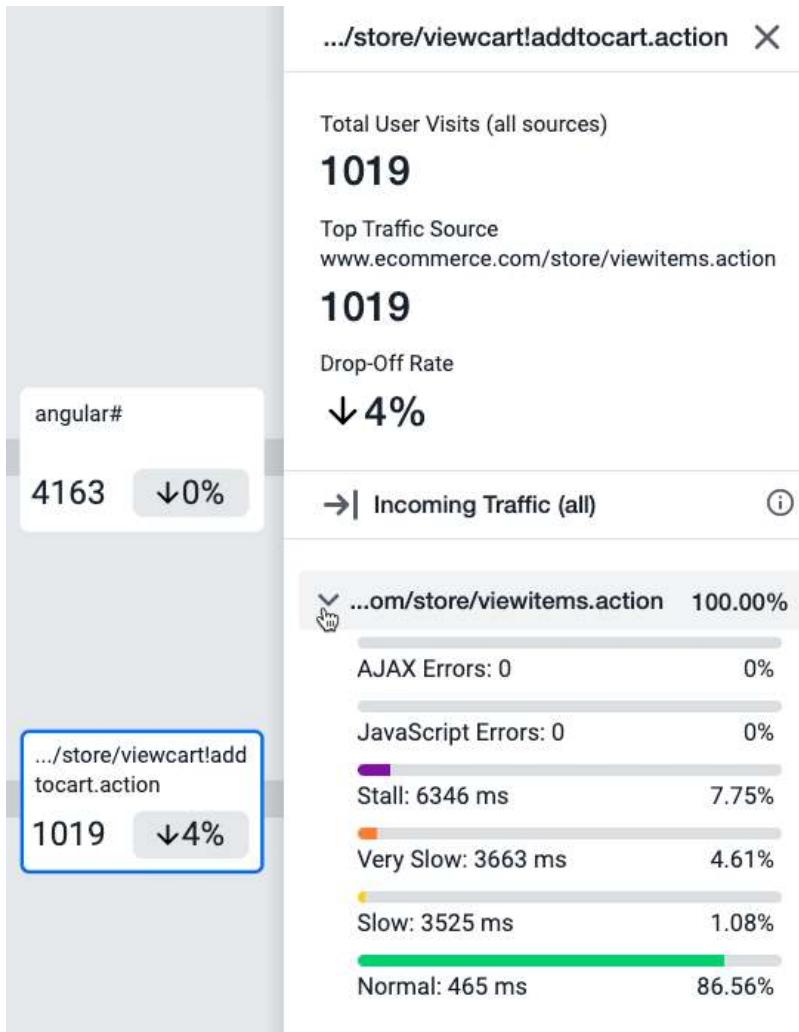

## End User Events

Each step in an Experience Journey Map user journey is visualized by end user events (browser pages, iOS views, or Android activities). Experience Journey Map displays the user journeys with the most traffic.

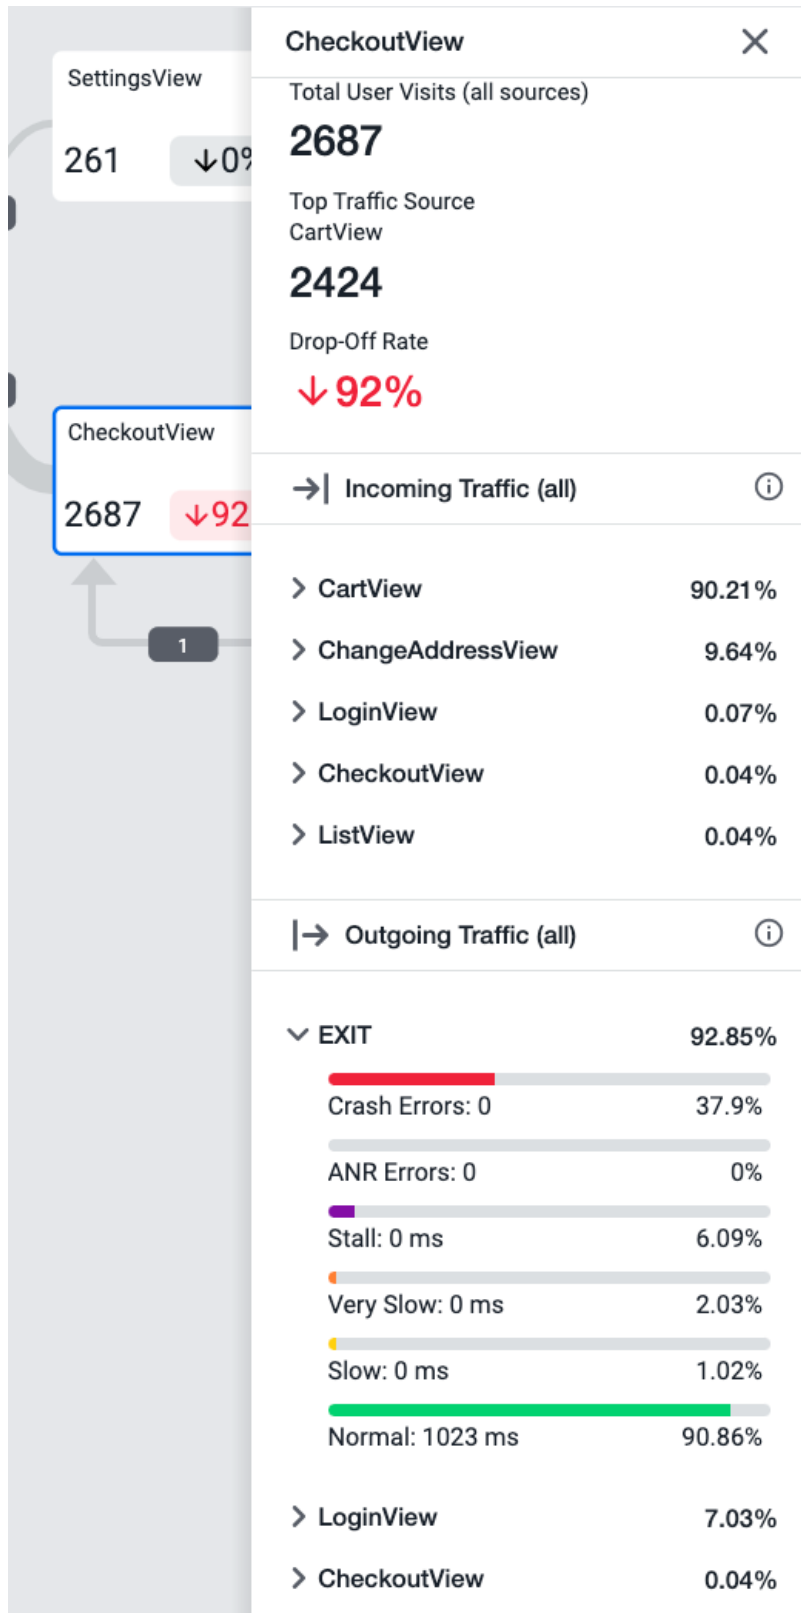

Click an end user event to see:

- Total user visits (all incoming traffic) to an end user event page/view/activity
- How users are navigating your app (user journeys)
- How each user journey is performing over time
- When users drop off your app

[Browser App](#)   Mobile App

[Browser App](#) [Mobile App](#)

## Traffic Segments

A traffic segment connects two end user events in a journey and contains data about what users experience in that journey. If the journey exceeds health performance metrics, a health status icon will appear on the traffic segment, will more details on the user impact of poor performance. See [Configure Experience Journey Map](#) to configure performance health thresholds.

Click a traffic segment to see:

- Number of users who journeyed from one end user event to the next
- Performance metrics for users within a journey
- Option to analyze individual browser or mobile sessions within a journey

## Browser vs. Mobile Apps in Experience Journey Map

The table below describes the differences in Experience Journey Map journeys and data for browser and mobile apps.

Component	Browser App	Mobile App
End User Event	<p>An end user event shows data for one browser page.</p> <p><b>View/Activity Naming</b></p> <p>To customize end user event names in the UI, see <a href="#">Configure Page Identification and Naming</a>.</p>	<p>An end user event shows data for one iOS view or Android activity.</p> <p><b>View/Activity Naming</b></p> <p>To customize how the mobile agent reports the view/activity names via the <code>SessionFrame</code> API, see the following:</p> <ul style="list-style-type: none"> <li>• <a href="#">Customize the iOS Instrumentation</a></li> <li>• <a href="#">Customize the Android Instrumentation</a></li> <li>• <a href="#">Customize the Xamarin Instrumentation</a></li> <li>• <a href="#">Customize the Cordova Instrumentation</a></li> </ul> <p><b>Hybrid Agent Support</b></p> <p>Hybrid agents (Cordova, React Native, and Xamarin) do not support individual screen tracking, which affects how Experience Journey Map displays events in a user journey. To ensure each screen is displayed in a user journey, we recommend using the <code>SessionFrame</code> API to define when a screen starts and ends. See documentation for each hybrid agent:</p> <ul style="list-style-type: none"> <li>• <a href="#">Customize the Xamarin Instrumentation</a></li> <li>• <a href="#">Customize the Cordova Instrumentation</a></li> <li>• <a href="#">Customize the React Native Instrumentation</a></li> </ul>
Default performance threshold metric	Performance thresholds (Slow, Very Slow, Stall, and Normal) are set to End User Response Time (EURT), or page load time.	Performance thresholds (Slow, Very Slow, Stall, and Normal) are set to the average time of mobile network requests.
Types of errors captured	JavaScript and AJAX errors.	Crashes and Application Not Responding (ANRs).
Analyze functionality	When you click <b>Analyze</b> , you are redirected to <a href="#">Browser RUM Analyze</a> with filters applied for that mapped browser page.	When you click <b>Analyze</b> , you are redirected to <a href="#">Mobile Sessions</a> with filters applied for that mapped mobile view/activity.

Component	Browser App	Mobile App
Misc.	Iframes are captured and included as a node with performance metrics, such as for SPA2 base pages.	You may notice that sometimes the performance thresholds broken down by severity do not add up to 100%. See <a href="#">Analyze Traffic</a> for an example. This is because for mobile apps, performance thresholds are set to an average of only the network request(s) triggered from a view/activity. If the number of triggered network requests is less than the number of total network requests, the performance threshold breakdown does not add up to 100%.

## Using Experience Journey Map

This page describes top use cases for Experience Journey Map and is categorized by application stakeholder: IT operations, developers, and application owners.

## IT Operations

Goal	Use Case
Prioritize performance-related incidents	<p>Investigate why users are experiencing Ajax errors on a browser application:</p> <ol style="list-style-type: none"> <li>1. In Experience Journey Map, you see that a correlation of Ajax errors, a high drop-off rate, and the majority of Ajax errors occurs on Internet Explorer browsers.</li> <li>2. <a href="#">Filter user journeys</a> by browser and notice that the trend maintains.</li> <li>3. Click on <b>Analyze</b> to see Browser Sessions with the criteria you filtered in Experience Journey Map.</li> </ol>
Create real-world, data-backed testing	<p>Create a data-backed <a href="#">Synthetic script</a> for browser application testing:</p> <ol style="list-style-type: none"> <li>1. In Experience Journey Map, look at top user journeys within the default time frame.</li> <li>2. Adjust the time frame to one day, one week, and one month.</li> <li>3. Identify the top user journeys in each time frame and note if there are consistencies throughout.</li> <li>4. Write a synthetic script to test those top user journeys.</li> </ol>
	<p>Investigate if crashes correlate with a specific mobile device version:</p> <ol style="list-style-type: none"> <li>1. In Experience Journey Map, click on a few iOS views containing crashes. You see that most users experiencing those crashes are using iPhone 8.</li> <li>2. <a href="#">Filter user journeys</a> by mobile device version to diagnose if one version is causing those crashes.</li> <li>3. Fix the issue related to the device version.</li> <li>4. Filter Experience Journey Map by that device version again and validate the fix.</li> </ol>

## Developers

Goal	Use Case
Prioritize and resolve errors	<p>Identify the source of iOS application crashes in the last 24 hours:</p> <ol style="list-style-type: none"> <li>1. In Experience Journey Map, click the traffic segment to identify the top user device and OS.</li> <li>2. Use this data to reproduce the crashes.</li> <li>3. Click <b>Analyze</b> on the traffic segment to view each mobile session crash and identify the mobile crash stack trace.</li> <li>4. Once you fix the issue, use Experience Journey Map to validate the fix.</li> </ol>

## Application Owners

Goal	Use Case
Manage and prioritize resource investments	<p>Evaluate user interactions with a new banking application feature:</p> <ol style="list-style-type: none"> <li>1. In Experience Journey Map, filter user journeys to see traffic metrics for the new feature.</li> <li>2. Depending on whether the new feature is gaining more or less traffic than expected, collaborate with IT operations and developers to increase or decrease resources around the feature.</li> </ol>

## Configure Experience Journey Map

This page describes how to configure Experience Journey Map. Though Experience Journey Map does not require configuration, you can adjust performance thresholds and customize end user event names to better suit your business needs.

### Configure User Experience Thresholds

You can configure the timing and standard deviations for performance thresholds such as Slow, Very Slow, and Stall. When you configure these deviations, the changes apply to all Controller views of that application, not just to Experience Journey Map. To configure from Experience Journey Map, go to **Info** ⓘ > **Configure thresholds**.

### Configure Performance Thresholds and Drop-off Rates

**i** To configure performance thresholds, you must have Controller  $\geq 20.8.0$  and a "Configure EUM" user permission. To configure user and role permissions in the Controller UI, go to **Settings** ⚙ > **Administration**.

### Toggle On or Off

You can toggle performance thresholds and drop-off rates on or off. When a threshold or drop-off rate is toggled off, the marker does not appear on Experience Journey Map. When you toggle a threshold on, the threshold resets to the previous value (and not necessarily the default value).

### Configure Values

For performance thresholds and drop-off rates, the percentage is set to the minimum traffic for a marker to appear on a user journey event. For example, if Ajax Errors is set to 30%, Experience Journey Map displays an error icon when 30% and more of user traffic experiences Ajax Errors. You can configure the values for performance thresholds and drop-off rates. The table below lists default performance thresholds values for existing and new applications.

[Browser Application](#)    [Mobile Application](#)

Threshold	Default Value
Javascript Error	20%
Ajax Errors	10%
Drop-off rate	10%
Slow	20%
Very Slow	10%
Stall	0%

[Browser Application](#)
[Mobile Application](#)

Threshold	Default Value
Crashes	0%
Application Not Responding	0%
Drop-off rate	10%
Slow	20%
Very Slow	10%
Stall	0%

## Customize End User Event Names

Experience Journey Map displays a collection of user journeys, which are made up of common end user events.

There are two options to customize how end user events are named:

- Add custom labels for end user events locally in Experience Journey Map.
- Customize how the agent reports End User Events names to the Controller.

## Add Custom Labels

Custom labels are available in Controller  $\geq 22.6.0$ .

You can add custom labels to end user event names to help you organize key user journeys. Custom labels are applied locally to end user events in Experience Journey Map and do not apply elsewhere in the Controller.

### About views and custom labels

Custom labels are applied across all views. Any custom label created in the default view will appear in [custom views](#), and vice versa.

To add a custom label:

1. Go to Experience Journey Map.
2. Click on an end user event.
3. In the pop-up, click the Customize Label icon .
4. Enter a label name and click **Save**.

To delete a custom label:

1. Click on an end user event.
2. In the pop-up, click the Customize Label icon .
3. Highlight the label name and press the **delete** button on your keyboard.
4. Click **Save**.

## Customize End User Event Names

By default, Experience Journey Map displays end user event names as they are originally reported, or configured from include/exclude rules (for browser apps) or the `SessionFrame` API (for mobile apps).

You can customize how end user events are reported to the controller. This can help you organize user journeys based on the primary user journeys meaningful to your business. For example, if you have a series of network requests reflecting steps to place an order on your E-commerce site, you can rename those URLs with pages names like "Order info," "Order review," and "Order confirmation."

- For browser applications, see [Configure Page Identification and Naming](#).
- For mobile applications, see [Configure Mobile Network Request Naming](#).

### Hybrid Agents and Event Naming

Hybrid agents (Cordova, React Native, and Xamarin) do not support individual screen tracking, which affects how Experience Journey Map displays events in a user journey. To ensure each screen is displayed in a user journey, we recommend using the `SessionFrame` API to define when a screen starts and ends. See documentation for each hybrid agent:

- [Customize the Xamarin Instrumentation](#)
- [Customize the Cordova Instrumentation](#)
- [Customize the React Native Instrumentation](#)

## Filter User Journeys

You can filter user journeys by the fields listed below to see user journeys through a helpful context, such as troubleshooting a crash by mobile device version. When you apply a filter, such as a mobile device version iOS 10, Experience Journey Map shows the top journeys for iOS 10 users.

To use the filters:

1. In the upper right-hand corner, click on the **Filter Panel** .
2. Select a filter(s).
3. Click **Apply**.

### Available Filters

The table below lists available filters for Experience Journey Map.

Application Type	Fields
Browser	<ul style="list-style-type: none"> <li>• Browser</li> <li>• City</li> <li>• Country</li> <li>• <a href="#">Custom User Data</a></li> <li>• Device</li> <li>• Device OS</li> <li>• Internet Service Provider (ISP)</li> <li>• Region</li> </ul>
Mobile	<ul style="list-style-type: none"> <li>• Application Version</li> <li>• Carrier</li> <li>• City</li> <li>• Connection Type</li> <li>• Country</li> <li>• <a href="#">Custom User Data</a></li> <li>• Device Model</li> <li>• Device Version</li> <li>• Region</li> <li>• OS Version</li> </ul>

### Using the Custom User Data Filter

The custom user data filter allows you to filter user journeys by user data strings you previously configured (strings with a maximum of 5000 values).

 Custom user data you configure is automatically included in the Experience Journey Map data collection.

To filter by custom user data:

1. Click on the **Filter Panel** .
2. In the panel, click on  > **Select Visible Filters**.
3. In the **Filter Panel** , check the "Custom User Data" box.
4. Start typing a data string. The screen will auto-populate with data available.
5. In the pop-up, check data you want to filter.
6. Click **Apply**.

 To configure custom user data, see:

- [Add Custom User Data to a Page Browser Snapshot](#)
- [Customize the iOS Instrumentation](#)
- [Customize the Android Instrumentation](#)

## Analyze Traffic Segments

A traffic segment connects two end user events and contains data about users who journeyed from one end user event to the next. The **Analyze** functionality allows you to drill down into individual browser or mobile sessions for that traffic segment. When you click **Analyze**, you are redirected to [Browser RUM Analyze](#) or [Mobile Sessions](#) with applied filters for the users who navigated from the previous end user event to the next.

**Analyze**

### Analyze User Journeys with Applied Filters

If you apply a filter and click **Analyze** on a traffic segment or end user event, the applied filters will carry over to [Browser RUM Analyze](#) or [Mobile Sessions](#).

### Create a Custom View

Related pages:

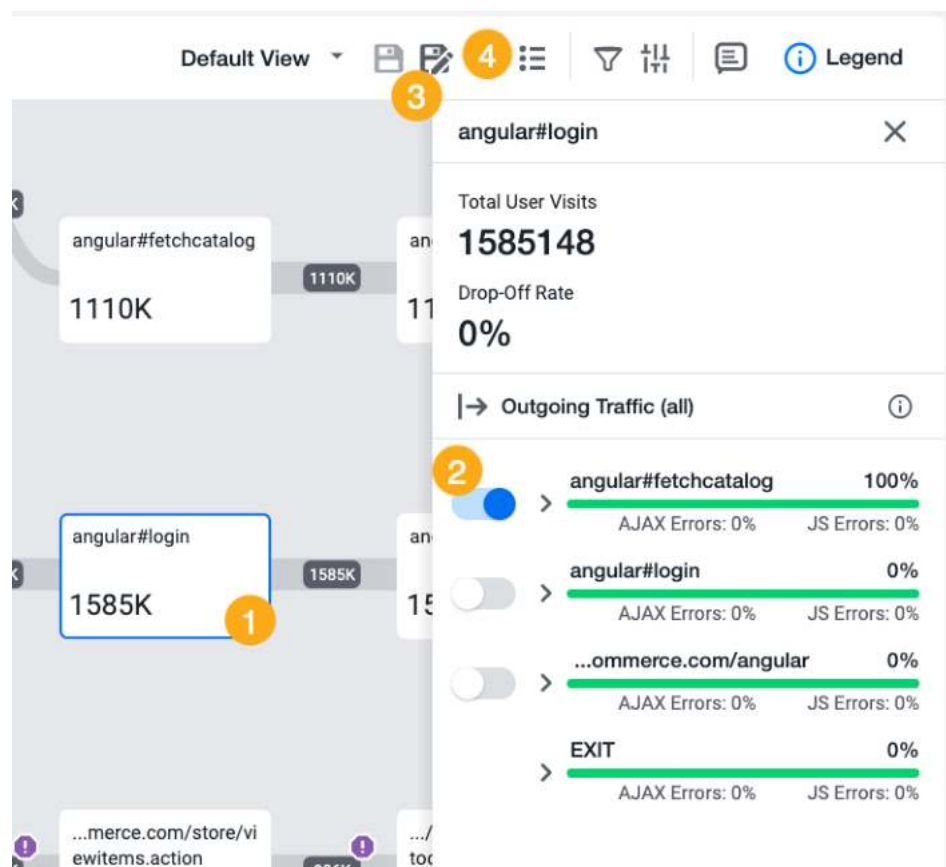

- [Add a Custom Label](#)

**i** Custom views are available with SaaS Controller >= 21.4.0.

The default Experience Journey Map view shows top user journeys on the entire application. If you want to see the top journeys for specific flows and events, you can create a custom view. For example, if you designed for different flows, such as a travel booking app for booking a hotel, a flight, and a rental car, you can create three custom views for each flow.

To create a custom view:

1. Click on any event of a user flow.
2. Toggle the next event you want to see.
3. Click  and name the custom view.
4. Click  to view, edit, and delete your custom views.

## Correlate Business Transactions for EUM

### Related pages:

- [Business Transactions](#)
- [GDPR Compliance](#)

This page describes how to correlate business transactions for End User Monitoring (EUM). You can correlate the network request events of EUM applications with the business transactions of [Business Applications](#). The EUM application can be a browser, mobile, or IoT application. The correlation is made

between EUM application beacons containing network request event information and instances of business transactions (transaction snapshots).

For detailed information, including how and what is correlated for each type of EUM application, see these pages:

- [Correlate Business Transactions for Browser RUM](#)
- [Correlate Business Transactions for Mobile RUM](#)
- [Correlate Business Transactions for IoT Monitoring](#)
- [Correlate Business Transactions for Synthetic API Monitoring](#)

## Benefits of Correlating Business Transactions

By correlating business transactions with network request snapshots, you can identify potential issues with the backend application that are causing bad user experiences. For example, you might find that a server error or a database query is causing a slow user experience.

### Before You Begin

To correlate business transactions:

1. Purchase [licenses](#) for Application Performance Monitoring (APM) and End User Monitoring (EUM).
2. Instrument a business application with a [supported app server agent](#).
3. Instrument an EUM application (browser, mobile, or IoT application).

**i** If [automatic business transaction correlation](#) is not supported for your app server agent, you can [manually enable business transaction correlation](#) in the Controller UI.

## Business Transaction Correlation Support for App Server Agents

This table shows the app server agents that support business transaction correlation.

- [Automatic correlation](#) support means that business transactions are automatically correlated.
- For [manual correlation](#), you must manually enable business transaction correlation.

App Server Agent	Type of Correlation Support
<a href="#">Java Agent</a>	Automatic (Java Agent >= 20.3.0, and Controller >= 20.4.0)
<a href="#">.NET Agent</a>	.NET Framework: Automatic (.NET Agent >= 20.9.0, and Controller >= 20.10.0)
	.NET Core: Automatic (.NET Agent >= 21.1.0, and Controller >= 20.10.0), Windows only
	Linux: Automatic (.NET Agent >= 21.5)
<a href="#">Node.js Agent</a>	Manual

App Server Agent	Type of Correlation Support
PHP Agent	Manual
Python Agent	Manual

## Access Business Transaction Correlation

To configure business transaction correlation:

1. In the **Application Dashboard**, click **Configuration > User Experience App Integration**.
2. Under the **Business Transaction Correlation** tab, there are two options depending on the [correlation support for your App Server Agents](#):
  - For agents with support for automatic correlation, see [Automatic Correlation of Business Transactions](#).
  - For agents without support for automatic correlation, see [Manually Enable Business Transaction Correlation](#).

## Automatic Correlation of Business Transactions

By default, the correlation of business transactions of business applications instrumented with Java Agent  $\geq 20.3.0$  is enabled.

Under the **Business Transaction Correlation** tab, you can choose to opt out or filter requests with match or exclude rules.

User Experience App Integration

Business Transaction Correlation    JavaScript Agent Injection

---

**What is Business Transaction Correlation?**

Business Transaction Correlation allows client-side requests in Browser & Mobile Apps to be correlated with server-side Business Transactions.

With a supported version, APM agents (Java, .NET, etc) may add cookies identifying the executing Business Transaction. A sample of Browser Snapshots & Mobile Network Requests will show correlated server-side Transaction Snapshots.

[Learn more about Correlating Business Transactions to RUM.](#)

**Enable Automatic Correlation by Upgrading to Supported Agents**

The following APM agents support automatic correlation, a process where agents add metadata allowing correlation of client and server-side measurements. For optimal results, ensure your agent fleet is running a supported version or above. Upgrading will enable correlation for all applications with no further action required. Check your deployed agent versions by navigating to Settings > AppDynamics Agents (requires Admin privileges).

[Upgrade to latest agents](#)

Java 20.3.0+  
 .NET Coming Soon

**Opt Out of Correlation**

If you do not want BT snapshots to be correlated to User Experience snapshots by default, you may [opt out of correlation](#). You can always opt in to correlation again.

---

**Filtering Options**

Customize when Business Transaction correlation headers will be attached to requests.

- > [Request Match Rules](#)
- > [Request Exclude Rules](#)

## Opt In to Automatic Correlation

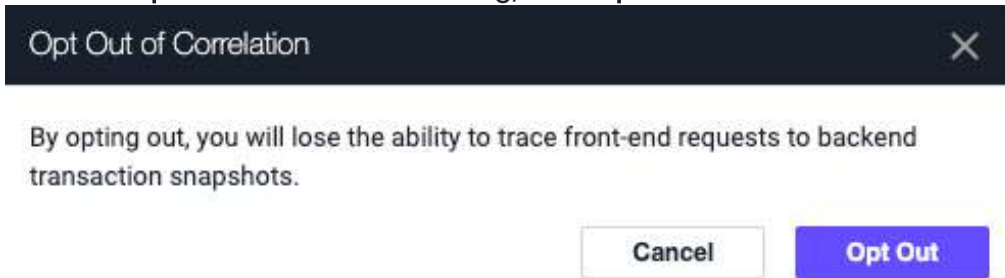

To opt in to have business transactions automatically correlated, you must use Java Agent  $\geq 20.3.0$ . If you are using an older version of the Java Agent, you must upgrade the agent.

For unsupported agents, you need to [manually enable business transaction correlation](#).

## Opt Out of Automatic Correlation

If business transaction correlation is enabled by default, you can opt out by:

1. In the **Application Dashboard**, click **Configuration > User Experience App Integration**.
2. Under the **Business Transaction Correlation > Opt Out of Correlation**, click **opt out of correlation**.
3. From the **Opt Out of Correlation** dialog, click **Opt Out**.

## Manually Enable Business Transaction Correlation

For app agents that do not support automatic correlation, you need to enable business transaction correlation in the Controller UI:

1. In the Controller UI, go to Applications and select an application.
2. On the left-hand panel, click **Settings > Configuration**
3. Click **User Experience App Integration > Enable Business Transaction Correlation**.
4. On the left-hand panel, click **Tiers & Nodes**.
5. Click on a node you want to enable correlation for. In Step 8, you have the option to apply the properties to all nodes in a tier, so it does not matter which node you initially select.
6. On the top menu bar, click **Actions > Configure App Server Agent**.
7. Click **Use Custom Configuration** and create two properties:
  - enable-eum-cookie:
    - **Name:** enable-eum-cookie
    - **Type:** boolean
    - **Value:** true
  - enable-eum:
    - **Name:** enable-eum
    - **Type:** boolean
    - **Value:** true
8. Click **Apply to all Nodes in this Tier**.

## Disable Business Transaction Correlation

To disable business transaction correlation:

1. In the **Application Dashboard**, click **Configuration > User Experience App Integration**.
2. Under the **Business Transaction Correlation** tab, toggle the **Enable** button.

## Filter Business Transactions for Correlation

You can also specify which business transactions includes or excludes correlation headers. If you do not add request match rules or request exclude rules, all requests have correlation headers by default.

To add a request match or exclude rule:

1. From **Filtering Options**, expand **Request Match Rules** or **Request Exclude Rules**.
2. Click **Add Rule**.
3. Check the **Method** to use the default HTTP method `GET` or select a different HTTP method.
4. Check the **URI** checkbox and select one of the matching methods from the dropdown:
  - **Starts With**
  - **Ends With**
  - **Contains**
  - **Equals**
  - **Matches RegEx**
  - **Is in List**
5. (Optional) Click  and check the **NOT** checkbox. This condition reverses the results by excluding the requests that match the specified parameters.
6. Click **Add Rule**.

## EUM Data

### Related pages:

- [Using the Controller APIs](#)

This page describes the types of EUM data, how data is collected, where data is stored, and where data is displayed in the Controller. For data retention and license consumption details, see [License Entitlements and Restrictions](#).

AppDynamics will start to filter (stop, and reject) all EUM traffic from the following regions: North Korea, Sudan, Cuba, Iran, Syria, Belarus, Russia, Crimea, and Donetsk and Luhansk regions of Ukraine. This begins February 23, 2023. If you have any questions or concerns, please contact your Account Manager, Customer Success Manager, or visit [AppDynamics Support](#).

## Types of EUM Data

With the iOS 14 release (supported by iOS Agent 20.10.0), Apple introduced a new data collection policy. See [iOS Data Collection Disclosure](#) for details.

### Metric Data

**Metrics** are data that reflect your application's performance. Browser RUM captures metrics from browser applications, such as timing and Ajax metrics. Mobile RUM captures metrics from mobile applications, such as crash metrics and network request metrics. You can view and analyze EUM metrics in the [Metric Browser](#).

To learn more about EUM metrics, see:

- [Browser RUM Metrics](#)

- [Browser Synthetic Metrics](#)
- [Mobile RUM Metrics](#)
- [Extensions and Custom Metrics](#)

## Custom Data

### Browser RUM

You can add specific user information from a browser snapshot of your application. The information is expressed as key-value pairs, appears in the **User Data** section of the snapshot, and is available for page snapshots, Ajax requests, and virtual pages. To learn how to set custom user data, see [Add Custom User Data to a Page Browser Snapshot](#).

### Mobile RUM

Mobile RUM custom data such as [Info Points](#), [Custom Timers](#), and [Custom Metrics](#) are considered metrics and stored as [mobile request event data](#). User data is another type of Mobile RUM custom data. Custom user data can be reported through network request events because user data is attached to each network request.

To learn how to set user data, see [User Data \(iOS SDK\)](#) or [User Data \(Android SDK\)](#).

## EUM Analytics Data

You can view EUM data in [Analytics](#) if you have a [Real User Monitoring Peak license](#). The EUM Analytics data consists of event data and is stored in the Events Service and [visualized in widgets](#). EUM Analytics provides data for these event types:

- [Browser Requests Event Data](#)
- [Browser Sessions Event Data](#)
- [Mobile Requests Event Data](#)
- [Mobile Sessions Event Data](#)
- [Mobile Crash Report Event Data](#)
- [Synthetic Sessions](#)
- [Connected Device Data](#)

## Cookies for Browser Applications

Browser RUM uses two different kinds of short-lived cookies for the JavaScript Agent to collect data and correlate events. Both types of cookies do not contain any personally identifiable information (PII) and are immediately deleted after being read.

- **ADRUM** cookie: Written by the JavaScript Agent, this cookie contains the referral page URL and some timing information to assist in gathering First Byte Time for some browser types. When the agent loads on the subsequent page, it reads the information and then deletes the cookie. If there is no agent on that page, the cookie is deleted when the browser is closed. For privacy purposes, the URL of the referral page is hashed.
- **ADRUM\_BT** cookies: Written by the server-side agent when the page is served from an instrumented server. These cookies help correlate browser data with related server-side performance data (Business Transactions).
  - **ADRUM\_BTa** : Contains the backend transaction ID as well as timing info and is used to correlate end-user experience with the health of the backend app.
  - **ADRUM\_BTg** : Contains the backend transaction ID and is used as an alternative method to correlate end-user experience with the health of the backend app.
  - **ADRUM\_BT[1-5]** : Contains the business transaction numbers as well as timing and error info for the first five business transactions, such as **ADRUM\_BT1** , **ADRUM\_BT2** , etc.
  - **ADRUM\_BTs** : Contains a link from a browser snapshot to a server snapshot.
  - **ADRUM\_BTh** : Written only if there was a server-side error.

**i** If Browser RUM detects that the page is HTTPS, the `Security` attribute is set for cookies. The `Security` attribute is a flag that forbids a cookie from being transmitted via an unencrypted HTTP connection.

- `SameSite` cookies: Provides the JavaScript Agent access to `ADRUM_BT` cookie to maintain Business Transaction correlation. When SameSite cookies are present, the agent has access to the `ADRUM_BT` cookie with Business Transaction data. Without SameSite cookies, the agent cannot parse Business Transaction data in the cookie sent from the application server. This is because the agent is loaded from a different domain than the browser website.

## Web Storage

Browser RUM stores key-value pairs in web storage to associate page views with a particular session and browser. The value for each key is a randomly generated ID.

The following lists the keys and the expiration time for each key-value pair:

- `ADRUM_AGENT_INFO` (never)
- `ADRUM_CLIENTINFO` (never)
- `ADRUM_XD_AGENT_ID` (never)
- `ADRUM_XD_AGENT_INFO` (1 week)

## Mobile Local Storage

Mobile agents use beacons to transmit metrics, app metadata, network requests, crashes, and custom data. When a beacon cannot be transmitted, the data is persisted in permanent storage within the container of the application and subject to the security configuration of the device and application. No encryption is currently being utilized. Once the network connection is restored, the beacons resume transmitting data. Because some of the data is provided by the developer's instrumentation of the app, such as breadcrumbs, user info, and the app (URLs, crash reports), some information is not explicitly collected by AppDynamics.

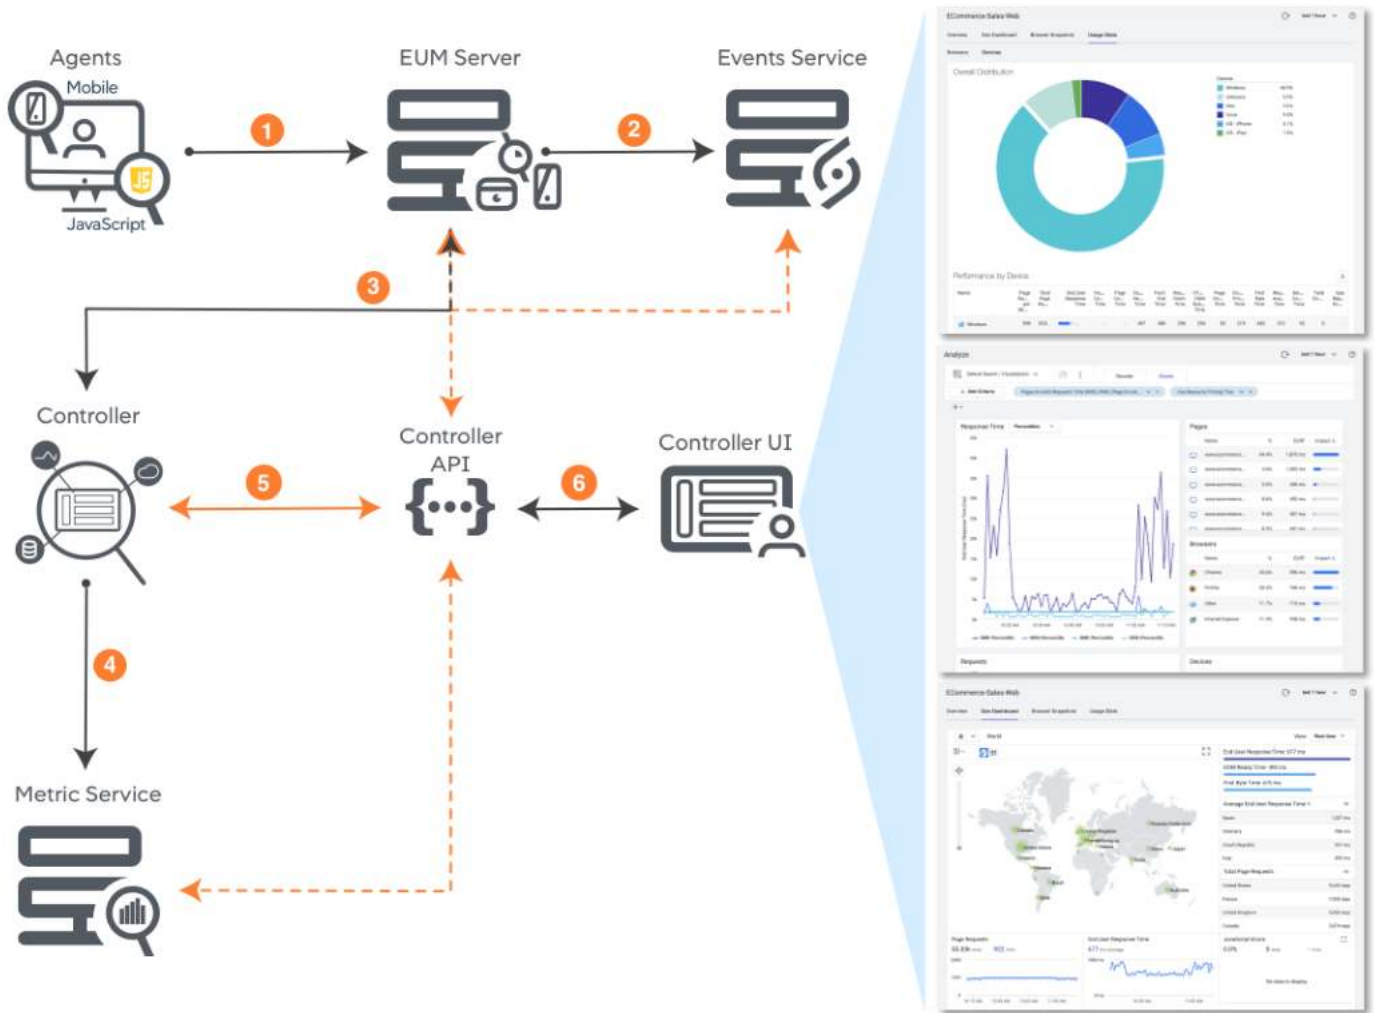

Mobile agents also locally store a randomly generated ID for tracking sessions and license usage. The ID is stored in the Events Service.

## Data Storage and Retrieval

AppDynamics uses four data storage components to store Browser RUM and Mobile RUM data: the EUM Server, the Events Service, the Metric Service, and the Controller. The Controller UI has no visibility into which storage component holds the data because it only interacts with the Controller API.

**1** Browser RUM utilizes a JavaScript Agent and Mobile RUM utilizes Mobile agents to send raw data to the EUM Server. The EUM Server verifies, aggregates, and packages the data once every minute. **2** The EUM Server sends the data to the Events Service and **3** to the Controller. **4** The Controller sends the data to the Metrics Service. **5** The Controller API fetches the data from one of the four data stores and **6** delivers it to the Controller UI when it receives data requests.

## Data Storage Details

### Browser RUM

This table shows where different Browser RUM data is stored. To see how long the data is retained, see [License Entitlements and Restrictions](#). Resource details are only available for those browser snapshots with resource timing.

	Controller	Events Service	EUM Server (SaaS/On-Premises)

### Mobile RUM Default Data Limits per Mobile App and App Key

Unit	Metric Limit	Network Requests	Max Event Size
Mobile App	N/A	500	1 MB
App Key	100,000	2000	

### Controller Mapping of Data

#### Browser RUM

This table shows the relationship between the Controller UI components and their data sources.

Controller Component	Storage Mechanism
Overview	Controller
Geo Dashboard	Controller
Browser Snapshots	Controller (no resource details) / EUM Server (SaaS/On-Premises) (resource details)
Usage Stats	Controller

Controller Component	Storage Mechanism
Sessions	EUM Server (SaaS/On-Premises), Events Service
Pages & Ajax Requests	Controller / Events Service (limited)
Analyze	Events Service

## Mobile RUM

This table shows the relationship between the Controller UI components and their data sources.

Controller Component	Storage Mechanism
Overview	Controller
Geo Dashboard	Controller
Usage Stats	Controller
Sessions	Events Service
Network Requests	Controller, Events Service (limited)
Network Requests Snapshots	Controller
Crashes	Events Service, EUM Server (SaaS/On-Premises)
Crashes Analyze	Events Service
Custom Data	Controller
Events	Controller

## Access EUM Data

In addition to accessing EUM data through the Controller UI, you can also access event data through [Analytics](#) and the [AppDynamics APIs](#). The AppDynamics APIs include the [Analytics Events API](#) and the [Metric and Snapshot API](#) that you can use to access EUM metric data.

If you have enabled Analytics and Browser RUM, you can use Browser Analytics to view data for these event types:

- [Browser Requests](#)
- [Browser Sessions](#)

---

If you have enabled Analytics and Browser Synthetic Monitoring, you can use Synthetic Analytics to view data for this event type:

- [Synthetic Sessions](#)

If you have enabled Analytics and Mobile RUM, you can use Mobile Analytics to view data for these event types:

- [Mobile Requests](#)
- [Mobile Sessions](#)
- [Mobile Crash Reports](#)

If you have enabled IoT Monitoring, you can use Connected Devices Analytics to view data for the event types below. You *do not* need to enable Analytics to use IoT Analytics.

- [Connected Device Data](#)

## Data and Deployment Models

AppDynamics offers SaaS and on-premises deployment models. You can access most Browser and Mobile RUM data from either deployment model.

## EUM Accounts, Licenses, and App Keys

This page covers account and licensing information for End User Monitoring (EUM).

- [View License Usage](#)
- [Overages](#)
- [License Key](#)
- [EUM App Key](#)
- [License Optimization and Usage Periods](#)

### View License Usage

To view your EUM license consumption in the Controller, go to  > **License**.

### Overages

If your license does not allow overages, AppDynamics stops reporting metrics after your license limit has been reached. If your license does allow overages and your usage exceeds the limit, AppDynamics continues reporting EUM metrics and bills you for the overages at the unit rate stipulated by your license agreement.

### License Key

If you have at least one EUM license type, you have an EUM Account, which has a name and a license key associated with it. This is the unique identifier that AppDynamics uses to associate EUM data to your account. You only need to know this information for troubleshooting purposes. The same key applies to all four EUM services. However, each product has its own types and metrics for allowed usage.

### EUM App Key

This is the unique identifier that AppDynamics uses to associate end user data to specific EUM applications. Each EUM application will be associated with one EUM App Key. For your applications to be monitored,

they will need to include the EUM App Key when reporting data. The EUM App Keys are also associated with an EUM account name and license key.

 Changing the license key does not affect existing EUM App Keys.

## License Optimization and Usage Periods

For EUM license metric definitions and data retention, see [License Entitlements and Restrictions](#).

EUM License	License Optimization	Usage Period
Real User Monitoring	See Browser and Mobile RUM rows below.	See the Browser and Mobile RUM rows below.
Browser RUM	If the value of Pageviews is greater than <b>Pageviews Allocated</b> and your license allows overages, you are incurring overage charges. If you need to stop incurring overage charges, you can <a href="#">disable Browser RUM</a> to stop end user monitoring and stop Pageviews from being charged (once disabled, expect a delay of approximately one minute).	The Browser RUM usage period is per year, even if you have a multi-year license. The meter resets every year based on the expiration of your license agreement. For example, if your license expires at 12:00pm PST on May 1, 2020, your usage period resets every year starting 12:00pm PST on May 1, 2021.

EUM License	License Optimization	Usage Period
Mobile RUM	<p>License consumption is affected when you have one instrumented application installed on multiple devices, multiple applications on the same device, or uninstalls followed by reinstalls:</p> <ul style="list-style-type: none"> <li>• If you install one instrumented application on two devices within a month, each device uses one <a href="#">Monthly Active Agent</a>.</li> <li>• If you uninstall and then reinstall an instrumented application multiple times within a month, each reinstall uses one Monthly Active Agent.</li> <li>• If you install two different instrumented applications on the same device within a month, each instrumented application consumes one Monthly Active Agents, so.</li> </ul> <p>Through SDKs, you can customize application instrumentation to choose which agents send data. For further instructions, see the following:</p> <ul style="list-style-type: none"> <li>• <a href="#">Customize the Android Instrumentation</a></li> <li>• <a href="#">Customize the iOS Instrumentation</a></li> <li>• <a href="#">Customize the Xamarin Instrumentation</a></li> <li>• <a href="#">Customize the Cordova Instrumentation</a></li> </ul>	<p>The Mobile RUM usage period begins and the meter resets on the first day of each month at 12:00pm PST. When your license consumption reaches 90% of your Monthly Active Agent allocation, you will see a warning in the Mobile RUM dashboard.</p>
Synthetic	<p>To help you optimize the use of your Synthetic Agent license, keep the following in mind:</p> <ul style="list-style-type: none"> <li>• Synthetic jobs are measured in terms of the time it takes to actually run the test in AppDynamics systems. Because it is not possible to know in advance how long a given test may take, you can set a timeout value when you create the job. If the job times out, you receive partial results.</li> <li>• Once you have used up your monthly allotment, all synthetic jobs are paused until the following month.</li> <li>• If there is a problem accessing a site, such as receiving a 5xx error, the system automatically runs the job again. You are charged for these retests.</li> <li>• If you see a session with the status INTERNAL_ERROR, this means there is a problem with AppDynamics infrastructure, and you will not be charged, even if the session contains partial results.</li> <li>• Adjusting synthetic job configurations, such as the number of browser types, frequency, and duration, may have an impact on license consumption. To gauge estimated consumption in the Controller, create a new job and see the section <b>Set a Timeout</b> (step 6).</li> <li>• Locations are user-defined. You can add multiple servers (agents) to a location to increase capacity, and this does not impact your license.</li> </ul>	<p>The usage period begins and the meter resets on the first day of each month at 12:00pm PST.</p>

EUM License	License Optimization	Usage Period
IoT	License consumption is based on Application Instances. We recommend that you register each Application Instance and each device so that you can correlate data with each data source. To reduce license consumption, you can register just one device with multiple Application Instances, or one Application Instance on multiple devices. However, in doing so, AppDynamics cannot differentiate data, such as errors, for each application instance or device unless each one is registered.	The usage period begins and the meter resets on the first day of each month at 12:00pm PST. The usage period for IoT is always the current month, even if you have a multi-year license.

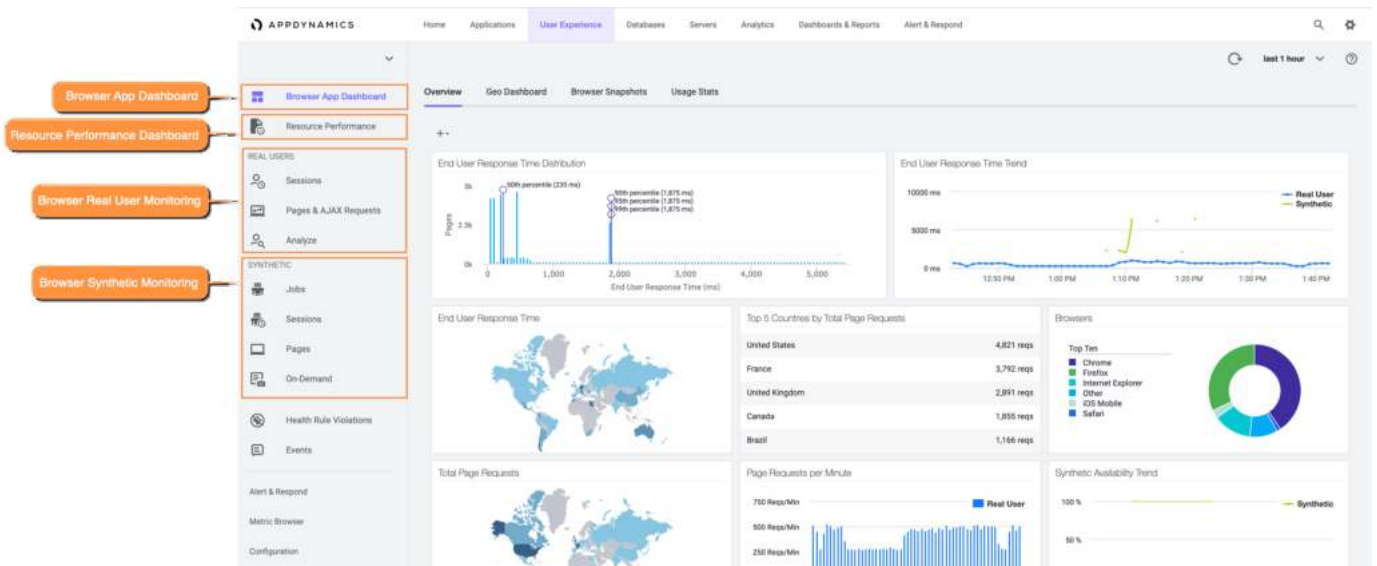

## Browser Monitoring

AppDynamics offers two products to monitor browser applications:

- [Browser Real User Monitoring](#) (Browser RUM) - Monitors how your web application is performing, using real user data to analyze application performance and user experience.
- [Browser Synthetic Monitoring](#) - Analyzes application availability and performance, using scheduled testing to analyze website availability.

## Overview of the Controller UI for Browser Monitoring

Browser RUM and Browser Synthetic Monitoring share two dashboards: Browser App Dashboard and Resource Performance Dashboard.

---

## Browser App Dashboard

The [Browser App Dashboard](#) provides a high-level understanding of how your application's overall performance. When you first navigate to a browser application, you are defaulted to the **Browser App Dashboard > Overview** tab. The **Overview** tab contains widgets for both Browser and Synthetic data.

## Resource Performance Dashboard

The [Resource Performance Dashboard](#) provides a high-level understanding of how your resources affect the performance of your browser application. You can use this dashboard to pinpoint resource-related performance issues affecting the user experience. You can toggle between viewing Browser and Synthetic data.

## Real Users

Browser RUM contains these UI tabs for more detailed real-user data analysis:

- [Browser RUM Sessions](#)
- [Pages & AJAX Requests](#)
- [Browser RUM Analyze](#)

## Synthetic

Browser Synthetic Monitoring contains these UI tabs for more detailed synthetic user data analysis:

- [Synthetic Jobs](#)
- [Synthetic Sessions](#)
- [Synthetic Pages](#)
- [Synthetic On-Demand](#)

## Differences Between Browser RUM and Browser Synthetic Monitoring

Although Browser Synthetic Monitoring and Browser RUM report similar metrics, there are differences in:

- Hardware
- Network connections
- Different browsers
- Browser caching is not present in synthetic sessions

If you see a sudden change in any of those metrics, you should compare the results of Browser Synthetic Monitoring and Browser RUM to determine if there is an existing problem.

## Performance Versus Workflows

Browser RUM excels at capturing the full breadth of performance and your real users' experience. Browser Synthetic Monitoring gives you confidence that your key workflows are always working and performing.

## Synthetic Metrics and Screenshots

Browser Synthetic Monitoring can collect certain data that Browser RUM cannot. For example, Browser Synthetic Monitoring provides screenshots, which help you see per-page testing. You can also use the Visually Complete Time metric and other related metrics to understand how users experience page load time.

---

## How to Use Browser RUM and Browser Synthetic Monitoring Together

### Identify Issues

Although Browser RUM can detect certain kinds of problems (like JavaScript exceptions), it cannot comprehensively test for functional correctness. For example, you may want to verify that your online store has reasonable prices a list of items. If your site is down entirely, then the JavaScript Agent will never be loaded, so errors or verifications will not be reported. Fortunately, Browser Synthetic Monitoring will keep running, discover the error, alert you, and provide detailed information about the problem.

### Control Environmental Factors

Hardware, browsers, operating systems, and networks complicate performance analysis in Browser RUM. Browser Synthetic Monitoring uses consistent hardware, software, and network configurations you set when you create a synthetic job, so if you see deviations in performance, you can be fairly certain a problem exists.

### Browser App Dashboard

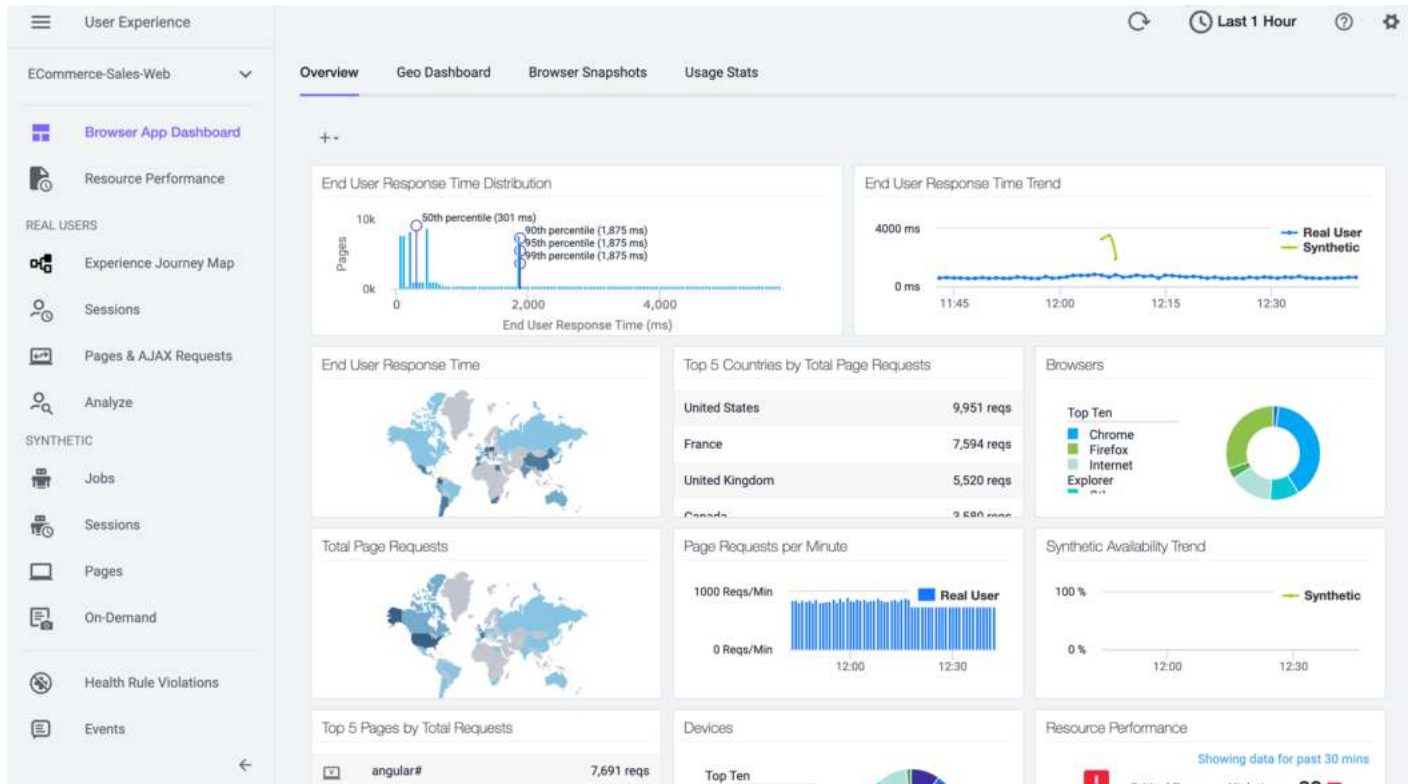

The **Browser App Dashboard** gives you a high-level overview of your browser application performance. To access the **Browser App Dashboard**:

1. In the Controller, go to **User Experience**.
2. Under **Browser Apps**, select an application.
3. In the left navigation bar, click **Browser App Dashboard**.

### Overview

The **Overview** tab displays a set of configurable widgets. The default widgets contain multiple graphs and lists featuring common high-level indicators of application performance. You can remove a widget by clicking the **X** icon and add a widget using the **+ ▾** icon.

**i** For SPA2 applications, the **Overview** tab only displays data for base pages and virtual page events. Data from Iframe and Ajax requests is not included. If you have an application that only has Iframe and Ajax requests, then the **Overview** tab will not display any data.

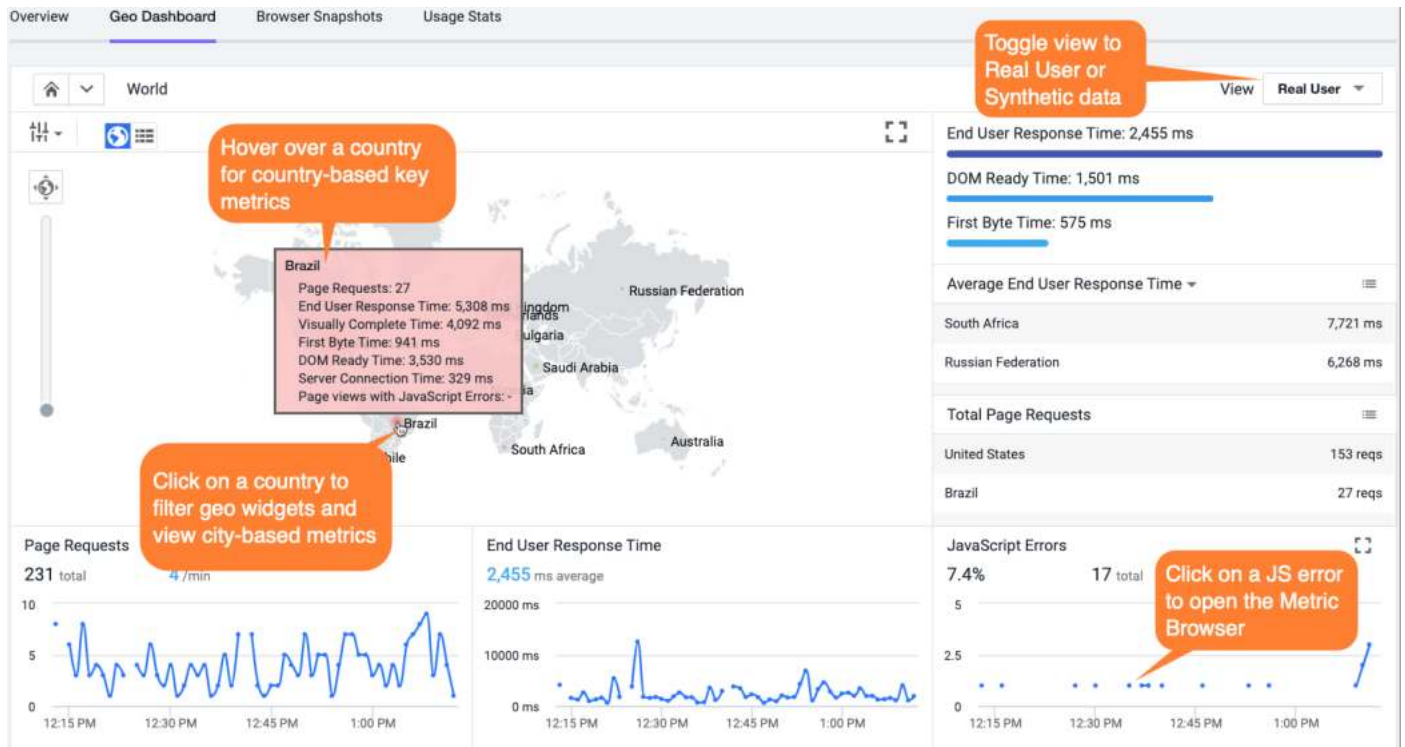

## Geo Tab

The **Geo** tab displays key performance metrics by geographic location based on page loads. If you are using Browser Synthetic Monitoring for an application, you can view either Real User or Synthetic data using the **View** dropdown. See [Browser Synthetic Monitoring versus Browser Real User Monitoring](#).

The metrics displayed throughout the dashboard are for the region currently selected on the Map or in the Grid. For example, on the map if click on France, the widgets and trend graphs update to display data for France.

See [Browser RUM Metrics](#) for definitions of the metrics.

## Map View Labels

The Map view displays load circles with labels for countries that are in the key timing metrics given in the right panel. Some countries and regions, however, are only displayed in the Grid view.

## Regions and Countries

Regions are subdivisions of a country, such as a state, province, or city. In the default Map view, key performance metrics are displayed by country. You can check the **Show regions in Global View** box to view the key performance metrics by region. The default Grid and Map views display key performance metrics by country, but you can view metrics based on region. Because the Map view displays fewer regions than the Grid view, if you do not see a region displayed in the Map view, switch to the Grid view.

See [Browser RUM Countries and Regions by Geo Dashboard](#) for a list of the countries and regions available in the Map and Grid views.

## Unknown Locations

An unknown location means the agent cannot determine the country from which the request originated.

You may also see metrics reported for a location named "Anonymous Proxy". This means that the agent cannot identify one or more private IP addresses, and the "Anonymous Proxy" represents aggregated metrics from those IP addresses.

One of the effects of Unknown regions is that it possible for a country to display as slow (red circles) on the global map, but when you drill down to the country all its regions appear normal (green circles). Or a country may display as normal on the global map, but some sub-regions may display as slow when you drill down.

---

## Browser Snapshots

The **Browser Snapshots** tab captures and displays a broad set of metrics associated with a single request. You can drill down into errors and view any server-side transaction snapshots associated with that request (if your app server is instrumented with server-side app agents). See [Browser Snapshots](#) for more information.

## Usage Stats

The **Usage Stats** tab presents aggregated page load usage data based on your users' browser type, device, and platform.

**Usage Stats** data helps you discover:

- The slowest browsers in terms of total end-user response time.
- The slowest browsers to render the response page.
- The browsers that most of your end users use.
- The browsers that most of your end users use in a particular country or region.

**Devices** data shows mobile access only via browsers on the device. **Devices** helps you discover:

- The slowest devices in terms of total end-user response time
- The slowest devices to connect to the server
- The devices that most of your end users use
- The devices that most of your end users use in a particular country or region

## Browser Snapshots

### Related pages:

- [Troubleshoot Business Transaction Performance with Transaction Snapshots](#)
- [Configure Browser Monitoring Snapshot Thresholds](#)
- [Add Custom User Data to a Page Browser Snapshot](#)

This page describes browser snapshots. When Browser RUM is enabled, the JavaScript Agent collects browser snapshots for:

- Every base page (including virtual pages), iframe, and Ajax request; these serve as a heartbeat snapshot
- The slowest page for every region, every device, and every browser
- Unique JavaScript errors; identified by script name and line number
- Unique Ajax errors; identified by the HTTP error code in the Ajax response

For more information about browser snapshot collection, see [Configure Browser Snapshot Collection](#).

## Browser Snapshots Tab

A list of available browser snapshots appears. You can change the time frame of your search by changing the **Time Frame** dropdown.

### List Key

-  Normal user experience
-  Slow user experience
-  Very slow user experience

 JavaScript errors (Hover over the icon for a popup with summary information)

 Correlated server-side transaction snapshot exists

 Snapshot includes resource timing information

## Browser Snapshot Types

There are three browser snapshot types, depending on whether the original object was a page, an iframe, or an Ajax request.

- [Page Snapshots](#)
- [Ajax Request Snapshots](#)
- [Iframe Snapshots](#)

## Page Snapshots

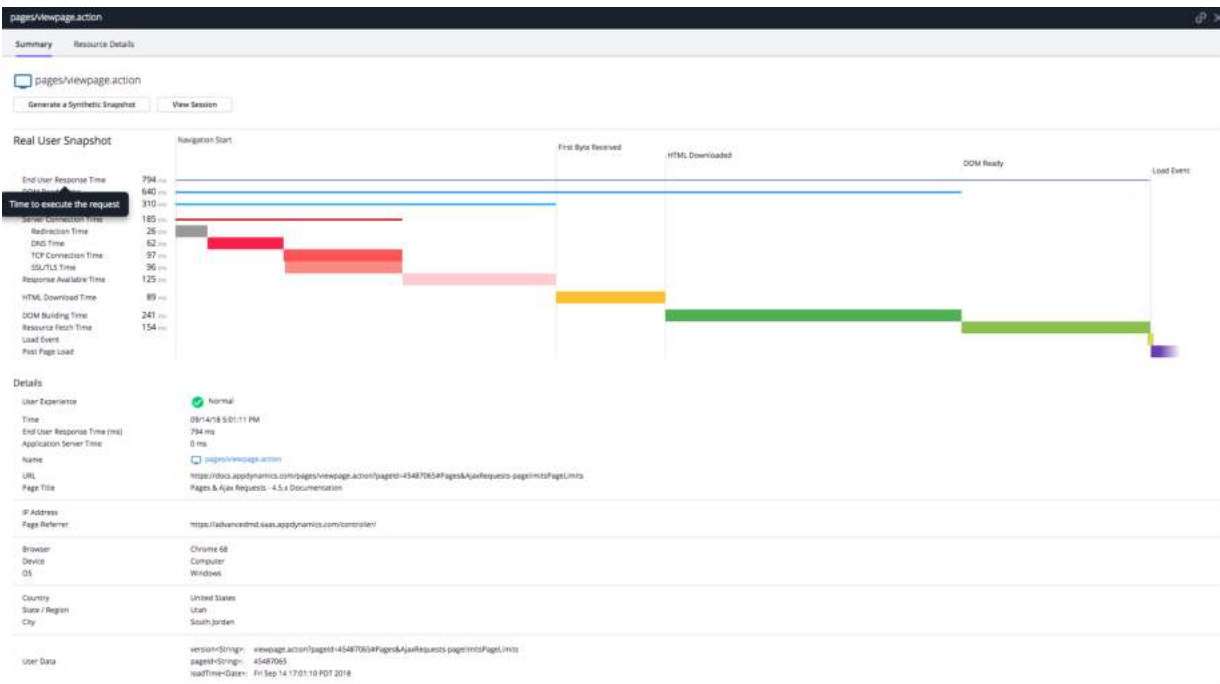

### Related pages:

- [Ajax Request Snapshots](#)
- [Iframe Snapshots](#)

Page snapshots give you a detailed look at individual browser page requests. The **Summary** tab covers the general characteristics of the page.

## Waterfall Graph

The top of the page snapshot **Summary** tab displays a waterfall graph of the overall transaction timing for the page. You can hover over each of the metrics to see a popup definition for that metric.

For more information about metrics, see [Browser RUM Metrics](#). Additional details associated with the snapshot, including any related snapshots and any custom user data, are displayed as a table below the graph.

## Generate a Synthetic Snapshot - SaaS Only

Synthetic snapshots use geographically distributed agents to create snapshots of web page download performance without the idiosyncratic and potentially skewing effects of real-user, last-mile performance. Click **Generate a Synthetic Snapshot** to create an on-demand synthetic snapshot to compare with a problematic real user monitoring snapshot.

## Correlated Transaction Snapshots and Business Transactions

If server-side correlation has been set up, a link to any related business transaction is shown:

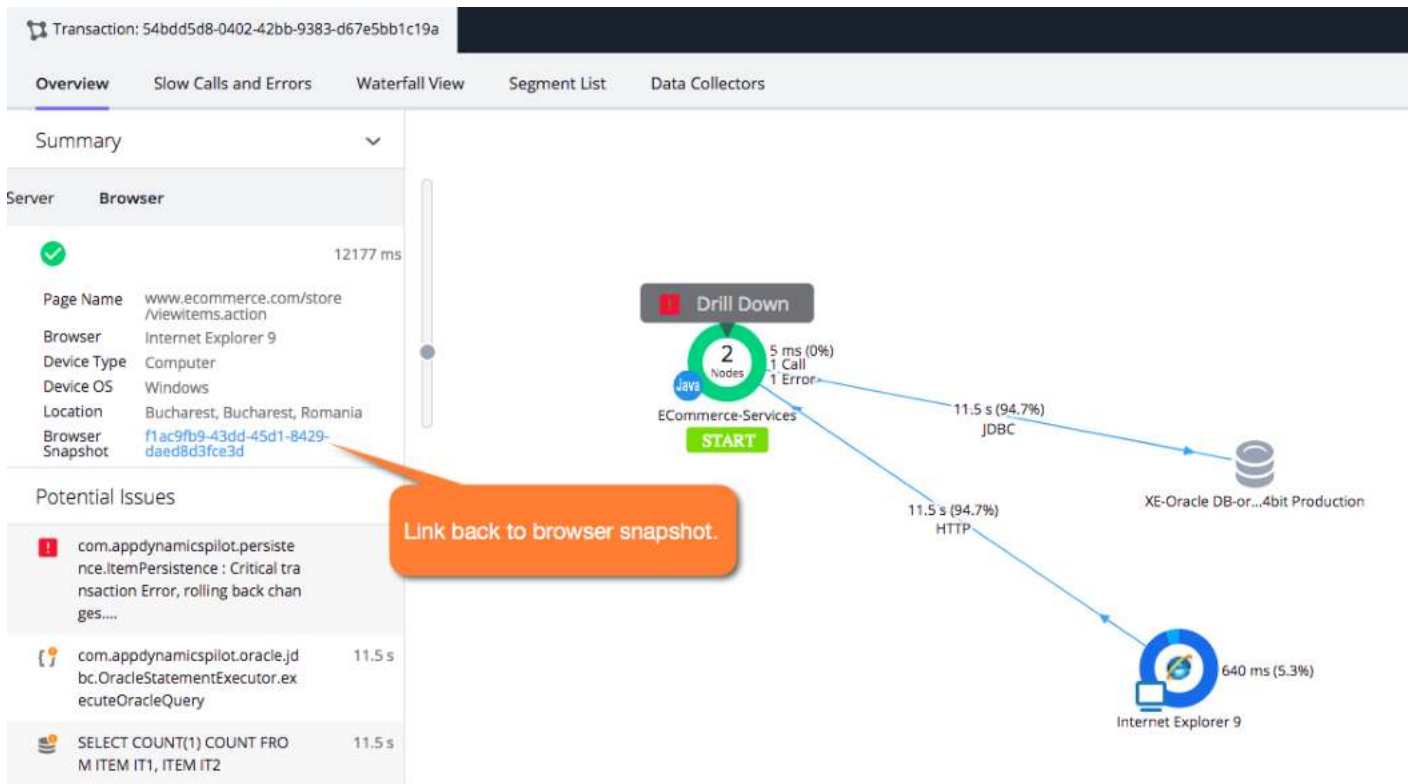

Clicking the link takes you to the flow map for that business transaction on the server side.

If the business transaction created a transaction snapshot, links to the business transaction, tier, and node flow maps are displayed, along with a direct link  to the transaction snapshot flow map. Cross-app correlation is supported.

In this case, the transaction snapshot also has a link back to the browser snapshot.

## JavaScript Errors

If there are JavaScript errors on the page, they are displayed below the waterfall graph.

You can configure to ignore errors if you are seeing too many irrelevant or excessive errors. See [Configure JavaScript and Ajax Error Detection](#) for instructions.

**i** When an error occurs in a script that is hosted on a domain other than the domain of the current page, most browsers prevent the JavaScript Agent from recording any details of the error. In such cases, the string `CROSSDOMAIN` is displayed as the **Script Origin**.

## User Data

If you have [custom user data](#) set up, the data appears in the **Details** section:

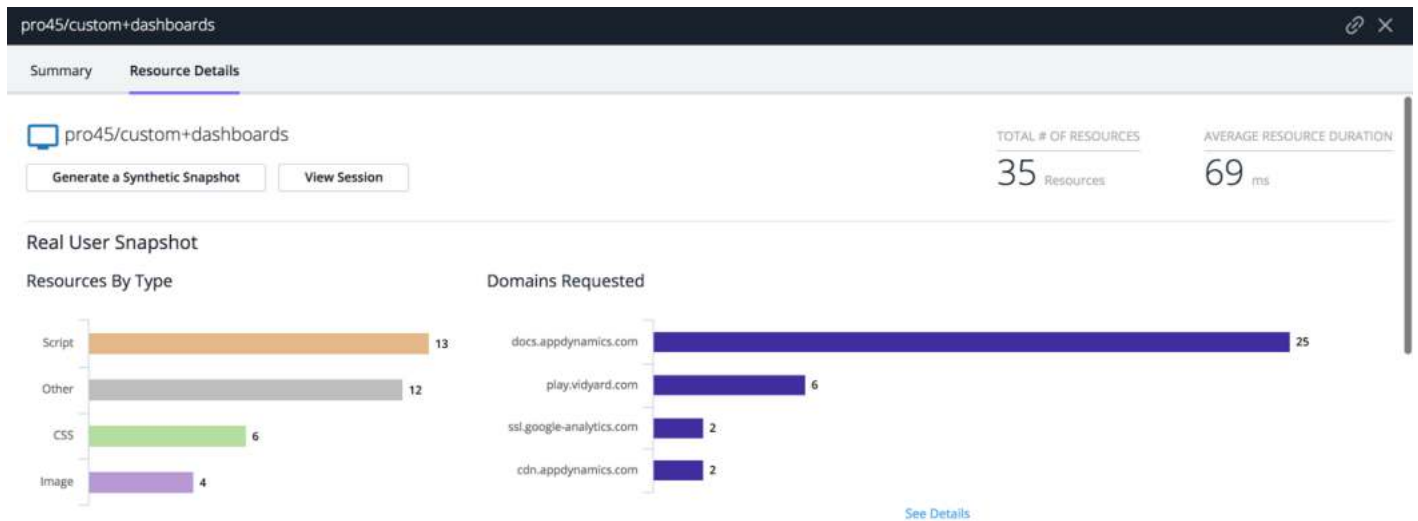

User Data

algo<String>: LOG(N)  
 Random Number<String>: 1938299132  
 hotel<String>: AppDynamics Resort

### Resource Details

If the [browser](#) supports the [Resource Timing API](#), the Resource Details tab gives you a detailed breakdown of the performance of resources—scripts, CSS files, fonts, SVGs, and images—as they are loaded into the page.

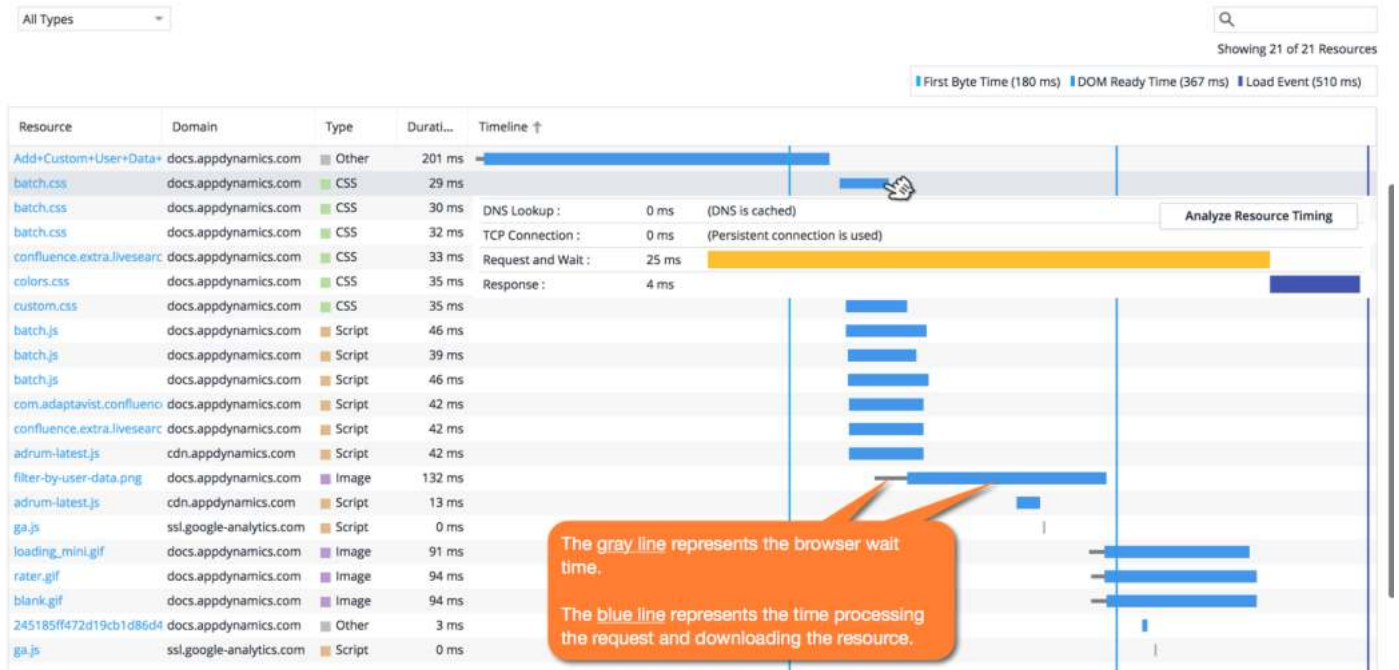

### Resource Waterfall

The **Resource Waterfall** provides a snapshot of when each resource was loaded in the page load process (before First Byte Time, before DOM Ready Time, before Onload), including the name of the resource, the domain from which it was fetched, the type of resource, and how long it took. You can filter the items by type using the upper-right dropdown and search using the search box.

To see more details, click any of the blue timelines. These are from the primary domain or cross-domains that have set the `Timing-Allow-Origin` HTTP header. See [Resource Timing Metrics](#) for descriptions and explanations about how the metrics are calculated.

Resource Waterfall

Grey timelines indicate cross-domains that have not set the `Time-Allow-Origin` HTTP header. Working with your CDN provider to add this header can mean you get better information on shared and CDN-served content.

### Unknown Metrics in Page Snapshots

Browser RUM captures metrics using your end-users' web browsers. Occasionally, you may see unknown data reported for one or metrics in a browser snapshot. This occurs on older or less sophisticated browsers that do not support the collection of a given metric.

See [Browser Monitoring Metrics](#) for details about which metrics may not be captured based on browser capabilities.

### Ajax Request Snapshots

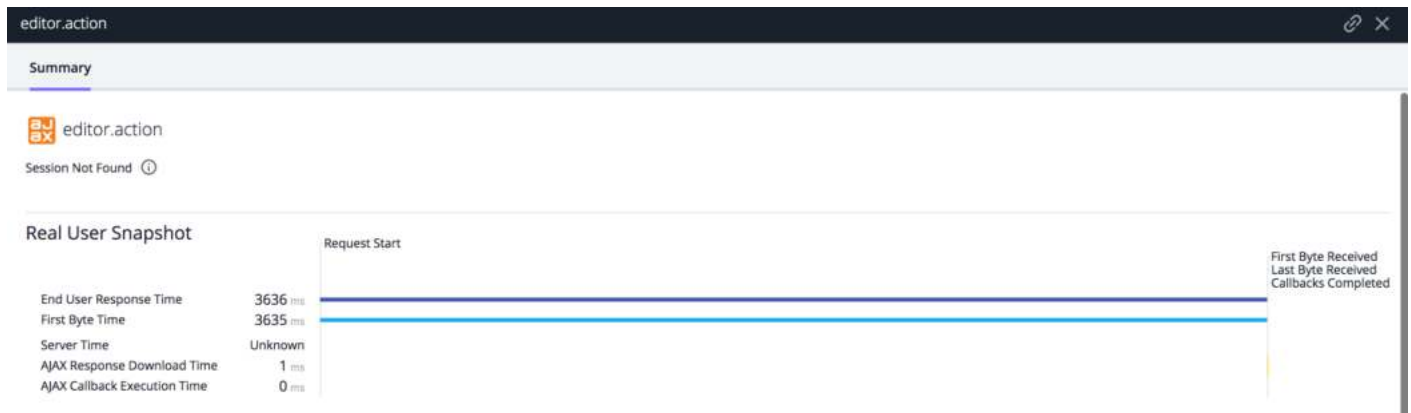

#### Related pages:

- [Page Snapshots](#)
- [Iframe Snapshots](#)

Ajax request snapshots give you a detailed look at an individual Ajax request. The **Summary** tab of the snapshot describes the general characteristics of the page.

## Waterfall Graph

The top of the Ajax snapshot displays a waterfall graph of the overall transaction timing for the Ajax request. The snapshot is labeled either a **Real User Snapshot** or a **Synthetic Snapshot** based on the origin of the request. You can hover over each of the metrics to see a popup definition for that metric.

For a detailed description of what these metrics mean, see [Browser RUM Metrics](#).

## Details

Much of the information is the same as you see for [page snapshots](#). The main differences are:

- If there is an Ajax error, the error code returned with it is listed.
- The parent page from which the Ajax call originates is listed.

You can configure errors to ignore if you are seeing too many errors that are not of interest. See [Configure JavaScript and Ajax Error Detection](#).

## Iframe Snapshots

### Related pages:

- [Page Snapshots](#)
- [Ajax Request Snapshots](#)

Iframe-based snapshots give you a detailed look at an individual iframe request. The UI display is identical to [Page Snapshots](#) except in the **Details** section, where the parent page may also be displayed.

Details

## Resource Performance Dashboard

### Deployment Support

#### Related pages:

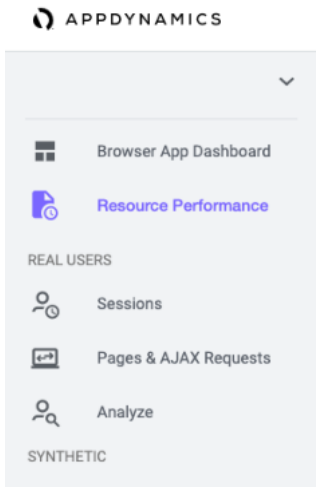

- [Use Cases for the Resource Performance Dashboard](#)
- [Browser RUM Metrics](#)
- [Configure Resource Violation Rules](#)

The **Resource Performance Dashboard** provides a high-level overview of how your resources affect the performance of your browser application. You can use this dashboard to pinpoint resource-related performance issues affecting the user experience, such as the following:

- A prioritized list of resource performance issues by comparing their performance against thresholds
- Changes in the number of resources
- Large resources (images, JavaScript, CSS, etc.)
- Size increase of resources impacting performance. For example, a page banner might be replaced with an uncompressed image, slowing down the page load.
- Slow CDNs
- Resources that haven't been compressed
- Comparison of real user and synthetic resource performance

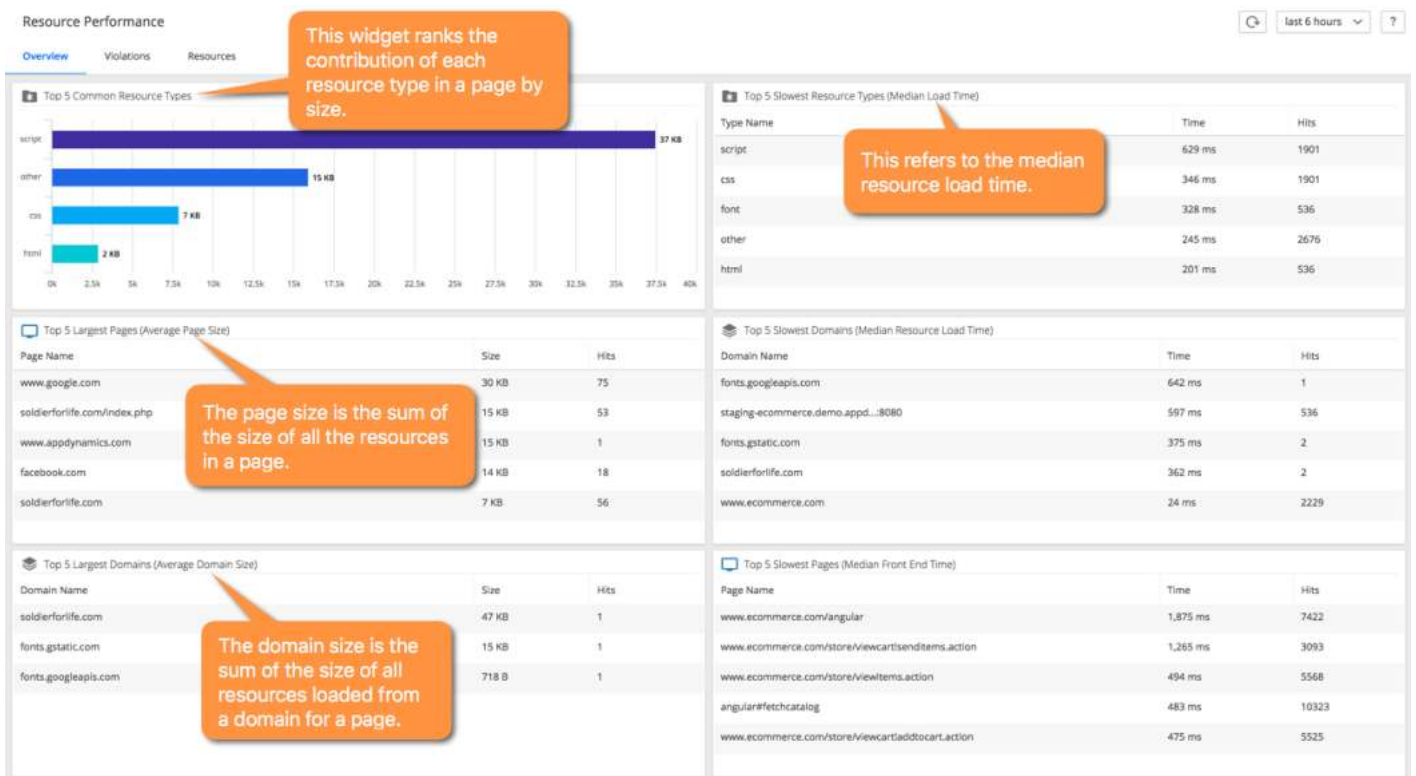

#### Overview of the Resource Performance Dashboard UI

Once you navigate to a browser application, the **Resource Performance Dashboard** is located on the left-side panel.

## Overview Tab

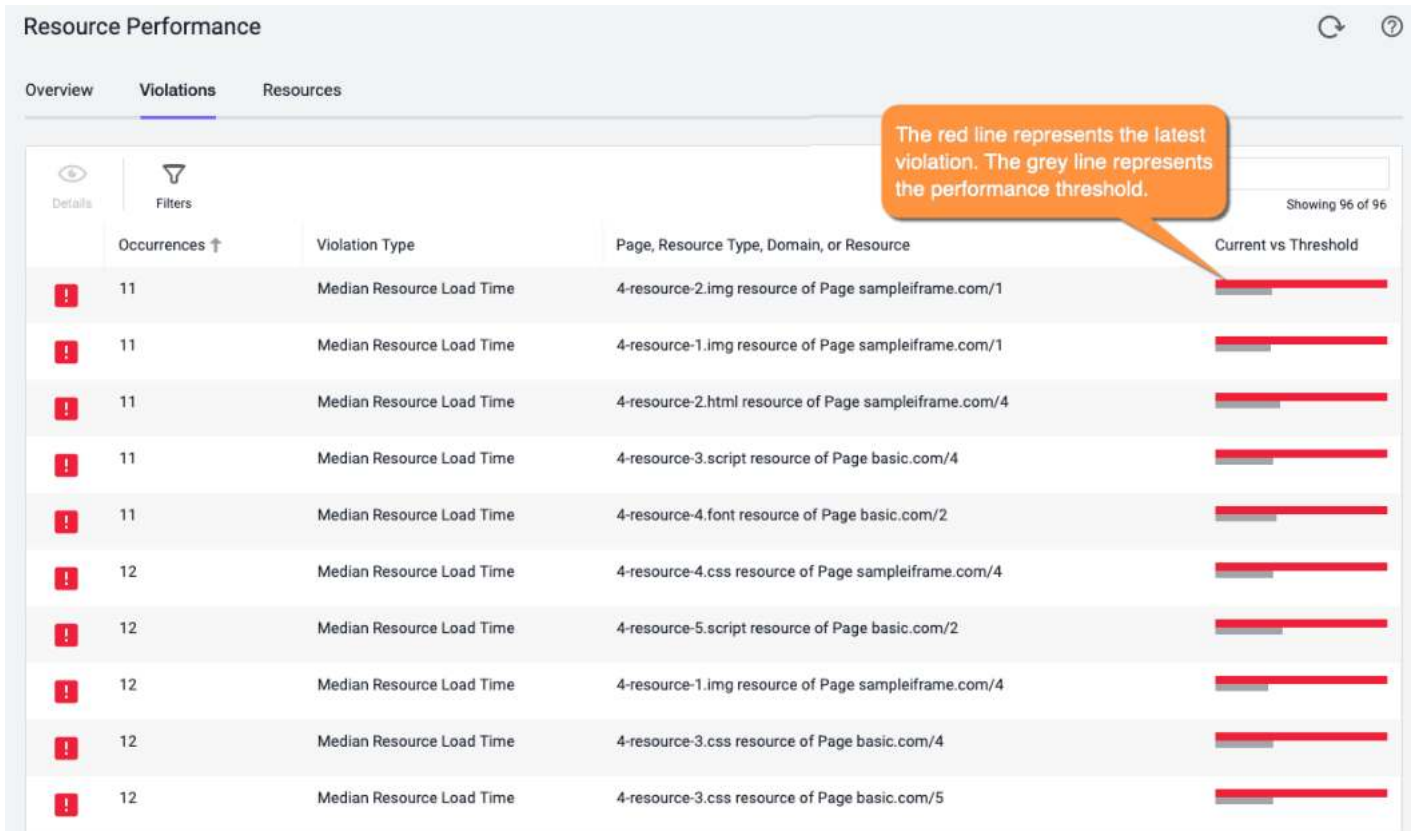

The **Overview** tab displays widgets providing high-level indicators of resource performance over a specified time period. The dashboard can be filtered to real user or synthetic data. The widgets only show a small number of resources, but you can click **See More** to view up to 100 resources per widget.

## Violations Tab

The **Violations** tab shows a list of pages, resource types, and domain or resource violations that have exceeded performance thresholds. You can use the **Violations** tab to not only find problematic resources, but also to become aware of sudden changes that negatively impacted the performance of

a resource. Clicking a specific violation leads to the **Resources** tab, and the data is filtered with that violation for further diagnostics. The configured violation rules are evaluated every 10 minutes for the last 30 minutes.

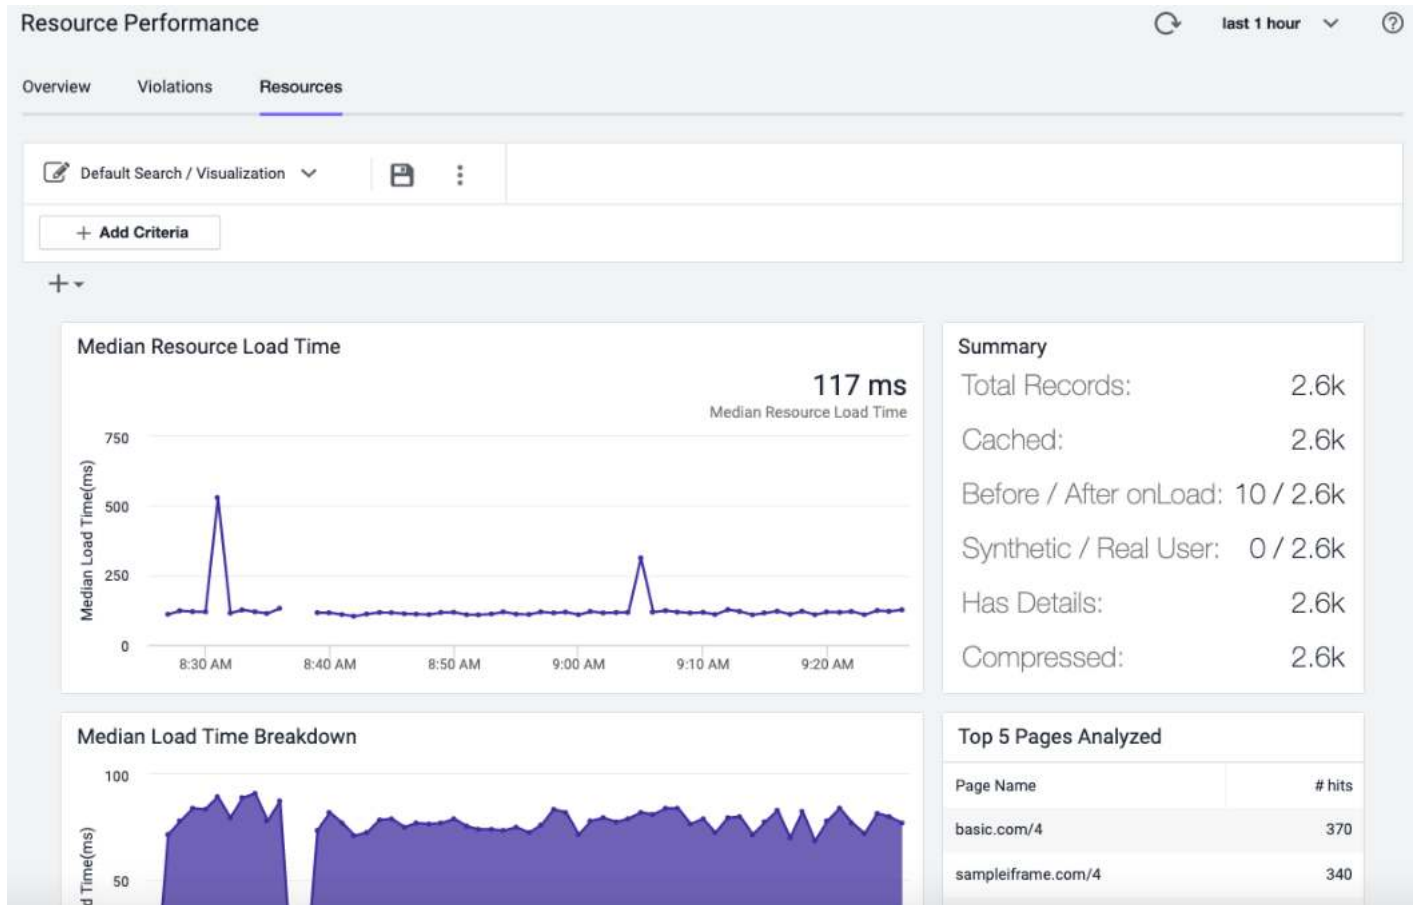

## Violation Types

The supported violation types include:

- Median Domain Load Time
- Average Domain Size
- Average Page Size
- Median Resource Load Time
- Average Resource Size
- Median Resource Type Load Time
- Average Resource Type Size

## Resources Tab

You can use the **Resources** tab to diagnose a problematic resource. You can also add criteria as a filter to the widgets. All use cases to troubleshoot a resource leads to the **Resources** tab where you can learn more about an individual resource's impact on an application. See [Use Cases](#) for examples.

### Additional Resource Performance Data Information

For the **Resource Performance Dashboard** to be effective, it is highly recommended that you set the `Timing-Allow-Origin` HTTP header in all of your CORS domains to enable access to resource timing information. Without this header, the JavaScript Agent cannot capture the resource size, and, of the supported [Resource Timing Metrics](#), only the resource load time can be calculated.

For information about resource performance data retention, see [License Entitlements and Restrictions](#).

### Use Cases for the Resource Performance Dashboard

The Resource Performance Dashboard provides a high-level overview of how your resources affect the performance of your browser application.

The table presents common troubleshooting and analysis use cases for resource performance.

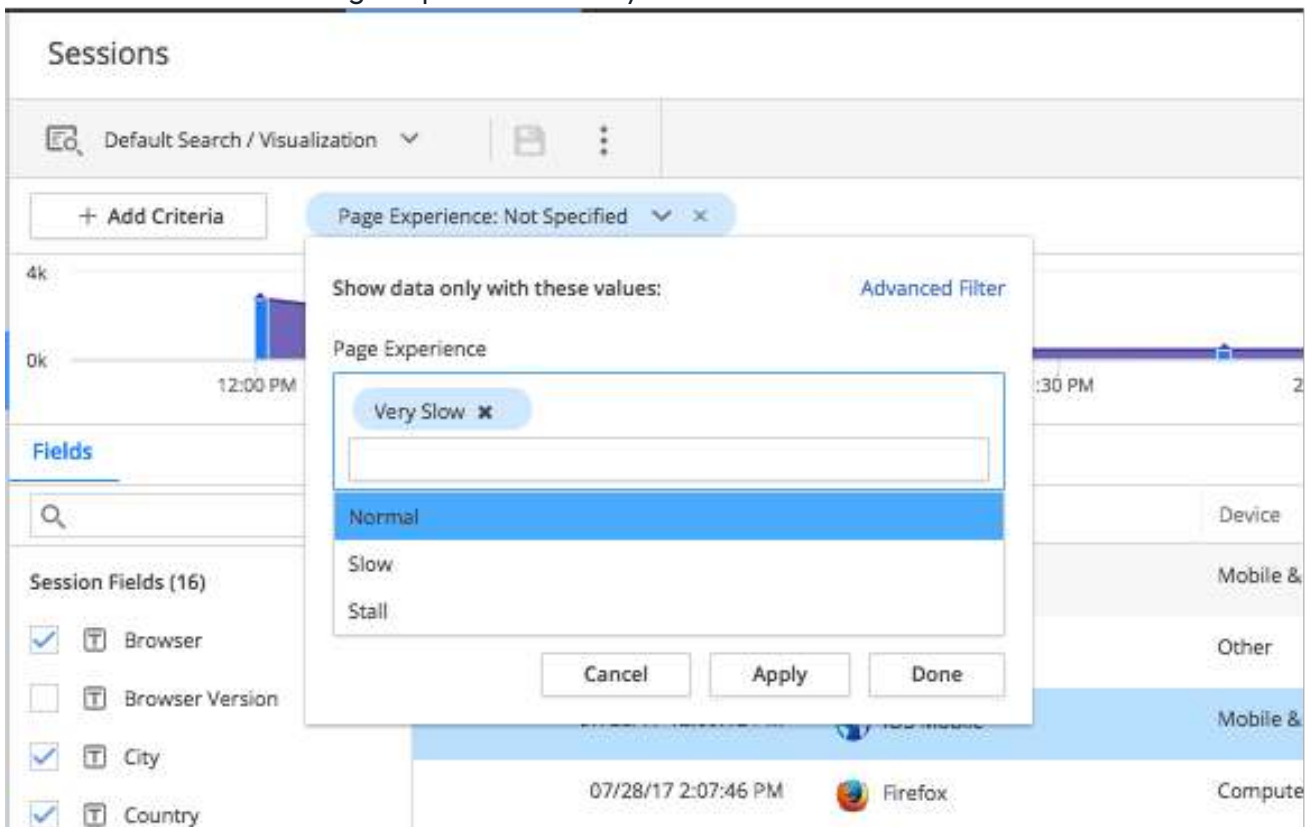

Goal	Use Case
Detect and resolve poor performance issues	<a href="#">Troubleshoot from Sessions</a>

Goal	Use Case
Track and monitor resource violations	<a href="#">Discover Top Resource Violations</a>
View a resource's performance from a particular region	<a href="#">Analyze Resources by Region</a>
Diagnose cause of lengthy load time for image resources	<a href="#">Diagnose Problematic Resources</a>

### Troubleshoot a Resource from Sessions

Follow these steps to troubleshoot a resource from **Sessions**:

1. Go to **Sessions**.
2. Add criteria and set the Page Experience to **Very Slow**.

3. Double-click on a session record.
4. In the **Session Summary** select the page with the longest **End User Response Time**.
5. In the **Waterfall** tab, click a problematic resource to open the **Resource Details** dialog.

## 6. Click Analyze Resource.

Session - 08/08/19 9:01:48 AM to 08/08/19 9:02:14 AM

Session Summary

posts	34,406 bytes	DNS Lookup	Cached
Duration	707 ms	Browser Wait	1 ms
Start Time	6,470 ms	Request and Wait	691 ms
		Response	15 ms

No other Sessions for this Agent

- You are redirected to **Resource Performance > Resources**. The resource becomes the filter for the dashboard data.

- In the widgets, look for patterns or possible factors such as geographic location, domains, and so on. See [Diagnose Problematic Resources](#) to learn some strategies for diagnosing resource issues.

**i** To rule out environmental factors such as network connections, browser, and so on, create a synthetic job that calls a page with the resource to confirm the resource is the problem.

### Discover Top Resource Violations

Follow these steps to determine which resource is causing the most performance violations:

- Go to the **Resource Performance > Violations**.
- Select the **Occurrences** column so that number of occurrences is in descending order.

3. Double-click the top-occurring violation.

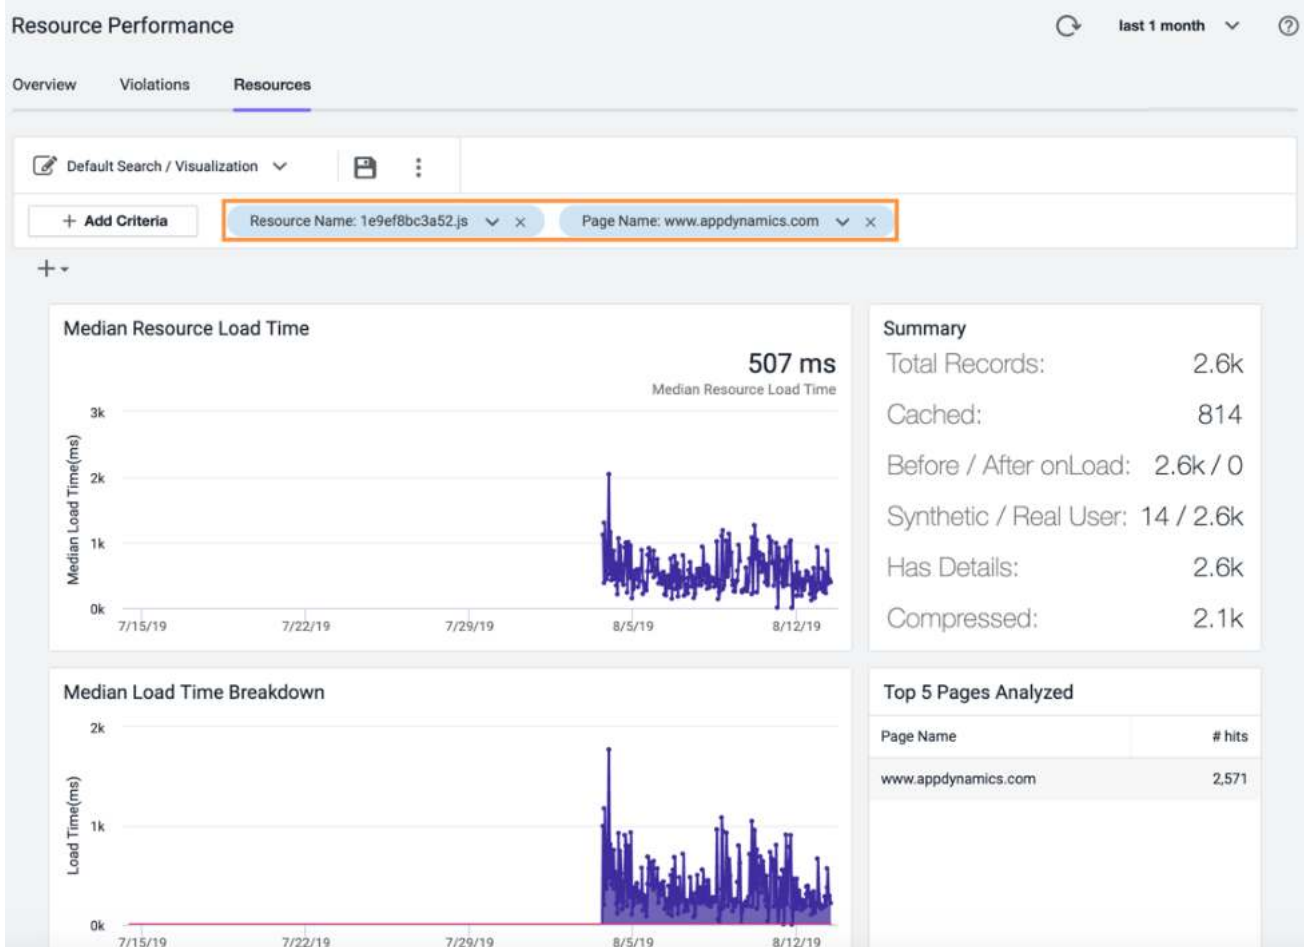

Resource Performance ↻ ?

Overview **Violations** Resources

Details Filters 🔍 Showing 106 of 106

	Occurrences ↓	Violation Type	Page, Resource Type, Domain, or Resource	Current vs Threshold
!	62	Avg Resource Size	1e9ef8bc3a52.js resource of Page www.appdynamics.com	
!	57	Avg Resource Type Size	img resources of Page www.appdynamics.com	
!	57	Avg Resource Size	homepage-hero-1920x0.png resource of Page www.appdynamics.com	
!	56	Median Resource Load Time	posts resource of Page www.appdynamics.com

!	41	Median Resource Load Time	ntnanetan.nif resource of Page www.appdynamics.com	

4. You are redirected to the **Resources** tab with information for the resource in violation.

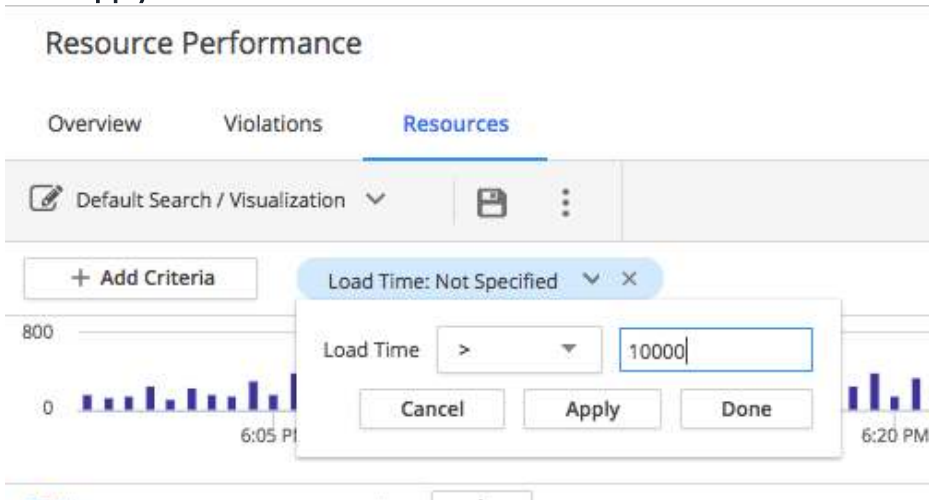

### Analyze Resources by Region

Follow these steps to analyze and monitor a resource based on a region:

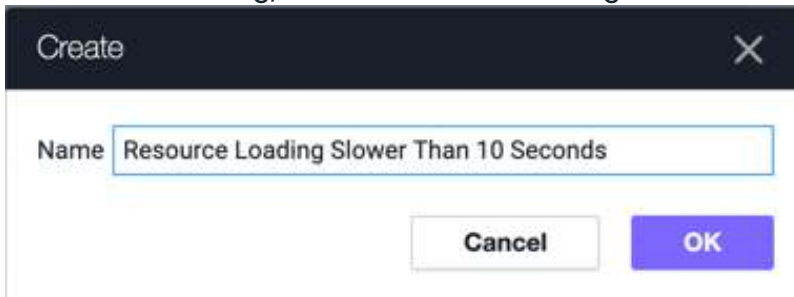

1. Go to the **Resources** tab.
2. From the **Add Criteria** drop-down, select **Load Time** and specify the value to be greater than 10000 (10 seconds).

3. Click **Apply**.

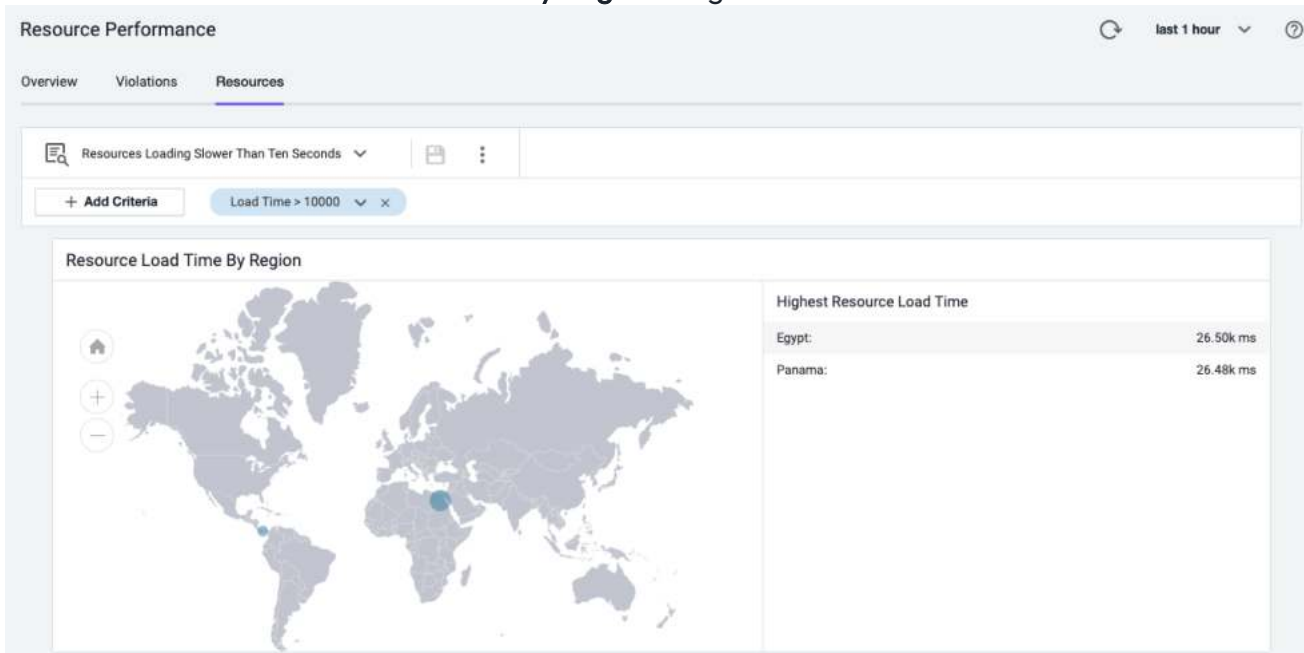

4. Click .

5. In the **Create** dialog, enter "Resources Loading Slower Than 10 Seconds," and click **OK**.

6. Scroll down to the **Resource Load Time by Region** widget.

## Diagnose Problematic Resources

Follow these steps to diagnose why certain image resources are taking a long time to load:

1. From the **Violations** tab, double-click on a resource. You are redirected to the **Resources** tab with the resource applied as a data filter.

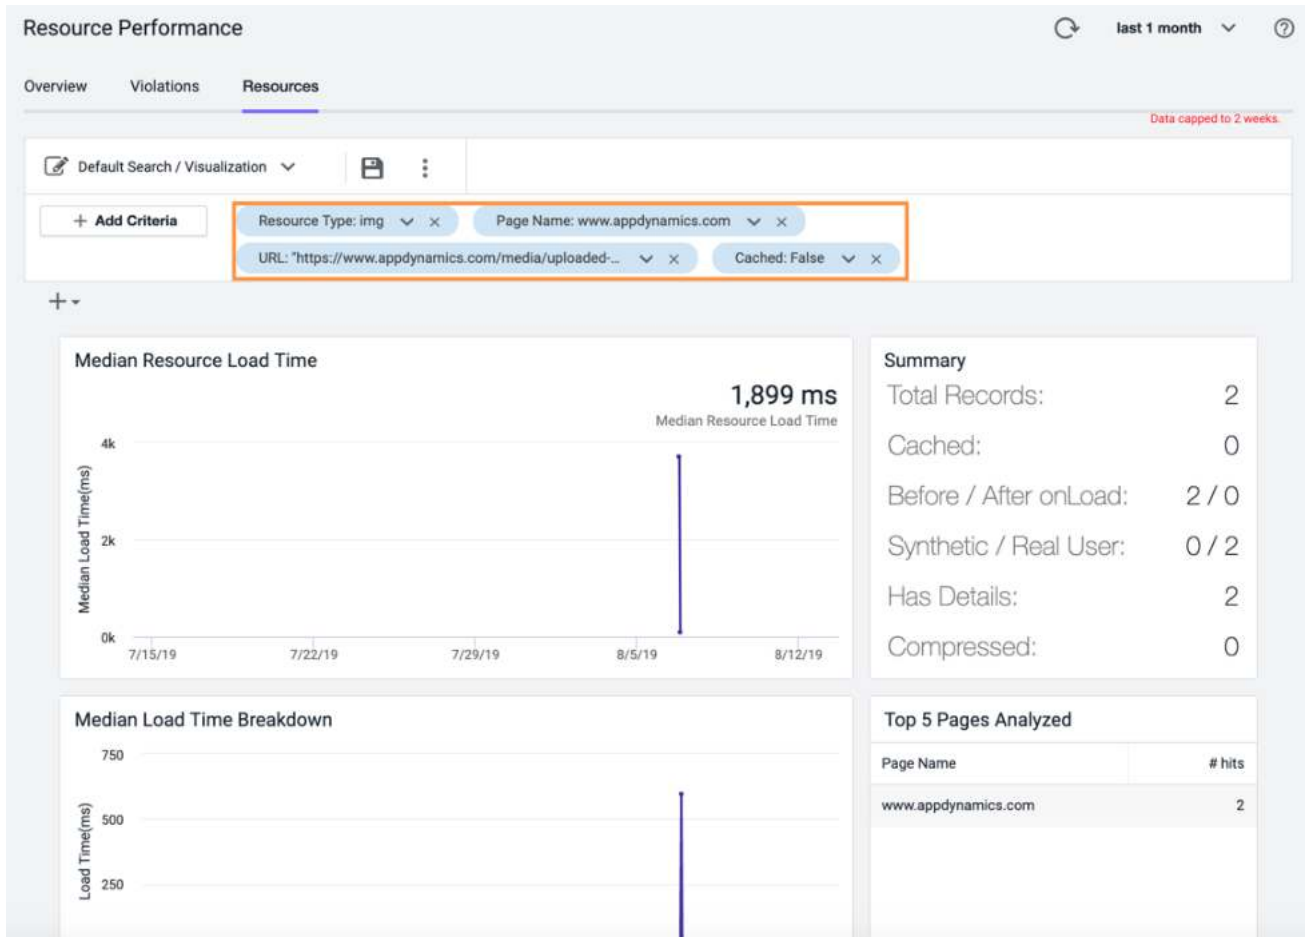

Resource Performance

Overview **Violations** Resources

Details Filters  Showing 109 of 109

Occurrences ↓	Violation Type	Page, Resource Type, Domain, or Resource	Current vs Threshold
85	Avg Resource Size	1e9ef8bc3a52.js resource of Page www.appdynamics.com	
81	Avg Resource Type Size	img resources of Page www.appdynamics.com	
81	Avg Resource Size	homepage-hero-1920x0.png resource of Page www.appdynamics.com	
76	Median Resource Type Load Time	other resources of Page www.appdynamics.com

62	Median Resource Type Load Time	script resources of Page www.appdynamics.com	
59	Median Resource Load Time	homepage-hero-1920x0.png resource of Page www.appdynamics.com	
58	Median Resource Load Time	1e9ef8bc3a52.js resource of Page www.appdynamics.com	
57	Median Resource Type Load Time	img resources of Page www.appdynamics.com	

2. Select criteria fields to determine possible causes, such as **Region, Cached, Compressed, Load Time, Domain**, and so on.
  - Example: Confirm that resources are cached or compressed.
  - Example: Add criteria that may indicate issues with the server based on the location of the resource, such as **DNS Lookup Time, Connection Time, Wait Time, and Request Time**.

3. Search for patterns that indicate the cause within the widgets, providing insights such as:

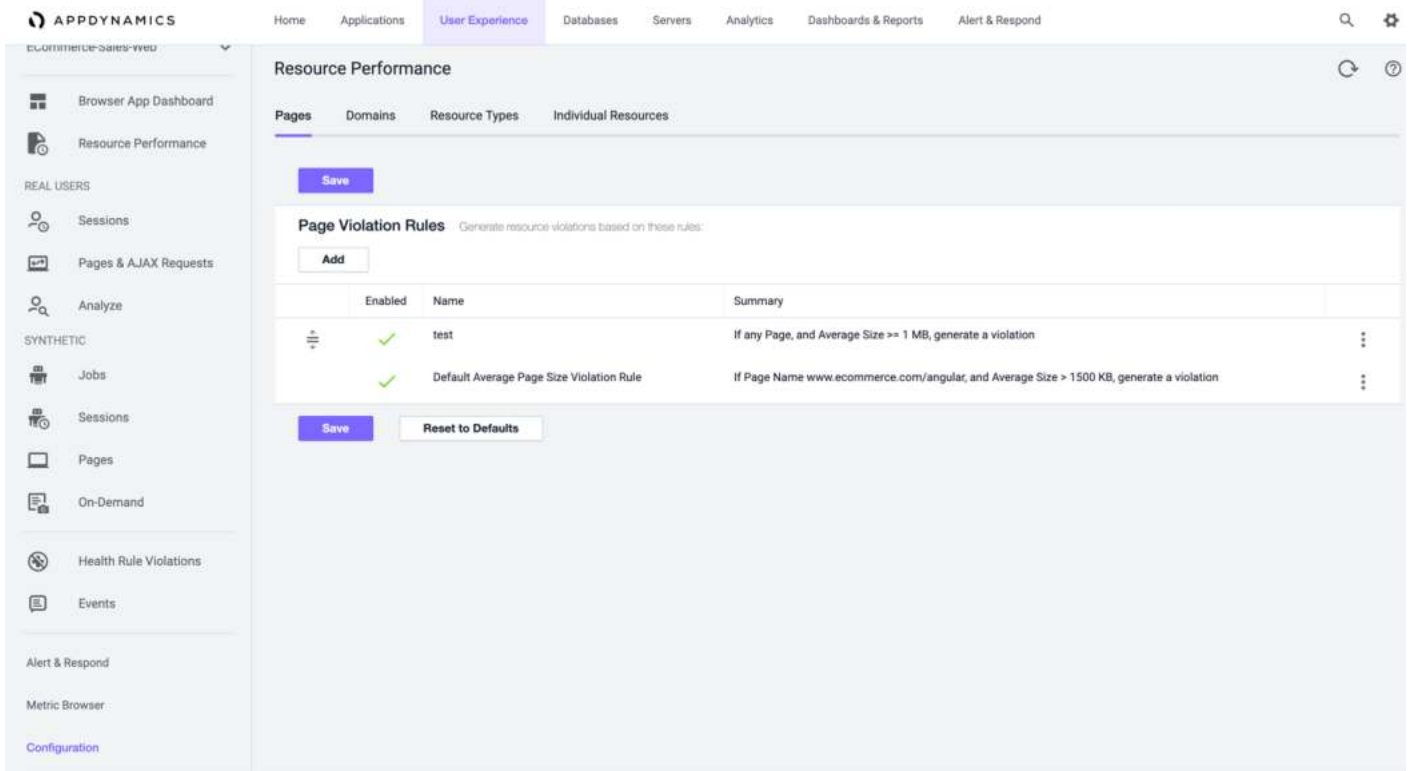

- Resource load time speed in certain regions
- Top pages using the resource
- Median load time breakdown showing that load time slows down at certain intervals
- Resource size increases

**i** To rule out environmental factors such as network connections, browser, and so on, create a synthetic job that calls a page with the resource to confirm the resource is the problem.

**Configure Resource Violation Rules**

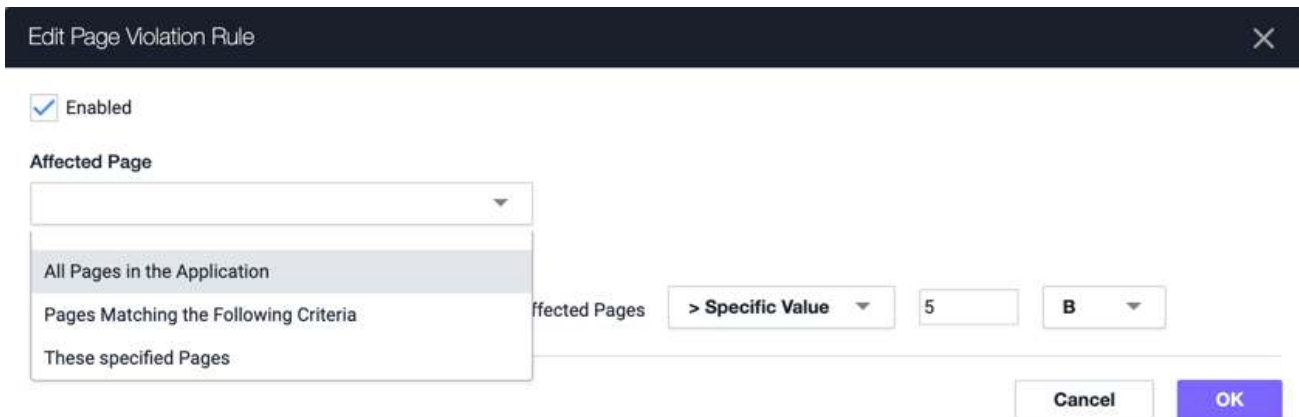

This page describes how to configure resource violation rules for the Resource Performance Dashboard. You can configure violation rules for pages, domains, resource types, and individual resources. You can use or edit the default rules per category or create your own rules. Resource Performance configuration is only available to admin-level users.

To configure resource violation rules, navigate to **Configuration > Resource Performance**.

## Pages Violation Rules

Page violations help monitor your most important pages and ensure they are light and efficient for end users. You can set violation rules for all pages, individual pages, or by pages matching query criteria within an application. The average page size can be set to megabytes, kilobytes, or bytes. This helps you troubleshoot application performance based on pages.

## Use Case

In this scenario, your home page size average is 1500 KB, and you want to be notified when it surpasses that threshold. You can set your home page at a maximum size of 1500 KB. If the violation rule is triggered, you will see the violation in the Violations tab as well as in the "Resource Performance" widget in the Browser App Dashboard.

## Domain Violation Rules

Domain violations help monitor the effects of domain performance on your application. You can set violation rules for all affected domains, individual domains, or by domains matching query criteria within an application. The median load time per page view can be set to milliseconds or seconds, and the average domain size can be set to megabytes, kilobytes, or bytes. This helps you troubleshoot poor application performance based on domains.

Affected Domain

All Domains in the Application
▼

Criteria

Generate a violation when Median Load Time per Page View ▼ > Specific Value ▼ 10 ms ▼ for any of

the Affected Domains for any of the Affected Pages

Cancel
OK

## Use Case

In this scenario, you want to monitor the performance of your CDN. You can set your CDN domains to a maximum median load time of 1000 ms for all domains in the application. If the violation rule is triggered, you will see the violation in the Violations tab as well as in the "Resource Performance" widget in the Browser App Dashboard.

## Resource Type Violation Rules

Resource type violations help monitor the effects of resource types, such as images, html, css, and so on, within your application. You can set violation rules for all affected resource types or by individual resource type within an application. You can also set the rule to one page, pages matching query criteria, or all pages in the application. The median load time per page view can be set to milliseconds or seconds, and the average domain size can be set to megabytes, kilobytes, or bytes. This helps you troubleshoot poor application performance based on resource types.

Criteria

Generate a violation when **Median Load Time per Page View** > Specific Value 10 ms for any of the Affected Resource Types for any of the Affected Pages

### Use Case

In this scenario, you want to monitor all the images in all pages across your application. You can set all images to maximum average size of 500 KB for all pages in the application. If the violation rule is triggered, you will see the violation in the Violations tab as well as in the "Resource Performance" widget in the Browser App Dashboard.

### Individual Resource Violation Rules

Individual resource violations help monitor the effects of one resource across your application. You can set violation rules for all affected resources or by resources matching query criteria within an application. The median load time per page view can be set to milliseconds or seconds, and the average domain size can be set to megabytes, kilobytes, or bytes. This helps you troubleshoot poor application performance based on individual resources.

Generate a violation when **Median Load Time per Page View** > Specific Value 2 ms for any of the Affected Resources for any of the Affected Pages

## Use Case

In this scenario, you want to monitor all resources on your home page. You can set all resources to a maximum load time per page view at 2 ms within the scope of the home page. If the violation rule is triggered, you will see the violation in the Violations tab as well as in the "Resource Performance" widget in the Browser App Dashboard.

## JavaScript Errors Dashboard

### Related pages:

- [Add Application Release Information](#)
- [Disable Long Stack Trace Reporting](#)

The JavaScript Errors dashboard captures detailed information about JavaScript errors that occur in your browser application. With the JavaScript Errors dashboard you can:

- View all JavaScript errors occurring in your browser app within a selected time frame.
- Drill down into a single error instance and its impact.
- View error instances and details listed by time stamp and page name.
- Upload maps and files to troubleshoot the error in the source code.

### Requirements

To access the JavaScript Errors dashboard, you need the following:

- SaaS Controller  $\geq$  22.2.0
- JavaScript Agent  $\geq$  22.2.0.

