AppDynamics Essentials	28
AppDynamics Concepts	28
User Interface.....	29
Application Performance Monitoring	29
Infrastructure Visibility with Database Visibility	29
End User Monitoring for Client Experience.....	30
Business iQ and Analytics for Business Impact.....	30
Use Metrics	31
Baselines and Thresholds	31
Health Rules, Policies, and Actions.....	32
Infrastructure Monitoring.....	32
Integrate and Extend AppDynamics.....	32

Deployment Planning Guide	33
Deployment Models	33
Network Port Requirements	35
Getting Started	35
Create an Account	36
Gain System Access.....	37
Install Application Agents	39
Connect Agents to the Controller Tenant.....	39
Continue with Your AppDynamics Deployment	40
Telemetry	40
Tutorials.....	40
Download AppDynamics Software	40
Deployment Overview.....	41
Controller Tenant Overview and Administration.....	41
AppDynamics Mobile App	53
SaaS Domains and IP Ranges.....	64
AppDynamics Support	84
Downloads	85
Sensitive Data Collection and Security	88
Prevent Sensitive Data Collection.....	88
SaaS Deployment.....	88
On-premises Deployment	88
Role-based Access Control	89
Suppress Raw SQL Capture.....	89
Hide Query Literals.....	89
Exclude Error Logs	89
Mask Log Analytics Values.....	90
Disable the Data Collector.....	90
Filter Sensitive Data in Environment Variables.....	90
Data Privacy Policy Dialog.....	90

Data Collection Dashboard	91
Metrics and Graphs	92
Metric Visualization Tools.....	93
Metrics	93
Metric Browser	93
Metric Data Resolution over Time.....	95
Percentile Metrics.....	99
Monitor Events	100
View and Monitor Events.....	100
Archive Events.....	101
Filter Custom Events.....	102
Monitor Application Change Events	102
Events Reference.....	104
Monitor Infrastructure.....	124
AIOps.....	125
Alert and Respond.....	125
Permissions.....	126
Alert and Respond Policy Structure	126
Alert and Respond Across the Platform.....	127
Example Use Cases	127
Policies.....	130
Anomaly Detection.....	136
Health Rules	153
Configure Health Rules	174
JMX Health Rules.....	196
Troubleshoot Health Rule Violations.....	200
Alert Sensitivity Tuning Questions and Answers	206
Actions.....	207
Email Digests.....	248
Alerting Templates	249

Configure and Enable Mutual TLS Authentication	255
Troubleshoot Alert and Respond Problems	261
Dashboards and Reports	262
Custom Dashboards.....	262
Reports	282
Dash Studio.....	285
User Preferences.....	343
User Preferences.....	343
My Account	343
View Preferences.....	343
Advanced User Preferences.....	344
Application Monitoring	344
Overview of Application Monitoring	345
Application Model Overview	345
Business Transactions.....	346
Business Applications.....	346
Nodes.....	346
Tiers	346
Entities	347
Backends.....	348
Integration with Other AppDynamics Modules	348
Install App Server Agents	349
Agent Installation Quick Start.....	350
Before Installing an Agent	350
Use the Getting Started Wizard	350
Agent Installation by Type.....	351
Application, Tier, and Node Naming Guidelines.....	351
App Agent Network Bandwidth Usage.....	352
Agent License Considerations	352
Agent Management	353

Agent-to-Controller Connections.....	437
Agent Installer	442
Java Agent.....	501
.NET Agent	662
NGINX Agent	826
Node.js Agent	835
PHP Agent	881
Python Agent.....	926
Serverless APM for AWS Lambda.....	983
Apache Web Server Agent.....	1039
C/C++ SDK.....	1061
Go SDK	1111
IBM Integration Bus Agent.....	1129
Deploy AppDynamics for Azure	1142
Machine Agents	1165
SELinux Installation Issues	1165
Administer App Server Agents	1166
Planning Agent Deployment.....	1167
Encrypt Agent Credentials.....	1167
Manage App Agents	1171
Agent Log Files.....	1173
Metrics Limits.....	1177
Historical and Disconnected Nodes	1178
Request Agent Log Files.....	1181
App Agent Node Properties	1183
App Agent Node Properties Reference	1185
Dynamic Language Agent Proxy	1261
Business Applications.....	1264
Organize Business Applications	1264
Permissions.....	1265

View Applications	1265
Modify Applications	1265
Application Performance Details	1266
Flow Maps	1266
Cross Application Flow	1270
Export and Import Business Application Settings.....	1272
Business Transactions.....	1276
What is a Business Transaction?	1276
Business Transaction in AppDynamics	1276
Best Practices to Create Business Transactions	1277
View Business Transactions.....	1278
Configure Business Transactions	1281
Organize Business Transactions	1285
Create Business Transaction Health Rules	1288
Monitor the Performance of Business Transactions	1288
Monitor the Business Transaction Security	1299
Troubleshoot Business Transaction Performance with Transaction Snapshots	1299
Service Endpoints.....	1312
Difference Between Service Endpoints and Business Transactions	1312
Customize Service Endpoints	1313
Service Endpoint Health Rules.....	1313
Monitor Service Endpoints.....	1313
Service Endpoint Limits	1316
Service Endpoint Metrics	1316
Tiers and Nodes	1316
View All Tiers and Nodes.....	1317
View Tier and Node Dashboards.....	1317
Create a Tier.....	1317
Rename Node, Tier, or Business Application in the UI.....	1317
Move and Rename Nodes	1317

Troubleshoot Node Problems	1319
Monitor JVMs.....	1320
Monitor JMX.....	1332
Monitor .NET Nodes.....	1335
Monitor CLR's	1339
Monitor IIS.....	1342
Monitor Node.js Processes.....	1344
Remote Services	1348
What is a Remote Service?	1348
Monitoring Information for Remote Services.....	1348
View Remote Service Performance on Flow Maps	1349
View Discovered Remote Services	1349
Slow Remote Service Calls.....	1350
Stale Remote Service Removal	1350
Group Remote Services on Flow Maps.....	1351
Monitor Databases.....	1352
Resolve Remote Services to Tiers.....	1357
Information Points.....	1358
Information Point Data: Code Metrics and Business Metrics.....	1358
Creating Information Points.....	1359
Viewing Information Point Data	1359
Java and .NET Information Points	1359
PHP Information Points	1360
AppDynamics for OpenTelemetry™	1366
Getting Started.....	1366
Next Steps	1366
Configure Collector	1366
Configure Resource Attributes.....	1374
Instrument Applications with AppDynamics for OpenTelemetry™	1375
View OpenTelemetry™ Data in the Controller UI	1386

Support for AppDynamics for OpenTelemetry™	1390
Filter Sensitive Data Using the Collector	1396
View OpenTelemetry™ Ingestion Data in the Controller UI	1400
Troubleshooting AppDynamics for OpenTelemetry	1401
Development Level Monitoring	1404
Development Level Monitoring and AppDynamics	1404
Effects of Development Mode.....	1404
Enable Development Level Monitoring	1405
Turn Off Development Level Monitoring	1405
Development Level Monitoring Limits.....	1406
Configure Instrumentation	1406
Access Instrumentation Settings	1407
Configuration Page Items	1407
Configure Instrumentation Overview.....	1407
Transaction Detection Rules.....	1418
Backend Detection Rules	1488
Error Detection	1537
Service Endpoint Detection.....	1543
Data Collectors.....	1545
Call Graph Settings	1551
Configure JMX Metrics from MBeans.....	1552
Asynchronous Transaction Demarcators	1560
Automatic Instrumentation of Specialist Packages/Frameworks	1561
Troubleshooting Applications	1577
Access Troubleshooting	1577
Restricting Memory Amounts.....	1577
Additional Help.....	1578
Slow Response Times	1578
Errors and Exceptions	1585
Slow Response Times for .NET	1588

Java Resource Issues	1591
Java Memory Leaks.....	1593
Java Memory Thrash.....	1596
Code Deadlocks for Java.....	1599
Thread Contention	1600
Event Loop Blocking in Node.js	1603
App Server Agents Supported Environments	1608
Java Agent Supported Platforms	1608
.NET Agent	1645
Supported Runtime Environments.....	1645
Automatically Discovered Business Transactions	1646
Supported Loggers for the .NET Agent	1647
Remote Service Detection	1648
Supported Windows Azure Remote Services.....	1649
Data Storage Detection.....	1650
.NET Agent Frameworks for OpenTelemetry	1651
Limitations	1651
Unsupported .NET Features	1651
Node.js Agent	1651
PHP Agent	1652
PHP Agent Support.....	1653
Python Agent	1658
Python Agent Support.....	1658
Apache Web Server Agent	1660
Apache Server Agent Support.....	1661
C++ Agent.....	1664
C/C++ Supported Platforms	1664
Go Language Agent.....	1664
Go Supported Platforms.....	1664
IIB Agent	1664

IIB Agent Support.....	1664
Application Security Monitoring.....	1665
Supported APM Agents	1666
Cisco Secure Application Components	1666
Cisco Secure Application Architecture	1667
Cisco Secure Application Requirements	1667
Software Requirements	1668
Resource Utilization and Performance Impact	1669
Browser Requirements	1669
Before You Begin.....	1669
Getting Started with Cisco Secure Application	1670
Next Steps	1672
Cisco Secure Application Policies.....	1672
Supported Runtime Policies	1672
Create a Runtime Policy.....	1673
Modify a Security Policy.....	1675
Alerts Using Cisco Secure Application	1675
Create an HTTP Alert	1676
Create an Email Alert.....	1677
Integrate Cisco Secure Application with Splunk.....	1678
AppDynamics IP Addresses	1678
Security Events.....	1678
Monitor Application Security Using Cisco Secure Application.....	1681
Select Scope for the Dashboard.....	1682
Navigate to AppDynamics Application or Tier Flowmap	1683
Monitor the Home Page of Cisco Secure Application.....	1684
Monitor Security Status of Applications.....	1688
Monitor Business Transactions	1692
Monitor Libraries.....	1697
Monitor Vulnerabilities	1700

Monitor Attacks.....	1705
Monitor Observations.....	1711
Cisco Secure Application for OpenTelemetry	1712
Before You Begin.....	1712
Configure the OpenTelemetry Java.....	1713
Configure the Cisco Secure Application Extension.....	1713
Troubleshooting.....	1714
Troubleshooting Cisco Secure Application Issues	1714
Cisco Secure Application Does Not Start	1714
Cisco Secure Application Permissions Are Unavailable in the Role Configuration.....	1714
Cisco Secure Application for OpenTelemetry Is Not Loading	1715
Disable Cisco Secure Application at Agent Start-up.....	1715
Security Events Widget Is Not Displayed in an Application Flow Map	1715
Number of Registered Nodes and Active Nodes Does Not Match	1715
Vulnerabilities or Attacks Are Not Displayed on the Home, Vulnerabilities, or Attacks Page.....	1715
Security Setting is Enabled and No Attacks Are Listed	1716
The Applications Page Display the Node Not Active Message for an Active Node	1716
Splunk Integration - Connection Issue	1716
End User Monitoring	1717
Overview of End User Monitoring	1717
Understand End User Activity	1719
View EUM Data.....	1720
On-Premise EUM Deployments	1720
Access the SaaS EUM Server.....	1720
How EUM Works with other AppDynamics Products.....	1721
Learn More.....	1721
Experience Journey Map.....	1722
Requirements.....	1722
Access Experience Journey Map	1722

Experience Journey Map UI.....	1722
Browser vs. Mobile Apps in Experience Journey Map	1728
Using Experience Journey Map	1730
Learn More.....	1730
Use Cases for Experience Journey Map.....	1730
Configure Experience Journey Map	1732
Filter User Journeys	1734
Analyze Traffic Segments	1736
Create a Custom View.....	1737
Correlate Business Transactions for EUM.....	1738
Benefits of Correlating Business Transactions	1739
Before You Begin.....	1739
Business Transaction Correlation Support for App Server Agents	1739
Access Business Transaction Correlation	1740
Automatic Correlation of Business Transactions.....	1740
Manually Enable Business Transaction Correlation.....	1741
Filter Business Transactions for Correlation.....	1742
EUM Data	1742
Types of EUM Data.....	1742
Data Storage and Retrieval	1744
Data Storage Details.....	1745
Controller Mapping of Data	1747
Access EUM Data.....	1748
Data and Deployment Models.....	1749
EUM Accounts, Licenses, and App Keys.....	1749
View License Usage	1749
Overages	1749
License Key.....	1749
EUM App Key	1749
License Optimization and Usage Periods	1750

Browser Monitoring	1752
Overview of the Controller UI for Browser Monitoring.....	1752
Differences Between Browser RUM and Browser Synthetic Monitoring	1753
How to Use Browser RUM and Browser Synthetic Monitoring Together.....	1754
Browser App Dashboard.....	1754
Resource Performance Dashboard.....	1764
JavaScript Errors Dashboard.....	1779
Browser Real User Monitoring.....	1783
Synthetic Monitoring	2033
Browser Synthetic Monitoring.....	2033
Synthetic API Monitoring	2101
Install the Private Synthetic Agent (Web and API Monitoring)	2129
Mobile Real User Monitoring	2196
How AppDynamics Agents Collect Data.....	2196
Get Started with Mobile RUM	2196
Get Started with Mobile RUM	2196
AppDynamics iOS Sample App	2200
Instrument iOS Applications	2201
Instrument Android Applications.....	2251
Instrument Xamarin Applications	2295
Instrument Cordova Applications.....	2322
Instrument React Native Applications.....	2341
Instrument Flutter Applications	2370
Instrument .NET MAUI Applications	2389
Overview of the Controller UI for Mobile RUM.....	2413
Configure the Controller UI for Mobile RUM.....	2467
Correlate Business Transactions for Mobile RUM	2475

AppDynamics Essentials

Welcome to the AppDynamics SaaS. This documentation set introduces you to the AppDynamics SaaS Deployment. AppDynamics helps you understand and optimize your business performance, ranging from software to infrastructure to business journeys.

We detail common concepts and procedures across all product modules, including APM, Application Analytics, End User Monitoring, and more. We also cover the Controller Tenant UI, which is the browser-based console you use to understand, configure, and troubleshoot your application environment.

To report issues with the documentation, email the AppDynamics Docs Team at appd-docs@cisco.com.

AppDynamics has implemented restrictions and will not enter into any negotiation with, or seek to solicit any interest from, any third party in relation to the sale or use of the AppDynamics products or software or any part thereof, whether directly or indirectly with any country or region subject to an embargo including but not limited to Cuba, Iran, North Korea, Sudan, Syria, and Crimea.

AppDynamics Concepts

Related pages:

- [Flow Maps](#)
- [SaaS Domains and IP Ranges](#)
- [Tiers and Nodes](#)

AppDynamics SaaS application enables management and monitoring of your application delivery ecosystem, ranging from mobile/browser client network requests to backend databases/servers and more. This global view across your application landscape allows you to quickly navigate through the distributed application into the call graphs and exception reports that individual hosts generate.

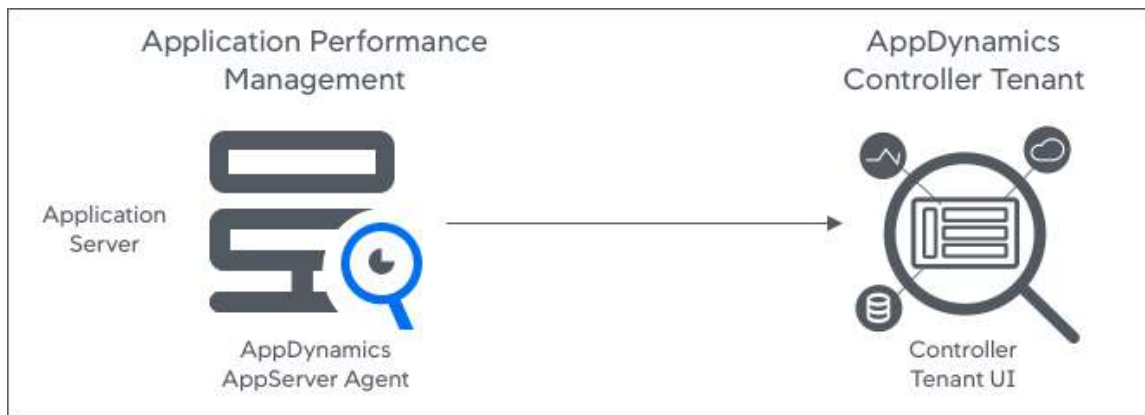

User Interface

AppDynamics provides a [Controller Tenant](#) to collect, store, analyze, and baseline the performance data collected by agents and a Controller Tenant UI to view and manage the information. You access the AppDynamics Controller Tenant UI through a URL that uses your Account name. Each Controller Tenant has a distinct set of users, reporting agents, and application monitoring configuration.

AppDynamics can host one or more accounts, where each account represents one Controller Tenant. AppDynamics SaaS deployment is a multi-tenant environment that allows you to access multiple Controller Tenants independently.

Application Performance Monitoring

At the tier level, AppDynamics provides a view of the runtime operation of your code via an AppDynamics [App Server Agent](#). The agent detects calls to a service entry point at the tier and follows the execution path for the call through the call stack. It sends data about usage metrics, code exceptions, exit calls to backend systems, and error conditions to your Controller Tenant. See [Install App Server Agents](#).

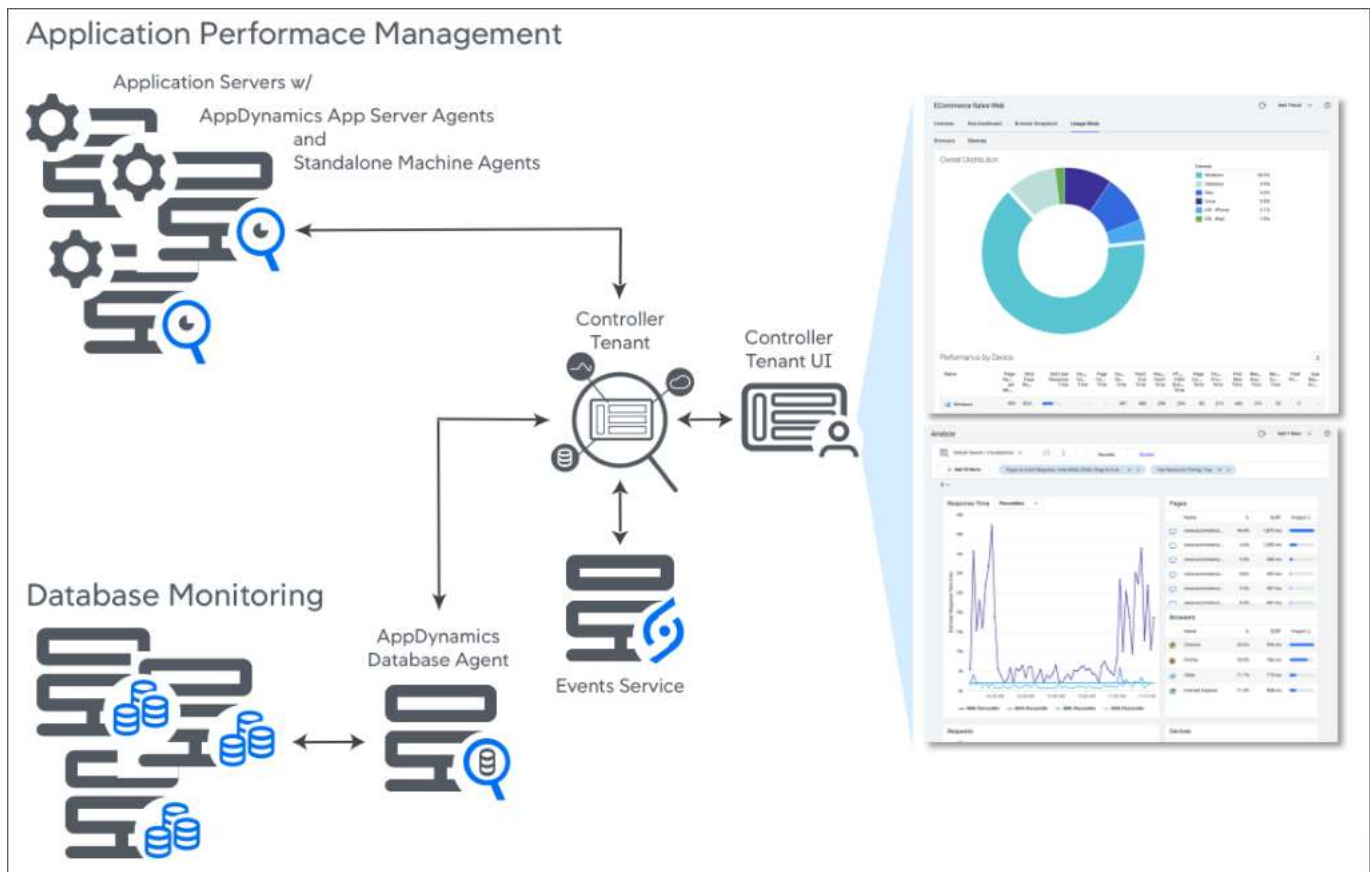

Most application environments contain more than one application server. They may contain distributed, interconnected servers and processes that participate in fulfilling a given user request. In this context, AppDynamics tracks transactions across distributed, heterogeneous services.

Infrastructure Visibility with Database Visibility

For greater visibility into your application delivery environment, you can add AppDynamics [Database Visibility](#) to the SaaS deployment.

Application Agents provide information about calls to backend databases, including errors and call counts. The Database Visibility module extends your visibility into the workings of the database server itself by providing you with information about query execution and performance with an agent-less profile.

AppDynamics [Infrastructure Visibility](#) contributes to your view of the data center by adding valuable information on the performance of the machines and networks in your environment.

In this deployment, the [Database Agent](#) collects information from the database servers and sends it to the Controller Tenant. Some of this information persists in the Events Service. The Events Service is the document storage component optimized for searching and storing high volumes of information. Database Analytics features may use the Events Service.

End User Monitoring for Client Experience

Server-side monitoring provides visibility into the end user's experience with application performance and suggests performance improvements to the server. End-user monitoring (EUM) extends those insights from the initial client request to the client device response. AppDynamics [End User Monitoring](#) allows you to collect information about where requests are coming from, what devices/channels users are using, and code performance once deployed on their devices. You have the visibility you need to investigate mobile crashes by displaying stack traces and other contextual data at the time of the crash and tying that to the Business Transaction data from the server.

Business iQ and Analytics for Business Impact

AppDynamics [Analytics](#) provides *Business iQ* to help you understand how the performance of your application environment and end-user applications relates to the business data of the transactions. It lets

you sort, order, and understand the data that composes the Business Transactions. You can drill into the log data that your environment generates. See [Using Analytics Data](#).

Use Metrics

A metric is a particular class of measurement, state, or event in the monitored environment. Many defaults relate to the overall performance of the application or business transaction, such as request load, average response time, or error rate. Others describe the state of the server infrastructure, such as percentage CPU busy or percentage of memory used.

Agents register the metrics they detect with the Controller Tenant. They then report measurements or occurrences of the metrics at regular intervals. You can view metrics using the [Metric Browser](#) in the Controller Tenant UI.

[Information points](#) are a type of metric that enables you to report on how your business (as opposed to your application) is performing. For example, you could set up an information point to total the revenue from the purchase on your website of a specific product or set of products. You can also use information points to report on how your code is performing, for example, how many times a specific method is called and how long it is taking to execute.

You can create extensions that use the machine agent to report [custom metrics](#) that you define. Just like the built-in AppDynamics metrics, these metrics incur a [baseline](#) that reports to the Controller Tenant.

As an alternative to using the Controller Tenant UI, you can access metrics programmatically with the [AppDynamics APIs](#).

Baselines and Thresholds

AppDynamics uses both self-learned baselines and configurable thresholds to identify application issues. A complex distributed application has a large number of performance metrics, and each metric is important in one or more contexts. It can be difficult to:

- Determine the values or ranges that are normal for a particular metric.
- Set meaningful thresholds on which to base and receive relevant alerts.
- Determine what is a 'normal' metric when the application or infrastructure undergoes change.

For these reasons, we provide anomaly detection based on dynamic baselines or thresholds.

AppDynamics automatically calculates dynamic baselines for your metrics, defining what is 'normal' for each metric according to actual usage. The platform uses these baselines to identify subsequent metric values that fall out of range. You no longer need to set up static thresholds in rapidly changing, error-prone application environments.

You can create health rules with conditions that use baselines to trigger alerts or other actions when performance problems are occurring or about to happen. See [Alert and Respond](#) and [Health Rules](#) and [Dynamic Baselines](#).

AppDynamics thresholds help you to maintain service level agreements (SLAs) and ensure optimum performance levels by detecting slow, very slow, and stalled transactions. Thresholds provide a way to associate the right business context with a slow request to isolate the root cause. See [Transaction Thresholds](#).

Health Rules, Policies, and Actions

AppDynamics uses dynamic baselining to establish typical behavior for your application automatically. You can set up health rules according to those standard baselines (or use other health indicators) to track non-optimal conditions.

Policies that allow you to connect such problematic events (such as the health rule critical event) with actions that can trigger alerts/remedial behavior addresses the system's issues long before your users will be affected.

AppDynamics supplies default health rules. You can customize the default health rules and create new rules specific to your environment. See [Alert and Respond](#).

The out-of-the-box health rules test business transaction performance as follows:

Business Transaction response time is much higher than normal

- Defines a critical condition as the combination of an average response time higher than the default baseline by three standard deviations and a load greater than 50 calls per minute.
- This rule defines a warning condition as the combination of an average response time higher than the default baseline by two standard deviations and a load greater than 100 calls per minute.

Business Transaction error rate is much higher than normal

- Defines a critical condition as the combination of an error rate greater than the default baseline by three standard deviations and an error rate higher than ten errors per minute and a load greater than 50 calls per minute.
- This rule defines a warning condition as the combination of an error rate greater than the default baseline by two standard deviations and an error rate greater than five errors per minute and a load greater than 50 calls per minute.

Infrastructure Monitoring

Monitoring infrastructure performance can add insight into underlying factors about performance. AppDynamics can alert you of the problem at the Business Transaction and infrastructure level.

AppDynamics provides preconfigured application infrastructure metrics and default health rules to enable you to discover and correct infrastructure problems. You can configure additional persistent metrics to implement a monitoring strategy specific to your business needs and application architecture.

You can view infrastructure metrics in the [Metric Browser](#). In this context, the Correlation Analysis and Scalability Analysis graphs are useful to understand how infrastructure metrics can correlate or relate to Business Transaction performance.

Integrate and Extend AppDynamics

The [AppDynamics Exchange](#) contains many extensions that you can download and if you cannot find what you need, you can develop your own.

AppDynamics extensions are available in the following categories:

- Monitoring Extensions add metrics to the existing set of metrics that AppDynamics agents collect and report to the Tenant. These can include metrics that you obtain from other monitoring systems. They can also include metrics that your system extracts from services that are not instrumented by AppDynamics, such as databases, LDAP servers, web servers, or C programs. See [Extensions and Custom Metrics](#).
- Alerting Extensions enable you to integrate AppDynamics with external alerting or ticketing systems and create custom notification actions. See [Email Templates](#) and [HTTP Request Actions and Templates](#).
- Performance testing extensions consist of performance-testing extensions.
- Built-in integration extensions that you must enable or configure. These include:

- [Integrate AppDynamics with Splunk](#)
- [Integrate AppDynamics with DB CAM](#)

Review [AppDynamics APIs](#) to create custom extensions and integration components.

Deployment Planning Guide

This page describes best-practice planning guidelines for the AppDynamics SaaS deployment.

It is important to plan your AppDynamics deployment according to your environment. Taking time to outline your system strategy provides a smooth process flow. You can use these guidelines to start working with AppDynamics.

Each AppDynamics customer account is a tenant of the AppDynamics cloud-based Software as a Service (SaaS) platform. AppDynamics refers to this as a [Controller Tenant](#). Once you install the necessary agents, AppDynamics automatically builds an environment of the chosen applications.

The Controller Tenant:

- Monitors your application workload.
- Uses machine learning to determine what is normal for your environment.
- Applies sensible defaults for detecting abnormal activity and application errors.

You can start using AppDynamics dashboards, flow maps, and monitoring tools in the Controller Tenant UI immediately without instrumentation and configuration. Later, you can customize the configuration for your specific environment and requirements.

i AppDynamics does not support requests that originate from any URL other than the Controller Tenant URL provided at registration or otherwise edited by AppDynamics. Due to system security improvements, requests from custom URLs are rejected and may cause a service disruption. If you require a custom URL, we recommend that you create a forward proxy in your environment.

[Plan Your Deployment](#) [First Day Tasks](#) [First Week Tasks](#) [First Month Tasks](#)

See [Getting Started](#) to begin with a trial or investigatory installation of AppDynamics. For testing, you can easily get AppDynamics running with a trial SaaS installation within two hours. However, deploying to a production environment adds many considerations to the initial installation process. You must consider security, network, and change management requirements that your organizational policies govern.

Deployment Models

An AppDynamics deployment monitors your environment and collects data using [agents](#). The Controller Tenant UI provides the access to view, understand, and analyze the data.

The AppDynamics SaaS deployment is a cloud-based solution that enables real-time visibility into the health and performance of your instrumented environment, with significantly lower cost and maintenance. A SaaS deployment provides these benefits:

- No need to install a Controller Tenant
- AppDynamics manages the server-side components of the AppDynamics Platform, including installation and upgrades

- Lower total costs, guaranteed availability, data security, significantly reduced maintenance, and automatic upgrades

Plan for Security

1. Determine the access control strategy for Controller Tenant UI users, including locally authenticated users and externally authenticated users ([LDAP](#), [SAML](#), and so on).
2. Determine SSL requirements and key management.

Devise an Agent Rollout Strategy

1. Determine your rollout strategy as manual, automated, or scripted.
2. Integrate rollout with your application deployment process.

Plan AppDynamics Model

1. Understand how your application maps to the AppDynamics concept of application, tier, and node. Determine the naming strategy for the model.
2. Devise a [Business Transaction](#) strategy. Determine which end-to-end business processes in your environment you want to monitor as Business Transactions.
3. Devise [End User Monitoring](#) (EUM) and [Analytics](#) data collection strategy.
4. Consider database and hardware monitoring strategy.

Define the Users Who Will Access AppDynamics

1. Identify the monitoring team or others who will administer AppDynamics. Ensure that they have the resources and skillset to maintain the environment.
2. Identify stakeholders from each group that will use AppDynamics.

Define the Monitoring Strategy

1. Assess the alert and health rule strategy that meets your requirements.
2. Define the reporting strategy.
3. Determine integration points with other systems (using extensions or REST API).

[Plan Your Deployment](#) [First Day Tasks](#) [First Week Tasks](#) [First Month Tasks](#)

First Day with AppDynamics

This procedure outlines a typical first day working with AppDynamics.

After you [install agents](#) and restart your applications, AppDynamics automatically builds an environment for your application. You can see the model in the dashboards and flow maps view of the Controller Tenant UI. The Controller Tenant:

- Monitors your application workload.
- Determines what is normal for your environment.
- Applies sensible defaults for detecting abnormal activity and application errors.

You can start using AppDynamics immediately without instrumentation and configuration. Later, you can customize the configuration for your environment and requirements.

1. [Create an Account](#).

2. Download and [install an AppDynamics Agent](#).
3. [Create and add users](#) to your account.
4. [Assign Controller Tenant access](#).
5. [Configure email/SMS](#) settings to enable notifications. AppDynamics configures the SMTP server.
6. Review the AppDynamics default settings, such as built-in [Health Rules](#) and [Dynamic Baselines](#).

[Plan Your Deployment](#) [First Day Tasks](#) [First Week Tasks](#) [First Month Tasks](#)

First Week with AppDynamics

1. Learn about the [Key Performance Indicator \(KPI\)](#) metrics.
2. Explore how the different AppDynamics products work together.
3. Create and organize your [Business Applications](#).
4. View and customize [Flow Maps](#).
5. Create [Custom Dashboards](#).
6. Verify or adjust your tier groups, nodes, and remote services.
7. Customize your [Health Rules](#).

[Plan Your Deployment](#) [First Day Tasks](#) [First Week Tasks](#) [First Month Tasks](#)

First Month with AppDynamics

1. Tune your service [entry points](#).
2. Manage [user roles and groups](#), or connect the Controller Tenant to an [external authentication provider](#).
3. Capture contextual information, [information points](#), and [data collectors](#).
4. Extend your [health rules](#) with custom [actions](#).
5. Define [Health Rule custom metrics](#), configure [database custom metrics](#), or add [integration modules](#) to AppDynamics.

Network Port Requirements

To deploy AppDynamics, you may need to modify the network components configuration to permit access to ports used in the AppDynamics deployment. The [SaaS Domains and IP Ranges](#) page describes the specific ports used in the system.

Getting Started

Related pages:

- [Release Upgrade Checklist](#)
- [Ask the AppDynamics Community](#)
- [Help and Support](#)
- [AppDynamics University](#)

This page provides an overview of the options for creating an account and how to get started using your AppDynamics online Account Management Portal and AppDynamics SaaS.

As part of your deployment, the AppDynamics provides:

- A Controller Tenant for data collection.
- A Controller Tenant UI for data analysis.
- An online [Account Management Portal](#) to manage your account, users, subscriptions, license usage, and role functionality.

 As a best practice, we recommend that you follow the [Deployment Planning Guide](#) and create a deployment plan for your environment and needs.

Create an Account

Your first step to working with AppDynamics is to create a SaaS account to fit your data security needs, application workflow, and business environment. Reviewing the [Deployment Planning Guide](#) will help you strategize.

 AppDynamics has implemented restrictions and will not enter into any negotiation with, or seek to solicit any interest from, any third party in relation to the sale or use of the AppDynamics products or software or any part thereof, whether directly or indirectly with any country or region subject to an embargo including but not limited to Cuba, Iran, North Korea, Sudan, Syria, and Crimea.

Choose an account type and deployment option. There is no limit to the number of users you can create with either option. See [AppDynamics Pro Trial and Lite Licenses](#).

[Self Service Trial](#) [Enterprise Account](#)

The default trial configuration is a Software-as-a-Service (SaaS) deployment hosted by AppDynamics.

1. Follow this [Start Free Trial](#) link.
2. Enter your information and create a secure password.
 - a. The email and password you enter will be your login throughout your AppDynamics trial experience. Therefore, it is essential that you use a valid email address.

 You can skip the form and chat with a live expert by using the online chat feature.

3. Agree to the terms and click **Get Started**.
4. Click **Launch AppDynamics**.

[Self Service Trial](#) [Enterprise Account](#)

The [Deployment Planning Guide](#) will help you determine how to set up your account to best suit your business. An AppDynamics customer account manager will work with your organization to determine the proper configuration.

Every user account must be created with a valid email. The email entered at account creation will be the user's login ID through the AppDynamics experience.

AppDynamics will provide you with a hosted Controller Tenant. You will receive an email with URL information and login instructions.

AppDynamics does not support user or agent requests that originate from any URL other than the Controller Tenant URL provided at registration or otherwise edited by AppDynamics. Due to system security improvements, requests from custom URLs will be rejected and may cause a service disruption. If a custom URL is required, we recommend that you create a forward proxy in your environment.

Once AppDynamics provides a hosted Controller Tenant, you will:

1. Choose and [install AppDynamics agents](#).
2. [Add users](#) through the Controller Tenant UI.
3. [Configure Email/SMS settings](#) to enable notifications on a preconfigured SMTP server.

Gain System Access

After you complete registration and create an account, you will have access to your Account Management Portal for online account administration and, if you opted for a SaaS deployment, access to your hosted Controller Tenant platform.

Online Account Administration

The [Account Management Portal](#) provides a secure online area where administrators can:

- Manage the company account and personal profile separately.
- Administer users, groups, subscriptions, and roles.
- [Configure an Identity Provider \(IdP\)](#).
- See a company overview of account details, subscription information, open support tickets, and active resource projects.
- Launch available AppDynamics Controller Tenants.
- [Download](#) agents, platforms, and product updates.

Your account type will determine the services available in the Account Management Portal.

See [2023-01-02_17-16-59_Account Administration](#).

1. Access the Welcome email sent to the address you used to create your account.
2. Click **Get Started**.
3. Follow the instructions.

Controller Tenant UI

An AppDynamics Controller Tenant is fundamental to every deployment. Integrated agents collect data from a monitored environment and send it to the Controller Tenant. The Controller Tenant UI is where you can view, understand, and analyze that data.

How you access your Controller Tenant depends on your deployment. Your account will include a subscription license for each product you purchased during registration. A subscription can have one or more modules and you can have multiple subscriptions, each one having a distinct lifecycle.

Choose your deployment configuration.

[Self Service Trial](#) [Enterprise Account](#)

When you complete registration with your valid email, the AppDynamics Operations team will use that address to send your SaaS URL and access details.

1. Click the SaaS URL provided in the email.
2. Enter the **Account Name** given in the email.
3. Click **Login** to access your new web-based Controller Tenant UI.
4. Navigate to **Getting Started > Getting Started Wizard**.
5. Select an agent from the **Application** list.
6. Follow the steps to install an agent. See [Install Agents](#).

[Self Service Trial](#) [Enterprise Account](#)

When you complete registration with your valid email, the AppDynamics Operations team will use that address to send information about the components you need to start instrumenting your application and access your AppDynamics SaaS account.

The first person to access the Controller Tenant UI must be the same person that initially registered with AppDynamics. This user can access the system and create a system administrator to delegate managerial capabilities if needed.

1. Follow the URL provided to log in to your web-based Controller Tenant UI.
2. Enter the **Account Name** and **User Name** given in the email.
3. Create a secure password by clicking **Forgot Password** to have a password reset link sent to the registered email.
4. Click **Login**.
5. Navigate to **Getting Started > Getting Started Wizard**.
6. Select an agent from the **Application** list.
7. Follow the steps to install an agent. See [Install Agents](#).

AppDynamics does not support user or agent requests that originate from any URL other than the Controller Tenant URL provided at registration or otherwise edited by AppDynamics. Due to system security improvements, requests from custom URLs will be rejected and may cause a service disruption. If a custom URL is required, we recommend that you create a forward proxy in your environment.

Install Application Agents

An AppDynamics deployment consists of multiple application agents to monitor different components in your environment. For installing most types of agents, you can use the **Getting Started Wizard** in the Controller Tenant UI.

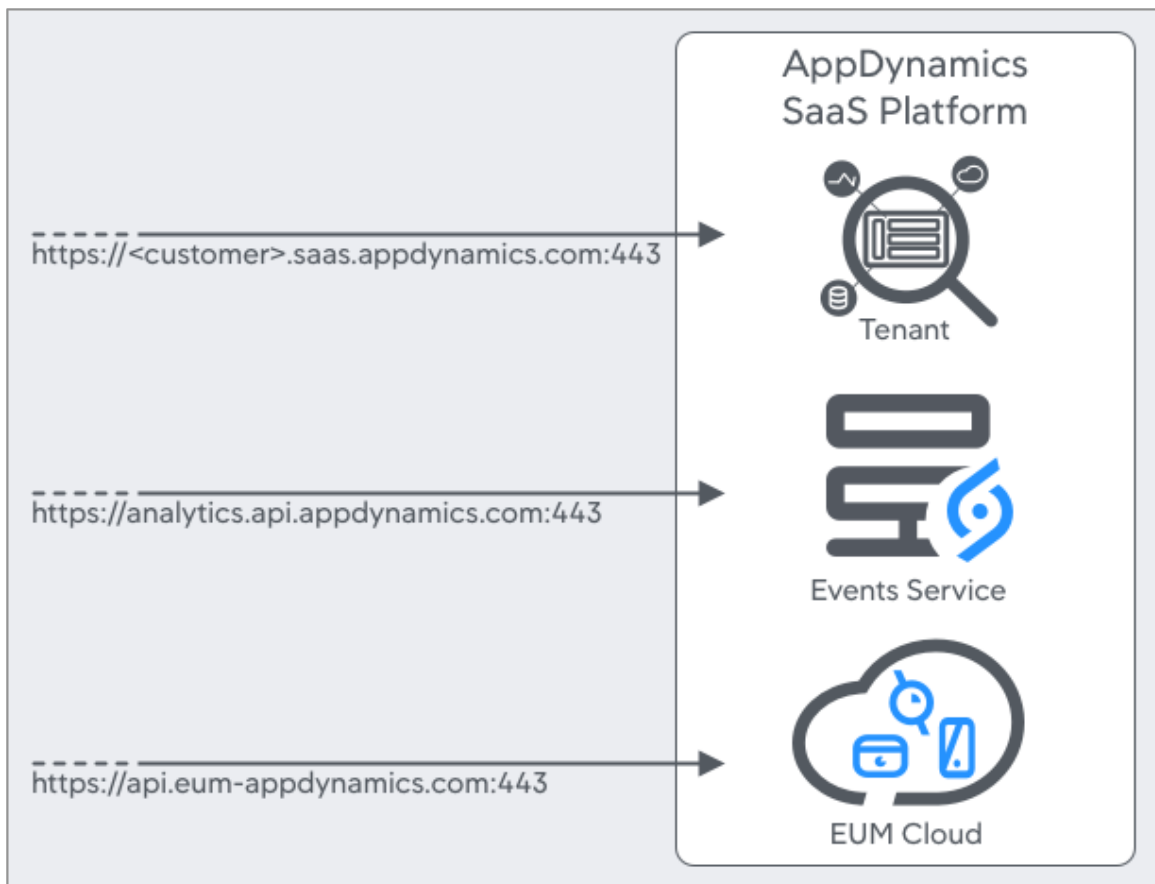

Log in to the Controller Tenant UI and navigate to **Applications > Create an Application > Create an Application using the Getting Started Wizard**. Follow the instructions in the Wizard to install agents in your application environment.

Review the [Install App Server Agents](#) documentation for instructions and guidance. AppDynamics provides an [Agent Installer](#) that simplifies the agent installation process and streamlines the deployment of the Java and Machine Agents.

Connect Agents to the Controller Tenant

The **Getting Started Wizard** automatically configures settings for connecting agents to the Controller Tenant. If you manually download agents, you must configure the Controller Tenant connections. You may need to adjust the configuration of network components, such as firewalls or proxies, to permit traffic from the agent to the Controller Tenant. The connection is unidirectional, meaning that agents always initiate the connections to the Controller Tenant.

This graphic shows the connections agents use to reach the platform.

Continue with Your AppDynamics Deployment

Best Practice

We recommend that you follow the [Deployment Planning Guide](#) and create a deployment plan for your environment and needs.

You can start using AppDynamics immediately without instrumentation and configuration. Then, at a later date, you can optimize the configuration to make the best use of AppDynamics for your environment and requirements. After you install agents and restart your applications, AppDynamics automatically builds an environment of your application. You can see the model in the dashboards and flow maps view of the Controller Tenant UI. The Controller Tenant monitors your application workload, uses machine learning to determine what is normal for your environment, and applies sensible defaults for detecting abnormal activity and application errors.

The timeline in the [Deployment Planning Guide](#) outlines a typical start to your AppDynamics journey.

Telemetry

AppDynamics may track and collect usage metrics and other data generated through your interaction with our software to improve our product and enhance your experience.

Tutorials

Learn more about specific areas of the AppDynamics by following one of these tutorials:

- [Install the Java Agent](#)
- [Install the .NET Agent for Windows](#)
- [Manual Injection of the JavaScript Agent](#)
- [Instrument iOS Applications](#)
- [Instrument Android Applications](#)
- [Instrument Xamarin Applications](#)
- [Instrument Applications with the IoT C/C++ SDK](#)
- [Instrument Applications with the IoT Java SDK](#)

Download AppDynamics Software

This page describes AppDynamics Download options and provides links to instructions for installing the appropriate AppDynamics software once you have an [AppDynamics account](#).

AppDynamics has implemented restrictions and will not enter into any negotiation with, or seek to solicit any interest from, any third party in relation to the sale or use of the AppDynamics products or software or any part thereof, whether directly or indirectly with any country or region subject to an embargo including but not limited to Cuba, Iran, North Korea, Sudan, Syria, and Crimea.

AppDynamics Download Options

You can download the AppDynamics software packages available for your account based on your subscription type from [AppDynamics Downloads](#).

1. Log in to accounts.appdynamics.com.
2. Select **Downloads**.

3. Follow the instructions on the [Account Management Portal Downloads](#) page to:
 - [Download agents](#)
 - [Automate downloads with cURL](#)
 - [Validate package downloads](#)

Deployment Overview

This page provides a brief overview of the AppDynamics deployment options.

AppDynamics provides Cisco Cloud Observability and the cloud-based Software as a Service AppDynamics SaaS solution. AppDynamics hosts and maintains both environments. You have the option to manage user account credentials via [SAML](#) or [LDAP](#) integration.

Every deployment includes:

- A Controller Tenant for data collection.
- A Controller Tenant UI to view, understand, and analyze the data.
- An online [Account Management Portal](#) to manage your account, users, subscriptions, license usage, and role functionality.

Every deployment requires:

- Installed [agents](#) to collect data from your monitored environment.
- [Network port requirements](#).
- [Health rules](#) to monitor system parameters.
- Validated users.

i AppDynamics does not support user or agent requests that originate from any URL other than the Tenant URL provided at registration or otherwise edited by AppDynamics. Due to system security improvements, requests from custom URLs will be rejected and may cause a service disruption. If you require a custom URL, we recommend that you create a forward proxy in your environment.

Controller Tenant Overview and Administration

This page describes the features of the AppDynamics Controller Tenant UI, which is the primary interface you use to monitor, troubleshoot, and analyze your entire application landscape from backend infrastructure/servers to the end user's application.

Controller Tenant UI Overview

Supported Web Browsers

The AppDynamics Controller Tenant UI is an HTML5-based browser application that works best with the latest version of any modern browser.

The Controller Tenant UI supports the latest versions of these browsers:

- Firefox
- Google Chrome
- Internet Explorer
- Microsoft Edge
- Safari

Because certain types of ad blockers can interfere with features in the Controller Tenant UI, we recommend disabling Adblock during use to avoid issues loading particular screens.

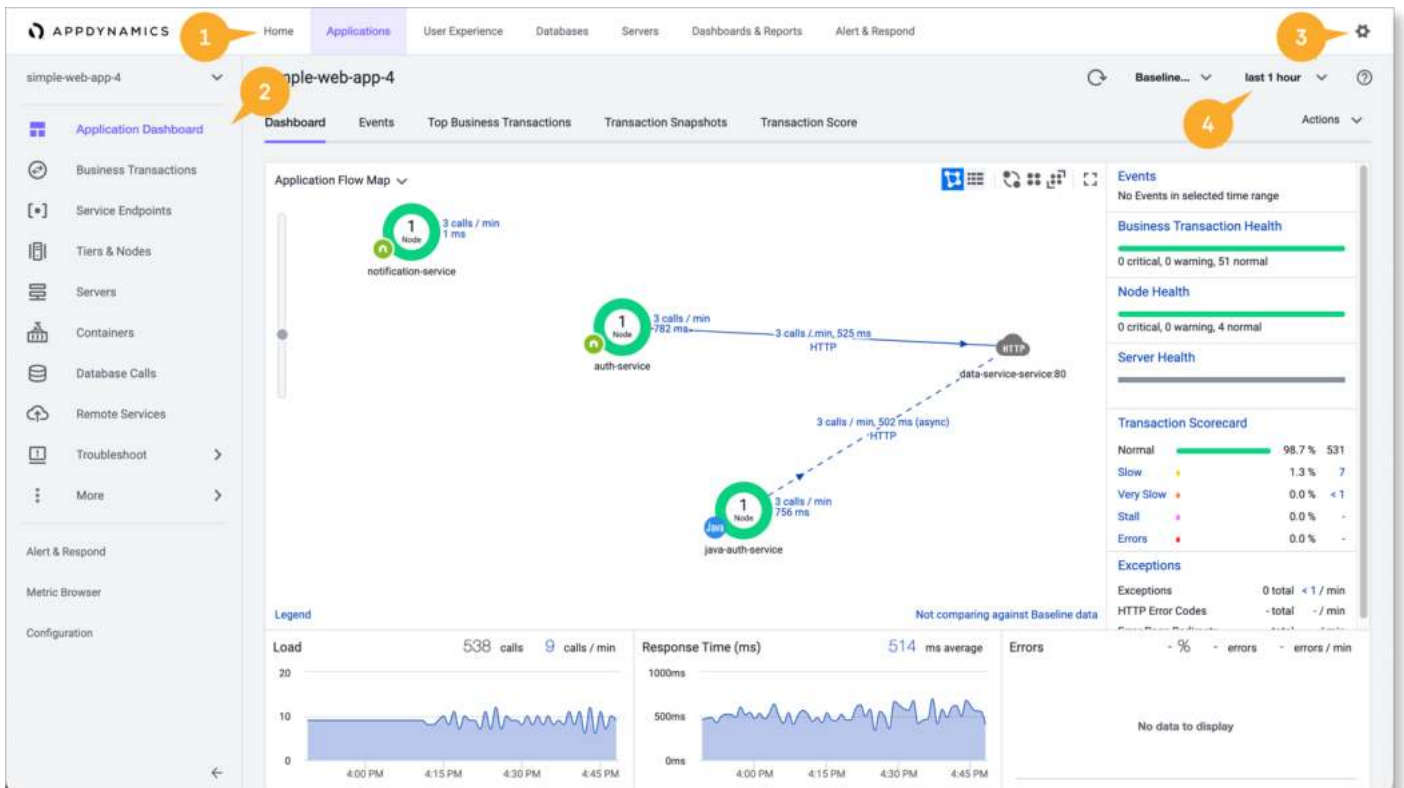

General Navigation

As you start using the Controller Tenant UI, it is helpful to familiarize yourself with the most commonly-used elements that we reference frequently in this documentation.

The precise controls and features available to you depend on your user account permissions and product module licenses. For example, you can have additional controls in application monitoring screens with an Analytics license. See [Manage Custom Roles](#).

Controller Tenant UI elements include:

- Top Navigation Bar **1** —use to navigate the product and cross-product feature areas, such as **Alert & Respond** and **Dashboard & Reports**.
- Left Navigation Menu **2** —use to access sections specific to the product area.
- Settings Menu **3** —access pages where you can customize the UI environment, view your account information, or, if permitted by your user role, configure administration settings such as adding user accounts, configuring authentication, and more. See [Manage Controller Tenant Users and Groups](#).
- Time Range Menu **4** —controls the time period for the metric data AppDynamics represents. See [Time Ranges and Settings](#).

View the Profile Details

You can view your profile information by clicking the profile icon . This lists the following information:

- Tenants that you are allowed to access
- Links to the Help and Support related pages

- Link to the Accounts portal

i You can view this icon only if the `miniprofile.controller.enabled` property is set to `true` in the `admin.jsp` page and if you log in using single-sign on.

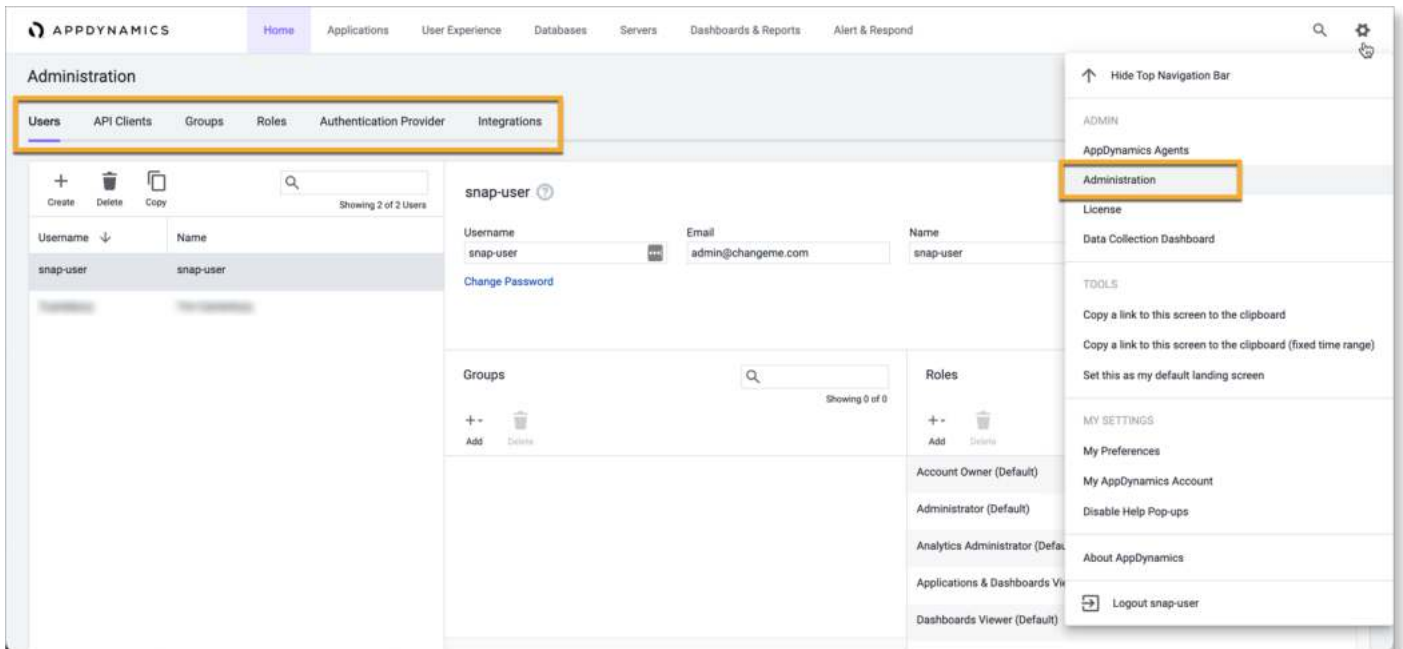

Administration Settings Overview

You can use the Controller Tenant UI to create and administer users specific to that Tenant. Use the [Account Management Portal](#) for global user account administration and Controller Tenant license subscription assignments.

 You must be a user with the Account Owner role to see Administration options.

Navigate to **Settings**  > **Administration**. The Controller Tenant Administration UI allows you to set up several Tenant-specific user options. If you have multiple accounts, you must configure each account individually for each Controller Tenant.

- **Users**—Create and administer users.
- **API Clients**—Create and use an API Client to provide secure access to the Tenant through REST API calls. See [API Clients](#).
- **Groups**—Create and use groups to assign and manage roles for users collectively.
- **Roles**—Create and use roles to define user privileges in the Tenant UI.
- **Authentication Provider**—Configure external authentication settings for the tenant user. See [LDAP for SaaS Deployments](#) or [SAML for SaaS Deployments](#).
- **Integrations**—Set up extension integrations to supplement AppDynamics capabilities. See [Integration Modules](#).

Time Ranges and Settings

The Time Range menu is continuously available. Your selection determines the range of data the UI displays, except in the case of pages such as the Scalability Analysis, where other time contexts apply. When you choose a new time range, it remains the active range as you navigate to other pages.

You can select a default **Standard** time range or enter a **Custom** range. Custom time ranges can be set to terminate in the past, making them useful for analyzing trends over time.

To create a custom time range:

1. Click **Custom** and select .
2. Enter a **Name** and optional **Description**.
3. Enter your start and end date and time selections in the dialogues.
4. Click **Save**.
5. Optionally, select **Share with Everyone** to share the range with all the other users of the Tenant.

To manage a custom time range:

1. Click **Custom** and select .
2. Select a time range.
3. Select to **Add, Edit, Delete, or Copy**.
4. Click **Apply**  to save the changes and update the session.

To enable 5 and 15-minute auto-refresh for a flow map:

1. Select **Standard**.
2. Select 5 or 15 minutes to display the **Auto-refresh** checkbox at the bottom of the list.
3. Select the **Auto-refresh** checkbox to automatically refresh the data.

Share Views With Other Users

Troubleshooting an application issue is often a collaborative effort that may involve multiple users. You can share a particular view of the Controller Tenant UI with a shareable URL that retains the currently active time range. A time range that is relative to the current time, such as "last 15 minutes," displays as a fixed time range in the sharable URL.

To share a view:

1. Select **Settings**  > **Copy a link to this screen to the clipboard**.
2. Paste and share the URL.

Enable the Email Server

This page provides instructions for configuring SMTP. You must configure the SMTP email server to enable email and SMS notifications and digests to be sent by the Controller Tenant.

Permissions

For this activity, users need the predefined Account Owner role or another role with the **Configure Email / SMS** permission.

Configure an SMTP server

1. In the Controller Tenant UI, from the top navigation menu bar, click **Alert & Respond > Email/ SMS Configuration**.

2. Provide the connection information for the SMTP host and port.
 - You must preconfigure a Controller Tenant with the appropriate settings:
 - i. **SMTP Host:** `mx.mail.svc.cluster.local`
 - ii. **SMTP Port:** 25
 No authentication is needed.
3. Customize the sender address in notification emails in the **From Address** field. By default, emails are sent by the root Controller Tenant user.

 When entering an email address in the **From Address** field, you have the following options:

- `<username>@appdynamics.com`
- `<username>@saas.appdynamics.com`
- `<username>@<customer_domain>` - Custom domains can be used, but require the domain to be verified using the Amazon Simple Email Service (SES). See <https://docs.aws.amazon.com/ses/latest/DeveloperGuide/verify-domain-procedure.html>.
- Leave the field blank: this will then default to `alert@appdynamics.com` for email notifications.

4. If the SMTP host requires authentication, configure the credentials in the **Authentication** settings.
5. If you want to add any text to the beginning of the notification, enter it in the **Notification Header Text** field.
6. If you are using SMS, perform one of the following actions:
 - Select **Default** and choose one of the available carriers from the pulldown menu.
 - Select **Custom** and enter the phone number receiving the message as `<phone number>@<sms gateway>`. For example, a mobile phone in the United States serviced by AT&T might be:

4151234567@txt.att.net

A mobile phone in the United Kingdom serviced by Textlocal might be:

7412345678@txtlocal.co.uk

See [SMS gateway by country](#).

7. Test the configuration by sending an email.
8. Save the settings.

Troubleshoot Notifications

If you do not receive notifications for health rule violations, it could be because the default SMTP server timeout period is too short.

SaaS Deployment Audit Log

This page describes how to schedule and manage a SaaS deployment Controller Tenant Audit Log. AppDynamics refers to a **Controller** Tenant as the Controller in some portions of the Controller Tenant UI. Consider them one and the same.

This audit capability creates an `audit.log` file that serves to monitor user activities and configuration changes in the Controller Tenant. Be aware that AppDynamics customers do not have access to the

`audit.log` file as it is held on the AppDynamics Controller Tenant server. To retrieve information, you must schedule the report and configure retrieval.

Create an Audit Report

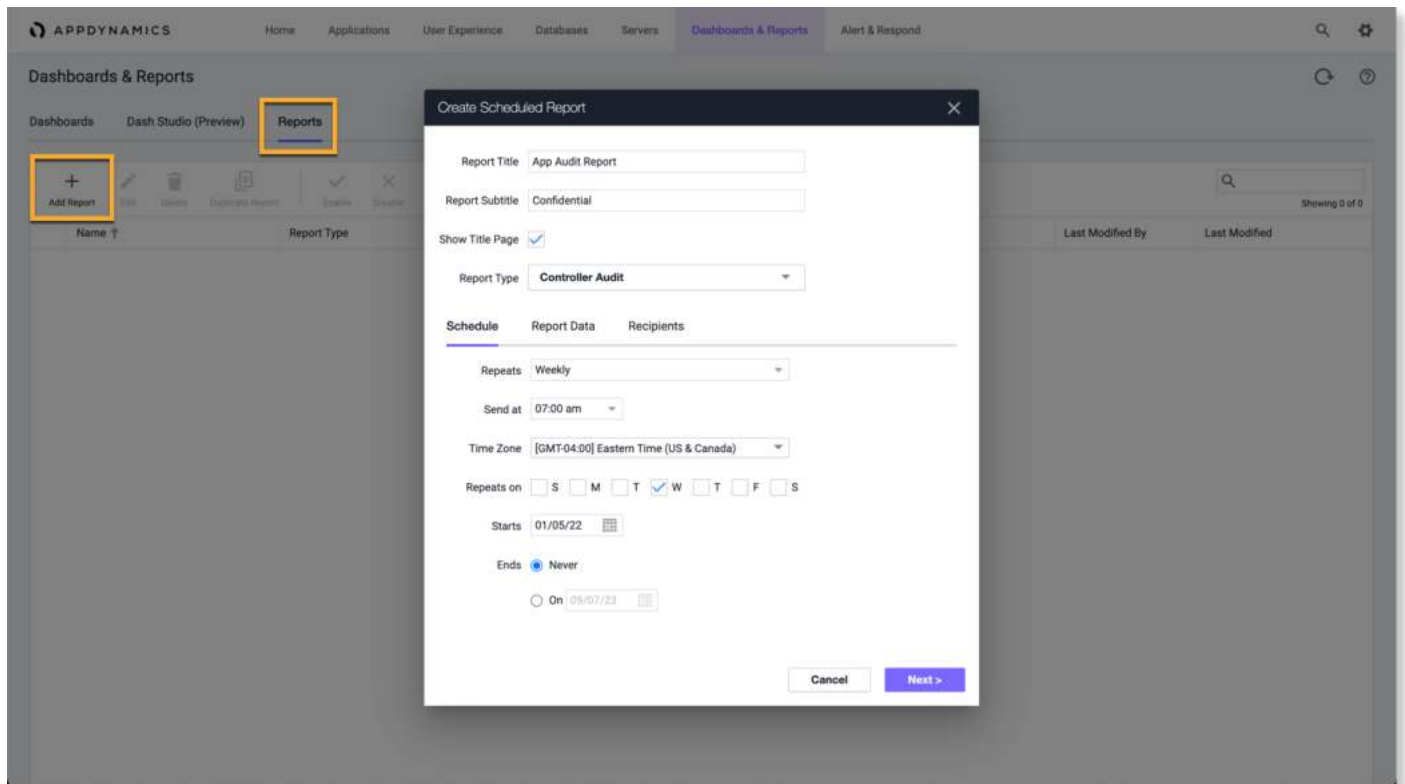

You can use this report to view changes made to the user information, Controller Tenant configuration, and application properties. The Controller Tenant Audit reports on the following attributes:

Date and time range	ObjectType
UserName	ObjectName
AccountName	ApiKeyId (if applicable)
Action	KeyName (if applicable)
ApplicationName	

You must have Company Admin permissions to view and configure scheduled reports.

1. Click **Dashboards & Reports > Reports > Add Report**.
2. Enter **Report Title** and **Report Subtitle**. You can label a report CONFIDENTIAL using **Report Subtitle**.
3. Optionally, select **Show Title Page** to include a title page at the beginning of your report file.
4. Click the **Report Type** dropdown and select **Controller Audit** to define the fields in the **Reports Data** tab.
5. Configure the **Schedule** for the report.
6. Select **Report Data** or click **Next**.
7. Click the **Timerange** dropdown to set **Standard** or **Custom** the time ranges. Custom time range options are available for all the **Report Types**.
8. Select your report file format as PDF, JSON, or CSV.
9. Optionally, uncheck the **Show Diff** box to remove the **Object Changes** column from your report file.
10. Click the **Filters** dropdown to select the data to include or exclude.
11. Enter the attribute value.
12. Click **+ Add** to select more filters.
13. Select **Recipients** or click **Next**.
14. Enter a recipient email. Click **Add** to send to more than one recipient.
15. Click **Save**.

Right-click anywhere in the **Reports** page for additional options as well as a **Send Report Now** option for an immediate look at the audit details.

Retrieve the Audit Log Report

The Audit Log Report is sent by email according to the addresses set up when creating the report. It captures the following information:

- User logins and information changes
- Controller Tenant configuration changes
- Application properties and object changes such as policies, health rules, and entities listed in the above table.
- Environment properties changes

AppDynamics supports PDF, JSON, and CSV output formats.

Retrieve Audit History via API

You can retrieve audit history through the `ControllerAuditHistory` API method, which returns the configuration and user activities record in a JSON or CSV file for the time range specified. This information is the same as that found in the file.

Format

GET `/controller/ ControllerAuditHistory?startTime=<start-time>&endTime=<end-time>&include=<field>:<value>&exclude=<field>:<value>`

For example:

```
http://localhost:8080/controller/ControllerAuditHistory?startTime=yyyy-MM-dd&&endTime=yyyy-MM-dd&include=filterName1:filterValue1&include=filterName1:filterValue1&exclude=filterName1:filterValue1&exclude=filterName1:filterValue1
```

```
curl --user user1@customer1:welcome "http://demo.appdynamics.com:8090/controller/ControllerAuditHistory?startTime=2015-12-19T10:50:03.607-0700&endTime=2015-12-19T17:50:03.607-0700&timeZoneId=America&Francisco&include=username:user1&include=action:LOGIN&exclude=accountName:system&exclude=action:OBJECT_UPDATE"
```

```
[{"timeStamp":1450569821811,"auditDateTime":"2015-12-20T00:03:41.811+0000","accountName":"customer1","securityProviderType":"INTERNAL","userName":"user1","action":"LOGIN"},{"timeStamp":1450570234518,"auditDateTime":"2015-12-20T00:10:34.518+0000","accountName":"customer1","securityProviderType":"INTERNAL","userName":"user1","action":"LOGIN"},{"timeStamp":1450570273841,"auditDateTime":"2015-12-20T00:11:13.841+0000","accountName":"customer1","securityProviderType":"INTERNAL","userName":"user1","action":"OBJECT_CREATED","objectType":"AGENT_CONFIGURATION"},... {"timeStamp":1450570675345,"auditDateTime":"2015-12-20T00:17:55.345+0000","accountName":"customer1","securityProviderType":"INTERNAL","userName":"user1","action":"OBJECT_DELETED","objectType":"BUSINESS_TRANSACTION"}, {"timeStamp":1450570719240,"auditDateTime":"2015-12-20T00:18:39.240+0000","accountName":"customer1","securityProviderType":"INTERNAL","userName":"user1","action":"APP_CONFIGURATION","objectType":"APPLICATION","objectName":"ACME Book Store Application"}, {"timeStamp":1450571834835,"auditDateTime":"2015-12-20T00:37:14.835+0000","accountName":"customer1","securityProviderType":"INTERNAL","userName":"user1","action":}
```

```
curl --user user1@customer1:welcome "http://127.0.0.1:8080/controller/ControllerAuditHistory?startTime=2019-05-28T08:00:03.607-0700&endTime=2019-05-28T11:32:03.607-0700&timeZoneId=America%2FSan%20Francisco&include=applicationName:ACME" [{"timeStamp":1559066415823,"auditDateTime":"2019-05-28T18:00:15.823+0000","accountName":"customer1","securityProviderType":"INTERNAL","userName":"user1","action":"LOGIN","objectId":0,"applicationName":"ACME"}]
```

Input parameters

Parameter Name	Parameter Type	Value	Mandatory
start-time	Query	Start time in the format: "yyyy-MM-dd'T'HH:mm:ss.SSSZ"	Yes
end-time	Query	End time in the format: "yyyy-MM-dd'T'HH:mm:ss.SSSZ"	Yes
time-zone-id	Query	Time zone	No

Parameter Name	Parameter Type	Value	Mandatory
include	Query	Restricted information in the audit history	No
exclude	Query	Restricted information in the audit history	No

 To control the size of the output, the range between the start-time and end-time cannot exceed 24 hours. For periods longer than 24 hours, use multiple queries with consecutive time parameters.

- Multiple filters of the same type are allowed.
- The backend API treats include filters with the same <field> and relationship as "OR", and filters with different <field> and relationship as "AND".
- There is no direct interaction between include and exclude filters.
- Each filter needs to be a parameter, e.g., `include=filterName1:filterValue1&include=filterName2:filterValue2`. See the below examples.

Audit Log Default Configuration Settings

This table shows the default settings for your Tenant. Please contact your AppDynamics account manager to edit these settings.

Name	Description	Value
audit.enabled	Enable or disable audit logging	true
audit.log.changes.persisted	Enable or disable audit log state change data persistence	true
audit.log.file.count	The number of log files for rotation once exceeding the size limit	1
audit.log.file.enabled	Enable logging audit information into a file	true
audit.log.file.location	Audit log file locations <empty value means <code>\$CONTROLLER_HOME/logs/audit.log</code> >	
audit.log.file.size	Maximum log file size (in bytes) for audit logging	500000000
audit.log.retention.period	Audit log retention period in hours (30 days)	720

 AppDynamics only retains audit logs for 30 days. If you wish to retain them longer, contact your account manager or download your scheduled reports regularly.

Entries Being Audited

AppDynamics Mobile App

The AppDynamics mobile app provides a fast and reliable way to access and share time sensitive, critical information as quickly as possible. The mobile app provides detailed information about Health Rule violations or detected anomalies that you can use to target and identify event causes quickly and easily anywhere, anytime.

The AppDynamics mobile app provides a top-down view of events and alerts in your instrumented environment so you can monitor the health and performance of your applications on iOS and Android devices. AppDynamics alerts notify you of application issues in your instrumented environment within minutes of the occurrence. The Events screen provides filters and time range options to refine your events list for targeted troubleshooting. As you navigate, each selection provides a deeper dive into the details of the reported event.

The AppDynamics mobile app currently supports application performance management (APM). The AppDynamics Classic app also supports end user monitoring (EUM), server infrastructure monitoring (SIM), and database monitoring (DBMon).

To install AppDynamics mobile app, use your mobile phone to scan this QR code.

Next Steps

To continue with AppDynamics mobile app, select from these options:

- [Install and Configure AppDynamics on Mobile Phones](#)
- [View and Analyze AppDynamics Data on Your Mobile Phone](#)
- [AppDynamics Mobile App Settings](#)

Install and Configure AppDynamics on Mobile Phones

Supported Environments and Versions

Before you install the AppDynamics mobile app, make sure your mobile phone and the Controller have the supported environment and version.

Support Environments

AppDynamics requires:

- Controller \geq 21.6
- iPhone: iOS \geq 12.0
- Android \geq 8.0 (Oreo)

Determine Your Controller Version

You can retrieve the version number from the command line of the Controller machine by accessing the `README.txt` file located in the Controller home directory or from the AppDynamics UI.

1. From the AppDynamics dashboard, click **Settings** .
2. Select **About AppDynamics**.
3. Note the AppDynamics Controller build number.

Install AppDynamics

AppDynamics supports both iOS and Android mobile phones. You can install the AppDynamics mobile app on a mobile phone by scanning a quick response (QR) code. Scanning the QR code using the phone camera navigates you to the App Store (for Apple) or Google Play (for Android) to locate and download the app.

1. Open the camera app on your mobile phone.
2. Center this QR code inside the frame on your camera screen:

3. Follow the instructions on your mobile phone.

Sign In and Configure Your Account

You can select one of several easy methods to sign in to your AppDynamics account. Using the QR code is the easiest method because scanning the QR code also helps you to configure your account. If your account supports SAML authentication, you can also use the **Sign in with SSO** button to sign in.

Sign In and Configure with QR Code

AppDynamics provides a short cut to configuring your accounts by allowing you to scan the QR code that is on the Controller. To use this short cut, you must have access to the Controller.

To sign in and configure your account by scanning the QR code:

1. On the **Sign in to your account** screen, tap **Scan QR code**, or tap **How to find your QR code** for instructions and swipe up to read them.
2. When prompted, grant AppDynamics camera access.
3. Center the QR code that is on the Controller UI inside the frame on your camera screen. Once properly centered, the QR code automatically launches the program to configure your account.

Sign In and Configure with the Controller URL

To sign in and configure your account without a QR code, you can use the Controller URL.

To sign in with a URL:

1. Enter the URL and press the return key. If the Controller does not support HTTPS, deselect **Use HTTPS**.
2. Tap **Next**.
3. Enter the account name and tap **Next**.
4. Enter your username and password.

5. Review the **AppDynamics EULA**, **Privacy Policy**, and **Terms of Use**, and then tap the checkbox to agree to them.
6. Optionally, tap the switch to save your password.
7. Tap **Sign In**.

The **Customize your Home** screen message displays.

Gain Access Through AppDynamics Links and Push Notifications

The AppDynamics mobile app recognizes certain AppDynamics-related links received through text, email, or third-party notification systems such as:

- PagerDuty
- Slack
- JIRA Service Desk
- ServiceNow and so on

When you tap the link on your mobile phone, you are prompted to sign in (if necessary) and then taken to the event detail within AppDynamics.

Other Sign In Screen Options

After you configure your account, you can perform any of these functions from the sign in screen:

- Tap **Use Touch ID** or **Use Face ID** (in Apple) or **Use Fingerprint** (in Android) to sign back in using a saved password.
- After configuring accounts, you can add or remove accounts by tapping . See [Add an Account](#).
- Tap to view the:
 - AppDynamics End User Licensing Agreement (EULA)
 - Privacy Policy
 - Terms of Use

Customize and Edit Your Screens

You can use the AppDynamics **Home**  screen to customize important metrics and entities. After customizing your **Home** screen, you must also customize your **Events**  list by choosing the applications to include in your **Events** list. The **Home** and **Events** screens must be customized for each account you add.

The first time you sign in, no data is available for you to view. Choose the applications and metrics to include in your **Home** and **Events** screens. You can customize and update your selections at any time to display new health-status and key-resource metric data. AppDynamics saves your configuration changes for each subsequent sign in.

[Customize and Edit Your Home Screen](#) [Customize Your Events Feed](#)

To customize your Home screen:

1. When you first sign in, **Customize your Home screen** displays. Tap **Get Started** to view the **Select the Entity** screen where you can create widgets. Subsequent sign ins display the **Home** screen, where you can change your selections.
2. On the **Select the Entity** screen (screen 1), the entity type is Application. Tap the **Search entity name** field to display the menu.
3. Find the entity that you want to monitor by typing the entity name in the **Search** field or swiping through the list.
4. Tap the entity.

5. Optionally, tap the switch to **Specify business transaction, tier, or node** (or **Specify business transaction, service, or service instance**) to create widgets.
 - a. Under **Select Entity Type**, tap **Business Transaction, Tier, or Node** (or **Business Transaction, Service, or Service Instance**) in the menu.
 - b. Tap the field under **Search entity name**. The **Search Entity Name** screen displays.
 - c. Find the entity that you want to monitor by typing the entity name in the **Search** field or swiping through the list.
 - d. Tap the entity.
6. Tap **Next**.
7. On the **Add Widgets** screen (screen 2), tap **Health Widget** ⁺ to add a health widget for the entity.
8. Tap **Metric Widgets** ⁺ to view the **Add Metric Widgets** list.
9. Tap to select the metric type and metric(s) you want to monitor. You can select multiple metrics to create multiple widgets in one step. To clear the selections from the list, tap **Clear all**.
10. Tap **Add**.
11. Tap **Next** to review your settings.
12. On the **Review** screen (screen 3), tapping **X** beside a widget name deletes the item. If you delete all of the widgets on the **Review** screen, the **Add Widgets** screen (screen 2) displays.
13. Tap **Previous** to edit, or tap **Save** to view the new widgets. New widgets are displayed at the bottom of the screen.
14. Once you tap **Save**, you can continue adding widgets. Either swipe up and tap ⁺ **Add new widgets**, or tap the pencil  and then tap ⁺ **Add new widgets**.
15. Tap **TimeRange**  to set a time period.

To edit or delete a widget:

1. To edit or delete a widget from the **Home** screen, tap the ellipsis **⋮** beside the widget name and select **Edit** or **Delete**.
 - **Edit** opens the **Select the Entity** screen. Return to step 2 of [Customize and Edit Your Home Screen](#).
 - **Delete** removes the widget from the list. You can create the widget again.

To move a widget:

1. Tap the pencil  in the upper-left corner of **Home** screen.
2. Touch and hold the drag bar  on a widget.
3. Drag the widget up or down to a new position in the list.
4. When finished, tap **Done** to save.

To add a new widget:

You can add multiple widgets for the same application in either of two ways:

1. On the **Home**  screen, either swipe up and tap ⁺ **Add new widgets**, or tap the pencil  and then tap ⁺ **Add new widgets**.
2. Return to step 2 of [Customize and Edit Your Home Screen](#).

To customize your Events feed:

1. Tap **Events**  at the bottom of the screen. The first time you set up your events feed, **Customize your Events feed** displays.
2. Tap **Get started**. The **Events Feed** screen in **Settings**  displays.
3. Tap the switches to the right of each application name that you want to view data for. You can:
 - Use the **Search** bar.
 - Tap the switch to **Select all applications**.
 - Swipe up to view each application in the **Applications** list.

When you have finished making your selections, tap **Events**  to see your changes to the **Events** list.

Next Steps

To continue with AppDynamics mobile app, select from these options:

- [View and Analyze AppDynamics Data on Your Mobile Phone](#)
- [AppDynamics Mobile App Settings](#)

View and Analyze AppDynamics Data on Your Mobile Phone

View and Analyze

In the AppDynamics mobile app, these two screens display metrics:

- **Home**  screen: Displays the widgets you created. Widgets identify the application and entity name, whether the widget is for a business transaction, application, tier, or node (or business transaction, application, service, or service instance), and the type of data that was selected for that widget during setup.
- **Events**  screen: Displays data for two event types: Health Rule Violations, and Anomalies. Events and alerts correspond to the health rules and event thresholds defined in the AppDynamics Controller UI. Anomaly detection provides details of the deviating metric and anomaly duration for the business transaction affected.

Both the **Home** and **Events** screens display data for the **TimeRange**  selected. If no data displays, try editing the **TimeRange** selections.

[From the Home Screen](#) Health Rule Violation Events (Events Screen) Anomaly Events (Events Screen)

To view entity data from the Home screen:

1. Tap a widget name. The screen displays tabs for **Details** and **Relationships**. **Details** displays by default.
 - Widget entity name and type
 - **Transaction Scorecard**: percentage data for speed, stalls, and errors
 - **Exceptions**: totals for exceptions, HTTP error codes, and page redirects (when viewing an application, tier, or node, or when viewing an application, service, or service instance)
 - **Errors**: average, total, and graphical data; touch and drag the vertical crosshair on any graph to simultaneously move all graphs to a specific point in time
 - **Response Time**: average and graphical data; touch and drag the vertical crosshair on any graph to simultaneously move all graphs to a specific point in time
 - **Load**: average, total, and graphical data; touch and drag the vertical crosshair on any graph to simultaneously move all graphs to a specific point in time
2. Tap the **Relationships** tab. A spinner indicates that data is loading. Wait for data to load. Here you can view the **Applications, Business Transactions, Tiers, and Nodes** (or **Applications, Business Transactions, Services, and Service Instances**) related to the selected entity. This screen is split into

sections by entity type. Within each entity type section, there are at most two health groups: healthy and unhealthy. The entity circle size represents the number of entities in that health group.

3. If available, tap a section with multiple entities. The entity list screen displays. You can filter by **All**, **Normal**, **Warning**, or **Critical**. The entity circle color corresponds to health status:
 - Green: normal
 - Yellow: warning
 - Red: critical
4. Tap an entity to see metric data in greater detail. Again the **Details** and **Relationships** tabs display. As you navigate, each selection provides a deeper dive into the details of the reported event. Tapping a section with a single entity displays **Details** and **Relationships** tabs for that selected entity.
5. Tap the left-facing arrow(s)  to go back.

From the Home Screen [Health Rule Violation Events \(Events Screen\)](#) Anomaly Events (Events Screen)

To view health rule violation event data from the Events screen:

1. Tap a health rule violation event on the **Events** screen. An event detail screen displays the current state of the event.
 - Event severity, health rule violation event type, and application name
 - **Summary** with the start time, violation state, and affected entity
 - Buttons to **View timeline** , **View details** , **View health rule**  or **Violation** , and **View suspected cause** 
 - If the event has violating conditions, the **Violation**  button displays. When tapped, a dropdown displays the **View health rule**  button.
 - If the event does not have violating conditions, the **View health rule**  button displays.
 - **View suspected cause**  is for health rule violation ongoing events that affect business transactions and are visible only if a root cause has been detected
 - **30m**, **1h**, **12h**, **1d**, **1w**, and **All** buttons are used to change the time frame for the data displayed in the graphs
 - **Errors**: average, total, and graphical data; touch and drag the vertical crosshair on any graph to simultaneously move all graphs to a specific point in time
 - **Response Time**: average and graphical data; touch and drag the vertical crosshair on any graph to simultaneously move all graphs to a specific point in time
 - **Load**: average, total, and graphical data; touch and drag the vertical crosshair on any graph to simultaneously move all graphs to a specific point in time
2. Tap **View Timeline** . A spinner indicates that data is loading. Wait for data to load. The **Timeline** screen displays the:
 - Health rule name
 - Total number of events in the violation
 - Current violation state (ongoing, canceled, or resolved)
 - Date event occurred; events are grouped into sections by date
 - Chronological history of the violation in descending chronological order (excludes continuous events)
 - Health rule violation status for each event in the violation; indicates time and severity of event and event type
 - Yellow triangle: warning
 - Red square: critical
 - Blue circle: information
3. Tap the left-facing arrow(s)  to go back.
4. Tap **View Details** to display tabs for **Details** and **Relationships**. A spinner indicates that data is loading. Wait for data to load. **Details** displays by default.
 - Header: affected entity name and type
 - **Transaction Scorecard**: percentage data for speed, stalls, and errors

- **Exceptions:** totals for exceptions, HTTP error codes, and page redirects (when viewing an application, tier, or node, or when viewing an application, service, or service instance)
 - **Errors:** average, total, and graphical data; touch and drag the vertical crosshair on any graph to simultaneously move all graphs to a specific point in time
 - **Response Time:** average and graphical data; touch and drag the vertical crosshair on any graph to simultaneously move all graphs to a specific point in time
 - **Load:** average, total, and graphical data; touch and drag the vertical crosshair on any graph to simultaneously move all graphs to a specific point in time
5. Tap the **Relationships** tab. A spinner indicates that data is loading. Wait for data to load. You can view the **Applications, Business Transactions, Tiers, and Nodes** (or **Applications, Business Transactions, Services, and Service Instances**) related to the selected entity. This screen is split into sections by entity type. Within each entity type section, there are at most two health groups: healthy and unhealthy. The entity circle size represents the number of entities in that health group.
 6. If available, tap a section with multiple entities. The entity list screen displays. You can filter by **All, Normal, Warning, or Critical**. The entity circle color corresponds to health status:
 - Green: normal
 - Yellow: warning
 - Red: critical
 7. Tap an entity to see metric data in greater detail. Again the **Details** and **Relationships** tabs display. As you navigate, each selection provides a deeper dive into the details of the reported event. Tapping a section with a single entity displays **Details** and **Relationships** tabs for that selected entity.
 8. Tap the left-facing arrow(s)  to go back to the summary screen.
 9. Tap **> Violation** (or **> Violations**, if more than one) to read the conditions that were met in order to trigger the violation. Violation(s) displays only if the event has violating condition(s). Otherwise, only the **View health rule >** button displays.
 10. Tap **View health rule** to read the health rule name and the criteria for triggering critical and warning responses. Health rules are created in the Controller.
 11. Tap the left-facing arrow(s)  to go back.
 12. If available, tap the **View suspected cause** button. **View suspected cause** is available for ongoing health rule violation events that affect business transactions for SaaS Controller $\geq 20.10.1$ and is visible only if a root cause has been detected. Tapping **View suspected cause** opens the **Suspected Cause** screen, which displays details for the first cause of the first issue.
 13. Optionally, tap **Copy** to copy the cause details to your clipboard to use in another application.
 14. Tap the left-facing arrow(s)  to go back.
 15. Swipe up to view **Errors, Response Time, and Load** data and graphs.
 16. Tap a timeframe (**30m, 1h, 12h, 1d, 1w, and All**) to see more or less graph detail. **All**, the default, shows incident start-time through end-time.
 17. Touch and drag the vertical crosshair on any graph to simultaneously move all graphs to a specific point in time. The graphs are color coded:
 - White: normal
 - Yellow: warning
 - Red: critical
 18. Tap the left-facing arrow(s)  to go back.

To view anomaly event data from the Events  screen:

1. Tap an anomaly event on the **Events** screen to view:
 - Event severity, anomaly event type, and application name
 - **Summary**: start time, violation state, deviating metric, and duration; contains **View timeline** > button
 - **Affects**: entity type and name of entity affected, averages and graphical data; touch and drag the vertical crosshair to move the graph to a specific point in time; contains **View details** > button
 - **Top Suspected Cause(s)**: suspected cause or tabs for up to three top suspected causes, suspected entity type and name, suspected cause summary, and suspected cause metric graph(s) for anomaly ongoing events; visible only if top suspected cause(s) are identified
2. Tap **View Timeline** > . Wait for data to load. A spinner indicates that data is loading. The **Timeline** screen displays:
 - Business transaction affected
 - Total number of events in the anomaly
 - Current anomaly state (ongoing, canceled, or resolved)
 - Date event occurred; events are grouped into sections by date
 - Chronological history of the anomaly in descending chronological order
 - Anomaly status for each event in the anomaly; indicates time and severity of event and event type
 - Yellow triangle: warning
 - Red square: critical
 - Blue circle: information
3. Tap the left-facing arrow(s) < to go back.
4. Tap **View Details** > to display tabs for **Details** and **Relationships**. A spinner indicates that data is loading. Wait for data to load. **Details** displays by default.
 - Header: affected entity name and type
 - **Transaction Scorecard**: percentage data for speed, stalls, and errors
 - **Errors**: averages and graphical data; touch and drag the vertical crosshair to move the graph to a specific point in time
 - **Response Time**: average and graphical data; touch and drag the vertical crosshair on any graph to simultaneously move all graphs to a specific point in time
 - **Load**: average, total, and graphical data; touch and drag the vertical crosshair on any graph to simultaneously move all graphs to a specific point in time
5. Tap the **Relationships** tab. A spinner indicates that data is loading. Wait for data to load. You can view the **Applications, Business Transactions, Tiers, and Nodes (or Applications, Business Transactions, Services, and Service Instances)** related to the selected entity. This screen is split into sections by entity type. Within each entity type section, there are at most two health groups: healthy and unhealthy. The entity circle size represents the number of entities in that health group.
6. If available, tap a section with multiple entities. The entity list screen displays. You can filter by **All, Normal, Warning, or Critical**. The entity circle color corresponds to health status:
 - Green: normal
 - Yellow: warning
 - Red: critical
7. Tap an entity to see metric data in greater detail. Again you see the **Details** and **Relationships** tabs. As you navigate, each selection provides a deeper dive into the details of the reported event. Tapping a section with a single entity displays **Details** and **Relationships** tabs for that selected entity.
8. Tap the left-facing arrow(s) < to go back to the summary screen.
9. If available, swipe up to **Top Suspected Cause(s)** (visible only if top suspected cause(s) are identified) to view the suspected cause or tabs for up to three top suspected causes.
10. If available, tap the tabs for the other suspected causes to view detail and graphs for each suspected cause.
11. Tap the left-facing arrow(s) < to go back.

Filter and Search

You can use a filter to specify the events that display on the **Events** screen. Changing a filter automatically updates the **Events** list so that it includes only those items that match your filter specifications.

To change your **Events** filters:

- Tap **Events**  to view the **Events** screen.
- Tap  **Filter** at the top of the **Events** screen. The **Filter Events** window displays.
- Tap to (de)select any filter(s) you want to use. Tap **Clear all** to clear all of your filters.
- Click **Apply** to close the window and view your filtered events. When you apply filters, the events that match your filter criteria display on the **Events** screen. **Filter** selections remain for each subsequent sign in.
- Tap the  in the upper-right corner of the **Filter Events** list to close the window without making changes and return to the **Events** list.
- Tap **TimeRange**  to change the time period. If no events display on the **Events** screen, try editing your **TimeRange** selections. Changing the **TimeRange**  on one screen also changes the **TimeRange** setting on the other screens that display the **TimeRange**  button. The **TimeRange**  selector can be found on the **Home** screen, **Events** screen, **Details** tab, **Relationships** tab, and entity list screen. **TimeRange** selections remain for each subsequent sign in.
- Tap **Search**  to enter an application name.

Next Steps

To continue with AppDynamics mobile app, select from these options:

- [Install and Configure AppDynamics on Mobile Phones](#)
- [AppDynamics Mobile App Settings](#)

AppDynamics Mobile App Settings

Access and Add Accounts

You can monitor your existing AppDynamics SaaS accounts or sign in to another account on your device by adding your accounts to the **Accounts** list. You can access **Manage Your Accounts** when you sign in to AppDynamics by tapping  in the upper-left corner of the **Welcome back** screen or by:

- Tapping  in the upper-left corner of the **Welcome back** screen, or
- Tapping  in **Settings** 

Each AppDynamics session uses a time-sensitive authentication token that begins when you sign in to each AppDynamics account. You can sign in to multiple accounts and work while the tokens are active. Once a token expires, you must sign in again. Contact your administrator to extend your session length.

Access a Different Account

To access a different account:

1. Tap **Settings** . Or tap  on the **Welcome back** screen and skip step 2.
2. Tap your account name to open **Manage Your Accounts**.
3. Tap a different account name and sign into that account. The account opens in the **Home** screen. Tapping **Done** closes the screen. While the authentication token for each account is active, you can move between them without re-entering your credentials.

Add an Account

To add an account:

1. Tap **Settings** . Or tap  on the **Welcome back** screen and skip step 2.
2. Tap your account name to open **Manage Your Accounts**.
3. Tap **+ Add another account**.
4. Enter a **Controller URL**, and then click **Next**. If the Controller does not support HTTPS, deselect **Use HTTPS**.
5. Enter the **Account Name**, and then click **Next**.
6. Enter the **Username** and **Password**, and then click **Sign In**. **Customize your Home screen** displays. See [Customize and Edit Your Screens](#).

Remove an Account

To remove an account:

1. Tap **Settings** . Or tap  on the **Welcome back** screen and skip step 2.
2. Tap your account name to open **Accounts**.
3. Tap **X** beside the name of the account that you want to remove.
4. When the warning messages asks you if you are sure you want to remove the account, click **Remove** to remove the account from the AppDynamics mobile app.
5. When finished, tap **Done**.

Change Your Push Notifications Settings

You can set AppDynamics to notify you when selected applications have an event or anomaly. These flags can help you to significantly reduce downtime. When notifications are enabled on both the Controller and your device, an alert message displays whenever an anomaly or health rule violation is detected even when AppDynamics is closed.

 To receive push notifications on your device, ensure the flag `push.notification.appdmobile.service.enabled` is set to "true" by an Administrator in the Controller Administration Console. If notifications are disabled in the Controller settings or device settings, a warning message displays for both iOS and Android devices.

To set up Push Notifications:

1. Tap **Settings** .
2. Tap **Push Notifications**. When the **Push Notifications** screen displays, the off/on switch is set to the *off* (left) position by default.
3. Tap the switch to enable **Push Notifications** (switch to *on* (right) position).
 - If you are using an iPhone, the first time you enable Push Notifications, a dialog displays. Tap **Allow** to enable your phone to receive Push Notifications. (Android devices bypass this step.)
 - If you receive a message stating that:
 - "Your administrator needs to enable notifications on the Administrator Console," contact your administrator to ensure that the corresponding value in the Controller is "true," and dismiss the error message.
 - **Push Notifications** is turned off in your device settings, tap **Enable** to access the device settings, and enable Push Notifications.
 - An error occurred and to try again, there may be a network or connection issue. Try the step again.
4. To choose what type of Push Notifications you want to receive, tap **All notifications** to receive all notifications, or leave **Specific notifications** selected to send notifications for applications selected in **Events Feed** settings.

5. Tap **Test notifications**. A message confirms that notifications are working. If an error message displays that the notifications are not working, try turning the setting off and then on again.
6. Tap the left-facing arrow  at the top of the screen to return to the **Settings** screen.

Edit the Events Feed

Use the **Events Feed** in the **Settings** menu to add or remove applications for viewing on the **Events** screen.

1. Tap **Settings**  and then **Events Feed**.
2. Tap **Select all applications** or tap individual applications.
3. Tap the left-facing arrow  at the top of the screen to return to the **Settings** screen.

Your changes are saved automatically. You can view them on the **Events**  screen.

Send Feedback about AppDynamics

You can provide feedback about the AppDynamics mobile app quickly and easily. Each time you send feedback, a log file may be attached with diagnostic data and error messaging that is automatically collected and sent with your message. You can delete the file at any time before sending your feedback.

To send feedback:

1. Tap **Settings**  and then tap **Send Feedback**. Your default mobile email client prepares to send a message to mobileapphelp@appdynamics.com.
2. Prepare your message and send it using your mobile device mail application.

Read AppDynamics Policies

You can read any of these policy statements by tapping them:

- Terms and Conditions
- Privacy Policy
- Legal Notices

To read a policy:

1. Swipe up to view the whole policy.
2. Tap the left-facing arrow  beside policy name to go back to the **Settings** screen.

Sign Out of AppDynamics

To securely close AppDynamics:

1. Tap **Settings**  at the bottom of the screen.
2. At the bottom of the **Settings** screen, tap  **Sign out: [account]**.
3. At the confirmation dialog, tap **Sign Out**.

Identify Your AppDynamics Build Version

The AppDynamics build version that is currently installed on your device is displayed at the bottom of the **Settings** screen.

1. Tap **Settings** .
2. Note your Version number at the bottom of the screen.

Metrics Tracking

To improve our product and enhance your experience, AppDynamics may track and collect usage metrics and other data generated through your interaction with AppDynamics. If you prefer not to participate you can opt-out through the Administration Console. You must be an administrator with the root user password to access the Administration Console.

Next Steps

To continue with AppDynamics mobile app, select from these options:

- [Install and Configure AppDynamics on Mobile Phones](#)
- [View and Analyze AppDynamics Data on Your Mobile Phone](#)

SaaS Domains and IP Ranges

AppDynamics agents in a SaaS-based deployment need to be able to reach the AppDynamics-hosted platform components. Depending on your network configuration, you may need to modify your firewall configuration to permit outbound connections from agents to the SaaS components.

This page lists the current AppDynamics SaaS IP ranges and domains for each region. Due to the SaaS architecture, you need to configure all ranges and individual IP addresses in your allowlists to ensure successful connectivity. Note that the IP addresses are subject to change. See [Firewall Considerations](#) for configuring the platform endpoints and tips for setting up firewalls.

Controller Tenants

SaaS Controller Tenants listen for incoming communication from agents on port 443. Thus, unless there is a DDOS attack, SaaS Controller Tenants have no rules to block any traffic on port 443.

All AppDynamics-hosted Components/Services

The AppDynamics-hosted components and services only support the TCP protocol. The list of domains on this page is not exhaustive. You might encounter domains and IP addresses not listed on the page that might require firewall access. If you determine that such domains require firewall access, you can include them in the firewall allow-list.

 AWS [Azure](#)

AppDynamics provides the following Azure cloud regions. Each region, in addition, provides a selection of agent locations.

Linux-based Synthetic Hosted Agent

Azure Cloud Region	IP Address	Agent Location in Controller UI
Oregon	20.61.190.16/28	Amsterdam
	20.235.179.192/28	Chennai
	4.200.129.176/28	Melbourne
	52.183.192.32/28	San Antonio
	4.205.52.64/28	Toronto
Sydney	4.200.129.176/28	Melbourne
Mumbai	20.235.179.192/28	Chennai
	52.183.192.32/28	San Antonio

Synthetic Agent Locations

Mapping of Execution Containers and Browser Locations

The table below lists the available browser locations as well as the corresponding provider and container location.

* Browser Location	Provider	Container Location
Ashburn, Virginia	AWS	US East (N. Virginia)
Montreal, Québec	AWS	
Toronto, Ontario	Azure	
Amsterdam, Netherlands	Azure	EU (Ireland)
Dublin, Ireland	AWS	
Frankfurt, Germany	AWS	
London, United Kingdom	AWS	
Milan, Italy	AWS	
Paris, France	AWS	
Hong Kong, China	AWS	
Seoul, South Korea	AWS	
Tokyo, Japan	AWS	
Chennai, India	Azure	Asia Pacific (Singapore)
Mumbai, India	AWS	
Singapore	AWS	
Melbourne, Australia	Azure	Asia Pacific (Sydney)
Sydney, Australia	AWS	

* Browser Location	Provider	Container Location
Boardman, Oregon	AWS	US West (Oregon)
San Francisco, California	AWS	
Sao Paulo, Brazil	AWS	
San Antonio, Texas	Azure	

Info

*Some of the locations are enabled only based on requests in the new regional clouds. To add missing locations in any regional cloud, raise a support ticket with the list of required locations.

Hosted Agent Coverage Variations

Synthetic hosted agents have the following coverage variations:

- The US EUM cloud has access to both AWS and Azure locations.
- The Frankfurt EUM cloud has access to only AWS locations.
- The Sydney EUM cloud has access to only AWS locations.
- The Bombay EUM cloud has access to only AWS locations.

AppDynamics Support

Have a question about using AppDynamics or running into a problem? This page describes the necessary steps to help resolve your questions.

Search the Documentation

You can search for information from:

- The **Search** field on the right side of the top menu bar enables you to search within the current version of a documentation set.
- The **Search** field in the center of the documentation portal (docs.appdynamics.com) enables you to search through all of our documentation.

You can search across AppDynamics information resources, including the Community, Knowledge Base, Support, and more in the [AppDynamics Support Center](#).

Ask the Community

If you have questions about using AppDynamics, ask the [AppDynamics Community](#).

Contact Support

If you need further assistance, contact your Account Representative or Technical Support.

For Technical Support, click the Help tab while logged in with your AppDynamics account in the [AppDynamics Support Center](#).

When requesting support, attach relevant logs for your issue(s):

- For log files from the Controller, see [Platform Log Files](#).
- For the heap, histogram, and thread dumps, see [Controller Dump Files](#).

Downloads

Download Cisco AppDynamics Software

[Cisco AppDynamics Downloads](#) is a central location to download agents, platforms, and security documentation as well as access your license entitlements and review system updates. The site provides download availability according to your subscription type and permissions.

Cisco AppDynamics has implemented restrictions and will not enter into any negotiation with, or seek to solicit any interest from, any third party in relation to the sale or use of the Cisco AppDynamics products or software or any part thereof, whether directly or indirectly with any country or region subject to an embargo including but not limited to Cuba, Iran, North Korea, Sudan, Syria, and Crimea.

Navigation Overview

There are quick links provided to assist with management functions:

- **Getting Started**—provides instructions for creating an account, gaining system access, and so on.
- **Entitlements**—provides license packages, package editions, and license restrictions.
- **Updates**—provides product announcements, releases, and resolved issues.
- **Automation**—provides guidance for automating new version downloads.

Download Options

Cisco AppDynamics provides downloads for monitoring agents, server platforms, and security documents.

You can use filter options or the **Search** field under [Available Downloads](#) to find software and packages.

Agents

Cisco AppDynamics updated all available Agents with fixes to address the Log4j vulnerability.

Cisco AppDynamics Agents monitor every line of code in your instrumented environment by using unique tags that are assigned to method calls and request headers. The agents capture performance activity and report to the Controller Tenant in real-time. Use the **Agents** download tab to access every available agent in each applicable version for three operating systems to match your environment.

Platforms

Cisco AppDynamics provides several versions of the Controller Tenant, End User Monitoring (EUM) servers, and Synthetic servers for download on OSX, Linux, and Windows platforms.

Security Documents

Cisco AppDynamics provides current Service Organization Control (SOC 2) compliance documentation and annual Penetration Test (PenTest) reports with user identity watermarks on each page. This self-service download option allows you to perform annual security validation quickly and easily.

Filter And Search Options

Refine Using Filters:

Each filter dropdown menu provides options that, when selected, automatically update the list of available downloads. If none display, edit your filter selections.

- **Type**—select one or more options for download.
- **Version**—choose the latest or one or more previous versions.
- **Operating System**—select one or more operating systems.
- **Compatible With Controller (Agent Only)**—choose the latest or one or more previous versions.

Search Field:

1. Type the name and/or version of the desired package in the **Search** field.
2. Press Enter on your keyboard to update the list of available packages for download.
3. If no options display, there are none that match your search criteria. You may want to try the filter options.

Once you have a list of available downloads:

1. Hover over **Checksums** in the **Description** column to view the MD5 and SHA256 hash functions for the component.
2. Click **View** to review the latest release notes.
3. Click **Download** to obtain the .zip file.
4. Click **cURL** to generate the code for cURL that includes a time-sensitive OAUTH access token.
5. Select **Copy to Clipboard**  and paste the code in your server, VM, or docker container within an hour.

Automate Cisco AppDynamics Software Downloads With CURL

When you download files, always copy or transfer the files in binary mode. If you want to transfer a file that you have downloaded on Windows to a Linux machine, use binary mode in your transfer program when you move the file to the destination Linux environment.

Where applicable, Cisco AppDynamics also publishes software for distribution on package manager repositories such as RPM, npm, pip, NuGet, and more. For products that are available via a package manager, you can find relevant instructions to retrieve and install the software in [Install the Machine Agent](#).

The following steps demonstrate how to use [cURL](#) to get the latest version of a Cisco AppDynamics software download.

1. Retrieve an OAUTH token with the download scope:

```
curl -X POST -d '{"username": "<username>", "password": "<password>", "scopes": ["download"]}' https://identity.msrv.saas.appdynamics.com/v2.0/oauth/token
```

2. View the latest version of each available product from <https://download.appdynamics.com/download/downloadfilelatest/>. For example:

```
curl https://download.appdynamics.com/download/downloadfilelatest/
```

3. Inspect the response (or parse via script) to find the `download_path` of the latest product version.
4. Download the binary by running the following command:
Replace `access_token` with your OAuth token from Step 1, and replace `url_to_file` with the `download_path` value from the response in Step 3.

```
curl -L -O -H "Authorization: Bearer <access_token>" <url_to_file>
```

Validate Software Package Downloads

You can use checksum validation and a digital signature (for specific packages) to validate software downloaded from Cisco AppDynamics Downloads. This validation requires the machine on which you validate a package to include a TLS 1.2 implementation.

Checksum Validation

1. Navigate to Cisco AppDynamics [Downloads](#).
2. Click **Checksums** beneath the software package description to display the MD5 and SHA256 checksums.

3. After your download completes, run a checksum tool and compare the results against the checksum information on the downloads page.

Digital Signatures

Cisco AppDynamics digitally signs the following packages using a certificate signed by a publicly known certificate authority:

- .NET Agent
- Cisco AppDynamics Controller Tenant for Windows MSI installer

Cisco AppDynamics digitally signs the following packages using a PGP key:

- Java Agent
- Machine Agent
- Machine Agent RPM package
- Python Agent pip package

Cisco AppDynamics hosts the PGP public key on <https://pgp.mit.edu/> under the User ID "help@appdynamics.com". See [Verify AppDynamics Software Downloads with PGP](#).

Sensitive Data Collection and Security

AppDynamics collects data on application performance, health, and resources, in addition to the application components (transactions, code libraries) and related infrastructure (nodes, tiers). Before deploying AppDynamics, you should ensure that your application is secure and does not expose sensitive data. This page describes how to prevent sensitive data collection in your application environment.

Prevent Sensitive Data Collection

If your environment contains sensitive data that should not be processed by an AppDynamics product or sent to the AppDynamics SaaS environment, you should avoid:

- Applications that transmit sensitive data in URL query parameters
- Enabling HTTP request parameter capture
- Enabling bind variable capture
- Applications that send sensitive data in error logs and log files
- Allowing method invocation data collection
- Log captures

If you do capture logs, ensure that you mask values in those logs. The following sections cover additional measures that you can take to ensure you do not expose sensitive data.

SaaS Deployment

AppDynamics supports encryption at rest in its SaaS deployments on personally identifiable information and sensitive business data.

On-premises Deployment

AppDynamics offers an on-premises solution for customers who want to maintain full control over their deployment of the software. With this type of implementation, AppDynamics has no access to the software

or the data it collects and processes. Customers subject to strict regulatory requirements for data security may want to consider an on-premises solution.

On-premises customers are responsible for encrypting their data by either using self-encrypting drives or other non-product solutions.

Role-based Access Control

You can use role-based access controls (RBAC) to limit the number of users who can access data collection features. The controls let you restrict a user's access to specific functions, data, analytics queries, and APIs.

You can control user access to data by specifying permissions for each user role. To configure user access, navigate to **Settings > Administration**. See [Analytics and Data Security](#) and [Manage Custom Roles](#).

Suppress Raw SQL Capture

Application Monitoring collects raw SQL as prepared statements captured with dynamic parameters bound to runtime values.

You can disable the capture of raw SQL if it contains sensitive data. When you disable raw SQL capture, the SQL call appears in its original form, but with question mark parameters in place of sensitive data.

To disable the capture of raw SQL for an application, navigate to **Configuration > Instrumentation > Call Graph Settings > SQL Capture Settings**. Uncheck **Capture Raw SQL**.

You can also disable bind variable capture. Bind variables are placeholders for literal data in your SQL statements. When you disable bind variable capture, the values of bind variables are not displayed. For more information, see [Call Graph Settings](#).

Hide Query Literals

Database Visibility hides query literals by default since queries can contain sensitive user data.

To verify that query literals are hidden for a database, navigate to **Configuration**. In the Security section, ensure that you have chosen **Remove literals from the queries**. See [Configure Query Literals Security](#).

You may also want to use bind variables as placeholders for literal data in your SQL statements.

Exclude Error Logs

Application Monitoring logs exceptions and errors that match parameters you specify in your custom logger. You may want to exclude sensitive payload data so that it does not show up in error logs.

To exclude a class in your application:

1. Navigate to **Tiers & Nodes > Actions > Configure App Server Agent**.
2. Select **Use Custom Configuration**.
3. Click (+) to create a new agent property.
4. Set the agent property name to exceptions-to-ignore.
5. Set the agent property value to the name of the class you want to exclude.

See [Error Detection](#).

Mask Log Analytics Values

When configured, Application Analytics collects performance data from your app server agents, data from your log files, and performance and sessions data from End User Monitoring. You can mask sensitive information in your log analytics data.

To mask log analytics data:

1. Navigate to **Analytics > Configuration > Log Analytics > Source Rules**.
2. Click the source rule that you want to specify masking for.
3. In the Field Management tab, next to ThreadName, you can specify the starting and ending position of the data you want to mask, and the character to use as the masking value.

See [Configure Log Analytics Using Source Rules](#).

Disable the Data Collector

You can suppress data collection of HTTP request payloads, raw SQL, and other user data.

For the Java Agent, configure the `disabled-features` node property in the Controller UI.

For the .NET Agent, edit the `config.xml` file and set the `disabled-features` property to the names of features that you want to disable.

```
<property name="disabled-features" value="RAW_SQL,LOG_PAYLOAD,METHOD_INV_DATA_COLLECTOR,HTTP_DATA_COLLECTOR,CUSTOM_EXIT_SNAP_DATA"/>
```

See [App Agent Node Properties Reference](#) and [.NET Agent Configuration Properties](#).

Filter Sensitive Data in Environment Variables

You can mask sensitive data found in Java environment variables and system properties. To mask sensitive data, add the `sensitive-data-filter` property to `app-agent-config.xml`. The valid attributes are `applies-to`, `match-type`, and `match-pattern`.

See the following pages to learn how to filter sensitive data:

- [Filter Sensitive Data \(Java Agent\)](#)
- [Filter Sensitive Data with the .NET Agent](#)
- [Filter Sensitive Data for Apache Agent](#)

Data Privacy Policy Dialog

Data collection has regulatory, legal, and customer-defined policies that you must follow. AppDynamics provides a data privacy policy reminder, in the form of a UI dialog, when you or your users configure parts of the AppDynamics products that could be used to collect regulated or other protected information.

This customizable statement is present in all areas of the AppDynamics UI where you can configure data collection. AppDynamics displays a default message if you have not made any customizations.

AppDynamics logs an event when it displays the data privacy policy dialog to you or another user.

Data Collection Dashboard

This page describes the Data Collection Dashboard, which displays all collected and processed data by AppDynamics.

About the Data Collection Dashboard

AppDynamics allows you to customize most data configurations. Due to the various AppDynamics agent types and products, you can change the configuration in many different places. This flexibility can make it challenging to keep track of all of your settings.

The Data Collection Dashboard addresses this challenge by providing a single, easy-to-access view of the current state of all of your configuration parameters that may affect your organization's security and privacy. The Data Collection Dashboard should help you understand what data AppDynamics is collecting for your configured application instance at any point in time.

The unified view is only available to admins.

To view the Data Collection Dashboard, click **Settings**  > **Data Collection Dashboard**.

The dashboard provides a read-only view. You can change the configuration values in the respective places of the platform.

 You can find online help for a data collector type. To do so, navigate to **Applications**, choose an application, and then click **Configuration > Instrumentation > Data Collectors**. Click **Help**  in the data collector box of interest to view more information on that particular data collector and how to configure it.

You can click **Export** to save a raw JSON file of the selected data collection settings and share with non-admins, auditors, and sales.

Data Collector Types

This table lists all of the data collector types that you can view on the Data Collection Dashboard.

Data Collector Type	Description
Agents Logging Session	Agents Logging Sessions log information with a specific type of logging information, such as application configuration changes, metric data, and system agent registrations.
Agents Metadata Default Config	Agents Metadata Default Configs collect app agents transaction metadata.
Browser Settings Config	Browser Settings Configs collect Browser RUM and Synthetic metrics.
Custom Data Browser	Custom Data Browsers customize the agent to collect custom metrics for the browser.

Data Collector Type	Description
Custom Data Mobile	Custom Data Mobiles customize the agent to collect custom data types such as information points, custom timers, and custom metrics.
DB Collector	Database Collectors run within the Database Agent to collect performance metrics about your database instances and servers.
DB Security Config	Database Security Configs collect literals, which can contain sensitive user data, retrieved from the database.
EUM Settings Config	EUM Settings Configs collect EUM metrics, custom data, and Analytics data.
GUID Injection	GUID Injections correlate logs and transaction analytics data to specific business transaction requests.
HTTP Request	HTTP Requests capture the URLs, parameter values, headers, and cookies of HTTP messages exchanged in a business transaction.
Information Points	Information Points reflect the data state across all invocations of a method, independently of business transactions.
Log Analytics Source Rule	Log Analytics Source Rules log data sources using job files to collect log analytics data.
Method Invocation	Method Invocations capture code data, such as method arguments, variables, and return values.
Mobile Settings Config	Mobile Settings Configs collect Mobile RUM metrics.
SIM HTTP User Service Config	SIM HTTP User Service Configs collect Machine Agent data using HTTP listeners.
SQL Data Collector	SQL Data Collectors collect the business data from SQL parameters for use in transaction analytics.

Metrics and Graphs

This page describes metrics and graphs in AppDynamics.

AppDynamics reports metrics for monitored systems over time. The Controller provides a variety of graphs and tools that visualize metric data so you can effectively analyze your application's performance.

Metric Visualization Tools

While metric data appears throughout the Controller, the Metric Browser is the main interface for you to inspect metrics. The Metric Browser displays all the metric values collected over the selected time period as an expandable tree.

In the browser, you can drag and drop metrics from the tree onto graphs to compare metrics and analyze patterns.

Metrics

AppDynamics includes a wealth of metrics that reflect your application's performance. It also lets you extend and adapt metrics in specific ways. Information points, for example, allow you to create metrics based on data collected from application values, such as method parameters or return values. Percentile metrics let you configure metrics at deviation points that are useful to you.

You can create a metric from any application parameter using custom metrics. See [Extensions and Custom Metrics](#) for information on custom metrics.

Metric Browser

This page describes how the Metric Browser provides a metrics-oriented view of the monitored environment for a selected time period.

In the Metric Browser, you can see metrics by nodes, business transactions, the overall application, and more. You can also compare two or more metrics and view metrics relative to a baseline. Use this tool when you want to drill into and analyze the details for a specific metric.

1. Click **Metric Browser**.
2. Expand a metric group and double-click an option for that metric to display in the graph. Add multiple metrics in the same manner to compare them.
3. Mark the checkbox for the type of data you want to see for each metric.
4. Select **Filters** () and choose how you want to view data:
 - **Show Tiers / Nodes with performance data** to show entities and metrics for [live entities](#) over the specified time range.
 - **Show Tiers / Nodes with no performance data** to show metrics/entities of entities that are not alive over the specified time range.
 - Select both checkboxes to show metrics and entities without checking the liveness of entities.
5. Select **Plot Points** to enable the plot points on the graph line.
6. Select a **Scale** option to adapt the scale of the y-axis unit according to the values in the graph.

To remove a single metric from the graph, click **X** or click **Clear** at the top of the metric browser to remove all metrics.

Name	<input checked="" type="checkbox"/> Obs.	<input checked="" type="checkbox"/> Min	<input type="checkbox"/> Max	<input type="checkbox"/> Sum	<input type="checkbox"/> Count	<input type="checkbox"/> Base	
 Overall Application Performance Calls per Minute	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	 
 Overall Application Performance Average Response Time (ms)	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>	

Metric Data Point Details

For most types of metrics in the browser, you can click any of the points in the graph to view more information about the metric observed at that point in time. The information shown includes the metric identifier, date and time of the observation and any of the following values relevant to the metric:

- **Obs**—The observed average of all data points seen for that interval. For the Percentile Metric for the App Agent for Java, this is the percentile value. For a cluster or a time rollup, this represents the weighted average across nodes or over time.
- **Min**—The minimum data point value for that interval.
- **Max**—The maximum data point value for that interval.
- **Sum**—The sum of all data point values for that interval. For the Percentile Metric for the App Agent for Java, this is the result of the percentile value multiplied by the Count.
- **Count**—The number of observations aggregated in that one point. For example, a count of five indicates that there were five one-minute data points aggregated into one point.
- **Base**—The baseline data for the metric. See [Viewing Metrics Relative to Baselines](#).

By selecting the checkbox that corresponds to the metric information at the bottom of the graph, such as Min, Max, Count, or Sum, you can graph that information for the metric over the time range shown in the browser. Checkboxes for only the types of information relevant to the metric can be selected.

i For node-level metrics only, min and max values are available for any count- or sum-based metrics and for when the metric is rolled up to hourly or daily data points. Min and max values are not visible for tier- and application-level metrics. Count- and sum-based metrics include errors per minute, calls per minute, and so on.

Analyze Performance for a Time Range

Once you identify a time frame of interest in the metric browser, you may want to see snapshots in that time range. To analyze snapshots during a time range in the browser, click and hold the start of the time range in the graph and drag to the end of the time range. Release to view the **Time Range** pane.

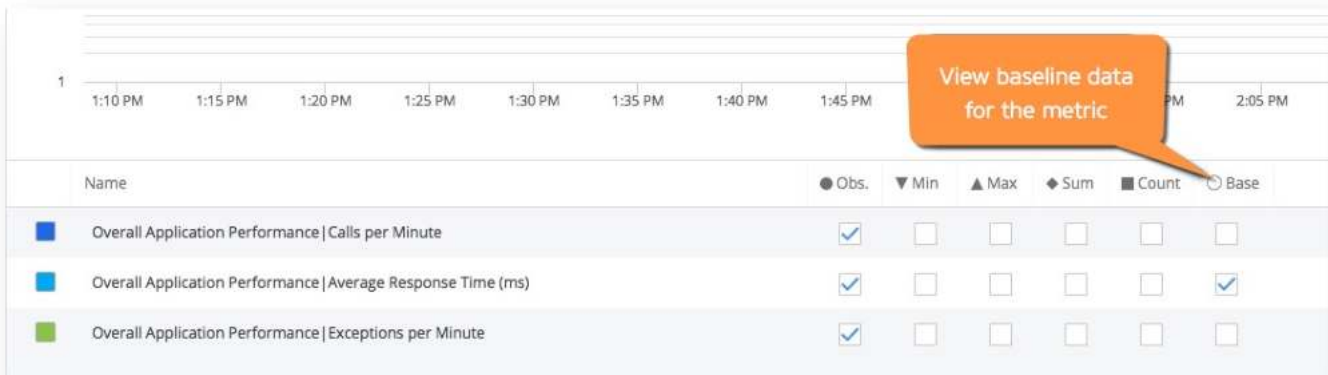

i If you do not see a metric in the browser, you can add certain metrics by editing node properties. See [App Agent Node Properties](#).

View Metrics Relative to Baselines

You can see how data in the Metric Browser compare to baseline values. Monitoring baseline deviation exposes performance metrics that might be violating your Service Level Agreements (SLAs). See [Dynamic Baselines](#).

To display baseline patterns, select the baseline option for the metric in the view options for the metric.

Export Metric Data

You can export metric data that is currently displayed to a comma-separated values (CSV) file.

Exported data includes all the data displayed, even if there is a time range selected. To export data only for a specific time range, first [set a global time range](#) and then export.

To export all data:

1. Select **Actions > Export Data**.
2. In the popup, you can either copy the data to your clipboard or click **Export Data** to download the data as a CSV file.

To export data for an individual metric in the graph, click **Download** at the bottom of the graph.

Metric Data Resolution over Time

You can view metrics in the Controller for different time intervals or resolutions.

i The metric data resolution and granularity information on this page are not applicable to the [Metric and Snapshot API](#).

Metric Generation and Time Zone Differences

In a distributed system, the metrics that the Controller collects may come from different time zones.

Before sending metrics to the Controller, agents normalize the times associated with the metrics by applying a UTC (Coordinated Universal Time) offset appropriate to their region.

In the Controller UI, all times display in the Controller user's local time. To render local times, the UI applies the offset needed to render UTC time into the user's time zone as configured on the device on which the browser is running.

While the time zone used in the UI is taken from the local environment and cannot be modified apart from changing the computer's system time, each UI user can adjust the format of the time display, as described in [Time Zone Settings](#).

While the Controller UI displays times in the local system time, specific timestamps generated by AppDynamics reflect the Controller system time. These include, for example, event timestamps in notification messages, which indicate the Controller system time.

 SaaS Controllers use Pacific Time (PT) as their system time.

Metrics Data Resolution

Depending on the period of time you're viewing in graphs, how old the data is, and the resolution of your monitor, graphs may display data at a granularity of 1, 2, 5, 10, 20, 30, 60, and multiples of 60 (120, 180, 240 and so on) minutes.

Metrics Data Retention and Deletion

Metrics data is retained and deleted according to the following:

- After 8 days, data at 1-minute resolution is deleted.
- After 365 days, data at 1-hour resolution is deleted.

View Rolled Up Data in Graphs

Depending on your environment, AppDynamics measures hundreds, thousands, or even tens of thousands of metric values each minute. To display these results over time in a meaningful way, AppDynamics rolls up the data at regular intervals (for example, at one-minute, ten-minute, and one-hour intervals) based on how long ago the metric was measured.

In graphs throughout the Controller UI, you can hover over a point on the chart to get the value of the metric data measured during the interval represented by the point. The point represents the beginning of the interval. The length of the interval depends on the selected time range. Admin-level users can adjust the amount of time data is retained at each resolution, although we do not generally recommend keeping data for longer than these default values. Default settings are listed below.

Rolled Up Data in Graphs

- For up to 8 days, data is rolled up every minute and displayed at a minimum of 1-minute resolution. Graphs may display data at intervals of 1, 2, 5, 10, 20, 30, 60, and multiples of 60 (120, 180, 240 and so on) minutes as previously described in [Metrics Data Retention](#). If the granularity is set to one, each point on the graph represents a 1-minute interval; the point represents the beginning of the minute. Therefore, when the granularity is set to one, the data presented for a 5:00 AM point represents the values measured from 5:00 AM to the millisecond before 5:01 AM. If the granularity is set to two, each point on the graph represents a 2-minute interval, and the data displayed for a 5:00 AM point represents the values measured from 5:00 AM to the millisecond before 5:02 AM.
- After 8 days, data is rolled up every hour and displayed at a minimum of 1-hour resolution. Graphs may display data at a granularity of 60, and multiples of 60 (120, 180, 240 and so on) minutes as previously described in [Metrics Data Retention](#). If the granularity is set to 60, each point on the graph represents a 1-hour interval; the point represents the beginning of the

hour. Therefore, when the granularity is set to 60, the data displayed for a 5:00 AM point represents the values measured from 5:00 AM to the millisecond before 6:00 AM. If the granularity is set to 120, each point on the graph represents a 2-hour interval, and the data displayed for a 5:00 AM point represents the values measured from 5:00 AM to the millisecond before 7:00 AM.

- After 365 days, data at 1-hour resolution is deleted.

One-Minute Resolution

Each point on the graph represents a roll-up of all the values measured during one minute. For example, if AppDynamics measures the response time for an application for 300 calls in a minute, the response time values of those 300 calls are averaged to present the Average Response Time (ART) for that minute. When you hover over a point on the chart, the Count figure represents how many times the metric data was measured during that minute.

In this graph, response time was measured 140 times between 2:57 and 2:58 PM and the ART for that minute was 889 ms.

In this chart, the time range was set for the last three hours, so the interval is one minute. The errors per minute value displayed at the 1:34 PM point represents the number of errors recorded during the minute from 1:34 PM to the millisecond just before 1:35 PM.

Ten-Minute Resolution

Metric data is displayed at a 10-minute resolution, and each point on the graph represents a roll-up of the values measured during that 10-minute period.

The ART for the rolled-up time period represents the true average. The ART aggregates the sum and count of the total requests for the period; it does not average the ARTs calculated for the previous roll-up granularity.

One-Hour Resolution

Metric data is displayed at a 1-hour resolution, and each point on the graph represents a roll-up of the values measured during that 60-minute period.

How the Last Interval Displays in a Chart

Because of the way rolled-up data displays, it may appear as if data is not included for the last increment in the time range. However, the last data point represents the last interval in the range.

For example, when you set a time range from 8 AM to 12 PM for a day that has been rolled up into 1-hour data points, you might expect to see five data points, one for 8 AM, 9 AM, 10 AM, 11 AM, and 12 PM. However, the returned data consists of four data points for the hours 8 AM, 9 AM, 10 AM, and 11 AM. The first data point, 8:00 AM, represents data collected from 8 AM to the millisecond just before 9 AM. The last data point, 11:00 AM, represents data collected from 11 AM to the millisecond just before 12 PM. So you are actually seeing data from 8 AM to 12 PM, even though the last data point in the graph is 11 AM.

View Charts for Long Time Ranges

For time ranges that are greater than three weeks, graphs in the UI such as the Slow Transaction graph show the 14th of each month as the time point on the x-axis. For a time range that is less than two full months, this means that the graph may only have a single point, the middle of the month encompassed by the time range.

View Details about Older Data

To review details for an issue that occurred during a period for which you have only 10-minute or 1-hour data, AppDynamics provides access to diagnostic data through Transaction Snapshots. For example, suppose you were seeing values for 2 AM and 3 AM three days ago, but you need to examine details about a problem you were alerted about that occurred at 2:15 AM that morning. You view Transaction Snapshots for the hour between 2 AM and 3 AM to see details about what happened during that time period. By default, snapshots are retained for two weeks, and individual snapshots can be archived. See [Troubleshoot Business Transaction Performance with Transaction Snapshots](#).

If you are viewing a graph in the Metric Browser, you can select a specific period in the chart and drill down to see Transaction Snapshots and other information. See [Analyzing Performance for a Specific Time Range](#).

Percentile Metrics

This page describes percentile metrics and how to modify default percentile collection.

A percentile is a value below which a given percentage of measurements in a set falls. For example, a 95th percentile value of 150 ms means that 95% of all values are 150 ms or less. See [Quick Tour of Percentile Metrics for Java](#).

Disable Percentile Metric Collection

The Java Agent and the .NET Agent capture percentile metrics by default. You can disable percentile metric collection in the Configure Percentile Metrics panel on the **Configuration > Slow Transaction Thresholds** page. Alternatively, manually setting the `disable-percentile-metrics` node property to `True` prevents the agent from collecting percentile metrics.

Specify Percentiles to Collect

By default, app agents capture the 95th percentile. You can indicate 5 whole numbers between 1 and 99 as Percentiles to Collect on the **Configuration > Slow Transaction Thresholds** page. You can apply the configuration changes to all existing business transactions or only to new transactions discovered after the configuration change.

Modify the Percentile Metric Algorithm

The agent uses one of the following methods to calculate percentile metrics:

- P Square algorithm (default): This option consumes the least amount of storage and incurs the least amount of CPU overhead. The accuracy of the percentile calculated varies depending on the nature of the distribution of the response times. You should use this option unless you doubt the accuracy of the percentiles presented.
- Quantile Digest algorithm: This option consumes slightly more storage and CPU overhead for the machine where the agent is running, but may offer better percentiles depending on how the response times are distributed.

To adjust the algorithm option, set the [App Agent Node Property](#) to `percentile-method-option`.

Monitor Events

Related Pages:

- [Create a Custom Event](#)
- [Transaction Thresholds](#)
- [Virtual War Rooms](#)

This page describes event monitoring in AppDynamics.

In the AppDynamics model, events represent a change in the state of a monitored application. An event can represent an error/exception generated by the application, the crossing of a performance threshold, or an operational change in the application (such as a JVM restart).

You can use events to investigate application issues underlying performance problems. You can define policies that generate notifications or perform actions when an event occurs. See [Alert and Respond](#).

View and Monitor Events

You can view and analyze events in the Controller UI. From the Database Visibility, Server Visibility, or user experience application pages in the UI, you can view events by clicking **Events** from the left navigation tree.

 The Controller displays a subset of the types of events generated in AppDynamics. You can access additional event types through the REST API. See [AppDynamics APIs](#).

To view events for application monitoring:

1. Navigate to **Events** on any business application, business transaction, tier or node dashboard to view events generated in the selected time frame.
2. Click **Filters** and select the type of event to display.
3. Review information about an event
 - If the event is an application change, such as an application restart, the details contain a description of the event.
 - If the event is a slow transaction or an error, the details are transaction snapshots from which you can drill down to the root cause of the problem.
4. From the **Event Details** dialog, right-click an event to start a war room, delete or archive the event, or test action execution.

Archive Events

An event is purged after two weeks, at which point it is no longer accessible. To save an event beyond the default snapshot lifespan for future analysis, you can archive the event.

Event Purging in Ephemeral Environments

Events associated with nodes that are deployed to machine instances in an ephemeral environment are subject to being purged. This occurs because the node associated with the events is identified by a label consisting of two discrete parts: a node name and a machine instance name. The node name is always fixed, but the machine instance name changes in ephemeral environments. Thus, when a node is redeployed to a new machine instance, the label identifying the node changes.

For example, the label for a node in an ephemeral environment might consist of the fixed node name "Node1" and the machine instance name "INSTANCE-M-T1": NodeINSTANCE-M-T1. When the node is redeployed to another machine instance, the label for the node could change because of the new machine instance to something such as "Node1INSTANCE-M-T2". If this occurs, the events associated with the first label "NodeINSTANCE-M-T1" could potentially be purged later.

Events Archived by Default

AppDynamics archives application configuration change events by default. In the Controller UI, these events display as **Application Configuration Change**. You can view the `APPLICATION_CONFIG_CHANGE` event type in the Controller UI or retrieve it with the [AppDynamics REST APIs](#).

Once `APPLICATION_CONFIG_CHANGE` events are archived or deleted, you can no longer retrieve them through the AppDynamics REST APIs.

Manually Archive Events

To manually archive events:

1. Select the event from the events list.
2. Click **Actions > Archive Event**.
3. Click **Archive** to confirm the action.

This  indicates that an event has been archived. You can click the column heading to sort by archived events.

Modify Event Retention Period (On-Premises Controllers)

For on-premises Controllers, administrators can modify the default two-week period by configuring the [events.retention.period](#) property in **Administration > Controller Settings**.

Filter Custom Events

The [AppDynamics REST API](#) enables you to define custom events. You can then filter on those events by creating a custom filter:

1. Open the filter options on the **Events** page.
2. Navigate to **Filter by Custom Events** and click **Add Property (+)**.
3. In the **Add Custom Event Filter** dialog, enter the name of the custom event type.
4. Optionally, specify filtering event properties as key/value pairs. The custom event needs to contain the property values you specify to satisfy the filter. If you add multiple properties, a matching value of **All** applies an **AND** operator to the list, meaning all properties need to match for the filter to be satisfied. **Any** indicates a logical **OR**, meaning at least one property must exist and match for the filter to be satisfied.

Monitor Application Change Events

Related Pages:

- [Policies](#)
- [Monitor Events](#)

This page describes monitoring application change events.

When investigating an application error or poor performance, you may want to see whether any application changes occurred at the same time as the error or issue. AppDynamics automatically detects and reports common application change events, such as app server restarts or changes to application environment variables. You can supplement automatically detected change events with custom application change events generated through the Controller or the REST API.

Application changes appear alongside other events in the [Events List](#). Similar to other types of events, you can view details for the event by double-clicking the event or view the details in the context of other performance indicators. They can also serve as triggering conditions for policies.

Manually Register Application Changes

You can manually add an application change event to AppDynamics. This capability enables you to log a change event which might otherwise not be detected by AppDynamics. Controller users can then correlate the event to performance data. For example, you may want to create an event when you push an updated version of the application.

Create an Application Change Event Manually

1. From the **Events** page, expand the **Actions** menu and choose **Register Application Change Event**.
2. In the **Register Application Change** dialog, configure the event. You can choose the type of event, the scope, and the time when the event should be registered.

Register Application Change Event

Description: Rolling out v2 update to Acme App

Type:

- Application Deployment
- Application Configuration Change

What is the scope of this change?

- Application Wide
- Affects a specific Tier(s) or Node(s):

Change Date/Time:

- Now
- Specific Date and Time

Buttons: Cancel, Register Application Change Event

3. Click **Register Application Change Event**. If **Now** is selected as the change time, the event appears in the events list immediately.
4. Double-click the event in the list to view more details about the event, including any actions triggered by the event as a result of a policy.

Automatically Register Application Changes

The [AppDynamics REST API](#) provides an alternative to creating application change events in the UI.

The API lets you automate event registration so that external systems can generate events based on their activities or conditions. For example, you can configure your release management system to generate an event in AppDynamics when it deploys an update to the application code, allowing you to correlate that event with application performance.

For information on creating a custom event through the REST API, see the [Create a Custom Event](#) method in [AppDynamics APIs](#).

Correlate Application Changes with Other Events

You can view application changes in the context with other events and performance indicators in various Controller UI pages.

View Application Changes with Other Events in Transaction Score Histogram

1. In the Application Dashboard, click the Transaction Score tab.
2. Scroll down to the **Events** histogram.
3. Click **Add Criteria**.
4. From the dropdown, select **Event Types**.
5. Unselect all of the criteria except **Application Changes**.

Application change events appear in the **Events** histogram, where they appear in the context of other performance indicators.

Events Reference

Related pages:

- [Monitor Events](#)
- [AppDynamics APIs](#)

This page lists these types of events generated in AppDynamics:

- Event types that are common to the platform, such as UI, configuration, and licensing-related events
- Events generated by the alert and response system
- Application monitoring events

Information on event types that are specific to a platform module, if available, appears with the module-specific documentation. For example, Database Agent events are listed on [Database Agent Events Reference](#).

Event types listed here that are not visible in the UI can be retrieved using the AppDynamics REST API.

Event	Description	Category	Visible in UI	More Info
ACTIVITY_TRACE	The agent sent an internal event containing activity traces. Activity traces enable the tracing of a code path that passes through a specified class/method. The App Agent for Java uses them to provide object instance tracking (OIT) and automatic leak detection (ALD)	AppDynamics Data	No	Java Memory Leaks, Object Instance Tracking for Java
ADJUDICATION_CANCELED	A designated approver has canceled a thread dump or remediation action that was triggered by a policy.		No	Actions Requiring Approval, Policies

Event	Description	Category	Visible in UI	More Info
AGENT_ADD_BLACKLIST_REG_LIMIT_REACHED	The agent Application Diagnostic Data (ADD) blacklist registration limit has been reached.		No	Customize System Notifications
AGENT_ASYNC_ADD_REG_LIMIT_REACHED	The agent async Application Diagnostic Data (ADD) registration limit has been reached.		No	
AGENT_CONFIGURATION_ERROR UI Display name: Agent Configuration Error	An agent configuration error has been detected.	AppDynamics Configuration Warnings	Yes	Troubleshoot .NET Agent Issues
APPLICATION_CRASH UI Display name: Application Crash	A crash has been detected for a JVM. The crash log file is updated.	Application Changes	Yes	
AGENT_DIAGNOSTICS UI Display name: Agent Diagnostics	Diagnostic information concerning agent activity, such as business transaction overflow or HTTP error code diagnostics, has been sent.	AppDynamics Data	No

TIER_DISCOVERED UI Display name: New Tier Discovered	A new tier has been added to the application.	Discovery	Yes	Policies
VERY_SLOW UI Display name: Very Slow Transactions	A business transaction is now very slow.	Slow Transactions	Yes	Troubleshoot Slow Response Times, Transaction Thresholds
WARROOM_NOTE	A War Room Note has been added.			Virtual War Rooms

Monitor Infrastructure

This page describes infrastructure monitoring in AppDynamics.

While business transaction performance is the main focus of a performance monitoring strategy, infrastructure performance provides additional insight into the underlying factors of business transaction performance. [Infrastructure Visibility](#) provides visibility into the underlying OS infrastructure and networks on which your applications run. These agents enable you to isolate, identify, and troubleshoot infrastructure problems that can affect application performance such as resource-hogging tiers.

AppDynamics provides preconfigured application infrastructure metrics and default health rules to enable you to discover and correct infrastructure problems. You can also configure additional persistent metrics to implement a monitoring strategy for your application architecture and business needs.

Additionally, you can view infrastructure metrics in the Metric Browser. **Correlation Analysis** and **Scalability Analysis** charts in the browser are useful for understanding how infrastructure metrics correlate to business transaction performance.

See [Overview of Infrastructure Visibility](#).

AIOps

AppDynamics uses the machine learning capabilities to automatically detect any performance issues in your applications and infrastructure. It helps you to quickly identify the root cause of the issues and troubleshoot it. The following capabilities are available:

Category	Feature	Description
Issue Detection	Dynamic Baseline	Uses algorithmic capabilities to identify deviations in metrics by considering historical behavior such as time-of-day variations and other seasonal patterns.
	Anomaly Detection	Automatically determines whether every Business Transaction in your application is performing normally and alerts you when they behave abnormally.
Root Cause Analysis and Troubleshooting	Automated Root Cause Analysis	Identifies the suspected cause of the Business Transaction anomalies by using the graph traversal algorithm.
	Automated Transaction Diagnostics	Automatically captures anomalous transactions and identifies suspected causes by analyzing slow methods, slow databases, and remote service calls.

Alert and Respond

Related Pages:

- [Manage Custom Roles](#)
- [Example Use Cases](#)

AppDynamics can generate notifications or invoke actions based on conditions or events you configure. Using the alert and respond feature, you can determine problems as they occur, or even before they occur.

Policies serve as central configuration artifacts for the alert and respond feature. A policy allows you to define the remedial actions that are invoked when one or more conditions are met or an event occurs. A health rule defines the performance condition or an event.

AppDynamics provides several pre-configured health rules that give you a head start to create your own health rules. You can also use built-in examples and customize them to match your application performance requirements. For example, the built-in health rules test for whether the *Business Transaction error rate is much higher than normal* or *CLR Garbage Collection Time is too high*. See [Default Health Rules](#) for more examples.

Actions automate the response to an event, such as, sending an alert, or performing diagnostic, or performing remediation actions. See [Alert and Respond API](#) to learn how to create custom URLs for notifications.

i Notification actions that use email or SMS and email digests require that the SMTP server be configured for the Controller. See [Enable the Email Server](#).

Email digests generate email messages about the conditions and events in a system based on a pre-defined schedule.

Permissions

Different users with different roles typically set up and use the various alert and respond features. Some permissions can be granted at the account level and some can be granted at the application or even the tier level.

Account Level Permissions

Alerting templates, Email templates, HTTP request templates, and Email/SMS configuration are account-level features. The scope for these features is the entire AppDynamics account and all the applications in that account. Users who have account-level roles that include the necessary permissions can create and manage account-level templates and configuration. These permissions belong to the predefined Account Owner role. The Account Owner can also create custom roles that include some of these permissions. For example, an account owner can create an email template manager role and assign that role to users, who can then create and modify email templates.

To create, manage, and configure these account-level features, you need the following permissions respectively:

- Configure Alerting Templates
- Configure Email Templates
- Configure HTTP Request Templates
- Configure Email / SMS

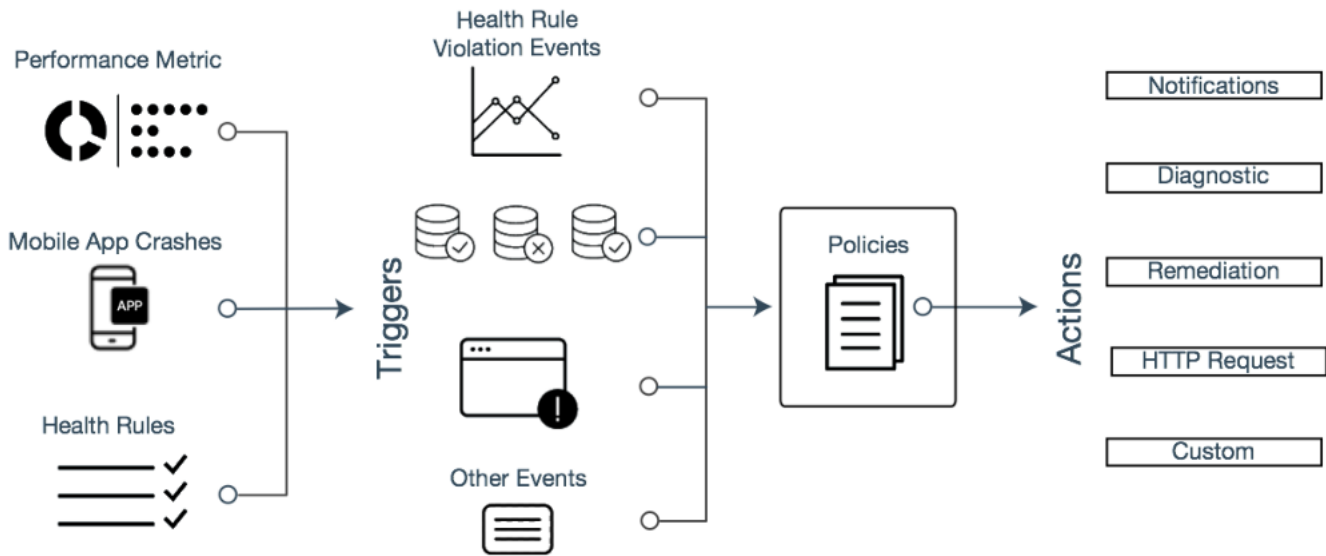

Application and Tier-Level Permissions

Policies, health rules, actions, and email digests are application-level or tier-level features. The scope of these features is the application or tier in which they were created. To create, manage, and configure these features, you need the following permissions respectively:

- Configure Policies: Create, edit or delete policies
- Configure Health Rules: Create, edit, or delete health rules
- Configure Actions: Create, edit, or delete actions on agent properties UI
- Configure Actions: Create, edit, or delete email digests

Alert and Respond Policy Structure

As shown in the following diagram, policies match event triggers with the action to be taken in response to those triggers.

Alert and Respond Across the Platform

The alert and respond features work across AppDynamics products, including Infrastructure Visibility, Analytics, EUM, and Application Monitoring. Unless otherwise noted, this section describes the features in the context of Application Monitoring, which, by its nature, offers the broadest range of configuration and use case options. Specific features as described may not apply to other AppDynamics products.

Additional usage notes include:

- Policy triggers for applications can be health rule violation events or other types of events. Policy triggers for databases and analytics must be health rule violation events.
- The types of actions that you can create for an application include notifications, diagnostics, remediation, HTTP requests, custom actions, and cloud auto-scaling. The types of actions that you can create for a database or analytics are limited to notifications, HTTP requests, and custom actions.
- The types of entities affected by a health rule are more limited for databases and analytics than for applications.
- For information on using policies triggered by browser synthetic events, see 'Alerting and Synthetics' in [Browser Synthetic Monitoring](#).

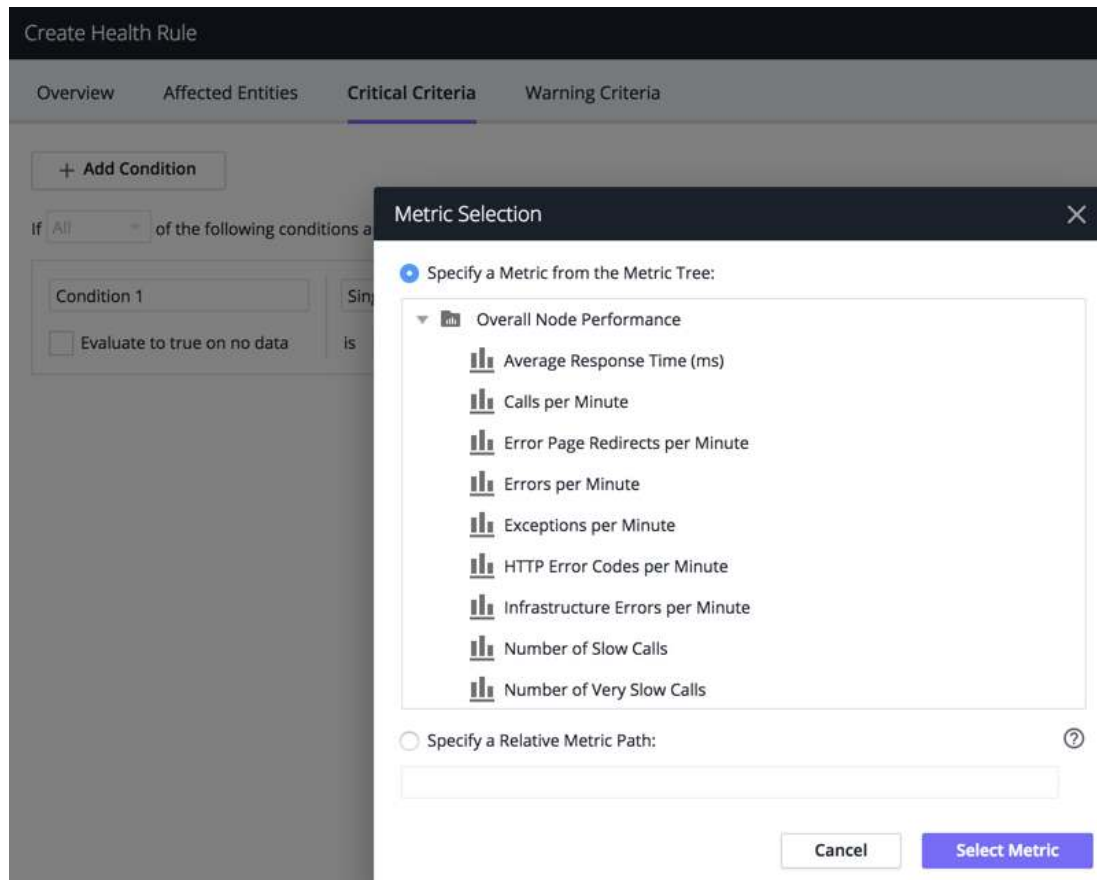

Example Use Cases

Related Pages:

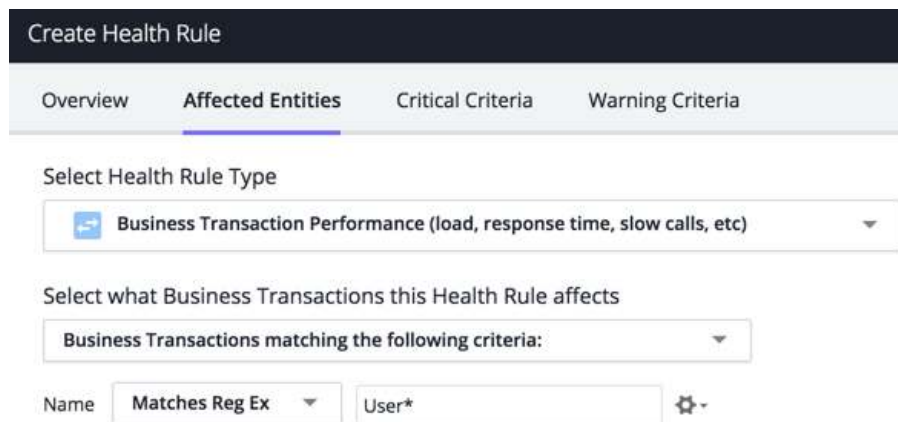

- [Alert and Respond](#)
- [Policies](#)
- [Health Rules](#)

This page provides use case examples for alert and response features:

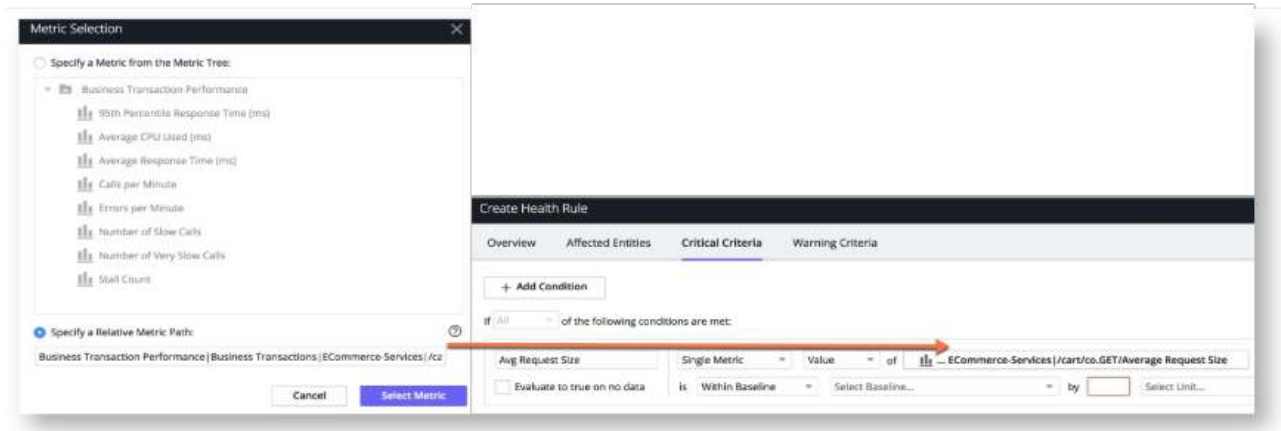

- Define health rules that apply to specific tiers or nodes. Instead of choosing specific nodes, you can trigger a rule when more than a certain percentage of nodes are unhealthy, say 20%.
- Start a diagnostic action for a business transaction.
- Alert when an app agent stops reporting to the Controller.
Create a node health rule based on the value of the Availability metric reported by the agent. If Availability is less than one, the agent is not reporting.

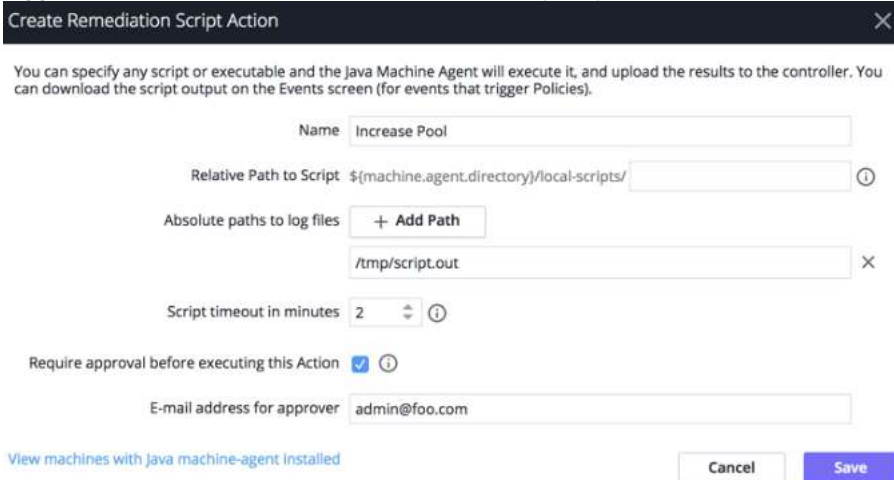

- Alert when the 95th percentile metrics for specific business transactions reach a certain value. You want to apply this rule only to business transactions with names beginning with *User*.

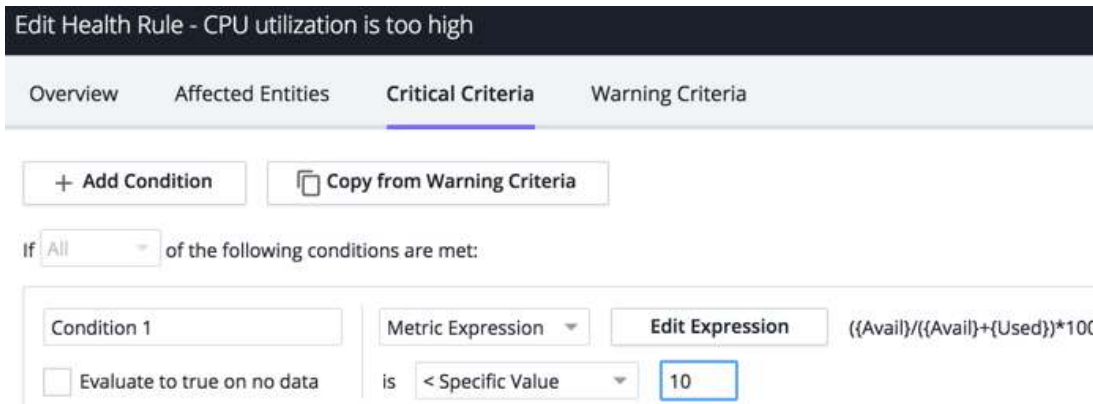

- You can generalize a health rule by specifying a relative metric path, rather than a specific metric. The health rule is evaluated for each of the affected business transactions. Use a relative metric path when you need to evaluate a single metric for multiple entities.

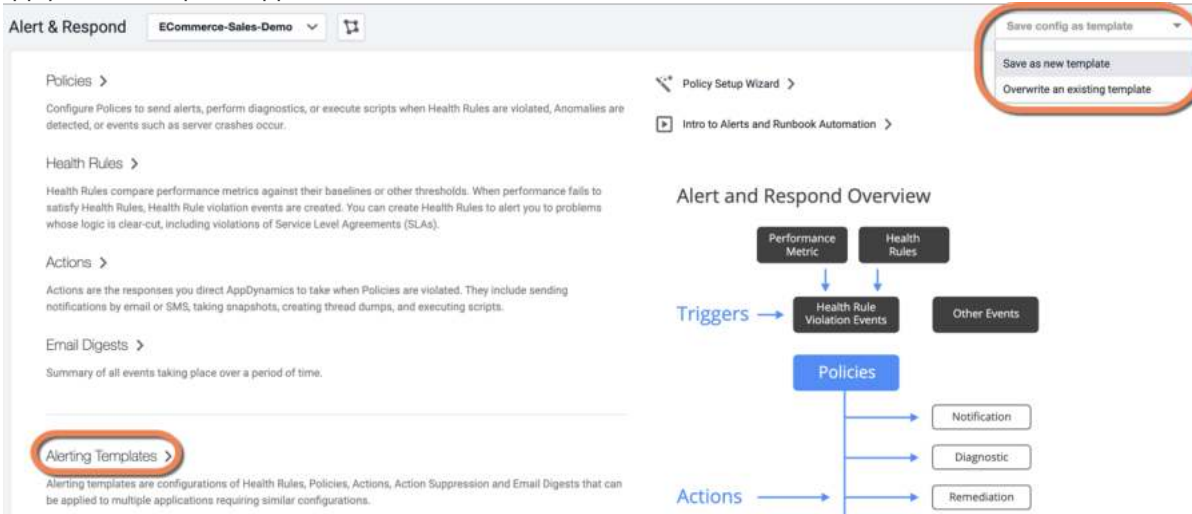

- You have a large operation with several development teams, each responsible for a different service. You create a health rule for one service and then copy it. Then create different policies in which you can pair each copy of the health rule to an alert addressed to the appropriate team.
- Start a script to change the size of the connection pool. You have an application that performs well for a normal load. However, peak loads can cause the application to slow. During peak load, the AppDynamics not only detects the connection pool contention but also allows you to create a remediation script that can automate increasing or decreasing the size of the connection pool. You can require human approval to run this script or just configure it to automatically execute when it is triggered. Create a runbook and associate it with a policy so that it will run when the connection pool is exhausted.

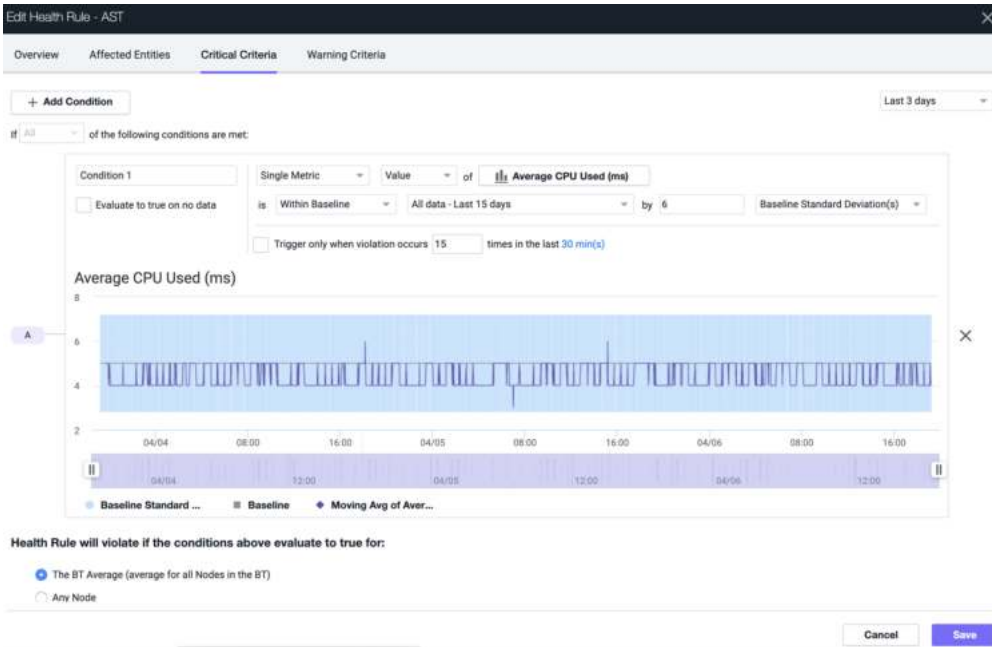

- Alert when the available disk volume is low. Use an expression including two metrics – available and used disk space – to be alerted when disk volume is low.

- When configuring **Alert and Respond** features for an application, you can select **Save Config as Template** to save the application configuration as a template. You can then apply this template to multiple applications to ensure consistency. To make a global configuration change, you can update the template selecting **Overwrite an existing template** and then re-apply it to the required applications.

- To avoid receiving false alerts and to ensure that you calibrate the sensitivity of health rules appropriately, you can use Alert Sensitivity Tuning (AST). AST helps you visualize the impact of the alerting configuration as and when you configure. AST provides instant insights in a graphical format that helps you fine-tune the alerts. Depending on the baseline configuration you define, a graphical view of the metric data for the given baseline configuration displays. The graphical view is instantly updated when you update any configuration. You can also view granular details by modifying the graphical view. The metric data presented in the graph helps you calibrate the sensitivity of the metric evaluation and the health rule.

Policies

Related Pages:

- [Health Rules](#)

- [Actions](#)
- [Configure Policies](#)

A policy consists of a trigger, which is based on one or more events, and an action, directly in response to the trigger. You can use policies to automate monitoring, alerting, and problem remediation.

View Policies

To view and create policies, access the Policies UI by selecting **Alert & Respond > Policies**.

The policy list displays all the policies created for your application, with its triggers and actions taken. You can modify a policy by double-clicking it in the policy list.

Policy Triggers

Policy triggers are events that cause the policy to fire. The events can be health-rule violation events or other types of events, such as hitting a slow transaction threshold or surpassing a resource pool limit. See [Health Rules](#), [Troubleshoot Health Rule Violations](#) and [Monitor Events](#).

The triggering events can be broad, affecting any object in the application, or very narrow, affecting a specific object. For example, you can have a broadly-defined policy that fires whenever a resource pool limit (such as >80% usage of EJB pools, connection pools and/or thread pools) is reached for any object in the application. Additionally, a narrowly-defined policy is one that would fire only when existing health rules on memory utilization or JVM garbage collection time are violated.

A policy is triggered when at least one of the specified triggering events occurs on at least one of the specified objects.

Policy Actions

You can assign the actions that are taken when a policy is triggered, such as an email or SMS notification. Other types of actions do more than just notify. For example, a resource pool violation can trigger a script that increases the pool size.

Other common actions include restarting an application server if it crashes, purging a message queue that is blocked, or triggering the collection of transaction snapshots. You can also trigger a custom action to invoke third-party systems.

Because the definition of health rules is separate from the definition of actions, you can specify different actions for an event in different contexts, such as a threshold crossing in either a tier or node context. See [Actions](#) for more information about the different types of actions.

Policy Actions in Batch

You can configure a policy to execute its actions either:

- Immediately for every triggering event.
For example, if in a two-second period a policy matched 100 events, it would start its actions 100 times as soon as each event occurred.
- Once a minute for all the events that triggered over the last minute. This is the batch option. The **Execute actions in batch** checkbox is selected by default.
For example, if in a two-second period, a policy matched 100 events and then no triggering events occurred for the next 58 seconds, the policy would start each action just once. The context for the actions would be all 100 events.

Which you choose depends primarily on the type of action. For a notification action, it probably doesn't make sense to send 100 emails or SMS messages in a few seconds. In this case, it makes sense to batch the actions with a summary of the events occurring during the last minute. This can be easily accomplished

using an email template that iterates through the event list. See the example in [Predefined Templating Variables](#).

However, if the actions are thread dumps, there is no reason to expect that all 100 events are on the same node. They might be on different nodes. For that kind of action, you probably want the thread dump to be taken for each event and also, not to wait another 58 seconds before taking the thread dump.

Configure Policies

Related Pages:

- [Monitor Events](#)
- [Health Rules](#)
- [Troubleshoot Health Rule Violations](#)
- [Actions](#)
- [Enable an Email Server](#)

You configure policies using these two methods:

- Use the Policy Setup Wizard for simple policies that send an email notification when a health rule is violated.
- Configure the policy manually for anything more complicated.

 To configure policies, you need the Configure Policies permission.

Policy Setup Wizard

For simple policies in the Controller, select **Alert & Respond > Policies > Policy Setup Wizard**.

To create a notification policy, you must set up an SMTP server and supply an email address. The policy is then created.

To modify the policy later, select the policy and click **Edit**.

Create Policy Manually

To create a policy manually in the Controller, select **Alert & Respond > Policies > Create Policy Manually**.

The **Create Policy** page contains the following panels:

- **Trigger:** Sets the events that trigger the policy, entities that are affected by the policy.
- **Health Rule Scope:** Defines the Health Rules that trigger the policy.
- **Object Scope:** Defines the objects that trigger the policy for application and user experience contexts.
- **Actions:** Set the actions to take when the policy is triggered.

In either panel, you can configure the policy name, enabled status, and whether to batch the actions executed by the policy.

Create Policies

1. Click **Alert & Respond**.
2. Click **Policies** either in the right panel or the left navigation pane.
3. Select the context for the policy (specific Application, User Experience, Databases, Servers, or Analytics) from the dropdown.
4. To create a new policy, click **Create Policy (+)**.

You can edit, copy, enable or disable, and delete a policy by clicking the appropriate button.

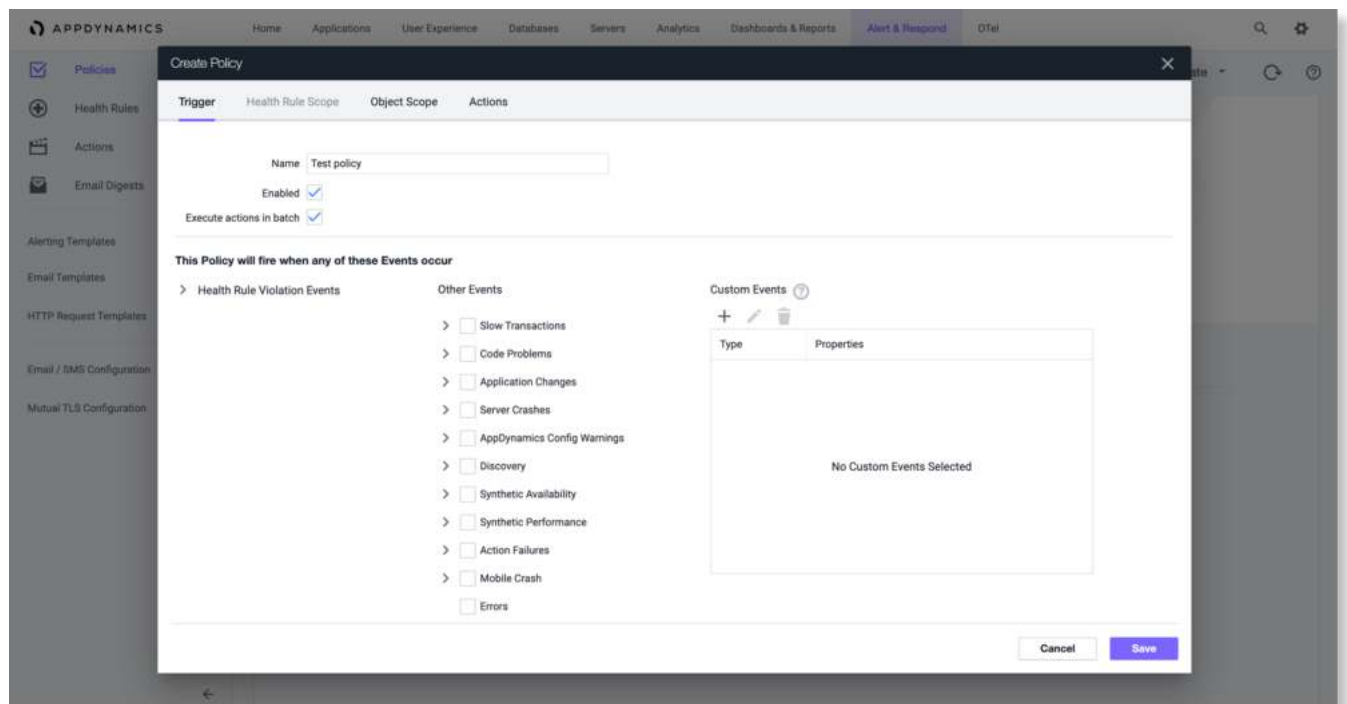

Configure Policy Triggers

The policy trigger panel defines the events and objects that cause the policy to run and invoke its actions.

For policy triggers that depend on health violation events, you must create the health rules before you can create a policy that uses them. See [Health Rules](#) and [Troubleshoot Health Rule Violations](#).

1. Click **Create Policy (+)** or select a policy and click **Edit** (pencil button).
2. Enter a name for the policy in the **Name** field.
3. To enable the policy, select the **Enabled** checkbox. To disable the policy, clear the **Enabled** checkbox. You can also enable or disable a policy by selecting it from the policy list and clicking **Enable** or **Disable**.
4. If you clear the **Execute actions in batch** checkbox, the policy starts its actions immediately for every triggering event. If you check this checkbox, the policy starts its actions once for all the triggering events that occurred in the last minute. See 'Policy Actions in Batch' in [Policies](#).
5. Select the **Trigger** panel if it is not already selected.
6. Check one or more types of events that should trigger the policy. You may need to click the arrow to display specific events within an event category.

If you check at least one health rule violation event, you can choose whether any or all health rule violations, or only specific health rule violations will trigger the policy.

If your AppDynamics environment includes browser synthetic monitoring, other additional events display for Synthetic Availability and Synthetic Performance. See 'Alerting and Synthetics' in [Browser Synthetic Monitoring](#).

You can optionally designate specific custom events to trigger the policy, using the **Custom Events** panel in the lower right corner. Click **+**.

Add Custom Event Filter
✕

Find Custom Events matching these criteria:

Custom Event Type

Properties (Optional) Match Any of the following properties:

=

[Learn more about custom events](#)

Specify the custom event type. Optionally, add particular properties on that event as key/value pairs.

- For **Any**, at least one property must exist and match.
- For **All**, all properties must exist and match.

Configure Health Rule Violation Triggers

The **Health Rule Scope** panel determines the scope of the health rule violations that trigger the policy. If you have not created a health rule, you can create one by selecting **Create Health Rule** in this panel.

1. If you have not already done so, edit the policy to which you want to add Health Rule triggers.
2. Select the **Health Rule Scope** panel, then select **Any Health Rules** if you want the policy triggered by a violation of any health rule.
3. To designate specific health rule violations to trigger the policy, click **+**, and then select the health rules from the embedded health rule browser. Click **Create Health Rule** to create a new health rule as the trigger for this policy.

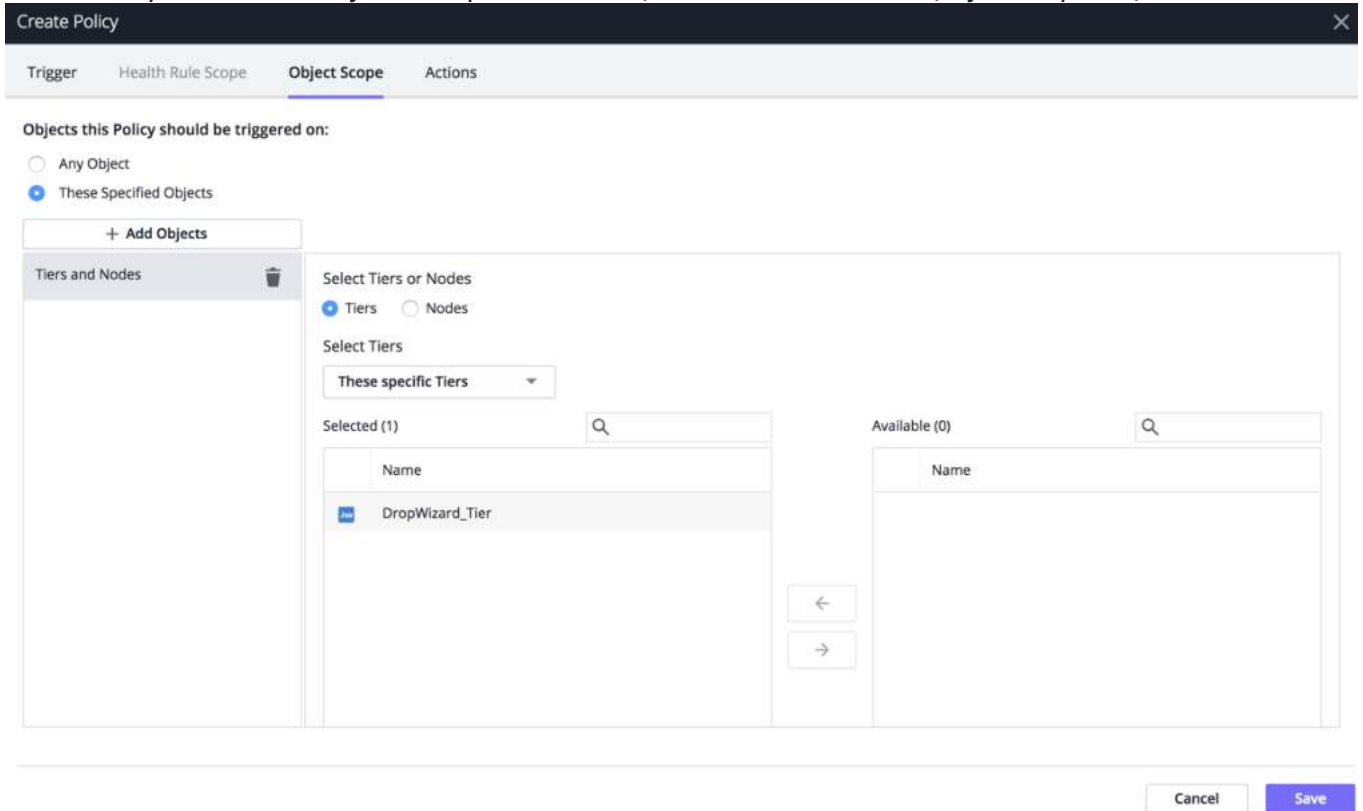

Health Rule Selection
✕

	Name	Type	Status
	backend	Databases & Remote Services	✔
	BT HR	Business Transaction Performance (load, response tim...	✔
	Business Transaction error rate is much higher than n...	Business Transaction Performance (load, response tim...	✘
	Business Transaction response time is much higher th...	Business Transaction Performance (load, response tim...	✔
	CLR Garbage Collection Time is too high	Node Health - Hardware, JVM, CLR (cpu, heap, disk I/O,...	✔
	CPU utilization is too high	Node Health - Hardware, JVM, CLR (cpu, heap, disk I/O,...	✔
	critical node transaction perf hr	Node Health - Transaction Performance (load. resoons...	✔

Configure Object Scope

The **Object Scope** panel defines the objects the policy is triggered on. The object scope applies only to business transaction performance type health rules and node health type health rules which comprise tiers and nodes.

1. When you have finished selecting the health rule violations that trigger the policy, click the **Object Scope** panel to select objects to be monitored in case of an event. If you select **Any Object**, the policy will be triggered by the configured events when they occur on any object in your application.
2. To restrict the policy to specific objects, select **These Specified Objects** and then choose the objects. For example, the following policy starts when selected events occur on the ECommerce Server tier. You can similarly restrict the objects to specific nodes, business transactions, Ajax Requests, and so forth.

You can restrict the affected nodes on the node name, on the type of node (such as Java and .NET) on nodes in certain tiers, or on criteria such as meta-info, environment variables, and JVM system environment properties. Meta-info includes key-value pairs for:

- key: `supportsDevMode`
- key: `ProcessID`
- key: `appdynamics.ip.addresses`
- any key passed to the agent in the `appdynamics.agent.node.metainfo` system property

To trigger by Health Rule Violation Events, leave the selection at **Any object**. Selecting **These specified objects** means that events occurring within the selected objects, for example, slow transactions, errors, and so forth, trigger the policy.

3. Click **Save**.

Configure Policy Actions

The policy actions panel binds an action to the trigger. It defines which actions the policy automatically initiates when the trigger causes the policy to start.

The actions must be created before you can create a policy that starts them. See [Actions](#) and the documentation for individual types of actions (for example, notification actions, remediation actions) for information on creating an action.

1. If you have not already done so, edit the policy to which you want to add actions. See [To Access the Policy Wizard](#).
2. Select the **Actions** panel.
3. Click **+**. The list of existing actions displays. The available actions vary depending on the product area selected for the policy, such as Applications, Servers, Databases and so on.
You can filter the list by selecting the checkboxes for the types of actions you want to see.
4. In the list of actions, select the action that you want this policy to execute and click **Select**.
If you do not see an appropriate action for your needs, click **Create**. For information on creating actions, see [Actions](#). After you have created the action, select it here to assign it to the policy that you are configuring.
5. Click **Save**.

You can optionally test whether your action will be fired using the [Test Action Execution](#). Ensure that the policy you are testing is enabled.

Test Action Execution

Related Pages:

- [Alert and Respond](#)
- [Monitor Events](#)
- [Configure Policies](#)
- [Actions](#)

An event represents an error or exception generated by the application, the crossing of a performance threshold, or an operational change in the application, such as a JVM restart.

You can view and analyze events in the Controller UI. From the **Database Visibility**, **Server Visibility**, or **User Experience** pages, you can view events by selecting **Events** from the left navigation panel. The events list also provides information on which policy actions are configured to start when a specific event occurs. It does not execute the actual actions configured for the policy.

This information provides answers to these questions:

- Why didn't my policy action execute? Perhaps policies are not actually configured to respond to an event as you thought they were.
- Why am I getting multiple actions, such as multiple emails, for the same event? Perhaps more than one policy is configured to perform the same action.

To see the actions that are triggered for an event:

1. In the events list, select the event for which you expect actions to start.
2. From the Actions menu, select **Test Action Execution**.

Anomaly Detection

Related Pages:

- [Enable and Configure Anomaly Detection](#)
- [Troubleshooting Anomalies](#)

The AppDynamics Anomaly Detection and Automated Root Cause Analysis are two features designed to reduce Mean Time To Resolution (MTTR) for application performance problems.

Anomaly Detection automatically determines whether every Business Transaction in your application is performing normally. Automated Root Cause Analysis helps you quickly determine the root cause for problems revealed by Anomaly Detection.

How Does Anomaly Detection Work?

Anomaly Detection uses machine learning capabilities to reduce the **Mean Time to Detect (MTTD)** when an anomaly occurs in a business transaction. It uses a specially designed algorithm that does not require you to configure anything. The Anomaly Detection algorithm works as follows:

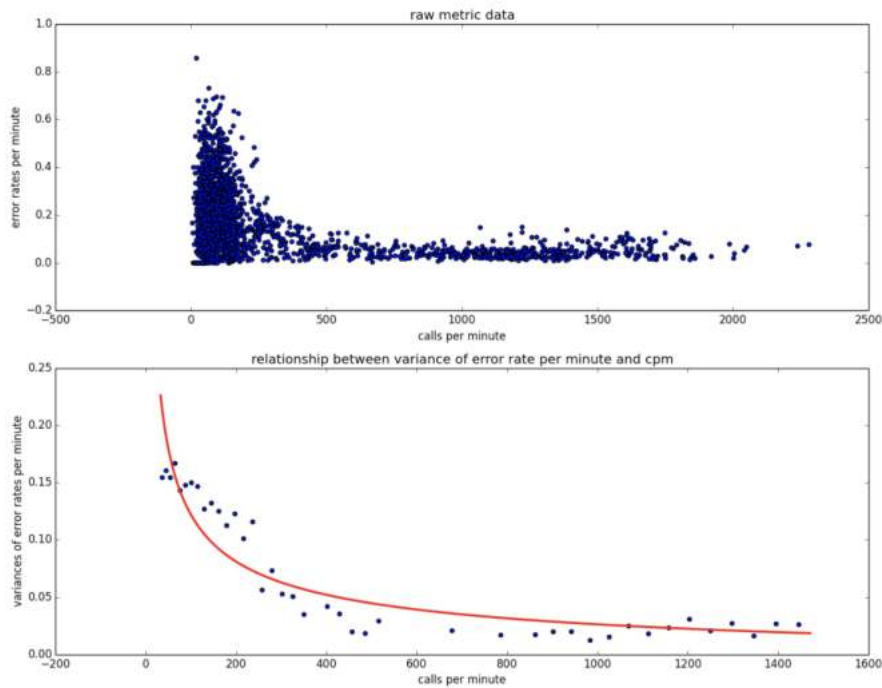

1. It detects if any abnormal reading is reported for the **Errors per minute (EPM)** metric.
2. It detects if any abnormal reading is reported for the **Average Response time (ART)** metric.
3. It then combines the data it learned from these metric readings using heuristics that are designed to reduce alert noise.

Anomaly Detection employs multiple techniques to ensure that the metric data it collects is accurate:

- It disregards any temporary spikes and periods of no data
- It normalizes the metric data. For example, when determining the EPM metric data, any spikes may not indicate a real problem unless there is a corresponding increase in **Calls per Minute (CPM)**. EPM data may not be useful in itself, hence, Anomaly Detection uses Error Rate (EPM/CPM).

- It does not apply traditional seasonal baselines. Instead, it correlates the variance of EPM and ART to CPM to obtain reliable results.

What is Root Cause Analysis (RCA)?

When an entity in your application has an anomaly, you will want to know why. Anomaly Detection uses AI capabilities to enable Automated Root Cause Analysis to monitor the health of all the entities in your application, and show you the suspected causes for every anomaly. You can confirm or negate the suspected causes with a brief look, and drill down into deviating metrics and snapshots, as desired. Thus, you can quickly determine the root cause of any anomaly in the application.

How Does RCA Work?

RCA reduces the Mean Time to Identification (MTTI) by automatically pointing to the source of the problem. RCA considers metrics to identify the fault domain, and snapshots and events from the entire application, to find and surface suspected problems. This holistic approach is performed in two parts:

1. Fault domain isolation—Identification of the exact location of the problem in the system
2. Impacted component analysis—Analysis of logs, snapshots, trace, infrastructure, and so on to determine the affected components

How is Anomaly Detection Different from Health Rules?

While both Anomaly Detection and health rules alert you to performance problems in your application, Anomaly Detection provides powerful insights that would be difficult to obtain using health rules.

Anomaly Detection	Health Rules
Anomaly Detection uses machine learning to discover the normal ranges of key business transaction metrics and alerts you when these metrics deviate significantly from expected values. This enables Anomaly Detection to identify a wider range of problems than a person could capture in Health Rules.	Health rules are manually created to apply logical conditions that one or more metrics must satisfy. For example, you could monitor the Average Response Time (ART) to check if this metric deviates from the configured baseline.
Anomaly Detection requires no configuration except when you want to limit anomaly alerting.	AppDynamics provides a default set of health rules and you create additional health rules manually as required, configuring time periods, trends, and schedules.
Anomalies are associated with business transactions.	Health rules apply to any entity, for example, business transactions, service endpoints.

Enable and Configure Anomaly Detection

Related topics:

- [Anomaly Detection](#)
- [Troubleshooting Anomalies](#)

Anomaly Detection must be enabled, but requires no configuration except to limit anomaly alerting. Enabling Anomaly Detection also enables Automated Root Cause Analysis.

i Anomaly Detection and Automated Root Cause Analysis are available to only SaaS customers.

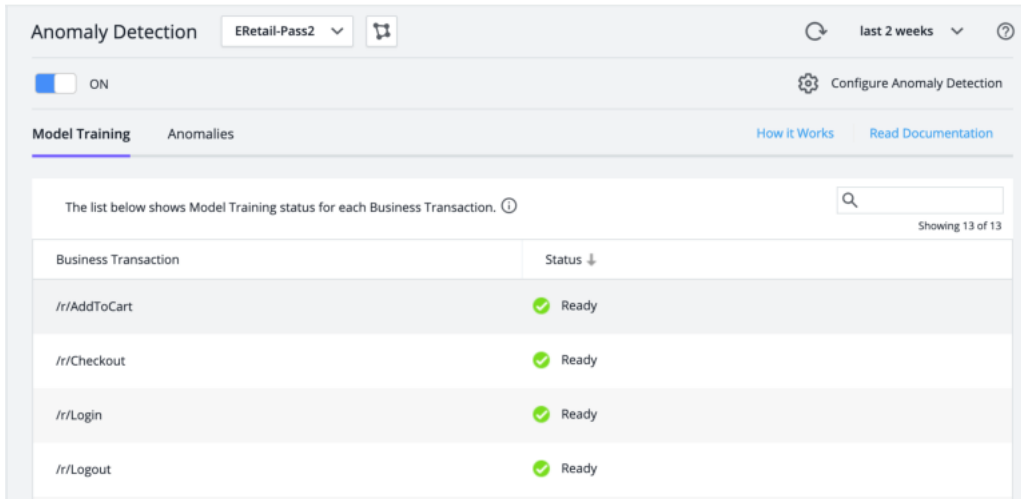

Enable Anomaly Detection

You need to enable Anomaly Detection separately for each application.

1. In **Alert & Respond > Anomaly Detection**, select the desired application from the dropdown, and toggle Anomaly Detection **ON**.
After you enable Anomaly Detection, it takes 48 hours for Anomaly Detection and Automated Root Cause Analysis to become available. During that time, the machine learning models train on the business transactions in your application.

2. Select **Alert & Respond > Anomaly Detection > Model Training** to view **Business Transaction** training status.

This table explains the training statuses of a **Business Transaction**.

Status	Meaning
In Training	Model training is in progress for the Business Transaction.
Ready	Model training is complete and the Business Transaction is healthy.
Warning	Model training is complete, but the Business Transaction has experienced one or more Warning level anomalies during the training period.
Critical	Model training is complete, but the Business Transaction has experienced one or more Critical level anomalies during the training period.
Not Available	Model training is incomplete and the Business Transaction is not visible to Anomaly Detection.

The models continue training as long as Anomaly Detection is enabled. If traffic to a **Business Transaction** is interrupted for long enough duration preventing training that day, Anomaly Detection continues to function using the models from the previous seven days.

i No machine learning models are trained for **Business Transactions** that have very low calls per minute (CPM), because the sample size will be so small that the resulting model will be unreliable.

Monitor Anomalies

1. From **Applications > Business Transactions**, select any **Business Transaction** of interest.

2. Click the **Warning** or **Critical** icon in the **Health** column.

Name	Health	Response Time (ms)	Calls / min	Errors / min	% Errors	% Slow Transactions	% Very Slow Transactions	% Stalled Transactions
/r/Checkout	!	262	244	144	40	0.6	0.3	0
/r/AddToCart	!	24	4	1	30	0	0.3	0
/r/Logout	✓	1	2	1	40	0	0	0
/r/Search	✓	1	2	0	6	0	0	0

A list of health rule violations and anomalies for the Business Transaction displays:

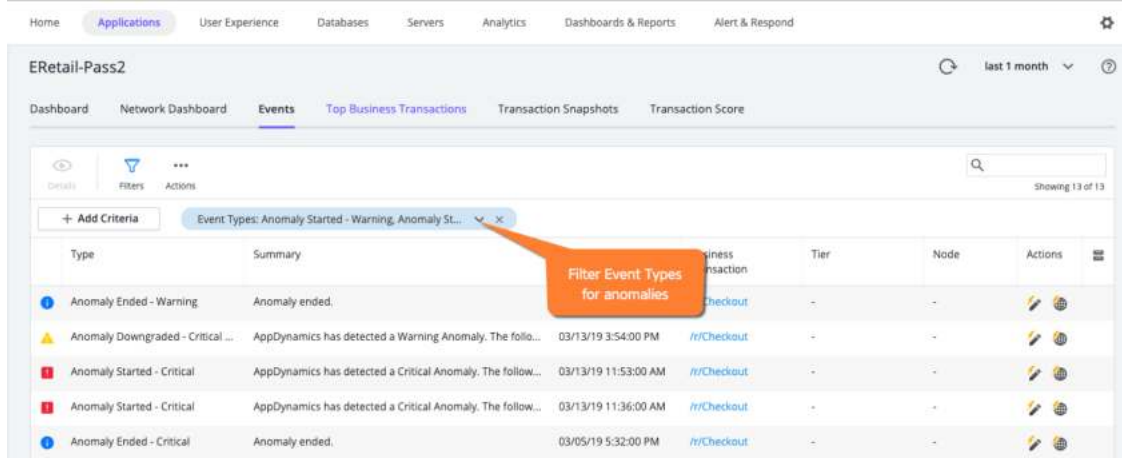

Violations	Status	Description	Start Time	End Time	Duration
! Business Transaction response time is much higher than normal	Resolved	AppDynamics has detected a problem. Business Transaction response time is much higher than normal is violating.	03/11/19 4:31:55 AM	03/11/19 4:34:55 AM	3 minutes
! Anomaly	Resolved	AppDynamics has detected a Critical Anomaly. The following metrics are deviating:	03/01/19 6:16:00 AM	03/01/19 7:05:00 AM	49 minutes
! Anomaly	Resolved	AppDynamics has detected a Warning Anomaly. The following metrics are deviating:	03/04/19 5:19:00 PM	03/04/19 5:46:00 PM	27 minutes
! Anomaly	Resolved	AppDynamics has detected a Critical Anomaly.	03/04/19 8:47:00 PM	03/04/19 9:03:00 PM	16 minutes

3. You can view the lists of anomalies in multiple ways. Monitoring anomalies can reflect how you work with AppDynamics. Choose any of these options to open a detailed view that includes the results of Automated Root Cause Analysis.

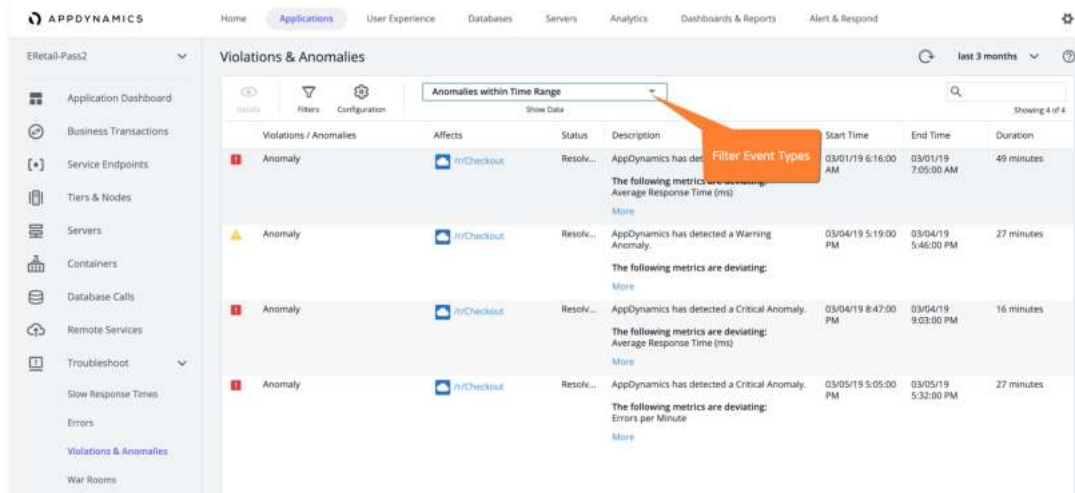

- If you set up and validate tools for a tools team:
View the anomaly details from **Alert & Respond > Anomaly Detection > Anomalies**

Affects	Status	Description	Start Time	End Time	Duration
! /r/Checkout	Resolved	AppDynamics has detected a Critical Anomaly. The following metrics are deviating: Average Response Time (ms)	03/01/19 6:16:00...	03/01/19 7:05:00...	49 minutes
! /r/Checkout	Resolved	AppDynamics has detected a Warning Anomaly. The following metrics are deviating: Average Response Time (ms)	03/04/19 5:19:00...	03/04/19 5:46:00...	27 minutes
! /r/Checkout	Resolved	AppDynamics has detected a Critical Anomaly. The following metrics are deviating: Average Response Time (ms)	03/04/19 8:47:00...	03/04/19 9:03:00...	16 minutes

- If you monitor applications for an application operations team:
 - From **Applications > Events**, filter **Event Types** to include anomalies

- From **Applications > Troubleshoot > Violations & Anomalies**, filter **Event Types** to include anomalies

You can configure policies to be triggered by anomalies, similar to the way you [configure policies to be triggered by Health Rules](#).

Configure Anomaly Detection

By default, Anomaly Detection alerts you about the anomalies found in all the Business Transactions in your application. However, you can configure Anomaly Detection to surface only those anomalies within the combination of Business Transactions, severity level, and detection sensitivity that you specify. Do this if you prefer to see fewer and more narrowly focused alerts:

1. Click **Configure Anomaly Detection** to open the configuration dialog.

2. Select one of the following **Business Transactions** on which you want Anomaly Detection to alert:

- **All Business Transactions in the Application** (this is the default selection)
- **Business Transactions within the specified Tiers**
- **These specified Business Transactions**
- **Business Transactions matching the following criteria:**
 - **Starts With**
 - **Ends With**
 - **Contains**
 - **Equals**
 - **Matches Regular Expression**
 - **Is in List**
 - **Is Not Empty**

 You can also select the **NOT** operator to reverse the criteria.

3. Select one of the following severity levels:

- **All Severities** (includes both **Warning** and **Critical**)
- **Critical**
- **Warning**

4. In **Detection Sensitivity**, select one of the following levels:

Sensitivity Level	Description
High	Use this level for business-critical services to ensure that no issue gets undetected in your environment. It triggers more alerts but with lower statistical confidence.
Medium	Use this level for services that are important to your business but not critical. By default, this sensitivity level is selected.
Low	Use this level for services that have low business impact and to avoid too many alerts.

5. If you want to test anomaly detection in a non-production environment, select **Yes, turn on test mode**.

 The test mode allows you to assess anomaly detection capabilities in non-production environments. In this mode, the anomaly detection accurately detects any performance issues even if metric data collection is low. You can use the test mode in your development or staging environments.

6. Click **Save** to complete the configuration.

Troubleshooting Anomalies

Related topics:

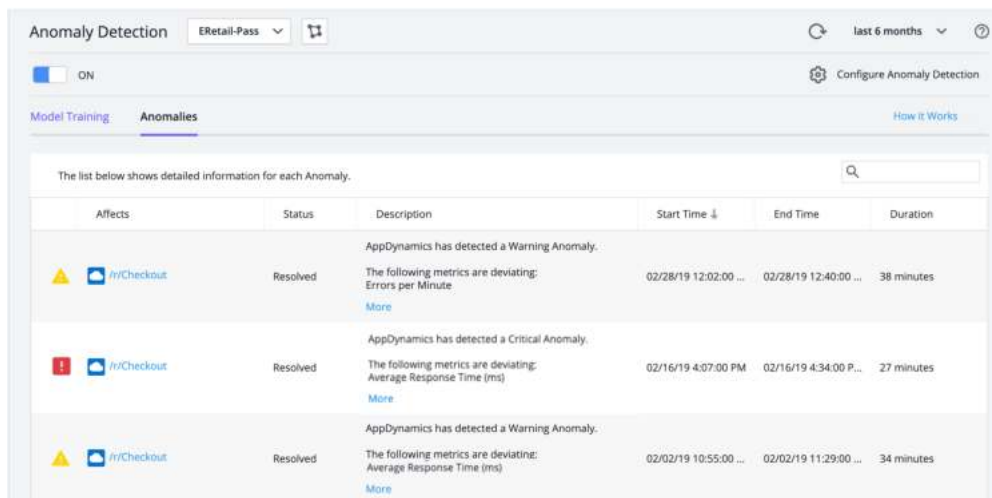

- [Anomaly Detection](#)
- [Enable and Configure Anomaly Detection](#)

To demonstrate techniques for using Anomaly Detection and Automated Root Cause Analysis effectively, this example follows an anomaly from the moment it surfaces until its root cause is confirmed. The troubleshooting process can begin with any of the [multiple ways to view anomalies](#). This example assumes that you start with the **Alert & Respond > Anomaly Detection** page.

 Anomaly Detection and Automated Root Cause Analysis are available to SaaS customers only.

Drill Into an Anomaly

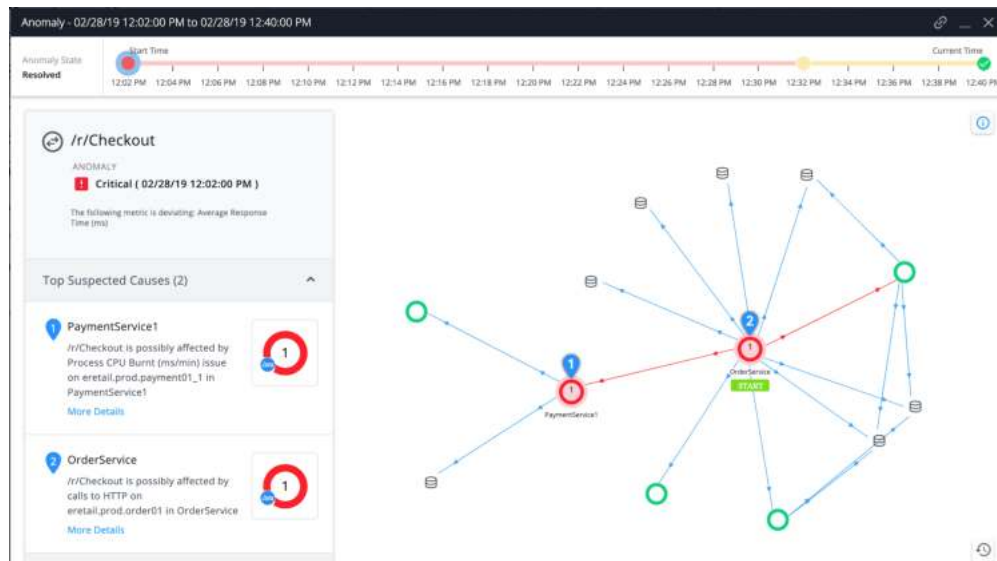

- In **Alert & Respond > Anomaly Detection**, view the Anomalies tab.

The screenshot shows the 'Anomaly Detection' page for 'ERetail-Pass'. The 'Anomalies' tab is selected. The table below shows detailed information for each anomaly.

Affects	Status	Description	Start Time ↓	End Time	Duration
 /r/Checkout	Resolved	AppDynamics has detected a Warning Anomaly. The following metrics are deviating: Errors per Minute More	02/28/19 12:02:00 ...	02/28/19 12:40:00 ...	38 minutes
 /r/Checkout	Resolved	AppDynamics has detected a Critical Anomaly. The following metrics are deviating: Average Response Time (ms) More	02/16/19 4:07:00 PM	02/16/19 4:34:00 P...	27 minutes
 /r/Checkout	Resolved	AppDynamics has detected a Warning Anomaly. The following metrics are deviating: Average Response Time (ms) More	02/02/19 10:55:00 ...	02/02/19 11:29:00 ...	34 minutes

- Double-click an anomaly to open the detailed view.

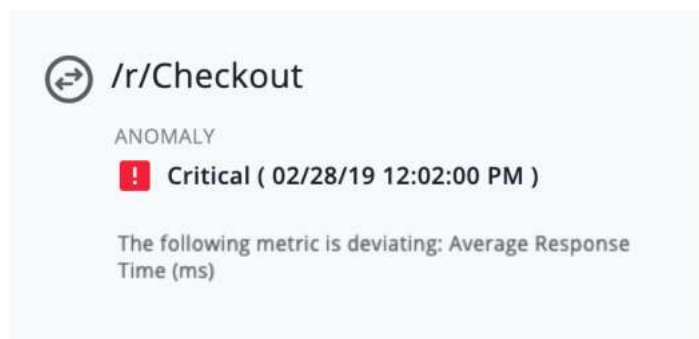

Initially, the page describes everything that is occurring during the anomaly's Start Time. To review how things change later in the anomaly's lifecycle, click events further along its timeline.

Examine the Anomaly Description

The anomaly description describes the anomaly in relation to its named Business Transaction, the severity level of the selected state transition event, and the top deviating Business Transaction metrics.

In this example, these are:

- Business Transaction: `/r/Checkout`
- Severity Level: Critical
- Top Deviating Metrics: Average Response Time

The deviating metric is Average Response Time indicating that checkout responding slowly is the problem.

Examine the Timeline

The state transition events mark the moments when the anomaly moves between **Warning** and **Critical** states.

- The timeline in this example begins in the **Critical** state, followed 30 minutes later by a transition to the **Warning** state, which lasts only eight minutes.
- Because this simple anomaly starts in the **Critical** state and remains there for most of its lifecycle, we can probably learn all we need to know from the initial event

By contrast, patterns that appear in more complicated timelines may help you to understand anomalies. For example, this timeline from a different anomaly repeatedly toggles from a brief **Warning** state to a longer **Critical** state:

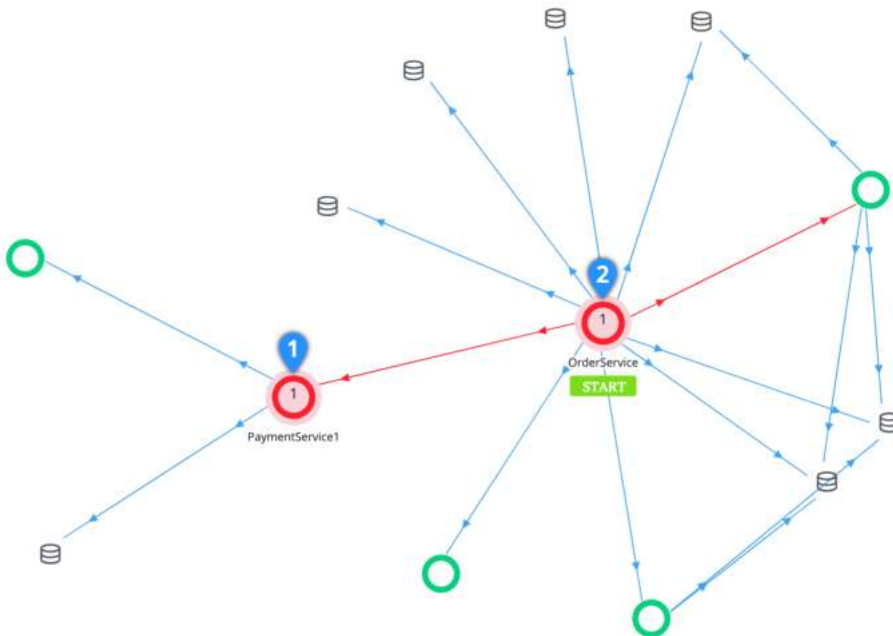

In this case, you should examine several state change events to determine what clues toggling between states offers about problems in your application.

Examine the Flow Map

The example flow map contains:

- The **START** label shows that the Business Transaction begins with the OrderService tier
- Between the OrderService tier and its numerous dependencies, two tiers are red—these are the tiers where the system has found Suspected Causes

You can now focus on determining which of the red tiers contains the root cause of the anomaly.

i Anomaly Detection flow maps are different

There are two types of flow maps in AppDynamics:

- Anomaly Detection and Automated RCA flow map (described on this page)
- Business Transaction flow map

Each of these flow maps detects deviating or unhealthy entities in its own way. Therefore, you will see some differences:

- The two flow maps may show a different health status (as represented by color) for the same entity because each one uses its own algorithm to determine health
- User preferences for positioning or hiding entities saved for the Business Transaction flow map have no effect on the Anomaly Detection flow map
- Some links between tiers might be shown in one type of flow map but hidden in the other
 - For example, when no data is flowing through a tier or between tiers:
 - Business Transaction flow map may hide them, as 'inactive' tiers or links
 - Anomaly Detection flow map may show them in order to represent the application topology completely

Examine the Top Suspected Causes

The Top Suspected Causes show likely root causes of a Business Transaction performance problem. In this case, we want to know why Checkout is responding slowly.

The first Suspected Cause is a Process CPU Burnt issue on the `eretail.prod.payment01_1` node of the `PaymentService1` tier:

1 PaymentService1

//r/Checkout is possibly affected by Process CPU Burnt (ms/min) issue on `eretail.prod.payment01_1` in PaymentService1

[More Details](#)

Hover over the Suspected Cause to highlight the relevant entities in the flow map. Everything but the critical path fades away, revealing that `OrderService`, where the Business Transaction starts, and which had a degraded response time, relies on `PaymentService1`:

//r/Checkout

ANOMALY

Critical (02/28/19 12:02:00 PM)

The following metric is deviating: Average Response Time (ms)

Top Suspected Causes (2)

1 PaymentService1

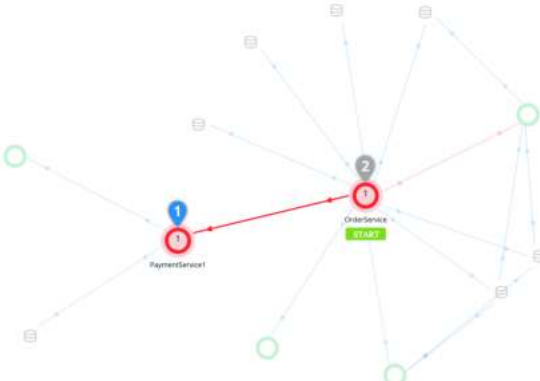

//r/Checkout is possibly affected by Process CPU Burnt (ms/min) issue on `eretail.prod.payment01_1` in PaymentService1

[More Details](#)

2 OrderService

//r/Checkout is possibly affected by calls to HTTP on `eretail.prod.order01` in OrderService

[More Details](#)

The second Suspected Cause is an HTTP call on `OrderService` itself.

2 OrderService

//r/Checkout is possibly affected by calls to HTTP on etail.prod.order01 in OrderService

[More Details](#)

Hover to highlight the affected entities:

//r/Checkout

ANOMALY

Critical (02/28/19 12:02:00 PM)

The following metric is deviating: Average Response Time (ms)

Top Suspected Causes (2)

1 PaymentService1

//r/Checkout is possibly affected by Process CPU Burnt (ms/min) issue on etail.prod.payment01_1 in PaymentService1

[More Details](#)

2 OrderService

//r/Checkout is possibly affected by calls to HTTP on etail.prod.order01 in OrderService

[More Details](#)

Which Suspected Cause is the root cause? Which is only a symptom of the overall problem?

- We have a plausible root cause in the Process CPU Burnt issue on PaymentService1 tier, which is ranked likeliest by the system.
- Meanwhile, the HTTP call on OrderService bears some analysis:
 - An HTTP call includes both a request and a response
 - We know that the tier on the other end, PaymentService1, has its own problem
 - Therefore, we can infer that the HTTP response from PaymentService1 is what makes the call slow

Now we see that both Suspected Causes originate with PaymentService1, and the HTTP call issue is really a side-effect of the Process CPU Burnt issue. The system's ranking makes sense.

As we continue to investigate, if we decide that the Process CPU Burn issue is not the root cause, we can reconsider the HTTP call.

i There can be anywhere from zero to three Top Suspected Causes. For example, if ART is high but every entity connected with ART is behaving normally, there are zero suspected causes because no suspected cause can be identified.

Drill Into a Suspected Cause

Click **More Details** for the Suspected Cause to review:

- Simplified timeline
- Metrics graphed over time

Two types of graphed metrics display:

- **Top Deviating Metrics** for the Business Transaction
- **Suspected Cause Metrics**

Examine Top Deviating Metrics for the Business Transaction

Deviating Business Transaction metrics can indicate why an anomaly was important enough to surface. (The system does not surface anomalies for every transitory or slight deviation in metrics. Such anomalies would be of dubious value, since their customer impact is minimal. For the same reason, anomalies are surfaced for Business Transactions which have a CPM of under 20.)

Each deviating metric is shown as a thin blue line (the metric's value) against a wide gray band (the metric's Expected Range).

You can:

- Scroll along the graph to compare a metric's value with its Expected Range at any time point
- Hover over a time point to view the metric's value and Expected Range in numerical form

i Hovering to view values in numerical form is essential when the Expected Range is so much smaller than the deviating metric values that the gray band “disappears” into the X axis.

In this example:

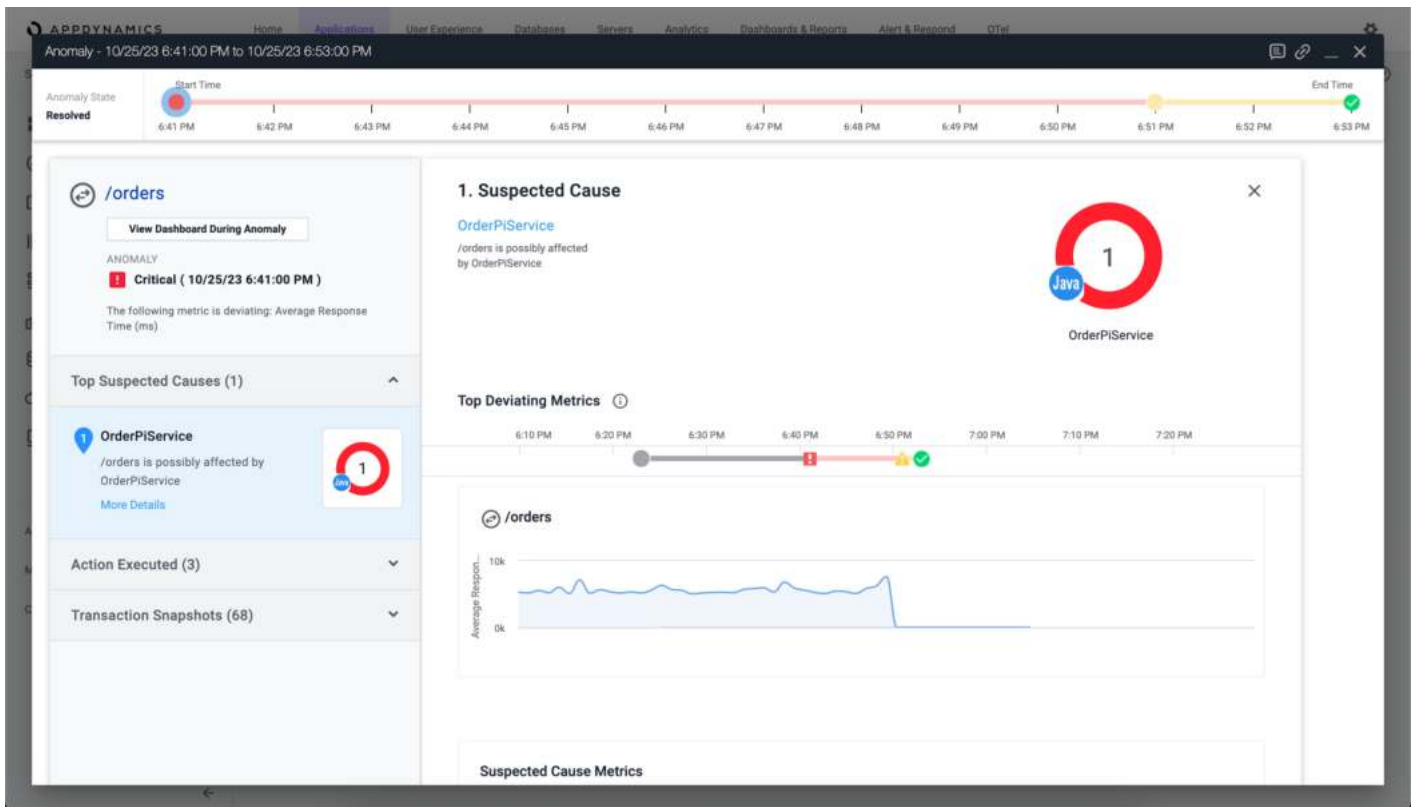

- The deviating metric spiked remained elevated for about 30 minutes, then subsided back into Expected Range
- Seven minutes after the metric returned to its Expected Range, the Severity Level changed from **Critical** to **Warning**, and eight minutes after that, to **Normal**

Hovering over time points tells us that for the period of deviation: the Average Response Time was around 1200 ms and above, while its Expected Range was from 370.08 to 721.24 ms

With a key metric elevated by this large amount, it made sense for the system to surface this anomaly.

i Because Top Deviating Metrics are at the Business Transaction level, they are the same for all Suspected Causes.

The **Top Deviating Metrics** timeline also displays the evaluation period of an anomaly in the grey color. The evaluation time period is the duration in which the data is analyzed to detect the anomaly. This timeline helps you to precisely identify the time when the issue started. The following image shows the evaluation period:

Examine Suspected Cause Metrics

You view, scroll through, and hover over Suspected Cause Metrics similar to Top Deviating Metrics.

i Top Deviating Metrics describe the Business Transaction, while Suspected Cause Metrics describe tiers or nodes further down in the entity tree. This means that if you have ART as a Top Deviating Metric and as a Suspected Cause Metric, *those are two different metrics*. Likewise, EPM as a Top Deviating Metric and as a Suspected Cause Metric are also two different metrics. While the Suspected Cause Metric likely contributes to the way the Top Deviating Metric behaves, the values of the two metrics will differ.

In this example,

- Suspected Cause Metrics are shown for the `eretail.prod.payment01_1` node within the `ProcessPayment1` tier
- That is the *only* node the tier has—if the tier had multiple nodes, metrics could be viewed separately for each node
- The pattern of elevation in the `Process CPU Burnt` and `Process CPU Used` metrics perfectly matches the pattern we saw in the Business Transaction metrics

The hypothesis is now confirmed:

1. CPU usage spiked on ProcessPayment1, a tier that is downstream from the tier where the Business Transaction starts
2. This slowed down response time on ProcessPayment1, including its HTTP response to the HTTP request from OrderService
3. The slow HTTP call, in turn, slowed response time on OrderService
4. Since OrderService is where the Checkout Business Transaction starts, Checkout has a slow response time anomaly
5. Since the Process CPU Burn issue on ProcessPayment1 is the Suspected Cause that's deepest in the entity tree, that is the root cause of the anomaly

Results

We used Anomaly Detection and Automated Root Cause Analysis to quickly find the root cause of a Business Transaction performance problem. What kind of time and effort did Anomaly Detection and Automated Root Cause Analysis save us in this case?

Recall that the tier where the Business Transaction started, OrderService, has multiple dependencies including other services and datastores. Anomaly Detection and Automated Root Cause Analysis eliminated (1) all but two tiers as origins of the slow response time on OrderService, and (2) all but the most relevant of the many metrics on those tiers.

You were spared the tedious process of investigating multiple metrics on each dependency in turn. Instead, you confirmed or negated Suspected Causes with a quick glance at timelines, flow maps, and metrics. Anomaly Detection and Automated Root Cause Analysis performed the vast majority of the work in root cause analysis, presenting you with the information you needed to quickly form and verify a hypothesis.

(Optional) Inspect Snapshots and Execute Actions

When you view an anomaly, you can inspect

- Business Transaction snapshots from the time period of the anomaly
- Actions executed as the result of policies you have configured for the Business Transaction

These are options of the standard troubleshooting flow. They are typically done as follow-up.

In this example:

- Suppose we want more context for the Process CPU Burnt issue on PaymentService1. We can view snapshots of transactions affected by that issue. Double-click a snapshot in the list to open it in its own pane, and if desired, drill down into details and call graphs.

Health Rules

Related pages:

- [Configure Health Rules](#)
- [Troubleshoot Health Rule Violations](#)
- [Policies](#)
- [Actions](#)

Health rules let you specify the parameters that represent what you consider normal or expected operations for your environment. The parameters rely on metric values, for example, the average response time for a business transaction or CPU utilization for a node.

When the performance of an entity affected by the health rule violates the rule's conditions, a health rule violation occurs. The health statuses are represented as critical, warning, normal, and unknown.

When the health status of an entity changes, a health rule violation event occurs. Examples of a health rule violation include:

- Starting
- Ending
- Upgrading from warning to critical or
- Downgrading from critical to warning

The health statuses of entities and health rule violations are surfaced in the controller user interface. A health rule violation event can also be used to trigger a policy, which can initiate automatic actions, such as, sending alerting emails or running remedial scripts.

You create health rules using the health rule wizard, described in [Configure Health Rules](#). The wizard groups commonly-used system entities and related metrics to simplify setting up health rules. You can also use the default health rules provided by AppDynamics as-is, or modify them.

Default Health Rules

AppDynamics provides a default set of health rules for some products, such as applications and servers. These default health rules vary depending on the entity. To see the default rules, before any health rules have been added to your AppDynamics installation:

1. From the Alert & Respond tab, click **Health Rules**.
2. Select the entity.
The default health rules for the selected entity are displayed.

If any of these predefined health rules are violated, the affected entities are marked in the UI as yellow-orange if it is a Warning violation and red if it is a Critical violation.

In many cases, the default health rules may be the only health rules that you need. You can edit and customize the health rules to suit your application. You can also disable the default health rules.

Health Rule Scopes

The health rule scope determines the set of default health rule types. You can choose the scope to get a set of default health rule types for applications, servers, or databases. For example, when you define a mobile application as the scope, the default health rules such as crash rates and HTTP/network error rates are displayed. Similarly, if you define the health rule scope for an application, the health rules would be for business transactions, CPU/memory utilization, and so on.

From **Alert & Respond > Health Rules**, you can select one of the following health rule scopes from the drop-down list:

- Applications
- User Experience: Browser Apps
- User Experience: Mobile Apps
- User Experience: API Monitoring
- Databases
- Servers
- Analytics

You can also create new health rules to add to the default set for each scope. You may want to add the health rule *app starts* to your mobile application. This health rule is not part of the default set of health rules in the mobile app scope, so you would just need to add a new health rule.

Health Rule Types

The health rule wizard groups health rules into types that are categorized by the entity that the health rule covers. This allows the wizard to display appropriate configuration items during the health rule creation.

The following table lists various health rule types.

Health Rule Type	Description
Transaction Performance	<ul style="list-style-type: none"> • Overall Application Performance: Groups metrics related to load, response time, slow calls, stalls, with applications. • Business Transaction Performance: Groups metrics related to load, response time, slow calls, stalls, so on, with business transactions.
Node Health	<ul style="list-style-type: none"> • Node Health-Hardware, JVM, CLR: Groups metrics like CPU and heap usage, disk I/O, so on, with nodes. • Node Health-Transaction Performance: Groups metric related to load, response time, slow calls, stalls, so on, with nodes. • Node Health-JMX: Java only, groups metrics related to connection pools, thread pools, so on, with specific JMX instances and objects in specific nodes and tiers.
User Experience-Browser Apps	<ul style="list-style-type: none"> • Pages: Groups metrics like DOM building time, JavaScript errors, so on, with the performance of application pages for the end-user. • IFrames: Groups metrics like first-byte time, requests per minute, so on, with the performance of iFrames for the end-user. • AJAX Requests: Groups metrics like Ajax callback execution time, errors per minute, so on, with the performance of Ajax requests for the end-user. • Virtual Pages: Groups metrics like End User Response Time, Digest Cycles, HTML Download Time, DOM Building Time, etc. for virtual pages created with Angular. See AngularJS Support for information on what these metrics mean in the context of virtual pages.
User Experience-Mobile Apps	<ul style="list-style-type: none"> • Mobile Apps: Groups metrics related to mobile app crashes, starts, and server calls as well as network requests and errors. • Network Requests: Groups metrics like HTTP and network errors, request time, and requests per minute with network requests.

Health Rule Type	Description
Servers	Groups metrics related to hardware resources.
Databases & Remote Services	Groups metrics related to response time, load, or errors with databases and other backends.
Advanced Network	Groups metrics related to Network Visibility, such as PIE (performance impact events), zero window, data retransmission, and errors.
Error Rates	Groups metrics related to exceptions, return codes, and other errors with applications or tiers.
Information Points	Groups metrics like response time, load, or errors with information points.
Service Endpoints	Java and .NET only; groups metrics like average response time, calls per minute, and errors per minute with service endpoints.
Custom	Presents all the metrics collected by the agent that could affect a single business transaction, a single node or overall application performance. Use this type to create rules that evaluate custom metrics .

When you select one of these health rule types, the wizard offers you the metrics commonly associated with that type in an embedded browser.

How to Set Up Health Rules?

AppDynamics recommends the following process to set up health rules for your application:

1. Identify the key metrics (performance indicators) on the key entities that you need to monitor.
2. Click **Alert & Respond > Health Rules** to examine any default health rules that are provided by AppDynamics.
 - Compare your list of metrics with the metrics configured for the default rules.
 - You can view the list of affected entities for each of the default health rules and modify them. See [Configure Affected Entities](#).
 - If the default health rules cover all the key metrics you need, determine if the pre-configured conditions are applicable to your environment. If required, [modify the conditions](#).

Define a [metric expression](#) to evaluate complex criteria for a condition.
Define a [boolean expression](#) to evaluate multiple health rule conditions.

3. If default health rules do not cover all your requirements or if you need finely-applied health rules to cover specific use cases, [create new health rules](#).
 - a. Identify the type of health rule that you want to create. See [Health Rule Types](#).
 - b. Decide which entities are affected by the new rule. See [Entities Affected by a Health Rule](#).
 - c. Define the conditions to monitor. See [Create and Configure Conditions](#).

4. If you want the health rules to be evaluated according to a pre-defined time schedule, create a health rule schedule. In some situations, a health rule is more useful if it is evaluated at a particular time. See [Health Rule Schedules](#).

After you set up health rules you must [configure](#) policies and actions to be executed when health rules are violated. See [Policies](#) and [Actions](#).

Additional Considerations

- Your application status is based on health rules for the current time range. If you disable old health rule policies or enable new ones, you might see errors in red in your application status, even if there are no current critical events based on the new policies. To verify that your new or disabled health rule policies have taken effect, change the time range in your dashboard to a smaller, more recent time frame.
- When you are configuring health rules for business transactions with baseline selected in the configured condition with a very fast average response time (ART) such as 25 ms, using standard deviation as a criterion can cause the health rule to be violated too frequently. The health rule may violate too frequently because a tiny increase in response time can represent multiple standard deviations. In this case, consider adding a second condition that sets a minimum ART as a threshold. For example, if you do not want to be notified unless ART is over 50 ms, you could set your threshold as ART > 2 Standard Deviations and ART > 50 ms.
- Similarly, when configuring health rules for calls-per-minute (CPM) metrics with baseline selected in the configured condition, the health rule may never be violated if the condition is using standard deviations, and the resulting value is below zero. In this case, consider adding a second condition that checks for a zero value, such as CPM < 2 Standard Deviations and CPM < 1.

Health Rule Schedules

Related Pages:

- [Health Rules](#)
- [Configure Health Rules](#)
- [Troubleshoot Health Rule Violations](#)
- [Policies](#)
- [Actions](#)

This page provides an overview of health rule schedules in AppDynamics.

The metrics associated with a health rule are evaluated according to a schedule that you control. You can configure:

- [when a health rule is in effect](#)
- [which data set should be used, based on time](#)
- [what special rules should be in place during a violation event](#)

Time evaluation for health rule schedules is based on the time zone you specify, regardless of the time zone of the Controller.

i For schedules created in AppDynamics controller version 4.5.15 or earlier, all schedules are executed based on the controller time zone. For schedules created in version 4.5.16 or later, schedules are executed based on the time zone you specify, irrespective of the controller time zone.

Health Rule Enabled Schedule

By default, health rules are always enabled. You can define schedules for evaluation of the health rules.

Built-in schedules exist for:

- End of business hours

- Weekday lunch
- Weekday mornings
- Weekdays
- Weekends
- Weeknights

You can also configure custom health rule schedules. The custom schedule allows you to define a time zone specific to your application, independent of the controller time zone. This eliminates the need to adjust the time zone manually if your application is in a separate time zone than that of the controller. For more details, see [Create and Manage Health Rule Schedules](#).

Health Rule Evaluation Time Frame

The health rule evaluation time frame is the period of time over which the data used to evaluate the health rule is collected.

Different kinds of metrics provide better results using different sets of data. You can manage how much data AppDynamics uses when it evaluates a particular health rule by setting the data collection time period. You can define an evaluation time frame between 1 minute to 120 minutes, which act as rolling time frame. The default value is 30 minutes. You can select the following values in the **Use data from last** drop-down:

1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100, 110, 120

 You can define a [persistence threshold](#) for a condition only if you have defined the evaluation time frame of 30 mins or less.

Health Rule Wait Time After Violation

The health rule wait time setting lets you control how often an event is generated while the conditions found to violate a health rule continue. If the controller determines that a health rule has been violated, with a status of either Critical or Warning, an Open Critical or Open Warning event is generated. This event is used to trigger any policies that match the health rule and initiate any actions that the policies require.

Once an Open event has occurred, the controller continues to evaluate the status of the health rule every minute. If the controller continues to detect the same violation, the violation remains open with the same status. A corresponding **Continues Critical** or **Continues Warning** event may be generated to link to any related policy.

A **Continues** event every minute might be too noisy for your health rule. The health rule's **Wait Time after Violation** setting is used to throttle how often these Continues events are generated for continuing health rule violations. The default is every 30 minutes.

To use Continues Critical and Continues Warning events, adjust the default **Wait Time after Violation** value to the desired frequency. Then configure a policy matching the health rule with the *Health Rule Violation Continues - Warning and/or Health Rule Violation Continues - Critical* events selected in the **Health Rule Violation Events** section of the policy settings.

 The violations displayed in the **Health Rules Violations** page, under **Troubleshoot**, are updated only when a health rule violation event is triggered.

If the Controller is unable to evaluate the rule—for example, if a node stops reporting—the Evaluation Status of the health rule is marked as a grey question mark or Unknown in the **Current Evaluation Status** tab in the right panel of the health rules list. The current violation event remains open until the Wait Time after Violation period has elapsed, at which point the violation event is closed and a new event is triggered, causing the Health status itself of the rule to display as *Unknown*.

The screenshot shows the 'Health Rules' page for 'ECommerce-Sales-Demo'. The 'Current Evaluation Status' tab is active, displaying a table of health rules. The table has columns for Tier, Policy Executed On, Health, Evaluation Status, and Status By Node. Several rules are listed, including 'Business Transaction error rate is much higher than normal', 'Business Transaction response time is much higher than normal', 'CLR Garbage Collection Time is too high', 'CPU utilization is too high', 'JVM Garbage Collection Time is too high', 'JVM Heap utilization is too high', 'Memory utilization is too high', and 'Network-Host: Packet drops too high'. The 'Evaluation Status' column for several rules shows a question mark, indicating that the controller is unable to evaluate the rule. An orange callout box points to one of these question marks with the text 'The Controller is unable to evaluate the rule'.

Health Rule Entities

Related Pages:

- [Health Rules](#)
- [Configure Health Rules](#)
- [Troubleshoot Health Rule Violations](#)
- [Policies](#)
- [Actions](#)

This page provides an overview of health rule entities in AppDynamics.

A health rule can evaluate metrics associated with an entire application or a limited set of entities. For example, you can create business transaction performance health rules that evaluate certain metrics for all Business Transactions in the application or node health rules that cover all the nodes in the application or all the nodes in specified tiers. The default health rules are in this category.

You can also create health rules that are applied to a limited set of entities in the application, or even a single entity such as a node or a JMX object or an error. For example, you can create a JMX health rule that evaluates the initial pool size and number of active connections for specific connection pools in nodes that share certain system properties.

Monitoring Serverless Entities

Serverless functions are tracked at the tier level. A serverless function is indicated by a lambda (λ) icon inside each tier. When you configure a health rule for an application comprising serverless entities, you can choose to monitor the serverless tiers in the **Affected Entities** tab. For information on how various health rules are evaluated for serverless entities comprising tiers for AWS Lambda, see [Evaluating Serverless Tiers](#).

The health rule wizard lets you specify which entities the health rule affects, enabling the creation of very specific health rules. For example, for a Business Transaction, you can limit the tiers that the health rule applies to, or limit the health rule application to specific business transactions by name or by names that match certain criteria.

Node Name Node Properties / Variables

Nodes with the following Meta-Info Properties ⓘ

Nodes with the following Environment Variables ⓘ

Nodes with the following JVM System Environment Properties (java nodes only) ⓘ

i The **Type of Node** pulldown menu does not allow you to specify Node.js, Python, or Web Service nodes. To restrict a health rule to these types of nodes, you can specify the affected entity as a tier and then select only Node.js or Python or Web Service tiers as needed. Or to more finely-tune the affected nodes, use the **Nodes matching the following criteria** menu item to specify node names or matching environment variables or meta-info to restrict the health rule to the nodes you want.

Entities Affected by a Health Rule

For an **Overall Application Performance Health Rule** type, the health rule applies to the entire application, regardless of the business transaction, tier, or node.

If you configure your Health Rule to work with tiers, you must also configure the parallel policy to work with tiers. However, if you configure your Health Rule to work with tiers, but your policy is configured with nodes first, you will not trigger any actions or notifications. The inverse is also true. The following screenshots show examples of a health rule and a policy created in the correct order.

Health Rule Conditions

Related Pages:

- [Health Rules](#)
- [Configure Health Rules](#)

- [Troubleshoot Health Rule Violations](#)
- [Policies](#)
- [Actions](#)

You define the acceptable range for a metric by establishing health rule conditions. A health rule condition sets the metric levels that constitute a **Warning** status or a **Critical** status.

A condition consists of a Boolean statement that compares the current value of a metric against one or more static or dynamic thresholds based on a selected baseline. If the condition is true, the health rule violates. The rules for evaluating a condition using multiple thresholds depend on configuration.

Static thresholds are straightforward. For example, is a business transaction's average response time greater than 200 ms? The condition is evaluated to 'true' if the average response time is greater than 200 ms and the health rule violates.

Dynamic thresholds are based on a percentage in relation to, or a standard deviation from, a baseline built on a rolled-up baseline trend pattern. A daily trend baseline **rolls up** values for a particular hour of the day during the last thirty days, whereas a weekly trend baseline **rolls up** values for a particular hour of the day, for a particular day of the week, for the last 90 days. For more information about baselines, see [Dynamic Baselines](#).

You can define a threshold for a health rule based on a single metric value or on a mathematical expression built from multiple metric values.

The following are typical health rule conditions:

- If the value of the Average Response Time is greater than the default baseline by 3 X the Baseline Standard Deviation . . .
- If the count of the Errors Per Minute is greater than 1000 . . .
- If the number of MB of Free Memory is less than 2 X the Default Baseline . . .
- If the value of **Errors per Minute/Calls per Minute** over the last 15 days > 0.2 . . .
This example combines two metrics in a single condition. You can use the [expression builder](#) embedded in the health rules wizard to create conditions based on a complex expression comprising multiple interdependent metrics.
- If the (average response time > baseline OR errors per minute > baseline) **AND** (calls per minute > the defined threshold) . . .
This example uses multiple conditions to evaluate the health rules. You can use the 'CUSTOM' option to define a boolean expression to evaluate the conditions.

Critical and Warning Conditions

Conditions are classified as either critical or warning conditions.

Critical conditions are evaluated before warning conditions. If you have defined a critical condition and a warning condition in the same health rule, the warning condition is evaluated only if the critical condition is not true.

The screenshot shows the 'Create Health Rule' window with tabs for Overview, Affected Entities, Critical Criteria, and Warning Criteria. Under 'Critical Criteria', there are two conditions defined:

- Condition 1:** Single Metric: Average Response Time (ms). Trend: Within Baseline (Weekly Trend - Last 3 months). Deviation: by 4. Evaluation: Baseline Standard Deviation(s).
- Condition 2:** Single Metric: Calls per Minute. Trend: > Specific Value. Value: 1000.

The configuration procedures for critical and warning conditions are identical, but you configure these two types of conditions in separate panels. You can copy a critical condition configuration to a warning configuration and vice-versa and then adjust the metrics in the copy to differentiate them. For example, in the **Critical Condition** panel you can create a critical condition based on the rule:

- If the Average Response Time is greater than 1000

Then from the Warning Condition panel, copy that condition and edit it to be:

- If the Average Response Time is greater than 500

As performance changes, a health rule violation can be upgraded from warning to critical if performance deteriorates to the higher threshold or downgraded from critical to warning if performance improves to the warning threshold.

Health Rule Violation Event

When metric levels exceed the acceptable range, conditions violate, a health rule violation event occurs. The details of the violation event are displayed on the Health Rule Violation window. This window displays the following details:

- Number of violation events
- Summary of each violation event
- Details of actions initiated in response to the violation event
- Timeline of each violation event

i When you define a trigger for the condition, the health rule violation event summary does not display any metric value as there is no single value. However, when you do not define any trigger for the condition, the health rule violation event summary displays the metric value.

Evaluation Criteria

When you define multiple conditions for a health rule, they are evaluated based on the criteria you define. You can use the following options to define the evaluation criteria:

- All: the health rule violates if all the conditions defined in the criteria evaluate to 'true'.
- Any: the health rule violates if one of the conditions defined in the criteria evaluates to 'true'.
- Custom: the health rule violates if the boolean expression with multiple conditions evaluates to 'true'.

Create Health Rule

Overview

Affected Entities

Critical Criteria

Warning Criteria

+ Add Condition

If All of the following conditions are met:

All
Any
Custom

Condition 1

Single Metric

is

Within Baseline

Evaluate to true on no data

For information on how to configure evaluation criteria, see [Configure Health Rule Evaluation Criteria](#).

The following table uses examples to illustrate how a health rule is evaluated based on the criteria and when it is considered to violate.

Health Rule Configuration	Evaluation	Example
Single condition	the condition evaluates to 'true'	A health rule that compares 'average response time' with a defined baseline.
Multiple conditions with 'ANY' evaluation criteria	one of the health rule conditions evaluates to 'true'	A health rule that monitors the health of business transaction may measure any of the following performance metrics: <ul style="list-style-type: none"> average response time or errors per min

Health Rule Configuration	Evaluation	Example
<p>Multiple conditions with 'ALL' evaluation criteria</p>	<p>all of the health rule conditions evaluate to 'true'</p>	<p>A health rule that monitors the health of business transaction measures all of the following metrics:</p> <ul style="list-style-type: none"> • response time • average response time greater than a baseline value, correlated with the application load <p>For example, 50 concurrent users on the system. A policy is defined such that a remedial action is initiated only if the load (calls per minute) is high although the response time threshold is reached.</p> <p>The first part of the condition evaluates the response time and the second part ensures that the health rule is violated only when there is sufficient load.</p>
<p>Multiple conditions with 'CUSTOM' evaluation criteria</p>	<p>the boolean expression with multiple conditions evaluates to 'true'</p> <div data-bbox="495 1150 995 1373" style="border: 1px solid #0070C0; background-color: #E6F2FF; padding: 5px; margin: 10px 0;"> <p> The condition is evaluated only if a valid combination of conditions using AND and OR operators is entered, else the evaluation fails.</p> </div> <p>To ensure that alerts are triggered quickly before there is any significant business impact, the health rules do not evaluate all the conditions in a boolean expression. The health rule starts evaluating the first condition and continues to evaluate the following conditions until it can deterministically mark the expression as true or false. As soon as the evaluation determines the expression to violate, an alert is triggered.</p>	<p>A health rule that monitors the health of a Business Transaction, measures the performance based on the following conditions:</p> <ul style="list-style-type: none"> • (average response time greater than baseline OR errors per min greater than baseline) <p>AND</p> <ul style="list-style-type: none"> • (calls per min greater than threshold)

Persistence Thresholds

Temporary spikes in metric performance data is a major cause of false alerts. Persistence thresholds allow you to define a sensitivity level for a health rule and thereby reduce the number of false alerts. You can define the number of times metric performance data should exceed the defined threshold during the evaluation time frame to constitute a violation and subsequently trigger an alert.

i You can define a persistence threshold for a condition only if you have defined an **evaluation time frame** of 30 minutes or less.

For example, when monitoring the CPU utilization, you would not want to be reported of a single violation (section A in the figure below) of the threshold. However, if the violation of threshold continues to occur multiple times (section B in the figure) during the evaluation time period, you would want to be alerted.

Alert Sensitivity Tuning

! Alert Sensitivity Tuning (AST) feature is enabled only if you create a health rule to monitor a business transaction, a service endpoint, or a remote service.

Deployment Support

It is important that you configure conditions appropriately to ensure that you do not miss any alerts or receive false alerts instead. With AST, you can view historical data for metrics and baselines when you configure conditions. This data helps visualize the impact of the configuration you define and assists in fine-tuning the configuration.

You can view a graphical representation of the metric data, threshold value, standard deviation, and baseline. The graphical view is instantly updated when you update any configuration. You can also view granular details by modifying the graphical view. To view granular details, you can:

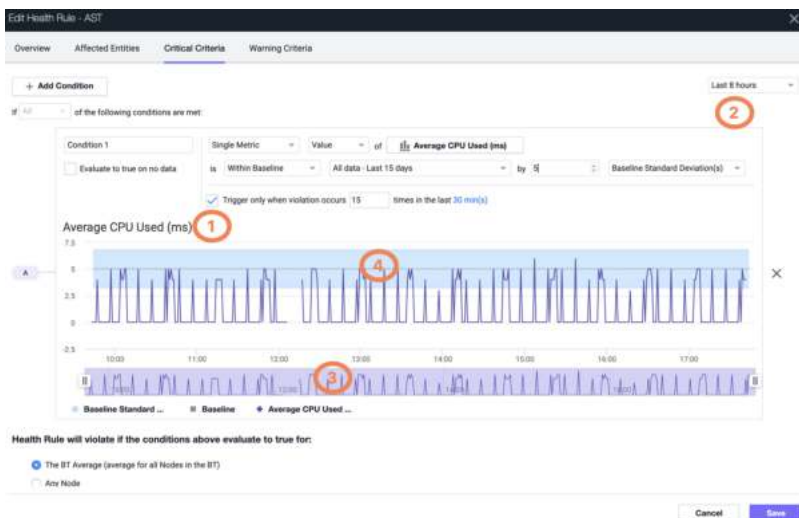

- increase the time period of the data capture to 1 day or 3 days.

i If data is not available for the selected time period, only available data is presented.

- adjust the time range in the graph to view the metric data details.
- hover over the metric data to view metric and baseline values at any given time.

You can analyze the data presented and then make adjustments to your configuration accordingly. For more information on fine-tuning a condition, see [Create a BT Health Rule and Fine-tune Metric Evaluation](#).

For example, if you select **Average CPU Used (ms)** (1) as a metric to be monitored for a health rule condition, you can view the past metric data for a time period of 8 hours (2). The graphical representation of the metric data indicates the baseline (3) and the baseline standard deviation (4). Based on this data, you can fine-tune the evaluation of the condition. This helps avoid false alerts and receive the alerts only when the health rule violates the conditions you define.

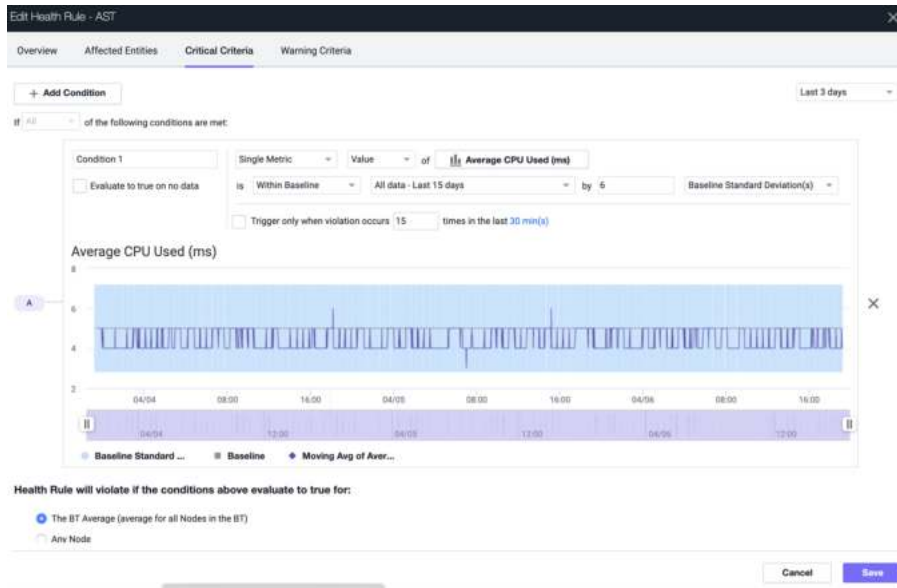

Moving Average

If you define a persistence threshold to evaluate a condition, the metric data for every minute is compared to the baseline and plotted on the AST graph. However, if you do not define the persistence threshold, a 'moving average' for the selected metric is plotted as follows:

1. Depending on the **Use data from last X**, the metric data for X minutes is considered.
2. On the **X+1**th minute, the average of the past X minutes is computed and denoted as the first point on the graph.
3. Similarly, the average for the following X minutes is computed and points are denoted on the graph for the rest of the time range.

Why Use Moving Average?

Unless persistence thresholds are used, health rules compare the moving average of a metric to a threshold or a baseline. Thus, representing the moving average in the graph is appropriate. For more information, see [Create a Health Rule and Fine-tune Metric Evaluation](#).

How are Conditions Evaluated if No Data is Reported?

The Evaluate to true on no data option controls the evaluation of the condition in cases where any metric on which the condition is based, does not return any data. The condition evaluates to 'unknown' (default) when no data is returned. If the health rule is based on all the conditions evaluating to true, having no data returned may affect whether the health rule triggers an action.

When you define a health rule evaluation time frame, reference data is collected for each data point. If the configured metric fails to report data during the time frame, the health rule condition is evaluated as follows:

Evaluate to true on no data	Trigger only when violation occurs x times in the last y min(s)	Condition Evaluation
Enabled	Enabled	<p>The condition is evaluated for each data point in the evaluation time frame. The condition evaluates to 'true' when metric fails to report any data for a given data point.</p> <p>For example, when you set the persistence threshold, X = 3 for an evaluation time frame, Y = 5. This means that 5 data points are required to evaluate the condition. Data is reported for 4 data points, no data is reported for 1 data point and the metric exceeds the threshold twice. The condition evaluates to 'true' for the minute when no data is reported.</p>

Evaluate to true on no data	Trigger only when violation occurs x times in the last y min(s)	Condition Evaluation
Enabled	Disabled	The condition evaluates as 'true' if a metric fails to report data for any data point during the evaluation time frame.
Disabled	Disabled	The condition does not evaluate to 'true' if the configured metric fails to report data for any data point during the evaluation time frame.

 Ensure that you disable **Evaluate to true on no data** for availability metrics.

Custom Boolean Expression

A condition consists of single or multiple statements that evaluate different metrics. You can define a single condition or multiple conditions to evaluate the performance metrics of your application. When you define multiple conditions, you may want to define an evaluation criteria using a boolean expression.

Advantages of using a boolean expression are:

- eliminates the need to create multiple health rules to monitor various performance metrics. Using a boolean expression allows you to evaluate complex criteria for multiple conditions in one go.
- well-calibrated boolean expression ensures reduced false alerts.
- easy to create and maintain health rules with complex evaluation criteria using simple condition names. Conditions are named as **A, B, C** and so on.
- allows the use of **AND** and **OR** operators to define a highly complex boolean expression. You can use a maximum of 8 operators in your boolean expression.

Evaluation Scope

The health rule evaluation scope defines how many nodes in the affected entities must violate the condition before the health rule is considered violated.

Evaluation scope applies only to business transaction performance type health rules and node health type health rules in which the affected entities are defined at the tier level.

For example, you may have a critical condition in which the condition is unacceptable for any node, or you may want to consider the condition a violation only if the condition is true for 50% or more of the nodes in a tier.

Options for this evaluation scope are:

- The tier average: Evaluation is performed on the tier average instead of the individual nodes.
- Any node: If any node exceeds the thresholds, the rule is violated.
- Percentage of the nodes: If x% of the nodes exceed the thresholds, the rule is violated.
- Number of nodes: If x nodes exceed the thresholds, the rule is violated.

Health Rule Management

Related Pages:

- [Health Rules](#)
- [Configure Health Rules](#)
- [Troubleshoot Health Rule Violations](#)
- [Policies](#)
- [Actions](#)

This page provides an overview of health rule management in AppDynamics.

To view current health rules, including the default health rules, and to access the health rule wizard, click **Alert & Respond > Health Rules**. Then choose the type of entity for which you want health rules from the pulldown menu at the top.