### Region Support

The JavaScript Errors dashboard is available in the following SaaS regions and cities:

Region	City
Americas	Oregon
	São Palo
EMEA	Frankfurt
	London
	Cape Town
APAC	Sydney
	Hong Kong
	Mumbai
	Singapore

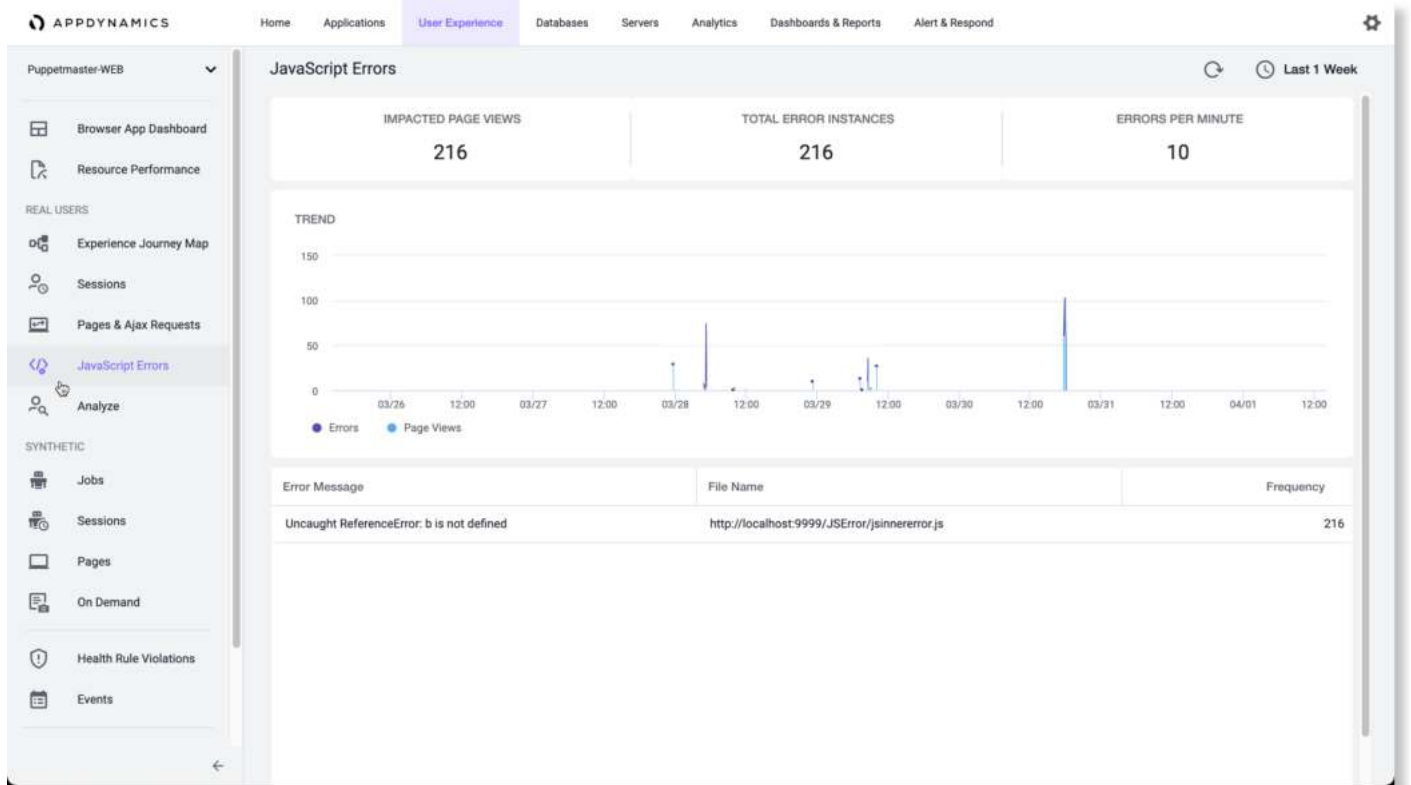

## JavaScript Errors Dashboard

To access the JavaScript Errors dashboard in the Controller UI:

1. Go to **User Experience** and select a browser app.
2. In the left-hand panel, click on **JavaScript Errors**.

The JavaScript Errors dashboard displays all JavaScript errors in a browser app within a time range. The Trend widget displays the error count and timestamp within a time frame.

In the table listing individual error messages, you can drill down into a single error instance by double-clicking on the error message, which takes you to the [JavaScript Error Summary](#) view.

## Error Summary

When you click on an error message from the JavaScript Error Dashboard, you are directed to the Summary tab which displays the following metrics:

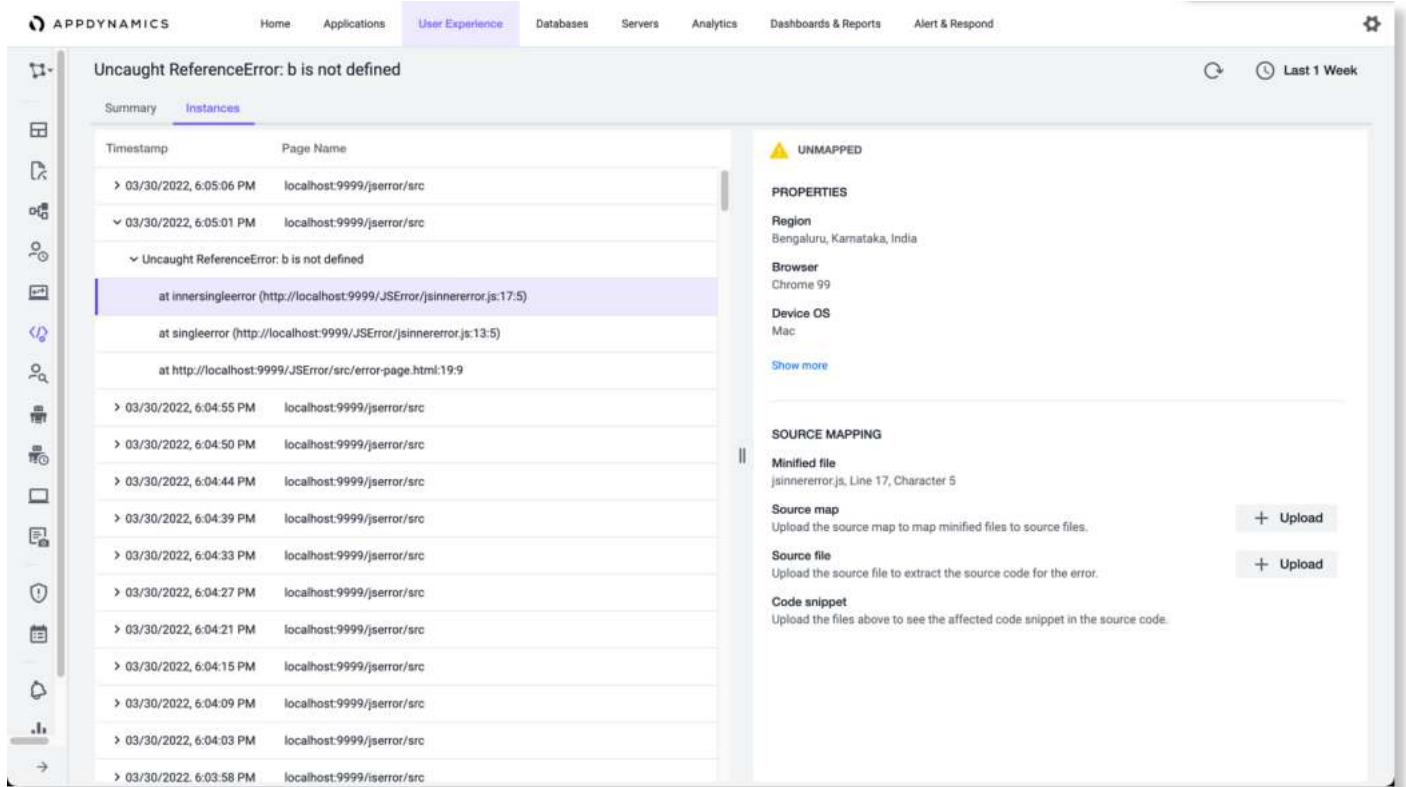

- Impacted Pageviews: Number of Pageviews (instances of browser app web pages) impacted by the error
- Error instances: Number of error instances across all web pages
- % of total error instances: One specific error divided by the total number of errors (across all web pages)
- Errors per minute: How many times this specific error occurred per minute
- First occurrence: Timestamp of the first error occurrence

## Error Instances

When looking at an individual error, the Instances tab lists details of every error.

On an error instance you can:

- Expand the error message to show the stack frames
- Click the stack frame to show the error properties, such as end-user device details and script origins.

In the Properties section, scroll down to [Source Mapping](#) where you can upload source map and source files to locate where the error occurred in source code.

## Source Mapping

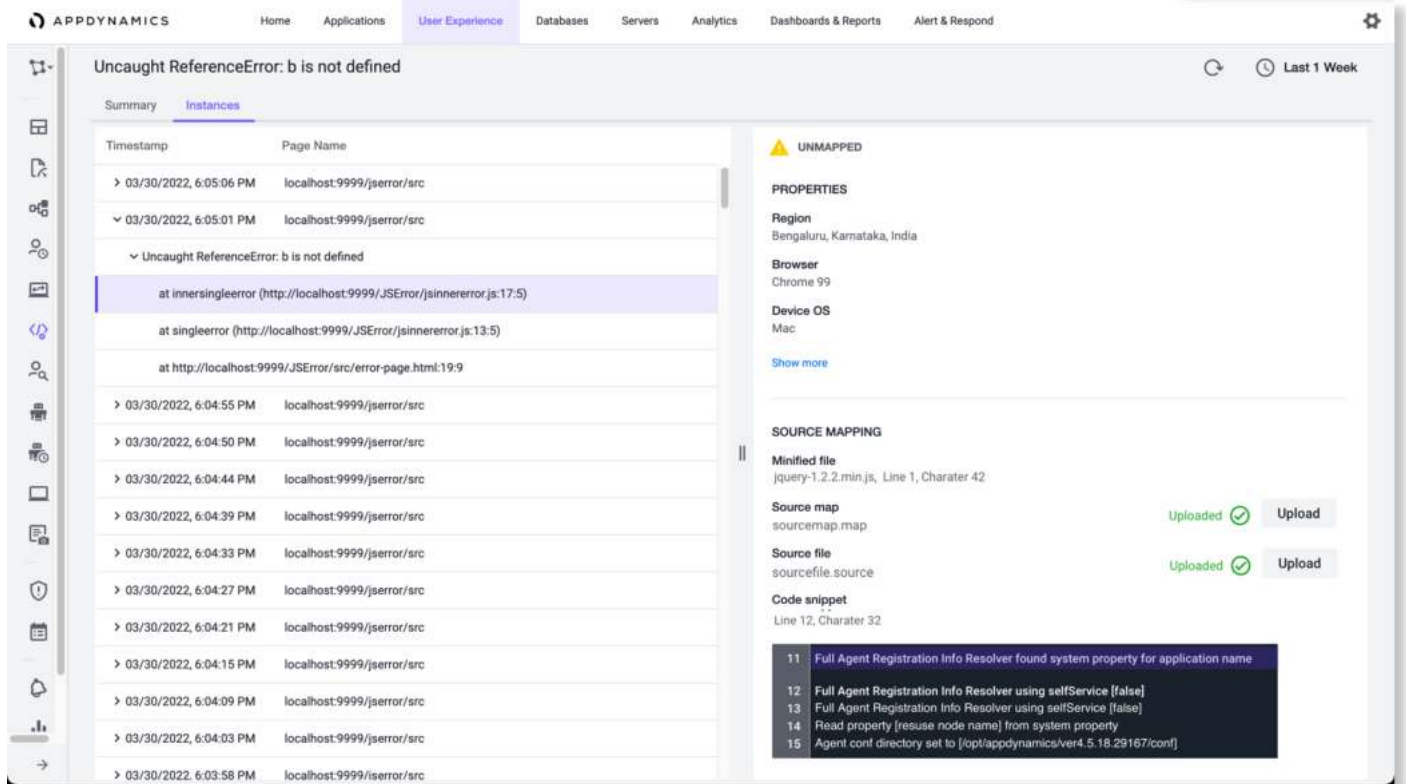

When troubleshooting errors, it's helpful to know exactly where the error occurred in the JavaScript code. You can upload your application's source map and source file to find the exact location of the error.

On the Instances tab, when you expand on the script origin of the error, the Source Mapping section allows you to upload a source map and source file to further troubleshoot the error. When you upload the map and files, the HTML snippet will populate with the file source code and highlight exactly where in the source code the error occurred.

To upload a source map and source file:

1. Expand on an error message.
2. Click on a stack frame.
3. In the Properties section, scroll down to Source Mapping.
4. Click **Upload** to upload the JSON source map and source files (The max size allowed for source map and source files is 10 MB).

Once the source map and source file are uploaded, the HTML snippet will populate with highlighted JavaScript where the error occurred. You can use these details to fix the errors.

## Source Mapping Tips and Recommendations

You have a few options for which source map and source files to upload. You can:

- Only upload the source map file (if the source map file also contains the source file).
- Upload the source map file first and then upload the source file.
- Only upload the source file (without the source map file).

If you upload the source map file after uploading source file, the source file uploaded will be removed automatically.

You can upload one or more source files. Once the source map files is uploaded, the UI shows a list of source files associated with that source map file.

We recommend that you use different names for source files that share the same source map. Even if the source files are located in different paths, if the first source file is named `/path/to/myBrowserApp.js` and the second source file is named `/different/path/to/myBrowserApp.js`, if you upload the first source file `/path/to/myBrowserApp.js`, and later upload the second source file `/different/path/to/myBrowserApp.js`, if you were to go back to the stack associated with the first source file, you would need to re-upload the first source file again. This is because the source files are persisted using their file name as an identifier.

### (Optional) Add Application Release Information in the JavaScript Agent

Before using the Source Mapping functionality, you can add your application's release information, such as release name, version, or key, in your application. When errors occur, the JavaScript Agent sends beacons containing error information and the release ID. When you upload the source map and source file to

---

troubleshoot errors, the release IDs will match and highlight the exact line of code that caused the error. See [Add Application Release Details](#) to configure the release ID.

## Browser Real User Monitoring

### Related pages:

- [End User Monitoring](#)

This page provides an overview of AppDynamics Browser Real User Monitoring (Browser RUM).

Browser Real-User Monitoring (Browser RUM) allows you to see how your web application is performing from the point of view of a real end user. You can drill into the data to explore how users experience your application in their web browsers and answer questions like:

- Which 1st or 3rd-party Ajax or iframe calls are slowing down page load time?
- How does server performance impact end-user experience in aggregate or in individual cases?

### Monitor Your Application

Browser RUM offers multiple ways to look at your data in real time. You can:

- Understand and improve your web page's performance
  - Know how your pages, Ajax requests (XHR, Fetch API calls), and IFrames are performing over time. See [The Pages & Ajax Requests View](#).
  - Gain insight into individual requests, with detailed charts on how your pages, Ajax requests, and IFrames load and build in your end user's browsers, with links, if enabled, to reports on server-side performance. See [Browser Snapshots](#).
  - Find your worst performing pages by multiple common metrics. See [Top Pages](#).
- Reduce errors
  - Learn which pages are loading with JavaScript errors, including the script file and line number that are creating the problem. See [Browser Snapshots](#).
- Learn about your users
  - See how your web users are connecting to your application by device/platform and browser. See [Browser App Dashboard](#).
  - Find out where geographically your web users are and how your application is performing across countries and regions. See [Browser App Dashboard](#).
  - Understand how users are navigating through your website and what actions they are taking. See [Browser RUM Sessions](#).

For more information on using Browser RUM, see [Overview of the Controller UI for Browser RUM](#).

### How Browser RUM Works

Browser RUM works in the following way:

1. An end user requests the first page from your web application.
2. Your web application executes whatever business logic that particular page requires.
3. Your web application creates the response page to return to the end user. The response page includes:
  - a. application-specific information.
  - b. a copy of a small JavaScript script that knows how to collect relevant performance information about that page. This script is called the JavaScript Agent.
4. The page, with the JavaScript Agent included, is returned to the end user.
5. As the page is being constructed in the browser, the script collects relevant information about the page's performance.
6. At approximately the same time as the `onload` event for the page fires, a copy of a somewhat larger JavaScript file, the JavaScript Agent extension, is downloaded asynchronously by the injected agent.
7. This second script packages the collected performance information and sends it via a web beacon to the EUM Server collector for processing.

8. The two scripts work together to collect and send performance information as the end user navigates through the instrumented pages of your application.

## Set Up and Configure Browser RUM

Browser RUM is easy to set up. It is also highly configurable. You can:

- Set up and enable Browser RUM. See [Set Up and Access Browser RUM](#).
- Instrument your application to work with Browser RUM. For more information, see [Configure the JavaScript Agent](#).
- Set up how your information appears in the Controller UI. For more information, see [Configure the Controller UI for Browser RUM](#).

## License and Enable Browser RUM

- Browser RUM requires a separate license and must be enabled before it is available for use. For information about licensing, including a description of the types of licenses, see [EUM Accounts, Licenses, and App Keys](#).
- For information on enabling or disabling Browser RUM, see [Enable and Disable Browser RUM](#).

## Set Up and Access Browser RUM

### Related pages:

- [EUM Accounts, Licenses, and App Keys](#)
- [Inject the JavaScript Agent](#)

This page explains how to set up Browser Real User Monitoring (Browser RUM). Browser RUM collects metrics on your end user's web browsers via the AppDynamics JavaScript Agent. Your web application must be configured to insert this agent into the web pages. This process is called injection. See [Inject the JavaScript Agent](#) on how to inject the JavaScript Agent into your web pages.

To access Browser RUM, you need an [EUM Account](#) and a Browser RUM license. EUM must be enabled through the Controller UI. You can [Enable and Disable EUM](#) if you decide not to use the feature.

### EUM Account

A special EUM account is required. An EUM account is created when you have a license for Browser RUM, Browser Synthetic, or Mobile RUM. There is an account license key associated with this account.

For on-premises customers, the account license key is set up within the Controller license file. If you added EUM after your initial installation, you may need to upload and install the new Controller license file. If you are a SaaS customer, the EUM license is set up in the SaaS Controller for you.

Each Browser RUM license provides a certain number of page views per year. For information on how to examine your current page view usage, see [EUM Accounts, Licenses, and App Keys](#).

### Access Browser Monitoring Configuration

Your data is displayed in the Controller UI in the context of an EUM application. You must assign unique names to EUM applications and business applications. For example, if you created the business application "E-Commerce", you cannot create a browser, mobile, or IoT application with that same name or vice versa. An EUM application name is associated with an EUM App Key, which identifies data coming into the Controller.

1. If you do not yet have an EUM application, click the **User Experience** tab, the **Browser Apps** tab, and the **+Add** button. You can create an application name either by using the **Getting Started Wizard** or by simply choosing an application name.

2. Open the EUM application you are interested in by double-clicking on the application name in the **Browser Apps** list.
3. In the left navigation bar of the application UI, click **Configuration**.

### Browser RUM Prerequisites

To turn on Browser RUM, you need to:

- [Enable Browser RUM](#)
- [Inject the JavaScript Agent](#) into your application pages

If you are an on-premises customer, your JavaScript Agent version should be equal to or less than your EUM Server version.

### Enable and Disable Browser RUM

At the top of the **Configuration > Instrumentation** page, toggle the **Browser Monitoring**:

The screenshot shows the 'Instrumentation' configuration page. At the top, 'Browser Monitoring' is toggled ON. Below this are tabs for 'Base Page and iFrames', 'AJAX', 'Virtual Pages', 'Errors', and 'Settings'. The 'Base Page and iFrames' tab is selected. It contains a 'Save' button, an 'Exclude Rules' section with an 'Add' button and an empty table, and an 'Include Rules' section with an 'Add' button and a table containing one rule: 'Default Naming Configuration' which is enabled and has a summary 'Name the Page using: Full-Domain; first 2 segments of the URL.'

To disable Browser RUM, toggle the switch to **OFF**.

### Inject the JavaScript Agent for Browser RUM into Your Application Pages

The JavaScript Agent for Browser RUM collects Browser RUM metrics. See [Browser RUM Metrics](#) for more detail.

The JavaScript Agent for Browser RUM must be inserted into the headers of the pages for which you want to see these metrics. This process is called *injection*. There are several ways to accomplish this. See [Inject the JavaScript Agent](#).

---

## External Access Locations

Browser RUM is made up of several components, which, in various configurations, can either be located on the Internet or hosted inside your own data center/network. On-premises access points are configured at installation or through the UI. If your installation requires access to any of these components on the Internet, see [Access the SaaS EUM Server](#) for more information.

If you are using the AppDynamics CDN to fetch the JavaScript Agent ( `adrum.js` ) and JavaScript Agent extension ( `adrum-ext.js` ), you also need to make sure that `cdn.appdynamics.com` is accessible from your network.

## Additional Browser RUM Configurations

You can also configure:

- [Page Identification and Naming](#)
- [JavaScript and Ajax Error Detection](#)
- [Browser Snapshot Thresholds](#)
- [Browser Snapshot Collection Rules](#)

## Overview of the Controller UI for Browser RUM

Browser RUM presents information in these views:

- An **Overview** dashboard, with sections for:
  - [widgets](#) for graphic display of common metrics
  - [map-based performance](#) display
  - [snapshots](#) of individual requests
  - [usage statistics](#) by browser and device/platform
- [Unified data for entire sessions](#), following an individual user's path as they navigate through your site
- Detailed information on the performance of individual pages, as
  - [aggregated lists](#) of page, Ajax, iframe, and virtual page request types
  - [multi-faceted data](#) from a complete data store

## Access a Browser RUM Application

To see the data for your app in the Controller UI, you must first open your application:

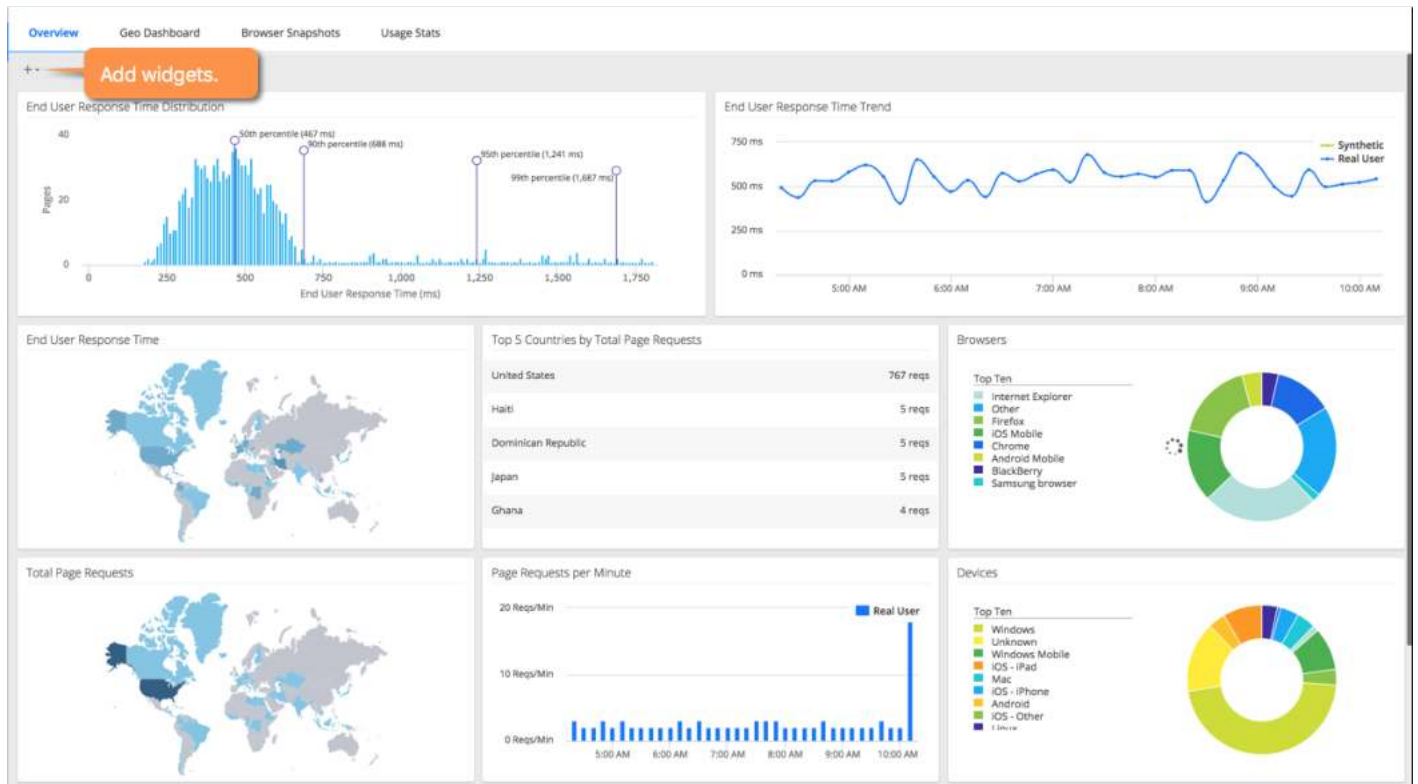

1. In the top tab bar, select **User Experience**. The list of instrumented Browser and Mobile Apps is displayed.
2. Make sure the **Browser App** tab is selected.
3. Double-click on the app you are interested in. The monitoring UI opens.

## Browser App Dashboard

This view is good for getting a high-level understanding of how your app is performing overall.

### Overview

The **Overview** tab is made up of a set of widgets showing common usage metrics. You can add, delete, move, and resize widgets as you wish. If you see a metric that interests you, click through to the main view. If you are using Synthetic, data from both RUM and Synthetic (separated by color) show up in some of the widgets.

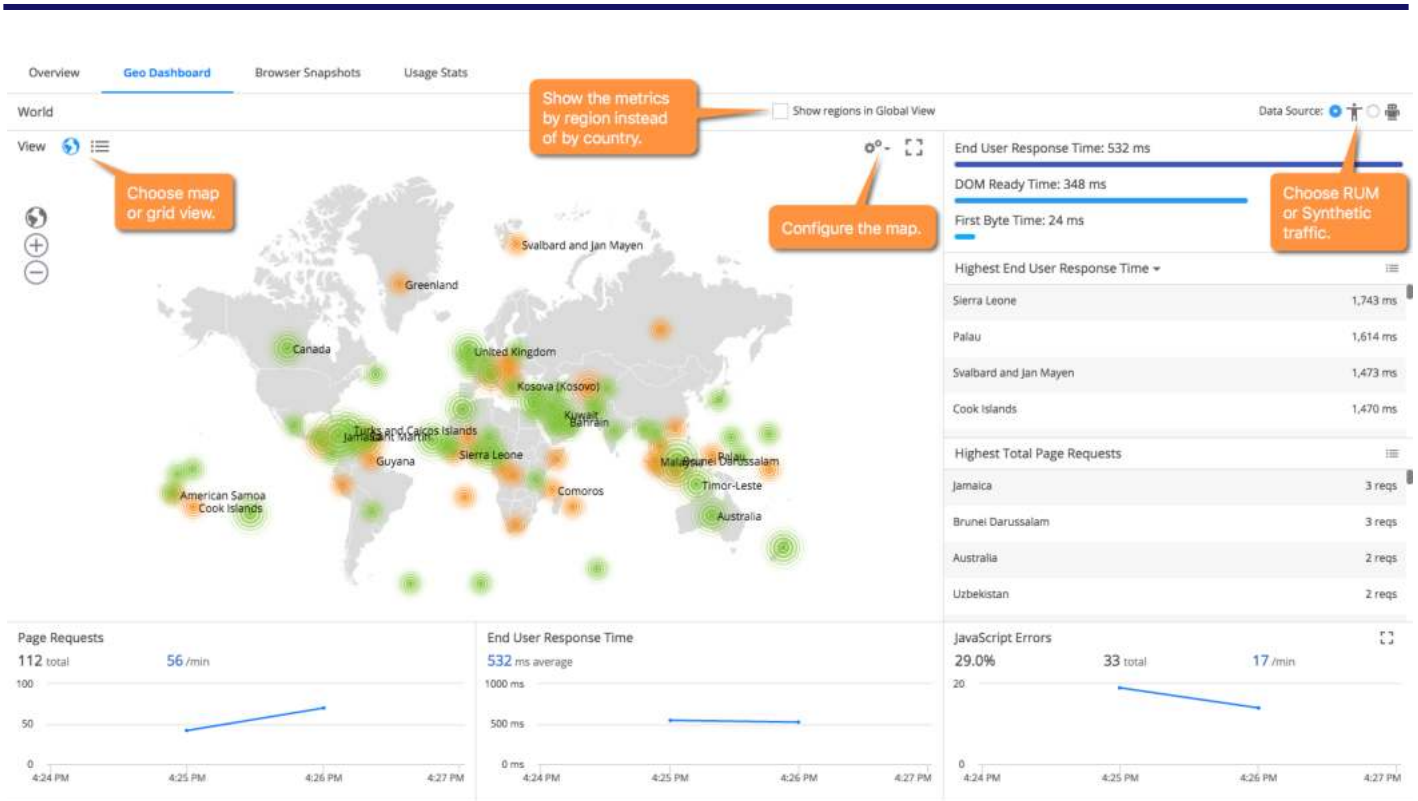

For more information, see [Browser App Dashboard](#).

### Browser App Geo Dashboard

The **Geo Dashboard** view provides high-level insight into how your application is performing across the world for your users. The size of a dot indicates the number of page views from that region, and the color indicates the average page load End User Response time in that region (red is slow). You can click to drill down to areas of specific interest. You can also see the same information presented in tabular form by clicking the grid icon in the upper left of the panel.

If you are using Synthetic, you can also select to see either RUM or Synthetic data displayed here. By default, the **Geo Dashboard** displays key performance metrics by country, but you can view performance metrics by region by checking the **Show regions in Global View**.

For more information, see [Browser App Dashboard](#).

**i** The option **View Dark Mode** has been removed from the **Geo Dashboard**.

## Browser Snapshots

The **Browser Snapshot** view provides access to detailed information for individual requests. The list includes both periodic snapshots of requests operating within normal boundaries and problem snapshots of requests that have exceeded one or more configurable performance criteria. Double-clicking a specific item takes you to a detailed graphical representation of the execution flow of that request and other data associated with it.

Overview   Geo Dashboard   **Browser Snapshots**   Usage Stats

For more information, see [Browser Snapshots](#).

### Usage Stats

The **Usage Stats** view presents aggregated page load usage data based on the browser type and device/platform employed by your users. The view also breaks down performance by type and usage by country.

For more information, see [Browser App Dashboard](#).

## Sessions

In most cases, users interact with your web application over a series of real (or virtual) pages. Sessions allow you to track your users' interactions across time, as they navigate through an entire engagement period with your app. Using Browser RUM Sessions, you can analyze session results from all requests, as stored in the AppDynamics Events Service. Use the **Records** tab to focus on pertinent data and the **Charts** tab to view a dashboard of useful graphics widgets. Or follow a session from page to page using the **Session Detail** dialog.

The screenshot shows the 'Sessions' view in AppDynamics. At the top, there's a search bar and a 'Manage saved searches.' callout. Below that, a '+ Add Criteria' button is highlighted with a 'Set criteria to filter results.' callout. A bar chart shows session activity over time from 5:00 AM to 10:30 AM. Below the chart is a 'Fields' sidebar with a 'Select fields to display.' callout. The main table lists session details with a 'Double-click to view session details.' callout. The table has columns for Session Start Time, Browser, Device OS, Country, Region, City, and Duration (sec). The table is paginated, showing 10 rows on page 1 of 8.9k total.

Session Start Time	Browser	Device OS	Country	Region	City	Duration (sec)
12/05/16 10:55:32 AM	Other	Unknown	United Kingdom	Greater London	Bromley	1.875 sec
12/05/16 10:55:30 AM	Firefox	Windows	Canada	Saskatchewan	Regina	1.875 sec
12/05/16 10:55:30 AM	Internet Explorer	Windows	Peru	Lima	Lima	0.487 sec
12/05/16 10:55:29 AM	Chrome	Linux	United States	Nevada	Reno	3.888 sec
12/05/16 10:55:29 AM	iOS Mobile	iOS - iPhone	United Kingdom	Bolton	Horwich	0.622 sec
12/05/16 10:55:27 AM	Firefox	Windows	Russian Federation	Kamchatka	Fedotyev	0.441 sec
12/05/16 10:55:22 AM	Firefox	Windows	Japan	Hokkaido	Sapporo	14.053 sec
12/05/16 10:55:19 AM	Firefox	Windows	France	Bretagne	Rennes	16.372 sec
12/05/16 10:55:19 AM	Internet Explorer	Windows	Germany	Hessen	Frankfurt	14.604 sec
12/05/16 10:55:19 AM	Chrome	Linux	United Kingdom	Ards	Donaghadee	5.211 sec

For more information, see [Browser RUM Sessions](#).

## Pages & Ajax Requests

This view is good for tracking the performance of individual pages and components as well as understanding any issues that may be emerging. The **Pages & Ajax Requests** view shows you an aggregated view of how each of your page, Ajax request, iframe, and virtual page types are performing over time. You can look at **All Pages** for an overall sense or select a **Top Pages** view to see the worst performing pages sorted by common metrics like Page views with JavaScript Errors and First Byte Time. And you can drill down to a graphical dashboard showing a wide range of charted performances characteristics for any specific request type.

Pages & AJAX Requests last 6 hours

With Load

Filter results by page types.

Select a view.

Showing 18 of 18

For more information, see [The Pages & Ajax Requests View](#).

## Analyze

The **Analyze** view allows you to query a complete repository of all traffic data that Browser RUM has collected in the past two weeks and display that data in multiple ways.

For more information, see [Browser RUM Analyze](#).

## Enable Browser RUM

Browser RUM requires a separate license and must be enabled before it is available for use.

For information about licensing, see [EUM Accounts, Licenses, and App Keys](#).

For information on enabling or disabling Web User Experience, see [Set Up and Access Browser RUM](#).

## Browser RUM Sessions

This page describes Browser RUM sessions, and the **Session UI** you use to view session data.

### Browser RUM Session

A Browser RUM session is a collection of chronological events for a particular end user from the start of a session to a configurable period of inactivity. An event represents an activity occurring at the moment in time that can be recorded, aggregated, and correlated at certain levels. In Browser RUM, events are limited to page loads, virtual page loads, iFrames, and Ajax requests.

**i** Only Ajax requests [configured to be published to the Events Service](#) are included in sessions.

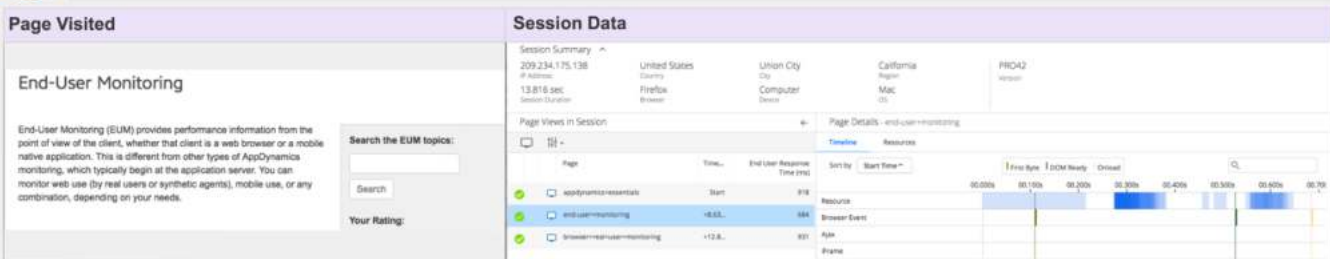

For example, when a user purchases product from an e-commerce site, the session might capture the page/virtual page loads, iFrames, or Ajax requests for the user logging in (start), selecting and paying for products, and logging out (end).

This figure describes how the user's actions cause events that are tracked in the session.

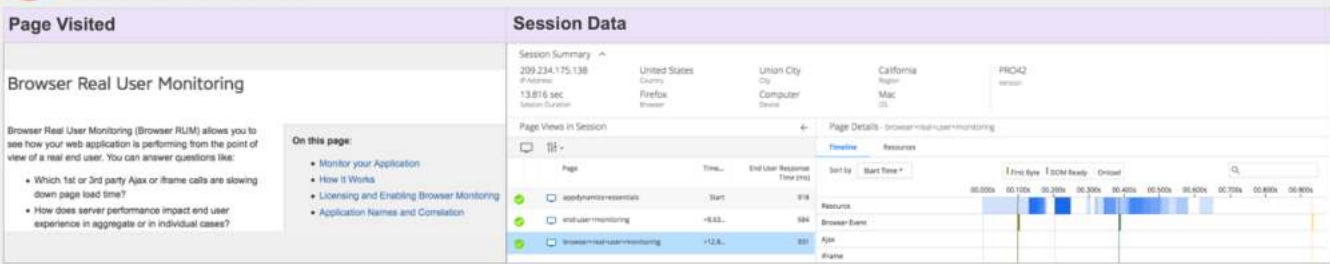

- 1 The end-user visits the site **AppDynamics Essentials**. The JavaScript Agent starts to collect information about the session, such as the page URL, the location of the user, the browser, device, and OS.

- 2 When the end-user visit another page, the new page URL is also added to the session information. In addition to seeing page metrics, you can see how long the user is viewing the page.

- 3 The end-user visits **Browser Real User Monitoring**, which is the last page visited in this session. The start time as well as the session duration are also recorded.

## RUM Sessions Importance

You can think of sessions as a time-based context to analyze a user's experience interacting with an application. By examining RUM sessions, you can understand how your applications are performing and how users are interacting with them. This enables you to better manage and improve your application, whether that means modifying the UI or optimizing performance.

## Use Cases

In some use cases, you can use RUM sessions to analyze a user's or a group's behavior. You analyze a user's behavior based on the user's unique ID across multiple sessions in what is called *sniping*. In addition, you can query for a segment of users with similar behavior, such as visiting a certain specific page or using a particular device. This technique of grouping users with similar behavior is called *bucketing*. Browser RUM sessions allow you to query users on a wide array of criteria such as the type of browser, device, location, landing page, IP address, and more.

---

## How EUM Captures RUM Sessions

The JavaScript Agent loads a temporary GUID into the browser local storage and then transmits beacons to the EUM Cloud or EUM Server that include this GUID. We can then use the GUID to track the user's device over the duration of one or more sessions. The EUM Cloud then publishes these events into a session record stored in the Events Service.

### Session Persistence

Sessions persist until a period of user inactivity that you configure in the controller. Sessions can also end when the GUID is removed from local storage, which can happen for a number of reasons. For example, the user could clear local storage or the browser is configured to clear the local storage when the browser is closed.

### Maximum Session Time

We don't technically limit the time of a session. Instead, we restrict the maximum number of events to 1000. You can, however, configure the maximum time for each event by [configuring session monitoring timeouts](#) and then derive the maximum time for a session by multiplying the configured session inactivity timeout by 1000. For example, if you configure the session inactivity timeout for each event to be five minutes, the maximum session time would be 5000 minutes. Of course, in this case, most sessions would not last 5000 minutes because end users would trigger events well before the maximum time of five minutes.

### Single Page / Multiple Page Sessions

When the browser cannot write the GUID to local storage, Browser RUM cannot track the user's device over one or more sessions. Instead, Browser RUM uses the temporary GUID in memory to create one-page or multiple *virtual* page sessions. Virtual pages are simply those sections of the DOM that are dynamically created and loaded into the current page.

### Privacy/Security of Session Data

We do not perform [browser or device fingerprinting](#). By default, we do not store user IP addresses. If you [configure the Controller to store IP addresses](#), then the IP addresses are stored for up to 14 days.

### Browser RUM Support for Sessions

#### JavaScript Agent Version Requirement for Sessions

You are required to use the JavaScript Agent  $\geq 4.2$ . Older versions of the JavaScript Agent do not support sessions.

#### Browser Requirements for Sessions

To use Browser RUM sessions, your browser is required to support for the following:

- [cross-origin resource sharing \(CORS\)](#) for beacons
- [local storage](#) for multiple-page sessions (single-page / multiple virtual page sessions don't need local storage)

Browser RUM sessions do not support beacons implemented with GIFs.

### Session Limits

The table below lists the limits for session operations per account.

Session Operations	Maximum Per Account
Stored session resource snapshots	10k per minute
Pending uploads of resource timing snapshots	100k
Published session beacons	10k per minute
Tracked sessions	5k per minute

**!** After the pending uploads of resource timing snapshots reach 100k, no further resource-timing snapshots are queued.

## Sessions UI

As in [Browser RUM Analyze](#), the main **Sessions** page is made up of two tabs:

- [Records](#)
- [Charts](#)

### Records

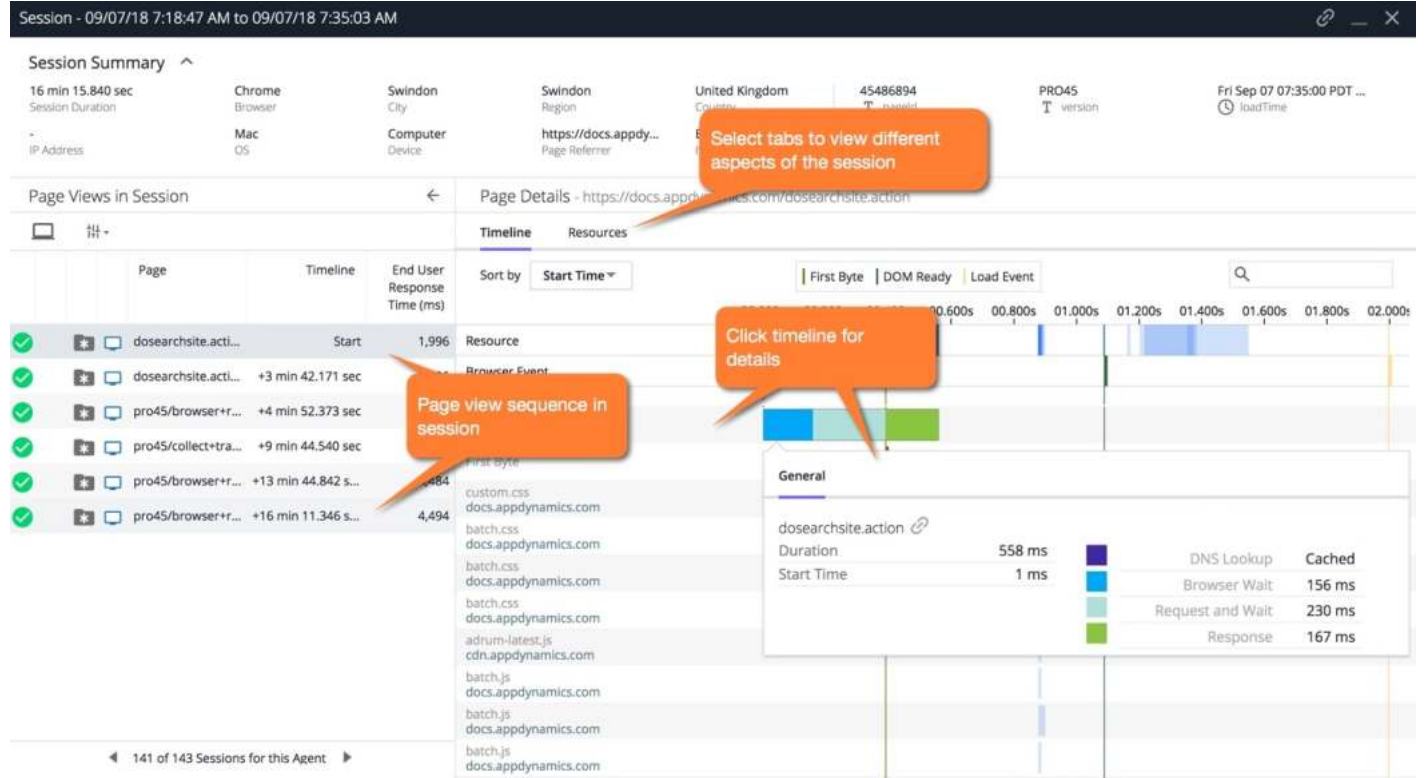

The Records tab lets you scan individual sessions and allows you to filter and sort to get exactly the data in which you are interested.

The screenshot displays the 'Sessions' interface with the 'Records' tab selected. It features a time-series chart at the top and a table of session records below. Callout boxes highlight key UI elements:

- Manage saved searches:** Points to the search icon and 'Default' dropdown.
- Set criteria to filter results:** Points to the '+ Add Criteria' button.
- Select fields to display:** Points to the 'Fields' sidebar on the left, which lists session attributes like Browser, City, and Device.
- Double-click to view session details:** Points to a row in the session table.

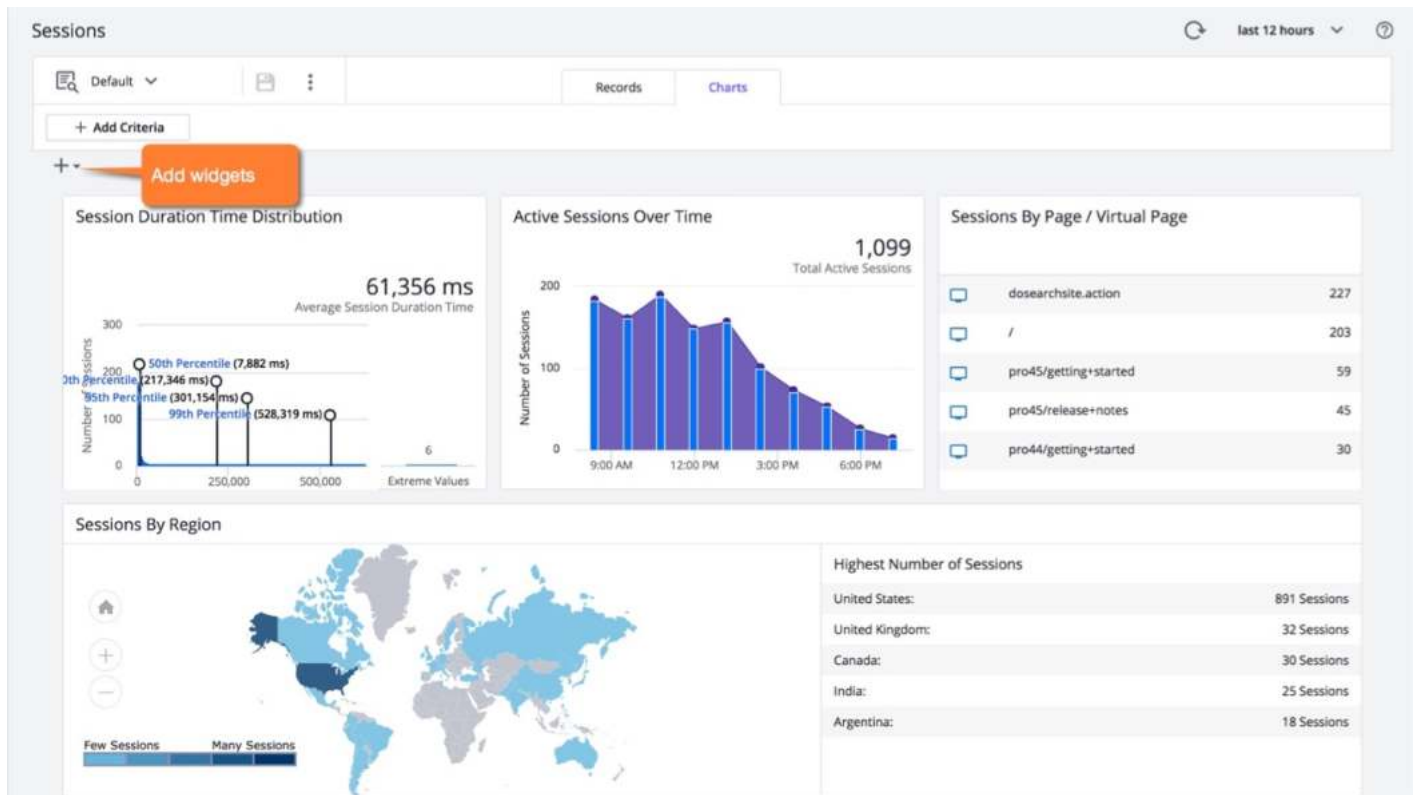

Session Start Time	Browser	Device	Device OS	Country	Region	City	Duration (sec)	Page View Count
09/07/18 7:18:47 AM	Chrome	Computer	Mac	United Kingdom	Switzerland		16 min 15.840 sec	6
09/07/18 7:29:19 AM	Chrome	Computer	Mac	United States	Virginia	Appomattox	1.333 sec	1
09/07/18 7:29:47 AM	Chrome	Computer	Windows	Poland	Mazowieckie	Mokotow	1 min 51.828 sec	5
09/07/18 7:30:31 AM	Chrome	Computer	Windows	Canada	Quebec	Quebec City	7.296 sec	2
09/07/18 7:30:57 AM	Chrome	Computer	Mac	United States	Utah	Salt Lake City	8 min 20.471 sec	5

Click **View Details** or double-click an item to see the information for a specific session. The sequence of page views for the session is shown on the left side of the screen. Select a specific page view to see detailed information, including a page load waterfall, tabular details for resources, and, if your backend is instrumented with AppDynamics, correlated server-side business transactions.

## Charts

The Charts tab provides you with a set of predefined widgets of the data set you have created plus a custom widget builder. As with the Charts tab of the **Analyze UI**, you can delete, re-add, resize, and drag-and-drop to move the widgets.

## Pages & Ajax Requests

The **Pages & Ajax Requests** page provides detailed information on how your pages, Ajax requests, iframes, and virtual pages perform over time.

### Access Pages & Ajax Requests

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Pages & Ajax Requests**.

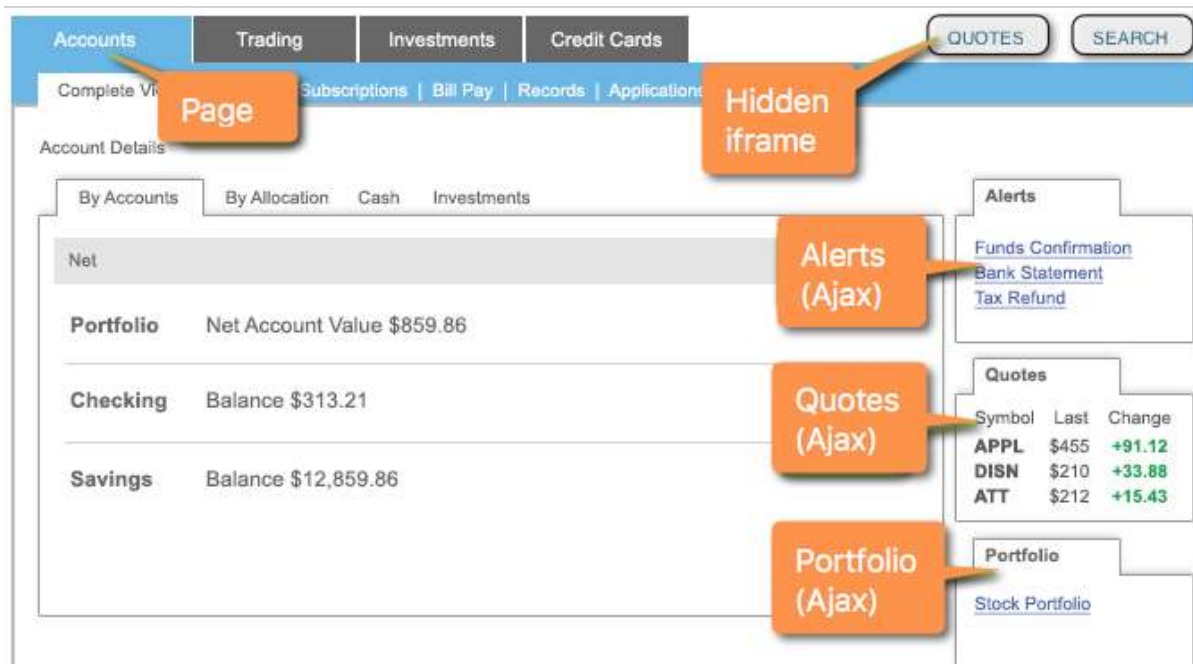

### What is a Page?

In Browser RUM, a page represents an individual source for the information that an end-user sees in one browser window.

### Types of Pages

A base page is the core HTML page, and may also include one or more iframes, which you can nest.

A base page or an iframe can also make one or more Ajax requests (using `XMLHttpRequest` or the Fetch API) to fetch data to display on the Web page.

You can collect Browser RUM metrics for base pages, iframes, Ajax requests, and virtual pages.

Each base page, iframe, Ajax request, and virtual page type is assigned a unique name, which you can configure. See [Configure Page Identification and Naming](#).

## Pages & Ajax Requests

The **Pages & Ajax Requests** page has two options: **All Pages** and **Top Pages**, selected using the dropdown in the upper right. **All Pages** displays a list showing a high-level summary of all the monitored types, along with their key performance indicators. **Top Pages** displays the ten worst performing items grouped by common metrics: Requests per Minute, Page Render Time, and so forth. Use this option for a quick start to troubleshooting.

### How the All Pages List is Organized

The **All Pages** list displays each monitored base page, iframe, Ajax request, and virtual page type.

Click a column header to sort the pages based on the column's metric.

To view a dashboard for a specific page item in the list, select it and click **View Dashboard** or just double-click the page. See [Page, Ajax, and Iframe Dashboards](#).

To filter the types of pages displayed in the list, select the type at the top of the list. Check **With Load** to see only pages currently reporting load.

### More Actions Menu

Using the **More Actions** menu, you can select a page in the list and make changes to it, including directing the agent to ignore the page and stop reporting metrics for it.

### Access Top Pages

Click the **View** dropdown on the upper-right side of the page and select **Top Pages** as a shortcut to troubleshooting the ten worst performing pages regarding various metrics.

## Page Limits

There is a limit of 500 total base pages (including virtual pages) plus iframes and 500 Ajax calls that can be individually tracked per application. If your usage exceeds these limits, the Controller begins to drop metrics. If your installation is approaching these limits, you can modify how your metrics are collected by:

- Limiting the number of pages you instrument. If you are using manual injection, remove the JavaScript Agent from pages that are less important. See [Inject the JavaScript Agent](#) for more on injection types. If you are using automatic injection, create request match rules and request exclude rules to restrict injection to pages that meet certain criteria. See [To Create Match Rules for Automatic Injection](#).
- Using custom naming rules to group similar pages together. See [Configure Page Identification and Naming](#).

If you reached your page limit, you need to delete the affected old page names before any new page names can be added to the database. Doing so also deletes any accumulated metrics for those page names.

## Page, Ajax, and IFrame Dashboards

Dashboards provide quick access to graphic representations of metrics for pages (including virtual pages), iframes, and Ajax request types. Each page, iframe, and Ajax request type has a dashboard. See [Page and IFrame Dashboards](#) and [Ajax Dashboard](#).

### Access These Dashboards

To view a dashboard for a page, iframe or Ajax request type:

1. Open the browser application in which you are interested.
2. On the left navigation bar of your application, select **Pages & AJAX Requests**.
3. From the list, select the page, iframe or Ajax request type in which you are interested.
4. Either double-click the item, or select the item and then click **Details**.

### Page and IFrame Dashboards

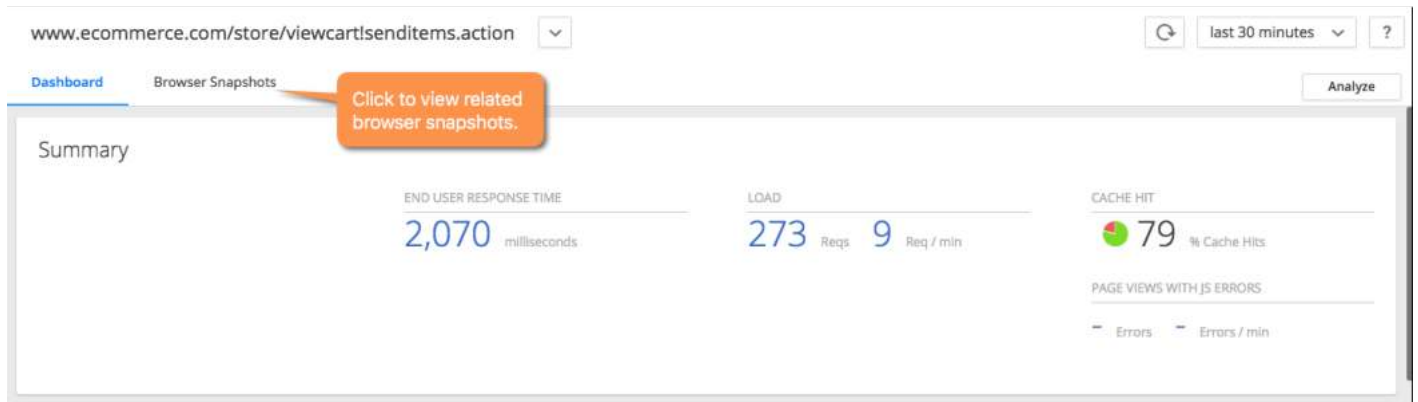

**Page** and **iframe** dashboards are divided into six areas:

- A summary of key performance indicators. To see browser snapshots associated with these instances of this page type, open the Browser Snapshots tab. To move to the **Analyze** view, click **View Analyze**.
- A waterfall graph of the entire load sequence. To see details for each set of data, use the **Trends/Details** checkboxes.
- Four sections of **Trends/Details** across time for the main performance categories:
  - Overall performance
  - Time between the request and the first byte of the response
  - Time taken by the server to process the request through the completion of the HTML download for the item
  - Time taken to process and render the item, including any external resources, in the browser
- Detailed information on the performance of Ajax requests and iframes for this item.

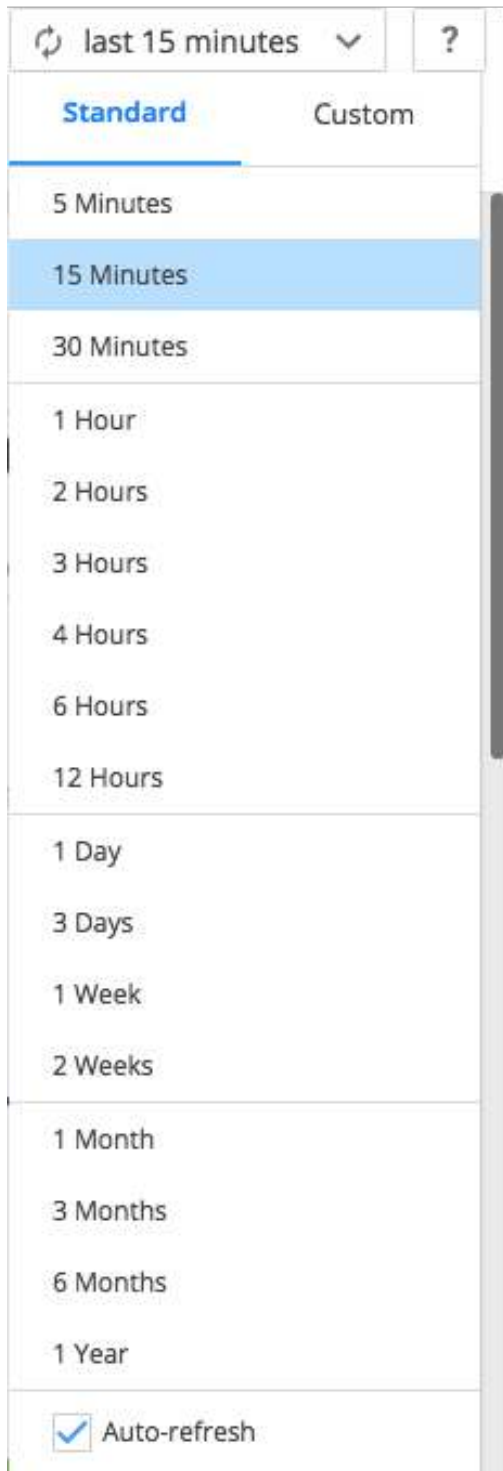

### Page Dashboard Summary Section

This section provides a quick overview of the item's performance over time.

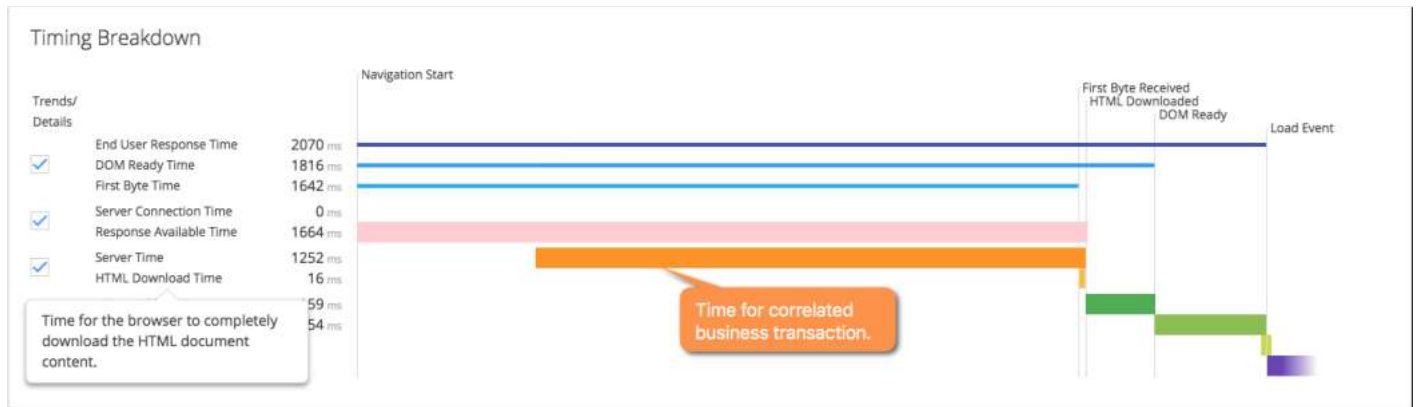

Key performance indicators—End User Response Time, Load, Cache Hits, and Page Views with JS errors—across the period selected in the timeframe dropdown from the upper-right side of the Controller UI are displayed across the top of the summary area. Cache Hits indicates a resource fetched from a cache, such as a CDN, rather than from the source. This metric is only reported when there is a correlated AppDynamics agent on the server-side source.

### Timing Breakdown

The waterfall graph shown below displays the average times needed for each aspect of the page load process. For more information on what each of the metrics measures, hover over its name on the left. A popup appears with a definition. See [Browser RUM Metrics](#).

To see detailed breakouts of the data behind the graph, check the **Trend/Detail** checkbox by the data group in which you are interested. To turn the details off, uncheck the checkbox.

**i** Some metrics—for example, TCP Connection Time—only appear if they have a non-zero value.

### Overall Performance

This section displays detailed trend graphs of key performance metrics measured across the selected timeframe. To see detailed information for a particular moment, hover over the graph and a popup with that information appears. To see any of the listed total metrics in the context of the metric browser, click the desired value (shown in link blue) on the left side of the panel. The **Metric Browser** appears, with that metric displayed. You can then use the **Metric Browser** to compare other related values in one display.

### Key Performance Times / Load

This section displays detailed trend graphs of key performance indicators and the request load across the selected timeframe. They measure:

- Time between the user's request and the completion of the page load of the response.
- Time between the user's request and the DOM being loaded.
- Time between the user's request and the browser receiving the first response byte.
- Number of requests per minute.

### Server Connect Time Breakdown / Response Available Time

This section displays detailed trend graphs of initial server connection metrics measured across the selected timeframe. They measure:

- Time the user's request takes in negotiating its initial connection with the server, which may include the DNS, TCP Connect, and SSL/TLS time. The **Total Server Connect** value is always displayed.
- Time between that initial connection and the time the first byte of information begins to arrive at the browser.

### Server Time / HTML Download Time / Related Business Transactions

This section displays detailed graphs for the time spent acquiring the page data:

- Time the request takes on the server.
- Time it takes to complete the download of the HTML to the page.

- If the request is correlated with a server-side app agent, related business transactions on the server are displayed. Cross-app correlation is supported.

## DOM Building Time / Resource Fetch Time / Page Resources Requested

This section displays detailed graphs for the time spent creating the page and getting resources. They measure:

- Time required by the browser to create the DOM from the end of the HTML download.
- Time required to fetch any external resources. For example, the results of a third-party Ajax request.

The **Page Resources Requested** section displays detailed graphs of when in the page load cycle individual external—first and third-party—resources are fetched, and how much time is taken to fetch them, based on the selected timeframe. They measure:

- Average time and load associated with that resource
- If the request is blocking or non-blocking
- Request and response time per resource request
- Type—iframe or Ajax—of the resource

To see the dashboard for any of the listed resources, click the name.

## Ajax Dashboard

The **Ajax Dashboard** is divided into three areas:

- A summary, with a waterfall graph of the entire load sequence. To see details for each set of data, use the **Trends/Details** checkboxes.
- Two sections of **Trends/Details** across time for the main performance categories:
  - Overall performance
  - Time used by the server to process the request through the browser's incorporation of the data into the HTML document

## Ajax Dashboard Summary Section

This section provides a quick overview of the item's performance over time.

Key performance indicators—End User Response Time, Load, Cache Hits and Views with Errors—across the period selected in the timeframe dropdown from the upper-right side of the GUI—are displayed across the top of the summary area.

A waterfall graph displays the average times needed for each aspect of the Ajax request load process.

For more information on what each of the metrics measures, hover over its name on the left side of the graph. A popup appears with a definition. See the graphic above for an illustration. See [Browser RUM Metrics](#).

To see detailed breakouts of the data behind the graph, check the **Trend/Detail** checkbox by the data group in which you are interested.

## Timing Breakdown

A waterfall graph shown below displays the average times needed for each aspect of the Ajax request. For more information on what each of the metrics measures, hover over its name on the left. A popup appears with a definition. See [Browser RUM Metrics](#).

To see detailed breakouts of the data behind the graph, check the **Trend/Detail** checkbox by the data group in which you are interested. To turn off details, uncheck the checkbox.

### Overall Performance

This section displays detailed trend graphs of key performance metrics, load requests, and Ajax request errors measured across the selected timeframe. To see detailed information for a particular moment, hover over the graph and a popup with that information appears. To see any of the listed total metrics in the context of the metric browser, click the desired value (shown in link-blue) on the left side of the panel. The [metric browser](#) appears, with that metric displayed. You can then use the metric browser to compare other related values in one display.

### Ajax Response Download and Ajax Callback Execution Time

This section displays detailed trend graphs of the Ajax response download time and the Ajax callback execution time. To see detailed information for a particular moment, hover over the graph to view a popup.

These metrics measure the total time for processing all server-side business transactions for this item.

- 
- Total time for the browser to completely download all of the Ajax responses
  - Time for the browser to complete any Ajax callbacks

## Browser RUM Analyze

### Related pages:

- [Analytics Browser Requests Data](#)
- [Analytics Browser Sessions Data](#)

Browser RUM collects data on every load event that you have instrumented, and it also takes detailed snapshots periodically and when performance issues are detected. Over time, the load event metrics are rolled up based on averages and percentiles. Sometimes you want to see results based on *all* of the data.

With **Browser Analyze**, every event is collected and stored for [a license specified period](#) in the AppDynamics Platform Events Service. Using the Analyze tab you can see results based on this cumulative data.

The **Analyze** view is comprised of two tabs:

- [Records](#)
- [Charts](#)

### Access the Browser Analyze View

1. Open the application in which you are interested.
2. On the left navigation bar, select **Analyze**.

### Records

The Records tab lets you scan individual events and filter and sort to get exactly the data set in which you are interested.

The screenshot shows the 'Analyze' interface with a search filter 'Has Resource Timing: True' applied. A table of resources is displayed with columns for Resources Loaded per Pageview, Browser Version, and Page Referrer. Callouts point to various UI elements: 'Manage searches' (top right), 'Select and view saved searches' (left sidebar), 'Filter results' (search bar), 'View details of selected item' (table row), 'Select fields to view' (left sidebar), and 'Filter pages by record type' (dropdown menu).

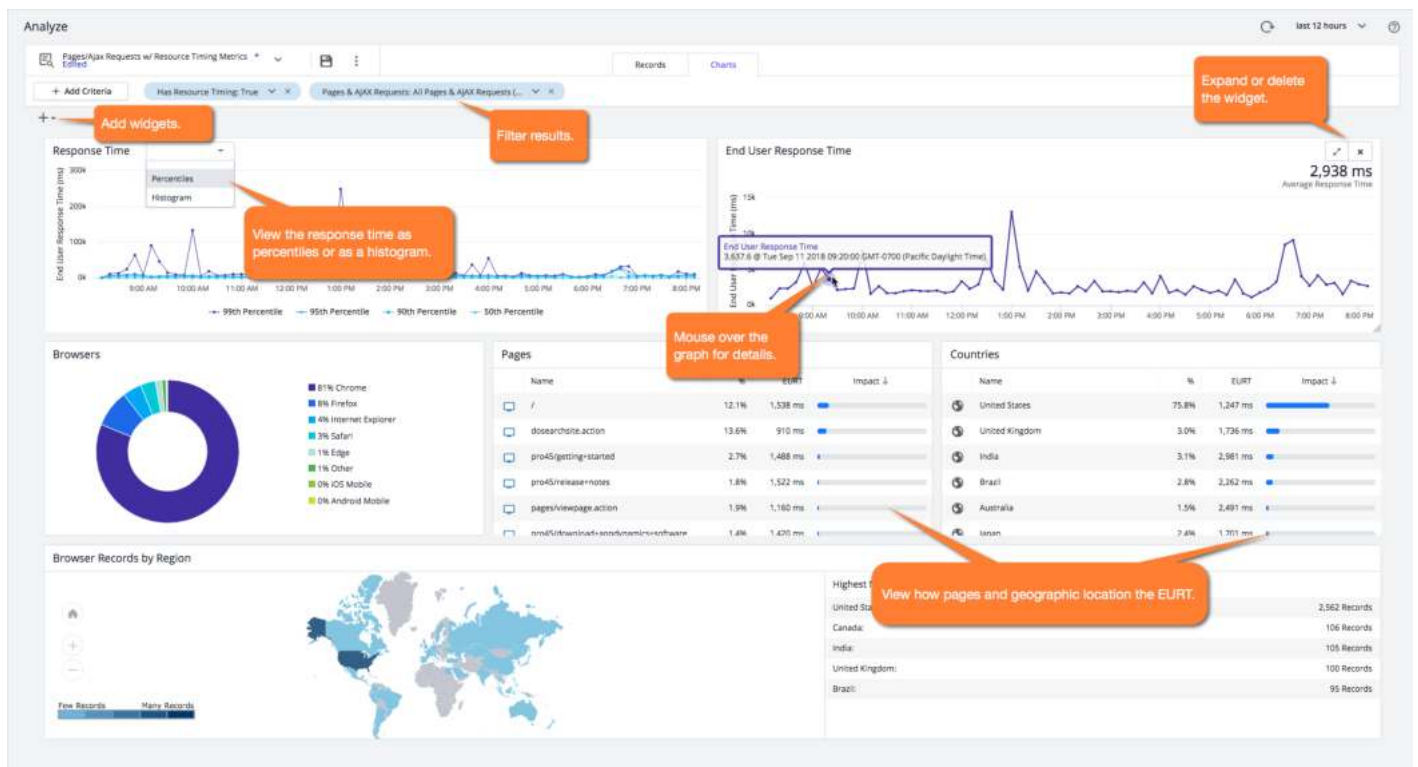

After you click **View Details**, you see the details of a particular request as a page with a **browser session** in the **Session Details** dialog.

The screenshot shows the 'Session Details' dialog for a session on 09/11/18. It includes a 'Session Summary' section with user and device information, a 'Page Views in Session' table, and a 'Page Details' section for the selected page. A resource waterfall chart shows the loading of various resources like batch.css, batch.js, and custom.css. Callouts highlight: 'The icon indicating the page/request includes resource timing metrics' (green checkmark), 'The request you selected shown as a page within a session' (table row), 'The page load waterfall for the request' (waterfall chart), and 'Click the resource to see more details' (resource bar).

## Charts

The Charts tab provides you with a set of predefined widgets that offer visualizations of the data set you have created.

You can quickly see how pages, browsers, and geographic location (such as, dimensions) affect the end user response time (EURT). You can also delete, re-add, resize, and drag-and-drop to move all of the widgets.

**i** The time series widgets such as **Response Time** and **End User Response Time** use median values, not averages.

## Request Number Differences in Browser Analyze and Pages & AJAX Requests

The number of requests for a page over a period of time should be the same in **Pages & AJAX Requests** and **Browser Analyze**, but they may vary for these reasons:

- If there are fewer requests given in **Browser Analyze**, the Events Service, which is responsible for the data in **Browser Analyze**, has probably not received all of the records yet. To verify this, compare the time of the last request for the page in **Browser Analyze** and **Pages & AJAX Requests**. The latter will most likely have a later timestamp.
- If there are more requests given in **Browser Analyze**, it's possible that the reason is because error records are included in the total number of requests in **Pages & AJAX Requests**, but listed separately in **Browser Analyze**. The errors are listed separately in **Browser Analyze** to enable you to investigate and understand the cause of the error.

## Browser Analyze versus Browser Request Analytics

The data shown on the **Analyze** page is processed and stored by the AppDynamics Platform Events Service. The **Charts** tab displays a set number of widely used chart types to let you explore your application's performance. A separate product, [AppDynamics Application Analytics](#), has a component called Browser

---

Analytics. This component is based on the same Events Service and uses the same data, but it offers additional capabilities, including:

- Additional predefined widgets, such as the funnel widget
- ADQL for searching the data
- Creating custom widgets
- Manipulating multiple dashboard types
- Longer retention time for data storage

Browser Analytics requires a license separate from the Browser RUM license.

To reduce noise in data stored in the Event Service, Ajax calls from the following tracker domains are no longer published to the Events Service:

- [.mixpanel.com](#)
- [.google-analytics.com](#)
- [.altocloud.com](#)
- [.optimizely.com](#)
- [inspectlet.com](#)

## Configure the Controller UI for Browser RUM

You can [enable or disable Browser RUM](#) with the **Browser Monitoring** toggle.

You can manage how Browser RUM information is displayed in the Controller UI, including:

- [The display names for your pages, Ajax requests, and iframes](#)
- [The display names for your virtual pages](#)
- [The errors that should be shown in the UI, and the ones that should not be shown](#)

You can also configure:

- [The thresholds for slow, very slow, and stalled transactions](#)
- [When browser snapshots should be taken](#)
- [Percentile levels you would like to display, if any](#)
- [Which Ajax requests should be sent to the Event Service](#)
- [The session timeout period](#)
- [Whether to store request IP addresses or not](#)

In addition, you can do the following:

- [Choose a hosting option for the JavaScript Agent](#)

To configure Browser RUM from the Controller UI, your user account must belong to a role that has the **Configure EUM** permission. See [End User Monitoring Permissions](#) for more information.

---

## Access the Browser RUM Instrumentation Configuration

To access the instrumentation configuration for a browser app:

1. Open the browser application in which you are interested.
2. From the left-hand navigation menu, click **Configuration**.
3. From the **Configuration** page, click **Instrumentation >**.

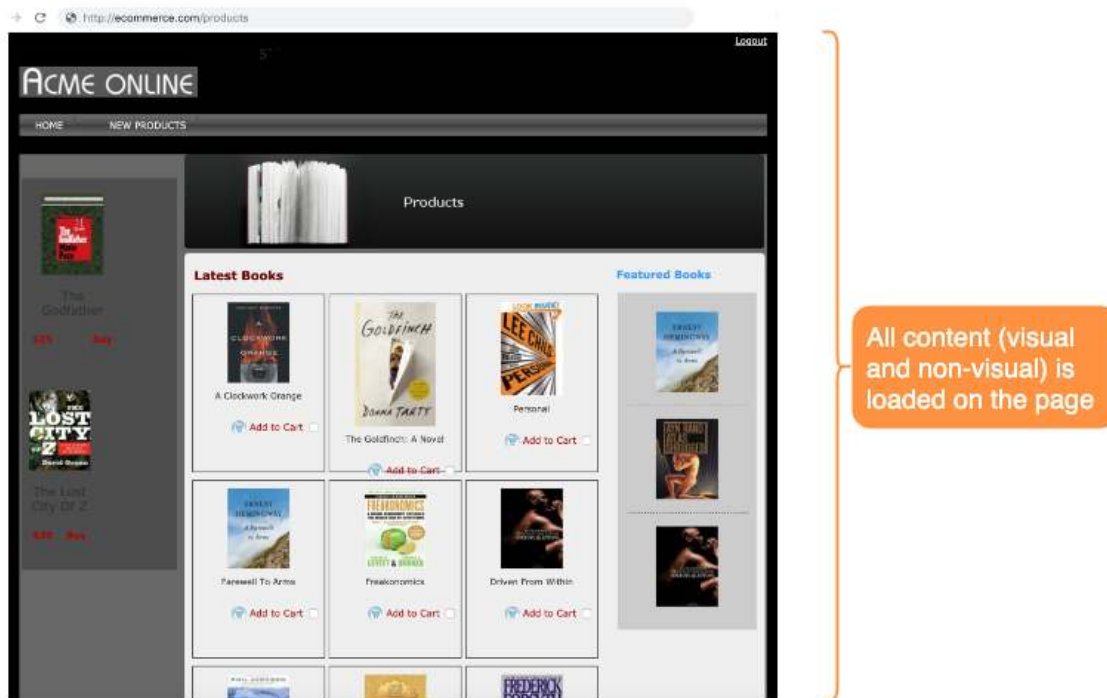

## Configure the Primary Metric

The default primary metric is set to End User Response Time (EURT), but you can choose between EURT and Visually Complete Time (VCT). Once the primary metric is configured, the Controller UI dashboards, summaries, and charts will automatically update to show trending data for that configured metric. This allows you to view the EUM event timing that is most relevant to your business needs.

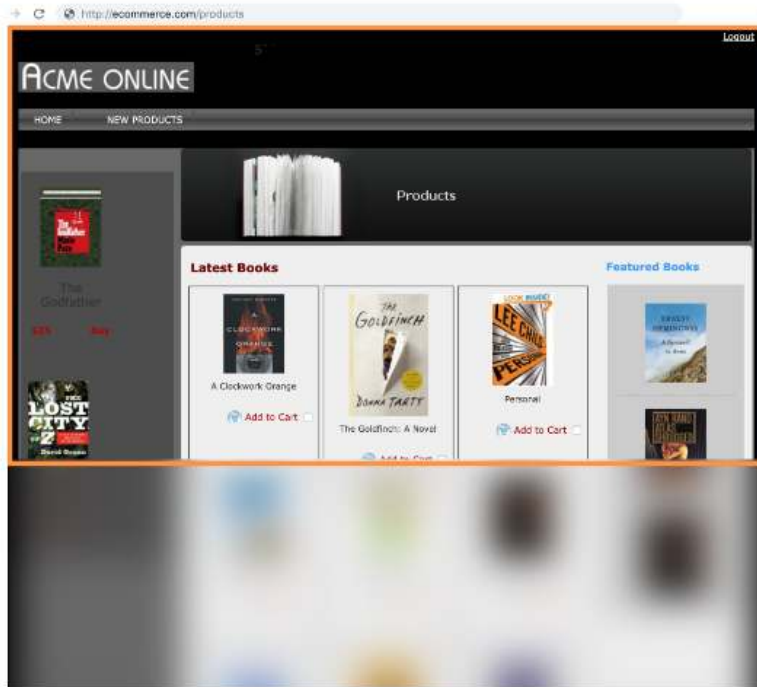

### Available Metrics

You can set the primary metric to EURT or VCT. The default primary metric is EURT. EURT tracks the total amount of time for all content on a web page to be loaded. VCT tracks the total amount of time for all visual content to be loaded in the viewport. To see how EURT and VCT are calculated for SPA pages, see [SPA2 Metrics](#).

EURT   VCT

EURT   VCT

All visual content is loaded in the viewport

### Primary Metric Visibility

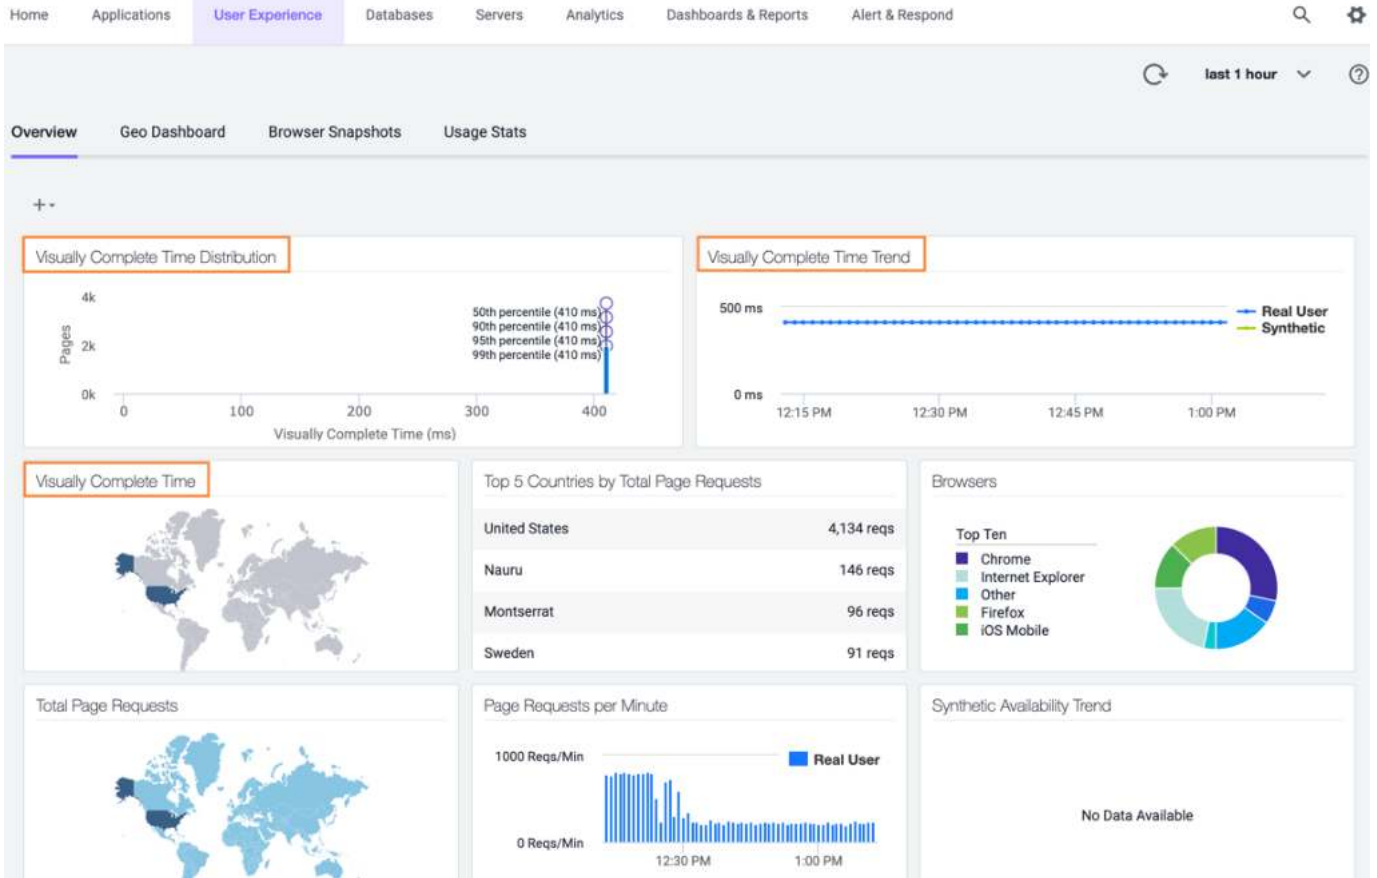

The primary metric is visible across several dashboards, charts, and summaries. The following screenshots are examples of primary metric visibility when configured to VCT.

[Browser App Overview](#)

[Geo Dashboard](#)

[Browser Snapshots](#)

[Pages & AJAX Requests](#)

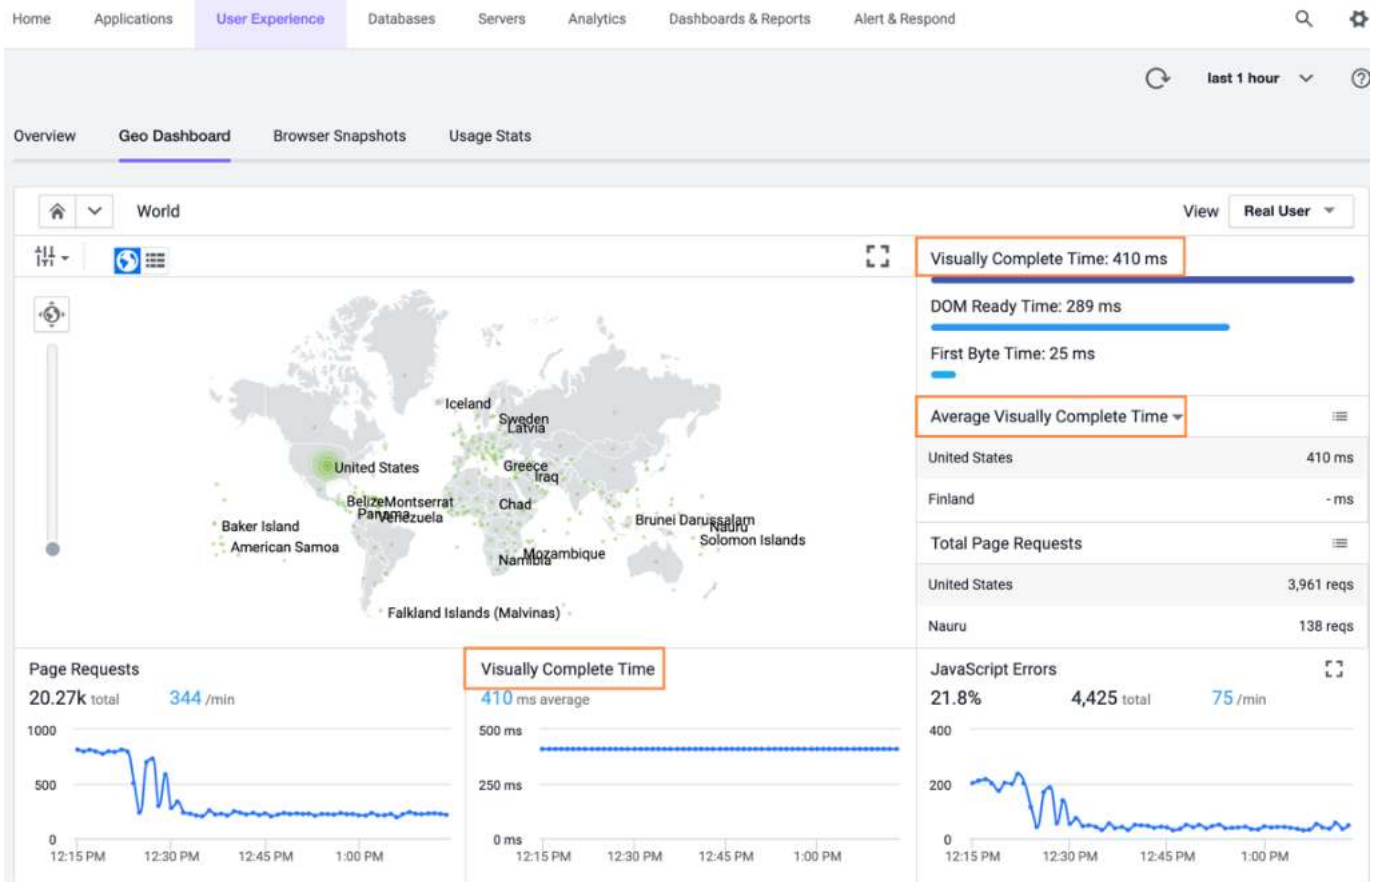

[Browser App Overview](#)

[Geo Dashboard](#)

[Browser Snapshots](#)

[Pages & AJAX Requests](#)

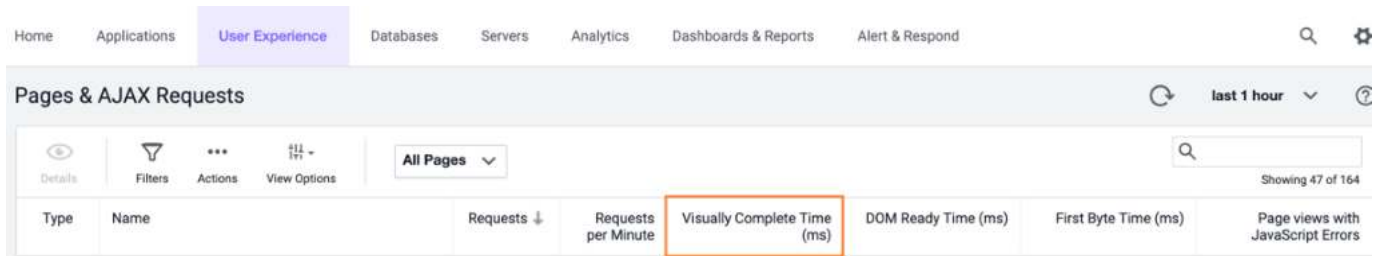

Browser App Overview    Geo Dashboard    Browser Snapshots    Pages & AJAX Requests

The screenshot shows the 'Browser Snapshots' view. At the top, there are navigation options: Details, Filters, Actions, and View Options. Below is a table with the following columns: Time (sorted descending), Visually Complete Time (ms), URL, Page, AJAX Request, iFrame, or Virtual Page, Bro..., Devl..., OS, Cou..., State / Regl..., and City. The 'Visually Complete Time (ms)' column is highlighted with an orange box.

Time ↓	Visually Complete Time (ms)	URL	Page, AJAX Request, iFrame, or Virtual Page	Bro...	Devl...	OS	Cou...	State / Regl...	City
Showing 0 of 0									

Browser App Overview    Geo Dashboard    Browser Snapshots    Pages & AJAX Requests

## Configure the Primary Metric

### Configure Primary Metric

To configure the primary metric, go to **Configuration > Instrumentation > Settings**.

### Disable the Primary Metric

For SPA2 applications, configuring the primary metric causes base page events to be sent on navComplete; previously the base page events were sent upon page load. This may cause slow performance, and you may want to disable the primary metric.

To disable the primary metric, add the following flag in your JavaScript code:

```
config.enablePrimaryMetrics = false
```

## Configure Page Identification and Naming

### Related pages:

- [Configure Virtual Page Naming](#)
- [Page, Ajax, and Iframe Dashboards](#)
- [Set Custom Page Names](#)

You can configure the display names by which various pages and iframes are referred to and sorted in Controller lists and dashboards. On this page, the term "pages" includes iframes and base pages.

With rules, you can:

- Use the AppDynamics default naming rule, which you can leave as is or modify.
- Create custom include rules to override the default convention.
- Create custom exclude rules to exclude from monitoring pages that meet certain criteria.
- Disable the default naming configuration and use only your custom include rule(s).

No matter how the page is named, AppDynamics always reports the page name in lowercase.

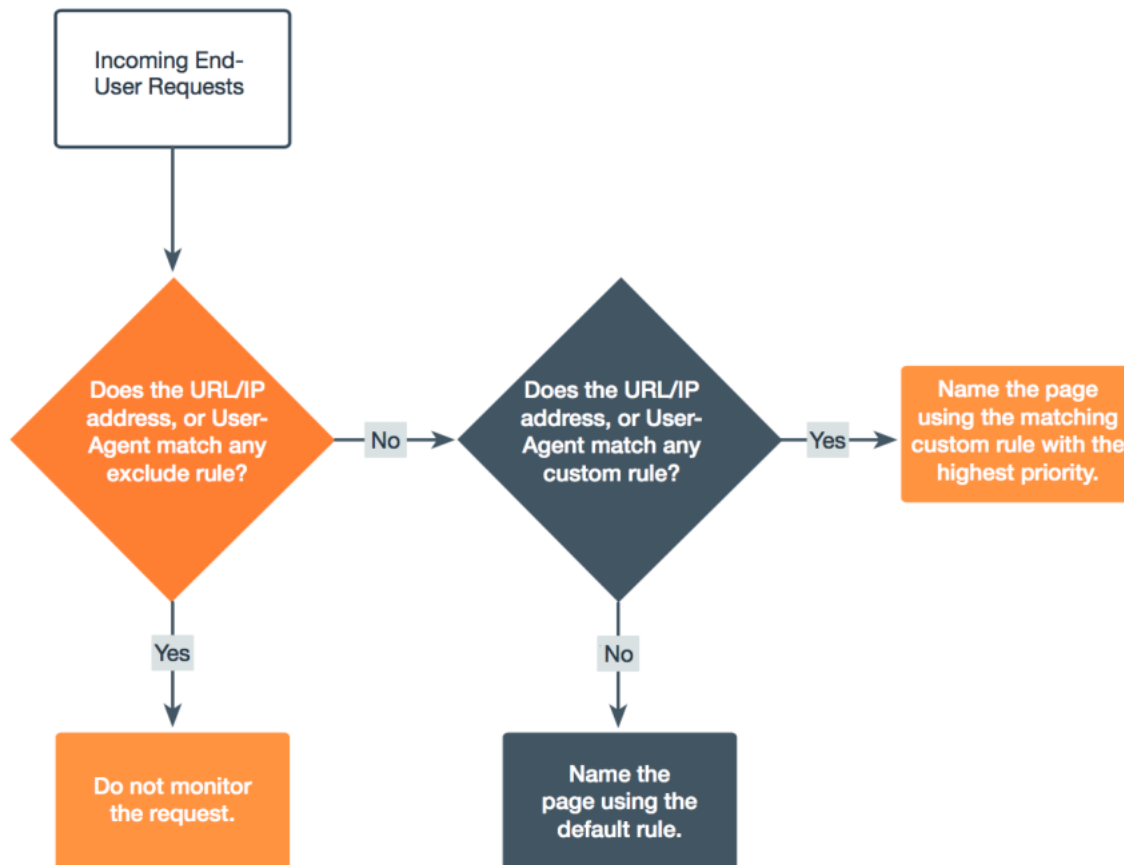

### Access Exclude/Include Rules

1. In the Controller, click the **User Experience** tab.
2. Click a browser application.

3. On the left navigation bar, click **Configuration**.
4. Click **Instrumentation >**.
5. From the **Base Page and iFrames** tab, define include/exclude rules or modify the Default Naming Configuration.
6. To save any configuration changes, click **Save**.

#### Evaluation Logic for Exclude/Include Rules

This is the order in which AppDynamics evaluates the page naming rules.

#### Default Page Naming Rules

If you enable the default naming configuration and do not modify it, AppDynamics identifies and names your pages using the first two segments of the page URL.

You can modify the default configuration by double-clicking **Default Naming Configuration** in the **Include Rules** section. This opens the **Include Rule** popup, where you can select the dropdown list **using parts of the URL** to include the protocol or domain in the name, use different segments of the URL, or include query parameters or anchors in the name.

Include Rule
✕

Enabled

**Name Pages**

using parts of the URL

Show Protocol (Ex: http, https, etc)

Show Domain (Ex: mywebsite.com)

Show Full Domain  Show Sub-domain

**Path Segments**

Don't use path segments

Use first 0 segments

Use last 2 segments

Use segment numbers

Query String Parameters to use in Page Name (Optional)

What part of anchor should be used in Page Name

Don't use the anchor

Use first 1 segments

Use last 1 segments

Use segment numbers

Cancel OK

You can also choose the dropdown **using a Regex match on the URL** to match page names by running a regular expression.

Include Rule
✕

Enabled

**Name Pages**

using a Regex match on the URL

Use regex on the URL  and use groups

Cancel OK

If you do not want to use the default convention at all, disable it by clearing the **Enabled** checkbox. In this case, you must configure at least one custom page naming rule so that AppDynamics can identify and name pages.

### Custom Include Rules

You can create custom include rules for identifying and naming pages.

To create a custom include naming rule, from the **Include Rules** section, click **Add**. Then you use the same **Include Rule** popup to configure the custom include rule to identify and name the page.

The order of the include rules in the list determines the priority of the rules: The rules at the top are evaluated first, and the rules at the bottom are evaluated last. You cannot change the priority of **Default Naming Configuration**, but you can modify or disable it.

### Guidelines for Using Regular Expressions in Include Rules

When using regular expressions to match URLs in your include rules, note the following guidelines:

- URL strings are case-sensitive. So, although the page names displayed in [Pages & Ajax Requests](#) are converted to lowercase, your regular expressions still need to match the case used in URLs that your include rule are trying to capture.

- Your regular expression should match the entire URL, from beginning to end, not just a section; otherwise, the rule will not match. This differs from using regular expressions in [custom match rules for naming transactions](#), which only need to match sections of the URL.
- Beacons for older browsers (primarily Internet Explorer 6-8) are sent using image requests, and therefore, have an inherent length limitation. To manage this limitation, Browser RUM does not support URLs longer than 180 characters, page names longer than 50 characters, and user data longer than 128 characters for these browsers.

### Limitations

- If you are using the regex expression "and use groups" to group pages by a custom page name (i.e. you want the page `/my-business/checkout` to display as `/checkout/my-business`), the regex logic defaults to ascending order of the groups. For example, the regex expression "and use groups = 3,2" will default to "use groups = 2,3".

### Example Include Rule

Suppose you have multiple pages that include the string `search/r/region` in their URLs, such as `search/r/region01`, `search/r/region23`, etc., and you want to name all the pages from that set as a single-page named `search/r/region`. By selecting the dropdown **using a Regex match on the URL**, you can enter a regular expression to remove the domain name and the number at the end of the URL, grouping all your `/search/r/region` URLs into one set. Because all the URLs contain `search/r/region`, AppDynamics now collects information for them all under the single-page name `search/r/region`. Otherwise, AppDynamics uses the default page naming rule or a rule with higher priority.

✕
**Include Rule**

Enabled

Rule Name

Criteria  
 This Include Rule applies to any URL that: Contains

Name Pages  
using a Regex match on the URL

Use regex on the URL  and use groups  ⓘ

Cancel
OK

### Custom Page Exclude Rules

You can configure custom exclude rules for pages in the same way you configure include rules. Any page with a URL matching the configuration is excluded from monitoring.

✕
**Exclude Rule**

Enabled

Rule Name

Criteria  
 This Exclude Rule applies to any URL that: Contains

Cancel
OK

---

## Configure Naming for Ajax Requests

### Related pages:

- [The Pages & Ajax Requests View](#)
- [Configure Page Identification and Naming](#)
- [Page, Ajax, and Iframe Dashboards](#)
- [Set Custom Page Names](#)

You can configure the display names by which Ajax requests are referred to and sorted in controller lists and dashboards.

### Access Naming Rules for Ajax Requests

In the Controller UI:

1. Go to **User Experience** and select a browser application.
2. On the left navigation bar, go to **Configuration > Instrumentation > AJAX > Monitor**.

### Naming Rules for Ajax Requests

The logic for naming Ajax requests is nearly identical to that for [naming virtual pages](#) in that you can use anchors (the part of the URL after the # ) to distinguish among Ajax requests. In these cases, using the **What part of anchor should be used in page name** section allows you to specify which Ajax request is being accessed correctly.

The difference in naming rules for Ajax requests is that you can also specify the HTTP method(s) to filter in the rule.

It is not required to select an HTTP method.

For example, the Ajax naming include rule below specifies the HTTP methods `POST` and `PUT` and is configured to show the HTTP method in the results displayed in the Controller UI:

Include Rule
✕

Enabled

**Rule Name**

**Criteria**  
 This Include Rule applies to any URL that

GET  POST  PUT  DELETE

**Name Pages**

Show HTTP Method (GET, POST, PUT, or DELETE)  
 Show Protocol (Ex: http, https, etc)  
 Show Domain (Ex: mywebsite.com)  
 Show Full Domain  Show Sub-domain

**Path Segments**  
 Don't use path segments  
 Use first  segments  
 Use last  segments  
 Use segment numbers  ⓘ

Query String Parameters to use in Page Name (Optional)

POST Parameters to use in Page Name (Optional)

**What part of anchor should be used in Page Name**  
 Don't use the anchor  
 Use first  segments  
 Use last  segments  
 Use segment numbers  ⓘ

## Configure Which Ajax Requests Are Sent to the Events Service

Modern web pages often include a large number of Ajax requests. Not all of these Ajax requests may be equally important to monitor, but they all equally affect [license entitlements and restrictions](#). Thus, you may want to configure which Ajax requests are sent to the Events Service to manage the impact on your overall Events Service usage.

To do this, you can create rules to specify the requests to be sent to the Events Service, either by excluding a request entirely, including a particular request or a sample of that request types by percentage or by just allowing the request to be sent. In general, the behavior follows this pattern:

- If no rules are specified, no data on Ajax requests is sent.
- If exclude rules are specified, and an Ajax request satisfies a rule, that data is *not* sent.
- If include rules are specified, any Ajax request that satisfies a rule is sent, based on sampling defined by the percentage indicated in the rule.
- If both include and exclude rules are specified, an Ajax request that satisfies an include rule but does *not* satisfy an exclude rule is sent.

- If you *only* configure exclude rules and the sample percentage, the non-excluded calls would be sampled at the specified rate.

See [Configure Page Identification and Naming](#) for more information about default naming rules and how rules are evaluated.

### Access Ajax Requests Rules

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation** >.
4. Select the **Ajax > Events Service** tab.

### Configure Exclude Rules

1. Click **Add** to create a new rule. The **Exclude Rule** popup appears.
2. Specify a display name for the rule.
3. Check **Enabled** to enable the rule.
4. Enter a string and select one of the options in the dropdown to match the URLs that you want to exclude from the Ajax requests.
5. Click **OK** to save the rule.

### Configure Include Rules

1. From the **Events Service Include Rules** section, click **Add** to create a new rule. The **Include Rule** popup appears.
2. Give your rule a display name.
3. Check **Enabled** to enable the rule.
4. For **Criteria**, enter a string and select one of the options in the dropdown to match URLs for including Ajax requests.
5. Configure how to name pages:
  - Select one of the options from the dropdown to determine the part of the URL.
  - Select the path segment.
  - Enter the query string to use in the page name.
  - Select the part of the anchor (or none) to use in the page name.
6. Click **Save**.

### Configure Virtual Page Naming

#### Related pages:

- [The Pages & Ajax Requests View](#)
- [Page, Ajax, and Iframe Dashboards](#)
- [Set Custom Page Names](#)

Web applications built using Single Page Application (SPA) principles minimize network traffic by transferring computing work for creating what the user sees to the browser. The initial page request downloads necessary data for constructing the application, with some possible exceptions. For example, HTML partials and fragments may be fetched dynamically from the backend in response to user interaction.

The individual views that the user sees are known as virtual pages. Browser RUM supports virtual pages created using the AngularJS framework, sometimes known simply as Angular.

In AngularJS, a virtual page is an individual view, comprised of the rendered template of the current route in the context of the main layout file. You can configure how AngularJS virtual pages are referred to and sorted in UI lists and dashboards. For more information on using Browser RUM with virtual pages, see [AngularJS Support](#).

### Access Virtual Page Naming Rules

1. Open the browser application in which you are interested.
2. On the left navigation bar, click **Configuration**.
3. Click **Instrumentation >**.
4. Select the **Virtual Pages** tab.

### Virtual Page Naming Rules

The logic for naming virtual pages is identical to that for [naming regular pages](#), with one exception. Because AngularJS pages can use anchors (the part of the URL after the #) to distinguish among virtual pages, in these cases, using the **What part of anchor should be used in page name** section allows you to specify which virtual page is being accessed correctly.

## Configure JavaScript and Ajax Error Detection

### Related pages:

- [Set Up and Access Browser RUM](#)
- [Browser Snapshots](#)

You can enable and disable reporting of JavaScript and Ajax request errors. When enabled, the Browser Monitoring UI reports Ajax request errors in the following places:

- **Geo Dashboard**
- **User Stats** page and device dashboards
- Page list
- Browser snapshots

Also, you can configure which errors are included in the error count by specifying the errors to "ignore". You can specify errors to ignore by:

- The script and/or error message
- Page
- URL

 "Ignored errors" are not actually ignored. They are still tracked, but the error count in the places where error totals are reported on the user interface is not incremented.

### Access Error Detection Rules

1. From the browser application you are interested in, click **Configuration**.
2. Click **Instrumentation >**.
3. Select the Errors tab.

### Enable and Disable Browser RUM Error Detection

In the Errors tab:

- Check/clear the **Enable JavaScript Error Capture** checkbox to enable/disable JavaScript error display.
- Check/clear the **Enable AJAX Request Error Capture** check box to enable/disable Ajax error display.

When both checkboxes are clear, no JavaScript or Ajax request errors are displayed.

Even if capture is enabled globally, you can configure certain errors to be ignored so that they are not counted in the error totals.

### Configure Rules to Ignore Errors based on Script or Error Message

You can configure the agent to ignore specific JavaScript errors that are identified by:

- a matching string pattern in the name of the script that generated the error
- the line number in the script
- a matching string pattern in the error message

You can specify one, two, or all three of these criteria. Configure more criteria to increase the granularity of which errors you ignore.

### Add Rules to Ignore Errors

From the **Ignore JavaScript Error Rules** section, click **Add** to open the **Ignore JavaScript Errors** popup. From there, you can enable the rule, specify the script name, line number, and optionally, the error message.

For example, the following configuration in the **Ignore JavaScript errors** section where all three fields are specified means "Ignore all errors generated by line 27 of a script whose name starts with "Nightly" and whose error message contains the string "WARNING::".

If the line number were not specified (e.g., set to 0), the configuration would mean "Ignore all errors generated any line of a script whose name starts with "Nightly" and whose error message contains the string "WARNING::".

If neither the line number nor the error message field was specified, the configuration would mean "Ignore all errors generated by any line of a script whose name starts with "Nightly".

If the error message were the only field specified, the configuration would mean "Ignore all errors generated by any script when the error message contains the string "WARNING::".

### Modify Rules

To modify an existing ignore rule, you can either double-click the rule in the list or select the rule and then click **Edit** from the dropdown. To remove an ignore rule, select the rule in the list and then click **Delete** from the dropdown.

### Configure Rules to Ignore Errors by Page

You can also ignore all errors generated by a specific page, iframe, or Ajax request.

From the **Ignore Errors from these Pages** section, click **Add** to open the **Ignore errors from specific Pages** popup, where you can create a rule for every page for which you want to ignore all errors.

To remove an ignore rule, select it in the list and click **Delete** from the dropdown.

### Configure Rules to Ignore Errors by URL

You can ignore all errors generated by a specific URL.

From the **Ignore Errors from these URLs** section, click **Add** to open the **Ignore errors from specific URLs** popup, where you can create a rule for every URL for which you want to ignore all errors.

To remove an ignore rule, select it in the list and click **Delete** from the dropdown.

### Configure Browser RUM Performance Thresholds

You can configure the thresholds that define slow, very slow, and stalled end-user requests. These thresholds are used to trigger browser snapshots. See [Transaction Thresholds](#) for a detailed discussion about static, dynamic, percentage, and standard deviation thresholds.

You can define Browser Monitoring thresholds as one of the following:

- a multiple of the standard deviation. The default standard deviation threshold duration is two hours. For example: "Experience is slow if end-user response time is slower than 3 X the standard deviation."
- a static value; For example: "Experience is stalled if end-user response time is slower than 30000 ms."

The default thresholds are:

- Slow = 3 x standard deviation
- Very Slow = 4 x standard deviation
- Stalled = 45000 ms

### Access Browser RUM Threshold Rules

1. Open the browser application in which you are interested.
2. On the left navigation bar, click **Configuration**.
3. Click **Instrumentation >**.
4. From the Settings tab, find the **Thresholds for Slow End User Experience** section.

### Configure Browser RUM Threshold Rules

1. Select the relevant radio button to indicate whether the threshold is based on standard deviations or static values.
2. Type the values in the fields or select them using the scrollbars for one or more of the following:
  - a. **Slow greater than**
  - b. **Very slow greater than**
  - c. **Stall greater than**
3. Click **Save**.

### Configure Browser Snapshot Collection

#### Related pages:

- [Browser Snapshots](#)
- [Set Up and Access Browser RUM](#)

Every page view and AJAX request sends a beacon to the EUM server. Every minute, the EUM server evaluates the collection of beacon samples and sends what are called "snapshots" to the Controller.

---

With browser snapshots, you can enable or disable:

- Slow snapshot collection, that is snapshots of requests where the End User Response Time is higher than the configured threshold.
- Periodic snapshot collection.
- Error snapshots, that is snapshots of requests for which a JavaScript error is reported or an Ajax request receives an HTTP error response. An error response is any HTTP code equal to or greater than 400.

If all three kinds of browser snapshot types—periodic, error, and slow response time—are disabled, the agent does not collect any browser snapshots.

### Access Snapshot Collection Rules

1. Open the browser application in which you are interested
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation >**.
4. Select the Settings tab.
5. Find the **Event Policy Configuration** section.

### Configure Snapshot Collection Rules

1. Check or clear the checkbox for one or more of the following:
  - **Enable Slow Snapshot Collection** to enable/disable slow response time snapshot collection.
  - **Enable Periodic Snapshot Collection** to enable/disable periodic snapshot collection.
  - **Enable Error Snapshot Collection** to enable/disable error snapshot collection.
2. Click **Save**.

### Configure Web Percentile Metrics

#### Related pages:

- [Browser App Dashboard](#)
- [EUM Data](#)

Parts of the Controller UI for Browser RUM rely on the processing done by the Events Service, including some of the widgets in the **Browser App Dashboard** and the **Analyze** page. For these metrics, you can choose to display either averages or percentiles.

A percentile is a measure that indicates a value below which a given percentage of values in a set falls: for example, the 99th percentile means that 99% of all values are below this level. Using percentiles can be a good way to reduce the impact of extreme outliers in performance metrics, which can be useful in the often noisy environments of end-user monitoring. The [Metric Browser](#) also displays the percentiles.

You can:

- Enable/disable percentile metric display
- Set up to four different percentile levels to be applied to metrics

### Access Configure Percentile Metrics

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation >**.
4. Select the **Settings** tab.
5. Find the **Configure Percentile Metrics** section.

### Configure Percentile Metrics

1. Check the **Enable Percentile Metrics** checkbox.
2. Enter up to four percentile levels to collect in the **Percentiles to Collect** fields. Each value must be a whole number between 1 and 99.

## Configure Session Monitoring Timeouts

You can control the timeframe for browser sessions by setting an inactivity limit. No activity beyond this limit is connected to previous activity as part of an individual session. See [Session Persistence](#) to learn more about how the duration of a session is determined.

### Access Session Monitoring

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation >**.
4. Select the Settings tab.
5. Find the **Configure Session Monitoring** section.

### Set Inactivity Timeout

From **Configure Session Monitoring**, set the number of minutes for the **Session Inactivity Timeout** field.

## Configure Request IP Address Storage - Browser

For security and privacy reasons, Browser RUM does *not* store source IP addresses associated with requests. To have Browser RUM store IP addresses associated with requests, follow the instructions below.

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation >**.
4. Select the Settings tab.
5. At the bottom of the Settings tab, check the **Store IP Address** checkbox to enable IP address storage. (By default, the box is *not* checked.)
6. Click **Save**.

## Inject the JavaScript Agent

### Related pages:

- [Overview of Injection Types](#)
- [Undo Injection](#)

This page describes how JavaScript Agent injection works, including the different injection types.

To instrument your application for Browser RUM, you must configure your JavaScript Agent and insert it into the page that is returned to the end user as part of the normal process it follows. The act of inserting the agent is called *injection*. There are several ways to inject the JavaScript Agent for Browser RUM into your web pages. You also have several JavaScript hosting options to choose from that offer differing degrees of control, simplicity, and reliability.

To configure the JavaScript Agent, see [Configure the JavaScript Agent](#).

## How the JavaScript Agent Works

The JavaScript Agent consists of two files: `adrum.js` and `adrum-ext.js`.

1. The file `adrum.js` is injected into each instrumented page, as close to the top as possible, as the page is served. The file loads synchronously at around 90 KB (30 KB with compression).
2. This first JavaScript file starts a timer and does some quick configuration and setup.
3. At the `onload` event, `adrum-ext.js` is fetched *asynchronously* to prevent blocking the page load. This is the code that does most of the heavy lifting. Once it has been fetched, it is cached for 24 hours on the browser.
4. When cross-domain session correlation is enabled, the first time a user visits a domain, the browser additionally loads the file `adrum-xd.html` to generate or load a piece of common information that enables cross-domain sessions. Future visits will not load `adrum-xd.html` again.
5. When the page has completed loading, the collected data is bundled into a beacon and sent to the EUM Server by `adrum-ext.js`.
6. The data is processed by the EUM Server and then made available for pickup by the Controller.

**i** Not all types of injection are supported on all frameworks and platforms. See the Script Injection columns in the [Supported Platform Matrix for Browser Monitoring](#) matrices to find out what types are supported for your application.

## Injection Methods

There are three methods for injecting the JavaScript Agent. See the following for each injection method:

- [Manual Injection of the JavaScript Agent](#)
- [Automatic Injection of the JavaScript Agent](#)
- [Assisted Injection](#)

## JavaScript Agent Hosting Options

The `adrum.js` file is inserted into the page when it is downloaded from your web application. The `adrum-ext.js` (and `adrum-xd.html` when cross-domain session correlation is enabled) file is loaded asynchronously by the `adrum.js` file. By default, `adrum-ext.js` and `adrum-xd.html` are fetched by the highly available Amazon CloudFront CDN infrastructure.

There are three hosting options for the JavaScript Agent:

- AppDynamics CDN - All the JavaScript Agent files are from the host `cdn.appdynamics.com`. This is the simplest hosting option and ideal for testing.
- Self-Hosting - You host all of the JavaScript Agent files. This option gives you the most control and is recommended for production.
- Shared Hosting - You host the main file `adrum.js`, but the other files that are loaded asynchronously are from the AppDynamics CDN. This choice offers control of the most important file of the JavaScript Agent and is ideal for small to medium-sized businesses that don't have the resources or prefer not to host the entire JavaScript Agent.

See [Manual Injection of the JavaScript Agent](#) for step-by-step instructions.

## Cross-domain Session Correlation

By default, Browser RUM sessions are restricted to one domain. Thus, when an end user navigates to a page in another domain or even subdomain, the session for that user is ended. You can, however, configure Browser RUM to enable sessions to continue across subdomains. Thus, when an end user navigates from `http://example1.com/` to `http://example2.com/`, the session will continue as long as the configured session inactivity time has not expired.

## How Sessions Are Correlated Across Multiple Domains

For sessions to be correlated across domains, each page is required to use HTTPS to load the file `adrum-xd.html` from the same URL. If your pages are fetching the files `adrum-ext.js` and `adrum-xd.html` files from the AppDynamics CDN (this includes the shared hosting use case), sessions will automatically be correlated across domains because the pages will be fetching the file `adrum-xd.html` from the AppDynamics CDN.

For those *self-hosting* the JavaScript Agent files, you will need to configure the JavaScript Agent to use HTTPS to load the `adrum-ext.js` file from the same URL. The `adrum-xd.html` file is served from the location of the `adrum-ext.js` file. See the sections below for configuration instructions for the two use cases.

## Configuration for Session Correlation Across Multiple Domains

### AppDynamics CDN / Shared Hosting

When using the AppDynamics CDN or shared hosting, your JavaScript Agent configurations must enable cross-domain session correlation and use HTTPS to call the `adrum-ext.js` file. Thus, in your JavaScript Agent configuration make sure you have the following lines:

```
...
config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
config.xd = {enable : true};
...
```

### Self-Hosting

When using self-hosting, your JavaScript Agent configurations must enable cross-domain session correlation and use HTTPS to call the `adrum-ext.js` file from the same URL. Thus, in your JavaScript Agent configuration make sure you have the following lines and that the value for `adrumExtUrlHttps` is the same for all pages requiring cross-domain session correlation.

```
...
// HTTPS is needed to fetch adrum-xd.html.
config.adrumExtUrlHttps = 'https://<your-adrum.ext-host>';
// This config enables cross-domain session correlation.
config.xd = {enable : true};
...
```

## Set the Geo Server URL

By default, end-users' locations are resolved using public geographic databases. You can host an alternate geo server for your countries, regions, and cities instead of using the default geo server hosted by AppDynamics. See [Host a Geo Server](#).

## Custom Configuration

You can add configuration for `adrum.js` to customize and extend the functionality of the JavaScript Agent. See [Configure the JavaScript Agent](#) for instructions and examples on adding custom configuration.

---

## JavaScript Agent Limitations

The JavaScript Agent cannot monitor and report the activity of [service workers](#) or [web workers](#). For example, if you use a service worker to make an XHR request, the JavaScript Agent will not be able to report it.

## Overview of Injection Types

You need to inject the JavaScript Agent into your web pages to use Browser RUM. There are several injection types that you can use depending on your use case. This page describes the different injection types, how they work, and when to use each type.

## Choosing an Injection Method

If you are uncertain which procedure to use to inject the agent into your web pages, follow these guidelines in the given order:

- If you want to use Browser RUM and do not have any app agents on the server side, use manual injection. See [Manual Injection of the JavaScript Agent](#).
- If automatic injection is available and works for your framework, use automatic injection. Automatic injection requires the least amount of effort because you do not have to manually instrument every page. Check the matrices at [Browser RUM Supported Environments](#) to see if automatic injection has been tested in your environment. Also, see [Automatic Injection of the JavaScript Agent](#).
- If you cannot use automatic injection, and you can edit the source code of *your web pages*, use manual injection. See [Manual Injection of the JavaScript Agent](#).
- If you cannot use automatic injection, and you can edit the source code of *your web application*, use one of the kinds of assisted injection. See [Assisted Injection-Using Attribute Injection](#).

## Manual Injection

Manual injection is supported on all platforms and frameworks. To set up a manually injected page:

- Choose a JavaScript Agent hosting option. See [JavaScript Agent Hosting Options](#) to learn what hosting option best suits your use case.
- Manually configure each page to find the location of the JavaScript Agent, so that it can be executed as the page is constructed by the browser.

For detailed instructions on using manual injection in your application, see [Manual Injection of the JavaScript Agent](#).

## Automatic Injection

If you are using a Java or .NET app agent on the server-side, and your application is running in an environment that supports any of the following:

- Apache Jasper JSP compiler (for Java) or
- ASP.NET or ASPX (for .NET) or
- ASP.NET Core (for .NET; Windows support only)

You *may* be able to use automatic injection, where the server-side app agent completely manages injecting the code at runtime. For instructions on using automatic injection in your application, see [Automatic Injection of the JavaScript Agent](#).

## Assisted Injection

Assisted injection is available in two variants. In both cases, some of the work is done manually by you and some of the work is done by the server-side Java or .NET app agent.

**i** Assisted injection is currently not supported for .NET Core.

### Assisted Injection Using Injection Rules (Java Only)

In this type of assisted injection, you configure rules that define which app server Java classes and methods write to the output stream of your application and the writer object that is used to do that writing. AppDynamics intercepts the method and injects the JavaScript Agent into the output stream. You also specify which server-side business transactions you wish to have instrumented in this way.

For detailed information on using this form of assisted injection, see [Assisted Injection](#).

### Assisted Injection Using Attribute Injection

In this type of assisted injection, you copy small code snippets appropriate to your framework into your page templates or other code that creates your pages. This snippet contains the two variables `JS_HEADER` and `JS_FOOTER`, which the app agent replaces with the appropriate information in the response object at runtime.

For detailed information on using this form of assisted injection, see [Using Attribute Injection](#).

### Container-Based Injection

If you are using Nginx or Apache as a web container or as a reverse proxy in front of your web container, you can use directives to inject the agent into the response object. See [Injection Using Nginx](#) or [Injection Using Apache](#).

### Manual Injection of the JavaScript Agent

This page describes how to instrument a browser application by manually injecting the JavaScript Agent. To configure the JavaScript Agent before injection, see [Configure the JavaScript Agent](#).

#### Manually Inject the JavaScript Agent

The Controller UI allows you to configure the JavaScript Agent, generate an HTML snippet, and add that snippet to the header of the web pages.

1. In the Controller UI, go to a browser application.
2. In the left navigation menu, select **Configuration > Configure JavaScript Agent**.
3. [Configure the JavaScript Agent](#).
4. Save and copy the HTML snippet.
5. Add the HTML snippet to the header of the web pages.

#### JavaScript Agent Placement

The recommended location for the JavaScript Agent is at the top of the `<head>` section. The `adrum.js` file captures the time as the page begins to load and measures that amount of time against the time that other timings are calculated for all browsers. Many modern browsers, however, support the Navigation Timing API (see [this list](#)), and for these browsers, timings can be acquired via the API. In this case, it is possible to place the JavaScript Agent somewhere else on the page, but useful timing information is only available for those `NavTime`-capable browsers.

## Synchronous Versus Asynchronous Script Load

AppDynamics recommends that the `adrum.js` file loads synchronously because once downloaded, the JavaScript Agent begins monitoring for page data such as Ajax events, resources, and errors. If `adrum.js` loads asynchronously for the first time (through the `async` attribute), the JavaScript Agent might not report all page data.

## Use Previous JavaScript Agent Versions

Previous versions of the agent can be found at the following location, where `VERSION` is the version number you want to access (for example, `4.5.0`).

```
http://cdn.appdynamics.com/adrum/adrum-VERSION.js
```

- If you are using a SaaS EUM Cloud and want a hosted version of `adrum.js`, AppDynamics recommends you use the `adrum-latest.js` version. However, you can use any version of the JavaScript Agent as it is compatible with any SaaS EUM Cloud version currently being deployed.
- If you are using an on-premises EUM Server and want to use a hosted version of `adrum.js`, you need to match the `adrum.js` version to your EUM Server version.
- For Controller versions, a JavaScript Agent version is compatible with Controller versions with the same or older versions. For example, JavaScript Agent `20.6.0` is compatible with Controller `<= 20.6.0`.

## Verify Manual Injection

Once the agent is injected, it can take the AppDynamics Controller a few minutes to discover and recognize the page, which must happen before data will begin to appear. If, however, you have configured your page using manual injection and are not seeing Browser RUM metrics after running load for a while, check the web page to confirm that the JavaScript Agent for Browser RUM is present in the page. If not, try injecting the script again.

If, after two attempts, you still do not see Browser RUM metrics, try one of the other injection schemes if they are available for your platform. See [Troubleshoot Browser RUM](#).

## Automatic Injection of the JavaScript Agent

This page describes how to instrument a browser application by automatically injecting the JavaScript Agent. Automatic injection uses AppDynamics server-side agents to automatically add the `adrum` header and footer to each of your web pages.

## Automatic Injection Support for Server-side Agents

The [Java Agent](#) and [.NET Agent](#) support automatic injection. See [.NET Supported Environments](#) for version specifics.

Automatic injection is available only for server-side applications built on these environments:

- Jasper-supported JSP (Java)
- ASP.NET
- ASP.NET Core
- ASPX (.NET) Framework
- Oracle WebLogic Server (JSPs) 12c, 14c (Java)

- Although the [Apache Agent](#) does *not* support automatic injection, you can [configure Apache](#) or [Nginx](#) to inject the JavaScript Agent.

- If the server-side application does not return well-formed HTML, the JavaScript Agent may not be able to instrument the page. For example, the JavaScript Agent may not be able to instrument HTML pages that are missing elements or have unclosed tags.

### JavaScript Agent and Controller Versions

The table below lists the Javascript Agent version deployed for auto-injection in each Controller version.

- i** The JavaScript Agent version does not match the Controller version because the Controller and agents have different release cycles.

Controller Version	JavaScript Agent Version Supported for Auto-Injection
21.9.0	21.7.0
21.4.0	20.12.0

## Access the User Experience App Integration Panel

1. From the **Applications** page, open the [business application](#) that you want to automatically inject the JavaScript Agent into your browser application.
2. From the left navigation bar, select **Configuration**.
3. Click **User Experience App Integration**.

### Enable Business Transaction Correlation

From **Business Transaction Correlation**, check the **Enable Business Transaction Correlation** checkbox to correlate Pages and Ajax requests with server-side business transactions.

#### Specify Business Transactions to Include Correlation Headers

You can also specify which business transactions will include or exclude correlation headers. If you do not add request match rules or request exclude rules, correlation headers will be added to all requests.

To add a request rule:

1. Click the **plus** icon. The **Create HTTP Request Match Rule** will display.
2. Check the **Method** checkbox and select an HTTP method that you want to match.
3. Check the **URI** checkbox and enter your criteria.
4. Click **Save**.

### Enable Automatic Injection

1. Select the JavaScript Agent Injection tab.
2. From the **Inject the JavaScript Agent configured for this Browser App** dropdown, select the browser application you want to use automatic injection.
3. Check the **Enable Automatic Injection of JavaScript** check box to enable automatic injection.
4. If you enabled automatic injection, click **OK** in the **Confirm Enabling Automatic Injection** dialog.
5. Click **Save** in the outer configuration pane.

## Configure Automatic Injection

After you have enabled automatic injection:

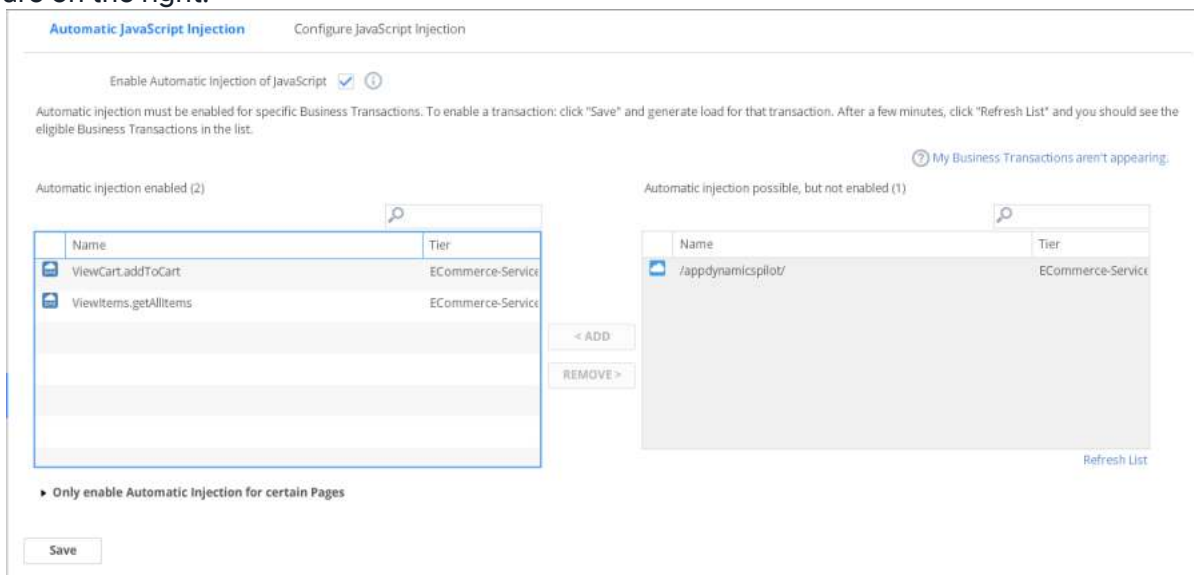

- You must specify the server-side business transactions for which automatic JavaScript injection is enabled.
- You can limit which pages to inject by creating custom match and exclude rules for automatic injection. If you do not configure these rules, by default AppDynamics injects all pages visited by the enabled business transactions.

Use these rules to fine-tune which business transactions to include or exclude from injection based on match criteria. For example, you can exclude all business transactions that have a certain string in their URLs or set a certain cookie. The configurations for include rules and exclude rules are similar. It depends on your situation whether it is more convenient to restrict transactions based on inclusion or exclusion.

### Specify Business Transactions for Automatic Injection

You must select at least one business transaction for automatic injection.

1. From the list on the right shown in the screenshot, select one or more business transactions. (If you don't see any business transactions, click **Refresh List**.) Not all your business transactions may appear here—the list includes only those transactions that AppDynamics can parse for automatic injection, those based on Jasper-compiled JSPs or ASP.NET, ASP.NET Core, or ASPX.NET pages.
2. Click **< Add** to move the business transaction to the list on the left.
3. Repeat until all the transactions you wish to enable are on the left and those you do not wish to enable are on the right.

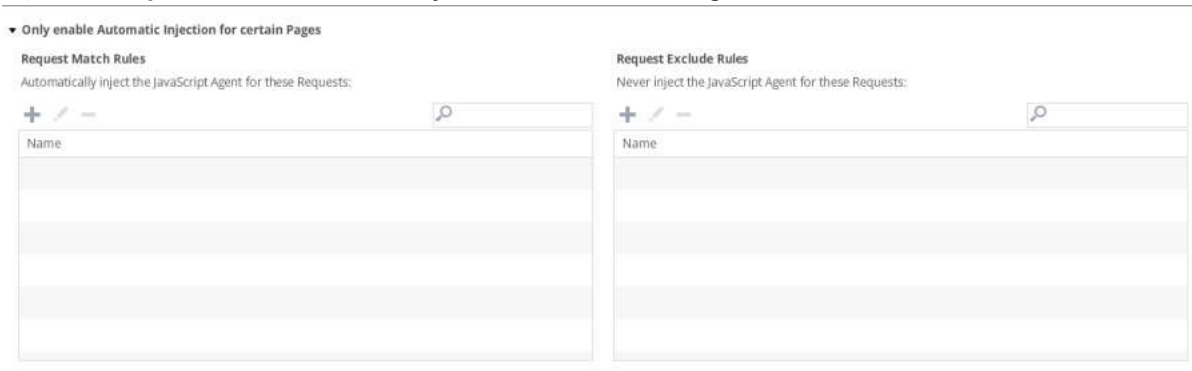

4. Click **Save**.

### Create Match Rules for Automatic Injection

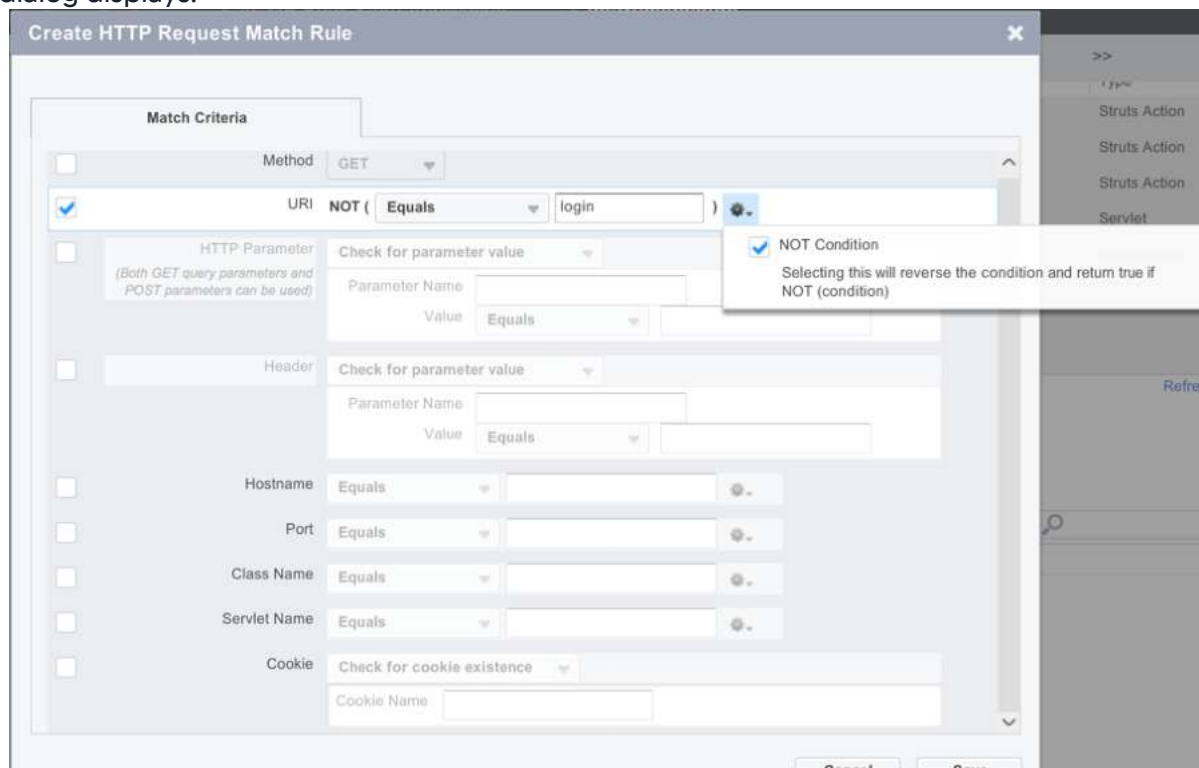

You may not wish to instrument every page in your application. For example, if your application has a very large number of pages, you might want to instrument only the key ones for your business, to avoid hitting licensing limits. Or, when you are in the setup and test phase, you might only want to instrument a few pages to keep your initial sample manageable.

Use match rules to include or exclude certain pages:

1. Expand **Only enable Automatic Injection for certain Pages** if it is closed.

2. Click the **plus** icon to create a match rule or an exclude rule. The **Create HTTP Request Match Rule** dialog displays.

3. Select one or more criteria to match. If you select multiple criteria, **all** must match for the rule to come into effect. Use the **gear** icon to set a NOT condition. See [Using Regular Expressions](#) for general information about match rules.
4. Click **Save**.
5. Click **Save** in the outer configuration pane.

You can later edit or remove a match rule by selecting it in the list and clicking the edit or delete icon.

## Injection Using Nginx

### Related pages:

- [Manual Injection of the JavaScript Agent](#)
- [Automatic Injection of the JavaScript Agent](#)

- [Using Attribute Injection](#)

If you are using Nginx as your web container, or use Nginx as a reverse proxy, you can use a container substitution module to automatically inject the JavaScript Agent into your pages. The module intercepts the response object as it is being returned and makes a string substitution.

### Download the Agent

You must first download the JavaScript Agent from the **Configuration** screen.

1. Open the browser application in which you are interested.
2. From the left navigation menu, select **Configuration**.
3. Click the **Configure and download JavaScript Agent**.
4. For the JavaScript hosting option, select **I will host all the JavaScript agent files**.
5. Click **Download** to download the JavaScript Agent.
6. Place the file somewhere accessible to the Nginx instance. The name of the saved file should be `adrum.js`.

### Configure Nginx with `ngx_http_sub_module`

The `ngx_http_sub_module` module is a filter that modifies a response by replacing one specified string by another. You can use this feature to have the server automatically inject the header portion of the JavaScript Agent into a served page. For more information on the process, see the Nginx documentation, [Module ngx\\_http\\_sub\\_module](#).

For example, modify the location context to replace the `<head>` tag with the `<head>` tag and the JavaScript Agent scripts.

### Sample Nginx Configuration

```
location / {
 sub_filter <head>
 '<head><script>window["adrum-app-key"]="<EUM_APP_KEY>";window["adrum-start-time"]=new
Date().getTime();</script><script type="text/javascript" src="//cdn.appdynamics.com/adrum/
adrum-latest.js"></script>';
 sub_filter_once on;
}
```

In the sample above, note that `/adrum-latest.js` is the path to a copy of the `adrum` file that is accessible to the server. Also, note the timer initialization `<script>window['adrum-start-time'] = new Date().getTime();</script>`. Keep these as close as possible to the top of the document, preferably right after the `<head>` tag, ensures the best possible timings.

**i** If you use `<meta>` tags, you should place them right after your `<head>` tag, and then place the JavaScript Agent directly after the last `<meta>` tag. This can avoid issues with some versions of IE.

You may need to escape some characters, depending on your platform. For example, on Mac OS:

```
location / {
```

```

sub_filter <head>
 '<head><script>>window[\'adrum-start-time\'] = new Date().getTime();</script><script
src="/adrum.js"></script>';
 sub_filter_once on;
}

```

**i** This Nginx module is often used for adding the Google Analytics script. Be careful not to overwrite any existing GA script when you do this.

Possible variations on the script string can be found in [Configure the JavaScript Agent](#).

Configure Nginx without `ngx_http_sub_module`

You can configure Nginx without the `ngx_http_sub_module` module if you prefer. Insert the required script into the `conf.d/default.conf` location.

Sample Nginx Configuration

```

location / {
 sub_filter <head>
 '<head><script>>window["adrum-app-key"]="<EUM_APP_KEY>";window["adrum-start-time"]=new
Date().getTime();</script><script type="text/javascript" src="//cdn.appdynamics.com/adrum/
adrum-latest.js"></script>';
 sub_filter_once on;
 }
}

```

## Injection Using Apache

### Related pages:

- [Manual Injection of the JavaScript Agent](#)
- [Automatic Injection of the JavaScript Agent](#)
- [Using Attribute Injection](#)
- [Using Injection Rules](#)

This page describes how to instrument a browser application using Apache to automatically inject the JavaScript Agent. If you are using Apache as your web container, or you are currently using, or willing to use, Apache as a reverse proxy, you can use a container substitution module to automatically inject the JavaScript Agent into your pages. The module intercepts the response object as it is being returned and makes a string substitution.

**i** This method uses the two Apache modules `mod_substitute` and `mod_filter`.

### Download the Agent

You must first download the JavaScript Agent from the Browser Monitoring configuration pane.

1. Open the browser application in which you are interested.
2. From the left navigation menu, select **Configuration**.
3. Click the **Configure and download JavaScript Agent**.

4. For the JavaScript hosting option, select **I will host all the JavaScript agent files**.
5. Click **Download** to download the JavaScript Agent.
6. Place the file somewhere accessible to the Apache instance. The name of the saved file should be `adrum.js`.

## Configure Apache

The basic configuration procedure includes:

1. [Make Sure the Modules are Loaded](#)
2. [Create an Adrum Configuration File](#)
3. [Add the Location of the Adrum Configuration File to httpd.conf](#)
4. [Restart the Web Server](#)

### Make Sure the Modules are Loaded

Check your global Apache `httpd.conf` file and make sure that the following two `LoadModule` commands are in the file:

```
LoadModule substitute_module modules/mod_substitute.so
LoadModule filter_module modules/mod_filter.so
```

### Create an Adrum Configuration File

Create a file named `adrum.conf` with contents similar to the example below, based on your Apache version. (See this [Stack Overflow](#) post for details.) In this case, the substitution rule covers the location of the entire site ( `Location /` ) but you can also recursively select a specific directory and its subdirectories by using `/somedirectory`.

#### Sample adrum.conf Apache 2.2

Replace the sample code below with your own JavaScript Agent script.

```
<Location "/">
 SetOutputFilter INFLATE;SUBSTITUTE;DEFLATE
 AddOutputFilterByType SUBSTITUTE text/html
 Substitute "s#<head>#<head><script>window['adrum-start-time'] = new Date().getTime();</
script><script>(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] ||
(window['adrum-config'] = {}));</script><script src='./adrum.js'></script>#inq"
</Location>
```

**i** If you use `<meta>` tags, you should place them right after your `<head>` tag, and then place the JavaScript Agent directly after the last `<meta>` tag and before other `<script>` tags. This can avoid issues with some versions of IE and improve the accuracy of the resource timing.

#### Sample adrum.conf Apache 2.4

Replace the sample code below with your own JavaScript Agent script.

```
<Location "/">
 AddOutputFilterByType SUBSTITUTE text/html
 Substitute "s#<head>#<head><script>>window['adrum-start-time'] = new Date().getTime();</
script><script>(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] ||
(window['adrum-config'] = {}));</script><script src='./adrum.js'></script>#inq"
</Location>
```

Where `./adrum.js` is the path to a copy of the `adrum` file that is accessible to the server. The flags after the `#` are:

- `i` - matching is case-insensitive
- `n` - pattern is treated as a fixed string (removing the `n` means the pattern is treated as a regular expression)
- `q` - module does not flatten the buckets after each substitution - this can speed performance.

For more information, see the Apache module docs [here](#).

If your `<head>` tag has an attribute like `<head lang="en">`, you can use a regex in the substitution string and omit the `n` flag. Replace the sample code below with your own JavaScript Agent script.

```
Substitute "s#(<head[^\>]*>)#$1<script>>window['adrum-start-time'] = new Date().getTime();</
script><script>(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] ||
(window['adrum-config'] = {}));</script><script src='./adrum.js'></script>#iq"
```

**i** Note the timer initialization: `<script>>window['adrum-start-time'] = new Date().getTime();</script>`. Injecting these scripts as close as possible to the top of the document, preferably right after the `<head>` tag, ensures the best possible timings.

Also, if you use `<meta>` tags, you should place them right after your `<head>` tag, and then place the JavaScript Agent directly after the last `<meta>` tag and before other `<script>` tags. This can avoid issues with some versions of IE and again improve the accuracy of the resource timing.

#### (Optional) Adjust for gzipped resources

If your page is compressed, the substitution won't work unless the content is INFLATED, the substitution is made, and then the content is DEFLATED. There are multiple ways to do this. For example, in the `FilterProvider` line:

```
FilterProvider AdrumFilter INFLATE;SUBSTITUTE;DEFLATE
resp=Content-Type $text/html
```

See this [Stack Overflow](#) post for more information. If you are using Apache as a proxy, you can also instruct it not to accept gzip-encoded content.

Add the Location of the Adrum Configuration File to `httpd.conf`

Add the following line to your global Apache `httpd.conf` file:

```
Include [absolutePathTo]/adrum.conf
```

Alternatively, you can add the directives to the `httpd.conf` file directly instead of creating a separate `adrum` file.

Restart the Web Server

To pick up the new configuration, restart:

```
sudo apcheectl -k restart
```

**i** If you get a warning "Useless use of AllowOverride in line 2 of `[absolutePathTo]/adrum.conf`", it can be ignored. It simply means `AllowOverride` is redundant. You can remove it if you wish.

Possible variations on the script string can be found in [Configure the JavaScript Agent](#).

### Other Alternatives

If you are setting up your automatic injection using an Apache instance that is configured as a reverse proxy, you *must* use the `Location` directive method described above, with the `ProxyPass` and `ProxyPassReverse` directives also in the `Location` directive. If you are using an Apache instance that is your primary web container you have two additional options for describing the actual substitution step:

- [Using the Directory Directive](#)
- [Using .htaccess](#)

### Use the Directory Directive

You can use the `Directory` directive instead of the `Location` directive.

### Use .htaccess

Add lines similar to this to an `.htaccess` file in the base document directory for your site, replacing your filter name for `<MyFilter>`. If you don't have an `.htaccess` file, create one:

### Apache 2.2

Replace the sample code below with your own JavaScript Agent script.

```
Substitute "s#<head>#<head><script>>window['adrum-start-time'] = new Date().getTime();</script><script>(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] || (window['adrum-config'] = {}));</script><script src='./adrum.js'></script>#inq"
```

```
AllowOverride Options
FilterDeclare <MyFilter>
FilterProvider <MyFilter> SUBSTITUTE resp=Content-Type $text/html
```

```

FilterChain <MyFilter>
Substitute "s#<head>#<head><script>>window['adrum-start-time'] = new Date().getTime();</
script><script>(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] ||
(window['adrum-config'] = {}));</script><script src='./adrum.js'></script>#inq"

```

## Apache 2.4

Replace the sample code below with your own JavaScript Agent script.

```

Substitute "s#<head>#<head><script>>window['adrum-start-time'] = new Date().getTime();</
script><script>(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] ||
(window['adrum-config'] = {}));</script><script src='./adrum.js'></script>#inq"

```

```

AddOutputFilterByType SUBSTITUTE text/html
Substitute "s#<head>#<head><script>>window['adrum-start-time'] = new Date().getTime();</
script><script>(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] ||
(window['adrum-config'] = {}));</script><script src='./adrum.js'></script>#inq"

```

Where `./adrum.js` is the path to a copy of the `adrum` file that is accessible to the server. Make sure `.htaccess` is world-readable.

## Assisted Injection

### Related pages:

- [Automatic Injection of the JavaScript Agent](#)
- [Injection Using Nginx](#)
- [Injection Using Apache](#)

This page describes how to instrument a browser application through assisted injection of the JavaScript Agent. Assisted injection is when your server-side application injects the JavaScript Agent into your browser application. You can configure your [business applications](#) to inject the JavaScript Agent into your browser applications.

### Types of Assisted Injection

You can perform assisted injection with rules or through attributes. This table summarizes the platforms supported for each type of assisted injection and the process for performing the assisted injection.

Type of Assisted Injection	Supported Platforms	Description
<a href="#">Injection Rules</a>	Java	<p>Type of assisted injection uses rules to configure which Java classes should be intercepted.</p> <p>You create the injection rules in the <b>User Experience App Integration Panel</b> of the Controller UI for the business application that will inject the JavaScript Agent.</p>
<a href="#">Attribute Injection</a>	Java, ASP.NET	<p>Type of assisted injection relies on templates that tell the app agent where to inject information.</p> <p>You enable attribute injection in the <b>User Experience App Integration Panel</b> of the Controller UI for the business application that will inject the JavaScript Agent.</p> <p>Additionally, you add code snippets in the page templates that determine where the JavaScript Agent is injected.</p>

### Injection Rules (Java Only)

To have your server-side application use assisted injection of the JavaScript Agent using injection rules, you define rules to configure:

- The Java classes and methods that should be intercepted
- The Java writer object and method to use to add the agent to the response object

 Assisted injection using rules is available for Java frameworks only.

#### Access the User Experience App Integration Panel

1. From the **Applications** page, open the [business application](#) that you want to automatically inject the JavaScript Agent into your browser application.
2. From the left navigation bar, select **Configuration**.
3. Click **User Experience App Integration**.

#### Create JavaScript Injection Rules

1. In the JavaScript Agent Injection tab, select a browser application from the **Inject the JavaScript Agent configured for this Browser App** dropdown.
2. From the Configure JavaScript Injection tab, expand **Create Injection Rules**.
3. Click the + icon to open the **Create Manual Injection Rule** dialog.
4. From the Where to Inject JavaScript tab:

- a. In the **Name** field, enter a name for the rule.
  - b. Check **Enable**.
  - c. In the **Class and Method to intercept** section, define match conditions for the class and method that write to the output stream in your application. This is the class that server-side agent intercepts for injection.
  - d. If the write method is overloaded:
    - i. Check the **Is this Method Overloaded?** checkbox.
    - ii. Click **Add Parameter**.
    - iii. Add the parameters that define the method.
  - b. In the **Pointer to the writer** section:
    - i. Select how to obtain a reference to the writer object using either the selected method with a configured number of parameters, return value, or invoked object.
    - ii. Specify a getter chain.
  - c. In the **Injection options** section, specify:
    - the output stream write method the server-side agent should use to inject the JavaScript Agent
    - when the injection should occur: when the method begins or when the method ends
    - which part of the script should be injected: the header or the footer
    - optional prefix to output before writing the header or footer, such as `<DOCTYPE . . . >`
5. Click **Create Injection Rule**.

## Attribute Injection

To have your server-side application use assisted injection of the JavaScript Agent using attribute injection, you:

- Enable attribute injection
- Copy code snippets into your page template

 Only [Servlet containers](#) supported assisted injection.

Access the User Experience App Integration Panel

1. From the **Applications** page, open the [business application](#) that you want to automatically inject the JavaScript Agent into your browser application.
2. From the left navigation bar, select **Configuration**.
3. Click **User Experience App Integration**.

Access the JavaScript Injection Configuration Panel

1. From the **User Experience App Integration** page, click the JavaScript Agent Injection tab.
2. In the JavaScript Agent Injection tab, select a browser application from the **Inject the JavaScript Agent configured for this Browser App** dropdown.

Copy Code Snippets into Your Page Template

These examples show code snippets that you can copy directly into your page templates or into other pages. These code snippets direct the app agent where to inject information. The header value must be injected at the very top of the `<head>` section and the footer value must be added at the very end of the code creating the page.

If you have already injected the header portion of the agent using manual injection, you can use these code snippets to automatically inject the footer data portion only. In this case, add only the `JS_FOOTER` values shown in the sections below.

### JSF

```
<h:outputText rendered="#{AppDynamics_JS_HEADER != null}" value="#{request.getAttribute("AppDynamics_JS_HEADER")}" escape="false"/>
<h:outputText rendered="#{AppDynamics_JS_FOOTER != null}" value="#{request.getAttribute("AppDynamics_JS_FOOTER")}" escape="false"/>
```

### JSP

```
<% if (request.getAttribute("AppDynamics_JS_HEADER") != null) { %> <%=request.getAttribute("AppDynamics_JS_HEADER")%> <% } %>
<% if (request.getAttribute("AppDynamics_JS_FOOTER") != null) { %> <%=request.getAttribute("AppDynamics_JS_FOOTER")%> <% } %>
```

### Servlet

```
if (request.getAttribute("AppDynamics_JS_HEADER") != null)
{
 out.write(request.getAttribute("AppDynamics_JS_HEADER").toString());
}
if (request.getAttribute("AppDynamics_JS_FOOTER") != null)
{
 out.write(request.getAttribute("AppDynamics_JS_FOOTER").toString());
}
```

### Groovy

```
<g:if test="${AppDynamics_JS_HEADER}">
 ${AppDynamics_JS_HEADER}
</g:if>

<g:if test="${AppDynamics_JS_FOOTER}">
 ${AppDynamics_JS_FOOTER}
</g:if>
```

### Velocity Template

```
#if ($AppDynamics_JS_HEADER)
 $AppDynamics_JS_HEADER
#end
#if ($AppDynamics_JS_FOOTER)
 $AppDynamics_JS_FOOTER
```

```
#end
```

## ASP.NET C#

```
<% if (Context.Items.Contains("AppDynamics_JS_HEADER"))
 Response.Write(Context.Items["AppDynamics_JS_HEADER"]); %>
<% if (Context.Items.Contains("AppDynamics_JS_FOOTER"))
 Response.Write(Context.Items["AppDynamics_JS_FOOTER"]); %>
```

## MVC Razor

```
@if(HttpContext.Current.Items.Contains("AppDynamics_JS_HEADER"))
{ @Html.Raw((string)HttpContext.Current.Items["AppDynamics_JS_HEADER"]) }
@if(HttpContext.Current.Items.Contains("AppDynamics_JS_FOOTER"))
{ @Html.Raw(HttpContext.Current.Items["AppDynamics_JS_FOOTER"].ToString()) }
```

## Undo Injection

### Related pages:

- [Manual Injection of the JavaScript Agent](#)
- [Automatic Injection of the JavaScript Agent](#)
- [Assisted Injection](#)

If you try one way to inject and it does not work, AppDynamics recommends that you undo the current injection configuration before implementing another one.

### Reverse Manual Injection

To undo manual injection, simply delete the JavaScript Agent from your web pages.

### Undo Automatic Injection

To undo automatic injection:

1. Navigate to the **Application Dashboard** of the application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration**.
3. From the **Inject the JavaScript Agent configured for this Browser App** dropdown, select your browser application.
4. From the Automatic JavaScript Injection tab, clear the **Enable Automatic Injection of JavaScript** check box.

### Undo Assisted Injection Using Attribute Injection

To undo assisted injection using attribute injection:

1. Navigate to the **Application Dashboard** of the application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration**.
3. From the **Inject the JavaScript Agent configured for this Browser App** dropdown, select your browser application.
4. From the Configure JavaScript Injection tab, clear the **Request Attribute Injection** check box.

## Undo Assisted Injection Using Injection Rules

To undo assisted injection using injection rules:

1. Navigate to the **Application Dashboard** of the application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration**.
3. From the **Inject the JavaScript Agent configured for this Browser App** dropdown, select your browser application.
4. From the **Configure JavaScript Injection** tab, double-click the rule that you'd like to disable.
5. Clear the **Enabled** check box.

You can also simply delete rules by selecting the rule and then clicking the **Delete** icon.

## Upgrade the JavaScript Agent

### Related pages:

- [Manual Injection](#)
- [Automatic Injection](#)
- [Assisted Injection](#)
- [Undo Injection](#)

This page covers how to upgrade the JavaScript Agent version. Upgrading to the latest version of the JavaScript Agent will allow you to use the [latest features and get the latest bug fixes](#).

The following sections will discuss possible compatibility issues, show you a new way to include the JavaScript Agent, and provide you with manual injection code examples for the [different JavaScript Agent hosting options](#).

### Compatibility Issues

For on-premises deployments, your JavaScript Agent version should be the same or older than your EUM Server version. For example, if you have deployed the EUM Server 20.3.0, the latest version of the JavaScript Agent you can use is 20.3.0. We recommend to [upgrade your EUM Server](#) to the latest version so you can take advantage of the latest JavaScript Agent features.

- If you are using a SaaS EUM Cloud and want a hosted version of `adrum.js`, AppDynamics recommends you use the `adrum-latest.js` version. However, you can use any version of the JavaScript Agent as it is compatible with any SaaS EUM Cloud version currently being deployed.
- If you are using an on-premises EUM Server and want to use a hosted version of `adrum.js`, you need to match the `adrum.js` version to your EUM Server version.
- For Controller versions, a JavaScript Agent version is compatible with Controller versions with the same or older versions. For example, JavaScript Agent 20.6.0 is compatible with Controller  $\leq 20.6.0$ .

### Injection Code Changes

If the URL to the server hosting your JavaScript Agent is the same for both HTTP and HTTPS, you should no longer use `document.write` to inject the `<script>` tag. Instead, just hardcode the `<script>` tag with the following syntax:

```
<script src="//cdn.appdynamics.com/adrum/adrum.js"></script>
```

## Injection Code for Different Hosting Options

The injection code will vary slightly depending on your deployment (SaaS/on-premises). The following provides you with code snippets for each type of deployment. Be sure to place the code snippets below right after the `<head>` tag.

[AppDynamics CDN](#)
[Self-Hosting](#)
[Shared Hosting](#)

In the string below:

- Replace the string `<EUM_APP_KEY>` in the code below with your own EUM app key.
- Replace `< eum-col.appdynamics.com >` in the code below with your corresponding collector URL.

```
<script charset='UTF-8'>
window['adrum-start-time'] = new Date().getTime();
(function(config){
 config.appKey = '<EUM_APP_KEY>';
 config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
 config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
 config.beaconUrlHttp = 'http://eum-col.appdynamics.com';
 config.beaconUrlHttps = 'https://eum-col.appdynamics.com';
 config.xd = {enable : false};
})(window['adrum-config'] || (window['adrum-config'] = {}));
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js'></script>
```

[AppDynamics CDN](#)
[Self-Hosting](#)
[Shared Hosting](#)

In the code snippet below:

- Replace the string `<EUM_APP_KEY>` with your own EUM app key.
- Replace the string `<your-cdn.com>` with the URL to your server hosting the JavaScript Agent.
- Replace `< eum-col.appdynamics.com >` in the code below with your corresponding collector URL.

```
<script charset='UTF-8'>
window['adrum-start-time'] = new Date().getTime();
(function(config){
 config.appKey = '<EUM_APP_KEY>';
 config.adrumExtUrlHttp = 'http://<your-cdn.com>';
 config.adrumExtUrlHttps = 'https://<your-cdn.com>';
 config.beaconUrlHttp = 'http://eum-col.appdynamics.com';
 config.beaconUrlHttps = 'http://eum-col.appdynamics.com';
 config.xd = {enable : false};
})(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//<your-cdn.com>/adrum/adrum.js'></script>
```

[AppDynamics CDN](#)
[Self-Hosting](#)
[Shared Hosting](#)

In the code snippet below:

- Replace the string `<EUM_APP_KEY>` with your own EUM app key.
- Replace the string `<your-cdn.com>` with the URL to where you're hosting the JavaScript Agent.
- Replace `< eum-col.appdynamics.com >` in the code below with your corresponding collector URL.

```

<script charset='UTF-8'>
window['adrum-start-time'] = new Date().getTime();
(function(config){
 config.appKey = '<EUM_APP_KEY>';
 config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
 config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
 config.beaconUrlHttp = 'http://eum-col.appdynamics.com';
 config.beaconUrlHttps = 'https://eum-col.appdynamics.com';
 config.xd = {enable : false};
})(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//<your-cdn.com>/adrum/adrum.js'></script>

```

## Configure the JavaScript Agent

### Related pages:

- [Injection Problems](#)
- [Inject the JavaScript Agent](#)

This page describes configuration and hosting options for the JavaScript Agent.

## Configure the JavaScript Agent

To configure the JavaScript Agent in the Controller:

1. Go to a browser application.
2. In the left-hand panel, go to **Configuration > Configure the JavaScript Agent**.
3. Select a [hosting option](#).
4. Customize the code snippet in **Step 2: Advanced settings (Optional)**.
5. Click **Save**.

### Configure Shared-Hosting

If you are using shared-hosting and do not want to use the default CDN, follow these instructions to provide your own CDN for only hosting the main JavaScript Agent file (`adrum-[version].js`):

1. From **Controller Admin**, go to **Controller Settings**.
2. For the values of settings `eum.jsagent.cdn.host.http` and `eum.jsagent.cdn.host.https`, enter the URLs where the JavaScript Agent files are being hosted.
3. Confirm these URLs match the URLs in the JavaScript snippet you want to inject.

### Configure Self-Hosting

If you are self-hosting and do not want to use the default CDN, follow these instructions to provide your own CDN for hosting all of the JavaScript Agent files:

1. From the **Controller Admin**, go to **Controller Settings**.
2. For the values of settings `eum.jsagent.cdn.host.http` and `eum.jsagent.cdn.host.https`, enter the URLs where the JavaScript Agent files are being hosted.

3. Confirm these URLs match the URLs in the JavaScript snippet you want to inject.

## Next Steps

After you configure the JavaScript Agent, inject the JavaScript snippet in your page HTML with one of these methods:

- [Manual Injection of the JavaScript Agent](#)
- [Automatic Injection of the JavaScript Agent](#)
- [Assisted Injection](#)

See [Overview of Injection Types](#) for differences between the injection methods.

## Add Custom User Data to a Page Browser Snapshot

### Related pages:

- [Page Snapshots](#)

You can add user information that is specific to your application to a browser snapshot. The information is expressed as key-value pairs that are attached the JavaScript Agent configuration and later included in the beacons sent to the EUM Server.

The JavaScript Agent initializes user data differently depending on the page type (base, Ajax, virtual) and the method used (immediately invoked function expressions, function pointers, and literals). See [Methods for Setting Custom User Data](#) to learn when the JavaScript Agent initializes the user data for each page type and method.

The maximum size allowed for user data in a page is 2048 characters (CORS beacon) or 100 bytes (image beacon). The maximum size includes the keys-value pairs, syntax characters such as braces, and quotation marks.

## View Custom User Data

Custom user data appears in **Browser Analyze**, **Browser Snapshots**, and **Sessions**. View the following tabs to learn more about how user data is viewed and used in the Controller UI.

[Browser Analyze](#)   [Browser Snapshots](#)   [Sessions](#)

In this **Browser Analyze** screenshot, the user data vehicleYear is used to sort the records. You can also select fields to view user data.

[Browser Analyze](#) [Browser Snapshots](#) [Sessions](#)

You view user data in the **Session Summary** of the **Session Details** dialog as shown in this screenshot. In sessions, the custom user data is only included when the base page with the custom user data is the first page of the session.

## Methods for Setting Custom User Data

You can use several methods to set custom data for each page type (base, Ajax, virtual). Each method has its own syntax, execution time, and use case. This table outlines the execution time and potential use case for each method and page type.

Method Type	Page Type	Execution Time	Potential Use Cases
Immediately Invoked Function Expressions (IIFE)	Base	These are JavaScript functions that run as soon as they are defined. They're also known as self-executing anonymous functions.	<p>If your base/virtual page or Ajax request depends on information from different resources, you can set static information for custom user data with IIFE.</p> <p>For example, if two different server scripts generate content for the base page, you could use the IIFE on the client to set the static user data.</p>
	Ajax		
	Virtual		

Method Type	Page Type	Execution Time	Potential Use Cases
Function pointers	Base	The JavaScript Agent executes function pointers when the <code>onload</code> event is triggered.	Data extracted from cookies, the page, and meta data.
	Ajax	This event is triggered when an Ajax call is made. Custom user data for the Ajax events are attached to AJAX requests.	Meta data regarding the Ajax request such as the URL, HTTP method, or the request payload.
	Virtual	This event is triggered when the virtual page is created. The virtual page is a dynamically recreated version of the base page, and custom user data set for <code>VPageView</code> events are attached to the virtual page records.	Use if the information is derived or found somewhere on the page because of the creation of the virtual page. User-specific fields or user data set based on the URL and DOM changes.
Literals	Base	You can simply use literal values to set custom data. The values, as with IIFE, are set as soon as the values are defined.	Constants, static data extracted and set on the server.
	Ajax		
	Virtual		

### User Data Types

For each event callback that is triggered, you can add user data by returning objects containing key-value pairs of different data types. Each user data type is an object containing properties of a specific data type.

Make sure the data type correctly matches the key-value pair. If you send the wrong key-value inside the `userData` object, such as adding a date key-value pair in a string data type, you will receive a generic error.

Data Type	Description	Example
<code>userData</code>	This data type is for setting one or more properties of type <code>string</code> . The value must be in a string, even if the value is set to a numeric value.	<pre>{   user: "john_thompson",   cart: "100.00" };</pre>
<code>userDataLong</code>	This data type is for setting one or more properties of type <code>long</code> and must be a numeric value without decimals.	<pre>{   numberOfProducts: 17,   numberOfSales: 1213 };</pre>
<code>userDataDouble</code>	This data type is for setting one or more properties of type <code>double</code> and must be a numeric value with decimals.	<pre>{   monthlyVisitFrequency: 0.13333333,   avgCustomerConversion: 0.0361922 };</pre>
<code>userDataBoolean</code>	This data type is for setting one or more properties of type <code>boolean</code> .	<pre>{   returnCustomer: true,   subscriber: false };</pre>
<code>userDataDate</code>	This data type is for setting one or more properties of type <code>date</code> . The value must be the converted Epoch value of the date.	<pre>{   epoch1: 1448675019877,   epoch2: 1418475982737 };</pre>

### Syntax of User Data Objects

You add user data as objects for each page event to the JavaScript Agent configuration. The base page, Ajax, and virtual pages have the following corresponding user data objects:

- `PageView`
- `Ajax`
- `VPageView`

The `PageView`, `Ajax`, and `VPageView` objects have slightly different syntaxes. `UserPageName` is only available for `PageView` and `VPageView`, and not for `Ajax` and `Error`.

```

userEventInfo: {
 "PageView": function(context) {
 return {
 userPageName: "String"
 userData: {
 userDataOne: "String",
 userDataTwo: "String",
 someKey: "String"
 },
 userDataLong: {
 longPropertyOne: Numeral,
 longPropertyTwo: Numeral,
 someKey: Numeral
 },
 userDataDouble: {
 userDataDoubleOne: Decimal,
 userDataDoubleTwo: Decimal,
 someKey: Numeral
 },
 userDataBoolean: {
 userDataBooleanOne: Boolean,
 userDataBooleanTwo: Boolean,
 someKey: Boolean
 },
 userDataDate: {
 epoch1: Epoch numeral,
 epoch2: Epoch numeral,
 currentTime: ((new Date()).getTime()),
 someKey: ((new Date()).getTime())
 }
 }
 }

 "Ajax" : function(context) {
 if (context.method.toLowerCase() === 'post') {
 var anyKey = "String";
 } else {
 variableName = "String";
 }
 return {
 userData: {
 userDataOne: "String",
 userDataTwo: "String"
 variableName: VariableName
 },
 userDataLong: {
 longPropertyOne: Numeral,
 longPropertyTwo: Numeral
 }
 }
 }
}

```

```

 },
 userDataDouble: {

 }
 }
 }
};

```

## Capture Ajax Data for Setting User Data

When setting user data for the Ajax event, the JavaScript Agent configuration provides a `context` object that has properties for the HTTP method, the request URL, and the request payload of the Ajax request. You can use this information to set values for the user data configuration object.

**i** The JavaScript Agent does not intercept or expose the response from the Ajax request. Thus, you can only include the request information (HTTP method, request URL, and request payload) in the user data that you report.

### Ajax Context Object

To access the URL and HTTP method of the Ajax request, you can simply access the `method` and `url` properties of the `context` object. For the request payload of the Ajax request, you need to first match the payload parameters (HTTP method or Ajax URL) to access the `data` property. See [Match the Ajax Payload Parameters](#) to learn how to define the filters to match the payload parameters.

The `context` object has the following properties:

Property	Description	Data Type	Requirement to Access Property
<code>method</code>	The HTTP method used to make the Ajax request.	string	XHR call
<code>url</code>	The URL used to make the Ajax request.	string	XHR call
<code>data</code>	The request payload attached to the Ajax request.	Any data type that can be passed as the <a href="#">body to <code>xhr.send</code></a> .	<ul style="list-style-type: none"> <li>XHR call</li> <li>XHR filter for the payload parameter</li> </ul>
<code>responseHeaders</code>	The response headers made available with the config, <code>getAjaxResponseHeaders</code> , separated by "   ".	string	<ul style="list-style-type: none"> <li>XHR call</li> <li><code>getAjaxResponseHeaders</code> configured with whichever header names you specified in <code>getAjaxResponseHeaders</code>.</li> </ul>

### Match the Ajax Payload Parameters

To access the request payload, you need to use `xhr.payloadParams` array to match the HTTP method and/or the Ajax URL. To match the Ajax URL, you can specify one or more patterns. To match the HTTP method, you include one or more objects specifying HTTP methods.

In the "Match HTTP Methods" example, the `payloadParams` array is used to match the HTTP methods "POST" and "GET". In the "Matching URLs" example, the `payloadParams` array is used to match URLs with the following string: `.*xhr/uptime'`.

[Match HTTP Methods](#)    [Match URLs](#)

```
<script type = 'text/javascript' charset = 'UTF-8' >
 window['adrum-config'] = {
 xhr: {
 payloadParams: [{
 method: 'POST'
 }, {
 method: 'GET'
 }]
 },
 ...
 }
}
```

Match HTTP Methods [Match URLs](#)

```

window['adrum-config'] = {
 xhr: {
 payloadParams: [{urls: [{pattern: '.*xhr/uptime'}]}]}
 },
 ...
}

```

## Ajax Payload Filter Examples

### Conventional Ajax Requests

In the following examples, the data from a conventional Ajax request payload is used to set custom user data. For capturing the request payload for Fetch API calls, see [Ajax Requests Using the Fetch API](#).

[Match HTTP Methods Example](#) [Match URLs Example](#)

This example only sets the user data configuration objects with data from the Ajax request payload if the HTTP method is `POST`.

```

<script type='text/javascript' charset='UTF-8'>
 window['adrum-config'] = {
 xhr: {
 payloadParams: [{method: 'POST'}]}
 },
 userEventInfo: {
 "Ajax" : function(context) {
 if (context.data && context.data.indexOf("purchase") > -1) {
 // The URLSearchParams API does not work on IE/Edge
 var payload = new URLSearchParams(context.data);
 return {
 userData: {
 username: payload.get("username"),
 email: payload.get("email"),
 phone: payload.get("phone")
 },
 userDataLong: {
 customerId: Number(payload.get("customer_id"),
 totalPurchases: Number(payload.get("total_purchases"))
 },
 userDataDouble: {
 purchaseTotal: Double(payload.get("total"))
 },
 userDataBoolean: {
 discounted: Boolean(payload.get("discounted"),
 vipMember: Boolean(payload.get("member"))
 },
 userDataDate: {

```

```

 purchaseTime: Date.now()
 }
 }
 }
};
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>

```

[Match HTTP Methods Example](#)
[Match URLs Example](#)

This example only sets the user data configuration objects with data from the Ajax request payload if the Ajax URL matches the pattern `".*/transaction"`. For example, the URL `http://example.com/transaction` would match the pattern and cause the user data configuration to be set with data from the Ajax request payload.

```

<script type='text/javascript' charset='UTF-8'>
 window['adrum-config'] = {
 xhr: {
 payloadParams: [{urls: [{pattern: '.*\/transaction'}]}]
 },
 userEventInfo: {
 "Ajax" : function(context) {
 if (context.data && (context.data.indexOf("username") > -1) &&
(context.data.indexOf("customer_id") > -1) && (customer.data.indexOf("phone") > -1)) {
 // The URLSearchParams API does not work on IE/Edge
 var payload = new URLSearchParams(context.data);
 return {
 userData: {
 username: payload.get("username"),
 email: payload.get("email"),
 phone: payload.get("phone")
 },
 userDataLong: {
 customerId: Number(payload.get("customer_id"))
 totalPurchases: Number(payload.get("total_purchases")) || 0
 },
 userDataDouble: {
 purchaseTotal: Number(payload.get("total")) || 0
 },
 userDataBoolean: {
 discounted: Boolean(payload.get("discounted")) || false,
 vipMember: Boolean(payload.get("member")) || false
 },
 userDataDate: {
 purchaseTime: Date.now()
 }
 }
 }
 }
 }
 }
}

```

```

 }
 };
}
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>

```

## Ajax Requests Using the Fetch API

The example below demonstrates how to use the JavaScript Agent configuration to match the HTTP method, the request URL, and the request body for Ajax calls using the Fetch API. The Fetch API call is also provided to add context. The JavaScript Agent **cannot access** the request body, however, if [you supply your own Request object](#) to the `fetch` method.

[Fetch API Call](#) [Match HTTP Method and URL Example](#)

This Fetch API example sets the from the Ajax request payload if the HTTP method is `POST`.

```

<script type='text/javascript' charset='UTF-8'>
 // Note: URLSearchParams() is not supported in IE/Edge
 let queryParams = new URLSearchParams(window.location.search.substr(1));
 fetch('https://my-json-server.typicode.com/typicode/demo/posts', {
 method: 'post',
 body: queryParams.toString()
 }).then(function(response) {
 return response.json();
 }).then(function(data) {
 console.log('Posted content:', data.request_url);
 });
</script>

```

[Fetch API Call](#) [Match HTTP Method and URL Example](#)

This example only sets the user data configuration objects with data from the Ajax request payload if the HTTP method is `POST` and the Ajax URL matches the pattern `"*/posts"`.

```

<script type='text/javascript' charset='UTF-8'>
 window['adrum-config'] = {
 xhr: {
 payloadParams: [{method: 'POST'}, {urls: [{pattern: '*/posts'}]}]
 },
 userEventInfo: {
 "Ajax": function (context) {
 var payload = null;
 if (context.data && (context.data.indexOf("id") > -1) && (context.data.indexOf("
title") > -1)) {
 // The URLSearchParams API does not work on IE/Edge
 payload = new URLSearchParams(context.data).toString();
 }
 }
 }
 };

```

```

 } else if (context.data && context.data.indexOf("id") > -1) {
 // The URLSearchParams API does not work on IE/Edge
 var params = new URLSearchParams(context.data);
 params.set("title", "Post for " + params.get("id"));
 payload = params.toString();
 } else {
 payload = "Payload is not available";
 }
 return {
 userData: {
 username: "xhr_user",
 cart: "218.50",
 payload: payload
 }
 }
 }
};
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>

```

## Ajax responseHeaders Example

The following example show you how to use `getAjaxResponseHeaders`, which takes either a string or an array of strings.

### [Match Ajax Response Headers Example](#)

This example defines the ajax response headers we want to capture, and uses `context.responseHeaders` to populate the `userData` field.

```

<script type='text/javascript' charset='UTF-8'>
 window['adrum-config'] = {
 getAjaxResponseHeaders: ['ResponseHeaderName1', 'ResponseHeaderName2'],
 userEventInfo: {
 "Ajax" : function(context) {
 if (context.responseHeaders) {
 let responseHeaders = context.responseHeaders;
 // Do a regex search on this variable to read from the responseHeader
 string as needed.
 // An example of a returned responseHeader string would be
 // content-type: text/javascript | content-length: 599622
 let header1 = "//Regex saved var here";
 let header2 = "//Regex saved var here";
 return {
 userData: {
 Header1: header1,
 Header2: header2
 }
 }
 }
 }
 }
 }

```

```

 }
 }
}
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>

```

## Custom User Data Examples

The following examples show you how to set custom data for different page types and using the different methods:

- [Setting User Data with Function Pointers](#)
- [Setting User Data with an Anonymous Function](#)
- [Setting User Data with Multiple Methods](#)

### Setting User Data with Function Pointers

The example below assigns a value to the `userPageName` property of the `PageView` object by executing the function `extractUserData`, which extracts data from the cookies.

```

< script type = 'text/javascript'
charset = 'UTF-8' >
 (function (config) {
 (function (info) {
 info.PageView = extractUserData;
 })(config.userEventInfo || (config.userEventInfo = {}))
 })(window['adrum-config'] || (window['adrum-config'] = {}));

function extractUserData() {
 var cookies = document.cookie.split(';');
 for (var i = 0; i < cookies.length; i++) {
 var cookie = cookies[i].trim();
 if (cookie.indexOf("role=") === 0) {
 var role = cookie.substring(5);
 }
 }
 return {
 userPageName: role
 };
} <
/script> <
script src = '//cdn.appdynamics.com/adrum/adrum-latest.js'
type = 'text/javascript'
charset = 'UTF-8' > < /script>

```

### Setting User Data with an Anonymous Function

You can also use anonymous functions that return an object as shown in this example for setting user data for virtual pages.

```
< script type = 'text/javascript'
charset = 'UTF-8' >
 (function (config) {
 (function (info) {
 info.VPageView = function () {
 return {
 userData: {
 version: window.location.href.split("/")[4],
 space: space(),
 email: getEmail()
 },
 userPageName: $('title').get(0).text,
 userDataDate: {
 currentTime: ((new Date()).getTime())
 },
 userDataBoolean: {
 watchingPage: watchingPage()
 }
 }
 }
 })
 })(config.userEventInfo || (config.userEventInfo = {}))
})(window['adrum-config'] || (window['adrum-config'] = {})); <
/script> <
script src = '//cdn.appdynamics.com/adrum/adrum-latest.js'
type = 'text/javascript'
charset = 'UTF-8' > </script>
```

### Setting User Data with Multiple Methods

You might also want to use a combination of literal values, named and anonymous functions as this example does for setting user data for the `Ajax` event. Note, the `context` object is only available for `Ajax` events, and this object has the properties `data` (stores the request payload), `method` (HTTP method used to make Ajax request), and `url` (the Ajax request URL).

```
<script type='text/javascript' charset='UTF-8'>
 (function(config){
 (function(info) {
 info.Ajax = function(context) {
 return {
 userPageName: $('title').get(0).text,
 userData: extractUserData(context)
 userDataBoolean: {
 "visited": true
 }
 }
 }
 });
 })(config.userEventInfo || (config.userEventInfo = {}))
```

```

})(window['adrum-config'] || (window['adrum-config'] = {}));

function extractUserData(context) {
 var cookies = document.cookie.split(';');
 for (var i = 0; i < cookies.length; i++) {
 var cookie = cookies[i].trim();
 if (cookie.indexOf("email=") === 0) {
 var role = cookie.substring(5);
 }
 }
 return {
 role: role,
 url: context.url,
 method: context.method
 };
}
</script>
<script src="//cdn.appdynamics.com/adrum/adrum-latest.js" type='text/javascript' charset='UTF-8'></script>

```

## Set Custom Page Names

### Related pages:

- [Configure Naming for Ajax Requests](#)
- [Configure Virtual Page Naming](#)

This page describes how to set custom page names. In the **Configuration > Instrumentation** page, you can configure rules that name pages, iframes and Ajax requests based on various parts of the page URL. See [Configure Page Identification and Naming](#).

You can also configure the JavaScript Agent to use any arbitrary string, not necessarily a part of the URL, to name a page or an iframe, but not an Ajax request. To do so, you assign a string of 760 characters or less to the `userPageName` property of the `PageView` object. If the string length exceeds 760 characters, the page name will not be set.

For example, this configuration shown below would set the page name to "My Custom Page". That page name would then be used to identify and group pages in the **Pages & AJAX Requests** page in the Controller UI.

```

<head>
 <script type='text/javascript' charset='UTF-8'>
 (function (config) {
 (function (info) {
 info.PageView = {
 userPageName: "My Custom Page"
 }
 })(config.userEventInfo || (config.userEventInfo = {}));
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script src="//cdn.appdynamics.com/adrum/adrum-latest.js" type='text/javascript' charset='UTF-8'></script>

```

```

 </head>

```

The default page name consists of the hostname, port, and path. For example, if the page URL is `http://example.com:8080/yourpath`, the default page name would be `example.com:8080/yourpath`.

## Set Custom Virtual Page Names

### Related pages:

- [Configure Page Identification and Naming](#)
- [Configure Naming for Ajax Requests](#)
- [Configure Virtual Page Naming](#)

This page explains how to create custom virtual page names. Using the API calls below, you can configure the JavaScript Agent to use any arbitrary string (not necessarily a part of the URL) to name a virtual page.

### Requirements

- You must have SPA2 monitoring enabled. See [Configure SPA2 Monitoring](#). If you are using [SPA1 monitoring](#), the method called to set the name the virtual page will be ignored.
- The virtual page name must consist of a string of 760 or fewer alphanumeric characters. If the string length exceeds 760 characters, the page name will not be set.

## Set Custom Names for Pre-existing Virtual Pages

To set a custom name for pre-existing virtual pages, you should use the API call `ADRUM.setVirtualPageName("myCustomVPName")`. This API should be called soon after you make your virtual page by means that the JavaScript Agent can track, such as with the browser API's `history.pushState / history.replaceState` or hash history changes.

For example:

```

head>
 <script charset='UTF-8' type='text/javascript'>
 window['adrum-start-time'] = new Date().getTime();
 (function(config){
 config.appKey = '<EUM_APP_KEY>';
 ...
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script charset='UTF-8' src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/
javascript' ></script>
 <script type='text/javascript' charset='UTF-8'>
 ...
 <!-- Browser API call triggering VP detection --->
 window.history.pushState({}, '', "#myUrlHere");
 <!-- Marking the previous virtual page with a custom name --->
 ADRUM.setVirtualPageName("myCustomVPName");
 </script>
</head>

```

## Set Custom Names for New Virtual Pages

To set a custom name for a new virtual page, use the method `setVirtualPageName` with `ADRUM.command`. The `ADRUM` object is globally accessible after you load the JavaScript Agent (`adrum-latest.js`).

For example:

```
<head>
 <script charset='UTF-8' type='text/javascript'>
 window['adrum-start-time'] = new Date().getTime();
 (function(config){
 config.appKey = '<EUM_APP_KEY>';
 ...
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script charset='UTF-8' src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/
 javascript' ></script>
 <script type='text/javascript' charset='UTF-8'>
 ...
 ADRUM.command("setVirtualPageName", "myCustomVPName");
 </script>
</head>
```

When you name a virtual page with `setVirtualPageName`, the custom name will be applied to the next virtual page you manually mark with `markVirtualPageBegin`. Thus, the virtual page currently being monitored will not get the custom name.

The code example below shows how to call the methods to manually mark the beginning and end of the virtual page as well as execute `setVirtualPageName` to name the next virtual page that is monitored. See [Report Virtual Pages](#) to learn how to manually mark the beginning and end of virtual pages with this JavaScript API.

```
.controller('VPNaming', ['$scope', '$http', function ($scope, $http) {
 $scope.startVirtualPageWithCustomUrl = function () {
 console.log("Marking the beginning of the virtual page and waiting for the
 end to be manually marked.");
 ADRUM.markVirtualPageBegin("homepage", true);
 }
 $scope.startVirtualPageNotWaitingForMarkVirtualPageEnd = function () {
 console.log("Marking the beginning of the virtual page and allowing the JS
 Agent to mark the end of the virtual page.");
 ADRUM.markVirtualPageBegin("homepage", false);
 }
 $scope.endVirtualPage = function () {
 console.log("Manually marking the end of the virtual page.");
 ADRUM.markVirtualPageEnd();
 }
 $scope.setVirtualPageName = function () {
 console.log("Setting a custom name for the next virtual page to be monitored:
 have it's beginning and end marked.");
 ADRUM.command("setVirtualPageName", "myCustomVPName");
 }
}
```

```

 }
 }
];
);

```

## Set Ajax Request Names Based on Captured POST Parameters

### Related pages:

- [Configure Virtual Page Naming](#)
- [Page, Ajax, and Iframe Dashboards](#)
- [Set Custom Page Names](#)

You can configure the JavaScript Agent to capture POST parameters and then use the parameter(s) to name the Ajax request in the **Pages & Ajax Requests** page. This enables you to identify and sort Ajax requests from the same page based on POST parameter(s).

For example, customers on your home page of your website can either register an account or log in. The Ajax request may pass the parameter `action` to reflect one of these user actions. By capturing the `action` parameter, you can differentiate the Ajax requests to monitor performance and debug issues.

### Configure the JavaScript Agent to Capture Parameters

You use the `xhr` object to configure the JavaScript Agent to capture POST parameters. The `xhr` object has the property `parameter` that is used to match resource URLs and define a callback for parsing the request body and return the desired results.

In the example below, the configuration sets a pattern to match the URL `http://www.mystore.com`, parses the request body, and returns an object containing the parameter `action`. As mentioned earlier, you could use a configuration like this to differentiate Ajax requests that are sending requests to register or log in users.

```

<script type='text/javascript' charset='UTF-8'>
 window['adrum-start-time'] = new Date().getTime();
 window['adrum-config'] = {
 xhr: {
 parameter : {
 urls : [{pattern : '^https?:\\/\\/www\\.mystore\\.com'}]},
 getFromBody: function(data) {
 if (typeof data === 'string') {
 var fields = data.split("&");
 for (var i = 0; i < fields.length; i++) {
 var keyAndValue = fields[i].split('=');
 if (keyAndValue.length > 1) {
 var key = keyAndValue[0],
 value = keyAndValue[1];
 if (key === 'action')
 return {action: value};
 }
 }
 }
 }
 }
 }
 }
}

```

```

 }
 }
</script>
<script charset='UTF-8'>
 (function(config){
 config.appKey = '<EUM_APP_KEY>';
 config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
 config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
 config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
 config.beaconUrlHttps = 'https://col.eum-appdynamics.com';
 config.xd = {enable : true};
 })(window['adrum-config'] || (window['adrum-config'] = {}));

 (function (cfg) {
 if (cfg.beacon) cfg.beacon.neverSendImageBeacon = true;
 else cfg.beacon = { neverSendImageBeacon: true };
 })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>

```

## Create an Ajax Include Rule

To name an Ajax request based on a captured request parameter, you need to define an include rule that specifies the captured POST parameter. See [Configure Naming for Ajax Requests](#) to learn how to create include rules for Ajax requests.

The example include rule below uses the full domain and the captured POST parameter to name the Ajax request in the **Pages & Ajax Requests** page. For example, if an Ajax request is made to `www.mystore.com` and the value of the `action` parameter is `register`, the Ajax request will be named `www.mystore.com/register`.

Include Rule
✕

Enabled

**Rule Name**

**Criteria**  
 This Include Rule applies to any URL that

GET 
  POST 
  PUT 
  DELETE

**Name Pages**

Show HTTP Method (GET, POST, PUT, or DELETE)  
 Show Protocol (Ex: http, https, etc)  
 Show Domain (Ex: mywebsite.com)  
 Show Full Domain  Show Sub-domain

**Path Segments**  
 Don't use path segments  
 Use first  segments  
 Use last  segments  
 Use segment numbers  ⓘ

Query String Parameters to use in Page Name (Optional)

POST Parameters to use in Page Name (Optional)

**What part of anchor should be used in Page Name**  
 Don't use the anchor  
 Use first  segments  
 Use last  segments  
 Use segment numbers  ⓘ

## View Results in Pages & Ajax Requests

From the **Pages & Ajax Requests** page, you can view the Ajax requests that are named based on your include rule.

Using the configuration and include rule shown above, you might see the following Ajax request with the name **mystore.com/register**.

Pages & AJAX Requests					
<span>Details</span>   <span>Filters</span>   <span>Actions</span>   <span>View Options</span>		<span>All Pages</span> ▾			
Type	Name	Requests ↓	Requests per Minute	End User Response Time (ms)	
	mystore.com/register	983,613	57	<div style="display: flex; align-items: center;"> <div style="width: 100px; height: 10px; background: linear-gradient(to right, #ccc, #ccc);"></div> <span>70</span> </div>	

## Handle the window.onerror Event

### Related pages:

- [JavaScript Errors](#)
- [Configure JavaScript and Ajax Error Detection](#)
- [Visualize JavaScript Errors](#)

If any script on your monitored web pages, including library code, sets the JavaScript `window.onerror` event, add the following method to the page immediately after setting `window.onerror` :

```
<script>
ADRUM.listenForErrors()
</script>
```

The JavaScript Agent ( `adrum.js` ) sets `window.onerror` to listen for uncaught JavaScript errors. If this listener is overwritten, errors are not reported.

The agent invokes your original `onerror` handler.

## Disable Browser Monitoring Programmatically

### Related pages:

- [Enable and Disable Browser RUM](#)

For pages in which the JavaScript Agent was injected manually, you can disable the agent programmatically by adding a script to the header.

To disable Browser Monitoring add the snippet below before `adrum.js` agent is injected.

```
window["adrum-disable"] = true
```

For example:

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 // before adrum.js
 window["adrum-disable"] = true
```

```

</script>

<script>
 window["adrum-start-time"] = new Date().getTime();
</script>
<!-- adrum.js injection -->
<script src="//cdn.appdynamics.com/adrum/adrum-latest.js" type='text/javascript' charset='
UTF-8'></script>
...
</head>

```

Old Browser Monitoring data is preserved, but no new monitoring data is collected while the agent is disabled.

You can re-enable monitoring by removing the disable script statement.

### Set the Exact Current Domain in the JavaScript Agent Cookie

This page describes how to set the current domain in the JavaScript Agent cookie.

The JavaScript Agent itself writes a session cookie to the page, for timing purposes. This cookie is set when the user clicks a link and the `unload` event is fired. By default, the cookie is set to the broadest possible version of the originating domain (such as, `*.domain.com`) to increase the likelihood that the next page opened in the same domain can access that cookie. See [Cookies and Browser Monitoring Data](#).

In some cases, however, it may be necessary to limit the cookie to the full exact domain name. To do this, add a flag in the `"adrum-start-time"` script to the header of each page right *after* the `<head>` tag and *before* the entry that includes the location of the agent (`adrum.js`). The flag should read:  
`window["adrum-use-strict-domain-cookies"] = true;`

After you include the start-time line, the strict domain flag, and the agent, the `<head>` section in your monitored web pages should look something like this:

```

<head>
 <script type='text/javascript' charset='UTF-8'>
 window["adrum-start-time"] = new Date().getTime();
 window["adrum-use-strict-domain-cookies"] = true;
 </script>
 <script src="//cdn.appdynamics.com/adrum/adrum-latest.js" type='text/javascript' charset='
UTF-8'></script>
 ...
</head>

```

### Limit Beacon Types

#### Related pages:

- [Alter or Eliminate the Page Title Captured in the Beacon](#)

The JavaScript Agent collects and sends information to the EUM Server via a beacon, either through Cross-Origin Resource Sharing (CORS) or an image beacon which returns a small, transparent `.gif` file.

If you want the agent to only use CORS to transport the beacon, you can turn off the image beacon request mechanism. To turn off the image beacon request, add the following snippet to your HTML preceding the injected `adrum.js` script:

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 (function (cfg) {
 if (cfg.beacon) cfg.beacon.neverSendImageBeacon = true;
 else cfg.beacon = { neverSendImageBeacon: true };
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>
 ...
</head>
```

## Alter or Eliminate the Page Title Captured in the Beacon

### Related pages:

- [Limit Beacon Types](#)
- [Set Custom Page Names](#)

In a standard Browser RUM beacon, the value for `document.title` is collected as part of the data to be sent in the beacon. You may want to alter or eliminate the page title for security or privacy reasons.

You can choose to:

- Not collect a page title at all
- Use a title that is created by a function with 0 arguments
- Use a title that is an arbitrary string

**i** The page title is different than the page name. The page title is just additional information included in browser snapshots, whereas, the page name is used to identify and group records in the **Pages & AJAX Requests** page.

## Remove a Page Title

To remove the page title entirely, add the following snippet to your page before you inject the `adrum.js` script:

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 (function (config) {
 (function (page) {
 page.captureTitle = false;
 })(config.page || (config.page = {}));
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>
```

```
...
</head>
```

## Use a Page Title Created by a Function

To use a function with no arguments to create a page title, before you inject the `adrum.js` script, define your function and call it, as in this example:

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 function title() { return document.title.split('-').slice(1,3).join('-'); } // define
 a function
 (function (config) {
 (function (page) {
 page.title = title; // call your function
 })(config.page || (config.page = {}));
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
 UTF-8' />
 ...
</head>
```

Something like this could be used, for example, to remove sensitive data from the page title.

## Use an Arbitrary String as a Page Title

To use any arbitrary string as the page title, before you inject the `adrum.js` script, set `page.title`.

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 (function (config) {
 (function (page) {
 page.title = "My Special Page Title";
 })(config.page || (config.page = {}));
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
 UTF-8'></script>
 ...
</head>
```

This would set the page title in the beacon to "My Special Page Title".

## Modify Resource Sampling Options

### Related pages:

- [Page Browser Snapshots](#)
- [Capture Resource Timing Data Without Loss](#)

Some pages use a very large number of resource files, more than can usefully be monitored. By default, the JavaScript Agent decides which resource files to monitor based on two factors:

- How the resources are ordered (the sampling algorithm used)
- The maximum number of resources to be evaluated

Both of these factors can be modified.

To modify the sampling algorithm, use `resTiming.sampler`. Possible values are:

- Top N: the resources that take the most time to load, up to the maximum number
- First N: the resources that load first, up to the maximum number
- Relevant N: the resources that are deemed "most relevant" by an algorithm that takes into account both overall load time and when in the sequence the resource loads. So, for example, something that takes a long time to load and is early in the load sequence is "more relevant" than something that takes exactly the same time to load, but does so later in the sequence, on the assumption that the former would have more impact on the overall user experience. This is the default.

To modify the maximum number of resources to be evaluated, use `resTiming.maxNum`.

For example, to sample based on Top N and to set the max number at 100, you could add the following snippet to your page, *before* you inject the `adrum.js` script.

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 (function (config) {
 config.resTiming = {
 sampler: "TopN",
 maxNum: 100
 };
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
 ...
</head>
```

## Set the Origin Location of the Request

### Related pages:

- [Geo Dashboard](#)

There are some cases where it would be useful to be able to set a specific IP address/location as the origin of the request by modifying the JavaScript Agent itself. Add the following snippet to your page, before you inject the `adrum.js` script:

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 window['adrum-config'] = (function(config) {
 config.geo = {
 localIP: "192.168.200.255",
 city: "San Francisco",
 region: "California",
 country: "USA"
 };
 return config;
 })(window['adrum-config'] || {});
```

```

</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>
</head>

```

You can use this snippet in two ways:

- Specify only the IP address, in which case this IP address has the highest precedence for use by the geo server, local or cloud-based, in resolving the request location.
- Specify all of IP, `country`, `region`, and `city`, in which case the request location is set by the script, and is not resolved by the Geo Server.

If you specify only some of the location parameters, the entire configuration is ignored. For example, if you only specified `country`, but not `region`, the entire configuration is ignored.

The value for `city` is only displayed in snapshots and can be any string. Using this value it is possible to specify location more precisely, as desired, for example, `San Francisco, Sutter Street`.

### Hide All or Parts of the URL Query String

#### Related pages:

- [Configure Resource URL Segments](#)

By default, we capture URLs with their query strings. Because query strings may result in very long URLs or contain information that you don't want to expose, you may want to prevent all or parts of the query string from being displayed in the Controller UI.

You can do this by configuring the JavaScript Agent to remove query strings from URLs for the following:

- pages
- virtual pages
- XHR calls
- referrers
- scripts
- resources

### Filter for URL Query Strings

The filter `filterURLQuery` is used to remove query strings from URLs. You can use it to remove all query strings or specific key-value pairs from query strings. The table below specifies the supported values and describes the result of the filter.

Filter	Value	Default	Description
<code>filterURLQuery</code>	<code>true</code>	No	Removes query strings from all URLs.
<code>filterURLQuery</code>	<code>false</code>	Yes	Retains the query strings for all URLs.

Filter	Value	Default	Description
filterURLQuery	array of strings	No	Each string represents a key in the query string. The given keys are removed from the query string. Strings that do not match keys in the query string will have no effect on the filtering.

**i** Unsupported values will result in the default behavior of retaining the entire query string for all URLs.

### Remove All Query Strings

The configuration below will remove all URL query strings, so you'll only see the domain name and the URL path in the Controller UI.

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 (function (config) {
 config.urlCapture = {
 filterURLQuery: true
 }
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>

</head>
```

### Remove Specific Keys From Query Strings

This configuration will remove the key-value pairs from the query string where the keys match the strings "name", "page", and "id" given in the array.

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 (function (config) {
 config.urlCapture = {
 filterURLQuery: ["name", "page", "id"]
 }
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
</head>
```

## Configure the JavaScript Agent to Use HTTPS

### Related pages:

- [Limit Beacon Types](#)
- [Enable the Content Security Policy \(CSP\)](#)

By default, the JavaScript Agent chooses the same transport (protocol) used to load the base page, but you can configure the JavaScript Agent to use HTTPS for a more secure network connection.

When configured to use HTTPS, the JavaScript Agent will use HTTPS to do the following:

- fetch `adrum-ext.js`
- fetch geolocation data

### Set the useHTTPSAlways Flag

Following the code example below, you can set the boolean `useHTTPSAlways` to `true` to configure the JavaScript Agent to always use HTTPS.

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 (function(cfg) {
 cfg.useHTTPSAlways = true;
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script src='https://cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript'
 charset='UTF-8'></script>
 ...
</head>
```

## Configure Resource URL Segments

### Related pages:

- [Hide All or Parts of the URL Query String](#)

This page covers how to configure URL segments for resources. To configure page URLs, see [Set Custom Page Names](#).

When the number of segments or the length of a segment exceeds the default maximum, the URL will appear truncated in the Controller UI. For example, the resources shown in the Resource Details tab or the **Session Details** dialog may display truncated because of the number of URL segments or the length of the segments in the URL.

You can set configurations for the JavaScript Agent that set the maximum number of segments and the maximum number of characters for each segment. This allows you to view more or even less of the resource URLs in the Controller UI.

### Segment Definition

A segment is a fragment of a URL. The following constitute one segment:

- `<protocol>://<domain-name>:<port>`
- `?key=value&key=value` (query string)
- `#someAnchor` (anchor)
- `/file-path/` (file path specified between two forward slashes)

For example, this URL consists of five segments: `http://example.com:8090/a/b.html#someAnchor?test=true&segments=5`

## Truncation Rules and Examples

The maximum number of segments determines how many segments will be displayed in the Controller UI. The last segment will always be shown, and then the first  $n$  number of segments until the maximum number is reached.

For example, if the original URL is `http://example.com:8090/a/b.html#someAnchor?test=true&segment=5` and the configured maximum number of segments is 3, then the Controller UI would display the following: `http://example.com:8090/a/...?test=true&segment=5`

The maximum length of segments determines how many characters of a segment will be displayed in the Controller UI. The truncation rules are slightly more complicated as they depend on the type of segment:

- For the segment `<protocol>://<domain-name>:<port>`, the `<protocol>` and `<port>` are displayed, and if the remaining amount of the maximum length is greater than the length of `<domain-name>`, then the entire domain name is displayed. If the remaining amount of the maximum length is less than the length of `<domain-name>`, then the Controller UI would only display `http...8090`.
- For query strings, anchors, and file paths, the first character (`?`, `#`, `/`) is displayed as well as the last  $n$  number of characters until the maximum length is reached. For example, for the segment `?test=true&segment=5`, if the maximum length is 10, then the segment will be displayed as the following: `?...segment=5`

## Default Values for Segments

The variable for setting the maximum number of segments to display is `maxResUrlSegmentNumber`. The variable for setting the maximum length of segments is `maxResUrlSegmentLength`.

The following are the default values for the two variables:

- `maxResUrlSegmentNumber=10`
- `maxResUrlSegmentLength=64`

## Set the Maximum Number of Segments

The code snippet below sets the maximum number of segments to display at 15.

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 (function(config){
 config.maxResUrlSegmentNumber = 15;
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>
 ...
</head>
```

## Set the Maximum Length of Segments

The code snippet below sets the maximum number of characters of segments to display at 100.

```

<head>
 <script type='text/javascript' charset='UTF-8'>
 (function(config){
 config.maxResUrlSegmentLength = 100;
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
 UTF-8'></script>
 ...
</head>

```

## Exclude Virtual Pages from Being Monitored

You can exclude virtual pages from being monitored based on the virtual pages' URLs. You define `exclude` filters to match URLs of virtual pages that you don't want to be monitored. You cannot, however, exclude virtual pages that you are [manually reporting with the SPA2 JavaScript API](#).

### Virtual Page Object

The `vp` object contains the `exclude` filter that specifies an array of patterns to match the URLs of virtual pages to exclude. By defining an `exclude` filter, you automatically [enable SPA2 monitoring](#).

```

"spa": {
 "spa2": {
 "vp": {
 "exclude": {
 "urls": [{"pattern": 'api'}, {"pattern": "resources"}]
 }
 }
 }
}

```

### Virtual Page Filter Example

To use the virtual page filter, you set the JavaScript Agent with the `exclude` filter before you inject the `adrum.js` script.

For example, in the code snippet below, the pattern would match and exclude all virtual pages with URLs that have the strings "contact", "api", or "api" followed by one or more characters.

```

<head>
 <script type='text/javascript' charset='UTF-8'>
 (function(config){
 config.spa = {
 spa2: {
 vp: {
 exclude: {
 "urls": [{"pattern": "contact"}, {"pattern": "api*"}]
 }
 }
 }
 }
 })
 </script>

```

```

 };
 })(window["adrum-config"] || (window["adrum-config"] = {}));
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
 UTF-8'></script>
 ...
</head>

```

## Set the Number of Ajax Requests

### Related pages:

- [Ajax Dashboard](#)
- [Ajax Request Snapshots](#)
- [Configure Naming for Ajax Requests](#)
- [Configure JavaScript and Ajax Error Detection](#)

This page covers how to set the number of Ajax Requests.

By default, the JavaScript Agent limits the Ajax requests (using XHR or the Fetch API) sent for base or virtual pages. The limit is 250 requests for single-page applications (SPAs) and 50 for non-SPAs. Although base or virtual pages normally do not send large amounts of Ajax requests, in some cases, a page may send redundant Ajax requests, especially those containing error reports.

For example, a series of redundant Ajax requests containing a dead loop of errors and exceptions with no new information could overload the EUM Server. To prevent an overload of Ajax requests, you can configure the JavaScript Agent to limit the number of Ajax requests sent for base and virtual pages.

## Set the Number of Ajax Requests

The code example below limits the number of Ajax request per base or virtual page to 7.

```

<head>
 <script type='text/javascript' charset='UTF-8'>
 window["adrum-start-time"] = new Date().getTime();
 window['adrum-config'] = {
 xhr: {
 maxPerPageView: 7
 }
 };
 ...
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
 UTF-8'></script>
 ...
</head>

```

## Set an Unlimited Number of Ajax Requests

For use cases where all Ajax requests for a page need to be captured, you can configure the JavaScript Agent to report an unlimited number of Ajax requests per page with the configuration `xhr.maxPerPageView`.

**i** To prevent an overload of Ajax requests, it is highly recommended to only use this configuration for use cases when you absolutely need to capture all Ajax requests.

The following code example configures the JavaScript Agent to report an unlimited number of Ajax requests per page:

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 window["adrum-start-time"] = new Date().getTime();
 window['adrum-config'] = {
 xhr: {
 maxPerPageView: "UNLIMITED"
 }
 };
 ...
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
 ...
</head>
```

### Capture Resource Timing Data Without Loss

Most browsers stop capturing resource timing data in a page when the number of resources reaches 150 because of the limit set by the [Resource Timing API](#). You can configure the JavaScript Agent for conventional web pages (non-single page applications) and single-page applications (SPAs), however, to overcome this limitation.

**i** For Internet Explorer, you currently *cannot* use the JavaScript Agent configuration above to override the Resource Timing API's default limit of resources returned by the browser.

Because the JavaScript Agent configuration is different for non-SPA and SPA, see these sections for details and instructions:

- [Set and Clear the Resource Timing Buffer for Non-SPAs](#)
- [Disable the Clearing of the Resource Timing Buffer for SPAs](#)

### Set and Clear the Resource Timing Buffer for Non-SPAs

For non-SPAs, you can configure the JavaScript Agent to use a buffer to capture resource timing data and then set a flag to clear the buffer once the beacon has transmitted the resource timing data to the EUM Server. Clearing the buffer clears the browser's resource buffer array and ensures that new resources will be sent in the next beacon.

**i** Overriding the Resource Timing API and clearing the buffer may affect JavaScript code on your page that is using the Resource Timing API. Thus, the JavaScript Agent uses the default set by the Resource Timing API unless you override the default by configuring the JavaScript Agent to set and clear the resource timing buffer.

### JavaScript Configuration Example

The `resTiming` object is used for configuring the buffer size (maximum number of resources to return) and whether the buffer is reset once the beacon is transmitted to the EUM Server. The code snippet below shows you how to specify the buffer size and set the flag for clearing the buffer with the properties `bufSize` and `clearResTimingOnBeaconSend`.

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 window['adrum-config'] = {
 resTiming: {
 bufSize: 200,
 clearResTimingOnBeaconSend: true
 }
 };
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
</head>
```

### Disable the Clearing of the Resource Timing Buffer for SPAs

For SPAs, the JavaScript Agent by default clears the resource timing buffer after it's full and saves the data in a local buffer. You can configure the JavaScript Agent so that the resource timing buffer is not cleared to capture resource timing data.

**i** If the resource timing buffer is not cleared, the resource timing correlation may miss some resources due to the buffer limit of the browser.

### JavaScript Configuration Example

The default for `clearResTiming` is `true`. Setting `clearResTiming` to `false`, as shown below, disables the automatic clearing of the resource timing buffer. The resource timing buffer for virtual pages will also not be cleared.

```
window['adrum-config'] = {
 ...
 "spa": {
 "spa2": {"clearResTiming": false}
 }
}
```

## Filter XHR Calls by URLs

### Related pages:

- [Set the Number of Ajax Requests](#)
- [Configure Naming for Ajax Requests](#)
- [Configure Which Ajax Requests Are Sent to the Events Service](#)

If you have many XHR calls (using XMLHttpRequest or the Fetch API) from your page that you do not need to monitor, you can use XHR filters so that the Agent only monitors a regex-defined list of specified calls.

When XHR calls are monitored, the absolute path of the XHR calls is provided to the JavaScript Agent. In the Controller UI, those monitored XHR calls will be displayed as configured by naming rules. If there are no naming rules, the absolute path of the XHR call is displayed.

### XHR Filters

You can use the XHR filters below to include or exclude XHR calls. The filters can be in the form of an XHR filter object or an array of XHR filter objects.

- `xhr.include`
- `xhr.exclude`

### Filter Object Structure

The XHR filter object has two properties: `urls` and `method`. The `urls` property is an array of objects containing a `pattern` property that specifies a regular expression for matching URLs. The `method` property is a string that specifies an HTTP method. You can use one or both of the properties. If you only use the `urls` array, the matched URLs will be either included or excluded for all HTTP methods. If you only specify `method`, all calls using the specified HTTP method will be either included or excluded.

The following is the general structure for the filter object:

```
{
 urls:
 [
 {
 pattern: ".*foo.*"
 },
 {
 pattern: ".*bar.*"
 }
],
 method: 'GET'
}
```

### XHR Filter Example

To use XHR filters, you must assign XHR filters to `xhr.include` and `xhr.exclude` before you inject the `adrum.js` script. It's important to note that the exclude patterns override the include patterns, so those URLs that are matched by both the include and exclude patterns will ultimately be excluded.

For example, in the code snippet below, the include pattern would match all HTTP requests to `http://somedomain/app_status/user-profile.jsp`, but the exclude pattern would exclude POST calls to that URL.

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 (function(config){
 (function(xhr) {
 xhr.include = {
 urls: [
 {
 pattern: ".*ajax_info.txt"
 },
 {
 pattern: ".*app_status.*"
 }
]
 };
 xhr.exclude = {
 urls = [
 {
 pattern: ".*user-profile.*"
 }
],
 method: "POST"
 };
 })(config.xhr || (config.xhr = {}));
 })(window["adrum-config"] || (window["adrum-config"] = {}));
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
 ...
</head>
```

## Report Events with the JavaScript API

The JavaScript API enables you to manually report events to the agent so that that it can time the various parts of your virtual page loads and correlate Ajax calls to those page loads. You can also capture and report errors using this API.

### Notify the Agent of Events

Events are reported to the JavaScript Agent (ADRUM) by calling the `ADRUM.report` method and passing in an event tracker object.

API	Description
<code>ADRUM.report(tracker: eventTracker);</code>	Notifies the agent of an event.

## Report Virtual Pages

### SPA1 Monitoring

For [SPA1 monitoring](#), use the event tracker [VPageView](#) to manually report virtual pages.

### SPA2 Monitoring

You are required to [enable SPA2 monitoring](#) to use the API below to manually report virtual pages for SPAs. These APIs will also work in non-SPAs if you enable SPA2 monitoring.

To report virtual pages, you mark the beginning and end of virtual pages with the methods below. Both methods are called from the `ADRUM` object. See also [Set Custom Virtual Page Names](#).

API	Parameter(s)	Default Value	Descriptions
<code>markVirtualPageBegin</code> (VPName: string, manuallyMarkVPEnd?: boolean)	VPName	N/A	Used to set the label for the virtual page. This label will be displayed in the Controller UI.  The virtual page name must consist of a string of 760 or fewer alphanumeric characters.  If the string length exceeds 760 characters, the page name will not be set.
	manuallyMarkVPEnd	true	A flag that indicates whether you or the JavaScript Agent mark the end of the virtual page.  When set to true, you need to call <code>markVirtualPageEnd</code> to report the virtual page.  When set to false, the JavaScript Agent will automatically mark the end of the virtual page.
<code>markVirtualPageEnd</code> )	N/A	N/A	Calling this method marks the end of the virtual page and triggers the JavaScript Agent to send a beacon with the virtual page information.

### How the API Works

The steps below describe the process of manually reporting virtual pages with the API:

1. Start monitoring a virtual page by manually marking the beginning of the virtual page with `ADRUM.markVirtualPageBegin(VPName, manuallyMarkVPEnd)`.

2. A beacon with the set virtual page name is sent to the EUM Server. If `manuallyMarkVPEnd` is set to `true`, the JavaScript Agent will wait for you to call `ADRUM.markVirtualPageEnd` to report the virtual page. If `manuallyMarkVPEnd` is set to `false`, the JavaScript Agent will automatically mark the end of the virtual page.
3. You either call `ADRUM.markVirtualPageEnd()` to mark the end of the virtual page or the JavaScript Agent automatically marks the end of the virtual page.
4. The JavaScript Agent reports the virtual page metrics to the EUM Server.

### Example of Reporting Virtual Pages

The Angular example below shows both ways to mark the beginning of a virtual page. The function `manualMarkVPEnd` calls `ADRUM.markVirtualPageBegin` that uses the default requiring you to manually mark the end of the virtual page. The function `allowJSAGENTMarkVPEnd` passes the value `false` as the second parameter, so that the JavaScript Agent will automatically mark the end of the virtual page for you.

```
angular.module('myApp.controllers', [])
 .controller('VPCtrl', ['$scope', '$http', function ($scope, $http) {
 $scope.manualMarkVPEnd = function () {
 console.log("Mark the beginning of the virtual page and wait for
markVirtualPageEnd() to be called.");
 ADRUM.markVirtualPageBegin("VPEXample-ManuallyMarkEnd");
 }
 $scope.allowJSAGENTMarkVPEnd = function () {
 console.log("Mark the beginning of the virtual page and allow the JS Agent to
mark the virtual page end.");
 ADRUM.markVirtualPageBegin("virtualPageExample-JSAGENTMarksEnd", false);
 }
 $scope.endVirtualPage = function () {
 console.log("Mark the end of the virtual page.");
 ADRUM.markVirtualPageEnd();
 }
 ...
 }
]);
```

### Report Events

Events are reported to the agent using event trackers. There are three different kinds of event trackers:

Event Tracker	Enabled for SPA2 Monitoring?	Description
<a href="#">VPageView</a>	No	Used to track the stages of a virtual page view.
<a href="#">Ajax</a>	Yes	Used to track Ajax requests.

Event Tracker	Enabled for SPA2 Monitoring?	Description
Error	Yes	Used to track errors.

### Common Properties

There are also two properties that are common to all tracker types:

- Gets or sets a URL

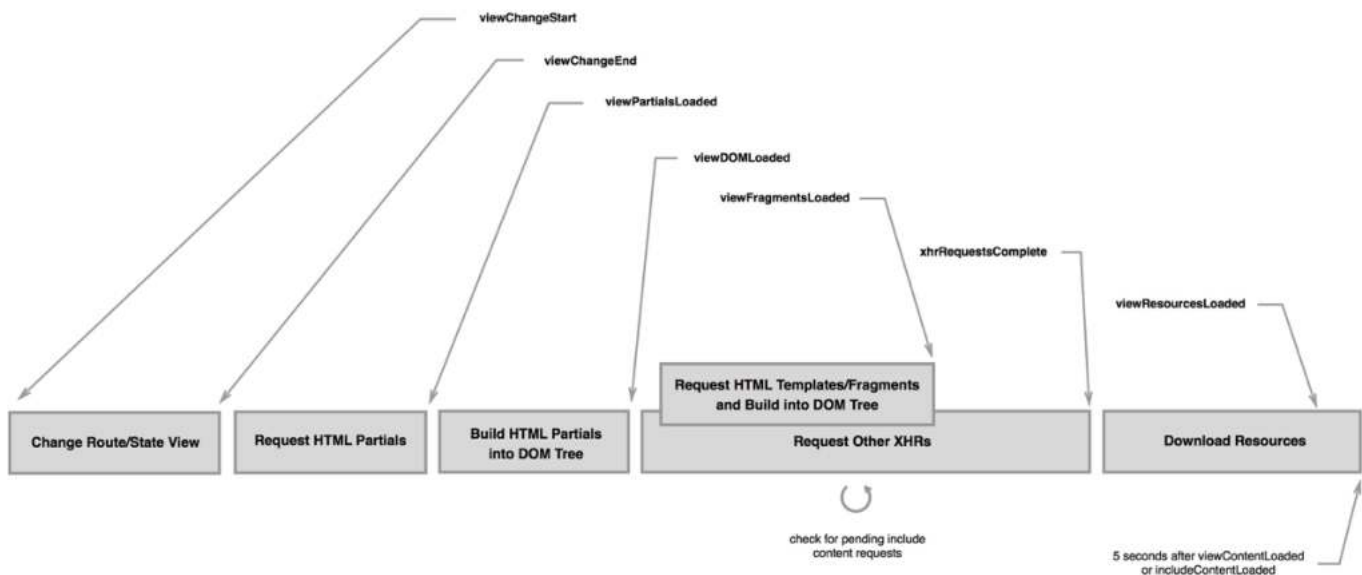

API	Description
<code>url(url?: string)</code>	Gets or sets a URL.

- Gets or sets the parent event identifier

API	Description
<code>parent(parent?: object)</code>	Gets or sets the parent event identifier.

### VPageView

The following is the page view load flow in SPA1 monitoring. You'll use the SPA1 monitoring API below to set timing marks to match the below workflow as closely as possible in your own single page app framework. For SPA2 monitoring, see [Report Virtual Pages: SPA2 Monitoring](#) to learn about the SPA2 APIs for manually reporting virtual pages.

Based on the marks you set, AppDynamics derives the following key timing metrics. Marks should be called in the order in which they occur in the flow. The following table describes which marks used to calculate each metric.

Full Metric Name	Short Metric Name	How Calculated
End User Response Time (not used for waterfall UI)	PLT	virtualPageStart to virtualPageEnd
HTML Download Time	DDT	viewChangeStart to viewChangeEnd
HTML Download and DOM Building Time	DRT	viewChangeStart to viewDOMLoaded
DOM Building Time	DPT	viewChangeEnd to viewDOMLoaded
DOM Ready Time (used instead of PLT for waterfall UI)	DOM	viewChangeStart to viewDOMLoaded

Instantiate using `ADRUM.events.VPageView()`.

API	Description
<code>start()</code>	Indicates when a virtual page starts. It automatically calls: <ul style="list-style-type: none"> <li><code>startCorrelatingXhrs()</code></li> <li><code>markVirtualPageStart()</code></li> </ul>
<code>end()</code>	Indicates when a virtual page ends. It automatically calls: <ul style="list-style-type: none"> <li><code>stopCorrelatingXhrs()</code></li> <li><code>markVirtualPageEnd()</code></li> </ul>
<code>startCorrelatingXhrs()</code>	Correlates the Ajax requests sent after this call with the virtual page view event. The last tracker calling this method wins. <div style="border: 1px solid #00aaff; padding: 5px; margin-top: 10px;"> <p><b>i</b> This method is called automatically in the <code>VPageView</code> constructor. When a <code>VPageView</code> is created, the AJAX requests made after that call are automatically correlated to that <code>VPageView</code>. Use this separate call only when you want to set up <a href="#">manual correlation</a>.</p> </div>
<code>stopCorrelatingXhrs()</code>	Stops correlating Ajax requests to the virtual page view event. <div style="border: 1px solid #00aaff; padding: 5px; margin-top: 10px;"> <p><b>i</b> Use this separate call only when you wish to set up <a href="#">manual correlation</a>.</p> </div>

API	Description
<b>Setters</b>	The default value for these is the time when the API is called.
<code>markViewChangeStart()</code>	Sets the view change start time.
<code>markViewChangeEnd()</code>	Sets the view change end time.
<code>markViewDOMLoaded()</code>	Sets the view DOM loaded time.
<code>markXhrRequestsCompleted()</code>	Sets the XHR requests completed time.
<code>markViewResourcesLoaded()</code>	Sets the view resources loaded time. This includes images, CSS files, and scripts.
<code>markVirtualPageStart()</code>	Sets the virtual page start time.
<code>markVirtualPageEnd()</code>	Sets the virtual page end time.
<b>Getters</b>	
<code>getViewChangeStart()</code>	Gets the view change start time.
<code>getViewChangeEnd()</code>	Gets the view change end time.
<code>getViewDOMLoaded()</code>	Gets the view DOM loaded time.
<code>getXhrRequestsCompleted()</code>	Gets the XHR requests completed time.
<code>getViewResourcesLoaded()</code>	Gets the view resources loaded time.
<code>getVirtualPageStart()</code>	Gets the virtual page start time.
<code>getVirtualPageEnd()</code>	Gets the virtual page end time.

## Ajax

Instantiate using `ADRUM.events.Ajax()`.

API	Description
<b>Property Setters/Getters</b>	Call this without a parameter to get the value and with a parameter to set the value.

API	Description
<code>method(method?: string)</code>	Gets or sets the method ("GET" or "POST") of the Ajax.
<b>Timing Setters</b>	The default value for these is the time when the API is called.
<code>markSendTime(sendTime?: number)</code>	Sets the time the request is sent.
<code>markFirstByteTime(firstByteTime?: number)</code>	Sets First Byte Time.
<code>markRespAvailTime(respAvailTime?: number)</code>	Sets Response Available Time.
<code>markRespProcTime(RespProcTime?: number)</code>	Sets the time the response is completely processed.
<b>Timing Getters</b>	
<code>getSendTime()</code>	Gets the time the request was sent.
<code>getFirstByteTime()</code>	Gets First Byte Time.
<code>getRespAvailTime()</code>	Gets Response Available Time
<code>getRespProcTime()</code>	Gets the time the response was completely processed.

## Errors

Instantiate using `ADRUM.events.Error()`.

API	Description
<b>Property Setters/Getters</b>	Call these without a parameter to get the value and with a parameter to set the value.
<code>msg(msg?: string)</code>	Gets or sets the error message.
<code>line(line?: number)</code>	Gets or sets the line number of source code where the error happened.

## Correlate Ajax Requests

Ajax requests can be correlated to virtual page views automatically or manually. When you create a vPageView tracker, `startCorrelatingXhrs()` is called automatically in the constructor, correlating any subsequent Ajax calls with that VPageView event. To set up manual correlation, call `stopCorrelatingXhrs()` to stop the automatic process and then call `startCorrelatingXhrs()` where you wish correlation to re-commence.

### Sample Code

#### Report a custom Error event by passing properties via setters

```
var errorT = new ADRUM.events.Error();
errorT.msg('I am a custom error at line 100');
errorT.line(100);
ADRUM.report(errorT);
```

#### Report a custom Error event by passing properties via the constructor

```
var errorT = new ADRUM.events.Error({
 msg: 'I am a custom error at line 100',
 line: 100
});
ADRUM.report(errorT);
```

#### Report a custom Ajax event passing properties via setters

```
var ajaxT = new ADRUM.events.Ajax();

// set url
ajaxT.url('your xhr Url');

// mark timings
ajaxT.markSendTime(100);
ajaxT.markFirstByteTime(200);
ajaxT.markRespAvailTime(300);
ajaxT.markRespProcTime(400);
ADRUM.report(ajaxT);
```

#### Set up backbone SPA monitoring

```
var AppRouter = Backbone.Router.extend({
```

```

routes: {
 "wines/:id": "wineDetails"
},
wineDetails: function (id) {
 var vpView = new ADRUM.events.VPageView();
 vpView.markVirtualPageStart();
 // vpView.markViewChangeStart();
 var wine = new Wine({id: id});
 wine.fetch({success: function(){
 vpView.markXHRRequestsCompleted();
 $("#content").html(new WineView({model: wine}).el);
 vpView.markViewDOMLoaded();
 vpView.markVirtualPageEnd();
 ADRUM.report(vpView);
 }});
 this.headerView.selectMenuItem();
}
});

```

### Correlate Ajax requests with VPageView Events

```

var vPageView = new ADRUM.events.VPageView({
 url: 'http://localhost/#virtualpage1',
});

vPageView.start();

// SPA view routing and HTML partials fetching
vPageView.markViewChangeStart()
// AJAX requests for the HTML partials are automatically correlated with the VPageView
...
vPageView.markViewChangeEnd();

// HTML partials inserted into Browser DOM tree
...
vPageView.markViewDOMLoaded();

// SPA HTML AJAX data fetching
// Data AJAX requests are automatically correlated with the VPageView
...

vPageView.markXHRRequestsCompleted();

// call this when ending a new virtual page
vPageView.end();

ADRUM.report(vPageView);

```

You can exclude certain Ajax calls from being monitored by configuring ADRUM itself. Before you invoke the `adrum.js` script at the top of your page, add lines similar to the following:

### Exclude Ajax from VPageView using ADRUM configuration

```

window['adrum-config'] = {
 "spa": {
 "angular": {
 "vp": {
 "xhr": {
 "exclude": {
 "urls": [{
 "pattern": 'heartBeatAjax'
 }]
 }
 }
 }
 }
 }
}

```

Or you can exclude certain Ajax calls using the `vPageView.stopCorrelatingXhrs()` call, and then turn correlation back on with `vPageView.startCorrelatingXhrs()`, as in the following:

### Exclude Ajax from VPageView event manually

```

var vPageView = new ADRUM.events.VPageView();
vPageView.stopCorrelatingXhrs();

var xhr = new XMLHttpRequest();
xhr.open('GET', '/heartBeatAjax');
xhr.send();

vPageView.startCorrelatingXhrs();

```

## Disable Monitoring of Fetch API Calls

By default, the JavaScript Agent reports Ajax requests made with XMLHttpRequest object (XHR) and the Fetch API.

You should only consider disabling monitoring support for the Fetch API for these use cases:

- You just started using the JavaScript Agent 4.5.6 and start to see JavaScript errors caused by asynchronous Ajax requests.
- Your browser app uses one of the libraries which modifies Javascript Promise:
  - [Bluebird](#)
  - [shim.js](#)
  - [Zone.js](#)

**i** If you use the zone.js library, you can still enable monitoring for the Fetch API by adding `isZonePromise = true` and `config.fetch = true` to your JavaScript snippet:

[SPA](#) [Non-SPA](#)

```
<script type='text/javascript' charset='UTF-8'>
 (function(config){
 config.fetch = true; // This is the default
 setting.
 config.isZonePromise = true;
 config.spa = {
 "spa2": true
 };
 })(window['adrum-config'] || (window['adrum-config'] =
 {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js'
 type='text/javascript' charset='UTF-8'></script>
```

[SPA](#) [Non-SPA](#)

```
<script type='text/javascript' charset='UTF-8'>
 (function(config){
 config.fetch = true;
 config.isZonePromise = true;
 })(window['adrum-config'] || (window['adrum-config'] =
 {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js'
 type='text/javascript' charset='UTF-8'></script>
```

## Disable Monitoring of Fetch API Calls

To disable monitoring for the Fetch API, add `config.fetch = false` to your JavaScript snippet:

[SPA](#) [Non-SPA](#)

```
<script type='text/javascript' charset='UTF-8'>
 (function(config){
 config.fetch = false;
 config.spa = {
 "spa2": true
 };
 })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
```

```
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
```

 SPA [Non-SPA](#)

```
<script type='text/javascript' charset='UTF-8'>
 (function(config){
 config.fetch = false;
 })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
```

## Disable the JavaScript Agent at Runtime

If you need to disable the JavaScript Agent at runtime, you must stop the agent from sending data to the EUM server. The agent sends data to the EUM Server through beacons, so you must use the `pauseReporting()` JavaScript API to stop sending beacons.

### Stop Sending Beacons

To stop the JavaScript from sending beacons, set `pauseReporting()` to `True`. The call can be added anywhere after ADRUM is loaded.

```
<script>
...
 function turnOffReporting() {
 ADRUM.pauseReporting(true);
 }
...
</script>
```

### Resume Sending Beacons

To resume the JavaScript to send beacons, set `pauseReporting()` to `false`. The call can be added anywhere after ADRUM is loaded.

```
<script>
...
 function turnOffReporting() {
 ADRUM.pauseReporting(false);
 }
...
</script>
```

## Add Nonce to adrum-ext.js

When implementing a [Content Security Policy](#), you might include the `nonce` global attribute in your HTML. You can add `nonce` to the `adrum.js` script tag, but you cannot add the `nonce` value to `adrum-ext.js`. This is because `adrum.js` loads `adrum-ext.js` at runtime. If the `nonce` value is not included in `adrum-ext.js`, then the browser will ignore that file and it will not execute `adrum-ext.js`.

To add `nonce` to `adrum-ext.js`, you have two options:

**i** We recommend you to dynamically generate `nonce` values and add them to `adrum-ext.js`.

1. (Preferred) Add the `nonce` value to the `adrum.js` script tag, and add the config variable `elementIdWithNonce`, where the value of `elementIdWithNonce` is the ID of the script element, which holds the `nonce` element. In the example below, `elementIdWithNonce` points to the "adrumScript" ID in the `adrum.js` script, which includes the `nonce` element.

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 (function (config) {
 config.elementIdWithNonce = "adrumScript";
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' nonce="EDNnf03nceI0fn39fn3e9h3sdfa" id="adrumScript" type='text/javascript' charset='UTF-8'></script>
 ...
</head>
```

2. Add the `nonce` value to any script tag, and add the config variable `elementIdWithNonce`, where the value of `elementIdWithNonce` is the ID of the script element, which holds the `nonce` element. In the example below, `elementIdWithNonce` points to the "userScript1" ID in the `userscript.js` script, which includes the `nonce` element.

```
<head>
 <script type='text/javascript' charset='UTF-8'>
 (function (config) {
 config.elementIdWithNonce = "userScript1";
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' nonce="EDNnf03nceI0fn39fn3e9h3sdfa" id="adrumScript" type='text/javascript' charset='UTF-8'></script>
 <script src='userscript.js' nonce="EDNnf03nceI0fn39fn3e9h3sdfa" id="userScript1" type='text/javascript' charset='UTF-8'></script>
 ...
</head>
```

## Disable the Primary Metric

For SPA2 applications, configuring the primary metric causes base page events to be sent on navComplete; previously the base page events were sent upon page load. This may cause slow performance, and you may want to disable the primary metric.

To disable the primary metric, add the following flag in your JavaScript code:

```
config.enablePrimaryMetrics = false
```

## Add Application Release Information

You can set the releaseID to the release name, ID, or version of your application containing the injected JavaScript Agent. When troubleshooting JavaScript errors, this helps map errors to the correct application source code.

There are two methods to specifying the release ID:

1. Configure the JavaScript Agent
2. Call the JavaScript Agent API

When a JavaScript error occurs, the JavaScript Agent sends error beacons to the Controller. If you add your application's release information, the agent will send error beacons with the release ID.

Then, when you need to troubleshoot an error, you can upload your application's source map/file, and the Controller UI will highlight the exact line of code that corresponds with that error. In the event that the source map/file name is the same for multiple application releases (i.e. the source map is named `my_app_source_map.js` for both 4.5.1 and 4.5.5 releases), you should specify the release ID so that error data sent to the Controller also contains the corresponding application release.

## Add the Release ID to the JavaScript Agent

Add the release ID as a string to `config.releaseID`.

For example:

```
<script type='text/javascript' charset='UTF-8'>
 (function(config){
 config.releaseId = "4.5.4";
 })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
```

## Call the Release ID with the JavaScript API

Call the release ID with `setAppReleaseId()`.

For example:

```
var setAppReleaseId = function () {
 ADRUM.setAppReleaseId("4.5.4");
}
```

```

window.history.pushState("setAppReleaseID");
}

```

## Disable Long Stack Trace Reporting

When JavaScript errors occur, the JavaScript Agent captures stack traces at every asynchronous calls and stitches them together with the original stack trace. This is called a long stack trace. However, when troubleshooting JavaScript errors, it may be helpful to disable capturing long stack traces. You may want to disable this if the long stack trace is too long - the Controller UI does not display long stack traces with more than 20,000 characters.

If disabled, the agent will only report the synchronous calls.

To disable `longStackTrace`, set `config.longStackTrace` to `false`:

```

<script type='text/javascript' charset='UTF-8'>
 (function(config){
 config.longStackTrace = false;
 })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>

```

## Measure the Page Loading Experience

This page describes how to enable the following metrics that helps you measure the page loading experience:

- [Google Core Web Vitals](#)
- [Speed Index](#)

Currently, Speed Index is supported only on AppDynamics On-Premises.

## Enable Core Web Vitals

Google Core Web Vitals is a set of metrics that measure the real-world user experience for loading performance, interactivity, and visual stability of the page. In AppDynamics SaaS, Core Web Vitals include the following metrics:

- **Largest Contentful Paint (LCP)** - Reports the render time of the largest image or text block on the page.
- **First input Delay (FID)** - Reports the page response time for the user interaction.
- **Cumulative Layout Shift (CLS)** - of the largest burst of layout shift scores for every unexpected layout shift that occurs during the entire lifespan of a page

Google refers to Core Web Vitals as one of the signals to rank the webpages so you may require to maintain a healthy metrics for your website that improves the SEO ranking and drives user traffic. For more information, see [Core Web Vitals](#).

In AppDynamics SaaS, enable Core Web Vitals while configuring the JavaScript Agent so that the agent collects these metrics for the browsers that are compatible with Google's Core Web Vitals library. You can analyze the scores of Core Web Vitals using AppDynamics Query Language (ADQL).

To view the Core Web Vitals metrics, enable Core Web Vitals while configuring the JavaScript Agent and inject the `adrum.js` script.

```
<script charset="UTF-8" type="text/javascript">
window["adrum-start-time"] = new Date().getTime();
(function(config){
 config.appKey = "SM-AFF-ACX";
 config.adrumExtUrlHttp = "http://cdn.appdynamics.com";
 config.adrumExtUrlHttps = "https://cdn.appdynamics.com";
 config.beaconUrlHttp = "http://eum-shadow-master-col.saas.appd-test.com";
 config.beaconUrlHttps = "https://eum-shadow-master-col.saas.appd-test.com";
 config.useHTTPSAlways = true;
 config.resTiming = {"bufSize":200,"clearResTimingOnBeaconSend":true};
 config.maxUrlLength = 512;
 config.enableCoreWebVitals = true;
})(window["adrum-config"] || (window["adrum-config"] = {}));
</script>
<script src="//cdn.appdynamics.com/adrum/adrum-23.8.0.4309.js"></script>
```

After you enable Core Web Vitals, create a custom dashboard using the metrics created by ADQL. For more information, see [Custom Dashboards](#).

## Correlate Business Transactions for Browser RUM

### Related pages:

- [Correlate Business Transactions for EUM](#)
- [Business Transactions](#)
- [Cookie Consent Management](#)

You can correlate page and Ajax requests with business transactions. The correlation is made between instances of page/Ajax requests (browser snapshots) and instances of business transactions (transaction snapshots).

## How Browser Application Network Requests Are Correlated

When an end user requests a page from your browser app:

1. The App Agent:
  - Sends HTTP headers identifying the business transaction and the HTML with the injected JavaScript Agent to the end user's browser.
  - Aggregates backend metrics and sends them along with the business transaction identifiers to the Controller. This serves as the content for the transaction snapshot.
2. The JavaScript Agent sends browser metrics and the business transaction identifiers (from the HTTP header) to the EUM Server. This serves as the content for the browser snapshot.
3. The Controller fetches the metrics and business transaction identifiers from the EUM Server. These business transaction identifiers are then used to correlate the browser snapshot with the transaction snapshots.

## View Business Transactions Correlated with Browser Applications

There are several ways to navigate from a browser snapshot to its correlated business transaction. The following steps show you one possible way.

1. From the **Browser App Dashboard**, click **Browser Snapshots**.

2. Click **Filters** and check the **Server Snapshot Exists** checkbox.
3. You should now only see browser snapshots that have transaction snapshots:

Overview Geo Dashboard **Browser Snapshots** Usage Stats

4. Double-click one of the browser snapshots to open the **Browser Snapshot Details** dialog containing a transaction snapshot.

5. You can then click links in the transaction snapshot or transaction snapshot itself to view corresponding pages in APM.

### Get Complete Timing Data for Correlated Business Transactions

**i** This functionality is currently not supported for .NET Core.

To get the full real execution time for correlated business transactions, your injection method may need to write the `JS_FOOTER` variable to your page. Manual injection gives the server-side agent the ability to write data only to the header of the page as it is being constructed by your web application.

It is possible that complete business-transaction timing information is not available at the moment that the header data is written. Using the footer allows the server-side agent to write timing data at the footer of the page, by which time a fuller picture of business transaction timing may be available.

You can write the `JS_FOOTER` data variable into the footer of a web page using the following techniques:

- If you use automatic injection for the injecting into the `head` element, you automatically get an injection into the footer as well.
- If you use manual injection for the `head` element, for applications built on Java platforms you can use assisted injection to inject into the footer. Or for applications built on Java servlet or ASP.NET platforms, you can use assisted injection using attribute injection.

---

If you cannot add the `JS_FOOTER` variable to your page, the timing shown for correlated business transactions may be the average response time for that transaction rather than the real execution time for that specific page.

### Avoid Tagging Cookies with the HttpOnly Flag

Servers set the `HttpOnly` flag on cookies to prevent their contents from being accessed by JavaScript. This is often done for session cookies to hide the session identifier as a security measure. The JavaScript Agent, however, needs to be able to read special cookies set by the AppDynamics server-side agent (all prefixed with `ADRUM`) to collect correlation information. If `HttpOnly` is set on these cookies, no server-side correlation information can be transmitted. Thus, make sure that your server does *not* set the `HttpOnly` flag on any cookies prefixed with `ADRUM`.

If you want to securely transmit cookies, use HTTPS. The app agent sets the `secure` flag if the originating base page is loaded over HTTPS.

These can be turned off, but that would prevent correlation from working for base pages unless the customer changes the page source code to use footer injection.

### Cookie Consent Management

This topic covers how you can manage end-user cookie consent requirements in the Controller.

#### AppDynamics and Cookie Consent

The AppDynamics [business transaction \(BT\) correlation with End User Monitoring \(EUM\)](#) feature collects user data from base pages, reports the data to the Controller, and correlates the end-user activity with backend performance in the UI. The cookies used for BT data collection are categorized as third-party cookies.

The base-page cookie consent setting requires cookie consent from users to correlate business transactions (BT) with EUM. In turn, the setting either activates or deactivates BT correlation based on how end users interact with your cookie consent requirements. When the setting is activated, you are requiring consent from your users to use cookies (on base pages) for business transaction correlation with EUM.

#### Configure the Base-page Cookie Consent Setting

 This setting requires Controller  $\geq 21.11.0$  and Java Agent  $\geq 21.9.0$ .

You have two options for configuring the base-page cookie consent setting: at the account level (applies to all applications under an account) or at the application level (applies to one application).

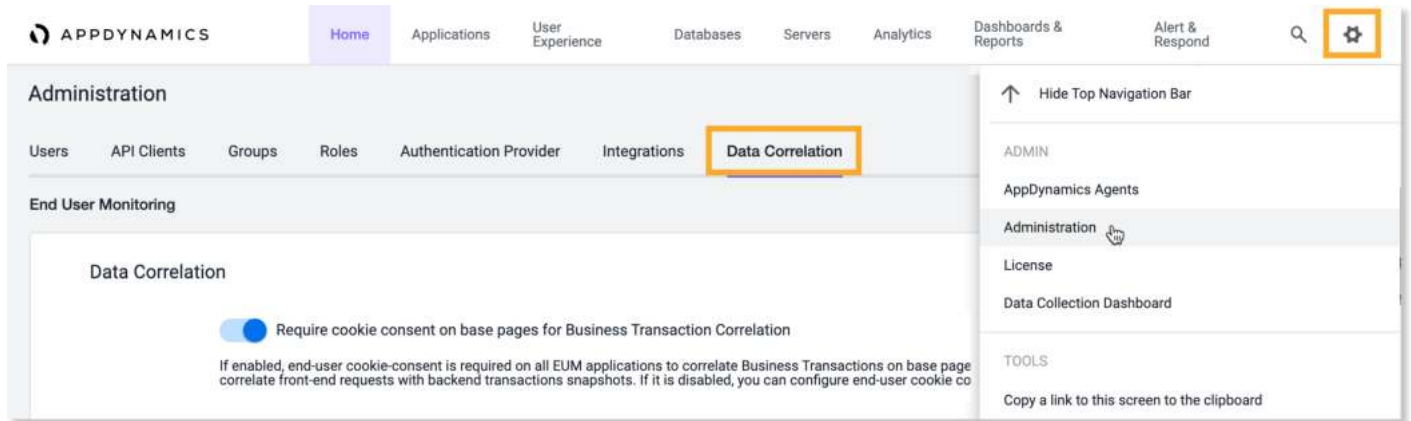

#### Account-level Configuration

When you configure the base-page cookie consent setting at the account level, all applications under that account are affected; but you can still make application-level configurations, such as deactivating the setting for one application.

To configure at the account level:

1. Go to **Settings > Administration > Data Correlation**.
2. Under **End User Monitoring**, toggle **Require cookie consent on base pages for Business Transaction Correlation** on.

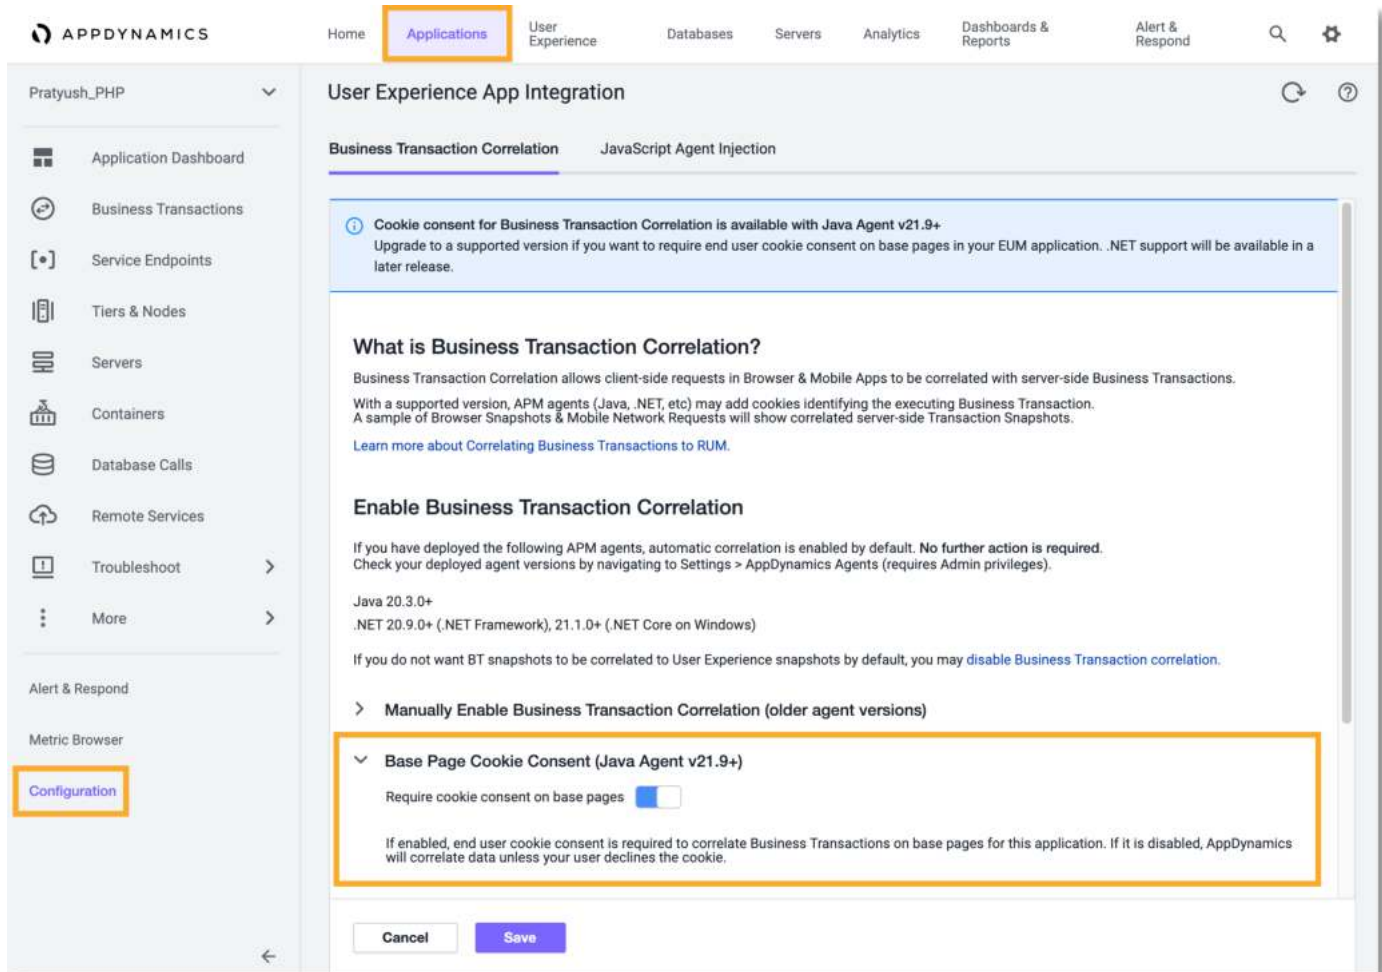

## Application-level Configuration

**i** If the base-page cookie consent setting is deactivated at the account level, you cannot activate it at the application level (the toggle will be greyed out).

To activate at the application level:

1. Go to **Applications > Configuration > User Experience App Integration > Business Transaction Correlation**.
2. Under **Base Page Cookie Consent**, toggle **Require cookie consent on base pages** on.

## Default Settings

### Business Transaction Correlation with EUM Setting

By default [with compatible agent versions](#), business transaction correlation with EUM is activated.

### Base-page Cookie Consent Setting

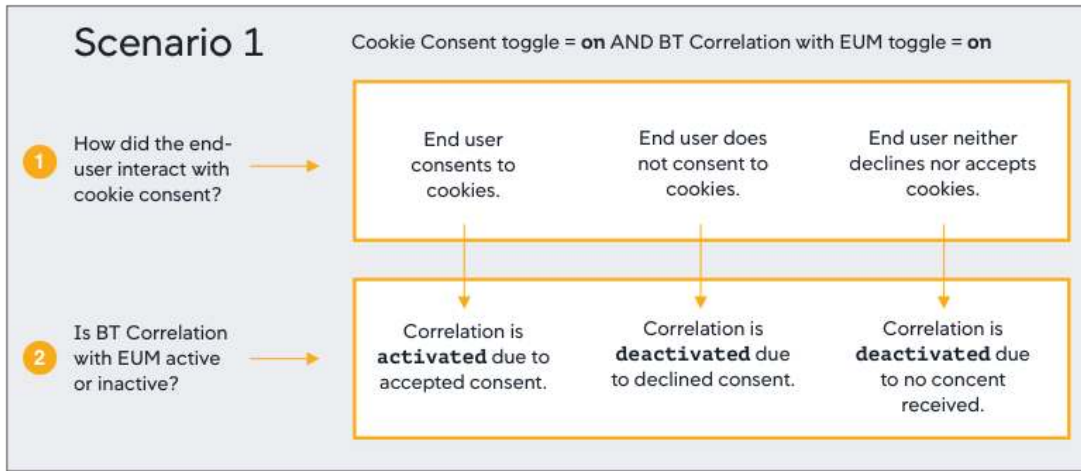

- For existing applications in Controller < 21.11.0, by default the setting is deactivated at both the account- and application-level.
- For new applications created in Controller >= 21.11.0, by default, the setting is activated at both the account- and application-level.

## End-user Interaction with Cookie Consent

The base-page cookie consent setting determines whether BT correlation with EUM is activated or deactivated (on base pages) based on how end users interact with your cookie consent requirements. The scenarios below demonstrate the interaction between the Controller settings and end-user responses to cookie consent.

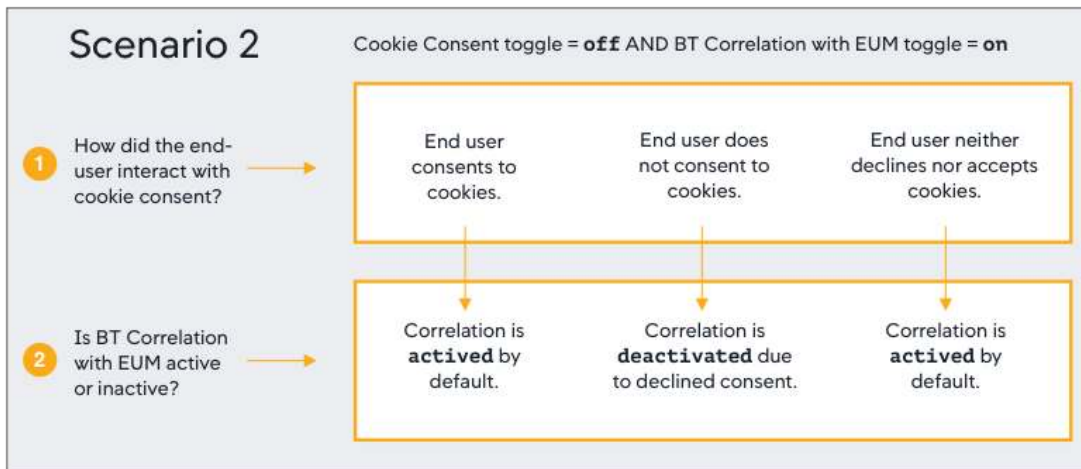

## When the Base-Page Cookie Consent Setting Is Activated

When the base-page cookie consent setting is activated, BT correlation with EUM is activated only if the end user actively consents to cookies. If the end user declines or neither declines nor accepts cookie, BT correlation is deactivated.

## When the Base-Page Cookie Consent Setting Is Deactivated

When the base-page cookie consent setting is deactivated, BT correlation with EUM is activated if the end user actively consents to cookies and if the end user neither declines nor accepts cookies.

## Monitor Single-Page Applications

Browser RUM's single-page application (SPA) monitoring enables you to:

- Monitor the performance/throughput of user experiences of SPAs.
- Troubleshoot and resolve SPA problems within the context of the page load.
- Assist with business decisions by analyzing SPA data through analytics.
- Enable developers to quickly ship better web applications to the marketplace.

## What Is SPA?

A single-page application (SPA) is a web technology and design paradigm that reduces browser-level page loads by using JavaScript to fetch resources and build pages. This creates a smoother, faster user experience more similar to a desktop or mobile application than a traditional web page. [React](#) and [Angular](#) are two popular JavaScript frameworks used to create SPAs.

### Base Pages vs. Virtual Pages

When a user navigates to a SPA, the initial page download is considered the "base page." The base page includes the HTML skeleton, the core CSS, and the JavaScript framework for fetching and constructing new content. The ensuing pages are constructed from resources downloaded with the base page or fetched dynamically from the backend in response to user interaction. This new content (or views) constructed from different sources by the SPA are called "virtual pages."

For SPAs, you will have base pages, virtual pages, and Ajax requests. From **Pages & AJAX Requests**, you are able to view all three types and details for each as shown below.

The screenshot shows the 'Pages & AJAX Requests' section of the AppDynamics interface. It features a table with two columns: 'Type' and 'Name'. The table contains the following entries:

Type	Name
Examples	
	demoapp.com:3000/cfs/servlettime
	demoapp.com:3000/reaction#
	#
	reaction#
	demoapp.com:3000/sockjs/info

An orange callout bubble with the text "Base page, Ajax request, and virtual page." points to the first three rows of the table.

### SPA1 and SPA2 Monitoring

Until 4.4.3, Browser RUM only provided auto-instrumentation for AngularJS 1 SPA applications. For other frameworks, you had to manually report events with the JavaScript Agent API. This limited auto-instrumentation for SPA is known as *SPA1 monitoring*.

From JavaScript Agent >= 4.5.16, Browser RUM has been certified for Angular 1-9 (as well as Angular 12 with JavaScript Agent 21.12.0). This support for the auto-instrumentation for all SPA frameworks is known as *SPA2 monitoring*.

This table describes the support for SPA1 and SPA2 monitoring:

SPA Monitoring Version	Auto-Instrumentation	Metrics	JavaScript API
SPA1	AngularJS 1 only	<ul style="list-style-type: none"> <li>• <b>Base / Virtual Pages:</b> <a href="#">Browser RUM page timing metrics</a></li> <li>• <b>Ajax Requests:</b> <a href="#">All available Ajax metrics</a></li> </ul>	Yes
SPA2	All SPA frameworks. Auto-instrumentation is certified for React and Angular 1-9 (JavaScript Agent >= 4.5.16 and Angular 12 (JavaScript Agent >= 21.12.0)).	<ul style="list-style-type: none"> <li>• <b>Base pages:</b> <a href="#">Browser RUM page timing metrics</a>, including End User Response Time (EURT), Visually Complete Time (VCT), and Page Complete Time (PCT)</li> <li>• <b>Virtual Pages:</b> End User Response Time (EURT), Visually Complete Time (VCT)</li> <li>• <b>Ajax Requests:</b> <a href="#">All available Ajax metrics</a></li> </ul>	Yes

### Which SPA Monitoring to Use?

In general, you are highly recommended to use SPA2 monitoring. For most applications, the JavaScript Agent using SPA2 monitoring identifies the SPA transitions deterministically and captures the metrics and resources correctly without you having to write any special configuration or call methods from the JavaScript Agent API. If your SPA applications are built with AngularJS 1, you can simply add some configuration to enable auto-instrumentation.

### View SPA2 Monitoring Data

Throughout the Controller, you can view [SPA2 Metrics](#) in various EUM dashboards in the Controller. You can also [Configure the Primary Metric](#) to choose a default displayed SPA2 metric for Browser RUM dashboards and widgets.

### Browser Snapshots

The Browser Snapshots tab displays a list of different types of pages as shown below. You can view relevant metrics for all the pages and other metrics for base pages and Ajax requests.

### Page, Ajax, and Iframe Dashboards

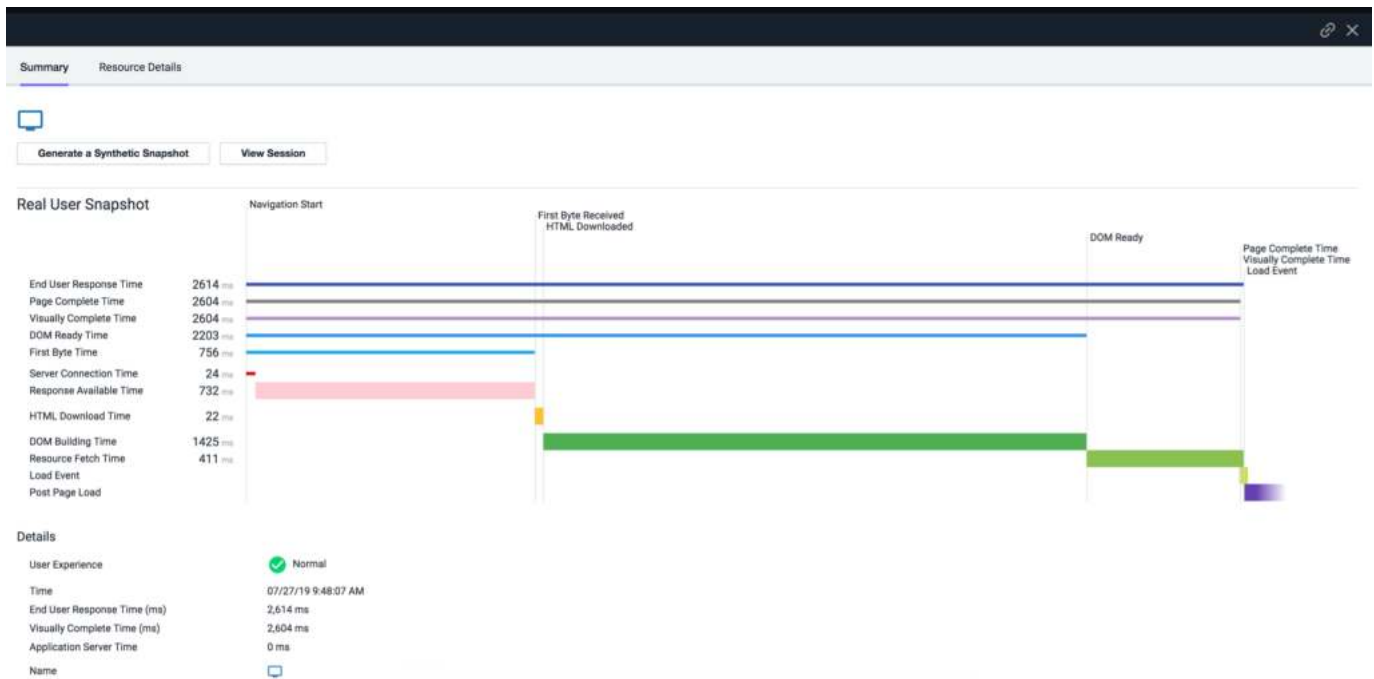

From the **Pages & AJAX Requests** page, you can double-click a page to view the **Page and IFrame Dashboards**. Dashboards for each page type will have a **Summary** section displaying the average metrics as well as a **Key Performance Times** section showing the requests and the metrics on a timeline.

The tabs below show the differences in the dashboard for each page type.

[Base Pages](#)   [Virtual Pages](#)   [Ajax Requests](#)

Base pages contain timing metrics such as End User Response Time, Page Complete Time, and Visually Complete time.

Base Pages [Virtual Pages](#) Ajax Requests

Virtual pages provide the resources requested.

Base Pages Virtual Pages [Ajax Requests](#)

Ajax Requests include a more limited set of timing metrics as well as Ajax-specific section for the **AJAX Response Download Time** and the **AJAX Callback Execution Time**.

### Key Performance Times

### Load

### AJAX Request Errors

### AJAX Response Download Time

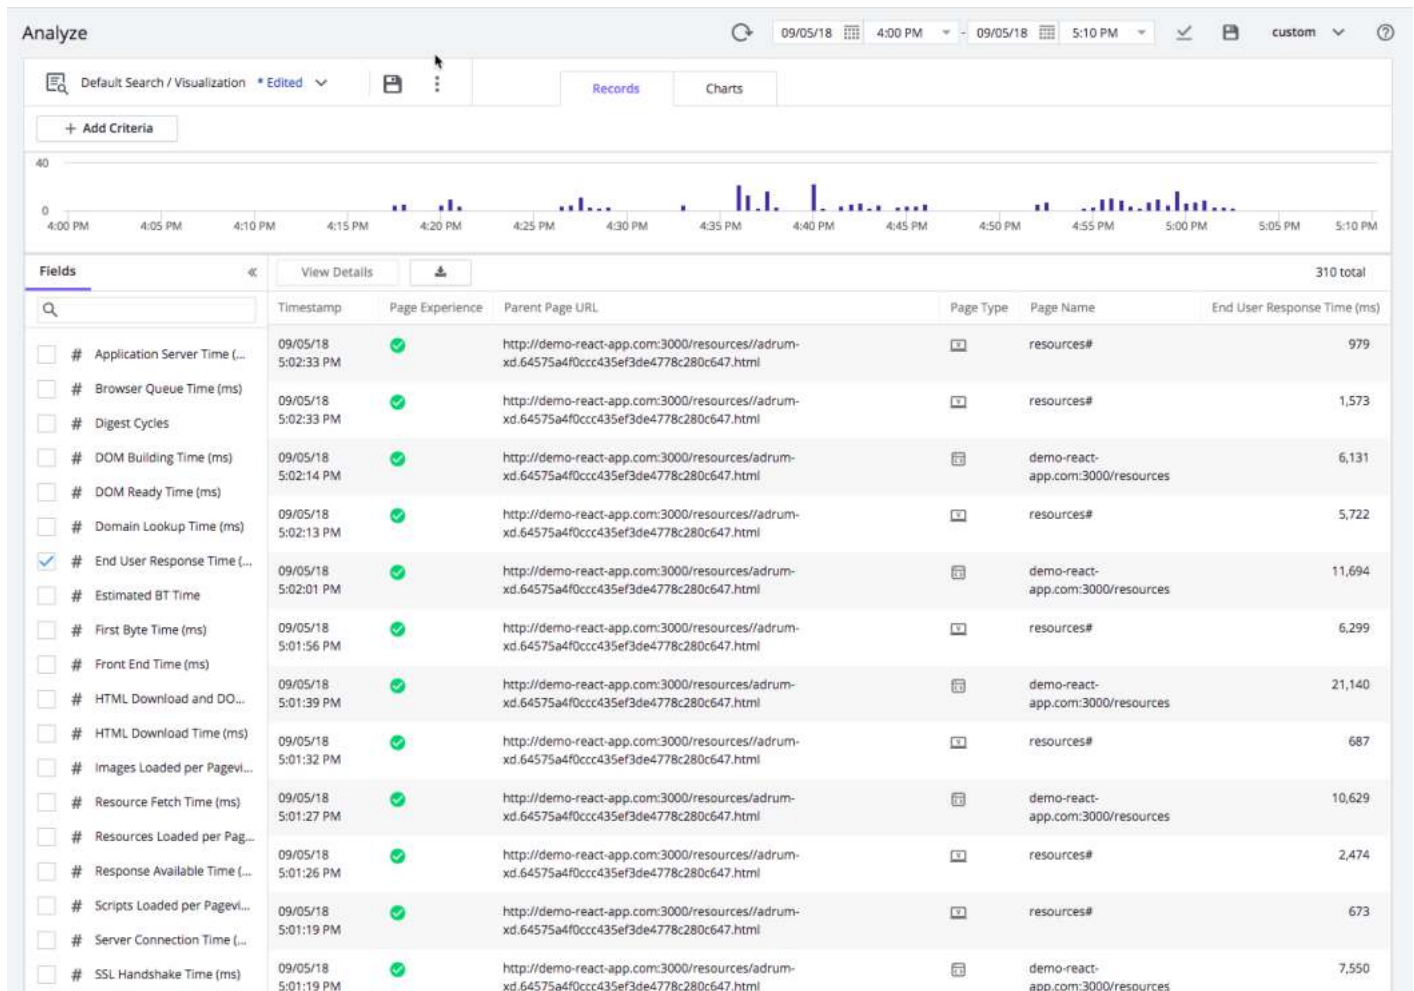

### AJAX Callback Execution Time

## Browser Analyze

From **Browser Analyze**, you can filter by criteria, such as page types shown in the screenshot below, and configure the fields you want to view.

## SPA1 Monitoring

**i** We recommend you use SPA2 Monitoring for all SPA frameworks, especially Angular 1–5 and React.

This page describes how to use SPA1 monitoring for AngularJS 1 applications and manually report events for Ember.js applications. This page also provides information about the AngularJS 1 support for SPA1 monitoring.

### SPA Requirements

- IE 10 and Edge is supported. IE  $\geq 10$  and Edge *cannot* be in compatibility mode with  $\leq$  IE 9 browsers.
- For non-AngularJS frameworks, the JavaScript Agent  $\geq 4.2$  is required.

### Manual Injection for Angular 1.x Applications

For non-Angular applications, `adrum.js` needs to be loaded before any other JavaScript on the page. When you are using AngularJS 1, however, you need to inject `adrum.js` after `angular.js`, but before `angular.js` is bootstrapped.

To learn which Angular versions have monitoring support, see [Monitoring Support for AngularJS](#).

## Manual Injection for Ember.js Applications

For [Ember.js](#) applications, you manually inject the JavaScript Agent much in the same way you would do for web pages loaded from an HTTP request. To monitor virtual pages, you manually start and end Virtual Page events based on events triggered when pages are dynamically created. You can also monitor virtual pages to report errors for pages.

The following sections will show you how to inject the JavaScript Agent and monitor virtual pages.

### Manual Injection of the JavaScript Agent

The file `app/index.html` is the HTML skeleton for all dynamics pages in Ember.js. Thus, you can inject the JavaScript Agent in this file so it is included in every page.

## Monitor Virtual Pages

When a user requests a new page, the route handler renders the associated template to form the new content of the virtual page. You can listen for events in the route handler indicating when the handler is started and completed, which in effect mark the lifetime of the virtual page. To monitor the virtual page,

you start a Virtual Page Event when the `activate` event is triggered, close the Virtual Page when the `deactivate` event is triggered, and then report the completed virtual page.

The code snippet below listens to the `activate` and `deactivate` events and reports the created virtual page event.