Current health rules are listed in the left panel. If you click one of these rules, a list appears in the right panel showing which entities this selected health rule affects and what the status of the latest evaluation is. You can also select the **Evaluation Events** tab to see a detailed list of evaluation events.

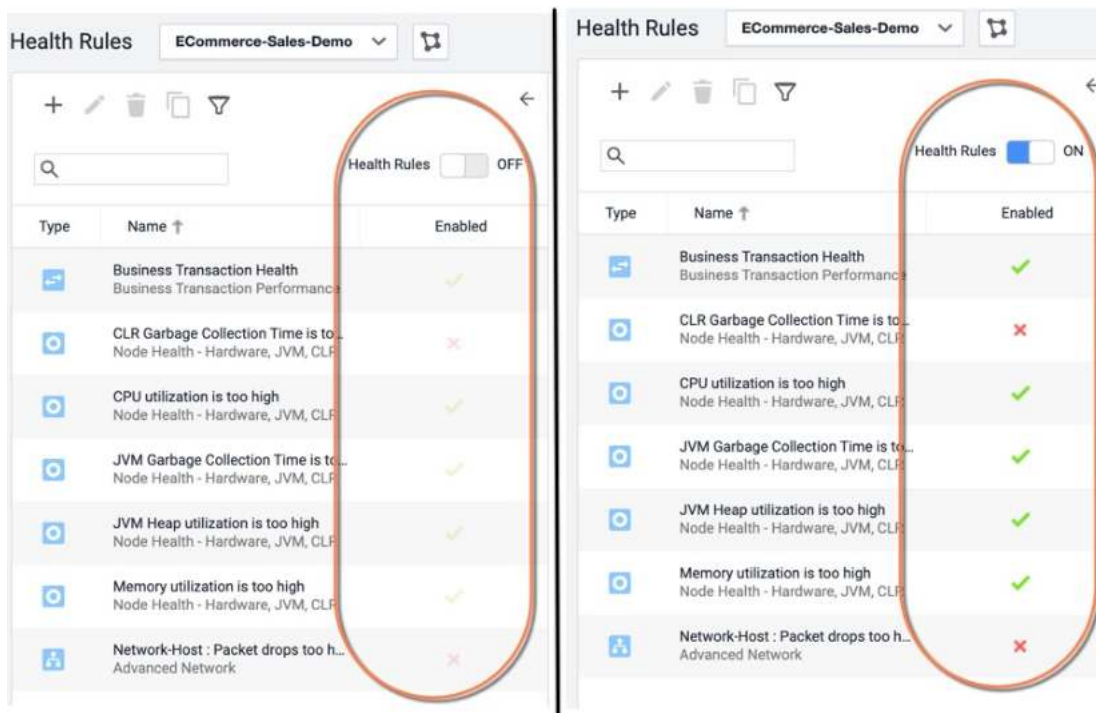

In the left panel, you can directly delete or duplicate a health rule. From here you can also access the health rule wizard to add a new rule or edit an existing one.

You can turn off the evaluation of all health rules in the selected entity by clearing the **Evaluate Health Rules** checkbox. Check it when you want health rule evaluation to start again.

See [Configure Health Rules](#) for details on using the health rule wizard.

Disable All Health Rules

You can disable the evaluation of all the health rules for a selected entity by setting the **Health Rules** toggle **OFF**. The **Health Rules** UI indicates the status of all the health rules.

To resume the health rule evaluation, set the toggle **ON**.

- You can disable the evaluation of an individual health rule in the **Create Health Rule** or **Edit Health Rule** dialog box by clearing the **Enabled** checkbox.
- When you disable the evaluation of all health rules, individual health rules are not evaluated even if you select the **Enabled** checkbox in the **Create Health Rule** or **Edit Health Rule** dialog box.

See [Configure Health Rules](#) for details on using the health rule wizard.

View Health Rule Status

Across the UI, health rule status is color-coded:

- Green is healthy
- Yellow/orange is a warning condition
- Red is a critical condition
- Grey indicates that the status of the health rule is unknown (for example, if the Controller cannot gather the data necessary to evaluate the rule)

If you see a health rule violation reported in the Controller UI, you can click it to get more information about the violation.

The status of a health rule changes depending on the health of the entities being monitored. If you update the evaluating condition of a health rule that was previously in an unknown state (Grey color), the following changes occur:

- If a metric is used for the first time in the evaluating condition of a health rule, the status change takes some time based on the **Use data from last \leftrightarrow min(s)** option.
- If a metric is already used in the evaluating condition of a health rule, the status change happens immediately when the warning or the critical condition is met.

Here are the health summary bars on the built-in dashboards:

Business Transaction Health

0 critical, 0 warning, 46 normal

Node Health

7 critical, 0 warning, 1 normal

Servers

0 critical, 7 warning, 0 normal

A health column is displayed in various lists, such as the tier list below:

Name	# of Nodes	Health
▶  Address-Services	1	
▶  Customer-Survey-Servi...	1	
▶  ECommerce-Services	2	
▶  Inventory-Services	1	
▶  Order-Processing-Servi...	1	
▶  Web-Tier-Services	1	

In the dashboards, health rule violations are displayed in the Events panel.

Events		
Health Rule Violations Started	19	
Node Health	19	
Application Changes	7	

Configure Health Rules

Related pages:

- [Health Rules](#)
- [Configuration Import and Export API](#)
- [Metric Browser](#)

This topic describes the detailed steps for configuring health rules using the health rule wizard. For more information on these settings, see [Health Rules](#).

Permissions

To create, edit, or delete health rules, you need the Configure Health Rules permission. For more information, refer to [Application Permissions](#).

Structure of the Health Rule Wizard

The health rule wizard contains four panels:

- **Overview:** Sets the health rule name, enabled status, the health rule schedule, evaluation period of the health rule data, and wait time post violation.
- **Affected Entities:** Sets the entities evaluated by the health rule. The options presented vary according to the health rule type you have defined.
- **Critical Criteria:** Sets the conditions, whether all or any of the conditions need to be true for a health rule violation to exist, and the evaluation scope—business transaction and node health policies defined at the tier level only—it also includes an expression builder to create complex expressions containing multiple metrics.

- Warning Criteria: Settings are identical to Critical Criteria, but configured separately.

You can navigate among these panels using the Back and Next buttons at the bottom of each panel or by clicking the panels in the wizard. You should configure the panels consecutively because the configuration of the health rule type determines the available affected entities in the Affected Entities panel as well as the available metrics in the Criteria panels.

i Important

You must configure the panels consecutively because the configuration of the health rule type determines the available affected entities in the **Affected Entities** panel as well as the available metrics in the **Criteria** panels.

Create and Configure a Health Rule

The following table outlines the steps required to create and configure a health rule:

1	Create a health rule.
2	Configure affected entities.
3	Configure health rule evaluation criteria.
4	Create and configure Conditions.

Create a Health Rule

Related Pages:

- [Health Rules](#)
- [Configuration Import and Export API](#)
- [Metric Browser](#)

You can use the default health rules provided by AppDynamic, modify them to map to your requirements, or define a custom health rule.

Access the Health Rule Wizard

1. Click **Alert & Respond** in the menu bar.
2. Click **Health Rules** either in the right panel or the left navigation pane.
3. Select the context for the health rule from the pulldown menu.
4. Do one of the following:
 - To create a new health rule, click the **+** icon.
 - To edit an existing health rule, select the health rule and click the **Edit** (pencil) icon.
 - To remove an existing health rule, select the health rule and click the **Delete** icon.

Configure Health Rule Details

You configure health rule details in the **Overview** panel.

1. Enter a name. If a name already exists, you can change it.
2. Check **Enabled** to enable the rule, clear the checkbox to disable it.
3. The Always option is pre-selected in the **When is the rule enabled?** drop-down list. If the health rule is enabled only at certain times, select other predefined schedules from the **When is the rule enabled?** drop-down list.

 To define a custom health rule schedule or modify the predefined time intervals, click **Manage Health Rule Schedules**. See [Create and Manage Health Rule Schedules](#).

4. Click the drop-down list **Use data from last \leftrightarrow min(s)** and select a number between 1 and 120 minutes. The value you specify is the latest time interval during which data is collected to determine if there is a health rule violation. This value applies to both critical and warning criteria. See [Health Rule Evaluation Time Frame](#).

 If you have defined a persistence threshold for the health rule condition, ensure that you define an evaluation time frame of 30 mins or less.

5. In the **Wait Time after Violation** field, enter the number of minutes to wait before re-evaluating the rule for the same affected entity in which the violation occurred. See [Health Rule Wait Time After Violation](#).

After you configure the Health Rule details in the **Overview** panel, proceed with the following steps.

1. Configure the entities affected for the health rule, see [Configure Affected Entities](#).
2. Define the evaluation criteria for the health rule, see [Configure Health Rule Evaluation Criteria](#).
3. Save your configuration.

Create and Manage Health Rule Schedules

1. In the Overview panel of the Create Health Rule wizard, click **Manage Health Rule Schedules**. The **Manage Health Rule Schedules** window lists all the predefined time intervals.
2. Select a predefined schedule in the **Manage Health Rule Schedules** window and click the **Edit** icon to see the details of the predefined schedule.
3. To edit a predefined schedule for health rule evaluation:
 - a. In the **Edit Schedule** window, make necessary changes.
 - b. Click **Save**.

 Schedules created in version 4.5.15 or earlier are set to 'Custom' type by default and the time zone is automatically set to the controller time zone.

4. To create a new health rule schedule:
 - a. Click the **+** icon. The **Create New Schedule** window appears.
 - b. Enter following details:
 - i. a name for the schedule.
 - ii. an optional description of the schedule.
 - c. If you want to evaluate the health rule only once,
 - i. Select **One Time**.
 - ii. Enter the **Start Date** and **Start Time**.
 - iii. Enter the **End Date** and **End Time** for the schedule.

- d. If you want to define a recurring schedule to evaluate the health rules,
- Select how often you want to evaluate the health rules:

Occurrence	Additional steps
Daily	<ol style="list-style-type: none"> Enter the Start Time and End Time.
Weekly	<ol style="list-style-type: none"> Select a specific day to execute the schedule. Enter the Start Time and End Time.
Monthly	<p>If you select a specific date of the month to execute the schedule:</p> <ol style="list-style-type: none"> Enter the Start Date and Start Time. Enter the End Date and End Time. <p>For example, you might want to evaluate the health rules on the 1st of every month from 6.00 AM to the 5th until 6.00 PM.</p> <p>If you select a specific day of the month to execute the schedule:</p> <ol style="list-style-type: none"> Select an occurrence and the Day. Enter the Start Time and End Time. <p>For example, you might want to evaluate the health rules on the first Monday of every month from 6.00 AM to 6.00 PM.</p>
Custom	<ol style="list-style-type: none"> Enter a Start Date and Start Time for the schedule as a cron expression. Enter an End Date and End Time for the schedule as a cron expression. <p>For example, the following custom schedule specifies:</p> <p>a start time value of <code>0 0 13 ? * 2-6</code> and</p> <p>end time of <code>0 0 15 ? * 2-6</code></p> <p>directing the health rule to be evaluated from 1 pm to 3 pm, Monday through Friday:</p>

e. Select a Time Zone applicable to your application.

5. Save your configuration.

Delete Health Rule Schedule

To delete a health rule evaluation schedule, select the schedule in the **Manage Health Rule Schedules** window and click **Delete** – the bin icon at the top. Click **OK** to confirm the deletion.

Create a Health Rule and Fine-tune Metric Evaluation

To ensure that you do not miss alerts or receive false alerts, you must configure alerts appropriately. Alert Sensitivity Tuning (AST) helps configure alerts with appropriate sensitivity by providing historical data for the metric or the baseline being configured. AST also visualizes the impact of the alert configuration.

Create a Health Rule and Fine-tune Metric Evaluation

You can create a health rule to monitor the parameters of an application entity and fine-tune the sensitivity of a health rule using Alert Sensitivity Tuning (AST).

- You must be a SaaS customer.
- You must be monitoring a business transaction, a service endpoint, or a remote service (affected entity).

1. In the entity (BT, SEP, or remote services) UI, select an entity from the list.
2. Right-click the entity and click **Create new Health Rule**. The **Create Health Rule** UI is displayed.
3. Configure the health rule overview details. For more information, see [Configure Health Rule Details](#).

4. In the **Affected Entities** panel, select the entities to be monitored.
5. In the **Critical Criteria** panel, select **+Add Condition**.
6. [Configure the health rule condition](#).
7. If required, select the **Warning Criteria** panel and define warning conditions as described in step 6.
8. Click **Save**. The health rule is saved.

Configure the Health Rule Condition

1. Enter a name for the condition in the first field of the condition row.
This name is used in the generated notification text and in the AppDynamics console to identify the violation.
2. From the drop-down list next to the condition name field, select the single metric or metric expression to evaluate the condition.
 - a. Single Metric:

Qualifier Type	Description
Minimum	The minimum value reported across the configured evaluation time length. Not all metrics have this type.
Maximum	The maximum value reported across the configured evaluation time length. Not all metrics have this type.
Value	<p>The arithmetic average of all metric values reported across the configured evaluation time length. This value is based on the type of metric.</p> <div style="border: 1px solid #add8e6; padding: 5px; margin-top: 10px;"> <p>i If you select the time rollup as SUM for custom metrics, the Value is the arithmetic sum of all metric values reported across the configured evaluation time length.</p> </div>
Sum	The sum of all the metric values reported across the configured evaluation time length.
Count	The number of times the metric value has been measured across the configured evaluation time length.
Group Count	The number of nodes contributing to a metric value, generally relevant for application or tier level metrics.
Current	The value for the current minute.

- i. From the **Value** drop-down list, select a qualifier for the metric from the following options:

- ii. Click **Select a Metric**. **Metric Selection** dialog box appears. The metric browser in the **Metric Selection** dialog box displays metrics appropriate to the health rule.
- iii. Select a metric from the list for the business transaction. Click **Select Metric**. A graphical view of the metric data for the last 8 hours appears.

i If you want to view the metric data for 1 day or 3 days, you can select the time period using the drop-down list.

- iv. From the drop-down list after the metric, select the type of comparison to evaluate the metric.
 - To limit the effect of the health rule to conditions during which the metric is within a defined range—standard deviations or percentages—from the baseline, select **Within Baseline** from the drop-down list. To limit the effect of the health rule to when the metric is not within that defined range, select **Not Within Baseline**. Then select the following:
 - baseline to use
 - numeric qualifier of the unit of evaluation
 - unit of evaluation
 For example:

Within Baseline of the Default Baseline by 3 Baseline Standard Deviations

- To compare the metric with a static literal value, select **< Specific value** or **> Specific Value** from the menu, then enter the specific value in the text field. For example:

Value of Errors per Minute > 100

- To compare the metric with a baseline, select **< Baseline** or **> Baseline** from the drop-down list, and then select the following:
 - baseline to use
 - numeric qualifier of the unit of evaluation
 - unit of evaluation.

You can use the Baseline Standard Deviation or Baseline Percentage as the unit of evaluation. For example:

Maximum of Average Response Time is > Baseline of the Daily Trend by 3 Baseline Standard Deviations

See [Dynamic Baselines](#) for information about the baseline options.

i **Baseline Percentages**

The *baseline percentage* is the percentage above or below the established baseline at which the condition will trigger. For example, if you have a baseline value of 850 and you have defined a baseline percentage of > 1%, the condition is true if the value is > $[850 + (850 \times 0.01)]$ or 859.

To prevent health rule violations from being triggered when the sample sets are too small, these rules are not evaluated if the load—the number of times the value has been measured—is less than 1000. For example, if a very brief time slice is specified, the rule may not violate even if the conditions are met, because the load is not large enough.

Depending on the baseline configuration you define, a graphical view of the metric data for the given baseline configuration is displayed. The graphical view is instantly updated when you update any configuration. You can also view granular details by zooming in on the graphical view. The metric data presented in the graph helps you calibrate the sensitivity of the metric evaluation.

b. Metric Expression:

- i. Select the **Metric Expression** option from the drop-down list and click **Add Expression**.
The **Metric Expression** window appears that allows you to construct a mathematical expression to use as a metric. For example, the following expression is created to measure the number of calls per CPU: Value of {calls} / {cpu} > 1.
- ii. In the **Variable Declaration** panel of the Mathematical Expression builder, click **+ Add variable** to add a variable.
- iii. In the **Variable Name** field, enter a name for the variable.
- iv. From the drop-down list next to the **Variable Name** field, select the qualifier for the metric from the following options:

Qualifier Type	Description
Minimum	The minimum value reported across the configured evaluation time length. This qualifier is not available for all the metrics.
Maximum	The maximum value reported across the configured evaluation time length. This qualifier is not available for all the metrics.

Qualifier Type	Description
Value	<p>The arithmetic average of all metric values reported across the configured evaluation time length. This value is based on the type of the metric.</p> <div style="border: 1px solid #00aaff; padding: 5px; margin-top: 10px;"> <p>i If you select the time rollup as SUM for custom metrics, the Value is the arithmetic sum of all metric values reported across the configured evaluation time length.</p> </div>
Sum	The sum of all the metric values reported across the configured evaluation time length.
Count	The number of times the metric value has been measured across the configured evaluation time length.
Group Count	The number of nodes contributing to a metric value, generally relevant for application or tier level metrics.
Current	The value for the current minute.

- v. Click **Select a metric** to open an embedded metric browser. To avoid erroneous evaluations, if any metric in the expression has a null value, the health rule is not evaluated.

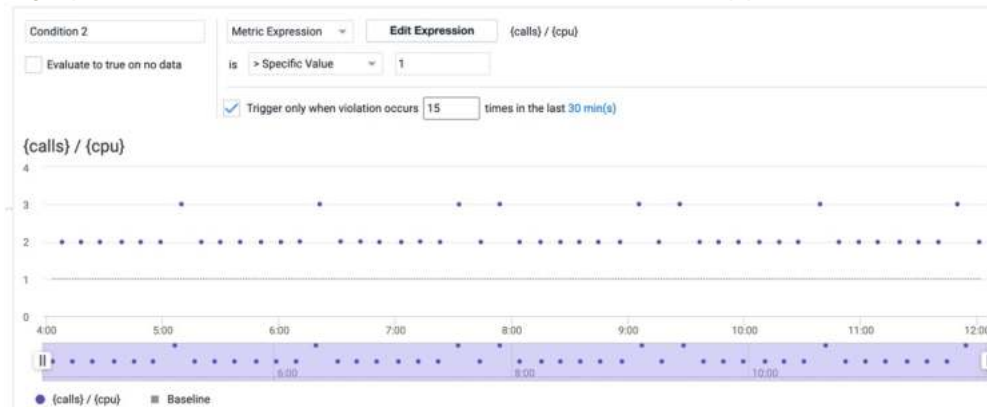

Expression	Null Value	Evaluation
a-b-c	a	entire expression is evaluated negative
a/b	b	the number 'a' is divided by zero, evaluates to an error
a*b	a or b	entire expression is evaluated as zero

- vi. Repeat Steps I through V for every metric that you use in the expression. You can remove a variable by clicking the **Delete** icon.
- vii. In the **Expression** pane, build the expression by clicking **Insert Variable** to insert variables created in the **Variable Declaration** pane along with appropriate mathematical signs.
- viii. When the expression is built, click **Save**.

- ix. Back on the **Critical Criteria** tab, select **< Specific value** or **> Specific Value** from the menu to compare the value of the metric evaluation with a static literal value, then enter the specific value in the text field. For example:

Value of {calls} / {cpu} > 1

A graphical view of the metric data for the last 8 hours appears.

i You can view the metric data for 1 day or 3 days by selecting the time period using the drop-down menu.

3. If you want the condition to evaluate to true when a configured metric does not return any data during the evaluation time frame, select the **Evaluate to true on no data** option. This option does not affect the evaluation of the unknown in the case where there is no enough data for the rule to evaluate. For example, if the health rule is configured to evaluate the last 30 minutes of data and a new node is added, the condition evaluates to unknown for the first 30 minutes even if the **Evaluate to true on no data** option is selected.
4. If you want to define a 'Persistence Threshold' for the condition to reduce false alerts:
 - a. Select **Trigger only when a violation occurs __ times in the last __ min(s)**.
 - b. Define the number of times metric performance data should exceed the defined threshold to constitute a violation.
 - c. If required, adjust the evaluation time frame by setting an alternate evaluation time frame.

i

- You can define a persistence threshold for a condition only if you have defined an evaluation time frame of 30 minutes or less.
- If you define a persistence threshold for a condition, the metric data is plotted directly on the AST graph. If you do not define a persistence threshold, a 'moving average' for the selected metric is plotted. For more information, see [Why Use Moving Average](#).

5. Specify the evaluation scope in the **Critical Criteria** and **Warning Criteria** panels, select the average of all nodes.

i AST graphical view is displayed only when you set the health rule evaluation scope to the average for all nodes.

Configure Affected Entities

Related Pages:

- [Health Rules](#)
- [Configuration Import and Export API](#)
- [Metric Browser](#)

This page provides an overview of affected entities in AppDynamics.

The **Affected Entities** panel lets you define what entities your health rule affects. The health rule type you select determines the metrics that are offered for configuration in subsequent panels of the health rule wizard.

To define the affected entities:

1. Select a health rule type from the drop-down list. Depending on the type of the health rule, you can configure the corresponding entities that are affected. See [Entities Affected by a Health Rule](#) for information about the types of entities that can be affected by the various health rule types.
2. Use the drop-down list to select the entities affected by this health rule.
3. If you select entities based on matching criteria, specify the matching criteria.
For example, if you select the Tier/Node Health - Transaction Performance as the health rule type, and if the health rule affects the nodes, you can restrict the health rule evaluation on the types of nodes or criteria such as meta-info, environment variables, and JVM system environment properties. Meta-info includes key-value pairs for:
 - key: `supportsDevMode`
 - key: `ProcessID`
 - key: `appdynamics.ip.addresses`
 - any key passed to the agent in the `appdynamics.agent.node.meta.info` system property

Points to Consider

- If you configure a health rule to evaluate a large number of entities (approximately one million or more), the health rule is automatically disabled to prevent any performance issues with the Controller. The logs of the disabled health rule are stored in the Controller and you can view the logs by using Splunk.
- The account owner receives an email notification for the disabled health rules. The email contains the following information:
 - the health rule names
 - the applications for which the health rules are disabled
- To enable the health rules again, you need to reduce the number of evaluating entities by applying additional entity filters.

Configure Health Rule Evaluation Criteria

Related Pages:

- [Health Rules](#)
- [Configuration Import and Export API](#)
- [Metric Browser](#)

This page provides an overview of evaluation criteria for health rules in AppDynamics.

After configuring the entities affected by the health rule, you must define the evaluation criteria.

The high-level process for configuring the criteria is:

1. Determine which type of evaluation criteria for the health rule:
 - **Critical Criteria**
 - **Warning Criteria**

Though the configuration processes for critical and warning conditions are identical, critical conditions are evaluated before warning conditions. If you have defined a critical condition and a warning condition in the same health rule, the warning condition is only evaluated if the critical condition is not true.

You can copy the settings between Critical and Warning condition panels and edit the fields, if required. For example, if you have already defined a critical condition and you want to create a warning condition that is similar, in the **Warning Condition** window click **Copy from Critical Condition** to populate the fields with settings from the Critical condition.

2. Determine the number and kind of metrics the health rule should evaluate. For each performance metric you want to use, create a condition using one of the following methods:

- Use a single metric
- Use a complex metric expression

For more information, see [Configure a Condition](#).

3. If you have defined multiple conditions, check if the health rule violates by selecting one of the following options:

- **All:** all conditions evaluate to true.
- **Any:** one of the conditions evaluates to true.
- **Custom:** if a boolean expression comprising all conditions evaluate to true.

4. For business transaction performance health rules and node health rule types that specify affected entities at the tier level, decide how many of the nodes must be violating the health rule to produce a violation event. See [Health Rule Evaluation Scope](#).

Create and Configure Conditions

Related Pages:

- [Health Rules](#)
- [Configuration Import and Export API](#)
- [Metric Browser](#)

This page provides an overview of conditions in AppDynamics.

You can define a condition or a set of conditions to evaluate the performance metrics of your application.

Use the following options to evaluate the conditions:

- [Expression builder](#) embedded in the health rules wizard to create a condition based on a complex expression comprising multiple interdependent metrics.
- [Custom boolean expression](#) to evaluate multiple conditions within a health rule. You can use the **AND** and **OR** operators in a boolean expression.

Create a Condition

1. In the **Critical Condition** or **Warning Condition** window, click **+ Add Condition** to add a new condition component. A row defining the condition is displayed.
2. [Configure the Condition as required](#).
3. Continue to add conditions as required. You can add a maximum of 8 conditions. Conditions are designated as A, B, C, and so on.
4. From the drop-down list above the conditions, select:
 - **All:** if all of the conditions must evaluate to true to constitute rule violation.
 - **Any:** if any of the conditions must evaluate to true to constitute rule violation.

- **Custom:** if a combination of conditions defined in a boolean expression must evaluate to true to constitute rule violation. For more information on how to create a custom boolean expression, see [Create a Custom Boolean expression](#).

5. For health rules based on the following health rule types, select:

- Business Transaction
- Node health-hardware
- Node health-transaction performance

You must specify the evaluation scope in the **Critical Criteria** and **Warning Criteria** panels:

Health Rule will violate if the conditions above evaluate to true for:

- The BT Average (average for all Nodes in the BT)
- Any Node
- % of the Nodes
- of the Nodes

 You can use Alert Sensitivity Tuning to configure health rule conditions for a business transaction, a service endpoint or a remote service only. You must set the health rule evaluation criteria to 'average of all nodes'. For more information, see [Alert Sensitivity Tuning](#).

If you select the percentage of nodes, enter the percentage. If you select the number of nodes, enter an absolute number.

Evaluating Serverless Tiers

When you monitor serverless entities comprising tiers for AWS Lambda, the health rules are evaluated as described below.

Health Rule Type	Affected Entities	Condition Evaluation Criteria	Evaluation
<ul style="list-style-type: none"> • Business transactions • Service endpoints • Error rates 	serverless tier(s)	The BT Average	Metrics are aggregated at the tier level.
	serverless node(s)	<ul style="list-style-type: none"> • Any node • % of the Nodes • Number of the Nodes 	Metrics for serverless tiers are aggregated at the tier level, while the metrics for other tiers are evaluated as per the defined criteria.
Tier/Node Health (Transaction Performance)	serverless tier(s)	<ul style="list-style-type: none"> • The Tier Average (average for all Nodes in the Tier) • Any node • % of the Nodes • Number of the Nodes 	Metrics for serverless tiers are aggregated at the tier level, regardless of the evaluation criteria defined.

Health Rule Type	Affected Entities	Condition Evaluation Criteria	Evaluation
	serverless node(s)	<ul style="list-style-type: none"> The Tier Average (average for all Nodes in the Tier) Any node % of the Nodes Number of the Nodes 	The performance of serverless tiers is not evaluated for Tier/Node Health (Hardware) health rules. AWS does not offer node-level dashboards or metrics because the serverless platform runtime instances spin up and down on-demand.
Tier/Node Health (Hardware)	<ul style="list-style-type: none"> serverless tier(s) serverless node(s) 	-	The performance of serverless tiers is not evaluated for Tier/Node Health (Hardware) health rules. AWS does not offer node-level dashboards or metrics because the serverless platform runtime instances spin up and down on-demand.

Configure a Condition

- In the first field of the condition row, enter a name for the condition. This name is used in the generated notification text and in the AppDynamics console to identify the violation.

 Ensure that you enter a unique name for each condition you define.

- From the drop-down list below the **Add Condition** button, define metrics to evaluate the condition, select:
 - Single metric to specify a simple metric.**
 - From the Value drop-down list, select a qualifier for the metric from the following options:

Qualifier Type	Description
Minimum	The minimum value reported across the configured evaluation time length. Not all metrics have this type.
Maximum	The maximum value reported across the configured evaluation time length. Not all metrics have this type.

Qualifier Type	Description
Value	<p>The arithmetic average of all metric values reported across the configured evaluation time length. This value is based on the type of the metric.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p>i If you select the time rollup as SUM for custom metrics, the Value is the arithmetic sum of all metric values reported across the configured evaluation time length.</p> </div>
Sum	The sum of all the metric values reported across the configured evaluation time length.
Count	The number of times the metric value has been measured across the configured evaluation time length.
Group Count	The number of nodes contributing to a metric value, generally relevant for application or tier level metrics.
Current	The value for the current minute.

b. To specify a simple metric, click **Select a Metric**. Metric Selection window is displayed. The metric browser in the **Metric Selection** window displays metrics appropriate to the health rule type. Alternatively, you can [define a relative metric path](#).

c. Select a metric to monitor and click **Select Metric**.

i You can use Alert Sensitivity Tuning to fine-tune metric evaluation for a health rule (that monitors BT, service endpoint or remote service). You must select a single metric to evaluate the condition. See [Create a Health Rule and Fine-tune Metric Evaluation](#) for more information.

or

- Metric Expression to [build a metric expression](#).

3. From the drop-down list after the metric, select the type of comparison to evaluate the metric.

- To limit the effect of the health rule to conditions during which the metric is within a defined range—standard deviations or percentages—from the baseline, select **Within Baseline** from the menu. To limit the effect of the health rule to when the metric is not within that defined range, select **Not Within Baseline**. Then select the baseline to use, the numeric qualifier of the unit of evaluation and the unit of evaluation. For example:

Within Baseline of the Default Baseline by 3 Baseline Standard Deviations

- To compare the metric with a static literal value, select **< Specific value, > Specific Value, = Specific Value, or != Specific Value**. And enter the specific value in the text field. For example:

Value of Errors per Minute > 100

- To compare the metric with a baseline, **select < Baseline or > Baseline** from the drop-down list, and then select the baseline to use, the numeric qualifier of the unit of evaluation and the unit of evaluation. You can use the Baseline Standard Deviation or Baseline Percentage as the unit of evaluation. For example:

Maximum of Average Response Time is > Baseline of the Daily Trend by 3 Baseline Standard Deviations

See [Dynamic Baselines](#) for information about the baseline options.

i **Baseline Percentages**

The *baseline percentage* is the percentage above or below the established baseline at which the condition will trigger. For example, if you have a baseline value of 850 and you have defined a baseline percentage of > 1%, the condition is true if the value is > $[850 + (850 \times 0.01)]$ or 859.

To prevent health rule violations from being triggered when the sample sets are too small, these rules are not evaluated if the load—the number of times the value has been measured—is less than 1000. For example, if a very brief time slice is specified, the rule may not violate even if the conditions are met, because the load is not large enough.

4. If you want the condition to evaluate to true whenever a configured metric does not return any data during the evaluation time frame, check the **Evaluate to true on no data** option. This option does not affect the evaluation of unknown in the case where there is no enough data for the rule to evaluate. For example, if the health rule is configured to evaluate the last 30 minutes of data and a new node is added, the condition evaluates to unknown for the first 30 minutes even if the **Evaluate to true on no data** box is checked.
5. If you want to define a '**Persistence Threshold**' for the condition to reduce false alerts:
 - a. Select 'Trigger only when a violation occurs __ times in the last __ min(s)'.
 - b. Define the number of times metric performance data should exceed the defined threshold to constitute a violation.
 - c. If required, adjust the evaluation time frame by setting an alternate evaluation time frame.

i You can define a persistence threshold for a condition only if you have defined an evaluation time frame of 30 minutes or less.

6. If you want to control the health rule status when metric data is unavailable for evaluation, use one of following options:
 - **Critical** or **Warning**: The health rule considers this no data scenario as Critical or Warning condition and the health rule status is shown in Red or Yellow respectively.
 - **Unknown**: The health rule considers the no data scenario as unknown and the health status is shown in Grey.
 - **Healthy**: The health rule considers the no data scenario as healthy and the health rule status is shown in Green.
7. Click **Save** when done.

Evaluation of Agent Availability Metrics

Using Health Rule Conditions to evaluate agent availability metrics can result in false positives. For example:

- Agents may not be connecting with controllers due to communication errors for a couple of minutes.
- Data may be delayed for a couple of minutes due to latency issues.

You can configure the health rules such that you get notified of any occasional one-to-two minute metric loss due to network issues, or when an agent fails to communicate to the controller. Configure your Health Rule as follows:

1. Select Nodes that the health rule affects. You can also set Tiers, however, it is recommended that you set Nodes.

2. Select Node Health - Hardware, JVM, CLR as the health rule **Type**.
3. Use the last five minutes, with a wait time of ten minutes.
4. Set your condition to be the Sum of < Specific value of three.

This configuration generates a violation when the agent is down for more than two minutes during the last five minutes.

Health Rule Violation for Agent Availability Metrics

The purpose of the availability metrics is to check if the applications monitored by agents are available.

If an agent goes down due to any reasons, the controller does not get the status of the corresponding application.

If a health rule is created for an availability metric, the health rule violates when the agent is down, and an alert is generated. This is because the situation is considered as no data received from the source and health rule is evaluated. In such case, the health rule violation does not indicate that your application is down. You can ignore such alert and disable the health rule.

The option **Evaluate to True on No Data** does not have any impact on such health rules.

Build an expression

To access the expression builder to create a complex expression as the basis of a condition, select the **Metric Expression** option from the drop-down list and click **Add Expression**. The **Metric Expression** window is displayed that allows you to construct a mathematical expression to use as a metric.

For example, the following expression is created to measure the percent of slow business transactions. See the [screenshot](#) that follows for the UI location where each step is performed.

1. In the **Variable Declaration** pane of the Mathematical Expression builder, click **+ Add variable** to add a variable.
2. In the **Variable Name** field enter a name for the variable.
3. From the drop-down list, select the qualifier for the metric from the following options:

Qualifier Type	Description
Minimum	The minimum value reported across the configured evaluation time length. This qualifier is not available for all the metrics.
Maximum	The maximum value reported across the configured evaluation time length. This qualifier is not available for all the metrics.
Value	<p>The arithmetic average of all metric values reported across the configured evaluation time length. This value is based on the type of the metric.</p> <div style="border: 1px solid #0070C0; background-color: #E6F2FF; padding: 5px; margin-top: 10px;"> <p>i If you select the time rollup as SUM for custom metrics, the Value is the arithmetic sum of all metric values reported across the configured evaluation time length.</p> </div>

Qualifier Type	Description
Sum	The sum of all the metric values reported across the configured evaluation time length.
Count	The number of times the metric value has been measured across the configured evaluation time length.
Group Count	The number of nodes contributing to a metric value, generally relevant for application or tier level metrics.
Current	The value for the current minute.

- Click **Select a metric** to open an embedded metric browser.

Health Rule Evaluation Condition

A health rule is not evaluated if any metric in the expression has a null value. This is to avoid erroneous evaluations as shown in the following examples:

Expression	Null Value	Evaluation
a-b-c	a	entire expression is evaluated negative
a/b	b	the number 'a' is divided by zero, evaluates to an error
a*b	a or b	entire expression is evaluated as zero

- Repeat steps 1 through 4 for each metric that you use in the expression.
You can remove a variable by clicking the delete icon.
- In the **Expression** pane, build the expression by clicking **Insert Variable** to insert variables created in the **Variable Declaration** pane along with appropriate mathematical signs.
- When the expression is built, click **Save**.

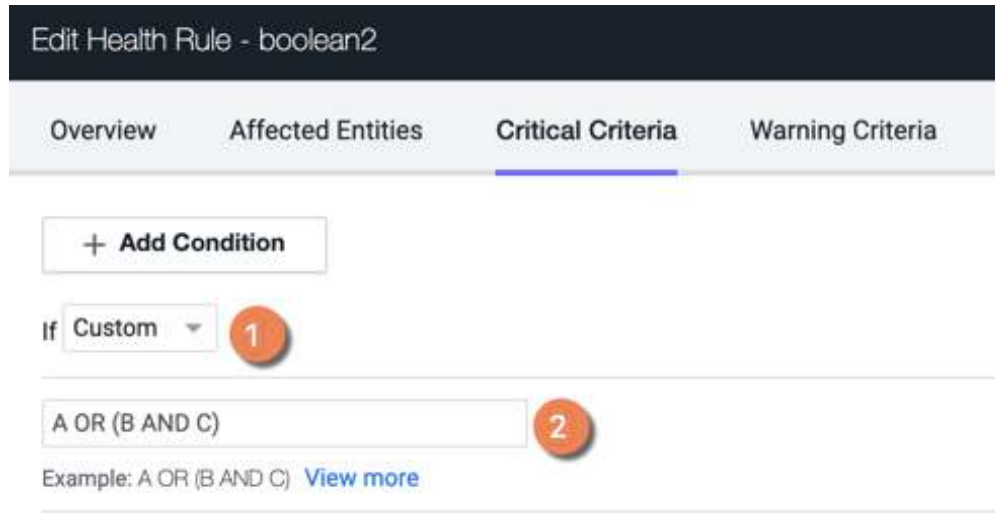

Create a Custom Boolean Expression

Once you define all the conditions required for the health rule, you can create a custom boolean expression to evaluate the health rule.

- From the drop-down list above the conditions, select **Custom** option.
- Enter a combination of conditions using **AND** and/or **OR** operators. For example, (A OR B) AND C.

 Ensure that you enter a valid combination of conditions using **AND** and **OR** operators, else the evaluation fails.

3. Click **Save**.

Modify the Custom Boolean Expression

1. Select the expression in the **Condition Combination** field.
2. Edit the boolean expression as required.
3. Click **Save**.

Delete a condition

Delete a condition component by clicking the delete (X) icon.

i If you delete a condition, update the boolean expression accordingly.

Define Custom Metrics for Multiple Entities

Related Pages:

- [Health Rules](#)
- [Configuration Import and Export API](#)
- [Metric Browser](#)

You can create health rules using custom metrics to monitor a single entity or multiple entities.

Create Health Rule Using Custom Metrics to Monitor Single Entity

To create a health rule using custom metric to monitor a single business transaction, node, or overall application performance:

1. When you [create a health rule](#), specify the health rule type as *custom*.

The screenshot shows the 'Create Health Rule' interface. At the top, there are four tabs: 'Overview', 'Affected Entities' (which is active), 'Critical Criteria', and 'Warning Criteria'. Below the tabs, there is a section titled 'Select Health Rule Type' with a dropdown menu showing 'Custom (use any metrics)'. Below that, there is a section titled 'What does this Health Rule affect?' with three radio button options: 'Application Performance' (selected), 'Business Transaction Performance', and 'Node Performance'. Each option has an information icon (i) next to it.

2. When you [configure the conditions](#), in the **Select Metric** window, choose to **Specify a Metric from the Metric Tree**.
3. Select the metric from the embedded metric browser.

Create Health Rule Using Custom Metrics to Monitor Multiple Entities

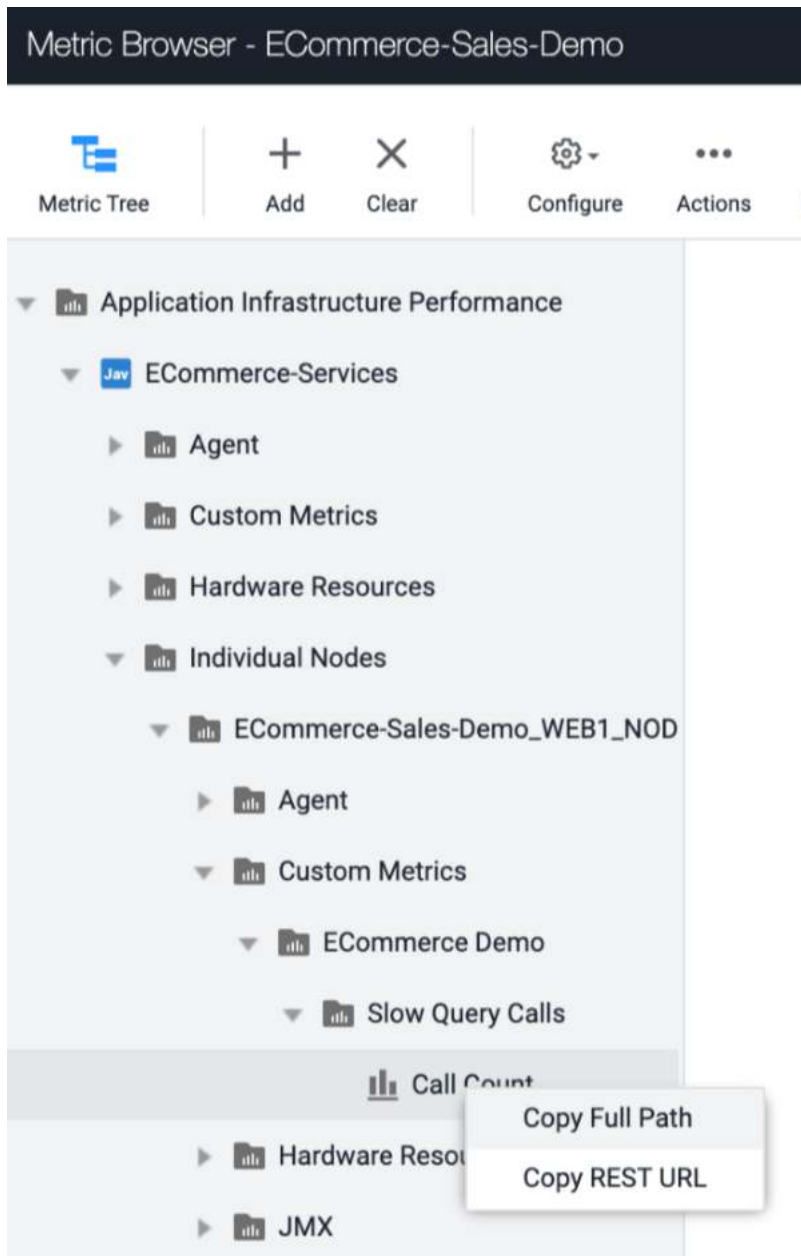

You can create a health rule that evaluates a custom metric that exists across various entities, for example across several nodes. You want to do this with one health rule; you do not want to create a separate health rule for each node. In this case, you need to specify a custom metric using the relative metric path to the metric instead of selecting the metric from the embedded metric browser.

1. [Get the custom metric path from the Metric Browser](#).
2. [Configure the health rule using the custom metric path as a relative path](#).

Get the Custom Metric Path for a Multi-Entity Metric

1. Navigate to the Metric Browser by selecting the **Metric Browser** in the left navigation pane.
2. Select the metric that you want to use for the condition.
3. Right-click and select **Copy Full Path**.
4. Save this value in a file from which you can copy it later.

The following example gets the metric path for the CPU %Busy metric for the Inventory Server tier. The CPU %Busy metric would be appropriate to use in a health rule that affects all the nodes in that tier.

Configure a Health Rule Condition That Evaluates a Custom Metric for Multiple Entities

1. In the **Overview** panel of health rule wizard choose the health rule type for the kind of entity that you are monitoring.
2. In the **Affected Entities** panel select the affected entity.
3. When you create the condition component that uses the metric, in the Select Metric window choose **Specify a Relative Path Metric**.
4. Crop the relative metric path that you saved from the metric browser by doing one of the following:
 - For all health rule types except Node Health-Hardware, JVM, CLR or Custom, crop the path to use the metric name along with the application name and category, for example, `Custom Metrics|ECommerce Demo|Slow Query Calls|`

Call Count .

Metric Selection ✕

Specify a Metric from the Metric Tree:

- Average End to End Latency (ms)
- Average Response Time (ms)
- Calls per Minute
- End to End Messages per Minute
- Error Page Redirects per Minute
- Errors per Minute
- Exceptions per Minute
- HTTP Error Codes per Minute
- Infrastructure Errors per Minute
- Normal Average Response Time (ms)

Specify a Relative Metric Path: ?

Custom Metrics|ECommerce Demo|Slow Query Calls|Call Count

Cancel

Select Metric

- For Node Health-Hardware, JVM, CLR and Custom health rule types, crop the path to use everything after the entity, for example, after the Node name. In the example below, the cropped path would look like this.

Metric Selection
✕

Specify a Metric from the Metric Tree:

- ▶  Agent
- ▶  Hardware Resources
- ▶  JVM
- ▶  CLR

Specify a Relative Metric Path: ?

Custom Metrics|Blitz|Aggregator|Dropped|G2 No Capacity

Cancel

Select Metric

5. Paste the cropped relative metric path in the relative metric path field of the **Metric Selection** window.
6. Click **Select Metric**.

JMX Health Rules

Related Pages:

- [Monitor JMX](#)
- [Configure JMX Metrics from MBeans](#)
- [Configure Health Rules](#)

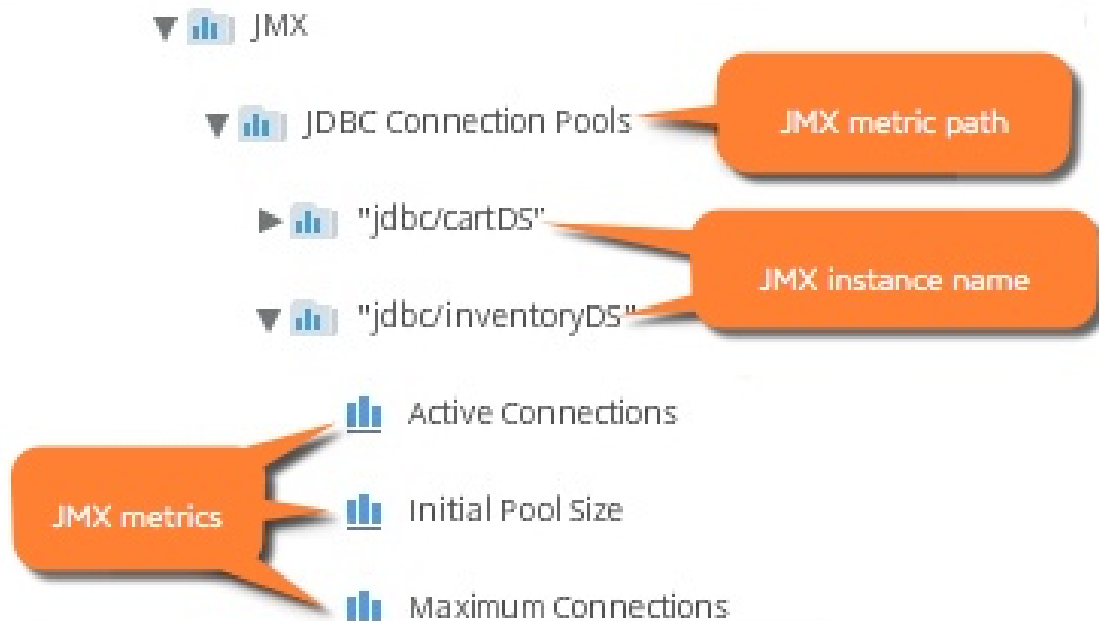

This page provides an overview of JMX health rules, which establish the health status of entities in a monitored Java application based on JMX metrics.

JMX Instance Names

For health rules based on JMX metrics, you can create health rules on a node or on an entity called a JMX instance name. If you create the health rule on the JMX instance name, you have the option of restricting it to specific nodes. If you create the health rule on the node, you have the option of restricting it to specific JMX instance names.

A JMX metric is identified by its JMX metric path, its JMX instance name, and its metric name. These are determined by the **Metric Path**, **Object Name Match Pattern**, and **Metric Name** fields specified in the AppDynamics **JMX metric MBean Configuration** screens. The instance name is derived from the value returned by the object match pattern. Identical JMX instance name values are considered distinct when their metric paths differ.

JMX instance names appear in the Metric Browser under the appropriate JMX metric path. Specific JMX metrics are reported under each JMX instance name.

For details about how JMX metrics are configured, see [Configure JMX Metrics from MBeans](#).

Creating JMX Health Rules

To create a health rule on one or more JMX metrics, in the **Affected Entities** panel of the health rule wizard, set the type of the rule to Node Health-JMX—connection pools, thread pools, and so on.

Determine what JMX objects the health rule will be evaluated on. In some IT organizations, different teams are responsible for different MBeans. In other organizations, different teams are responsible for different nodes or tiers.

The way your organization is set up determines how you think about JMX health, especially where it intersects with node health.

- As a team member responsible for a node, do you consider your node unhealthy because one or more of its MBeans is unhealthy? If so, which nodes or how many?
- As a team member responsible for your JMX infrastructure, are you primarily interested in the health of your JMX data regardless of the nodes that use it? Or are you interested in just specific JMX metrics in specific nodes? Which ones?

i It is recommended to have the JMX rule with instance identifier because it helps in selecting the metric under category in the metric select tree of the UI.

For the purpose of configuring JMX health rules and using them in policies, the ultimate question is: who will receive the alert when the agent reports unhealthy performance detected by JMX metrics? The flexibility of the AppDynamics health rules lets you fine-tune your JMX health rules so that the right people are alerted for the code for which they are responsible.

Select whether the affected entity should be the JMX instance name or the node. In either case, you can configure the rule to cover one of the following scopes:

- All JMX instance names in the application
- Specific JMX instance names
- All nodes in the application
- Specific nodes in the application
- Nodes within the specified tiers
- Nodes matching a given criteria

You can limit the evaluation of the health rule to either the specified JMX instance names or nodes depending on the evaluation scope.

JMX Health Rules Affecting a Node

In one organization, teams are responsible for nodes. Mark is responsible for `WEB1_NODE`, Tao for `WEB2_NODE`, and so on.

If an MBean in `WEB1_NODE` generates JMX metrics that violate a critical condition, and a health rule is configured to evaluate a JMX object in that node, Mark or someone on Mark's team will get an alert. The configuration of the health rule would be:

Create Health Rule

Overview **Affected Entities** Critical Criteria Warning Criteria

Select Health Rule Type
Tier / Node Health - JMX (connection pools, thread pools, etc)

Select what JMX Objects this Health Rule will be evaluated on ⓘ
Select JMX Objects JMX/JDBC Connection Pools ⓘ Evaluate metrics in this path only

Find JMX Objects by
 JMX Instance Names Nodes This rule affects one or more nodes

Select what Nodes this Health Rule affects
These specified Nodes:

Selected (1)

Name	Tier
Node-8000	/Users/deepanshu...

This rule affects only this node

Available (3)

Name	Tier ↑
Node-8003	/Users/deep...
Node-8001	/Users/deep...
Node-8002	/Users/deep...

Limit Evaluation to these JMX Instance Names
All JMX Instances in the Application

If different people on Mark's team are responsible for different MBeans used in `WEB1_NODE`, they could refine the rule further by selecting specific JMX instance names for evaluation. For example, the last decision of this configuration can restrict the rule to evaluate only metrics in the `jdbc/ECommerceDB` JMX instance name.

Mark's team could create a similar rule for the remaining JMX instance names to use in a policy that alerts whoever on Mark's team is responsible for the `jdbc/OracleECommerceD` JMX instance names.

Mark's team could also create different rules that evaluate a different set of JMX metrics by choosing a different metric path in the Select JMX Objects field. For example, they could select **All Web Container Runtimes**.

For problems on `WEB2_NODE`, they would create a different health rule with `WEB2_NODE` as the affected node, so that the alerts for those problems go to Tao's team.

JMX Health Rules Affecting a JMX Instance Name

In another organization, teams are responsible for various parts of the JMX infrastructure. Mary is responsible for `jdbc/OracleECommerceDB`, Meera for `jdbc/ECommerceDB`, and so on, regardless of which nodes use these MBeans.

So if metrics in `jdbc/OracleECommerceDB` violate a critical condition, they want Mary to get the alert because her team is responsible. The configuration of the health rule would be:

The screenshot shows the 'Create Health Rule' dialog box with the following configuration and callouts:

- Select Health Rule Type:** Tier / Node Health - JMX (connection pools, thread pools, etc). Callout: "This health rule affects JMX objects of one or more nodes."
- Select what JMX Objects this Health Rule will be evaluated on:** JMX|JDBC Connection Pools. Callout: "Evaluate JMX metrics in this path only"
- Find JMX Objects by:** JMX Instance Names (selected), Nodes.
- Select what JMX Instance Names this Health Rule affects:** These specific JMX Instance Names: [Empty field]. Callout: "Select JMX objects with the specified name"
- Selected (1):** Table with columns Name and Path. Row: "jdbc/OracleECommerceDB", JDBC Connection P...
- Available (1):** Table with columns Name and Path. Row: "jdbc/ECommerceDB", JDBC Connection P...
- Limit Evaluation to these Nodes:** All Nodes in the Application. Callout: "Limit evaluation to specified nodes only"

The rule could be refined to evaluate the JMX metrics in the specified JMX instance names in all nodes in the application or only in specific nodes.

Troubleshoot Health Rule Violations

Related Pages:

- [Health Rules](#)
- [Configure Health Rules](#)
- [Policies](#)
- [Alert and Respond](#)
- [Business Transactions](#)

A health rule is violated when the health rule processor detects that the health rule's critical or warning condition is true. In this case, a health rule violation is created with a status of Open, and a Health Rule Violation Started - Critical event or a Health Rule Violation Started - Warning event is generated.

A health rule violation ends when it is either: resolved (the agent reports metrics that indicate that the violated condition is no longer true) or canceled (the health rule processor can no longer accurately assert that the health rule violation continues to violate or that it has ended).

When a violated health rule goes into an unknown state and remains in that state until **Wait Time after Violation**, the health rule violation event is canceled after **Wait Time after Violation** is over.

When the violation status of a health rule becomes resolved, a *Health Rule Violation Canceled - Critical* event or a *Health Rule Violation Ended - Warning* event is generated.

The health rule violation status is canceled when:

- The health rule is edited
- The health rule is disabled
- Affected entities or evaluation entities on which the health rule is based are added or removed
- The metric values on which the health rule violation is based become UNKNOWN
- The health rule continues to violate straight for 72 hours

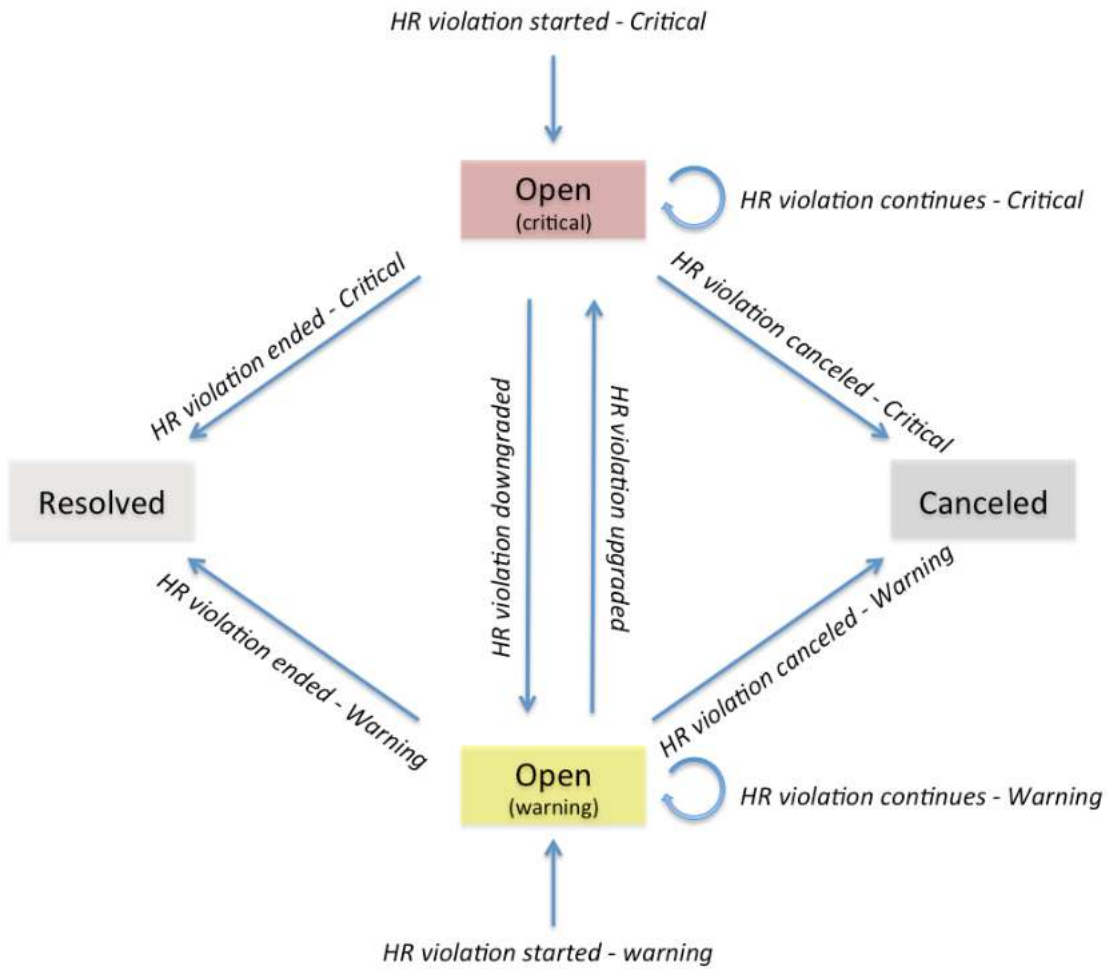

If you want to extend the health rule violation status even after 72 hours of continuous violation, contact your Cisco Accounts team.

When the violation status of a health rule becomes *Canceled*, a *Health Rule Violation Ended - Canceled* event or a *Health Rule Violation Canceled - Warning* event is generated.

If the same health rule is violated after a violation of it has been resolved or canceled, a new health rule violation is started.

During the life of a single health rule violation, there may be other types of health rule violation events such as Health Rule Violation Ungraded/Downgraded/Continues events.

The figure below illustrates the health rule violation life cycle.

The boxes represent the health rules violation statuses that you see in the health rule violations list in **Troubleshoot > Health Rule Violations**. To get more information about a particular violation, select the violation in the list and click **Details**. You can also view the health rule violations in the Controller UI.

	Health Rule Viol...	Health Rule tier has v...	09/18/18 5:31:55 PM

Because there is a set of default health rules, you may see health rule violations reported for your application even if you have not set up your own health rules. Violations reported for the `APPDYNAMICS_DEFAULT_TX` business transaction are for default health rule violations in the All Other Traffic business transaction.

When a health rule violates, you might see a difference of approximately two to three minutes between the time stamps of the violating metrics on the **Metric Browser** window and the corresponding event on the **Events** tab of an application. The time stamp of the violating metrics is earlier than the time stamp of the corresponding event. This difference is because of the time taken by the agents to send data to the Controller.

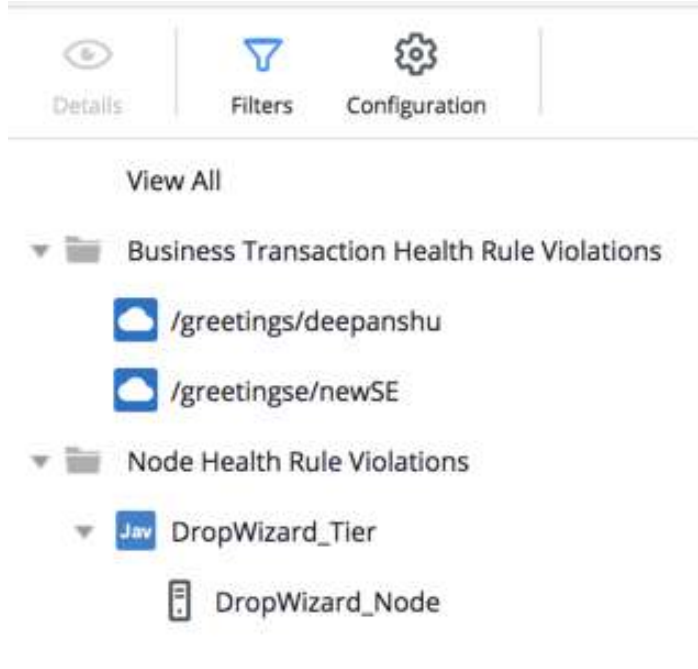

Find Health Rule Violations

To find all health rule violations:

1. In the left navigation pane, click **Troubleshoot > Health Rule Violations**.
The list of health rule violations displays.

 You can also access this screen directly from the left navigation pane of an EUM application.

2. Select **All Health Rule Violations in the Time Range** or **Only Health Rule Violations Open Now** from the drop-down list.
It is possible that health rule violations that were reported are no longer open because remedial action has been taken or performance has improved on its own.
3. You can filter the list. To see the filters, click **Filters**. To hide them, click **Filters** again.
With the filters showing in the left filters panel, you can select the health rule violations that you want to troubleshoot.
You can view all health rule violations or expand the nodes in the tree to select by health rule type or affected entity, such as business transaction, tier or node.

You can filter health rule violations by entering the name of the health rule in the search field on the upper right.

The health rule violations are displayed in the right panel, with their affected entity, status, description, start time, end time and duration, if ended.

Examine a Health Rule Violation

To view details about a particular health rule violation:

1. Select the health rule violation row in the list.
2. Click **View Health Rule Violation Details**.

In the **Health Rule Violation** summary window, you can click the **Affects** link to see the dashboard of the entity affected by the health rule. Alternately, click the **View Dashboard During Health Rule Violation** button to view the dashboard at the time the violation occurred.

i The hyperlink to access the affected entity dashboard is not displayed for a Server health rule with entity type `Machine_Instance` when a health rule violation occurs. Navigate to the **Health Rule** window, **Affected Entities** tab to view the list of affected entities.

You can also access details of a health rule violation from the health indicators in the UI. For example, if you see the red indicator on the dashboard indicating that Business Transaction Health or Server Health is critical, click it to get the list of business transactions or tiers and then click the icon in the **Health** column of the list.

View Actions Triggered by a Health Rule Violation

For health rules that trigger actions configured by policies, you can get information about the action that was executed.

To view the action triggered by a health rule violation:

1. In the dashboard of the entity affected by the health rule violation, click the **Events** tab.
2. In the events list, locate the health rule violation that you are interested in examining. If an action was triggered by the health rule violation event, you will see an event icon in the **Actions** column of the list.
3. Select the row for the event.
4. Click **Details**.
5. In the health rule violation window, click the **Actions Executed** tab.

Alert Sensitivity Tuning Questions and Answers

As an on-prem customer, can I fine-tune a health rule using AST?

No, AST is available for SaaS customers only.

Can I use AST to fine-tune a health rule that monitors any entity?

You can use AST to fine-tune health rules that monitor business transactions, service endpoints, or remote services only. You must set the health rule evaluation scope to 'average for all nodes' of the affected entity.

How is the metric data presented in the AST graph?

If you define a persistence threshold for a condition, the metric data is plotted directly on the AST graph. If you do not define a persistence threshold, a 'moving average' for the selected metric is plotted. For more information, see [Why use 'moving average'?](#)

What is a moving average? How is it helpful?

Unless persistence thresholds are used, health rules compare the moving average of a metric to a threshold or a baseline. Thus, representing the moving average in the graph is appropriate.

Can I define 'persistence threshold' for a health rule if I plan to use AST?

Yes, you can define 'persistence threshold' for a health rule. However, you will not be able to use the moving average for the metric. For more information, see [Moving Average](#).

How does AST help calibrate the sensitivity of the health rule?

Depending on the baseline configuration you define, AST presents a graphical view of the metric data for the given baseline configuration. The graphical view is instantly updated when you update any configuration. You can also view granular details by modifying the graphical view. The historical metric data presented in the graph helps you calibrate the sensitivity of the metric evaluation (thus the sensitivity of the health rule).

I am not able to see the AST graphical view, how can I get the graphical view?

The graphical view may not be displayed due to multiple reasons. Check if you have:

- created the health rule for a business transaction, a service endpoint, or a remote service.
- set the health rule evaluation scope to 'average of nodes'.

Can I use AST to configure 'Critical' and 'Warning' criteria?

Yes, you can use AST to configure conditions for both critical and warning criteria.

Will AST impact the evaluation of boolean expression for health rule conditions?

There is no change in the evaluation of boolean expressions for health rule conditions.

Can I use AST to edit an existing health rule?

Yes, you can use AST when editing an existing health rule.

Actions

This page provides an overview of actions in AppDynamics.

An action is a predefined, reusable, automated response to an event. You can use actions to automate your runbooks.

A policy can trigger an action in response to any event. You configure which actions are triggered by which events when you configure [policies](#).

Types of Actions

You can create these types of actions:

- [Notification](#)
- [Diagnostic](#)
- [Remediation](#)
- [JIRA](#)
- [HTTP Request](#)

Not all actions are applicable to all application environments or to all situations. Below are some general guidelines concerning different types of actions. For more details, see the pages on the specific actions before you assign an action to a policy.

- The diagnostic thread dump actions can be performed only on nodes running a Java agent.

- The diagnostic session actions can be triggered only by violations of business transaction performance health rules or by slow or stalled transaction events since these are the events that produce a view into transaction snapshots.
- Remediation actions run a local script in a node and are available on nodes running on machines that have an [installed Machine Agent](#).

Actions Limits

The Controller limits the actions invoked based on the number of triggering events per event type. There is a maximum of ten events for any single event type that can trigger actions in a given minute. If the number of triggering events per type exceeds the limit, the actions that would have been triggered by the excess events are not started. You will not see a visual indication that these actions are not being started.

For example, your application can have up to ten Health Violation Started events triggering actions and up to ten Resource Pool Limit Reached events triggering actions within the same minute. But if you have eleven Health Violation Started events firing, the action that would be triggered by the eleventh event is not started.

To reduce unnecessary actions, there is a limit on the number of diagnostic and remediation actions that AppDynamics will invoke. The default limit is five actions per minute per machine for each type of action.

If, for example, a policy is configured on all the nodes where there are 100 nodes triggering actions, AppDynamics randomly selects five of the actions to execute.

To avoid exceeding the limits, design your policies so that they do not trigger an excessive number of actions for any particular event. You can generate fewer events by configuring the affected entities of your health rules at the tier level. See [entities affected by a health rule and by health rule types in Health Rules](#).

Actions Requiring Approval

For actions that take thread dumps or run a local script, you can optionally require email approval to run the action whenever it is triggered. If you check this option, human intervention is required before the automated action actually starts.

If you specify the approval required option when you configure the action, when the action is triggered an email containing a link is sent to the configured email address. The link presents a login screen (if the user is not already logged in to AppDynamics) and after the user logs in, a dialog requesting approval to take the thread dump or run the script. The user can click in this dialog to approve and start the action or cancel the action.

If you do not check the **Require Approval** option before executing the **Action** checkbox, the action will start automatically with no human intervention.

Create and Modify Actions

To configure actions, you need the Configure Actions permission.

To access the Actions configuration panels:

1. Click **Alert & Respond** in the menu bar.
2. Click **Actions** either in the right panel or the left navigation pane.
3. Select the context for the action (Application, User Experience Browser App, Databases, Servers, Analytics) from the pulldown menu.

The list of configured actions displays. You can filter the types of actions by checking the type in the

pulldown filter. If no action types are checked, there is no filtering; however if at least one type is checked, then only actions of that type display.

4. Do one of the following:

- To create a new action, click the **Create Action (+)** icon. After you have clicked **Create Action**, the instructions provided depend on the type of action you are creating.
- To edit an existing action, select the action and click the **Edit** (pencil) icon.
- To remove an existing action, select the action and click the **Delete (-)** icon.

View Actions

While actions are being triggered by events, you can get a summary of their execution in the **Actions** column in the **Events** list. You can access the **Events** list from the Events tab of the application, tier, or node dashboard.

The icon type indicates action type; an icon in the **Actions** column indicates that an action was triggered for this event. If the action icon is greyed out, the action is either still executing or failed to complete. If the icon fully displays, then the action executed successfully.

Action Suppression

You can prevent policies from firing actions for a configurable time period.

Notification Actions

Related Pages:

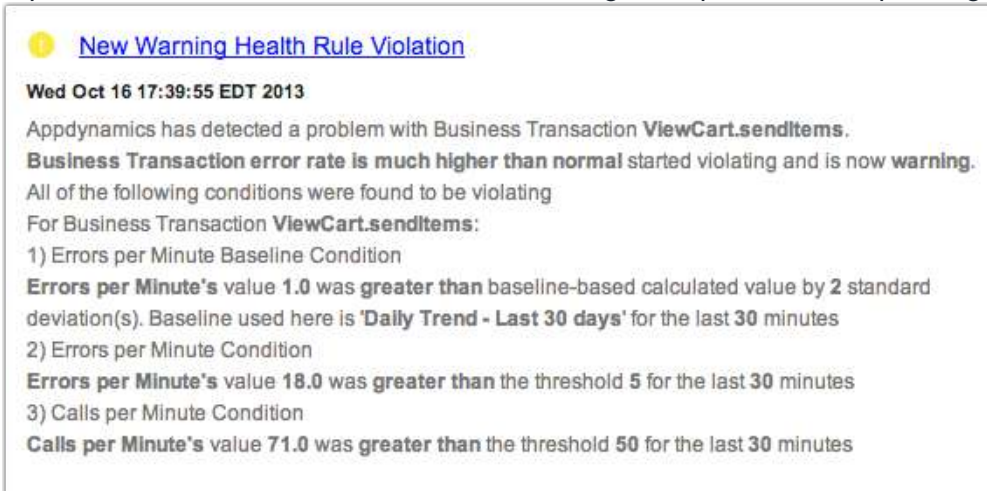

- [Alert and Respond](#)
- [Policies](#)
- [Email Templates](#)
- [Enable the Email Server](#)

A notification action sends an email or SMS to a recipient or recipient list. You can create an email notification with or without an email template.

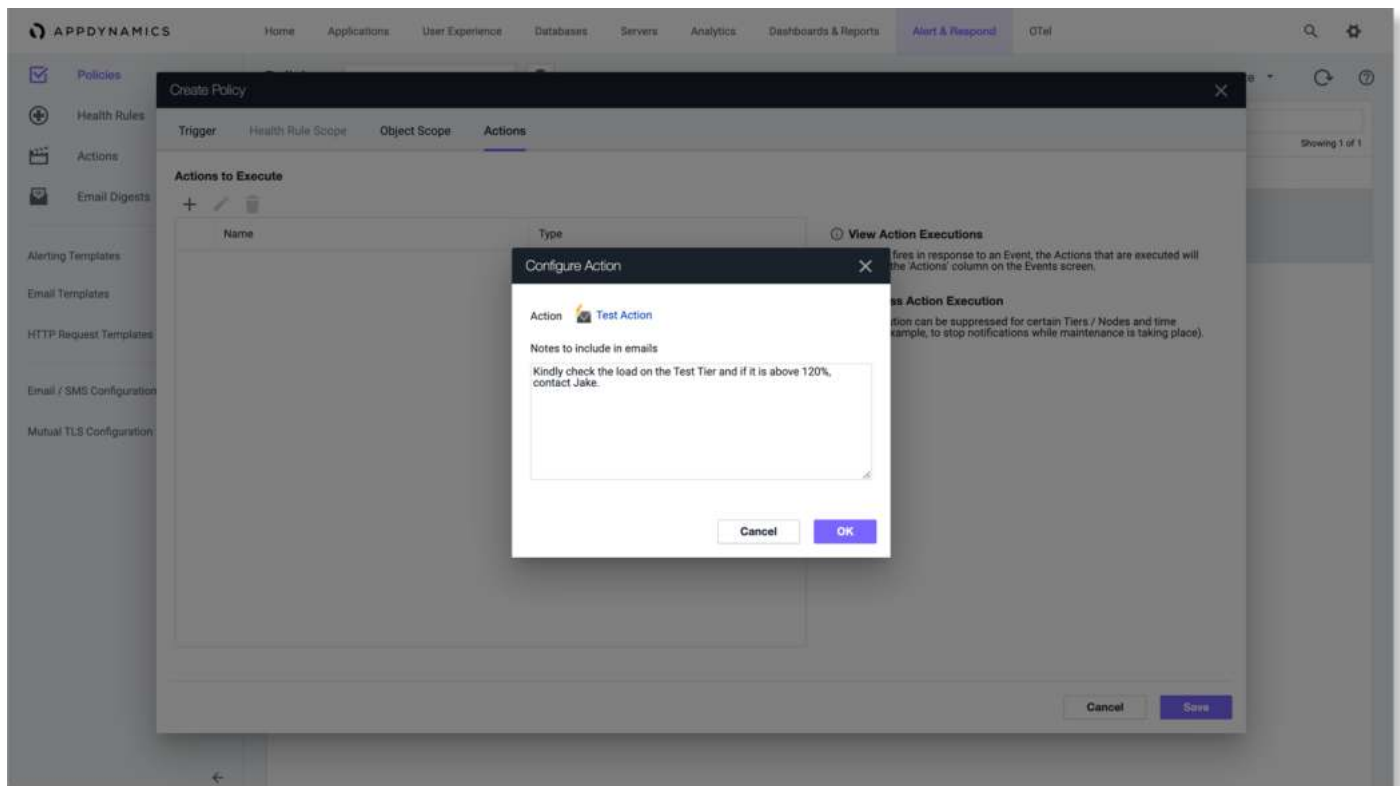

Email Notification Without a Template

For an email notification without a template, the contents of the email are automatically generated by the policy that triggers the action. The generated message contains a direct link to the Controller UI that details the triggering event, which is the place for the recipient to start troubleshooting the problem. You must provide the email addresses of the notification recipients. By default, all notifications are timestamps based on the time zone of your Controller. You can also change to a preferred time zone.

If you create an email notification without using a template, the recipients get following message:

When you configure a policy to start an email notification action that has not been created with a template, you can add an optional note to the email. This note is applied only when the action is invoked by the particular policy. By adding an optional note, you can customize email notifications for the policies that invoke them.

Email Notification With a Template

For an email notification with a template, you must provide the name of the email template to use. The email template specifies the message and is not generated automatically by the policy that triggers the action.

The template also provides for addressing multiple recipients. You can add and delete recipients when you create an action using the template. All the notifications timestamps are in Pacific Time (PST).

The email template must already exist before you can use it in an action. Email templates are created by users who have account-level permissions to create templates. See [Email Templates](#) for information about creating templates.

The body of the message is specified in the email template. It is not generated automatically.

All the text in the message must be created in the template. Customization is accomplished through the use of variables in the message body, which are replaced by actual values when the message is sent.

You can use a template to:

- Reuse the notification in other policies
- Customize the body of the message
- Decorate the notification with your own branding
- Add custom SMTP headers to the email
- Control whether the email is sent once or several times for each event
- Control the maximum number of triggering events listed in the email using a clamp limit
- Integrate with third-party email APIs, such as Remedy

Create Email Notification

To create an email notification:

1. Click **Alert & Respond > Actions**.
2. Select an application, database, server, or analytics from the dropdown list.
3. Click **+ Create** to create an action.
4. Under Notifications, select **Send an email**. To use a template to create the email notification, check **Use template?**
5. Click **OK**.
6. Do one of the following:
 - If you are not using a template:
 - i. Enter the name of the action.
 - ii. Enter the preferred time zone of your location. By default, the time zone of your browser is displayed.
 - iii. Enter the email address in the **To**, **Cc**, and **Bcc** fields to which you want to send the notification. You can add multiple email addresses in these fields. Use comma to separate multiple email addresses. For example, [user1@example.com](#), [user2@example.com](#), [user3@example.com](#).
 - If you are using a template:
 - i. Enter the name of the action.
 - ii. Select the appropriate template from the dropdown list. Unless disallowed by the template, you can add recipients at this time but you cannot remove any of the required recipients that were configured in the email template.
 - iii. Enter the email address in the **To**, **Cc**, and **Bcc** fields to which you want to send the notification. You can add multiple email addresses in these fields. Use comma to separate multiple email addresses. For example, [user1@example.com](#), [user2@example.com](#), [user3@example.com](#).
7. Click **Save**.

If email and SMS settings have not been configured for AppDynamics, configure them now. See [Configure an SMTP Server](#).

SMS Notifications

The content of the SMS is automatically generated. It contains:

- Notification header
- Application name
- Triggered time

Notifications of health rule violations also include: Name of health rule violated

Event notifications also include:

- Event notification configuration name
- Map of event types to the number of these events

An SMS notification configuration specifies the phone number of the recipient. All the notifications timestamps are in Pacific Time (PST).

To create an SMS notification:

1. Access the **Actions Configuration** panel. See Create and Modify Actions in [Actions](#).
2. Under **Notifications**, select **Send an SMS message** in the **Create Action** panel.
3. Enter the phone number to send the notification.
4. Click **OK**.

If you have not configured email and SMS settings for AppDynamics, configure them now. See [Enable the Email Server](#).

Email Templates

You must have account-level Configure Email Templates permission to create an email template. See [Alert and Respond](#).

Access Email Templates

Although the configuration settings are self-explanatory, some template configuration features and options require additional information.

1. Click **Alert & Respond > Email Templates**.
2. Click an existing template to view, edit, or delete it or click **New +** to create a template.
3. Edit or define the template.
4. Click **Save**.

Custom Templating Variables

You can use variables that replace values in the message body when the email is sent.

The template recognizes a set of predefined variables. Review [Predefined Templating Variables](#) to verify the variable you want does not already exist.

If the predefined variables do not meet your needs, you can optionally configure custom variables. When a predefined variable and a custom variable are both configured with the same variable name, the template uses the predefined variable.

You can use the following characters while configuring custom variables:

- Alphabetic characters (a...z, A...Z)
- Numeric characters (0...9)
- Hyphen (-)
- Underscore (_)

The template uses Apache Velocity version 2.3 to process the variables. See the [Velocity User Guide](#).

Admin Email Recipients

To add a recipient, enter an email address and click **+ Add**. To remove a recipient, click **–**.

If the **Allow custom email recipients** checkbox is selected in the template, users of the email template can add additional email recipients when they create the email notification. However, they cannot delete any of the recipients configured by the template. Clear this checkbox if you do not want to allow template users the ability to modify the recipient list.

The only way to remove a required recipient is by modifying the template.

Email Template

Enter the subject line and the body of the message. AppDynamics recommends including both an HTML version and a plain text version. You can use any predefined or custom templating variables in both the HTML and plain text message bodies. Use `background-color` instead of `background` for HTML email templates.

For-each loops are supported. See [Predefined Templating Variables](#).

Custom Email Headers

Use this section to add custom SMTP headers to the message.

One Email Per Event

Several separate events, or separate occurrences of the same event, could potentially invoke the same notification action.

The **One Email Per Event** setting controls whether the action bundles the emails triggered by those events. The effect is:

- If selected, the email is sent once every minute, no matter how many events triggered the notification within that minute. This is the default.
- If not selected, an email is sent every time an event triggers it. In this case, if ten events trigger the action, the email is sent ten times, even if all those events occurred within a single minute.

Event Clamp Limit

If you have not selected the **One Email Per Event** checkbox, you might want to limit the display of the events that triggered the action in the email, especially if the potential list of events could be long. The clamp limit is the number of most recent triggering events to be shown in the email. This setting is disabled if **One Email Per Event** is selected.

Test Email Template

After you save the email template, you can [test the template](#) by sending an email.

Test Email Templates

This page provides instructions on testing email templates in AppDynamics.

After you save the email template, you can test the template by sending an email.

1. In the **Create Email Template** dialog, click **Test**.
2. In the **Email Template Test** dialog, specify the test variables to use for the test. These variables can be different from those in the real emails that are sent automatically.

3. Set the log level or the amount of detail that you want to see: **INFO**, **WARN**, **ERROR**, **TRACE**, and **DEBUG**.
The log level defaults to **DEBUG**, but you can change this using the **Log Level** dropdown.
4. Specify the type of events that trigger the email action along with the count. You can add more triggers if required.
5. Click **Save**.

Run Test

When you run the test, an email is sent when the action is triggered. You also receive a transcript of the test.

If the results are not what you expect, you may need to modify the email template, the event triggers, or both, before you use the template in an action.

Diagnostic Actions

This page provides an overview of diagnostic actions in AppDynamics.

A diagnostic action can:

- Start a diagnostic session to collect snapshots
- Take a thread dump for Java only

When performance is slow or your application is experiencing a lot of errors, you can start a diagnostic action to find the root cause.

You can start a diagnostic session only for a health rule that monitors business transactions.

A diagnostic session provides a view into captured transaction snapshots with full call graphs. These snapshots help you diagnose violations of business transaction performance health rules or slow or stalled transaction events. The affected entity of the event triggering a diagnostic session must be a business transaction.

A thread dump is a general-purpose snapshot of the state of all threads that are part of a JVM process. The state of each thread is presented with a stack trace that shows the contents of each thread's stack. Thread dumps are used for diagnosing JVM performance problems, such as code deadlocks.

Diagnostic Session Actions

A diagnostic session is always associated with a business transaction. It shows transaction snapshots with full call graphs to help you drill down to the root cause of a problem.

To create a diagnostic session action:

1. Access the **Actions Configuration** pane. See Create and Modify Actions in [Actions](#).
2. Under **Diagnostics**, select **Start a Diagnostic Session on the selected Business Transactions** in the **Create Action** pane and click **OK**.
3. After entering a name for the action, the duration of the diagnostic session in minutes and the number of snapshots to take per minute, select whether a diagnostic session will be started for any business transaction affected by the event or for specific business transactions.
If you choose specific business transactions, specify the business transactions that will trigger the diagnostic session by moving them from the available list to the selected list. The business transactions that you can specify are not limited to those that triggered the action.
4. Click **OK**.

Diagnostic Action Results

The results of a diagnostic action that has executed are available in the events list for the event that triggered the action. To get the details of a diagnostic session or a thread dump that has been initiated by an action:

1. In the **Events** list, locate the row for the event that triggered the action for which you want to see the results.
2. In the **Actions** column:
 - Click  to see the details of a thread dump action.
 - Click  to see the details of a diagnostic session action.

On disk, the thread dumps are stored in the `app_agent_operation_logs` directory in the Controller Home. The files are named based on the ID in the `app_agent_operation` table.

Threads identified by `AD Thread` are threads initiated by the AppDynamics app agent code.

Thread Dump Actions

 Users need the Agent Advanced Operation permission to request a thread dump.

Agent Limit on Thread Dumps

One thread dump operation is executed at a time. They are not executed in parallel. If additional thread dump requests are received while one is being executed, they are queued with a limit of five per agent.

If the five thread dumps per agent limit is exceeded, the console shows an event with a thread dump operation that was skipped because of the limit and the associated action dialog for the executed policy links to this event.

To create a thread dump action:

1. Access the [Create Action](#) pane.
2. Under **Diagnostics**, select **Take a thread dump** in the **Create Action** pane and click **OK**.
3. Enter a name for the action, the number of samples to take and the interval between the thread dumps in milliseconds. If you want to mandate an approval before the thread dump action can be started, check the **Require approval before executing this Action** checkbox and enter the email address of the individual or group that is authorized to approve the action. See [Actions Requiring Approval](#).
4. Click **OK**.

 When a thread dump action is triggered by a backend discovery event, if the backend is not resolved quickly the policy will not start the thread dump.

Action Execution for Nodes

When you create a policy for `Code Deadlock` and then select a thread dump action, the following behavior occurs based on the action execution on the nodes:

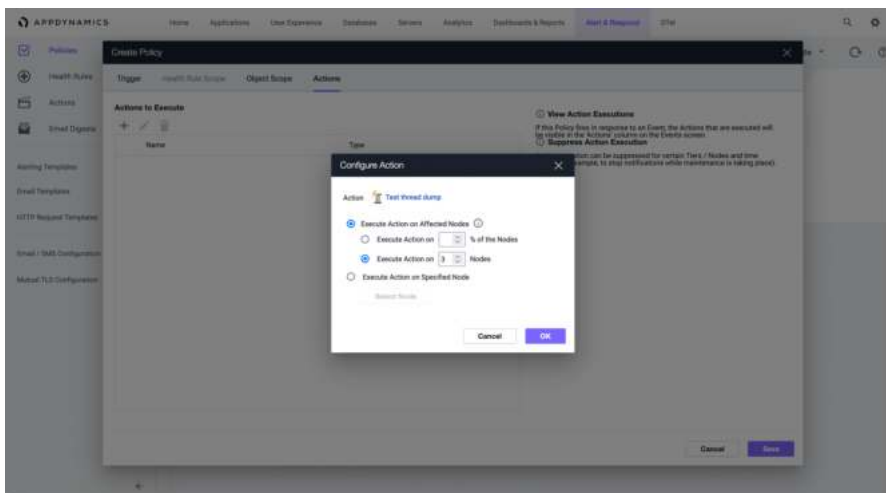

- If the percentage input for the nodes is less than 100%, the affected nodes on which the action is executed is randomly selected. Even if the percentage is low, the action is executed on at least one affected node.

For example, if there are violations on five nodes, and the input percentage is 40%, AppDynamics randomly selects two nodes and executes the thread dump on them. Further, if there are violations on five nodes, and the input percentage is only 10%, AppDynamics still randomly selects one node and executes the thread dump on it.

- If there is an absolute input for the number of nodes, the affected nodes on which the action is executed is randomly selected.

For example, if there are violations on 5 nodes, and the input absolute value is 3, AppDynamics randomly selects 3 nodes and executes the thread dump on them.

Remediation Actions

A remediation action runs a local script in a node. The script executes on the machine from which it was invoked or on the node specified by the remediation action configuration. You can use this type of action to automate your runbook procedures. You can optionally configure the remediation action to require human approval before the script is started. See [Actions Requiring Approval](#).

- Remediation actions are not available for servers.
- You can create and run a remediation action for a health rule with application, tier, or node as an affected entity. Ensure that you select the same entities when you define the **Object Scope** for the associated policy.
- Select an **Application** and then create **Actions** to view the **Remediation Action** option.

Prerequisites for Local Script Actions

- The Machine Agent must be installed running on the host on which the script executes. To see a list of installed Machine Agents for your application, click **View machines with machine-agent installed** in the bottom left corner of the remediation script configuration window.
- To be able to run remediation scripts, the Machine Agent must be connected to an on-premises Controller or to a SaaS Controller via SSL. Remediation script execution is disabled if the Machine Agent connects to a SaaS Controller on an unsecured (non-SSL) HTTP connection.
- The Machine Agent OS user must have full permissions to the script file and the log files generated by the script and/or its associated child processes.
- The script must be placed in `<agent install directory>\local-scripts`.
- The script must be available on the host on which it executes.
- Processes spawned from the scripts must be daemon processes.

Remediation Scripts

A remediation script is run on the machines that you specify in the remediation script configuration. You can run the script from the machine affected by the violation that triggered the action or from a central management server. It is not necessary for an app agent to be running on the machine on which the script executes; just a Machine Agent.

Remediation Example

The remediation action, named `increasePool`, executes a local script named `runbook.sh`, which increases the size of the connection pool on the JVM.

Create Remediation Script Action

You can specify any script or executable and the Java Machine Agent will execute it, and upload the results to the controller. You can download the script output on the Events screen (for events that trigger Policies).

Trigger Health Rule Scope Object Scope Actions

Name

Enabled

Execute actions in batch

This Policy will fire when any of these Events occur

Health Rule Violation Events

- Health Rule Violation Started - Warning
- Health Rule Violation Started - Critical
- Health Rule Violation Continues - Warning
- Health Rule Violation Continues - Critical

Other Events

- > Slow Transactions
- Code Problems
 - Code Deadlock
 - Resource Pool Limit Reached

Create a Local Script (Remediation) Action

To create a remediation action:

1. Access the **Create Action** pane. See Create and Modify Actions in [Actions](#).
2. Select **Run a script or executable on problematic Nodes** in the **Create Action** pane and click **OK**.
3. After entering a name for the action, in the field that terminates the Relative path to script entry, enter the rest of the path to the executable script.

Remediation scripts must be stored in a sub-directory of the machine agent installation. The sub-directory must be named `local-scripts`. These paths are all valid:

```

${machine.agent.directory}/local-scripts/runMe.sh
${machine.agent.directory}/local-scripts/johns_scripts/
runMe.sh
${machine.agent.directory}/local-scripts/ops/johns_scripts/
runMe.sh

```

4. Click the **+** to enter the absolute paths of any log files that the script writes to that you want to be included in the script output.
5. Enter the timeout period for the script process in minutes.
6. To mandate an approval before the script action can be started, select the **Require approval before executing this Action** check box and enter the email address of the individual or group that is authorized to approve the action. See [Actions Requiring Approval](#) for more information.

Specify the Nodes on Which the Action Will Run

When you bind the action to a policy, you specify the nodes on which the script should execute. You can configure the number of nodes or the percentage of nodes or you can configure a specific node. This flexibility allows you to configure scripts to run from a central management server, not just the node on which the violation occurred.

In the **Configure Action** pane of the policy actions to execute, either:

- Select **Execute Action on Affected Nodes** and the percentage of the nodes or the number of nodes on which to run the script.
- To designate the specific node on which to run the script, select **Execute Action on Specified Node**, and select the node on which the script should run from the popup node browser. You can either save the configuration or change it to designate a different node.

Review the Local Script Output

1. In the **Events** list, locate the row for the event that triggered the action for which you want to see the results.
2. In the **Actions** column of the selected row, click the remediation script icon.
3. In the script results list, select the script output that you want and click **Download Local Script Result**.

 When a remediation action is triggered by a backend discovery event, if the backend is not resolved quickly the policy will not start the local script.

Remediation Scripts

A remediation script is run on the machine that you specify in the [remediation script configuration](#). You can run the script from the machine affected by the violation that triggered the action or from a central management server. It is not necessary for an app agent to be running on the machine on which the script executes; just a Machine Agent.

Guidelines for Remediation Scripts

By default, the script is a shell script in `/bin/sh` invoked with the `-ex` option, unless the script has a header, in which case the interpreter in the header is used. For example, if the script header is `#!/bin/perl`, the Perl interpreter is invoked.

A process exit code of zero indicates that the script execution succeeded. A non-zero exit code indicates that it failed.

The script should be written as generically as possible to allow it to run on any of the nodes for which it is invoked. AppDynamics exports the following environment variables to the script runtime to provide context regarding the environment and the event that triggered the action.

Environment Variable	Cardinality (1 or M)	Notes
APP_ID	1	Identity of the application.
APP_NAME	1	Name of the application.
EVENT_TIME	1	Timestamp of the event.
EVENT_ID	1	Identity of the event.
EVENT_TYPE	1	type of event, such as: ERROR, APPLICATION_ERROR, APPLICATION_INFO, STALL, BT_SLA_VIOLATION, DEADLOCK, MEMORY_LEAK, MEMORY_LEAK_DIAGNOSTICS, LOW_HEAP_MEMORY, ALERT, CUSTOM, APP_SERVER_RESTART, BT_SLOW, SYSTEM_LOG, INFO_INSTRUMENTATION_VISIBILITY, AGENT_EVENT, INFO_BT_SNAPSHOT, AGENT_STATUS, SERIES_SLOW, SERIES_ERROR, ACTIVITY_TRACE, OBJECT_CONTENT_SUMMARY, DIAGNOSTIC_SESSION, HIGH_END_TO_END_LATENCY, APPLICATION_CONFIG_CHANGE, APPLICATION_DEPLOYMENT, AGENT_DIAGNOSTICS, MEMORY, LICENSE

Environment Variable	Cardinality (1 or M)	Notes
ENV_STARTUP_ARGS	1	Process args
ENV_SYSTEM_PROPERTIES	1	JVM System Props, when Java
AFFECTED_ENTITY	1	Affected Entity that triggered the event
SEVERITY	1	Severity level of the event. Possible values are: <ul style="list-style-type: none"> • ERROR– Indicates that the event is of the severity level "error". • INFO– Indicates that the event is of the severity level "information". • WARN– Indicates that the event is of the severity level "warning".

Remediation scripts must be stored in a sub-directory of the machine agent installation. The sub-directory must be named `local-scripts`. The following paths are all valid.

```

${machine.agent.home}/local-scripts/runMe.sh
${machine.agent.home}/local-scripts/johns_scripts/runMe.sh
${machine.agent.home}/local-scripts/ops/johns_scripts/runMe.sh

```

Troubleshooting Remediation Scripts

To troubleshoot your remediation script, look for the process in the Machine Agent log. The log location path is: `<machine_agent_home>/logs/machine-agent.log`

This snippet from the Machine Agent log shows both error and success messages from running a local script named `script.sh`.

```
[Agent-Scheduler-1] 07 May 2013 18:20:24,580 ERROR RunLocalScriptEventHandler - Error occurred while executing run local script operation

RunLocalScript succeeded

HTTP Request Actions and Templates

An HTTP request action sends an HTTP request in response to an event. These types of actions allow you to integrate AppDynamics' policies with third-party HTTP APIs.

You can configure an HTTP/HTTPS proxy for an on-premise Controller to filter access to the web server. When you configure a proxy, the HTTP request actions are routed through the HTTP proxy or HTTPS proxy, depending on the endpoint. See [Configure HTTP/HTTPS Proxy](#).

You create an HTTP request action using an HTTP request template. The template describes the HTTP request and is reusable by different HTTP request actions within an AppDynamics account.

After you create a template, users in the Controller UI can create actions that use it. The template displays as an option after the user selects the **Make an HTTP Request** option in the **Create Action** pane and accesses the **Configure Action** pane.

Required Permissions

To create or modify HTTP Request Templates, users need the account-level **Configure HTTP Request Templates** permission.

Access HTTP Action Templates

To access existing templates or to create new ones, click **Alert & Respond** in the menu bar, and then select **HTTP Request Templates**.

You can either:

- Click an existing template from the HTTP Request Templates list to view, edit, or delete it.
- Click the **New +** icon to create a template.

Create or Modify an HTTP Request Template

When creating or modifying templates, click the **Info** icons in the template to get information about how to complete the configuration.

After you have created a template, click **Save** at the bottom to save it.

Custom Templating Variables

You can use variables that replace values in the URL path and payload when the HTTP request is sent. For each loops are supported.

The template already knows a set of predefined variables, which are described in [Predefined Templating Variables](#). Check this list before you create any custom templating variables. Chances are the variable you want to use has already been defined.

You can optionally configure custom variables if the predefined variables do not meet all your needs. When a predefined variable and a custom variable are both configured with the same variable name, the template uses the predefined variable.

The template uses Apache Velocity version 1.7 to process the variables. See the [Velocity User Guide](#) for details about usage.

Request URL

Enter the URL for the request in the Raw URL field and select the URL encoding scheme from the pulldown menu. Only UTF-8 and ISO_8858-1 are supported. Verify that the Encoded URL is the exact request to send.

Request URL ⓘ

Method

Raw URL

URL Encoding

Encoded URL

Authentication

You can define basic authentication for your HTTP request. Select **BASIC authentication type** from the **Type** dropdown only if the communication is encrypted. If the communication is not encrypted, we recommend not to use any authentication. After selecting the authentication type, specify the authentication username and password.

You can also upload a TLS certificate and turn on mutual TLS option to authenticate AppDynamics Controller with third party applications such as Slack, PagerDuty, and ServiceNow. This mutual authentication verifies that the alerts (HTTP request actions) sent to the third-party applications are from AppDynamics and not from a malicious entity. See [Configure and Enable Mutual TLS Authentication](#).

i By default, the Mutual TLS Configuration feature is only available in the AppDynamics Controller Tenant UI with the Account Owner role. You can also create a custom role and enable this feature. For more information about the roles, see [Manage Custom Roles](#).

Custom Request Headers

You can define custom headers for the HTTP requests. Custom Request Headers can contain custom templating variables or predefined templating variables encoded as `$(VARIABLE_NAME)`.

For a complete list of predefined variables, see [Predefined Templating Variables](#). Check this list before you create any custom templating variable. See the [Velocity User Guide](#) for details.

Payload

To include a payload in your HTTP request, define the **MIME Type** from the dropdown. You can encode the payload using UTF-8 or ISO-8859-1 encoding.

Response Handling Criteria

Success or Failure

If you do not specify any response-handling criteria for either success or failure, the HTTP response is always success.

Otherwise:

- Failure criteria are evaluated before success criteria. As soon as a match is found on a fail criterion, the response is set to failure and the remaining fail match conditions, if there are any, are not evaluated.
- If no failure criteria are matched, the success criteria are then evaluated.

If no success criteria are configured, the response will always be success as long as no fail criteria were previously matched.

Otherwise:

- If you specify at least one success criterion, there must be a match on a success criterion for the response to be success. In other words, if any success criteria are configured but not matched, the response will be failure.

Both failure and success criteria are considered in the order in which they appear in the template.

Criteria With and Without Payload

You can set separate criteria for the same status code. For example, you can set one criterion on a status with payload as success and another criterion on the same code without payload as failure.

Or, you can set separate criteria for the same status code with payload of different content types. For example, payload of type `application/xml` and `application/xhtml+xml` might be success and payload of other types could be failure.

Content Types for Payload

You can specify the content type for the payload using the dropdown that displays for requests for which the **Expect Payload** checkbox is selected.

If you do not know the content type but the request expects payload, use `*/*` to specify all content types.

This configuration returns a success response for a `200` status code with an XML payload. Any other code will cause the request to return a failure response.

Response Handling Criteria (i)

Failure Criteria

Evaluate the following criteria first. Set action result to "failure" when the HTTP response matches any of the following.

Status Code	Expect Payload	Content Type	

[+ Add Failure Criteria](#)

Success Criteria

Evaluate the following only if there is no match in the above failure criteria. Set the action result to "success" if there is a match in the following, else set it to "failure".

Status Code	Expect Payload	Content Type	
200	<input checked="" type="checkbox"/>	application/xml	-

[+ Add Success Criteria](#)

One Request Per Event

Several separate events, or separate occurrences of the same event, could potentially invoke the same HTTP action.

The **One Request Per Event** setting controls whether the action bundles the HTTP requests.

If this checkbox is clear, the HTTP request is sent once every minute, no matter how many events triggered the action within that time frame. This is the default.

If this checkbox is checked, the request is sent every time an event triggers it. In this case, if ten events trigger the action, the HTTP request is sent ten times, even if all those events occurred within a single minute.

You might want to send one request per event, checkbox checked, if you are trying to log tickets and your ticketing system API does not support bulk create. However, if it does, you probably want a single bulk request every minute, checkbox clear.

Event Clamp Limit

If you have not selected the **One Request Per Event** checkbox and the list of triggering events could be large, you might want to limit the display of the events that triggered the action in the response. The clamp limit is the n most recent triggering events. The default -1 indicates no limit. This setting is ignored if **One Request Per Event** is selected.

Timeouts and Redirects

- **Connect Timeout:** The maximum number of milliseconds to wait for the request to reach the server.
- **Socket Timeout:** The maximum number of milliseconds to wait to receive the response.

- **Max Redirects:** The maximum number of times that a single request can redirect.

Test the Template

To test the template, click **Test** at the bottom of the template configuration.

Configure Test

In the **Template Test** configuration pane, specify the test variables to use for the test. These variables may be different from those that will be used in the real requests that will be automatically sent when the HTTP action is live.

Also, specify the type of events that trigger for the test.

The log level defaults to **INFO**, but you can change this using the **Log Level** dropdown.

This sample test template configuration simulates three **POLICY OPEN CRITICAL** events triggering this action. More triggers could be added.

Run Test

When you run the test, the request is sent when it is triggered. You receive a transcript of the run.

If the results are not what you expect, you may need to modify the template test configuration, the HTTP action template, or both, before you use the template in an action.

Template Examples

Some examples of the templates for the following third party applications:

- [Microsoft Teams](#)
- [Opsgenie](#)
- [PageDuty](#)

- Slack

Create a Template for Microsoft Teams

To send an HTTP request action to Microsoft Teams from AppDynamics, you must create a template in AppDynamics. When AppDynamics triggers an action in response to an event, you can view the details of the action in your Microsoft Teams channel.

i This document contains references to the Microsoft documentation. AppDynamics does not own any rights and assumes no responsibility for the accuracy or completeness of such third-party documentation.

Before you Begin

1. Create a channel in your Microsoft Teams and provide an appropriate name. For example, `AppDynamics Alerts`. This channel is used to receive alerts from AppDynamics. See [Microsoft Teams documentation](#).
2. Create an incoming webhook to the channel that you have created in your Microsoft Teams. See [Microsoft Teams documentation](#).
3. Copy the webhook URL from Microsoft Teams and keep it securely for later use. AppDynamics uses this URL to send the alerts to Microsoft Teams.

Create a Template

1. In the menu bar, click **Alert & Respond**.
2. Click **HTTP Request Templates**.
3. Enter a name for the template. For example, `Send alerts to Microsoft Teams`.
4. In the **Request URL** section:
 - a. Select **POST** as **Method**.
 - b. Enter the webhook URL in the **Raw URL** field.
 - c. Select **UTF-8** as **URL Encoding**.
5. In the **Authentication** section, select **NONE** as **Type**. If you want to enable mutual TLS authentication, select **Also Turn on Mutual TLS**. For more information about mutual TLS, see [Configure and Enable Mutual TLS Authentication](#).
6. In the **Payload** section:
 - a. Select **application/json** as **MIME Type**.
 - b. Select **UTF-8** as **Payload Encoding**.
 - c. Enter the following payload in the text box:

```
{
  "@context": "http://schema.org/extensions",
  "@type": "MessageCard",
  "title": "Event Detected for ${latestEvent.application.name} on node
  ${latestEvent.node.name}",
  "text": "${latestEvent.displayName} - ${latestEvent.eventTime} :
  ${latestEvent.eventMessage} ",
```

```
"themeColor": "#if($latestEvent.severity == "INFO")0075FF#elseif($latestEvent.severity ==
==
"WARN" )ff9500#elseif($latestEvent.severity == "ERROR" )ff3b30#end", "sections": [
{
"activityTitle": "Severity: $latestEvent.severity",
"images": [ {
"image": "${latestEvent.severityImage.deepLink}"
} ]
}, {
"value": "[here](${latestEvent.deepLink})" },
{
"facts": [
{
"name": "View Event",
"value": "[click here](${latestEvent.deepLink})",
},
{
"name": "Open Controller",
"value": "[click here](${controllerUrl} )" }
] },
] }
```

7. In the **Settings** section, select the **One Request Per Event** option.
8. Click **Save**.

Create a Template for Opsgenie

To send an HTTP request action to Opsgenie from AppDynamics, you must create a template in AppDynamics. When AppDynamics triggers an action in response to an event, you can view the details of the action in your Opsgenie.

i This document contains references to the Atlassian documentation. AppDynamics does not own any rights and assumes no responsibility for the accuracy or completeness of such third-party documentation.

Before you Begin

1. Integrate AppDynamics with Opsgenie. For more information, see the Atlassian [Opsgenie](#) documentation.
2. Copy the webhook URL generated by Opsgenie and keep it securely for later use. AppDynamics uses this URL to send the alerts to Opsgenie.

Create a Template

1. In the menu bar, click **Alert & Respond**.
2. Click **HTTP Request Templates**.
3. Enter a name for the template. For example, **Send alerts to Opsgenie**.
4. In the **Request URL** section:
 - a. Select **POST** as **Method**.
 - b. Enter the webhook URL in the **Raw URL** field.
 - c. Select **UTF-8** as **URL Encoding**.

5. In the **Authentication** section, select **NONE** as **Type**. If you want to enable mutual TLS authentication, select **Also Turn on Mutual TLS**. For more information about mutual TLS, see [Configure and Enable Mutual TLS Authentication](#).
6. In the **Payload** section:
 - a. Select **application/json** as **MIME Type**.
 - b. Select **UTF-8** as **Payload Encoding**.
 - c. Enter the following payload in the text box:

```
{
  "event_name": "${latestEvent.displayName}",
  "event_guid": "${latestEvent.guid}",
  "event_id": "${latestEvent.id}",
  "policy": "${policy.name}",
  "event_time": "${latestEvent.eventTime}",
  "app_id": "${latestEvent.application.id}",
  "app_name": "${latestEvent.application.name}",
  "event_message": "${latestEvent.eventMessage}",
  "severity": "${latestEvent.severity}",
  "event_deep_link": "${latestEvent.deepLink}",
  "controller_url": "${controllerUrl}",
  "node_id": "${latestEvent.node.id}",
  "node_name": "${latestEvent.node.name}",
  "summary": "${latestEvent.summaryMessage}",
  "event_type": "${latestEvent.eventType}",
  "tier_id": "${latestEvent.tier.id}",
  "tier_name": "${latestEvent.tier.name}"
  #if(${latestEvent.healthRuleEvent} == true)
  , "health_rule_id": "${latestEvent.healthRule.id}",
  "health_rule_name": "${latestEvent.healthRule.name}",
  "incident_id": "${latestEvent.incident.id}",
  "incident_name": "${latestEvent.incident.name}"
  #end
}
```

7. In the **Response Handling Criteria** section, click **+ Add Success Criteria** and do the following:
 - a. Select **200** as **Status Code**.
 - b. Select the **Expect Payload** check box.
 - c. Select **application/json** as **Content Type**.
8. In the **Settings** section, select the **One Request Per Event** option.
9. Click **Save**.

Create a Template for PagerDuty

To send an HTTP request action to PagerDuty from AppDynamics, you must create a template in AppDynamics. When AppDynamics triggers an action in response to an event, you can view the details of the action in your PagerDuty.

i This document contains references to the PagerDuty documentation. AppDynamics does not own any rights and assumes no responsibility for the accuracy or completeness of such third-party documentation.

Before you Begin

1. Integrate AppDynamics with PagerDuty. See [PagerDuty](#).
2. Copy the integration key and keep it securely for later use. AppDynamics uses this key to send alerts to PagerDuty.

Create a Template in AppDynamics

1. In the menu bar, click **Alert & Respond**.
2. Click **HTTP Request Templates**.
3. Enter a name for the template. For example, `Send alerts to PagerDuty`.
4. In the **Custom Templates Variables** section, click **+ Add Variables** and add the following:

Variable	Default Value
pd_event_type	<ul style="list-style-type: none"> ◦ To open incidents, enter <code>trigger</code> ◦ To close incidents, enter <code>resolve</code>
pd_integration_key	Enter the integration key copied from PagerDuty

5. In the **Request URL** section:
 - a. Select **POST** as **Method**.
 - b. Enter https://events.pagerduty.com/generic/2010-04-15/create_event.json in the Raw URL field.
 - c. Select **UTF-8** as **URL Encoding**.
6. In the **Authentication** section, select **NONE** as **Type**. If you want to enable mutual TLS authentication, select **Also Turn on Mutual TLS**. For more information about mutual TLS, see [Configure and Enable Mutual TLS Authentication](#).
7. In the **Payload** section:
 - a. Select **application/json** as **MIME Type**.
 - b. Select **UTF-8** as **Payload Encoding**.
 - c. Enter the following payload in the text box:

```
{
  "service_key": "${pd_integration_key}",
  "incident_key": "${latestEvent.node.name} - ${latestEvent.application.name}",
  "event_type": "${pd_event_type}",
  "description": "${latestEvent.displayName} on ${latestEvent.node.name}",
  "client": "AppDynamics",
  "client_url": "${controllerUrl}",
  "details": {
    "Event Name": "${latestEvent.displayName}",
    "Summary": "${latestEvent.summaryMessage}",
    "Event ID": "${latestEvent.id}",
    "GUID": "${latestEvent.guid}",
  }
}
```

```

    "Event Time": "${latestEvent.eventTime}",
    "Event Type": "${latestEvent.eventType}",
    "Event Type Key": "${latestEvent.eventTypeKey}",
    "Application Name": "${latestEvent.application.name}",
    "Node Name": "${latestEvent.node.name}",
    "Message": "${latestEvent.eventMessage}",
    "Severity": "${latestEvent.severity}"
  },
  "contexts": [
    {
      "type": "image",
      "src": "${latestEvent.severityImage.deepLink}",
      "alt": "${latestEvent.severity}"
    },
    {
      "type": "link",
      "href": "${latestEvent.deepLink}",
      "text": "View this transaction in AppDynamics"
    }
  ]
}

```

8. In the **Response Handling Criteria** section, click **+ Add Success Criteria** and do the following:
 - a. Select **200** as **Status Code**.
 - b. Select the **Expect Payload** check box.
 - c. Select **application/json** as **Content Type**.
9. In the **Settings** section, select the **One Request Per Event** option.
10. Click **Save**.

Create a Template for Slack

To send an HTTP request action to Slack from AppDynamics, you must create a template in AppDynamics. When AppDynamics triggers an action in response to an event, you can view the details of the action in your Slack channel.

i This document contains references to the Slack documentation. AppDynamics does not own any rights and assumes no responsibility for the accuracy or completeness of such third-party documentation.

Before you Begin

1. Create an app in Slack by using the [Slack API](#) wizard. This app accepts the HTTP requests sent to Slack.
2. Copy the webhook URL generated by the Slack app and keep it securely for later use. AppDynamics uses this URL as a target to send alerts to Slack.

Create a Template in AppDynamics

1. In the menu bar, click **Alert & Respond**.
2. Click **HTTP Request Templates**.
3. Enter a name for the template. For example, `Send alerts to Slack`.
4. In the **Request URL** section:

- a. Select **POST** as **Method**.
 - b. Enter the webhook URL of the Slack app in the **Raw URL** field.
 - c. Select **UTF-8** as **URL Encoding**.
5. In the **Authentication** section, select **NONE** as **Type**. If you want to enable mutual TLS authentication, select **Also Turn on Mutual TLS**. For more information about mutual TLS, see [Configure and Enable Mutual TLS Authentication](#).
6. In the **Payload** section:
- a. Select **application/json** as **MIME Type**.
 - b. Select **UTF-8** as **Payload Encoding**.
 - c. Enter the following payload in the text box:

```
#set( $sm = ${!latestEvent.summaryMessage.replace("'", "*")} )
#set( $sm = $sm.replace("<b>", "*") )
#set( $sm = $sm.replace("</b>", "*") )
#set( $sm = $sm.replace("<br>", " ") )
#set( $sm = $sm.replace("null", " ") )

{
  "blocks": [
    {
      "type": "section",
      "text": {
        #if( ${latestEvent.severity} == "ERROR" )
          "type": "mrkdwn",

7. In the **Settings** section, select the **One Request Per Event** option.
8. Click **Save**.

JIRA Actions

A JIRA action allows AppDynamics to automatically create a JIRA issue when an AppDynamics event is triggered. The event triggers an HTTP custom action for creating a JIRA issue.

You can configure an HTTP/HTTPS proxy for an on-premise controller to filter access to the web server. When you configure a proxy, the JIRA actions are routed through the HTTP proxy or HTTPS proxy, depending on the endpoint. See [Configure HTTP/HTTPS Proxy](#).

JIRA Action Details

The JIRA action is based on templates where each template can be preconfigured with the project, issue type, assignee, and priority. When a JIRA action is triggered, it creates a ticket with those fields in it.

There is a rate limit for the action, which is set to 100 by default. This means the JIRA action will not create more than 100 tickets a minute for an account. Administrators on on-prem Controllers can modify the default by configuring the flag, `max.jira.actions.per.min`, in the **Controller Settings** section of the [Administration Console](#).

This new action needs to be created similar to the rest of the actions, and associated with a health rule for all transition events of the rule (OPEN, CONTINUES, UPGRADE, DOWNGRADE, CLOSE, CANCEL).

This table describes the JIRA action and transitions.

Health Rule Transition (Event)	Reason for Transition	JIRA Action
OPEN (CRITICAL or WARNING)	Health rule violation started.	Creates a JIRA issue. Response of this action provides the JIRA ID which is persisted against the incident.
CONTINUES (CRITICAL or WARNING)	Health rule violation continues.	Fetches the JIRA issue that corresponds to the health rule / affected entity, and updates the JIRA with a comment with the latest violation summary.

Health Rule Transition (Event)	Reason for Transition	JIRA Action
UPGRADE (WARNING → CRITICAL)	Health rule violation now critical.	Fetches the JIRA issue that corresponds to the health rule / affected entity, and updates the JIRA with a comment with the latest violation summary. May change the priority of the issue.
DOWNGRADE (CRITICAL → WARNING)	Health rule violation now warning.	Fetches the JIRA issue that corresponds to the health rule / affected entity, and updates the JIRA with a comment with the latest violation summary. May change the priority of the issue.
CLOSE	Health rule thresholds back within limits, incident closed.	Fetches the JIRA issue that corresponds to the health rule / affected entity, and resolves the JIRA.
CANCEL	Health rule configuration has changed or system lifecycle (restart, entity deleted) caused incident to be cancelled.	Fetches the JIRA issue that corresponds to the health rule / affected entity, and resolves the JIRA.

Create a JIRA Action

To create a JIRA action:

1. Access the **Actions Configuration** pane. See Create and Modify Actions in [Actions](#).

2. Select **Create or Update a JIRA Ticket** in the **Create Action** pane and click **OK**.

Create Action [X]

Select what type of action to create:

Notifications

- Send an email Use template?
- Send an SMS message

Diagnostics

- Start a Diagnostic Session on the selected Business Transactions
- Take a thread dump

Remediation

- Run a script or executable on problematic Nodes

Issue Tracking System Integrations

- Create or Update a JIRA Ticket

HTTP Request

- Make an HTTP Request

Custom Action

- Run a Custom Action that has been uploaded to the Controller

Cancel **OK**

3. Name the action, choose either **Create Ticket** or **Update Ticket**, and select the project, issue type, assignee, and priority from the dropdown menus.

4. Click **Save**.

You can now associate a health rule with a policy that executes the JIRA action. The Atlassian JIRA integration must be set up for the alerts and policies to run.

Configure HTTP/HTTPS Proxy

You can configure an HTTP/HTTPS proxy for an on-premise Controller. When you configure a proxy, the HTTP request actions or JIRA actions are routed through the HTTP proxy or the HTTPS proxy, depending on the endpoint.

Add HTTP Proxy Details to the Configuration File

The `domain.xml` configuration file is the global configuration for managed hosts. Add the HTTP proxy details to the `domain.xml` file as follows:

1. Locate and edit `domain.xml` for the domain.
This is usually located under: `<Controller-Installation-Directory>/appserver/glassfish/domains/domain1/config/domain.xml`.
2. Add the following JVM option to enable the HTTP proxy support for alerting actions:

```
<jvm-options>-Dappdynamics.alerting.actions.http.enable.proxy=true</jvm-options>
```

The HTTP proxy support for alerting actions is disabled by default.

i You can also enable the HTTP proxy support for alerting actions at, `/private/ControllerFlagsServlet` endpoint. You must have admin credentials to enable this option.

3. Add the following JVM options to configure the HTTP and HTTPS proxy authentication parameters, namely, host, port, user, and password.

```
<jvm-options>-Dhttp.proxyHost=$HOST</jvm-options>
<jvm-options>-Dhttp.proxyPort=$PORT</jvm-options>
<jvm-options>-Dhttp.proxyUser=$USER</jvm-options>
<jvm-options>-Dhttp.proxyPassword=$PASSWORD</jvm-options>
<jvm-options>-Dhttps.proxyHost=$HOST</jvm-options>
<jvm-options>-Dhttps.proxyPort=$PORT</jvm-options>
<jvm-options>-Dhttps.proxyUser=$USER</jvm-options>
<jvm-options>-Dhttps.proxyPassword=$PASSWORD</jvm-options>
```

Ensure that you provide a plain text password only.

Proxy parameter changes are not hot-swappable. This means that you need to restart the Controller to ensure that the changes are reflected.

i If you want to exclude some domains from being accessed via the proxy, add them as follows:

```
<jvm-options>-Dhttp.nonProxyHosts=localhost|*.abcd.com|
xyz.com</jvm-options>
```

Action Suppression

You can temporarily suppress a policy's automatic invocation of actions and alerts. You may want to do this while you are performing maintenance on or troubleshooting a component.

To see action suppression configurations created for an application:

1. Click **Alert & Respond > Actions**.
2. Select the desired component such as **Applications**, **User Experience**, **Databases**, or **Servers**.
3. Click **Action Suppression**.

You can configure the entities that the action suppression affects for each object. Within the time period configured for the action suppression, no policy actions are invoked for health rule violation events that occur on the specified objects. You can disable the reporting of metrics for agents associated with the object for which actions are suppressed. This option can cause reported metrics to change without notice. If you see a sudden unexpected change in reported metrics for an object, review the action suppression configurations list to determine whether action suppression with reporting disabled is currently active for that object.

Objects Affected by Action Suppression for an Application

You can configure action suppression for a specific time period to apply to a specific object or several objects. These entities can be the objects of action suppression:

- Application
- Business Transaction
- Tier

- Node
- Server

The table lists the entities for which you can suppress the actions depending on the configured object scope for an application.

Object Scope	Affected Entities
Application	All entities within the application.
Business Transaction	<ul style="list-style-type: none"> • All business transactions in the application. • All business transactions within specific tiers. • Specific business transactions. • Business transactions with names having patterns that match certain criteria (such as all business transactions with names that start with "XYZ").
Tiers	<ul style="list-style-type: none"> • All tiers in the application. • Specific tiers. <p>In a tier-level configuration, the suppression affects:</p> <ul style="list-style-type: none"> • all the nodes in the specified tier(s) • individual node health rules as well as tier-level health rules <p>For example, if a tier-level health rule is configured to invoke an action when a percentage of the nodes violates the condition, and then action suppression is configured on certain nodes in that tier, those nodes are still evaluated by the tier-level health rule.</p>
Nodes	<ul style="list-style-type: none"> • All nodes • Java nodes • .NET nodes • PHP nodes <p>Within these node types you can suppress actions for:</p> <ul style="list-style-type: none"> • All nodes • Nodes in specific tiers • Specific nodes • Nodes with names, meta-info, environment variables or JVM system environment properties with specified matching criteria <p>In a node-level configuration, the suppression affects node health rules only.</p>
Servers	<ul style="list-style-type: none"> • All servers • Specific servers

Objects Affected by Actions Suppression for Databases

The table lists the entities for which you can suppress the actions depending on the configured object scope for databases.

Object Scope	Affected Entities
All Databases	All databases in the account
Specific Databases	Databases that you have selected in the account

Objects Affected by Actions Suppression for Servers

The table lists the entities for which you can suppress the actions depending on the configured object scope for servers.

Object Scope	Affected Entities
Any Object	All objects within the servers.
Subgroups	<ul style="list-style-type: none"> All subgroups of the servers Specific subgroups
Servers	<ul style="list-style-type: none"> All servers in the account All servers within the specific subgroups Specific servers Servers matching the specific criteria such as starts with, ends with, contains, equal, or matches Reg Ex.

Health Rules Affected by Action Suppression

By default, an action suppression configuration applies to actions triggered by all events that are generated by the configured objects.

You can refine the configuration to apply only to actions triggered by specific health rule violations. For example, if an application contains HealthRuleA, HealthRuleB and HealthRuleC, but only HealthRuleC is configured for action suppression, actions will continue to be invoked for violations of HealthRuleA and HealthRuleB during the configured time period.

Disable Health Rule Evaluation

Suppressing an action does not suppress the evaluation of any health rules linked to the action through a policy. Health rule violation events continue to be raised even when actions are suppressed. You can turn off the evaluation of a specific health rule or all health rules. See [Disable All Health Rules](#).

Configure and Manage Action Suppressions

You can create, edit, or delete an action suppression in the **Action Suppression** tab. To access the action suppression configuration, click **Alert & Respond > Actions > Action Suppression**.

Create an Action Suppression

-  Configure the panels in the same order as displayed in the interface, because the configuration of the object scope determines the available affected entities present in the object scope panel.

1. In the **Action Suppression** panel, click the **Create +** icon. The **Create Action Suppression** wizard appears.
2. In the **Overview** panel, enter a name for the action suppression. You can use alphanumeric characters to specify a name.

-  Ensure that you specify a unique name.

3. To prevent the agents defined in the object scope from reporting metric data during the action suppression active time frame, select **Disable Agent Reporting**.
4. From the **Time Zone** dropdown, select a time zone based on your location.
5. To suppress actions only once, configure these **One Time** settings:
 - **Planned Maintenance:** Select this option if you want to suppress actions for an upcoming planned maintenance or downtime period of your system. Specify the following:
 - i. **Start Time:** The time to start action suppression. You can choose:
 - **Now**—to suppress actions immediately.
 - **After**—to suppress actions after the defined number of minutes.
 - **Date**—to suppress actions on a date, at a defined time.
 - ii. **End Time:** The time to stop action suppression. You can choose:
 - **After**—to stop suppressing the actions after the defined number of minutes.
 - **Date**—to stop suppressing actions on a date, at a defined time.
 - **Unplanned Past Outage:** Select this option if you want to record an unplanned maintenance or downtime period of your system that happened in the past. This option is useful when you want to exclude the metrics reported by the agents during the unplanned maintenance or downtime period from reporting and analytics. Specify the following:
 - i. **Start Time:** The past date and time when the unplanned maintenance or downtime had started.
 - ii. **End Time:** The past date and time when the unplanned maintenance or downtime had ended.
6. To suppress actions on a recurring basis, configure these **Recurring** settings:
 - **Daily**—to suppress actions every day from the defined **Start Time** to the **End Time**.
 - **Weekly**—to suppress actions on a specific day of a week from the defined **Start Time** to the **End Time**.
 - **Monthly**—to suppress actions on a specific date or a day of the month.
 - **Specific date**—to suppress actions starting on a specified **Start Date** and **Start Time** through the **End Date** and **End Time**.
 - **Specific day**—to suppress actions starting on a specified day and **Start Time** through the **End Time**.
7. In the **Object Scope** panel, select what entities that the action suppression affects. Depending on the type of object, you can configure the corresponding entities that are affected. See [Entities Affected](#) for information about the type of entities that can be affected by various objects.
8. To suppress actions only for the violations caused by specified health rules:
 - a. In the **Health Rule Scope** panel, select **Suppress Action execution for these specified Health Rules**.
 - b. Click **Add**. The **Health Rule Selection** dialog appears.
 - c. Select the health rules and click **Select Health Rule(s)**.
9. Click **Create**.

Edit an Action Suppression

To modify an action suppression configuration, click the **Edit** icon.

Delete an Action Suppression

To delete a configured action suppression, click the **Delete** icon. A dialog asks you to confirm the deletion.

Predefined Templating Variables

This page describes the predefined variables that can be used in an HTTP request template or in an email template. The policy engine substitutes the value of the variable in the context of the triggering event(s) when it sends the actual request or email.

Form Variable Names

To form a predefined variable name, combine the base name of the variable with a field of its corresponding info class. You can use the base name with the corresponding info class only for example, you can use the base name `action` with info class `ActionInfo` only.

If an info class has no fields associated, use the base name as the variable. For example, to use the controller URL as a variable in a template, use `${controllerUrl}`.

If an info class comprises multiple fields, select a single field and associate it with the base name. For a list of fields associated with an info class, see [Info Class Fields](#).

For example:

- To use the account name as a variable in a template, combine the base name `account` with the `name` field of the `EntityInfo` class to form the variable `${account.name}`.
- To use the trigger time of an action as a variable, combine the base name `action` with the `triggerTime` field of the `ActionInfo` class to form the variable `${action.triggerTime}`.

You can chain the segments of a variable name where the info class field type is yet another info class.

For example, to use the name of an application in which the latest triggering event occurred:

- Combine the `latestEvent` base name with the `application` field of the `EventInfo` class.
- The field type of the `application` field is `EntityInfo` which is yet another info class, hence select the `name` field of the `EntityInfo` class.
- Form the variable name by appending the segments:
`{ <base name>.<field name of info class1>.<field name of info class2> }`
`${latestEvent.application.name}`.

Base Names

This tables describes the base names for the predefined variables with their corresponding info classes.

Base Name	Description	Info Class
<code>account</code>	Account in which the action was triggered.	<code>EntityInfo</code>
<code>policy</code>	Policy that triggered the action.	<code>PolicyInfo</code>
<code>action</code>	Triggered action.	<code>ActionInfo</code>
<code>topSeverity</code>	<code>INFO</code> , <code>WARN</code> or <code>ERROR</code> .	<code>NotificationSeverity</code>

Base Name	Description	Info Class
topSeverityImage	Severity image or icon.	ImageInfo
notificationConfigText	Email actions only.	String
controllerUrl	URL of the controller.	String
appDynamicsIcon	-	ImageInfo
appDynamicsLogo	-	ImageInfo
latestEvent	Most recent triggering event.	EventInfo
fullEventList	List of events that triggered the action.	List<EventInfo>
fullEventsByTypeMap	List of events that triggered the action, grouped by type.	Map<String, List<EventInfo>>
clampLimit	Optional setting, limit on how many triggering events to display.	int
clamped	True if clamp limit is set.	boolean
clampedEventList	<i>n</i> most recent triggering events if clamped.	List<EventInfo>
clampedEventsByTypeMap	<i>n</i> most recent triggering events if clamped, grouped by type.	Map<String, List<EventInfo>>
fullEventsNodeMap	Node level variables to be used in email and HTTP templates.	Map<EventInfo, NodeTemplateVariables>

Info Class Fields

From the previous Base Names table, use the fields in the appropriate class to form the variable to use in a template.

```

class EventInfo {
  EventType eventType
  long id
  String guid
  String eventTypeKey
  Date eventTime
  String displayName

```

```

String summaryMessage
String eventMessage
EntityInfo application
EntityInfo tier
EntityInfo node
EntityInfo db
List<EntityInfo> affectedEntities
boolean healthRuleEvent
EntityInfo anomaly // * Only defined in case of anomaly event
EntityInfo healthRule // * Only defined when healthRuleEvent == true
EntityInfo incident // * Only defined when healthRuleEvent == true
boolean healthRuleViolationEvent
NotificationSeverity severity
ImageInfo severityImage
boolean btPerformanceEvent // * true when eventType matches one of the BT performance event
types
String deepLink
}

class ImageInfo {
  String name
  String fileName
  String mimeTypeRef
  String deepLink
}

class EntityInfo {
  EntityType entityType
  String entityTypeDisplayName
  long id
  String name
}

class ActionInfo extends EntityInfo {
  Date triggerTime
}

class PolicyInfo extends EntityInfo {
  boolean digest
  digestDurationInMins
}

class PolicyInfo {
  EntityType entityType
  String entityTypeDisplayName
  long id
  String name
  boolean digest
  int digestDurationInMins
}

```

```

class ActionInfo {
    EntityType entityType
    String entityTypeDisplayName
    long id
    String name
    Date triggerTime
}
enum NotificationSeverity { INFO, WARN, ERROR }

class NodeTemplateVariables {
    private long id;
    private String name;
    private long tierId;
    private String tierName;
    private long machineId;
    private String machineName;
    private boolean machineAgentPresent;
    private String machineAgentVersion;
    private boolean appAgentPresent;
    private String appAgentVersion;
    private String ipAddresses;
    private AgentType agentType;
}

```

- The private String ipAddresses field contains hostnames instead of IP addresses.
- Sample values of EventType : POLICY_OPEN_WARNING, POLICY_CONTINUES_WARNING, POLICY_OPEN_CRITICAL, POLICY_CONTINUES_CRITICAL, POLICY_UPGRADED, POLICY_DOWNGRADED, POLICY_CLOSE_WARNING
- Sample values of EntityType : BUSINESS_TRANSACTION, TIER_NODE, SERVICE_ENDPOINTS, INFORMATION_POINTS, SERVERS_IN_APPLICATION, AJAX_REQUEST, DATABASES_IN_APPLICATION, MOBILE_NETWORK_REQUESTS

Examples

HTTP request example for most recent triggering event:

```

http://myController:8080/controller/rest/applications/${latestEvent.application.name}/nodes/${latestEvent.node.name}

```

HTTP request example iterating through a list of triggering events:

```
#foreach(${event} in ${fullEventList})
  http://myController:8080/controller/rest/applications/${event.application.name}/nodes/${event.node.name}
#end
```

Email with dynamically varying subject example:

If you have several health rules to monitor your application and one policy to send email notification for all the health rules, you might find it difficult to search for the correct information in the notification. You can define a variable to dynamically update the email subject based on the event that triggered the notification.

Ensure that you define the subject variable in the email body and include it in the subject field.

```
Subject: $subject
Body:
...
<!-- Subject changes dynamically based on the triggering event -->
#foreach(${events} in ${fullEventList})
#set($subject = ${events.eventType.toString()}) #end
...
```

Email HTML body example:

AppDynamics uses this email template to notify the details of the events occurring on an application. You can customize the required event details you want notified by enabling the event types.

```
<!-- Default AppDynamics email template -->

#if( ${notificationConfigText} != '' )
${notificationConfigText}
#else
AppDynamics
#end
Event Notification for the "${latestEvent.application.name}" Application
Event Notification Name: ${policy.name}
Event Notification Severity: ${topSeverity}

Summary of events occurring during the ${policy.digestDurationInMins}+ minute(s) prior to $
{action.triggerTime}:
## Summary table
|| Event Type | Count ||
## Copy this row for each event type and count
#foreach($eventTypeEntry in $fullEventsByTypeMap.entrySet())
|| ${eventTypeEntry.getKey()} | ${eventTypeEntry.getValue().size()} ||
#end

## Full List of Events
The following events occurred during the time frame:
#if ($clamped)
```

Warning: The event list has been clamped at `${clampLimit}` results! Please see the event and/or request snapshot viewers **for** the full list of events.

```
#end
|| Event Time | Event Type | Severity | Tier | Node | Summary ||

#foreach($eventList in $clampedEventsByTypeMap.values())
  #foreach($event in $eventList)
    || ${event.eventTime} | ${event.displayName} | ${event.severity} | ${event.db.name} | ${event.tier.name} | ${event.node.name} | ${event.summaryMessage} ||
  #end
#end
Event Notification from AppDynamics.
This is an auto-generated email summarizing events on the "${latestEvent.application.name}" application. You are receiving this because you are configured as a recipient on the "${policy.name}" event notification. This is not necessarily an exhaustive list of all events during this time frame. Only those event types enabled in the notification will appear in this message.
```

Example to extract event details using iteration:

These examples iterate through the `eventList` to extract the details of each event occurring during the specified time.

```
<h1>Summary of events occurring during the ${policy.digestDurationInMins}+ minute(s) prior to ${action.triggerTime}</h1>

<table>

#foreach(${eventList} in ${fullEventsByTypeMap.values()})
  #foreach(${event} in ${eventList})

    <tr>
      <td>
        <!-- Event icon -->
        
      </td>
      <td>
        <!-- Event name with event link -->
        <a href="${event.deepLink}">${event.displayName}</a>
      </td>
      <td>
        <!-- Event message -->
        ${event.eventMessage}
      </td>
    </tr>

  #end
#end

</table>
```

Example code to list all variables:

```
<h1>variables below </h1>
${fullEventsNodeMap}
<h2>map elements below</h2>
#foreach(${value} in ${fullEventsNodeMap.values()})
${value}
${value.name}
#end
```

If these predefined variables do not meet your needs, you can define your own custom variables for use in these templates in the **Create Template** pane.

 Do not use any of the predefined variable names for your custom variables.

Email Digests

This page provides an overview of email digests in AppDynamics. In addition to specific actions that are triggered by specific events, you can create an email digest that reports a summary of specific events to a recipient list on a schedule.

Permissions

To create, edit, or delete email digests, a user must have the Configure Actions, Configure Health Rules, and Configure Policies permissions.

Sample Email Digest

This is a sample of an email digest that is sent every hour:

Error Digest

Summary of events occurring during the 60+ minute(s) prior to Fri Oct 18 15:02:55 EDT 2013:

Count	Event Type
318	ERROR

[Business Transaction Error](#)

Fri Oct 18 14:52:51 EDT 2013

[Error] - com.appdynamicspilot.oracleJDBC.OracleQueryExecutor : Could not get JDBC Connection; nested exception is org.apache.commons.dbcp.SQLNestedException: Cannot create PoolableConnectionFactory (IO Error: The Network Adapter could not establish the connection)
com.appdynamicspilot.oracleJDBC.OracleQueryExecutor : This may be ignored in case of Oracle is not setup -

[Business Transaction Error](#)

Create an Email Digest

To create an email digest, navigate to **Alert & Respond > Email Digests** on either the right panel or in the left navigation pane. Follow the steps in the wizard to create the digest.

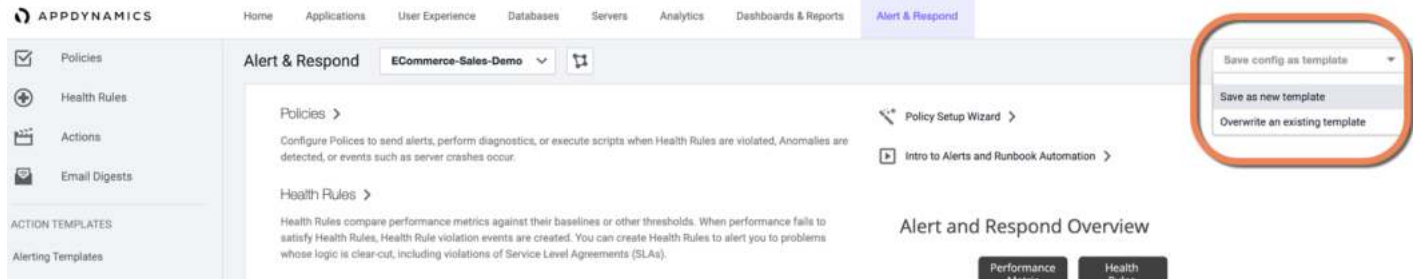

Alerting Templates

An alerting template is a configuration of features such as Health Rules, Policies, Actions, Action Suppression, Schedules, and Email Digests. You can save the **Alert & Respond** configuration of an existing application as a template. Templates help maintain consistent configuration across various applications regardless of their location, version, or environment.

How to Use an Alerting Template

You can save the **Alert and Respond** configuration of an existing application as a template. You can use the **Save as new template** option. You can apply the template to other applications to replicate the configuration.

After configuring an alerting template, if you require to change the configuration and apply the changes to all the applications, use the **Overwrite an existing template** option. The existing template is overwritten. You can then re-apply the template to the desired applications. For more information, see [Configure and Manage Alerting Templates](#).

Alerting Template Operations

To view alerting templates, select **Alert & Respond > Alerting Templates**. The alerting templates list displays all templates. You can create and manage the templates using the **Alerting Template** interface.

This table lists the template operations:

Operation	Description
	View the configuration details of the selected template(s). For more information, see View Alerting Template Details .
	Create a new template. For more information, see Create an Alerting Template .
	Overwrite a selected template. Any changes you make, overwrite the existing configuration when you save the template. For more information, see Overwrite an Alerting Template . When you edit a template, the updates are not applied to applications using the template. You must re-apply the template to the desired applications.
	Delete an existing template. For more information, see Delete an Alerting Template . The configuration of applications using the template remains intact even after you delete the template.
	Import a saved template configuration. Use this option when you have saved the configured alerting template and want to apply it to other applications.
	Export a template configuration for future use. Use this option when you have configured an alerting template and want to save it for future use.

Operation	Description
	Apply a template to the selected application(s). For more information, see Apply Template to Application(s) .
<input type="text" value="Search"/> 	Search for a template.

Configure and Manage Alerting Templates

You can create a new alerting template in **Alert & Respond > Alerting Templates**. Alternatively, you can configure the **Alert and Respond** features in the Controller UI and save the configuration as an alerting template.

 JMX Health Rules are not supported.

View Alerting Template Details

To view the configuration details of an existing alerting template:

1. Select a template.
2. Click the view icon to view the configuration details.
3. To edit the template, view template history, or apply the template to other application(s), click **More**.

Create an Alerting Template

Ensure that you create and configure the health rules, policies, actions, action suppression, and email digests you plan to use to create the alerting template before you create the template.

1. Click the create icon. The **New Template** wizard displays.
2. Enter a name for the template. You can use alphanumeric characters to specify a name. Ensure that you specify a unique name.
3. If required, include a description. Click **Next**.
4. Select an **Application** from the list displayed in **Choose an Application**. The configuration you define for this application is saved as a template. Click **Next**.
5. Select the following feature configuration as required:
 - a. Policies
 - b. Health Rules
 - c. Actions
 - d. Action Suppression
 - e. Email Digests
6. Click **Next**.
7. Review the configuration settings you have defined. Click **Save**.

Overwrite an Alerting Template

If you make any inadvertent updates to a template, the changes cannot be reverted. You can update the template using the overwrite option, which overwrites the existing configuration with the updates you made when you save the template.

1. Select the template and click the overwrite icon. The **Overwrite Existing Template** wizard displays.
2. Select the application whose configuration you want to save as a template. Click **Next**.
3. Modify the pre-configured features as necessary. Click **Next**.
4. Review the configuration settings you have defined. Click **Overwrite**.

Once you overwrite the configuration of a template and save it, you cannot revert the changes.

Any updates made to the template are not applied to all the applications using the template. You must re-apply the modified template to applications.

Delete an Alerting Template

You can delete a template if you no longer use it. When you delete a template, the applications using the template are not affected. The application configuration also remains intact. You can continue to use the applications as before.

1. Select the template and click the delete icon.
2. Click **Delete**.

 Once you delete a template, you cannot restore it.

Import an Alerting Template

You can import a saved alerting template and apply it to other applications.

1. Click the import icon. The **Import Template** dialog displays.
2. Click  and select a file to import.

 Ensure that:

- You select a JSON file to import.
- The file you want to import has a unique name, otherwise the file is not imported.

3. Click **Import**. The selected file is imported and displays in the **Alerting Templates** UI.

Export an Alerting Template

You can export a saved alerting template and apply it to applications in other accounts.

1. Select a template to export.
2. Click the export icon. The **Template exported successfully** message displays.

Apply Template to Application(s)

After you create an alerting template, you can apply the template to multiple applications.

1. In the **Alert & Respond > Alerting Templates**, select the template and click . The **Apply Template** wizard displays.
2. In **Choose Application(s)**, select the applications to apply the template. Click **Next**. Use the **Search** option if the list of templates is too long.
3. To add the template configuration (such as policies, health rules, and actions) to the existing configuration of the selected applications:
 - a. In **Choose How to Apply Template**, select **Add/Merge**. Click **Apply**. The **Add/Merge** operation status displays.

- b. The alerting configuration of the template is added to the selected application(s).
- c. If you see an error or warning for an application, refer to **Check the Status of the Applications** to fix it.

 If the entities (such as Health Rule, Policy, Action, Action Suppression, or Email Digest) exist in the template and the application, the configuration of the template entity replaces the configuration of the application entity.

4. To replace the existing configuration of an application with the configuration of the selected template:
 - a. Select **Replace**.
 - b. Click **Apply**.
 - c. A confirmation dialog displays. Click **Yes** to confirm. The **Replace** operation status displays.

 This operation replaces the alerting configuration of all the entities of the selected application(s), such as the health rules, policies, and actions, with that of the alerting configuration of the template. The existing alerting configuration of the selected application(s) is deleted permanently. Perform this operation only if you want to replace all the entities you have configured.
If you see an error or warning for an application, refer to **Check the Status of the Applications** to fix it.

Check the Status of the Applications

You can check if the template was successfully applied to all the applications.

1. Click the **Status** of the template. The **Template History** page listing the status of each application displays.
2. If an error is listed on the **Template History** page, click the error to determine the cause of the error and the exact location.
3. Fix the error and then re-apply the template to the affected application.

Alerting Template Questions and Answers

This page lists some questions and answers that help you use the alerting template.

As an on-premises customer, will I be able to use the alerting template?

Yes, this feature is available for on-premises users.

Will this feature require an agent upgrade?

This feature does not require any agent upgrade.

Do I need role-based access privileges to use alerting templates?

No, any user can create and manage alerting templates.

When I update a template, will the changes be applied to all applications using the template?

No, when you update a template, you need to re-apply the template to the application(s) to ensure that the updates are reflected.

Where can I view all the templates I created?

You can view the template library in the **Alert & Respond > Alerting Templates** UI. For more details, see [View Alerting Template Details](#).

What are two ways to create a template?

You can save the Alert and Respond configuration of an existing application as a template using the **Save as new template** option.

After configuring an alerting template, if you require to change the configuration, use the **Overwrite an existing template** option.

Can I apply a template without selecting an application?

No, you can apply a template only to an application. Hence, you must select an application.

Where can I track the status of applying a template?

You can check if the template was successfully applied to all the applications. From the **Alert & Respond > Alerting Templates** UI, click the **Status** of the template. The **TEMPLATE HISTORY** page listing the status of each application displays.

Will updates to a template be applied to an application that is being edited by someone?

No, the template history page displays an error in the status column. Complete your edits to the application, then apply the updated template.

When I update a template, will I be able to revert the changes?

No, once you configure a template and save it, you cannot revert the changes. If you make any inadvertent updates to a template, you can overwrite the configuration and save the template again. For more information, see [Overwrite an Alerting Template](#).

Can I edit a template?

You can overwrite the configuration of an existing template. If you make any inadvertent updates to a template, you can overwrite the configuration and save it. For more information, see [Overwrite an Alerting Template](#).

When I delete a template, what happens to the applications using the template?

When you delete a template, the applications using the template are not affected. The application configuration also remains intact. You can continue to use the applications as before.

When I update a feature (for example a Health Rule) and re-apply the template, will the other associated features (like Policies, Actions) get selected by default?

Yes, when you update a feature within a template and re-apply it, all other associated features are selected by default.

Can I restore a deleted template?

Once you delete a template, it is lost, you cannot restore it.

Can I make an update to a single application without affecting the other applications using the template?

1. In the **Alert and Respond** UI, select the application you want to update.

2. Select the feature you want to modify (for example, policy, health rule).
3. Update the required configuration and save.

I made an inadvertent change to a template, how can I correct it?

You can delete the template, create a new one, and apply the template to the required applications.

 Once you delete a template, you cannot restore it.

Can I overwrite a template?

You can overwrite the configuration of a template and save it. You must re-apply the template to all applications. You can either replace an existing application configuration or append to it.

How can I apply a template to an existing application?

You can apply a template to an existing application with two methods:

- **Add/Merge**—The alerting configuration of the template is added to the selected application(s). If the entities (such as Health Rule, Policy, Action, Action Suppression, or Email Digest) exist in both the template and the application, the configuration of the template entity replaces the configuration of the application entity.
- **Replace**—This operation replaces the alerting configuration of all the entities of the selected application(s), such as the health rules, policies, and actions, with that of the alerting configuration of the template. The existing alerting configuration of the selected application(s) is deleted permanently. Only perform this operation if you want to replace all the entities you have configured.

For more information, see [Apply Template to Application\(s\)](#).

Can I apply a template to multiple applications at a time?

Yes, you can. For more information, see [Apply Template to Application\(s\)](#).

Configure and Enable Mutual TLS Authentication

Mutual TLS is a mutual authentication method that encrypts the traffic between the client and the server by authenticating each other using their public-private key pair.

In AppDynamics Controller, you can enable **Mutual TLS** to authenticate the Controller with third-party applications such as Slack, PagerDuty, and ServiceNow. This mutual authentication verifies that the alerts (HTTP request actions) sent to the third-party applications are from AppDynamics and not from a malicious entity.

Configuring mutual TLS authentication involves the following steps:

1. [Generate a Certificate Signing Request \(CSR\) for your TLS certificate](#)
2. [Get the CSR signed from a Certificate Authority and upload the signed TLS certificate](#)
3. [Enable mutual TLS authentication in HTTP request actions](#)

 By default, the Mutual TLS Configuration feature is only available in the AppDynamics Controller Tenant UI with the Account Owner role. You can also create a custom role and enable this feature. For more information about the roles, see [Manage Custom Roles](#).

Generate a Certificate Signing Request

To configure mutual TLS authentication, you need to first generate a certificate signing request (CSR) to get your TLS certificate:

1. In the AppDynamics Controller Tenant UI, click **Alert & Respond > Mutual TLS Configuration**.
2. Click **+ New Certificate Signing Request (CSR)**.
3. Enter the following details:
 1. **Organization (Optional)**. The legal name of your organization.
 2. **Department (Optional)**. The name of your department handling the certificate.
 3. **Country**. Select the country where your organization is located. By default, the country selected is the United States. Note that this field is mandatory and can't be left blank.
 4. **State (Optional)**. The name of the state where your organization is located.
 5. **City (Optional)**. The name of the city where your organization is located.
- Click **Generate CSR**.
- Click **Download CSR** to download the `.csr` file. Note that you can also copy the content and save as a `.csr` file.

When you generate a CSR, AppDynamics creates a public- private key pair. The public key is available with the CSR and the private key resides with AppDynamics in a secure key store.

Sign the CSR and Upload the Signed TLS Certificate

After downloading the CSR file, you must get it signed from a certificate authority (CA) of your choice. You can then upload the signed TLS certificate. AppDynamics Controller also supports certificate chain. A certificate chain consists of a leaf certificate and intermediate certificates.

i The intermediate certificate must be created by using the `.ext` file provided by your certificate authority.

To upload the signed TLS certificate on your AppDynamics Controller:

1. Click **Upload New Client Certificate**.
2. Upload the signed TLS certificate (`.pem` file) directly or copy and upload the Base64 encoded text from the TLS certificate.

i If you have a certificate chain, upload only the leaf and intermediate certificates as a single `.pem` file. Or copy and upload the Base64 encoded text of the the leaf and intermediate certificates. Do not upload the root certificate.

The following sample illustrates a certificate chain that consists of a leaf certificate and an intermediate certificate:

i **Certificate chain sample**

-----END CERTIFICATE-----

```

Points to consider:

Before uploading a new TLS certificate, ensure the following points are met:

- The certificate must be either in the `.pem` or `.crt` format.

- The certificate encoding scheme must be Base64.
- The certificate must have a valid expiry date.
- The certificate must be a client certificate.
- The certificate must match with the corresponding CSR.
- For a certificate chain,:
 - all the certificates must be uploaded by using a single `.pem` file.
 - the first certificate must be the leaf certificate and the subsequent certificates must be the intermediate certificates. Each certificate must be signed by the subsequent certificate.
 - the leaf certificate must be a client certificate.
 - the leaf certificate must have a valid expiry date.
 - the leaf certificate must match the corresponding CSR.
 - the length of the certificate chain must not be greater than the length specified in the flag `appdynamics.controller.alerting.mtls.max.certificate.chain.length`. See [Controller Setting for Certificate Chain Length](#).

If you face any error while uploading the signed TLS certificate, refer [Troubleshoot Mutual TLS Certificate Issues](#).

View the TLS Certificate

Click **Alert & Respond > Mutual TLS Configuration** to view the uploaded TLS certificate. You can also click **Download Certificate** to download the `.pem` file.

If you have generated a CSR that is not yet used, you can view and download the unused CSR.

Enable Mutual TLS in HTTP Request Actions

After uploading the TLS certificate, you can enable the mutual TLS authentication for HTTP request actions. AppDynamics fetches the TLS certificate and attaches it with the HTTP request actions (alerts). On third-party endpoints that are configured to receive alerts from AppDynamics, the certificate helps to verify that the alerts are from AppDynamics.

To enable the mutual TLS authentication:

1. Click **Alert & Respond > HTTP Request Templates**.
2. Do one of the following:
 - Select an existing template for which you want to enable mutual TLS and click **Edit**.
 - Click the **+ New** icon to create a template. See [Create or Modify an HTTP Request Template](#).
3. In the **Authentication** section, select the **Also Turn on Mutual TLS** option.

 This option is enabled only if you have uploaded a TLS certificate.

4. Click **Save**.

Controller Setting for Certificate Chain Length

The Cisco Accounts team can specify the maximum length of the certificate chain.

To change the length of the certificate chain:

1. Log in to the Controller administration console using the root user password.

```
http://<controller host>:<port>/controller/admin.jsp
```

2. Select **Controller Settings**.

3. Locate the flag `appdynamics.controller.alerting.mtls.max.certificate.chain.length` and update its value. The default value is 2.
4. Click **Save**.

Troubleshoot Mutual TLS Certificate Issues

When you upload a signed TLS certificate on your AppDynamics Controller, the Controller validates the certificate. If the certificate does not conform to the upload requirements, you see an error and the upload fails. This document explains the errors that you might encounter and how to resolve them.

Error: Certificate information does not match the CSR

When you generate a certificate signing request (CSR), AppDynamics creates a public-private key pair. The private key resides with AppDynamics in a secure key store. The public key is available with the CSR. You need to get the same CSR signed by a Certificate Authority (CA) of your choice to get the signed TLS certificate. For mutual TLS to work, you must upload the signed TLS certificate to your AppDynamics Controller. When you upload a TLS certificate that is signed using a different CSR, the public-private key pair mismatches and AppDynamics Controller displays an error.

Resolution:

You must upload a signed TLS certificate that is signed with the same CSR so that the public-private key pair matches.

Error: Only client certificates are supported

In the mutual TLS authentication, AppDynamics Controller acts as a client and the endpoint to send the alerts acts as a server. Therefore, when you upload a signed TLS certificate, AppDynamics Controller checks whether the certificate is a client certificate. If you upload a server certificate, you get this error.

Resolution:

From **Alert & Respond > Mutual TLS Configuration**, download an used CSR or generate a CSR and get it signed by a CA. Then upload the signed TLS certificate.

Error: Only Base 64-encoded certificates are supported

AppDynamics Controller supports only the Base64-encoded certificates for mutual TLS authentication. Base64 is the industry standard format for encoding the SSL certificate content. The following example shows a Base64-encoded certificate, where the content is enclosed within `BEGIN CERTIFICATE` and `END CERTIFICATE` clause:

```
-----BEGIN CERTIFICATE-----
MIIB0TCCATqgAwIBAgIQUq+2SdEkLr5K6xqjSEvRsDANBgkqhkiG9w0BAQUFADAU
MRIwEAYDVQQDEwLsb2NhbGhvc3QwHhcNMTIwODA0MDA0TEyWhcNMTcwODA0MDAw
MDAwWjAUMRIwEAYDVQQDEwLsb2NhbGhvc3QwZ8wDQYJKoZIhvcNAQEBBQADgY0A
...
Y2nd44bYEpmaby7XJ5UIGekuD3VixT2S+2bCwkRR+9/+7vggR2q7l7YEktM2mFBI
yqOM0roAw+5cdc06c/B7UimwKFczsyhi9LUIr3rXI42FdXBHw==
-----END CERTIFICATE-----
```

If you upload a signed TLS certificate that is not Base64-encoded, you get this error.

Resolution:

Copy and upload the Base64 encoded text along with the `BEGIN CERTIFICATE` and `END CERTIFICATE` clauses from the TLS certificate.

Error: The certificate has expired

The signed TLS certificate has an expiry date specified by the applicant or the CA. If you upload a TLS certificate that has already expired, you get this error.

Resolution

From **Alert & Respond > Mutual TLS Configuration**, generate a CSR and get it signed by a CA. Then upload the signed TLS certificate.

Error: Certificate chain is not valid.

The certificate chain must have a leaf certificate and intermediate certificates. The first certificate must be the leaf certificate and the subsequent certificates must be the intermediate certificates. Each certificate must be signed by the subsequent certificate. If you upload a certificate chain where this order is missing, you get this error.

Resolution

Upload a valid certificate chain that contains the certificates in the correct sequence.

Error: Certificate chain depth cannot be more than the limit.

The maximum length of the certificate chain that you can use depends on the value in the flag `appdynamics.controller.alerting.mtls.max.certificate.chain.length`. This flag resides in the **Controller Settings** page. By default, the flag value is two. If the length of your uploaded certificate chain is more than specified value, you get this error.

Resolution

Upload the certificate chain whose length is within the value specified in the flag `appdynamics.controller.alerting.mtls.max.certificate.chain.length`. However, you can update the value of the flag. See [Controller Setting for Certificate Chain Length](#).

Troubleshoot Alert and Respond Problems

Health Rules

Why do I see consistent false alerts; logs display an error 'Error sending metrics'?

This happens when you configure a highly sensitive condition for a health rule.

When you define a very small evaluation time frame (for example, 3 mins) for a health rule condition, few configured metrics may fail to report data during the short time frame due to reasons such as network errors. This may not be the norm, however, alerts are triggered even if a single data point is not reported leading to consistent false alerts.

AppDynamics recommends that you configure a higher time frame to evaluate a health rule condition.

Dashboards and Reports

This page provides an overview of dashboards and reports in AppDynamics.

Dashboards and Reports are useful for getting a high-level understanding of the health and performance of your system on a regular basis.

Dashboards provide a graphical overview of the selected data made available for quick access. Custom dashboards let you create and arrange widgets to give users a visual overview of the data of interest to them. A War Room is similar to a dashboard, but it is interactive. The chat facility in virtual war rooms enable visually-enhanced collaborative troubleshooting in real-time in response to high priority events.

Reports capture and share AppDynamics data from dashboards to recipients. Reports can be automatically generated on a regular schedule.

Custom Dashboards

Deployment Support

Related Pages:

- [Create and Manage Custom Dashboards and Templates](#)
- [Virtual War Rooms](#)
- [Custom Dashboard Permissions](#)
- [Dashboard Recovery](#)

This page provides an overview of custom dashboards in AppDynamics.

A custom dashboard enables you to display a specific set of metrics and data points on one screen. You can display application, server, and database metrics reported by AppDynamics agents. You can also supplement the AppDynamics built-in dashboards (such as the application dashboard, tier dashboard, and so on) and display metrics that are of interest to a particular audience.

You can use custom dashboards to present selected metrics for a user who only needs a relatively narrow or focused view of the data. For example, an executive may only need a high-level view of system performance and activity. You can assign such users to the predefined Custom Dashboard Viewer role. Any user with a custom dashboard viewer role can view custom dashboards.

i Regardless of application-level or other restrictions configured for that data, a custom dashboard viewer can view all data that the dashboard owner is permitted to view on the controller-level custom dashboards.

Instead of using the Custom Dashboard Viewer role, you can share a custom dashboard.

You can use Controller-level custom dashboards to:

- Provide a customized view of application, server, and database performance data.
- Aggregate data from different applications on the same Controller

-
- Compare data from different applications on the same Controller
 - Show a single view of both live and historical data
 - Share data with other users and stakeholders

Create Custom Dashboards

To create a Controller-level custom dashboard, navigate to **Dashboards & Reports > Dashboards > Create Dashboard**. In the **Dashboards** panel, click an existing dashboard to edit it.

To create or edit a custom dashboard, a user needs to have the Can Create Custom Dashboards permission. See [Visibility and Permissions](#).

Custom Dashboard Templates

To create or edit a custom dashboard template, a user needs to have the Configure 'My Dashboards' for Tiers and Nodes permission.

Create a custom dashboard template to:

- Compare overall application or infrastructure performance against individual tier or node performance
- Show a standard set of metrics for multiple tiers and nodes

You create and access dashboard templates from the My Dashboards tab of the built-in tier or node dashboard. From there, you can create a new dashboard template for that tier/node or use dashboard templates that were created for other tiers/nodes in the same application by association.

Although the process for configuring Controller-level and tier or node-level dashboard templates is similar, the two sets of dashboards are separate. In other words, you cannot associate a Controller-level dashboard with a tier/node through the My Dashboards tab, nor can you access from the Controller-level dashboards list any tier and node level dashboards outside the application in which they were created.

The dashboard and template names must be unique Controller-wide. You cannot create a custom dashboard using an existing dashboard template name, nor can you create a dashboard template using an existing custom dashboard name.

You can export custom dashboards and dashboard templates to a JSON file and then import them where you need them.

View Strategies

For AppDynamics Users

If you have set up default view permissions to custom dashboards, any user who is logged in to the Controller can view a custom dashboard.

Users can also be granted view, edit, [share](#), and delete permissions on specific dashboards.

The Dashboards Viewer predefined role has permissions to view custom dashboards. You can grant this role to users or groups who need access to custom dashboards. See [Custom Dashboard Permissions](#) for details.

For the Public

Sharing a Controller-level custom dashboard makes the dashboard available to viewers who do not have AppDynamics accounts.

If the dashboard is shared, anyone who has been sent a direct link to the dashboard URL can view it. If someone has the URL and the dashboard is not shared or no longer shared, they see a message that the resource is not available when they try to access that URL.

To control Controller-level custom dashboard sharing, click **Share** on the menu of the custom dashboard configuration.

There is no comparable sharing mechanism for external viewers without Controller credentials to access tier- and node-level custom dashboards based on templates. To access these types of dashboards, the user must be logged in to the Controller and have custom dashboard view permissions on the specific dashboard.

The availability of sharing mechanism is now controlled by the Share permission of the user.

Simplify the Data Displayed

If a chart in a custom dashboard is displaying more data than you want, click the legend for the data that you want to remove from the chart. You can click the greyed-out legend to restore the display.

Widgets

Related Pages:

- [Create and Manage Custom Dashboards and Templates](#)
- [Use Wildcards in Metric Definitions](#)
- [Configuration Import and Export API](#)
- [Visualize Analytics Data](#)

This page provides an overview of widgets in AppDynamics. You can use widgets to create visual representations of your data in custom dashboards and war rooms.

If your platform is licensed for Analytics, you can display the results of Analytics searches on custom dashboards as well. See [Visualize Analytics Data](#) for more information.

Widget Types

Most widget types in custom dashboards and war rooms will be familiar to you if you have worked with numeric charts before. This section provides information for certain widget features that may require additional explanation.

Time Series Graph

The standard time-series graph displays one or more values over time in various formats: line, area, column, scatter diagram.

If you configure a widget for a war room that examines metrics on a Java node, consider the streaming graph widget described in [Virtual War Rooms](#). The streaming widget updates more frequently (every five seconds) than the standard time series widget (every 60 seconds) for collaborative real-time troubleshooting.

Events are grouped by time of resolution at the bottom of the graph. You can choose what events to display when you enable **Events Overlay** and configure the event queries for the graph.

Pie Chart

Pie charts or donut charts display multiple values as proportional slices of a whole. The data series should meaningfully total 100% of some series. For example, CPU Busy + CPU Idle + CPU Stolen on a single node or tier.

Gauge Widget

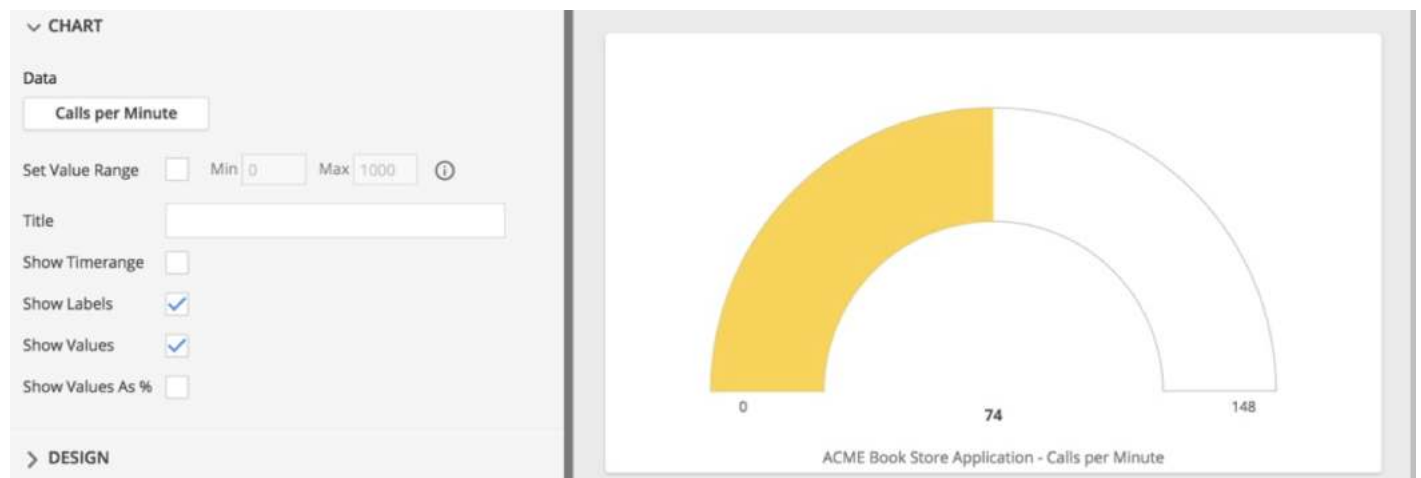

The gauge widget displays the magnitude of a metric value with respect to minimum and maximum values, both by the extent to which the gauge is filled and by the color of the fill.

You can set the minimum and maximum values displayed by the widget. Set the maximum to the highest acceptable maximum or a value close to it so that the gauge is configured for metrics within acceptable values for your site. If you do not set them, default values are used.

This table explains the color coding for gauge widgets.

Percentage	Color	Status
0-10%	Green	OK
10-50%	Gradient from green to yellow	OK trending to WARNING
50-90%	Gradient from yellow to red	WARNING trending to CRITICAL
90-100%	Red	CRITICAL

This gauge example displays the calls per minute metric without any special configuration for minimum and maximum values. The current value is 74 cpm, which is midway between the minimum (0) and maximum (148) for the time period in the WARNING range.

If you set the **Max Value** to 1000, the gauge color changes to green because 74 cpm falls within the OK range.

Streaming Graph Widget

A streaming graph widget is similar visually to a time-series graph, but it is updated every five seconds in contrast to every 60 seconds in the time-series graph.

For Java nodes only, the war room supports the streaming graph widget. It displays data from only a single specified node and only a Java node. This feature is not supported for any of the other agents. To display streaming data from multiple nodes, you need to create multiple widgets.

Log Tail Widget

The war room supports a log tail widget used for Java nodes only to share a log file or parts of one.

The log tail widget displays the contents of the file specified by its Path property. The Path is the absolute path to the log file on the machine on which the selected node is running. If you provide a regular expression in the widget properties, the widget displays only those lines in the log file that match the regular expression. If no regular expression is provided, the widget displays the entire log file. Note that applying a regular expression filter will only adjust lines that come after you have specified the filter. Previous lines will remain filtered based on the previous rule. The widget uses the Java conventions for regular expressions.

If the log file rolls over during the request, the response to the log tail request is undefined.

Issue Tracking Widget

The issue tracking widget displays information about an issue or a list of issues that you have selected. You can choose any detail, people, and date fields that you would like to display. Any updates made to the tracked issue is reflected on the widget.

This widget is only available once you have integrated AppDynamics with Atlassian JIRA.

Metric Value

You can specify a title for the widget as well as a format string that adds the name of the selected metric, the time range, or the name of the function. Alternatively, you can use a separate label widget to explain the metric value.

You have the option of formatting metric values by abbreviating them and removing trailing zeros. Abbreviations only apply to numbers over one million. Metric values are always integers on dashboards with single metrics, therefore decimal formatting does not apply.

Metric Expression

The ability to set the number of decimal places allows you to display decimal values less than one, as well as decimals for larger numbers. If your decimal limit is set to zero, then the remove trailing zeros feature is turned off by default.

Health Status

This is a health bar, filtered table, or status light circle of health statuses for entities, such as applications, business transactions, tiers, nodes, databases, servers, and health rules. After choosing an entity type to show the health for, you have the option to narrow the scope or simply display all.

It is important to note that when selecting tiers as your entity, the color of the health status depends on the statuses of all the health rules that are configured for the tiers. For example, if there are four health rules for the tiers, then the color of the widget will reflect the cumulation of all of their statuses. The widget displays

green for normal, yellow for warning, and red for critical status. See [Configure Health Rule Conditions](#) to learn how the metrics that define warning and critical health statuses are set.

When using the circle visual, you have the option of manipulating the display by choosing its aggregation type: either **Ratio Graph** or **Most Severe Status**.

Event List

This is a filtered table of events that occurred within the specified time range.

IFrame

You may want to include a shared custom dashboard in another custom dashboard when you have different operators who focus on particular dashboards and you want to roll them all up into a primary dashboard for management.

To display information from another dashboard or from another website inside this custom dashboard, you need the URL. You can get the URL for a pane by clicking **Settings > Copy a link to this screen to the clipboard**.

The IFrame widget is sandboxed. Advanced HTML features, such as forms and Javascript, will not work with the IFrame widget.

Widget Data

Some widgets, such as a time series graph, can display a single value or multiple values. Some widgets, such as a donut, must display multiple values to make sense. Others, such as a gauge or a metric value, display only a single value.

Specify a Function of a Metric Value for a Single Entity

When you specify the data to display in a widget, you use a pulldown menu in the **Add Series** panel to select which function of the value to display:

- **Minimum:** Minimum value, only available for averaged metrics
- **Maximum:** Maximum value, only available for averaged metrics
- **Value:** Contains the average or the sum across the time range depending on the metric
- **Sum:** Aggregated value of the metric over the time range
- **Count:** Count of the observed values over the time range
- **Current:** Sum of the most recent minute's metric data values across all the included nodes

You can also use a metric expression to specify a metric. The behavior is similar to using an expression for a health rule. For more details about metric expressions, see how to build an [expression for Health Rules](#).

Dashboard widget metric expressions currently cannot properly handle fraction or float constants that are less than one. These metrics are treated as zero. They work properly when they are a fraction, or float values greater than one.

Specify Metrics in Multiple Entities Using a Wildcard

You can use a wildcard to specify a metric that evaluates across several similar entities for metrics in these metric hierarchy branches:

- Hardware Resource
- JVM
- CLR

- Custom Metrics

See [Use Wildcards in Metric Definitions](#) for instructions.

Exclude Data from the Custom Dashboard During Maintenance or Outage

You can exclude data from the **Custom Dashboard** widgets for the period specified in **Action Suppression**. The metrics during the application maintenance or outage on your application can be inaccurate. So, you may want to exclude this information from the dashboard.

When you are adding or editing any widget, complete the following steps to exclude data for the period specified in **Action Suppression**.

1. In the **Data** panel, click the **Add** icon.
2. Expand the **Advanced** panel.
3. In the **Exclude Maintenance Window** section, select **Exclude**.

i Currently, this option is available in the following scenarios only:

- Non-recurring planned maintenance or outage.
- Objects of Action Suppression is **Application** for APM, BRUM, and MRUM applications. See [Configure and Manage Action Suppression](#).
- Metric category is either **Overall application performance** and **Custom**.
- **Single Metric** value.
- On the **Analytics** page, if the metrics uses ADQL, the query must only use `=` operator in the `Where` clause to match the application name or key.

4. Click **Save**.

On **Custom Dashboards**, if you are using time series charts, the suppressed period appears blank and it helps you identify the application downtime. The widgets like pie charts, gauge, and metric value exclude the suppressed data from its calculation.

Empty Data Series

It is possible that no data is available for a particular metric within the specified time range while for other time ranges valid data is reported. When this occurs, the label for the empty data series appears in the legend but no data is displayed. For example, no line in a time-series graph or slice in a pie chart.

Enable Limits on the Number of JMX Instances or Nodes for a Single Entity

You can use account-level configurations to enable dashboard or widget limits on large numbers of JMX instances or nodes instrumented in one application while returning widget data. This also includes threshold checks for business transactions, errors, servers, and backend data. This applies to the JMX type metric in the widget **Type of Nodes** menu. The **All Nodes in the Application** option becomes disabled if the number of nodes exceeds the threshold. An error is returned if the number of any threshold is exceeded on the backend. This should help prevent outages.

Widget Properties

Widget properties vary to some extent based on the type of the widget.

Most of the widget properties in the configuration forms are self-explanatory. This list describes some of the less obvious properties:

- **Metric Display Name:** You can choose the display name for the metrics in a widget. Specify one or more of the following substitution variables to determine the metric display name:
 - `#{#}`: Number the displayed metrics based on sorting with the rollup value

- $\{m\}$: Metric name
- $\{e\}$: Entity name

For example, if specify $\{m\}$, the widget displays the full metric name.

- **Static Thresholds:** You can create static threshold with a specific value for graph widgets. The threshold appears as a line on the graph.
- **Double click action:** Some widgets have an option to define the result of double-clicking the widget. You can configure the double click action to open the **Metric Browser** or a URL specified by the Drilldown URL value.
- **Drilldown URL:** The Drilldown URL specifies the URL of an AppDynamics panel you want the widget to open when you double-click the widget. For example, if you see an increase in slow requests and want to investigate the cause, you may want to jump to the **App Servers List** of all tiers from your dashboard by double-clicking a widget. To get the URL for a specific panel, click **Settings > Copy a link to this screen to the clipboard**.
- **Time Range:** Widgets can use the global or dashboard time range or a time range that is specific to the widget. If you choose a widget-specific time range, select the widget time range from the pulldown menu.
- **Events Overlay:** You can configure specific events to overlay on the graph widget to show how specific events may correlate with performance. Check the **Show Events** checkbox and create the query to define which events should be overlaid.

Configuring Widgets

Set up or modify widgets with the widget palette in Edit mode.

If you configure widgets for a war room, you will see an additional category for Streaming Data widgets. To add widgets to the war room space the presenter must be in edit mode. To enter edit mode, click **Edit**. If it is not visible and you are the presenter, you are already in edit mode. You can duplicate one or more widgets at a time and delete any widget as required.

To configure a new widget:

1. Click **Edit**.
2. Click **Add Widget**. The widget palette displays.
3. Click the widget in the palette. The configuration form displays on the left side of the configuration panel.
4. Configure both the widget data and the widget properties. After you configure the data, a preview of the widget displays. The preview updates as you set more properties.
5. Click **Save**.

To modify an existing widget:

1. Click **Edit**.
2. Click the widget in the dashboard.
3. Click the settings icon in the upper right corner of the widget.
4. Use the form to modify the widget.
5. Click **Save**.

Use Wildcards in Metric Definitions

Related Pages:

- [Configure Health Rules](#)
- [Create and Manage Custom Dashboards and Templates](#)
- [Metric Browser](#)

This page provides an overview of wildcards in AppDynamics. In a Custom Dashboard widget or Health Rule, you can use a wildcard to specify a metric that evaluates across several entities, such as multiple hardware entities or memory pools.

The wildcard feature is supported for metrics in the Hardware Resources, JVM, and CLR branches of the metric hierarchy. The wildcard features is only supported for custom metrics that are created with a monitoring extension as described in [Extensions and Custom Metrics](#).

To use wildcards:

1. [Define the relative metric path](#) to the metric that you want to display. This involves getting the full metric path in the Metric Browser and then trimming it.
2. [Modify the relative metric path](#) to apply to multiple entities.
3. [Paste the modified relative path](#) in the metric selector for the widget or health rule that you are configuring.

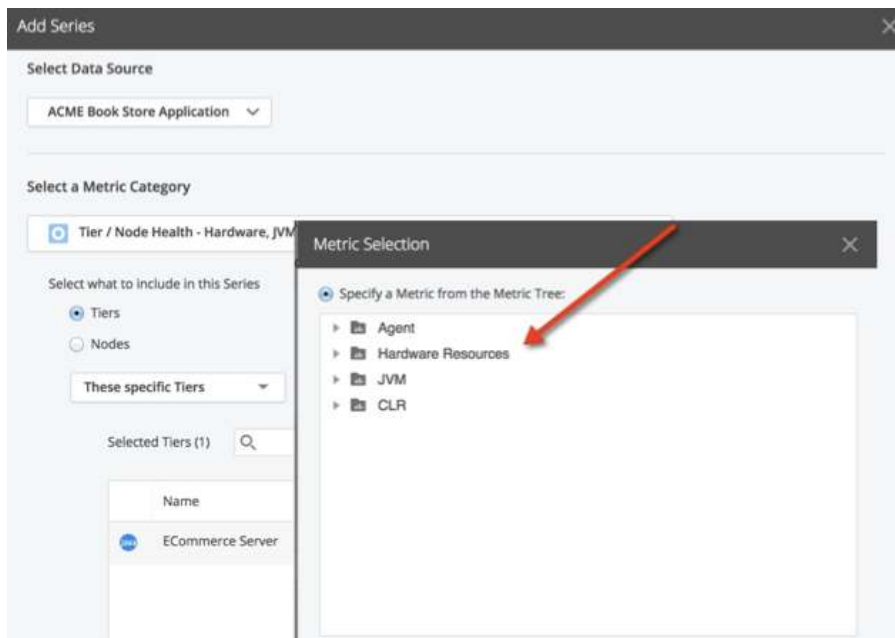

Define the Relative Metric Path

A metric path is a pipe-delineated path to a specific metric. In the Controller UI, hover over a metric in the Metric Browser to get the full metric path. Right-click the metric to view the **Copy Full Path** option.

To define the relative metric path, truncate the leftmost part of the full metric path.

To know how much to truncate for a particular use case, look at the embedded metric browser in the **Metric Selection** panel of the widget or health rule configuration that you are setting up. By the time you have reached this selector, you will have configured the application, tiers, or nodes of the metric that you want to select.

Use the category in the **Metric Selection** panel as the first segment of the relative metric path, truncating everything from the full metric path that comes before that segment. In the example, the first segment would be Agent, Hardware Resources, JVM, or CLR.

As per the preceding example, the full metric path copied from the Metric Browser is Application Infrastructure Performance|ECommerce Server|Hardware Resources|Disks|dev-dm-1|% CPU Time.

Truncate everything to the left of the category selected in the Metric Selection panel that is, Hardware Resources in this example, as the display in the embedded Metric Browser starts with Hardware Resources.

The relative metric path is: Hardware Resources|Disks|dev-dm-1|% CPU Time.

Consider another example where the full metric path copied from the Metric Browser is: Application Infrastructure Performance|ECommerce Server|Individual Nodes|ECommerceAppNode|Hardware Resources|Disks|dev-dm-1|% CPU Time.

The relative metric path after truncating everything to the left of the Hardware Resources is: Hardware Resources|Disks|dev-dm-1|% CPU Time.

Modify the Relative Metric Path

Replace a single segment in the relative metric path with an asterisk to indicate that the metric should be evaluated for all the entities represented by that segment.

 Multiple asterisks in a single metric path are not supported.

For example:

The relative metric path is: Hardware Resources|Disks|dev-dm-1|% CPU Time, and you want to display or create a health rule condition on the % CPU time for all of the disks in that tier or node.

Substitute the asterisk for the disk name as: Hardware Resources|Disks|*|% CPU Time.

 An Asterisk at the end of a relative path is not supported.
For example, "Hardware Resources|Disks|C|*" is not supported.

Configure the Metric for Multiple Entities

In the **Metric Selection** panel for the dashboard widget or health rule, you can configure metric for multiple entries.

To configure the metric for multiple entities:

1. Select **Specify Relative Metric Path** on the bottom of the **Metric Selection** panel.
2. Paste the modified, wild-carded relative metric path and click **Select Metric**.

Verify the Metric Specification

When you configure a relative metric specification for multiple similar entities in a custom dashboard, multiple metrics display in the widget.

Wildcards Replace Entire Path Segments

An asterisk replaces the entire segment in the path. You cannot use it to replace only a portion of a string because they are used in regular expressions.

For example, the following usage in an attempt to get the ART for all the business transactions beginning with **View** is not valid and not supported:

Business Transaction Performance|Business Transactions|ECommerce Server|View*|Average Response Time (ms).

Specify Average Response Time (ms) to get ART for all the business transactions on the ECommerce Server.

Colons in the Metric Path

The colon, if any, in the metric path is translated into a pipe. Only one segment is allowed between pipes. The colons and pipes can be used interchangeably.

For example:

The colon in the metric path, Application Infrastructure Performance|ECommerce Server|JVM|Memory:Heap|Committed (MB) is translated to Application Infrastructure Performance|ECommerce Server|JVM|Memory|Heap|Committed (MB).

For the relative metric path, to get metrics for both heap committed and non-heap committed, specify JVM|Memory|*|Committed (MB). Do not specify JVM|*|Committed (MB).

Create and Manage Custom Dashboards and Templates

Related Pages:

- [Custom Dashboards](#)
- [Widgets](#)

- [Import and Export Custom Dashboards and Templates Using the UI](#)

This page describes how to create and manage dashboards.

 Permissions to create, view, edit, and delete custom dashboards are set through roles. See [Custom Dashboard Permissions](#) and [Manage Custom Roles](#).

Access and Create Custom Dashboards

For Controller-level dashboards:

1. Click **Dashboards & Reports** to view existing custom dashboards or to create a new one.
2. If existing dashboard names display, click **Dashboards**.
3. Click **+ Create Dashboard**.
4. Add widgets to the dashboard.
5. Click **OK**.

For tier/node-level dashboard templates:

1. In an application, in the built-in tier or node dashboard in which you want to create or use a custom dashboard template, click **My Dashboards**.
2. If there are no associated custom dashboards for the entity, click **+ Create a new Custom Dashboard**.
3. If you want to associate an existing dashboard with the entity, click **Associate Dashboards** from the dropdown of the dashboard with which you want to associate the entity. See [Associate a Custom Dashboard Template with a Tier or Node](#).

A dashboard has no content until you add widgets to it. See [Widgets](#).

General Dashboard Characteristics

- **Name**—Dashboard names must be unique per Controller.
- Two layout types:
 - **Grid**—This is the default type that gives you a flexible layout that is easy to rearrange on the canvas. The grid layout also scales in size when viewed on mobile devices. You cannot overlap widgets using this layout type.
 - **Absolute**—Use this type to control width and height and the exact placement of widgets on the canvas. With the absolute layout, you can overlap widgets and use **Send to Front** or **Send to Back** actions to control what displays.
- **Configurable auto-refresh Interval**—Sets the data refresh rate in seconds.
- **Dashboard Time Range**—This setting applies only to Controller-level dashboards. From the **Time Range** dropdown, you can set a global time range for the dashboard. When you add widgets, you can specify whether the widgets use this global time range or a widget-specific time range. If you do not specify a widget-specific time range, the global time range is used for all the widgets.

Access the Dashboard Operations

While you are in edit mode, your changes are automatically saved. To save changes manually, disable **Auto-Save** and click **Save**. There is no way to save your changes manually.

If you are accessing a dashboard on a mobile phone, click the **Mobile** icon for a better viewing experience. To access various operations concerning the dashboard, click **Actions**.

Widget Operations

You must be in edit mode to add and modify widgets. See [Widgets](#).

Widget Operation	Procedure
Access the widget palettes	In the dashboard configuration panel, click + Add Widget .
Add a widget to the dashboard	<ol style="list-style-type: none"> 1. In the left panel of the Add Widget panel, select the context. 2. Click the widget in the palette on the right.
View and edit the widget properties panel	Click the Gear icon in the upper right corner of the widget.
Delete one or more widgets	<ul style="list-style-type: none"> • Select the widgets and click Delete, or; • Right-click the widget and select Delete.
Duplicate one or more widgets	<ul style="list-style-type: none"> • Select the widgets and click Duplicate, or; • Right-click the widget and select Duplicate.
Copy/paste a widget	<ul style="list-style-type: none"> • Select the widget and click Copy, then click Paste, or; • Select the widget, right-click, and select Copy. Then, right-click the widget again, and select Paste.
Edit the properties of multiple widgets	<ol style="list-style-type: none"> 1. Hold down your command key and select the widgets you want to edit the properties for. 2. Click Edit. 3. From the Edit <number of widgets> Widgets dialog, select the properties you want to apply to all the widgets, and click OK.

Note that not all widgets share the same properties, and Analytics widgets cannot be edited using the multi-widget editing feature.

Delete or Modify a Custom Dashboard

For existing Controller-level custom dashboards:

1. Click **Dashboards & Reports**.
2. Click **Dashboards**.
3. In the Dashboards list, select the dashboard that you want to edit, delete, copy, share, or export, and click the appropriate button.

For existing dashboard templates:

In the My Dashboards tab of an entity associated with the dashboard:

- To modify an existing dashboard template, select it in the list and click **Edit** (pencil).
- To remove an existing dashboard, click **Manage Dashboards** from the dropdown, select the template in the list, and then click **Delete**.

Associate a Custom Dashboard Template with a Tier or Node

The My Dashboards tab of the built-in tier and node dashboards provides access to custom dashboards that are associated with the tier or node.

To view an associated custom dashboard populated with data from the entity, click the dashboard in the list displayed by the My Dashboards tab.

To associate one or more existing dashboard templates with the entity:

1. Click **Associate Existing Dashboard with the Tier/Node** for an entity that has no associated dashboards. Alternatively, click **Associate Dashboards** from the dropdown for an entity that already has at least one associated dashboard.
2. In the dashboard picker, move the dashboards to associate from the **Available Dashboards** list to the **Selected Dashboards** list.

To disassociate a dashboard template with an entity:

1. In the dropdown, click **Associate Dashboards**.
2. In the dashboard picker, move the dashboards to disassociate from the **Selected Dashboards** list to the **Available Dashboards** list.

Dashboard Templates Associated Across Applications

All the widgets in a custom dashboard template that is associated with a tier or node in a different application must use the default baseline if they use a baseline.

To set a widget's baseline to the default baseline, or to verify that it is set, in the **Select Baseline** section of the **Advanced** panel of the widget **Edit Series** pane, select **Default Baseline**.

Manage Custom Dashboard Templates

To perform miscellaneous operations on dashboard templates:

1. In the dropdown, click **Manage Dashboards**.
2. From the **Tier or Node Dashboards** panel, you can:
 - Delete, copy, import, or export a selected dashboard template.
 - Create a new dashboard template.
 - Associate an existing template with tiers or nodes in the application.
 - View and edit an existing dashboard template.

Import and Export Custom Dashboards and Templates Using the UI

This page provides instructions on importing and exporting custom dashboards in AppDynamics.

Exporting custom dashboards and templates generates a JSON file that you can import into another AppDynamics Controller.

You can import and export custom dashboards and templates, from the Controller UI, or programmatically with the REST API. See [Configuration Import and Export API](#) to import and export programmatically.

Export Custom Dashboards

To export a custom dashboard in the Controller UI:

- From the custom dashboard list, select the dashboard that you want to export and select **Export** in the **Dashboards** menu bar.
- From the dashboard editor of the dashboard that you want to export while in **Edit** mode, select **Export Dashboard** from the **More Actions** dropdown.

If you have edit permissions for dashboards, you can use either method. If you do not have edit permissions, use the **Export** option from the custom dashboard list.

The dashboard is exported to a file named `CustomDashboard_<dashboard_name>_<unique_id>.json`. Optionally, you can rename the file before importing it.

Export Custom Dashboard Templates

After creating a custom dashboard, you can export it as a template. Templates enable you to quickly create new dashboards.

To export a custom dashboard template, click **Export** in the toolbar of the custom dashboard.

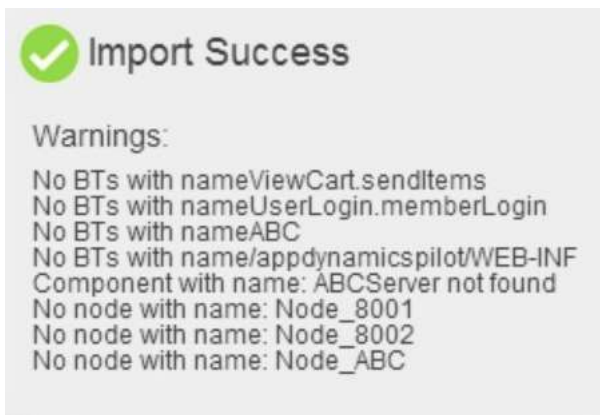

Importing and exporting are for re-using the template in a different application or a different Controller. If you want to use the template in another tier or node in the same application, you do not have to export and import it. You can simply associate it. See [Associate a Custom Dashboard Template with a Tier or Node](#).

Import Custom Dashboards

You can import a dashboard file to create a new dashboard based on a previously exported one.

1. From the custom dashboards list, click **Import** in the menu bar.
2. Click **Choose File** and navigate to the previously exported JSON file that you want to import.
3. Click **Open**.
4. Click **Import**.

If the metrics, nodes, tiers, or applications used in the exported dashboard do not exist in the new Controller environment, warning messages display:

Even when the metrics are not available in the new Controller environment, your import succeeds and saves the widgets and layout of the dashboard. You can modify the widget properties substituting different metrics to create a similar-looking dashboard in the new environment.

Import Custom Dashboard Templates

1. From the pulldown of the My Dashboards tab of the tier or node dashboard from which you want to import a template, click **Manage Dashboards**.
2. In the Tiers/Nodes Dashboards list of dashboard templates, select the dashboard template that you want to import and click **Import**.

Dashboard Recovery

This page provides instructions on recovering custom dashboards in AppDynamics.

When you delete a user from the user list, any custom dashboard that the user created becomes non-functional with no permissions and is unable to execute properly. This impacts all associated dashboard-based reports and shares. To solve this problem, you can use the **Recover** option.

Recovering a non-functional dashboard reassigns ownership to the recovering user which automatically makes the custom dashboard, its shares, and related reports functional again.

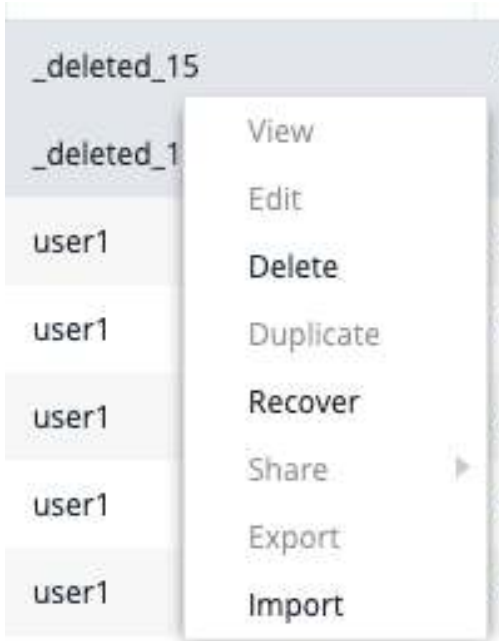

i The **Recover** option is active only when the dashboard owner is a deleted user.

To recover a non-functioning dashboard:

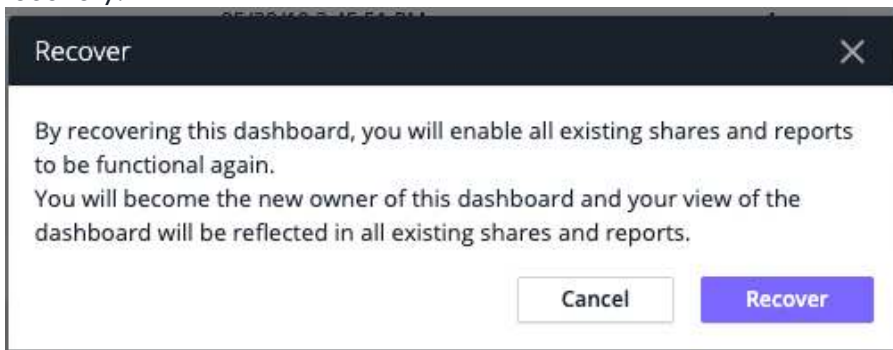

1. Log in to the Controller as a user with VIEW_DASHBOARDS and CREATE_DASHBOARDS permissions.
2. Access the custom dashboards listing page.
3. Select the non-functioning dashboard and right-click to access the context menu. When the owner of the dashboard is active, the **Recover** option remains disabled:

i When the owner is deleted, the **Recover** option is enabled automatically.

4. Select **Recover** from the context menu. This confirmation dialog displays for a single dashboard recovery:

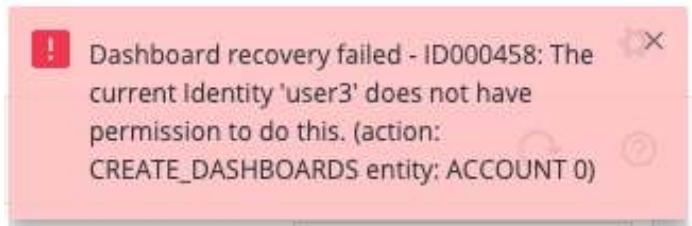

i You can select multiple non-functional dashboards and recover all of them at once. To select multiple custom dashboards, use **Ctrl-Click** for non-contiguous rows and **Shift-Click** for contiguous rows. You must ensure that the owners of all the selected dashboards are deleted users, otherwise the **Recover** option remains disabled.

5. Once the dashboard is recovered successfully, this message popover displays:

 To recover a dashboard, you must have the `CREATE_DASHBOARD` permission. If you execute the **Recover** option without this permission, this message displays:

See [Custom Dashboard Permissions](#).

Duplicating a dashboard creates a new dashboard with the same capabilities as the non-functioning dashboard. However, duplication does not create the shares or the associated reports. The result is that the new dashboard operates using a deleted user's permissions (as with Recover), but you must create the shares and reports manually.

In some cases, duplicating the inactive dashboard helps you regain control over the shares and reports. However, there may be some cases when duplication would not work. You should use the Recover option to retain all existing shares and related reports instead of duplication.

Virtual War Rooms

Related Pages:

- [Custom Dashboards](#)
- [Monitor Events](#)
- [Create and Manage Custom Roles](#)
- [Widgets](#)

This page provides an overview of virtual war rooms in AppDynamics.

A war room is a combination of interactive dashboard and notes, integrating a real-time custom dashboard with collaborative troubleshooting in a focused chat room. When troubleshooting an issue, you can add notes and data using a timeline that is visible to all war room participants immediately.

The virtual war room:

- Orients everyone to the same page by viewing the same real-time data.
- Keeps the focus on metrics that translate to the business value the application delivers.
- Fosters communication among a broad audience.
- Identifies resolution criteria and assigns ownership for resolution tasks.

Start a War Room

Start a virtual war room or a collaborative chat room when you want to troubleshoot an issue.

 You must have account-level permission (Create War Rooms) to start a war room.

1. Start creating a war room using one of these three options:
 - Navigate to **Applications > Troubleshoot > War Rooms > My Active War Rooms**, click **Start a War Room**.
 - Navigate to **Applications > Application Dashboard > Events > Actions**, click **Start a War Room**. Access the events list through the Events tab available in many of the built-in dashboards.

-
- If you integrated Atlassian JIRA, navigate to **Applications > Troubleshoot > Health Rule Violations** and click **Start War Room** under the JIRA/War Room column.
2. Navigate to **JIRA Issue > AppDynamics Incident** and click **Start or Join a War Room associated with this Incident**.
 3. Name your war room and click **OK** to create a new room, or select **From Template** to create a new room using available war room templates. See [War Room Templates](#).
 4. Click **Add Widget** to add your widgets to the war room. See [Widgets](#).
 5. Click **Save**.

You can view all the war rooms you created on the **My Active War Rooms** page, and edit your widgets using the **Actions** menu.

War Room Templates

You can re-use the layout of an existing war room by saving a war room as a war room template. This can save time in creating new war rooms with numerous widgets. You can save an existing war room as a template while you are working on it, or just before you close it.

Create a War Room Template

1. From the Actions menu of the current war room from which you want to create a template, click **Save as Template**. Alternatively, when you end a war room, select **Save as Template**.
2. Provide a name for the template and an optional description.
3. Click **OK**.

The new template is now available to create other war rooms. You can view all your war room templates under **War Rooms > Templates**.

Delete a War Room Template

1. Click **War Rooms > Templates**.
2. From the list of war room templates, select the template to delete.
3. Click **Delete Template** and confirm the deletion.

Manage Presenters

The user who starts a war room is the first presenter.

Only the presenter can:

- Modify the collaboration space to add, delete, and configure widgets.
- Make any other participant a presenter. There can only be one presenter at a time.
- Share and stop sharing the war room with other participants.
- End the war room.

Presenters can also do everything that participants can do.

Change a Presenter

Right-click on any participant name in the participant list and select **Make Presenter**.

The ability to edit and control sharing of the collaborative dashboard and to end the war room passes to the new presenter. Other participants cannot see the war room until the presenter shares it. This enables the presenter to set up widgets privately before showing the war room to others.

End the War Room

Click **End War Room**. When prompted, confirm that you want to end it.

Only the presenter can end the war room. A war room is automatically ended after 60 minutes of inactivity. Inactivity means no participants are viewing the war room pane.

Manage Participants

Everyone who has joined the war room but who is not currently a presenter is a participant. A participant can be:

- An AppDynamics participant is an authenticated UI user with access to the AppDynamics account that is hosting the war room.
- A guest participant does not log in to the AppDynamics UI, but has been invited to join by an AppDynamics participant. This user type functions as an anonymous, read-only participant.

AppDynamics participants can:

- View a war room to which they have been invited.
- Invite other participants.
- Add notes.
- Start a new war room, if the participant has Create War Rooms permission.

Guest participants can view a war room to which they have been invited.

View a War Room

You can view only the war rooms in which you are a presenter or a participant. The list does not display all the war rooms currently in progress on the Controller.

To view a war room, you should have created one, got invited to one, or have access to the shared URL available to anonymous users.

To access a war room, either:

- Click the link in the invitation that you received to join the war room.
- Click **Troubleshoot > War Rooms**, and then select the war room to join from the war rooms list.

Invite Another Participant to the War Room

Send a link to invite another participant to the war room:

1. From your active war room, click **+ | Participants**.
2. From the **Invite Users** pane, copy the URL for joining this War Room.
3. Email or SMS the link to the persons whom you are inviting, with instructions to click the link from a browser.
4. Click **OK** to close the **Invite Users** pane.

After clicking the link, the recipient is invited to log in as an AppDynamics participant or as an anonymous guest.

Add a Note

1. From your active war room, click **+ | War Room Notes**.
2. From the **Enter Notes** pane:
 - a. Enter your note in the text field.
 - b. (Optional) Qualify your note as good or bad.
 - c. Click **Post**.

Automatic Save, Synchronize, and Archive a War Room

The war room is automatically saved and all participants' views of it are synchronized whenever the presenter makes a modification to the dashboard. The saving and synchronizing happens continually and is transparent to the participants when it occurs. In addition, the presenter can always force a save and sync manually by clicking **Save** at the top of the war room dashboard.

If you restart the Controller while a war room is in progress, the war room is saved and you can access it after the Controller comes back online.

Reports

This page provides an overview of reports in AppDynamics.

AppDynamics extracts data from dashboards and creates scheduled reports. You can configure automatic report generation for a regular schedule or create reports manually.

Scheduled Reports

Scheduled reports are automatically created on a regular interval. AppDynamics creates reports with the data pulled from Dashboards and sends it to the configured list of email recipients, as scheduled. To deliver a report instantly, select the **Send Report Now** option available for a report.

You must have account-level permissions to view and configure scheduled reports. See [account-level permissions](#).

Report Types and Formats

You can schedule periodic generation and delivery of these report types to a list of email recipients:

Report Type	Captured Information
Application Health Report	<p>Application health data from the application dashboard that includes:</p> <ul style="list-style-type: none"> • Business transaction and server health data. • Transaction scorecard. • Events and exceptions. • Load, response time, and errors graphs.
Dashboard Report	Dashboard data in the selected custom dashboard.

Report Type	Captured Information								
Controller Audit Report	<p>Audit entries that include:</p> <ul style="list-style-type: none"> • User logins and information changes. • Controller configuration changes. • Environment properties changes. • Application properties and object changes such as policies, health rules, and the entities listed here: <table border="1"> <tr> <td>Date and time range</td> <td>ObjectType</td> </tr> <tr> <td>UserName</td> <td>ObjectName</td> </tr> <tr> <td>Action</td> <td>ApiKeyId (if applicable)</td> </tr> <tr> <td>ApplicationName</td> <td>ApiKeyName (if applicable)</td> </tr> </table> <p>AppDynamics supports PDF, JSON, and CSV file formats for this report type.</p>	Date and time range	ObjectType	UserName	ObjectName	Action	ApiKeyId (if applicable)	ApplicationName	ApiKeyName (if applicable)
Date and time range	ObjectType								
UserName	ObjectName								
Action	ApiKeyId (if applicable)								
ApplicationName	ApiKeyName (if applicable)								
Home Screen Report	Overview data from the home page.								
All Applications Summary	Data summary from the applications page.								
User Experience: Browser Apps	Browser RUM data from the Browser App Dashboard Overview page.								

Manage Scheduled Reports

You can create and deliver scheduled reports on a regular interval. To create a report identical to the existing one, you can duplicate the existing scheduled report and modify relevant fields, as required. You can add a set of email recipients for the report delivery.

In addition to the scheduled delivery of reports, use the **Send Report Now** option to send the generated report immediately to the email recipients. From the **Reports** page, select your report and click **Send Report Now** from the right-click menu.

Create a Scheduled Report

You need to have the account-level Configure Scheduled Reports permission to create scheduled reports.

1. Click **Dashboards & Reports > Reports > Add Report**.
2. From the **Create Scheduled Report** page, you can customize your report:
 - a. Enter **Report Title** and **Report Subtitle**.

You can label a report CONFIDENTIAL using **Report Subtitle**.

- b. Optionally, select **Show Title Page** to include a title page at the beginning of your report file.

- c. Select your **Report Type** from the dropdown. Based on this selection, fields in the **Report Data** tab vary.
- d. Make necessary changes in the Schedule, Report Data, and Recipients tabs, and then click **Save**.

Create a Controller Audit Scheduled Report

Use this report to view changes made to the user information, Controller configuration, and application properties.

1. Click **Dashboards & Reports > Reports > Add Report**.
2. Enter **Report Title** and **Report Subtitle**.

 You can label a report CONFIDENTIAL using **Report Subtitle**.

Optionally, select **Show Title Page** to include a title page at the beginning of your report file.

3. Select **Report Type > Controller Audit** to define the fields in the **Reports Data** tab.
4. Set the time ranges. You can create and manage custom time range, if required.

 Custom time range options are available for all the Report Types.

5. Select your report file format as PDF, JSON, or CSV.
Optionally, uncheck **Show Diff** to remove the **Object Changes** column from your report file.
6. Select the data to include or exclude from the dropdown. Repeat as necessary with these options:

Filter Type	Attribute	Attribute Value	Result
Exclude/Include	Same	Different	Audit entries matching with any of the attributes are excluded/ included.
Exclude/Include	Different	Different	Only audit entries matching with all of the attribute values are excluded/included.

7. Enter the attribute value.
8. Click **+Add**.

Alternative

You can use the Controller audit log that replicates the Controller Audit Report. This audit log monitors user activities and configuration changes in the Controller. See [Controller Audit Log](#).

Scheduled Report Management

You can manage scheduled reports from the **Dashboards & Reports > Reports > Scheduled Reports** page. To edit, duplicate, enable, disable, export, import, and delete reports, use the menu bar on the **Scheduled Reports** page, or the right-click menu options available for each report in the list.

Managing a report requires account-level permissions such as View Scheduled Reports and Configure Scheduled Reports.

To create and send the scheduled report on a regular interval, ensure that you have enabled the report. You can disable a scheduled report to put it on hold for a certain length of time. You can verify the current status of a report using the **Enabled** column in the list of reports. For any report in the list, you can use the **Send Report Now** option to generate and deliver it instantly.

Dash Studio

AppDynamics Dash Studio is a next generation dashboard designed to make building dashboards faster and easier. It is available in the Dash Studio tab under **Dashboards & Reports**. The previously created dashboards are still available unmodified, under the Dashboards tab.

SaaS requires versions \geq 4.5.15.1.

- [Visual Dashboard Editor](#)
- [Dash Studio Layout](#)
- [Dash Studio Widgets](#)
- [Dashboard Variables](#)
- [Data Binding](#)
- [ThousandEyes Integration with AppDynamics](#)

Visual Dashboard Editor

This page provides an overview of the Dashboard Editor in AppDynamics.

The Dashboard Editor is available next to the existing Dashboards tab. The Dashboard Editor allows you to:

- Quickly align widgets.
- Resize widgets on a dashboard by grabbing the edges of the widget with a click-and-drag to resize.
- Select multiple widgets, copy and paste them using GUI controls, or using command-C or command-V controls, so that you can replicate them on a single dashboard.
- Edit widget titles by editing the widgets directly.
- Edit widget attributes such as: titles, line colors, and labels.
- Access commonly used tools from the toolbar with a single click.

What's New? Button

The **What's New** button provides information about the latest updates in the Dash Studio.

Click the **Show Documentation** button to access the online documentation for Dash Studio.

Dashboard Library

All dashboards created in the Dash Studio are available in the **Dashboard Library**, which provides a list of all Dash Studio dashboards. Select the **Show My Dashboards Only** toggle button to see a list of dashboards created in the Dash Studio.

Dashboard Editor

The new dashboard canvas offers a visually attractive and responsive display in both edit and view modes. The canvas and associated toolbars:

- Allow you to easily edit the dashboards manually.
- Allow widget data binding and editing of some widget properties (such as, titles and graph axes labels) on the canvas directly.
- Are architected to enable future functionality such as, repeating widgets and allowing column width lock in responsive dashboards.

Edit and View Modes

To optimize the Dash Studio experience, you can switch between these two display modes:

- **View** mode (default mode for dashboards)
- **Edit** mode

In **View** mode, the toolbar disappears, and the dashboard displays to the largest extent possible in the browser panel in which it is housed.

The **Edit** mode enables you to edit the content of the selected dashboard. To return to the dashboard library from the **Edit** mode, click  on the top-left of the page.

You can apply these layouts to your dashboard:

- Responsive Layout
- Fixed Aspect Ratio

The **View** icon (available on the top-right of the page) allows you to preview the dashboard. On the preview page, click the **Edit** icon to return to the Dashboard Editor.

Feedback Button

Use the **Feedback** button to submit feedback about your experience using Dash Studio. The submitted feedback is sent to the AppDynamics product team.

Auto Refresh Interval

Enable the **Auto Refresh Interval** option under the **Dashboard Properties** panel to refresh the dashboard automatically at specific intervals. Auto-refresh ensures that the dashboard data and layout is refreshed regularly. You can select an option from the **Auto Refresh Interval** dropdown or select **Custom** from the list of options to customize the interval value. The default refresh interval is two minutes. The set interval value persists when you switch between edit and view mode, and when you share, import, or export a dashboard.

Help Popover

The **Help** popover appears at various places on the dashboard UI. This popover provides details about features, concepts, and product changes. Click "**Okay, got it!**" to close the popover.

Dashboard Sharing

The sharing capability in Dash Studio allows you to share the dashboard with business users and with those who do not have an AppDynamics account. This helps multiple users access the dashboard and enables effective collaboration among the users.

You can also:

- Stop sharing the dashboard.
- Copy the shared URL to the clipboard.
- Open the shared URL in a new panel.

Import and Export Dashboards

This feature allows you to export and import JSON dashboard metadata between Dash Studio instances running in different environments.

Export Dashboard

To export a dashboard in Dash Studio:

1. Select the dashboard to export from the dashboard list.

 The **Export** icon () is enabled only when you select a dashboard from the dashboard list.

2. Click **Export** () when available in the dashboard toolbar.
The exported dashboard is generated as a JSON file on your system. You can rename the downloaded file later.

Export Dashboard with Edit Permissions

To export the selected dashboard with **Edit** permissions:

1. Right-click on the selected dashboard.
2. Select **Export** () icon from the dropdown.
The exported dashboard is generated as a JSON file on your system.

Import Dashboard

To import a previously exported dashboard file in Dash Studio:

1. Click **Import** () to display the **Custom Dashboard Import** dialog.
2. Click **Choose File** and navigate to the previously exported JSON file that you want to import.
3. Click **Open**.
4. Click **Import** to open the imported dashboard and display it with a new name.

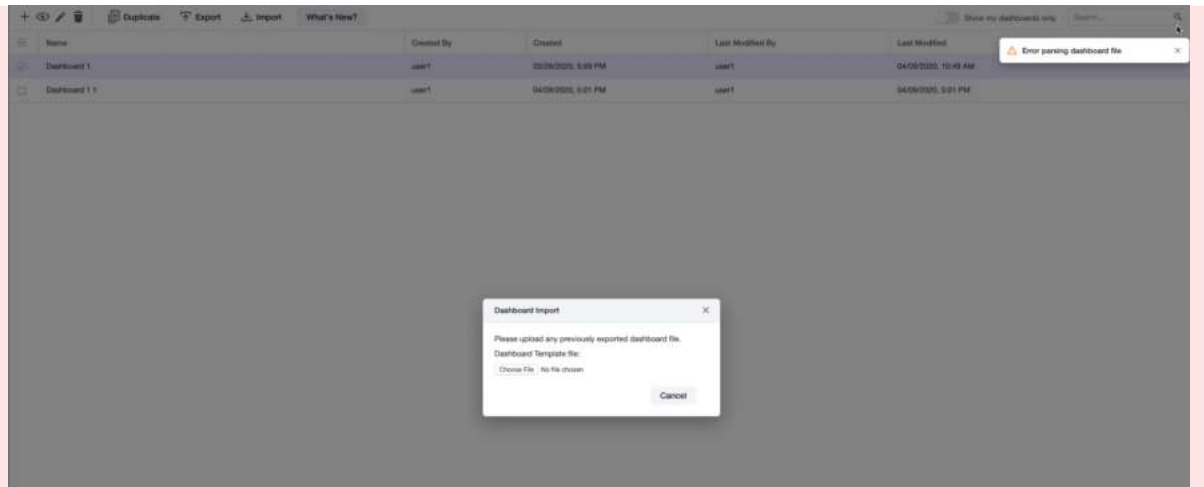

Import Dashboard with Edit Permissions

To import the selected dashboard with **Edit** permissions:

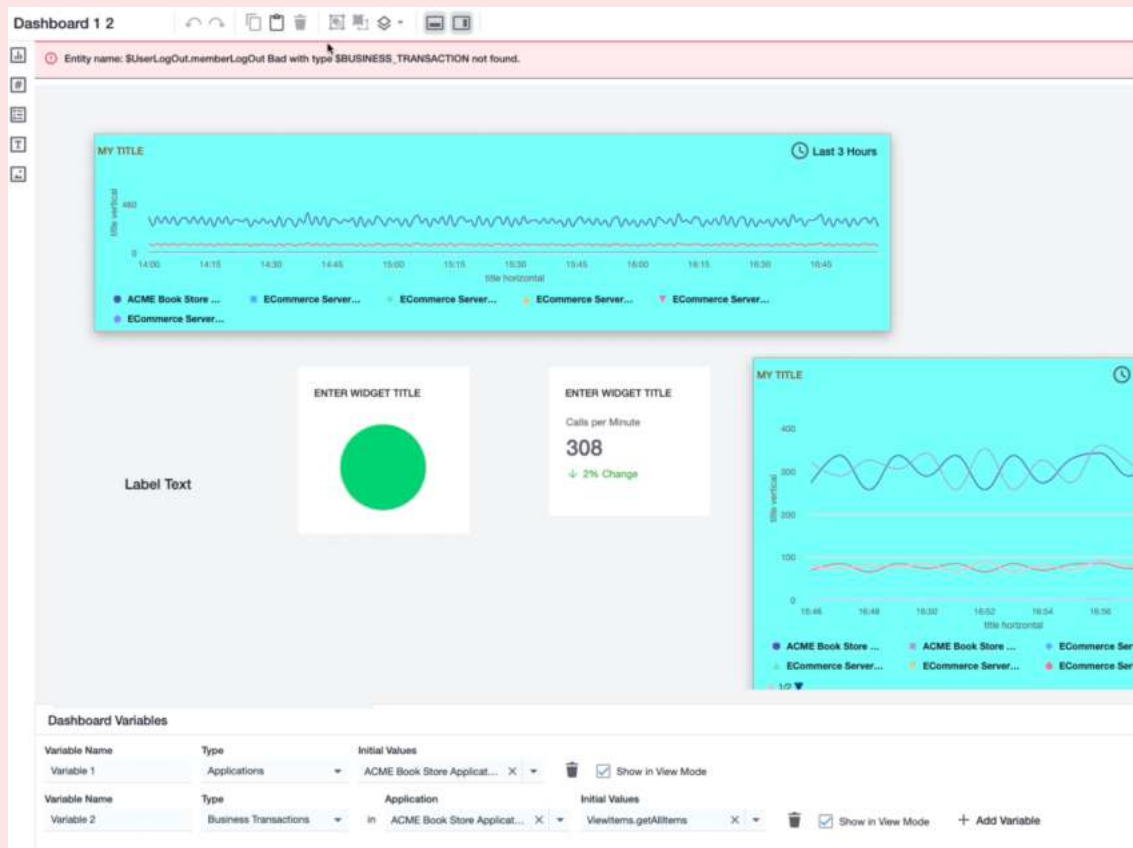

1. Right-click on the selected dashboard.
2. Select **Import** () from the dropdown.
3. Click **Choose File** to navigate to the dashboard file to import.
4. Click **Open**.
5. Click **Import** to open the imported dashboard and display it with a new name.

 These errors may display when you try to import a dashboard file:

- Parsing error when you import a bad or malformed dashboard file.

- File Not Found error when you import a dashboard from another Controller.

Dash Studio Layout

This page provides an overview of the Dash Studio layout in AppDynamics.

You can organize the dashboard layout and explore important system data in the Dash Studio. You can find required dashboards, delete dashboards, and create new ones. You can also place widgets on the canvas in

the Responsive Mode layout and Fixed Aspect Ratio layout. The canvas is a backdrop where you can drop content in, such as widgets.

Dashboard Organization

Create Dashboards

Dash Studio allows you to create a dashboard without having to name it, or indicate its layout or characteristics. If you accidentally close a dashboard without naming it, the dashboard is auto-saved and named "Untitled-X." X is the next untitled dashboard in the collection of dashboards that you are authorized to access and is saved in the Dashboard Creation Directory. Untitled-X displays as the dashboard title on the page as soon as the new dashboard canvas loads. You can rename the dashboard later.

Auto-Save

Dashboards are auto-saved by default.

Responsiveness and Sizing

You can resize the Dashboard canvas to any size which enables you to switch between editing and viewing mode. By default, the dashboard automatically resizes to fit on the page. The width of some columns in the dashboard are locked so that when you resize a dashboard, a locked column is not resized. The default canvas sizing fits the dimensions of a typical laptop.

Dashboard Editor Actions	Description
Adding Widget	You can drag and drop widgets from the toolbar onto the dashboard canvas.
Alignment and Placement	You can place the widgets anywhere on the dashboard canvas, including placing widgets on top of other widgets or running off the edge of the canvas itself. Use the red alignment lines as a quick visual to check the alignment of the widgets. These lines also indicate when the widgets are at an appropriate distance from other widgets.
Group Creation	You can select multiple widgets by dragging a box over them with a mouse, or holding Shift and selecting all widgets with a mouse click.
Selection and Undo/Redo/ Copy/Paste	<p>You can select widgets, or groups of widgets by clicking them, or dragging a mouse-generated box over by holding down the left mouse button. You can select multiple widgets by either dragging the box, or by a command-click action.</p> <ul style="list-style-type: none"> You can undo or redo an action using a toolbar command, or by command-Z and command-Y functionality on the keyboard. You can copy, cut or paste groups of widgets using a toolbar command, or by command-C, command-X, or command-V functionality on the keyboard.

Dashboard Editor Actions	Description
Selection in Edit Mode	<p>You can select widgets or groups in edit mode by clicking them, or dragging a mouse-generated box over by holding down the left mouse button. You can select multiple widgets by either dragging the box, or by command-click action. In view mode, data queries are not exposed. To drill down to the next data level, you must double-click.</p> <ul style="list-style-type: none"> • For Widgets: Single click selects a widget, enables its movement, and exposes an editing icon at the top right of the widget. To edit data, click on the editing icon. Double-click on the widget to drill down to the next data level. Google Data Studio is a good example of this interaction. • For Groups: Single click a group selects that group, enables its movement, and exposes the editing icon. Clicking again selects the widget. Double-clicking a widget in a group has the same effect as clicking once on the group, and then clicking the widget. To drill down on the widget, you must double-click again.

Edit and View Modes

You can view Dashboards in these two modes:

- **Edit** mode
- **View** mode

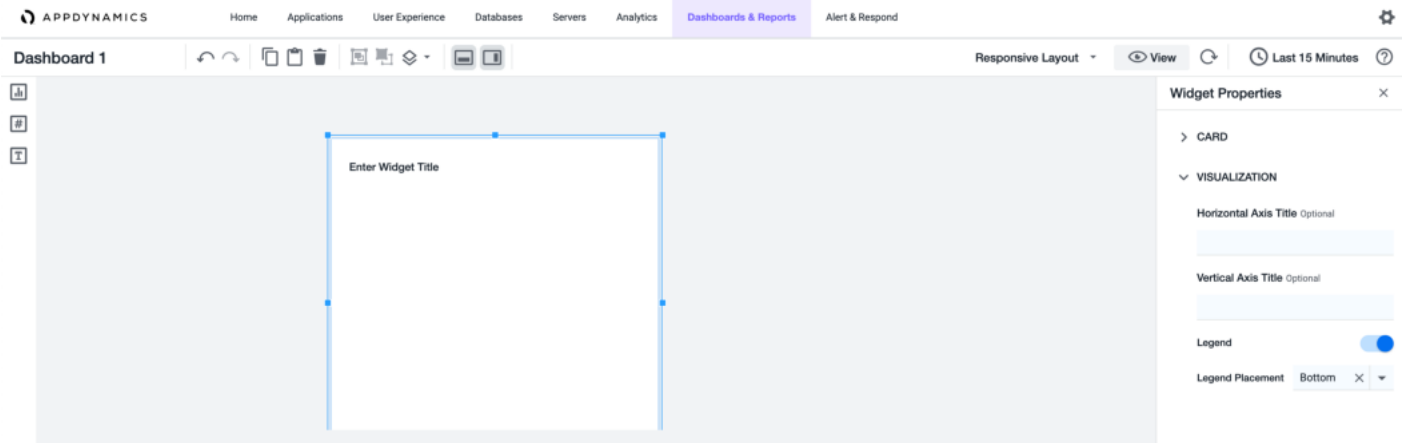

By default dashboards are in **View** mode. The toolbar does not display in **View** mode.

General Layout

Toolbar

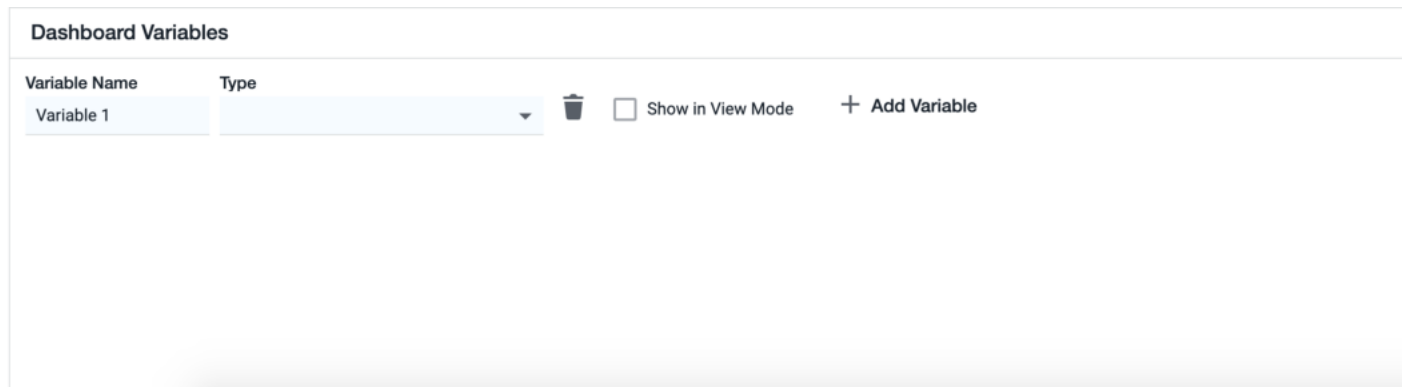

The dashboard editor tools available in the toolbar enable you to perform these actions:

Actions	Description
Undo and Redo	The toolbar has two buttons for undo and redo actions on a dashboard. You can also perform these actions using command+Z and command+Y keyboard functions.
Copy, Paste, and Delete	You can use tools from the editing toolbar to copy, paste, or delete widgets, or containers from a dashboard. You can also perform these actions using command-C, command-V, and the Delete keys on the keyboard.
Dashboard title	You can edit dashboard title. By default, a new dashboard is titled "Untitled Dashboard."

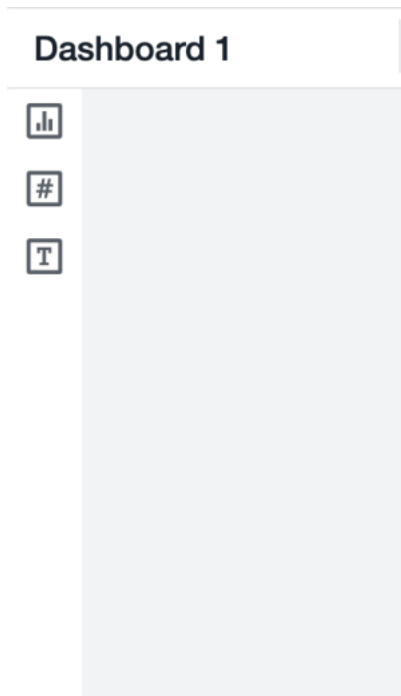

Data Panel

The [Data Toolbar](#) at the bottom of the Dashboard Editor enables you to bind containers and visualizations to data. See [Data Binding](#) for details.

Widget Palette

The **Widget Palette** on the left-side of the Dashboard Editor allows you to drag and drop widgets from the palette on to the canvas.

Widget Properties Panel

The **Properties Panel** on the right-hand side of the Dashboard Editor enables you to set the properties of a widget, such as: background color, shadow, padding, and basic display options.

Dash Studio Widgets

This page provides an overview of existing Dash Studio widgets in AppDynamics. Widgets create a visual representation of your data in the dashboards.

Card Component

Cards are small containers for placing the widgets. Cards have a title, border, and sometimes a footer and actions related to the specific context of the Card. These containers have text labels to clearly describe the information. You can rename or delete them.

Grouped Widgets

The widget grouping functionality enables you to organize two or more widgets on a card component or on their respective cards. You can apply widget properties to the entire group of widgets instead of a single widget.

- Each widget is created on a card by default.
- A card component, for a widget or group of widgets, has a title and a background.

Create a Widget Group

To create a group:

1. Select two or more widgets.

2. Click the group icon  in the top panel.
Select one of these options:
 - **Group** - Groups the widgets on their respective cards.
 - **Group In Card** - Groups the widgets on a card component.

To separate the widgets in a group, click the ungroup icon  in the top panel.

Group Properties

You can apply these properties to modify the appearance of grouped widgets:

CARD

Property	Description
Group In Card	Group all the selected widgets on a card.
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces between the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

GROUP TIME RANGE

See [group time range](#).

Time Ranges

Global Time Range

The **Global Time Range Selector** option on the top right enables you to set a time range for the dashboard. This can be for the last five minutes, hours, weeks, or even months.

Widget Time Range

You can compare widgets across different time ranges by setting a time range that is distinct from the global time range.

To set the time range for a single widget independent of other widgets:

1. Select the widget to set its time range.
2. Go to **Widget Properties** on the left panel and click **Time Settings**. Two options display under **Widget Time Range: Inherit From Dashboard** and **Unique To This Widget**.
3. Select **Unique To This Widget** and set a time range distinct from Global Time Range. Select the **Show Time Range** toggle to display the time range on the top of the selected widget:

 You can enable the **Show Time Range** toggle for a widget to change its time range in **View** mode.

Group Time Range

You can set the time range for a set of [grouped widgets](#) using the **Group Time Range** option under **Group Properties** panel. It provides these options:

- **Inherit Time Range** - Set the same time range as the global time range for each widget of the group.
- **Group Specific Time Range** - Set the time range for each widget of the group by selecting an option from the dropdown. You can also click **Custom** to create a customized time range.

Toggling the **Show Time Range** option hides or displays the time range in the upper-right corner of each widget in the group.

Simple Navigations

Simple navigation actions in Dash Studio enables basic user interactions and helps you to seamlessly navigate to any specific part of the product. The navigation actions allow you to drill down into complex and detailed information about a selected entity. You can utilize this capability as part of the troubleshooting processes and for root cause analysis.

 This feature is available only for Time Series, Pie, Label, Metric Number, and Image widgets.

Navigate with a Single Click

To perform navigation actions with just a click in the view mode, click the widget for which you want to set this action:

1. Click **Single Click Action** option available under the **Widget Properties** panel.

It displays the following options:

- **Destination Type** - You can select one of the following:
 - **Metric Browser** - This option is selected by default. Click the widget in the view mode to navigate to the selected metric browser.
 - **URL - Destination Link** field displays, where you must enter the desired link. Click the widget in the view mode to navigate to the selected link.
 - **Dashboard - Dashboard Name** field displays when you select this option. Enter the name of an existing dashboard or select an option from the dropdown list. The following option displays if the selected destination dashboard contains variables:
 - **Variable Passing 1** - This option allows you to modify the default value of multiple variables in an existing Dashboard.

 For example, if “Dashboard 1” has a variable named “Nodes 1” with value “Node_8000”, you can change the preset value of “Nodes” to any other desired Node value using **Variable Passing 1**. Similarly you can modify a second variable named “Nodes 2” in the same dashboard using the subsequent field, **Variable Passing 2**.

Click the widget in the view mode to navigate to the selected dashboard.

- **Show In** - Select **Current page** or **New Window**.

2. Click the **View** icon at the top right after entering valid details.

In the View mode, click the widget to navigate to the appropriate destination.

Widget Types

These widget types are available in the Dash Studio.

Time Series Widget

A Time Series widget is a two-dimensional time-based series of data points connected by a line. There can be multiple lines on one chart.

Widget Properties

You can select the following options under the **Widget Properties** panel to modify the visual appearance of the Time Series widget:

CARD

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces between the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

VISUALIZATION

Property	Description
Horizontal Axis Title	Set the title of the horizontal axis on the widget. This is optional.
Vertical Axis Title	Set the title of the vertical axis on the widget. This is optional.
Legend	Set the legend.
Legend Placement	Place the legend at the bottom or on the right-side of the widget.

THRESHOLD

You can define performance baselines in a widget by adding a **Threshold** value. You can add multiple thresholds to a widget, which enables you to set threshold values based on the severity.

Property	Description
Label	Set name of the threshold.
Value	Set threshold value to be set.
Color	Set color of the threshold line. By default, it is black in color.

WIDGET TIME RANGE

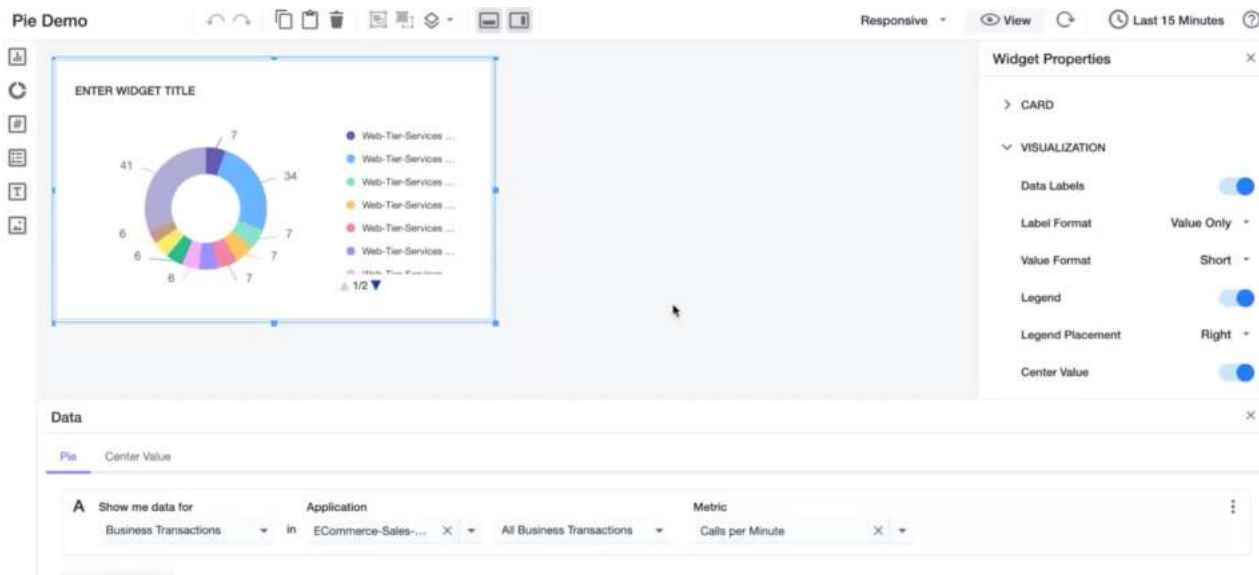

See [widget time range](#).

COMPARE TIME RANGE

See [time range comparisons](#).

Pie Widget

Pie widget displays single consolidated values for a series of metrics for a given time range as a pie visualization.

Widget Properties

You can select these options under the **Widget Properties** panel to modify the appearance of the Pie widget:

CARD

Property	Description
Background Color	Set the background color of the widget. You can either leave the default option as it is or customize it.
Padding	Add extra spaces between the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

VISUALIZATION

Property	Description
Data Labels	Define the individual data points that you can turn on or off.
Label Format	Set the format of the label. You can select one of the following options: <ul style="list-style-type: none"> • Value and Name • Value only
Value Format	Set the format of the label value. You can select one of the following options: <ul style="list-style-type: none"> • Long • Short • Percent
Legend	Set the legend, which describes the value of each pie slice of the widget.
Legend Placement	Place the legend on right side or bottom of the widget.
Center Value	Set the unit value.
Center Value Format	Set the format of the center unit value.
Center Value Unit:	Set the unit for the center value. This is optional.

WIDGET TIME RANGE

See [widget time range](#).

SINGLE CLICK ACTION

See [single click action](#).

Metric Number

A Metric Number chart highlights a single value/KPI and is typically created by:

- A single measure which can be specified using the Data Panel.
- Combining or aggregating multiple metrics.

The value display shows:

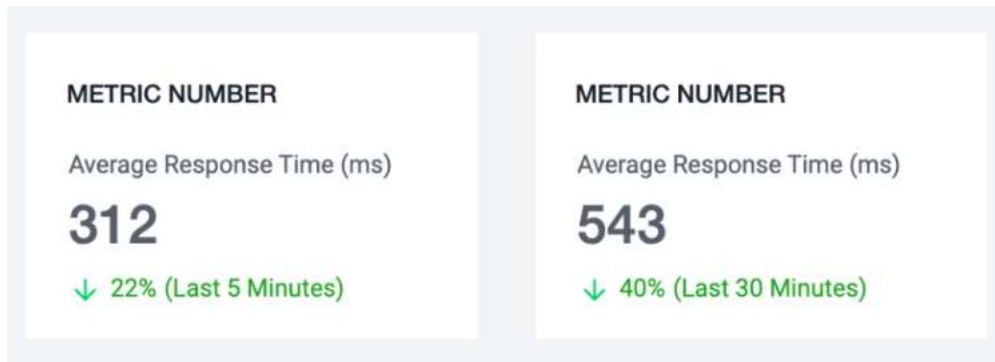

- A single measure or metric value at any instant.
- A comparison of two values (either two different metrics or a metric at different points of time).
- An aggregation of metrics across many objects or a large interval of time.

If the trend of a value over time is concerning, you can enrich these charts with contextual information to better interpret the present value, or the change in value over a time period. These charts can display numbers and text, for example, date and time of an incident.

You can also display the metric value, or a combination of these values in various ways, such as selecting a single metric:

- By name associated with a particular entity, or object that you want to learn more about.
- Aggregated across all entities of a certain type, or a provided sub-list of entities.
- Aggregated for a sub-list of entities which is dynamically determined.

The metric number helps you understand the metric value at the current point in time, and also the pattern of the metric value over a time interval.

Widget Properties

You can select these options under the **Widget Properties** panel to modify the appearance of the Metric Number widget:

CARD

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces between the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

VISUALIZATION

Property	Description
Show Metric Name	Hide or show the name of the metric.
Unit Name	Set the unit of widget value. This is optional.
Number Format	Set the format of the widget value. You can select one of the following options: <ul style="list-style-type: none"> • Short • Long • Percent
Horizontal Alignment	Set the text alignment to left, center, or right.

WIDGET TIME RANGE

See [widget time range](#).

COMPARE TIME RANGE

See [time range comparisons](#).

SINGLE CLICK ACTION

See [single click action](#).

Gauge Widget

The Gauge widget enables you to present the metric data on a relative scale. The status is indicated by an arc, where the left end is the minimum value and the right end is the maximum value.

Following are the three types of Gauge widgets:

- Status Gauge - The default Gauge widget is the status Gauge.
- Target Gauge widget - The Gauge widget in the target mode is called the Target Gauge widget. The Target Gauge enables you to set a target value for the metrics. It is set on an arc with a triangular indicator that points to the target value. The threshold values are hidden on this type of widget.
- Threshold widget - This widget displays the threshold values. It provides a visual alert through color changes.

- i** Gauge widget currently supports only the following [data binding](#) options:
- ADQL Query
 - Applications
 - ThousandEyes

Widget Properties

You can select these options under the **Widget Properties** panel to modify the visual appearance of the Gauge widget:

CARD

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces at the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

VISUALIZATION

Property	Description
Metric Name	Hide or display the name of the metric.
Value	Hide or display the value of the metric.
Value Format	Set the format of the value. You can select one of the following options: <ul style="list-style-type: none"> • Long • Short • Percent.
Min and Max Values	Hide or display the maximum and minimum value to be displayed on the widget.
Set Value Range	Set the maximum and minimum value to a desired input.
Target	Enable this option to turns the status Gauge into a Target Gauge widget. You can set it to None , Fixed , or Percentage .

 If **Target** option is enabled, all the threshold values on the widget are hidden.

THRESHOLD

Property	Description
Reverse Threshold Order	Reverse the color order for threshold values. By default, the color order is green for normal, yellow for warning, and red for critical but when you enable this toggle button the order changes to red for normal, yellow for warning, and green for critical.
All Threshold Values	Display all threshold values on the widget and the Target option gets disabled automatically.
Threshold Starting Values (%)	Set the threshold range between 0 to 100% where: <ul style="list-style-type: none"> • Normal range is between 0 and the defined normal threshold value. • Warning range is between the normal threshold value and warning threshold value • Critical is when it exceeds the warning threshold value

 If threshold option is enabled, **Target** option is hidden from the panel.

WIDGET TIME RANGE

See [widget time range](#).

SINGLE CLICK ACTION

See [single click action](#).

Health Widget

A Health Widget provides different visualizations of the health information of one or more entities for a specified time range. Use this widget to create and view health information of one, or more entities at a time, for Applications, Business Transactions, Tiers, Nodes, and Health Rules. By default, the Health widget displays health information as a ratio pie. The ratio pie visualization provides an additional option of displaying a metric value at the center of the donut pie.

Widget Properties

You can select these options under the **Widget Properties** panel to modify the appearance of the Health widget:

CARD

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.

Property	Description
Padding	Add extra spaces between the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

VISUALIZATION

Property	Description
Display as	<p>Display the widget on the dashboard as a:</p> <ul style="list-style-type: none"> • Ratio Donut: By default, the Health Widget displays as a Ratio Donut. <ul style="list-style-type: none"> ◦ Label Format: Use to change the format of the label by showing either the Count and Type or just the Count. ◦ Center Value Unit: Use to set the unit value. ◦ Data Labels: Use to turn data labels on or off. • Traffic Light: Displays the health information of critical, warning, and normal status as a traffic light. The health status shown is the overall health status of a list of entities based on the Aggregation Type. <div style="border: 1px solid #00aaff; padding: 5px; margin: 10px 0;"> <p> "Worst Health" is the only Aggregation Type currently supported for the Health widget. It shows the worst health status in the given list of entities. Additional aggregation types will be included in future releases.</p> </div> <ul style="list-style-type: none"> • Ratio Bar and List: Displays health status as a ratio bar with the list of all the entities being monitored (with a health icon next to it). You can modify the size of the bar with Bar Size from small to medium. You can use the Font Weight option to change the appearance of the font inside the widget to Light, Medium, and Strong. • Ratio Bar: Displays the health status as a ratio bar. • List: Displays the health status as a list.
Data Labels	Hide or show the individual data points that you can turn on or off.

Property	Description
Label Format	Set the format of the label. You can select one of the following options: <ul style="list-style-type: none"> Count Only Count and Type
Center Value Format	Set the format of the center unit value.
Center Value Unit:	Set the unit for the center value. This is optional.

WIDGET TIME RANGE

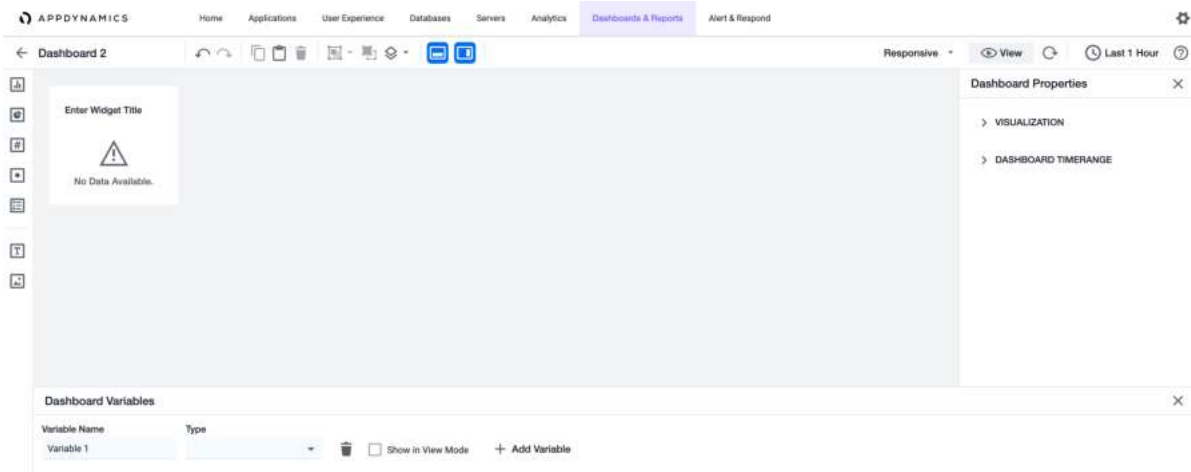

See [widget time range](#).

View Health Information

From a Data Panel, you can select the data type whose health information is to display on the Health widget.

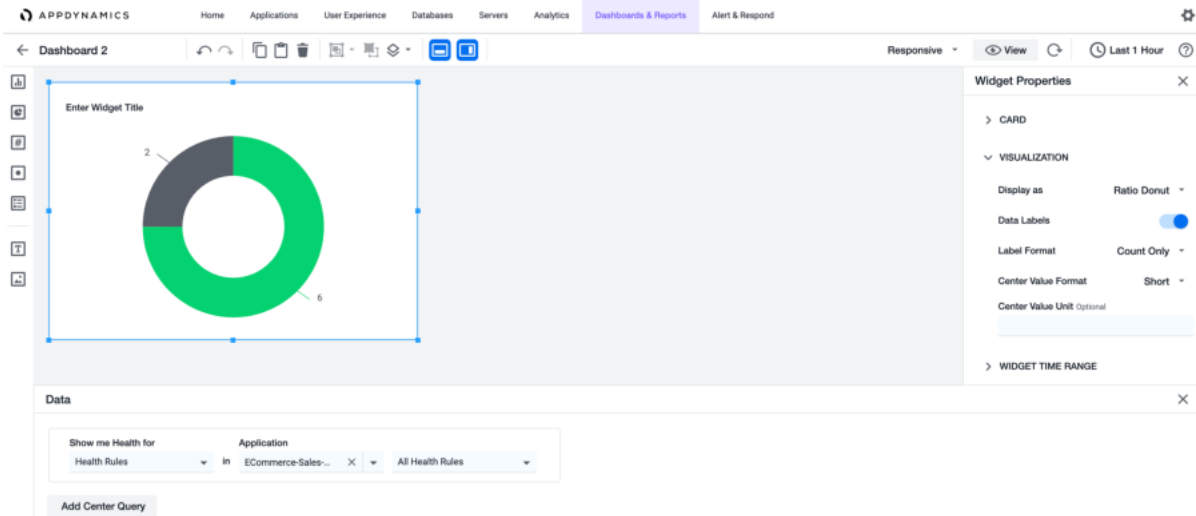

For example, supposed you want to know the health status of the ECommerce application.

1. Choose a value from the **Show me data for** dropdown based on the data type you want to display.

For this example, select Health Rules.

2. The subsequent input fields displayed in the **Data Panel** are specific to the data type selected in the previous step. Click the **Application** dropdown and select the application for which you want to drill down the data.
3. From the next dropdown, select a specific **Named** Health Rule from the popover list or select **All Health Rules**. For example, if you select **All Health Rules**, the Health widget displays as:

After you specify valid inputs for all fields, the widget will update on the canvas and display the results. To view the center value, click **Add Center Query**.

Datagrid Widget

The Datagrid widget provides a quick view of the list of entities associated with all the events on the Dash Studio. You can use this widget to present a collection of data in a tabular format. It improves the troubleshooting capabilities by reducing the number of drill-downs required to perform and navigate to other panels.

Widget Properties

You can select these options under the **Widget Properties** panel to modify the appearance of the Datagrid widget:

CARD

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces between the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.

Property	Description
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

VISUALIZATION

Property	Description
Column sorting	Sort items in the widget columns.
Column resizing	Adjust or resize the width of the widget columns based on the content contained in the viewport of the Datagrid.
Search	Search for objects in the widget.
Grid footer	Hide or display the footer content.
Row height	Adjust the height of the rows.
Filter panel	Display a list of filters.

WIDGET TIME RANGE

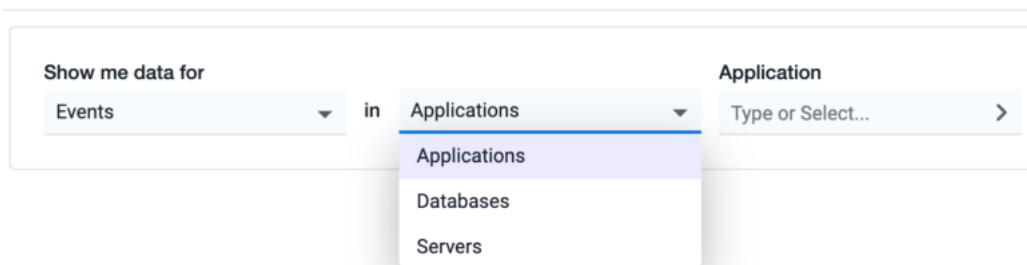

See [widget time range](#).

View List of Events

To view a list of events for a given data source, select the Datagrid widget icon  from the widget palette:

1. Under **Data** panel, click **Show me data for** and select **Events**.
2. Click the subsequent dropdown and select the data source for which you want to see the list of events. **Applications** is selected in this example.

Data

 The subsequent inputs shown in the **Data** panel are specific to the data type selected from the previous step.

3. Click **Application** and select one from the list of options. You can also enter the name of the application manually.

Data

Once you specify valid inputs for all the required fields, the widget is updated on the canvas and displays these results:

Click the **Filter Panel**  icon on the top-right corner of the Datagrid widget to see the available filters to apply.

 To view information such as summary, details, actions executed, and comments about the selected event, double-click the specific row of the widget. Based on your analysis of the event information, you can start a war room, delete the event, archive it, or test the action. You can also resize the widget in vertical and horizontal directions by dragging the edges.

Label Widget

A Label Widget is a simple text string that enables you to add text on the dashboard canvas.

Widget Properties

You can select these options under the **Widget Properties** panel to modify the appearance of the Label widget:

CARD

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces between top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.

VISUALIZATION

Property	Description
Font Color	Specify the color of the text inside the widget.
Font Size	Specify the size of the text within the widget.
Horizontal Alignment	Define horizontal alignment of the text in the widget.
Vertical Alignment	Define vertical alignment of the text in the widget.

SINGLE CLICK ACTION

See [single click action](#).

Image Widget

You can use the Image Widget to add images to a new dashboard.

Data

Image
 56-apple-512.png

Widget Properties

You can select these options under the **Widget Properties** panel to modify the appearance of the Image widget:

CARD

Property	Description
Background Color	Set the background color of the widget. You can either leave the the default option as it is or customize it.
Padding	Add extra spaces between top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.

VISUALIZATION

Property	Description
Image Scale	Set the image size. You can select one of the following options: <ul style="list-style-type: none"> • Scale to Fit • Original Size • Stretch

Iframe Widget

The Iframe widget allows you to embed data in your dashboards from another dashboard or website. This helps you to manage dashboards when you have multiple operators who focus on particular dashboards and you want to roll them all up into a primary dashboard.

To enable the Iframe widget:

1. Log in to the Controller UI as an administrator.
2. Select **Settings > Administration**.
3. Select **Integration > Dash Studio Iframe**.
4. Toggle the **Enable iframe widgets**.
5. Under **Accepted Domains**, either select **Any domain** or **Specific domains**. When you select **Specific domains** and specify the domains, only those domains are supported on the dashboard.

The controller's domain will be automatically accepted, in addition to the domains specified on the admin page.

6. Click **Save**.

i You must refresh the browser or re-login to the Controller for the changes to take effect.

Configure the Iframe widget:

1. Navigate to **Dashboards & Reports > Dash Studio**, and then create a dashboard.
2. Select the Iframe widget and specify the URL under **Data**.

i The sandbox option is selected by default. Advanced HTML features, such as forms and Javascript, do not work unless the URL is in the same domain as the dashboard. If you want to show these features, turn off sandbox.

i You can click **View Accepted Domains** to view the list of domains that your system administrator has enabled.

You can also embed the Geo Dashboard map within the Iframe. To display the map widget within the Iframe:

- a. Navigate to **Browser App Dashboard > Geo Dashboard** or **Mobile App Dashboard > Geo Dashboard**.
 - b. Copy the URL of the map widget.
 - c. Paste the URL under **Data**.
3. Click **Embed**.

Widget Properties

You can select these options under the **Widget Properties** panel to modify the appearance of the Iframe widget:

CARD

Property	Description
Background Color	Set the background color of the widget. You can either leave the default option as it is or customize it.
Padding	Add extra spaces between the top and bottom of the text within the widget. The default value is 1.
Border	Set the border around the widget.
Shadow	Set a shadow around the widget.
Title	Define a title for the widget.
Title Alignment	Align the title of the widget.

Property	Description
Title Color	Set the color of the widget title.
Subtitle	Define a subtitle for the widget.

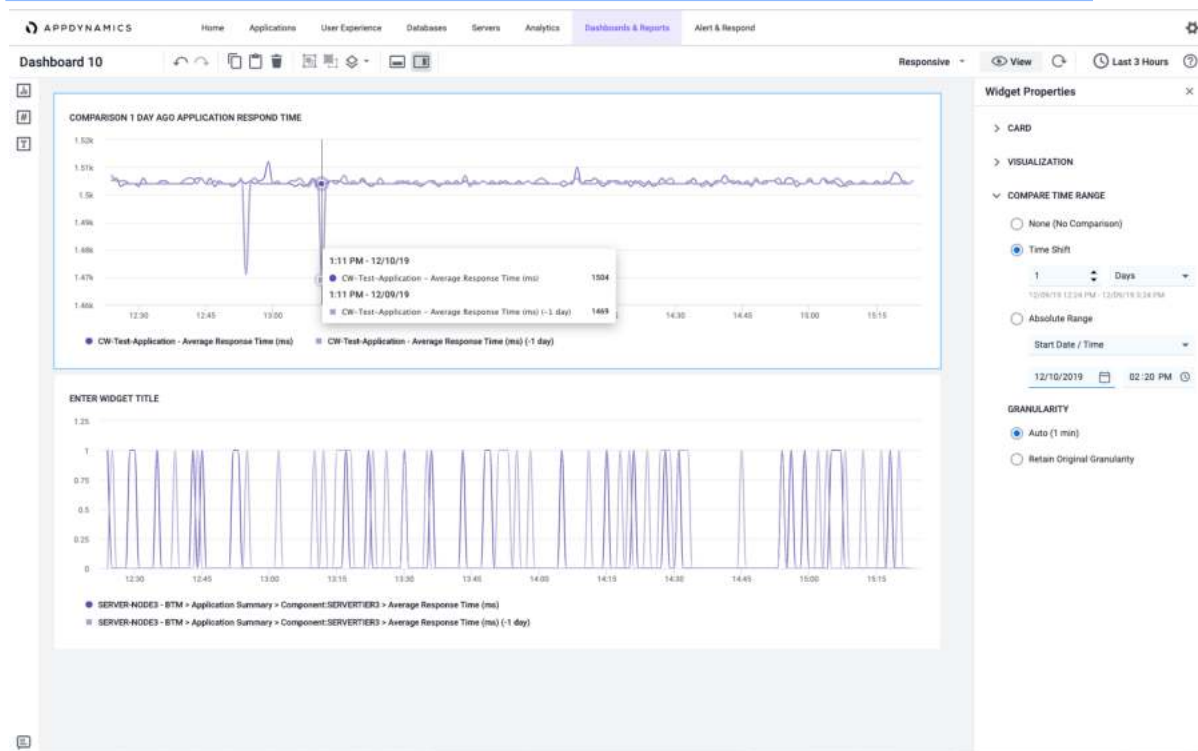

Time Range Comparisons

This page describes the time range comparison feature in AppDynamics.

You can use the time range comparison in Dash Studio to identify differences in the application performance trends for two time periods. You can align two time periods of the same data and compare. For instance, it might be useful to compare an application’s average response time on the previous day with the same day last week.

- Comparisons are currently available only for Time Series widget and Metric Number widget.
- All Data Panel options for Time Series widget and Metric Number widget support comparisons.
- Global time range (for example “Last 4 hours”) is selected for the entire dashboard by default.

The default global time range is denoted as T1 and time comparisons are performed using this time range.

Compare Two Time Periods

To compare two time periods on a widget:

1. Select the widget from the widget panel.
2. Expand the **Compare Time Range** section under the **Widget Properties** panel.
3. Set a second time range (denoted as T2) with the same duration as the global time range. You can shift T2 back in time based on the settings in the **Compare Time Range** section.

You can select one of the following options:

- **None:** This is the default setting for all the widgets when initially placed on the canvas. Select this option to exclude time comparison.
- **Previous Time Range:** This option compares the same length of time range (T2) as the current time range (T1). For example, if T1 is "Last 1 hour", you can select a one-hour time range from an earlier time of the day.

- If you open or import an existing dashboard with the **None** option, the **Previous Time Range** option gets selected automatically.
- This option is applicable only for the Metric Value widget.

- **Time Shift:** This option shifts current widget time range (T1) back by the selected amount of time to become T2. For example, if T1 is "Last 1 hour" and the Time Shift is set to 2 Hours, T2 is 2 hours earlier than T1. When you select this option, you first specify a whole number not less than one as the first input and then select one of the available time options (minutes, hours, days, or weeks) from the dropdown.
- **Absolute Range:** Use this option to specify the T2 comparison time range by selecting either the **Start Date/Time**, or the **End Date/Time** of the range. For example, if T1 is "Last 1 hour" and you select this option, you can use the date and time inputs to select a start of 8 days ago at 11 am. T2 would thus be 11 am to 12 pm on that specific day. After you set the second or third options, T1 and T2 are superimposed over the same chart space in the Time Series widget.

When you select an option other than **None**, you can turn these on:

- **Reverse Trend Color:** Reverse the color of the relative trend of the widget value.
- **Compared Value Only:** Hide the current value, and show the compared values.

Granularity

By default, Dash Studio matches granularities if there are differences between T1 and T2 time ranges. AppDynamics stores less recent data at a lower granularity which means fewer data points are displayed on the data series in Dash Studio. To perform an apples-to-apples comparison, Dash Studio is set to **Auto** by default and shows both T1 and T2 time ranges using the same granularity (even if they differ). However, you can change this behavior by selecting the **Retain Original Granularity** option instead of the **Auto** option. When you select **Retain Original Granularity** option, both T1 and T2 show data at their original granularities. This makes comparing behaviors difficult, but the newer data is highly granular.

- Showing the time range comparison doubles the number of data series on the chart. If initially three lines are shown in the widget time range without the comparison, six are shown when the comparison is defined. As new data is received, the widget and its comparisons are updated continuously.
- AppDynamics stores a reduced granularity (fewer data points) for older time ranges.
- Granularity is not available for Metric Number widget.

Time Zone Setting

You can adjust the time zone setting to collaborate and troubleshoot issues with more accuracy. You can align the time zone with other users working in different time zones and eliminate issues such as translating the timestamp of your location to another user's time zone.

To set the time zone:

1. Click the gear icon located at the top right of the page.

2. Select **My Preferences** from the listed options.
The **My Preferences** page displays an option to select a time zone.
3. Select the **Display Time Zone** dropdown and choose your time zone from the available options. In this example,
4. Click **Reload** to reload the browser and reflect the time zone update.
5. To verify the new time zone setting, open an existing dashboard.

Dashboard Variables

This page provides an overview of dashboard variables in AppDynamics.

You can use dashboard variables to quickly change the data that widgets display without creating a new widget. You can create a series of widgets that show the same metric for a different entity, and view information from multiple applications by simply switching the variable linked to application name. You can also build a dashboard by copying groups of widgets and switching the variable set for each group.

Dash Studio enables you to toggle with ease between variables at the dashboard-level, or group-level. You can define and set variables at various levels of the dashboard, whether for the dashboard at a high level, or for the group at the group level. You can define the variables that you want to set for a group.

Define Variables

You can define variables in a dashboard and across an assembly.

Set Variables

You can set variables to change the values used by a variable across an assembly or within a container. This can occur at the container level and assembly level.

Inherit Variables

Group Variable Inheritance

For group level, variable inheritance is inherited from parents to children. For example, a group inherits its variable definition from the dashboard in which it sits, however the dashboard does not inherit variable definitions from a group. This is because you cannot define variables at the group level.

Assembly Variable Inheritance

For assemblies, the sibling assemblies inherit variable definition from their siblings. For example, an assembly inherits its variable definition from the assembly from which it was made.

Nested Variables

You can nest one variable within another variable. For example, you can create a tier variable within an application variable and then bind the data using these variables.

 Nested variables support tiers, nodes, and business transactions.

Data Binding

You can use the **Data** panel to query and display data for a selected widget. Additionally, you can:

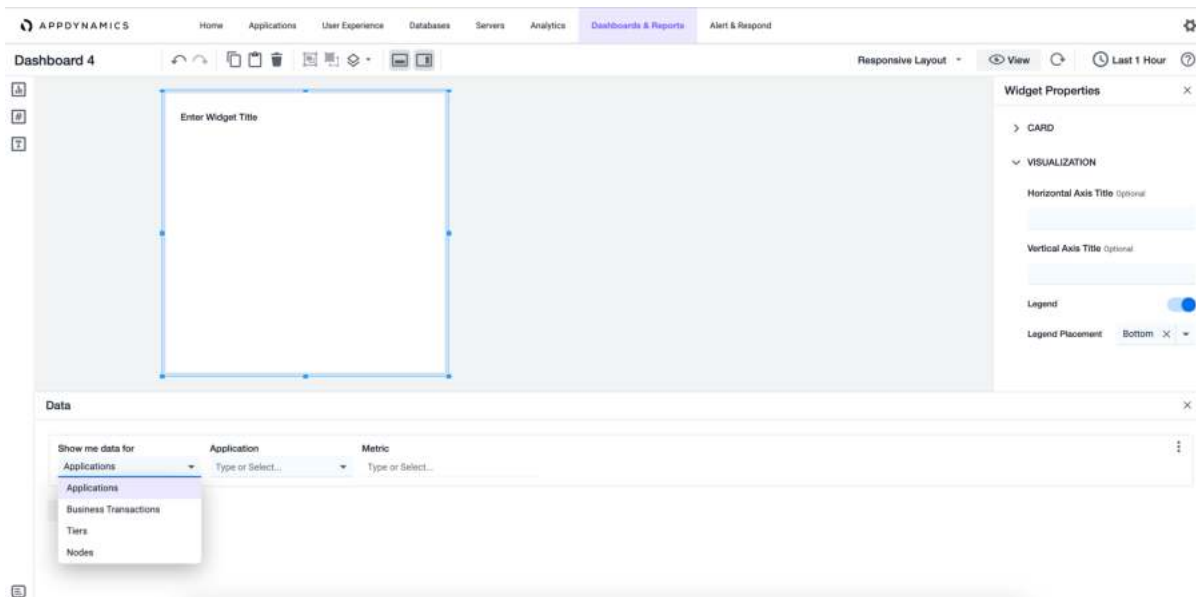

- Construct queries that span your environment.
- Add important attributes and relationships to your queries.
- Quickly access data when you do not know the metric path.
- Construct sophisticated queries.
- Query both metric and analytics data in the same query.
- Query custom metrics.

Data Queries

The **Data** panel is structured around queries. Each query follows a sentence-like format, starting with a selection of the data type of the query. Many fields in the **Data** panel support typeahead functionality.

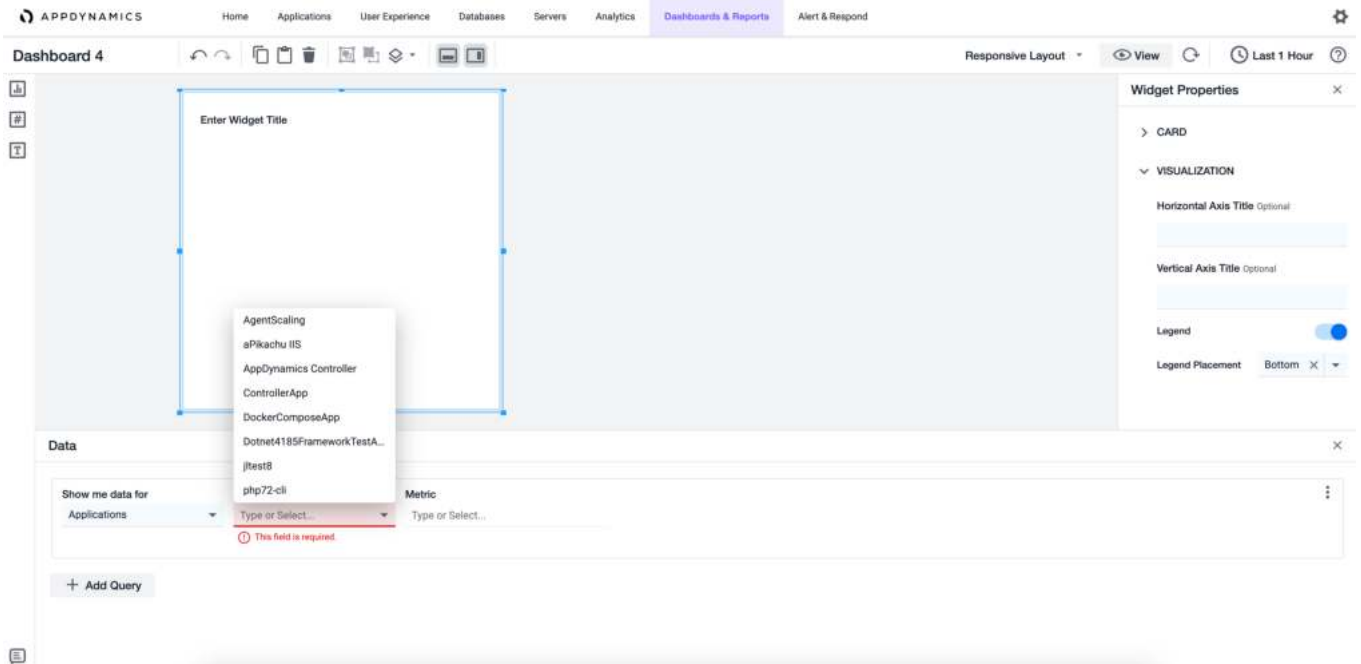

In this example, you want to know errors per minute for the nodes in an application.

1. Select a value from the **Show me data for** dropdown based on the data type you wish to display.

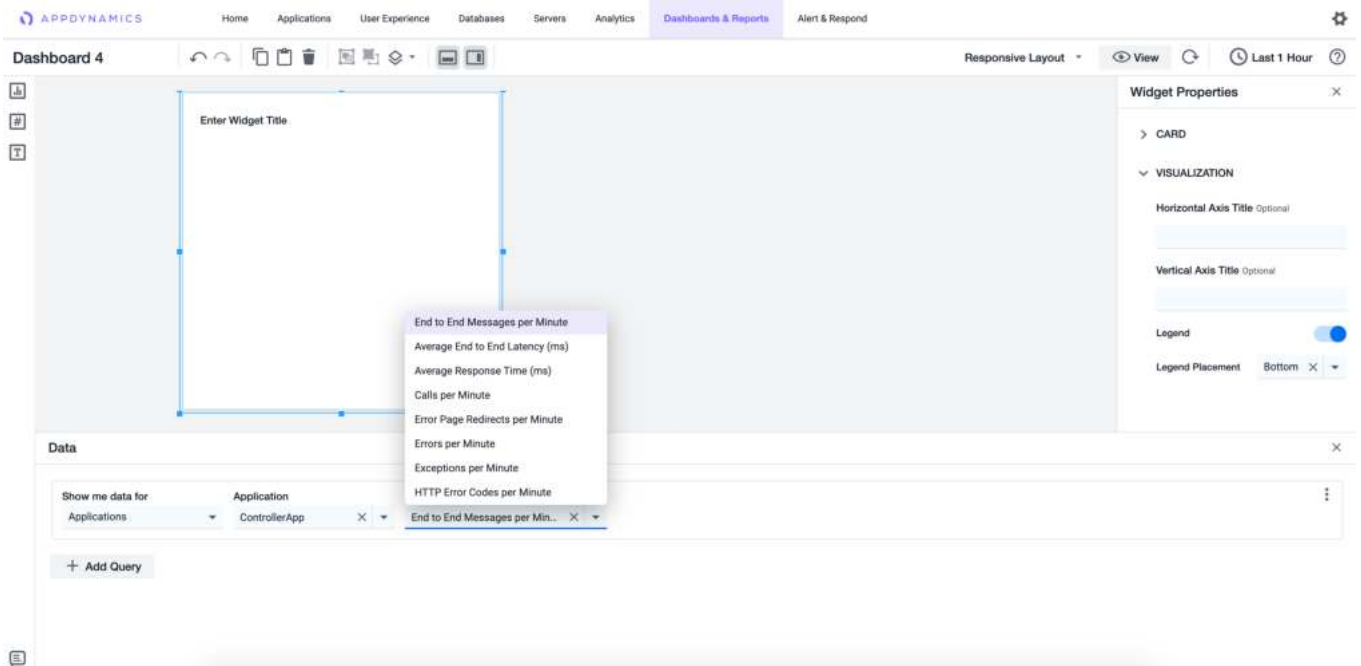

In this example, select **Applications**.

2. The subsequent inputs shown in the **Data** panel are specific to the data type you selected in the previous step. In this example, use the **Application** dropdown to select the application for which you want to drill down the data.

3. The next dropdown is **Metric**. The **Metric** dropdown changes based on the data type. For example, the node displays two more inputs before you select the metric.
4. Select the metric you wish to display on the widget. You can also click the vertical ellipsis \equiv to set the baseline, change the default metric function, set the limit, and change the default chart type.

When you select the **Function** query option, **Value** is selected by default. You can change it to view your desired output.

The **Function** dropdown contains the following options:

- **Value:** Contains the average or the sum across the time range depending on the metric
- **Minimum:** Minimum value, only available for averaged metrics
- **Maximum:** Maximum value, only available for averaged metrics
- **Sum:** Aggregated value of the metric over the time range
- **Count:** Count of the observed values over the time range
- **Current:** Sum of the most recent minute's metric data values across all the included nodes

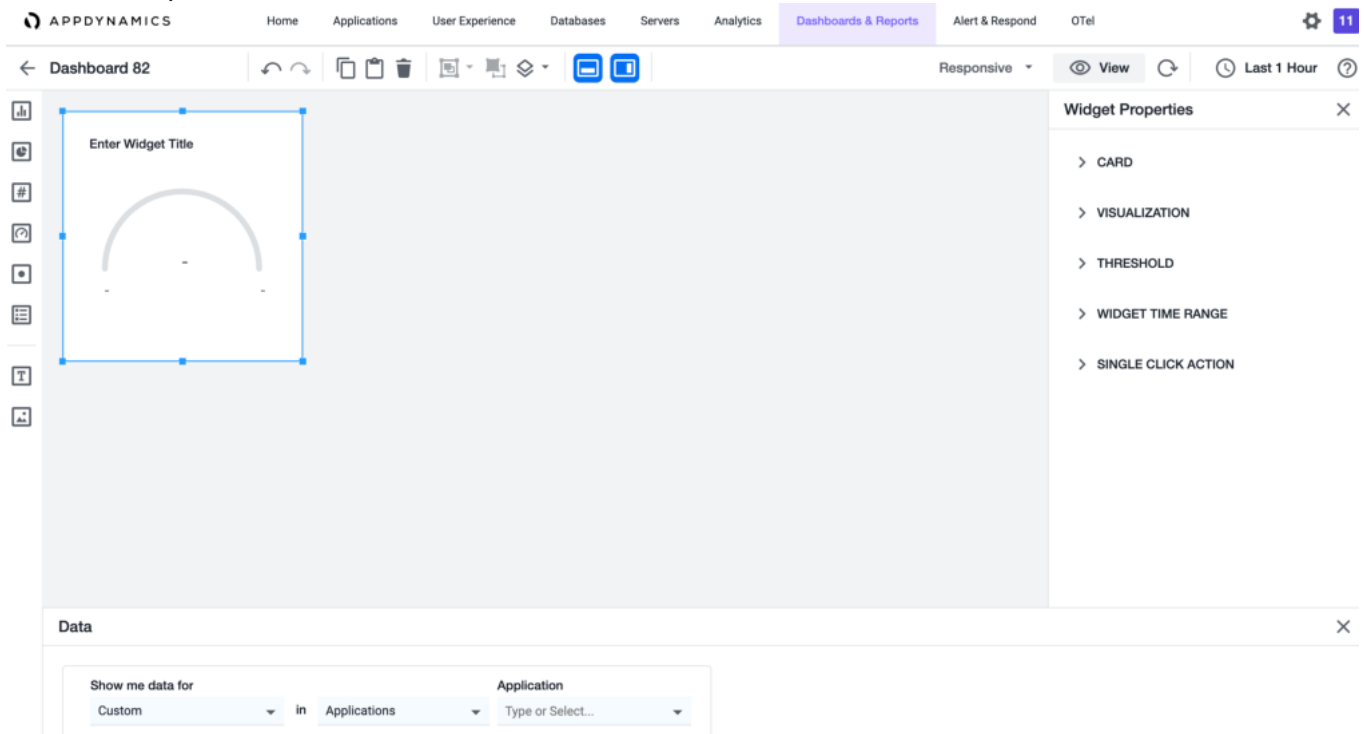

After you have specified valid inputs for all fields in the query, the widget is updated on the canvas and shows the query result.

Custom Query

The **Custom** query allows you to select any metric from the metric tree when binding data to a widget. You can configure it to display the metrics you have logged through the EUM or APM Agents. The query displays the metrics on Dash Studio to monitor the end-user performance.

In this example, you want to know the count of the slow query calls custom metric.

1. On the **Data** panel, select **Custom** from **Show me data for**.

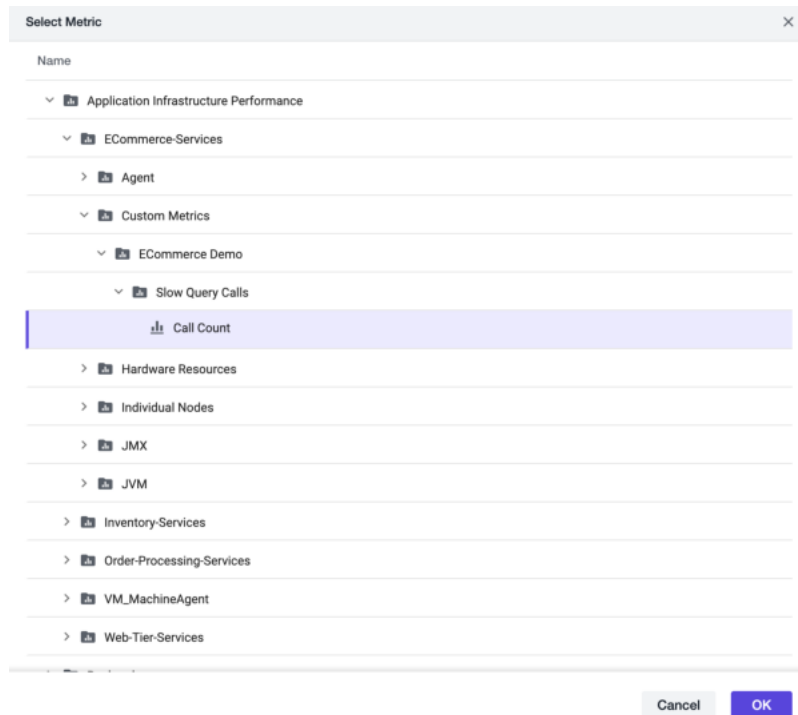

2. Select **Applications**.

i You can select either applications, browser applications, or mobile applications. Applications is used for this example.

3. The subsequent inputs shown on the **Data** panel are specific to the data type you selected in the previous step. Use the **Application** dropdown to select the application for which you want to drill down the data.

- The next dropdown is **Metric Name**. You can either copy and paste the absolute metric name or click **Select** to browse and choose the metric.

After you have specified valid inputs for all fields in the query, the widget is updated on the canvas and shows the query result.

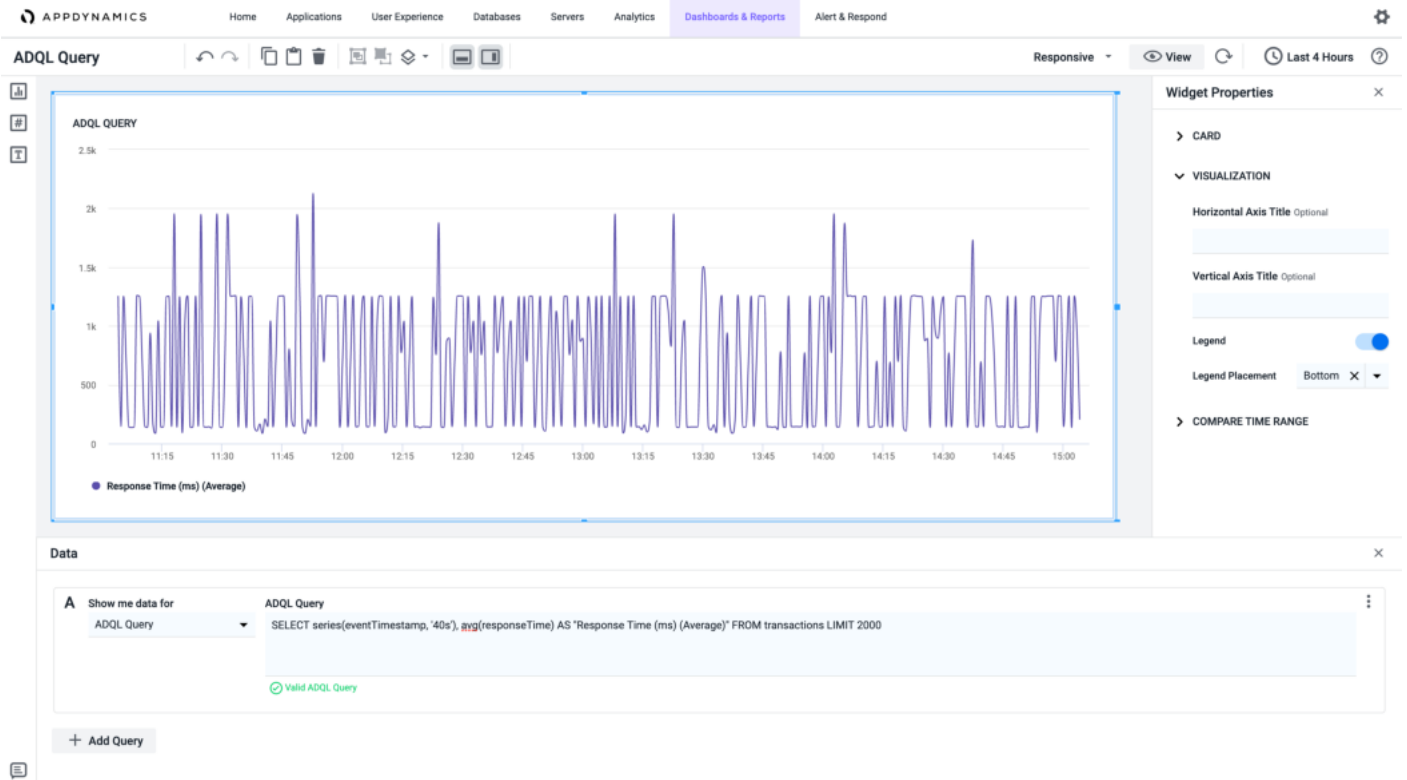

ADQL Queries

ADQL (AppDynamics Data Query Language) Query is a metrics query available in the **Data** panel for dashboards created in Dash Studio. Use this query to filter and create customized metrics for Analytics data.

ADQL Query data binding uses Analytics queries written in ADQL. After selecting the **ADQL Query** option from **Show me data for** dropdown, you can either type or paste an ADQL query. See [ADQL Reference](#) for the syntax of these query statements.

i To view data reflected in the Time Series widget in Dash Studio, you must enter a valid ADQL Query for series. You must include the `series` expression in the ADQL query statement otherwise it does not display a series. ADQL Query is available for the **Time Series** widget only.

After you type or paste the query in the input field, moving the cursor away from the input field automatically validates the query. For a **Valid ADQL Query** (displayed in green), the data displays in the widget on the canvas. For any invalid query, an error message displays in red.

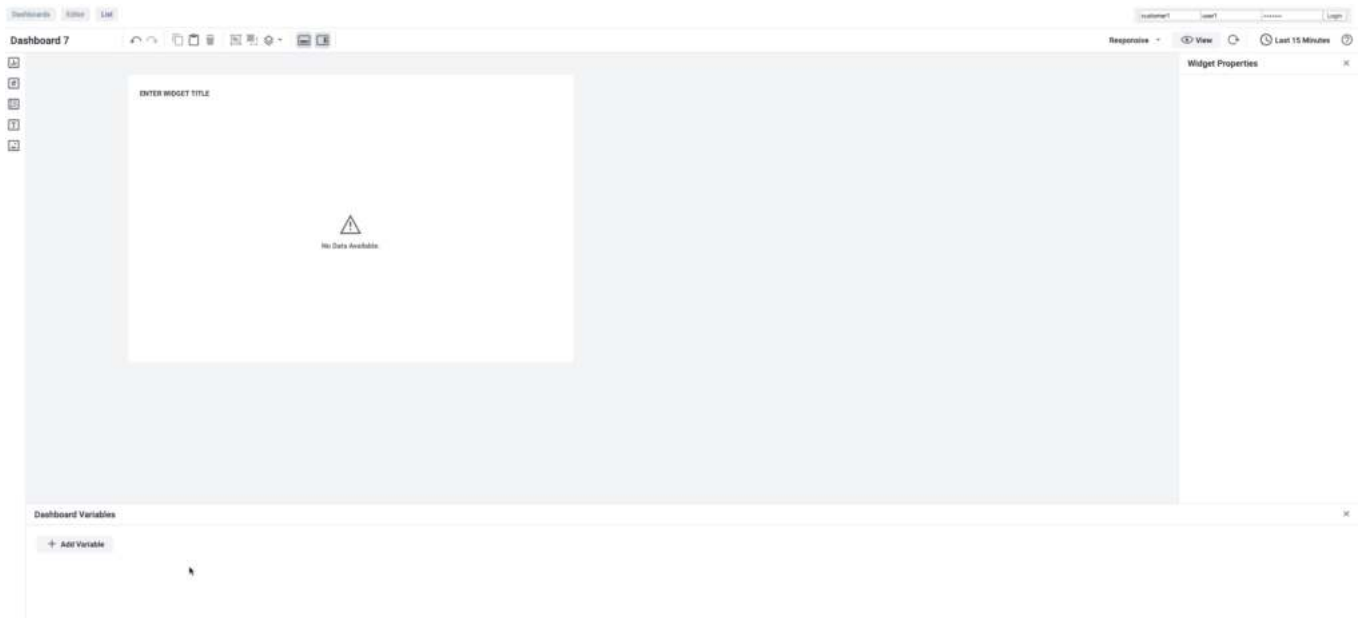

Variables in ADQL Queries

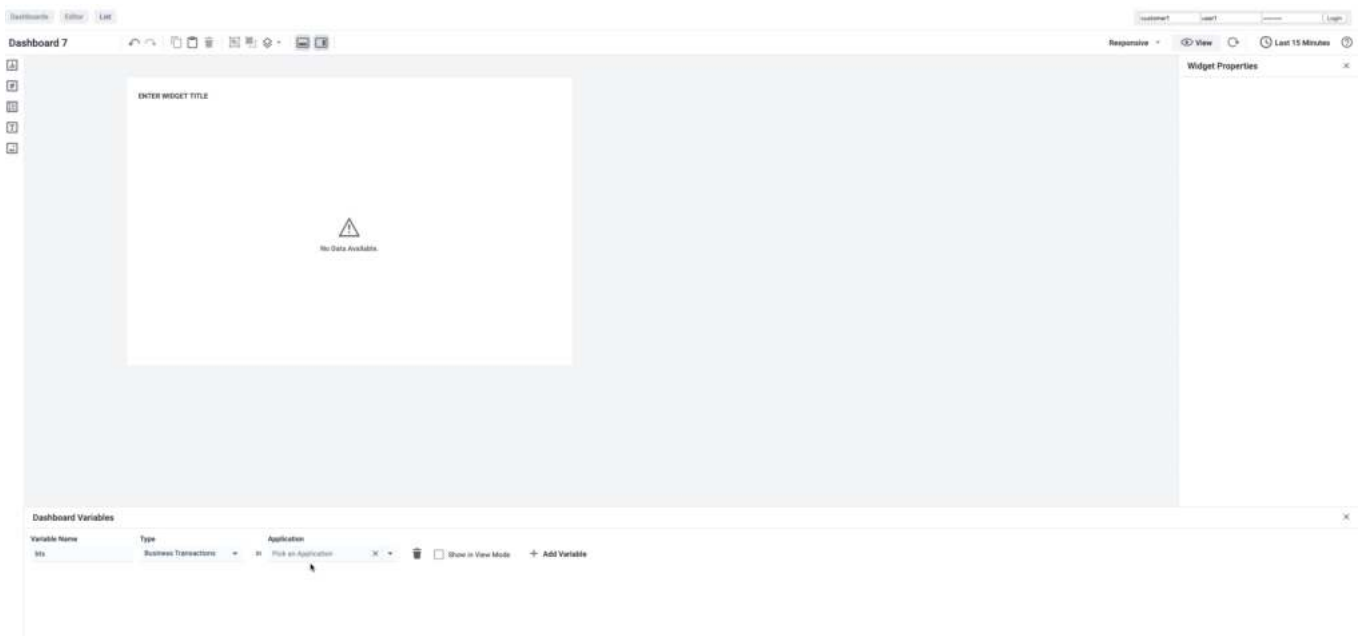

Variables in ADQL queries enable you to dynamically change the values passed into the queries.

For example, you want to use a variable for an application within an ADQL query.

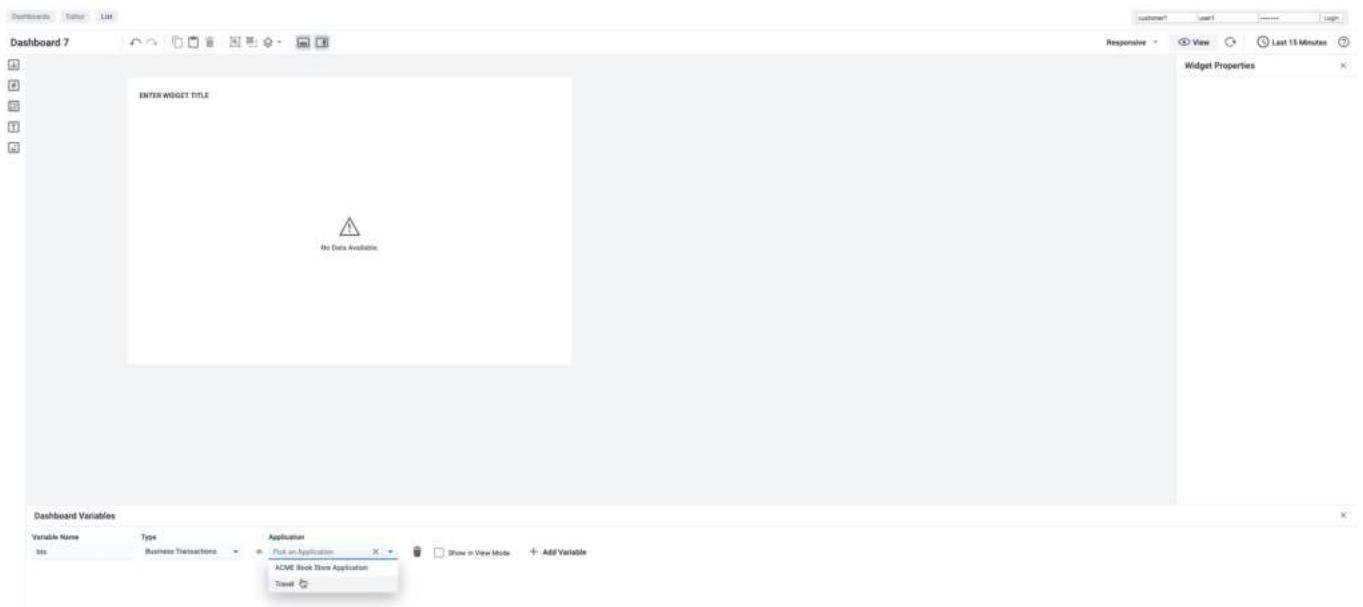

1. Click **+ Add Variable** under the **Dashboard Variables** panel.

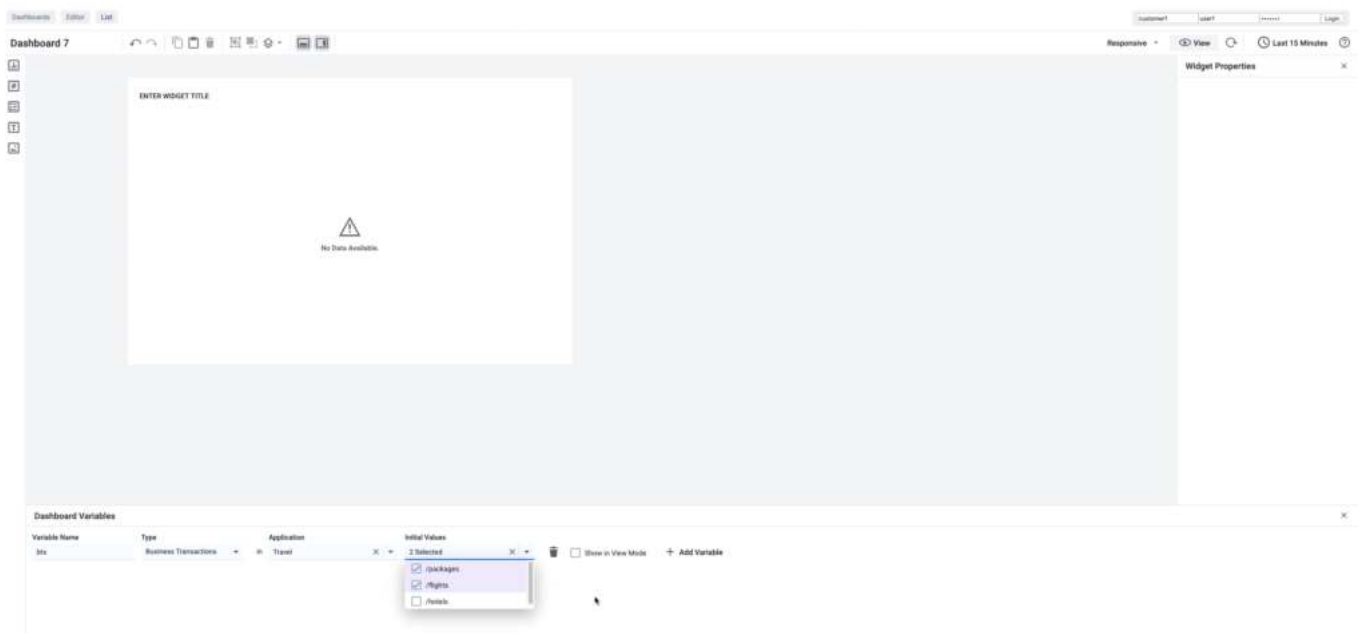

2. Enter a value in the **Variable Name** field and select the variable type in the **Type** dropdown.

3. Select an application in the **Application** dropdown.

The subsequent inputs shown in the **Dashboard Variables** panel are specific to the data type selected in the previous step. In this example, it is the **Initial Values** dropdown, which enables you to select the business transaction for which you want to drill down the data.

4. Select the **Initial Values**, and then select the **Show in View Mode** checkbox.

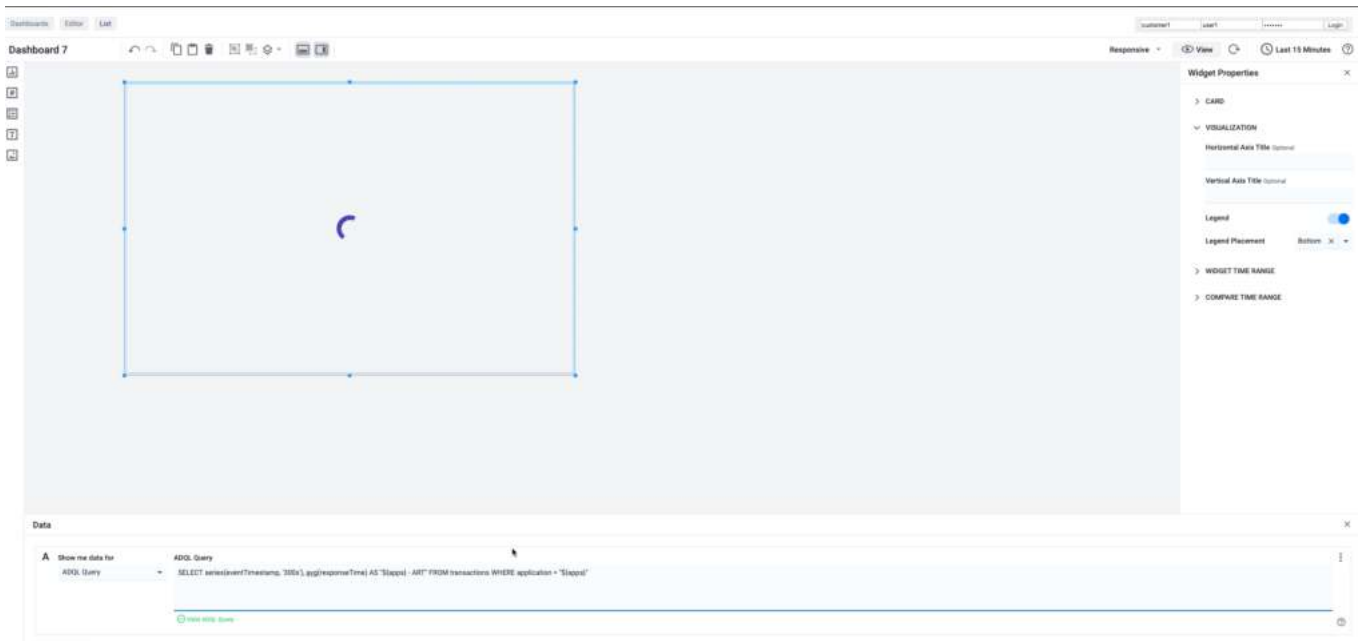

Dashboard Variables			
Variable Name	Type	Application	Initial Values
bts	Business Transactions	in Travel	2 Selected

🗑️ 👁️ Show in View Mode + Add Variable

Click the widget to change **Data Panel** from variable data to widget data.

5. Choose a value from the **Show me data for** dropdown.

In this example, select **ADQL Query**, and then enter the query in the **ADQL Query** field:

After you enter a valid query, the widget displays:

6. Click **View** on the top-right of the page. The subsequent dashboard page enables you to change the application by clicking the **\$app** dropdown.

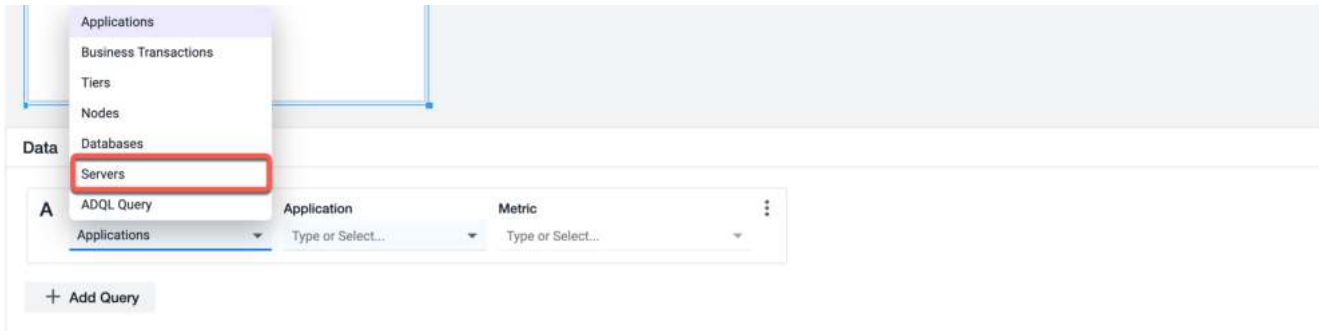

Server Metrics

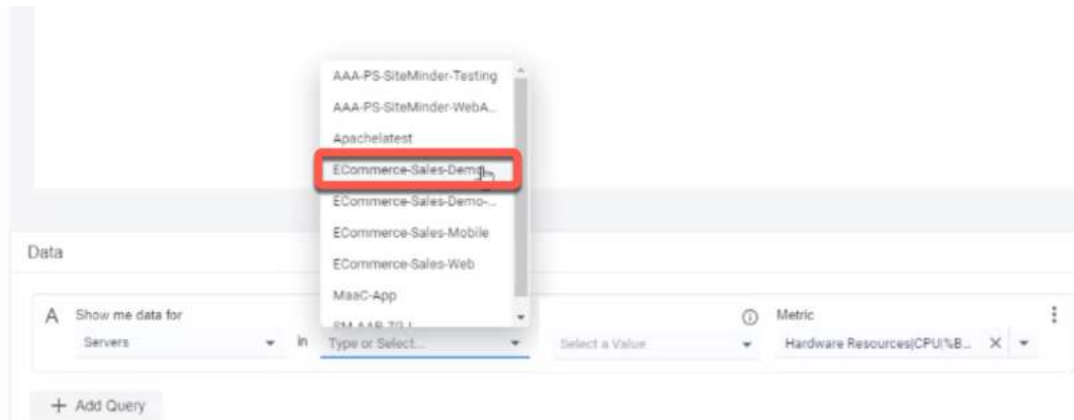

Server Metrics [also known Server Infrastructure Monitoring (SIM) Metrics] is a data binding option available in the **Data** panel of Dash Studio. Use this option to filter and create customized metrics for server monitoring.

To filter and create customized metrics for one or more servers:

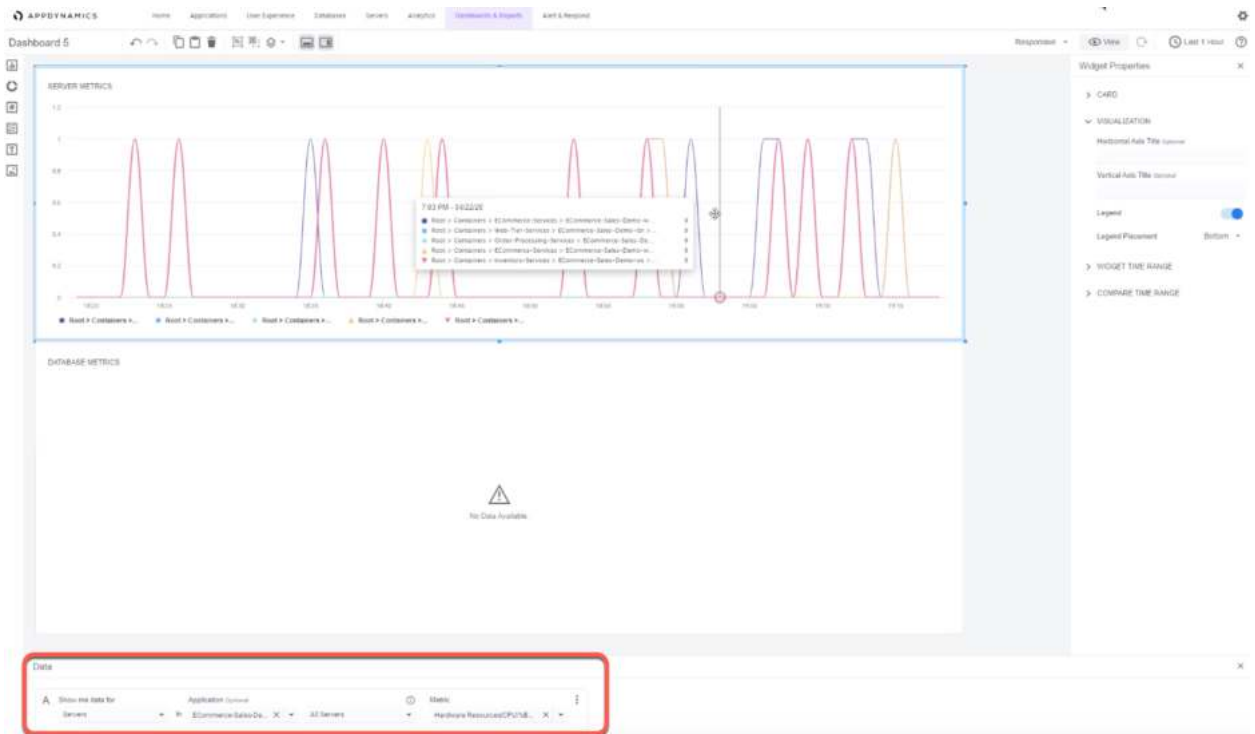

1. Click the **Show me data for** dropdown and select **Servers**.

2. Click the **Application** dropdown and select the application for which you want to drill down the data.

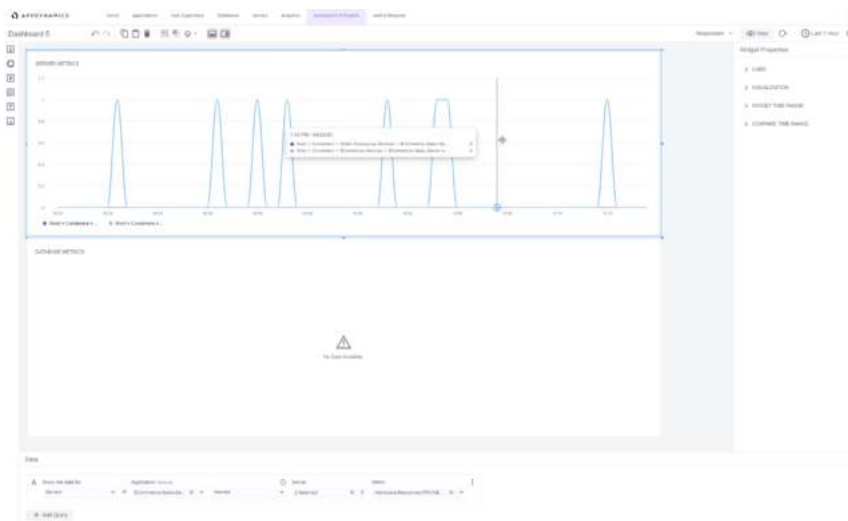

3. Click **Select a Value** and select one of these options:
 - **All Servers:** Select this option to show data across all applications. If you select this option, then the **Application** selected in the previous step becomes optional. If you select **All Servers**, the next input field in the **Data** panel automatically changes to **Metric**. Select the metric value you wish to display on the widget from the dropdown, or by manually entering a value in the input field.

i If none of the applications are selected, then the widget displays data for stand-alone applications only, and not for the applications included in the application tree.

- **Named:** Select this option to specify individual servers known to the specific application that you chose in step 2. If you select **Named**, the next input field in the **Data** panel changes to **Server**. Select one or more servers from the **Server** dropdown, and the metric value from the **Metric** dropdown.

- **Within:** Select this option to select the tier, or tiers, of the server you wish to display in the server chart.

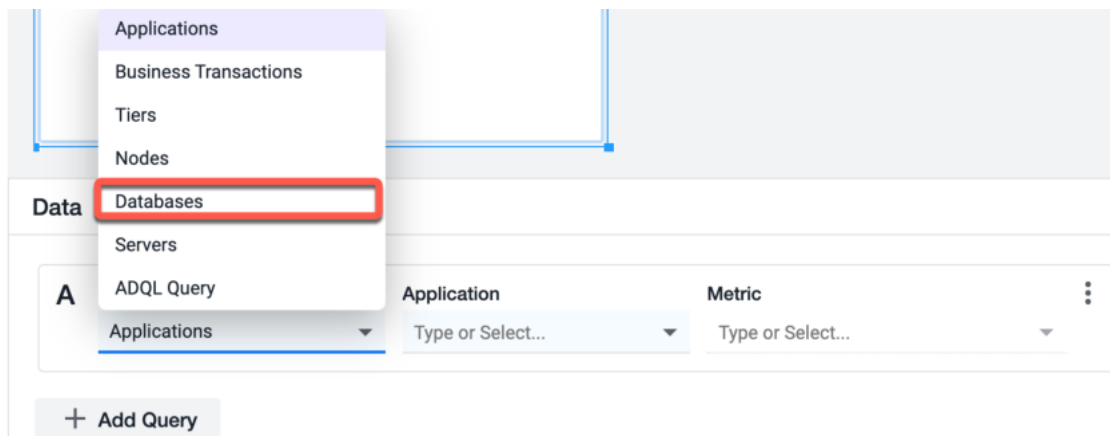

Database Metrics

Database Metrics is a data binding option available in the **Data** panel of Dash Studio. Use this option to filter and create customized metrics for database monitoring.

i The Metric Number widget does not support Database metrics.

For example, to monitor a specific database or multiple databases:

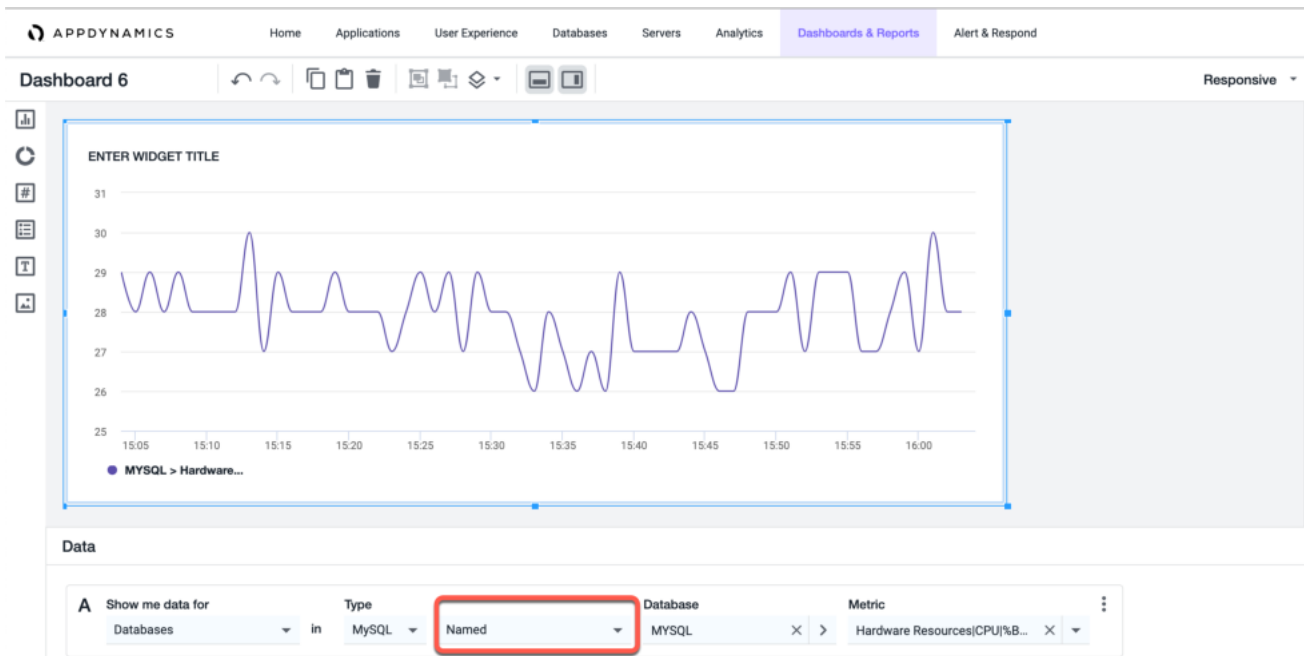

1. Click the **Show me data for** dropdown, and then select **Databases**.

2. Click **Type** and select the required database from the dropdown to display the metrics on the widget.

3. Click **Select a Value** and choose one of these options:
 - **All Databases:** Displays data for all the databases.
 - **Named:** Displays data for a specific database. You can select the required database from the subsequent input field **Database** that displays when you select **Named**.
If you have defined a database variable, you can select the variable instead of the database. See [Dashboard Variables](#) to define variables.
4. Click **Metric** and select the metric value, or enter a value manually. The database metric chart displays.

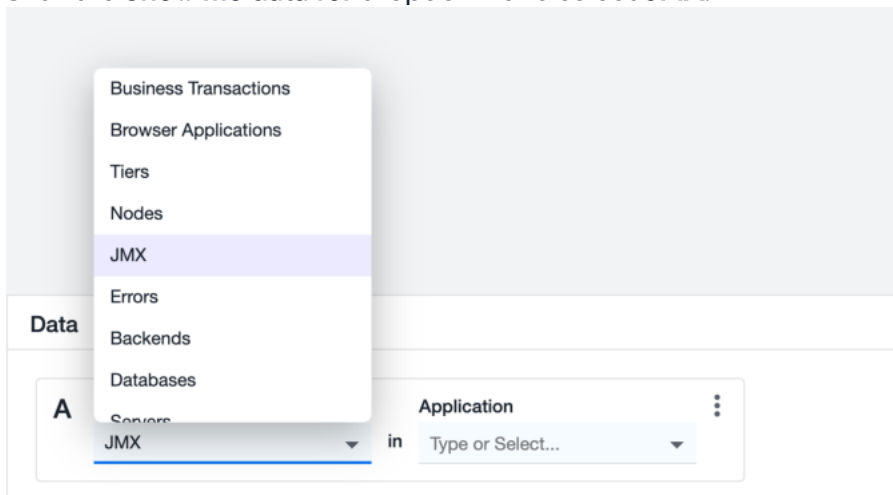

JMX

JMX (Java Management Extensions) is a data binding option available in the **Data** panel for dashboards created in Dash Studio. Use this option to filter the entities by nodes and monitor the JMX metrics for the given set of nodes.

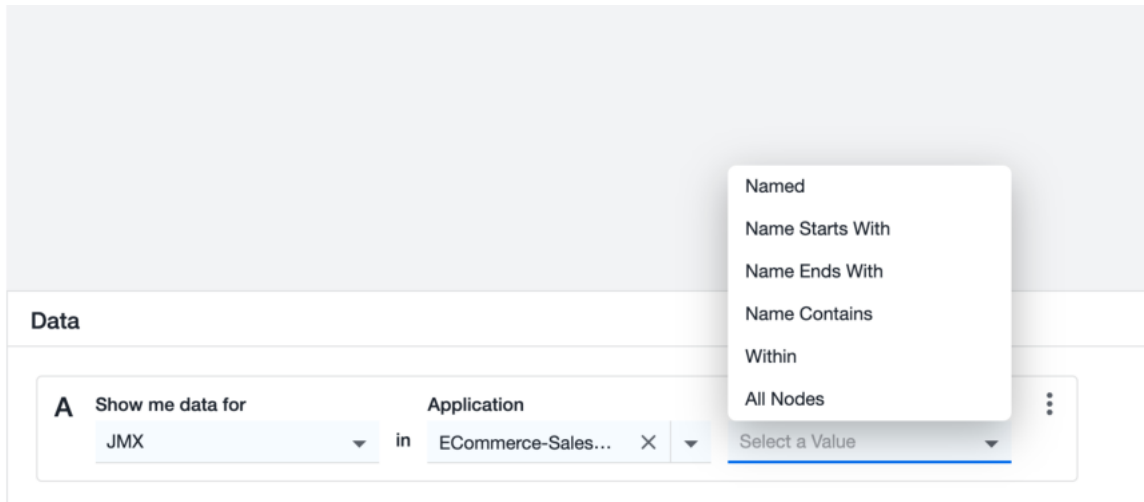

For example, to monitor JMX metrics of a node or multiple nodes:

1. Click the **Show me data for** dropdown and select **JMX**.

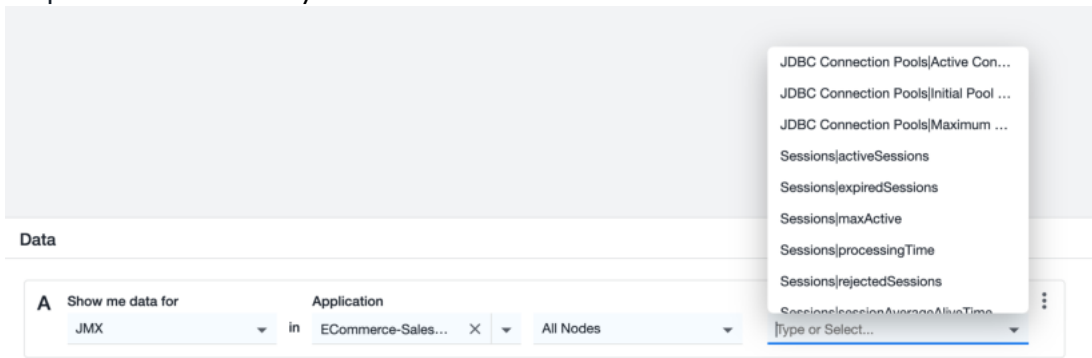

The subsequent inputs shown in the **Data** panel are specific to the data type selected in this step.

2. Click the **Application** dropdown and select the application for which you want to drill down the data.
3. Click **Select a Value** and select a node filter from the dropdown.

4. Select a **JMX** metric. You can enter the name of the metric in the field manually or select from the dropdown. This list is dynamic.

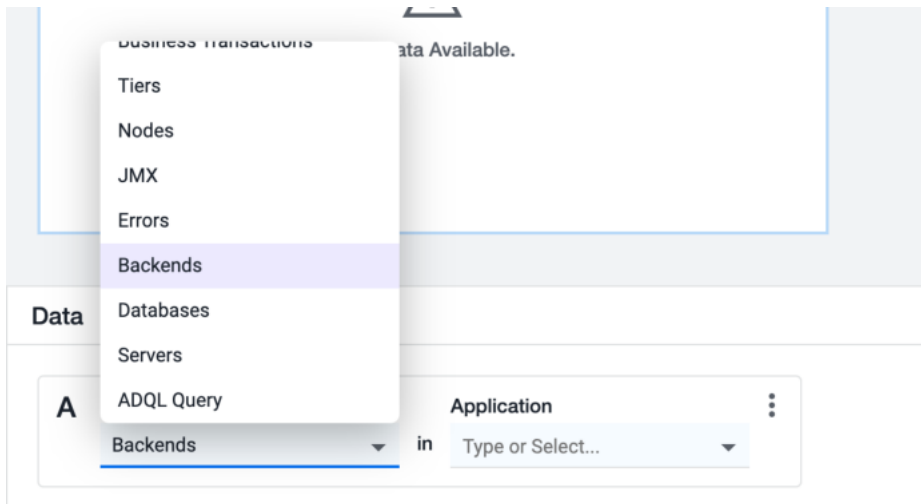

- Entries do not display if the selected entry is not a Java application, or if there are no JMX metrics for the selected application.
- The metric selector parses the Java Application metric tree dynamically for all available JMX metrics and displays them as a flattened list.
- Currently, only the JMX metrics that are 2 levels deep from a JMX folder in the metric tree are available in Dash Studio.

Backends

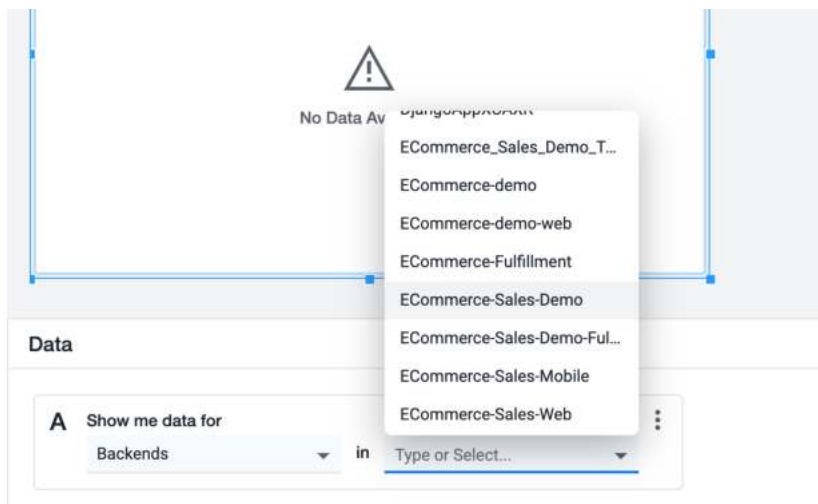

Backends is a data binding option available in the **Data** panel for dashboards created in Dash Studio. Use this option to filter the backend entities.

To monitor **Backends**:

1. Click the **Show me data for** the dropdown and select **Backends**.

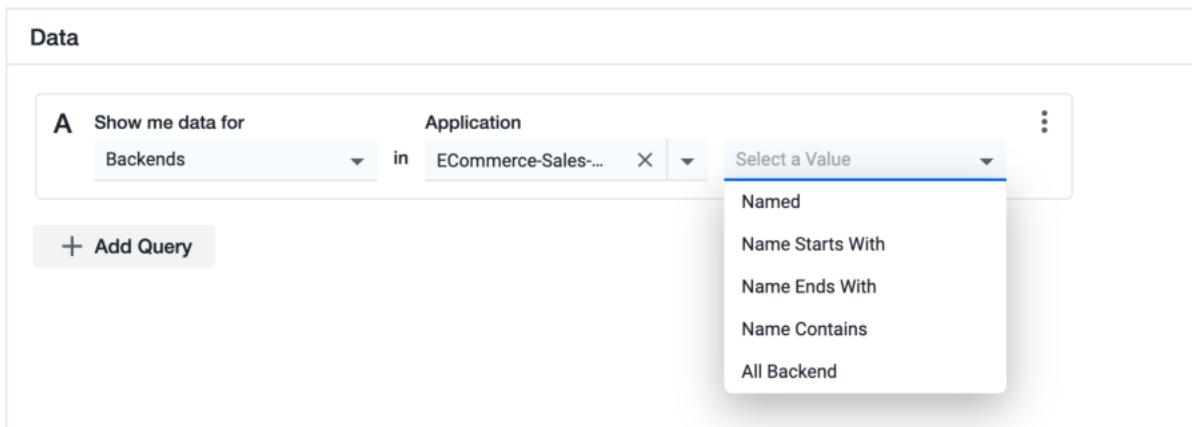

2. Click **Type or Select** and then select the application to display the metrics on the widget.

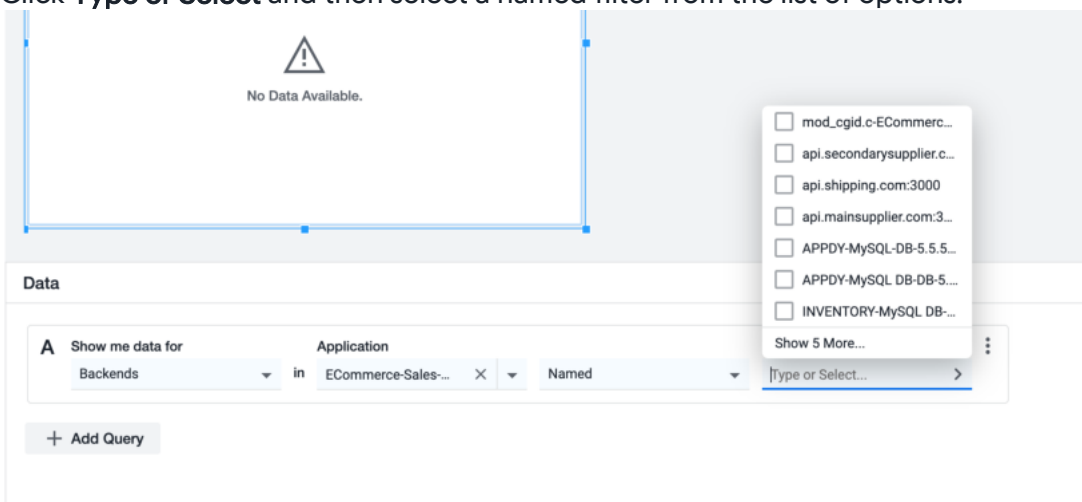

3. Click **Select a Value** and then select the filter you want to apply:

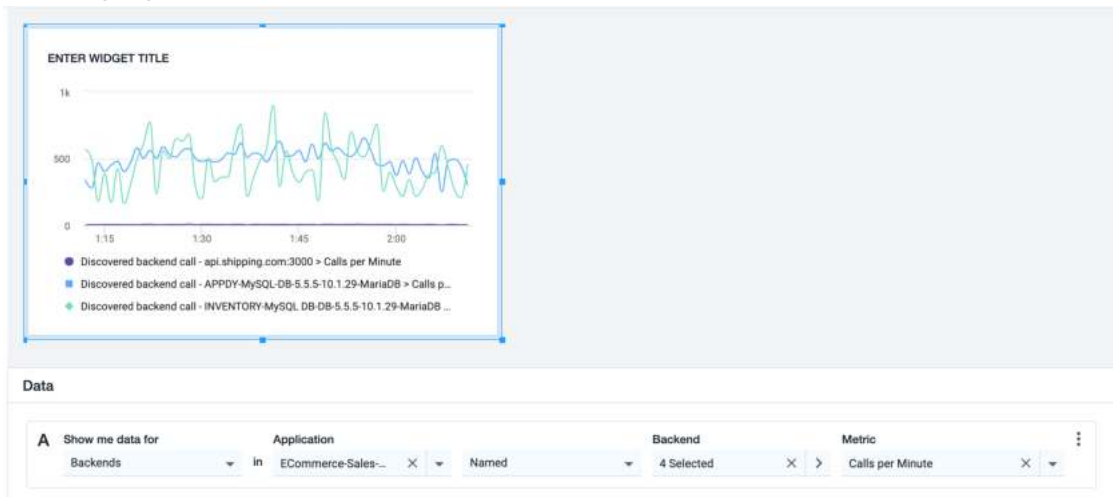

- Named
- Name Starts with
- Name Ends With
- Name Contains
- All Backend

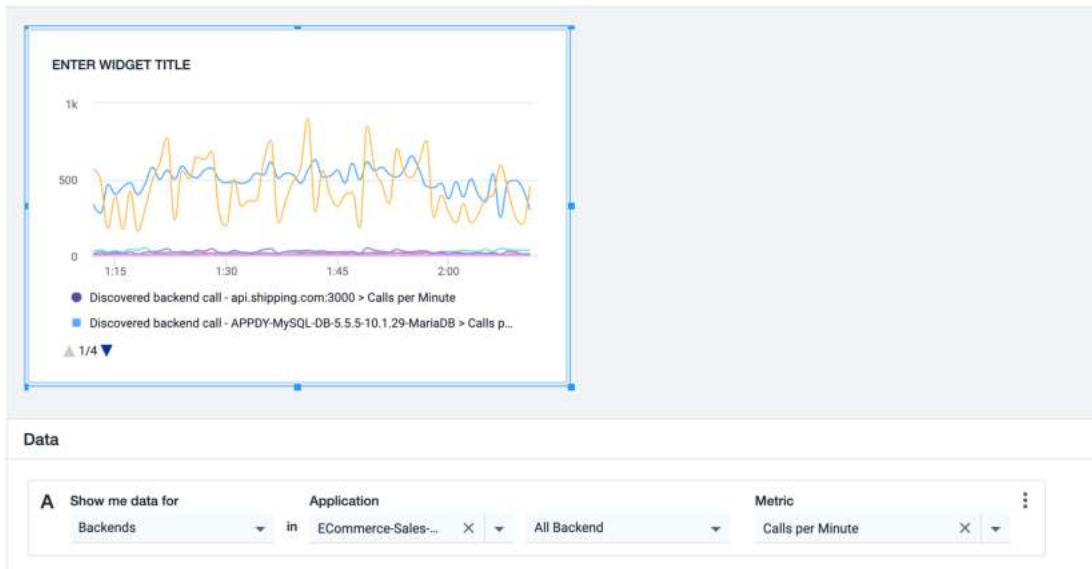

4. Click **Type or Select** and then select a named filter from the list of options.

5. Click **Metric** and select the backend metric value.

The metric chart displays:

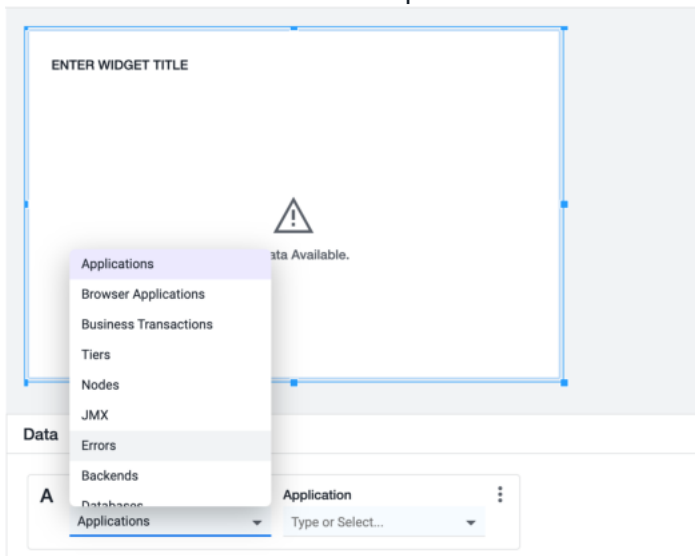

Errors Data Binding

Errors is a data binding option available in the **Data** panel for dashboards created in Dash Studio. Use this option to filter the error entities.

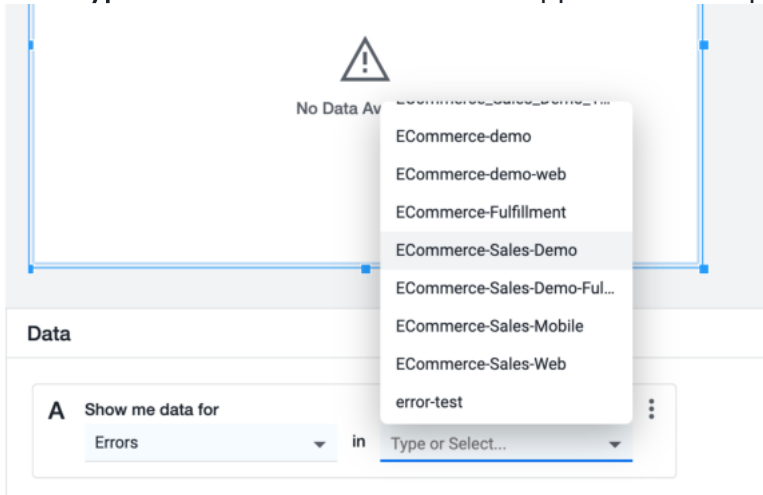

To monitor error entities:

1. Click the **Show me data for** dropdown and then select **Errors**.

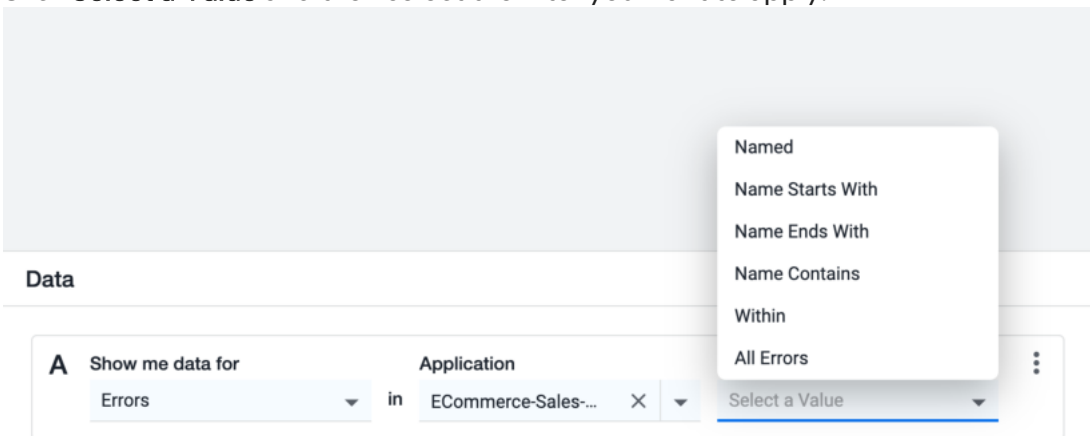

The subsequent inputs shown in the **Data** panel are specific to the data type selected in this step.

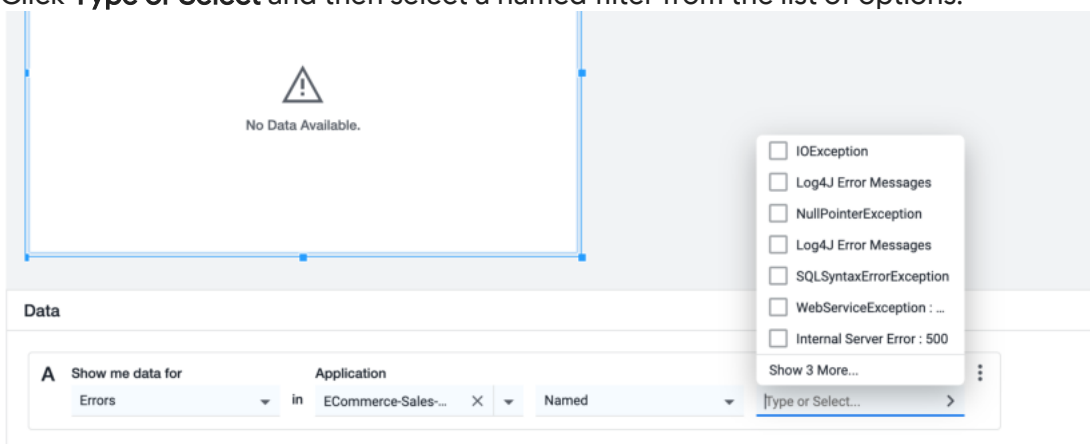

2. Click **Type or Select** and then select the application to display the metrics on the widget.

3. Click **Select a Value** and then select the filter you want to apply.

4. Click **Type or Select** and then select a named filter from the list of options.

5. Click **Metric** and select the metric value.

Browser Applications Metrics

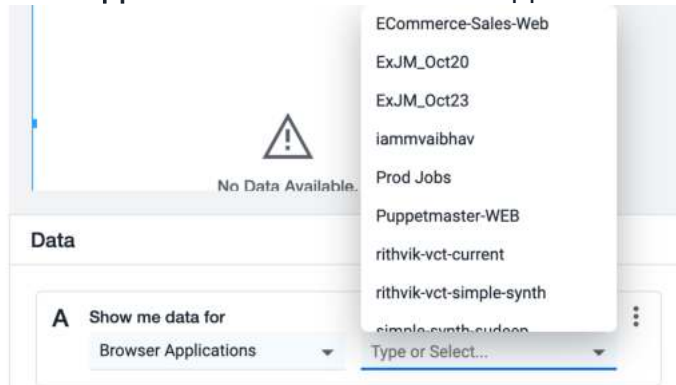

Browser Applications metrics [also known as the Browser Real-User Monitoring (BRUM) metrics] is a data binding option available in the **Data** panel of Dash Studio. Use this option to filter and create customized metrics to view the performance of the web applications.

To filter and create customized metrics for one or more browser applications:

1. Under **Data** panel, click the **Show me data for** dropdown and then select **Browser Applications**.

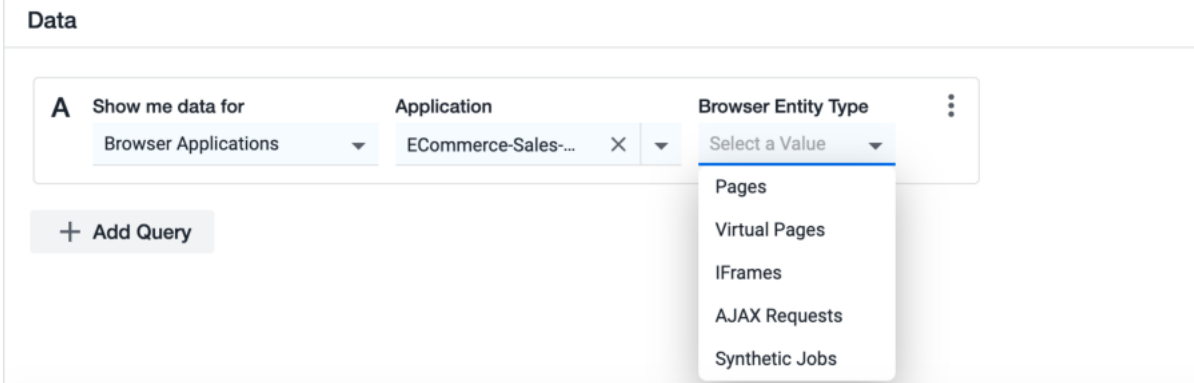

2. Click **Application** and then select the application for which you want to drill down the data.

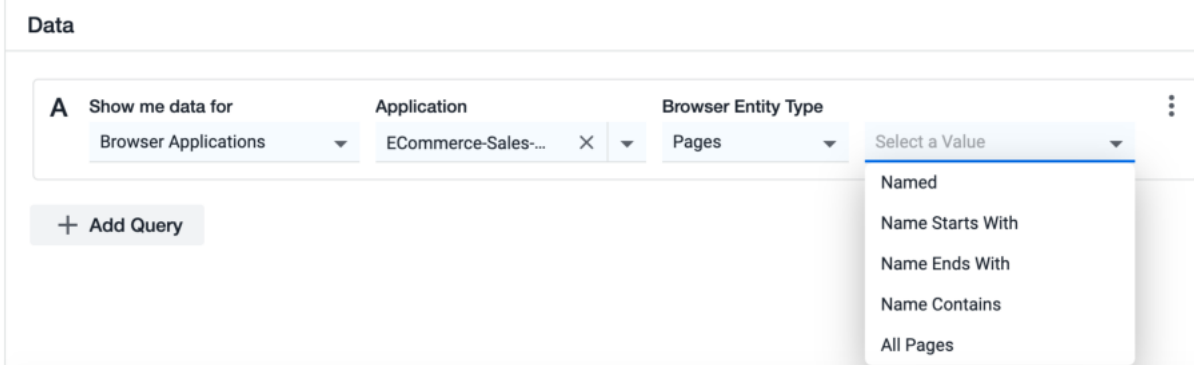

i The subsequent inputs shown in the **Data** panel are specific to the data type selected in the previous step.

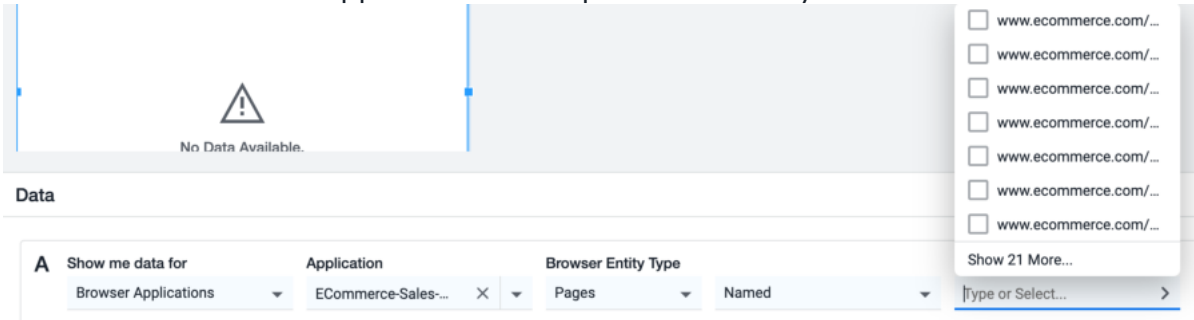

3. Click the **Browser Entity Type** dropdown and select an entity type from the list of options.

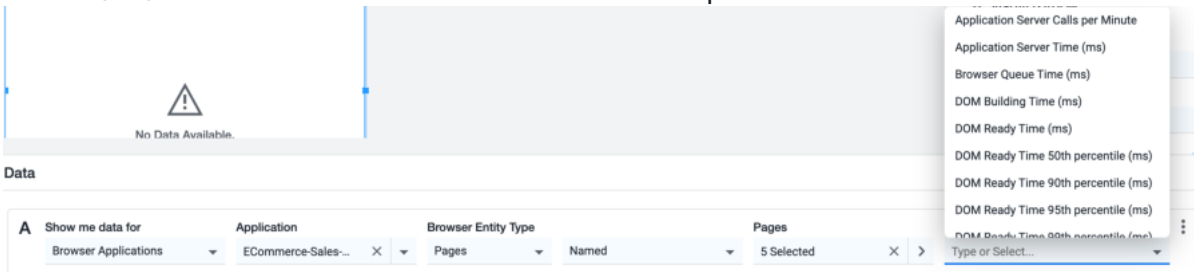

4. Click **Select a Value** and select the filter that you want to apply.

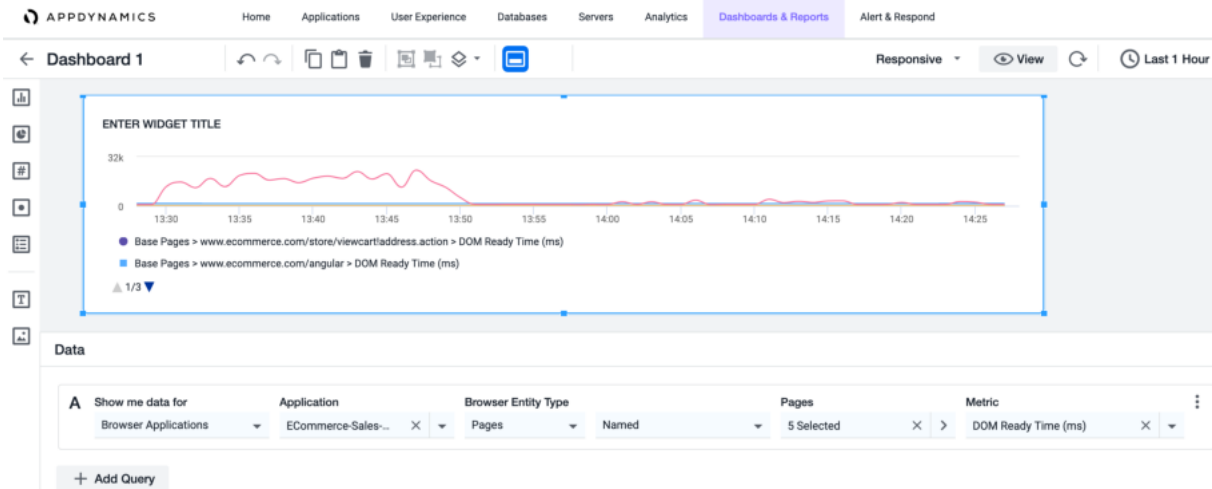

5. Click **Type or Select** and then select one or more browser applications from the list of options, or enter the name of the browser application in the input field manually.

6. Click **Metric** and select a metric value from the list of options.

The Browser Applications metric chart displays:

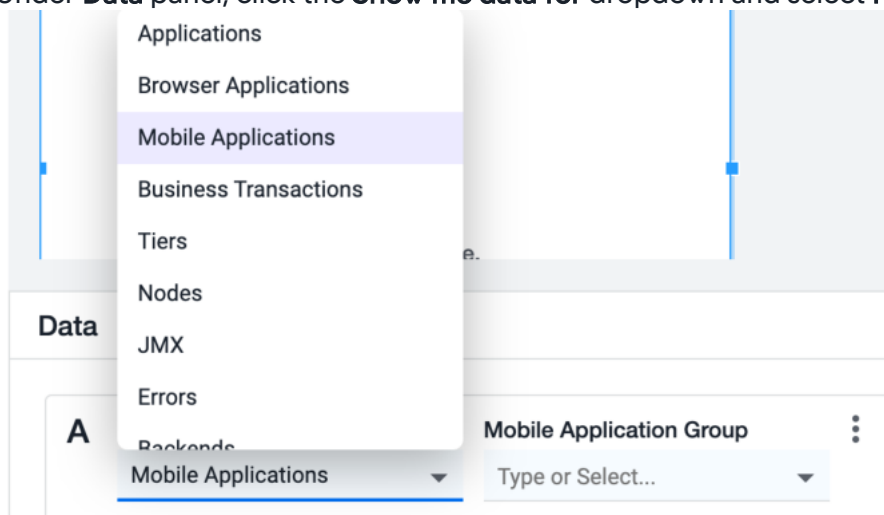

Mobile Applications Metrics

Mobile Applications metrics [also known as the Mobile Real-User Monitoring (MRUM) metrics] is a data binding option available in the **Data** panel of Dash Studio. Use this option to filter and create customized metrics to view the performance of mobile applications.

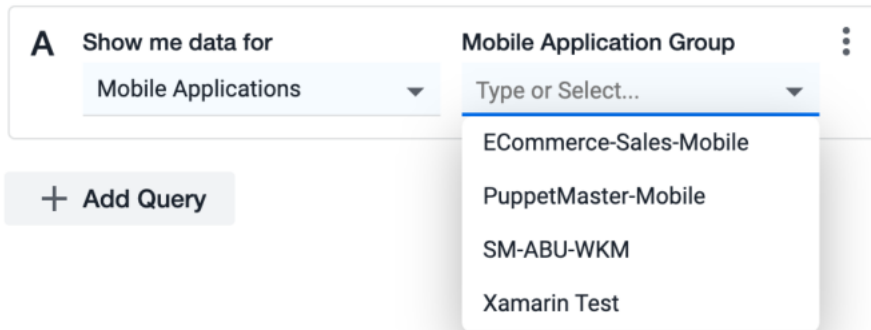

To filter and create customized metrics for one or more mobile applications:

1. Under **Data** panel, click the **Show me data for** dropdown and select **Mobile Applications**.

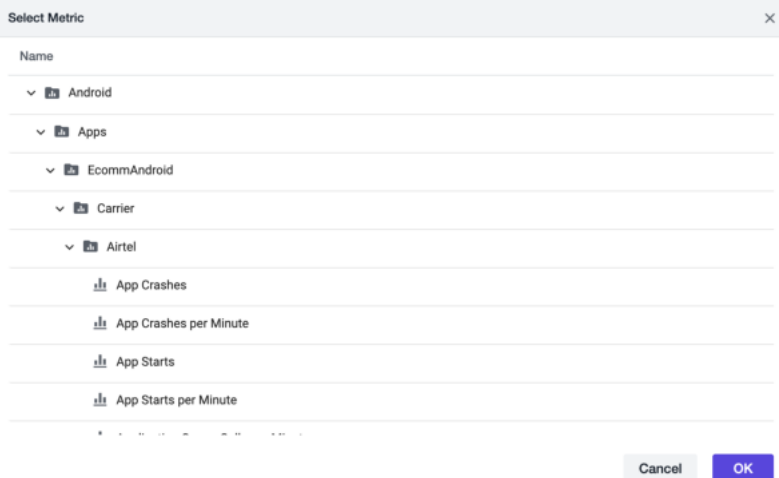

2. Click **Mobile Application Group** and then select the application for which you want to drill down the data.

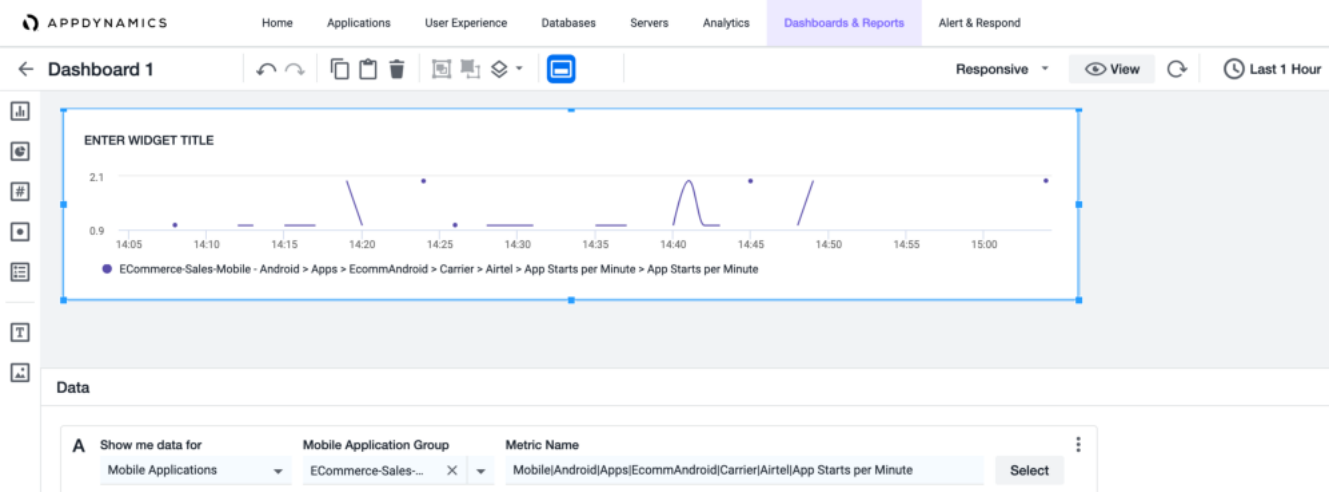

Data

3. Click the **Select** under **Metric Name** dropdown and select a metric from the list of options.

4. Click **OK**. The Mobile Applications metric chart displays:

ThousandEyes Integration with AppDynamics

ThousandEyes is a network intelligence SaaS platform that provides deep insights about the network and external dependencies. AppDynamics and ThousandEyes integration delivers a full stack solution you can use to correlate your network to the application performance. You can identify network related performance issues to reduce the impact on critical applications.

You can visualize ThousandEyes data along with application data on the dashboard created in [Dash Studio](#).

- Analyze performance bottlenecks in your network at a glance
- Drill down to the root cause of performance issues
- Monitor key metrics
- Reduce Mean Time to Resolution (MTTR)

To configure the ThousandEyes token and to enable ThousandEyes query, see the following pages:

- [Enable the ThousandEyes Token](#)
- [Configure the ThousandEyes Dashboard](#)

Enable the ThousandEyes Token

 To enable the integration for a SaaS Controller version older than 21.5.0, you need to raise a ticket at help.appdynamics.com.

Before you can access the ThousandEyes network data, you must configure the ThousandEyes token in your [ThousandEyes Account](#). See [account settings](#).

To access the ThousandEyes data, configure the ThousandEyes token by performing the following steps:

 You must have AppDynamics admin privileges access to this page. To request access contact the AppDynamics support.

1. Click the gear icon at the top-right corner of the Home page and select **Administration**. The **Administration** page displays.
2. Click the **Integrations** tab.
3. Click the **ThousandEyes** tab. The **ThousandEyes Integration** page displays.
4. Click the **Enable ThousandEyes Integration** toggle.
5. Enter the token value in the **Authorization Token** field manually or you can copy and paste it.

The token must be in the format `Bearer<space><token>`.

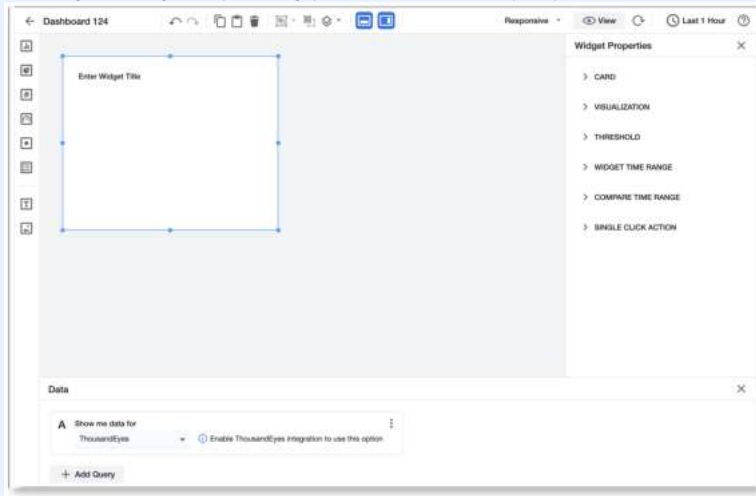

i You can retrieve the authorization token by logging in to [ThousandEyes Account](#).

6. Click **Save**.

i On disabling the ThousandEyes integration on the **Administration** page:

- If you select ThousandEyes query in **Show me data for** dropdown list, it displays a warning message requesting you to enable the query:

- The existing widgets that use ThousandEyes query do not render ThousandEyes data.

Configure the ThousandEyes Dashboard

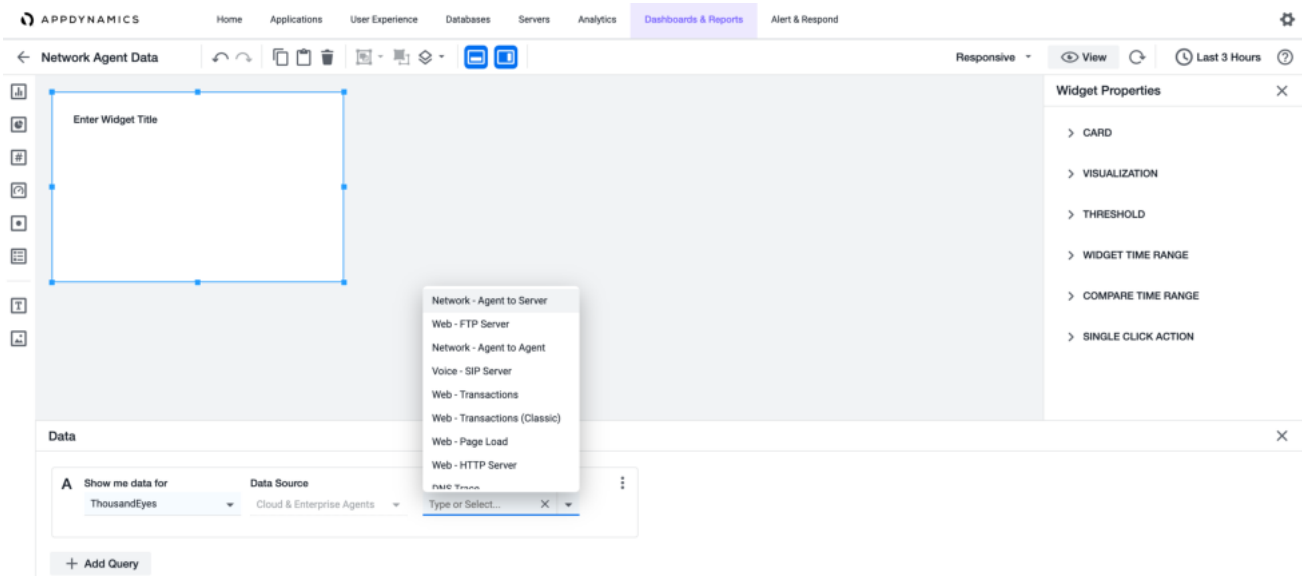

The ThousandEyes query is a metrics query available in the **Data** panel for dashboards created in Dash Studio. Enable this query to troubleshoot network performance issues related to latency, packet loss, and bandwidth utilization. See [ThousandEyes platform](#).

To filter and create customized metrics to analyze the performance of your network:

1. Click **Dashboards and Reports** and select the **Dash Studio** tab.
2. Click **+** to create a new dashboard or you can open an existing dashboard.
3. Select a widget from the widget panel.

i Only the Time Series, Metric Number, and Gauge widget support the ThousandEyes query.

4. Click the **Show me data for** dropdown in the **Data** panel.
5. Select **ThousandEyes** from the dropdown. You can add only one ThousandEyes query per widget. **Data Source** field displays with the **Cloud & Enterprise Agents** option set by default.

- The Data Source option allows you to choose an agent type to gain insights about network and application performance. See [agent types in ThousandEyes](#).
- Dash Studio supports only one agent type, Cloud & Enterprise Agents.

6. Click **Metric Category** and select a category from the dropdown list.
7. Click **Metric** and select a metric value from the dropdown list.
8. Click **Group By** to select how to group the selected metric value. You can group the metrics using one of these options:
 - **Agent Labels** - Logical grouping of agents.
 - **Agents** - Agents installed at various locations.
 - **Tests** - Network assets to be monitored. See [tests](#).
 - **Test Labels** - Logical grouping of multiple tests.

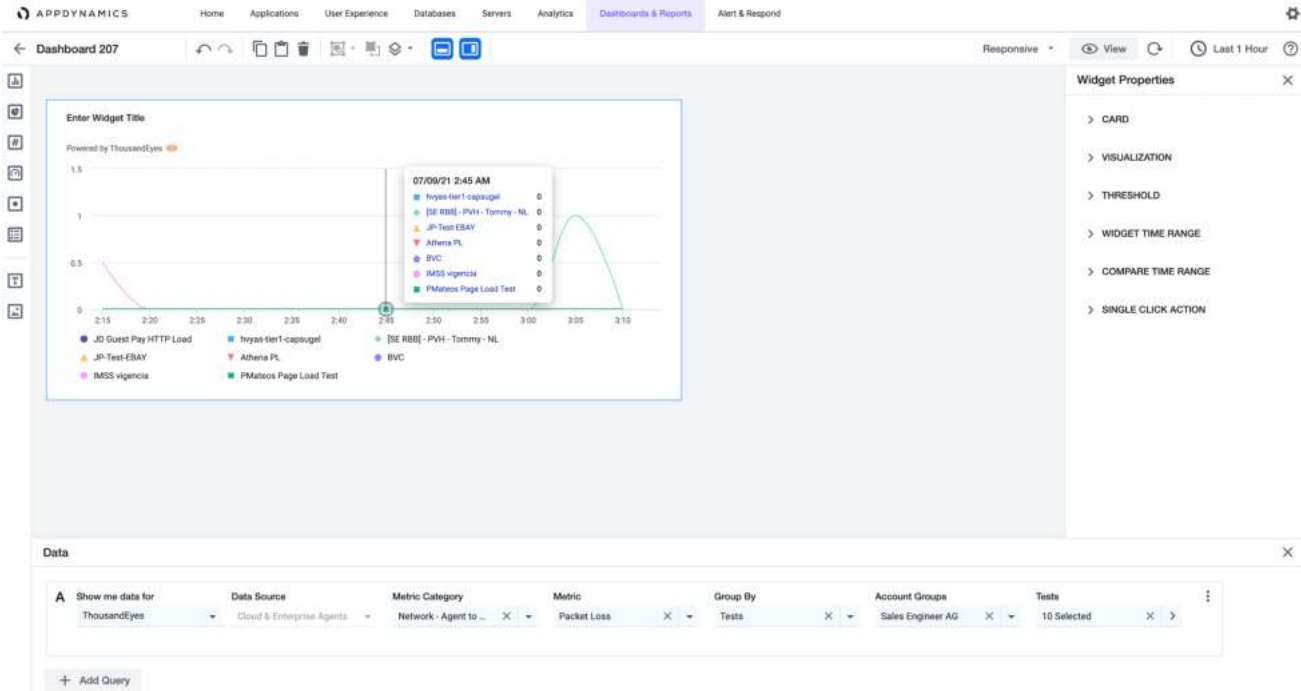

The **Group By** option is available only for the Time Series widget.

9. Click **Account Groups**, then select a group from the dropdown list. The default account group is selected if you do not choose any group.
10. Click **Tests**.

When you select an account group, you can choose only the associated tests of that account group.

After you enter valid inputs in all the fields, the widget displays this output:

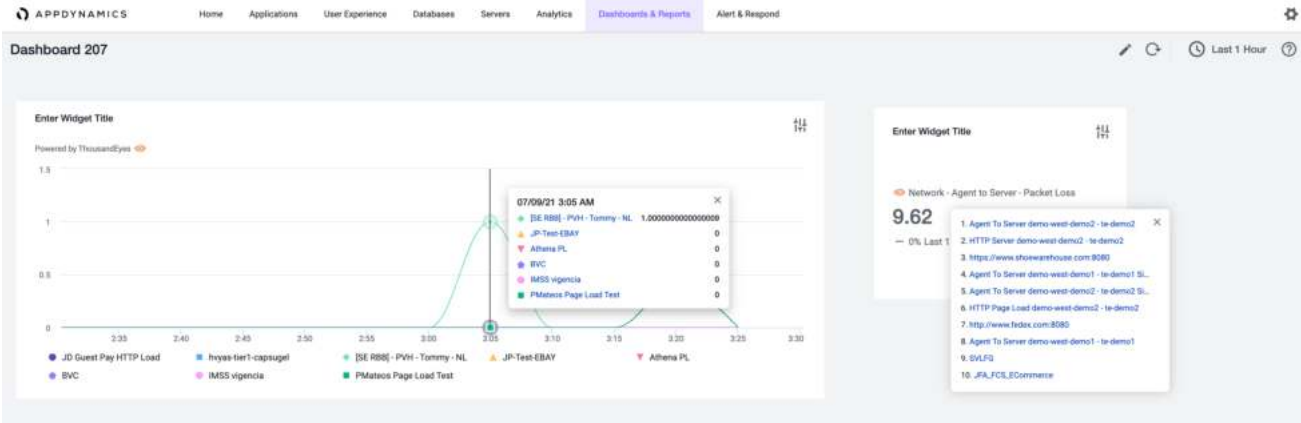

i The dropdown list does not display the disabled test.

On completing successful ThousandEyes binding, the **Powered by ThousandEyes** icon displays for the Time Series widget.

- i** The maximum supported time range is 90 days.
- Time Range Comparison is not available for ThousandEyes data.

On the Time Series widget, you can hover over the graph to view the ThousandEyes tests. On the Metric Number widget, you can hover over the numerical value to view the ThousandEyes tests. Clicking on any of the test links redirects you to the ThousandEyes dashboard.

User Preferences

This page provides an overview of user preferences in AppDynamics. Controller UI users can change their passwords, account settings, date and time format, and other preferences on the **My Preferences** page.

User Preferences

You can access the controls for changing your display name, contact email, or password from the **My Preferences** page by clicking the **Edit** link under your email. The controls require you to enter your password to complete the change.

The display name is the name that the Tenant uses to identify you in specific screen text and messages. For example, it appears in notifications to other Tenant users when you share a dashboard with them. You cannot change your username. To change your username, you need to have an administrator delete your account and create another one with the new name.

Some user account settings are attributes of local users (that is, users validated against credentials stored in AppDynamics). If your Tenant is configured to use an external authentication mechanism instead, such as SAML or LDAP, you need to change the equivalent settings in the external system instead.

My Account

This is where you can update your personal account information and configure your AppDynamics mobile app. You are not able to edit your **Username** as it is part of the SAML federation.

Password Requirements

Strong passwords are required for local accounts. A secure password must meet these requirements:

- A minimum of eight characters
- Contain both uppercase and lowercase letters
- At least one number
- At least one special character
- Not the same as your username or email address

AppDynamics Mobile App Configuration

AppDynamics provides a quick response (QR) code to set up the mobile app on your iPhone or Android phone.

Click **View Configuration Code** and follow the instructions provided. See [AppDynamics Mobile App](#).

View Preferences

The Tenant UI provides the following user preferences:

- **Date Format:** By default, the format is MM/DD/YY (for example, 09/25/14). Choose an alternate format from the dropdown.
- **Display Time Zone:** Select or search for your time zone.
- **Use 24-Hour Time Format:** Enable this option if you want the UI to represent time in 24-hour time format instead of 12-hour clock format.
- **Enable Help Pop-ups:** Help popups provide contextual help text in the Tenant UI. By default, they are enabled. To prevent help popups from appearing in the UI, clear this checkbox. Alternatively, you can prevent individual popups by selecting the **Don't Show Again** checkbox when the popup appears. To clear the list of popups marked as *Don't Show Again*, click **Reset All**.
- **Default Palette:** Select from various color palettes for the UI.

You may need to log out of the UI and log back in to see the effects of your changes.

Advanced User Preferences

The user preferences page presents advanced options that include debug mode.

Debug Mode

We recommend that you enable debug mode only when directly advised to do so by AppDynamics Support.

The debug mode in the Tenant UI is primarily intended for internal use by the AppDynamics development team. In some cases, you may be asked to enable debug mode when consulting with AppDynamics Support, for example, when you are troubleshooting an issue. However, it is important to note that specific debug mode options can negatively impact Tenant performance.

Application Monitoring

AppDynamics SaaS provides end-to-end visibility into the performance of your applications.

AppDynamics works with popular programming languages such as Java, .NET, Node.js, PHP, Python, C/C++ , and more, enabling you to:

- Troubleshoot problems such as slow response times and application errors.
- Automatically discover application topology and how components in the application environment work together to fulfill key business transactions for its users.
- Measure end-to-end business transaction performance, along with the health of individual application and infrastructure nodes.
- Receive alerts based on custom or built-in health rules, including rules against dynamic performance baselines that alert you to issues in the context of business transactions.
- Analyze your applications at the code execution level using snapshots.

Overview of Application Monitoring

Related pages:

- [Flow Maps](#)
- [Metrics and Graphs](#)

After you understand the basics of AppDynamics, you can learn how AppDynamics models application environments. The model serves as the framework around which AppDynamics organizes and presents performance information.

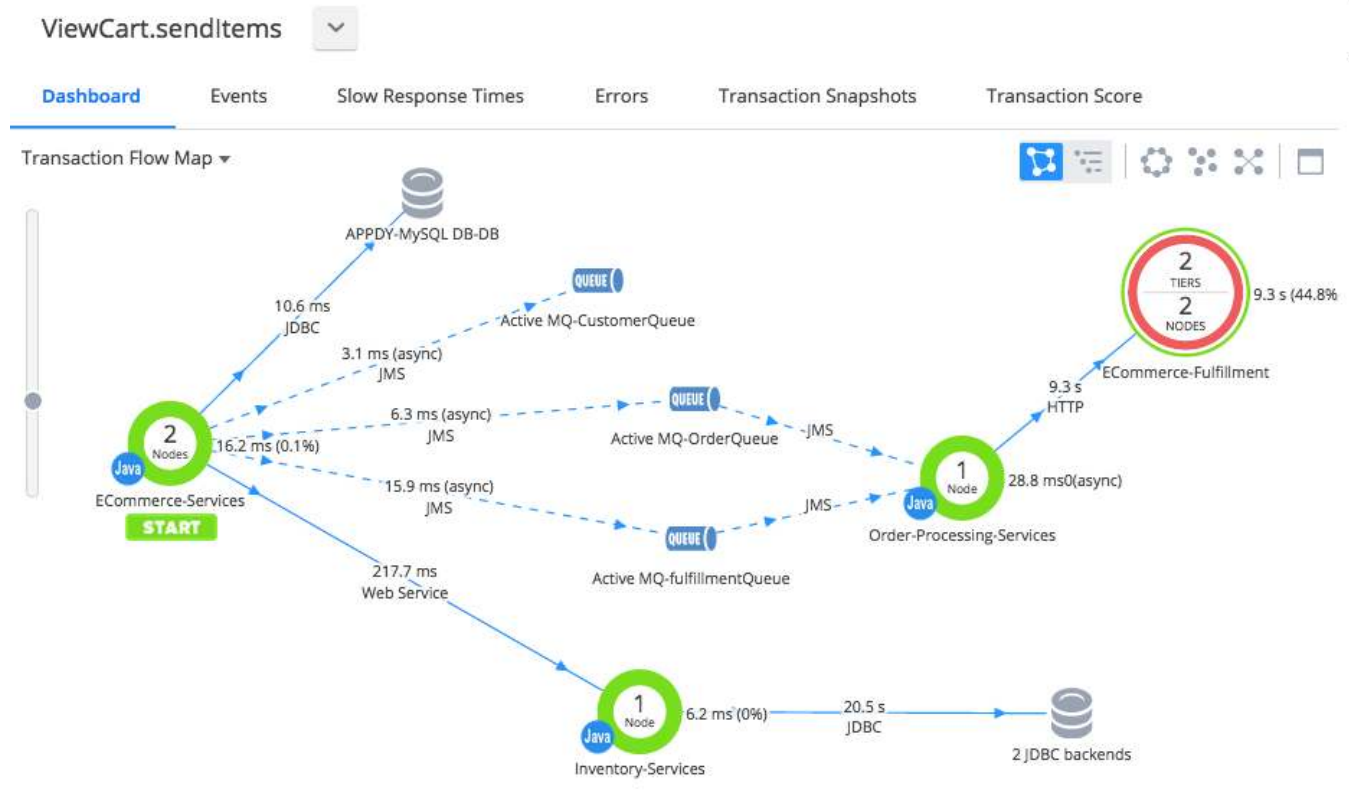

Application Model Overview

A typical application environment consists of different components that interact in a variety of ways to fulfill requests from the application's users:

- Web applications served from an application server
- Databases or other data stores
- Remote services such as message queues and caches

AppDynamics app agents automatically discover the most common application frameworks and services. Using built-in application detection and configuration settings, agents collect application data and metrics to build flow maps.

A [flow map](#) visually represents the components of your application to help you understand how data flows among the application components. For example, the business transaction flow map for a simple e-commerce application shows data flowing between web services, message queues, and databases:

Automatic detection lets you start exploring AppDynamics features quickly. As your understanding of AppDynamics matures and you identify areas unique to your environment, you can refine your application model.

Business Transactions

In the AppDynamics model, a [business transaction](#) represents the data processing flow for a request, most often a user request. In real-world terms, many different components in your application may interact to provide services to fulfill the following types of requests:

- In an e-commerce application, a user logging in, searching for items or adding items to a cart
- In a content portal, a user requests content such as sports, business, or entertainment news
- In a stock trading application, operations such as receiving a stock quote, buying or selling stocks

AppDynamics app agents discover requests to your application as entry points to a business transaction. Similar requests, such as user login, are treated as multiple instances of the same business transaction. The agents tag the request data and trace the request path as it passes from web servers to databases and other infrastructure components. AppDynamics collects performance metrics for each [tier](#) that processes the business transaction.

Because AppDynamics orients performance monitoring around business transactions, you can focus on the performance of your application components from the user perspective. You can quickly identify whether a component is readily available or if it is having performance issues. For instance, you can check whether users are able to log in, check out or view their data. You can see response times for users, and the causes of problems when they occur.

Business Applications

A [business application](#) is the top-level container in the AppDynamics model. A business application contains a set of related services and business transactions.

In a small AppDynamics deployment, only a single business application may be needed to model the environment. In larger deployments, you may choose to divide the model of the environment into several business applications.

The best way to organize business applications for you depends on your environment. A leading consideration for most cases, however, is to organize business applications in a way that reflects work teams in your organization, since role-based access controls in the Controller UI are oriented by business application.

Nodes

A [node](#) in the AppDynamics model corresponds to a monitored server or JVM in the application environment. A node is the smallest unit of the modeled environment. Depending on the agent type, a node may correspond to an individual application server, JVM, CLR, PHP application, or Apache Web server.

Each node identifies itself in the AppDynamics model. When you configure the agent, you specify the name of the node, tier, and business application under which the agent reports data to the Controller.

Tiers

A [tier](#) is a unit in the AppDynamics model composed of a grouping of one or more nodes. How you organize tiers depends on the conceptual model of your environment.

Often a tier is used to a group of a set of identical, redundant servers. But that is not strictly required. You can group any set of nodes, identical or not, for which you want performance metrics to be treated as a unit into a single tier.

The single restriction is that all nodes in a single tier must be the same type. That is, a tier cannot have mixed types of agents, such as both .NET and Java nodes.

The traffic in a business application flows between tiers, as indicated by lines on the flow map, which are annotated with performance metrics.

In the AppDynamics model:

- There is no interaction among nodes within a single tier
- An application agent node cannot belong to more than one tier

Entities

An entity is any object that AppDynamics monitors, such as an application, tier, node, or even a business transaction. Entities typically have associated metrics, events, and a health status.

Historical and Live Entity Data

The Controller has an entity liveness module that tracks the "live" or "historical" status of the the four entity types: application, tier, node, and business transaction for 365+ days.

- **Historical:** Oldest time (a year before the latest Controller restart) to the latest Controller restart time
- **Live:** Latest Controller restart time until the current time

Anchor Metrics for Entities

The entities have special metrics called *anchor metrics* that are used to determine the *liveness* of the entity. This table lists the anchor metrics for each of the entities.

Entity	Anchor Metric
Application	Agent App Availability
Tier	Agent App Availability
Node	Agent App Availability
Business Transactions (BTs)	BTM BTs BT: %d Component: %d Calls per Minute

Liveness Status

The liveness of an entity affects the associated entities as the liveness is rolled up the hierarchy. If the entity type in the table is live, you can determine the liveness of the associated entities in the right column.

Live Entity	Liveness Status
Application	An app is alive if any tiers in this app are alive

Live Entity	Liveness Status
Tier	A tier is alive if any nodes in this tier are alive
Node	Any metrics from the particular node
Business Transactions (BTs)	BT metrics, Calls per Minute

How the Controller Displays Live Entities

Based on entity liveness status of the selected time range, the Controller determines whether to count and display entities in these places:

- Flowmap
- Tier and Node list pages. This is also determined by the **Performance Data** checkboxes. See Live Entity Data in Flowmaps.
- Metric tree of the **Metric Browser**
- Custom dashboards
- AppDynamics REST APIs related to topology such as the [Application Model API](#).

Backends

A [backend](#) is a component that is not instrumented by an AppDynamics agent but one that participates in the processing of a business transaction instance. A backend may be a web server, database, message queue, or another type of service.

The agent recognizes calls to these services from instrumented code (called exit calls). If the service is not instrumented and cannot continue the transaction context of the call, the agent determines that the service is a backend component. The agent picks up the transaction context at the response at the backend and continues to follow the context of the transaction from there.

Performance information is available for the backend call. For detailed transaction analysis for the leg of a transaction processed by the backend, you need to instrument the database, web service, or other application.

Integration with Other AppDynamics Modules

This section describes how other AppDynamics SaaS products work with Application Monitoring to provide complete, full visibility on application health and user experience.

Application Monitoring and Infrastructure Visibility

[Infrastructure Visibility](#) provides end-to-end visibility into the hardware and networks on which your applications run. You can use Infrastructure Visibility to identify and troubleshoot problems that affect application performance such as server failures, JVM crashes, and hardware resource utilization. There are three classes of Infrastructure Visibility functionality:

- You use the [Machine Agent](#) to collect basic hardware metrics. One Machine Agent license is included with each App Agent license that you purchase. You can deploy this Machine Agent only on the same machine where the App Agent is installed. The functionality provided by the Machine Agent includes:
 - Basic hardware metrics from the server OS. For example, %CPU and memory utilization, disk and network I/O
 - Custom metrics passed to the Controller by extensions

- Run remediation scripts to automate your runbook procedures. You can optionally configure the remediation action to require human approval before the script is started.
- Run JVM Crash Guard to monitor JVM crashes and optionally run remediation scripts
- If you have a [Server Visibility](#) license, the Machine Agent provides this additional functionality:
 - Extended hardware metrics such as machine availability, disk/CPU/virtual-memory utilization, and process page faults
 - Monitor application nodes that run inside Docker containers and identify container issues that impact application performance
 - Tier Metric Correlator, which enables you to identify load and performance anomalies across all nodes in a tier
 - Monitor internal or external HTTP and HTTPS services
 - Group servers together so that health rules can be applied to specific server groups
 - Define alerts that trigger when certain conditions are met or exceeded based on monitored server hardware metrics
- [Network Visibility](#) monitors traffic flows, network packets, TCP connections, and TCP ports. Network Agents leverage the APM intelligence of App Server Agents to identify the TCP connections used by each application. Network Visibility includes this functionality:
 - Detailed metrics about dropped/retransmitted packets, TCP window sizes (Limited / Zero), connection setup/teardown issues, high round trip times, and other performance-impacting issues
 - Network Dashboard that highlights network KPIs (Key Performance Indicators) for tiers, nodes, and network links
 - Right-click dashboards for tiers, nodes, and network links that enable quick drill-downs from transaction outliers to network root causes
 - Automatic mapping of TCP connections with application flows
 - Automatic detection of intermediate load balancers that split TCP connections
 - Diagnostic mode for collecting advanced diagnostic information for individual connections

Application Monitoring and Browser Real User Monitoring

When you add End-User Monitoring to Application Performance Management, you can correlate business transaction performance to the user experience for those transactions. See [Correlate Business Transactions for Browser RUM](#).

If app server agents run on the applications that serve your browser applications, you can further configure the app server agents to inject JavaScript agent into the code that runs on the browser. Access the settings to configure injection in the Applications Configuration page. See [Automatic Injection of the JavaScript Agent](#) and [Assisted Injection](#).

Application Monitoring and Database Visibility

In Application Monitoring, a database called by an instrumented node is considered a remote service. You can get a significant amount of information on the interaction between the application node and database, but not from the database server perspective. When using Database Visibility with Application Monitoring, you can drill down to detailed database performance information directly from application flow maps. See [Access Database Visibility from Application Monitoring Views](#).

Application Monitoring and Analytics

For those times when tracing application code does not provide enough clues to track down the cause of a problem, AppDynamics provides visibility into the transaction logs that can be correlated to specific business transaction requests. Log correlation visibility requires a license for both Transaction Analytics and Log Analytics. See [Business Transaction and Log Correlation](#).

Install App Server Agents

Related pages:

- [Agent and Controller Tenant Compatibility](#)
- [SELinux Installation Issues](#)

Instrumenting an application adds the AppDynamics application agent (app agent) into the runtime process of the application. This page provides an overview of how to install agents in the application environment.

 All use cases for App Server agents are supported on AWS Outposts similarly as in other deployment options.

Agent Installation Quick Start

The **Getting Started Wizard** in the AppDynamics Controller walks you through the steps to download and configure an agent for your application. This section provides an overview of how to use the wizard.

The wizard generates a fully configured agent, including a node identity. You should run the wizard for each application instance you want to monitor, or until you understand how to customize the configuration manually.

Before Installing an Agent

Ensure that:

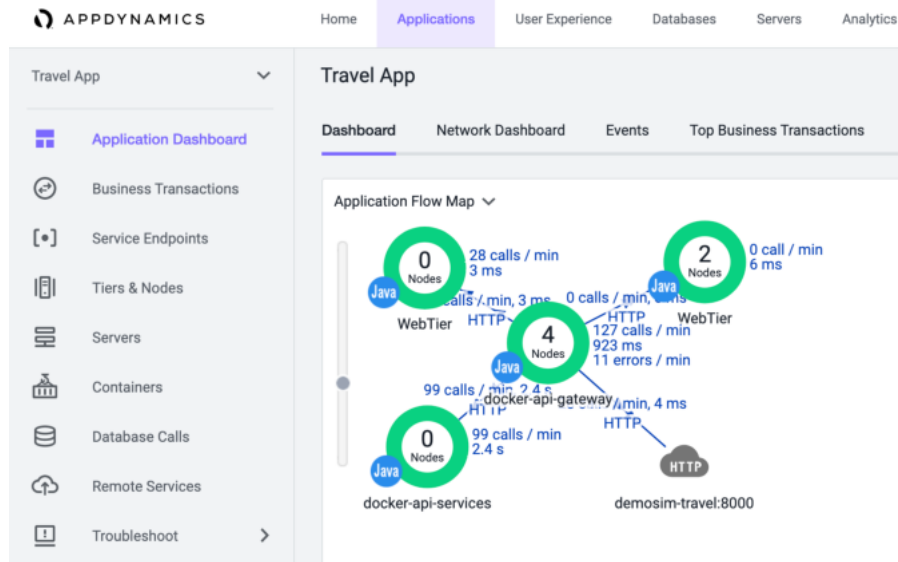

- The agent supports your application environment. See [App Server Supported Environments](#).
- You can access the application host with a user account that has sufficient privileges to install the agent and—for certain installation types—restart the application.
- The application host has network connectivity to the Controller. Proxies or firewalls on the network between the agent and Controller may require additional configuration.

Use the Getting Started Wizard

After verifying the requirements, follow the workflow as guided by the wizard:

1. Open the wizard from the home page in the Controller UI by clicking **Getting Started**.
2. Enter the configuration values for the application instance as described in the wizard. You name the node and indicate the tier and business application to which it will belong. If you are not sure of the best values to use, you can use temporary names and change them later.
3. When finished, download the agent. How you download the agent varies by agent type. In most cases, the agent comes as a ZIP file that you extract and install in the startup routine of your server. For other types of agents, you may need to modify the instrumented source code, for example, by including the agent library. The wizard walks you through it for each agent type.
4. Install the agent on your app server.
5. Apply load to your application. If you are instrumenting a production application, this will happen with customer interaction. Otherwise, create some test load on your application. The agent instruments the application code and reports metrics back to the Controller.

6. View your application in the **Application Dashboard**. For example:

The wizard makes it easy to perform a basic agent installation with minimally required settings, such as the Controller host and port, SSL, application name, and tier name. For advanced options or more complicated scenarios, you need to perform a manual installation of the agent. For more information, see the agent-specific link in the following section.

Agent Installation by Type

For detailed installation information by agent type, see these topics:

- [Java Agent](#)
- [.NET Agent](#)
- [Node.js Agent](#)
- [PHP Agent](#)
- [Python Agent](#)
- [Serverless APM for AWS Lambda](#)
- [Apache Web Server Agent](#)
- [C/C++ SDK](#)
- [Go Language Agent](#)
- [IBM Integration Bus Agent](#)
- [Machine Agent](#)
- [SAP Monitoring Using AppDynamics](#)

For automated deployment guidelines, see [Controller Deployment](#).

Application, Tier, and Node Naming Guidelines

The maximum length of an application or tier name is 100 characters. The maximum length of a node name is 225 characters for Linux and 500 characters for all other operating systems. In your tier, node, and application names, you should avoid certain special characters. The characters you can use are listed on the [Tiers and Nodes](#) page.

Generally, node names should be unique. However, nodes that reside on different tiers and different machines (hosts) can have duplicate node names.

Within a business application, node names *should always be unique* in the following use cases:

- If the nodes reside on the same tier, but on different machines
- If the nodes reside on the same machine, but on different tiers
- Node names and machine names must be unique. When a node is registered to a Controller, it is associated with the machine it is on, and cannot be moved to another machine without changing the node name. ▼

If the nodes names are the same in the aforementioned use cases, the nodes will not register or report successfully.

i Nodes on proxy-based agents can have duplicate names on the same tier and same machine.

To rename an application, see [Business Applications](#).

For node naming conventions by agent type, see the installation page for that agent, such as [Node.js Agent](#) or [PHP Agent](#).

App Agent Network Bandwidth Usage

These guidelines can help you estimate how much bandwidth overhead will be added to your environment by deploying AppDynamics agents.

Keep in mind that the exact bandwidth required for a deployment varies greatly depending on the nature of your application, the agent configuration, and the AppDynamics features you use. The best way to determine the bandwidth overhead is to test the AppDynamics deployment in a staging environment that mirrors as closely as possible the live operating environment.

1. The approximate bandwidth used by a single Java Agent with the default configuration is five to eight kilobytes per second.
2. Scaling of additional agents is linear. That is, if the average bandwidth usage for an app agent in a given deployment is five kilobytes, adding 10 means that bandwidth usage will be 5×10 , or 50 kilobytes.
3. While the average bandwidth used is five to eight kilobytes per second, agents send data to the Controller in bursts rather than as a steady stream of data. When testing bandwidth usage, to determine the actual kilobytes per second used by an agent, you need to observe and average out traffic over the course of at least several minutes.
4. When testing bandwidth usage in the environment, keep in mind that different types of tiers will generate a different amount of load. For instance, a database tier tends to generate more traffic between the agent and Controller than an application server tier. For the best possible estimate, the test should take this into account.

Agent License Considerations

For agent-based license units—including APM, database monitoring, and server monitoring—licenses are allocated to the first agents that register with the Controller up to the licensed limit. For example, with five agent licenses, the first five agents that connect to the Controller are licensed.

Agent licenses are not bound to a particular machine or application. Therefore, a transfer of an agent-based license can be accomplished simply by shutting down the application that runs the licensed agent—uninstalling the agent if the application will need to be restarted—and starting up the new application with the newly installed agent. Once the agent disconnects, a license unit is freed for the second agent.

For application monitoring agents (Java, .NET, Node.JS, and so on), a license validation cycle runs every five minutes. It causes the agents to connect and validate that available license units are not exceeded.

Historical usage data is captured during this cycle and stored as five-minute usage data. Every hour, the five-minute usage data is rolled up in hour usage data, which includes data on license unit usage. The five-minute data is purged after a few hours.

Agent Management

Agent Management provides agent lifecycle management by using either [Smart Agent](#), [Smart Agent Command Line](#) tool, or collection of other tools depending on your configuration environment. These tools simplify the management of agents, enabling you to automate the agent operations, such as install, upgrade, and rollback.

This is helpful for performing agent operations in a large-scale environment. For example, as an ITOps you would want to install an APM agent on more than 1000 machines. Installing the agents on the machines manually is a tedious task. Using the agent management tools, you can install agents on all the machines with an initial configuration.

You can use the following features of Agent Management either through Smart Agent or using the supported automation tools that you want to use :

- Discover the agents that are running in your environment
- Export the inventory of your agents
- Install the same type of agents to the required machines at a time
- Upgrade the agents
- Rollback app server and Machine Agents to the previous version

Smart Management of Agents

To get started with the lifecycle management of the agents through the UI, you must install Smart Agent on all the machines that you require to manage. See [Smart Agent](#).

When you have installed Smart Agent, you can perform the following tasks from the Agent Management page on the AppDynamics Controller UI:

- [Install Agents](#)
- [Upgrade Agents](#)
- [Rollback Agents](#)

Get Started

The following pages will help you get started:

- [Supported Platforms](#)
- [Supported Application Workflow](#)
- [Agent Management UI](#)
- [Supported Automation Tools to Deploy Agents](#)
- [Quick Start with Smart Agent](#)
- [Smart Agent](#)

Inclusion of such references are for informational purposes only and are not intended to promote or otherwise suggest a relationship between AppDynamics and the third party.*

Supported Platforms

Agent Management is supported on the following environments:

Platform	Install Process
Linux	<ul style="list-style-type: none"> • Manual install • Ansible • Smart Agent
Containers	<ul style="list-style-type: none"> • Smart Agent Command Line
DockerFile	<ul style="list-style-type: none"> • Smart Agent Command Line (In Dockerfiles) • Docker
Kubernetes	<ul style="list-style-type: none"> • Smart Agent Command Line (In Dockerfiles) • Kubernetes
EKS, AKS, GKE	<ul style="list-style-type: none"> • Smart Agent Command Line (In Dockerfiles)
Cloudfoundry	Cloud Foundry
Tanzu	

Supported Application Workflow

The workflows will help you determine the tools that you can use for Agent Management.

Buildtime Workflow

The buildtime workflow is the workflow used when you install the agent when building the application environment. This type of workflow is common in Container environments.

Agent Management provides the following tools to install the agent in the buildtime workflow:

- [Smart Agent Command Line](#)
- [Docker](#)
- [Kubernetes](#)
- [Cloud Foundry](#)

Runtime Workflow

The runtime workflow is the workflow used when you already have an application running and you are installing the agent for the existing application.

Agent Management provides the following tools to perform the agent operations in the runtime workflow:

- [Smart Agent](#)
- [Ansible](#)

Supported Automation Tools to Deploy Agents

You can use any of the following automation tools to integrate Agent Management:

- [Ansible](#)

- [Docker](#)
- [Cloud Foundry](#)
- [Kubernetes](#)

Ansible

 This document contains references to the Ansible® documentation. AppDynamics does not own any rights and assumes no responsibility for the accuracy or completeness of such third-party documentation.

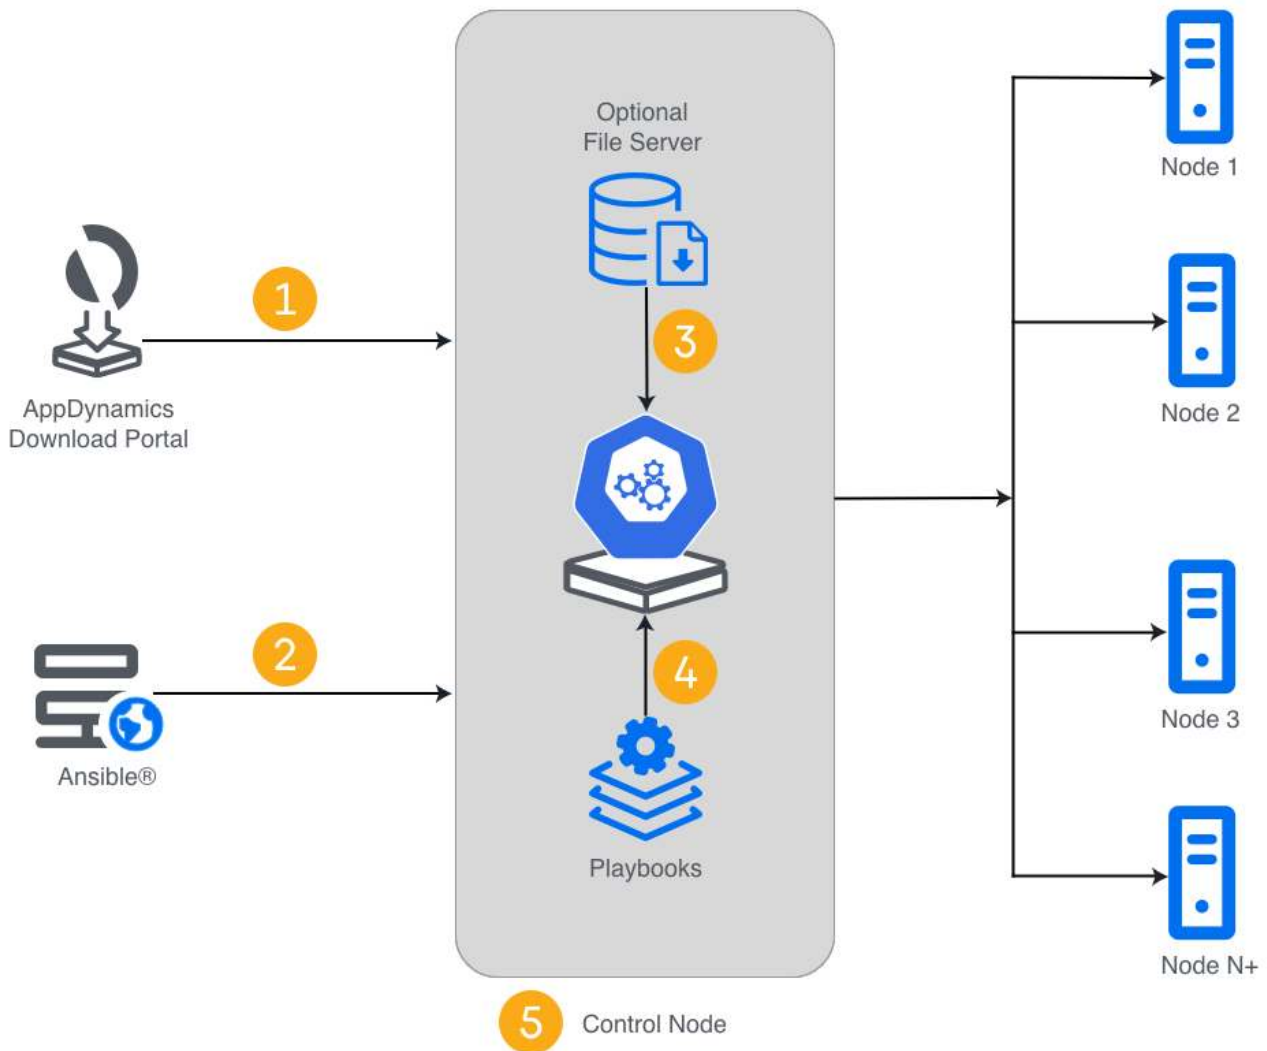

The AppDynamics Ansible Collection installs and configures AppDynamics agents. You can automatically download all the supported agents from the [Ansible Galaxy](#) to the Ansible® control node. If you are using the on-prem version, download the agents from the local repository. This makes it easy to retrieve and upgrade agents.

For a description of available deployment options, see [Common Role Variables](#).

The AppDynamics Ansible Collection is built to support (immutable) infrastructure as code deployment, where agents are upgraded with basic configuration. Hence, the collection does not consider any manual configuration changes on the target servers.

 Custom agent configurations are supported only if these configurations are written to an Ansible role. The AppDynamics Ansible Collection will overwrite any local or pre-existing configuration with the variables that are defined in the playbook. Therefore, we strongly recommend that you convert any custom agent configuration into an Ansible role to ensure consistency of deployments and configurations across your estate.

The following diagram explains the workflow:

- 1 Download AppDynamics Agents from the AppDynamics Download portal or custom endpoint
- 2 Download the AppDynamics Ansible Collection from galaxy.ansible.com.
- 3 (Optional) Download the agent binaries from the custom endpoint if maintaining a file server.
- 4 Configure the agents using playbook. See [Playbooks](#).
- 5 The Control Node, which comprises of file server and playbooks, pushes the configuration to the managed nodes.

Requirements

- Requires Ansible >=2.12.0

- Supports most Debian and RHEL-based Linux distributions, and Windows

 The AppDynamics Ansible Collection supports auto-instrumentation of JBoss(Wildfly) and Tomcat, on Linux only.

- Windows OS requires Powershell >= 5.0
- Network/firewall access to download AppDynamics agents from <https://download-files.appdynamics.com> and <https://download.appdynamics.com> on the Ansible control node
- `jq` is required on the Ansible control node. It is recommended that you install it manually (this requires `sudo` access), or run the `install_jq.yaml` playbook in the `playbook` folder. For example: `ansible-playbook install_jq.yaml --ask-become-pass -e 'ansible_python_interpreter=/usr/bin/python'`
- `lxml` is required if you need to enable enhanced agent logging (DEBUG, TRACE, and so on). We recommend that you install it manually on the Ansible control node using `pip3 install lxml`, or run the `install_lxml.yaml` playbook in the `playbook` folder
- Download the Agent playbook based on the application

Important

- If multiple agents are restarted simultaneously after installation, it can cause performance issues on Controller. We recommend restarting the applications in a phased manner.
- If you are downloading agents from AppDynamics Downloads Portal, we recommend using a fork value of 20. You can use a custom download path for a higher fork value. See [Custom Download Path](#).

Install the AppDynamics Collection

1. Use the following command on your Ansible control node to install the [AppDynamics Collection](#) from Ansible Galaxy. Do not add `-force` if you are installing it for the very first time.

```
ansible-galaxy collection install --force appdynamics.agents
```

2. (Optional) If you are using a local file server as a custom endpoint use the following command:

```
ansible-galaxy collection install ./appdynamics-agents-<version>.tar.gz
```

3. Create a playbook (for example, `customer-playbook.yaml`) with configuration to install and deploy AppDynamics agents in the managed machines using the `ansible-playbook` command.

Example

```
$ ansible-playbook customer-playbook.yaml
```

4. (Optional) Configure the `ansible.cfg` file with the following command to log the agent installation status.

```
[defaults]
```

```
callbacks_enabled= appdynamics.agents.appd_agent_status
```

 The tools for managing agents do not impact extensions deployed or installed outside the agent install directory. For Machine agents, the tools for managing agents ensure that Machine Agent extensions are re-deployed after an upgrade. If you are uncertain about the potential impact of the extensions that you may be using, contact your Account Manager or Customer Success Manager. You can also use our [support portal](#).

Playbooks

The playbooks folder in the AppDynamics Ansible Collections contains example playbooks for each agent type.

You can use the example playbooks in the collection installation folder.

The `playbooks/vars` directories contain constant variables such as `enable_ssl`, `controller_port`, etc. You can either include YAML files in the playbook as shown in the following Java example, or overwrite the variables in the playbooks.

 Check the [precedence rules](#) of Ansible, before continuing the installation.

When you install the AppDynamics Collection, you can use the following agents:

Agent Type	Description
<code>sun-java7</code> or <code>java7</code>	Agent to monitor Java applications running on JRE version 1.7 and less
<code>sun-java</code> or <code>java</code>	Agent to monitor Java applications running on JRE version 1.8 and above
<code>dotnet_msi</code>	Machine global agent to monitor .Net and .Net Framework applications on Windows
<code>machine</code>	64-Bit Machine agent ZIP bundle with JRE for Windows and Linux
<code>python</code>	Agent to Monitor Python applications on Linux.
<code>php</code>	Agent to Monitor PHP applications on Linux or Redhat-based system
<code>node</code>	Agent to Monitor NodeJS application on Linux

Custom Agent Download Path

i This is not applicable to .Net Agent MSI.

If you do not want playbooks to download the agent files from the official AppDynamics Downloads portal, you can use the following variable in playbooks to install the agents from your preferred location.

Variable	Description	Applicable Agents
<code>download_protocol</code>	The mechanism to download the agent, example values are: <ul style="list-style-type: none"> <code>http</code> - to transfer files from a file server <code>local</code> - to transfer files from your control node <code>nfs</code> - transfer file from a shared filesystem 	All
<code>download_uri</code>	The location of the agent file. It can be URL or the absolute/relative path on the local/NFS filesystem	All
<code>linux_install_root</code>	Use this to configure the folder where all installed agent and backup files reside. For example, for Java agent, <code><linux_install_root>/java-agent</code> and <code><linux_install_root>/backup/java-agent</code> is created. The default value is <code>/opt/appdynamics</code> for Linux.	Apache, Java, Machine, .Net, Node.js, PHP, Python
<code>windows_install_root</code>	Similar to <code>linux_install_root</code> , to be used on Windows hosts. The default value is <code>C:/appdynamics</code> .	Apache, Java, Machine, .Net
<code>linux_custom_agent_install_path</code>	Use this to specify the Agent installation path and override the default installation path which is the root directory (see <code>linux_install_root</code> , and <code>windows_install_root</code>). The agent backup resides in the root directory and is not configured by this variable. The agent files are installed in this directory. Do not specify this path to store the files of <code>linux_install_root</code> .	Apache, Java, Machine, .Net, Node.js, PHP, Python
<code>windows_custom_agent_install_path</code>	Similar to <code>linux_custom_agent_install_path</code> , to be used on Windows hosts.	Apache, Java, Machine, .Net

Common Role Variables

Variable	Description	Applicable Agents
agent_action	To perform an upgrade, install, rollback, or uninstall.	All
agent_dir_permission.user	To assign user file permissions for the Java Agent on Linux. The user and group selected must already exist on the host if <code>create_appdynamics_user</code> is set to <code>No</code> .	Java
agent_dir_permission.group	To assign group file permissions for the Java Agent on Linux. The user and group selected must already exist on the host if <code>create_appdynamics_user</code> is set to <code>No</code> .	Java

Variable	Description	Applicable Agents
agent_log_level	The log level for the agent. The valid options are — info, trace, debug, warn, error, fatal, all, and off. This setting is applied to all the loggers named in the agent_loggers list.	Java, Machine, PHP
agent_loggers	To set the log level on the list of loggers. The logger names vary from agent to agent. The default is set to *, com.singularity, com. Update this variable with loggers specific to the target agent. See log4j files in the /conf/logging directory.	Java, Machine

Variable	Description	Applicable Agents
<code>agents_to_set_loggers_for</code>	<p>The list of agents to apply the log-level changes. For example, to set the log level of all deployed agents to <code>info</code>, initialize the variable to <code>java</code>.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p>i This variable should not be set when using the logger role as part of agent deployments. The <code>agent_type</code> variable will be used to determine how the log level needs to be adjusted during the installation.</p> </div>	Java, Machine
<code>agent_type</code>	<p>The AppDynamics agent type. For example, <code>java</code>.</p>	All
<code>agent_version</code>	<p>The AppDynamics agent version. The value can be <code>latest</code> or an agent version, for example, <code>23.2.0</code>.</p> <p>AppDynamics uses calendar versioning. For example, if a Java Agent is released in February of 2023, its version will be <code>23.2.0</code>.</p>	All

Variable	Description	Applicable Agents
appdynamics_user	AppDynamics functional user name. The default is <code>appdynamics</code> .	Java, Machine
application_name	The application name. This variable is mandatory for all the <code>java</code> roles.	All
controller_account_name	The AppDynamics Controller account name.	All
controller_account_access_key	The access key for the Controller account. This should be placed in the vault.	All
controller_host_name	The Controller hostname. Do not include <code>http(s)</code> .	All
controller_port	The Controller port.	All

Variable	Description	Applicable Agents
<code>create_appdynamics_user</code>	To create AppDynamics functional user on Linux.	Java, Machine
<code>dir</code>	The base directory for agent files. Default: <code>/tmp/appd/</code>	All
<code>enable_proxy</code>	Set to <code>true</code> to apply agent proxy settings to the agent configuration. Assign the <code>proxy_host</code> and <code>proxy_port</code> variables.	Java, .Net
<code>enable_ssl</code>	Indicate if SSL is enabled in the Controller or not.	All

Variable	Description	A p p l i c a b l e A g e n t s
init_and_validate_agent_variables	This variable controls running the common role initialization (which sets download URLs and Controller parameters). When using the logger role in isolations (that is not as part of agent installation) the value should be <code>false</code> .	J a v a, M a c h i n e

Variable	Description	A p p l i c a b l e A g e n t s
keep_backup	Use when agent_action is uninstall. Set to true to keep the agent backup files after uninstalling. Default value is false.	A p a c h e, J a v a, M a c h i n e, N o d e. j s, P H P, P y t h o n

Variable	Description	Applicable Agents
<code>linux_install_root</code>	<p>Use this to configure the folder where all installed agent and backup files reside. For example, for Java agent, <code><linux_install_root>/java-agent</code> and <code><linux_install_root>/backup/java-agent</code> is created. The default value is <code>/opt/appdynamics</code> for Linux.</p>	<p>Apache, Java, Machine, Node.js, PHP, Python</p>

Variable	Description	Applicable Agents
<code>linux_custom_agent_install_path</code>	<p>Use this to specify the Agent installation path and override the default installation path which is the root directory (see <code>linux_install_root</code>). The agent backup resides in the root directory and is not configured by this variable. The agent files are installed in this directory. Do not specify this path to store the files of <code>linux_install_root</code>.</p>	<p>A p a c h e, J a v a, M a c h i n e, N o d e. j s, P H P</p>

Variable	Description	A p p l i c a b l e A g e n t s
max_agent_backup_count	Maximum allowed backups per agent. The default value is one.	J a v a

Variable	Description	Applicable Agents
node_name	The AppDynamics node name for <code>java</code> roles.	Apache, Java, Machine, Node.js, PHP, Python

Variable	Description	A p p l i c a b l e A g e n t s
proxy_host	Host name/IP address of the proxy to route agent data.	J a v a, . N e t
proxy_port	Host port number of the proxy to route agent data.	J a v a, . N e t

Variable	Description	Applicable Agents
tier_name	The AppDynamics tier name. This variable is mandatory for all the <code>java</code> roles.	Apache, Java, Machine, Node.js, PHP, Python

Variable	Description	A p p l i c a b l e A g e n t s
windows_install_root	Similar to linux_install_root , to be used on Windows hosts. The default value is C:/appdynamics .	A p a c h e, J a v a, M a c h i n e, N o d e. j s, P H P, P y t h o n

Variable	Description	Applicable Agents
<code>windows_custom_agent_install_path</code>	Similar to <code>linux_custom_agent_install_path</code> , to be used on Windows hosts.	Apache, Java, Machine, Node.js, PHP, Python

To get started, select your agent:

Apache Agent	.Net Agent
Java Agent	Node.js Agent
IIB Agent	PHP Agent
Machine Agent	Python Agent

i Ansible® is a registered trademark of Red Hat, Inc. in the United States and other countries.

Ansible Configuration for Apache Agent

The following is an example of Ansible® role to install Apache Agent:

```

---
- hosts: all
  tasks:
    - name: Include variables for the controller settings
      include_vars: vars/controller.yaml

    - include_role:
        name: appdynamics.agents.apache
      vars:
        agent_version: 22.12.1
        # possible value:
        #   - latest: Latest version
        #   - 22.12.1: Any Specific version number
        agent_type: apache
        agent_action: upgrade
        # possible value:
        #   - upgrade: upgrade currently installed agent to agent_version
        #   - install: install agent_version
        #   - rollback: rollback to previous backup if any
        #   - uninstall: uninstall and clean up everything

        # Apache specific Args
        #apache_conf_path:
        # possible value:
        #   - /etc/httpd/conf/httpd.conf #default path in case of RedHat
        #   - /etc/apache2/apache2.conf #Default path in case of Debian
        #   - #any custom path where the conf file is located.

```

Apache Agent Variables

i The following variables are applicable to the `appdynamics_agent.conf` file. For more information, see [Configure the Apache Agent](#).

Variable	Description
<code>appdynamics_enabled</code>	Set to <code>ON</code> to enable web server monitoring
<code>appdynamics_proxy_host</code>	Proxy server hostname or IP address
<code>appdynamics_proxy_port</code>	Proxy server port
<code>appdynamics_launch_proxy</code>	When set to <code>ON</code> , the agent launches the proxy automatically when on startup. If <code>OFF</code> , you must launch the proxy.
<code>appdynamics_resolve_backends</code>	Controls the way Apache module backends appear in the Controller UI.
<code>appdynamics_trace_as_error</code>	If <code>ON</code> , tracepoints are written as errors to the Apache logs, by default <code>error_log</code> .
<code>appdynamics_report_all_instrumented_modules</code>	If <code>OFF</code> , the agent reports only modules that occur during the HANDLER stage of Apache request processing.
<code>appdynamics_backend_name_segments</code>	The number of URL segments that are displayed in the backend naming.
<code>appdynamics_proxy_comm_dir</code>	Path to the directory containing the domain control socket which the agent uses to start an AppDynamics node. The default value is <code><agent_install_directory>/logs/appd-sdk</code> .
<code>appdynamics_request_cache_cleanup_interval</code>	Timeout in milliseconds after which the request cache is cleaned up by Java proxy.
<code>appdynamics_mask_cookie</code>	Specify if filtering is enabled or not. Set it <code>ON</code> for cookie filtering to be enabled. The default value is <code>OFF</code> .
<code>appdynamics_mask_cookie_pattern</code>	Specify the pattern that when matched, filters the value of that cookie.

Variable	Description
appdynamics_mask_sm_user	Specify if filtering is enabled or not. Set it ON for sm_user filtering to be enabled. The default value is OFF.
appdynamics_delimiter	Specify the character that you want to use as URL segment endpoints.
appdynamics_segment	Specify a comma-separated list to indicate the segments that you want the agent to filter
appdynamics_match_filter	The type of filter to be used to match the URL amongst the following: NOT_EMPTY
appdynamics_match_pattern	Specify the string that you want to be filtered with the match-filter
custom_agent_config_path	Specify the absolute path to the agent configuration file for future upgrades. Make sure that you add the agent configuration file path to the <code>apache.conf</code> file.

i Ansible® is a registered trademark of Red Hat, Inc. in the United States and other countries.

Ansible Configuration for Java Agent

The following sections provide the example use cases for the Java Agent Ansible roles:

Install Java Agent on Linux or Windows

Example 1: Ansible® role used to install Java Agent on Windows or Linux without any application instrumentation:

```

---
- hosts: all
  tasks:
    - name: Include variables for the controller settings
      # Include all yaml files under the vars directory
      include_vars:
        dir: vars
        extensions:
          - 'yaml'
          - 'yml'
    - include_role:
        name: appdynamics.agents.java
      vars:

```

```

agent_version: 21.1.0
agent_type: java
agent_action: upgrade # can be upgrade/install/rollback/uninstall, defaults to
upgrade when unspecified
application_name: "IoT_API" # agent default application
tier_name: "java_tier" # agent default tier
  
```

Example 2: Ansible role for installing Java Agent with changing Java startup script and performing restart:

```

---
- hosts: single-java-host
  tasks:
    - name: Include variables for the controller settings
      # Include all yaml files under the vars directory
      include_vars:
        dir: vars
        extensions:
          - 'yaml'
          - 'yml'
    - import_role:
        name: appdynamics.agents.java
        public: yes
    vars:
      agent_version: 21.1.0
      agent_type: java
      application_name: "BIGFLY" # agent default application
      tier_name: "java_tier" # agent default tier
    - name: Edit startup script with new java startup variables
      lineinfile:
        path: /opt/application/startAll.sh
        # Line to Search/Match against
        regexp: '^(.*)(-jar.*$)'
        # Line to Replace with
        line: '\1 -javaagent:{{ java_agent_dest_folder_linux }}/javaagent.jar
-Dappdynamics.agent.nodeName=application-1 \2'
      backup: yes
      backrefs: yes
      state: present
      notify: RestartingApp
    - name: Allow appuser write to appd logs folder
      user:
        name: appuser
        groups:
          - appdynamics
        append: yes
      become: yes
  handlers:
    - name: RestartingApp
      command: '/opt/application/stopAll.sh && /opt/application/startAll.sh'
      args:
        chdir: '/opt/application/'
  
```

Instrument JBoss/Wildfly

The features of this role are:

- Java Agent installation for Linux
- Instrument Jboss/Wildfly
- Automatic applications restart (if `systemd` service is present)
- Java Agent start verification

Example 1: Install Java Agent and instrument one or more applications.

```

---
- hosts: all
  tasks:
    - name: Include variables for the controller settings
      # Include all yaml files under the vars directory
      include_vars:
        dir: vars
        extensions:
          - 'yaml'
          - 'yml'
    - include_role:
        name: appdynamics.agents.java
        # use java role variables in the following instrumentation tasks when public: yes
        public: yes
      vars:
        agent_version: 21.1.0
        agent_type: java

    - include_role:
        name: appdynamics.agents.instrument_jboss
      vars:
        # instrument jboss:
        application_name: "IoT_API2"
        tier_name: "Jboss"
        jboss_service: wildfly
        app_user: wildfly
        restart_app: yes
        jboss_config: /opt/wildfly/bin/standalone.sh
  
```

Example 2: This role ensures that all instrumented applications have access to the Java Agent logs directory.

In some cases, when the application PID user is not local on the Linux host, it cannot be added to the AppDynamics group. In such a case, you can let the application user own the Java Agent directory instead.

```

---
- hosts: all
  tasks:
    - name: Include variables for the controller settings
      # Include all yaml files under the vars directory
  
```

```

include_vars:
  dir: vars
  extensions:
    - 'yaml'
    - 'yml'
- include_role:
  name: appdynamics.agents.java
  # use java role variables in the following instrumentation tasks when public: yes
  public: yes
  vars:
    agent_version: 21.1.0
    agent_type: java
    # single app mode: Can skip appdynamics user creation and own java-agent directory by
    app user (wildfly in this case)
    create_appdynamics_user: no
    agent_dir_permission:
      user: wildfly
      group: wildfly
- include_role:
  name: appdynamics.agents.instrument_jboss
  vars:
    # instrument jboss:
    application_name: "IoT_API2"
    tier_name: "Jboss"
    jboss_service: wildfly
    app_user: wildfly
    restart_app: yes
    jboss_config: /opt/wildfly/bin/standalone.sh
  
```

JBoss Instrumentation Variables

Variable	Description	Required	Default
app_user	User that runs this application. It must be provided, so write permissions are given to the java-agent logs directory	Y	jboss
jboss_service	Systemd service that should be restarted if restart_app is set to 'yes'	N	
restart_app	Set to 'yes' to automatically restart instrumented service	N	no
backup	Whether original config file should be backed up before any changes	N	False

Variable	Description	Required	Default
jboss_config	Jboss/Wildfly config to instrument. Provide a path to jboss standalone.sh	Y	/opt/wildfly/bin/standalone.sh

Instrument Apache Tomcat

The features of this role are:

- Java Agent installation for Linux
- Instrumentation of Apache Tomcat
- Automatic applications restart (if `systemd` service is present)
- Java Agent start verification

Example 1: Install Java Agent and instrument one or more applications.

```

---
- hosts: all
  tasks:
    - name: Include variables for the controller settings
      # Include all yaml files under the vars directory
      include_vars:
        dir: vars
        extensions:
          - 'yaml'
          - 'yml'
    - include_role:
        name: appdynamics.agents.java
        # use java role variables in the following instrumentation tasks when public: yes
        public: yes
      vars:
        agent_version: 21.1.0
        agent_type: java

    - include_role:
        name: appdynamics.agents.instrument_tomcat
      vars:
        # instrument tomcat:
        tomcat_service: tomcat9
        application_name: "IoT_API22"
        tier_name: "Tomcat"
        app_user: tomcat
        restart_app: yes
        tomcat_config: /usr/share/tomcat9/bin/setenv.sh

```

Example 2: To ensure all instrumented applications have access to the Java Agent logs directory.

In some cases, when the application PID user is not local on the Linux host, it cannot be added to the AppDynamics group. In such a case, you can let the application user own the Java Agent directory instead.

```

---
```

```

- hosts: all
  tasks:
    - name: Include variables for the controller settings
      # Include all yaml files under the vars directory
      include_vars:
        dir: vars
        extensions:
          - 'yaml'
          - 'yml'
    - include_role:
        name: appdynamics.agents.java
        # use java role variables in the following instrumentation tasks when public: yes
        public: yes
      vars:
        agent_version: 21.1.0
        agent_type: java
        # single app mode: Can skip appdynamics user creation and own java-agent directory by
        app user (tomcat in this case)
        create_appdynamics_user: no
        agent_dir_permission:
          user: tomcat
          group: tomcat

    - include_role:
        name: appdynamics.agents.instrument_tomcat
      vars:
        # instrument tomcat:
        tomcat_service: tomcat9
        application_name: "IoT_API22"
        tier_name: "Tomcat"
        app_user: tomcat
        restart_app: yes
        tomcat_config: /usr/share/tomcat9/bin/setenv.sh
  
```

Tomcat Instrumentation Variables

Variable	Description	Required	Default
app_user	The user that runs this application. It must be provided, so write permissions are given to the java-agent logs directory	Y	tomcat
tomcat_service	Systemd service that should be restated if restart_app is set to 'yes'	N	
add_service_override	If enabled, adds systemd override file to explicitly allow write permissions to AppDynamics java-agent dir. Required for tomcat9 installed on ubuntu20.04	N	yes

Variable	Description	Required	Default
restart_app	Set to 'yes' to automatically restart instrumented service	N	no
backup	Whether the original config file should be backed up before any changes	N	no
tomcat_config	Choose which tomcat configuration file to modify. You must set the full path to the setenv.sh file, for example, <CATALINA_HOME>/bin/setenv.sh . If Tomcat is installed with yum on RHEL distributions, this file is not invoked by the startup script. In that case, it can be set to /etc/tomcat/conf.d/appdynamics.conf instead.	Y	

Ansible® is a registered trademark of Red Hat, Inc. in the United States and other countries.

Ansible Configuration for IIB Agent

The following is an example of Ansible® role to install IIB Agent on AIX or Redhat based Linux system.

```

---
- hosts: all
  tasks:
    - name: Include variables for the controller settings
      include_vars:
        # Include all yaml files under the vars directory
        dir: vars
        extensions:
          - 'yaml'
          - 'yml'

    - include_role:
        name: appdynamics.agents.iib
      vars:
        agent_version: latest
        # possible value:
        #   - latest: Latest version
        #   - 22.10.0.5500.0: Any Specific version number
        agent_type: iib
        agent_action: upgrade
        # possible value:

```

```
# - upgrade: upgrade currently installed agent to agent_version
# - install: install agent_version
# - rollback: rollback to previous backup if any
```

IIB Agent Variables

Variable	Description	Possible Values	Required	Default
<code>iib_log_dir</code>	Path to the directory containing the IIB agent log files.	directory path	Optional	<code>/tmp/appd</code>
<code>iib_user_exit</code>	The exit name of the user. This must be in the alphanumeric format, as provided in the <code>mqsichangebroker</code> command.	<code>ecom</code>	Optional	None
<code>iib_flow_level_visibility_enabled</code>	Set 1 to enable, and 0 to disable. See IIB Agent Flow Level Visibility .	0, 1	Optional	0
<code>iib_node_reuse</code>	The node name reuse function enables users to reuse the node names of historical VMs for new VMs. It prevents the rapid increase of differently named nodes, especially when the nodes are identical processes that run over different times. This helps you monitor environments with short-life VMs. See Enable the Node Name Reuse .	<code>true</code> or <code>false</code>	Optional	None
<code>iib_node_reuse_prefix</code>	Use this property when <code>iib-node-reuse</code> is set to <code>true</code> . If you do not set this property, the agent generates node names as per the internal node name standards of IBM. See Enable the Node Name Reuse .	<code>ecom</code>	Optional	None
<code>config_file_path</code>	Use this property to set the path for node or server configuration files. You can specify multiple paths separated by a comma.	<code>/opt/node1.conf.yaml</code> , <code>/opt/node2.conf.yaml</code>	Optional	None

Variable	Description	Possible Values	Required	Default
<code>iib_controller_certificate_file</code>	Full path to the PEM format X509 certificate for SSL. See, Enable SSL for the C/C++ SDK for more information on how to obtain the certificate file.	<code>/etc/controller/iib.pem</code>	Optional	None

i Important

- For IIB Agent configurations, see [Install the IIB Agent](#).
- Set the necessary variable for Controller in the `controller-info.xml` file. See [Common Role Variables](#).

Custom Proxy Configuration Variables

Variable	Description	Possible Values	Required	Default
<code>controller_proxy_host</code>	Host name or IP address of the proxy. It is required to connect the agent to the Controller.	<code>ecommerce.proxy.com</code>	Optional	None
<code>controller_proxy_port</code>	Proxy port to route data to the Controller through a proxy server.	<code>8090</code>	Optional	None
<code>controller_proxy_username</code>	Proxy username required to log in to proxy server host.	<code>ecommerce-user</code>	Optional	None
<code>controller_proxy_password</code>	The password for authenticating the proxy user.	<code>/etc/ecommerce/passwd</code>	Optional	None
<code>controller_proxy_passwordfile</code>	The full path name of a file containing the password to authenticate the proxy user.	<code>/etc/ecommerce/passwd</code>	Optional	None

i Ansible® is a registered trademark of Red Hat, Inc. in the United States and other countries.

Ansible Configuration for Machine Agent

The following is an example of Ansible® role to install Machine Agent on Linux, Windows, Solaris, and AIX:

```

---
- hosts: all
  tasks:
    - include_role:
        name: appdynamics.agents.machine
      vars:
        # Define Agent Type and Version
        agent_version: 20.9.0
        agent_type: machine
        machine_hierarchy: "AppName|Owners|Environment|" # Make sure it ends with a |
        sim_enabled: "true"
        # Analytics settings
        analytics_event_endpoint: "https://fra-ana-api.saas.appdynamics.com:443"
        enable_analytics_agent: "true"
        # Your controller details
        controller_account_access_key: "123key" # Please add this to your Vault
        controller_host_name: "fieldlab.saas.appdynamics.com" # Your AppDynamics controller
        controller_account_name: "customer1" # Please add this to your Vault
        enable_ssl: "false"
        controller_port: "8090"
        controller_global_analytics_account_name: 'customer1_e52eb4e7-25d2-41c4-
a5bc-9685502317f2' # Please add this to your Vault
        # config properties docs - https://docs.appdynamics.com/display/latest/
Machine+Agent+Configuration+Properties
        # Can be used to configure the proxy for the agent
        java_system_properties: "-Dappdynamics.http.proxyHost=10.0.4.2
-Dappdynamics.http.proxyPort=9090" # mind the space between each property

```

i In Linux and Windows, the Ansible role starts and runs the Machine agent as a service during installation, upgrade, and rollback. In Solaris and AIX, the Ansible role will install, upgrade, and roll back the machine agent. However, you must start the Machine agent manually.

Machine Agent Variables

Variable	Description
java_system_properties	To configure proxy settings for agents
analytics_event_endpoint	Specify Events Service URL in this variable
enable_analytics_agent	To enable Analytics Agent for the Machine Agent
sim_enabled	Enable server infrastructure monitoring

Variable	Description
<code>controller_global_analytics_account_name</code>	Global account name of the Controller

Ansible Configuration for .Net Agent MSI

i This document contains references to the Ansible® documentation. AppDynamics does not own any rights and assumes no responsibility for the accuracy or completeness of such third-party documentation.

The following sections provide the example use cases for the .Net Agent MSI Ansible role.

i **Important**

1. Agent upgrade using this Ansible role does not retain the previous .Net Agent MSI configurations. It overrides the existing configuration with the configuration you specify in the role. If configuration details are not specified in the role, a default minimal configuration is used. Ensure that you back up all important configurations before running this role.
2. .Net Agent MSI rollback is not supported in the following scenarios:
 - If .Net Agent MSI was never installed on the machine or the previous .Net Agent MSI installation is not managed by this role
 - If the rollback is already performed. Rollback to only one previous version is supported

Install .Net Agent MSI

Example 1: Ansible® role used to install .Net Agent MSI with the following basic features:

- Installs the latest .Net Agent
- Auto generates the Controller application name
- Instruments all IIS applications. You must restart IIS after installation.

i In this playbook, the parameters to communicate with the Controller are included from `vars/args.yaml`.

```
---
- name: .Net Agent MSI Minimal Configuration
```

```

hosts: windows
tasks:
  - name: Include variables for the controller settings
    # Include all yaml files under the vars directory
    ansible.builtin.include_vars:
      dir: vars
      extensions:
        - 'yaml'
        - 'yml'

  - ansible.builtin.include_role:
      name: appdynamics.agents.dotnet_msi

```

Example 2: Ansible role used to install .Net Agent MSI with the following extended features:

- Installs the .Net Agent version 22.12.0
- Defines a specific Controller application name. You specify a controller application name that the role utilizes during configuration.
- Instruments only specific IIS applications with or without default tier and node names. You must restart IIS after installation.
- Instrument standalone applications with or without default tier and node names. You must restart the standalone applications after installation.

In the below playbooks, the parameters to communicate with the controller are defined in the playbook.

```

---
- name: .Net Agent MSI Extended Configuration
  hosts: windows
  tasks:
    - ansible.builtin.include_role:
        name: appdynamics.agents.dotnet_msi
      vars:
        agent_version: '22.12.0'
        # Your controller details
        controller_host_name: 'something.saas.appdynamics.com'
        controller_port: '443'
        enable_ssl: 'true'
        controller_account_name: 'customer1'
        controller_account_access_key: '123456'
        application_name: 'DotNetAgent_Application'

        monitor_all_IIS_apps: 'false'

        iis_applications:
          # instrument a web application 'PaymentService' under a web site 'Default Web
          Site'
          - site: 'Default Web Site'
            path: '/PaymentService'
            # default tier: 'site/path'
            # default node: 'host-tier'

```

```

# instrument an entire web site 'BillingWebSite'
- site: 'BillingWebSite'
  tier_name: 'BillingWebSiteTier'
  node_name: 'BillingWebSiteNode'

standalone_applications:
  # instrument any execution of a standalone application 'login.exe'
  - executable: 'login.exe'
    # default tier: 'executable'
    # default node: 'host-tier'

# instrument a standalone application 'checker.exe' with a specific set of command
line arguments
- executable: 'checker.exe'
  command_line: '-arg1 value1 -flag1'
  tier_name: 'CheckerTier'
  node_name: 'CheckedNode'

```

.Net Agent Variables

Variable	Description	Possible Values	Required	Default
custom_ad_setup_file	Defines a local path to the custom installation configuration file on the Ansible control node. It can be a static file or a dynamic Jinja template.	System path	N	
custom_config	Defines a local path to the custom config.xml static file on the Ansible controlling node. It takes precedence over other configuration settings.	System path	N	
enable_tls12	Enable Controller SSL TLS1.2 connection.	[true, false]	N	false
iis_applications	List of IIS applications to monitor. It can be useful if monitor_all_IIS_apps = false or custom tier and node names are required for an application. See .NET Agent Configuration Properties .		N	

Variable	Description	Possible Values	Required	Default
<code>iis_application.site</code>	Name of the IIS website.		Y (for each IIS application if <code>iis_applications</code> is defined)	
<code>iis_application.path</code>	Path to the IIS web application relative to the IIS website. The path must begin with '/'. If the path is missing the default value '/' indicates that all applications under the website are instrumented.		N	'/'
<code>iis_application.tier_name</code>	Controller Tier Name for the IIS application.		N	<code>iis_application.site/iis_application.path</code> (if the path is defined or <code>iis_application.site</code>)
<code>iis_application.node_name</code>	Controller Node Name for the IIS application.		N	<code>hostname-iis_application.tier_name</code>
<code>monitor_all_IIS_apps</code>	Enable monitoring of all IIS applications.	[<code>true</code> , <code>false</code>]	N	<code>true</code>
<code>restart_app</code>	Set to <code>true</code> to restart the IIS if it is installed on the system. However, the role will not restart the standalone applications added or removed from instrumentation. <div style="border: 1px solid #0070C0; padding: 5px; background-color: #E6F2FF; margin-top: 10px;"> <p>i All the applications added or removed from instrumentation must be restarted for agent changes to take effect.</p> </div>	[<code>true</code> , <code>false</code>]	N	<code>false</code>

Variable	Description	Possible Values	Required	Default
<code>standalone_applications</code>	List of .Net standalone applications to monitor. See .NET Agent Configuration Properties .		N	
<code>standalone_application_executable</code>	Name of the executable file for the standalone application (with or without extension).		Y (for each standalone application if <code>standalone_applications</code> is defined)	
<code>standalone_application_command_line</code>	Command line arguments for the executable to limit the monitoring to a specific execution of the application.		N	
<code>standalone_application_tier_name</code>	Controller Tier Name for standalone application.		N	<code>standalone_application_executable</code>
<code>standalone_application_node_name</code>	Controller Node Name for standalone application.		N	<code>hostname-standalone_application_tier_name</code>

i This document contains references to the Ansible documentation. AppDynamics does not own any rights and assumes no responsibility for the accuracy or completeness of such third-party documentation.

Set .Net Agent MSI Environment Variables

You can use the `ansible.windows.win_environment` Ansible module to set .Net Agent MSI environment variables. The following example defines the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` environment variable on the system where the Agent will be installed. For more information, see [Modify environment variables on Windows hosts](#).

```
---
- name: .Net Agent MSI Test Play
  hosts: windows
  tasks:
    - name: Include variables for the controller settings
      # Include all yaml files under the vars directory
      ansible.builtin.include_vars:
        dir: vars
```

```

    extensions:
      - 'yaml'
      - 'yml'

  - ansible.windows.win_environment:
    state: present
    name: 'APPDYNAMICS_AGENT_UNIQUE_HOST_ID'
    value: '{{ ansible_hostname }}' # can be jinja template like in this example or a
static `value` if needed
    level: machine

  - ansible.builtin.include_role:
    name: appdynamics.agents.dotnet_msi

```

Install and Upgrade .Net Agent MSI on a Certain Tier/Node

.Net Agent MSI performs a global machine-wise installation. You can not install different versions of the agent on the machine. Also, all applications on a machine are instrumented using the same version of the agent

To update the Agent on a specific Windows machine, create the Ansible inventory file and run the playbook on the desired hosts. For more information, see [How to build your inventory](#).

```

---
# updating agent version on certain windows machines only
- name: .Net Agent MSI Test Play
  hosts: windows_region_1 # a group 'windows_region_1' should be defined in ansible inventory
  and lisy all desired machines
  tasks:
    - ansible.builtin.include_role:
      name: appdynamics.agents.dotnet_msi
      vars:
        agent_version: '22.12.0' # or providing custom_config or any other changes to the
        configuration

```

To update the list of instrumented applications within a machine, add or remove the desired application from the role configuration and rerun the playbook.

Ansible Configuration for Node.js Agent

i **Note**

- Ensure that you are using Node.js version 14.x-18.x.
- Ensure that you restart the agent after installation.

The following is an example of an Ansible® role to install Node.js Agent on Linux:

```

---
- hosts: linux
  tasks:
    - include_role:
      name: appdynamics.agents.node
    vars:
      agent_version: latest # [latest or provide the specific agent version]
      agent_type: node
      agent_action: upgrade # can be upgrade/install/rollback, default upgrade when
unspecified
      controller_account_access_key: "123key" # Please add this to your Vault
      controller_host_name: "fieldlab.saas.appdynamics.com" # Your AppDynamics controller
      controller_account_name: "customer1" # Please add this to your Vault
      enable_ssl: "false"
      controller_port: "8090"

```

Ensure that you restart the agent after installation using the following command:

```
node -r appd-config.js app.js
```

Node.js Agent Variables

Variable	Description	Default	Possible Values	Required
agent_version	Node.js agent version to be installed.	latest	latest, [agent version in x.x.x.x format]	No
node_agent_enableGraphQL	Use this if your application uses graphql.	false	true, false	No
node_agent_debug_logging	To run the application with debug logging enabled.	false	true, false	No
npm_registry	To run the application in debug mode.	https://registry.npmjs.org		No

Ansible Configuration for PHP Agent

The following sections provide the example use cases for the PHP Agent Ansible Role:

Example 1: The following is an example of Ansible® role to install PHP Agent on Linux:

```

---
- hosts: all
  tasks:
    - include_role:
        name: appdynamics.agents.php
      vars:
        agent_version: latest
        agent_type: php
        agent_action: upgrade
        application_name: e-commerce
        controller_account_access_key: "123key"
        controller_host_name: "fieldlab.saas.appdynamics.com"
        controller_account_name: "customer1"
        enable_ssl: false
        controller_port: 8090
        tier_name: tier1
        node_name: node1
        log_directory: "/opt/appdynamics/php-agent/ecommerce_logs"
        zts_support: false

        # proxy configs
        proxy_host: master.ecommerce-proxy.com
        proxy_port: 8080
        proxy_user: ecommerce-user
        proxy_password_file: /etc/ecommerce/passwd
        proxy_ctrl_dir: /ecommerce/proxy_dir/
  
```

Example 2: The following is an example of Ansible role to upgrade PHP Agent on Linux where agent is already installed:

```

---
- hosts: all
  tasks:
    - include_role:
        name: appdynamics.agents.php
      vars:
        agent_version: latest
        agent_type: php
        agent_action: upgrade
        application_name: e-commerce
        controller_account_access_key: "123key"
  
```

```

controller_host_name: "fieldlab.saas.appdynamics.com"
controller_account_name: "customer1"
enable_ssl: false
controller_port: 8090
tier_name: tier1
node_name: node1
log_directory: "/opt/appdynamics/php-agent/ecommerce_logs"
zts_support: false
linux_custom_agent_install_path: "/home/ubuntu/ecommerce_agent/" #this path should
contain the agent files (eg: install.sh ,php etc)
custom_agent_ini_file: "/etc/php/7.4/cli/conf.d/appdynamics_agent.ini" #this file
should contain your agent controller details
  
```

PHP Agent Variables

Variable	Description	Possible Values	Required	Default
custom_agent_ini_file	Set the absolute path of the appdynamics_agent.ini file.	<custom path> By default, it takes the default .ini file path set in PHP settings	Yes, if linux_custom_agent_install_path is defined	None
enable_cli	Set to true if you want to enable the CLI mode.	true or false	Optional	None
enable_cli_long_running	Set to true to defend PHP in long-running CLI applications. See Configure the Agent for PHP CLI Applications .	true or false	Optional	false
ignore_permissions	Set to true if you want to ignore file and directory permission issues.	true or false	Optional	None
log_directory	Specify your logs directory. By default, logs folder is created inside agent directory.	<agent-directory>/logs	Optional	<agent-directory>/logs

Variable	Description	Possible Values	Required	Default
<code>php_executable_path</code>	Specify the path for the PHP binary.	<code>/usr/bin/php</code>	Optional	<code>global php path set</code>
<code>php_ini_dir</code>	Directory for the <code>appdynamics_agent.ini</code> file.	<code>/etc/php/</code>	Required on Ubuntu and when the default PHP CLI binary cannot be determined.	<code>global php ini path set</code>
<code>php_extension_dir</code>	Extensions directory for the <code>appdynamics_agent.so</code> file.	<code>/etc/php/extensions/</code>	Required on Ubuntu and when the default PHP CLI binary cannot be determined.	<code>global php extension path set</code>
<code>php_version</code>	Version of PHP that you are instrumenting. Valid formats are version numbers to one or two decimal positions, for example, 7.4 and 7.4.29.	<code>7.4.29</code>	Required when the default PHP CLI binary cannot be determined or there is no PHP CLI binary.	<code>global php version set</code>
<code>zts_support</code>	Set to <code>true</code> to install PHP ZTS agent.	<code>true</code> or <code>false</code>	Optional	<code>false</code>

i Important

1. Use the `php -i | grep appdynamics_agent.ini` command to get the `appdynamics_agent.ini` path. Set the `custom_agent_ini_file` with the absolute file path if your agent is not installed in default location or if you are using `linux_custom_agent_install_path`.
2. If you want to install agent in PHP version which is not set globally, you must define the following variables. These are mandatory variables for all `agent_action`:
 - `php_executable_path`
 - `php_ini_dir`
 - `php_extension_dir`
 - `php_version`

Custom Proxy Configuration Variables

Variable	Description	Possible Values	Required	Default
proxy_host	Proxy host to route data to the Controller through a proxy server.	master.ecommerce-proxy.com	Optional	None
proxy_port	Proxy port to route data to the Controller through a proxy server.	8090	Optional	None
proxy_user	Proxy user required to log in to proxy server host.	ecommerce-user	Optional	None
proxy_password_file	Proxy password file to log in to proxy server host.	/etc/ecommerce/passwd	Optional	None
proxy_ctrl_dir	The proxy control directory. If not specified, the installer creates a temporary directory.	/ecommerce/proxy_dir/	Optional	None

i Ansible® is a registered trademark of Red Hat, Inc. in the United States and other countries.

Ansible Configuration for Python Agent

The following sections provide the example use cases for the Python Agent Playbook:

Install Python Agent

Example 1: Ansible® role used to install Python Agent with the following features:

- Installs Python Agent on Linux (Debian, Alpine, and RedHat)
- Creates a backup if existing installation is detected

```

---
- hosts: all
  tasks:
    - name: Include variables for the controller settings
      # Include all yaml files under the vars directory
      include_vars:
        dir: vars
        extensions:
          - 'yaml'
          - 'yml'

    - include_role:
        name: appdynamics.agents.python
  
```

```

vars:
  agent_version: 22.10.0.5500.0
  # possible value:
  #     - latest: Latest version
  #     - 22.10.0.5500.0: Any Specific version number
  agent_type: python
  agent_action: upgrade
  # possible value:
  #     - upgrade: upgrade currently installed agent to agent_version
  #     - install: install agent_version
  #     - rollback: rollback to previous backup if any
  #     - uninstall: uninstall agent
  # Python specific Args
  install_env: default # [default - (main python path taken automatically), virtualenv
- (virtualenv path need to be provided)]
  # possible value:
  #     - default: install agent in global python
  #     - virtualenv: install agent to specific virtualenv
  virtualenv_path: /home/ansible/venv
  # possible value:
  #     - /home/ansible/venv: virtualenv path
  #     - None
  install_agent_from: appd-portal
  # possible value:
  #     - pypi: Download agent from PYPI
  #     - appd-portal: Download agent from AppD portal

```

Example 2: Ansible role to start a sample application with Python Agent:

```

---
- hosts: all
  tasks:
    - name: Include variables for the controller settings
      # Include all yaml files under the vars directory
      include_vars:
        dir: vars
        extensions:
          - 'yaml'
          - 'yml'

    - include_role:
        name: appdynamics.agents.python

    - name: Start Sample Python app
      shell: "nohup pyagent run -c /opt/appdynamics/python-agent/appd.cfg python3 /home/
ubuntu/app.py &"
      async: 100
      poll: 0
      register: status
      failed_when: "'FAILED' in status.stdout"

```

Config path and the application path has to be changed accordingly.

Python Agent Variables

Variable	Description	Default	Possible Values	Required
agent_config_path	Specify the absolute path (including the file path) for the manually created configuration file containing the agent configuration data.	None.	agent_destination_directory	No
analytics_host	Analytics Agent hostname.	localhost		No
analytics_port	Analytics Agent port.	9090		No
analytics_ssl	Set to ON to enable SSL communication with the Analytics Agent.	OFF		No
analytics_ca_file	Certificate of the CA authority that signed the certificate of Analytics Agent.			No
eum_disable_cookie	When set to ON , the agent does not add EUM correlation data to WSGI response headers.	OFF	OFF, ON	No
eum_user_agent_allowlist	If specified overwrites the default allowlist for user agents added as EUM correlation data headers. Use it to specify alternate user agents as a comma-separated list. Use '*' to allow all user agents.	Mozilla, Opera, WebKit, Nokia		No
install_agent_from	Install Agent from PYPI or Appdynamics Download portal	pypi	pypi, appd-portal	Yes

Variable	Description	Default	Possible Values	Required
<code>install_env</code>	Python Environment where to install Appdynamics Agent (global or virtual environment)	<code>default</code>	<code>default, virtualenv</code>	Yes
<code>log_level</code>	Directory to write proxy and agent logs	<code>warning</code>	<code>warning, debug, info</code>	No
<code>log_debugging</code>	The log level for the agent.		<code>off, on</code>	No
<code>log_dir</code>	Directory to write debug level logs	<code>/tmp/appd/logs</code>		No
<code>node_reuse</code>	Reuse node names	-	<code>true, false</code>	No
<code>node_reuse_prefix</code>	Node name prefix while reusing node names	-	-	No
<code>pypi_index_url</code>	Change the pypi index url to any internal artifactory	https://pypi.org/simple		No
<code>snapshot_exit_calls_details_length</code>	Specifies the number of characters in the details string describing exit calls in transaction snapshots.	100		No
<code>transaction_monitor_bt_max_duration_ms</code>	The maximum duration of a business transaction in milliseconds.	12000		No
<code>virtualenv_path</code>	Path to <code>virtualenv</code> . It is required if <code>install_env</code> is set to <code>virtualenv</code>	<code>none</code>	<code>None, venv_path</code>	Yes, if <code>install_env = virtualenv</code> No, if <code>install_env = default</code>

Variable	Description	Default	Possible Values	Required
wsgi_script	Path to WSGI script file.			No
wsgi_callable	Name of WSGI callable in script/module.	application		No
wsgi_module	The fully-qualified name of the application module.			No

i Ansible® is a registered trademark of Red Hat, Inc. in the United States and other countries.

Docker

This page describes how to use a Docker file to copy the App Server Agent files to the Docker image.

i When the Cluster Agent is installed in a cluster, AppDynamics recommends Cluster Agent auto-instrumentation. See [Auto-Instrument Applications with the Cluster Agent](#).

A common method to instrument a containerized application is to include the AppDynamics App Server Agent when building the application image. You add a `COPY` command to the Dockerfile to copy the agent files to the image. The `COPY` command copies the application binary to the Docker container image. If an App Server Agent upgrade is required, you must rebuild the image with the new agent files.

See the language-specific container installation page for instructions on how to use a Dockerfile:

- [Install the Java Agent in Containers](#)
- [Install the .NET Agent for Linux in Containers](#)
- [Install the Node.js Agent in Containers](#)

Dockerfile Example

In this example for a Java application, the Java Agent files in the `AppServerAgent` folder are copied to the application image and the application JAR file. The agent environment variables are set before the start script runs.

```
FROM openjdk:8-jre-slim

COPY myapp.jar /app
COPY AppServerAgent/ /opt/appdynamics

ENV APPDYNAMICS_AGENT_APPLICATION_NAME=<value>
ENV APPDYNAMICS_AGENT_TIER_NAME=<value>
```

```

ENV APPDYNAMICS_AGENT_ACCOUNT_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=<value>
ENV APPDYNAMICS_CONTROLLER_HOST_NAME=<value>
ENV APPDYNAMICS_CONTROLLER_PORT=<value>
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED=<value>
ENV APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME=true
ENV APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME_PREFIX=<value>

COPY ./startup.sh /startup.sh
RUN chmod +x /startup.sh
ENTRYPOINT ["/bin/bash", "/startup.sh"]
  
```

Cloud Foundry

With version 4.6.x of AppDynamics Application Performance Monitoring for VMware Tanzu tile is shipped with the AppDynamics extension buildpack, `appdbuildpack`, which can be used along with the standard buildpacks using the Cloud Foundry™ multiple buildpack workflow. The buildpack serves as a single point for AppDynamics support.

i The Java buildpack does not support the multi-buildpack approach. Therefore, AppDynamics support is implemented directly in the Java buildpack and the multi-buildpack approach is not used for Java applications.

Before You Begin

- Cloud Foundry Command Line Interface (cf CLI) v6.38 or later is required to use multiple buildpacks. See [Installing the cf CLI](#).
- CloudFoundry Environment with AppDynamics Tile installed and configured with controller(s) information.
- An application that you want to instrument. See, [Sample Application](#).

You can also refer to the [AppDynamics Application Performance Monitoring for VMware Tanzu](#) documentation.

Sample Applications

You can find sample applications demonstrating the multi-buildpack approach in the [GitHub repository](#).

AppDynamics Buildpack Workflow

The following workflow demonstrates the workflow for using AppDynamics BuildPack. This is used for instrumenting applications running in cloud foundry (cf) environments.

i This document contains references to the Cloud Foundry™ documentation. AppDynamics does not own any rights and assumes no responsibility for the accuracy or completeness of such third-party documentation.

1. Install or upgrade [AppDynamics Application Performance Monitoring for VMware Tanzu tile version v4.6.x or later](#). See [Installing and Configuring AppDynamics](#).

When the AppDynamics APM for VMware Tanzu tile is installed, a buildpack with the name **appdbuildpack** is displayed in your list of cf environment buildpacks:

```

buildpacks

$ cf buildpacks
Getting buildpacks...

buildpack          position      enabled  locked  filename
stack
dotnet_core_buildpack  1           true    false  dotnet-core_buildpack-
cached-cflinuxfs2-v2.2.0.zip
hwc_buildpack        2           true    false  hwc_buildpack-cached-
windows2016-v3.0.2.zip  windows2016
appdbuildpack        25          true    false  appdynamics_buildpack-
v4.5.513.zip

```

2. Verify if the `appdynamics` service is present in the environment along with the service plans created during the tile installation.

```

buildpacks

$ cf marketplace -s appdynamics
service plan      description      free or paid
pcf-appd          pcf-appd        free
pcf-appd-test     pcf-appd-test   free

```

3. Create service instance with the following command (in this example, the service instance is `appdynamics_service_instance`):

```

buildpacks

$ cf create-service appdynamics pcf-appd appd

```

i Non Tile Workflow

For Cloud Foundry environments that do not support tiles, perform the following:

- a. Download AppDynamics Buildpack from [AppDynamics Application Performance Monitoring for VMware Tanzu](#) and upload it to your environment using the `cf create -buildpack` command.
- b. Create the user-provided service (for example, `appdynamics_service_instance`) as mentioned in [AppDynamics](#)

Service Broker and Buildpacks - APM FAQs, then continue with step 4.

4. Edit the application `manifest.yml` with the following details:
See the [Workflow Table](#) for sample buildpacks.
 - a. In `services` section, bind to the AppDynamics service instance (in this example it is `appdynamics_service_instance`)
 - b. In the `buildpacks` section, include the `appdbuildpack` and standard buildpack specific to the application framework or language
 - c. In the `env` section, set these environment variables:
 - `APPD_AGENT` to the type of the application you are instrumenting (in this example it is .NET Core application)
 - (Optional) `APPD_AGENT_HTTP_URL` to download specific agent bits from an HTTP location
 - (Optional) `APPD_CONF_HTTP_URL` to download custom configuration files, corresponding to the AppDynamics agent, from an HTTP location

manifest.yml

```

cloudfoundry-apps/cf-NET-sample/ViewEnvironment (master)$ cat manifest.yml
---
applications:
- name: cf-net-application-sample
  memory: 2G
  buildpacks:
    - appdbuildpack          # appdynamics buildpack (required)
    - dotnet_core_buildpack # language specific buildpack
  services:
    - appdynamics_service_instance # appdynamics service instance (required)
  env:
    APPD_AGENT: dotnetcore # type of agent needed for instrumentation (required)
    APPD_AGENT_HTTP_URL: https://www.nuget.org/api/v2/package/AppDynamics.Agent.Distrib.Micro.Windows/4.5.7 # download url (optional)
    APPD_CONF_HTTP_URL: http://appdconf.apps.lawndale.cf-app.com/dotnetcore/1/ # url where configuration files are present (optional)
    
```

5. Push your application by using the cf CLI command

```
cloudfoundry-apps/cf-NET-sample/ViewEnvironment (master)$ cf push
```

AppDynamics Agent Values

Language	Standard BuildPack	APPD_AGENT value
.NET Framework (Windows)	hwc_buildpack	dotnet
.NET Core (Linux)	dotnet_core_buildpack	dotnet-linux
.NET Core (Windows)	binary_buildpack	dotnet-windows

Language	Standard BuildPack	APPD_AGENT value
Python	python_buidpack	python
GoLang	go_buildpack	golang
NodeJS	nodejs-buildpack	nodejs

Downloading Agent Bits

AppDynamics Buildpack provides a way to download specific agent bits by fetching binaries from custom download URLs in addition to the default behavior of fetching agents from standard download points (such as appd download server, pypi, nuget, and so on).

You can specify the `APPD_AGENT_HTTP_URL` as the download URL that is hosting AppDynamics Agent.

Custom Configuration

AppDynamics Buildpack also provides a way to override basic configuration or add custom configuration files to the agent. The buildpack can fetch the configuration either locally or remotely. The buildpack fetches files with the same names that is used for a specific agent. To fetch remotely from a custom download point, host the configuration files corresponding to the agent on a HTTP server under a url and set `APPD_AGENT_HTTP_URL` to that url

Workflow Table

The following table describes the language/framework specific settings that can be applied while pushing the applications with `appdbuildpack`.

The column descriptions are as following:

- **APPD_AGENT Value:** Value of the `APPD_AGENT` environment variable that needs to be set while pushing the application with `appdbuildpack`.
- **Configuration File Names:** This list represents the names of files that will be picked by `appdbuildpack` when hosted locally or remotely.
 - When hosted remotely, these files should be present under URL specified by `APPD_CONF_HTTP_URL`.
 - When hosted locally, the files should be present under `appdynamics/conf` folder, which is next to application bits.
- **Sample Manifest:** An example buildpack to push an application with all the settings with `appdbuildpack` for instrumentation

i Here, we have used `appdynamics_service_instance` as the service instance, which is created before running the command from service broker `appdynamics service` or user-provided service (<https://docs.pivotal.io/partners/appdynamics/faqs.html#s2>).

Language	APPD_AGENT Value	Allowed Custom Configuration File Names	Sample Manifest
DotNetCore (Linux)	dotnetcore	<ul style="list-style-type: none"> AppDynamicsConfig.json AppDynamicsAgentLog.json 	<div data-bbox="959 436 1495 531" style="border: 1px solid black; padding: 5px; margin-bottom: 10px;"> edit manifest.yml </div> <pre data-bbox="959 537 1495 1192"> cloudfoundry-apps/cf-NET-sample/ ViewEnvironment (master)\$ cat manifest.yml --- applications: - name: cf-net-core memory: 2G buildpacks: - appdbuildpack - dotnet_core_buildpack services: - appdynamics_service_instance env: APPD_AGENT: dotnetcore APPD_AGENT_HTTP_URL: <optional> APPD_CONF_HTTP_URL: <optional> </pre>

Language	APPD_AGENT Value	Allowed Custom Configuration File Names	Sample Manifest
DotNet (HWC)	dotnet	<ul style="list-style-type: none"> AppDynamicsConfig.json AppDynamicsAgentLog.json 	<div data-bbox="959 438 1495 531" style="border: 1px solid black; background-color: #f0f0f0; padding: 5px;"> <p>edit manifest.yml</p> </div> <pre data-bbox="959 531 1495 1289"> cloudfoundry-apps/cf-NET-sample/ ViewEnvironment (master)\$ cat manifest.yml --- applications: - name: cf-net memory: 2G buildpacks: - appdbuildpack - hwc_buildpack services: - appdynamics_service_instance # appdynamics service instance (required) env: APPD_AGENT: dotnet APPD_AGENT_HTTP_URL: <optional> APPD_CONF_HTTP_URL: <optional></pre>

Kubernetes

You can instrument Kubernetes® applications using one of these methods:

- [Use Init Containers to Instrument Applications](#)
- [Use a Docker file to Instrument Applications](#)
- [Auto-Instrument Applications with the Cluster Agent](#)

To configure agents for manually instrumented applications, see [Best Practices to Configure Agents in Kubernetes](#).

To establish APM correlation between the Cluster Agent and manually instrumented applications, see [Manually Configure App Agents to Correlate with the Cluster Agent](#).

i Kubernetes® is a trademark of The Linux Foundation®.

Use Init Containers to Instrument Applications

This page describes how to use the init containers option to copy agent files into a Kubernetes® application container at deploy time.

i When the Cluster Agent is installed in a cluster, AppDynamics recommends Cluster Agent auto-instrumentation. See [Auto-Instrument Applications with the Cluster Agent](#).

The init containers option is available in Kubernetes environments used to run additional containers at startup that helps initialize an application. Once the init containers have completed their initialization tasks, they terminate but leave the application container(s) running. For the App Server Agent installation, init containers are used as a delivery mechanism to copy the agent files into the application container at deploy time. See [Init Containers Option in Kubernetes](#).

Copying the agent files at deploy time (instead of at build time) provides advantages over explicitly copying the agent files and dependencies into the application image. The init containers option simplifies the image build process because:

- You do not need to update each application's Dockerfile to copy the agent files.
- You do not need to rebuild the application image for agent upgrades.

See the language-specific container installation page for how to use an init container:

- [Install the Java Agent in Containers](#)
- [Install the .NET Agent for Linux in Containers](#)
- [Install the Node.js Agent in Containers](#)

Kubernetes Init Container Deployment Spec Example

In the Kubernetes deployment spec example for a Java application, the init container is a second Docker image that contains the App Server Agent files. Because this Docker image is built separately from the application image, you do not need to rebuild the application image when you add or upgrade the App Server Agent.

```

1  kind: Deployment
2  spec:
3    containers:
4      -
5        image: "repo/java-app:v1"
6        name: java-app
7        volumeMounts:
```

```

8         -
9         mountPath: /opt/appdynamics
10        name: appd-agent-repo
11    initContainers:
12        -
13        command:
14            - cp
15            - "-ra"
16            - /opt/appdynamics/.
17            - /opt/temp
18        image: "docker.io/appdynamics/java-agent:20.6.0"
19        name: appd-agent
20        volumeMounts:
21            -
22            mountPath: /opt/temp
23            name: appd-agent-repo
24    volumes:
25        -
26        emptyDir: {}
27        name: appd-agent-repo
  
```

Dockerfile Example

In this example for a Java application, the Java Agent files in the `AppServerAgent` folder are copied to the application image and the application JAR file. The agent environment variables are set before the start script runs.

```

FROM openjdk:8-jre-slim

COPY myapp.jar /app
COPY AppServerAgent/ /opt/appdynamics

ENV APPDYNAMICS_AGENT_APPLICATION_NAME=<value>
ENV APPDYNAMICS_AGENT_TIER_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=<value>
ENV APPDYNAMICS_CONTROLLER_HOST_NAME=<value>
ENV APPDYNAMICS_CONTROLLER_PORT=<value>
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED=<value>
ENV APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME=true
ENV APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME_PREFIX=<value>

COPY ./startup.sh /startup.sh
RUN chmod +x /startup.sh
ENTRYPOINT ["/bin/bash", "/startup.sh"]
  
```

Best Practices to Configure Agents in Kubernetes

This page describes best practices to use when configuring App Server Agents in a Kubernetes environment and manually instrumenting applications using init containers or a Dockerfile.

This page does not apply to applications that use the Cluster Agent auto-instrumentation to configure agents. See [Auto-Instrument Applications with the Cluster Agent](#).

You can configure App Server Agents in Kubernetes using environment variables. Depending on the use case, you have three options to set environment variables:

- [Use ConfigMaps to Configure the App Server Agent](#)
- [Use Secrets for the Controller Access Key](#)
- [Set Application-Specific Configuration in the Deployment Spec](#)

See the language-specific container installation page to implement these best practices:

- [Install the Java Agent in Containers](#)
- [Install the .NET Agent for Linux in Containers](#)
- [Install the Node.js Agent in Containers](#)

Gather Login Credentials

To access AppDynamics, you need your login credentials and the URL from where you can access your organization's AppDynamics Controller(s). If you do not have this information, contact your AppDynamics administrator.

Use ConfigMaps to Configure the App Server Agent

When instrumenting a container running in Kubernetes, each App Server Agent requires that you set environment variables to configure:

- Connection parameters
- Application metadata
- Agent behavior

You can use ConfigMaps to store an application's environment variables in a Kubernetes object within the scope of a namespace. ConfigMaps are an optimal [twelve-factor](#) method used to manage agent configuration shared across multiple Kubernetes applications within a namespace.

Controller credentials configuration is stored in a single ConfigMap, and shared with each application in the namespace that reports to that Controller. If you use multiple Controllers across different environments, such as development, test, and production, you can store different ConfigMaps in the namespaces associated with those environments.

Use Secrets for the Controller Access Key

The Controller access key is another configuration that you can pass to App Server Agents as an environment variable. Sensitive data is stored in a Kubernetes namespace using a Secret, rather than a ConfigMap. You can use Kubernetes Secrets to obfuscate values rather than manipulate them in plaintext.

Set Application-Specific Configuration in the Deployment Spec

The AppDynamics Controller application tier name identifies a service that reports under a particular AppDynamics application. An application tier name is an example of agent configuration that is different for each Kubernetes application but typically does not vary across environments and namespaces. Application-specific configuration, similar to the tier name, is easier to define in the Kubernetes deployment spec directly.

Verify the Environment Variables

After you set the agent environment variables, you can verify that they were added to your application.

To verify the environment variables:

1. Create a ConfigMap.
2. Create a Secret.
3. Create an environment variable in the deployment spec.
4. Restart the application container.
5. Log in to the container using `kubectl exec`:

```
kubectl -n ecommerce exec -it <pod name> /bin/sh
```

6. List the AppDynamics environment variables available in the container to confirm they are defined and have the correct values:

```
env | grep APPD
APPDYNAMICS_AGENT_APPLICATION_NAME=<value>
APPDYNAMICS_AGENT_ACCOUNT_NAME=<value>
APPDYNAMICS_CONTROLLER_HOST_NAME=<value>
...
```

Agent Management User Interface

You can view all the installed agents on the **Agent Management** tab in the Controller UI. You can navigate using any of the following ways on the Controller UI to view the **Agent Management** tab:

- **Home > Agent Management > Manage Agents**
- **Settings > Agent Management > Manage Agents**

 You require to be an administrator to access the Agent Management UI. Currently, you can manage only App Server Agents, and Machine Agents by using Smart Agents.

When you click **Manage Agents**, you can view the following Agent details:

- App Server Agents
- Machine Agents
- Smart Agents
- Database Agents
- Analytics Agents
- Network Visibility Agents
- Cluster Agents

The screenshot shows the 'Agent Management' interface. At the top, there are navigation tabs: Agents, Tasks In Progress, History, and Config Management. Below these are sub-tabs for different agent types: App Server Agents, Machine Agents, Smart Agents, Database Agents, Analytics Agents, Network Visibility Agents, and Cluster Agents. A table lists various agents with columns for Status, Type, Version, Smart Agent ID, Unique Host ID, Managed, Application, Tier, Node, Monitoring, and All Monitors. The right-hand pane displays 'Upgrades Available (8)' with details for DB Agent 23.9.0.3436, PHP Agent 23.7.1.751, Node.js Agent 23.10.0, and JAVA Agent 23.9.1.35149.

Sta...	Type	Version	Smart Agent ID	Unique Host ID	Managed	Application	Tier	Node	Monitoring...	All Monitors...
	Python	0.0.0.0		320d5d3237ab	No	Enterprise-Se...	CISCOBRAIN A...	CISCO-APP-U-N...	Enabled	false
	Java	22.9.1.34265		(NULL)-M-82HH	No	BTSoc18	Tier1	Node1	Enabled	false
	Java	23.8.0.35032		0c6cc27e6d3	No	SangrahApp	OrderService	CustomPojoRef...	Enabled	false
	Java	23.9.1.35149		0251b6ce4038	No	HybridAgentS...	Tier1_Springbo...	Node1_Springbo...	Enabled	false
	Java	23.10.0.35144		29887c45f728	No	OT_PYTHON...	JAVA_DOWN_S...	JAVA_NODE_D...	Enabled	false
	Webserver			17399377d29f	No	Apache_Nara...	Apache_narasi...	Apache2_1	Enabled	false
	Java	23.8.0.34823		228eb2294e1a	No	APP-SLRVS	TIER-MOLHC	NODE-LKKDB	Enabled	false
	Java	23.10.0.35168		2e5e3b73fbdb	No	OT_PYTHON...	JAVA_UP_SER...	JAVA_NODE_UP...	Enabled	false
	Node	23.10.0.0		2468bb9a8906	No	Hybrid09Hybr...	Tier2Hybrid_Hy...	Node2Hybrid...	Enabled	false
	Node	23.10.0.0		13a3efc3a9f8	No	Hybrid09Hybr...	Tier2Hybrid_Hy...	Node2Hybrid...	Enabled	false
	Node	23.10.0.0		1f3b4163149	No	Hybrid09Hybr...	Tier2Hybrid_Hy...	Node2Hybrid...	Enabled	false
	Node	23.10.0.0		1ad823c21bfb	No	Hybrid09Hybr...	Tier2Hybrid_Hy...	Node2Hybrid...	Enabled	false
	Node	23.10.0.0		06b85c3f1424	No	Hybrid09Hybr...	Tier2Hybrid_Hy...	Node2Hybrid...	Enabled	false
	Java	23.8.0.34823		06b85c3f1424	No	APP-SLRVS	TIER-MOLHC	NODE-LKKDB	Enabled	false

On the right pane you can view details of the agents that require an upgrade.

The Agent Management page provides the following details:

- [Agents](#)
- [Tasks In Progress](#)
- [History](#)
- [Config Management](#)

Agents

This displays all agents with the inventory details. The following sections include the agent details and actions that you can perform on the respective agents:

- [App Server Agents](#)
- [Machine Agents](#)
- [Smart Agents](#)
- [Database Agents](#)
- [Analytic Agents](#)
- [Network Visibility Agents](#)
- [Cluster Agents](#)

If you have not installed Smart Agent, the **Smart Agent ID** and **Managed** columns will not display any value.

App Server Agents

Inventory:

Name	Description
Status	<p>Displays the status of the agents on which the application is running.</p> <ul style="list-style-type: none"> • The Latest icon  represents that the corresponding agent type is running the latest version. • The Out of Date icon  represents that the corresponding agent type has a version which is no longer supported. • The Update Available icon  represents that the corresponding agent type has a version that is not the latest, hence requires to be updated. • The Unknown icon  represents that the version is unknown. It can be because the machine is not connected to the network or the machine is down.
Type	The type of the agent such as Java, Python, Node, Webserver, and Dotnet.
Version	The current version of the agent.
Smart Agent ID	<p>The ID of the Smart Agent that manages the corresponding app agent.</p> <p>If the value is not displayed, then Smart Agent is not installed.</p>
Unique Host ID	The unique ID of the host on which the agent is running.
Managed	The value can be Yes if the agent is managed by Smart Agent and No if the agent is not managed by Smart Agent.
Application	The application on which the corresponding agent is running.
Tier	The service running on the corresponding application.
Node	The service instance of the service running on the application.
Monitoring Status	The value is enabled if monitoring is enabled for the corresponding agent. The value is disabled if the monitoring is disabled for the corresponding agent.
All Monitoring Disabled	<why do we need this?>

Actions:

Action Menu	Description
View Node Dashboard	To view the Nodes & Tier dashboard of the required node. You can click the checkbox next to the specific agent, then click View Node Dashboard .
Filters	<p>To filter based on your requirement. Click Filters > Add Criteria.</p> <p>You can use Filters to add different filter criteria based on your requirement. For example, to see all Java Agents that have outdated versions:</p> <ol style="list-style-type: none"> 1. Click Filters > Add Criteria 2. Select Agent Type 3. Select Java Agent from the drop down 4. Click Done 5. Click Add Criteria to add another criteria for versions 6. Select Version Status 7. Click the Version Status dropdown, and then select Out of Date 8. If you just want to have a quick view of the list, click Apply <p>You can close this to not use this criteria. However, if you click Done, the criteria is used for filtering the list.</p>
Enable	To enable the selected agents. Select the required agents, then click Enable . The Monitoring Status displays as Enabled .
Disable	To disable the selected agents. Select the required agents, then click Disable . The Monitoring Status displays as Disabled .
Configure	To configure the node properties of the selected agent. Select the agent, then click Configure .
Upgrade	To upgrade the selected agents. Select the required agents, then click Upgrade .
Delete	To delete the selected agents. Select the agents that you want to delete, then click Delete .
Reset	<p>Resetting the Agent is a way to force the agent to register itself with the Controller in the same way it does at JVM/CLR startup, but without restarting the JVM/CLR.</p> <p>In the case of JVMs, if the agent is monitoring Collections using the Automatic Leak Detection or Custom Memory Structure feature, then resetting it will clear out these monitored Collections. The JVM will need to be restarted in order to start monitoring them again.</p>

Action Menu	Description
Actions	To perform the following actions: <ul style="list-style-type: none"> • Select applications to bulk enable • Select applications to bulk disable • Select applications to bulk reset • Rollback to previous version • Export grid data
Export Grid Data	To export the grid data in CSV format. It provides details of all the available app agents. Click Export Grid Data .

Machine Agents

Inventory:

Name	Description
Status	<p>Displays the status of the agent on which the application is running.</p> <ul style="list-style-type: none"> • The Latest icon  represents that the corresponding Machine Agent is running the latest version. • The Out of Date icon  represents that the corresponding Machine Agent has a version which is no longer supported. • The Update Available icon  represents that the corresponding Machine Agent has a version that is not the latest, hence requires to be updated. • The Unknown icon  represents that the version is unknown. It can be because the machine is not connected to the network or the machine is down.
Version	The current version of the Machine Agent.
Smart Agent ID	<p>The ID of the Smart Agent that manages the corresponding Machine Agent.</p> <p>If the value is not displayed, then Smart Agent is not installed.</p>
Unique Host ID	The unique ID of the host on which the agent is running.
Managed	The value is Yes if the Smart Agent is installed and No if the Smart Agent is not installed.

Name	Description
Application	The application on which the corresponding agent is running.
Monitoring Status	The value is enabled if monitoring is enabled for the corresponding agent. The value is disabled if the monitoring is disabled for the corresponding agent.

Actions:

Action Menu	Description
Details	To view the server summary of the selected Machine Agent. You can click the checkbox next to a specific agent, then click Details .
Filters	To filter based on your requirement. Click Filters . You can use Filters to add different filter criteria based on your requirement.
Enable	To enable the selected agents. Select the required agents, then click Enable .
Disable	To disable the selected agents. Select the required agents, then click Disable .
Configure	To configure the node properties of the selected agent. Select the agent, then click Configure .
Upgrade	To upgrade the selected agents. Select the required agents, then click Upgrade .
Delete	To delete the selected agents. Select the agents that you want to delete, then click Delete .
Reset	Resetting the Agent is a way to force the agent to register itself with the Controller in the same way it does at JVM/CLR startup, but without restarting the JVM/CLR. In the case of JVMs, if the agent is monitoring Collections using the Automatic Leak Detection or Custom Memory Structure feature, then resetting it will clear out these monitored Collections. The JVM will need to be restarted in order to start monitoring them again.
Actions	To perform the following actions: <ul style="list-style-type: none"> • Select applications to bulk enable • Select applications to bulk disable • Select applications to bulk reset • Rollback to previous version • Export grid data

Action Menu	Description
Export Grid Data	To export the grid data in CSV format. It provides the details of all the available machine agents. Click Export Grid Data .

Smart Agents

Inventory:

Name	Description
Status	<p>Displays the status of the Smart Agent on which the application is running.</p> <ul style="list-style-type: none"> The Latest icon  represents that the corresponding Smart Agent is running the latest version. The Out of Date icon  represents that the corresponding Smart Agent has a version which is no longer supported. The Update Available icon  represents that the corresponding Smart Agent has a version that is not the latest, hence requires to be updated. The Unknown icon  represents that the version is unknown. It can be because the machine is not connected to the network or the machine is down.
Version	The version of the Smart Agent.
Smart Agent ID	The ID of the Smart Agent that is installed on the host machine to manage the agents.
Hostname	The hostname of the machine on which the corresponding Smart Agent is running.
Application	The number of applications using the corresponding Smart Agent.
Connected Agents	The number of agents (app server agents or Machine Agents)

Actions:

Action Menu	Description
Details	To view the application summary on which the selected Smart Agent is installed. The summary includes application names along with the number of connected agents. You can click the checkbox next to a specific smart agent, then click Details .
Filters	To filter based on your requirement. Click Filters > Add Criteria . You can use Filters to add different filter criteria based on your requirement.
Upgrade	To upgrade the selected smart agents. Select the required smart agents, then click Upgrade .
Export Grid Data	To export the grid data in CSV format. It provides all the details of all the smart agents. Click Export Grid Data .

Database Agents

Inventory:

Name	Description
Hostname	The hostname of the machine on which the Database Agent is installed.
Version	The current version of the Database Agent.
Agent Name	The name that you specify for the corresponding agent during installation.
Status	The status of the agent.
Start Time	The time when the agent starts or restarts.

You cannot perform any action on this agent page.

Analytics Agents

Inventory:

Name	Description
Name	The name of the Analytics Agent that was specified during installation.

Name	Description
Unique Host ID	The unique ID of the host machine on which Analytics Agent is installed.
Version	The current version of the Analytics Agent.
Last Connected	The date and time when the agent was last connected to the Controller.
Log Pipeline Health	The health status of the Log Analytics pipeline.
Transaction Pipeline Health	The health status of Transaction Analytics pipeline.

To view the Analytics Agent summary, you can double click the required Analytics Agent or select the agent, then click **Details**.

You can filter the details based on name and health of the pipelines.

Network Visibility Agents

Inventory:

Name	Description
Unique Host ID	The unique ID of the host machine on which Network Visibility Agent is installed.
Hostname	The hostname of the machine on which the Network Visibility Agent is installed.
Application(s)	The application(s) on which the corresponding Network Visibility Agent is installed.
Agent Version	The current version of the Network Visibility Agent.
OS Name	The name of the Operating System on which the application is installed.
OS Version	The version of the Operating system on which the application is installed.

Name	Description
Dynamic Monitoring Mode	The values can be any of the following: <ul style="list-style-type: none"> • KPI – Network KPI metrics for all monitored objects (application flows, tiers, nodes, and network links) except individual connections. • Diagnostic – Network KPI metrics for all monitored objects, including connections. • Advanced – All network metrics for all monitored objects, including connections.
Enabled	The Enabled icon represents that the agent is enabled.

Actions:

You can select the required Network Visibility Agent and perform the following actions:

Action Menu	Description
Details	To view the summary of the selected Network Visibility Agent.
Pcap Configuration	To configure the packet capture for the selected agent.
Change DMM	Select the agent(s) for which you require to change the Dynamic Monitoring Mode.
Start Pcap	Select the agent(s) on which you require to start the packet capture.
Enable	Select the agent(s) that you want to enable, then select Enable .
Disable	Select the agent(s) that you want to disable, then select Disable .
Delete	Select the agent(s) that you want to delete, then select Delete .

Cluster Agents

Inventory:

Name	Description
Cluster name	The name of the Cluster Agent that you specified during the installation.
Version	The version of the installed Cluster Agent.
Kubernetes Version	The Kubernetes Version on which the Cluster Agent is running.
Status	The status of the Cluster Agent.

Actions:

You can select the required Cluster Agent and perform the following actions:

Action Menu	Description
Details	To view the summary of the selected Cluster Agent.
Delete	To delete a Cluster Agent. Select the required agent that you want to delete, then click Delete .
Enable	To enable a Cluster Agent. Select the required agent that you want to enable, then click Enable .
Disable	To disable a Cluster Agent. Select the required agent that you want to disable, then click Disable .
Configure	To edit the Cluster Agent Namespace. This is available for users who have administrator permissions.

Tasks In Progress

This displays details of all the tasks such as install, upgrade, or rollback that are in progress. You can click and download the log file for the required agent to view the log details.

History

This displays the details of what all tasks such as install, upgrade, or rollback were performed. You can click and download the log file for the required agent to view the log details.

Config Management

The Import Config dialog enables you to upload a `config.xml` file to the Controller, and specify a unique name for the configuration.

- Use a naming convention that helps you identify the type of machine for the configuration.
- Consider using a date or version scheme for the configuration name.
- Click a configuration, then click **Edit Config** to modify the configuration name.
- Double-click a config to display the XML. You can copy the XML, but you cannot modify it.

Smart Agent

Smart Agent allows you to manage the agent operations (install, upgrade, and rollback) for the [supported agents](#) by using the Controller user interface. It also provides [Smart Agent CLI](#) option for advanced configurations.

You can use the Controller UI to view all the installed agents with the inventory details. The Smart Agent inventory is also displayed along with other agent inventory details.

 You must install Smart Agent on each host where you want to use the Controller UI to perform the agent management.

Before You Begin

Ensure you meet the following requirements to use Smart Agent:

- AppDynamics Controller version $\geq 23.11.0$
- Sufficient agent licenses
- Required permissions. See [Permissions](#) to determine the user permissions required to run Smart Agent.
- Required Memory: 10 MB - 15 MB Idle and 500 MB during install, upgrade, or rollback
- Required Disk: 500 MB

Supported Agents

Currently, Smart Agent manages the following agents:

- Apache Web Server
- Java
- Machine Agent
- Node.js
- PHP
- Python

 You cannot monitor the Machine Agent Extension through the UI. During an upgrade, existing extensions will get carried forward to the higher version.

You cannot configure the Machine Agent Remediation script through the UI.

Permissions

You require the following permissions to use Smart Agent:

- [Install Permission](#)
- [Smart Agent Service Permission](#)

Installation Permissions

Installation Type	Details
Linux Package Manager	<ul style="list-style-type: none"> By default most linux package managers require the <code>sudo</code> access for installation of any RPM, DEB, or APK artifacts. Therefore, it is required for Smart Agent binary installation. If you have access to install rpms and debs on machine without <code>sudo</code> you can install it without the <code>sudo</code> access. However, you should have following permissions: <ul style="list-style-type: none"> install (to modify yum, deb, and apk databases) write to <code>/etc/environment</code> file
Zip	If you install agent manually using the zip file, you do not require any <code>sudo</code> access.

Smart Agent Service Permissions

The Smart Agent service can be configured to run with a given user and group during installation by setting `APPD_USER` and `APPD_GROUP` environment variables during installation. The values of user and group you want to use depends on the agents you want to manage. The following table lists the required user and group values for each agent:

Agent Type	APPD_USER	APPD_GROUP
PHP	root	root
Apache	root	root
Java	anyUser	anyUser
Python	root	root
Nodejs	anyUser	anyUser
Machine	root	root

Next Step

- For basic Smart Agent installation with minimal required settings, see [Quick Start with Smart Agent](#).
- For end-to-end process of installing and configuring Smart Agent, see [Get Started with Smart Agent](#).

Quick Start

You can get started with managing the supported agents on any host from the Controller UI.

- Unzip the the `appdsmartagent_<version>.tar.gz` file.
- Run the following command to install the Smart Agent:

Debian

```
sudo apt install appdsmartagent_<version>_amd64.deb
```

Centos/RHEL

```
sudo yum install appdsmartagent_<version>_amd64.rpm
```

3. Configure Smart Agent.
Edit `/opt/appdynamics/appdsmartagent/config.ini` and add `ControllerURL` , `AccountName` , `AccountAccessKey` , `ControllerPort` information.
4. Start the Smart Agent.