```
import Ember from 'ember';
import config from '../config/environment';

export default Ember.Route.extend({
 beforeEnterAbout: Ember.on('activate', function(){
 console.log('hello about');
 config.aboutVpView = new ADRUM.events.VPageView();
 config.aboutVpView.start();
 }),
 afterEnterRental: Ember.on('deactivate', function(){
 console.log('goodbye about');
 config.aboutVpView.end();
 ADRUM.report(config.aboutVpView);
 })
});
```

### Use Virtual Pages to Capture Errors

You can also create actions in the routing handlers that can be monitored through virtual pages. For example, you might want to monitor Ajax calls. You can create an action that performs the Ajax call and then use a Virtual Page event to capture the results and errors as shown in the code snippet below.

```
actions: {
 makeXhrCall() {
 config.xhrVpView = new ADRUM.events.VPageView();
 config.xhrVpView.start();
 var xmlHttp = new XMLHttpRequest();
 xmlHttp.onreadystatechange = function () {
 if (xmlHttp.readyState === 4) {
 console.log(xmlHttp.responseText);
 config.xhrVpView.end();
 ADRUM.report(config.xhrVpView);
 }
 };
 xmlHttp.open("GET", "http://localhost:3000", true);
 xmlHttp.send(null);
 }
}
```

### Monitoring Support for AngularJS 1

The JavaScript Agent supports monitoring by default for [AngularJS versions 1.x](#).

### Routing Engines

AngularJS 1 applications that have multiple Views use a *route* to move from one virtual page to another. You can use Browser RUM to instrument any virtual page that uses either of two routing engines, [ngRoute](#) or [ui-router](#).

## Metrics

Because virtual pages are constructed in the browser, normal page view metrics must be adjusted. In essence, what a metric for AngularJS 1 must do is correlate the time between various routing events, using their timestamps. Metrics are calculated as follows:

Full Metric Name	Short Metric Name	Calculation
End User Response Time (not used for waterfall UI)	PLT	virtualPageStart to virtualPageEnd
HTML Download Time	DDT	viewChangeStart to viewChangeEnd
HTML Download and DOM Building Time	DRT	viewChangeStart to viewDOMLoaded
DOM Building Time	DPT	viewChangeEnd to viewDOMLoaded
DOM Ready Time (used instead of PLT for waterfall UI)	DOM	viewChangeStart to viewDOMLoaded

Because the two routing engines function in slightly different ways, what the AppDynamics event consists of differs slightly, based on the engine.

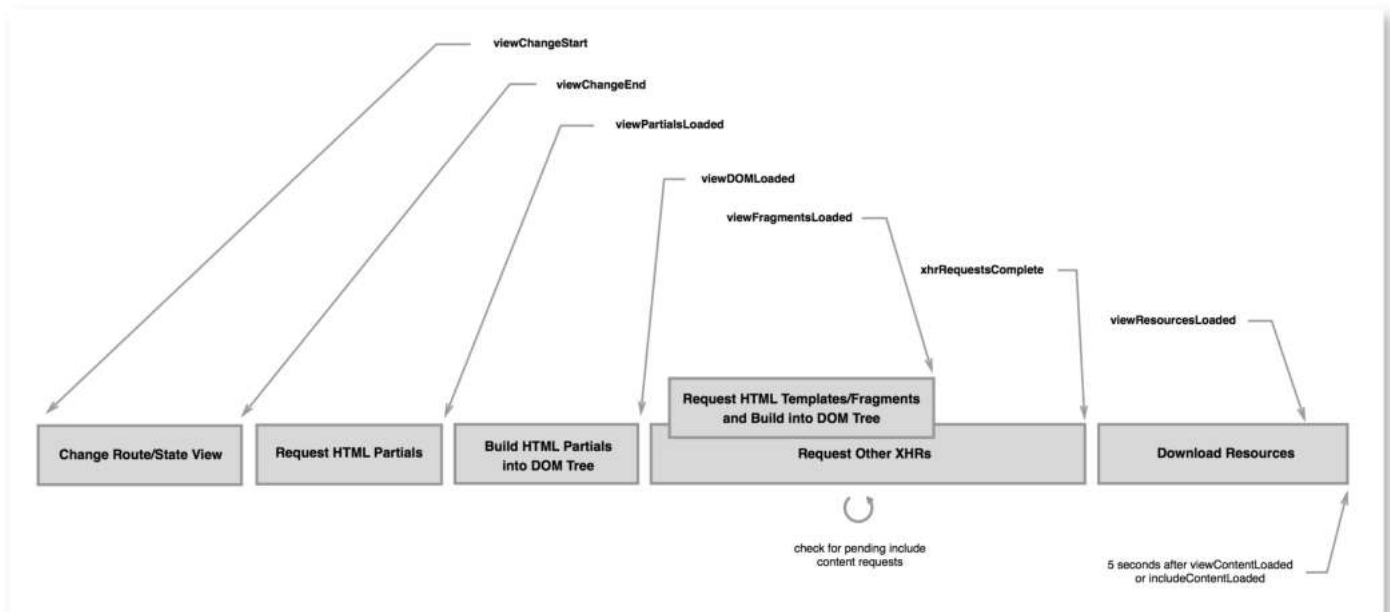

AppDynamic Event Name	ngRoute Equivalent	ui-router Equivalent
virtualPageStart	locationChangeStart	stateChangeStart
viewChangeStart	routeChangeStart	stateChangeStart
viewChangeEnd	routeChangeSuccess	stateChangeSuccess
viewDOMLoaded	viewContentLoaded	viewContentLoaded (may happen multiple times - timestamp overwritten each time)
viewFragmentsLoaded	load time of the last HTML fragment	
xhrRequestsCompleted	response time of the last XHR requests	

AppDynamic Event Name	ngRoute Equivalent	ui-router Equivalent
<code>viewResourcesLoaded</code>	load time of the last resources	
<code>virtualPageEnd</code>	the latest one among <code>viewContentLoaded</code> , <code>xhrRequestsCompleted</code> , and <code>viewResourcesLoaded</code>	

### Page Load Process Visualized

Visualized the page load process looks something like this:

Compare these to the standard page metrics, which are shown in [Browser RUM Metrics](#).

### Exclude Heartbeats or Background Requests from Timings

You may wish to exclude certain events from your virtual page timings. To do this, you can customize the JavaScript Agent when you [inject](#) it.

Add the following snippet *before* you add the JavaScript Agent file, `adrum.js`, to the page:

#### Option for excluding XHRs

```
<script type="text/javascript">
(function(config) {
 (function(spa) {
 (function(angular) {
 (function(vp) {
```

```

 vp.xhr = {
 "exclude": {
 "urls": {
 pattern: '.*\/dealActiveUsers'
 }
 }
 };
 })(angular.vp || (angular.vp = {}));
})(spa.angular || (spa.angular = {}));
})(config.spa || (config.spa = {}));
})(window["adrum-config"] || (window["adrum-config"] = {}));
</script>

```

### Enable Resource Timing Collection for Virtual Pages

By default, Virtual Pages for AngularJS 1 do not include resource timing metrics. You need to set the Angular virtual page property `includeResTimingInEndUserResponseTiming` to `true`.

The JavaScript configuration below shows you how to enable resource timing collection for AngularJS 1 virtual pages. The configuration also sets limits for XHR calls per page, the buffer size for resource timings, and sets the flag for clearing resource timing metrics when a beacon is sent.

```

window['adrum-config'] = {
 "xhr": {
 "maxPerPageView": 10000
 },
 "resTiming": {
 bufSize: 300,
 "clearResTimingOnBeaconSend": true
 },
 "spa": {
 "angular": {
 "vp": {
 "metrics": {
 "includeResTimingInEndUserResponseTiming": true
 }
 }
 }
 }
}

```

### View Correlated Server Times

Since there isn't a regular HTML page timing to which correlated server timings can be linked, to view server times you must drill down from the Dashboard or Snapshot virtual page view to the component XHR requests. The server times can be seen there.

### SPA2 Monitoring

For SPA2, you only need to set a flag to enable the JavaScript Agent to auto-instrument SPAs. When SPA2 auto-instrumentation is enabled, the JavaScript Agent:

- Detects virtual pages
- Measures the end-to-end time for virtual pages
- Correlates resources, JavaScript errors, and Ajax requests
- Names virtual pages

To enable SPA2 monitoring, see [Configure SPA2 Monitoring](#).

### How SPA2 Monitoring Works

The diagram below demonstrates how the JavaScript Agent defines the start and end points for the End User Response Time (EURT) metric and correlates with Ajax requests, resources, and JavaScript errors.

Step	Browser Activity	JavaScript Agent Actions
1	The user navigates to the base page of a SPA. The HTML skeleton, core CSS, and JavaScript are loaded into the browser.	The JavaScript Agent sends a beacon for the base page.
2	From the base page, the user clicks a button to view products. The URL changes as the virtual page is loaded through a combination of previously downloaded content and from new content fetched through Ajax requests.	The JavaScript marks the user action as the start time of the virtual page.

Step	Browser Activity	JavaScript Agent Actions
3	User actions and the browser activity cease for five seconds. The browser activity includes requesting resources, making Ajax calls, and so on.	<p>The JavaScript Agent or your code using the JavaScript API marks the end time of the virtual page as the last time browser activity was seen after the URL changed. The JavaScript Agent then sends a beacon for the virtual page; however, if the virtual-page load stalls on one slow activity, the JavaScript Agent waits eight seconds before marking the end of the virtual page.</p> <p>Any activities such as Ajax requests, resource loads, and JavaScript errors that happened during the virtual page load will be correlated to that virtual page.</p> <p>There are some kinds of browser activities that aren't accessible to JavaScript. For example, the time that the browser takes render the DOM to the screen after the DOM has been updated. Therefore, if your virtual pages don't request any resources, you will likely see a very fast EURT (&lt;10ms).</p>

### SPA2 Metrics

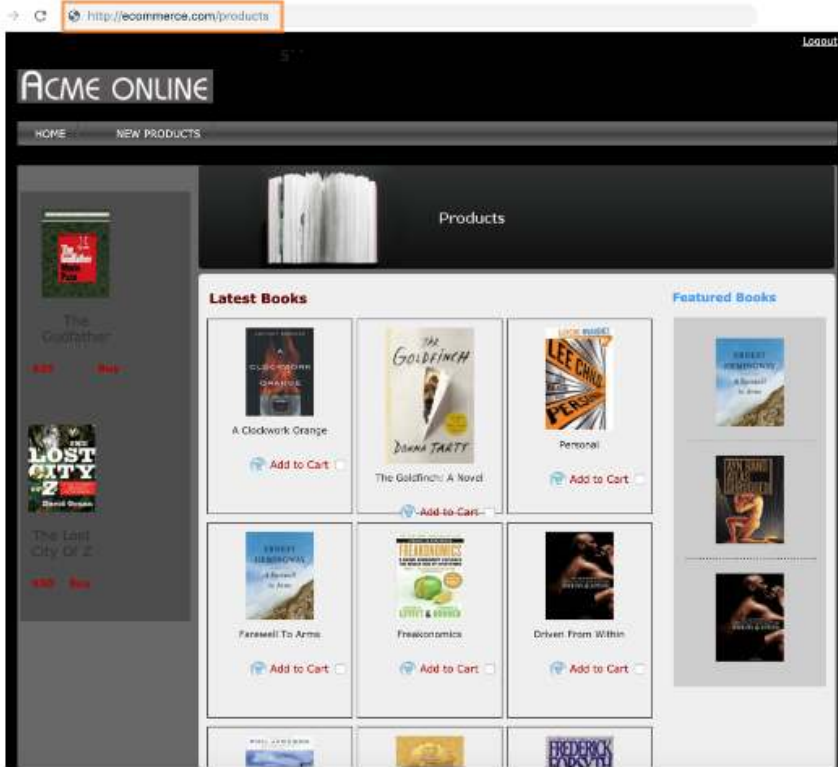

Browser RUM calculates metrics differently for base pages, Ajax requests, and virtual pages. The diagrams below demonstrate the differences between base page and virtual page metrics from the end-user perspective. See [Browser RUM Metrics](#) for metric definitions.

For base pages, Browser RUM calculates End User Response Time (EURT), Visually Complete Time (VCT), and Page Complete Time (PCT). For virtual pages, Browser RUM calculates EURT and VCT.

#### End User Response Time

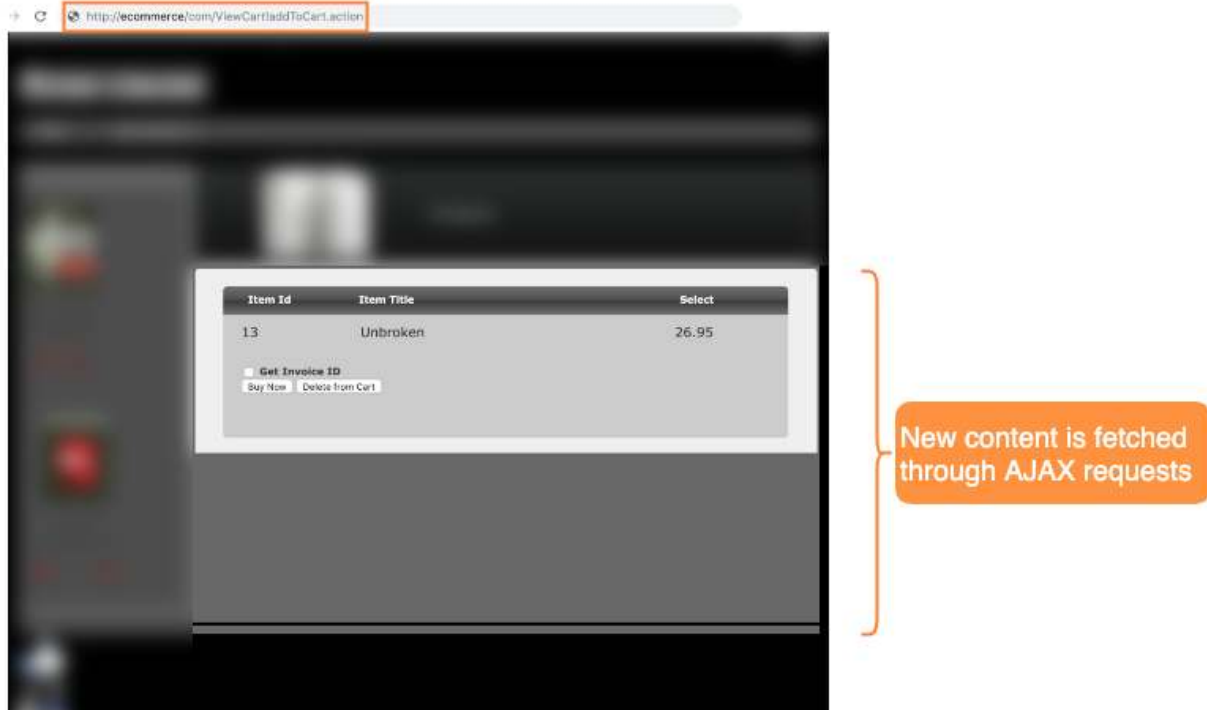

End User Response Time (EURT) calculates the total time for all content (visual and non-visual) to be loaded on a page.

Base Page    Virtual Page

All content (visual and non-visual) is loaded on the page

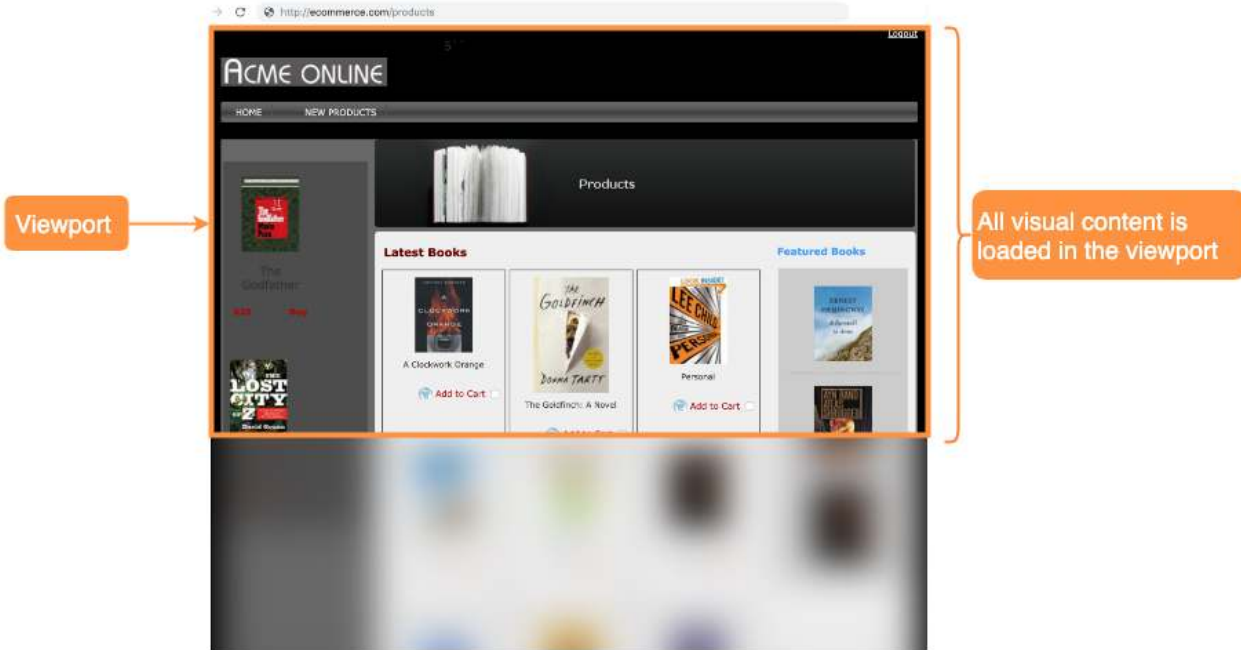

Base Page [Virtual Page](#)

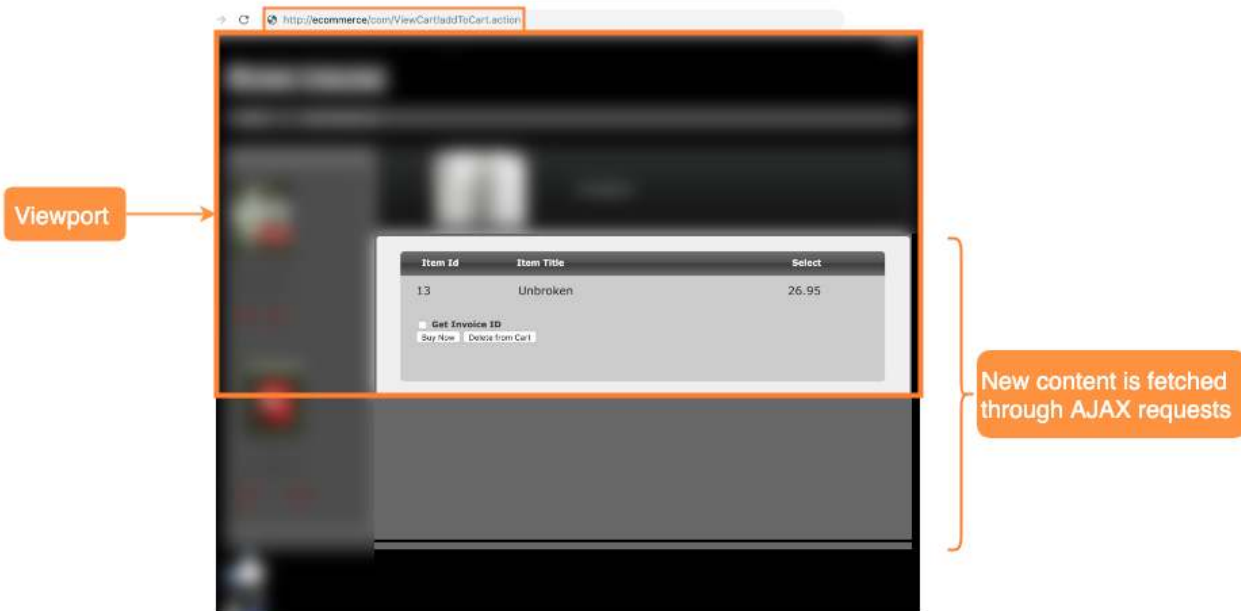

## Visually Complete Time

Visually Complete Time (VCT) calculates the point in time when the browser has finished loading all visual content in the viewport.

[Base Page](#) Virtual Page

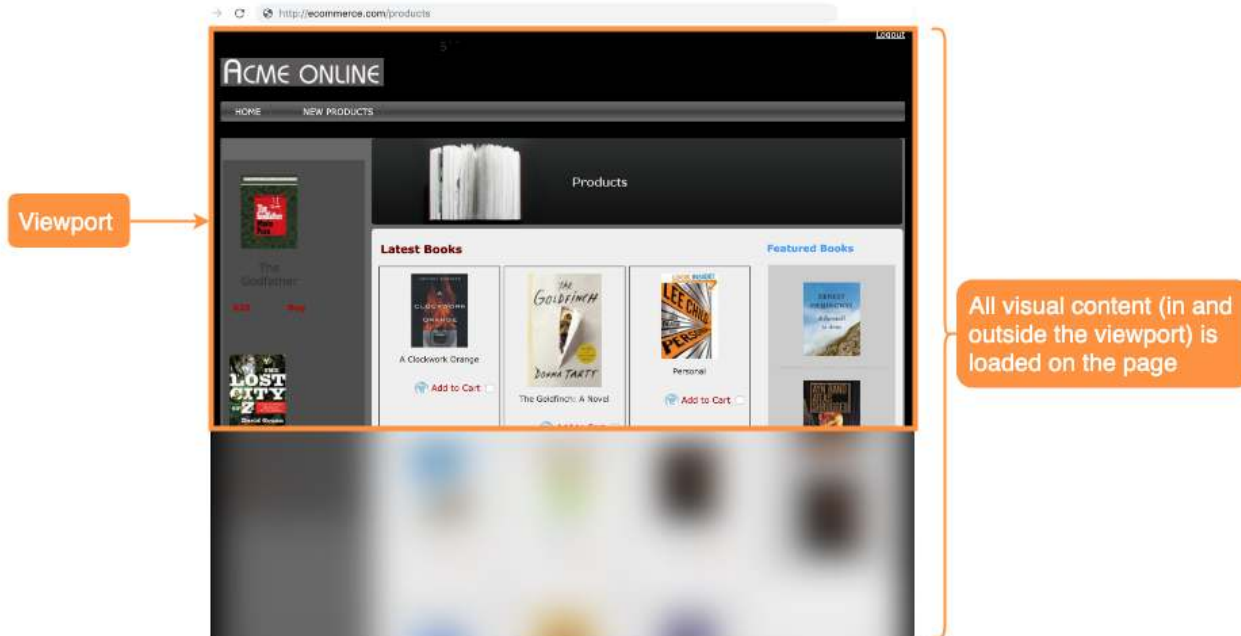

Base Page Virtual Page

Page Complete Time

Page Complete Time (PCT) is a SPA2 metric for base pages only. PCT calculates the point in time when the browser has finished loading all visual content on the page, regardless of whether the content is in or outside the viewport.

## Configure SPA2 Monitoring

### SPA2 Requirements

- JavaScript Agent  $\geq$  4.4.3
- Controller / EUM Server  $\geq$  4.4.3 (for on-premises deployments)
- [Enable SPA2 monitoring](#)
- IE 10 and Edge are supported. IE  $\geq$  10 and Edge *cannot* be in compatibility mode with IE  $\leq$  9 browsers.
- For non-AngularJS frameworks, the JavaScript Agent  $\geq$  4.2 is required.
- Angular support:
  - Angular 12 SPAs are supported by JavaScript Agent  $\geq$  21.12.0.
  - Angular 10-11 SPAs are supported by JavaScript Agent  $\geq$  21.7.0.
  - Angular 6-9 SPAs are supported by JavaScript Agent version  $\geq$  4.5.16.

**i** To manually report and name virtual pages with the JavaScript Agent API, you will need to use the JavaScript Agent  $\geq$  4.5. The JavaScript Agent  $\geq$  4.4.3 does not support the use of the JavaScript Agent API to manually report events.

### Enable/Disable SPA2 Monitoring

In the JavaScript Agent configuration, set `spa2` to `true` and then inject the JavaScript Agent as shown below. You can use either `manual` or `automatic` injection. The default value for `spa2` is `false`, so to enable SPA2 monitoring, you must set `spa2` to `true`.

**i** Make sure you set the configuration, including enabling SPA2 monitoring, *before* you load the JavaScript Agent.

```
<script charset='UTF-8'>
 window['adrum-start-time'] = new Date().getTime();
 (function(config){
 config.appKey = '<EUM_APP_KEY>';
 config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
 config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
 config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
 config.beaconUrlHttps = 'https://col.eum-appdynamics.com';
 config.xd = {enable : false};
 config.spa = {
 "spa2": true
 };
 })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
```

### Disable SPA2 Monitoring

To disable SPA2 auto-instrumentation, just set `spa2` to `false`. Although the default value for `spa2` is `false`, you are recommended to set the configuration to `false` and *not* just remove it.

### Migrate from SPA1 to SPA2 Monitoring

To migration from SPA1 to SPA2 monitoring:

1. Read [SPA1 and SPA2 Monitoring](#) to confirm that your use case is suitable for SPA2.
2. Meet the [SPA2 requirements](#).
3. [Enable SPA2 monitoring](#).

### Fetch API Support for SPA2 Monitoring

The JavaScript Agent monitors Fetch API calls by default for all SPAs except for Angular applications.

For Angular.js and Angular 2-9 applications, follow these steps to ensure Fetch API calls are monitored.

1. The JavaScript Agent is configured to monitor Fetch API calls by default. Make sure that your JavaScript Agent configuration *doesn't* have the following:

```
config.fetch = false
```

2. Load the JavaScript Agent before Angular (recommended, but not required).

```
<script src="adrum.js"></script>
<script src="angular.js"></script>
```

3. Add the following configuration to ensure the JavaScript Agent monitors the Angular application correctly.

[>=Version 4.5.15](#) <=Version 4.5.14

```
function(config) {
 ...
 config.isZonePromise = true;
 ...
})(window['adrum-config'] || (window['adrum-config'] = {}));
```

>=Version 4.5.15 [<=Version 4.5.14](#)

```
function(config) {
 ...
 config.angular = true;
 ...
})(window['adrum-config'] || (window['adrum-config'] = {}));
```

## Troubleshoot SPA Monitoring

This page describes how to troubleshoot issues with monitoring SPAs.

### Problems With Dynamically Loading the JavaScript Agent

Because Angular allows you to dynamically load modules with `AppdInitServlet`, you may be tempted to dynamically load `adrum.js`. The problem with dynamically loading `adrum.js`, however, is that this could cause a race condition between the time `adrum.js` is evaluated and the time `angular.js` is bootstrapped. This race condition can result in JavaScript Agent missing virtual pages or XHR events.

You can avoid this race condition by doing the following:

- Loading Angular first and then immediately loading the JavaScript Agent. See [Load Angular and the JavaScript Agent](#).
- [Bootstrap Angular](#) after you have loaded the JavaScript Agent.

### Load Angular and the JavaScript Agent

The key here is simply to make sure that you load `angular.js` first and then immediately load `adrum.js` as shown below.

```
<script src="angular.js"></script>
<script src="adrum.js"></script>
```

## Bootstrap Angular

Manual (Recommended)

After you have loaded `adrum.js`, you can then bootstrap Angular through [manual initialization](#). You should load both `angular.js` and `adrum.js` as soon as possible, so that the JavaScript Agent can get more accurate metrics about the page load and the HTML DOM Ready /Build time. The examples below follow the recommended procedure of first loading `angular.js`, then `adrum.js`, and then bootstrapping `angular.js`

[AppDynamics CDN](#)   [Self-Hosting](#)   [Shared Hosting](#)

```

<!doctype html>
<html>
 <head>
 <script src="http://code.angularjs.org/snapshot/angular.js"></script>
 <script charset='UTF-8'>
 window['adrum-start-time'] = new Date().getTime();
 (function(config){
 config.appKey = '<EUM_APP_KEY>';
 config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
 config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
 config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
 config.beaconUrlHttps = 'https://col.eum-appdynamics.com';
 config.xd = {enable : false};
 })(window['adrum-config'] || (window['adrum-config'] = {}));

 </script>

 [Self-Hosting](#)  
 [Shared Hosting](#)

```

<!doctype html>
<html>
 <head>
 <script src="http://code.angularjs.org/snapshot/angular.js"></script>
 <script>
 // Assumes that you downloaded the JS Agent and copied it to the 'js'
 directory of your app root.
 (function(config){
 config.appKey = '<EUM_APP_KEY>';
 config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
 config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
 config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
 config.beaconUrlHttps = 'https://col.eum-appdynamics.com';
 config.xd = {enable : false};
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 </head>
 <body>
 <div ng-controller="TestController">
 It's {{currentTime}}!
 </div>
 </body>
</html>

```

```

 </script>
 <script src='//<your-cdn.com>/adrum/adrum.js' type='text/javascript'
charset='UTF-8' />
 </head>
 <body>
 <div ng-controller="TestController">
 It's {{currentTime}}!
 </div>
 <script>
 angular.module('angularApp', [])
 .controller('TestController', ['$scope', function ($scope) {
 $scope.currentTime = new Date().toLocaleString();
 }]);
 angular.element(document).ready(function() {
 angular.bootstrap(document, ['angularApp']);
 });
 </script>
 <script src="js/adrum.js"></script>
 </body>
</html>

```

### Deferred (Optional)

If manual bootstrap is not possible, you can use [deferred bootstrap](#). What this means is that you pause the bootstrap until `adrum.js` is successfully loaded, at which point, you resume the bootstrapping with `angular.resumeBootstrap()` as shown in the example below.

```

<!doctype html>
<html>
 <head>
 <script src="http://code.angularjs.org/snapshot/angular.js"></script>
 <script>
 // This defers the bootstrap.
 window.name = 'NG_DEFER_BOOTSTRAP!';
 angular.module('angularApp', [])
 .controller('TestController', ['$scope', function ($scope) {
 $scope.currentTime = new Date().toLocaleString();
 }]);
 angular.element(document).ready(function() {
 angular.bootstrap(document, ['angularApp']);
 });
 </script>
 // For simplicity, we're just showing the injection snippet using the AppDynamics
 CDN.
 <script charset='UTF-8'>
 window['adrum-start-time'] = new Date().getTime();
 (function(config){
 config.appKey = '<EUM_APP_KEY>';
 config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
 config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';

```

```

 config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
 config.beaconUrlHttps = 'https://col.eum-appdynamics.com';
 config.xd = {enable : false};
 })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src="//cdn.appdynamics.com/adrum/adrum-latest.js" type="text/javascript"
charset='UTF-8'></script>
</head>
<body>
 <div ng-controller="TestController">
 It's {{currentTime}}!
 </div>
 <script>
 // Resume the bootstrapping.
 angular.resumeBootstrap()
 </script>
</body>
</html>

```

### Manually Initializing the JavaScript Agent (Optional)

If `adrum.js` loads successfully, but does not initialize, you can manually initialize it by calling `ADRUM.ng.ngMonitor.init()` as shown below. This will force the JavaScript Agent to initialize even after the Angular bootstrap.

```

<html>
 <head>
 <script src="http://code.angularjs.org/snapshot/angular.js"></script>
 <script>
 // This defers the bootstrap.
 window.name = 'NG_DEFER_BOOTSTRAP!';
 angular.module('angularApp', [])
 .controller('TestController', ['$scope', function ($scope) {
 $scope.currentTime = new Date().toLocaleString();
 }]);
 angular.element(document).ready(function() {
 angular.bootstrap(document, ['angularApp']);
 });
 </script>
 </head>
</doctype html>
<html>
 <head>
 <script src="http://code.angularjs.org/snapshot/angular.js"></script>
 <script>
 // This defers the bootstrap.
 window.name = 'NG_DEFER_BOOTSTRAP!';
 angular.module('angularApp', [])
 .controller('TestController', ['$scope', function ($scope) {
 $scope.currentTime = new Date().toLocaleString();
 }]);
 angular.element(document).ready(function() {

```

```

 angular.bootstrap(document, ['angularApp']);
 });
</script>
// For simplicity, we're just showing the injection snippet using the AppDynamics
CDN.
<script charset='UTF-8'>
 window['adrum-start-time'] = new Date().getTime();
 (function(config){
 config.appKey = '<EUM_APP_KEY>';
 config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
 config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
 config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
 config.beaconUrlHttps = 'https://col.eum-appdynamics.com ';
 config.xd = {enable : false};
 })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript'
charset='UTF-8'></script>
</head>
<body>
 <div ng-controller="TestController">
 It's {{currentTime}}!
 </div>
 <script>
 // Resume the bootstrapping.
 angular.resumeBootstrap();
 ADRUM.ng.ngMonitor.init();
 </script>
</body>
</html>

```

**i** In some cases, you may be able to place `ADRUM.ng.ngMonitor.init()` before `angular.resumeBootstrap()`.

## Enable the Content Security Policy (CSP)

This page describes how to enable Content Security Police (CSP) so your application is compatible with Browser RUM.

### Directives Required for CSP

To enable CSP for instrumented applications, you add the following required directives in the `Content-Security-Policy` header:

- `script-src`
- `connect-src`

In certain cases, you are also required to use the following directives:

- `child-src`
- `frame-ancestors`
- `img-src`

## script-src

The `script-src` directive specifies the location of `adrum-ext.js`. By default, `adrum-ext.js` is loaded from our content delivery network (CDN) at `cdn.appdynamics.com`. The example below shows how you might use the `script-src` directive.

```
script-src cdn.appdynamics.com;
```

To measure first-byte time accurately, include the following line at the top of pages:

```
window["adrum-start-time"] = new Date().getTime();
```

For this line to be read, you also need to set the `script-src` directive to `'unsafe-inline'` as shown here:

```
script-src 'unsafe-inline';
```

**i** Skip `unsafe-inline` if you require to add nonce to the CSP, see [Add Nonce to adrum-ext.js](#).

## connect-src

The `connect-src` directive specifies the location where beacons are sent. If you are using the SaaS-based EUM, you might use something like the following:

```
connect-src col.eum-appdynamics.com;
```

If you are using on-prem EUM, you would have `connect-src` point to your EUM Server.

## child-src

For cross-domain sessions, we load `adrum-xd.html` into an `iframe`. By default, this is loaded from our CDN, so you need to have `child-src` specify a CDN as shown below.

```
child-src cdn.appdynamics.com;
```

## frame-ancestors

If `adrum-xd.html` is hosted locally, you would use the `frame-ancestors` directives in the following way:

```
frame-ancestors /path/to/adrum-xd.html;
```

## img-src

In older browsers, we send our beacons as image beacons. Although older browsers don't support CSP, you can configure the JavaScript Agent to always send image beacons. You do this using `img-src` directive to specify the beacon location as shown in the example below.

```
img-src col.eum-appdynamics.com;
```

## Example Content-Security-Policy Header

The following `Content-Security-Policy` header loads the `adrum` files from our CDN and then sends beacons to our SaaS-based EUM.

```
Content-Security-Policy: connect-src 'self' col.eum-appdynamics.com; script-src 'unsafe-inline' cdn.appdynamics.com; img-src cdn.appdynamics.com; child-src cdn.appdynamics.com
```

## Host a Geo Server

AppDynamics hosts a Geo Server that resolves the user's geographic location based on the request's reported IP address. You may prefer to host your own Geo Server if:

- You have intranet applications where the public IP address does not provide meaningful location information but the user's private IP does.
- You have a hybrid application where some users access the application from a private location and some access it from a public one. If a user doesn't come from a specific private IP range mapped by the custom geo server, the system can be set to default to the public Geo Server.

The custom Geo Server supports an HTTP header, `AD-X-Forwarded-For`. You can use this to declare an IP address specifically for the purpose of geo resolution. Custom Geo Server also supports the HTTP header `X-Real-IP`.

To host a custom geo server:

1. [Download the Geo Server File](#)
2. [Set the Location of the Geo Server](#)
3. [Create the IP Mapping File](#)

## Requirements for Geo Server Host

- 2 GB of memory
- Java 8.x

## Download and Install the Geo Server File

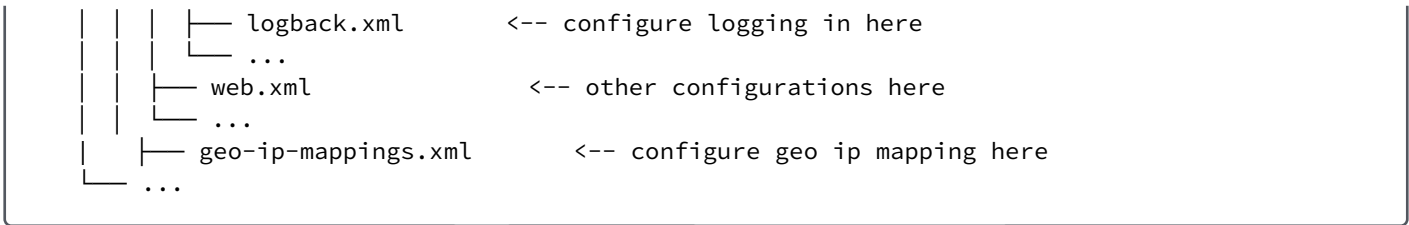

Download the `GeoServer.zip` file from AppDynamics at <https://download.appdynamics.com/download>.

Uncompress the zip to a `GeoServer` folder with the following structure:

```

├── GeoServer
│ ├── schema.xsd <-- schema for geo-ip-mapping.xml configuration
│ ├── geo
│ │ ├── WEB-INF
│ │ └── classes

```

To install the geo server, copy the `geo` folder to the `TOMCAT_HOME/webapps` of your Tomcat server. Do not deploy the server in the same container as the Controller.

### Set the Location of the Geo Server

Enter the URL, including the context root, of your hosted geo server in the **Geo Server URL** field in the **Browser RUM** configuration screen in the Controller UI as shown below.

#### Configure and download JavaScript Agent

#### Set the Geo Server URL

*optional*

http://

https://

**⚠** If you are using manual injection for your JavaScript agent, you must make sure that the copy of the script that you use is one that you have downloaded *after* this URL is set.

### Create the IP Mapping File

The `geo-ip-mappings.xml` IP mapping file specifies the locations for which Browser RUM provides geographic data. It maps IP addresses to geographic locations.

Use the sample file in the `geo` subdirectory as a template. Any modifications at runtime are reloaded without a restart.

This file contains a `<mapping>` element for every location to be monitored. The file has the following format.

```

<mappings>
 <mapping>
 <subnet from="192.168.1.1" mask="255.255.255.0"/>

```

```

 <location country="United States" region="California"
city="San Francisco"/>
 </mapping>

 <default country="United States" region="California"
city="San Francisco"/>
</mappings>

```

You can also use IP-range-based mapping instead of subnet-based:

```

<mapping>
 <ip-range from="10.240.1.1" to="10.240.1.254" />
 <location country="France" region="Nord-Pas-de-Calais"
city="ENGLOS" />
</mapping>

```

This data is visible in browser snapshots and can be used to filter browser snapshots for specific locations: The `<country>`, `<region>`, and `<city>` elements are required. If the values of `<country>` and `<region>` do not correspond to an actual geographic location already defined in the geographic database, map support is not available for the location in the map panel, but Browser RUM metrics are displayed for the location in the grid view of the geographic distribution, end user response time panel, trend graphs, browser distribution panel, and in the Metric Browser. The `<city>` element can be a string that represents the static location of the end-user. You will notice a `<default>` element. If there is an IP address that is not covered by your IP mapping file, this is the value that is used. To use a public geo server for non-covered IP addresses, see [Using a Hybrid Custom-Public Geo Server Setup](#).

The screenshot shows the AppDynamics user interface. The top navigation bar includes 'Home', 'Applications', 'User Experience', 'Analytics', 'Dashboards & Reports', and 'Alert & Respond'. The left sidebar has 'Browser App Dashboard' selected. The main content area is titled 'docs.appdynamics.com' and shows 'Browser Snapshots' data. A 'Filter by location' dialog box is overlaid on the table, with an orange arrow pointing to the 'Geography' section. The dialog has 'Server Side' and 'Geography' sections. The 'Geography' section has input fields for 'Country' (Japan), 'State / Region' (Miyagi), and 'City' (Natori). The table below shows a list of browser snapshots with columns for 'Server Side', 'Geography', 'Time', 'End User Response Time (ms)', and 'URL'. The 'Geography' column shows green checkmarks for each row, indicating that the filter criteria are being applied to the data.

Server Side	Geography	Time	End User Response Time (ms)	URL
<input type="checkbox"/>	Country: Japan	03/10/17 3:56:5...	1,018	https://docs
<input type="checkbox"/>	State / Region: Miyagi	03/10/17 3:56:3...	626	https://docs
<input type="checkbox"/>	City: Natori	03/10/17 3:56:2...	132	https://docs
<input type="checkbox"/>		03/10/17 3:56:2...	56	https://docs
<input type="checkbox"/>		03/10/17 3:56:2...	54	https://docs

The valid names for country and region are those used in the map in the geo dashboard. You can hover over a region in the dashboard to see the exact name (including spelling and case) of the region. See [The Browser Geo Dashboard View](#).

### Using a Hybrid Custom-Public Geo Server Setup

If you want Browser RUM to evaluate any non-mapped IP address using the public geo server, remove the `<default>` element. In this case, locating any non-mapped IP address is done in the EUM cloud, not locally.

### Customize File Locations

You can customize where certain files are stored in the GeoServer directory.

#### Change Log Location

By default, logs are written to `TOMCAT_HOME/logs`, but you can configure this using `TOMCAT_HOME/webapps/geo/WEB-INF/classes/logback.xml`. Open the file with a text editor and edit the `LOG_HOME` property.

```
<property name="LOG_HOME" value="{path-to-file}/logs"/>
```

#### Change Mapping File Location

By default, the geo server looks for `geo-ip-mappings.xml` in `TOMCAT_HOME/webapps/geo/`. To change the location, open `TOMCAT_HOME/webapps/geo/WEB-INF/web.xml` with a text editor and change value for `AD_GEO_CONFIG_FILE`.

```
<web-app ...>
 <!-- ... -->
 <servlet>
 <servlet-name>FrontControllerServlet</servlet-name>
 <servlet-class>com.appdynamics.eum.geo.web.FrontControllerServlet</servlet-class>
 <context-param>
 <param-name>AD_GEO_CONFIG_FILE</param-name>
 <param-value>{path-to-file}/geo-ip-mappings.xml</param-value>
 </context-param>
 <!-- ... -->
 </servlet>
 <!-- ... -->
</web-app>
```

**i** In previous versions of the geo server, the enclosing tag was a `<context-param>`. This has now been changed to an `<init-param>`.

### Browser RUM Metrics

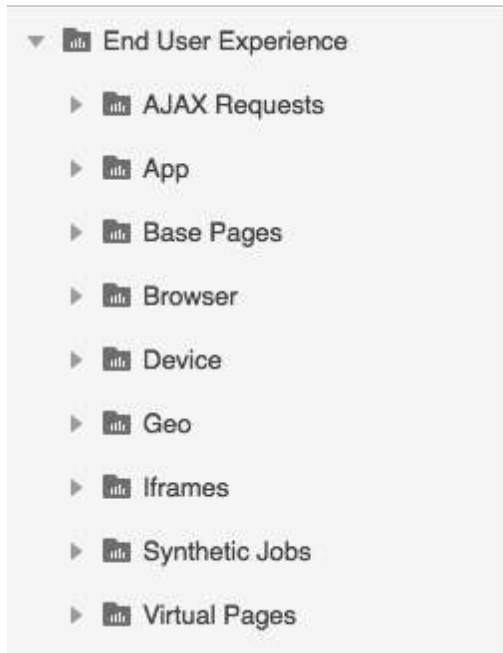

#### Related pages:

- [AppDynamics APIs](#)

- [WC3 Navigation Timing API](#)

- [Browser RUM Timing Metrics Overview](#)
- [Timing Metric Definitions](#)
- [Ajax Metrics Availability](#)
- [Resource Timing Metrics](#)
- [Configure Timing Metrics](#)

Key Browser RUM metrics display on the **Geo, Pages & AJAX Requests**, and **Usage Stats** dashboards. They are also visible on the **All Pages** and **Top Pages** lists and in the [Metric Browser](#).

In addition, the **Metric Browser** enables you to view these metrics in the context of Ajax requests, Iframes, applications, base pages, browsers, devices, and geographic locations.

You can build custom health rules based on Browser RUM Page, Ajax, and Iframe metrics in the health rule builder. Use these rules to automatically monitor key metrics in your installation. See [Health Rules](#).

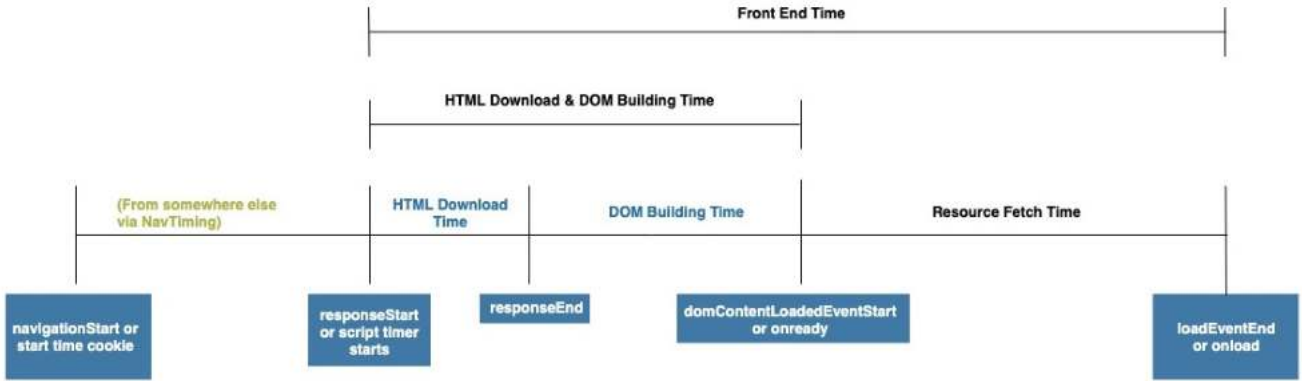

### Browser RUM Timing Metrics Overview

The following provides an overview of the first Browser RUM page and Iframe timing metrics. For key Ajax metrics, see [Ajax Metrics Availability](#). Metrics in blue are available only from NavTime browsers. You may see a value of `unknown` for some metrics taken using older browsers.

When users begin to load the first instrumented page, the JavaScript Agent starts a timer. The timer or the NavTime `responseStart` starts the first-page timing.

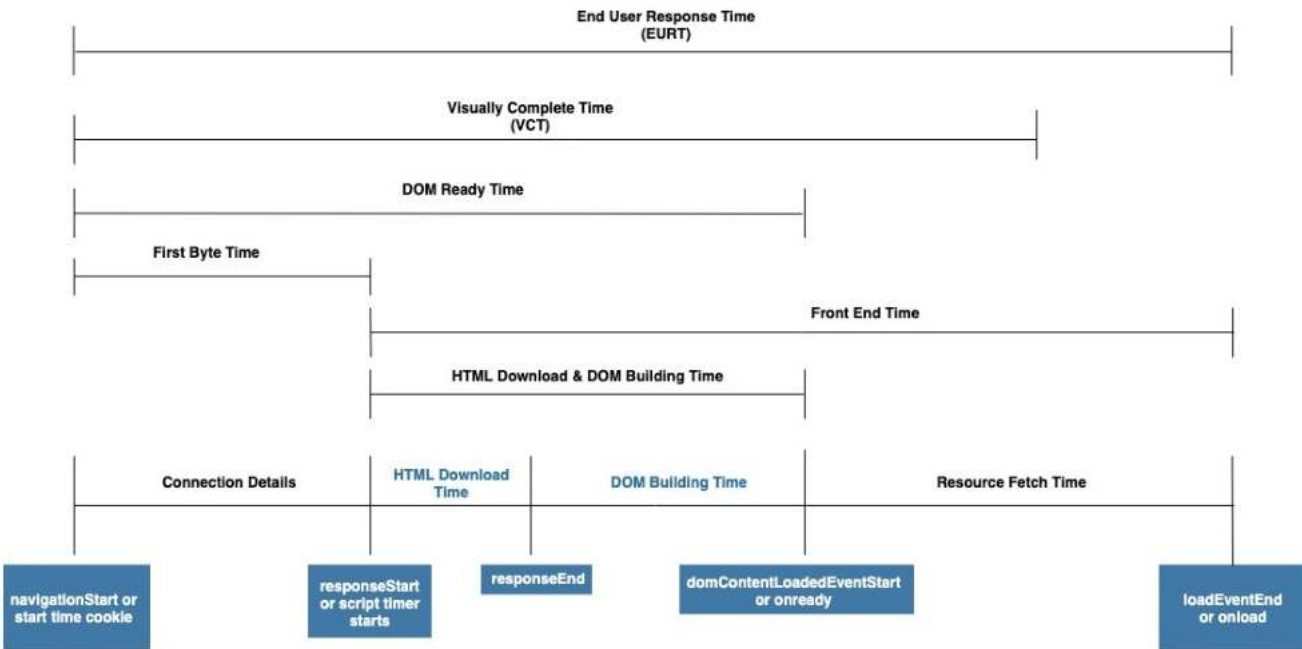

[First Page](#)   Subsequent Pages   Connection Details

**First Page**

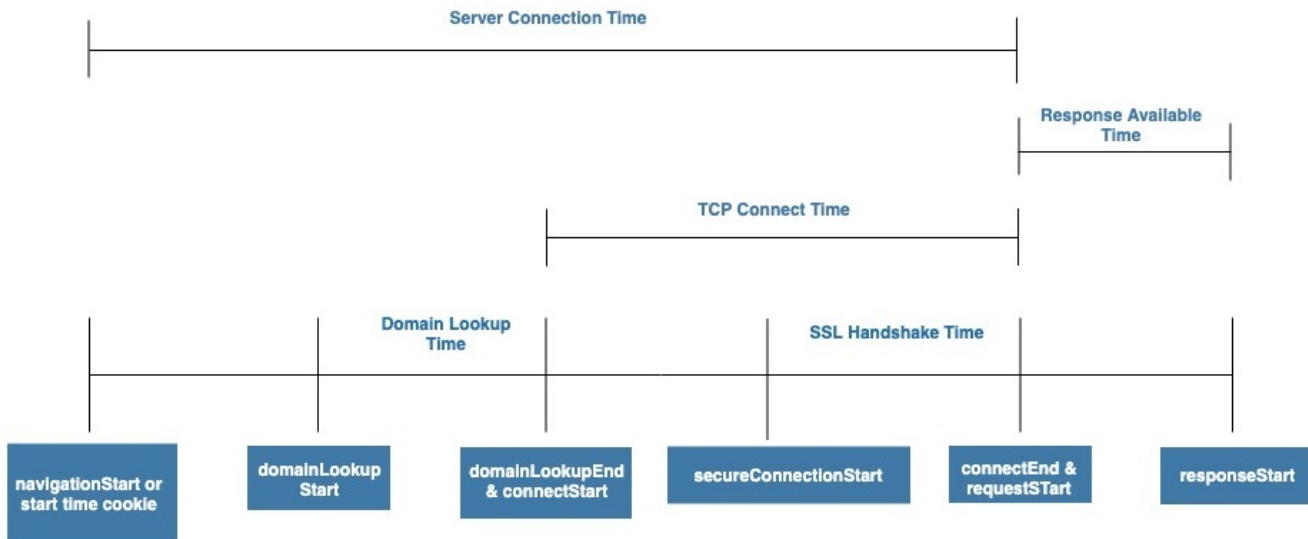

First Page [Subsequent Pages](#) [Connection Details](#)

**Subsequent Pages**

First Page [Subsequent Pages](#) [Connection Details](#)

## Connection Details

**i** Because a NavTime browser always sets `navigationStart`, you can retrieve this information even on the first page a user loads from your site.

NavTiming-capable browsers also provide highly granular information on connection details.

### Timing Metric Definitions

Timing metrics are the average times, in milliseconds, over the time range selected in the Controller UI or REST API call. The three-letter abbreviation is the short name as it is recorded in the web beacon.

Name (Short Name)	NavTiming Capable Browsers <sup>1</sup>	Browsers without NavTiming Support	Available For ...	Definition
Ajax Callback Execution Time (DPT)	<code>responseEnd</code> to <code>domContentLoadedEventStart</code> (context of the Ajax object)	<code>responseEnd</code> to <code>domContentLoadedEventStart</code> (context of the Ajax object)	Ajax Requests (XHR, Fetch API)	Time for the browser to process the Ajax response. This typically includes the time to apply the response data to the DOM.

Name (Short Name)	NavTiming Capable Browsers <sup>1</sup>	Browsers without NavTiming Support	Available For ...	Definition
Ajax Response Download Time (DDT)	responseStart to responseEnd (context of the Ajax object)	responseStart to responseEnd (context of the Ajax object)	Ajax Requests (XHR, Fetch API)	Time for the browser to download the complete Ajax response.
Ajax Request Errors per Minute (Short name based on ARE entries)			<ul style="list-style-type: none"> <li>• Ajax Requests (XHR, Fetch API)</li> <li>• App</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> </ul>	Total number of Ajax requests that generate an error per minute.
Ajax Requests per Minute (Short name based on PLC entries)			<ul style="list-style-type: none"> <li>• App</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> </ul>	Total number of Ajax requests per minute.
Application Server Calls per Minute			<ul style="list-style-type: none"> <li>• Ajax Requests (XHR, Fetch API)</li> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframes</li> </ul>	Number of requests that actually hit the application server, rather than a cache.
Application Server Time (also called Server Time in the UI)			<ul style="list-style-type: none"> <li>• Ajax Requests (XHR, Fetch API)</li> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframe</li> </ul>	Processing time for requests on the application server.

Name (Short Name)	NavTiming Capable Browsers <sup>1</sup>	Browsers without NavTiming Support	Available For ...	Definition
Browser Queue Time			<ul style="list-style-type: none"> <li>• Ajax (XHR, Fetch API)</li> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframes</li> </ul>	
DOM Building Time (DPT)	<code>responseEnd</code> to <code>DOMContentLoadedEventStart</code>	N/A	<ul style="list-style-type: none"> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframes</li> </ul>	Time for the browser to build the Document Object Model (DOM) and make it available for JavaScript to apply rendering logic.
DOM Ready Time (DOM) <sup>2</sup>	<code>navigationStart</code> to <code>DOMContentLoadedEventStart</code>	Time between the writing of the <code>starttime</code> cookie on the previous page and an internal handler's <code>onready</code> event, similar to <code>jquery.onready()</code> .	<ul style="list-style-type: none"> <li>• App</li> <li>• Base Pages</li> <li>• Geo</li> </ul>	Interval between the time that a user initiates a request and the time that the <code>DOMContentLoaded</code> event (or the internal handler's <code>onready</code> event) occurs.
Domain Lookup Time (DNS)	<code>domainLookupStart</code> to <code>domainLookupEnd</code>	N/A	<ul style="list-style-type: none"> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframes</li> </ul>	Time to complete the domain lookup portion of the server connection time.

Name (Short Name)	NavTiming Capable Browsers <sup>1</sup>	Browsers without NavTiming Support	Available For ...	Definition
End User Response Time (PLT) <sup>2</sup>	navigationStart to loadEventEnd	Time between the writing of the starttime cookie on the previous page and the onload event.	<ul style="list-style-type: none"> <li>• Ajax Requests (XHR, Fetch API)</li> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframes</li> </ul>	<p>Average interval between the time that a user initiates a request and the completion of the page load of the response in the user's browser.</p> <p>In the context of an Ajax request, it ends when the response has been completely processed.</p> <p>For information about End User Response Time for SPA2 pages, see <a href="#">SPA2 Metrics</a>.</p>
First Byte Time (FBT) <sup>2</sup>	navigationStart to responseStart	Time between the writing of the starttime cookie on the previous page and when the page's JavaScript Agent begins executing.	<ul style="list-style-type: none"> <li>• Ajax Requests (XHR, Fetch API)</li> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframes</li> </ul>	<p>Interval between the time that a user initiates a request and the time that the browser receives the first response byte.</p> <p>In the context of an Ajax request, First Byte Time is the interval between the Ajax request dispatch and the time that the browser receives the first response byte.</p>
Front End Time (FET)	responseStart to loadEventEnd	Time between when the page's JavaScript Agent begins executing and the onload event.	<ul style="list-style-type: none"> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframes</li> </ul>	<p>Interval between the arrival of the first byte of text response and the completion of the response page rendering by the browser.</p> <p>Includes HTML Download, DOM Building Time, and Resource Fetch Time.</p>

Name (Short Name)	NavTiming Capable Browsers <sup>1</sup>	Browsers without NavTiming Support	Available For ...	Definition
HTML Download and DOM Building Time (DRT)	responseStart to domContentLoadedEventStart	Time between when the page's JavaScript Agent begins executing and an internal handler's onreadystatechange event, similar to <code>jquery.onreadystatechange()</code> .	<ul style="list-style-type: none"> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframes</li> </ul>	<p>Time to make the complete HTML document (DOM) available for JavaScript to apply rendering logic.</p> <p>Includes the HTML Download and the DOM Building Time.</p>
HTML Download Time (DDT)	responseStart to responseEnd	N/A	<ul style="list-style-type: none"> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• IFRAME</li> </ul>	Time for the browser to download the complete HTML document content.
Iframe Requests per Minute (Short name based on PLC entries)			<ul style="list-style-type: none"> <li>• App</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> </ul>	Total number of IFRAME requests per minute.
Images Loaded per Pageview			<ul style="list-style-type: none"> <li>• Ajax (XHR, Fetch API)</li> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframes</li> </ul>	<p>Total number of images in a <code>pageview</code>.</p> <p>Calculated after page has completely loaded.</p>
Page Complete Time (PCT)	N/A	N/A	<ul style="list-style-type: none"> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> </ul>	<p>Total time for the browser to render all visual page elements (both in and out of the viewport). Available for SPA base pages only.</p> <p>For information about Page Complete Time for SPA2 pages, see <a href="#">SPA2 Metrics</a>.</p>

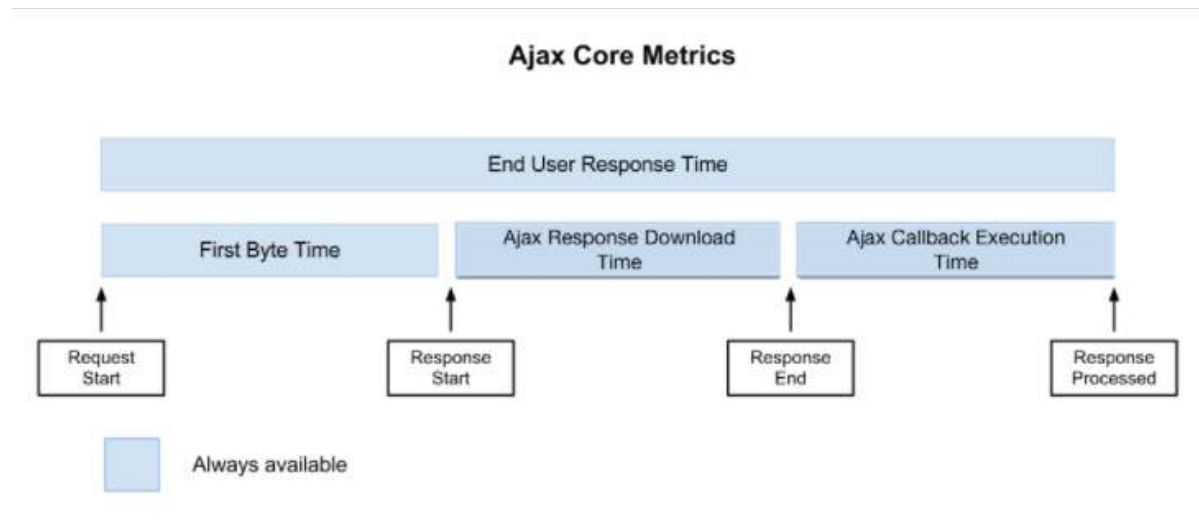

Name (Short Name)	NavTiming Capable Browsers <sup>1</sup>	Browsers without NavTiming Support	Available For ...	Definition
Page Requests per Minute (Short name based on PLC entries)			<ul style="list-style-type: none"> <li>• App</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> </ul>	Total number of Page requests per minute.  This is the metric displayed across most of the UI.
Page views with JavaScript Errors per minute (Short name based on EPM entries)			<ul style="list-style-type: none"> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframes</li> </ul>	Total number of page views that contain JavaScript errors per minute.
Resource Fetch Time	<code>domContentLoadedEventStart</code> to <code>loadEventEnd</code>	Time between an internal handler's <code>onready</code> event, similar to <code>jquery.onready()</code> , and <code>onload</code> .	<ul style="list-style-type: none"> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframes</li> </ul>	Time for the browser to complete the download of remaining resources, including images, and finish rendering the page.
Resources Loaded per Pageview			<ul style="list-style-type: none"> <li>• Ajax (XHR, Fetch API)</li> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframes</li> </ul>	Total number of resources in a <code>pageview</code> .  Calculated after the page has completely loaded.
Requests per Minute (Short name based on PLC entries)			<ul style="list-style-type: none"> <li>• Ajax Requests (XHR, Fetch API)</li> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframes</li> </ul>	Total number of requests (Page + Ajax + Iframe) per minute.

Name (Short Name)	NavTiming Capable Browsers <sup>1</sup>	Browsers without NavTiming Support	Available For ...	Definition
Scripts Loaded per Pageview			<ul style="list-style-type: none"> <li>Ajax (XHR, Fetch API)</li> <li>App</li> <li>Base Pages</li> <li>Browser</li> <li>Device</li> <li>Geo</li> <li>Iframes</li> </ul>	<p>Total number of scripts in a pageview .</p> <p>Calculated after the page has completely loaded.</p>
Server Connection Time (SCT)	navigationStart to requestStart	N/A	<ul style="list-style-type: none"> <li>App</li> <li>Base Pages</li> <li>Browser</li> <li>Device</li> <li>Geo</li> <li>Iframes</li> </ul>	<p>Interval between the time that a user initiates a request and the start of fetching the response document from the server or application task.</p> <p>Includes the time spent on redirects, domain lookups, TCP connects and SSL handshakes.</p>
SSL Handshake Time (SSL) <sup>3</sup>	secureConnectionStart to connectEnd	N/A	<ul style="list-style-type: none"> <li>App</li> <li>Base Pages</li> <li>Browser</li> <li>Device</li> <li>Geo</li> <li>Iframes</li> </ul>	<p>Time taken to complete the SSL handshake.</p>
TCP Connect Time (TCP)	connectStart to connectEnd	N/A	<ul style="list-style-type: none"> <li>App</li> <li>Base Pages</li> <li>Browser</li> <li>Device</li> <li>Geo</li> <li>Iframes</li> </ul>	<p>Time to complete the TCP connect portion of the server connection time, the equivalent of one network roundtrip of latency.</p>
Total Resource Redirect Time			<ul style="list-style-type: none"> <li>Ajax (XHR, Fetch API)</li> <li>App</li> <li>Base Pages</li> <li>Browser</li> <li>Device</li> <li>Geo</li> <li>Iframes</li> </ul>	<p>Time for all redirects associated with fetching resources.</p> <p>Calculated after the page has completely loaded.</p>

Name (Short Name)	NavTiming Capable Browsers <sup>1</sup>	Browsers without NavTiming Support	Available For ...	Definition
Visually Complete Time (VCT)	N/A	N/A	<ul style="list-style-type: none"> <li>• App</li> <li>• Base Pages</li> <li>• Browser</li> <li>• Device</li> <li>• Geo</li> <li>• Iframes</li> </ul>	<p>Total time for all visual elements within the first screen (above-the-fold content) to load in an end user's browser. Calculated using the last visual change to the page in a browser window.</p> <p>For information about Visually Complete Time for SPA2 pages, see <a href="#">SPA2 Metrics</a>.</p>

### Ajax Metrics Availability

Because Ajax requests occur in the context of the larger page, these four core metrics are always available, regardless of the browser type.

For more information on which browsers support the Navigation Timing API, see the [Can I Use](#) website.

### Resource Timing Metrics

Resource timing metrics are the median times in milliseconds. The resource timing metrics shown in the Resource Performance Dashboard are raw data.

Metric Name	How It's Calculated	Description
Browser Wait	<code>startTime</code> or <code>redirectEnd</code> to <code>fetchStart</code>	Time from the redirection or request start until the browser begins to fetch the resource.
Redirect Time	<code>redirectStart</code> to <code>redirectEnd</code>	Time for all redirects associated with fetching resources.
DNS Wait Time	<code>fetchStart</code> to <code>domainLookupStart</code>	Time from when the browser starts to fetch the resource until the browser starts the domain name lookup for the resource.
DNS Time	<code>domainLookupStart</code> to <code>domainLookupEnd</code>	Time to complete the domain lookup portion of the server connection time.
TCP Wait Time	<code>domainLookupEnd</code> to <code>connectStart</code>	Time for the browser to find the domain name for the resource before a connection is made.
Connection Time	<code>connectStart</code> to <code>connectEnd</code>	Time to complete the establish the TCP connection for a resource: the equivalent of one network roundtrip of latency.
SSL Time	<code>secureConnectionStart</code> to <code>connectEnd</code> (if <code>secureConnectionStart</code> exists)	Time to establish a secure connection to the server.
Request Wait Time	<code>connectEnd</code> to <code>requestStart</code>	Time for the request is made for a resource from the server, cache, or local resource before the connection is closed.
Request Time	<code>requestStart</code> to <code>responseStart</code>	Time for the browser to complete the request for a resource from the server, cache, or local resource.
Response Time	<code>responseStart</code> to <code>responseEnd</code>	Time for the browser to download the complete HTML document content. In the context of an Ajax request, the time for the browser to download the complete Ajax response.

Metric Name	How It's Calculated	Description
First Byte Time	<code>startTime</code> to <code>responseStart</code>	Time from when the request is made until the first byte of the resource is received by the browser.
Resource Load Time	<code>startTime</code> to <code>responseEnd</code>	Time for the browser to start a request and receive a response for a resource.
Browser Queue Time	Browser Wait + DNS Wait Time + Request Wait Time	Total wait time of the resource.
TCP Time	<code>secureConnectionStart</code> to <code>connectStart</code>	Time spent to establish a secure connection to the server (same as SSL Time).

For a more information, see [Resource Timing Attributes](#).

### Configure Timing Metrics

If your application continuously sends Ajax requests or resources, you may want to configure the default JavaScript timing metrics below.

For example, if in your SPA2 app the Ajax requests are sent at a faster rate (i.e 2 seconds) than the default `maxInactive` time (3 seconds), the Page Load Time metric could be incorrectly inflated. To fix this, you could configure `maxInactiveTime` to 2 seconds so Page Load Time matches the rate of the Ajax requests.

#### **maxResourceQuietTime**

If all registered resources are loaded and the time elapsed between `currentTime` and last resource load time is  $\geq$  `maxQuietTime`, the resource observer stops.

```
(function(config){
 config.navComplete = {
 maxResourceQuietTime: 5000 // For SPA2 applications, the default value is
 5000 (5 seconds). For non-SPA applications, the default value is 1000 (1 second).
 };
})(window['adrum-config'] || (window['adrum-config'] = {}));
```

#### **maxXhrQuietTime**

If all XHRs are successful and the time elapsed between `currentTime` and last XHR load time is  $\geq$  `maxQuietTime`, the XHR observer stops.

```
(function(config){
 config.navComplete = {
 maxXhrQuietTime: 3000 // For SPA2 applications, the default value is 3000 (3
seconds). For non-SPA applications, the default value is 1000 (1 second).
 };
})(window['adrum-config'] || (window['adrum-config'] = {}));
```

### **i** About timing metrics and NavComplete

`maxResourceQuietTime` and `maxXhrQuietTime` contribute toward the page observation period to be marked complete ( `navComplete` ). There are two ways for `navComplete` to occur:

1. Both the XHR observer (`maxXhrQuietTime`) and the resource observer (`maxResourceQuietTime`) have stopped running.
2. The time elapsed since the last download activity has exceeded the `maxQuietTime`. This means enough time has passed since the latest resource or XHR load.

Once either of these scenarios is reached, the JavaScript Agent will consider the page to be complete, mark the timing as Visually Complete Time, and report the page to AppDynamics.

### **maxInactiveTime**

`maxInactiveTime` is the current time minus when the last resource (i.e. Ajax call) happened. If this value is greater than `maxInactiveTime`, the navigation observer is assumed complete and the Visually Complete Time value is sent.

```
(function(config){
 config.navComplete = {
 maxInactiveTime: 3000 // For SPA2 applications, the default value is 3000 (3
seconds). For non-SPA applications, the default value is 1000 (1 second).
 };
})(window['adrum-config'] || (window['adrum-config'] = {}));
```

## **Browser RUM Supported Environments**

This page describes the supported environments and versions for Browser RUM.

### **Browser RUM Support**

#### **Browser Compatibility**

- IE 10, 11, Edge
- Chrome >= 1.0.154.60, including Mobile
- Headless Chrome >= 59
- Firefox, including Mobile
- Safari >= 4, including Mobile
- Opera >= 12

**i** Browsers are rapidly evolving, and not all versions have been individually tested with Browser RUM. You can view the [browser versions likely to support the Resource Timing API](#).

### Browser Requirements for Sessions

To use Browser RUM sessions, your browser is required to support for the following:

- [cross-origin resource sharing \(CORS\)](#) for beacons
- [local storage](#) for multiple-page sessions (single-page / multiple virtual page sessions don't need local storage)

**i** Browser RUM sessions do not support beacons implemented with GIFs.

### JavaScript Agent Version Requirement for Sessions

You are required to use the JavaScript Agent  $\geq 4.2$ . Older versions of the JavaScript Agent do not support sessions.

### Injection Types for Browser RUM in Java Environments

Listed below are the injection types with their supported frameworks/technologies:

- **Automatic Injection:** JavaServer Pages (JSP) compiled using the [Jasper compiler](#). Jasper is the default JSP compiler in [Tomcat](#), [Glassfish](#), and [JBoss](#).
- **Assisted Injection:** All [Servlet](#) frameworks.
- **Manual Injection:** All technologies that generate HTML pages.

See [Inject the JavaScript Agent](#) for details.

### Injection Types for Browser RUM in .NET Environments

AppDynamics certifies Browser RUM instrumentation for the following .NET environments:

- .NET Framework
- .NET Core

### Browser RUM Instrumentation for .NET Framework

Supported Runtime Environments for Browser RUM .NET Framework include:

Microsoft IIS versions 6.0, 7.0, 7.5, 8.0, 8.5

- All listed frameworks support [manual injection of the JavaScript Agent for Browser RUM](#).
- The Script Injection column lists additionally supported script injection strategies. See [Inject the JavaScript Agent](#) for details.

Web Application/AJAX Frameworks	Versions	Additional Supported Script Injection Methods
ASP.NET Web Forms (.aspx)	3, 4	<a href="#">Automatic, Using Attribute Injection</a>
ASP.NET MVC Web Forms (.aspx)	3 - 5	<a href="#">Automatic, Using Attribute Injection</a>
ASP.NET MVC Razor	3 - 5	<a href="#">Automatic, Using Attribute Injection</a>

Web Application/AJAX Frameworks	Versions	Additional Supported Script Injection Methods
Microsoft SharePoint	2007, 2010	Automatic

**i** AppDynamics does not support Browser RUM instrumentation of legacy ASP ( .asp ) pages.

### Browser RUM Instrumentation for .NET Core

AppDynamics currently supports .NET Agent for Windows >= 21.1, and .NET Agent for Linux >= 21.5.

Web Application/AJAX Frameworks	Versions	Supported Script Injection Methods
ASP.NET Core MVC	3.1, 5	Automatic
ASP.NET Core Razor Pages	3.1, 5	Automatic

### Browser RUM Countries and Regions by Geo Dashboard

The countries and regions in the sections below can be displayed in the **Geo Dashboard**. Each of these countries and regions also displays their own aggregate Browser RUM data. Data can be collected from areas not in the following list, but it will not be displayed in these parts of the interface. Some countries and regions are only displayed in the grid view.

#### Countries

#### Grid View

## Troubleshoot Browser RUM

These pages provide methods to solve common problems:

- [Browser RUM License Troubleshooting](#)
- [Browser RUM Metrics Not Reported](#)
- [Pages Not Monitored](#)
- [Injection Problems](#)
- [Browser Snapshot Problems](#)
- [Connection Problems](#)
- [Create a HAR File to Troubleshoot Web Download Issues](#)

### Browser RUM License Troubleshooting

#### Related pages:

- [EUM Accounts, Licenses, and App Keys](#)

The following sections discuss how to solve common license problems.

#### No EUM Account License Key

The EUM account license is separate from the Controller license. Although the license file includes the EUM license key, the EUM account license is provisioned separately.

Controllers cannot share an EUM license key, but applications can.

If you need an EUM license, call your AppDynamics sales representative or email [salesops@appdynamics.com](mailto:salesops@appdynamics.com).

#### Browser RUM Not Working in Production

If you are running more than one Controller, each instance requires a unique license. Make sure you are not trying to use the same license on more than one Controller.

#### Browser RUM Metrics Not Reported

This page provides a high-level overview to check your Browser RUM setup.

#### Check for Load

Make sure there is load running on your app for the pages that you want to monitor for the selected period.

When Browser RUM discovers a new page, iframe, or Ajax call for the first time, there will be a several minute delay before data for it appears in the Controller UI.

- It takes up to two or three minutes for the agent to register with the Controller. No metrics are captured during this time.
- After the page is registered and traffic starts flowing, it can take an additional two or three minutes for the metrics to appear in the AppDynamics console.
- After that, the delay between an end-user click and the appearance of Browser RUM data is two to three minutes.

#### Confirm Browser RUM Is Enabled

Make sure you enable Browser RUM for the app. Enable it if it is disabled. See [Enable and Disable Browser Monitoring](#).

#### Ensure Pages Are Instrumented

Examine the source of your web page to ensure that you have instrumented the pages that you want to monitor.

## Check Connectivity

Make sure there is connectivity from the browser to the EUM Cloud.

## Examine Beacons for Issues

If beacons are not present or their status is not valid, verify your Browser RUM configuration. See [Set Up and Access Browser RUM](#).

To examine your instrumented application for issues, verify the following:

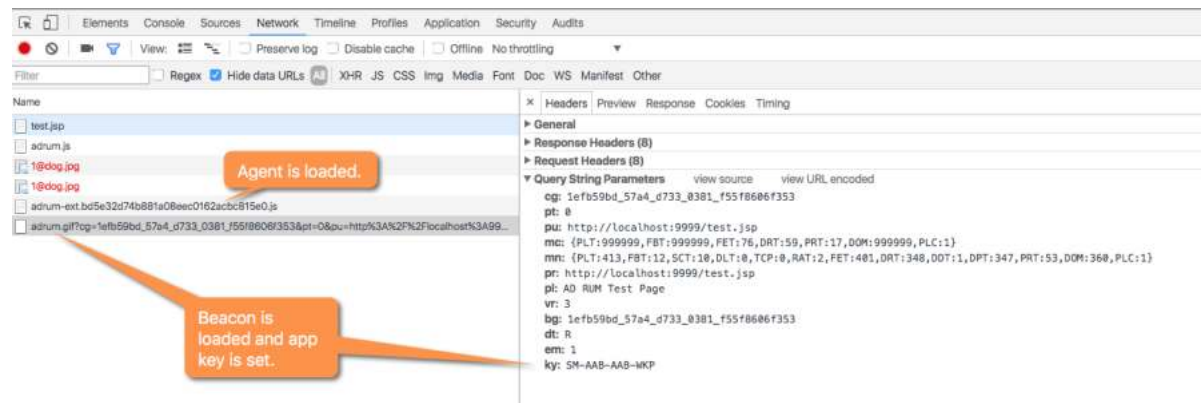

- The JavaScript Agent extension ( `adrum.ext` ) is loaded and its status is OK (200).
- The EUM beacon is sent:
  - As a `.gif` request—older browsers
  - A GET request for `adrum.gif` is loaded, and its status is OK (200).
  - The `ky` parameter in the beacon is set to your application key.
  - As a CORS-based request—deprecated
  - A POST request has been sent with a status of OK (200).
  - The app key is sent in the body of the beacon.
  - As a CORS-based request
  - A POST request has been sent with a status of OK (200).
  - The app key is sent in the URL.

**i** Beacons for using image requests have an inherent length limitation. Because of this, URLs longer than 180 characters, page names longer than 50 characters, and user data (key and value combined) longer than 113 characters are not supported in these browsers.

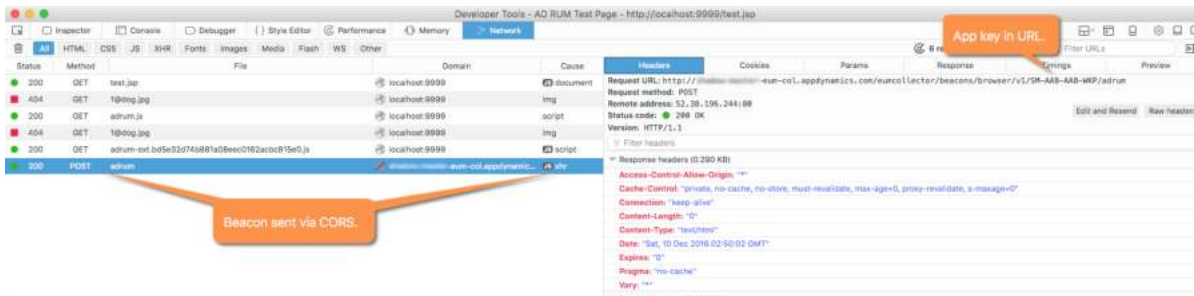

## Use Developer Tools to Examine Your Application

You can use the developer tools in your web browser to examine your application.

This screenshot shows a `.gif` -based beacon in Chrome.

This screenshot shows a CORS-based beacon with a key in the URL path.

Create a [HAR file](#) to confirm that the browser is downloading the expected resources for your web page.

### Pages Not Monitored

You may find that some pages have not been monitored as expected. This page may help you determine the reason why these pages have not been monitored.

### Verify Pages Have Been Injected

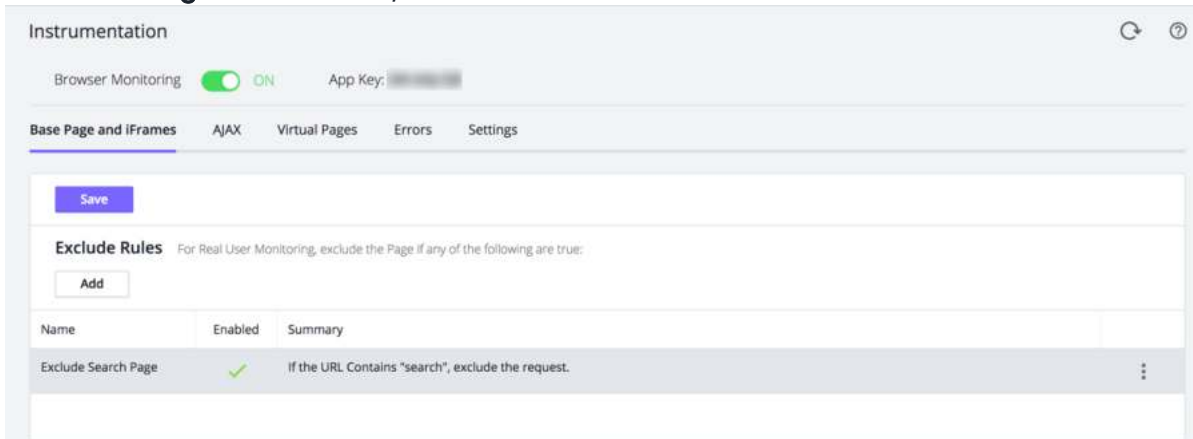

If only some web pages are not reporting data, first verify that those pages have been injected with the JavaScript Agent. See [Verifying that the JavaScript Agent for Browser RUM was injected](#).

### Check Exclude Rules

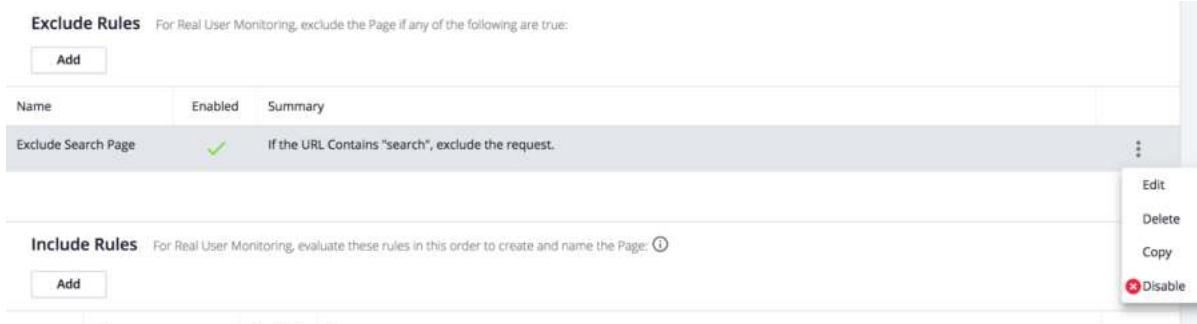

If the agent has been injected, the page may have been excluded from monitoring by custom exclude rules. You can check and modify these rules.

To access custom exclude rules for pages:

1. Click **Configuration > Instrumentation**.
2. Click the **Base Pages and iFrames** tab.
3. From **Base Pages and iFrames**, check the custom rules under the **Exclude Rules** section.

4. To examine and/or modify a custom exclude rule select it in the list and click the  icon:

5. If you want to remove a custom exclude rule, select and click **Delete**.

### Check Automatic Injection Configuration

In addition, certain pages could have been excluded by the injection configuration. This can happen when automatic injection is used with a limited set of pages enabled for injection. If you used automatic injection, check your automatic injection configuration to see if the missing pages are enabled for injection.

Examine the **Request Match Rules** and **Request Exclude Rules** lists under **Only enable Automatic Injection for certain Pages** in the **Automatic JavaScript Injection** tab. See [Automatic Injection of the JavaScript Agent](#). Pages can also be bypassed by assisted injection using injection rules when an injection rule specifies only classes and methods to be injected. If you used assisted injection with injection rules, check your injection rules. See [Assisted Injection](#).

### Configure the JavaScript Agent to Monitor Older Browsers

The JavaScript Agent by default supports modern browser and no longer tests or certifies the collection and reporting of data from older browsers. If you find that older browsers are accessing your web pages and that they are not being monitored, you can configure the JavaScript Agent to monitor older browser with the following configuration.

```
(function(config){
 ...
 "beacon": { "neverSendImageBeacon": false },
 ...
})(window['adrum-config'] || (window['adrum-config'] = {}));
```

### Ajax Requests Not Monitored

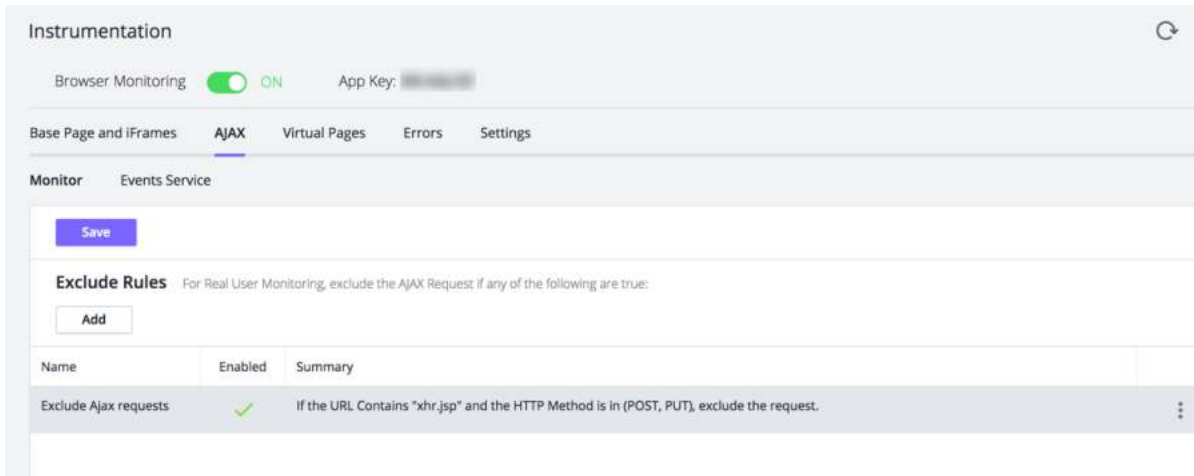

You may find that some Ajax requests have not been monitored as expected. The page may help you determine why these pages have not been monitored.

### Check Exclude Rules

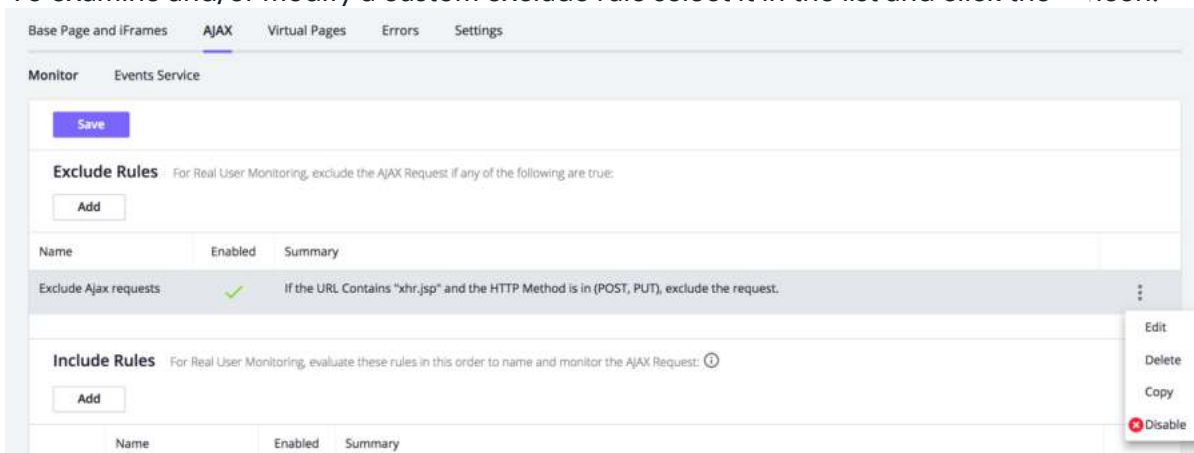

If the agent has been injected, the Ajax event may have been excluded from monitoring by custom exclude rules. You can check and modify these rules.

To access custom exclude rules for pages:

1. Click **Configuration > Instrumentation**.
2. From the AJAX tab, check the custom rules under the **Exclude Rules** section.

3. To examine and/or modify a custom exclude rule select it in the list and click the  icon:

4. If you want to remove a custom exclude rule, select and click **Delete**.

### Verify That XHR Objects Were Reused Correctly

Browser RUM can monitor multiple Ajax calls made from a reused `XMLHttpRequest` object, but if the `XMLHttpRequest` object is reused (opened) before the last request is completed, the JavaScript agent cannot collect all the metrics for all the Ajax requests.

#### Incorrect Method to Reuse XMLHttpRequest Object

In the example below, the `xhr` object is making a request to `/multi-bt` before the request to `/xhr/uptime` has completed, so the JavaScript Agent only reports the second Ajax request to `/multi-bt`.

```
function reuseXHRBeforeReady() {
 var xhr = new Xhr();
 xhr.open("GET", "/xhr/uptime");
 xhr.onreadystatechange = safe(function() {
 if (xhr.readyState == 4) {
 if (typeof(console) !== "undefined" && console !== null && console.log)
 console.log("onreadystatechange for xhr1: " + xhr.responseText);
 }
 });
 xhr.send();
 // ... later ...
 xhr.open("GET", "/multi-bt");
 xhr.send();
}
```

```

 document.getElementById("result").innerHTML = xhr.responseText;
 }
});
xhr.send(null);
xhr.open("GET", "/multi-bt");
xhr.onreadystatechange = safe(function() {
 if (xhr.readyState == 4) {
 if (typeof(console) !== "undefined" && console !== null && console.log)
 console.log("onreadystatechange for xhr2: " + xhr.responseText);
 document.getElementById("result").innerHTML = xhr.responseText;
 }
});
xhr.send(null);
}

```

When an Ajax request cannot be reported because the `XMLHttpRequest` object is reused (opened) before the last request is completed, the JavaScript Agent logs that an Ajax request was *not* reported in a message similar to the one below. You will most likely have to modify your JavaScript so that new Ajax requests are only made after previous requests are completed.

```

EXT~ The reused XHR object calls open() before finishes last job. No event of XHR to '" +
this._adrumAjaxT.url() + "' is reported.

```

### Correct Method to Reuse XMLHttpRequest Object

The correct method to reuse the `XMLHttpRequest` object to make more than one request is to nest the calls so that new calls are only made when previous calls have been completed. In the example below, the call to `/xhr/multi-bt2` is only made when the call to `/multi-bt` has completed, so both calls are reported as Ajax requests.

```

function reuseXHR() {
 var xhr = new Xhr();
 xhr.open("GET", "/xhr/uptime");
 xhr.onreadystatechange = safe(function() {
 if (xhr.readyState == 4) {
 document.getElementById("result").innerHTML = xhr.responseText;
 xhr.open("GET", "/multi-bt");
 xhr.onreadystatechange = safe(function() {
 if (xhr.readyState == 4) {
 if (typeof(console) !== "undefined" && console !== null && console.log)
 console.log("onreadystatechange for xhr2: " + xhr.responseText);
 document.getElementById("result").innerHTML = xhr.responseText;

 // Reuse xhr again
 xhr.open("GET", "/xhr/multi-bt2");
 xhr.onreadystatechange = safe(function() {
 console.log("/xhr/multi-bt2 responded.");
 });
 xhr.send(null);
 }
 });
 }
 });
}

```

```

 });
 xhr.send(null);
 }
});
xhr.send(null);
}

```

## Check Injection Configuration

In addition, certain Ajax requests could have been filtered out by the injection configuration. This can happen when the injection uses [XHR filters to limit which Ajax requests are monitored](#). Check your injection configuration to verify that the filtering did not prevent the calls from being monitored.

## Injection Problems

You must inject the JavaScript Agent for Browser RUM into every page that you want to monitor.

## Verify Injection

View the source of your web page. When automatic or assisted injection is used, you should see the script for the JavaScript Agent inline in the web page. When manual injection is used, you will see:

```
<script src="/path_to_adrum.js"/>
```

If you used manual injection, use the normal procedures that you use to verify other types of code changes in your web pages. Keep in mind that various caches, such as the server page, CDN or browser caches, can prevent the page from actually being reloaded. If you cannot get manual injection to work, try one of the other injection schemes if they are available for your platform. See [Inject the JavaScript Agent](#) for information about the various injection strategies.

## Verify Automatic Injection is Enabled

To verify that automatic injection is enabled:

1. Open the business application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration > JavaScript Agent Injection**.
3. From **Inject the JavaScript Agent configured for this Browser App**, confirm that your browser app receiving the automatic injection is selected.
4. Select the Automatic Injection tab.
5. Confirm that the **Enable Automatic Injection of JavaScript** checkbox is checked.
6. Verify that automatic injection is enabled for all of the business transactions that you want to monitor. If some of those business transactions are in the **Automatic injection possible, but not enabled list**, move them to the **Automatic injection enabled list**. If the business transaction that you want to monitor does not appear in either list, automatic injection is not possible for that business transaction.
7. Click **Save** if you made any changes.

See [Automatic Injection of the JavaScript Agent](#) for information about creating and enabling injection rules.

## Verify Assisted Injection is Enabled

To verify that assisted attribute injection is enabled:

1. Open the business application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration > JavaScript Agent Injection**.
3. From **Inject the JavaScript Agent configured for this Browser App**, confirm that your browser app receiving the automatic injection is selected.
4. Select the Configure JavaScript Injection tab.
5. Confirm that the **Request Attribute Injection** is checked.
6. Click **Save** if you made any changes.

To verify that assisted injection using injection rules is enabled:

1. Open the business application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration > JavaScript Agent Injection**.
3. From **Inject the JavaScript Agent configured for this Browser App**, confirm that your browser app receiving the automatic injection is selected.
4. Select the Configure JavaScript Injection tab.
5. Confirm that there are enabled injection rules in the table under **Create Injection Rules**.
6. From the Where to Inject JavaScript tab, confirm that the rules are correct.
7. From the Inject for these Business Transactions tab, confirm that the rules are applied for the desired business transactions.
8. Click **Save** if you made any changes.

See [Assisted Injection](#) for information about creating and enabling injection rules.

### Change Your Injection Strategy

If you try one way to inject the JavaScript Agent and it does not work, it is best to undo the current injection configuration before implementing another one.

- To undo automatic injection, clear the **Enable Automatic Injection of JavaScript** check box.
- To undo assisted injection using attribute injection, clear the **Request Attribute Injection** check box, and manually delete the code snippets.
- To undo manual injection, manually delete the JavaScript Agent code from your web pages.
- To undo assisted injection using injection rules, clear the **Enable** check box for each injection rule in the injection rules list.

If multiple copies of the agent exist on a page, the second copy does not execute.

### Fix Page Rendering Issues

The rendering of pages in some browsers, in particular, Internet Explorer (IE), may be adversely affected by the JavaScript Agent injection.

After you have confirmed that the JavaScript Agent injection is causing the issue, try the following:

1. [Inject the JavaScript Agent after the last `<meta>` element.](#)
2. [Inject the JavaScript Agent just before the closing `<head>` element.](#)

If you are using automatic injection, see [Troubleshoot Automatic Injection](#).

Injecting the JavaScript Agent just before the closing `<head>` tag is *not* the recommended practice because the JavaScript Agent will not capture the resource timing metrics for resources loaded before it. Thus, only do this as a last resort.

### Inject After Last Meta Element

To avoid rendering issues and capture resource timing metrics, you are recommended to inject the JavaScript injection right after the last `<meta>` element in the `<head>` as shown below.

```

<head>
 <meta charset="UTF-8">
 <meta name="description" content="Fancy Web Page">
 <meta name="keywords" content="HTML,CSS,XML,JavaScript">
 <meta name="author" content="John Doe">
 <meta name="viewport" content="width=device-width, initial-scale=1.0">

 // Injection of the JavaScript Agent after the last <meta> tag
 <script charset='UTF-8'>
 window['adrum-start-time'] = new Date().getTime();
 (function(config){
 config.appKey = 'SH-AAB-AAC-XAR';
 config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
 config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
 config.beaconUrlHttp = 'http://eum-col.appdynamics.com';
 config.beaconUrlHttps = 'https://eum-col.appdynamics.com';
 config.xd = {enable : false};
 })(window['adrum-config'] || (window['adrum-config'] = {}));
 </script>
 <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='U
 TF-8' />
 // The rest of the JS and CSS files
 <script src="https://code.jquery.com/jquery-<version>.js" integrity="sha256-DZAnKJ/
 6XZ9si04Hgrsxu/8s717jcIzLy3oi35EouyE=" crossorigin="anonymous"></script>
 <script src="js/custom-script.js"></script>
 <link type="text/css" rel="stylesheet" href="css/custom-style.css" />
 ...
</head>

```

### Inject Before the Closing Head Element

On rare occasions, some browsers, in particular, Internet Explorer (IE), will still render the page incorrectly because of where the JavaScript Agent is injected. In such cases, as a last resort, try injecting the JavaScript Agent right before the closing `<head>` element:

```

<head>
 <meta charset="UTF-8">
 <meta name="description" content="Fancy Web Page">
 <meta name="keywords" content="HTML,CSS,XML,JavaScript">
 <meta name="author" content="John Doe">
 <meta name="viewport" content="width=device-width, initial-scale=1.0">
 <script src="https://code.jquery.com/jquery-<version>.js" integrity="sha256-DZAnKJ/
 6XZ9si04Hgrsxu/8s717jcIzLy3oi35EouyE=" crossorigin="anonymous"></script>
 <script src="js/custom-script.js"></script>
 <link type="text/css" rel="stylesheet" href="css/custom-style.css" />
 ...
 // Injection of the JavaScript Agent before the closing <head> tag
 <script charset='UTF-8'>

```

```

window['adrum-start-time'] = new Date().getTime();
(function(config){
 config.appKey = 'SH-AAB-AAC-XAR';
 config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
 config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
 config.beaconUrlHttp = 'http://eum-col.appdynamics.com';
 config.beaconUrlHttps = 'https://eum-col.appdynamics.com';
 config.xd = {enable : false};
})(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8' />
</head>

```

## Troubleshoot Automatic Injection Issues

If you are using the .NET Agent to automatically inject the JavaScript Agent into pages and the pages are not rendering correctly:

1. Use manual injection and make sure that the JavaScript Agent is injected after the last <meta> element.
2. If you cannot use manual injection, [add the registered node property eum-header-beforeendofheadtag](#) to a Web tier or particular nodes. This node property configures the .NET Agent in the specified tier or nodes to inject the JavaScript Agent right before the closing <head> tag.

## Browser Snapshot Problems

This page provides help with troubleshooting problems with browser snapshots.

### No Browser Snapshots

If you do not see any browser snapshots, it is possible that browser snapshot collection has been disabled. If periodic collection and error collection and slow collection are all disabled, the agent does not collect any browser snapshots. See [Configure Browser Snapshot Collection](#).

Also, check the thresholds that define slow end-user experience. AppDynamics collects browser snapshots only for slow-performing requests, so if the thresholds are set too high, no requests are flagged as slow. See [Configure Browser RUM Performance Thresholds](#).

### No Correlation between Browser Snapshots and Business Transactions

You get server-side correlation with browser snapshots only if the business transactions associated with the browser snapshot are running on application servers instrumented with AppDynamics app agents. This could explain why you do not see any or do not see all of the business transactions that you expect to see. Check which of your servers are instrumented by app agents and which are not. You may need to get more AppDynamics app agent licenses to get correlation.

If the app servers are all instrumented with AppDynamics app agents, it is possible that the business transactions that you expect to see were not injected with the JavaScript Agent for Browser Monitoring. This can happen when automatic injection is used with a limited set of business transactions enabled for injection. If you used automatic injection, check your automatic injection configuration to see if the missing business transactions are enabled for injection. See [Verifying that the JavaScript Agent for Browser RUM was injected](#) and [Automatic Injection of the JavaScript Agent](#). Business transactions can also be excluded with assisted injection using injection rules when an injection rule specifies only certain business

transactions to be injected. If you used assisted injection with injection rules, check your injection rules. See [Assisted Injection](#).

### No Transaction Snapshots Associated with Browser Snapshots

Even if all your app servers are instrumented with AppDynamics app agents, it is possible that no associated transaction snapshots were captured at the time of the browser snapshot. For example, if no transactions were slow at the time of the browser snapshot, you probably will not see any transaction snapshots. See [Troubleshoot Business Transaction Performance with Transaction Snapshots](#) for information about when transaction snapshots are captured. You can modify transaction snapshot capture.

On the browser side, if a browser snapshot is associated with a transaction snapshot, you will see it in the **Transaction Snapshots** section of the browser snapshots. See [Business Transactions in Browser Snapshots](#). On the server side, if a transaction snapshot is associated with a browser snapshot, you will see an EUEM GUID in the **ADDITIONAL DATA** tab in the transaction snapshot. See [Troubleshoot Business Transaction Performance with Transaction Snapshots](#).

### Not Getting Full Timing Data for Business Transactions Associated with Browser Snapshots

To ensure full business transaction timing information using older agents and controllers (3.8 and before), you need to inject the JavaScript footer for Browser RUM into the footer of your web pages. Manual injection of the agent does not inject into the footer, so you need to use another injection method to get this functionality.

See [Getting Full Timing Data for Associated Business Transactions](#) and [Choosing Your Injection Method](#).

### No Correlation between Cross Domain AJAX Requests and Business Transactions

Your JavaScript Agent may not be able to correlate Ajax requests with business transactions because browsers restrict access to certain HTTP response headers. Your application, however, can explicitly give browsers access to HTTP headers by sending the HTTP response header `Access-Control-Expose-Headers` with a list of the headers that you want the JavaScript Agent to access.

The process of correlating cross-domain Ajax requests and business transactions consists of the following two steps:

1. Set the agent, tier, or application node property `always-add-eum-metadata-in-http-headers` to `true`. If this property doesn't exist, you need to add and register it as described in [Add a Registered Node Property](#).
2. Modify the application code, so that the returned response header includes the field `Access-Control-Expose-Headers` as shown below:

```
Access-Control-Expose-Headers:
ADRUM_0,ADRUM_1,ADRUM_2,ADRUM_3,ADRUM_4,ADRUM_5,ADRUM_6,ADRUM_7,ADRUM_8,ADRUM_9,ADRUM_10,
ADRUM_11,ADRUM_12,ADRUM_13,ADRUM_14,ADRUM_15,ADRUM_16,ADRUM_17,ADRUM_18
```

### Connection Problems

If your browser cannot connect to the AppDynamics EUM cloud and you use an on-premises Controller, but not an on-premises EUM Server, it is possible that:

- You have no Internet connectivity
- A firewall is blocking the port

## Verify Connectivity

Navigate to [SaaS Domains](#) and select your geolocation. Find the EUM API Domain and add the following endpoint: `eumaggregator/ping`

If you receive a "ping" in the panel, you should be able to connect to the EUM Cloud.

**i** If you are using IE on a Windows system, make sure the browser itself does not have a proxy (with authentication) set up. If it does, the test link may work but not the actual connection.

Make sure you have also unblocked any firewalls and verified the keystore entries.

## Unblock Your Firewall

The Controller needs to be able to use HTTP over SSL (HTTPS) on port 443 to reach the EUM Cloud Aggregator in your region.

Navigate to [SaaS Domains](#) and select your geolocation. Find the EUM API Domain and add the following endpoint: `eumaggregator/ping`

If your Controller is behind a firewall, you can either open your Controller's firewall or use a forward proxy.

To open the firewall, see the instructions unique to your firewall.

**i** You only need to open the firewall for the specific host and port, not for the entire `*.eum-appdynamics.com` domain.

Use a Forward Proxy:

1. Set up an HTTP proxy to your SaaS EUM API Server. Navigate to [SaaS Domains](#) and select your geolocation. Find the EUM API Domain and add the following endpoint: `eumaggregator/ping`

**i** This is a cleartext/pass-through proxy. Authentication is not supported on the first level. If the client network itself requires authentication, you must set up an intermediate proxy between your Controller and this proxy to pass on the credentials you need to get out of your network.

2. Configure the HTTP proxy host and port in the `<Controller-Installation-Directory>/appserver/glassfish/domains/domain1/config/domain.xml` file by adding the following JVM options to the existing `java-config` element:

```
<jvm-options>
 -Dappdynamics.controller.http.proxyHost=myhost
</jvm-options>
<jvm-options>
 -Dappdynamics.controller.http.proxyPort=8888
</jvm-options>
```

3. Restart the Controller's app server.

## JavaScript Errors

This page provides helpful tips for finding and solving common JavaScript errors.

### Enable Error Reporting

It is possible that reporting is disabled or that certain JavaScript or Ajax errors that you would like to be reported have been configured to be ignored. See [Configure JavaScript and Ajax Error Detection](#).

If another script on your monitored pages sets the JavaScript `window.onerror` event, this setting can interfere with Browser RUM error capture. See [Handle the window.onerror Event](#).

### Visualize JavaScript Errors

To view and analyze JavaScript errors, you can use two functionalities:

- Use the JavaScript Errors Dashboard to view and troubleshoot specific errors. See [JavaScript Errors Dashboard](#).
- Use Analytics to query your Browser Request event data and create a JavaScript exception and error summary dashboard. See [Visualize JavaScript Errors](#).

### View Error Information for Cross-Domain JavaScript

By default and for security reasons, most modern browsers do not provide access to the error information in `window.onerror` for scripts that are loaded from other domains. To access this error information, you need to enable [cross-origin resource sharing \(CORS\)](#). Firefox and Chrome both allow you to enable CORS by making small changes to your server and `script` element in your HTML.

If you have **not** enabled CORS, the error message "CROSSORIGIN" displays:

#### JavaScript Errors

Script Origin	Line #	Message
CROSSORIGIN	0	Script error

Once CORS is enabled, you will be able to see error details like those shown here.

Also, when you can navigate to your page from Chrome and then open **JavaScript Console > Network > Headers**, you'll see the HTTP response header `access-control-allow-origin: *`.

In the following sections, we're going to show you how to make changes to access the error information in `window.onerror` cross-domain scripts.

#### Server Change

To [enable CORS](#), you need to add this header to responses that are not from the same domain as the caller:

```
Access-Control-Allow-Origin: *
```

#### Script Tag Change

The `script` element has a new non-standard attribute called `crossorigin`. The most secure value for `crossorigin` would be `anonymous`. So, you'll have to modify your script tags to look like the following.

```
<script src="http://sub.domain.com/adrum.js" crossorigin="anonymous"></script>
```

## Browser Support for CORS

In the future, we expect most browsers to enable CORS. Internet Explorer 10+ already has native support for CORS and reports errors to `window.onerror` for both local and cross-domain scripts. See [CORS: Browser support](#) to see a list of browsers/layout engines that support CORS.

## Synthetic Monitoring

- [Browser Synthetic Monitoring](#)
- [Synthetic API Monitoring](#)
- [Install the Private Synthetic Agent \(Web and API Monitoring\)](#)

## Browser Synthetic Monitoring

### Related pages:

- [Browser Synthetic Monitoring versus Browser Real User Monitoring](#)
- [Get Started with Browser Synthetic Monitoring](#)

Browsers Synthetic Monitoring uses geographically distributed Synthetic Agents to continuously test key user workflows in your application. This allows you to monitor the correctness and performance of multi-step flows independently of the user-generated load.

There are two ways of using Synthetic:

- **Scheduled jobs:** Use this to test your pages on a recurring basis to ensure they continue to perform well. Upload a Python WebDriver script to exercise multi-step workflows. Using this feature requires a Synthetic Pro license. See [Browser Synthetic Licenses](#) for more information.
- **On-demand snapshots:** Use this to collect performance data right now. This is useful for ad-hoc analysis. This feature is available with both Synthetic Lite and Pro licenses.

There are two deployment types for Synthetic Agents:

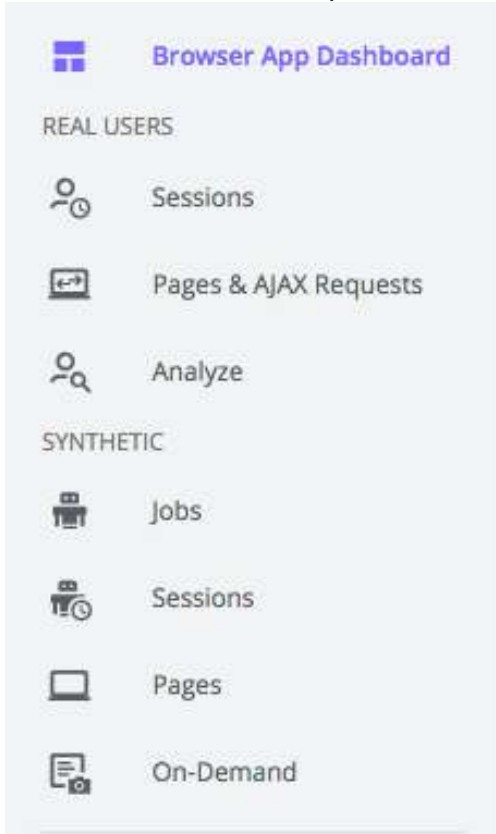

- **Synthetic Hosted Agents:** AppDynamics hosts these Synthetic Agents. This deployment is recommended for testing public websites.
- **Synthetic Private Agents:** You install and host Synthetic Agents on your machines. This enables you to test internal sites and services. For more information, see [Install the Private Synthetic Agent \(Web and API Monitoring\)](#).

Separate licenses are required for the Synthetic Hosted Agent and the Synthetic Private Agent. See [Synthetic Agent Licenses](#) for details.

## Access Synthetic

1. Open the browser application that you want to test with Synthetic or create a new one if you're just getting started.

2. Select one of the menu options under **SYNTHETIC** in the left navigation bar.

### Scheduled Jobs

The **Jobs**, **Sessions**, and **Pages** options are only displayed if you have a Browser Synthetic Pro license.

- **Jobs:** Create and manage recurring jobs. See [Get Started with Browser Synthetic Monitoring](#).
- **Sessions:** View individual executions of your jobs (i.e., "sessions") and perform an analysis to understand where the problems are.
- **Pages:** View aggregated page-level statistics collected from Synthetic. This is particularly useful for comparing Browser RUM with Synthetic.

**i** You can also see some synthetic results in the context of real user traffic in the [Browser App Dashboard](#).

### On-Demand Snapshots

Create and view on-demand snapshots using [On-Demand](#).

### Website Authentication Methods

The following table lists the authentication methods that are supported and not supported in Synthetic Monitoring.

Supported	Not Supported
Websites that authenticate through an explicit login page	Integrated Windows Authentication (see <a href="#">windows authentication</a> )

## Browser Support

Agent	Supported Browsers
Hosted Agent	<ul style="list-style-type: none"> <li>• <a href="#">Chrome 86</a></li> <li>• <a href="#">Firefox 72</a></li> <li>• <a href="#">IE 11</a></li> </ul> <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> <p><b>i</b> You can use the Firefox 72 and IE 11 browsers only as an emulation in Chrome 86. For more information, see <a href="#">Changes to Synthetic Monitoring browsers</a>.</p> </div>
Private Synthetic Agent (K8S Container Agent)	<ul style="list-style-type: none"> <li>• <a href="#">Chrome 86</a></li> </ul>

## Limitations

### Browser Extensions

Browser Synthetic Monitoring does not support monitoring for the browser extensions [Adobe Flash](#), [Microsoft Silverlight](#), or [Java applets](#).

### Single-Page Applications (SPAs)

Browser Synthetic Monitoring does not fully support SPA. Instead of reporting the base page and virtual pages separately like Browser RUM does, Browser Synthetic Monitor reports all the virtual pages with the base page, so you will only see one page in the Synthetic Sessions.

### Multiple Window Tests

Browser Synthetic Monitoring supports running tests in multiple windows for Firefox and Chrome, but *not* for Internet Explorer Browser.

### Chrome Version 86

This page provides details about the impact of updating the current browser version to headless Chrome Version 86.

- Chrome version 86 is available for:
  - SaaS Controllers
  - On-premise Controllers >=21.4.x with Synthetic Server >=21.4.1
- Jobs in AWS locations get executed in Linux-based agents with Chrome version 86
- Jobs in Azure locations get executed in Windows-based agents with Chrome version 86
- The behavior changes described on this page are not applicable for the agents in Azure locations

### Browser Version

Current Browser	New Browser	Impact	Action
Chrom e version s - 64, 79, 81, and 83	Headle ss Chrom e Version 86	The <code>driver.maximize_window</code> and <code>fullscreen_n_window</code> commands are not supported because of a <a href="#">bug</a> in Selenium ChromeDriver for headless Chrome.	Use the <code>set_window_size()</code> command instead of <code>driver.maximize_window</code> and <code>fullscreen_window</code> commands.
		Headless version includes major security enhancements and changes in the browser engine that results in increased page load time and session duration.	<ul style="list-style-type: none"> <li>• Increase the timeout configuration as required in the scripts.</li> <li>• Update the performance and alerting configurations as required.</li> </ul>
		Some Python based Selenium scripts that run successfully in Chrome version 64 fail with "Script broken" error in Chrome version 86. This happens due to incompatibility between the Selenium commands and the latest Chrome web-driver.	<ul style="list-style-type: none"> <li>• Update the scripts to fix this issue.</li> <li>• If the scripts pass locally with Chrome version 86 (Headless Chrome), reach out to the AppDynamics support team.</li> </ul>

Current Browser	New Browser	Impact	Action
		<p>Current Behaviour: Sessions with 4xx errors are not treated as client errors in certain cases</p>	<p>No action required.</p>
		<p>Headless Chrome does not support extensions or embedded PDF viewer. The PDF is downloaded and viewable in resource waterfall but screenshot is not present. Hence, you can verify the availability of a PDF file but cannot take a screenshot.</p>	<p>You can verify the availability of the PDF document by sending an HTTP request using Python request library and <code>assert</code> on the response code.</p> <p>Following is a sample script:</p> <pre data-bbox="716 814 1495 1125"> import requests  response = requests.get ("https:// www.mohfw.gov.in/pdf/ PreventionandManagementofCOVID19FLWEnglish.pdf") print ("Got response " + str(response.status_code)) assert (response.status_code == 200) </pre>
		<p>Some element selectors may not work with Headless Chrome. This can occur because of differences in how pages render across browser types and versions.</p>	<p>Update the script to change the element selector to point to the appropriate element.</p> <p>For example, if you are locating the element using an <code>xpath</code> attribute that does not work with a website loaded in Headless Chrome, then:</p> <ul style="list-style-type: none"> <li>• Fix the <code>xpath</code></li> <li>Or,</li> <li>• Use another method to select the element, such as <code>find_element_by_id</code>.</li> </ul> <p>For the complete list of how to select elements, see <a href="#">Locating Elements</a>.</p>

Current Browser	New Browser	Impact	Action
		<p>During multi-tab script flows, if the new tab is triggered indirectly, such as by an element click, the initial resources do not get captured in the new tab.</p> <p>This occurs because of a <a href="#">puppeteer bug</a>.</p>	Open the tab directly in the script and perform any operation.

### Agent Machine Configuration

Current Browser	New Browser	Impact	Action
Machine configuration: 2vCPU 8GB RAM	<ul style="list-style-type: none"> <li>Container configuration: min 1 vCPU - max 1.75 vCPU, 2GB RAM.</li> <li>Uses burst-able limits of Kubernetes for better resource utilisation.</li> </ul>	The page load time and session duration might increase.	<ul style="list-style-type: none"> <li>Increase the timeout configuration as required in the scripts.</li> <li>Update the performance and alerting configurations as required.</li> </ul>

### Job Execution Environment

Current Browser	New Browser	Impact	Action
Jobs are executed in Windows environment.	Jobs are executed in K8S based Alpine containers.	<p>If the website serves content based on operating system (OS), the scripts created based on windows environment fail.</p> <p>Scripts fail with 4xx error in some cases.</p> <div style="border: 1px solid #007bff; padding: 5px; margin-top: 10px;"> <p><b>i</b> This issue might occur when the server denies access to Linux agents or when website access is restricted only in Windows environment.</p> </div>	<p>Update the scripts with Linux environment based content.</p> <p>Provide access to Linux agent.</p>

Current Browser	New Browser	Impact	Action
		<ul style="list-style-type: none"> <li>The NAT based address can be different from the existing allowlisted IPs. So the existing allowlisting may not work.</li> <li>Session might fail with '4XX client error'</li> </ul>	Update the IP allowlisting based on the IP addresses mentioned at <a href="#">Synthetic Hosted Agent</a> .
		<p>The jobs with OS or file system based commands fail.</p> <div style="border: 1px solid #00aaff; padding: 5px; background-color: #e6f2ff;"> <p><b>i</b> As per AppDynamics security standards, jobs are executed in stateless environments meant only for the execution of web tests. Hence, OS/file system based commands are not supported.</p> </div>	If you have used OS or file system based commands in your scripts, remove those commands.

### Network Throttling

Current Browser	New Browser	Impact	Action
Network throttling feature is implemented using a third party library.	Network throttling is implemented using Chrome browser dev tools protocols.	<ul style="list-style-type: none"> <li>The network throttling accuracy is improved.</li> <li>Jobs which have configured network throttling may observe increased session duration.</li> </ul>	Either increase the timeout value or re-configure the throttling speed of the job.

### Agent Changes

As part of the [Agent change in Azure locations](#) on April 25, 2023, AppDynamics started executing jobs in 5 Azure locations in Linux [agents](#).

If any of your jobs fail due to the following errors, perform the steps mentioned in the **Action** column:

Current Agent	New Agent	Impact	Action
Windows	Linux	<ul style="list-style-type: none"> <li>HTTP_CLIENT_ERROR</li> <li>CONNECTION_ERROR</li> <li>NAME_NOT_RESOLVED</li> <li>HTTP_SERVER_ERROR</li> <li>TIMEOUT</li> <li>RESOURCE_ERROR</li> </ul>	Update the IP whitelisting for the <a href="#">Azure locations</a> if your web applications are not accessible over the internet.

Current Agent	New Agent	Impact	Action
Windows	Linux	<ul style="list-style-type: none"> <li>• TIMEOUT</li> <li>• SCRIPT_BROKEN</li> <li>• SCRIPT_ASSERTION</li> <li>• RESOURCE_ERROR</li> </ul>	<ol style="list-style-type: none"> <li>1. Update the script to fix these errors.</li> <li>2. Update the timeouts.</li> </ol>

## Chrome Browser 117

### Browser Synthetic Monitoring versus Browser Real User Monitoring

Browser Synthetic User Monitoring (Browser SUM) and Browser Real-User Monitoring (Browser RUM) both have the same goal of helping you improve your user's experience. The difference between the two is how they are used to accomplish this goal.

This page describes the monitoring differences, and how to use the two monitoring types together.

#### Identify Issues

Although Browser RUM can detect certain kinds of problems (like JavaScript exceptions), it cannot comprehensively test for functional correctness. For example, you may want to verify that your online store has reasonable prices a list of items. If your site is down entirely, then the JavaScript Agent will never be loaded, so errors or verifications will not be reported. Fortunately, Browser SUM will keep running, discover the error, alert you, and provide detailed information about the problem.

#### Control Environmental Factors

Performance analysis in Browser RUM is complicated by the wide range of hardware, browsers, operating systems, and networks with which users access your site. Browser SUM uses consistent hardware, software, and network configurations, so if you see deviations in performance, you can be fairly certain a problem exists.