```
systemctl restart smartagent
```

5. From Controller UI, navigate to **Home > Agent Management > Manage Agents** to start managing your agents

For more information about Smart Agent see, [Smart Agent](#).

Get Started

For the list of supported platforms, see [Supported Platforms](#) and for other Smart Agent requirements, see [Smart Agent](#).

This document contains references to the Ansible® documentation. AppDynamics does not own any rights and assumes no responsibility for the accuracy or completeness of such third-party documentation.

This table outlines the steps to get started with Smart Agent:

1	Install Smart Agent
2	Configure Smart Agent
3	Start Smart Agent Process
4	Validate Smart Agent Installation

Install Smart Agent

You can install Smart Agent by using one of the following ways:

Install Smart Agent on the Host Machine by Logging in to Each Machine

For Debian:

```
sudo env APPD_USER=<root-user> APPD_GROUP=root APPD_SMARTAGENT_PYTHON3=<path to python> apt
install ~/appdsmartagent_<version>_amd64.deb
```

For Centos/RHEL:

```
sudo env APPD_USER=<root-user> APPD_GROUP=root APPD_SMARTAGENT_PYTHON3=<path to python> apt
install ~/appdsmartagent_<version>_amd64.rpm
```

The following table provides the variable details:

Variable Name	Description	Required	Default Value
APPD_USER	User with which Smart Agent Process should run	No	root
APPD_GROUP	Group with which Smart Agent Process should run	No	root
APPD_SMARTAGENT_PYTHON3	Python3 interpreter to be used by Smart Agent	No	/opt/appdynamics/appdsmartagent/plugins/appenv

Install Smart Agent on Multiple Nodes from a Host Machine

```
./appd install smartagent --install-agent-from {artifact_path} --inventory {hosts} --connection
ssh --auto-start
```

 To know more about managed nodes, see [How to build your inventory](#).

Important

By default, the lightweight Python3 (PyPy) is bundled with AppDynamics Smart Agent CLI to run a few components. This lightweight Python is sufficient to carry tasks on the local host. However, the remote installations at a larger scale require a full-featured Python.

Install CLI using the following commands if you are performing remote installations at scale:

```
[sudo] APPD_SMARTAGENT_PYTHON3=<path to python3 installed on the machine> apt
install ./appdsmartagent-cli_<version>_amd64.deb
[sudo] APPD_SMARTAGENT_PYTHON3=/usr/local/bin/python3.11 apt install ./appdsmartagent-
cli_<version>_amd64.deb
```

Python3 versions 3.9 to 3.11 are supported.

For information about Smart Agent CLI, See [Smart Agent Command Line Utility](#).

Configure Smart Agent

You require to configure Smart Agents to register with Controller. Edit the `/opt/appdynamics/appdsmartagent/config.ini` file for the required Smart Agent configuration. Ensure that you update the following parameters:

- **ControllerURL** : The URL of the Controller on which you want to establish the connection with the Smart Agent.
- **ControllerPort** : The port to which the Smart Agent connects to the Controller. It is `8090` for an on-premises Controller and `443` for a SaaS Controller.
- **AccountAccessKey** : The account access key on the Controller.
- **AccountName** : The account name on the Controller to which the Smart Agent will report.

config.ini

```
ControllerURL    = http://localhost
ControllerPort  = 8090
AgentType       =
AccountAccessKey =
AccountName     =

[CommonConfig]
ServiceName     =
ServiceNamespace =
RequestTimeoutSeconds = 0
AgentName       =
PollingIntervalInSec =

[Identity]
InstanceUID    =
InstalledTime  =

[OAuth]
OAuthID       =
OAuthSecret   =
AuthEndpoint  =
TenantID      =
Scopes        =

[HTTPClientSettings]
Timeout = 0

[TLSClientSetting]
Insecure = false
```

```
[TLSSetting]
CAFile =
CertFile =
KeyFile =
```

Start Smart Agent Process

Smart Agent is managed as Linux system service. Use the following command to start the Smart Agent service:

Restart Smart Agent

```
$ [sudo]systemctl service start smartagent.service
```

Validate Smart Agent Installation

Ensure that Smart Agent installation is successful by validating the following steps:

1. Validate the [status of Smart Agent service on the host machine](#).
2. Validate the [status of Smart Agent registration on the Controller UI](#).

Status of Smart Agent Service on the Host

Run the following command from the host machine to check the status of Smart Agent service:

Validate

```
$ [sudo] systemctl status appdsmartagent.service
```

Validate Status of the Smart Agent Registration on the UI

1. Navigate to **Home > Agent Management > Manage Agents > Smart Agents**
2. The smart agent entry for the host on which it is installed gets displayed in the table.

Auto-attach Java and NodeJS Agents

Smart Agent provides the auto-attach feature to auto instrument a Java application with AppDynamics Java Agent or a NodeJS application with AppDynamics NodeJS Agent. You can use Smart Agent Command Line Interface for additional configuration.

Supported Runtimes and Frameworks:

- **Java:** Tomcat, Weblogic, Springboot, JBoss, Glassfish and plain Java applications
- NodeJS

Advanced Auto-Attach Configuration

To use advanced configuration to auto-attach the agent to the applications, You must have AppDynamics command line utility installed. See [Smart Agent Command Line Utility](#).

Configure Smart Agent ld_preload.json

You can overwrite the default `ld_preload.json` (which will attach the agent to all supported Java frameworks and NodeJS applications) and add your own with your updated rules. The default location for `ld_preload.json` is `/etc/opt/appdynamics/ld_preload.json`.

Use the configure command on Smart Agent CLI (appd CLI) to overwrite the configuration.

Example Configure Command

```
appd configure smartagent --attach-configure-file { path_to_ld_preload_json }
```

This copies the `ld_preload.json` from control node to managed node.

Filters

The JSON configuration is broken into sections per supported runtime. For example, Java, NodeJS. For each section, you can provide a set of filters using regular expressions and also define a filter to auto attach or ignore the discovered application(s). The filters are applied in an order. The regular expressions are applied to the entire command line.

Example regex:

```
{
  "name": "instrument node applications",
  "regex": "node .*\\.js.*$",
  "instrument": true
},
{
  "name": "ignore npm commands",
  "regex": "npm",
  "instrument": false
}
```

Startup scripts such as, `/opt/tomcat/bin/startup.sh` launch the Java applications internally with certain parameters. Auto-attach monitors the launch of the Java application and not of the shell script(s).

Manage the Agents

You can perform the following tasks from the [Agent Management UI](#) to manage the App Server Agents and Machine Agents:

- [Install Agents](#)
- [Upgrade Agents](#)
- [Rollback Agents](#)

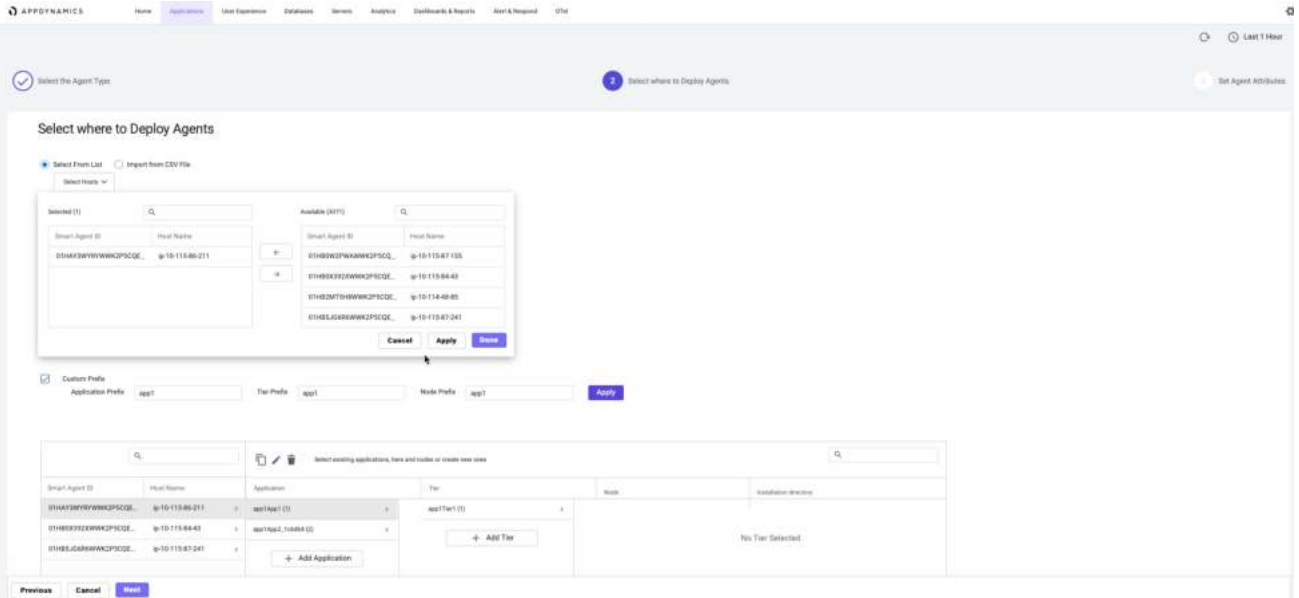

If you do not have [Smart Agent](#) installed, these tasks cannot be performed through the Controller UI. To install Smart Agent, see [Get Started](#).

Install Agents

You can install agents on a machine by using the UI only if Smart Agent is installed on the same machine.

Perform the following to install the supported agents:

1. Click **Home > Agent Management > Manage Agents**
2. Click **Install Agent** in the right pane
3. Select the type of agent and then click **Next**
4. Select one of the following to specify the location for deploying the Agent, then click **Next**.
 - **Select from List:** You can select the host on which Smart Agent is installed from the list, then click the left arrow to list it under selected table. You can select multiple hosts. You can add multiple agents for a single host and multiple hosts can be selected by repeating this step.

- **Import from CSV file:** You can upload a CSV file with required columns such as HostName, SmartAgentID, Application, Tier, Node, and Installation Directory.
5. Select **Custom Prefix** if you want a prefix to be added to the application, node and tier names, else proceed with specifying the application details.
 6. Configure the agent attributes on the **Set Agent Attributes** page, then click **Install**. You can select **Additional Configuration** to add more configuration details. Use the agent specific custom configurations to specify in **Custom Configuration**. For the list of keys that you can use see the agent variables in the specific agent page under [Ansible](#).
 7. Check the install status in **Tasks in Progress**. You can search for the specific host and check the log file. After the task is completed the task is added to the **History** tab.

 The log file is generated after the task is complete.

Rollback Agents

Rollback is available only if you have upgraded the agent by using the UI at least once. You can rollback only to the last version that was used.

If you require to rollback to the previously installed agent version, perform the following on the **Agent Management** page:

1. Select **Agents > App Server Agents** or **Agents > Machine Agent**.
2. Select the required agents that you require to rollback to the previous version.
3. Click **Actions>Rollback to previous version**.
4. On the confirmation dialog box, click **OK** if you are sure that you want to rollback to the previous version.

Upgrade Agents

You can upgrade multiple agents of the same type. Under **App Agents** or **Machine Agents**, select the required agent type that you want to upgrade.

i It is recommended to upgrade to the latest version. Also, refer to the agent specific documentation to meet all the prerequisites before performing an upgrade.

1. Select the agent(s) that you want to upgrade, then click **Upgrade**.
2. Select one of the following options:
 - **Default Upgrade:** to use the latest version with the default configuration.
 - **Custom Upgrade:** to specify the version and change other settings.
3. For Custom Upgrade:
 - a. Select the version that you want to upgrade in **Available Versions**.
 - b. Select the source from where you are downloading the agent.
 - c. Retain the same configuration or edit it as required.
The attributes are displayed based on the selected agent.
4. (Optional) You can use the agent specific custom configurations to specify in **Custom Configuration**. For the list of keys that you can use, see the agent variables table in the agent specific pages under [Ansible](#).
5. Check the upgrade status in **Tasks in Progress**.
You can search for the specific host and check the log file. After the task is completed it is added to the **History** tab.

Smart Agent Command Line Utility

The AppDynamics Smart Agent command line utility (CLI) is a standalone service that is capable of managing nodes on remote or local hosts. You can install the Smart Agent CLI independently to manage any supported agents. This utility is helpful during the [buildtime workflow](#).

Supported platforms

You can use the Smart Agent command line utility on any of the following platforms:

- RedHat
- Debian

Use Command Line Utility

This is syntax of the command that you can use to perform agent operations by using the Smart Agent CLI:

```
appd { operation } { agent } --{ options }
```

You can use this syntax for [APM agents](#) and [Smart Agents](#).

APM Agents

To manage the app server agents and Machine Agents, the following are the supported values that you can use in the CLI command from the Smart Agent CLI utility:

Parameters	Values	Details
operation	<ul style="list-style-type: none"> install upgrade rollback uninstall 	You can perform install, upgrade, rollback, and uninstall operations using the CLI command.
agent	<ul style="list-style-type: none"> java machine node python php db apache iib 	These are the supported agents on which you can perform the operations using the CLI command.
options	<p>Agent options</p> <ul style="list-style-type: none"> --version --app-name --node-name --tier-name --backup <p>Connection options</p> <ul style="list-style-type: none"> --inventory --connection <p>Install options</p> <ul style="list-style-type: none"> --install-dir --install-agent-from <p>Config options</p> <ul style="list-style-type: none"> --config --profile 	<p>These are the available flag options for the operation on APM agents. The flag options are categorized into the following:</p> <ul style="list-style-type: none"> Agent options Connection options Install options Configuration options

For example: To install Java Agent 23.9.0, run the following command on the Smart Agent CLI:

```
appd install java --version 23.9.0
```

Smart Agent CLI Option-Operation Grid

Operation	Install	Upgrade	Uninstall	Rollback
Flags options	version string (latest) (-v) profile string (default) (-p) config string (-c) install-dir string (-d) app-name string (-a) node-name string (-n) tier-name string (-t) inventory string (-i) connection string (-q) hosts string (-m) instal-agent-from string (-l)	version string (latest) (-v) profile string (default) (-p) config string (-c) install-dir string (-d) app-name string (-a) node-name string (-n) tier-name string (-t) inventory string (-i) connection string (-q) hosts string (-m) instal-agent-from string (-l)	backup bool (-b) inventory string (-i) connection string (-q) hosts string (-m)	inventory string (-i) connection string (-q) hosts string (-m)

Smart Agents

To manage the Smart Agents, the following are the supported values that you can use in the CLI command from the Smart Agent CLI utility:

Arguments	Values	Details
operation	<ul style="list-style-type: none"> install upgrade configure uninstall 	You can perform install, upgrade, rollback, and uninstall operations using the CLI command.
agent	<ul style="list-style-type: none"> smartagent 	The Smart Agent on which you can perform the operations using the CLI command.

Arguments	Values	Details
options	<p>Agent options</p> <ul style="list-style-type: none"> <code>--version</code> <p>Download options</p> <ul style="list-style-type: none"> <code>--smartagent-download-url</code> <code>--install-agent-from</code> <p>Connection options</p> <ul style="list-style-type: none"> <code>--inventory</code> <code>--connection</code> <p>Install options</p> <ul style="list-style-type: none"> <code>--install-dir</code> <p>Config options</p> <ul style="list-style-type: none"> <code>--config</code> <code>--profile</code> <p>Smartagent options</p> <ul style="list-style-type: none"> <code>smartagent-download-url</code> <code>--auto-start</code> <code>--attach-configure-file</code> 	<p>These are the available flag options for the operation on APM agents. The flag options are categorized into the following:</p> <ul style="list-style-type: none"> Agent options Download options Connection options Install options Configuration options Smart Agent options

For example:

```
appd install smartagent --install-agent-from {path_to_local_artifact} --auto-start
```

Smart Agent CLI Option-Operation Grid

Operation	Install	Upgrade	Uninstall	Configure
Flags options	version string (latest) (-v) profile string (default) (-p) config string (-c) inventory string (-i) connection string (-q) hosts string (-m) instal-agent-from string (-l)	version string (latest) (-v) profile string (default) (-p) config string (-c) inventory string (-i) connection string (-q) hosts string (-m) instal-agent-from string (-l)	inventory string (-i) connection string (-q) hosts string (-m)	inventory string (-i) connection string (-q) hosts string (-m) attach-configure-file string (-f)

Default Values for Smart Agent CLI Utility Flag Options

Option	Default Value
version string (latest) (-v)	latest
profile string (default) (-p)	default
config string (-c)	/opt/appdynamics/appdcli/config.ini
install-dir string (-d)	""
app-name string (-a)	""
node-name string (-n)	""
tier-name string (-t)	""
inventory string (-i)	""
connection string (-q)	local
hosts string (-m)	all
install-agent-from string (-l)	""
backup string (-l)	false
attach-configure-file string (-f)	""

Examples Scenarios

Install Java on Local Machine with Default Values

```
appd install java
```

Install Java, Node and Machine Agents into the Local Machine or Container with Custom Configuration

You can add these commands in your Dockerfile, Terraform scripts or any CI/CD scripts (local artifact for machine):

```
appd install java --config /tmp/config.ini --app-name demo-java-app --tier-name demo-java-tier
appd install node -c /tmp/config.ini --app-name demo-node-app --node-name demo-node-name
appd install machine -c /tmp/config.ini --app-name demo-machine-app --install-agent-from /vagrant/appdynamics-machine-agent-23.9.10.zip
```

Install Machine Agent to Multiple Hosts in the hosts File

You can run the following command for the mass install of agents on any number of hosts with a single command:

```
appd install machine -c /tmp/config.ini --inventory ./hosts --connection ssh --app-name demo-machine-app
```

Install Smart Agent on Host Machines

When Smart Agent is installed on the host machine, the `smartagent` service autostarts and is controlled by a flag. You can onboard smart agent to multiple hosts:

```
appd install smartagent --install-agent-from /vagrant/appdsmartagent_23.10.0-964_amd64.deb -c ./config.ini -i ./hosts -q ssh --auto-start
```

Agent-to-Controller Connections

AppDynamics app agents need to connect to an AppDynamics Controller to retrieve configuration data and send back information about the monitored environment. This page provides information about the connections between the agents and Controller.

Connection Settings

The connection between the agent and Controller is a one-way connection initiated by the agent. Therefore, you only need to configure connection settings in the agent.

To connect an agent to the Controller, you must provide this information:

- **Controller host:** The hostname of the Controller to connect to. Agents may connect directly to the Controller or through a proxy.
- **Controller port:** The port on which the Controller listens for agent traffic. Agents use port 443, which is the same port as the browser connection to the Controller UI.
- **Account name:** The name of the account listed in the Controller. A single tenant Controller has two accounts, a default account name, customer1, and an internal system account. For most connections, use the default account name.
- **Global Account name:** The Global Account name is used for certain connections, such as to the Events Service or from the Analytics Agent.
- **Account access key:** A unique key associated with the Controller account. See [Find Your Account and Access Key](#).
- **SSL enabled:** If the agent should connect using SSL.

If you downloaded the agent through the Getting Started Wizard in the Controller, the Controller host, port, and account settings are already configured.

To connect the agents in your environment to a SaaS Controller or an on-premises Controller through a proxy, configure the agent properties to use the host and port settings of the Controller. For an example, see [Java Agent Configuration Properties](#) for proxy settings descriptions.

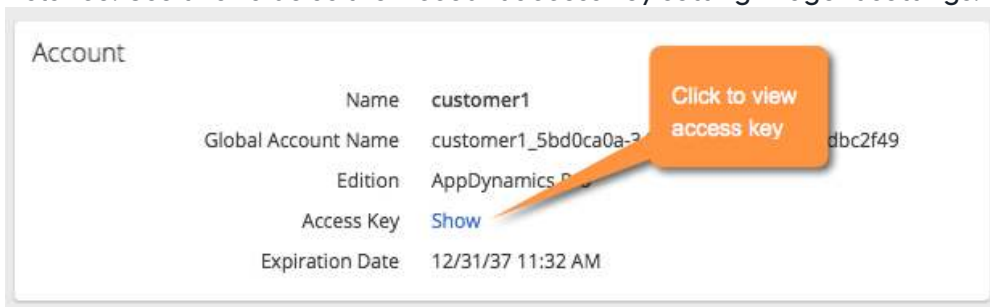

To connect to SaaS Controllers from agents in environments that limit outbound connections, set firewall rules that permit access to AppDynamics SaaS components. For a list of SaaS IP addresses, see [SaaS Domains and IP Ranges](#).

Find Your Account Name and Access Key

To configure the agent manually rather than through the Agent Download Wizard, set the Controller host and port, account name, and account access key settings manually. If you have an Admin account, you can find your account name and access key in the AppDynamics Controller UI. If you are not an admin, ask your administrator for your access key.

To view your account name and default access key:

1. Log in to the Controller UI as a user with view license permissions.
2. Click the gear icon  and select **License**.
3. Click on the Account tab. The account name appears next to the **Name** label. The account name is customer1 in a single tenant, on-premises Controller; the account name varies on SaaS Controllers.
4. Click **Show** next to the **Access Key** label to reveal the account default access key setting for this instance. Use this value as the Account access key setting in agent settings.

If you create license rules in addition to the default rule, the access key for each rule appears in the Rules tab.

Secure the Connection

The .NET Agent uses the settings in the container to negotiate the SSL protocol with the Controller. Normally you do not need to configure the security protocol for the .NET Agent.

For the Java Agent, see the [Agent and Controller Tenant Compatibility](#) for a list of the default security protocols for different versions of the Java Agent.

If the default security protocol for your version of the Java Agent is incompatible with the Controller or an intervening proxy, pass the `-Dappdynamics.agent.ssl.protocol` system property to set the protocol to one of these security protocols:

- SSL
- TLS
- TLSv1.2
- TLSv1.1

Important

Effective December 31, 2023, AppDynamics will no longer accept network connections utilizing TLS 1.0 and 1.1 protocols. See [End of Support Notice: Disabling TLS 1.0 and 1.1](#).

Use the following format:

```
java -javaagent:<agent_home>/javaagent.jar ...
-Dappdynamics.agent.ssl.protocol <protocol> ...
```

Controller-specific security considerations vary between SaaS and on-premises Controllers, as described below.

On-premises Controller Secure Connections

An on-premises Controller has both an active secure (HTTPS) port and an HTTP port. Agents can use either port to connect to the Controller. By default, the certificate used for the secure connection is a self-signed certificate. The .NET Agents cannot connect on a secure port that uses a self-signed certificate, so you must apply your own certificate to the secure port. App Agents connecting to an AppDynamics SaaS Controller must use an HTTPS connection.

To implement SSL for the Controller-agent connection:

- Set the application server primary port to the SSL port, 8181 by default. See [Port Settings](#).
- Install a trusted certificate. See [Controller SSL and Certificates](#).
- Configure your agents for SSL. See [App Agent Security](#) and [Machine Agent Security](#).

SaaS Controller Secure Connections

SaaS Controllers require the use of SSL. Therefore, you only need to enable SSL in the configuration settings for your agents and connect them to the secure Controller port, 443. See [App Agent Security](#) and [Machine Agent Security](#).

App Agent Security

To configure your agents for SSL, set these SSL-related properties:

- Set `controller-ssl-enabled` to `true`.

- Set the `controller-port` to the correct value for either on-premises or SaaS Controller.

In multi-tenant and SaaS environments, App Agents authenticate themselves to the Controller using the required account name and account access key values set in the connection properties configuration file.

Machine Agent Security

For information on the security settings related to the Machine Agent connection to the Controller, see [Machine Agent Configuration Properties](#).

Verify the Connection

You can verify that an app agent is reporting to the Controller from the **Tiers & Nodes** list in the Controller UI. See [Tiers and Nodes](#). You can also verify the connection from the AppDynamics Agents page, under the gear icon, see [Manage App Agents](#).

In the **Tiers & Nodes** pages, the **App Agent Status** column indicates the status of the agent connection to the Controller. A green arrow icon indicates active connected agents, a red down arrow indicates an agent that has been previously recognized but is not currently connected.

If the agent is not reporting to the Controller, see troubleshooting information:

- [Troubleshooting Java Agent Issues](#)
- [Troubleshoot .NET Agent Issues](#)
- [Dynamic Language Agent Proxy](#)
- [Resolve PHP Agent Installation Issues](#)

If traffic is not being properly correlated between tiers, make sure that any network components, such as load balancers or routers that sit between monitored nodes, are preserving the AppDynamics correlation header from HTTP traffic.

Agent-Controller Communication Intervals

Each AppDynamics agent has multiple communication channels for different purposes that initiate connections to the Controller independently, and at different time intervals.

- The agent configuration channel queries the Controller for any new configuration changes, and downloads these changes when available, every 60 seconds.
- The agent metric channel posts all new periodic metrics, including JMX, Windows performance counters, and business transaction metrics to the Controller every 60 seconds.
- If there are new business transactions that have not been seen before by the agent, they are posted to the Controller for registration every 10 seconds.
- If the agent has collected any new snapshots or events, they are posted to the Controller every 20 seconds.

Information Sent to the Controller

This table shows the types of information that is collected by an application agent and sent to the Controller.

Metric	Description
Server Request GUID	A unique GUID identifying a request, known as a Business Transaction, in the form of <code>xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx</code> where <code>x</code> is a lower-case hexadecimal digit.

Metric	Description
Application Entry Points	Transaction entry points are identified among various frameworks and technologies. This includes Servlet URIs, Struts Action and Method name, Spring Bean Name and Method Name, JMS queue destination or listener name, Web Service/WCF action/operation name, PHP Virtual Name, and more.
Application Exit Points	Transaction exit points are identified among various frameworks and technologies. This includes: HTTP URL end points, JMS queue/destination, type, and vendor; database URL endpoint and vendor/version, web service Service Name, cache name and URL endpoint.
Performance Metrics	In general, for each monitored metric in AppDynamics, a response time, call rate, and error rate are collected. Each of these metrics also have an automatic baseline derived for each respective metric value.
Thread Stack Traces	Code level method execution metrics that comprise the application request are collected. This data includes the class and method that executed and the line number within the source code. Note that less than 5% of transactions will have stack traces collected. Errors/Exceptions and stack trace of error data will be collected.
SQL Query Values	If assigned with administrative permissions, SQL query variables within a query can be enabled, collected, and viewed. Note that the parameter data is collected for less than 5% of transactions. Configuration changes are logged in an audit log that is available for security review.
Data Collectors	If assigned with administrative permissions, data in the form of HTTP values or method payload can be collected and viewed. Note that a specific data collectors and code payload accessors require explicit configuration to be collected. Note, data is collected for less than 5% of transactions. Configuration changes are logged in an audit log that is available for security review.
Hostname	The DNS hostname of the machine (virtual/physical) from where the agent is installed and reporting monitoring data.
IP Address Internet Protocol (IP)	IP Address Internet Protocol (IP) address of the machine (virtual/physical) where the agent is sending monitoring data from.

Metric	Description
CPU Usage	The value of CPU that is consumed on the monitored machine/virtual machine.
Memory Usage	The value of physical memory that is consumed on the monitored/virtual machine.
Network I/O Usage	The value of network I/O that is consumed on the monitored machine/virtual machine.
Disk I/O Usage	The value of disk I/O that is consumed on the monitored machine/virtual machine.
JVM Performance	JVM Heap Usage, JVM Memory Pools Settings, Garbage Collection performance, JVM System/Start-up Options, MBean metric values (for example, connection pool names and metric values, such as active connections, maximum connections, and so on)

Blitz Load Profile

Blitz is a horizontally scalable data processing platform for SaaS deployments. It collects metric data from agents, which it then aggregates and stores.

The 10M metrics/min Blitz load profile includes the following agents and churn information:

- Active load 10MM with 24K nodes. Total registered metrics is 40M.
- Node distribution:
 - DotNet = 3K
 - SIM Machine Agents OR Docker Containers = 30K
 - DBMon Data Collectors = 1K
 - Java Nodes = 16K
 - EUM Browser Apps = 60
- Java Node Churn: 1K/hr
- Either SIM or Docker Churn
 - Sim Node Churn = 40/hr (1% of 4K SIM nodes)
 - Docker Churn = 200 containers/hr
- Node purger enabled with hard-limit of 4K and soft-limit of 10K
- SIM node purger enabled with a deletion max limit of 300/hr

Agent Installer

Agent Installer is in maintenance mode. Use [Agent Management](#).

Deployment Support

i The Agent Installer requires microservices configuration performed by AppDynamics.

The AppDynamics Agent Installer simplifies deployment to instrument your applications faster. You can manage applications instrumented by the Agent Installer with minimal code changes in [Monitoring Settings](#).

Agent Installer Linux and Windows Operating Systems

[On Linux:](#) [On Windows:](#)

- Deploys Java and Machine Agents.
- Automatically instruments applications.
- Assigns unique names to tiers and nodes.
- Upgrades and rollbacks the agents.

[On Linux:](#) [On Windows:](#)

Deploys Machine Agents.

You can deploy other agents using the Getting Started Wizard.

Agent Installer Overview

The Agent Installer works with these items:

[On Linux:](#) [On Windows:](#)

- *Agent Installer* - Executable installer inside the `appdynamics-zero-agent-<version>.zip` file (representing the Agent Installer Platform). The Agent Installer installs the Agent Installer Platform with Java, and Machine Agents on a system. You access the installer from the Controller UI.
- *Decorator* - Library responsible for automatically instrumenting new processes with AppDynamics APM agents. The library auto-instruments the application and auto-names tiers and nodes for the Controller.
- *Agent Installer Platform* - Software bundle that manages the Decorator, Java Agent, and Machine Agent. Enables automatic instrumentation and reports the status of various processes to the Controller UI. Collective term for the decorator, agent `daemon`, agent binaries.
- *Downloader* - Script (`zero-agent.sh`) that downloads individual zip files containing the Java and Machine (if applicable) Agents, and Agent Installer Platform.
- *Watchdog* - Agents installed with the Agent Installer can be managed with the `Watchdog` process.
- *Updater* - Responsible for the rollback and upgrade of the monitoring agents.

[On Linux:](#) [On Windows:](#)

- *Agent Installer* - Executable installer inside the `appdynamics-zero-agent-windows-64-<version>.zip` file (representing the Agent Installer Platform). The Agent Installer installs the Agent Installer Platform with Machine Agent on a system. You access the installer from the Controller UI.
- *Agent Installer Platform* - Software bundle that manages the Machine Agent. Send metrics to the Controller UI. Collective term for the agent `daemon`, agent binaries.
- *Downloader* - Script (`zero-agent.ps1`) that downloads individual zip files containing the Machine Agent, and the Agent Installer Platform.
- *Watchdog* - Agents installed with the Agent Installer can be managed with the `Watchdog` process.
- *Updater* - Responsible for the rollback and upgrade of the monitoring agents.

Agent Installer Requirements

The Agent Installer requires the following components, permissions, and supported environments.

- Applications will not instrument properly if file directories have their permissions changed by other processes, such as configuration management tools like Ansible.

AppDynamics Components

- The Agent Installer requires SaaS Controller => 20.6.0.
- You also need sufficient APM licenses to use the Java and Machine Agents. No additional license is required for the Agent Installer Platform.

Configure and Unblock Your Firewall

You may need to configure your firewall rules to allow outgoing traffic to certain URLs including:

- Access to your AppDynamics Controller: `<customername>.saas.appdynamics.com/*` to allow APM traffic.
- Access to the AppDynamics download files site: accounts.appdynamics.com/downloads to download the agent binaries.

Agent Installer Permission

- To configure access and roles, you must either be the AppDynamics Account owner, or have Administrator permissions.

To use the Agent Installer, you need **Install Agent** account-level permission and at least one of the following:

- Any default role (except for the Analytics Administrator role)
- Any application-level permission
- **Execute Workflow** account-level permission

Install Agent permission is not added to any default role.

Supported Environments

This table lists the Agent Installer supported environments. JVM and Application Server requirements only apply if you install the Java Agent. The Agent Installer does not support Windows installations.

Agent Installer Supported Environments

Operating System	<p>Linux (64 bit). Fully tested flavors:</p> <ul style="list-style-type: none"> • CentOS 7, 8 • RHEL 7, 8 • Ubuntu 18.04 • Fedora 31 • Debian 10 <p>Other Linux operating systems and versions should work but are not certified by AppDynamics.</p> <p>Windows Server (64 bit). Fully tested flavors:</p> <ul style="list-style-type: none"> • Windows 2019 • Windows 2016
JVM (only on Linux)	<ul style="list-style-type: none"> • Open => JDK 1.6 • Oracle => JDK 1.7 • IBM JDK => 1.6
Application Server (only on Linux)	<ul style="list-style-type: none"> • Apache Tomcat • Jboss Wildfly • GlassFish • Websphere • Weblogic

See [Java Supported Environments](#) and [Machine Agent Requirements and Supported Environments](#) for version compatibility.

Agent and Process Limitations

This table lists the active agent registrations, process, and process group limitations for the Agent Installer:

Agent	Maximum Per-Account Limit
Active agent registrations	1000
Process	Maximum Per-Account Limit
Managed processes	10,000
Unmanaged processes	10,000
Managed processes in a single installation	100
Unmanaged processes in a single installation	100
Process Group	Maximum Per-Account Limit
Managed process groups	1000

Unmanaged process groups	1000
Managed process groups in a single installation	100
Unmanaged process groups in a single installation	100

Available Agents with the Agent Installer

The Agent Installer deploys the Agent Installer Platform, which downloads monitoring agents to your machine. You can install:

- Java Agent Legacy >= 4.5.19 - only on Linux
- Java Agent JDK8+ >= 22.3.0 - only on Linux
- Machine Agent >= 20.3.0

If you install Machine Agent on a host that doesn't have the AppDynamics application agent installed, then the Machine Agent works with the following: application name selected, tier name: your hostname, and node name: hostname `<zero-agent-generated-hash-string>`.

Use the Agent Installer to Deploy an Agent

i Application names cannot contain a single quotation mark ('). When you install Java JDK8+ with the Agent Installer, the OpenTelemetry resource attributes `service.namespace` and `service.name` are mapped to the AppDynamics application name and tier name.

To use the Agent Installer to deploy an agent:

1. From the Controller UI, select **Home > Agent Installer**.
2. From the **Specify Application to Deploy to** dropdown, select an existing application, or select **New application** and enter its name.
3. Download and run the Agent Installer using either an [express installation](#) or a [custom installation](#) method.

See [Deploy an Agent Using the Agent Installer API](#).

Express Installation Method

1. The **Express installation** method is selected as the default. You can download and install the latest version of all available agents.
 - a. The Java Agent type, Java JDK8+, is the default for express installation with OpenTelemetry disabled.
 - b. The Machine Agent for express installation disables Server Visibility and .NET Compatibility Mode.
2. Copy and run the first command to download the latest available agents.
3. Select  (top right corner of the second command) to copy and run the second command to install the agents. Additionally, you can select **Show command** to reveal the full command with your access key.
4. Restart the application processes you want to monitor.
5. Click **Next** to continue with the instrumentation.

After you finish installing the agents, you are redirected to the [Monitoring Settings](#) tab to view instrumented tiers and nodes.

Custom Installation Method

 Your OpenTelemetry data may transit through regions different from where your Controller is hosted, if you configure your OpenTelemetry Collector using an AppDynamics endpoint located outside of the region, where your Controller is hosted. See [Support for AppDynamics for OpenTelemetry™](#).

1. Select **Custom installation**.
2. Select the agents **Java Agent** (Legacy or JDK8+) or **Machine Agent** you want to install.
3. (Optional): Enable OpenTelemetry for Java Agent JDK8+. To do this, add traces exporter, metrics exporter, and OTLP Endpoint.
4. (Optional): Enable Server Visibility or .NET Compatibility Mode for the Machine Agent.
5. Copy and run the command into your terminal (on Linux) / PowerShell (on Windows) window or automated tools.
6. Determine how to run the Agent Installer by setting user permissions:

[On Linux:](#) [On Windows:](#)

- Select **Instrument processes for all system users** (requires `sudo` access) to run the Agent Installer with `sudo` permission and enable the Agent Installer Platform for *all* users on the host.
 - By default, the services run as root. To configure the services to run as a different user, add the parameter: `--run-as <user>`.
 - By default, the processes that run by all users will be instrumented. To instrument processes run by specific users, add the parameter: `--filter-by-users <user1>, <user2>`, or the parameter: `--filter-by-groups <group1>, <group2>`.
- Select **Instrument processes for an individual user** to run the Agent Installer without `sudo` permission and enable the Agent Installer Platform for the *current* user only. See [Sudo vs. Non-Sudo Access](#).

[On Linux:](#) [On Windows:](#)

- By default the installed services run as the `LOCAL SYSTEM`. To configure the services to run as a local service account:
 - Add the `run-as` and `password` parameters for the Windows account.
 - If a service account is used (e.g. `NT AUTHORITY\LOCAL SERVICE`) then the password parameter will not be provided. Use a password that contains a minimum of sixteen characters.

7. After confirming the user installation permissions, select  (top right corner of the command) to copy and run the command. To reveal the full command with your access key, select **Show command**.
 - a. When you run the command on a designated host, the agent files download onto that host *only*. To install agents on multiple hosts, select [Run the Agent Installer on Multiple Hosts](#).
8. Restart the application processes you want to monitor.
9. Click **Next** to continue with the instrumentation.

After you finish installing the agents, you are redirected to the [Monitoring Settings](#) tab to view instrumented tiers and nodes.

Sudo Versus Non-Sudo Access (on Linux)

You can run the Agent Installer with or without `sudo` permission.

✓ AppDynamics recommends using the `sudo` command to install the agents for all users in your system.

This table describes the differences between `sudo` and `non-sudo` installations:

	sudo Installation	Non-sudo Installation
Description	Installs the agents on all supported processes for all users in your system.	Installs the agents for the current user only.
Automatic Instrumentation Process	By default, integrates with <code>systemd</code> to ensure the agents always run. See Customize Agent Installer to override this behavior.	Auto-instruments processes that are started by the installing user, running under a Linux shell such as <code>bash</code> .

Instrument `systemd` -Managed Processes in a Non- `sudo` Environment

To enable the instrumentation of a `systemd` -managed application process in non- `sudo` Agent Installer Platform installations, the profile of the `systemd` service responsible used to load the application process must define the `LD_PRELOAD` environment variable using the path to the decorator library.

The actual path varies based on the operating system and product installation directory. This example shows an updated Apache Tomcat `systemd` service profile on CentOS 7:

```
$ grep LD_PRELOAD /etc/systemd/system/apache-tomcat-7.service Environment=LD_PRELOAD=/home/centos/appdynamics/zeroagent/lib64/libpreload.so
```

After the profile has been updated, you must reload the `systemctl` daemon and restart the application for the changes to take effect:

```
$ sudo systemctl daemon-reload
$ sudo systemctl restart apache-tomcat-7.service
```

Run the Agent Installer on Multiple Hosts

You can download the Agent Installer once and run on multiple hosts. To install the agent bundle across multiple hosts, distribute the binaries to all applicable machines. For example, these steps show how to move files across hosts using the `tar` command.

1. Download the agent bundle. See [Use the Agent Installer to Deploy an Agent](#).
2. Distribute the Agent Installer to multiple hosts.
 - a. Make sure you are in the same directory in which you downloaded the agent bundle.
 - b. Use the `tar` command to place the script in a single file:

```
tar cvf zero-agent.tar *
```

c. Copy the file to multiple hosts:

```
scp zero-agent.tar <target host>:<directory>
```

d. Extract the archived script in the same directory:

```
tar xvf zero-agent.tar
```

3. Complete the Agent Installer deployment using the [custom installation method](#).

Customize the Agent Installer

See [Customize Agent Installer](#).

Upgrade and Rollback the Agent Installer

See [Upgrade and Rollback the Agents](#).

Enable Server Visibility and .NET Compatibility Mode

See [Enable Server Visibility and .NET Compatibility Mode with Agent Installer](#) to enable Server Visibility and .NET Compatibility Mode for Machine Agent, using the configure command.

Node Name Format

The Node name format changes starting with versions ≥ 22.4 . Upgrading to version 22.4 automatically changes the Node name for the existing environment after restart.

 The `<serverName>` is applicable for the `jboss` appserver type.

Agent Installer Version	Node Name Format	Node Name Example
<22.4	<code><hostName>-<First 4 systemId><Last 4 systemId>-[hash of Tiername]-<serverName></code>	ubuntu_host-sefd-er43-rextderutq
≥ 22.4	<code><hostName>-<First 4 systemId><Last 4 systemId>-[hash of JavaUniquePath]-<serverName></code>	ubuntu_host-sefd-er43-texdreodrx

For systems with the Machine Agent enabled, and not the Java Agent enabled, the Node and Tier name have the following format:

Node Name Format	Node Name Example
<hostName>-<First 4 agentId>-<Last 4 agentId>-[hash of agentId]	centos7_j7-4c97-d243-e77979f4d4911864
Tier Name Format	Tier Name Example
<hostName>	centos7_j7

Uninstall the Agent Installer

To uninstall the Agent Installer in the terminal, navigate to the directory where the Agent Installer Platform is installed, and run the command:

[On Linux:](#) [On Windows:](#)

```
languagebash<install-directory>/bin/zfictl uninstall
```

[On Linux:](#) [On Windows:](#)

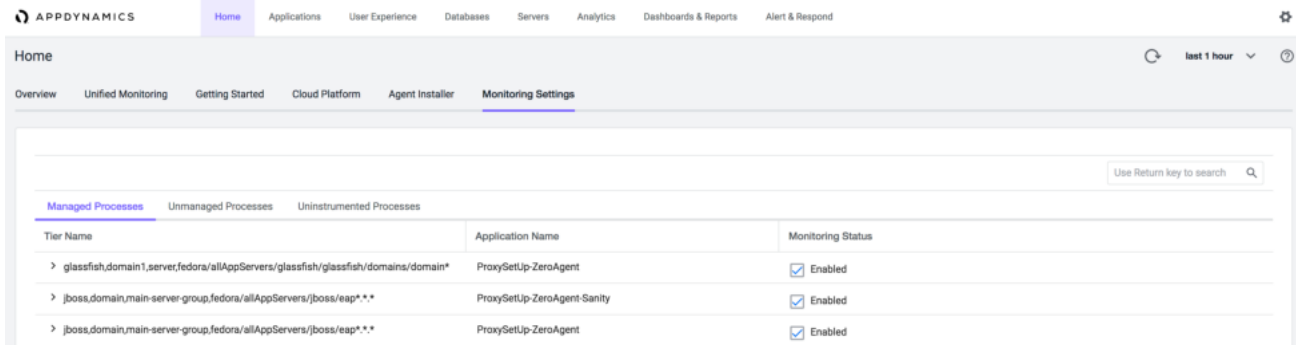

```
<install-directory>\bin\zfictl.exe uninstall
```

Monitoring Settings

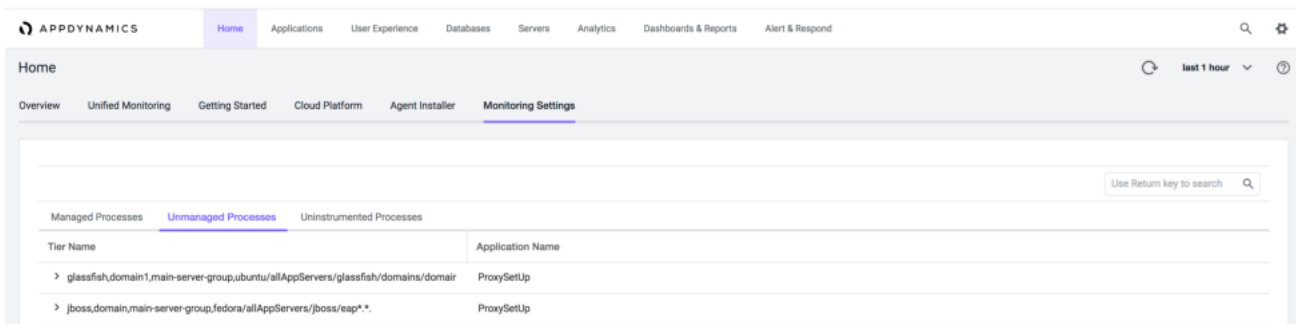

This page describes how to use Monitoring Settings to monitor and update the processes instrumented by the Agent Installer.

In the Controller UI, select **Home > Monitoring Settings**. The Monitoring Settings page is an interface that displays tiers, nodes, and applications associated with the Agent Installer. The Monitoring Settings page contains three tabs:

- Managed Processes
- Unmanaged Processes
- Uninstrumented Processes
- Tier Naming Rules

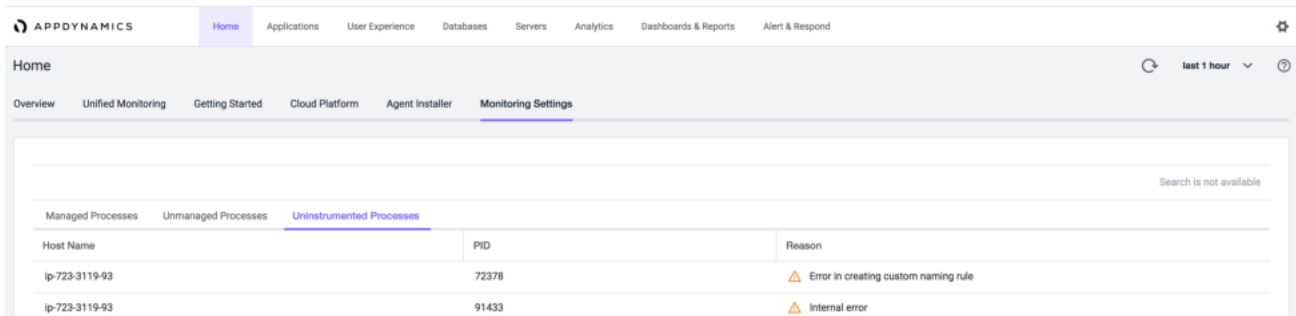

You can view and scroll through pages of processes and tiers where tiers are listed by their associated application. For example, a tier may be monitored by a Java Agent configured with Agent Installer.

From both the Managed Processes and Unmanaged Processes tabs:

- By default, all nodes under a tier are collapsed. To expand the tier and review its nodes, select the arrow next to the **Tier Name**.
- Search on a tier name, application name, or node name by entering the search string in the upper-right corner **Search** box and pressing Return.
To facilitate searching, you can right-click an application name, and then select **Copy application name** from the popup to copy that name to the clipboard and then paste into the **Search** box.

i Search is not available from the Uninstrumented Processes tab.

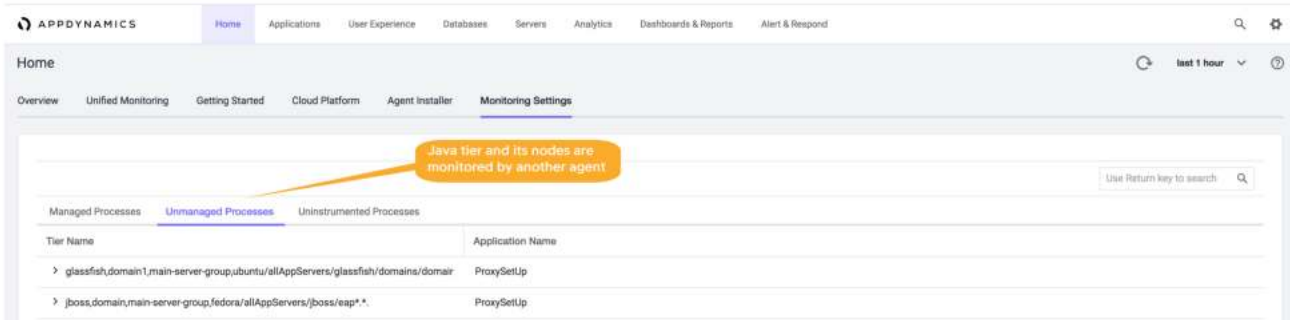

Managed and Unmanaged Tiers

A tier is considered "managed" when it has been instrumented with the Agent Installer. In the Monitoring Settings tab, managed tiers are those that you can enable or disable in the Controller UI.

You may see tiers listed on the Monitoring Settings page that you cannot change in the UI. A tier is considered "unmanaged" when it cannot be instrumented by the Agent Installer. Unmanaged tiers include

tiers that have been instrumented manually with the Java Agent or managed outside of AppDynamics. To monitor the unmanaged tiers, you must remove your previous configuration and restart the processes.

Change Managed Tiers and Nodes Status

To disable monitoring for specific tiers, uncheck one or more tiers you want to disable.

Restart all affected processes (on all affected hosts). This messages displays in the UI when the process is ready to restart:

Enabled (pending)

i Restart this process to apply changes. **i**

i When you disable monitoring, the changes are not immediately recognized by the Agent Installer Platform. Wait until you see a message to restart processes in the Monitoring Settings tab. If you restart processes before you see the message, the change does not take effect.

Disable Instrumentation of Specific Hosts

To reduce license consumption, you can disable the instrumentation of application server types that you do not want to monitor.

In the terminal, enter this command: `<install-directory>/bin/zfictl configure --disable-instrumentors=java, <app-server-type>`

The location `<install-directory>` refers to the directory in which you installed the Agent Installer.

This table lists the supported values for `<app-server-type>` :

App Server	Accepted Value
Tomcat	tomcat
JBoss	jboss
GlassFish	glassfish

App Server	Accepted Value
WebLogic	weblogic
WebSphere	websphere
Plain (non-application server) Java applications	java
All app server types	all

Tier Naming Rules

You can use the Tier Naming Rules functionality to customize the tier name of any managed Java process. To filter, add, edit, delete, disable, import and export new rules, see [Manage Tier Naming Rules](#).

Overview Unified Monitoring Getting Started Agent Installer **Monitoring Settings**

Search is not available

Managed Processes Unmanaged Processes Uninstrumented Processes **Tier Naming Rules**

Priority
 Import
 Export
 Naming Rules Preview

Priority	Rule Name	Application Scope	Application Server Type Name	Enabled
1	test_upgrade	ALL	ALL	✓
2	Demo-Rule1	ALL	TOMCAT	✓
3	Demo-Rule2	ALL	TOMCAT	✗

Customize Agent Installer

This page explains how to fine-tune the Agent Installer configuration. Changes apply to the Agent Installer Platform configuration file, `config.json`.

Customize Agent Installer Platform Configuration

The Agent Installer Platform has several commands available to customize the configuration. You can run the commands during or after installation, and issue the commands to the `zfiectl` executable, located in the Agent Installer Platform directory. The Agent Installer Platform periodically checks the configuration file and applies the changes.

i Do not modify the `zero-config.json` file directly as this may result in undefined behavior.

Command Name	Description
<code>configure</code>	Modify the Agent Installer Platform configuration file.

Command Name	Description
<code>stop</code>	Stop running the Agent Installer Platform.
<code>stop <agent></code>	Stop running an individual agent on the Agent Installer Platform.
<code>start</code>	Start or restart the Agent Installer Platform. Automatically done for <code>sudo</code> installations.
<code>start <agent></code>	Start or restart an individual agent on the Agent Installer Platform.
<code>status</code>	View or print the status of the managed agents.
<code>purge</code>	Remove the Agent Installer Platform, Java, and Machine Agents and all configuration files from your machine.
<code>uninstall</code>	Remove the Agent Installer Platform, Java, and Machine Agents from your machine, but retain the configuration files.

View Command Flags

To view the available flags for a command, enter:

```
<install-directory> bin/zfictl <command> -h
```

For example, to view the available flags for the `install` command, enter:

```
<install-directory> bin/zfictl install -h
```

The output example displays the flags with the data type for the parameters and descriptions for the `install` command:

```
<install-directory> bin/zfictl install -h
...
Install Agent Installer Platform

Usage:
  zfictl install [flags]

Flags:
  --log-level string          Logging level (choose from [panic fatal error
warning info debug trace])
  --max-log-rate int         Maximum log msg rate (default -2)
```

```

--disable-instrumentors strings Instrumentors to disable (choose from [java tomcat
jboss glassfish weblogic websphere all])
--enable-instrumentors strings Instrumentors to enable (choose from [java tomcat
jboss glassfish weblogic websphere all])
--application string Controller application name
--account string Controller account name
--access-key string Account access key
--service-url string Service URL
--javaagent string Java agent (choose from [dynamic ibm sun])
--jboss-log-manager-modify LogManager args for JBoss (choose from [true false])
--proxy-url string Proxy URL
--install-path string Agent Installer Platform installation path (default
"/opt/appdynamics/zeroagent")
--systemd Install in systemd (default true)
-h, --help help for install

```

Run Commands with Flags During and After Installation

You can run commands in the `zfictl` binary after installation. To make changes during installation, add flags to the installation script.

For example, to configure the log level to `info`:

During installation (as a flag), enter:

```

sudo ./zero-agent.sh install --application 'AgentInstallerTestApp' --account 'project-zero'
--access-key 'myaccesskey' --service-url 'https://test.saas.appd-test.com' --log-level=info

```

After installation (using the `zfictl` executable), enter:

```

<install-directory> bin/zfictl configure --log-level=info

```

Connect the Agent Installer Platform to a Proxy

The Agent Installer supports connections with unencrypted proxies only. To configure the `zfictl` executable to use a proxy connection, enter:

```

<install-directory> bin/zfictl configure --proxy-url=http://localhost:1001

```

Change Tier Names

The Agent Installer automatically creates a name for every instrumented tier. To create names, the installer extracts information from the Java process, such as the application server name.

Contact AppDynamics Support to change the name of an instrumented tier. Because an AppDynamics Support representative applies the changes, you need to create a new user named `appd_rule_user`, and then give `appd_rule_user` **Install Agent** permission only. This secures your sensitive data.

When you contact AppDynamics Support, provide the log in credentials for `appd_rule_user`.

Override `systemd` Integration

If you do not want the Agent Installer to integrate with `systemd` in a `sudo` installation, add `-systemd false` to the install command, see [Sudo Versus Non-Sudo Access](#). For example:

```
sudo ./zero-agent.sh install --application 'AgentInstallerTestApp' --account 'project-zero'
--access-key 'myaccesskey' --service-url 'https://test.saas.appd-test.com' --systemd=false
```

Maintain Continuous Operation with `watchdog`

The Agent Installer includes a `watchdog` process to ensure continued operation of these standalone agents and their related processes:

- Agent Installer Platform Daemon
- Machine Agent

If you integrate the Agent Installer with `systemd`, a profile is created for the `watchdog` process to ensure that it starts after a planned or unplanned reboot of the system. The `systemd` profile also restarts the `watchdog` process if it was terminated during regular operation.

If you do not integrate the Agent Installer with `systemd` (by setting `--systemd=false`), you can create a `systemd` profile after installation.

If you do not have a `systemd` profile, then you must start the `watchdog` process manually to ensure operation of the standalone agents and their related processes.

i If you enabled the SELinux module on your system, then you must configure it to ensure that the `watchdog` and other Agent Installer Platform processes are not blocked.

To start the `watchdog` process, enter:

```
<install-directory> bin/zfictl start
```

To stop the `watchdog` process, enter:

```
<install-directory> bin/zfictl stop
```

See [Agent Installer](#) for more information.

Start or Stop Individual Agents

You can use the `watchdog` process to start and stop individual agents (Machine or Zero) on the Agent Installer Platform. You can also view or print the status of the managed agents.

For example, to start the Machine Agent, enter:

```
<install-directory> bin/zfictl start machine
Starting Machine Agent
...
Machine Agent started successfully
```

For example, to stop the Zero Agent, enter:

```
<install-directory> bin/zfictl stop zero
Stopping Zero Agent
...
Zero Agent stopped successfully
```

To view or print the status of the managed agents, enter:

```
<install-directory> bin/zfictl status
```

Secure Agent Installer Platform

This page describes how to secure sensitive information in the Agent Installer Platform configuration file.

How to Secure the Agent Installer Platform Configuration File

The Agent Installer Platform configuration file, `config.json`, contains potentially sensitive information, such as the agent access key used by the Java and Machine Agent to connect to the Controller. By default, the Agent Installer Platform can be read by any user of the system after it is installed. The default permissions allow the Agent Installer Platform to auto-instrument new processes started on your system by any user.

Block Access to the Agent Installer Platform

You can block access to the Agent Installer Platform configuration file and still allow the agent to auto-instrument processes for authorized users or groups.

Change the default permissions:

1. Define an authorized group.

```
groupadd appdynamics-zero-agent
```

2. Add users to the authorized group. For example, the `usermod` command adds a user named `tomcat-user` to the `appdynamics-zero-agent` group. Run this command for each user that creates Java processes you want the Agent Installer Platform to auto-instrument.

```
usermod -a -G appdynamics-zero-agent tomcat-user
```

3. Navigate to the directory where the Agent Installer Platform was installed; the default directory is `/opt/appdynamics/zeroagent`.

```
cd <zero-agent-install-directory>
```

4. Change directories to the Agent Installer Platform's configuration file directory.

```
cd configs
```

5. Change the group ownership of the `config.json` file to the authorized group created in Step 1.

```
chgrp appdynamics-zero-agent config.json
```

6. Change the permissions associated with the `config.json` file.

```
chmod 640 config.json
```

Configuration File Access

The Agent Installer Platform configuration file has the following access:

- Owning user - read and write
- Authorized group - read only
- All other users - no access

Unauthorized access to the file is not permitted. If a non-authorized user starts a Java process, it is not auto-instrumented by the Agent Installer Platform. However, it does not prevent the new Java process from starting.

Upgrade and Rollback the Agents

This page describes how to upgrade and rollback the agents. To upgrade and rollback the agents, you find the `systemID`, find the type of agent you want to upgrade to, and then find the agent version you have available. A `systemID` is an ID that identifies the Agent Installer system. This functionality is only available using the API. See [Agent Installer Platform Service API](#).

i Purge is followed by the installation of the new version of the Agent Installer Platform.

Supported Versions

Versions	Description
>= 21.10.0	An upgrade and rollback is supported for Java Agent Legacy and Machine Agent (Linux).

Versions	Description
>= 22.5.0	<ul style="list-style-type: none"> • Upgrade and rollback supported for Java Agent JDK8+ (Linux), along with the OpenTelemetry configuration update. • Upgrade and rollback supported for Machine Agent (Windows). • Support for Server Visibility (Linux and Windows) and .NET Compatibility (Windows) update using the Machine Agent.

Custom Agent Configurations

The following custom configurations are kept during the upgrade and rollback process:

[Java Agent on Linux:](#) Machine Agent:

```
path: <zero agent path>/java/javaagent/ver***/conf/*.xml
```

Java Agent on Linux: [Machine Agent:](#)

```
path: <zero agent path>/zeroagent/agents/machineagent/conf/logging/log4j.xml
path: <zero agent path>/zeroagent/agents/machineagent/conf/controller-info.xml
path: <zero agent path>/zeroagent/agents/machineagent/monitors
```

For details on the Machine Agent configurations, see [Configure the Machine Agent](#).

Find the System Information

Find all of the systems that are installed with the Agent Installer. This API provides all `systemIDs` and `hostnames` that are present under one account. This API also provides the previous versions of the monitoring agents, which is used to rollback the Agent Installer.

Format:

```
GET /maintenance/systemInfos
```

Request Example:

```
curl --location --request GET 'https://demo.saas.appdynamics.com/zero/v1beta/maintenance/systemInfos' --header 'Authorization: Bearer {AuthToken}'
```

Response Example:

```
{
```

```

"total": 2,
"items": [
  {
    "systemId": "1cbcf90-95ab-4366-b614-1bfab44a9305",
    "hostname": "jboss_host",
    "applicationName": "HelloWorld",
    "rootInstall": true,
    "curVersions": [
      {
        "type": "JAVA",
        "version": "20.3.0.1183"
      }
    ],
    "prevVersions": [
      {
        "type": "JAVA",
        "version": "20.3.0.1183"
      }
    ]
  },
  {
    "systemId": "c44f978d-8db6-452f-9387-9b852d8df03a",
    "hostname": "windows_host",
    "applicationName": "HelloWorld",
    "rootInstall": true,
    "versions": [
      {
        "type": "MACHINE_WINDOWS",
        "version": "22.3.0.3296"
      }
    ],
    "prevVersions": [
      {
        "type": "MACHINE_WINDOWS",
        "version": "22.1.0.3252"
      }
    ]
  }
]
}

```

Find the Agent Versions

To find the agent versions, see [Find Agent Versions](#).

Upgrade Agent Versions

Now that you have the `systemIDs`, `hostname`, and the latest versions, trigger the upgrade using the API. Once the request is accepted, you receive a `maintenanceID`. The upgrade happens asynchronously, and you can use the `maintenanceID` to track the progress of the upgrade.

 Specifying the configurations is optional. If none are added, then configurations currently running in the Agent Installer are used. You can upgrade from Java Agent Legacy to Java Agent JKD8+, but you cannot upgrade from Java Agent JDK8+ to Java Agent Legacy.

Format:

POST /maintenance/upgrade/systems

Request Examples:

[On Linux:](#) [On Windows:](#)

```
{
  "systemDetails": [
    {
      "systemId": "28f7a681-6010-4150-8940-ebec25841215",
      "hostname": "hostname1"
    },
    {
      "systemId": "28f7a681-6010-4150-8940-ebec25841216",
      "hostname": "hostname2"
    }
  ],
  "versions": [
    {
      "type": "JDK8_PLUS",
      "version": "22.4.0.33722"
    },
    {
      "type": "MACHINE",
      "version": "22.4.0.3344"
    }
  ],
  "configurations": {
    "enableOtel": true,
    "otelProperties": {
      "tracesExporter": "otlp,logging",
      "metricsExporter": "otlp,logging",
      "otlpEndpoint": "http://localhost:4317"
    },
    "enableSim": true
  }
}
```

[On Linux:](#) [On Windows:](#)

```
{
  "systemDetails": [
    {
      "systemId": "c44f978d-8db6-452f-9387-9b852d8df03a",
      "hostname": "windows_host"
    }
  ],
  "versions": [
    {
      "type": "MACHINE_WINDOWS",
      "version": "22.4.0.3344"
    }
  ],
  "configurations": {
    "enableSim": true,
    "dotnetCompaibility": true
  }
}
```

Input Parameters:

Parameter Name	Parameter Type	Description	Mandatory
systemDetails.systemId	Body	ID of the Agent Installer system.	Yes
systemDetails.hostname		Hostname of the Agent Installer system.	
versions.type		Type of the monitoring agents.	
versions.verison		Versions of the monitoring agents to upgrade.	
configurations.enableOtel		Configuration to enable OpenTelemetry for Java Agent JDK8+.	No
configurations.otelProperties		Configurations for OpenTelemetry exporter.	Yes, only when enableOtel is true.

Parameter Name	Parameter Type	Description	Mandatory
configurations.otelProperties.tracesExporter		Configuration for OpenTelemetry traces exporter. Supported values: <code>otlp</code> , <code>logging</code> .	
configurations.otelProperties.metricsExporter		Configuration for OpenTelemetry metrics exporter. Supported values: <code>otlp</code> , <code>logging</code> .	
configurations.otelProperties.otlpEndpoint		Configuration for OpenTelemetry OTLP Collector endpoint.	
configurations.enableSim		Configuration to enable Server Visibility for the Machine Agent.	No
configurations.dotnetCompatibility		Configuration to enable .NET Compatibility Mode for the Machine Agent.	No

Response Examples:

    "dotnetCompatibility": true
  }
}

```

Rollback the Upgrade

To rollback the upgrade, trigger the below API with the `systemIDs`, `hostname`, and the previous versions. Once the request is accepted, you will receive a response with a `maintenanceID`.

The rollback happens asynchronously, and uses the `maintenanceID`. Rollback does not accept any of the configuration inputs, whichever configurations were previously running in the Agent Installer will be used.

Format:

```
POST /maintenance/rollback/systems
```

Request Examples:

[On Linux:](#) [On Windows:](#)

```
curl --location --request POST 'https://demo.saas.appdynamics.com/zero/v1beta/maintenance/rollback/systems' \
--header 'Authorization: Bearer {AuthToken}' \

  ]
}
```

Fetch All Maintenance Request History

Use this API to retrieve the entire upgrade and rollback request history. The history provides the overall `maintenance` status, and not the status of the individual systems.

Format:

```
GET /maintenance/history
```

Request Example:

```
curl --location --request GET 'https://demo.saas.appdynamics.com/zero/v1beta/maintenance/history' --header 'Authorization: Bearer {AuthToken}'
```

Response Example:

```
{
  "total": 2,
  "items": [
    {
      "maintenanceId": "d601aacc-97a4-479e-b2b3-db095fef34fc",

]
}

```

Fetch a Specific Maintenance Request Record

Use this API to retrieve a specific upgrade and rollback `maintenance` record using the `maintenanceID`. The record provides the overall maintenance status, and not the status of the individual systems.

Format:

```
GET /maintenance/history/{maintenanceId}
```

Request Example:

```
curl --location --request GET 'https://demo.saas.appdynamics.com/zero/v1beta/maintenance/history/{maintenanceId}' --header 'Authorization: Bearer {AuthToken}'
```

Input Parameters:

Parameter Name	Parameter Type	Description	Mandatory
maintenanceId	Path	ID from the rollback and upgrade request.	Yes

Response Examples:

[On Linux:](#) [On Windows:](#)

```
{
  "maintenanceId":"d601aacc-97a4-479e-b2b3-db095fef34fc",
  "operation":"UPGRADE",
  "status":"PENDING",
  "startedAt":"2021-10-25T18:20:55.196Z",
  "updatedAt":"2021-10-25T18:20:55.196Z",
  "maintAgentVersions":[
    {
      "type":"JAVA",
      "version":"20.3.0.1183"
    }
  ],
  "affectedSystemIds":[
    "d601aacc-97a4-479e-b2b3-db095fef34fc"
  ],
  "failedSystemMaintenanceIds":[
    "d601aacc-97a4-479e-b2b3-db095fef34fc"
  ],
  "configurations":{
    "enableOtel":true,
    "otelProperties":{
      "tracesExporter":"otlp,logging",
      "metricsExporter":"otlp,logging",
      "otlpEndpoint":"http://localhost:4317"
    },
    "enableSim":true,
    "dotnetCompatibility":null
  }
}
```

[On Linux:](#) [On Windows:](#)

```
{
  "maintenanceId":"d601aacc-97a4-479e-b2b3-db095fef34fd",
  "operation":"UPGRADE",
```

```

"status": "SUCCEEDED",
"startedAt": "2022-05-11T18:20:55.196Z",

],
"failedSystemMaintenanceIds": null,
"configurations": {
  "enableSim": true,
  "dotnetCompatibility": true
}
}

```

Fetch All System Maintenance Records

Use this API to retrieve all of the system maintenance statuses of a particular maintenance request using the `maintenanceId`.

When an upgrade for an agent is requested, the Agent Installer automatically upgrades to the latest version. Then, it is represented by the `implicitMaintenance` field in the response. The configuration maintenance occurs after the version maintenance. Then, it is represented by the `"operation": "CONFIGURATIONS"` field in the response.

Format:

```
GET /maintenance/history/{maintenanceId}/systemMaintenances
```

Request Example:

```
curl --location --request GET 'https://demo.saas.appdynamics.com/zero/v1beta/maintenance/history/{maintenanceId}/systemMaintenances' --header 'Authorization: Bearer {AuthToken}'
```

Input Parameters:

Parameter Name	Parameter Type	Description	Mandatory
<code>maintenanceId</code>	Path	ID from the rollback and upgrade request.	Yes

Response Examples:

[On Linux:](#) [On Windows:](#)

```
{
  "total": 3,

Fetch a Specific System Maintenance Record

Use this API to retrieve a specific system maintenance record using the `systemMaintenanceId`.

Format:

```
GET /maintenance/systemMaintenances/{systemMaintenanceId}
```

Request Example:

```
curl --location --request GET 'https://demo.saas.appdynamics.com/zero/v1beta/maintenance/systemMaintenances/{systemMaintenanceId}' --header 'Authorization: Bearer {AuthToken}'
```

Input Parameters:

Parameter Name	Parameter Type	Description	Mandatory
<code>systemMaintenanceId</code>	Path	ID of the system maintenance activity.	Yes

Response Example:

```

{
  "systemMaintenanceId": "d601aacc-97a4-479e-b2b3-db095fef34fc",
  "systemId": "d601aacc-97a4-479e-b2b3-db095fef34fc",
  "hostName": "HostName",

```

```

"startedAt": "2021-10-25T18:30:52.377Z",
"updatedAt": "2021-10-25T18:30:52.377Z",
"logsAvailable": false,
"status": "SUCCEEDED",
"prevAgentVersions": [
  {
    "type": "JAVA",
    "version": "20.3.0.1183"
  }
],
"maintAgentVersions": [
  {
    "type": "JAVA",
    "version": "20.3.0.1183"
  }
],
"curAgentVersions": [
  {
    "type": "JAVA",
    "version": "20.3.0.1183"
  }
],
"implicitMaintenance": false
}

```

Fetch System Maintenance Failure Log

Use this API to retrieve the failure log of a particular system maintenance activity using the `systemMaintenanceId`. The max log return is 4,096 characters, if the number exceeds this limit, then logs will be reduced.

Format:

```
GET /maintenance/systemMaintenances/{systemMaintenanceId}/log
```

Request Example:

```
curl --location --request GET 'https://demo.saas.appdynamics.com/zero/v1beta/maintenance/systemMaintenances/{systemMaintenanceId}/log' --header 'Authorization: Bearer {AuthToken}'
```

Input Parameters:

Parameter Name	Parameter Type	Description	Mandatory
<code>systemMaintenanceId</code>	Path	ID of the system maintenance activity.	Yes

Deploy an Agent Using the Agent Installer API

This page describes how to deploy an agent using the Agent Installer API. See [Agent Installer Platform Service API](#).

i Linux supports the Java and Machine Agents, and Windows only supports the Machine Agent.

Find the Agent Versions

Obtain the latest version of available agents using the API:

Format:

```
GET /install/agentVersions?latest={true|false}&osType={linux|windows}
```

Request Example:

On Linux: On Windows:

```
curl --location --request GET 'https://demo.saas.appdynamics.com/zero/v1beta/install/agentVersions?latest=false&osType=linux --header 'Authorization: Bearer {AuthToken}'
```

On Linux: On Windows:

```
curl --location --request GET 'https://demo.saas.appdynamics.com/zero/v1beta/install/agentVersions?latest=false&osType=windows --header 'Authorization: Bearer {AuthToken}'
```

Response Example:

On Linux: On Windows:

```
{
  "total":1,
  "items":[
    {
      "os":"linux",
      "agents":[
        {
          "agentType":"jdk8_plus",
          "descriptions":[
            {
```

```

        "version":"22.4.0.33722",

  ]
}

```

Obtain the Download Command

Use the version from the previous API to obtain the download command from the API:

Format:

```
GET /install/downloadCommand?jdk8PlusVersion={jdk8PlusVersion}&javaVersion={javaVersion}
&machineVersion={machineVersion}&zeroVersion={zeroVersion}&multiline={true|false}
&osType={windows|linux}
```

Request Example:

[On Linux:](#) [On Windows:](#)

```
Java Agent Legacy:
curl --location --request GET 'https://demo.saas.appdynamics.com/zero/v1beta/install/
downloadCommand?
javaVersion=latest&machineVersion=21.10.0.3188&zeroVersion=latest&multiline=true&osType=li
nux' --header 'Authorization: Bearer {AuthToken}'
```

```
Java JDK8+:
curl --location --request GET 'https://demo.saas.appdynamics.com/zero/v1beta/install/
downloadCommand?
jdk8PlusVersion=22.4.0.33722&machineVersion=latest&zeroVersion=latest&multiline=true&osTyp
e=linux' --header 'Authorization: Bearer {AuthToken}'
```

[On Linux:](#) [On Windows:](#)

```
curl --location --request GET 'https://demo.saas.appdynamics.com/zero/v1beta/install/
downloadCommand?
machineVersion=21.10.0.3188&zeroVersion=latest&multiline=true&osType=windows' --header
'Authorization: Bearer {AuthToken}'
```

Response Example:

[On Linux:](#) [On Windows:](#)

```
Java Agent Legacy:
[
  "cd $(mktemp -d -t appd-zero-XXXXXX)",
  "&& curl https://download-files.saas.appdynamics.com/download-file/zero-agent-
bootstrap/22.2.0.1462/appdynamics-zero-agent-bootstrap-22.2.0.1462.sh -o zero-agent.sh",
```

```

    "&& chmod +x zero-agent.sh",
    "&& ./zero-agent.sh download sun-java -u https://download-files.saas.appdynamics.com

]

```

Obtain the Install Command

i Application names cannot contain a single quotation mark ('). When you install Java JDK8+ with the Agent Installer, the OpenTelemetry resource attributes `service.namespace` and `service.name` are mapped to the AppDynamics application name and tier name.

Running the command will take you to a new temporary directory. Obtain the command from the API below and then execute it from the same directory:

Format:

```
GET /install/installCommand?sudo={true|false}&application={appName}&accessKey={accessKey}
&serviceUrl={serviceUrl}&osType={windows|linux}&otelEnabled={true|false}
&tracesExporter={tracesExporter}&metricsExporter={metricsExporter}
&otlpEndpoint={collectorEndpoint}&simEnabled={true|false}&dotnetCompatibility={true|false}
```

Request Example:

On Linux: On Windows:

```
curl --location --request GET 'https://demo.saas.appdynamics.com/zero/v1beta/install/
installCommand?sudo=true&application=helloWorld&accessKey=fb19d1d6-6858-5fea-
b6ed-302480e5c580&serviceUrl=https://
demo.saas.appdynamics.com&osType=linux&otelEnabled=true&tracesExporter=otlp,logging&metric
sExporter=otlp,logging&otlpEndpoint=https://demo.saas.appdynamics.com/otlp-
collector&simEnabled=true' --header 'Authorization: Bearer {AuthToken}'
```

On Linux: On Windows:

```
curl --location --request GET 'https://demo.saas.appdynamics.com/zero/v1beta/install/
installCommand?application=helloWorld&accessKey=fb19d1d6-6858-5fea-
b6ed-302480e5c580&serviceUrl=https://
demo.saas.appdynamics.com&osType=windows&simEnabled=true&dotnetCompatibility=true' --
header 'Authorization: Bearer {AuthToken}'
```

Response Example:

On Linux: On Windows:

```
[
```

```
"sudo ./zero-agent.sh install --application 'helloWorld' --account 'demo' --access-key
'fb19d1d6-6858-5fea-b6ed-302480e5c580' --service-url 'https://demo.saas.appdynamics.com'
--enable-sim 'true' --enable-otel 'true' --traces-exporter 'otlp,logging' --metrics-
exporter 'otlp,logging' --otlp-endpoint 'https://demo.saas.appdynamics.com/otlp-
collector'"
]
```

On Linux: [On Windows:](#)

```
[
".\\zero-agent.ps1 install --application 'helloWorld' --account 'demo' --access-key
'fb19d1d6-6858-5fea-b6ed-302480e5c580' --service-url 'https://demo.saas.appdynamics.com'
--enable-sim 'true' --dotnet-compatibility 'true'"
]
```

Manage Tier Naming Rules

You can use the Tier Naming Rule functionality to customize the tier name of any managed Java process. Each tier rule maps to a specific server type. Tier Naming Rules allows you to create Rego policies so that the Agent Installer can discover tier names. To do that, the tier naming format or rule condition must have a valid Rego expression. AppDynamics recommends recreating Rego Policies using Tier Naming Rules. See [Rego Policy Language](#).

 For information on the Agent Installer API, see [Agent Installer Platform Service API](#).

Tier Naming Format

Format	Description	Example
tier-name-format	The format contains only literals and the tier name appears the same as the format.	View example... tier-name-format
tier- <AppServerType>- format	The mix of literals and attributes. The tier name is evaluated after passing the attribute and replaces the value of the attribute. Attributes are defined within the angular bracket <AppServerType> .	View example... <ul style="list-style-type: none"> tier-tomcat-format for tomcat application server tier-jboss-format for jboss application server tier-glassfish-format for glassfish application server tier-java-format for plain java application

Format	Description	Example
<pre>`input.CmdlineArray[count(input.CmdlineAr ray) - 1]`</pre>	<p>The expression is made inside the <code>` `</code>. This does not have an attribute, and there is no change in the expression.</p>	<p>View example...</p> <pre>"CmdlineArray": ["/ usr/lib/jvm/java-1.8.0- openjdk-1.8.0.252.b09-2 .el7_8.x86_64/jre/bin/ java", "- Djava.util.logging.mana ger=org.apache.juli.Cla ssLoaderLogManager", "- classpath", "/usr/lib/ jvm/java-1.8.0- openjdk-1.8.0.252.b09-2 .el7_8.x86_64/lib/ tools.jar:/home/ Ecommerce.jar", "EcommerceApplication"]</pre> <p>Assuming the command line is the value above, the tier name format is <code>EcommerceApplication</code>.</p>

Format	Description	Example
<pre>`<CmdlineArray>[count(<CmdlineArray>) - 1]`</pre>	<p>The expression is made inside the <code>` `</code>. The attributes are parsed.</p>	<p>View example...</p> <pre>"CmdlineArray": ["/usr/lib/jvm/java-1.8.0-openjdk-1.8.0.252.b09-2.el7_8.x86_64/jre/bin/java", "-Djava.util.logging.manager=org.apache.juli.ClassLoaderLogManager", "-classpath", "/usr/lib/jvm/java-1.8.0-openjdk-1.8.0.252.b09-2.el7_8.x86_64/lib/tools.jar:/home/Ecommerce.jar", "EcommerceApplication"]</pre> <p>Assuming the command line is the value above, the tier name format is <code>EcommerceApplication</code>.</p>

Filter Tier Naming Rules

[Using the UI](#) [Using the API](#)

1. Go to the **Tier Naming Rules** tab.
2. Click **Filter Panel**.
3. Select how you want to filter out a tier naming rule. Options: **Status, Enabled, Disabled**.
4. Select or type the **Application Scope**.
5. Select the **Application Server Type**.
6. Click **Apply**.

[Using the UI](#) [Using the API](#)

Format:

```
POST /customNaming/rules/query
```

Request Example:

```
curl --location --request POST 'https://demo.saas.appdynamics.com/zero/v1beta/customNaming/rules/query' --header 'Authorization: Bearer {AuthToken}'
--header 'Content-Type: application/json' \
--data-raw
{
  "enabled": true,
  "appServerTypes": [
    "TOMCAT"
  ],
  "applicationNames": [
    "EcommerceApplication"
  ]
}
```

Response Example:

```
{
  "total": 2,
  "customConfigFocusedDtoList": [
    {
      "id": "56112e75-6308-4d04-b9fa-e336b967bc59",
      "ruleName": "TomcatRule1",
      "priority": 1,
      "version": 1,
      "enabled": true,
      "appServerTypes": [
        "TOMCAT"
      ],
      "applicationNames": [
        "EcommerceApplication"
      ]
    },
    {
      "id": "6b8701db-b7d3-4017-8001-ba9de952cd82",
      "ruleName": "TomcatRule2",
      "priority": 2,
      "version": 1,
      "enabled": true,
      "appServerTypes": [
        "TOMCAT"
      ],
      "applicationNames": [
        "EcommerceApplication"
      ]
    }
  ]
}
```

```
}

```

Add New Tier Naming Rules

[Using the UI](#) [Using the API](#)

1. Go to the **Tier Naming Rules** tab.
2. Click **+ Add New Rule**.
3. Enter the following:
 - a. **Rule Name**
 - b. **Tier Naming Format:** Use any characters, words, and variables to define your naming format.
 - c. **Application Server Types:** Select the application server type that the naming rule will apply to.
 - d. **Conditions:** Select values that match the conditions that will be added to the tier.

 All string comparisons are case sensitive.

- e. **Application Scope:** Only tiers in the selected applications will be evaluated against the conditions.
4. Click **Create rule**.
View tier scenarios...

Scenario 1: If an existing tier name (Tier 1) is disabled, and a new tier name (New Tier 1) is discovered by the tier rule, the new tier (New Tier 1) will be disabled by default.

Scenario 2: If an existing tier name (Tier 1) is disabled, and it is modified to an existing tier name (Tier 2), by the change of tier rules the status of the tier name (Tier 2) will be not change.

[Using the UI](#) [Using the API](#)

Format:

```
POST /customNaming/rules
```

Request Example:

```
curl --location --request POST 'https://demo.saas.appdynamics.com/zero/v1beta/customNaming/rules' --header 'Authorization: Bearer {AuthToken}' \
--header 'Content-Type: application/json' \
--data-raw
{
  "ruleName": "TomcatRule",
  "tierNamingFormat": "tomcat-tier-prod",
  "processType": "JAVA",
  "appServerTypes": [
    "tomcat"
  ],
  "priority": 1,
}
```

```

"ruleConditions": [
  {
    "keyName": "<cmdlineArray[_]>",
    "conditionType": "contains",
    "value": "-Dcatalina.home=/staging/apache-tomcat-9.0.6"
  }
],
"applicationNames": [
  "ALL"
]
}

```

Response Example:

```

{
  "id": "9a7dfb82-480f-4beb-b72c-a3692b54fdec",
  "ruleName": "TomcatRule",
  "tierNamingFormat": "tomcat-tier-prod",
  "processType": "JAVA",
  "version": 1,
  "appServerTypes": [
    "tomcat"
  ],
  "priority": 1,
  "enabled": true,
  "ruleConditions": [
    {
      "keyName": "<cmdlineArray[_]>",
      "conditionType": "CONTAINS",
      "value": "-Dcatalina.home=/staging/apache-tomcat-9.0.6",
      "sequence": 0
    }
  ],
  "applicationNames": [
    "ALL"
  ]
}

```

Obtain Tier Naming Rule Details

[Using the API](#)

Format:

```
GET /customNaming/rules/{Id}/details
```

Request Example:

```
curl --location --request GET 'https://demo.saas.appdynamics.com/zero/v1beta/customNaming/rules/0c328c2e-d6ab-4343-bcff-792a77c45413/details' \
--header 'Authorization: Bearer {AuthToken}'
```

Response Example:

```
{
  "id": "56112e75-6308-4d04-b9fa-e336b967bc59",
  "ruleName": "TomcatRule1",
  "tierNamingFormat": "tomcat-tier-prod",
  "processType": "JAVA",
  "version": 1,
  "appServerTypes": [
    "TOMCAT"
  ],
  "priority": 1,
  "enabled": true,
  "ruleConditions": [
    {
      "keyName": "<CmdlineArrya[_]>",
      "conditionType": "CONTAINS",
      "value": "-Dcatalina.home",
      "sequence": 1
    },
    {
      "keyName": "<envVarMap.HOSTNAME>",
      "conditionType": "EQUAL",
      "value": "localhost",
      "sequence": 2
    }
  ],
  "applicationNames": [
    "EcommerceApplication"
  ]
}
```

Edit Tier Naming Rules

[Using the UI](#) [Using the API](#)

1. Go to the **Tier Naming Rules** tab.
2. Select the **Rule Name** that you want to edit.
3. Click **Edit rule**.
4. Edit the following:
 - a. **Tier Naming Format**

- b. Application Server Types
- c. Conditions

 All string comparisons are case sensitive.

- d. Application Scope
5. Click **Update rule**.

Using the UI [Using the API](#)

Format:

PUT /customNaming/rules/{Id}

Request Example:

```
curl --location --request PUT 'https://demo.saas.appdynamics.com/zero/v1beta/customNaming/rules/9a7dfb82-480f-4beb-b72c-a3692b54fdec' --header 'Authorization: Bearer {AuthToken}' \
--header 'Content-Type: application/json' \
--data-raw
{
  "id": "9a7dfb82-480f-4beb-b72c-a3692b54fdec",
  "ruleName": "TomcatRule",
  "tierNamingFormat": "tomcat-tier-prod",
  "processType": "JAVA",
  "version": 1,
  "appServerTypes": [
    "tomcat"
  ],
  "priority": 1,
  "enabled": true,
  "ruleConditions": [
    {
      "keyName": "<cmdlineArray[_]>",
      "conditionType": "CONTAINS",
      "value": "-Dcatalina.home=/staging/apache-tomcat-9.0.6",
      "sequence": 0
    },
    {
      "keyName": "<envVarMap.HOSTNAME>",
      "conditionType": "EQUAL",
      "value": "localhost",
      "sequence": 0
    }
  ],
  "applicationNames": [
    "ALL"
  ]
}
```

```
}

```

Response Example:

```
{
  "id": "9a7dfb82-480f-4beb-b72c-a3692b54fdec",
  "ruleName": "TomcatRule",
  "tierNamingFormat": "tomcat-tier-prod",
  "processType": "JAVA",
  "version": 2,
  "appServerTypes": [
    "tomcat"
  ],
  "priority": 1,
  "enabled": true,
  "ruleConditions": [
    {
      "keyName": "<cmdlineArray[_]>",
      "conditionType": "CONTAINS",
      "value": "-Dcatalina.home=/staging/apache-tomcat-9.0.6",
      "sequence": 0
    },
    {
      "keyName": "<envVarMap.HOSTNAME>",
      "conditionType": "EQUAL",
      "value": "localhost",
      "sequence": 0
    }
  ],
  "applicationNames": [
    "ALL"
  ]
}
```

Delete Tier Naming Rules

[Using the UI](#) [Using the API](#)

1. Go to the **Tier Naming Rules** tab.
2. Select the **Rule Name** that you want to delete.
3. Click **Delete Confirmation**.

[Using the UI](#) [Using the API](#)

Format:

```
DELETE /customNaming/rules/{Id}
```

Request Example:

```
curl --location --request DELETE 'https://demo.saas.appdynamics.com/zero/v1beta/customNaming/rules/9a7dfb82-480f-4beb-b72c-a3692b54fdec' --header 'Authorization: Bearer {AuthToken}'
```

Response Example:

No response

Enable Tier Naming Rules

[Using the UI](#) [Using the API](#)

1. Go to the **Tier Naming Rules** tab.
2. Select the **Rule Name** that you want to enable.
3. Click **Enable rule**.

[Using the UI](#) [Using the API](#)

Format:

```
POST /customNaming/rules/{Id}/enable
```

Request Example:

```
curl --location --request POST 'https://demo.saas.appdynamics.com/zero/v1beta/customNaming/rules/9a7dfb82-480f-4beb-b72c-a3692b54fdec/enable' --header 'Authorization: Bearer {AuthToken}'
```

Response Example:

No response

Disable Tier Naming Rules

[Using the UI](#) [Using the API](#)

1. Go to the **Tier Naming Rules** tab.
2. Select the **Rule Name** that you want to disable.
3. Click **Disable rule**.

Using the UI [Using the API](#)

Format:

```
POST /customNaming/rules/{Id}/disable
```

Request Example:

```
curl --location --request POST 'https://demo.saas.appdynamics.com/zero/v1beta/customNaming/rules/9a7dfb82-480f-4beb-b72c-a3692b54fdec/disable' --header 'Authorization: Bearer {AuthToken}'
```

Response Example:

No response

Edit Priorities for Tier Naming Rules

[Using the UI](#) [Using the API](#)

1. Go to the **Tier Naming Rules** tab.
2. Click **Priority**.
3. Drag and drop rows to rearrange the tier naming rules priority.
4. Click **Save priority order**.

The evaluation of a tier name follows the priority order of the configuration rule defined. If none of the rules match, then the default tier name is set by the Agent Installer.

Using the UI [Using the API](#)

Format:

```
PATCH /customNaming/rules/bulk
```

Request Example:

```
curl --location --request PATCH 'https://demo.saas.appdynamics.com/zero/v1beta/customNaming/rules/bulk' --header 'Authorization: Bearer {AuthToken}' --header 'Content-Type: application/json' \
--data-raw
{
  "total": 1,
  "items": [
```

```

    {
      "id": "79962b2d-9afb-40e8-9529-428c5077e702",
      "priority": 1,
      "version": 1
    },
    {
      "id": "9a7dfb82-480f-4beb-b72c-a3692b54fdec",
      "priority": 2,
      "version": 1
    }
  ]
}

```

Response Example:

```

{
  "total": 2,
  "items": [
    {
      "ruleName": "TomcatRule1",
      "status": "SUCCESS",
      "description": null
    },
    {
      "ruleName": "TomcatRule2",
      "status": "SUCCESS",
      "description": null
    }
  ]
}

```

Import Tier Naming Rules

[Using the UI](#) [Using the API](#)

1. Go to the **Tier Naming Rules** tab.
2. Click **Import**.
3. Select the JSON file you want to import.
4. Click **Upload**.
5. Click **Done** once the file has been successfully uploaded.

[Using the UI](#) [Using the API](#)

Format:

```
POST /customNaming/templates/import
```

Request Example:

```
curl --location --request POST 'https://demo.saas.appdynamics.com/zero/v1beta/customNaming/templates/import' --header 'Authorization: Bearer {AuthToken}' --header 'Content-Type: application/json' --form 'file=@<filePath>'
```

Response Example:

```
{
  "total": 2,
  "items": [
    {
      "ruleName": "TomcatRule3",
      "status": "SUCCESS",
      "description": null
    },
    {
      "ruleName": "TomcatRule4",
      "status": "SUCCESS",
      "description": null
    }
  ]
}
```

Export Tier Naming Rules

[Using the UI](#) [Using the API](#)

1. Go to the **Tier Naming Rules** tab.
2. Click **Export**.
3. Click **Allow** to download the file to local system.

[Using the UI](#) [Using the API](#)

Format:

```
POST /customNaming/rules/export
```

Request Example:

```
curl --location --request POST 'https://demo.saas.appdynamics.com/zero/v1beta/customNaming/rules/export' --header 'Authorization: Bearer {AuthToken}' --header 'Content-Type: application/json'
```

Response Example:

The response is a file in JSON format

Preview the Status of a Tier Naming Rule

[Using the UI](#) [Using the API](#) [More information](#)

1. Go to the **Tier Naming Rules** tab.
2. Click **Naming Rules Preview**.
3. Preview the status of each rule: **Impacted processes**, **In progress**, and **No changes**.
4. Click **Done**.

[Using the UI](#) [Using the API](#) [More information](#)

Format:

POST /customNaming/preview

Request Example:

```
curl --location --request POST 'https://demo.saas.appdynamics.com/zero/v1beta/customNaming/preview' --header 'Authorization: Bearer {AuthToken}' --header 'Content-Type: application/json' \
--data-raw
{
  "applicationNames" : [
    "ECommerceApp"
  ],
  "curTierInformation": [
    {
      "tierName": "tier1",
      "ruleName": "rul1e1"
    }
  ],
  "expectedTierInformation": [
    {
      "tierName": "tier1",
      "ruleName": "rul1e1"
    }
  ],
  "previewStatus" : false
}
```

Response Example 1:

```

{
  "total": 1,
  "items": [
    {
      "nodeName": "Node1",
      "applicationName": "EcommerceApp",
      "curTierInformation": {
        "tierName": "Tier1",
        "ruleName": "Rule1"
      },
      "expectedTierInformation": {
        "tierName": "NewTier1",
        "ruleName": "NewRule1"
      },
      "previewStatus": true,
      "previewMessage": "Restart to Apply"
    }
  ]
}

```

Response Example 2:

```

{
  "total": 2,
  "items": [
    {
      "nodeName": "Node1",
      "applicationName": "EcommerceApp",
      "curTierInformation": {
        "tierName": "Tier1",
        "ruleName": "Rule1"
      },
      "expectedTierInformation": {
        "tierName": "NewTier1",
        "ruleName": "NewRule1"
      },
      "previewStatus": true,
      "previewMessage": "Restart to Apply"
    },
    {
      "nodeName": "Node2",
      "applicationName": "EcommerceApp",
      "curTierInformation": {
        "tierName": "Tier1",
        "ruleName": "Rule1"
      },
    },
  ]
}

```

```

    "previewStatus": true,
    "previewMessage": "No Change"
  }
]
}

```

Using the UI Using the API [More information](#)

i Once a configuration changes, you can use the Preview API to identify the affect of an existing tier name, before restarting the Java process. The Preview status is only supported in versions >=22.4. Older versions of the agent display in the **Failure** status, as not supported.

Default Rules

The table below shows default values for tier naming rules.

AppServerType	Sub Category	Default Name	Example
tomcat	tomcat	tomcat,<JavaUniquePath>	tomcat,/staging/apache*.*
	tomEE	tomee,<JavaUniquePath>	tomee,/staging/apache*.*
jboss	standalone	jboss,standalone,<JavaUniquePath>	jboss,standalone,/staging/jboss*.*
	domain	jboss,domain,<JBossServerGroupName>,<JavaUniquePath>	jboss,domain,defaultServer,/staging/jboss*.*
glassfish	glassfish	glassfish,<GlassfishDomainName>,<GlassfishInstanceName>,<JavaUniquePath>	glassfish,domain1,domain1,/staging/glassfish*.*
weblogic	weblogic	weblogic,<WeblogicDomainName>,<WeblogicInstanceName>,<JavaUniquePath>	weblogic,domain,weblogic1,/staging/weblogic*.*

AppServerType	Sub Category	Default Name	Example
websphere	WebSphereWAS	webspherewas, <WebSphereCellName>, <WebSphereServerName>, <JavaUniquePath>	webspherewas, wascell, wasServer, /staging/websphere*. *
	Liberty	websphereliberty, <WebSphereLibertyServerName>, <JavaUniquePath>	websphereliberty, liberty, /staging/websphere*. *
java	using jar file	java, <JavaMainJar>	java, ECommerceApp.jar
	using java class name	java, <JavaMainClass>, <JavaUniquePath>	java, EcommerceApplication, /staging/EcommerceApplicaton/**

Enable Server Visibility and .NET Compatibility Mode with Agent Installer

This page describes how to enable and disable Server Visibility or .NET Compatibility Mode for Machine Agent, with the Agent Installer configure command. See [Server Visibility Requirements and Supported Environments](#).

i To enable or disable Server Visibility or .NET Compatibility, a restart of the Machine Agent is not required.

Enable Server Visibility

Server Visibility provides an expanded set of Server Visibility metrics.

On Linux: On Windows:

```
<install-directory> bin/zfictl configure --enable-sim=true
```

On Linux: On Windows:

```
<install-directory> bin\zfictl.exe configure --enable-sim=true
```

Disable Server Visibility

[On Linux:](#) [On Windows:](#)

```
<install-directory> bin/zfictl configure --enable-sim=false
```

[On Linux:](#) [On Windows:](#)

```
<install-directory> bin\zfictl.exe configure --enable-sim=false
```

Enable .NET Compatibility Mode

.NET compatibility mode allows you to collect and view machine or server metrics with the Machine and .NET Agents installed. See [.NET Compatibility Mode](#).

[On Windows:](#)

```
<install-directory> bin/zfictl configure --dotnet-compatibility=true
```

Disable .NET Compatibility Mode

[On Windows:](#)

```
<install-directory> bin/zfictl configure --dotnet-compatibility=false
```

Java Agent

Related pages:

- [AppDynamics Essentials](#)
- [Install the Machine Agent](#)
- [Administer App Server Agents](#)

To monitor Java applications in the Controller, you need to install the AppDynamics Java Agent on each server that hosts applications to be monitored. You can use the [AppDynamics Agent Installer](#) to streamline the deployment of the Java Agent. The Agent Installer simplifies the agent installation process.

If you downloaded the agent from the [AppDynamics Downloads Center](#), see [Install the Java Agent](#).

Before You Begin

1. Verify support for your application environment at [Java Supported Environments](#).

2. Confirm you have access to a compatible controller. See [Agent and Controller Tenant Compatibility](#).
3. Confirm the connection settings to the Controller where your agent will report data:
 - If you use a SaaS Controller, AppDynamics sent you the Controller hostname in your Welcome Email. Use port 443 for HTTPS or port 80 for HTTP.
 - If you use an on-premises Controller, you supplied hostname and port at install time.
4. Verify you have access to the machine where the application runs as a user account with privileges to install the agent software and restart the application.
5. Verify that the machine where the application runs can connect to the Controller. Proxies or firewalls on the network between the agent and Controller may require additional configuration.

Install the Agent

To install the agent using the **Agent Download Wizard** in the Controller UI:

1. Log in to the Controller UI and access the **Getting Started Wizard for Java**.
2. Follow the steps in the wizard to configure and download the agent. The agent guides you through some preliminary configuration steps.
3. As an administrator on the machine running your Java application, unzip the `AppServerAgent.zip` file.
For example, on Linux unzip the agent to `home/appdynamics`. This is the `<agent_home>` directory.

```
unzip AppServerAgent.zip -d /opt/appdynamics/appagent
```

4. Add the Java Agent binary to the application process, typically by passing the agent JAR file as a startup argument to the application. For information by framework and application type, see [Agent Installation by Java Framework](#).

When completed, you can restart your application and view data reported by the agent in the Controller UI. From there, you can install more agents or [begin monitoring](#) your application environment.

Tier and Node Naming in the Java Getting Started Wizard

Each monitored JVM must have a unique combination of tier and node name in AppDynamics. Naming the components in the wizard varies between the self-service trial edition of AppDynamics and the non-trial edition:

- For the self-service Pro Trial edition of AppDynamics Pro, the wizard names the application and tier for you using the format described in the following section. You can always change the names later.
- For a non-trial edition, you name the application and tier in the wizard, while the wizard generates the node name.

For self-service trials of AppDynamics Pro, the getting started wizard uses the following naming scheme to identify agents:

- Node name: `<app_server_type>@<hostname>:<port>`
For example: `JBoss@appserver1.example.com:8080`
- Tier name: `MyTier`
- Application name: `MyApp`

The port number in the node name ensures that each node has a unique name if there is more than one app server on the same machine.

If the application server listens on multiple ports, the node name uses the lowest of the port numbers. Notice that the lowest port number may not be the primary port for the host. For instance, if a server listens

for client requests at 8080 but listens for shutdown requests on port 8005, the node will be named with the 8005 port.

The Controller identifies distinct tiers based on traffic flow between nodes. All tiers belong to a single business application, MyApp.

Java Supported Environments

This page lists the application environments and versions supported by the AppDynamics Java Agent.

i If your application environment is unavailable in the Supported Environments list, suggest it as an idea in the [AppDynamics Idea Exchange](#) portal.

Java Agent Supported Platforms

In the following tables, note that:

- A dash ("-") in a table cell indicates that this column is not relevant or not supported for that particular environment.
- In cases where no version is provided, assume that all versions are supported. Contact AppDynamics Sales for confirmation.
- For environments that require additional configuration, a separate table describing or linking to configuration information follows the support matrix.
- For environments supported by AppDynamics End User Monitoring, see [Supported Environments and Versions - Web EUM](#).
- For environments supported by AppDynamics Server Visibility, [Machine Agent Requirements and Supported Environments](#).

JVM Support

The AppDynamics Java Agent uses the standard JVM Tool Interface (JVMTI) mechanism allowing it to instrument any software running on a JVM supporting this mechanism.

AppDynamics certifies the successful operation of the basic mechanisms of instrumentation used by the agent on the following Java runtimes. These capabilities are supported on both JRE or full JDK installations.

Where the agent supports the following advanced memory monitoring features, they are listed for the JVM: Object Instance Tracking (OIT), Automatic Leak Detection (ALD), Content Inspection (CI), and Access Tracking (AT).

i Unless listed on this page, builds downloaded from other sources are not officially supported.

JVM	OS	Memory Monitoring Features
Eclipse Adoptium 17, 18, 19, and 20	Linux, Windows, MacOS	OIT (supported only for Hotspot JVM), ALD, CI, AT
Amazon Corretto 8, 11, 17, 18, 19, and 20	Linux, Windows	OIT, ALD, CI, AT
Azul Zing 15.x.	Linux x64	OIT, ALD

JVM	OS	Memory Monitoring Features
Azul Zulu OpenJDK 8, 9, 10, 11, 13, 14, 15, 16, 17, 18, and 19 JDK11 is supported from 4.5.6 onwards JDK13 is supported from 4.5.15 onwards JDK14 is supported from 20.4.0 onwards JDK15 is supported from 20.10.0 onwards JDK16 is supported from 21.4.0 onwards JDK17 is supported from 21.11.0 onwards JDK18 is supported from 22.7.0 onwards JDK19 is supported from 23.1.0 onwards	Linux, Windows	OIT, ALD, CI, AT
JVM - BellSoft Liberica JDK 8, 11, 16, 17, 18, and 19	Linux, Windows, MacOS	OIT, ALD
GraalVM 20.0.0, 20.2.0, 21.1.0, 21.3.0	Linux, Windows, MacOS	OIT, ALD, CI, AT
HP OpenVMS		

JVM	OS	Memory Monitoring Features
IBM JVM 1.8.x	AIX, HP-UX, Linux, Solaris, Windows, z/OS	<p>ALD, CI</p> <p>Object instance tracking, automatic leak detection, and custom memory structure monitoring are not supported with the AppDynamics IBM Java Agent. IBM JVMs can be instrumented with the AppDynamics Sun Java Agent to work around this limitation; however, this only enables automatic leak detection and custom memory structure monitoring.</p> <p>Object instance tracking is not available. Working around this limitation can result in negative performance impact and is not recommended. In such cases, the IBM JVM needs to be restarted to enable custom memory structure monitoring.</p>
Oracle Rockit JVM 28.1+	Linux Intel 64, Windows	

JVM	OS	Memory Monitoring Features
<p>Oracle/Sun JVM 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, and 20</p> <p>JDK11 is supported from 4.5.6 onwards</p> <p>JDK12 is supported from 4.5.11 onwards</p> <p>JDK13 is supported from 4.5.15 onwards</p> <p>JDK14 is supported from 20.4.0 onwards</p> <p>JDK15 is supported from 20.10.0 onwards</p> <p>JDK16 is supported from 21.4.0 onwards</p> <p>JDK17 is supported from 21.11.0 onwards</p> <p>JDK18 is supported from 22.7.0 onwards</p> <p>JDK19 is supported from 23.1.0 onwards</p> <p>JDK20 is supported from 23.10.0 onwards</p>	<p>Solaris Sparc 64, Windows, Linux</p>	<p>OIT, ALD, CI, AT</p> <p>Content Inspection and Access Tracking require a JVM restart.</p>

JVM	OS	Memory Monitoring Features

JVM Application Server and Framework Support

AppDynamics supports the use of the Java Agent to instrument any application component running on a supported JVM, irrespective of how that component is built. It can automatically discover the topology and behavior of complex enterprise applications without requiring deep technical knowledge of the application's underlying code.

Frequently, Java-based systems employ standard framework code to implement business logic. Automatic instrumentation of framework code relies on knowledge of the business logic and programming patterns employed by the framework. AppDynamics instrumentation targets processing hand-offs between components, called [entry points and exit points](#), either within the JVM or between JVMs. This includes hand-offs between frameworks in cases where multiple frameworks are being used together. This section covers the capabilities for frameworks for which AppDynamics provides automatic detection rules.

Monitoring application components built using frameworks not listed here may require custom configuration. The custom configuration may involve, for example, custom [POJO entry or exit points](#). If you understand how the application behaves internally, you can easily configure this type of instrumentation. For more complex configuration tasks, contact your account representative to discuss how to engage the AppDynamics customer success organization.

JVM Language Frameworks Support

No additional configuration is required for these frameworks.

Vendor	JVM Language Framework	Version	Correlation/Entry Points	Exit Points	Transports	Notes
Open Source	Akka Actor	2.1 – 2.5.x	Yes	Yes	Netty	4.3.1 required for 2.4.x 2.5x support includes Persistence Remoting exit/entry supported

Vendor	JVM Language Framework	Version	Correlation/Entry Points	Exit Points	Transports	Notes
Open Source	Akka HTTP Name: akka-http-stream-entry - enabled Type: Boolean Default: False	Akka Actor 2.6 Akka HTTP upto 10.2.6 Scala 2.11, 2.12	Yes	Yes	HTTP	EUM is supported Support for Non-Route DSL
Open Source	Http4s Blaze Client	Blaze versions: 0.21.1, 0.21.0, 0.20.23, 0.20.5 scala 2.11, 2.12	No	Yes	HTTP	-
Open Source	Groovy	-	Yes	Yes		
Open Source	Ktor	1.0.x -1.6.x	Yes (Netty Engine)	-	HTTP	EUM is supported
Open Source	Play for Scala Play for Java	2.1 – 2.8 Scala 2.11, 2.12	Yes	-	HTTP over Netty server Akka HTTP server	Includes framework specific entry and exit points Play EUM-APM correlation supported
Open Source	Scala	2.11.6				

Vendor	JVM Language Framework	Version	Correlation/Entry Points	Exit Points	Transports	Notes
Open Source	Spray toolkit (Spray.io)	1.1.x 1.1.3	Yes	Yes	HTTP	Entry points are detected and configurable as servlet entry point and exit points as HTTP exits
Pivotal	Grails	-	-	-	-	

Java Framework Support

The Java Agent supports these Java frameworks. Some require additional configuration as indicated in the Configuration Notes column.

Vendor	Framework	Version	SOA protocol (WebServices)	Auto Naming	Entry Points	Exit Points	Detection	Configuration Notes
Adobe	BlazeDS	-	HTTP and JMS adaptor	-	Yes		-	See Example Message Queue Backend Configuration .
Adobe	ColdFusion	8.x, 9.x	-	-	Yes	-	Configuration required for transaction discovery	Configuration is required for transaction discovery. See: <ul style="list-style-type: none"> • Java Business Transaction Detection • Servlet Entry Points

Vendor	Framework	Version	SOA protocol (WebServices)	Auto Naming	Entry Points	Exit Points	Detection	Configuration Notes
Apache	Cassandra with Thrift framework	-	-	-	Yes	Yes	Apache Thrift Entry and Exit points are detected	
Apache	Struts	1.x, 2.x	-	-	Yes		Struts Actions are detected as entry points; struts invocation handler is instrumented	See Struts Entry Points .
Apache	Tapestry	5	-	-	Yes	-	Not by default	See: <ul style="list-style-type: none"> • Java Business Transaction Detection • Servlet Entry Points
Apache	Wicket	-	-	No	Yes	-	Not by default	See: <ul style="list-style-type: none"> • Java Business Transaction Detection • Servlet Entry Points

JDBC Drivers and Database Servers Support

The Java Agent supports these JDBC driver and database server environments. AppDynamics can follow transactions using these drivers to the designated database.

JDBC Vendor	Driver Version	Driver Type	Database Server	Database Version
Apache	10.9.1.0	Embedded or client	Derby	-
Apache	-	-	Cassandra	-

JDBC Vendor	Driver Version	Driver Type	Database Server	Database Version
Progress	DataDirect	data connectivity for ODBC and JDBC driver access, data integration, and SaaS and cloud computing solutions	-	-
IBM	JDBC 3.0 version 3.57.82 or JDBC 4.0 version 4.7.85	DB2 Universal JDBC driver	DB2	9.x
IBM	JDBC 3.0 version 3.66.46 or JDBC 4.0 version 4.16.53	DB2 Universal JDBC driver	DB2	10.1
IBM	-	DB2 Universal JDBC driver	DB2	11.x
IBM	-	Type IV	Informix	-
Maria				1.4.x - 2.6.x
Microsoft	4	Type II	MS SQL Server	2012
Oracle MySQL, MySQL Community	5.x, 6.x, 8.x	Type II, Type IV	MySQL	5.x
Oracle	RAC			
Oracle	9i, 10g 11g, 12c, 18c, 19c	Type II, Type IV	Oracle Database	8i+
Open Source PostgreSQL	42.2.5	Type IV	Postgres	8.x, 9.x, 11x
Sybase	jConnect	Type IV	Sybase	-
Teradata			Teradata	-

Notes:

- Type II is a C or OCI driver
- Type IV is a thin database client and is a pure Java driver

NoSQL/Data Grids/Cache Servers Support

The Java Agent supports these NoSQL, data grids and cache server environments. Some require additional configuration.

Vendor	Database/Data Grid/Cache	Version	Correlation/Entry Points	JM X	Configuration Notes

Business Transaction Error Detection

The Java Agent supports the following logging frameworks for business transaction error detection:

- Apache Log4j and Log4j 2
- java.util.logging
- Simple Logging Facade for Java (SLF4J)
Support for the following method has been added: `public void error(String format, Object... argArray)`
- Logback

To instrument other types of loggers, see [Error Detection](#).

Install the Java Agent

Related pages:

- [Download AppDynamics Software](#)
- [Java Agent Configuration Properties](#)
- [Enable SSL for the Java Agent](#)
- [SELinux Installation Issues](#)

To begin monitoring a Java application using AppDynamics, you install the AppDynamics Java Agent into the application JVM:

1. Download the agent distribution to the machine where your Java application runs.
2. Configure the Java Agent settings. This configuration section of this page describes manual configuration. For more options, see [Administer the Java Agent](#).
3. Add the agent to the JVM process.

Prepare to Install the Java Agent

Consider the following as you decide where and how to deploy the AppDynamics Java Agent:

- The user under which the JVM runs must have write privileges to the conf and logs directories in the Java Agent home (privileges to the conf (<JAVA_AGENT_HOME>/ver<VERSION>/)). To achieve this, you can install the agent as the same user that owns the JVM or as an administrator on the host machine. You can restrict the remaining contents of the agent directory to read-only access.
- To secure communications between the Java Agent and your Controller, see [Enable SSL for the Java Agent](#).
- If the agent connects to the Controller through a local proxy, you must configure proxy settings for the agent. See "Proxy Properties for the Controller" in [Java Agent Configuration Properties](#).
- The Java Agent supports sharing a single agent between multiple JVMs running on the same machine. If you choose this deployment scenario, you will want to specify settings in a combination of [system properties](#) and the versioned configuration file. See [Instrument Multiple JVMs on a Single Machine](#) for example configurations.

For cURL installation, see [Download AppDynamics Software](#).

i The AppDynamics Java Agent is one type of bytecode injection (BCI) agent. To prevent unforeseen issues with other BCI agents, AppDynamics only supports environments running the Java Agent as the sole BCI agent on the JVM.

You can run multiple BCI Agents on the JVM at your own risk. For Java Agent <= 4.5.16, you can decrease the chances of conflict with other agents by specifying the following command-line option:

```
-Dappdynamics.agent.prefer.retransformClasses=true
```

Java Agent >= 4.5.17 automatically enables this option if they detect the presence of other agents.

Instrument a Custom Java Runtime Image

You can use the Java Agent to instrument an application running on a custom Java runtime image constructed with J-link. To instrument the agent, the custom runtime requires these modules:

- `jdk.management`
- `java.logging`
- `jdk.unsupported`

i `jdk.jcmd` is not a required module for the custom runtime. However, it is required for the proper functioning of Object Instance Tracking. See [Object Instance Tracking for Java](#). AppDynamics assumes that all packages from Java.se are installed.

Java Agent Resource Overhead

The Java Agent typically adds between 0% to 2% additional CPU consumption.

However, certain factors can increase CPU overhead from the agent beyond 2%. These include the use of resource-intensive AppDynamics features, such as asynchronous transaction tracking. Very active environments or configuration settings that result in a high number of metrics or snapshots reported per minute can also affect agent resource consumption.

In all cases, AppDynamics recommends that you test the agent in a staging environment, and monitor resource consumption of your application to ensure that it remains within proper operating parameters.

If your application operates within a small margin of its existing memory resource allocation, you may choose to increase the allocation for the application. AppDynamics recommends allocating the following amounts of additional Heap and PermGen space to accommodate the agent:

- Maximum heap size (`-Xmx`): 100 MB in addition to the amount required by the application
- Maximum PermGen (permanent generation) heap size (`-XX:MaxPermSize`): 20 MB in addition to the amount required by the application. The setting for MaxPermSize is applicable only for Java 6 or Java 7.
- For network bandwidth consumption, see [App Agent Network Bandwidth Usage](#).

Download and Unzip the Java Agent Distribution

You can get the agent from the Agent Download Wizard. If you have never installed an agent before, the wizard is a good place to start. The wizard populates the configuration file in the agent you download with Controller connection settings and identifying settings for the agent. After you download the agent, you can install it in the JVM.

Alternatively, you can download the agent manually, as follows:

1. Download the Java Agent ZIP file from [AppDynamics Download Center](#).
2. Extract the ZIP file to the destination directory as the same user or administrator of the JVM. Note the following:
 - Extract the Java Agent to a directory that is outside of your container or application server runtime directories, such as to `\usr\local\appdynamics\appagent`.
 - All files should be readable by the user under which the JVM runs. The user must have write privileges to the `conf` and `logs` directories in the Java Agent home. One way to achieve this is to install the agent as the same user that owns the JVM or as an administrator on the host machine.
 - The application server's runtime directory should be writable by the Java Agent as well.

For information on the contents of the Java Agent home directory, see [Java Agent Directory Structure](#).

Configure the Java Agent

If you downloaded the agent from the Agent Download Wizard in the Controller, you can skip to [the next section](#), as the agent is already configured.

To configure the settings manually (or verify the wizard settings):

1. Edit the versioned configuration file:

```
<agent_home>/<version_number>/conf/controller-info.xml
```

 The controller-info.xml is one of several approaches available for supplying configuration settings. For others, see [Java Agent Configuration Properties](#).
2. Modify the connection settings to the Controller:
 - `controller-host` : Set to the IP address or hostname of the Controller. If the agent needs to connect through a proxy, see "Proxy Properties for the Controller" in [Java Agent Configuration Properties](#).
 - `controller-port` : Set to the primary listening port number on the Controller. By default:
 - For a SaaS Controller, use 80 for HTTP or 443 for HTTPS
 - For an on-premises Controller, use 8090 for HTTP or 8181 for HTTPS
3. Direct the agent to connect to the Controller by SSL (HTTPS) by setting the `controller-ssl-enabled` value to true. See [Enable SSL for the Java Agent](#).
4. Identify the business application, tier, and node that this the monitored JVM belongs to in the AppDynamics application model using these settings:
 - `application-name`
 - `tier-name`
 - `node-name`

In a self-service Trial edition of AppDynamics Pro, the agent uses a default naming scheme, see [Java Agent](#). You can use automatic naming with a standard edition of AppDynamics Pro by adding this property:

```
<auto-naming>true</auto-naming>
```

5. If the agents connects to a SaaS Controller or other multi-tenant Controller, configure the Account Name. For all Controllers, configure the Account Access Key.

- `account-name`
- `account-access-key`

This information is provided in the Welcome email from the AppDynamics Team when you acquired the Controller. For a multi-tenant on-premises Controller, you can find this information in `<controller_home>/initial_account_access_info.txt`

6. See [Java Agent Configuration Properties](#) and configure any additional properties required in your environment.

The following shows a `controller-info.xml` file with sample configuration values:

```
<controller-info>
  <controller-host>192.168.1.20</controller-host>
  <controller-port>8090</controller-port>
  <application-name>ACMEOnline</application-name>
  <tier-name>InventoryTier</tier-name>
  <node-name>Inventory1</node-name>
</controller-info>
```

Load the Java Agent in a JVM

After configuring the agent settings, you can add the agent to the JVM. The exact steps for doing so vary by framework. The general approach involves specifying the agent as a `-javaagent` argument to the startup command for the JVM.

Ensure to add the `-javaagent` argument before the `-jar` argument.

The argument should indicate the location of the Java Agent JAR file:

```
-javaagent:<agent_home>/javaagent.jar
```

On Windows, include the drive letter in the path to the agent:

```
-javaagent:C:<agent_home>\javaagent.jar
```

i In some scenarios, you need to use double backslashes instead of single backslashes. For example:

```
-javaagent:C:\\appdynamics\\javaagent.jar
```

Adding `javaagent` to the startup script requires a restart of the JVM. If it's not possible to restart the JVM when you are installing the agent and modifying the JVM start up script, you can attach the agent dynamically to the running Java process.

See [Agent Installation by Java Framework](#) for more information on how to install Java Agent by Java framework or technology.

Attach the Java Agent to a Running JVM Process

Attaching the agent to a running JVM allows you to install the Java Agent without requiring a JVM restart. This approach would normally be used alongside adding the `-javaagent` argument to the JVM startup script, or some other persistent approach to ensure that the agent is loaded again at the next JVM restart. However, the dynamic attachment allows you to install the agent when restarting the JVM is not possible or convenient.

i In some scenarios, you need to use double backslashes instead of single backslashes. For example:

```
-javaagent:C:\\appdynamics\\javaagent.jar
```

Dynamic agent attachment works if:

- JVM is => 1.6.
- JVM is an Oracle (HotSpot) JVMs (unavailable for IBM or JRockit JVMs).

Other considerations include:

- Do not attach the agent dynamically to an environment that is already instrumented (either by the AppDynamics Java Agent or another type of agent). Doing so can cause unforeseeable issues and errors.
- Attaching the AppDynamics Java Agent to a running environment will impact the performance of the application while the agent performs the class retransformation needed to instrument the application. The agent overhead will return to its [normal operating level](#) when it finishes the process, but it is important to consider the potential performance impact to production services.

To attach the agent to the JVM:

1. Determine the PID of the JVM to which you want to attach.

For Linux, use:

```
ps -A | grep java
```

On Windows, use:

```
jps -l
```

2. Run the following command, replacing the placeholders for the path to the `tools.jar` file in your JDK, path to the AppDynamics Java Agent home directory, and the JVM process ID with values appropriate for your environment:

```
java -Xbootclasspath/a:<path_to_jdk>/lib/tools.jar -jar /
<agent_home>/javaagent.jar <jvm_process_id>
appdynamics.controller.hostName=<controller_hostname>, appdyna
mics.controller.port=<controller_port_no>, appdynamics.control
```

```
ler.ssl.enabled=false, appdynamics.agent.applicationName=<app_name>, appdynamics.agent.tierName=<agent_tier_name>, appdynamics.agent.nodeName=<agent_node_name>
```

Use the equivalent paths for Windows, including drive letter. The following shows an example with system output included:

```
[appduser@my_centos6 ~]$ ps -A | grep java
6780 pts/1    00:00:04 java
[appduser@my_centos6 ~]$ java -Xbootclasspath/a:/usr/java/jdk1.7.0_79/lib/tools.jar -jar /home/appduser/appagent/javaagent.jar 6780
Attaching to VM [6780]
agent path >>>/home/appduser/appagent/javaagent.jar=
```

Verify Java Agent Installation

After an installation, the agent log in `<agent_home>/logs` will contain this message:

```
Started AppDynamics Java Agent Successfully
```

If the agent log file is not present, the Java Agent may not be accessing the `javaagent` command properties. To troubleshoot, check the application server log file where `STDOUT` is logged. It will have the fallback log messages, useful for troubleshooting the agent.

Also, verify that the agent is able to connect to the Controller in the Controller UI. To verify, log in to the Controller UI and click the **Settings** icon at the top right of the page, and then **AppDynamics Agents**. In the list, search for the agent by machine hostname.

Install the Java Agent in Containers

This page explains how to install the Java Agent in a containerized environment. See [Container Platforms](#) to for your options. There are three options to install the Java Agent with containers:

- [Use Auto-Instrumentation](#)
- [Use Init Containers](#)
- [Use a Dockerfile](#)

Use Auto-Instrumentation

i This scenario applies to containers running in Kubernetes where the Cluster Agent is installed.

This option uses the Auto-Instrumentation feature of the Cluster Agent. It is the recommended option because it offers the highest level of automation and the simplest operational experience for instrumenting Java applications in a Kubernetes cluster.

To get started, see [Auto-Instrument Applications with the Cluster Agent](#).

Use Init Containers

 This scenario applies to containers running in Kubernetes.

This option uses Kubernetes init containers to copy the agent binaries into the application container. It is the recommended option when Auto-Instrumentation is not possible. In this use case, it assumes there are two containers:

- Application image is built without any Java Agent binaries.
- Second init container image is built and only contains the Java Agent binaries.

The deployment spec for the application is configured to copy the agent binaries to the running application container. To use init containers to copy the agent binaries:

1. [Build the Java Application Image](#)
2. [Build the Java Agent Init Container Image](#)
3. [Redirect Agent Output to Stdout](#)
4. [Add the Init Container to the Deployment Spec](#)
5. [Set the Java Agent Environment Variables](#)
6. [Add the -javaagent Argument to the Deployment Spec](#)
7. [\(OpenShift only\) Set the APPDYNAMICS_AGENT_UNIQUE_HOST_ID Environment Variable](#)
8. [\(On-Premises Controller only\) Copy the Controller Certificates to the Container](#)

Build the Java Application Image

When building the Java application image, do not include the Java Agent binaries.

Build the Java Agent Init Container Image

The Java Agent image is built separately from the application image and can be reused across multiple Java application deployments. This [Dockerfile](#) is an example of building the Java Agent init container image using a multi-stage build. Alternatively, the init container can reference a pre-built image from AppDynamics on [Docker Hub](#).

Redirect Agent Output to Stdout

It is a best practice to redirect agent output to `stdout` in containerized environments. If you build your own Java Agent init container image, you can redirect the Java agent output to `stdout` by updating the `ver<version>/conf/logging/log4j2.xml` file that is provided in the download package. Add two `<AppenderRef ref="Console"/>` elements as shown in the [example log4j2.xml file](#). If you use a pre-built image from AppDynamics on [Docker Hub](#), you can replace the default `ver<version>/conf/logging/log4j2.xml` file based on the [example log4j2.xml file](#) using a ConfigMap. Follow the same procedure shown for [Copy the Controller Certificates to the Container](#).

Add the Init Container to the Deployment Spec

Edit the deployment spec to add the required sections that allow you to copy the agent binaries from the init container to the application image.

The following snippet from a deployment spec shows the required `volumes`, `volumeMounts`, and `initContainer` definitions. The code example assumes the Java application image is published to `myrepo/java-app:v1` and the init container image uses the pre-built image `docker.io/appdynamics/java-agent:20.6.0`:

```

kind: Deployment
spec:
  containers:
  - name: java-app
    image: myrepo/java-app:v1
    volumeMounts:
    - mountPath: /opt/appdynamics
      name: appd-agent-repo
  initContainers:
  - command:
    - cp
    - -r
    - /opt/appdynamics/.
    - /opt/temp
    name: appd-agent
    image: docker.io/appdynamics/java-agent:20.8.0
    volumeMounts:
    - mountPath: /opt/temp
      name: appd-agent-repo
  volumes:
  - name: appd-agent-repo
    emptyDir: {}
  
```

Set the Java Agent Environment Variables

To set all of the required Java Agent environment variables, you must follow these steps as explained in [Best Practices to Configure Agents in Kubernetes](#).

- [Use ConfigMaps to Configure the App Server Agent](#)
- [Use Secrets for the Controller Access Key](#)
- [Set Application-Specific Configuration in the Deployment Spec](#)

Use ConfigMaps to Configure the App Server Agent

1. Use a ConfigMap to set the Java Agent environment variables that are shared across applications in a namespace:

```

apiVersion: v1
data:
  APPDYNAMICS_AGENT_APPLICATION_NAME: "eCommerce"
  APPDYNAMICS_AGENT_ACCOUNT_NAME: "<value>"
  APPDYNAMICS_CONTROLLER_HOST_NAME: "<value>"
  APPDYNAMICS_CONTROLLER_PORT: "<value>"
  APPDYNAMICS_CONTROLLER_SSL_ENABLED: "<value>"
  APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME: "true"
  APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME_PREFIX: "<value>"
kind: ConfigMap
metadata:
  name: ecommerce-java-config
  
```

2. Apply the ConfigMap to the namespace:

```
kubectl -n ecommerce apply -f ecommerce-java-config.yaml
```

3. Update the deployment spec to reference the ConfigMap:

```
spec:
  containers:
  - name: java-app
    envFrom:
    - configMapRef:
      name: ecommerce-java-config
  ...
```

Use Secrets for the Controller Access Key

1. Create a Secret using `kubectl` :

```
kubectl -n ecommerce create secret generic appd-agent-secret --from-literal=access-key=<access-key>
```

2. Update the deployment spec to reference the Secret:

```
spec:
  containers:
  - name: java-app
    env:
    - name: APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY
      valueFrom:
        secretKeyRef:
          name: appd-agent-secret
          key: access-key
```

Set Application-Specific Configuration in the Deployment Spec

Set the application-specific tier name environment variable `APPDYNAMICS_AGENT_TIER_NAME` in the deployment spec:

```
spec:
  containers:
  - name: java-app
    env:
    - name: APPDYNAMICS_AGENT_TIER_NAME
      value: ecommerce-service
```

Add the `-javaagent` Argument to the Deployment Spec

Edit the deployment spec to add the `-javaagent` argument to the application container startup command as shown in the example:

```
spec:
  containers:
    command: ["/bin/sh"]
    args: ["-c", "java -javaagent:/opt/appdynamics/javaagent.jar -jar /myapp.jar"]
```

Note that for some Java frameworks such as Spring Boot, you can leverage the standard `JAVA_TOOL_OPTIONS` environment variable to include the `-javaagent` argument.

(OpenShift Only) Set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` Environment Variable

For Java applications running in OpenShift, set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` environment variable to enable APM correlation with the Cluster Agent. Since the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` value depends on a runtime value, set this environment variable in the container startup command.

For example, for an OpenShift 3.10 or 3.11 environment, set the environment variable as shown:

```
spec:
  containers:
    command: ["/bin/sh"]
    args: ["-c", "APPDYNAMICS_AGENT_UNIQUE_HOST_ID=$(sed -rn '1s#.*/#; 1s/docker-({12}).*/\1/p' /proc/self/cgroup) && java -javaagent:/opt/appdynamics/javaagent.jar -jar /myapp.jar"]
```

For your use case, see values documented in [Manually Configure App Agents to Correlate with the Cluster Agent](#).

(On-Premises Controller Only) Copy the Controller Certificates to the Container

If on-premises Controller certificates are required, define a ConfigMap to reference the `cert` file and use a `volume mount` in the deployment spec to mount the ConfigMap contents to the container.

```
$ kubectl create configmap appd-cert --from-file=cacerts.jks
```

Add the `cert` file, in this example, `appd-cert`, to the container file system using `volumes` and `volumeMounts` as shown in the deployment spec snippet:

```
kind: Deployment
spec:
  containers:
    image: myrepo/java-app:v1
    volumeMounts:
      - name: appd-cert
        subPath: cacerts.jks
        mountPath: /opt/appdynamics/ver4.5.11.26665/conf/cacerts.jks
  volumes:
    - name: appd-cert
      configMap:
        name: appd-cert
```

Example Configuration for Using an Init Container

A complete example of a deployment spec that uses an init container to copy the agent binaries can be found on Github: `java-app.yaml`.

Use a Dockerfile

i This scenario applies to containers running in Docker and Kubernetes.

This option uses a Dockerfile to copy the Java Agent to the Docker image at build time. To use the option, create a single image that contains both the application and Java Agent binaries.

To copy the agent into the application image during the Docker image build:

1. Download and Unzip the Java Agent
2. Redirect Agent Output to Stdout
3. Copy the Agent Binaries to the Image
4. Set the Java Agent Environment Variables
5. Add the `-javaagent` Argument to the Startup Command
6. (OpenShift only) Set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` Environment Variable
7. (On-Premises Controller only) Copy the Controller Certs to the Image

Download and Unzip the Java Agent

[Download](#) the Java Agent from the AppDynamics Downloads center or [programmatically download the agent](#). The agent is packaged as a zip file. In a shell, unzip the AppServer Agent to the `AppServerAgent` directory:

```
$ unzip AppServerAgent-<version>.zip -d AppServerAgent
```

Redirect Agent Output to Stdout

It is a best practice to redirect agent output to `stdout` in containerized environments. To redirect the output of the Java Agent to `stdout`, edit the `ver<version>/conf/logging/log4j2.xml` file and add two `<AppenderRef ref="Console"/>` elements as shown in the [example log4j2.xml file](#).

Copy the Agent Binaries to the Image

Edit the Dockerfile to copy the unpackaged agent binaries to the target folder:

```
COPY AppServerAgent/ /opt/appdynamics/
```

Set the Java Agent Environment Variables

If you are running the application in a non-Kubernetes environment (using `docker run` for example), set the agent environment variables in the Dockerfile. For example:

```
ENV APPDYNAMICS_AGENT_APPLICATION_NAME=<value>
ENV APPDYNAMICS_AGENT_TIER_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_NAME=<value>
```

```

ENV APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=<value>
ENV APPDYNAMICS_CONTROLLER_HOST_NAME=<value>
ENV APPDYNAMICS_CONTROLLER_PORT=<value>
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED=<value>
ENV APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME=true
ENV APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME_PREFIX=<value>
  
```

For Kubernetes applications, omit these environment variables from the Dockerfile and set them using ConfigMaps and Secrets as described in [Best Practices to Configure Agents in Kubernetes](#).

The reuse node name and prefix environment variables are required to support unique naming for multiple container instances for the same application image. See [Reuse Node Name](#).

Add the `-javaagent` Argument to the Startup Command

Edit the Dockerfile to include the `-javaagent` argument in the image start command based on the location where the agent binaries were copied. For example:

```

ENV JAVA_OPTS -javaagent:/opt/appdynamics/javaagent.jar
CMD ["java", "$JAVA_OPTS", "-jar", "/myapp.jar"]
  
```

Note that for some Java frameworks such as Spring Boot, the existing `JAVA_TOOL_OPTIONS` environment variable can be leveraged to include the `-javaagent` argument.

(OpenShift Only) Set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` Environment Variable

For Java applications running in OpenShift, set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` environment variable to enable APM correlation with the Cluster Agent. Since the value depends on a runtime value, set this environment variable in the image startup script using the values documented in [Manually Configure App Agents to Correlate with the Cluster Agent](#). For example, for an OpenShift 3.10 or 3.11 environment, add this startup script `startup.sh` to the Docker image:

```

#!/bin/bash
# OpenShift 3.10 or 3.11:
APPDYNAMICS_AGENT_UNIQUE_HOST_ID=$(sed -rn '1s#.*/##; 1s/docker-({12}).*/\1/p' /proc/self/cgroup)
exec java $JAVA_OPTS -jar /myapp.jar
  
```

and update the startup command in the Dockerfile to reference it:

```

CMD ["/startup.sh"]
  
```

(On-Premises Controller Only) Copy the Controller Certs to the Image

For Java Agents communicating with an on-premises Controller, edit the Dockerfile to copy the cert file containing the on-premises certs to the agent `conf` folder. For example:

```

COPY ./onprem-cacerts.jks /opt/appdynamics/ver4.5.11.26665/conf/cacerts.jks
  
```

See [Enable SSL for the Java Agent](#).

Example Configuration for Using a Dockerfile

This [Dockerfile](#) builds a single image with the application and agent binaries included and this [Kubernetes deployment spec](#) references that Docker image. This [Dockerfile](#) uses a multi-stage build and downloads and unzips the agent.

Example Log4j Configuration File

This updated `ver<version>/conf/logging/log4j2.xml` configuration file redirects the Java Agent logs to stdout. It adds `<AppenderRef ref="Console"/>` to the Root element.

```
<?xml version="1.0" encoding="UTF-8"?>
<Configuration status="INFO" monitorInterval="2">
  <Appenders>
    <Console name="Console" target="SYSTEM_OUT">
      <PatternLayout pattern="%t %d{ABSOLUTE} %5p %c{1} - %m%n" />
    </Console>
    <ADRRFAAppender name="DefaultAppender" fileName="agent.log">
      <PatternLayout pattern="%t %d{DATE} %5p %c{1} - %m%n" />
      <SizeBasedTriggeringPolicy size="20 MB" />
      <ADRRolloverStrategy max="5" />
      <RegexFilter regex=".*REST.*" onMatch="DENY" onMismatch="ACCEPT" />
    </ADRRFAAppender>
    <ADRRFAAppender name="BCTAppender" fileName="ByteCodeTransformer.log">
      <PatternLayout pattern="%t %d{DATE} %5p - %m%n" />
      <SizeBasedTriggeringPolicy size="20 MB" />
      <ADRRolloverStrategy max="5" />
    </ADRRFAAppender>
    <ADRRFAAppender name="RESTAppender" fileName="REST.log">
      <PatternLayout pattern="%t %d{DATE} %5p %c{1} - %m%n" />
      <RegexFilter regex=".*REST.*" onMatch="ACCEPT" onMismatch="DENY" />
      <SizeBasedTriggeringPolicy size="20 MB" />
      <ADRRolloverStrategy max="5" />
    </ADRRFAAppender>
    <ADRRFAAppender name="DynamicServiceAppender" fileName="dynamic-service.log">
      <PatternLayout pattern="%t %d{DATE} %5p %c - %m%n" />
      <SizeBasedTriggeringPolicy size="20 MB" />
      <ADRRolloverStrategy max="5" />
    </ADRRFAAppender>
    <ADRRFAAppender name="BusinessTransactionsLogger" fileName="BusinessTransactions.log">
      <PatternLayout pattern="%t %d{DATE} %5p - %m%n" />
      <SizeBasedTriggeringPolicy size="20 MB" />
      <ADRRolloverStrategy max="5" />
    </ADRRFAAppender>
    <ADRRFAAppender name="DataPipelineAppender" fileName="data-pipeline.log">
      <PatternLayout pattern="%t %d{DATE} %5p %c - %m%n" />
      <SizeBasedTriggeringPolicy size="20 MB" />
      <ADRRolloverStrategy max="5" />
    </ADRRFAAppender>
    <ADRRFAAppender name="APIAppender" fileName="api.log">
      <PatternLayout pattern="%t %d{DATE} %5p %c - %m%n" />
      <SizeBasedTriggeringPolicy size="20 MB" />
    </ADRRFAAppender>
  </Appenders>
</Configuration>
```

```

    <ADRolloverStrategy max="5" />
  </ADRRAFAppender>
</Appenders>
<Loggers>

```

Agent Installation by Java Framework

These pages describe individual considerations and instructions for installing the Java Agent for some of the application servers supported for the Java Agent.

- [Apache Cassandra Startup Settings](#)
- [Apache Tomcat Startup Settings](#)
- [Apple WebObjects Startup Settings](#)
- [Coherence Startup Settings](#)
- [GlassFish Startup Settings](#)
- [IBM WebSphere and InfoSphere Startup Settings](#)
- [JBoss and Wildfly Startup Settings](#)
- [Jetty Startup Settings](#)

- [Mule ESB Startup Settings](#)
- [Oracle WebLogic Startup Settings](#)
- [OSGi Infrastructure Configuration](#)
- [Resin Startup Settings](#)
- [Apache Solr Startup Settings](#)
- [Standalone JVM Startup Settings](#)
- [Tanuki Service Wrapper Settings](#)
- [Tibco ActiveMatrix BusinessWorks Service Engine Settings](#)
- [webMethods Startup Settings](#)
- [Java Security Manager Configuration](#)
- [WSO2 API Microgateway Startup Settings](#)

Apache Cassandra Startup Settings

The Java Agent bootstraps using the `javaagent` command line option. Add this option to the `cassandra` (Linux) or `cassandra.bat` (Windows) file.

Instrument Cassandra in a Windows Environment

1. Open the `apache-cassandra-x.x.x\bin\cassandra.bat` file.
2. Add the Java Agent `javaagent` path to the `JAVA_OPTS` variable. Make sure to include the drive in the full path to the Java Agent directory.

```
-javaagent:<agent_home>\javaagent.jar
```

For example:

```
set JAVA_OPTS=-ea
    -javaagent:C:\appdynamics\agent\javaagent.jar
    -javaagent:"%CASSANDRA_HOME%\lib\jamm-0.2.5.jar
    . . .
```

3. Restart the Cassandra server for the changes to take effect.

Instrument Cassandra in a Linux Environment

1. Open the `apache-cassandra-x.x.x/bin/cassandra.in.sh` file.
2. Add the `javaagent` argument at the top of the file:

```
JVM_OPTS=-javaagent:<agent_home>/javaagent.jar
```

For example:

```
JVM_OPTS=-javaagent:/home/software/appdynamics/agent/javaagent.jar
```

3. Restart the Cassandra server for the changes to take effect.

Apache Tomcat Startup Settings

To instrument applications on Apache Tomcat, add the Java Agent JAR location as a Catalina environment, or `CATALINA_OPTS` variable.

Instrument Apache Tomcat

1. Open (or create if it doesn't already exist) the `setenv.sh` (Linux) or `setenv.bat` (Windows) file. For Tomcat 6 and later, you can put the file in the `CATALINA_BASE/bin` directory. For previous versions of Tomcat, put the file in the `CATALINA_HOME/bin` directory
2. Add the `-javaagent` argument to the file as a Catalina environment variable, as follows:

On Linux:

```
export CATALINA_OPTS="$CATALINA_OPTS -javaagent:<agent_home>/javaagent.jar"
```

Replace `<agent_home>` with the full path to the Java Agent JAR file.

For example:

```
export CATALINA_OPTS="$CATALINA_OPTS -javaagent:/home/appserver/appagent/javaagent.jar"
```

On Windows:

```
set CATALINA_OPTS=%CATALINA_OPTS% -javaagent:"Drive:<agent_home>\javaagent.jar"
```

For example

```
set CATALINA_OPTS=%CATALINA_OPTS% -javaagent:C:\appagent\javaagent.jar
```

3. Restart the application server for the changes to take effect. For more information on running Tomcat as a service, see [Setting Properties and Options on Startup](#).

Instrument Tomcat When Running as a Windows Service

When running Tomcat as a Windows service, add the `javaagent` argument to your Tomcat startup properties. These instructions apply to Apache Tomcat >= 6.x.

To install the Java agent in Tomcat running as a Windows service:

1. Ensure that you are using administrator privileges.
2. Run the Apache `tomcat<version>w.exe` utility to configure your tomcat service to load the appdynamics agent (where `<version>` represents the major version number of the tomcat being instrumented).

For example:

```
tomcat8w //ES//<servicename>
```

3. Click the **Java** tab and in the **Java Options** add:

```
-javaagent:<agent_home>\javaagent.jar
```

4. Restart the Tomcat service to have the changes take effect.

Apple WebObjects Startup Settings

This page describes how to instrument applications written with WebObjects 5.4.3 on OSX 10.9 systems.

We will use one of the developer examples to illustrate how to instrument an application created with Apple WebObjects. After installing WebObjects, you can find most of the artifacts in the following directories:

```
/Developer/Examples/JavaWebObjects
/Developer/Applications/WebObjects
```

When you run the `HelloWorld` application at `/Developer/Examples/JavaWebObjects/HelloWorld`, a script file is generated:

```
/Developer/Examples/JavaWebObjects/HelloWorld/dist/legacy/
HelloWorld.woa/HelloWorld
```

Open the generated script file to edit. Towards the end of the file, line 310 in the following example, appears the Java execute line:

```
304 #
305 # Launch the application.
306 #
307 echo Launching ${SCRIPT_NAME}.woa ...
308
309 echo ${JAVA_EXECUTABLE} ${JAVA_EXECUTABLE_ARGS} -classpath W0Bootstrap.jar com.webobjects_bootstrap.W0Bootstrap ${COMMAND_LINE_ARGS}
310 eval exec ${JAVA_EXECUTABLE} ${JAVA_EXECUTABLE_ARGS} -classpath W0Bootstrap.jar com.webobjects_bootstrap.W0Bootstrap ${COMMAND_LINE_ARGS}
-
-
-
```

Add the standard Java Agent arguments to the Java execution script for the `HelloWorld` application:

```
307 echo Launching ${SCRIPT_NAME}.woa ...
308
309 echo ${JAVA_EXECUTABLE} ${JAVA_EXECUTABLE_ARGS} -classpath W0Bootstrap.jar com.webobjects_bootstrap.W0Bootstrap ${COMMAND_LINE_ARGS}
310 eval exec ${JAVA_EXECUTABLE} ${JAVA_EXECUTABLE_ARGS} -Dappdynamics.controller.hostName=localhost \
311 -Dappdynamics.controller.port=8080 \
312 -Dappdynamics.agent.accountName=customer1 \
313 '-Dappdynamics.agent.accountAccessKey=SJ5b2m7d1\354' \
314 -Dappdynamics.controller.ssl.enabled=false \
315 -Dappdynamics.agent.applicationName=play-correlation \
316 -Dappdynamics.agent.uniqueHostId=play-correlation \
317 -Dappdynamics.agent.tierName=standalone-tier \
318 -Dappdynamics.agent.nodeName=standalone-node \
319 -javaagent:/Users/akilman/Work/codebase/agent/java/core/build/temp/javaagent.jar \
320 -agentlib:jdwp=transport=dt_socket,server=y,suspend=n,address=5006 \
321 -classpath W0Bootstrap.jar com.webobjects_bootstrap.W0Bootstrap ${COMMAND_LINE_ARGS}
NORMAL /Developer/Examples/JavaWebObjects/HelloWorld/dist/legacy/HelloWorld.woa/HelloWorld
```

Note: Single quotes and extra escape to account for 'eval'

You can configure business transaction name using getter-chains. For more information, see

- [Using Getter Chains](#)
- See "Split by POJO Method Call" on [Split Servlet Transaction by Payload Examples](#)

Coherence Startup Settings

To add the `javaagent` command in Oracle Coherence:

1. In the `<coherence_home>/bin/cache-server.sh` file, update the following:

```
$JAVAEXEC -server -showversion $JAVA_OPTS -javaagent:<agent_home>/javaagent.jar -cp
"$COHERENCE_HOME/lib/coherence.jar" com.tangosol.net.DefaultCacheServer $1
```

2. Restart the application server to have the changes take effect.

GlassFish Startup Settings

Oracle GlassFish is an OSGi-based application container. This page describes how to set configure class bootloader settings and load the Java Agent in the runtime JVM.

Instrument Oracle GlassFish

1. Add the location of the Java Agent JAR file as a `-javaagent` JVM option in the `GlassFish` domain. You can add the agent using the `asadmin` tool as follows:
For Windows:

```
glassfish4\bin\asadmin.bat create-jvm-options '-
javaagent:<Drive_letter>:<agent_home>\javaagent.jar'
```

For Linux:

```
glassfish4\bin\asadmin create-jvm-options "-javaagent\:/home/appduser/javaagent/
javaagent.jar"
```

Ensure you escape the colon character on Linux.

2. Configure the boot delegation entry for the AppDynamics package:
 - In GlassFish 3.x to 3.1.2, open the `config.properties` file located at `<glassfish_home>/glassfish/osgi/felix/conf` and add the following package prefix to the `config.properties` file:
`org.osgi.framework.bootdelegation=com.singularity.*`
 - In GlassFish => 3.1.2, in the boot delegation list in the `<glassfish_home>/glassfish/config/osgi.properties` file, add `com.singularity.*`

For example:

```
eclipselink.bootdelegation=oracle.sql, oracle.sql.*

# There is no need to use bootdelegation except for the following issues:
# 1. EclipseLink
# 4. NetBeans profiler packages exist in parent class loader (see issue #8612)
# 5. BTrace exists in bootclasspath.
org.osgi.framework.bootdelegation=${eclipselink.bootdelegation}, \
                                com.sun.btrace, com.sun.btrace.*, \
                                org.netbeans.lib.profiler, org.netbeans.lib.profiler.*, \
                                com.singularity.*

# The OSGi R4.2 spec says boot delegation uses the boot class loader by default. We need
# to configure it to use the framework class loader because that class loader is
```

3. Restart the application server.

To verify the configuration, review the `domain.xml` file located at `<glassfish_home>\domains\<domain_name>\config`. The `domain.xml` file should have an entry for the `-javaagent` option.

Instrument Oracle GlassFish with the Admin Console

1. Start the GlassFish application server.
2. Navigate to the GlassFish admin console (`http://localhost:4848/`).
3. Navigate to **Configurations > server-config > JVM Settings**.
4. Click the **JVM Options** tab and click **Add JVM Option** to add a blank field in the list.

5. Add the following path of the `javaagent.jar` file in the blank field:

```
-javaagent:/home/appduser/javaagent/javaagent.jar
```

6. Click **Save** on the right top corner.
7. Restart the GlassFish application server and `<glassfish_home>\domains\<domain_name>\config`. The `domain.xml` file must contain an entry for the `-javaagent` option.

```
<jvm-options>-Djavax.net.ssl.keyStore=${com.sun.aas.instanceRoot}/config/keystore.jks</jvm-options>
<jvm-options>-DANTLR_USE_DIRECT_CLASS_LOADING=true</jvm-options>
<jvm-options>-Xmx512m</jvm-options>
<jvm-options>-Dfelix.fileinstall.bundles.startTransient=true</jvm-options>
<jvm-options>-javaagent:/Users/debadash/Documents/AppServerAgent-20.8GA/javaagent.jar</jvm-options>
<jvm-options>-Dcom.ctc.wstx.returnNullForDefaultNamespace=true</jvm-options>
<jvm-options>-client</jvm-options>
<jvm-options>-Dosgi.shell.telnet.ip=127.0.0.1</jvm-options>
<jvm-options>-Dcom.sun.enterprise.security.httpsOutboundKeyAlias=s1as</jvm-options>
<jvm-options>-Djavax.net.ssl.trustStore=${com.sun.aas.instanceRoot}/config/cacerts.jks</jvm-options>
<jvm-options>-XX:NewRatio=2</jvm-options>
</java-config>
```

About Glassfish AMX Support

AppDynamics supports Glassfish AMX MBeans.

Set the `boot-amx` node property to enable AMX MBeans. See [boot-amx](#).

You will see the AMX domain in the MBean Browser in the **JMX** tab of the node dashboard.

IBM WebSphere and InfoSphere Startup Settings

The Java Agent passes the `-javaagent` argument command line option to WebSphere to ensure the App Server Agent has the correct permissions to monitor your app.

Security Requirements and Configuration

Full permissions are required for the agent to function correctly with WebSphere. Grant all permissions on both the server level and the profile level.

Run WebSphere with Security Enabled

To run WebSphere while J2EE security or Global security is enabled, you must make changes to WebSphere's `server.policy` file to prevent problems with the interaction between WebSphere and the Java Agent.

A `codeBase` value indicates the location of the source code. You must grant permissions to the code from that location. The `codeBase` is a URL value, and depends on the characters at the end. A `codeBase` with a trailing `"/-"` matches all files, both class and JAR files, in the directory and recursively all files in subdirectories contained in the directory.

1. Navigate to the `server.policy` file, located in `<websphere_home>/properties` or in `<websphere_profile_home>/properties`.
2. Add this code block to the WebSphere `server.policy` file:

Syntax

```
grant codeBase "file:</full/path/to/agent_install_directory>/-" { permission
java.security.AllPermission; };
```

Example

```
grant codeBase "file:/opt/appdynamics/javagent/agent4.5.1.23676/-" { permission
java.security.AllPermission; };
```

3. Save the file.

Performance Monitoring Statistic

Under **Application servers** > `<server_name>` > **Performance Monitoring Infrastructure (PMI)**, set a **Currently monitored statistic set** to an option other than **None** for the JMX functionality to work.

Instrument WebSphere 7.x, 8.x, and 9.x, or InfoSphere 8.x

1. Log in to the administrative console for the WebSphere node where you want to install the App Server Agent.
2. In the administrative console, select **Servers > Server Types > WebSphere application servers**.
3. Select the name of your server.

4. In the **Server Infrastructure** section, select **Java and Process Management > Process Definition**.

The screenshot shows the 'Process Definition' configuration page. The breadcrumb trail is 'Application servers > server1 > Process definition'. Below the breadcrumb, there is a description: 'Use this page to configure a process definition. A process definition defines the command line information necessary to start or initialize a process.' The page is divided into two main sections: 'General Properties' and 'Additional Properties'.

General Properties:

- Executable name: [Text input field]
- Executable arguments: [Text area]
- Start command: [Text input field]
- Start command arguments: [Text area]
- Stop command: [Text input field]
- Stop command arguments: [Text area]
- Working directory: [Text input field] (value: \${USER_INSTALL_ROOT})
- Executable target type: [Dropdown menu] (value: JAVA_CLASS)
- Executable target: [Text input field] (value: com.ibm.ws.runtime.WsServer)

Additional Properties:

- Java Virtual Machine
- Environment Entries
- Process execution
- Process Logs
- Logging and tracing

At the bottom of the 'General Properties' section, there are buttons for 'Apply', 'OK', 'Reset', and 'Cancel'.

5. Under the **Additional Properties** section, select **Java Virtual Machine**.

The screenshot shows the 'Additional Properties' configuration page. The breadcrumb trail is 'Application servers > server1'. Below the breadcrumb, there is a description: 'Use this page to configure an application server. An application server is a server that provides services required to run enterprise applications.' The page is divided into two main sections: 'General Properties' and 'Additional Properties'.

General Properties:

- Name: [Text input field] (value: server1)
- Node name: [Text input field] (value: ubuntuNode01)
- Run in development mode
- Parallel start
- Start components as needed
- Access to internal server classes: [Dropdown menu] (value: Allow)

Server-specific Application Settings:

- Classloader policy: [Dropdown menu] (value: Multiple)
- Class loading mode: [Dropdown menu] (value: Classes loaded with parent class loader first)

Additional Properties:

- Container Settings
 - Session management
 - SIP Container Settings
 - Web Container Settings
 - Portlet Container Settings
 - EJB Container Settings
 - Container Services
 - Business Process Services
- Applications
 - Installed applications
- Server messaging
 - Messaging engines
 - Messaging engine inbound transports
 - WebSphere MQ link inbound transports
 - SIB service
- Server Infrastructure
 - Java and Process Management
 - Administration
 - Java SDKs
- Communications
 - Ports
 - Messaging
- Performance
 - Performance Monitoring Infrastructure (PMI)
 - Performance and Diagnostic Advisor Configuration

At the bottom of the 'General Properties' section, there are buttons for 'Apply', 'OK', 'Reset', and 'Cancel'.

- Enter the `javaagent` option with the full path to the AppDynamics `javaagent.jar` file in the **Generic JVM arguments** field.

For Windows:

```
-javaagent:<Drive Letter>:\agent install location\javaagent.jar
```

For Linux:

```
-javaagent:<agent install location>/javaagent.jar
```

- Click **OK**.

WebSphere uses Equinox as its OSGi container. In some cases, you may also need to add the Java agent packages to the OSGi `bootdelegation` system property:

```
-Dorg.osgi.framework.bootdelegation=META-INF.services,com.singularity.*,com.ibm.*
```

Instrument WebSphere 6.x

1. Log in to the administrative console for the WebSphere node where you want to install the Java Agent.
2. In the left navigation tree, select **Servers > Application servers**.
3. Click the name of your server in the list of servers.

For quick access, place your bookmarks here in the bookmarks bar.

-javaagent:E:\test1\AppServi

Additional Properties

- Custom Properties

6. Click **OK**.

Instrument WebSphere 5.x

1. Log in to the administrative console of the WebSphere node where you want to install the App Server Agent.
2. In the administrative console, click **Servers**.
3. Click **Application Servers**.
4. Click the name of your server.
5. Under **Additional Properties**, click **Process Definition**.
6. On the next page, under **Additional Properties**, click **Java Virtual Machine**.
7. Enter the `javaagent` option with the full path to the Java Agent `javaagent.jar` file in the **Generic JVM arguments** field.

For Windows:

```
-javaagent:<Drive Letter>:<agent install location>\javaagent.jar
```

For Linux:

```
-javaagent:<agent install location>/javaagent.jar
```

8. Click **OK**.

Verify the Java Agent Configuration

Verify the configuration settings by checking the `server.xml` file of the WebSphere node where you installed the Java Agent. The `server.xml` file should have this entry:

```
<jvmEntries ... genericJvmArguments='-javaagent:E:\test1\AppServerAgent\javaagent.jar'  
  disableJIT="false"/>
```

JBoss and Wildfly Startup Settings

This page describes how to install the AppDynamics Java Agent on Red Hat JBoss Enterprise Application Server and JBoss Wildfly.

Before You Install

To install the agent on JBoss or Wildfly, you add the Java Agent and log manager packages to the server startup routine.

The configured location varies based on your framework version:

- In Linux, add the settings to `standalone.conf` or `standalone.sh`.
- In Windows, add the settings to `standalone.conf.bat`.
- If using JBoss 4.x or 5.x, add the configuration to `run.sh` for Linux or `run.bat` for Windows.

Initialize the JVM

To install the Java Agent on JBoss EAP or JBoss Wildfly, you need to initialize the JVM. Run this parameter:

```
JAVA_OPTS="$JAVA_OPTS  
-Djboss.modules.system.pkgs=org.jboss.byteman,com.singularity"
```

If you do not initialize the JVM, the installation generates a "class not found" exception.

Ensure that the property `jboss.modules.system.pkgs` is available in the environment. If the property is present, then add `com.singularity` to it.

For example:

```
-Djboss.modules.system.pkgs=org.jboss.byteman,com.singularity
```

If the property is not present, then configure a new one:

```
-Djboss.modules.system.pkgs=com.singularity
```

Standalone Mode Agent Installation

These instructions assume the use of Red Hat JBoss (Application Server 7.x or Enterprise Application Server >= 6.x).

To install the Java Agent on JBoss Standalone:

[Linux](#) [Windows](#)

1. Open the `bin/standalone.sh` file.
2. Add the following `javaagent` argument:

```
export JAVA_OPTS="$JAVA_OPTS -javaagent:/agent_install_dir/javaagent.jar"
```

3. Specify the argument above the following section of `standalone.sh`:

```
...
while true;do
if [ "x$LAUNCH_JBOSS_IN_BACKGROUND" = "X" ]; then
# Execute the JVM in the foreground
eval "\"$JAVA\" -D\"[Standalone]\"$JAVA_OPTS \
\"-Dorg.jboss.boot.log.file=$JBOSS_LOG_DIR/boot.log\" \
\"-Dlogging.configuration=file:$JBOSS_CONFIG_DIR/logging.properties\" \
-jar \"$JBOSS_HOME/jboss-modules.jar\" \
```

4. Restart the application server.
5. Add the following to the end of the `standalone.conf` file in the `JAVA_OPTS` section.

```
-Djava.util.logging.manager=org.jboss.logmanager.LogManager -Xbootclasspath/p:{{}}
<path_to_jboss_logmanager>/jboss-logmanager-<version>.jar
```

JDK9 and above, `-Xbootclasspath/p` option has been removed; use `-Xbootclasspath/a` instead.

```
-Djava.util.logging.manager=org.jboss.logmanager.LogManager -Xbootclasspath/a:
<path_to_jboss_logmanager>/jboss-logmanager-<version>.jar
```

6. Replace `<path_to_jboss_logmanager>` and `<version>` with the path and log manager JAR filename for your system. See [Making the LogManager Location Dynamic](#) for information on making the path dynamic.

 **Note**

Step 5 and Step 6 are required only if the log manager errors manifest. Also, repeat Step 4 after this change.

[Linux](#) [Windows](#)

1. In the `standalone.bat` file, add the following javaagent argument.

```
set JAVA_OPTS=%JAVA_OPTS% -javaagent:\agent_install_dir\javaagent.jar
```

2. Specify the argument above the following section in `standalone.bat` :

```
RESTART
"%JAVA%" %JAVA_OPTS% ^
"-Dorg.jboss.boot.log.file=%JBOSS_LOG_DIR%\server.log" ^
"-Dlogging.configuration=file:%JBOSS_CONFIG_DIR%/logging.properties" ^
-jar "%JBOSS_HOME%\jboss-modules.jar" ^
-mp "%JBOSS_MODULEPATH%" ^
-jaxpmodule "javax.xml.jaxp-provider" ^
org.jboss.as.standalone ^
"-Djboss.home.dir=%JBOSS_HOME%" ^
%SERVER_OPTS%
```

3. Restart the application server.
4. Add the following to the end of the `standalone.conf.bat` file in the `JAVA_OPTS` section.

```
-Djava.util.logging.manager=org.jboss.logmanager.LogManager -Xbootclasspath/p:{{{
<path_to_jboss_logmanager>\jboss-logmanager-<version>.jar
```

JDK9 and above, `-Xbootclasspath/p` option has been removed; use `-Xbootclasspath/a` instead.

```
-Djava.util.logging.manager=org.jboss.logmanager.LogManager -Xbootclasspath/a:
<path_to_jboss_logmanager>/jboss-logmanager-<version>.jar
```

5. Replace `<path_to_jboss_logmanager>` and `<version>` with the path and log manager JAR filename for your system. See [Making the LogManager Location Dynamic](#) for information on making the path dynamic.

Note

Step 4 and Step 5 are required only if the log manager errors manifest. Also, repeat Step 3 after this change.

Dynamic LogManager Location

On standalone JBoss instances, instead of hard coding the path and name of the log manager JAR, you can use [glob pattern matching](#) techniques to make the path to the log manager file dynamic, so that it is resilient to change or variances among systems.

The exact steps to accomplish this varies by environment. These sections provide an example of this configuration on Windows and Linux systems, and are meant as a starting point for your own implementation.

Windows

In Windows, the `standalone.conf.bat` gets this additional snippet:

```

...
rem jboss.modules.system.pkgs
set JAVA_OPTS=%JAVA_OPTS%
-Djboss.modules.system.pkgs=org.jboss.byteman,com.singularity,org.jboss.logmanager

rem java.util.logging
set JAVA_OPTS=%JAVA_OPTS%
-Djava.util.logging.manager=org.jboss.logmanager.LogManager

rem bootclasspath
set LOGMANAGER=
for /f %i in ('dir /b "%JBOSS_HOME%\modules\system\layers\base\org\jboss\logmanager\main\jboss-logmanager-*.jar"') do (
    set LOGMANAGER_JAR=%JBOSS_HOME%\modules\system\layers\base\org\jboss\logmanager\main\%i
)
set JAVA_OPTS=%JAVA_OPTS% -Xbootclasspath/p:%LOGMANAGER_JAR%
  
```

The path to the LogManager JAR file under the JBoss home can vary by JBoss version. Be sure to check your system and adjust the path as shown in the example accordingly.

Linux

In Linux, you can populate the path dynamically with the following code:

```

JBOSS_MODULES_SYSTEM_PKGS
="org.jboss.byteman,com.singularity,org.jboss.logmanager"

JAVA_OPTS="$JAVA_OPTS
-Djava.util.logging.manager=org.jboss.logmanager.LogManager"
JAVA_OPTS="$JAVA_OPTS -Xbootclasspath/p:${ls ${JBOSS_HOME}/modules/system/layers/base/org/jboss/logmanager/main/jboss-logmanager-*.jar}"
  
```

If using the `${JBOSS_HOME}` variable, as in the example, be sure to set the variable to the directory to the JBoss installation directory on your system.

The path to the `LogManager` JAR file under the JBoss home can vary by JBoss version. Be sure to check your system and adjust the path as shown in the example accordingly.

Domain Mode Agent Installation

For domain mode, the location in which you need to configure the settings depends upon specifics for your environment. Keep in mind that a domain is made up of these components:

- A domain controller, the administration and configuration server. The `domain.xml` configuration file is the global configuration for the managed hosts.
- Host controllers, which manage a particular host containing one or more application server nodes. There can be any number of host controllers and nodes. The `hosts.xml` file contains settings for the nodes on that host machine.

Where you put the configuration, therefore, varies as follows:

- `domain.xml` : Settings that can be identical for all hosts in the managed domain (i.e., the log manager and agent files are at the same location on all machines) can go into the `domain.xml` file for the Domain Controller.
- `host.xml` : Settings that need to be specialized for individual hosts (for example, if the paths to relevant files on hosts vary) need to go into the `host.xml` file.

You can add configuration settings to both `domain.xml` and `host.xml`, depending on which are global and which are host-specific. The following sections show an example of adding general settings to the domain configuration and node name setting to the host configuration.

Domain.xml Configuration

1. Locate and edit `domain.xml` for the domain. This is usually located under `$JBOSS_HOME/domain/configuration/`.
2. Find the `system-properties` element and add a property named `jboss.modules.system.pkgs` with a value of `com.singularity` to the existing system properties. For example:

```
<system-properties>
  <!-- IPv4 is not required, but setting this helps avoid unintended use of IPv6 --
  >
  <property name="java.net.preferIPv4Stack" value="true"/>
  <property name="jboss.modules.system.pkgs" value="com.singularity"/>
</system-properties>
```

This property tells the JBoss class loader to load the AppDynamics packages. This is required for the Java Agent to run.

Ensure that the property `jboss.modules.system.pkgs` is available in the environment. If the property is present, then add `com.singularity` to it.

For example:

```
-Djboss.modules.system.pkgs=org.jboss.byteman,com.singularity
```

If the property is not present, then configure a new one:

```
-Djboss.modules.system.pkgs=com.singularity
```

3. Under the server group name where you want to enable your agents, add the JVM options using the appropriate values for your agent location, JBoss application name, and tier name.

```
<server-group name="main-server-group" profile="full">
  <jvm name="default">
    <heap size="1303m" max-size="1303m"/>
    <permgen max-size="256m"/>
    <jvm-options>
      <option value="-javaagent:<agent_install_dir>/javaagent.jar"/>
      <option value="-Dappdynamics.agent.applicationName=JBOSS-EAP-APP"/>
      <option value="-Dappdynamics.agent.tierName=JBOSS-EAP-TIER"/>
    </jvm-options>
  </jvm>
  <socket-binding-group ref="full-sockets"/>
</server-group>
```

Changes to the `domain.xml` file require a restart of the management host to take effect. The changes are not propagated to server hosts until they are restarted as well.

Host.xml Configuration

For each host, specify the AppDynamics node name in the `host.xml` file, usually located under `$JBOSS_HOME/domain/configuration/`.

Add the `-Dappdynamics.agent.nodeName` JVM option to specify the node name for this instance:

```
<servers>
  <server name="server-one" group="main-server-group">
    <jvm name="default">
      <jvm-options>
        <option value="-
agentlib:jdwp=transport=dt_socket,address=8787,server=y,suspend=n"/>
        <option value="-Dappdynamics.agent.nodeName=JBOSS-EAP-NODE-1"/>
      </jvm-options>
    </jvm>
  </server>
  <server name="server-two" group="main-server-group" auto-start="true">
    <socket-bindings port-offset="150"/>
    <jvm name="default">
```

```

    <jvm-options>
      <option value="-Dappdynamics.agent.nodeName=JBOSS-EAP-NODE-2"/>
    </jvm-options>
  </jvm>
</server>
<server name="server-three" group="other-server-group" auto-start="false">
  <socket-bindings port-offset="250"/>
</server>
</servers>

```

For brevity, comments have been removed from the sample.

Troubleshooting JBoss Startup Issues

Most issues installing the Java Agent on JBoss result from conflicts between startup arguments. That is, settings you add for the Java Agent may be overridden or conflict in other ways with existing arguments. Such issues are not always easy to detect.

The best way to begin troubleshoot such startup issues is to print and inspect the startup arguments that JBoss actually gets when attempting to start. To do this, view JBoss process information during startup using the following command. You need to issue this command while the start up attempt is occurring but before it fails.

```
ps -ef | grep [o]rg.jbossas | tr ' ' '\n' | sed -e '/^$/d'
```

Troubleshooting JBoss Shutdown Issues

When enabling the JMXremote features of the JVM on a JBoss 5.1.2 server configuration, the following error is generated when calling the `/bin/shutdown.sh`:

```

javax.management.JMRuntimeException: Failed to load
MBeanServerBuilder class
org.jboss.system.server.jmx.MBeanServerBuilderImpl:
java.lang.ClassNotFoundException:
org.jboss.system.server.jmx.MBeanServerBuilderImpl

```

Resolution

Sometimes, there is `JAVA_OPTS` parameter in the environment, and it affects to a java process when the JVM start.

From the reason that EAP uses `JAVA_OPTS` parameter internally, it should not be in the environment.

To clear the parameter in the environment, executing the following from a console:

1. `export JAVA_OPTS=""`
2. `env|grep JAVA_OPTS`
`JAVA_OPTS= <You will see this message>`
3. `shutdown.sh -s jnp://localhost:1099 -u USER -p PASSWORD`

Root Cause

JMX related options should not be set in `JAVA_OPTS` when calling `shutdown.sh`. Ensure `JAVA_OPTS` is only set when starting JBoss EAP, not when running.

Jetty Startup Settings

This page describes how details for instrumenting the Jetty web server with the AppDynamics Java Agent vary depending on the version of Jetty you are using.

Instrument Jetty Version 8.x or 9.x

You can instrument Jetty with the AppDynamics agent either from the server startup command, or by editing the Jetty startup configuration file.

- To add the agent to Jetty at the command line, pass the `javaagent` argument with the fully qualified location of the Java agent JAR file when starting the Jetty server. For example:

```
java -javaagent:./<agent_home>/javaagent.jar -jar start.jar
```

- To use the startup configuration file, edit the `start.ini` file in the Jetty base directory by adding these lines:

```
--exec
-javaagent:./<agent_home>/javaagent.jar
```

Be sure to specify the location of the AppDynamics `javaagent.jar` file in the `javaagent` argument as appropriate for your system. Restart the Jetty server after modifying the configuration file to have your changes take effect.

Instrument Jetty Version 6.x or 7.x

For Jetty version 6.x or 7.x, you can add the `javaagent` command line option to your `jetty.sh` file:

- Open the `jetty.sh` start script file.
- Add the following `javaagent` argument to the beginning of the script.

```
java -javaagent:./<agent_home>/javaagent.jar
```

- Save the script file.
- Restart the application server for the changes to take effect.

Custom Exclude Rule for WebAppContext

For the Eclipse version of Jetty, to enable AppDynamics to detect business transactions based on web services, you need to create a Servlet exclude rule for the default Jetty servlet `org.eclipse.jetty.webapp.WebAppContext`.

This ensures that AppDynamics can detect business transactions based on the web services provided by your web applications while ignoring unmapped URL or URLs for the underlying framework.

Mule ESB Startup Settings

To load the Java Agent in Mule ESB, pass the Java Agent JAR location as a JVM argument to Mule.

Mule ESB 3.X or later uses the Tanuki configuration environment. To specify JVM arguments in your Mule ESB environment, you need to configure them as additional parameters to the [Tanuki Java Service Wrapper](#) configuration file, `wrapper.conf`, as described below.

Configuring the Tanuki Service Wrapper

1. Open the Java Service Wrapper configuration file:
`<MULE_HOME>/conf/wrapper.conf`
2. Find the location indicated for Java Additional Parameters:

```
# Java Additional Parameters
wrapper.java.additional.1=
```

3. Add the path to the Java Agent JAR file as a JVM argument using a `wrapper.java.additional.n` parameter, as follows.

```
wrapper.java.additional.n="-javaagent:/path_to_appagent/javaagent.jar"
wrapper.java.additional.n.stripquotes=TRUE
```

Where "n" is the next available integer among the `wrapper.java.additional` parameters already in the `wrapper.conf` file, if any. The numbers serve to identify each Java Additional Parameter in the file. Do not skip numbers when adding the property. Replace `path_to_appagent` to the path to the `javaagent.jar` file in your system. The `stripquotes` parameter is necessary only if there are spaces in the path or filename, but is safe to include if not.

For example, on a Linux system and with seven Java parameters already in the file, add the following properties:

```
wrapper.java.additional.8="-javaagent:/opt/AppDynamics/Agent/app_agent/javaagent.jar"
wrapper.java.additional.8.stripquotes=TRUE
```

i There may be additional `wrapper.java.additional` properties defined in other Mule files. These are generated by the system. As indicated by comments preceding these properties, you should not make changes directly to the properties. Mule automatically auto-increments the index number for these properties based on the highest integer number used in `wrapper.conf`, so you do not need to modify or otherwise account for the index numbers of auto-generated configuration properties.

i If you are using the following processors, End User Monitoring (EUM) might not work as expected. This happens because Mule interferes with the AppDynamics headers.

```
<custom-processor class="com.mulesoft.gateway.extension.Proxy
RequestHeadersProcessor" />
<custom-processor class="com.mulesoft.gateway.extension.Proxy
ResponseHeadersProcessor" />
```

Oracle WebLogic Startup Settings

To enable the AppDynamics Java Agent add the `javaagent` command-line option to the WebLogic startup file. If you start and stop clustered WebLogic servers using Node Manager, configure server startup in the WebLogic Server Administration Console.

Instrument Oracle WebLogic for Windows

1. Open the `startWebLogic.cmd` file, located at `<weblogic_version_install_dir>\user_projects\domains\<domain_name>\bin`.
2. Add following `javaagent` argument to the application server start script.

```
set JAVA_OPTIONS=%JAVA_OPTIONS% -javaagent:"<drive>:\<agent_home>\javaagent.jar"
```

- The `javaagent` argument must reference the full path of the agent installation directory, including the drive letter.
- The command must precedes the WebLogic start commands, for example:

```
@REM Enable the AppDynamics Java Agent
set JAVA_OPTIONS=%JAVA_OPTIONS% -javaagent:"E:\
AppDynamics\AppServerAgent\javaagent.jar"
@REM AppDynamics Java Agent END

@REM START WEBLOGIC
echo starting weblogic with Java version:
%JAVA_HOME%\bin\java %JAVA_VM% -version
```

3. Restart the application server for the changes to take effect.

Instrument Oracle WebLogic for an Application Running as a Windows Service

Some applications have a pre-compiled startup method that installs WebLogic as a Windows service.

To add the agent to the service:

1. Open the script file that starts the application service, such as `install_XXXX_Server_Start_Win_Service.cmd`.
2. Add the `javaagent` command before the line starting with "`set CMDLINE=%JAVA_VM% . . .`" such as:

```
set CLASSPATH=%MYSERVER_CLASSPATH%;%PRE_CLASSPATH%;%WEBLOGIC_CLASSPATH%;%POST_CLASSPATH%;%WLP_POST_CLASSPATH%

set JAVA_VM=%JAVA_VM% %JAVA_DEBUG% %JAVA_PROFILE%

set WLS_DISPLAY_MODE=Production

@REM Enable the AppDynamics Java Agent
set JAVA_OPTIONS=%JAVA_OPTIONS% -javaagent:"<drive>:\<agent_home>\javaagent.jar"
@REM AppDynamics Agent END

set CMDLINE=%JAVA_VM% %MEM_ARGS% -classpath %CLASSPATH% %JAVA_OPTIONS% weblogic.Server"
```

3. Open a command prompt and run the following script to remove the existing Windows Service for your application:

```
install_XXXXX_Server_Start_Win_Service.cmd
XXXXX_xxxxx_Production_Server R
```

4. Install the updated Windows Service for your application:

```
install_XXXXX_Server_Start_Win_Service.cmd
XXXXX_xxxx_Production_Server I
```

5. From the **WebLogic** web console, stop your application.
6. Start your application (which also starts WebLogic) from the Windows Services application, where the Windows service name = XXXXX_xxxx_Production_Server.
7. Ensure that your application is working properly.

See [Creating a Server-Specific Script](#) in the Oracle documentation.

Instrument Oracle WebLogic for Linux

1. Edit `startWebLogic.sh` located at `<weblogic_<version#>_install_dir>/user_projects/domains/<domain_name>/bin/startWebLogic.sh`.
2. Add the following to the beginning of your application server start script:

```
export JAVA_OPTIONS="$JAVA_OPTIONS -javaagent:/agent_home/javaagent.jar"
```

- The `javaagent` argument must reference the full path of the agent installation directory.
- The `export` command precedes the WebLogic start commands, for example:

```
#Enable the AppDynamics Java Agent
export JAVA_OPTIONS="$JAVA_OPTIONS -javaagent:/opt/AppDynamics/
AppServerAgent/javaagent.jar"

# START WEBLOGIC
```

```
echo "starting weblogic with Java version:"
${JAVA_HOME}/bin/java ${JAVA_VM} -version
```

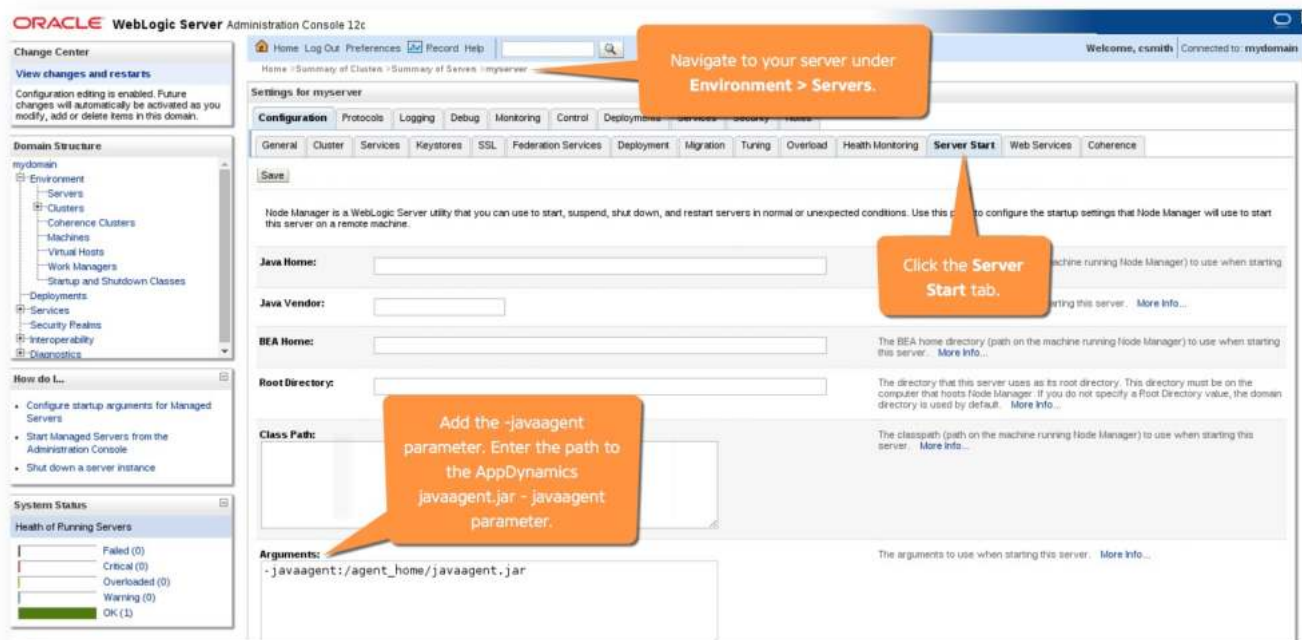

- Restart the application server for the changes to take effect.

Instrument Clustered WebLogic Servers

For clustered WebLogic servers, you start and stop using Node Manager, and configure server startup in the WebLogic Server Administration Console.

- Open the **WebLogic Server Administration Console**. See [Overview of the Administration Console](#).
- Navigate to **Environment > Servers** and click your server in the **Server List**.
- Click the **Server Start** tab.
- Add the `javaagent` argument and set the value to the path to the Java Agent:

```
-javaagent : /<agent_home>/javaagent.jar
```

- Restart the application server.

Java 2 Security Configuration

If you have enabled Java 2 security on your WebLogic server, you must add this code block to the `weblogic.policy` file:

```
grant codeBase "file:/<agent_home>/-"
{ permission java.security.AllPermission; };
```

OSGi Infrastructure Configuration

The GlassFish application server versions 3.x and later uses OSGi architecture. By default, OSGi containers follow a specific model for bootstrap class delegation. Classes that are not specified in the container's `CLASSPATH` are not delegated to the bootstrap `ClassLoader`; therefore you must configure the OSGi containers for the Java Agent classes.

See [GlassFish Startup Settings](#) and [GlassFish OSGi Configuration per Domain](#).

To ensure that the OSGi container identifies the Java Agent, specify this package prefix:

```
org.osgi.framework.bootdelegation=com.singularity.*
```

This prefix follows the regular boot delegation model so that the Java Agent classes are visible.

If you already have existing boot delegations, add "`com.singularity.*`" to the existing path separated by a comma. For example:

```
org.osgi.framework.bootdelegation=com.sun.btrace., com.singularity.
```

Configure Eclipse Equinox

If running Eclipse Equinox under Glassfish:

1. Open the `config.ini` file located at `<glassfish install directory>/glassfish/osgi/equinox/configuration`.
2. Add this package prefix to the `config.ini` file:

```
org.osgi.framework.bootdelegation=com.singularity.*
```

If running Eclipse Equinox under the WebSphere Application Server Liberty profile:

1. Open the `bootstrap.properties` file in the JVM directory `<WLP_home>/usr/servers/<server_name>` for editing.
2. Add this code line:

```
org.osgi.framework.bootdelegation=com.singularity.*
```

See [Getting Started with Equinox](#).

Configure Apache Sling

1. Open the `sling.properties` file. The location of the `sling.properties` varies depending on the Java platform.
In the Sun/Oracle implementation, the `sling.properties` file is located at `<java.home>/lib`.
2. Add this package prefix to the `sling.properties` file:

```
org.osgi.framework.bootdelegation=com.singularity.*
```

Configure JIRA or Confluence

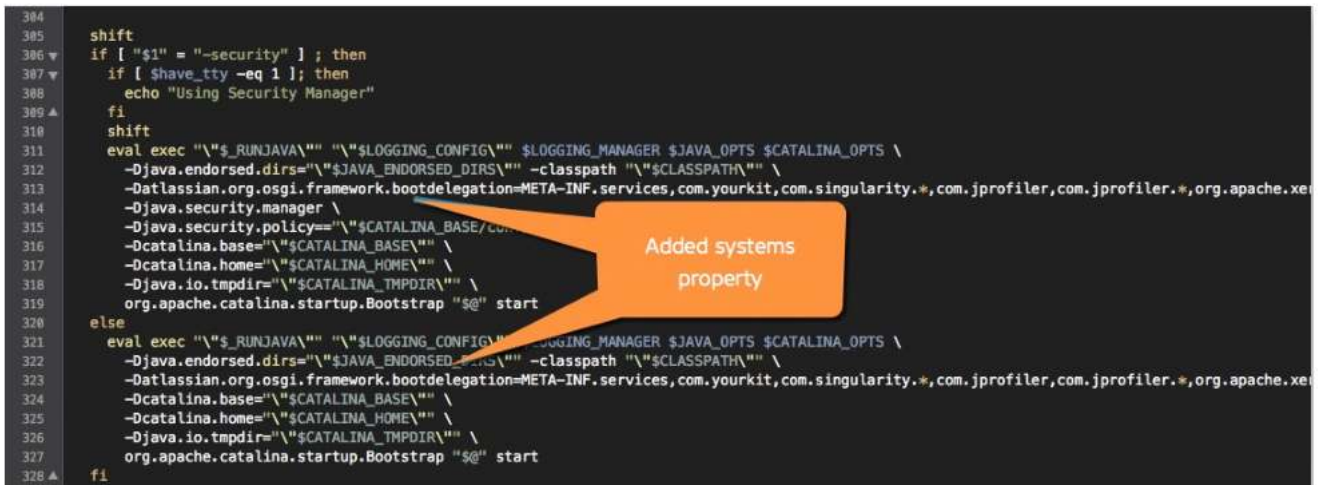

For JIRA >= 5.1.8, and Confluence >= 5.3:

1. Open the startup script (that is, `catalina.sh`) for editing.
2. Look for the `start` command block (look for "`elif ["$1" = "start"] ; then`")
3. Add the following Java system property alongside the existing properties in both `else` blocks:

```
-Datlassian.org.osgi.framework.bootdelegation.extra=com.singularity.*
```

4. Add the property to the run command block as well to instrument the application started in run mode. For example:

```
384
385 shift
386 if [ "$1" = "-security" ] ; then
387 if [ $have_tty -eq 1 ] ; then
388 echo "Using Security Manager"
389 fi
390 shift
391 eval exec "\${_RUNJAVA}" "\${LOGGING_CONFIG}" "\${LOGGING_MANAGER} \$JAVA_OPTS $CATALINA_OPTS \
392 -Djava.endorsed.dirs="\${JAVA_ENDORSED_DIRS}" -classpath "\${CLASSPATH}" \
393 -Datlassian.org.osgi.framework.bootdelegation=META-INF.services,com.yourkit,com.singularity.*,com.jprofiler,com.jprofiler.*,org.apache.xer
394 -Djava.security.manager \
395 -Djava.security.policy="\${CATALINA_BASE}/conf/catalina.policy" \
396 -Dcatalina.base="\${CATALINA_BASE}" \
397 -Dcatalina.home="\${CATALINA_HOME}" \
398 -Djava.io.tmpdir="\${CATALINA_TMPDIR}" \
399 org.apache.catalina.startup.Bootstrap "$@" start
400 else
401 eval exec "\${_RUNJAVA}" "\${LOGGING_CONFIG}" "\${LOGGING_MANAGER} \$JAVA_OPTS $CATALINA_OPTS \
402 -Djava.endorsed.dirs="\${JAVA_ENDORSED_DIRS}" -classpath "\${CLASSPATH}" \
403 -Datlassian.org.osgi.framework.bootdelegation=META-INF.services,com.yourkit,com.singularity.*,com.jprofiler,com.jprofiler.*,org.apache.xer
404 -Dcatalina.base="\${CATALINA_BASE}" \
405 -Dcatalina.home="\${CATALINA_HOME}" \
406 -Djava.io.tmpdir="\${CATALINA_TMPDIR}" \
407 org.apache.catalina.startup.Bootstrap "$@" start
408 fi
```

5. Before the comment line 'Execute The Requested Command', add the `-javaagent` argument to the file as a new Java option:

[Linux](#) [Windows](#)

```
JAVA_OPTS="\${JAVA_OPTS} -javaagent:<agent_home>/javaagent.jar"
```

[Linux](#) [Windows](#)

```
set JAVA_OPTS=%JAVA_OPTS% -javaagent:"Drive:<agent_home>\javaagent.jar"
```

6. Restart the application.

Configure Other OSGi-based Containers

For other OSGI-based runtime containers, add this package prefix to the appropriate OSGi configuration.

```
file.org.osgi.framework.bootdelegation=com.singularity.*
```

Resin Startup Settings

The Java Agent bootstraps using the `javaagent` command-line option. Add this option to the `resin.sh` or `resin.bat` file.

Instrument Resin 1.x - 3.x for Windows

1. Open the `resin.bat` file, located at `<resin_home>/bin`.
2. At the beginning of your application server start script, add the `javaagent` argument with the full path (including drive) to the `javaagent.jar` file on your system:

```
exec JAVA_EXE -javaagent:"<drive>:\<agent_home>\javaagent.jar"
```

3. Restart the application server to have the changes take effect.

Instrument Resin 1.x - 3.x for Linux

1. Open the `resin.sh` file, located at `<resin_home>/bin`.
2. At the beginning of your application server start script, add the `javaagent` argument with the full path to the `javaagent.jar` file on your system:

```
exec $JAVA_EXE -javaagent:"<agent_home>/javaagent.jar"
```

For example:

```

/mnt/resin-pro-4.0.18/bin/resin.sh - root@ec2-184-72-162-149.compute-1.amazonaws.com
#
# trace script and simlinks to find the wrapper
#
if test -z "${RESIN_HOME}"; then
  script=`/bin/ls -l $0 | awk '{ print $NF; }'`

  while test -h "$script"
  do
    script=`/bin/ls -l $script | awk '{ print $NF; }'`
  done

  bin=`dirname $script`
  RESIN_HOME="$bin/.."
fi
exec $JAVA_EXE -javaagent:"/mnt/agent/3.2/javaagent.jar" -jar ${RESIN_HOME}/lib/resin.jar $*

```

3. Restart the application server for the changes to take effect.

Instrument Resin 4.x

1. To install the Java Agent into Resin => 4.X, edit the `./conf/resin.xml` file and add:

```
<jvm-arg>-Xmx512m</jvm-arg>
<jvm-arg>-javaagent:<agent_home>/javaagent.jar</jvm-arg>
```

2. Restart the application server for the changes to take effect.

Apache Solr Startup Settings

This page describes how to instrument Apache Solr with the Java Agent.

Instrument Solr in a Linux Environment

1. Open a terminal.
2. Execute the following commands to add the `javaagent` argument to the Solr server:

```
>cd $Solr_Installation_Directory
>java -javaagent:"<agent_install_directory>/javaagent.jar" -jar start.jar
```

For the argument value, reference the full path to the Java Agent installation directory.

Instrument Solr in a Windows Environment

1. Add the Java Agent to the Solr configuration file, `solr.in`.
You can find the file at:
`<solr-install-dir>\bin\solr.in`
2. Add the following line just below "REM set SOLR_OPTS=%SOLR_OPTS%":

```
set SOLR_OPTS=%SOLR_OPTS%
-javaagent:"<java_agent_location>\javaagent.jar"
```

3. Restart the Solr service.

Standalone JVM Startup Settings

AppDynamics works with applications running outside of an application server or container.

To install the agent on a standalone JVM, pass the path to the Java Agent when running the Java application in the following form:

```
java -javaagent:"/<agent_home>/javaagent.jar" <classname>
```

Ensure to add the `-javaagent` argument before the `-jar` argument. The `javaagent` argument value must reference the full path to the Java Agent home directory, including the drive on Windows. The classname should be the fully qualified class name with `main` method.

For example, the is an example of the command on a Windows system:

```
java -javaagent:"C:\AppDynamics\agentDir\javaagent.jar" com.main.HelloWorld
```

On Linux, it would be:

```
java -javaagent:"/mnt/AppDynamics/agentDir/javaagent.jar" com.main.HelloWorld
```

Tanuki Service Wrapper Settings

Related pages:

- [Tanuki Service Wrapper Properties](#)
- [Example Configuration](#)
- [More Help On Tanuki Service Wrapper](#)

The Java Agent bootstraps use the `javaagent` command-line option. Add this option to the Tanuki Service `wrapper.conf` file.

Configure the Tanuki Service Wrapper

1. Open the `wrapper.conf` file to edit.
2. Add a `wrapper.java.additional` property that contains the `javaagent` option with the location of the Java Agent JAR file. For example:

```
wrapper.java.additional.6=-javaagent:C://agent//javaagent.jar
```

Tibco ActiveMatrix BusinessWorks Service Engine Settings

Related pages:

- [TIBCO Product Documentation](#)
- [TIBCO Community: tibbr](#)

With Tibco ActiveMatrix BusinessWorks Service Engine, each application is started in its own JVM. As a result, for each application that you want to monitor, you must configure the Java Agent in the startup settings for the configuration file of that application.

The file to configure is usually the TRA file named for the application. For example:

```
<application_name>.tra
```

Instrument the Tibco Application

1. Open the TRA file for the application you want to monitor and add this code to the file:

```
java.extended.properties=-javaagent:/opt/appagent/  
javaagent.jar
```

AppDynamics recommends that you include all `-D` system property arguments in one `java.extended.properties` line. Otherwise, the `-javaagent` property may be overwritten.

2. Restart the application to have the changes take effect using the command-line tool `bwengine.sh` (or `.exe`) or the Tibco Admin UI.

Since Tibco traffic commonly takes the form of incoming SOAP actions sent through HTTP requests to a single URL (for example, `/BusinessServices/WebGateway`), it's likely that you will need to create a POJO

split rule in the AppDynamics configuration to differentiate business transactions for Tibco. For information, see "Split by POJO Method Call" on [Split Servlet Transaction by Payload Examples](#).

webMethods Startup Settings

You can instrument the webMethods Integration Server or My webMethods Server by adding the Java Agent to the startup script of the server.

The Java agent settings can go in the `runtime.bat/runtime.sh` file, or the `server.bat/server.sh` file under the `bin` subdirectory of the server home.

Instrument webMethods with the Tanuki Wrapper

For webMethods servers that use the Tanuki Java service wrapper for start-up, you need to configure the agent in the `wrapper.conf` file. See [Tanuki Service Wrapper Settings](#).

Note that the order of arguments in the file is important. Specifically, when instrumenting an OSGI-based platform, the agent configuration must precede the `bootclasspath` argument.

For example, the following listing shows the Java options used in a sample `wrapper.conf` file:

```
# Java Additional Parameters
...
wrapper.java.additional.4=-XX:MaxPermSize=256M
wrapper.java.additional.5=-javaagent:/opt/appd/appagent/
javaagent.jar
wrapper.java.additional.6=-Xbootclasspath/
a:"%OSGI_INSTALL_AREA%/lib/runtime/platform-jaasproxy.jar"
```

Java Security Manager Configuration

Run in a JVM with Security Enabled

To enable a Java Security Manager and instrument the JVM, you need to edit the active security policy file to prevent problems within the interaction between JVM and the Java Agent. The Java Agent requires the change listed in the code block. You can locate the policy file by inspecting the value of the `java.security.policy` system property.

Add this code block to the JVM `server.policy` file:

```
grant codeBase "file:<app_agent_path>/-"
{
  permission java.security.AllPermission;
};
```

WSO2 API Microgateway Startup Settings

You can instrument WSO2 API Microgateway by adding the Java Agent to JVM arguments in the executable file of the gateway. Perform the following steps based on your environment to attach the Java Agent:

i Java Agent supports only the HTTP1 protocol for entry and exit.

[Linux or macOS](#) [Docker](#) [Windows](#)

1. Open the executable file named "gateway" at `<MGW_HOME>/bin` in a text editor.
2. In `java_cmd_gateway ()` under `$JAVA_OPTS`, add :

```
-javaagent:/path_to_appagent/javaagent.jar
```

3. Save the executable and start the gateway.

[Linux or macOS](#) [Docker](#) [Windows](#)

1. Navigate to the docker container in which the microgateway is running using the following command:

```
docker exec -it <container_id> /bin/bash
```

2. Open the executable file named "gateway" at `wso2/bin` inside the docker container in a text editor.
3. In `java_cmd_gateway ()` under `$JAVA_OPTS`, add :

```
-javaagent:/path_to_appagent/javaagent.jar
```

4. Save the gateway file.
5. Fetch the process id of Java process running inside the container using the following command:

```
ps -eaf | grep java
```

6. Kill the process `<process_ID>`:

```
kill -9 <process_ID>
```

7. Start the gateway again by running the jar:

```
wso2/bin/gateway <executable_jar>
```

[Linux or macOS](#) [Docker](#) [Windows](#)

1. Open the executable file named "gateway" at <MGW_HOME>/bin in a text editor.
2. In `runTools` under "SET JAVA_CMD", after "%JAVA_OPTS% ^" add the following:

```
-javaagent:/path_to_appagent/javaagent.jar
```

3. Save the executable and start the gateway.

Install the AppDynamics Site Extension for Java

You can use the Windows Azure Portal to add the AppDynamics Azure Site Extension to your Azure App Service web app. Azure Site Extension is used by Ops teams that may not have access to source files, or would not like to modify or recompile them, yet still want to monitor their Azure projects and solutions.

Prepare to Install

To install the AppDynamics for Windows Azure Site Extension, you need:

- Connection information for your [AppDynamics Controller](#). See [Agent and Controller Tenant Compatibility](#).
- A Windows Azure account.
- An Azure web app to monitor.

If you are upgrading from a previous version, see [Upgrade the AppDynamics Azure Site Extension](#).

Add the AppDynamics Azure Site Extension

Add the AppDynamics Azure Site extension as you would any site extension for any Azure web app.

1. Log in to the Windows Azure Portal.
2. Browse to your web app. To configure the Java Agent using environment variables, add the environment variables before you install the AppDynamics Azure Site Extension. See [Configure the agent using environment variables](#).
3. From the **DEVELOPMENT TOOLS** list, click **Extensions**.
4. Click **+Add** to install the version of the **AppDynamics Java Agent** you want to add to your web app. After you install the AppDynamics Azure Site Extension, it displays in the installed extensions list.

Configure the Controller Connection

There are two options to configure the Java Agent to connect to the AppDynamics Controller:

- Configure the Controller connection using the [Kudu Console](#).
- Configure the Controller connection settings using [environment variables](#).

See [Agent-to-Controller Connections](#).

Configure the Agent with the Kudu Console

When you add the AppDynamics Azure Site Extension to your web app, you can interactively configure the Java Agent using the Kudu Console.

1. Navigate to the AppDynamics Controller Configuration page in the Kudu Console:
`http://{web app}.scm.azurewebsitesJava/appdynamics/`
 For example: `https://myazureexample.scm.azurewebsitesJava/appdynamics/`

2. On the AppDynamics Controller Configuration page, enter your Controller connection information. For example:

APPDYNAMICS | Windows Azure

AppDynamics Controller Configuration

Enter the following information to monitor your Azure application with AppDynamics. You should have received this from your sign up email or from your AppDynamics sales representative.

Controller Host	Port
<input type="text" value="mycompany.saas.appdynamics.com"/>	<input type="text" value="443"/>
Enable SSL <input checked="" type="checkbox"/>	
Account Name	
<input type="text" value="MyAccount"/>	
Access Key	
<input type="text" value="123dd45d-6fc7-8901-a234-567ed890bd12"/>	
Application Name ⓘ	
<input type="text" value="MyAzureApp"/>	
<input type="button" value="Validate"/>	

3. Click **Validate** to test the connection to the AppDynamics Controller and save your settings.
4. Restart your web app. After you apply some load to your web app, you can view it on [flow maps](#) in the AppDynamics Controller UI.

Configure the Agent Using Environment Variables

Configuring the Java Agent using environment variables allows for unattended configuration. To configure agents, add the environment variables before you install the AppDynamics Azure Site Extension:

1. Navigate to **SETTINGS > Application Settings** for your web app.
2. Add the Java Agent environment variables under **App settings**:
 - APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY: A unique key associated with the Controller account.
 - APPDYNAMICS_CONTROLLER_HOST_NAME: The hostname of the AppDynamics Controller.
 - APPDYNAMICS_CONTROLLER_SSL_ENABLED: Set it to `True` to enable SSL connection to the Controller. Otherwise set it to `False`.
 - APPDYNAMICS_AGENT_ACCOUNT_NAME: The account name you use to log on to the Controller.
 - APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY: The account key you use to log on the Controller.
 - APPDYNAMICS_AGENT_APPLICATION_NAME: The business application name in the Controller.
 - APPDYNAMICS_AGENT_TIER_NAME: The tier name in the Controller.
 - APPDYNAMICS_AGENT_NODE_NAME: The node name in the Controller.
3. Restart your web app. After you apply some load to your web app, you can view it on [flow maps](#) in the AppDynamics Controller UI.

Upgrade the AppDynamics Azure Site Extension

When you click the **Extensions** tab for your web app, the Microsoft Azure Portal displays the currently installed version of the AppDynamics Azure Site Extension. The **Update Available** column of the installed extensions list indicates if there is a more recent minor release of the Java Agent available. If so, you can click to update the extension from the list.

Upgrade a Major Version of the Java Agent

AppDynamics maintains major release versions of the Java Agent as separate site extensions. Therefore, you must uninstall the installed version of the AppDynamics Azure Site Extension before you upgrade to a new major release:

1. Log in to the Windows Azure Portal.
2. Stop your web app.
3. Click the **AppDynamics Azure Site Extension** from the list of installed extensions and click **Delete** to uninstall it.
4. Install the new version of the AppDynamics Azure Site Extension as normal.

Instrument Java System Classes

The Java Agent excludes system classes like `java.lang.*` from instrumentation by default. To enable instrumentation for a system class, use an agent configuration property.

Instrumented system classes add to the resource overhead introduced by the agent. The amount of overhead depends on the number of calls to the classes. AppDynamics recommends that you instrument a few nodes first and monitor the performance for these nodes before configuring all nodes in your system.

To instrument a Java system class:

1. Open the `<agent_home>/conf/app-agent-config.xml` file for the node where you want to enable instrumentation.
2. Add an `<override-system-exclude>` element with the fully qualified system class name to be instrumented in the `<bci-processing-excludes>` element. The `<override-system-exclude>` element is used to allowlist classes (for example, `'com.sun.jersey'`) for instrumentation despite a blacklist (`'com.sun.*'`).

For example:

```
<bci-processing-excludes>
<override-system-exclude filter-type="equals" filter-value="com.sun.jersey"/>
</bci-processing-excludes>
```

You can use these filter types:

- equals
- startswith
- contains

3. Restart the JVM for which you have modified the XML file. Once you restart the JVM, the package will be included in the instrumentation.

Instrument JVMs in a Dynamic Environment

Application environments are increasingly dynamic. For example, in AWS or Rackspace hosted environments, an administrator can online or offline nodes quickly because of workload resulting in an environment where there can be many, short-lived JVMs.

Dynamic Environment Considerations

The AppDynamics app agent operates substantially the same way in a dynamic environment as it does in a traditional data center. However, these considerations apply when deploying agents in dynamic environments:

- Ensure that the agents can reach your Controller. Particularly if your Controller operates on-premises while the agents run on hosted servers, you need to ensure that the agents can access the Controller through the firewalls in your environment.
- Configure custom node expiration handling. By default, the Controller manages the lifecycle for a node based on default timeout settings. You will likely want to reduce the default expiration times for nodes, as described in [Historical and Disconnected Nodes](#). To manage this directly, rather than relying on activity timeouts, a strategy would be to run a script in the JVM before it shuts down that invokes the mark-nodes-historical resource in the [AppDynamics REST API](#) to declare itself historical to the Controller.
- Depending on the nature of your environment, it may not make sense to track each JVM instance as a distinct node in AppDynamics, since the set of nodes, in this case, would be boundless. Also, since the JVMs are identical, representing them as different nodes in AppDynamics does not best reflect the logical model of the environment.

Configure the Agent for Dynamic Environments

You can configure AppDynamics to reuse node names for dynamic environments. With node name reuse enabled, after a node is shut down and [marked as historical](#) in AppDynamics, the name of the node becomes available for reuse in subsequently registered nodes. You can also specify a node name prefix when reusing node names to indicate the association between all concurrently running JVMs for the dynamic application.

To configure the agent for this environment, use these properties:

- [Reuse Node Name Property](#) - To enable re-use of node names.
- [Auto Node Name Prefix Property](#) - To set the prefix used for automatically-named nodes.

When enabled, the Controller manages name assignments for the agents. It forms node names by appending a sequentially incremented number as the suffix to the prefix you specify. Be sure to avoid specifying the node name using any other mechanism (such as in `controller-info.xml` file or through a system property).

This listing shows sample settings for the properties as they may appear in a startup script:

```
-Dappdynamics.agent.reuse.nodeName=true
-Dappdynamics.agent.reuse.nodeName.prefix=CloudActivator_
```

When you have enabled reuse node name, the Java Agent logs to standard output after starting up and before registration with the Controller. To troubleshoot agent registration failure, you may want to write the log files to a file instead.

To configure the agent to write logs to a file, edit the `log4j-unknown.xml` at `<agent_home>/<version_number>/conf/logging` and uncomment the `AgentLog Appender` :

```
<!-- To log files to an "unknown" folder before the agent registers
      with the Controller, uncomment the line below -->
```

```
<appender-ref ref="AgentLogAppender"/>
```

This change causes the log files of an agent prior to registration to be written to a directory named "unknown" rather than standard output.

Mark Dynamic Nodes as Historical at Shutdown

As indicated in the [Instrument JVMs in a Dynamic Environment](#) section, setting the node name reuse flag causes the JVM to report graceful shutdowns, allowing the Controller to mark the corresponding node as historical. If you are not reusing node names, you can use one of these alternative methods to mark a node as historical:

- Set this system property at JVM startup:

```
-Dappdynamics.jvm.shutdown.mark.node.as.historical=true
```

- Set this property in `app-agent-config.xml` to `true` :

```
<app-agent-configuration>
  ...
  <configuration-properties>
    ...
    <property name="appdynamics.jvm.shutdown.mark.node.as.historical" value="true"/>
  </configuration-properties>
</app-agent-configuration>
```

Note

If your application environment abortively terminates JVMs rather than allowing them to shut down gracefully, arrange for your orchestration framework to use the controller API ([Configuration API > Mark Nodes as Historical](#)) to mark the node as historical at the same time as it terminates the node.

Controller Handling of Historical Nodes

If a node has been out of contact with the Controller for a certain amount of time, the Controller marks the node as a historical node. The Controller suspends certain types of processing activities for the node, such as rule evaluation. See [Historical and Disconnected Nodes](#).

Instrument JVMs in Restricted Environments

Some restricted environments do not allow any changes to the JVM startup script. For these environments, you can use the environmental variable `JAVA_TOOLS_OPTIONS` in a wrapper script that allows you to specify the initialization of tools, specifically, `-javaagent` .

Create the Wrapper Script

1. Create a wrapper script using this format:

```
{{JAVA_TOOLS_OPTIONS="-javaagent:/opt/appdynamics/appserveragent/javaagent.jar -
Dappdynamics.controller.hostName=<controller_host>
-Dappdynamics.controller.ssl.enabled=false -Dappdynamics.controller.port=<port>
-Dappdynamics.agent.applicationName=<application_name>
-Dappdynamics.agent.tierName=<tier_name>
```

```
-Dappdynamics.agent.nodeName=<node_name>" }  
export JAVA_TOOLS_OPTIONS
```

i To specify spaces for the application, tier, or node names, use backslashes and quotes around the value, for example:

```
-Dappdynamics.agent.applicationName="\$APPLICATION_NAME\"
```

2. Add the original startup script to the wrapper script.
3. Make the new script executable, for example, `chmod 750 wrapperscript.sh`.
4. Run your new wrapper startup script.

Full example: `startApplicationWithAppDynamics.sh`

```
#!/bin/bash  
  
JAVA_TOOLS_OPTIONS="-javaagent:/opt/appdynamics/appserveragent/javaagent.jar  
-Dappdynamics.controller.hostName=<controller_host>  
-Dappdynamics.controller.ssl.enabled=false -Dappdynamics.controller.port=<port>  
-Dappdynamics.agent.applicationName=<application_name>  
-Dappdynamics.agent.tierName=<tier_name> -Dappdynamics.agent.nodeName=<node_name>"  
  
export JAVA_TOOLS_OPTIONS  
  
/path/to/original/script/startup.sh $*
```

Instrument JVMs Started by Batch or Cron Jobs

You can configure the Java Agent for those JVMs that run as cron or batch jobs where the JVM runs only for the duration of the job.

Configure the Java Agent

1. Add the application and tier name to the `controller-info.xml` file.
2. Add the `appdynamics.cron.vm` property to the AppDynamics `javaagent` command in the startup script of your JVM process:

```
-javaagent:<agent_home>/javaagent.jar -Dappdynamics.agent.nodeName=${NODE_NAME}  
-Dappdynamics.cron.vm=true
```

The `appdynamics.cron.vm` property creates a delay between the end of the main method and the JVM exit so that the Agent has time to upload metrics to the Controller.

Use the Script Name as the Node Name

You can use the name of the script that executes a cron or batch job in the node name. These commands set the value of variable `NODE_NAME` using the combination of the script and hostname. Add these commands to the startup script of the JVM.

```
# Use the name of the script (no path, no extension) as the name of the node.
```

```

NODE_NAME=sample
NODE_NAME="${NODE_NAME%%.}"
echo $NODE_NAME
# Localize the script to the host.
NODE_NAME="$NODE_NAME@$HOSTNAME"

```

Use Environment Variables for Java Agent Settings

As an alternative to using system properties or `controller-info.xml` to configure the agent, you can use environment variables. Environment variables allow agent identity settings to be populated with dynamic environments which may be unique for the JVM.

Environment Variables

To configure the agent with environment variables, set the value of the environment variables. Environment variables exist for most of the agent settings you can configure in the `controller-info.xml` file, such as the application name, node name, and connection settings.

For example, set the node name for the agent using an environment variable using `APPDYNAMICS_AGENT_NODE_NAME`. On Linux, you would enter this command:

```
export APPDYNAMICS_AGENT_NODE_NAME=node23
```

When the agent subsequently starts up, the agent takes `node23` as its node name. Typically, the environment variable would be set as part of the start-up routine of the JVM and populated with values determined at startup.

Environment Variables Used by the Agent

The Java Agent takes configuration settings from the following environment variables, when set:

Environment Variable	Equivalent property
<code>APPDYNAMICS_CONTROLLER_HOST_NAME</code>	<code><controller-host></code>
<code>APPDYNAMICS_CONTROLLER_PORT</code>	<code><controller-port></code>
<code>APPDYNAMICS_CONTROLLER_SSL_ENABLED</code>	<code><controller-ssl-enabled></code>
<code>APPDYNAMICS_AGENT_APPLICATION_NAME</code>	<code><application-name></code>
<code>APPDYNAMICS_AGENT_TIER_NAME</code>	<code><tier-name></code>
<code>APPDYNAMICS_AGENT_NODE_NAME</code>	<code><node-name></code>
<code>APPDYNAMICS_AGENT_ACCOUNT_NAME</code>	<code><account-name></code>

Environment Variable	Equivalent property
APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY	<account-access-key>
APPDYNAMICS_AGENT_UNIQUE_HOST_ID	Unique host name
APPDYNAMICS_AGENT_BASE_DIR	<agent-runtime-dir>
APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME	-Dappdynamics.agent.reuse.nodeName
APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME_PREFIX	-Dappdynamics.agent.reuse.nodeName.prefix

Notice that not all configurable agent settings are configurable through environment variables. For those settings, you need to use system properties or `controller-info.xml`, as described on [Java Agent Configuration Properties](#).

Use System Properties for Java Agent Settings

The Java Agent can accept configuration settings specified as system properties. This is useful when you have more than one JVM running on a machine and need to set node properties dynamically.

The JVMs may be in the same tier, or on different tiers in the AppDynamics model. In either case:

- All common information should be configured using `controller-info.xml`.
- All information unique to a JVM should be configured using the system properties (`-D` option) in the startup script.
- Information in the startup scripts always overrides the information in the `controller-info.xml` file.

[Java Agent Configuration Properties](#) describes the system properties available for the Java Agent. See [Install the Java Agent](#).

Reference System Properties

You can reference system properties from the command line, or in the agent configuration file to specify the node name, tier name, or other agent configuration properties dynamically.

For example, consider a Java application started with a script named `startserver.sh`. The script defines a system property as:

```
-Dserver.name=$1
```

The property `server.name` will get the value of the first argument passed when starting the script. For example, the following command to start the JVM would bind the `server.name` property to the value `ecommerce01`:

```
startserver.sh ecommerce01
```

You can use this value in your agent configuration by setting the `-Dappdynamics.agent.nodeName` property at startup:

```
-Dappdynamics.agent.nodeName=${server.name}
```

Or, you can use the value in the `controller-info.xml` file, using this format:

```
${system_property_name}
```

For example:

```
<controller-info>
  ...
  <node-name>${server.name}</node-name>
</controller-info>
```

Note that `server.name` is the name of a sample system property used here to identify the node. Use an appropriate system property that is available in your environment for the Java Agent node name.

To have tier names assigned dynamically, supply a dynamic value to the tier name property:

```
java -javaagent:<agent_home>/javaagent.jar
-Dappdynamics.agent.tierName=$tierName
-Dappdynamics.agent.nodeName=$nodeName
```

Combine Properties

You can combine multiple system properties to name nodes or tiers. For example, in `controller-info.xml`, combine properties as:

```
${system_property_name_1}${system_property_name_2}
```

You can combine system properties with literals. In the following example `"_"` and `"inventory"` are literals.

```
${myhost.name}_${myserver.name}.inventory
```

You can use existing system properties for the Controller host and port settings as well; however, combining properties as shown here is not supported for those settings.

Enable Reverse Proxy for Java Agent

By default, the reverse proxy is disabled. You can use one of the following properties or environment variables to enable it.

Node Property	System Property	Environment Variable
<code>enable-reverse-proxy</code>	<code>appdynamics.reverse.proxy.enabled = true/false</code>	<code>APPDYNAMICS_REVERSE_PROXY_ENABLED = true/false</code>

The environment variable takes precedence over the system property. To disable the reverse proxy configuration, all three must be `false` or not set.

When the agent makes an API call to the Controller, the agent checks the node property status, if set to:

- `true` - The required host header is added to the request.
- `false` - The agent checks the value of the environment variable. If the environment variable is set to `true`, the required host header is added to the request. If the environment variable is set to `false`, the agent checks the system value property. If the system value property is set to `true`, the required host header is added to the request. If set to `false`, the reverse proxy is not enabled and the host header is not added to the request.

You can utilize Java agent reverse proxy to:

- Configure two or more Controllers
- Mask the Controller hostname for additional security
- Load balance multiple Controllers.

Important

When the reverse proxy is enabled, the API calls from agent to Controller fail because API calls need the host header to know the domain to which calls are made. Enabling reverse proxy masks the Controller hostname which results in the `503 Service Unavailable` error. To fix this issue, the agent adds the host header to the request derived from the `accountName` of Controllers that has the reverse proxy enabled.

Administer the Java Agent

This page describes how to maintain the AppDynamics Java Agent and how to tune its configuration for your requirements. These include, for example, how to upgrade the agent to a new version and how configure SSL for the agent.

Configuration Options and Precedence

You can control many aspects of the operation of the Java Agent through its configuration settings. The agent provides several approaches for specifying these settings, as listed below.

The order of the list matches the priority of the settings. The agent applies the first non-empty value for a configuration property it encounters, given the following order.

1. Environment variables. See [Use Environment Variables for Java Agent Settings](#).
2. System properties passed in the start command for the JVM.
3. Versioned **agent properties**: `<agent_home>/<version_number>/conf/agent.properties`.
4. Global **agent properties**: `<agent_home>/conf/agent.properties`.
5. Versioned configuration file: `<agent_home>/<version_number>/conf/controller-info.xml`.
6. Global configuration file: `<agent_home>/conf/controller-info.xml`.

i Not all properties are available as environment variables, system properties, or XML elements for the `controller-config.xml`. Property references include only the available configuration methods.

Choose an Effective Configuration Strategy

- Use versioned agent properties and versioned configuration files before using global agent properties and global configuration files. This minimizes any impact of configuration format changes in future agent releases.
- The agent only reads versioned agent properties and versioned configuration files from one versioned directory. During upgrades, manually migrate configurations from directories for previous versions. See [Upgrade the Java Agent](#).
- The Agent Download Wizard automatically configures the agent using a versioned configuration file. The configuration in `controller-info.xml` statically defines the agent identity.
- For dynamic or elastic environments that require flexible agent identity, use an approach that provides for the dynamic node identification.
For example, pass node identify or other agent configuration settings dynamically using environment variables or system properties.
- For shared binaries among multiple JVM instances, AppDynamics recommends you use a combination of configuration files and startup properties to configure the app agent. In this case, you configure properties common to all JVMs in the `controller-info.xml` file. Then specify the properties unique to each JVM using environment variables or system properties. See [Instrument Multiple JVMs on a Single Machine](#) for example configurations.
- For some properties, you can use system properties already defined in the startup script as the Java Agent property values. For more information, see [Use System Properties for Java Agent Settings](#).

System Properties Sample Configuration

The following command demonstrates a startup script that includes system properties to start and configure the Java Agent. The application is "ACMEOnline", the tier is "Inventory", and the node is "Inventory1". `SampleApplication` is the application file.

```
java -javaagent:/home/appdynamics/agent/javaagent.jar
-Dappdynamics.controller.hostName=mycontroller.example.com
-Dappdynamics.controller.port=8090
-Dappdynamics.agent.applicationName=ACMEOnline
-Dappdynamics.agent.tierName=Inventory
-Dappdynamics.agent.nodeName=Inventory1 MyApplication.jar
```

i System property values are case-sensitive.

Agent Properties Sample Configuration

The Java Agent does not include an `agent.properties` file by default. The file is a list of key-value pairs of system properties. For example:

```
appdynamics.controller.hostName=mycontroller.example.com
appdynamics.controller.port=8090
```

- The JVM treats properties from the `agent.properties` file the same as system properties. Values in `agent.properties` do not override any properties passed explicitly in the JVM startup script.

- You can also include system properties not specific to AppDynamics in the `agent.properties` file. Values from `agent.properties` do not override values passed in the JVM startup script.
- Do not include `-D` switch for keys in the `agent.properties` file.

controller-info.xml Sample File

The `controller-info.xml` file resides in `<agent_home>/<version_number>/conf`. Comments in the file from the agent distribution describe the settings. They have been removed in the following example for brevity.

```
<?xml version="1.0" encoding="UTF-8"?>
<controller-info>
  <controller-host>192.168.1.20</controller-host>
  <controller-port>8090</controller-port>
  <controller-ssl-enabled>false</controller-ssl-enabled>
  <application-name>ACMEOnline</application-name>
  <tier-name>InventoryTier</tier-name>
  <node-name>Inventory1</node-name>
  <agent-runtime-dir></agent-runtime-dir>
  <enable-orchestration>false</enable-orchestration>
  <account-name>customer1</account-name>
  <account-access-key>341bf72e-7d7a-1234-b33d-9n712nn574</
account-access-key>
  <force-agent-registration>false</force-agent-registration>
</controller-info>
```

For a complete list of configuration settings, see [Java Agent Configuration Properties](#).

Java Agent Directory Structure

Unzipping the Java Agent distribution archive extracts the following files and directories to the current directory.

Java Agent Directory Contents

Files/ Direct ories	Description
<code>conf</code>	Common configuration files. The configuration files in this directory are used by an agent if a more specific version of the configuration file does not exist in the version-specific <code>conf</code> directory, <code>ver<version_number>/conf</code> .
<code>javaagent.jar</code>	The common JAR file used to bootstrap the Java Agent. To enable the agent, pass the fully qualified location of this file as the <code>--javaagent</code> argument value to the JVM at startup.

Files/ Directories	Description
readme.txt	Instructions and notes for installing the Java Agent.
utils	Binary files for utilities shared across versions of the agent.
ver<version_number>	<p>The <code>javaagent.jar</code> file, configuration files, and other resources specific for this version of the Java Agent. This directory is named to reflect the Java Agent version number, such as <code>ver4.4.0.5</code>.</p> <p>Among other things, the directory contains:</p>
conf	The configuration files used by this version of the Java agent, including <code>controller-info.xml</code> , <code>app-agent-config.xml</code> , and more. These settings in these files take precedence over the configuration file in the <code><agent_home>/conf</code> directory.
external-services	Dynamically loaded modules that extend the agent, such as the Analytics Data Sources dynamic service.
javaagent.jar	A version-specific JAR file that serves as the Java agent binary. Do not use this Java agent JAR when configuring instrumenting directly. Use <code>javaagent.jar</code> in the root directory instead.
lib	Libraries that support the operation of this version of the Java agent.
logs	Log files written by the agent.
sdk	Samples, APIs, and Javadoc for extending the capabilities of the AppDynamics Java Agent.
utils	Binary files for utilities that are specific to this version of the agent.

You can point the JVM argument at the top-level `javaagent.jar`, as it allows you to upgrade the agent without changing how you deploy your application (unzip the new agent version and place it at the old location on the file system). The top-level jar has a specific version that behaves the same as the `javaagent.jar` under the directory with the same version number in its name.

The version-specific `javaagent.jar` allows you to use different versions of the agent and at the same time re-use the same top-level config files. You can point different applications JVM arg at different versions of the agent.

Contents of the conf Directory

The files located in this directory are commonly used for agent configuration and deployment.

- `transactions.xml` : Configuration settings for business transactions identified by the agent.
- `controller-info.xml` : Configuration settings that identify the node, tier, and application associated with the data that this agent reports to the AppDynamics Controller, along with connection settings for the Controller. For more information, see [Java Agent Configuration Properties](#).
- `app-agent-config.xml` : Local configuration settings for this agent. The settings in this file override any equivalent settings specified globally for the AppDynamics deployment. This file is typically used for short-term property settings or for debugging agent issues.
- `jmx` : Files for configuring the JMX and Websphere PMI metrics.
- `logging / log4j2.xml` : Flags to control logging levels for the agent. It is highly recommended not to change the default logging levels.

Java Agent Logging

By default, the AppDynamics Java Agent writes log files to the `<agent_home>/ver<version_number>/logs/<node_name>` directory.

See [Agent Log Files](#) for information about how the logs are organized into sets that rollover.

Configure Appender Attributes

Each logger has one or more appenders. Each appender specifies where, and in what format, the data is logged. For each appender, you can configure these attributes:

Attribute	Description	Type	Default Value
<code>fileName</code>	The name of the log file.	String	-
<code>name</code>	The name of the appender.	String	-
<code>directory</code>	The directory that the log file is saved to.	String	""
<code>immediateFlush</code>	Whether or not to immediately flush log data. Options: <code>true</code> , <code>false</code>	String	true
<code>bufferSize</code>	The size, in MB, of the event buffer. The buffer temporarily stores messages before they are written to disk.	String	256 KB

Configure Log File Sizes and Rollovers

You may want to limit the length of your agent log files to make troubleshooting easier. To do this, you can specify a maximum size for your log files. When a log reaches that size, it is then rolled over: the log file gets zipped, and a new blank log file is generated to store the next batch of log data. By default, a log file has a maximum size of 20 MB and can be rolled over four times. See [Troubleshooting Java Agent Issues](#).

You can configure log rollover attributes in the `log4j2.xml` file.

1. In `log4j2.xml`, find the `ADRRFAAppender` element that you want to configure rollover attributes for.
2. Modify the `ADRRolloverStrategy` element and set values for these attributes:

Attribute	Description	Type
max	The maximum number of log files. When the maximum number of files is reached, the oldest log file after the initial log file is deleted.	String
compressionLevel	The degree of file compression, with 0 being uncompressed and 9 being the most compressed.	String
format	The file format that the log is saved in. Options: zip, gz	String

For example:

```
<ADRRAFAppender name="BusinessTransactionsLogger"
fileName="BusinessTransactions.log">
  <PatternLayout pattern="[%t] %d{DATE} %5p - %m%n" />
  <SizeBasedTriggeringPolicy size="20 MB" />
  <ADRollerStrategy max="5", compressionLevel="8",
format="zip" />
</ADRRAFAppender>
```

In the above example, "5" is the total number of log files with backups per appender type per set that we keep. In essence, each agent restart will create {number of appenders} files as a set. Then each file can grow up to "5" files total consisting of the first file and 4 backup log files before it rolls over.

3. Modify the `SizeBasedTriggeringPolicy` element and set values for these attributes:

Attribute	Description	Type
size	The maximum log file size, in MB, before a log is rolled over. By default, the size is 20MB before the rollover, because the logs are compressed.	String

Modify the Log Directory Location

To specify a different log directory, use this system property:

```
-Dappdynamics.agent.logs.dir
```

The default logging directory is `<agent_home>/ver<version_number>/logs/<node_name>`.

Set the Agent Log Level

The default logging level for most log files is `INFO`. Higher logging levels consume more disk space; you can change the logging level to `warn` or `error` to reduce the amount of logging. You can control the logging level for the Java Agent by changing the value of the "level" attribute in the `log4j2.xml` file in the versioned logging configuration file directory: `<agent_home>/<version_number>/conf/logging`. A restart of the application or agent is not required when changing the agent log level. For example, to set the log level to `DEBUG`:

```
<!-- to control the logging level of the agent log files, use
the level attribute below. value="all|trace|debug|info|warn|
error"-->
<AsyncLogger name="com.singularity" level="debug"
additivity="false">
  <AppenderRef ref="Default"/>
  <AppenderRef ref="RESTAppender"/>
</AsyncLogger>
```

Direct Logging to Syslog

Instead of having the Java Agent write to the default log directory in the agent home directory, you can configure the agent to direct logging output to `syslog`. The agent supports syslog-based logging through `log4j SyslogAppender`.

Configure the Agent to Send Logs to syslog

1. Open this configuration file in the agent home to edit:
`<agent_home>/ver<version_number>/conf/logging/log4j2.xml`
2. Add this section to the configuration file:

```
<Syslog name="SyslogAppender" facility="LOCAL1"
host="localhost" port="514" protocol="TCP">
  <PatternLayout pattern="[%t] %d{DATE} %5p %c - %m%n"/>
</Syslog>
```

3. Configure the agent to redirect its logs to this appender. Find and replace this section of the file:

```
<!-- to control the logging level of the agent log files, use
the level attribute below. value="all|trace|debug|info|warn|
error"-->
<AsyncLogger name="com.singularity" level="info"
additivity="false">
  <AppenderRef ref="Default"/>
```

```
<AppenderRef ref="RESTAppender"/>
</AsyncLogger>
```

With the following:

```
<!-- to control the logging level of the agent log files, use
the level attribute below. value="all|trace|debug|info|warn|
error"-->
<AsyncLogger name="com.singularity" level="info"
additivity="false">
    <AppenderRef ref="SyslogAppender"/>
    <AppenderRef ref="RESTAppender"/>
</AsyncLogger>
```

Enable SSL for the Java Agent

Related pages:

- [Encrypt Agent Credentials](#)
- [Install the Java Agent](#)

This page describes how to secure communication between the Java Agent and these AppDynamics components using SSL:

- AppDynamics Controller: Before you configure the agent to communicate with the Controller through SSL, you must either use a SaaS Controller or configure the on-premises Controller to use SSL. See [Gather SSL Configuration Details](#).
- AppDynamics Analytics Agent: Before you configure the agent to communicate with the Analytics Agent through SSL, you must [Enable SSL for the Analytics Agent](#).

The Java Agent supports extending and enforcing the SSL trust chain when in SSL mode.

Gather SSL Configuration Details

In preparation to secure Java Agent communications through SSL, you need information about the SSL configuration of the Controller or the Analytics Agent:

- The SSL port:
 - For SaaS Controllers, the SSL port is 443.
 - For on-premises Controllers, the default SSL port is 8181, but you may configure the Controller to listen for SSL on another port.
 - You configure the port for the Analytics Agent using the `ad.dw.http.port` property. See [Enable SSL for the Analytics Agent](#).
- The signature method for the certificates:
 - A publicly known certificate authority (CA) signed the certificate. This applies for DigiCert, Verisign, Thawte, and other commercial CAs.
 - A CA internal to your organization signed the certificate. Some companies maintain internal certificate authorities to manage trust and encryption within their domain.
 - The Controller or Analytics agent uses a self-signed certificate.

Establish Trust for the Controller SSL Certificate

To establish trust between the Java Agent and the AppDynamics Controller, you must import the root certificate for the authority that signed the Controller's certificate into the agent truststore.

i If you secured your on-premises Controller with a self-signed certificate, see [Keystore Certificate Extractor Utility](#) for instructions to create the agent truststore.

1. Obtain the root certificate for the authority that signed the certificate for the Controller.
 - a. For SaaS Controller deployments only: You can download the DigiCert root certificates at the following location: <https://www.digicert.com/digicert-root-certificates.htm>. Ensure to include at least the following certificates:
 - DigiCert Global Root CA
 - DigiCert Global Root G2
 - DigiCert Global Root G3
 - DigiCert TLS ECC P384 Root G5
 - DigiCert TLS RSA4096 Root G5
 - b. You must import only the Root CA Certificate into the Java SSL Trust Store because Host Certificates have a very short lifespan and change often. Trusting the Root CA Certificate ensures uninterrupted connectivity to the controller when the Host Certificate changes before expiry.
2. Run the Java `keytool` command to import the root certificate. The command creates the keystore in the versioned agent configuration directory if it does not exist:

```
keytool -import -alias rootCA -file <root_certificate_file_name> -keystore <agent_home>/<version_number>/conf/cacerts.jks -storepass <truststore_password>
```

For example:

```
keytool -import -alias ControllerRootCA -file /usr/home/appdynamics/DigicertGlobalRootCA.pem -keystore /usr/local/appagent/4.3.0.0/conf/cacerts.jks -storepass MySecurePassword
```

i Make note of the truststore password, you need it to configure the Java Agent.

Enable SSL between the Java Agent and the Controller

Configure these system properties in the versioned `controller-info.xml`: `<agent_home>/<version_number>/conf/controller-info.xml`. See [SSL Configuration Properties](#) for full details on each property.

- Controller Port: The SSL port for the controller. 443 for AppDynamics SaaS.
`<controller-port>443</controller-port>`
- Controller SSL Enabled: true.
`<controller-ssl-enabled>>true</controller-ssl-enabled>`
- Controller Keystore Password: The plaintext password for the agent truststore.
`<controller-keystore-password>MySecurePassword</controller-keystore-password>`
If you enabled the Secure Credential Store, encrypt the password and enter it here. See [Encrypt Agent Credentials](#).

- Controller Keystore Filename: Path of the agent truststore relative to `<agent_home>/<version>/conf`. Required if you use a truststore other than the default `<agent_home>/<version_number>/conf/cacerts.jks`.
`<controller-keystore-filename>../../../../conf/cacerts.jks</controller-keystore-filename>`

 You can also configure these system properties in the JVM startup script. See [Java Agent Configuration Properties](#).

Restart the JVM after you complete the configuration changes.

Sample Controller-info.xml with SSL and Secure Credential Store Encryption Enabled

```
<?xml version="1.0" encoding="UTF-8"?>
<controller-info>
  <controller-host>mycompany.saas.appdynamics.com</controller-host>
  <controller-port>443</controller-port>
  <controller-ssl-enabled>true</controller-ssl-enabled>
  <!-- Encrypted Controller keystore / agent trust store password -->
  <controller-keystore-password>Tw49bd0hdCMB0Q5pFMMuYA/cA5B4pouVPkv48ovRm6c=</controller-keystore-password>
  <controller-keystore-filename>../../../../conf/cacerts.jks</controller-keystore-filename>
  ...
  <!-- Secure Credential Store configuration -->
  <!-- Enable the Secure Credential Store -->
  <use-encrypted-credentials>true</use-encrypted-credentials>
  <!-- Path to they secure credential keystore -->
  <credential-store-filename>/opt/appdynamics/secretKeyStore</credential-store-filename>
  <!-- Obfuscated secure credential keystore password -->
  <credential-store-password>n/8GvAZsKk4gM3Z6g+XQ1w==</credential-store-password>
</controller-info>
```

Establish Trust for the Analytics Agent SSL Certificate

To establish trust between the Java Agent and the Analytics Agent, you must import the root certificate for the authority that signed the Analytics Agent's certificate into the agent truststore.

1. Obtain the root certificate for the authority that signed the certificate for the Analytics Agent.
2. Run the Java `keytool` command to import the root certificate into the JRE truststore.

```
keytool -import -trustcacerts -alias analytics-agent -file <root_certificate_file_name>
-keystore $JAVA_HOME/jre/lib/security/cacerts
```

For example:

```
keytool -import -trustcacerts -alias analytics-agent -file /usr/home/appdynamics/
MyAnalyticsCert.crt -keystore $JAVA_HOME/jre/lib/security/cacerts
```

Establish Trust for Analytics without an Analytics Agent

You can retrieve Transaction Analytics data through Java Agent `>= 4.5.16` without the need for a dedicated Analytics Agent. In this deployment model, the Java Agent communicates with the Events Service directly.

If you use a custom trust store for the Java Agent, you need to establish trust with the Events Service to enable Transaction Analytics without an Analytics Agent. These commands demonstrate how to import the Events Service certificate to the Java Agent trust store:

- Using a signed certificate:

```
keytool -import -trustcacerts -v -alias events_service -file /path/to/CA-cert.txt
-keystore cacerts.jks
```

- Using a self-signed certificate:

```
keytool -import -v -alias events_service -file events_service.crt -keystore cacerts.jks
```

If you do not establish trust for the private certificate, you cannot retrieve Transaction Analytics data through your Java Agent. Any applications and business transactions you have configured for Transaction Analytics cannot be enabled if the Java Agent cannot communicate with the Events Service.

You can override this behavior using the `-Dappdynamics.force.default.ssl.certificate.validation` property. See [Java Agent Configuration Properties](#) for details.

Enable SSL Between the Java Agent and the Analytics Agent

To enable the Java Agent to access the Analytics Agent over SSL, configure the `appdynamics.analytics.agent.url` system property for the JVM.

- Use the HTTPS protocol.
- Use the Analytics Agent SSL port. The port should be the same value as the Analytics Agent `ad.dw.http.port` property. See [Enable SSL for the Analytics Agent](#).

```
-Dappdynamics.analytics.agent.url=https://<analytics_agent_host>:<analytics_agent_port>/v2/sinks/bt
```

For example:

```
java -javaagent:/home/appdynamics/agent/javaagent.jar
-Dappdynamics.controller.hostName=mycontroller.example.com
-Dappdynamics.controller.port=8090 -Dappdynamics.analytics.agent.url=https://
my.analytics.host.example.com:9090/v2/sinks/bt
-Dappdynamics.agent.applicationName=ACMEOnline -Dappdynamics.agent.tierName=Inventory
-Dappdynamics.agent.nodeName=Inventory1 ACMEOnline.jar
```

Restart the JVM after you complete the configuration changes.

Secure the Java Agent Truststore

To prevent tampering with the Java Agent truststore, you should:

- Secure the truststore file through filesystem permissions:
 - Make the agent truststore readable by any user.
 - Make the truststore owned by a privileged user.
 - Make the truststore writable only by the specified privileged user.
- Secure the agent configuration files so that they are only readable by the agent runtime user and only writable by a privileged user:
 - Versioned configuration file: `<agent_home>/<version_number>/conf/controller-info.xml`.

- Global configuration file: `<agent_home>/conf/controller-info.xml`.

Keystore Certificate Extractor Utility

The Keystore Certificate Extractor Utility exports certificates from the Controller's Java keystore and writes them to an agent truststore. It installs to this location:

```
<agent_home>/<version_number>/utils/keystoreextractor/kr.jar
```

To avoid copying the Controller keystore to an agent machine, you can run this utility from the Controller server. Access the agent distribution on the Controller at this location:

```
<controller_home>/appserver/glassfish/domains/domain1/appagent
```

1. Execute `kr.jar` and pass these parameters:

- The full path to the Controller's keystore:

```
<controller_home>/appserver/glassfish/domains/domain1/config/keystore.jks
```

- The truststore output file name. By default, the agent looks for a Java truststore file named `cacerts.jks` in the `<agent_home>/<version>/conf` directory in the agent home.
- The password for the Controller's certificate, which defaults to "changeit". If you don't include a password, the extractor applies the password "changeit" to the output truststore.

```
/<full path to application JRE>/bin/java -jar kr.jar <controller_home>/appserver/  
glassfish/domains/domain1/config/keystore.jks cacerts.jks  
<controller_certificate_password>
```

2. Install the agent trust store to the versioned agent configuration directory:

```
<agent_home>/<version_number>/conf/
```

Configure the Java Agent for FIPS Compliance

1. Rename the existing secure credential keystore file.
2. Initialize a new secure credential keystore using the Secure Credential Store (SCS) utility.
The SCS utility is available at: `<javaagent_home>/verX.X.X.X/utils/scs/scs-tool.jar`.
3. Run the Secure Credential Store utility `generate_ks` command with the following parameters:
 - `filename` : Absolute path where the utility will create the secure credential keystore. Use this path for `<credential-store-filename>` in agent configuration.
 - `storepass` : The secure credential keystore password. Use the obfuscated version of this password as the value for `<credential-store-password>` in agent configuration.
 - `format` (For FIPS-compliant users only): The format of the secure credential keystore.

Example Command

```
java -jar scs-tool.jar generate_ks -filename '<>/secretKeyStoreFIPS' -storepass 'MyCredentialStorePassword' -format FIPS
```

The Secure Credential Store utility confirms the creation and initialization of the keystore.

Expected Output

```
Successfully created and initialized new KeyStore file: /opt/appdynamics/secretKeyStore
Verification - New KeyStore file: /opt/appdynamics/secretKeyStoreFIPS is properly
initialized.
```

- Run the following command to obfuscate the plain text password.

CODE

```
java -jar scs-tool.jar obfuscate -plaintext 'MyCredentialStorePassword'
```

The output is an encrypted string that looks like

```
s_-001-12-5pA2yIp3rZY=zIgMiWjtFhMRAtpN4FI6U12PRVghqTpnFHmTN7Rh6HY= .
```

- Run the following command using the obfuscated password from Step 4 to encrypt the actual Controller account access key.

CODE

```
java -jar scs-tool.jar encrypt -filename '<>/secretKeyStoreFIPS' -storepass '<output_from_step_above>' -plaintext '<controller_account_access_key>' -format FIPS
```

The output is an encrypted string that looks like -001-24-mEE2dy63UbE/u93idMxfew==JZgvmqT/+OddN+sLH43mx145FNoducIM44qeYczBnc5tbUoay3x8qc/Z3pDlGC4C .

- Modify the `controller.xml` file using the outputs of Step 4 and Step 5. The following is an example of the `controller.xml` file.

CODE

```
<controller-info>
  <controller-host><controller_url></controller-host>
  <controller-port><port></controller-port>
```

```

<controller-ssl-enabled><true/false></controller-ssl-enabled>

Resolve SSL Issues

If you run into problems with the version of TLS/SSL, see [SSL Compatibility between Java Agent and Controller](#) and [AppDynamics Agent SSL Protocol](#).

Upgrade the Java Agent

To upgrade the AppDynamics Java Agent, you copy the existing agent directory to a backup location and replace it with the new agent directory. You then copy configuration file changes made in the old directory to the new agent directory and restart the application server.

This page provides additional background information and step-by-step instructions.

About the Upgrade

Before you begin, review the [Release Notes](#) for changes that affect your environment. If you are upgrading both the Controller and agents, first upgrade the Controller and then upgrade the Java Agents.

Also, if upgrading multiple agents in your monitored environment, upgrade the agents for the tiers on which business transactions are originated last. For more information about this requirement, along with Controller and agent compatibility information, see [Agent and Controller Tenant Compatibility](#).

Upgrading the agent requires a restart of the application server.

An agent upgrade requires no action on the Controller.

Before starting, download the latest version of the Java Agent for your JVM from the [AppDynamics Download Center](#).

Upgrade the Java Agent

1. Shut down the application server where the Java Agent is installed.
2. Create a backup copy of the current agent installation directory.
3. Extract the Java Agent archive to a new directory
4. Rename the existing agent directory.

5. Rename the new directory to the original name of the old agent directory. The new agent directory and its containing files should have the same directory path as the original one. Using the same directory path avoids the task of manually changing the agent-related configurations in your JVM startup script.
6. Copy `controller-info.xml` and, if necessary, `agent.properties` from the old agent config directory to the following location in the new directory:

```
<agent_home>/<version>/conf
```

For example:

```
appd_javaagent/ver4.0.0.0/conf
```

7. If you previously made changes to the `app-agent-config.xml` or other configuration files, copy those changes to the new file as well.

i If you are using an SSL port (`ssl-enabled=true`) to communicate with the Controller UI, make sure that you copy the TrustStore files to the new directory. For example, copy the `cacerts.jks` from the old backup agent directory (`<version>/conf/`) to the new upgraded directory (`<agent_home>/<version>/conf/`). Also, make sure that the agent TrustStore file (`cacerts.jks`) is readable by the agent user.

8. Restart the application server.

Once completed, you can archive the original directory and remove it from the application server home.

Uninstall the Java Agent

Related pages:

- [Manage App Agents](#)
- [Install the Java Agent](#)
- [Java Agent Configuration Properties](#)

If you delete an app agent from the Controller UI, as described in [Manage App Agents](#), but do not shut down the JVM that the Java Agent runs on, the Java Agent will reappear in the UI the next time it connects to the Controller.

To prevent a Java Agent from connecting to the Controller, you need to remove the Java Agent settings from the JVM configuration. This frees the license associated with the agent in the Controller and makes it available for use by another app agent. This page describes how to uninstall a Java Agent from the JVM configuration.

Uninstall the Java Agent

1. Stop the application server on which the Java Agent is configured.

2. Remove the `-javaagent` argument in the startup script of the JVM.
3. Remove any system properties configured for the Java Agent from the startup script of your JVM.
4. Restart the application server.

Tune Java Agent Performance

This page describes how to get the best performance from Java Agents. You can view performance statistics for deployed app agents in the diagnostic data panel.

View Agent Diagnostic Data

The agent diagnostic data shows you information about the performance of App Server agents. You can view the data from the Agents page in the Controller UI.

From the Node Dashboard of the node that contains the agent you want to view, click the Agent Diagnostic Stats subtab. Click **View Diagnostics for all Agents** to view statistics for all agents.

Business Transaction Thresholds

AppDynamics determines whether transactions are slow, very slow, or stalled based on the thresholds for Business Transactions. AppDynamics recommends using standard deviation based dynamic thresholds. See [Transaction Thresholds](#).

Snapshot Collection Thresholds

Snapshot collection thresholds determine when snapshots are collected for a Business Transaction. Too many snapshots can affect performance. Therefore, you should consider snapshot collection thresholds carefully in production or load testing scenarios. See [Transaction Thresholds](#).

Suggested Scheduling Settings

- 10 minutes for deployments with less than 10 BTs
- 20 minutes for deployments from 10 to 50 BTs
- 30 minutes for deployments from 50 to 100 BTs
- 60 minutes for deployments larger than 100 BTs

Suggested Diagnostic Session Settings

- Settings for Slow requests (%value): 20 – 30
- Settings for Error requests (%value): 10 – 20
- Click **Apply to all Business Transactions**.

Tune Call Graph Settings

You can tune call graph settings from the **Call Graph Settings** page, as described in [Call Graph Settings](#).

Suggested SQL Query Time and Parameters

- Increase the **Minimum SQL query time** to 100 ms from the default of 10 ms.
- Enable **Filter SQL Parameter Values**.

Memory Monitoring

Memory monitoring features such as leak detection, object instance tracking, and custom memory should be enabled only for a specific node or nodes when debugging a memory problem. Automatic leak detection is on-demand, and therefore, the leak detection will execute only for the specified duration.

When you observe periods of growth in the heap utilization (%), you should enable on-demand memory leak capture. See [Java Memory Leaks](#).

Agent Heap Storage Monitoring and Shutdown

The Java Agent monitors the heap storage used by the instrumented application and shuts itself down when conditions indicate excessive utilization of Java heap storage by the application. The agent takes this measure not necessarily because it is likely to be the source of the memory pressure—in fact, it can help you diagnose the root cause of the issue—but as a final protective measure to help relieve the pressure on available memory for the application.

Typical reasons for excessive heap utilization include:

- Java heap space is too small compared to your application traffic and footprint
- Java heap memory leak
- A rogue thread is consuming a large amount of memory in a short amount of time

Java Agent monitoring of heap storage works as follows. The agent checks heap utilization every 30 seconds. When it detects that heap utilization has exceeded 95%, the Java Agent checks for a garbage collection event. When garbage collection occurs, it checks heap utilization again. If usage still exceeds the threshold, the agent shuts itself down and logs the following agent event:

```
ERROR HeapShortageMonitor - Agent shutdown triggered because max heap usage percentage reached
```

If heap memory utilization exceeds the threshold, but garbage collection never occurs, the agent resumes normal monitoring after 30 seconds. If the heap usage remains above the threshold, the heap shortage monitor resumes checking for garbage collection, as it did previously.

You can use a Java Agent node property to control whether heap storage monitoring is enabled and the action that results from excessive heap utilization. The `heap-storage-monitor-enabled` controls whether it is enabled (true, by default), and the `heap-storage-monitor-shutdown-action` property determines the triggered action, between:

- true: If the heap threshold is exceeded, the agent is disabled.
- false: If the threshold is exceeded, a warning-level message is written to the agent log and warning event is sent to the Controller (of type AGENT_EVENT with the text: "AppDynamics agent has detected shortage of JVM Heap Storage").

Troubleshooting Java Agent Issues

This page describes techniques for troubleshooting agent installation and operation. In particular, it describes how to find and interpret information in agent log files.

Resolve Java Agent Startup Issues

The first thing the Java agent does upon application startup is to register with the Controller. Once registered, the agent should appear in the **Settings > AppDynamics Agents** list.

If you do not see the agent in the list within a few minutes, check the following:

1. Make sure you have restarted the application server.
2. Verify that the `javaagent` argument has been added to the startup script of your JVM.
3. Verify that you configured the agent-controller communication properties and agent identification properties in the `controller-info.xml` file or as system properties in the startup script of your JVM. See [Java Agent Configuration Properties](#).

4. Check the Agent logs directory located at `<agent_home>/ver<version_number>/logs/<node_name>` or the `agent.log` file.
5. Verify that the Agent is compatible with the Controller. See [Agent and Controller Tenant Compatibility](#) and [Troubleshoot Controller Issues](#).

Locate the Java Agent Log Files

Agent log files are located in the `<agent_home>/ver<version_number>/logs/<node_name>` folder.

The `agent.log` file is the recommended file to help you with troubleshooting. This log can indicate the following:

- [Incomplete information in your Agent configuration](#)
- [The Controller port is blocked](#)
- [Incorrect file permissions](#)

Error messages related to starting the Java Agent use this format:

```
ERROR com.singularity.JavaAgent - Could Not Start Java Agent
```

Resolve Incomplete Agent Configuration Issues

This table lists typical error messages for incomplete Agent configuration:

Error Message	Solution
Cannot connect to the Agent - ERROR com.singularity.XMLConfigManager - Incomplete Agent Identity data, Invalid Controller Port Value	<p>This indicates that the value for the Controller port in <code>controller-info.xml</code> is missing. Add the Controller port and host value to resolve:</p> <ul style="list-style-type: none"> • For on-premises Controller installations: 8090 for HTTP and 8181 for HTTPS. • For Controller SaaS service, use the default HTTPS port 443.
Caused by: com.singularity.ee.agent.configuration.a: Could not resolve agent-controller basic configuration	<p>This is usually caused because of incorrect configuration in the <code>Controller-info.xml</code> file.</p> <p>Ensure that the information for agent communication (Controller host and port) and agent identification (application, tier and node names) is correctly configured.</p> <p>Alternatively, you can also use the system properties (-D options) or environment variables to configure these settings.</p>

Unblock the Controller Port

This table lists the typical error message when the Controller port is blocked in your network:

Error Message	Solution
<p>ERROR com.singularity.CONFIG.ConfigurationChannel - Fatal transport error: Connection refused</p> <p>WARN com.singularity.CONFIG.ConfigurationChannel - Could not connect to the controller/invalid response from controller, cannot get initialization information, controller host \x.x.x.x\, port 8090, exception Fatal transport error: Connection refused</p>	<p>Try pinging the Controller from the machine where you have configured the application agent.</p> <p>To check if a port is blocked in the network, use the commands:</p> <ul style="list-style-type: none"> • <code>netstat -an</code> for Windows • <code>nmap</code> for Linux. <p>The default ports are:</p> <ul style="list-style-type: none"> • For on-premises Controller installations: 8090 for HTTP and 8181 for HTTPS. • For Controller SaaS service, use the default HTTPS port 443.

Correct File Permission Issues

This table lists typical error message when the file permissions are not correct:

Error Message	Solution
<p>ERROR com.singularity.JavaAgent - Could Not Start Java Agent</p> <p>com.singularity.ee.agent.appagent.kernel.spi.c: Could not start services"</p>	<p>This is usually caused because of incorrect permissions for log files. To troubleshoot:</p> <p>Confirm whether the user who is running the server has read and write permission on the agent directories.</p> <p>If the user has chmod a-r equivalent permission, change the permission to chmod a+r "<agent_home>"</p>

Maximum Async Handoff Call Graph Samples Error

This error indicates that the number of handoffs in an asynchronous has exceeded the limit:

```
"WARN AsyncHandOffIdentificationInterceptor - Reached maximum limit 500 of async handoff call graph samples. No more samples will be taken" Error
```

This can result from transactions being misidentified as async transactions. In AppDynamics >= 3.6, all Runnables, Callables, and Threads are instrumented by default except those that are excluded by the agent configuration in `app-agent-config.xml`.

In some environments, this may result in too many classes being instrumented, or cause common classes in a framework that implements the Runnable interface to be mistaken for asynchronous activity when it is not, for example, Groovy applications using Clojure.

To debug, check the call graph for asynchronous activities that are misidentified as asynchronous activities. If found, exclude the packages that are not really asynchronous activities. See [Configure the Thread Correlation in Java Agent](#).

Fatal Transport Error While Connecting to URL

The Java Agent comes with Network Visibility enabled by default. This error appears if the Network Visibility Agent process is not running on the host:

```
[AD Thread Pool-Global0] 27 Apr 2022 07:35:28,539 ERROR
NetVizAgentRequest - Fatal transport error while connecting to
URL http://127.0.0.1:3892/api/agentinfo?
timestamp=0&agentType=APP_AGENT&agentVersion=1.11.4:
org.apache.http.conn.HttpHostConnectException: Connect to
127.0.0.1:3892 [/127.0.0.1] failed: Connection refused
(Connection refused)
```

If Network Visibility is not required in your environment, you can ignore this error.

Java Agent Configuration Properties

Related pages:

- [Administer the Java Agent](#)
- [Use System Properties for Java Agent Settings](#)
- [Instrument JVMs in a Dynamic Environment](#)

This page is a reference for the configuration properties for the AppDynamics Java Agent. If you are also installing a Machine Agent on the same machine with the Java Agent, see [Machine Agent Installation Scenarios](#).

Agent-Controller Communication Properties

The following are the Agent-Controller communication properties:

AWS Instance

The `appdynamics-aws-instance-enabled` property helps to enable agent retrieval of AWS instance-id by default during registration.

If Java Agent is running on an AWS instance, then the agent log includes *Agent AWS instance-id:<instance-id-of-host>* else the agent log includes *Agent AWS instance-id:null*.

The property is enabled by default and the agent log includes `Agent AWS instance-id retrieval enabled: true`. To disable the property, set `appdynamics.aws.instance.enabled=false`. The agent log includes `Agent AWS instance-id retrieval enabled: false`.

System Property: `-Dappdynamics.aws.instance.enabled`

Environment Variable: APPDYNAMICS_AWS_INSTANCE_ENABLED**Type:** Boolean**Default:** True**Required:** Yes**Controller Host**

The hostname or the IP address of the AppDynamics Controller. Example values are `192.168.1.22` or `myhost` or `myhost.example.com`. This is the same host that you use to access the AppDynamics browser-based user interface. For an on-premises Controller, use the value for Application Server Host Name that was configured when the Controller was installed. If you are using the AppDynamics SaaS Controller service, see the Welcome email from AppDynamics.

Element in controller-info.xml: `<controller-host>`**System Property:** - `Dappdynamics.controller.hostName`**Environment Variable:** APPDYNAMICS_CONTROLLER_HOST_NAME**Type:** String**Default:** None**Required:** Yes, if the Enable Orchestration property is `false`.

If Enable Orchestration is `true`, and if the app agent is deployed in a compute cloud instance created by an AppDynamics workflow, do not set the Controller host unless you want to override the auto-detected value. See [Enable Orchestration Property](#).

Controller Port

The HTTP(S) port of the AppDynamics Controller. This is the port used to access the AppDynamics browser-based user interface.

If the Controller SSL Enabled property is set to `true`, specify the HTTPS port of the Controller; otherwise specify the HTTP port. See [Controller SSL Enabled Property](#).

Element in controller-info.xml: `<controller-port>`**System Property:** - `Dappdynamics.controller.port`**Environment Variable:** APPDYNAMICS_CONTROLLER_PORT**Type:** Positive Integer

Default: For On-premises installations, port `8090` for HTTP and port `8181` for HTTPS are the defaults. For the SaaS Controller Service, use port `443` for HTTPS connections.

Required: Yes, if the Enable Orchestration property is `false`.

If Enable Orchestration is `true`, and if the app agent is deployed in a compute cloud instance created by an AppDynamics workflow, do not set the Controller port unless you want to override the auto-detected value. See [Enable Orchestration Property](#).

SSL Configuration Properties**Controller SSL Enabled**

If true, specifies that the agent should use SSL (HTTPS) to connect to the Controller. If `SSL Enabled` is true, set the `Controller Port` property to the HTTPS port of the Controller. See [Controller Port Property](#).

Element in controller-info.xml: `<controller-ssl-enabled>`

System Property: `-Dappdynamics.controller.ssl.enabled`

Environment Variable: `APPDYNAMICS_CONTROLLER_SSL_ENABLED`

Type: Boolean

Default: False

Required: No

Controller Keystore Password

The plain text value of the Controller certificate password. If `Use Encrypted Credentials` is true, encrypt the password. See [Encrypt Agent Credentials](#).

Element in controller-info.xml: `<controller-keystore-password>`

System Property: `-Dappdynamics.controller.keystorePassword`

Environment Variable: `APPDYNAMICS_CONTROLLER_KEystore_PASSWORD`

Type: String

Default: None

Required: No

Controller Keystore Filename

By default, the agent looks for a Java truststore file named `cacerts.jks` in the `<agent_home>/<version>/conf` directory in the agent home. Use this property to enable full validation of Controller SSL certificates with a different Java truststore file. See [Enable SSL for the Java Agent](#).

Element in controller-info.xml: `<controller-keystore-filename>`

System Property: `-Dappdynamics.controller.keystoreFileName`

Environment Variable: `APPDYNAMICS_CONTROLLER_KEystore_FILENAME`

Type: String

Default: None

Required: No

Force Default SSL Certificate Validation

Used to override the default behavior for SSL validation. The property can have three states:

- **true:** Forces the agent to perform full validation of the certificate sent by the controller, enabling the agent to enforce the SSL trust chain. Use this setting when a public certificate authority(CA) signs your Controller SSL certificate. See [Enable SSL On-Premises with a Trusted CA Signed Certificate](#).
- **false:** Forces the agent to perform minimal validation of the certificate. This property disables full validation of the Controller's SSL certificate. Use this setting when full validation of a SaaS certificate fails.
- **unspecified:** The validation performed by the agent depends on the context:
 - If the agent is connecting to a SaaS controller, full validation is performed.

- If the agent is connecting to an on-premises Controller and the `cacerts.jks` file is present, then full validation is performed using the `cacerts.jks` file.
- If the agent is connecting to an on-premises Controller, and there is no `cacerts.jks` file, then minimal validation is performed

System Property: - `Dappdynamics.force.default.ssl.certificate.validation`

Type: Boolean

Default: None

Required: No

i The force default SSL validation property also applies when connecting the Java Agent to the Events Service for Transaction Analytics. See [Enable SSL for the Java Agent](#).

AppDynamics Agent SSL Protocol

The SSL compatibility table in [Agent and Controller Tenant Compatibility](#) lists the default security protocol for the different versions of the Java Agent. If the default security protocol for your version of an agent is incompatible with the Controller or it is incompatible with an intervening proxy, pass the `-Dappdynamics.agent.ssl.protocol` system property to configure one of these security protocols:

- SSL
- TLS
- TLSv1.2
- TLSv1.1

System Property: - `-Dappdynamics.agent.ssl.protocol`

Type: String

Default: See [Agent and Controller Tenant Compatibility](#)

Required: No

Configure Allowed TLS/SSL Protocols

Agent communication over TLS/SSL causes the agent to initialize the JVM security subsystem, which sets a permitted list of protocols. By default, AppDynamics excludes SSLv3 and TLSv1 protocols due to the known vulnerabilities.

Once the JVM initializes, the list of permitted protocols cannot be changed. If you want to prevent the agent from disabling SSLv3 or TLSv1 protocols, you can configure them to be allowed by naming one (or both, separated by a comma) protocols using this property:

System Property: - `Dappdynamics.agent.tls.allowedAlgorithms`

Type: String

Default: None

Required: No

This example allows both SSLv3 and TLSv1 to be used by the JVM:

```
-Dappdynamics.agent.tls.allowedAlgorithms=SSLv3, TLSv1
```

i This property is applicable from the 4.5.13 version of Java Agent.

Configure Disabled TLS/SSL Protocols

Agent communication over TLS/SSL causes the agent to initialize the JVM security subsystem, which sets a permitted list of algorithms.

Once the JVM initializes, the list of permitted protocols cannot be changed. If you want to prevent the agent from enabling certain algorithms, you can configure them to be disabled by naming one (or both, separated by a comma) algorithms using this property:

System Property: -Dappdynamics.agent.tls.disabledAlgorithms

Type: String

Default: None

Required: No

This example disables both RSASSA-PSS and RSAPSS signature algorithms in the JVM:

```
-Dappdynamics.agent.tls.disabledAlgorithms=RSASSA-PSS,RSAPSS
```

Secure Credential Store Properties

Use Encrypted Credentials

Before you enable Use Encrypted Credentials, see [Encrypt Agent Credentials](#) for instructions on how to initialize the Secure Credential Store.

Set [Use Encrypted Credentials](#) to True to configure the agent to use credentials encrypted with the Secure Credential Store. When you enable Use Encrypted Credentials, you must supply the Credential Store Filename and the obfuscated Credential Store Password.

When Use Encrypted Credentials is true, encrypt the following:

- Account Access Key
- Controller Keystore Password
- Proxy Password

Element in controller-info.xml: `<use-encrypted-credentials>`

Type: Boolean

Default: False

Required: No

Credential Store Filename

The absolute path to the Secure Credential Store keystore. See [Encrypt Agent Credentials](#).

Element in controller-info.xml: `<credential-store-filename>`

Type: String

Default: None

Required: If [Use Encrypted Credentials](#) is set to True

Credential Store Password

The obfuscated keystore password for the Secure Credential Store. See [Encrypt Agent Credentials](#).

Element in controller-info.xml: `<credential-store-password>`

Type: String

Default: None

Required: If Use Encrypted Credentials is set to True

Agent Identification Properties

Automatic Naming

If enabled and other agent identification properties are not specified in other settings, the tier and application for the agent are automatically named. The default names are in the format MyApp and MyTier.

Element in controller-info.xml: `<auto-naming>`

Type: Boolean

Default: None

Required: No

Application Name

The name of the logical business application that this JVM node belongs to. Note that this is not the deployment name(ear/war/jar) on the application server.

If a business application of the configured name does not exist, it is created automatically.

Element in controller-info.xml: `<application-name>`

System Property: - `Dappdynamics.agent.applicationName`

Environment Variable: `APPDYNAMICS_AGENT_APPLICATION_NAME`

Type: String

Default: None

Required: Yes

Tier Name

The name of the tier that this JVM node belongs to. Note that this is not the deployment name (ear/war/jar) on the application server.

If the JVM or application server startup script already has a system property that references a tier, such as `-Dserver.tier`, you can use `${server.tier}` as the tier name. See [Use System Properties for Java Agent Settings](#).

The agent registers the named tier with the Controller, if the tier does not already exist, the first time it connects with the Controller. If a tier with the name already exists in the Controller model, the agent is associated with the existing tier.

Element in controller-info.xml: `<tier-name>`

System Property: - `Dappdynamics.agent.tierName`

Environment Variable: `APPDYNAMICS_AGENT_TIER_NAME`

Type: String

Default: None

Required: Yes

Node Name

The name of the node. Where JVMs are dynamically created, use the system property to set the node name.

If your JVM or application server startup script already has a system property that can be used as a node name, such as `-Dserver.name`, you could use `${server.name}` as the node name. You could also use expressions such as `${server.name}_${host.name}.MyNode` to define the node name. See [Use System Properties for Java Agent Settings](#).

In general, the node name must be unique within the business application and physical host. If you want to use the same node name for multiple nodes on the same physical machine, create multiple virtual hosts using the Unique Host ID property. See [Unique Host ID](#).

Element in controller-info.xml: `<node-name>`

System Property: - `Dappdynamics.agent.nodeName`

Environment Variable: `APPDYNAMICS_AGENT_NODE_NAME`

Type: String

Default: None

Required: Yes

Reuse Node Name

Set this property to true to reuse node names in AppDynamics. When you set the property to true, you do not need to supply a node name, but you do need to provide a node name prefix using `-Dappdynamics.agent.reuse.nodeName.prefix`.

i When `ReuseNodeName/prefix` and a node name is used, the `ReuseNodeName` property is given precedence.

This property is useful for monitoring environments where there are many JVMs with short life spans. When true, AppDynamics reuses the node names of historical JVMs for new JVMs. This avoids a proliferation of differently named nodes in AppDynamics over time, particularly when the nodes are essentially identical processes that run over different times. An example of this environment is a z/OS Dynamic Workload Manager based-environment where new JVMs are launched and shut down based on actual workload.

AppDynamics generates a node name with App, Tier and Sequence number. The node names are pooled. For example, the sequence numbers are reused when the nodes are purged (based on the node lifetime).

When the Java Agent starts up, it logs output to the console until it registers with the Controller and the Controller generates the node name. To configure the agent to write logs to a file, edit the `log4j-unknown.xml` at `<agent_home>/<version_number>/conf/logging`. See [Instrument JVMs in a Dynamic Environment](#).

The Controller reuses node names based on the node retention period property.

System Property: `-Dappdynamics.agent.reuse.nodeName`

Environment Variable: `APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME` (New in 4.5.8)

Type: Boolean

Default: False

Required: No

Example: With the following configuration, the Controller generates a node name with the prefix "reportGen". Node names will have suffixes -1, -2, and so on, depending on the number of nodes are running in parallel. The name of a node that is shut down and qualifies as a historical node may be reused by a new node.

```
-Dappdynamics.agent.reuse.nodeName=true  
-Dappdynamics.agent.reuse.nodeName.prefix=reportGen
```

Reuse Node Name Prefix

When you configure the agent to reuse node names, use this property to specify the prefix the Controller uses to generate node names dynamically.

System Property: `-Dappdynamics.agent.reuse.nodeName.prefix`

Environment Variable: `APPDYNAMICS_JAVA_AGENT_REUSE_NODE_NAME_PREFIX` (New in 4.5.8)

Type: String

Default: None

Required: When `-Dappdynamics.agent.reuse.nodeName=true`

Example: Using the following property specifications, the agent directs the Controller to generate a node name with the prefix "reportGen". Node names will have suffixes --1, --2, and so on, depending on how many nodes are running in parallel.

```
-Dappdynamics.agent.reuse.nodeName=true  
-Dappdynamics.agent.reuse.nodeName.prefix=reportGen
```

Self Service

Configure the Java Agent to automatically name nodes based upon the platform. For automatic node naming to work, you must specify an application name and a tier name.

System Property: `-Dappdynamics.agent.selfService`

Type: String

Values:

tibco: The Java Agent names nodes for the TIBCO process name. See [Configure the Java Agent for TIBCO BusinessWorks](#) for more information.

Default: None

Required: No

Account Properties

If the AppDynamics Controller is running in multi-tenant mode or if you are using the AppDynamics SaaS Controller, specify the account name and key for the agent to authenticate with the Controller.

If you are using the AppDynamics SaaS Controller, the account name is provided in the Welcome email sent by AppDynamics. You can also find this information in the `<controller_home>/initial_account_access_info.txt` file.

If the Controller is running in single-tenant mode, you only need to configure the account access key. You can find the unique access key for your Controller instance from the [Observe License Usage](#) page in the UI.

Account Name

The account name used to authenticate with the Controller.

Element in controller-info.xml: `<account-name>`

System Properties: - `Dappdynamics.agent.accountName`

Environment Variable: `APPDYNAMICS_AGENT_ACCOUNT_NAME`

Type: String

Default: None

Required: Yes for AppDynamics SaaS Controller and other multi-tenant users; no for single-tenant users.

Account Access Key

The account access key used to authenticate with the Controller. If Use Encrypted Credentials is true, encrypt the account access key. See [Encrypt Agent Credentials](#).

Element in controller-info.xml: `<account-access-key>`

System Properties: - `Dappdynamics.agent.accountAccessKey`

Environment Variable: `APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY`

Type: String

Default: None

Required: Yes

i If you provide application keys through JVM system properties or environment variables, ensure that you use quotes to wrap any shell special characters that may be contained within application keys to prevent the Shell from interpreting them. See the shell documentation for more detail.

Proxy Properties for the Controller

Use the proxy properties to configure the agent to connect to the Controller through a proxy.