#### Use Synthetic Metrics and Screenshots to Understand the User Experience

Browser SUM can collect certain data that Browser RUM cannot. For example, Browser SUM provides [screenshots](#), which shows you the current situation. You can also use the [Visually Complete](#) and related metrics to understand how users experience page load time.

#### Performance Versus Workflows

Browser RUM excels at capturing the full breadth of performance that your real users experience. Browser SUM gives you confidence that your key workflows are always working and performing.

#### Differences Between Synthetic and Browser RUM Metrics

Although Browser SUM and Browser RUM report similar metrics, you should be wary of comparing them because of these differences:

- Hardware
- Network connections
- Different browsers
- Browser caching is not present in synthetic sessions

If you see a sudden change in any of those metrics, however, you should compare the results of Browser SUM and Browser RUM to see if there is an existing problem.

## Get Started with Browser Synthetic Monitoring

### Related pages:

- [Configure Synthetic Jobs](#)
- [Synthetic Scripts](#)
- [Synthetic Sessions](#)

This page describes Browser Synthetic Monitoring, including how to access the **Jobs** page, create a job that measures a URL, view the results from the **Sessions** page, and finally how to edit and delete your job.

### Create a Job

1. Open one of your browser applications.
2. Click **Jobs** to open the **Jobs** page.
3. If you don't have any previous jobs, click **Create a New Job >**. If you have previous jobs, click **Add**.
4. From the **New Job** dialog:
  - a. For **Specify your Test**, enter a URL in the **URL** field and "Example Job" in the **Name** field.
  - b. For **Choose Browsers**, select Chrome.
  - c. For **Choose Locations**, click **+** and select any location.
  - d. Click **Save**.

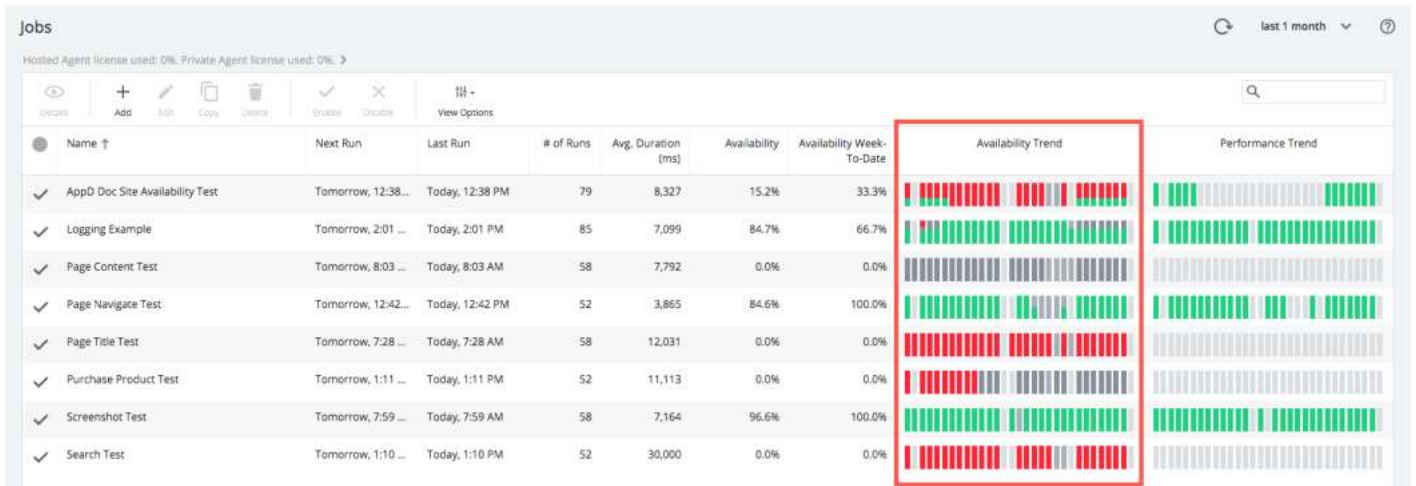

See [Configure Synthetic Jobs](#).

### Monitor Job Trends

From the Synthetic Job Dashboard, you can quickly monitor the availability and performance trends of synthetic jobs.

### Availability Trends

The **Availability Trend** column that displays the status of the executed jobs as shown in the screenshot below. The **Availability Trend** shows the session status based on the coloring codes listed in [Availability Trend Status Codes](#). The session status is not based on health rules. See [Session Status](#).

**i** The session status is not based on health rules. See [Session Status](#).

### Availability Trend Status Codes

The **Availability Trend** shows the session status based on the coloring codes listed in this table.

Availability Trend Status Color	Session Status
Green	OK
Yellow	WARNING
Red	FAILED
Dark gray	BROKEN
Light gray	INTERNAL_ERROR

### Understanding the Availability Metric

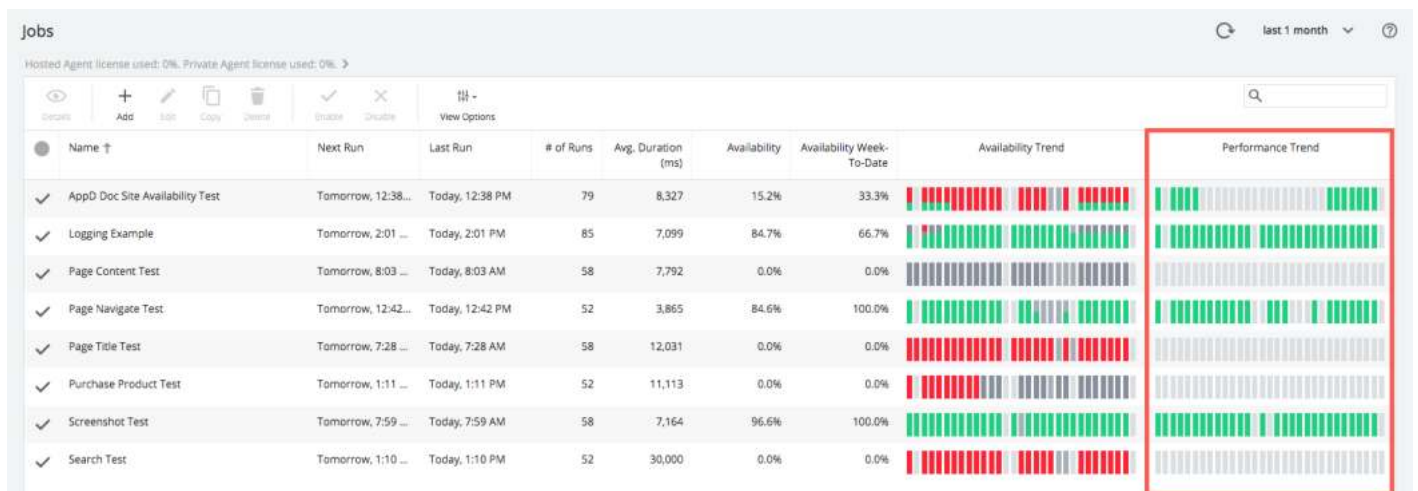

The Availability metric is the percentage of successful sessions for a given time range. That is the percentage of sessions with status as OK or WARNING within the given time range.

The **View Options** enables you to view the availability over periods not restricted to the specified time frame. The following list describes the availability options:

- **Availability Last-24-Hours** - The availability for the last 24 hours from the moment the page is refreshed/opened.
- **Availability Month-to-Date** - The availability from the starting moment (12 AM) of the current month according to user's timezone until the current time (page refreshed/opened).
- **Availability Week-to-Date** - The availability from the starting moment (12 AM) of the current week Monday according to user's timezone, considering week starts on Monday, till now (page refreshed/opened).

### Performance Trends

The **Performance Trend** column displays the performance threshold status of the executed jobs as shown in the screenshot below. The **Performance Trend** column only displays successful sessions: those with the status of OK or WARNING. The performance trend statuses are based on the [configured performance thresholds](#) for the synthetic job.

For example, if the **Availability Trend** column shows 5 OK and 5 FAILED status counts (50% green, 50% red), then the corresponding **Performance Trend** column will show only 5 OK counts (100% green). If the **Availability Trend** column has 5 failed and 5 broken (50% red, 50% gray) jobs, that is all unsuccessful, then corresponding Performance Trend column will show no count that is an empty bucket (light gray).

### Performance Trend Status Codes

As with the availability status, colors are used in the trend column to indicate performance status:

Performance Trend Status Color	Description
Green	No threshold violated: Green.
Yellow	Warning threshold violated.
Red	Critical threshold violated.

 A job can have a warning violation for one metric and a critical violation for another metric. In this case, the critical violation will override the warning violation.

### View the Results

1. From the **Jobs** page, verify that your job has a check next to it indicating that the job has been enabled.
2. After a few minutes, you should see a time that your job was last run and some metrics.
3. Select your job and click **Details**.
4. You should now see the results for your job on the **Sessions** page.

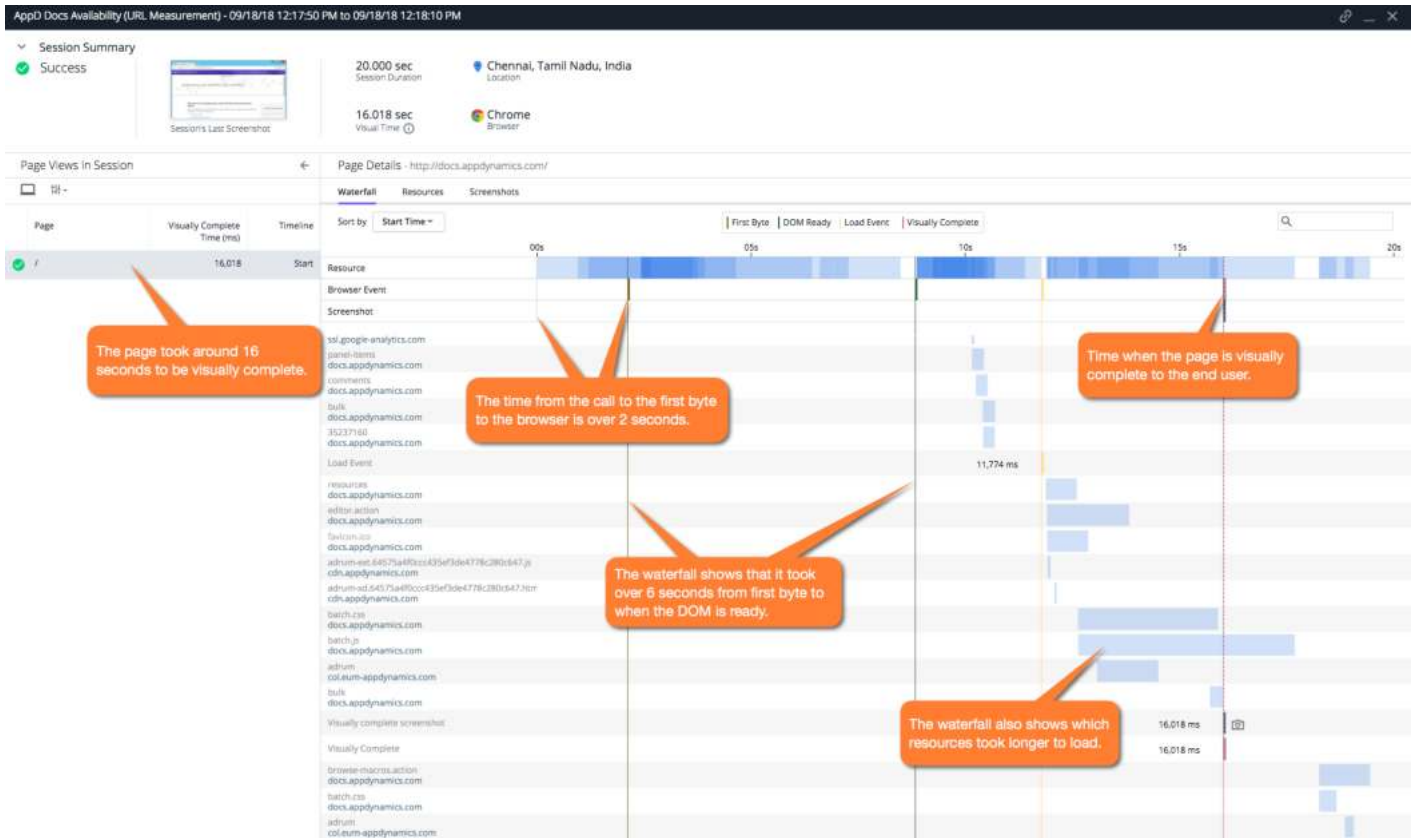

### Understand the Results

You can understand the results in several different ways and levels from the **Sessions** page. You can sort session results by criteria and then examine the details of a specific session in the **Session Details**. From the Charts tab of the **Sessions** page, you can then view widgets representing aggregated session data in charts and a configurable set of fields for each session.

### Examine Session Details

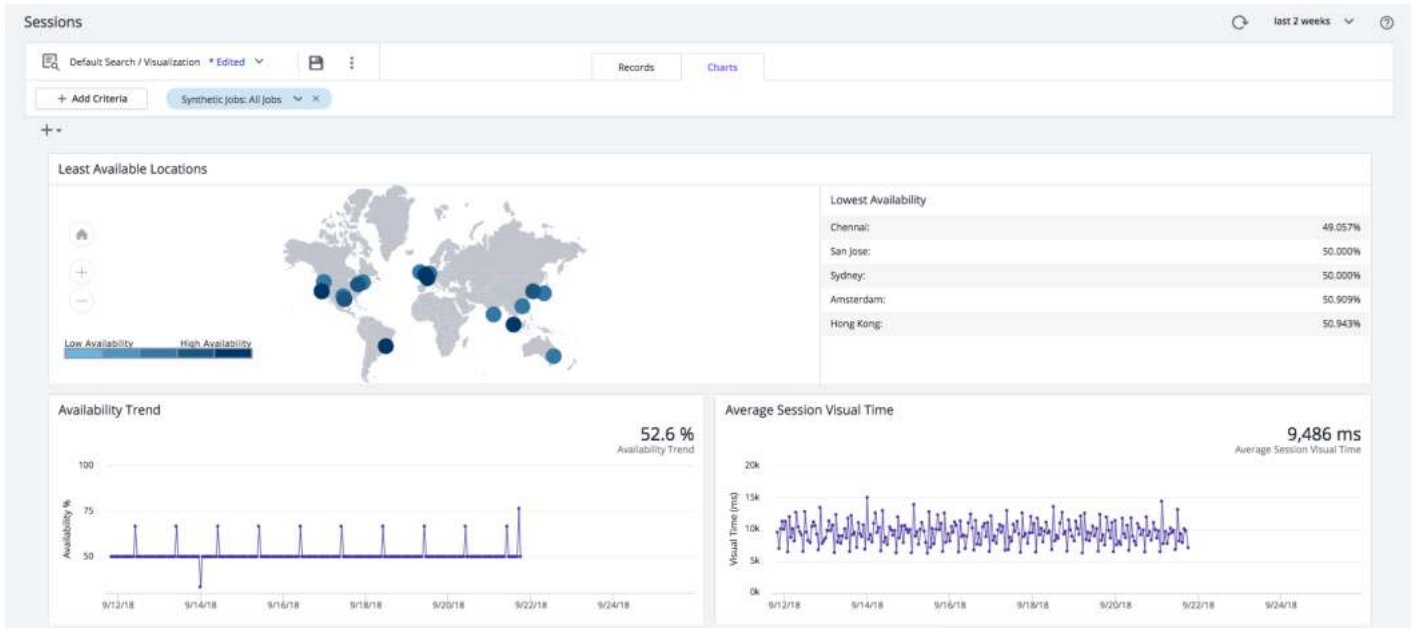

You can double-click any session to get a summary of the session, page details, and a breakdown of details for each page in the session. You'll be able to view how the page loaded, the resources that were requested, and the business transaction for each page. You can use this information to find where network latency occurs or where scripts break.

For example, from the **Session Details** dialog, you can determine that the visually complete (when the user would see the completely loaded page) took around 16 seconds and then examine the duration of the page load from the HTTP request to the first byte, from the first byte to DOM ready, and finally from DOM ready to visually complete.

### Get a Quick Overview

From the **Sessions** page, you can click the **Charts** tab to view widgets representing aggregated session data. For example, the **Lowest Availability** widget shows you what locations are the least available, so you can confine and focus on issues in specific locations.

## Synthetic Jobs

Web Monitoring synthetic jobs are configurable, scheduled tests that mimic end-user actions in remote browsers in supported locations. Synthetic jobs consist of URL measurements or [synthetic scripts](#). To create a job, see [Get Started with Browser Synthetic Monitoring](#).

API Monitoring jobs simulate interactions with applications or services from any location. To create a job, see [Get Started with API Monitoring](#).

## Support

Web Monitoring jobs support these versions and libraries:

Support Type	Description
Browser Versions	<ul style="list-style-type: none"> <li><a href="#">Chrome</a></li> </ul>
Python Versions	<ul style="list-style-type: none"> <li>Python 2</li> <li>Python 3</li> </ul>
Python Libraries	<ul style="list-style-type: none"> <li><a href="#">selenium</a></li> <li><a href="#">Requests</a></li> <li><a href="#">pysftp</a></li> </ul>

API Monitoring jobs support Node.js v14 (LTS), and you can import any [Node.js](#) modules. Additionally, API Monitoring jobs support these modules:

Modules	Version
@xmldom/xmldom	0.7.3
assert	2.0.0
buffer	6.0.3
form-data	4.0.0
got	11.8.2
jose	3.15.4
normalize-url	6.1.0
tunnel	0.0.6
xml-crypto	2.1.3

Modules	Version
xml2js	0.4.23
zlib	1.0.5

## Locations

You can execute Synthetic Monitoring jobs in AppDynamics managed hosted agents or private agents:

Agents	Location
Hosted Agent	Web Monitoring: <a href="#">22 locations</a> (AWS and Azure) API Monitoring: <a href="#">17 locations</a> (AWS)
Private Agent	<a href="#">Location</a>

## Maturity Levels

When you create a synthetic job, it is added to a queue based on the creation timestamp. Scheduled jobs are assigned a maturity level that influences when they will be executed in the synthetic job queue. The table below describes the two supported maturity levels.

Maturity Level	Description
Junior	The Junior maturity level consists of synthetic jobs that are created or updated within two hours. Once two hours have passed since the last update or creation of the job, the Junior job maturity level is promoted to Senior maturity level. The promotion from Junior to Senior maturity is only performed only if enough capacity has been allocated. This avoids negatively affecting jobs which are currently executing.
Senior	The Senior maturity level consists of synthetic jobs that have been created or updated more than two hours ago. Synthetic jobs with Senior maturity level have ample allocated resources to be executed.

## Execution Order

The execution order of synthetic jobs depends on the job priority and the job creation time. Synthetic jobs are only executed if they are in the job queue. Job priority is based on several factors: job type, job maturity, and your [Browser Synthetic Monitoring license](#). The table below shows how the job priority is calculated. The actual job execution order depends on the job priority and job creation timestamp.

**i** Synthetic jobs are only executed if they are in the job queue. If the max job queue size has been reached, however, no additional synthetic jobs will be added to the queue until the queue size decreases. The max queue size is defined by the priority, license, type, and maturity level.

Queue	Job Type	Job Seniority
High-priority	Scheduled	Senior
	On-demand	N/A
Low-priority	Scheduled	Junior

### Execution Cadence

The synthetic job scheduler executes jobs according to the following cron-based expression:

<second> <minute> <hour> <day-of-month> <month> <day-of-week> <year>

When you schedule a job, you choose how frequently the job runs. It is recommended you choose a larger unit of time (hours or days) that can evenly divide into the smaller unit of time (minutes or hours). For example, if a job is scheduled to run every 15 minutes, the job runs four times within the hour. This results in the job consistently repeating every hour without interruption to the schedule.

However, if you schedule a job such that a larger unit of time that does not divide evenly into the smaller unit of time, such as running every 50 minutes, then the job does not run at consistent times. For example, if the first job starts at 7:03, then the job will run at 7:53, 8:03, 8:53, and so on, resulting in a disruption to the schedule.

### Execution Errors

The following table provides job execution error messages, the cause of the error, and the associated error code.

Error Message	Cause of Error	Error Code
Skipped; still waiting for a previous job execution	An attempt was made to queue a high-priority measurement request from a scheduled job before the previous measurement request from the same job, and location-browser combination has been processed.	TARDY

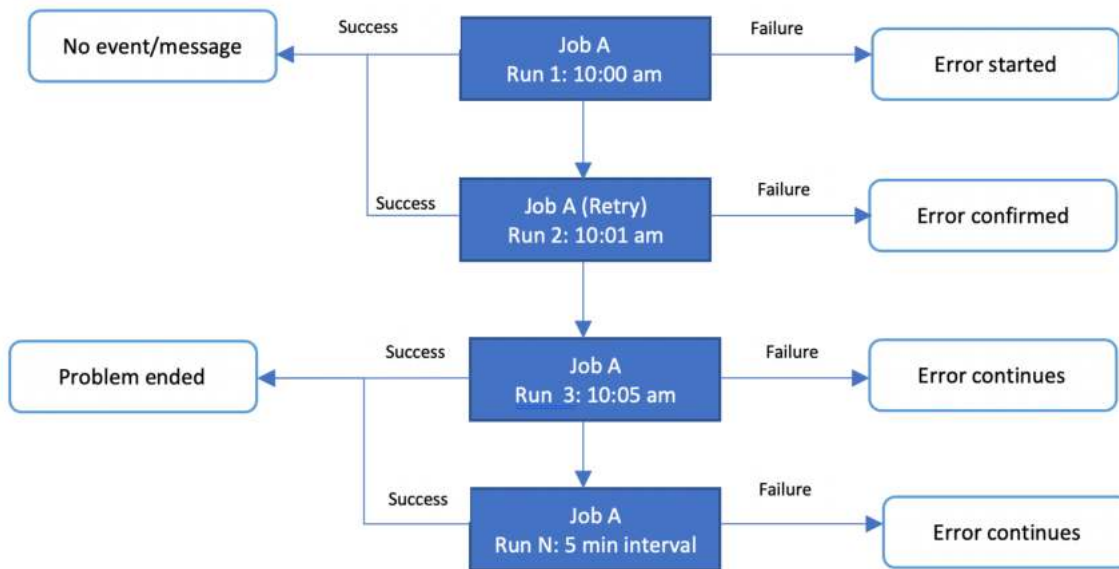

Error Message	Cause of Error	Error Code
Skipped while new capacity is being added	An attempt was made to queue a low-priority measurement request from a scheduled job before the previous measurement request from the same job, and location-browser combination has been processed.	TARDY_ONBOARDING
Skipped while new capacity is being added	An attempt was made to queue a measurement request from a junior job beyond the maximum respective queue capacity.	ONBOARDING
Testing location is overloaded	An attempt was made to request measurement from a senior job beyond the maximum respective queue capacity.	THROTTLED

### Health Rule Violation Events

You can configure health rule violation events, such as triggering an event when a job fails. To set health rule violation events, [create an alerting policy for synthetic jobs](#).

This diagram shows the retest process for a job failure and its triggered events. In this example, Job A is scheduled to run at 10:00 am at a five minute interval. If successful, no event or message is triggered; if it fails, "Error started" is triggered, and the job retests. If successful, no even or message is triggered; if it fails, "Error started" is triggered, and the job retests. If successful, "Problem ended" is triggered; if it fails, "Problem ended" is triggered, and the job retests. As long as the job continues to fail, the job will retest every 5 minutes and continue triggering "Error continues".

**i** Immediate retest reruns the job immediately after the first failure. All other retest configurations execute the job as per the configured job schedule.

1. Job A is executed at 10:00 am
  - If Job A succeeds, then no event/message is generated
  - If Job A fails, then the "Error started" event is generated
2. Job A is retested immediately at 10.01 am (**Previous execution:** Job A during execution at 10.00 am, and "Error started" event is generated)
  - If Job A succeeds, then no event/message is generated
  - If Job A fails, then the "Error confirmed after retest" event is generated
3. Job A is executed at 10:05 am (**Previous execution:** Job A failed during retest at 10.01 am, and the "Error confirmed after rest" event is generated)
  - If Job A succeeds, then the "Problem ended" event is generated
  - If Job A fails, then the "Error continues" event is generated
4. Job A is executed at the next scheduled time (**Previous execution:** Job failed and "Error continues" event is generated)
  - If Job A succeeds, then the "Problem ended" event is generated
  - If Job A fails, then the "Error continues" event is generated

- i**
- If the immediate retest based on availability errors or performance threshold is configured, then the "Error started" event is generated.
  - If the error is confirmed during the retest, then the "Error confirmed" event is triggered.
  - If the error is not confirmed during the retest, then no event is generated.

## Configure Synthetic Jobs

### Related Pages:

- [Get Started with Browser Synthetic Monitoring](#)
- [Alerts for Browser Synthetic Monitoring](#)

This page describes how to use the Controller UI to configure a synthetic job. You can schedule when, where, and how often a job runs, set timeouts, configure performance thresholds to trigger warning and critical events, and customize connection speeds. Before configuring a job, see [Getting Started with Browser Synthetic Monitoring](#).

### Specify your Test

Synthetic Jobs use either a specific URL or webdriver script to test one or more web pages. If your site requires authentication, you must create a script that performs the authentication to log onto your site. See [Synthetic Scripts](#) for more information.

To use a URL:

1. Select "Measure a URL".
2. In the URL field, enter a site or page URL.
3. In the Name field, enter a name for the job. This name appears in the Jobs list in the Controller UI.

**1. Choose a Test Type** ⓘ

Create a webdriver script in Python to execute your test. [More Info...](#)

Python 3

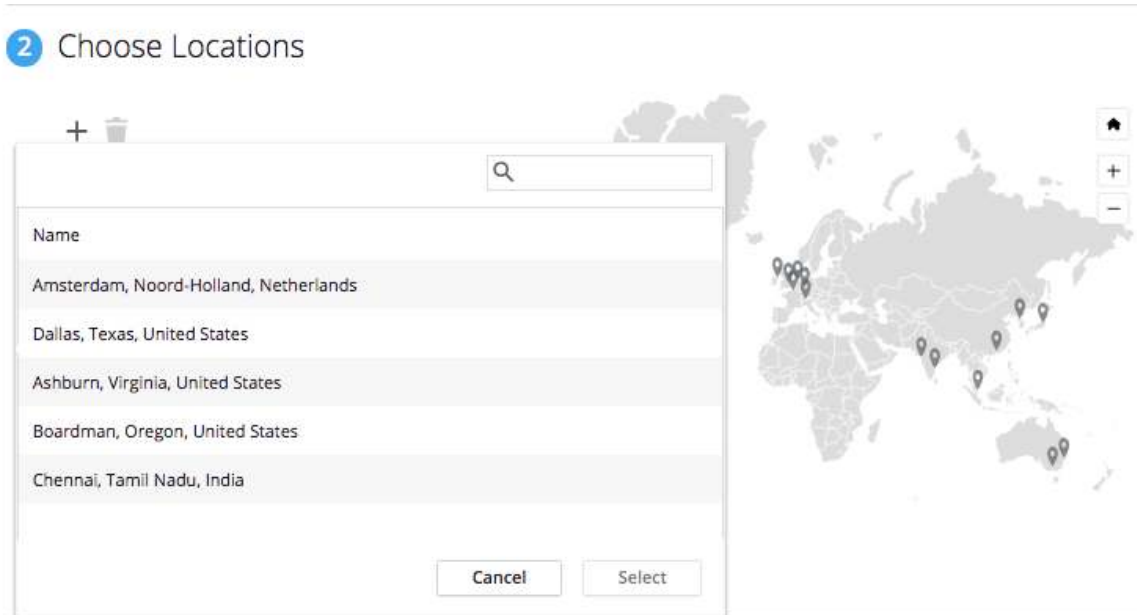

```

1 pageUrl = "http://www.appdynamics.com"
2 driver.get(pageUrl)
3 assert "AppDynamics" in driver.title, "Title should contain AppDynamics"

```

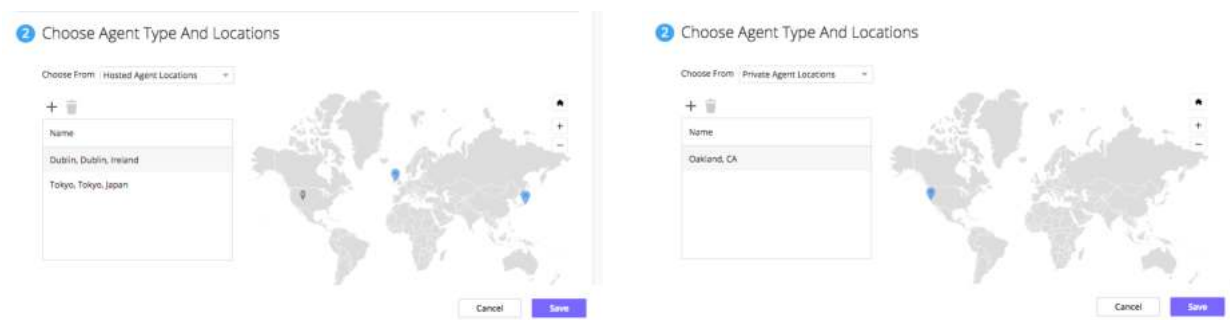

## Choose Locations

You can choose one or more locations in which the job runs. This can also be configured to test all of the locations every time or one location each time the job runs. For a complete list of Synthetic Agent locations, see [Synthetic Agent Locations](#).

## Hosted Agent Locations and Synthetic Private Locations

If you have deployed a [Install the Private Synthetic Agent \(Web and API Monitoring\)](#), you can choose from **Hosted Agent Locations** or **Private Agent Locations**. The **Hosted Agent Locations** are where AppDynamics hosts public synthetic agents. The **Private Agent Locations** are where you are hosting your synthetic private agents.

## Schedule Jobs

**!** On-premises Controllers only: Under **Set a Schedule > More Options**, the **Between** option does not support minute-level scheduling.

When you create or edit your job, you can define the job schedule.

## Create Multiple Schedules for One Job

 The multiple schedules feature is supported only in SaaS Controllers 22.2.0 and later versions.

You can create multiple schedules for the same job. Each schedule can have its own time zone, frequency, and execution interval. This allows you to execute the job in different frequencies:

Frequency	Example
Different intervals in a day	<p><b>Schedule 1:</b> Execute the job in 1-minute frequency from 8 AM to 8 PM</p> <p><b>Schedule 2:</b> Execute the job in 5-minute frequency from 8:01 PM to 7.59 AM</p>
Different days of the week	<p><b>Schedule 1:</b> Execute the job in 1-minute frequency on weekdays</p> <p><b>Schedule 2:</b> Execute the job in 5-minute frequency on weekends</p>
Different time zones	<p><b>Schedule 1:</b> Execute the job in 1-minute frequency from 8 AM to 8 PM in the PST time zone</p> <p><b>Schedule 2:</b> Execute the job in 5-minute frequency from 8 AM to 8 PM in the BST time zone</p>
Different date interval	<p><b>Schedule 1:</b> Execute the job in 1-minute frequency from February 21, 2022, to March 31, 2022</p> <p><b>Schedule 2:</b> Execute the job in 5-minute frequency from April 1, 2022, to March 31, 2026</p>

 You can create a maximum of three schedules per job.

Click **Add Schedule** to configure another schedule for the same job. You must create at least one schedule.

### 3. Set a Schedule

Run every

More Options

Time Zone

Between  09:00 AM and 05:00 PM

From  1/19/2022 07:47 PM To 1/19/2022 07:47 PM

Only on These Days  S  M  T  W  T  F  S

Add Schedule

### 3. Set a Schedule

**Schedule**

Run every 15 MINUTES between 09:00 and 17:00 in UTC Time Zone

From Wed Jan 19 2022 19:47 to Wed Jan 19 2022 19:47

On Monday, Tuesday, Wednesday, Thursday and Friday

Run every

More Options

Time Zone

Between  09:00 AM and 12:00 PM

From  1/20/2022 10:33 AM To 1/20/2022 10:33 AM

Only on These Days  S  M  T  W  T  F  S

Add Schedule

**i** You can prevent the execution of jobs during the maintenance period. Let us assume you have a four-hour maintenance period on March 21, 2022 (1:01 AM - 5:00 AM). Then, you can configure multiple schedules as follows:

- **Schedule 1:** Execute the job in 1-minute frequency from 8:00 AM on February 21, 2022, to 1:00 AM on March 21, 2022
- **Schedule 2:** Execute the job in 1-minute frequency from 5:01 AM on February 21, 2022, to 12:00 AM on March 21, 2026

## Choose Browsers

A job can run on one or more different types of browsers.

For the Chrome browser, you can select one of the following versions:

- Chrome version 86: See [Chrome Version 86](#) for information about the behavior of Chrome version 86.
- Chrome version 117: This is currently in the Beta phase. When you select Chrome version 117 (Beta), you agree to the [Beta Terms and Conditions](#).

### 4. Select Browsers

The screenshot shows a form with four browser options, each with a checkbox and a version dropdown menu. The 'Chrome' checkbox is checked, and its version dropdown is open, showing '117 (Beta)' selected. The other options are 'Firefox' (checkbox unchecked, version '117 (Beta)'), 'IE11' (checkbox unchecked, version '86'), and 'Mobile' (checkbox unchecked, version 'Custom').

By selecting and using 'Chrome 117 (Beta)', you agree to the [Beta Terms and Conditions](#), which shall govern your use of such browser version.

**⚠ On-premises Controllers only:** When you create a job and navigate to the **Select Browsers** section, multiple options for Chrome versions appear in the drop-down menu. When you save the job, the selected Chrome version is not saved. Regardless of the selected Chrome version, the job will be executed on Chrome version 86.

### 4. Select Browsers

The screenshot shows a form with four browser options, each with a checked checkbox and a version dropdown menu. The 'Chrome' checkbox is checked, and its version dropdown is open, showing '86' selected. The other options are 'Firefox' (checkbox checked, version '86'), 'IE11' (checkbox checked, version '83'), and 'Mobile' (checkbox checked, version '64').

For mobile browsers, you can specify a platform, such as the iPhone 7 Plus or Pixel. When a job runs on mobile browsers, it is actually running a Chrome browser emulator with the specified platform properties.

#### 4. Select Browsers

- Chrome
- Version:
- Firefox
- IE11
- Mobile

Galaxy S8

- Galaxy S8
- HiDPI laptop
- Pixel
- Pixel C
- Pixel XL
- iPad
- iPhone 7
- iPhone 7 Plus
- iPhone SE

#### 5. Choose

Connection (Traffic Shaping)

#### 6. Set Time

Maximum amount of time the job runs  
Seconds 30

**i** When you select **Mobile > Custom**, then the values of the **Browser** and **Device Model** columns on the **Sessions** page are displayed as "unknown".

**i** Chrome version 86 in AWS locations is executed in Linux-based agents. All other browsers are executed in Windows-based agents running either on Windows 2012 or Windows 2012 R2.

#### Customize Connection Speeds

The connection speed helps keep performance consistent and realistic. If you choose **Native Connection**, the job will run at the maximum speed available to AppDynamics data centers. The default is **Cable (5/1 Mbps 28ms RTT)**.

**4** Choose Connection Speed ⓘ

Connection Speed

#### Set Timeouts

Synthetic jobs consume licenses based on the duration of the job, so you can set a timeout to help limit the license consumption. If the job times out, data will still be collected until the timeout expires. The default suggestion for job timeout is 15 seconds for a URL and 30 seconds for a script. You can adjust the timeout as preferred, but keep in mind that short timeouts might result in unsuccessful sessions, and long timeouts might result in overconsumption of licenses.

## 6 Set a Timeout

Maximum amount of time spent trying to complete the job:  
Seconds

This job will generate 138 sessions per day. This may consume up to 0 license blocks per month, or 0.00% of your license. After the job runs for a while, you can check the Job List for an updated estimate based on average session duration.

## Configure Availability Rules

You can configure the synthetic job to check the availability of pages and resources. For example, you can set the session status for when a page fails to load or when a resource is missing or inaccessible.

The screenshot below is a configuration to treat the session as **Failed** if any page fails to load and to treat the session as **Warning** if any resource fails to load. If the job navigates to a page with an HTTP 4xx or 5xx status code, the session status will be set to `FAILED`. This will trigger a Critical Event. If a resource fails to load, the session status will be set to `WARNING`, which will trigger a Warning Event. To set up alerts, see [Alerts for Browser Synthetic Monitoring](#).

You can use the **Trigger an error event for failed sessions** option to choose when to trigger the "Error confirmed" event. By default, the "Error confirmed" event is triggered after an immediate retest. You can also choose to trigger the "Error confirmed" event:

- Immediately when the job fails or
- After 2, 3, 5, or 10 consecutive failures

This helps you avoid false-positive alerts that may occur because of network failure, intermittent issues, or other issues.

**i** In the case of the default "After an immediate retest" option, the "Error started" event is generated immediately when the job fails, and the "Error confirmed" event is generated after the immediate retest. In the case of other options, only the "Error confirmed" event gets generated.

## 7. Configure Availability Rules

## 8. Configure Performance Thresholds (optional)

See [Health Rule Violation Events](#) for more information.

Use the **Advanced Options** to ignore or only consider selected resources. For example, the screenshot below might be used to ignore the font resource (which browsers may not have) and only consider high-impact resources like CSS, JavaScript, etc.

## 7. Configure Availability Rules

If any page fails to load treat session as Failed ▼

If any resource fails to load treat session as Warning ▼

Trigger an error event for failed sessions After an immediate retest ▼

Advanced Options ^

Ignore resources when URL contains fonts

Only consider resources when URL contains png,jpg,gif,js,css,mov

i Favicons are always ignored when checking the availability of resources.

## Configure Performance Thresholds

You can specify the job performance thresholds to send alerting events. For an example of the health rule violation process, see [Health Rule Violation Events](#).

If you check one or both of the "**Automatically retest after warning events**" or "**Automatically retest after critical events**" boxes, and the event is generated, then the job will be triggered to re-execute immediately per unconfirmed warning or critical event. For example, if the **Critical Events** threshold is exceeded, the event **Critical Started** will be triggered, and the job will rerun until the event **Critical Continues** is confirmed. Learn more about the synthetic job retest process.

**8** Configure Performance Thresholds (optional) ⓘ ^

Trigger a warning event when

+ Add Threshold  Automatically retest after warning events

End User Response Time ▼ Is greater than 5000 ms after retest 🗑️

Trigger a critical event when

+ Add Threshold  Automatically retest after critical events

End User Response Time ▼ Is greater than 10000 ms after retest 🗑️

From the **Events** page shown below, you can see that the results of the first and successive tests exceeded the threshold for synthetic availability and triggered the **Error Started**, **Error confirmed after restart**, **Error Continues**, and **Problem Ended** events.

The screenshot shows the 'Ecommerce App' dashboard in AppDynamics. A filter menu is open, allowing selection of event types. The menu includes sections for Synthetic Availability, Synthetic Performance, and Mobile Crash. The Synthetic Performance section is expanded, showing options like Problem Ended, Warning Started, Warning Confirmed, Warning Continues, Critical Started, Critical Confirmed, and Critical Continues, all of which are checked. The background shows a table of error events with columns for Type, Description, and Time.

Type	Description	Time
Error Started	an unconfirmed error from Tokyo, Tokyo, Japan in Firefox	09/19/18 5:42:37 AM
Error Continues	in ongoing error from Tokyo, Tokyo, Japan in Chrome	09/19/18 5:17:52 AM
Error Continues	in ongoing error from Tokyo, Tokyo, Japan in Firefox	09/19/18 5:16:52 AM
Error Continues	in ongoing error from Tokyo, Tokyo, Japan in Firefox	09/19/18 4:55:47 AM
Error Continues	in ongoing error from Tokyo, Tokyo, Japan in Chrome	09/19/18 4:55:16 AM
Error Continues	in ongoing error from Tokyo, Tokyo, Japan in Chrome	09/19/18 4:17:46 AM
Error Continues	in ongoing error from Tokyo, Tokyo, Japan in Firefox	09/19/18 4:17:46 AM
Error Continues	in ongoing error from Tokyo, Tokyo, Japan in Chrome	09/19/18 3:56:06 AM
Error Continues	in ongoing error from Tokyo, Tokyo, Japan in Firefox	09/19/18 3:55:52 AM
Error Continues	in ongoing error from Tokyo, Tokyo, Japan in Chrome	09/19/18 3:17:38 AM
Error Continues	in ongoing error from Tokyo, Tokyo, Japan in Firefox	09/19/18 3:17:22 AM
Error Continues	in ongoing error from Tokyo, Tokyo, Japan in Firefox	09/19/18 2:58:09 AM
Error Continues	Synthetic job [Page Title Test] has an ongoing error from Tokyo, Tokyo, Japan in Chrome	09/19/18 2:57:15 AM
Problem Ended	Synthetic job [Screenshot Test] from Tokyo, Tokyo, Japan in Firefox is now OK	09/19/18 2:46:15 AM

## Synthetic Scripts

Browser Synthetic Monitoring allows you to write Python scripts using the [Selenium WebDriver library](#) to create scheduled tests that can mimic end-user actions in remote browsers in supported locations. For supported Python versions and libraries, see [Synthetic Jobs](#).

You can use synthetic scripts to test performance, features, end-user flows, and the end-user experience.

For example, your synthetic script might do the following:

1. Visit your website.
2. Search for products.
3. Add items to a shopping cart.
4. Check out the shopping cart and assert that the total price of the cart is correct.
5. Enter payment details.
6. Complete the purchase.

## Benefits of Using Synthetic Scripts

Using synthetic scripts, you can:

- find broken user flows

- improve the performance of your site by finding where response times in your web applications are slow
- test new features

## How Scripts Are Run

The entire process can be simplified into the following steps:

1. You add your script to a synthetic job in the Controller UI.
2. The synthetic job is transmitted to the Synthetic servers, where it is scheduled to be run.
3. When it's time for your job to run, a container is created just for your script.
4. Your script runs in the container, controlling a web browser using [Remote WebDriver](#).
5. After the script finishes running, the agent collects browser metrics and sends them to the Controller UI.

The Controller UI receives and displays the metrics from your synthetic job.

## Get Help

In the [Knowledge Base forum](#), read our [Synthetic Scripts FAQ](#). If you can't find the answer to your question, submit your questions to the community.

## Write Your First Script

### Related pages:

- [Locate DOM Elements](#)
- [Wait for DOM Elements](#)
- [Work with Screenshots](#)
- [Add Logs to Troubleshoot](#)
- [Verify Program Correctness](#)

This page describe how to create a synthetic job and view the results.

## Write a Script

Before you create a Synthetic Job with a custom script, you will need to write a Python WebDriver script and [get it working locally](#). For a good introduction to scripting, AppDynamics recommends reading the [Selenium Python Bindings](#) documentation.

Before running your scripts in Synthetic Jobs, AppDynamics recommends reading the [differences between Python and synthetic scripts](#) as you may need to make some modifications.

### Tools for Writing Scripts

For a full-fledged script recorder, use the Firefox add-on [Katalon Recorder \(Selenium IDE for Firefox 55+\)](#). The resulting script will work with Browser Synthetic, but as with most auto-generated code, expect to make manual changes to improve it.

### Constraints for Writing Scripts

`driver.get` should always point to a proper HTML page and not to resources.

- `driver.get()` works well for HTML pages.
- Some of the session data might be incomplete or incorrect if you try to get resources directly.

## Test Scripts Locally

Testing scripts locally is one of the best ways to take advantage of utilities to help you write scripts and then run them locally. To run scripts locally, complete the [installation instructions](#) given in the Selenium Python Bindings documentation and then run the script as you would any Python script.

### Understand the Differences Between Python and Synthetic Scripts

When you are ready to write synthetic scripts, you should be aware that although Browser Synthetic can run unmodified Python scripts, there are few differences:

- The driver initialization code can be *removed* because the variable `driver` is automatically created and initialized with the browser selected in the **Job** creation UI. Thus, the example code below that initializes a driver would be replaced by our logic that then returns the variable `driver`.

```
This initialization code or any initialization code
will be replaced with Synthetic Monitoring logic, and
the singleton `driver` will be available.
from selenium import webdriver

driver = webdriver.Firefox()
```

If your script initializes a driver, it is okay to keep it: Synthetic will just ignore your initialized driver and instead return the driver it automatically created.

- Only one driver can be run within a synthetic session. Any attempt at creating new drivers will return the automatically instantiated driver (a singleton).
- Scripts interacting with multiple windows will work; however, the session results will merge the results for all windows into one waterfall.

## Create a Synthetic Job with Your Script

Once you have completed and tested your scripts, the next step is to create a Synthetic Job with your script:

1. From the **New Job** dialog, check the **Run a script** radio button.
2. Enter **My First Script** in the **Name** field.
3. Take a look at the sample WebDriver script, but do not change it.
4. For **Choose Browsers**, select **Chrome** and **Firefox**.
5. For **Choose Locations**, add a couple of different locations.
6. Click **Save**.

### View Results

All date and time functions in the synthetic script return time in the UTC time zone. For example, if a script is scheduled on July 30 at 12am PST from the San Francisco location, and in the script it calls the following function:

```
import datetime
.....
dt = datetime.datetime.now()
print(str(dt))
```

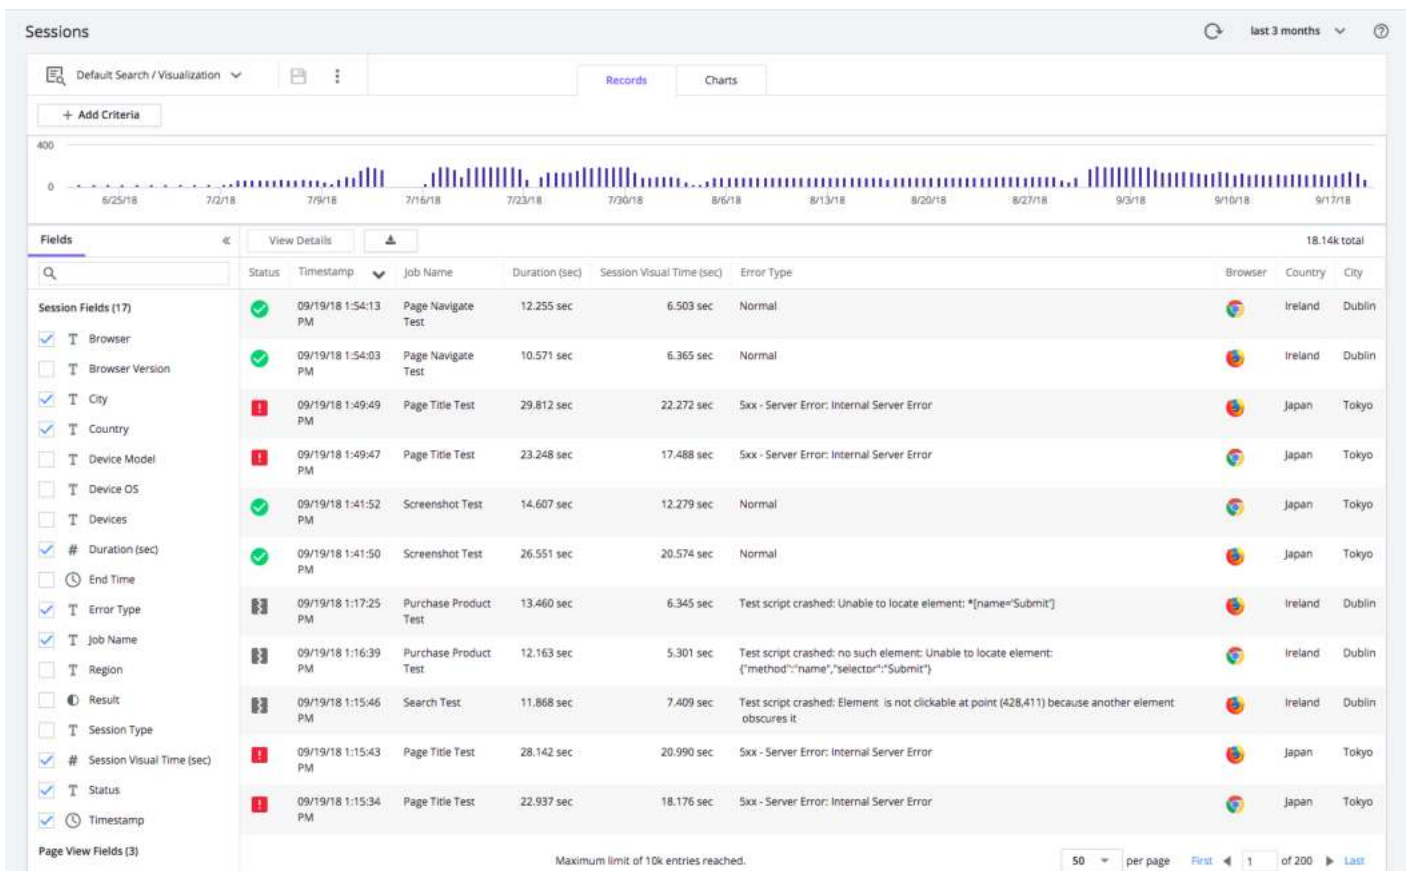

It will return the time as:

2020-07-30 07:00:00.000000

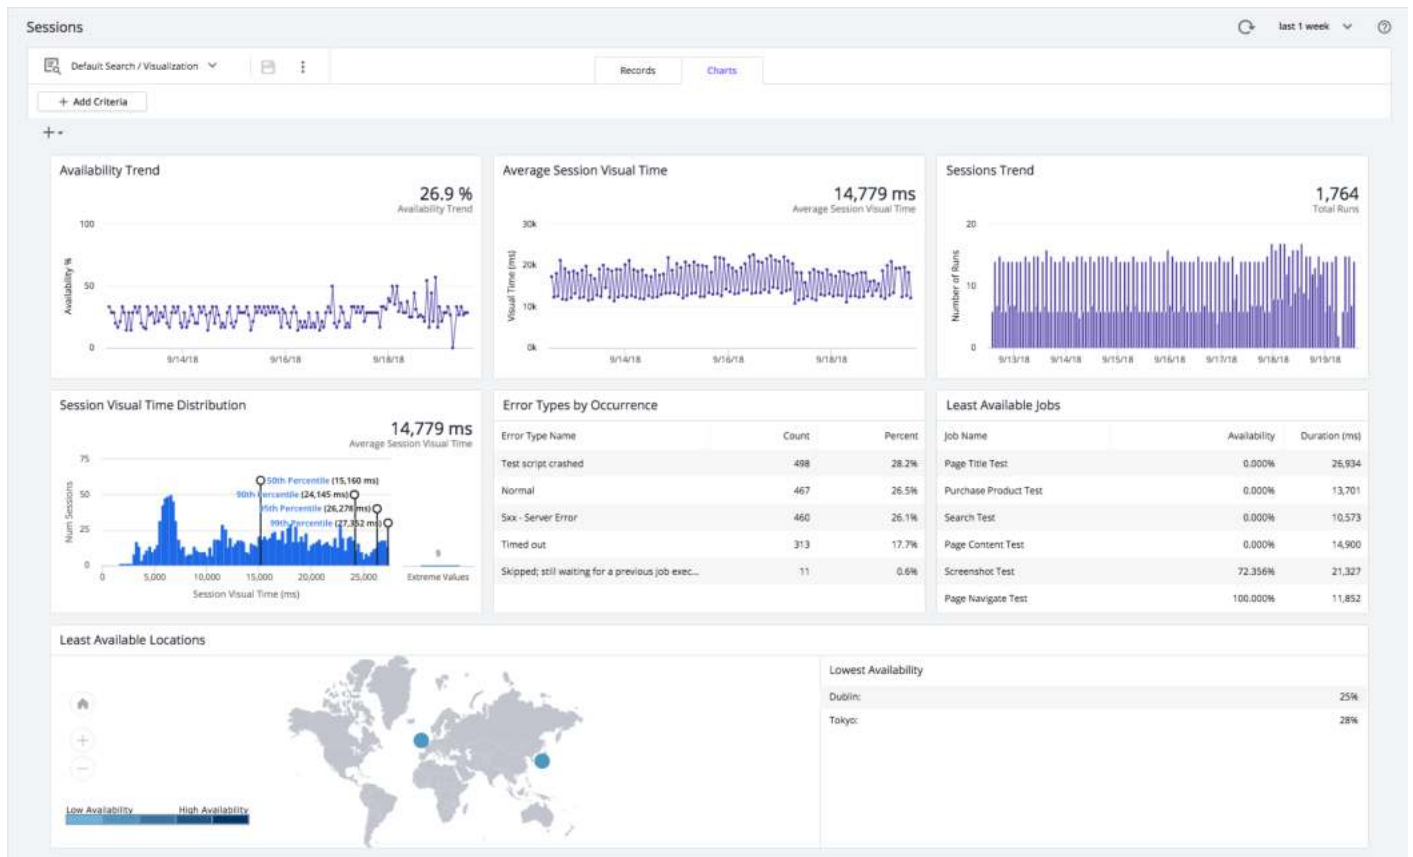

You have two types of views for the results. From the **Jobs** page, where you create a job, you can see your job and a summary of the results after the job has been run for both Synthetic Hosted/Private Agents.

Name	Next Run	Last Run	Created	Updated	Avg. Duration (ms)	Availability (%)	# of Runs	Usage
URL Measurement Test with the Synthetic Private Agent	Today, 1:51 PM	Today, 1:36 PM	Today, 1:22 PM	Today, 1:22 PM	13,395	100.000	2	5%
URL Measurement Test with the Synthetic Hosted Agent	Today, 1:42 PM	Today, 1:38 PM	Today, 1:23 PM	Today, 1:38 PM	15,000	83.333	6	0%
Script Test with the Synthetic Private Agent	Today, 1:54 PM	Today, 1:39 PM	Today, 1:23 PM	Today, 1:23 PM	17,720	50.000	4	5%
Script Test with the Synthetic Hosted Agent	Today, 1:42 PM	Today, 1:39 PM	Today, 1:24 PM	Today, 1:39 PM	11,547	100.000	7	0%

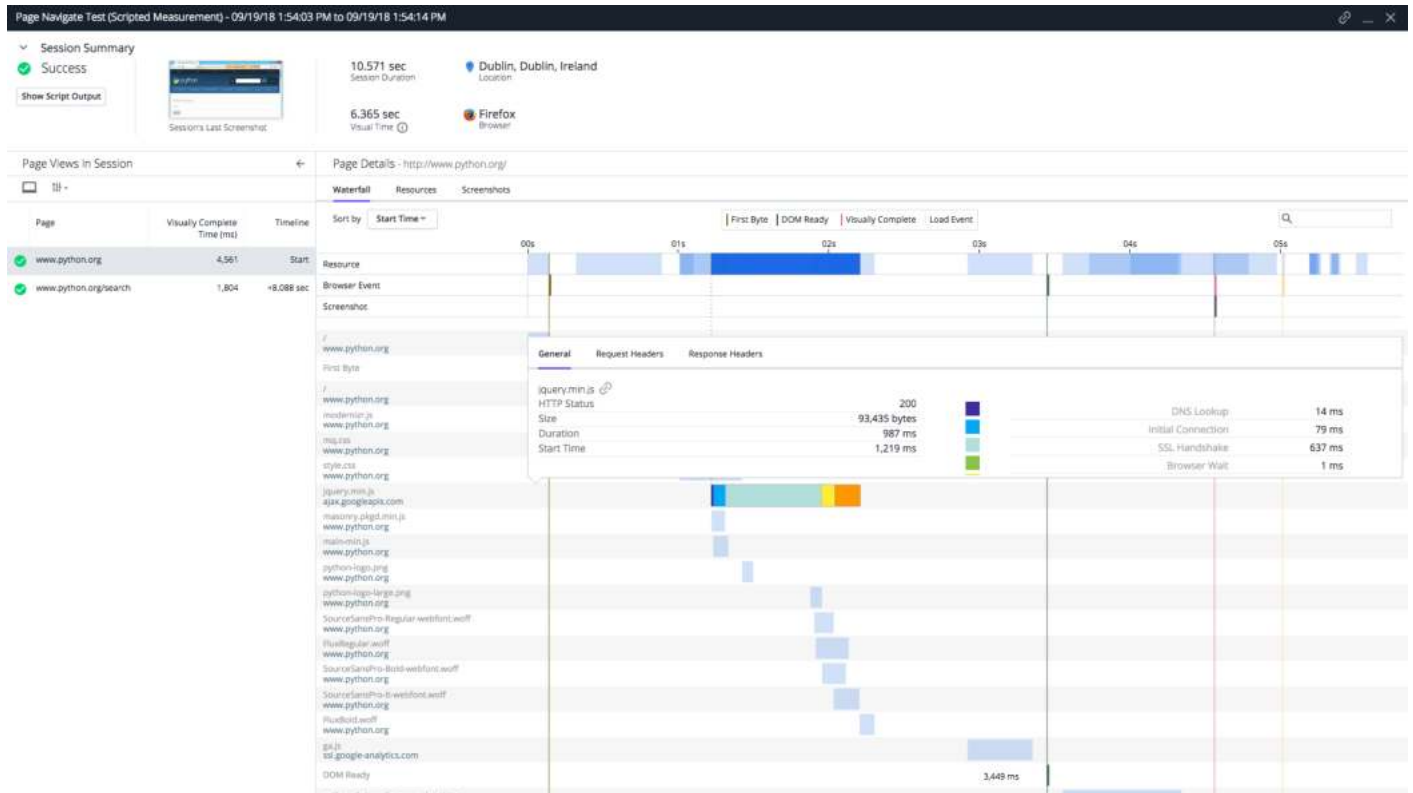

You can also see more detailed results from the **Sessions** page. You can get there by either double-clicking your job or by clicking **Sessions** in the left navigation bar.

To see the metrics as charts, click the **Charts** tab:

From the Records tab, you can double-click a session to view the **Session Details** dialog:

## Locate DOM Elements

### Related pages:

- [Write Your First Script](#)
- [Wait for DOM Elements](#)
- [Work with Screenshots](#)
- [Add Logs to Troubleshoot](#)
- [Verify Program Correctness](#)

Your synthetic script simulates end-user interactions, so you'll need to be able to locate the DOM elements of your web pages. For example, your script might click on buttons, links, or enter text into text fields: this requires your script being able to locate and then select relevant HTML elements.

## Methods for Locating Elements

The Selenium WebDriver library provides CSS selectors and XPath statements for selecting HTML elements. See [4. Locating Elements](#) for the list of the library methods and usage examples.

## Best Practices for Locating Elements

When locating elements, you are recommended to do the following. Think of it as a checklist.

- Understand the following about your application:
  - the DOM structure
  - which pages are dynamically and statically loaded
  - which elements of a page are loaded and visible.

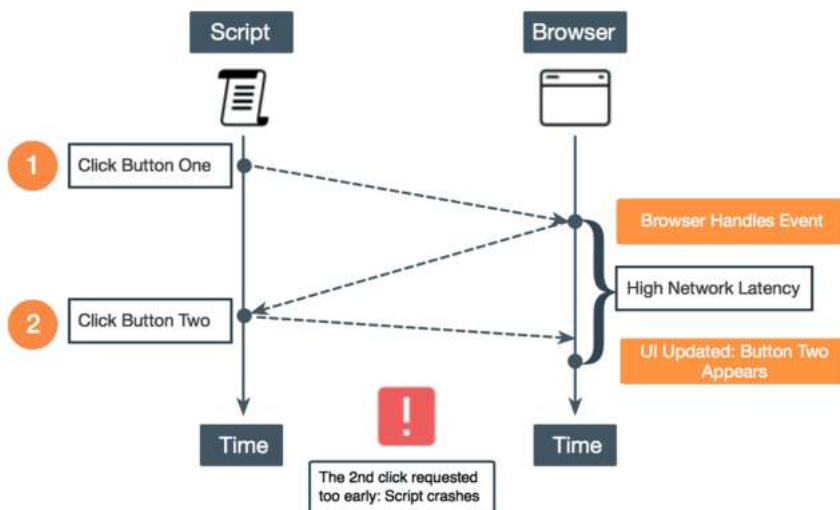

- Use unique IDs for elements and selectors that are as short as possible: Selectors break all the time. Long hierarchical selectors break more easily than shorter ones, and using short selectors will reduce script maintenance over time.
- Click on the user-visible element instead, or send a **Return** key instead of submitting forms using the method `submit()`.
- Pay attention to element visibility. The specification is complex, and the results are not always what users expect. See the [WebDriver specification](#) for more information.

## Wait for DOM Elements

### Related pages:

- [Write Your First Script](#)
- [Locate DOM Elements](#)
- [Work with Screenshots](#)
- [Add Logs to Troubleshoot](#)
- [Verify Program Correctness](#)

Your script might be accessing a UI component that is not available in the DOM. The cause could be network latency, as shown in the diagram below, or the DOM simply isn't ready to access.

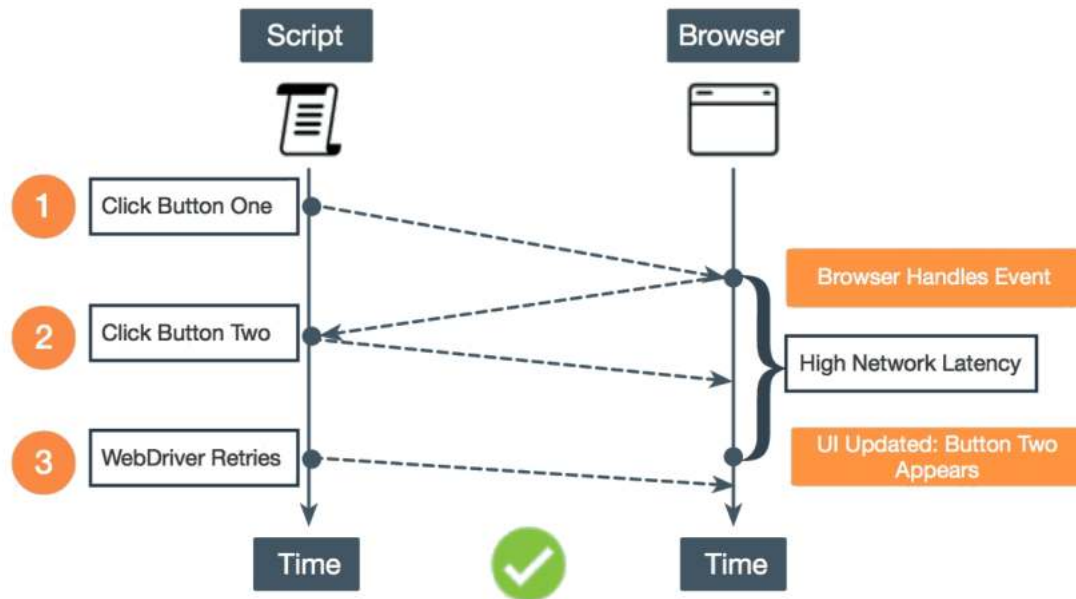

You can avoid this issue by using either an explicit or implicit wait. The following section discusses the different types of waits and when to use each.

### Explicit Versus Implicit

The WebDriver function `driver.implicitly_wait(n)` configures WebDriver for the remainder of a session. If you try to access an element that is not available, WebDriver will retry for up to `n` seconds to find that element in the DOM. This simple approach is often sufficient to make your scripts work reliably.

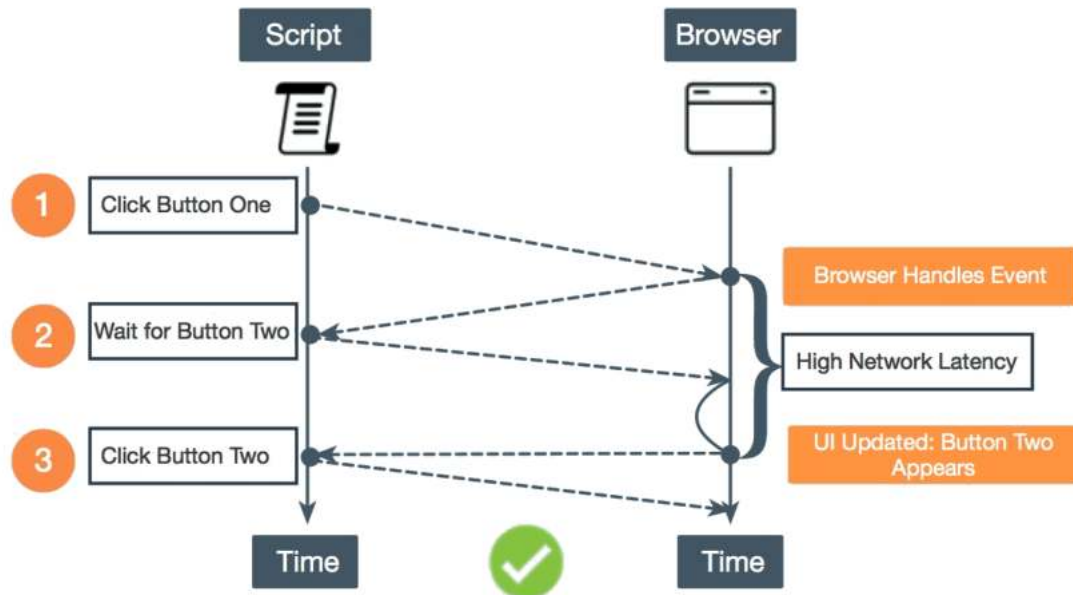

In the diagram below, the `WebDriver` retries to click **Button 2** until it's available.

An explicit wait is code that requires a certain condition to occur before continuing to execute code. Although you may be tempted to use `time.sleep()` to wait for an element to be available, you should avoid doing this. Instead, use the WebDriver API methods given in [5.1. Explicit Waits](#) of the Selenium Python Bindings documentation that enable you to wait for *expected conditions*.

In the diagram below, the explicit wait stipulates to click **Button 2** (action) only when the button is available (the condition).

## Work with Screenshots

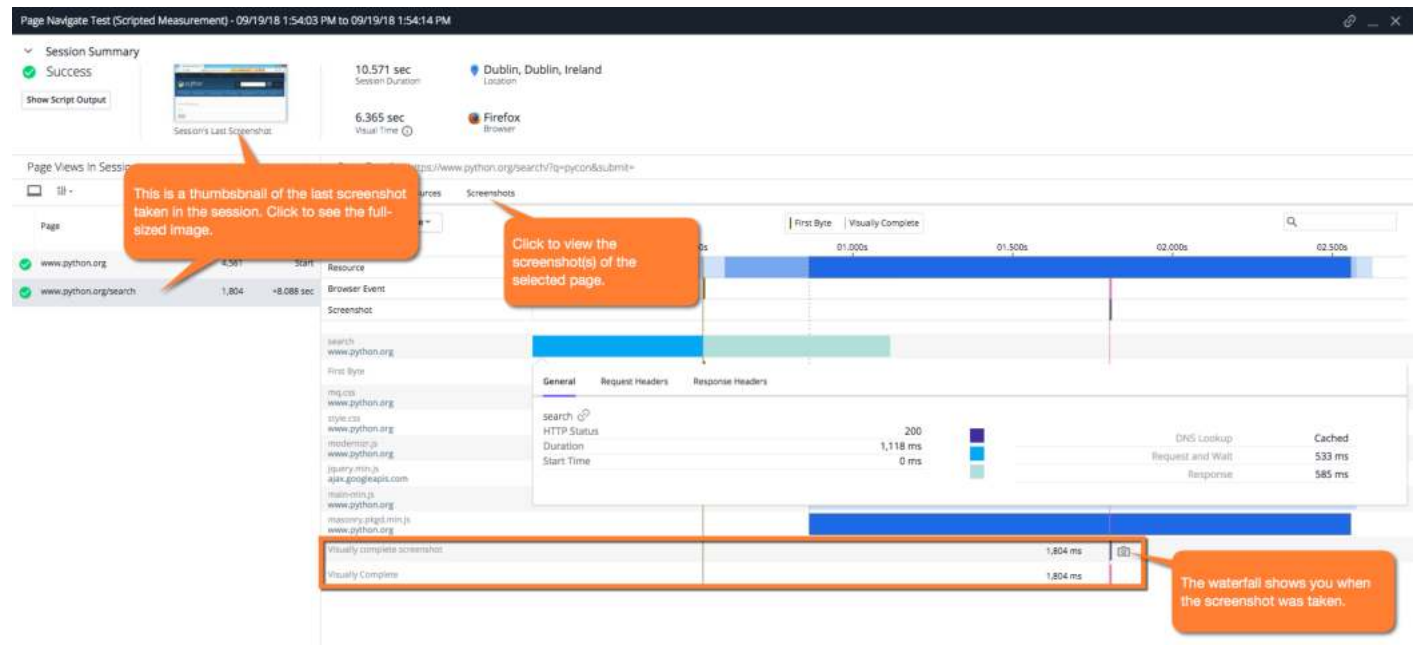

### Related pages:

- [Write Your First Script](#)
- [Locate DOM Elements](#)
- [Wait for DOM Elements](#)
- [Add Logs to Troubleshoot](#)
- [Verify Program Correctness](#)

Synthetic jobs will automatically take screenshots for you, but you might want to manually take screenshots to debug issues.

### Where to Find Screenshots

The **Session Details** dialog displays screenshots for each page, the last screenshot taken in the session, and a screenshot icon in the waterfall showing when the screenshot was taken. You can also view the larger version of the page screenshot from the Screenshots tab.

## When to Use Screenshots to Debug

If interactions with a page are resulting in failures, you can use a screenshot to detect whether the UI component is on the page. For example, a screenshot can be used to determine if you are trying to click a button that isn't on the page or that is being overlapped by another HTML component. You may also want to manually take a screenshot if your job is timing out to diagnose an issue with the page because screenshots are not be automatically taken for timed out jobs.

## How to Take Manual Screenshots

Although screenshots are taken by default, you can manually take screenshots at any point during the execution of your script using either of the following:

```
driver.get_screenshot_as_file("homepage.png")
driver.save_screenshot("myscreenshot.png")
```

## Add Logs to Troubleshoot

### Related pages:

- [Write Your First Script](#)
- [Locate DOM Elements](#)
- [Wait for DOM Elements](#)
- [Work with Screenshots](#)
- [Verify Program Correctness](#)

You can use logs to track the progress of your scripts and to better understand what is happening while the script is executing.

## Print Statements

The simplest way to log messages is with print statements. You can use them to inspect objects or to determine where an issue is located.

For example, you can determine whether an element was selected on a page by displaying the contents of the object:

```
elem = driver.find_element_by_id("wiki-content")
print(elem)
```

If the script results are incomplete, you can use a series of print statements to pinpoint where the problem might have occurred:

```
print("Getting the web page 'appdynamics.com'.")
driver.get("http://docs.appdynamics.com")

print("Getting the content for the container with the ID 'wiki-content'.")
elem = driver.find_element_by_id("wiki-content")

element = driver.find_element_by_xpath("//select[@name='name']")
all_options = element.find_elements_by_tag_name("option")
for option in all_options:
 print("Value is: %s" % option.get_attribute("value"))
 option.click()
```

## Logging Package

You can import the `logging` package to log different types of error messages.

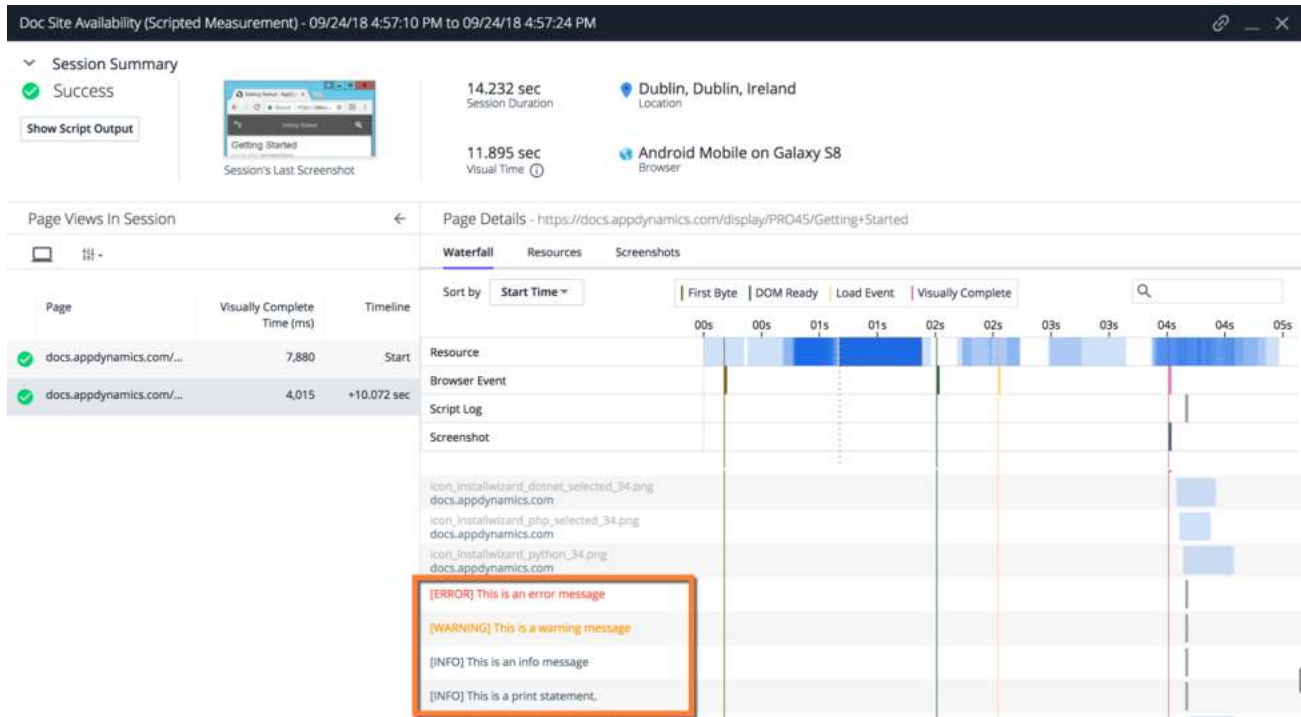

To import the `logging` package and set the log level to `DEBUG` :

```
import logging
logging.getLogger().setLevel(logging.DEBUG)
```

Once you have imported the `logging` package, you can generate different types of logs:

```
print('Starting the monitoring test')
pageUrl = "https://www.appdynamics.com"
driver.get(pageUrl) logging.info("info message")
logging.debug("Debug message")
logging.warning("Warning message")
logging.error("error message") print('Landed on page successfully!')
```

The different types of errors are then color-coded in the waterfall of the **Session Details** dialog.

The script output will label the different log messages by the severity as shown below.

Script Output

Time (sec)	Severity	Message
0.006	INFO	Starting measurement
0.007	INFO	Executing WebDriver script
0.008	INFO	Starting the monitoring test
0.008	DEBUG	POST {url: 'https://www.appdynamics.com'}
9.656	DEBUG	Finished Request
9.656	INFO	info message
9.656	DEBUG	Debug message
9.657	WARNING	Warning message
9.657	ERROR	error message
9.657	INFO	Landed on page successfully!
9.657	DEBUG	GET
10.956	DEBUG	Finished Request
10.959	INFO	WebDriver script completed successfully!
10.971	DEBUG	DELETE
11.026	DEBUG	Finished Request

Copy to Clipboard   Download

## Import Python Packages in Synthetic Scripts

Synthetic scripts are executed in short-lived containers where you can use pre-installed Python packages. Your script is restricted to the container and the container's lifespan.

### Pre-installed Libraries

The following modules are installed in containers and can be accessed by importing them into your synthetic scripts.

- [selenium](#)
- [Requests](#)
- [pysftp](#)

- 'os', 'socket', and, 'subprocess' modules will be disallowed for any new job.
- All existing jobs will continue to run.

### Upload and Download Files with SFTP

One of the packages installed on these containers is `pysftp`, which you can use to upload and download files with SFTP.

The following code sample shows the basic functionality of the package.

```
import pysftp
cnopts = pysftp.CnOpts()
cnopts.hostkeys = None
The <hostname> can be in either of the following formats: ftp.domain.ca || http://
ftp.domain.ca
with pysftp.Connection('<hostname>', username='xxxx', password='xxxxxx', cnopts=cnopts) as
sftp:
 # Change to the directory 'public'
 with sftp.cd('public'):
 # Fetch the remote file
 sftp.get('<remote_file_name>')
 # Upload the same file to a remote location
 sftp.put('<local_file_name>')
```

### Make HTTP Requests

You can use the HTTP library `requests` to make HTTP requests within your synthetic scripts. The following example makes a GET request to the public GitHub Events API. See [Requests: HTTP for Humans™](#) to learn more about the library's functionality and usage.

```
import requests

r = requests.get('https://api.github.com/events?per_page=1')
print("Status Code: %s\n" %(r.status_code))
print ("Headers: \n%s\n" %(r.headers))
print("Response: \n%s" %(r.text))
```

## Verify Program Correctness

You can use assertion statements to determine that your script is receiving the expected results. You use the session status to determine session status whether your jobs have failed because of an uncaught exception or an assertion statement failed.

This page provides an assertion example that shows how to use the session status to determine which scripts have issues.

### Use Assertions to Verify Expected Results

Assert statements use a simple syntax to verify an expected result. You can also provide a message to display if the assertion fails. In the example below, the message "Title should contain AppDynamics" will be displayed if the assertion fails.

```
Get page and check the title
driver.get("http://https://ecommerce.com/view.html/ref=nav_cart")
assert "E-Commerce Shopping Cart" in driver.title, "Title should contain E-Commerce Shopping Cart"

Click link and confirm URL is correct
driver.find_element_by_link_text("Place your order").click()
assert "ThankYouCart" in driver.current_url
```

You can also verify that a string is not in the result or the truth of a mathematical expression. Assert statements that are false will result in a session status of `FAILED`.

```
Confirm the page doesn't gives a 500 error.
assert "500 Internal Server Error" not in driver.page_source
Confirm the footer is on the page.
footer = driver.find_elements_by_class_name('footer-body')
assert len(footer) > 0, "Footer couldn't be found."
```

### Use the Session Status to Find Script Issues

The two-session statuses `BROKEN` and `FAILED` indicate that the script had an issue. If the session status is `BROKEN`, it means that your script threw an uncaught exception. You'll most likely need to review your code and look for errors. See [Exceptions](#) for a list of common exceptions.

If the session state is `FAILED`, an assert statement failed or if you checked "Fail on page load error" and the page failed to load. You'll need to determine why your assertion statement failed or why the page couldn't be loaded.

You can view the results of assertion statements in the session status detail and script output. From the **Session Details** page, you can view failed assert statements in a red exception box at the top and from the **Waterfall** tab:

The screenshot shows the 'Session Summary' section with a 'Failure' status. A red box highlights an 'Exception' message: 'AssertionError: assert "500 Internal Server Error" not in driver.page\_source'. The 'Page Views In Session' table shows a failed view for 'httpstat.us/500'. The 'Waterfall' chart shows various page load events, with a red box at the bottom indicating the error: '[ERROR] AssertionError: assert "500 Internal Server Error" not in driver.page\_source'.

Failed assert statements will also appear in the **Script Output** dialog:

The 'Script Output' dialog displays a table of log entries. A red box highlights an error entry at 24.231 seconds: 'AssertionError: assert "500 Internal Server Error" not in driver.page\_source. Traceback (most recent call last): Line 12, in <synthetic script> assert "500 Internal Server Error" not in driver.page\_source'.

Time (sec)	Severity	Message
0.000	INFO	Starting measurement [f298f52e-ffa1-4f6b-a8a1-07c14d34f735~ce0bef13-f7c3-478e-b952-3e94f86d0052]
0.000	INFO	Executing WebDriver script

## Select Client Certificates

**i** This page is solely intended for use with the Synthetic Private Agent. You will *not* be able to run some of the synthetic scripts below with the Synthetic Hosted Agent.

When using client certificates, you may need to select the certificate from a dialog. To do this, you will need to install the Python [pyautogui library](#) on the host machine of your Synthetic Private Agent. The `pyautogui` library enables you to navigate the UI to select a client certificate.

### Install the PyAutoGUI Library

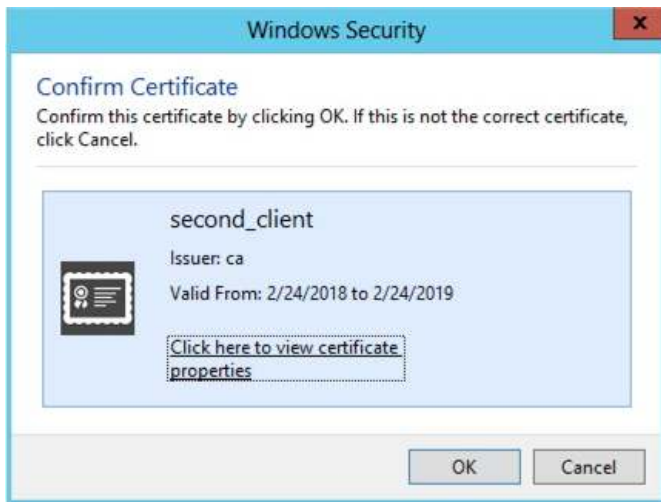

To install the PyAutoGUI Library:

1. Log in to the host machine for the Synthetic Private Agent as the `agent_user`.
2. Open a PowerShell console.
3. Use `pip` to install the library:

```
pip install pyautogui
```

### Select the Only Client Certificate

When you manually navigate to a site that uses client certification, IE10 may prompt you with an alert dialog to select one client certificates as seen below:

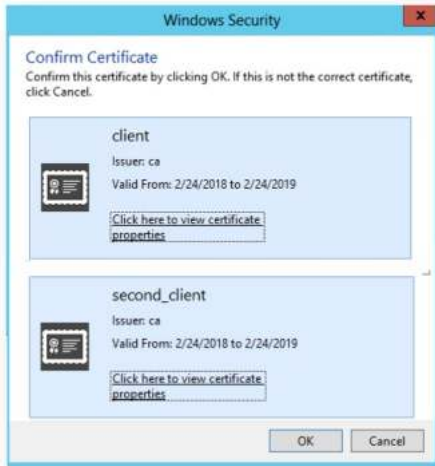

To select the client certificate from a synthetic script, your code could focus on the alert dialog and accept the given client certificate as performed by the synthetic script below.

```
sslUrl = "https://yourdomain.com/"
driver.get(sslUrl)
Move focus to the dialog
alert = driver.switch_to_alert()
Accept the client cert
alert.accept()
```

## Select Certificate from List

In the case where your synthetic job needs to select one client certificate from a list presented in the alert dialog as shown below, you can use the [PyAutoGUI Library](#) to select and accept the client certificate that you want.

In the example below, you use `switch_to_alert` to focus on the alert dialog, and then use the `pyautogui` library to navigate to the correct certificate (tab), select it (enter), and then navigate to the OK button to select it (tab, enter).

```
import pyautogui
pyautogui.FAILSAFE = False
sslUrl = "https://yourdomain.com/"
driver.get(sslUrl)
driver.switch_to_alert()
pyautogui.press(['tab', 'enter', 'tab', 'enter'])
```

You may have many more client certificates to choose from, so you will have to figure out the best way to use the PyAutoGUI APIs to navigate around the alert dialogue to select and accept the correct client certificate. See [Keyboard Control Functions](#) in the PyAutoGUI documentation for more information.

## Synthetic Agent Locations

The primary purpose of Browser Synthetic Monitoring is to perform browser-based testing. To help you test browsers in the locations of your users, Browser Synthetic provides agents in locations around the world. Your scripts, however, are run in a separate location for the security reasons discussed in the next section.

## Security Considerations for Scripting

The browsers configured in synthetic jobs are run on shared Windows machines. Because synthetic scripts are written in native Python, they are not run on the shared Windows machines. Instead, each synthetic script is executed in isolation within a Docker container in a location mapped to the configured browser location. This isolation of the agents and scripts guarantees the safety of the data handled by the scripts and has no effect on the performance of the agent.

## How This Affects Your Synthetic Jobs

You should understand how the locations of the agent/browser and where the script is executed may affect your synthetic job. For example, if the location of the execution container and the configured browser are not in the same region, you may expect to see some network latency. Also, if you are using the Python [Requests library](#) to make HTTP requests, you should know where the request is being made from.

The following sections provide some insight as to how your job may be affected.

### URL Measurements

URL Measurements are used to test site availability and will not be affected because no script is being executed.

### Synthetic Scripts

Your script can use different libraries to make HTTP requests. The [WebDriver API](#) is used to mimic the browser making HTTP requests. To make cURL-like requests to test REST APIs or to retrieve data, you can use an HTTP library such as the [Requests library](#). The tables below describe how the script is executed and the types of problems you may encounter.

[WebDriver HTTP Requests](#)    [Other HTTP Libraries](#)

Script Execution Flow	Potential Issues
<ol style="list-style-type: none"> <li>1. You add your script to a synthetic job and configure the browser location in the <b>Controller UI</b>.</li> <li>2. The synthetic job is transmitted to the Synthetic servers.</li> <li>3. When the synthetic job is ready to run:               <ol style="list-style-type: none"> <li>a. A Docker container is created.</li> <li>b. The Docker container communicates with agents in selected regions.</li> <li>c. The script is executed within the container.</li> </ol> </li> <li>4. The script commands are run in a browser using the <a href="#">Remote WebDriver</a>.</li> <li>5. After the script finishes running, the agent collects browser metrics and sends them to the Controller UI.</li> <li>6. The <b>Controller UI</b> receives and displays the metrics from your synthetic job.</li> </ol>	<p>The <a href="#">WebDriver API</a> is used to test the functionality of web pages. You may experience network latency between the execution of the script and the results if the locations of the Docker container and the browser are different.</p> <p>Because the script is running in a different location, network latency may increase the time to complete the execution of the script. The browser test results collected through this process, however, are <b>not</b> affected by this latency, and thus, the results will be reliable.</p>

[WebDriver HTTP Requests](#)    [Other HTTP Libraries](#)

Script Execution Flow	Potential Issues
<ol style="list-style-type: none"> <li>1. You add your script to a synthetic job and configure the browser location in the <b>Controller UI</b>.</li> <li>2. The synthetic job is transmitted to the Synthetic servers.</li> <li>3. When the synthetic job is ready to run:               <ol style="list-style-type: none"> <li>a. A Docker container is created.</li> <li>b. The Docker container communicates with agents in selected regions.</li> <li>c. The script is executed within the container.</li> </ol> </li> <li>4. After the script finishes running, the agent sends the script output to the Controller UI.</li> <li>5. The <b>Controller UI</b> receives and displays the output from your synthetic job in the script console.</li> </ol>	<p>If you are using something other than WebDriver to make HTTP requests, such as the <a href="#">Requests library</a>, you should know where the HTTP request is being made from.</p> <p>You should also understand that the Controller UI only captures browser metrics, so you may want to capture output from your requests in the script console.</p>

### Mapping of Execution Containers and Browser Locations

The table below lists the available browser locations as well as the corresponding provider and container location.

* Browser Location	Provider	Container Location
Ashburn, Virginia	AWS	US East (N. Virginia)
Montreal, Québec	AWS	
Toronto, Ontario	Azure	
Amsterdam, Netherlands	Azure	EU (Ireland)
Dublin, Ireland	AWS	
Frankfurt, Germany	AWS	
London, United Kingdom	AWS	
Milan, Italy	AWS	
Paris, France	AWS	

* Browser Location	Provider	Container Location
Hong Kong, China	AWS	Asia Pacific (Tokyo)
Seoul, South Korea	AWS	
Tokyo, Japan	AWS	
Chennai, India	Azure	Asia Pacific (Singapore)
Mumbai, India	AWS	
Singapore	AWS	
Melbourne, Australia	Azure	Asia Pacific (Sydney)
Sydney, Australia	AWS	
Boardman, Oregon	AWS	US West (Oregon)
San Francisco, California	AWS	
Sao Paulo, Brazil	AWS	
San Antonio, Texas	Azure	

## Info

\*Some of the locations are enabled only based on requests in the new regional clouds. To add missing locations in any regional cloud, raise a support ticket with the list of required locations.

## Hosted Agent Coverage Variations

Synthetic hosted agents have the following coverage variations:

- The US EUM cloud has access to both AWS and Azure locations.
- The Frankfurt EUM cloud has access to only AWS locations.
- The Sydney EUM cloud has access to only AWS locations.
- The Bombay EUM cloud has access to only AWS locations.

## Credential Vault for Web Monitoring

### Deployment Support

Credential Vault securely stores the credentials used in Synthetic web monitoring jobs. When you create a job with a synthetic script, you can add a credential, such as a username and password, to log in to an application and inject a reference to the stored credential into the script. When the job runs, the synthetic script uses that reference to retrieve the credentials stored in the Credential Vault.

### How to Use Credential Vault

1. Go to  > **Tools > Manage Synthetic Credentials.**
2. [Add a credential in a key-value pair to Synthetic Credential Vault.](#)
3. [Create a synthetic job using a synthetic script.](#)
4. [Inject the credential key into the synthetic script.](#)

 The job runs and retrieves the credential value associated with the credential key.

5. The synthetic job runs and retrieves the credential value associated with the credential key.

### Add Synthetic Credentials

In Credential Vault, you can add credentials one-by-one or import multiple credentials.

### Syntax Rules

This table describes credential syntax rules used for creating credentials and adding credentials to the synthetic scripts:

Element	Rule
Keys	<ul style="list-style-type: none"> <li>1-100 characters</li> <li>Alphanumeric characters, hyphens, and underscores only</li> <li>Keys must be unique per EUM account</li> </ul>
Values	<ul style="list-style-type: none"> <li>5000 characters</li> <li>Any non-control, printable UTF-16 characters</li> </ul>
Credential key name (used in synthetic scripts)	"<%key%>"

### Add a Single Credential

 If you want to use a combination of credentials, such as a username and password combination, you must create two separate credentials: one credential for the username and one for the password.

To add a single credential for a sample email:

1. Go to  > **Tools > Manage Synthetic Credentials**.
2. Click **Add**.
3. Enter a key and value. Make sure you follow [syntax rules](#).
4. (Optional) Select an associated application. When you search for credentials in the synthetic script, associated credentials are suggested first.

Add/Edit
✕

**Key**

**Value**

**Application Optional**

Application
▾

Cancel

OK

### Import Multiple Credentials

You can add multiple credentials at once using the **Import** button.

To add multiple credentials for sample emails and passwords:

1. Go to  > **Tools > Manage Synthetic Credentials**.
2. Click **Import**.
3. Copy and paste credentials or type them line by line. Make sure you follow [syntax rules](#).

- The maximum number of credentials that can be imported at once is 250.
- You cannot add associated applications to imported credentials. After importing, you must edit each credential individually to add the associated application.

#### Example

1	email_key=user123@email.com
2	password_key=Password123
3	email_key=user456@email.com
4	password_key=Password456

### Use Credentials in a Synthetic Script

You can retrieve a credential value by inserting the corresponding credential key in a script. Credentials associated with a specific application appear first when you start typing the key in the script.

To create a synthetic job:

1. Go to **User Experience > Jobs > Add**.
2. Add your synthetic script. See [Write Your First Script](#).
3. Enter the credential key using the syntax " <%key%> " .

Synthetic Script
<pre>driver.find_element_by_id("email").send_keys("&lt;%email_key%&gt;") driver.find_element_by_id("pass").send_keys("&lt;%password_key%&gt;")</pre>

### User Permissions

In the Controller Administration UI, you can configure roles and groups with Account-level. You can add roles and groups to users based on the requirement. The **Manage Credential Vault** permission allows you to manage access control of the Credential Vault.

 After upgrading to 23.8, the **Manage Credential Vault** permission gets added automatically to all the roles with existing **Administration, Agents, Getting Started Wizard** permission. This process takes approximately five hours to complete. If you do not want the administrator users to access the Credential Vault, remove the **Manage Credential Vault** permission for those users.

Before Upgrading to 23.8	After Upgrading to 23.8
<p><b>Administration, Agents, Getting Started Wizard</b> permission has the following privileges:</p> <ul style="list-style-type: none"> <li>Manage all users</li> <li>Add, edit, and delete credentials</li> <li>View both keys and values of stored credentials</li> <li>View users, timestamps, and associated applications columns</li> </ul>	<p><b>Manage Credential Vault</b> permission gets automatically added to all the roles with existing <b>Administration, Agents, Getting Started Wizard</b> permission. This permission has the following privileges:</p> <ul style="list-style-type: none"> <li>Manage all users</li> <li>Add, edit, and delete credentials</li> <li>View both keys and values of stored credentials</li> <li>View users, timestamps, and associated applications columns</li> </ul> <div style="background-color: #e1f5fe; padding: 10px; margin-top: 10px; border: 1px solid #bbdefb;"> <p> From 23.8 onwards, when you assign a user with the <b>Administration, Agents, Getting Started Wizard</b> permission, the user does not have access to the Credential Vault by default.</p> </div>

Before Upgrading to 23.8	After Upgrading to 23.8
<p><b>View Credential Vault</b> permission has the following privileges:</p> <ul style="list-style-type: none"> <li>• View keys of stored credentials</li> <li>• View users, timestamps, and associated applications columns</li> </ul>	<p><b>View Credential Vault</b> permission has the following privileges:</p> <ul style="list-style-type: none"> <li>• View keys of stored credentials</li> <li>• View users and timestamps columns</li> </ul>

To create a role with the Manage Credential Vault:

1. Go to  > **Administration** > **Roles**.
2. Under **Roles**, click **Create**.
3. Add a role name.
4. Under **Account**, click **Add+**.
5. Select one of the following permissions based on the role that you are creating:
  - Manage Credential Vault
  - View Credential Vault
6. Under **User and Groups with this Role**, add users and/or groups.

## Alerts for Browser Synthetic Monitoring

### Related pages:

- [Policies](#)
- [Health Rules](#)
- [Actions](#)

You can set policies and alerts based on synthetic events, or you can set thresholds to trigger alerts when you create or edit a synthetic job.

### Synthetic Event Types

The following two types of synthetic events are supported and can be used to trigger policies and actions:

- Synthetic Availability
- Synthetic Performance

You can set policies with alerts for these synthetic events, selecting either or both warning or critical conditions.

### Synthetic Policies

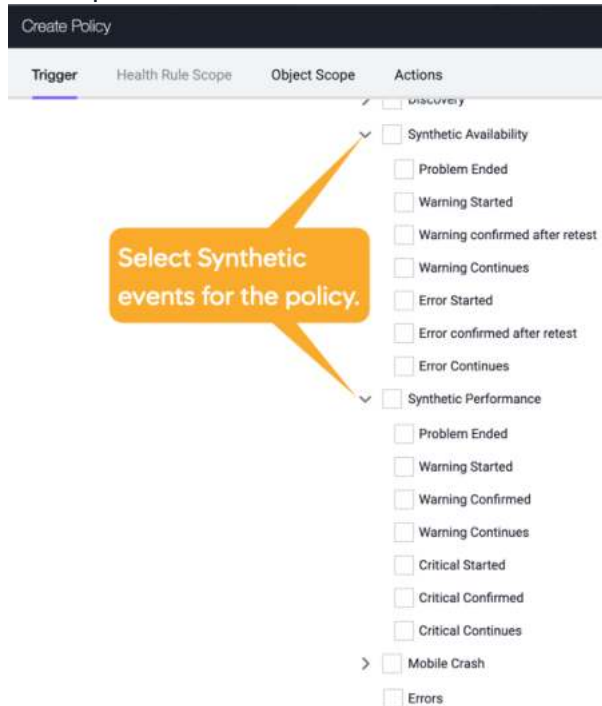

You can use Synthetic Availability and Performance events to trigger policies, which can, for example, send an alerting email. See [Configure Policies](#) for more information.

### Create Policy for Synthetic Availability

You can select warning and/or error events for policies for Synthetic Availability.

1. From the **Browser App** menu, click **Alert & Respond**.
2. Click **Policies**.
3. From the **Policies** page, click **Create Policy Manually**.
4. From the **Create Policy** dialog, enter a name for your policy.

5. Check the **Synthetic Availability** checkbox to select all the **Synthetic Availability** events or check one or more specific events.

6. Click **Next**.
7. Create an action to be executed when any of the **Synthetic Availability** events are triggered. See [Actions](#) for more information.

## Site Availability

Availability is based on the session status:

- Single URL jobs
  - Warning = 4xx response, (session status is either **WARNING** or **BROKEN** )
  - Error = 5xx response, timeout, cannot contact application ( **FAILED** )
- Scripted jobs
  - Warning = your script threw an uncaught exception ( **BROKEN** ) or the session status is **WARNING**.
  - Error = your script had an assertion failure or timed out ( **FAILED** )

## Performance Issues

Performance events are based on the criteria you set up when you set up scheduled jobs. For an example of the health rule violation process, see [Health Rule Violation Events](#).

## Create Policy for Synthetic Performance Events

You can select warning and/or error events for policies for Synthetic Performance.

1. From the **Browser App** menu, click **Alert & Respond**.
2. Click **Policies**.
3. From the **Policies** page, click **Create Policy Manually**.
4. From the **Create Policy** dialog, enter a name for your policy.
5. Check the **Synthetic Performance** check box to select all the **Synthetic Performance** events or check one or more specific events.

6. Click **Next**.
7. Create an action to be executed when any of the **Synthetic Performance** events are triggered. See [Actions](#) for more information.

### Configure Performance Thresholds

You can also configure performance thresholds that will trigger events when the thresholds are exceeded.

1. Click **+ Add** to add a new job.
2. In the **New Job** popup, scroll down to **Configure Performance Thresholds**:
3. From either **Trigger a warning event when** or **Trigger a critical event when**:
  - Click **+ Add Threshold** to add a [performance threshold](#) for triggering a warning/critical event.
  - Select a performance threshold, enter a value that will trigger a warning event.
  - Select when the event should fire—immediately or after 2, 3, 5, or 10 consecutive failures.

#### 8 Configure Performance Thresholds (optional) ⓘ

Trigger a warning event when

**+ Add Threshold**

End User Response Time is greater than 5000

Automatically retest after warning events

Trigger a critical event when

**+ Add Threshold**

Visually Complete Time is greater than 10000 ms

Automatically retest after critical events

after 3 consecutive failures

Select metric and threshold.

Automatically retests an event or consecutive failures.

4. You can select multiple performance thresholds by clicking **+ Add Threshold** multiple times.

### Performance Thresholds

The following are the supported performance thresholds. Follow the links for descriptions of the performance thresholds.

- [End User Response Time](#)
- [Fully Loaded Time](#)
- [Visually Complete Time](#)
- [First Byte Time](#)
- [Start Render Time](#)
- [Bytes per Pageview](#)

### Synthetic Sessions

You use the **Session** page to analyze synthetic sessions. A synthetic session is a record of the complete sequence of events that make up one synthetic test. A session can cover one page or, in the case of scripted jobs, can extend to multiple pages. All session timestamps are in local time, regardless of the configured scheduled job's timezone.

A session begins at the first navigation start in the sequence and continues until the last page is fully loaded. In the case of single-page sessions, the session begins and ends when the *page* is fully loaded (the session duration represented by the metric Visually Complete). Like [Browser RUM Analyze](#) and [Network Request Analyze](#), the Synthetic Sessions view enables you to analyze results from *all* synthetic sessions.

 For single-page applications (SPAs), sessions will include the base page and its virtual pages as *one* page: the base page.

## Session Status

Sessions can have one of four statuses:

- **OK** : The test ran successfully and returned data.
- **WARNING** : The test ran successfully, but there were inaccessible resources.
- **BROKEN** : Your job has an error. You can find the error in the script console output.
  - In single URL jobs, the test received a 4xx response.
  - In scripted jobs, your script threw an uncaught exception. This can, for example, happen if you try to perform an action, like a click, on an element which is not on the page you are testing.
- **FAILED** : The synthetic test has detected a problem with your site. When failed jobs have the status **FAILED** , an event is created and the job is run again to confirm there was an error.
  - In single URL jobs, one of the following occurred:
    - the browser couldn't reach the URL
    - the browser received a 5xx response
    - the session timed out
  - In scripted jobs, your script had an assertion failure or timed out.

## Session UI

### Records

The Records tab enables you to scan individual requests and allows you to filter and sort to get exactly the data set in which you are interested.

The screenshot shows the 'Sessions' dashboard. At the top, there's a search bar with 'Default Search / Visualization' and a 'Records' tab. Below it is a bar chart showing session counts over time. A callout 'Create and save a search' points to the search bar. Below the chart is a table of sessions. A callout 'Filter sessions by field' points to the 'Fields' sidebar on the left, which lists various session attributes like Browser, City, and Duration. Another callout 'Click a session for details' points to a session entry in the table. The table has columns for Date/Time, URL, Session Visual Time, Duration, and Status. The bottom of the table shows pagination: '50 per page', 'First', '1 of 17', and 'Last'.

The values of **Session Visual Time** and **Duration** may not match. This can happen because **Session Visual Time** is the average of visually complete time, and **Duration** is the aggregate of the page load time.

**Metric definitions:**

- **Session Visual Time:** the average of visually complete time of all pages in the job.
- **Visually Complete:** Visually Complete time on a page is the point in time when the browser has finished rendering viewable content as compared to the entire content of the page.
- **Duration:** Duration or Session Duration is the aggregate of the page load time of all pages in a job and the time taken by any other execution logic in the script.
- **Page load time:** the time taken to download and display the entire content of a page in the browser window.

**Session Details**

Select a specific session and click **View Details** to see detailed information, including a page load waterfall and tabular details for resources. In multi-page sessions, the left navigation allows you to select each page from the sequence.

The screenshot displays the 'Synthetic UI Job - 9z9 (URL Measurement)' interface. At the top, it shows the session status as 'Success' and a 'Copy the session link' button. Key metrics include a 'Session Duration' of 4.252 sec and a 'Visual Time' of 4.045 sec. The location is identified as 'Amsterdam, Noord-Holland, Netherlands'. A 'Session's Last Screenshot' is shown on the left. The main area features a 'Page Views In Session' table and a 'Page Details' waterfall chart. The table lists the page 'www.appdynamics.com' with a duration of 4,045 ms. The waterfall chart shows various resources like 'ctm-core.js', 'www.cisco.com', 'jquery.min.js', and 'utils.min.js'. Callouts highlight features: 'Select a page from the session' points to the table row; 'View a breakdown of resources and a list of resource domains.' points to the 'Resources' tab; 'View a screenshot of the selected page' points to the 'Screenshots' tab; and 'View load details of a resource' points to the 'Analyze Resource Timing' panel for 'www.appdynamics.com', which shows an HTTP Status of 200 and a size of 122,720 bytes.

## Business Transactions

When a business and a browser application have [correlated business transactions](#), you can also create synthetic jobs from that browser application that makes requests to the business application to get business transactions in synthetic sessions. You can view business transactions in the Waterfall and the Business Transactions tabs of the **Session Details** dialog.

If you see  **View Snapshot >** next to resource in the waterfall, that indicates that there was a correlated business transaction. Clicking it will take you to the business transaction snapshot from the backend.

You can also click the Business Transactions tab to see a list of the server-side business transactions this request initiated. Click through to the related **Business Transaction** dashboards.

## Script Output

If you used a script, you can click through to see any script output.

Script Output
✕

Time (sec)	Severity	Message

Click **Copy to Clipboard** to copy the script output to your clipboard or **Download** to download the script output.

### Session Screenshots

Synthetic captures screenshots of the browser as your job runs. By default, it takes one screenshot per page, when the page is finished rendering. Screenshots are retained for 30 days.

In scripted jobs, you can [call an API from your script](#) to take a maximum of 10 screenshots per page. The screenshot will be of the visibly complete content in the viewport (won't include the browser chrome).

The Screenshots tab shown below displays the screenshot as a 200 x 150 image. The resolution of the screenshot will be the same as the device where the screenshot was taken.

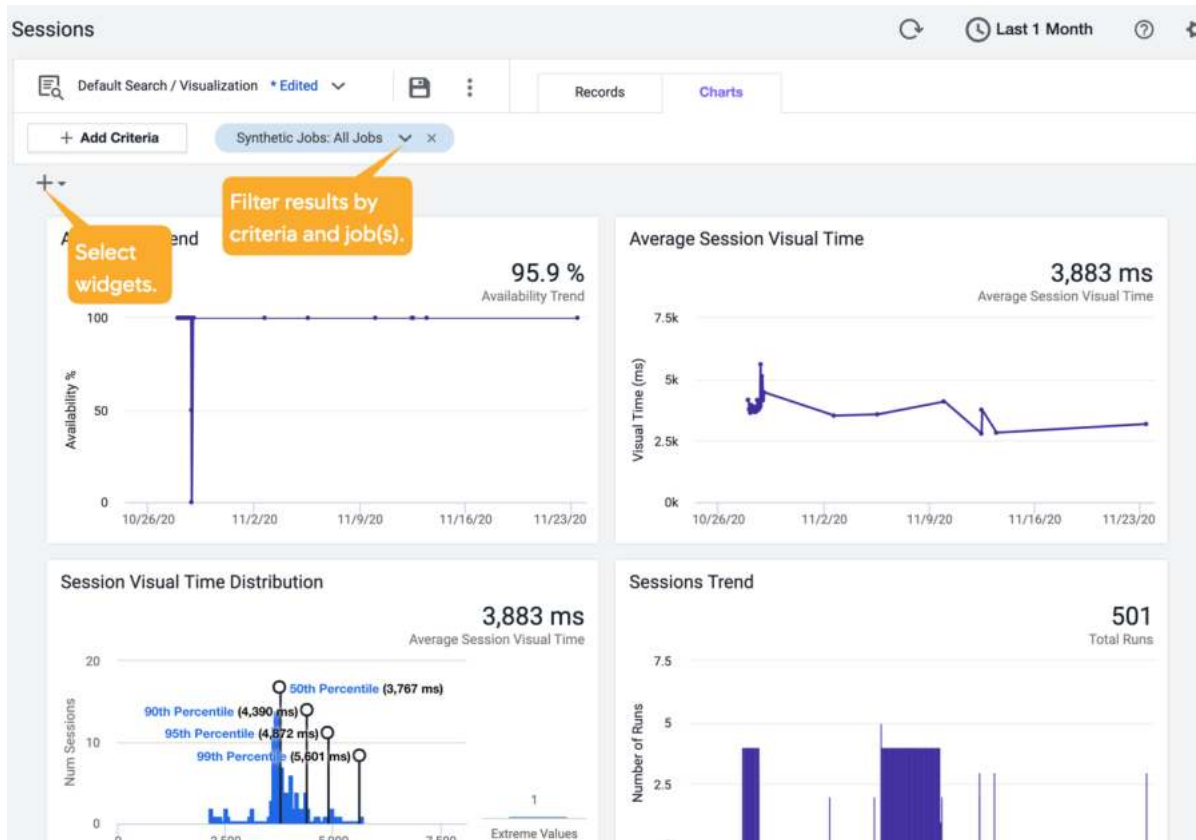

The Waterfall tab will contain the visually complete screenshot and any custom screenshots (e.g., `screenshot2` in the screenshot below) triggered by the script.

## Charts

The Charts tab provides you with a set of widgets that offer predefined visualizations of the data set you have created, allowing you to create a dashboard. You can delete, re-add, resize, and drag-and-drop to move the widgets.

## Analyze Session Results

You understand the results of your synthetic jobs through sessions. From session details, you can determine if there were errors, what type of errors, and diagnose what factors are affecting performance. The following sections show you how to analyze synthetic session results for errors and performance issues.

### Errors

#### Determine Type of Error

At this time, you should be able to determine the type of error by the **Status** and **Error Type** fields. The **session status** indicates whether your jobs are passing, failing (there is a problem with the system being tested), or broken (there is a problem with the job itself). The **Error Type** field gives more information about the cause of the error.

#### Understand the Error

1. From the **Sessions > Records** tab, select a session with an error and click **View Details**.
2. From the **Session Details** dialog, you can view when the error occurred and the returned error message in the Waterfall tab.
3. If your job used a custom script, you can click **Show Script Output** to view the script results. You can download or copy the results as well.
4. You can also view the screenshot to see how the error might be manifested to end users. You might want to display the errors in a more user-friendly way and possibly omit error details.

## Performance

One of the best ways to see if your job is having performance issues is to view widgets representing aggregated metrics in the Charts tab. With a quick glance, you can see if there are site availability issues, where end users might be having bad user experiences, how long sessions are lasting, and how long it's taking for pages to be visually complete.

### Network Latency

The Waterfall tab shows you a timeline of when resources are loaded and plots the events First Byte, DOM Ready, Load Event, and Visually Complete that mark significant and discreet moments from the time the browser receives data until the user can see a complete page.

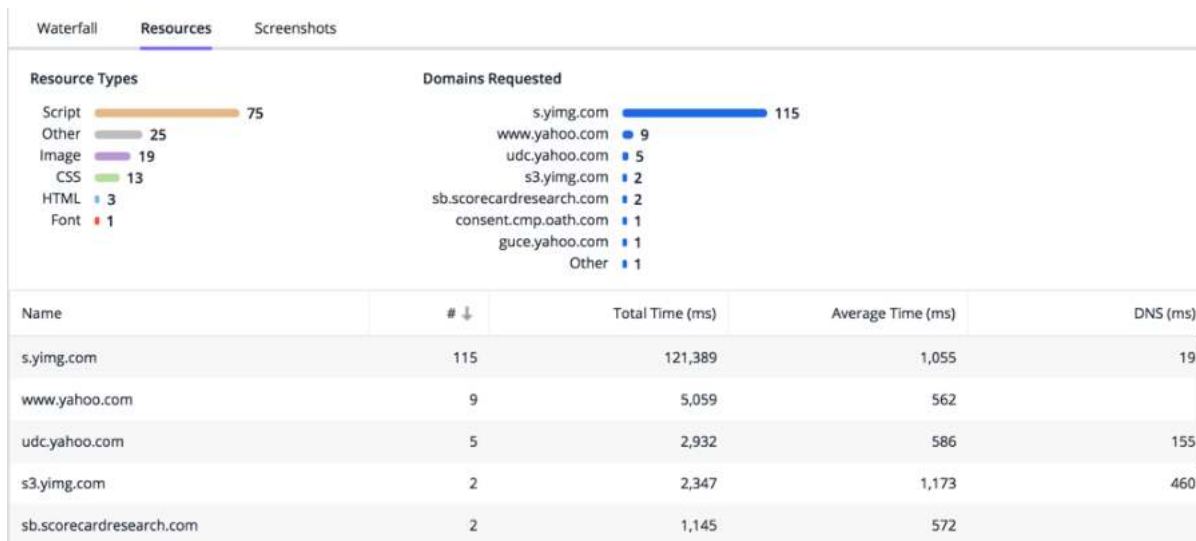

To understand session performance, you can compare the end user response time (the same as the `onLoad` time) of a page with the session duration. This gives you an idea of which pages are taking too long to load and how that might be affecting the session.

You can also click one of the bars to determine if a resource is taking a long time to load. For example, if an image is taking too long to load, you can take actions to optimize the loading time such as caching the image, reducing its size, confirm that the image is the size that you're displaying it, or not use the image at all.

### Problematic Resources

The **Session Details** dialog shows you the final session state and the session state set by each page. The final session state is indicated in the top-left corner, whereas, the session state set by each page is shown in the **Page Views in Session** sidebar. In the screenshot below, the  icon indicates that the first page set the session status to "Warning". From the Waterfall tab, you can also discover which resources didn't load, either marked in yellow for the "Warning" state or in red for the "Failed" state.

The Resources tab shows you the number of resources by category, the domains requested, and key performance metrics that you can use to sort the results. You can quickly identify resources that are slowing the page load and potential DNS problems.

You can also configure your synthetic jobs to check the availability of resources. You can set the session status to **Failed** or **Warning** when resources are unavailable. See [Configure Availability Rules](#) for configuration instructions. When the session status is set to **Failed** or **Warning**, Browser Synthetic Monitoring triggers corresponding events that can be used to create alerts. This enables you to be alerted when resources are missing. See [Alerts for Browser Synthetic Monitoring](#) to learn how to create availability policies.

### View the Effects of Performance Issue

Screenshots will show you what your user is seeing. From the screenshot, you can determine whether the content has completely loaded (text, images, containers, UI components) and the page is styled correctly (CSS).

From the Waterfall tab, you can determine when the screenshot (visually complete) and view a small thumbnail by hovering over the camera icon.

The screenshot displays the AppDynamics interface for a URL measurement. At the top, the session summary shows a 'Success' status, a 'Session Duration' of 4.036 sec, and a 'Visual Time' of 3.642 sec. The location is identified as 'Amsterdam, Noord-Holland, Netherlands' and the browser used is 'Chrome'. Below this, the 'Page Views In Session' section shows a single page view for 'www.appdynamics.com' with a 'Visually Complete Time (ms)' of 3,642 and a 'Timeline' starting at 'Start'. The main area is the 'Page Details' for 'https://www.appdynamics.com/'. It features a 'Waterfall' chart with a timeline from 00s to 06s. The chart shows various resource loading events, including 'Resource', 'Browser Event', 'Script Log', and 'Screenshot'. A specific event for 'Visually Complete' is highlighted at 3,642 ms, with a camera icon next to it. A tooltip for this event shows a larger screenshot of the page content, including the text 'Flawless connections for a...'. The interface also includes a search bar and a 'Sort by Start' dropdown menu.

By navigating to the Screenshots tab and double-clicking the screenshot, you can view a larger screenshot to see details such as the styling, UI components, and content.

### Synthetic Pages

You use the **Pages** view to see an aggregated view of how each page visited in your jobs is performing over time.

The metrics shown in the **Pages** view are aggregated across all jobs, so if multiple jobs visit the same page,

Type	Name	Requests ↓	End User Response Time (ms)	DOM Ready Time (ms)	First Byte
	www.google.com	7	1,933	966	
	docs.appdynamics.com/display/pro45	4	23,87	7,975	
	www.google.com/search	1	841	760	
	www.appdynamics.com	1	14,18	3,144	

their metrics will be aggregated.

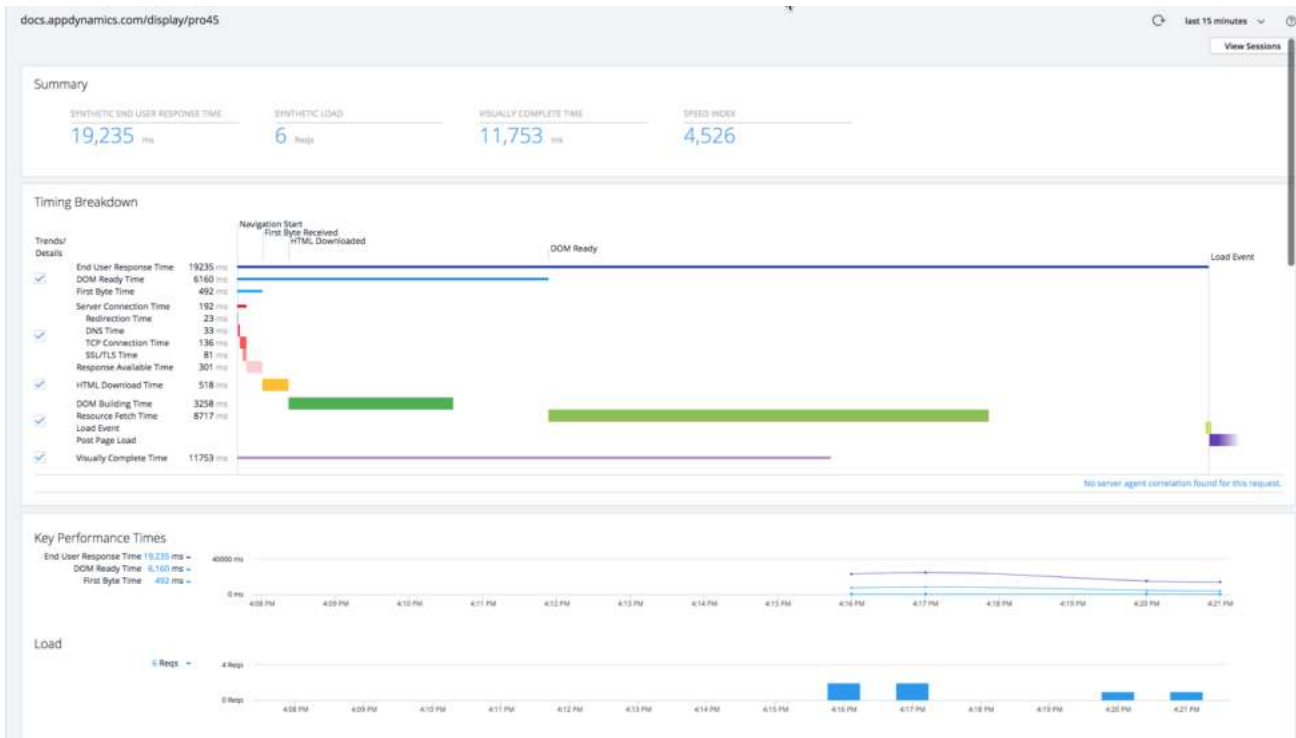

You can also [Configure Page Identification and Naming](#) using the same mechanism as Browser RUM uses.

### Pages Details

Just as in the Browser RUM view you can filter the dataset and manage which pages are displayed and which metrics are shown. If you select an individual page and click **Details**, you are shown a **Page** dashboard very similar to the [Browser RUM Pages Dashboard](#).

The **Synthetic Pages Dashboard**, however, includes some additional metrics. To understand these added synthetic metrics, you can hover over the metric name and a tooltip explaining the metric popup. See [Browser Synthetic Metrics](#).

## Request Synthetic Snapshots On-Demand

Browser Synthetic On-Demand allows you to take quick snapshots of single pages whenever you wish. See [Browser Synthetic Metrics](#).

**i** Browser Synthetic On-Demand is only available on SaaS deployments of the Controller.

### Create an On-Demand Snapshot

To create an on-demand session, click **+ Generate a Snapshot** at the top of the **On-Demand** list page.

After the **Generate a Synthetic Snapshot** popup appears:

1. Provide the URL of the page you wish to test.
2. From the dropdown, select where the request should originate and which browser should be used.
3. Click **Generate Snapshot**.

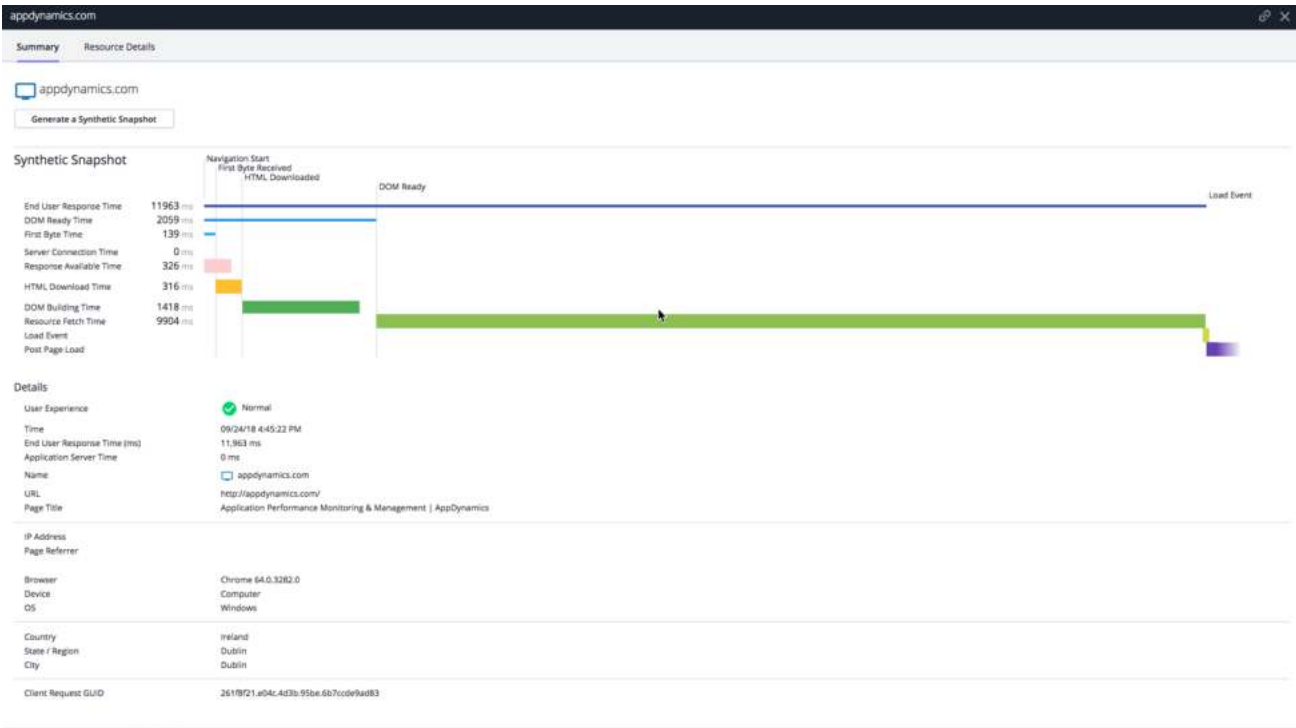

The image shows a modal window titled 'Generate a Synthetic Snapshot' with a close button (X) in the top right corner. The form contains the following fields:

- URL:
- Location:
- Browser:  (with a dropdown menu showing options: Chrome, Firefox, IE10, IE11)
- 

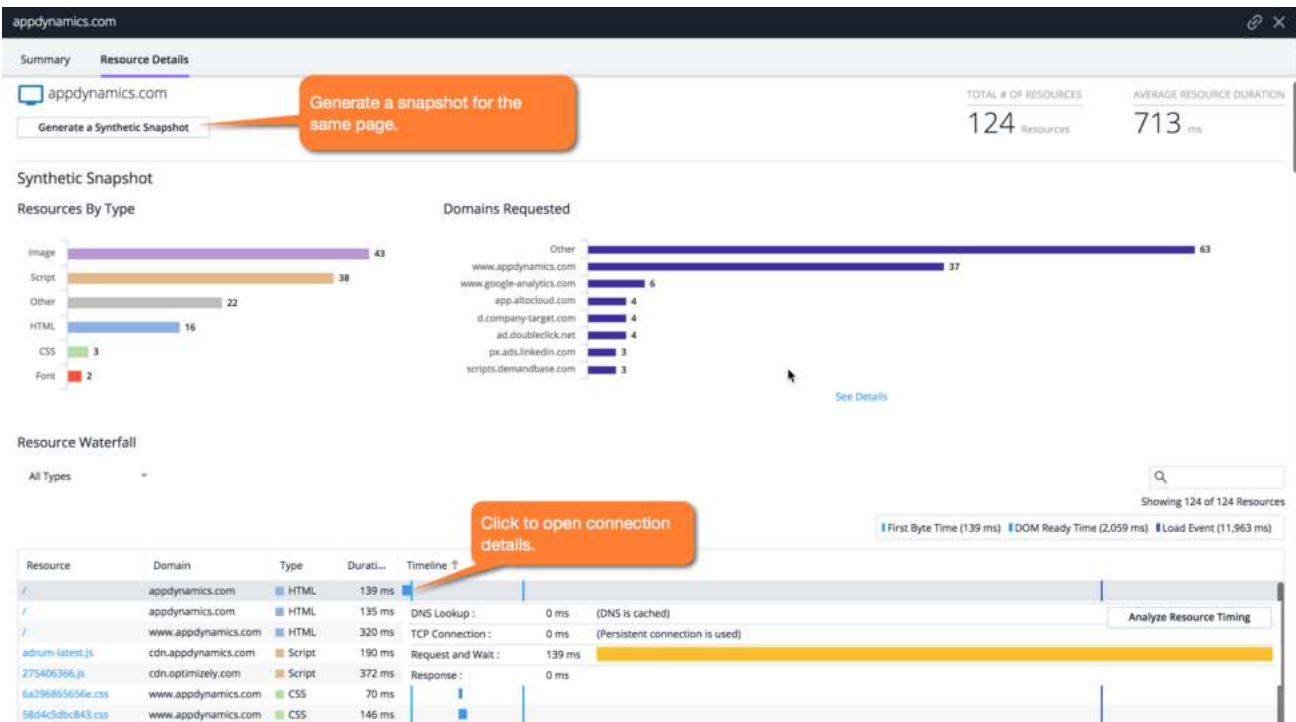

At the top of the form, it says 'Enter a URL to execute a single test using Synthetic Monitoring.'

### View On-Demand Snapshot Results

When the test completes, it is marked as **Done** in the Snapshot list. To see the detailed results, click the test. The Summary tab provides a waterfall of the page load and additional request details.

The Resource Details tab provides visualizations of **Resources by Type** and **Domains Requested** and a waterfall displaying the download of every resource. Click a waterfall bubble to see connection details. **Domains Requested** is also presented as a table.