 Proxy authentication cannot be used in conjunction with agent SSL. To connect the agent through a proxy via SSL, the proxy must be open (not require the agent to authenticate).

Proxy Host

The proxy host name or IP address.

System Property: - `Dappdynamics.http.proxyHost`

Type: String

Default: None

Required: No

Proxy Port

The proxy HTTP(S) port.

System Property: - `Dappdynamics.http.proxyPort`

Type: Positive Integer

Default: None

Required: No

Proxy User Name

The name of the user that is authenticated by the proxy host.

System Property: - `Dappdynamics.http.proxyUser`

Type: String

Default: None

Required: No

Proxy Password

The absolute path to the file containing the password of the user that is authenticated by the proxy host. The password must be the first line of the file.

If [Use Encrypted Credentials](#) is false, enter the password in plain text. If [Use Encrypted Credentials](#) is true, encrypt the password. See [Encrypt Agent Credentials](#).

System Property: - `Dappdynamics.http.proxyPasswordFile`

Type: String

Default: None

Required: No

Example: -Dappdynamics.http.proxyPasswordFile=/path/to/file-with-password

Other Properties

Enable Orchestration

When set to true, enables auto-detection of the controller host and port when the app server is a compute cloud instance created by an AppDynamics orchestration workflow. See [Controller Host Property](#) and [Controller Port Property](#).

In a cloud compute environment, auto-detection is necessary for the Create Machine tasks in the workflow to run correctly.

If the host machine on which this agent resides is not created through AppDynamics workflow orchestration, this property should be set to false.

Element in controller-info.xml: `<enable-orchestration>`

Type: Boolean

Default: False

Required: No

Agent Runtime Directory

Sets the directory under which all files the agent writes at runtime. If this property is specified, all agent logs are written to `<Agent-Runtime-Directory>/logs/node-name` and transaction configuration is written to the `<Agent-Runtime-Directory>/conf/node-name` directory. The log folder location can be overridden with the `appdynamics.agent.logs.dir` property.

Element in controller-info.xml: `<agent-runtime-dir>`

System Property: - `Dappdynamics.agent.runtime.dir`

Environment Variable: `APPDYNAMICS_AGENT_BASE_DIR`

Type: String

Default: `<agent_home>/nodes`

Required: No

Redirect Logfiles

Sets the destination directory to which the logs will be written to.

System Property: - `Dappdynamics.agent.logs.dir`

Type: String

Default: `<agent_home>/logs/<Node_Name>`

Required: No

Custom Path for agent conf Directory

Sets a custom path for the agent conf directory. This is where the agent reads its static config files from. If you need to change `custom-activity-correlation.xml` or `app-agent-config.xml` and the agent installation is read-only, this instructs the agent to read the static config files from elsewhere.

System Property: - `Dappdynamics.agent.conf.dir`

Type: String

Default: `<agent_home>/ver4.5.x.x.x/conf`

Required: No

Force Agent Registration

Set to true only under these conditions:

- The agent has been moved to a new application or tier from the UI, and
- You want to override that move by specifying a new application name or tier name in the agent configuration

Element in controller-info.xml: `<force-agent-registration>`

Type: Boolean

Default: False

Required: No

Auto Node Name Prefix

Set this property if you want the Controller to generate node names automatically using a prefix that you provide.

The Controller generates node names by concatenating the specified prefix with a UUID suffix. For example, if you set the prefix as follows:

```
-Dappdynamics.agent.auto.node.prefix=JoannaAutoNode
```

The generated node name is

```
JoannaAutoNode_d39dbfc1-6f4b-4eb7-a788-c1c0135b6bcb
```

This property provides a similar function to the Reuse Node Name Prefix Property property. However, this property is not meant to be used in combination with reusing node names; use Reuse Node Name Prefix Property for those cases instead.

Element in controller-info.xml: Not applicable

System Property: -`Dappdynamics.agent.auto.node.prefix=<your_prefix>`

Type: String

Default: Serial number maintained by the Controller appended to the tier name

Required: No

Cron/Batch JVM

Set this property to true if the JVM is a batch/cron process. You can use this property to stall the shutdown to allow the agent to send metrics before shutdown.

Element in controller-info.xml: Not applicable

System Property: -`Dappdynamics.cron.vm`

Type: Boolean

Default: False

Required: No

Unique Host ID

Logically partitions a single physical host or virtual machine such that it appears to the Controller that the application is running on different machines. Set the value to a string that is unique across the entire managed infrastructure. The string may not contain any spaces. If you have a machine agent associated with the application monitored by the app agent, then this property must be set on the machine agent to the same value. See [Machine Agent Installation Scenarios](#).

System Property: `-Dappdynamics.agent.uniqueHostId`

Environment Variable: APPDYNAMICS_AGENT_UNIQUE_HOST_ID

Type: String

Default: None

Required: No

Agent Meta Info

Allows you to associate arbitrary information with a node, which can then be used as a basis for applying health rules or policies by node. For example, you can exclude a health rule from applying to agents tagged as test agents based on a `meta-info` property. Pass the property in `key;value` format (for example, "`key1;value1;key2;value2`"). Do not use semicolons as value(s) as it is used as a delimiter.

For information on using the properties in health rules or policies (along with built-in `meta-info` properties), see [Configure Health Rules](#) or [Configure Policies](#).

System Property: `-Dappdynamics.agent.node.metaInfo`

Type: String

Default: None

Required: No

Low Entropy

Addresses agent startup issues in systems with low to zero entropy available for seeding the PRNG algorithm. This is set to true by default. The NativePRNGNonBlocking algorithm is used through SecureRandom if the system property `appdynamics.low.entropy` is set. Windows is not affected by this change as it does not support NativePRNGNonBlocking, and continues to use the existing Secure Random implementation.

System Property: `appdynamics.low.entropy=true`

Element in controller-info.xml: No

Environment Variable: No

Type: Boolean

Default: True

Required: No

If `appdynamics.low.entropy=true` then the agent takes measures to ensure it does not block when generating random values, even in the absence of entropy.

For example: From Java Agent 20.11, the agent defaults to using NativePRNGNonBlocking as its SecureRandom implementation. This will try to use a non-blocking low entropy algorithm for UUID generation. Note that NativePRNGNonBlocking is not supported on Windows and defaults to the existing implementation of SHA1PRNG.

Analytics Agent

For use with the transaction analytics feature with a remote (or non-default) Analytics agent. See [Enable the App Server Agent for a Remote Analytics Agent](#).

System Property: `-Dappdynamics.analytics.agent.url`

Element in controller-info.xml: No

Environment Variable: No

Type: String

Default: `http://localhost:9090/v2/sinks/bt`

Required: No

Use Simple Hostname

By default (unless overridden with the `uniqueHostId` system property), the agent determines the host name of the OS it is running in by reverse DNS lookup. In some circumstances, this host name may be set as the fully qualified domain name of the host name. If this property is set to true, the agent removes any domain name and uses the simple hostname to identify the host. In cases where the host name is an IP address (which happens if the DNS lookup fails) the full IP address in string form is used. The host name is used in mapping metrics gathered by the machine agent to application nodes (see [Unique Host ID Property](#)).

Element in controller-info.xml: `<use-simple-hostname>`

Type: Boolean

Default: False

Required: No

For example: If this property is set to true '`server.mydomain.com`' becomes 'server'.

Dynamic Services JAR Signing

When set to `True`, it enables automatic JAR signing of the dynamic services. In addition, it identifies vulnerabilities in the dynamic service workflow. Also, it provides checks to prevent loading and executing code from a malicious dynamic service.

When Set to `False`, disables the JAR signing.

Element in controller-info.xml: `<enable-jar-signing>`

Type: Boolean

Default: True

Required: No

Filter Sensitive Data

By default, the AppDynamics Java Agent sends transaction data to the Controller that your organization may classify as privileged information. Although such data is useful for diagnosis and troubleshooting, security considerations may require you to filter certain information from view in the Controller. You can use:

- Sensitive URL filters to exclude sensitive information from a URL in snapshot details.
- Sensitive message filters to exclude sensitive data that the application may place in log messages or exception detail messages.

Data Filter Format

Data Filters are used when setting up URLs in snapshots or analytics.

```
{
  "appliesTo": "...",
  "matchPattern": "..."
}
```

- `matchPattern` (required): A regular expression defining the sensitive data that triggers the filtering.
- `appliesTo` (required): A tag defining on which kind of data the pattern should be applied. The possible values are `env-vars`, `http-cookies`, `http-session-key`, `http-headers`, `http-params`, and `user-data`.
 - `env-vars` tags are defined by the default two data filters that contain a `password` or `key`. However, these filters can be overwritten with a valid custom filter for the environment variables.
 - `Http` and `user-data` tags are considered only when processing data in **Transaction Snapshots** or in **Analytics Reports**.

Default Sensitive Data Filters

When you enable a sensitive data filter, the Controller displays asterisks for the values of matching environment variables or system properties. By default, the Java Agent enables two sensitive data filters by passing the configuration to the `addAppAgentSensitiveDataFilters()` method:

```
{
  "messageFilters": [
    { "messageType": "throwable",
      "matchPattern": "test" },
    { "messageType": "throwable",
      "matchPattern": "ip",
      "redactionRegex": "(\\d+\\.)+\\d+" }
  ],
  "dataFilters": [
    { "appliesTo": "http-headers",
      "matchPattern": "test" }
  ],
  "urlFilters": [
    { "delimiter": "/",
      "segment": "1,2",
      "matchPattern": "test1",
```

```

    "paramPattern": "test2" }
  ]
}

```

Add a Sensitive URL Filter

You can use sensitive URL filters to configure the agent to obfuscate sensitive information from the URLs in transaction snapshot details.

1. Add a sensitive URL filter element as a child of the sensitive URL filters element:

```

{
  "delimiter": "...",
  "segment": "...",
  "matchPattern": "...",
  "paramPattern": "..."
}

```

- `delimiter` :
- `segment` : Specify a comma-separated list to indicate the segments that you want the agent to filter. Segment numbering starts from 1.
- `match-pattern` : Specify the string that you want to be filtered by the `match-filter` .
- `param-pattern` : Specify the regular expression matching the query parameters to filter.
- Specify the character that you want to use as URL segment endpoints. The agent splices the URL at each delimiter instance to create the segments. For HTTP, use the forward slash character "/".

The indexing starts from 1 and that the protocol names (`http://`, `https://`, ...) are not treated as special cases, so for URLs containing protocol: " `http://myapp.example.com/sensitive/data?first_name=abc&last_name=xyz` " the segments are:

- `http:`
- " "
- `myapp.example.com`
- `sensitive`
- `data`

For example, the following configuration splits the URL on the "/" character and masks the fourth segment and the param-pattern in the third segment of the URL. In this case, the segmentation and obfuscation apply only to URLs containing "myapp".

```

{
  "delimiter": "/",
  "segment": "4",
  "matchPattern": "myapp",
  "paramPattern": "[a-z]+_name"
}

```

The exit call to `https://myapp.example.com/sensitive/data?first_name=abc&last_name=xyz` break s down to three segments: " `https://myapp.example.com/` ", " `sensitive` ", and " `data?` "

`first_name=abc&last_name=xyz`". The Controller shows the masked values of the URL and the param-pattern display `https://myapp.example.com/*****/data?first_name=***&last_name=***` in the snapshot details.

In case you do not use any values for the query parameters, the Controller does not mask any query parameters in the URL.

Add a Sensitive Message Filter

You can use sensitive message filters to configure the agent to obfuscate sensitive information contained within text messages collected by the agent from log messages, or detail messages from exceptions.

1. Add a sensitive message filter element as a child of the sensitive message filters element:

```
{
  "messageType": "",           // type of message for which the filter applies
  "matchPattern": "",         // regex filter to search in data
  "redactionRegex": ""       // regex filter of how masking is applies(optional), by default
                              masks entire data
}
```

- `messageType` specify throwable
- `matchPattern` specify the pattern that, when matched, opts the message in for redaction
- `redactionRegex` specify a regular expression identifying data that should be redacted from the `opted-in` messages

For example, if an application includes secret numeric values in its exception messages, the following configuration would mask any references of it:

```
{
  "messageType": "throwable",
  "matchPattern": "test",
  "redactionRegex": "\\d+"
}
```

 The exception message: ``Unable to update the user profile (ID: 4215908), corrupted or incoherent data given`` will be collected as ``Unable to update the user profile (ID: ****), corrupted or incoherent data given.``

Optimize Heap Mode

The `enable-optimised-heap-mode` node property helps to fine-tune the agent heap consumption to deliver optimized performance. Additionally, exceptions are handled on the asynchronous entry maps to prevent stalled Business Transactions.

Element in `controller-info.xml`: `<enable-optimised-heap-mode>`

System Property: - `Dappdynamics.enable.optimised.heap-mode` `{{}}`

Type: `Boolean`

Default: `Disabled`

Required: **Yes**

Configure the URL Segment Limit

You can configure the number of URL segments that Java Agent sends to Analytics. The default limit is 20 URL segments.

For example, the below command configures the limit to 18 URL segments.

```
-Dappdynamics.analytics.servletSpy.maxUriSegmentCount=18
```

IBM Java Agent

Under most circumstances, the IBM Java Agent works the same as the Java Agent. This page describes information specific to the IBM Java Agent.

Supported JVMs

IBM JVM 1.5.x, 1.6.x, and 1.7.x

Instrument the IBM Java Agent

To change instrumentation for the IBM Java Agent, you must restart the IBM JVM. By default, the IBM Java Agent does not apply BCI changes without restarting the JVM. This is because in the IBM VM (J9 1.6.0) the implementation of re-transformation affects performance (changes the JIT behavior such that less optimization occurs).

These changes require that you restart the IBM JVM:

- Automatic leak detection
- Custom memory structures
- Information points
- Custom POJO rules for transaction detection
- Custom exit point rules
- End User Monitoring (EUM), when you enable it and/or disable it after first enabling it

Instrument WebSphere/InfoSphere with WebSphere Security Enabled

If your WebSphere/InfoSphere environment includes a security-enabled WebSphere Application Server, several InfoSphere Master Data Management (MDM) Server clients require security configuration.

See [IBM WebSphere and InfoSphere Startup Settings](#).

Configure the Thread Correlation in Java Agent

A pivotal part of the functionality of the Java Agent is tracing activity within the JVM such that all the activity (both internal and external to the JVM) that results from servicing any given inbound request can be associated with the request itself. In simple cases, each request is processed by one Java thread, making it only necessary to track the processing of that single thread, in a pattern widely known as 'thread per request'.

This was the case for JEE applications prior to the introduction of version 3.0 of the servlet specification (introduced in Java EE 6). In systems where a significant amount of time is spent waiting for external resources, the thread per request model is inefficient because many application threads spend most of their lifetime blocked awaiting external responses.

This observation motivated the asynchronous servlet capabilities provided as part of servlet 3 and also motivates many of the increasingly prevalent reactive frameworks that are in common usage (for example, Play, Akka, Vert.x and Spring Reactor). To correctly correlate transactions end to end in applications using this architectural approach, the agent must follow transactions from thread to thread to enable it to measure and link all the elements of work performed on behalf of each request, irrespective of which thread that work is executed on.

The agent provides two mechanisms for thread tracking, known as 'Constructor mode' and 'Executor mode' (for Java Agent $\geq 20.11.0$).

These are two alternative approaches to the correlation of cross-thread transaction activity:

- **Constructor Mode Thread Tracing** - This is the mode that instruments *Threads*, *Runnable*s, and *Callable*s based on their creation. The agent used this mode formerly as the default mode.
- **Executor Mode Thread Tracing** - This tracking mode is the default mode and is based on instrumenting executor frameworks that are commonly used by the majority of applications and frameworks. This mode makes agent operation more efficient, especially in cases where large use of threading is in place, for example, in the presence of the Play, Akka, Vert.x, and Spring Reactor reactive frameworks.

Select the Thread Correlation Mode

You can select the thread correlation mode used by the agent using the `async-instrumentation-strategy` property within the `app-agent-config.xml` configuration file.

To run the applications in the Constructor mode, modify the value of `async-instrumentation-strategy` property, or use the following java command-line option:

```
-Dappdynamics.async.instrumentation.strategy=constructor
```

The system property takes precedence over the configuration file. You cannot change the configured thread instrumentation mode during runtime.

Constructor Mode Thread Tracing

When the agent is in Constructor Mode, transaction activity is tracked from thread to thread by instrumenting the constructors of *Runnable* objects, and their run methods, such that the agent can link the creation point of the object with their actual execution. Since in many cases the work executed by *Runnable* objects does not relate to the Business Transaction context within which they were created, the agent provides for exclude rules to limit which threads are tracked. The agent configuration maintains a default set which you can fine-tune when necessary.

Constructor Mode Configuration

You configure classes for multithreaded correlation in the `<excludes>` child elements of the `<fork-config>` element in the `<agent_home>/conf/app-agent-config.xml` file.

The default configuration excludes the Java, Org, WebLogic and WebSphere classes:

```
<fork-config>
  <!-- exclude java and org -->
  <excludes filter-type="STARTSWITH" filter-value="com.singularity"/>
  <excludes filter-type="STARTSWITH" filter-value="java/,javax/,com.sun/,sun/,org"/>
```

```
<!-- exclude weblogic and websphere -->
<excludes filter-type="STARTSWITH" filter-value="com.bea/,com.weblogic/,weblogic/,com.ibm
/,net/sf/,com/mchange/" />
. . .
```

The agent supports package names where the levels in the hierarchy are either separated by dots (.) or slashes (/). The agent converts the dots to slashes internally.

Custom Configuration

You can edit the `app-agent-config.xml` file to exclude additional classes from thread correlation. All classes not excluded are by default included.

Use the `<excludes>` element to specify a comma-separated list of classes or packages to be excluded. Use the singular form, `<excludes>`, to specify a single class or a package.

For includes, you must specify each package or class individually using the `<include>` element. You can include a sub-package or subclass of an excluded element by specifying the sub-package or subclass with an `<include>` element. If a classname is matched by both an exclude and include pattern, the more specific pattern matched prevails. That is, an include match with `org.example.myclass` prevails over an exclude match for `org.example`.

Configuration Using Node Properties

You can also configure which classes or packages to include or exclude using a node property. See [thread-correlation-classes](#) and [thread-correlation-classes-exclude](#).

Disable Thread Correlation at the Agent

To disable thread correlation (which disables end-to-end asynchronous transaction monitoring as well) at the agent, use one of these:

- Set the Java agent node property [thread-correlation-classes-exclude](#) to disable asynchronous monitoring for all the relevant classes.
`thread-correlation-classes-exclude=a,b,c,d,e,f,...z`
- Add the following line under the `fork-config` section of the `app-agent-config.xml` file.
`<exclude filter-type="REGEX" filter-value=".*"/>`

Executor Mode Thread Tracing

i Executor mode is the default mode for instrumenting the asynchronous tasks beginning with the Java Agent 20.11 release.

When the agent is in Executor mode, transaction activity is tracked from thread to thread by instrumenting `Executor.execute()` and similar method(s) such that the agent can identify application work to track as that work is being scheduled.

Benefits of Executor Mode

- Reduces the agent's resource consumption for most use cases
- Enables tracking thread hand-offs using the new agent API
- Improves reliability of last thread on tier asynchronous transaction demarcation
- Allows Service Endpoints to measure the response time of services implemented using asynchronous frameworks

Behavior of Service Endpoints in Executor Mode

The behavior of Service Endpoints differs between the Constructor and Executor modes. In Constructor mode, each asynchronous transaction segment is represented by its own Service Endpoint, and the Service Endpoint corresponding to the transaction entry point shows the execution time of the initiating thread as shown:

Name	Response Time (ms)	Calls	Calls / min	Errors	Errors / min	Type	Tier
 /AsyncServletOne/one	112	15	3	0	0	Servlet	WebServer
 RequestProcessor	1,126	15	3	0	0	Async	WebServer
 AsyncServlet\$RequestProcessor\$\$Lambda\$7	119	15	3	0	0	Async	WebServer
 AsyncServlet\$RequestProcessor\$\$Lambda\$8	95	15	3	0	0	Async	WebServer

With the Executor instrumentation strategy, metrics for a single Service Endpoint are reported, with a response time corresponding to the execution time of the entire asynchronous transaction as shown below.

Name	Response Time (ms)	Calls	Calls / min	Errors	Errors / min	Type	Tier
 /AsyncServletOne/one	684	15	3	0	0	Servlet	WebServer

Currently, each service entry point must match a transaction entry point. Configuration of Service Endpoints at other points within the execution of asynchronous transactions is *not* supported in the Executor mode. Additionally, Service Endpoints only report if placed within the context of executing a Business Transaction when the agent is in Executor mode.

Raw Threads Support

Support for raw threads differs between the Executor and Constructor modes. While Constructor mode supports tracking of all threads created in the context of a transaction, the Executor mode supports only non-daemon threads that are started in the context of a transaction. The daemon status is inherited from the parent thread which can cause unexpected results. For example, the worker threads in an application server are often daemon threads, so any thread started directly within servlet code is not tracked in the Executor mode unless the application explicitly unsets its daemon status.

Node Properties

This table presents the node properties which are specific for the executor-based instrumentation strategy, or which work differently than for the constructor-based instrumentation strategy (default).

Property	Default value	Description
thread-correlation-classes	none	These properties have the same effect in the Executor mode as in Constructor mode, however, their use is discouraged in Executor mode, especially when used to limit the costs of thread tracking. Due to the differences in implementation of the async hand-offs, any performance gains achieved using these settings in constructor mode are likely to be available using the out of the box settings in Executor mode.
thread-correlation-classes-exclude		
min-transaction-stall-threshold-in-seconds	60	For Executor mode only, the transactions will not get checked for stall unless they run at least the specified number of seconds

Exclude Selected Activities from Transactions

Asynchronous frameworks use lower-level asynchronous mechanisms that are not related to the processing of user transactions (for example, a thread pool might grow and shrink automatically, depending on the load or a framework might initialize its thread pool upon the first use). You must ignore threads used in these contexts since their lifecycle is not bound to any individual application transaction.

To facilitate the exclusion of such asynchronous components (usually Threads and other Runnables), the Executor mode offers a mechanism called *capture suppression*. The suppression is tied to a specific method by a suppression rule in the `async-config` section of `app-agent-config.xml`. Consider the following example of such a rule provided by default:

```
<job>
  <match-class type="matches-class"><name filter-type="EQUALS" filter-value="java.util.concurrent.ThreadPoolExecutor"/></match-class>
  <match-method><name filter-type="EQUALS" filter-value="addWorker"/></match-method>
  <action type="suppression"/>
</job>
```

The `addWorker` method on the `java.util.concurrent.ThreadPoolExecutor` class is a private method invoked by `ThreadPoolExecutor` whenever a new worker thread is to be created, started and added to the pool. Since such threads are not directly associated with any individual transaction at the point of creation, a suppression rule is used in order that any asynchronous task hands offs occurring within this method will not get associated with the transaction. Any asynchronous tasks subsequently executed by these threads will be associated with the transaction that created the task.

Trace Multithreaded Transactions for Java

Related pages:

- [End-to-End Latency Performance](#)

- [Configure the Thread Correlation in Java Agent](#)

The Java Agent can automatically track multithreaded applications. It correlates threads from classes that implement `Runnable` or `Callable` interfaces or extend the `Thread` class. Processes with such threads are identified in AppDynamics as asynchronous.

Monitor Asynchronous and Thread Processing Activity

You can monitor performance around asynchronous calls and multithreaded activity in a variety of ways. It's helpful to understand what AppDynamics considers to be an asynchronous activity, what information it provides on that activity, and how that information relates to thread execution at the code level.

These sections describe the type of information available given various thread and exit call execution scenarios.

Asynchronous Exit Call

In the most common case, an asynchronous exit call is an exit call made by a thread that is spawned by a thread other than the primary business transaction thread.

The primary thread, in this case, is the one on which an entry point call is received. A common pattern for this case is when the `main()` function in the application spawns multiple threads as request handlers to receive and process requests. For example:

Flow maps in the Controller UI show this connection as a dotted line (asynchronous connection).

AppDynamics considers the call to be an asynchronous call only due to the context in which it was invoked. If the exit call is made from thread 2, as shown in the following illustration, the call may be considered asynchronous from the perspective of the overall design of the application, but is not considered asynchronous in the context of the business transaction:

Without a business transaction, AppDynamics does not track asynchronous activity.

AppDynamics does not differentiate between the two common patterns in asynchronous processing, Wait-for-Completion (in which the threads report back into the primary thread) and Fire-and-Forget (in which the primary thread may finish processing before spawned threads do). Both are represented the same way in the Controller UI, although they would usually be distinguished by their execution time, in which the primary thread for a Wait-for-Completion transaction would exceed any of the child processes, whereas Fire-and-Forget the primary thread may be shorter than child processes.

Logical Asynchronous Exit Calls

An exception to the scenario described in the previous section exists for exit calls to backend systems which—from a conceptual point of view—are considered asynchronous in the AppDynamics model.

Message queue tiers such as JMS are considered logically asynchronous, so flow maps show connections to message queues as dotted lines (asynchronous connections) as well. Therefore, the following JMS exit call would be shown as an asynchronous call in a flow map, while the JDBC call would not be.

Time on Tier

Exit calls are one consideration in understanding multithreaded application performance; another consideration is the actual time spent processing a request.

For example, consider the following processing scenario. This occurs on a single tier. In fulfilling a request, the entry point thread spawns multiple child threads that report back to the primary thread to assemble the response.

For the transaction, the response time metric represents the time from when the request arrived at the entry point to the point the response was sent. However, while this may accurately represent the user experience of the transaction, it does not reflect the processing burden on the system, since many threads participate in the transaction. A slow performing thread may or may not be evident based on the user experience of the transaction.

To better understand the complete cost of the transaction in terms of time spent processing, you can use the time on tier metric. This metric shows the aggregate processing time for each of the threads involved in processing a request. In other words, the total execution time of threads 2, 3 and 4 from the figure, along with the processing time between the entry point and response for thread 1.

The value of the time on tier metric is indicated by the `async` tag in business transaction dashboards.

End-to-End Processing

A response from an entry point thread may not best represent the logical end of a business transaction.

For example, consider an application in which an entry point method in a request handler spawns multiple threads, including one to serve as the final response handler. The request handler then returns a preliminary response to the client. By default, this stops the clock for purposes of measuring the response time for that business transaction. Meanwhile, the spawned threads continue to execute until completion, at which point the response handler generates the final response to the client.

In this case, the initial response time is much shorter than the full logical transaction execution time.

End-to-end metrics let you monitor logical transactions that use this programming pattern. End-to-end metrics include the end-to-end transaction time, the number of end-to-end transactions per minute, and the number of slow end-to-end message processing events.

To enable end-to-end metrics, you configure an Asynchronous Transaction as described in [Asynchronous Transaction Demarcators](#).

View Threads and Thread Tasks in the Metric Browser

In a multithreaded transaction, AppDynamics reports key business transaction performance metrics for individual threads in a Thread Tasks branch of the tier in the Metric Browser. The Thread Tasks branch is present in the Metric Browser only for multithreaded transactions. The Metric Browser path is **Business Transaction Performance > Business Transactions > tier-name > business-transaction-name > Thread Tasks**. Thread Tasks also appear for tiers under Overall Application Performance, where you can see metrics on specific calls made by each thread in a node or in a tier.

Thread Metrics in Health Rules

For each asynchronous thread spawned in the course of executing a business transaction, AppDynamics collects and reports these metrics:

- Average response time
- Calls per minute
- Errors per minute

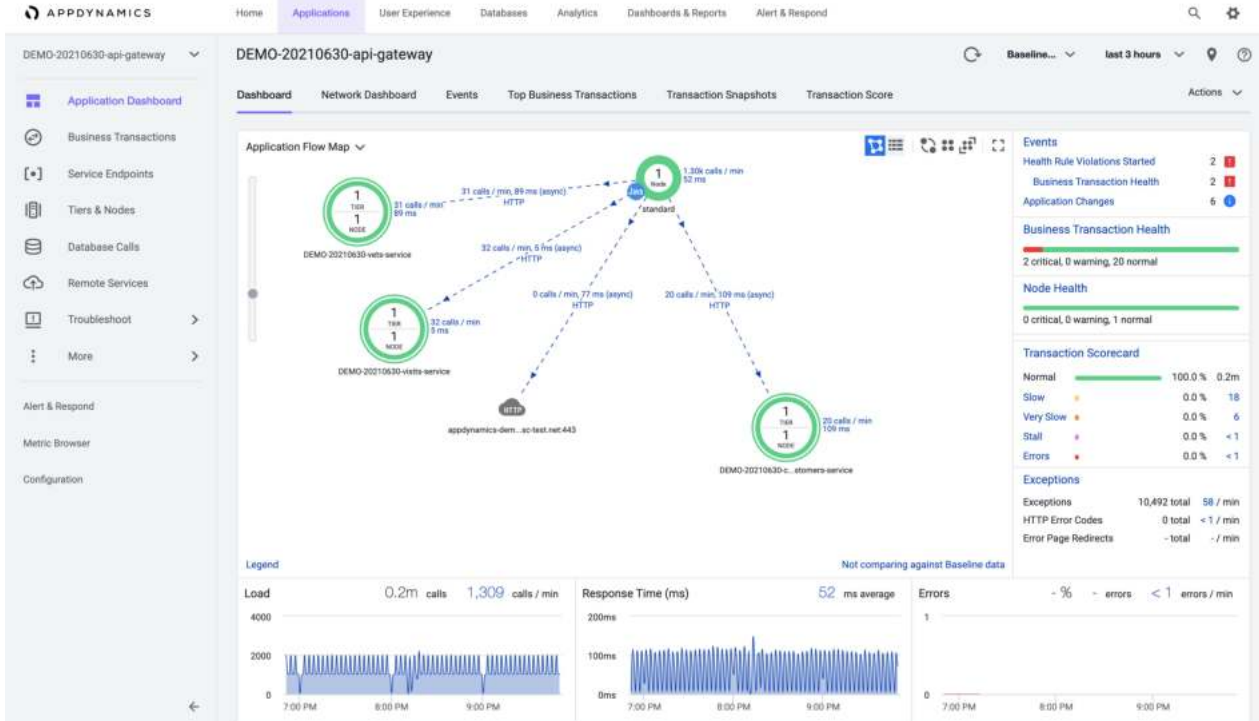

You can create custom health rules based on the performance metrics for a thread task. When you click the metric icon in the Health Rule Wizard, the embedded metric browser includes the Thread Tasks if the entity for which you are configuring the health rule spawns multiple threads. See [Configure Health Rules](#).

Monitor Azure Spring Cloud with Java Agent

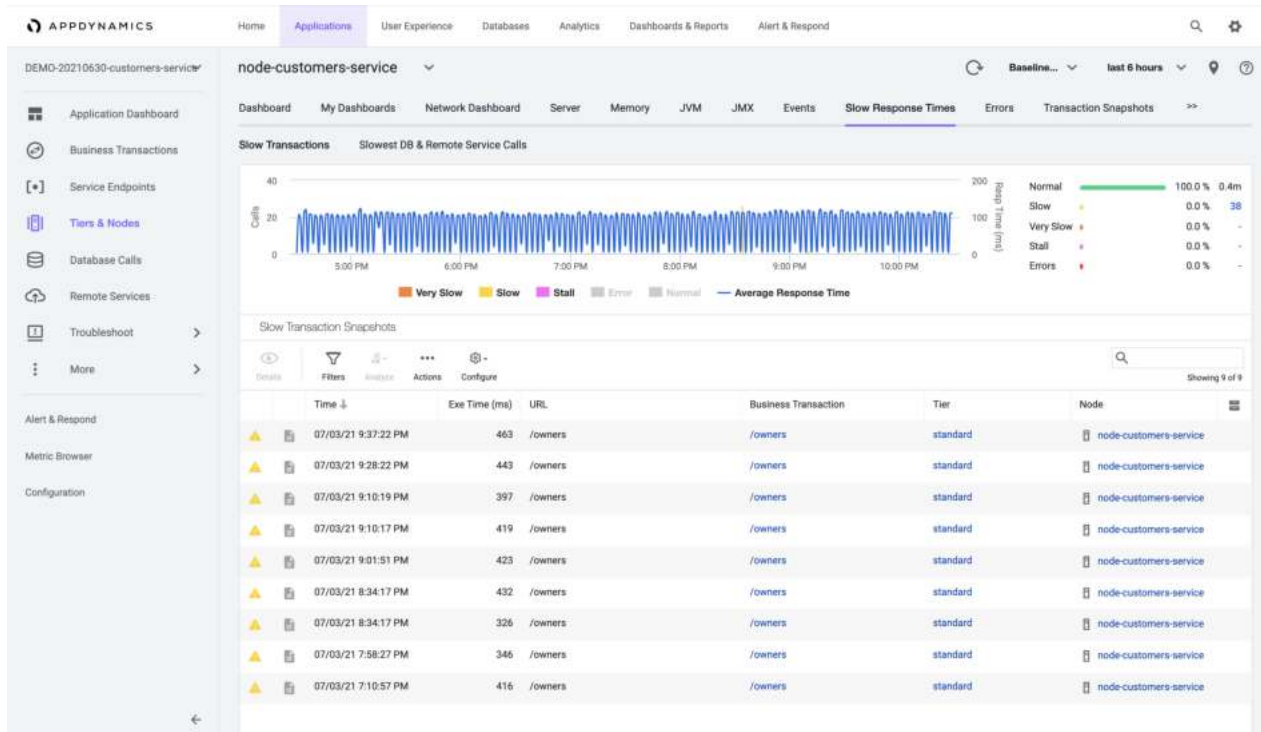

Related pages:

- [Download AppDynamics Software](#)
- [Java Agent Configuration Properties](#)

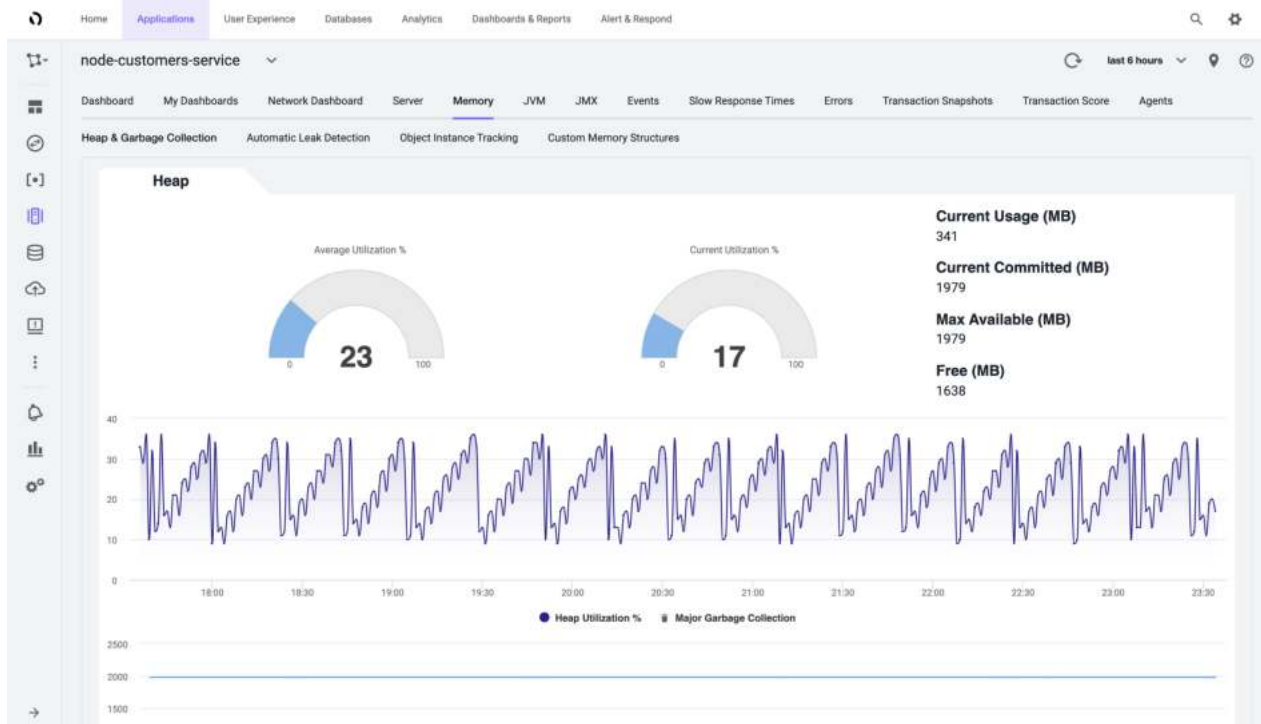

AppDynamics Java Agent helps you monitor the workloads running in [Azure Spring Cloud](#). To gain visibility into the topology of the application along with the data flows between the services, activate the AppDynamics Java Agent on services that make up your Azure Spring Cloud application.

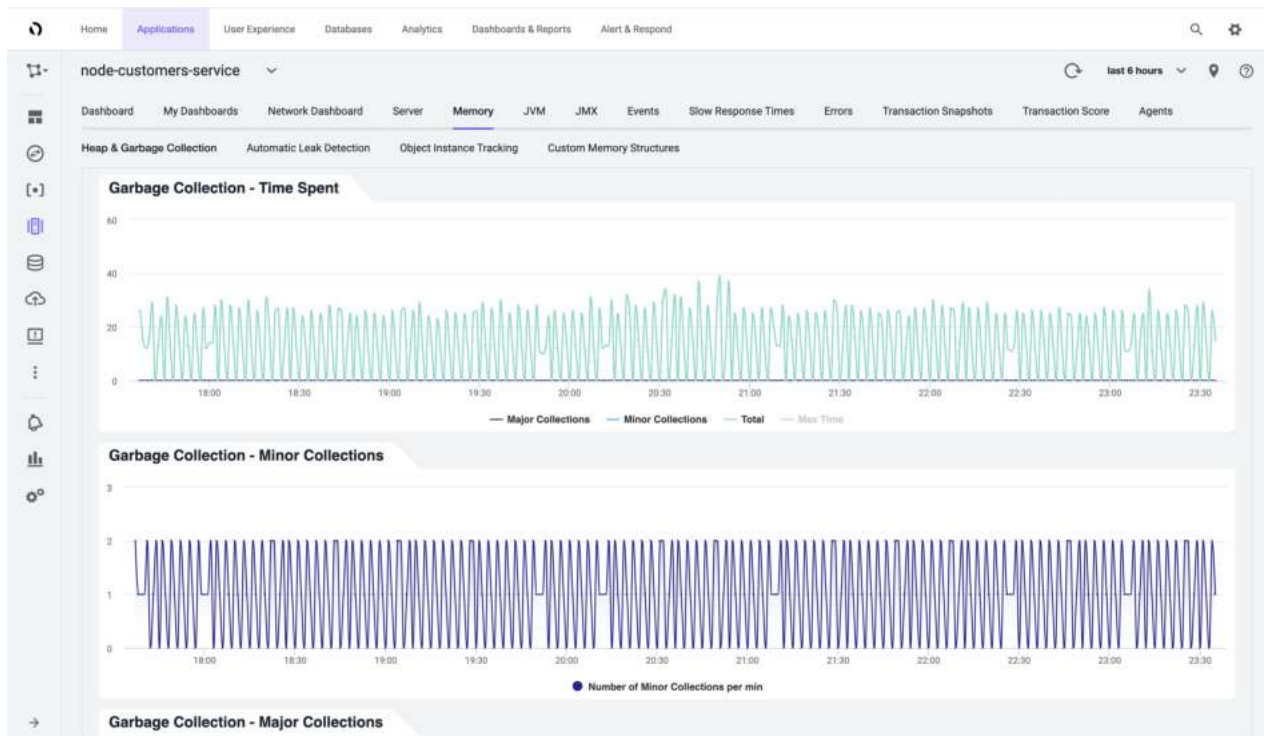

The AppDynamics Java Agent also provides root-cause analysis of slow or error transactions within the Azure Spring Cloud application.

The AppDynamics Java agent provides JVM memory usage of services within the Azure Spring Cloud application along with garbage collection information.

Prerequisites

To monitor the Spring Cloud workloads with AppDynamics, you can use the agent with your Azure Spring Cloud application. To do this, perform these steps:

- Create an AppDynamics account
- Install the Azure CLI. For instructions, see [How to install the Azure CLI](#).

Limitations

The AppDynamics Java Agent is deployed as a read-only artifact within the Azure Spring Cloud environment. This results in some limitations in features available through the Java agent. The limitations are:

- Agent configuration through files (`controller-info.xml` , `agent.properties`) is not available.
- Configuration of agent logging levels through files (`log4j2.xml`) is not available.
- Custom correlation configuration through XML file is not available.

Use the Java Agent with Azure Spring Cloud

You can activate the Java Agent with the Azure Spring Cloud apps in these two ways:

- [Activate the AppDynamics Java in-process Agent with Azure CLI](#)
- [Activate the AppDynamics Java in-process Agent with Azure Portal](#)

Activate the AppDynamics Java in-process Agent with Azure CLI

1. Create an instance of Azure Spring Cloud.
2. Create an application:

```
```shell
```

```
az spring-cloud app create --name "appName" --is-public true \
-s "resourceName" -g "resourceGroupName"``
```

### 3. Create a deployment with the AppDynamics agent and environment variables.

You must access the `APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY`, `APPDYNAMICS_AGENT_ACCOUNT_NAME` and `APPDYNAMICS_CONTROLLER_HOST_NAME` to connect to AppDynamics and customize other variables as per your requirement.

```
``shell
az spring-cloud app deploy --name "appName" --jar-path app.jar \
-s "resourceName" -g "resourceGroupName" \
--jvm-options="-javaagent:/opt/agents/appdynamics/java/javaagent.jar" \
--env APPDYNAMICS_AGENT_APPLICATION_NAME=<YOUR_APPLICATION_NAME> \
APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=<YOUR_AGENT_ACCESS_KEY> \
APPDYNAMICS_AGENT_ACCOUNT_NAME=<YOUR_AGENT_ACCOUNT_NAME> \
APPDYNAMICS_AGENT_NODE_NAME=<YOUR_AGENT_NODE_NAME> \
APPDYNAMICS_AGENT_TIER_NAME=<YOUR_AGENT_TIER_NAME> \
APPDYNAMICS_CONTROLLER_HOST_NAME=<YOUR_APPDYNAMICS_CONTROLLER_HOST_NAME> \
APPDYNAMICS_CONTROLLER_SSL_ENABLED=true \
APPDYNAMICS_CONTROLLER_PORT=443
```

Azure Spring Cloud pre-installs the AppDynamics Java Agent to the following path: `/opt/agents/appdynamics/agent/javaagent.jar`.

### Activate the AppDynamics Java in-process Agent with Azure Portal

1. On the Azure portal, find the app you want to monitor by clicking **Settings > Apps** on the left navigation pane.
2. Click the application to navigate to the **Configuration** page.
3. Click **Configuration** on the left navigation pane to add, update, or, delete the environment variables of the application in the Environment variables tab.
4. Click **General settings** to add, update or delete the JVM Options of the application in the General settings tab.  
`-javaagent:/opt/agents/appdynamics/java/javaagent.jar`
5. Click **Save**.
6. Click **Restart** to ensure the configuration is complete.

### Configure Using the Environment Variables or System Properties

You can use these environment variables to configure the setup to use the agent with your Azure Spring Cloud application:

Environment Variable
<code>APPDYNAMICS_CONTROLLER_HOST_NAME</code>
<code>APPDYNAMICS_CONTROLLER_PORT</code>
<code>APPDYNAMICS_CONTROLLER_SSL_ENABLED</code>

## Environment Variable

APPDYNAMICS\_AGENT\_APPLICATION\_NAME

APPDYNAMICS\_AGENT\_TIER\_NAME

APPDYNAMICS\_AGENT\_NODE\_NAME

APPDYNAMICS\_AGENT\_ACCOUNT\_NAME

APPDYNAMICS\_AGENT\_ACCOUNT\_ACCESS\_KEY

APPDYNAMICS\_AGENT\_UNIQUE\_HOST\_ID

APPDYNAMICS\_JAVA\_AGENT\_REUSE\_NODE\_NAME

APPDYNAMICS\_JAVA\_AGENT\_REUSE\_NODE\_NAME\_PREFIX

You can also use these system properties:

- Dappdynamics.controller.hostName

- Dappdynamics.controller.port

- Dappdynamics.controller.ssl.enabled

- Dappdynamics.agent.applicationName

- Dappdynamics.agent.tierName

- Dappdynamics.agent.nodeName

- Dappdynamics.agent.reuse.nodeName

- Dappdynamics.agent.reuse.nodeName.prefix

- Dappdynamics.agent.selfService

- Dappdynamics.agent.accountName

- Dappdynamics.agent.accountAccessKey

-Dappdynamics.agent.uniqueHostId

```
-Dappdynamics.agent.node.metaInfo
```

For a description of these system properties, see [Java Agent Configuration Properties](#). To locate the account and account access key, see [Agent-to-Controller Connections](#).

## AppDynamics Agent Logging

By default, Azure Spring Cloud prints the info level logs of the AppDynamics agent to `STDOUT`. The logs are mixed with the application logs. You can find the explicit agent version from the application logs.

You cannot configure the `controller-info.xml`. Therefore, to obtain debug logs, you must set the environment variable for the log level on the app within ASC and then restart the app.

To run the command for capturing the ASC logs, see [az spring-cloud app log](#).

## Use the Java Agent API and Instrumentation SDK

This page describes the Java Agent API, instrumentation SDK (iSDK), and the [common use cases for the API](#).

### Java Agent API and iSDK

AppDynamics automatically detects an application activity out-of-the-box. For supported application frameworks, the agent ships with an out-of-the-box configuration that applies instrumentation to the application that identifies the following:

- Where the Business Transaction activity starts
- Where thread handoffs occur
- Where calls to downstream systems are made, and how to inject correlation headers into outbound messages and retrieve them from inbound messages. This ensures that AppDynamics can establish the end-to-end transaction flow through the application architecture

For frameworks that do not benefit from out-of-the-box support, the agent provides a set of Agent APIs that allow the application developer to make code changes to add calls to the agent. This enables the agent to identify and follow Business Transactions as they execute, providing end-to-end visibility for any application.

For scenarios where it is not possible to change the application code, for example, to add instrumentation to a third-party product or framework, an 'instrumentation SDK' is provided that supports the use of these APIs. The iSDK enables developers to build 'interceptors', which the agent injects into application bytecode at specified points on startup. These interceptors can contain any Java code (including calls to the Agent API), which is executed when the code provided in the interceptor is run before, or after the intercepted method itself, executes.

You can seamlessly combine any Agent APIs with the out-of-the-box instrumentation to support situations where a mixture of supported and unsupported frameworks are in use (for example, a standard servlet making an external call using a proprietary API).

The Java Agent API enables you to programmatically:

- Define Business Transactions
- Define Exit Calls
- Inform the agent when the application hands-off transaction processing between threads
- Add application data to snapshots or transaction analytics
- Report custom metrics

When instrumenting any application, the Agent API design prioritizes the success of the application transactions over instrumentation. Therefore, if any of the Agent API calls fail, they do not throw exceptions disrupting the transaction flow, but log messages to aid diagnosis. This indicates that there is no hard dependency between the application and the presence of the AppDynamics Java Agent within the JVM.

See <https://sdkdocs.appdynamics.com/java-agent-api/v20.6/> for the Javadoc reference for the agent API. User guides for the [Agent API](#) and the [instrumentation SDK](#) are also provided to illustrate the usage and common use cases.

## Install the Dependency

You can access the Agent API jar directly, or download it from Maven Central or from the AppDynamics portal. The library version changes with each new API release, and is not tightly coupled to the version of the underlying agent.

To use Maven Central, add the dependency to your build files in one of the following:

- Gradle:

```
dependencies {
 compile group: 'com.appdynamics.agent', name: 'agent-api', version: '20.6.0.30246'
}
```

or

- Maven:

```
<dependency>
 <groupId>com.appdynamics.agent</groupId>
 <artifactId>agent-api</artifactId>
 <version>20.6.0.30246</version>
</dependency>
```

## iSDK Overview

The instrumentation SDK (iSDK) part of the Java Agent API enables you to create custom instrumentation to apply to the code in your application at runtime, and avoid making development time changes to instrument the code.

You can use the iSDK to implement interceptors making use of the imperative Java Agent APIs and apply custom instrumentation to proprietary applications or frameworks. This custom instrumentation works with the out-of-the-box instrumentation provided by the agent.

iSDK users need to create separate custom interceptor jar files that instrument their code at application startup when deployed with the Java Agent in the `sdk-plugins` directory. To remove custom instrumentation, remove the custom interceptor jar files from the agent deployment.

## Use the iSDK

This procedure outlines how to use the iSDK:

1. Set up your development environment.
2. Set up your project.

3. Implement your interceptor(s).
4. Build your files.
5. Deploy.

## Set Up Your Development Environment

To use the iSDK, you must write code with the external dependency of the iSDK library. To do this, these tools must be available:

- A Java IDE – Eclipse or IntelliJ. The following examples are for IntelliJ usage.
- Gradle.

## Set Up Your Project

To set up your project:

1. In IntelliJ, create a new Gradle project for your work. The `build.gradle` file is created in the project directory that you specify.
2. Add the required information to your project's `build.gradle` file by following the procedure in the next section.

## Install the Dependency

To use the iSDKs, do one of the following:

- Access the Agent API jar directly
- Download it from Maven Central
- Download it from the AppDynamics portal

The library version changes with each new API release, and is not tightly coupled to the version of the underlying agent.

For use with Maven Central, add the dependency to your build files in one of the following:

- Gradle:

```
dependencies {
 compile group: 'com.appdynamics.agent', name: 'agent-api', version: '20.6.0.30246'
}
```

or

- Maven:

```
<dependency>
 <groupId>com.appdynamics.agent</groupId>
 <artifactId>agent-api</artifactId>
 <version>20.6.0.30246</version>
</dependency>
```

See <https://sdkdocs.appdynamics.com/java-agent-api/v20.6/> for Javadoc reference for the Agent API.

**i** Refresh your gradle project in intellij and run "gradlew idea" if you want intellij to reference the source properly when auto-populating methods and so on.

After this setup, you must be able to use IntelliJ to create a class, extend an iSDK template class, and auto-populate missing methods.

Deploy the iSDK with Agent API

To leverage Agent API functionality with the iSDK, you must package it with your custom interceptor jar. To accomplish this in Grade:

1. Create a configuration for iSDK:

```
configurations {
 isdk
}
```

2. Add the Agent-API dependency to this configuration:

```
dependencies {
 compile group: 'com.appdynamics.agent', name: 'agent-api', version: '20.6.0.30246'
 isdk group: 'com.appdynamics.agent', name: 'agent-api', version: '20.6.0.30246'
 ...
}
```

3. Inside your task for generating the interceptors jar, include the `AppdynamicsAgent` class inside the jar:

```
jar {
 configurations.isdk.collect {
 it.isDirectory() ? from(it) : from(zipTree(it)) {
 include 'com/appdynamics/agent/api/AppdynamicsAgent.class'
 }
 }
 includeEmptyDirs = false
}
```

**i** To accomplish this in Maven, you must write an Ant Task to include the `AppdynamicsAgent` class with your jar.

## Implement Your Interceptor

### Class or Method Identification

For all use cases, you must identify the class and method that you wish to instrument. This is also true when configuring custom POJO instrumentation using the User Interface but the technique is much different in the SDK.

## Create Custom Interceptors and Rules

### Implement Your Instrumentation Logic

The iSDK provides a class called `AGenericInterceptor`, which must be subclassed with the desired custom interceptor logic.

The agent examines .jar files deployed to the agent's `sdk-plugins` directory and looks for classes that extend `AGenericInterceptor`. These classes must implement the required abstract methods.

One key method all interceptors must implement is the `initializeRules` method, which returns a list of objects that extend the `IRule` interface. These `IRules` represent where in the code you must apply a given interceptor (class name, method name, method params, and so on).

If interceptors need to perform reflection on any of the java objects used in the instrumented code, an interface, `IReflector`, is provided to facilitate such reflection at runtime.

### Important Methods to Implement in `AGenericInterceptor`

- `initializeRules` - Returns a list of objects that describe where in the code the interceptor must be placed
- `onMethodBegin` - Any code in the body of this method is run before the execution of the instrumented method
- `onMethodEnd` - Any code in the body of this method is run after the execution of the instrumented method

**i** `AGenericInterceptors` can be combined with the Agent API to start or end transactions, add data to snapshots, and so on.

These interceptors can be applied anywhere in the code, rather than just the beginning or end of a method. Also, they collect local variable information. Specific methods in the Rule builder, such as `atLineNumber`, `atField`, `atLocalVariable`, and so on only apply to this variety of iSDK interceptor.

- i**
- jars placed directly in the top-level "sdk-plugins" directory are also loaded.
  - You can use the manifest attribute "Plugin-Classes: <comma separated list of fully qualified class names>" in your plug-in jar to specify specific classes to load as plug-ins. This improves jar loading performance, if the plug-in jar contains many classes that are not plug-ins.

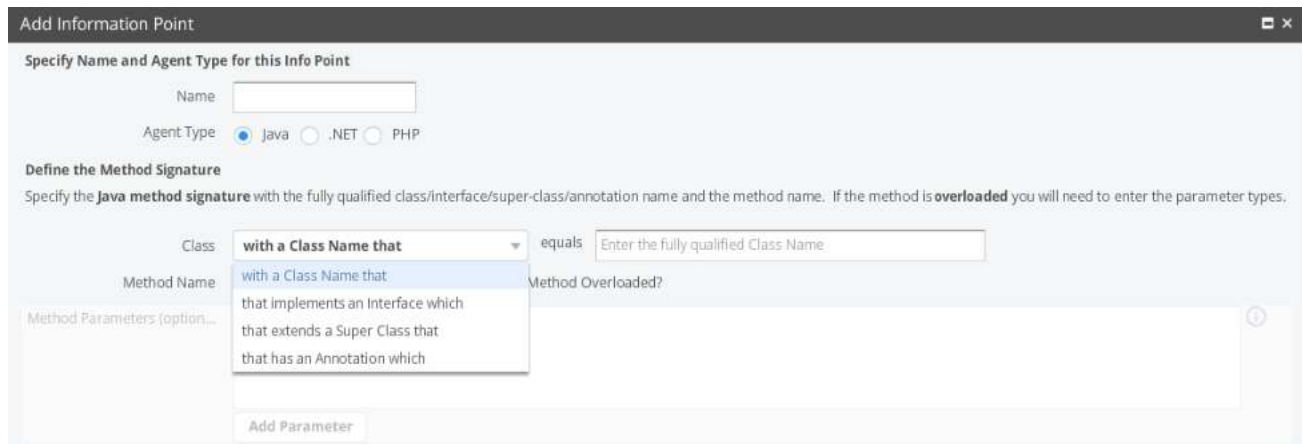

### Use the Rule and Rule.Builder Classes

A `Rule` defines a set of classes to instrument. Your iSDK code returns a `java.util.List` of `Rule` objects from a method named `initializeRules`. Rules are created using the **builder pattern** – a `Rule.Builder` object is created using a match string:

```
Rule.Builder builder = new Rule.Builder("com.mynamespace.MyClass");
```

See the [javadocs](#) for all classes referenced in this section.

This is similar to what you have to do in the UI. For example, in the **Add Information Point** configuration screen, you must specify a name to match on – either a concrete class name, abstract class name, interface name or annotation name. The argument to the `Rule.Builder` constructor is the same as what you specify into the class match text box in the image below.

You then modify the `Rule.Builder` by calling APIs on the `Rule.Builder` class. `Rule.Builder` supports [fluent style](#) so that your code can be compact.

You need the following:

- Class match string: Given in the constructor to `Rule.Builder`
- Class match type: Set the `SDKClassMatchType` using `builder.setClassMatchType`
- Class match string match type: Set the `SDKStringMatchType` for the method using `builder.classStringMatchType`
- Method match string using `builder.setMethodMatchString`
- Method match type: Set the `SDKStringMatchType` for the method using `builder.methodStringMatchType`

The following is a screenshot of an `initializeRules()` method for creating an arbitrary interceptor. Note the following:

- The style is a mixture of fluent and iterative (lines have chained invocations, but multiple lines are still used)
- The class match is for an exact classname match to a concrete class ( `SDKClassMatchType.MATCHES_CLASS` and `SDKStringMatchType.EQUALS` for `classStringMatchType` )
- The method match is for an exact method name string match ( `SDKStringMatchType.EQUALS` for `methodStringMatchType` )

```
private static final String CLASS_TO_INSTRUMENT = "com.appdynamics.util.async.TrackedCallable";
private static final String METHOD_TO_INSTRUMENT = "linkContext";

private static int pc = 0;

public List<Rule> initializeRules() {
 Rule.Builder bldr = new Rule.Builder(CLASS_TO_INSTRUMENT);
 bldr = bldr.classMatchType(SDKClassMatchType.MATCHES_CLASS).classStringMatchType(SDKStringMatchType.EQUALS);
 bldr = bldr.methodMatchString(METHOD_TO_INSTRUMENT).methodStringMatchType(SDKStringMatchType.EQUALS);
 List<Rule> result = new ArrayList<>();
 result.add(bldr.build());

 return result;
}
```

### Implement the Interceptor Logic

The Java code to be run when the custom interceptor is hit is provided in the `onMethodBegin` and/or `onMethodEnd` methods of the interceptor object.

A code example of a simple interceptor that leverages the Agent API is shown below.

```

public class SampleGenericInterceptor extends AGenericInterceptor {

 public SampleGenericInterceptor() {
 super();
 }

 @Override
 public List<Rule> initializeRules() {
 List<Rule> rules = new ArrayList<Rule>();
 rules.add(new Rule.Builder("Main").methodMatchString("genericInterceptorTarget").build());
 return rules;
 }

 public Object onMethodBegin(Object invokedObject, String className, String methodName, Object[] paramValues) {
 System.out.print("In begin");
 AppdynamicsAgent.startTransaction("SampleGenericInterceptorBT", null, EntryTypes.POJO, false);
 Map<String, String> keyVsValue = new HashMap<String, String>();
 keyVsValue.put("foo", "bar");
 AppdynamicsAgent.getEventPublisher().publishEvent("an event happened", "INFO", "AGENT_STATUS", keyVsValue);
 return null;
 }

 public void onMethodEnd(Object state, Object invokedObject, String className, String methodName, Object[] paramValues, Throwable thrownException, Object returnValue) {
 System.out.print("In end");
 Transaction currentTransaction = AppdynamicsAgent.getTransaction();
 Set<DataScope> dataScopes = new HashSet<DataScope>();
 dataScopes.add(DataScope.SNAPSHOTS); // collect data for BT snapshot.
 currentTransaction.collectData("key", "value", dataScopes);
 currentTransaction.end();
 }
}

```

## Use the IReflector Interface

All iSDK classes have access to a toolbox interface called `IReflector`. This interface provides functionality that enables the use of Java reflection. Within any class that extends one of the template classes, the user can call `getNewReflectionBuilder()` to get an instance of `IReflectionBuilder`.

**i** `getNewReflectionBuilder()` must be called in the constructor of your plug-in class. You may hit a `NullPointerException` if it is called elsewhere.

This interface supports the following methods:

---

```
/**
 * load a class. classLoader specified in the IReflector.execute method
 **/
IReflectionBuilder loadClass(String className);

/**
 * Create a new object
 * @param className class to create
 * @param argTypes argument types
 * @return this
 */
IReflectionBuilder createObject(String className, String... argTypes);

/**
 * Invoke a static method
 * @param methodName method to invoke
 * @param searchSuperClass search super classes for the method. Else only
declared methods are called
 * @param argTypes for overloaded methods
 * @return this
 */
IReflectionBuilder invokeStaticMethod(String methodName, boolean
searchSuperClass, String... argTypes);

/**
 * Similar to invoke static method, invoke a instance method
 * @param methodName method to invoke
 * @param searchSuperClass search super classes for the method. Else only
declared methods are called
 * @param argTypes for overloaded methods
 * @return this
 */
IReflectionBuilder invokeInstanceMethod(String methodName, boolean
searchSuperClass, String... argTypes);

/**
 * Access a field
 * @param fieldName field name to access
 * @param searchSuperClass should search super class for the field name
 * @return this
 */
IReflectionBuilder accessFieldValue(String fieldName, boolean
searchSuperClass);
```

These can be called in any order, essentially forming a getter chain. After crafting your chain of calls, the build() method must be called, returning an IReflector.

The IReflector is used by invoking its execute() method:

```

/**
 * Execute the reflector chain
 * @param classLoader required - classloader referenced to load classes
 * @param target The steps will start executing on this object. null if first
step is loadClass or staticMethod
 * @param params params to be passed to the steps
 * @return returns with correct cast
 * @throws ReflectorException
 */
<E> E execute(ClassLoader classLoader, Object target, Object[]... params)
throws ReflectorException;

/**
 * Execute the reflector chain
 * @param classLoader required - classloader referenced to load classes
 * @param target The steps will start executing on this object. null if first
step is loadClass or staticMethod
 * @param params params to be passed to the steps
 * @return returns with correct cast
 * @throws ReflectorException
 */
<E> E execute(ClassLoader classLoader, Object target, OperationParams params)
throws ReflectorException;

```

The use of these reflectors is often critical for getting the desired functionality (extracting values from payloads, decorating objects with correlation headers, and so on).

## Java Agent API Documentation

See the [AppDynamics APM Agent API](#) for the Java Agent.

## Java Agent API User Guide

This page provides examples that describe how you can implement common use cases for the Agent API. See the javadoc at <https://sdkdocs.appdynamics.com/java-agent-api/v20.6/>.

## Common Use Cases

The following are the common use cases for the Agent API.

### Start and End a Synchronous Business Transaction

The following example shows code that starts a Business Transaction called 'Checkout' whenever the method `checkout()` is called. The Business Transaction ends when the method returns. Encapsulating the method body in a try or finally block ensures that you end the Business Transaction even if the method itself throws an exception or otherwise terminates without reaching the end.

```

public String checkout(List<ItemOrders> orders) {
 Transaction transaction = null;
 try {
 transaction = AppdynamicsAgent.startTransaction("Checkout", null, EntryTypes.POJO,
false);

```

```

 /*****
 * Method Body Here
 *****/
 } finally {
 if (transaction != null) {
 transaction.end();
 }
 }
}

```

Alternatively, you can use try-with-resources pattern:

```

public String checkout(List<ItemOrders> orders) {
 try (Transaction transaction = AppdynamicsAgent.startTransaction("Checkout", null,
EntryTypes.POJO, false)) {
 /*****
 * Method Body Here
 *****/
 }
}

```

In this case, the Business Transaction ends when the try block closes.

### Start and End an Asynchronous Business Transaction

This example shows code that starts a Business Transaction called 'CheckoutAsync' whenever the method `checkoutAsync()` is called. The originating segment created for the Business Transaction ends when the method `endSegment()` is called on the Business Transaction, or when it is closed if used in a try-with-resources construct. Encapsulating the method body in a try/finally block ensures that we end the segment even if the method itself throws an exception or otherwise terminates without reaching the end.

```

//The thread where the Business Transaction starts
public String checkoutAsync(List<ItemOrders> orders) {
 Transaction transaction = null;
 try {
 transaction = AppdynamicsAgent.startTransaction("CheckoutAsync", null,
EntryTypes.POJO, true);
 //mark handoff to link this segment with the end segment
 transaction.markHandoff(commonPayload);

 /*****
 * Method Body Here
 *****/
 } finally {
 if (transaction != null) {
 transaction.endSegment();
 }
 }
}

```

Alternatively, the try-with-resources pattern is supported:

```
//The thread where the Business Transaction starts
public String checkoutAsync(List<ItemOrders> orders) {
 try (Transaction transaction = AppdynamicsAgent.startTransaction("CheckoutAsync", null,
 EntryTypes.POJO, true)) {
 //mark handoff to link this segment with the end segment
 transaction.markHandoff(commonPayload);

 /*****
 * Method Body Here
 *****/

 }
}
```

This ends the segment in the thread where the Business Transaction was started when the try block closes. The Business Transaction itself needs to be ended in the method where the asynchronous Business Transaction ends:

```
//The thread where the Business Transaction ends
public String checkoutAsyncEnd(List<ItemOrders> orders, Transaction transaction, Object
commonPayload) {
 //link to the originating segment
 Transaction transactionSegment = AppdynamicsAgent.startSegment(commonPayload);

 /*****
 * Method Body Here
 *****/
 if (transactionSegment != null) {
 transactionSegment.endSegment();
 }
 if (transaction != null) {
 transaction.end();
 }
}
```

### Set the Transaction Name After a Start

The following example shows how to set the transaction name after it has been started. This is useful if you want to split transactions based on events that happen in your application:

**i** Transaction name can only be set after a start on the originating segment, and if no async hand-offs or exits have been made.

```
public String checkout(List<ItemOrders> orders) {
```

```

AppdynamicsAgent.startTransaction("Checkout", null, EntryTypes.POJO, false);
/*****
 * Method Body Here
 *****/
if (orders.isEmpty()) {
 AppdynamicsAgent.setCurrentTransactionName("Empty Cart");
}
AppdynamicsAgent.getTransaction().end();
}

```

## Start a Transaction Using OOTB Servlet Naming Rules

The following example shows how to leverage automatic servlet naming rules to name a transaction:

```

public String checkout(List<ItemOrders> orders) {
 Map<String, String> headers = new HashMap<String, String>();
 headers.put("header1", "headerValue1");
 Map<String, String[]> parameters = new HashMap<String, String[]>();
 Map<String, Object> cookies = new HashMap<String, Object>();
 cookies.put("chip", "ahoy");
 ServletContext.ServletContextBuilder contextBuilder = new
 ServletContext.ServletContextBuilder()
 .withURL(new URL("https://www.yourstore.com/endpoint/to/checkout"))
 .withParameters(parameters)
 .withHeaders(headers)
 .withCookies(cookies)
 .withSessionAttributes(new HashMap<String, Object>())
 .withRequestMethod("GET")
 .withHostValue("hostValue")
 .withHostOriginatingAddress("hostOriginatingAddress");
 Transaction t = AppdynamicsAgent.startServletTransaction(contextBuilder.build(),
 EntryTypes.HTTP, null, false);
 /*****
 * Method Body Here
 *****/
 t.end();
}

```

## Define an Exit Call

For an `inventoryServer.verifyQuantities(orders)`, which makes a request to another process, you can monitor that request as an Exit Call. This helps to continue monitoring the Business Transaction through the call to the downstream server and identify the time spent in the remote service. You can do this by modifying the method as follows:

```

public void verifyQuantities(List<ItemOrders> orders) {
 ExitCall exitCall = null;
 try {
 exitCall = AppdynamicsAgent.getTransaction().startExitCall("Quantity Check",
 "Inventory Server", ExitTypes.HTTP, false);
 }
}

```

```

 /*****
 * Method Body
 *****/
 } finally {
 if (exitCall != null) {
 exitCall.end();
 }
 }
}

```

Alternatively, if you want to use HTTP Backend detection rules, you can use the `startHttpExitCall` method:

```

public void verifyQuantities(List<ItemOrders> orders) {
 ExitCall exitCall = null;
 try {
 Map<String, String> identifyingProps = new HashMap<String, String>();
 URL url = new URL("https://www.appdynamics.com/solutions/microservices/");
 exitCall = AppdynamicsAgent.getTransaction().startExitCall(identifyingProps, url,
false);
 /*****
 * Method Body
 *****/
 } finally {
 if (exitCall != null) {
 exitCall.end();
 }
 }
}

```

The above code modifications define the Exit Call that manifests it as a remote service in the controller. To tag and follow the request into an instrumented downstream tier, add a correlation header:

```

public void verifyQuantities(List<ItemOrders> orders) {
 ExitCall exitCall = null;
 try {
 exitCall = AppdynamicsAgent.getTransaction().startExitCall("Quantity Check",
"Inventory Server", ExitTypes.HTTP, false);

 // Generate the appdynamics correlation header
 String correlationHeader = exitCall.getCorrelationHeader();

 // ... Method code including request creation

 // Modify the request/payload to include the correlation header
 inventoryRequest.addHeader(AppdynamicsAgent.TRANSACTION_CORRELATION_HEADER,
correlationHeader);

 } finally {
 if (exitCall != null) {

```

```

 exitCall.end();
 }
}

```

The following example shows how to instrument an asynchronous exit:

```

public class StartEndAsyncExitCall {

 private void makeAsyncExitTransaction() throws Exception {
 System.out.println("Starting transaction");
 try (Transaction transaction = AppdynamicsAgent.startTransaction("StartEndAsyncExitCa
ll", null, EntryTypes.POJO, true)) {
 Thread.sleep(1000);
 new TransactionEndingThread(transaction).start();
 System.out.println("Starting exitcall");
 ExitCall exitCall = null;
 exitCall = transaction.startExitCall("Custom", "Custom", ExitTypes.CUSTOM, true);
 new ExitCallEndingThread(exitCall).start();
 }
 }

 public class TransactionEndingThread extends Thread {
 Transaction transaction = null;

 TransactionEndingThread(Transaction transaction) {
 this.transaction = transaction;
 }

 public void run() {
 try {
 Thread.sleep(1000);
 } catch (InterruptedException e) {
 e.printStackTrace();
 }
 transaction.end();
 System.out.println("Ending transaction");
 }
 }

 public class ExitCallEndingThread extends Thread {
 ExitCall exitCall = null;

 ExitCallEndingThread(ExitCall exitCall) {
 this.exitCall = exitCall;
 }

 public void run() {
 try {
 Thread.sleep(50);
 } catch (InterruptedException e) {

```

```

 e.printStackTrace();
 }
 exitCall.end();
 System.out.println("Ending exitcall");
}
}
}

```

### Define an Asynchronous Thread Handoff

If your checkout method also does a thread handoff and executes some business logic that you want to monitor in a separate thread, register the worker thread with the Business Transaction:

```

public String checkout(List<ItemOrders> orders) {
 Transaction transaction = null;
 try {
 transaction = AppdynamicsAgent.startTransaction("Checkout", null, EntryTypes.POJO,
false);

 // ... Method code

 // Custom thread handoff using custom queue
 asyncTaskQueue.add(task);

 } finally {
 if (transaction != null) {
 transaction.end();
 }
 }
}

```

To instrument this, modify the add method to mark a thread handoff and then start a new segment where the thread begins running:

```

public class AsyncTaskQueue {
 public void add(Task task) {
 AppdynamicsAgent.getTransaction().markHandoff(task);

 /*****
 * Method Body
 *****/
 }
}

```

```

public class Task {
 public void run() {
 Transaction transaction = null;
 try {

```

```

 transaction = AppdynamicsAgent.startSegment(this);

 /*****
 * Method Body
 *****/
 } finally {
 if (transaction != null) {
 transaction.endSegment();
 }
 }
}

public void cancel() {
 AppdynamicsAgent.cancelHandoff(this);

 /*****
 * Method Body
 *****/
}
}

```

The task object is used by the agent to link the segments. Correlating thread segments using the agent API requires that the agent is running in the [Executor](#) mode.

#### Add Data to Snapshot or Analytics

In many instances, there are values of interest in the code that are helpful to add to the snapshot. This aids in the root cause diagnosis of issues or to send to the AppDynamics Business Transaction analytics to help answer real-time business-oriented questions about your application. Data reported using this API appears in the same way as it had been collected with a [Method Invocation Data collector](#).

To report a total checkout amount to Business Transaction analytics and have it presented in the APM snapshots, use the following code:

```

private static final Set<DataScope> dataScopeSet = new
 HashSet(Arrays.asList(DataScope.ANALYTICS, DataScope.SNAPSHOTS));

public String checkout(List<ItemOrders> orders) {
 Transaction transaction = null;
 try {
 transaction = AppdynamicsAgent.startTransaction("Checkout", null, EntryTypes.POJO,
false);

 // ... Method code

 double shoppingCartTotal = total(orders);
 transaction.collectData("cart total", Double.toString(shoppingCartTotal),
dataScopeSet);

 } finally {
 if (transaction != null) {

```

```

 transaction.end();
 }
}

```

## Define a Custom Metric or Event

It can also be useful to report a value as a custom metric:

```

public String checkout(List<ItemOrders> orders) {

 // ... Method code

 double shoppingCartTotal = total(orders);
 AppdynamicsAgent.getMetricPublisher().reportSumMetric("Cart Total", (long)
shoppingCartTotal);

}

```

**i** It is recommended to provide a metric path along with the metric name in the code with format: `Server|Component:<TierName>|Custom Metrics|<MetricName>`, while publishing the metric.

Reporting custom metrics and events is possible irrespective of the Business Transaction context.

## Monitor OpenAI API with Java Agent

### Related pages:

- [Download AppDynamics Software](#)
- [Java Agent Configuration Properties](#)

AppDynamics Java Agent helps you monitor the OpenAI API usage and related metrics. It monitors the `CompletionRequest` and `ChatCompletionRequest` type requests created using the [TheoKanning OpenAI Java](#) framework to the OpenAI backend.

The following metrics are reported at the application, tier, and node levels:

- Calls per minute
- Cost
- Errors per minute
- Tokens

The following are the example metric paths:

- **Per model metric path** - `Application Infrastructure Performance|OpenAI_Tier|OpenAI|ada|Cost`
- **All model cumulative metrics path** - `Application Infrastructure Performance|OpenAI_Tier|OpenAI|Cost - All Models`
- **Net application level metrics path** - `Overall Application Summary|OpenAI - Cost - ada`

**i** These metrics are reported even if the exit call is outside the business transaction. However, the Average Response Time(ms) metric is not reported when the exit call is outside the business transaction.

## Prerequisites

Ensure that you meet the following prerequisites to monitor the OpenAI API exit calls with AppDynamics:

- Install Java Agent 23.7.0 or later. See [Install the Java Agent](#).
- Set the `enable-openai-metrics` node property to `true`.
- Install [Python 3.0](#), to run the Python script required to create custom dashboards. These custom dashboards are imported into the Controller UI and display OpenAI-related metrics. See [Import and Export Custom Dashboards and Templates Using the UI](#).

## Create a Custom Dashboard

1. Download [Custom\\_Dashboard\\_v1.0.zip](#). It contains the following four files:

Filename	Description
<code>template_app.json</code>	The template to create the application-level dashboard.
<code>template_tier.json</code>	The template to create the tier-level dashboard.
<code>main.py</code>	Python script to create the dashboards.
<code>readme.md</code>	Description of the solution.

2. Run the following command:

```
cd Custom_dashboard_script
python3 main.py
```

The preceding command prompts you to specify the dashboard type (application or tier) that you want to create.

3. Based on your selected dashboard type, you will be prompted to specify the following dashboard details.

[Application Level Dashboard Details](#)

[Tier Level Dashboard Details](#)

Variable	Description	Default	Possible Values	Required
Application Name	The application created in the Controller with OpenAI monitoring enabled.	none	openai_app_1	Yes
OpenAI Endpoints Host Name	The hostname of the OpenAI backend.	api.openai.com	api.openai.com	Optional
OpenAI Endpoints Port	The port of the OpenAI backend.	443	443	Optional
Dashboard Name	The dashboard name to be displayed on <b>Dashboard &amp; Reports</b> in the Controller UI.	openai_app_dashboard	openai_app_dashboard	Optional
Output File Name	The output dashboard filename.	app_dashboard.json	app_dashboard.json	Optional

[Application Level Dashboard Details](#)
[Tier Level Dashboard Details](#)

Variable	Description	Default	Possible Values	Required
Application Name	The application created in the Controller with OpenAI monitoring enabled.	none	openai_app_1	Yes
Tier Name	Name of the Tier exposed to OpenAI backend calls.	none	openai_tier_1	Yes
Business Transaction Name	The name of the business transaction reported to the host.	openai_tier_business_name	openai_bt	Optional

Variable	Description	Default	Possible Values	Required
OpenAI Endpoints Host Name	The hostname of the OpenAI backend.	api.openai.com	api.openai.com	Optional
OpenAI Endpoints Port	The port of the OpenAI backend.	443	443	Optional
Dashboard Name	The dashboard name to be displayed on <b>Dashboard &amp; Reports</b> in the Controller UI.	openai_tier_dashboard	openai_tier_dashboard	Optional
Output File Name	The output dashboard .json filename.	tier_dashboard.json	tier_dashboard.json	Optional

4. Import the dashboard in the Controller UI. See [Create and Manage Custom Dashboards and Templates](#).

## .NET Agent

To monitor .NET applications with AppDynamics, you install the .NET Agent on the servers where the applications run. You only need to install the agent once per server even to monitor more than one application on the server. This page describes how to install the .NET Agent for IIS applications using the Getting Started wizard in the Controller.

For alternative approaches, see:

- [Install the .NET Agent for Windows](#), if you downloaded the agent directly from the [AppDynamics Download Center](#).
- [Configure the .NET Agent for Windows Services and Standalone Applications](#), if you monitor Windows services or standalone applications.

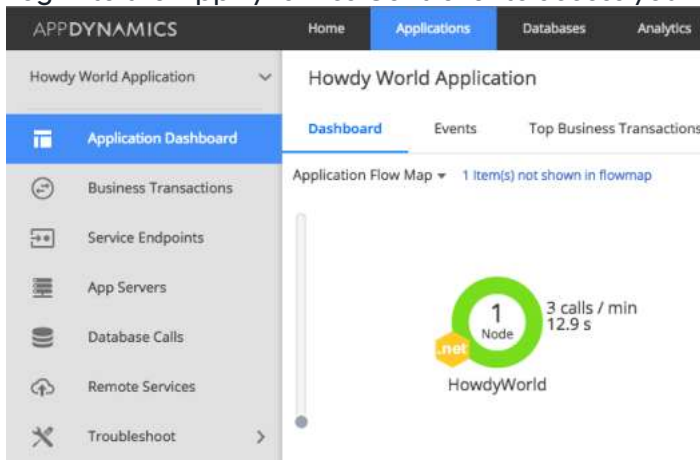

### Before You Begin

1. Verify support for your environment at [.NET Supported Environments](#).
2. Confirm that you have access to a compatible Controller. See [Agent and Controller Tenant Compatibility](#).
3. Confirm the connection settings to the Controller where your agent will report data:
  - If you use a SaaS Controller, AppDynamics sent you the Controller hostname in your Welcome Email. Use port 443 for HTTPS, or port 80 for HTTP.
  - If you use an on-premises Controller, you supplied the hostname and port during installation.
4. Verify that you have access to the machine (where the application runs) as a user account with privileges to install the agent software. Then, restart the application.
5. Verify that the machine where the application runs can connect to the Controller. Proxies or firewalls on the network between the agent and Controller may require additional configuration.

## Install the .NET Agent

To install the agent for IIS applications:

1. Log in to the Controller UI and access the Getting Started Wizard for .NET.
2. Follow the steps in the wizard to configure and download the agent. The wizard guides you through some preliminary configuration steps.  
When finished, the wizard enables you to download the agent as a ZIP archive named (in format of): `dotNetAgent-Portal-<architecture>-<version>.zip`.
3. Extract the agent archive on the destination computer.
4. Launch an elevated command prompt with full administrator privileges.
5. Execute the Installer.bat file you extracted. The batch file installs the agent and starts the AppDynamics Agent Coordinator service.
6. Restart IIS.
7. If you are in a testing environment, apply load to your application to view the activity in the Controller UI.
8. Log in to the AppDynamics Controller to access your application and view activity similar to:

Next, you can install more agents, or begin monitoring your application. See [AppDynamics Essentials](#).

## .NET Supported Environments

### Supported Runtime Environments

This section lists the environments where the .NET Agent does some automatic discovery after little or no configuration. See [Browser RUM Supported Environments](#) for additional supported environments.

**i** Out-of-process IIS applications should be instrumented as standalone applications.

### OS Versions

All versions of Windows (x86/x64) and Linux (x64) operating systems (OS) are supported by the target runtime and operating system vendor.

## Runtimes

**i** AppDynamics only supports versions of .NET Framework that Microsoft currently supports. Previous versions not listed are not supported by Microsoft, or by AppDynamics. See [Microsoft .NET Framework Supported Versions](#).  
However, AppDynamics supports all .NET applications running on the below-mentioned runtimes. For example, when .NET Framework 3.5 SP1 is installed on the server, the .NET Framework 2.0 applications are also supported.

- Microsoft .NET Framework: 3.5 SP1, 4.6.2, 4.7.x, 4.8.x
- Microsoft .NET: 6, 7, 8

## Hosts

- Managed Standalone Applications
- Managed Windows Services
- Microsoft IIS
- Microsoft SharePoint 2010, 2013 as services running inside IIS

## Microsoft Windows Azure

- Azure App Services on Windows in the Azure Portal
  - Web Apps
  - Web Jobs
  - API Apps
  - Container Services

For Azure App Services, certain infrastructure monitoring features are not supported, those include: CLR crash reporting, machine snapshots, and Windows performance counter monitoring.

- Azure Cloud Services
  - Web Roles
  - Worker Roles

## Automatically Discovered Business Transactions

The .NET Agent discovers business transactions for the following frameworks by default. The agent enables detection without additional configuration.

Type	Custom Configuration Options?	Downstream Correlation?
ASP.NET*	Yes	Yes
ASP.NET MVC 2 ASP.NET MVC 3 ASP.NET MVC 4 ASP.NET MVC 5	Yes	Yes
ASP.NET Core	Yes	Yes

Open Web Interface for .NET (OWIN) web API	Yes	Yes
.NET Remoting	No	See <a href="#">Enable Correlation for .NET Remoting</a> .
Windows Communication Foundation (WCF)	No	Yes
Web Services including SOAP	No	Yes
<b>Message Queues</b>		
Apache ActiveMQ NMS framework and related MQs	No	Yes
IBM WebSphere MQ	No	Yes
Microsoft Message Queuing (MSMQ)	No	Yes
Microsoft Service Bus / Windows Azure Service Bus	No	Yes
NServiceBus over MSMQ or RabbitMQ transport	No	Yes
RabbitMQ	Yes	Yes
TIBCO Enterprise Message Service	No	Yes
TIBCO Rendezvous	No	Yes
Windows Azure Queue	No	No

\* The .NET Agent automatically discovers entry points for ASP.NET web forms with the Async property set to "true" in the [Page directive](#).

### Supported Loggers for the .NET Agent

- Log4Net
- NLog
- System Trace
- Windows Event Log
- Loggers on .NET Core that implement the Microsoft.Extensions.Logging.ILogger API

If you are using a different logger, see [Error Detection](#).

## Remote Service Detection

The .NET Agent automatically detects these remote service types. The agent enables detection by default. You do not need to perform extra configuration.

Type	Custom Configuration Options?	Async Detection?*	Downstream Correlation?
CosmosDB: <ul style="list-style-type: none"> <li>• v2.x (Microsoft.Azure.DocumentDB.Core)</li> <li>• v3.x (Microsoft.Azure.Cosmos)</li> </ul>	No	See <a href="#">Asynchronous Exit Points for .NET</a> .	N/A
Directory Services, including LDAP	No	No	N/A
HTTP	Yes	See <a href="#">Asynchronous Exit Points for .NET</a> .	Yes
MongoDB: C# and .NET MongoDB Driver version 1.10, 2.0	No	See <a href="#">Asynchronous Exit Points for .NET</a> .	N/A
.NET Remoting	Yes	No	See <a href="#">Enable Correlation for .NET Remoting</a> .
WCF	Yes	See <a href="#">Asynchronous Exit Points for .NET</a> .	Yes
WCF Data Services	Yes	No	No
Web Services, including SOAP	Yes	See <a href="#">Asynchronous Exit Points for .NET</a> .	Yes
Azure Service Fabric Remoting v1 and v2—for the .NET Microservices Agent	-	-	-
<b>Data Integration</b>			
Microsoft BizTalk Server 2010, 2013	No	Yes	See <a href="#">Correlation Over Microsoft BizTalk</a> .

Message Queues			
Apache ActiveMQ NMS framework and related MQs	Yes	No	Yes
IBM WebSphere MQ (IBM XMS)	Yes	No	Yes
Microsoft Message Queuing (MSMQ)	Yes	See <a href="#">MSMQ Backends for .NET</a>	See <a href="#">MSMQ Backends for .NET</a>
Microsoft Service Bus / Windows Azure Service Bus	No	Async exit points only	Yes
NServiceBus over MSMQ or RabbitMQ transport	No	See <a href="#">NServiceBus Backends for .NET</a>	Yes
RabbitMQ	See <a href="#">RabbitMQ Backends for .NET</a>	No	Yes
TIBCO Enterprise Message Service	Yes	No	Yes
TIBCO Rendezvous	Yes	No	Yes
Windows Azure Queue	No	No	No

\* The agent discovers asynchronous transactions for the Microsoft .NET 4.5 framework. See [Asynchronous Exit Points for .NET](#).

### Supported Windows Azure Remote Services

Type	Customizable Configuration?	Downstream Correlation?
Azure Blob	No	No
Azure Queue	No	No
Microsoft Service Bus	No	Yes

## Cache Clients

Type	Customizable Configuration?	Async Detection?*	AppD for Databases?
StackExchange.Redis	No	Yes	No

## Data Storage Detection

The .NET Agent automatically detects the following data storage types. The agent enables detection by default. You do not need to perform extra configuration.

Type	Customizable Configuration?	Async Detection?*	AppD for Databases?
ADO.NET (see supported clients below)	Yes	Yes	No
Windows Azure Blob Storage	No	Yes	No
Windows Azure File Storage	No	Yes	No
Windows Azure Table Storage	No	Yes	No

\* The agent discovers asynchronous transactions for the Microsoft .NET 4.5 framework. See [Asynchronous Exit Points for .NET](#).

## Supported ADO.NET Clients

AppDynamics can monitor any ADO.NET client version and type. Clients we've tested include the following:

Database Name	Database Version	Client Type
Oracle	10, 11, 12	ODP.NET
Oracle	10, 11, 12	Microsoft Provider for Oracle
MySQL	5.x	Connector/Net and ADO.NET
Microsoft SQL Server*	2005, 2008, 2012	ADO.NET

\*Microsoft, SQL Server, and Windows are registered trademarks of Microsoft Corporation in the United States and other countries.

## Other Backends

- ADO.NET backend calls (SqlClient, MySql, SQLite, PostgreSQL)
- EntityFramework

## .NET Agent Frameworks for OpenTelemetry

Vendor	Framework	Version(s)	Entry Points	Exit Points
Microsoft	ASP.NET Core	6.0	Yes	-
Microsoft	Web Services (HttpClient)	6.0	-	Yes

## Limitations

- Tier network dashboard is not supported on .NET Core / .NET runtime.
- Node memory is not supported on Linux.
- Cisco Secure Application does not support single file deployment.
- For .NET Framework, AppDynamics reports vulnerable assemblies. To see if an agent is reporting correctly, navigate to the Cisco Secure Application dashboard, go to **Application**, click the desired **Tier**, then click the desired **Node** name. After selecting the **Node**, you can view the **Last Dependency Reported** column.

## Unsupported .NET Features

- [Assembly trimming](#)
- [Assembly unloadability](#)
- [Trim self-contained deployments, and executables](#)

## Install the .NET Agent for Windows

### Related pages:

- [Configure the .NET Agent](#)
- [Unattended Installation for .NET](#)
- [Upgrade the .NET Agent for Windows](#)
- [Download AppDynamics Software](#)

To monitor IIS applications, Windows services, or standalone applications, install the AppDynamics .NET Agent once on each machine that hosts managed .NET applications. At startup, the agent initializes an individual instance of itself for each application running in the CLR.

This page describes a new installation for the .NET Agent using the MSI package.

- To install from the command line, see [Unattended Installation for .NET](#).
- To install the AppDynamics Site Extension for Windows Azure, see [Install the AppDynamics Azure Site Extension for .NET](#).
- To install the AppDynamics .NET Microservices Agent using one of the new AppDynamics NuGet Packages, see [.NET Microservices Agent](#).
- To upgrade, see [Upgrade the .NET Agent](#).

## Installation Overview

1. [Prepare to Install](#).
2. [Install the agent](#).
3. [Configure the agent](#).
4. Restart instrumented applications.
  - For Microsoft IIS, the [configuration utility](#) provides an option to restart IIS or not.

- If you do not restart IIS, monitoring does not begin until the next time IIS restarts.
- You must restart Windows services and standalone applications manually.

## Prepare to Install

Review these requirements before you install the .NET Agent:

- You must enable Windows Management Instrumentation service on the machine where you are installing the .NET Agent, and the service must be running.
- To run the .NET Agent and the Machine Agent on the same machine, you must enable .NET Compatibility Mode on the Machine Agent. See [.NET Compatibility Mode](#).

## Install the .NET Agent

1. Download the MSI installer package from the [AppDynamics Download Center](#).
2. Run the MSI installer package.
3. Read the End User Agreement and click to accept. Then, click **Next**.
4. (Optional) On the Confirm location panel, change the .NET Agent installation directories, including:
  - Destination directory for the .NET Agent executables and supporting files.
  - Parent directory for local data including agent configuration files and log files.
 See [.NET Agent Directory Structure](#) for the default directories.

 You can also change the destination of the logs directory later using the [AppDynamics Agent Configuration utility](#).

5. On the User Account Control panel, click **Yes** to allow the installer to make changes to the computer. If the current account does not have administrator privileges, the installer prompts you to supply the password for an administrator account.
6. Wait for the installation to complete.
7. For new installs, AppDynamics recommends you launch the [AppDynamics Agent Configuration utility](#).

If you encounter problems installing, see [Troubleshoot .NET Agent Issues](#)

## Configure the .NET Agent

Launch the AppDynamics Agent Configuration utility to configure the .NET Agent.

- For Microsoft IIS applications, see [Configure the .NET Agent](#).
- For Windows services or standalone applications, see [Configure the .NET Agent for Windows Services and Standalone Applications](#).

## Configure the .NET Agent

### Related pages:

- [Install the .NET Agent for Windows](#)
- [Name .NET Tiers](#)
- [Configure the .NET Agent for Windows Services and Standalone Applications](#)
- [Unattended Installation for .NET](#)

After you install the AppDynamics .NET Agent, configure the agent based on the types of applications to monitor:

- For Microsoft IIS applications, use the configuration utility with either automatic or manual tier naming.

- For Windows services or standalone applications, use the configuration utility, and then manually update the config.xml. See [Configure the .NET Agent for Windows Services and Standalone Applications](#).

You can instrument any combination of IIS Applications, Windows services, and standalone applications on a single server. Run the [configuration utility](#) to configure IIS, then follow the instructions for Windows services and Standalone applications.

Use the [AppDynamics Agent Configuration Utility](#) to configure the agent immediately after installation, or make changes to existing agent configurations. The utility configures the agent for one machine at a time.

## Prepare to Configure the .NET Agent

- [Install the .NET Agent for Windows](#).
- You need these account credentials based on your installation type:
  - Single-tenant: Membership in a role with the View License account level permission. See [Manage Custom Roles](#).
  - Multi-tenant or SaaS: Your AppDynamics Welcome Email that contains your account credentials.
- Uninstall any pre-existing profiler, such as Ant, VS 2010 Performance Tools, or others. The [configuration utility](#) alerts you if it finds a pre-existing profiler.
- Determine your [tier naming](#) scheme:
  - [Automatic](#)
  - [Manual](#)
  - Pre-configured using [Config Management](#) in the Controller

**i** The [configuration utility](#) must restart IIS to apply configurations. The utility offers you the option to restart IIS or not. If you choose not to restart, configurations apply the next time IIS restarts.

## File System Security Settings

These Windows accounts require specific file system permissions:

- The account you use to run your web application as defined by its application pool, or the Windows service account.
- The account you use to run the AppDynamics Agent Coordinator, by default the Local System account.

The required permissions are:

- Write permission to the .NET App Agent logs directory.  
Default: Windows Server 2008 and later: %ProgramData%\AppDynamics\DotNetAgent\Logs
- Read and Execute permissions to the .NET App Agent install directory.  
Default: C:\Program Files\AppDynamics\AppDynamics .NET Agent
- Read and Execute permissions in the web application installation directory.  
For example: C:\inetpub\wwwroot\myapp

## Configure the .NET Agent

1. Start the Agent Configuration Utility. In the Windows pane, select **AppDynamics > .NET Agent > AppDynamics Agent Configuration**.

If a warning message displays, click **Yes** to exit and uninstall any pre-existing profiler.

**i** Use the Registry editor to check the Windows registry and ensure that the uninstall process cleaned up the registry entries. Use the warning message to identify any undeleted profiler environment variables. See [Troubleshoot .NET Agent Issues](#).

2. If the configuration utility detects legacy agent configurations from the .NET Agent <= 3.7.7, it displays the **Upgrade Configuration** pane. Choose either:

- **Yes** to remove legacy configurations. See [Upgrade the .NET Agent for Windows](#).

Removing legacy configurations modifies `web.config` files and causes IIS to restart affected applications.

- **No** to retain legacy configurations.

When the utility discovers no further profiler conflicts, or after any configuration clean up, it displays the welcome pane.

- From the Log directory permissions pane, you can optionally change the location of the log directory. Click **Change** and select a new location.
- If needed, enter an account to grant log directory permissions. Click **Add**. If a warning message displays, verify that the account is valid on the system. The wizard confirms the list of accounts.
- From the Controller Configuration pane, enter the Controller access information and credentials.
  - The AppDynamics Agent Configuration utility only supports the configuration of one Controller and business application per server.
    - Use tiers to organize different applications you instrument on a single server, or
    - Manually configure support for multiple business applications. See [Configure Multiple Business Application Support for .NET](#).
  - Enter the Controller server name, or IP and port number.
  - For single-tenant accounts, enter your Account Access Key. Locate your credentials under **Settings > License** in the Controller.
  - For multi-tenant accounts, click **Multi-Tenant Controller**. Enter the Account Name and Account Access Key as provided to you by AppDynamics.
  - For a secure connection, click **Enable SSL**.
    - Make sure you have secured the Controller with a trusted certificate. See [Enable SSL for the .NET Agent](#).
    - When you enable SSL, the agent secures communication to the Controller using the protocols set for `ServicePointManager.SecurityProtocol` in your application.
    - By default, the configuration utility enables TLS 1.2, making it the first option in the list of secure protocols. This affects all secure communications from your application, not just requests to the AppDynamics Controller. To disable TLS 1.2, click to deselect this option.
  - If needed, enter the HTTP proxy information. Proxies that use authentication require additional configuration.
- Click **Test Controller Connection** to verify the connection.
 

The Application Configuration pane displays existing business application information from the Controller and Controller connection status.
- Configure the business application for the Controller:
  - If you already have a business application on the Controller, click **Existing Applications from the Controller** and click the appropriate business application. If you have not defined business applications in the Controller, the utility displays an empty list.
  - Click **New Application** to define a new business application. Be careful about spellings and capitalization and note down the exact name. Ampersands are not supported in application names.
  - To use [Config Management](#) in the Controller, click **Register Machine with No Application**.
- Click **Next** to advance to Assign IIS applications to tiers where you can use one of the tier naming options.

#### Automatically Name IIS Tiers

- In the Assign IIS applications to the tiers pane, click **Automatic**.
- If prompted, click **OK** to confirm the Automatic configuration. The configuration utility summarizes the configuration settings.
- By default when you click **Next**, the configuration utility restarts IIS.

**i** If you do not want to apply the configuration right away, uncheck the box. The Agent Configuration Utility saves the information and applies it the next time you restart IIS.

4. If you proceed and click **Next**, the configuration utility logs its activities, including stopping and restarting IIS, and reports any problems. Review the summary for any issues in red font. The green font indicates the logged events. The summary shows any Warnings (W) or Errors (E).
5. Click **Done**.

#### Manually Name IIS Tiers

1. From the Assign IIS applications to tiers pane, click **Manual**, then click **Next**.
2. Assign IIS Applications to AppDynamics tiers by selecting a tier on the right and a business application on the left. The utility highlights the assigned tier in boldface.

**i** For large IIS installations, use the Max IIS tree depth pulldown to display all the projects. A large tree depth may take some time to view.

To create new tiers, enter a name and click **Add Tier**.

3. When you are done click **Next**.
4. On the **Configuration Summary** pane, uncheck **Restart IIS** if you do not want to immediately restart IIS. You may restart later to apply your changes, or they will take effect after a reboot.
5. If you proceed and click **Next**, the Configuration Utility logs its activities, including stopping and restarting IIS, and reports any problems.
6. Review the configuration log summary. As it applies the configuration, AppDynamics generates a log of the configuration activities and displays a summary. Review the summary for any issues in red font. The green font indicates the logged events. The summary shows any Warnings (W) or Errors (E).
7. When finished, click **Next**. The wizard completes.

#### Use Config Management

1. From the Assign IIS applications to the tiers pane, click **Register Machine with No Application**, and then click **Next**.
2. From the Configuration Summary pane, uncheck **Restart IIS** if you do not want to immediately restart IIS. You may restart later to apply your changes, or they will take effect after a reboot.
3. Follow the instructions on [Manage Configuration for .NET](#) to assign a configuration from the Controller. The .NET Agent and .NET Machine Agent do not report metrics to the Controller until after you assign a configuration using the Config Management tool.

See [Troubleshoot .NET Agent Issues](#).

#### .NET Agent SSL Support

When a .NET Agent establishes a secure (SSL) connection with a Controller, the .NET Agent uses a default mechanism embedded in the .NET framework to verify a Controller (server) certificate which relies on the local Trust Store. As a result, the Controller certificate must be signed by one of the publicly trusted authorities.

Therefore, if the Controller uses:

- a self-signed certificate, or
- a certificate signed by a custom authority

Then the SSL connection cannot be established until:

- a self-signed certificate, or
- a custom authority are manually added to the local Trust Store.

**i** If a Controller uses a certificate signed by a publicly trusted authority, then no extra set up is required.

If you do not want to manually add a certificate to the local Trust Store, you can configure the .NET Agent to consume the Controller custom trusted certificate and establish a secured connection automatically.

### Limitations

Custom trusted certificate validation is supported with these noted limitations for the .NET runtimes:

- .NET Core >= 2.0
- .NET Framework >= 4.7.2
- .NET Standard >= 2.1

**i** You may use applications that were compiled using earlier .NET versions as long as the .NET runtime is later than or equal to the listed limitations.

If you reach a runtime limitation, then you can either:

- Upgrade the .NET runtime to a supported version, or
- Add a Controller custom certificate to the local Trust Store, disable the feature, and then continue using the SSL connection to a Controller based on the default validation mechanism.

### Supported Configurations

You can configure the Controller Custom Trusted Certificates by providing either a:

- Path to one certificate file: A file may contain one, or multiple valid certificates, in one of these formats:
  - Base-64 Encoded X.509 (.cer)
  - DER Encoded Binary X.509 (.cer)
  - PKCS 7 (.p7b)
  - PKCS 12 (.pfx)

Or

- Folder containing multiple certificate files: A folder may contain several files with one or multiple certificates inside; and the folder may contain subfolders. There is no limitation on the structure except that all files in the folder must contain valid certificates; if one file is not a valid certificate, then all of them are ignored.

Select only one of these configurations. If you configure both a certificate file and a certificate folder, then a warning displays alerting you that only the certificate file will be used in the configuration.

You are not required to provide a private key in your certificate files; only a public key is required. AppDynamics does not expose any sensitive information from the provided certificates. Use caution when providing files to an outside source.

### Standalone Windows Agent Configuration

Configure the `config.json` file:

```
{
 "controller": {
 "certfile": "C:\certs\certificate.crt",
 "certdir": "C:\certs\",
 }
}
```

## Environment Variables Used for Standalone Windows Agent

Using the command line, set these environment variables to override the `config.json` file:

```
APPDYNAMICS_CONTROLLER_SSL_CERTFILE=C:\certs\certificate.crt
APPDYNAMICS_CONTROLLER_SSL_CERTDIR=C:\certs\
```

## Agent MSI Agent Configuration

Configure the `config.json` file without overriding the environment variables:

```
<appdynamics-agent xmlns:xsd="http://www.w3.org/2001/XMLSchema" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
 <controller ssl-certificate-file = "C:\certs\certificate.crt" ssl-certificate-directory = "C:\certs\" >
 ...
 </controller>
 ...
</appdynamics-agent>
```

## Parity Difference with Linux .NET Agent <= 20.11.x

These are the existing parity differences with Linux .NET Agent <= 20.11.x:

- Certificate files formats are extended.
- Multiple certificates are supported in files.
- There is no name constraint for the files.
- There is no constraint on the folder structure.
- Full framework is supported.
- You are not required to provide a full chain of the Controller certificates. You can configure the .NET Agent trust using an end leaf certificate, or just a custom authority certificate, or both; whichever is convenient.

## Enable SSL for the .NET Agent

### Related pages:

- [Secure the Platform](#)
- [Administer the .NET Agent](#)
- [.NET Agent Configuration Properties](#)

This page describes how to configure the AppDynamics .NET Agent to connect to the Controller with SSL.

## Requirements

Before you configure the agent to enable SSL, gather this information:

- 
- Identify the Controller SSL port:
    - For SaaS Controllers, the SSL port is 443.
    - For on-premises Controllers, the SSL port is 8181 by default, but it is possible to configure on-premises Controllers to use other ports at installation.
  - Identify the signature method for the Controller's SSL certificate:
    - A publicly known certificate authority (CA) signed the certificate. This applies for Verisign, Thawte, and other commercial CAs.
    - A CA internal to your organization signed the certificate. Some companies maintain internal certificate authorities to manage trust and encryption within their domain.
    - .NET Agent supports self-signed certificates when these conditions exist:
      - The Common Name (CN) on the certificate matches the URL of the Controller that the agent is calling.
      - The public key for the self-signed certificate is installed on the Windows Trusted Root Certification Authorities store where the agent is installed.

## Establish Trust for the Controller's SSL Certificate

The .NET Agent requires that the Common Name (CN) on the Controller certificate matches the DNS name of the Controller. Additionally, certificates for the root CA that signed the Controller's SSL certificate must reside in the Windows Trusted Root Certification Authorities store for the Local Computer.

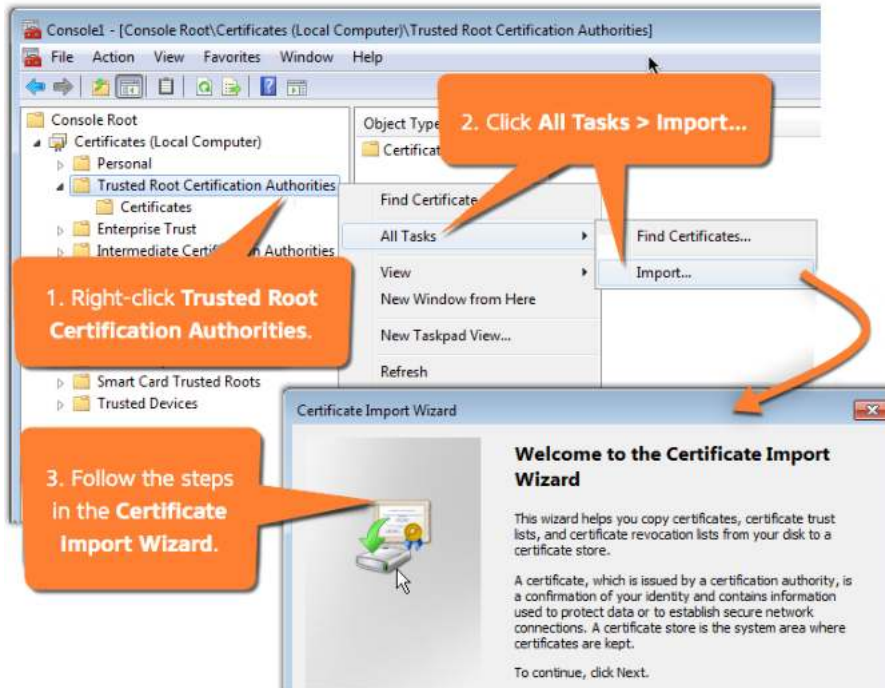

### Certificates Signed by a Publicly Known Certificate Authority

The root certificates for most publicly trusted CA signing authorities, such as DigiCert, Verisign, Thawte, and other commercial CAs, are in the Trusted Root Certification Authorities store by default.

### Certificates Signed by an Internal Certificate Authority

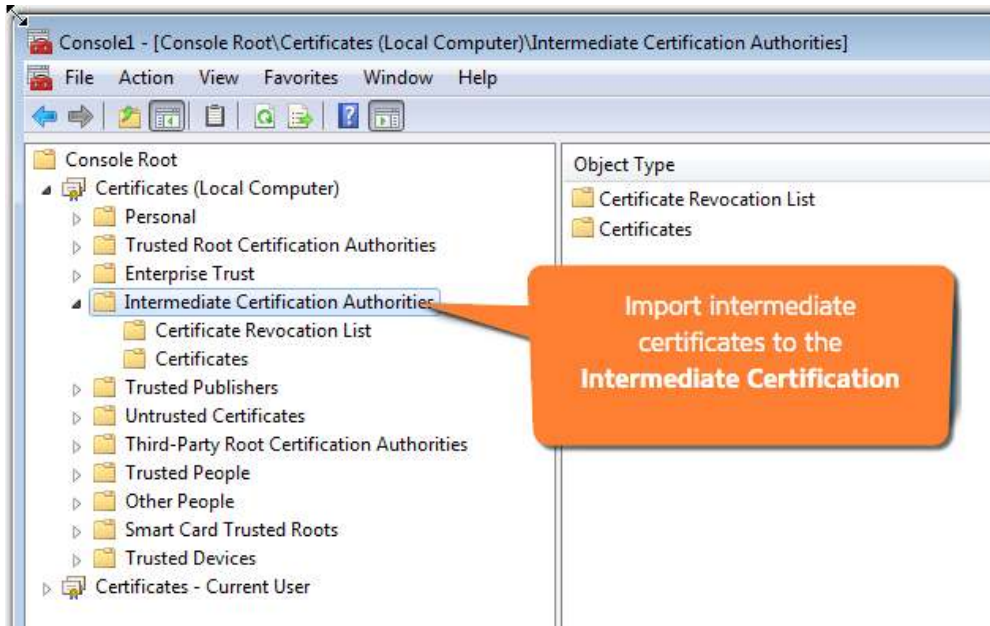

If your organization uses internal CA to sign certificates, you may need to obtain the root CA certificate from your internal security management resource. To import the root certificate, see [Adding Certificates to the Trusted Root Certification Authorities store for a Local Computer](#).

This example shows how to use the Certificate snap-in for the Microsoft Management Console to import a certificate for a Trusted Root Certification Authority:

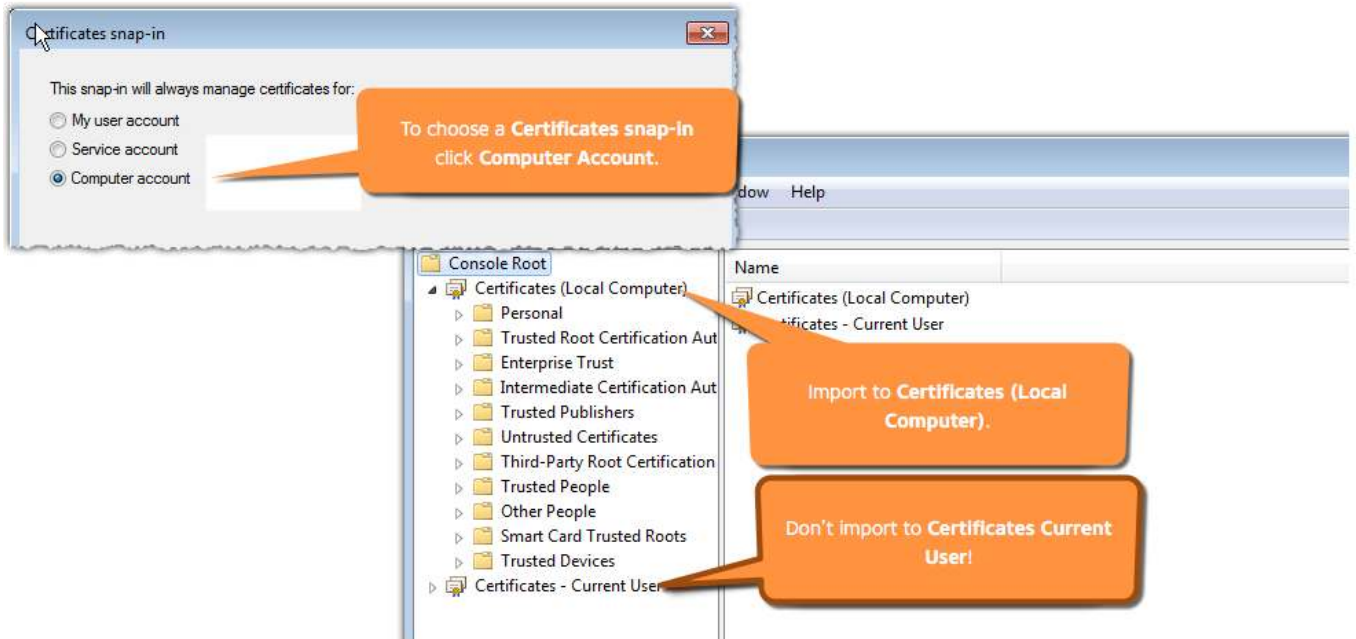

**i** If an intermediate CA signed the Controller certificate, you must import the certificate for the intermediate CA in addition to the one for the root CA that signed the intermediate CA certificate. If your Controller is publicly accessible, you can use a certificate checker to identify the certificates required to complete the trust chain.

This example shows the **Intermediate Certification Authorities** store:

### Certificate Management Tips

- If you imported certificates for a root or intermediate CA, verify the certificate store where you imported them. Import them to **Certificates (Local Computer)**.

- The AppDynamics SaaS Controller uses certificates signed by DigiCert. In some cases, SaaS customers must import the DigiCert root certificates into the **Windows Trusted Root Certification Authorities** store.
- In some cases system administrators set up group policies that require external certificates be imported to the **Third-Party Root Certification Authorities** store. If importing the certificate for the root CA to the **Windows Trusted Certification Authorities** store is not successful, then try the **Third-Party Root Certification Authorities** store.

### Enable SSL for the .NET Agent

You can update the SSL settings for the agent by:

- Using the [AppDynamics Agent Configuration Utility](#), or
- Editing the settings directly in the `config.xml`

When you enable SSL for the .NET Agent, you automatically enable SSL for the .NET Machine Agent.

### Configure SSL Using the AppDynamics Agent Configuration Utility

1. Launch the AppDynamics Agent Configuration utility.
2. In **Controller Configuration**, set the **Port Number** to the SSL port for the Controller.
  - For a SaaS Controller, set the **Port Number** to `443`.
  - For an on-premises Controller, set the **Port Number** to the on-premises SSL port. The default is `8181`.
3. Click **Enable SSL**.
  - When you enable SSL, the agent secures communication to the Controller using the protocols set for `ServicePointManager.SecurityProtocol` in your application.
  - By default, the configuration utility enables TLS 1.2, making it the first option in the list of secure protocols. This affects all secure communications from your application, not just requests to the AppDynamics Controller. To disable TLS 1.2, click to deselect this option.
4. Click **Next** and proceed with the rest of the panes to complete the configuration.
5. Restart instrumented applications: IIS applications or application pools, Windows services, and standalone applications.

If you use automatic tier configuration, restart IIS. For example, open a command prompt and enter:

```
iisreset
```

Upon restart, the agent connects with the Controller via SSL.

### Configure SSL Using config.xml

1. Open the `config.xml` file as administrator. See [Administer the .NET Agent](#).
2. Update the following SSL settings:
  - Controller port attribute: set to the on-premises SSL port. The default is `8181`. See [Controller Port Attribute](#).
  - Controller SSL attribute: set to `true`. See [Controller SSL Attribute](#). When you enable SSL, the agent secures communication to the Controller using the protocols set for `ServicePointManager.SecurityProtocol` in your application.
  - Controller enable TLS 1.2 attribute: Optionally set to `true` to add TLS 1.2 as the first option in the list of protocols. This affects all secure communications from your application, not just requests to the Controller.
3. Save your changes.
4. Restart the `AppDynamics.Agent.Coordinator` service.
5. Restart instrumented applications: IIS applications or application pools, Windows services, and standalone applications.

If you use Automatic configuration, restart IIS. For example, open a command prompt and run:

```
iisreset
```

Upon restart, the agent connects with the Controller via SSL.

### Sample SaaS SSL config.xml Configuration

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://
www.w3.org/2001/XMLSchema">
```

```
<controller host="mycompany.saas.appdynamics.com" port="443" ssl="true" enable_tls12="true">
 <application name="MyDotNetApplication" />
</controller>
...
</appdynamics-agent>
```

### Sample On-Premises SSL config.xml Configuration

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://
www.w3.org/2001/XMLSchema">
 <controller host="mycontroller.mycompany.com" port="8181" ssl="true" enable_tls12="true">
 <application name="MyDotNetApplication" />
 </controller>
 ...
</appdynamics-agent>
```

### Troubleshooting Issues

If you verified all prerequisites and still have communication issues, verify that the default ciphers are enabled in Windows Server.

Check this Registry key:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\SecurityProviders\SCHANNEL\Ciphers\
```

If subkeys exist, your operations team may have disabled certain ciphers.

### Encrypt Credentials in .NET Agent Configuration

#### Related pages:

- [Unattended Installation for .NET](#)
- [Upgrade the .NET Agent for Windows](#)

By default, the AppDynamics .NET Agent stores these credentials in the `config.xml` file:

- Controller account authentication
- Proxy server authentication

For environments where security policies require you to secure credentials stored on disk, you can run an [unattended installation](#) that encrypts the credentials for the .NET Agent and writes them to the Windows Credential Manager.

Storing credentials for the .NET Agent using the Windows Credential Manager updates the `config.xml` file to use a schema which the AppDynamics Agent Configuration utility does not support. If you follow these instructions, then you cannot use the configuration utility to make configuration changes afterward. If you launch the configuration utility on a server where you have stored credentials in the Windows Credential Manager, the utility prompts you to delete the configurations.

## Requirements

- You must run the `AppDynamics.Agent.Coordinator` service as the `LocalSystem` account.
- To modify credentials after installation, you need [Windows Sysinternals](#).

## Setup Configuration File

You must generate a setup configuration file to run an unattended installation. See 'Setup Configuration File Properties' on [Unattended Installation for .NET](#).

### New Installation

For new installations, use one of these methods to create the setup configuration file:

- Run the AppDynamics Agent Configuration utility from the command line and pass the `-s` parameter to specify the setup configuration file destination. For this option, you must execute the .NET Agent MSI installer package on one machine before running the configuration utility.

```
%ProgramFiles%\AppDynamics\AppDynamics .NET
Agent\AppDynamics.Agent.Winston.exe -s <path to setup configuration file>
```

- Manually create a setup configuration file from a sample template.

Remove any plain-text authentication elements from the setup configuration file. You pass the credentials as part of the unattended installation command:

- Controller Account element:  
`<account name="myaccount" password="myaccesskey"/>`
- Proxy Authentication element: If you are using a proxy authentication, use this format in the setup configuration file.  
`<proxy host="myproxy.example.com" port="3128" enabled="true">`  
`<authentication enabled="true" domain="mydomain.com"/>`  
`</proxy>`

### Upgrade

If your upgrade meets the criteria for an in-place upgrade on [Upgrade the .NET Agent for Windows](#), you can encrypt the credentials for the .NET Agent and upgrade the agent at the same time.

Copy the AppDynamics Agent element from your existing `config.xml` file to the setup configuration file. Remove any plain-text authentication elements from the setup configuration file. You pass the credentials as part of the unattended installation command:

- Controller Account element:  
`<account name="mycontroller.saas.appdynamics.com" password="myaccesskey"/>`
- Proxy Authentication element:  
`<authentication enabled="true" user_name="my_proxy_user" password="password"`  
`domain="my_windows_domain"/>`

### Sample Setup Configuration File

This example shows a setup configuration file that instruments: two IIS Applications, `MainBC` and `SampleHTTPService`; a Windows service, `BasicWindowsService`; and a standalone application, `MyStandaloneApp.exe`.

```

<winston>
 <logFileDirectory directory="C:
 \ProgramData\AppDynamics\DotNetAgent\Logs" />
 <logFileFolderAccessPermissions
 defaultAccountsEnabled="false">
 <account name="NT AUTHORITY\LOCAL SERVICE"
 displayName="LOCAL SERVICE" />
 <account name="NT AUTHORITY\SYSTEM" displayName="SYSTEM" />
 <account name="NT AUTHORITY\NETWORK SERVICE"
 displayName="NETWORK SERVICE" />
 <account name="IIS_IUSRS" displayName="ApplicationPool
 Identity" />
 </logFileFolderAccessPermissions>
 <appdynamics-agent xmlns:xsi="http://www.w3.org/2001/
 XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/
 XMLSchema">
 <controller host="mycontroller.appdyanmics.com" port="443"
 ssl="true">
 <application name="My Business Application" />
 </controller>
 </machine-agent />

 <app-agents>
 <IIS>
 <applications>
 <application path="/" site="MainBC">
 <tier name="Main Site" />
 </application>
 <application path="/" site="SampleHTTPService">
 <tier name="HTTP Services" />
 </application>
 </applications>
 </IIS>
 <standalone-applications>
 <standalone-application name="BasicWindowsService"
 args="-x">
 <tier name="Windows Service Tier"/>
 </standalone-application>
 <standalone-application
 executable="MyStandaloneApp.exe">
 <tier name="Standalone App" />
 </standalone-application>
 </standalone-applications>

```

```

 </app-agents>

 </appdynamics-agent>
</winston>

```

## Install from the Command Line

To install the .NET Agent from the command line:

1. Download the .NET Agent MSI Installer Package from the [AppDynamics Download Center](#).
2. Launch an elevated command prompt with full administrator privileges. See [Start a Command Prompt as an Administrator](#).

**i** Logging on to Windows as a member of the Administrators group does not grant sufficient permissions to run the installer.

3. Stop IIS and, if you are upgrading, stop instrumented Windows services and Standalone applications.
4. Run this command to install the agent with encrypted credentials. See [command line options](#) for descriptions.

```

msiexec /i <path_to_MSI_installer_package> /l log.txt /q
AD_SETUPFILE=<path_to_setup_configuration_file>
AD_SECURED_CREDENTIALS=true AD_CONTROLLER_ACCOUNT_NAME=<SaaS
or multi-tenant account>
AD_CONTROLLER_ACCOUNT_ACCESS_KEY=<access key>
AD_PROXY_USERNAME=<proxy user name> AD_PROXY_PASSWORD=<proxy
password>

```

For example:

```

msiexec /i "%USERPROFILE%\Downloads\dotNetAgentSetup.msi" /l
log.txt /q AD_SETUPFILE="%USERPROFILE%
\Documents\SetupConfig.xml" AD_SECURED_CREDENTIALS=true
AD_CONTROLLER_ACCOUNT_NAME=MyAppDynamicsAccount
AD_CONTROLLER_ACCOUNT_ACCESS_KEY=changeme
AD_PROXY_USERNAME=MyProxyUser AD_PROXY_PASSWORD=ProxyPass

```

The MSI installer package installs the .NET Agent and encrypts the credentials and writes them to the Windows Credential Store. It adds the Controller secure attribute to the [Controller element](#) in the `config.xml` file and sets the value to `true` :

```
<controller host="mycontroller.appdyanmics.com" port="443"
ssl="true" secure="true">
```

5. Start IIS. Restart or start instrumented Windows services and standalone applications.

### Update Credentials in the Windows Credential Manager

The .NET Agent includes a Credentials Tool for you to modify credentials stored in the Windows Credential Manager. To change credentials under the Local System account, you need to use [PsExec](#) to launch the command prompt.

1. If you have not already, download and install [Windows Sysinternals](#).
2. Use [PsExec](#) to launch a command prompt as the Local System account.

```
psexec -i -s cmd.exe
```

3. Run the Credentials Tool and pass the updated credentials.

```
"%programfiles%\AppDynamics\AppDynamics .NET
Agent\AppDynamics.CredentialsTool.exe"
AD_CONTROLLER_ACCOUNT_NAME=<SaaS or multi-tenant account>
AD_CONTROLLER_ACCOUNT_ACCESS_KEY=<access key>
AD_PROXY_USERNAME=<proxy user name> AD_PROXY_PASSWORD=<proxy
password>
```

### Command Line Options

- `AD_SECURED_CREDENTIALS` : Set to `true` to encrypt credentials to the Windows Credential Store and configure the agent to use the encrypted credentials.
- `AD_CONTROLLER_ACCOUNT_NAME` : The account name for the SaaS or multi-tenant Controller.
- `AD_CONTROLLER_ACCOUNT_ACCESS_KEY` : The account access key for the SaaS or multi-tenant Controller.
- `AD_PROXY_USERNAME` : The proxy server user account.
- `AD_PROXY_PASSWORD` : The password for the proxy server user account.
- `AD_PROXY_DOMAIN` : The domain for the proxy server user account.

### Private Key and Client Certificate for NET Agents

To enable mutual SSL authentication, the .NET Agent loads the client certificate and private key from your local computer's personal Certificate Store. The instrumented application identities need the ability to access the private key of the client certificate.

#### Import the Private Key into the Certificate Store

To import the private key into the Certificate Store:

1. From your Microsoft Management Console (MMC), navigate to and expand **Certificates (Local computer) > Personal > Certificates**.
2. Right-click **Certificates**.
3. Expand **All Tasks > Import**.

4. From the Import panel, change the Filter to **All** or **.pfx** files.
5. Select the \*.pfx file.
6. Enter your password and then complete the import procedure.

By default, for IIS applications (Full Framework and .NET Core hosted in- and out-of-process), the `IIS_IUSRS` group must have read access to the private key. For standalone, self-hosted .NET Core, and IIS applications running on application pools using custom service accounts, the appropriate accounts and groups have read access to the private key.

To add read access to the private key:

1. From your Microsoft Management Console (MMC), navigate to and expand **Certificates (Local computer) > Personal > Certificates**.
2. Right-click **Certificates**.
3. Expand **All Tasks > Manage Private Keys** to display a popup.
4. Add the application identities or user groups (as needed) and then add read access to the private key.

### Configure the Certificate Attribute

To use the certificate from the Certificate Store, you must add the certificate thumbprint as the `certificate` attribute.

To obtain the certificate thumbprint:

- a. From your Microsoft Management Console (MMC), navigate to and expand **Certificates (Local computer) > Personal > Certificates**.
- b. Double-click the certificate.
- c. From the **Details** tab, locate the thumbprint.
- d. Add the thumbprint as the `certificate` attribute:

[For MSI Agents](#)   
 [For Standalone Agents](#)   
 [For Azure App Services \(Azure PaaS\)](#)

Add to the `config.xml` file:

```
<controller host="controller.host.name" port="443" ssl="true" enable_tls12="true">
 <application name="application.name" />
 <account name="account.name" password="account.password" />
 <ssl-mutual-auth enabled="true" certificate="certificate.thumbprint"></ssl-
mutual-auth>
</controller>
```

[For MSI Agents](#)   
 [For Standalone Agents](#)   
 [For Azure App Services \(Azure PaaS\)](#)

Add to this file:

```
{
 "controller": {
 "host": "controller.host.name",
 "port": 443,
```

```
"ssl": true,
"enable_tls12" : true,
"account": "account.name",
"password": "account.password",
"ssl_mutual_auth":{
 "enabled": true,
 "certificate" : "certificate.thumbprint"
}
}
```

[For MSI Agents](#)   [For Standalone Agents](#)   [For Azure App Services \(Azure PaaS\)](#)

Add to this file:

```
{
 "controller": {
 "host": "controller.host.name",
 "port": 443,
 "ssl": true,
 "enable_tls12" : true,
 "account": "account.name",
 "password": "account.password",
 "ssl_mutual_auth":{
 "enabled": true,
 "certificate" : "certificate.thumbprint"
 }
 }
}
```

For Azure App Services, you can import the client certificate to Azure by using the Azure portal:

For the imported certificate to be available for client authentication, you must set the thumbprint of the client certificate in the `WEBSITE_LOAD_CERTIFICATES` environment variable:

## Configure the .NET Agent for Windows Services and Standalone Applications

### Related pages:

- [Configure the .NET Agent](#)
- [.NET Agent Configuration Properties](#)

The .NET Agent automatically instruments IIS applications only. However, you can follow these instructions to manually configure the .NET Agent to instrument Windows services or standalone .NET applications.

If your web application is not configured to run as an in-process handler, the application may run as `dotnet.exe` or `mywebappapplication.exe`. In this scenario, the application's site name and application path are not discovered automatically. You must configure these applications manually, and provide tier and node names that best describe the application.

## Before You Begin

To instrument Windows services and standalone .NET applications, edit the .NET Agent configuration file, `config.xml`.

**i** If your application runs using the default domain, you must manually instrument it. AppDynamics does not automatically instrument the default domain out-of-the-box. To determine whether you should use the default domain, and how to configure it, see [Instrument the DefaultDomain for Standalone Applications](#).

Before starting, verify that the services or applications you want to instrument are .NET applications rather than native applications or another type of application. From a command line, enter:

```
tasklist /m "mscor*"
```

**!** This command is for 64-bit processes only. For 32-bit processes, use the process explorer to view the dependencies of the process, and determine if there are any .NET .dll files loaded into the file.

The output lists the processes with DLLs starting with `mscor *`, indicative of .NET processes. Processes not displaying on the list are not .NET processes, and you cannot instrument them with the .NET Agent.

If you have previously instrumented IIS applications on the server that hosts the Windows services and standalone applications, the server should already have a `config.xml` file that you can edit. If not, perform these steps to generate one:

1. [Install the .NET Agent for Windows](#).
2. Run the [AppDynamics Agent Configuration](#) utility.

To avoid instrumenting IIS applications, select the manual tier naming approach and omit the step of assigning tiers for the IIS application. This disables instrumentation for the IIS applications and enables you to instrument only the intended Windows services or standalone applications.

The utility performs these configuration tasks:

1. Changes the location of the logs directory, and assigns permissions.
2. Configures and tests connectivity to the Controller.
3. Sets the business application for the agent.

## Manually Configure the .NET Agent

Once you have configured the Controller properties for the .NET Agent, instrument your Windows service or standalone application by adding the Standalone Applications element to the `config.xml`.

1. Edit the `config.xml` file as an administrator. See [Administer the .NET Agent](#).

If you have not instrumented any IIS applications, the file contains the minimal configuration for the Controller connectivity and the Machine Agent. Verify the Controller properties and the Business Application name (shown in this example):

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/
XMLSchema">
 <controller host="mycontroller.example.com" port="8090"
ssl="false">
 <application name="My Business Application" />
 </controller>
 ...
</appdynamics-agent>
```

If you have already instrumented IIS applications, those configurations display under the IIS element.

2. Add a single standalone applications element, `standalone-applications` under the `app-agents` element, and under the `standalone-applications` element, add a standalone application element, `standalone-application` for each Windows service or standalone application to instrument. For example:

```
...
<app-agents>
 ...
 <standalone-applications>
 <standalone-application
executable="MyStandaloneApp.exe">
 <tier name="Standalone Tier 1" />
 </standalone-application>
 <!-- Instrument a standalone application using a
partial path. -->
 <standalone-application
executable="MyApplication\MyOtherStandaloneApp.exe">
 <tier name="Standalone Tier 2" />
 </standalone-application>
 <!-- Instrument a Windows service using arguments. -->
 <!-- The following example matches the command
"MyWindowsService.exe -d -x -r". -->
 <standalone-application
executable="MyWindowsService.exe" command-line="-x">
 <tier name="Windows Service Tier" />
 </standalone-application>
 </standalone-applications>
```

```
</app-agents>
```

```
...
```

#### In the standalone application element configuration:

- Use the `tier` element to assign the instrumented application to a tier in the Controller. See [.NET Agent Configuration Properties](#).
- Identify the executable file of the application in the Standalone Application element `executable` attribute using one of these formats:
  - Executable name: For example, `MyStandaloneApp.exe` or `MyWindowsService.exe`. The file extension is optional, so `MyStandaloneApp` is valid. If you use `dotnet.exe` to start the .NET Core application, then specify `"dotnet.exe"` as the application executable (see Sample Configuration File).
  - Full or partial path to the executable: For example, `C:\Program Files\MyApplication\MyStandaloneApp.exe` or `MyApplication\MyStandaloneApp.exe`. Use the full or partial path to assign different AppDynamics tiers to separate instances of the same executable file running from different paths.
  - To differentiate between two instances of the same executable, specify any unique portion of the command line invocation format of the application, such as an argument, in the Standalone Application command-line attribute.

You can discover the path to a Windows service executable in the Services panel of the administrative tools. In Services, click the service and select **Properties**. The path display in the General tab.

3. Restart the `AppDynamics.Agent.Coordinator` service.
4. Restart the Windows service or standalone application.
5. If your Windows service or standalone application does not implement an [auto-detected framework](#), you must configure a [POCO entry point](#) for a class or method in your service for the agent to begin instrumentation.

### Sample Configuration File

This sample `config.xml` shows instrumentation for a Windows service and standalone application:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
 <controller host="mycontroller.mycompany.com" port="8090"
ssl="false">
 <application name="My Business Application" />
 </controller>
 <machine-agent />
 <app-agents>
 <IIS>
 <applications />
 </IIS>
 <standalone-applications>
 <standalone-application
executable="MyWindowsService.exe" command-line="-x">
```

```

 <tier name="Windows Service Tier" />
 </standalone-application>
 <standalone-application
executable="MyStandaloneApp.exe">
 <tier name="Standalone Tier" />
 </standalone-application>
 </standalone-applications>
</app-agents>
</appdynamics-agent>

```

If the .Net Core application is published as an executable, then you can configure it similar to .NET Framework applications by specifying the executable name, and optionally, the command line. However, if the application is published as a library, then you start it by by invoking the `dotnet.exe` tool.

This sample configuration shows how to instrument a .NET Core standalone application hosted by the `dotnet.exe`:

```

<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-
instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
 <controller host="mycontroller.mycompany.com" port="8090"
ssl="false">
 <application name="My Business Application" />
 </controller>
 <machine-agent />
 <app-agents>
 <IIS>
 <applications />
 </IIS>
 <standalone-applications>
 <standalone-application executable="dotnet.exe" command-
line="MyApp.dll"> //command-line option instructs the agent to
monitor only "MyApp"
 <tier name="DotNet Core Tier" />
 </standalone-application>
 </standalone-applications>
 </app-agents>
</appdynamics-agent>

```

## Troubleshooting

### Intermittent Loss of Windows Services Instrumentation

When instrumenting Windows Services, there may be cases where the instrumented service initializes before the `AppDynamics.Agent.Coordinator` service. When this happens, the Profiler shuts down and no instrumentation occurs. This problem is uncommon.

These procedures describe how to overcome this problem for Windows 2008, and Windows >= 2012.

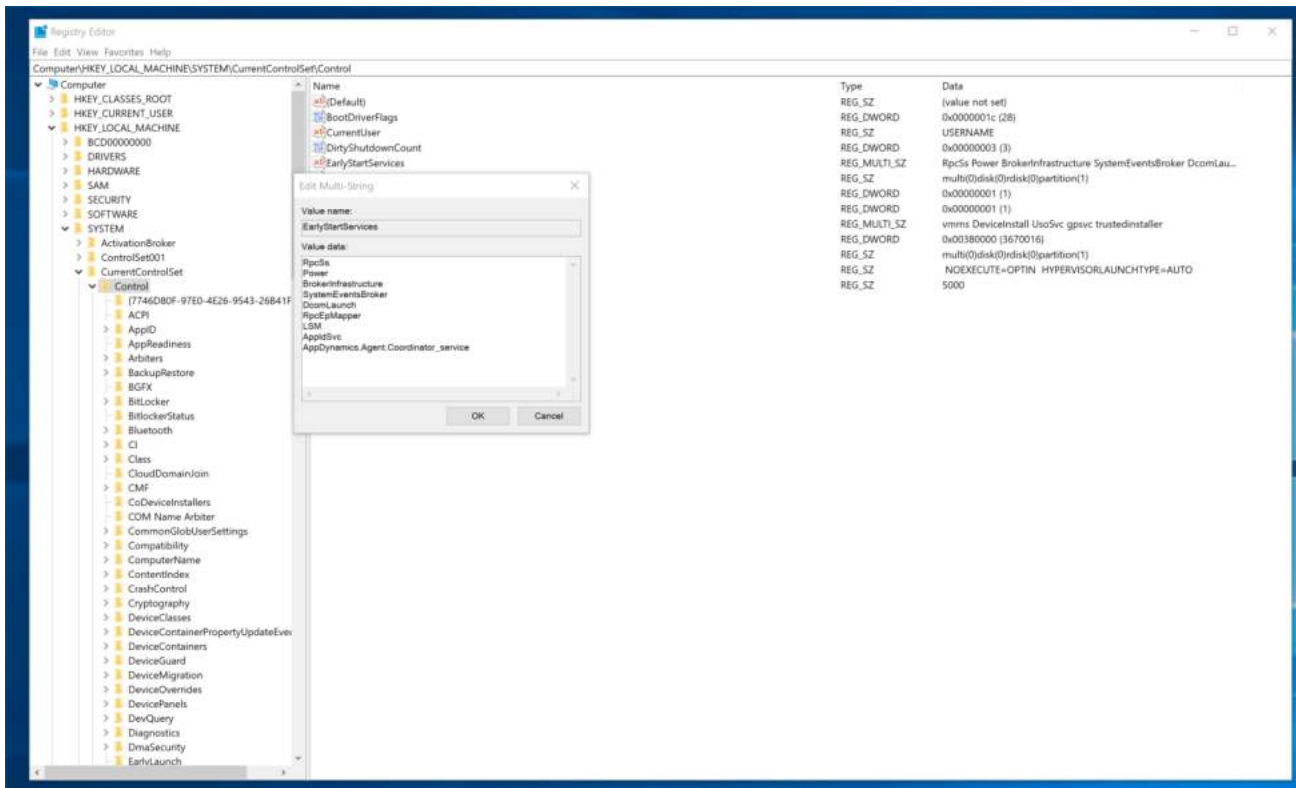

### Windows 2008

If you are using Windows 2008, please contact AppDynamics Support for assistance.

### Windows >= 2012

To ensure the `AppDynamics.Agent.Coordinator` service initializes before the instrumented Windows Service, you must modify the registry.

Edit the Reg key `EarlyStartServices @HKLM:\SYSTEM\CurrentControlSet\Control`, and add `AppDynamics.Agent.Coordinator_service` to the list of early start services.

### Name .NET Tiers

#### Related pages:

- [Configure the .NET Agent](#)
- [Name .NET Nodes](#)

In AppDynamics, a tier represents a service in your application environment, such as an ASP.NET front end, WCF service, .NET web service, or standalone application. Tiers display on flow maps, so you should name your tiers that is logical and easy to understand for your users.

Use the AppDynamics .NET Agent Configuration Utility to map IIS sites to tiers (see [Configure the .NET Agent](#)). Some manual configuration options require you to edit the `config.xml` file (see [Administer the .NET Agent](#)).

### Name IIS Tiers Automatically

Name IIS tiers automatically using the [configuration utility](#). Select Automatic on the Assign IIS applications to the tiers pane. The .NET Agent instruments all IIS sites except the Default Web Site and names the tiers using this scheme:

IIS site/app

The agent omits `app` when the application is the root application for the IIS site.

Use this option when:

- You are new to AppDynamics and the .NET Agent.
- You want to instrument all IIS applications, and your team understands the form of IIS application names.

**i** Automatic Tier Naming for the .NET Agent does not automatically assign a virtual application to a tier. To map virtual applications to tiers, see [Name IIS Tiers Manually](#).

### Name Azure Tiers Automatically

The .NET Agent automatically names Azure tiers using these schemes:

- Cloud Services: Azure role name
- App Services: Azure site name

To customize tier naming for Azure, see [Name IIS Tiers Manually](#).

### Name IIS Tiers Manually

The .NET Agent provides two options to name IIS tiers manually, using the configuration utility, or editing the `config.xml` file directly.

#### Use the Configuration Utility

On the Assign IIS applications to tiers pane, select **Manual**. The configuration utility enables you to create new tiers and assign IIS applications to tiers.

Use this option when:

- You do not want to instrument all IIS applications on the server
- You want custom tier names
- You want to assign multiple applications to a single tier

#### Edit the `config.xml` Directly

Use this option to customize Azure tier names, or when it is not possible to use the configuration utility.

For each IIS tier to instrument, add an application element as a child element of the IIS applications element in the `config.xml` file. You can specify a static IIS tier name, or a regular expression (which is helpful for variable Azure site names). For the full syntax and an example, see [.NET Agent Configuration Properties](#).

For example, to add all Azure sites that begin with `MvcWebRole` to a tier named `My Azure Tier` using a regular expression:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsd="http://www.w3.org/2001/XMLSchema" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
 <controller host="natedemocon1.cloudapp.net" port="8090" ssl="false">
 <application name="AzureEmailService" />
 <account name="customer1" password="APJC234bcd$123" />
 </controller>
 <machine-agent />
 <app-agents azure="true" azure-role-name="" azure-role-instance-id="">

 <IIS>
 <applications>
 <!-- Configure IIS tier names with a regular expression. -->
 <application path="/" site="MvcWebRole.*" site-regex="true">
 <tier name="My Azure Tier"/>
 </application>
 </applications>
 </IIS>
 <standalone-applications>
 <standalone-application executable="WaWorkerHost.exe">
 <tier name="" />
 </standalone-application>
 </standalone-applications>
 </app-agents>
</appdynamics-agent>
```

## Name Windows Service or Standalone Application Tiers

See [Configure the .NET Agent for Windows Services and Standalone Applications](#) on how to name tiers for each instrumented Windows service or standalone application manually in the config.xml.

## Name .NET Nodes

### Related pages:

- [Configure the .NET Agent](#)
- [Name .NET Tiers](#)

## IIS Node Naming

By default, AppDynamics .NET Agent names nodes use a combination of the Windows machine name, the tier name, and the name of the .NET application, as shown in this format:

```
<machine NetBIOS name>-<tier>-<IIS site>/<app>
```

However, you may omit elements in the name under these conditions:

- The app name is omitted when the application is the root application for the IIS site.
- The tier name is omitted when the tier name is the same as the IIS site name.

These examples show IIS node naming.

### Example 1

WIN-86M7CEJ06P5-Order Server-OrderSvc

- WIN-86M7CEJ06P5 is the machine NetBIOS name.
- Order Server is the tier name.
- OrderSvc is the IIS site name. The application is the site root, so the agent omits the application name.

### Example 2

WIN-86M7CEJ06P5-Order Server-Store/ProcessOrder

- Store is the IIS site name.
- ProcessOrder is the application name within the site.

Different .NET versions of the same application have their own versions of the CLR and run on independent processes. Therefore, the agent identifies the two processes as different nodes.

## IIS Web Gardens

The syntax for web gardens is the same as IIS Nodes, except that the agent appends a zero-based process index to differentiate the worker processes:

```
<machine NetBIOS name>-<tier>-<IIS site>/<app>-<process index>
```

When IIS first launches web garden processes, the agent assigns a sequential index to each process. However, when IIS recycles a process, the agent re-uses the available index freed by the terminated process. Therefore, there is no correlation between the index sequence and the chronological start of the process.

Sometimes more nodes display than the maximum number of worker processes. This occurs when a long-running request prevents a process from shutting down before its replacement launches.

## Windows Service or Standalone Application Nodes Naming

By default, the agent names Windows service and standalone application nodes as:

```
<machine NetBIOS name>-<tier>-<Windows service name or executable name>
```

The agent omits tier when the tier name is the same as the service name or executable name.

These examples show Windows service and standalone application naming.

### Example 1

WIN-86M7CEJ06P5-MyWindowsService

- WIN-86M7CEJ06P5 is the machine name.
- MyWindowsService is the Windows service name.

### Example 2

WIN-86M7CEJ06P5-MyStandaloneApp.exe

- WIN-86M7CEJ06P5 is the machine name.
- MyStandaloneApp.exe is the executable file name.

## Unattended Installation for .NET

### Related pages:

- [Configure the .NET Agent](#)

- [.NET Agent Configuration Properties](#)
- [Configure the .NET Agent for Windows Services and Standalone Applications](#)

The .NET Agent provides a command-line unattended installation when you have multiple servers that require the same AppDynamics configuration. Using unattended installation, you only configure once, and then use the command-line scripts to automate installation and instrumentation on multiple servers

To install and configure the agent manually, see [Install the .NET Agent for Windows](#).

### Create a Setup Configuration File

You can use the .NET Agent MSI installer package to specify the path to a setup configuration file to perform an unattended installation. The setup configuration file contains all the properties you need to enable instrumentation for your .NET applications.

You must run the .NET Agent MSI installer package on one machine before you can use the AppDynamics Agent Configuration utility to create a setup configuration file. See [Install the .NET Agent for Windows](#).

Setup configuration files created in previous versions of the AppDynamics Agent Configuration utility work with the 4.0 installer.

1. Launch the AppDynamics Agent Configuration utility from the command line. Use the `-s` parameter to specify the setup configuration file destination.

```
%ProgramFiles%\AppDynamics\AppDynamics .NET
Agent\AppDynamics.Agent.Winston.exe -s <path to setup
configuration file>
```

For example:

```
%ProgramFiles%\AppDynamics\AppDynamics .NET
Agent\AppDynamics.Agent.Winston.exe -s "c:
\temp\configurationSavedSetupConfiguration.xml"
```

2. Complete the steps of the configuration wizard step.  
The configuration utility saves the setup configuration file to the path you specified.

 The configuration utility only configures instrumentation for IIS applications.

3. (Optional) To perform the unattended installation for Windows services or for standalone applications, you must edit the setup configuration file manually. See [Configure the .NET Agent for Windows Services and Standalone Applications](#).

### Sample Setup Configuration File

This example shows a setup configuration file that instruments: two IIS Applications, MainBC and SampleHTTPService; a Windows service, MyWindowsService.exe; and a standalone application, MyStandaloneApp.exe.

The configuration file sets the log directory to `C:\ProgramData\AppDynamics\DotNetAgent\Logs`, and grants write permission to four accounts.

```

<winston>
 <logFileDirectory directory="C:
\ProgramData\AppDynamics\DotNetAgent\Logs" />
 <logFileFolderAccessPermissions
defaultAccountsEnabled="false">
 <account name="NT AUTHORITY\LOCAL SERVICE"
displayName="LOCAL SERVICE" />
 <account name="NT AUTHORITY\SYSTEM" displayName="SYSTEM" />
 <account name="NT AUTHORITY\NETWORK SERVICE"
displayName="NETWORK SERVICE" />
 <account name="IIS_IUSRS" displayName="ApplicationPool
Identity" />
 </logFileFolderAccessPermissions>
 <appdynamics-agent xmlns:xsi="http://www.w3.org/2001/
XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/
XMLSchema">
 <controller host="mycontroller.mycompany.com" port="8090"
ssl="false">
 <application name="My Business Application" />
 <account name="customer1" password="changeme" />
 </controller>
 <machine-agent />
 <app-agents>
 <IIS>
 <applications>
 <application path="/" site="MainBC">
 <tier name="Main Site" />
 </application>
 <application path="/" site="SampleHTTPService">
 <tier name="HTTP Services" />
 </application>
 </applications>
 </IIS>
 <standalone-applications>
 <standalone-application
executable="MyStandaloneApp.exe">
 <tier name="Standalone App" />
 </standalone-application>
 <standalone-application
executable="MyWindowsService.exe">
 <tier name="Windows Service" />
 </standalone-application>
 </standalone-applications>
 </app-agents>
 </appdynamics-agent>
</winston>

```

```

 </standalone-application>
 </standalone-applications>
</app-agents>
</appdynamics-agent>
</winston>

```

## Unattended Installation

Before you perform an unattended installation, verify these requirements:

- Microsoft Distributed Transaction Coordinator (MSDTC): MSDTC must run under the NT Authority\NetworkServices account. See [Verify MSDTC on the Troubleshoot .NET Agent Issues](#) page.
- Windows Management Instrumentation (WMI)

To perform an unattended installation:

1. Launch an elevated command prompt with full administrator privileges. See [Start a Command Prompt as an Administrator](#). Logging on to Windows as a member of the Administrators group does not grant sufficient permissions to run the installer.
2. Run the agent MSI installer package from the elevated command prompt. Use the `AD_SetupFile` parameter to pass the absolute file path to the setup configuration file. You can also use the following command for troubleshooting:

```

msiexec /i dotNetAgentSetup64.msi /q /norestart /lv %TEMP%
\AgentInstaller.log AD_SetupFile=<absolute path to setup
config.xml>

```

You can set these optional parameters:

`INSTALLDIR` : Specify the directory to install the .NET Agent executables and supporting files.

`DOTNETAGENTFOLDER` : Specify the parent directory for local data including agent configuration files and log files.

For example:

```

msiexec /i dotNetAgentSetup64.msi /q /norestart /lv %TEMP%
\AgentInstaller.log AD_SetupFile=C:\temp\SetupConfig.xml
INSTALLDIR=D:\AppDynamics DOTNETAGENTFOLDER=D:
\AppDynamicsData

```

**i** If you specify the `DOTNETAGENTFOLDER` on the command line and a `logFileDirectory` in the setup configuration file, the agent creates config and data folders under `DOTNETAGENTFOLDER` but writes the log files to the `logFileDirectory` specified in the setup configuration file.

3. Start the `AppDynamics.Agent.Coordinator` process.

```
net start AppDynamics.Agent.Coordinator
```

4. Restart applications you have instrumented: IIS services, Windows services, and standalone applications.

For example, to restart IIS:

```
iisreset
```

## Setup Configuration File Properties

### Winston Element

The Winston element is the root element of the configuration file.

Required element: `<winston>`

### Log File Directory Element

The Log File Directory element is a child element of the Winston element. Use the `directory` attribute to specify the log directory. If you omit the `logFileDirectory` element, AppDynamics uses the default directory:

Windows Server 2008 and later: `%ProgramData%\AppDynamics\DotNetAgent\Logs`

Optional element: `<logFileDirectory directory="C:\ProgramData\AppData\DotNetAgent\Logs" />`

### Log File Folder Access Permissions Element

The Log File Folder Access Permissions is a child element of the Winston element. Unless you set the `defaultAccountsEnabled` attribute to `false`, AppDynamics grants write access to the Logs folder for the default accounts:

- LOCAL SERVICE
- SYSTEM
- NETWORK SERVICE
- ApplicationPool Identity

Optional element: `<logFileFolderAccessPermissions defaultAccountsEnabled="false">`

### Account Element

The Account element is a child element of the Log File Folder Access Permissions element. Create an `Account` element for the Windows account you use to run your application.

Set the `name` attribute to the name of the account you use to run your application, that is the account for the application pool for IIS or the Windows service account.

The `displayName` attribute is a user-friendly name you choose for the account. The display name shows up in log entries about assigning permissions for the account.

Optional element: `<account name="MyAppPoolIdentity" displayName="Custom ApplicationPool Identity" />`

---

For example, if you run a Windows service under a domain account:

```
<account name="MYDOMAIN\service_acct" displayName="Domain Service Account" />
```

## AppDynamics Agent Element

The AppDynamics Agent element is a child of the Winston element. It follows the same format as the `config.xml` file to define the agent configuration for all your .NET applications. See [.NET Agent Configuration Properties](#).

Required element: `<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">`

## Upgrade the .NET Agent for Windows

### Related pages:

- [Agent and Controller Tenant Compatibility](#)
- [Install the .NET Agent for Windows](#)
- [Configure the .NET Agent](#)
- [.NET Agent Directory Structure](#)
- [Troubleshoot .NET Agent Issues](#)

The MSI installer package for AppDynamics .NET Agent installs updated agent files and maintains legacy configurations. When you upgrade from .NET Agent < 3.9, or prior to 3.9, you must first uninstall the existing .NET Agent.

If you use the AppDynamics Azure Site Extension, see [Install the AppDynamics Azure Site Extension for .NET](#).

## Requirements

- Before you begin, review the [Release Notes](#).
- AppDynamics requires an account access key for agent connections to single-tenant Controller accounts. AppDynamics <= 4.1 only required an account access key for multi-tenant Controller accounts. If you have a single-tenant Controller, you can locate the account access key in the Controller under **Settings > License > Account**. You must be a member of a role with the View License account level permission, see [Manage Custom Roles](#).

The .NET Agent only supports in-place upgrade for these versions:

- >= 3.9

Major and minor releases after the currently installed version. For patch releases, you must uninstall the existing agent before upgrading.

For example, to install the patch release 4.1.0.1 over 4.1.0.0, uninstall the existing agent before upgrading.

## Upgrade the .NET Agent from >= 3.9

Except for patches to the current version, you do not need to uninstall the old agent first when you upgrade from the .NET Agent >= 3.9.

1. Stop `w3wp` processes for instrumented IIS applications. Stop instrumented Windows services or standalone applications.
2. Download the MSI installer package from [AppDynamics Downloads](#).

3. Launch an elevated command prompt with full administrator privileges. Logging on to Windows as a member of the Administrators group does not grant sufficient permissions to run the installer. See [Start a Command Prompt as an Administrator](#).
4. If you use a single-tenant Controller account, in the Controller click **Settings > License > Account** to view your access key.
5. Run a command-line agent install. For single-tenant Controller accounts, specify your account access key using the `AD_CONTROLLER_ACCOUNT_ACCESS_KEY` parameter. For example:

```
msiexec /i "%USERPROFILE%\Downloads\dotNetAgentSetup.msi" /l
log.txt /q AD_CONTROLLER_ACCOUNT_ACCESS_KEY=changeme
```

The installation runs silently in the background.

**i** If you forget to add the account access key for a single-tenant Controller account, you can run the Agent Configuration Utility or manually add it to the config.xml later. See [Account Element](#).

6. (Optional) Add the parameter `INSTALLDIR=<path to installation directory>` if you have changed the installation directory. For example:

```
msiexec /i "%USERPROFILE%\Downloads\dotNetAgentSetup.msi" /l
log.txt /q AD_CONTROLLER_ACCOUNT_ACCESS_KEY=changeme
INSTALLDIR=<path to installation directory>
```

7. Restart IIS:
  - Launch the AppDynamics Agent Configuration utility and click **Restart IIS** on the Configuration Summary window.
  - or
  - Execute `iisreset` from the command line.

Restart Windows services and standalone applications.

## Upgrade the .NET Agent from 3.7.8 through 3.8.6

### Uninstall the Old Agent Version

1. Stop IIS, instrumented Windows services, and instrumented standalone applications.

**i** If you shut down IIS but continue to see active IIS Worker Processes, check the Application Pools pane in the IIS Manager and stop any started application pools. Failing to stop instrumented applications before uninstalling the .NET Agent may require you to reboot the machine.

2. Stop the `AppDynamics.Agent.Coordinator` service.
3. In the Control Panel, select Add/Remove Programs. Remove the `AppDynamics .NET Agent`.

**i** In some cases, another process interferes with the .NET Agent uninstallation process by locking the profiler.dll. If uninstallation fails, use a utility such as [Process Explorer](#) to see if a process is using profiler.dll. If so, terminate the process. Otherwise, try rebooting the machine. Then retry the uninstallation.

## Install the New Agent Version

1. Stop `w3wp` processes for instrumented IIS applications. Stop instrumented Windows services or standalone applications.
2. Download the MSI installer package from the [AppDynamics Downloads](#).
3. Launch an elevated command prompt with full administrator privileges. Logging on to Windows as a member of the Administrators group does not grant sufficient permissions to run the installer. See [Start a Command Prompt as an Administrator](#).
4. If you use a single-tenant Controller account, in the Controller click **Settings > License > Account** to view your access key.
5. Run a command-line agent install. For single-tenant Controller accounts, specify your account access key using the `AD_CONTROLLER_ACCOUNT_ACCESS_KEY` parameter. For example:

```
msiexec /i "%USERPROFILE%\Downloads\dotNetAgentSetup.msi" /l
log.txt /q AD_CONTROLLER_ACCOUNT_ACCESS_KEY=changeme
```

The installation runs silently in the background.

**i** If you forget to add the account access key for a single-tenant Controller account, you can run the Agent Configuration Utility or manually add it to the config.xml later. See [Account Element](#).

6. Restart IIS:
  - Launch the AppDynamics Agent Configuration utility and click **Restart IIS** on the Configuration Summary window.
  - or
  - Execute `iisreset` from the command line.

Restart Windows services and standalone applications.

## Upgrade the .NET Agent from <= 3.7.7

Identify the right upgrade path based upon the method of tier naming and assignment (manual or automatic) and the type of application you instrument:

- If you use manual tier naming and assignment, the installer package upgrades configurations for IIS applications and Windows services.
- If you used automatic tier naming and assignment, run the configuration utility to update configurations.
- If you used standalone applications with 3.7.7 or earlier, follow the steps for standalone applications on [Configure the .NET Agent for Windows Services and Standalone Applications](#).

After installation, you may need to run the configuration utility to update your configuration and optionally remove legacy configurations.

## Uninstall the Old.NET Agent Version

1. Stop IIS and instrumented Windows services.

**i** If you shut down IIS but continue to see active IIS Worker Processes, check the Application Pools pane in the IIS Manager and stop any started application pools. Failing to stop instrumented applications before uninstalling the .NET Agent may require you to reboot the machine.

2. Stop the `AppDynamics.Agent.Coordinator` service.

3. In the Control Panel, select Add/Remove Programs. Remove the `AppDynamics .NET Agent`.

**i** In some cases, another process interferes with the .NET Agent uninstallation process by locking the profiler.dll. If uninstallation fails, use a utility such as [Process Explorer](#) to see if a process is using profiler.dll. If so, terminate the process. Otherwise, try rebooting the machine. Then retry the uninstallation.

Install the New .NET AgentVersion

1. Stop `w3wp` processes for instrumented IIS applications. Stop instrumented Windows services or standalone applications.
2. Download the MSI installer package from [AppDynamics Downloads](#).
3. Launch an elevated command prompt with full administrator privileges. Logging on to Windows as a member of the Administrators group does not grant sufficient permissions to run the installer. See [Start a Command Prompt as an Administrator](#).
4. Optional, if you use a single-tenant Controller account, in the Controller click **Settings > License > Account** to view your access key.
5. Run a command-line agent install. For single-tenant Controller accounts, specify your account access key using the `AD_CONTROLLER_ACCOUNT_ACCESS_KEY` parameter. For example:

```
msiexec /i "%USERPROFILE%\Downloads\dotNetAgentSetup.msi" /l
log.txt /q AD_CONTROLLER_ACCOUNT_ACCESS_KEY=changeme
```

The installation runs silently in the background.

**i** If you forget to add the account access key for a single-tenant Controller account, you can run the Agent Configuration Utility or manually add it to the config.xml later. See [Account Element](#).

6. Restart IIS:

- Launch the AppDynamics Agent Configuration utility and click **Restart IIS** on the Configuration Summary window.
- Execute `iisreset` from the command line.

Restart Windows services.

If you used the following environment variables with the earlier version, the MSI installer migrates the configurations to the new configuration file:

- `AppDynamicsAgent_CallGraphOptions`
- `AppDynamicsAgent_DisableAppPools`

- AppDynamicsAgent\_EnableInProcesses
- AppDynamicsAgent\_IgnoreCLREnv
- AppDynamicsAgent\_Profiler\_Classes

## Configure the .NET Agent

Configure the agent based on your method of tier generation and assignment: automatic or manual.

- i** The .NET Agent configuration utility only supports the configuration of one Controller per server. To configure multiple business applications, see [Configure Multiple Business Application Support for .NET](#)

### Configure the Agent Using Automatic Tier Generation and Assignment

If you used automatic configuration with the earlier version of the .NET Agent, run the configuration utility to configure the agent:

1. Use the .NET Agent Configuration utility to reconfigure instrumentation for IIS applications. Choose **Automatic** for the method of tier generation and assignment. See [Configure the .NET Agent](#).
2. Configure instrumentation for Windows services manually. See [Configure the .NET Agent for Windows Services and Standalone Applications](#).

### Configure the Agent Using Manual Tier Generation and Assignment

For agents using manual tier generation and assignment, the installer package migrates the configurations for IIS applications and for Windows services to the `config.xml`. At this stage, the configuration for IIS applications and Windows services is complete.

### Clean Up Legacy Configurations

You can clean up legacy configurations by launching the AppDynamics Agent Configuration utility. When the utility detects agent settings from a previous version, it offers you the option to clean up.

The cleanup procedure modifies the `web.config` files causing an IIS restart.

1. Launch the AppDynamics Agent Configuration utility.
2. Select **Yes** to clean up old AppDynamics configurations.
3. Proceed through the wizard.
  - Verify or update the log directory, and grant write permissions to it.
  - Verify the controller connection information.
  - Verify or update manual tier assignment.

The utility removes these configurations:

- AppDynamics configurations from `web.config` files for IIS applications and `application.config` files for Windows services.
- Environment variables:
- AppDynamicsAgent\_IgnoreCLREnv
  - AppDynamicsAgent\_CallGraphOptions
  - AppDynamicsAgent\_EnableInProcesses
  - AppDynamicsAgent\_DisableAppPools
  - AppDynamicsAgent\_Profiler\_Classes

### Resume Monitoring

Start IIS and instrumented Windows services.

## Troubleshoot .NET Agent Issues

### Related pages:

- [Install the .NET Agent for Windows](#)
- [Configure the .NET Agent](#)
- [Instrument SharePoint](#)
- [.NET Agent on Windows Logging](#)
- [.NET Instrumentation Topics on the Community Knowledge Base](#)

This page describes issues you may encounter when installing the .NET Agent.

### Verify Agent Controller Communication

Use the AppDynamics UI to verify that the agent can connect to the Controller.

1. In a browser open:

```
http://<controller-host>:<controller-port>/controller
```

If you cannot connect to the Controller in Internet Explorer, see [Check Internet Explorer proxy settings](#).

2. Log in to the AppDynamics UI.
3. Select the application to open the Application Dashboard.
4. In the left navigation panel, select **Servers > Tiers & Nodes** and open the Health tab.

The Health tab lists the tiers, their nodes, and App Agent Status. When an agent successfully reports to the Controller, an *up* arrow symbol displays.

See [Agent-to-Controller Connections](#).

- When deploying multiple agents for the same tier, determine if the correct number of nodes reports into the same tier.
- After sending a request to your web application, data should display on the AppDynamics UI. The agents should display in the Application Flow Map of the Application Dashboard.

If no data displays after a few minutes:

- Verify that the Agent is writing its log files.  
Windows Server 2008 and later: %ProgramData%\AppDynamics\DotNetAgent\Logs\AgentLog.txt
- If the log file exists, open it and review for errors.
- If the log file does not exist, run the Windows Event Viewer and review the application messages.

- If there are no AppDynamics event messages, look for messages from the .NET Runtime.

### Check Internet Explorer Proxy Settings

**i** Use this procedure to resolve issues connecting to the AppDynamics Controller when step 1 of 'Verify Agent Controller Connection' fails. To configure the .NET Agent to work through a proxy, see 'Controller Element' on [.NET Agent Configuration Properties](#).

Misconfigured proxy settings in Internet Explorer may cause the App Agent for .NET to fail to connect to the Controller.

If the test Controller connection fails on the Controller Configuration pane in the AppDynamics Agent Configuration utility:

1. Verify the Controller host and port settings are correct.
2. In Internet Explorer, open:

```
http://<controller-host>:<controller-port>/controller
```

3. If the connection also fails in Internet Explorer, check the proxy settings. See [Change IE Proxy Settings](#).
4. Correct or remove any incorrect proxy settings.

### Checklist for Resolving .NET Agent Installation Issues

	Item	Notes
✓	Run the installer as Administrator.	<a href="#">Verify Administrative privileges</a>
✓	Verify that MSDTC is enabled and that it is running under the correct account.	<a href="#">Verify MSDTC is enabled and running under the correct account</a>
✓	Verify permissions for Agent directory.	<a href="#">Verify that the .NET Agent directory has the correct permissions</a> based on the site's application pool identity.
✓	Verify that the Agent is compatible with the Controller.	<a href="#">Agent and Controller Tenant Compatibility</a>
✓	Verify the correct settings in the config.xml :  Windows Server 2008 and later: %ProgramData% \AppDynamics\DotNetAgent\Config\config.xml	Update the config.xml file to include the <a href="#">.NET Agent Configuration Properties</a> .

## Resolve .NET Agent Installation Issues

If the Agent installation is failing, check these configurations in your environment:

### Verify Administrative Privileges

Ensure that you have administrative privileges when you launch the installer. If the current user doesn't have sufficient privileges, the installer prompts you for an administrator password.

### Verify MSDTC is Enabled and Running for the Correct Account

If you encounter an error that MSDTC is not enabled or it is running for the wrong account, launch an elevated command prompt with full administrative privileges and execute this command:

```
msdtc -install
```

Even if MSTDC is already installed, this command resets the service to run using the "NT Authority\NetworkServices" account.

### Generate a Log for Agent Installation Failures

If the installer fails, use this command-line utility to launch the installer:

```
msiexec /i $Path_to_the_MSI_File /l*v verbose.log
```

A verbose log for the .NET Agent is created at the same location where you saved the installer file.

### Rectify Failed Installation Caused by Other APM Products

The .NET Agent installation may fail if there are other Application Performance Management (APM) products installed in the same managed environment. Remove the associated *Environment* subkey for certain services for the installed APM products.

To remove the associated environment subkey for W3SVC and WAS services in the registry:

1. Run Regedit or regedt32.
2. In regedit.exe, locate these registry keys:  
 HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet\services\W3SVC  
 HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet\services\WAS
3. Expand the keys.
4. Modify the `Environment` subkey to delete these values:

```
COMPLUS_ProfAPI_ProfilerCompatibilitySetting=EnableV2Profiler
COR_ENABLE_PROFILING=1
COR_PROFILER= {a GUID}
```

5. Restart the services. See [How to restart the W3SVC and WAS services?](#)

## Resolve Configuration Errors

- Set your IIS applications to a Full trust level. .NET Agent reporting will not work if an IIS application is set to anything other than a Full trust level.
- Ensure that you have correctly configured the `config.xml` file for the App Agent for .NET. See [.NET Agent Configuration Properties](#).
- If you manually edited the `config.xml` file, check the `AgentLog.txt` file and `WarnLog.txt` file for errors. Invalid XML displays in the log as:

```
2014-03-13 10:49:18.7199 1232 dllhost 1 1 Error ConfigurationManager Error reading the configuration file
```

- Resolve Log Issues

The .NET Agent writes logs to these directories:

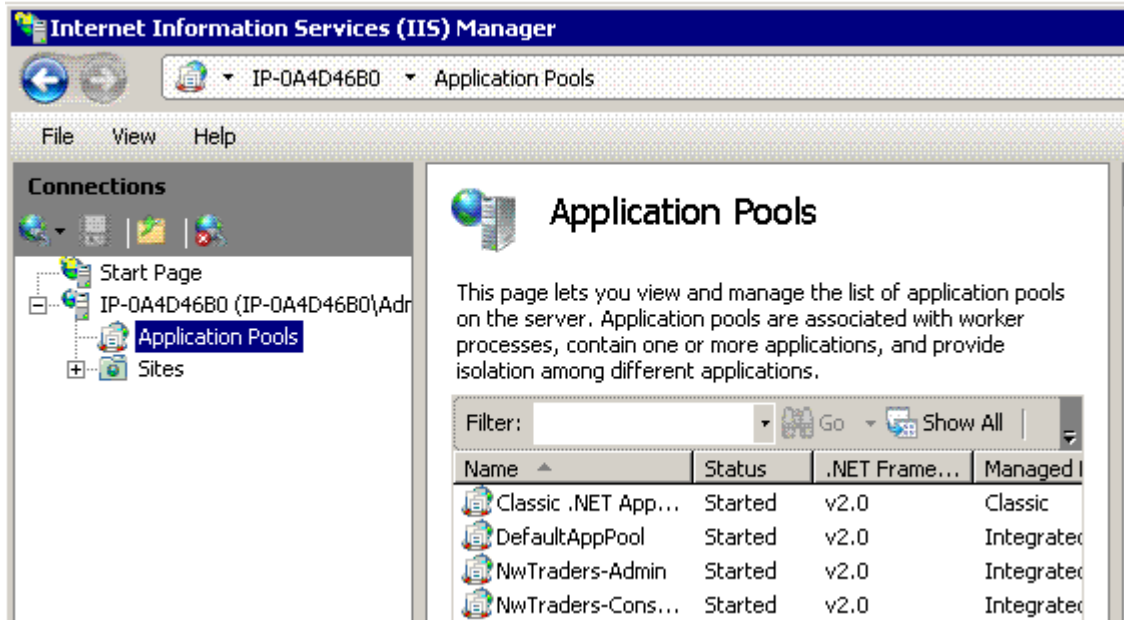

```
%ProgramData%\AppDynamics\DotNetAgent\Logs
```

The agent will not generate logs if the agent directory does not have sufficient permissions.

Verify that the .NET Agent Directory has the Correct Permissions

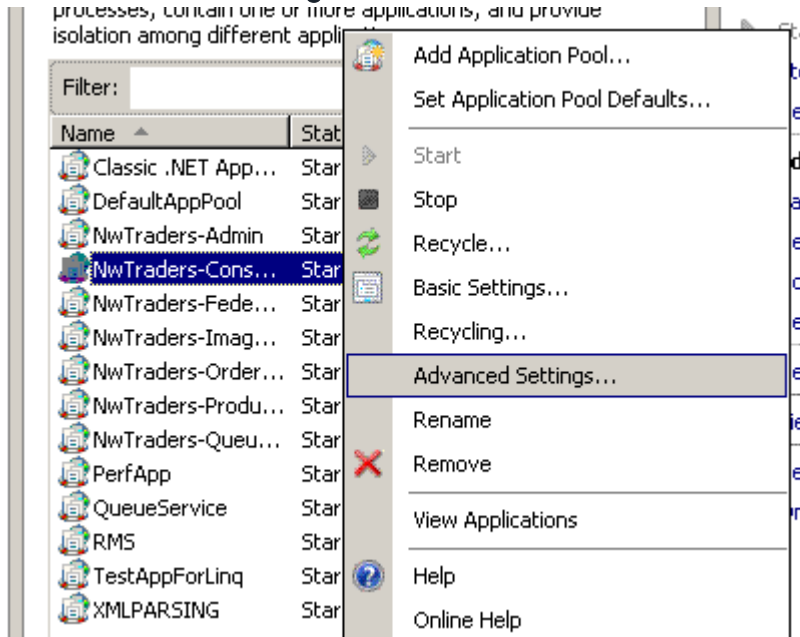

1. Select **IIS > Application pools**.

IIS displays the list of application pools for your machine.

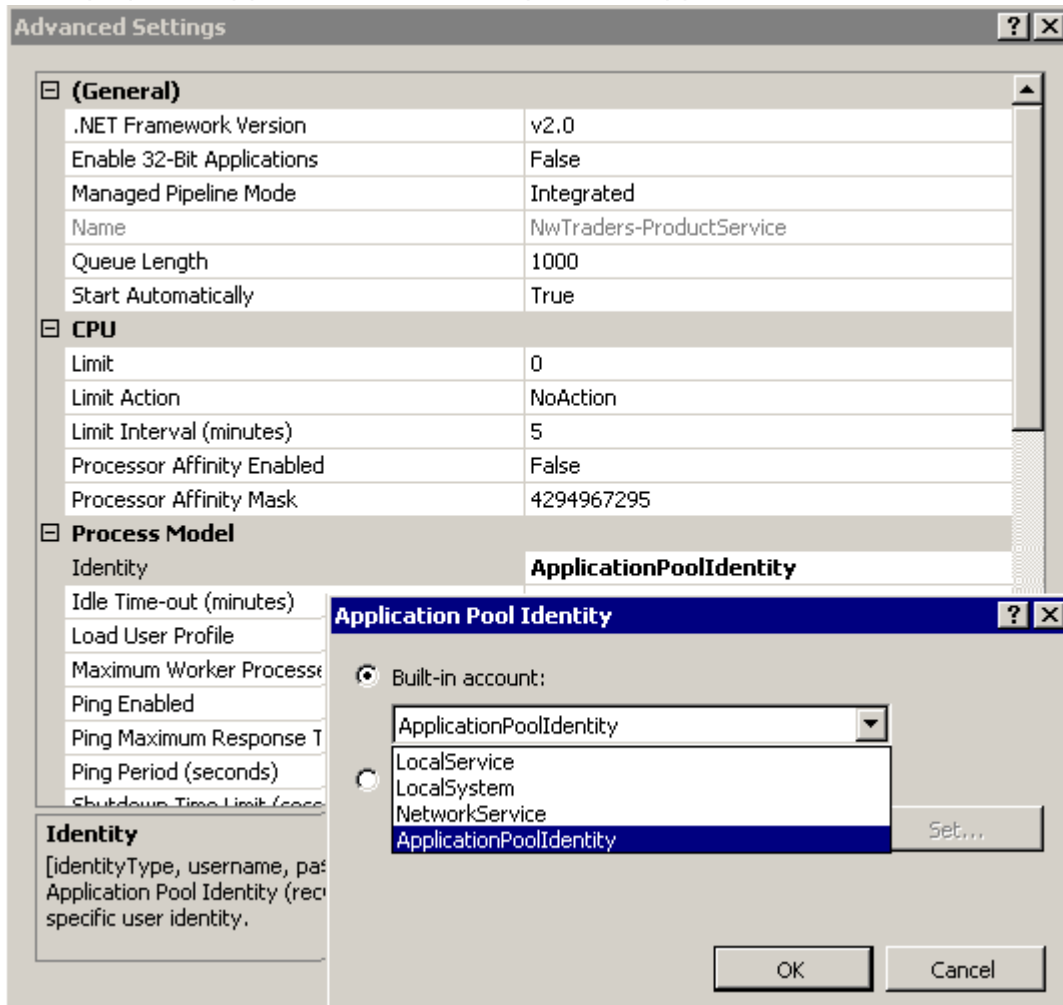

2. Right-click a particular application pool.

3. Select **Advanced Settings**.

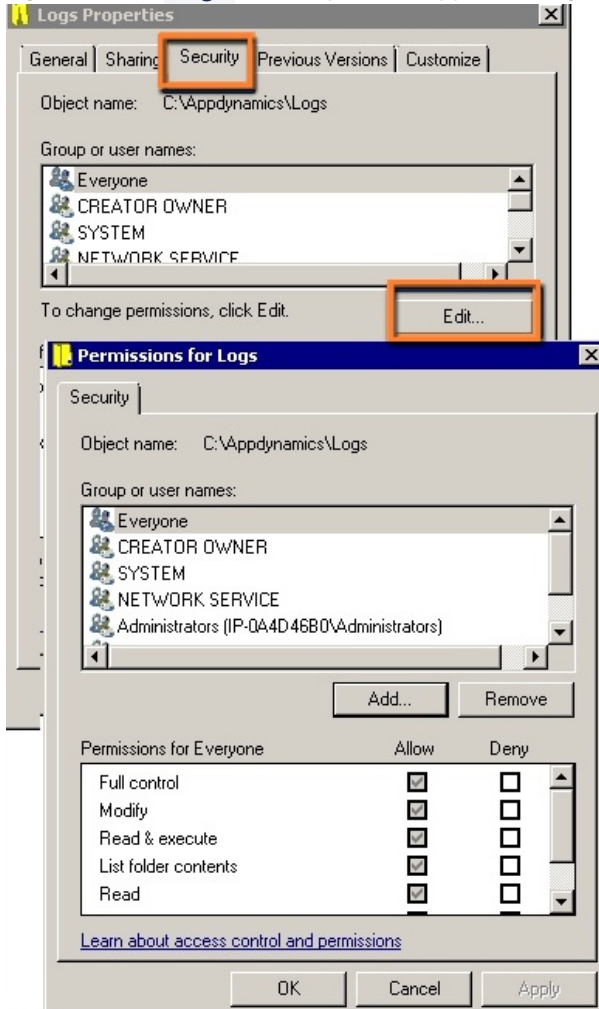

IIS displays the Application Pool Identity for that application.

4. Ensure that your Agent Directory also has the same permissions as your site application pools.
  - Navigate to AppDynamics .NET App Server Agent directory location.

- Right-click the **Logs** directory for the App Server Agent and select **Properties**.

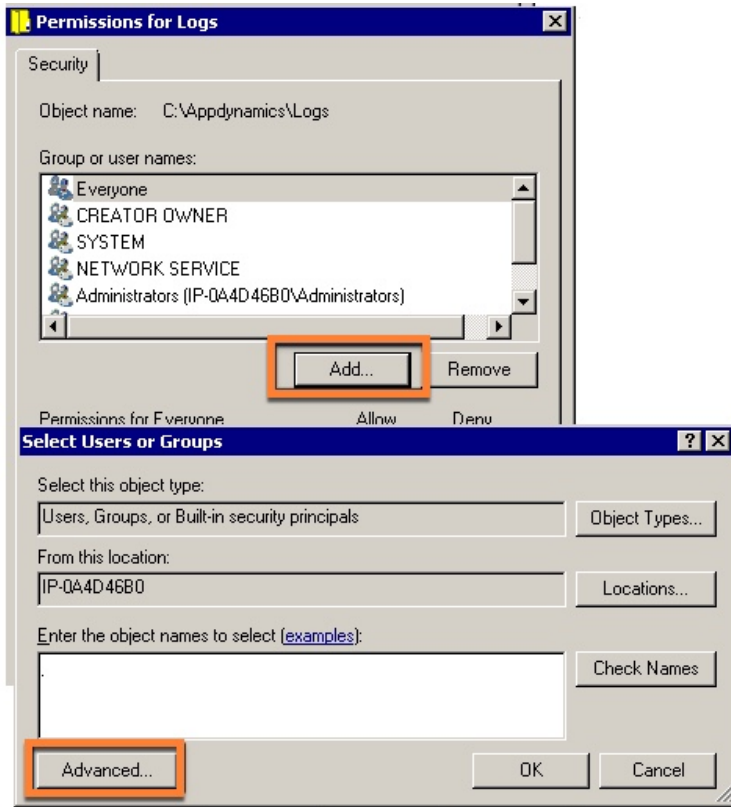

- Select the Security tab, and verify that the same Application Pool Identity is specified for the .NET Agent directory.

If the Agent logs directory does not have the required permissions:

1. In the Security tab, select **Edit**.
2. Select **Add** to add new permissions to the Agent directory.

3. Select **Advanced**.

4. Click **Find Now** to find all the users, groups, or built-in security principals on your machine.
5. Select the required group from the list and click **OK**. Review the information that follows for Allowed groups.
6. Provide the read and write permissions for the selected user/group/security principal to the Agent directory and click **OK**.
7. Click **Apply**.

Allowed Groups for Different IIS Versions

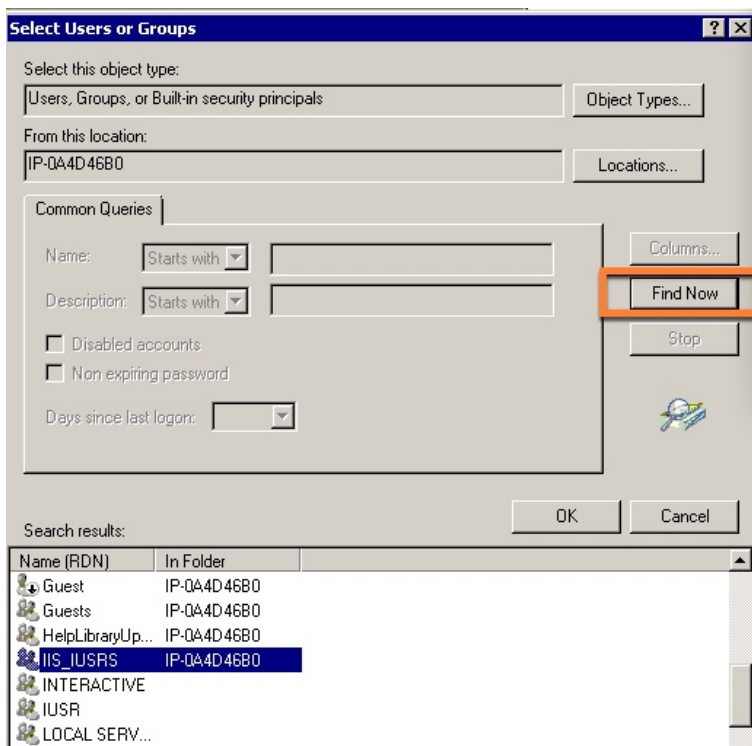

For IIS 6.x, these settings are applicable for Application Pool Identities:

Application Pool Identity	Permission Level
LocalService	LOCAL SERVICE
LocalSystem	SYSTEM
NetworkService	NETWORK SERVICE
Custom Account	Provide the exact name of the account.

For IIS >= IIS 7.0, these settings are applicable for Application Pool Identities:

Application Pool Identity	Permission Level
LocalService	LOCAL SERVICE
LocalSystem	SYSTEM
NetworkService	NETWORK SERVICE
ApplicationPoolIdentity	Provide the group level permissions for IIS_IUSRS Group See the screenshot that follows
Custom Account	Provide the exact name of the account.

For example, if your application has the identity `ApplicationPoolIdentity`, you must provide the permissions for `IIS_IUSRS` group to your agent directory.

### Another Version of AppDynamics Detected

 AppDynamics recommends that you contact support to resolve this issue.

.NET Agent >= 20.3 supports .NET Core. If you used the Microservice Agent to monitor .NET Core applications you can monitor .NET Core with the full .NET Agent. You may receive an error message in the MSI Installer stating that another version of AppDynamics is detected.

The Microservice Agent uses a JSON file to store configuration information while the .NET Agent uses an XML file. The data does not migrate between these files.

To fix this issue, you need to map the data in the JSON file to the XML file, `config.xml` and remove environment variables. If you have completed the instructions above and still see the error, you may need to reboot your machine. You may want to plan reboots according to your planned outage schedule.

### Known Issues

You may ignore the following error from the `AppDynamics.Agent.Coordinator` service in the `agent.log` or `warn.log`:

```
2015-12-01 10:12:03.0435 3872 AppDynamics.Coordinator 1 7 Warn
MaxQueueItemAgePolicy MaxQueueItemAge is beyond the integer
limit: 13093467123
```

### Instrument SharePoint

Business operations must ensure their internal and external teams have full access to the content and collaborative services that SharePoint offers. To do that, administrators need an APM solution with total visibility across the SharePoint environment. AppDynamics works with SharePoint to provide details for complex tasks such as end-user monitoring, log analytics, and server support.

By using AppDynamics to monitor SharePoint, you can:

- Monitor most SharePoint components (web applications, search components, workflow and Office Web Apps), using a mixture of .NET APM agents, EUM agents, analytics agents, and machine agents.
- Understand what is occurring on the end-user page, and document navigation and browsing using End User Monitoring.
- View APM partitions of user activity by content web applications.
- Gain insights into Office Web Apps document rendering behavior.
- View more details on search and query usage.

 AppDynamics is not a replacement for the Systems Center Operations Management (SCOM) pack or a well-planned IBM Tivoli implementation, particularly when just interpreting PerfMon counters. SharePoint Server 2013 integrates with SCOM, which is very useful but still optional. AppDynamics is not meant to be a replacement for native monitoring tools but rather work together with tools from Microsoft and its robust partner ecosystem.

Before implementing this solution, download and [read this eBook](#), and work with an AppDynamics expert in your organization, or AppDynamics Professional Services.

### Uninstall the .NET Agent

This page describes how to uninstall the .NET Agent. This procedure frees the license associated with the agent and makes it available for another app agent to use.

 Do not follow these instructions if you are doing an upgrade. To upgrade to a new version, see [Upgrade the .NET Agent for Windows](#).

To uninstall the .NET Agent completely:

1. Stop IIS, instrumented Windows services, and instrumented standalone applications.

**!** Failing to stop instrumented applications before uninstalling the agent requires you to reboot the machine to complete the uninstall.

2. Stop the `AppDynamics.Agent.Coordinator` service.
3. From the Control Panel, select **Add/Remove Programs**, and remove the **AppDynamics .NET Agent**.
4. The uninstall procedure does not remove configuration files. You must delete the configuration directory: `%ProgramData%\AppDynamics`
5. Restart IIS, Windows services, and standalone applications.

**i** In some cases, another process interferes with the .NET Agent uninstallation process by locking the `profiler.dll`. If uninstallation fails, use a utility such as [Process Explorer](#) to see determine if a process is using `profiler.dll`. If so, then terminate the process; otherwise, reboot the machine. Then, retry the uninstallation.

## Administer the .NET Agent

### Related pages:

- [.NET Agent Configuration Properties](#)
- [Manage Configuration for .NET](#)

The .NET Agent uses a single configuration file to control agent behavior and .NET Machine Agent behavior. The configuration file specifies Controller connectivity, .NET Machine Agent operations, and app agent functionality for IIS applications, Windows services, and standalone applications. The single configuration file enables you to:

- Maintain agent configurations separately from `web.config` files
- Instrument Windows services and standalone applications without environment variables
- Control agent behavior for specific applications with hierarchical configuration

You use the AppDynamics Controller to upload and manage .NET Agent configuration files. From the Controller, you can deploy a configuration to a machine or multiple machines where the agent is installed. See [Manage Configuration for .NET](#).

## Configure Agent Properties

You configure the agent properties in the `config.xml` file in the agent `Config` directory. To edit the `config.xml`, you must launch the editor as an administrator. When you run the .NET Agent Configuration Utility, it writes the `config.xml` file to one of these locations:

- Windows Server 2008 and later  
`%ProgramData%\AppDynamics\DotNetAgent\Config\config.xml`
- Windows Azure  
For Windows Azure deployments, the .NET Agent NuGet package contains the `config.xml` file. Sample `config.xml` files install to this location:  
`%ProgramFiles%\AppDynamics\AppDynamics .NET Agent\SampleConfigurations`

**i** After you edit the `config.xml` file, you must restart the `AppDynamics.Agent.Coordinator` service. Then restart your IIS services, Windows services, or standalone applications for your instrumentation changes to take effect.

## Customize .NET Agent Behavior in `config.xml`

Some .NET Agent configurations require that you edit the `config.xml` :

1. Shut down the `AppDynamics.Agent.Coordinator` service.
2. Edit the `config.xml` file as an administrator.
3. Modify the XML file according to the configuration instructions.
4. Save the `config.xml` file.
5. Start the `AppDynamics.Agent.Coordinator` service.
6. In some cases, you may need to restart IIS, instrumented Windows services, or instrumented Standalone applications. See individual .NET Agent administration topics.

## Example Minimal `config.xml`

The most basic configuration shows the required sections for agent configuration. This example instruments all IIS applications using the `automatic` element, `<automatic />`. For this example, AppDynamics does not instrument Windows services or standalone applications.

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://
www.w3.org/2001/XMLSchema">
 <controller host="mycontroller.mycompany.com" port="8090" ssl=false">
 <application name="MyDotNetApplication" />
 <account name="customer1" password="changeme" />
 </controller>
 <machine-agent />
 <app-agents>

 <IIS>
 <automatic />
 </IIS>

 </app-agents>
</appdynamics-agent>
```

## Agent Log Files

The configuration file that controls log files for the .NET Agent is located here:

```
%ProgramFiles%\AppDynamics\AppDynamics .NET Agent\AppDynamicsAgentLog.config
```

The configuration file uses [NLog configuration format](#).

## .NET Agent Directory Structure

### Related pages:

- [Install the .NET Agent for Windows](#)
- [Administer the .NET Agent](#)

This page describes the .NET agent directory structure for Windows Server 2008 and later.

## Executables

The .NET Agent executables and supporting files install to the `AppDynamics .NET Agent` directory:

```
%ProgramFiles%\AppDynamics\AppDynamics .NET Agent
```

## Log files

The `Logs` directory defaults to this location:

```
%ProgramData%\AppDynamics\DotNetAgent\Logs
```

## Agent Configuration Files

The .NET Agent writes the `config.xml` configuration file to the `Config` directory:

```
%ProgramData%\AppDynamics\DotNetAgent\Config
```

If you use [Config Management](#), the .NET Agent stores backup configuration files in the `Config\Backup` directory.

## Coordinator Service Configuration Files

The AppDynamics Agent Coordinator service writes configuration files from the Controller to the `Data` directory:

```
%ProgramData%\AppDynamics\DotNetAgent\Data
```

## About Windows Server System Directory Variables

`%ProgramData%` is located at `<system drive>\Program Data`.

## .NET Agent Configuration Properties

### Related pages:

- [Administer the .NET Agent](#)
- [Configure the .NET Agent](#)
- [Name .NET Tiers](#)
- [Configure the .NET Agent for Windows Services and Standalone Applications](#)
- [.NET Agent for Linux Environment Variables](#)

This page describes the .NET Agent configuration properties that you set in the agent `config.xml` file. You can set some of these properties using Windows System Environment Variables. See [.NET Agent Environment Variables](#). To edit the file and apply your changes, see [Administer the .NET Agent](#).

**i Environment Variables Reference**

You can use environment variables in the agent config.xml file for node, tier, and application names. To include an environment variable, reference it by specifying `%<variable>%`, which you can combine with other characters; for example, `Web-%COMPUTERNAME` translates to `Web-HOST23`.

**AppDynamics Agent Element**

The `appdynamics-agent` element is the root container element for configurations in the config.xml.

Required Element:

```
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
```

**Controller Element**

The `controller` element is a child of the `appdynamics-agent` element. It specifies the connection information for the AppDynamics Controller.

**i** The .NET Agent configuration utility only supports the configuration of one Controller per server.

Required Element:

```
<controller host="mycontroller.mycompany.com" port="8090" ssl="false" enable_tls12="false" high_availability="false" secure="false" enable_config_deployment="true"
```

**Controller host attribute**

The `controller host` attribute indicates the hostname or the IP address of the AppDynamics Controller. For an on-premises Controller, use the value for Application Server Host Name you provided when you installed the Controller. If you use the AppDynamics SaaS Controller, see the Welcome email from AppDynamics.

Type: String  
Default: None  
Required: Yes

**Environment Variable:** APPDYNAMICS.CONTROLLER.HOSTNAME

**Controller port attribute**

The `controller port` attribute specifies the HTTP or HTTPS port of the AppDynamics Controller. If the `controller ssl` attribute is set to `true`, specify the HTTPS port of the Controller; otherwise, specify the HTTP port.

Type: Positive Integer  
Default: 8090

- For On-premises installations, the defaults are port 8090 for HTTP and port 8181 for HTTPS.
- For the SaaS Controller, use port 80 for HTTP or port 443 for HTTPS.

---

Required: Yes

Environment Variable: APPDYNAMICS.CONTROLLER.PORT

Controller ssl attribute

To enable encryption over SSL between the agent and the Controller, set the controller `ssl` attribute to `true`.

Type: Boolean

Default: false

Required: No

Environment Variable: APPDYNAMICS.CONTROLLER.SSL.ENABLED

Controller enable TLS 1.2 attribute

When you enable SSL, the agent secures communication to the Controller using the protocols set for `ServicePointManager.SecurityProtocol` in your application. Set the controller `enable TLS 1.2` attribute to `true` to add TLS 1.2 as the first option in the list of protocols. This affects all secure communications from your application, not just requests to the AppDynamics Controller.

Type: Boolean

Default: false

Required: No

Controller high availability attribute

If you have your Controller setup for high availability, set the controller `high availability` attribute to `true`.

Type: Boolean

Default: false

Required: No

Controller secure attribute

If you set up the .NET Agent to encrypt credentials, the MSI installer package automatically sets the `controller secure` attribute to `true`. When `controller secure` is `true`, the .NET Agent ignores any credentials in the Account element or the Proxy element and uses the credentials from the Windows Credential Store. See [Encrypt Credentials in .NET Agent Configuration](#)

Type: Boolean

Default: false

Required: No

Controller enable config deployment attribute

By default, the .NET Agent checks for configuration updates to the `config.xml` from the Controller. If you want to disable the agent from `config.xml` configuration files from the Controller set the `controller enable config deployment` attribute to `false`. See [Manage Configuration for .NET](#).

Type: Boolean

Default: true

Required: No

## Controller Application Element

The `controller application` element is a child of the `controller` element. It indicates the name of the logical business application you see in the Controller interface.

The .NET Agent configuration utility only supports one business application per server. Use one of the following methods to support multiple applications:

- Use tiers to organize different applications you instrument on a single server.
  - Or manually configure support for multiple business applications, see [Configure Multiple Business Application Support for .NET](#).
- i** Multiple application support requires different configuration elements, including the `<applications>` container element.

Required Element: `<application name="MyDotNetApplication"/>`

### Application name attribute

Set the `application name` attribute to the business application you use in the Controller. If the application name does not exist, the Controller will create it when the agent registers. All instrumented applications in the `config.xml` register with the same business application in the Controller. See [Overview of Application Monitoring](#).

Type: String, may also reference an environment variable. See [Reference of Environment Variables](#).

Default: None

Required: Yes

Environment Variable: APPDYNAMICS.AGENT.APPLICATIONNAME

**i** You specify a Tier for individual applications in the [App Agents Element](#).

## Account Element

The `account` element is a child of the `controller` element. If the AppDynamics Controller runs in multi-tenant mode or if you use the AppDynamics SaaS Controller, specify the account name. For single-tenant accounts the default account name is `customer1`. If you are using the AppDynamics SaaS Controller, the account name is provided in the Welcome email from AppDynamics.

The agent requires to use your account access key as a password to authenticate with the Controller. For single-tenant accounts, you can view the access key in the Controller under Settings > License. If you are using the AppDynamics SaaS Controller, the account access key is provided in the Welcome email from AppDynamics.

Required Element: `<account name="mycompany" password="myaccesskey"/>`

### Account name attribute

The `account name` attribute indicates the account name for the SaaS or multi-tenant Controller.

Type: String

Default: For single-tenant Controllers, the agent assumes the default of `customer1` if you do not specify an account name.

Required: Only for SaaS or multi-tenant Controllers.

Environment Variable: APPDYNAMICS.AGENT.ACCOUNTNAME

### Account password attribute

---

The `account password` attribute indicates the account access key for the Controller.

Type: String  
Default: None  
Required: Yes

Environment Variable: APPDYNAMICS.AGENT.ACCOUNTACCESSKEY

#### Proxy Element

The `proxy` element is a child of the `controller` element. Use it to configure the connection to the Controller through a proxy server with no authentication.

Optional Element: `<proxy host="proxy-name" port="3128" enabled="true"/>`

#### Proxy host attribute

The `proxy host` attribute indicates the proxy server hostname or IP address.

Type: String  
Default: None  
Required: host is required for the proxy element

#### Proxy port attribute

The `proxy port` attribute indicates the proxy server port.

Type: Positive Integer  
Default: None  
Required: port is required for the proxy element

#### Proxy enabled attribute

To enable Controller access through a proxy server, set the `proxy enabled` attribute to `true`.

Type: Boolean  
Default: true  
Required: No

#### Proxy - Authentication Element

The `authentication` element is a child of the `proxy` element. Use the `authentication` element to enable proxy authentication and to supply the credentials for your proxy server. For environments where security policies require you to secure credentials stored on disk, you can [encrypt the credentials](#) and store them in the Windows Credential Manager.

Optional Element: `<authentication enabled="true" user_name="my_proxy_user" password="password" domain="my_windows_domain"/>`

#### Proxy authentication enabled attribute

Set the `proxy authentication enabled` attribute to `true` to configure the agent to send credentials to a proxy server.

Type: Boolean  
Default: false  
Required: No

### Proxy authentication username attribute

The `proxy authentication username` attribute indicates the name of the proxy user.

Type: String

Default: None

Required: The username attribute is required for the Authentication element

### Proxy authentication password attribute

The `proxy authentication password` attribute indicates the password for the proxy user.

Type: String

Default: None

Required: No

### Proxy authentication domain attribute

The `proxy authentication domain` attribute specifies the domain or realm where the username is located. This could be the host computer name, an Active Directory domain or DNS domain.

Type: String

Default: None

Required: No

### Sample Controller Configuration with Proxy Authentication enabled

In this example, the agent accesses the controller through the proxy, `myproxy.example.com` using proxy authentication. The .NET Agent uses the credentials `MyProxyUser@mydomain.com` with password `password` to access the proxy server.

```
<controller host="mycontroller.example.com">
 <application name="MyDotNetApplicaition" />
 <proxy host="myproxy.example.com" port="3128" enabled="true">
 <authentication enabled="true" user_name="MyProxyUser" password="password" domain="mydomain.com"/>
 </proxy>
</controller>
```

### Machine Agent Element

The `machine-agent` element is a child of the AppDynamics Agent element. An empty `machine-agent` element enables the default instrumentation for the .NET machine agent. See [Monitor CLR](#)s and [Monitor IIS](#)

Enable optional additional Microsoft Performance Counters or .NET Agent instrumentors as children of the Machine Agent element.

Required Element: `<machine-agent/>`

### Machine Snapshot Element

The `machine-snapshot` element is a child of the `machine-agent` element. Use it to tune the settings for machine snapshots in your environment. If you do not specify an attribute, the agent uses the default values for that attribute. See [Machine Snapshots for .NET](#) and [Configure Machine Snapshots for .NET](#).

```
Optional Element: <machine-snapshot enabled="true" window-size="600" samples-per-window="60" violations-per-window="6" max-percent-cpu="80" max-percent-memory="80" max-queue-item-age="100" periodic-collection="600" />
```

#### Machine Snapshot enabled attribute

Set the `machine-snapshot enabled` attribute to `false` to disable machine snapshots.

Type: Boolean  
 Default: true  
 Required: No

#### Machine Snapshot window size attribute

Specify the window size time range in seconds for the .NET Machine Agent to take samples. During a window, the agent takes samples and checks them for breached thresholds: `max percent CPU`, `max percent memory`, and `max queue item age`.

Type: Integer  
 Default: 600  
 Required: No

#### Machine Snapshot samples per window attribute

Specify the number of samples the .NET Machine Agent takes during the specified window. For example, if the `window size` is 600 and the `samples per window` is 60, the agent takes a sample once every 10 seconds.

Type: Integer  
 Default: 60  
 Required: No

#### Machine Snapshot violations per window attribute

When the .NET Machine Agent detects the number of violations per window for one threshold, it takes a snapshot. The agent only takes one snapshot per window for thresholds exceeded. For example, if `violations per window` is set to 6, and six samples show memory usage at 80% or greater, the agent takes a snapshot. The counters for each threshold are separate.

Type: Integer  
 Default: 6  
 Required: No

#### Machine Snapshot max percent memory attribute

When the .NET Machine agent detects memory usage on the machine equals or exceeds the `max percent memory` value, it flags the sample as a violation. The minimum value is 20. The maximum value is 100.

---

Type: Integer

Default: 80

Required: No

Machine Snapshot max percent CPU attribute

When the .NET Machine agent detects CPU usage on the machine equals or exceeds the `max percent cpu` value, it flags the sample as a violation. The minimum value is 20. The maximum value is 100.

Type: Integer

Default: 80

Required: No

Machine Snapshot max queue item age attribute

When the .NET Machine agent detects the oldest item in the IIS queue equals or exceeds the `max queue item age` value in milliseconds, it flags the sample as a violation.

Type: Integer

Default: 100

Required: No

Machine Snapshot periodic collection attribute

The .NET Machine agent takes one snapshot per periodic collection time range. Specify the value in seconds. The minimum is 60 seconds.

Type: Integer

Default: 600

Required: No

CLR Crash Reporting Element

The `clr-crash-reporting` element is a child element of the `machine-agent` element. Use the `clr-crash-reporting` element to control whether or not the .NET Machine Agent reports CLR crash events to the Controller. See [Monitor CLR Crashes](#)

Optional Element: `<clr-crash-reporting enabled="true"/>`

CLR Crash Reporting enabled attribute

Set the `clr-crash-reporting enabled` attribute to `false` to stop reporting CLR Crash events to the controller.

Type: Boolean

Default: true

Required: No

Process Monitor Element

The `process-monitor` element is a child element of the `machine-agent` element. By default, the agent enables process monitoring for all IIS processes.

Optional Element: `<process-monitor report-all-iis-processes="true"/>`

Process Monitor report all IIS processes attribute

---

---

Set the `report-all-iis-processes` attribute to `false` to enable process monitoring only for instrumented IIS processes.

Type: Boolean

Default: true

Required: No

#### Metrics Element

The `metrics` element is a child element of the `machine-agent` element. By default, the machine agent registers a maximum of 200 metrics. Use the `metrics` element to increase the number of metrics the .NET Machine Agent can register. See [Metrics Limits](#)

Use caution when increasing the metric registration limits. Increasing the limit can increase the resource overhead for agents and Controller.

Optional Element: `<metrics max-metrics="200"/>`

#### Metrics max-metrics attribute

Specify the maximum number of metrics the .NET Machine Agent can register.

Type: Integer

Default: 200

Required: No

#### Perf-metrics Element

The `perf-metrics` element is a child element of the `metrics` element. By default, the machine agent collects and reports a full set of performance metrics. You can modify the priority level for the performance metrics to limit the metrics the agent collects and thereby decrease agent overhead. For a full list of metrics and their priorities, see [Manage Windows Performance Metrics](#) Optional Element: `<perf-metrics priority-level="3">`

#### Perf-metrics priority-level attribute

Specify the set of performance metrics for the machine agent to collect as follows:

- 0 - disable metric collection
- 1 - collect only high priority metrics
- 2 - collect high and medium priority metrics
- 3 - collect all metrics: high, medium, and low priority

Type: Integer in the range 0 - 3

Default: 3

Required: If you use the `perf-metrics` element.

#### Perf-metric Element

The `perf-metric` element is a child element of the `perf-metrics` element. If you set the `perf-metric` priority to 0 to disable general collection of performance metrics, you can use the `perf-metric` element to enable individual performance metrics. You cannot enable individual metrics with `perf-metric` priority greater than 0.

Optional Element: `<perf-metric name="<metric_path>"/>`

#### Perf-metric name attribute

Specify the full path of the performance metric. See the example below for the `% Busy` metric and the `Errors Unhandled During Execution` metric.

Type: String: metric path

Default: N/A

Required: If you use the `perf-metric` element.

### Sample Machine Agent Configuration with Individual Performance Metrics

```
<machine-agent>
 <metrics>
 <!-- Disable collection of performance metrics in general. -->
 <perf-metrics priority-level="0">
 <!-- Enable collection of individual performance metrics. -->
 <perf-metric name="Hardware Resources|CPU|%Busy"/>
 <perf-metric name="ASP.NET Applications|Errors Unhandled During Execution"/>
 </perf-metrics>
 </metrics>
</machine-agent>
```

### Performance Counters Element

The `perf-counters` element is a child of the `machine-agent` element. It is a container for all performance counters.

Optional Element: `<perf-counters>`

### Performance Counter element

The `perf-counter` element is a child of the `perf-counters` element. For a list of performance counters to enable, see [Performance Counters in the .NET Framework](#)

Optional Element: `<perf-counter cat="category" name="name" instance="instance"/>`

### Performance Counter cat attribute

The `perf-counter` `cat` attribute indicates the performance counter category.

Type: String

Default: None

Required: Category is required for the `perf-counter` element.

### Performance Counter name attribute

The `perf-counter` `name` attribute indicates the performance counter name.

Type: String

Default: None

Required: Name is required for the `perf-counter` element.

### Performance Counter instance attribute

The `perf-counter` `instance` attribute is the performance counter instance value.

Type: String

Default: None

Required: Instance is required for the `perf-counter` element.

### Sample Machine Agent Configuration with Performance Counters

```
<machine-agent>
 <!-- Additional machine level Performance Counters -->
 <perf-counters>
 <perf-counter cat="Network Interface" name="Bytes Sent" instance="Local Area
Connection"/>
 </perf-counters>
</machine-agent>
```

### Instrumentation Element

The `instrumentation` element is a child of the `machine-agent` element. It allows you to enable additional .NET Agent instrumentors such as [thread correlation](#) or [correlation for .NET remoting](#).

Optional Element: `<instrumentation>`

### Instrumentor Element

The `instrumentor` element is a child of the `instrumentation` element. The `instrumentor` element specifies the .NET Agent instrumentor to implement.

Optional Element: `<instrumentor name="instrumentor name" enabled="true"/>/>`

### Instrumentor name attribute

The `instrumentor name` attribute indicates the instrumentor name.

Type: String

Default: None

Required: Name is required for the Instrumentor element.

### Instrumentor enabled attribute

Set the `instrumentor enabled` attribute to `true` to enable instrumentation.

Type: Boolean

Default: false

Required: No.

 The current configuration syntax is `enabled="true"`. Versions prior to 3.7.8 used `disabled="false"`.

### Sample Machine Agent Configuration with Thread Correlation Instrumentors

```
<machine-agent>
 <!--Enable thread correlation-->
 <instrumentation>
 <instrumentor name="ThreadCorrelationThreadPoolCLR2Instrumentor" enabled="true"/>
 <instrumentor name="ThreadStartCLR2Instrumentor" enabled="true"/>
 <instrumentor name="ThreadStartCLR4Instrumentor" enabled="true"/>
 </instrumentation>
</machine-agent>
```

```
</instrumentation>
</machine-agent>
```

### Additional .NET Agent Instrumentors

- See [Thread Correlation for .NET](#)
- See [Enable Correlation for .NET Remoting](#)
- See [Enable Instrumentation for WCF Data Services](#)

### App Agents Element

The `app-agents` element is a child of the `appdynamics agent` element. It is a container for app agent configurations for IIS applications, Windows services, and standalone applications.

Required Element: `<app-agents enabled="true">`

#### App agents enabled attribute

To disable application monitoring on the server, set the `app-agents enabled` attribute to `false`.

Type: Boolean

Default: true

Required: No

### Default Profiler Element

The default `profiler` element is a child of the `app-agents` element. It defines customizations to the default profiler behavior for all instrumented .NET applications on the machine: IIS applications, application pools, Windows services, and standalone applications.

Optional Element: `<profiler>`

#### Profiler - Disabled Features Element

The `disabled-features` element is a child of the `profiler` element. Use this property to disable data collection mechanisms at the agent level for security or privacy reasons. This configuration overrides any configuration set by the Controller.

Optional Element: `<disabled-features value="NONE"/>`

#### Disabled features value attribute

The `disabled-features value` attribute is a comma-separated list of features to disable. The available values are as follows:

- `LOG_PAYLOAD`: Override the `log-request-payload` node property to suppress logging HTTP request payloads
- `RAW_SQL`: Override the `capture-raw-sql` node property to suppress logging raw SQL output
- `CUSTOM_EXIT_SNAP_DATA`: Suppress snapshot data from custom exits points
- `METHOD_INV_DATA_COLLECTOR`: Suppress method invocation data collector user data
- `HTTP_DATA_COLLECTOR`: Suppress HTTP request data collector user data
- `INFO_POINT`: Suppress information point metrics
- `ALL`: Disable all the available features
- `NONE`: Don't disable features

Type: String  
Default: NONE  
Required: No

#### Profiler - Successful Exit Code Element

The `successful-exit-code` element is a child of the `profiler` element. The default successful exit code determines whether or not the agent flags a CLR restart event as graceful or not for Windows services or standalone applications. This configuration does not apply to IIS.

Optional Element: `<successful-exit-code value="0"/>`

#### Successful exit code value attribute

Type: Integer  
Default: 0  
Required: No

#### Profiler - Runtime Reinstrumentation Element

The `runtime-reinstrumentation` element is a child of the `profiler` element. Use this property to configure runtime reinstrumentation. See [Configure Runtime Reinstrumentation for .NET](#)

Optional Element: `<runtime-reinstrumentation enabled="true" interval="60000" optimize="true" />`

#### Runtime reinstrumentation enabled attribute

Set to `true` to enable runtime reinstrumentation.

Type: Boolean  
Default: false  
Required: No

#### Runtime reinstrumentation interval attribute

The frequency in milliseconds that the agent checks for configuration updates that initiate runtime reinstrumentation.

Type: Integer  
Default: 60000 milliseconds  
Minimum: Because runtime reinstrumentation adds a small amount of system overhead, AppDynamics recommends a minimum interval of 1 minute or 60000 milliseconds.  
Required: No

#### Sample Default Profiler Configuration

```
<app-agents>
 <profiler>
 <disabled-features value="LOG_PAYLOAD,RAW_SQL,CUSTOM_EXIT_SNAP_DATA"/>
 <!-- Set the successful exit code for Windows services and standalone applications to
"1." -->
 <successful-exit-code value="1"/>
 <!-- Enable Runtime reinstrumentation -->
 <runtime-reinstrumentation enabled="true" interval="60000" />
```

```

 </profiler>
 ...
</app-agents>

```

## App Agents - IIS Element

The `IIS` element is a child of the `app-agents` element. There are three options to configure IIS applications:

- Automatic configuration
- Application pool configuration
- Application configuration

The settings for any application pool apply to all applications within the app pool unless the individual application has a specific configuration.

Explicit child-level configurations override parent-level configurations. Otherwise, children inherit parent configurations.

Optional Element: `<IIS>`

### Exclude child applications attribute

By default, when you instrument an IIS application, the .NET Agent instruments any child applications and assigns them to the same tier as the parent. To prevent the agent from automatically instrumenting child applications, set `exclude-child-applications` to `true`. For instance: `<IIS exclude-child-applications="true">`

If you disable instrumentation for child applications in general, you can instrument-specific child applications using the IIS Application element.

Type: Boolean

Default: false

Required: No

### IIS Automatic Instrumentation Element

The `automatic` element is a child of the `IIS` element. Use the `automatic` element to enable or disable automatic instrumentation for all IIS apps. You can configure automatic instrumentation and manual instrumentation both. Manual configurations override automatic ones.

Optional Element: `<automatic enabled="false" />`

### Automatic enabled attribute

Set the `automatic enabled` attribute to `true` to enable instrumentation for all IIS applications. This is the default setting if you use the .NET Agent Configuration Utility automatic configuration option. To disable automatic instrumentation for all IIS applications, set the value to `false`.

Type: Boolean

Default: true

Required: No

### IIS Application name enabled attribute

By default, the agent does not report an IIS application name. To view the IIS application name in the CLR metadata, set the `iis-application-name-enabled` attribute to `true`. For example, `<automatic iis-application-name-enabled="true" />`. When enabled, the name appears as the `iis-application-name` value in the CLR metadata.

Type: Boolean

Default: false

Required: No

### IIS Application Pools Element

The `IIS application pools` element is a child of the `IIS` element. It is a container element for all the IIS application pools you configure for instrumentation.

Optional Element: `<application-pools>`

### IIS Application Pool Element

The `application-pool` element is a child of the `application-pools` element. You may have multiple application pool elements distinguished by the name attribute. Use the application pool element to configure the app agent for all applications within an application pool. For more information on IIS application pools, see [Managing Application Pools in IIS](#)

 Application-specific configurations in the IIS Applications element override application pool configurations.

Optional Element: `<application-pool name="DefaultAppPool" enabled="false">`

### Application pool name attribute

The `application-pool name` attribute indicates the name of the IIS Application Pool.

Type: String

Default: None

Required: Name is required for the application-pool element.

### Application pool enabled attribute

Set the `application-pool enabled` attribute to `false` to disable instrumentation for all applications in the application pool. Set the value to `true` to instrument all applications in the application pool.

Type: Boolean

Default: None. Defaults to `true` if not specified.

Required: No

### Application Pool Tier Element

The `tier` element is a child of the `application-pool` element. If you enable instrumentation for an application pool, you must use a `tier` element to assign the applications of a pool to a tier in the Controller. See [Overview of Application Monitoring](#)

Required Element: `<tier name="Inventory" />`

### Tier name attribute

Use the `tier name` attribute to specify the tier.

---

Type: String, may also reference an environment variable. See [Reference of Environment Variables](#).

Default: None

Required: Yes

### IIS Applications Element

The IIS `applications` element is a child of the `IIS` element. It is a container element for all the IIS applications you configure for instrumentation.

Optional Element: `<applications>`

### Application Element

The `application` element is a child of the `applications` element. Use multiple application elements to instrument different sites and applications. To learn more about IIS sites and applications, see [Understanding Sites, Applications, and Virtual Directories on IIS 7 and Above](#)

Optional Element: `<application path="/" site="FirstSite" port="8008"site-regex="false">`

### Application site attribute

The `application site` attribute indicates the root site in IIS for the application. The site name accepts a [regular expression](#) for cases like Windows Azure where you may only know a partial site name. If you use a regular expression, set the Application site-regex attribute to true.

Type: String

Default: None

Required: The site is required for the Application element.

### Application site-regex attribute

Set the `application site-regex` attribute to `true` to treat the value of the Application `site` attribute as a [regular expression](#).

Type: Boolean

Default: false

Required: No

### Application path attribute

The `application path` attribute indicates the path of the application, relative to the root site. Use the forward slash to indicate the root site and instrument all children applications. Use the path to an application to instrument the specific application and any children.

For example, Site1 hosts two applications `AppX` and `AppY`. To instrument Site 1, `AppY` and `AppZ`, set the path to `/`. To instrument `AppY`, but not `AppZ`, set the path to `/AppY`.

Type: String

Default: /

Required: `path` is required for the `application` element.

### Application port attribute

For cases where two or more sites in IIS 6 have the same site name, set the site `port` attribute to differentiate between the sites.

Type: Positive Integer

Default: None

Required: No

Application enabled attribute

In certain cases you may want to enable instrumentation for a parent application, but disable it for a child application. In this case create an `application` element for the child application to disable and set the `application enabled` attribute to `false`.

Type: Boolean

Default: true

Required: No

Application Tier Element

The `tier` element is a child of the `application` element. If you enable instrumentation for an application, you must use a `tier` element to assign the application to a tier in the Controller. See [Overview of Application Monitoring](#)

Required Element: `<tier name="Consumer" />`

Tier name attribute

The `tier name` attribute indicates the business application tier.

Type: String, may also reference an environment variable. See [Reference of Environment Variables](#).

Default: None

Required: Yes

Sample IIS Application Configuration

```

<IIS>
 <!-- Automatic instruments all IIS applications when enabled. -->
 <automatic enabled="false" />

 <!-- Application Pool agent configurations -->
 <application-pools>
 <!-- Do not instrument applications in DefaultAppPool when "enabled" attribute is set
to false. -->
 <application-pool name="DefaultAppPool" enabled="false">
 <tier name="Tier Name"/>
 </application-pool>

 <!-- Instrument applications in the OtherAppPool and assign them to the Inventory
tier. -->
 <application-pool name="OtherAppPool">
 <tier name="Inventory"/>
 </application-pool>
 </application-pools>
 <applications>
 <!-- Instrument all applications in the First Site. -->
 <application path="/" site="FirstSite">
 <tier name="Order"/>
 </application>
 </applications>

```

```

 </application>
 <!-- Instrument the /app application and child apps in the Second Site -->
 <!-- but not the root Second Site application. -->
 <application path="/app" site="SecondSite">
 <tier name="Consumer"/>
 </application>
 <!-- Regular expression for site name -->
 <!-- assigns all sites beginning with "MyRole" to the Credit Services tier. -->
 <application path="/" site="MyRole_\w+" site-regex="true">
 <tier name="Credit Services"/>
 </application>

 </applications>
</IIS>

```

## App Agents - Standalone Applications Element

The `standalone-applications` element is a child of the `app-agents` element. It is a container element for all the Windows services and standalone applications you configure for instrumentation. See [Configure the .NET Agent for Windows Services and Standalone Applications](#)

Optional Element: `<standalone-applications>`

### Standalone Application Element

The `standalone-application` element is a child of the `standalone-applications` element. It specifies a Windows service or standalone application to instrument.

Optional Element: `<standalone-application executable="MyWindowsApplication.exe" command-line="">`

### Standalone Application executable attribute

The `standalone-application executable` attribute specifies the file name of the Windows application to instrument. Set the Standalone Application element executable attribute to one of the following:

- Executable name: for example, `MyStandaloneApp.exe` or `MyWindowsService.exe`. The file extension is optional, so `MyStandaloneApp` also works.
- Full path to the executable: for example, `C:\Program Files\MyApplication\MyStandaloneApp.exe`
- Partial path to the executable: for example, `MyApplication\MyStandaloneApp.exe`. Use the full or partial path to the executable when you want to assign different tiers to separate instances of the same executable running from different paths.

Type: String

Default: None

Required: Yes

### Standalone Application command-line attribute

To differentiate between two instances of the same executable, specify any unique portion of the application command line, such as an argument, in the `standalone-application command-line` attribute.

Type: String

Default: None

Required: No

## Standalone application app-domain-name attribute

For applications with multiple application domains, the `app-domain-name` attribute enables you to limit instrumentation to specific application domains. See [Configure Application Domain Monitoring](#)

Type: String  
 Default: None  
 Required: No

## Standalone Application Tier Element

The `tier` element is a child of the `standalone-application` element. If you enable instrumentation for an application, you must use a `tier` element to assign the application to a tier in the Controller. See [Overview of Application Monitoring](#).

Required Element: `<tier name="Consumer" />`

## Tier name attribute

The `tier name` attribute indicates the business application tier.

Type: String, may also reference an environment variable. See [Reference of Environment Variables](#)  
 Default: None  
 Required: Yes

Environment Variable: APPDYNAMICS.AGENT.TIERNAME

## Sample Windows Service and Standalone Application Configuration

```
<standalone-applications>
 <standalone-application executable="ExampleApplication.exe">
 <tier name="Standalone Application Tier"/>
 </standalone-application>
 <!-- Instrument a Windows service using arguments. -->
 <!-- The following example matches the command "MyWindowsService.exe -d -x -r". -->
 <standalone-application executable="MyWindowsService.exe" command-line="-x">
 <tier name="Windows Service Tier"/>
 </standalone-application>
</standalone-applications>
```

## .NET Agent Environment Variables

### Related pages:

- [.NET Agent Configuration Properties](#)
- [Administer the .NET Agent](#)
- [Configure the .NET Agent](#)
- [Name .NET Tiers](#)
- [Configure the .NET Agent for Windows Services and Standalone Applications](#)

This page describes the .NET configuration properties you can set using Windows System Environment Variables.

## Agent Account Name

---

Specifies the account name for the SaaS or multi-tenant Controller.

**Environment Variable:** APPDYNAMICS.AGENT.ACCOUNTNAME

**Type:** String

**Default:** For single-tenant Controllers, the agent assumes the default of "customer1" if you do not specify an account name.

**Required:** Only for SaaS or multi-tenant Controllers.

Agent Application Name

Specifies the business application you use in the Controller. If the application name does not exist, the Controller will create it when the agent registers. See [Overview of Application Monitoring](#).

**Environment Variable:** APPDYNAMICS.AGENT.APPLICATIONNAME

**Type:** String

**Default:** None

**Required:** Yes

Agent Account Password

Specifies the account access key for the Controller.

**Environment Variable:** APPDYNAMICS.AGENT.ACCOUNTACCESSKEY

**Type:** String

**Default:** None

**Required:** Yes

Agent Node Name

The name of the node.

In general, the node name must be unique within the business application and physical host. If you want to use the same node name for multiple nodes on the same physical machine, create multiple virtual hosts using the Unique Host ID property. See Unique Host ID.

**Environment Variable:** APPDYNAMICS\_AGENT\_NODE\_NAME

**Type:** String

**Default:** None

**Required:** Yes

Agent Reuse Node Name

Set this environment variable to true to reuse node names in AppDynamics. When you set the property to true, you don't need to supply a node name, but you do need to provide a node name prefix using `appdynamics.agent.reuse.nodeName.prefix`.

This property is useful for monitoring environments where there are many CLR's with short life spans. When true, AppDynamics reuses the node names of historical CLR's for new CLR's. This avoids a proliferation of differently named nodes in AppDynamics over time, particularly when the nodes are essentially identical processes that run over different times.

AppDynamics generates a node name with App, Tier, and Sequence number. The node names are pooled. For example, the sequence numbers are reused when the nodes are purged (based on the node lifetime).

When the .NET Agent starts up, it logs output to the console until it registers with the Controller and the Controller generates the node name.

---

The Controller reuses node names based on the [node.retention.period](#) property.

**Environment Variable:** `appdynamics.agent.reuse.nodeName`

**Type:** Boolean

**Default:** False

**Required:** No

Example: Using the following environmental variable specifications, the Controller generates a node name with the prefix "reportGen". Node names will have suffixes --1, --2, and so on, depending on the number of nodes are running in parallel. The name of a node that is shut down and qualifies as a historical node may be reused by a new node.

```
appdynamics.agent.reuse.nodeName=true
```

```
appdynamics.agent.reuse.nodeName.prefix=reportGen
```

#### Agent Reuse Node Name Prefix

When you configure the agent to reuse node names, use this property to specify the prefix the Controller uses to generate node names dynamically.

**Environment Variable:** `appdynamics.agent.reuse.nodeName.prefix`

**Type:** String

**Default:** None

**Required:** When `appdynamics.agent.reuse.nodeName = true`

**Example:** Using the following environmental variable specifications, the agent directs the Controller to generate a node name with the prefix "reportGen". Node names will have suffixes --1, --2, and so on, depending on how many nodes are running in parallel.

```
appdynamics.agent.reuse.nodeName=true
```

```
appdynamics.agent.reuse.nodeName.prefix=reportGen
```

#### Agent Tier Name

Specifies the name of the tier that this .NET node belongs to. Note that this is not the deployment name on the application server.

**Environment Variable:** `APPDYNAMICS_AGENT_TIER_NAME`

**Type:** String

**Default:** None

**Required:** Yes

#### Agent Unique Host ID

Logically partitions a single physical host or virtual machine such that it appears to the Controller that the application is running on different machines. Set the value to a string that is unique across the entire managed infrastructure. The string may not contain any spaces. If you have a machine agent associated with the application monitored by the app agent, then this property must be set on the machine agent to the same value. See [Standalone Machine Agent Installation Scenarios](#).

**Environment Variable:** `APPDYNAMICS_AGENT_UNIQUE_HOST_ID`

**Type:** String

---

**Default:** None

**Required:** No

#### AWS Instance ID

If the app that you are instrumenting runs on AWS, then .NET Agent supports collecting the AWS Instance ID. To collect the AWS Instance ID, set `APPDYNAMICS.AWS.INSTANCE.ENABLED=true`

**Environment Variable:** APPDYNAMICS.AWS.INSTANCE.ENABLED

**Type:** Boolean

**Default:** false

**Required:** No

#### Controller Hostname

Specifies the hostname or the IP address of the AppDynamics Controller. For an on-premises Controller, use the value for Application Server Host Name you provided when you installed the Controller. If you use the AppDynamics SaaS Controller, see the Welcome email from AppDynamics for the name of your Controller.

**Environment Variable:** APPDYNAMICS.CONTROLLER.HOSTNAME

**Type:** String

**Default:** None

**Required:** Yes, may also be set in the agent config.xml file or using the agent configuration utility.

#### Controller Port Number

Specifies the HTTP(S) port of the AppDynamics Controller. If the `APPDYNAMICS.CONTROLLER.SSL.ENABLED` environment variable is set to true, specify the HTTPS port of the Controller; otherwise, specify the HTTP port.

**Environment Variable:** APPDYNAMICS.CONTROLLER.PORT

**Type:** Positive Integer

**Default:** 8090

- For On-premises installations, the defaults are port 8090 for HTTP and port 8181 for HTTPS.
- For the SaaS Controller, use port 80 for HTTP or port 443 for HTTPS.

**Required:** Yes, may also be set in the agent config.xml file or using the agent configuration utility.

#### Controller SSL Enabled

When set to "true" enables encryption over SSL between the agent and the Controller.

**Environment Variable:** APPDYNAMICS.CONTROLLER.SSL.ENABLED

**Type:** Boolean

**Default:** false

**Required:** No, may also be set in the agent config.xml file or using the agent configuration utility.

#### HTTP Proxy Host

The name of the proxy host.

**Environment Variable:** APPDYNAMICS\_PROXY\_HOST\_NAME

**Type:** String

**Default:** None

---

Required: No, may also be set in the agent `AppDynamicsConfig.json` file in the `"proxy"` section.

#### HTTP Proxy Port

The port number of the proxy.

Environment Variable: `APPDYNAMICS_PROXY_PORT`

Type: Positive integer

Default: None

Required: No, may also be set in the agent `AppDynamicsConfig.json` file in the `"proxy"` section.

#### HTTP Proxy User

The name of the user that connects to the proxy.

Environment Variable: `APPDYNAMICS_PROXY_AUTH_NAME`

Type: String

Default: None

Required: No, may also be set in the agent `AppDynamicsConfig.json` file in the `"proxy"` section.

#### HTTP Proxy Password

The password of the user that connects to the proxy.

Environment Variable: `APPDYNAMICS_PROXY_AUTH_PASSWORD`

Type: String

Default: None

Required: No, may also be set in the agent `AppDynamicsConfig.json` file in the `"proxy"` section.

#### HTTP Proxy Domain

The domain that connects to the proxy.

Environment Variable: `APPDYNAMICS_PROXY_AUTH_DOMAIN`

Type: String

Default: None

Required: No, may also be set in the agent `AppDynamicsConfig.json` file in the `"proxy"` section.

#### Reference of Environment Variables

The .NET Agent (through the `config.xml` file) can reference any environment variables when configuring Agent Node Name, Agent Tier Name, or Controller Application Name.

These environment variables can be referenced in the configuration file or in the agent environment variables for the node, tier, and application names listed above. To include an environment variable, reference it by specifying `%<variable>%` which can be combined with the other characters; for example, `Web-%COMPUTERNAME%` will be translated to `Web-HOST23`.

#### Configure Multiple Business Application Support for .NET

##### Related pages:

- [.NET Agent Configuration Properties](#)
- [Overview of Application Monitoring](#)

By default, applications on a single Windows host are mapped to a single business application in the Controller. If needed, you can manually configure the .NET Agent to map different applications on the same Windows host to different business applications in the Controller.

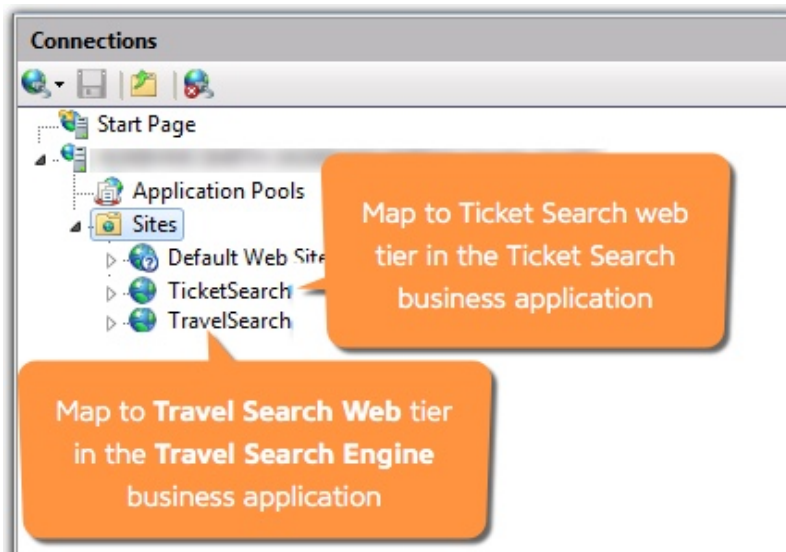

To map applications on a single host to a different business application, you must edit the `config.xml` file manually. The AppDynamics Agent Configuration utility does not offer this configuration option.

After configuring multiple application support, you cannot use the configuration utility to make configuration changes afterward. If you launch the configuration utility on a server where you configured multiple application support, the utility prompts you to delete the configurations.

### Prepare to Configure Multiple Business Applications

Before you configure the .NET Agent, you must install the agent. Use the AppDynamics Agent Configuration utility to perform basic configuration tasks.

1. Identify how to organize your business applications and identify the business application names. For example, consider a Windows host running IIS. The IIS instance serves two applications for two separate customers: Ticket Search and Travel Search. The applications perform similar functions, but it makes sense to monitor them separately because they function independently. In this case, create two business applications based upon the application name: Ticket Search Engine and Travel Search Engine.
2. Map your IIS applications or application pools, Windows services, and standalone applications to tiers in the different business applications. For example, map the TicketSearch site to the Ticket Search Web tier in the Ticket Search Engine business application. Map the TravelSearch site to the Travel Search Web tier in the Travel Search Engine business application.

3. If you have not already done so, install the .NET Agent. See [Install the .NET Agent for Windows](#).
4. Run the AppDynamics Agent Configuration utility to generate a `config.xml` and configure the Controller connection. See [Configure the .NET Agent](#).
5. When prompted, select **Manual** for the method of tier generation and assignment.

**i** The configuration utility only supports mapping one business application per server.

## Manually Configure the .NET Agent

Once you have configured the Controller properties for the .NET Agent, instrument your .NET Applications in the config.xml.

1. Open the `config.xml` file as administrator and edit the file. See 'Where to Configure Agent Properties' on [Administer the .NET Agent](#).
2. Copy the `controller applications` block and paste it as a child element of the `controller` element. Replace any existing `<applications>` or `<application>` elements:

### Show Controller applications code block

```
<!--Configure multiple business applications-->
<applications>
 <application name="ApplicationName1" default="true"/>
 <application name="ApplicationName2"/>
</applications>
```

3. Add an `application` element for each of the business applications in the Controller.
  - Edit the `name` attribute for the `application` elements to match the business application names in the Controller. If the application does not exist, the Controller creates it.
  - Set the `default` attribute to `true` for one `application` element. If the agent cannot find a match for the business application name in the IIS application, Windows service, or standalone application configuration, the tier reports to the default business application.

In this example, `Ticket Search` is the default business application:

### Show TicketSearch example

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
 <controller host="mycontroller.mycompany.com" port="8090" ssl="false">
 <account name="customer1" password="changeme" />
 <!--Configure multiple business applications-->
 <applications>
 <application name="Ticket Search" default="true"/>
 <application name="Travel Search"/>
 </applications>
 </controller>
 ...
```

4. Add configuration elements for the IIS applications or application pools, Windows services, or standalone applications to instrument.

For IIS applications, add the `applications` block as a child of the `IIS` element. Replace the existing `applications` element. See [IIS Applications Element](#).

### Show IIS Application configuration.

```

<applications>
 <application path="/" site="FirstSite" controller-application="Application1">
 <tier name="FirstSite Tier"/>
 </application>
 <application path="/" site="SecondSite" controller-application="Application2">
 <tier name="SecondSite Tier"/>
 </application>
</applications>

```

For IIS application pools, add the `application-pools` block as a child of the `IIS` element. Replace the existing `< application-pools>` element. See [IIS Application Pools Element](#).

**Show IIS Application Pool configuration.**

```

<application-pools>
 <application-pool name="MyAppPool1" controller-application="Application1">
 <tier name="App1 AppPool Tier"/>
 </application-pool>
 <application-pool name="MyAppPool2" controller-application="Application2">
 <tier name="App2 AppPool Tier"/>
 </application-pool>
</application-pools>

```

For Windows services or standalone applications, add the `standalone-applications` block as a child of the `app-agents` element. See [Standalone Applications Element](#).

**Show Windows service and standalone application configuration**

```

<standalone-applications>
 <standalone-application executable="MyStandaloneApp.exe" controller-application="ApplicationName1">
 <tier name="Standalone App Tier"/>
 </standalone-application>
 <standalone-application executable="MyWindowsService.exe" command-line="-x"
 controller-application="ApplicationName2">
 <tier name="Windows Service Tier"/>
 </standalone-application>
</standalone-applications>

```

##### 5. Configure your application elements:

- Add the corresponding element for each IIS application or application pool, Windows service, or standalone application to instrument. See [.NET Agent Configuration Properties](#).
- For each application element set the `controller-application` attribute to the name of the corresponding business application. If you omit the `controller-application` attribute, the agent adds the application to a tier in the configured default business application.
- Set the `tier` element `name` attribute to the business application tier name.

##### 6. After you complete configuration, save the changes to the `config.xml` file.

##### 7. Restart the `AppDynamics.Agent.Coordinator` service.

##### 8. Restart IIS applications or application pools, Windows services, and standalone applications.

- 
9. As your applications begin processing traffic, the agent registers them with the Controller. Log on to the Controller to see that your applications have registered with the corresponding business application.

### Sample Configuration

This sample `config.xml` file demonstrates configuration for multiple business applications in the Controller. Because the Windows service `TicketService` does not specify a `controller-application` attribute, it reports to the default business application, `Ticket Search Engine`. All applications in the `TravelAPIPool` pool report to the `Travel Search Engine`.

### Show sample config.xml

```

<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://
www.w3.org/2001/XMLSchema">
<controller host="mycontroller.mycompany.com" port="8090" ssl="false">
<!--Configure multiple business applications-->
 <applications>
 <application name="Ticket Search Engine" default ="true"/>
 <application name="Travel Search Engine"/>
 </applications>
</controller>
<machine-agent />
<app-agents>
 <IIS>
 <automatic enabled="false" />
 <application-pools>
 <application-pool name="TravelAPIPool" controller-application="Travel Search Engine">
 <tier name="Travel APIs"/>
 </application-pool>
 </application-pools>
 <applications>
 <application path="/" site="TicketSearch" controller-application="Ticket Search Engine">
 <tier name="Ticket Search Web"/>
 </application>
 <application path="/" site="TravelSearch" controller-application="Travel Search Engine">
 <tier name="Travel Search Web"/>
 </application>
 </applications>
 </IIS>
 <standalone-applications>
 <standalone-application executable="StandaloneApp.exe" controller-application="Ticket
Search Engine">
 <tier name="Ticket Standalone Tier"/>
 </standalone-application>
 <standalone-application executable="WindowsService.exe" command-line="-x" controller-
application="Travel Search Engine">
 <tier name="Travel Windows Service Tier"/> </standalone-application>
 </standalone-applications>
 </app-agents>
</appdynamics-agent>

```

## Agent Configuration Properties for Multiple Application Support

Multiple business application support includes configuration properties for the .NET Agent. These configuration properties supersede the ones documented in [.NET Agent Configuration Properties](#).

### Controller Applications Element

The `applications` element is a child of the `controller` element. It is a container element for all controller applications elements that map to business applications in the Controller.

Required Element: `<applications>`

---

## Controller Application Element

The `controller application` element is a child of the `controller applications` element. It indicates the name of the logical business application you see in the Controller. When you have more than one Controller Application element, you must set the default attribute to `true` for one of them.

Required Element: `<application name="MyDotNetApplication" default="true"/>`

### Application name attribute

Set the application `name` attribute to the business application name in the Controller. If the application name does not exist, the Controller creates it when the agent registers.

Type: String

Default: None

Required: Yes

### Application default attribute

Set the application `default` attribute to `true` for one `controller application` element. Instrumented applications without the `controller application` attribute register with the default business application in the Controller.

Type: Boolean

Default: false

Required: For one application in multiple application configurations

## Controller-Application Attribute

The `IIS application`, `IIS application-pool`, `windows-service`, and `standalone-application` elements accept the `controller-application` attribute. Set the value to the `controller application` element name. If you do not include a `controller-application` attribute, the application registers with the default business application.

For example, an IIS application:

```
<application path="/" site="MySite" controller-application="My Business Application">
```

Type: String

Default: None

Required: No

## Disable Instrumentation for an IIS Application Pool

### Related pages:

- [Administer the .NET Agent](#)
- [.NET Agent Configuration Properties](#)

When you install the .NET Agent on a machine and use automatic tier naming, the agent instruments every IIS application by default. If you do not need to monitor all application pools, disable monitoring for selected pools.

1. Open the `config.xml` file for editing as administrator. See 'Where to Configure Agent Properties' on [Administer the .NET Agent](#)

2. Add the `application-pools` block as a child of the `IIS` element. See [.NET Agent Configuration Properties](#)

```
<application-pools>
 <!-- Do not instrument applications in DefaultAppPool when "enabled" attribute is set
 to false -->
 <application-pool name="DefaultAppPool" enabled="false" >
 <tier name="Disabled App Pool" />
 </application-pool>
</application-pools>
```

 `tier` is a required element even if you are disabling an app pool.

3. Set the `application-pool` element name attribute to the application pool name. This example disables instrumentation for the `DefaultAppPool`. You may add multiple `application-pool` elements.
4. Restart the `AppDynamics.Agent.Coordinator` service.
5. Restart IIS.

## Configure Application Domain Monitoring

### Related pages:

- [Instrument DefaultDomain for Standalone Applications](#)
- [Application Domains](#)
- [.NET Agent Configuration Properties](#)
- [Configure the .NET Agent for Windows Services and Standalone Applications](#)

You can configure the .NET Agent to monitor ASP.NET applications with multiple Application Domains (AppDomains). This page assumes that you have a working knowledge of AppDomains and are familiar with the AppDomain implementation in your application.

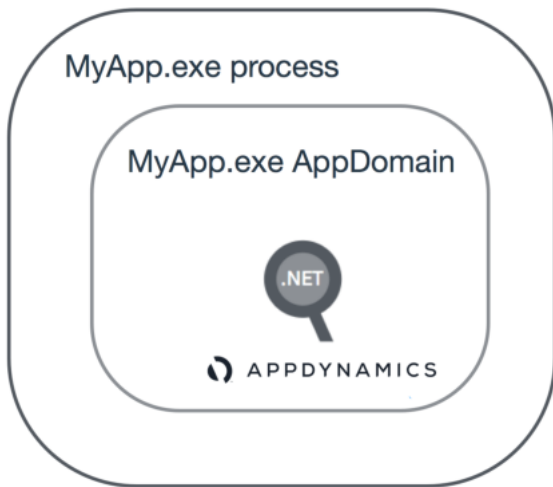

This page does not describe the System Domain, Shared Domain, or DefaultDomain AppDomains that the CLR instantiates before it executes the managed code. If your standalone application runs in the DefaultDomain, see [Instrument the DefaultDomain for Standalone Applications](#).

### AppDomains in .NET

Windows uses processes to manage security and performance isolation between running applications. Process isolation ensures that the application's running code does not interfere with another application. However for applications that share data, making calls between Windows processes can introduce complications and performance issues. AppDomains enable developers to create several applications that run inside a single process but maintain application isolation.

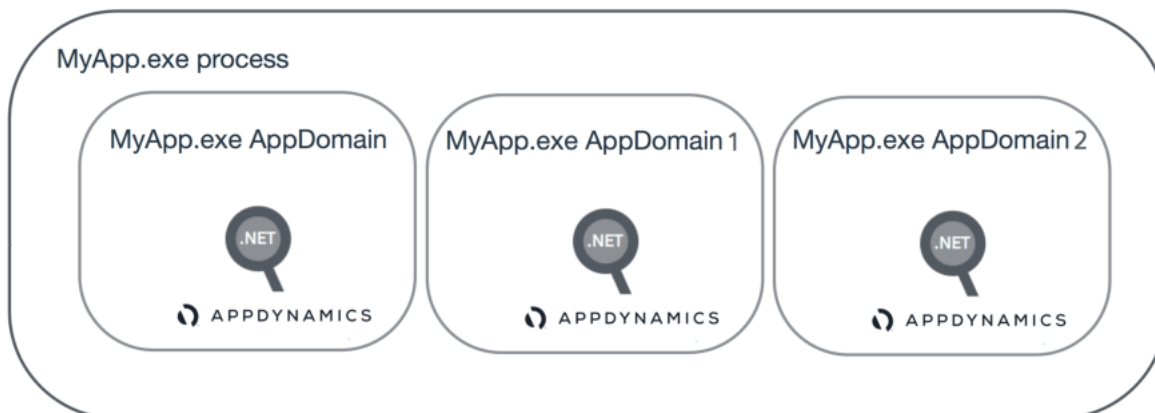

#### Single Application Domain

When a single application runs inside its own process, the runtime host manages the AppDomain. The application executable and the AppDomain have the same name. The .NET Agent installs itself inside the single AppDomain and creates a node for the application.

### Multiple Application Domains

When developers include multiple AppDomains in an application, all the AppDomains run inside a single process. The application executable may have the same name as one AppDomain, but there are other, uniquely-named AppDomains. By default, the agent installs itself inside all the AppDomains and creates nodes for them.

### Configure Monitoring for Multiple Application Domains

If the application you monitor contains multiple AppDomains, the App Agent for .NET automatically instruments each AppDomain and creates a node. You can configure the .NET Agent to instrument only the AppDomains you specify. Use this to exclude AppDomains you do not want to monitor, and to limit the number of nodes in a tier.

You can configure application domain monitoring for:

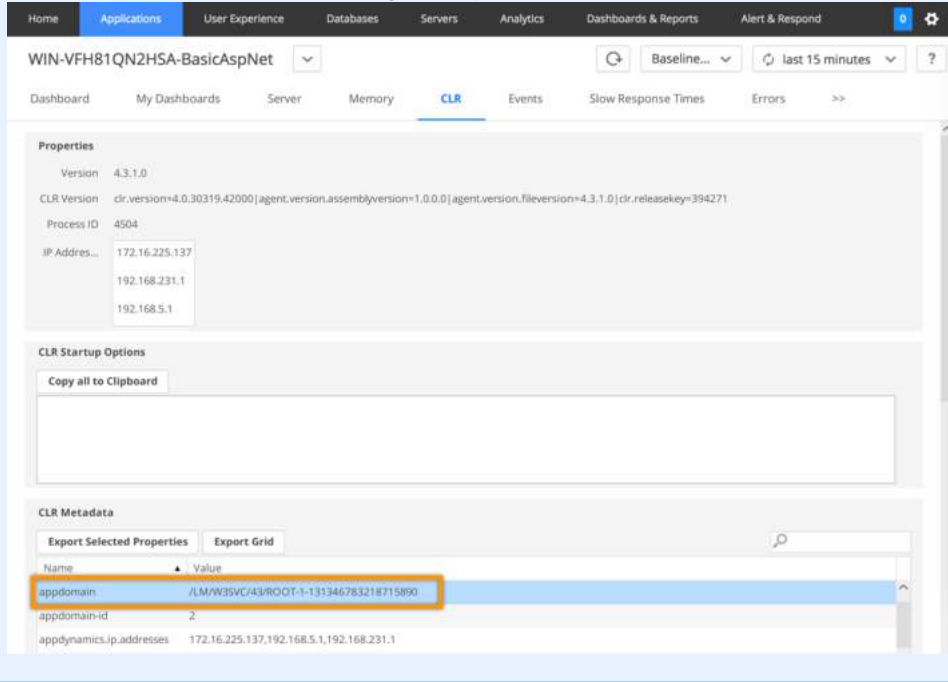

- Windows Services
- Standalone Applications

Configure all instrumentation settings for the .NET Agent in the config.xml file. See [Administer the .NET Agent](#).

1. Identify the name of the AppDomains to instrument.

**i** If you have already instrumented your application, the AppDomain names display in the Node Dashboard.

Click the node in the left navigation pane, then click **CLR**.

2. Launch a text editor as administrator.
3. Edit the `config.xml` file as an administrator. See [Administer the .NET Agent](#).
4. Find the element that corresponds to your application with multiple AppDomains:  
Standalone Application element: `<standalone-application executable="MyWindowsApplication.exe">`
5. Add the `app-domain-name` attribute to the element.  
For example, to instrument the `MyApp.exe` AppDomain for the `MyApp.exe` standalone application:

```
<standalone-application executable="MyApp.exe" app-domain-name="MyApp.exe">
 <tier name="StandaloneApplication Tier"/>
</standalone-application>
```

**i** As soon as you instrument one AppDomain in the `config.xml` file, the agent instruments only the AppDomains you specify. Other AppDomains are not instrumented.

6. To instrument additional AppDomains, add an element for each AppDomain as if they were separate applications.  
For example, to instrument `MyAppDomain1` in `MyApp.exe`:

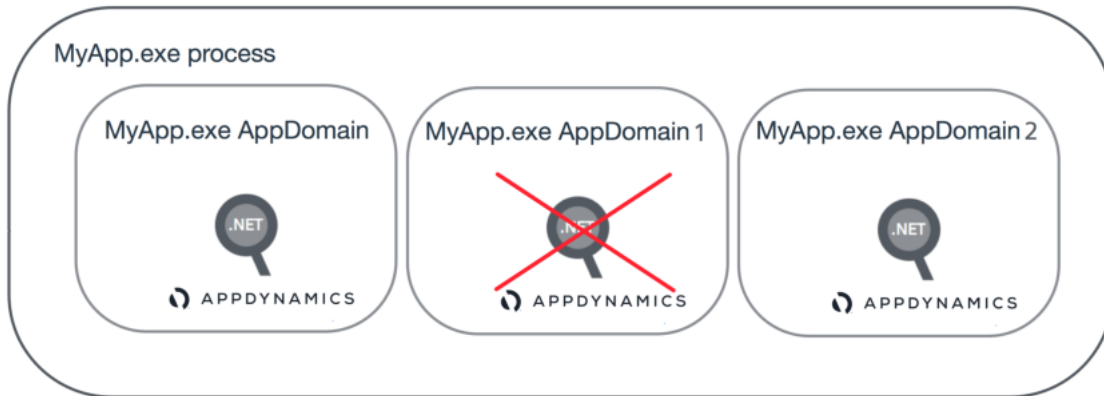

```
<standalone-application executable="MyApp.exe" app-domain-name="MyAppDomain1">
```

```
<tier name="StandaloneApplication Tier"/>
</standalone-application>
```

7. Save the `config.xml` file.
8. Restart the `AppDynamics.Agent.Coordinator` service.
9. Restart instrumented applications: Windows services or standalone applications.

### Sample Standalone Application Configuration with Multiple AppDomains

This sample `config.xml` file shows the configuration for the application, `MyApp.exe`. Instrumentation only applies to the AppDomains specified in the `config.xml` file: `MyApp.exe` and `MyAppDomain2`.

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://
www.w3.org/2001/XMLSchema">
 <controller host="mycontroller.mycompany.com" port="8090" ssl=false">
 <account name="customer1" password="changeme" />
 <application name="MyDotNetApplication" />
 </controller>
 <machine-agent />
 <app-agents>
 <standalone-applications>
 <standalone-application executable="MyApp.exe" app-domain-name="MyApp.exe">
 <tier name="StandaloneApplication Tier"/>
 </standalone-application>
 <standalone-application executable="MyApp.exe" app-domain-name="MyAppDomain2">
 <tier name="StandaloneApplication Tier"/>
 </standalone-application>
 </standalone-applications>
 </app-agents>
</appdynamics-agent>
```

### Instrument the DefaultDomain for Standalone Applications

#### Related pages:

- [Configure the .NET Agent for Windows Services and Standalone Applications](#)
- [POCO Entry Points](#)

- [.NET Agent Configuration Properties](#)

By default, the .NET Agent does not instrument the .NET `DefaultDomain AppDomain`. Before you instrument the `DefaultDomain`:

- Follow the instructions to instrument a [standalone application](#)
- Create a [POCO entry point](#) for a class/method in the application

If you complete those steps and still do not see business transactions in the Controller, check if your managed code runs in the `DefaultDomain`. If so, you must configure the agent to instrument the `DefaultDomain`.

### Check if Your Application Runs in the DefaultDomain

If you are unfamiliar with your application's managed code, you can use the agent logs to identify the AppDomain.

1. Open the agent log:  
Windows Server 2008 and later: `%ProgramData%\AppDynamics\DotNetAgent\Logs\AgentLog.txt`
2. Search the agent log for `AppDomain`.  
Few log entries contain `AppDomain` when the agent starts up. Look for an entry by `dllhost` or your instrumented application similar to the following:

```
2013-12-16 08:23:02.3120 3068 MYPROGRAM 1 1 Info Configuration
appDomainName=DefaultDomain appDomainId=1 iis-app=null site=null port=null appPoolId=
2013-12-16 08:23:02.6240 3192 dllhost 1 17 Info ConfigurationManager Not instrumenting
DefaultDomain for pid 3068
```

In this example, `MYPROGRAM` is the name of the instrumented standalone application. You can see the name of the AppDomain in the log entry, `appDomainName=DefaultDomain`.

### Instrument the DefaultDomain

1. Open the `config.xml` file for editing as administrator. See 'Where to Configure Agent Properties' on [Administer the .NET Agent](#)
2. Copy the code block below to a child element of the `standalone-application` element. See [.NET Agent Configuration Properties](#)

```
<profiler>
 <instrument-defaultdomain enabled="true"/>
</profiler>
```

 The Profiler element must follow the Standalone Application Tier element.

For example:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
 <controller host="mycontroller.mycompany.com" port="8090" ssl="false">
 <application name="My Business Application" />
 <account name="customer1" password="changeme" />
 </controller>
 <standalone-application>
 <profiler>
 <instrument-defaultdomain enabled="true"/>
 </profiler>
 </standalone-application>
</appdynamics-agent>
```

```

</controller>
<machine-agent />
<app-agents>
 <IIS>
 <applications />
 </IIS>
 <standalone-applications>
 <standalone-application executable="MyStandaloneApp.exe">
 <tier name="Standalone Tier" />
 <profiler>
 <instrument-defaultdomain enabled="true"/>
 </profiler>
 </standalone-application>
 </standalone-applications>
</app-agents>
</appdynamics-agent>

```

3. Save the `config.xml` file.
4. Restart the `AppDynamics.Agent.Coordinator` service.
5. Restart the standalone application for your changes to take effect.

## Configure the .NET Machine Agent

### Related pages:

- [Administer the .NET Agent](#)
- [.NET Agent Configuration Properties](#)
- [Monitor Windows Hardware Resources](#)

The AppDynamics .NET Agent includes an embedded .NET Machine Agent that runs as part of the `AppDynamics.Agent.Coordinator` service. Among other things, the Machine Agent regularly gathers system performance data and reports it back to the Controller as metrics.

Note: Because the .NET Agent includes an embedded .NET Machine Agent, it consumes a Machine Agent license. Meaning that installing .NET Agent, consumes both one APM license, and one Machine Agent license.

**i** Do not confuse the .NET Machine Agent with the Machine Agent, a Java application. The Machine Agent provides the capability to use extensions such as plugins, metric listeners, and orchestrations. See [Machine Agent](#).

The app agent MSI file and .NET Agent Configuration Utility automatically install and configure the .NET Machine Agent to connect to the Controller. The connection information is the same for the app agent and the .NET Machine agent. See [Configure the .NET Agent](#).

To manage the .NET Machine Agent from the Controller, see 'Manage the .NET Machine Agent' on [Monitor Windows Hardware Resources](#).

### Customize .NET Machine Agent Behavior

Customize instrumentation settings for the [Machine Agent element](#) in the `config.xml` file. See 'Where to Configure Agent Properties' on [Administer the .NET Agent](#).

1. Shut down the `AppDynamics.Agent.Coordinator` service.

2. Edit the `config.xml` file as an administrator. See 'Where to Configure Agent Properties' on [Administer the .NET Agent](#).
3. Modify the `machine-agent` element and add any children elements according to the .NET Machine Agent configuration topics.
4. Save the `config.xml` file.
5. Start the `AppDynamics.Agent.Coordinator` service.
6. In some cases, you may need to restart IIS, instrumented Windows services or instrumented applications. See individual .NET Machine Agent configuration topics.

## .NET Machine Agent Configuration Options

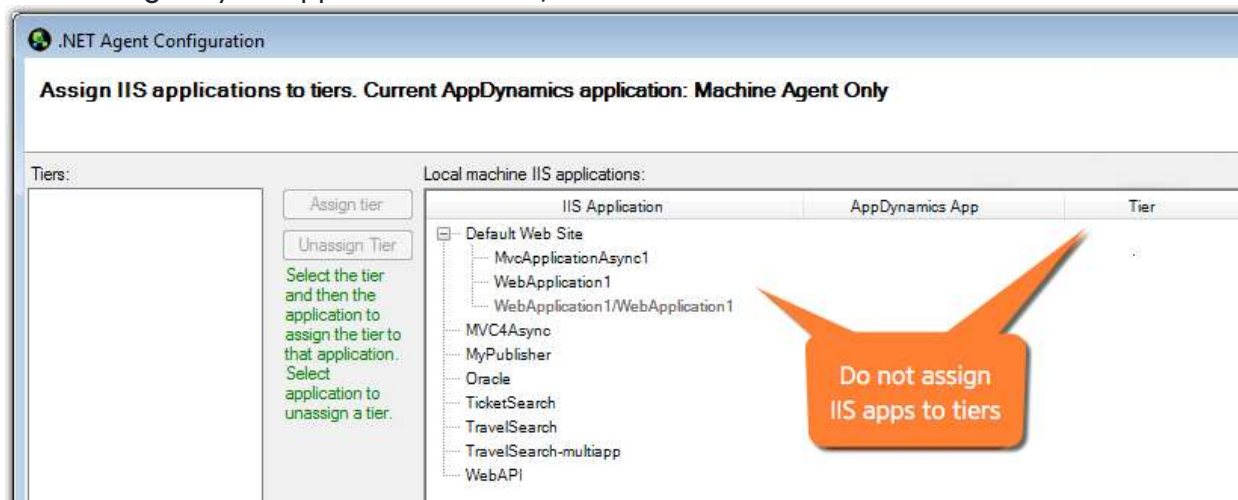

These topics describe specific customizations for the .NET Machine Agent:

- [Manage Windows Performance Metrics](#)
- [Thread Correlation for .NET](#)
- [Enable Correlation for .NET Remoting](#)
- [Enable Instrumentation for WCF Data Services](#)
- [Configure Machine Snapshots for .NET](#)

## Configure the .NET Machine Agent Without App Agents

If you want to monitor the Windows hardware performance data, but do not want to monitor any .NET applications, you can configure the .NET Machine agent to run without the .NET Agent.

1. [Install the .NET Agent for Windows](#).
2. Launch the AppDynamics Agent Configuration utility and follow the steps until you reach the Assign IIS applications to tiers pane.
3. Click **Manual** for the method of tier generation and assignment and click **Next**.
4. Do not assign any IIS applications to tiers, click **Next**.

**i** If you configured any Windows services or applications, manually disable those agents in the `config.xml` file.

5. Continue with the remaining steps and click **Done**.

Monitoring resumes for the .NET Machine Web Agent only. Metrics appear in the Controller under the Machine Agent tier, see [Monitor Windows Hardware Resources](#).

## Manage Windows Performance Metrics

The AppDynamics .NET Machine Agent uses Microsoft Performance Counters to gather and report .NET metrics. To manage the metrics that the agent collects:

- Tune the set of metrics that the agent automatically collects
- Configure the agent to collect metrics from additional counters that are not part of the default settings

## Tune the Default Performance Metrics for the .NET Agent

The .NET Agent prioritizes the default set of Performance Counters into three categories: low, medium, and high. By default, the agent is set to collect metrics for all three categories.

[Click here to view the default metric priorities...](#)

Metric Browser Location	Metric	Priority
ASP.NET	Application Restarts	3 - Low
ASP.NET	Applications Running	3 - Low
ASP.NET	Request Wait Time	2 - Medium
ASP.NET	Requests Disconnected	3 - Low
ASP.NET	Requests Queued	1 - High
ASP.NET	Requests Rejected	3 - Low
ASP.NET	Worker Process Restarts	3 - Low
ASP.NET Applications	Anonymous Requests	3 - Low
ASP.NET Applications	Anonymous Requests/Sec	3 - Low
ASP.NET Applications	Cache API Entries	3 - Low
ASP.NET Applications	Cache API Hit Ratio	3 - Low
ASP.NET Applications	Cache API Turnover Rate	3 - Low
ASP.NET Applications	Cache Total Entries	3 - Low
ASP.NET Applications	Cache Total Hit Ratio	3 - Low
ASP.NET Applications	Cache Total Turnover Rate	3 - Low
ASP.NET Applications	Errors During Compilation	3 - Low

Metric Browser Location	Metric	Priority
ASP.NET Applications	Errors During Execution	3 - Low
ASP.NET Applications	Errors During Preprocessing	3 - Low
ASP.NET Applications	Errors Total	2 - Medium
ASP.NET Applications	Errors Total/sec	2 - Medium
ASP.NET Applications	Errors Unhandled During Execution	3 - Low
ASP.NET Applications	Errors Unhandled During Execution/ sec	3 - Low
ASP.NET Applications	Output Cache Entries	3 - Low
ASP.NET Applications	Output Cache Hit Ratio	3 - Low
ASP.NET Applications	Output Cache Turnover Rate	3 - Low
ASP.NET Applications	Pipeline Instance Count	3 - Low
ASP.NET Applications	Requests Executing	3 - Low
ASP.NET Applications	Requests Failed	3 - Low
ASP.NET Applications	Requests in Applicaton Queue	1 - High

ASP.NET Applications	Transactions Aborted	3 - Low
ASP.NET Applications	Transactions Committed	3 - Low
ASP.NET Applications	Transactions Pending	3 - Low
ASP.NET Applications	Transactions Total	3 - Low
ASP.NET Applications	Transactions/sec	3 - Low
CLR	Process CPU Burnt %	2 - Medium
CLR -> Classes	Current Loaded Class Count	3 - Low
CLR -> Classes	Total Classes Loaded	3 - Low
CLR -> Locks and Threads	Contention Rate Per Sec	2 - Medium
CLR -> Locks and Threads	Current Logical Threads	2 - Medium
CLR -> Locks and Threads	Current Physical Threads	2 - Medium
CLR -> Locks and Threads	Sink Blocks in Use	2 - Medium
CLR -> Memory -> Heap	Committed (bytes)	1 - High
CLR -> Memory -> Heap	Current Usage (bytes)	1 - High
CLR -> Memory -> Heap	Gen 0 Usage (bytes)	1 - High
CLR -> Memory -> Heap	Gen 1 Usage (bytes)	1 - High
CLR -> Memory -> Heap	Gen 2 Usage (bytes)	1 - High

Metric Browser Location	Metric	Priority
CLR -> Memory -> LOH	Current Usage (bytes)	1 - High
Hardware Resources -> CPU	%Busy	1 - High
Hardware Resources -> CPU	%Idle	3 - Low
Hardware Resources -> Disks	%Free	1 - High
Hardware Resources -> Disks	KB read/sec	3 - Low
Hardware Resources -> Disks	KB written/sec	3 - Low
Hardware Resources -> Disks	MB Free	1 - High
Hardware Resources -> Disks	Reads/sec	1 - High
Hardware Resources -> Disks	Writes/sec	1 - High
Hardware Resources -> Memory	Free %	3 - Low
Hardware Resources -> Memory	Free (MB)	3 - Low
Hardware Resources -> Memory	Total (MB)	1 - High
Hardware Resources -> Memory	Used %	1 - High
Hardware Resources -> Memory	Used (MB)	2 - Medium
Hardware Resources -> Network	Incoming KB/sec	2 - Medium
Hardware Resources -> Network	Incoming packets/sec	3 - Low
Hardware Resources -> Network	Outgoing KB/sec	2 - Medium
Hardware Resources -> Network	Outgoing packets/sec	3 - Low
IIS	CPU %	1 - High
IIS	Number of Working Processes	3 - Low
IIS	Working Set	1 - High

Metric Browser Location	Metric	Priority
IIS -> Application Pools -> <name>	CPU %	1 - High
IIS -> Application Pools -> <name>	Number of Working Processes	3 - Low
IIS -> Application Pools -> <name>	Working Set	1 - High
IIS -> INFO	VersionMajor	3 - Low
IIS -> INFO	VersionMinor	3 - Low

To reduce the number of metrics that the agent sends to the Controller, or to view less than a full set of metrics, you can configure that agent to collect fewer performance metrics. You can also set the agent to only collect specific metrics from the list. See [.NET Agent Configuration Properties](#).

### Configure Additional Performance Counters for .NET

If the agent does not monitor performance counters you are interested in, you can add additional performance counters.

1. Shut down the `AppDynamics.Agent.Coordinator` service.
2. Open the `config.xml` file for editing as an administrator. See 'Where to Configure Agent Properties' on [Administer the .NET Agent](#).
3. Add the Performance Counters block as a child of the Machine Agent element.

```
<perf-counters>
 <perf-counter cat="" name="" instance=""/>
</perf-counters>
```

4. Create a Performance Counter element for each performance counter you want to add. Use any of the performance counters as specified in [Performance Counters in .NET Framework](#).
  - Set the `cat` attribute to the category of the performance counter.
  - Set the `name` attribute to the performance counter name.
  - Set the `instance` attribute to the instance of the performance counter.
    - If the counter does not have an instance name, leave an empty string `""`.
    - If a particular performance counter has many instances, you can specify the following options to report the sum of all instances:
      - `instance = "*" OR`
      - `instance = "all"`

For example, to add the performance counter for measuring CPU Idle time(%), add this element in the `<perf-counters>` block:

```
<perf-counter cat="Processor" name="% Idle Time"
instance="_Total"/>
```

5. Save the `config.xml` file.
6. Start the `AppDynamics.Agent.Coordinator` service.

After you enable Performance Counter metrics, they display under the Custom Metrics tree in the Metric Browser.

### Sample .NET Machine Agent Configuration with Performance Counters

```
<machine-agent>
 <!-- Additional machine level Performance Counters -->
 <perf-counters>
 <perf-counter cat="Processor" name="% Idle Time" instance="_Total"/>
 <!-- Perf counter with no instance name -->
 <perf-counter cat="Memory" name="Available MBytes" instance="" />
 </perf-counters>
</machine-agent>
```

### Enable Correlation for .NET Remoting

#### Related pages:

- [.NET Backend Detection](#)
- [Remote Services](#)

Developers use [.NET remoting](#) to build distributed applications that share objects across processes or across application domains running in the same process. AppDynamics disables correlation for .NET remoting functions by default.

### Instrument Applications that Use .NET Remoting

You can configure the .NET Agent to discover .NET remoting entry and exit points.

1. Open the `config.xml` file for editing as administrator. See 'Where to Configure Agent Properties' on [Administer the .NET Agent](#)
2. Copy the code block below to a child element of the Machine Agent element. See [.NET Agent Configuration Properties](#)

```
<instrumentation>
 <instrumentor name="RemotingMscorlibEntryInstrumentor" enabled="true"/>
 <instrumentor name="RemotingExitInstrumentor" enabled="true"/>
</instrumentation>
```

For example:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
 ...
 <machine-agent>
 <!--Enable correlation for .NET remoting-->
 <instrumentation>
 <instrumentor name="RemotingMscorlibEntryInstrumentor" enabled="true"/>
 <instrumentor name="RemotingExitInstrumentor" enabled="true"/>
 </instrumentation>
 </machine-agent>
</appdynamics-agent>
```

```

 </instrumentation>
 </machine-agent>
 ...
</appdynamics-agent>

```

3. Save the `config.xml` file.
4. Restart the `AppDynamics.Agent.Coordinator` service.
5. Restart instrumented applications for your changes to take effect.

If the agent does not discover the entry points after configuration, [specify an agent trigger](#).

### Specify an Agent Trigger

.NET remoting entry point functions execute in low-level .NET libraries that may not trigger automatic agent instrumentation. If the agent does not discover the .NET remoting entry points after configuration you can specify a function that triggers the agent to begin instrumentation.

1. Identify a function to trigger the agent to begin instrumentation. The function can be any function that executes as part of the application process.

For example, consider the following code for a `MovieTicket` remoting object. In this case, use the function `GetTicketStatus` to trigger the agent.

```

using System;
namespace MovieGoer
{
 public class MovieTicket : MarshalByRefObject
 {
 public MovieTicket()
 {
 }
 public string GetTicketStatus(string stringToPrint)
 {
 return String.Format("Enquiry for {0} -- Sending back status: {1}",
 stringToPrint, "Ticket Confirmed");
 }
 }
}

```

2. Edit the `config.xml` file as an administrator. See [Administer the .NET Agent](#).
3. Update the Instrumentation element to include the `AgentTriggerInstrumentor` attribute. See [.NET Agent Configuration Properties](#).

```

<instrumentation>
 <instrumentor name="AgentTriggerInstrumentor" enabled="true" args="" />
 <instrumentor name="RemotingMscorlibEntryInstrumentor" enabled="true"/>
 <instrumentor name="RemotingExitInstrumentor" enabled="true"/>
</instrumentation>

```

4. Set the `AgentTriggerInstrumentor` `args` value to the name of the trigger function, using information in the code block in step 1. The `args` value should be formatted as follows: `namespace.public_class.public_string`.

For example:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
...
 <machine-agent>
 <!--Enable correlation for .NET remoting-->
 <instrumentation>
 <instrumentor name="AgentTriggerInstrumentor" enabled="true" args="MovieGoer.MovieTicket.GetTicketStatus" />
 <instrumentor name="RemotingMscorlibEntryInstrumentor" enabled="true"/>
 <instrumentor name="RemotingExitInstrumentor" enabled="true"/>
 </instrumentation>
 </machine-agent>
...
</appdynamics-agent>
```

5. Save the `config.xml` file.
6. Restart instrumented applications for your changes to take effect.

## Thread Correlation for .NET

### Related pages:

- [Configure Backend Detection for .NET](#)
- [Remote Services](#)

By default, the AppDynamics .NET Agent enables multi-threaded correlation for these patterns on the Common Language Runtime (CLR)  $\geq 4.x$ :

- `Task.Start`
- `Task.Run`
- `TaskFactory.StartNew`

The .NET Agent also supports thread correlation for the following patterns which are disabled by default:

- `Thread.Start` on the CLR 2.x and CLR 4.x
- `ThreadPool.QueueUserWorkItem` on the CLR 2.x and CLR 4.x

For AppDynamics  $< 4.3$ , for the .NET Agent, you did not need to configure correlation for `ThreadPool.QueueUserWorkItem` for the CLR 4 in the `config.xml` file. If you explicitly call `ThreadPool.QueueUserWorkItem` for the CLR 4, when you upgrade to the .NET Agent 4.5 from an earlier version, you must enable the instrumentor for `ThreadPool.QueueUserWorkItem` on the CLR 4 in the `config.xml` file.

## Configure Thread Correlation for .NET

Configure all instrumentation settings for the .NET Agent in the `config.xml` file. See [Administer the .NET Agent](#)

1. Open the `config.xml` file for editing as an administrator. See [Administer the .NET Agent](#).
2. Copy the code block below to a child element of the Machine Agent element. See [Machine Agent Element](#).

```
<instrumentation>
 <instrumentor name="ThreadCorrelationThreadPoolCLR2Instrumentor" enabled="true"/>
 <instrumentor name="ThreadCorrelationThreadPoolCLR4Instrumentor" enabled="true"/>
 <instrumentor name="ThreadStartCLR2Instrumentor" enabled="true"/>
 <instrumentor name="ThreadStartCLR4Instrumentor" enabled="true"/>
</instrumentation>
```

For example:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
...
 <machine-agent>
 <!--Enable thread correlation-->
 <instrumentation>
 <instrumentor name="ThreadCorrelationThreadPoolCLR2Instrumentor" enabled="true"/>
 <instrumentor name="ThreadCorrelationThreadPoolCLR4Instrumentor" enabled="true"/>
 <instrumentor name="ThreadStartCLR2Instrumentor" enabled="true"/>
 <instrumentor name="ThreadStartCLR4Instrumentor" enabled="true"/>
 </instrumentation>
 </machine-agent>
...
</appdynamics-agent>
```

The configuration syntax is `enabled="true"`.

3. Save the `config.xml` file.
4. Restart the `AppDynamics.Agent.Coordinator` service.
5. Restart instrumented applications for your changes to take effect.

## Enable Instrumentation for WCF Data Services

### Related pages:

- [.NET Business Transaction Detection](#)
- [.NET Agent Configuration Properties](#)

This page describes how to configure the AppDynamics .NET Machine agent to enable instrumentation for Windows Communication Foundation (WCF) Data Services including WCF RIA Services for Microsoft LightSwitch.

1. Open the `config.xml` file for editing as administrator. See [Administer the .NET Agent](#).
2. Copy the code block below to a child element of the Machine Agent element. See [.NET Agent Configuration Properties](#).

```
<instrumentation>
 <instrumentor name="WCFDSEntryInstrumentor" enabled="true" />
</instrumentation>
```

For example:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
...
<machine-agent>
 <!--Enable instrumentation for WCF Data Services correlation-->
 <instrumentation>
 <instrumentor name="WCFDSEntryInstrumentor" enabled="true" />
 </instrumentation>
</machine-agent>
...
</appdynamics-agent>
```

The configuration syntax is `enabled="true"` .

3. Save the `config.xml` file.
4. Restart the `AppDynamics.Agent.Coordinator` service.
5. Restart instrumented applications for your changes to take effect.

### Configure Machine Snapshots for .NET

The .NET Machine Agent takes machine snapshots to capture vital system data for Windows and IIS. Use these guidelines to tune the frequency the .NET Machine Agent takes machine snapshots in your environment. See [Machine Snapshots for .NET](#).

### Default Settings and Configuration Considerations

By default, the .NET Machine Agent takes machine snapshots under these conditions:

- Periodic collection: The agent takes one snapshot every 10 minutes.
- Breached thresholds: The .NET Machine Agent takes samples of machine statistics every 10 seconds within a 10-minute window. For each sample, the agent checks the CPU percent usage, the memory percent usage, and the oldest item in the IIS application pool queue. The agent flags a sample as a violation when the current usage meets or exceeds one of these thresholds:
  - CPU at 80% or higher
  - Memory at 80% or higher
  - IIS application pool queue item older than 100 milliseconds

The agent takes a snapshot when it identifies 6 violations of a single type, such as CPU usage, within the window. The agent only takes one snapshot per window for breached thresholds.

With the default window size of ten minutes and the violations per window of six, the sixth violation of a single type triggers a machine snapshot:

The 6th violation in the window triggers a snapshot.

Before you change the machine snapshot settings, determine which configuration options work best for your environment. Use these questions and considerations to help determine your threshold settings:

- What percentage CPU or memory usage might flag the beginnings of an issue in your environment?
- How long is too long for items to wait in the IIS queue?
- Do you expect occasional CPU or memory spikes?
- Are periodic collections every ten minutes frequent enough?
- Make sure the value for violations is larger than the number of samples per window.

For example, if you decrease the window size to 60 seconds and take six samples per window, the agent takes samples at the same frequency as the default settings, once every 10 seconds. However, you are likely to get more snapshots because the agent only takes one snapshot per window. If you set the violations per window to five, the agent takes a snapshot any time half the samples in the window violate a specific threshold. See [.NET Agent Configuration Properties](#).

### Configure Machine Snapshots for the .NET Machine Agent

Configure all instrumentation settings for the .NET Machine Agent in the config.xml file:

1. Open the `config.xml` file for editing as an administrator. See [Administer the .NET Agent](#).
2. Copy the code block below to a child element of the AppDynamics Agent element. See [AppDynamics Agent Element](#).

```
<machine-agent>
 <machine-snapshot enabled="true" window-size="600" samples-per-window="60"
 violations-per-window="6" max-percent-cpu="80" max-percent-memory="80" max-queue-item-
 age="100" periodic-collection="600" />
</machine-agent>
```

- i** If you have already customized the .NET Machine Agent, only copy the `machine-snapshot` element and paste it as a child of the `machine-agent` element.
3. Edit the values for the `machine-snapshot` element attributes:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
...
 <machine-agent>
 <!--Configure machine snapshots-->
 <machine-snapshot enabled="true" window-size="60" samples-per-window="10" violations-per-window="5" max-percent-cpu="80" max-percent-memory="80" max-queue-item-age="100" periodic-collection="600"/>
 </machine-agent>
...
</appdynamics-agent>
```

4. Save the `config.xml` file.
5. Restart the `AppDynamics.Agent.Coordinator` service.

### Configure Runtime Reinstrumentation for .NET

By default, you must restart your monitored application after you create or update:

- POCO transaction detection entry points
- POCO service endpoints
- Custom exit points
- Method invocation and HTTP data collectors
- Information points

When you enable runtime reinstrumentation, the .NET Agent detects the types of instrumentation changes and automatically requests the CLR to recompile the affected code. With runtime reinstrumentation enabled, you do not need to restart your application for the instrumentation changes to take effect. See [Administer the .NET Agent](#).

### Requirements

Runtime reinstrumentation works for .NET Framework  $\geq$  4.5.2. To verify the framework version in the `web.config` file of your application, enter:

```
<system.web>
 <compilation targetFramework="4.5.2" />
 <httpRuntime targetFramework="4.5.2" />
</system.web>
```

### Configure Runtime Reinstrumentation for .NET

Configure all instrumentation settings for the .NET Agent in the `config.xml` file:

1. Open the `config.xml` file for editing as an administrator. See [Administer the .NET Agent](#).
2. Copy the code block below to a child element of the `app-agents` element. See [Default Profiler Element](#).

```
<profiler>
```

```
<runtime-reinstrumentation enabled="true" interval="60000" />
</profiler>
```

For example:

```
<?xml version="1.0" encoding="utf-8"?>
<appdynamics-agent xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema">
...
<app-agents>
 <profiler>
 <!-- Enable runtime instrumentation -->
 <runtime-reinstrumentation enabled="true" interval="60000"/>
 </profiler>
...
</app-agents>
</appdynamics-agent>
```

3. If appropriate configure the `runtime-reinstrumentation` options:

- `enabled` : Set to `true` to enable runtime instrumentation. Default: `false`
- `interval` : The frequency the agent checks for configuration updates in milliseconds. Default: `60000` .

**i** Because runtime instrumentation adds a small amount of system overhead, AppDynamics recommends a minimum interval of 1 minute or `60000` milliseconds. The .NET Agent checks for configuration updates every minute, so it may take up to 2 minutes for instrumentation to take effect with the default setting of `60000` milliseconds.

4. Save the `config.xml` file.
5. Restart the `AppDynamics.Agent.Coordinator` service.
6. Restart instrumented applications for your changes to take effect.

### Filter Sensitive Data with the .NET Agent

By default, the AppDynamics .NET Agent sends transaction data to the Controller that your organization may classify as privileged information. Although this data is useful for diagnosis and troubleshooting, security considerations may require you to filter certain information from view in the Controller. You can use sensitive data filters to exclude environment variables or URLs in the Controller or information in snapshot details.

Sensitive Data Filters are available for the .NET Windows and Linux Agents (as of 21.4).

#### Add a Sensitive Data Filter

To instrument sensitive data filters, you edit the .NET Agent configuration file. See [Administer the .NET Agent](#).

1. Edit a versioned agent configuration file:
  - Full .NET Agent: `config.xml`
  - Standalone Agent: `config.json`
2. Add a `sensitive-data-filter` element as a child of the Sensitive Data Filters element using one of these attributes:

```
<!-- Filter environment variable values sent to controller -->
<sensitive-data-filters>
 <sensitive-data-filter applies-to="environment-variables,system-properties,http-headers,http-cookies" match-type="EQUALS|CONTAINS|STARTSWITH|ENDSWITH" match-pattern=""/>
</sensitive-data-filters>
```

#### Sensitive Data Filter Attributes:

- Specify a comma-separated list in the `applies-to` attribute to filter `environment-variables`, `system-properties`, or data collectors (`http-headers`, `http-cookies`)
- Set the `match-type` attribute as:
  - EQUALS
  - CONTAINS
  - STARTSWITH
  - ENDSWITH
- Specify a string to match for the `match-pattern` attribute. String matches are case insensitive. The pattern matches the environment variable and system property names, not values.

#### 3. Restart the .NET Agent and application.

In this example, the .NET Agent checks for environment variables beginning with the string "DB\_". The Controller displays the values of matching environment variables and system properties as asterisks. For example, an environment variable `DB_USER` is obfuscated and replaced with an asterisk in the Controller.

Example config.xml file:

```
</sensitive-data-filters>
 <sensitive-data-filter applies-to="environment-variables,system-properties" match-type="STARTSWITH" match-pattern="DB_"/>
</sensitive-data-filters>
```

Example config.json file:

```
sensitive-data-filters: [
{
 "applies-to": "environment-variables, system-properties",
 "match-type": "STARTSWITH",
 "match-pattern": "DB_"
}
]
```

### Add a Sensitive URL Filter

You can use sensitive URL filters to configure the agent to obfuscate sensitive information in the URLs in the Controller.

To instrument sensitive URL filters, you edit the .NET Agent configuration file. See [Administer the .NET Agent](#).

#### 1. Edit a versioned agent configuration file:

- Full .NET Agent: `config.xml`
- Standalone Agent: `config.json`

2. Add attributes to the `sensitive-url-filters` element:

```
<sensitive-url-filters>
 <sensitive-url-filter delimiter=""
 segment=""
 match-filter="EQUALS | INLIST | STARTSWITH | ENDSWITH | CONTAINS | REGEX |
NOT_EMPTY"
 match-pattern="pattern"
 param-pattern=""/>
</sensitive-url-filters>
```

**Sensitive URL Filter Attributes:**

- `delimiter` : Specify the character that you want to use as URL segment endpoints. The agent splices the URL at each delimiter instance to create the segments. For HTTP, use the forward-slash character "/". In the case of a forward slash, the agent does not split on the slashes immediately following the protocol. For example, " <https://myapp.example.com/> " constitutes a single segment. By default, the delimiter is "/".
- `segment` : Specify a comma-separated list to indicate the segments that you want the agent to filter. Segment numbering starts from 1.
- `match-pattern` : Specify the string that you want to be filtered by the `match-filter` .
- `param-pattern` : Specify the regular expression matching the query parameters to filter.

For example, this configuration splits the URL on the "/" character and masks the second segment, and the param-pattern in the third segment of the URL. In this example, the segmentation and obfuscation apply only to URLs containing " myapp ".

```
<!-- Filter URL/URI segments and query parameters -->
<sensitive-url-filters>
 <sensitive-url-filter delimiter="/"
 segment="2"
 match-filter="CONTAINS"
 match-pattern="myapp"
 param-pattern="[a-z]+"/>
</sensitive-url-filters>
```

If you do not use any values for the query parameters, the Controller does not mask any query parameters in the URL.

The exit call to `https://myapp.example.com/sensitive/data?first_name=abc&last_name=xyz` break s down to three segments:

- "https://myapp.example.com"
- "sensitive"
- "data?first\_name=abc&last\_name=xyz"

The Controller shows the masked values of the URL and the param-pattern displays `https://myapp.example.com/*****/data?first_name=***&last_name=***` in the snapshot details.

**Add a Sensitive Message Filter**

You can use the `sensitive-message-filters` element to obfuscate sensitive information contained within text messages collected from exception messages.

1. Edit a versioned agent configuration file.
2. Add attributes to the `sensitive-message-filters` element:

```
<Sensitive-message-filters>
 <Sensitive-message-filter message-type="all"
 match-type="EQUALS|CONTAINS|STARTSWITH|ENDSWITH|REGEX"
 match-pattern="CASESENSITIVE_PATTERN"
 redaction-regex="SENSITIVE_INFO_REGEX_GROUP"/>
</Sensitive-message-filters>
```

#### Sensitive Message Filter Attributes:

- `message-type` : Specify `all`
- `match-type` : Specify the type of match that should be used to opt-in messages for redaction
- `match-pattern` : Specify the pattern that, when matched, opts the message in for redaction
- `redaction-regex` : Specify a regular expression identifying data that should be redacted from the opted-in messages

This example filters out a test where `match-pattern` contains `"Sensitive"`.

```
<Sensitive-message-filters>
 <Sensitive-message-filter message-type="all"
 match-type="CONTAINS"
 match-pattern="Sensitive"
 redaction-regex="[0-9]+"/>
</Sensitive-message-filters>
```

## Manage Configuration for .NET

### Related pages:

- [Administer the .NET Agent](#)
- [.NET Agent Configuration Properties](#)

Highly-scaled environments frequently contain multiple machines that run the same .NET applications and therefore use the same AppDynamics .NET Agent configuration. Manual configuration updates to several machines can be tedious and error-prone.

Use the Config Management tool in the AppDynamics Controller to upload and manage .NET Agent `config.xml` files. By default the .NET Agent checks for configuration updates from the Controller every minute. Use the Config Management tool to assign configurations to machines where the .NET Agent is running.

Click **Settings > AppDynamics Agents > Config Management** to manage all the .NET Agent configurations files for your machines.

### Requirements

- Membership in a role with 'Administer user, groups, roles, authentication, and so on' account level permission.
- A valid `config.xml` configuration file. The Config Management tool does not validate the `config.xml` file.
- .NET Agent >= 4.1 installed on machines where you plan to deploy configuration.

.NET Agents deployed on Azure Cloud Services using the AppDynamics NuGet package do not register for Config Management because web role and worker role machine names are not always unique. Duplicate machine names may lead to unexpected consequences.

## Identify the Configuration File

To start managing your configurations in the Controller, identify a configuration file or set of configuration files to upload. If you are not familiar with .NET Agent configuration, AppDynamics recommends you use the Agent Configuration Utility on each machine to configure the agent. See [Administer the .NET Agent](#) and [Configure the .NET Agent](#).

For a full list of configuration properties, see [.NET Agent Configuration Properties](#).

- Use `config.xml` files configured with the AppDynamics Agent Configuration Utility to help ensure the XML is valid.
- Use the `config.xml` file from a previously-configured machine as a template for similar machines that need the exact same configuration.

## Import Configuration

The Import Config dialog enables you to upload a `config.xml` file to the Controller, and specify a unique name for the configuration.

- Use a naming convention that helps you identify the type of machine for the configuration.
- Consider using a date or version scheme for the configuration name.
- Click a configuration, then click **Edit Config** to modify the configuration name.
- Double-click a config to display the XML. You can copy the XML, but you cannot modify it.

## Assign Configuration to Machines

The Config Management tool enables you to assign machines to a configuration, or change the configuration from one to another. After you assign the configuration in the Controller, the .NET Agent automatically downloads the configuration file.

- If a machine does not have a managed configuration, the Config Management tool displays it following `Machine with no assigned templates`.

If you select the **Register Machine with No Application** option on the Application Configuration pane in the AppDynamics Agent Configuration utility, the Controller lists the machine in the **Machines** section with no assigned templates.

- Drag and drop to assign a machine to a configuration.
- The .NET Agent checks for updated configurations every minute.
- The agent backs up the old `config.xml` file as `config-<date>.xml` in the backup subdirectory of the `econfig` directory. See [.NET Agent Directory Structure](#).
- If the agent detects an invalid `config.xml` file, it does not apply the managed configuration and it raises an Agent Configuration Error event in the Controller. The event summary indicates the affected tiers and nodes.
- Regardless of the Controller connection information in the managed configuration, the agent always retains existing Controller connection information.
- After the agent receives and validates the assigned configuration, any changes take effect after the app pools recycle or IIS restarts. You must restart Windows services or standalone applications. It is unnecessary to restart the AppDynamics Agent Coordinator service.

## Opt Out of Configuration Management

To configure an agent so that it does not receive configuration files from the Controller, set the `enable_config_deployment` Controller attribute to `false` in the `config.xml` file. See [.NET Agent Configuration Properties](#).

For example:

```
<controller host="mycontroller.saas.appdynamics.com" port="443"
ssl="true" enable_config_deployment="false">
```

## Restore an Old Configuration

If you mistakenly assign a configuration, follow this procedure to restore a previous version of the config.xml:

1. On the Config Management pane, drag the machine from its currently assigned configuration to **Machine with no assigned templates**.
2. On the machine itself, rename the existing configuration file, `config.xml`, to a name such as `config.old.xml`.
3. Copy the backup config file from the Backup subdirectory to the `Config` directory. Backup files are named using this format: `config-<date>.xml`.
4. Rename the backup config file to `config.xml`.
5. Optionally edit the `config.xml` to opt out of Config Management.
6. Restart the AppDynamics Agent Coordinator service.
7. Restart Windows services, instrumented Windows services, and instrumented standalone applications.

## .NET Agent on Windows Logging

### Related pages:

- [Agent Log Files](#)
- [Troubleshoot Agentless Analytics Issues](#)
- [Troubleshoot .NET Agent Issues](#)

This page provides an overview of logging for the .NET Agent on Windows. The .NET Agent hosts log files in the `%ProgramData%\AppDynamics\DotNetAgent\Logs` directory. To learn how logs are organized into sets that rollover, see [Agent Log Files](#).

### Log File Size

Within a set, the first file for the agent log can reach 5 MB. This file never gets deleted because it contains valuable information about the context in which the agent was started.

Each of the remaining logs in the set can reach a maximum of 5 MB.

To allow for several restarts and all possible logs that could be generated (.NET Agent, Business Transaction, and REST), the maximum number of rollover logs is five. The maximum size per set is  $5 \text{ MB} + (5 \times 5 \text{ MB}) = 30 \text{ MB}$ .

Some log files, such as `SamplingInfo` and `Winston` are configured differently and can be 9 MB in size with only two archive files.

Profiler logging is different; a logging framework called Boost logs to the Profiler folder and creates one file per instrumented process. While Boost uses the archive files and max size, it has two other limits: one to limit the number of files in the Profiler folder (defaults to 50) and the other to limit the max size (defaults to 30 MB).

---

## Control the .NET Agent Log Files

 When you upgrade the .NET Agent to versions  $\geq 22.6.0$ , ensure that the version of the configuration contains the property, `concurrentWrites="true"`.

You can control the .Net Agent log files by changing the `<target>` settings in the `AppDynamicsAgentLog.config` file found in the .NET Agent installation directory.

```

<targets async="true">
 <target name="logfile" xsi:type="File" concurrentWrites="true" archiveAboveSize="5000000"
 maxArchiveFiles="5" createDirs="true" fileName="AgentLog.txt" layout="${longdate} $
 {processid} ${processname} ${appdomainid} ${threadid} ${level} ${logger:shortName=True} $
 {message}"/>
 <target name="RESTHeartbeat" xsi:type="File" concurrentWrites="true" archiveAboveSize="50
 00000" maxArchiveFiles="5" createDirs="true" fileName="RESTHeartbeat.txt" layout="${longdate}
 ${processid} ${processname} ${appdomainid} ${threadid} ${level} ${logger:shortName=True} $
 {message}"/>
 <target name="RESTfile" xsi:type="File" concurrentWrites="true" archiveAboveSize="5000000
 " maxArchiveFiles="5" createDirs="true" fileName="RESTCommunications.txt" layout="${longdate}
 ${processid} ${processname} ${appdomainid} ${threadid} ${level} ${logger:shortName=True} $
 {message}"/>
 <target name="warnfile" xsi:type="File" concurrentWrites="true" archiveAboveSize="5000000
 " maxArchiveFiles="5" createDirs="true" fileName="WarnLog.txt" layout="${longdate} $
 {processid} ${processname} ${appdomainid} ${threadid} ${level} ${logger:shortName=True} $
 {message}"/>
 <target name="bcifile" xsi:type="File" concurrentWrites="true" archiveAboveSize="5000000"
 maxArchiveFiles="5" createDirs="true" fileName="ByteCode.txt" layout="${longdate} $
 {processid} ${processname} ${appdomainid} ${threadid} ${level} ${logger:shortName=True} $
 {message}"/>
 <target name="btlog" xsi:type="File" concurrentWrites="true" archiveAboveSize="5000000"
 maxArchiveFiles="5" createDirs="true" fileName="BusinessTransactionsLog.txt" layout="$
 {longdate} ${processid} ${processname} ${appdomainid} ${threadid} ${level} $
 {logger:shortName=True} ${message}"/>
 <target name="CoordinatorRecovery" xsi:type="File" concurrentWrites="true"
 archiveAboveSize="2000000" maxArchiveFiles="2" createDirs="true" fileName="CoordinatorRecove
 ryLog.txt" layout="${longdate} ${processid} ${processname} ${appdomainid} ${threadid} $
 {level} ${logger:shortName=True} ${message}"/>
 <target name="Winston" xsi:type="File" concurrentWrites="true" archiveAboveSize="9000000"
 maxArchiveFiles="2" createDirs="true" fileName="Winston.txt" layout="${longdate} $
 {processid} ${appdomainid} ${threadid} ${message}"/>
 <target name="SamplingInfo" xsi:type="File" concurrentWrites="true" archiveAboveSize="900
 0000" maxArchiveFiles="2" createDirs="true" fileName="SamplingInfo.txt" layout="${longdate} $
 {processid} ${appdomainid} ${threadid} ${level} ${logger:shortName=True} ${message}" />
 <target name="Analytics" xsi:type="File" concurrentWrites="true" archiveAboveSize="900000
 0" maxArchiveFiles="2" createDirs="true" fileName="Analytics.txt" layout="${longdate} $
 {processid} ${appdomainid} ${threadid} ${message}" />
 <target name="Profiler" xsi:type="File" concurrentWrites="true" archiveAboveSize="1200000
 0" maxArchiveFiles="2" createDirs="true" fileName="Profiler" layout="${longdate} ${processid}
 ${appdomainid} ${threadid} ${level} ${logger:shortName=True} ${message}" />
</targets>

```

## Control the .NET Agent Loggers

You control the logging level for the .NET Agent by changing the value of the `minlevel` parameter in the `AppDynamicsAgentLog.config` file found in the .NET Agent installation directory.

The log configuration is per server. The .NET Machine Agent and the .NET Agent read the same configuration file and write to the same set of output files.

```

<logger name="com.appdynamics.REST.HeartBeatLog" minlevel="Info" writeTo="RESTHeartbeat" final="
true" />
 <logger name="*" minlevel="Warn" writeTo="warnfile" />
 <logger name="com.appdynamics.BusinessTransactions" minlevel="Info" writeTo="btlog" final="
true" />
 <logger name="com.appdynamics.bci.*" minlevel="Info" writeTo="bcifile" final="true" />
 <logger name="com.appdynamics.REST.*" minlevel="Info" writeTo="RESTfile" final="true" />
 <logger name="AppDynamics.Agent.Coordinator.Recovery.*" minlevel="Info" writeTo="Coordina
torRecovery" final="true" />
 <logger name="com.appdynamics.METRICS.MetricSender" minlevel="Info" writeTo="RESTfile"
final="true" />
 <logger name="AppDynamics.Winston.*" minlevel="Info" writeTo="Winston" final="true" />
 <logger name="com.appdynamics.tm.AFastBackendResolver" minlevel="Warn" writeTo="logfile"
final="true" />
 <logger name="com.appdynamics.ManagedAgentAPI.DumpStats" minlevel="Trace" writeTo="Sampli
ngInfo" final="true" />
 <logger name="com.appdynamics.ee.service.analytics.Analytics" minlevel="Info" writeTo="An
alytics" final="true" />
 <logger name="com.appdynamics.profiler.*" minlevel="Info" writeTo="Profiler" />
 <logger name="*" minlevel="Info" writeTo="logfile" />

```

## .NET Microservices Agent

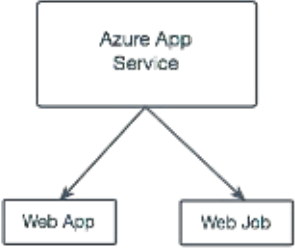

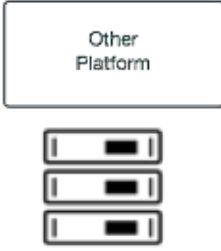

To monitor standalone applications on different platforms, install the .NET *microservices agent* on the solution of your choice. Where and how you install the .NET microservices agent depends on your platform—for example, Azure App Service or Service Fabric—and what applications you want to monitor. For example, you can now monitor applications developed using .NET Core for Windows using the .NET microservices agent.

**i** You need the default `AppDynamicsConfig.json` file in one of the following .NET Agent probing paths: `<appfolder>\<appdll>.AppDynamicsConfig.json`, `<appfolder>\AppDynamicsConfig.json`, or `<profilerpath>\AppDynamicsConfig.json` to ensure that the agent works. The application `dll` name should be without a `.dll` or `.exe` extension. Having the `AppDynamicsConfig.json` file placed in an application folder signals to the profiler that it needs to monitor the application. This limitation is put into place to avoid multiple applications from being instrumented on a Windows machine. Currently, we do not have this limitation on Linux.

## Before You Begin

To accurately determine the steps you need to take to deploy a .NET microservices agent to your solution, review this decision matrix to determine the appropriate path for your platform and applications.

**Where is your application hosted?**

			
<p>For .NET Agent Deployment</p> <p>Windows Support Only</p> <p>Web Job does not require any specific configuration; it is instrumented at the Web App level.</p> <p>If application was created on .NET Core, use NuGet package <code>Azure.AppService.Windows</code>.</p> <p>If application was created on .NET Framework, and you do not need to modify the application source, use the <code>AppDynamics Site Extension</code>.</p> <p>If application was created on .NET Framework, and you need to modify the application source, use NuGet package <code>AppDynamics.Agent.Azure.AppService.Windows</code>.</p>	<p>For .NET Agent Deployment</p> <p>Use the NuGet package <code>AppDynamics.Agent.Azure.CloudServices</code>.</p>	<p>For .NET Agent Deployment</p> <p>See the AppDynamics Service Fabric documentation for instructions.</p>	<p>For .NET Agent Deployment</p> <p>If application was created on .NET Framework, MSI-only installation</p> <p>If application was created on .NET Core:</p> <p>Windows Support Only</p> <p>If you need to modify the application source, use the NuGet Package <code>AppDynamics.Agent.Windows</code>, then set your environment variables.</p> <p>If you do not need to modify the application source, download the distribution package and extract the files, then set your environment variables.</p>

**Install the .NET Microservices Agent**

Review this table to determine which NuGet package you should use to install the .NET microservices agent. For details about managing NuGet packages, see the [documentation](#) for your version of Visual Studio.

<p><code>AppDynamics.Agent.Distrib.Micro.Windows</code></p>	<p>AppDynamics NuGet package for .NET. This package <i>should not</i> be installed directly and is intended for download and file distribution. This package is used for Azure Service Fabric deployments. See <a href="#">Install AppDynamics for Azure Service Fabric</a>.</p>
<p><code>AppDynamics.Agent.Windows</code></p>	<p>AppDynamics .NET Core microservices agent for Windows. Recommended for standalone installations. See <a href="#">Install the .NET Core Microservices Agent for Windows</a>.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> This package does not support .NET Framework, only .NET Core for Windows.</p> </div>
<p><code>AppDynamics.Agent.Azure.CloudServices</code></p>	<p>AppDynamics .NET agent for Azure Cloud Services. See <a href="#">Install AppDynamics for Azure Cloud Services</a>.</p>

<p>AppDynamics.Agent.Azure.AppService.Windows</p>	<p>AppDynamics .NET microservices agent for Azure App Service. This package is intended for applications deployed to Azure App Service (Azure Web Apps and Azure API Apps). See <a href="#">Install the AppDynamics .NET Microservices Agent</a> and <a href="#">Install AppDynamics for Azure App Service</a>.</p>
---------------------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

## Install the .NET Core Microservices Agent for Windows

To monitor an application executed on Windows, you install the AppDynamics .NET Core microservices agent for Windows to your project. Additionally, you can instrument .NET standalone services or IIS services using the [MSI installer](#). Then, set the environment variables for your Controller.

**i** You need the default `AppDynamicsConfig.json` file in one of the following .NET Agent probing paths: `<appfolder>\<appdll>.AppDynamicsConfig.json`, `<appfolder>\AppDynamicsConfig.json`, or `<profilerpath>\AppDynamicsConfig.json` to ensure that the agent works. The application dll name should be without a `.dll` or `.exe` extension. Having the `AppDynamicsConfig.json` file placed in an application folder signals to the profiler that it needs to monitor the application. This limitation is put into place to avoid multiple applications from being instrumented on a Windows machine. Currently, we do not have this limitation on Linux.

## Install the .NET Core Microservices Agent

Before you install the .NET Core microservices agent, ensure that you have access to the AppDynamics Controller where your application metrics will display.

You can deploy the .NET Core microservices agent using either of these methods:

- Deploy the .NET Core microservices agent during development using IDE and Visual Studio
- Deploy the .NET Core microservices agent separately to different development teams to divide controls, pipelines, and CI/CD processes

### Deploy the .NET Core Microservices Agent During Development

1. Install the `AppDynamics.Agent.Windows` NuGet package in your project. See your IDE documentation.

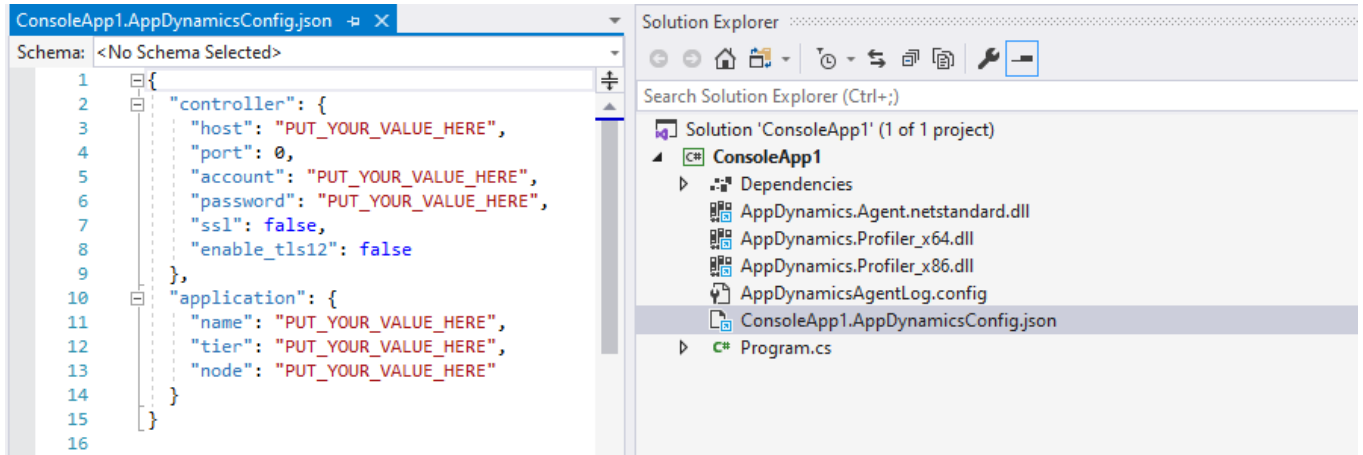

When you install the NuGet package, the `AppDynamicsConfig.json` file is copied to the project's root directory. A link file prefixed with the project name is included as content to the project. All the files are copied to the app's output directory after the build.

2. Set up these environment variables for your system application:

```
CORECLR_ENABLE_PROFILING=1
CORECLR_PROFILER={39AEABC1-56A5-405F-B8E7-C3668490DB4A}
CORECLR_PROFILER_PATH_32=<actual_path>\AppDynamics.Profiler_x86.dll
CORECLR_PROFILER_PATH_64=<actual_path>\AppDynamics.Profiler_x64.dll
```

Where `<actual_path>` is the complete path to the `AppDynamics.Profiler.dll`.

- Open the `AppDynamicsConfig.json` file and update the file with your AppDynamics Controller information.

- Use these options to configure the .NET Agent to connect to the AppDynamics Controller:
  - During development: As shown in the previous screenshot, you can enter your environment variables in the `AppDynamicsConfig.json` file, and save it in source control.
  - During build: Define your `msbuild` parameters or [environment variables](#) that are passed to the `AppDynamicsConfig.json` file at build time. The `AppDynamicsConfig.json` file does not exist at build time, so if you are defining your `msbuild` parameters or environment variables at build time, you will need to ignore it in source control so that the new `AppDynamicsConfig.json` file can be created.
  - During runtime: Enter your [environment variables](#) in Azure.
- Deploy the application.

### Deploy the .NET Core Microservices Agent Separately to Different Development Teams

By using this deployment method, you divide controls, pipelines, and CI/CD processes among different development teams. Additionally, you may encounter a situation where it may not be possible to return to the project solution and add the agent (particularly if the software was developed by a third party).

- From [nuget.org](https://www.nuget.org/packages/AppDynamics.Agent.Distrib.Micro.Windows/), download the NuGet package `AppDynamics.Agent.Distrib.Micro.Windows` from <https://www.nuget.org/packages/AppDynamics.Agent.Distrib.Micro.Windows/>.
- Extract (unzip) the `dlls` and `AppDynamicsConfig.json` configuration file from the Nuget package to a folder.
- Update the `AppDynamicsConfig.json` configuration file as required.
  - Make a copy of the of the `AppDynamicsConfig.json` file and rename it to `<< executable_name >>.AppDynamicsConfig.json`. For example, `<< servicefabricapplicationname >>.AppDynamicsConfig.json`.
  - Copy `AppDynamics.Agent.dll`, `AppDynamics.Profiler_x64.dll`, `AppDynamicsAgentLog.config`, `AppDynamicsConfig.json` from `<< nuget_package >> \content\AppDynamics` and add these files in the solution of each of the service project at the top level, not under any subfolders.
  - Make a copy of `AppDynamicsConfig.json` and rename it to: `<<executable_name>>.AppDynamicsConfig.json`, for example, `<<servicefabricapplicationname>>.AppDynamicsConfig.json`. Put it into the root of each service project.

**i** When you rename the `.json` file to the application name, do not include `.exe` at the end of your application name.

- d. Right-click the files in the AppDynamics sub-folder, and then select **Copy Always**.
- e. Update `<<executable_name>>.AppDynamicsConfig.json` with your configuration information:

```
{
 "controller":
 {
 "host": "",
 "port": 0,
 "account": "",
 "password": ""
 },
 "application":
 {
 "name": ""
 }
}
```

Do not specify node; it will be assigned automatically. Specifying tier is optional because it could be assigned automatically.

4. Set up these environment variables for your system application:

```
CORECLR_ENABLE_PROFILING=1
CORECLR_PROFILER={39AEABC1-56A5-405F-B8E7-C3668490DB4A}
CORECLR_PROFILER_PATH_32=<actual_path>\AppDynamics.Profiler_x86.dll
CORECLR_PROFILER_PATH_64=<actual_path>\AppDynamics.Profiler_x64.dll
```

Where `<actual_path>` is the complete path to the `AppDynamics.Profiler.dll`.

**i** If you use an in-process hosting for IIS, add the property, `<AppDynamicsUseCatchAllConfig>True</AppDynamicsUseCatchAllConfig>` in the csproject. Then, the config will be named `AppDynamicsConfig.json`.

## .NET Agent for Linux

### Related pages:

- [Create an ASP.NET Core web app in Azure](#)
- [Overview of Application Monitoring](#)
- [Business Transactions](#)

You use the AppDynamics .NET Agent for Linux to monitor the performance of .NET Core applications running on Linux OS.

The agent supports these features:

- ASP.NET MVC transactions. See [Name MVC Transactions by Area, Controller, and Action](#).
- ASP.NET WebAPI transactions
- ASP.NET Razor Pages transactions
- HttpClient backend calls
- ADO.NET backend calls such as SqlClient, MySql, SQLite, and PostgreSQL
- EntityFramework
- Upstream and downstream correlation using HTTP

- Snapshot waterfall view with async support
- Redis exit calls
- Detects and monitors calls to an Oracle database

You can run the AppDynamics .NET Agent for Linux on microservice platforms, such as those based on Docker containers and Pivotal Cloud Foundry (PCF). See AppDynamics [Pivotal Cloud Foundry](#) and [.NET Agent for Linux Advanced Configuration Options](#).

The .Net Agent for Linux is supported on AppDynamics Controller  $\geq$  4.4.1. See [.NET Supported Environments](#).

## Install the .NET Agent for Linux

### Related pages:

- [.NET Agent for Linux](#)
- [Create an ASP.NET Core web app in Azure](#)
- [Overview of Application Monitoring](#)
- [Business Transactions](#)

## Getting Started

Before you begin, review these prerequisites:

1. Confirm you have access to a compatible Controller. See [Agent and Controller Tenant Compatibility](#).
2. Confirm the connection settings to the Controller where your agent will report data:
  - If you use a SaaS Controller, AppDynamics sent you the Controller host in your Welcome Email. Use port 443 for HTTPS or port 80 for HTTP.
  - If you use an on-premises Controller, you supplied the host and port during installation.
3. Verify you have access to the machine where the application runs as a user account with privileges to install the agent software and restart the application.
4. Verify that the machine where the application runs can connect to the Controller. Proxies or firewalls on the network between the agent and Controller may require additional configuration.
5. Verify that the application environment meets the requirements on prior to running the agent. See [.NET Supported Environments](#).

## Applications and Licenses Overview

Ensure you have these applications and licenses:

- .NET Core application running on Linux
- .NET license for each .NET Core application running on Linux. See [Observe License Usage](#).

## Binaries Overview

Download the agent binaries from the [AppDynamics Download Site](#) and then extract them from the zip file into the desired folder.

The archive contains these files:

- `AppDynamics.Agent.netstandard.dll`
- `libappdprofiler.so`
- `libappdprofiler_glibc.so`
- `libappdprofiler_musl.so`
- `README.md`

 You must extract all four of the agent binaries from the zip file.

## Deployment

There are two options for starting your deployment using Docker:

- [Create Your Own Image](#), start your agent from scratch
- [Run an Existing Image](#), if you already have the .NET Agent enabled

### Create Your Own Image

You can use the ASP.NET sample application from Microsoft and a Dockerfile to build your own image and get started:

1. Download the [binaries](#).
2. Update the Dockerfile variables to configure the connection to the Controller and your application identity in AppDynamics.
3. Create the Docker image.

This is an example Dockerfile with commented instructions:

```
FROM mcr.microsoft.com/dotnet/core/samples:aspnetapp

Requirements
Have the following files alongside the Dockerfile:
* libappdprofiler.so
* AppDynamics.Agent.netstandard.dll

Instructions
Building image: docker build --rm -t appdynamicstest:latest .
Running container: docker run --rm -p 8000:80 appdynamicstest:latest
Open the application using http://localhost:8000/

Copy agent binaries to the image from current folder
RUN mkdir -p /opt/appdynamics/dotnet
ADD libappdprofiler.so /opt/appdynamics/dotnet/
ADD libappdprofiler_glibc.so /opt/appdynamics/dotnet/
ADD libappdprofiler_musl.so /opt/appdynamics/dotnet/
ADD AppDynamics.Agent.netstandard.dll /opt/appdynamics/dotnet/

Mandatory settings required to attach the agent to the .NET application
ENV CORECLR_PROFILER={57e1aa68-2229-41aa-9931-a6e93bbc64d8} \
 CORECLR_ENABLE_PROFILING=1 \
 CORECLR_PROFILER_PATH=/opt/appdynamics/dotnet/libappdprofiler.so

Configure connection to the controller
ENV APPDYNAMICS_CONTROLLER_HOST_NAME=controller.saas.appdynamics.com
ENV APPDYNAMICS_CONTROLLER_PORT=443
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED=true
ENV APPDYNAMICS_AGENT_ACCOUNT_NAME=account-name
ENV APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=access-key

Configure application identity in AppDynamics
ENV APPDYNAMICS_AGENT_APPLICATION_NAME="My Application"
ENV APPDYNAMICS_AGENT_TIER_NAME="Sample Tier"
ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME=true
```

```
ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX="Instance"

It is possible to configure .NET agent using AppDynamicsConfig.json configuration file
instead of environment variables
ADD AppDynamicsConfig.json /opt/appdynamics/dotnet/
```

### Alpine OS:

Applications running on Alpine require an additional mandatory environment variable, `LD_LIBRARY_PATH`, such as `ENV LD_LIBRARY_PATH=/opt/appdynamics/ dotnet`.

## Run an Existing Image

You can run an existing image with an agent enabled. This is the simplest way to start because it does not require building a new image:

1. Download the [aforementioned binaries](#).
2. Update the Docker command variables to configure the connection to the Controller and your application identity in AppDynamics.
3. Run the command in the desired folder where you extracted the agent binaries from the zip file. You can replace `$(pwd)` in the command with this folder.

This example runs the sample application. It assumes you have AppDynamics binaries in the current directory:

### Example command to run existing image with .NET agent enabled

```
docker run \
-p 8000:80 \
-e CORECLR_PROFILER={57e1aa68-2229-41aa-9931-a6e93bbc64d8} \
-e CORECLR_ENABLE_PROFILING=1 \
-e CORECLR_PROFILER_PATH=/opt/appdynamics/dotnet/libappdprofiler.so \
-e APPDYNAMICS_CONTROLLER_HOST_NAME=controller.saas.appdynamics.com \
-e APPDYNAMICS_CONTROLLER_PORT=443 \
-e APPDYNAMICS_CONTROLLER_SSL_ENABLED=true \
-e APPDYNAMICS_AGENT_ACCOUNT_NAME=account-name \
-e APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=access-key \
-e APPDYNAMICS_AGENT_APPLICATION_NAME="My Application" \
-e APPDYNAMICS_AGENT_TIER_NAME="Sample Tier" \
-e APPDYNAMICS_AGENT_REUSE_NODE_NAME=true \
-e APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX="Instance" \
-v "$(pwd)":/opt/appdynamics/dotnet/ \
mcr.microsoft.com/dotnet/core/samples:aspnetapp
```

### On Alpine OS

Applications running on Alpine require an additional mandatory environment variable, `LD_LIBRARY_PATH`, such as `-e LD_LIBRARY_PATH=/opt/appdynamics/ dotnet \`

---

The command mounts agent files as a volume and sets environment variables required for the agent to attach.

### Startup Flow

During the application startup, the AppDynamics agent writes messages to the console as well as the application and .NET framework.

This .NET Agent startup console output indicates proper agent initialization:

```
appd.agent.profiler(Info): ...
```

See [.NET Agent for Linux Troubleshooting](#).

### .NET Agent for Linux Container Installation

You can install the .NET Agent for Linux in container environments, such as Docker and Kubernetes.

#### Overview of Container Installation

To learn more about installation AppDynamics agents in containers, see:

- [Container Platforms](#)
- [Install the .NET Agent for Linux in Containers](#)

#### Install the .NET Agent in Containers

To install the .NET Agent in containers, see:

- [Prepare to Install the .NET Agent in Containers](#)
- [Install the .NET Agent in Containers](#)

#### Prepare to Install the .NET Agent for Linux in Containers

##### Related pages:

- [.NET Agent for Linux](#)
- [Install the .NET Agent for Linux in Containers](#)
- [Create an ASP.NET Core web app in Azure](#)
- [Overview of Application Monitoring](#)
- [Business Transactions](#)

Before you install the .NET Agent for Linux in a container environment, make sure you meet the requirements and complete the steps listed on this page.

#### General Requirements

##### Verify that:

- The machine where the application runs can connect to the Controller. Proxies or firewalls on the network between the agent and Controller may require additional configuration.
- The application environment meets the requirements on [.NET Supported Environments](#).

##### Ensure you have these applications and licenses:

- .NET Core application running on Linux
- .NET license for each .NET Core application running on Linux. See [Observe License Usage](#).

#### Controller Requirements

Confirm you meet the following Controller requirements:

- Access to a compatible Controller. See [Agent and Controller Tenant Compatibility](#) for details.
- Confirm the connection settings to the Controller where your agent reports data:
  - SaaS Controllers: AppDynamics sent you the Controller host in your Welcome Email. Use port 443 for HTTPS or port 80 for HTTP.
  - On-premises Controller: you supplied the host and port at install time.

## .NET Agent Environment Variables

Applications running in an Alpine Linux container require an additional mandatory environment variable, `LD_LIBRARY_PATH`, which can be defined in the Dockerfile as follows:

```
ENV LD_LIBRARY_PATH=/opt/appdynamics/dotnet
```

See the `AppDynamicsConfig.json` file example on [.NET Agent for Linux Advanced Configuration Options](#) for more details.

## Install the .NET Agent for Linux in Containers

This page explains how to install the .NET Agent for Linux in a Docker or Kubernetes containerized environment. There are three ways to install the .NET Agent for Linux with containers:

- [Use Auto-Instrumentation](#)
- [Use Init Containers](#)
- [Use a Dockerfile](#)

### Use Auto-Instrumentation

**i** This scenario applies to containers running in Kubernetes where the Cluster Agent is installed.

This option uses the Auto-Instrumentation feature of the Cluster Agent. It is the recommended option because it offers the highest level of automation and the simplest operational experience for instrumenting .NET applications in a Kubernetes cluster.

To get started, see [Auto-Instrument Applications with the Cluster Agent](#).

### Use Init Containers

**i** Init container installation requires a Kubernetes environment.

You can use Kubernetes init containers to instrument the .NET Agent. In this method, the init container copies the agent binaries into the application container at runtime. The deployment spec used by the application references two containers:

- Application container based on an image that does not contain any .NET Agent binaries
- Second init container based on an image that only contains the .NET Agent binaries.

The deployment spec is updated to reference these two containers and copy the agent binaries from the init container to the application container at deployment time. Once the copy is performed, the init container terminates.

To use init containers to copy the .NET Agent for Linux binaries, perform these steps:

1. [Build the .NET Core Application Image](#)

2. [Build the .NET Agent for Linux Init Container Image](#)
3. [Add the Init Container to the Deployment Spec](#)
4. [Set the .NET Agent for Linux Environment Variables](#)
5. [Set the APPDYNAMICS\\_AGENT\\_UNIQUE\\_HOST\\_ID Environment Variable](#)
6. [Copy the AppDynamicsConfig.json File to the Container](#)
7. [\(On-Premises Controller Only\) Copy the Controller Certs to the Container](#)
8. [Example Configuration for Using an Init Container](#)

### Build the .NET Core Application Image

Build a .NET Core application image. Do not include the .NET Agent for Linux binaries.

### Build the .NET Agent for Linux Init Container Image

Build the .NET Agent for Linux image separately from the application image. You can reuse this image across multiple .NET Core application deployments.

Alternatively, the init container can reference a pre-built image from AppDynamics on [Docker Hub](#).

### Add the Init Container to the Deployment Spec

Edit the deployment spec to add the required sections that allow you to copy the agent binaries from the init container to the application image.

The following snippet from a deployment spec shows the required `volumes`, `volumeMounts`, and `initContainers` definitions. The code example assumes the .NET Core application image is published to `dotnet-samples:aspnetapp` and the init container image uses the pre-built image `docker.io/appdynamics/dotnet-core-agent:<version>` (where `<version>` is the .NET Agent version; for example, `21.5.0`):

```
kind: Deployment
spec:
 containers:
 - name: dotnet-app
 image: microsoft/dotnet-samples:aspnetapp
 volumeMounts:
 - mountPath: /opt/appdynamics
 name: appd-agent-repo
 initContainers:
 - name: appd-agent
 image: docker.io/appdynamics/dotnet-core-agent:<version>
 volumeMounts:
 - mountPath: /appdynamics
 name: appd-agent-repo
 volumes:
 - name: appd-agent-repo
 emptyDir: {}
```

### Set the .NET Agent for Linux Environment Variables

To set all of the required .NET Agent environment variables, you must follow the steps in [Best Practices to Configure Agents in Kubernetes](#) listed below:

1. [Use ConfigMaps to Configure the App Server Agent](#)
2. [Use Secrets for the Controller Access Key](#)
3. [Set Application-Specific Configuration in the Deployment Spec](#)

## Use ConfigMaps to Configure the App Server Agent

1. Use a ConfigMap to set the .NET Agent for Linux environment variables that are shared across applications in a namespace:

```

apiVersion: v1
data:
 CORECLR_PROFILER: "{57e1aa68-2229-41aa-9931-a6e93bbc64d8}"
 CORECLR_ENABLE_PROFILING: "1"
 CORECLR_PROFILER_PATH: "/opt/appdynamics/libappdprofiler.so"
 APPDYNAMICS_AGENT_APPLICATION_NAME: "<value>"
 APPDYNAMICS_AGENT_ACCOUNT_NAME: "<value>"
 APPDYNAMICS_CONTROLLER_HOST_NAME: "<value>"
 APPDYNAMICS_CONTROLLER_PORT: "<value>"
 APPDYNAMICS_CONTROLLER_SSL_ENABLED: "<value>"
 APPDYNAMICS_AGENT_REUSE_NODE_NAME: "true"
 APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX: "<value>"
 # variables required to send transaction analytics data
 APPDYNAMICS_ANALYTICS_HOST_NAME: "<value>"
 APPDYNAMICS_ANALYTICS_PORT: "<value>"
 APPDYNAMICS_ANALYTICS_SSL_ENABLED: "<value>"
kind: ConfigMap
metadata:
 name: appd-dotnet-config

```

Note that the analytics host, port and ssl settings depend on how the Analytics Agent is deployed. See [Deploy Analytics in Kubernetes](#) for options.

2. (Optional) If you are running your .NET Core application in an Alpine Linux container, set `LD_LIBRARY_PATH` in the ConfigMap:

```

apiVersion: v1
data:
 CORECLR_PROFILER: "{57e1aa68-2229-41aa-9931-a6e93bbc64d8}"
 CORECLR_ENABLE_PROFILING: "1"
 CORECLR_PROFILER_PATH: "/opt/appdynamics/libappdprofiler.so"
 LD_LIBRARY_PATH: "/opt/appdynamics"
 ...
kind: ConfigMap
metadata:
 name: appd-dotnet-config

```

3. Apply the ConfigMap to the namespace:

```
kubectl -n dotnetapp apply -f appd-dotnet-config.yaml
```

4. Update the deployment spec to reference the `ConfigMap` :

```
spec:
 containers:
 - name: dotnet-app
 envFrom:
 - configMapRef:
 name: appd-dotnet-config
 ...
```

Use Secrets for the Controller Access Key

1. Create a Secret using `kubectl` :

```
kubectl -n dotnetapp create secret generic appd-agent-secret --from-literal=access-key=<access-key>
```

2. Update the deployment spec to reference the Secret:

```
spec:
 containers:
 - name: dotnet-app
 env:
 - name: APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY
 valueFrom:
 secretKeyRef:
 name: appd-agent-secret
 key: access-key
 ...
```

Set Application-Specific Configuration in the Deployment Spec

1. Set the application-specific tier name environment variable `APPDYNAMICS_AGENT_TIER_NAME` in the deployment spec:

```
spec:
 containers:
 - name: dotnet-app
 env:
 - name: APPDYNAMICS_AGENT_TIER_NAME
 value: dotnet-service
```

Set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` Environment Variable

**i** The `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` environment variable is supported in version 20.7.0+ of the .NET Agent for Linux. For earlier versions, a property must be set in `AppDynamicsConfig.json` based on a runtime value. See this example [deployment spec](#).

Set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` environment variable to enable APM correlation with the Cluster Agent. Since the value depends on a runtime value, set this environment variable in the container startup command using the values documented in [Manually Configure App Agents to Correlate with the Cluster Agent](#). For example, for a Kubernetes environment with the Docker runtime, set the environment variable as shown ( `export` is required):

```
kind: Deployment
spec:
 containers:
 image: microsoft/dotnet-samples:aspnetapp
 command: ["/bin/sh"]
 args: ["-c", "export APPDYNAMICS_AGENT_UNIQUE_HOST_ID=$(sed -rn '1s#.*/#; 1s/(.{12}).*/\
 \1/p' /proc/self/cgroup) && dotnet aspnetapp.dll"]
 ...
```

### Copy the AppDynamicsConfig.json File to the Container

Some .NET Agent for Linux options must be set in the `AppDynamicsConfig.json` file. This includes setting the `outputtype` to `console`, which facilitates sending the agent logs to log aggregation tools and viewing the logs using `kubectl logs`.

1. Create a ConfigMap based on the contents of `AppDynamicsConfig.json` :

```
$ kubectl -n dotnetapp create configmap appd-config --from-file=AppDynamicsConfig.json
```

2. Update the deployment spec to add the `AppDynamicsConfig.json` file to the container file system. Use `volumes` and `volumeMounts` that reference the ConfigMap contents:

```
kind: Deployment
spec:
 containers:
 image: microsoft/dotnet-samples:aspnetapp
 command: ["/bin/sh"]
 args: ["-c", "export APPDYNAMICS_AGENT_UNIQUE_HOST_ID=$(sed -rn '1s#.*/#; 1s/(.
 {12}).*/\1/p' /proc/self/cgroup) && dotnet aspnetapp.dll"]
 volumeMounts:
 - name: appd-config
 subPath: AppDynamicsConfig.json
 mountPath: /opt/appdynamics/AppDynamicsConfig.json
 volumes:
 - name: appd-config
```

```
configMap:
 name: appd-config
```

### (On-Premises Controller Only) Copy the Controller Certs to the Container

If the .NET Agent for Linux communicates with an on-premises Controller, the Controller certs must be copied to the container. See [Enable SSL for the .NET Agent](#).

1. Define a ConfigMap to reference the cert file. Use a volume mount in the deployment spec to mount the ConfigMap contents to the container:

```
$ kubectl create configmap appd-cert --from-file=cacerts
```

2. Add the cert file to the container file system using `volumes` and `volumeMounts` as shown in the deployment spec snippet:

```
kind: Deployment
spec:
 containers:
 image: microsoft/dotnet-samples:aspnetapp
 volumeMounts:
 - name: appd-cert
 subPath: cacerts
 mountPath: /opt/appdynamics/cacerts
 volumes:
 - name: appd-cert
 configMap:
 name: appd-cert
```

3. Set the `APPDYNAMICS_CONTROLLER_SSL_ENABLED` and `APPDYNAMICS_CONTROLLER_SSL_CERTFILE` environment variables in the ConfigMap. See [.NET Agent for Linux Environment Variables](#).

```
apiVersion: v1
data:
 CORECLR_PROFILER: "{57e1aa68-2229-41aa-9931-a6e93bbc64d8}"
 CORECLR_ENABLE_PROFILING: "1"
 CORECLR_PROFILER_PATH: "/opt/appdynamics/libappdprofiler.so"
 APPDYNAMICS_CONTROLLER_SSL_ENABLED: true
 APPDYNAMICS_CONTROLLER_SSL_CERTFILE: /opt/appdynamics/cacerts
 ...
kind: ConfigMap
metadata:
 name: appd-dotnet-config
```

### Example Configuration for Using an Init Container

This [Dockerfile](#) is an example of building the .NET Agent for Linux init container image using a multi-stage build. A complete example of a deployment spec that uses an init container to copy the agent binaries can be found on Github: [dotnet-app.yaml](#).

## Use a Dockerfile

**i** This scenario applies to containers running in Docker and Kubernetes.

You can use a Dockerfile to copy the .NET Agent for Linux to the Docker image at build time. To use the option, create a single image that contains both the application and .NET Agent for Linux binaries.

To copy the agent into the application image during the Docker image build:

1. [Download and Unzip the .NET Agent for Linux](#)
2. [Copy the Agent Binaries to the Image](#)
3. [Set the .NET Agent for Linux Environment Variables](#)
4. [Set the APPDYNAMICS\\_AGENT\\_UNIQUE\\_HOST\\_ID Environment Variable](#)
5. [Copy the AppDynamicsConfig.json File to the Image](#)
6. [\(On-Premises Controller only\) Copy the Controller Certs to the Image](#)
7. [Example Configuration for Using a Dockerfile](#)

### Download and Unzip the .NET Agent for Linux

Download the .NET Agent for Linux [programmatically](#) or from the [downloads portal](#). The agent is packaged as a zip file. In a shell, unzip it to the `AppDynamics-DotNetCore-linux-x64` folder:

```
$ unzip AppDynamics-DotNetCore-linux-x64-<version>.zip -d AppDynamics-DotNetCore-linux-x64
```

### Copy the Agent Binaries to the Image

Edit the Dockerfile to copy the unpackaged agent binaries to the target folder:

```
COPY AppDynamics-DotNetCore-linux-x64/ /opt/appdynamics/
```

### Set the .NET Agent for Linux Environment Variables

If your application runs in a non-Kubernetes environment (for example, using `docker run`), set the agent environment variables in the Dockerfile. For example:

```
ENV CORECLR_PROFILER="{57e1aa68-2229-41aa-9931-a6e93bbc64d8}"
ENV CORECLR_ENABLE_PROFILING=1
ENV CORECLR_PROFILER_PATH="/opt/appdynamics/libappdprofiler.so"
ENV APPDYNAMICS_AGENT_APPLICATION_NAME=<value>
ENV APPDYNAMICS_AGENT_TIER_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=<value>
ENV APPDYNAMICS_CONTROLLER_HOST_NAME=<value>
ENV APPDYNAMICS_CONTROLLER_PORT=<value>
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED=<value>
ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME=true
ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX=<value>
variables required to send transaction analytics data
ENV APPDYNAMICS_ANALYTICS_HOST_NAME=<value>
```

```
ENV APPDYNAMICS_ANALYTICS_PORT=<value>
ENV APPDYNAMICS_ANALYTICS_SSL_ENABLED=<value>
```

For Kubernetes applications, omit these environment variables from the Dockerfile and set them using ConfigMaps and Secrets.

The reuse node name and prefix environment variables are required to support unique node naming for multiple container instances for the same application image. See [.NET Agent for Linux Environment Variables](#). The analytics host, port and ssl settings depend on how the Analytics Agent is deployed. See [Deploy Analytics in Kubernetes](#) for options.

If you are running your .NET Core application in an Alpine Linux container, set `LD_LIBRARY_PATH` to the location of the agent binaries. For a Docker application, set `LD_LIBRARY_PATH` in the Dockerfile:

```
ENV CORECLR_PROFILER="{57e1aa68-2229-41aa-9931-a6e93bbc64d8}"
ENV CORECLR_ENABLE_PROFILING=1
ENV CORECLR_PROFILER_PATH="/opt/appdynamics/libappdprofiler.so"
ENV LD_LIBRARY_PATH="/opt/appdynamics"
...
```

For a Kubernetes application, set `LD_LIBRARY_PATH` in the ConfigMap.

Set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` Environment Variable

**i** The `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` environment variable is supported in version 20.7.0+ of the .NET Agent for Linux. For earlier version, a property must be set in `AppDynamicsConfig.json` based on a runtime value. This must be performed in the container [startup script](#).

For Kubernetes applications, set the `APPDYNAMICS_AGENT_UNIQUE_HOST_ID` environment variable to enable APM correlation with the Cluster Agent. Since the value depends on a runtime value, set this environment variable in the container startup command using the values documented in [Manually Configure App Agents to Correlate with the Cluster Agent](#). For example, for a Kubernetes environment with a Docker runtime, set the environment variable as shown ( `export` is required):

```
kind: Deployment
spec:
 containers:
 image: microsoft/dotnet-samples:aspnetapp
 command: ["/bin/sh"]
 args: ["-c", "export APPDYNAMICS_AGENT_UNIQUE_HOST_ID=$(sed -rn '1s#.*/#; 1s/(.{12}).*/\
\1/p' /proc/self/cgroup) && dotnet aspnetapp.dll"]
 ...
```

Copy the AppDynamicsConfig.json File to the Image

Some .NET Agent for Linux options must be set in the `AppDynamicsConfig.json` file. This includes setting the `outputtype` to `console`, which facilitates sending the agent logs to log aggregation tools. Create the `AppDynamicsConfig.json` file with the required configuration.

1. Edit the Dockerfile to copy `AppDynamicsConfig.json` to the image:

```
COPY ./AppDynamicsConfig.json /opt/appdynamics/AppDynamicsConfig.json
```

(On-Premises Controller only) Copy the Controller Certs to the Image

For .NET Agent for Linux agents communicating with an on-premises Controller, the Controller certs must be copied to the image. See [Enable SSL for the .NET Agent](#).

1. Edit the Dockerfile to copy the file containing the on-premises certs to the image. For example:

```
COPY ./onprem-cacerts /opt/appdynamics/conf/cacerts
```

2. Set the `APPDYNAMICS_CONTROLLER_SSL_ENABLED` and `APPDYNAMICS_CONTROLLER_SSL_CERTFILE` environment variables. See [.NET Agent for Linux Environment Variables](#). For a Docker application, set these environment variables in the Dockerfile:

```
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED="true"
ENV APPDYNAMICS_CONTROLLER_SSL_CERTFILE="/opt/appdynamics/cacerts"
```

For a Kubernetes application, set these environment variables in the ConfigMap.

Example Configuration for Using a Dockerfile

This [Dockerfile](#) builds a single image with the application and agent binaries included and this [Kubernetes deployment spec](#) references that Docker image.

## .NET Agent for Linux Environment Variables

### Related pages:

- [.NET Agent Configuration Properties](#)
- [Administer the .NET Agent](#)
- [Configure the .NET Agent](#)
- [Name .NET Tiers](#)

This is a reference page for the configuration properties for the .NET Agent for Linux that you can set using system environment variables.

**i** Linux environment variables are case sensitive, and Windows environment variables are not.

### Agent Account Name

Specifies the account name for the SaaS or multi-tenant Controller.

---

Environment Variable: `APPDYNAMICS_AGENT_ACCOUNT_NAME`

Type: String

Default: For single-tenant Controllers, the agent assumes the default of `customer1` if you do not specify an account name.

Required: Only for SaaS or multi-tenant Controllers.

### Agent Application Name

Specifies the business application you use in the Controller. If the application name does not exist, the Controller will create it when the agent registers. See [Overview of Application Monitoring](#).

Environment Variable: `APPDYNAMICS_AGENT_APPLICATION_NAME`

Type: String

Default: None

Required: Yes

### Agent Account Password

Specifies the account access key for the Controller.

Environment Variable: `APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY`

Type: String

Default: None

Required: Yes

### Agent Node Name

The name of the node.

In general, the node name must be unique within the business application and physical host. To use the same node name for multiple nodes on the same physical machine, create multiple virtual hosts using the Unique Host ID property. See [Unique Host ID](#).

Environment Variable: `APPDYNAMICS_AGENT_NODE_NAME`

Type: String

Default: None

Required: Yes

### Agent Reuse Node Name

Set this environment variable to true to reuse node names in AppDynamics. When you set the property to true, you don't need to supply a node name, but you do need to provide a node name prefix using `APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX`.

This property is useful for monitoring environments where there are many CLR's with short life spans. When true, AppDynamics reuses the node names of historical CLR's for new CLR's. Reusing node names avoids a proliferation of differently named nodes in AppDynamics over time, particularly when the nodes are essentially identical processes that run over different times.

AppDynamics generates a node name with App, Tier, and Sequence number. The node names are pooled. For example, the sequence numbers are reused when the nodes are purged (based on the node lifetime).

When the .NET Agent for Linux starts up, it logs output to the console until it registers with the Controller and the Controller generates the node name.

---

The Controller reuses node names based on the `node.retention.period` property. See [Historical and Disconnected Nodes](#).

Environment Variable: `APPDYNAMICS_AGENT_REUSE_NODE_NAME`

Type: Boolean

Default: False

Required: No

Example: Using the following environmental variable specifications, the Controller generates a node name with the prefix `reportGen`. Node names will have suffixes `--1`, `--2`, and so on, depending on the number of nodes are running in parallel. The name of a node that is shut down and qualifies as a historical node may be reused by a new node.

```
APPDYNAMICS_AGENT_REUSE_NODE_NAME=true
```

```
APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX=reportGen
```

### Agent Reuse Node Name Prefix

When you configure the agent to reuse node names, use this property to specify the prefix the Controller uses to generate node names dynamically.

Environment Variable: `APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX`

Type: String

Default: None

Required: When `APPDYNAMICS_AGENT_REUSE_NODE_NAME=true`

Example: Using the following environmental variable specifications, the agent directs the Controller to generate a node name with the prefix `reportGen`. Node names will have suffixes `--1`, `--2`, and so on, depending on how many nodes are running in parallel.

```
APPDYNAMICS_AGENT_REUSE_NODE_NAME=true
```

```
APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX=reportGen
```

### Agent Tier Name

Specifies the name of the tier that this .NET node belongs to. Note that this is not the deployment name on the application server.

Environment Variable: `APPDYNAMICS_AGENT_TIER_NAME`

Type: String

Default: None

Required: Yes

### Analytics SSL Enabled

Specifies whether or not the .NET Agent for Linux sends the default transaction data to the Analytics Agent via SSL.

Environment Variable: `APPDYNAMICS_ANALYTICS_SSL_ENABLED`

Type: String

Default: False

Required: No

---

## Analytics Hostname

Specifies the hostname or IP address of the analytics host.

Environment Variable: `APPDYNAMICS_ANALYTICS_HOST_NAME`

Type: String

Default: None

Required: No

## Analytics Port

Specifies the port number of the analytics port.

Environment Variable: `APPDYNAMICS_ANALYTICS_PORT`

Type: Positive integer

Default: None

Required: No

## Console Logger

Specifies the logging mode of the Console Logger.

Environment Variable: `appdynamics.outputMode`

Type: String {CONSOLE, ERROR, DEBUG, NONE}

Default: CONSOLE

Required: Not required, this is optional.

## Controller Hostname

Specifies the hostname or the IP address of the AppDynamics Controller. For an on-premises Controller, use the value for Application Server Host Name you provided when you installed the Controller. If you use the AppDynamics SaaS Controller, see the Welcome email from AppDynamics for the name of your Controller.

Environment Variable: `APPDYNAMICS_CONTROLLER_HOST_NAME`

Type: String

Default: None

Required: Yes, may also be set in the agent `AppDynamicsConfig.json` file as `"host"`.

## Controller Port Number

Specifies the HTTP(S) port of the AppDynamics Controller. If the `APPDYNAMICS_CONTROLLER_SSL_ENABLED` environment variable is set to `true`, specify the HTTPS port of the Controller; otherwise, specify the HTTP port.

Environment Variable: `APPDYNAMICS_CONTROLLER_PORT`

Type: Positive Integer

Default: 8090

- For On-premises installations, the defaults are port 8090 for HTTP and port 8181 for HTTPS.
- For the SaaS Controller, use port 80 for HTTP or port 443 for HTTPS.

Required: Yes, may also be set in the agent `AppDynamicsConfig.json` file as `"port"`.

## Controller SSL Enabled

When set to `true` enables encryption over SSL between the agent and the Controller.

---

Environment Variable: `APPDYNAMICS_CONTROLLER_SSL_ENABLED`

Type: Boolean

Default: false

Required: No, may also be set in the agent `AppDynamicsConfig.json` file as `"ssl"`.

### Controller SSL Certfile

The path to the folder containing certificate files used to connect to the SSL-enabled Controller.

Environment Variable: `APPDYNAMICS_CONTROLLER_SSL_CERTFILE`

Type: String

Default: None

Required: No. Optionally, you can set in the agent `AppDynamicsConfig.json` file as `"certfile"`.

### Controller SSL Certdirectory

The path to the folder containing the certificate directory used to connect to the SSL-enabled Controller.

 Certificate directory values are valid only if you do not input certificate files (`APPDYNAMICS_CONTROLLER_SSL_CERTFILE`).

Environment Variable: `APPDYNAMICS_CONTROLLER_SSL_CERTDIR`

Type: String

Default: None

Required: No. Optionally, you can set in the agent `AppDynamicsConfig.json` file as `"certdir"`.

### Controller TLS 1.2 Enabled

When set to `true` enables TLS 1.2 protocol for encrypted SSL connection between the agent and the Controller. This property enables when "Controller SSL Enabled" is also enabled.

Environment Variable: `APPDYNAMICS_ENABLE_TLS_12`

Type: Boolean

Default: False

Required: No. Optionally, you can set in the agent with the `enable_tls12` property in configuration.

### HTTP Proxy Host

The name of the proxy host.

Environment Variable: `APPDYNAMICS_PROXY_HOST_NAME`

Type: String

Default: None

Required: No, may also be set in the agent `AppDynamicsConfig.json` file in the `"proxy"` section.

### HTTP Proxy Port

The port number of the proxy.

Environment Variable: `APPDYNAMICS_PROXY_PORT`

Type: Positive integer

Default: None

---

Required: No, may also be set in the agent `AppDynamicsConfig.json` file in the `"proxy"` section.

### HTTP Proxy User

The name of the user that connects to the proxy.

Environment Variable: `APPDYNAMICS_PROXY_AUTH_USER`

Type: String

Default: None

Required: No, may also be set in the agent `AppDynamicsConfig.json` file in the `"proxy"` section.

### HTTP Proxy Password

The password of the user that connects to the proxy.

Environment Variable: `APPDYNAMICS_PROXY_AUTH_PASSWORD`

Type: String

Default: None

Required: No, may also be set in the agent `AppDynamicsConfig.json` file in the `"proxy"` section.

### Sample Agent Configuration File

The following environment variables can be set in the `AppDynamicsConfig.json` file:

- `APPDYNAMICS_CONTROLLER_HOST_NAME`
- `APPDYNAMICS_CONTROLLER_PORT`
- `APPDYNAMICS_CONTROLLER_SSL_ENABLED`
- `APPDYNAMICS_CONTROLLER_SSL_CERTFILE`
- `APPDYNAMICS_CONTROLLER_SSL_CERTDIR`

The example file below demonstrates how to set these variables:

```

"controller":
{
 "host": "ControllerHost",
 "port": 8181,
 "account": "customer1",
 "password": "test",
 "ssl": true,
 "certdir": "/opt/appdynamics/dotnet/conf/",
 "certfile": "/opt/appdynamics/dotnet/conf/cacerts.pem",
 "enable_tls12": true,
 "proxy":
 {
 "host" : "proxy",
 "port" :900,
 "authentication" :
 {
 "username" : "user",
 "domain" : "domainname",
 "password" : "pwd"
 }
 }
}

```

## Configure Analytics for .NET Agent for Linux

### Related pages:

- [Analytics](#)
- [.NET Agent for Linux Environment Variables](#)

AppDynamics Application Analytics enables you to do real-time analysis of business performance that is correlated with the performance of your application software.

### Configure Analytics Settings

If you are configuring the .NET Agent for Linux to send the default transaction data to the Analytics Agent, add a setting for the analytics host and port using either environment variables or in the agent json configuration file, config.json.

### Configure Analytics Settings via JSON

The following json syntax shows the analytics configuration settings:

```
"analytics: { "host": <analyticsHostName>, "port: <analyticsPort>, "ssl": <true || false> }"
```

### Configure Analytics Settings via Environment Variables

The following are the environment variables that you can use to configure Analytics:

- APPDYNAMICS\_ANALYTICS\_SSL\_ENABLED
- APPDYNAMICS\_ANALYTICS\_HOST\_NAME
- APPDYNAMICS\_ANALYTICS\_PORT

See [.NET Agent for Linux Environment Variables](#).

## .NET Agent for Linux Advanced Configuration Options

This page describes the advanced configuration properties for the AppDynamics .NET Agent for Linux you use to enable the .NET Agent to work without Docker. Before you start instrumenting your applications with the .NET Agent, you must use the current version of the .NET Core 2.0+. See [.NET Agent Configuration Properties](#).

### Agent Configuration File

**i** The agent configuration file is similar to the one used to configure .NET Core Agent on Windows.

Once you have deployed the agent, you can customize the instrumentation of your application.

You can edit the `AppDynamicsConfig.json` file using this information:

```
{
 "controller": {
 "host": "controller.saas.appdynamics.com",
 "port": 443,
 "account": "account-name",
 "password": "access-key",
 "ssl": true
 "proxy": {
 "host": "proxy-host",
 "port": 9090,
 "authentication": {
 "username": "proxy-user",
 "password": "proxy-password"
 }
 }
 },
 "application": {
 "name": "My Application",
 "tier": "Sample tier",
 "node": "Instance1",
 "reusenodename": "true",
 "nodenameprefix": "prefix"
 },
 "analytics": {
 "host": "localhost",
 "port": 9090
 }
}
```

**i** The .NET Agent for Linux supports reuse node name configuration to help manage monitoring environments where there are many CLR's with short life spans. The CLR node names are reused to avoid a proliferation of differently named nodes in AppDynamics. Include the " reusenodename " : "true" configuration, with " nodenameprefix ": "prefix" to enable reuse node name without having to supply a specific node name. You can also use environment variables to configure reuse node name, such as ENV APPDYNAMICS\_AGENT\_REUSE\_NODE\_NAME=true and ENV APPDYNAMICS\_AGENT\_REUSE\_NODE\_NAME\_PREFIX=<prefix> .

**!** .NET Agent for Linux does not support extended functionality, such as specifying instrumentors and allowlisting. Do not specify these if you copy the configuration from .NET Core Agent on Windows.

### Configuration Options

You can enable the agent to work without Docker. However, you must ensure that the OS is supported by the current agent.

1. Make these files available to the application. They can be located next to the application files or in a separate folder:
  - AppDynamics.Agent.netstandard.dll
  - libappdprofiler.so
  - libappdprofiler\_musl.so
  - libappdprofiler\_glibc.so
2. Create these environment variables by adding them to your application:

Environment Variable Name	Value
CORECLR_PROFILER	{57e1aa68-2229-41aa-9931-a6e93bbc64d8}
CORECLR_ENABLE_PROFILING	1
CORECLR_PROFILER_PATH	Path to the libappdprofilerdynamic library. For example, <application_folder_path>/libappdprofiler.so See <a href="#">.NET Agent for Linux</a> to determine the location of the libappdprofiler.so library.

You can create environment variables on multiple levels so it is important that you set them in the context of the monitored application:

- Environment variables are inherited from global host level.
  - Environment variables are parent process or service.
  - Environment variables are set prior to the start of the application using the shell script or similar.
3. Place the agent configuration file next to the appropriate binaries. There are two supported options:
    - Global agent configuration file - You can place the AppDynamicsConfig.json file next to the agent binaries. This method ensures that the default option to monitor each application configured is used for the agent.

The .NET Agent for Linux does not support overriding node name in the agent configuration. Therefore, monitoring multiple applications on the same host using global configuration is not supported. Only the first application reports.

- Local agent configuration - You can place the `[appname].AppDynamicsConfig.json` file next to the application binaries, where `[appname]` should match your application DLL/EXE name. Using this option, you can attach AppDynamics configuration to the application package and deploy it as a bundle. It is activated when you set the proper environment variables and the agent binaries are present.

Local agent configuration has higher priority than global configuration.

## Log Configuration Options

By default, you can use the boost log for both the profiler and the .NET Agent. Logging occurs even if no log file exists. By default, these three log files are created:

- Agent Log - Filename is `Agent_%N.log` and the default log level is `INFO`.
- Profiler Log - Filename is `Profiler_%N.log` and the default log level is `INFO`.
- Warn Log - Filename is `Warn_%N.log` and the default log level is `WARN`.

- If all logging configurations from `AppDynamicsConfig.json` failed to initiate, three default file loggers (`Agent Log`, `Profiler Log`, `Warn Log`) are initiated.
- If `Default File Loggers` failed to initiate, `Console Logger` is initiated.

The log configuration is read during the profiler initialization. Before the log configuration is read, some logs are printed to the console.

This table describes the properties that you can configure in the log configuration file.

Log Property	Description	
max_size	Maximum total size of stored files, in bytes. Default value is 10485760 bytes (10 MB).	<ul style="list-style-type: none"> <li>Maximum capacity per logger is: <code>max_size * max_files</code>.</li> <li>Rotation occurs when the file size reaches <code>max_size</code>.</li> </ul>
max_files	Maximum total number of stored files. Default value is 10.	<p>For example, if you configure the Agent log using the default values for <code>max_size</code> and <code>max_files</code>:</p> <ul style="list-style-type: none"> <li>When a log file (<code>Agent_0.log</code>) reaches its <code>max_size</code> (10 MB), a new file named (<code>Agent_1.log</code>) is created.</li> <li>Once it reaches the maximum number of files, the older file is deleted and a new file is created. The log directory is updated with a new set of files [<code>Agent_1.log</code>, <code>Agent_2.log</code>, ..... <code>Agent_9.log</code>, <code>Agent_10.log</code>], <code>Agent_0.log</code> is deleted, and a new file named <code>Agent_10.log</code> is created.</li> </ul> <p>If the log directory contains the log files from a previous run, then the newly initiated agent creates a log file using an incremental value from the previous run. For example, If the previous run has two agent logs, <code>Agent_0.log</code> and <code>Agent_1.log</code>, then the newly initiated Agent creates <code>Agent_3.log</code>.</p>
directory	The root directory. It accepts both relative and absolute path; however, no environment variable is accepted. Default value is <code>%TEMP%/appd/dotnet</code> .	
filename	The file name. By default, no process ID is included in the file name; however, you can include and configure the process ID in the filename ( <code>%P</code> ). For example, if you configure the filename as <code>Log_%P_%N.log</code> , then the filename appears as <code>Log_1123_0.Log</code> (where 1123 is the process ID). Default value is <code>Agent_%N.log</code> (where <code>%N</code> represents the incremental value starting from 0).	
exclude_tid	Determines whether to include the native thread ID in the log file. Default value is <code>false</code> .	
level	The minimum log level. Accepts these values: <code>Trace</code> , <code>Debug</code> , <code>Info</code> , <code>Warn</code> , <code>Error</code> , and <code>Fatal</code> . Default value is <code>Info</code> . These values are case-insensitive.	

Log Property	Description
channel	<p>This field accepts:</p> <ul style="list-style-type: none"> <li>Fully qualified class name.</li> <li>Class name with wildcard ( * ) at the start, end, or at both the ends of the name.</li> <li>Empty channel name, or .* or *. These values are used as the default channel names.</li> </ul>

**i** To incorporate any changes you made to the logging configuration, you must restart the application. The auto reload feature for logging configuration is not supported.

### Log Content Example

This log example shows content for the `Agent_0.log` file:

```
Agent_0.log

2021-05-24 15:26:03.741862 2056 11672 3 INFO [com.appdynamics.LifetimeManager] Initializing via agent bootstrap
```

Whereas:

- `2021-05-24 15:26:03.741862` is the timestamp.
- `2056` is the process ID.
- `11672` is the native thread ID.
- `3` is the managed thread ID.
- `INFO` is the log level.
- `com.appdynamics.LifetimeManager` is the channel name.
- `Initializing via agent bootstrap` is the log content.

### Log Structure

This log example contains two processes: `11120` and `76890`. Based on the log configuration, each process has its own set of log files.

- If process `11120` is initiated first, then it may create `Agent_0.log` (for Agent logs) and `Profiler_0.log` (for Profiler logs).
- When process `76890` is initiated, then it may create `Agent_1.log` (for Agent logs) and `Profiler_1.log` (for Profiler logs).
- Whichever log file reaches its maximum size first, its next log file is created by adding an incremental number to the file name. Log ordering is not maintained and differs for each process.

```
Logs

Profiler_0.log
```

```

Profiler_1.log
Warn_0.log
BusinessTransactionsLog_0.log
....
....
....
Agent_0.log
Agent_1.log
Profiler_2.log
....
....
....
Agent_2.log

```

### Supported Features

This table describes the supported Boost log features:

Feature	Description
Log order rules	<p>No rules are processed after a final rule matches.</p> <p>Rules are applied:</p> <ul style="list-style-type: none"> <li>◦ Based on the order of the logging configuration in the <code>AppDynamicsConfig.json</code> file.</li> <li>◦ When the log message channel name matches the channel name of the log configuration.</li> <li>◦ When the severity of the log message <math>\leq</math> the level of the log configuration.</li> </ul> <div style="border: 1px solid #00aaff; padding: 5px; margin-top: 10px;"> <p><b>i</b> However, if the log is written using the first logger, and the channel name is matched using the second logger with a wildcard, the second logger will not write messages to log files.</p> </div>
level	Minimal level to log.
Wildcard character (*)	<ul style="list-style-type: none"> <li>• If the wildcard is in the middle of a word (for example, <code>com.*.test</code>), then it is used as the default channel name ( * )</li> <li>• You can include a wildcard at: <ul style="list-style-type: none"> <li>◦ The beginning (for example, <code>*.appdynamics.test</code>)</li> <li>◦ The end (for example, <code>com.appdynamics.*</code>)</li> <li>◦ Both the beginning and end (for example, <code>*.appdynamics.*</code>)</li> </ul> </li> </ul>

### Log Order Rules Examples

For this log order rules example, there are N loggers: `logger1`, `logger2` ... `loggerN`.

where `loggerN` depends on `logger(N-1)` ... `logger1`.

and `logger(N-1)` depends on `logger(N-2)` ...`logger1`, and so on.

1. Example A: The `"ByteCode"` log is part of the `"AgentLog"`. As a result, no logging occurs through `ByteCode` logger. This is based on the order of the logging configuration in the `AppDynamicsConfig.json` file.

```
{"filename" : "RESTHeartbeat", "level" : "Info", "channel" :
"com.appdynamics.REST.HeartBeatLog" },
{"filename" : "AgentLog", "level" : "Info", "channel" : "*"},
{"filename" : "ByteCode", "level" : "Info", "channel" : "com.appdynamics.bci.*" }
```

Example B: The "RESTHeartbeat" log is part of "REST". As a result, the "RESTHeartbeat" log is ignored.

```
{"filename" : "REST", "level" : "Info", "channel" : "com.appdynamics.REST.*" },
{"filename" : "RESTHeartbeat", "level" : "Info", "channel" :
"com.appdynamics.REST.HeartBeatLog" }
```

2. Although "RESTHeartbeat" and "REST" log have the exact same channel name, only the `minLogLevel` of the first logger is considered. In this case, it is "Info".

```
{"filename" : "REST", "level" : "Info", "channel" : "com.appdynamics.REST.HeartBeatLog"
},
{"filename" : "RESTHeartbeat", "level" : "Trace", "channel" :
"com.appdynamics.REST.HeartBeatLog" }
```

3. Channels not written through loggers "RESTHeartbeat" and "ByteCode" are written through the "AgentLog" logger.

 The AgentLog will not have any entries from RESTHeartbeat or ByteCode.

```
{"filename" : "RESTHeartbeat", "level" : "Info", "channel" :
"com.appdynamics.REST.HeartBeatLog" },
{"filename" : "ByteCode", "level" : "Info", "channel" : "com.appdynamics.bci.*" },
{"filename" : "AgentLog", "level" : "Info", "channel" : "*"} }
```

## Log Configuration Examples

This example shows how to set logging configuration. Each log file can have its own set of configurations.

### AppDynamicsConfig.json

```
{
 "controller": {
 "host": "....."
 },
 "application": {
 "name": "..."
 },
 "log": [
 {
```

```

 "filename": "Profiler",
 "level": "INFO",
 "directory": "/tmp/appd/logs",
 "channel": "appd.agent.Profiler"
 },
 {
 "filename": "BusinessTransactionsLog",
 "level": "INFO",
 "channel": "com.appdynamics.BusinessTransactions"
 },
 {
 "filename": "RESTHeartbeat",
 "level": "INFO",
 "channel": "com.appdynamics.REST.HeartBeatLog"
 },
 {
 "filename": "ByteCode",
 "level": "INFO",
 "channel": "com.appdynamics.bci.*"
 },
 {
 "filename": "RESTCommunications",
 "level": "INFO",
 "channel": "com.appdynamics.REST.*"
 },
 {
 "filename": "RESTCommunications",
 "level": "INFO",
 "channel": "com.appdynamics.METRICS.MetricSender"
 },
 {
 "filename": "SamplingTrace",
 "level": "TRACE",
 "channel": "com.appdynamics.ManagedAgentAPI.DumpStats"
 },
 {
 "filename": "Analytics",
 "level": "INFO",
 "channel": "com.appdynamics.ee.service.analytics.Analytics",
 "max_size": 31457280,
 "max_files": 2,
 "directory": "./logs",
 "exclude_tid": false
 },
 {
 "filename": "Agent",
 "level": "INFO",
 "channel": "*"
 },
 {
 "filename": "Warn",

```

```

 "level": "WARN",
 "channel": "*"
 }
]
}

```

This example shows multiple log entries for the same file (both the directory and filename have the same value). The file log configuration uses the first entry, and all subsequent configuration for `max_size`, `max_files` and `exclude_tid` is ignored.

### AppDynamicsConfig.json

```

{
 "filename": "agent",
 "level": "TRACE",
 "max_size":1000000,
 "max_files":2,
 "channel": "com.appdynamics.METRICS.MetricSender"
},
{
 "filename": "agent",
 "level": "DEBUG",
 "max_size":2000000,
 "max_files":2,
 "channel": "com.appdynamics.METRICS.*"
},
{
 "filename": "agent",
 "level": "INFO",
 "max_size":3000000,
 "max_files":1,
 "channel": "com.appdynamics.*"
}
}

```

## .NET Agent for Linux Troubleshooting

This page describes general techniques when troubleshooting the AppDynamics .NET Agent for Linux deployment problems, and provides a few specific scenarios you may encounter with workarounds.

### Agent Startup Situations

The agent startup is dependent on three basic steps:

1. .NET Core loads the agent using profiler settings in the environment variables.
2. AppDynamics agent loads the configuration and additional library.
3. AppDynamics agent registers on the Controller using connection details found in the configuration file.

The sample startup console output on [.NET Agent for Linux](#) indicates a successful startup when going through these steps.

The following situations may occur:

Symptom	Probable root causes
No console output from AppDynamics was written to the console	<ul style="list-style-type: none"> <li>Environment variables were not set correctly</li> <li>Agent binaries do not match the OS version</li> </ul>
Agent complains about failing to load the configuration file	AppDynamicsConfig.json or [appname].AppDynamicsConfig.json were not found in the corresponding folders.
Agent complains about HTTP errors	Agent failed to communicate to the Controller using connection settings provided in the configuration file.

### Accessing Logs While Running Docker Container in the Background

The default agent configuration redirects all agent output to the console. This is enabled for troubleshooting purposes.

If you are running the container in the background—`-d` for detach—it is possible to access all output using the following Docker command:

```
docker logs <container id>
```

### Default Agent Log Files Location

The agent log files location is at `/tmp/appd/dotnet` by default.

You can change this setting to redirect all logs to the console output for a single view troubleshooting by adding the following configuration to the `AppDynamicsConfig.json` file as follows:

```
"log": [
 {
 "outputtype": "console"
 }
]
```

### .NET Agent for Linux Business Transaction Configuration

#### Related pages:

- [.NET Agent for Linux](#)
- [Overview of Application Monitoring](#)
- [Business Transactions](#)
- [ASP.NET Entry Points](#)
- [POCO Entry Points](#)
- [Custom Match Rules](#)

**i** As of 4.5.9, you can configure simple POJO or ASP.NET business transactions for the .NET Agent for Linux through the Controller UI. The .NET Agent for Linux 4.5.9 works with Controller  $\geq 4.4.1$ , but the customizable transaction detection and configuration capabilities require Controller  $\geq 4.5.2$ . For Controller 4.4.2 - 4.5.1, and the .NET Agent for Linux, AppDynamics defaults to using the first two segments of the URI for ASP.NET business transaction naming.

## Define Custom ASP.NET Business Transactions Using the Controller UI

You can create [ASP.NET](#) business transactions detection include and exclude rules with criteria that match HTTP Requests against:

**i** Transaction splitting is supported for the HTTP request criteria.

- Method
- URI
- HTTP parameter
- Header
- Cookie

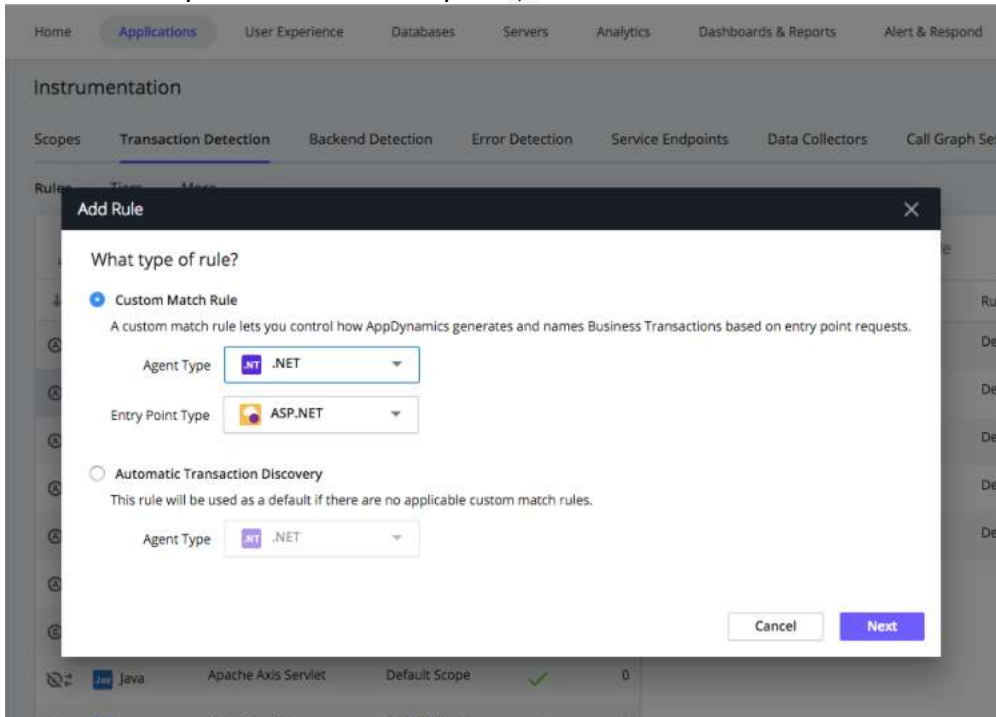

Although these HTTP request options display in the dropdown list, they are not supported by the .NET Agent for Linux. There is no effect if you configure them in the UI.

- Hostname
- Port
- Class name

You customize business transactions for the .NET Agent for Linux similarly as other agents. Click **Configure > Instrumentation > Add Rule** and then select to create either an include or exclude rule.

ASP.NET Business Transaction Detection Rule Example

This example shows how to create a .NET Agent custom match rule that uses an ASP.NET entry point to exclude all requests whose URI equals / healthcheck.

This Rule Summary specifies an *exclude* match rule. You must create an *include* rule before you can create an *exclude* rule to omit some of the transactions monitored by the include rule.

 Exclude Transactions discovered by this rule

Agent Type .NET

Entry Point Type ASP.NET

Name

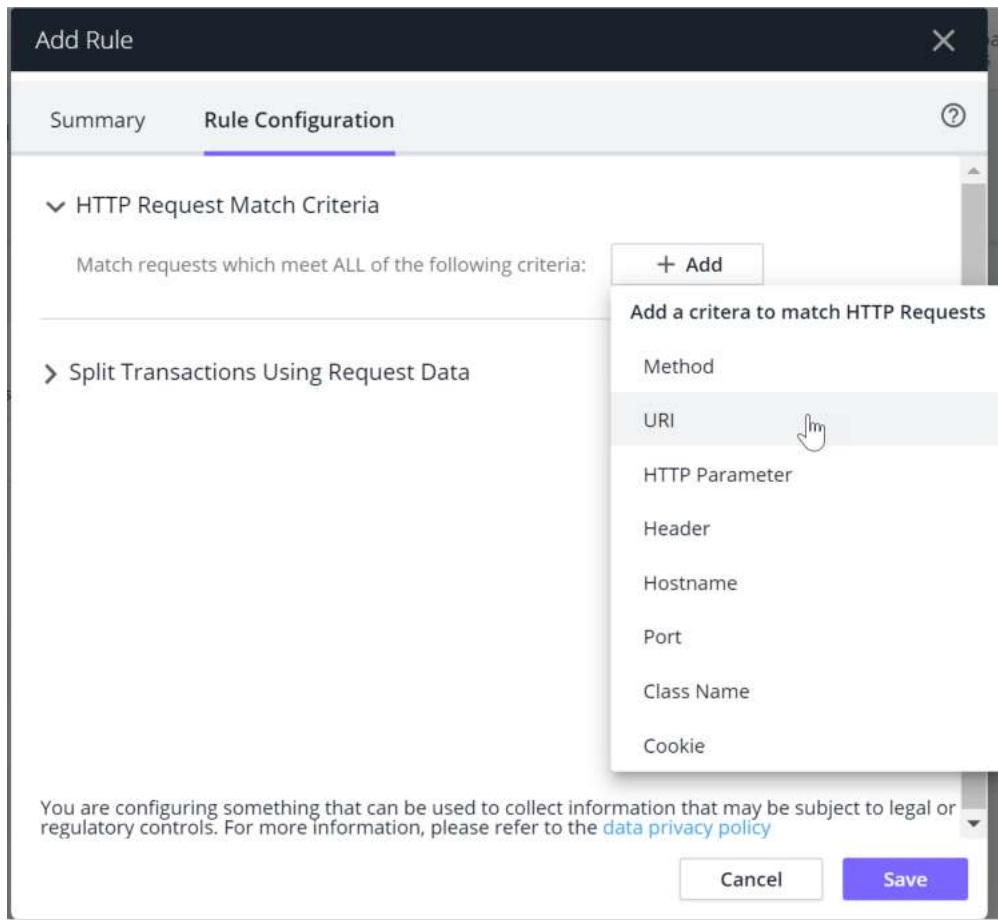

Enabled

Priority  ⓘ

Description

Scope

You specify the HTTP request criteria by using the URI attribute of the HTTP request to compare against. Valid criteria are **Method**, **URI**, **HTTP Parameter**, **Header**, and **Cookie**. You can split the transactions based on these request match criteria.

This HTTP request match criteria specifies where the URI equals */healthcheck*.

The screenshot shows the 'Add Rule' dialog box with the 'Rule Configuration' tab selected. Under 'HTTP Request Match Criteria', there is a match rule for 'URI' using the 'Equals' operator with the value '/healthcheck'. Below this, the 'Split Transactions Using Request Data' section is expanded, showing a checked checkbox for 'Split Transactions Using Request Data' and a dropdown menu for 'Use' followed by the text 'in Transaction names'. At the bottom right, there are 'Cancel' and 'Save' buttons.

## Define Custom POCO Business Transactions Using the Controller UI

Using the .NET Agent for Linux, you can create POCO business transaction rules that match synchronous or asynchronous transactions by:

- Method name
- Class name

Although these Match Classes options display in the dropdown list, they are not supported. However, there is no effect if you configure them in the UI:

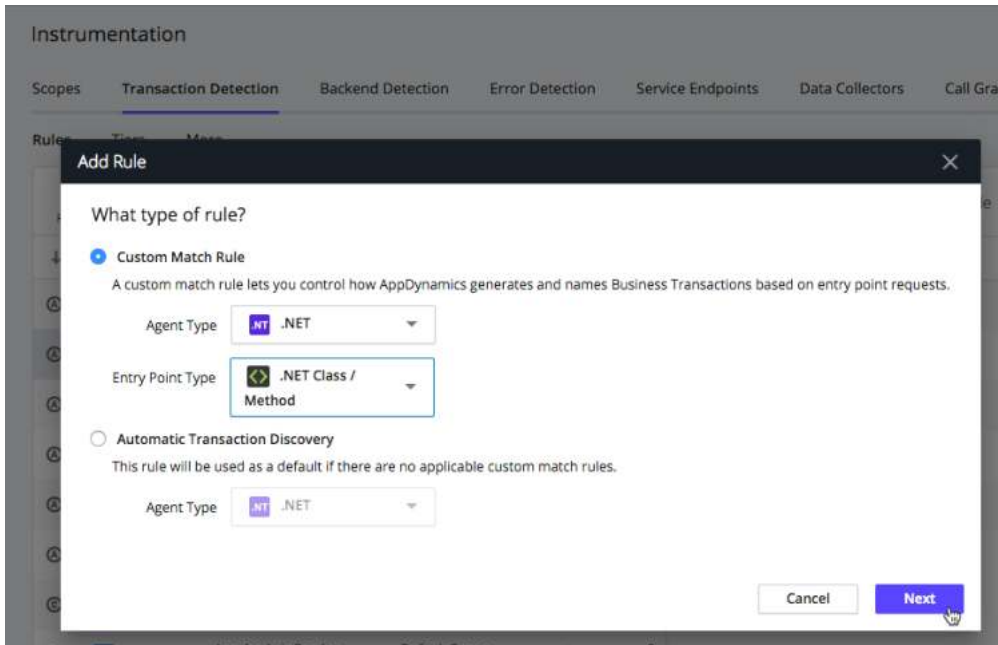

- that implements an interface which
- that extends a super class that
- that has an Annotation which

Additionally, these criteria are not supported:

- Transaction splitting using method/class data
- Background jobs
- Interface, base class or annotation POCO conditions

## Example POCO Business Transaction Detection Rule Example

This example shows how to create a .NET Agent custom match rule that uses a POCO entry point to include all requests whose class equals `MyCompanyJobs.JobProcessor` and the method name equals `OnEvent`.

This Rule Summary specifies an *include* match rule. You must create an include rule before you can create an exclude rule to omit some of the transactions monitored by the include rule.

- [Configure the .NET Agent](#)
- [.NET Agent Directory Structure](#)
- [Troubleshoot .NET Agent Issues](#)

This page describes how to upgrade the .NET Agent for Linux on VMs such as Docker and on hardware running Linux.

Upgrading the .NET Agent for Linux updates the agent files and maintains legacy configurations.

### .NET Agent for Linux 21.5

.NET Agent for Linux 21.5 incorporates significant architectural changes to accelerate the development of missing features in the Linux Agent relative to .NET Agent for Windows.

 These architectural changes do not affect .NET Agent for Windows (MSI and Microservices).

Generally, .NET Agent for Linux 21.5 maintains parity with existing features in .NET Agent for Linux < 21.5. However, due to architectural updates, there are differences between .NET Agent for Linux >= 21.5 and .NET Agent for Linux < 21.5. See the [.NET Agent 21.5 release notes](#) for a detailed explanation.

Before you upgrade to .NET Agent for Linux 21.5, please review the differences in this table:

Difference	.NET Agent for Linux >= 21.5	.NET Agent for Linux < 21.5
Pre-built Docker Image	<p>The .NET Agent Docker image does not have an OS Layer after version 21.5.</p> <p>This allows copying agent binaries from shared volume for initContainer, Kubernetes. initContainer for Kubernetes does not need a base OS.</p>	<p>The .NET Agent Docker image does have an OS Layer before version 21.5.</p>

Difference	.NET Agent for Linux >= 21.5	.NET Agent for Linux < 21.5
<p>HTTP URL backend for: Default naming</p>	<p>.NET Agent uses the full URL including http:// host:port in the naming.</p> <p>Full URL address is used.</p> <p>For example, two calls to these addresses:</p> <ul style="list-style-type: none"> <li>• http://service.cisco.com/api/add/12</li> <li>• http://service.cisco.com/api/add/32</li> </ul> <p>Results with these two backend names:</p> <ul style="list-style-type: none"> <li>• http://service.cisco.com/api/add/12</li> <li>• http://service.cisco.com/api/add/32</li> </ul>	<p>.NET Agent uses the URI path of the URL for the naming. It excludes http:// host:port, but assumes the "/" prefix as the name.</p> <p>Uses the URI path prefixed with a "/".</p> <p>For example, two calls to these addresses:</p> <ul style="list-style-type: none"> <li>• http:// service.cisco.com/api/add/ 12</li> <li>• http:// service.cisco.com/api/add/ 32</li> </ul> <p>Results with these two backend names:</p> <ul style="list-style-type: none"> <li>• /api/add/12</li> <li>• /api/add/32</li> </ul>

Difference	.NET Agent for Linux >= 21.5	.NET Agent for Linux < 21.5
<p>HTTP URL backend for: Custom naming</p>	<p>.NET Agent uses the full URL including http:// host:port in the naming.</p> <p>The URL address split by "/" counts http:// host:port as the first three segments:</p> <ul style="list-style-type: none"> <li>• "http:"</li> <li>• ""</li> <li>• "host:port"</li> </ul> <p>For example, two calls to these addresses with first five URL segments using "/" as the split and merge delimiter:</p> <ul style="list-style-type: none"> <li>• http://service.cisco.com/api/add/12</li> <li>• http://service.cisco.com/api/add/32</li> </ul> <p>Results with one backend name:</p> <ul style="list-style-type: none"> <li>• http://service.cisco.com/api/add</li> </ul>	<p>.NET Agent uses the URI path of the URL for the naming. It excludes http:// host:port, but assumes the "/" prefix as the name.</p> <p>The URL address split by "/" counts segments starting from the prefixed "/" in the URI path.</p> <p>For example, two calls to these addresses with first three URL segments using "/" as the split and merge delimiter:</p> <ul style="list-style-type: none"> <li>• http:// service.cisco.com/api/add/ 12</li> <li>• http:// service.cisco.com/api/add/ 32</li> </ul> <p>Results with one backend name:</p> <ul style="list-style-type: none"> <li>• /api/add</li> </ul>

Difference	.NET Agent for Linux >= 21.5	.NET Agent for Linux < 21.5
Sensitive data filtering for environment variables	<p>To filter sensitive data for environment variables:</p> <ol style="list-style-type: none"> <li>1. Add this sensitive data filter to the AppDynamicsConfig.json configuration file (located next to the Agent DLL file):</li> </ol> <pre data-bbox="698 630 1263 877"> {   "applies-to": "environment-variables",   "match-type": "CONTAINS",   "match-pattern": "" } </pre> <ol style="list-style-type: none"> <li>2. To integrate this filter with the Agent configuration file, see <a href="#">Filter Sensitive Data with the .NET Agent</a>.</li> </ol>	Available using the APPDYNAMICS_AGENT_MASK_ENV_VARS environment variable with the Linux Agent.
Process identity	Not available	Available
In-process async call chain segments limit	5 per node (default)	10 per node (default)
<p>POCO definitions for the generic format changes any existing generic method POCO definitions and must be re-defined using the new format.</p> <div data-bbox="126 1360 626 1654" style="border: 1px solid #0070C0; padding: 5px; background-color: #E6F2FF;"> <p><b>i</b> Similar to POCO definitions, the new format applies to any similar definitions for Custom Exits, Custom Data collectors, and so on because their support is enabled in the .NET Agent for Linux.</p> </div>	<p>This shows the common format used to define generic POCO rules for all .NET Agents:</p> <p><u>Format</u></p> <pre data-bbox="649 1360 1185 1470"> class: GenericClass`2 method: GenericMethod&lt;T1,T2&gt;(T1,T2,T1,T2) </pre>	<p>This shows the common format used to define generic POCO rules for all .NET Agents:</p> <p><u>Format</u></p> <pre data-bbox="1282 1470 1494 1743"> class: GenericClass`2 method: GenericMethod(!T1,!T2,!!M1,!!M2) </pre>
Alpine 3.9 and 3.10	Not supported	Supported

Difference	.NET Agent for Linux >= 21.5	.NET Agent for Linux < 21.5
Analytics Agent connection configuration through the <code>AppDynamicsConfig.json</code> configuration file or through the <code>APPDYNAMICS_ANALYTICS_*</code> environment variables.	Not supported  Use the single environment variable <code>appdynamics.analytics.agent.url</code> to specify the full Analytics Agent URL, such as <code>http://localhost:9090/v2/sinks/bt</code> .	Supported
Analytics Agent SSL trust configuration in JSON or agent specific environment variables.	Not supported  The SSL connection works if the certificate used by the Analytics Server is trusted by the operating system. As a workaround, you can configure the certificate using the <code>SSL_CERT_FILE/SSL_CERT_DIR</code> environment variable.  <div style="border: 1px solid #0070C0; padding: 5px; background-color: #E6F2FF;">  This is a global setting that overrides your SSL configuration for all connections.         </div>	Supported with these environment variables: <ul style="list-style-type: none"> <li>• <code>APPDYNAMIC_CONTROLLER_SSL_CERTFILE</code></li> <li>• <code>APPDYNAMIC_CONTROLLER_SSL_CERTDIR</code></li> </ul>
Usage of multiple Base-64 encoded certificates (PEM) in a single file with <code>APPDYNAMICS_CONTROLLER_SSL_CERTFILE</code> .	Supported with these noted limitations: <ul style="list-style-type: none"> <li>• The multiple certificates (PEM) file cannot be greater than 1 Mb.</li> <li>• You must format each certificate file with a decorated header and a footer, and the first line in the file should be the header of the first certificate.</li> <li>• if any certificate fails to load, then the entire file is ignored and the feature is disabled.</li> </ul>	Supported

## Requirements

- Before you begin, review the [Release Notes](#) for changes that affect your environment.
- AppDynamics requires an account access key for agent connections to single-tenant Controller accounts. AppDynamics < 4.1 only requires an account access key for multi-tenant Controller accounts. Single-tenant Controller customers can find the account access key in the Controller under **Settings > License > Account**.

You must be a member of a role with the View License account level permission. See [Manage Custom Roles](#).

## Binaries Overview

After downloading the agent binaries, you must extract them from the zip file into the folder you want.

The folder should contain these files:

- AppDynamics.Agent.netstandard.dll
- libappdprofiler.so
- libappdprofiler\_glibc.so
- libappdprofiler\_musl.so

### Upgrade the .NET Agent for Linux

1. Unzip the .NET Agent for Linux installation package to a temporary directory.
2. Replace the existing agent binaries with their latest versions. The files to replace are:
  - libappdprofiler.so
  - AppDynamics.Agent.netstandard.dll
3. Copy these files to the same directory:
  - libappdprofiler\_glibc.so
  - libappdprofiler\_musl.so
4. Restart your application, or rebuild and then run your container image with the new versions of the agent binaries.

### Upgrade the .NET Agent for Linux - Using Init Containers for Versions > 21.5.0

.NET core agent images do not have OS layer for version  $\geq 21.5.0$ . The `cp` command used with older images will not work and the deployment spec needs to be updated.

To update the deployment, see [Add the Init Container to the Deployment Spec](#).

### Upgrade the .Net Agent for Linux - Using DockerFile with Prebuilt Agent Image for Versions > 21.5.0

.NET core agent images for versions  $\geq 21.5.0$  do not contain the OS Layer.

To copy the agent Dynamic-link library (DLL), view the example Docker file:

```
FROM mcr.microsoft.com/dotnet/core/sdk:3.1 AS build-env
WORKDIR /app

Copy csproj and restore as distinct layers
COPY *.csproj ./
RUN dotnet restore

Copy everything else and build
COPY . ./
RUN dotnet publish -c Release -o out

Appdynamics dotnet core agent image (same image can be used for Debian and Alpine
distributions)
FROM appdynamics/dotnet-core-agent:21.5.1 AS agent

FROM mcr.microsoft.com/dotnet/core/aspnet:3.1
WORKDIR /app
COPY --from=build-env /app/out .
COPY --from=agent /opt/appdynamics /opt/appdynamics

Mandatory settings required to attach the agent to the .NET application
ENV CORECLR_PROFILER={57e1aa68-2229-41aa-9931-a6e93bbc64d8}
ENV CORECLR_ENABLE_PROFILING=1
```

```

ENV CORECLR_PROFILER_PATH=/opt/appdynamics/libappdprofiler.so

Configure connection to the controller
ENV APPDYNAMICS_CONTROLLER_HOST_NAME=<<Controller Host>>
ENV APPDYNAMICS_CONTROLLER_PORT=80
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED=false
ENV APPDYNAMICS_AGENT_ACCOUNT_NAME=<<Account name>>
ENV APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=<<Access Key>>
ENV APPDYNAMICS_PREVIEW_FEATURE_ENABLED=true

Configure application identity in AppDynamics
ENV APPDYNAMICS_AGENT_APPLICATION_NAME="Test application"
ENV APPDYNAMICS_AGENT_TIER_NAME="Test Tier"
ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME=true
ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX="Instance"

EXPOSE 80
ENTRYPOINT ["dotnet", "Sample.dll"]

```

## .NET Support Advisory

### Summary

Due to a bug in .NET 6, an exception is thrown after reading a whole file, if the file is not a multiple of read buffer size. The file is `System.IO.IOException: 'The parameter is incorrect.'`

To read more about this bug, see [.NET Runtime Issue 50858](#) and [.NET Runtime Issue 6285](#).

### Affected Software

This bug is known to impact .NET MSI APM Agents (agents installed through MSI package) running on Windows, specifically when instrumenting .NET 6 applications.

### Impact

.NET MSI APM Agents running on Windows, instrumenting .NET 6 applications will provide the following error, while attempting to read agent configuration. The effect of this exception is that the .NET 6 application will not be instrumented.

```

System.IO.IOException: The parameter is incorrect. at
System.IO.Strategies.BufferedFileStreamStrategy.ReadFromNonSeekableAsync(Memory`1
 destination, CancellationToken cancellationToken) at
System.Threading.Tasks.TaskToApm.End[TResult](IAsyncResult asyncResult) at
System.IO.Strategies.BufferedFileStreamStrategy.EndRead(IAsyncResult asyncResult) at
System.IO.FileStream.EndRead(IAsyncResult asyncResult) at
AppDynamics.Agent.Communication.IPC.NamedPipeClient.DeserializeResponse(FileStream strm,
 Int32 timeout, CommandStatus& status).

```

### Resolution

To resolve the issue:

Option 1: This issue is addressed by Microsoft in .NET 6.0.1, see [.NET Runtime Pull 61410](#). Upgrading to .NET 6.0.1 will resolve the issue.

Option 2: Set the environment variable at the system scope or application scope:

- **Name:** DOTNET\_SYSTEM\_IO\_USENET5COMPATFILESTREAM
- **Value:** 1

Option 3: Use .NET Microservice Agents to instrument the .NET 6 application.

Since the .NET Microservice Agent doesn't depend on IPC communication to coordinator service, it is not impacted.

### Use Grammars to Configure the .NET Agent

This page describes the grammars to configure the .NET Agent. Grammars allow you to configure application names, tier names, and node names. See [Install the .NET Core Microservices Agent for Windows](#).

Setting up grammars is optional, and if they are not set, then the `cmd` grammar is the default grammar.

### Supported Grammars

Grammar Name	Description	Prefix	Examples
<code>cmd</code>	The <code>cmd</code> grammar only supports environment variables. To add environment variables, use the format <code>%NAME%</code> .	Use the prefix <code>!</code> <code>cmd!</code> to use <code>cmd</code> grammar.	<ul style="list-style-type: none"> <li>• <code>{"tier" : "!cmd!webApi-%COMPUTERNAME%"}</code></li> <li>• <code>{"tier" : "paymentApi-%COMPUTERNAME%"}</code></li> </ul>
<code>ps</code>	The <code>ps</code> grammar supports agent properties and environment variables. Use the format <code>\${property:NAME}</code> for agent properties, and use the format <code>\${env:NAME}</code> for environment variables.	Use the prefix <code>!</code> <code>ps!</code> to use <code>ps</code> grammar.	<code>{"tier" : "!ps!webApi-\${env:COMPUTERNAME}_\${property:IIS_VIRTUAL_APPLICATION_PATH}"}</code>

## Supported Agent Properties

Agent Property Name	Agent Property Description	Example
IIS_VIRTUAL_APPLICATION_PATH	The IIS Virtual Application Path is used by the application. This property is always prefixed with the / symbol and is supported by ASP.NET and ASP.NET Core applications hosted on IIS with the in and out-of-process hosting model.	/myPath

## NGINX Agent

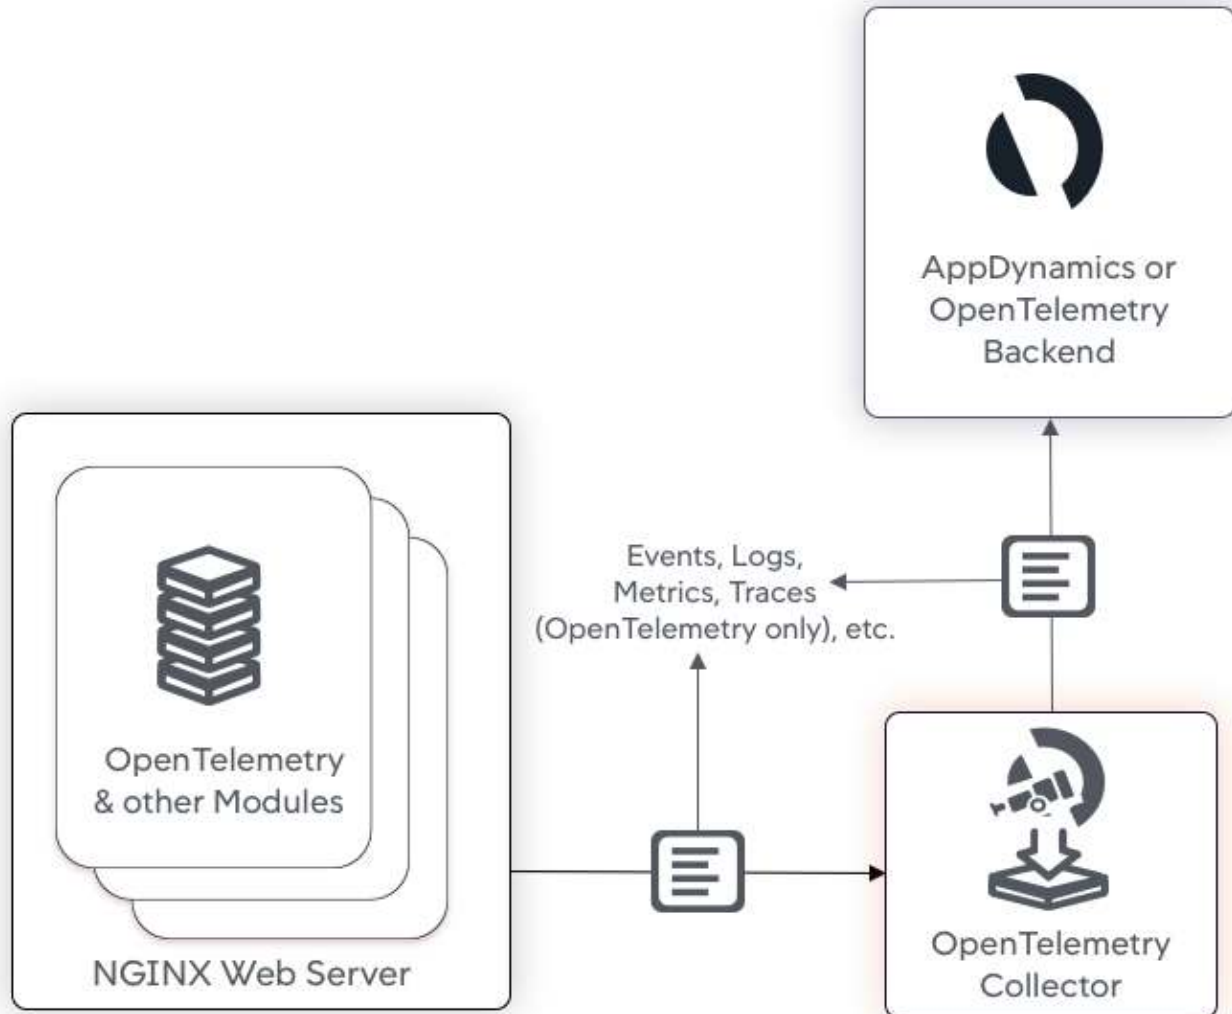

NGINX Web Server Agent is an open-source agent. To report an issue, go to [NGINX Agent OpenTelemetry Community Issues](#) portal.

The NGINX Web Server Agent monitors NGINX web servers and NGINX reverse proxy. It provides end-to-end visibility into the application performance. It is an open-source agent, which makes it cost-effective and secure. Below are some of its key features:

- The correlation of Business Transactions from upstream web server agents to downstream agents (updated Java, Node.js, and .Net AppDynamics agents) helps you resolve issues faster.
- The implementation of OpenTelemetry does not require a proxy to communicate with the Controller. However, it requires [OpenTelemetry Collector](#) to communicate with the AppDynamics Backend.

The NGINX Web Server Agent emits traces based on OpenTelemetry specification. The AppDynamics backend converts these traces into usable metrics like Calls Per Minute, Average Response Time, etc.

## Agent Deployment Architecture

### Next Steps

1. [NGINX Agent Supported Environments](#)
2. [Install the NGINX Agent](#)
3. [Upgrade the Agent](#)
4. [NGINX Agent Logging](#)
5. [Uninstall the Agent](#)

### NGINX Agent Supported Environments

The agent supports the x86-64 platforms. See [Supported Platforms](#).

## Install the NGINX Agent

You can download the agent artifact from the agent from [GitHub](#). For more information about this artifact, see [OTel Web Server Module](#). This agent is based on CentOS 7 and contains shared libraries for Apache and NGINX instrumentation. The shared libraries are available at `WebServerModule/Apache` or `WebServerModule/Nginx` for respective web servers. However, the common libraries for OpenTelemetry are available at `sdk_lib/lib/`. The shared libraries are used for both Apache and NGINX instrumentation.

Currently, the agent build is based on the x86-64 architecture. Therefore, the artifact should work on any Linux distribution running on the x86-64 platform and having `glibc version >= 2.17`.

## Download and Install the Agent

1. Download the agent from [GitHub](#).
2. Extract and install the agent to `/opt`.

```
tar -xf opentelemetry-webserver-sdk-x64-linux.tgz -C /opt
cd /opt/opentelemetry-webserver-sdk/
./install.sh
```

3. Copy the `conf/nginx/opentelemetry_module.conf` file to `/opt/`. See [Sample OpenTelemetry Module Configuration File](#).
4. Edit the directives values according to your deployment environment. For example, `NginxModuleOtelExporterEndpoint` must point to the Collector URL.
5. Edit the `nginx.conf` file to provide a reference to `opentelemetry_module.conf` and shared library. See [Sample NGINX Configuration File](#).
6. Follow the below command sequence and location while referring to `conf/nginx/nginx.conf`.

```
load_module /opt/opentelemetry-webserver-sdk/WebServerModule/Nginx/
ngx_http_opentelemetry_module.so;
include /opt/opentelemetry_module.conf;
```

7. Before you start the NGINX Agent, update `LD_LIBRARY_PATH` to load OpenTelemetry dependencies.

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/opentelemetry-webserver-sdk/sdk_lib/lib
```

### Sample opentelemetry\_module.conf

```
1 NginxModuleEnabled ON;
2 #NginxModule Otel Exporter details
3 NginxModuleOtelSpanExporter otlp;
4 NginxModuleOtelExporterEndpoint docker.for.mac.localhost:4317;
5 # SSL Certificates
6 #NginxModuleOtelSslEnabled ON
7 #NginxModuleOtelSslCertificatePath
8 #NginxModuleOtelSpanProcessor Batch
9 #NginxModuleOtelSampler AlwaysOn
```

```

10 #NginxModuleOtelMaxQueueSize 1024
11 #NginxModuleOtelScheduledDelayMillis 3000
12 #NginxModuleOtelExportTimeoutMillis 30000
13 #NginxModuleOtelMaxExportBatchSize 1024
14 NginxModuleServiceName DemoService;
15 NginxModuleServiceNamespace DemoServiceNamespace;
16 NginxModuleServiceInstanceId DemoInstanceId;
17 NginxModuleResolveBackends ON;
18 NginxModuleTraceAsError ON;
19 #NginxModuleWebserverContext DemoService DemoServiceNamespace DemoInstanceId
20 #NginxModuleSegmentType custom
21 #NginxModuleSegmentParameter 15,1,6,7

```

### Sample nginx.conf

```

1 user nginx;
2 worker_processes 1;
3
4 error_log /var/log/nginx/error.log warn;
5 pid /var/run/nginx.pid;
6
7 load_module /opt/opentelemetry-webserver-sdk/WebServerModule/Nginx/
ngx_http_opentelemetry_module.so;
8
9 events {
10 worker_connections 1024;
11 }
12
13
14 http {
15 include /etc/nginx/mime.types;
16 default_type application/octet-stream;
17
18 log_format main '$remote_addr - $remote_user [$time_local] "$request" '
19 '$status $body_bytes_sent "$http_referer" '
20 '"$http_user_agent" "$http_x_forwarded_for"';
21
22 access_log /var/log/nginx/access.log main;
23
24 sendfile on;
25 #tcp_nopush on;
26
27 keepalive_timeout 65;
28
29 #gzip on;
30
31 include /etc/nginx/conf.d/*.conf;
32 include /opt/opentelemetry_module.conf;

```

33

}

## Configuration Directives

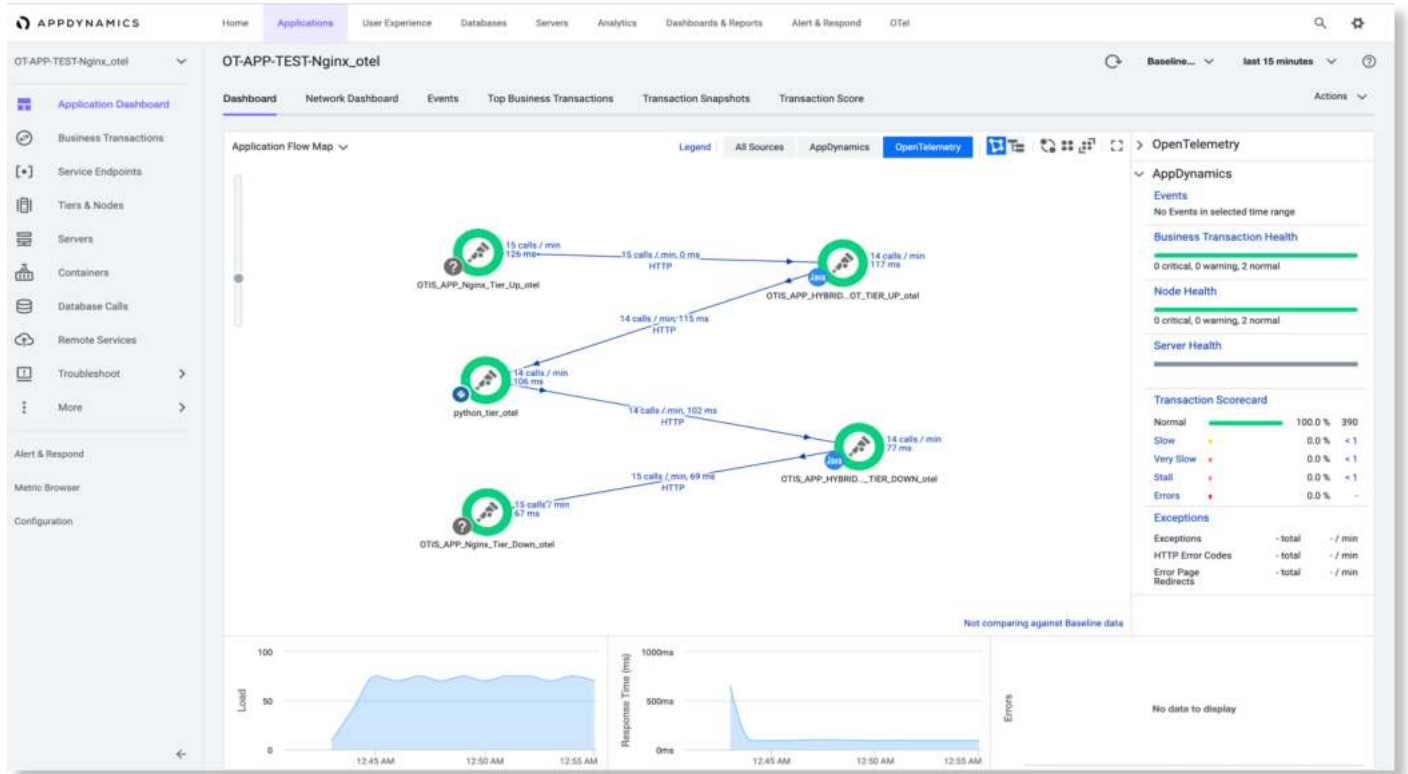

You can configure these directives based on your deployment needs. A dash ("-") in a table cell indicates that this column is not relevant to the directive.

Directives	Default Value	Configuration Requirement	Remarks
<code>NginxModuleEnabled</code>	ON	Optional	Required to instrument NGINX web server.
<code>NginxModuleOtelSpanExporter</code>	otlp	Optional	Specify the span exporter to be used. Currently, the supported values are <code>otlp</code> and <code>ostream</code> .
<code>NginxModuleOtelExporterEndpoint:</code>		Required	OpenTelemetry exports to this endpoint. For example, <code>docker.for.mac.localhost:4317</code> .
<code>NginxModuleOtelSpanProcessor</code>	batch	Optional	Supported values are <code>simple</code> and <code>batch</code> .
<code>NginxModuleOtelSampler</code>	AlwaysOn	Optional	Supported values are <code>AlwaysOn</code> and <code>AlwaysOff</code> .
<code>NginxModuleOtelMaxQueueSize</code>	2048	Optional	The maximum span queue size. After this size limit is reached, spans are dropped.
<code>NginxModuleOtelScheduledDelayMillis</code>	5000	Optional	The delay interval in milliseconds between two consecutive exports.
<code>NginxModuleOtelExportTimeoutMillis</code>	30000	Optional	The time duration in milliseconds that export can run before it is canceled.
<code>NginxModuleOtelMaxExportBatchSize</code>	512	Optional	The maximum batch size of every export. It must be smaller or equal to <code>maxQueueSize</code> .

Directives	Default Value	Configuration Requirement	Remarks
NgInxModuleServiceName	-	Required	A namespace for the ServiceName.
NgInxModuleServiceNamespace	-	Required	Logical name of the service.
NgInxModuleServiceInstanceId	-	Required	The string ID of the service instance.
NgInxModuleTraceAsError	-	Optional	Trace level for logging to Apache log.
NgInxModuleWebserverContext	-	Optional	Takes 3 values (separated by space) ServiceName , ServiceNamespace , and ServiceInstanceId .
NgInxModuleSegmentType	-	Optional	Specify the string ( FIRST/LAST/CUSTOM) to be filtered for the span name creation.
NgInxModuleSegmentParameter	-	Optional	Specify the segment count or segment numbers that you want to display for the span creation.

### Visualizing on AppDynamics

This image shows how the NGINX Agent data is visualized on the AppDynamics Controller.

## Upgrade the Agent

1. Shut down the NGINX server.
2. Move or rename the agent install directory, `/opt/opentelemetry-webserver-sdk` to create a backup.
3. Download the new version of the agent and extract it into `/opt/opentelemetry-webserver-sdk`.
4. Change directory to the agent install directory:

```
cd <agent_install_directory>
```

5. Run the installer:

```
./install.sh
```

It is not necessary to change the configuration when you use the same directory location as the old agent installation.

6. Restart the NGINX server.

## NGINX Agent Logging

The agent generates two types of logs:

- Agent log
- Core log

## Agent Log

The agent log contains information about the transactions that the agent processes and sends to the downstream agent.

By default, these logs are saved as `var/log/nginx/error.log`. You can enable or disable these logs by using the `AppDynamicsTraceAsError` in `opentelemetry_module.conf` parameter.

The naming convention of the default agent logs are:

- `error.log` : the current log
- `error.log.1` : most recent log
- `error.log.2` : second recent log
- `error.log.3` : third recent log
- `error.log.4` : fourth recent log
- `error.log.5` : fifth recent log

The agent creates and rotates a maximum of six log files. The maximum log file size is 20 MB, which gives you a maximum of 120 MB of recent log data at one time.

### Sample Error Log Output

```
2021/06/17 05:37:22 [error] 25439#25439: Starting Appdynamics Modlue init
2021/06/17 05:37:22 [error] 25439#25439: Registering handlers for modules in different phases
2021/06/17 05:37:22 [error] 25439#25439: Ending Appdynamics Modlue init
```

## Core Log

The core logs are saved as `/opt/opentelemetry-webserver-sdk/logs/sdk.log` and are of three types:

- `sdk.log`
- `api.log`
- `api-user.log`

The naming convention of the default agent logs are:

- `sdk.log` : the current log
- `sdk.log.1` : most recent log
- `sdk.log.2` : second recent log
- `sdk.log.3` : third recent log
- `sdk.log.4` : fourth recent log
- `sdk.log.5` : fifth log

Similarly, the `api.log` and the `api-user.log` files are created. The agent creates and rotates a maximum of six log files. The maximum log file size is 20 MB, which gives you a maximum of 120 MB of recent log data for each core log type.

You can edit the `<webserver_agent_install_dir>/conf/appdynamics_sdk_log4cxx.xml` file to change the default logging behavior.

 When the default log behavior is changed, a service restart is required.

### Sample sdk.log Output

```
2021-06-16 05:14:00.506 UTC INFO 38616[0x7f5d7b535700] [agent.SdkWrapper] ServiceNamespace:
electronics ServiceName: e-commerce ServiceInstanceId: 71410b7jan13

2021-06-16 05:14:00.508 UTC INFO 38616[0x7f5d7b535700] [agent.SdkWrapper] Exporter created
with ExporterType: otlp

2021-06-16 05:14:00.508 UTC INFO 38616[0x7f5d7b535700] [agent.SdkWrapper] Processor created
with ProcessorType: batch

2021-06-16 05:14:00.508 UTC INFO 38616[0x7f5d7b535700] [agent.SdkWrapper] Sampler created
with SamplerType : always_on

2021-06-16 05:14:00.508 UTC INFO 38616[0x7f5d7b535700] [agent.SdkWrapper] Tracer created
with LibraryName: and LibraryVersion
```

### Sample Code to Print sdk.log

```
LOG4CXX_DEBUG(mLogger, "Starting AgentCore with initial Config "<< *initConfig);
```

## Uninstall the Agent

1. Remove the include statement for the NGINX Agent from the HTTP server configuration. For example in `nginx.conf`, remove this line:

#### CODE

```
load_module /opt/opentelemetry-webserver-sdk/WebServerModule/Nginx/
ngx_http_opentelemetry_module.so;
include /opt/opentelemetry_module.conf;
```

2. Restart the NGINX server.
3. Uninstall the agent:

#### CODE

```
<agent_install_directory>/install.sh -u
```

4. Optionally, remove any remaining AppDynamics files:
  - `<agent_install_directory>`
  - `/tmp/appd-sdk`

## Node.js Agent

### Related pages:

- [Monitor Node.js Processes](#)

This page provides an overview of the Node.js Agent, which enables automated transaction detection and correlation across your Node.js-enabled environment.

### Node Naming for Node.js Agents

Each instrumented Node.js process corresponds to a node in the AppDynamics model.

The nodes are named by combining the prefix that you specify for the nodeName in the requires statement that you add to the application source code when you install the Node.js agent with a hyphen and a digit.

For example, if you designate a prefix of MyNode for the nodes in the MyTier tier, the nodes in that tier are named MyNode-0, MyNode-1, MyNode-2, and so on.

### Instrument a Node.js Application Overview

The Getting Started Wizard provides instructions on installing the agent. In the Controller **Home** page, click **Getting Started > Node.js**.

The wizard provides the minimum information that the agent needs to communicate with the AppDynamics Controller:

- Controller Host
- Controller Port
- SSL (optional)
- Application Name
- Tier Name

### Node.js Supported Environments

This page provides an overview of supported environments for the Node.js Agent.

 The Node.js Agent is supported on [RedHat](#), and [Docker Hub](#).

### Node.js Agent Versions

Agent Versions	Node.js Versions
23.7.0 - 23.10.0	14, 15, 16, 17, 18, 19, 20
23.5.0	12, 13, 14, 15, 16, 17, 18, 19
23.3.0	12, 13, 14, 15, 16, 17, 18

Agent Versions	Node.js Versions
22.9.0 - 23.2.0	12, 13, 14, 15, 16, 17
21.8.0 - 22.8.0	12, 13, 14, 15, 16

## Operating Systems

- Docker images for Node 18 are only available for Alpine Linux in versions  $\geq 22.11.0$ .
- Alpine Linux Docker  $\geq 3.7$  on 64-bit platform
- Linux distribution based on glibc 2.5 and later and the x86/x86-64 architecture
- Mac OS X  $\geq 10.8$ , x86/x86-64 architecture
- Windows Server 2012 R2 and later on 64-bit platform with Node.js  $\geq 0.12.0$

## Transaction Naming

Entry Type	Default Transaction Naming
Node.js Web	URI

## HTTP Exit Points

Supported HTTP Exit Points
Node.js HTTP client library

See [Node.js Documentation](#) for the Node.js HTTP client library.

## Database Exit Points

Supported Database Exit Points
Cassandra
Couchbase
DynamoDB (using AWS SDK Driver)
Redis (up to 3.x driver only)
Memcached
MongoDB
MSSQL
MySQL
PostgreSQL

- NoSQL  
AppDynamics displays NoSQL databases as Remote Services.

## Node.js Settings Reference

### Related pages:

- [Configure Transaction Analytics for Node.js, PHP, and Python Applications](#)
- [Install the Node.js Agent](#)

This page describes the available settings that configure the Node.js Agent.

You can use environment variables for some of the settings. To apply the settings, add them to the `require` statement for the Node.js Agent in the monitored application.

The Node.js Agent no longer supports the proxy as of version 21.9.

### General Settings

The following table is the complete list of settings in the `require` statement that you insert into your application code. Not all of these settings are required.

Property Name	Description
<code>controllerHostName</code>	The IP address or hostname of your Controller. For SaaS, you will receive this URL in your welcome email from AppDynamics. For on-premises, you will set these when you install the Controller.
<code>controllerPort</code>	The port to which the agent connects to the Controller. It is 8090 for an on-premises Controller and 443 for a SaaS Controller.
<code>controllerSslEnabled</code>	Set this property to true if connecting to the Controller via SSL.
<code>accountName</code>	The account name on the Controller to which this agent will report.
<code>accountAccessKey</code>	Account access key on the Controller.
<code>applicationName</code>	Name that represents the entire application in the AppDynamics console.
<code>tierName</code>	Name that represents your Node.js app or service in the flow maps.
<code>nodeName</code>	Name of the Node.js process to be monitored by this agent. See <a href="#">Node Names</a> .
<code>noNodeNameSuffix</code>	Optional, set to true if you do not want the agent to add a suffix, such as <code>-0</code> , <code>-1</code> , <code>-2</code> , and so on, to the node name. See <a href="#">Node Names</a> .

Property Name	Description
<code>proxyHost</code> , <code>proxyPort</code>	Set these options to route data to the Controller through a proxy server. The <code>proxyHost</code> is the hostname or IP address of the proxy server. The <code>proxyPort</code> is the proxy server's HTTP or HTTPS port, whichever you are using. If you set the host, you must set the port well.
<code>proxyUser</code> , <code>proxyPasswordFile</code>	Configure the proxy username and password file if the proxy server requires credentials.
<code>proxy</code>	Set this property to true if you want to use the Java proxy version of the Node.js Agent.
<code>alwaysAddEumMetadataInHttpHeaders</code>	Set this property to true to have the Node.js Agent write business transaction metadata to the XHR header and in a cookie even if the request is considered cross-origin. See the description for the equivalent setting <code>always-add-eum-metadata-in-http-headers</code> in <a href="#">Node.js Agent Node Properties Reference</a> .
<code>btEntryPointDelayDisabled</code>	true   false - Optional, defaults to false. Setting this property to true accelerates the startup of business transactions, but it can adversely affect the drill-down in distributed transactions.
<code>debug</code>	Set this property to true to enable debug level logging for the agent. The default is false.
<code>logging</code>	The location, level, and other settings related to agent logging. See <a href="#">Node.js Agent Logging</a> .
<code>maxProcessSnapshotsPerPeriod</code>	Optional. The default is 2. The number of automatic process snapshots allowed in <code>processSnapshotCountResetPeriodSeconds</code> seconds.
<code>processSnapshotCountResetPeriodSeconds</code>	Optional. The default is 60. Frequency, in seconds, at which the automatic process snapshot count is reset to 0.
<code>autoSnapshotDurationSeconds</code>	Optional. The default is 10. Length, in seconds, of automatically-triggered process snapshots.
<code>proxyAutoLaunchDisabled</code>	true   false - Optional, defaults to false. Set this property to true if you need to manually launch the proxy for this agent. See <a href="#">Start the Proxy Manually for Node.js</a> .

Property Name	Description
<code>proxyCtrlDir</code>	Directory path for the directory containing the domain control socket file which the agent uses to start an AppDynamics node. Optional, set manually if you are setting up a multi-tenant proxy. See <a href="#">Share a Proxy Among Node.js Agents</a> .
<code>rootTmpDir</code>	Directory path for the root of the directory that stores the agent files. Optional, defaults to <code>/tmp/appds</code> .
<code>tmpDir</code>	Directory path for the subdirectory of the root directory for the monitored node. Optional, defaults to a hash of the Controller information for the instrumented node.
<code>reuseNode</code>	Set this property to true to enable reusing node names. This property is useful for monitoring environments where there are many nodes with short life spans. The default is false.  Note: A <b>SIGTERM (15)</b> shutdown of the Node.js process is a requirement for <code>reuseNode</code> feature.
<code>reuseNodePrefix</code>	Set this property to the string that prefixes the node name when <code>reuseNode</code> is set to true. The Controller uses this prefix to generate unique node names dynamically.
<code>certificateFile</code>	Directory path for the directory containing the .pem SSL certificate file.
<code>uniqueHostId</code>	The unique host ID can be set to any value that will identify the host. If a value is not specified, the agent will generate the host ID. This setting is only available for the proxyless version of the Node.js Agent.

## Analytics Settings

You can configure the Node.js Agent to send default transaction data to the Analytics Agent.

To add a setting for the Analytics host and port with the following format, specify the host and port numbers. The Analytics Agent may report on the same or different host and port numbers from the Node.js Agent.

```
analytics: {
 host: <analyticsHostName>,
 port: <analyticsPortNumber>,
 ssl: <true / false>
}
```

**i** In Analytics Settings, ensure to specify the values for the variables in their supported data types.

Variables	Supported Data Type
host	String
port	Number
ssl	Boolean

To configure Analytics data limits, see [Configure Transaction Analytics for Node.js, PHP, and Python Applications](#).

### Windows Settings

On Windows, the Node.js Agent requires three additional ports:

- proxyCommPort : default is 10101
- proxyRequestPort : default is 10102
- proxyReportingPort : default is 10103

See [Run the Node.js Agent on Windows](#).

### Filter Sensitive Data

If your application contains sensitive data that should not be displayed in the Controller, you can apply the following data filters to the require statement of the Node.js Agent.

#### Add a Sensitive Data Filter

When you enable a sensitive data filter, the Controller displays asterisks for the values of matching environment variables or system properties.

```
dataFilters: [{
 "appliesTo": "http-headers",
 "matchPattern": "host"
}],
```

#### Environment Variable Filter

By default, the Node.js Agent enables a sensitive data filter with an environment variables/system properties that contain the case-insensitive substring `password|key`.

```
dataFilters: [{
 "appliesTo": "env-vars",
 "matchPattern": "password|key"
}],
```

## Sensitive URL Filter

You can use sensitive URL filters to configure the agent to obfuscate sensitive information from the URLs in the **Transaction Snapshot** details.

```
urlFilters: [{
 "delimiter": "/",
 "segment": "1",
 "matchPattern": "a",
 "paramPattern": "bar"
}],
```

The sensitive URL filter checks for the `matchPattern` in one segment. To check for additional segments, you can add an additional JSON array.

The filter processes requests in the following format: `/aa/bb/cc` → `***/bb/cc`.

 The `matchpattern/parampattern` is a standard regex.

Property Name	Description
<code>urlFilters</code>	An array that you can add more objects to if you want more rules on the segment.
<code>delimiter</code>	Specifies the desired character as the URL segment endpoints. The agent splices the URL at each delimiter instance to create the segments.
<code>segment</code>	Needs to be at least one number and in ascending order (such as <code>3,5</code> or <code>2,6</code> ). Wildcards ( <code>*</code> ) are not possible.

## URL Segment Filter

With the `matchpattern` regex, the Node.js Agent decides whether or not to filter a specified segment.

If you have multiple rules, list the more specific rule before the more general rule. The rules listed in the array are evaluated based on order.

Rule A:

```
{
 'delimiter': '/',
 'matchPattern': '[0-9a-z]{8}-[0-9a-z]{4}-[0-9a-z]{4}-[0-9a-z]{4}-[0-9a-z]{12}\\/.{50,}',
 'segment': '3,5'
}
```

Rule B:

```
{
 'delimiter': '/',
 'matchPattern': '[0-9a-z]{8}-[0-9a-z]{4}-[0-9a-z]{4}-[0-9a-z]{4}-[0-9a-z]{12}',
 'segment': '3'
}
```

In this example, the first rule, Rule A, should be listed before Rule B because rule A masks the third and fifth segment.

If Rule B were to be listed and evaluated before Rule A, the third segment will be masked and the fifth segment will not be masked, potentially revealing sensitive information.

### URL Parameter Filter

With the paramPattern regex, the Node.js Agent decides whether or not to filter a specified query parameter.

If you need to mask all URL parameters, you can add further instruction to the array.

```
{ "delimiter": "/", "matchPattern": "", "segment": "99", "paramPattern": ".*"}
```

The Node.js Agent will filter out all URL parameters.

### Sensitive Message Filter

You can use sensitive message filters to configure the agent to obfuscate sensitive information contained within text messages collected by the agent from log messages or detail messages from exceptions.

```
messageFilters: [{
 "messageType":
 "throwable",
 "matchPattern":
 "Error.*MySQL.",
 "redactionRegex": "SQL"
}]
```

### Environment Variables

If you have not provided the required settings in the require statement, the agent uses the values of the following environment variables if those variables are set. If both are set, the `require` statement value takes precedence over the environment variable.

Environment Variable	Maps to
APPDYNAMICS_CONTROLLER_HOST_NAME	controllerHostName
APPDYNAMICS_CONTROLLER_PORT	controllerPort
APPDYNAMICS_CONTROLLER_SSL_ENABLED	controllerSslEnabled

Environment Variable	Maps to
APPDYNAMICS_AGENT_ACCOUNT_NAME	accountName
APPDYNAMICS_LOGGER_OUTPUT_TYPE	You can stream logs to <code>stdout</code> by setting its value to <code>console</code> .
APPDYNAMICS_LOGGER_LEVEL	You can set the logging level of the agent. Possible values include: <code>FATAL</code> , <code>ERROR</code> , <code>WARN</code> , <code>INFO</code> , <code>DEBUG</code> , and <code>TRACE</code> .
APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY	accountAccessKey
APPDYNAMICS_AGENT_APPLICATION_NAME	applicationName
APPDYNAMICS_AGENT_TIER_NAME	tierName
APPDYNAMICS_AGENT_NODE_NAME	nodeName
APPDYNAMICS_AGENT_UNIQUE_HOST_ID	-
APPDYNAMICS_ANALYTICS_HOST_NAME	host —in Analytics settings
APPDYNAMICS_ANALYTICS_PORT	port —in Analytics settings
APPDYNAMICS_ANALYTICS_SSL_ENABLED	ssl —in Analytics settings
UNIQUE_HOST_ID	uniqueHostId The unique host ID can be set to any value that will identify the host. If a value is not specified, the agent will generate the host ID.  <div style="border: 1px solid #007bff; background-color: #e6f2ff; padding: 5px; border-radius: 5px;"><span style="color: #007bff; font-weight: bold;">i</span> This environment variable is available by default (not for Java proxy mode).</div>

### Node Reuse for Node.js Agent

A **SIGTERM (15)** shutdown of the Node.js process is a requirement for `reuseNode` feature.

## Reuse Node Name

To reuse node names in AppDynamics, you have to set the `reuseNode` property to `true`. When you set this property to true, you do not have to supply a node name, but you do need to provide a node name prefix using `reuseNodePrefix`.

**i** When `reuseNode` and a `nodeName` are used, the `reuseNodePrefix` property is given precedence over the `nodeName`.

This property is useful for monitoring environments where there are many VMs (Virtual Machines) with short life spans, and for container environments. When set to true, AppDynamics reuses the node names of historical VMs for new VMs. This avoids a proliferation of differently named nodes in AppDynamics over time, particularly when the nodes are essentially identical processes that run over different times.

AppDynamics generates a node name with App, Tier, and Sequence number, and the node names are pooled. For example, the sequence numbers are reused when the nodes are purged (based on the node lifetime).

**System Property:** `reuseNode`

**Type:** Boolean

**Default:** False

**Required:** No

## Reuse Node Name Prefix

When you configure the agent to reuse node names, use this property to specify the prefix that the Controller uses to generate node names dynamically.

**System Property:** `reuseNodePrefix`

**Type:** String

**Default:** None

**Required:** When `reuseNode=true`

**i** Reuse node feature example:  
With the following configuration, the Controller generates a node name with the prefix "reportGen". Node names will have suffixes -1, -2, and so on, depending on the number of nodes are running in parallel. The name of a node that is shut down and qualifies as a historical node may be reused by a new node.

```
reuseNode=true reuseNodePrefix=reportGen
```

## Install the Node.js Agent

### Related pages:

- [Download AppDynamics Software](#)
- [Install the Node.js Agent \(Java Proxy\)](#)

This page provides instructions on how to install the Node.js Agent.

The Getting Started Wizard in the Controller provides the easiest way to get started with the AppDynamics Node.js Agent. The wizard constructs a pre-configured require statement for the agent based on your input.

## Before You Begin

You must add a require statement to the source code of your Node.js application to install the Node.js Agent. In addition to running the AppDynamics Controller, you need to have write access to the application source code and the ability to restart the Node.js application, which installs the agent.

The Getting Started Wizard in the Controller generates the require statement for you. It populates the statement with the connection settings for the Controller and the values you provide for the wizard to model the Node.js application in AppDynamics.

For installation on Windows, see [Supported Environment](#) for your version of Windows and install the [Visual C++ Redistributable for Visual Studio 2015](#).

## About Node.js Agent Node Identity

You configure the identify of a Node.js application instance using the node name setting. By default, the agent uses the value configured for `nodeName` as a prefix and adds a dash and number as a suffix. For example, given the following setting:

```
nodeName=MyNode
```

The first node to start with this configuration would be named `MyNode-0`. Auto-numbered suffixes on node names are most useful for machines with more than one worker process.

If you are not running multiple worker processes, you can prevent auto-numbering in node names by setting `noNodeNameSuffix` to `true`. In the following example, the node would be named `MyNode`.

```
nodeName=MyNode
noNodeNameSuffix=true
```

If you are instrumenting worker processes on different machines, keep in mind that each application and node name combination must be unique. Therefore, be sure to specify different node name prefixes for each server, for example, by configuring `nodeName=Server1` for the first server and `nodeName=Server2` for the second server.

If you are instrumenting a Node.js application that uses the PM2 process manager, set the node suffix name to `process.env.pm_id`.

## Use the Node.js Agent with the Machine Agent

If you install the Machine Agent on the machine hosting the instrumented Node.js node and you specify the tier and node name in the `controller-info.xml` file of the Machine Agent, the Node.js Agent will fail to register.

To avoid this problem:

- Install the Node.js Agent before you install the Machine Agent.
- If you install the Machine Agent on the machine hosting the instrumented Node.js node, do not specify the application, tier, or node name in the machine agent's `controller-info.xml` file. If you do, the Node.js Agent may fail to register.

## Install the Node.js Agent

To install the agent, run the install command in the directory of your application and add a `require` comm and to add the agent module to your application.

If you are using Node.js 0.8.1 through 0.8.18, see [Set User Agent for Node.js 0.8.1 through 0.8.18](#) before running the install command.

### Install via `npm`

Refer to [Agent and Controller Tenant Compatibility](#) to determine which versions of the Node.js Agent are compatible with your Controller.

To install the latest agent, run the following command:

```
npm install appdynamics@next
```

If you know which specific version of the Node.js agent you want to install, you can specify it:

```
npm install appdynamics@<x.y.z>
```

If you are using npm 5, you must disable the lock file by setting `package-lock=false` in the npm configuration settings.

The version of npm that ships with Node.js v6 does not automatically run post-install scripts used by 4.5.12 and later versions of the agent. AppDynamics recommends using the latest Node.js version.

If Node.js v6 must be used, npm needs to be updated prior to installing the agent:

```
npm install -g npm
npm install appdynamics
```

## Add the Require Statement

Paste the following require statement as the very first line of your application source code before any other require statement. Then, replace the variables with the values for your setup. To find your account name and access key, select **Settings**  and then **License**.

```
require("appdynamics").profile({
 controllerHostName: '<controller host name>',
 controllerPort: <controller port number>,
 controllerSslEnabled: false, // Set to true if controllerPort is SSL
 accountName: '<AppDynamics_account_name>',
 accountAccessKey: '<AppDynamics_account_key>', //required
 applicationName: 'your_app_name',
 tierName: 'choose_a_tier_name',
 nodeName: 'choose_a_node_name'
});
```

For reference information on the settings, along with other settings you can use, see [Node.js Settings Reference](#).

You can place the `require` statement as the first line in the require statement of another module that appears as the first line of code.

In this case, you would need to modify your point-of-entry source file; this it can be just a single line to the `require()` the file that you place the call to the agent into; for example, `require("<script-that-initializes-the-agent>")`. You could also parameterize the `profile()` call to name different instances without having to have multiple versions of the agent initialization script.

If it is not possible to place the `require` statement as the first line of code, you can insert the statement elsewhere, but it must occur before the `require()` of any core or third party module that needs to be instrumented. In general, the `require("appdynamics")` statement should occur as early as possible in the code.

If the source file you use to load the agent from is an ES6 module, use `import appdynamics from "appdynamics"; appdynamics.profile({ ... })` instead of, `require("appdynamics").profile({ ... })`.

## Test the Configuration

To verify the installation, restart the application and put load on it. The new node should appear in the flow map for the business application you specified in the configuration.

## Stop the Node.js Application

By default, closing the Node.js application stops the application.

## Run with Other Profiling Tools

The agent is incompatible with other profiling tools, such as running the node process with the `--inspect` flag.

## Instrument a Node.js Cluster

If your application uses the cluster module, place the `appdynamics.profile require` statement in both the primary and worker processes.

## Set User Agent for Node.js 0.8.1 through 0.8.18

If running a Node.js version between 0.8.1 and 0.8.18, inclusive, you need to set the `user-agent npm` property before you run the `npm install` command.

The syntax is:

```
npm config set user-agent "node/<version> {linux|darwin} {x64|i86}"
```

For example:

```
npm config set user-agent "node/v0.8.14 linux x64"
```

## Resolve Installation Issues for Node.js

If you are trying to install the Node.js Agent on a version of Node.js that the agent does not support, the installation will fail and you will see a message similar to the following:

```
npm ERR! notsup Unsupported
npm ERR! notsup Not compatible with your version of node/npm: appdynamics@3.9.3
npm ERR! notsup Required: {"node":">=0.8.0 <=0.10.31"}
npm ERR! notsup Actual: {"npm":"1.4.28","node":"0.10.32"}
...
```

See [Node.js Supported Environments](#).

## Install the Node.js Agent in Containers

### Related pages:

- [Container Platforms](#)

This page explains your options to install the Node.js Agent in a containerized environment:

- [Use Auto-Instrumentation](#)
- [Use Init Containers](#)
- [Use a Dockerfile](#)

### Use Auto-Instrumentation

**i** This scenario applies to containers running in Kubernetes where the Cluster Agent is installed.

This option uses the Auto-Instrumentation feature of the Cluster Agent. It is the recommended option because it offers the highest level of automation and the simplest operational experience for instrumenting Node.js applications in a Kubernetes cluster.

To get started, see [Auto-Instrument Applications with the Cluster Agent](#).

### Use Init Containers

**i** This option applies to containers running in Kubernetes.

This option uses Kubernetes init containers to copy the Node.js Agent binaries into the application container when the application starts up. It assumes that the application image is built without any Node.js Agent binaries and that a second init container image is built which contains the Node.js Agent binaries. The deployment spec for the application is configured to copy and send the agent binaries to the running application container.

To copy the agent binaries with init containers:

1. [Build the Node.js Application Image](#)
2. [Build the Node.js Agent Init Container Image](#)
3. [Add the Init Container to the Deployment Spec](#)
4. [Set the Node.js Agent Environment Variables](#)
5. [Set the `UNIQUE\_HOST\_ID` Environment Variable](#)
6. [\(On-Premises Controller Only\) Copy the Controller Certs to the Container](#)

**i** These steps assume the application image is built using Node.js version 8 and later, which supports the `NODE_OPTIONS` environment variable. This environment variable is set in a ConfigMap. For Node.js versions 7 and earlier, refer to this [example](#) that uses a start script to include the `appdynamics` package.

### Build the Node.js Application Image

Build the Node.js application image based on the application binaries and dependencies. Do not include the Node.js Agent binaries or settings in the application image.

### Build the Node.js Agent Init Container Image

The agent init container image is built separately from the application image and can be reused across multiple Node.js application deployments.

**i** For Linux and Alpine environments, the Node.js Agent init container images are available on [Dockerhub](#). For all other deployment environments, continue with the following instructions to build the init container image.

The Node.js and operating system versions of the init container image should match the Node.js and operating system versions of the application image to ensure that compatible Node.js Agent binaries are selected when running `npm install`. For more information, see [Node.js Supported Environments](#).

The Node.js and operating system versions are determined by the `FROM node:14.4-alpine` statement in the Dockerfile:

```
FROM node:14.4-alpine
...
```

Follow these steps to build the init container image:

1. Create a `shim.js` file that contains a `require` statement for `appdynamics`. Set the `reuseNode` property to `true`. Set `reuseNodePrefix` to the value of an environment variable that will be provided in a ConfigMap in a later step:

```
require("appdynamics").profile({
 reuseNode: true,
 reuseNodePrefix: process.env.APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX
});
```

2. If the Node.js Agent should report Transaction Analytics data, add the analytics properties to the `require` statement and set the value to environment variables that will be provided in a ConfigMap in a later step. See [Node.js Settings Reference](#).

```
require("appdynamics").profile({
```

```

reuseNode: true,
reuseNodePrefix: process.env.APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX,
analytics: {
 host: process.env.APPDYNAMICS_ANALYTICS_HOST_NAME,
 port: process.env.APPDYNAMICS_ANALYTICS_PORT,
 ssl: process.env.APPDYNAMICS_ANALYTICS_SSL_ENABLED
}
});

```

3. If the Node.js Agent communicates with an on-premises Controller, add the `certificateFile` property and set it to the location where the `cert` file will be copied in a later step:

```

require("appdynamics").profile({
 reuseNode: true,
 reuseNodePrefix: process.env.APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX,
 certificateFile: /opt/appdynamics/cacerts
});

```

4. In the Dockerfile, copy `shim.js` to the image:

```
COPY ./shim.js /opt/appdynamics/shim.js
```

5. Run the `npm install` command to resolve the `appdynamics` package:

```

$ cd appdynamics
$ npm install appdynamics@next

```

6. In the Dockerfile, copy the contents of the folder containing the `appdynamics` package to the image:

```
COPY appdynamics/ /opt/appdynamics/
```

For a complete example of building the Node.js Agent init container image using a multi-stage build, see [this Dockerfile](#).

### Add the Init Container to the Deployment Spec

Edit the deployment spec to add the sections required to copy the agent binaries from the init container to the application image.

The following snippet from a deployment spec shows the required `volumes`, `volumeMounts`, and `initContainer` definitions. It assumes the Node.js application image is published to `myrepo/nodejs-app:v1` and the init container image is published to `myrepo/appd-nodejs:latest`. The `shim.js` file from the init container image is copied to `/opt/appdynamics/shim.js` in the application container.

```

kind: Deployment
spec:
 containers:
 - name: nodejs-app

```

```

 image: myrepo/nodejs-app:v1
 volumeMounts:
 - mountPath: /opt/appdynamics
 name: appd-agent-repo
 initContainers:
 - command:
 - cp
 - -r
 - /opt/appdynamics/.
 - /opt/temp
 name: appd-agent
 image: myrepo/appd-nodejs:latest
 volumeMounts:
 - mountPath: /opt/temp
 name: appd-agent-repo
 volumes:
 - name: appd-agent-repo
 emptyDir: {}

```

## Set the Node.js Agent Environment Variables

To set all of the required Node.js Agent environment variables, try the following options depending on your use case:

- [Use ConfigMaps to Configure the App Server Agent](#)
- [Use Secrets for the Controller Access Key](#)
- [Set Application-Specific Configuration in the Deployment Spec](#)

See [Best Practices to Configure Agents in Kubernetes](#) for more information.

## Use ConfigMaps to Configure the App Server Agent

1. Use a ConfigMap to set the agent environment variables that are shared across Node.js applications in a namespace. For example, see this `appd-nodejs-config.yaml` snippet:

```

apiVersion: v1
data:
 APPDYNAMICS_AGENT_APPLICATION_NAME: eCommerce
 APPDYNAMICS_AGENT_ACCOUNT_NAME: <value>
 APPDYNAMICS_CONTROLLER_HOST_NAME: <value>
 APPDYNAMICS_CONTROLLER_PORT: <value>
 APPDYNAMICS_CONTROLLER_SSL_ENABLED: <value>
 APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX: <value>
 APPDYNAMICS_AGENT_NODE_NAME: <value> # not used in node name but required by Node.js
agent
 APPDYNAMICS_LOGGER_OUTPUT_TYPE: console
 NODE_OPTIONS: '--require /opt/appdynamics/shim.js'
 # variables required to send transaction analytics data
 APPDYNAMICS_ANALYTICS_HOST_NAME: <value>
 APPDYNAMICS_ANALYTICS_PORT: <value>
 APPDYNAMICS_ANALYTICS_SSL_ENABLED: <value>
kind: ConfigMap

```

```

metadata:
 name: appd-nodejs-config

```

The `NODE_OPTIONS` environment variable, supported in Node.js 8 and later, sets the `--require` option to the location of the `shim.js` file copied from the init container image. The analytics host, port and ssl settings depend on how the Analytics Agent is deployed. See [Deploy Analytics in Kubernetes](#) for options.

2. Apply the ConfigMap to the namespace:

```
$ kubectl -n ecommerce apply -f appd-nodejs-config.yaml
```

3. Update the deployment spec to reference the ConfigMap:

```

spec:
 containers:
 - name: nodejs-app
 envFrom:
 - configMapRef:
 name: appd-nodejs-config
 ...

```

### Use Secrets for the Controller Access Key

1. Create a Secret using `kubectl`:

```
$ kubectl -n ecommerce create secret generic appd-agent-secret --from-literal=access-key=<access-key>
```

2. Update the deployment spec to reference the Secret:

```

spec:
 containers:
 - name: nodejs-app
 env:
 - name: APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY
 valueFrom:
 secretKeyRef:
 name: appd-agent-secret
 key: access-key
 ...

```

### Set Application-Specific Configuration in the Deployment Spec

Set the application-specific tier name environment variable `APPDYNAMICS_AGENT_TIER_NAME` in the deployment spec:

```
spec:
 containers:
 - name: nodejs-app
 env:
 - name: APPDYNAMICS_AGENT_TIER_NAME
 value: nodejs-service
```

### Set the `UNIQUE_HOST_ID` Environment Variable

Set the `UNIQUE_HOST_ID` environment variable to enable APM correlation with the Cluster Agent. Since the value depends on a runtime value, set this environment variable in the container startup command with the values in [Manually Configure App Agents to Correlate with the Cluster Agent](#).

For a Kubernetes environment with the Docker runtime, set the environment variable as shown in the following example:

```
spec:
 containers:
 - command: ["/bin/sh"]
 args: ["-c", "export UNIQUE_HOST_ID=$(sed -rn '1s#.*/#; 1s/(.{12}).*/\\1/p' /proc/self/cgroup) && node /nodejsapp/myapp.js"]
```

### (On-Premises Controller Only) Copy the Controller Certs to the Container

If on-premises Controller certs are required, define a ConfigMap to reference the `cert` file and use a volume mount in the deployment spec to mount the ConfigMap contents to the container.

```
$ kubectl create configmap appd-cert --from-file=cacerts
```

Add the cert file to the container file system using `volumes` and `volumeMounts` as shown in the deployment spec snippet:

```
kind: Deployment
spec:
 containers:
 - image: myrepo/nodejs-app:v1
 volumeMounts:
 - name: appd-cert
 subPath: cacerts
 mountPath: /opt/appdynamics/cacerts
 volumes:
 - name: appd-cert
 configMap:
 name: appd-cert
```

The `mountPath` value should match the `certificateFile` property in the `shim.js` file used when building the init container image.

## Example Configuration for Using an Init Container

See this [deployment spec](#) for a complete example using an init container to copy the agent binaries.

### Use a Dockerfile

**i** This option applies to containers running in Docker and Kubernetes.

This option uses a Dockerfile to include the Node.js Agent binaries in the Docker image at build time. It assumes a single image is built that contains the application and Node.js Agent binaries.

To include the agent in the application image during the image build:

1. [Perform the Node.js Agent Installation Steps](#)
2. [Copy the Application Folder to the Image](#)
3. [Set the Node.js Agent Environment Variables](#)
4. [Set the UNIQUE\\_HOST\\_ID Environment Variable](#)
5. (On-Premises Controller only) [Copy the Controller Certs to the Image](#)

### Perform the Node.js Agent Installation Steps

Perform the installation steps described in [Install the Node.js Agent](#).

1. Run the NPM command to include the `appdynamics` package from your application folder:

```
$ cd nodejsapp
$ npm install appdynamics@next
```

2. Add the `require` statement to the application source code and include `reuseNode` and `reuseNodePrefix` properties. Set the `reuseNodePrefix` property to refer to an environment variable that will be set in a later step:

```
require("appdynamics").profile({
 reuseNode: true,
 reuseNodePrefix: process.env.APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX
});
```

The reuse node name and prefix properties are required to support unique naming for multiple container instances for the same application image. See [Node.js Settings Reference](#).

3. If the Node.js Agent should report transaction analytics data, add the analytics properties to the `require` statement and set the value to an environment variable that will be set in a later step. See [Node.js Settings Reference](#).

```
require("appdynamics").profile({
 reuseNode: true,
 reuseNodePrefix: process.env.APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX,
 analytics: {
 host: process.env.APPDYNAMICS_ANALYTICS_HOST_NAME,
 port: process.env.APPDYNAMICS_ANALYTICS_PORT,
```

```

 ssl: process.env.APPDYNAMICS_ANALYTICS_SSL_ENABLED
 }
});

```

## Copy the Application Folder to the Image

Edit the Docker file to copy the application folder to the image:

```
COPY nodejsapp/ /nodejsapp/
```

## Set the Node.js Agent Environment Variables

If you are running the application in a non-Kubernetes environment (using `docker run` for example), set the agent environment variables in the Dockerfile. For example:

```

ENV APPDYNAMICS_AGENT_APPLICATION_NAME=<value>
ENV APPDYNAMICS_AGENT_TIER_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=<value>
ENV APPDYNAMICS_CONTROLLER_HOST_NAME=<value>
ENV APPDYNAMICS_CONTROLLER_PORT=<value>
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED=<value>
ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX=<value>
ENV APPDYNAMICS_AGENT_NODE_NAME=<value> # not used in node name but required by Node.js agent
ENV APPDYNAMICS_LOGGER_OUTPUT_TYPE=console
variables required to send transaction analytics data
ENV APPDYNAMICS_ANALYTICS_HOST_NAME=<value>
ENV APPDYNAMICS_ANALYTICS_PORT=<value>
ENV APPDYNAMICS_ANALYTICS_SSL_ENABLED=<value>

```

For Kubernetes applications, omit these environment variables from the Dockerfile and set them using ConfigMaps, Secrets, and the deployment spec as described in [Use Init Containers](#). The analytics host, port and ssl settings depend on how the Analytics Agent is deployed. See [Deploy Analytics in Kubernetes](#) for options.

## Set the `UNIQUE_HOST_ID` Environment Variable

Set the `UNIQUE_HOST_ID` environment variable to enable APM correlation with the Cluster Agent. Since the value depends on a runtime value, set this environment variable in the image startup script using the values documented in [Manually Configure App Agents to Correlate with the Cluster Agent](#).

For a Kubernetes environment with a Docker runtime, add the following startup script `startup.sh` to the Docker image in the following example:

```

#!/bin/bash
OpenShift 3.10 or 3.11:
UNIQUE_HOST_ID=$(sed -rn '1s#.*##; 1s/(.{12}).*/\1/p' /proc/self/cgroup)
exec node /nodejsapp/myapp.js

```

## (On-Premises Controller only) Copy the Controller Certs to the Image

For Node.js Agents communicating with an on-premises Controller, edit the Dockerfile to copy the cert file containing the on-premises certs to the image.

For example:

```
COPY ./onprem-cacerts /opt/appdynamics/cacerts
```

Update the application source code to add the `certificateFile` property in the `require` statement. Set the `certificateFile` path to the location of the cert file.

```
require("appdynamics").profile({
 reuseNode: true,
 reuseNodePrefix: process.env.APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX,
 certificateFile: /opt/appdynamics/cacerts
});
```

## Node.js Agent API User Guide

### Related pages:

- [Node.js Agent API Reference](#)
- [Node.js Supported Environments](#)
- [Backend Detection Rules](#)

The AppDynamics Node.js Agent APIs enable the Node.js Agent to monitor business transactions that a web application performs outside the context of an HTTP request or an application that is not web-based.

### Business Transaction Definition

You define a custom business transaction using `appd.startTransaction()` and `end()`.

If the custom transaction runs for a long time or if it crosses an asynchronous boundary, you can use `resume()` to rejoin the running transaction.

A downstream transaction in a distributed transaction cannot start until its upstream transaction has made its exit call.

The order of transactions respects the nonlinear nature of Node.js applications. An upstream transaction might end immediately after its exit call completes or sometime later. It is not necessary for an upstream transaction to end before or after its downstream transaction starts or ends. It is possible for a downstream transaction to end before its upstream transactions have ended.

### Marking a Transaction as an Error Transaction

An error transaction is one in which an exception occurred. It is reported as an error transaction and not as a slow, very slow or stalled transaction, even if the transaction in which the error occurred was also slow or stalled.

To attach a JavaScript error object to a transaction using the Node.js APIs do one of the following:

- Use `trx.markError()` passing in the JavaScript error object.
- Attach the error object to the HTTP response associated with the transaction as `response.error`.

When an error is marked, the status code defaults to 500, unless you set it using one of the following techniques:

- Use `trx.markError()` passing in the JavaScript error object and the optional status code.
- Set the `statusCode` property in the error object passed to `trx.markError()` as `error.StatusCode`.
- Set the `statusCode` property on the `response.error` object as `response.error.StatusCode`.

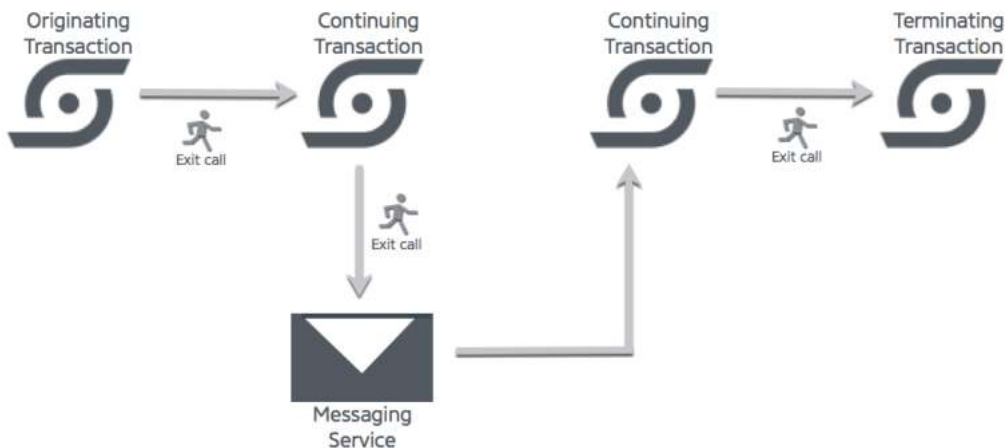

## Transaction Correlation Management

Transaction correlation is the functionality that maintains the business transaction context across all tiers—servers—traversed by a distributed transaction. The tiers may be built on platforms other than Node.js. For example, Java, .NET, and PHP tiers may participate in a distributed business transaction in which a Node.js tier participates, as originating, continuing or terminating tiers in the transaction.

The Node.js Agent APIs provide facilities for managing transaction correlation among various transactions, which may be custom or automatically-detected.

While the AppDynamics default auto-detection mechanism obtains transaction correlation information from an incoming HTTP request, the Node.js Agent APIs allow you to obtain this information from other sources, such as a custom field in a Redis cache entry, and to supply it to your custom transactions. You can use the APIs to support forward correlation by supplying transaction correlation information on exit calls that you make to downstream transactions.

A downstream transaction starts after its immediate upstream transaction makes its exit call. That call could be a direct exit call to the next tier or a call to a backend service that does some processing, such as publishing a message onto a queue.

## Exit Call Management

An exit call is either a custom exit call or an automatically-detected exit call. A transaction needs its exit call object to create correlation information to provide to a downstream transaction that needs to correlate with it.

### Custom Exit Calls

If you want an exit call to be reported to the controller, and it is not automatically detected by the agent, create a custom exit call with `startExitCall()` and end it with `endExitCall()`.

See [Node.js Supported Environments](#) for the list of backends that are automatically detected by the Node.js Agent. If the exit call invokes a backend not listed on this page, you probably need to create a custom exit call.

You can also use a `beforeExitCall()` callback function to check for the existence of an automatically-detected exit call.

Processing a custom exit call is straightforward. First, create the exit call and then pass its returned `ExitCall` object to `createCorrelationInfo()` to create a string-encoded correlation information object that a downstream transaction can fetch later.

### Workflow for a custom exit call

```
// start a custom transaction
var trx = appd.startTransaction(. . .)
. . .

// start a custom exit call
exit = trx.startExitCall(. . .);

// create correlation information
cinfo = trx.createCorrelationInfo(exit)
//store cinfo where it can be made available to a downstream transaction

// make the exit call
. . .
trx.endExitCall(. . .)
```

### Automatically Detected Exit Calls

The code executing in your custom transaction might make an exit call that is automatically detected by the Node.js Agent.

In this case, you can provide a `beforeExitCall()` callback function to process that exit call. When your code makes an automatically-detected exit call, the agent intercepts the exit call request and invokes the callback, if you have provided one. Then it allows the application to proceed with the exit call request.

You would install a `beforeExitCall()` callback function for the following purposes:

- To test for the existence of an automatically-detected exit call  
If you are uncertain that the exit call will be automatically detected, you can install a callback function to test for the exit call. If the callback is not invoked, the exit call is not automatically detected.

```
// start a custom transaction
var trx = appd.startTransaction(. . .)
. . .

var detected = false;
trx.beforeExitCall = function(call) { detected = true; return call; };

// make the exit call
```

```

. . .
// test whether the exit call was automatically detected
if (detected == false)
. . .

```

If `detected` is `false` after the exit call, you need to create a custom exit call to report the exit call to the Controller. If `detected` is `true`, you can capture the exit call and create the correlation information with the callback.

- To capture the `ExitCall` object to create correlation information

```

// start a custom transaction
var trx = appd.startTransaction(. . .)
. . .

trx.beforeExitCall = function getExitInfo(exitCall) {
 // create the correlation header from the captured exit call
 var c = trx.createCorrelationInfo(exitCall);
 // store c somewhere
 // ... (c)
 return exitCall;
}
// make the exit call

```

- To modify the exit call that is reported to the Controller

```

// start a custom transaction
var trx = appd.startTransaction(. . .)
. . .

trx.beforeExitCall = function customExitCallHandler(exitCall) {
 // don't report database access for this transaction
 if (exitCall.isSql) return;
 // customize label for all other exit calls in this transaction
 exitCall.label += " (my custom transaction)";
 return exitCall;
}
// make the exit call

```

## Workflow: Create Originating Transaction with Correlation Information

In this scenario, you create a custom originating transaction and the correlation header that a downstream transaction will need to correlate with it.

1. Start a custom transaction: `var trx=appd.startTransaction(...)`.
2. Either start a custom exit call using `e=trx.startExitCall(einfo)` or capture a detected exit call by installing a callback function to `e=trx.beforeExitCall(e)`.
3. Create correlation information from the exit call: `c=trx.createCorrelationInfo(e)`.
4. Store the correlation information.
5. Make the exit call.
6. Optionally provide a `trx.exitCallCompleted(e)` callback function, if you want to modify what is reported to the controller based on information obtained from the execution of the exit call.

7. If you created a custom exit call, end the exit call after you have processed the exit call response: `trx.endExitCall(e)`.
8. End the transaction: `trx.end()`.

### Workflow: Create Terminating Transaction Correlated with Upstream Transaction

In this scenario, you create a custom transaction, which needs to correlate with an upstream transaction but not with another downstream transaction.

1. Retrieve the correlation information stored by the previous transaction.
2. Parse the retrieved correlation information into a correlation header: `ch=appd.parseCorrelationInfo(c)`.
3. Start a custom transaction using the correlation header: `trx=appd.startTransaction(ch)`.
4. Optionally make an exit call.
5. End the transaction: `trx.end()`.

### Workflow: Create Continuing Transaction Correlated with Upstream and Downstream Transactions

In this scenario, you create a continuing transaction that needs to correlate both with an upstream originating transaction and a downstream transaction. It uses the correlation techniques described in both of the previous workflows.

1. Retrieve correlation information stored by the previous transaction.
2. Parse the retrieved correlation information into a correlation header: `ch=appd.parseCorrelationInfo(c1)`.
3. Start a custom transaction using the correlation header: `trx=appd.startTransaction(ch)`.
4. Either start a custom exit call using `e=trx.startExitCall(einfo)`, or capture a detected exit call by installing a callback function to `e=trx.beforeExitCall(e)`.
5. Create correlation information from the exit call in this transaction: `c2=trx.createCorrelationInfo(e)`.
6. Store the correlation information for the next downstream transaction.
7. Make the exit call.
8. Optionally provide a `trx.exitCallCompleted(e)` callback function, if you want to modify what is reported to the controller based on information obtained from the execution of the exit call.
9. If you created a custom exit call, end the exit call after you have processed the exit call response: `trx.endExitCall(e)`.
10. End the transaction: `trx.end()`.

## Node.js Agent API Reference

### Related pages:

- [Node.js Agent API User Guide](#)
- [Backend Detection Rules](#)

This page describes the Node.js Agent API. The Node.js Agent APIs include methods to manage business transactions and exit points in Node.js applications.

### API Call List

- [appd.startTransaction\(transactionInfo\)](#)
- [TimePromise.prototype.resume\(\)](#)
- [TimePromise.prototype.end\(error\)](#)
- [appd.getTransaction\(request\)](#)
- [appd.addAnalyticsData\(key, value\)](#)

- `appd.addSnapshotData(key, value)`
- `appd.markError(error, [statusCode])`
- `txn.markError(error, [statusCode])`
- `txn.addSnapshotData(key, value)`
- `txn.onSnapshotCaptured(txn)`
- `txn.addAnalyticsData(key, value)`
- `txn.onResponseComplete(req, res)`
- `exitCall.addAnalyticsData(key, value)`
- `TimePromise.prototype.startExitCall(exitCallInfo)`
- `TimePromise.prototype.endExitCall(exitCall, error)`
- `TimePromise.prototype.beforeExitCall(exitCall)`
- `TimePromise.prototype.exitCallCompleted(exitCall)`
- `appd.parseCorrelationInfo(source)`
- `TimePromise.prototype.createCorrelationInfo(exitCall, doNotResolve)`

## Loading the AppDynamics Module

You can use the APIs in your application by adding the `appdynamics` Node.js module in a `require` statement, after `appd.profile()`.

```
var appd = require('appdynamics');
appd.profile({ . . . })

...

var transaction = appd.startTransaction(...);
...

transaction.end();
```

## Basic Business Transaction Management

### `appd.startTransaction(transactionInfo)`

- `transactionInfo` string, `HttpRequest` or `CorrelationHeader`

The `transactionInfo` parameter can be one of the following:

- A string specifying the name of the custom transaction. The following characters cannot be used in transaction names: `{`, `}`, `[`, `]`, `|`, `&`, and `;`.
- A `HttpRequest` object. Normal transaction matching and naming rules are applied, and any included RUM and/or transaction correlation information is picked up automatically.
- A `CorrelationHeader` object providing information to correlate with a transaction that is upstream to this one. See `parseCorrelationInfo()`.

Creates and starts a custom business transaction and returns a transaction handle as a `TimePromise` instance, which is used for subsequent operations on this transaction.

### `TimePromise.prototype.resume()`

Re-joins a long-running or asynchronous transaction.

Call `resume()` :

- When a long-running transaction needs to be kept alive beyond the default transaction timeout of five minutes. This prevents the agent from assuming the transaction has failed and then deleting the transaction.

- When the code being instrumented crosses an async boundary. This re-associates the current execution context with the correct transaction and ensures any exit calls performed are charged to the right transaction.

### TimePromise.prototype.end(error)

- `error`: any; optional

Ends the transaction and reports transaction information to the Controller.

If an `error` is passed, the error is associated with the transaction and the transaction is flagged as an error transaction.

### appd.getTransaction(request)

- `request`: HTTP request object

Returns a handle to the business transaction associated with the specified request, if one exists. If no associated business transaction exists, returns false.

Use `appd.getTransaction()` to access both custom and automatically detected business transactions.

### appd.addAnalyticsData (key, value)

- `key`: key to custom data being added
- `value`: value being added for this key

Attaches custom data to Analytics generated for the current transaction. Your application does not require a transaction handle.

To enable this feature, the Analytics settings in the require statement must be set. See [Node.js Settings Reference](#). For information about Analytics, see [Analytics Data Sources](#).

### appd.addSnapshotData (key, value)

- `key`: key to custom data being added
- `value`: value being added for this key

Attaches custom data to snapshots generated for the current transaction.

`addSnapshotData()` can be called on a transaction at any time, but the added data is used only when a transaction snapshot is generated. For information on when transaction snapshots are generated, see [Troubleshoot Business Transaction Performance with Transaction Snapshots](#).

The following sample adds session count to USER DATA in the snapshot:

```
txn.addSnapshotData("active sessions", my.api.getSessionCount());
```

If the data to be added to the snapshot is available after the transaction completes, it can be attached using a `txn.onSnapshotCaptured(txn)` callback. This technique avoids overhead for collecting the data when no snapshot has been generated. The custom data is exposed in the **USER DATA** tab of the transaction snapshot details in the Controller UI.

### appd.markError(error, [statusCode])

- `error`: JavaScript error object
- `statusCode`: optional transaction status code

This value can also be passed as a `statusCode` property on the `error` object.

If neither a `statusCode` parameter nor an `error.statusCode` property in the `error` parameter is provided, the status code defaults to `500`.

See also [TimePromise.prototype.end\(error\)](#) for another way to attach an error object to a business transaction.

Marks the transaction as an error transaction. The marked transaction is reported as an error transaction and not as a slow, very slow or stalled transaction, even if the transaction was also slow or stalled.

### **txn.markError(error, [statusCode])**

- `error` JavaScript error object
- `statusCode` optional transaction status code. This value can also be passed as a `statusCode` property on the `error` object.

If neither a `statusCode` parameter nor an `error.statusCode` property in the `error` parameter is provided, the status code defaults to `500`.

See also [TimePromise.prototype.end\(error\)](#) for another way to attach an error object to a business transaction.

Marks the transaction as an error transaction. The marked transaction is reported as an error transaction and not as a slow, very slow or stalled transaction, even if the transaction was also slow or stalled.

### **txn.addSnapshotData(key, value)**

- `key`: key to custom data being added
- `value`: value being added for this key

Attaches custom data to snapshots generated for this transaction.

`addSnapshotData()` can be called on a transaction at any time, but the added data is used only when a transaction snapshot is generated. For information on when transaction snapshots are generated, see [Troubleshoot Business Transaction Performance with Transaction Snapshots](#).

The following sample adds session count to USER DATA in the snapshot.

```
txn.addSnapshotData("active sessions", my.api.getSessionCount());
```

If the data to be added to the snapshot is available after the transaction completes, it can be attached using a `txn.onSnapshotCaptured(txn)` callback. This technique avoids overhead for collecting the data when no snapshot has been generated. The custom data is exposed in the **USER DATA** tab of the transaction snapshot details in the Controller UI.

### **txn.onSnapshotCaptured(txn)**

- `txn`: transaction

Callback method that can be set on a transaction to add custom data to the transaction snapshot. Used with `txn.addSnapshotData(key, value)`.

When the `callback` function is supplied, the agent invokes this API immediately after capturing a transaction snapshot.

If specified, the `callback` is invoked on transaction completion, if the transaction triggers a snapshot.

You must define a function to call and assign it to the callback.

```

mytxn.onSnapshotCaptured = customTitle (txn) {
 // get book title for current transaction instance
 title = getBookTitle();
 txn.addSnapshotData ("book title", title);
}

```

Note that `txn === mytxn`. It is passed into the callback so the callback does not need to be defined in the same scope as `mytxn`.

### `txn.addAnalyticsData(key, value)`

- `key`: key to analytics data being added
- `value`: value being added for this key

Attaches custom data to Analytics generated for this transaction. If your application has a transaction handle, you can call `txn.addAnalyticsData(key, value)`. If not, use `appd.addAnalyticsData(key, value)`.

To enable this feature, the Analytics settings in the require statement must be set. See [Node.js Settings Reference](#). For more information about Analytics, see [Analytics Data Sources](#).

### `txn.onResponseComplete(req, res)`

- `req`: HTTP request for the transaction
- `res`: HTTP response for the transaction

Callback method that can be set on a transaction to be notified when the associated HTTP response has been completed. This can be used with `txn.addAnalyticsData(key, value)` to add data from response after it is complete, before the transaction completes. When the callback function is supplied, the agent invokes this API immediately after the HTTP response completes, before closing out the transaction. You must define a function to call and assign it to the callback.

```

mytxn.onResponseComplete = function customTitle (req, res) {
 // get status code of HTTP response
 code = res.statusCode;
 txn.addAnalyticsData ("http response code", code);
};

```

## Exit Call Management

### `exitCall.addAnalyticsData (key, value)`

- `key`: key to analytics data being added
- `value`: value being added for this key

Attaches existing Analytics data generated for this transaction to the exit call.

Attaches custom data to Analytics generated for this transaction. If your application has a transaction handle, you can call `txn.addAnalyticsData(key, value)`. If not, use `appd.addAnalyticsData(key, value)`.

To enable this feature, the Analytics settings in the require statement must be set. See [Node.js Settings Reference](#).

### TimePromise.prototype.startExitCall(exitCallInfo)

- `exitCallInfo` object

The `exitCallInfo` object has the following required properties:

- `exitType` : string—the type of exit call, one of "EXIT\_HTTP", "EXIT\_DB", "EXIT\_CACHE", "EXIT\_RABBITMQ", "EXIT\_WEBSERVICE"
- `label` : string—label for the exit call in the AppDynamics UI
- `backendName` : string—name of the backend remote system or service
- `identifyingProperties` : Object—a hash of name/value pairs uniquely identifying the remote system or service being called. See [Backend Identifying Properties](#).

Creates and starts a custom exit call, described by the `exitCallInfo` object.

You can supply more identifying properties in addition to the required ones.

Returns an `ExitCall`. See [Exit Call Properties](#).

#### Sample exitCallInfo Object for MySQL

```
{
 exitType: "EXIT_DB",
 label: "New SQL",
 backendName: "NewDB"
 identifyingProperties: {
 "HOST": "database-server",
 "PORT": "12345",
 "DATABASE": "my-database",
 "VENDOR" = "MYSQL"
 },
 ...etc...
}
```

### TimePromise.prototype.endExitCall(exitCall, error)

- `exitCall`: `ExitCall` instance returned by `startExitCall()`
- `error`: any; optional

Ends a custom exit call and attaches it to this transaction.

If an `error` is passed, the error is associated with the exit call, and the exit call is flagged as being in an error state.

### TimePromise.prototype.beforeExitCall(exitCall)

- `exitCall`: `ExitCall`

Returns an `ExitCall`.

Optional callback for modifying an automatically-detected (not custom) exit call.

The agent invokes this API immediately before your application makes the exit call when you supply a callback function. You can use the callback to:

- Modify the exit call that is reported to the controller.
- Suppress all reporting of the exit call by returning nothing.

- Capture the exit call to create correlation information for a downstream transaction.

The following is an example of a modify exit call reported to the Controller.

```

txn.beforeExitCall = function customExitCallHandler(exitCall) {
 // don't report database access for this transaction
 if (exitCall.isSql) return;
 // customize label for all other exit calls in this transaction
 exitCall.label += " (my custom transaction)";
 return exitCall;
}

```

### TimePromise.prototype.exitCallCompleted(exitCall)

- `exitCall`: ExitCall

Optional. Returns an ExitCall. Callback for modifying either a custom exit call created by `startExitCall()` or an automatically-detected exit call on completion of the exit call.

The agent invokes this API immediately after an exit call completes when you supply a callback function.

Use `exitCallCompleted()` to modify how the exit call is reported to the Controller by returning a modified exit call. Do not modify the backend identifying properties using this callback.

The following code is an example that modifies the exit call reported to the Controller.

```

txn.exitCallCompleted = function customExitCallPostProcessor(exitCall) {
 // report MongoDB read and write operations as distinct exit calls
 if (exitCall.backendName === "MongoDB")
 exitCall.label += " " + exitCall.category;
}

```

## Transaction Correlation Management

### appd.parseCorrelationInfo(source)

- `source`: String or `HttpRequest`

Describes the upstream transaction with which to correlate. If a `HttpRequest` object is passed, it must have a transaction correlation header attached.

On success, returns a `CorrelationHeader` object that can be used by `startTransaction()` to create a transaction that is correlated with the upstream transaction described by `source`. Returns `false` if `source` could not be parsed. This can occur if the source is an HTTP request with no correlation header attached or the string parameter is not recognized as a correlation header.

HTTP requests made through the standard `http.request()` API have correlation information added automatically. You can correlate a custom transaction created in response to an HTTP request made from another Node.js process by passing the incoming request as `source`.

For other exit call types, you need to define how correlation information is attached to the originating transaction and retrieved in the downstream transaction.

## TimePromise.prototype.createCorrelationInfo(exitCall, doNotResolve)

- `exitCall`: ExitCall
- `doNotResolve`: optional, true|false

The input `exitCall` is one of the following:

- For a custom exit call, value returned from `startExitCall()`.
- For an automatically-detected exit call, input parameter to the `beforeExitCall()` callback.

Set the `doNotResolve` parameter to `true` if you do not want the backend to be resolved to a tier. It defaults to `false`, which means that the backend is resolved to the calling tier. You may want to set this for an exit call to a service, such as a messaging queue, that does not have a 1:1 relationship between the consumer and producer of the service. For more information see [Resolve Remote Services to Tiers](#).

Returns a string-encoded correlation header, which a downstream transaction can use to correlate with this transaction.

### Exit Call Properties

This table describes the properties of the exit call object for each detected exit call type.

A dash (–) in a table cell indicates that the property is present in a discovered exit call but its format is unspecified. This allows you to set your own values when you create custom exit calls.

N/A indicates that the property is not used with that exit call type. Discovered exit calls may have additional properties not documented here.

Property	HTTP	MySQL	Postgres	MongoDB	Memcached	Redis
<code>backendName</code>	"HTTP"	"MySQL"	"PostgreSQL"	"MongoDB"	"Memcached"	"Redis"
<code>label</code>	String	String	String	String	String	String
<code>method</code>	String	N/A	N/A	N/A	N/A	N/A
<code>requestHeaders</code>	Object	N/A	N/A	N/A	N/A	N/A
<code>responseHeaders</code>	Object	N/A	N/A	N/A	N/A	N/A
<code>statusCode</code>	Integer	N/A	N/A	N/A	N/A	N/A
<code>category</code>	"read" "write"	N/A	N/A	"read" "write"	N/A	N/A
<code>user</code>	N/A	String	String	N/A	N/A	N/A

Property	HTTP	MySQL	Postgres	MongoDB	Memcached	Redis
command	String (URL)*	SQL query executed	SQL query executed	N/A	N/A	N/A

\* host, port and path; does not include query string.

### Backend Identifying Properties

This table lists the identifying properties for the backends that are automatically detected by the Node.js Agent.

In the Controller UI, these properties are visible in the upper right panel of the backend dashboards.

Backend Service	Exit Call Type	Identifying Properties
HTTP Server	"EXIT_HTTP"	"HOST", "PORT"
MySQL Server	"EXIT_DB"	"Host", "Port", "Database", "Vendor" = "MYSQL"
Postgres Server	"EXIT_DB"	"Host", "Port", "Database", "Vendor" = "POSTGRESQL"
MongoDB Server	"EXIT_DB"	"Server Pool" <sup>1</sup> , "Database", "Vendor" = "MONGODB"
Memcached	"EXIT_CACHE"	"EXIT_CACHE", "Server Pool" <sup>1</sup>

Backend Service	Exit Call Type	Identifying Properties
Redis Server	"EXIT_CACHE"	"Server Pool" <sup>2</sup>

<sup>1</sup> "\n" separated list of server addresses in <host>:<port> format.

<sup>2</sup> single server address in <host>:<port> format.

## Node.js Agent Logging

### Related pages:

- [Dynamic Language Agent Proxy](#)
- [Node.js Java Proxy Mode](#)

This page explains logging for the default mode of the Node.js Agent.

By default, the Node.js Agent generates log information at the informational level. You can increase/decrease the logging verbosity, change the log file location, and configure other logging settings.

### Node.js Agent Logging Location

The log file appears at the following location on the machine where the Node.js Agent runs:

```
/tmp/appd/<hash>/appd_node_agent_<datetime>.log
```

If you are running the Node.js Agent, <hash> is generated by the agent.

In Windows, you can find the tmp directory with `cd %tmp% d` and then look for the <hash> directory.

### Configure Node.js Agent Logging

To configure logging, use the logging module configuration in the Node.js require statement. You can change the level, maximum size/number of files, and mode.

The following sample shows the logging settings in default mode:

```
{
 ...

 logging: {
 'logfiles': [
 {
 'root_directory': '/tmp/appd',
 'filename': 'echo_%N.log',
 'level': 'TRACE',
 'max_size': 5242880,
 'max_files': 10,
 'outputType': 'console' // Set this parameter if you want to log to STDOUT/STDERR.
 Omit this parameter if you want to log to a file.
 }
]
 }
}
```

```
...
}
```

The level determines the verbosity of logging output and can contain one of the following values listed from least to most verbose:

- FATAL
- ERROR
- WARN
- INFO
- DEBUG
- TRACE

By default, once the size of the logging files on disk reaches the maximum size, old logs are purged. You can reduce or increase the size, depending on your needs and the disk space available on the machine.

### Debug Logging

Instead of the logging configuration above, you can use this shortcut to set `DEBUG` to true, resulting in debug level logging.

```
debug : true,
```

The location of the debug log file is written to standard output.

See [Node.js Agent Settings](#).

### Node.js Agent Node Properties

#### max-continuing-concurrent-snapshots

A limit for the number of concurrent snapshots continuing on this tier or node. For example, if too much overhead is being taken by snapshots, then tweak this value to reduce the snapshots.

<b>Type:</b>	Integer
<b>Default Value:</b>	200
<b>Platform(s):</b>	Node.js

### max-continuing-snapshots-per-minute

A limit for the number of snapshots continuing on this tier or node per minute. For example, if too much overhead is being taken by snapshots, then tweak this value to reduce the snapshots.

<b>Type:</b>	Integer
<b>Default Value:</b>	100
<b>Platform(s):</b>	Node.js

### max-error-snapshots-per-minute

A limit for the number of snapshots on this tier or node per minute to capture errors. For example, if too many error snapshots are being seen, then tweak this value to reduce *noise* in the snapshots.

<b>Type:</b>	Integer
<b>Default Value:</b>	5
<b>Platform(s):</b>	Node.js

### max-originating-concurrent-snapshots

A limit for the number of concurrent snapshots originating on this tier or node. For example, if too much overhead is being taken by snapshots, then tweak this value to reduce the snapshots.

<b>Type:</b>	Integer
<b>Default Value:</b>	5
<b>Platform(s):</b>	Node.js

## max-originating-snapshots-per-minute

A limit for the number of snapshots originating on this tier or node per minute. For example, if too much overhead is being taken by snapshots, then tweak this value to reduce the snapshots.

<b>Type:</b>	Integer
<b>Default Value:</b>	20
<b>Platform(s):</b>	Node.js

### Upgrade the Node.js Agent

If you are upgrading both the Controller and agents, first upgrade the Controller and then upgrade the agents.

Also, if you are upgrading multiple agents in your monitored environment, upgrade the agents for the tiers on which business transactions originate last. For more information about this requirement, along with Controller and agent compatibility information, see [Agent and Controller Tenant Compatibility](#).

To upgrade the Node.js agent:

1. Stop the Node.js application.
2. From the root directory of the application for which you want to upgrade the agent, uninstall the old version of the agent by entering:

```
npm uninstall appdynamics
```

3. From the same directory install the new version by entering:

```
npm install appdynamics@<version>
```

The version is the three-digit version number of the new version that you are installing; for example, 4.1.1.

4. Restart the Node.js application.

### Uninstall the Node.js Agent

To uninstall the Node.js Agent:

1. From the application root directory of the application from which you want to uninstall the agent enter:

```
npm uninstall appdynamics
```

2. Remove the `"require("appdynamics")"` statement from your Node.js applications.
3. Restart the Node.js application.

## gRPC Support for the Node.js Agent

This page describes how to use the HTTP naming rules required to name gRPC Business Transactions.

 To form the gRPC URI, you link the `SERVICE_NAME` and the `OPERATION_NAME` resulting in: `URI = SERVICE_NAME/OPERATION_NAME`. Then, the naming rule uses the `URI = SERVICE_NAME/OPERATION_NAME` to generate the gRPC Business Transactions name.

## Automatic Naming Rules

To add automatic naming rules:

1. From the **Add Rule** tab, click **Rule Configuration**.
2. Under the **Configure Naming** tab, select which part of the URI to use in the **Transaction Name**:
  - a. Click **Use the full URI** to use the full URI in the **Transaction Name**.
  - b. Click **Use a part of the URI** to use only a part of the URI in the **Transaction Name**. If you select **Use a part of the URI**, you can only use one or two segments of the URL.
3. Click **Save**.

## Custom Naming Rules

To add custom naming rules:

1. From the **Add Rule** tab, click **Rule Configuration**.
2. Under **HTTP Request Match Criteria**, click **+Add**.
3. Click **URI**.
4. Select **Split Transactions Using Request Data**.
5. In the dropdown, you can select the **first few URI segment(s)** or the **last few URI segment(s)** in the **Transaction names**.
  - a. You can only use one or two segments of the URL.
6. Click **Save**.

## Node.js Java Proxy Mode

### Related pages:

- [Dynamic Language Agent Proxy](#)

This page provides an overview of the Java proxy mode for the Node.js Agent.

 The Node.js Agent no longer supports the proxy as of version 21.9.

Every Node.js Agent on a machine launches a proxy instance, creating a control directory for the proxy based on a unique combination of application, tier, and node names for the agent. The control directory contains the configuration for the agent and the domain control socket, which is what the agent uses to start an AppDynamics node.

If you are running multiple Node.js Agents on a single machine, you can configure them to use a shared Java proxy. Referred to as a "multi-tenant proxy," the shared proxy reduces the overhead of additional proxies and is a required configuration for external process managers, such as PM2.

You can use the Java proxy mode as the Node.js Agent supports the existing Java proxy.

## Install the Node.js Agent (Java Proxy)

### Related pages:

- [Run the Node.js Agent on Windows](#)
- [SELinux Installation Issues](#)

This page provides instructions on how to install the Node.js Agent in the Java proxy mode.

The Getting Started Wizard in the Controller provides the easiest way to get started with the AppDynamics Node.js Agent. The wizard constructs a pre-configured require statement for the agent based on your input.

### Before You Begin

You must add a require statement to the source code of your Node.js application and install the Node.js Agent. In addition to running the AppDynamics Controller, you need to have write access to the application source code and the ability to restart the Node.js application, which installs the agent.

The Getting Started Wizard in the Controller generates the require statement for you. It populates the statement with the connection settings for the Controller and the values you provide for the wizard to model the Node.js application in AppDynamics.

For installation on Windows, see [Supported Environment](#) to determine the appropriate version of Windows and install the [Visual C++ Redistributable for Visual Studio 2015](#).

### Install the Node.js Agent

To install the agent, run the install command in the directory of your application and add a `require` comm and to add the agent module to your application.

If you are using Node.js 0.8.1 through 0.8.18, see [Set User Agent for Node.js 0.8.1 through 0.8.18](#) before running the install command.

Install via `npm`

Refer to [Agent and Controller Tenant Compatibility](#) to determine which versions of the Node.js Agent are compatible with your Controller.

To install the latest agent in the Java proxy mode, run the following command:

```
npm install --appd_include_java_proxy=true appdynamics
```

To run the Node.js Agent on Windows with the Java proxy, see [Run the Node.js Agent on Windows](#).

### Add the Require Statement

Paste the following require statement as the very first line of your application source code before any other require statement. Replace the variables with the values for your setup. To find your account name and access key, select **Settings**  and then **License**.

```
require("appdynamics").profile({
 controllerHostName: '<controller host name>',
```

```

controllerPort: <controller port number>,
controllerSslEnabled: false, // Set to true if controllerPort is SSL
accountName: '<AppDynamics_account_name>',
accountAccessKey: '<AppDynamics_account_key>', //required
applicationName: 'your_app_name',
tierName: 'choose_a_tier_name',
nodeName: 'choose_a_node_name',
proxy: true
});

```

For reference information on the settings, along with other settings you can use, see [Node.js Settings Reference](#).

You can place the `require` statement as the first line in the require statement of another module that appears as the first line of code.

In this case, you would need to modify your point-of-entry source file; this it can be just a single line to the `require()` the file that you place the call to the agent into; for example, `require("<script-that-initializes-the-agent>")`. You could also parameterize the `profile()` call to name different instances without having to have multiple versions of the agent initialization script.

If it is not possible to place the require statement as the first line of code, you can insert the statement elsewhere, but it must occur before the `require()` of any core or third party module that needs to be instrumented. In general, the `require("appdynamics")` statement should occur as early as possible in the code.

### Test the Configuration

To verify the installation, restart the application and put load on it. The new node should appear in the flow map for the business application you specified in the configuration.

### Stop the Node.js Application

When running the Node.js Agent with the Java proxy, configure the script/mechanism that stops an instrumented Node.js instance to use the SIGTERM signal if possible. SIGKILL ( `kill -9` ) prevents the resources for the agent's Java proxy from being released.

When running the Node.js Agent in the multi-tenant mode, you must manually shut down the Java proxy after stopping your Node.js application.

### Run with Other Profiling Tools

The agent is incompatible with other profiling tools, such as running the node process with the `--inspect` flag.

### Instrument a Node.js Cluster

If your application uses the cluster module, place the `appdynamics.profile require` statement in both the primary and worker processes.

Running the Node.js Agent with the Java proxy does not require a manual launch of the proxy. Running the Node.js Agent with the Java proxy and an external process manager (such as PM2) for your application requires a manual launch of the proxy component.

See [Sharing a Proxy Among Node.js Agents](#).

## Run the Node.js Agent on Windows

### Related pages:

- [Install the Node.js Agent](#)
- [Start the Proxy Manually for Node.js](#)
- [Share a Proxy Among Node.js Agents](#)
- [Dynamic Language Agent Proxy](#)
- [SELinux Installation Issues](#)

This page provides instructions on how to run the Node.js Agent in the Java proxy mode on a Windows machine.

### Proxy Ports

 The Node.js Agent no longer supports the proxy as of version 21.9.

Depending on your Node.js environment on Windows, you may need to configure three ports in the Node.js require statement. These port settings are:

- `proxyCommPort` : Default is 10101
- `proxyRequestPort` : Default is 10102
- `proxyReportingPort` : Default is 10103

All three ports must be inclusive of the 1024—65535 range.

### Auto-Launch Windows Environments

The default behavior is for the agent to auto-launch the Java proxy, where `proxyAutoLaunchDisabled` is `false`.

If you allow the agent to auto-launch and you have one Node.js process per machine, the agent will automatically use the default port values if they are available. In this case, you do not have to configure these settings.

If the default ports are not available, configure these settings to ports that are available in the require statement in the `require` statement.

If you have multiple Node.js processes on a single machine each reporting to its own proxy, each process needs its own set of ports. In this case, configure unique settings for all three ports in the `require` statement for each process.

### Manual-Launch Windows Environments

Some environments have multiple Node.js processes on the same machine, all reporting to a single proxy. In these environments, it is necessary to launch the proxy manually, where `proxyAutoLaunchDisabled` is `true` and to configure the three port settings.

The `proxyCommPort` setting in the `require` statement and the `commPort` option to the `runProxy.cmd` must be the same value. The agent and the proxy must use the same port.

The `proxyRequestPort` and the `proxyReportingPort` are two unused TCP ports that the user running the proxy has permission to bind to on Windows.

Each distinct app-tier-node combination on a single machine must use different request and reporting ports. Two processes reporting as the same app-tier-node may use the same request and reporting ports. Set these ports in the `require` statement for each app/tier/node combination.

## Execute runProxy Manually on Windows

By default, the proxy component is automatically started when you start the agent. If you have configured the agent to manually launch the proxy, use the following command.

Before any traffic is run on the instrumented server, execute `runProxy.cmd` to start the proxy using the following syntax. If you use the optional `-d` option, it must precede the `-j` option.

```
Usage: runProxy.cmd [-d <proxyDir>] -j <jreDir> [logDir] [commPort]
```

### Options:

```
-d <proxyDir> the directory where the proxy is installed; optional, defaults to the
directory containing the runProxy.cmd script
-j <jreDir> the directory where the JRE is installed; required
logDir the directory the proxy should log to; optional, defaults to <proxyDir>\logs
[commPort] port used for the proxy control channel on Windows; defaults to 10101; if
specified it must match the proxyCommPort setting in the require statement
```

The following example assumes that the command is run from the root of the Node.js application instrumented by the agent.

```
.\node_modules\appdynamics\node_modules\appdynamics-proxy\proxy\runProxy.cmd
-j .\node_modules\appdynamics\node_modules\appdynamics-jre\jre /var/log/proxy
.\node_modules\appdynamics\node_modules\appdynamics-proxy\proxy\logs
10101
```

## Execute the runProxy Command Manually on Windows Task Scheduler

You can schedule the runProxy command in the Windows Task Scheduler.

1. Open Task Scheduler.
2. Click **Create Basic Task**.
3. In the General tab, enter a name for your task.
4. Select **Run whether user is logged on or not**.
5. Check **Run with highest privileges**.
6. In the Triggers tab, add a new trigger. Set the trigger to when the device starts.
7. In the Actions tab, create a new action. Set the action to **Start a program**.
8. In the **Program/script** field, enter:  
`<app_root>/node_modules/appdynamics-proxy/proxy/runProxy.cmd`
9. In the **Add arguments** field, enter:  
`-d <app_root>/node_modules/appdynamics-proxy -j <app_root>/node_modules/appdynamics-jre/jre %TEMP% 10101`
10. In the **Start in** field, enter:  
`<app_root>/node_modules/appdynamics-proxy/proxy`
11. Click **OK** to finish the wizard.
12. Reboot the system, and check the Task Manager for a Java process.

## Share a Proxy Among Node.js Agents

### Related pages:

- [Start the Proxy Manually for Node.js](#)
- [User Preferences](#)

This page describes how to configure multiple Node.js Agents on a machine to share a single, multi-tenant Java proxy.

 The Node.js Agent no longer supports the proxy as of version 21.9.

### Configure a Shared Proxy

1. Stop the Node.js application.
2. Create directories for the agent and the agent logs and for the proxy control directory. The permissions on this directory must be readable and executable by the application user that the application and writable by the proxy user.

For example:

```
mkdir /tmp/appd /tmp/appd/logs /tmp/appd/proxy_ctrl_dir
```

When you upgrade the Node.js Agent, you may want to create these directories automatically.

3. Disable automatic proxy launching for each agent. In the AppDynamics `require.profile()` block, set `proxyAutoLaunchDisabled` to `true` and set the `proxyCtrlDir` to the directory that you created.

For example:

```
...
proxyAutoLaunchDisabled: true,
proxyCtrlDir: '/tmp/appd/proxy_ctrl_dir',
...
```

4. Ensure that each agent that reports to the multi-tenant proxy is configured with a unique node name.
5. Before you start the agents, start the shared Java proxy and pass the agent control directory from the `proxyCommunicationDir` argument to the `runproxy` script. AppDynamics recommends that you configure the proxy to start on system startup. See [Start the Proxy Manually for Node.js](#).
6. Restart the Node.js application. The nodes should appear in the Controller UI flow maps in a couple minutes.

### Proxy Sharing Limits

By default, a single proxy can handle up to ten agents. If you need to run more, you will have to adjust the `maxHeapSize` and `maxPermSize` settings in the `runproxy` script.

When adding agents, use debug mode and monitor the `proxy.out` file, which indicates whether the proxy is running out of heap. The file is visible when running in debug mode.

### Start the Proxy Manually for Node.js

### Related pages:

- [Run the Node.js Agent on Windows](#)

This page describes how to manually launch the Java proxy for Node.js.

 The Node.js Agent no longer supports the proxy as of version 21.9.

Upon startup, the Node.js Agent automatically executes the `runproxy` shell script, which starts the Java proxy. This process is suitable for most situations, but there are some cases where you may want to suppress automatic proxy startup and manually launch the proxy.

For example, you are using an external process manager or you are running a Node.js cluster on a machine and want to reduce overhead of multiple proxies.

As the Node.js process owner, you will need to launch the proxy manually.

The following example configures the manual Java proxy launch:

```
nohup /<application_root_dir>/node_modules/appdynamics-proxy/proxy/runProxy -j /
<application_root_dir>/node_modules/appdynamics-jre/jre -- /tmp/appd/proxy_ctrl_dir /tmp/
appd/logs &
```

For the full description of the `runProxy` script syntax for PHP applications, see [Start the PHP Agent Proxy Manually](#).

## Node.js Agent Logging (Java Proxy)

### Related pages:

- [Proxy Logging](#)
- [Dynamic Language Agent Proxy](#)

This page explains Node.js Agent logging for the Java proxy mode.

By default, the Node.js Agent generates log information at the informational level. You can increase/decrease the logging verbosity, change the log file location, and configure other logging settings.

### Node.js Agent Logging Location

The log file appears at the following location on the machine where the Node.js Agent runs:

```
/tmp/appd/<hash>/appd_node_agent_<datetime>.log
```

If you are running the Node.js Agent, `<hash>` is generated by the agent.

On Windows, you can find the `tmp` directory with `cd %tmp% d` and then look for the `<hash>` directory.

### Configure Node.js Agent Logging

To configure logging, use the logging module configuration in the Node.js `require` statement. You can change the level, maximum size/number of files, and mode.

The following sample shows the logging settings when you are in the Java proxy mode:

```
{
 ...
```

```

logging: {
 'root_directory': '/tmp/appd',
 'filename': 'echo_%N.log',
 'level': 'TRACE',
 'max_size': 5242880,
 'max_files': 10,
 'outputType': 'console' // Set this parameter if you want to log to STDOUT/STDERR. Omit
this parameter if you want to log to a file.
}

...
}

```

The level determines the verbosity of logging output and can contain one of the following values listed from least to most verbose:

- FATAL
- ERROR
- WARN
- INFO
- DEBUG
- TRACE

By default, once the size of the logging files on disk reaches the maximum size, old logs are purged. You can reduce or increase the size, depending on your needs and the disk space available on the machine.

### Proxy Logging

The Java proxy logs the transactions that are accepted from the agent and sent to the Controller. The proxy generates logs independently of the Node.js Agent's logging level or activity.

When the Node.js Agent launches the proxy, it prints the directory path at which the proxy is logging to its own log. By default, the proxy log is in `/tmp/appd/<hash>/proxy/logs`.

See [Dynamic Agent Proxy Logging](#).

### Debug Logging

Instead of the logging configuration above, you can use this shortcut to set `DEBUG` to true, resulting in debug level logging.