---

## Browser Synthetic Metrics

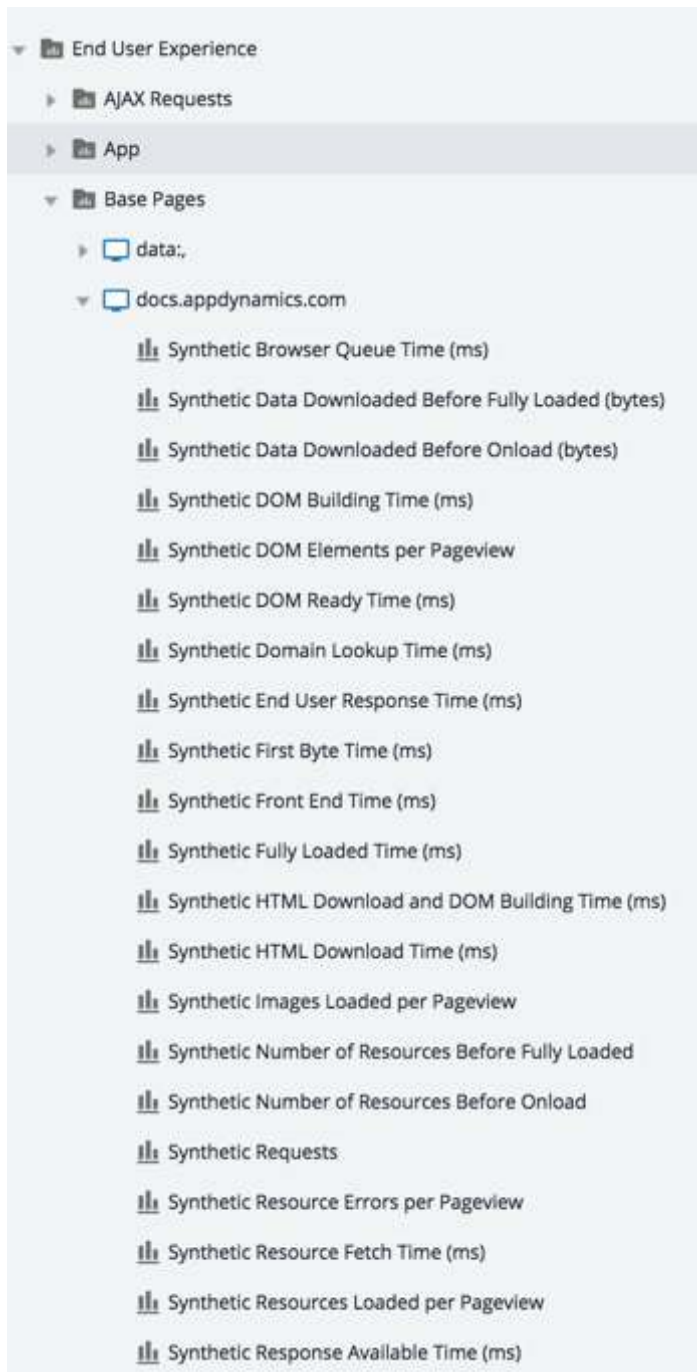

### Related pages:

- [Browser RUM Metrics](#)
- [Analytics Synthetic Sessions Data](#)

Many of the metrics collected by Browser Synthetic are identical to those collected by [Browser RUM](#). Additional synthetic-only metrics are defined in [Browser Synthetic Metrics Defined](#).

Key Browser RUM metrics are displayed on the **Geo**, **Sessions**, and **Pages** dashboards. They can also be seen in the **Metric Browser**, just like RUM metrics, giving you the ability to view these metrics in the context of Ajax requests, iframes, applications, base pages, browsers, devices, and geographic locations.

Metrics will only appear in the **Metric Browser** if there is synthetic data. For example, if your synthetic jobs do not have failed sessions, the metric **Failed Sessions** will not appear.

There are also metrics for specific tests and, under the **Synthetic Jobs** heading, for Synthetic job health overall.

## Browser Synthetic Metrics Defined

Name	Definition
<b>Availability</b>	<p>The ratio of <code>OKAY</code> sessions (successful) to all sessions, expressed per-million: 0 (for all failed) to 1,000,000 (for all succeeded). The ratio is calculated using the following: (# of successful sessions/# of total sessions) * 1,000,000.</p> <p>Availability is represented in per-million instead of as a percentage because Controller metrics are given as integers, making expressing the availability as a percentage less precise. For example, although the availability percentage in actuality might be 99.99%, it would only be able to be expressed as an integer such as 100% or 99%.</p> <p>To convert per-million to a percentage, just divide by Availability (ppm) by 10,000. For example, if Availability (ppm) is 999,800, then Availability (%) is 99.98%. Most Controller UI components display metrics as percentages, but the <b>Metric Browser</b>, which shows "raw data", shows the value per-million.</p>
<b>Billable Time</b>	<p>The seconds that were billed against your <a href="#">Synthetic license</a>.</p>
<b>Broken Sessions</b>	<p>The number of sessions that completed with the session status <code>BROKEN</code>, indicating that the job has an error. You can find the error in the script console output.</p>
<b>Data Downloaded Before Fully Loaded</b>	<p>The bytes of data downloaded by the browser between the navigation start of a page and the navigation start of the next page or the end of the session. In particular, includes any resources loaded after the page <code>load</code> event.</p>
<b>Data Downloaded Before Onload</b>	<p>The bytes of data downloaded by the browser between the navigation start for a page and the <code>load</code> event for that page.</p>
<b>DOM Elements per Pageview</b>	<p>The number of DOM elements present on a page at the time of the page's <code>load</code> event. Includes sub-documents in frames.</p>
<b>Failed Sessions</b>	<p>The number of sessions that completed with the session status <code>FAILED</code>, indicating the synthetic test has detected a problem with your site. See <a href="#">Session Status</a> for more information.</p>

Name	Definition
<b>Fully Loaded Time</b>	The time from the start of the initial navigation until 2 seconds of no network activity has passed after Document Complete. This will usually include any activity that is triggered by JavaScript after the main page loads. The Fully Loaded Time is given in milliseconds and percentiles.
<b>Job Executions</b>	Total number of sessions (per browser, per location) for a given job.
<b>Number of Resources Loaded Before Fully Loaded</b>	See <b>Data Downloaded Before Fully Loaded</b> above.
<b>Number of Resources Loaded Before Onload</b>	See <b>Data Downloaded Before Onload</b> above.
<b>Ok Sessions</b>	The number of sessions that completed with the session status <code>OK</code> , indicating the synthetic job ran successfully and returned data.
<b>Pages per Session</b>	The number of pages per session.
<b>Session Duration</b>	For scripted jobs: the time needed to execute the script from the first line to the last line. For URL jobs: the time from when the browser initiated the first HTTP request until the last resource was loaded.
<b>Sessions with Resource Errors</b>	The number of sessions that had missing or inaccessible resources.
<b>Session Visual Time (SVT)</b>	This metric captures the time the browser spent loading pages. Relative to <b>Session Duration</b> , this excludes the script process time and the time your script was interacting with content on a given page.  Specifically, the <b>Session Visual Time</b> for a session is the sum of the <b>Visually Complete Times</b> for each page.
<b>Speed Index</b>	This metric captures whether a page renders incrementally or all at once. For example, if two pages both take five seconds to finish rendering, but one is mostly rendered after a second, while the other is blank until the last moment. Then the first page will have a <b>Speed Index</b> close to 1000, while the second will have a <b>Speed Index</b> close to 5000 (the <b>Visually Complete</b> time in milliseconds).

Name	Definition
Visually Complete	The time when an end-user would determine that the page is visually complete in the viewport. This time is calculated by using the last visual change to the page and is in milliseconds. The page represents the viewable content (the viewport) in a browser window. The default size for a browser window is 1024 x 768.
Warning Sessions	The number of sessions that completed with the session status <code>WARNING</code> , indicating the test ran successfully, but there were inaccessible resources.

## Browser Synthetic Monitoring Troubleshooting

### Synthetic Jobs Do Not Run After Registering on Linux-Based Private Synthetic Agent

#### Issue:

Registration on Linux-based Private Synthetic Agent v21.5.0 is complete. However, after creating jobs in the Controller, the jobs do not run.

The Heimdall pod logs show the following exception:

```
org.springframework.data.r2dbc.BadSqlGrammarException: executeMany; bad SQL grammar [INSERT INTO heimdall.measurement (measurement_id, schedule_id, location_id, browser_type, account, job_type, last_updated, measurement_status, duration_secs, measurement_details) VALUES ($1, $2, $3, $4, $5, $6, $7, $8, $9, $10)]; nested exception is io.r2dbc.postgresql.ExceptionFactory$PostgresqlBadGrammarException: [22001] value too long for type character varying(50)
```

#### Resolution:

Log in to the Postgres database pod and modify the `location_id` column size:

1. Run this command to log in to the database:

```
kubectl exec -it service/postgres --namespace measurement -- psql --username synthuser
```

2. Run this command to modify the `location_id` column:

```
ALTER TABLE heimdall.measurement ALTER COLUMN location_id TYPE character varying(256);
```

## Synthetic API Monitoring

 Synthetic API Monitoring is not currently supported for on-premises Controllers.

Synthetic API monitoring enables you to monitor the availability and performance of HTTP(s) based APIs. These APIs can be internal, external, or third-party APIs and from different geo-locations across the globe. You can monitor private and public APIs in these scenarios:

- Private APIs
  - APIs exposed by the microservices or web services
  - APIs used for communication between webpage (frontend) and backend
- Public APIs
  - APIs exposed to customers
  - Third-party APIs such as payment gateways and maps
  - Partner APIs

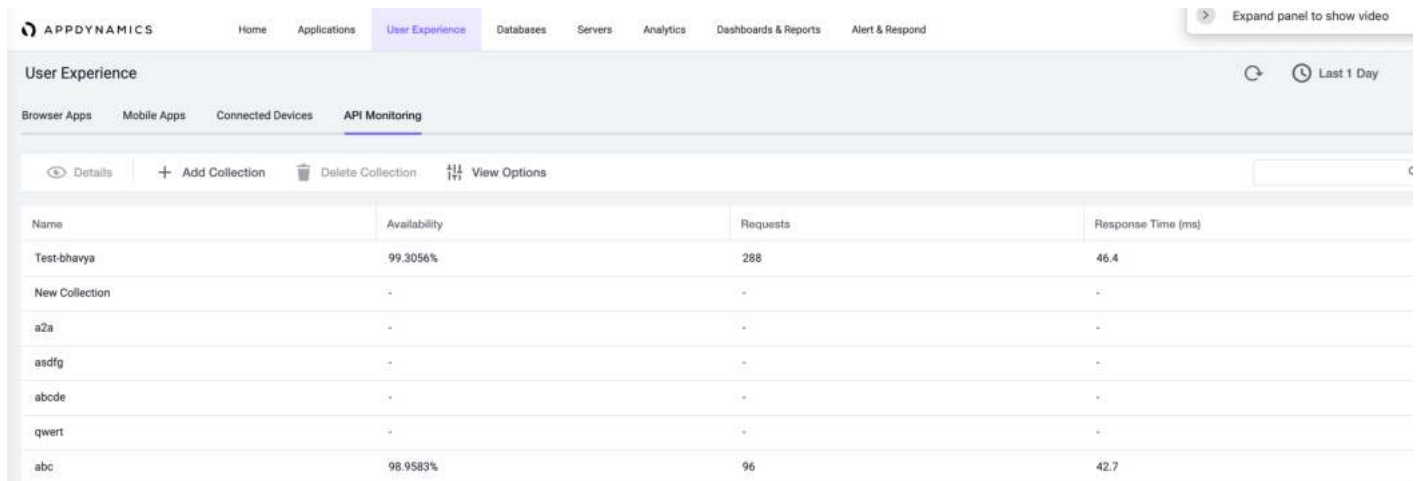

## API Collection

An API collection is a group of all the APIs or API jobs in a microservice or application.

The API collection view displays these API details:

- Average availability
- Total API requests
- Average response time

You need access to API collection to add, view, or delete the API collection.

The screenshot shows the 'User Experience' section of the AppDynamics interface, specifically the 'API Monitoring' tab. It features a table with columns for Name, Availability, Requests, and Response Time (ms). The table lists several API collections, including 'Test-bhavya' with 99.3056% availability and 288 requests, and 'abc' with 98.9583% availability and 96 requests. There are also buttons for '+ Add Collection', 'Delete Collection', and 'View Options'.

Name	Availability	Requests	Response Time (ms)
Test-bhavya	99.3056%	288	46.4
New Collection	-	-	-
a2a	-	-	-
asdfg	-	-	-
abcde	-	-	-
qwerty	-	-	-
abc	98.9583%	96	42.7

## API Jobs

You can use an API job to monitor a single API or a sequence of APIs. You can use JavaScript to create API jobs.

### Sample JavaScript

```
(async () => {
```

```
// GET Request
var response = await client.get("https://www.google.com/");
console.log(response.statusCode); // 200
console.log(response.statusMessage); // OK
console.log(response.body); // HTML Body

// POST, PUT or DELETE Request
response = await client.post("https://www.google.com/");
response = await client.put("https://www.google.com/");
response = await client.delete("https://www.google.com/");
})(); // Make sure to call the async function at the end.
```

Using JavaScript, you can implement various authentication mechanisms, encrypt the payload, parse the response, and validate the response time, response size, response content, and so on.

**i** You can store the credentials required for API authentication in the [Synthetic credential vault](#), and use them in JavaScript.

For more JavaScript examples, see [API Monitoring scripts](#).

You can configure API Jobs to:

- Trigger alert events based on performance issues.
- Execute API jobs periodically from the configured locations. You can configure the jobs to execute in any timezone on any day, and time of the week. The minimum frequency support for API monitoring is one minute.
- Configure timeout to cause jobs to fail when the time to execute the jobs exceeds a specified duration. By default, the API jobs timeout when the job execution does not complete within five minutes. Jobs that fail due to timeout indicate an availability issue.
- Trigger warning or critical error events based on the response time of the API jobs. You can also configure the warning or critical events to retest a specific number of times before triggering the events to avoid false positives. See [Health Rule Violation Events](#) to view the event status of a failure event.

**i** You can execute API jobs from any of the [17 AWS Locations](#); in each location, or in one location per execution interval.

See [Configure API Monitoring Jobs](#).

You can update the job configuration to change how the API job is executed. Create a new job, or select an existing job and click **Edit** to update the configuration.

### 1. Configure API Requests

What do you want to call this API job?

Job Name

Script Editor

Enter your JavaScript code below.

```

1 // Javascript based API Monitoring Test
2
3 const assert = require("assert");
4 (async () => {
5 var response = await client.get("<URL>");
6 assert.equal(response.statusCode, 200);
7 assert.equal(response.statusMessage, "OK");
8 for(var key in response.headers) {
9 console.log(`${key} : ${response.headers[key]}`);
10 }
11 assert.equal(response.body, "response body");
12 })()
```

### 2. Select Locations

Select which remote servers to run your synthetic job on:

Type or Select... ✕

<input type="checkbox"/>	Name
⚠	

Test all locations every time  
 Test one location each time (round-robin)

Cancel
Save

The list of all the created API jobs is available in the **API Jobs** list view. You can view the availability and performance trends of these API jobs in this view. Use the time window filter to display the API jobs trends of a particular time interval.

The **API Jobs** list view also displays the average response size, the number of executed locations, and the number of executions in the selected time interval.

<input type="checkbox"/>	✕	Multiple API Records #2			-	-	-
<input type="checkbox"/>	✓	test			17745	1	60
<input type="checkbox"/>	✓	Test			17735	1	59
<input type="checkbox"/>	✓	test - different URL			291344	1	60

## Session List

Each execution of the API jobs is available in the **Jobs Sessions** view.

The **Records** tab displays the availability trend of the selected API job at the top. The list of each API job execution displays below the availability trend. You can use the filter option to filter the jobs based on specific criteria and focus on issues during troubleshooting.

 A job-level duration is the time required to execute a job script. However, the duration displayed under the **APIs** page is the time required to execute a particular API.

Click on a particular session to view the API details and response details.

**API Details:** Displays additional details, such as the start time, end time, and duration of the following parameters:

- Wait
- DNS
- TCP
- Request
- First byte
- Download
- Total

**Response Details:** Displays the following details:

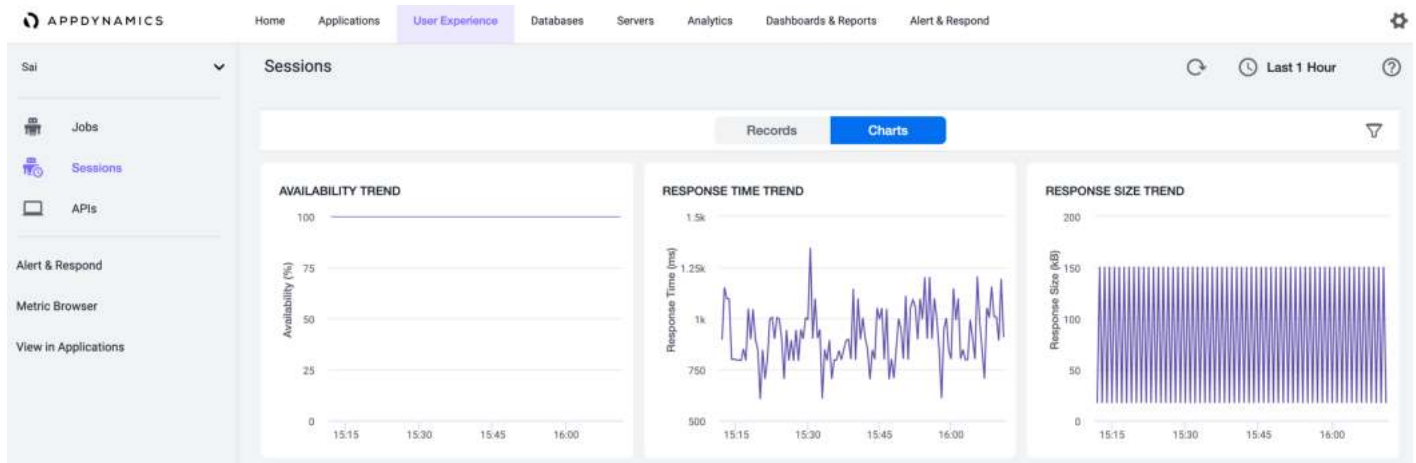

- Status code
- Response time
- Response size
- Response details
- Response payload

If any API fails, the error details are displayed, and the reason if the system can identify the cause. The response payload is displayed for the successful APIs.

 Response payload is displayed after the job executes for less than an hour.

The **Charts** tab displays the availability trend, response time trend, and response size trend of the selected API jobs.

Users without the administrator role cannot view the session data. If you want a user to provide view permissions to the session data, perform the following steps:

1. Navigate to > **Administration > Roles**.
  2. Select the role and click **Analytics**.
  3. Under **Events**, select **Synthetic Sessions** from the **Type** dropdown.
  4. If you want the users to view session data of only specific collections, then click **Add** under **Can view synthetic data from the following App Keys** and select the app keys.
  5. Click **Save**.
- Users that are assigned to this role can view the session data.

## Session Details

The detail of each API job execution is available on the **Session Details** page. The **Session Summary** displays the console logs, session size, session time, and location.

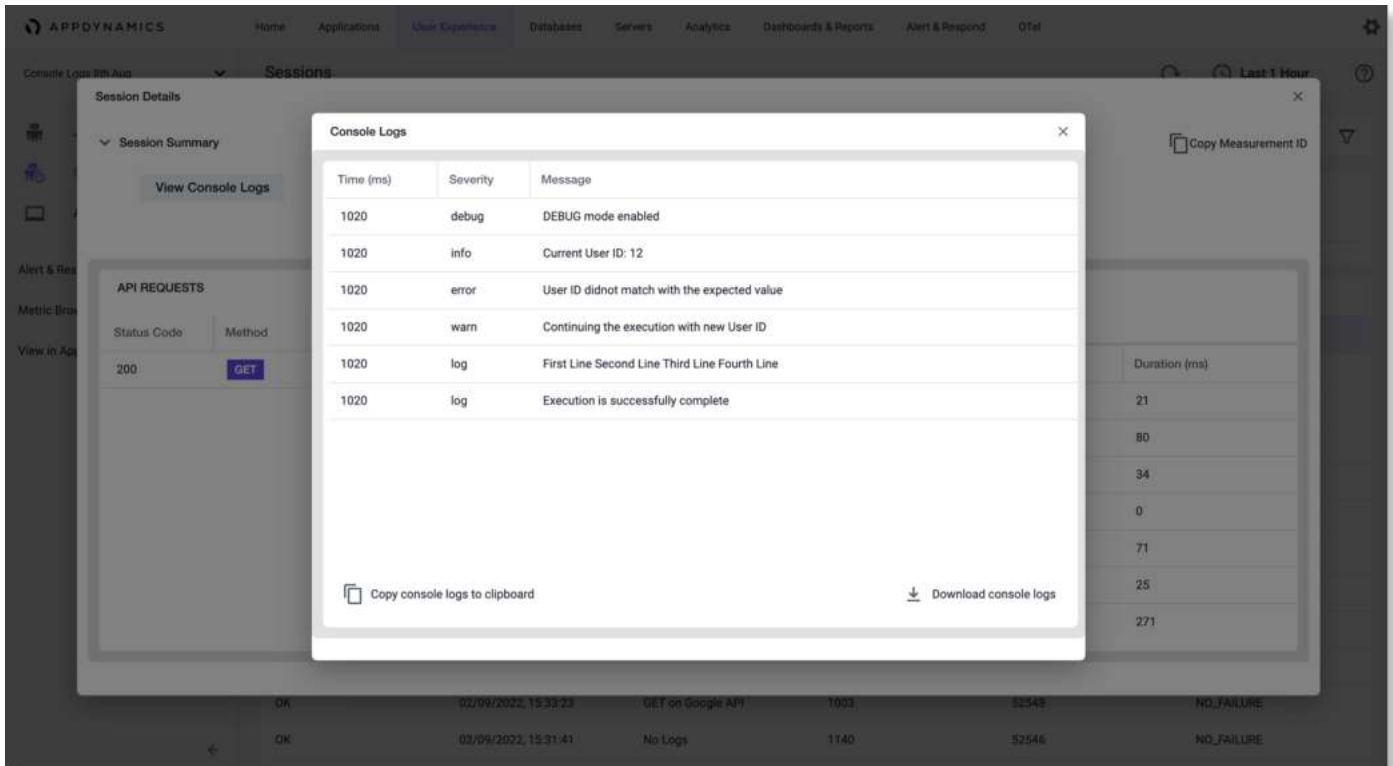

While creating the API monitoring jobs, you can include console logs in [JavaScript](#) to display the logs under **Console Logs**. You can add the following console logs based on the severity:

- Log
- Debug
- Info
- Error
- Warning

Click **View Console Logs** to view different types of console logs.

If no logs are captured, a message is displayed that no logs are available. If the number of logs captured reaches the limit of 100, a warning message is displayed.

You can also copy the entire console logs to clipboard or download them as a text file.

The console logs have the following limits:

- 100 log entries per API are captured
- Each message has a maximum limit of 0.5 Kb or 512 characters

On the **Session Summary** page, the status code, method used, and URL of the API requests are displayed on the left-hand side.

On the right-hand side, the page displays the information of each API executed in the API job. The start time, end time, and the duration of these parameters for each API are available on this page:

- Wait
- DNS
- TCP
- SSL and TLS
- Request time
- First byte
- Download time
- Total time

### API Summary

The APIs page provides a summary of all the APIs across different jobs. It displays the number of requests, response size, and duration of the APIs. You can filter the time range for which you want to see the data.

The screenshot shows the AppDynamics 'APIs' page. The top navigation bar includes 'Home', 'Applications', 'User Experience', 'Databases', 'Servers', 'Analytics', 'Dashboards & Reports', 'Alert & Respond', and 'OTel'. The left sidebar has 'Jobs', 'Sessions', 'APIs', 'Alert & Respond', and 'Metric Browser'. The main content area displays a table of API requests.

Name	Requests	Response Size (Bytes)	Duration(ms)
GET https://www.google.com/	29	54	398
GET https://2cee-2001-420-5403-405-00-35.ap.ngrok.io/framep	7	2	894
GET http://www.google.com/	5	52	192

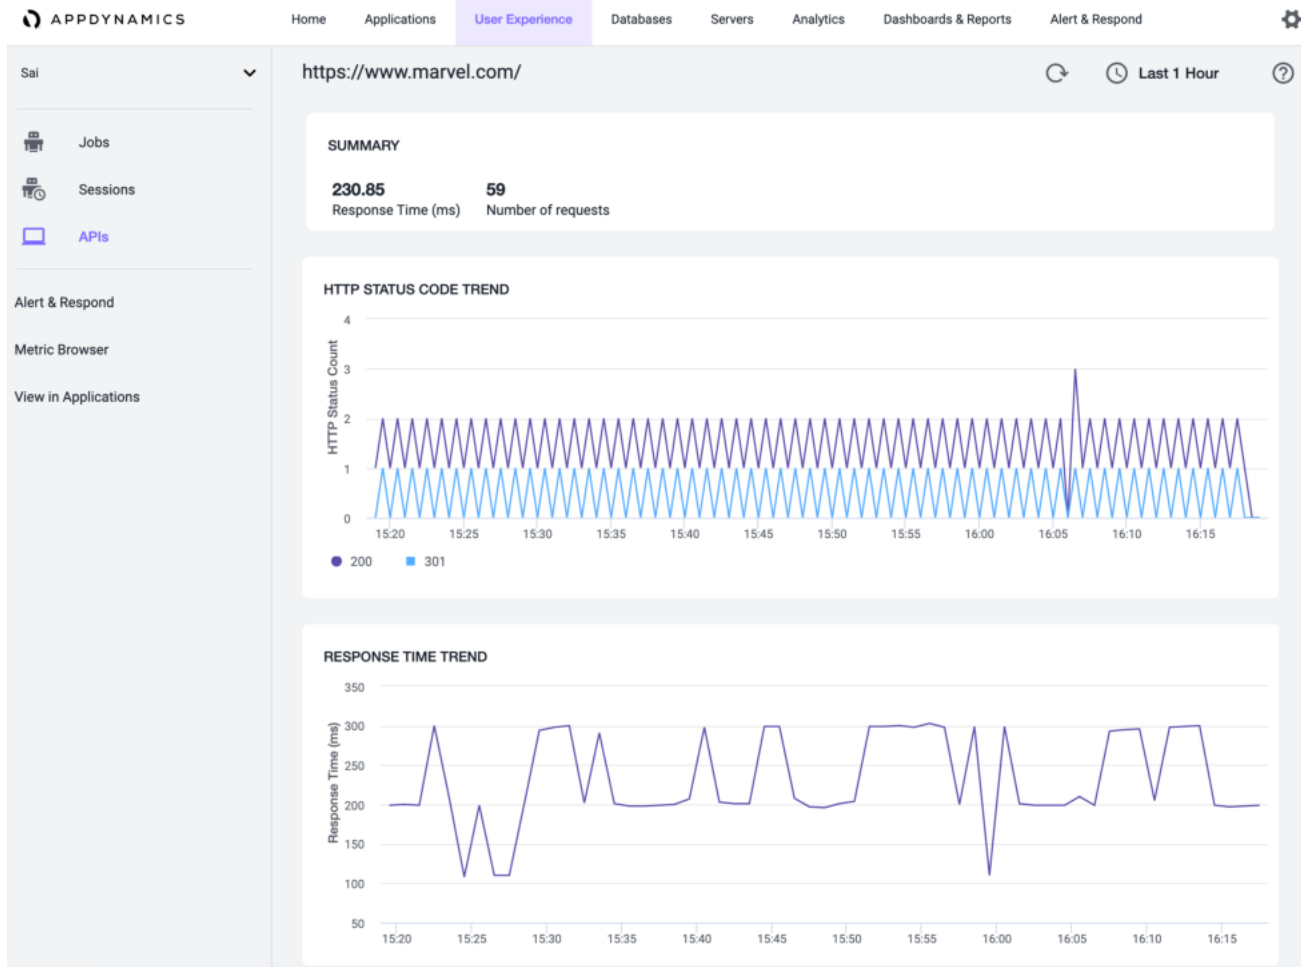

**i** API duration is different than the job duration. The API duration is the time required to execute a particular API. However, the duration displayed under the **Sessions** page is the time required to execute a job script.

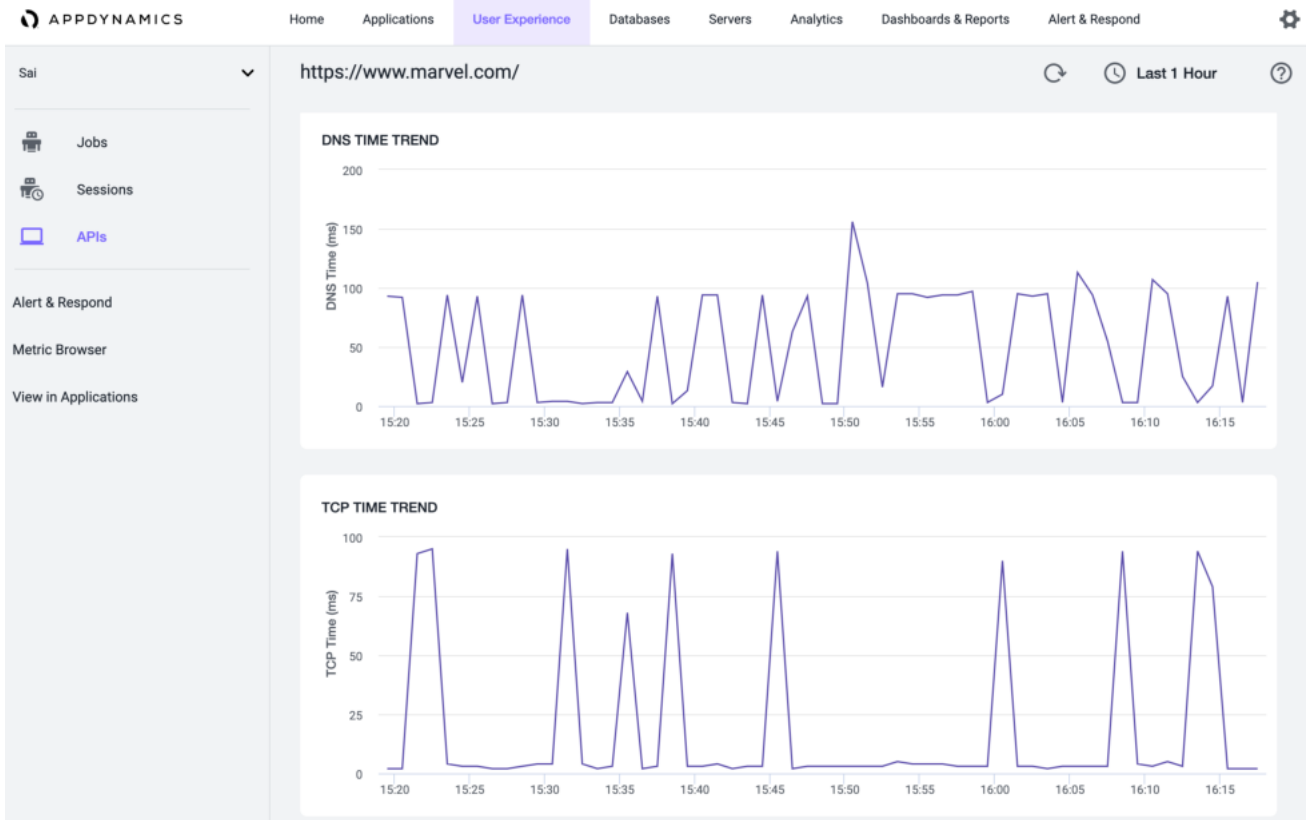

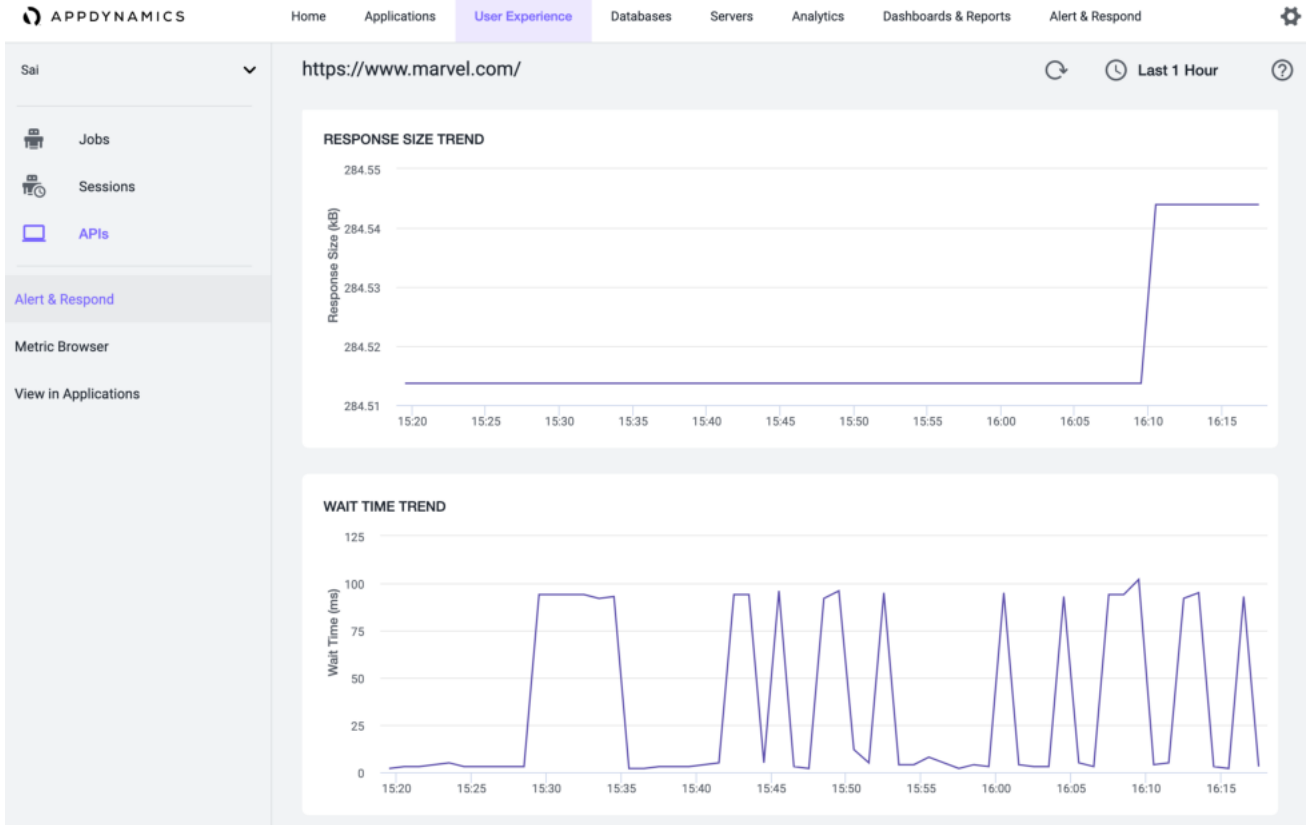

## API Details

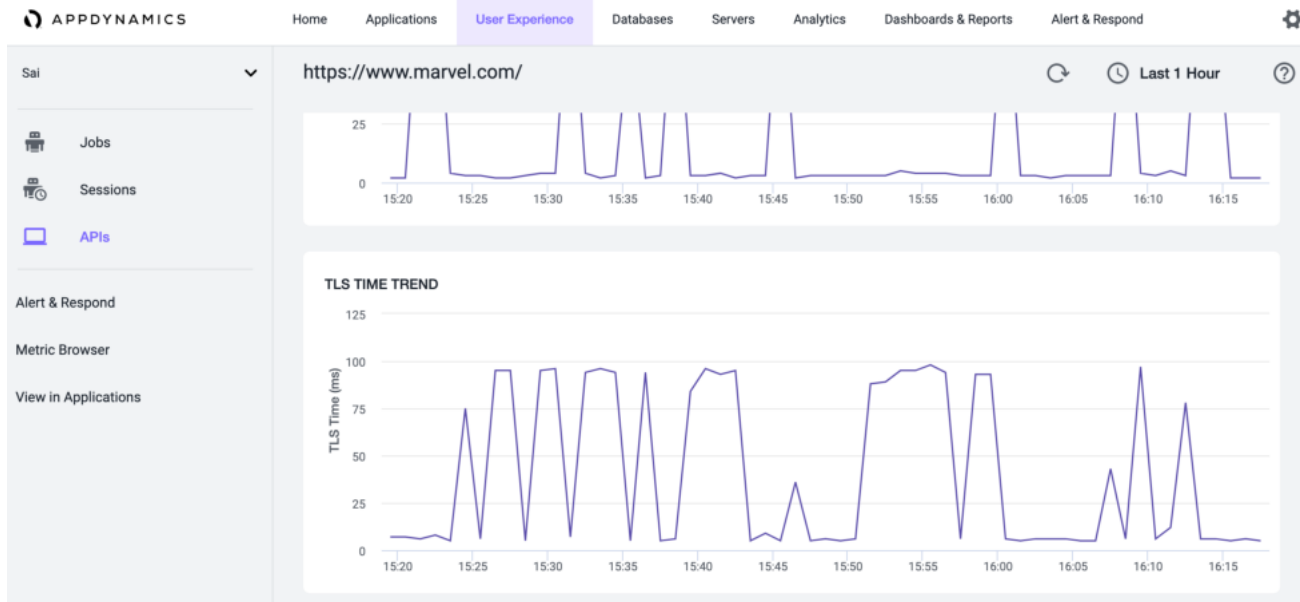

You can select an API and click **Details** to view the details of that particular API. Alternatively, you can also double-click an API to view the details. The individual API page provides a summary of that API, such as response time and the number of requests.

The page also displays graphs of these parameters:

- HTTP status code trend
- Response time trend
- Response size trend
- Wait time trend
- DNS time trend
- TCP time trend
- TLS time trend

### View API Trends Across Jobs in Different Collections

You can click **View Options** to configure the columns that you want to display or hide.

You can filter the APIs using the **Selected Collections** option. By default, only the APIs of the parent collection are displayed.

Click **Selected Collections** and select the API collections of which you want to view the APIs. All the APIs of the selected collections are displayed. When you choose more than one collection, and if an API is common to all the collections, it displays that API's consolidated data.

For example, if <https://www.google.com/> is part of two collections, then the displayed data, such as the number of requests, response size, and duration, is the cumulative data of both the collections.

### Configure API Monitoring Jobs

This page describes how to configure an API monitoring job.

You can configure these details for an API monitoring job:

- Schedule when, where, and how often a job runs.
- Set timeouts.
- Set performance thresholds to trigger warning and critical events.

### Create a Job

1. On the Controller UI, click **User Experience > API Monitoring**.
2. Click **Add Collection** and specify a collection name.
3. Click **Add**.
4. Select the newly created collection and add a job.

A new job configuration page appears; proceed with the following steps:

### Configure API Requests

Specify a name for the API job, and then you can configure API requests through one of the following options:

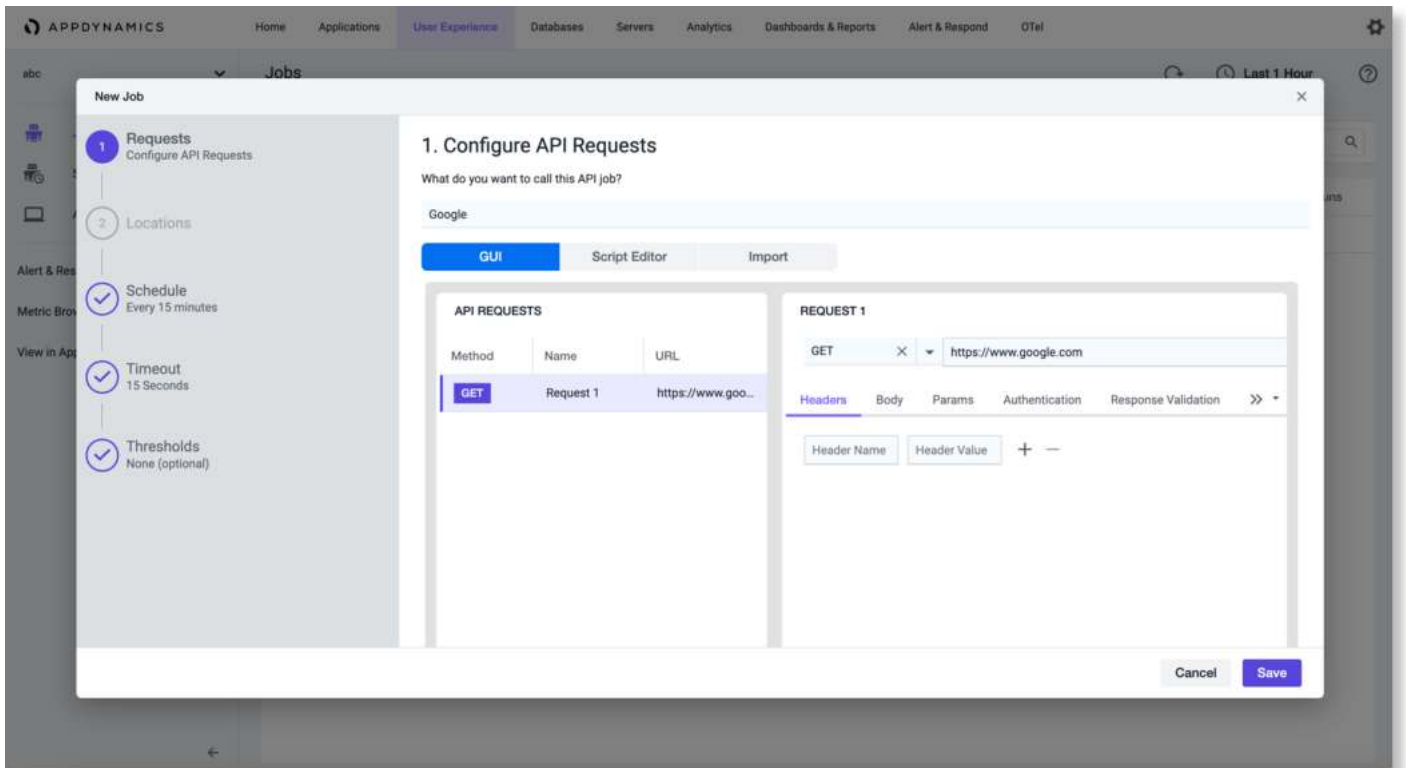

- [GUI](#)
- [JavaScript](#)
- [Import API Collection](#)

## GUI

If you do not want to manually create JavaScripts for configuring jobs, the **GUI** option provides an easy way to configure jobs.

Click **GUI** and configure an API request:

The **API Requests** pane on the left displays the API request that you configure. The API request that you create is named Request 1, you can edit the name later from the API requests list view.

1. Select an HTTP method from the right pane. The supported methods are `GET` , `POST` , `PUT` , and `DELETE` .
2. Specify the URL to which you want to make the API call.
3. Specify the following details based on the method type:

Tabs	Description
Header	Enter a header name and value as key-value pair.

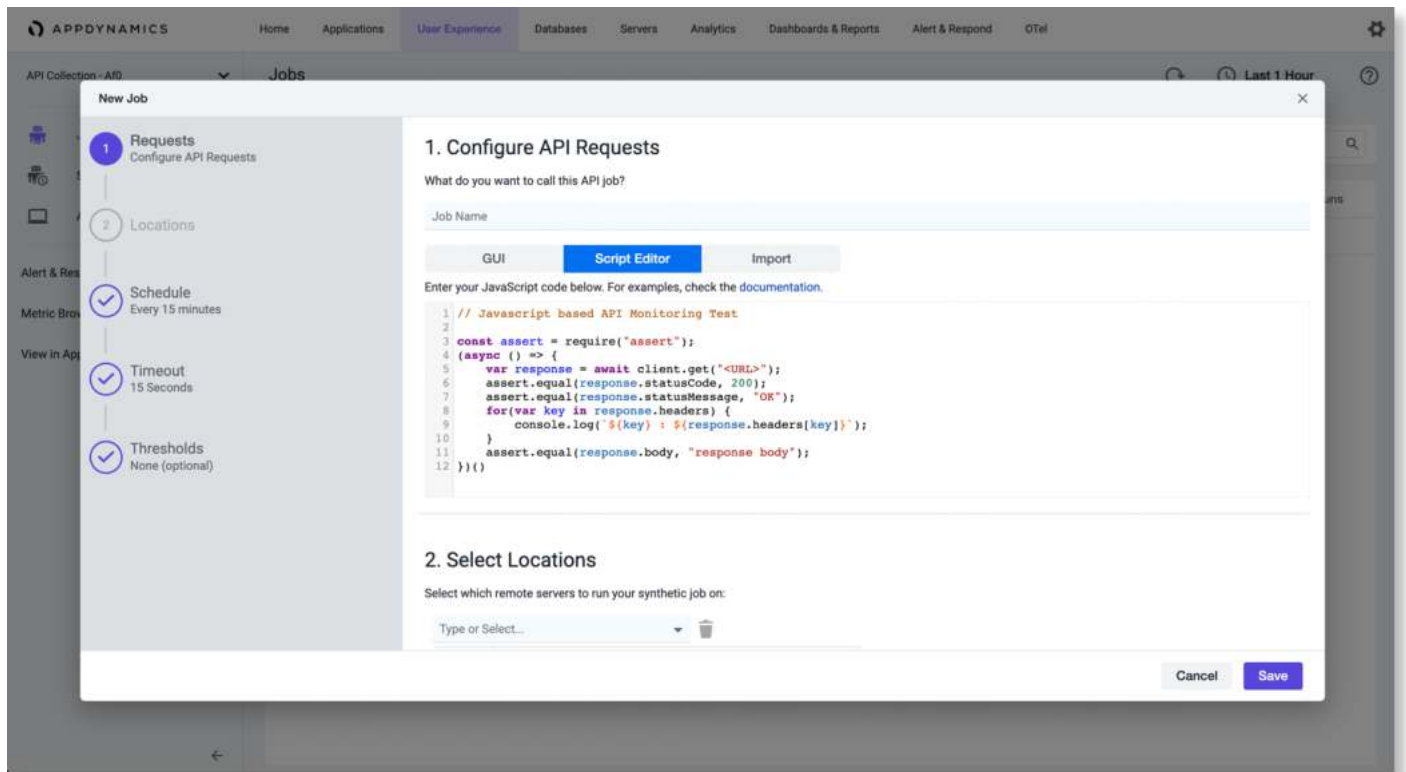

Tabs	Description
Body	<p>XML and JSON body types are supported.</p> <p>Select a body type and enter the details. For example:</p> <pre data-bbox="678 443 1495 653"> {   title: "foo"   body: "bar",   userId: 100, }</pre>
Params	<p>Enter the parameter that you want to query along with the value.</p>
Authentication	<p>The following authentication types are supported:</p> <ul style="list-style-type: none"> <li>◦ <b>Basic Auth:</b> Specify the username and password.</li> <li>◦ <b>Token:</b> Specify the bearer token.</li> <li>◦ <b>No Auth:</b> No value is required.</li> </ul> <p>You can also store your secrets in the <a href="#">Synthetic Credential Vault</a>.</p>
Response Validation	<p>You can validate the response by adding assertions.</p> <p>For example, when you select <b>Status Code</b>, <b>=</b>, and enter the value as <code>200</code>, then the job will be successful only when the status code is <code>200</code>. Similarly, you can add multiple assertions, such as response content, and response time.</p>
Initialise	<p>You can create initial variables. Specify a variable name and a value. Then you can use it using the following syntax:</p> <pre data-bbox="678 1367 1495 1451"> {{&lt;variable-name&gt;}}</pre>
Settings	<p>Select the <b>Follow Redirects</b> option if the API redirects to another API.</p> <p>When you enable <b>Follow Redirects</b>, you can specify the maximum number under <b>Follow Redirects count</b>. This indicates the number of redirects that are checked for the particular URL.</p>

### Create JavaScript

Create a JavaScript for your job and enter it in the **Script Editor**.

For sample JavaScripts for API Monitoring, see [JavaScript](#).

## Import API Collection from Postman

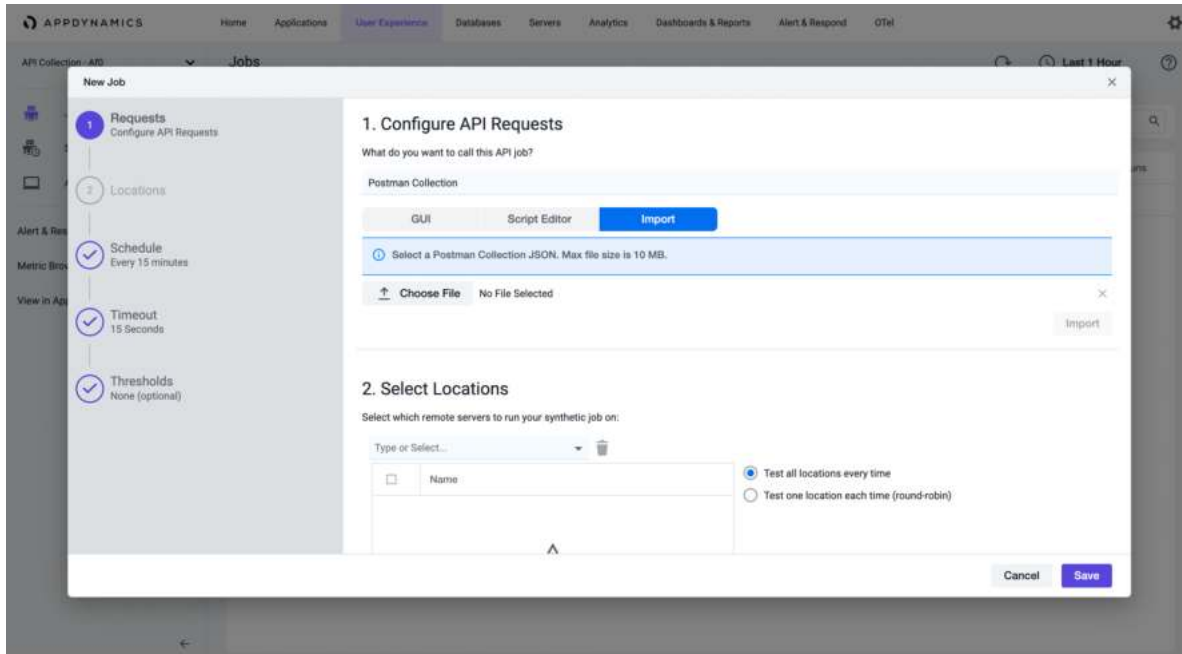

You can import the API collections of Postman to the API monitoring jobs.

Instead of manually creating the API collections again on Controller, you can import the existing API collections of Postman.

You must first export the API collection as a JSON file from Postman, and then import the JSON file to API Monitoring jobs. Choose the recommended **Collection v2.1** while exporting. Exporting the file as **Collection v2** is not supported.

Perform the following steps to import the Postman collections:

1. Click **Import > Choose File**, and then select the API collection JSON file that you exported from Postman.

2. Click **Import**.
3. When you get the success message, review the script on the **Script Editor** tab.

**i** Any string enclosed with double curly brackets `{{ }}` is a variable. You must replace the variable manually with an appropriate value.

You can verify if the collections are imported by navigating to **User Experience > API Monitoring**.

### Select Locations

You can select one or more locations in which the job runs. You can configure the job to test all of the locations every time or one location each time the job runs. For a complete list of Synthetic Agent locations, see [Synthetic Agent Locations](#).

Use the hosted agents to monitor public API endpoints. You can use hosted agents to monitor the API jobs from locations where the real API traffic or request is generated.

Use the private agents to monitor the private APIs. For example, APIs used within a customer network.

## 2. Select Locations

Select which remote servers to run your synthetic job on:

Boardman, Oregon, United States

<input type="checkbox"/>	Name
<input type="checkbox"/>	Boardman, Oregon, United States

Test all locations every time  
 Test one location each time (round-robin)

- The **Hosted Agent Locations** are where AppDynamics hosts public synthetic agents. AppDynamics has hosted agents in [17 locations](#) (AWS locations only). You can execute the API monitoring jobs from these 17 hosted agent locations.
- If you have deployed an API Monitoring Private Synthetic Agent, you can choose from **Hosted Agent Locations** or **Private Agent Locations**.
- The **Private Agent Locations** are where you host your private synthetic agents. You can set up private synthetic agents in any of these [environments](#).

### Set a Schedule

The multiple schedules feature is supported only in SaaS Controllers 22.2.0 and later versions.

You can define the job schedule when you create or edit your job.

You can create multiple schedules for the same job. Each schedule can have its own time zone, frequency, and execution interval. This allows you to execute the job in different frequencies:

Frequency	Example
Different intervals in a day	<p><b>Schedule 1:</b> Execute the job in 1-minute frequency from 8 AM to 8 PM</p> <p><b>Schedule 2:</b> Execute the job in 5-minute frequency from 8:01 PM to 7.59 AM</p>
Different days of the week	<p><b>Schedule 1:</b> Execute the job in 1-minute frequency on weekdays</p> <p><b>Schedule 2:</b> Execute the job in 5-minute frequency on weekends</p>
Different time zones	<p><b>Schedule 1:</b> Execute the job in 1-minute frequency from 8 AM to 8 PM in the PST time zone</p> <p><b>Schedule 2:</b> Execute the job in 5-minute frequency from 8 AM to 8 PM in the BST time zone</p>
Different date interval	<p><b>Schedule 1:</b> Execute the job in 1-minute frequency from February 21, 2022, to March 31, 2022</p> <p><b>Schedule 2:</b> Execute the job in 5-minute frequency from April 1, 2022, to March 31, 2026</p>

 You can create a maximum of three schedules per job.

Click **Add Schedule** to configure another schedule for the same job. You must create at least one schedule.

### 3. Set a Schedule

Run every

More Options

Time Zone

Between  09:00 AM and  05:00 PM

From  1/19/2022 07:47 PM To  1/19/2022 07:47 PM

Only on These Days  S  M  T  W  T  F  S

**Add Schedule**

### 3. Set a Schedule

**Schedule** ✎ 🗑

Run every 15 MINUTES between 09:00 and 17:00 in UTC Time Zone

From Wed Jan 19 2022 19:47 to Wed Jan 19 2022 19:47

On Monday, Tuesday, Wednesday, Thursday and Friday

---

Run every

More Options

Time Zone

Between  09:00 AM  and 12:00 PM

From  1/20/2022  10:33 AM  To 1/20/2022  10:33 AM

Only on These Days  S  M  T  W  T  F  S

✎ 🗑

Add Schedule

**i** You can prevent the execution of jobs during the maintenance period. Let us assume you have a four-hour maintenance period on March 21, 2022 (1:01 AM - 5:00 AM). Then, you can configure multiple schedules as follows:

- **Schedule 1:** Execute the job in 1-minute frequency from 8:00 AM on February 21, 2022, to 1:00 AM on March 21, 2022
- **Schedule 2:** Execute the job in 1-minute frequency from 5:01 AM on February 21, 2022, to 12:00 AM on March 21, 2026

### Set Timeout Period

You can configure timeout to make the jobs fail if the time taken to execute the jobs exceeds a certain duration. By default, the API jobs timeout if the job execution does not complete within 5 minutes.

**i** A job that fails because of timeout is considered an availability issue.

### 4. Set Timeout Period

Maximum amount of time spent trying to complete the job

Seconds

### Configure Performance Thresholds

This is an optional step. You can configure performance thresholds that will trigger warning or critical synthetic events when the thresholds are exceeded.

## Availability Configuration

API jobs failure irrespective of the reason, namely, invalid status code, response content validation, response size validation, and so on, are configured to be reported as an availability event by default. To avoid false positives, you can configure to re-test the jobs a specific number of times before triggering the events.

## Performance Events

You can configure API jobs to trigger warning or critical error events based on the response time of the API jobs. To avoid false positives, you can configure to re-test the jobs a specific number of times before triggering the events.

### 5. Configure Performance Thresholds (optional) ⓘ

Trigger a warning event when

Automatically retest after warning events

Total Response Ti... is greater than 5000 ms Immediately

Trigger a critical event when

Automatically retest after critical events

Total Response Ti... is greater than 10000 ms Immediately

For storing credentials in the Synthetic Credential Vault, see [Credential Vault for Web Monitoring](#).

## Correlate Business Transactions for Synthetic API Monitoring

You can correlate every session with the business transaction that is used for completing the request. With this correlation, you can find the root cause of any degradation or failure in the session. The correlation is made between sessions and instances of business transactions (transaction snapshots).

### How Sessions Are Correlated

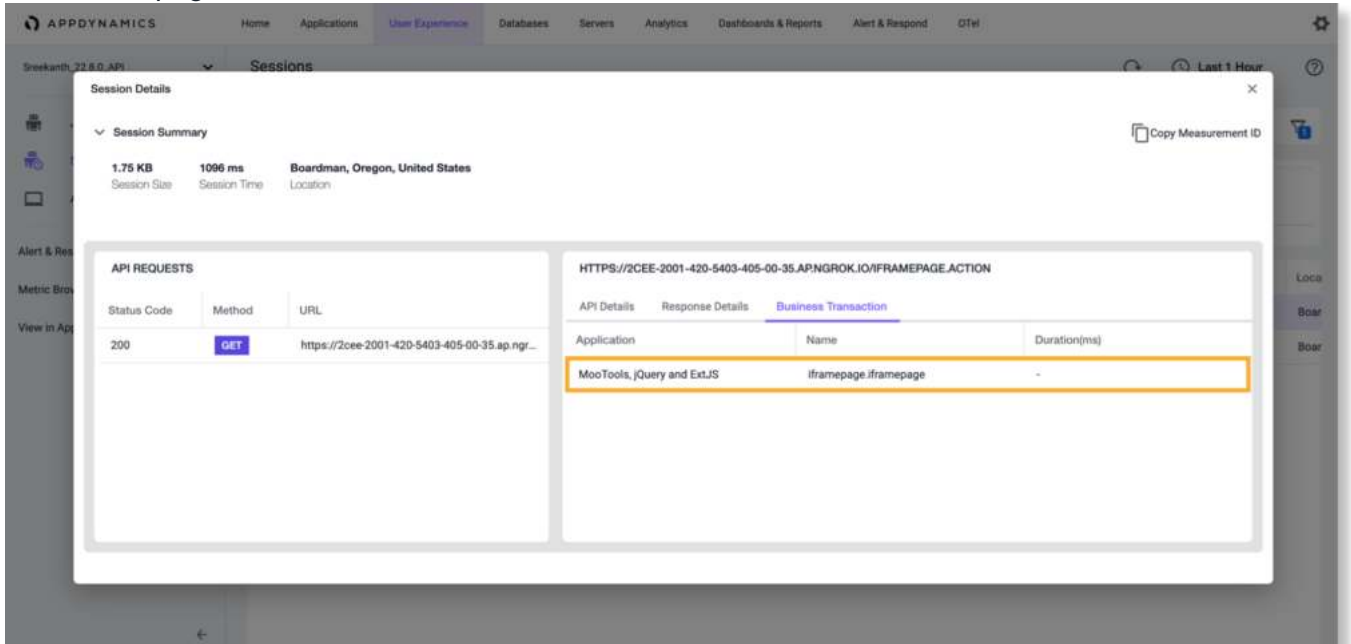

1. When the Synthetic Agent sends a request to a client server that has any AppDynamics agent installed, the Synthetic Agent receives some traces in the form of HTTP headers. For the supported agents, see [App Server Agents](#).
  - a. The Synthetic Agent sends an HTTP request to the client server and includes the `allow_bt_cookie=true` header:
  - b. The client server sends the response over HTTP. If the client server has any AppDynamics APM agents installed, it sends traces for the business transaction triggered through the call in the form of a cookie header.
2. AppDynamics processes the headers to correlate the backend data with the API monitoring session.

### View Business Transactions Correlated with Session Details

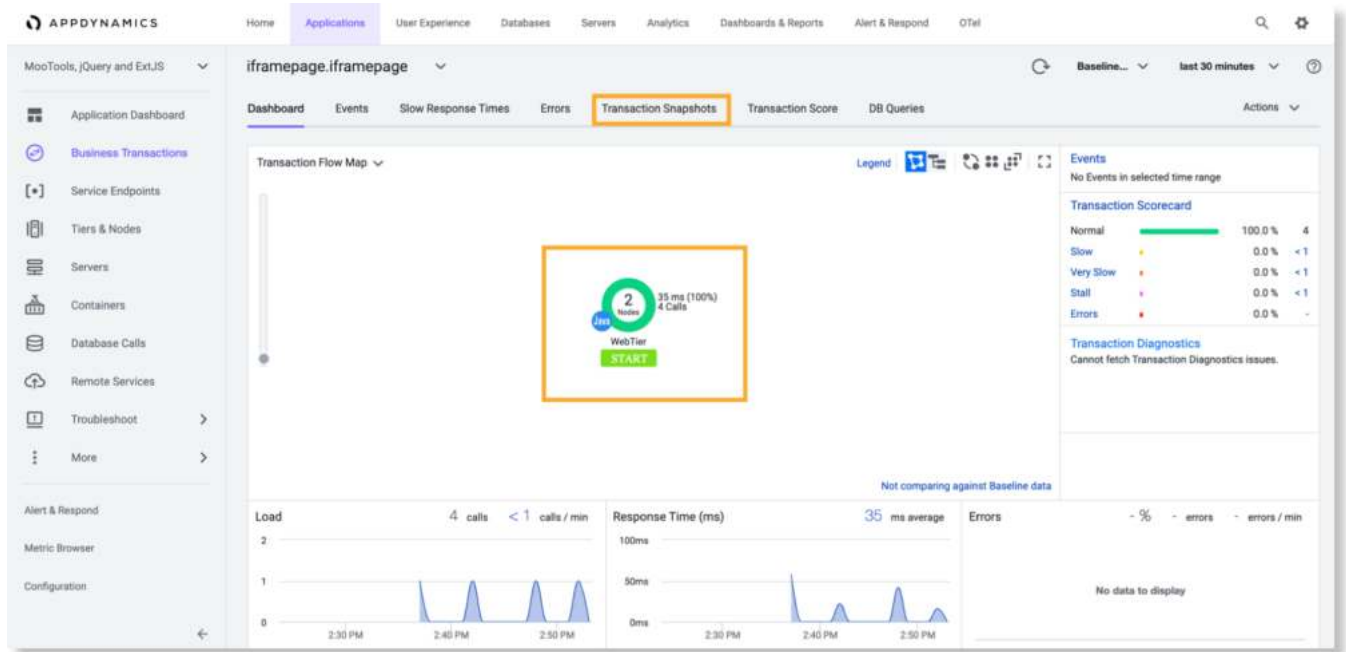

To navigate from a **Session Details** page to its correlated business transaction, perform the following steps:

1. On the Controller, click **User Experience > API Monitoring**.

2. Select an API collection, then click **Sessions**.
3. Double-click the API for which you want to view the correlated business transaction.
4. On the **Session Details** page, click **Business Transaction**.
5. Double-click the business transaction name. This automatically navigates you to the correlated business transaction page.

6. Click the snapshot to view the details of the transaction or click **Transaction Snapshots** to view the corresponding pages in APM.

Time	Exe Time (ms)	End to End Latency Time (ms)	URL	Business Transaction	Tier	Node
06/16/22 4:32:26 PM	20	20	/iframepage.action	iframepage.iframepage	WebTier	DVISHNU-M-82FZ
06/16/22 4:20:36 PM	25	25	/iframepage.action	iframepage.iframepage	WebTier	DVISHNU-M-82FZ
06/16/22 4:07:26 PM	47	47	/iframepage.action	iframepage.iframepage	WebTier	DVISHNU-M-82FZ
06/16/22 3:52:26 PM	58	58	/iframepage.action	iframepage.iframepage	WebTier	DVISHNU-M-82FZ
06/16/22 3:42:26 PM	121	121	/iframepage.action	iframepage.iframepage	WebTier	DVISHNU-M-82FZ

## Credential Vault for API Monitoring

### Deployment Support

Credential Vault securely stores the credentials used in Synthetic API monitoring jobs. When you create a job with a synthetic script or API monitoring script, you can add a credential, such as a username and password, to log in to an application and inject a reference to the stored credential into the script. When the job runs, the API monitoring script uses that reference to retrieve the credentials stored in the Credential Vault.

### How to Use Synthetic Credential Vault

1. Go to **Tools > Manage Synthetic Credentials**.
2. **Add a credential in a key-value pair to Synthetic Credential Vault.**
3. **Create a synthetic job using a synthetic script.**
4. **Inject the credential key into the synthetic script.**

**i** The job runs and retrieves the credential value associated with the credential key.

5. The synthetic job runs and retrieves the credential value associated with the credential key.

## Add Synthetic Credentials

In Credential Vault, you can add credentials one-by-one or import multiple credentials.

### Syntax Rules

This table describes credential syntax rules used for creating credentials and adding credentials to the API monitoring scripts:

Element	Rule
Keys	<ul style="list-style-type: none"> <li>• 1-100 characters</li> <li>• Alphanumeric characters, hyphens, and underscores only</li> <li>• Keys must be unique per EUM account</li> </ul>
Values	<ul style="list-style-type: none"> <li>• 5000 characters</li> <li>• Any non-control, printable UTF-16 characters</li> </ul>
Credential key name (used in synthetic scripts)	"<%key%"

### Add a Single Credential

**i** If you want to use a combination of credentials, such as a username and password combination, you must create two separate credentials: one credential for the username and one for the password.

To add a single credential for a sample email:

1. Go to  > **Tools > Manage Synthetic Credentials**.
2. Click **Add**.
3. Enter a key and value. Make sure you follow [syntax rules](#).
4. (Optional) Select an associated application. When you search for credentials in the API monitoring script, associated credentials are suggested first.

Add/Edit
✕

**Key**

**Value**

**Application Optional**

## Import Multiple Credentials

You can add multiple credentials at once using the **Import** button.

To add multiple credentials for sample emails and passwords:

1. Go to  > **Tools > Manage Synthetic Credentials**.
2. Click **Import**.
3. Copy and paste credentials or type them line by line. Make sure you follow [syntax rules](#).

- The maximum number of credentials that can be imported at once is 250.
- You cannot add associated applications to imported credentials. After importing, you must edit each credential individually to add the associated application.

### Example

```
1 email_key=user123@email.com
2 password_key=Password123
3 email_key=user456@email.com
4 password_key=Password456
```

## Use Credentials in an API Monitoring Script

You can retrieve a credential value by inserting the corresponding credential key in a script. Credentials associated with a specific application appear first when you start typing the key in the script.

To create an API monitoring job:

1. Go to **User Experience > API Monitoring > Jobs > Add**.
2. Add your API monitoring script. See [Write Your First Script](#).
3. Enter the credential key using the syntax "`<%key%>`".

### API Monitoring Script

```
var response = await client.get("https://authenticate-me-api.com", {
 headers: {
 api_token: <%api_token%>
 }
});
```

You can store the Certificate Authority (CA) content in the Synthetic Credential Vault.

To store the CA content in the Synthetic Credential Vault, you can override the default trusted CA certificate by using the [Advanced HTTPS API of the got client](#):

1. Configure the `certificateAuthority` option. This stores the CA certificate .pem file contents in the `certificate_authority_pem` file.
2. Specify the following string in the script:

```
var response = await client.get("https://authenticate-me-
api.com", {
 https: {
 certificateAuthority: %certificate_authority_pem%
 }
});
```

### User Permissions

In the Controller Administration UI, you can configure roles and groups with Account-level. You can add roles and groups to users based on the requirement. The **Manage Credential Vault** permission allows you to manage access control of the Credential Vault.

After upgrading to 23.8, the **Manage Credential Vault** permission gets added automatically to all the roles with existing **Administration, Agents, Getting Started Wizard** permission. This process takes approximately five hours to complete.

If you do not want the administrator users to access the Credential Vault, remove the **Manage Credential Vault** permission for those users.

Before Upgrading to 23.8	After Upgrading to 23.8
<p><b>Administration, Agents, Getting Started Wizard</b> permission has the following privileges:</p> <ul style="list-style-type: none"> <li>• Manage all users</li> <li>• Add, edit, and delete credentials</li> <li>• View both keys and values of stored credentials</li> <li>• View users, timestamps, and associated applications columns</li> </ul>	<p><b>Manage Credential Vault</b> permission gets automatically added to all the roles with existing <b>Administration, Agents, Getting Started Wizard</b> permission. This permission has the following privileges:</p> <ul style="list-style-type: none"> <li>• Manage all users</li> <li>• Add, edit, and delete credentials</li> <li>• View both keys and values of stored credentials</li> <li>• View users, timestamps, and associated applications columns</li> </ul> <div data-bbox="808 678 1393 940" style="border: 1px solid #0070C0; background-color: #D9E1F2; padding: 10px; margin-top: 10px;"> <p> From 23.8 onwards, when you assign a user with the <b>Administration, Agents, Getting Started Wizard</b> permission, the user does not have access to the Credential Vault by default.</p> </div>
<p><b>View Credential Vault</b> permission has the following privileges:</p> <ul style="list-style-type: none"> <li>• View keys of stored credentials</li> <li>• View users, timestamps, and associated applications columns</li> </ul>	<p><b>View Credential Vault</b> permission has the following privileges:</p> <ul style="list-style-type: none"> <li>• View keys of stored credentials</li> <li>• View users and timestamps columns</li> </ul>

To create a role with the Manage Credential Vault:

1. Go to  > **Administration** > **Roles**.
2. Under **Roles**, click **Create**.
3. Add a role name.
4. Under **Account**, click **Add+**.
5. Select one of the following permissions based on the role that you are creating:
  - Manage Credential Vault
  - View Credential Vault
6. Under **User and Groups with this Role**, add users and/or groups.

### Alerts for Synthetic API Monitoring

You can set health rules and policies for API monitoring to trigger alerts on API metrics and synthetic events. The alerts help you to determine problems in your APIs as they occur, or even before they occur. Further, AppDynamics can generate notifications or invoke actions based on conditions or events you configure.

Configuring alerts for API monitoring is supported in SaaS Controller >=22.8.

## Alerts for Synthetic API Monitoring Metrics

You can use the following API monitoring metrics to trigger alerts:

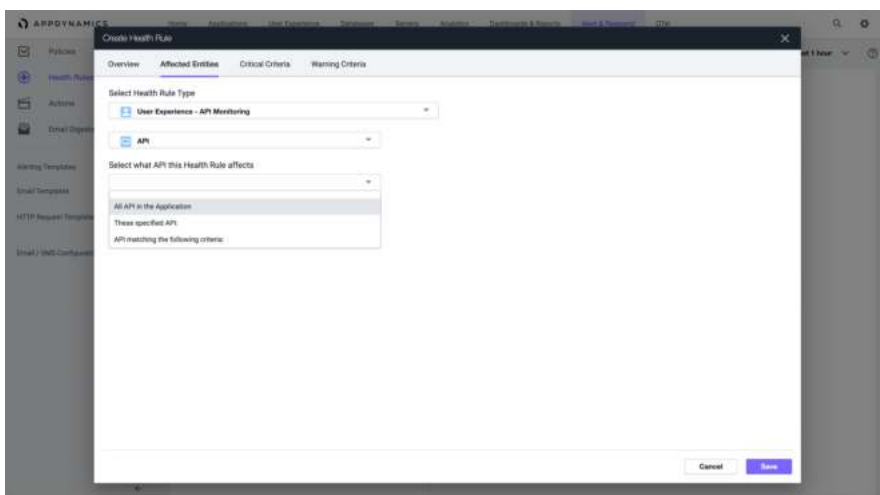

- Synthetic API TLS Time (ms)
- Synthetic API 2xx - Successful
- Synthetic API Total Time (ms)
- Synthetic API TCP Time (ms)
- Synthetic API Requests Count
- Synthetic API First Byte Time (ms)
- Synthetic API DNS Time (ms)
- Synthetic API Wait Time (ms)
- Synthetic API Response Size (Bytes)
- Synthetic API Request Time (ms)
- Synthetic API Download Time (ms)
- 5xx - Server Error
- 4xx - Client Error

## Create Health Rules to Monitor Synthetic APIs

With health rules, you can define what is the normal or expected behavior of your APIs. See [Configure Health Rules](#).

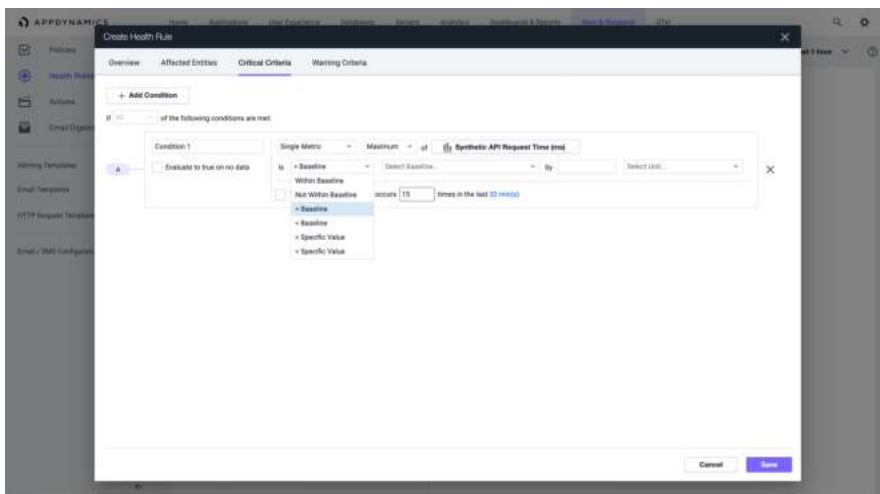

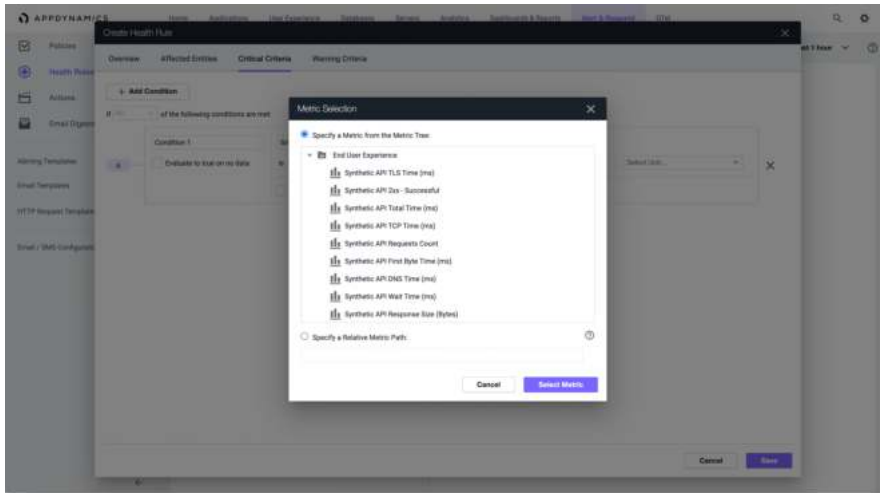

To create a health rule for APIs:

1. From the top navigation bar, click **Alert & Respond**.
2. From the drop-down menu next to Alert & Respond, select the **User Experience: API Monitoring** entity.
3. Click **Health Rules**.
4. Do one of the following:
  - a. To create a new health rule, click the **+** icon.
  - b. To modify an existing health rule, select the health rule and click the **Edit** (pencil) icon.
5. In the Overview tab, enter a name for your Health Rule. The other fields display default values and you can edit them based on your requirements.
6. In the Affected Entities tab, you can select all APIs, a few specific APIs, or APIs with specific matching criteria to apply the health rule.

7. In the Critical and Warning Criteria tabs, you can add conditions to trigger a health rule violation on the list of supported API metrics with **fixed** values or **dynamic baseline** thresholds. See [Critical and Warning](#)

## Conditions.

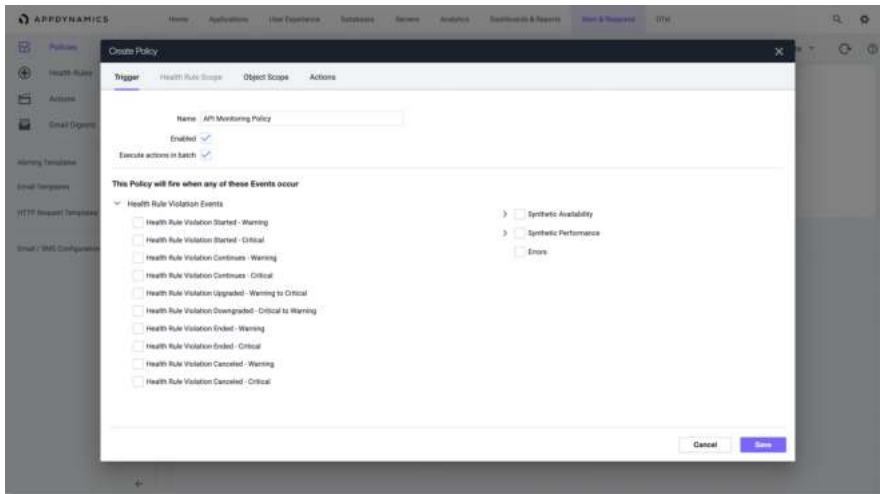

8. Click **Save** to complete the configuration.

### Create Policy for Synthetic APIs

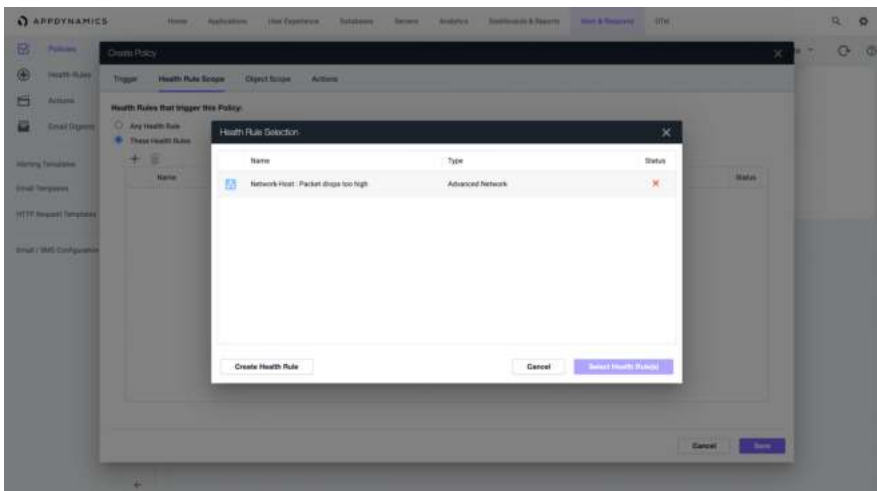

You can create policies to send alerts when the health rules for your APIs violate. You are notified about these alerts via an email, SMS, JIRA, or HTTP webhooks. See [Configure Policies](#).

To create policies for APIs:

1. From the top navigation bar, click **Alert & Respond**.
2. From the drop-down menu next to Alert & Respond, select the **User Experience: API Monitoring** entity.
3. Click **Policies**.
4. From the **Policies** page, click **Create Policy Manually**.
5. From the **Create Policy** dialog, enter a name for your policy.
6. From the **Health Rule Violation Events** list, select one or more specific events.

7. In the Health Rule Scope tab:
  - a. Select **Any Health Rule** to apply policy to all health rules.
  - b. Select **These Health Rules** to apply policy to specific health rules.

8. In the Object Scope tab, select **Any Object**.
9. In the Actions tab, you add any existing actions you have already created or create a new action to be executed when any of the health rule violation events are triggered. See [Actions](#).
10. Click **Save** to complete the configuration.

## Alerts for Synthetic Jobs

You can use the following synthetic events to trigger policies:

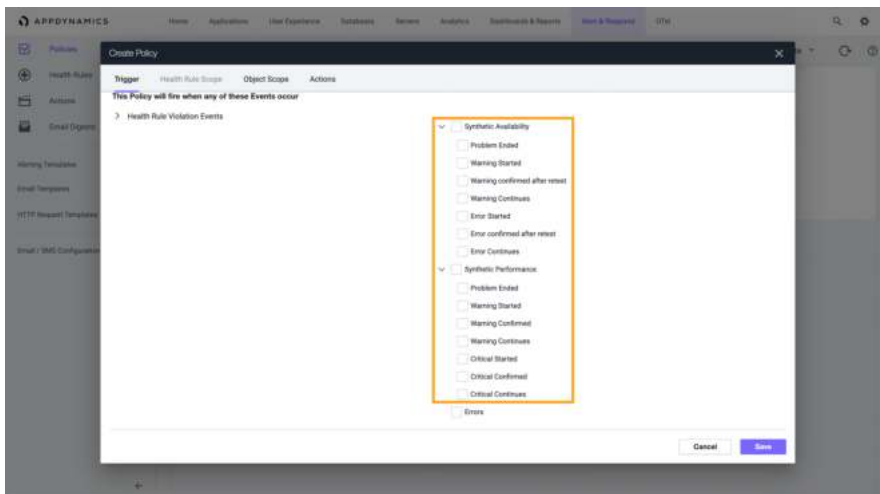

- Synthetic Availability
- Synthetic Performance

## Create Policy for Synthetic Events

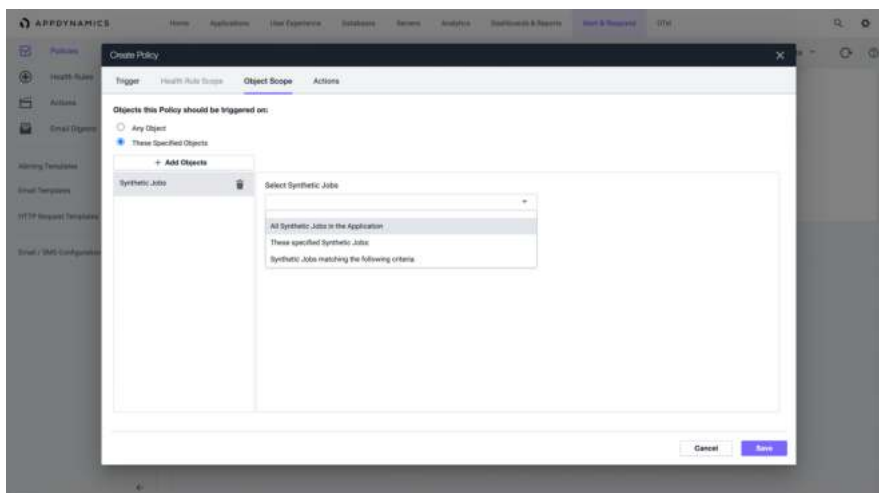

Similar to APIs, you can also create policies to send alerts when the health rules for your synthetic events are violated. You are notified about these alerts via an email, SMS, JIRA, or HTTP webhooks. See [Configure Policies](#).

To create policies for synthetic events:

1. From the top navigation bar, click **Alert & Respond**.
2. From the drop down list next to Alert & Respond, select the **User Experience: API Monitoring** entity.
3. Click **Policies**.
4. On the **Policies** page, click **Create Policy Manually**.
5. On the **Create Policy** dialog box, enter a name for your policy.
6. From the **Synthetic Availability** list, select all the **Synthetic Availability** events or check one or more specific events.
7. From the **Synthetic Performance** list, select all the **Synthetic Performance** events or check one or more specific events.

8. In the Object Scope tab:
  - a. Select **Any Object** to apply policy to all synthetic jobs.
  - b. Select **These Specified Objects** to apply policy to specific synthetic jobs.

9. In the Actions tab, you add any existing actions you have already created or create a new action to be executed when any of the synthetic events are triggered. See [Actions](#).
10. Click **Save** to complete the configuration.

## Install the Private Synthetic Agent (Web and API Monitoring)

### Deployment Support

This page describes the hardware components required for the Web Monitoring Private Synthetic Agent (PSA) and API Monitoring Private Synthetic Agent (PSA) to run in the Docker engine, Kubernetes cluster, and Minikube.

Web Monitoring PSA supports these platforms:

- SaaS Controllers
- On-premises Controller  $\geq 21.4.1$  with on-premise Synthetic Server  $\geq 21.4.1$
- [Chrome browser](#)
- x86-64 architecture

API Monitoring PSA supports these platforms:

- SaaS Controllers  $\geq 21.11$
- Javascript
- x86-64 architecture

- Web Monitoring PSA on Google Cloud Platform is not supported with an on-premise Synthetic server
- API monitoring PSA is not supported with on-premise Controllers

## Prerequisites

Docker	Kubernetes	Minikube	OpenShift
<ul style="list-style-type: none"> <li>• Docker <math>\geq v24.0.6</math></li> <li>• Python <math>\geq 3</math></li> <li>• License units (SaaS and On-Premise):                             <ul style="list-style-type: none"> <li>◦ Browser Synthetic Monitoring - Private Agent - Per Location</li> <li>◦ Browser Synthetic Monitoring - Private Agent - Unlimited Location</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Kubernetes cluster                             <ul style="list-style-type: none"> <li>◦ Amazon EKS: v1.25.0 - 1.27.0</li> <li>◦ Azure AKS: v1.25.0 - 1.27.1</li> </ul> </li> <li>• Python <math>\geq 3</math></li> <li>• License units (SaaS and On-Premise):                             <ul style="list-style-type: none"> <li>◦ Browser Synthetic Monitoring - Private Agent - Per Location</li> <li>◦ Browser Synthetic Monitoring - Private Agent - Unlimited Location</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Minikube <math>\geq v1.30.1</math></li> <li>• K8 Client v1.27.1</li> <li>• Python <math>\geq 3</math></li> <li>• License units (SaaS and On-Premise):                             <ul style="list-style-type: none"> <li>◦ Browser Synthetic Monitoring - Private Agent - Per Location</li> <li>◦ Browser Synthetic Monitoring - Private Agent - Unlimited Location</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• OpenShift Client v4.13.0</li> <li>• Kustomize v4.5.7</li> <li>• Server v4.13.12</li> <li>• Kubernetes v1.26.7</li> <li>• Python <math>\geq 3</math></li> <li>• License units (SaaS and On-Premise):                             <ul style="list-style-type: none"> <li>◦ Browser Synthetic Monitoring - Private Agent - Per Location</li> <li>◦ Browser Synthetic Monitoring - Private Agent - Unlimited Location</li> </ul> </li> </ul>

## Hardware Requirements

The following tables list the hardware components and their recommended configuration for Docker, Kubernetes, and Minikube environments:

### Docker

Component	Description	Minimum			Recommended				
		Instance	CPU	RAM (GB)	Disk (GB)	Instance	CPU	RAM (GB)	Disk (GB)
Heimdall	An orchestrator that connects to the Synthetic Cloud to fetch measurement jobs for the PSA cluster.	1	1	1		1	2	2	
Apache Ignite	In memory cache	1	0.5	0.5	2	1	1	1	20
Web Monitoring Measurement Container	A temporary or short-lived container auto-orchestrated by Heimdall to execute Web Monitoring measurements.	As per your requirement	0.5	1		As per your requirement	1.25	2	

API Monitoring Measurement Container	A temporary or short-lived container auto-orchestrated by Heimdall to execute API Monitoring measurements.	As per your requirement	0	0.1		As per your requirement	0	0.1	
--------------------------------------	------------------------------------------------------------------------------------------------------------	-------------------------	---	-----	--	-------------------------	---	-----	--

**Kubernetes**

Component	Description	Minimum Configuration		Recommended Configuration			
		# Instances	Per Instance	# Instances	Per Instance		
Heimdall	An orchestrator that connects to the Synthetic Cloud to fetch measurement jobs for the PSA cluster.	1	Processor: 2 vCPU Memory: 4 GB RAM	2	Processor: 3 vCPU Memory: 5 GB RAM		
Apache Ignite	In memory cache	1	Processor: 0.5 vCPU Memory: 0.5 GB RAM	2	Processor: 1 vCPU Memory: 1 GB RAM		
Measurement Container	A temporary or short-lived container auto-orchestrated by Heimdall to execute every measurement.  (Web Monitoring PSA) The measurement container image can be customized to install additional libraries.	Based on need, a temporary container instance is scheduled for every measurement	Burst-able CPU-RAM		Based on need, a temporary container instance is scheduled for every measurement	Burst-able CPU-RAM	
			<b>Web Monitoring PSA:</b> Min: 0.5 vCPU, 1 GB RAM Max: 1.25 CPU, 2 GB RAM	<b>API Monitoring PSA:</b> 0.1 vCPU and 100 MB RAM		<b>Web Monitoring PSA:</b> Min: 0.5 vCPU, 1 GB RAM Max: 1.25 CPU, 2 GB RAM	<b>API Monitoring PSA:</b> 0.1 vCPU and 100 MB RAM

**Minikube**

Component	Description	Minimum			Recommended				
		Instance	CPU	RAM (GB)	Disk (GB)	Instance	CPU	RAM (GB)	Disk (GB)
Minikube	Minikube is a lightweight Kubernetes implementation that creates a VM on your local machine and deploys a simple cluster containing only one node.	1	4	4		1	8	8	
Heimdall	An orchestrator that connects to the Synthetic Cloud to fetch measurement jobs for the PSA cluster.	1	1	1		2	2	2	
Apache Ignite	In memory cache	1	0.5	0.5	2	2	1	1	20
Web Monitoring Measurement Container	A temporary or short-lived container auto-orchestrated by Heimdall to execute Web Monitoring measurements.	As per your requirement	0.5	1		As per your requirement	1.25	2	

API Monitoring Measurement Container	A temporary or short-lived container auto-orchestrated by Heimdall to execute API Monitoring measurements.	As per your requirement	0	0.		As per your requirement	0	0.	
			1	1			1	1	

### Number of Measurement Containers

You can calculate the number of required concurrent containers using this formula:

$$((\text{Number of Jobs}) \times (\text{Average job duration in minutes}) / (\text{Frequency in minutes}))$$

For example, the number of containers required for 10 jobs with an average duration of 30 seconds per job executed at 5-minute interval needs:

$$(10 \times (30/60)) / 5 = 1 \text{ container}$$

### Concurrent Measurements

The Kubernetes cluster specifications determine the number of concurrent measurements that can be executed. Any submission of jobs beyond the infra limits leads to the queuing of jobs in the Kubernetes cluster. To scale the number of concurrent jobs automatically, enable cluster auto-scaler. K8S auto-scaler functionality depends on the cloud or the managed service provider.

To set up Web Monitoring PSA and API Monitoring PSA in any of these environments, see:

- [Set up PSA in Docker Engine](#)
- [Set up PSA in Red Hat OpenShift](#)
- [Set up PSA in Amazon EKS](#)
- [Set up PSA in Minikube](#)
- [Set up PSA in Azure AKS](#)
- [Set up PSA in Bare Metal K8s Using Amazon EC2](#)
- [Set up the Web Monitoring PSA in a Windows Environment Using Minikube](#)
- [Configure Web Monitoring PSA and API Monitoring PSA](#)

### Set up PSA in Docker Engine

You can set up PSA in the Docker engine using the automation script, which is available with the installation zip file. When you run the installation command, the script automatically builds the docker image and deploys PSA.

### Supported Operating System

- Linux (CentOS and Ubuntu)
- macOS with Intel or M1 processor
- Windows

Installing PSA using the automated script is not supported on Windows. To install PSA on Windows, see [Deploy PSA on Windows](#).

The following table illustrates the differences between installing PSA in Kubernetes and Docker:

Kubernetes	Docker
Heimdall and Ignite are deployed as pods on the existing Kubernetes cluster through Helm Charts.	Heimdall and Ignite are deployed as containers.
Heimdall creates Web Monitoring and API Monitoring measurement job pods through Kube APIs.	Heimdall creates Web Monitoring and API Monitoring measurement job containers through Docker APIs.
When the measurement is ready, Heimdall deletes the job pods through the Kube APIs.	When the measurement is ready, Heimdall deletes the job containers through the Docker APIs.

### Download the PSA Installation Files

Download the PSA installation zip file from the [Appdynamics Downloads Portal](#) or from the beta upload tool. This file contains Docker files for sum-chrome-agent, sum-api-monitoring-agent, sum-heimdall, Helm charts, and automation scripts. To build an image for sum-chrome-agent, sum-api-monitoring-agent, and sum-heimdall, ensure that Docker is installed. You can download and install Docker from [here](#) if it is not installed.

### Deploy PSA in Docker

1. Unzip the PSA installation zip file.
2. Run the following command to install PSA in a Docker engine:

```
./install_psa -e docker -l -v -u <Shepherd-URL> -a <EUM-account> -k <EUM-key> -c
<location-code> -d <location-description> -t <location-name> -s <location-state> -o
<location-country> -i <location-latitude> -g <location-longitude> -p <PSA-tag> -r
<heimdall-replica-count> -z <agent-type> -m <chrome-agent_min/max-memory> -n <API-
agent_min/max-memory> -x <chrome-agent_min/max-CPU> -y <API-agent_min/max-CPU> -b
<heimdall_min/max-memory> -f <heimdall_min/max-CPU> -q <ignite-persistence>
```

A sample installation command looks like this:

```
./install_psa -e docker -u <Shepherd-URL> -a <EUM-account> -k <EUM-key> -c DEL -d Delhi
-t Delhi -s DEL -o India -i 28.70 -g 77.10 -p 23.5 -r 1 -z all -m 100Mi/500Mi -n 100Mi/
100Mi -x 0.5/1.5 -y 0.1/0.1 -b 2Gi/2Gi -f 2/2 -q true
```

The following table describes the usage of the flags in the command. Asterisk (\*) on the description denotes mandatory parameters.

Flag	Description
-e	Environment For example, Docker, Minikube, or Kubernetes.
-l	Load images to the Minkube environment
-v	Debug mode
-u	*Shepherd URL For example, <a href="https://sum-shadow-master-shepherd.saas.appd-test.com/">https://sum-shadow-master-shepherd.saas.appd-test.com/</a> See <a href="#">Shepherd URL</a> .
-a	*EUM Account For example, a <code>ti-23-2-saas-nov2</code>
-k	*EUM Key For example, <code>2d35df4f-92f0-41a8-8709-db54eff7e56c</code>
-c	*Location Code For example, <code>DEL</code> for Delhi, <code>NY</code> for New York
-d	*Location Description For example, <code>'Delhi, 100001'</code>
-t	*Location City For example, Delhi
-s	*Location State For example, <code>CA</code> for California
-o	*Location Country For example, India, United States
-i	Location Latitude For example, <code>28.70</code> for Delhi
-g	Location Longitude For example, <code>77.10</code> for Delhi

Flag	Description
-p	*PSA release tag For example, 23.5
-r	Heimdall replica count
-z	Agent type For example, web, api, or all
-m	Minimum/Maximum memory in Mi/Gi for <code>sum-chrome-agent</code>
-n	Minimum/Maximum memory in Mi/Gi for <code>sum-api-monitoring-agent</code>
-x	Minimum/Maximum CPU for <code>sum-chrome-agent</code>
-y	Minimum/Maximum CPU for <code>sum-api-monitoring-agent</code>
-b	Minimum/Maximum memory in Mi/Gi for <code>sum-heimdall</code>
-f	Minimum/Maximum CPU for <code>sum-heimdall</code>
-q	Specify <code>true</code> or <code>false</code> to enable or disable Ignite Persistence.

### Monitor PSA

To monitor the CPU and memory usage of the Heimdall and Ignite containers, run the following command:

```
./monitoring_psa
```

### Deploy PSA on Windows

Perform the following steps:

1. Navigate to the `sum-chrome-agent` directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-chrome-agent:<agent-tag> .
```

2. Navigate to the `sum-api-monitoring-agent` directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-api-monitoring-agent:<agent-tag> .
```

3. Navigate to the `sum-heimdall` directory and copy the docker file:

```
cp ./docker-PSA/Dockerfile-PSA
```

4. Build the Heimdall image:

```
docker build -f Dockerfile-PSA -t sum-heimdall:<heimdall-tag> .
```

5. Navigate to `./docker-psa/appdynamics` and update the following details in the `onprem.yaml` file:

- Shepherd URL
- EUM credentials
- Registration location
- Agent tag

6. Navigate to `./docker-psa` and update the Heimdall tag in the `docker-compose.yaml` file.

7. Perform Docker compose:

```
docker-compose up -d
```

### Upgrade PSA

Perform the following steps to upgrade PSA:

1. Download and unzip the PSA installation zip file.

 The `upgrade_psa -h` command displays the parameters that you can specify.

2. Run the following command:

```
./upgrade_psa -d -v <PSA-release-tag>
```

The following table describes the usage of the flags in the command. The asterisk (\*) on the description denotes a mandatory parameter.

Flag	Description
-d	Debug mode
-v	*PSA release tag. This is the version to which you are upgrading. For example, 23.9.0.

### Uninstall PSA

To uninstall PSA, run the following commands:

Operating System	Command
Linux and macOS	<pre>./uninstall_psa -e docker -p</pre>
Windows	<ol style="list-style-type: none"> <li><pre>docker ps -a</pre></li> <li> <pre>docker rm &lt;heimdall-containerID&gt; docker rm &lt;ignite-containerID&gt;</pre> </li> </ol>

### Set up PSA in Red Hat OpenShift

To deploy the Web Monitoring PSA and API Monitoring PSA in OpenShift, you must create OpenShift clusters in Amazon EKS or Azure AKS. You can set up the PSA in one of the following ways:

Deploy Manually	Deploy Using the Automation Script
<ol style="list-style-type: none"> <li><a href="#">Build and customise the Docker image.</a></li> <li><a href="#">Tag and push images to the Registry.</a></li> <li><a href="#">Deploy PSA in OpenShift Manually</a></li> <li><a href="#">Monitor the Kubernetes cluster.</a></li> </ol>	<ol style="list-style-type: none"> <li><a href="#">Deploy PSA in OpenShift Using the Automation Script</a></li> <li><a href="#">Monitor the Kubernetes cluster.</a></li> </ol>

 This document contains links to AWS CLI documentation. AppDynamics makes no representation as to the accuracy of AWS CLI documentation because AWS CLI controls its own documentation.

 If you use the automated script, you must manually set up the OpenShift cluster and nodes and log in to container registries before deploying PSA.

### Build and Customise the Docker Image

#### (Optional) Configure Proxy Server

When you configure a proxy server, it applies to all the domains.

Configure a proxy server by specifying the proxy server address on the `values.yaml` file. See [Key-Value Pairs Configuration](#).

 If you make any changes to the `bypass_list` after building the docker image, you must rebuild the docker image.

To bypass any domains from the proxy server, perform the following steps:

**i** Configuring the bypass list is supported only on Web Monitoring PSA.

1. Navigate to the `sum-chrome-agent/agent` directory.
2. Open the `chrome.py` file.
3. Navigate to the following string:

```
if self._proxy_server:
 chrome_options.add_argument('--proxy-server={}' .format(self._proxy_server))
```

4. Append the following details:

```
bypass_list = ["*abc.com", "*xyz1.com", "*xyz2.com"]
chrome_options.add_argument('--proxy-bypass-list=%s' % ";".join(bypass_list))
```

Domain URLs that you specify in `bypass_list` are not redirected to the proxy server. You can add any number of domains in the `bypass_list`. All other unspecified domain URLs are redirected to the proxy server.

5. Build the docker image.

**i** If you make any changes to the `bypass_list` after building the docker image, you must rebuild the docker image.

### Build and Customise the PSA Docker Image

You can download the zip file for Simple Synth PSA installation from the Appdynamics Downloads Portal or from the beta upload tool.

This file contains Dockerfiles to install the agents and set up monitoring:

- **Web Monitoring PSA:** Dockerfiles for `sum-chrome-agent`, `sum-heimdall`, and Helm charts
- **API Monitoring PSA:** Dockerfiles for `sum-api-monitoring-agent`, `sum-heimdall`, and Helm charts

To build an image for `sum-chrome-agent`, `sum-api-monitoring-agent`, and `sum-heimdall`, ensure that Docker is installed. If it is not installed, you can download and install Docker from [here](#).

For `sum-chrome-agent`:

1. Unzip the zip file to access the `sum-chrome-agent` directory.
2. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA-0penshift -t sum-chrome-agent:<agent-tag> .
```

For `sum-api-monitoring-agent`:

1. Unzip the zip file to access the `sum-api-monitoring-agent` directory.
2. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA-Openshift -t sum-api-monitoring-agent:<agent-tag> .
```

For sum-heimdall:

1. Unzip the zip file to access the sum-heimdall directory.
2. Navigate to the Openshift-PSA directory and run the following command:

```
docker build -f Dockerfile-PSA-Openshift -t sum-heimdall:<heimdall-tag> .
```

**i** You can use any value for <heimdall-tag> and <agent-tag>, but ensure that you use the same value in the subsequent [steps](#).

**i** If you are using macOS with an M1 chip, use the following commands:

#### sum-chrome-agent

```
docker buildx build -f Dockerfile-PSA-Openshift --platform=linux/amd64 -t sum-chrome-agent:<agent-tag> .
```

#### sum-heimdall

```
docker buildx build -f Dockerfile-PSA-Openshift --platform=linux/amd64 -t sum-heimdall:<heimdall-tag> .
```

#### sum-api-monitoring-agent

```
docker buildx build -f Dockerfile-PSA-Openshift --platform=linux/amd64 -t sum-api-monitoring-agent:<api-tag> .
```

### (Optional) Add Custom Python Libraries

**i** This section is applicable only for Web Monitoring PSA.

In addition to the available standard set of libraries, you can add custom Python libraries to the agent to use in scripted measurements. You build a new image based on the image you loaded as the base image.

1. Create a Dockerfile and then create `RUN` directives to run `python` `pip`. For example, to install the library `algorithms` you can create a Dockerfile:

```
Use the sum-chrome-agent image we just loaded as the base image
FROM sum-chrome-agent:<agent-tag>
```

```
Install algorithm for python3 on top of that
RUN python3 -m pip install algorithms==0.1.4

We can add more RUN directives for installing more libraries
RUN python3 -m pip install ...
```

 You can create any number of `RUN` directives to install the required libraries.

2. To build the new image, enter:

```
docker build -t sum-chrome-agent:<agent-tag> - < Dockerfile
```

The newly built agent image contains the required libraries.

### Tag and Push Images to the Registry

You must tag and push the images to a registry for the cluster to access it. The Amazon EKS clusters pull the images from Elastic Container Registry (ECR), which is the managed registry provided by AWS.

To tag the images, enter:

#### Web Monitoring PSA:

```
docker tag sum-heimdall:<heimdall-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/
sum-heimdall:<heimdall-tag>
docker tag sum-chrome-agent:<agent-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/
sum-chrome-agent:<agent-tag>
```

#### API Monitoring PSA:

```
docker tag sum-heimdall:<heimdall-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/
sum-heimdall:<heimdall-tag>
docker tag sum-api-monitoring-agent:<agent-tag>
<aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-api-monitoring-agent:<agent-tag>
```

You need to replace `<aws_account_id>` & `<region>` with your account id and region values.

To create repositories, enter:

#### Web Monitoring PSA:

```
aws ecr create-repository --repository-name sum/sum-heimdall
aws ecr create-repository --repository-name sum/sum-chrome-agent
```

#### API Monitoring PSA:

```
aws ecr create-repository --repository-name sum/sum-heimdall
aws ecr create-repository --repository-name sum/sum-api-monitoring-agent
```

To push the images, enter:

### Web Monitoring PSA:

```
aws ecr get-login-password --region us-west-2 | docker login --username AWS --password-stdin
<aws_account_id>.dkr.ecr.<region>.amazonaws.com
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall:<heimdall-tag>
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-chrome-agent:<agent-tag>
```

### API Monitoring PSA:

```
aws ecr get-login-password --region us-west-2 | docker login --username AWS --password-stdin
<aws_account_id>.dkr.ecr.<region>.amazonaws.com
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall:<heimdall-tag>
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-api-monitoring-
agent:<agent-tag>
```

### Deploy PSA in OpenShift Manually

**i** Ensure that you follow the applicable sequence of steps when installing Web Monitoring PSA and API Monitoring PSA, respectively; some steps are common for both procedures.

The application is deployed to the cluster after the images are in the Registry. You use the Helm chart to deploy and create all Kubernetes resources in the required order.

1. Install Helm following these [instructions](#).
2. Create a new `ignite` namespace to run the Apache Ignite pods.

**⚠** Ensure that you first run the Apache Ignite commands and then run the Heimdall commands.

To create a new `ignite` namespace, enter:

```
kubectl create namespace ignite
```

Before you deploy Apache Ignite, you must set some configuration options. To view the configuration options, navigate to the previously downloaded `ignite-psa.tgz` file and enter:

```
helm show values ignite-psa.tgz > values-ignite.yaml
```

**i** If you want to enable persistence, set `persistence > enabled`. This is an optional configuration.

- To deploy the Helm chart using the above-mentioned configuration, navigate to the previously downloaded `ignite-psa.tgz` file and enter:

```
helm install synth ignite-psa.tgz --values values-ignite.yaml --namespace ignite
```

All the Kubernetes resources are created in the cluster, and you can use Apache Ignite. After a few seconds, Apache Ignite initializes and is visible in the Controller.

- To verify if the pods are running, enter:

```
kubectl get pods --namespace ignite
```

Proceed to the next steps only after the Apache Ignite pods run successfully.

- Create a new `measurement` namespace to run Heimdall and measurement pods. To create a new `measurement` namespace, enter:

```
kubectl create namespace measurement
```

Using a single command, you can deploy the Helm chart, which contains the deployment details. To deploy the agent, use the Helm chart `sum-psa-heimdall.tgz` in the zip file that you downloaded previously. Before you deploy the Private Synthetic Agent, you must set some configuration options. To view the configuration options, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm show values sum-psa-heimdall.tgz > values.yaml
```

These are the configuration key-value pairs that you need to edit in the `values.yaml` file:

**Web Monitoring PSA:**

Configuration Key	Value
<code>heimdall &gt; repository</code>	<code>&lt;aws_account_id&gt;.dkr.ecr.&lt;region&gt;.amazonaws.com/sum/sum-heimdall</code>
<code>heimdall &gt; tag</code>	<code>&lt;heimdall-tag&gt;</code>
<code>heimdall &gt; pullPolicy</code>	<code>Always</code>
<code>chromeAgent &gt; repository</code>	<code>&lt;aws_account_id&gt;.dkr.ecr.&lt;region&gt;.amazonaws.com/sum/sum-chrome-agent</code>
<code>chromeAgent &gt; tag</code>	<code>&lt;agent-tag&gt;</code>

Configuration Key	Value
shepherd > url	Shepherd URL
shepherd > credentials	credentials
shepherd > location	agent location

**API Monitoring PSA:**

Configuration Key	Value
heimdall > repository	<aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall
heimdall > tag	<heimdall-tag>
heimdall > pullPolicy	Always
apiMonitoringAgent > repository	<aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-api-monitoring-agent
apiMonitoringAgent > tag	<agent-tag>
ingressBandwidth	1024k or more, based on your requirements.
egressBandwidth	1024k or more, based on your requirements.
shepherd > url	Shepherd URL
shepherd > credentials	credentials
shepherd > location	agent location

You can leave the rest of the values set to their defaults or configure them based on your requirements. See [Configure Web Monitoring PSA and API Monitoring PSA](#) for details on shepherd URL, credentials, location, and optional key-value pairs.

**i** If the Kubernetes cluster is locked down, and you cannot make cluster-wide configuration, you can make pod-level changes. For example, if you want to change the pod-level DNS server setting to use your internal nameservers for DNS name resolution, specify the following details in the `values.yaml` file:

```
agentDNSConfig:
 enabled: true
 dnsPolicy: "None"
 dnsConfig:
 nameservers: ["4.4.4.4"]
 searches: ["svc.cluster.local", "cluster.local"]
```

If you need to add multiple nameservers, do the following:

- a. Set `dnsPolicy` to "None" in the `values.yaml` file.

```
agentDNSConfig:
 enabled: true
 dnsPolicy: "None"
 dnsConfig:
 nameservers: ["1.1.1.1", "2.2.2.2", "3.3.3.3"]
 searches: ["measurement.svc.cluster.local",
 "svc.cluster.local", "cluster.local"]
```

Ensure that the first nameserver specified under `nameservers` is the `cluster-default` nameserver.

- b. Set `Upstream coredns` policy to `sequential`. For more information, see [coredns](#).

6. To deploy the Helm chart using the above-mentioned configuration, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm install heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
```

All the Kubernetes resources are created in the cluster, and you can use Heimdall. After a few seconds, Heimdall initializes and is visible in the Controller.

7. To verify if the pods are running, enter:

```
kubectl get pods --namespace measurement
```

To make any changes to `values.yaml` after the initial deployment, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm upgrade heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
```

**!** To remove the deployment:

```
helm uninstall heimdall-onprem --namespace measurement
```

This is not recommended unless it is required.

## Deploy PSA in OpenShift Using the Automation Script

### Prerequisite

Before running the PSA installation script:

- [Create an OpenShift cluster](#) and configure the cluster in Kubeconfig.
- Log in to the image registry.
- Download the `pyyaml` package v6.01.

Perform the following steps to install PSA:

1. Unzip the PSA installation zip file.
2. Run the following command to install PSA :

```
./install_psa -e openshift -l -v -u <Shepherd-URL> -a <EUM-account> -k <EUM-key> -c <location-code> -d <location-description> -t <location-name> -s <location-state> -o <location-country> -i <location-latitude> -g <location-longitude> -p <PSA-tag> -r <heimdall-replica-count> -z <agent-type> -m <chrome-agent_min/max-memory> -n <API-agent_min/max-memory> -x <chrome-agent_min/max-CPU> -y <API-agent_min/max-CPU> -b <heimdall_min/max-memory> -f <heimdall_min/max-CPU> -q <ignite-persistence> -j <ingress_and_egress_bandwidth> -w <heimdall_proxy_server>~<api_monitoring_proxy_server>~<web_monitoring_proxy_server>
```

A sample installation command looks like this:

```
./install_psa -e openshift -u <Shepherd-URL> -a <EUM-account> -k <EUM-key> -c DEL -d Delhi -t Delhi -s DEL -o India -i 28.70 -g 77.10 -p 23.5 -r 1 -z all -m 100Mi/500Mi -n 100Mi/100Mi -x 0.5/1.5 -y 0.1/0.1 -b 2Gi/2Gi -f 2/2 -q true -j 2048k -w 127.0.0.1:8887~127.0.0.1:8888~127.0.0.1:8889
```

The following table describes the usage of the flags in the command. Asterisk (\*) on the description denotes mandatory parameters.

Flag	Description
-e	Environment For example, Docker, Minikube, or Kubernetes.
-l	Load images to the Minkube environment
-v	Debug mode
-u	*Shepherd URL
-a	*EUM Account

Flag	Description
-k	*EUM Key
-c	*Location Code For example, DEL for Delhi, NY for New York
-d	*Location Description For example, 'Delhi, 100001'
-t	*Location City For example, Delhi
-s	*Location State For example, CA for California
-o	*Location Country For example, India, United States
-i	Location Latitude For example, 28.70 for Delhi
-g	Location Longitude For example, 77.10 for Delhi
-p	*PSA release tag For example, 23.5
-r	Heimdall replica count
-z	Agent type For example, web, api, or all
-m	Minimum/Maximum memory in Mi/Gi for sum-chrome-agent
-n	Minimum/Maximum memory in Mi/Gi for sum-api-monitoring-agent
-x	Minimum/Maximum CPU for sum-chrome-agent
-y	Minimum/Maximum CPU for sum-api-monitoring-agent

Flag	Description
-b	Minimum/Maximum memory in Mi/Gi for <code>sum-heimdall</code>
-f	Minimum/Maximum CPU for <code>sum-heimdall</code>
-q	Specify <code>true</code> or <code>false</code> to enable or disable Ignite Persistence.
-j	Specify a single value for the API monitoring agent's ingress and egress bandwidth. The default value for OpenShift is 1024k. AppDynamics recommends keeping a value greater than or equal to that for OpenShift deployments.
-w	Specify the proxy servers for Heimdall, API, and Web monitoring, separated by a tilde(~).  If you do not need to set up any proxy server, you can leave it blank.

3. Specify the Docker registry URL when prompted.

### Monitor the Kubernetes Cluster

The Helm chart `sum-psa-monitoring.tgz` in the zip you downloaded installs the monitoring stack. This Helm chart installs `kube-prometheus-stack` along with a custom Grafana dashboard to monitor the Private Simple Synthetic Agent.

**i** Monitoring the deployment is optional; however, we highly recommend that you monitor the cluster to check its health periodically.

### Install the Monitoring Stack

1. To create a separate `monitoring` namespace, enter:

```
kubectl create namespace monitoring
```

To review configuration options, enter:

```
helm show values sum-psa-monitoring.tgz > values-monitoring.yaml
```

This generates a `values-monitoring.yaml` file that contains all the configuration options. To modify and pass the generated `values-monitoring .yaml` file while installing the Helm chart, enter:

```
oc adm policy add-scc-to-group anyuid system:authenticated
```

```
helm install psa-monitoring sum-psa-monitoring.tgz --values values-monitoring.yaml --namespace monitoring
```

2. After the monitoring stack is installed, you can Launch Grafana (which runs inside the cluster) to view the dashboard. To access Grafana from outside the cluster, you can configure port forwarding or set up [Ingress](#). To configure port forward to access it locally, enter:

```
kubectl port-forward svc/psa-monitoring-grafana 3000:80 --namespace monitoring
```

3. Launch localhost:3000 from the browser and log in using the default credentials with username as admin and password as prom-operator. A dashboard named Private Simple Synthetic Agent displays and provides details about the Kubernetes cluster, Apache Ignite, Heimdall, and running measurements.

## Uninstall PSA

To uninstall PSA, run the following command:

```
./uninstall_psa -e openshift -p
```

## Upgrade PSA in Red Hat OpenShift

### Upgrade the Private Synthetic Agent

To upgrade the PSA, perform the following steps:

1. [Build the Docker Image](#)
2. (Optional) [Add Custom Python Libraries](#)
3. [Tag and Push Images to the Registry](#)
4. [Update the Helm Chart](#)
5. [Upgrade the PSA](#)

#### Build the Docker Image

1. Download the latest version of the PSA file from the Appdynamics Downloads Portal. This file contains Dockerfiles for sum-chrome-agent, sum-heimdall, and Helm charts used to install the agent and set up monitoring.
2. Build image for sum-heimdall:

**i** To build an image for sum-chrome-agent and sum-heimdall, ensure that Docker is installed. If it is not installed, you can download and install Docker from [here](#).

- a. Unzip the file to access the sum-heimdall directory.
- b. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-heimdall:<heimdall-tag> .
```

**i** You can use any value for `<heimdall-tag>` and `<agent-tag>`, but ensure that you use the same value in the subsequent steps.

## Add Custom Python Libraries

This is an optional step. In addition to the available standard set of libraries, you can add custom Python libraries to the agent to use in scripted measurements. You build a new image based on the image you loaded as the base image.

1. Create a Dockerfile and then create `RUN` directives to run `python pip`. For example, to install the library `algorithms` you can create a Dockerfile:

```
Use the sum-chrome-agent image we just loaded as the base image
FROM sum-chrome-agent:<agent-tag>

Install algorithm for python3 on top of that
RUN python3 -m pip install algorithms==0.1.4

We can add more RUN directives for installing more libraries
RUN python3 -m pip install ...
```

**i** You can create any number of `RUN` directives to install the required libraries.

2. To build the new image, enter:

```
docker build -t sum-chrome-agent:<agent-tag> - < Dockerfile
```

The newly built agent image contains the required libraries.

## Tag and Push Images to the Registry

**i** Managed Kubernetes services, such as EKS or AKS, provide container registries where you can push your image. No other configuration is needed. Kubernetes cluster within EKS or AKS will have access to these images.

You must tag and push the images to a registry for the cluster to access them. The Amazon EKS clusters pull the images from the Elastic Container Registry (ECR), which is the managed registry provided by AWS.

Since the Vanilla K8S runs on AWS infrastructure, Kubernetes Operations (kops) creates and assigns appropriate roles to the cluster nodes, and they can directly access the ECR. You do not need any other configuration. Hence, the process is the same for both EKS and Vanilla K8S using EC2.

To tag the images, enter:

```
docker tag sum-heimdall:<heimdall-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall:<heimdall-tag>
docker tag sum-chrome-agent:<agent-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-chrome-agent:<agent-tag>
```

You need to replace `<aws_account_id>` & `<region>` with your account id and region values.

To create repositories, enter:

```
aws ecr create-repository --repository-name sum/sum-heimdall
aws ecr create-repository --repository-name sum/sum-chrome-agent
```

To push the images, enter:

```
aws ecr get-login-password --region us-west-2 | docker login --username AWS --password-stdin <aws_account_id>.dkr.ecr.<region>.amazonaws.com
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall:<heimdall-tag>
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-chrome-agent:<agent-tag>
```

Update the Helm Chart

Follow these [steps](#) and update the configuration key-value pairs in the `values.yaml` file:

Upgrade the PSA

Navigate to the new Linux distribution folder and run this command:

```
helm upgrade heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
```

## Set up PSA in Amazon EKS

Set up the Web Monitoring PSA and API Monitoring PSA in Amazon Elastic Kubernetes Service (Amazon EKS) as follows. If you want to set up PSA in an existing Kubernetes cluster, skip the [Create the Kubernetes Cluster](#) section.

1. [Create the Kubernetes Cluster.](#)
2. [Deploy PSA in EKS](#)
3. [Monitor the Kubernetes cluster.](#)

This document contains links to AWS CLI documentation. AppDynamics makes no representation as to the accuracy of AWS CLI documentation because AWS CLI controls its own documentation.

You can deploy PSA on an existing Kubernetes cluster in public or private clouds. The automation scripts do not support Kubernetes cluster creation.

- If you use the automated script, you must manually set up the Kubernetes cluster and nodes and log in to container registries before deploying PSA.
- If you use a separate registry, specify the registry in the automated script before deploying PSA:
  - a. Open the `install_psa` file and go to the `push_images_to_docker_registry()` function.
  - b. Under that function, after `${DOCKER_REGISTRY_URL}/`, specify the registry names of `sum-chrome-agent`, `sum-api-monitoring-agent`, and `sum-heimdall`.
  - c. Under the `generate_psa_k8s_deployment()` function, update the repository names on the YAML values.
- You must build the images on the host with the same OS type of Kubernetes cluster nodes.

## Create the Kubernetes Cluster

To create a Kubernetes cluster in Amazon EKS:

1. [Install](#) and [configure](#) AWS CLI.
2. Based on your platform, install `eksctl` following the instructions [here](#).
3. To create a Kubernetes cluster, enter:

```
EKSCTL_CLUSTER_NAME=eks-heimdall-onprem-cluster
EKSCTL_NODEGROUP_NAME=eks-heimdall-onprem-worker-nodes
EKSCTL_KUBERNETES_VERSION=1.x.x
```

```
eksctl create cluster \
--name ${EKSCTL_CLUSTER_NAME} \
--version ${EKSCTL_KUBERNETES_VERSION} \
--region us-west-2 \
--zones us-west-2a,us-west-2b,us-west-2c \
--nodegroup-name ${EKSCTL_NODEGROUP_NAME} \
--node-type t3.2xlarge \
--nodes 4 \
--nodes-min 2 \
--nodes-max 6 \
--ssh-access \
--ssh-public-key ~/.ssh/id_rsa.pub \
--managed \
--vpc-nat-mode Disable
```

Replace the `EKSCTL_KUBERNETES_VERSION` with one of the [EKS Kubernetes versions](#).

**i** The node-type, nodes, nodes-min, and nodes-max in the code snippet are selected based on the recommended configuration type. You can specify a configuration of your choice with a different type and number of nodes. See [EC2 instance types](#).

## Access the Cluster

To access the Kubernetes cluster, follow these [instructions](#) to install kubectl, a utility to interact with the cluster.

To verify that the cluster is running, enter:

```
kubectl get nodes
```

## (Optional) Configure Proxy Server

**i** Configuring a proxy server is supported only on Web Monitoring PSA.

When you configure a proxy server, it applies to all the domains. To configure a proxy server only for certain domains, perform the following steps:

1. Navigate to the `sum-chrome-agent/agent` directory.
2. Open the `chrome.py` file.
3. Navigate to the following string:

```
if self._proxy_server:
 chrome_options.add_argument('--proxy-server={}'.format(self._proxy_server))
```

4. Append the following details:

```
bypass_list = ["*abc.com", "*xyz1.com", "*xyz2.com"]
chrome_options.add_argument('--proxy-bypass-list=%s' % ";".join(bypass_list))
```

Domain URLs that you specify in `bypass_list` are not redirected to the proxy server. You can add any number of domains in the `bypass_list`. All other unspecified domain URLs are redirected to the proxy server.

5. Specify the proxy server address on the `values.yaml` file. See [Key-Value Pairs Configuration](#).

**i** If you make any changes to the `bypass_list` after building the docker image, you must rebuild the docker image.

## Deploy PSA in EKS

Download the PSA installation zip file from the [Appdynamics Downloads Portal](#) or from the beta upload tool. This file contains Docker files for sum-chrome-agent, sum-api-monitoring-agent, sum-heimdall, Helm charts, and automation scripts. To build an image for sum-chrome-agent, sum-api-monitoring-agent, and

sum-heimdall, ensure that Docker is installed. You can download and install Docker from [here](#) if it is not installed.

Perform the following steps to install PSA:

1. Unzip the PSA installation zip file.
2. Run the following command to install PSA in EKS:

```
./install_psa -e kubernetes -l -v -u <Shepherd-URL> -a <EUM-account> -k <EUM-key> -c <location-code> -d <location-description> -t <location-name> -s <location-state> -o <location-country> -i <location-latitude> -g <location-longitude> -p <PSA-tag> -r <heimdall-replica-count> -z <agent-type> -m <chrome-agent_min/max-memory> -n <API-agent_min/max-memory> -x <chrome-agent_min/max-CPU> -y <API-agent_min/max-CPU> -b <heimdall_min/max-memory> -f <heimdall_min/max-CPU> -q <ignite-persistence>
```

A sample installation command looks like this:

```
./install_psa -e kubernetes -u <Shepherd-URL> -a <EUM-account> -k <EUM-key> -c DEL -d Delhi -t Delhi -s DEL -o India -i 28.70 -g 77.10 -p 23.5 -r 1 -z all -m 100Mi/500Mi -n 100Mi/100Mi -x 0.5/1.5 -y 0.1/0.1 -b 2Gi/2Gi -f 2/2 -q true
```

The following table describes the usage of the flags in the command. Asterisk (\*) on the description denotes mandatory parameters.

Flag	Description
-e	Environment For example, Docker, Minikube, or Kubernetes.
-l	Load images to the Minkube environment
-v	Debug mode
-u	*Shepherd URL For example, <code>https://sum-shadow-master-shepherd.saas.appd-test.com/</code>
-a	*EUM Account For example, <code>Ati-23-2-saas-nov2</code>
-k	*EUM Key For example, <code>2d35df4f-92f0-41a8-8709-db54eff7e56c</code>

Flag	Description
-c	*Location Code For example, DEL for Delhi, NY for New York
-d	*Location Description For example, 'Delhi, 100001'
-t	*Location City For example, Delhi
-s	*Location State For example, CA for California
-o	*Location Country For example, India, United States
-i	Location Latitude For example, 28.70 for Delhi
-g	Location Longitude For example, 77.10 for Delhi
-p	*PSA release tag For example, 23.5
-r	Heimdall replica count
-z	Agent type For example, web, api, or all
-m	Minimum/Maximum memory in Mi/Gi for sum-chrome-agent
-n	Minimum/Maximum memory in Mi/Gi for sum-api-monitoring-agent
-x	Minimum/Maximum CPU for sum-chrome-agent
-y	Minimum/Maximum CPU for sum-api-monitoring-agent
-b	Minimum/Maximum memory in Mi/Gi for sum-heimdall

Flag	Description
-f	Minimum/Maximum CPU for <code>sum-heimdall</code>
-q	Specify <code>true</code> or <code>false</code> to enable or disable Ignite Persistence.

## Monitor the Kubernetes Cluster

The Helm chart `sum-psa-monitoring.tgz` in the zip you downloaded installs the monitoring stack. This Helm chart installs `kube-prometheus-stack` along with a custom Grafana dashboard to monitor the Private Simple Synthetic Agent.

**i** Monitoring the deployment is optional; however, we highly recommend that you monitor the cluster to check its health periodically.

## Install the Monitoring Stack

1. To create a separate `monitoring` namespace, enter:

```
kubectl create namespace monitoring
```

To review configuration options, enter:

```
helm show values sum-psa-monitoring.tgz > values-monitoring.yaml
```

This generates a `values-monitoring.yaml` file that contains all the configuration options. To modify and pass the generated `values-monitoring.yaml` file while installing the Helm chart, enter:

```
helm install psa-monitoring sum-psa-monitoring.tgz --values values-monitoring.yaml --namespace monitoring
```

2. After the monitoring stack is installed, you can Launch Grafana (which runs inside the cluster) to view the dashboard. To access Grafana from outside of the cluster, you can configure port forwarding or set up [Ingress](#). To configure port forward to access it locally, enter:

```
kubectl port-forward svc/psa-monitoring-grafana 3000:80 --namespace monitoring
```

3. Launch `localhost:3000` from the browser and log in using the default credentials with username as `admin` and password as `prom-operator`. A dashboard named Private Simple Synthetic Agent displays and provides details about the Kubernetes cluster, Apache Ignite, Heimdall, and running measurements.

## Uninstall PSA

To uninstall PSA, run the following command:

```
./uninstall_psa -e kubernetes -p
```

## Upgrade PSA in Amazon Elastic Kubernetes Service

### Upgrade the Private Synthetic Agent

To upgrade the PSA, perform the following steps:

1. [Build the Docker Image](#)
2. (Optional) [Add Custom Python Libraries](#)
3. [Tag and Push Images to the Registry](#)
4. [Update the Helm Chart](#)
5. [Upgrade the PSA](#)

#### Build the Docker Image

1. Download the latest version of the PSA file from the Appdynamics Downloads Portal. This file contains Dockerfiles for sum-chrome-agent, sum-heimdall, and Helm charts used to install the agent and set up monitoring.
2. Build image for sum-heimdall:

**i** To build an image for sum-chrome-agent and sum-heimdall, ensure that Docker is installed. If it is not installed, you can download and install Docker from [here](#).