```
debug : true,
```

The location of the debug log file is written in standard output.

See [Node.js Agent Settings](#).

### Vulnerability Reporting on Node.js Agent

This page goes over the Vulnerability Reporting feature that is available on the Node.js Agent. Vulnerability Reporting detects package vulnerabilities that are in your node application. The Node.js Agent reads package information from your application `package.json` file, then communicates this information to the Cisco AppDynamics Secure backend.

---

## Configure Vulnerability Reporting

To enable Vulnerability Reporting from the Node.js Agent, add the following to your `appd.require` statement:

```
require("appdynamics").profile({
 ...
 secureAppEnabled: true,
 ...
});
```

For more information on configuring Cisco Secure Application with the Node.js Agent, see [Getting Started with Cisco Secure Application](#) and [Monitor Vulnerabilities](#).

## PHP Agent

### Related pages:

- [AppDynamics Essentials](#)
- [PHP Supported Environments](#)
- [Dynamic Language Agent Proxy](#)

This page describes the PHP Agent, the application monitoring agent for web and CLI PHP applications in AppDynamics.

### About the PHP Agent

The PHP agent component discovers and monitors business transactions, application services, and backends in your PHP application. It injects AppDynamics instrumentation into the application at runtime.

The AppDynamics [agent proxy](#) is a Java process that handles the communication between the PHP agent and the Controller. The proxy reports performance metrics to the Controller, where the data is stored, baselined, and analyzed. You can access this performance data interactively using the Controller console or programmatically using the AppDynamics REST API.

The proxy component starts automatically when you start the PHP Agent. For some applications, such as for PHP CLI applications, you need to start the proxy separately from the agent. You need to provide for proxy startup either manually or in scripts.

### Deployment Overview

The proxy is the component that connects the agent and the controller. If you can ping the Controller but the agent is not connecting, it is possible that the proxy did not start or that the proxy is not configured correctly. See [Resolve PHP Agent Installation Issues](#) and [Dynamic Language Agent Proxy](#).

When the connection is successfully established, log in to the Controller to monitor your application. See [AppDynamics Essentials](#) to get started.

### Single Application Per Web Server Instance

This is the default setup assumed by the installer—multiple servers, each with a single application.

Each application has its own agent and its own agent and proxy. There is a single tier and a single node for each application.

### Single Application Per Web Server Instance with Multi-Tenant Proxy

This scenario also assumes multiple servers, each with a single application.

In this case, each application has its own agent component but all the agents share a single proxy. There is a single tier and a single node for each application. Sharing a proxy can save some overhead in some situations. See [Use a Shared Proxy for PHP Agents](#).

### Multiple Applications on a Single Server

This scenario assumes multiple applications running in a single server.

There is one agent and one proxy supporting multiple applications. By default, the proxy automatically starts when the server starts. The applications can be configured with different tiers and nodes.

---

See [Multiple PHP Apps on a Single Server](#) for information on how to configure the Apache vhosts or FPM pool config blocks.

## Getting Started with the Download Wizard

If you have never installed the agent, the best way to start is with the Getting Started Wizard in the Controller. The Getting Started Wizard walks you through configuration steps and helps you download the agent. To access the wizard, in the **Home** page of the Controller, click **Getting Started** and then **PHP**.

The wizard provides the minimum information that the agent needs to communicate with the AppDynamics Controller: Controller host and port, optionally SSL, application name and tier name.

## Node Naming in a PHP Environment

A PHP runtime instance maps to a node. Your naming convention may depend on your exact environment. Use a name that clearly identifies the Web service that corresponds to the node. Some options are:

- `hostName-appName-nodeName`
- `hostName- tierName -nodeName`
- `appName-nodeName`
- `tierName -nodeName`
- `IP address`
- `fully qualified domain name`

## PHP Supported Environments

### Related pages:

- [PHP Business Transaction Detection](#)

## PHP Agent Support

### PHP Versions

PHP Agent supports these versions of PHP:

- 7.4
- 8.0
- 8.1
- 8.2

PHP ZTS Agent supports these versions of PHP:

- 7.4
- 8.0
- 8.1
- 8.2

## PHP Web Servers

Apache 2.2 and 2.4 in these modes:

- `prefork` mode using `mod_php`
- worker MPM mode using `mod_fastcgi` with `php -fpm` or `mod_fcgid` with `php - cgi`

Any web server compatible with `php -fpm`.

## Operating Systems

- Any Linux distribution based on `glibc>=2.17` or `GLIBCXX_>=3.4.19` and the x86 64-bit architecture.
- Alpine Linux `>=3.18`.

**i** For Alpine Linux, we recommend that you use the latest release of the supported PHP Versions.

**i** The PHP agent does not support Power Architecture.

### PHP Frameworks and Protocols

Framework/Protocol	Version < PHP 8	Version = PHP 8	Version = PHP 8.1, 8.2	Entry Point Type
Drupal	7	-	-	Drupal
Drupal	8	9.1+	9.1+	PHP MVC
WordPress	3.4+, 4.x, 5.x	5.6+	*	Wordpress
Zend	1, 2, 3	3+	3+	PHP MVC
CodeIgniter	2.x, 3.x, 4.x	3+	3+	PHP MVC
FuelPHP	1.5x, 1.6x, 1.8x	1.8.2	1.8.2	PHP MVC
Magento	1.5, 1.6, 1.7, 2.3			PHP MVC

Framework/Protocol	Version < PHP 8	Version = PHP 8	Version = PHP 8.1, 8.2	Entry Point Type
Symfony	1, 2, 3, 4	5.2+	5.2+	PHP MVC
CakePHP	2.x, 3.x, 4.x	4+	4+	PHP MVC
Laravel	5.7, 6, 8, 9.x	6.20+	6.20+	PHP MVC
HTTP	-	-	-	PHP Web
CLI	-	-	-	PHP CLI

\*For PHP 8.1, the WordPress 5.9+ versions will be supported in upcoming releases. You can still use WordPress, but the agent might not collect the data properly.

**i** PHP 8.x supports the framework versions only from the mentioned versions. The versions below these are not supported.

If your PHP framework is not listed here, the agent detects your entry points as PHP Web and names the business transactions based on the first two segments of the URI — the default naming convention for PHP Web transactions. So it is still possible to monitor applications on *unsupported* frameworks. Laravel BTs are detected as symfony, as laravel itself is built on top of symfony.

**i** There are few limitations of the PHP Agent. The PHP Agent does not:

- Support Zend Monitor
- Officially support plug-ins that encrypt and, or obfuscate PHP code such as Zend Guard or ionCUBE Loader
- Support compatibility with the Xdebug module
- Support the `pcntl_fork` function which forks the child/sub-processes

## Transaction Naming

Framework/Environment	Default Transaction Naming
Drupal	page callback name
Wordpress	template name
PHP MVC Frameworks	controller:action
PHP Modular MVC Frameworks	module:controller:action
PHP Web	URI
PHP Web Service	service name.operation name
PHP CLI	last two segments of the script's directory path plus the name of the script

Virtual host prefixing is available for all supported entry point types except PHP CLI.

## PaaS Providers

PaaS Provider	Buildpack
Pivotal Cloud Foundry	<a href="https://github.com/Appdynamics/php-buildpack">https://github.com/Appdynamics/php-buildpack</a> See <a href="http://docs.pivotal.io/appdynamics/index.html">http://docs.pivotal.io/appdynamics/index.html</a> for information about integration with PCF.

## Exit Points

Supported HTTP Exit Points
<code>curl/curl-multi*</code>
<code>drupal_http_request()</code>
<code>fopen()</code> , <code>file_get_contents()</code>

## Supported HTTP Exit Points

`Zend_HTTP_Client::request()`

\*The total time reported for a `curl/multi_curl` request in the Controller is the same as reported by the function `curl_getinfo`. Also, we report the the following execution metrics in the exit call details for the `curl/multi_curl` request which are included in the total time:

- `namelookup_time`
- `connect_time`
- `pretransfer_time`
- `redirect_time`

## Supported Database Exit Points

MySQL old native driver (removed for PHP 7)

MySQLi Extension\*

OCI8

PDO

PostgreSQL accessed via PDO and pgsql extensions

\* `mysqli_multi_query` is not supported.

## Supported Cache Exit Points

Memcache

Memcached

Predis 0.8.5 and 1.1.1, on PHP versions 7.0 and higher

Phredis 4.1

Although Predis is a full PHP client library, the PHP Agent supports Predis as an exit point only, not as an entry point.

## Supported Web Service Exit Points

PHP SOAPClient

NuSOAP 0.9.5

## Supported Message Queue Exit Points

RabbitMQ

RabbitMQ support requires the [amqp extension](#).

RabbitMQ is not supported on PHP 8.2 because amqp extension is not compatible with PHP 8.2.

## Opcode Cache Compatibility

Alternative PHP Cache (APC)	
-----------------------------	--

## Install the PHP Agent

### Related Pages:

- [Download AppDynamics Software](#)
- [AppDynamics Download Portal](#)
- [SELinux Installation Issues](#)

This page provides an overview of AppDynamics PHP Agent installation.

### Installation Overview

In the Controller UI, the Getting Started Wizard walks you through the configuration and installation steps for the PHP Agent.

The installer that you get from the wizard uses the PHP directory specified in your environment PATH variable to determine where to install the agent. If you are instrumenting a PHP installation not specified in your PATH, you can manually configure and invoke the RPM or script installer.

The PHP Agent runs on Linux and MacOS machines. The PHP Agent is designed for PHP operating environments in which:

- There is a single PHP installation
- PHP is running in a single Apache or FPM pool
- Standard packages have been used to install PHP, Apache and/or PHP-FPM
- No customizations have been made to the PHP configuration

The PHP Agent may work in environments that do not meet all assumptions. However, you should use extra care in installing and thoroughly testing the PHP agent and application in a staging environment.

### Before Starting

Before attempting to install the AppDynamics PHP Agent, confirm that you use a [supported PHP version](#). You can check your PHP version using this command:

```
php -i
```

The PHP Agent *does not work* with PHP applications that are built with the `enable-debug` configuration

option or in any build otherwise compiled with debugging symbols. To determine whether the application was built with debugging symbols, you can use this command:

```
php -i | grep -e "Debug Build"
```

The response should be:

```
Debug Build => no
```

You can get the PHP Agent distribution from the [AppDynamics Download Portal](#). Be sure to get the distribution file appropriate for your system:

- For RedHat or CentOS, use the RPM Package Manager distribution, such as PHP Agent—64-bit RPM.
- For all other Linux distributions, use the distribution identified PHP Agent—64-bit Linux.
- For MacOS, use PHP Agent—64-bit OSX

At installation time, you will need to provide Controller connection settings and identifying information for this PHP node. The Getting Started Wizard walks you through this configuration, so if it is your first time installing an AppDynamics Agent, we recommend using the Getting Started Wizard. For general information about the Controller connection settings, see [Agent-to-Controller Connections](#).

To complete the instrumentation, you will need to stop and start the Apache Server. Be sure to perform the installation in a way that minimizes disruption to service users, if applicable.

**i** Do not install the PHP Agent along with other non-AppDynamics Application Performance Management (APM) tools, especially in a production environment. The PHP Agent installation may fail if there are other APM products installed in the same managed environment.

## Installing the PHP Agent

These topics provide installation details for various scenarios:

- To use install.sh, see [Install the PHP Agent by Shell Script](#). Use install.sh to install on OSX as well as Linux.
- To use RPM, see [Install the PHP Agent by RPM](#).
- To use PHP ZTS, see [Install the PHP Agent with PHP ZTS](#).
- To instrument PHP CLI, see also [Configure the Agent for PHP CLI Applications](#).
- To instrument an application on MacOS, see [MacOS X Installation Considerations](#).
- To instrument multiple PHP applications running on the same server, see [Multiple PHP Apps on a Single Server](#).

For cURL installation, see [Download AppDynamics Software](#).

## Files Added by Installation

### PHP configuration files

For AppDynamics, the PHP configuration files of interest are the `php.ini` and `appdynamics_agent.ini` fragment. AppDynamics settings can be found in either `.ini` file, depending on the operating system under which your PHP is installed.

The PHP Agent installer adds the `appdynamics_agent.ini` file to the directory that contains your `php.ini` file. You can find this directory using the following command:

```
php -i | grep -e "Additional .ini files parsed"
```

If the installer is not able to determine the directory where the ini fragments for your PHP deployment live, it displays the required AppDynamics ini fragment and prompts you to copy and paste it into your main `php.ini` file.

Also, see <http://php.net/manual/en/configuration.file.php> for information about possible locations.

### .so files

The installer also installs the `appdynamics_agent.so` file in your PHP extensions directory. You can find this directory using the following command:

```
php -i | grep extension_dir
```

### Logs

There is an agent log and a proxy log for each application.

By default, the agent log is written to `$(php_agent_install)/logs/agent.log`. The log contains the transactions that the agent processes and then sends to the proxy. The default pattern for agent log naming is:

- `agent.log` : the current log
- `agent.log.1` : most recent log
- `agent.log.2` : second most recent log
- `agent.log.3` : third most recent log
- `agent.log.4` : fourth most recent log
- `agent.log.5` : fifth recent log

By default, the proxy log is written to `$(php_agent_install)/logs/proxy_$(date).log`. This log contains the transactions that the proxy accepts from the agent and then sends to the Controller.

If you configure the logs directory with the `--log-dir` option, the proxy logs are written to the same directory as the agent logs.

For information about the location of log files generated by an RPM installation, see RPM Log file in [Install the PHP Agent by RPM](#).

### Using a Machine Agent on a PHP Node

You can install a machine agent on a node that runs the PHP Agent. However, note that if you install the machine agent on a PHP Agent node and you specify the tier and node name in the `controller-info.xml` file of the machine agent, the PHP Agent will not successfully register with the Controller.

To avoid this problem:

- Install the PHP Agent before you install the machine agent
- If you install the machine agent on the machine hosting the instrumented PHP node, do not specify the application, tier or node name in the `controller-info.xml` file of the machine agent. If you do, the PHP Agent may fail to register.

### Install the PHP Agent by Shell Script

#### Related pages:

- [AppDynamics Downloads](#)
- [Install the PHP Agent](#)

This page describes how to install the PHP Agent using the included `install.sh` script.

## Installing the PHP Agent

These steps describe how to install the PHP Agent with the installation script, `install.sh`.

1. Verify support and system requirements for your environment as described in [Install the PHP Agent](#).
2. Create the `php-agent` installation directory. The directory should be owned by the same user that runs Apache or PHP-FPM (FastCGI Process Manager). AppDynamics recommends naming the directory `/opt/appdynamics/php-agent`.

**i** This document refers to the PHP Agent installation directory as: `<php_agent_install>`. Replace the `<php_agent_install>` syntax with the full path to your agent installation directory. For example, change `<php_agent_install>` to `/opt/appdynamics/php-agent`

3. If there is more than one Apache instance on a machine, run `install.sh` once for each Apache instance, each time with the appropriate `php_ini` dir and `php_ext` dir options.

See [Run the PHP Proxy Daemon Manually](#)

See [Files Added to Your Installation](#)

From the command line, change directories to the PHP agent installation directory and untar the agent distribution tarball, as in the following example:

```
cd <php_agent_install>
tar -xvjf appdynamics-php-agent-x64-linux.tar.bz2
```

4. Set the following permissions on your `<php_agent_install>` directory.
  - `php` : Make every directory that leads to the PHP agent logs directory readable and executable by all and writable by the directory owner:

```
chmod -R 755 <php_agent_install>
```

- `logs` : If possible, make the logs subdirectory readable/writable/executable by all:

```
chmod 777 <php_agent_install>/logs
```

Directory access permissions of 777 may be too permissive for some organizations. In this case, simply make sure that the directory is owned by the `apache / php / proxy` user.

5. Run the installation script using this syntax:

```
<php_agent_install>/install.sh [-s]
-a=<account_name>@<account_access_key>
[--http-proxy-host=<proxy_host>] [--http-proxy-
port=<proxy_port>] [-e <php_ext_dir>] [-i <php_ini_dir>]
```

```
[-p <php_binary_dir>] [-v <php_version>]
 <controller-host> <controller-port> <app_name> <tier_name>
 <node_name>
```

The command arguments are described as follows:

- `-s` option: You can optionally specify the `-s` option if you want the agent to use SSL (HTTPS) to connect to the controller. In this case, set the Controller port to the HTTPS port of the controller.
- `-a account_name@account_access_key`: The required controller account name and account key. To find your account name and access key, click  in the upper right corner of the AppDynamics UI, then click **License**.
- `http-proxy-host` and `http-proxy-port`: Set the `<http-proxy-host>` and `<http-proxy-port>` to route data to the controller through a proxy server. The `<http-proxy-host>` is the hostname or IP address of the proxy server. The `<http-proxy-port>` is the proxy server HTTP or HTTPS port, whichever you are using. If you set the `http-proxy-host` you must set the `http-proxy-port` as well.
- `http-proxy-user`, `http-proxy-password-file`: The username and password file if using a proxy and the proxy server requires credentials.
- `-e` option: Extensions directory for the `appdynamics_agent.so` file. Needed on Ubuntu as well as when the default PHP CLI binary cannot be determined.
- `-i` option: `ini` directory for the `appdynamics_agent.ini` file. Needed on Ubuntu as well as when the default PHP CLI binary cannot be determined.
- `-v` option: version of PHP that you are instrumenting. Valid formats are version numbers to one or two decimal positions, for example, `7.4` and `7.4.29`. Needed only when the default PHP CLI binary cannot be determined or there is no PHP CLI binary.
- `-p` option: path to the PHP binary
- `enable-cli-long-running`: Set to `true` to defend PHP in long-running CLI applications. Defaults to `false`. See [Long-Running CLI Applications with the Suhosin Patch](#).
- `--log-dir=<dir>`: The directory to which the agent and proxy logs should be written. Defaults to the `<php_agent_install>/logs` directory.
- `--proxy-ctrl-dir=<dir>`: The proxy control directory. If not specified, the installer creates a temporary directory.

If all options are used, the `-e`, `-i` and `-v` options have precedence over the `-p` option.

 On Ubuntu, the installation needs to be performed as the root user. Also, you need to use the `-e` option to indicate the correct extensions directory for the `appdynamics_agent.so` file and the `-i` option for the correct `ini` directory for the `appdynamics_agent.ini` file.

6. Restart the webserver, unless you are installing an agent to monitor PHP-CLI only.

If your installation failed, see [Resolve PHP Agent Installation Issues](#).

### Installation Command Samples

The following illustrates a sample command to install the agent:

```
install.sh controller 8090 -a=PHPCust@XC6v2n8m2$543 myApp myTier
myNode
```

To install the agent using SSL, use the `-s` switch, as follows:

```
install.sh -s -a=PHPCust@XC6v2n8m2$543
controller1.appdynamics.com 8818 myApp myTier myNode
```

The following sample command illustrates installation with a proxy server present:

```
install.sh --http-proxy-host=myproxyhost --http-proxy-port=8099
-a=PHPCust@XC6v2n8m2$543 controller 8090 myApp myTier myNode
```

## Install the PHP Agent by RPM

### Related pages:

- [Resolve PHP Agent Installation Issues](#)
- [Install the PHP Agent](#)
- [Download AppDynamics Software](#)
- [AppDynamics Download Portal](#)

You can use the AppDynamics PHP Agent RPM to install the PHP Agent on RedHat or CentOS Linux systems.

### About the RPM Installer

You must use the PHP Agent RPM installer as the root user.

You pass configuration settings for the agent to the installer using environment variables rather than command-line arguments. Before starting—or as part of your installation script—you need to set the environment variables. You can configure settings such as node name, tier name, business application name, and others for the agent. However, the installer will provide sensible defaults if not provided.

The RPM installer determines the location of your PHP installation based on the PATH environment variable. It uses the first PHP installation that it encounters in the PATH to configure the installer. If you have installed PHP in a non-standard location, you must provide the directory of your PHP binary in the `APPD_PHP_PATH` environment variable.

Before starting, get the RPM package from the [AppDynamics Download Portal](#).

### Installing the PHP Agent with RPM

To install PHP Agent with RPM:

1. Verify support and system requirements for your environment as described in [Install the PHP Agent](#).
2. Set environment variables with the configuration settings for the agent if needed. The account key is a required setting. Other settings may be required depending on your environment. See [RPM Environment Variables](#) for more information. Alternatively, you can pass environment variables to the installation script directly.
3. Run the installer.

```
sudo rpm -i <package_name>
```

Replace `<package_name>` with the name of the package you downloaded.

If you are using `sudo` to pass the environment variables to the installation script you can use:

```
sudo APPD_PHP_PATH=/opt/php rpm -i <package_name>
```

or

```
APPD_PHP_PATH=/opt/php sudo -E rpm -i <package_name>
```

If the install reports errors, check the log file as described in [RPM Log File](#).

4. Restart Apache. Not required if you are installing an agent to monitor PHP CLI only.

The RPM installs a single agent. If you have more than one PHP installation on the machine, run the RPM once for each PHP installation, each time with the appropriate `APPD_PHP_PATH` and `APPD_CONF_NODE` settings.

### RPM Environment Variables

Environment Variable	Description	Default	Required?
<code>APPD_PHP_PATH</code>	Directory containing the PHP binary	None	If your PHP binary is not in a standard location. By default, the installer uses the PHP CLI binary to determine where to install the app agent.
<code>APPD_PHP_CONFIGURATION_DIR</code>	INI directory in which to install the <code>appdynamics_agent.ini</code> file. Takes precedence over the <code>APPD_PHP_PATH</code> setting.	Directory containing your <code>php.ini</code> file. See information on files added to your installation in <a href="#">Install the PHP Agent</a> .	If your PHP binary is not in the standard location or if no PHP CLI binary is available.
<code>APPD_PHP_EXTENSIONS_DIR</code>	Extensions directory in which to install the <code>appdynamics_agent.so</code> file. Takes precedence over the <code>APPD_PHP_PATH</code> setting.	Your PHP extensions directory. See information on files added to your installation in <a href="#">Install the PHP Agent</a> .	If your PHP binary is not in the standard location or if no PHP CLI binary is available.

Environment Variable	Description	Default	Required?
APPD_PHP_VERSION	Version of PHP that you are instrumenting. Valid formats are version numbers to one or two decimal positions, for example, 7.4 and 7.4.29 are both valid. Takes precedence over the APPD_PHP_PATH setting.	Version used by your PHP CLI binary	If no PHP CLI binary is available, along with the APPD_PHP_CONFIGURATION_DIR and APPD_PHP_EXTENSION_DIR variables.
APPD_CONF_CONTROLLER_HOST	Controller hostname	localhost	
APPD_CONF_CONTROLLER_PORT	Controller port	8080	
APPD_CONF_APP	Application name	MyApp	
APPD_CONF_TIER	Tier name	Hostname of the machine running the script—same as the node name	
APPD_CONF_NODE	Node name	Hostname of the machine running the script	
APPD_CONF_ACCOUNT_NAME	Account name	Defaults to customer1.	If you have an on-premises AppDynamics Controller running in multi-tenant mode or if you are using the AppDynamics SaaS Controller.
APPD_CONF_ACCESS_KEY	Account key	None	Yes. To find your access key, click  in the upper right corner of the AppDynamics UI, then click <b>License</b> .

Environment Variable	Description	Default	Required?
APPD_CONF_SSL_ENABLED	True to enable SSL communication with the controller, false otherwise	false	
APPD_CONF_HTTP_PROXY_HOST	Hostname or IP address of the http proxy server	None	If you want to route data to the controller through a proxy server.
APPD_CONF_HTTP_PROXY_PORT	HTTP or HTTPS port of the http proxy server; must be set if APPD_CONF_HTTP_PROXY_HOST is set	None	If you want to route data to the controller through a proxy server.
APPD_CONF_HTTP_PROXY_USER	Username on the http proxy server	None	If you want to route data to the controller through a proxy server that requires a username.
APPD_CONF_HTTP_PROXY_PASSWORD_FILE	Password on the http proxy server	None	You want to route data to the controller through a proxy server that requires a password.
APPD_PROXY_CTRL_DIR	Initial control communication directory between the agent and the Java proxy	None	
APPD_CONF_LOG_DIR	Directory to which the agent writes the agent and proxy logs	<php_agent_install>/logs	
APPD_CONF_CLI_LONG_RUNNING_ENABLED	Defends PHP in long-running CLI applications.	false	Advisable if instrumenting long-running CLI applications. See Long-Running CLI Applications with the Suhosin Patch in <a href="#">Configure the Agent for PHP CLI Applications</a> .

---

## Updating the Installation

Any changes that you made to the configuration files are preserved when you re-run the installer. RPM saves your original settings and a `ppdynamics_agent_log4cxx.xml` files with the settings from the previous installation.

### RPM Installation Log File

If errors occurred during installation, a message displays the location of the log file generated in the `/tmp` directory. Examine this log file to identify the cause of the problem. A successful installation does not produce a log file.

### Uninstall the PHP Agent using RPM

If you installed the agent using RPM, use RPM to uninstall it, as follows:

```
sudo rpm -e appdynamics-php-agent-<version>
```

Notice that you need to identify the version of the package. To find the version of the package that you installed, you can enter:

```
rpm -qa | grep appdynamics-php-agent
```

The existing configurations are saved in a tar file in `/tmp`, as indicated upon completion of the uninstall process.

### Install PHP Agent with PHP ZTS

The PHP Agent supports Zend Thread Safe (ZTS) for PHP 7.4. PHP Agent integrates with the ZTS mode, which helps to instrument multithreaded applications on PHP. This enables you to view the end-to-end business transaction flow and exit calls without breaks in correlation or end-to-end visibility.

 PHP ZTS is currently supported only for Linux (64 bit).

### PHP Agent Install Overview

The Getting Started Wizard in the Controller UI guides you through the configuration and installation steps for the PHP Agent. The installer uses the PHP directory specified in the `PATH` environment variable to determine the installation location. If you are instrumenting a PHP installation not specified in the `PATH` variable, you can manually configure and invoke the [script installer](#).

The PHP Agent runs on Linux OS machines. The PHP Agent is designed for operating environments in which:

- There is a single PHP installation
- PHP is running in a single Apache or FPM pool
- Standard packages are used to install PHP, Apache and/or PHP-FPM
- No customizations are made to the PHP configuration

**i** Ensure that you meet the preceding requirements before deploying the PHP Agent in the production environment. We recommend that you first deploy the agent in the staging/pre-production environment.

## Prerequisites

- Ensure that PHP ZTS is installed.  
Before you install the AppDynamics PHP Agent, ensure that you use a [supported PHP version](#). You can check your PHP version using the following command:

```
php -i
```

- The PHP Agent does not work with PHP applications that are built with the enable-debug configuration option or in any build otherwise compiled with debugging symbols. To determine whether the application was built with debugging symbols, use the following command:

```
php -i | grep -e "Debug Build"
```

The expected response must be:

```
Debug Build => no
```

- You can get the PHP Agent distribution from the [AppDynamics Download Portal](#). Ensure to get the distribution file appropriate for your system. For all Linux distributions, use the distribution identified as PHP ZTS Agent 64-bit Linux.
- During the installation, you must provide Controller connection settings and identifying information for this PHP node. The Getting Started Wizard guides you through this configuration, therefore if you are installing an AppDynamics Agent for the first time, it is recommended to use the Getting Started Wizard. For information about the Controller connection settings, see [Agent-to-Controller Connections](#).
- To complete the instrumentation, you need to stop and start the Apache Server. Ensure to perform the installation in a way that minimizes disruption to service users, if applicable.

**!** Do not install the PHP Agent along with other non-AppDynamics Application Performance Management (APM) tools, especially in a production environment. The PHP Agent installation may fail if there are other APM products installed in the same managed environment.

## Install PHP Agent with ZTS

The following topics provide installation details for various scenarios:

- To use `install.sh`, see [Install the PHP Agent by Shell Script](#). Use `install.sh` to install on Linux.
- To instrument PHP CLI, see [Configure the Agent for PHP CLI Applications](#).
- To instrument multiple PHP applications running on the same server, see [Multiple PHP Apps on a Single Server](#).

For cURL installation, see [Download AppDynamics Software](#).

### Files Added Post the PHP ZTS Install

The following files are added after installing the PHP Agent:

- Configuration files

For AppDynamics, the two PHP configuration files are: `php.ini` and `appdynamics_agent.ini` fragment. AppDynamics settings can be found in either of the `.ini` files, depending on the operating system under which your PHP is installed. The PHP Agent installer adds the `appdynamics_agent.ini` file to the directory that contains your `php.ini` file. You can find this directory using the following command:

```
php -i | grep -e "Additional .ini files parsed"
```

If the installer is not able to determine the directory where the ini fragments for your PHP deployment exist, it displays the required AppDynamics ini fragment and prompts you to copy and paste it into your main `php.ini` file. Also, see <http://php.net/manual/en/configuration.file.php> for information about the possible locations for the configuration file.

- `.so` files

The installer also installs the `appdynamics_agent.so` file in your PHP extensions directory. You can find this directory using the following command:

```
php -i | grep extension_dir
```

- Logs

For each application, there is an agent log and a proxy log. By default, the agent log is written to `$(php_agent_install)/logs/agent.log`. The log contains the transactions that the agent processes and then sends to the proxy. The default pattern for agent log naming is:

- `agent.log`: the current log
- `agent.log.1`: most recent log
- `agent.log.2`: second most recent log
- `agent.log.3`: third most recent log
- `agent.log.4`: fourth most recent log
- `agent.log.5`: fifth recent log

You can find the licenses of the third-party libraries under the directory `license` in the agent installation folder: `appdynamics-php-zts-agent-linux_x64/license`.

## Install a Machine Agent on a PHP Node

You can install a Machine Agent on a node that runs the PHP Agent. However, if you install the Machine Agent on a PHP Agent node and you specify the tier and node name in the `controller-info.xml` file of the Machine Agent, the PHP Agent does not successfully register with the Controller.

To avoid this:

- Install the PHP Agent before you install the Machine Agent
- If you install the Machine Agent on the machine hosting the instrumented PHP node, do not specify the application, tier or node name in the `controller-info.xml` file of the Machine Agent. If you do, the PHP Agent may fail to register.

## Configure the Agent for PHP CLI Applications

### Related pages:

- [Start the PHP Agent Proxy Manually](#)
- [PHP Agent Configuration Settings](#)

If you are instrumenting a PHP CLI Application with the AppDynamics PHP Agent, after installing the agent you need to take a few additional configuration steps described here.

## Instrumenting PHP CLI Applications

When instrumenting a PHP CLI application, you need to provide for the startup of the proxy daemon, as follows:

1. Create the proxy control directory, which is used for agent/proxy communication.
2. In your PHP configuration file— `php.ini` or `appdynamics_agent.ini` depending on your environment. Include the following settings:
  - `agent.cli_enabled = 1`
  - `agent.auto_launch_proxy = 0`
  - `agent.proxy_ctrl_dir = <proxy control directory>`

If you are using the RPM installer to install the agent you may have configured the proxy control directory using the `APPD_PROXY_CTRL_DIR` environment variable. See [Install the PHP Agent by RPM](#). This environment variable takes precedence over the setting in the ini file.
3. Before running any traffic through the CLI, run the proxy from the directory into which you installed the PHP agent, passing the proxy control directory and proxy log directory as arguments.

```
proxy/runProxy <proxy_control_dir> <log_dir>
```

For example:

```
proxy/runProxy /tmp/proxy.communication /tmp/agentLogs
```

For the full set of options to runProxy, see [Start the PHP Agent Proxy Manually](#).

## PHP CLI and the Apache Web Server

If you have PHP CLI applications and an Apache web server on the same machine, your setup depends on whether you want all the traffic reported against a single AppDynamics node or separate nodes. A separate proxy is required for each AppDynamics node that you want to monitor in the controller.

If you want all the CLI traffic to be reported against one node and all the web traffic to be reported against a different node, configure Apache to auto-launch the proxy (the default) and configure CLI to use a manually-launched proxy. This requires separate `.ini` files—one for the web PHP with `agent.auto_launch_proxy` set to `1` and another for PHP CLI with `agent.auto_launch_proxy` set to `0`.

If you want the web traffic and the CLI traffic to be reported against the same node, configure both Apache and CLI to use the same manually launched proxy.

## Long-Running CLI Applications with the Suhosin Patch

A side effect of the [Suhosin patch](#) is that it prevents the PHP Agent from ensuring cleanup in long-running CLI applications.

If your PHP has the Suhosin patch, it is possible that resources will not be freed in long-running applications. Thus memory leaks could result if the application itself does not explicitly free these resources.

The `long-running-cli` feature defends PHP applications in an environment in which both of the following conditions exist:

- PHP with the Suhosin patch is running on Debian or Ubuntu. It is common for Debian and Ubuntu PHPs to have this patch. This feature is not needed for PHPs with only the Suhosin extension, which is different from the patch. Be aware that some PHPs use both the extension and the patch.
- Using the [PHP Agent API](#), you are instrumenting a CLI application that has multiple unbounded business transactions running on the same process,

## How the Long-Running CLI Feature Works

At installation time, if the installer determines that PHP has the Suhosin patch and CLI is enabled—`agent.cli_enabled=1`—the value of the installer option results as follows:

- If `true`, a fatal error is generated and the installer terminates. With the option set, the installer refuses to instrument a long-running CLI application on a PHP installation with the Suhosin patch.
- If `false`—the default—the installation continues and warns that memory leaks could occur in long-running CLI processes.

If the installer determines that PHP does not have the Suhosin patch, the installation continues. Long-running CLI processes are supported by the agent, since there is no Suhosin patch.

If the agent could not determine whether your PHP has the Suhosin patch at installation but it does detect the patch at runtime, having set the installer option to 'true' prevents the agent from instrumenting any CLI processes, not just long-running ones. This prevents the Suhosin-patched PHP from exiting.

If CLI is enabled and the installer did not terminate because of the detection of the Suhosin patch, AppDynamics recommends that you install the agent with the `enable-cli` long-running option—shell script installs—or the `APPD_CONF_CLI_LONG_RUNNING_ENABLED` environment variable—for RPM installs—set to `true`. This will defend your PHP if the patch is detected at runtime.

If the CLI part of your application does not get instrumented, because the installer detected the Suhosin patch, you can unset the option by setting the `agent.cli_long_running` option in the PHP ini file to `off`. Or alternatively, you can re-install with the installer.

## Multiple PHP Apps on a Single Server

### Related pages:

- [Install the PHP Agent](#)
- [PHP Business Transaction Detection](#)
- [Overview of Application Monitoring](#)

If you follow only the default installation instructions, the PHP Agent treats your entire PHP deployment as a business application with a single tier with a single node. It models your AppDynamics environment this way even if in reality you have multiple PHP applications running in the same Apache or PHP-FPM pool.

You may have configured your PHP applications as different virtual hosts or FPM pools. With multi-application/single-server (MASS) support, you can monitor several PHP applications running on the same server as separate AppDynamics entities, represented as different business applications, different tiers or different nodes. Multiple applications running in the same PHP server can have separate metrics, dashboards, health rules, events, and so on. You can monitor them on different controllers, even from different AppDynamics accounts. You can mix and match the settings to configure the AppDynamics model that works best for monitoring your entire PHP application environment.

AppDynamics recommends that you not instrument more than ten applications on a single server.

## Download and Install

To set up your PHP installation for multiple nodes, download a single agent from AppDynamics.

Then follow the instructions in [Install the PHP Agent by RPM](#)—RedHat and CentOSX—and [Install the PHP Agent by Shell Script](#)—all other Linux and Mac OS—for instrumenting the agent. Configure the required settings using an app/tier/node configuration that fits one of the applications you are instrumenting. Make sure you configure the [required settings](#) listed below.

Then, for each additional application that you want the agent to monitor, add an AppDynamics configuration with different settings that reflect how you want the performance metrics to be reported in your AppDynamics model.

### Required Configuration Settings for Multi-Node Support

The required settings for multi-node support for each monitored app are:

- `agent.controller.hostName`
- `agent.applicationName`
- `agent.tierName`
- `agent.nodeName`
- `agent.accountName`

It may be necessary to configure additional settings depending on your environment, for example, if you need to route data to the AppDynamics controller through a proxy server.

### Where to Configure Settings

There are three files from which the PHP Agent configuration settings are read:

1. `appdynamics_agent.ini`
2. Apache (vhost) or FPM (fpm-pool) configuration (overrides 1)
3. `.htaccess` for Apache or `.user.ini` for FPM (overrides 1 and 2)

When you instrument your first application, passing the required settings on the command-line—shell script install—or through environment variables (RPM install), those settings are written to `appdynamics_agent.ini`.

To apply different sets of settings for the different applications, as best practice specify the settings in each vhost or FPM pool config block.

#### Sample Apache Configuration

Here are sample virtual host configurations for two applications running on the same server.

#### Virtual Host Configuration for the `api` App

```
<VirtualHost *:80>
 ServerName api.myhost.com
 DocumentRoot "/var/www/api"
 ErrorLog "/private/var/log/apache2/api_error.log"
 CustomLog "/private/var/log/apache2/api_access.log" common

 php_value agent.applicationName API
 php_value agent.tierName api-tier1
 php_value agent.nodeName api-node1
 php_value agent.controller.hostName
 appd1.saas.appdynamics.com
```

```
php_value agent.controller.port 8080
php_value agent.accountName customer1
php_value agent.accountAccessKey 123456789
</VirtualHost>
```

### Virtual Host Configuration for the `frontend` App

```
<VirtualHost *:80>
 ServerName www.myhost.com
 DocumentRoot "/var/www/frontend"
 ErrorLog "/private/var/log/apache2/www_error.log"
 CustomLog "/private/var/log/apache2/www_access.log" common

 php_value agent.applicationName FrontEnd
 php_value agent.tierName frontend-tier1
 php_value agent.nodeName frontend-node1
 php_value agent.controller.hostName
appd1.saas.appdynamics.com
 php_value agent.controller.port 8080
 php_value agent.accountName customer1
 php_value agent.accountAccessKey 123456789
</VirtualHost>
```

### Sample FPM Configuration

Here are sample FPM configurations for two applications running on the same server.

#### .conf Configuration for the "api" App

```
api.conf:

php_value[agent.applicationName] = API
php_value[agent.tierName] = api-tier1
php_value[agent.nodeName] = api-node1
php_value[agent.controller.hostName] =
appd1.saas.appdynamics.com
php_value[agent.controller.port] = 8080
php_value[agent.accountName] = customer1
php_value[agent.accountAccessKey] = 123456789
```

## .conf Configuration for the `frontend` App

```

www.conf:

php_value[agent.applicationName] = FrontEnd
php_value[agent.tierName] = frontend-tier1
php_value[agent.nodeName] = frontend-node1
php_value[agent.controller.hostName] =
appd1.saas.appdynamics.com
php_value[agent.controller.port] = 8080
php_value[agent.accountName] = customer1
php_value[agent.accountAccessKey] = 123456789

```

### Use a Shared Proxy for PHP Agents

#### Related pages:

- [Install the PHP Agent](#)

By default, if you are running multiple agents, each agent automatically launches its own Java proxy to communicate with the controller.

However, if you are running multiple PHP Agents on the same machine, you can reduce your overhead by setting up the agents to report to a single shared or multi-tenant proxy. In this case, you would need to start that proxy manually.

The number of nodes that can report to a single proxy is limited by the size of the heap given to the proxy. You may need to adjust the `maxHeapSize` and `maxPermSize` settings in the `runproxy` script if you have a large number of agents reporting to a single proxy.

#### Setting up a Multi-Tenant Proxy

1. Configure each agent for manual launch of the proxy. To do this, in the PHP configuration file—`php.ini` or `appdynamics_agent.ini` depending on your setup—for each agent, set the `agent.auto_launch_proxy` value to `0`.
2. Configure a single proxy control directory for all the agents that will share the proxy. They must all be on the same machine. To do this, in the PHP configuration file for each agent, set `agent.proxy_ctrl_dir` to the same proxy control directory. The permissions on this directory should be readable and executable by the process that runs Apache and writable by the process that runs the proxy.
3. Before you start the agents, arrange to launch the proxy manually, passing the proxy control directory configured in step 2 as the `proxyCommunicationDir` argument to the `runProxy` script. See information on executing the `runProxy` in [Start the PHP Agent Proxy Manually](#). AppDynamics recommends launching the proxy on system startup.
4. Verify that each agent reporting to the multi-tenant proxy is configured with a unique `app_name` / `node_name` combination. The `app_name` and `node_name` are arguments to the agent install script.

## Start the PHP Agent Proxy Manually

### Related pages:

- [Use a Shared Proxy for PHP Agents](#)
- [Configure the Agent for PHP CLI Applications](#)

When the PHP agent starts, it automatically starts the Java proxy that handles communication between the PHP agents and the controller.

Automatic startup of the proxy works for the great majority of situations. However, you can suppress the automatic startup of this script and run it manually. You would do this if:

- You plan to instrument a PHP CLI entry point. The PHP CLI entry point requires manual startup of the proxy and immediate creation of the node on startup.
- You have multiple Apache or FPM pools on the same machine reporting to the same proxy.

To do this, you first need to configure the agent for manual proxy launch. Then you need to launch the proxy manually.

### Configure the Agent for Manual Proxy Launch

The PHP Agent configuration needs to be modified to reflect manual launching.

To configure the agent for manual launching:

1. Open the PHP configuration file for editing. The file is `php.ini` or `appdynamics_agent.ini`, depending on your setup.
2. Set the `agent.auto_launch_proxy` setting to `0`.
3. Set the `agent.proxy_script` to the path of the `runproxy` that you want to use. The file in the script is relative to the root of the PHP agent. You can specify the absolute path if you prefer.
4. Set the `agent.proxy_ctrl_dir` to the directory to use for initial control communication between the agent and the proxy. This directory contains the domain control socket, which the agent uses to start an AppDynamics node. This directory is where the agent gets the configuration for the node. The application user must have read permission on the `proxy_ctrl_dir`.

Whenever you install the PHP agent, the installer overwrites the `runproxy` script and the `appdynamics_agent.ini` file, but not the `php.ini`. If you re-install, you need to reset the `agent.auto_launch_proxy` setting in the `appdynamics_agent.ini` file before you restart the server.

### Run the Proxy

Before any traffic runs on the instrumented server, execute the `runProxy` script to start the proxy.

The following lists the full set of options for the `runProxy` script. The proxy control directory is required.

```
Usage: runProxy options -- proxyCommunicationDir logDirectory [jvmOption=jvmOptionValue
 [jvmOption=jvmOptionValue [...]]
```

#### Options:

```
-r <dir>, --proxy-runtime-dir=<dir> #Specifies proxy runtime directory
-d <dir>, --proxy-dir=<dir> #Specifies root proxy directory
-j <dir>, --jre-dir=<dir> #Specifies root JRE directory
-v, --verbose #Enable verbose output
-h,--help #Show this
```

```

jvmOption
-Dappdynamics.controller.hostName=<hostName> #Set the host name or IP address of
the AppDynamics Controller
-Dappdynamics.controller.port=<port> #Set the HTTP(S) port of the
AppDynamics Controller
-Dappdynamics.agent.applicationName=<applicationName> #Set the name of the logical
business application
-Dappdynamics.agent.tierName=<tierName> #Set the name of the logical tier
-Dappdynamics.agent.nodeName=<nodeName> #Set the name of the instrumented
node
-Dappdynamics.agent.accountName=<accountName> #Set the account name used to
authenticate with the Controller
-Dappdynamics.agent.accountAccessKey=<accessKey> #Set the account access key used to
authenticate with the Controller
-Dappdynamics.controller.ssl.enabled=<true> #Set if the agent should use SSL
(HTTP(S) to connect to the Controller
-Dappdynamics.agent.uniqueHostId=<uniqueHostId> #Set a unique host ID for the App
agents

```

The following shows an example:

```

./proxy/runProxy -d ./proxy -r /tmp/appd/my_app/my_tier/
my_node /tmp/proxy.communication /tmp/agentLogs

./proxy/runProxy /tmp/proxy.communication /tmp/agentLogs
-Dappdynamics.controller.hostName=controller.appd.com
-Dappdynamics.controller.port=8090
-Dappdynamics.agent.uniqueHostId=myUniqueHost

./proxy/runProxy -d ./proxy /tmp/proxy.communication /tmp/
agentLogs -Dappdynamics.agent.accountName=myAccount
-Dappdynamics.agent.accountAccessKey=mYaCcEsSkEy

./proxy/runProxy -r /tmp/appd/app1/tier1/node1 /tmp/
proxy.communication /tmp/agentLogs
-Dappdynamics.agent.applicationName=my_app
-Dappdynamics.agent.tierName=my_tier
-Dappdynamics.agent.nodeName=my_node

```

A node is created when the agent first detects traffic on it.

Every time you reboot the server, you need to execute the `runProxy` script if you have opted to start the proxy manually.

---

## Resolve PHP Agent Installation Issues

If traffic does not display in the Controller after you have installed the AppDynamics PHP Agent and started the instrumented server, try these troubleshooting steps.

### Ensure that the Agent is Installed in the Correct Directory

It is possible that the agent was installed in the wrong directory. Verify the location of your PHP installation.

- Verify the location of your PHP by running `phpinfo`. See <http://us1.php.net/phpinfo>.

Then check where the installer actually installed the agent files.

- The `appdynamics_agent.ini` file should be in the same directory that contains the `php.ini` file for your PHP installation.
- The `appdynamics_agent.so` file should be in the extensions directory for your PHP installation.

See [Files Added to Your Installation](#) for information about how to locate these directories.

In addition, on Linux you can use `pstree` to locate the agent. The `pstree` command displays the AppDynamics agent running under Apache if the agent is installed properly. See <http://freecode.com/projects/pstree>.

If the agent files are not in the correct directories, re-install the agent with the `-i` and `-e` options.

### Re-install the agent

If the app agent is not installed in the right directory, re-install the agent using the `install.sh` installer with the `-i` and `-e` options. Use the `-i` to install the `appdynamics_agent.ini` file in the same directory as your `php.ini` file and the `-e` option to install the `appdynamics_agent.so` file in the same directory as your PHP extensions directory. See [Install the PHP Agent by Shell Script](#).

If you initially installed the agent using the RPM installer, you can find the shell script installer at `/usr/lib/appdynamics-php-agent/install.sh`.

### Check error messages in the installation output

When you reinstall, examine carefully any error messages in the output of the install script, especially those that direct you to copy some settings into your `php.ini` file.

If necessary copy those settings into the `php.ini` file. See [PHP Agent Configuration Settings](#) for information on common settings that may be missing.

### Check the AppDynamics Settings Block in the Configuration

Run this command:

```
php -i | less
```

and examine the output. You should see an `appdynamics_agent.ini` file and a configuration block listing appdynamics `ini` values.

### Confirm User Permissions

Check that the following permissions are set:

```
chown -R <apacheuser>:<apacheuser> <php_agent_install>
chmod -R 755 <path_to_php_agent_install_logs>
chmod 777 <php_agent_install>/logs
```

## Verify that the Proxy is Running

The Java proxy is the part of the agent that communicates with the Controller. If the agent is installed in the right place, confirm that the Java proxy is running.

1. From the command line enter, `ps aux | grep java`.
2. Inspect the list. You should see output similar to the following if the proxy is running:

```
/usr/lib/appdynamics-php-agent/proxy/jre/bin/java -server
-Xmx120m -classpath /usr/lib/appdynamics-php-agent/proxy/conf/
logging/*:/usr/lib/appdynamics-php-agent/proxy/lib/*:/usr/lib/
appdynamics-php-agent/proxy/lib/tp/*:/usr/lib/appdynamics-php-
agent/proxy/* -Djava.library.path=/usr/lib/appdynamics-php-
agent/proxy/lib/tp -Dappdynamics.agent.logs.dir=/usr/lib/
appdynamics-php-agent/logs -Dcomm=/tmp/ad-siJ4rp
-DagentType=PHP_APP_AGENT -Dappdynamics.agent.runtime.dir=/usr/
lib/appdynamics-php-agent/proxy
com.appdynamics.ee.agent.proxy.kernel.Proxy
```

If you are instrumenting a PHP CLI script, you need to start the proxy manually. You may also need to start the proxy manually if you have special requirements for running Java processes. See [Start the PHP Agent Proxy Manually](#).

## Check the Configuration Properties

It is possible that the properties that the proxy uses to communicate with the Controller were not set properly.

You can modify these properties in the `php.ini` or `appdynamics_agent.ini` file, wherever they are set in your environment. See [PHP Agent Configuration Settings](#).

## Upgrade the PHP Agent

### Related pages:

- [Install the PHP Agent](#)
- [Uninstall the PHP Agent](#)
- [Resolve PHP Agent Installation Issues](#)

If you are upgrading both the Controller and agents, first upgrade the Controller and then upgrade the agents.

Also, if you are upgrading multiple agents in your monitored environment, upgrade the agents for the tiers on which business transactions originate last. For more information about this requirement, along with Controller and agent compatibility information, see [Agent and Controller Tenant Compatibility](#).

## Upgrade the PHP Agent

1. Shut down the web server or `php-fpm`.
2. Copy the controller host, controller port, application name, tier name and node name property values from your `ini` file.  
If you are running in multi-tenant mode, also copy the account name and account access key property values.
3. Recursively remove or rename the old AppDynamics PHP installation directory.
4. Download and extract the most recent agent tarball.
5. Run the installation script.  
You must pass the controller access key as one of the options to the installer.  
To find your access key, click  > **License** > **Account**.
6. Restart Apache or `php-fpm`.

 If you are using the agent to monitor PHP CLI without running a web server, you can omit steps 1 and 6.

## Uninstall the PHP Agent

### Related pages:

- [Install the PHP Agent by Shell Script](#)
- [Install the PHP Agent by RPM](#)

The method you use to install the agent varies based on the installation mechanism you used. If you are not sure which method was used, see [Checking the Installation Method](#).

### Uninstall an RPM-Installed PHP Agent

1. If one is running, shut down the web server. This may not apply for a PHP CLI application.
2. Run the following command:

```
rpm -e appdynamics-php-agent-<version>
```

where `<version>` is the package you installed. You can find the version using:

```
rpm -qa | grep appdynamics-php-agent
```

### Uninstall a Script-Installed PHP Agent

If you installed the agent using `install.sh`, uninstall that agent as follows:

1. Shut down the web server, if one is running. This may not apply for PHP CLI application.
2. From the PHP agent install directory, run the PHP installer with the `-u` option:

```
install.sh -u
```

3. Delete the `< php_agent_install >` directory.

### Checking the Installation Method

If you used the Agent Download Wizard, it might not be obvious which installer was used since the installer is called by the `runme.sh` wizard script.

Normally, if **RHEL and CentOS** was selected in the wizard, the RPM installer was used. If **All Other Linux OS** was selected in the wizard, the shell script installer was used. So use the appropriate uninstall command based on the command that was used to install the agent.

If you do not know which selection was checked in the wizard, run:

```
rpm -qa | grep appdynamics-php-agent
```

If this does not list any results, assume that the shell script installer was used to install the agent.

### PHP Agent Configuration Settings

The PHP installers write information that the agent uses to communicate with the Controller to the AppDynamics Agent section of the [PHP configuration files](#).

By default, the PHP Agent marks an HTTP error response, such as status code 4xx response as an error. When the following setting is added to the `php.ini` file, it will not mark the HTTP error response as an error.

```
agent.http_error_detection = false
```

This is different from some of the other AppDynamics application agents, which write this information to an XML file called `controller-info.xml`.

If you re-install the agent, the installer overwrites your settings only if you are using a fragments directory. It never overwrites the `php.ini` file. You can edit the [PHP configuration files](#) after installation to add, delete or modify these settings.

If a setting documented as *required* is not provided, the agent will not start. In this case, the agent logs the error to the web server error log. For example, if the `controller.Hostname` is not set you would see the following message in the Apache error log:

```
[AD agent] agent.controller.hostName is not set. Agent is disabled.
```

If after successful startup you remove a required setting or set it to an empty value, the change is ignored as long as the application is running, using the original value of the setting as it was at startup. If you change a required setting to a different valid value, restart the web server to apply the change.

The Controller information settings are described below:

---

### **agent.controller.hostName**

This is the host name or the IP address of the AppDynamics Controller. Example values are 192.168.1.22, `myhost` or `myhost.abc.com`. This is the same host that you use to access the AppDynamics browser-based user interface. For an on-premises Controller, use the value for application server hostname that was configured when the Controller was installed.

This setting is required.

### **agent.controller.port**

This is the HTTP(S) port of the AppDynamics Controller. This is the same port that you use to access the AppDynamics browser-based user interface.

If `agent.controller.ssl.enabled` is `true`, specify the HTTPS port of the Controller; otherwise, specify the HTTP port. See [agent.controller.ssl.enabled](#).

For on-premises installations, port 8090 for HTTP and port 8181 for HTTPS are the defaults.

This setting is required.

### **agent.applicationName**

This is the name of the logical business application that the instrumented node belongs to.

If a business application of the configured name does not exist, it is created automatically.

This setting is required.

### **agent.tierName**

This is the name of the logical tier that this node belongs to.

This setting is required.

### **agent.nodeName**

This is the name of the instrumented node.

This setting is required.

### **agent.accountName**

This is the account name used to authenticate with the Controller.

This setting is required if the AppDynamics Controller is running in multi-tenant mode or if you are using the AppDynamics SaaS Controller. It specifies the account name for the agent to use to authenticate with the Controller. If you are using the AppDynamics SaaS Controller, the Welcome email sent by AppDynamics provides the account name.

This setting is not required if the Controller is running in single-tenant mode.

### **agent.accountAccessKey**

This is the account access key used to authenticate with the Controller.

This setting is required. To find your access key, click the gear () icon in the upper right corner of the AppDynamics UI, then click **License**.

### **agent.controller.ssl.enabled**

When set to `true`, this setting specifies that the agent should use SSL (HTTPS) to connect to the Controller. If `agent.controller.ssl.enabled` is `true`, set the `agent.controller.port` to the HTTPS port of the Controller.

### **agent.proxy\_ctrl\_dir**

This specifies the initial control communication directory between the agent and the proxy. Needed only for a manual proxy start. See [Start the PHP Agent Proxy Manually](#)

### **agent.uniqueHostId**

When you add this setting to the `php.ini` file in the PHP Agent, you can set a unique host ID for the App agents.

```
agent.uniqueHostId = <Insert uniqueHostId>
```

For example, `agent.uniqueHostId = AppDynamics`

### **agent.http\_error\_detection=true**

When adding this setting to `php.ini`, the PHP agent, marks HTTP error response, such as status code 4xx response as an error.

## **Node Reuse for PHP Agent**

This page describes how to use the node reuse feature for the PHP Agent.

### **Reuse Node Name**

This property is useful for monitoring environments where there are many VMs (Virtual Machines) with short life spans. When set to `true`, AppDynamics reuses the node names of historical VMs for new VMs. Therefore, this prevents the rapid increase of differently named nodes, especially when the nodes are identical processes that run over different times.

AppDynamics generates a node name with App, Tier, and Sequence number, and the node names are pooled. For example, the sequence numbers are reused when the nodes are purged (based on the node lifetime).

1. Edit the PHP configuration file, `php.ini` or `appdynamics_agent.ini` depending on your environment.
2. In the PHP configuration file, configure the following settings:

```
agent.nodeReuse
```

When the value of `agent.nodeReuse` is set to `true`, the agent uses reuse node name. The default value is `false`.

```
agent.nodeReusePrefix
```

When you configure the agent to reuse node names, use the `agent.nodeReusePrefix` property to specify the prefix that the controller uses to generate node names dynamically.

This setting is required when `agent.nodeReuse` is set to `true`.

An example of the reuse node feature:

With the following configuration in the `php.ini` file, the Controller generates a node name with the prefix `reportGen`. Node names will have suffixes `-1`, `-2`, and so on, depending on the number of nodes are running in parallel. The name of a node that is shut down and qualifies as a historical node that may be reused by a new node.

```
agent.nodeReuse=true agent.nodeReusePrefix=reportGen
```

**Note**

When `agent.nodeReuse` and a node name is used, the `agent.nodeReusePrefix` property is given precedence.

## PHP Agent API User Guide

### Related pages:

- [PHP Agent API Reference](#)
- [PHP Supported Environments](#)

This page describes the PHP Agent API and provides example use cases for the API.

### About the PHP Agent API

The PHP Agent API enables you to:

- Define custom business transactions programmatically
- Provide correlation headers for entry points not supported by default detection
- Create custom exit calls to discover backends that are not automatically detected by the PHP Agent

### Include the AppDynamics API Header

You should include the `appdynamics_api_header.php` file in your application to ensure that it works correctly if the agent is uninstalled or temporarily disabled. This file contains empty API functions that will prevent the application from throwing errors if the agent is not present.

The `appdynamics_api_header.php` file is located in the PHP Agent package in the same directory as the `install.sh` script.

To include the header file:

1. Copy `appdynamics_api_header.php` to where you keep the header files for the monitored application.
2. Make sure that `appdynamics_api_header.php` is in your include path.
3. Then add the following to your script:

```
require 'appdynamics_api_header.php';
```

## Parts of a Script are Business Transactions

If you have a long PHP script application that performs a number of discrete tasks, but you want the agent to detect only one or more of them as business transactions, enclose the code for each of those tasks within `appdynamics_start_transaction()` and `appdynamics_end_transaction()` calls. The agent detects those blocks as separate business transactions. Otherwise, the agent detects the entire script as a single business transaction.

## Handling Business Transaction Code Executing in a Loop

For a script-based CLI application that executes in a loop, perhaps fetching items from a database or remote service, you may want the agent to detect every iteration of the loop as a separate business transaction. In this case, enclose the code inside the loop within `appdynamics_start_transaction()` and `appdynamics_end_transaction()` calls.

If you do not do this, the agent will aggregate each iteration through the loop into a single business transaction.

In the following example, the agent detects a business transaction named `getItem` for every iteration.

```
while (true){
 appdynamics_start_transaction("getItem", AD_CLI);
 //your code goes here
 . . .
 appdynamics_end_transaction();
}
```

## Correlating with an Upstream Service

If you have a distributed business transaction in which a tier needs to correlate with an upstream service that is not an entry point supported by the PHP Agent, you can maintain transaction correlation using `appdynamics_continue_transaction()` in the downstream tier, passing it the correlation header from the service.

You need to extract the correlation header from the service as shown in the following sample. The sample function extracts the correlation header from each message in an AMQP message queue and passes it to `appdynamics_continue_transaction()`.

After processing the message, it calls `appdynamics_end_transaction()`, which ends the continuation of the transaction on the calling tier. The `appdynamics_end_transaction()` call does not end the entire distributed transaction in the case where that tier makes a distributed call to another downstream tier.

```

function amqp_receive($exchangeName, $routingKey, $queueName) {
 $amqpConnection = amqp_connection();
 $channel = new AMQPChannel($amqpConnection);
 $queue = new AMQPQueue($channel);
 $queue->setName($queueName);
 $queue->bind($exchangeName, $routingKey);
 while($message = $queue->get()) {
 // Extracting the correlation header.
 echo("Message #".$message->getDeliveryTag()." ".$message->getBody()."\n");
 echo("Correlation header: " . $message->getHeader("singularityheader"));
 // Passing correlation header to API.
 appdynamics_continue_transaction($message->getHeader("singularityheader"));
 doStuff($message);
 // End transaction.
 appdynamics_end_transaction();
 }
 if(!$amqpConnection->disconnect()) {
 throw new Exception("Could not disconnect !");
 }
}

```

If the service is not a supported entry point and you do not do this, the tier will not be correlated with the upstream transaction.

### Make Socket-based HTTP Calls Example

While the API does not include built-in calls for socket-based HTTP call, you can implement monitoring of socket-based HTTP exit calls yourself as shown in the following example:

```

<?php

function doSocketHTTPCall($url, $corrHeader = null)
{
 $parts = parse_url($url);
 $fs = @fsockopen($parts['host'], isset($parts['port']) ? $parts['port'] : 80, $errno,
$error);
 if (!$fs)
 return null;
 $send = "GET {$parts['path']} HTTP/1.1\r\n" .
 "Host: {$parts['host']}\r\n" .
 "Connection: Close\r\n";
 if ($corrHeader)
 $send .= "singularityheader: $corrHeader\r\n";
 $send .= "\r\n";
 fwrite($fs, $send);
 $data = stream_get_contents($fs);
 fclose($fs);
 return $data;
}

$url = 'http://httpstat.us/200';

```

```

$parts = parse_url($url);

$exitCall = appdynamics_begin_exit_call(
 AD_EXIT_HTTP,
 'HTTP Status Service',
 array('HOST' => $parts['host'],
 'PORT' => (string)$parts['port'])
);

doSocketHTTPCall($url);

appdynamics_end_exit_call($exitCall);
?>

```

### Inject a Correlation Header into an HTTP Payload Example

The next example injects a correlation header into the socket-based HTTP payload.

```

<?php

$url = 'http://myhost.mydomain/continue.php';
$parts = parse_url($url);

$exitCall = appdynamics_begin_exit_call(
 AD_EXIT_HTTP,
 'HTTP Status Service',
 array('HOST' => $parts['host'],
 'PORT' => (string)$parts['port'])
);

$corrHeader = $exitCall->getCorrelationHeader();

doSocketHTTPCall($url, $corrHeader);

appdynamics_end_exit_call($exitCall);
?>

```

The next example shows how to use a non-exclusive flag to start an exit call that may be wrapping other exit calls. The outer socket-HTTP call is started, then the `file_get_contents()` call is processed by the agent normally, and finally, the outer call is finished. We also pass the exception object to report any errors. The end result is that both backends are displayed on the flowmap.

```

<?php

class SocketHTTPException extends Exception
{
}

$url = 'http://httpstat.us/200';
$javaTierURL = 'http://myhost.mydomain/process.jsp';

```

```

$parts = parse_url($url);

$exitCall = appdynamics_begin_exit_call(
 AD_EXIT_HTTP,
 'HTTP Status Service',
 array('HOST' => $parts['host'],
 'PORT' => (string)$parts['port']),
 false
);

$contents = file_get_contents($javaTierURL);

if (doSocketHTTPCall($url) == null) {
 $error = new SocketHTTPException("something bad happened");
}

appdynamics_end_exit_call($exitCall, $error);

?>

```

## PHP Agent API Reference

### Related pages:

- [PHP Agent API User Guide](#)

The PHP Agent APIs support custom business transaction definition and correlation. They provide a way to generate multiple business transactions in a single PHP request.

They also enable you to monitor exit calls that are not automatically detected by the PHP Agent.

### API Reference Overview

The operations in the API fall into two categories, business transaction management and exit call management.

Business transaction management methods are:

- `bool appdynamics_start_transaction($transaction_name, $entry_point_type)`
- `bool appdynamics_continue_transaction($correlation_header, $entry_point_type)`
- `bool appdynamics_end_transaction()`

Exit call management methods are:

- `ADExitCall appdynamics_begin_exit_call($type, $label, $properties, $exclusive=true)`
- `void appdynamics_end_exit_call(ADExitCall $exitCall, $exception = null)`
- `string ADExitCall::getCorrelationHeader()`
- `void ADExitCall::setSQLQueryInfo($querystring, $boundparams)`

The following sections detail the methods in the API.

### Start Transaction

Starts a custom business transaction.

#### Format

```
bool appdynamics_start_transaction($transaction_name, $entry_point_type)
```

---

## Description

If the business transaction initiated by this call is not matched by an `appdynamics_end_transaction()` call, the transaction terminates at the end of the request or script.

Custom business transactions cannot be nested. If you call `appdynamics_start_transaction()` multiple times before calling `appdynamics_end_transaction()`, the last `appdynamics_start_transaction()` is used and the previous calls are discarded.

## Parameters

`$transaction_name`: The name used for the transaction in the controller. The following characters are not allowed in transaction names: { } [ ] | & ;

`$entry_point_type`: Indicates the framework or protocol of the entry point. Valid entry point types are provided as PHP extension constants, shown below:

- `AD_WEB`
- `AD_MVC`
- `AD_DRUPAL`
- `AD_WORDPRESS`
- `AD_CLI`
- `AD_WEBSERVICE`

Entry point types are case sensitive.

## Returns

True on success, false on failure.

Failure conditions are reported in the Apache log. Reasons for failure include:

- Invalid transaction name, contains disallowed characters
- Invalid entry point type
- Agent not initialized
- EUM headers were sent prior to the `appdynamics_start_transaction()` call.
- Correlation headers were sent prior to the `appdynamics_start_transaction()` call.

## Continue Transaction

Correlates a custom business transaction with an upstream service.

## Format

```
bool appdynamics_continue_transaction($correlation_header, $entry_point_type)
```

## Description

Used by a downstream tier to correlate with a service that is not an entry point supported by the PHP Agent.

## Parameters

`$correlation_header`: Correlation header of the upstream service with which to correlate.

It is the developer's responsibility to extract the correlation information from the service to provide the `$correlation_header`. See [getCorrelationHeader\(\)](#).

---

`$entry_point_type` : Optional parameter that indicates the framework or protocol of the entry point for the continued transaction. By default, the value is automatically set to `AD_CLI` when the application is running in CLI mode, and `AD_WEB` otherwise.

Use this parameter to indicate a different originating PHP application type for continuing transactions that cross PHP types, such as for a transaction originating at a PHP web application that crosses to a PHP CLI leg of the transaction.

Valid entry point types are provided as PHP extension constants:

- `AD_WEB`
- `AD_MVC`
- `AD_DRUPAL`
- `AD_WORDPRESS`
- `AD_CLI`
- `AD_WEBSERVICE`

Entry point types are case sensitive.

### Return

Returns true on success, false on failure.

### End Transaction

Ends a transaction created by a previous call to `appdynamics_begin_transaction()` or continued by `appdynamics_continue_transaction()`.

### Format

```
bool appdynamics_end_transaction()
```

### Description

When paired with an `appdynamics_continue_transaction()` call, this call ends the transaction on the tier being continued but does not end any subsequent calls downstream from that tier that are part of the distributed transaction.

If the business transaction is invalid or if there were no previous `appdynamics_begin_transaction()` or `appdynamics_continue_transaction()` calls in the request/script, this function returns false and throws a warning message that is captured by the application and reported as an exception.

Your application is recommended to wrap `appdynamics_begin_transaction()` and handle possible exceptions so that they are not logged as application exceptions.

### Begin Exit Call

Marks the start of an exit call.

### Format

```
ADExitCall appdynamics_begin_exit_call($type, $label, $properties, $exclusive=true)
```

### Parameters

`$type`: The type of exit call. Must be one of the following:

- `AD_EXIT_HTTP`
- `AD_EXIT_DB`

- AD\_EXIT\_CACHE
- AD\_EXIT\_RABBITMQ
- AD\_EXIT\_WEBSERVICE

**\$label**

Label for the exit call in the AppDynamics UI. Use a label under 40 characters long so that it fits in flowmaps.

**\$properties**

An associative array of identifying properties—name/value pairs—for the exit call. Property names and values must be strings.

Each exit call type has its own properties. There is no validation of property names, but each exit type has traditionally used the names listed below.

type					
AD_EXIT_HTTP	"HOST"	"PORT"	"URL"	"QUERY_STRING"	
AD_EXIT_DB	"HOST"	"PORT"	"DATABASE"	"VENDOR"	"URL"
AD_EXIT_CACHE	"SERVER POOL"	"VENDOR"			
AD_EXIT_RABBITMQ	"HOST"	"PORT"	"EXCHANGE"	"ROUTING KEY"	
AD_EXIT_WEBSERVICE	"SERVICE"	"OPERATION"	"SOAP ACTION"	"VENDOR"	"URL"

For AD\_EXIT\_DB exit call type it is advisable to specify at least HOST , PORT and VENDOR , as these properties are used by the AppDynamics DB integration. The VENDOR property for AD\_EXIT\_DB backends should be one of the following:

- MYSQL
- POSTGRESQL
- SQLSERVER
- ORACLE
- SYBASE
- DB2

**\$exclusive** : Boolean that Indicates whether the exit call is exclusive.

Only one exclusive exit call can be in progress at a time. For example, if this API is used to start an HTTP exit call and there is a mysql\_connect() call immediately following it, the MySQL call will not be detected while the HTTP call is in progress. An exclusive exit call has to be explicitly ended before subsequent exit calls can be detected or initiated.

Exit calls are exclusive by default, but you can make them non-exclusive by setting this parameter to false.

See the last code sample in the 'Scenario: Application makes socket-based HTTP calls' in [PHP Agent API User Guide](#) for an example of how setting this flag to false can be used to support nested exit calls.

## Return

Returns an instance of the `ADExitCall` class on success, `NULL` on error.

## End Exit Call

Marks the end of an exit call.

## Format

```
void appdynamics_end_exit_call(ADExitCall $exitCall, $exception = null)
```

## Parameters

`$exitCall`: An object representing the exit call to be ended, and returned from its `appdynamics_begin_exit_call()`.

`$exception`: An exception object—either Exception class or one derived from it—specifying if an error occurred during the exit call.

## Get Correlation Header

Returns the correlation header for this exit call. The returned correlation header can be passed to `appdynamics_continue_transaction` to correlate with this exit call.

See also the 'Scenario: Application makes socket-based HTTP calls' 'ample in [PHP Agent API User Guide](#) for an example of injecting the correlation header into an HTTP payload.

## Format

```
string ADExitCall::getCorrelationHeader()
```

## Set SQL Query Info

Sets the SQL query for this exit custom call.

## Format

```
void ADExitCall::setSQLQueryInfo($querystring, $boundparams)
```

## Parameters

`$querystring`: String containing the SQL query. Use question marks to indicate the bound parameters.

`$boundparams`: Optional comma-separated array of bound parameters as quoted strings.

## Example

```
$exitCall->setSQLQueryInfo("SELECT * FROM mytable where id1=? and id2=?;", ('Susie', '12345'));
```

## PHP Agent Logging

For the PHP Agent there is an agent log and a proxy log for each instrumented application.

## Agent Log

The agent log is located at `$<php_agent_install>/logs/agent.log`. The log contains the transactions that the agent processes and then sends to the proxy.

The default pattern for agent log naming is the following:

- `agent.log` : the current log
- `agent.log.1` : most recent log
- `agent.log.2` : second most recent log
- `agent.log.3` : third most recent log
- `agent.log.4` : fourth most recent log
- `agent.log.5` : fifth recent log.

The agent creates and rotates a maximum of six log files. Maximum log size is 20 MB, which gives you a maximum of the most recent 120 MB of log data at one time.

## Proxy Log

The proxy log is located `$<php_agent_install>/logs/proxy_$date.log`. This log contains the transactions that the proxy accepts from the agent and then sends to the Controller. See [Proxy Logging](#) and [Dynamic Language Agent Proxy](#).

## Redaction of URL Segments and Query Parameters

By default, AppDynamics PHP Agent sends transaction data to the Controller that your organization may classify as privileged information. Though this data is useful for diagnosis and troubleshooting, security considerations may require you to filter certain sensitive information from being displayed on the Controller. You can use the following for the security considerations:

- URL filters to exclude sensitive information from a URL in snapshot details.
- Data filters to exclude sensitive HTTP cookies.

## Add a URL Filter

1. Edit the PHP configuration file, `php.ini` or `appdynamics_agent.ini` depending on your environment.
2. In the PHP configuration file, configure the following settings. If a value in the ini file for any of the following config contains any non-alphanumeric characters, it must be enclosed within double-quotes (") as per the PHP guidelines.
  - Config Delimiter: Specify the character that you want to use as the configuration delimiter for the sensitive data filter for redaction. The config delimiter must be chosen such that it should not occur in the redaction config strings. This value is REQUIRED.

For example:

```
agent.sensitive_data_filter.configDelimiter = "|"
```

- URL Delimiter: Specify the character that you want to use as URL segment endpoints. The agent splits the URL at each delimiter instance to create the segments. For HTTP, use the forward-slash character "/". For a forward slash, the agent does not split on the slashes immediately following the protocol. For example, "https://myapp.example.com/" constitutes a single segment. By default, the delimiter is "/" but this is REQUIRED for successful redaction.

For example:

```
agent.sensitive_data_filter.delimiter = "/"
```

**i** '#' and ';' cannot be used as a delimiter or configDelimiter because the ini file considers it as a comment.

- Segment: Specify a comma-separated list to indicate the segments that you want the agent to filter. Segment numbering starts from 1 and providing 0 or negative value fails to redact the segments with an error message in the agent logs. The segment numbers must be in the ascending order. This value is REQUIRED.

For example:

```
agent.sensitive_data_filter.segment = "2,3"
```

- Matchfilter: Specify the type of filter to be used to match the URL among - NOT\_EMPTY | EQUALS | STARTSWITH | ENDSWITH | CONTAINS | REGEX . PERL standard must be followed if REGEX is used. The value is REQUIRED.

For using this correctly, query parameters must not be considered for match-filtering. With an example of the call "https://myapp.example.com/sensitive/data?first\_name=abc&last\_name=xyz", to specify match-filter as STARTSWITH, it matches a specified string starting with the hostname "https://myapp.example.com" in this example. If the URL contains the port in the hostname, it must be present in the config string. Similarly for ENDSWITH, it will correspond to the last segment leaving out the query parameters, "data" in this case, as query parameters are never reported in the snapshots.

For example:

```
agent.sensitive_data_filter.matchFilter = "CONTAINS"
```

- MatchPattern: Specify the string that you want to be filtered by the match-filter. This value is REQUIRED.

For example:

```
agent.sensitive_data_filter.matchPattern = "myapp"
```

- ParamPattern: Specify the regular expression matching the query parameters to filter. PERL Standard should be followed for the regular expression. This value is OPTIONAL.

For example:

```
agent.sensitive_data_filter.paramMatcher = "[a-z]+_name"
```

For example, the following configuration splits the URL on the "/" character and masks the second segment and the ParamPattern in the third segment of the URL. Here, the segmentation and obfuscation apply only to URLs containing "myapp".

```
agent.sensitive_data_filter.configDelimiter = "|"
agent.sensitive_data_filter.delimiter = "/"
agent.sensitive_data_filter.segment = "2"
agent.sensitive_data_filter.matchFilter = "CONTAINS"
```

```
agent.sensitive_data_filter.matchPattern = "myapp"
agent.sensitive_data_filter.paramMatcher = "[a-z]+_name"
```

The exit call to "https://myapp.example.com/sensitive/data?first\_name=abc&last\_name=xyz" breaks down to three segments: "https://myapp.example.com", "sensitive", and "data?first\_name=abc&last\_name=xyz". The Controller shows the masked values of the URL and the param-pattern display "https://myapp.example.com/\*\*\*\*\*/data?first\_name=\*\*\*&last\_name=\*\*\*\*" in the snapshot details.

If you do not use any values for the query parameters, the Controller does not mask any query parameters in the URL.

### Redaction of Multiple URLs

Due to the limitations of the PHP configurations, if you want to redact multiple URLs separately, arguments must be written separated by the config delimiter as described below:

```
agent.sensitive_data_filter.configDelimiter = "|"
agent.sensitive_data_filter.delimiter = "/|/"
agent.sensitive_data_filter.segment = "1,2,3|1,4"
agent.sensitive_data_filter.matchFilter = "CONTAINS|ENDSWITH"
agent.sensitive_data_filter.matchPattern = "One|.php"
agent.sensitive_data_filter.paramMatcher = "[a-z]+_name|[a-z]+_name"
```

Each '|' separated values correspond to an additional URL filter added. For 'n' number of separate URL filters, you need to have 'n' different 'I' configurations correspondingly. These filters work independently on the URLs and will redact based on the configurations specified for each filter. The first matching configuration is used for the redaction.

**i** For a successful redaction, ensure that each configuration contains the same number of configuration segments.

### Data Filter for Cookies

You can use Cookie filters to configure the agent to obfuscate sensitive information from the URLs in transaction snapshot details.

1. Edit the PHP configuration file, `php.ini` or `appdynamics_agent.ini` depending on your environment.
2. Add sensitive cookie filter element as directives:
  - AppDynamicsCookieMatchPattern: Specify a regular expression identifying cookies that must be redacted.

For example:

```
agent.sensitive_data_filter.cookieMatcher = "cookieKey"
```

- For masking multiple cookies values simultaneously, provide names of all those cookies separated by the config delimiter as a single string as follows:

```
agent.sensitive_data_filter.cookieMatcher = "PHPSESSID|X-CSRF-TOKEN|cookiekey"
```

If the config delimiter is present in the cookie name itself, change it to something else such that it should not occur in the cookie matcher strings.

## Python Agent

### Related pages:

- [Dynamic Language Agent Proxy](#)

This page describes how to install and administer the Python Agent, the runtime agent used to monitor Python with AppDynamics Application Monitoring.

### Python Agent Architecture

The Python Agent discovers, and maps and tracks metrics for business transactions, app services, and backends in your web application by injecting instrumentation into the Python application at runtime. The agent operates from inside the WSGI server that contains the instrumented application.

The [agent proxy](#) is a Java process that handles the communication between the Python Agent and Controller. The proxy reports performance metrics to the Controller, where the data is stored, analyzed, and presented.

As shown in the following figure, the proxy can serve multiple Python Agents simultaneously.

In pure Python environments, the proxy is automatically started when you start the Python Agent. In other types of environments, you need to start the proxy manually.

However the proxy is started, the commands that start the agent check whether the proxy is running before attempting to start it.

### Install the Agent Overview

If you have never installed the agent, the best way to start is with the Getting Started Wizard in the Controller. This installer configures your agents with the values that you supply in the wizard.

If you downloaded the agent from [PyPI](#), use the instructions in [Install the Python Agent](#) to instrument your application manually. In this case, see [Python Agent Settings](#) for a complete list of all the Python Agent settings that you can use to instrument the agent.

### Getting Started with the Download Wizard

The Getting Started Wizard walks you through configuration steps and helps you download the agent. To access the wizard, from the home page of the Controller, click **Getting Started** and then **Python**.

The wizard provides for a minimally configured agent, with settings for the Controller connection, the business application name, and tier name. For advanced scenarios, see [Install the Python Agent](#).

## Python Supported Environments

### Related pages:

- [Python Agent](#)

## Python Agent Support

### Python Versions

The Python agent supports these Python versions:

- **Linux:** Python 3.7, 3.8, 3.9, 3.10, and 3.11
- **Alpine Linux:** Python 3.7, 3.8, 3.9, 3.10, and 3.11

### Operating Systems

The Python agent operates on:

- Linux distribution based on glibc 2.12+ and x86 64-bit architecture
- Alpine Linux (3.13+) distribution based on musl 1.2.2+ and x86 64-bit architecture

 The Python agent does not support Power Architecture.

## Python Frameworks and Protocols

Python Agent supports:

- ASGI supported frameworks such as FastAPI
- WSGI supported frameworks such as Django, Flask, CherryPy, Bottle, and Pyramid
- Tornado

You can configure the agent to instrument any WSGI-based and ASGI-based application or framework as Python Web, including but not limited to those listed in the following tables.

At present, the Python agent fully supports exception detection in Django, Flask, CherryPy, Bottle, Pyramid, Tornado, and FastAPI frameworks. Other frameworks and custom applications may install exception handlers that effectively hide some exceptions from the agent. In such cases, the agent will only detect exceptions during exit calls, missed exceptions that are propagated to the WSGI or ASGI middleware, and exceptions reported via the custom business transaction API.

ASGI-Based Framework	Version	Notes
FastAPI	0.72.0 - 0.95.0	Only HTTP endpoints are supported

WSGI-Based Frameworks	Version	Notes
WSGI	1.0	<b>Entry point type:</b> Python web <b>Default transaction naming:</b> the first two segments of the URI
Bottle	0.12.19	
CherryPy	18.6.1	
Django	3.1.6	
Flask	1.1.2	
PasteDeploy	2.1.0	
Pyramid	2.0	
mod_wsgi	4.7.1	

Miscellaneous Frameworks	Version	Notes
Tornado	3.2 - 4.5, 5.x (without asyncio), and 6.0	<b>Entry point type:</b> Python web <b>Default transaction naming:</b> the first two segments of the URI

### Database Exit Points

Supported Database Exit Points	Version
cx_Oracle <div style="border: 1px solid #00aaff; padding: 5px; margin-top: 10px;">  Both <code>Connect()</code> and <code>SessionPool()</code> connection handlers are supported.           </div>	8.x.x
MongoDB	3.1+
MySQL-Python	
mysqlclient	

Supported Database Exit Points	Version
MySQL Connector/Python	
Psycopg 2	
PyMySQL	
TorMySQL	

### HTTP Exit Points

Supported HTTP Exit Points
httplib*
httplib2
requests
urllib
urllib2
urllib3
tornado.httpclient

\* The agent detects calls to any external library built on top of `httplib`. Therefore, backend calls to such services, such as boto, dropbox, python-twitter are detected and displayed as HTTP exit calls.

### Cache Exit Points

Supported Cache Exit Points
Memcache
Redis-py

### Install the Python Agent

#### Related Pages:

- [SELinux Installation Issues](#)

This page describes how to prepare the application environment and install the AppDynamics Python Agent.

### Before You Begin

1. Verify support for your application environment at [Python Supported Environments](#).
2. Verify that the machine where you will install the agent can access the [Python Package Index](#).
3. Provide a WSGI-based application to monitor.
4. Verify that you can access the machine where the application runs as a user with privileges to install the agent software and restart the application. Verify that you have a user account with these privileges.
5. If you are using uWSGI, set `enable-threads=1` in the uWSGI configuration file. The agent requires multi-threading.

There is a known incompatibility between the Python Agent and versions of uWSGI installed via OS packages managers such as 'apt-get'. For this reason, AppDynamics recommends installing uWSGI from [pip](#) to avoid this issue.

6. If the application to monitor runs in a virtual environment, activate the virtual environment. For example, the following source command activates a virtual environment:

```
source /<path_to_virtual_environment>/bin/activate
```

Activating a virtual environment is not necessary if the application runs in the global Python environment.

### Install the Agent

Log in to the machine on which the Python application runs using appropriate user credentials, as follows:

- For a virtual environment, you need to be the user who owns the virtual environment.
- For the global Python environment, you need to run the install command as root.

You can install the agent using one of the installation methods explained in the following sections.

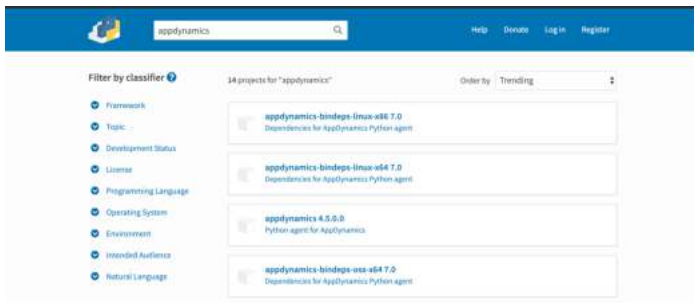

#### pip Installation

To install or upgrade to the latest version of the agent, run the `pip install` command:

Platform	Command
Linux	<div style="display: flex; justify-content: space-between; margin-bottom: 10px;"> <span><a href="#">Default JRE</a></span> <span><a href="#">Custom JRE</a></span> </div> <hr style="border: 0.5px solid #ccc;"/> <div style="border: 1px solid #ccc; padding: 5px; margin-bottom: 10px;"> <pre>pip install -U appdynamics</pre> </div> <div style="display: flex; justify-content: space-between; margin-bottom: 10px;"> <span><a href="#">Default JRE</a></span> <span><a href="#">Custom JRE</a></span> </div> <hr style="border: 0.5px solid #ccc;"/> <div style="border: 1px solid #ccc; padding: 5px;"> <pre>pip install -U appdynamics-without-jre</pre> </div>

Platform	Command
Alpine Linux	<p><a href="#">Default JRE</a>   <a href="#">Custom JRE</a></p> <hr/> <pre>apk add libstdc++ pip install -U appdynamics-alpine</pre> <p><a href="#">Default JRE</a>   <a href="#">Custom JRE</a></p> <hr/> <pre>apk add libstdc++ pip install -U appdynamics-alpine-without-jre</pre>

When there are multiple packages, you can locate the agent using the `pip list` command or using the List packages facility at <https://pypi.python.org/pypi> and then find `appdynamics` in the output. Here is a sample output:

**i** For production deployments, AppDynamics recommends that you freeze the versions of dependencies so that they are not upgraded in production without first being deployed to your test/staging environments. The command to install or upgrade to a particular version of the AppDynamics Python Agent is:

```
pip install -U
appdynamics==<released_agent_version>
```

For example:

```
pip install -U appdynamics==22.1.0.0
```

This command always installs the exact same version of the agent each time it is run.

### Installation from AppDynamics Download Portal

1. Download `PythonAgent*.tar.bz2` file (based on the target platform) from the portal and untar the contents to a folder.

Run the following command to ensure that you have the latest pip to support wheel installation:

```
pip install --upgrade pip
```

2. Run the following command to install the wheel format:

Platform	Command
Linux	<pre>pip install -f &lt;untar_folder&gt; appdynamics</pre>
Alpine Linux	<pre>pip install -f &lt;untar_folder&gt; appdynamics-alpine</pre>

### Configure the Agent

Provide a configuration file that specifies the required AppDynamics settings for agent-Controller communication. The file should be in [Python ConfigParser format](#). The Python application user must have read access on the configuration file.

Note that lines in the configuration file must not start with spaces. Lines that begin with a # are comments and are ignored by the agent.

The following is a simple sample configuration file with minimum required settings.

```
[agent]
app = <app_name>
tier = <tier_name>
node = <node_name>

[controller]
host = <controller_host>
port = <controller_port>
ssl = true
account = <your AppDynamics controller account name>
accesskey = <your AppDynamics controller account access key>
```

Note the following points in the configuration:

1. The `ssl` settings determines whether the agent connects to the Controller by SSL. This is required for SaaS Controllers.
2. The `account` value is required if you are using a SaaS account or a multi-tenant on-premises controller. It defaults to `customer1` for a single tenant controller.
3. The `accesskey` is required for all controllers. To find your account name and access key, click  in the upper right corner of the AppDynamics UI, then click **License**.
4. Other settings, such as `ssl`, `http-proxy` or `wsgi_module`, may be required for your environment. See [Python Agent Settings](#) for a complete list of settings.

When you instrument an application using `pyagent run`, you pass the configuration file path as a parameter to the `pyagent run` command. In other deployments set the `APPD_CONFIG_FILE` environment variable as illustrated below in the samples for [uWSGI with Emperor](#) and [Apache with mod\\_wsgi](#).

**i On Alpine Linux Platform:**

AppDynamics recommends that you use the `init` process. When you specify an `init` process, it ensures that the responsibilities of an init system, such as reaping zombie processes, are performed inside the created container. You can use `--init` as an argument with the `docker run` command. For example:

```
docker run -idt --privileged --init --name <container-name>
<container-id> sh
```

You can use `tini` as the Entrypoint of the docker file.

**Sample command**

```
RUN apk add --no-cache tini
Tini is now available at /sbin/tini
ENTRYPOINT ["/sbin/tini", "--"]
```

**Run the agent using your JRE**

Configure the agent with the proxy settings in any of the following scenarios:

- You want to use the JRE that is installed in your machine instead of the Python Agent's default JRE.
- You have installed the Python Agent without JRE.

```
...
[proxy]
installed_jre_path=/usr/lib/jvm/java-17-openjdk
use_installed_jre=True
...
```

**i** Python Agent first checks for `installed_jre_path` . If it is not set, then the Python Agent checks for `JAVA_HOME` .

For more information about directives, see [Python Agent Settings](#).

## Instrument the Application

Which instrumentation instructions to use depends on how the application is deployed, from these deployment options:

- [pyagent run](#)
- [uWSGI with Emperor](#)
- [Apache with mod\\_wsgi](#)

Irrespective of your Python environment, if you built your application using PasteDeploy, you can install the Python Agent by modifying the PasteDeploy configuration. See [PasteDeploy](#).

### pyagent run

If you can control the way your WSGI server is invoked, you can instrument the application using `pyagent run` . This command runs your WSGI server with the Python agent enabled. This option is generally possible if you use a process launcher/manager that takes a command to execute. For example, frameworks managed by Supervisor, uWSGI without Emperor, init.d scripts, and so on.

To use the `pyagent run` command, prepend to your existing application run command the `pyagent run` command, passing the AppDynamics configuration file described in [Configure the Agent](#) as a parameter.

Do not overwrite `PYTHONPATH` for any reason. Doing so will prevent the `pyagent run` command from loading the agent. If you need to add to `PYTHONPATH`, use the `pythonpath` configuration variable. For example, these commands add `/foo` and `/bar` to the `PYTHONPATH` instead of overwriting it:

Correct way to add to `PYTHONPATH`:

```
pythonpath = /foo
pythonpath = /bar
```

Do not add the values to `PYTHONPATH` using the following syntax. This is the wrong way to add to `PYTHONPATH`:

```
env = PYTHONPATH=/foo:/bar
```

### Using supervisorctl

If you use `supervisorctl` , after updating your Supervisor configuration you must use the `supervisorctl reload` command to have the Python agent loaded. Supervisor does not re-read its configuration files when you use the `supervisorctl restart` command.

To verify that the agent was loaded, look for the Python agent log file. Its default location is `/tmp/appd/logs/<app_name>-<node_name>.log` . For example, if your application name is `myapp` and your node name is `mynode` as specified in the agent configuration file, and you have not changed the location of the log file, the log file will be `/tmp/appd/logs/myapp-mynode` .

If the log file exists, the agent was loaded. If the log file does not exist, the agent was not loaded, in which case you should try reloading the Supervisor configuration with `supervisorctl reload`.

## Django and Flask

If your framework is Django or Flask, simply prepend `pyagent run` to your run command. For example, if your current run command looks like this:

```
gunicorn -w 8 -b '0.0.0.0:9000' example.app:application
```

Replace it with the following:

```
pyagent run -c <path_to_appdynamics_config_file> -- gunicorn -w
8 -b '0.0.0.0:9000' example.app:application
```

## Other Pure Python WSGI-Based Frameworks

If you use a WSGI-based framework that is not Django or Flask:

1. In the AppDynamics configuration file, specify your WSGI application by setting the `APPD_WSGI_MODULE` directive to point to your app module. See [Python Agent Settings](#).
2. Prepend `pyagent run` to your run command.
3. Run the AppDynamics-generated application.

For example, if your run command looks like this:

```
gunicorn -w 8 -b '0.0.0.0:9000' example.app:application
```

Replace it with these two commands:

```
pyagent run -c /path/to/appdynamics.cfg -- gunicorn -w 8 -b
'0.0.0.0:9000'
appdynamics.scripts.wsgi:application
```

## uWSGI with Emperor

If your environment is uWSGI with Emperor, you need to modify your WSGI configuration files and then manually launch the proxy.

uWSGI Emperor is a process manager specific to the uWSGI server. It does not allow you to control how the uWSGI processes that it manages are launched and therefore cannot be used with the `pyagent run` command.

The location of the WSGI configuration files is deployment-dependent. See <http://uwsgi-docs.readthedocs.org/en/latest/Emperor.html> for details of Emperor deployment.

To instrument an application for uWSGI with Emperor:

1. Create the configuration file described in [Configure the Agent](#).
2. Modify the uWSGI configuration file. Do one of the following, depending on whether the configuration uses a module directive or a wsgi-file directive:

#### Module Directive

If the uWSGI configuration has a module directive such as the following:

```
module = yourcompany.sample:app
```

modify that configuration by changing the module setting and adding the `APPD_WSGI_MODULE` and `APPD_CONFIG_FILE` settings to look like this, assuming that you have stored the configuration file in `/etc/appdynamics.cfg`:

```
env = APPD_CONFIG_FILE=/etc/appdynamics.cfg
env = APPD_WSGI_MODULE=yourcompany.sample:app
module = appdynamics.scripts.wsgi:application
```

#### WSGI-File Directive

If the uWSGI configuration has a `wsgi-file` directive:

```
wsgi-file = /var/www/yourcompany/sample.py
callable = app
```

Modify the configuration to look like the following, assuming you have stored the configuration file in `/etc/appdynamics.cfg`:

```
env = APPD_CONFIG_FILE=/etc/appdynamics.cfg
env = APPD_WSGI_SCRIPT_ALIAS=/var/www/yourcompany/sample.py
env = APPD_WSGI_CALLABLE_OBJECT=app
module = appdynamics.scripts.wsgi
```

3. Before running any traffic through the instrumented application, manually launch the proxy by executing:

```
pyagent proxy start
```

### Apache with mod\_wsgi

The Python Agent beta supports only `mod_wsgi` configurations that use `WSGIScriptAlias` that point to a single WSGI file. For example, the following type of configuration is supported:

```
WSGIScriptAlias /books /var/www/acme/bookstore/app.wsgi
```

If, instead, the script alias points to a directory, or if the script is using the `WSGIScriptAliasMatch` directive, contact [python@appdynamics.com](mailto:python@appdynamics.com) to discuss how the Python Agent can be deployed in your environment.

If the environment is Apache with `mod_wsgi` with a supported configuration as described above, you need to modify its `mod_wsgi` configuration files and manually launch the proxy.

To instrument an app for Apache with `mod_wsgi`:

1. Create the configuration file described in [Configure the Agent](#).
2. Modify the `mod_wsgi` configuration file.

If the `mod_wsgi` configuration file has an entry like this:

```
WSGIScriptAlias /books /var/www/acme/bookstore/app.wsgi
WSGICallableObject application
```

modify it to look like this, assuming that you have stored the configuration file in `/etc/appdynamics.cfg`:

```
SetEnv APPD_CONFIG_FILE /etc/appdynamics.cfg
SetEnv APPD_WSGI_MODULE acme.bookstore:app
WSGIScriptAlias /books /<path_to_virtualenv>/lib/python2.7/
site-packages/appdynamics/scripts/wsgi.py
```

3. Before running any traffic through the instrumented app, manually launch the proxy by executing:

```
pyagent proxy start
```

## PasteDeploy

You can instrument a Python application built with PasteDeploy by modifying your PasteDeploy configuration to use a composite factory supplied by AppDynamics. This feature can be used to instrument applications described by the other deployment options if they were built with PasteDeploy.

The AppDynamics composite factory is named `egg:appdynamics#instrument`. It requires a parameter named `target` that points to the application to the original application and the full path to the `APPD_settings`.

To instrument an application built with PasteDeploy:

1. Manually launch the AppDynamics proxy:

```
pyagent proxy start
```

2. In the PasteDeploy configuration file, rename the existing composite to a unique name. For example, if the existing composite configuration for an application named `metadata` is:

```
[composite:metadata]
use = egg:Paste#urlmap
/: meta
```

you could rename it:

```
[composite:_orig_metadata]
use = egg:Paste#urlmap
/: meta
```

3. Create a new composite section for the `metadata` application above the original one that you just renamed, as follows:
  - a. Give the name of the old renamed application to the new composite application.
  - b. Configure it to use the AppDynamics composite factory: `egg:appdynamics#instrument`.
  - c. Set its target to the renamed application.
  - d. Set the AppDynamics configuration file environment variable, `APPD_CONFIG_FILE`, to the path of your configuration file. For example:

```
[composite:metadata]
use = egg:appdynamics#instrument
target = orig_metadata
APPD_CONFIG_FILE = /etc/appdynamics.cfg
```

You can also set other APPD\_ configuration variables here. For example, `APPD_LOGS_DIR=/var/log/appdynamics`.

4. Restart the application.

## Start the Python Agent Proxy Manually

### Related pages:

- [Install the Python Agent](#)
- [Python Agent Settings](#)

If you use the `pyagent run` command to instrument your application, the proxy is automatically started when you start the agent.

However, you may need to arrange to start the proxy separately from the agent. The most likely reason you would need to do this is because your Python environment uses uWSGI with Emperor or Apache with

`mod_wsgi`. You can do so using the `pyagent run` command described here. Only use this command only if you need to launch the proxy manually.

### Directory Configuration Setting

The command you use to start the proxy needs to read the directory configuration setting, `APPD_DIR`, the base directory for the AppDynamics Python Agent configuration. Make sure it is correctly set. The default is `/tmp/appd/`.

You can make this setting available to the proxy in any of the following ways:

- Setting the environment variable `APPD_DIR` manually.
- Setting the `APPD_CONFIG_FILE` environment variable to point to the configuration file and then setting the base directory in the configuration file. See [Install the Python Agent](#).
- Passing in the path to the configuration file to the `pyagent proxy` command using `-c ( --config-file )` option as illustrated below.

### Start, Stop, and Restart Options for the `pyagent proxy`

To start, stop, or restart the proxy, use the `pyagent run` command, passing the desired operation and any options. The options include:

- `--debug (-d)`: starts the proxy in debugging mode
- `--no-watchdog`: disables the proxy watchdog (not recommended)
- `--config-file (-c)`: path to the Python Agent configuration file

Usage:

```
pyagent proxy start|stop|restart start_options -- [jvmOption
[jvmOption [...]]
```

### Examples:

```
pyagent proxy start -c appdynamics.config -d
pyagent proxy restart -c appdynamics.config -d
pyagent proxy stop -c appdynamics.config
```

**i** When agent is stopped without stopping the proxy it continues to be shown as active for the next 5 minutes. To avoid the application from reappearing in the controller, it is recommended that you wait for at least 5 minutes before deleting the application after the agent shut down.

### Upgrade the Python Agent

If you are upgrading both the Controller and agents, first [upgrade the Controller](#) and then upgrade the agents.

To upgrade the Python to the latest version of the 22.x agent, run this command:

```
pip install -U appdynamics\<22.x
```

The upgrade will take effect the next time you restart the agent.

## Uninstall the Python Agent

### Related pages:

- [Python Agent](#)

You can remove Python Agent instrumentation from your application by reverting deployment script changes made when installing the agent to remove all `pyagent` commands and APPD environment variables.

Removing instrumentation is generally sufficient for most purposes when it comes to uninstalling the Python Agent, however, you can additionally remove the Python Agent packages using `pip`.

Because `pip install appdynamics` installed a separate dependencies package as well as the agent, two `pip uninstall` commands are required:

```
pip uninstall appdynamics
pip uninstall <python_agent_package>
```

If you do not know which package is installed, you can find out using `pip freeze` and `grep`:

```
pip freeze | grep appdynamics
```

## Python Agent Settings

You can configure operating settings for the Python Agent using a configuration file or by setting environment variables in the application environment. This page lists the Python Agent settings.

See [Configure the Agent](#) for information about the configuration file.

**i** Older version of the environment variables are backward compatible and are deprecated which will eventually be removed in future releases. You will have to update the environment variables to the latest version. The new environment variables take precedence over the deprecated variables in case both are set in an environment (eg. `APPDYNAMICS_AGENT_APPLICATION_NAME` takes precedence over the deprecated `APPD_APP_NAME` if both are set).

**[instrumentation]**

Directive	Description	Example	Default	Environment Variable
<code>enable_openai</code>	Enable or disable OperAI instrumentation.	<code>true</code> or <code>false</code>	<code>false</code>	<code>APPDYNAMICS_ENABLE_OPENAI</code>

**[agent]**

Directive	Description	Example	Default	Environment Variable
<code>app</code>	App Name	<code>MyApp</code>	<i>Required</i>	<code>APPDYNAMICS_AGENT_APPLICATION_NAME</code>
<code>tier</code>	Tier Name	<code>web-fe</code>	<i>Required</i>	<code>APPDYNAMICS_AGENT_TIER_NAME</code>
<code>node</code>	Node Name	<code>web-fe1</code>	<i>Required</i>	<code>APPDYNAMICS_AGENT_NODE_NAME</code>
<code>dir</code>	Base directory for files related to the AppDynamics agent	<code>/mysite/appd/agent/python/</code>	<code>/tmp/appd/</code>	<code>APPDYNAMICS_AGENT_BASE_DIR</code>
<code>nodereuse</code>	Reuse Node Name	<code>true</code> or <code>false</code>	<i>Optional</i>	<code>APPDYNAMICS_AGENT_REUSE_NODE_NAME</code>
<code>nodereuseprefix</code>	Reuse Node Name Prefix	<code>My Node Name</code>	<i>Optional</i>	<code>APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX</code>
<code>uniquehostid</code>	Unique host id for the app agents		<i>Optional</i>	<code>APPDYNAMICS_AGENT_UNIQUE_HOST_ID</code>

**[agent:proxy]**

Directive	Description	Example	Default
<code>curve-enabled</code>	<code>APPDYNAMICS_CURVE_ENABLED</code>	<code>on</code>	<code>off</code>

Directive	Description	Example	Default
<code>curve-zap-enabled</code>	APPDYNAMICS_CURVE_ZAP_ENABLED	<code>on</code>	<code>off</code>
<code>curve-public-dir</code>	APPDYNAMICS_CURVE_PUBLIC_KEY_DIR	<code>/tmp/certificates</code>	<code>/tmp/appd/certs/public</code>
<code>curve-secret-dir</code>	APPDYNAMICS_CURVE_SECRET_KEY_DIR	<code>/tmp/secret-certificates</code>	<code>/tmp/appd/certs/secret</code>
<code>curve-agent-public-file</code>	APPDYNAMICS_CURVE_AGENT_PUBLIC_KEY_FILE	<code>/tmp/certs/agent.key</code>	<code>/tmp/appd/certs/public/&lt;node_name&gt;.key</code>
<code>curve-agent-secret-file</code>	APPDYNAMICS_CURVE_AGENT_SECRET_KEY_FILE	<code>/tmp/certs/agent.key_secret</code>	<code>/tmp/appd/certs/secret/&lt;node_name&gt;.key_secret</code>
<code>curve-proxy-public-file</code>	APPDYNAMICS_CURVE_PROXY_PUBLIC_KEY_FILE	<code>/tmp/certs/proxy.key</code>	<code>/tmp/appd/certs/public/proxy.key</code>
<code>curve-proxy-secret-file</code>	APPDYNAMICS_CURVE_PROXY_SECRET_KEY_FILE	<code>/tmp/certs/proxy.key_secret</code>	<code>/tmp/appd/certs/secret/proxy.key_secret</code>

### [wsgi]

Directive	Description	Example	Default	Environment Variable
<code>script</code>	Path to WSGI script file	<code>/var/www/acme/bookstore.py</code>	<code>n/a</code>	APPDYNAMICS_WSGI_SCRIPT_ALIAS
<code>callable</code>	Name of WSGI callable in script/module	<code>app</code>	<code>application</code>	APPDYNAMICS_WSGI_CALLABLE_OBJECT
<code>module</code>	Fully-qualified name of app module	<code>acme.bookstore:app</code>	<code>n/a</code>	APPDYNAMICS_WSGI_MODULE

If both the `script` and `module` directives are specified, the `module` directive takes precedence.

The `module` value may be the fully-qualified name of a module, or it may be the fully-qualified name of a module followed by a colon and the name of the WSGI callable in that module. In the latter form, the `module` directive overrides the `callable` directive.

Both the long-form of the `module` directive and the `callable` directive may take either the name of a symbol, or the name of a symbol followed by an empty pair of parentheses. In the latter form, the callable is taken to be the result of calling the callable specified by the directive. This latter form can be used with Django; for example:

```
module = django.core.handlers.wsgi:WSGIHandler()
```

**[log]**

Directive	Description	Example	Default	Environment Variable
<code>dir</code>	The directory to write proxy and agent logs to	<code>/var/log/appdynamics</code>	<code>/tmp/appd/logs</code>	<code>APPDYNAMICS_LOGS_DIR</code>
<code>level</code>	The level to log at one of: warning, info, or debug	<code>debug</code>	<code>warning</code>	<code>APPDYNAMICS_LOGGING_LEVEL</code>
<code>debugging</code>	On to write DEBUG level logs to stderr and log files	<code>on</code>	<code>off</code>	<code>APPDYNAMICS_DEBUG_LOG</code>

**[controller]**

This section specifies configuration for the AppDynamics Controller.

Directive	Description	Example	Default	Environment Variable
<code>host</code>	Controller host	<code>mycontroller.example.org</code>	<i>Required</i>	<code>APPDYNAMICS_CONTROLLER_HOST_NAME</code>
<code>port</code>	Controller port	<code>9000</code>	8090 for HTTP on-prem 443 for HTTPS, in which case SSL must also be set	<code>APPDYNAMICS_CONTROLLER_PORT</code>

Directive	Description	Example	Default	Environment Variable
ssl	Is SSL set be used to talk to the controller? on or off	on	off	APPDYNAMICS_CONTROLLER_SSL_ENABLED
account	AppDynamics Controller account	user1	For a single-tenant controller defaults to customer1 . Otherwise required.	APPDYNAMICS_AGENT_ACCOUNT_NAME
accesskey	AppDynamics Controller account access key	XC6v2n8m2\$543	<i>Required.</i> To find your account name and access key, click  in the upper right corner of the AppDynamics UI, then click <b>License</b> .	APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY

Directive	Description	Example	Default	Environment Variable
certfile	<p>Controller Certificate</p> <div style="border: 1px solid #add8e6; padding: 10px;"> <p><b>i</b></p> <ul style="list-style-type: none"> <li>This certfile must be the default agent keystore (found under <code>site-packages/appdynamics_proxysupport/lib/security/cacerts</code>) with necessary additional <code>.pem/.cert</code> certs embedded within it using <code>keytool</code>.</li> <li>Java proxy supports only <code>.jks</code> and <code>.pkcs12</code> formats in the keystore. If you want to include <code>.cert</code> format in Java proxy, run the following command:  <pre>keytool -import -alias rootCA -file /etc/ssl/certs/ca-certificates.crt -keystore cacerts.jks -storepass changeit</pre> </li> </ul> </div>	<code>/tmp/ssl/cacerts</code>	Optional	<code>APPDYNAMICS_CONTROLLER_SSL_CERTFILE</code>

**[controller:http-proxy]**

If you need to use an HTTP proxy to talk to your Controller, use this section to configure the HTTP proxy.

Directive	Description	Example	Default	Environment Variable
host	HTTP proxy host	<code>proxy.example.org</code>	<i>n/a</i>	<code>APPDYNAMICS_HTTP_PROXY_HOST</code>
port	HTTP proxy port	<code>8090</code>	<code>80</code>	<code>APPDYNAMICS_HTTP_PROXY_PORT</code>
user	HTTP proxy user	<code>proxyuser</code>	<i>n/a</i>	<code>APPDYNAMICS_HTTP_PROXY_USER</code>
password-file	HTTP proxy password file	<code>/etc/http-proxy.passwd</code>	<i>n/a</i>	<code>APPDYNAMICS_HTTP_PROXY_PASSWORD_FILE</code>

**[proxy]**

Directive	Description	Example	Default	Environment Variable
<code>max-heap-size</code>	Max heap size for proxy	450m	300m	APPDYNAMICS_MAX_HEAP_SIZE
<code>min-heap-size</code>	Min heap size for proxy	100m	50m	APPDYNAMICS_MIN_HEAP_SIZE
<code>max-perm-size</code>	Max permanent generation size	150m	120m	APPDYNAMICS_MAX_PERM_SIZE
<code>proxy-debug-port</code>	Port number to which to attach the JAVA debugger	8092	None	APPDYNAMICS_PROXY_DEBUG_PORT
<code>start-suspended</code>	Specifies whether to debug proxy startup with a JAVA debugger.	on	off	APPDYNAMICS_START_SUSPENDED
<code>debug-opt</code>	Specifies the debug opt for debugging	<code>-agentlib:jdwp=transport=dt_socket,server=y,suspended=n,address=8090</code>	None	APPDYNAMICS_DEBUG_OPT
<code>agent</code>	Specifies the Agent type (Eg PYTHON_APP_AGENT, NODEJS_APP_AGENT etc)	NODEJS_APP_AGENT	PYTHON_AGENT	APPDYNAMICS_AGENT_TYPE
<code>tcp-comm-host</code>	Host over which the agent-proxy TCP communication takes place	127.0.0.1	Default	APPDYNAMICS_TCP_COMM_HOST
<code>tcp-comm-port</code>	Port over which initial communication requests between the agent and proxy occurs	8080	None	APPDYNAMICS_TCP_COMM_PORT

Directive	Description	Example	Default	Environment Variable
<code>tcp-reporting-port</code>	Port for reporting transport (Agent only property)	10010	None	APPDYNAMICS_TCP_REPORTING_PORT
<code>tcp-request-port</code>	Port for request and config transport (Agent only property)	10011	None	APPDYNAMICS_TCP_REQUEST_PORT
<code>tcp-port-range</code>	Port range to allocate request and report port for agents (Proxy only property)	10000-10100	None	APPDYNAMICS_TCP_PORT_RANGE
<code>use_installed_jre</code>	To use the custom JRE that is installed on your machine to run proxy. For more information, see <a href="#">Run the agent using your JRE</a> .	True	None	APPDYNAMICS_USE_INSTALLED_JRE
<code>installed_jre_path</code>	Path of the installed JRE to run proxy.   Python Agent first checks for <code>installed_jre_path</code> . If it is unset, then the Python Agent checks for <code>JAVA_HOME</code> .	<code>/usr/lib/jvm/java-17-openjdk</code>	None	APPDYNAMICS_INSTALLED_JRE_PATH
<code>tls-version</code>	Supports TLS version 1.2 and 1.3.	TLSv1.3	TLSv1.2	APPDYNAMICS_TLS_VERSION

 If `PROXY_DEBUG_PORT` is defined, then `-agentlib:jdpw=transport=dt_socket,server=y,suspend=${START_SUSPENDED},address=${PROXY_DEBUG_PORT}` is used as the debug opt. `PROXY_DEBUG_PORT` takes priority over `DEBUG_OPT` if both are specified. Also ensure that `PROXY_DEBUG_PORT` is not set if you want to use a self defined `DEBUG_OPT`.

**[eum]**

Directive	Description	Example	Default	Environment Variable
<code>disable-cookie</code>	If set, the agent does not add EUM correlation data to WSGI response headers.	<code>on</code>	<code>off</code>	<code>APPDYNAMICS_EUM_DISABLE_COOKIE</code>
<code>user-agent-allowlist</code>	If specified overwrites the default allowlist for user agent added as EUM correlation data headers Use this setting to specify alternate user agents as a comma separated list. Use '*' to allow all user agents.	<code>'iPad, Android'</code>	<code>'Mozilla, Opera, WebKit, Nokia'</code>	<code>APPDYNAMICS_EUM_USER_AGENT_ALLOWLIST</code>

**[services:snapshot]**

Directive	Description	Example	Default	Environment Variable
<code>exit-call-details-length</code>	Specifies the number of characters in the details string describing exit calls in transaction snapshots.	<code>200</code>	<code>100</code>	<code>APPDYNAMICS_EXIT_CALL_DETAILS_LENGTH</code>

**[services:transaction-monitor]**

Directive	Description	Example	Default	Environment Variable
<code>bt-max-duration-ms</code>	Maximum duration of a business transaction in milliseconds.	<code>60000</code>	<code>120000</code>	<code>APPDYNAMICS_BT_MAX_DURATION_MS</code>

[services:analytics]

Directive	Description	Example	Default	Environment Variable
host	Analytics Agent host	analytics-agent.example.org	localhost	APPDYNAMICS_ANALYTICS_HOSTNAME
port	Analytics Agent port	9000	9090	APPDYNAMICS_ANALYTICS_PORT
ssl	Set it <b>on</b> to enable SSL communication with the Analytics Agent	on	off	APPDYNAMICS_ANALYTICS_SSL_ENABLED
ca-file	Certificate of the CA authority that signed the certificate of Analytics Agent. <div style="border: 1px solid #00aaff; padding: 5px; margin-top: 10px;"> <p><b>i</b> The certificate format must be .pem If there are intermediate certificate authorities, specify the path of the chain of trust in place of the root certificate authority.</p> </div>	/tmp/certs/ca-cert.pem	optional	APPDYNAMICS_ANALYTICS_CAFILE

## Node Reuse for Python Agent

### Reuse Node Name

To reuse node names in AppDynamics, you have to set `nodereuse` property to `true`. When you set this property to true, you do not have to supply a node name, but you do need to provide a node name prefix using `nodereuseprefix`.

**i** When `nodereuse` and a node name is used, the `nodereuseprefix` property is given precedence.

This property is useful for monitoring environments where there are many VMs (Virtual Machines) with short life spans. When set to true, AppDynamics reuses the node names of historical VMs for new VMs. This avoids a proliferation of differently named nodes in AppDynamics over time, particularly when the nodes are essentially identical processes that run over different times.

AppDynamics generates a node name with App, Tier, and Sequence number, and the node names are pooled. For example, the sequence numbers are reused when the nodes are purged (based on the node lifetime).

**System Property:** `nodereuse`

**Type:** Boolean

**Default:** False

**Required:** No

### Reuse Node Name Prefix

When you configure the agent to reuse node names, use this property to specify the prefix that the Controller uses to generate node names dynamically.

**System Property:** `nodereuseprefix`

**Type:** String

**Default:** None

**Required:** When `nodereuse=true`

Reuse node feature example:

With the following configuration, the Controller generates a node name with the prefix "reportGen". Node names will have suffixes -1, -2, and so on, depending on the number of nodes are running in parallel. The name of a node that is shut down and qualifies as a historical node may be reused by a new node.

```
nodereuse=true nodereuseprefix =reportGen
```

## TCP Mode Configuration

By default, Python Agent and Java proxy communicate with each other using Inter-Process Communication (IPC).

However, using Transmission Control Protocol (TCP) communication is beneficial in these scenarios:

- When you want the Java proxy and Python Agent to run over different host operating systems.
- In containers (such as Docker and Kubernetes), where mounting the same volume for all the containers is possible but not recommended.

To enable TCP communication, set `tcp-comm-port` to a valid port. The Python Agent and Java proxy can now communicate using TCP rather than IPC.

The Java proxy listens to the incoming connection requests from agents over the `APPDYNAMICS_TCP_COMM_PORT`. The communication occurs for every agent over these two unique ports:

- Reporting port
- Request port

These ports can be set by either the agent or the proxy.

### TCP Mode Configuration - Environment Variables

For `cfg` file versions of the environment variables, see [Python Agent Settings](#).

This table lists the TCP mode configuration environment variables:

Environment Variable Name	Description
APPDYNAMICS_TCP_COMM_HOST	<ul style="list-style-type: none"> <li>For Java proxy - Defines the host over which the proxy listens to the incoming connections.</li> <li>For Python Agent - Defines the host over which the agent tries to communicate with the proxy.</li> </ul>
APPDYNAMICS_TCP_COMM_PORT	<ul style="list-style-type: none"> <li>The port over which the initial communication occurs.</li> <li>You should set it to enable TCP communication.</li> </ul>
APPDYNAMICS_TCP_PORT_RANGE (Proxy only)	The port range over which the proxy allocates ports to communicate with the agents.
APPDYNAMICS_TCP_REPORTING_PORT (Agent only)	<ul style="list-style-type: none"> <li>The port for reporting transport between the agent and proxy.</li> <li>If this variable is not set, then the proxy assigns a port to the agent in APPDYNAMICS_TCP_PORT_RANGE</li> </ul>
APPDYNAMICS_TCP_REQUEST_PORT (Agent only)	<ul style="list-style-type: none"> <li>The port for request and configuration transport between the agent and proxy.</li> <li>If this variable is not set, then the proxy assigns a port to the agent in APPDYNAMICS_TCP_PORT_RANGE</li> </ul>

## Deploy Python Agent with Shared Proxy on Kubernetes

**i** Kubernetes does not support exposing a [range of ports](#) for the Proxy service. This prevents the Proxy service from allocating and using two ports for each Python Agent.

This page describes how to deploy Python Agent with shared Java proxy on Kubernetes. You can deploy the shared Java proxy using one of these methods:

- Expose a continuous range of ports in the proxy service for the proxy-agent communication
- Run the proxy pod as a static pod with `hostNetwork: true`

**i**

- Applications that run with Python Agent must run in pods. You can scale the Python Agent pods up and down.
- The proxy runs as a single, separate pod and is exposed to the Python Agents through a service. You should not scale or replicate the proxy pod.

### Expose Continuous Range of Ports Manually in the Proxy Service

To deploy the shared Java proxy manually:

- Expose a few ports (atleast two times the number of agents) using the YAML file in Kubernetes in the proxy service.
- Configure the Python Agent using either of these methods:
  - Set the `APPDYNAMICS_TCP_PORT_RANGE` to the exposed port range to enable the proxy service to allocate ports to the Python Agent.

- When the Python Agent selects request and report port, set the `APPDYNAMICS_TCP_REQUEST_PORT` and the `APPDYNAMICS_TCP_REPORTING_PORT` to a port in the exposed port range.

### Run the Proxy Pod as a Static Pod

You can run the TCP proxy pod as a static pod which makes it use the host network. The TCP proxy is bound to the host IP address and ports.

To deploy the shared proxy by running the proxy pod:

1. Set `hostNetwork: true` in the proxy pod.
2. Set the `APPDYNAMICS_TCP_COMM_HOST` to the host IP address in the Python Agent pods.

### Set Up CurveZMQ for Encrypted Communication

By default, the communication between Java Proxy and Python Agent is not encrypted. This page describes how to configure communication between Java Proxy and Python Agent and encrypt and authenticate using CurveZMQ. CurveZMQ is an authentication and encryption protocol for ZeroMQ.

To set up CurveZMQ, perform these steps:

1. [Generate Certificates](#)
2. [Enable Curve Encryption](#)
3. [Enable Curve Authentication](#)

#### Generate Certificates

The Python Agent and Java Proxy automatically generate CurveZMQ certificates if you enable the Curve encryption. CurveZMQ uses certificates to encrypt and authenticate communication between Python Agent and Java Proxy. To generate the certificates manually, use this Python script:

```
import appdynamics.agent
import appdynamics_bindeps.zmq.auth
This creates a <cert_name>.key and <cert_name>.key_secret in the <certs_directory>
public_file and secret_file will be set to the publickeyfile name and secret keyfile
name respectively
public_file, secret_file =
appdynamics_bindeps.zmq.auth.create_certificates(certificates_directory, cert_name)
```

You must ensure that these environment variables point to the correct CurveZMQ certificates:

- `APPDYNAMICS_CURVE_AGENT_PUBLIC_KEY_FILE`
- `APPDYNAMICS_CURVE_AGENT_SECRET_KEY_FILE`
- `APPDYNAMICS_CURVE_PROXY_PUBLIC_KEY_FILE`
- `APPDYNAMICS_CURVE_PROXY_SECRET_KEY_FILE`

See the [Curve Environment Variables](#) table.

#### Enable Curve Encryption

To enable and encrypt the communication between Java Proxy and Python Agent, set the `APPDYNAMICS_CURVE_ENABLED` variable to `Yes`.

#### Enable Curve Authentication

Before enabling Curve authentication (ZAP or ZeroMQ Authentication Protocol), ensure that:

- The Python Agent public keys (which to connect to the proxy) and the Java Proxy public keys are located in a directory.
- Java Proxy can access the directory or the directory is located inside the Java Proxy container.
- The `APPDYNAMICS_CURVE_PUBLIC_KEY_DIR` environment variable points to that directory.

To enable Curve authentication, set the `APPDYNAMICS_CURVE_ZAP_ENABLED` variable to `True`.

The proxy then authenticates the agent if the agent's public keys are available in `APPDYNAMICS_CURVE_PUBLIC_KEY_DIR`. The proxy does not accept connection requests from the agent if the public keys are not available.

### Curve Environment Variables

This table describes the available Curve environment variables.

Environment Variable	Description
<code>APPDYNAMICS_CURVE_ENABLED</code>	Sets whether Curve is enabled.
<code>APPDYNAMICS_CURVE_ZAP_ENABLED</code>	Sets whether Curve ZAP (authentication) is enabled.
<code>APPDYNAMICS_CURVE_PUBLIC_KEY_DIR</code>	Location of the Curve public certificates.
<code>APPDYNAMICS_CURVE_SECRET_KEY_DIR</code>	Location of the Curve secret certificates.
<code>APPDYNAMICS_CURVE_AGENT_PUBLIC_KEY_FILE</code>	Curve public key file for the agent. If the file does not exist, then the agent attempts to create it.
<code>APPDYNAMICS_CURVE_AGENT_SECRET_KEY_FILE</code>	Curve secret key file for the agent. If the file does not exist, then the agent attempts to create it.
<code>APPDYNAMICS_CURVE_PROXY_PUBLIC_KEY_FILE</code>	Curve public key file for the proxy. If the file does not exist, then the proxy attempts to create it.
<code>APPDYNAMICS_CURVE_PROXY_SECRET_KEY_FILE</code>	Curve secret key file for the proxy. If the file does not exist, then the proxy attempts to create it.

### Backend Resolution for the Python Agent

Backend resolution is the association of a backend (through identity) to node or tier.

## Problem

In the traditional way of handling flow maps, it is shown that the upstream tier connects directly to downstream tier when it makes an exit call. If the Service Proxy is present in between them, controller is unable to identify the Service Proxy as a backend.

The inaccurate identification of the backend component causes the system to periodically change the association of the single backend with one of the potential target downstream tiers to which the Service Proxy could route. This results in an incorrect flowmap with the wrong metrics.

## Solution

A Service Proxy is marked as a backend and shown on the flow map. This Service Proxy ensures that the requests from the upstream tiers to the downstream tiers are displayed accurately. The metrics are reported accurately and shown in such a way that the metrics tally between the tiers.

In the following figure, it is illustrated that 192.168.1.9 backend is identified as Service Proxy and requests coming from tier11 will be routed to tier21 and tier22 via this Service Proxy. Also it distributes the metrics (call/min) accurately between tier21 and tier22 which is 8 and 7 respectively. This collectively is equal to 15 which is the same as upstream metric.

Once the Service Proxy is marked as backend, re-resolution stops.

## How the Backend Resolution Works for Python Agent?

The backend resolution works when the `backend.detect.loadbalancer.enabled` and `backend.detect.urimismconfig.enabled` flags are set to true on the controller. Once the flags are set, if the backend switches between the tiers only then the backend is marked as a Service Proxy. All the upstream agents are informed that a backend is marked as a Service Proxy. But only those versions of agents that support the Service Proxy feature start reporting the metrics to the controller.

After the Controller identifies a Service Proxy for the Backend Resolution, the Python Agent gets the information that a Service Proxy has been detected and the agent sends the right metric to the controller. The upstream agent version should also support the Service Proxy feature for this to work as designed. If the agent is not upgraded, then the Service Proxy is not detected and the backend is reverted as a normal backend and the Controller will function with the previous behavior.

Therefore, it is recommended that a compatible agent is used in the Backend resolution.

## Enable the Service Proxy

The Service Proxy detection is enabled on the Controller by setting the `backend.detect.loadbalancer.enabled` and `backend.detect.urimisconfig.enabled` flags. For more information, see [Service Proxy Overview](#).

## Service Proxy Overview

In Application Performance Management (APM), the service that is called in an application environment is usually identified by specific properties, such as the host or port properties. However in an environment with a gateway or service proxy, the host and port actually identify a *device* instead of the ultimate downstream tier that handles the request.

This inaccurate identification of the backend destination causes the system to periodically change the association of the single backend with one of the potential target downstream tiers to which the gateway could route. This results in the joining of incomplete flow maps and inconsistencies between tiers that are included within Business Transaction snapshots, and the corresponding Business Transaction flow map.

The service proxy identification feature enables the system to resolve and identify the correct backend, and displays the correct component structure in the flow map. The service proxy detects these changes in the backend association and instructs the upstream Agent to identify the affected backend(s) as a service proxy.

As a result, the flow map will show a service proxy (represented by this icon ) between the upstream and downstream tiers, for example:

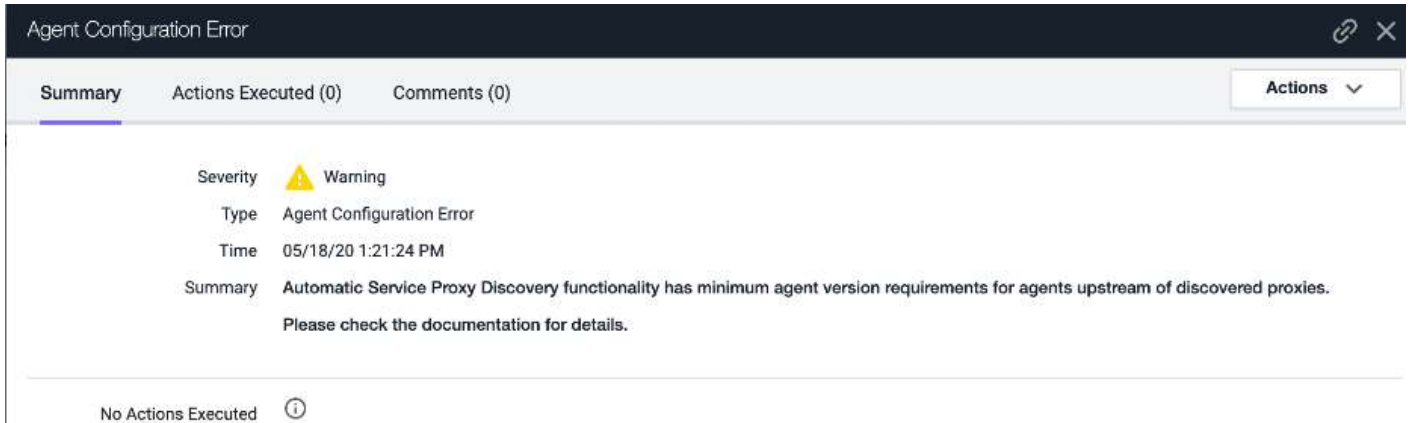

The service proxy is also visible in the Remote Services list:

Remote Services							
last 5 minutes							
Name ↑	Type	Response Time (ms)	Calls	Calls / min	Errors	Errors / min	
 backendresolution:7900	HTTP	2,004	100	20	0	0	

If the upstream Agent is an older version than what is currently supported, an event is generated with the following Agent Configuration Error message:

 The service proxy feature is supported on Python Agent version 21.6.0 and later.

Agent Configuration Error

Summary    Actions Executed (0)    Comments (0)    Actions ▾

Severity  Warning

Type Agent Configuration Error

Time 05/18/20 1:21:24 PM

Summary Automatic Service Proxy Discovery functionality has minimum agent version requirements for agents upstream of discovered proxies.  
Please check the documentation for details.

No Actions Executed 

The service proxy icon is also available on these flow maps:

- Application Dashboard
- Tiers and Nodes
- Drill Down Backend Node
- Transaction Snapshot (Waterfall View)

### Enable Service Proxy Detection

The backend is identified as a service proxy in the Controller.

-  For *SaaS customers*: To request that your Controller has the service proxy feature enabled, you should work closely with your AppDynamics account representative.
- For on-premises customers: To enable the service proxy feature:
- [2023-10-19\\_05-04-05\\_Access the Administration Console.](#)
  - Open the admin.jsp page in the Controller from the url:  
`<controllerhost>:<controllerport>/admin.jsp`
  - Access **Controller Settings**.
  - Search for these two properties, and set each of them to `true` :
    - `backend.detect.loadbalancer.enabled = true`
    - `backend.detect.urimisconfig.enabled = true`
  - Save your changes.

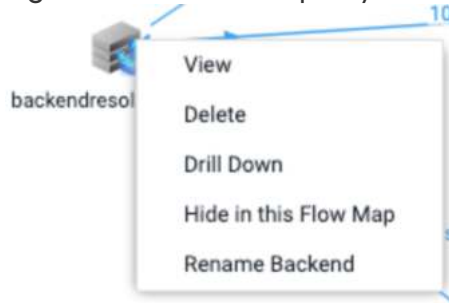

Once the Controller resolves the backend, it then sends the configuration information to the Agent.

### Delete a Service Proxy

If you remove the service proxy from the infrastructure but continue to use the same host and same port for the downstream nodes, then the service proxy will still show on the flow map. You must manually delete the service proxy to directly resolve the upstream and downstream tiers correctly.

To delete a service proxy for a backend node:

1. Right-click the service proxy icon from the flow map to open a popup menu.

2. Select **Delete**.

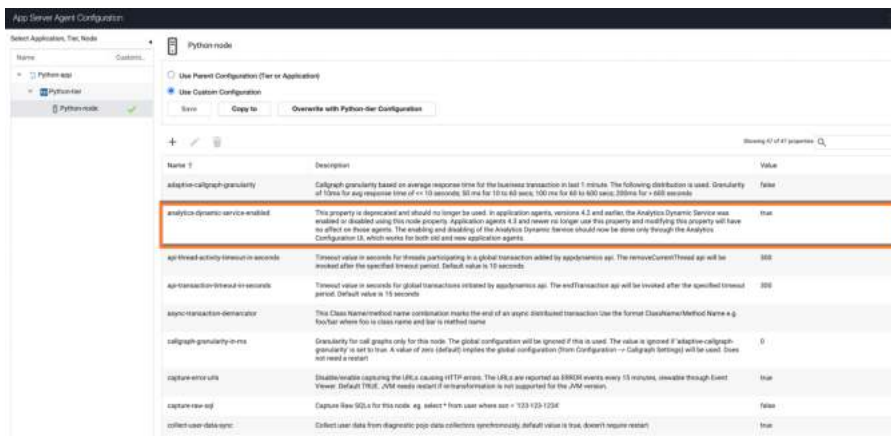

## Enable Transaction Analytics for Python Agent

This page describes the high-level steps to enable Transaction Analytics for the Python Agent.

1. [Install and configure the Analytics Agent.](#)
2. [Configure the Python Agent](#) to collect and send the transaction analytics data.
3. (Optional) [Enable SSL between the Python Agent and the Analytics Agent.](#)

To update the Transaction Analytics properties, see `[services:analytics]` under [Python Agent Settings](#).

To report analytics for Controller versions  $\leq 21.10$ , set the `analytics-dynamic-service-enabled=true` node property. For details on how to add node properties, see [Add a Registered Node Property](#).

## Install the Python Agent in Containers

This page explains your options to install the Python Agent in a containerized application.

When deploying the Python Agent in a containerized application, you need to deploy both the Dynamic Languages Proxy and the Python Agent:

- [Deploy the Dynamic Languages Proxy](#)
- [Deploy the Python Agent in the Application Container](#)

## Deploy the Dynamic Languages Proxy

The [Dynamic Languages Proxy](#) acts as a communication gateway between the Python Agent running in the application process and the AppDynamics Controller.

You can use one of two available options to deploy the Dynamic Languages Proxy, either the:

- [Sidecar Container](#) (recommended): This option follows the best practice of one process per container. The Dynamic Language Proxy runs in a sidecar container separate from the application container, or
- [Application Container](#): This option uses the default configuration to run the proxy in the same container as the application.

### Deploy Dynamic Languages Proxy in a Sidecar Container (recommended)

AppDynamics recommends following the best practice of maintaining one process per container.

1. To use a sidecar container to run the Dynamic Languages Proxy, add the `--use-manual-proxy` parameter when starting the Python application.

```
pyagent run --use-manual-proxy python ./app.py
```

The `--use-manual-proxy` parameter prevents the Python Agent agent from starting the Dynamic Languages Proxy as a separate process in the same application container, which is the default behavior.

2. Configure the deployed sidecar container to run the proxy. This Kubernetes deployment spec snippet shows how to define a second container named `proxy` that uses the [dl-proxy image](#) published on Docker Hub.

```
apiVersion: apps/v1
kind: Deployment
metadata:
 name: mypython-app
spec:
 <...>
 spec:
 containers:
 - name: mypython-app
 image: myrepo/python-app-with-appd:v1
 <...>
 - name: proxy
 image: docker.io/appdynamics/dl-proxy:latest
 imagePullPolicy: Always
 env:
 - name: APPDYNAMICS_DEBUG_LOG
 value: "on"
 - name: APPDYNAMICS_LOGGING_LEVEL
 value: "debug"
 - name: APPDYNAMICS_TCP_COMM_HOST
 value: "0.0.0.0"
 - name: APPDYNAMICS_TCP_COMM_PORT
 value: "9091"
 - name: APPDYNAMICS_TCP_PORT_RANGE
 value: "10000-10100"
 ports:
 - containerPort: 9091
 protocol: TCP
```

```
resources:
 ...
```

## Deploy Dynamic Languages Proxy in the Application Container

If you prefer to run the proxy as a separate process in the same container as the application, omit the `--use-manual-proxy` parameter when starting the Python application.

```
pyagent run python ./app.py
```

The Python Agent automatically starts a separate process for the proxy in the same container. Avoid adding a sidecar container to the deployment so only the application container is defined.

## Deploy the Python Agent in the Application Container

To instrument a Python application, the required Python Agent packages must be deployed to the application container and loaded by the application at startup. The available options are:

- [Use a Dockerfile](#): This option uses a Dockerfile to deploy the Python Agent in the application Docker image at build time.
- [Use Init Containers](#): This option uses Kubernetes init containers to deploy the Python Agent into the application container when the application starts up. Using the init containers option does not require any changes to the application Docker image.

For each of these options, the steps assume the use of a sidecar to run the Dynamic Languages Proxy and that you have `kubectl` installed.

Once you have deployed the Python Agent, see [Validate the Python Agent Install](#).

**i** Note that Cluster Agent auto-instrumentation is not supported for Python applications running in Kubernetes clusters where the Cluster Agent is installed. See [Container Platforms](#).

## Use a Dockerfile

**i** This option applies to containers running in Docker and Kubernetes.

This option uses a Dockerfile to deploy the Python Agent in the Docker image at build time. The built Docker image must contain the application and the Python Agent.

To deploy the agent in the application image during the image build:

1. [Copy the Application Files to the Image](#)
2. [Perform the PIP Install](#)
3. [Copy the Controller Certs to the Image \(on-premises Controller only\)](#)
4. [Use Pyagent to Run the Application](#)
5. [Set the Python Agent Environment Variables](#)
6. [Validate the Python Agent Install](#)

Copy the Application Files to the Image

Edit the Dockerfile to copy the application folder, and set up the requirements and start script:

```
COPY mypythonapp/ /app/
WORKDIR /app
COPY requirements.txt .
RUN chmod +x ./app.py
EXPOSE 8080
```

### Perform the PIP Install

Run the `pip install` command as described in [Install the Python Agent](#). Specify the version of the latest `appdynamics` release from the [AppDynamics Python project](#). For example:

```
RUN pip install -U appdynamics==21.12.2.4693 -r requirements.txt
```

### Copy the Controller Certs to the Image (On-Premises Controller Only)

For Python Agents communicating with an on-premises Controller, edit the Dockerfile to copy the `cacerts` file containing the on-premises certs to the image and set the `APPDYNAMICS_CONTROLLER_SSL_CERTFILE` environment variable.

For example:

```
COPY ./onprem-cacerts /opt/appdynamics/cacerts
ENV APPDYNAMICS_CONTROLLER_SSL_CERTFILE=/opt/appdynamics/cacerts
```

### Use Pyagent to Run the Application

Use `pyagent` to run the application based on the use of Flask or Django frameworks. See [Install the Python Agent](#) for additional support of WSGI frameworks. Include the `--use-manual-proxy` parameter to prevent the Dynamic Languages Proxy from starting in the application container.

```
CMD pyagent run --use-manual-proxy python ./app.py
```

A complete Dockerfile Pyagent example:

```
FROM python:3.7

Use latest version from https://pypi.org/project/appdynamics/#history
ENV APPD_AGENT_VERSION=21.12.2.4693

COPY mypythonapp/ /app/
WORKDIR /app
RUN chmod +x ./app.py

EXPOSE 8080

RUN pip install -U appdynamics==${APPD_AGENT_VERSION} -r requirements.txt
```

```
CMD pyagent run --use-manual-proxy python ./app.py
```

## Set the Python Agent Environment Variables

**i** Note that `APPDYNAMICS_TCP_COMM_PORT` should be set to an available port in the application and proxy container and is used for the agent to proxy communication. See [TCP Mode Configuration](#).

How you set the Python Agent environment variables depends on how you deploy the image. For a Docker deployment, set the agent environment variables in the Dockerfile, or external file you supply, as a parameter to `docker run`. For example:

```
ENV APPDYNAMICS_TCP_COMM_PORT=9091
ENV APPDYNAMICS_AGENT_APPLICATION_NAME=<value>
ENV APPDYNAMICS_AGENT_TIER_NAME=<value>
ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME=true
ENV APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_NAME=<value>
ENV APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY=<value>
ENV APPDYNAMICS_CONTROLLER_HOST_NAME=<value>
ENV APPDYNAMICS_CONTROLLER_PORT=<value>
ENV APPDYNAMICS_CONTROLLER_SSL_ENABLED=<value>
```

For Kubernetes applications, set these environment variables using configmaps, secrets, and the deployment spec as described in [Best Practices to Configure Agents in Kubernetes](#).

1. Use a `configmap` to set the agent environment variables that are shared across Python applications in a namespace, as shown in this `appd-python-config.yaml` example:

```
apiVersion: v1
data:
 APPDYNAMICS_TCP_COMM_PORT: "9091"
 APPDYNAMICS_AGENT_APPLICATION_NAME: "<value>"
 APPDYNAMICS_AGENT_REUSE_NODE_NAME: "<value>"
 APPDYNAMICS_AGENT_ACCOUNT_NAME: "<value>"
 APPDYNAMICS_CONTROLLER_HOST_NAME: "<value>"
 APPDYNAMICS_CONTROLLER_PORT: "<value>"
 APPDYNAMICS_CONTROLLER_SSL_ENABLED: "<value>"
kind: ConfigMap
metadata:
 name: appd-python-config
```

2. Apply the `configmap` to the application namespace:

```
$ kubectl -n <app-ns> apply -f appd-python-config.yaml
```

3. Update the deployment spec to reference the `configmap`:

```
spec:
 containers:
 - name: python-app
 envFrom:
 - configMapRef:
 name: appd-python-config
 ...
```

4. Create a secret for the Controller access key using `kubectl` :

```
$ kubectl -n <app-ns> create secret generic appd-agent-secret --from-literal=access-key=<access-key>
```

5. Update the deployment spec to reference the secret:

```
spec:
 containers:
 - name: python-app
 env:
 - name: APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY
 valueFrom:
 secretKeyRef:
 name: appd-agent-secret
 key: access-key
 ...
```

6. Set the application-specific tier name environment variable `APPDYNAMICS_AGENT_TIER_NAME` in the deployment spec:

```
spec:
 containers:
 - name: python-app
 env:
 - name: APPDYNAMICS_AGENT_TIER_NAME
 value: python-service
 - name: APPDYNAMICS_AGENT_REUSE_NODE_NAME_PREFIX
 value: python-service
 ...
```

7. Add the proxy container

```
spec:
 containers:
 ...
 - name: proxy
 image: appdynamics/dl-proxy:latest
 imagePullPolicy: Always
```

```

env:
 - name: APPDYNAMICS_DEBUG_LOG
 value: "on"
 - name: APPDYNAMICS_LOGGING_LEVEL
 value: "debug"
 - name: APPDYNAMICS_TCP_COMM_HOST
 value: "0.0.0.0"
 - name: APPDYNAMICS_TCP_COMM_PORT
 value: "9091"
 - name: APPDYNAMICS_TCP_PORT_RANGE
 value: "10000-10100"
ports:
 - containerPort: 9091
 protocol: TCP
resources:
 limits:
 cpu: 500m
 memory: 900M
 requests:
 cpu: 400m
 memory: 600M
...

```

Below is a complete example of a Kubernetes Deployment spec:

```

apiVersion: apps/v1
kind: Deployment
metadata:
 name: mypython-app
spec:
 selector:
 matchLabels:
 name: mypython-app
 replicas: 1
 template:
 metadata:
 labels:

 protocol: TCP
 resources:
 limits:
 cpu: 500m
 memory: 900M
 requests:
 cpu: 400m
 memory: 600M
 restartPolicy: Always

apiVersion: v1
kind: Service
metadata:
 name: mypython-app
spec:
 selector:
 name: mypython-app
 ports:
 - name: "8080"
 port: 8080
 targetPort: 8080
 type: LoadBalancer
status:
 loadBalancer: {}

```

## Use Init Containers

**i** This option applies to containers running in Kubernetes.

This option uses Kubernetes init containers to install the Python Agent into the application container when the application starts up. The Use of init containers requires that the application image is built without the Python Agent. The benefit of this option is that it does not require changes to the application image.

The init container provides a startup script that is used to override the default application startup command. It runs `pip` to install the Python Agent dependencies in the application container and then starts the application based on the configured `APP_ENTRY_POINT` environment variable.

To instrument a Python application using init containers:

1. [Build the Application Image Without the Python Agent](#)
2. [Add the Init Container to the Deployment Spec](#)
3. [Set the Python Agent Environment Variables](#)
4. [Validate the Python Agent Install](#)

### Build the Application Image Without the Python Agent

The following example is Dockerfile that builds an application image without including the Python Agent dependency.

```
FROM python:3.7

COPY mypythonapp/ /app/
WORKDIR /app
RUN chmod +x ./app.py

EXPOSE 8080

RUN pip install -r requirements.txt

CMD pyagent run python ./app.py
```

### Add the Init Container to the Deployment Spec

The deployment spec below illustrates the changes required to use an init container:

- Line 16: The `appd-python-init` init container is defined and copies the contents of the init container to the application container.
- Line 22: The `init` container references the [python-agent-init image from Docker Hub](#).
- Line 78: A volume mount is defined to share the contents of the init container with the application container.
- Line 30: The application startup command is overridden to run the script `run-with-agent.sh`, which is copied from the init container.
- Line 34: `APP_ENTRY_POINT` and `APPDYNAMICS_AGENT_VERSION` are defined on the application container to specify the app entry point and agent version used by `run-with-agent.sh`. `APPDYNAMICS_AGENT_VERSION` has the format a.b.c.d and is based on the version number listed on the [PyPi AppDynamics release page](#).

**i** We recommend you to deploy Dynamic Languages proxy for better performance.

Use the following code samples depending on your proxy type:

[Dynamic Languages Proxy \(Manual\)](#)    Default Proxy

```

apiVersion: apps/v1
kind: Deployment
metadata:
 name: mypython-app-init
spec:
 selector:

```

## Set the Python Agent Environment Variables

When using an init container, set the Python Agent environment variables for Kubernetes as described in [Use a Dockerfile](#).

## Validate the Python Agent Install

Once you have deployed the Python application with the Python Agent and generated load on the application, the application should appear in the AppDynamics Controller based on the configured application, tier, and node names. To troubleshoot communication issues between the agent and the proxy, or proxy and Controller log on to the application and proxy containers. Note that logs will not appear until the application process receives requests.

```

check that the app and proxy containers are running
kubectl -n <app ns> get pods
NAME READY STATUS RESTARTS AGE
mypython-app-7687956c77-q5z85 2/2 Running 0 40s

if both containers aren't running, check events regarding image pulls, etc
kubectl -n <app ns> get events

```

```
check the Python Agent logs in the application container for issues communicating with the
proxy running in the sidecar
kubectl -n <app ns> exec -it <pod name> -c <app container name> /bin/bash
cd /tmp/appd/logs
cat <app-node names>.log

check the proxy logs for issues communicating with the AppDynamics Controller
kubectl -n <app ns> exec -it <pod name> -c proxy /bin/bash
cd /tmp/appd/logs/<app folder>
cat agent.<timestamp>.log
```

## Python Agent Debugging and Logging

### Logging Settings

Logging is configured in the logging section of the AppDynamics configuration file. See [Python Agent Settings](#) and [Python Agent](#).

#### Logging Levels

Set the logging level for the amount of detail that you want to see: `INFO` , `WARNING` or `DEBUG` . The default is level is `WARNING` .

For maximum debugging information, set the logging level to `DEBUG` . Debug-level logs show the information that the Python Agent is sending to the proxy, which can be useful for debugging the agent.

For quick debugging, set the debugging configuration option to `on` . This causes debug-level logs to be written to both stderr and log files.

This is the behavior you can expect with various combinations of logging level and debug settings:

The various combinations of logging level and debug settings produce behavior as follows:

- `level=info, debugging=off` : Info-level logs are written to the log file
- `level=warning, debugging=off` : Warning-level logs are written to the log file
- `level=debug, debugging=off` : Debug-level logs are written to the log file
- `level=info, debugging=on` : Debug-level logs are written to the log file and to stderr
- `level=warning, debugging=on` : Debug-level logs are written to the log file and to stderr
- `level=debug, debugging=on` : Debug-level logs are written to the log file and to stderr

The Proxy logging level is separate and is not affected by the configuration settings of the Agent logging levels. Proxy logging level is "info" by default. Typically, you can redirect that output to a file if desired. In case if you wish to increase the logging level output, you must do so by starting the Proxy manually. First assign the new logging level within the Proxy's configuration file ( `proxy/conf/logging/log4j.xml` ) and then invoke the Proxy task.

**i** There is no way to automatically adjust the Proxy logging level from the Agent configuration file settings.

#### Location and Names of Agent Log Files

Agent logs are written in the directory specified by the `dir` directive, `APPD_LOGS_DIR` in the logging section of the configuration file.

---

For each node, the log is output to a file named `APP_NAME-<NODE_NAME>.log`. These files live in the log dir directory, `APPD_LOGS_DIR`.

The agent creates and rotates a maximum of five log files. Maximum log size is 20 MB, which gives you a maximum of the most recent 100 MB of log data at one time.

For example:

1. myApp-myNode.log
2. myApp-myNode.log.1
3. myApp-myNode.log.2
4. myApp-myNode.log.3
5. myApp-myNode.log.4

### Location of Proxy Logs

The proxy logs are always written to dir `APPD_LOGS_DIR`, which defaults to `/tmp/appd/logs`, `APPD_DIR/logs`.

### Python Agent API

#### Related pages:

- [Python Agent API Guide](#)
- [Python Agent API Reference](#)

The Python Agent APIs provide facilities to support:

- Custom business transactions
- Custom exit points
- Custom data collectors

### Python Agent API Guide

#### On this page:

- [Custom Business Transactions](#)
- [Custom Exit Calls](#)

#### Related pages:

- [Python Agent API Reference](#)
- [Python Supported Environments](#)
- [Business Transactions](#)
- [Backend Detection Rules](#)

The Python Agent APIs:

- Let you programmatically define custom business transactions that would not automatically be detected by the agent.
- Let you create custom exit calls to discover and monitor backends and that are not automatically detected by the agent.

If your instrumented application starts up and you do not see all the business transactions or backends that you expect to see, first check [Python Supported Environments](#) to see if your framework or exit point is supported. If not, you can use the APIs to instrument your code manually.

### Custom Business Transactions

You can use the `start_bt()` and `end_bt()` methods to surround the code that you want to monitor as a custom business transaction.

Or you can use the "bt" context manager. Consider using the `bt` context manager where you start and end the business transaction in the same code. For example, where you can wrap the whole business transaction in a `with` statement.

For example, given the code:

```

setup()
do_work()
teardown()

```

you want to report `do_work()` as a business transaction.

Use `start_bt()` and `end_bt()`

This example uses `start_bt()` and `end_bt()` to create a business transaction named `do_work`.

```

from appdynamics.agent import api as appd
setup()

bt_handle = appd.start_bt('do work')
try:
 do_work()
except Exception as exc:
 raise
finally:
 appd.end_bt(bt_handle, exc)

teardown()

```

Use bt context manager

If the business transaction starts and ends in the same context, you can use the `bt` context manager instead. This is simpler:

```

setup()

with bt('do work'):
 do_work()

teardown()

```

### Custom Exit Calls

You can use the `start_exit_call()` and `end_exit_call()` methods to create a custom exit call from a specific business transaction to a backend that the Python Agent does not automatically detect.

The business transaction must be a custom business transaction.

✓ If you want to make a custom exit call from a business transaction that is normally automatically detected, you can exclude that business transaction to prevent it from being automatically detected and then create it as a custom business transaction. This enables you to get the BtHandle that you need to create the custom exit call. See [Configure Python Web Custom Match and Exclude Rules](#) for information on excluding a business transaction.

Given the code:

```
try:
 db = custom_db.connect(host='financials-lb', port=3456)
 all_employees = db.query_path('/financials/employees')
 individual_contributors = all_employees.filter(lambda r: r.level < 3)
 salaries_by_dept = individual_contributors.sum(value='salary', group='dept', as='total')

 for dept, total in salaries_by_dept.extract('dept', 'total'):
 report_salary_data(dept, total)
```

You want to send the query via an exit call to a proprietary database.

You want the database to be labeled `Financials Database` in the Controller UI.

You want the backend properties that appear in the backend dashboard to appear as:

**Host:**

`financials-lb`

**Port:**

`3456`

**Vendor:**

`custom db`

The following examples assume you are wrapping the exit call in a custom business transaction named `department rollup`, created in another part of your code.

Use `start_exit_call()` and `end_exit_call()`

This example uses `start_exit_call()` and `end_exit_call()`.

```
from appdynamics.agent import api as appd
appd.init()

Set the identifying properties
FINANCIALS_ID_PROPS = {'Host': 'financials-lb', 'Port': 3456, 'Vendor': 'custom db'}

with appd.bt('department rollup') as bt_handle:
 # Start the exit call
 exit_call = appd.start_exit_call(bt_handle, appd.EXIT_DB, 'Financials Database',
 FINANCIALS_ID_PROPS)
 exc = None
```

```

try:
 db = custom_db.connect(host='financials-lb', port=3456)
 all_employees = db.query_path('/financials/employees')
 individual_contributors = all_employees.filter(lambda r: r.level < 3)
 salaries_by_dept = individual_contributors.sum(value='salary', group='dept', as='total')

 for dept, total in salaries_by_dept.extract('dept', 'total'):
 report_salary_data(dept, total)
except Exception as exc:
 raise # Assuming something above handles exceptions for you
finally:
 #End the exit call
 end_exit_call(exit_call, exc)

```

### Use exit\_call context manager

If the business transaction starts and ends in the same context, you can use the simpler `exit_call` context manager instead.

```

from appdynamics.agent import api as appd
appd.init()

with appd.bt('department rollup') as bt_handle:
 with appd.exit_call(bt_handle, appd.EXIT_DB, 'Financials Database', FINANCIALS_ID_PROPS):
 db = custom_db.connect(host='financials-lb', port=3456)
 all_employees = db.query_path('/financials/employees')
 individual_contributors = all_employees.filter(lambda r: r.level < 3)
 salaries_by_dept = individual_contributors.sum(value='salary', group='dept', as='total')

 for dept, total in salaries_by_dept.extract('dept', 'total'):
 report_salary_data(dept, total)

```

The next example starts a custom exit call to a Cassandra backend from a business transaction that was auto-detected by the Python Agent default Flask instrumentation. It uses the Flask import feature to get the request object which it passes to `appd_get_active_bt_handle()`.

### Get bt handle using the flask request context

```

from flask import request
from appdynamics.agent import api as appd

@app.route('/metrics/recent')
def metrics_recent():
 bt = appd.get_active_bt_handle(request) # Get the active BT from the Flask request object

```

```
with appd.exit_call(bt, appd.EXIT_DB, 'cassandra time-series', {'VENDOR': 'Cassandra',
'SERVER POOL': '10.0.0.1'}):
 load_recent_data_from_cassandra()
```

Other supported frameworks have different mechanisms for getting the request object.

## Python Agent API Reference

### On this page:

- [Access to the APIs](#)
- [Start and Stop Agent](#)
- [Business Transaction Management](#)
- [Exit Call Management](#)
- [Context Managers](#)
- [HTTP Status Codes](#)

### Related pages:

- [Install the Python Agent](#)
- [Python Agent Settings](#)
- [Python Agent API Guide](#)

The Python Agent APIs provide facilities to support:

- Custom business transactions
- Custom exit points
- Custom data collectors

### List of the APIs:

- `init(envirion=None, timeout_ms=NO_TIMEOUT)`
- `shutdown(timeout_ms=None)`
- `start_bt(name, correlation_header=None)`
- `end_bt(bt_handle, exc=None)`
- `add_snapshot_data(bt_handle, key, value)`
- `get_active_bt_handle(request)`
- `start_exit_call(bt_handle, exit_type, display_name, identifying_properties, optional_properties=None)`
- `end_exit_call(exit_call_handle, exc=None)`
- `make_correlation_header(bt_handle, exit_call_handle)`
- `bt(name, correlation_header=None)`
- `exit_call(bt_handle, exit_type, display_name, identifying_properties, optional_properties=None)`

## Access to the APIs

Before your app can access the Python Agent APIs, install the Python Agent using:

```
pip install appdynamics
```

Then at the top of the instrumented application add:

```
from appdynamics.agent import api as appd
```

## Start and Stop Agent

```
init(envirion=None, timeout_ms=NO_TIMEOUT)
```

Initializes the Python Agent.

Call this function at the very beginning of your instrumented application, preferably before any other imports and before creating any other threads.

Agent initialization occurs `asynchronously`. `init()` returns immediately if no timeout is specified but it is possible that the agent will not immediately be ready to report business transactions. In this case, the `start_bt()` method will return `None`.

This function will never raise an exception.

Returns True if the agent is properly configured, False if the agent is not properly configured.

To be properly configured the agent configuration file must contain the minimal settings and possibly some additional settings if they are required for your environment. See Configure the Agent in [Install the Python Agent](#) for the minimal settings and [Python Agent Settings](#) for the complete list.

*environ: dict, optional*

If specified, a dictionary of environment variables to use to override the agent's configuration, derived from the actual OS environment variables.

*timeout\_ms: int or None, optional*

Timeout interval in milliseconds.

By default, `init()` returns immediately, even if the Python agent has not received its configuration from the controller. If `timeout_ms` is `None`, `init()` blocks until the agent is properly configured. Otherwise, `init()` waits for up to `timeout_ms` for agent to become properly configured.

`shutdown(timeout_ms=None)`

Shuts down the Python Agent. The agent stops reporting metrics to the Controller.

This function ends all active business transactions and waits for them to finish reporting to the controller before returning.

*timeout\_ms: int, optional*

By default, this function waits until all pending business transactions have been reported before returning. If `timeout_ms` is set, this function will return after `timeout_ms`, regardless of whether all business transactions have been reported.

## Business Transaction Management

`start_bt(name, correlation_header=None)`

Starts a business transaction of the specified name.

There can only be one active business transaction per thread. Attempts to start subsequent business transactions in the same thread will return `None`.

Returns a `BtHandle` on starting the transaction or `None` if no transaction was started.

*name: str*

Name of the business transaction being started. The following characters cannot be used in business transaction names: `{ } [ ] | & ;`

---

*correlation\_header: str, optional*

If specified, a correlation header that has been generated by another AppDynamics agent and passed to this agent as a string. A correlation header provides information to enable this transaction to correlate with a transaction that is upstream to this one.

`end_bt(bt_handle, exc=None)`

Ends the business transaction identified by `bt_handle`.

*bt\_handle: BtHandle*

Identifies the business transaction being ended. The handle is returned by [start\\_bt\(\)](#).

*exc: Exception (list of Exceptions), optional*

If an exception occurred during processing this business transaction that you have caught with a try-except block, and you wish to report the exception as part of the business transaction, pass the exception as the `exc`.

If Multiple exceptions are part of the same business transaction and you wish to report all of them, pass the list of exceptions as the `exc`.

`add_snapshot_data(bt_handle, key, value)`

Attaches custom data to transaction snapshots generated for the business transaction identified by `bt_handle`.

The custom data is exposed in the `USER DATA` tab of the transaction snapshot details in the Controller UI.

The custom data is added to the business transaction but reported only when a transaction snapshot is generated. See [Troubleshoot Business Transaction Performance with Transaction Snapshots](#) for information on when transaction snapshots are generated.

*bt\_handle: BtHandle*

Identifies the business transaction to which custom data is added. The handle is returned by [start\\_bt\(\)](#).

*key: bytes or unicode*

Name of the data item to be reported in the snapshot.

If passed as bytes, the buffer must represent a UTF-8 encoded string.

*value: any*

Value of the data.

If passed as bytes, the data is treated as a UTF-8 encoded string. If passed as unicode, it is directly reported.

All other objects are converted to `str(value)`.

`get_active_bt_handle(request)`

Returns a `BtHandle` to the business transaction associated with the request object or `None` if no such business transaction was found.

This is useful for passing a business transaction handle to another API function, such as `start_exit_call()` when the business transaction was created by the default Python Agent instrumentation rather than through the APIs.

#### *request object*

The request object associated with an active business transaction. Varies depending on the framework in which the business transaction was started.

See the documentation for the applicable framework to find out how to get the request object.

Framework	Documentation for the Request Object
Flask	<a href="https://flask-cn-doc.readthedocs.io/en/latest/reqcontext.html">https://flask-cn-doc.readthedocs.io/en/latest/reqcontext.html</a>
Django	<a href="https://docs.djangoproject.com/en/1.8/ref/request-response/">https://docs.djangoproject.com/en/1.8/ref/request-response/</a>
CherryPy	<a href="https://cherrypy.readthedocs.io/en/latest/basics.html">https://cherrypy.readthedocs.io/en/latest/basics.html</a>
WSGI environ	<a href="https://www.python.org/dev/peps/pep-0333/">https://www.python.org/dev/peps/pep-0333/</a>

## Exit Call Management

`start_exit_call(bt_handle, exit_type, display_name, identifying_properties, optional_properties=None)`

Starts a custom exit call from within the specified business transaction.

There can be only one active exit call per business transaction. Attempts to start subsequent exit calls will return None.

Returns an ExitCallHandle that identifies this exit call.

*bt\_handle: BTHandle*

Identifies the business transaction making the exit call. Handle is returned from `start_bt()`.

*exit\_type: int*

The type of exit call. Valid values are:

- `appd.EXIT_HTTP`
- `appd.EXIT_DB`
- `appd.EXIT_CACHE`
- `appd.EXIT_QUEUE`

*display\_name:str*

Name used to identify this exit call in the controller. This is the label that will be used to display the exit call in the AppDynamics UI.

*identifying\_properties: dict*

A dictionary of name/value pairs that uniquely identify the downstream component being called.

In the Controller UI, these properties are visible in the upper right panel of the backend dashboards.

The key of the dict is the name of the property; the value is the value of the property.

*operation: str, optional*

A string describing the operation that is being performed, such as the URL of an HTTP request or an SQL query.

*optional\_properties: dict, optional*

A dictionary of name/value pairs that identify additional properties for this exit call. In the Controller UI, these properties are visible in the Exit Calls and Async Activities modal in the snapshot drill-down pane.

`end_exit_call(exit_call_handle, exc=None)`

Ends the exit call identified by `exit_call_handle`.

*exit\_call\_handle: ExitCallHandle*

Identifies the exit call being ended. The handle is returned from `start_exit_call()`.

*exc: Exception*

If an exception occurred during the exit call that you have caught with a `try-except` block, and you wish to report the exception as part of the exit call, pass the exception as the `exc` argument.

`make_correlation_header(bt_handle, exit_call_handle)`

Make a correlation header for a custom exit call.

If you are performing custom exit calls to other instrumented tiers, adding a correlation header allows continuing business transactions on the downstream tier.

It is up to you to send the header, as well as parse it at the other end and pass it to `start_bt()`.

Returns a tuple of header name and header value, or None if correlation is disabled.

*bt\_handle: BtHandle*

A handle identifying the business transaction.

*exit\_call\_handle: ExitCallHandle*

A handle identifying the exit call.

## Context Managers

`bt(name, correlation_header=None)`

Context manager for reporting some work as a business transaction. Yields a `BtHandle`.

If you need to start and end the transaction in different places in the code, use `start_bt()` and `end_bt()`.

`exit_call(bt_handle, exit_type, display_name, identifying_properties, optional_properties=None)`

Context manager for adding exit calls to a business transaction. Yields an `ExitCallHandle`.

If you need to start and end exit calls in different places in your code, you can use `start_exit_call()` and `end_exit_call()`.

## HTTP Status Codes

HTTP status codes will not cause error transactions when you use the using the Python Agent API to instrument your application, regardless of the error detection configuration.

## Monitor OpenAI API with Python Agent

### Related pages:

- [Download AppDynamics Software](#)

AppDynamics Python Agent helps you monitor the OpenAI API usage and related metrics. It monitors the `ChatCompletion` and `Completion` type requests created using the `openai-python` framework to the OpenAI backend.

**i** Python Agent supports OpenAI <= 0.28.1.

The following metrics are reported at the application, tier, and node levels:

- Calls per minute
- Cost
- Errors per minute
- Tokens

The following are the example metric paths:

- **Per model metric path** - `Application Infrastructure Performance|OpenAI_Tier|OpenAI|ada|Cost`
- **All model cumulative metrics path** - `Application Infrastructure Performance|OpenAI_Tier|OpenAI|Cost - All Models`
- **Net application level metrics path** - `Overall Application Summary|OpenAI - Cost - ada`

**i** These metrics are reported even if the exit call is outside the business transaction. However, the Average Response Time(ms) metric is not reported when the exit call is outside the business transaction.

## Prerequisites

Ensure that you meet the following prerequisites to monitor the OpenAI API exit calls with AppDynamics:

- Install Python Agent 23.8.0 or later. See [Install Python Agent](#).
- Import [custom dashboards](#) and [templates](#).

## Create a Custom Dashboard

1. Download [Custom\\_Dashboard\\_v1.0.zip](#). It contains the following four files:

Filename	Description
<code>template_app.json</code>	The template to create the application-level dashboard.

Filename	Description
template_tier.json	The template to create the tier-level dashboard.
main.py	Python script to create the dashboards.
readme.md	Description of the solution.

- Run the following command:

```
cd Custom_dashboard_script
python3 main.py
```

The preceding command prompts you to specify the dashboard type (application or tier) that you want to create.

- Based on your selected dashboard type, you will be prompted to specify the following dashboard details.

[Application Level Dashboard Details](#)    Tier Level Dashboard Details

Variable	Description	Default	Possible Values	Required
Application Name	The application created in the Controller with OpenAI monitoring enabled.	none	openai_app_1	Yes
OpenAI Endpoints Host Name	The hostname of the OpenAI backend.	api.openai.com	api.openai.com	Optional
OpenAI Endpoints Port	The port of the OpenAI backend.	443	443	Optional
Dashboard Name	The dashboard name to be displayed on <b>Dashboard &amp; Reports</b> in the Controller UI.	openai_app_dashboard	openai_app_dashboard	Optional
Output File Name	The output dashboard .json filename.	app_dashboard.json	app_dashboard.json	Optional

Application Level Dashboard Details [Tier Level Dashboard Details](#)

Variable	Description	Default	Possible Values	Required
Application Name	The application created in the Controller with OpenAI monitoring enabled.	none	openai_app_1	Yes
Tier Name	Name of the Tier exposed to OpenAI backend calls.	none	openai_tier_1	Yes
Business Transaction Name	The name of the business transaction reported to the host.	openai_tier_bt_name	openai_bt	Optional
OpenAI Endpoints Host Name	The hostname of the OpenAI backend.	api.openai.com	api.openai.com	Optional
OpenAI Endpoints Port	The port of the OpenAI backend.	443	443	Optional
Dashboard Name	The dashboard name to be displayed on <b>Dashboard &amp; Reports</b> in the Controller UI.	openai_tier_dashboard	openai_tier_dashboard	Optional
Output File Name	The output dashboard .json filename.	tier_dashboard.json	tier_dashboard.json	Optional

4. Import the dashboard in the Controller UI. See [Create and Manage Custom Dashboards and Templates](#).

## Serverless APM for AWS Lambda

### Deployment Support

AppDynamics Serverless Application Performance Monitoring (Serverless APM) for AWS Lambda gives you visibility into the performance of your application's components that run as functions on serverless compute environments.

Serverless APM gives you an end-to-end view of applications through [business transaction correlation](#). Serverless APM correlates business transactions between AWS Lambda functions and:

- Components instrumented with AppDynamics app agents
- Devices instrumented with AppDynamics End User Monitoring (EUM) agents

Additionally, Serverless APM correlates business transactions through serverless functions, such as an AWS Lambda function that invokes another function.

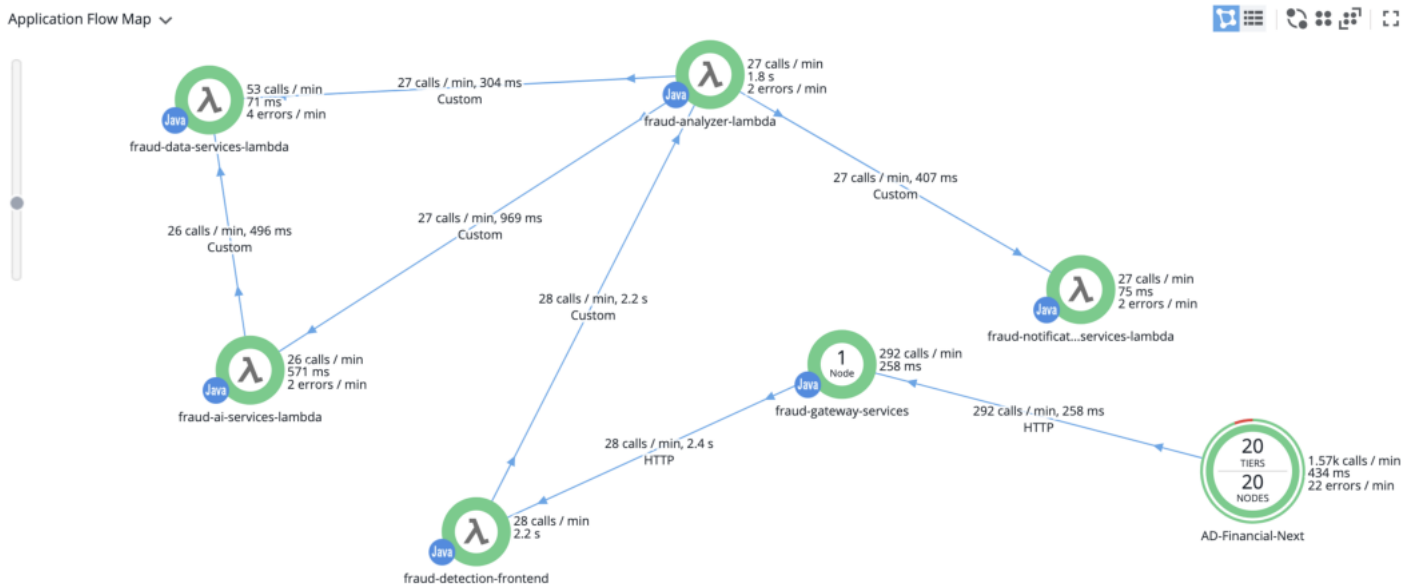

### Serverless APM in the Controller

When business applications contain serverless functions, the Controller experience differs slightly in flow maps, dashboards and metric browser pages, and health rules.

### Flow Maps

Flow maps are a dynamic visual representation of your monitored environment's components and activities. When business applications have serverless functions, you cannot view the nodes within flow map tiers because of the opaque nature of serverless platforms. A serverless icon replaces the node count in the application flow map.

The screenshot below depicts an application composed of AWS Lambda tiers:

## Dashboards and Metric Browser Pages

You can view AWS Lambda functions on your application dashboards and metrics pages. All functionality is identical to that which you would get with any other tier type, with the exception of node-level granularity. AWS Lambda tiers do not offer node-level dashboards or metrics because serverless platform runtime instances spin up and down on demand.

## Health Rules

When you configure a health rule for an application comprised of serverless functions, you can choose to monitor the serverless tiers or business transactions that originate in or flow through the serverless functions. See [Configure Health Rules](#).

## Get Started

Serverless APM requires a subscription through AWS Marketplace. See [Subscribe to Serverless APM for AWS Lambda](#) to get started.

If you have already subscribed to Serverless APM, you can begin instrumentation. See:

- Learn how Serverless APM [correlates business transactions](#) with the Serverless Tracer.
- [Set environment variables](#) to enable Tracer-to-Controller communication.
- Instrument the [Java Serverless Tracer](#), [Node.js Serverless Tracer](#), or [Python Serverless Tracer](#). The tracer's language matches your AWS function code's implementation.

*Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of Amazon.com, Inc. or its affiliates in the United States and/or other countries.*

## Subscribe to Serverless APM for AWS Lambda

This page contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation because Amazon controls its own documentation.

This page explains how to subscribe to Serverless APM for AWS Lambda. AppDynamics provides Serverless APM functionality in the form of a tracer library. See [Serverless APM](#).

## Requirements

Serverless APM for AWS Lambda supports AWS Lambda functions implemented in Java, Node.js, or Python. A subscription to Serverless APM requires:

- AppDynamics SaaS Controller  $\geq$  4.5.11.
- An active [AppDynamics Pro](#) account.
- An AppDynamics Premium or Enterprise license, using either the [Agent-based Licensing model](#) or the [Infrastructure-based Licensing model](#).
- Your Controller access key. This requires you to be an AppDynamics Account Owner or have Administrator privileges.
- AWS Identity and Access Management (IAM) role with permission to one of these [policies](#):
  - [AWSMarketplaceManageSubscriptions](#)
  - [AWSMarketplaceFullAccess](#)

## Subscribe to Serverless APM

Subscribe to AppDynamics Serverless APM for AWS Lambda through AWS Marketplace.

1. In the AWS Marketplace, navigate to the [AppDynamics Serverless APM for AWS Lambda](#) listing.

2. Click **Continue to Subscribe**.
3. [Sign in](#) to your AWS account.
4. Click **Subscribe**. A message, Congratulations! You are now subscribed!, appears confirming your subscription.  
If the Subscribe button is unavailable:
  - a. Navigate to **Having issues signing up for your product?**
  - b. Select **click here**.
  - c. Proceed to step six.
5. Click **Set Up Your Account**.
6. Enter your SaaS Controller URL and Controller Access Key (Default), then click **Continue**.
  - The SaaS Controller URL must be a full path URL with no whitespace or trailing slashes.
  - Registration may take up to 30 seconds.
  - You can only access the registration page through AWS Marketplace.
  - Do not close the registration page while it attempts to connect to the Controller. If you close the registration page, you will have to subscribe again through AWS Marketplace.
7. Click **Getting Started** to learn more about [Serverless APM for AWS Lambda](#).

### Subscribe Multiple Controllers

You can subscribe multiple Controllers to Serverless APM, as long as each Controller meets the requirements described on this page. Begin with step 4a in [Subscribe to Serverless APM](#) above and complete the steps for each Controller.

### Unsubscribe from Serverless APM for AWS Lambda

Unsubscribe from Serverless APM for AWS Lambda to stop all tracing by AppDynamics.

1. Sign in to the AWS Management Console.
2. Go to **Your Account > Your Software Subscriptions > SaaS**. Locate the **AppDynamics Serverless APM for AWS Lambda** subscription.
3. Select **Cancel Subscription**. **Cancel Subscription** unsubscribes all Controllers from Serverless APM.

You can disable Serverless APM at any time. When you disable Serverless APM, the tracer continues to monitor any instances currently executing until those instances finish. Requests executed by instances started after you disable the tracer are not monitored.

 Technical support is available through [AppDynamics Support](#). All billing related questions are handled by [AWS Marketplace](#).

*Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of Amazon.com, Inc. or its affiliates in the United States and/or other countries.*

### View the Serverless APM Subscription

After you have subscribed to Serverless APM for AWS Lambda, you can view your subscription and its status through your AppDynamics account.

### Verify Your Serverless APM Subscription

You can verify your subscription to Serverless APM for AWS Lambda in your AppDynamics account.

1. Go to <https://accounts.appdynamics.com/subscriptions> and sign in.
2. Navigate to the **License Usage** tab and select the Controller you subscribed to Serverless APM.
3. Select the license to confirm that **Serverless APM for AWS Lambda** subscription is activated.

Under the **Usage** column, you can view the date your subscription began and access billing information on the [AWS Console](#). Serverless APM for AWS Lambda matches the **Usage Period** of your APM license, regardless of the Serverless APM subscription status.

The screenshot shows the AppDynamics interface with the 'License Usage' tab selected. A table lists licenses with columns for Product, Product Family, Usage, and Usage Period. One row is highlighted for 'Serverless APM for AWS Lambda'.

Product	Product Family	Usage	Usage Period
Serverless APM for AWS Lambda	Application Performance Management	<a href="#">View in AWS Console</a>	Jan 10, 2022 - Jan 11, 2022

### Check Your Serverless APM Subscription Status

You can check your Serverless APM for AWS Lambda subscription status in your AppDynamics account. To access your account, see the instructions in [Verify Your Serverless APM Subscription](#). Click the **License Usage** tab, select your Controller, and select **Serverless APM for AWS Lambda**.

The **Contract term** displays the start and end date of your subscription.

The screenshot shows the details for the 'Serverless APM for AWS Lambda' subscription. It includes a 'Usage limit' of 1 license unit(s) and a 'Contract term' of Jan 3, 2016 - Jan 1, 2038 (16 years left), which is highlighted with an orange box.

Usage limit	Contract term
1 license unit(s)	Jan 3, 2016 - Jan 1, 2038 (16 years left)

*Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of Amazon.com, Inc. or its affiliates in the United States and/or other countries.*

---

## Troubleshoot the Serverless APM Subscription

 This document contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation because Amazon controls its own documentation.

This page provides troubleshooting information for issues that may arise when subscribing to Serverless APM for AWS Lambda.

### Subscribe Button Unavailable

After an AWS user clicks **Subscribe** on the AWS product listing, the button is unavailable for future visits to the AWS Marketplace subscription page. To complete the subscription process, see step four in [Subscribe to Serverless APM for AWS Lambda](#).

### Error Messages

You may encounter error messages while subscribing through the AWS Marketplace.

#### Upgrade to Enable Serverless APM for AWS Lambda

This error message refers to your current Controller version and AppDynamics edition. To subscribe to serverless monitoring, you need SaaS Controller 4.5.11 and an active [AppDynamics Pro](#) edition.

- **AppDynamics SaaS Controller >= 4.5.11**

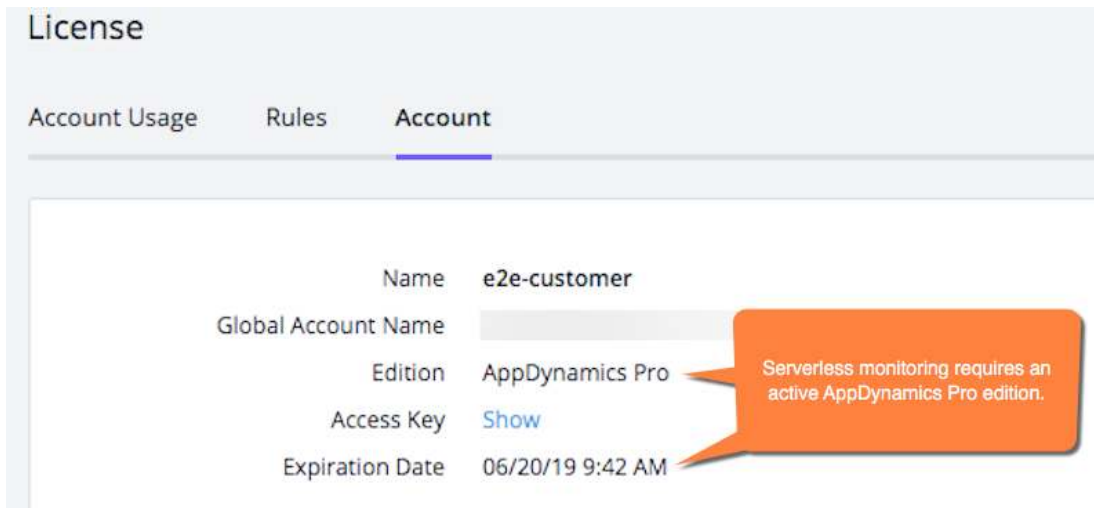

Serverless APM for AWS Lambda is available for AppDynamics Pro SaaS Controllers. Your Controller must be >= 4.5.11. You can request an upgrade if you have a previous version of the Controller. To view your current AppDynamics build version in the Controller UI, select  > **About AppDynamics**.

Serverless monitoring is not available for on-premises Controllers at this time.

- **Active AppDynamics Pro Edition**

You need an active AppDynamics Pro edition to enroll in serverless monitoring. If you are currently enrolled in a trial or unpaid edition, or if your account is inactive, purchase a license.

To view your current AppDynamics edition and expiration date in the Controller UI, select  > **License > Account**.

### Incorrect Credentials

You need your SaaS tenant URL and the access key for the Controller you want to enable. You must be an AppDynamics Account Owner or Administrator to view the Controller access key. To find your Controller access key, see [Agent-to-Controller Connections](#).

### Controller Already Registered

You cannot register a single Controller for serverless monitoring multiple times. You can view your current Serverless APM for AWS Lambda subscriptions in your AppDynamics account.

1. Go to <https://accounts.appdynamics.com/subscriptions>.
2. Sign in to your account.
3. Select the desired Controller.
4. In the License Usage tab, find **Serverless APM for AWS Lambda**.

**i** Technical support is available through [AppDynamics Support](#). All billing related questions are handled by [AWS Marketplace](#).

*Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of Amazon.com, Inc. or its affiliates in the United States and/or other countries.*

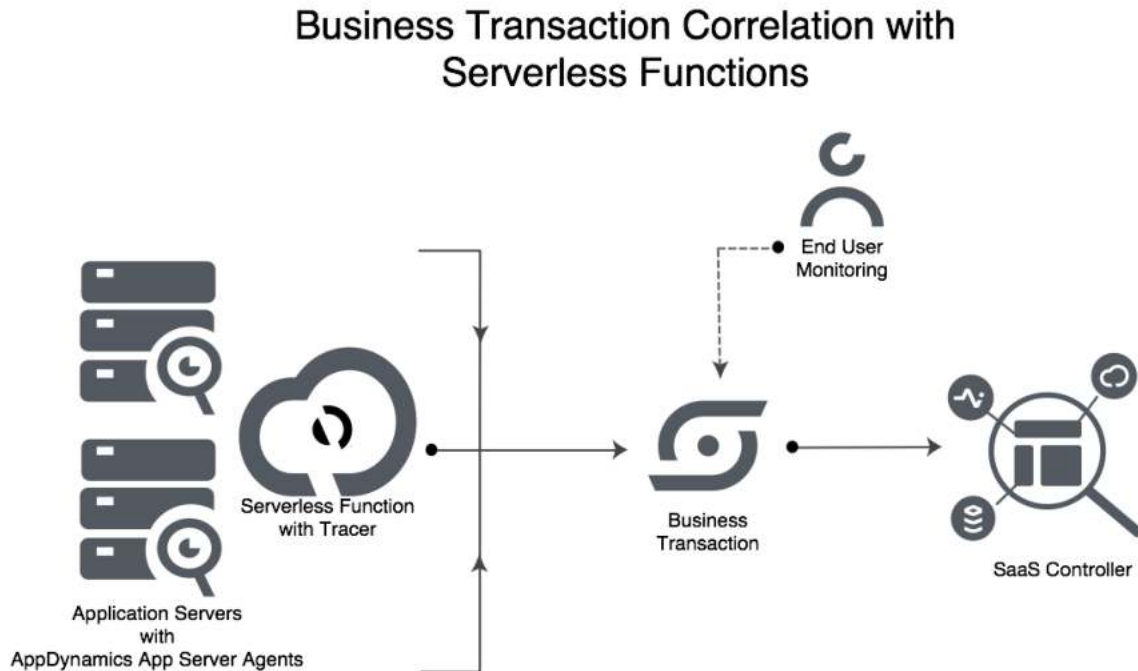

### Serverless APM Business Transaction Correlation

AppDynamics provides Serverless Application Performance Monitoring (Serverless APM) functionality in the form of a serverless tracer, available in [Java](#), [Node.js](#), and [Python](#). This page discusses how the tracer correlates business transactions.

### Business Transaction Correlation Architecture

The Serverless Tracer correlates [business transactions](#) with upstream and downstream components. Business transactions can be started or continued within application components instrumented with APM agents or Lambda tracers providing end to end transaction visibility in AppDynamics.

This diagram illustrates how the tracer correlates business transactions through a serverless function to APM and EUM agents:

## Business Transaction Correlation Process

Business transaction correlation occurs through an opaque correlation string that the application passes across the wire. First, the tracer generates the correlation string at an exit call, and then the application passes the correlation string to the downstream components. The downstream component retrieves the correlation string to continue the business transaction. This process enables the Serverless Tracer to correlate business transactions.

## Correlation String Transportation

Your application needs to pass the correlation string, generated by the tracer, to correlate a business transaction between multiple services. The correlation string must be serialized and communicated alongside the application payload.

## Inbound HTTP Calls

If you pass the correlation string through an HTTP call, the string is passed as an HTTP header. The tracer searches for the key that holds the correlation header string in your function's invocation object. Correlation occurs when the Serverless Tracer finds the correlation header key. If the key cannot be found, the tracer creates a new business transaction.

## Other Protocols

For protocols other than HTTP, you need to define protocol-specific transportation of the correlation string to enable business transaction correlation.

The tracer creates a new business transaction if:

- You have not arranged for the correlation string to be passed, or
- The tracer cannot find the correlation string.

To get started, see [Set Up the Serverless APM Environment](#).

*Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of Amazon.com, Inc. or its affiliates in the United States and/or other countries.*

## Set Up the Serverless APM Environment

This page describes required and optional environment variables, including HTTP proxy support, and how to input the variables in the AWS Management Console.

### Serverless Tracer Support

#### Java Versions

The Java Serverless Tracer supports Java 8.

#### Node.js Versions

The Node.js Serverless Tracer supports Node.js 10.x, 12.x, 14.x, 16.x, and 18.x.

#### Python Versions

The Python Serverless Tracer supports Python 3.7, 3.8, and 3.9.

### Configure Environment Variables

To instrument Serverless APM for AWS Lambda, you must configure the environment variables listed in the table below. Enter all applicable information as key-value environment variables in the AWS Management Console.

**i** When you change an environment variable, any existing instances complete execution using the previous value. All new requests execute with the updated value.

Environment Variable	Description	Default	Required	Example Value
APPDYNAMICS_ACCOUNT_NAME	Account name associated with the Controller used by your AWS Lambda function.	<AppDynamics_account_name>	Yes	customer1
APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY	Access key for your Controller. See <a href="#">Agent-to-Controller Connections</a> .	<AppDynamics_account_key>	Yes	AB1a2b3c4\$123

Environment Variable	Description	Default	Required	Example Value
APPDYNAMICS_APPLICATION_NAME	Name of the application where the tracer is instrumented.	<Your_app_name>	Yes	testApp
APPDYNAMICS_CONTROLLER_HOST	Host associated with the Controller used by your AWS Lambda function. Do not include http:// or https://	<Controller_host_name>	Yes	<accountname>.saas.appdynamics.com
APPDYNAMICS_CONTROLLER_PORT	Port associated with your Controller.	443	No	8080
APPDYNAMICS_DISABLE_AGENT	Disables the Serverless Tracer and stops all serverless application monitoring. Accepted values are true and false.	false	No	true
APPDYNAMICS_ENABLE_EUM	Used by the Node.js Serverless Tracer to enable End User Monitoring for AWS Lambda functions. Set to true to enable EUM or false to disable EUM. See <a href="#">Integrate the Node.js Serverless Tracer with End User Monitoring</a> for details.	false	No	true
APPDYNAMICS_EUM_AJAX	When set to true ensures EUM data is always returned in Ajax form. For example, ADRUM_0, ADRUM_1, and so on.	false	No	true
APPDYNAMICS_HTTP_TIMEOUT_MS	HTTP timeout in milliseconds for the tracer to send data downstream.	2000	No	3000
APPDYNAMICS_LOG_LEVEL	Log level for the tracer. Accepted values are DEBUG, INFO, WARN, ERROR, and FATAL.	INFO	No	INFO

Environment Variable	Description	Default	Required	Example Value
APPDYNAMICS_SERVERLESS_API_ENDPOINT	AppDynamics endpoint that the tracer to reports to. Serverless API endpoints are available for the following AWS regions: Sydney, Frankfurt, and Oregon.	<https://your-endpoint-name-api.saas.appdynamics.com/>	Yes	<ul style="list-style-type: none"> <li>Asia Pacific (Sydney): https://syd-sls-agent-api.saas.appdynamics.com</li> <li>EU (Frankfurt): https://fra-sls-agent-api.saas.appdynamics.com</li> <li>US West (Oregon): https://pdx-sls-agent-api.saas.appdynamics.com</li> </ul>
APPDYNAMICS_TIER_NAME	The name of your AWS Lambda function.	<Your_tier_name>  Defaults to the name of your AWS Lambda function.	No	serverlessTestTier

### HTTP Proxy Support

To enable HTTP Proxy Support, define the following variables in the AWS Management Console:

Environment Variable	Description	Example Value
APPDYNAMICS_HTTP_PROXY_HOST	Publicly-accessible hostname of the proxy.	myproxy.example.com
APPDYNAMICS_HTTP_PROXY_PORT	Port on which the proxy is running.	8080

Environment Variable	Description	Example Value
APPDYNAMICS_HTTP_PROXY_SERVER_CERTIFICATE	Relative path to the proxy server's certificate. Required if your proxy server runs on a self-signed certificate for your AWS Lambda function to trust the proxy. If you have configured your runtime environment to trust your proxy server, you do not need this variable.	resources/ proxy- cert.pem

Additionally, you can add credentials for your proxy server's basic authentication. Add the following variables in the AWS Management Console:

Environment Variable	Description	Example Value
APPDYNAMICS_HTTP_PROXY_USER	Username associated with your basic authentication.	user1
APPDYNAMICS_HTTP_PROXY_PASSWORD	Relative path to the proxy server's basic authentication password. Required for your proxy server's password to trust your AWS Lambda function.	password123
APPDYNAMICS_HTTP_PROXY_PASSWORD_FILE	Plaintext file to the proxy server's basic authentication password file. Update your deployment package to contain the proxy server's password file. Required for your proxy server's password to trust your AWS Lambda function.	resources/ proxy- password.txt

When you add basic credentials, you are required to include either `APPDYNAMICS_HTTP_PROXY_PASSWORD` or `APPDYNAMICS_HTTP_PROXY_PASSWORD_FILE`. If you include both, the tracer only passes `APPDYNAMICS_HTTP_PROXY_PASSWORD_FILE`.

### Add Environment Variables in the AWS Console

To add environmental variables through the AWS Management Console:

1. Sign in to the [AWS Management Console](#).
2. Go to **AWS Services** and open **Lambda**.
3. Select your AWS Lambda function.
4. Go to **Environment variables** and enter your function's key-value pair environment variables.
5. Click **Save**.

The following image shows an example of all required environment variables:

## Environment variables

You can define environment variables as key-value pairs that are accessible from your function code. These are useful to store configuration settings without the need to change function code. [Learn more](#)

APPDYNAMICS_ACCOUNT_NAME	customer1	Remove
APPDYNAMICS_APPLICATION_NAME	testApp	Remove
APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY	AB1a2b3c4\$123	Remove
APPDYNAMICS_CONTROLLER_HOST	customer1.saas.appdynamics.com	Remove
APPDYNAMICS_SERVERLESS_API_ENDPOINT	https://pdx-sls-agent-api.saas.appdynamics.com	Remove
Key	Value	Remove

► Encryption configuration

## Java Serverless Tracer

This page describes requirements, download instructions, and an instrumentation overview for the Java Serverless Tracer.

### Before You Begin

Ensure that your setup meets these requirements:

- Existing AWS Lambda functions implemented in Java
- Active Serverless APM for AWS Lambda [subscription](#)
- AppDynamics SaaS Controller >= 4.5.11

### Instrumentation Overview

Instrumentation of Serverless APM for AWS Lambda consists of three steps:

1. [Declare a Dependency on the Java Serverless Tracer](#)
2. [Choose an Instrumentation Method](#)
  - a. [Automatic Tracer Instrumentation](#)
  - b. [Manual Tracer Instrumentation](#)
3. [Verify the Serverless Tracer instrumentation](#)

### Declare a Dependency on the Java Serverless Tracer

AppDynamics provides Serverless APM functionality in the form of a tracer library.

Express your project's dependency on the Java Serverless Tracer using [Apache Maven](#) or [Gradle](#) as follows:

[Maven](#) [Gradle](#)

```
<dependency>
 <groupId>com.appdynamics</groupId>
```

```
<artifactId>lambda-tracer</artifactId>
<version>20.03.1391</version>
</dependency>
```

Maven [Gradle](#)

```
dependencies {
 compile group: 'com.appdynamics', name: 'lambda-tracer', version: '20.03.1391'
}
```

If you do not use Apache Maven or Gradle, [contact AppDynamics](#) to obtain the Serverless Tracer JAR file.

## Instrumentation Options

You can instrument the tracer:

- Automatically, using AppDynamics class `MonitoredRequestStreamHandler`, or
- Manually, using AppDynamics method `AppDynamics.getTracer(context)`.

## Automatic Tracer Instrumentation

You can automatically instrument the tracer if your function uses the `RequestStreamHandler` interface.

In automatic instrumentation, your function inherits the tracer's configurations. Automatic instrumentation preconfigures the tracer to:

- Create, start, and stop a transaction
- Locate any correlation header
- Report transaction errors

`RequestStreamHandler` and `RequestHandler` are predefined handlers provided by AWS. See [AWS documentation](#).

## Manual Tracer Instrumentation

In manual tracer instrumentation, the method `AppDynamics.getTracer(context)` instantiates the tracer at the beginning of your function's entry point method. Manually instrument the tracer if:

- Your AWS Lambda function does not implement the `RequestStreamHandler` interface.
- You do not want your function to inherit configurations from the `MonitoredRequestStreamHandler`.
- Your AWS Lambda functions are multi-threaded, to ensure that behavior is defined. See [Synchronize the Tracer](#) for more details.

Manual tracer instrumentation requires you to perform these actions:

- Instantiate the tracer
- Create, start, and stop a transaction
- Locate a correlation header
- Report transaction errors

The AWS Lambda context object in Java, `context`, is provided by AWS. See [AWS documentation](#).

## Synchronize the Tracer

For both instrumentation options, you should synchronize any access to the tracer.

In automatic instrumentation, you need to synchronize the transaction object returned by the `getTransaction()` method.

In manual instrumentation, you need to synchronize the tracer object returned by the `getTracer()` method. Manual tracer instrumentation is required for multi-threaded use of the tracer.

*Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of Amazon.com, Inc. or its affiliates in the United States and/or other countries.*

## Automatic Tracer Instrumentation

Automatic tracer instrumentation consists of these steps:

1. [Instantiate the Tracer](#)
2. [\(Optional\) Override Correlation Header Method](#)
3. [Obtain a Transaction Object](#)
4. [Create External Exit Calls](#)

## Instantiate the Java Serverless Tracer

Automatic instantiation is compatible with `RequestStreamHandler` interfaces. All other interfaces require manual instantiation.

`RequestStreamHandler` is a predefined handler provided by AWS. See [AWS documentation](#) for more information.

To automatically instantiate the tracer:

1. Make your current handler class extend AppDynamics `MonitoredRequestStreamHandler`.
2. Rename your handler class's existing method `handleMonitoredRequest`.

The code snippet demonstrates how to instantiate the tracer automatically:

```
package <MyTestPackage>;
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;

//AppDynamics tracer imports
import com.appdynamics.serverless.tracers.aws.api.AppDynamics;
import com.appdynamics.serverless.tracers.aws.api.MonitoredRequestStreamHandler;
import com.appdynamics.serverless.tracers.aws.api.ExitCall;
import com.appdynamics.serverless.tracers.aws.api.Tracer;
import com.appdynamics.serverless.tracers.aws.api.Transaction;

//Keyword extends makes MonitoredRequestStreamHanlder your project's superclass
public class <MaryHadALittleLambda> extends MonitoredRequestStreamHandler {

 @Override
```

```

//Change your method to handleMonitoredRequest
public void handleMonitoredRequest(InputStream input, OutputStream output, Context
context) throws IOException {
 }

// Your AWS Lambda function code starts here, for example
int letter = 0;
while((letter = input.read()) >= 0) {
 output.write(Character.toUpperCase(letter));
}
}

```

### (Optional) Override Correlation Header Method

Automatic instrumentation uses the `MonitoredRequestStreamHandler` class, which provides default logic to find a correlation header.

If you need to use a custom transport mechanism for your correlation header, you must override the tracer's default logic in the `getCorrelationHeader()` method. Insert your custom logic to find the inbound correlation header so the tracer can return the inbound header.

The code snippet demonstrates how to override the `getCorrelationHeader()` method:

```

//(Optional)Override getCorrelationHeader().
//Only override if the tracer will not be able to find a correlation header using its pre-
configured logic.

@Override
public String getCorrelationHeader(InputStream input, Context context) {
//Logic to find the inbound header goes here, so the inbound header can be returned
return "correlation-header";
}

```

### Obtain a Transaction Object

The `MonitoredRequestStreamHandler` class creates a transaction for you automatically. However, you need to obtain the `transaction` object for use with exit calls.

The code snippet below demonstrates how to obtain the `transaction` object:

```

//Obtain your transaction for use with exit calls.
Transaction transaction = getTransaction();

```

### Create External Exit Calls

The `createExitCall` method is used to obtain an `exitCall` object. Exit call objects record the time spent in external exit calls and allow for correlation of downstream activity.

#### Exit Call Types and Identifying Properties

In the Controller, each exit call has a distinct type, determined by a set of identifying properties.

The `exitCall` types and identifying properties are listed below:

exitCall Type	Identifying Properties
HTTP	HOST PORT URL QUERY STRING
JDBC	URL HOST PORT DATABASE VERSION VENDOR
WEB SERVICE	SERVICE URL OPERATION SOAP ACTION VENDOR
CUSTOM	Any user-defined set of properties

### Create an Exit Call

Call `createExitCall()` on your `transaction` object.

The following code sample demonstrates how you might perform an external exit call:

```
public void makeExitCall(URL url){
 HttpURLConnection conn = (HttpURLConnection)url.openConnection();

 String outgoingHeader = null;
 String callType = null;
 Map<String, String> identifyingProperties = new HashMap<>();

 //Below properties are appropriate for an inter-AWS Lambda call
 identifyingProperties.put("DESTINATION", functionName);
 identifyingProperties.put("DESTINATION_TYPE", "LAMBDA");
 callType="CUSTOM";

 //Below properties are appropriate for an external HTTP call
 identifyingProperties.put("HOST", url.getHost());
```

```

identifyingProperties.put("PORT", String.valueOf(url.getPort()));
callType="HTTP";

//Define the createExitCall method to obtain an exitCall object.
ExitCall exitCall = transaction.createExitCall(callType, identifyingProperties);
outgoingHeader = exitCall.getCorrelationHeader();
exitCall.start();

try {
// Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY is the name of the header that
should be set

 if (outgoingHeader != null) {
 conn.setRequestProperty(Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY,
outgoingHeader); // set the correlation header on an HttpURLConnection
 }

// Make the exit call here

} finally {
 exitCall.stop();
}
}

```

## Making Multiple External Exit Calls

If one AWS Lambda function makes multiple exit calls, each function should be identified by a unique `exitCall` object. To make multiple exit calls, create new `exitCall` objects for each distinct exit call. The `exitCall` objects are not reusable.

*Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of [Amazon.com](https://www.amazon.com), Inc. or its affiliates in the United States and/or other countries.*

## Manual Tracer Instrumentation

Manual tracer instrumentation consists of these steps:

1. [Instantiate the Tracer](#)
2. [Create a Transaction](#)
3. [Start and Stop a Transaction](#)
4. [Create External Exit Calls](#)

## Instantiate the Java Serverless Tracer

To instantiate the tracer, call the `AppDynamics.getTracer(context)` method. Place the method at the beginning of your function's entry point method.

The code snippet demonstrates how to instantiate the tracer:

```

@Override
 public void handleRequest(InputStream input, OutputStream output, Context context) throws
IOException {

```

```

//Instantiate the tracer.
Tracer tracer = AppDynamics.getTracer(context);

//Your AWS Lambda function code begins here.
int letter = 0;
while((letter = input.read()) >= 0) {
 output.write(Character.toUpperCase(letter));
}
}

```

## Create a Transaction

Next, you need to create transactions. A transaction is a monitored segment in a larger business transaction. Creating a transaction involves locating the correlation header, which the tracer uses to pass contextual information downstream.

Transactions either:

- Start a new business transaction, or
- Continue an existing business transaction

### Start a New Business Transaction

A transaction that originates in the current function does not have an inbound correlation header. To create a business transaction, use the `createTransaction()` method and provide an empty correlation header.

### Continue an Existing Business Transaction

To continue an existing business transaction, you need to locate an inbound correlation header. You can locate a correlation header automatically or manually.

If the tracer cannot find the correlation header, the tracer creates a new business transaction.

### Continue a Business Transaction by Locating the Correlation Header Automatically

Use the `createTransaction(inputStream, context)` method to create a transaction that locates the correlation header automatically. This method searches your code's object schema for a key called `singularityheader` in the `inputStream` object. The correlation header finds the `singularityheader` key, then continues the business transaction.

**i** The tracer reads the `inputStream` object, which is configured to be read once. If your application needs to read the `inputStream` object, you must use a converter method to allow both the tracer and your application to read the stream.

The code snippet shows an example of how to create a transaction and automatically locate the correlation header:

```

public class <LambdaChops> implements RequestStreamHandler {
 @Override
 public void handleRequest(InputStream input, OutputStream output, Context context) throws
 IOException {
 Tracer tracer = AppDynamics.getTracer(context);
 }
}

```

```

 //Use a converter method if you need to read your inputStream more than once. The tracer
 reads your inputStream once.
 inputStream = InputStreamConverter.convertToMarkSupportedInputStream(input);

 //Create a transaction.
 Transaction transaction = tracer.createTransaction(input, context);

 //Your AWS Lambda function code begins here.
 int letter = 0;
 while((letter = input.read()) >= 0) {
 output.write(Character.toUpperCase(letter));
 }
}

```

### Create a Transaction by Locating the Correlation Header Manually

To create a transaction that locates the correlation header using custom logic, you need to manually parse a `correlationHeader` string. Next, call the `createTransaction()` method and provide the `correlationHeader` object. This process gives you full control over the parsing of your function's input payload.

The code snippet shows an example of how to obtain the correlation header string and create a transaction:

```

public class <LambdaChops> implements RequestHandler {
 @Override
 public 0 handleRequest(InputStream input, OutputStream output, Context context) {
 Tracer tracer = AppDynamics.getTracer(context);

 //Manually parse the correlation string.
 String inputAsString = IOUtils.toString(inputStream, Charset.forName("UTF-8"));
 JsonParser parser = new JsonParser();
 JsonObject inputObject = parser.parse(inputAsString).getAsJsonObject();

 String correlationHeader = "";
 if (inputObject.has(Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY)) {
 correlationHeader =
inputObject.get(Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY).getAsString();
 } else {
 // Try reading from HTTP headers
 if (inputObject.has("headers")) {
 JsonObject httpHeaders = inputObject.getAsJsonObject("headers");
 if (httpHeaders.has(Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY)) {
 correlationHeader =
httpHeaders.get(Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY).getAsString();
 }
 }
 }
 }
}

```

```

 // Create transaction object using the correlation header. If the correlationHeader
 string is empty, the transaction you create uses the default transaction name.
 Transaction transaction = tracer.createTransaction(correlationHeader);

 //Your AWS Lambda function code starts here
 ...
 }

```

## Start and Stop a Transaction

After creating a transaction, you need to set transaction boundaries. Use the `transaction.start()` and `transaction.stop()` methods to place boundaries around any section of code that you want the tracer to monitor.

As a best practice, you can report all events, even if your function crashes, by running your entire function within a `try` block, and then stopping the transaction within a `finally` block.

This code sample demonstrates how to start and stop a transaction that monitors an entire function:

```

@Override
public void handleRequest(InputStream input, OutputStream output, Context context) throws
IOException {
 Tracer tracer = AppDynamics.getTracer(context);
 Transaction transaction = tracer.createTransaction(input, context);

 //Start the transaction monitoring.
 transaction.start();
 try {
 int letter = 0;
 while((letter = input.read()) >= 0) {
 output.write(Character.toUpperCase(letter));
 }

 //Stop the transaction monitoring. Place in a finally block to monitor all events.
 } finally {
 transaction.stop();
 AppDynamics.cleanup();
 }
}

```

## Create External Exit Calls

The `createExitCall` method is used to obtain an `exitCall` object. Exit call objects record the time spent in external exit calls and allow for correlation of downstream activity.

### Exit Call Types and Identifying Properties

In the Controller, each exit call has a distinct type, determined by a set of identifying properties.

This table lists the `exitCall` types and identifying properties:

exitCall Type	Identifying Properties
HTTP	HOST PORT URL QUERY STRING
JDBC	URL HOST PORT DATABASE VERSION VENDOR
WEB SERVICE	SERVICE URL OPERATION SOAP ACTION VENDOR
CUSTOM	Any user-defined set of properties

### Create an External Exit Call

Call `createExitCall()` on your transaction object.

The following code sample demonstrates how you might perform an external exit call:

```

public void makeExitCall(URL url){

 HttpURLConnection conn = (HttpURLConnection)url.openConnection();

 String outgoingHeader = null;
 String callType = null;
 Map<String, String> identifyingProperties = new HashMap<>();

 //Below properties are appropriate for an inter-AWS Lambda call
 identifyingProperties.put("DESTINATION", functionName);
 identifyingProperties.put("DESTINATION_TYPE", "LAMBDA");
 callType="CUSTOM";

 //Below properties are appropriate for an external HTTP call

```

```

identifyingProperties.put("HOST", url.getHost());
identifyingProperties.put("PORT", String.valueOf(url.getPort()));
callType="HTTP";

//Define the createExitCall method to obtain an exitCall object.
ExitCall exitCall = transaction.createExitCall(callType, identifyingProperties);
outgoingHeader = exitCall.getCorrelationHeader();
exitCall.start();

try {
// Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY is the name of the header that
should be set

 if (outgoingHeader != null) {
 conn.setRequestProperty(Tracer.APPDYNAMICS_TRANSACTION_CORRELATION_HEADER_KEY,
outgoingHeader); // set the correlation header on an HttpURLConnection
 }

// Make the exit call here

} finally {
 exitCall.stop();
}
}

```

## Create Multiple External Exit Calls

If one AWS Lambda function makes multiple exit calls, each function should be identified by a unique `exitCall` object. To make multiple exit calls, create new `exitCall` objects for each distinct exit call. The `exitCall` objects are not reusable.

*Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of Amazon.com, Inc. or its affiliates in the United States and/or other countries.*

### Java Serverless Tracer API

This page describes how to use the Java Serverless Tracer API to fine-tune your configuration.

#### Transaction Error Reports

If you automatically instrument the tracer, transaction errors are reported if an exception is thrown. If you manually instrument the tracer, transaction error reports are optional and require manual configuration.

If your business logic defines the transaction as in error for any reason, you can customize the error report method to mark the transaction in error.

To create transaction error reports, use `transaction.reportError()`.

The `transaction.reportError()` method reports one error per invocation. You can also use `transaction.reportError()` for any `errorMessage` or `errorName`:

```
transaction.reportError(errorName, errorMessage);
```

## Exit Call Error Reports

You can report errors and exceptions that occur during exit call execution using the `exitCall.reportError()` method. You must call the method before `transaction.stop()`.

Use `exitCall.reportError()` for any exception or subclass:

```
exitCall.reportError(exception);
```

You can also use `exitCall.reportError()` for a specific `errorName` or `errorMessage`.

```
exitCall.reportError(errorName, errorMessage);
```

## Override the Tracer's Default Behavior

If you prefer to customize the function and business transaction names, or keep the tracer settings in your code, you can override the environment variables using the `AppDynamics.Config.Builder` object. This option allows you to retrieve values at runtime from any desired source.

```
AppDynamics.Config.Builder configBuilder = new AppDynamics.Config.Builder();
configBuilder.accountName(accountName)
 .applicationName(appName)
 .tierName(tierName)
 .controllerHost(controllerHost)
 .controllerPort(controllerPort)
 .defaultBtName(context.getFunctionName() + "_bt")
 .controllerAccessKey(controllerAccessKey)
 .lambdaContext(context);
```

Implementation of the `configBuilder` object differs slightly depending on which instrumentation method you choose, automatic or manual.

### Automatic Instrumentation

Automatic instrumentation uses the `MonitoredRequestStreamHandler` class, which implements a factory method, `getConfigBuilder()`, to instrument the tracer.

You can override this factory method and use any builder method to configure environment variables.

The code snippet shows how to enter variables in your code for automatic instrumentation:

```
@Override
public AppDynamics.Config.Builder getConfigBuilder(Context context) {
 String controllerHost = System.getenv("APPDYNAMICS_CONTROLLER_HOST");
 int controllerPort = Integer.parseInt(System.getenv("APPDYNAMICS_CONTROLLER_PORT"));
```

```

String accountName = System.getenv("APPDYNAMICS_ACCOUNT_NAME");
String appName = System.getenv("APPDYNAMICS_APPLICATION_NAME");
String tierName = System.getenv("APPDYNAMICS_TIER_NAME");
String controllerAccessKey = System.getenv("APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY");

AppDynamics.Config.Builder configBuilder = new AppDynamics.Config.Builder();
configBuilder.accountName(accountName)
 .applicationName(appName)
 .tierName(tierName)
 .controllerHost(controllerHost)
 .controllerPort(controllerPort)
 .defaultBtName(context.getFunctionName() + "_bt")
 .controllerAccessKey(controllerAccessKey)
 .lambdaContext(context);
return configBuilder;
}

```

## Manual Instrumentation

In manual instrumentation, the overloaded version of the `AppDynamics.getTracer()` method configures the tracer's settings. The overloaded method takes a `configBuilder` object as a parameter, instead of the `context` object, to instrument the tracer.

When you use this variant of `AppDynamics.getTracer()`, you must pass the `context` object via the `AppDynamics.Config.Builder.lambdaContext()` method.

The code snippet shows how to **enter** variables in your code for manual instrumentation.

```

@Override
public void handleRequest(InputStream input, OutputStream output, Context context) throws
IOException {
 String controllerHost = System.getenv("APPDYNAMICS_CONTROLLER_HOST");
 int controllerPort = Integer.parseInt(System.getenv("APPDYNAMICS_CONTROLLER_PORT"));
 String accountName = System.getenv("APPDYNAMICS_ACCOUNT_NAME");
 String appName = System.getenv("APPDYNAMICS_APPLICATION_NAME");
 String tierName = System.getenv("APPDYNAMICS_TIER_NAME");
 String controllerAccessKey = System.getenv("APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY");
 AppDynamics.Config.Builder configBuilder = new AppDynamics.Config.Builder();
 configBuilder.accountName(accountName)
 .applicationName(appName)
 .tierName(tierName)
 .controllerHost(controllerHost)
 .controllerPort(controllerPort)
 .defaultBtName(context.getFunctionName() + "_bt")
 .controllerAccessKey(controllerAccessKey)
 .lambdaContext(context);

 //Replace the context object with config.Builder.build()
 Tracer tracer = AppDynamics.getTracer(configBuilder.build());
}

```

## Integrate the Java Serverless Tracer with End User Monitoring

**i** This document contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation since Amazon controls its own documentation.

Serverless APM for AWS Lambda is designed to integrate with your existing [End User Monitoring \(EUM\)](#) configurations. The EUM integration provides complete end-to-end visibility on the performance of your web and mobile applications, linking calls from an end-user device through your serverless functions to continue your business transactions

AWS Lambda functions can correlate EUM and AWS Lambda-originated business transactions, in conjunction with the following EUM agents:

- [Browser Real User Monitoring \(Browser RUM\)](#)
- [Mobile Real User Monitoring \(Mobile RUM\)](#)
- [IoT Monitoring](#)

Integration of the Java Serverless Tracer with End User Monitoring consists of these steps:

1. [Add and Return EUM Metadata](#)
2. [Configure Response Header Mappings](#)
  - a. [Use the Amazon API Gateway](#)
  - b. [Use AWS Lambda Proxy Integration](#)
3. [Update the Front End Application](#)
4. [Enable CORS configuration \(If applicable\)](#)
5. [Troubleshoot the EUM Integration](#)

**i** This document assumes you are familiar with AppDynamics End User Monitoring. See [End User Monitoring](#) for more information.

### Before You Begin

Ensure your deployment has:

- An AWS Lambda function instrumented with the Java Serverless Tracer
- Active EUM licenses and JavaScript agents

## Add and Return EUM Metadata

To integrate EUM with the tracer, you need to query the `transaction` object and return EUM metadata.

Call the method below after stopping a transaction. Assign each string separately, in the order specified, to the headers `ADRUM_0`, `ADRUM_1`, `ADRUM_2`, and `ADRUM_3` for consumption by the downstream JavaScript Agent.

```
public void stopTransactionAndRecordEUM(OutputStream output) throws IOException {
 Transaction transaction = getTransaction();

 // Your AWS Lambda function code

 //You must call transaction.stop(); before calling transaction.getEumMetadata();
 transaction.stop();
 // call transaction.getEumMetadata(); function to query transaction object for EUM metadata
 List<String> eumMetadata = transaction.getEumMetadata();
}
```

## Configure Response Header Mappings

Configure response header mappings to pass ADRUM\_# headers back to the browser. You can configure response header mappings using the AWS API Gateway or pass them directly using AWS Lambda Proxy Integration.

### Response Header Mappings in Amazon API Gateway

Add header mappings for each ADRUM\_# header in the Amazon API Gateway. To configure response header mappings in the Amazon API Gateway, refer to the [Amazon documentation](#).

The screenshot illustrates how to map these headers in the AWS API Gateway:

← Method Execution / - POST - Integration Response

First, declare response types using [Method Response](#). Then, map the possible responses from the backend to this method's response types.

Lambda Error Regex	Method response status	Output model	Default mapping
-	200		Yes

Map the output from your Lambda function to the headers and output model of the 200 method response.

Lambda Error Regex: default

Content handling: Passthrough

Header Mappings

Response header	Mapping value
ADRUM_3	integration.response.body.eumMetadata[3]
ADRUM_1	integration.response.body.eumMetadata[1]
ADRUM_2	integration.response.body.eumMetadata[2]
ADRUM_0	integration.response.body.eumMetadata[0]

Mapping Templates

Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of Amazon.com, Inc. or its affiliates in the United States and/or other countries.

Next, return the ADRUM\_# headers as part of the AWS Lambda function output. You can use another field name, as long your function code is consistent with the response header mappings.

This code snippet shows how to add the headers field to an output object class:

```
// add the field eumMetadata to your output object class
// return the EUM ADRUM_n headers in the output object
String outputString = "success";
Output outputObj = new Output(outputString);
OutputObj.eumMetadata = eumMetadata;
output.write(new Gson().toJson(outputObj).getBytes(StandardCharsets.UTF_8));
```

## Response Header Mappings in AWS Lambda Proxy Integration

As an alternative to custom integration, AWS Lambda proxy integration allows the client to call each function in the backend and returns output in a JSON format. Map these responses by adding each single-value ADRUM\_ *n* header directly to the headers field in your output object class. Refer to the [Amazon documentation](#) for details.

### Update the Front End Application

To see the correlation between EUM and AWS Lambda-originated business transactions, you must inject the JavaScript Agent into your browser's HTML, as described in the [EUM documentation](#).

### Enable CORS Configuration

Browsers require cross-origin resource sharing (CORS) for functions that access responses from browser requests to a domain other than the base page's domain. You must explicitly grant cross-domain access to all applicable ADRUM\_ *n* headers.

To enable CORS configuration, define the required AWS response headers in the Amazon API Gateway:

- **Access-Control-Expose-Headers** - maps the custom ADRUM headers. These headers must have the names ADRUM\_0 through ADRUM\_3 to be compatible with the JavaScript Agent.
- **Access-Control-Allow-Methods** - check the header(s) with the appropriate method.
- **Access-Control-Allow-Origin** - set to the full URL of the web page that originated the request, including schema, hostname, and port.

See [AWS documentation](#) for advanced headers and additional details.

The screenshot illustrates how to enable CORS in the Amazon API Gateway:

## Enable CORS

Gateway Responses for **-test-api API**  DEFAULT 4XX  DEFAULT 5XX ⓘ

Methods  POST  OPTIONS ⓘ

Access-Control-Allow-Methods POST, OPTIONS ⓘ

Access-Control-Allow-Headers 'Content-Type,X-Amz-Date,Authorizatio' ⓘ

Access-Control-Allow-Origin\* 'http://my-saas-service.com:8000' ⓘ

### ▼ Advanced

Access-Control-Expose-Headers ADRUM\_0, ADRUM\_1, ADRUM\_2, AD ⓘ

Access-Control-Max-Age  ⓘ

Access-Control-Allow-Credentials  ⓘ

Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of Amazon.com, Inc. or its affiliates in the United States and/or other countries.

After you have enabled CORS, you must define the response header mappings. To configure response header mappings in the Amazon API Gateway, refer to the [Amazon documentation](#).

The screenshot illustrates response header mappings after CORS configuration:

Response header	Mapping value ⓘ	
ADRUM_3	integration.response.body.eumHeaders[3]	
ADRUM_1	integration.response.body.eumHeaders[1]	
Access-Control-Expose-Headers	'ADRUM_0,ADRUM_1,ADRUM_2,ADRUM_3'	
ADRUM_2	integration.response.body.eumHeaders[2]	
Access-Control-Allow-Credentials	'true'	
Access-Control-Allow-Methods	'POST, OPTIONS'	
Access-Control-Allow-Origin	'http://localhost:8000'	
ADRUM_0	integration.response.body.eumHeaders[0]	

Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of Amazon.com, Inc. or its affiliates in the United States and/or other countries.

## Troubleshoot the EUM Integration

If you do not see a correlation between EUM data and business transactions, collect an HTTP Archive (HAR) file that captures the activity in your browser. Use the HAR file to confirm all necessary CORS headers are set and expected data populates in the ARUM\_# headers.

The EUM documentation provides additional [troubleshooting advice](#).

## Use the AppDynamics AWS Lambda Extension to Instrument Serverless APM at Runtime

This page explains how to use the AppDynamics AWS Lambda Extension for Serverless APM (the AppDynamics Lambda extension), the recommended way to inject the Serverless Tracer at runtime. Use this option to dynamically add a layer to a Node.js or Python application.

**i** The AppDynamics AWS Lambda extension does not work with the Node.js Serverless Tracer version 23.3.404.

**i** This document is intended to provide information specifically for using the AppDynamics AWS Lambda Extension for Serverless APM in conjunction with AppDynamics. AWS Lambda is managed by AWS and is a separate product from AppDynamics solutions.

- For questions related to AWS Lambda, see [AWS Lambda Documentation](#).
- For questions related to AppDynamics AWS Lambda Extension for Serverless APM, see [Serverless APM for AWS Lambda](#).

## Before You Begin

After you [subscribe](#) to Serverless APM for AWS Lambda and set up your [environment variables](#), you can begin instrumentation. Ensure that your setup meets the following requirements:

- Existing AWS Lambda functions built with Node.js versions 12.x, 14.x, 16.x, 18.x or Python 3.7-3.9
- Active [Serverless APM for AWS Lambda subscription](#)
- AppDynamics SaaS Controller version >=4.5.11
- Supported AWS Regions: eu-central-1, eu-north-1, eu-west-1, eu-west-2, eu-west-3, ap-northeast-1, ap-northeast-2, ap-south-1, ap-southeast-1, ap-southeast-2, ca-central-1, sa-east-1, us-east-1, us-east-2, us-west-1, us-west-2

## Use AWS Lambda Layers to Inject the Serverless Tracer at Runtime

To install the Node.js or Python Serverless Tracer, configure your Lambda function to use the layer implementing the AppDynamics AWS Lambda Extension for Serverless APM. The method for doing this differs, depending on whether your Lambda function is packaged as a zip archive or as a container image.

### Add the AWS Lambda Extension to Your Function when packaged as a zip archive

To pull the AppDynamics layer from Amazon, add the Amazon Resource Number (ARN) to your Lambda using either the AWS Management Console UI or the AWS CLI.

1. [Add the AWS Lambda Extension to Your Function](#)
2. [Configure Environment Variables](#)

Instrument a Lambda Function using the AWS UI

1. In the AWS Management Console console, select **Compute > Lambda**.
2. From the **AWS Lambda** panel, select a lambda that you want to instrument.

3. Select **Layers**.
4. Click **Add a layer**.
5. Under **Choose a layer**, select **Specify an ARN**.
6. Under **Specify an ARN**, enter the AWS Layer information:

```
arn:aws:lambda:us-west-2:338050622354:layer:appdynamics-lambda-extension:25
```

The ARN region changes based on the AWS region where the lambda is deployed. For example, if your lambda is **Europe (Frankfurt) eu-central-1**, use:

```
arn:aws:lambda:eu-central-1:338050622354:layer:appdynamics-lambda-extension:25
```

7. Click **Add**.
8. To verify the layer is added to the lambda, click **Layers**. Under **Layers**, the **appdynamics-lambda-extension** displays.
9. See [Configure the Environment Variables](#).

Instrument a Lambda Function using AWS CLI

To pull the AppDynamics layer from Amazon, using the AWS CLI:

1. See [Configuring a function to use layers](#).
2. See [Configure the Environment Variables](#).

### Configure Environment Variables

To finish injecting the tracer into AWS Lambda, configure environment variables depending on your programming language and version:

Node 10.x, Node 12.x, Node 14.x, Node 16.x, Node 18.x, Python 3.8, and Python 3.9

Add the environment variable `AWS_LAMBDA_EXEC_WRAPPER` with the value: `/opt/appdynamics-extension-script`:

```
AWS_LAMBDA_EXEC_WRAPPER = /opt/appdynamics-extension-script
```

For Python 3.7

Add an environment variable `APPDYNAMICS_PYTHON_AUTOINSTRUMENT` with the value set to `true`:

```
APPDYNAMICS_PYTHON_AUTOINSTRUMENT = true
```

### Add the AWS Lambda Extension to Your Function when packaged as a container image

When your Lambda functions are deployed as container images, Lambda layers cannot be added via the function configuration. Instead, you must package the extension as part of your container image during the build process. For more details refer to [this AWS Blog article](#).

To add the AppDynamics Lambda extension to your Lambda container, you will need to use a Dockerfile like those provided below:

[Node.js 18](#)
[Node.js 16](#)
[Node.js 14](#)

To build the container image containing your code as well as the AppDynamics Lambda extension, make sure you have the correct Dockerfile in your current directory and use the docker build command; for example:

```

docker build --build-arg version_number=$version_number --build-arg access_key=$(aws
configure get aws_access_key_id) --build-arg secret_key=$(aws configure get
aws_secret_access_key) --build-arg region=$(aws configure get region) -t <your tag> --build-
arg cachebust=$(date +%s) .

```

## Verify your Serverless Tracer Instrumentation

See [Verify the Serverless Tracer Instrumentation](#).

*Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of Amazon.com, Inc. or its affiliates in the United States and/or other countries.*

## Node.js Serverless Tracer

This page describes how to use the Node.js Serverless Tracer with AWS Lambda functions during development. The preferred method is to use the AppDynamics AWS Lambda Extension. See [Use the AppDynamics AWS Lambda Extension to Instrument Serverless APM at Runtime](#).

### Before You Begin

After you have [subscribed](#) to Serverless APM for AWS Lambda and set up your [environment variables](#), you can begin instrumentation. Ensure that your setup meets the following requirements:

- Existing AWS Lambda functions built with Node.js versions 12.x, 14.x, 16.x, and 18.x
- Active [Serverless APM for AWS Lambda subscription](#)

- AppDynamics SaaS Controller >= 4.5.11

**i** This document contains links to Amazon Web Services (AWS) documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation because Amazon controls its own documentation.

## Install the Node.js Serverless Tracer Using `npm` During Development for ES6

To instrument your ES6 lambda, you can install the Node.js Serverless Tracer using these steps.

1. Run the following command to import the tracer:

```
import tracer from "appdynamics-lambda-tracer";

tracer.init();
```

2. To add the tracer to your application, add a `require` statement in your application code's primary file that includes the Lambda `handler` function:

```
const tracer = require('appdynamics-lambda-tracer');
```

3. Instrument the Function with the Node.js Serverless Tracer. The code snippet below demonstrates how to instrument a serverless function with the tracer:

```
export const handler = tracer.functionWrapper(async (event) => {
 // YOUR CODE HERE
 return "Hello World";
});
```

## Install the Node.js Serverless Tracer Using `npm` During Development for CommonJS

To instrument your CommonJS lambda we recommend the AWS Lambda Extension. You can also install the Node.js Serverless Tracer using these steps:

1. [Download the Node.js Serverless Tracer](#)
2. [Add the Require Statement](#)
3. [Instrument the Function with the Node.js Serverless Tracer](#)

### Download the Node.js Serverless Tracer

To install the tracer, navigate to the directory where the `package.json` file resides. Run the following `npm` command:

```
npm install appdynamics-lambda-tracer --save
```

The command downloads the tracer dependency into a `node_modules/` folder.

## Add the Require Statement

To add the tracer to your application, add a `require` statement in your application code's primary file that includes the AWS Lambda `handler` function:

```
const tracer = require('appdynamics-lambda-tracer');
```

Remember to add the tracer's `require` statement before any other `require` statement.

## Instrument the Function with the Node.js Serverless Tracer

Initialize the Node.js Serverless Tracer below the `require` statement, by calling the `tracer.init` method .

To complete instrumentation, call `tracer.mainModule(module)` as the last line of your code.

The code snippet below demonstrates how to instrument a serverless function with the tracer:

```
const tracer = require('appdynamics-lambda-tracer');
//Initialize the tracer
tracer.init();

// Your AWS Lambda handler function code here, for example:
exports.handler = async (event) => {
 // TODO implement
 const response = {
 statusCode: 200,
 body: JSON.stringify('Hello from Lambda!'),
 };
 return response;
};
//Complete the instrumentation
tracer.mainModule(module);
```

**i** By default, the Node.js Serverless Tracer automatically discovers exit calls passed over HTTP or inter-AWS Lambda calls. You need to create an exit call if your function does not use these protocols. See [Node.js Serverless Tracer API](#).

## Next Steps

You are ready to [Verify the Serverless Tracer Instrumentation](#).

You can also [Integrate the Node.js Serverless Tracer with End User Monitoring](#) or use the [Node.js Serverless Tracer API](#).

*Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of Amazon.com, Inc. or its affiliates in the United States and/or other countries.*

## Node.js Serverless Tracer API

This page describes how to fine-tune your configuration with the Node.js Serverless Tracer API.

## Create or Modify Exit Calls

If your function uses ES6 or includes exit calls other than HTTP or inter-AWS lambda calls, you need to create an exit call.

The following code snippet demonstrates how to create an exit call for an AWS Lambda function that calls a MySQL database:

```
// Use the exit call API in your AWS Lambda handler function

module.exports.myLambdaHandler = async function () {
 const queryPromise = new Promise(function (resolve, reject) {
 const dbConfig = {
 host: '127.0.0.1', // The host where MySQL server runs
 port: 3306, // Note that this is not an identifying property. Identifying properties
 // must be strings
 user: 'root',
 database: 'movies'
 };
 const mysql = require('mysql');
 const mysqlClient = mysql.createPool(dbConfig);
 mysqlClient.getConnection(function (err, connection) {
 if (err) {
 reject({
 statusCode: 500,
 body: 'Couldn't make the connection to mysql client.'
 });
 return;
 }
 // Create an Exit Call
 var exitCall = tracer.startExitCall({
 exitType: 'DB',
 exitSubType: 'DB',
 identifyingProperties: {
 'HOST': '127.0.0.1', // The host where MySQL server runs
 'PORT': '3306',
 'DATABASE': 'movies',
 'VENDOR': 'MYSQL'
 }
 });
 });
 connection.query('SELECT * FROM ClassicHits', function (err, results) {
 connection.release();
 if (err) {
 reject({
 statusCode: 500,
 body: 'Mysql query failed'
 });
 return;
 }
 });
 });

 // Stop the Exit Call
 tracer.stopExitCall(exitCall);
}
```

```

 resolve({
 statusCode: 200,
 body: JSON.stringify(results)
 });
 });
});
return queryPromise;
}

```

### Exit Call Types and Identifying Properties

Each exit call in the Controller has a distinct type determined by a set of identifying properties. The exit call types, subtypes, and identifying properties are listed below. For exit call subtypes, you can use the examples in the table or an empty string. Identifying properties must be strings.

Exit Call Type	Exit Call Subtype	Identifying Properties
HTTP	HTTP	HOST PORT URL QUERY STRING
DB	DB	URL HOST PORT DATABASE VERSION VENDOR
CACHE	CACHE	VENDOR SERVER POOL
CUSTOM	CASSANDRA CQL COUCHBASE AMAZON WEB SERVICES MONGODB	Any user-defined set of properties.

**i** The following interceptors are supported and do not require manual instrumentation in CommonJS:

- `aws_sdk` for `lambda.invoke` and `lambda.invokeAsync`
- `http` and `https` libraries

## Transaction Correlation through API-defined Exits

If you manually create an exit call for the Node.js Serverless Tracer, you need to locate the correlation header. This is required if your function does not use HTTP or inter-AWS Lambda exit calls.

The code snippet below demonstrates how you can create the correlation header:

```

module.exports.myLambdaHandler = function () {
 // Start Exit Call
 var exitCall = tracer.startExitCall({
 // Fill in with the exit call information
 });

 //Get your correlation header
 if (exitCall) {
 var correlationHeader = tracer.createCorrelationInfo(exitCall);
 }

 /*
 * Your exit call code.
 * Pass the correlation header in the exit call for downstream correlation.
 */

 // Stop the exit call
 if (exitCall) {
 tracer.stopExitCall(exitCall);
 }
}

```

## Transaction Error Reports

By default, exceptions are automatically detected by the tracer. If your business logic defines the transaction as "in error" for any other reason, you can customize the error report method to mark the transaction in error.

The following code snippet demonstrates how to create a transaction error report:

```

// Transaction Error Report
module.exports.apiTransactionErrorReport = function(event, context, callback) {
 setTimeout(function () {
 tracer.reportTransactionError(new Error('API Error'));
 callback(null, {
 statusCode: 200,
 });
 }, 100);
}

```

```

 body: 'Transaction Error Reported'
 });
}, 100);
}

```

## Exit Call Error Reports

By default, the tracer automatically discovers exit calls passed over HTTP or inter-AWS Lambda calls. Use the `reportExitCallError` method to report errors and exceptions that occur during exit call execution.

The following code snippet demonstrates how to create an exit call error report:

```

// Use the Exit Call API in your AWS Lambda handler function

module.exports.myLambdaHandler = async function () {
 const queryPromise = new Promise(function (resolve, reject) {
 const dbConfig = {
 host: '127.0.0.1', // The host where your MySQL server runs
 port: 3306, // Note that this is not an identifying property. Identifying properties
 // must be strings
 user: 'root',
 database: 'movies'
 };
 const mysql = require('mysql');
 const mysqlClient = mysql.createPool(dbConfig);
 mysqlClient.getConnection(function (err, connection) {
 if (err) {
 reject({
 statusCode: 500,
 body: 'Couldn\'t make the connection to mysql client.'
 });
 return;
 }
 // Create an Exit Call
 var exitCall = tracer.startExitCall({
 exitType: 'DB',
 exitSubType: 'DB',
 identifyingProperties: {
 'HOST': '127.0.0.1', // The host where your MySQL server runs
 'PORT': '3306',
 'DATABASE': 'movies',
 'VENDOR': 'MYSQL'
 }
 });
 });
 connection.query('SELECT * FROM ClassicHits', function (err, results) {
 connection.release();

 //Create an Exit Call error report
 if (err) {
 tracer.reportExitCallError(exitCall, 'MYSql error', 'Failed in making the query');
 reject({
 statusCode: 500,

```

```

 body: 'Mysql query failed'
 });
 return;
}
resolve({
 statusCode: 200,
 body: JSON.stringify(results)
});
});
});
});
return queryPromise;
}

```

## Override the Tracer's Default Behavior

If you prefer to customize the function/business transaction names or keep the tracer settings in your source code, override the [environment variables](#) to retrieve values at runtime from any desired source.

The following code snippet demonstrates how to override the default behavior of the tracer:

```

tracer.init({
 controllerHostName: 'controllerHost',
 controllerPort: 8080,
 accountAccessKey: 'controllerAccountAccessKey',
 accountName: 'controllerAccountName',
 applicationName: 'applicationName',
 tierName: 'tierName',
 serverlessApiEndpoint: 'serverlessApiEndpoint',
 proxyHost: 'proxyHost',
 proxyPort: '80',
 proxyUser: 'proxyUser',
 proxyPassword: 'proxyPassword',
 certificateFile: 'proxyCertFile',
 debug: true
});

```

*Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of [Amazon.com, Inc.](#) or its affiliates in the United States and/or other countries.*

## Integrate the Node.js Serverless Tracer with End User Monitoring

**i** This document contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation since Amazon controls its own documentation.

Serverless APM for AWS Lambda is designed to integrate with your existing [End User Monitoring \(EUM\)](#) configurations. EUM integration [provides complete](#) end-to-end visibility on the performance of your web and mobile applications, linking calls from an end-user device through your serverless functions to continue your business transactions

AWS Lambda functions can correlate EUM and AWS Lambda-originated business transactions, in conjunction with the following EUM agents:

- [Browser Real User Monitoring](#) (Browser RUM)
- [Mobile Real User Monitoring](#) (Mobile RUM)
- [IoT Monitoring](#)

 This document assumes you are familiar with AppDynamics End User Monitoring. See [EUM documentation](#) for more information.

## Before You Begin

Ensure your deployment has:

- An AWS Lambda function instrumented with the Node.js Serverless Tracer
- Active EUM licenses and JavaScript Agents

## Add the EUM Environment Variable

By default, EUM integration is turned off for the Node.js Serverless Tracer.

To enable EUM integration, set the `APPDYNAMICS_ENABLE_EUM` environment variable to `true`. See [Set Up the Serverless APM Environment](#) for more details.

## Configure Response Header Mappings

Configure response header mappings to pass `ADRUM_n` headers back to the browser. You can configure response header mappings:

- Using the AWS API Gateway
- Passing directly via AWS Lambda Proxy Integration
- Returning EUM metadata in your function code

### Response Header Mappings in Amazon API Gateway

Add header mappings for each `ADRUM_n` header in the Amazon API Gateway. To configure response header mappings in the Amazon API Gateway, refer to the [Amazon documentation](#).

The table below lists the required response headers and their mapping values:

Response Header	Mapping Value
<code>ADRUM_3</code>	<code>integration.response.body.headers.ADRUM_3</code>
<code>ADRUM_2</code>	<code>integration.response.body.headers.ADRUM_2</code>
<code>ADRUM_1</code>	<code>integration.response.body.headers.ADRUM_1</code>
<code>ADRUM_0</code>	<code>integration.response.body.headers.ADRUM_0</code>

## Response Header Mappings in AWS Lambda Proxy Integration

As an alternative to custom integration, AWS Lambda proxy integration allows the client to call each function in the backend and returns output in a JSON format. Map these responses by adding each single-value `ADRUM_n` header directly to the `headers` field in your output object class. Refer to the [Amazon documentation](#) for details.

## Response Header Mappings for All Other Invocations

To gather EUM metadata, you need to configure response header mappings. This code sample invokes an `appDEumHeaders` method on the tracer. This method returns an object containing the `ADRUM_n` headers. Pass this object to the downstream service for consumption by the downstream JavaScript Agent.

The code snippet below demonstrates how you can return EUM metadata:

```
module.exports.myLambdaHandler = function (event, context, callback) {
 setTimeout(function () {

 ///Call a transaction object
 let appDBusinessTxn = tracer.getCurrentTransaction();

 //Stop the transaction
 tracer.stopTransaction();

 //Return EUM Metadata
 let appDEumHeaders = tracer.getEumMetadata(appDBusinessTxn);
 callback(null, {
 eumMetadata: appDEumHeaders,
 data: 'Call to Lambda is a success'
 });
 }, 300);
}
```

## Update the Front End Application

To see the correlation between EUM and AWS Lambda-originated business transactions, you must inject the JavaScript Agent into your browser's HTML, as described in [Inject the JavaScript Agent](#).

## Enable CORS Configuration

Browsers require cross-origin resource sharing (CORS) for functions that access responses from browser requests to a domain other than the base page's domain. You must explicitly grant cross-domain access to all applicable `ADRUM_n` headers.

To enable CORS configuration, define the required AWS response headers in the Amazon API Gateway:

- **Access-Control-Expose-Headers** - maps the custom `ADRUM` headers. These headers must have the names `ADRUM_0` through `ADRUM_3` to be compatible with the JavaScript Agent.
- **Access-Control-Allow-Methods** - check the header(s) with the appropriate method.
- **Access-Control-Allow-Origin** - set to the full URL of the web page that originated the request, including schema, hostname, and port.

See [AWS documentation](#) for advanced headers and additional details.

The screenshot illustrates how to enable CORS in the Amazon API Gateway:

## Enable CORS

Gateway Responses for **-test-api API**  DEFAULT 4XX  DEFAULT 5XX ⓘ

Methods  POST  OPTIONS ⓘ

Access-Control-Allow-Methods POST, OPTIONS ⓘ

Access-Control-Allow-Headers 'Content-Type,X-Amz-Date,Authorizatio' ⓘ

Access-Control-Allow-Origin\* 'http://my-saas-service.com:8000' ⓘ

▼ Advanced

---

Access-Control-Expose-Headers ADRUM\_0, ADRUM\_1, ADRUM\_2, AD ⓘ

Access-Control-Max-Age  ⓘ

Access-Control-Allow-Credentials  ⓘ

Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of [Amazon.com, Inc.](#) or its affiliates in the United States and/or other countries.

After you have enabled CORS, you must define the response header mappings. To configure response header mappings in the Amazon API Gateway, refer to the [Amazon documentation](#).

The table below lists response header mappings and example mapping values for CORS configuration:

Response Header	Example Mapping Value
Access-Control-Expose-Headers	`ADRUM_0,ADRUM_1,ADRUM_2,ADRUM_3`
Access-Control-Allow-Credentials	`true`
Access-Control-Allow-Methods	`POST,OPTIONS`
Access-Control-Allow-Origin	`http://my-saas-service.com:8000`

(Optional) If you connect your function to the Amazon API Gateway via a proxy integration, define the CORS response header mappings in your function code:

```
//Return EUM Metadata
let appDEumHeaders = tracer.getEumMetadata(appDBusinessTxn);
let returnHeaders = {
 'Access-Control-Allow-Origin': 'http://my-saas-service.com:8000',
 'Access-Control-Allow-Credentials': true,
 'Access-Control-Expose-Headers': 'ADRUM_0,ADRUM_1,ADRUM_2,ADRUM_3'
};
```

## Troubleshoot the EUM Integration

If you do not see a correlation between EUM data and business transactions, collect an HTTP Archive (HAR) file that captures the activity in your browser. Use the HAR file to confirm all necessary CORS headers are set and expected data populates in the ARUM\_ *n* headers.

The EUM documentation provides additional [troubleshooting advice](#).

## Python Serverless Tracer

This page provides requirements and an overview of the instrumentation process for Python functions during development. The preferred method is to use the AppDynamics AWS Lambda Extension. See [Use the AppDynamics AWS Lambda Extension to Instrument Serverless APM at Runtime](#).

**i** This document contains links to Amazon Web Services (AWS) documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation because Amazon controls its own documentation.

## Before You Begin

Ensure that your setup meets the following requirements:

- Existing AWS Lambda functions implemented in Python >= 3.7
- Python Package Installer (the `pip` version must match the Python version of your AWS Lambda function)
- AppDynamics SaaS Controller >= 4.5.16

## Install the Python Serverless Tracer

**i** The Python Serverless Tracer is available for Python >= 3.7. The version of the tracer you obtain from PyPi needs to match the version of Python you use to run your function code in AWS.

The Python Serverless Tracer is available for download in [PyPi](#) repository. You can install the Python Serverless Tracer locally or package it with your AWS Lambda function code.

## Install Locally

Run a `pip install` command to install the tracer in your local environment:

```
pip install appdynamics-lambda-tracer
```

If you install the tracer locally, you need to package the tracer with your AWS Lambda function at runtime.

### Package with AWS Lambda Functions

Run the following command to include the tracer in your function's package:

```
pip install --target ./package/ appdynamics-lambda-tracer
```

See [AWS documentation](#) to learn more about packaging dependencies in your functions.

### Instrument Your Function Code

To instrument your AWS Lambda function, add these lines of code:

```
import appdynamics # Add AppDynamics libraries. Must be the first line of code

@appdynamics.tracer # Must come before the handler function
def my_handler(event, context):
 print("Hello world!")
```

### Exit Call Instrumentation

By default, the Python Serverless Tracer automatically discovers HTTP, Amazon DynamoDB, and inter-AWS Lambda exit calls. Use the Python Tracer API to create an exit call if you want visibility into other types of external calls made by your function. See [Python Serverless Tracer API](#).

**i** This document contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation because Amazon controls its own documentation

*Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of [Amazon.com, Inc.](#) or its affiliates in the United States and/or other countries.*

### Python Serverless Tracer API

This page describes how to use the Python Serverless Tracer API to modify the behavior of the tracer within your AWS Lambda function.

#### Create Exit Calls

Exit calls are automatically instrumented for HTTP, Amazon DynamoDB, and inter-AWS Lambda calls. All other protocols need to manually create an exit call.

To create an exit call, use the `ExitCallContextManager` method in a `with` statement to wrap the exit call. The method takes the following *required* parameters:

- `exit_point_type`: Type of the exit call
- `exit_point_sub_type`: Subtype of the exit call
- `identifying_properties`: Properties defining the exit call

The `ExitCallContextManager` method automatically reports any runtime exceptions that occur within the method's scope as exit call errors.

The code sample below demonstrates how to use the exit call method for a MySQL database:

```
import appdynamics # Add AppDynamics libraries. Must be the first line of code

@appdynamics.tracer
def handler(event, context):
 with appdynamics.ExitCallContextManager(exit_point_type="DB", exit_point_sub_type="DB",
 identifying_properties={"VENDOR": "MYSQL"}) as ec:
 data = fetch_from_db()
```

### Exit Call Types and Identifying Properties

In the Controller, each exit call has a distinct type, determined by a set of identifying properties. Include at least one identifying property for each exit call type.

The `exitCall` types, subtypes, and identifying properties are listed below. For exit call subtypes, you can use the examples listed in the table or use an empty string.

Exit Call Type	Exit Call Subtype	Identifying Properties
HTTP	HTTP	HOST PORT URL QUERY STRING
DB	DB	URL HOST PORT DATABASE VERSION VENDOR
CACHE	CACHE	VENDOR SERVER POOL

Exit Call Type	Exit Call Subtype	Identifying Properties
CUSTOM	<ul style="list-style-type: none"> <li>Cassandra CQL</li> <li>Couchbase</li> <li>Amazon Web Services</li> <li>Mongo DB</li> </ul>	Any user-defined set of properties

The following interceptors are supported and do not require manual instrumentation:

- Boto client:
  - Lambda: `invoke`, `invokeAsync`
  - DynamoDB: `batch_get_item`, `batch_write_item`, `create_table`, `delete_table`, `delete_item`, `get_item`, `put_item`, `update_item`
- Tornado
- http libraries

### Create Exit Call Error Reports

The `ExitCallContextManager` method automatically reports errors. If you want to add custom error reports, use the `report_exit_call_error` method. The method takes the following parameters:

- `error_name`: Name of the error
- `error_message` (Optional): Descriptive error message
- `http_status_code` (Optional): The HTTP status code if available.

The code sample below demonstrates how you can use the exit call error report method:

```
import appdynamics
@appdynamics.tracer
def handler(event, context):
 #Create an exit call
 with appdynamics.ExitCallContextManager("DB", "DB", {"HOST": "ec2-12-123-123-12.us-west-2.compute.amazonaws.com", "PORT": "3306", "DATABASE": "movies", "VENDOR": "MYSQL"}) as ec:
 movies = fetch_movies_from_mysql_db()
 if movies == None:
 #Create an exit call error report
 ec.report_exit_call_error(error_name="DBError", error_message="Item not found")
 #ec is the object returned by ExitCallContextManager above
```

### Create Transaction Error Reports

By default, the Python Tracer automatically detects transaction error reports. You can customize these error reports using the `appdynamics.report_error(error_name: str, error_message: str)` method to report transaction errors. The method takes the following parameters:

- `error_name` : Name of the error

- `error_message` (Optional): Descriptive error message

The code sample below demonstrates how you can use the transaction error report method:

```
import appdynamics # Add AppDynamics libraries. Must be the first line of code
import requests #Add request library

@appdynamics.tracer # Must come before the handler function
def my_handler(event, context):
 try:
 r = requests.get('https://api.github.com/events')
 except Exception as e:
 appdynamics.report_error(error_name=type(e).__name__, error_message=str(e)) # Reports
 a transaction error
```

## Integrate the Python Tracer with End User Monitoring

Serverless APM for AWS Lambda is designed to integrate with your existing [End User Monitoring \(EUM\)](#) configurations. EUM integration [provides complete](#) end-to-end visibility on the performance of your web and mobile applications, linking calls from an end-user device through your serverless functions to continue your business transactions

AWS Lambda functions can correlate EUM and AWS Lambda-originated business transactions, in conjunction with the following EUM agents:

- [Browser Real User Monitoring \(Browser RUM\)](#)
- [Mobile Real User Monitoring \(Mobile RUM\)](#)
- [IoT Monitoring](#)

 This document assumes you are familiar with AppDynamics End User Monitoring. See [End User Monitoring](#).

## Before You Begin

Ensure your deployment has:

- An AWS Lambda function instrumented with the Python Serverless Tracer
- Active EUM licenses and JavaScript Agents

## Add the EUM Environment Variable

By default, EUM integration is turned off for the Python Serverless Tracer.

To enable EUM integration, set the `APPDYNAMICS_ENABLE_EUM` environment variable to `true`. See [Set Up the Serverless APM Environment](#).

## Configure Response Header Mappings

Configure response header mappings to pass `ADRUM_n` headers back to the browser. You can configure response header mappings:

- Using the AWS API Gateway
- Passing directly via AWS Lambda Proxy Integration
- Returning EUM metadata in your function code

## Response Header Mappings in Amazon API Gateway

Add header mappings for each `ADRUM_n` header in the Amazon API Gateway. To configure response header mappings in the Amazon API Gateway, refer to the [Amazon documentation](#).

This table lists the required response headers and their mapping values:

Response Header	Mapping Value
<code>ADRUM_3</code>	<code>integration.response.body.headers.ADRUM_3</code>
<code>ADRUM_2</code>	<code>integration.response.body.headers.ADRUM_2</code>
<code>ADRUM_1</code>	<code>integration.response.body.headers.ADRUM_1</code>
<code>ADRUM_0</code>	<code>integration.response.body.headers.ADRUM_0</code>

## Response Header Mappings in AWS Lambda Proxy Integration

As an alternative to custom integration, AWS Lambda proxy integration allows the client to call each function in the backend and returns output in a JSON format. Map these responses by adding each single-value `ADRUM_n` header directly to the `headers` field in your output object class. See the [Amazon documentation](#).

## Response Header Mappings for All Other Invocations

To gather EUM metadata, you need to configure response header mappings. This code sample invokes an `appDEumHeaders` method on the serverless tracer. This method returns an object containing the `ADRUM_n` headers. Pass this object to the downstream service for consumption by the downstream JavaScript Agent.

The code snippet below demonstrates how you can return EUM metadata:

```
@appdynamics.tracer
def my_lambda_handler(event, context):

 #Get the current transaction object
 transaction = appdynamics.get_current_transaction()

 #Stop the transaction
 appdynamics.stop_transaction()

 #Return EUM metadata
 eum_headers = appdynamics.get_eum_metadata(transaction)
 return {
 "eum_metadata": eum_headers,
 "data": "call to Lambda is a success"
 }
```

## Update the Front End Application

To see the correlation between EUM and AWS Lambda-originated business transactions, you must inject the JavaScript Agent into your browser's HTML, as described in the [Inject the JavaScript Agent](#).

## Enable CORS Configuration

Browsers require cross-origin resource sharing (CORS) for functions that access responses from browser requests to a domain other than the base page's domain. You must explicitly grant cross-domain access to all applicable ADRUM\_0 headers.

To enable CORS configuration, define the required AWS response headers in the Amazon API Gateway:

- **Access-Control-Expose-Headers** - maps the custom ADRUM headers. These headers must have the names ADRUM\_0 through ADRUM\_3 to be compatible with the JavaScript Agent.
- **Access-Control-Allow-Methods** - check the header(s) with the appropriate method.
- **Access-Control-Allow-Origin** - set to the full URL of the web page that originated the request, including schema, hostname, and port.

See [AWS documentation](#) for advanced headers and additional details.

The screenshot illustrates how to enable CORS in the Amazon API Gateway:

## Enable CORS

Gateway Responses for **-test-api API**  DEFAULT 4XX  DEFAULT 5XX ⓘ

Methods  POST  OPTIONS ⓘ

Access-Control-Allow-Methods POST, OPTIONS ⓘ

Access-Control-Allow-Headers 'Content-Type,X-Amz-Date,Authorizatio' ⓘ

Access-Control-Allow-Origin\* 'http://my-saas-service.com:8000' ⓘ

### ▼ Advanced

Access-Control-Expose-Headers ADRUM\_0, ADRUM\_1, ADRUM\_2, AD ⓘ

Access-Control-Max-Age  ⓘ

Access-Control-Allow-Credentials  ⓘ

Amazon Web Services, the AWS logo, AWS, and any other AWS Marks used in these materials are trademarks of Amazon.com, Inc. or its affiliates in the United States and/or other countries.

After you have enabled CORS, you must define the response header mappings. To configure response header mappings in the Amazon API Gateway, see the [Amazon documentation](#).

This table lists response header mappings and example mapping values for CORS configuration:

Response Header	Example Mapping Value
Access-Control-Expose-Headers	`ADRUM_0,ADRUM_1,ADRUM_2,ADRUM_3`
Access-Control-Allow-Credentials	`true`
Access-Control-Allow-Methods	`POST,OPTIONS`
Access-Control-Allow-Origin	`http://my-saas-service.com:8000`

(Optional) If you connect your function to the Amazon API Gateway via a proxy integration, define the CORS response header mappings in your function code:

```
Return EUM Metadata
eum_headers = appdynamics.get_eum_metadata(transaction)
```

```
return_headers = {
 'Access-Control-Allow-Origin': 'http://my-saas-service.com:8000',
 'Access-Control-Allow-Credentials': True,
 'Access-Control-Expose-Headers': 'ADRUM_0,ADRUM_1,ADRUM_2,ADRUM_3'
}
```

## Troubleshoot the EUM Integration

If you do not see a correlation between EUM data and business transactions, collect an HTTP Archive (HAR) file that captures the activity in your browser. Use the HAR file to confirm all necessary CORS headers are set and expected data populates in the ARUM\_0 headers.

The EUM documentation provides additional [troubleshooting advice](#).

 This document contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation since Amazon controls its own documentation.

## Verify the Serverless Tracer Instrumentation

 This document contains links to AWS documentation. AppDynamics makes no representation as to the accuracy of Amazon documentation because Amazon controls its own documentation.

After you set environment variables and instrument the Serverless Tracer, you can verify successful instrumentation.

## Test the Function

[Deploy your function](#) to AWS and test in the AWS Management Console.

You need to create a test load on your function to see activity within AppDynamics. If your test log yields no errors, the tracer successfully instrumented.

 To protect your production code, the tracer never fails your function. Your function may execute successfully yet fail to instrument the tracer. Check the logs of each AWS Lambda test in the AWS Management Console to confirm Serverless APM successfully instrumented.

## View in the Controller

Your AWS Lambda function appears on the flow map after a few minutes of processing application load.

To view your function in AppDynamics:

1. Log in to your AppDynamics Controller.
2. Navigate to **Applications** and find your new application.

---

## Apache Web Server Agent

### Related pages:

- [Apache Web Server Backend Detection](#)
- [Transaction Detection for Apache Web Servers](#)

The Apache Web Server Agent discovers, maps, and tracks metrics for business transactions, app services, and backends in your web application by injecting instrumentation into the Apache server at runtime.

-  AppDynamics contributes to the open-source Apache Web Server agent. This agent is OpenTelemetry based and integrates seamlessly with the AppDynamics backend. For more information, see [Open Source Apache Web Server Agent](#).

### About the Apache Web Server Agent

The Apache Agent automatically discovers incoming HTTP requests to Apache Web Server nodes as business transaction entry points. AppDynamics uses URI-based naming for transactions originating at Apache Agent nodes. The agent discovers exit points to Apache modules and resolves them to the downstream tier or backend. See [Apache Web Server Backend Detection](#).

Business transaction naming is limited to URLs or the WEB type. This provides limited options for match and split rules.

The Apache Agent tracks the following metrics for web servers:

- Calls per minute and time spent in the web server tier
- Calls per minute and time spent in Apache module backends
- Number of errors

The agent identifies slow and stalled transactions according to [dynamic baselines](#). When it detects an HTTP response code greater than 400, the agent identifies the transaction as an error transaction.

[Transaction snapshots](#) taken on Apache Web Server nodes include the following data:

- URL
- HTTP error codes
- HTTP request data:
  - Cookie, including JSESSIONID
  - Referer
  - X-Forwarded-For
  - SM\_USER
- Exit calls to Apache modules

### Agent Deployment Architecture

The Apache Web Server Agent consists of these components:

- Apache extension
- AppDynamics agent proxy

The **agent proxy** is a Java process that handles communication between the Apache Web Server Agent and Controller. The proxy transmits the raw performance data from the agent to the Controller, which stores, analyzes, and presents the data.

As a separate process, the agent proxy must be started separately from the monitored web server. You can start the proxy manually or configure it to start automatically by setting `AppDynamicsLaunchProxy` in `appdynamics_agent.conf`. Whether the proxy is started automatically or manually, the commands that start the agent check whether the proxy is already running and do not attempt to start it again if it is.

### Naming Apache Web Server Nodes

Each web server instance maps to a node in the AppDynamics model. When naming Apache Web Server nodes, be sure to use a meaningful name. Some options are:

- `hostName-appName-nodeName`
- `hostName-tierName-nodeName`
- `appName-nodeName`
- `tierName-nodeName`
- IP address
- fully qualified domain name

### Supported Apache Web Servers

#### Related pages:

- [Browser RUM Supported Environments](#)

## Apache Server Agent Support

### Apache Web Servers

#### Supported Apache Web Server Version

- Apache HTTP Server 2.2.x
- Apache HTTP Server 2.4.x
- IBM HTTP Server >= 7.0
- Oracle HTTP Server >= 11g

### Operating Systems

- Any Linux distribution x86 64-bit architecture based on `glibc` >= 2.34.
- AIX (Advanced Interactive eXecutive) 7.2 (7200-05-03-2148 or later) running on PowerPC Architecture

 Apache Agent on AIX supports only 64-bit architecture and Apache 2.4.

- Alpine Linux >= 3.18.3

 Apache Agent on Alpine supports only 64-bit architecture and Apache 2.4.

- RHEL9 or later is supported from Apache Agent 23.8.x onwards.

 If you encounter an ELF warning message, it may be related to the incorrect version of `glibc`. Verify that your operating system has a suitable `glibc` version.

### Automatically Discovered Business Transactions

The Apache Agent automatically discovers the following business transactions:

Type	Custom Configuration Options	Downstream Correlation
Web (HTTP)	Yes	Yes

By default, the agent excludes requests for the following static file types:

```

bm jar png
p jpe pps
ca g properties
b jpg swf
cla js tif
ss mo txt
co v zip
nf mp

```

css 3  
 do mp  
 c 4  
 gif pdf  
 ico

## Remote Service Detection

### Apache Modules

The Apache Agent automatically detects loaded Apache modules as remote services. The agent excludes a list of common modules from detection.

#### Show the list of excluded modules...

core.c	mod_cgi.c	mod_negotiation.c
http_core.c	mod_data.c	mod_perl.c

mod_authz_host.c		
mod_authz_owner.c		
mod_authz_user.c		
mod_autoindex.c		
mod_cache.c		
mod_cache_disk.c		

For End User Monitoring, the Apache Agent does not support automatic injection of the Javascript `adrum` header and footer to instrument web pages.

### Third-Party Modules

The Apache Agent  $\geq 20.5$  requires the use of the latest version of SiteMinder 12.52 SP1 to eliminate a known bug in SiteMinder.

### Install the Apache Agent

#### Related pages:

- [Download AppDynamics Software](#)

- [Install the Machine Agent](#)
- [SELinux Installation Issues](#)

To monitor the performance of your Apache HTTP Server, IBM HTTP Server (IHS), or Oracle HTTP Server, install the AppDynamics Apache Agent on the servers where you run Apache, IHS or OHS. The agent instruments the Apache server and sends performance data to a Java proxy, which in turn sends data to the AppDynamics Controller.

If you are using the Apache Monitoring Extension with the Machine Agent, you can continue to use it. You may need to restart the Machine Agent after installing the Apache Agent.

## Before Starting

Ensure that the web server version and operating system are supported. See [Supported Apache Web Servers](#).

Also verify the following requirements on the machine on which you are installing the agent:

- Perform the installation under the same user and group that Apache is using when spawning worker processes and threads.
- Ensure that the machine on which the agent runs has random or urandom set appropriately. This is because certain functions in the Apache Agent are dependent on random number generation. Else, it can lead to abrupt behavior such as log files or directories may not be created, nothing is reported from the agent to the Controller, and so on.
- Ensure that the ulimit setting for open file descriptors is set such that neither the Apache worker process or the Proxy task does not exceed it to avoid resource contention. \*\*
- Check the open file descriptor limit of the userid that the proxy and/or Apache worker process must have: For the MPM\_Worker mode, the number of file descriptors must be set using the following calculation: **1024 + ServerLimit + (2 \* ServerLimit \* ThreadsPerChild)**. For all other modes, you must set the number of file descriptors using the calculation: **(Total number of concurrently active Apache workers \* 2) + 1024**. The open file descriptor setting can be found in /etc/security/limits.conf, but the setting requires a host reboot to become effective, or set through the "ulimit -n" command for the current userid's session only.
- For Linux, check for modules with dependencies on `libstdc++.so.6`. See [Special Considerations for Apache Web Servers with libstdc++.so.5 Modules](#). This is most common with IHS and OHS.
- For AIX dependencies, see [Prerequisites for Apache Agent Installation on AIX](#).
- Ensure that the machine on which the agent runs has a locale environment set properly. As some functions in the Apache Agent have a dependency on the locale it could lead to a crash otherwise.
- Based on the agent's requirement, you can select one of the following and set the environment variable as:

```
export LANG=en_US.UTF-8
export LANGUAGE=$LANG
export LC_ALL=$LANG
```

Or

```
export LANG=en_US.UTF-8
```

Or

```
export LC_ALL=C
```

## Download and Install the Apache Agent

To guarantee performance and stability, you should install one agent for each Apache instance. Do not exceed two Apache instances per agent.

1. Download the Apache Agent from the Getting Started wizard or <https://accounts.appdynamics.com/downloads>.
2. Extract the agent to `/opt`.

[Alpine and Linux](#)   [AIX](#)

```
tar -xzvf appdynamics-sdk-native-nativeWebServer-<64bit | 32bit>-<alpine-linux |
linux>-<version>.tgz -C /opt
```

[Alpine and Linux](#)   [AIX](#)

```
gzip -c appdynamics-sdk-native-nativeWebServer-64bit-aix-<version>.tgz | tar xvf - -C /
opt
```

The agent installs to `/opt/appdynamics-sdk-native`. This is the `<agent_install_directory>`. If you are installing multiple agents, you must create separate install directories for each agent.

3. Grant the Apache, IHS, or OHS owner read and write permissions to the logs directory: `<agent_install_directory>/logs`.
4. Run `install.sh`. This script installs the agent proxy.