- a. Unzip the file to access the `sum-heimdall` directory.
- b. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-heimdall:<heimdall-tag> .
```

**i** You can use any value for `<heimdall-tag>` and `<agent-tag>`, but ensure that you use the same value in the subsequent [steps](#).

#### Add Custom Python Libraries

This is an optional step. In addition to the available standard set of libraries, you can add custom Python libraries to the agent to use in scripted measurements. You build a new image based on the image you loaded as the base image.

1. Create a Dockerfile and then create `RUN` directives to run `python` `pip`. For example, to install the library `algorithms` you can create a Dockerfile:

```
Use the sum-chrome-agent image we just loaded as the base image
FROM sum-chrome-agent:<agent-tag>

Install algorithm for python3 on top of that
```

```
RUN python3 -m pip install algorithms==0.1.4

We can add more RUN directives for installing more libraries
RUN python3 -m pip install ...
```

**i** You can create any number of `RUN` directives to install the required libraries.

2. To build the new image, enter:

```
docker build -t sum-chrome-agent:<agent-tag> - < Dockerfile
```

The newly built agent image contains the required libraries.

### Tag and Push Images to the Registry

**i** Managed Kubernetes services, such as EKS or AKS, provide container registries where you can push your image. No other configuration is needed. Kubernetes cluster within EKS or AKS will have the access to these images.

You must tag and push the images to a registry for the cluster to access them. The Amazon EKS clusters pull the images from Elastic Container Registry (ECR), which is the managed registry provided by AWS.

Since the Vanilla K8S runs on AWS infrastructure, Kubernetes Operations (kops) creates and assigns appropriate roles to the cluster nodes and they can directly access the ECR. You do not need any other configuration. Hence, the process is the same for both EKS and Vanilla K8S using EC2.

To tag the images, enter:

```
docker tag sum-heimdall:<heimdall-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall:<heimdall-tag>
docker tag sum-chrome-agent:<agent-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-chrome-agent:<agent-tag>
```

You need to replace `<aws_account_id>` & `<region>` with your account id and region values.

To create repositories, enter:

```
aws ecr create-repository --repository-name sum/sum-heimdall
aws ecr create-repository --repository-name sum/sum-chrome-agent
```

To push the images, enter:

```
aws ecr get-login-password --region us-west-2 | docker login --username AWS --password-stdin
<aws_account_id>.dkr.ecr.<region>.amazonaws.com
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall:<heimdall-tag>
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-chrome-agent:<agent-tag>
```

Update the Helm Chart

Follow these [steps](#) and update the configuration key value pairs in the `values.yaml` file:

Upgrade the PSA

Navigate to the new Linux distribution folder and run this command:

```
helm upgrade heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace
measurement
```

## Set up PSA in Minikube

- Minikube is installed in a single machine. Hence, it is not scalable or highly available when you set up PSA in Minikube.
- Functionality-wise, there is no difference between PSA in Minikube and PSA in AKS, EKS, or any other Kubernetes cluster.

This page describes setting up Web Monitoring PSA and API Monitoring PSA in Minikube.

### (Optional) Configure Proxy Server

Configuring a proxy server is supported only on Web Monitoring PSA.

When you configure a proxy server, it applies to all the domains. To configure a proxy server only for certain domains, perform the following steps:

1. Navigate to the `sum-chrome-agent/agent` directory.
2. Open the `chrome.py` file.
3. Navigate to the following string:

```
if self._proxy_server:
 chrome_options.add_argument('--proxy-server={}'.format(self._proxy_server))
```

4. Append the following details:

```
bypass_list = ["*abc.com", "*xyz1.com", "*xyz2.com"]
chrome_options.add_argument('--proxy-bypass-list=%s' % ";".join(bypass_list))
```

Domain URLs that you specify in `bypass_list` are not redirected to the proxy server. You can add any number of domains in the `bypass_list`. All other unspecified domain URLs are redirected to the proxy server.

5. Specify the proxy server address on the `values.yaml` file. See [Key-Value Pairs Configuration](#).

**i** If you make any changes to the `bypass_list` after building the docker image, you must rebuild the docker image.

## Deploy PSA in Minikube

Download the PSA installation zip file from the [Appdynamics Downloads Portal](#) or from the beta upload tool. This file contains Docker files for sum-chrome-agent, sum-api-monitoring-agent, sum-heimdall, Helm charts, and automation scripts. To build an image for sum-chrome-agent, sum-api-monitoring-agent, and sum-heimdall, ensure that Docker is installed. You can download and install Docker from [here](#) if it is not installed.

Perform the following steps to install PSA:

1. Unzip the PSA installation zip file.
2. Run the following command to install PSA in Minikube:

```
./install_psa -e minikube -l -v -u <Shepherd-URL> -a <EUM-account> -k <EUM-key> -c <location-code> -d <location-description> -t <location-name> -s <location-state> -o <location-country> -i <location-latitude> -g <location-longitude> -p <PSA-tag> -r <heimdall-replica-count> -z <agent-type> -m <chrome-agent_min/max-memory> -n <API-agent_min/max-memory> -x <chrome-agent_min/max-CPU> -y <API-agent_min/max-CPU> -b <heimdall_min/max-memory> -f <heimdall_min/max-CPU> -q <ignite-persistence>
```

A sample installation command looks like this:

```
./install_psa -e minikube -u <Shepherd-URL> -a <EUM-account> -k <EUM-key> -c DEL -d Delhi -t Delhi -s DEL -o India -i 28.70 -g 77.10 -p 23.5 -r 1 -z all -m 100Mi/500Mi -n 100Mi/100Mi -x 0.5/1.5 -y 0.1/0.1 -b 2Gi/2Gi -f 2/2 -q true
```

The following table describes the usage of the flags in the command. Asterisk (\*) on the description denotes mandatory parameters.

Flag	Description
-e	Environment For example, Docker, Minikube, or Kubernetes.
-l	Load images to the Minkube environment
-v	Debug mode
-u	*Shepherd URL For example, <code>https://sum-shadow-master-shepherd.saas.appd-test.com/</code>

Flag	Description
-a	*EUM Account For example, <code>Ati-23-2-saas-nov2</code>
-k	*EUM Key For example, <code>2d35df4f-92f0-41a8-8709-db54eff7e56c</code>
-c	*Location Code For example, <code>DEL</code> for Delhi, <code>NY</code> for New York
-d	*Location Description For example, <code>'Delhi, 100001'</code>
-t	*Location City For example, Delhi
-s	*Location State For example, <code>CA</code> for California
-o	*Location Country For example, India, United States
-i	Location Latitude For example, <code>28.70</code> for Delhi
-g	Location Longitude For example, <code>77.10</code> for Delhi
-p	*PSA release tag For example, <code>23.5</code>
-r	Heimdall replica count
-z	Agent type For example, web, api, or all
-m	Minimum/Maximum memory in Mi/Gi for <code>sum-chrome-agent</code>

Flag	Description
-n	Minimum/Maximum memory in Mi/Gi for <code>sum-api-monitoring-agent</code>
-x	Minimum/Maximum CPU for <code>sum-chrome-agent</code>
-y	Minimum/Maximum CPU for <code>sum-api-monitoring-agent</code>
-b	Minimum/Maximum memory in Mi/Gi for <code>sum-heimdall</code>
-f	Minimum/Maximum CPU for <code>sum-heimdall</code>
-q	Specify <code>true</code> or <code>false</code> to enable or disable Ignite Persistence.

## Monitor the Kubernetes Cluster

The Helm chart `sum-psa-monitoring.tgz` in the zip you downloaded installs the monitoring stack. This Helm chart installs [kube-prometheus-stack](#) along with a custom Grafana dashboard to monitor the Private Simple Synthetic Agent.

**i** Monitoring the deployment is optional; however, we highly recommend that you monitor the cluster to check its health periodically.

## Install the Monitoring Stack

1. To create a separate `monitoring` namespace, enter:

```
kubectl create namespace monitoring
```

To review configuration options, enter:

```
helm show values sum-psa-monitoring.tgz > values-monitoring.yaml
```

This generates a `values-monitoring.yaml` file that contains all the configuration options. To modify and pass the generated `values-monitoring.yaml` file while installing the Helm chart, enter:

```
helm install psa-monitoring sum-psa-monitoring.tgz --values values-monitoring.yaml --namespace monitoring
```

2. After the monitoring stack is installed, you can Launch Grafana (which runs inside the cluster) to view the dashboard. To access Grafana from outside of the cluster, you can configure port forwarding or set up [Ingress](#). To configure port forward to access it locally, enter:

```
kubectl port-forward svc/psa-monitoring-grafana 3000:80 --namespace monitoring
```

3. Launch `localhost:3000` from the browser and log in using the default credentials with username as `admin` and password as `prom-operator`. A dashboard named Private Simple Synthetic Agent displays and provides details about the Kubernetes cluster, Apache Ignite, Heimdall, and running measurements.

## Uninstall PSA

To uninstall PSA, run the following command:

```
./uninstall_psa -e -p -m
```

The following table describes the usage of the flags in the command.

Flag	Description
-e	Environment For example, Docker, Minikube, or Kubernetes.
-p	Uninstall PSA only
-m	Uninstall PSA and Minikube

## Upgrade PSA in Minikube

### Upgrade the Private Synthetic Agent

To upgrade the PSA, perform the following steps:

1. [Build the Docker Image](#)
2. (Optional) [Add Custom Python Libraries](#)
3. [Tag and Push Images to the Registry](#)
4. [Update the Helm Chart](#)
5. [Upgrade the PSA](#)

### Build the Docker Image

1. Download the latest version of the PSA file from the Appdynamics Downloads Portal. This file contains Dockerfiles for `sum-chrome-agent`, `sum-heimdall`, and Helm charts used to install the agent and set up monitoring.
2. Build image for `sum-heimdall`:

 To build an image for `sum-chrome-agent` and `sum-heimdall`, ensure that Docker is installed. If it is not installed, you can download and install Docker from [here](#).

- a. Unzip the file to access the `sum-heimdall` directory.
- b. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-heimdall:<heimdall-tag> .
```

**i** You can use any value for `<heimdall-tag>` and `<agent-tag>`, but ensure that you use the same value in the subsequent [steps](#).

## Add Custom Python Libraries

This is an optional step. In addition to the available standard set of libraries, you can add custom Python libraries to the agent to use in scripted measurements. You build a new image based on the image you loaded as the base image.

1. Create a Dockerfile and then create `RUN` directives to run `python` `pip`. For example, to install the library `algorithms` you can create a Dockerfile:

```
Use the sum-chrome-agent image we just loaded as the base image
FROM sum-chrome-agent:<agent-tag>

Install algorithm for python3 on top of that
RUN python3 -m pip install algorithms==0.1.4

We can add more RUN directives for installing more libraries
RUN python3 -m pip install ...
```

**i** You can create any number of `RUN` directives to install the required libraries.

2. To build the new image, enter:

```
docker build -t sum-chrome-agent:<agent-tag> - < Dockerfile
```

The newly built agent image contains the required libraries.

## Tag and Push Images to the Registry

**i** Managed Kubernetes services, such as EKS or AKS, provide container registries where you can push your image. No other configuration is needed. Kubernetes cluster within EKS or AKS will have the access to these images.

To tag the images, enter:

```
docker save sum-heimdall:<heimdall-tag> | (eval $(minikube docker-env) && docker load)
docker save sum-chrome-agent:<agent-tag> | (eval $(minikube docker-env) && docker load)
```

## Update the Helm Chart

Follow these [steps](#) and update the configuration key value pairs in the `values.yaml` file:

Upgrade the PSA

Navigate to the new Linux distribution folder and run this command:

```
helm upgrade heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
```

## Set up PSA in Azure AKS

Set up the Web Monitoring PSA and API Monitoring PSA in Azure AKS as follows. If you want to set up PSA in an existing Kubernetes cluster, skip the [Create the Kubernetes Cluster](#) section.

1. [Create the Kubernetes Cluster](#).
2. [Deploy PSA in AKS](#).
3. [Monitor the Kubernetes cluster](#).

This document contains links to Azure CLI documentation. AppDynamics makes no representation as to the accuracy of Azure CLI documentation because Azure CLI controls its own documentation.

You can deploy PSA on an existing Kubernetes cluster in public or private clouds. The automation scripts do not support Kubernetes cluster creation.

- If you use the automated script, you must manually set up the Kubernetes cluster and nodes and log in to container registries before deploying PSA.
- If you use a separate registry, specify the registry in the automated script before deploying PSA:
  - a. Open the `install_psa` file and go to the `push_images_to_docker_registry()` function.
  - b. Under that function, after ``${DOCKER_REGISTRY_URL}`/`, specify the registry names of `sum-chrome-agent`, `sum-api-monitoring-agent`, and `sum-heimdall`.
  - c. Under the `generate_psa_k8s_deployment()` function, update the repository names on the YAML values.
- You must build the images on the host with the same OS type of Kubernetes cluster nodes.

## Create the Kubernetes Cluster

To create a Kubernetes cluster in Azure AKS:

1. [Install and authenticate](#) Azure CLI.
2. To create a resource group, enter

```
RESOURCE_GROUP=heimdall-onprem
az group create --name $RESOURCE_GROUP --location eastus
```

3. To create a container registry, enter:

```
ACR_NAME=heimdallonprem
az acr create --resource-group $RESOURCE_GROUP --name $ACR_NAME --sku Basic
```

4. To create a cluster, enter:

```
CLUSTER_NAME=heimdall-onprem
az aks create \
 --resource-group $RESOURCE_GROUP \
 --name $CLUSTER_NAME \
 --enable-managed-identity \
 --kubernetes-version 1.x.x \
 --node-count 4 \
 --node-vm-size Standard_D8s_v3 \
 --generate-ssh-keys \
 --attach-acr $ACR_NAME
```

**i** Replace the `kubernetes-version` in the above code with one of the supported versions. See [Supported Kubernetes versions](#).

**i** The `node-vm-size` and `node-count` in the above code are selected according to the recommended configuration type. You can specify a configuration of your choice with a different type and number of nodes. See [node-vm-size](#).

**i** You must be the owner or administrator of the Azure subscription to run the `--attach-acr` command.

### Access the Cluster

To access the Kubernetes cluster, follow these [instructions](#) to install kubectl, a utility to interact with the cluster.

To verify that the cluster is running, enter:

```
kubectl get nodes
```

### (Optional) Configure Proxy Server

**i** Configuring a proxy server is supported only on Web Monitoring PSA.

When you configure a proxy server, it applies to all the domains. To configure a proxy server only for certain domains, perform the following steps:

1. Navigate to the `sum-chrome-agent/agent` directory.
2. Open the `chrome.py` file.
3. Navigate to the following string:

```
if self._proxy_server:
 chrome_options.add_argument('--proxy-server={}'.format(self._proxy_server))
```

4. Append the following details:

```
bypass_list = ["*abc.com", "*xyz1.com", "*xyz2.com"]
chrome_options.add_argument('--proxy-bypass-list=%s' % ";".join(bypass_list))
```

Domain URLs that you specify in `bypass_list` are not redirected to the proxy server. You can add any number of domains in the `bypass_list`. All other unspecified domain URLs are redirected to the proxy server.

5. Specify the proxy server address on the `values.yaml` file. See [Key-Value Pairs Configuration](#).

**i** If you make any changes to the `bypass_list` after building the docker image, you must rebuild the docker image.

## Deploy PSA in AKS

Download the PSA installation zip file from the [Appdynamics Downloads Portal](#) or from the beta upload tool. This file contains Docker files for `sum-chrome-agent`, `sum-api-monitoring-agent`, `sum-heimdall`, Helm charts, and automation scripts. To build an image for `sum-chrome-agent`, `sum-api-monitoring-agent`, and `sum-heimdall`, ensure that Docker is installed. You can download and install Docker from [here](#) if it is not installed.

Perform the following steps to install PSA:

1. Unzip the PSA installation zip file.
2. Run the following command to install PSA in AKS:

```
./install_psa -e kubernetes -l -v -u <Shepherd-URL> -a <EUM-account> -k <EUM-key> -c <location-code> -d <location-description> -t <location-name> -s <location-state> -o <location-country> -i <location-latitude> -g <location-longitude> -p <PSA-tag> -r <heimdall-replica-count> -z <agent-type> -m <chrome-agent_min/max-memory> -n <API-agent_min/max-memory> -x <chrome-agent_min/max-CPU> -y <API-agent_min/max-CPU> -b <heimdall_min/max-memory> -f <heimdall_min/max-CPU> -q <ignite-persistence>
```

A sample installation command looks like this:

```
./install_psa -e kubernetes -u <Shepherd-URL> -a <EUM-account> -k <EUM-key> -c DEL -d Delhi -t Delhi -s DEL -o India -i 28.70 -g 77.10 -p 23.5 -r 1 -z all -m 100Mi/500Mi -n 100Mi/100Mi -x 0.5/1.5 -y 0.1/0.1 -b 2Gi/2Gi -f 2/2 -q true
```

The following table describes the usage of the flags in the command. Asterisk (\*) on the description denotes mandatory parameters.

Flag	Description
-e	Environment For example, Docker, Minikube, or Kubernetes.
-l	Load images to the Minkube environment
-v	Debug mode
-u	*Shepherd URL For example, <code>https://sum-shadow-master-shepherd.saas.appd-test.com/</code>
-a	*EUM Account For example, <code>Ati-23-2-saas-nov2</code>
-k	*EUM Key For example, <code>2d35df4f-92f0-41a8-8709-db54eff7e56c</code>
-c	*Location Code For example, <code>DEL</code> for Delhi, <code>NY</code> for New York
-d	*Location Description For example, <code>'Delhi, 100001'</code>
-t	*Location City For example, Delhi
-s	*Location State For example, <code>CA</code> for California
-o	*Location Country For example, India, United States
-i	Location Latitude For example, <code>28.70</code> for Delhi
-g	Location Longitude For example, <code>77.10</code> for Delhi

Flag	Description
-p	*PSA release tag For example, 23.5
-r	Heimdall replica count
-z	Agent type For example, web, api, or all
-m	Minimum/Maximum memory in Mi/Gi for sum-chrome-agent
-n	Minimum/Maximum memory in Mi/Gi for sum-api-monitoring-agent
-x	Minimum/Maximum CPU for sum-chrome-agent
-y	Minimum/Maximum CPU for sum-api-monitoring-agent
-b	Minimum/Maximum memory in Mi/Gi for sum-heimdall
-f	Minimum/Maximum CPU for sum-heimdall
-q	Specify true or false to enable or disable Ignite Persistence.

## Monitor the Kubernetes Cluster

The Helm chart `sum-psa-monitoring.tgz` in the zip you downloaded installs the monitoring stack. This Helm chart installs `kube-prometheus-stack` along with a custom Grafana dashboard to monitor the Private Simple Synthetic Agent.

**i** Monitoring the deployment is optional; however, we highly recommend that you monitor the cluster to check its health periodically.

## Install the Monitoring Stack

1. To create a separate `monitoring` namespace, enter:

```
kubectl create namespace monitoring
```

To review configuration options, enter:

```
helm show values sum-psa-monitoring.tgz > values-monitoring.yaml
```

This generates a values-monitoring `.yaml` file that contains all the configuration options. To modify and pass the generated values-monitoring `.yaml` file while installing the Helm chart, enter:

```
helm install psa-monitoring sum-psa-monitoring.tgz --values values-monitoring.yaml --namespace monitoring
```

2. After the monitoring stack is installed, you can Launch Grafana (which runs inside the cluster) to view the dashboard. To access Grafana from outside of the cluster, you can configure port forwarding or set up Ingress. To configure port forward to access it locally, enter:

```
kubectl port-forward svc/psa-monitoring-grafana 3000:80 --namespace monitoring
```

3. Launch `localhost:3000` from the browser and log in using the default credentials with username as `admin` and password as `prom-operator`. A dashboard named Private Simple Synthetic Agent displays and provides details about the Kubernetes cluster, Apache Ignite, Heimdall, and running measurements.

## Uninstall PSA

To uninstall PSA, run the following command:

```
./uninstall_psa -e kubernetes -p
```

## Upgrade PSA in Azure AKS

### Upgrade the Private Synthetic Agent

To upgrade the PSA, perform the following steps:

1. [Build the Docker Image](#)
2. (Optional) [Add Custom Python Libraries](#)
3. [Tag and Push Images to the Registry](#)
4. [Update the Helm Chart](#)
5. [Upgrade the PSA](#)

### Build the Docker Image

1. Download the latest version of the PSA file from the Appdynamics Downloads Portal. This file contains Dockerfiles for `sum-chrome-agent`, `sum-heimdall`, and Helm charts used to install the agent and set up monitoring.
2. Build image for `sum-heimdall`:

 To build an image for `sum-chrome-agent` and `sum-heimdall`, ensure that Docker is installed. If it is not installed, you can download and install Docker from [here](#).

- a. Unzip the file to access the `sum-heimdall` directory.
- b. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-heimdall:<heimdall-tag> .
```

**i** You can use any value for `<heimdall-tag>` and `<agent-tag>`, but ensure that you use the same value in the subsequent [steps](#).

## Add Custom Python Libraries

This is an optional step. In addition to the available standard set of libraries, you can add custom Python libraries to the agent to use in scripted measurements. You build a new image based on the image you loaded as the base image.

1. Create a Dockerfile and then create `RUN` directives to run `python` `pip`. For example, to install the library `algorithms` you can create a Dockerfile:

```
Use the sum-chrome-agent image we just loaded as the base image
FROM sum-chrome-agent:<agent-tag>

Install algorithm for python3 on top of that
RUN python3 -m pip install algorithms==0.1.4

We can add more RUN directives for installing more libraries
RUN python3 -m pip install ...
```

**i** You can create any number of `RUN` directives to install the required libraries.

2. To build the new image, enter:

```
docker build -t sum-chrome-agent:<agent-tag> - < Dockerfile
```

The newly built agent image contains the required libraries.

## Tag and Push Images to the Registry

**i** Managed Kubernetes services, such as EKS or AKS, provide container registries where you can push your image. No other configuration is needed. Kubernetes cluster within EKS or AKS will have the access to these images.

You must tag and push the images to a registry for the cluster to access them. You have to use the `ACR_NAME` environment variable while creating the cluster.

To tag the images, enter:

```
ACR_LOGIN_SERVER=$ACR_NAME.azurecr.io
docker tag sum-heimdall:<heimdall-tag> $ACR_LOGIN_SERVER/sum-heimdall:<heimdall-tag>
```

```
docker tag sum-chrome-agent:<agent-tag> $ACR_LOGIN_SERVER/sum-chrome-agent:<agent-tag>
```

To push the images, enter:

```
az acr login --name $ACR_NAME
docker push $ACR_LOGIN_SERVER/sum-heimdall:<heimdall-tag>
docker push $ACR_LOGIN_SERVER/sum-chrome-agent:<agent-tag>
```

Update the Helm Chart

Follow these [steps](#) and update the configuration key value pairs in the `values.yaml` file:

Upgrade the PSA

Navigate to the new Linux distribution folder and run this command:

```
helm upgrade heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace
measurement
```

## Set up PSA in Bare Metal K8s Using Amazon EC2

Set up the Web Monitoring PSA and API Monitoring PSA in Bare Metal K8s using Amazon EC2 as follows. If you want to set up PSA in an existing Kubernetes cluster, skip the [Create the Kubernetes Cluster](#) section.

1. [Create the Kubernetes Cluster.](#)
2. [Build and customize the Docker image.](#)
3. [Save Images to Minikube's Docker Daemon.](#)
4. [Deploy the Web Monitoring PSA and API Monitoring PSA.](#)
5. [Monitor the Kubernetes cluster.](#)

**i** Most of the steps are common for both Web Monitoring PSA and API Monitoring PSA. Wherever applicable, the differences in steps are highlighted.

**⚠** This document contains links to AWS CLI documentation. AppDynamics makes no representation as to the accuracy of AWS CLI documentation because AWS CLI controls its own documentation.

## Create the Kubernetes Cluster

**i** You can use kops to create your own managed Kubernetes cluster on AWS. If you want to create self-managed cluster on a different cloud or your own datacenter, you might want to look into other tools like Kubeadm or Kubespray. See [installing Kubernetes with deployment tools](#).

To create a Kubernetes cluster in Bare Metal K8s:

1. [Install](#) and [configure](#) AWS CLI.
2. To create IAM Role, enter.

```
aws iam create-group --group-name kops

aws iam attach-group-policy --policy-arn arn:aws:iam::aws:policy/AmazonEC2FullAccess --
group-name kops
aws iam attach-group-policy --policy-arn arn:aws:iam::aws:policy/AmazonRoute53FullAccess
--group-name kops
aws iam attach-group-policy --policy-arn arn:aws:iam::aws:policy/AmazonS3FullAccess --
group-name kops
aws iam attach-group-policy --policy-arn arn:aws:iam::aws:policy/IAMFullAccess --group-
name kops
aws iam attach-group-policy --policy-arn arn:aws:iam::aws:policy/AmazonVPCFullAccess --
group-name kops

aws iam create-user --user-name kops

aws iam add-user-to-group --user-name kops --group-name kops

aws iam create-access-key --user-name kops
```

3. Configure AWS CLI credentials using `aws configure` with the access key obtained in the previous step.
4. Based on your platform, install kops following these [instructions](#).
5. To create S3 bucket, enable versioning by entering:

```
bucket_name=heimdall-onprem-kops-state-store
aws s3api create-bucket \
--bucket ${bucket_name} \
--create-bucket-configuration LocationConstraint=us-west-2

aws s3api put-bucket-versioning --bucket ${bucket_name} --versioning-configuration
Status=Enabled
```

6. To create cluster, enter:

```
export KOPS_CLUSTER_NAME=heimdall-onprem.k8s.local
export KOPS_STATE_STORE=s3://${bucket_name}
export KOPS_KUBERNETES_VERSION=1.x.x

kops create cluster \
--node-count=4 \
--node-size=t3.2xlarge \
--zones=us-west-2a \
--kubernetes-version=${KOPS_KUBERNETES_VERSION} \
--name=${KOPS_CLUSTER_NAME}

kops update cluster --name ${KOPS_CLUSTER_NAME} --yes
```

**i** Specify the `KOPS_KUBERNETES_VERSION` from one of the [compatible versions](#).

**i** The `node-size` and `node-count` in the above code snippet are selected according to recommended configuration type. You can specify a configuration of your choice with a different type and number of nodes. See [EC2 instance types](#).

7. To validate if the cluster is running (might take some time for cluster to set up and run), enter:

```
kops validate cluster
```

### Access the Cluster

To access the Kubernetes cluster, follow these [instructions](#) to install kubectl, a utility to interact with the cluster.

To verify that the cluster is running, enter:

```
kubectl get nodes
```

### (Optional) Configure Proxy Server

**i** Configuring a proxy server is supported only on Web Monitoring PSA.

When you configure a proxy server, it applies to all the domains. To configure a proxy server only for certain domains, perform the following steps:

1. Navigate to the `sum-chrome-agent/agent` directory.
2. Open the `chrome.py` file.
3. Navigate to the following string:

```
if self._proxy_server:
 chrome_options.add_argument('--proxy-server={}'.format(self._proxy_server))
```

4. Append the following details:

```
bypass_list = ["*abc.com", "*xyz1.com", "*xyz2.com"]
chrome_options.add_argument('--proxy-bypass-list=%s' % ";".join(bypass_list))
```

Domain URLs that you specify in `bypass_list` are not redirected to the proxy server. You can add any number of domains in the `bypass_list`. All other unspecified domain URLs are redirected to the proxy server.

5. Specify the proxy server address on the `values.yaml` file. See [Key-Value Pairs Configuration](#).

**i** If you make any changes to the `bypass_list` after building the docker image, you must rebuild the docker image.

## Build and Customize the Docker Image

You can download the zip file for Simple Synth PSA installation from the Appdynamics Downloads Portal or from the beta upload tool.

This file contains Dockerfiles to install the agents and set up monitoring:

- **Web Monitoring PSA:** Dockerfiles for `sum-chrome-agent`, `sum-heimdall`, and Helm charts
- **API Monitoring PSA:** Dockerfiles for `sum-api-monitoring-agent`, `sum-heimdall`, and Helm charts

To build an image for `sum-chrome-agent`, `sum-api-monitoring-agent`, and `sum-heimdall`, ensure that Docker is installed. If it is not installed, you can download and install Docker from [here](#).

For `sum-chrome-agent`:

1. Unzip the zip file to access the `sum-chrome-agent` directory.
2. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-chrome-agent:<agent-tag> .
```

For `sum-api-monitoring-agent`:

1. Unzip the zip file to access the `sum-api-monitoring-agent` directory.
2. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-api-monitoring-agent:<agent-tag> .
```

For `sum-heimdall`:

1. Unzip the zip file to access the `sum-heimdall` directory.
2. Navigate to this directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-heimdall:<heimdall-tag> .
```

**i** You can use any value for `<heimdall-tag>` and `<agent-tag>`, but ensure that you use the same value in the subsequent [steps](#).

**i** If you are using macOS with an M1 chip, use the following commands:

### sum-chrome-agent

```
docker buildx build -f Dockerfile-PSA --platform=linux/amd64 -t sum-chrome-agent:<agent-tag> .
```

### sum-heimdall

```
docker buildx build -f Dockerfile-PSA --platform=linux/amd64 -t
sum-heimdall:<heimdall-tag> .
```

### sum-api-monitoring-agent

```
docker buildx build -f Dockerfile-PSA --platform=linux/amd64 -t
sum-api-monitoring-agent:<api-tag> .
```

## (Optional) Add Custom Python Libraries

**i** This section is applicable only for Web Monitoring PSA.

In addition to the available standard set of libraries, you can add custom Python libraries to the agent to use in scripted measurements. You build a new image based on the image you loaded as the base image

1. Create a Dockerfile and create `RUN` directives to run python pip. For example, to install the library `algorithms` you can create a Dockerfile:

```
Use the sum-chrome-agent image we just loaded as the base image
FROM sum-chrome-agent:<agent-tag>

Install algorithm for python3 on top of that
RUN python3 -m pip install algorithms==0.1.4

We can add more RUN directives for installing more libraries
RUN python3 -m pip install ...
```

**i** You can create any number of `RUN` directives to install the required libraries.

2. To build the new image, enter:

```
docker build -t sum-chrome-agent:<agent-tag> - < Dockerfile
```

The newly built agent image contains the required libraries.

## Tag and Push Images to the Registry

You must tag and push the images to a registry for the cluster to access it. It can be done in the following ways:

## Bare Metal K8S using EC2

Vanilla K8S runs on AWS infrastructure. As kops create and assign appropriate roles to the cluster nodes, they can directly access Elastic Container Registry (ECR), without any other configuration.

To tag images, enter:

### Web Monitoring PSA:

```
docker tag sum-heimdall:<heimdall-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall:<heimdall-tag>
docker tag sum-chrome-agent:<agent-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-chrome-agent:<agent-tag>
```

### API Monitoring PSA:

```
docker tag sum-heimdall:<heimdall-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall:<heimdall-tag>
docker tag sum-api-monitoring-agent:<agent-tag> <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-api-monitoring-agent:<agent-tag>
```

Replace `<aws_account_id>` and `<region>` with your account and region values.

To create repositories, enter:

### Web Monitoring PSA:

```
aws ecr create-repository --repository-name sum/sum-heimdall
aws ecr create-repository --repository-name sum/sum-chrome-agent
```

### API Monitoring PSA:

```
aws ecr create-repository --repository-name sum/sum-heimdall
aws ecr create-repository --repository-name sum/sum-api-monitoring-agent
```

To push the images, enter:

### Web Monitoring PSA:

```
aws ecr get-login-password --region us-west-2 | docker login --username AWS --password-stdin <aws_account_id>.dkr.ecr.<region>.amazonaws.com
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall:<heimdall-tag>
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-chrome-agent:<agent-tag>
```

### API Monitoring PSA:

```
aws ecr get-login-password --region us-west-2 | docker login --username AWS --password-stdin <aws_account_id>.dkr.ecr.<region>.amazonaws.com
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-heimdall:<heimdall-tag>
```

```
docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/sum/sum-api-monitoring-agent:<agent-tag>
```

## Bare Metal K8S using Private Registry

**i** If you are managing your own Kubernetes cluster which is not on AWS, then you must deploy your own registry server. See [deploy a registry server](#).

To tag images, enter:

### Web Monitoring PSA:

```
docker tag sum-heimdall:<heimdall-tag> <REGISTRY_HOST>:<REGISTRY_PORT>/sum-heimdall:<heimdall-tag>
docker tag sum-chrome-agent:<agent-tag> <REGISTRY_HOST>:<REGISTRY_PORT>/sum-chrome-agent:<agent-tag>
```

### API Monitoring PSA:

```
docker tag sum-heimdall:<heimdall-tag> <REGISTRY_HOST>:<REGISTRY_PORT>/sum-heimdall:<heimdall-tag>
docker tag sum-api-monitoring-agent:<agent-tag> <REGISTRY_HOST>:<REGISTRY_PORT>/sum-api-monitoring-agent:<agent-tag>
```

Replace `<REGISTRY_HOST>` and `<REGISTRY_PORT>` to what you configured while deploying the registry.

To push the images, enter:

### Web Monitoring PSA:

```
docker login <REGISTRY_HOST>:<REGISTRY_PORT>
docker push <REGISTRY_HOST>:<REGISTRY_PORT>/sum-heimdall:<heimdall-tag>
docker push <REGISTRY_HOST>:<REGISTRY_PORT>/sum-chrome-agent:<agent-tag>
```

### API Monitoring PSA:

```
docker login <REGISTRY_HOST>:<REGISTRY_PORT>
docker push <REGISTRY_HOST>:<REGISTRY_PORT>/sum-heimdall:<heimdall-tag>
docker push <REGISTRY_HOST>:<REGISTRY_PORT>/sum-api-monitoring-agent:<agent-tag>
```

## Deploy the Web Monitoring PSA and API Monitoring PSA

**i** Ensure that you follow the applicable sequence of steps when installing Web Monitoring PSA and API Monitoring PSA, respectively; some steps are common for both procedures.

The application is deployed to the cluster after the images are in the Registry. You use the Helm chart to deploy and create all Kubernetes resources in the required order.

1. Install Helm following these [instructions](#).
2. Create a new `ignite` namespace to run Apache Ignite pods.

 Ensure that you first run the Apache Ignite commands and then run the Heimdall commands.

To create a new `ignite` namespace, enter:

```
kubectl create namespace ignite
```

Before you deploy Apache Ignite, you must set some configuration options. To view the configuration options, navigate to the previously downloaded `ignite-psa.tgz` file and enter:

```
helm show values ignite-psa.tgz > values-ignite.yaml
```

 If you want to enable persistence, set `persistence > enabled`. This is an optional configuration.

3. To deploy the Helm chart using the above-mentioned configuration, navigate to the previously downloaded `ignite-psa.tgz` file and enter:

```
helm install synth ignite-psa.tgz --values values-ignite.yaml --namespace ignite
```

All the Kubernetes resources are created in the cluster, and you can use Apache Ignite. After a few seconds, Apache Ignite initializes and is visible in the Controller.

4. To verify if the pods are running, enter:

```
kubectl get pods --namespace ignite
```

Proceed to the next steps only after the Apache Ignite pods run successfully.

5. Create a new `measurement` namespace to run Heimdall and measurement pods.

To create a new `measurement` namespace, enter:

```
kubectl create namespace measurement
```

Using a single command, you can deploy the Helm chart, which contains the deployment details. To deploy the agent, use the Helm chart `sum-psa-heimdall.tgz` in the zip file that you downloaded previously. Before you deploy the Private Synthetic Agent, you must set some configuration options. To view the configuration options, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm show values sum-psa-heimdall.tgz > values.yaml
```

These are the configuration key-value pairs that you need to edit in the `values.yaml` file:  
**Web Monitoring PSA Using EC2:**

Configuration Key	Value
<code>heimdall &gt; repository</code>	<code>&lt;aws_account_id&gt;.dkr.ecr.&lt;region&gt;.amazonaws.com/sum/sum-heimdall</code>
<code>heimdall &gt; tag</code>	<code>&lt;heimdall-tag&gt;</code>
<code>heimdall &gt; pullPolicy</code>	<code>always</code>
<code>chromeAgent &gt; repository</code>	<code>&lt;aws_account_id&gt;.dkr.ecr.&lt;region&gt;.amazonaws.com/sum/sum-chrome-agent</code>
<code>chromeAgent &gt; tag</code>	<code>&lt;agent-tag&gt;</code>
<code>shepherd &gt; url</code>	Shepherd URL
<code>shepherd &gt; credentials</code>	credentials
<code>shepherd &gt; location</code>	agent location

**API Monitoring PSA Using EC2:**

Configuration Key	Value
<code>heimdall &gt; repository</code>	<code>&lt;aws_account_id&gt;.dkr.ecr.&lt;region&gt;.amazonaws.com/sum/sum-heimdall</code>
<code>heimdall &gt; tag</code>	<code>&lt;heimdall-tag&gt;</code>
<code>heimdall &gt; pullPolicy</code>	<code>always</code>
<code>apiMonitoringAgent &gt; repository</code>	<code>&lt;aws_account_id&gt;.dkr.ecr.&lt;region&gt;.amazonaws.com/sum/sum-api-monitoring-agent</code>
<code>apiMonitoringAgent &gt; tag</code>	<code>&lt;agent-tag&gt;</code>
<code>shepherd &gt; url</code>	Shepherd URL
<code>shepherd &gt; credentials</code>	credentials
<code>shepherd &gt; location</code>	agent location

**Web Monitoring PSA Using Private Registry:**

Configuration Key	Value
heimdall > repository	<REGISTRY_HOST>:<REGISTRY_PORT>/sum-heimdall
heimdall > tag	<heimdall-tag>
heimdall > pullPolicy	always
chromeAgent > repository	<REGISTRY_HOST>:<REGISTRY_PORT>/sum-chrome-agent
chromeAgent > tag	<agent-tag>
privateRegistry	true
shepherd > url	Shepherd URL
shepherd > credentials	credentials
shepherd > location	agent location

**API Monitoring PSA Using Private Registry:**

Configuration Key	Value
heimdall > repository	<REGISTRY_HOST>:<REGISTRY_PORT>/sum-heimdall
heimdall > tag	<heimdall-tag>
heimdall > pullPolicy	always
apiMonitoringAgent > repository	<REGISTRY_HOST>:<REGISTRY_PORT>/sum-api-monitoring-agent
apiMonitoringAgent > tag	<agent-tag>
privateRegistry	true
shepherd > url	Shepherd URL
shepherd > credentials	credentials
shepherd > location	agent location

**i** **After configuring using Private Registry**

Create registry credentials:

```
kubectl create secret docker-registry regcred --docker-
server=<REGISTRY_HOST>:<REGISTRY_PORT> --docker-
username=<your-name> --docker-password=<your-pword> --docker-
email=<your-email> --namespace measurement
```

Patch the default service account of the measurement namespace to use the `regcred` registry credentials:

```
kubectl patch serviceaccount default -p '{"imagePullSecrets":
[{"name": "regcred"}]}' --namespace measurement
```

You can leave the rest of the values set to their defaults or configure them based on your requirements. See [Configure Web Monitoring PSA and API Monitoring PSA](#) for details on shepherd URL, credentials, location, and optional key-value pairs.

**i** You need to replace `<aws_account_id>` and `<region>` with your account and region values.

**i** If the Kubernetes cluster is locked down, and you cannot make cluster-wide configuration, you can make pod-level changes. For example, if you want to change the pod-level DNS server setting to use your internal nameservers for DNS name resolution, specify the following details in the `values.yaml` file:

Configuration Key	Value
<code>agentDNSConfig:</code>	
<code>enabled:</code>	<code>true</code>
<code>dnsConfig:</code>	
<code>nameservers:</code>	<code>["4.4.4.4"]</code>
<code>searches:</code>	<code>["svc.cluster.local", "cluster.local"]</code>

6. To deploy the Helm chart using the above-mentioned configuration, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm install heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
```

All the Kubernetes resources are created in the cluster, and you can use Heimdall. After a few seconds, Heimdall initializes and is visible in the Controller.

7. To verify if the pods are running, enter:

```
kubectl get pods --namespace measurement
```

To make any changes to the `values.yaml` after the initial deployment, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm upgrade heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
```

 To remove the deployment:

```
helm uninstall heimdall-onprem --namespace measurement
```

This is not recommended unless it is required.

## Monitor the Kubernetes Cluster

The Helm chart `sum-psa-monitoring.tgz` in the zip you downloaded installs the monitoring stack. This Helm chart installs [kube-prometheus-stack](#) along with a custom Grafana dashboard to monitor the Private Simple Synthetic Agent.

 Monitoring the deployment is optional; however, we highly recommend that you monitor the cluster to check its health periodically.

## Install the Monitoring Stack

1. To create a separate `monitoring` namespace, enter:

```
kubectl create namespace monitoring
```

To review configuration options, enter:

```
helm show values sum-psa-monitoring.tgz > values-monitoring.yaml
```

This generates a `values-monitoring.yaml` file that contains all the configuration options. To modify and pass the generated `values-monitoring.yaml` file while installing the Helm chart, enter:

```
helm install psa-monitoring sum-psa-monitoring.tgz --values values-monitoring.yaml --namespace monitoring
```

2. After the monitoring stack is installed, you can Launch Grafana (which runs inside the cluster) to view the dashboard. To access Grafana from outside of the cluster, you can configure port forwarding or set up Ingress. To configure port forward to access it locally, enter:

```
kubectl port-forward svc/psa-monitoring-grafana 3000:80 --namespace monitoring
```

3. Launch localhost:3000 from the browser and log in using the default credentials with username as `admin` and password as `prom-operator`. A dashboard named Private Simple Synthetic Agent displays and provides details about the Kubernetes cluster, Apache Ignite, Heimdall, and running measurements.

## Upgrade PSA in Bare Metal K8s

### Upgrade the Private Synthetic Agent

To upgrade the PSA, perform the following steps:

1. [Build the Docker Image](#)
2. (Optional) [Add Custom Python Libraries](#)
3. [Tag and Push Images to the Registry](#)
4. [Update the Helm Chart](#)
5. [Upgrade the PSA](#)

#### Build the Docker Image

1. Download the latest version of the PSA file from the Appdynamics Downloads Portal. This file contains Dockerfiles for `sum-chrome-agent`, `sum-heimdall`, and Helm charts used to install the agent and set up monitoring.
2. Build image for `sum-heimdall`:

**i** To build an image for `sum-chrome-agent` and `sum-heimdall`, ensure that Docker is installed. If it is not installed, you can download and install Docker from [here](#).

- a. Unzip the file to access the `sum-heimdall` directory.
- b. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-heimdall:<heimdall-tag> .
```

**i** You can use any value for `<heimdall-tag>` and `<agent-tag>`, but ensure that you use the same value in the subsequent [steps](#).

#### Add Custom Python Libraries

This is an optional step. In addition to the available standard set of libraries, you can add custom Python libraries to the agent to use in scripted measurements. You build a new image based on the image you loaded as the base image.

1. Create a Dockerfile and then create `RUN` directives to run `python pip`. For example, to install the library `algorithms` you can create a Dockerfile:

```
Use the sum-chrome-agent image we just loaded as the base image
FROM sum-chrome-agent:<agent-tag>

Install algorithm for python3 on top of that
RUN python3 -m pip install algorithms==0.1.4

We can add more RUN directives for installing more libraries
RUN python3 -m pip install ...
```

 You can create any number of `RUN` directives to install the required libraries.

2. To build the new image, enter:

```
docker build -t sum-chrome-agent:<agent-tag> - < Dockerfile
```

The newly built agent image contains the required libraries.

### Tag and Push Images to the Registry

If you are managing your own Kubernetes cluster, then you must deploy your own registry server. For more details, see [Deploy a Registry Server](#).

After deploying the registry, tag and push the images.

 Replace `<REGISTRY_HOST>` and `<REGISTRY_PORT>` with the values that you used while deploying the registry.

To tag the images, enter:

```
docker tag sum-heimdall:<heimdall-tag> <REGISTRY_HOST>:<REGISTRY_PORT>/sum-heimdall:<heimdall-tag>
docker tag sum-chrome-agent:<agent-tag> <REGISTRY_HOST>:<REGISTRY_PORT>/sum-chrome-agent:<agent-tag>
```

To push the images, enter:

```
docker login <REGISTRY_HOST>:<REGISTRY_PORT> docker push <REGISTRY_HOST>:<REGISTRY_PORT>/sum-heimdall:<heimdall-tag>
docker push <REGISTRY_HOST>:<REGISTRY_PORT>/sum-chrome-agent:<agent-tag>
```

Update the Helm Chart

Follow these [steps](#) and update the configuration key value pairs in the `values.yaml` file:

Upgrade the PSA

Navigate to the new Linux distribution folder and run this command:

```
helm upgrade heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
```

### Set up the Web Monitoring PSA in a Windows Environment Using Minikube

- Minikube is installed in a single machine. Hence, it is not scalable or highly available when you set up PSA in Minikube.
- Functionality-wise, there is no difference between PSA in Minikube and PSA in AKS, EKS, GKE, or any other Kubernetes cluster.

Set up the Web Monitoring PSA in a Windows environment using Minikube as follows:

1. [Create an Azure Windows Virtual Machine](#)
2. [Set up Minikube in the Azure Windows Virtual Machine](#)
3. [Deploy Heimdall in the Minikube Cluster](#)

### Create an Azure Windows Virtual Machine

Perform the following steps:

1. Log in to the [Azure Portal](#).
2. Navigate to **Virtual Machines**.
3. Click **Create > Virtual Machine**, and then under **Instance details**, specify the following details:

Field	Description
Virtual machine name	Specify a name for the virtual machine.
Image	Windows Server 2019 Datacenter - Gen2
Size	Standard_D8s_v3 - 8 vcpus, 32 GiB memory (US\$ 483.26/month)

In the above scenario, a basic machine with 8 vCPUs and 32Gb memory is selected. For a higher load, you may have to select a bigger machine.

4. Under **Administrator account**, specify a username and password.

5. Click **Review + create**.

 The virtual machine deployment may take a few minutes to complete. When the deployment is complete, you can view the new virtual machine Under **Virtual Machines**.

6. Open the virtual machine, and click **Connect > RDP**.
7. On the next page, click **Download RDP File** to download the file.
8. Open the RDP file that you downloaded in the previous step. You will be prompted to specify a username and password. Use the username and password you created in [step 4](#).

 Any Remote Desktop application must be installed on your machine to open the file.

### Set up Minikube in the Azure Windows Virtual Machine

Perform the following steps:

1. Log in to the Virtual Machine that you created.
2. Install the [Chocolatey package manager](#).
3. Restart the Virtual Machine and open a new Powershell as an administrator.
4. Install Minikube:

```
choco install minikube
```

5. Install the Docker Desktop application:

```
choco install docker-desktop
```

6. Restart the Virtual Machine.
7. Launch the Docker Desktop application, then go to **Settings > Resources**.

 By default, only limited CPUs and Memory are allotted to Docker. Increase the resources allocation because the agent setup will run inside docker.

Example resource allocation:

Resources	Value
CPU's	8
Memory	25 GB
Swap	1 GB

Resources	Value
Disk image size	64 GB

8. Start the Minikube cluster:

```
minikube start --driver=docker
```

 This command also sets up `kubectl` .

### Deploy Heimdall in the Minikube Cluster

1. [Create the Kubernetes Cluster.](#)
2. [Build and customize the Docker image.](#)
3. [Save Images to Minikube's Docker Daemon.](#)
4. [Deploy the Private Synthetic Agent.](#)

### Create the Kubernetes Cluster

When you install Minikube on your machine, it comes with its Docker environment. If you build the Docker images on your machine and use those images for the Kubernetes deployment, it pulls the images from the Docker registry or hub and produces an error while starting the pod. This occurs because your machine's docker daemon and the Minikube docker daemon are different. Therefore, you must ensure that you use the Minikube docker daemon to build the docker images.

To use Minikube docker daemon, run this command:

```
minikube -p minikube docker-env | Invoke-Expression
```

Download the zip file for Simple Synth PSA installation from the Appdynamics Downloads Portal or from the beta upload tool, and then copy the file to your virtual machine.

To start the Kubernetes cluster:

```
minikube start --kubernetes-version=v1.x.x
```

### Build and Customize Image

Extract the SimpleSynthPrivateAgent.zip file in the virtual machine and perform these steps:

For sum-chrome-agent:

1. Unzip the zip file to access the sum-chrome-agent directory.
2. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-chrome-agent:<agent-tag> .
```

For sum-heimdall:

1. Unzip the zip file to access the sum-heimdall directory.
2. Navigate to the directory and run the following command:

```
docker build -f Dockerfile-PSA -t sum-heimdall:<heimdall-tag> .
```

**i** You can use any value for <heimdall-tag> and <agent-tag>, but ensure that you use the same value in the subsequent steps.

Verify that the images are built:

```
docker images
```

### Add Custom Python Libraries

This is an optional step. In addition to the available standard set of libraries, you can add custom Python libraries to the agent to use in scripted measurements. You build a new image based on the image you loaded as the base image.

1. Create a Dockerfile and create `RUN` directives to run python pip. For example, to install the library `algorithms` you can create a Dockerfile:

```
Use the sum-chrome-agent image we just loaded as the base image
FROM sum-chrome-agent:<agent-tag>

Install algorithm for python3 on top of that
RUN python3 -m pip install algorithms==0.1.4

We can add more RUN directives for installing more libraries
RUN python3 -m pip install ...
```

**i** You can create any number of `RUN` directives to install the required libraries.

2. To build the new image, enter:

```
docker build -t sum-chrome-agent:<agent-tag> - < Dockerfile
```

The newly built agent image contains the required libraries.

### Save Images to Minikube's Docker Daemon

You must tag and push the images to a registry for the cluster to access them. Execute the following command to save the images to Minikube docker:

```
docker save sum-heimdall:<heimdall-tag> | (eval $(minikube docker-env) && docker load)
docker save sum-chrome-agent:<agent-tag> | (eval $(minikube docker-env) && docker load)
```

## Deploy the Web Monitoring PSA

The application is deployed to the cluster after the images are in the Registry. You use the Helm chart to deploy and create all Kubernetes resources in the required order.

1. Install Helm using the Chocolatey package manager:

```
choco install kubernetes-helm
```

2. Create a new measurement namespace where Heimdall, Postgres database, and measurement pods will run.
3. To create a new measurement namespace, enter:

```
kubectl create namespace measurement
```

Using a single command, you can deploy the Helm chart which contains the deployment details. To deploy the agent, you use the Helm chart `sum-psa-heimdall.tgz` in the zip file that you downloaded previously. Before you deploy the Private Synthetic Agent, you must set some configuration options. To view the configuration options, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm show values sum-psa-heimdall.tgz > values.yaml
```

These are the configuration key value pairs that you need to edit in the `values.yaml` file:

Configuration Key	Value
heimdall > repository	sum-heimdall
heimdall > tag	<heimdall-tag>
heimdall > pullPolicy	Never
agent > repository	sum-chrome-agent
agent > tag	<agent-tag>
shepherd > url	Shepherd URL
shepherd > credentials	credentials

Configuration Key	Value
shepherd > location	agent location

You can leave the rest of the values set to their defaults or configure them based on your requirements.

- To deploy the Helm chart using the above-mentioned configuration, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm install heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
```

All the Kubernetes resources are created in the cluster and you can use Heimdall. After a few seconds, Heimdall initializes and is visible in the Controller.

- To verify if the pods are running, enter:

```
kubectl get pods --namespace measurement
```

To make any changes to the `values.yaml` after the initial deployment, navigate to the previously downloaded `sum-psa-heimdall.tgz` file and enter:

```
helm upgrade heimdall-onprem sum-psa-heimdall.tgz --values values.yaml --namespace measurement
```

 To remove the deployment:

```
helm uninstall heimdall-onprem --namespace measurement
```

This is not recommended unless it is required.

## Configure Web Monitoring PSA and API Monitoring PSA

This page describes how to configure the Web Monitoring PSA and API Monitoring PSA.

### In-Script Metadata Configuration

When you run Synthetic Jobs as scripted measurements, you can specify certain configuration options using in-script metadata. You must include these yaml-based configurations at the beginning of the script in the form of a comment block.

### Set Custom User Agent for Synthetic Scripts

To modify the default browser specific `user-agent` header to a custom `user-agent` header, add this in-script metadata at the beginning of the Synthetic script:

```
'''yaml
requestHeader:
 userAgent: "custom user agent"
'''
driver.get('http://127.0.0.1:20000/green.html')
```

### Include Synthetic Traffic in Browser RUM Traffic

The `user-agent` request headers in the Synthetic scripts are tagged so that the requests are not included in Browser RUM pages. You can set `tagUserAgent` to `false` to include the Synthetic traffic in the Browser RUM pages.

Enter the following in-script metadata at the beginning of the Synthetic script:

```
'''yaml
requestHeader:
 userAgent: "custom user agent"
 tagUserAgent: false
'''
driver.get('http://127.0.0.1:20000/green.html')
```

### Kubernetes Configuration

After you set up the Kubernetes cluster, push the images to the Docker registry, and deploy the Web Monitoring PSA or API Monitoring PSA using `sum-psa-heimdall.tgz` Helm chart, a `values.yaml` file is generated. Use the `values.yaml` file to dynamically configure the values while deploying the Web Monitoring PSA and API Monitoring PSA.

### Key-Value Pairs Configuration

You can replace the optional configuration values in the `values.yaml` file with the values in the table:

Configuration	Key-Value Pair	Description
Heimdall replica count	<code>heimdall &gt; replicaCount</code>	Indicates the Heimdall replica count.
Heimdall Resource allocations	<ul style="list-style-type: none"> <li><code>heimdallResources &gt; min_cpu</code></li> <li><code>heimdallResources &gt; max_cpu</code></li> <li><code>heimdallResources &gt; min_mem</code></li> <li><code>heimdallResources &gt; max_mem</code></li> </ul>	Indicates the Heimdall Resource allocation.

Configuration	Key-Value Pair	Description
Measurement Container Resource allocations	<p><b>Web Monitoring PSA:</b></p> <ul style="list-style-type: none"> <li>chromeAgentResources &gt; min_cpu</li> <li>chromeAgentResources &gt; max_cpu</li> <li>chromeAgentResources &gt; min_mem</li> <li>chromeAgentResources &gt; max_mem</li> </ul> <p><b>API Monitoring PSA:</b></p> <ul style="list-style-type: none"> <li>apiMonitoringAgentResources &gt; min_cpu</li> <li>apiMonitoringAgentResources &gt; max_cpu</li> <li>apiMonitoringAgentResources &gt; min_mem</li> <li>apiMonitoringAgentResources &gt; max_mem</li> </ul>	Indicates the measurement container resource allocations.
Logging level	logging > level to ERROR, WARN, INFO, DEBUG, or TRACE	Indicates the logging level. The default value is DEBUG.
Node selectors	<ul style="list-style-type: none"> <li>heimdallNodeSelector &gt;</li> <li>agentNodeSelector &gt;</li> </ul>	Apply Node selectors for Heimdall and measurement containers to schedule these components on specific nodes.

Configuration	Key-Value Pair	Description
Proxy	<p><b>Heimdall:</b></p> <pre>heimdall:   enabled: false   server: "&lt;proxy server address&gt;"</pre> <p><b>Web Monitoring PSA:</b></p> <pre>browserMonitoringAgent:   enabled: false   server: "&lt;proxy server address&gt;"</pre> <p><b>API Monitoring PSA:</b></p> <pre>apiMonitoringAgent:   enabled: false   server: "&lt;proxy server address&gt;"</pre>	<p>Configure the PSA to use a proxy for all requests leaving the cluster. Set the <code>enabled</code> field to <code>true</code> and specify the proxy server address in the <code>server</code> field in this format:</p> <pre>&lt;scheme&gt;://&lt;hostname&gt;:&lt;port&gt;</pre> <p>You can configure the same proxy server for all components or different proxy servers for each component.</p> <div style="border: 1px solid #00aaff; padding: 10px; margin-top: 10px;"> <p><b>i</b> This configuration is set to the deployment level and applies to all the domains or tests for that particular EUM license. If you have multiple proxy servers, you can use one proxy server for Web monitoring and another for API monitoring. All the tests will go through the configured proxy server irrespective of the domain.</p> </div>

### Connect Agent to the Synthetic Server

When deploying the Web Monitoring PSA or API Monitoring PSA in the Kubernetes cluster, you must specify the agent registration information in the `values.yaml` file. Heimdall uses this information to register itself with the Synthetic Server. Once registered, you can view the agent in the Controller and run measurements.

#### Shepherd URL

To connect the agent to a hosted Synthetic Cloud region, enter one of these shepherd URLs in the `values.yaml` file:

Region	Shepherd URL
us-west-2	<a href="https://synthetic.api.appdynamics.com">https://synthetic.api.appdynamics.com</a>
eu-central-1	<a href="https://fra-synthetic.eum-appdynamics.com">https://fra-synthetic.eum-appdynamics.com</a>

Region	Shepherd URL
ap-southeast-2	<a href="https://syd-synthetic.eum-appdynamics.com">https://syd-synthetic.eum-appdynamics.com</a>
ap-south-1	<a href="https://bom-synthetic.eum-appdynamics.com">https://bom-synthetic.eum-appdynamics.com</a>
eu-west-2	<a href="https://lon-synthetic.eum-appdynamics.com">https://lon-synthetic.eum-appdynamics.com</a>
ap-east-1	<a href="https://hkg-synthetic.eum-appdynamics.com">https://hkg-synthetic.eum-appdynamics.com</a>
sa-east-1	<a href="https://gru-synthetic.eum-appdynamics.com">https://gru-synthetic.eum-appdynamics.com</a>
af-south-1	<a href="https://cpt-synthetic.eum-appdynamics.com">https://cpt-synthetic.eum-appdynamics.com</a>
ap-southeast-1	<a href="https://singapore-synthetic.eum-appdynamics.com">https://singapore-synthetic.eum-appdynamics.com</a>

To connect the agent to your on-premises Synthetic Server, enter the shepherd URL ( `http://<on-premises-synthetic-server-host>:10101` ) in the `values.yaml` file.

**i** On-premises Synthetic Server versions  $\geq$  21.4.1 are supported. If you are on an older version, you must upgrade Synthetic Server to connect to the Linux-based PSA.

### EUM Account and License Key

To connect the agent to the Controller, you need the EUM account and license key.

Follow the given steps to obtain this information:

1. Navigate to the SaaS Controller.
2. Click the settings icon at the top-right corner to navigate to **License > Account Usage**.
3. Scroll down to the **User Experience** section.

Enter Account Name and License Key in the `values.yaml` file.

Configuration Key	Configuration Value
<code>shepherd &gt; credentials &gt; eumAccount</code>	Account Name
<code>shepherd &gt; credentials &gt; eumKey</code>	License Key

### Location Information

To identify the location of the agent, enter the following `shepherd > location` details in the `values.yaml` file:

- `name` - A user-friendly string for the location.
- `code` - A unique alphanumeric string with four to ten characters that identifies the location where the agent is running. You must create this ID based on the location name.

- `latitude`, `longitude` - Navigate to the GPS Coordinates with [Google Maps](#) to get the latitude and longitude of your location.

## Mobile Real User Monitoring

### Related pages:

- [Get Started with Mobile RUM](#)

Mobile Real User Monitoring (Mobile RUM) allows you to understand your native (iOS, Android) or hybrid (Xamarin, Cordova-based, React Native, Flutter, .NET MAUI) mobile applications as your end users actually use it.

Use Mobile RUM to:

- Understand and improve your mobile application's performance.
- Reduce crashes.
- Reduce errors.
- Learn about your users.
- Customize the data that Mobile RUM returns.

### How AppDynamics Agents Collect Data

To use Mobile RUM, you add a small piece of highly performant code, the Mobile Agent, to the source of your mobile application. This process is called *instrumenting* and is described in [Instrument iOS Applications](#), [Instrument Android Applications](#), [Instrument Xamarin Applications](#), [Instrument Cordova Applications](#), [Instrument Flutter Applications](#), and [Instrument React Native Applications](#).

As your end users interact with your application, the agent collects [metrics and any error information](#) on the application's performance and sends that information to the EUM Server, where it is processed. The EUM Server then makes the data available to the AppDynamics controller UI, where it is displayed in a series of dashboards and charts.

If your application crashes, the agent also creates a *crash snapshot* with information to help you analyze what happened, including the crashed function, the source file containing the crashed function, the line number, if available, and a stack trace of the application at the time of the crash, along with various other identifying data. And if the server-side application with which your mobile app interacts is also instrumented, you can get correlated metric information for the entire round-trip request life cycle.

### Get Started with Mobile RUM

To get started with Mobile RUM, see [Get Started with Mobile RUM](#).

### Get Started with Mobile RUM

To get started with Mobile RUM, you will need to follow these steps:

1. [Check your prerequisites](#)
2. [Review Controller capacity](#)
3. [Evaluate your mobile application](#)
4. [Complete the Getting Started Wizard](#)
5. [Instrument and verify your app](#)
6. [Configure network request naming and thresholds](#)

## Check Your Prerequisites

Before you can use AppDynamics to monitor your mobile application, you need to make sure you have the following prerequisites:

- An AppDynamics account with access to an AppDynamics Controller
- A Mobile RUM License
- Access to your mobile application source code

## Review Your Controller Capacity

If you use an on-premises Controller and plan to monitor mobile applications, assess your Controller's capacity to accommodate the increase in the number of metrics that Mobile RUM will generate. The number of individual metric data points generated depends on the level of activity of your mobile applications. As a rough guide, the use of Mobile RUM can increase the number of metric data points by as much as 15 to 25K per instrumented application, if your applications are heavily accessed by mobile users. The actual number depends on how many network requests your applications receive.

**i** The number of separate RUM metric *names* saved in the Controller database can be larger than the kinds of individual data points saved. For example, a metric name for a metric for iOS 5 might still be in the database even if all your users have migrated away from iOS 5. So, the metric name would no longer have an impact on resource utilization, but it would count against the default limit in the Controller for metric names per application. The default limit for *names* is 200,000 for Browser RUM and 100,000 for Mobile RUM.

## Evaluate Your Mobile Application

By default, Mobile RUM can monitor your application in two ways: network requests and crash reporting.

If you want to collect information on network requests, your application must make HTTP calls using specific classes:

- An iOS application must use `NSURLConnection` or `NSURLSession` to generate network requests.
- An Android application must itself (i.e., not via an external framework) use `URLConnection`, `HttpsURLConnection`, `HttpClient`, `OkHttp`, or `ch.boye.httpclientandroidlib` to generate network requests.
- Using the SDK, custom HTTP libraries can also be monitored and used by the agent itself. See [Customize the iOS Instrumentation](#) and [Customize the Android Instrumentation](#) for more information.

Even if your application does not generate network requests, or if you do not want to monitor that activity, you can use AppDynamics purely to monitor crashes. You can also extend the Mobile Agents using the SDK to collect other data, like how your application is functioning internally.

## Complete the Getting Started Wizard

Use the **Getting Started Wizard** to create a mobile app group, get an EUM App Key, and guide you through the instrumentation process. Once you have successfully completed the steps in the wizard, Mobile RUM will automatically be enabled for the created mobile app group.

1. In the Controller UI, select **Applications**.
2. Click **Create Applications**.
3. Select **Create Applications Using the Getting Started Wizard**.

4. In **User Experience**, go to the **Mobile** section and select the application type and complete the wizard.

**i** Your Controller must have a Mobile RUM license before you can enable the Mobile RUM functionality.

## Enable Mobile RUM

To enable Mobile RUM:

1. Open your mobile application.
2. From the left-hand navigation bar, click **Configuration**.
3. Toggle the **Mobile Monitoring** switch to **ON**.

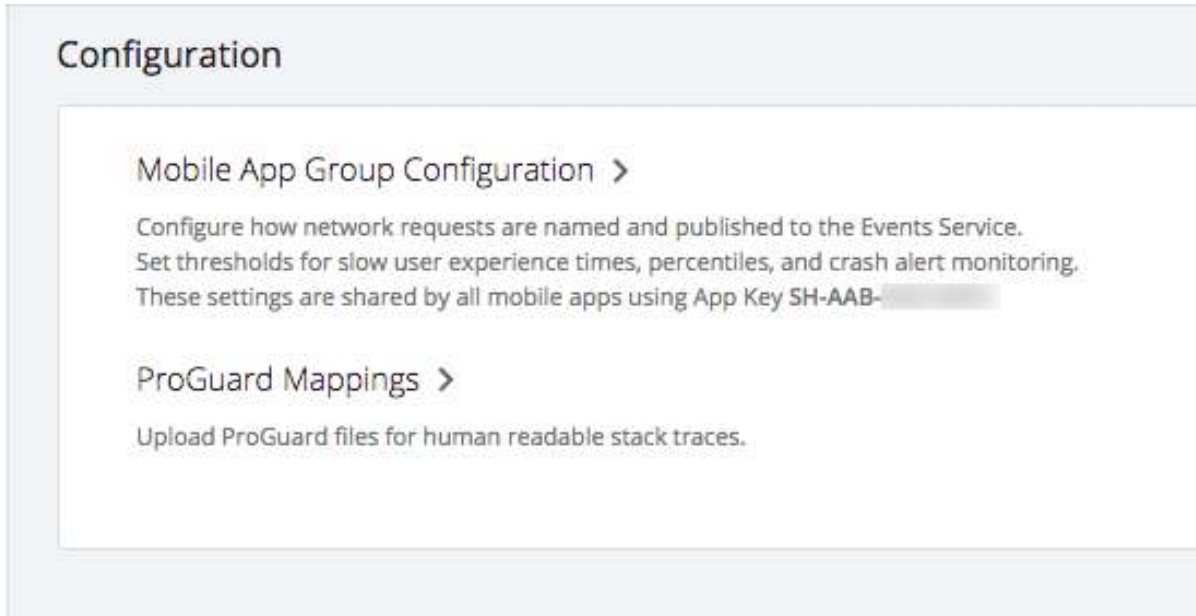

The screenshot shows the 'Mobile App Group Configuration' page. At the top, 'Mobile Monitoring' is toggled ON. Below this, there are tabs for 'Network Requests' and 'Settings'. Under 'Network Requests', there are sub-tabs for 'Monitor' and 'Events Service'. The 'Monitor' sub-tab is active, showing a 'Save' button and an 'Exclude Rules' section with an 'Add' button. Below that is an 'Include Rules' section with a table of rules. The table has columns for 'Name', 'Enabled', and 'Summary'. One rule is listed: 'Default Naming Configuration' with a green checkmark in the 'Enabled' column and the summary 'Name the Network Request using: Full-Domain; first 2 segments of the URL.' There is also a 'Save' button at the bottom of the 'Include Rules' section.

## Get Your Application Key

To find your App Key after you've completed the **Getting Started Wizard**:

1. Open your mobile application.
2. From the left-hand navigation bar, click **Configuration**.

- From the **Configuration** page, you can view the EUM App Key in the **Mobile App Group Configuration** section as shown below.

## Instrument and Verify Your App

The method you follow to instrument your app depends on your platform:

- [Instrument iOS Applications](#)
- [Instrument Android Applications](#)
- [Instrument Xamarin Applications](#)
- [Instrument Cordova Applications](#)

## Configure Network Request Naming and Thresholds

You can customize how you want the Controller to name your application's requests and what performance thresholds you want to be in effect. See [Configure the Controller UI for Mobile RUM](#).

## External Access

Mobile RUM is made up of several components, any or all of which can either be located on the Internet or hosted inside your own data center/network. On-premises access points are configured at installation or through the UI. If your installation requires access to any of these components on the Internet, see [Access the SaaS EUM Server](#) for more information.

## Confirm the Mobile Agent Connection to the Controller

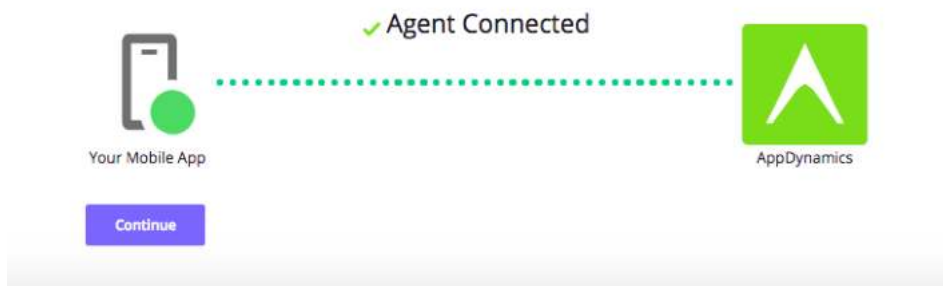

### Related pages:

- [Instrument iOS Applications](#)
- [Instrument Android Applications](#)

After you have instrumented your application, the **Getting Started Wizard** will show you a verification that the Mobile Agent has connected to the Controller.

## 5 Verify Your Instrumentation

Generate network requests on your instrumented application.

If you left the **Getting Started Wizard**, you can always verify the instrumentation by doing the following:

1. In the Controller, open **User Experience > Mobile Apps**.
2. Check the list of registered mobile applications to verify that the application is registered with the Controller. You can also use view some basic information about the app such as the health, sessions, crashes, network request information, and whether the monitoring is enabled.

Name	Health	Sessions	Crashes	Crash Rate	Network Requests	Network Requests per Minute	Network Errors per Minute	Monitoring En..
ECommerce - Android	✓	1,059	53	5.3%	6,461	14		Enabled
ECommerce - iOS	✓	1,054	70	6.2%	6,410	14		Enabled
ECommerce - E2E - EUM								
ECommerce - Sales - Mobile								
ECommerce - iOS	✓	4,814	309	5.9%	23,316	32	1	Enabled
ECommerce - Android	✓	4,687	313	6.2%	23,210	32	1	Enabled

3. Start monitoring your application. See [Overview of the Controller UI for Mobile RUM](#).

## AppDynamics iOS Sample App

AppDynamics offers an iOS Sample App where you can explore an instrumented sample application and look at code snippets to learn how to instrument your own iOS application. The Sample App contains a selection of examples showing how a mobile app on the iOS platform is instrumented with the AppDynamics iOS Agent.

### Sample App Features

In the Sample App you can:

- Build and run the Sample App.
- Explore the UI in the Sample App to see examples and code snippets, which helps you learn how to instrument your own app.
- Use the running Sample App to generate events and look at the logs in the Xcode console, which helps you verify and understand the way instrumentation works.
- View the results that show up in the AppDynamics Controller UI, which helps you see how events in the Sample App are reflected in the Controller.

### Who Can Use the Sample App

Anyone can use the Sample App to test and demo AppDynamics mobile instrumentation features. You only need the the following:

- Access to an AppDynamics Controller
- Some knowledge of Xcode

## Get the Sample App

The Sample App is hosted on Github at [github.com/CiscoDevNet/AppDynamicsSampleAppiOS](https://github.com/CiscoDevNet/AppDynamicsSampleAppiOS). See the [README file in Github](#) for instructions.

## Instrument iOS Applications

 With the iOS 14 release (supported by iOS Agent 20.10.0), Apple introduced a new data collection policy. See [iOS Data Collection Disclosure](#).

Before you can monitor your iOS application, you will need to instrument your application to enable the iOS Agent to collect mobile metrics.

After you have [set up and accessed Mobile RUM](#), follow these instructions:

1. [Install the iOS SDK](#)
2. [Instrument an iOS Application](#)
3. [Customize the iOS Instrumentation](#) (Optional)
4. [Troubleshoot the iOS Instrumentation](#) (Optional)

## Install the iOS SDK

### Related pages:

- [Instrument an iOS Application](#)
- [Customize the iOS Instrumentation](#)
- [Troubleshoot the iOS Instrumentation](#)

 With the iOS 14 release (supported by iOS Agent 20.10.0), Apple introduced a new data collection policy. See [iOS Data Collection Disclosure](#) for details.

The AppDynamics iOS SDK framework helps you to monitor the performance and activities of an iOS application. You can add the AppDynamics iOS SDK in your Xcode environment from the AppDynamics GitHub repository.

You can install the iOS SDK using CocoaPods, Swift Package Manager, or by manually downloading and installing it. We recommended that you use CocoaPods or Swift Package Manager to install the iOS SDK because it handles the dependencies, the build settings, and simplifies [upgrading](#).

- 
- Swift Package Manager install is supported for iOS Agent 23.10.1 or higher.
  - Download the list of copyrights and licenses for each Open Source components in iOS Agent. See, [Release Notes](#).

Follow the instructions for your preferred installation method:

- [CocoaPods Install](#)
- [Manual Install](#)
- [Swift Package Manager Install](#)

## iOS SDK Install Requirements

You must have the supported Xcode version.

Installation Type	Xcode Version
CocoaPods and Manual	>=7
Swift Package Manager	>=14.1

## CocoaPods Install

1. Add the line below to a `target` block in your Podfile:

```
pod 'AppDynamicsAgent'
```

For example:

```
platform :ios, '8.0'
use_frameworks!

target 'YourApp' do
 pod 'AppDynamicsAgent'
end
```

2. In your project directory, run this command:

```
pod install
```

## Manual Install

To manually install the iOS SDK, follow these steps:

- [Download the iOS SDK](#)
- [Add the Framework to the App](#)
- [Add Required Libraries](#)
- [Set the -ObjC Flag](#)
- [Update iOS Agent Using Swift Package Manager](#)

## Download the iOS SDK

1. Navigate to the [AppDynamics Download page](#).
2. From the **APP AGENT** list, check the **Mobile RUM Agent - iOS** checkbox.
3. Click **Download** for the latest iOS Agent that will appear in the **Releases** results. This downloads a file named `iOSAgent-<version>.zip`.

## Add the Framework to the App

 You can only use a Swift framework if that framework was built with the exact same version of Swift as the Xcode compiling your app.

1. Unzip `iOSAgent-<version>.zip`.
2. Import the `ADEUMInstrumentation.framework` (or `ADEUMInstrumentation.xcframework`) folder into your project Xcode.

 If you don't see that Xcode has automatically added the correct path(s), add a project-relative path to your frameworks.

## Add Required Libraries

The AppDynamics iOS Agent requires these libraries:

- `SystemConfiguration.framework`
- `CoreTelephony.framework`
- `libz.dylib` or `.tbd`

To add the libraries:

1. Select the target that builds your app in Xcode.
2. Select the Build Phases tab.
3. Expand the **Link Binary With Libraries** section.
4. If any of the above libraries are not listed:
  - Click the **+** button.
  - Locate the missing library in the list.
  - Click **Add**.

Repeat this step for each missing library.

## Set the -ObjC Flag

You also need to add the `-ObjC` flag to Other Linker Flags.

1. Select your project in the **Project Navigator**.
2. In the target list, select the target that builds your application.
3. Select the Build Settings tab.
4. Scroll to **Linking** and open.
5. Go to **Other Linker Flags** and double-click to open the popup.
6. If the `-ObjC` flag is not in your list, click **+** and add it.

 The `-ObjC` flag is necessary because the iOS Agent defines categories with methods that can be called at runtime, and by default, these methods are not loaded by the linker. As a result, you'll get an **"unrecognized selector"** runtime exception. The use of `-ObjC` ensures the methods will be loaded.

---

## Swift Package Manager Install

 Swift Package Manager install is supported for iOS Agent 23.10.1 or higher.

Complete the following steps in your Xcode environment to add the AppDynamics iOS SDK package:

1. Navigate to **File > Add Packages**.
2. In the search bar, specify the following GitHub URL:  
<https://github.com/CiscoDevNet/AppDynamicsAgent.git>
3. Specify the version that you want to add.
4. Click **Add Package**.
5. Select the package and the target application.
6. Click **Add Package**.

After you add the package, complete the following:

1. [Add the Required Libraries](#).
2. [Set the -Objc Flag](#).
3. [Automatically Upload the dSYM File to AppDynamics with Each Build](#).

## Update iOS Agent Using Swift Package Manager

Complete the following steps in your Xcode environment:

1. In the Package Dependencies section, navigate to the AppDynamics Agent package.
2. Right click the AppDynamics Agent package and click Update Package
3. Change the version rule to match the update version.

For more information, see [Adding package dependencies to your app](#).

## Upgrade the iOS SDK

### Upgrade with CocoaPods

1. In your project directory, run this command: `$ pod update`
2. Rebuild.

### Upgrade Manually

To pick up new features or to get crucial bug fixes you want to upgrade the iOS SDK in your app.

1. [Download the updated SDK](#).
2. [Replace the .framework file using the updated SDK](#).
3. Rebuild your app.

## Instrument an iOS Application

Follow these steps to get your EUM App Key and instrument your iOS apps.

- [Get Your Application Key](#)
- [Initialize the Agent](#)
- [Generate a dSYM File](#)
- [Monitor Crashes with the dSYM File](#)
- [Customize the Instrumentation \(Optional\)](#)
- [Configure the iOS Agent for On-Premises Deployments \(Optional\)](#)

## Get Your Application Key

After you completed the **Getting Started Wizard**, you were given an EUM App Key. You will need this key when you modify the source code. In some cases, multiple mobile applications can share the same key.

If you have completed the **Getting Started Wizard**, but don't have your EUM App Key, see [Get Your Application Key](#).

## Initialize the Agent

[Objective-C](#)   [Swift](#)   [Apple Watch Extensions](#)

Edit your app's `AppDelegate.m` file to initialize the Mobile Agent as soon as the app launches. This registers your application and only needs to be done once in your code.

1. In the `AppDelegate.m` file, add this `import` statement:

```
#import <ADEumInstrumentation/ADEumInstrumentation.h>
```

2. In the method `didFinishLaunchingWithOptions`, create an `ADEumAgentConfiguration` object with the EUM App Key that you received when completing the **Getting Started Wizard** to initialize the iOS Agent:

```
// Example EUM App Key: "AAA-AAB-AUM"
ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc]
initWithAppKey:<#EUM_APP_KEY#>];
```

Your code should look something like the following:

```
#import <ADEumInstrumentation/ADEumInstrumentation.h>
#import "AppDelegate.h"

// ...
-(BOOL)application:(UIApplication *)application didFinishLaunchingWithOptions:
(NSDictionary *)launchOptions
{
 // Example EUM App Key: "AAA-AAB-AUM"
 ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc]
initWithAppKey:<#EUM_APP_KEY#>];
 // other tasks
 return YES;
}
```

3. Configure the iOS Agent to report metrics and screenshots to the [SaaS EUM Server in your region](#) and initialize the agent by passing the `ADEumAgentConfiguration` object to the method `initWithConfiguration`. If you are using an on-premises EUM Server, see [Configure the iOS Agent for On-Prem Deployments \(Optional\)](#).

```
#import <ADEumInstrumentation/ADEumInstrumentation.h>
#import "AppDelegate.h"

// ...
-(BOOL)application:(UIApplication *)application didFinishLaunchingWithOptions:
(NSDictionary *)launchOptions
{
 ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc]
initWithAppKey:<#EUM_APP_KEY#>];
 //The default SaaS EUM Server and Screenshot Service are in the Americas,
 // so you can omit the following settings if you are in the Americas.
 config.collectorURL = "https://<your_region>-col.eum-appdynamics.com";
 config.screenshotURL = "https://<you_region>-image.eum-appdynamics.com/";
 [ADEumInstrumentation initWithConfiguration: config];
 // other tasks
 return YES;
}
```

4. (Optional) If your application is using another tool to report crashes, the iOS Agent may warn you with the following message:

```
Agent has detected a third party crash reporting tool. You may wish to disable
AppDynamics Crash Reporting by setting the crashReportingEnabled configuration flag to
NO
```

You are recommended to use only one crash reporting tool for better results. See [Disable Crash Reporting](#) for instructions on how to disable the iOS Agent's crash reporting.

5. Save the file.

Objective-C [Swift](#) Apple Watch Extensions

The iOS Agent is compatible with applications created using the Swift programming language.

1. In your application's `AppDelegate` class, add this `import` statement:

```
import ADEumInstrumentation
```

2. In the `AppDelegate` class `didFinishLaunchingWithOptions`, create an `ADEumAgentConfiguration` object with the EUM App Key that you received when completing the **Getting Started Wizard** to initialize the iOS Agent:

```
#import <ADEumInstrumentation/ADEumInstrumentation.h>
#import "AppDelegate.h"

// ...
```

```
func application(_ application: UIApplication, didFinishLaunchingWithOptions
launchOptions: [UIApplication.LaunchOptionsKey: Any]?) -> Bool {
 let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>)
}
```

- Configure the iOS Agent to report metrics and screenshots to the [SaaS EUM Server in your region](#), and initialize the agent by passing the `initWith()` method that takes the `ADEumAgentConfiguration` object as a parameter.

**i** If you are using an on-premises EUM Server, see [Configure the iOS Agent for On-Prem Deployments \(Optional\)](#).

```
#import <ADEumInstrumentation/ADEumInstrumentation.h>
#import "AppDelegate.h"

// ...
func application(_ application: UIApplication, didFinishLaunchingWithOptions
launchOptions: [UIApplication.LaunchOptionsKey: Any]?) -> Bool {
 let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>)
 config.collectorURL = "https://<your_region>.eum-appdynamics.com"
 config.screenshotURL = "https://<your_region>-image.eum-appdynamics.com"
 ADEumInstrumentation.initWith(config)
 // other tasks
 return true
}
// ...
```

- (Optional) If your application is using another tool to report crashes, the iOS Agent will warn you with the following message:

```
Agent has detected a third party crash reporting tool. You may wish to disable
AppDynamics Crash Reporting by setting the crashReportingEnabled configuration flag to
NO
```

We recommend you use only one crash reporting tool for better results. See [Disable Crash Reporting](#) for instructions on how to disable the iOS Agent's crash reporting.

- Save the file.

Objective-C   Swift   [Apple Watch Extensions](#)

Apps written for watchOS 1 contain a WatchKit extension that runs on the user's iPhone, but watchOS 2 also supports a new architecture, where the [WatchKit](#) extension runs on the Apple Watch itself. AppDynamics supports the watchOS 1 architecture, but not the new watchOS 2 architecture. Note that apps using the watchOS 1 architecture can run on both watchOS 1 and 2, so if your application is designed for watchOS 1, you can use AppDynamics on both versions of watchOS.

Because watchOS 1 apps are functionally launched in response to an interaction with the Watch UI, the SDK initialization code should be called at the point of that interaction in the iPhone app, which is usually not at the extension's `AppDelegate.m` call. The syntax remains the same.

## Generate a dSYM File

To enable the agent to provide human-readable information in the crash snapshots that are produced if the application crashes, compile with the `DWARF with dSYM file` option to generate a debug symbols (dSYM) file for the application. For more details about why you would want to do this, see [Get Human-Readable Crash Snapshots](#).

1. In Xcode, select your project in the **Project Navigator**.
2. In the target list, select the target that builds your application.
3. Select the **Build Settings** tab.
4. In the **Build Options** section, make sure that the **Debug Information Format** is set to `DWARF with dSYM File`.
5. Rebuild the Xcode project.

## Monitor Crashes with the dSYM File

This step is optional but highly recommended if you plan to monitor crashes. AppDynamics needs the dSYM file for the application to produce human-readable stack traces for crash snapshots.

For instructions, see [Upload the dSYM File](#).

## Customize the Instrumentation (Optional)

The `ADEumInstrumentation` class has additional methods to allow you to extend the kinds of data you can collect and aggregate using AppDynamics. There are five basic kinds of extensions that you can create:

- Custom timers: any arbitrary sequence of events within your code timed, even spanning multiple methods
- Custom metrics: any integer-based data you wish to collect
- User data: any string key/value pair you think might be useful
- Information points: how often a single method is invoked, and how long it takes to run
- Breadcrumbs: context for a crash

See [Customize the iOS Instrumentation](#).

## Configure the iOS Agent for On-Premises Deployments (Optional)

By default, the agent is configured to send its beacons to the EUM Cloud, which is an instance of the EUM Server running on AWS. If you wish to instrument your app in an environment that is using an on-premises version of the EUM Server, you need to modify the URL to which the agent sends its beacons. You do this using the `ADEumAgentConfiguration` object to set the Collector URL and the Screenshot Service URL to your on-premises EUM Server URL.

**i** The iOS Agent knows which path to use to make calls to different services (Collector/Screenshot Service). For example, if the EUM Server URL is `https://myEUMServerURL.com:7001`, the iOS Agent will know to use `https://myEUMServerURL.com:7001/eumcollector` to make requests to the EUM Collector. By specifying the Collector URL, you will *not* be able to use the SaaS deployment of the EUM Cloud for the Screenshot Service.

To get the EUM Server URL:

1. Open the [Administration Console](#).
2. From the left navigation bar, click **Controller Settings**.
3. In the search field, enter **eum.beacon.host** or **eum.beacon.https.host** if you're using HTTPS.
4. Copy the value for the configuration. This is your EUM Server URL.

The code examples below show how to set the Collector URL and Screenshot Service URL using Objective-C and Swift.

[Objective-C](#) [Swift](#)

```
ADEumAgentConfiguration *adeumAgentConfig = [[ADEumAgentConfiguration alloc]
initWithAppKey:<#EUM_APP_KEY#>];
// Set the Collector URL and Screenshot Service URL to the EUM Server URL.
adeumAgentConfig.collectorURL = <#COLLECTOR_URL:PORT#>;
adeumAgentConfig.screenshotURL = adeumAgentConfig.collectorURL;
[ADEumInstrumentation initWithConfiguration:adeumAgentConfig];
```

[Objective-C](#) [Swift](#)

```
let configuration = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>)
// Set the Collector URL and Screenshot Service URL to the EUM Server URL.
config.collectorURL = <#COLLECTOR_URL:PORT#>
config.screenshotURL = config.collectorURL
ADEumInstrumentation.initWith(configuration)
```

## Enable HTTP to Send Beacons to On-Premises EUM Servers

If you use an on-premises EUM Server and you wish to use HTTP to dispatch your beacons to the EUM Server, starting with iOS 9 you need to set a flag in your app's `info.plist` file to allow it to use the unsecured connection. By default, HTTPS is enforced in all iOS 9 applications by App Transport Security (ATS), and the iOS Agent complies with ATS when used with the EUM Cloud.

## Customize the iOS Instrumentation

### Related pages:

- [Install the iOS SDK](#)

**i** Because the agent [stores data about events in a local buffer](#) before reporting the information, you are recommended to use the APIs with discretion.

### Collect Additional Types of Data

You can use methods available in the `ADEUMInstrumentation` class to collect six additional types of data:

Type of Data	Description	Specifications	Where Data is Displayed
<a href="#">Info points</a>	How often a method is invoked, and how long it takes to run.	<ul style="list-style-type: none"> <li>• Data is numeric</li> <li>• Names must consist of alphanumeric characters and/or spaces</li> </ul>	<ul style="list-style-type: none"> <li>• <a href="#">Metric Browser</a></li> <li>• <a href="#">Custom Data</a></li> <li>• <a href="#">Network Request Snapshots</a></li> <li>• <a href="#">Mobile Sessions</a></li> <li>• <a href="#">Network Request Analyze</a></li> </ul>
<a href="#">Custom timers</a>	Any arbitrary sequence of events within your code timed, even spanning multiple methods.	<ul style="list-style-type: none"> <li>• Data is numeric</li> <li>• Metric names must consist of alphanumeric characters and/or spaces</li> </ul>	<ul style="list-style-type: none"> <li>• <a href="#">Metric Browser</a></li> <li>• <a href="#">Custom Data</a></li> </ul>
<a href="#">Custom metrics</a>	Any integer-based data you wish to collect.	<ul style="list-style-type: none"> <li>• Data is numeric</li> <li>• Metric names must consist of alphanumeric characters and/or spaces</li> </ul>	<ul style="list-style-type: none"> <li>• <a href="#">Metric Browser</a></li> <li>• <a href="#">Custom Data</a></li> </ul>

Type of Data	Description	Specifications	Where Data is Displayed
User data	Any string key/value pair you think might be useful. This data is included with all listed instrumentation types until it is cleared.	<ul style="list-style-type: none"> <li>Data can be any type</li> <li>Metric names have no restrictions</li> </ul>	<ul style="list-style-type: none"> <li>Network Request Snapshots</li> <li>Mobile Sessions</li> <li>Network Request Analyze</li> <li>Crash Snapshots</li> </ul>
Breadcrumbs	The context for a crash.	<ul style="list-style-type: none"> <li>Data can be any data type</li> <li>Metric names have no restrictions</li> </ul>	<ul style="list-style-type: none"> <li>Network Request Snapshots</li> <li>Mobile Sessions</li> <li>Network Request Analyze</li> <li>Crash Snapshots</li> </ul>
User interaction	Capture when users press buttons, click on lists, and select text.	<ul style="list-style-type: none"> <li>Data can be any data type</li> <li>Metric names have no restrictions</li> </ul>	<ul style="list-style-type: none"> <li>Network Request Snapshots</li> <li>Mobile Sessions</li> <li>Network Request Analyze</li> </ul>

**i** When you have set up additional data types, the Mobile Agent packages that data in a mobile beacon. Normally, the beacon is transmitted when the instrumented app sends an HTTP request or when the app is restarted following a crash, but if custom data has been collected and neither of those events has occurred for at least five minutes, the custom data is sent at that time.

### Info Points

Information points allow you to track how your own code is running. You can see how often a method is invoked, and how long it takes to run, by using `beginCall` and `endCall`, something like the following:

[Objective-C](#) [Swift](#)

```

- (void)myMethod
{
 id tracker = [ADEumInstrumentation beginCall:self selector:_cmd];
 // Implementation of method here ...
 [ADEumInstrumentation endCall:tracker];
}

```

[Objective-C](#) [Swift](#)

```
func myMethod() {
 let tracker = ADEumInstrumentation.beginCall(self, selector: #function)
 // Implementation of method here ...
 ADEumInstrumentation.endCall(tracker)
}
```

If an exception is thrown, it is also reported. This information appears in the **Custom Data** view in the Controller UI.

### Custom Timers

Custom timers allow you to time any arbitrary sequence of events within your code, even spanning multiple methods, by using `startTimer` and `stopTimer`. For example, to track the time a user spends viewing a screen, the instrumentation could look like this:

[Objective-C](#) [Swift](#)

```
- (void)viewDidAppear:(BOOL)animated {
 [super viewDidAppear:animated];
 [ADEumInstrumentation startTimerWithName:@"View Lifetime"];
}
- (void)viewDidDisappear:(BOOL)animated {
 [super viewDidDisappear:animated];
 [ADEumInstrumentation stopTimerWithName:@"View Lifetime"];
}
```

[Objective-C](#) [Swift](#)

```
func viewDidAppear(_ animated: Bool) {
 super.viewDidAppear(animated)
 ADEumInstrumentation.startTimer(withName: "View Lifetime")
}
func viewDidDisappear(_ animated: Bool) {
 super.viewDidDisappear(animated)
 ADEumInstrumentation.stopTimer(withName: "View Lifetime")
}
```

This information appears in the **Custom Data** view of the Controller UI.

Calling `startTimerWithName` again with the same name value resets a named timer.

## Custom Metrics

Any integer-based data can be passed to the agent. The first parameter to the `report.MetricWithName` call is the name you want the metric to appear under in the Controller UI. The metric name should only contain alphanumeric characters and spaces. Illegal characters are replaced by their ASCII hex value.

Reporting a metric called "My custom metric", for example, would look something like this:

```
[ADEumInstrumentation reportMetricWithName:@"My custom metric" value:<#VALUE HERE#>];
```

This information appears in the **Custom Data** view of the Controller UI.

## Custom User Data

You can set, and later remove any string key/value pair using with the following methods:

- `setUserData(key, value, success, error)`
- `removeUserData(key)`

Once this is set, user data continues to be sent along with any instrumentation for network requests, sessions, or crashes. You can remove any previously set user data on a per-key basis. Alternatively, you can remove previously set user data for all keys using `clearAllUserData()`.

### Parameters

The following table describes the parameters:

Name	Type	Description
key	string	The key identifying the key-value pair.
value	string	The value associated with the key.
success	function	The user-defined callback for successful cases.
error	function	The user-defined callback for failed cases.

### Example

The code example below shows how to set user data with the SDK API:

[Objective-C](#) [Swift](#)

```
- (void) onUserLoggedIn:(NSString *)userid {
 [ADEumInstrumentation setUserData:@"User ID" value:userid];
 ...
}
```

[Objective-C](#) [Swift](#)

```
func onUserLogged(in userid: String?) {
 ADEumInstrumentation.setUserData("User ID", value: userid)
}
```

The code example below shows how to remove user data with the SDK API:

[Objective-C](#) [Swift](#)

```
- (void) onUserLoggedIn:(NSString *)userid {
 [ADEumInstrumentation removeUserData:@"User ID"];
 ...
}
```

[Objective-C](#) [Swift](#)

```
func onUserLogged(in userid: String?) {
 ADEumInstrumentation.removeUserData("User ID")
 ...
}
```

You can also set user data with values of other types (Long, Boolean, Double, Date) using the following methods:

- [setUserDataLong:value](#)
- [setUserDataBoolean:value:](#)
- [setUserDataDouble:value:](#)
- [setUserDataDate:value:](#)

#### Understanding `clearAllUserData()`

The `clearAllUserData()` API clears all user data in the sense of clearing all of the above enumerated types of data at once. It does not clear any other data outside of the scope of items set with the AppDynamics `setUserData()` list of APIs described above. Also, it does not remove any user data already attached to existing instrumentation beacons that were previously queued for sending, and it does not affect user data attached on a per-request basis to network request instrumentation.

#### Example

The code example below shows how to use the `clearAllUserData` SDK API:

[Objective-C](#) [Swift](#)

```
- (void) onUserLoggedOut {
 [ADEumInstrumentation clearAllUserData];
 ...
}
```

Objective-C [Swift](#)

```
func onUserLoggedOut() {
 ADEumInstrumentation.clearAllUserData()
 ...
}
```

## Breadcrumbs

Breadcrumbs allow you to situate a crash in the context of your user's experience. Set a breadcrumb when something interesting happens. If your application crashes at some point in the future, the breadcrumb will be displayed along with the crash report.

There are two ways of leaving breadcrumbs:

- [Crash Reports Only](#)
- [Modal](#)

Using this method means that breadcrumbs are reported in crash reports only.

```
+ (void)leaveBreadcrumb:(NSString *)breadcrumb
```

Using this method lets you fine tune where the breadcrumbs are reported, either only in crash reports or in crash reports *and* sessions.

```
+ (void)leaveBreadcrumb:(NSString *)breadcrumb mode:(ADEumBreadcrumbVisibility)mode
```

Where `mode` is either:

- `ADEumBreadcrumbVisibilityCrashesOnly`
- `ADEumBreadcrumbVisibilityCrashesAndSessions`

**i** If the breadcrumb is over 2048 characters, it is truncated. If it is empty or nil, no breadcrumb is recorded. Each crash report displays the *most recent* 99 breadcrumbs.

## Capture User Interactions

You can enable the iOS Agent to track certain UI events triggered by user interactions. Once user interactions have been captured, you can sort sessions by UI event and view UI events in the timeline of the session waterfall.

You can capture when users do one or all of the following:

- press buttons
- select table cells
- select text fields
- select text views

### Security and Privacy Concerns

The interaction capture mode is disabled by default for security and privacy reasons as user interactions may contain sensitive information. Moreover, this potential security and privacy issue may be compounded if you enable both the capturing of UI interactions and screenshots.

## Enable User Interaction Capture Mode

To enable user interaction capture mode, you assign the capture mode to the property `interactionCaptureMode` of the `ADEumAgentConfiguration` object. The instrumentation code example below configures the iOS Agent to capture all the supported types of user interactions.

```
ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc] initWithAppKey:
<#EUM_APP_KEY#>];
config.interactionCaptureMode = ADEumInteractionCaptureModeAll;
[ADEumInstrumentation initWithConfiguration:config];
```

You can also configure the iOS Agent to only capture one type of user interaction:

```
ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc] initWithAppKey:
<#EUM_APP_KEY#>];
config.interactionCaptureMode = ADEumInteractionCaptureModeButtonPressed;
[ADEumInstrumentation initWithConfiguration:config];
```

## Programmatically Take Screenshots

By default, mobile screenshots are enabled on the agent-side but disabled on the Controller-side. To programmatically take manual screenshots, you must [enable screenshots in the Controller UI](#) and add the following API:

Objective-C    Swift

```
[ADEumInstrumentation takeScreenshot];
```

Objective-C [Swift](#)

```
ADEumInstrumentation.takeScreenshot()
```

## Disable Screenshots

You can disable screenshots from the Controller UI or with the iOS SDK. To disable screenshots with the iOS SDK, set the property `screenshotsEnabled` of the `ADEumAgentConfiguration` object to `NO` for Objective-C and `false` for Swift as shown below.

[Objective-C](#) [Swift](#)

```
ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc] initWithAppKey:
<#EUM_APP_KEY#>];
config.screenshotsEnabled = NO;
[ADEumInstrumentation initWithConfiguration:config];
```

Objective-C [Swift](#)

```
let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>);
config.screenshotsEnabled = false;
ADEumInstrumentation.initWith(config);
```

## Block and Unblock Screenshots

You can also use the iOS SDK to block screenshots from being taken during the execution of a code block. This just temporarily blocks screenshots from being taken until you unblock screenshots. This enables you to stop taking screenshots in situations where users are entering personal data, such as on login and account screens.

The `ADEumInstrumentation` class provides the methods `blockScreenshots` and `unblockScreenshots` to block and unblock screenshots. If screenshots are disabled through the property `screenshotsEnabled` of the `ADEumAgentConfiguration` object or through the Controller UI, these methods have no effect. You can also call `screenshotsBlocked` to check if screenshots are being blocked.

The following example demonstrates how you could use the API to block and unblock screenshots for a user login.

[Objective-C](#) [Swift](#)

```
#import "ADEumInstrumentation.h"
...
```

```

- (IBAction)loginUser:(id)sender {
 if(![ADEumInstrumentation screenshotsBlocked]) {
 [ADEumInstrumentation blockScreenshots];
 }
 LoginCredentials creds = [UserLogin getUserCreds];
 if(creds.authorized) {
 [LoginUser redirectToProfile:creds.user]
 [ADEumInstrumentation unblockScreenshots];
 }
}
...

```

Objective-C [Swift](#)

```

import ADEumInstrumentation
...

@IBAction func loginUser(_ sender: UIButton) {
 if(!ADEumInstrumentation.screenshotsBlocked()) {
 ADEumInstrumentation.blockScreenshots()
 }
 let creds = UserLogin.getUserCreds()
 if(creds.authorized) {
 LoginUser.redirectToProfile(creds.user)
 ADEumInstrumentation.unblockScreenshots()
 }
}
...

```

## Disable the Agent to Stop Sending User Data to the Collector

You can disable the agent to stop sending all data to the collector while the agent is initialized and running. For example, you can disable the agent if your app has an option for users to opt-out of monitoring for privacy reasons.

### shutdownAgent

The `shutdownAgent` call stops outgoing data to the collector, and does not persist data on the device.

[Objective-C](#) [Swift](#)

```
[ADEumInstrumentation shutdownAgent];
```

Objective-C [Swift](#)

```
ADEumInstrumentation.shutdownAgent()
```

- The call only stops the traffic out of the agent.
- Once the agent has been initialized, the call cannot be removed, and a license will have been consumed.
- If you want to make this state permanent for a device, add code in UserDefaults to save the state and use that flag to conditionally initialize the agent in your code.

### restartAgent

To re-enable the agent and reverse `shutdownAgent`, use `restartAgent`.

[Objective-C](#) [Swift](#)

```
[ADEumInstrumentation restartAgent];
```

[Objective-C](#) [Swift](#)

```
ADEumInstrumentation.restartAgent();
```

- This call will respect the server side calls that can remotely shutdown the agent in a similar way.
- The call is only in effect while the app is running.
- The call will be ignored if the agent has been remotely disabled.
- If the call is removed from memory and the app restarts, or the device is rebooted, the agent will be initialized as normal.

### Add a Crash Reporting Callback

You may want to make crash report information that Mobile RUM collects available to other parts of your code, for example, to Google Analytics, if you are using it. To enable you to pass on summary crash information, you can set up a crash report runtime callback. To get a callback when the iOS Agent detects and then reports a crash, you need to implement the following protocol in your code:

```
@protocol ADEumCrashReportCallback <NSObject>
- (void)onCrashesReported:(NSArray<ADEumCrashReportSummary *> *)crashReportSummaries;
@end
```

 This callback is invoked on your app's UI thread, so any significant work should be done on a separate work thread.

Each `ADEumCrashReportSummary` passed in has the following properties:

```
@interface ADEumCrashReportSummary : NSObject

/** Uniquely defines the crash, can be used as key to find full crash report. */
@property (nonatomic, readonly) NSString *crashId;

/** The exception name, may be `nil` if no `NSException` occurred. */
@property (nonatomic, readonly) NSString * ADEUM_NULLABLE exceptionName;

/** The exception reason, may be `nil` if no `NSException` occurred. */
@property (nonatomic, readonly) NSString * ADEUM_NULLABLE exceptionReason;

/** The Mach exception signal name */
@property (nonatomic, readonly) NSString *signalName;

/** The Mach exception signal code */
@property (nonatomic, readonly) NSString *signalCode;

@end
```

If you are sending the information to another analytics tool, such as Google Analytics, it is best to include all five properties:

- `exceptionName` and `exceptionReason` are optional and useful for a quick identification of what the crash is. These are only present if the crash cause occurred within an exception reporting runtime, such as Objective-C.
- `signalName` and `signalCode` are useful for quick identification of the crash. These are from the system and are independent of the runtime.
- For additional information, `crashId` can be used to look up the crash in the AppDynamics Controller UI.

For example, to print the crash information to iOS's logger, you could implement an `ADEumCrashReportCallback` class like this:

```
// assumes the containing object has "adopted" the protocol
- (void)onCrashesReported:(NSArray<ADEumCrashReportSummary *> *)summaries {
 for (ADEumCrashReportSummary *summary in summaries) {
 NSLog(@"Crash ID: %@", summary.crashId);
 NSLog(@"Signal: %@ (%@)", summary.signalName, summary.signalCode);
 NSLog(@"Exception Name:\n%@", summary.exceptionName);
 NSLog(@"Exception Reason:\n%@", summary.exceptionReason);
 }
}
```

You set the object that implements the `ADEumCrashReportCallback` protocol during agent configuration:

```
ADEumAgentConfiguration *config = [ADEumAgentConfiguration new];
config.crashReportCallback = myCrashReportCallback;
```

Your callback is invoked, on the main/UI thread, if a crash from a previous run is detected and collected. See the [latest iOS SDK documentation](#).

## Disable Crash Reporting

Crash reporting is enabled by default, but you can manually disable crash reporting through the instrumentation configuration. If you are using other crash reporting tools, you might disable crash reporting to minimize conflicts and optimize the crash report results.

You can disable crash reporting by configuring the instrumentation with the `crashReportingEnabled` property as shown in the following code example:

[Objective-C](#) [Swift](#)

```
ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc] initWithAppKey:appKey];
config.crashReportingEnabled = No
[ADEumInstrumentation initWithConfiguration:config];
```

[Objective-C](#) [Swift](#)

```
let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>);
config.crashReportingEnabled = false;
ADEumInstrumentation.initWith(config);
```

## Report Errors and Exceptions

The `domain: String` used to initialize the standard `NSError` object used for `reportError` should not use unique string such as Hashes, StackTraceID or ThreadID. Including those will create an infinite number of `Error Group` which will impact performance.

To add unique error strings and values, you have two data collection options:

- Add a string value as a breadcrumb. If the event/error, you are reporting has a single value attached, add the value to `leaveBreadcrumb`. See [Breadcrumbs](#)
- Add string name and integer values. If the event/error, you are reporting has both name and integer values attached, add the values to `reportMetricWithName`. See [Custom Metrics](#).

You can report exceptions using the method `reportError` from the `ADEumInstrumentation` class. Reported exceptions will appear in session details.

The method can have the following two signatures:

Objective-C Function Signature	Description
<pre>(void)reportError:(NSError *)error withSeverity (ADEumErrorSeverityLevel)severity;</pre>	<p>Use this signature to report errors, set the <a href="#">severity level</a> of the issue, and send the stack trace.</p> <p>This function signature sends the stack trace by default. If you don't want to send the stack trace, use the function signature below with the additional argument <code>andStackTrace</code> and set its value to <code>NO</code>.</p> <div style="background-color: #fff9c4; padding: 10px; border: 1px solid #ccc;"> <p> The domain: <code>String</code> used to initialize the standard <code>NSError</code> object used for <code>reportError</code> should not use unique string such as <code>Hashes</code>, <code>StackTraceID</code> or <code>ThreadID</code>. Including those will create an infinite number of <code>Error Group</code> which will impact performance.</p> <p>To add unique error strings and values, you have two data collection options:</p> <ul style="list-style-type: none"> <li>• Add a string value as a breadcrumb. If the event/error, you are reporting has a single value attached, add the value to <code>leaveBreadcrumb</code>. See <a href="#">Breadcrumbs</a></li> <li>• Add string name and integer values. If the event/error, you are reporting has both name and integer values attached, add the values to <code>reportMetricWithName</code>. See <a href="#">Custom Metrics</a>.</li> </ul> </div>

Objective-C Function Signature	Description
<pre>(void)reportError:(NSError *)error withSeverity: (ADEumErrorSeverityLevel)severity andStackTrace:(BOOL)stacktrace;</pre>	<p>Use this signature to report errors, set the <a href="#">severity level</a> of the issue, and explicitly specify whether the stack trace should be included.</p> <p>If you include the stack trace with the reported error by setting <code>stacktrace</code> to <code>YES</code>, you can view the stack trace in the <b>Code Issues Details</b> dialog.</p> <p>To report the error without the stack trace, set <code>stacktrace</code> to <code>NO</code>.</p> <div style="border: 1px solid #ccc; background-color: #fff9c4; padding: 10px; margin-top: 10px;"> <p> The string message used to construct a new throwable used for <code>reportError</code> should not use unique string such as hashes, <code>StackTraceID</code> or <code>ThreadID</code>. Including those will create an infinite number of <code>Error Group</code> which will impact performance. To add unique error strings and values, you have two data collection options:</p> <ul style="list-style-type: none"> <li>• Add a string value as a breadcrumb. If the event/error, you are reporting has a single value attached, add the value to <code>leaveBreadcrumb</code>. See <a href="#">Breadcrumbs</a></li> <li>• Add string name and integer values. If the event/error, you are reporting has both name and integer values attached, add the values to <code>reportMetricWithName</code>. See <a href="#">Custom Metrics</a>.</li> </ul> </div>

### Severity Levels

You can also set one of the following severity levels for an issue. With the severity level, you can filter errors in the **Code Issues Dashboard** or **Code Issues Analyze**.

- `ADEumErrorSeverityLevelInfo`
- `ADEumErrorSeverityLevelWarning`
- `ADEumErrorSeverityLevelCritical`

### Examples of Reporting Errors

The example below uses the API to report possible exceptions and set the severity level to `ADEumErrorSeverityLevelCritical` for a failed attempt to perform a file operation:

[Objective-C](#)   [Swift](#)

```
NSError *err = nil;
[[NSFileManager defaultManager] contentsOfDirectoryAtPath:@"pathToFile" error:&err];
if (err) {
```

```
[ADEumInstrumentation reportError:err withSeverity:ADEumErrorSeverityLevelCritical,
andStackTrace: NO];
} else {
 ...
}
```

Objective-C [Swift](#)

```
var err: Error? = nil
try? FileManager.default.contentsOfDirectory(atPath: "pathToFile")
if err != nil {
 ADEumInstrumentation.reportError(err, withSeverity: ADEumErrorSeverityLevelCritical,
andStackTrace: false)
} else {
 ...
}
```

You can also create and report custom errors with the following. Note that because `reportError` is not passed the argument `andStackTrace`, by default, the stack trace is automatically included with the error.

The `domain: String` used to initialize the standard `NSError` object used for `reportError` should not use unique string such as Hashes, `StackTraceID` or `ThreadID`. Including those will create an infinite number of `Error Group` which will impact performance.

To add unique error strings and values, you have two data collection options:

- Add a string value as a breadcrumb. If the event/error, you are reporting has a single value attached, add the value to `leaveBreadcrumb`. See [Breadcrumbs](#)
- Add string name and integer values. If the event/error, you are reporting has both name and integer values attached, add the values to `reportMetricWithName`. See [Custom Metrics](#).

Objective-C [Swift](#)

```
NSString *domain = @"com.YourCompany.AddUsers.ErrorDomain";
NSString *desc = NSLocalizedString(@"Unable to add user.", @"");
NSDictionary *userInfo = @{ NSLocalizedDescriptionKey : desc };
NSError *error = [NSError errorWithDomain:domain
 code:-101
 userInfo:userInfo];
[ADEumInstrumentation reportError:error withSeverity: ADEumErrorSeverityLevelWarning];
```

Objective-C [Swift](#)

```
var domain = "com.YourCompany.AddUsers.ErrorDomain"
```

```
var desc = NSLocalizedString("Unable to add user.", comment: "")
var userInfo = [NSLocalizedStringKey: desc]
var error = NSError(domain: domain, code: -101, userInfo: userInfo)
ADEumInstrumentation.reportError(error, withSeverity: ADEumErrorSeverityLevelWarning)
```

## Configure Application-Not-Responding (ANR) Detection

By default, the iOS Agent does not detect ANR issues, and when ANR detection is enabled, the ANR issues are reported without stack traces. You must manually enable ANR detection and set a flag to include stack traces through the iOS Agent configuration. For more information about ANR monitoring, see [Code Issues](#). To specify thresholds for ANR issues, see [Configure Application Not Responding Thresholds](#).

### Enable ANR Detection

You enable the detection of ANR issues by configuring the instrumentation with the `anrDetectionEnabled` property as shown below.

[Objective-C](#) [Swift](#)

```
ADEumAgentConfiguration *adeumAgentConfig = [[ADEumAgentConfiguration alloc]
initWithAppKey: <#EUM_APP_KEY#>];
// Enable ANR detection
adeumAgentConfig.anrDetectionEnabled = YES;
[ADEumInstrumentation initWithConfiguration:adeumAgentConfig];
```

[Objective-C](#) [Swift](#)

```
let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>);
// Enable ANR detection
config.anrDetectionEnabled = true;
ADEumInstrumentation.initWith(config);
```

### Report Stack Traces with ANRs

In addition to enabling ANR detection, you set the property `anrStackTraceEnabled` to `YES` (Objective-C) or `true` (Swift) to report stack traces with the ANRs.

[Objective-C](#) [Swift](#)

```
ADEumAgentConfiguration *adeumAgentConfig = [[ADEumAgentConfiguration alloc]
initWithAppKey: <#EUM_APP_KEY#>];
// Enable ANR detection
adeumAgentConfig.anrDetectionEnabled = YES;
// Set the flag to include stack traces with ANRs
```

```
adeumAgentConfig.anrStackTraceEnabled = YES;
[ADEumInstrumentation initWithConfiguration:adeumAgentConfig];
```

Objective-C [Swift](#)

```
let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>)
// Enable ANR detection
config.anrDetectionEnabled = true
// Set the flag to include stack traces with ANRs
config.anrStackTraceEnabled = true
ADEumInstrumentation.initWith(config)
```

## Configure Hybrid Application Support

By default, the iOS Agent instruments [iOS WKWebViews](#), but does not collect and report Ajax calls. See [Hybrid Application Support](#) for an overview and an explanation of how it works.

You can configure the static or runtime configuration to disable hybrid application support or modify its behavior. The sections below show you how to change the defaults for hybrid support through either runtime or static configuration.

### Runtime Configuration for Hybrid Application Support

The code example below disables the injection of the JavaScript Agent. By disabling the injection, the WKWebViews in your application will not be instrumented and Ajax calls will not be reported.

```
ADEumAgentConfiguration *adeumAgentConfig = [[ADEumAgentConfiguration alloc] initWithAppKey:
<#EUM_APP_KEY#>];
// Disable the JavaScript Agent Injection
adeumAgentConfig.jsAgentEnabled = NO;
[ADEumInstrumentation initWithConfiguration:adeumAgentConfig];
```

The JavaScript Agent injection is enabled by default. To also enable the collection and reporting of Ajax calls:

```
ADEumAgentConfiguration *adeumAgentConfig = [[ADEumAgentConfiguration alloc] initWithAppKey:
<#EUM_APP_KEY#>];
// Enable the collection and reporting of Ajax calls
adeumAgentConfig.jsAgentAjaxEnabled = YES;
[ADEumInstrumentation initWithConfiguration:adeumAgentConfig];
```

### Static Configuration for Hybrid Application Support

You should use static configuration for the following reasons:

- force the instrumentation of WKWebViews and/or Ajax calls (override the runtime configuration)

- disable hybrid support and override the runtime configuration
- set the URL to your self-hosted JavaScript Extension file

The table below describes the supported properties and provides the default value for the `info.plist` file.

Property	Default Value	Description
<code>serverJsAgentEnabled</code>	<code>true</code>	<p>If the client receives a <code>false</code> for this flag, then the JavaScript Agent will be disabled. Thus, the WKWebViews and Ajax requests will not be monitored.</p> <p>The injection occurs during the creation of a new WKWebView. So, if a WKWebView is created when this flag is set to <code>false</code>, that particular WKWebView won't be instrumented even if the flag is subsequently set to <code>true</code>.</p>
<code>ForceWebviewInstrumentation</code>	<code>false</code>	When set to <code>true</code> , the iOS Agent will inject the JavaScript Agent into the WKWebViews regardless of the runtime configuration.
<code>ForceAjaxInstrumentation</code>	<code>true</code>	When set to <code>true</code> , Ajax operations will always be collected and reported regardless of the runtime configuration.
<code>ADRUMExtUrlHttp</code>	<a href="http://cdn.appdynamics.com">http:// cdn.appdynamics.com</a>	<p>The JavaScript Agent consists of two components: the base JavaScript Agent and the JavaScript Agent extension. The base JavaScript Agent is built into the Mobile Agent binary and injected according to the rules above.</p> <p>After initialization, the JavaScript Agent fetches the JavaScript Agent extension from the URLs specified by these properties.</p>
<code>ADRUMExtUrlHttps</code>	<a href="https://cdn.appdynamics.com">https:// cdn.appdynamics.com</a>	

### Example Configuration

The example `info.plist` below forces the instrumentation of WKWebViews (overriding the runtime configuration), but does not force the collection and reporting of Ajax requests. The configuration also sets the URL where the JavaScript Extension file is obtained.

```
<plist>
 <dict>
 ...
 <key>ADEUM_Settings</key>
```

```

<dict>
 <key>ForceWebViewInstrumentation</key>
 <true/>
 <key>ForceAjaxInstrumentation</key>
 <false/>
 <key>ADRUMExtUrlHttp</key>
 <string>http://<your-domain>/adrum.cdn</string>
 <key>ADRUMExtUrlHttps</key>
 <string>https://<your-domain>/adrum.cdn</string>
</dict>
...
</dict>
</plist>

```

## Programmatically Control Sessions

By default, a mobile session ends after a period of user inactivity. For example, when a user opens your application, the session begins and only ends after the user stops using the app for a set period of time. When the user begins to use the application again, a new session begins.

Instead of having a period of inactivity to define the duration of a session, however, you can use the following API to programmatically control when sessions begin and end:

```
- (void)startNextSession
```

When you call the method `startNextSession` from the `ADEumInstrumentation` class, the current session ends and a new session begins. The API enables you to define and frame your sessions so that they align more closely with business goals and expected user flows. For example, you could use the API to define a session that tracks a purchase of a product or registers a new user.

Excessive use of this API will cause sessions to be throttled (excessive use is >10 calls per minute per iOS Agent, but is subject to change). When not using the API, sessions will fall back to the default of ending after a period of user inactivity.

## Example of a Programmatically Controlled Session

In the example below, the current session ends and a new one begins when the check out is made.

[Objective-C](#)   [Swift](#)

```

-(void) checkout {
 AppDelegate *appDelegate = (AppDelegate *) [[UIApplication sharedApplication]
delegate];
 NSString *checkoutUrl = [appDelegate.url stringByAppendingString:@"rest/cart/co/"];
 NSURL *url = [NSURL URLWithString:checkoutUrl];
 NSMutableURLRequest *request = [[NSMutableURLRequest alloc] initWithURL:url
cachePolicy:NSURLRequestUseProtocolCachePolicy timeoutInterval:60.0];
 NSURLResponse *response = nil;
 NSError *error = nil;
}

```

```

NSData *body = [NSURLConnection sendSynchronousRequest:request
returningResponse:&response error:&error];
const char *responseBytes = [body bytes];
if (responseBytes == nil)
 checkoutResponse = [NSString stringWithUTF8String:"Could not connect to the
server"];
else {
 checkoutResponse = [NSString stringWithUTF8String:responseBytes];
 [ADEumInstrumentation startNextSession];
}
}

```

Objective-C [Swift](#)

```

func checkout() {
 let appDelegate = UIApplication.shared.delegate as? AppDelegate
 let checkoutUrl = appDelegate?.url ?? "" + ("rest/cart/co/")
 let url = URL(string: checkoutUrl)
 var request: NSMutableURLRequest? = nil
 if let url = url {
 request = NSMutableURLRequest(url: url, cachePolicy: .useProtocolCachePolicy,
timeoutInterval: 60.0)
 }
 var response: URLResponse? = nil
 var error: Error? = nil
 var body: Data? = nil
 if let request = request {
 body = try? NSURLConnection.sendSynchronousRequest(request, returning: &response)
 }
 let responseBytes = Int8(body?.bytes ?? 0)
 if responseBytes == nil {
 checkoutResponse = String(utf8String: "Could not connect to the server")
 } else {
 checkoutResponse = String(utf8String: &responseBytes)
 ADEumInstrumentation.startNextSession()
 }
}
}

```

## Start and End Session Frames

You can use the `SessionFrame` API to create session frames that will appear in the session activity. Session frames provide context for what the user is doing during a session. With the API, you can improve the names of user screens and chronicle user flows within a business context.

## Use Cases

The following are common use cases for the `SessionFrame` API:

- One `ViewController` performs multiple functions and you want more granular tracking of the individual functions.

- A user flow spans multiple ViewController or user interactions. For example, you could use the API to create the session frames "Login", "Product Selection", and "Purchase" to chronicle the user flow for purchases.
- You want to capture dynamic information based on user interactions to name session frames, such as an order ID.

## SessionFrame API

The table below lists the three methods you can use with session frames. In short, you start a session frame with `startSessionFrame` and then use the returned `ADEumSessionFrame` object to rename and end the session frame.

[Objective-C](#) [Swift](#)

Class	Method	Description
ADEumInstrumentation	+ (ADEumSessionFrame *)startSessionFrame:(NSString *)name	Use this to start and name your session frame. Naming session frames enable you to easily identify and track the frames in the <b>Sessions Dialog</b> .
ADEumSessionFrame	- (void)updateName:(NSString *)name	Rename the session frame name. You call this method from the <code>ADEumSessionFrame</code> object returned from <code>startSessionFrame</code> .
ADEumSessionFrame	- (void)end	End the session frame. You call this method from the <code>ADEumSessionFrame</code> object returned from <code>startSessionFrame</code> .

[Objective-C](#) [Swift](#)

Class	Method	Description
ADEumInstrumentation	startSessionFrame(_ name: String?) -> ADEumSessionFrame	Use this to start and name your session frame. Naming session frames enable you to easily identify and track the frames in the <b>Sessions Dialog</b> .
ADEumSessionFrame	updateName(_ name: String?)	Rename the session frame name. You call this method from the <code>ADEumSessionFrame</code> object returned from <code>startSessionFrame</code> .
ADEumSessionFrame	end()	End the session frame. You call this method from the <code>ADEumSessionFrame</code> object returned from <code>startSessionFrame</code> .

## Session Frame Example

In the following example, the `SessionFrame` API is used to track user activity during the checkout process:

[Objective-C](#) [Swift](#)

```
#import "ADEumSessionFrame.h"
...
@property (nonatomic, strong) ADEumSessionFrame *checkoutSessionFrame;

- (IBAction)checkoutCartButtonClicked:(id)sender {
 // The user starting to check out starts when the user clicks the checkout button
 // this may be after they have updated quantities of items in their cart, etc.
 checkoutSessionFrame = [ADEumInstrumentation startSessionFrame:@"Checkout"];
}

- (IBAction)confirmOrderButtonClicked:(id)sender {
 // Once they have confirmed payment info and shipping information, and they
 // are clicking the "Confirm" button to start the backend process of checking out
 // we may know more information about the order itself, such as an Order ID.
 NSString *newSessionName = [NSString stringWithFormat:@"Checkout: Order ID %@",orderId];
 [checkoutSessionFrame updateName:newSessionName];
}

- (void)processOrderCompleted {
 // Once the order is processed, the user is done "checking out" so we end
 // the session frame
 [checkoutSessionFrame end];
 checkoutSessionFrame = nil;
}

- (void)checkoutCancelled {
 // If they cancel or go back, you'll want to end the session frame also, or else
 // it will be left open and appear to have never ended.
 [checkoutSessionFrame end];
 checkoutSessionFrame = nil;
}
```

[Objective-C](#) [Swift](#)

```
import ADEumSessionFrame
...
var checkoutSessionFrame: ADEumSessionFrame?
@IBAction func checkoutCartButtonClicked(_ sender: UIButton) {
```

```

 // The check out starts when the user clicks the checkout button.
 // This may be after they have updated quantities of items in their cart, etc.
 checkoutSessionFrame = ADEumInstrumentation.startSessionFrame("Checkout")
 }

 @IBAction func confirmOrderButtonClicked(_ sender: UIButton) {
 // Once users have confirmed payment info and shipping information, and they
 // are clicking the "Confirm" button to start the backend process of checking out,
 // we may know more information about the order itself, such as an order ID.
 let newSessionName = "Checkout: Order ID \(orderId)"
 checkoutSessionFrame.updateName(newSessionName)
 }

 func processOrderCompleted() {
 // Once the order is processed, the user is done "checking out", so we end the session
 // frame.
 checkoutSessionFrame.end()
 checkoutSessionFrame = nil
 }

 func checkoutCancelled() {
 // If they cancel or go back, you'll want to end the session frame also, or else it
 // will be
 // left open and appear to have never ended.
 checkoutSessionFrame.end()
 checkoutSessionFrame = nil
 }
}

```

## Configure the Agent for Custom App Names

By default, AppDynamics detects the application name by extracting the last segment from the [bundle ID](#). There may be cases, however, where you deploy the same app binary with different bundle IDs to various regional app stores. To make sure all the data belonging to one app is collected and displayed together, despite varying bundle IDs, you can set a common name by giving the apps a custom name. To do this, set the application name property in the `ADEumAgentConfiguration` instance that you use to set up `ADEumInstrumentation`. See the [latest iOS SDK documentation](#) for more information.

By default, AppDynamics stores the application name from the bundle ID string. However, the Controller UI only displays the last segment of the bundle ID string, which is after the last dot (if present). For example, if the bundle ID is `com.example.appdynamics.HelloWorld`, the application name in the UI will display "HelloWorld." This applies to both default and custom app names.

```
@property (nonatomic, strong) NSString *applicationName;
```

## Configure the Agent for Ignoring Some HTTP Requests

In some cases, HTTP requests using NSURL are used for internal purposes in an application and do not represent actual network requests. Metrics created based on these requests are not normally useful in tracking down issues, so preventing data on them from being collected can be useful. To ignore specific NSURL requests, set the `excludedURLPatterns` property in the `ADEumAgentConfiguration` instance that you use to set up `ADEumInstrumentation`. Use the simplest regex possible. See the [latest iOS SDK documentation](#).

```
@property (nonatomic, strong) NSSet * excludedURLPatterns;
```

## Use the Agent with a Custom HTTP Library

The iOS Agent automatically detects network requests when the underlying implementation is handled by either by the `NSURLConnection` or the `NSURLSession` classes. This covers the great majority of iOS network requests. In some cases, however, mobile applications use custom HTTP libraries.

- To have the iOS Agent detect requests from a custom library, [add request tracking code](#) to your application manually, using the `ADEumHTTPRequestTracker` class.
- To [set headers to allow correlation](#) with server-side processing, use the `ADEumServerCorrelationHeaders` class.
- To [configure the agent to use your custom library](#) to deliver its beacons over HTTP, use the `ADEumCollectorChannel` protocol and the `ADEumAgentConfiguration` class.

## Add Request Tracking

To add request tracking manually, you tell the agent when the request begins and when it ends. You also set properties to tell the agent the status of the response.

### Start Tracking a Request

To begin tracking an HTTP request, call the following method immediately before sending the request.

You must initialize the agent using one of the `ADEumInstrumentation`'s `initWithKey` methods before using this method.

```
@interface ADEumHTTPRequestTracker : NSObject
...
+ (ADEumHTTPRequestTracker *)requestTrackerWithURL:(NSURL *)url;
```

Where `url` is the URL being requested. This parameter must not be `nil`.

To complete tracking an HTTP request, immediately after receiving a response or an error, set the appropriate [properties](#) on the tracker object and call the following method to report the outcome of the request back to the agent. You should not continue to use this object after calling this method. To track another request, call `requestTrackerWithURL` again.

```
- (void)reportDone;
```

## Set Request Tracker Properties

The following properties should be set on the `requestTrackerWithURL` object to describe to the agent the results of the call:

```
@property (copy, nonatomic) NSError *error;
```

Indicates the failure to receive a response, if this occurred. If the request was successful, this should be `nil`.

```
@property (copy, nonatomic) NSNumber *statusCode;
```

Reports the HTTP status code of the response, if one was received.

- If a response was received, this should be an integer.
- If an error occurred and a response was not received, this should be `nil`.

```
@property (copy, nonatomic) NSDictionary *allHeaderFields;
```

Provides a dictionary representing the keys and values from the server's response header. The format of this dictionary should be identical to the `allHTTPHeaderFields` property of `NSURLRequest`. The dictionary elements consist of key/value pairs, where the key is the header key name and the value is the header value.

If an error occurred and a response was not received, this should be `nil`.

### Example

Given a request snippet like this:

```
- (NSData *)sendRequest:(NSURL *) url error:(NSError **)error {
 // implementation omitted
 NSData *result = nil;
 if (errorOccurred) {
 *error = theError;
 } else {
 result = responseBody;
 }
 return result;
}
```

Adding the tracker could look something like this:

```
- (NSData *)sendRequest:(NSURL *)url error:(NSError **)error {
 ADEumHTTPRequestTracker *tracker = [ADEumHTTPRequestTracker requestTrackerWithURL:url];
 // implementation omitted
 NSData *result = nil;
```

```

 if (errorOccurred) {
 *error = theError;
 tracker.error = theError;
 } else {
 tracker.statusCode = theStatusCode;
 tracker.allHeaderFields = theResponseHeaders;
 result = responseBody;
 }
 [tracker reportDone];
 return result;
}

```

### Enable Server-Side Correlation

To enable correlation between your request and server-side processing, add specific headers to outgoing requests that the server-side agent can detect and return the headers obtained from the server-side agent in the response to make them available to the iOS Agent.

This is done automatically for standard HTTP libraries.

```

@interface ADEumServerCorrelationHeaders : NSObject
+ (NSDictionary *)generate;
@end

```

You must:

1. Call the `generate` method and set the generated headers *before* sending a request to the backend.
2. Report back the response headers, using the `allHeaderFields` property shown above.

### Attach Custom Data to a Network Request

You can attach custom data to a network request by calling one (or multiple) of the following methods to add attributes to `ADEumHTTPRequestTracker`:

- `setUserDataLong:value:`
- `setUserDataBoolean:value:`
- `setUserDataDouble:value:`
- `setUserDataDate:value:`

#### Sample

```

- (NSData *)sendRequest:(NSURL *)url error:(NSError **)error {
 ADEumHTTPRequestTracker *tracker = [ADEumHTTPRequestTracker requestTrackerWithURL:url];
 // implementation omitted
 NSData *result = nil;
 if (errorOccurred) {
 *error = theError;
 tracker.error = theError;
 }
}

```

```

} else {
 tracker.statusCode = theStatusCode;
 tracker.allHeaderFields = theResponseHeaders;
 result = responseBody;
}

// Custom data can be added to this one request.
// Different types can be used.
// The data added will only appear for this network request and will not persist.
[tracker setUserData:@"trackerStringKey" value:@"Test String Value"];
[tracker setUserDataLong:@"trackerLongKey" value:66004024];
[tracker setUserDataBoolean:@"trackerBooleanKey" value:1];
[tracker setUserDataDouble:@"trackerDoubleKey" value:5905400.6];
[tracker setUserDataDate:@"trackerDateKey" value:[NSDate date]];

[tracker reportDone];
return result;
}

```

## Configure Beacon Channel to Use Custom HTTP Library

The iOS Agent uses HTTP to deliver its beacons. To have the agent use your custom HTTP library for this purpose, do the following.

1. Implement a class that conforms to this protocol:

```

/**
 * Protocol for customizing the connection between the agent SDK and the collector.
 */
@protocol ADEumCollectorChannel <NSObject>

/**
 * Sends a request synchronously and returns the response received, or an error.
 *
 * The semantics of this method are exactly equivalent to NSURLConnection's
 * sendSynchronousRequest:returningResponse:error: method.
 *
 * @param request The URL request to load.
 * @param response Out parameter for the URL response returned by the server.
 * @param error Out parameter used if an error occurs while processing the request. May be
 * NULL.
 */
- (NSData *)sendSynchronousRequest:(NSURLRequest *)request returningResponse:
(NSURLResponse **)response error:(NSError **)error;
@end

```

2. Set the `collectorChannel` property in `ADEumAgentConfiguration` before initializing `ADEumInstrumentation`, passing in an instance of your class that implements `ADEumCollectorChannel`. See the [latest iOS SDK documentation](#).

```
@property (nonatomic, strong) id<ADEumCollectorChannel> collectorChannel;
```

## Transform URLs for Network Requests

When your application makes network requests, you may not want to report URLs containing sensitive information to the EUM Server. You can instead transform the network request URL before reporting it or ignore it altogether.

To do so:

1. [Implement a network request callback](#) that modifies or ignores specific URLs.
2. [Register the network request callback](#) in the initialization code.

## Implement the Network Request Callback

The callback that modifies or ignore specific URLs is an implementation of the protocol below. The callback method `networkRequestCallback` is synchronous, so it is recommended that you return from the function quickly.

```
- (BOOL)networkRequestCallback:(ADEumHTTPRequestTracker *)networkRequest
```

### Transforming URLs

The `networkRequestCallback` method, in general, should follow the steps below to transform URLs:

1. Identify specific URLs using techniques such as regex or pattern matching.
2. Modify the `url` property of the `ADEumHTTPRequestTracker` object. (Modifying other properties of the `ADEumHTTPRequestTracker` object will be ignored.)
3. Assign a valid URL to the `url` property.
4. If you need the request and response headers, use the following fields:
  - `allHeaderFields` - It returns the response headers.
  - `allRequestHeaderFields` - It returns the request headers.
5. Return `YES` (Objective-C) or `true` (Swift).

The first step is optional as you could choose to transform the URLs of all network requests.

[Objective-C](#) [Swift](#)

```
- (BOOL)networkRequestCallback:(ADEumHTTPRequestTracker *)networkRequest
{
 NSString *maskURL = @"http://networkrequest-mask.com";
 NSURL *url = [NSURL URLWithString:maskURL];
 networkRequest.url = url;
 return YES;
}
```

[Objective-C](#) [Swift](#)

```
func networkRequestCallback(_ networkRequest: ADEumHTTPRequestTracker?) -> Bool {
 let maskURL = "http://networkrequest-mask.com"
 let url = URL(string: maskURL)
 networkRequest?.url = url
 return true
}
```

In general, however, you would want to identify and transform URLs that contain sensitive information as implied in the example below:

[Objective-C](#) [Swift](#)

```
- (BOOL)networkRequestCallback:(ADEumHTTPRequestTracker *)networkRequest
{
 NSString *urlString = networkRequest.url.absoluteString;
 BOOL returnBeacon = YES;
 NSString *maskURL = @"http://customer-account.com";
 if (![urlString rangeOfString:@"accountInfo"].location == NSNotFound) {
 networkRequest.url = [NSURL URLWithString:maskURL];
 }
 return returnBeacon;
}
```

[Objective-C](#) [Swift](#)

```
func networkRequestCallback(_ networkRequest: ADEumHTTPRequestTracker?) -> Bool {
 let urlString = networkRequest?.url.absoluteString
 returnBeacon = true
 let maskURL = "http://customer-account.com"
 if !(Int((urlString as NSString)?.range(of: "accountInfo").location ?? 0) ==
 NSNotFound) {
 networkRequest?.url = URL(string: maskURL)
 }
 return returnBeacon
}
```

## Ignoring URLs

If the `networkRequestCallback` method returns false, the beacon is dropped. The general process for ignoring beacons is as follows:

1. Identify specific URLs using techniques such as regex or pattern matching.
2. Return `false`.

You could theoretically ignore all network requests by having the callback `networkRequestCallback` always return `NO` (Objective-C) or `false` (Swift):

[Objective-C](#) [Swift](#)

```
- (BOOL)networkRequestCallback:(ADEumHTTPRequestTracker *)networkRequest
{
 return NO;
}
```

[Objective-C](#) [Swift](#)

```
func networkRequestCallback(_ networkRequest: ADEumHTTPRequestTracker?) -> Bool {
 return false
}
```

In general, though, you would identify network requests that you didn't want to monitor and return `NO` (Objective-C) or `false` (Swift) to ignore the network request as implied by this example.

[Objective-C](#) [Swift](#)

```
- (BOOL)networkRequestCallback:(ADEumHTTPRequestTracker *)networkRequest
{
 NSString *urlString = networkRequest.url.absoluteString;
 BOOL returnBeacon = YES;
 if (!([urlString rangeOfString:@"avatar"].location == NSNotFound)) {
 returnBeacon = NO;
 }
 return returnBeacon;
}
```

[Objective-C](#) [Swift](#)

```
func networkRequestCallback(_ networkRequest: ADEumHTTPRequestTracker?) -> Bool {
 let urlString = networkRequest?.url.absoluteString
 var returnBeacon = true
 if !(Int((urlString as NSString)?.range(of: "avatar").location ?? 0) == NSNotFound) {
 returnBeacon = false
 }
 return returnBeacon
}
```

## Register the Callback

After implementing the callback, you register the object implementing the protocol method in the initialization code as shown below. When the iOS Agent is ready to create a network request beacon, it will first call the callback with an `ADEumHTTPRequestTracker` object.

[Objective-C](#) [Swift](#)

```
ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc] initWithAppKey:
<#EUM_APP_KEY#>];
config.networkRequestCallback = self;
[ADEumInstrumentation initWithConfiguration:config];
```

[Objective-C](#) [Swift](#)

```
let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>)
config.networkRequestCallback = self
ADEumInstrumentation.initWith(config)
```

## Enable Logging and Set Logging Level

You use the method `loggingLevel` to enable and set the logging level. You can set logging to one of the following levels:

- `ADEumLoggingLevelOff`
- `ADEumLoggingLevelAll`
- `ADEumLoggingLevelVerbose`
- `ADEumLoggingLevelDebug`
- `ADEumLoggingLevelInfo`
- `ADEumLoggingLevelWarn`
- `ADEumLoggingLevelError`

**i** Use verbose, all, and debug levels of logging only for troubleshooting and be sure to turn off for production.

## Examples

Objective-C   Swift

```

-(BOOL)application:(UIApplication *)application didFinishLaunchingWithOptions:
(NSDictionary *)launchOptions
{
 // appKey should be assigned your EUM app key
 ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc] initWithAppKey:
<#EUM_APP_KEY#>];
 config.loggingLevel = ADEumLoggingLevelAll;
 [ADEumInstrumentation initWithConfiguration:config];
 ...
}

```

Objective-C   Swift

```

func application(_ application: UIApplication, didFinishLaunchingWithOptions
launchOptions: [UIApplicationLaunchOptionsKey: Any]?) -> Bool {
{
 // appKey should be assigned your EUM app key
 let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>)
 config.loggingLevel = .all
 ADEumInstrumentation.initWithConfiguration(config)
 ...
 return true
}
}

```

## iOS SDK Documentation

See the [latest iOS SDK documentation](#) or the previous versions listed below:

- <https://sdkdocs.appdynamics.com/ios-sdk/22.12/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/22.5/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/22.3/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/22.2/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/22.1/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/21.12/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/21.8/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/21.6/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/21.5/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/21.2/html/>

## Upload the dSYM File

Related pages:

- [Manage dSYM Files](#)
- [Troubleshoot the iOS Instrumentation](#)

AppDynamics requires the dSYM file for the application to produce human-readable stack traces for crash snapshots. For details about the importance of snapshots, see [Get Human-Readable Crash Snapshots](#).

If you update the application, you are required to provide the new dSYM file for the new application version. The dSYM file contains a UUID that links it to a specific Xcode build, so AppDynamics can unambiguously match the correct dSYM file with an incoming crash report with no additional information.

To upload the dSYM file:

1. [Enable the dSYM file.](#)
2. [Set up your environment to upload the file automatically each time you build or upload the file manually.](#)

### Enable the dSYM File

To enable the agent to provide human-readable information in the crash snapshots that are produced if the application crashes, compile with the `DWARF with dSYM` file option to create a debug symbols file for the application.

To enable dSYM:

1. In Xcode, select your project in the **Project Navigator**.
2. In the target list, select the target that builds your application.
3. Select the Build Settings tab.
4. In the **Build Options** section, make sure that the **Debugging Information Format** is set to `DWARF with dSYM File`.

### Automatically Upload the dSYM File to AppDynamics with Each Build

Automating the upload of your dSYM file reduces the number of manual steps required for each build and ensures that all builds have appropriate dSYM files available for AppDynamics to use.

1. In Xcode, select your project from the **Project Navigator**.
2. Click on the application target.
3. Select the Build Phase tab in the **Settings** editor.
4. Click the + icon in the upper left corner of the main panel.
5. Select **New Run Script Phase** from the dropdown.
6. In the script box, add these lines:

[Cocoapods and Manual Installation](#)    Swift Package Manager

```
export ADNUM_ACCOUNT_NAME="<Account_Name_HERE>" // From the View License - End User
Monitoring section of the License Page
export ADNUM_LICENSE_KEY="<License_Key_HERE>" // From the View License - End User
Monitoring section of the License Page
SCRIPT=$(/usr/bin/find "${SRCROOT}" -name xcode_build_dsym_upload.sh | head -n 1)
/bin/sh "${SCRIPT}"
```

```
export ADRUM_ACCOUNT_NAME="<Account_Name_HERE>" // From the View License - End User Monitoring section of the License Page
export ADRUM_LICENSE_KEY="<License_Key_HERE>" // From the View License - End User Monitoring section of the License Page
SCRIPT=$(/usr/bin/find "${BUILD_DIR%Build/}SourcePackages" -name
xcode_build_dsym_upload.sh | head -n 1)
/bin/sh "${SCRIPT}"
```

7. There are also some optional parameters you can set if desired. To set them, add the following line(s) after the second `export` statement above. Set to `1` to enable.

```
export ADRUM_UPLOAD_WHEN_BUILT_FOR_SIMULATOR=0
export ADRUM_TREAT_UPLOAD_FAILURES_AS_ERRORS=0
export ADRUM_EUM_PROCESSOR="<EUM_SERVER_URL>"
```

The last statement should be used to set the URL for [regional cloud location for SaaS-based EUM accounts](#), or for on-premise server.

## Manually Upload the dSYM File to AppDynamics

To upload the file manually:

1. [Get the dSYM file from Xcode.](#)
2. [Upload the dSYM file to AppDynamics using the UI](#)  
or  
[Upload the dSYM File to AppDynamics Using the API.](#)
3. [Check Uploaded dSYMs Using the REST API.](#)

### Get the dSYM file from Xcode

1. In Xcode, run the Xcode build: **Product > Build.**
2. View the log navigator: **View > Navigators > Show Report Navigator.**

 Older versions of Xcode used **Show Log Navigator.**

3. Click the log entry for the most recent build.
4. Near the end of the log, find and mouse over the log entry named `Generate <Your_App_Name>.app.dSYM`.
5. Click the button on the right side of the entry to expand it.  
The end of the displayed command is the path to the dSYM file.
6. Navigate to this dSYM file in the Finder.
7. Right-click on the dSYM file and choose **Compress.**
8. Upload to AppDynamics the `.zip` file that **Finder** generates.

## Upload the dSYM File to AppDynamics Using the UI

1. From the Mobile App menu, click **Configuration**.
2. Click **Mobile App Configuration**.
3. Under **dSYM Files**, click the **+** icon.
4. From the **Upload Missing dSYM Mapping** dialog, click **Choose File**.  
The uploader expects a file with a `.zip` extension.
5. In the file browser, select the zipped dSYM file for your instrumented application.
6. Click **Upload**.

## Upload the dSYM File to AppDynamics Using the REST API

The API uses HTTP basic authentication. The username is your EUM account name and the password is your EUM license key.

Set up your HTTP basic authentication credentials

1. In the upper-right corner of the Controller UI, click **Settings > License**.
2. From the Account Usage tab, swipe down to the **User Experience** section.
3. Click **Show** next to License Key to display the EUM license key. This is your password for authentication.
4. [URL-encode](#) the EUM account name and the EUM license key.

Send the dSYM File

Send the dSYM as a zip archive in the body of a `PUT` request to following [URI](#):

[Americas](#) [EMEA](#) [APAC](#)

`https://api.eum-appdynamics.com/v2/account/<EUM_Account_Name>/ios-dsym`

[Americas](#) [EMEA](#) [APAC](#)

`https://fra-api.eum-appdynamics.com/v2/account/<EUM_Account_Name>/ios-dsym`

[Americas](#) [EMEA](#) [APAC](#)

`https://syd-api.eum-appdynamics.com/v2/account/<EUM_Account_Name>/ios-dsym`

You must set a Content-Type header, `-H Content-Type:application/octet-stream`, and your URL-encoded account name (the username) and license key (the password) to the call.

## Sample Request and Response

This is a sample request and response using the REST API.

### Upload Request

The following example uses `curl` to send a dSYM file named `UISampleApp.app.dSYM.zip`. The EUM account name is "Example account" and the password is "Example-License-Key-4e8ec2ae6cfe", the EUM License Key. The plus signs replace spaces in the account name when the account name is URL-encoded.

[Americas](#) [EMEA](#) [APAC](#)

```
curl -v -H Content-Type:application/octet-stream --upload-file UISampleApp.app.dSYM.zip --
user Example account:Example-License-Key-4e8ec2ae6cfe https://api.eum-appdynamics.com/v2/
account/Example+account/ios-dsym
```

Americas [EMEA](#) APAC

```
curl -v -H Content-Type:application/octet-stream --upload-file UISampleApp.app.dSYM.zip --
user Example account:Example-License-Key-4e8ec2ae6cfe https://fra-api.eum-appdynamics.com/
v2/account/Example+account/ios-dsym
```

Americas EMEA [APAC](#)

```
curl -v -H Content-Type:application/octet-stream --upload-file UISampleApp.app.dSYM.zip --
user Example account:Example-License-Key-4e8ec2ae6cfe https://syd-api.eum-appdynamics.com/
v2/account/Example+account/ios-dsym
```

## Upload Response

The successful output of the sample request looks like this:

[Americas](#) EMEA APAC

```
* About to connect() to api.eum-appdynamics.com port 443 (#0)* Trying ::1...
* connected
* Connected to api.eum-appdynamics.com (::1) port 443 (#0)

## Check Uploaded dSYMs Using the REST API

You can check to make sure that your dSYMs have successfully uploaded using two REST APIs.

1. [Get a list of the UUIDs for the last 50 dSYMs you have uploaded.](#)
2. [Check if a specific dSYM has been uploaded.](#)

### List of the Last 50 dSYMs Uploaded

The `dsymQuery` method allows you to retrieve a list of UUIDs for up to the last 50 dSYM files that have been uploaded to your account, along with the time they were uploaded. The response is displayed as JSON, by upload time, with the most recent first.

1. Set up your authentication as described in [Upload the dSYM File to AppDynamics Using the REST API](#).
2. Create a GET request of the form:

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://<EUM_Cloud/
Server_Host:Port>/v2/account/Example+account/crash-symbol-file-query/dsym
```

- `EUM_Cloud` refers to SaaS-based EUM Cloud URLs. For a complete list, see [SaaS Domains and IP Ranges](#).
- `EUM_Server_Host` refers to the URL pointing to your on-premises EUM Server.
- `EUM_Account_Name` is your EUM account name.
- `GUID_To_Check` is the GUID of the ProGuard file in which you are interested.

### Sample Request

[Americas](#) [EMEA](#) [APAC](#)

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://api.eum-
appdynamics.com:443/v2/account/Example+account/crash-symbol-file-query/dsym
```

[Americas](#) [EMEA](#) [APAC](#)

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://fra-api.eum-
appdynamics.com:443/v2/account/Example+account/crash-symbol-file-query/dsym
```

[Americas](#) [EMEA](#) [APAC](#)

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://syd-api.eum-appdynamics.com:443/v2/account/Example+account/crash-symbol-file-query/dsym
```

## Sample Response

```
{"dSymFiles":[
{"uploadTime":"mm/dd/yyyy 14:15:32","UUID2":"my_uuid2"},
{"uploadTime":"mm/dd/yyyy 14:15:32","UUID":"my_uuid"}
]}
```

## Check for Specific dSYM by UUID

The `checkForDSymFile` method allows you to check if a specific dSYM by UUID has been uploaded. The upload time is returned in the response.

1. Set up your authentication as described in [Upload the dSYM File to AppDynamics Using the REST API](#).
2. Create a GET request of the form:

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://<EUM_Cloud/Server_Host:Port>/v2/account/Example+account/crash-symbol-file-query/dsym/uuid/<UUID_to_Check>
```

- `EUM_Cloud` refers to SaaS-based EUM Cloud URLs. For a complete list, see [SaaS Domains and IP Ranges](#).
- `EUM_Server_Host` refers to the URL pointing to your on-premises EUM Server.
- `EUM_Account_Name` is your EUM account name.
- `GUID_To_Check` is the GUID of the ProGuard file in which you are interested.

## Sample Request

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://<EUM_Cloud/Server_Host:Port>/v2/account/Example+account/crash-symbol-file-query/dsym/uuid/<UUID_to_Check>
```

## Sample Response

```
{"uploadTime":"mm/dd/yyyy 14:15:32","UUID":"my_uuid"}
```

## Manage dSYM Files

### Related pages:

- [Upload the dSYM File](#)

## Manage dSYM Files with Bitcode Enabled

With iOS 9, Apple introduced a new mode of building and distributing iOS apps called [App Thinning](#). As part of this initiative, apps containing bitcode are delivered.

If you choose to create your app containing bitcode, the process of acquiring your dSYM files for upload while you are in local development, debugging, and testing mode (Xcode on simulators or [Devices](#)) is exactly the same as in earlier versions.

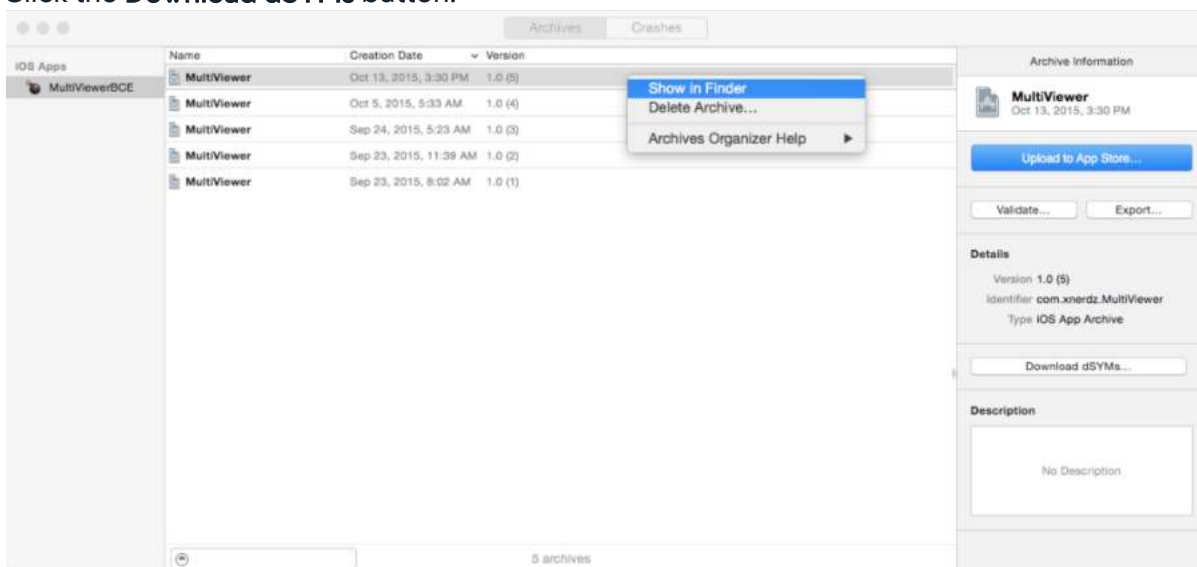

It also works if you are using [Ad Hoc Provisioning](#). But once you have used [iTunes Connect](#) to upload your application to Apple, for either TestFlight beta testing or application release, you have to take a few additional steps to get your dSYM files for use with AppDynamics.

## Get and Upload the Correct dSYM File

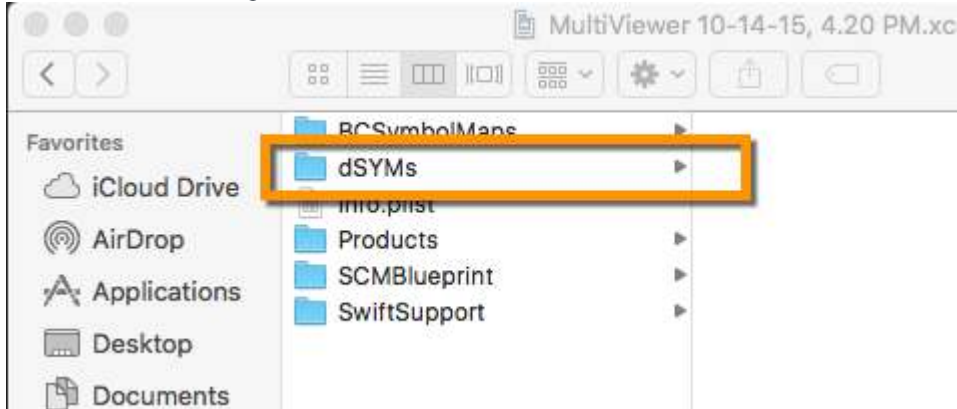

As part of the process of preparing to upload your application using iTunes Connect, you [create an archive](#). After the app is uploaded to iTunes Connect, it is processed by Apple. To have the correct version of the dSYM for AppDynamics, you must download this processed version to your local archive.

To download the processed dSYM file, in the Xcode **Archives Organizer**:

1. Make sure this version of the application is available for download (either TestFlight or the iTunes store).
2. In the **Archives** organizer, select the archive for this version.
3. Click the **Download dSYMs** button.

- Right-click the `.xcarchive` file you receive and select **Show in Finder**. Right-click again and select **Show Package Contents**, and select the **dSYM** folder.

- Zip this directory and upload.

See the [Apple Developer docs](#).

### Upload Missing dSYM Files

If you have crashes that AppDynamics could not symbolicate because it did not have a correct dSYM file, you get an error message in the **Crashes Details** dialog.

The screenshot shows the 'Crashes Details' dialog for a SIGSEGV error in 'promoviev : 327'. The 'Crash Summary' tab is active, showing 8299 total crashes and 1001 impacted users. A 'Crash Trend' graph shows crash frequency over time. The 'Stack Trace at 05/24/19 7:00:55 PM' shows a crash in 'Thread 0' with the following frames:

Address	Symbol	Offset	Symbol	Function
0-2	libsystem_platform.dylib - libsystem_c.dylib	0x35b09978 - 0x35a18ac0	_platform_memmove - _strncpy_chk	
3	ECommerce-iOS	0x000ac9fe	promoviev (Promo.m : 327)	
4-18	UIKit - UIKit	0x27951cd6 - 0x2798218a	-[UIApplication sendAction:to:from:forEvent:] - UIApplicationMain	
19	ECommerce-iOS	0x000e0d5a		
20	libdyld.dylib	0x359a1870	start	

The 'Properties' panel on the right shows 'Events Prior to Crash' and 'User Data'. A warning icon indicates 'Some dSYM files need to be uploaded. Upload'.

If you click **Upload missing dSYM files in Instrumentation**, a list of dSYM hashes appears. Match the missing files with the dSYMs in your archives, as shown above. If necessary, click **Download dSYMs** to update the archive. Upload the necessary files to AppDynamics.

To upload a missing dSYM file, see [Upload the dSYM File](#)

Some of the missing dSYM files that AppDynamics reports may belong to simulation/debug builds that have crashed. In this case, the dSYMs may no longer be available.

## Troubleshoot the iOS Instrumentation

### Related pages:

- [Install the iOS SDK](#)
- [Instrument an iOS Application](#)
- [Customize Your Instrumentation With the iOS SDK](#)

This page provides instructions and tips for solving some common iOS instrumentation issues.

### Agent Not Detecting Requests

First, confirm that you are using either the `NSURLConnection` or the `NSURLSession` class. By default, you are required to make network requests. If you are using a custom HTTP library, make sure you follow the instructions given in [Use the Agent with a Custom HTTP Library](#).

If you are using `NSURLSession`, be sure to create an instance of `NSURLSession` *after* initializing the iOS agent. This is because the agent may not be aware of objects created before the instrumentation is initialized.

### Unrecognized Selector Error

If you are instrumenting your app using the manual method and you see this error message:

```
+[NSURLConnection ADEumInsertHooks]: unrecognized selector sent to class <hex value>
```

Then, you did not add `-ObjC` to your link flags. See [Set the -ObjC Flag](#) for instructions.

## Instrument Android Applications

### Related pages:

- [Customize the Android Build](#)
- [Customize the Android Instrumentation](#)
- [Upgrade the Android Agent](#)

To instrument Android Applications, you need to first build the application for the platform you are using and then add the instrumentation code.

To get started, follow the instructions below:

1. [Build the Android Application](#)
2. [Instrument the Android Application](#)

### Build the Android Application

To build your application, follow the instructions for your platform:

- [Gradle/Android Studio](#)
- [Maven](#)
- [Ant](#)

## Gradle/Android Studio

Complete the following steps to configure the build for your Android application:

1. [Confirm the compatibility of your Gradle, Android Tools with the AppDynamics plugin versions.](#)
2. [Install the Android Agent.](#)
3. [Activate the plugin.](#)

### Install the Android Agent

Use the native package system to install the Android Agent. In the app module `build.gradle`, add the class path of the AppDynamics Gradle Plugin to the build path dependencies clause. For `classpath 'com.appdynamics:appdynamics-gradle-plugin:'` use the latest Android Agent version from the AppDynamics Downloads Portal. However, you can use an older version of the AppDynamics plugin for [compatibility between your Gradle and Android Tools](#) or for other reasons.

**i** If you are unable to use the Android Gradle plugin 3.4.1 or higher, you will have to use the Android Agent 20.4.0 or an earlier version.

```
buildscript {
 repositories {
 mavenCentral()
 }
 dependencies {
 classpath 'com.android.tools.build:gradle:1.1.0'
 classpath 'com.android.tools.build:gradle:3.4.1' // 3.4.1 or higher
 classpath 'com.appdynamics:appdynamics-gradle-plugin:<android-agent-version>' // Set
to your Android Agent version.
 }
}
allprojects {
 repositories {
 mavenCentral()
 }
}
```

### Activate the Plugin

In your module-level `build.gradle`, add the `adeum` plugin immediately after the `com.android.application` plugin, so that it looks similar to the example below:

```
apply plugin: 'com.android.application'
apply plugin: 'adeum' // this line added for AppDynamics
```

### Apache Maven Project

If your application is a [Maven Project](#):

1. Add the following code to the `<dependencies>` section:

```
<dependency>
 <groupId>com.appdynamics</groupId>
 <artifactId>appdynamics-runtime</artifactId>
 <version>1.0</version>
</dependency>
```

2. Add the following code to the `<plugins>` section:

```
<plugin>
 <groupId>com.appdynamics</groupId>
 <artifactId>appdynamics-maven-plugin</artifactId>
 <version>1.0</version>
 <executions>
 <execution>
 <phase>implementation</phase>
 <goals>
 <goal>adinject</goal>
 </goals>
 </execution>
 </executions>
</plugin>
```

## Ant/Eclipse

See the Knowledge Base article [Use Ant to Build Android Apps with the AppDynamics Android SDK](#) for instructions.

## Instrument the Android Application

After you have completed [building your application](#), follow the steps below:

1. [Add the Required Permissions](#)
2. [Get the Application Key](#)
3. [Modify the Source](#)
4. [Run the Build](#)
5. [Verify Instrumentation](#)

### Add the Required Permissions

Open your application's `AndroidManifest.xml` file and verify that it has these permissions:

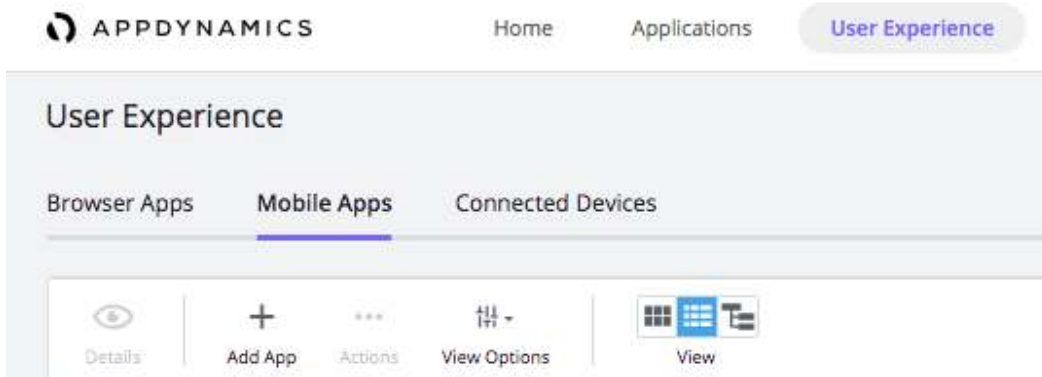

```
<uses-permission android:name="android.permission.INTERNET"></uses-permission>
<uses-permission android:name="android.permission.ACCESS_NETWORK_STATE"></uses-permission>
```

If both of these permissions are not present, add them.

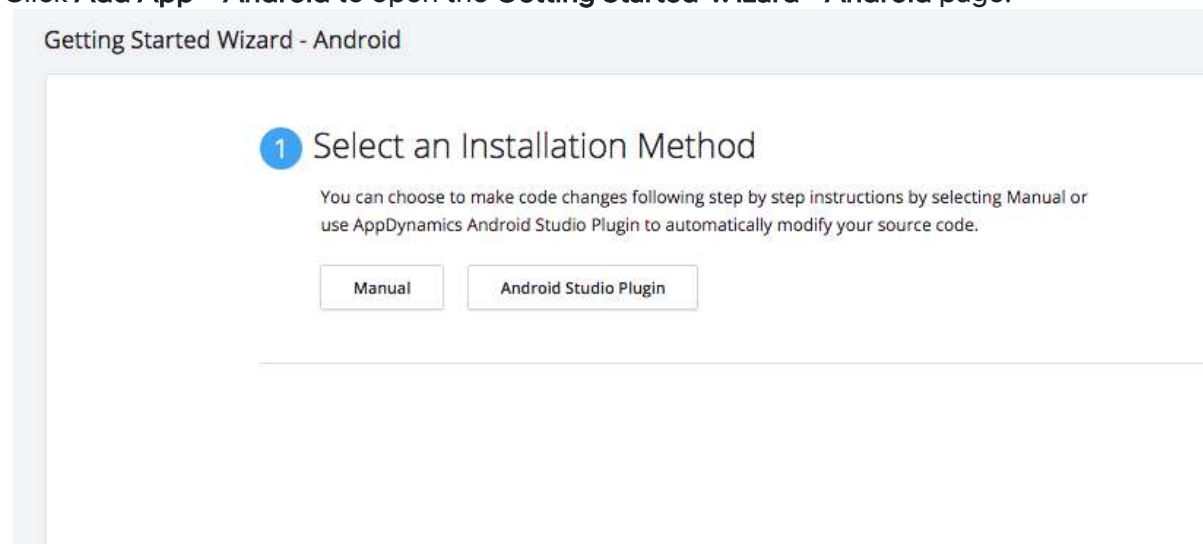

### Get Your EUM App Key

To get your EUM App Key in the Controller UI:

1. From the top navigation bar of your Controller UI, go to **User Experience > Mobile Apps**.

2. Click **Add App > Android** to open the **Getting Started Wizard - Android** page.

3. Click **Manual**.

**i** Due to AppDynamics no longer supporting Android Studio  $\geq 4.0$ , we do not recommend using the Android Studio Plugin installation method as of May 2020 (when Android Studio 4.0 released). Instead, please follow the manual installation method in the steps below.

4. Select **Create a new Mobile App Group**, enter an application name, and click **Continue**.

5. Copy the displayed App Key and the Collector URL.

Create a new Mobile App Group (you can always change this name later):

My Test App

Continue

Your App Key is: SH-  
Your Collector URL is: <https://eum-col.appdynamics.com>

### Modify the Source

1. In the source file that defines your application's primary Activity, add the following import:

```
import com.appdynamics.eumagent.runtime.Instrumentation;
```

2. In your primary Activity's `onCreate()` method, add the following lines, passing in the EUM App Key from [Step 2](#) above:

```
Instrumentation.start(<EUM_APP_KEY>, getApplicationContext());
```

3. Save the file. Your code should look something like this:

```
import com.appdynamics.eumagent.runtime.Instrumentation;
...
@Override public void onCreate(Bundle savedInstanceState) {
 Instrumentation.start(<EUM_APP_KEY>, getApplicationContext());
 ...
}
```

4. Configure the Android Agent to report metrics and screenshots to the [SaaS EUM Server and Screenshot Service in your region](#) when initializing the agent with the methods `withCollectorURL` and `withScreenshotURL`. (If you are using an on-premises EUM Server, see [Customize the Agent Configuration](#) for implementation details.)

```
import com.appdynamics.eumagent.runtime.Instrumentation;
...
@Override public void onCreate(Bundle savedInstanceState) {
 Instrumentation.start(AgentConfiguration.builder()
 .withAppKey("<EUM_APP_KEY>")
 .withContext(getApplicationContext())
```

```

 // The default SaaS EUM Server and Screenshot Service are in the Americas,
 // so you can omit the following settings if you are in the Americas.
 .withCollectorURL("https://<your_region>-col.eum-appdynamics.com")
 .withScreenshotURL("https://<your_region>-image.eum-appdynamics.com/")
 .build());
 ...
 }

```

5. In your module-level `build.gradle` file, add your AppDynamics account information as configurations in the `adeum` snippet. If you complete this step in the Getting Started Wizard, the configurations will populate in the UI code snippet. If you cannot get the EUM App Key from the **Getting Started Wizard**, see [Access Browser Monitoring Configuration](#).

```

dependencies {
 implementation 'com.appdynamics:appdynamics-runtime:<latest version>'
 // This line is added for AppDynamics.
}

adeum { // This section is added for AppDynamics.
 account {
 name '<account name>'
 licenseKey '<key>'
 }
}

```

- a. If you are using Android Studio, you need to add a build script block to the top of your project's `build.gradle` file:

```

// project level build.gradle

buildscript {
 dependencies{
 classpath("com.appdynamics:appdynamics-gradle-plugin:<latest-version>")}

 repositories {
 mavenCentral()
 }
}

```

Alternatively, you can use the plugin block and define the `resolutionStrategy` block in the `settings.gradle` file:

```

// project level build.gradle
plugins{
 id 'com.appdynamics.appdynamics-gradle-plugin' version<version>
}
// settings.gradle
repositories{

```

```

 gradlePluginPortal()
 mavenCentral()
 }
 resolutionStrategy {
 eachPlugin {
 plugin
 -> if (plugin.requested.id.id
 == "com.appdynamics.appdynamics-gradle-plugin") {
 useModule("com.appdynamics:appdynamics-gradle-plugin:<latest-version>")
 }
 }
 }
}

```

## Run the Build

Build your Android app following the instructions for your build system:

- [Android Studio](#)
- [Gradle](#)
- [Maven](#)

Here is an example of something you would see in your console:

```

[injector] /
=====
[injector] | AppDynamics BCI Instrumentation
summary |
[injector]
\=====
[injector]
[injector]
[injector] - Total number of classes visited (#720
classes)
[injector] - Total number of classes instrumented (#1
classes)
[injector] - Total number of classes failed to
instrument (#2 classes)
[injector] - Total number of features discovered (#3)
[injector]

```

## Verify the Instrumentation

Based on the build system you used, verify that the instrumentation was successful:

- [Gradle/Android Agent Installer Plugin](#)
- [Maven](#)
- [Ant](#)

## Gradle/Android Agent Installer Plugin

If you didn't use the `-i` flag, check to make sure there is a line in your console output that contains "inject". If you don't see this information printed in your console, either your project is incorrectly configured or the injector failed to run completely. There is a very detailed log of this process either at `<project>/target/appdynamics_eum_android_bci.log` or `<module>/target/appdynamics_eum_android_bci.log`.

## Maven

If you don't see this information printed in your console, either your project is incorrectly configured or the injector failed to run completely. There is a very detailed log of this process either at `<project>/target/appdynamics_eum_android_bci.log` or `<module>/target/appdynamics_eum_android_bci.log`.

## Ant

If you don't see this information printed in your console, either your project is incorrectly configured or the injector failed to run completely. There is a very detailed log of this process either at `<project>/target/appdynamics_eum_android_bci.log` or `<module>/target/appdynamics_eum_android_bci.log`.

## Customize the Android Build

### Related pages:

- [Customize the Android Instrumentation](#)

[Instrument Android Applications](#) showed you how to use the bare minimum configuration to build your application.

The following pages show you how to add additional configuration to customize your build:

- [Automatically Upload Mapping Files](#)
- [Configure ProGuard to Prevent Obfuscation and Class Removal](#)
- [Exclude Classes from Being Instrumented](#)
- [Enable/Disable Instrumentation for Build Types](#)
- [Enable/Disable Android Crash Reporting](#)

## Automatically Upload Mapping Files

You can configure the build to add your EUM account information so that you can automatically upload your ProGuard or DexGuard mapping files for crash reports with each build.

This is the recommended way of managing these types of mapping files, although manual modes are available for uploading mapping files. If you do not use ProGuard or DexGuard to obfuscate your files you can ignore this section. See [Configure ProGuard to Prevent Obfuscation and Class Removal](#).

### DexGuard Limitation

DexGuard mapping files must be in the default location. This means that your DexGuard configurations should not specify `--printMapping`, which changes where to print the mapping file.

## Upload to the SaaS EUM Server

If you are using the SaaS EUM Server, provide your account name and license key to automate uploading as follows:

Specify the appropriate URL in your code to automatically upload the mapping files.

- For SaaS, set the region's endpoint if the following conditions are true:
  - The ProGuard/Dexguard mapping files or NDK symbol files are automatically uploading to the application server during the build process.
  - Region's endpoint is different from <https://api.eum-appdynamics.com> (default value).
 Find the EUM API URLs for the required region from [SaaS Domains and IP Ranges](#).
- For the On-Premises EUM server, specify `ON_PREM_COLLECTOR_URL`.

```

adeum {
 url SaaS_EUM_API_URL/ ON_PREM_COLLECTOR_URL
 //For SaaS, set the region's endpoint if the ProGuard/Dexguard mapping files or NDK
 symbol files are automatically uploading to the application server during the build process
 and region's endpoint is different from https://api.eum-appdynamics.com (default value). Find
 the EUM API URLs for the required region from https://docs.appdynamics.com/paa/saas-domains-
 and-ip-ranges.
 // For on-prem it is the public collector URL.
 account {
 licenseKey EUM_LICENSE_KEY name EUM_ACCOUNT_NAME
 } symbolMappingFileUpload {
 failBuildOnUploadFailure false
 }
 enabled true // This specifies whether the entire build should fail if mapping file upload
 fails. Enabled refers to whether auto-uploading of mapping file is enabled.
}
 excludeClasses = ['android.support.multidex.*', 'okio.**'] // This specifies any classes
 customers would like to exclude from auto-instrumentation. The notation is standard java
 package/class specification used in Gradle.
 enabledForDebugBuilds = true // Whether auto-instrumentation is enabled for debug builds,
 true by default.
 enabledForReleaseBuilds = true // Whether auto-instrumentation is enabled for release
 builds, true by default.
 webViewCallbackCrashReportingEnabled = false // Auto-instrumentation is enabled for
 WebChromeClient and WebViewClient
 ...

// This block specifies how to handle native crashes. By default, this is not enabled.
 nativeCrashHandling {
 if (BUILD_NDKLIB) {
 enabled = true
 symbolUpload {
 variantLibraryPaths = ["appRelease": "ndkLib/obj/local"]
 }
 }
 }
}

```

```
}

```

## Upload to the On-Premises EUM Server

If you are using an on-premises deployment, in addition to supplying your account name and license, you must also assign the URL to your on-premises EUM Server to the `url` property as shown:

```
adeum{
 // The account information is also needed for on-prem deployments.
 account {
 name "The EUM Account Name from the License screen"
 licenseKey "The EUM License Key from the License screen"
 }
 ...
 // Add this information to point to the on-prem EUM Server.
 url "https://<your-on-prem-eum-server>:7001"
}
```

## Modify the Default Upload Behavior

You can also modify the default upload behavior for both on-premises and SaaS deployments. For on-premises deployments, you will need to provide the URL to your on-premises EUM Server with the `url` property.

The configuration example below sets `failBuildOnUploadFailure` to `true`, so that the build will fail if the upload to the URL specified by `url` is unreachable. The object `symbolMappingFileUpload` is used for both ProGuard and DexGuard mapping files. If you don't want your build to fail because the ProGuard or DexGuard mapping file couldn't be uploaded, do *not* modify the default setting.

```
adeum{
 ...
 // Add this information to point to the on-prem EUM Server.
 url "https://<your-on-prem-eum-server>:7001"

 // Add this information if you want to modify upload behavior. symbolMappingFileUpload {
 failBuildOnUploadFailure true // If true, will fail build. Defaults to false.
 enabled true //enables automatic uploads. Defaults to true
 }
}
```

## Configure ProGuard to Prevent Obfuscation and Class Removal

If you use ProGuard to verify or optimize your code, add the following lines to the ProGuard configuration file `proguard-rules.pro` under Gradle Scripts to prevent ProGuard from obfuscating or removing classes needed for proper instrumentation.

```
-keep class com.appdynamics.eumagent.runtime.DontObfuscate
-keep @com.appdynamics.eumagent.runtime.DontObfuscate class *
{ *; }
```

## Configure ProGuard to Prevent Obfuscation and Class Removal

### Related pages:

- [Automatically Upload Mapping Files](#)

If you use ProGuard to verify or optimize your code, add the following lines to the ProGuard configuration file `proguard-rules.pro` under Gradle Scripts to prevent ProGuard from obfuscating or removing classes needed for proper instrumentation.

```
-keep class com.appdynamics.eumagent.runtime.DontObfuscate
-keep @com.appdynamics.eumagent.runtime.DontObfuscate class * { *; }
```

## Exclude Classes from Being Instrumented

You can exclude one or more class names from being instrumented, using the "adeum" `excludeClasses` snippet.

Class names can contain wildcards:

- '?' for a single character
- '\*' for any number of characters, but *not* the package separator
- '\*\*' for any number of (any) characters
- '\$' prefix for an inner class name

To exclude named classes from instrumentation, add the class names to the `excludeClasses` array, using matching patterns where needed:

```
...
adeum {
 // Excludes all the classes in the android.support.multidex and okio packages.
 excludeClasses = ['android.support.multidex.*', 'okio.**']
}
...
```

## Enable/Disable Instrumentation for Build Types

This page describes how to enable and disable instrumentation for Android build types.

### Default Instrumentation for Build Types

Auto-instrumentation is enabled by default, however, you can disable it by build type, product flavor, or build variant using the configuration option:

```
adeum {
 ...
```

```

disabledForBuildTypes = ["debug"]
disabledForProductFlavors = ["app"]
disabledForVariants = ["appDebug"]
webViewCallbackCrashReportingEnabled = false // Auto-instrumentation is enabled for
WebChromeClient and WebViewClient
...
}

```

### Verify the Instrumentation State at Runtime

If one or more of your builds have disabled instrumentation, you need to disable the instrumentation check at runtime. You can set boolean fields in the build configuration to disable the runtime verification of instrumentation. The runtime verification of instrumentation is on by default. You can turn it off using the method `withAutoInstrument`.

In the build configuration, you can set a boolean value for the `CHECK_ENABLED` field for build types. The table below shows the config value, the instrumentation state, and then describes the runtime behavior of your applications.

Config Value	Instrumentation State	Runtime Behavior
true	Enabled	The agent will verify that instrumentation has been enabled before initializing.
	Disabled	The agent will verify that the instrumentation has not been enabled and then thrown an <code>IllegalState</code> exception.
false	Enabled	The agent will initialize without checking whether instrumentation has been enabled.
	Disabled	

For example, in the build configuration below, the field `CHECK_ENABLED` is set to `true` for the release build and `false` for the debug build.

The agent for the `debug` build will not verify if instrumentation has been enabled before executing instrumentation code, whereas, the application code for the `release` build will check before executing the instrumentation code.

```

...
android {
 // usual stuff
 buildTypes {
 // usual stuff
 release { //these lines added for AppDynamics
 //release based configuration
 // The release build by default is not "debuggable".
 // The build config "CHECK_ENABLED" will be accessible in the runtime
 environment.
 }
 }
}

```

```

 // This enables the Android Agent to verify that the instrumentation has been
 enabled before running the initialization code.
 // If instrumentation has not been enabled, an "IllegalState" exception is
 thrown.
 buildConfigField "boolean", "CHECK_ENABLED", "true"
 }
 debug {
 // Setting 'CHECKED_ENABLED' to "false" means the Android Agent will run the
 initialization code without confirming that
 // instrumentation has been enabled. No exception will be thrown.
 buildConfigField "boolean", "CHECK_ENABLED", "false"
 }
}
...

```

If the value of `CHECK_ENABLED` is `true`, the Android Agent will confirm that instrumentation has been enabled before executing the initialization code. If the value is `false`, the Android Agent executes the initialization code regardless of whether instrumentation has been enabled.

The following instrumentation initialization code shows you how to check the value of the build config `CHECK_ENABLED` with the method `withCompileTimeInstrumentationCheck`.

```

import com.appdynamics.eumagent.runtime.Instrumentation;
...
Instrumentation.start(
 AgentConfiguration config = AgentConfiguration.builder()
 .withAppKey(<EUM_APP_KEY>)
 .withContext(this)
 .withCompileTimeInstrumentationCheck(BuildConfig.CHECK_ENABLED)
 .build();
);
...

```

## Enable/Disable Android Crash Reporting

You can report native crashes caused by native Android libraries. This feature is available for all architectures supporting the [Android Native Development Kit \(NDK\)](#).

### Native Crash Handler

When instrumentation is initialized, the native crash handler loads the AppDynamics library `libadeum`. At entry points of your code, a signal handler is injected into the running process. After a signal is handled, `libadeum` restores the previous signal handler. (This enables you to use different methods to handle signals.)

The handler collects and writes the information about the native crash into a temporary file. When the application is restarted, the temporary file is read, processed, and the crash information is displayed in the Controller UI.

## Configuration for Native Crash Reporting

By default, however, this feature is turned off, so you need to add the section `nativeCrashHandling` and set `enabled` to `true`. In addition, you point the library paths in the `variantLibraryPaths` array for each build variant to write the symbol files locally and transmit the symbol files to the EUM Server. You can also specify a build ID for a project build. After you build the project, the build ID can be found in `build/appDynamics/ndkSym<VariantName>/<AppBuildID>`. If not specified, the build ID of the most recently built project will be used.

```

adeum {
 // Other configuration if needed.

 // Enable native crash handling; the default is false.
 nativeCrashHandling {
 enabled = true
 symbolUpload {
 buildId = "<your_custom_build_id>"
 variantLibraryPaths = ["release": "ndkLib/obj/local", "debug": "ndkLib/obj/debug",
...]
 }
 }
}

```

## Configuration for the Android App Bundle

If you using [Android App Bundle](#), you need to add the following line to your app module `build.gradle` for crashes to symbolicate correctly.

```
android.bundle.enableUncompressedNativeLibs=false
```

## View Source Code Information in the Stack Trace

You have two different ways to view symbol information in the stack trace:

1. From the **Crash Details** dialog, [download the crash report and use a utility like `ndk-stack`](#) to view the crash report with source code level symbolizations.
2. [Upload the symbol files and then view the stack trace](#) in the **Crash Details** dialog.

### Download the Crash Report and Use `ndk-stack`

1. From the **Crash Dashboard**, double-click one of the crashes listed in the **Unique Crashes** widget.
2. From the **Crash Details** dialog, click **Download** to download the crash report.
3. Run `ndk-stack` (or a similar utility) on the downloaded crash report as the input file to generate a crash report with source code level symbolizations.

### Upload the Symbol File and View the Stack Trace

You are recommended to automatically generate and upload symbol files, but you can also manually generate and upload the symbol files, too. After you upload the symbol files, when the app with the same

---

build ID as the UUID of the uploaded `ndkSYM` file crashes, you will see the file name and the line number next to the C/C++ function name for each frame of the stack trace shown in the **Crash Details** dialog.

### Automatically Generate and Upload Symbol Files

You can run the following `gradle` command to generate and upload the symbol files to the EUM Server. Replace `<VariantName>` with the build variant names you defined in the configuration. For example, in the configuration above, the `<VariantName>` could be `release` or `debug`.

```
$ gradle appDynamicsUploadNDKSymbolFile<VariantName>
```

### Manually Generate and Upload Symbol Files

To generate symbol files, run the following `gradle` command, where `<VariantName>` is the build variant names. The generated symbol file will be written to `build/appDynamics/ndkSym<VariantName>/<AppBuildID>/<AppBuildID>.ndkSYM.zip`.

```
$ gradle appDynamicsGenerateNDKSymbolFile<VariantName>
```

To manually upload the generated symbol file, use the following `cURL` command, replacing the `<ndkSymZipFile>` with your generated symbol file, `<Account Name>` with your EUM Account name, and `<License Key>` with your EUM License Key.

```
$ curl -v -H Content-Type:application/octet-stream --upload-file <ndkSymZipFile> --user <Account Name>:<License Key> https://api.eum-appdynamics.com/v2/account/<Account Name>/android-ndksym
```

## Customize the Android Instrumentation

### Related pages:

- [Instrument an Android Application](#)
- [Android SDK Documentation](#)

Once you have instrumented your Android application with the Android SDK, you can also use the APIs exposed by the SDK to customize the data for your application that appears in the Controller UI. The following sections show you how to use the Android API to customize your instrumentation.

- [Collect Additional Types of Data](#)
- [Add a Crash Reporting Callback](#)
- [Disable Crash Reporting](#)
- [Report Errors and Exceptions](#)
- [Disable the Agent to Stop Sending User Data to the Collector](#)

- [Block/Unblock Screenshots](#)
- [Transform URLs for Network Requests](#)

- [Enable Logging and Set Logging Level](#)
- [Android SDK Documentation](#)

**i** Because the Android Agent [stores data about events in a local buffer](#) before reporting the information, we recommend you use the APIs with discretion.

### Collect Additional Types of Data

The `Instrumentation` class has additional methods to allow you to extend the kinds of application data you can collect and aggregate using Mobile RUM. There are six basic kinds of extensions that you can create:

Extension	Description	Specification	Where Data is Displayed in the Controller UI
<a href="#">Info points</a>	How often a method is invoked, and how long it takes to run.	<ul style="list-style-type: none"> <li>• Data is numeric</li> <li>• Names must consist of alphanumeric characters and/or spaces</li> </ul>	<ul style="list-style-type: none"> <li>• <a href="#">Metric Browser</a></li> <li>• <a href="#">Custom Data</a></li> <li>• <a href="#">Network Request Snapshots</a></li> <li>• <a href="#">Mobile Sessions</a></li> <li>• <a href="#">Network Request Analyze</a></li> </ul>
<a href="#">Custom timers</a>	Any arbitrary sequence of events within your code timed, even spanning multiple methods.	<ul style="list-style-type: none"> <li>• Data is numeric</li> <li>• Metric names must consist of alphanumeric characters and/or spaces</li> </ul>	<ul style="list-style-type: none"> <li>• <a href="#">Metric Browser</a></li> <li>• <a href="#">Custom Data</a></li> </ul>
<a href="#">Custom metrics</a>	Any integer-based data you wish to collect.	<ul style="list-style-type: none"> <li>• Data is numeric</li> <li>• Metric names must consist of alphanumeric characters and/or spaces</li> </ul>	<ul style="list-style-type: none"> <li>• <a href="#">Metric Browser</a></li> <li>• <a href="#">Custom Data</a></li> </ul>
<a href="#">User data</a>	Any string key/value pair you think might be useful. This data is included with all listed instrumentation types until it is cleared.	<ul style="list-style-type: none"> <li>• Any data type</li> <li>• Metric names have no restrictions</li> </ul>	<ul style="list-style-type: none"> <li>• <a href="#">Network Request Snapshots</a></li> <li>• <a href="#">Mobile Sessions</a></li> <li>• <a href="#">Network Request Analyze</a></li> <li>• <a href="#">Crash Snapshots</a></li> </ul>

Extension	Description	Specification	Where Data is Displayed in the Controller UI
<a href="#">Breadcrumbs</a>	The context of a crash.	<ul style="list-style-type: none"> <li>Any data type</li> <li>Metric names have no restrictions</li> </ul>	<ul style="list-style-type: none"> <li><a href="#">Network Request Snapshots</a></li> <li><a href="#">Mobile Sessions</a></li> <li><a href="#">Network Request Analyze</a></li> <li><a href="#">Crash Snapshots</a></li> </ul>
<a href="#">User interactions</a>	Captured when users press buttons, click on <b>lists</b> , and select text.	<ul style="list-style-type: none"> <li>Any data type</li> <li>Metric names have no restrictions</li> </ul>	<ul style="list-style-type: none"> <li><a href="#">Network Request Snapshots</a></li> <li><a href="#">Mobile Sessions</a></li> <li><a href="#">Network Request Analyze</a></li> </ul>

When you have set up info points, custom timers, custom metrics, and/or user data, the Mobile Agent packages that data in a mobile beacon. Normally, the beacon is transmitted when the instrumented application sends an HTTP request or when the application starts after a crash, but if custom data has been collected and neither of those events has occurred for at least 5 minutes, the custom data is sent at that time.

### Info Points

Information points allow you to track how your own code is running. You can see how often a method is invoked, how long it takes to run, and if an exception is thrown. The simplest way to set up an information point is to use the `@InfoPoint` annotation. For example:

```
@InfoPoint
public void infoPointMethod(String arg1, int arg2, long value) {
 System.out.println("Executing infoPointMethod!");
}
```

You can also do this manually, using the `CallTracker` interface. For example, to collect information on the `downloadImage` method, you could use code similar to this:

```

private void downloadImage(URL url) {
 CallTracker tracker =
 Instrumentation.beginCall("com.example.android.awesomeapp.ImageDownloader",
"downloadImage")
 .withArguments(url);
 try {
 //download image.
 tracker.reportCallEnded()
 } catch(Exception e) {
 //handle exception thrown
 tracker.reportCallEndedWithException(e);
 }
}

```

This information appears in the **Custom Data** view of the Controller UI.

### Custom Timers

Custom timers allow you to time any arbitrary sequence of events within your code, even spanning multiple methods, by using `startTimer` and `stopTimer`.

```

public class MyActivity extends Activity {
 @Override
 protected void onStart(){
 Instrumentation.startTimer("Time Spent on MyActivity");
 //your code here.
 }

 @Override
 protected void onStop(){
 Instrumentation.stopTimer("Time Spent on MyActivity");
 //your code here.
 }
}

```

The methods `startTimer(String)` and `stopTime(String)` can be called from different threads. Calling `startTimer` again with the same name value resets a named timer.

This information appears in the **Custom Data** view of the Controller UI.

### Custom Metrics

Any integer-based data can be passed to the Android Agent. The first parameter to the `reportMetric` call is the name you want the metric to appear under in the Controller UI. The metric name should only contain alphanumeric characters and spaces. Illegal characters are replaced by their ASCII hex value.

For example, to track the number of times your users click the checkout button in your UI, you could use code similar to this.

```

findViewById(R.id.checkout_button).setOnClickListener(new View.OnClickListener(){
 @Override

```

```

 public void onClick(View view){
 //run your checkout routine.
 Instrumentation.reportMetric("Checkout Count", 1);
 }
 });

```

This information appears in the **Custom Data** view of the Controller UI.

### Custom User Data

You can set and later remove any string key/value pair you think might be useful with the following methods:

- `setUserData(key, value, success, error)`
- `removeUserData(key)`

Once this is set, user data will continue to be sent along with any instrumentation for network requests, sessions, or crashes for the rest of the current run of the application. You can remove any previously set user data on a per-key basis. Alternatively, you can remove previously set user data for all keys at once using `clearAllUserData`.

### Parameters

The following table describes the parameters:

Name	Type	Description
key	string	The key identifying the key-value pair.
value	string	The value associated with the key.
success	function	The user-defined callback for successful cases.
error	function	The user-defined callback for failed cases.

### Example

The code example below shows how to set user data with the SDK API:

```

void onUserLoggedIn(String userid) {
 Instrumentation.setUserData("User ID", userid);
 ...
}

```

The code example below shows how to remove user data with the SDK API:

```

void onUserLoggedIn(String userid) {
 Instrumentation.removeUserData("User ID", userid);
 ...
}

```

This information is available in **Network Request Analyze** and is added to any crash snapshot. Keys and values are limited to 2048 characters each.

You can also set user data with values of other types (Long, Boolean, Double, Date) using the following methods:

- `setUserDataLong`
- `setUserDataBoolean`
- `setUserDataDouble`
- `setUserDataDate`

## Breadcrumbs

Breadcrumbs allow you to situate a crash in the context of your user's experience. Set a breadcrumb when you want to capture a series of events. If your application crashes at some point in the future, the breadcrumb will be displayed along with the crash report.

There are two ways of leaving breadcrumbs:

- Crash Reports Only
- Modal

### Crash Reports Only

Using this method means that breadcrumbs are reported in crash reports only.

```
public static void leaveBreadcrumb(java.lang.String breadcrumb)
```

### Modal

Using this method lets you fine tune where the breadcrumbs are reported, either only in crash reports or in crash reports *and* sessions.

```
public static void leaveBreadcrumb(java.lang.String breadcrumb, int mode)
```

Where `mode` is either:

- `CRASHES_ONLY`
- `CRASHES_AND_SESSIONS`

If the `breadcrumb` is over 2048 characters, it is truncated. If it is empty, no breadcrumb is recorded. Each crash report displays the most recent 99 breadcrumbs.

## Add a Crash Reporting Callback

You may want to make crash report information (that the Android Agent collects) available to other parts of your code, for example, to Google Analytics. To enable passing on summary crash information, you can set up a crash report runtime callback. To get a callback when the Android Agent detects and then reports a crash, implement the following interface in your code:

```
public interface CrashReportCallback {
 void onCrashesReported(Collection<CrashReportSummary> summaries);
}
```

The Android Agent sends a collection of crash report summaries instead of an individual callback in the event that there is more than one crash, producing multiple crash report summaries.

The method `onCrashesReported` is invoked during the next initialization of the Android Agent after a crash has occurred.

This callback is invoked on your app's UI thread, so any work should be done on a separate work thread.

Each `CrashReportSummary` has the following properties:

```
public class CrashReportSummary {
 public final String crashId;
 public final String exceptionClass;
 public final String exceptionMessage;
}
```

If you are sending the information to another analytics tool, such as Google Analytics, we recommend to include all three properties: `exceptionClass` and `exceptionMessage` are useful for quick identification of the crash, and `crashId` is useful to look up the crash in the Controller UI.

For example, to print the crash information to Android's logger, you could implement a `CrashReportCallback` class like this:

```
public static class MyCrashReportCallback implements CrashReportCallback {
 @Override
 public void onCrashesReported(Collection<CrashReportSummary> summaries) {
 for (CrashReportSummary crash : summaries) {
 Log.e("MyApp", "Crash Detected: " + crash.exceptionClass + " : " +
 crash.exceptionMessage + " (" + crash.crashId + ")");
 }
 }
}
```

You set your callback as using the `AgentConfiguration` object:

```
final AgentConfiguration config = AgentConfiguration.builder()
 .withAppKey(appKey)
 .withContext(context)
 .withCrashCallback(new MyCrashReportCallback())
 .build();
```

Your callback is invoked after a crash, during the next initialization, on the main thread. For more information, see the [latest JavaDocs](#) for the complete Android SDK API.

## Disable Crash Reporting

Crash reporting is enabled by default, but you can manually disable crash reporting through the instrumentation configuration. If you are using other crash reporting tools, you might disable crash reporting to minimize conflicts and optimize the crash report results.

You can disable crash reporting by configuring the instrumentation with the `crashReportingEnabled` property as shown in the following:

```
let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>);
config.crashReportingEnabled = false;
ADEumInstrumentation.initWith(config);
```

## Report Errors and Exceptions

The string message used to construct a new throwable used for `reportError` should not use unique string such as hashes, `StackTraceID` or `ThreadID`. Including those will create an infinite number of `Error Group` which will impact performance.

To add unique error strings and values, you have two data collection options:

- Add a string value as a breadcrumb. If the event/error, you are reporting has a single value attached, add the value to `leaveBreadcrumb`. See [Breadcrumbs](#)
- Add string name and integer values. If the event/error, you are reporting has both name and integer values attached, add the values to `reportMetric`. See [Custom Metrics](#).

You can report exceptions using the method `reportError` from the `Instrumentation` class. Reported exceptions will appear in session details.

You can also set one of the severity levels below for an issue. With the severity level, you can filter errors in the **Code Issues Dashboard** or **Code Issues Analyze**.

- `ErrorSeverityLevel.INFO`
- `ErrorSeverityLevel.WARNING`
- `ErrorSeverityLevel.CRITICAL`

The example below uses the API to report possible exceptions and sets the severity level to `ErrorSeverityLevel.CRITICAL` (critical) when writing to a file.

```
private void writeToFile(String filePath, String data) {
 try {
 OutputStream outputStream = new FileOutputStream(filePath);
 Writer outputStreamWriter = new OutputStreamWriter(outputStream);
 outputStreamWriter.write(data);
 outputStreamWriter.close();
 } catch (IOException e) {
 Log.e("Exception", "File write failed: " + e.toString());
 Instrumentation.reportError(e, ErrorSeverityLevel.CRITICAL);
 }
}
```

## Disable the Agent to Stop Sending User Data to the Collector

You can disable the agent to stop sending all data to the collector while the agent is initialized and running. For example, you can disable the agent if your app has an option for users to opt-out of monitoring for privacy reasons.

## shutdownAgent

The `shutdownAgent` call stops outgoing data to the collector, and does not persist data on the device.

```
Instrumentation.shutdownAgent();
```

- The call only stops the traffic out of the agent.
- Once the agent has been initialized, the call cannot be removed, and a license will have been consumed.
- If you want to make this state permanent for a device, add code in `UserDefaults` to save the state and use that flag to conditionally initialize the agent in your code.

## restartAgent

To re-enable the agent and reverse `shutdownAgent`, use `restartAgent`.

```
Instrumentation.restartAgent();
```

- The call will respect the server side calls that can remotely shutdown the agent in a similar way.
- The call is only in effect while the app is running.
- The call will be ignored if the agent has been remotely disabled.
- If the call is removed from memory and the app restarts, or the device is rebooted, the agent will be initialized as normal.

## Configure Hybrid Support

By default, the Android Agent instruments [Android WebViews](#) by injecting the JavaScript Agent into WebViews. See [Hybrid Application Support](#) for an overview and an explanation of how it works.

### Runtime Configuration for Hybrid Support

The code example below disables the injection of the JavaScript Agent. If the client receives a `false` for this flag, then the JavaScript Agent will be disabled. Thus, WebViews will not be instrumented, and Ajax requests will not be monitored.

```
Instrumentation.start(
 AgentConfiguration.builder()
 .withAppKey(getString(R.string.app_key))
 .withContext(applicationContext)
 .withJSAgentInjectionEnabled(false)
 .build())
```

The injection occurs during the creation of a new `WKWebView`. So, if a `WKWebView` is created when this flag is set to `false`, that particular `WKWebView` won't be instrumented even if the flag is subsequently set to `true`.

The collection and reporting of Ajax calls are disabled by default. To enable the injection and the collection and reporting of Ajax calls, pass `true` to the method `jsAgentEnabled` in the instrumentation configuration as shown below.

```
Instrumentation.start(
 AgentConfiguration.builder()
 .withAppKey(getString(R.string.app_key))
 .withContext(applicationContext)
```

```
.withJSAgentAjaxEnabled(true)
.build()
```

## Programmatically Control Sessions

By default, a mobile session ends after a period of user inactivity. For example, when a user opens your application, the session begins and only ends after the user stops using the application for a set period of time. When the user begins to use the application again, a new session begins.

Instead of having a period of inactivity to define the duration of a session, however, you can use the following API to programmatically control when sessions begin and end:

```
void startNextSession()
```

When you call the method `startNextSession` from the Instrumentation class, the current session ends and a new session begins. The API enables you to define and frame your sessions so that they align more closely with business goals and expected user flows. For example, you could use the API to define a session that tracks a purchase of a product or registers a new user.

Excessive use of this API will cause sessions to be throttled (excessive use is >10 calls per minute per Android Agent, but is subject to change). When not using the API, sessions will fall back to the default of ending after a period of user inactivity.

## Example of a Programmatically Controlled Session

In the code example below, the current session ends and a new one begins when the check out is made.

```
public void checkoutCart(){
 if (currentCartItems!=null && currentCartItems.size()>0){
 CheckoutTask checkoutReq = new CheckoutTask();
 checkoutReq.execute(getEndpoint() + "cart/co");
 currentCartItemsMap.clear();
 convertItemsMaptoList();
 Instrumentation.startNextSession();
 } else {
 displayToast("There are no items in the cart");
 }
}
```

## Start and End Session Frames

You can use the `SessionFrame` API to create session frames that will appear in the session activity. Session frames provide context for what the user is doing during a session. With the API, you can improve the names of user screens and chronicle user flows within a business context.

## Use Cases

The following are common use cases for using the `SessionFrame` API:

- One Activity performs multiple functions and you want more granular tracking of the individual functions.
- A user flow spans multiple activities or user interactions. For example, you could use the API to create the session frames "Login", "Product Selection", and "Purchase" to chronicle the user flow for purchases.

- You want to capture dynamic information based on user interactions to name session frames, such as an order ID.

## SessionFrame API

The table below lists the three methods you can use with session frames.

Class	Method	Description
Instrumentation	<pre> <b>static</b> SessionFrame startSessionFrame(String sessionFrameName)           </pre>	<p>Use this to start and name your session frame.</p> <p>Naming session frames enable you to easily identify and track the frames in the <b>Sessions Dialog</b>.</p>
SessionFrame	<pre> <b>static void</b> updateName(String updatedSessionFrameName)           </pre>	<p>Use this to start and name your session frame.</p> <p>Naming session frames enable you to easily identify and track the frames in the <b>Sessions Dialog</b>.</p>
SessionFrame	<pre> <b>static void</b> end()           </pre>	<p>End the session frame. You call this method from the <code>SessionFrame</code> object returned from <code>startSessionFrame</code>.</p>

## Session Frame Example

In the following example, the `ShoppingCartActivity` class uses the `SessionFrame` API to track user activity during the checkout process.

```

public class ShoppingCartActivity extends Activity {

 SessionFrame checkoutSessionFrame;

 public void onCheckoutCartButtonClicked() {
 // The user starts the checkout by clicking the checkout button.
 // This may be after they have updated the quantities of items in the cart, etc.
 checkoutSessionFrame = Instrumentation.startSessionFrame("Checkout");
 }

 public void onConfirmOrderButtonClicked() {
 // Once they have confirmed payment info and shipping information, and they
 // are clicking the "Confirm" button to start the backend process of checking out,
 // we may know more information about the order itself, such as an order ID.
 checkoutSessionFrame.updateName("Checkout: Order ID " + orderId);
 }

 public void onProcessOrderCompleted() {

```

```

 // Once the order is processed, the user is done "checking out", so we end the session
 frame.
 checkoutSessionFrame.end();
 checkoutSessionFrame = null;
 }

 public void onCheckoutCanceled() {
 // If the user cancels or returns to the cart, you'll want to end the session frame also,
 or else it will be
 // left open and appear to have never ended.
 checkoutSessionFrame.end();
 checkoutSessionFrame = null;
 }
}

```

## Use a Custom HTTP Library

The Android Agent automatically detects network requests when the underlying implementation is handled by any one of the supported network libraries. To have the Android Agent detect requests from a custom library, [add request tracking code](#) to your application manually, using the `HttpRequestTracker` interface.

## Supported Network Libraries

The libraries below cover the great majority of Android network requests. In some cases, however, mobile applications use custom HTTP libraries.

- `HttpURLConnection`
- `HttpsURLConnection`
- `HttpClient` classes
- `OkHttp`
- `OkHttp3`
- `ch.boye.httpclientandroidlib`

To [set headers to allow correlation](#) with server-side processing, use the `ServerCorrelationHeaders` class.

## Add Request Tracking

To add request tracking manually, you use an `HttpRequestTracker` object to tell the agent when the request begins and when it ends and to report fields of the response to the agent.

### Start Tracking a Request

To begin tracking an HTTP request, use an instance of the following interface.

You must initialize the agent using the `Instrumentation.start` method before using this interface.

```

public interface HttpRequestTracker {
 public Exception getException();
 public HttpRequestTracker withException(Exception e);

 public String getError();
 public HttpRequestTracker withError(String error);
}

```

```

public int getResponseCode();
public HttpRequestTracker withResponseCode(int responseCode);

public Map<String, List<String>> getResponseHeaderFields();
public HttpRequestTracker withResponseHeaderFields(Map<String, List<String>>
responseHeaderFields);

/**
 * Stops tracking an HTTP request.
 *
 * Immediately after receiving a response or an error, set the appropriate fields and call
 this method to
 * report the outcome of the HTTP request. You should not continue to use this object
 after calling this
 * method -- if you need to track another request, obtain a new instance.
 */
public void reportDone();
}

```

## Example

Given a request snippet like this:

```

public byte[] sendRequest(URL url) throws HttpException {
 try {
 // implementation omitted
 return responseBody;
 } catch (UnderlyingException e) {
 throw new HttpException(e);
 }
}

```

Adding the tracker could look like this:

```

public byte[] sendRequest(URL url) throws HttpException {
 HttpRequestTracker tracker = Instrumentation.beginHttpRequest(url);
 try {
 // implementation omitted
 tracker.withResponseCode(theResponseCode)
 .withResponseHeaderFields(theResponseHeaderFields)
 .reportDone();
 return responseBody;
 } catch (UnderlyingException e) {
 tracker.withException(e)
 .reportDone();
 throw new HttpException(e);
 }
}

```

## Attach a Custom User Data Property to a Network Request

You can attach a [custom user data](#) property to a specific network request by adding user data to `HttpRequestTracker`.

```
public HttpRequestTracker withUserData(String key, String value)
public HttpRequestTracker withUserLong(String key, Long value)
public HttpRequestTracker withUserBoolean(String key, Boolean value)
public HttpRequestTracker withUserDouble(String key, Double value)
public HttpRequestTracker withUserDate(String key, Date value)
```

### Example

```
public byte[] sendRequest(URL url) throws HttpException {
 HttpRequestTracker tracker = Instrumentation.beginHttpRequest(url);
 try {
 // implementation omitted
 tracker.withResponseCode(theResponseCode)
 .withResponseHeaderFields(theResponseHeaderFields)
 .withUserData("key", "value")
 .withUserLong("number", 100)
 .withUserBoolean("boolean", true)
 .withUserDouble("double", 1.1234)
 .withUserDate("date", 1609488000)
 .reportDone();
 return responseBody;
 } catch (UnderlyingException e) {
 tracker.withException(e)
 .reportDone();
 throw new HttpException(e);
 }
}
```

## Enable Server-Side Correlation

To enable correlation between your request and server-side processing, add specific headers to outgoing requests that the server-side agent can detect.

This is done automatically for standard HTTP libraries.

```
public class ServerCorrelationHeaders {
 public static Map<String, List<String>> generate();
}
```

You must:

1. Call the `generate` method and set the generated headers *before* sending a request to the backend.
2. Report back the response headers, using data from the `withResponseHeaderFields` field.

## Override the Request/Response Content-Length

- You can generally obtain the content lengths of the network request and response by passing the headers with `HttpRequestTracker.withRequestHeaderFields()` and `HttpRequestTracker.withResponseHeaderFields()`.
- If for some reason this does not work for your custom HTTP tracking (i.e. the network library doesn't populate those fields until its being transmitted), then you can still report the request and response content lengths using `HttpRequestTracker.withRequestContentLength(Long length)` and `HttpRequestTracker.withResponseContentLength(Long length)`.
- For example, you want to track a request that has a `byte` array of content. You can report the request content length by passing the size of the byte array:

```
byte[] requestContent;
HttpRequestTracker tracker;
tracker.withRequestContentLength(requestContent.size());
```

## Customize the Agent Configuration

To customize the behavior of the agent itself, you pass the `AgentConfiguration` object to the `Instrumentation.start` method. The `AgentConfiguration` object allows you to:

- Point to an on-premises EUM Server
- Enable logging
- Custom-set the application name, which is useful if you deploy the same application binary with different package names to different geographic areas. This ensures that all the data ends up being processed under the same name.
- Ignore HTTP requests internal to your application that are not used for network requests
- [Configure the agent to use your custom HTTP library to send its beacons](#)

## Syntax

See the [latest JavaDocs](#) for more information.

```
Instrumentation.start(AgentConfiguration.builder()
 .withAppKey("<EUM_APP_KEY>")
 .withContext(getApplicationContext())
 .withCollectorURL(collectorURL*) // The URL of the EUM Server(on-prem)
 .withCompileTimeInstrumentationCheck(true) // Set to false if you are using features of
the SDK only, like custom HTTP support, but not to instrument your app.
 .withLoggingEnabled(true)//set default INFO logging. Tagged "AppDynamics".
 .withApplicationName(applicationName)//set a custom app name
 .withExcludedUrlPatterns(excludedUrlPatterns) // Set excluded url regex patterns for
http tracking
 .withCollectorChannelFactory(collectorChannelFactory()) // The custom HTTP
implementation to use
 .build());
```

\*For a list of URLs of EUM servers, see [SaaS Domains and IP Ranges](#).

## Configure the Agent to Use Custom HTTP Library

The Android Agent uses HTTP to deliver beacons. If you want the agent use your custom HTTP library to deliver beacons:

1. Implement a class that extends the following abstract class:

```

public abstract class CollectorChannel {
 private URL url;
 private int connectTimeout;
 private int readTimeout;
 private Map<String, List<String>> requestProperties = new HashMap<String,
List<String>>();
 private String requestMethod;

 public void setURL(URL url) {
 this.url = url;
 }

 public URL getURL() {
 return url;
 }

 public void setConnectTimeout(int connectTimeout) {
 this.connectTimeout = connectTimeout;
 }

 public int getConnectTimeout() {
 return connectTimeout;
 }

 public void setReadTimeout(int readTimeout) {
 this.readTimeout = readTimeout;
 }

 public int getReadTimeout() {
 return readTimeout;
 }

 public void addRequestProperty(String property, String value) {
 if (!requestProperties.containsKey(property)) {
 requestProperties.put(property, new ArrayList<String>());
 }
 requestProperties.get(property).add(value);
 }

 public Map<String, List<String>> getRequestProperties() {
 return Collections.unmodifiableMap(requestProperties);
 }

 public void setRequestMethod(String requestMethod) {
 this.requestMethod = requestMethod;
 }

 public String getRequestMethod() {
 return requestMethod;
 }
}

```

```

public abstract OutputStream getOutputStream() throws IOException;

public abstract InputStream getInputStream() throws IOException;

public abstract int getResponseCode() throws IOException;

public abstract Map<String,List<String>> getHeaderFields() throws IOException;
}

```

This interface is loosely based on `URLConnection`.

2. Implement a version of the `CollectorChannelFactory` interface:

```

public interface CollectorChannelFactory {

 /**
 * Returns a new instance of CollectorChannel.
 *
 * If you want to supply a custom CollectorChannel, implement this interface, and
 return
 * an instance of your concrete implementation of CollectorChannel from this method.
 */
 public CollectorChannel newCollectorChannel();
}

```

The implementation of `newCollectorChannel` should return a new instance of your implementation of `CollectorChannel`.

3. Pass the `CollectorChannelFactory` to the `AgentConfiguration` object.

## Capture User Interactions

You can enable the agent to track certain user interactions. Once user interactions have been captured, you can sort sessions by UI event and view the UI event in the timeline of the session waterfall.

You can capture when users do one or all of the following:

- Press buttons
- Select a text field
- Click a list item

## Security and Privacy Concerns

The interaction capture mode is disabled by default for security and privacy reasons as user interactions may contain sensitive information. This potential security and privacy issue may be compounded if you enable both the capturing of UI interactions and screenshots.

## Enable User Interaction Capture Mode

To enable user interaction capture mode, pass the capture mode to the method `withInteractionCaptureMode()` from an `AgentConfiguration` object. The instrumentation code example below configures the Android Agent to capture all the supported types of user interactions.

```
Instrumentation.start(AgentConfiguration.builder()
 .withAppKey("<EUM_APP_KEY>")
 .withContext(getApplicationContext())
 .withInteractionCaptureMode(InteractionCaptureMode.All)
 .build());
```

You can also configure the Android Agent to only capture one type of user interaction:

```
Instrumentation.start(AgentConfiguration.builder()
 .withAppKey("<EUM_APP_KEY>")
 .withContext(getApplicationContext())
 .withInteractionCaptureMode(InteractionCaptureMode.ButtonPressed)
 .build());
```

### Programmatically Take Screenshots

By default, mobile screenshots are enabled on the agent-side but disabled on the Controller-side. To programmatically take manual screenshots, you must [enable screenshots in the Controller UI](#) and add the following API:

```
Instrumentation.takeScreenshot();
```

For example, you can take a screenshot after loading a UI element to view how the element is displayed to your users:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
 super.onCreate(savedInstanceState);
 setContentView(R.layout.activity_spinner_with_toast);
 spinner = (Spinner) findViewById(R.id.spnOptions);
 btnSpinnerVal = (Button) findViewById(R.id.btnSpinnerValue);
 loadSpinner();
 Instrumentation.takeScreenshot();
}
```

### Disable Screenshots

You can [disable screenshots from the Controller UI](#) or with the Android SDK. To disable screenshots with the Android SDK, use the method `withScreenshotsEnabled(false)` from the `AgentConfiguration` class:

```
Instrumentation.start(AgentConfiguration.builder()
 .withAppKey("<EUM_APP_KEY>")
```

```

 .withContext(getApplicationContext())
 .withScreenshotsEnabled(false)
 .build();
 }

```

## Block/Unblock Screenshots

You can also use the Android SDK to block screenshots from being taken during the execution of a code block. This just temporarily blocks screenshots from being taken until you unblock screenshots. This enables you to stop taking screenshots in situations where users are entering personal data, such as on login and account screens.

You use the methods `Instrumentation.blockScreenshots()` and `Instrumentation.unblockScreenshots()` to block and unblock screenshots. If screenshots are disabled through `AgentConfiguration.Builder.withScreenshotsEnabled(true)` or through the Controller UI, these methods have no effect. You can call `Instrumentation.screenshotsBlocked()` to check if screenshots are being blocked.

The following example demonstrates how you could use the API to block and unblock screenshots when displaying user information.

```

public class UserAccountActivity extends Activity {
 ...
 public void displayCustomerAccount() {
 // Check to see if screenshots are blocked
 if (! Instrumentation.screenshotsBlocked()) {
 // If screenshots aren't blocked, block them before showing customer details
 Instrumentation.blockScreenshots();
 }
 // Code to display customer details
 displayAccount(this.user);
 // After you're done, unblock screenshots
 Instrumentation.unblockScreenshots();
 }
 ...
}

```

## Transform URLs for Network Requests

When your application makes network requests, you may not want to report URLs containing sensitive information to the EUM Server. You can instead transform the network request URL before reporting it or ignore it altogether:

1. Implement a network request callback that modifies or ignores specific URLs.
2. Register the network request callback in the initialization code.

### Implement the Network Request Callback

The callback that modifies or ignores specific URLs is an implementation of the interface below. The method `onNetworkRequest` is synchronous, we recommend that you return from the function quickly.

```
public interface com.appdynamics.eumagent.runtime.NetworkRequestCallback {
 boolean onNetworkRequest(HttpRequestTracker httpRequestTracker);
}
```

## Transforming URLs

The `onNetworkRequest` method, in general, should follow the steps below to transform URLs:

1. Identify specific URLs using techniques such as regex or pattern matching.
2. Modify the `url` property of the `HttpRequestTracker` object.
3. Assign a valid URL to the `url` property. Modifying other properties of the `HttpRequestTracker` object will be ignored.
4. Return `true`.

The first step is optional as you could choose to transform the URLs of all network requests.

```
private static class myNetworkRequestCallback implements
 com.appdynamics.eumagent.runtime.NetworkRequestCallback {
 @Override
 public boolean onNetworkRequest(HttpRequestTracker httpRequestTracker) {
 URL urlMask = new URL("http://networkrequest-mask.com/");
 httpRequestTracker.withURL(urlMask);
 return true;
 }
}
```

In general, however, you would want to identify and transform URLs that contain sensitive information. For example:

```
private static class myNetworkRequestCallback implements
 com.appdynamics.eumagent.runtime.NetworkRequestCallback {
 @Override
 public boolean onNetworkRequest(HttpRequestTracker httpRequestTracker) {
 String urlString = httpRequestTracker.getURL().toString();
 try {
 URL url = new URL("http://customer-account.com/");
 if (urlString.contains("accountInfo")) {
 // Change the URL for calls to Facebook
 httpRequestTracker.withURL(url);
 return true;
 }
 } catch (MalformedURLException e) {
 return false;
 }
 return true;
 }
}
```

## Ignoring URLs

If the `onNetworkRequest` method returns `false`, the beacon is dropped. The general process for ignoring beacons is:

1. Identify specific URLs using techniques such as regex or pattern matching.
2. Return `false`.

You could also ignore all network requests with the following implementation of `onNetworkRequest`:

```
private static class myNetworkRequestCallback implements
com.appdynamics.eumagent.runtime.NetworkRequestCallback {
 @Override
 public boolean onNetworkRequest(HttpRequestTracker httpRequestTracker) {
 return false;
 }
}
```

In general, you would identify network requests that you didn't want to monitor and return `false` to ignore the network request. For example:

```
private static class myNetworkRequestCallback implements
com.appdynamics.eumagent.runtime.NetworkRequestCallback {
 @Override
 public boolean onNetworkRequest(HttpRequestTracker httpRequestTracker) {
 String urlString = httpRequestTracker.getURL().toString();
 try {
 URL url = new URL("http://socialnetworksite.com/");
 if (urlString.contains("avatar")) {
 // Ignore calls for avatars
 return false;
 }
 } catch (MalformedURLException e) {
 return false;
 }
 return true;
 }
}
```

## Register the Network Request Callback

After implementing the callback, you register it in the initialization code. When the Android Agent is ready to create a network request beacon, it will first call the callback with an `HttpRequestTracker` object.

To register the callback in the initialization code:

```
Instrumentation.start(AgentConfiguration.builder()
 .withContext(getApplicationContext())
 .withAppKey("<EUM_APP_KEY>")
 .withNetworkRequestCallback(new myNetworkRequestCallback())
 .build());
```

## Enable Logging and Set Logging Level

You use the method `withLogLevel` of the class `AgentConfiguration` to enable logging and set the logging level. You can set logging to one of the following levels:

- `LOGGING_LEVEL_NONE`
- `LOGGING_LEVEL_INFO`
- `LOGGING_LEVEL_VERBOSE`

Use verbose logging only for troubleshooting. Make sure to disable for production.

### Example:

```
AgentConfiguration config = AgentConfiguration.builder()
config.withAppKey(appKey)
config.withContext(context)
 .withLogLevel(Instrumentation.LOGGING_LEVEL_VERBOSE)
 .build();
Instrumentation.start(config);
```

## Android SDK Documentation

For the complete SDK API documentation, see the [latest JavaDocs](#) or the previous versions listed below:

## Manually Upload Mapping Files

### Related pages:

- [Automatically Upload Mapping Files](#)

If you have obfuscated your code and want to monitor crashes, you will be required to upload the ProGuard or DexGuard mapping files. AppDynamics requires the mapping file for the application to produce human-readable stack traces for crash snapshots. For details on the importance of snapshots, see [Get Human-Readable Crash Snapshots](#).

DexGuard is built on ProGuard, so the Controller UI and some of the REST API for uploading mapping files will refer to ProGuard for both ProGuard and DexGuard files.

This page describes the requirements, the available methods, and instructions to manually upload the mapping files.

**i** We recommend you set up [automatic uploading](#) of the ProGuard or DexGuard mapping files using Gradle and your `build.gradle` file.

## Requirements

If you update your application, you are required to upload the new version of the mapping file.

To manually upload the mapping files, you are required to associate the mapping file with the correct version of the application by providing the following:

- Android package name for the application
- Version code for that application (specified in either the `AndroidManifest.xml` file or the `build.gradle` file)

## Upload Methods

You can then either upload the mapping file using the **Upload Missing ProGuard Mappings** dialog in the Controller UI or use a special REST API. Perform the upload separately for each ProGuard mapping file that you are providing. You can also check your uploads with a separate REST API.

See the following sections for instructions:

### Upload ProGuard Mappings in the Controller UI

1. From the left-hand panel, click **Configuration**.
2. Click **ProGuard Mapping & NDK Symbol Files**.
3. From the **Upload Missing ProGuard Mapping** dialog:
  - a. Enter the version code (a number) for the package. This is the `versionCode` property specified in either the `AndroidManifest.xml` file or the `build.gradle` file of the application for which this mapping file was generated.
  - b. Click **Choose File**.  
The uploader expects a file with the `.txt` extension. The file is named `mapping.txt`.
  - c. In the file browser, locate and select the mapping file and click **Open**.
  - d. Click **Upload**.

### Upload ProGuard Mappings with the REST API

The API uses HTTP basic authentication. The username is your AppDynamics EUM account name and the password is your EUM license key.

#### Send the mapping file

Send the mapping file as a text file in the body of the PUT request to the following URL:

[Americas](#)   [EMEA](#)   [APAC](#)

`https://api.eum-appdynamics.com/v2/account/<MyAccountName>/<androidPackageName>/<versionCode>/proguard-mapping`

Americas EMEA APAC

```
https://fra-api.eum-appdynamics.com/v2/account/<MyAccountName>/<androidPackageName>/<versionCode>/proguard-mapping
```

Americas EMEA APAC

```
https://syd-api.eum-appdynamics.com/v2/account/<MyAccountName>/<androidPackageName>/<versionCode>/proguard-mapping
```

See [SaaS Domains and IP Ranges](#) for more EUM server locations.

These parameters are required:

- `MyAccountName` : the URL-encoded version of your account name.
- `androidPackagename` : the name of the Android package for which this mapping file was generated.
- `versionCode` : the string representation of the "versionCode" property specified in either the `AndroidManifest.xml` file or the `build.gradle` file of the application for which this mapping file was generated.

The request body contains the mapping file. You are required to add a `Content-Type` header, `-H Content-Type:text/plain`, and your account name and license key/password to the call.

### Sample Request and Response Using the REST API

This is a sample request and response using the REST API.

#### Upload Request

The following example uses curl to send a ProGuard mapping file. You would use a similar command to send a DexGuard mapping file. The account name is "Example account" and the license key/password is "Example-License-Key-4e8ec2ae6cfe". The plus signs replace spaces in the account name when the account name is URL-encoded. The package name of the Android application is "com.example.networklogger". The mapping file corresponds to the version with `versionCode`.

Americas EMEA APAC

```
curl -v -H Content-Type:text/plain --upload-file mapping.txt --user Example+account:Example-License-Key-4e8ec2ae6cfe https://api.eum-appdynamics.com/v2/account/Example+account/com.example.networklogger/1/proguard-mapping
```

Americas EMEA APAC

```
curl -v -H Content-Type:text/plain --upload-file mapping.txt --user
Example+account:Example-License-Key-4e8ec2ae6cfe https://fra-api.eum-appdynamics.com/v2/
account/Example+account/com.example.networklogger/1/proguard-mapping
```

Americas [EMEA](#) [APAC](#)

```
curl -v -H Content-Type:text/plain --upload-file mapping.txt --user
Example+account:Example-License-Key-4e8ec2ae6cfe https://syd-api.eum-appdynamics.com/v2/
account/Example+account/com.example.networklogger/1/proguard-mapping
```

## Upload Response

The successful output of the example request looks like this:

[Americas](#) [EMEA](#) [APAC](#)

## Check Uploaded Mapping Files Using the REST API

You can check to make sure that your mapping files have successfully uploaded using two REST APIs.

1. [Get a list of the GUIDs for the last 50 mapping files you have uploaded.](#)
2. [Check if a specific mapping file has been uploaded.](#)

### List of the Last 50 Mapping Files Uploaded

The `proguardQuery` method allows you to retrieve a list of GUIDs for up to the last 50 mapping files (ProGuard or DexGuard) that have been uploaded to your account, along with the time they were uploaded. The response is displayed as JSON, by upload time, with the most recent first.

1. Set up your authentication as described in [Upload with the API](#).
2. Create a GET request of the form:

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://<EUM_Cloud/
EUM_Server_Host:port>/v2/account/<EUM_Account_Name>/crash-symbol-file-query/proguard
```

- `EUM_Cloud` refers to SaaS-based EUM Cloud URLs. For a complete list, see [SaaS Domains and IP Ranges](#).
- `EUM_Server_Host` refers to the URL pointing to your on-premises EUM Server.
- `EUM_Account_Name` is your EUM account name.
- `GUID_To_Check` is the GUID of the ProGuard file in which you are interested.

### Sample Request

[Americas](#)   [EMEA](#)   [APAC](#)

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://api.eum-
appdynamics.com:443/v2/account/<EUM_Account_Name>/crash-symbol-file-query/proguard
```

[Americas](#)   [EMEA](#)   [APAC](#)

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://fra-api.eum-
appdynamics.com:443/v2/account/<EUM_Account_Name>/crash-symbol-file-query/proguard
```

Americas EMEA APAC

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://syd-api.eum-appdynamics.com:443/v2/account/<EUM_Account_Name>/crash-symbol-file-query/proguard
```

## Sample Response

```
{
 "proguardFiles": [
 {
 "packageName": "my_package_name1",
 "version": "1",
 "uploadTime": "mm/dd/yyyy 16:09:23",
 "GUID": "my_build_id1"
 },
 {
 "packageName": "my_package_name2",
 "version": "1",
 "uploadTime": "mm/dd/yyyy 16:09:23",
 "GUID": "my_build_id2"
 }
]
}
```

## Check for Specific Mapping File by GUID

The `checkForProguardFile` method allows you to check if a specific ProGuard or DexGuard file by GUID has been uploaded. The upload time is returned in the response.

- Set up your authentication as described in [Upload with the REST API](#).
- Create a GET request of the form:

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://<EUM_Cloud/EUM_Server_Host:port>/v2/account/<EUM_Account_Name>/crash-symbol-file-query/proguard/guid/<GUID_To_Check>
```

- `EUM_Cloud` refers to SaaS-based EUM Cloud URLs. For a complete list, see [SaaS Domains and IP Ranges](#).
- `EUM_Server_Host` refers to the URL pointing to your on-premises EUM Server.
- `EUM_Account_Name` is your EUM account name.
- `GUID_To_Check` is the GUID of the ProGuard file in which you are interested.

## Sample Request

Americas EMEA APAC

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://api.eum-appdynamics.com:443/v2/account/<EUM_Account_Name>/crash-symbol-file-query/proguard/guid/my_build_id1
```

Americas EMEA APAC

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://fra-api.eum-appdynamics.com:443/v2/account/<EUM_Account_Name>/crash-symbol-file-query/proguard/guid/my_build_id1
```

Americas EMEA APAC

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://syd-api.eum-appdynamics.com:443/v2/account/<EUM_Account_Name>/crash-symbol-file-query/proguard/guid/my_build_id1
```

### Sample Response

```
{"packageName":"mypackagename","version":"1","uploadTime":"mm/dd/yyyy 16:09:23","GUID":"my_build_id1"}
```

## Troubleshoot the Android Instrumentation

### Related pages:

- [Instrument Android Applications](#)
- [Customize the Android Build](#)
- [Customize the Android Instrumentation](#)

This page provide instructions and tips for solving some common Android instrumentation issues.

### Dex Failure After Upgrading Agent

If you build your application with Gradle and you get a dex failure after upgrading the Mobile Agent, you likely need to clear the Gradle cache.

### Use Android Studio

To clear the cache using Android Studio:

1. Select **Build > Clean Project**.
2. Select **File > Invalidate Caches**.

 Sometimes a restart is also necessary.

### Using the Command Line

To clear the cache using the command line:

1. Stop Gradle.

```
$ gradlew --stop
```

2. You may also need to refresh dependencies.

```
$ gradlew --refresh-dependencies
```

You can also try removing the AppDynamics cached images.

1. Find the images.

```
$ find ~/.gradle/caches -name com.appdynamics
```

2. Delete them.

```
$ find ~/.gradle/caches -name com.appdynamics -print0 | xargs -0 rm -r
```

### Instrumentation Appears to Be Running After Being Disabled

If you disabled the instrumentation in Android using the Gradle flag `enabledForDebugBuilds`, but the instrumentation task still runs, this is because of the Transform API.

Android Gradle Plugin 1.5.0 introduced the Transform API that the Android Agent uses to do the bytecode injection. Due to the limitations of the Transform API, even when instrumentation is disabled, the `transformClassesWithAppDynamicsForDebug` task will still appear in the Gradle task log. To ensure that it is not actually instrumenting, run `gradlew` with `--info` flag to show the info logs.

You should see the following log:

```
Instrumentation is disabled for this build variant. Just copying
the input files to fulfill Transform contract.
```

### Crashes Are Not Reported After Using Custom Default Uncaught Exception Handler

Install your exception handler before you start the Android Agent. When an uncaught exception is handled by the agent, it will first store the crash report, and then call your exception handler.

### Network Requests Are Not Being Reported

Please see the [list of supported networking libraries](#). If your library is not on the list, you can always [report these network requests manually](#).

For builds with the `debuggable` attribute, auto-instrumentation (the `enableInstrumentation` build attribute) is disabled to improve build speeds, and you cannot enable auto-instrumentation for those builds. Debuggable builds using Android Agent 20.5.0-20.7.0 do not auto-instrument network requests.

### Exclude Classes from Being Instrumented

- `excludeClasses`

---

## Enforce a Different Runtime Version from the Plugin Version

- `dependencies.compile 'com.appdynamics:appdynamics-runtime:4.5.+'`  
`adeum.dependencyInjection.enabled = false`

## Upgrade the Android Agent

As new features are added to the agent, you will need to upgrade the Android SDK in your app. The process of installing and updating the latest Android SDK is the same.

To upgrade, you simply update the build file for your platform:

- [Gradle/Android Studio](#)
- [Maven](#)

## Instrument Xamarin Applications

Before you can monitor your Xamarin application, you will need to instrument your application to enable the Xamarin Agent to collect mobile metrics.

After you have [set up and accessed Mobile RUM](#), follow these instructions:

1. [Confirm supported platforms](#)
2. [Understand the limitations of the Xamarin Agent](#)
3. [Instrument a Xamarin Application](#)
4. [\(Optional\) Enable Automatic Instrumentation of Network Requests](#)
5. [\(Optional\) Customize the Xamarin Instrumentation](#)
6. [\(Optional\) Point to an On-Premises EUM Server](#)

## Xamarin Agent Support

### Supported Platforms

- iOS and Android platforms

 All other platforms will build and run without errors, but no monitoring will occur.

### Supported Libraries

- .Net Standard 2.0 (with Xamarin Agent  $\geq 20.10.0$ )

#### Recommendations

Xamarin  $\leq 50.2$  only supported the instrumentation of applications that reference the Portable Class Libraries (PCL). From Xamarin  $\geq 50.3$ , the Xamarin Agent only supports the .NET Standard library and the instrumentation of applications that reference the .NET Standard library. If you still need PCL support, you are recommended to use Xamarin  $\leq 50.2$ .

## Instrument Xamarin Applications

Follow the steps below to manually instrument your Xamarin iOS, Android, and Forms apps.

## Add the Xamarin Agent Package

1. Get the Xamarin Agent from the [NuGet Gallery](#). Follow the instructions given in [Adding a Package](#) to add the package AppDynamics Xamarin Agent from [nuget.org](#).
2. Add the Xamarin.Forms package from [AppDynamics.Agent.Forms](#).
3. In the `Xamarin.Android` project, add the following to `MainActivity.cs` under `OnCreate`:

```
AppDynamics.Droid.Agent.Init(this, bundle);
```

### Example

```
public class MainActivity : global::Xamarin.Forms.Platform.Android.FormsAppCompatActivity {
 protected override void OnCreate(Bundle bundle) {
 base.OnCreate(bundle); //existing code
 global::Xamarin.Forms.Forms.Init(this, bundle);

 AppDynamics.Droid.Agent.Init(this, bundle); //initialize the agent on the Android
 Platform

 LoadApplication(new App());
 }
}
```

## Get Your Application Key

Complete the **Getting Started Wizard** to get an EUM App Key. You will need this key when you modify the source code. In some cases, multiple mobile applications can share the same key.

Because there is no Xamarin platform option, you will need to choose either Android or iOS. For Android, you will need to select **Manual**.

If you have completed the **Getting Started Wizard**, but don't have your EUM App Key, see [Get Your Application Key](#).

## Add the Required Permissions (Android Deployments Only)

Open the file `Properties/AndroidManifest.xml` and verify that it has these permissions:

```
<uses-permission android:name="android.permission.INTERNET"></uses-permission>
<uses-permission android:name="android.permission.ACCESS_NETWORK_STATE"></uses-permission>
```

If these permissions are not present, add them to the file `Properties/AndroidManifest.xml`.

## Initialize the Agent

To initialize the Xamarin Agent, you use the code below for iOS and Android. Use the EUM app key (enter as a string) that you received after completing [step 2](#).

```
var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
```

```
AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
```

**i** If you are running an on-premises EUM Server, you need to specify the URL to the EUM Server. See [Point to an On-Premises EUM Server \(Optional\)](#) to learn how.

## Forms Solution

For Forms Solutions, you only need to place the initialize code in the constructor of the `App.xaml.cs` file for the Xamarin Agent to instrument both Android and iOS applications.

```
public App()
{
 InitializeComponent();
 // This initialization code is used by both iOS and Android apps.
 var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
 AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
 MainPage = new FormsExamplePage();
}
```

If you have application code in the `MainActivity.cs` file for Android or `AppDelegate.cs` for iOS that you want to instrument, however, you should initialize the Xamarin Agent in those files as you would do for [iOS Solutions](#) and [Android Solutions](#).

## iOS Solution

For iOS apps, you place the initialize code in the `AppDelegate.cs` file in the method `FinishedLaunching` of the class `AppDelegate` as shown below.

```
public class AppDelegate : UIApplicationDelegate
{
 // class-level declarations
 public override UIWindow Window
 {
 get;
 set;
 }
 public override bool FinishedLaunching(UIApplication application, NSDictionary launchOptions)
 {
 // The two lines below initialize the AppDynamics instrumentation.
 var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
 AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
 ...
 return true;
 }
 ...
}
```

You may also consider placing it in the `Main.cs` in the method `Main`.

## Android Solution

In the `MainActivity.cs` file, place the initialization code in the method `OnCreate`:

```
class MainActivity {

 protected override void OnCreate(Bundle savedInstanceState) {
 // The two lines below initialize the AppDynamics instrumentation.
 var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
 AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
 ...
 }
}
```

## Build the Application

Run and build your application from Visual Studio. From the **Getting Started Wizard**, you should see that the application has **connected and the instrumentation has been verified**.

**i** For iOS projects with Xamarin Agent  $\geq 21.6.0$ , you must add the additional `MtouchExtraArgs --registrar:static` for each simulator build configuration, such as the debug and release builds. This does not apply for physical device configurations since the static registrar is already the default. If the iOS project file is edited directly, the build configuration should contain the `MtouchExtraArgs` element:

```
<PropertyGroup Condition=" '$(Configuration)|$(Platform)' ==
'Debug|iPhoneSimulator' ">
 ...
 <MtouchExtraArgs>--registrar:static</MtouchExtraArgs>
</PropertyGroup>
"
```

## (Optional) Enable Xamarin Automatic Instrumentation

The Xamarin Agent can automatically inject Xamarin-specific instrumentation code into your project. You can:

1. **Automatically track** `HttpClient` or `Refit` network requests.
2. **Automatically track** `Xamarin.Forms` pages.
3. **Automatically track** `Xamarin.Forms` UI elements.

This can be achieved using a different beta nuget package called `AppDynamics.Agent.AutoInstrument.Fody`.

## Set Up the `AppDynamics.Agent.AutoInstrument.Fody` Package

1. Add the `AppDynamics.Agent` package.
2. Add the `AppDynamics.Agent.AutoInstrument.Fody` package.

**i** To install the `AppDynamics.Agent.AutoInstrument.Fody` beta package, check the "Include prereleases" option in order for the version to be displayed.

3. Build the solution.

After you build the solution, two files should be generated automatically:

- `FodyWeavers.xml`
- `FodyWeavers.xsd`

These files should be checked into source control.

**i** If the above files are not generated automatically, a new file called `FodyWeavers.xml` should be created manually with the following content:

```
<Weavers xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance" xsi:noNamespaceSchemaLocation="FodyWeavers.xsd">
 <AppDynamics.Agent.AutoInstrument />
</Weavers>
```

If the project is already using `Fody`, these files will already be there and only the `FodyWeavers.xml` file has to be updated to include the `AppDynamics.Agent.AutoInstrument` weaver.

For example:

```
<Weavers xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance" xsi:noNamespaceSchemaLocation="FodyWeavers.xsd">
 ... Existing weavers ...
 <AppDynamics.Agent.AutoInstrument />
</Weavers>
```

### (Optional) Customize Your Instrumentation

The Xamarin SDK has additional classes to allow you to extend the kinds of application data you can collect and aggregate using Mobile RUM. See [Customize the Xamarin Instrumentation](#).

### (Optional) Point to an On-Premises EUM Server

To use an on-premises EUM Server, you pass the URL to the on-premises EUM Server when you initialize the instrumentation with the EUM App Key from [Get Your Application Key](#):

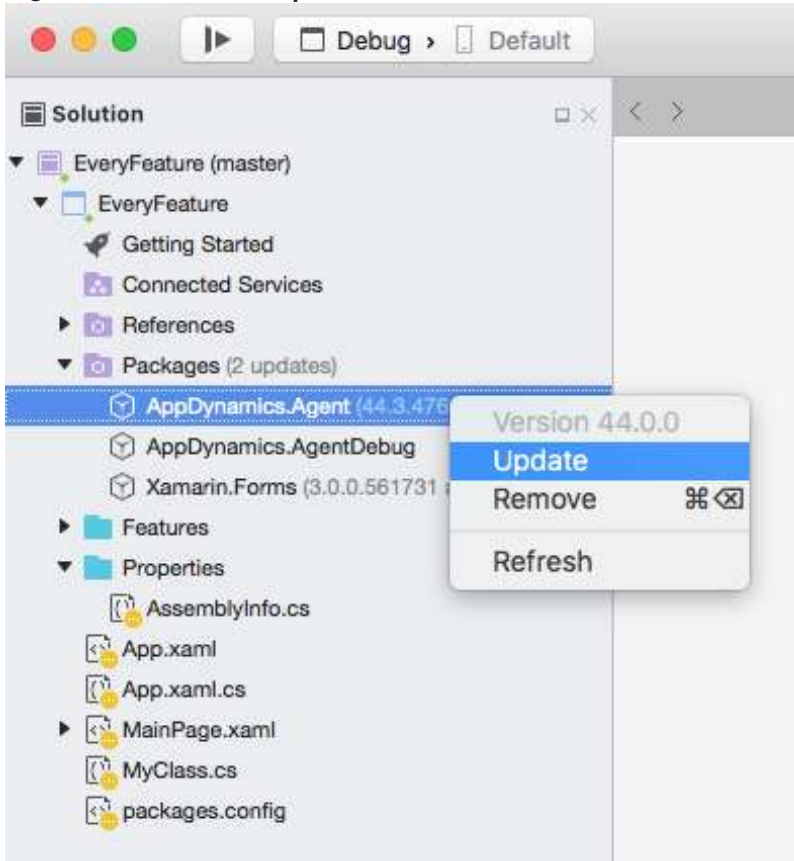

```
var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
```

```
config.CollectorURL = <COLLECTOR_URL:PORT>;
AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
```

## Upgrade the Xamarin Agent

As new features are added to the agent, you will need to upgrade the Xamarin Agent package in your app.

1. From Visual Studio, open the Xamarin application that has the AppDynamics Agent package.
2. From the **Packages** folder, select the AppDynamics Agent.
3. Right-click and click **Update**.

## Customize the Xamarin Instrumentation

### Related pages:

- [Instrument Xamarin Applications](#)
- [Xamarin SDK Documentation](#)

The following sections show you how to use the Xamarin SDK to customize your instrumentation.

- [Customize Xamarin Automatic Instrumentation](#)
- [Track Calls](#)
- [Timing Events](#)
- [Report Metrics](#)
- [Add Tracking to HTTP Requests](#)
- [Leave Breadcrumbs](#)
- [Change the App Key](#)
- [Disable the Agent to Stop Sending User Data to the Collector](#)

- [Report Errors and Exceptions](#)
- [Report Aggregate Exceptions as Crashes](#)
- [Disable Crash Reporting](#)
- [Add a Crash Reporting Callback](#)
- [Start and End Session Frames](#)
- [Add User Data](#)
- [Set the Logging Level \(Optional\)](#)
- [Transform URLs for Network Requests](#)
- [Configure and Take Screenshots](#)
- [Disable Screenshots](#)
- [Block and Unblock Screenshots](#)
- [WebView Instrumentation \(JavaScript Agent Injection\)](#)
- [Fragment Tracking](#)
- [View Controller Tracking](#)
- [Instrument Xamarin.Forms](#)
- [Xamarin SDK Documentation](#)

 Because the agent [stores data about events in a local buffer](#) before reporting the information, you are recommended to use the APIs with discretion.

## Customize Xamarin Automatic Instrumentation

You can customize automatic instrumentation of the following:

- [Automatic Network Request Instrumentation](#)
- [Automatic Page Tracking Instrumentation](#)
- [Automatic UI Tracking Instrumentation](#)

To make customizations to automatic instrumentation, make sure you have the `AppDynamics.Agent.AutoInstrument.Fody` package added to your project. See [Set Up Automatic Network Request Instrumentation](#).

### Customize Automatic Network Request Instrumentation

When automatic network request instrumentation is enabled, the weaver will search the project for all new instances of `HttpClient` or `Refit` usages. In instances that are found, the agent instrumentation code will be injected to the `HttpClient` or `Refit` request.

You can further customize the automatic instrumentation at the project level or class level (see sections below). For example, you could:

1. Enable the automatic instrumentation at a project level from the `FodyWeavers.xml` file, but exclude some files at the class level using the `DisableNetworkInstrumentation` attribute.
2. Disable the automatic instrumentation at a project level from the `FodyWeavers.xml` file, but include some files at the class level using the `EnableNetworkInstrumentation` attribute.

 If you are using [semi-automatic network request tracking](#) via the `HttpRequestTrackerHandler`, the network request will not be reported twice.

### Enable/Disable at the Project Level

You can enable or disable automatic instrumentation at the project level using the `NetworkInstrumentationEnabled` flag in the `FodyWeavers.xml` file.

For example:

```
<Weavers xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchemaLocation="
FodyWeavers.xsd">
 ... Existing weavers ...
 <AppDynamics.Agent.AutoInstrument NetworkInstrumentationEnabled="true"/>
</Weavers>
```

### Enable/Disable at the Class Level

You can enable or disable automatic instrumentation at the class level by using one of the following attributes per class:

1. `[EnableNetworkInstrumentation]`

```
[EnableNetworkInstrumentation]
public class MyClass
{
 ...
}
```

2. `[DisableNetworkInstrumentation]`

```
[DisableNetworkInstrumentation]
public class MyClass
{
 ...
}
```

### Recommendations

- If you are using [manual network request tracking](#), you will see duplicate entries for the same network request. To avoid this, you can either remove the manual instrumentation or use the `DisableNetworkInstrumentation` attribute on that class.
- If your HTTP requests are handled in a different project, you should add both the `AppDynamics.Agent` and `AppDynamics.Agent.AutoInstrument.Fody` to that project as well for instrumentation to work.
- If you are using a `HttpClient` instance generated in another library, you should only create and use the instance within the same project for instrumentation to work. Automatic instrumentation works by targeting new `HttpClient` instances within the project.

### Customize Automatic Page Tracking Instrumentation

When automatic page tracking instrumentation is enabled, the weaver will search the project for all instances of `Xamarin.Forms Page` in the project and inject the instrumentation code.

#### Enable/Disable at the Project Level

You can enable or disable automatic Page Tracking instrumentation at the project level using the `PageTrackingInstrumentationEnabled` flag in the `FodyWeavers.xml` file:

```
<Weavers xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchemaLocation="
FodyWeavers.xsd">
 ... Existing weavers ...
 <AppDynamics.Agent.AutoInstrument PageTrackingInstrumentationEnabled="true"/>
</Weavers>
```

### Enable/Disable at the Class Level

You can enable or disable automatic instrumentation at the class level by using one of the following attributes per class:

1. [EnablePageTracking]

```
[EnablePageTracking]
public class MyPage : Xamarin.Forms.ContentPage
{
 ...
}
```

2. [DisableUITracking]

```
[DisablePageTracking]
public class MyPage : Xamarin.Forms.ContentPage
{
 ...
}
```

### Automatic UI Tracking Instrumentation

When automatic UI tracking instrumentation is enabled, the weaver will search the project for all instances of `Xamarin.Forms Button`, `Entry` and `ListView` in the project and inject the instrumentation code.

### Enable/Disable at the Project Level

You can enable or disable automatic instrumentation at the project level using the `UITrackingInstrumentationEnabled` flag in the `FodyWeavers.xml` file.

For example:

```
<Weavers xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchemaLocation="
FodyWeavers.xsd">
 ... Existing weavers ...
 <AppDynamics.Agent.AutoInstrument UITrackingInstrumentationEnabled="true"/>
</Weavers>
```

### Enable/Disable at the Class Level

You can enable or disable automatic instrumentation at the class level by using one of the following attributes per class:

1. [EnableUITracking]

```
[EnableUITracking]
public class MyPage : Xamarin.Forms.ContentPage
{
 ...
}
```

2. [DisableUITracking]

```
[DisableUITracking]
public class MyPage : Xamarin.Forms.ContentPage
{
 ...
}
```

### Automatic UI Tracking and XAML

Automatic UI Tracking works with both XAML and code-behind UI elements. But even though code-behind UIs are automatically instrumented, there's a required extra step to auto-instrument XAML. Add the following configuration to your `.csproj` file:

```
<PropertyGroup>
 <FodyDependsOnTargets>
 XamlC
 </FodyDependsOnTargets>
</PropertyGroup>
```

Automatic UI Tracking only works with pre-compiled XAML, so you will need to use `XamlCompilationOptions.Compile`:

```
[XamlCompilation(XamlCompilationOptions.Compile)]
```

By default, a project created with a Visual Studio `Xamarin.Forms` template will already include this. See [XAML Compilation in Xamarin.Forms](#) for more information.

### Track Calls

You can instrument methods to see how often the instrumented a method is invoked and how long it takes to run. To do this, add a call at the beginning and end of the method you'd like to instrument.

In the example below, the code executed in the constructor for the class `ShoppingCart` will be tracked and reported. In your own code, start tracking calls by specifying the class and method in `BeginCall` and then complete the tracking and report the data by calling `ReportCallEnded`.

```
using AppDynamics.Agent;
...

```

```

public class ShoppingCart {
 public ShoppingCart() {

 // Code to create the shopping cart
 }
 void CheckOut(int custId, int transactionId) {
 var tracker = Instrumentation.BeginCall("ShoppingCart", "CheckOut", custId,
transactionId);
 // The code placed here will be tracked and reported.
 tracker.ReportCallEnded();
 }
}

```

## Timing Events

Sometimes you want to time an event in your application that spans multiple methods. You can do this by calling `StartTimerWithName` when the event starts, and then `StopTimerWithName` when it ends. For example, to track the time a user spends viewing a screen, the instrumentation might look something like the following:

```

using AppDynamics.Agent;
...
async private void StartCapturePreview_Click(object sender, RoutedEventArgs e) {
 capturePreview.Source = captureManager;
 Instrumentation.StartTimerWithName("CapturePreview");
 await captureManager.StartPreviewAsync();
}
async private void StopCapturePreview_Click(object sender, RoutedEventArgs e) {
 await captureManager.StopPreviewAsync();
 Instrumentation.StopTimerWithName("CapturePreview");
}

```

## Report Metrics

To report other types of data, you can use a metric. The metric name should only contain alphanumeric characters and spaces. Illegal characters are replaced by their ASCII hex value. The metric value must be a long integer.

The snippet below shows how you might report a metric.

```

using AppDynamics.Agent;
...
Instrumentation.ReportMetricWithName("Database Rows", 5123);

```

## Add Tracking to HTTP Requests

### Semi-automatic HTTP Tracking

The `HttpMessageHandler` handles all the tracking and error handling. It can also include other inner handlers if you are already using a custom `HttpMessageHandler` for other purposes, such as for logging.

To add semi-automatic tracking, instantiate a `HttpClient` and pass the `HttpRequestTrackerHandler` :

```
var client = new HttpClient(new HttpRequestTrackerHandler());
```

Then, all the requests sent using the client will be already instrumented:

```
response = await client.GetAsync(uri);
```

**i** If you already have `HttpMessageHandler` passed to the `HttpClient` (for example, adding a logging handler), you must instantiate `HttpRequestTrackerHandler` and pass the existing handler to the constructor:

```
var loggingHandler = new MyLoggingHandler();
var client = new HttpClient(new
 HttpRequestTrackerHandler(loggingHandler));
```

## Manual HTTP Tracking

You can manually report a network request using the `AppDynamics.Agent.HttpRequestTracker` class.

The example below uses `HttpRequestTracker` with the `System.Net.Http.HttpClient` class. The `tracker` object synchronously captures and reports the network request as well as any network errors.

```
using AppDynamics.Agent;
...
public async Task<string> Fetch(Uri uri) {
 var client = new HttpClient();
 // Create AppDynamics Tracker
 var tracker = HttpRequestTracker.Create(uri);
 // Add AppDynamics Server Correlation Headers
 foreach (var header in ServerCorrelationHeaders.Generate) {
 // Each header could have multiple values
 foreach (var value in header.Value) {
 client.DefaultRequestHeaders.Add(header.Key, value);
 }
 }
 HttpResponseMessage response = null;
 try {
 response = await client.GetAsync(uri);
 } catch (Exception ex) {
 // Capture any network errors.
 tracker.Exception = ex;
 tracker.ReportDone();
 throw ex; //you decide to throw it or not
 }
}
```

```

if (!response.Equals(null)) {
 // Capture request information such as the
 // status code, status message, and headers.
 tracker.ResponseCode = (int)response.StatusCode;
 tracker.StatusLine = response.ReasonPhrase;
 tracker.ResponseHeaderFields = response.Headers;
 tracker.ReportDone();
 return await response.Content.ReadAsStringAsync();
}
return null;
}

```

### Attach a Custom User Data Property to a Network Request

You can attach a [custom user data](#) property to a specific network request by adding user data to `HttpRequestTracker`.

```

public HttpRequestTracker withUserData(String key, String value)
public HttpRequestTracker withUserLong(String key, Long value)
public HttpRequestTracker withUserBoolean(String key, Boolean value)
public HttpRequestTracker withUserDouble(String key, Double value)
public HttpRequestTracker withUserDate(String key, Date value)

```

### Example

```

public byte[] sendRequest(URL url) throws HttpException {
 HttpRequestTracker tracker = Instrumentation.beginHttpRequest(url);
 try {
 // implemented
 tracker.withResponseCode(theResponseCode)
 .withResponseHeaderFields(theResponseHeaderFields)
 .withUserData("key", "value")
 .withUserLong("number", 100)
 .withUserBoolean("boolean", true)
 .withUserDouble("double", 1.1234)
 .withUserDate("date", 1609488000)
 .reportDone();
 return responseBody;
 } catch (UnderlyingException e) {
 tracker.withException(e)
 .reportDone();
 throw new HttpException(e);
 }
}

```

## Leave Breadcrumbs

You can leave breadcrumbs to mark interesting events. For example, if your application crashes, the breadcrumbs you left with be displayed in the crash report and could provide context. You can also configure the breadcrumb to appear in sessions.

The following is the method signature for leaving breadcrumbs:

```
static void AppDynamics.Agent.Instrumentation.LeaveBreadcrumb(string breadcrumb,
BreadcrumbVisibility mode)
```

You use the mode to set the visibility of the breadcrumb. The visibility defines where you will see the breadcrumb in the Controller UI. The value of `mode` can be one of the following:

- `BreadcrumbVisibility.CrashesOnly` – The breadcrumb will only appear in crash snapshots.
- `BreadcrumbVisibility.CrashesAndSessions` – The breadcrumb will appear in crash snapshots and sessions.

Thus, you would use the method below to set breadcrumbs that are only reported in crash reports:

```
using AppDynamics.Agent;
...
Instrumentation.LeaveBreadcrumb("GetUserInfo", BreadcrumbVisibility.CrashesOnly);
```

If you would like to see the breadcrumb in crash reports and sessions:

```
using AppDynamics.Agent;
...
Instrumentation.LeaveBreadcrumb("GetUserInfo", BreadcrumbVisibility.CrashesAndSessions);
```

## Change the App Key

You can use the Xamarin Agent API to dynamically change the EUM app key. You receive the EUM App Key when creating a mobile app in the Controller UI. See [Get Started with Mobile RUM](#) for information about getting the EUM App Key.

The API to change app keys is available through the `Instrumentation` class.

```
Instrumentation.ChangeAppKey("NEW-APP-KEY");
```

## Disable the Agent to Stop Sending User Data to the Collector

You can disable the agent to stop sending all data to the collector while the agent is initialized and running. For example, you can disable the agent if your app has an option for users to opt-out of monitoring for privacy reasons.

### `shutdownAgent`

The `shutdownAgent` call stops outgoing data to the collector, and does not persist data on the device.

```
using AppDynamics.Agent;
...
Instrumentation.shutdownAgent();
```

- The call only stops the traffic out of the agent.
- Once the agent has been initialized, the call cannot be removed, and a license will have been consumed.
- If you want to make this state permanent for a device, add code in UserDefaults to save the state and use that flag to conditionally initialize the agent in your code.

### restartAgent

To re-enable the agent and reverse `shutdownAgent`, use `restartAgent`.

```
using AppDynamics.Agent;
...
Instrumentation.restartAgent();
```

- This call will respect the server side calls that can remotely shutdown the agent in a similar way.
- The call is only in effect while the app is running.
- The call will be ignored if the agent has been remotely disabled.
- If the call is removed from memory and the app restarts, or the device is rebooted, the agent will be initialized as

### Report Errors and Exceptions

You can report exceptions using the method `reportError` from the `Instrumentation` class. Reported exceptions will appear in session details.

You can also set one of the severity levels below for an issue. With the severity level, you can filter errors in the **Code Issues Dashboard** or **Code Issues Analyze**.

- `ErrorSeverityLevel.INFO`
- `ErrorSeverityLevel.WARNING`
- `ErrorSeverityLevel.CRITICAL`

The example below uses the API to report possible exceptions and sets the severity level to `ErrorSeverityLevel.CRITICAL` (critical) when writing to a file

```
using AppDynamics.Agent;
...
try {
 // possible exception //
}
catch (Exception e){
 Instrumentation.ReportError(exception, ErrorSeverityLevel.CRITICAL);
}
```

## Report Aggregate Exceptions as Crashes

You can configure the Xamarin Agent to report aggregate exceptions (handled and unhandled) as crashes by setting the boolean property `EnableAggregateExceptionHandling` to `true`. When the property is set to `false`, only unhandled exceptions are reported. The default value is `false`.

The following code example configures the Xamarin Agent to report aggregate exceptions (handled and unhandled) as crashes.

```
using AppDynamics.Agent;
...
var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
AppDynamics.Agent.Instrumentation.EnableAggregateExceptionHandling = true;
AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
...
```

## Disable Crash Reporting

Crash reporting is enabled by default, but you can manually disable crash reporting through the instrumentation configuration. If you are using other crash reporting tools, you might disable crash reporting to minimize conflicts and optimize the crash report results.

You can disable crash reporting by configuring the instrumentation with the `crashReportingEnabled` property as shown in the following:

```
var config = AgentConfiguration.Create(<EUM_APP_KEY>);
config.CrashReportingEnabled = false;
Instrumentation.InitWithConfiguration(config);
```

## Add a Crash Reporting Callback

You may want to make crash report information (that the Xamarin Agent collects) available to other parts of your code, such as to Google Analytics. To enable passing on summary crash information, you can set up a crash report runtime callback:

1. To get a callback when the Xamarin Agent detects and then reports a crash, subscribe to the following event that is a part of the **IAgentConfiguration** interface:

```
event EventHandler<IEnumerable<CrashReportSummary>> OnCrash;
```

The `OnCrash` event is raised during the next initialization of the Xamarin Agent after a crash has occurred. This event is raised on your app's UI thread, so any work should be done on a separate work thread.

2. The Xamarin Agent sends a collection of crash report summaries instead of an individual callback in the event that there is more than one crash, producing multiple crash report summaries. Each `CrashReportSummary` has the following properties:
  - `ExceptionName` : useful for quick identification of the crash
  - `ExceptionReason` : useful for quick identification of the crash

- `ExceptionId` : useful to look up the crash in the Controller UI