```
<agent_install_directory>/install.sh
```

5. For an agent to monitor your Apache instance, you must launch the proxy. If you are monitoring multiple Apache instances, we recommend that you manually launch each proxy, and set `AppDynamicsLaunchProxy` to `OFF` for every Apache instance. The next step is to create the agent configuration file and configure the agent.

For cURL installation, see [Download AppDynamics Software](#).

## Configure the Apache Agent

1. Create a configuration file for the AppDynamics Apache Web Server agent, such as `appdynamics_agent.conf`, in the Apache, IHS, or OHS configuration directory. For example:

```
touch /etc/<path_to_webserver_dir>/conf/
appdynamics_agent.conf
```

- In the `appdynamics_agent.conf` file, configure the following settings. If you have multiple agents installed, you must edit the `appdynamics_agent.conf` file for each agent, specifying which directory the agent load modules are located. Ensure that each Apache instance references a different `appdynamics_agent.conf` file, and that each file specifies a different agent install directory.

For multiple Apache web server instances that share the same Apache Agent, ensure that `Comm dirs`, set using `AppdynamicsProxyCommDir` directive, for each proxy process is different. Also ensure that the node names in each server configuration file, `appdynamics_agent.conf`, are also different.

- `LoadFile` : Loads the AppDynamics Agent SDK shared library. Assuming the agent is installed in `/opt`, the setting would be `/opt/appdynamics-sdk-native/sdk_lib/lib/libappdynamics_native_sdk.so`. Make sure to set this parameter for Alpine and Linux. This parameter is not applicable to AIX environments.  
For example:

```
LoadFile /opt/appdynamics-sdk-native/sdk_lib/lib/libzmq.so.5
LoadFile /opt/appdynamics-sdk-native/sdk_lib/lib/libappdynamics_native_sdk.so
```

`libappdynamics_native_sdk.so` has a runtime dependency on `libzmq` and `libuuid`. These libraries can be found in the same directory as `libappdynamics_native_sdk.so`.

- `LoadModule` : Loads the AppDynamics Apache Agent shared library. The correct module is `libmod_appdynamics.so` for Apache 2.4 and `libmod_appdynamics22.so` for Apache 2.2. Required.

OHS and IHS 7.x - 8.x require the Apache 2.2 module. IHS 9.x uses the Apache 2.4 module.

Apache 2.4 example:

```
LoadModule appdynamics_module /opt/appdynamics-sdk-native/WebServerAgent/Apache/
libmod_appdynamics.so
```

Apache 2.2 example:

```
LoadModule appdynamics_module /opt/appdynamics-sdk-native/WebServerAgent/Apache/
libmod_appdynamics22.so
```

- `AppDynamicsEnabled` : Must be included and set to `ON` for web server monitoring to be enabled. Otherwise, monitoring is disabled by default. For example:

```
AppDynamicsEnabled ON
```

To disable monitoring, set to `OFF` or remove the AppDynamics module `include` statement (see [Install the Apache Agent](#)) from the Apache configuration file.

- `AppDynamicsControllerHost` : Hostname or IP address of the AppDynamics controller to connect to. Required.  
For example

```
AppDynamicsControllerHost mycontroller.saas.appdynamics.com
```

- `AppDynamicsControllerPort` : Controller HTTP(S) port. For SaaS, use 443 for HTTPS or 80 for HTTP. For on-premises, HTTP defaults to 8090 and HTTPS defaults to 8181. Optional. Configure if you do not want to use these defaults. If you are using HTTPS, the SSL setting ( `AppDynamicsControllerSSL` ) must also be set.  
For example:

```
AppDynamicsControllerPort 80
```

- `AppDynamicsControllerSSL` : Set to connect to the Controller over SSL. Default is `OFF` . Set to `ON` to enable SSL connection and also set the `AppDynamicsControllerPort` to an HTTPS port.  
Example:

```
AppDynamicsControllerSSL OFF
```

- `AppDynamicsAccountName` : AppDynamics account name. For on-premises controllers, find your credentials under  > **License** in the Controller. For SaaS Controllers, AppDynamics provides your credentials in your Welcome email. Required.  
Example:

```
AppDynamicsAccountName MyCompany
```

- `AppDynamicsAccessKey` : AppDynamics account access key. For on-premises Controllers, find your credentials under  > **License** in the Controller. For SaaS Controllers, AppDynamics provides your credentials in your Welcome email. Required.  
Example:

```
AppDynamicsAccessKey zd8yjh5yuy5k
```

- `AppDynamicsProxyHost` : Proxy server hostname or IP address. Optional. Use if the agent connects to the Controller through a HTTP proxy server.
- `AppDynamicsProxyport` : Proxy server port. Optional. Use if the agent connects to the Controller through a HTTP proxy server
- `AppDynamicsApplication` : AppDynamics application name. See [Overview of Application Monitoring](#). Required.  
For example:

```
AppDynamicsApplication MyWS2App
```

- `AppDynamicsTier` : AppDynamics tier name. See [Overview of Application Monitoring](#). Required.  
For example:

```
AppDynamicsTier MyWS2
```

- `AppDynamicsNode` : AppDynamics node name. See [Overview of Application Monitoring](#). The node name is required and each node name must be unique.  
For example:

```
AppDynamicsNode WS2_1
```

## Sample `appdynamics_agent.conf`

```
#Load the AppDynamics SDK.

LoadFile /opt/appdynamics-sdk-native/sdk_lib/lib/libzmq.so.5
LoadFile /opt/appdynamics-sdk-native/sdk_lib/lib/libappdynamics_native_sdk.so

#Load the Apache Agent. In this example for Apache 2.4
LoadModule appdynamics_module /opt/appdynamics-sdk-native/WebServerAgent/Apache/
libmod_appdynamics.so

AppDynamicsEnabled On

#AppDynamics Controller connection.
AppDynamicsControllerHost mycontroller.saas.appdynamics.com
AppDynamicsControllerPort 80
AppDynamicsControllerSSL OFF

#Account credentials
AppDynamicsAccountName MyCompany
AppDynamicsAccessKey zd8yjh5yuy5k

#Configure Controller connection through an HTTP proxy server.
#AppDynamicsProxyHost <proxy host>
#AppDynamicsProxyPort <proxy port>

#Business application, tier, node
AppDynamicsApplication MyApache2App
AppDynamicsTier Apache2
AppDynamicsNode Apache2_1
```

## Launch the Proxy

To launch the proxy manually, run `runSDKProxy.sh` using the user ID of the Apache worker threads.

[AIX](#) [Alpine and Linux](#)

```
nohup <agent_install_directory>/runSDKProxy.sh --jre-dir=<jre-
path> >>/dev/null 2><agent_install_dir>/logs/proxy.out &
```

[AIX](#) [Alpine and Linux](#)

```
nohup <agent_install_directory>/runSDKProxy.sh >>/dev/null
2><agent_install_dir>/logs/proxy.out &
```

It is recommended that you create a Unix System Service that automatically starts the proxy at system startup.

**i** The Proxy expects the appropriate (64- vs. 32-bit) `libstdc+6` library location. If you are installing the Apache Agent on a 64-bit OS that supports running a 32-bit Apache HTTP Server, make sure that the downloaded Apache Agent matches (i.e., is 32-bit), and that the `libstdc+6` library is 32-bit as well. If you have both 64-bit and 32-bit versions of that library, make sure you are pointing to the correct version using the command `export LD_PRELOAD=<path to 32bit library>` before starting `runSDKProxy`.

### Additional Directives

You may need to set the following optional directives unless instructed by AppDynamics support:

- `AppDynamicsBackendNameSegments`– The number of URL segments that are displayed in the backend naming. This is only applicable for requests routing through the `mod_proxy`, when Apache is acting as a reverse proxy server, also-known-as a gateway server. Specify the rule configuration for backend naming in the `appdynamics_agent.conf` file. The default value is `0` and only the IP address of the request URL is displayed. If you set a value of `2`, then the first two segments along-with the IP address are displayed. Therefore for a request proxying to `http://1.1.1.1/services/admin/abc`, the backend is named as `http://1.1.1.1/services/admin`.  
For example:

```
AppDynamicsBackendNameSegments 2
```

- `AppDynamicsResolveBackends`– Controls the way Apache module backends appear in the Controller UI. If `ON`, metrics for Apache modules are shown as part of downstream tiers or backends. Module backends do not appear on flow maps. If `OFF`, Apache module backends appear in the flow maps with their own metrics. See [Apache Modules](#). Defaults to `ON`. Optional.  
For example:

```
AppDynamicsResolveBackends OFF
```

- `AppDynamicsTraceAsError`– If `ON`, tracepoints are written as errors to the Apache logs, by default `error_log`. Default is `OFF`. Optional.  
For example:

```
AppDynamicsTraceAsError OFF
```

- `AppDynamicsReportAllInstrumentedModules`– If `OFF`, the agent reports only modules that occur during the `HANDLER` stage of Apache request processing. If `ON`, the agent reports modules during all stages of Apache request processing. The default is `OFF`.  
For example:

```
AppDynamicsReportAllInstrumentedModules OFF
```

- `AppDynamicsLaunchProxy`– If `ON`, the agent launches the proxy automatically when on startup. If `OFF`, you need to manually launch the proxy. If your system uses any command to do a graceful restart of Apache, such as `log rotate`, or if your system encounters heavy loads, you should set this property to `OFF`. The default is `OFF`.  
For example:

```
AppDynamicsLaunchProxy OFF
```

For information about how to examine and resolve proxy issues that may prevent an application agent from connecting to the Controller, see [Dynamic Language Agent Proxy](#).

You may want to launch the proxy manually for debugging. For example, to set a different proxy root directory or runtime directory or to output additional debugging information.

- A `ppDynamicsProxyJreDir` - Specify the JRE path.

This parameter applies only to the AIX platform. This parameter becomes mandatory if `AppDynamicsLaunchProxy` is enabled. However, the JRE path gets discarded if `AppDynamicsLaunchProxy` is disabled, in this case, you must launch the proxy manually. See [Launch the Proxy](#).

- `AppDynamicsRequestCacheCleanupInterval` - Timeout in milliseconds after which the request cache is cleaned up by Java proxy. Proxy consists of a queue that takes all the requests from the agents and stores these requests for processing. Sometimes, this message queue can have an enormous cache within an interval of a minute under high load scenarios. Therefore as a preventive measure, a cleanup timer with a default value of 60 secs is available. To monitor long transactions, increase the cleanup interval, but you must be vigilant of the high cache or memory usage. For example:

```
AppDynamicsRequestCacheCleanupInterval 120000
```

If you are running the proxy manually, then while running the `launch proxy` command add the following flag:

```
--req-cache-cleanup-interval=120000
```

- `AppDynamicsProxyCommDir` - Path to the directory containing the domain control socket, which the agent uses to start an AppDynamics node. Defaults to `<agent_install_directory>/logs/appd-sdk`. If you modify this setting, make sure that the directory path does not exceed 107 characters, which is the Linux limit to the socket file name size. If the directory path is too long, you will get an error message when the agent attempts to start.

```
AppDynamicsProxyCommDir <agent_install_directory>/proxy/altcommdir
```

- For Filtering sensitive-data and privileged information, see [Filter Sensitive Data](#).

## Configure the Apache Server for AppDynamics

1. Add an include for the AppDynamics Apache Agent configuration to the server configuration. Ensure that the AppDynamics module is loaded after any modules you want to be instrumented. Any modules loaded after the AppDynamics agent are excluded from instrumentation and monitoring. For example, add the following as the last line in the applicable configuration file - `httpd.conf` (CentOS), `apache2.conf` (Ubuntu and Debian), and `httpd.conf_64` (AIX):

```
#Include AppDynamics Apache Agent Configuration
Include conf/appdynamics_agent.conf
```

If you are running multiple instances of the web server, modify the `.conf Include` path to match the configuration file name for that instance. For example:

```
#Include AppDynamics Apache Agent Configuration.
Include conf/appdynamics_agent1.conf
```

- Restart the web server. For example, for Apache on CentOS:

```
apachectl restart
```

- Apply load to your web server to activate instrumentation.

The AppDynamics Apache Agent automatically detects the incoming HTTP calls as [business transactions](#). It detects loaded modules as backends. Log in to the AppDynamics Controller to begin monitoring.

### Map Virtual Hosts to AppDynamics Tiers

By configuring virtual hosts, Apache Web Server administrators can have a single Apache Web Server instance act as the entry point for what appears to be different websites from the end user's perspective.

In the AppDynamics application model, it will usually make sense to represent each virtual host configured in an Apache Web Server as its own tier. This tends to better represent the logical model of the environment and reduces the likelihood of quickly exhausting tier business transaction limits for an Apache Web Server that proxies a large application environment.

To associate different virtual hosts with different tiers, add the `AppDynamicsApplicationContext` directive to the virtual host configuration, supplying the application, tier and node name as arguments, as follows:

```
AppDynamicsApplicationContext <application> <tier> <node>
```

For example:

```
Listen 80
<VirtualHost *:80>
 DocumentRoot "/www/example1"
 ServerName site1.example.com
 ...
 AppDynamicsApplicationContext MyApp site1.example.com:80
node01
</VirtualHost>

<VirtualHost *:80>
 DocumentRoot "/www/example2"
 ServerName site2.example.org
 ...
 AppDynamicsApplicationContext MyApp site2.example.org:80
```

```
node01
</VirtualHost>
```

In the example above, the tier name is a combination of the virtual machine `ServerName` and port number. You are not required to include the `ServerName` and port number in the tier name, but they can be useful for identifying which virtual machines are creating business transactions. We recommend using a tier name that best represents the purpose of the virtual machine.

The Apache Web Server Agent associates incoming requests to the AppDynamics context based upon the virtual host server and port in the request.

Note that instead of using virtual hosts to multi-host from Apache, an administrator may run multiple instances of the Apache Web Server with a distinct `httpd.conf` file—on Ubuntu and Debian, this file is called `apache2.conf`—for each instance. In this case, you would instrument the Apache Web Server by creating an AppDynamics agent configuration file for each instance, and include each configuration file in the `httpd.conf` file of the corresponding instance. See [Configure the Apache Agent](#).

### Set Unique Host ID for App Agents

To set a unique host ID for the App agents, add the following command to the `runProxy` file:

```
set -- "$@" -Dappdynamics.agent.uniqueHostId="<your-unique-host-id>"
```

For example, you can add the following to the `<agent_install_directory>/proxy/runProxy` file.

```
set -- "$@" -Dappdynamics.agent.logs.dir=${logsDir}
set -- "$@" -Dcomm=${proxyCommunicationDir}
set -- "$@" -DagentType=${agentType}
set -- "$@" -Dappdynamics.agent.uniqueHostId="<your-unique-host-id>"
set -- "$@" -Dappdynamics.agent.runtime.dir=${proxyRuntimeDir}
set -- "$@" -Dlog4j.ignoreTCL=true
set -- "$@" -XX:MaxPermSize=${maxPermSize}
```

**i** You must set the unique host ID again after an agent upgrade.

## Apache Agent Directories

This page describes the directories for the Apache Agent.

### Agent Install Directory

The agent install directory `<agent_install_directory>` is the `appdynamics-sdk-native` directory where you installed the agent.

For example, if you un-tarred the agent to `/opt`, the agent home would be: `/opt/appdynamics-sdk-native`.

It contains the following files:

- `install.sh` to install the Apache Agent and the agent proxy.
- `runSDKProxy.sh` to start the agent proxy.

## WebServerAgent Directory

The `<agent_install_directory>/WebServerAgent` directory contains the Apache Agent libraries.

The Apache subdirectory contains the Apache modules for the Apache Agent:

- For Apache 2.2: `libmod_appdynamics22.so`
- For Apache 2.4: `libmod_appdynamics.so`

## Conf Directory

The `<agent_install_directory>/conf` directory contains the logging configuration files:

- A logging configuration template: `appdynamics_sdk_log4cxx.xml.template`
- A log configuration file: `appdynamics_sdk_log4cxx.xml`

## Logs Directory

The logs `<agent_install_directory>/logs` directory contains the logs for the Apache Agent and the agent proxy.

## Proxy Directory

The proxy `<agent_install_directory>/proxy` directory contains the agent proxy files.

## Proxy Control Directory

The proxy control directory contains the domain control socket, which the agent uses to start an AppDynamics node. Defaults to `<agent_install_directory>/logs/appd-sdk`. You need to pass this path to the `runProxy` script if you are starting the proxy manually.

## Troubleshoot Apache Agent Installation

If you installed the Apache Agent and are experiencing problems, try these troubleshooting suggestions.

### Undefined Symbol Error

An error message similar to the following typically indicates that you have loaded the incorrect agent library for the version of Apache you are using.

```
ERROR
httpd: Syntax error on line 953 of /srv/jas/app/embcms/
HTTPServer/cma1-dev2/conf/httpd.conf: Syntax error on line 7
of /srv/jas/app/embcms/HTTPServer/cda0-dev2/conf/
appdynamics.conf: Cannot load /srv/jas/data/AppDynamics/
WebAgent/WebServerAgent/Apache/libmodappdynamics.so into
server: /srv/jas/data/AppDynamics/WebAgent/WebServerAgent/
Apache/libmod_appdynamics.so: undefined symbol: ap_log_error
```

Check the description of LoadModule on [Install the Apache Agent](#) to make sure that you are loading the correct module. For example, for Apache 2.2, your LoadModule directive should be:

```
LoadModule appdynamics_module /srv/jas/data/AppDynamics/
WebAgent/ApacheAgent/Apache/libmod_appdynamics22.so
```

### App Crash Caused by libstdc++ Mismatch

The AppDynamics agent uses libstdc++ v6. If your application uses a different version of libstdc++ and the modules were not loaded in the correct order, the wrong library routines could be called. If you get a dump with a long stack trace, this could be the cause. See [Apache with libstdc++5 Considerations](#) for information on how to prevent this.

### Tier Name Not Specific to the Apache Agent

When the Apache Agent and Machine Agent are hosted on the same server, and the Machine Agent is started before the Apache Agent, then the tier is registered as a Java tier that prevents the Apache Agent from registering itself.

An error message is displayed in the Apache Agent logs:

```
Is your agent attempting to register to the wrong tier?
```

### Workaround

1. Stop the Machine Agent and Apache Agent.
2. Delete the tier from the Controller UI.
3. Restart the Apache Agent first and allow it to register the tier.
4. Restart the Machine Agent.

### Apache with libstdc++5 Considerations

#### Related pages:

- [Install the Apache Agent](#)

The Apache Agent depends on libstdc++6. Some servers, primarily IHS and OHS, have modules built with libstdc++.so.5. This conflict can prevent Apache from starting successfully.

### Check for libstdc++5 Dependencies

To determine if your web server has libstdc++.so.5 dependencies:

1. Change directory to your web server's modules directory.
2. Run this command:

```
ldd *.so 2>&1 | grep -v 'execution permission' | grep
'libstdc++.so.5'
```

3. If this command returns any results—for example, `libstdc++.so.5 => /lib64/libstdc++.so.5` — your server has a dependency on libstdc++.so.5.

## Resolution Overview

To avoid libstdc++5 conflicts, force libstdc++6 to load before libstdc++5 when Apache is started. The general steps for performing this configuration are:

1. Identify the paths to libstdc++.so.6.
2. Determine the correct libstdc++.so.6 path for your installation.
3. Use the LD\_PRELOAD environment variable to have libstdc++6 preloaded.

These steps are detailed in the following sections.

### Identify the Paths to libstdc++.so.6

From a command prompt, run:

```
ldconfig -p | grep libstdc++.so.6
```

This will return one or more paths. For example:

```
/lib64/libstdc++.so.6
/lib/libstdc++.so.6
```

### Determine the Correct libstdc++.so.6 Path for the Installation

If more than one path is returned, determine which is the correct path for your Apache Server installation.

If you are running a 64-bit operating system, but a 32-bit version of IHS or OHS, choose the 32-bit version, which in our example would be:

```
/lib/libstdc++.so.6
```

### Add the Export LD\_PRELOAD Command

Open the envvars \*\* file, which is located in the /bin directory of your IHS or OHS installation. Add the following line, using the path to the libstdc++.so.6 path that you determined in the previous step.

```
export LD_PRELOAD=<path-to-libstdc++.so.6>
```

This will cause libstdc++.so.6 to be loaded before libstdc++.so.5, and the conflict will be averted.

### Prerequisites for Apache Agent Installation on AIX

The Apache Agent installation requires the following libraries from the IBM-supported portals:

1. libstdc++10
2. libiconv (1.17)
3. coreutils (9.0)
4. jre (1.8 or later)

Run the following command to load the necessary libraries before starting the Apache Agent.

```
export LIBPATH=/opt/freeware/lib/gcc/powerpc-ibm-aix7.2.0.0/10/pthread:/usr/opt/freeware/lib:<agent-install-directory>/sdk_lib/lib
```

In the above command:

- `</opt/freeware/lib/gcc/powerpc-ibm-aix 7.2.0.0/10/pthread>` - Contains `libstdc++.a` or any directory where `libstdc++` is installed. The `aix7.2.0.0/10` directory can have multiple `libstdc++.a` libraries. Make sure to choose the library available in the `/pthread` directory.
- `</usr/opt/freeware/lib >` - Contains `libiconv.a`.
- `<agent-install-directory>/sdk_lib/lib>` - Contains `libappdynamics_native_sdk.so` and `libzmq.a` as the dependencies of `libmod_appdynamics.so`.

## Upgrade the Apache Agent

To upgrade the agent:

1. Kill the `proxy` process.

If you do not know the PID of the `proxy` process you can get it by running this command:

```
ps -aux | grep "proxy"
```

Then kill the process as follows:

```
kill <PID>
```

2. Shut down the web server.
3. Move/rename the agent install directory, `/opt/appdynamics- sdk -native` to make a backup.
4. Download the new version of the agent and extract it into `/opt/appdynamics- sdk -native`.
5. Change directory to the agent install directory:

```
cd <agent_install_directory>
```

6. Run the installer:

```
./install.sh
```

It is not necessary to change the configuration when you use the same directory location as the old agent installation.

7. Launch the proxy process:

To launch the proxy manually, run `runSDKProxy.sh` using the user ID of the Apache worker threads.

```
nohup <agent_install_directory>/runSDKProxy.sh >>/dev/null
2><agent_install_dir>/logs/proxy.out &
```

It is recommended that you create a Unix System Service that automatically starts the proxy at system startup.

**i** The Proxy expects the appropriate (64- vs. 32-bit) `libstdc+6` library location. If you are installing the Apache Agent on a 64-bit OS that supports running a 32-bit Apache HTTP Server, make sure that the downloaded Apache Agent matches (i.e., is 32-bit), and that the `libstdc+6` library is 32-bit as well. If you have both 64-bit and 32-bit versions of that library, make sure you are pointing to the correct version using the command `export LD_PRELOAD=<path to 32bit library>` before starting `runSDKProxy`.

8. Restart the web server.

### Uninstall the Apache Agent

1. Remove the include statement for the AppDynamics Apache Agent from the HTTP server configuration. For example in `httpd.conf`— on Ubuntu and Debian, this file is called `apache2.conf` — remove this line:

```
Include conf/appdynamics_agent.conf
```

2. Restart the web server.
3. Optionally remove the following files:
  - `libmod_appdynamics.so`— for Apache 2.4.x— or `libmod_appdynamics22.so`— for Apache 2.2.x— from the web server modules directory, if your administrator put it there
  - `appdynamics_agent.conf` or similar from the web server configuration directory
4. Kill the proxy process.
5. Uninstall the agent:

```
<agent_install_directory>/install.sh -u
```

6. Optionally remove any remaining AppDynamics files:
  - `<agent_install_directory>`
  - `/tmp/appd-sdk`

### Apache Agent Logging

#### Related pages:

- [Dynamic Language Agent Proxy](#)

The Apache Agent generates these two logs:

- Agent log
- Proxy log

### Agent Log

The agent log contains information about the transactions that the agent processes and sends to the proxy.

The log is located at `$(apache_agent_install)/logs/agent.log`. By default this is `/opt/appdynamics-sdk-native/logs/agent.log`.

The default pattern for agent log naming is the following:

- `agent.log` : the current log
- `agent.log.1` : most recent log
- `agent.log.2` : second most recent log
- `agent.log.3` : third most recent log
- `agent.log.4` : fourth most recent log
- `agent.log.5` : fifth recent log.

The agent creates and rotates a maximum of six log files. Maximum log size is 20 MB, which gives you a maximum of the most recent 120 MB of log data at one time.

## Proxy Log

The proxy log contains information about the transactions between the proxy and the Controller.

The proxy log consists of a file named `proxyCore.log` located at `$(apache_agent_install)/logs/proxyCore_$(date).log` and other files named `agent.<datestamp>.log` located at `$(apache_agent_install)/logs/<node_name>/agent.<datestamp>.log`.

See [Dynamic Agent Proxy Logging](#).

## Filter Sensitive Data for Apache Agent

### Related pages:

- [Install the Machine Agent](#)

### Add Sensitive Data Filter for Cookies

You can use sensitive Cookie filters to configure the agent to obfuscate sensitive information from the URLs in transaction snapshot details.

1. Edit the Apache Agent configuration file: `<path_to_webserver_dir>/conf/appdynamics_agent.conf`
2. Add sensitive cookie filter element as directives:
  - `AppDynamicsMaskCookie ON`
  - `AppDynamicsCookieMatchPattern pattern`
    - `AppDynamicsMaskCookie`: Specify if filtering is enabled or not. Set it `ON` for cookie filtering to be enabled. Default value is `OFF`.
    - `AppDynamicsCookieMatchPattern`: Specify the pattern that when matched, filters value of that cookie.
3. Enabling `AppDynamicsMaskCookie` masks values of all the cookies associated with the given request. To filter selective cookies, set the following:
  - Add `AppDynamicsCookieMatchPattern` and provide the full name of the cookie whose value needs to be masked as `AppDynamicsCookieMatchPattern < pattern >`.

For example:

```
AppDynamicsCookieMatchPattern PHPSESSID
```

A substring of a cookie name does not mask any value in the transaction snapshot. Ensure that you enter the Full name of the cookie for this directive.

- For masking multiple cookies values simultaneously, provide names of all those cookies separated by '|' as a single string:

`AppDynamicsCookieMatchPattern < pattern1|pattern2|pattern3>`

For example:

`AppDynamicsCookieMatchPattern PHPSESSID|X-CSRF-TOKEN|cookiekey`

If '|' is present in the cookie name itself, the agent cannot mask those cookies as '|' is used as a name separator in `AppDynamicsCookieMatchPattern` directive.

### Add Sensitive Data Filter for the SM\_USER

You can use SM\_USER filter to configure the agent to obfuscate sensitive information from the URLs in transaction snapshot details.

1. Edit the Apache Agent configuration file: `<path_to_webserver_dir>/conf/appdynamics_agent.conf`.
2. Add sensitive SM\_USER filter element as directive:
  - `AppDynamicsMaskSmUser ON`
  - `AppDynamicsMaskSmUser`: Specify if filtering is enabled or not. Set it `ON` for sm\_user filtering to be enabled. Default value is `OFF`.

Enabling this masks the values of all the SM\_USER associated with the given request.

### Filter Certain URL Segments or Query Parameters

By default, the AppDynamics Apache Agent sends transaction data to the Controller that your organization may classify as privileged information. Although such data is useful for diagnosis and troubleshooting, security considerations may require you to filter certain sensitive information from view in the Controller. You can use `Sensitive URL` filters to exclude sensitive information from a URL in snapshot details.

#### Add a Sensitive URL Filter

1. Edit the `appdynamics_agent.conf` configuration file in the path: `<path_to_webserver_dir>/conf/appdynamics_agent.conf`.
2. In the `appdynamics_agent.conf` file, configure the following settings:
  - `AppDynamicsDelimiter`: Specify the character that you want to use as URL segment endpoints. The agent splices the URL at each delimiter instance to create the segments. For HTTP, use the forward slash character "/". For the forward slash, the agent does not split on the slashes immediately following the protocol. For example, "https://myapp.example.com/" constitutes a single segment. By default, the delimiter is "/" but this is **REQUIRED** for successful filtering.

For example:

`AppDynamicsDelimiter /`

Note that `#` cannot be used as a delimiter as the configuration file cannot process it.

- `AppDynamicsSegment`: Specify a comma-separated list to indicate the segments that you want the agent to filter. Segment numbering starts from 1. If you specify 0 or negative values, the agent fails to redact the segments. This attribute is **REQUIRED**.

For example:

```
AppDynamicsSegment 2,3
```

- `AppDynamicsMatchfilter` : The type of filter to be used to match the URL amongst the following: `NOT_EMPTY | EQUALS | STARTSWITH | ENDSWITH | CONTAINS | REGEX` . Default is `NOT_EMPTY` , but `REQUIRED`.

For using this correctly, query parameters should not be considered for match-filtering. With an example of the call "https://myapp.example.com/sensitive/data?first\_name=abc&last\_name=xyz", to specify match-filter as `STARTSWITH`, it matches a specified string starting with the hostname "myapp.example.com" in this case. Similarly for `ENDSWITH`, it will correspond to the last segment leaving out the query parameters, "data" in this case, as query parameters are never reported in the snapshots.

For example:

```
AppDynamicsMatchfilter CONTAINS
```

- `AppDynamicsMatchpattern` : Specify the string that you want to be filtered with the match-filter. This attribute is `REQUIRED`.

For example:

```
AppDynamicsMatchpattern one
```

For example, the following configuration splits the URL on the "/" character and masks the third and fifth segments of the URL. In this case, the segmentation and obfuscation apply only to URLs containing "myapp":

```
AppDynamicsDelimiter /
AppDynamicsSegment 3,5
AppDynamicsMatchfilter CONTAINS
AppDynamicsMatchpattern myapp
```

The exit call to "https://myapp.example.com/customer/customerid/account/accountid/data?first\_name=abc&last\_name=xyz" breaks down to six segments: "https://myapp.example.com", "customer", "customerid", "account", "accountid" and "data?first\_name=abc&last\_name=xyz". The Controller shows the masked values of the URL: " /customer/\*\*\*\*\*/account/\*\*\*\*\*/data" in the snapshot details. "https://myapp.example.com" corresponds to segment number 1 and so on.

As the query parameters are never sent to the controller, so they are not filtered. In the transaction snapshots, the URLs are sent by default without the query parameters but now after masking the corresponding URL segments.

### Filter Multiple URLs

Due to the limitations of the Apache configurations, if you want to filter multiple URLs separately, the arguments need to be written with '|' separated as described below:

```
AppDynamicsDelimiter /|/
AppDynamicsSegment 1,2,3|1,4
AppDynamicsMatchfilter CONTAINS|ENDSWITH
```

```
AppDynamicsMatchpattern One|.php
```

Each '|' separated values correspond to an additional URL filter added. For 'n' number of separate URL filters, you need to have 'n' different 'I' configurations correspondingly. These filters behave independently on the URLs and will filter based on the configurations specified for each filter.

**i** You must define all the configuration settings, though the configurations assume the default values. If you miss defining a particular setting in case of multiple filtering, the filtering fails.

## C/C++ SDK

### Related pages:

- [SELinux Installation Issues](#)

This page provides an overview of the C/C++ SDK for C/C++ applications in AppDynamics. The SDK Agent provides transaction/backend reporting, automatic tier mapping, automatic dynamic baselining, health rules, data collectors, and transaction snapshots. Altogether, these tools provide visibility into application load and response times, as well as any custom metrics you define.

To monitor the C and C++ applications, add some API calls to the source code. Once running, the SDK registers Business Transactions with the Controller. You can then see your application flow map monitor performance in the Controller.

For the C/C++ SDK reference documentation, see the latest [C/C++ SDK documentation](#).

### C/C++ SDK Supported Environments

#### C/C++ Supported Platforms

#### Operating Systems

- Any Linux distribution based on glibc >= 2.5 and the x86 32-bit or x86 64-bit architecture
- Windows Server >= 2012 R2
  - Visual Studio >= 2015

**i** To develop with the C++ SDK, you need Visual Studio >= 2015 . However, the SAP ABAP Agent on Windows leverages the same SDK and does not require development work. You must install the Visual Studio C++ Redistributable; the full development environment is not required.

### Use the C/C++ SDK

#### On this page:

- [Add the AppDynamics Header File to the Application](#)
- [Initialize the Controller Configuration](#)
- [Initialize the SDK](#)
- [Create Alternate Application Contexts](#)
- [Create Business Transactions](#)

- [Create Business Transactions With an Alternate Application Context](#)
- [Add Business Transaction Errors](#)
- [Manage Business Transaction Snapshots](#)
- [Create Backends](#)
- [Manage Exit Calls](#)
- [Create Custom Metrics](#)
- [Generate Call Graphs](#)
- [Generate Pre-populated Call Graphs \(C++ Only\)](#)
- [Analytics Support for C++ SDK](#)
- [Terminate the Agent](#)

### Related pages:

- [C/C++ SDK Reference](#)
- [Overview of Application Monitoring](#)
- [Business Transactions](#)

This page provides an overview of how to use the C/C++ SDK.

The SDK provides routines for creating/managing business transactions, transaction snapshots, backends, exit points, and custom metrics.

To instrument your applications with the C/C++ SDK, obtain the most current version of the C/C++ SDK. See [C/C++ SDK](#).

### Add the AppDynamics Header File to the Application

After downloading the SDK, you are ready to add AppDynamics instrumentation to your C/C++ application. The first step is to include the AppDynamics header file at the top of your `main` function file:

```
#include <path_to_SDK>/sdk_lib/appdynamics.h
```

### Initialize the Controller Configuration

Controller information settings permit the agent to connect to the Controller. Some settings are required for all applications, while others are needed only for certain types of application environments. For example, if the agent needs to connect to the Controller via an internal proxy in your network, you need to set up the connection settings for the proxy. See [C/C++ SDK Reference](#) for a list of the settings and information about which ones are required.

In your application, assign values to the required settings.

For example, to set the Controller connection information:

```
const char APP_NAME[] = "SampleC";
const char TIER_NAME[] = "SampleCTier1";
const char NODE_NAME[] = "SampleCNode1";
const char CONTROLLER_HOST[] = "controller.somehost.com";
const int CONTROLLER_PORT = 8080;
const char CONTROLLER_ACCOUNT[] = "customer1";
const char CONTROLLER_ACCESS_KEY[] = "MyAccessKey";
const int CONTROLLER_USE_SSL = 0;
```

To create the default application context, declare an `appd_config` struct with the Controller settings.

For example:

```
struct appd_config* cfg = appd_config_init(); // appd_config_init() resets the configuration
object and pass back an handle/pointer
appd_config_set_app_name(cfg, APP_NAME);
appd_config_set_tier_name(cfg, TIER_NAME);
appd_config_set_node_name(cfg, NODE_NAME);
appd_config_set_controller_host(cfg, CONTROLLER_HOST);
appd_config_set_controller_port(cfg, CONTROLLER_PORT);
appd_config_set_controller_account(cfg, CONTROLLER_ACCOUNT);
appd_config_set_controller_access_key(cfg, CONTROLLER_ACCESS_KEY);
appd_config_set_controller_use_ssl(cfg, CONTROLLER_USE_SSL);
```

## Initialize the SDK

In your `main` function, call these initialization functions:

1. Initialize the `config` structure as shown in the previous section.
2. Initialize the SDK by passing the configuration structure to `appd_sdk_init()`.

If `appd_sdk_init()` returns zero, the SDK is initialized successfully. Non-zero indicates failure because the SDK could not reach the Controller.

The following example illustrates how to initialize the SDK:

```
int initRC = appd_sdk_init(cfg);

if (initRC) {
 std::cerr << "Error: sdk init: " << initRC << std::endl;
 return -1;
}
```

**i** All SDK calls including `appd_sdk_init()` and `fork()` should only occur in the forked process, never in the parent process. Each child call should behave independently and cannot share handles between the process and other SDK-instrumented child processes.

## Create Alternate Application Contexts

The SDK presumes a default application context that has no name associated with it.

To create the default application context, use the `appd_config_init()` command which returns a pointer to the default configuration structure. Then, use setter commands to modify the fields within the structure. Once all relevant fields are set, use the `appd_sdk_init()` call to initialize the SDK with the default application context.

All other application contexts are created with an associated name and a collection of separate setter methods.

To create an alternate application context, pass the `appd_context_config_init()` command the name of your alternate application context. This will return a pointer to the alternate application context configuration structure. Then, use the `_context_` setter commands to modify the fields within the structure. Once all relevant fields are set, use the `appd_sdk_add_app_context()` call to initialize the SDK, passing it the alternate application context structure pointer.

```
// create the alternate application context
appd_context_config* cfg2 = appd_context_config_init("My_Context");
...

// add additional setter commands to initialize the alternate application context
appd_context_config_set_controller_account(cfg2, ac.second.ac_account_get().c_str());
appd_context_config_set_controller_access_key(cfg2, ac.second.ac_access_key_get().c_str());
appd_context_config_set_controller_host(cfg2, ac.second.ac_host_get().c_str());
appd_context_config_set_controller_port(cfg, ac.second.ac_port_get());
appd_context_config_set_controller_use_ssl(cfg2, ac.second.ac_use_ssl_get() ? 1 : 0);
appd_context_config_set_app_name(cfg2, ac.second.ac_app_get().c_str());
appd_context_config_set_tier_name(cfg2, ac.second.ac_tier_get().c_str());
appd_context_config_set_node_name(cfg2, ac.second.ac_node_get().c_str());

// initialize the alternate application context
appd_sdk_add_app_context(cfg2);
```

## Create Business Transactions

Define a Business Transaction by enclosing the code that constitutes the request that you want to monitor between `appd_bt_begin()` and `appd_bt_end()` calls. `appd_bt_begin()` returns a handle to use in subsequent routines that affect that business transaction.

If you are creating a business transaction that correlates with an upstream business transaction, pass the correlation header of the upstream transaction so the new transaction that you are creating can correlate with it. See `appd_exitcall_get_correlation_header()` in [C/C++ SDK Reference](#). If the transaction does not need to correlate with another transaction, pass `NULL` for the correlation header parameter.

You can optionally store the business transaction handle in the global handle registry with a guid for easy retrieval later using `appd_bt_store()`. Retrieve the handle from the global handle registry using `appd_bt_get()`.

The following example demonstrates setting a business transaction:

```
// start the "Checkout" transaction
appd_bt_handle btHandle = appd_bt_begin("Checkout", NULL);

// Optionally store the handle in the global registry
appd_bt_store(btHandle, my_bt_guid);
...

// Retrieve a stored handle from the global registry
appd_bt_handle myBtHandle = appd_bt_get(my_bt_guid);
...
```

```
// end the transaction
appd_bt_end(btHandle);
```

Between starting and ending the transaction, you can perform operations such as adding errors to the business transaction, defining the transaction snapshot attributes, adding backends and exit calls, and so on.

When the business transaction ends, via a call to `appd_bt_end()`, the agent stops reporting metrics for the business transaction.

### Create Business Transactions With an Alternate Application Context

You can create a business transaction with an alternate application context using `appd_bt_begin_with_app_context()` and `appd_bt_end()` calls. In addition to the parameters passed to `appd_bt_begin()`, the `appd_bt_begin_with_app_context()` also takes an application context name string, as defined by the call to `appd_context_config_init()`.

`appd_bt_begin_with_app_context()` returns a handle to use in subsequent routines that affect that business transaction.

The following example demonstrates setting a business transaction with an alternate application context:

```
// create the alternate application context
appd_context_config* cfg2 = appd_context_config_init("My_Context");
...

// add additional setter commands to initialize the alternate application context
appd_context_config_set_controller_account(cfg2, ac.second.ac_account_get().c_str());
appd_context_config_set_controller_access_key(cfg2, ac.second.ac_access_key_get().c_str());
appd_context_config_set_controller_host(cfg2, ac.second.ac_host_get().c_str());
appd_context_config_set_controller_port(cfg, ac.second.ac_port_get());
appd_context_config_set_controller_use_ssl(cfg2, ac.second.ac_use_ssl_get() ? 1 : 0);
appd_context_config_set_app_name(cfg2, ac.second.ac_app_get().c_str());
appd_context_config_set_tier_name(cfg2, ac.second.ac_tier_get().c_str());
appd_context_config_set_node_name(cfg2, ac.second.ac_node_get().c_str());

// initialize the alternate application context
appd_sdk_add_app_context(cfg2);

// start the "Checkout" transaction with the alternate application context
appd_bt_handle btHandle = appd_bt_begin_with_app_context("My_Context", "Checkout", NULL);

// end the transaction
appd_bt_end(btHandle);
```

When the business transaction ends, via a call to `appd_bt_end()`, the agent stops reporting metrics for the business transaction. Between starting and ending the transaction, you can perform operations such as adding errors to the business transaction, defining the transaction snapshot attributes, adding backends and exit calls, and so on.

## Add Business Transaction Errors

Use `appd_bt_add_error()` to report business transaction errors. If you set this function parameter, `markBTAsError` the transaction is reported as an [error transaction](#) when the error occurs. For the function `{{appd_bt_add_error,}}`, the Controller database truncates log messages that exceed 5,000 characters.

The SDK provides an `enum` to classify the error level as `APPD_LEVEL_NOTICE`, `APPD_LEVEL_WARNING`, or `APPD_LEVEL_ERROR`.

## Manage Business Transaction Snapshots

When the agent is monitoring a business transaction, it automatically creates [transaction snapshots](#), which describe instances of the business transaction at certain points in time. Transaction snapshots are extremely useful for troubleshooting poor performance because they contain a lot of detail.

You do not have to modify anything to create these snapshots, other than create the business transaction, but you can add calls to:

- Find out if a snapshot is being taken
- Provide additional data in a snapshot
- Set the URL for a snapshot

## Determine if the Agent is Taking a Snapshot Now

The agent does not constantly collect screenshot due to high cost. By default, it collects a snapshot every ten minutes, but this schedule is configurable. See [Configure Snapshot Periodic Collection Frequency](#).

You can determine if a snapshot is happening using `appd_bt_is_snapshotting()`, which returns non-zero if the agent is collecting a snapshot. The main reason to do this is to avoid the wasted overhead for collecting user data for a snapshot or setting the snapshot URL if no snapshot is currently being collected.

## Add Business Transaction User Data

You can optionally add data to transaction snapshots. For example, you might want to know which users are getting a lot of errors, from which regions users are experiencing slow response times or which methods are slow. In the Controller UI, the data appears in the USER DATA tab of the transaction snapshot.

If a snapshot is occurring, use `appd_bt_add_user_data()` passing a key and value for the data that you want the snapshot to collect. For the function `{{appd_bt_add_user_data,}}`, the Controller database truncates log messages that exceed 5,000 characters.

## Add Snapshot URL

A snapshot URL allows Controller users to share a snapshot with others. You can set a URL for the current snapshot using `appd_bt_set_url()`.

## Set Snapshot Example

```
void setSnapshotAttributes(appd_bt_handle btHandle, int minute, int halfsec)
{
 // do this only if the agent is collecting a snapshot
 if (appd_bt_is_snapshotting(btHandle))
 {
 char nameBuf[30];
```

```

char valueBuf[30];
// add custom data to the snapshot
snprintf(nameBuf, sizeof(nameBuf), "BT:%p\n", btHandle);
snprintf(valueBuf, sizeof(valueBuf), "Minute:%d Second:%d\n", minute, halfsec/2);
appd_bt_add_user_data(btHandle, nameBuf, valueBuf);

static int snapCount = 0;
int switchVal = snapCount % 4;

// report errors, but only ERROR_LEVEL errors are marked as error transactions
if (switchVal)
{
 appd_error_level errorLevel;
 bool markBtAsError;
 switch (switchVal)
 {
 case 1:
 errorLevel = APPD_LEVEL_NOTICE;
 markBtAsError = false;
 snprintf(nameBuf, sizeof(nameBuf), "NOTICE BT:%p M:%d S:%d\n", btHandle,
minute, halfsec/2);
 break;
 case 2:
 errorLevel = APPD_LEVEL_WARNING;
 markBtAsError = false;
 snprintf(nameBuf, sizeof(nameBuf), "WARNING BT:%p M:%d S:%d\n", btHandle,
minute, halfsec/2);
 break;
 case 3:
 errorLevel = APPD_LEVEL_ERROR;
 markBtAsError = true;
 snprintf(nameBuf, sizeof(nameBuf), "ERROR BT:%p M:%d S:%d\n", btHandle,
minute, halfsec/2);
 break;
 }
 appd_bt_add_error(btHandle, errorLevel, nameBuf, markBtAsError, markbtaserror);
}
snapCount++;
// set the snapshot url
snprintf(nameBuf, sizeof(nameBuf), "http://bt-%p.com", btHandle);
appd_bt_set_url(btHandle, nameBuf);
}
}

```

## Create Backends

A backend is a database or a remote service such as a message queue, HTTP service or cache service that your application uses. A backend component is not itself monitored by the application agent, but the agent monitors calls to it from instrumented servers. You need to create backends in the instrumented environment so that the agent can discover them. This involves:

- Declaring the backend

- Setting its identifying properties
- Optionally configuring how the backend is presented in the AppDynamics UI
- Adding the backend to the instrumented application

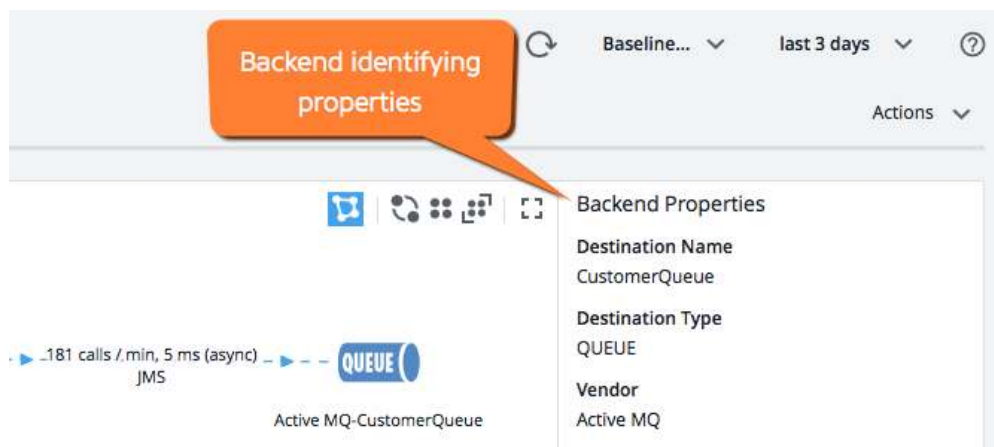

## Declare the Backend

You must declare a backend using `appd_backend_declare()` before the agent can detect it. After you declare a backend, you don't need to declare it again if the backend is used by other business transactions in a single SDK instance. A backend must be of one of the supported types listed under 'Exit Call Types' in [C/C++ SDK Reference](#).

## Identify the Backend

A backend also has identifying properties, which you set using `appd_backend_set_identifying_property()`. The properties vary depending on the type of the backend and the types of information that you want to display. The Controller displays identifying properties in backend dashboards. You must set at least one identifying property for the type of any backend that you plan to add.

The following shows the backend properties in the Controller UI for an ActiveMQ:

## Resolve to a Tier

By default, the Controller doesn't display a detected backend as a separate entity in flowmaps, but the agent reports its metrics as part of the downstream tier. If you want to display the backend as a separate component and not resolved to the tier, use `appd_backend_prevent_agent_resolution()`. See [Resolve Remote Services to Tiers](#).

## Add to Application

After you declare and configure the backend, add it to the application so the agent can detect it.

## Backend Example

The following listing shows an example of setting up a database backend.

```
// declare a backend, only once for this SDK instance
const char backendOne[] = "first backend";
appd_backend_declare(APPD_BACKEND_HTTP, backendOne);
```

```

// set the host property
rc = appd_backend_set_identifying_property(backendOne, "HOST", "sqs-us-west-hostname");
if (rc) {
 std:cerr << "Error: appd_backend_set_identifying_property: " << rc << ".";
 return -1;
}

// do not resolve the backend to the tier
rc = appd_backend_prevent_agent_resolution(backendOne);
if (rc) {
 std:cerr << "Error: appd_backend_prevent_agent_resolution: " << rc << ".";
 return -1;
}

// add the backend
rc = appd_backend_add(backendOne);
if (rc)
{
 std:cerr << "Error: appd_backend_add: " << rc << ".";
 return -1;
}

```

## Manage Exit Calls

When an application makes a call to another component—a detected backend or another application server—the agent reports metrics on those calls.

Define an exit call by enclosing the code that constitutes the exit call between `appd_exitcall_begin()` and `appd_exitcall_end()` calls. `appd_exitcall_begin()` returns a handle to use in subsequent routines that affect that exit call. An exit call occurs in the context of a business transaction.

You can optionally store the exit call handle in the global handle registry with a guid for easy retrieval later with `appd_exitcall_store()`. Retrieve the handle from the global handle registry with `appd_exitcall_get()`.

Pass the business transaction handle and the destination backend to `appd_exitcall_end()`.

You can optionally add details to an exit call as any arbitrary string. The details are reported in the exit call details in the transaction snapshots in the Controller UI:

Name	Type	Class	Method	Line Number	Self Time	% Time	Total Time	% Time	From	To
com.appdynamics.jdbc.MPreparedStatement:executeQuery	POJO	com.appdynamics.jdbc.MPreparedStatement	executeQuery	Unknown	13ms	0.2%	13ms	0.2%	Inventory S...	Oracle-10.0.0

Type	Details	Count	Time (ms)	% Time	From	To
JDBC	insert into OrderRequest ( item_id, notes ) val...	1	10	0.1%	Inventory S...	Oracle-10.0.0

You can also add errors to an exit call using `appd_exitcall_add_error()`. Use the enum for the error levels. You can also add an error message.

### Simple Exit Call Example

```
// start the exit call to backendOne
appd_exitcall_handle ecHandle = appd_exitcall_begin(btHandle, backendOne);

...

// optionally store the handle in the global registry
appd_exitcall_store(ecHandle, my_ec_guid);

...
// retrieve a stored handle from the global registry
appd_exitcall_handle myEcHandle = appd_exitcall_get(my_ec_guid);

// set the exit call details
rc = appd_exitcall_set_details(ecHandle, "backend ONE");
if (rc) {
 std::cerr << "Error: exitcall details1";
 return -1;
}

// add an error to the exit call
appd_exitcall_add_error(ecHandle, APPD_LEVEL_ERROR, "exitcall1 error!", true);

// end the exit call
appd_exitcall_end(ecHandle)
```

### Correlate with Other Business Transactions

A correlation header contains the information that enables the agents to continue the flow of a business transaction across multiple tiers.

An SDK can correlate with other SDKs as well as other AppDynamics agents—such as Java, .NET or PHP—that perform automatic correlation for certain types of entry and exit points.

#### Correlate with an Upstream Tier

When your instrumented process receives a continuing transaction from an upstream agent that supports automatic correlation:

1. Using a third-party `http_get_header()` function, extract the header named `APPD_CORRELATION_HEADER_NAME` from the incoming HTTP payload.
2. Pass the header to `appd_bt_begin()`. For example:

```
const char* hdr = http_get_header(req, APPD_CORRELATION_HEADER_NAME);
appd_bt_handle bt = appd_bt_begin("fraud detection", hdr);
```

If the header retrieved by the `http_get_header()` function is valid, the business transaction started by the `appd_bt_begin()` call will be a continuation of the business transaction started by the upstream service.

### Correlate with a Downstream Tier

The downstream agent is watching for a correlation header named `singularityheader` in the HTTP payload.

If your SDK agent is making an exit call to a downstream agent that supports automatic correlation:

1. Set the name of the correlation header using `APPD_CORRELATION_HEADER_NAME`.
2. Begin the exit call.
3. Retrieve the correlation header from the exit call using the `appd_exitcall_get_correlation_header()` function.
4. Using third-party HTTP functions, prepare an HTTP POST request.
5. Inject a header named `APPD_CORRELATION_HEADER_NAME` with the value of the correlation header retrieved in step 3 into the outgoing payload of the HTTP request.
6. Make the request. For example:

```

const char* const APPD_CORRELATION_HEADER_NAME = "singularityheader";

appd_exitcall_handle inventory = appd_exitcall_begin(bt, "inventory");
const char* hdr = appd_exitcall_get_correlation_header(inventory);
http_request req;
http_init(&req, HTTP_POST, "https: //inventory/holds/%s", sku);
http_set_header(&req, APPD_CORRELATION_HEADER_NAME, hdr);
http_perform(&req);

...

```

### cURL Downstream Correlation Example

The following example uses the cURL library to correlate with a downstream transaction.

```

#include <curl/curl.h>
. . .
. . .
// get the correlation header into the response
class LibcurlURLGet
{
public:
 LibcurlURLGet(const std::string& url) : url(url), curlHandle(NULL) {}
 std::string GetResponse(const char* correlationHeader)
 {
 CURLcode res;
 Response response;
 curlHandle = curl_easy_init();
 if (curlHandle)
 {
 curl_easy_setopt(curlHandle, CURLOPT_URL, url.c_str());
 }
 }
}

```

```

 curl_easy_setopt(curlHandle, CURLOPT_WRITEFUNCTION, WriteDataCallback);
 curl_easy_setopt(curlHandle, CURLOPT_WRITEDATA, &response);
 if(correlationHeader && strlen(correlationHeader))
 {

// start new added code

 std::string singularityHeader(APPD_CORRELATION_HEADER_NAME);
 singularityHeader.append(": ");
 singularityHeader.append(correlationHeader);

// end new added code

 curl_slist* slistNewHeaders = 0;
 slistNewHeaders = curl_slist_append(slistNewHeaders, correlationHeader);
 curl_easy_setopt(curlHandle, CURLOPT_HTTPHEADER, slistNewHeaders);
 }
 res = curl_easy_perform(curlHandle);
 if(res != CURLE_OK)
 {
 }
}
curl_easy_cleanup(curlHandle);
return response.GetResponseString();
}
private:
class Response
{
public:
 std::string GetResponseString()
 {
 return sResponse;
 }
 void AppendResponse(void* ptr, size_t sizeBytes)
 {
 sResponse.append((char*)ptr, sizeBytes);
 }
private:
 std::string sResponse;
};
static size_t WriteDataCallback(void* ptr, size_t size, size_t nmemb, Response* response)
{
 response->AppendResponse(ptr, size * nmemb);
 return size * nmemb;
}
std::string url;
CURL* curlHandle;
};

...
// start an exit call from the current transaction
appd_exitcall_handle echandle1 = appd_exitcall_begin(btHandle1, tier2);

```

```

...
// before exiting get the correlation header
const char* corrHeader1 = appd_exitcall_get_correlation_header(ecHandle1);

// put the correlation in the HTTP response
std::string response = urlGet.GetResponse(corrHeader1);

...
// start the next business transaction to correlate with the previous one
appd_bt_handle btHandle = appd_bt_begin("Verify", response)

```

## Create Custom Metrics

You can create custom metrics to supplement built-in metrics such as Business Transaction call count and response time. You can also create metrics for multiple application contexts.

Custom metrics are dependent on the application context; in situations with multiple contexts, you must specify the correct context name for custom metrics to apply to the associated application context. See [Create Alternate Application Contexts](#).

If you create a custom metric in a node, the custom metric will appear in every other node in the tier.

For example, the default application context uses a null pointer or empty string as its name. The `appd_sdk_init` method tells the SDK to connect to the Controller and create the default application context (i.e. no name is specified).

```

struct appd_config* cfg = appd_config_init();
appd_config_set_controller_host(cfg, host.c_str());
appd_config_set_controller_port(cfg, port);
appd_config_set_controller_account(cfg, account_name.c_str());
appd_config_set_controller_access_key(cfg, access_key.c_str());
appd_config_set_controller_use_ssl(cfg, useSSL?1:0);
appd_config_set_app_name(cfg, app_name.c_str());
appd_config_set_tier_name(cfg, tier_name.c_str());
appd_config_set_node_name(cfg, node_name.c_str());
appd_sdk_init(cfg);

```

To specify an alternative application context, you must provide a name string (not a default null pointer). Use the `appd_sdk_add_appd_context` method to create an alternative application context. In the example below, we create an alternative application context called "context2." You will use that name string to create custom metrics, not the actual configuration structure.

```

const char* name = "context2";
struct appd_context_config* cfg2 = appd_context_config_init(name);
appd_context_config_set_controller_account(cfg2, ac.second.ac_account_get().c_str());
appd_context_config_set_controller_access_key(cfg2, ac.second.ac_access_key_get().c_str());
appd_context_config_set_controller_host(cfg2, ac.second.ac_host_get().c_str());

```

```

appd_context_config_set_controller_port(cfg, ac.second.ac_port_get());
appd_context_config_set_controller_use_ssl(cfg2, ac.second.ac_use_ssl_get() ? 1 : 0);
appd_context_config_set_app_name(cfg2, ac.second.ac_app_get().c_str());
appd_context_config_set_tier_name(cfg2, ac.second.ac_tier_get().c_str());
appd_context_config_set_node_name(cfg2, ac.second.ac_node_get().c_str());

appd_sdk_add_app_context(cfg2);

```

The Custom Metrics path may or may not go the same Controller; similar to business transactions in separate nodes, your program can process two business transactions from different nodes: one aligns with the default application context and the other with the alternative application context. You must specify that your method strings begin with `Custom Metrics|`, not `Custom Metric|`.

You can use the following methods to create a custom metric:

- `appd_custom_metric_add()`
- `appd_custom_metric_report()`

[Default Application Context](#)    [Alternate Application Context](#)

The `appd_custom_metric_add()` method registers a custom metric for the default context.

```

appd_custom_metric_add(nullptr, "Custom Metrics|my_default_custom_metric" ,
time_rollup_type, cluster_rollup_type, hole_handling_type);

```

The `appd_custom_metric_report()` creates an application context named "my\_default\_custom\_metric."

```

appd_custom_metric_report(nullptr, "Custom Metrics|my_default_custom_metric",some_value);

```

[Default Application Context](#)    [Alternate Application Context](#)

For an alternative context, the `appd_custom_metric_add()` method registers a custom metric for the alternative application context.

```

appd_custom_metric_add(name, "Custom Metrics|my_second_custom_metric" , time_rollup_type,
cluster_rollup_type, hole_handling_type);

```

or

```

appd_custom_metric_add("context2", "Custom Metrics|my_second_custom_metric" ,
time_rollup_type, cluster_rollup_type, hole_handling_type);

```

The `appd_custom_metric_report` creates a default application context and an alternative application context named `my_second_custom_metric`.

[Default Application Context](#)    [Alternate Application Context](#)

```
appd_custom_metric_report(name, "Custom Metrics|my_second_custom_metric",some_value);
```

Default Application Context    [Alternate Application Context](#)

```
appd_custom_metric_report("context2", "Custom Metrics|my_second_custom_metric",some_value)
;
```

In the Controller, the custom metrics folder appears under the associated tier as "Custom Metrics" in the **Metric Browser** with two entities: `my_default_custom_metric` and `my_second_custom_metric`.

The following example illustrates a call with both method signatures.

```
appd_custom_metric_add("app_context", "Custom Metrics|Memory|Total Memory Usage",
APPD_TIMEROLLUP_TYPE_AVERAGE, APPD_CLUSTERROLLUP_TYPE_INDIVIDUAL,
APPD_HOLEHANDLING_TYPE_RATE_COUNTER);
```

The method passes the application context ("Total Memory Usage") and the path to the metric (**Custom Metrics > Memory** in the **Metric Browser**) to the Controller. The additional parameters define how the metric is processed. With the metric declared, your code can then report data to the metric with the `appd_custom_metric_report()` method, as follows:

```
appd_custom_metric_report("app_context", "Custom Metrics|Memory|Total Memory Usage", 1234);
```

See [C/C++ SDK Resource Management](#) to simplify your instrumentation on C++ applications.

## Metric Handling Parameters

Like built-in metrics, the Controller applies some standard processing functions to custom metric values. These functions can define, for example, how the metric is rolled up over time. How the Controller processes a custom metric depends on the nature of the metric; for a metric that represents the state of the machine, the Controller captures the last observed value for the metric. For a call rate metric, the Controller uses an average value. The following section provides information about the parameters you can use to define metric handling by the Controller.

### Time Rollup Type

The `time_rollup_type` parameter tells the Controller how to roll up values for the metric over time. There are three ways in which the Controller can roll up metrics, as follows:

- It can calculate the average of all reported values in the time period. An example of a built-in metric that uses this is the `Average Response Time` metric.
- Sum of all reported values in that minute. This operation behaves like a counter. An example metric is the `Calls per Minute` metric.
- Current is the last reported value in the minute. If no value is reported in that minute, the last reported value is used. An example of a metric that uses this would be a machine state metric, such as `Max Available (MB)` metric.

## Cluster Rollup Type

The `appd_cluster_rollup_type` parameter tells the Controller how to aggregate metric values for the tier—a cluster of nodes.

- Individual: Aggregates the metric value by averaging the metric values across each node in the tier. For example, `Hardware Resources|Memory|Used %` is a built-in metric that uses the individual rollup type.
- Collective: Aggregates the metric value by adding up the metric values for all the nodes in the tier. For example, `Agent|Metric Upload|Metrics uploaded` is a built-in metric that uses the collective rollup type.

## Hole Handling Type

A particular metric may not report data for a given minute. The `appd_hole_handling_type` parameter tells the Controller how to set the metric count for that time slice. The count is set to zero if the hole handling type is `REGULAR_COUNTER`, and set to one if `RATE_COUNTER`. In effect, `REGULAR_COUNTER` does not affect aggregation while `RATE_COUNTER` does.

For example, consider four time slices with the data 9, 3, 0, 12. Notice that the third time slice is zero filled, with no metric being reported for that time slice. The sum of the values is  $9+3+0+12 = 24$ .

If the metric is `REGULAR_COUNTER`, the count for the third time slice would be zero, and therefore the overall count would be  $1+1+0+1 = 3$ . If the metric is `RATE_COUNTER` the overall count would be  $1+1+1+1 = 4$ . In the case of the `REGULAR_COUNTER`, the average would be  $24/3 = 8$ , while for the `RATE_COUNTER` the average would be  $24/4 = 6$ .

Built-in metrics that use the regular counter hole-handling type include `Average Response Time`, `Average CPU Used`, and `Number of Stalls`. Built-in metrics that use the rate counter hole-handling type include `BT Calls per minute` and `Errors per minute`.

## Generate Call Graphs

You can use the C/C++ SDK to instrument methods so that they are reported and displayed in the call graph. You can instrument methods in one of the following ways:

- Use the `APPD_AUTO_FRAME` macro, C++ only
- Use `appd_frame_begin` and `appd_frame_end`

### Instrument Methods with the `APPD_AUTO_FRAME` Macro

You can use the `APPD_AUTO_FRAME` macro to instrument applications built on C++ frameworks. The macro is equivalent to calling the `appd_frame_begin` and `appd_frame_end` methods.

1. Specify the business transaction that you want to instrument calls for, and configure the root of the call graph.

```
appd::sdk::BT bt("mybt");
APPD_AUTO_FRAME(bt);
method1(bt);
method2(bt);
```

2. Instrument the methods as shown below.

```
void method1(appd::sdk::BT& bt)
```

```

{
 APPD_AUTO_FRAME(bt);
 // Code for method1...
}
void method2(appd::sdk::BT& bt)
{
 APPD_AUTO_FRAME(bt);
 // Code for method2...
}

```

The methods must have access to the business transaction so the business transaction can be passed into the method as an argument.

### Instrument Methods with the `appd_frame_begin` and `appd_frame_end` Functions

You can instrument methods for applications that are built on non-C++ frameworks. To instrument a method, you call `appd_frame_begin` at the beginning of the method, and `appd_frame_end` at the end of the method. When you do this, the duration of the method call is automatically calculated and reported in the call graph.

If your method makes an exit call, you can instrument the exit call by wrapping the exit call code between `appd_exitcall_begin` and `appd_exitcall_end`.

The code samples below show three methods that are each instrumented using `appd_frame_begin` and a `ppd_frame_end`, and then called in a root method, `main()`. The second sample method, `method2()`, contains an exit call.

```

void method1()
{
 appd_frame_handle frameHandle = appd_frame_begin(btHandle, APPD_FRAME_TYPE_CPP, nullptr,
 APPD_FUNCTION_NAME, __FILE__, __LINE__);
 // code for method1
 appd_frame_end(btHandle, frameHandle);
}

```

```

void method2()
{
 appd_frame_handle frameHandle = appd_frame_begin(btHandle, APPD_FRAME_TYPE_CPP, nullptr,
 APPD_FUNCTION_NAME, __FILE__, __LINE__);
 // code for method2
 appd_exitcall_handle exitCallHandle = appd_exitcall_begin(btHandle, BACKEND_NAME);
 // code for exit call
 appd_exitcall_end(exitCallHandle);
 appd_frame_end(btHandle, frameHandle);
}

```

```

void method3()
{
 // To illustrate instrumenting a method where this SDK cannot be used
}

```

```
// method3 is a wrapper for the call of the actual method which will show up in the call graph
appd_frame_handle frameHandle = appd_frame_begin(btHandle, APPD_FRAME_TYPE_CPP, "Test",
"Compute", "C:\\modules\\source\\Test.cs", 143);
// call the wrapped method
appd_frame_end(btHandle, frameHandle);
}
```

The `main()` method below is the root of the call graph. It specifies the business transaction that invokes the three methods above by passing the transaction into `appd_bt_begin` and `appd_bt_end`.

```
int main(int argc, char **argv)
{
// initialize AppDynamics
btHandle = appd_bt_begin(TRANSACTION_NAME, "");
appd_frame_handle frameHandle = appd_frame_begin(btHandle, APPD_FRAME_TYPE_CPP, nullptr,
APPD_FUNCTION_NAME, __FILE__, __LINE__);
// code for main
method1();
method2();
method3();
appd_frame_end(btHandle, frameHandle);
appd_bt_end(btHandle);
}
```

The sample methods above are represented by the call graph shown below:

Name	Time (ms)	Percent %	Exit Calls / Threa
c:\source\main.cpp:230	41 ms (self)	10.2%	
c:\source\main.cpp:173	120 ms (self)	29.9%	
c:\source\main.cpp:180	160 ms (self)	39.8%	HTTP
C:\modules\source\Test.cs:143	81 ms (self)	20.1%	

## Generate Pre-populated Call Graphs (C++ Only)

The previous section describes instrumenting your C/C++ application by calling the instrumentation methods in your code. However, if you do not have the option of modifying your source code, you can generate call graphs that are populated with data from sources such as log files.

To generate a pre-populated call graph:

1. Create the root of the call graph by instantiating a `CallGraph` class. The `CallGraph` class takes the following parameters:
  - `bt` : The business transaction.
  - `class_name` : The name of the class that contains the root of the call graph.
  - `method_name` : The name of the method that represents the root of the call graph.
  - `file_path` : The file path to the class.
  - `line_number` : The line number of the method.
  - `time_msec` : The time taken by this frame (method) in milliseconds.

- `frame_type` : The type of the frame (the language for the method). Currently, `APPD_FRAME_TYPE_CPP` is the only option.

The following example demonstrates a `CallGraph` instantiation.

```
appd::sdk::CallGraph callGraph(bt, "Class1", "main", "/src/file1.cc", 276, 100,
APPD_FRAME_TYPE_CPP);
```

2. Create the call graph tree by calling `add_child` on the root and on any of the added children:

```
callGraph.root() .add_child("Class2", "method1", "/src/file2.cc"), 101, 40,
APPD_FRAME_TYPE_CPP) .add_child("Class2", "method2", "/src/file2.cc"), 523, 30,
APPD_FRAME_TYPE_CPP); auto& cge1 = callGraph.root() .add_child("Class3", "method1", "/
src/file3.cc"), 27, 30, APPD_FRAME_TYPE_CPP); cge1.add_child("Class3", "method2", "/src/
file3.cc"), 430, 15, APPD_FRAME_TYPE_CPP);
```

3. Call `add_to_snapshot` on the call graph. For this to work, the business transaction must be snapshotting.

```
callGraph.add_to_snapshot();
```

## Analytics Support for C++ SDK

Two of the existing API methods, which were previously only used for adding data to a snapshot, will now send Analytics data if Analytics is enabled for the current Business Transaction on the Controller:

- Set URL for a snapshot: the URL is set for a snapshot if one is occurring. The data should be either 7-bit ASCII or UTF-8. You can call this function when a snapshot does not occur. When the given Business Transaction is not snapshotting, this function returns immediately. However, if extracting the data to pass to this function is expensive, you can use `appd_bt_is_snapshotting` to check if the Business Transaction is snapshotting before extracting the data and calling this function.

```
void appd_bt_set_url(appd_bt_handle bt, const char* url);
```

- param `bt`: The business transaction to add the user data to, if it is taking a snapshot.
- param `url`: The value of the URL for the snapshot as 7-bit ASCII or UTF-8.
- Add user data to a snapshot: the data should be either 7-bit ASCII or UTF-8. You can call this function when a snapshot does not occur or if Analytics is not enabled. If the data is only for snapshotting and extracting the data to pass to this function is expensive, you can use `appd_bt_is_snapshotting` to check if the Business Transaction is snapshotting before extracting the data, and calling this function.

```
void appd_bt_add_user_data(appd_bt_handle bt, const char* key, const char* value);
```

- param `bt`: The business transaction to add the user data to, if it is taking a snapshot.
- param `key`: The name of the user data to add to the snapshot as 7-bit ASCII or UTF-8.
- param `value`: The value of the user data to add to the snapshot as 7-bit ASCII or UTF-8.

These API methods existed previously, but their behavior did not extend to reporting data to Analytics. To correctly connect to Analytics, initialize using the following configuration APIs:

```
void appd_config_set_analytics_host(struct appd_config* cfg, const char* host);
```

- param host: The host for the Analytics Agent, which defaults to `localhost`.

```
void appd_config_set_analytics_port(struct appd_config* cfg, const unsigned short port);
```

- param port: The port that the Analytics Agent listens on, which defaults to `9090`.

## Terminate the Agent

Just before the application exits, terminate the SDK:

```
appd_sdk_term();
```

## Enable SSL for the C/C++ SDK

### Related pages:

- [Use the C/C++ SDK](#)

This page explains how to configure the C/C++ Agent to connect to the Controller using SSL. To enable the SSL on the C/C++ Agent:

1. Open your application to the file where you configure the Controller settings.
2. Set `const int CONTROLLER_USE_SSL = 1;`
3. In the `appd_config` struct, include the following method:

```
appd_config_set_controller_use_ssl(cfg, CONTROLLER_USE_SSL);
```

If you are using a self-signed certificate, you must do the following:

1. Get the Controller certificate by running the following command:

```
openssl s_client -connect <hostname>:<port> -showcerts < /dev/null | openssl x509 > cert.pem
```

2. Update the `certificate_file` Controller setting to point to absolute path to certificate.

```
appd_config_set_controller_certificate_file(cfg, <Path to Cert File>);
```

## Check the Certificate `CommonName`

The certificate `CommonName` must match the Controller hostname. If they do not match, you must re-configure the certificate on the Controller.

You can check the `CommonName` by running the following command:

```
openssl s_client -connect <CONTROLLER_HOST>:<CONTROLLER_PORT> -showcerts
```

The `CommonName` appears above the `BEGIN CERTIFICATE` line.

### Related pages:

- [Use the C/C++ SDK](#)
- [C++ SDK RAII \(Resource Management Is Initialization\)](#)

This page describes the functions, structures, and environment variables defined in the C/C++ SDK to instrument C/C++ applications.

The API includes functions to create business transactions, transaction backends/exit points, and define custom metrics.

### Basic Types

The C/C++ SDK defines the following opaque types:

- `appd_bt_handle` : A handle to an active business transaction
- `appd_exitcall_handle` : A handle to an active exit call
- `struct appd_config*` : A pointer to a configuration object
- `struct appd_context_config*` : A pointer to a context configuration object

### appd\_config\_init

Initializes an empty configuration structure. Call this function before before calling `appd_sdk_init()`.

#### Format

```
APPD_API struct appd_config * appd_config_init ()
```

#### Parameters

- `cfg` : AppDynamics configuration object.

---

### **appd\_config\_set\_analytics\_enabled**

Set an enable/disable flag for Analytics Agent reporting. When disabled, Analytics-related logging messages are suppressed.

Format

```
APPD_API void appd_config_set_analytics_enabled(struct appd_config* cfg, const unsigned short enable)
```

Parameters

- `cfg` : AppDynamics configuration structure for the C/C++ SDK.
- `enable` : The enable/disable flag for the Analytics Agent. If the value is non-zero, the agent is enabled. If the value is zero (default setting), then the agent is disabled.

### **appd\_config\_set\_app\_name**

Set business application name.

Format

```
appd_config_set_app_name(cfg, APP_NAME);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `APP_NAME` : Name of the application.

### **appd\_config\_set\_tier\_name**

Set tier name.

Format

```
appd_config_set_tier_name(cfg, TIER_NAME);
```

Parameters

- `cfg`: AppDynamics configuration object.
- `TIER_NAME` : Name of the tier.

### **appd\_config\_set\_node\_name**

Set node name.

Format

```
appd_config_set_node_name(cfg, NODE_NAME);
```

Parameters

- `cfg` – AppDynamics configuration object.
- `NODE_NAME` – Name of the node.

### **appd\_config\_set\_controller\_host**

Set hostname of the Controller.

Format

```
appd_config_set_controller_host(cfg, CONTROLLER_HOST);
```

---

## Parameters

- `cfg` : AppDynamics configuration object.
- `CONTROLLER_HOST` : Name of the Controller host.

### **appd\_config\_set\_controller\_port**

Set the port number on which the Controller is listening.

#### Format

```
appd_config_set_controller_port(cfg, CONTROLLER_PORT);
```

#### Parameters

- `cfg` : AppDynamics configuration object.
- `CONTROLLER_PORT` : Port number that the Controller is listening on.

### **appd\_config\_set\_controller\_account**

Set the account name for connecting to the Controller.

#### Format

```
appd_config_set_controller_account(cfg, CONTROLLER_ACCOUNT);
```

#### Parameters

- `cfg` : AppDynamics configuration object.
- `CONTROLLER_ACCOUNT` : Account name that the Controller is connected to.

### **appd\_config\_set\_controller\_access\_key**

Set the access key for connecting to the Controller.

#### Format

```
appd_config_set_controller_access_key(cfg, CONTROLLER_ACCESS_KEY);
```

#### Parameters

- `cfg` : AppDynamics configuration object.
- `CONTROLLER_ACCESS_KEY` : Access key for connecting to the Controller.

### **appd\_config\_set\_controller\_use\_ssl**

Specify whether SSL should be used to communicate with the Controller.

#### Format

```
appd_config_set_controller_use_ssl(cfg, CONTROLLER_USE_SSL);
```

#### Parameters

- `cfg` : AppDynamics configuration object.
- `CONTROLLER_USE_SSL` : Whether to use SSL to connect with the Controller. Set to a non-zero integer for true. Set to the integer zero for false. Note that SaaS Controllers require this to be set to non-zero.

### **appd\_config\_set\_controller\_http\_proxy\_host**

Optional. Set the hostname of the HTTP proxy if using an HTTP proxy to talk to Controller.

---

## Format

```
appd_config_set_controller_http_proxy_host(cfg, CONTROLLER_HTTP_PROXY_HOST);
```

## Parameters

- `cfg` : AppDynamics configuration object.
- `CONTROLLER_HTTP_PROXY_HOST` : Hostname of the HTTP proxy if using an HTTP proxy to talk to Controller.

## **appd\_config\_set\_controller\_http\_proxy\_port**

Optional. Set the port number of the HTTP proxy. Default is 80.

## Format

```
appd_config_set_controller_http_proxy_port(cfg, CONTROLLER_HTTP_PROXY_PORT);
```

## Parameters

- `cfg` : AppDynamics configuration object.
- `CONTROLLER_HTTP_PROXY_PORT` : Port name of the HTTP proxy. Default is 80.

## **appd\_config\_set\_controller\_http\_proxy\_username**

Optional. Set the username to connect to the HTTP proxy with.

## Format

```
appd_config_set_controller_http_proxy_username(cfg, CONTROLLER_HTTP_PROXY_USERNAME);
```

## Parameters

- `cfg` : AppDynamics configuration object.
- `CONTROLLER_HTTP_PROXY_USERNAME` : Username to connect to the HTTP proxy with.

## **appd\_config\_set\_controller\_http\_proxy\_password**

Optional. Set the password to connect to the HTTP proxy with.

## Format

```
appd_config_set_controller_http_proxy_password(cfg, CONTROLLER_HTTP_PROXY_PASSWORD);
```

## Parameters

- `cfg` : AppDynamics configuration object.
- `CONTROLLER_HTTP_PROXY_PASSWORD` : Password to connect to the HTTP proxy with.

## **appd\_config\_set\_controller\_http\_proxy\_password\_file**

Optional. Set the file containing password to connect to the HTTP proxy with.

## Format

```
appd_config_set_controller_http_proxy_password_file(cfg,
CONTROLLER_HTTP_PROXY_PASSWORD_FILE);
```

## Parameters

- `cfg` : AppDynamics configuration object.
- `CONTROLLER_HTTP_PROXY_PASSWORD_FILE` : File containing password to connect to the HTTP proxy with.

### appd\_config\_set\_controller\_certificate\_file

Optional. Set the the CA certificate file name. Set this if you choose to use your own certificate file.

Format

```
appd_config_set_controller_certificate_file(cfg, CONTROLLER_HTTP_CERTIFICATE_FILE);
```

Parameters

- `cfg` : AppDynamics configuration object.
- `CONTROLLER_CERTIFICATE_FILE` : Name of the certificate file. Defaults to the included `ca-bundle.crt` file.

### appd\_config\_set\_controller\_certificate\_dir

Optional. Set the full path to the CA certificate file. Set this if you have multiple certificate files.

Format

```
appd_config_set_controller_certificate_dir(cfg, CONTROLLER_HTTP_CERTIFICATE_DIR);
```

Parameters

- `cfg` : AppDynamics configuration object.
- `CONTROLLER_CERTIFICATE_DIR` : Full path to the certificate files.

### appd\_config\_set\_flush\_metrics\_on\_shutdown

Specify whether to collect metrics in the final minute before SDK shutdown—via `appd_sdk_term`. By default, metrics reported in the minute before shutdown are lost. If you enable metric flushing, then you can retain the metrics reported in the final minute before shutdown.

Format

```
APPD_API void appd_config_set_flush_metrics_on_shutdown(struct appd_config* cfg, int enable);
```

Parameters

- `cfg` : AppDynamics configuration object.
- `int` : Set to a non-zero integer to enable flushing metrics to the Controller. Default is 0.

**i** By setting this flag, the `appd_sdk_term()` is blocked until the underpinning agent logic has uploaded the metric data. By not using this flag, any metrics collected since the last Controller update is discarded. Depending on the load on the Controller, flushing the metrics can take anywhere between 60 and 120 seconds on average or longer. Do not use this flag if you need the termination/tear-down logic to complete immediately.

### appd\_config\_set\_logging\_min\_level

Set the minimum level of logging that is allowed. If `APPD_LOG_LEVEL_TRACE`, all log messages are allowed. If `APPD_LOG_LEVEL_FATAL`, only the most severe errors are logged. The default is `APPD_LOG_LEVEL_INFO`.

Format

```
appd_config_set_logging_min_level(cfg, LOGGING_MIN_LEVEL);
```

#### Parameters

- `cfg` : AppDynamics configuration object.
- `LOGGING_MIN_LEVEL` : The minimum level of logging that is allowed.
- `APPD_LOG_LEVEL_TRACE`
- `APPD_LOG_LEVEL_DEBUG`
- `APPD_LOG_LEVEL_INFO`
- `APPD_LOG_LEVEL_WARN`
- `APPD_LOG_LEVEL_ERROR`
- `APPD_LOG_LEVEL_FATAL`

#### `appd_config_set_logging_log_dir`

Set the directory to log to. The process running the SDK must have permissions to create this directory, if it does not already exist, to list the files within it, and to write to the files within it.

#### Format

```
appd_config_set_logging_log_dir(cfg, LOGGING_LOG_DIR);
```

#### Parameters

- `cfg` : AppDynamics configuration object.
- `LOGGING_LOG_DIR` : The directory where you want to store log files. Defaults to `/tmp/appd`.

#### `appd_config_set_logging_max_num_files`

Set the maximum number of log files allowed per tenant. Log files are rotated when they reach this number.

#### Format

```
appd_config_set_logging_max_num_files(cfg, LOGGING_MAX_NUM_FILES);
```

#### Parameters

- `cfg` : AppDynamics configuration object.
- `LOGGING_MAX_NUM_FILES` : The maximum number of log files allowed per tenant. Default is 10.

#### `appd_config_set_logging_max_file_size_bytes`

Set the maximum size of an individual log file, in bytes. Log files are rotated when they reach this size.

#### Format

```
appd_config_set_logging_max_file_size_bytes(cfg, LOGGING_MAX_FILE_SIZE_BYTES);
```

#### Parameters

- `cfg` : AppDynamics configuration object.
- `LOGGING_MAX_FILE_SIZE_BYTES` : The maximum size of an individual log file, in bytes. Default is `5 * 1024 * 1024`.

#### `appd_config_set_init_timeout_ms`

Set the number of milliseconds you want `appd_sdk_init` (an asynchronous action) to wait until it has received controller configuration and is ready to capture business transactions. Set this if you want to capture short-running business transactions that occur at application startup and you don't mind the delay of waiting for the Controller to send the configuration.

#### Format

```
appd_config_set_init_timeout_ms(cfg, INIT_TIMEOUT_MS);
```

### Parameters

- `cfg`: AppDynamics configuration object.
- `INIT_TIMEOUT_MS`: The number of milliseconds you want `appd_sdk_init` (an asynchronous action) to wait until it has received controller configuration and is ready to capture business transactions.
  - X: Wait up to X milliseconds for Controller configuration.
  - 0: Do not Wait for Controller configuration.
  - -1: Wait indefinitely until Controller configuration is received by agent
  - Default is 0.

### appd\_config\_getenv

Set the environment variable for configuring the SDK. Environment variables are not read by default. You must call this function to configure the SDK via environment variables.

For a list of available environment variables, see [Environment Variables](#).

### Format

```
APPD_API void appd_config_getenv(struct appd_config * cfg, const char * prefix);
```

### Parameters

- `cfg`: AppDynamics configuration object.
- `prefix`: The prefix of the environment variable name, where the environment variable name is <prefix>.<base>.

### appd\_context\_config\_init

Initializes and returns an empty context configuration structure.

### Format

```
APPD_API struct appd_context_config* appd_context_config_init(const char* context_name)
```

### Parameters

- `context_name`: Name for this context.

### appd\_context\_config\_set\_controller\_host

Add the Controller host to the application context.

### Format

```
APPD_API void appd_context_config_set_controller_host (struct appd_context_config * context_cfg, const char * host)
```

### Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier and node name for this context.
- `host`: Name of the Controller host.

### appd\_context\_config\_set\_controller\_port

Add the Controller port to the application context.

### Format

---

```
APPD_API void appd_context_config_set_controller_port (struct appd_context_config
* context_cfg, const unsigned short port)
```

#### Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `port`: Port number that the Controller is listening on.

#### **appd\_context\_config\_set\_controller\_account**

Add the Controller port to the application context.

#### Format

```
APPD_API void appd_context_config_set_controller_port (struct appd_context_config
* context_cfg, const char * acct)
```

#### Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `account`: Account name that the Controller is connected to.

#### **appd\_context\_config\_set\_controller\_access\_key**

Add the Controller access key to the application context.

#### Format

```
APPD_API void appd_context_config_set_controller_port (struct appd_context_config
* context_cfg, const char * key)
```

#### Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `key`: Access key for connecting to the Controller.

#### **appd\_context\_config\_set\_controller\_use\_ssl**

Add the Controller access key to the application context.

#### Format

```
APPD_API void appd_context_config_set_controller_port (struct appd_context_config
* context_cfg, unsigned int * ssl)
```

#### Parameters

- `context_cfg`: An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `ssl`: Set to a non-zero integer for true. Set to the integer zero for false. Note that SaaS Controllers require this to be set to non-zero.

#### **appd\_context\_config\_set\_controller\_http\_proxy\_host**

Optional. Set the hostname of the HTTP proxy if using an HTTP proxy to talk to controller.

#### Format

---

```
APPD_API void appd_context_config_set_controller_http_proxy_host(struct appd_context_config
* context_cfg, const char * host);
```

#### Parameters

- `context_cfg` : An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `host` : Hostname of the HTTP proxy if using an HTTP proxy to talk to Controller.

#### **appd\_context\_config\_set\_controller\_http\_proxy\_port**

Optional. Set the hostname of the HTTP proxy if using an HTTP proxy to talk to Controller.

#### Format

```
APPD_API void appd_context_config_set_controller_http_proxy_host(struct
appd_context_config * context_cfg, const unsigned short port);
```

#### Parameters

- `context_cfg` : An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `port` : Port name of the HTTP proxy. Default is 80.

#### **appd\_context\_config\_set\_controller\_http\_proxy\_username**

Optional. Set the username to connect to the HTTP proxy with.

#### Format

```
APPD_API void appd_context_config_set_controller_http_proxy_host(struct
appd_context_config * context_cfg, const char * user);
```

#### Parameters

- `context_cfg` : An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `user` : Username to connect to the HTTP proxy with.

#### **appd\_context\_config\_set\_controller\_http\_proxy\_password**

Optional. Set the password to connect to the HTTP proxy with.

#### Format

```
APPD_API void appd_context_config_set_controller_http_proxy_host(struct
appd_context_config * context_cfg, const char * pwd);
```

#### Parameters

- `context_cfg` : An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `pwd` : Password to connect to the HTTP proxy with.

#### **appd\_context\_config\_set\_controller\_http\_proxy\_password\_file**

Optional. Set the password to connect to the HTTP proxy with.

#### Format

```
APPD_API void appd_context_config_set_controller_http_proxy_host(struct
appd_context_config * context_cfg, const char * file);
```

#### Parameters

- `context_cfg` : An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `file` : File containing password to connect to the HTTP proxy with.

#### **appd\_context\_config\_set\_controller\_certificate\_file**

Optional. Set the CA certificate file name. Set this if you choose to use your own certificate file.

#### Format

```
APPD_API void appd_context_config_set_controller_http_proxy_host(struct
appd_context_config * context_cfg, const char * file);
```

#### Parameters

- `context_cfg` : An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `file` : Name of the certificate file. Defaults to the included `ca-bundle.crt` file.

#### **appd\_context\_config\_set\_controller\_certificate\_dir**

Optional. Set the full path to the CA certificate file. Set this if you have multiple certificate files.

#### Format

```
APPD_API void appd_context_config_set_controller_http_proxy_host(struct
appd_context_config * context_cfg, const char * dir);
```

#### Parameters

- `context_cfg` : An AppDynamics context configuration object indicating the business application, tier, and node name for this context.
- `dir` : Full path to the certificate files.

#### **appd\_custom\_event\_start**

This function starts the definition of a custom event. Returns a handle to the defined event. By calling `appd_custom_event_end()`, the definition of the event is signaled as complete. The event handle returns null on failure.

#### Format

```
APPD_API appd_event_handle appd_custom_event_start(const char* application_context,
enum appd_event_severity severity, const char* event_sub_type, const char* summary)
```

#### Parameters

- `application_context` : This string picks one agent out of multiple agents running in multi-tenant mode. If the value is null, the default agent is used.
- `severity` : This is an enum representing the severity of the event. Valid values are `APPD_EVENT_SEVERITY_INFO`, `APPD_EVENT_SEVERITY_WARNING`, and `APPD_EVENT_SEVERITY_ERROR`.
- `event_sub_type` : The string containing the subtype of the custom event. This can be used in the Controller to filter the custom events belonging to a specific subtype.
- `summary` : A string with a brief description of the event.

---

## appd\_custom\_event\_add\_detail

This function adds a detail made up of a name and a value to the definition of a custom event. Returns a non-zero value on success, otherwise zero. This call can be made between the calls of `appd_custom_event_start()` and `appd_custom_event_end()`. This function can be called multiple times to add details to the event. The event handle returned by `appd_custom_event_start()` identifies the right event to add the detail to. If multiple calls to this function are made with the same detail name, then the detail value from the most recent call will be used to associate that detail name.

### Format

```
APPD_API int appd_custom_event_add_detail(appd_event_handle event_handle, const char* detail_name, const char* detail_value)
```

### Parameters

- `detail_name` : This string contains the name of the detail that needs to be added. If the value is null or empty, the API fails and returns zero.
- `detail_value` : This string contains the name of the value that needs to be added. If the value is null or empty, the API fails and returns zero.
- `event_handle` : Refers to the event to which the detail needs to be added to. If the value is null or invalid, the API fails and returns zero.

## appd\_custom\_event\_add\_property

This function adds a property made up of a name and a value to the definition of a custom event. Returns a non-zero value on successful, otherwise zero. This call can be made between the calls of `appd_custom_event_start()` and `appd_custom_event_end()`. This function can be called multiple times to add properties to the event. The event handle returned by `appd_custom_event_start()` identifies the right event to add the property to. This property can be used in the Controller to filter the custom events. If multiple calls to this function are made with the same property name, then the property value from the most recent call will be used to associate that property name.

### Format

```
APPD_API int appd_custom_event_add_property(appd_event_handle event_handle, const char* property_name, const char* property_value)
```

### Parameters

- `event_handle` : Refers to the event to which the property needs to be added to. If the value is null or invalid, the API fails and returns zero.
- `property_name` : This string contains the name of the property to be added. If the value is null or empty, the API fails and returns zero.
- `property_value` : This string contains the value of the property to be added. If the value is null or empty, the API fails and returns zero.

## appd\_custom\_event\_end

Signals to the C++ SDK that the event definition is complete and queues the event to be sent to the Controller. Returns a zero value on success, otherwise a non-zero value.

### Format

```
APPD_API int appd_custom_event_end(appd_event_handle event_handle)
```

### Parameters

- `event_handle` : Used to refer to the event. If the value is null or invalid, the API fails and returns zero.

### **appd\_eum\_get\_cookie**

Returns an EUM-ADRUM cookie for a business transaction in an EUM-enabled browser application. You can call this function between `appd_bt_begin()` and `appd_bt_end()`.

At this time, `appd_eum_get_cookie` works only on snapshots that contain call graphs. See [Correlate Business Transactions for EUM](#) for more information.

#### Format

```
APPD_API const char* appd_eum_get_cookie(appd_bt_handle bt, int https, int short_form,
const char* referrer_url, const char* path)
```

#### Parameters

- `bt` : The handle to the business transaction that the EUM-ADRUM cookie is generated for.
- `https` : When set to a non-zero value, this flag indicates that the incoming request uses the HTTPS protocol. This flag is used to make the EUM cookie secure.
- `short_form` : When set to a non-zero value, this flag indicates that shortened names will be used for sub-cookie names inside the EUM cookie.
- `referrer_url` : The URL of the page from which user made the request. This can be set to `NULL` or `""` if the referrer URL is unknown.
- `path` : The URL path where the cookie will be stored. This can be set to `"/"` in most cases. If set to `NULL` or `""`, the default value `"/"` is used.

#### Returns

On success, the function returns a string that contains a cookie key and a cookie value separated by `=`. Do not free the memory associated with the returned cookie string; when you call `appd_bt_end()`, memory is automatically released.

If EUM is disabled or no configuration information has been received from the Controller, then `NULL` is returned.

### **appd\_sdk\_add\_app\_context**

Initialize the AppDynamics SDK.

#### Format

```
APPD_API int appd_sdk_add_app_context (struct appd_context_config * context_cfg)
```

#### Parameters

- `context_cfg` : An AppDynamics context configuration object indicating the business application, tier, and node name for this context.

### **appd\_sdk\_init**

Initialize the AppDynamics C/C++ SDK. An instrumented application must call this function once, preferably during application startup.

**i** When using `fork()`, the `appd_sdk_init()`, and all other SDK calls, should occur only in the forked process, never in the parent, and each child should behave as its own process, and never share handles between the process itself and other SDK instrumented child processes.

#### Format

```
APPD_API int appd_sdk_init (const struct appd_config * config)
```

#### Parameters

- `config`: AppDynamics configuration settings that enable communication between the agent and the Controller.

#### Returns

Zero on success, otherwise a non-zero value. If the return value is not zero, a log message describes the error.

#### **appd\_sdk\_term**

Stop the C/C++ SDK. Ends all active business transactions for this agent and stops agent metric reporting to the controller.

**i** If you execute the agent for less than a few minutes, the agent may not have enough time to fully report to the Controller, as this action is done once every 60 seconds. To ensure that any remaining data is transmitted to the Controller, wait at least one minute before issuing the `appd_sdk_term()` call.

#### Format

```
APPD_API void appd_sdk_term()
```

#### **appd\_bt\_begin**

Start a Business Transaction or continue an existing transaction.

Keep in mind that each application is limited to 200 registered business transactions, and each agent is limited to 50 registered business transactions. Like transactions discovered by other types of agents, business transactions that exceed the limit that are reported by the C/C++ SDK are included in the "all other traffic" grouping. Ensure that your agent does not create excessive business transactions and that your implementation does not introduce the possibility of business transaction explosion.

#### Format

```
APPD_API appd_bt_handle appd_bt_begin (const char * name, const char * correlation_header)
```

#### Parameters

- `name`: The name for the business transaction. In the case of a continuing transaction in the current business application with a valid correlation header, the SDK uses the name from the header. Do not use the following characters in transaction names: `{ } [ ] | &`;

- `correlation_header` : A correlation header if this is a continuing transaction, else `NULL` . If specified, the correlation header has been generated by another AppDynamics agent and made available to this agent as a string. The correlation header provides information to enable this transaction to correlate with an upstream transaction.

## Returns

An opaque handle for the business transaction that was started.

## `appd_bt_begin_with_app_context`

Start a business transaction or continue an existing transaction in a multi-tenant Controller environment.

## Format

```
APPD_API appd_bt_handle appd_bt_begin_with_app_context (const char * context, const char * name, const char * correlation_header)
```

## Parameters

- `context` : The application context name that this business transaction belongs to.
- `name` : The name for the business transaction. In the case of a continuing transaction in the current business application with a valid correlation header, the SDK uses the name from the header. Do not use the following characters in transaction names: { } [ ] & ;
- `correlation_header` : A correlation header if this is a continuing transaction, else `NULL` . If specified, the correlation header has been generated by another AppDynamics agent and made available to this agent as a string. The correlation header provides information to enable this transaction to correlate with an upstream transaction.

## `appd_bt_enable_snapshot`

Enables a snapshot for a given business transaction. This call can be made between the calls of `appd_bt_begin()` and `appd_bt_end()` . Returns a non-zero value if the snapshot is successfully enabled, otherwise returns a zero.

## Format

```
APPD_API int appd_bt_enable_snapshot(appd_bt_handle bt)
```

## Parameters

- `bt` : The handle to the business transaction for which the snapshot needs to be enabled.

## `appd_bt_end`

End the given business transaction.

## Format

```
APPD_API void appd_bt_end (appd_bt_handle bt)
```

## Parameters

- `bt` : The handle to the business transaction to end.

## `appd_bt_get`

Get a BT handle associated with the given GUID by `appd_bt_store` .

## Format

```
APPD_API appd_bt_handle appd_bt_get (const char * guid)
```

## Parameters

- `guid` : The globally unique identifier that was passed to `appd_bt_store` .

## Returns

The handle to the business transaction associated with the given GUID.

In the following cases the SDK logs a warning and returns a handle that you may safely use in other API functions but that will cause these functions to immediately return without doing anything:

- The SDK does not find a handle associated with the GUID.
- The call ended before the SDK could retrieve the handle.

## `appd_bt_is_snapshotting`

Reports whether the agent is currently taking a transaction snapshot. Useful before calling `appd_add_user_data()` or `appd_bt_set_url()` , since those potentially expensive functions would do nothing if called when a snapshot is not being taken.

### Format

```
APPD_API char appd_bt_is_snapshotting (appd_bt_handle bt)
```

### Parameters

- `bt` : The handle to the business transaction to check for snapshotting.

### Returns

Non-zero if the given business transaction is taking a snapshot. Otherwise, zero.

## `appd_bt_set_url`

Set URL for a snapshot (if one is being taken).

URL is set for a snapshot if one is occurring. Data should be either 7-bit ASCII or UTF-8.

It is safe to call this function when a snapshot is not occurring. When the given business transaction is NOT snapshotting, this function immediately returns. However, if extracting the data to pass to this function is expensive, you can use `appd_bt_is_snapshotting` to check if the business transaction is snapshotting before extracting the data and calling this function.

### Format

```
APPD_API void appd_bt_set_url (appd_bt_handle bt, const char * url)
```

### Parameters

- `bt` : The business transaction to add the user data to, if it's taking a snapshot.
- `url`: The value of the URL for the snapshot as 7-bit ASCII or UTF-8.

## `appd_bt_override_start_time_ms`

Takes a time, in milliseconds, representing the number of milliseconds elapsed since Jan 1, 1970 UTC. The time specified for this function overrides the default start time, which is the time at which the `appd_bt_begin()` API is called according to the system clock. By overriding the start time with a specific value, the BT internal start time is disabled, and the specified start time is reported to the Controller.

This function is located in the `appdynamics_advanced.h` file, and is only used in special cases.

#### Format

```
APPD_API void appd_bt_override_start_time_ms(appd_bt_handle bt, unsigned int timeMS);
```

#### Parameters

- `bt` : The business transaction to override the timing of
- `timeMS` : Time in milliseconds since start of epoch (midnight, Jan 1, 1970 UTC).

### **appd\_bt\_override\_time\_ms**

Takes a time, in milliseconds, that overrides the business transaction response time as reported for this business transaction to the Controller.

The C/C++ SDK maintains its own, internal timer for the response time for the business transaction. This timer reflects the elapsed time spent between the `bt_begin` and `bt_end` calls. In some cases, you may want to set the business transaction timer directly, overriding the default business transaction response timer. For instance, this may be useful for integrating external monitoring systems with AppDynamics.

It is important to note that when calling this function, the reported business transaction will be either the time you specify or the sum of all exit call timings for the transaction, whichever is greatest. This is because a business transaction cannot be reported to take less time than the total of the exit calls it contains.

This function is located in the `appdynamics_advanced.h` file, and is only used in special cases.

#### Format

```
APPD_API void appd_bt_override_time_ms(appd_bt_handle bt, unsigned int timeMS);
```

#### Parameters

- `bt` : The business transaction for which to set the response time.
- `timeMS` : The time the business transaction took, in milliseconds.

### **appd\_bt\_store**

Store a BT handle for retrieval with `appd_bt_get`.

This function allows you to store a BT in a global registry to retrieve later. This is convenient when you need to start and end a BT in separate places, and it is difficult to pass the handle to the BT through the parts of the code that need it.

When the BT is ended, the handle is removed from the global registry.

#### Format

```
APPD_API void appd_bt_store (appd_bt_handle bt, const char * guid)
```

#### Parameters

- `bt`: The BT to store.
- `guid`: A globally unique identifier to associate with the given BT.

#### Example

```
int begin_transaction(uint64_t txid, uint64_t sku, float price)
```

```

{
 appd_bt_handle bt = appd_bt_begin("payment-processing", NULL);
 appd_bt_store(bt, std::to_string(txid).c_str());
 // ...
}

```

## appd\_bt\_add\_error

Add an error to a business transaction.

Errors are reported as part of the business transaction. However, you can add an error without marking the business transaction as an error (e.g., for non-fatal errors).

### Format

```

APPD_API void appd_bt_add_error (appd_bt_handle bt, enum appd_error_level level,
const char * message, int mark_bt_as_error)

```

### Parameters

- `bt`: The handle to the business transaction to which the error is added.
- `level`: The error levels are `APPD_LEVEL_NOTICE`, `APPD_LEVEL_WARNING`, and `APPD_LEVEL_ERROR`.
- `message`: Error message for this error.
- `mark_bt_as_error`: If true, the business transaction experiencing this error is marked as an error transaction. In this case, the business transaction is counted only as an error transaction. It is not also counted as a slow, very slow or stalled transaction, even if the transaction was also slow or stalled. If false, the business transaction is not marked as an error transaction.

## appd\_bt\_add\_user\_data

Attaches user data to transaction snapshots generated for the specified business transaction.

The user data is added to the business transaction but reported only when a transaction snapshot is occurring. In the Controller UI, the user data appears in the **Business Data** tab of the transaction snapshot details.

It is safe to call this function when a snapshot is not occurring. When the specified business transaction is not taking a snapshot, this function immediately returns.

If extracting the data to pass to this function is expensive, you can use `appd_bt_is_snapshotting()` to check if the business transaction is actually taking a snapshot before extracting the data and calling this function.

Data should be either 7-bit ASCII or UTF-8.

### Format

```

APPD_API void appd_bt_add_user_data (appd_bt_handle bt, const char * key, const char
* value)

```

### Parameters

- `bt`: The business transaction to add the user data to, if it's taking a snapshot.
- `key`: The name of the user data to add to the snapshot as 7-bit ASCII or UTF-8.
- `value`: The value of the user data to add to the snapshot as 7-bit ASCII or UTF-8.

---

## appd\_backend\_add

Add a declared backend to the current business application. Use `appd_backend_declare` to declare a backend before adding it.

This function fails if the type of the backend being added does not have at least one identifying property.

### Format

```
APPD_API int appd_backend_add (const char * backend)
```

### Parameters

- `backend`: Pointer to the backend.

### Returns

Zero on success, otherwise a non-zero value. If the return value is not zero, a log message describes the error.

## appd\_backend\_declare

Declare the existence of a backend. Call this only if the backend is not already registered with the C++ SDK instance.

### Format

```
APPD_API void appd_backend_declare (const char * type, const char * unregistered_name)
```

### Parameters

- `type`: The type of the backend, from these options:
  - `APPD_BACKEND_HTTP`
  - `APPD_BACKEND_DB`
  - `APPD_BACKEND_CACHE`
  - `APPD_BACKEND_RABBITMQ`
  - `APPD_BACKEND_WEBSERVICE`
  - `APPD_BACKEND_JMS`
- `unregistered_name`: The name of the backend. Must be unique to the C++ SDK instance.

## appd\_backend\_prevent\_agent\_resolution

Call to prevent a downstream agent from resolving as this backend. If used, this must be called before `appd_backend_add()`.

Normally, if an agent picks up a correlation header for an unresolved backend, it will resolve itself as that backend. This is usually the desired behavior.

However, if the backend is actually an uninstrumented tier that is passing through the correlation header (for example, a message queue or proxy), then you may wish the backend to show up distinct from the tier that it routes to. If you call this function, correlation headers generated for exit calls to this backend in the SDK will instruct downstream agents to report as distinct from the backend.

For example: if you have Tier A talking to uninstrumented Backend B which routes to instrumented Tier C, if you do NOT call this function, the flow map will be A > C. If you DO call this function, the flow map will be A > B > C.

### Format

```
APPD_API int appd_backend_prevent_agent_resolution (const char * backend)
```

#### Parameters

- `backend`: Pointer to the declared backend.

#### Returns

Zero on success, otherwise a non-zero value. If the return value is not zero, a log message describes the error.

### appd\_backend\_set\_identifying\_property

Sets an identifying property of a backend. Call once for every identifying property that you want to set. Call this function after `appd_backend_declare()` and before `appd_backend_add()`.

A backend's identifying properties uniquely identify the downstream component being called. In the Controller UI, these properties are visible in the upper right panel of the backend dashboards.

You must set at least one identifying property when you add a backend of one of the built-in exit call types. The valid properties vary by the following exit call type.

Exit Call Type	Valid Identifying Properties
APPD_BACKEND_HTTP	HOST , PORT , URL , QUERY STRING
APPD_BACKEND_DB	HOST , PORT , DATABASE , VENDOR , VERSION
APPD_BACKEND_CACHE	SERVER POOL , VENDOR
APPD_BACKEND_RABBITMQ	HOST , PORT , ROUTING KEY , EXCHANGE
APPD_BACKEND_WEBSERVICE	SERVICE , URL , OPERATION , SOAP ACTION , VENDOR
APPD_BACKEND_JMS	DESTINATION , DESTINATIONTYPE , VENDOR
APPD_BACKEND_WEBSPHEREMQ	HOST , PORT , DESTINATION , DESTINATIONTYPE , MAJOR VERSION , VENDOR

#### Format

```
APPD_API int appd_backend_set_identifying_property (const char * backend, const char * key, const char * value)
```

#### Parameters

- `backend`: Pointer to the backend.
- `key`: Name of the property. For example, DESTINATION or PORT.
- `value`: Value of the property. For example, Order Queue or 3304

## Returns

Zero on success, otherwise a non-zero value. If the return value is not zero, a log message describes the error.

## appd\_custom\_metric\_add

Report a custom metric.

### Format

```
APPD_API void appd_custom_metric_add (const char * application_context, const char * metric_path, enum appd_time_rollup_type time_rollup_type, enum appd_cluster_rollup_type cluster_rollup_type, enum appd_hole_handling_type hole_handling_type)
```

### Parameters

- `application_context`: The application context for this custom metric.
- `metric_path`: The path of the custom metric. This path defines where the custom metric appears in the Metric Browser. Use a pipe character to separate branches in the path. For example, `Custom Metrics|MyCustomMetric` defines `MyCustomMetric` as a top-level metric in the tree.
- `time_rollup_type`: Specifies how to rollup metric values for this metric over time, from the following:
  - `APPD_TIMEROLLUP_TYPE_AVERAGE`: Compute the average value of the metric over time.
  - `APPD_TIMEROLLUP_TYPE_SUM`: Compute the sum of the value of the metric over time.
  - `APPD_TIMEROLLUP_TYPE_CURRENT`: Report the current value of the metric.
- `cluster_rollup_type`: Specifies how to rollup metric values for this metric across clusters, from the following:
  - `APPD_CLUSTERROLLUP_TYPE_INDIVIDUAL`: Roll-up the value individually for each member of the cluster.
  - `APPD_CLUSTERROLLUP_TYPE_COLLECTIVE`: Roll-up the value across all members of the cluster.
- `hole_handling_type`: Specifies how to handle holes—gaps where no value has been reported from this metric, from the following:
  - `APPD_HOLEHANDLING_TYPE_RATE_COUNTER`: Considers the gap or 0 value to be meaningful in the aggregation of the metric.
  - `APPD_HOLEHANDLING_TYPE_REGULAR_COUNTER`: Does not consider the gap or 0 value to be meaningful in the aggregation of the metric.

For additional information on these parameters, see [Create Custom Metrics](#).

## appd\_custom\_metric\_report

Report a value for a given metric.

### Format

```
APPD_API void appd_custom_metric_report (const char * application_context, const char * metric_path, long value)
```

### Parameters

- `application_context`: The application context for this custom metric.
- `metric_path`: The path of the metric to report, as defined by `appd_custom_metric_add`.
- `value`: The value to report for the metric. The way the value is aggregated is specified by the roll-up parameters to `appd_custom_metric_add`.

## appd\_exitcall\_add\_error

Add an error to the exit call.

### Format

---

```
APPD_API void appd_exitcall_add_error (appd_exitcall_handle exitcall, enum
appd_error_level level, const char * message, int mark_bt_as_error)
```

### Parameters

- `exitcall` : Handle to the exit call.
- `level` : The level of this error are `APPD_LEVEL_NOTICE` , `APPD_LEVEL_WARNING` , and `APPD_LEVEL_ERROR` .
- `message` : Error message for this error.
- `mark_bt_as_error` : If true, the business transaction making the exit call that is experiencing this error is marked as an error transaction. In this case, the business transaction is counted only as an error transaction. It is not also counted as a slow, very slow or stalled transaction, even if the transaction was also slow or stalled. If false, the business transaction is not marked as an error transaction.

### **appd\_exitcall\_begin**

Start an exit call to the specified backend as part of a business transaction.

### Format

```
APPD_API appd_exitcall_handle appd_exitcall_begin (appd_bt_handle bt, const char * ba
ckend)
```

### Parameters

- `bt` : Handle to the business transaction making the exit call.
- `backend` : The destination backend of the exit call. AppDynamics does not automatically detect backends for Go applications, so you must specify the destination backend.

### Returns

An opaque handle to the exit call that was started.

### **appd\_exitcall\_end**

Complete the exit call.

### Format

```
APPD_API void appd_exitcall_end (appd_exitcall_handle exitcall)
```

### Parameters

- `exitcall` : Handle to the exit call being ended.

### **appd\_exitcall\_get**

Get a handle to an exit call associated with a GUID via `appd_exitcall_store()` .

### Format

```
APPD_API appd_exitcall_handle appd_exitcall_get (const char * guid)
```

### Parameters

- `guid` : The globally unique identifier that was passed to `appd_exitcall_store()` .

### Returns

The handle to the exit call associated with the given GUID.

In the following cases, the SDK logs a warning and returns a handle that you may safely use in other API functions but that will cause these functions to immediately return without doing anything:

- The SDK doesn't find a handle associated with the GUID.
- The call ended before the SDK could retrieve the handle.

### **appd\_exitcall\_get\_correlation\_header**

Get the header for correlating a business transaction.

If a business transaction makes exit calls that you wish to correlate across, you should retrieve the correlation header and inject it into your exit call's payload.

The returned string is freed when the exit call ends. Do not free it yourself.

Format

```
APPD_API const char* appd_exitcall_get_correlation_header
(appd_exitcall_handle exitcall)
```

Parameters

- `exitcall`: Handle to the exit call.

Returns

On success returns a 7-bit ASCII string containing the correlation information. You can inject this string into the exit call's payload. A downstream agent can then extract the header from that payload and continue the business transaction.

On error, returns the default header that prevents downstream business transaction detection.

### **appd\_exitcall\_override\_start\_time\_ms**

Takes a time, in milliseconds, representing the number of milliseconds elapsed since Jan 1, 1970 UTC. The time specified for this function overrides the default start time, which is the time at which the `appd_exitcall_begin()` API is called according to the system clock. By overriding the start time with a specific value, the exit call's internal start time is disabled, and the specified start time is reported to the Controller.

This function is located in the `appdynamics_advanced.h` file, and is only used in special cases.

Format

```
APPD_API void appd_exitcall_override_time_ms(appd_exitcall_handle exitCall, int64_t timeMS);
```

Parameters

- `exitCall`: The exit call for which to override the start time
- `timeMS`: The time that you want to override the exit call start time

### **appd\_exitcall\_override\_time\_ms**

Takes a time, in milliseconds, that overrides the exit call time reported to the Controller.

The C/C++ SDK maintains its own internal timer for the time it takes to complete the exit call. In some cases, you may want to disable the exit call's internal timer. For instance, this can be useful for reporting exit calls that are recorded in external monitoring systems and read into an SDK program.

This function is located in the `appdynamics_advanced.h` file, and is only used in special cases.

## Format

```
APPD_API void appd_exitcall_override_time_ms(appd_exitcall_handle exitCall, int64_t timeMS);
```

## Parameters

- `exitCall` : The exit call for which to set the completion time
- `timeMS` : The time that you want to override the exit call time.

## appd\_exitcall\_set\_details

Set the details string for an exit call. This can be used, for example, to add the SQL statement that a DB backend has executed as part of the exit call. This data is then visible in the exit calls details UI for the transaction snapshot.

## Format

```
APPD_API int appd_exitcall_set_details (appd_exitcall_handle exitcall, const char * details)
```

## Parameters

- `exitcall` : Handle to the exit call.
- `details` : An arbitrary string to add to the exit call.

## Returns

Zero on success, otherwise a non-zero value. If the return value is not zero, a log message describes the error.

## appd\_exitcall\_store

Store an exit call handle for retrieval with `appd_exitcall_get()` .

This function allows you to store an exit call in a global registry to retrieve later. This is convenient when you need to start and end the call in separate places, and it is difficult to pass the handle through the parts of the code that need it.

The handle is removed when the exit call (or the BT containing it) ends.

## Format

```
APPD_API void appd_exitcall_store (appd_exitcall_handle exitcall, const char * guid)
```

## Parameters

- `exitcall` : The exit call to store.
- `guid` : A globally unique identifier to associate with the given call.

## Example

```
appd_exitcall_handle ec = appd_exitcall_begin(bt, "authdb");
appd_exitcall_store(ec, "login-exit");
```

## appd\_frame\_begin

Records the start of a method call in the call stack. To track the duration of your method call, you must call `appd_frame_begin` near the start of the method code, and `appd_frame_end` when the method returns.

### Format

```
APPD_API appd_frame_handle appd_frame_begin(appd_bt_handle bt, enum appd_frame_type
frame_type,
const char* class_name, const char* method_name, const char* file, unsigned int
line_number);
```

### Parameters

- `bt` : The business transaction for the call graph.
- `frame_type` : The type of the frame. When used in C or C++ code, use `APPD_FRAME_TYPE_CPP` .
- `class_name` : The name of the class if this method is a member of the class. This value cannot be NULL.
- `method_name` : The name of the method. This value cannot be NULL.
- `file` : The path of the source file.
- `line_number` : The line number in the source file.

### Returns

An opaque handle for the frame. NULL if an error occurred.

## appd\_frame\_end

Records the end of a method call in the call stack. To track the duration of your method call, you must call `appd_frame_begin` near the start of the method code, and `appd_frame_end` when the method returns.

### Format

```
APPD_API void appd_frame_end(appd_bt_handle bt, appd_frame_handle frame);
```

### Parameters

- `bt` : The business transaction for the call graph.
- `frame` : The handle of returned by the corresponding `appd_frame_begin` call.

## Environment Variables

You can configure the following environment variables for the C/C++ SDK.

Environment Variable	Value
<code>APP_NAME</code>	The name of the application.
<code>CONTROLLER_ACCESS_KEY</code>	The access key for connecting to the Controller.
<code>CONTROLLER_ACCOUNT</code>	The account name for connecting to the Controller.
<code>CONTROLLER_HOST</code>	The hostname of the Controller.

Environment Variable	Value
<code>CONTROLLER_PORT</code>	The port number on which the Controller is listening.
<code>CONTROLLER_HTTP_PROXY_HOST</code>	If using an HTTP proxy to talk to the Controller, the hostname of that HTTP proxy.
<code>CONTROLLER_HTTP_PROXY_PASSWORD</code>	The password for connecting to the HTTP proxy.
<code>CONTROLLER_HTTP_PROXY_PASSWORD_FILE</code>	The file containing password to connect to the HTTP proxy with.
<code>CONTROLLER_HTTP_PROXY_PORT</code>	The port number of the HTTP proxy.
<code>CONTROLLER_HTTP_PROXY_USERNAME</code>	The username to connect to the HTTP proxy with.
<code>CONTROLLER_USE_SSL</code> (optional)	To disable SSL, set to <code>off</code> , <code>0</code> , <code>f</code> , or <code>false</code> . To enable SSL, set to <code>on</code> , <code>1</code> , <code>t</code> , or <code>true</code> .
<code>CONTROLLER_CERTIFICATE_FILE</code>	The SSL certificate file name for connecting to the Controller.
<code>CONTROLLER_CERTIFICATE_DIR</code>	The directory where the SSL certificate is located.
<code>FLUSH_METRICS_ON_SHUTDOWN</code>	To enable metric flushing before shutdown, set to a non-zero integer. To disable metric flushing before shutdown, set to <code>0</code> (default).
<code>INIT_TIMEOUT_MS</code>	The number of milliseconds that you want <code>appd_sdk_init</code> , an asynchronous action, to wait until it has received Controller configuration and is ready to capture business transactions.
<code>LOGGING_LOG_DIR</code>	The directory that the logs are saved to.
<code>LOGGING_LEVEL</code>	The level of severity for which activity is logged. Options: <code>all</code> , <code>trace</code> , <code>debug</code> , <code>info</code> , <code>warn</code> , <code>error</code> .
<code>LOGGING_MAX_NUM_FILES</code>	The maximum number of log files that can be saved.
<code>LOGGING_MAX_FILE_SIZE_BYTES</code>	The maximum log file size that can be saved.
<code>NODE_NAME</code>	The name of the node.

Environment Variable	Value
TIER_NAME	The name of the tier.
UNIQUE_HOST_ID (optional)	The identifier of the physical host or virtual machine that the agent is installed on.

## C++ SDK RAI (Resource Management Is Initialization)

### Related pages:

- [C/C++ SDK Reference](#)

This page describes the Resource Acquisition Is Initialization (RAII) functions defined in the C/C++ SDK to instrument C++ applications.

For C++ applications, you can use the `BT` and `ExitCall` classes to simplify your instrumentation. With these classes, you do not need to manually call `appd_bt_end()` and `appd_exitcall_end()`. When the `BT` or `ExitCall` object goes out of scope, the SDK calls its destructor and the business transaction/exit call automatically ends.

The following code example use these classes.

```
{
 appd::sdk::BT bt("mybt");
 appd::sdk::ExitCall ec(bt, "auth");
 if (!make_auth_call())
 {
 bt.add_error(APPD_LEVEL_ERROR, "Authorization failed");
 return -1;
 }
 issue_api_call();
}
```

The above code example is equivalent to this:

```
{
 appd_bt_handle bt = appd_bt_begin("mybt", NULL);
 appd_exitcall_handle ec = appd_exitcall_begin(bt, "auth");
 if (!make_auth_call())
 {
 appd_bt_add_error(bt, APPD_LEVEL_ERROR, "Authorization failed", 0);
 appd_exitcall_end(ec);
 appd_bt_end(bt);
 return -1;
 }
 issue_apI_call();
 appd_exitcall_end(ec);
 appd_bt_end(bt);
}
```

When the BT lifetime depends on the non-deterministic lifetimes of other objects, you can use a shared pointer to a BT to keep the BT alive for the lifetimes of its dependencies. In this example, the BT ends when the last reference to it ends.

```

{
 //Initialize the BT with a shared pointer
 auto bt = std::make_shared<appd::sdk::BT>("compute");
 auto prod = createProducer(bt);
 auto consumers = createConsumers(bt, NUM_WORKERS);
 //Variable BT goes out of scope with no further references.
 //BT ends automatically.
}

```

For managing exit calls with complex lifetimes, consider using smart pointers `std::unique_ptr<appd::sdk::ExitCall>` or `std::shared_ptr<appd::sdk::ExitCall>`.

### appd::sdk::BT

A RAII pattern constructor for C++ applications. For a new Business Transaction, this constructor creates the business transaction object and a handle to that object. This function continuous existing transactions and adds the correlation header if one is passed.

When the business transaction object goes out of scope, the SDK automatically ends the business transaction. A business transaction object cannot be copied.

#### Format

```

appd::sdk:: BT(const std::string& name)
appd::sdk:: BT(const std::string& name, const std::string& correlation_header)
appd::sdk:: BT(const char* name, const char* correlation_header=NULL)

```

#### Parameters

- `name`: Business transaction name, passed as either a `string&` or `char *`, depending on which constructor you choose. In the case of a continuing transaction in the current business application with a valid correlation header, the SDK uses the name from the header.
- `correlation_header`: Optional correlation header, passed as either a `string&` or `char *`, depending on which constructor you choose.

### appd::sdk::Event

This class is used to create an event in C++ and provides a convenient way of creating events. See [C/C++ SDK Reference](#).

#### Format

```

appd::sdk::Event::Event
(const std::string& application_context,
enum appd_event_severity severity,
const std::string& even_sub_type,
const std::string& summary,
const std::map<std::string, std::string>& properties,
const std::map<std::string, std::string>& details)

```

## Parameters

- `application_context` : This string picks an agent out of multiple agents running in multi-tenant mode. If this value is empty, then the default agent is used.
- `details` : A map of name and value pairs. An empty map is a valid argument. The name and value associated with a detail cannot be empty; that is an error.
- `event_sub_type` : The string containing the subtype of the custom event. This can be used in the Controller to filter the custom events belonging to a specific subtype.
- `properties` : A map of name and value pairs. An empty map is a valid argument. The name and value associated with a property cannot be empty; that is an error.
- `severity` : This is an enum representing the severity of the event. Valid values are `APPD_EVENT_SEVERITY_INFO` , `APPD_EVENT_SEVERITY_WARNING` and `APPD_EVENT_SEVERITY_ERROR` .
- `summary` : A string giving a brief description about the event.

## `appd::sdk::Event::report`

This method in Event class is equivalent to `appd_custom_event_end()` in functionality. See [C/C++ SDK Reference](#).

This function returns boolean value as `true` if the definition of the event is successful and queuing of the event (to send to the Controller) is successful. Otherwise, returns false.

## Format

```
appd::sdk::Event event(<arguments>);
bool status = event.report();
```

## `appd::sdk::ExitCall`

A RAII pattern constructors for C++ applications. Constructs an ExitCall object and creates a handle to that object. You must declare a backend and assign it at least one identifying property before you use the backend to instantiate the ExitCall object.

When the ExitCall object goes out of scope, the SDK automatically ends the ExitCall.

An ExitCall object cannot be copied.

## Format

```
appd::sdk::ExitCall(BT& bt, const char* backend)
appd::sdk::ExitCall (BT& bt, const std::string& backend)
```

## Parameters

- `BT& bt` : Handle to the business transaction making the exit call.
- `backend` : The destination backend of the exit call. Passed as either a `string&` or `char *`, depending on which constructor you choose.

## `appd::sdk::Frame`

Use the Frame class to enable call graphs for your C++ application. You can use the Frame class to instrument the methods that you want to track, as an alternative to calling `appd_frame_begin` and `appd_frame_end` . You must pass the following parameters into the Frame class:

## Format

```
Frame(BT& bt, appd_frame_type frame_type, const char* class_name, const char*
method_name, const char* file, unsigned int line_number)
```

## Parameters

- `bt` : The BT object that owns this function call.
- `frame_type` : The type of the frame. When used in C++ RAII code, use `APPD_FRAME_TYPE_CPP`.
- `class_name` : The name of the class if this method is a member of the class, else `NULL`.
- `method_name` : The name of the method. You can use `__FUNCTION__` or `__PRETTY_FUNCTION__`; any available compiler macro.
- `file` : The path of the source file. You can use `__FILE__` or any available compiler macro.
- `line_number` : The line number in the source file. You can use `__LINE__` or any available compiler macro.

## Install the C/C++ SDK on Windows

### Related pages:

- [Download AppDynamics Software](#)
- [Install the C/C++ SDK on Linux](#)

To install the C/C++ SDK on Windows:

1. Download the C/C++ SDK from the [AppDynamics Downloads Portal](#) that corresponds to the bit number for your operating system (32-bit or 64-bit). The incorrect bit–SDK version compatibility will cause a linker error about missing symbols.
2. Extract the downloaded SDK zip file to the directory where you want to place the SDK, such as `C:\AppDynamics`.
3. Add the SDK lib directory to the system PATH, for example, add `C:\AppDynamics\appdynamics-cpp-sdk\lib` to `%PATH%`.
4. Configure your Visual Studio project to have the include path and link the AppDynamics library in **Open Project > Properties**.
  - a. From the sidebar, unfold **C/C++** and choose **General**. In the new pane, change **Additional Include Directories** to add: `C:\AppDynamics\appdynamics-cpp-sdk\include`.
  - b. From the sidebar, unfold **Linker** and choose **Input**. In the new pane, change **Additional Dependencies** to add: `C:\AppDynamics\appdynamics-cpp-sdk\lib\appdynamics.lib`.
5. Modify your program to use the AppDynamics C/C++ SDK. See [C/C++ SDK Reference](#) and [Use the C/C++ SDK](#).

## Install the C/C++ SDK on Linux

### Related pages:

- [Download AppDynamics Software](#)
- [Install the C/C++ SDK on Windows](#)

To install the C/C++ SDK on Linux:

1. Download the C/C++ SDK from the [AppDynamics Downloads Portal](#).
2. Extract the SDK to the desired SDK home directory location, such as in `/opt`:

```
sudo tar xvzf appdynamics-sdk-native-64bit-linux-VERSION.tar.gz -C /opt
```

Replace `VERSION` in the file name with the version of the downloaded SDK.

3. Update your build scripts to be able to access the AppDynamics SDK library files:
  - a. Add `/opt/appdynamics-cpp-sdk/lib` to your library path. For example, `-L/opt/appdynamics-cpp-sdk/lib`.
  - b. Add `-lappdynamics` to your link options.

4. Modify your program to use the AppDynamics C/C++ SDK. See [C/C++ SDK Reference](#) and [Use the C/C++ SDK](#).
5. Ensure that the `ulimit` setting for open file descriptors on the operating system is set to a sufficient number. At a minimum, you will need two file descriptors for each active thread that calls the C++ SDK `appd_sdk_init()` function.

## Go SDK

### Related pages:

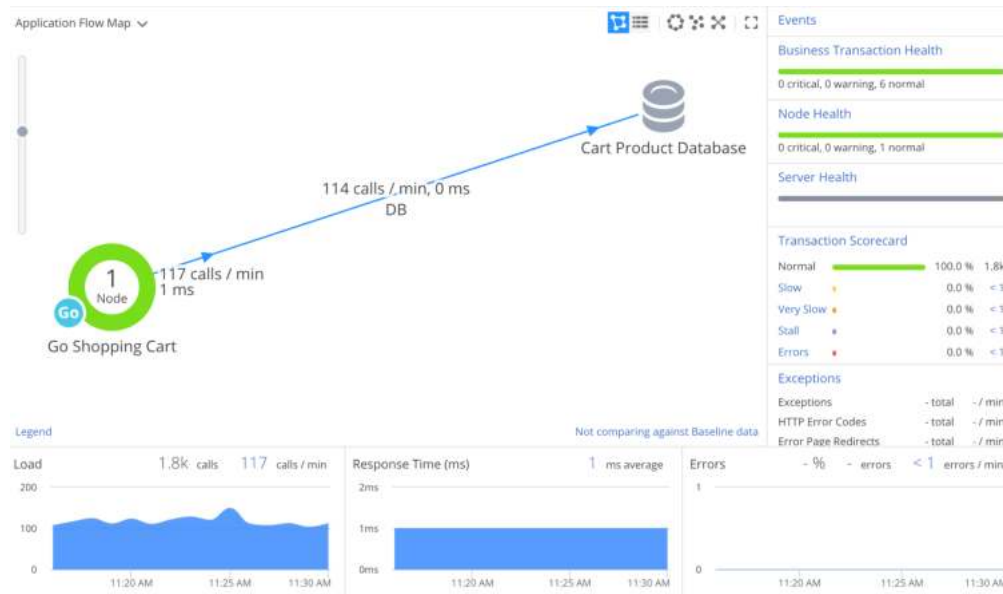

- [SELinux Installation Issues](#)

This page describes how to install and instrument the app server agent for Go applications. AppDynamics monitors applications that have been created with the Go SDK.

The Go SDK can:

- Trace transactions through Go tiers
- Surface Go runtime errors
- Report backend calls made by Go services

Once the agent connects to the Controller, you can see flow maps, key performance indicators, errors, and more for the Go tier.

### Limitations

The Go SDK uses `cGo` in the background. In Go, when you are calling out to C/C++, the code converts the current Goroutine to an OS thread. This is a limitation of the runtime, not the Go SDK. If you are running the agent with many Go routines and make Go SDK calls within the Go routines in your application code, there may be a risk of reaching the OS thread limit. If you encounter this limitation, contact [AppDynamics Support](#).

---

## Go Language Supported Environments

### Go Supported Platforms

#### Language Support

All Go language versions are currently supported.

#### Operating Systems

- Any Linux distribution based on `glibc`  $\geq 2.5$ , and the x86 32-bit or x86 64-bit architecture
- Mac OS X  $\geq 10.8$  on x86/x86-64 architecture

 AppDynamics does not currently support Mac on Apple silicon (Apple M1 chip, ARM-based architecture).

### Use Go SDK

#### On This Page:

- [Before You Begin](#)
- [Import the AppDynamics API File to the Application](#)
- [Initialize the Controller Configuration](#)
- [Initialize the Agent](#)
- [Create Business Transactions](#)
- [Manage Business Transaction Snapshots](#)
- [Create Backends](#)
- [Manage Exit Calls](#)
- [Correlate with Other Business Transactions](#)
- [Terminate the Agent](#)

This page provides instructions and an overview of the GO SDK, which provides routines for creating and managing Business Transactions, Transaction Snapshots, backends, and exit calls in AppDynamics.

#### Before You Begin

Before instrumenting your applications with the Go SDK, you will need the current version of the Go SDK. See [Install the Go SDK](#) and [Download AppDynamics Software](#) to install the SDK.

#### Import the AppDynamics Package to the Application

After downloading the SDK, you are ready to add AppDynamics instrumentation to your Go application. The first step is to import the AppDynamics package:

```
import appd "appdynamics"
```

#### Initialize the Controller Configuration

Controller information settings permit the SDK to connect to the Controller. Some settings are required for all applications while others are required only for certain types of application environments. For example, if the SDK needs to connect to the Controller via an internal proxy in your network, set up the connection settings for the proxy. See [Go SDK Reference](#) for a complete list of settings and which ones are required.

Assign values to the required settings in your application. For example, to set the Controller connection information:

```

cfg := appd.Config{}

cfg.AppName = "exampleapp"
cfg.TierName = "orderproc"
cfg.NodeName = "orderproc01"
cfg.Controller.Host = "my-appd-controller.example.org"
cfg.Controller.Port = 8090
cfg.Controller.UseSSL = false
cfg.Controller.Account = "customer1"
cfg.Controller.AccessKey = "secret"
cfg.InitTimeoutMs = 1000 // Wait up to 1s for initialization to finish

```

Notice the `InitTimeoutMs` field. Once you initialize the configuration, you pass the configuration object to the call to initialize the agent via `InitSDK()`. The `InitTimeoutMs` field can have these values:

- When set to `0`, the default, the `InitSDK()` function operates as an asynchronous action, so that the initialization call does not block your program.
- Setting the value to `-1` instructs the program to wait indefinitely until the controller configuration is received by the agent, that is, the `InitSDK()` method returns control. This is useful when you want to capture short-running Business Transactions that occur at application startup and you do not mind the delay of waiting for the Controller to send the configuration.
- Alternatively, set it to a specific number of milliseconds to wait.

If you use a multi-tenant Controller (SaaS or on-premises multi-tenant), you need to create the context for the multi-tenant environments using the `AddAppContextToConfig()` method. You can then pass the context as a parameter to methods for performing particular operations, such as starting a Business Transaction or adding custom metrics. See [Go SDK Reference](#) for `AddAppContextToConfig()` and related methods.

## Initialize the Agent

Initialize the agent by passing the configuration structure to `InitSDK()` in your main function.

If `InitSDK()` returns `nil`, the agent is initialized successfully. If an error returns, it is likely because the agent could not reach the Controller.

For example, to initialize the SDK:

```

if err := appd.InitSDK(&cfg); err != nil {
 fmt.Printf("Error initializing the AppDynamics SDK\n")
} else {
 fmt.Printf("Initialized AppDynamics SDK successfully\n")
}

```

## Create Business Transactions

Define a Business Transaction by enclosing the code that constitutes the request you want to monitor between `StartBT()` and `EndBT()` calls. `StartBT()` returns a handle to use in subsequent routines that affect that business transaction.

If you are creating a Business Transaction that correlates with an upstream Business Transaction, pass the correlation header of the upstream transaction so the new transaction that you are creating can correlate

with it. See [Go SDK Reference](#) for `GetExitcallCorrelationHeader()`. If the transaction does not need to correlate with another transaction, pass an empty string for the correlation header parameter.

You can optionally store the Business Transaction handle in the global handle registry with a GUID for easy retrieval later using `StoreBT()`. Retrieve the handle from the global handle registry using `GetBT()`.

For example, to set a Business Transaction:

```
// start the "Checkout" transaction
btHandle := appd.StartBT("Checkout", "")

// Optionally store the handle in the global registry
appd.StoreBT(btHandle, my_bt_guid)
...

// Retrieve a stored handle from the global registry
myBtHandle = appd.GetBT(my_bt_guid)

// end the transaction
appd.EndBT(btHandle)
```

Between starting and ending the transaction, you can perform operations such as adding errors to the business transaction, defining the transaction snapshot attributes, adding backends and exit calls, and so on.

When the business transaction ends via a call to `EndBT()`, the agent stops reporting metrics for the business transaction.

### Add Business Transaction Errors

Use `AddBTError()` to report Business Transaction errors. If you set this function's `markBTAsError` parameter, the transaction is reported as an [Error Transaction](#) when the error occurs.

The SDK provides constants classifying the error level as `APPD_LEVEL_NOTICE`, `APPD_LEVEL_WARNING` or `APPD_LEVEL_ERROR`.

### Manage Business Transaction Snapshots

The agent automatically creates [Troubleshoot Business Transaction Performance with Transaction Snapshots](#) when monitoring a Business Transaction. Transaction snapshots are useful for troubleshooting poor performance because they describe instances of the business transaction at certain points in time.

Other than creating the Business Transaction, you do not have to modify anything to create these snapshots, but you can add calls to:

- Determine if a snapshot is being taken
- Provide additional data in a snapshot
- Set the URL for a snapshot

### Determine if the Agent is Taking a Snapshot Now

Due to high cost, the agent does not constantly collect snapshots. By default, it collects a snapshot every ten minutes, but this schedule is configurable. See [Configure Snapshot Periodic Collection Frequency](#).

You can determine if a snapshot is happening using `IsBTSnapshotting()`, which returns `true` if the agent is collecting a snapshot. This method avoids wasted overhead in collecting user data for a snapshot or setting the snapshot URL if no snapshots are being collected.

### Add Business Transaction User Data

You can optionally add data to transaction snapshots. For example, you might want to know which users are getting a lot of errors, or from which regions users are experiencing slow response times, or which methods are slow. In the Controller UI, the data appears in the USER DATA tab of the transaction snapshot.

If a snapshot is occurring, use `AddUserDataToBT()` passing a key and value for the data that you want the snapshot to collect.

### Add Snapshot URL

If a snapshot is occurring, you can set a URL for the current snapshot using `SetBTURL()`.

### Set Snapshot Example

```
func setSnapshotAttributes(bt appd.BtHandle, key, value string) {
 if appd.IsBTSnapshotting(bt) {
 appd.AddUserDataToBT(bt, key, value)
 appd.SetBTURL(bt, "user/login")
 }
}
```

### Create Backends

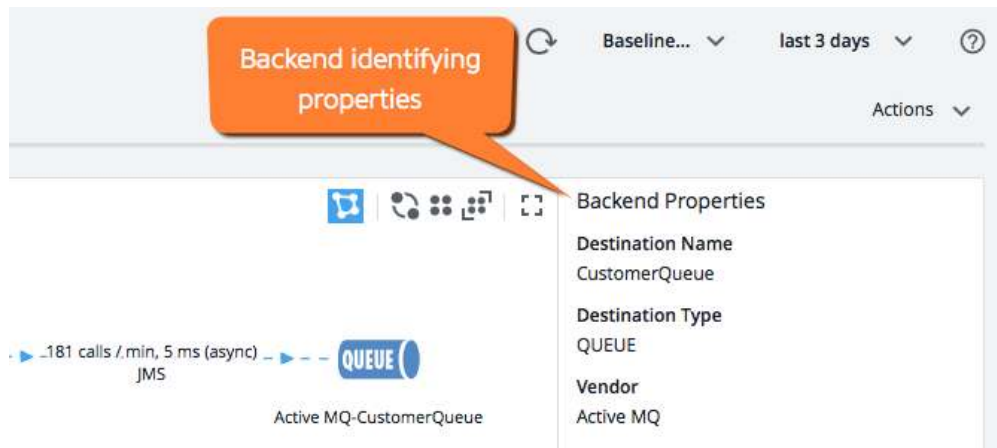

A backend is a database or a remote service such as a message queue, HTTP service, or cache service that your application uses. A backend component is not itself monitored by the application agent, but the agent monitors calls to it from instrumented servers. You need to create backends in the instrumented environment so that the agent registers them. Creating and adding the backend to the instrumented application involves:

- Naming the backend
- Setting its identifying properties
- Optionally, configuring how the backend is presented in the Controller UI

### Identifying Properties

A backend has identifying properties. These vary depending on the type of the backend and the types of information that you want to display. The Controller displays identifying properties in backend dashboards. You must set at least one identifying property for the type of any backend that you plan to add.

The following shows the backend properties in the Controller UI for an Oracle database:

## Resolve to a Tier

By default the Controller doesn't display a detected backend as a separate entity in flow maps, but the agent reports its metrics as part of the downstream tier. If you want to display the backend as a separate component and not resolved to the tier, set `resolve` to `false`. See [Resolve Remote Services to Tiers](#).

## Backend Example

The following listing shows an example of setting up a database backend.

```
backendName := "Cart Product Database"
backendType := "DB"
backendProperties := map[string]string {
 "DATABASE": "sqlite3",
}
resolveBackend := false

appd.AddBackend(backendName, backendType, backendProperties, resolveBackend)
```

## Manage Exit Calls

When an application makes a call to another component, such as a detected backend or another application server, the agent reports metrics on those calls.

Define an exit call by enclosing the code that constitutes the exit call between `StartExitCall()` and `EndExitcall()` calls. `StartExitcall()` returns a handle to use in subsequent routines that affect that exit call. An exit call occurs in the context of a Business Transaction.

You can optionally store the exit call handle in the global handle registry with a guid for easy retrieval later using `StoreExitcall()`. Retrieve the handle from the global handle registry using `GetExitcall()`.

You can optionally add details to an exit call as any arbitrary string with `SetExitcallDetails()`. The details are reported in the exit call details in the transaction snapshots in the Controller UI:

executeQuery															
Name	com.appdynamics.jdbc.MPreparedStatement.executeQuery														
Type	POJO														
Class	com.appdynamics.jdbc.MPreparedStatement														
Method	executeQuery														
Line Number	Unknown														
					<table border="1"> <tr> <td>Self Time</td> <td>13ms</td> <td>0.2%</td> </tr> <tr> <td>Total Time</td> <td>13ms</td> <td>0.2%</td> </tr> </table>					Self Time	13ms	0.2%	Total Time	13ms	0.2%
Self Time	13ms	0.2%													
Total Time	13ms	0.2%													
Exit Calls															
Type	Details	Count	Time (ms)	% Time	From	To									
JDBC	insert into OrderRequest ( item_id, notes ) val..	1	10	0.1%	Inventory S...	Oracle-10.0.0									

You can also add errors to an exit call using `AddExitcallError()`. Use the enum for the error levels. You can also add an error message.

### Simple Exit Call Example

```
// start the exit call to backendName
ecHandle := appd.StartExitcall(btHandle, backendName)

...

// optionally store the handle in the global registry
appd.StoreExitcall(ecHandle, my_ec_guid)

...

// retrieve a stored handle from the global registry
myEcHandle := appd.GetExitcall(my_ec_guid)

// set the exit call details
if err := appd.SetExitcallDetails(myEcHandle, "Exitcall Detail String"); err != nil {
 log.Print(err)
}

// add an error to the exit call
appd.AddExitcallError(myEcHandle, appd.APPD_LEVEL_ERROR, "exitcall error!", true)

// end the exit call
appd.EndExitcall(myEcHandle)
```

### Correlate with Other Business Transactions

A correlation header contains the information that enables the agents to continue the flow of a Business Transaction across multiple tiers.

An SDK agent can correlate with other SDK agents as well as other AppDynamics agents, such as Java, .NET, or PHP, that perform automatic correlation for certain types of entry and exit points.

### Correlate with an Upstream Tier

When your instrumented process receives a continuing transaction from an upstream agent that supports automatic correlation:

1. Using a third-party `Header.Get()` function, extract the header named `APPD_CORRELATION_HEADER_NAME` from the incoming HTTP payload.
2. Pass the header to `StartBT()`. For example:

```
hdr := req.Header.Get(appd.APPD_CORRELATION_HEADER_NAME)
bt := appd.StartBT("Fraud Detection", hdr)
```

If the header retrieved by the `Header.Get()` function is valid, the business transaction started by the `StartBT()` call will be a continuation of the Business Transaction started by the upstream service.

### Correlate with a Downstream Tier

The downstream agent is watching for a correlation header named `singularityheader` in the HTTP payload.

If your SDK agent is making an exit call to a downstream agent that supports automatic correlation:

1. Set the name of the correlation header using `APPD_CORRELATION_HEADER_NAME`.
2. Begin the exit call.
3. Retrieve the correlation header from the exit call using the `GetExitcallCorrelationHeader()` function.
4. Using third-party HTTP functions, prepare an HTTP POST request.
5. Inject a header named `APPD_CORRELATION_HEADER_NAME` with the value of the correlation header retrieved in Step 3 into the outgoing payload of the HTTP request.
6. Make the request. For example:

```
inventoryEchandle := appd.StartExitcall(btHandle, "Inventory DB")
hdr := appd.GetExitcallCorrelationHeader(inventoryEchandle)

client := &http.Client{
 CheckRedirect: redirectPolicyFunc,
}

req, err := http.NewRequest("POST", "https://inventory/holds/xyz", nil)
// ...
req.Header.Add(appd.APPD_CORRELATION_HEADER_NAME, hdr)
resp, err := client.Do(req)
// ...

...
```

### Terminate the Agent

Terminate the agent right before the application exits:

```
appd.TerminateSDK()
```

## Go SDK Reference

Use the AppDynamics Go SDK to instrument Google Go applications. The API includes functions for creating business transactions, transaction backends, exit points, and so on. See [Use Go SDK](#).

### Basic Types

The AppDynamics Go SDK defines these opaque types:

- `BtHandle` : A handle to an active business transaction
- `ExitcallHandle` : A handle to an active exit call

### Config Struct

The `Config` struct contains settings used by the agent to connect to the AppDynamics Controller. The structure serves an equivalent function of the agent configuration files described in [Agent-to-Controller Connections](#).

The `Config` struct is defined as follows:

```
type Config struct {
 AppName, TierName, NodeName string
 Controller Controller
 InitTimeoutMs int
 Initialized uint // a special field used by the underlying AppDynamics libraries. Do not
 use.
 Logging LoggingConfig
 UseConfigFromEnv bool
 EnvVarPrefix string
}
```

The structure is made up of these fields:

- `AppName` : Name of the business application to which this node belongs.
- `TierName` : Name of the tier to which this node belongs. A tier is a group of identical or similar nodes. An *originating tier* is the tier that receives the first request of a business transaction. A *downstream tier* is a tier that is called from another tier, thus continuing a business transaction.
- `NodeName` : The monitored application server to be monitored by this agent.
- `Controller` : Connection settings for the Controller. This struct is defined as:

```
type Controller struct {
 Host string
 Port uint16
 Account, AccessKey string
 UseSSL bool
 HTTPProxy HTTPProxy
 CertificateFile
 CertificateDir
}
```

The `Controller` struct contains these fields:

- `Host` : Controller host.
- `Port` : Controller port; defaults to 8080.
- `Account` : Name of your AppDynamics account.
- `Access_key` : Key to your AppDynamics account. To find your access key, click the settings (gear) icon in the upper right corner of the AppDynamics UI, then click License.

- `UseSSL` : Enable SSL communication with the controller; the default is false. Set to true to enable. If you set `UseSSL` to true, the default certificate, `ca-bundle.crt`, is used. To use your own certificate, specify your certificate file and directory in the `CertificateFile` and `CertificateDir` parameters.
- `HTTPProxy` : If the agent needs to connect to the Controller via a local HTTP proxy, use this struct to specify connection settings for the proxy.
- `CertificateFile` : The file name of the SSL certificate.
- `CertificateDir` – The directory where the certificate is located.
- `InitTimeoutMs` : The initialization function, `InitSDK` relies on the Controller configuration to start business transactions. To prevent the initialization function from blocking your application, you can use this setting. It lets you instruct `InitSDK` whether to wait for the Controller configuration and if so how long to wait before starting business transactions. Valid values are:
  - `N`: Wait for up to N milliseconds for the Controller configuration.
  - `0`: Do not wait for the Controller configuration. This is the default.
  - `-1`: Wait indefinitely until the Controller configuration is received by the agent.
- `Logging` : Logging settings for the controller. This struct is defined as:

```
const (
 APPD_LOG_LEVEL_DEFAULT LogLevel = iota
 APPD_LOG_LEVEL_TRACE
 APPD_LOG_LEVEL_DEBUG
 APPD_LOG_LEVEL_INFO
 APPD_LOG_LEVEL_WARN
 APPD_LOG_LEVEL_ERROR
 APPD_LOG_LEVEL_FATAL
)
type LoggingConfig struct {
 BaseDir string
 MinimumLevel LogLevel
 MaxNumFiles uint
 MaxFileSizeBytes uint
}
```

The `Logging` struct contains these fields:

- `BaseDir` : The absolute path to the directory where log files are written. If left empty, the default is `/tmp/appd`.
- `MinimumLevel` : One of the `APPD_LOG_LEVEL_XXX` constants that are shown above. The default is `APPD_LOG_LEVEL_INFO`.
- `MaxNumFiles` : The maximum number of logging files to store on disk. Once this maximum is hit, older logs are rotated out.
- `MaxFileSizeBytes` : The maximum size of the log files before they are rotated.
- `UseConfigFromEnv` : Set to `true` if you want the SDK to check for any configuration environment variables and use those configuration values for initialization. Note that because this happens on initialization, the environment variable settings override the configuration you set in your program.
- `EnvVarPrefix` : If `UseConfigFromEnv` is set to `true`, use this property to specify the prefix to use for environment variable names. The default prefix is `APPD_SDK`.

If the agent needs to connect to the Controller via a local HTTP proxy server, you need to configure the settings for the proxy server. You can do so using the `HTTPProxy` struct, defined as follows:

```
type HTTPProxy struct {
 Host string
 Port uint16
 Username, PasswordFile string
}
```

The `HTTPProxy` struct has the following fields:

- **Host:** Hostname or IP address of the HTTP proxy server
- **Port:** Port of the proxy server
- **Username:** Proxy server user name
- **PasswordFile:** Proxy server password file

## ContextConfig Struct

You use the `ContextConfig` struct for calls that apply to multi-tenant Controller environments.

```
type ContextConfig struct {
 AppName string
 TierName string
 NodeName string
}
```

The `ContextConfig` struct has these fields:

- **AppName:** Name of the business application to which this node belongs.
- **TierName:** Name of the tier to which this node belongs. A tier is a group of identical or similar nodes. An *originating tier* is the tier that receives the first request of a business transaction. A *downstream tier* is a tier that is called from another tier, thus continuing a business transaction.
- **NodeName:** The monitored application server to be monitored by this agent.

## AddAppContextToConfig

Add application context to the AppDynamics configuration for a multi-tenant Controller.

### Format

```
func AddAppContextToConfig(cfg *Config, context string, contextCfg *ContextConfig)
error
```

### Parameters

- **cfg:** AppDynamics configuration object.
- **context:** A unique identifier used to refer to this context.
- **contextCfg:** An AppDynamics context configuration object indicating the business application, tier, and node name for this context.

## InitSDK

Initialize the AppDynamics Go SDK. An instrumented application must call this function once, preferably during application startup.

### Format

```
func InitSDK(cfg *Config) error
```

### Parameter

**cfg:** AppDynamics configuration settings that enable communication between the agent and the Controller.

### Returns

nil on success, otherwise an error value

---

## TerminateSDK

Stop the AppDynamics Go SDK. Ends all active business transactions for this agent and stops agent metric reporting to the Controller.

### Format

```
func TerminateSDK()
```

## StartBT

Start a business transaction or continue an existing transaction.

Keep in mind that each application is limited to 200 registered business transactions, and each agent is limited to 50 registered business transactions. Unlike transactions discovered by other types of agents, business transactions that exceed the limit that are reported by the Go SDK are not included in the all other traffic grouping. This means that it's up to you to ensure that your agent does not create excessive business transactions. Use care to ensure that your implementation does not introduce the possibility of business transaction explosion.

### Format

```
func StartBT(name, correlation_header string) BtHandle
```

### Parameters

- **name**: The name for the business transaction. In the case of a continuing transaction in the current business application with a valid correlation header, the SDK uses the name from the header. Do not use the following characters in transaction names: {}[]!&;
- **correlation\_header**: A correlation header if this is a continuing transaction, else NULL. If specified, the correlation header has been generated by another AppDynamics agent and made available to this agent as a string. The correlation header provides information to enable this transaction to correlate with an upstream transaction.

### Returns

An opaque handle for the business transaction that was started.

## StartBTWithAppContext

Start a business transaction or continue an existing transaction in a multi-tenant Controller environment.

### Format

```
func StartBTWithAppContext(context, name, correlation_header string) BtHandle
```

### Parameters

- **context**: The application context name that this business transaction belongs to.
- **name**: The name for the business transaction. In the case of a continuing transaction in the current business application with a valid correlation header, the SDK uses the name from the header. Do not use the following characters in transaction names: {}[]!&;
- **correlation\_header**: A correlation header if this is a continuing transaction, else NULL. If specified, the correlation header has been generated by another AppDynamics agent and made available to this agent as a string. The correlation header provides information to enable this transaction to correlate with an upstream transaction.

## EndBT

End the given business transaction.

---

## Format

```
func EndBT(bt BtHandle)
```

## Parameter

**bt**: The handle to the business transaction to end.

## GetBT

Get a BT handle associated with the given guid by `appd_bt_store`.

## Format

```
func GetBT(guid string) BtHandle
```

## Parameter

**guid**: The globally unique identifier that was passed to `appd_bt_store`.

## Returns

The handle to the business transaction associated with the given guid.

In the following cases the SDK logs a warning and returns a handle that you may safely use in other API functions but that will cause these functions to immediately return without doing anything:

- The SDK doesn't find a handle associated with the guid
- The call ended before the SDK could retrieve the handle

## IsBTSnapshotting

Reports whether the agent is currently taking a transaction snapshot. Useful before calling `AddUserDataToBT` or `SetBTURL`, since those potentially expensive functions would do nothing if called when a snapshot is not being taken.

## Format

```
func IsBTSnapshotting(bt BtHandle) bool
```

## Parameter

**bt**: The handle to the business transaction to check for snapshotting.

## Returns

true if the given business transaction is taking a snapshot. Otherwise, false.

## SetBTURL

Set the URL for a snapshot, if one is being taken. It is safe to call this function when a snapshot is not occurring. When the given business transaction is not snapshotting, this function immediately returns. However, if extracting the data to pass to this function is expensive, you can use `IsBTSnapshotting` to check if the business transaction is snapshotting before extracting the data and calling this function. The `url` argument data should be either 7-bit ASCII or UTF-8.

## Format

```
func SetBTURL(bt BtHandle, url string)
```

## Parameters

- `bt`: The business transaction to add the user data to, if it is taking a snapshot.
- `url`: The value of the URL for the snapshot as 7-bit ASCII or UTF-8.

## StoreBT

Store a BT handle in a global registry to retrieve later with `GetBT`. This is convenient when you need to start and end a business transaction in separate places, and it is difficult to pass the handle to the business transaction through the parts of the code that need it.

When the business transaction is ended, the handle is removed from the global registry.

## Format

```
func StoreBT(bt BtHandle, guid string)
```

## Parameters

- `bt`: The BT to store.
- `guid`: A globally unique identifier to associate with the given BT.

## AddBTError

Add an error to a business transaction. Errors are reported as part of the business transaction. However, you can add an error without marking the business transaction as an error (e.g., for non-fatal errors).

## Format

```
func AddBTError(bt BtHandle, level ErrorLevel, message string, mark_bt_as_error bool)
```

## Parameters

- `bt`: The handle to the business transaction to which the error is added.
- `level`: The error level, from the following:
  - `APPD_LEVEL_NOTICE`
  - `APPD_LEVEL_WARNING`
  - `APPD_LEVEL_ERROR`
- `message`: Error message for this error.
- `mark_bt_as_error`: If true, the business transaction experiencing this error is marked as an error transaction. In this case, the business transaction is counted only as an error transaction. It is not also counted as a slow, very slow or stalled transaction, even if the transaction was also slow or stalled. If false, the business transaction is not marked as an error transaction.

## AddUserDataToBT

Attaches user data to transaction snapshots generated for the specified business transaction.

The user data is added to the business transaction but reported only when a transaction snapshot is occurring. In the Controller UI, the user data appears in the USER DATA tab of the transaction snapshot details.

It is safe to call this function when a snapshot is not occurring. When the specified business transaction is not taking a snapshot, this function immediately returns.

If extracting the data to pass to this function is expensive, you can use `IsBTSnapshotting` to check if the business transaction is actually taking a snapshot before extracting the data and calling this function.

The data in the `value` argument should be either 7-bit ASCII or UTF-8.

## Format

```
func AddUserDataToBT(bt BtHandle, key, value string)
```

## Parameters

- `bt` – The business transaction to add the user data to, if it's taking a snapshot.
- `key` – The name of the user data to add to the snapshot as 7-bit ASCII or UTF-8.
- `value` – The value of the user data to add to the snapshot as 7-bit ASCII or UTF-8.

## AddBackend

Add a backend to the business application.

This function fails if the type of the backend being added does not have at least one identifying property.

## Format

```
func AddBackend(name, backendType string, identifyingProperties map[string]string, resolve bool) error
```

## Parameters

- `name`: The name of the backend. Must be unique to the Go SDK instance.
- `backendType`: The type of the backend, from these options:
  - `APPD_BACKEND_HTTP`
  - `APPD_BACKEND_DB`
  - `APPD_BACKEND_CACHE`
  - `APPD_BACKEND_RABBITMQ`
  - `APPD_BACKEND_WEBSERVICE`
  - `APPD_BACKEND_JMS`
- `identifyingProperties`: A map of key/value pairs that contain the backend's identifying properties. The properties uniquely identify backend. In the Controller, these properties appear in the upper right panel of the backend dashboards. You must set at least one identifying property when you add a backend of one of the built-in exit call types. The valid properties vary per exit call type as indicated below.

Exit Call Type	Valid Identifying Properties
<code>APPD_BACKEND_HTTP</code>	"HOST", "PORT", "URL", "QUERY STRING"
<code>APPD_BACKEND_DB</code>	"HOST", "PORT", "DATABASE", "VENDOR", "VERSION"
<code>APPD_BACKEND_CACHE</code>	"SERVER POOL", "VENDOR"
<code>APPD_BACKEND_RABBITMQ</code>	"HOST", "PORT", "ROUTING KEY", "EXCHANGE"
<code>APPD_BACKEND_WEBSERVICE</code>	"SERVICE", "URL", "OPERATION", "SOAP ACTION", "VENDOR"
<code>APPD_BACKEND_JMS</code>	"DESTINATION", "DESTINATIONTYPE", and "VENDOR"

For example, a key `PORT` would have a value of `3304`.

- `resolve`: Set the property to false to prevent a downstream agent from resolving as this backend. If true, the default, an agent that detects a correlation header for an unresolved backend resolves itself as that backend. However, if the backend is actually an uninstrumented tier that is passing through the correlation header—for example, a message queue or proxy—you may wish the backend to show up distinct from the tier that it routes to. If false, correlation headers generated for exit calls to this backend will instruct downstream agents to report as distinct from the backend.

---

For example, if you have Tier A connecting to uninstrumented Backend B, which routes to instrumented Tier C, the setting affects the flow map as follows:

- True, the flow map will be A > C.
- False, the flow map will be A > B > C.

## Returns

nil on success, otherwise an error value

## AddExitcallError

Add an error to the exit call.

## Format

```
func AddExitcallError(exitcall ExitcallHandle, level ErrorLevel, message string, mark_bt_as_error bool)
```

## Parameters

- `exitcall`: Handle to the exit call.
- `level`: The level of this error, from the following:
  - `APPD_LEVEL_NOTICE`
  - `APPD_LEVEL_WARNING`
  - `APPD_LEVEL_ERROR`
- `message`: Error message for this error.
- `mark_bt_as_error`: If true, the business transaction making the exit call that is experiencing this error is marked as an error transaction. In this case, the business transaction is counted only as an error transaction. It is not also counted as a slow, very slow or stalled transaction, even if the transaction was also slow or stalled. If false, the business transaction is not marked as an error transaction.

## StartExitcall

Start an exit call to the specified backend as part of a business transaction.

## Format

```
func StartExitcall(bt BtHandle, backend string) ExitcallHandle
```

## Parameters

- `bt`: Handle to the business transaction making the exit call.
- `backend`: The destination backend of the exit call. AppDynamics does not automatically detect backends for Go applications, so you must specify the destination backend.

## Returns

An opaque handle to the exit call that was started.

## EndExitcall

Complete the exit call.

## Format

```
func EndExitcall(exitcall ExitcallHandle)
```

## Parameter

`exitcall`: Handle to the exit call being ended.

---

## GetCRollupType

Specify how to roll up values for the metric over time.

### Format

```
func GetCRollupType(rollUp RollupType)
```

### Parameters

- `rollUp`: The approach for rolling up metrics. The following roll-up options are valid:
  - `APPD_TIMEROLLUP_TYPE_AVERAGE`: The average of all metric values across each node in the tier.
  - `APPD_TIMEROLLUP_TYPE_SUM`: Sum of all reported values in the minute.
  - `APPD_TIMEROLLUP_TYPE_CURRENT`: The last reported metric in the minute.

## GetCClusterRollupType

Specify how to aggregate metric values for the tier (a cluster of nodes).

### Format

```
func GetCClusterRollupType(rollUp ClusterRollupType)
```

### Parameters

- `rollUp`: The approach for rolling up metrics. The following roll-up options are valid:
  - `APPD_CLUSTERROLLUP_TYPE_INDIVIDUAL`: The average of all metric values across each node in the tier.
  - `APPD_CLUSTERROLLUP_TYPE_COLLECTIVE`: The sum of all metric values for all the nodes in the tier.

## GetExitcall

Get a handle to an exit call associated with a guid via `StoreExitcall`.

### Format

```
func GetExitcall(guid string) ExitcallHandle
```

### Parameter

`guid`: The globally unique identifier that was passed to `appd_exitcall_store()`.

### Returns

The handle to the exit call associated with the given guid.

In the following cases the SDK logs a warning and returns a handle that you may safely use in other API functions but that will cause these functions to immediately return without doing anything:

- The SDK doesn't find a handle associated with the guid
- The call ended before the SDK could retrieve the handle

## GetExitcallCorrelationHeader

Get the header for correlating a business transaction.

If a business transaction makes exit calls that you want to correlate across, retrieve the correlation header using this function and inject it into your exit call's payload.

The returned string is freed when the exit call ends. Do not free it yourself.

---

## Format

```
func GetExitcallCorrelationHeader(exitcall ExitcallHandle) string
```

## Parameter

`exitcall`: Handle to the exit call.

## Returns

On success, returns a 7-bit ASCII string containing the correlation information. You can inject this string into the payload of the exit call. A downstream agent can then extract the header from that payload and continue the business transaction.

On error, returns the default header that prevents downstream business transaction detection.

## SetExitcallDetails

Set the details string for an exit call. This can be used, for example, to add the SQL statement that a DB backend has executed as part of the exit call. This data is then visible in the exit calls details UI for the transaction snapshot.

## Format

```
func SetExitcallDetails(exitcall ExitcallHandle, details string) error
```

## Parameters

- `exitcall`: Handle to the exit call.
- `details`: An arbitrary string to add to the exit call.

## Returns

Nil on success, otherwise an error value

## StoreExitcall

Store an exit call handle in a global registry for later retrieval with `GetExitcall`. This is useful when you need to start and end a call in separate places, and it is difficult to pass the handle through the parts of the code that need it.

The handle is removed when the exit call, or the BT containing it, ends.

## Format

```
func StoreExitcall(exitcall ExitcallHandle, guid string)
```

## Parameters

- `exitcall`: The exit call to store.
- `guid`: A globally unique identifier to associate with the given call.

## Example

```
ExitcallHandle ec = StartExitcall(bt, "authdb");
StoreExitcall(ec, "login-exit");
```

---

## Install the Go SDK

### Related pages:

- [Download AppDynamics Software](#)

To install the Go SDK:

1. Download the Go SDK distribution from the [AppDynamics Downloads Portal](#).
2. Extract the Go SDK Zip in your Go workspace.

After installing the Go SDK, you are ready to instrument your Go application with the API.

## IBM Integration Bus Agent

The IBM Integration Bus (IIB) Agent allows you to see the activity flow in your IIB instance. You can use the AppDynamics IIB Agent to do the following:

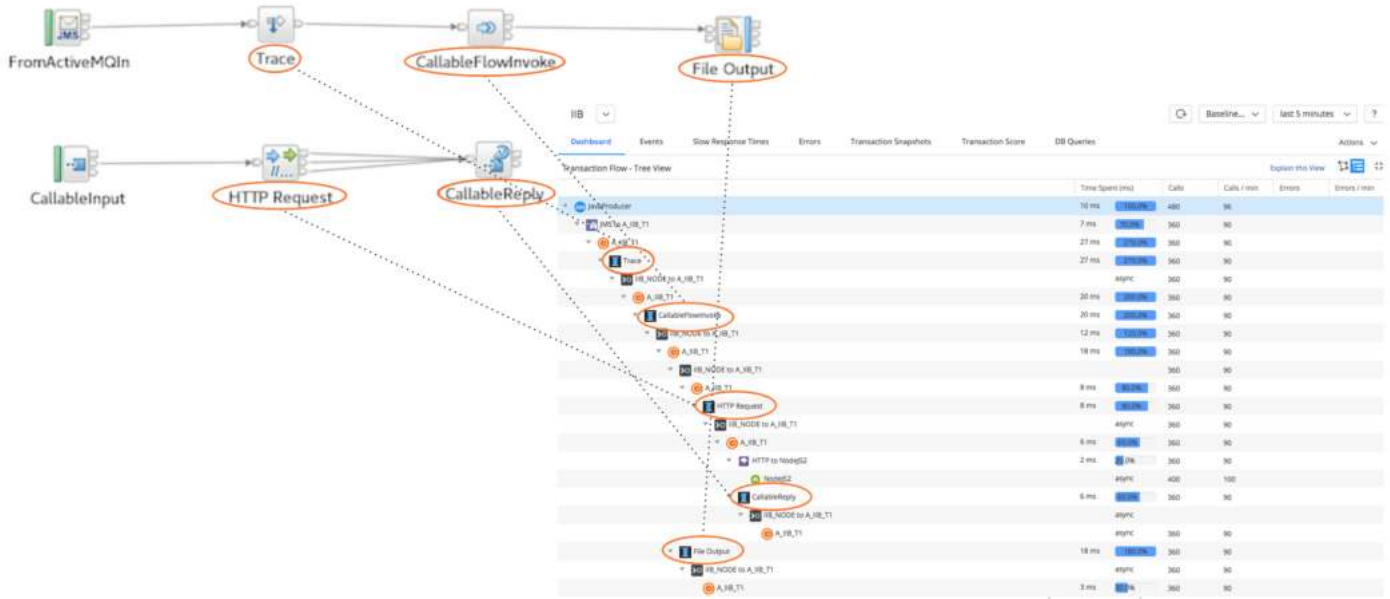

- Correlate business transactions that flow through IIB to identify where time is spent processing transactions in the larger end-to-end architecture.
- Measure where business transaction processing time is spent within IIB flows, allowing operations staff and flow developers to identify any bottlenecks within the flows.

 This page describes IBM IIB in the context of it being monitored by AppDynamics. For a full description of IBM IIB and its capabilities, refer to the IBM product documentation.

### How It Works

The agent supports inbound and outbound correlation for HTTP, JMS, and IBM MQ messaging nodes. You can identify business transactions that originate in the broker itself by the transaction name, which contains the message flow name and the message flow node name where the BT originated.

To measure where the time is spent within the flows, the agent models each message flow node as a thread (with thread names corresponding to the message flow node name). You can view the per-node timings in the tree view of the Business Transactions dashboard for any business transaction that passed through IIB, as shown below:

The IIB Agent also reports message flow node timing data, represented as thread segments in transaction snapshots, for business transactions that flow through IIB. Message flow node timing data is displayed in the Waterfall View.

Each broker is represented in the AppDynamics flow map as a tier, which is named as you specified in the configuration. Individual broker processes register with AppDynamics as nodes. The node names are generated from the Broker name and the Execution Group name.

Use the `<node-reuse-prefix>prefixName</node-reuse-prefix>` property when `node-reuse` is set to `true`. If you do not set this property, the IIB agent generates node names as per the internal node name standards of IBM. See [Enable the Node Name Reuse](#).

## IIB Supported Environments

### IIB Agent Support

This page provides the supported versions, operating systems, and node types of the IIB agent. The AppDynamics IIB agent supports the Linux and AIX operating systems.

### Operating Systems

The IIB agent supports these operating systems:

- Linux x86-64
- AIX v7.1 and v7.2

### IIB Versions

The IIB Agent supports these versions of IIB for the Linux and AIX operating systems:

Operating System	IIB Version
Linux (Any Linux distribution based on glibc >= 2.17)	<ul style="list-style-type: none"> <li>• IIB v10</li> <li>• ACE v11</li> <li>• ACE v12</li> </ul>
AIX 7.1 (minimum patch level 7100-03-09-1717 or 7100-04-04-1717)	<ul style="list-style-type: none"> <li>• IIB v10</li> </ul>
AIX 7.2	<ul style="list-style-type: none"> <li>• IIB v10</li> <li>• ACE v11 (requires ACE Fix Pack &gt;= v11.0.0.9)</li> <li>• ACE v12</li> </ul>

## IIB Node Types

The agent can continue business transactions detected upstream at these node types:

- SOAPInput
- HTTPInput
- JMSInput
- MQInput

The agent can detect and tag exit calls for downstream correlation at these node types:

- SOAPRequest
- HTTPRequest
- JMSOutput, JMSReply
- MQOutput, MQReply

For MQ, we use the MQRFH2 message header to provide correlation. Any applications consuming MQ messages from IIB with the IIB agent must support the MQRFH2 header.

The agent can detect database backend calls for these node types:

- DatabaseRetrieve
- DatabaseRoute

All nodes are represented within AppDynamics Business Transactions as Threads. You can view the per node timings in the tree view of the Business Transaction dashboard and in the transaction snapshots.

## Install the IIB Agent

### Related pages:

- [Download AppDynamics Software](#)
- [mqsichangeuserexits command](#)
- [cciRegisterUserExit](#)
- [SELinux Installation Issues](#)

To begin monitoring IIB, you must install the IIB agent.

### Install the Agent

1. Download the agent from <https://download.appdynamics.com/download/>.
2. Extract the IIB agent zip file into your chosen installation directory.

For cURL installation, see [Download AppDynamics Software](#).

### Configure the IIB Agent

The page guides you on how to integrate Appdynamics IIB Agent on Linux and AIX. The installation steps for IIB agent for IIB v9 and v10 are the same for Linux and AIX. The installation steps for IIB, ACE 11, and ACE 12 are provided in a separate tab.

**i** ACE is currently supported on Linux and AIX v7.2.

1. Specify the settings for the agent-controller communication. In the `controller-info.xml` file, set these properties:
  - `account-name` : Account name of the controller login.
  - `account-access-key` : Access key. This key is used for verification with the controller.
  - `application-name` : Name of the application that the IIB server belongs to.
  - `controller-host` : Hostname of the controller.
  - `controller-port` : Port number of the controller.
  - `controller-proxy-host`: Host name or IP address of any proxy required for the agent to connect to the controller.
  - `controller-proxy-port`: Port number of any proxy required for the agent to connect to the controller.
  - `controller-proxy-username`: Username for authenticating with the proxy.
  - `controller-proxy-password`: Password for authenticating with the proxy user.
  - `controller-proxy-passwordfile`: Full path name of a file containing the password for authenticating with the proxy user.
  - `controller-ssl-enabled` : SSL login. Set `1` to enable, `0` to disable.
  - `controller-cert-file`: Full path to the PEM format X509 certificate for SSL.  
See, [Enable SSL for the C/C++ SDK](#) for more information on obtaining the file.
  - `log-dir` : Path to the directory containing the IIB agent log files. The default path is `/tmp/appd` . Logs that are written before this configuration are logged in this path.
  - `log-level` : Level of the logs. Set this property to `trace|debug|info|warning|error` . `Error` is the highest priority and `trace` is the lowest priority.
  - `tier-name` : Name of the tier representing the broker.
  - `user-exit` : Exit name of the user. This must be in the alphanumeric format, as provided to the `mqsichangebroker` command.
  - `<log-settings> </log-settings>`: Log settings of the agent. For more information, see [Configure Agent Log File Size](#).
  - `disable-correlation`: Enable or disable correlation of specific backends. Set `1` to enable, `0` to disable.
  - `disable-http-correlation`: Set `1` to enable, `0` to disable.
  - `disable-jms-correlation`: Set `1` to enable, `0` to disable.
  - `disable-mq-correlation`: Set `1` to enable, `0` to disable.
  - `flow-level-visibility-enabled`: Flow level visibility option. Set `1` to enable, `0` to disable. The default value is `0`. See [IIB Agent Flow Level Visibility](#).
  - `<node-reuse>true</node-reuse>`: Set this property to reuse the node names of historical VMs for new VMs. It prevents the rapid increase of differently named nodes. See [Enable the Node Name Reuse](#).
  - `<node-reuse-prefix>prefixName</node-reuse-prefix>`: Use this property when `node-reuse` is set to `true`. If you do not set this property, the IIB agent generates node names as per the internal node name standards of IBM. See [Enable the Node Name Reuse](#).
2. Run the following command to stop the broker. To configure user exits, your broker must be stopped.

```
mqsistop <broker_name>
```

3. Install the IIB agent user exit. Ensure that the IIB agent user exit is enabled by default, for all the flows. Perform the steps based on the version applicable to you.

[IIB 10](#) [ACE 11, ACE 12](#)

Run the following command:

```
mqsichangebroker <broker_name> -x <install-directory> -e <user_exit_name>
```

[IIB 10](#) [ACE 11, ACE 12](#)

Perform the following in the `node.conf.yaml` file. You can find the file in the path: `<path-to-installation-directory>/<broker-name>/node.conf.yaml`.

UserExits:

- `activeUserExitList: '<User Exit Name>'` #Specify the name of user exit
- `userExitPath: '<path>'` #specify the path.

 The agent starts and stops with the broker, if it is installed on the broker.

4. Run the following command to start the broker.

```
mqsistart <broker_name>
```

For IIB 10, you can monitor a subset of your message flows. You can exclude flows that are of less importance from being monitored by running the following command:

```
mqsichangeflowuserexits <broker_name> -e <integrationServerName> -f <MessageFlow> -k <application_name> -i <user_exit_name>
```

## Partial Instrumentation of Brokers

[IIB 10](#) [ACE 11, ACE 12](#)

If you have a high volume of activity flow in your IIB instance, you may want to select only the critical flows to instrument. Perform the following to instrument flows on an opt-in basis:

1. Install the agent with the following command to instrument flows on an opt-in basis.

```
mqsichangebroker <broker_name> -x <install-directory>
```

2. Add the agent to individual flows with the following command:

```
mqschangeflowuserexits <broker_name> -a <user_exit_name> -e <integrationServerName> -f
<MessageFlow> -k <application_name>
```

**i** An application node registers for each broker process that has one or more instrumented flows deployed to it. Business transactions are only created (or continued) for flows where the agent's user exit is active.

## IIB 10 [ACE 11, ACE 12](#)

If you have a high volume of activity flow in your ACE instance, you may want to select only the critical integration servers to instrument.

To instrument integration servers on an opt-in basis, edit the following in the `server.conf.yaml` file. You can find the file in the path "`<path-to-installation-directory>/<broker-name>/servers/<server-name>/server.conf.yaml`".

1. UserExits:
  - `activeUserExitList: '<UserExitName>'` #specify the name of an installed user exit to activate.
  - `userExitPath: '<path>'` #specify the path.
2. Set the following parameters in the 'UserExits' configuration of the `node.conf.yaml` as blank.
 

UserExits:

  - `activeUserExitList: ''` #set it as an empty string.
  - `userExitPath: ''` #set it as an empty string.
3. Restart the broker.

**i** AppDynamics Agent is enabled only for those integration servers that have been instrumented and not for all the servers. Business transactions are only created (or continued) for integration servers where the agent's user exit is active.

## Configure Agent Log File Size

AppDynamics IIB Agent creates a separate log file for each execution group. Therefore, each log continuously grows, even if the execution group is not instrumented.

Hence, a need to stop pushing the updates to the logs for non-instrumented execution groups arises. AppDynamics IIB Agent now allows you to configure the log file size according to your requirement.

The following setting in the configuration file, `controller-info.xml` allows you to configure the log file size of the agent:

```
<log-settings>
<log-setting broker="" execution-group="">
<max-file-size></max-file-size>
</log-setting>
</log-settings>
```

The settings are defined as follows:

Setting	Description
<log-settings></log-settings>	Header tag
<log-setting broker="" execution-group="">	Broker name and the execution group name, which must be strings
<max-file-size> </max-file-size>	The maximum size of the log file. The format is <number><unit> . For example, 5 MB. Valid units are "MB" or "KB". The accepted range in KB is [200KB, 999KB] and in MB it is [1MB, 999MB]. Every execution group has its own log file.

However, you need to note the following guidelines for the configuration:

- If a broker is not named, the setting applies to all the brokers.
- If an execution group is not named, the setting applies to all the execution groups.
- An execution group name must be accompanied by a broker name.

**i** If you include the log setting, log-rotation is set to 1, else the default value of 5 is considered as the log rotation.

### Example

For example, in the following configuration, there are three instances of log setting:

```
<controller-info>
<controller-host></controller-host>
<controller-port></controller-port>
<controller-ssl-enabled></controller-ssl-enabled>
<account-name></account-name>
<account-access-key></account-access-key>
<application-name></application-name>
<tier-name></tier-name>
<user-exit></user-exit>
<log-level></log-level>
<enable-extended-logging></enable-extended-logging>
<controller-cert-file></controller-cert-file>
<controller-cert-dir></controller-cert-dir>
<log-settings>
<log-setting broker="" execution-group="">
<max-file-size>200KB</max-file-size>
</log-setting>
<log-setting broker="Broker1" execution-group="EG1">
<max-file-size>2MB</max-file-size>
</log-setting>
<log-setting broker="Broker1" execution-group="">
<max-file-size>3MB</max-file-size>
```

```
</log-setting>
</log-settings>
</controller-info>
```

The order of preference is mentioned in the following table. The preference order is defined as 1 → 2 → 3 → 4. Hence, if an order is invalid or does not match, then the next valid order is considered.

Order Number	Preferences	Order Template
1	Execution-Group	<code>&lt;log-setting broker="Broker1" execution-group="EG1"&gt;</code>
2	Broker	<code>&lt;log-setting broker="Broker1" execution-group=""&gt;</code>
3	Across multiple-broker	<code>&lt;log-setting broker="" execution-group=""&gt;</code>
4	Default	Agent default is applied which is 10MB

The following are the valid values, for different execution groups when used with the above example configurations.

Broker Name	Execution Group Name	Valid Values (max-file-size)
Broker1	EG1	2MB
Broker1	All other EGs	3MB
All other Brokers	All other EGs	200KB

### Enable the Node Name Reuse

The node name reuse function enables users to reuse the node names of historical VMs for new VMs. It prevents the rapid increase of differently named nodes, especially when the nodes are identical processes that run over different times. This helps you monitor environments with short-life VMs.

To enable this function, specify the following in the IIB configuration (`controller-info.xml`) file.

```
<node-reuse>true</node-reuse>
<node-reuse-prefix>prefixName</node-reuse-prefix>
```

The `node-reuse-prefix` property allows the controller to generate node names dynamically using the prefix `<prefixName>`. The nodes running in parallel are differentiated by suffixes (-1, -2, -3, and so on), depending on the number of nodes running. It generates a node name with App, Tier, and Sequence number when enabled. It also pools the node names. For example, the sequence numbers are reused when the nodes are purged (based on the node lifetime).

Once a node shuts down, it becomes a historical node, and its name can be used as a new node. However, if a node shuts down unexpectedly or forcefully, the agent does not inform the controller about the shutdown. In this case, the node name is not reused. To avoid forceful shutdowns, you can use `terminationGracePeriod`. IIB agent recommends `terminationGracePeriod` of 60 seconds.

For more information on `terminationGracePeriod`, see [Kubernetes best practices: terminating with grace](#).

If you do not specify this function, the IIB agent generates internal node names based on IBM standards.

## Troubleshooting

If you experience any functional issues with the agent, review the following information and supply it to the AppDynamics Support.

- The agent log. The IIB agent writes status information into the configured log directory, or `/tmp/appd` if the configuration has not been read at the time the message is logged. The status information can help diagnose issues with the agent.
- The system log. The IIB broker writes status messages into the system log. The messages include information about the loading and operation of user exits, such as the AppDynamics IIB agent.
- Abend files in the IIB errors directory. The default location is `/var/mqsi/common/errors`.
- Core files, if they exist.

**i** If the user-exit name provided in the `controller-info.xml` file is not alphanumeric, the broker cannot load the agent and fails to start.

If you have an issue with the agent or if you want to disable it, perform the following:

1. Stop the broker `mqsisstop <broker-name>`.
2. Perform the following based on the version applicable to you.

**IIB 10** ACE 11, ACE 12

Remove the AppDynamics user exit `mqsichangebroker <broker-name> -x "" -e ""`

**IIB 10** ACE 11, ACE 12

Set the following parameters in the `node.conf.yaml` file as an empty string.

```
UserExits:
 activeUserExitList: ""
 userExitPath: ""
```

3. Start the broker `mqsisstart <broker-name>`.

## Disable the IIB Agent

**IIB 10** ACE 11, ACE 12

If you have enabled the agent on a flow-by-flow basis, perform the following for each flow the agent is enabled on.

1. Stop the broker `mqsistop <broker-name>`.
2. Disable the user exit for each flow `mqsichangebroker <broker-name> -a "" -e <integrationServerName> -f <messageFlow> -k <applicationName>`.
3. Start the broker `mqsistart <broker-name>`.

#### IIB 10 [ACE 11, ACE 12](#)

If you have enabled the agent on integration server level, perform the following for each servers.

1. Stop the broker `mqsistop <broker-name>`.
2. Set the following parameters in the `server.conf.yaml` file as an empty string. You can find the file at the location: "`<path-to-installation-directory>/<broker-name>/servers/<server-name>/server.conf.yaml`".
 

```
UserExits:
 activeUserExitList:"
 userExitPath:"
```
3. Start the broker `mqsistart <broker-name>`.

### Turn off MQRFH2 Injection Added by AppDynamics Monitor Agent Tool

For IIB Agents that use the MQ mechanism, the MQRFH2 message header is used to provide correlation to downstream tiers. Any applications consuming MQ messages from an upstream IIB agent must support the MQRFH2 header standards to provide end-to-end correlation.

In a situation where the downstream agent reports the error MQRC\_HEADER\_ERROR (MQRC 2142) while parsing the message from an IIB agent via MQ, you can perform one of the following:

- Update the downstream consumer to accept the MQRFH2 header structure by upgrading the downstream software to a version that supports MQRFH2.
- Disable MQ correlation in IIB Agent by setting `<disable-mq-correlation>1</disable-mq-correlation>` in the `controller-info.xml` file and restart the agent.
- Change the MQ PROPCTL property to `NONE` on the destination queue. See [https://www.ibm.com/support/knowledgecenter/en/SSFKSJ\\_7.5.0/com.ibm.mq.mig.doc/q008230\\_.htm](https://www.ibm.com/support/knowledgecenter/en/SSFKSJ_7.5.0/com.ibm.mq.mig.doc/q008230_.htm).

### Troubleshooting for IBM MQ .NET Clients

AppDynamics Monitor Agent tool adds an additional RFH header to the MQ message before adding the message to the queue. Because of this additional RFH header, IBM MQ .NET Clients may report an MQRC\_HEADER\_ERROR (MQRC 2142) while parsing the message. Following is the sample RFH header that gets added to MQMessage.

```
RFH ...x..."...3...MQSTRP...<usr><singularityheader
dt="string" >notxdetect
=True</singularityheader></usr>
```

The RFH2 structure begins with `<usr><singularityheader dt="string" >`. This RFH header is added by the AppDynamics Monitor Agent tool and not by MQ.

Perform these steps to disable the additional header on the tool:

1. Go to **Configuration > Instrumentation > Backend Detection**.
2. Click on your application name, go to the .NET tab and click **Queues**.
3. Click **Edit Automatic Discovery** and in the popup, clear the **Correlation Enabled** checkbox.

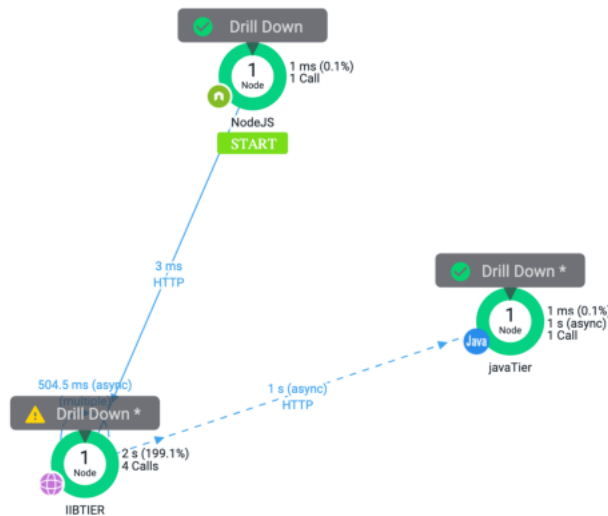

## IIB Agent Flow Level Visibility

Flow Level Visibility feature captures the time spent on each message flow and any exit calls made from the message flow. Unlike the existing agent flow, Flow level does not capture the time spent on every node in the message flow. All the other features such as BT correlation, snapshots, exit calls, and so on remain unchanged. The difference is only visible in the Tree View in Business Transaction and Water Fall View in Transaction Snapshots. This difference is demonstrated with an example below:

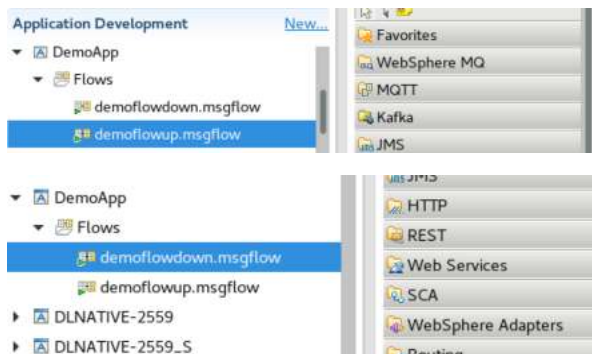

### Existing IIB Agent Flow

In the existing IIB Agent default visibility, the agent gathers timings for each node in an IIB flow.

Consider the following illustration that shows the information captured by the existing framework for the flow **NodeJS--->IIB--->Java**:

The broker within the IIB tier runs the following two message flows: demoflowup and demoflowdown. demoflowup makes a call to demoflowdown, which in turn, makes a backend call.

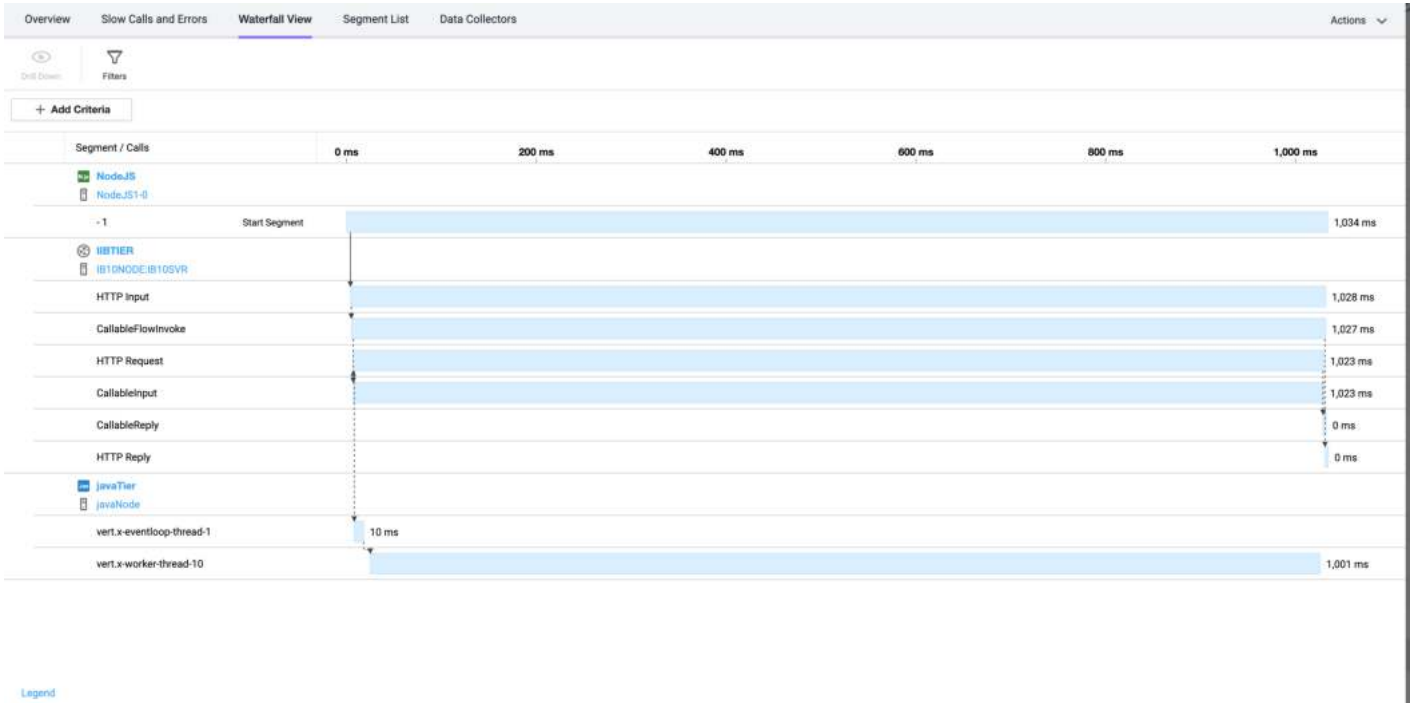

The following image displays the business transaction tree view and the transaction snapshot waterfall view for transactions flowing through the IIB application:

Transaction Flow - Tree View

[Explain this View](#)  

	Time Spent (ms)	Success %	Calls	Calls / min	Errors	Errors / min
NodeJS	1017 ms	100.0%	99	20		
HTTP to IIBTIER	1016 ms	99.9%	79	20		
IIBTIER	1012 ms	99.5%	78	20		
HTTP Input	1012 ms	99.5%	78	20		
IIB_NODE to IIBTIER	async		56	19		
IIBTIER	1011 ms	99.4%	56	19		
CallableFlowInvoke	1011 ms	99.4%	56	19		
IIB_NODE to IIBTIER	async		56	19		
IIBTIER	504 ms	49.6%	112	37		
HTTP Reply	1 ms	0.1%	56	19		
IIB_NODE to IIBTIER	async		56	19		
CallableInput	1007 ms	99.0%	56	19		
IIB_NODE to IIBTIER	async		56	19		
IIBTIER	1006 ms	98.9%	56	19		
HTTP Request	1006 ms	98.9%	56	19		
IIB_NODE to IIBTIER	async		56	19		
IIBTIER	1 ms	0.1%	56	19		
CallableReply	1 ms	0.1%	56	19		
IIB_NODE to IIBTIER	async		56	19		
HTTP to JavaTier	1004 ms	98.7%	56	19		
JavaTier	1003 ms	98.6%	56	19		

## Flow Level Visibility

To reduce the cost of collecting the node level data, a new mode for the agent to provide flow-level visibility is introduced. In this mode, timings are collected only for flow start and end and any external calls made from within a flow. Therefore, the expected CPU cost of instrumenting the flows with the agent is reduced, especially for complex flows.

The business transaction tree and snapshot views from the sample application are provided below to illustrate the difference in data granularity with flow-level visibility enabled.

When you set the flow-level-visibility-enabled flag as 0 or 1, you might need to delete the BT in the tree view so that the tree view gets updated appropriately.

---

## Deploy AppDynamics for Azure

AppDynamics integrates seamlessly with Microsoft Azure. AppDynamics offers visibility into .NET code execution and Microsoft Azure services out of the box, allowing you to troubleshoot performance bottlenecks and optimize the performance of your Microsoft Azure applications.

## AppDynamics for Azure App Service

To install and deploy AppDynamics for Azure App Service:

- For Ops teams: Install the AppDynamics Azure Site Extension for .NET or Java:
  - See [Install the AppDynamics Azure Site Extension for .NET](#)
  - See [Install the AppDynamics Site Extension for Java](#)
- For Dev teams: Install the **AppDynamics.Agent.Azure.AppService.Windows** NuGet package and configure the .NET agent in Azure App Service. See [Install the AppDynamics .NET Microservices Agent](#) and [Install AppDynamics for Azure App Service](#).

## AppDynamics for Azure Cloud Services and Azure Service Fabric

To install and deploy AppDynamics for Azure Service Fabric, see [Install AppDynamics for Azure Service Fabric](#).

If you are instrumenting Cloud Services, see [Install AppDynamics for Azure Cloud Services](#).

### Upgrade the AppDynamics for Windows Azure NuGet Package

If you are currently using the AppDynamics.WindowsAzure NuGet Package, you will need to upgrade to a new NuGet package, depending on your Azure platform. See [Upgrade AppDynamics.WindowsAzure NuGet Package](#).

## Install AppDynamics for Azure App Service

### Related Pages:

- [SELinux Installation Issues](#)

There are two ways to install the .NET microservices agent into Azure App Service:

- Use the AppDynamics Azure Site Extension for .NET or Java:
  - See [Install the AppDynamics Azure Site Extension for .NET](#).
  - See [Install the AppDynamics Site Extension for Java](#).
- Use the AppDynamics for Windows Azure NuGet Package: See [.NET Microservices Agent](#).

Azure Site Extension is used by Ops teams that may not have access to source files, or would not like to modify or recompile them, yet still want to monitor their Azure projects and solutions.

The NuGet Package is used by Dev teams to deploy the .NET agent so they can include the agent binaries, scripts, and configurations in their project and configure it using Visual Studio or other IDE.

### Install the AppDynamics Azure Site Extension for .NET

You can use the Microsoft Azure Portal to add the AppDynamics Azure Site Extension to your Azure App Service web app. Azure Site Extension is used by Ops teams that may not have access to source files, or would not like to modify or recompile them, yet still want to monitor their Azure projects and solutions.

---

## Prepare to Install

To install the AppDynamics for Microsoft Azure Site Extension, you need:

- Connection information for your [AppDynamics Controller](#). See [Agent and Controller Compatibility](#).
- A Microsoft Azure account.
- An Azure web app to monitor.

If you are upgrading from a previous version, see [Upgrade the AppDynamics Azure Site Extension](#).

## Add the AppDynamics Azure Site Extension

Add the AppDynamics Azure Site extension as you would any site extension for any Azure web app.

1. Log in to the Microsoft Azure Portal.
2. Browse to your web app.

 To configure the .NET Agent using environment variables, add the environment variables before you install the AppDynamics Azure Site Extension. See [Configure the Agent Using Environment Variables](#).

3. From the **DEVELOPMENT TOOLS** list, click **Extensions**.
4. Click **+Add** to install the version of the **AppDynamics Azure Site Extension** you want to add to your web app.

After you install the AppDynamics Azure Site Extension, it appears in the installed extensions list.

## Add the AppDynamics Azure Site Extension Using an ARM Template

You can deploy the AppDynamics Azure Site Extension to Azure App Services using an Azure Resource Manager (ARM) template.

The following procedure uses Visual Studio Community 2017.

To create and deploy an ARM template:

1. From your web application in Visual Studio, select **File > New Project**.
2. Click **Cloud**, then click **Azure Resource Group**, then click **OK**.
3. From the **Select Azure Template** dialog, click **Web App**, then click **OK**.
4. Under your newly-created Resource Group, click the **Website.json** file.
5. Under JSON outline in the left pane, right-click **resources**, then select **Add New Resource**.
6. In the Add Resource dialog box, select **Application Settings for Web Apps**, enter a name, then click **OK**.
7. Under the properties section, enter your AppDynamics Controller information. The following example shows the **Website.json** file with the application properties for AppDynamics.
8. Add a new **apiVersion** section with your Azure Site Extension details:

```
{
 "apiVersion": "2015-08-01",
 "name": "[variables('webSiteName')]",
 "type": "Microsoft.Web/sites",
 "location": "[resourceGroup().location]",
 "tags": {
 "[concat('hidden-related:', resourceGroup().id, '/providers/Microsoft.Web/serverfarms/', parameters('hostingPlanName'))]": "Resource",
 "displayName": "Website"
 },
 "dependsOn": [
 "[resourceId('Microsoft.Web/serverfarms/', parameters('hostingPlanName'))]"
],
 "properties": {
 "name": "[variables('webSiteName')]",
 "serverFarmId": "[resourceId('Microsoft.Web/serverfarms', parameters('hostingPlanName'))]"
 },
 "resources": [
 {
 "apiVersion": "2016-08-01",
 "name": "appsettings",
 "type": "config",
 "dependsOn": [
 "[resourceId('Microsoft.Web/Sites', variables('webSiteName'))]"
],
 "properties": {
 "appdynamics.controller.hostName": "<host_name>",
 "appdynamics.controller.port": "<port_name>",
 "appdynamics.controller.ssl.enabled": "true",
 "appdynamics.agent.accountName": "<account_name>",
 "appdynamics.agent.accountAccessKey": "[parameters(<InKeyVault>)]",
 "appdynamics.agent.applicationName": "<application_name>",
 "appdynamics.agent.tierName": "<tier_name>",
 "appdynamics.agent.nodeName": "node_name"
 }
 },
 {
 "apiVersion": "2015-08-01",
 "name": "AppDynamics.WindowsAzure.SiteExtension.4.5.release",
 "type": "siteextensions",
 "dependsOn": [
 "[resourceId('Microsoft.Web/Sites', variables('webSiteName'))]"
]
 }
],
}
```

Here is the sample text for copying or pasting:

```
{
 "apiVersion": "2015-08-01",
 "name": "[variables('webSiteName')]",
 "type": "Microsoft.Web/sites",
 "location": "[resourceGroup().location]",
 "tags": {
 "[concat('hidden-related:', resourceGroup().id, '/providers/Microsoft.Web/serverfarms/', parameters('hostingPlanName'))]": "Resource",
 "displayName": "Website"
 },
 "dependsOn": [
 "[resourceId('Microsoft.Web/serverfarms/', parameters('hostingPlanName'))]"
],
 "properties": {
 "name": "[variables('webSiteName')]",
 "serverFarmId": "[resourceId('Microsoft.Web/serverfarms', parameters('hostingPlanName'))]"
 },
 "resources": [
 {

```

```

 "apiVersion": "2016-08-01",
 "name": "appsettings",
 "type": "config",
 "dependsOn": [
 "[resourceId('Microsoft.Web/Sites', variables('webSiteName'))]"
],
 "properties": {
 "appdynamics.controller.hostName": "mycompany.saas.appdynamics.com",
 "appdynamics.controller.port": "443",
 "appdynamics.controller.ssl.enabled": "true",
 "appdynamics.agent.accountName": "mycompany",
 "appdynamics.agent.accountAccessKey": "[parameters('AppDAccessKeyInKeyVault')]",
 "appdynamics.agent.applicationName": "HelloWorldSecureAppDKey",
 "appdynamics.agent.tierName": "TestTier",
 "appdynamics.agent.nodeName": "TestNode"
 }
 },
 {
 "apiVersion": "2015-08-01",
 "name": "AppDynamics.WindowsAzure.SiteExtension.4.5.Release",
 "type": "siteextensions",
 "dependsOn": [
 "[resourceId('Microsoft.Web/Sites', variables('webSiteName'))]"
]
 },

```

## Configure the Controller Connection

You have the following options to configure the .NET Agent to connect to the AppDynamics Controller:

- Configure the Controller connection using the [Kudu console](#).
- Configure the Controller connection settings using [environment variables](#).

See [Agent-to-Controller Connections](#).

### Configure the Agent with the Kudu Console

When you add the AppDynamics Azure Site Extension to your web app, you can interactively configure the .NET Agent using the Kudu Console.

1. Navigate to the AppDynamics Controller Configuration page in the Kudu Console:  
<http://{web app}.scm.azurewebsites.net/appdynamics/>  
 For example: <https://myazureexample.scm.azurewebsites.net/appdynamics/>

2. On the AppDynamics Controller Configuration page, enter your Controller connection information. For example:

APPDYNAMICS | Windows Azure

## AppDynamics Controller Configuration

Enter the following information to monitor your Azure application with AppDynamics. You should have received this from your sign up email or from your AppDynamics sales representative.

Controller Host	Port
<input type="text" value="mycompany.saas.appdynamics.com"/>	<input type="text" value="443"/>
Enable SSL <input checked="" type="checkbox"/>	
Account Name	
<input type="text" value="MyAccount"/>	
Access Key	
<input type="text" value="AB1a2b3c4\$123"/>	
Application Name ⓘ	
<input type="text" value="MyAzureApp"/>	
<input type="button" value="Validate"/>	

3. Click **Validate** to test the connection to the AppDynamics Controller and save your settings.
4. Restart your web app.  
After you apply some load to your web app, you can view it on [flow maps](#) in the AppDynamics Controller UI.

### Configure the Agent Using Environment Variables

You can use environment variables to configure the .NET Agent for unattended configuration.

To configure .NET Agents, add the environment variables before you install the AppDynamics Azure Site Extension:

1. Navigate to **SETTINGS > Application Settings** for your web app.
2. Add the .NET Agent environment variables under **App settings**:
  - appdynamics.controller.hostName: address for the AppDynamics Controller
  - appdynamics.controller.port: Controller port
  - appdynamics.agent.accountName: account name you use to log in to the Controller
  - appdynamics.agent.accountAccessKey: account key you use to log in to the Controller
  - appdynamics.agent.applicationName: business application name in the Controller
  - appdynamics.controller.ssl.enabled: set to `True` to enable SSL connection to the Controller; otherwise set to `False`.
  - appdynamics.proxy.hostName: name of the proxy host
  - appdynamics.proxy.authDomain: (Windows only) domain name of the proxy server

- `appdynamics.proxy.port`: port number of the proxy
  - `appdynamics.proxy.authName`: name of the user who connects to the proxy
  - `appdynamics.proxy.authPassword`: password of the user who connects to the proxy
  - `appdynamics.enable.tls12`: set to True to enable transport layer security (TLS) 1.2; otherwise set to False.
3. Restart your web app. After you apply some load to your web app, you can view it on [flow maps](#) in the AppDynamics Controller UI.

### Specify Which WebJobs to Monitor

Use the `APPDYNAMICS.PROCESSLIST` environment variable to specify which WebJobs the .NET Agent monitors.

Environment Variable: `APPDYNAMICS.PROCESSLIST`

Type: Strings separated by "|"

Default: None. When undefined, the agent instruments all WebJob running in the app service. When defined, the .NET Agent instruments only the specified processes.

Required: No

Usage Cases:

- Environment 1: An Azure app service with no WebJobs, where the Appdynamics .NET Agent site extension is installed and configured. After defining the environment variable `AppDynamics.ProcessList` with the value `w3wp.exe`, the `Daasrunner.exe` WebJob, which is a default WebJob that is added to all app services, is not instrumented.
- Environment 2: An Azure app service, with two WebJobs, `webjob1.exe` and `webjob2.exe`, where the Appdynamics .NET Agent site extension is installed and configured. After defining the environment variable `AppDynamics.ProcessList` with the value `w3wp.exe`, only the worker process serving the actual web app will be instrumented and no WebJobs will be instrumented. With the environment variable value set to `w3wp.exe|webjob1.exe`, the worker process serving the web app and the `webjob1.exe` are instrumented, but the `webjob2.exe` is not instrumented. With the `AppDynamics.ProcessList` removed from the App settings of the Azure app service, all the WebJobs, including `Daasrunner.exe` are instrumented, including the worker process serving the web app.

### Upgrade the AppDynamics Azure Site Extension

When you click on the Extensions tab for your web app, the Microsoft Azure Portal displays the currently installed version of the AppDynamics Azure Site Extension. The Update Available column of the installed extensions list indicates if there is a more recent minor release of the .NET Agent available. If so, you can click to update the extension from the list.

Upgrade a Major Version of the .NET Agent

AppDynamics maintains major release versions of the .NET Agent as separate site extensions. Therefore you need to uninstall the installed version of the AppDynamics Azure Site Extension before you upgrade to a new major release:

1. Log in to the Microsoft Azure Portal.
2. Stop your web app.
3. Click on the AppDynamics Azure Site Extension from the list of installed extensions and click **Delete** to uninstall it.
4. Install the new version of the AppDynamics Azure Site Extension as normal.

**i** If you are upgrading from .NET Agent 4.2 and you used environment variable configuration, you must update your web app environment variables. See [configure the agent using environment variables](#). Note that the APPD\_UNATTENDED variable is no longer required.

## Install the AppDynamics .NET Microservices Agent

Install the NuGet package **AppDynamics.Agent.Azure.AppService.Windows** to add the .NET microservices agent directly to projects you plan to deploy to Windows Azure. This package works for Azure App Service (formerly Azure Websites): Web Apps and API Apps.

### Prepare to Install the NuGet Package

To install the AppDynamics for Windows Azure NuGet package you need:

- Connection information for your AppDynamics Controller
- Visual Studio >= 2012
- A Visual Studio solution to monitor
- Windows Azure SDK
- Windows Azure account

These instructions assume you are familiar with NuGet package management in Visual Studio and with the Microsoft Azure Portal. You can also try the step-through tutorial on how to instrument an App Service on the [community knowledgebase](#).

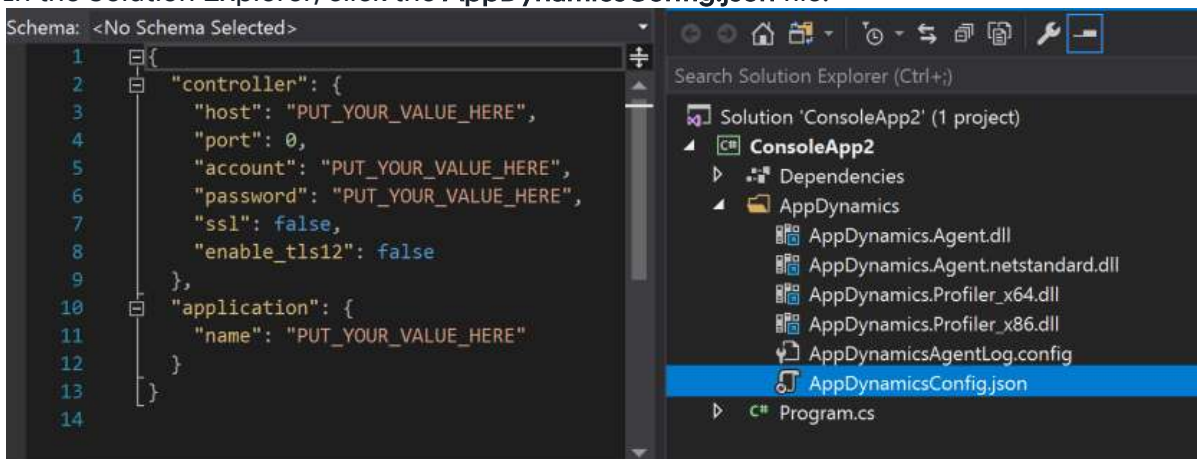

### Add the .NET Microservices Agent to Your Azure Solution

Use the NuGet package manager to browse the nuget.org package source and install the **AppDynamics.Agent.Azure.AppService.Windows** package to your Azure solution in Visual Studio.

**i** For details about managing NuGet packages, see the [documentation](#) for your version of Visual Studio.

The **AppDynamics.Agent.Azure.AppService.Windows** package installation prompts you as follows:

1. The installer may ask you to verify your changes. If so, click **OK**.
2. Click **I accept** to agree to the terms of the license.
3. In the Solution Explorer, click the **AppDynamicsConfig.json** file.

- 
4. Enter the connection information for your AppDynamics Controller in the area on the left.

### Configure the Controller Connection

You have the following options to configure the .NET Agent to connect to the AppDynamics Controller:

- During development: As shown in the previous screenshot, you can enter your environment variables in the `AppDynamicsConfig.json` file, and save it in source control.
- During build: Define your msbuild parameters or [environment variables](#) that are passed to the `AppDynamicsConfig.json` file at build time. `AppDynamicsConfig.json` does exist at build time. So, if you're defining your msbuild parameters/env variables at build time, you will need to ignore it in source control so that the new `AppDynamicsConfig.json` file will be created.
- During runtime: Enter your [environment variables](#) in Azure.

By default, the .NET microservices agent names Azure tiers as site name. The .NET microservices agent names Azure nodes by machine name appended with the website hostname.

### Monitor Virtual Applications of Azure Web Apps

#### Related links:

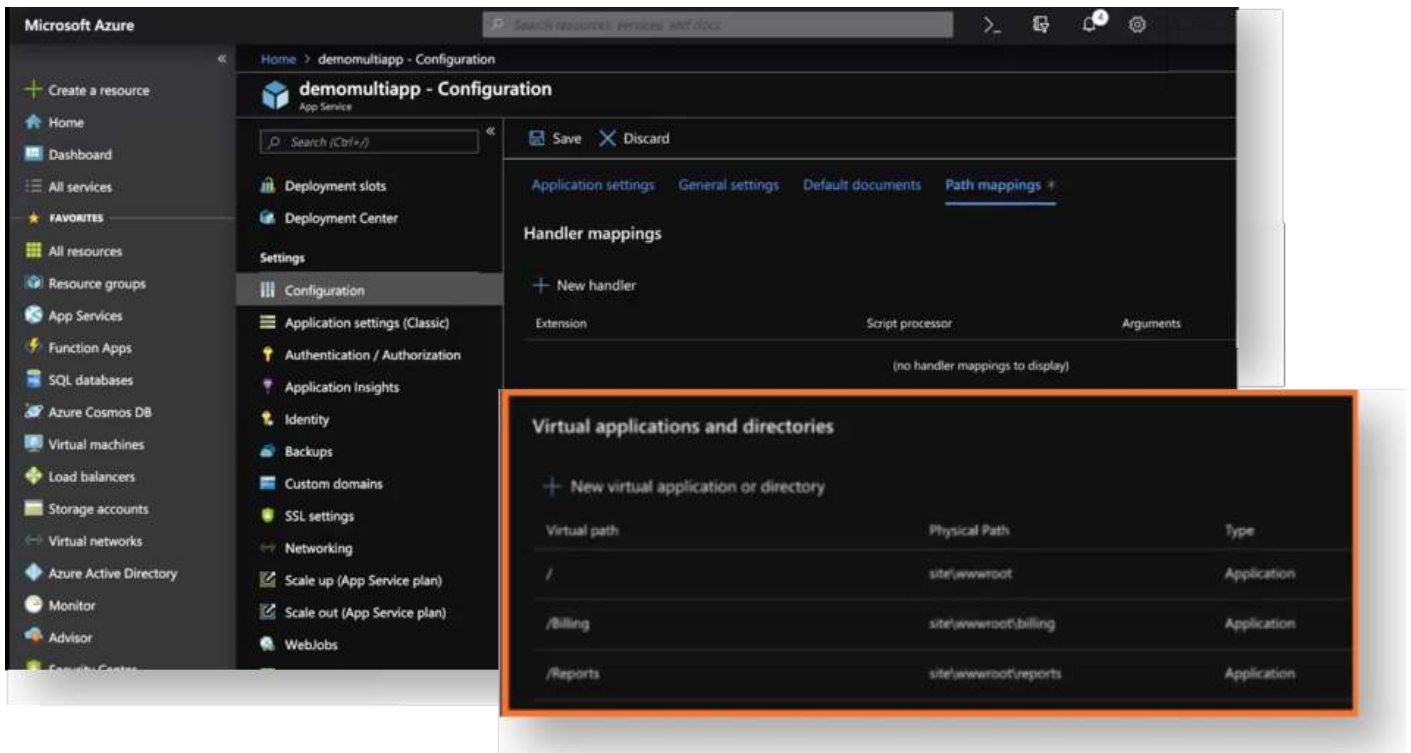

- [Deploy AppDynamics for Azure](#)

This page applies to the .NET Agent in the Azure App services environment. It describes how the .NET Agent by default names your virtual application tiers and nodes and also how you can customize tier names. You can automatically name the tiers of virtual applications using either a default or custom method:

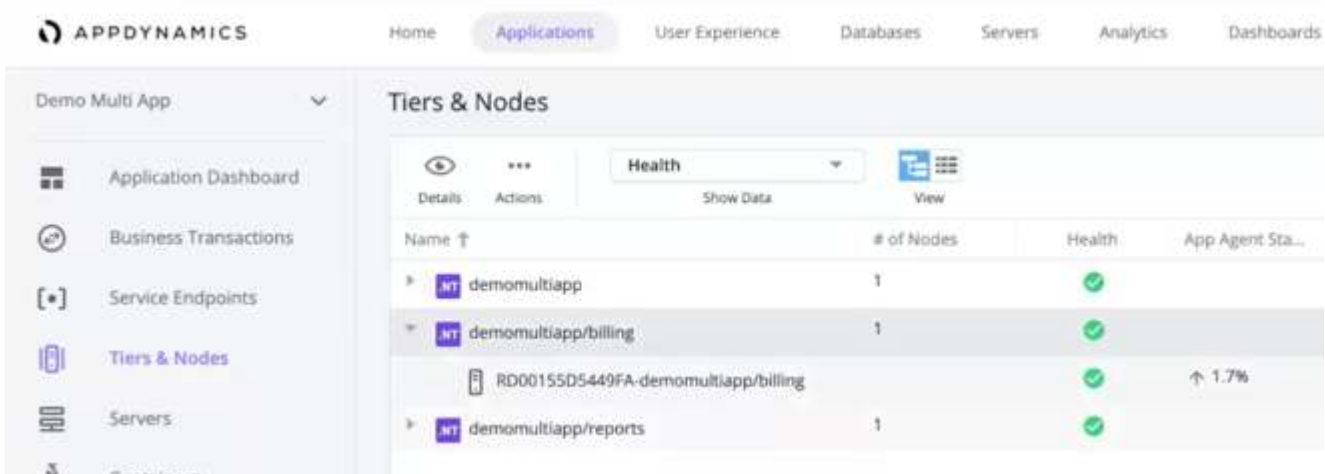

- Default: AppDynamics creates new tiers for each virtual directory. Each tier contains a node representing the virtual directory.
- Custom: When you specify a tier name in the `AppDynamicsConfig.json` file, all virtual directory applications will report as nodes under this tier.

#### Default Behavior

The following shows the Azure Web Apps configuration of the *demomultiapp* application with three virtual apps, the main application and two sub-applications.

Once you instrument the application with the .NET Agent, restart the application and apply load to it, the .NET Agent reports metrics for the application and virtual applications. In the Controller UI, each virtual application node appears under a separate tier. The name of the tier consists of the name of the application appended with the virtual path of the sub-application. For example, *demomultiapp/billing* as shown below. The name of the node is the same as the tier name prepended with the name of the virtual machine on which it runs.

You can manually edit the tier name in the Controller UI.

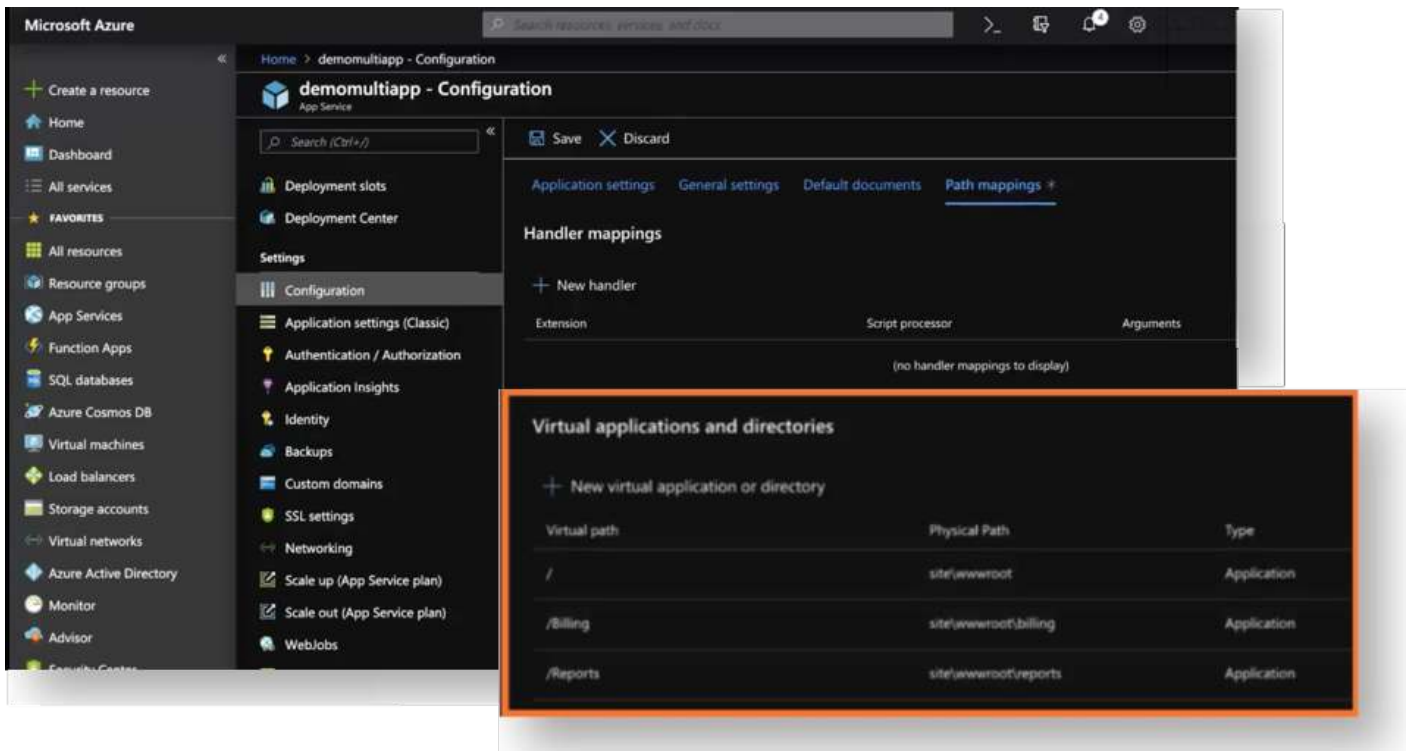

## Customize Tier Names

Rather than creating a tier for each virtual application, all virtual applications can report as nodes under a single tier. The tier name specified in the `AppDynamicsConfig.json` file sets the tier name.

- When you instrument your application using the .NET Agent site extension, the .NET Agent automatically instruments all virtual directories and applications. However, all AppSettings set at the root app are inherited by all virtual applications.
- For NuGet-based deployments, the agent uses the `AppDynamicsConfig.json` file deployed in the same path as the Profiler DLL and ignores the `AppDynamicsConfig.json` file settings for individual virtual apps in the deployment.

For example, in Azure Web Apps we have the following virtual app and sub-applications.

By default, the tier name of the application in the `AppDynamicsConfig.json` file is `null`. The following edited version of the `AppDynamics.Config.json` file shows a tier name of *Business App 15*. Note that the node name cannot be changed as its value is automatically updated as the application scales vertically and horizontally.

```

{
 "controller": {
 "host": "111.111.111.111",
 "port": 8008,
 "account": "admin",
 "password": "11111111",
 "ssl": false,
 "enable_tls12": true,
 "proxy": {}
 },
 "application": {
 "name": "Demo Multi App",
 "tier": "Business App 15",
 "node": null
 },
 "instrumentors": {
 "customCorrelationConfig": null,
 "enable": true,
 "disable": false
 }
}

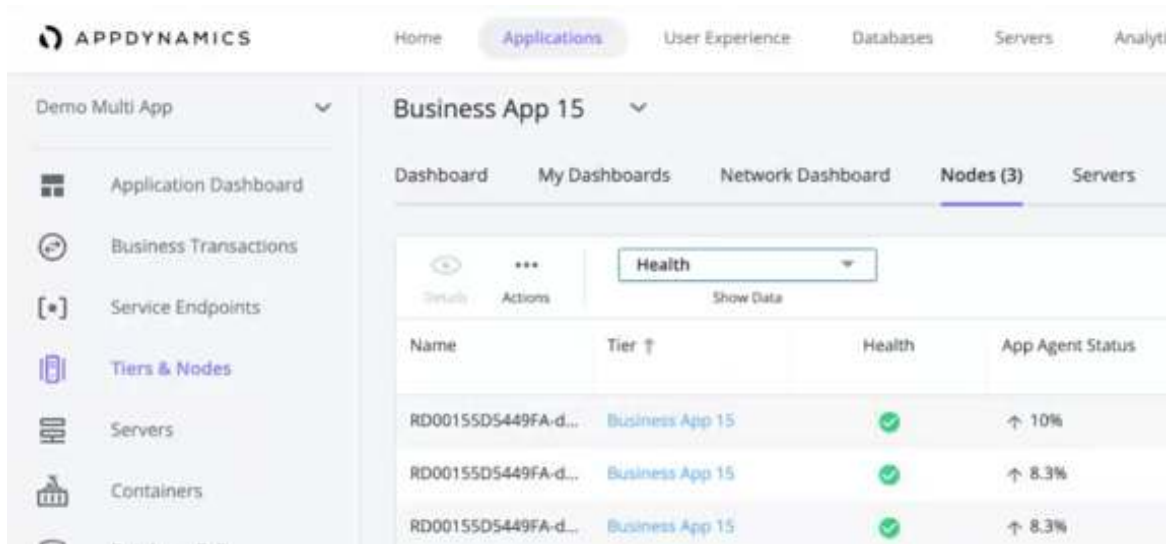

```

After the application is restarted, the virtual app tier name appears as *Business App 15*. When you expand the tier on the Tiers & Nodes Dashboard, you see the nodes of the virtual applications and the root application.

Name	# of Nodes	Health	App Agent Sta...
Business App 15	3	Green	
RD00155D5449FA-demomultiapp		Green	↑ 3.3%
RD00155D5449FA-demomultiapp/billing		Green	↓ 1.7%
RD00155D5449FA-demomultiapp/reports		Green	↓ 1.7%

The Nodes Dashboard displays the nodes of the tier *Business App 15* in a similar manner.

Nodes of the virtual application are displayed in the Controller UI using the name of the virtual machine the app is running on, followed by the name of the virtual application as it appears in Azure Web Apps.

**i** The current agent configuration file does not support targeting different virtual applications for customized tier naming, however, you can manually create .NET tiers and move the nodes to different tiers in the Controller UI.

### Prevent Daas Instrumentation

You can prevent the agent from instrumenting the Daasrunner process by creating the environment variable `AppDynamics.ProcessList` and setting it to `w3wp.exe`. This environment variable acts as an allowlist, where only the processes specified will be instrumented. Then delete the Daas tier and the Daasrunner node on the **Tiers & Nodes Dashboard**. You might also want to include WebJob processes in this list. See [Install the AppDynamics Azure Site Extension for .NET](#).

### Limitations

In this version, you cannot customize the tier names of virtual sub-applications in the `AppDynamicsConfig.json` file.

Also, this version does not support monitoring virtual apps together with deployment slots.

### Instrument Azure Functions with the .NET Agent

**i** This document contains links to Microsoft documentation, which are provided for reference and informational purposes only. AppDynamics is not affiliated, associated, authorized, or endorsed by Microsoft, or any of its subsidiaries or its affiliates, and as such makes no representation as to the accuracy or content of Microsoft documentation.

AppDynamics serverless monitoring for Azure Functions gives you visibility into the performance of your applications that run as functions on Microsoft Azure. The .NET Agent supports Azure Functions hosted on

---

App Service plans. Once installed, the .NET Agent automatically discovers business transactions in your Azure Functions.

You can monitor your applications running in Azure Functions exactly as you would any other application instrumented with the .NET Agent. Correlate business transactions between and through Azure Functions receive snapshots, create callgraphs, and integrate functions with End User Monitoring.

## Before You Begin

Before you start instrumenting the .NET Agent with Azure Functions, make sure you meet the following requirements:

### Microsoft Azure Requirements

- Applications hosted on the [AppService plan](#)
- Azure Functions versions 1.x, 2.x, and 3.x
- An instrumented Azure Function that is
  - implemented in .NET and
  - hosted on Windows OS
- For EUM correlation to work, you need to disable the the Azure Function instrumentors, `AzureFunctionsEntryInstrumentor` and `AzureFunctionsGenericTriggerInstrumentor`. After disabling these instrumentors, the agent will start to monitor ASP.NET traffic. Then, you need to add the node property: `aspdotnet-core-instrumentation` with the value `HTTP`.

### AppDynamics Requirements

- [Microservice licenses](#)
- .NET Agent version  $\geq 4.5.16$

### Install AppDynamics Azure Site Extension

To add the AppDynamics Azure Site extension:

1. Log in to the Windows Azure Portal.
2. Browse to **Function App** and select the desired function.
3. Select **Platform Features > Site Extensions > +Add**.
4. Click **Choose Extensions** and select AppDynamics Azure Site Extension 4.5.
5. Click **Legal Terms**. Review AppDynamic's legal terms and conditions and select **OK**.
6. Click **OK** in the **Add Extension** menu to complete the installation.
7. Restart the function app.

After you install the AppDynamics Azure Site Extension, it appears in the list of the installed extensions.

### Connect the .NET Agent to the Controller

You can connect your Azure Function apps to your Controller using the Kudu Console.

1. Navigate to the AppDynamics Controller Configuration page in the Kudu Console:  
`http://{web app}.scm.azurewebsites.net/appdynamics/`  
For example: `https://myazureexample.scm.azurewebsites.net/appdynamics/`

2. On the AppDynamics Controller Configuration page, enter your Controller connection information. For example:

APPDYNAMICS | Windows Azure

## AppDynamics Controller Configuration

Enter the following information to monitor your Azure application with AppDynamics. You should have received this from your sign up email or from your AppDynamics sales representative.

Controller Host	Port
<input type="text" value="mycompany.saas.appdynamics.com"/>	<input type="text" value="443"/>
Enable SSL <input checked="" type="checkbox"/>	
Account Name	
<input type="text" value="MyAccount"/>	
Access Key	
<input type="text" value="AB1a2b3c4\$123"/>	
Application Name ⓘ	
<input type="text" value="MyAzureApp"/>	
<input type="button" value="Validate"/>	

3. Click **Validate** to test the connection to the AppDynamics Controller and save your settings.
4. Restart your function app.

### Verify Instrumentation

To verify Azure Function instrumentation, view the function on [flow maps](#) in the AppDynamics Controller UI.

### Azure Function Names in the Controller UI

In the Controller, the business transaction names match the Azure Function name.

HTTP Trigger functions are named using two segments of the function URL. You can change the name of HTTP Trigger functions in [custom transaction naming](#).

*Microsoft Azure, the Azure logo, Azure, and any other Microsoft Marks used in these materials are trademarks of [Microsoft.com, Inc.](#) or its affiliates in the United States and/or other countries.*

### Automate .NET for Azure Functions Deployment

This page describes how to scale instrumentation of Azure Functions with the .NET Agent.

## Add the AppDynamics Azure Site Extension Using an ARM Template

You can deploy the AppDynamics Azure Site Extension to Azure App Services using an Azure Resource Manager (ARM) template. This procedure uses Visual Studio Community 2017.

To create and deploy an ARM template:

1. From your web application in Visual Studio, choose **File > New Project**.
2. Click **Cloud**, then click **Azure Resource Group**, then click **OK**.
3. From the **Select Azure Template** dialog box, click **Web App**, then click **OK**.
4. Under your newly-created Resource Group, click the Website.json file.
5. Under JSON outline in the left pane, right-click **resources**, then choose **Add New Resource**.
6. In the Add Resource dialog box, select **Application Settings for Web Apps**, enter a name, then click **OK**.
7. Under the properties section, enter your AppDynamics Controller information. The following example shows the Website.json file with the application properties for AppDynamics.
8. Add a new resource for the Site Extension, as shown in the following example:

```
{
 "apiVersion": "2015-08-01",
 "name": "[variables('webSiteName')]",
 "type": "Microsoft.Web/sites",
 "location": "[resourceGroup().location]",
 "tags": {
 "[concat('hidden-related:', resourceGroup().id, '/providers/Microsoft.Web/serverfarms/', parameters('hostingPlanName'))]": "Resource",
 "displayName": "Website"
 },
 "dependsOn": [
 "[resourceId('Microsoft.Web/serverfarms/', parameters('hostingPlanName'))]"
],
 "properties": {
 "name": "[variables('webSiteName')]",
 "serverFarmId": "[resourceId('Microsoft.Web/serverfarms', parameters('hostingPlanName'))]"
 },
 "resources": [
 {
 "apiVersion": "2016-08-01",
 "name": "appsettings",
 "type": "config",
 "dependsOn": [
 "[resourceId('Microsoft.Web/Sites', variables('webSiteName'))]"
],
 "properties": {
 "appdynamics.controller.hostName": "mycompany.saas.appdynamics.com",
 "appdynamics.controller.port": "443",
 "appdynamics.controller.ssl.enabled": "true",
 "appdynamics.agent.accountName": "mycompany",
 "appdynamics.agent.accountAccessKey": "[parameters('AppDAccessKeyInKeyVault')]",
 "appdynamics.agent.applicationName": "HelloWorldSecureAppDKey",
 "appdynamics.agent.tierName": "TestTier",
 "appdynamics.agent.nodeName": "TestNode"
 }
 }
]
}
```

```

 }
 },
 {
 "apiVersion": "2015-08-01",
 "name": "AppDynamics.WindowsAzure.SiteExtension.4.5.Release",
 "type": "siteextensions",
 "dependsOn": [
 "[resourceId('Microsoft.Web/Sites', variables('webSiteName'))]"
]
 },

```

## Configure the Agent Using Environment Variables

**i** If you want to configure the .NET Agent using environment variables, add the environment variables before you install the AppDynamics Azure Site Extension.

Configuring the .NET Agent using environment variables allows for unattended configuration. To configure agents in this manner, add the environment variables before you install the AppDynamics Azure Site Extension, as follows:

1. In the Azure Portal, open your Azure Function.
2. Navigate to **Function app settings > Manage application settings**.
3. Click **+New Application Setting** and enter your environment variables as name/value pairs.

The table below lists the available environment variables:
