- **Potentially Leaking**—Potentially leaking collections display as red. You should start diagnostic sessions on potentially leaking objects.
- **Status**—Indicates if a diagnostic session has been started on an object.
- **Collection Size Trend**—A positive and steep growth slope indicates a potential memory leak.

To identify long-lived collections, compare the JVM start time and Object Creation Time.

If no captured collections display, ensure that you have the correct configuration for detecting potential memory leaks.

Enable Memory Leak Detection

Memory leak detection is available through the **Automatic Leak Detection** feature. Once the **Automatic Leak Detection** feature is turned on and a capture session has been started, AppDynamics tracks all frequently used collections. Therefore, using this mode results in higher overhead.

1. Turn on **Automatic Leak Detection** mode only when a memory leak problem is identified
2. Click **Start On Demand Capture Session** to start monitoring frequently used collections and detect leaking collections.
3. After you identify and resolve the leak, turn the capture session and the leak detection modes off.
4. Start diagnosis on one individual collection at a time to achieve optimum performance.

Troubleshoot Memory Leaks

After detecting a potential memory leak, troubleshooting the leak involves performing these three actions:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- [Select the Collection Object that you want to monitor](#)
- [Use Content Inspection](#)
- [Use Access Tracking](#)

Select the Collection Object to Monitor

On the Automatic Leak Detection dashboard, right-click the class name and click **Drill Down**.

For performance reasons, start the troubleshooting session on a single collection object at a time.

Use Content Inspection

Content Inspection identifies which part of the application the collection belongs to so that you can start troubleshooting. It allows monitoring histograms of all the elements in a particular collection.

Enable Automatic Leak Detection by starting an On Demand Capture Session, select the object you want to troubleshoot, and then follow the steps listed below:

1. Click the Content Inspection tab.
2. Click **Start Content Summary Capture Session** to start the content inspection session.
3. Enter the session duration. Allow at least 1 – 2 minutes for data generation.
4. Click **Refresh** to retrieve the session data.
5. Click on the snapshot to view details about an individual session.

Use Access Tracking

Use Access Tracking to view the actual code paths and business transactions accessing the collections object.

As described above in [Workflow to Troubleshoot Memory Leaks](#), enable Automatic Leak Detection, start an On Demand Capture Session, select the object you want to troubleshoot, and then follow the steps listed below:

1. Select the Access Tracking tab
2. Click **Start Access Tracking Session** to start the tracking session.
3. Enter the session duration. Allow at least 1-2 minutes for data generation.
4. Click **Refresh** to retrieve session data.
5. Click the snapshot to view details about an individual session.

The troubleshooting information pane shows the Java stack trace associated with the session. By default, the stack trace is shown to a depth of 10 lines. If you would like to temporarily increase the number of lines captures, you can use the `maximum-activity-trace-stack-depth` Java Agent property described on [App Agent Node Properties Reference](#).

Increasing the stack trace depth can consume a significant amount of system resources. You must remove the property or set it back to the default value of 10 after you have captured the desired information.

Java Memory Thrash

Memory thrash is caused when a large number of temporary objects are created in very short intervals. Although these objects are temporary and are eventually cleaned up, the garbage collection mechanism may struggle to keep up with the rate of object creation. This may cause application performance problems. Monitoring the time spent in garbage collection can provide insight into performance issues, including memory thrash.

For example, an increase in the number of spikes for major collections either slows down a JVM or indicates potential memory thrash. Use object instance tracking to isolate the root cause of the memory thrash. To configure and enable object instance tracking, see [Object Instance Tracking for Java](#).

AppDynamics automatically tracks object instances for the top 20 core Java (system) classes and the top 20 application classes.

The Object Instance Tracking subtab provides the number of instances for a particular class and graphs the count trend of those object in the JVM. It provides the shallow memory size (the memory footprint of the object and the primitives it contains) used by all the instances.

Analyze Memory Thrash

Once a memory thrash problem is identified in a particular Classes collection, start the diagnostic session by drilling down into the suspected problematic class.

Select the class name to monitor and click **Drill Down** at the top of the Object Instance Tracking dashboard or right-click the class name and select the **Drill Down** option.

 For optimal performance, trigger a drill-down action on a single instance or class name at a time.

After the drill down action is triggered, data collection for object instances is performed every minute. This data collection is considered to be a diagnostic session and the Object Instance Tracking dashboard for that class is updated with this icon , to indicate that a diagnostic session is in progress.

The Object Instance Tracking dashboard indicates possible cases of memory thrash. Prime indicators of memory thrash problems indicated on the Object Instance Tracking dashboard are:

- **Current Instance Count:** A high number indicates the possible allocation of a large number of temporary objects.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

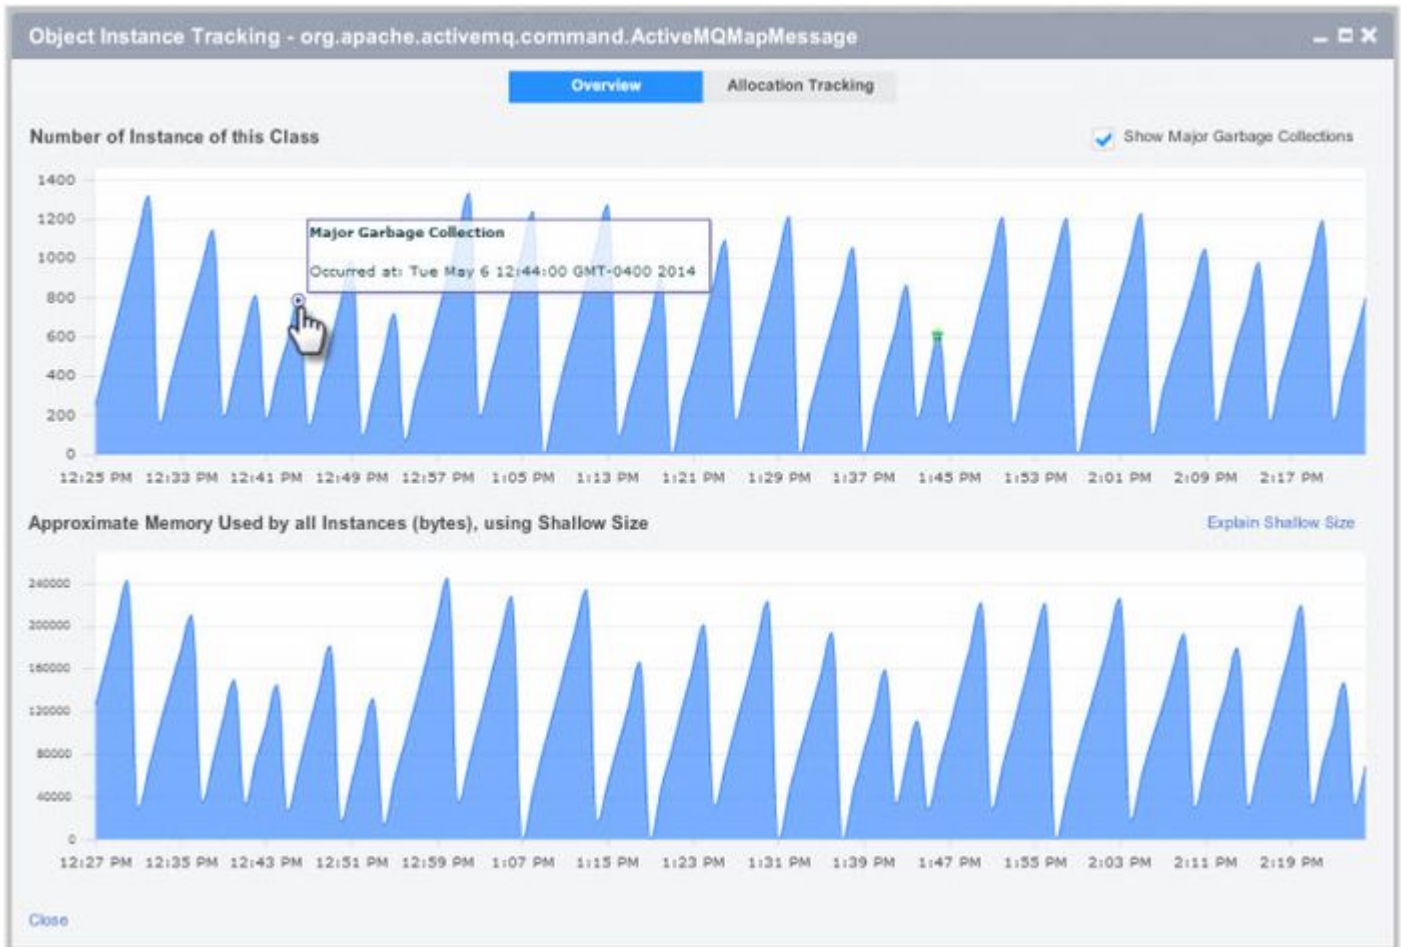

- **Shallow Size:** Is the approximate memory used by all instances in a class. A large number for shallow size signals potential memory thrash.
- **Instance Count Trend:** A saw wave is an instant indication of memory thrash.

If you suspect you have a memory thrash problem at this point, then you should verify that this is the case. See [To verify memory thrash](#).

Verify Memory Thrash

Select the class name to monitor and click **Drill Down** at the top of the Object Instance Tracking dashboard. On the Object Instance Tracking window, click **Show Major Garbage Collections**.

The following Object Instance Tracking Overview provides further evidence of a memory thrash problem.

If the instance count doesn't vary with the garbage collection cycle, it is an indication of a potential leak and not a memory thrash problem. See [Java Memory Leaks](#).

Troubleshoot Java Memory Thrash Using Allocation Tracking

Allocation Tracking tracks all the code paths and those business transactions that are allocating instances of a particular class. It detects those code path/business transactions that are creating and throwing away instances.

To use allocation tracking:

1. Using the **Drill Down** option, trigger a diagnostic session.
2. Click the Allocation Tracking tab.
3. Click **Start Allocation Tracking Session** to start tracking code paths and business transactions.
4. Enter the session duration and allow at least 1 to 2 minutes for data generation.
5. Click **Refresh** to retrieve the session data.
6. Click a session to view its details.
7. Use the Information presented in the Code Paths and Business Transaction panels to identify the origin of the memory thrash problem.

Monitor Java Object Instances

If the application uses a JRE (rather than a JDK), use these steps to enable object instance tracking:

1. Ensure the tools.jar file is in the `jre/lib/ext` directory.
2. On the Node Dashboard, click the Memory tab.
3. On the Memory tab, click the Object Instance Tracking subtab.
4. Click **On** and then **OK**.

See [Object Instance Tracking for Java](#).

Code Deadlocks for Java

By default, the Java Agent detects code deadlocks. You can find deadlocks and see their details using the Events list or the REST API.

Code Deadlocks and Their Causes

In multi-threaded development environments, it is common to use more than a single lock. However, sometimes deadlocks will occur. Here are some possible causes:

- The order of the locks is not optimal
- The context in which they are being called (for example, from within a callback) is not correct
- Two threads may wait for each other to signal an event

Finding Deadlocks Using the Events List

Select **Code Problems** (or just **Code Deadlock**) in the Filter By Event Type list to see code deadlocks in the Events list. The following list shows two deadlocks in the ECommerce tier.

The screenshot shows the AppDynamics interface with the following elements:

- Top Bar:** Includes icons for 'Hide Filters', 'View Event Details', 'Delete', 'Archive', and 'Register Application Change'. It also shows 'Viewing 2 events' and a search icon.
- Event List Table:**

Type	Summary	Time	Business T	Tier	Node	Policy
Code Deadlock	JVM de...	09/19/12 4:		EComm...		
Code Deadlock	JVM de...	09/19/12 4:		EComm...		
- Filter by Event Type Panel:**
 - Policy Violations:**
 - Policy Violation Started
 - Policy Violation changed from Warning to Critical
 - Policy Violation changed from Critical to Warning
 - Policy Violation Ended
 - Select Policies:**
 - Business Transaction Performance Policies (2)
 - Node Health - Hardware, JVM, CLR Policies (5)
 - Slow Transactions
 - Errors
 - Code Problems**
 - Code Deadlock
 - Resource Pool Limit Reached

To examine a code deadlock, double-click the deadlock event in the events list and then click the Code Deadlock Summary tab. Details about the deadlock are in the Details tab. See [Monitor Events](#).

Find Deadlocks Using the REST API

You can detect a DEADLOCK event-type using the AppDynamics REST API. For details, see the example [Retrieve event data](#).

Thread Contention

Works with:

Thread contention arises when two or more threads attempt to access the same resource at the same time. This page describes how AppDynamics helps you diagnose and resolve thread contention issues.

Performance Issues Resulting from Thread Contention

Multithreaded programming techniques are common in applications that require asynchronous processing. Although each thread has its own call stack in such applications, threads may need to access shared resources, such as a lock, cache, or counter. See [Enabling Thread Correlation](#).

While synchronization techniques can help to prevent interference between threads in such scenarios, they may nevertheless compete for access to shared resources. This can result in application performance degradation or even data integrity issues.

AppDynamics can help you identify and resolve problems relating to thread contention in business transactions and service endpoints. See [Trace Multithreaded Transactions for Java](#).

Thread Contention Detection

AppDynamics detects thread contention based on the thread state of the instrumented application.

It identifies these block or waiting states in the JVM:

- Acquiring a lock (`MONITOR_WAIT`)
- Waiting for a condition (`CONDOR_WAIT`)
- Sleeping (`OBJECT_WAIT`)
- A blocking I/O operation

The `OBJECT_WAIT` state is triggered when the application makes one of the following calls:

- `Thread.sleep`
- `Object.wait`
- `Thread.join`
- `LockSupport.parkNanos`
- `LockSupport.parkUntil`
- `LockSupport.park`

The Controller alerts you to possible thread contention problems in the **Potential Issues** pane of the Business Transaction Flow Map. From there, you can use the browser to access additional information about blocked and waiting threads in business transactions or service endpoints, and determine the cause of the performance problem.

The following sections explain how you use the browser to surface contention information for business transaction and service endpoints.

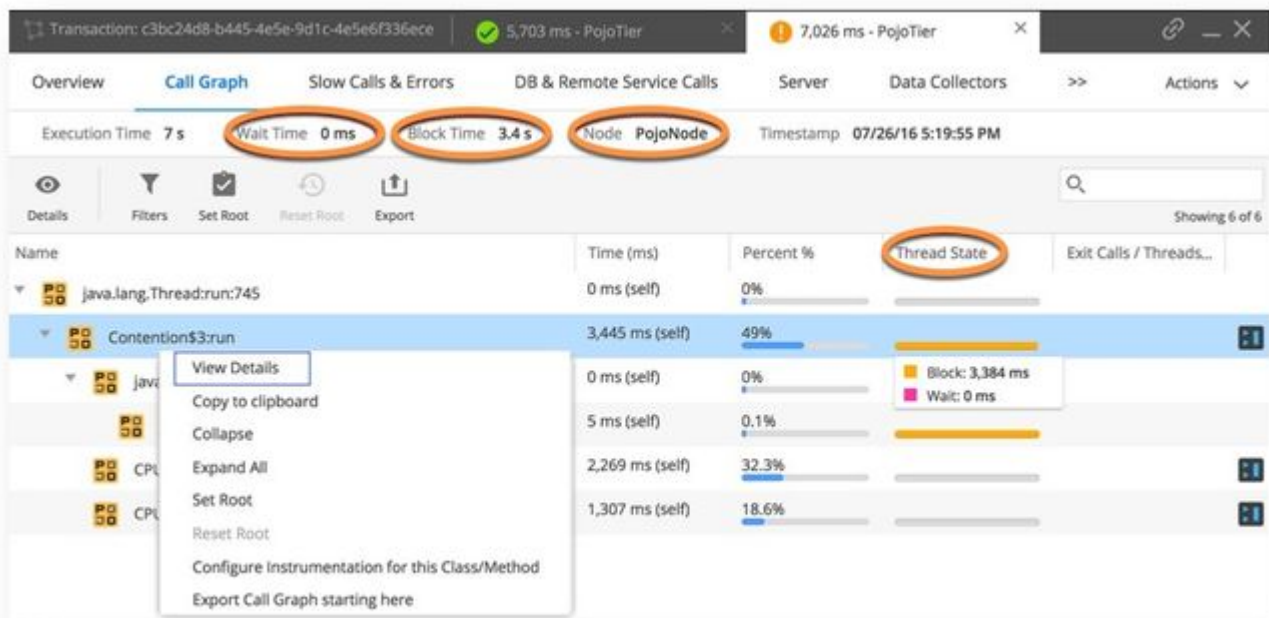

Thread Contention in Transaction Snapshots

To view information about thread contention:

1. In the transaction snapshot navigation page, look for items labeled as *Thread Contention* issues in the **Potential Issues** pane. The time column indicates blocked or wait time:

Potential Issues		
	com.pcappd.threadcontention.CPUBurnerUtil.findPrimes	18.8 s
	java.lang.Object.wait	12 s
	com.pcappd.threadcontention.MultiLock\$4.run	6.4 s
	Thread Contention - Blocked on java.lang.Object@246ae04d	6.4 s

2. To display more information about the blocked method, click the thread contention item and select **Drill Down into Call Graph**:

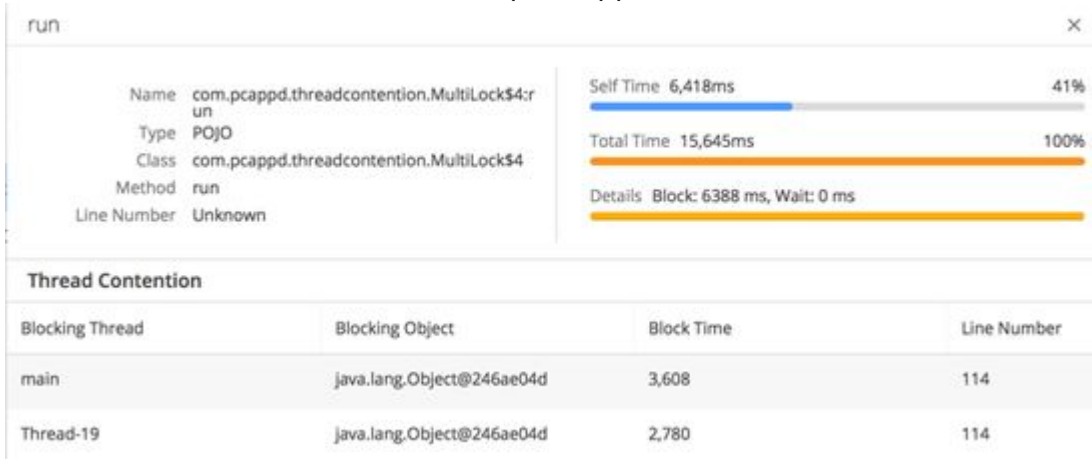

The call graph shows the following information relevant to thread contention:

- In the **Call Graph** header, **Wait Time** and **Block Time** indicate aggregate measures for the thread in one segment of the business transaction.
- In the **Call Graph** header, **Node** specifies the name of the node hosting the contending threads, `PojoNode` in the example above.
- The **Time** column indicates the total self time for the method.
- The **Percent%** column shows the amount of time spent in the method as a percentage of overall time for the thread.

- The **Thread State** Column indicates the degree of thread contention issues for the method. Gray means no problems; yellow to red shading signals the severity of contention problems. (When you hover over the bar, a breakdown of the elements that make up the thread state is shown: This includes Block time and Wait time by default. To include Cpu Time in the Thread State detail, Dev mode must be enabled.)

3. Right-click on any method with a thread state that indicates block or wait times and select **View Details**. The Thread Contention details pane appears:

The Thread Contention details pane displays the name of the blocked method in the top left corner and adds the following information in the Thread Contention table:

Element	Meaning
Blocking Thread	The thread holding a lock on the blocking object.
Blocking Object	The object that the blocked thread is waiting to access.
Block Time	The amount of time waiting to access the object.
Line Number	The line number in the blocked method where the blocking object is being accessed. With respect to the example above, <code>run</code> is attempting to access a locked object at line 114.

The order in which blocking threads are shown in the table is not significant; it does not imply a call order or time sequence.

i In **development mode**, AppDynamics reports explicit locks such as `java.util.concurrent.locks.ReentrantLock` as Wait Time instead of Block Time in the Thread Details Call Graph view. Take this into consideration when monitoring business transactions and analyzing performance related to lock contentions.

Thread Contention in Service Endpoints

You can view thread contention information for service endpoint methods in AppDynamics. Call graphs identify service endpoint methods with this icon: .

Select **More > Service Endpoints** from the menu bar to view thread contention information by service endpoint.

Export Contention Information

When you export the Call Graph for a Business Transaction, AppDynamics includes Transaction Contention information.

- The Summary pane includes **Block Time** data: the block time specified is the sum of all block times for the blocked methods shown in the CallGraph pane.

Summary	
User Experience	VERY_SLOW
Execution Time	7026 ms
CPU Time	2158 ms (30.71%)
Block Time	3389 ms (48.24%)
Transaction Timestamp	07/26/16 5:19:55 PM (server) 07/26/16 5:10:26 PM (agent)
Summary	[Continuing] Request was slower than the Standard Deviation threshold: 4.0
Tier	PojoTier
Node	PojoNode
Business Transaction	MultiObjLockBT

- The Call Graph pane lists block time by method:

Call Graph

```

java.lang.Thread:run: 745(execution time: 0 ms of 7026 ms total, block time: 0 ms of 3389 ms total)
Contention$3:run: Unknown (execution time: 3445 ms of 7026 ms total, block time: 3384 ms of 3389 ms total)
java.util.concurrent.locks.ReentrantLock:lock: 285(execution time: 0 ms of 5 ms total, block time: 0 ms of 5 ms total)
java.util.concurrent.locks.LockSupport:park: 175(execution time: 5 ms of 5 ms total, block time: 5 ms of 5 ms total)
CPUBurnerUtil:findPrimes: Unknown (execution time: 2269 ms of 2269 ms total)
CPUBurnerUtil:findPrimes: Unknown (execution time: 1307 ms of 1307 ms total)
    
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Event Loop Blocking in Node.js

You can use process snapshots to examine Node.js event loop activity and identify functions with high CPU times that are blocking the event loop.

Latency in Node.js Event Loops

The event loop of a Node.js process is a single thread that polls for incoming connections and executes all application code. When a Node.js request makes a call to an external database, remote service or the filesystem, the event loop automatically directs the application's control flow to some other task, including other connections or callbacks.

CPU-intensive operations block the event loop, preventing it from handling incoming requests or finishing existing requests. A CPU-intensive operation in one business transaction may cause slowness in other business transactions.

Process Snapshots In AppDynamics

A process snapshot describes an instance of a CPU process on an instrumented Node.js node. It generates a process-wide flame graph for a Node.js process over a configurable time range.

Process snapshots provide visibility into the Node.js event loop across all business transactions for the duration of the process snapshot. Process snapshots are useful when the main troubleshooting tools (such as, business transaction snapshots) are inconclusive because the source of latency is a CPU-intensive operation in another business transaction. You can use lists of process snapshots to identify which functions have high CPU times. From the list, you can select and examine process snapshots to identify exactly which functions in your code are blocking the CPU.

For a given Node.js node or tier, you can access the list of process snapshots from the Process Snapshots tab of the node or tier dashboard. You can filter the process snapshot list to display only the snapshots that you are interested in. You can filter by execution time, whether the snapshot is archived, and the GUID of the request. If you access the list from the tier dashboard, you can also filter by node.

For more information on how process snapshots are generated and how to configure them, see [Manage Node.js Process Snapshots](#).

To learn how process snapshots and business transaction snapshots are created, see [Process Snapshots and Business Transaction Snapshots](#).

Process snapshots persist for 14 days, unless you archive them, in which case they are available forever.

A process snapshot contains these tabs:

- Overview
- Flame Graph
- Call Graph
- Allocation Call Graphs
- Hot Spots

Overview

Summarizes the snapshot. Contents vary based on the available information.

Usually contains at least the total execution time, tier and node of the process, timestamp, slowest method and request GUID.

Flame Graph

Provides a visualization of each stack frame's frequency on the CPU over the duration of a process snapshot. The frame's position relative to the bottom-most stack depicts the call-stack depth.

The flame graph contains the same information as the call graph, but allows you to quickly spot methods that are consuming more CPU resources relative to others.

The method corresponding to the stack frame on the top edge of the flame graph represents the method's CPU resource consumption frequency.

To identify long-running CPU executions, look for long horizontal cells on the top edge of the flame graph.

A healthy Node.js process has minimal CPU-blocking activity; correspondingly, a flame graph for a healthy Node.js process has minimal long, horizontal cells along the top edge of its flame graph. See [The Flame Graph](#).

Call Graph

Shows the total execution time and the percentage of the total execution time of each method on the process's call stack. The numbers at the ends of the methods are the line numbers in the source code. You can filter out methods below a certain time to simplify the graph and isolate the trouble spots.

The **Time** and **Percentage** columns identify which calls take the longest time to execute.

To see more information about a call, select the call and click **Details**.

Allocation Call Graph

Available only for process snapshots that are collected manually. See [Manage Node.js Process Snapshots](#).

Shows the amount and percentage of the memory allocated and not freed by each method on the process's call stack during the process snapshot. You can use the **Method Size** slider to configure how much memory a method must allocate to be displayed in the allocation call graph. You can also filter out methods that consume less than a certain amount of memory to simplify the graph and isolate the trouble spots.

The **Size** and **Percentage** columns identify which calls consume the most memory.

The agent cannot report allocations made prior to the beginning of the allocation snapshot.

The allocation reported in the snapshot is the memory that is still referenced when the snapshot ends: memory allocated during the snapshot period minus memory freed during the snapshot period.

For more information about a call, select the call and click **Details**.

Hot Spots

This tab displays the calls by execution time, with the most expensive calls at the top. To see the invocation trace of a single call in the lower panel, select the call in the upper panel.

Use the **Method Time** slider in the upper right corner to configure how slow a call must be to be considered a hot spot.

Manage Node.js Process Snapshots

Related pages:

- [Event Loop Blocking in Node.js](#)
- [Node.js Metrics](#)
- [Process Snapshots and Business Transaction Snapshots](#)

This page describes how process snapshots are generated and viewed.

Automatic Process Snapshot Generation

When a business transaction snapshot is triggered by periodic collection or by a diagnostic session, a ten-second process snapshot is automatically started. By default, the agent starts no more than two process snapshots per minute automatically, but this behavior is configurable.

You can also start process snapshots manually on demand. See [Collect Process Snapshots Manually](#).

Configure Automatic Collection

You can configure automatic process snapshot collection using these settings:

- `processSnapshotCountResetPeriodSeconds` : Frequency, in seconds, at which the automatic process snapshot count is reset to 0; default is 60 seconds.
- `maxProcessSnapshotsPerPeriod` : Number of automatic process snapshots allowed in `processSnapshotCountResetPeriodSeconds` seconds; default is 2 snapshots.
- `autoSnapshotDurationSeconds` : Duration of an automatically-generated process snapshot; default is 10 seconds.

To configure these settings, add them to the `require` statement in your application source code as described in [Install the Node.js Agent](#). Then stop and restart the application.

Collect Process Snapshots Manually

If you want to generate some process snapshots now, you can start them manually.

1. Navigate to the dashboard for the tier or node for which you want to collect process snapshots.
2. Click the Process Snapshots tab.
3. Click **Collect Process Snapshots**.
4. If you are in the **Tier** dashboard, select the node for which you want to collect snapshots from the **Node** dropdown. If you are in the **Node** dashboard, you can only set up snapshot collection for that node.
5. Enter how many seconds you want to collect process snapshots for this node. The maximum is 60 seconds.
6. Click **Create**.

The agent collects process snapshots for the configured duration. Process snapshots that are started manually include an allocation call graph that shows how much memory has been allocated and not freed during the period recorded by the snapshot.

Process Snapshots and Business Transaction Snapshots

Related pages:

- [Transaction Snapshots](#)
- [Manage Node.js Process Snapshots](#)

This page explains the relationship between transaction snapshots and process snapshots created by the Node.js Agent.

V8 Sampler

Node.js is built on the V8 JavaScript engine, which includes a code sampler.

The Node.js Agent uses the V8 sampler to create process-wide [process snapshots](#), which contain call graphs of the methods on the Node.js process's call stack.

Call Graph Data in Snapshots

Call graph data displays in business transaction snapshots as well as process snapshots.

When you view a business transaction snapshot, the displayed call graph specific to the transaction instance is derived from the concurrent process snapshot call graph.

When you view a process snapshot, the complete call graph of all the business transactions executed while the process snapshot was captured is displayed.

The call graph in a business transaction snapshot displays a view of the data from a concurrent process snapshot that is filtered to display only time in methods attributable to the specific business transaction. It is a subset of the concurrent process snapshot call graph.

For this reason, you might see an execution time for a method in a business transaction call graph that is less than the execution time for the same method in the concurrent process snapshot call graph. This would indicate that some calls to that method were made outside the context of the business transaction instance captured by the transaction snapshot.

The summary tab of a transaction snapshot includes a link to the process snapshot that was taken during the time covered by the transaction snapshot.

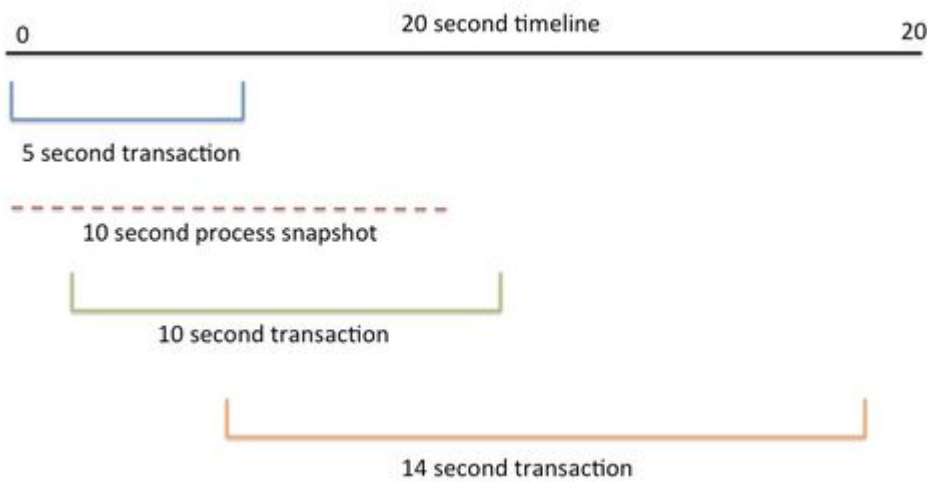

Business Transaction Snapshots Trigger Process Snapshots

To provide call graph data associated with business transaction snapshots, the agent starts a ten-second process snapshot whenever it starts a business transaction snapshot that is triggered by periodic collection or a diagnostic session if there is no existing process snapshot in progress for the current process. Process snapshots do not overlap. Periodic collection means that a business transaction is collected at periodic intervals, by default every ten minutes, but configurable. Diagnostic session means that either the agent has detected a pattern of possible performance issues and automatically started capturing transaction snapshots or a human has manually started a diagnostic session for the same reason.

Concurrent Business Transaction and Process Snapshots

The result presented is a process snapshot that ran concurrently with a business transaction. How well the two snapshots line up depends on the relative durations and start times of the transaction and the process snapshots.

In the scenario sketched below, all of the five-second blue transaction's calls, and most of the 10-second green transaction's calls are captured by a 10-second process snapshot, but only the about half of the 14-second orange transaction snapshot's calls.

If you find that your business transactions are running longer than your process snapshots, you can increase the default length of a process snapshot in the `autoSnapshotDurationSeconds` setting in the `require` statement.

Information Points

This page describes information points in AppDynamics. You can use information points to define custom metrics based on methods you configure. Information points are similar to data collectors; while data collectors show application data in the context of a business transaction, information points reflect data state across all invocations of a method, independent of business transactions. You can also apply computations to the values, for example, representing the sum or average for a method return value or input parameter.

 To create, edit, or delete information points, you need the **Configure Information Points** permission.

Information Point Data: Code Metrics and Business Metrics

When you configure an information point, you automatically receive the KPI metrics (called *code metrics*) for the information point method.

The code metrics are:

- Total call count
- Calls per minute count
- Errors per minute
- Average response time

You can supplement the KPI metrics with custom business metrics for the information point.

Business metrics reflect the value of runtime data, such as the method parameter, return value, or a value captured by getter chain on the object on which the identified method was invoked. The business metric value represents either the sum or average of the values of the code point you identify as the information point.

Information points can give you significant insight into how the performance of an application corresponds to business performance. For example, depending on the nature of your application, you could use it to resolve business questions such as:

- What is the average value of the credit card total?
- How many credit cards did my application process in a certain time period, regardless of the business transaction?
- What was the average time spent processing a credit card transaction?

A example of a practical use of an information point is ignored exceptions. Exceptions, especially one that occurs frequently, can contribute to CPU spikes in a JVM. If you configure the exception to be ignored in AppDynamics, for example, if it is generated in the underlying application framework and does not have a direct bearing on your application performance, it may not be readily evident to you when the exception is affecting your application. An information point that counts the exception occurrence can help you identify the additional overhead.

Creating Information Points

To create information points, see [Java and .NET Information Points](#) and [PHP Information Points](#).

Viewing Information Point Data

You can view information point values in various places in the Controller UI, including the following:

- **Information Points page:** The primary page for viewing and administering information points is the **Information Points** page. From there, click on an information point to view a histogram of the metrics for the information point for the selected time period.
- **Metric Browser:** The metrics also appear in the Metric Browser under the Information Points folder.
- **REST API:** Business metrics can be accessed from the [AppDynamics REST API](#).
- **Business Transaction Snapshots:** Information point data does not appear in transaction snapshots by default, but you can configure it to appear by setting the `enable-info-point-data-in-snapshots` node property to `true`. When the `enable-info-point-data-in-snapshots` node property is set, information point calls appear in the User Data section of the snapshot. See [App Agent Node Properties](#).

Java and .NET Information Points

Applies to:

This page describes how to create information points for Java and .NET applications. For PHP-based information points, see [PHP Information Points](#).

Before Starting

Ensure that you have the ability to restart the application while minimizing user impact. To apply the configuration for a new information point for .NET and JVM 1.5 applications, you must restart the application server.

You must be logged in to the Controller as a user with Configure Information Points permissions. See [Manage Custom Roles](#).

Create an Information Point from a Transaction Snapshot

You can create an information point from the call graph of a transaction snapshot that includes the method.

When you locate an invocation of the method in the call graph, right-click it and select the option to configure instrumentation on this class or method. Your selection creates an information point

Create and Manage Information Points Manually

You can create, view, and modify information points on the **More > Information Points** page.

To create an information point, you must specify the class and method for which you want to collect information, along with other identifying information. For details on using the UI to configure code matching for an information point, see [Data Collectors](#).

Information points are evaluated based on the execution of the method on which they are placed. Any match conditions apply to the state of the data at that time.

To collect business metrics from the method, from the **Edit Information Point** page, select **Add** to add a custom metric for the information point. You can configure and customize the type of data you want to collect for business metrics. Select **Save** when you are finished.

PHP Information Points

This page describes how to define information points for PHP applications.

[Information points](#) reflect key performance metrics and custom metrics for methods and code data points that you configure.

About PHP Information Points

To create an information point for PHP:

1. Define the information point using JSON notation.
2. In the definition, specify the method for the information point
3. Optionally, specify a point in the code that you want to capture as a custom metric, such as a parameter value or return value.
4. Navigate to **More > Information Points** and add an information point.
5. Choose **PHP** as the agent type and then paste the definition into the information point text box.

The elements of the definition correspond to configuration options available in the **Add Information Point** dialog for Java or .NET applications.

However, for PHP, the information point is defined in JSON syntax, and there are a few limits on configuration options. For one, class matching is limited to classname-based matches only. (Superclass matching or annotation matching are not available.) Also, you can only define a single match condition on a matched method. (A match condition refines the match of a method by testing a parameter or return value.)

If you do not configure a custom metric, the information point captures the generic KPIs for a matched method (response time, calls and calls per minute, errors and errors per minute). Custom metrics extend the information point by capturing the return or parameter value of a method, or the value of an invoked object.

Before Starting

To create information points in the Controller UI, you need to be logged in as a user with **Configure Information Points** permissions. See [Manage Custom Roles](#).

Method Match Conditions

A match definition specifies the method associated with the value you want to capture as an information point. The match definition must specify the method, but it may also specify the containing class and a refining match condition. The match condition can test the value of a method parameter, return value, or the return value of an invoked object.

Use this template to create a match definition:

```
{
  "probe": {
    "phpDefinition": {
      "classMatch": {
```

```
    "type": "MATCHES_CLASS",
    "classNameCondition": {
      "type": "EQUALS",
      "matchStrings": [
        "<class name>"
      ]
    }
  },
  "methodMatch": {
    "methodNameCondition": {
      "type": "EQUALS",
      "matchStrings": [
        "<method name>"
      ]
    }
  }
}
```

Edit the JSON objects in the following way:

- `classMatch` is optional. If you do not want to specify a class to match, delete the `classMatch` object from the `phpDefinition` object.
- If you are using the class match, set the value for the `classNameCondition` match string to the class name.
 - The class must be defined as a separate file from the file in which it is instantiated and invoked.
 - If your class names are defined in a namespace, escape the backslashes in the namespace with an escape backslash.
- `methodMatch` is required. Set the value for the `methodNameCondition` match string to the method name.

The following values are required for PHP information points:

- `classMatch` type: `MATCHES_CLASS`
- `classNameCondition` type: `EQUALS`
- `methodNameCondition` type: `EQUALS`

For example, the following JSON creates an information point on a class for which the class name equals `CheckoutManager` and the method name `processPayment` :

```
{
  "probe": {
    "phpDefinition": {
      "classMatch": {
```

```

        "type": "MATCHES_CLASS",
        "classNameCondition": {
            "type": "EQUALS",
            "matchStrings": [
                "Bundy\\ShoesBundle\\Entity\\CheckoutManager"
            ]
        },
        "methodMatch": {
            "methodNameCondition": {
                "type": "EQUALS",
                "matchStrings": [
                    "processPayment"
                ]
            }
        }
    }
}

```

If creating an information point primarily to capture KPI metrics for the method, it is likely you will define the class for the method. However, if you are creating an information point to implement a code metric, you may only need to specify method name matching.

This example shows a method match that tracks how many times a method is called:

```

{
  "probe": {
    "phpDefinition": {
      "methodMatch": {
        "methodNameCondition": {
          "type": "EQUALS",
          "matchStrings": [
            "deleteCartItems"
          ]
        }
      }
    }
  }
}

```

```
}

```

Match Conditions

A match condition (defined by a `matchConditions` object) lets you refine the method matching criteria by specifying a match condition based on a parameter or return value or the value returned by an invoked object.

A match condition is optional, but there can be at most one for the information point. If you do not supply a match condition, the information point includes all invocations of the matched method.

The condition consists of a match type and the comparison operator that defines the data to be compared. The match types are:

- EQUALS
- NOT_EQUALS
- LT
- GT
- LE
- GE
- NOT
- AND
- OR

The comparison operator is an expression node that defines a left side (`lhs`) and a right side (`rhs`) of the operation. It contains:

- a type: `ENTITY`, `STRING`, or `INTEGER`
- a value, which is an `entityValue`, `stringValue`, or `integerValue`

If the type is `ENTITY`, the `entityValue` has one of the following types: `INVOKED_OBJECT`, `RETURN_VALUE`, or `PARAMETER`. If the type of the `entityValue` is `PARAMETER`, the `parameterIndex` indicates the 0-based numeric index of the parameter on which to match. So if the method takes two parameters, for example, the first being a string and second an integer, a `parameterIndex` of 0 matches against the string and a `parameterIndex` of 1 matches the integer value.

The information point in the following example only matches invocations of the `processPayment` method in which the second parameter (at parameter index 1) equals `VISA`.

```
{
  "probe": {
    "phpDefinition": {
      "methodMatch": {
        "methodNameCondition": {
          "type": "EQUALS",

```

```

    "matchStrings": [
      "processPayment"
    ]
  },
  "matchCondition": {
    "type": "EQUALS",
    "comparisonOp": {
      "lhs": {
        "type": "ENTITY",
        "entityValue": {
          "type": "PARAMETER",
          "parameterIndex": 1
        }
      },
      "rhs": {
        "type": "STRING",
        "stringValue": "VISA"
      }
    }
  }
}
}
}
}
}
}
}

```

Metric Definitions

You can define custom metrics for data captured by an information point using the `metricDefinitions` object in your information point definition. Custom metrics appear in the Metric Browser and in the dashboard for the information point. You can create health rules based on a custom metric and retrieve custom metric values using the AppDynamics REST API.

There can be multiple custom metrics for a single information point. For example, one metric might be based on the average and one on the accumulated (sum) of the information point's values.

A `metricDefinitions` object consists of one or more definitions, each having the following structure:

- a name
- a rollup type (`AVERAGE` or `SUM`)
- data, which consists of a type, (`ENTITY` , `STRING` , or `INTEGER`) and a value (`entityValue` , `stringValue` , or `integerValue`)

If the type is `ENTITY`, the `entityValue` has a type, which is `INVOKED_OBJECT`, `RETURN_VALUE`, or `PARAMETER`. If the type of the `entityValue` is `PARAMETER`, the zero-based `parameterIndex` indicates the parameter on which to base the match. A return value or parameter metric cannot be an array.

For example, the following `metricDefinitions` object defines two custom metrics: `VisaTotal`, which reports the sum of the Visa payments processed and `VisaAverage`, which reports the average value of the Visa payments processed.

```
"metricDefinitions": [
  {
    "name": "VisaTotal",
    "rollup": "SUM",
    "data": {
      "type": "ENTITY",
      "entityValue": {
        "type": "RETURN_VALUE"
      }
    }
  },
  {
    "name": "VisaAverage",
    "rollup": "AVERAGE",
    "data": {
      "type": "ENTITY",
      "entityValue": {
        "type": "RETURN_VALUE"
      }
    }
  }
]
```

Sample JSON Information Point Configuration

This is an example that you can copy and paste into the JSON text field in the PHP information point window. It produces two metrics, named `VisaTotal` and `VisaAverage`.

```

{
  "probe": {
    "phpDefinition": {
      "classMatch": {
        "type": "MATCHES_CLASS",
        "classNameCondition": {
          "type": "EQUALS",
          "matchStrings": [
            "CheckoutManager"
          ]
        }
      },
      "methodMatch": {
        "methodNameCondition": {
          "type": "EQUALS",
          "matchStrings": [
            "processPayment"
          ]
        }
      },
      "matchCondition": {
        "type": "EQUALS",
        "comparisonOp": {
          "lhs": {
            "type": "ENTITY",
            "entityValue": {
              "parameterIndex": 1,
              "type": "PARAMETER"
            }
          },
          "rhs": {
            "type": "STRING",
            "stringValue": "VISA"
          }
        }
      }
    }
  },
  "metricDefinitions": [
    {
      "name": "VisaTotal",

```

```
    "rollup": "SUM",
    "data": {
      "entityValue": {
        "type": "RETURN_VALUE"
      },
      "type": "ENTITY"
    }
  },
  {
    "name": "VisaAverage",
    "rollup": "AVERAGE",
    "data": {
      "type": "ENTITY",
      "entityValue": {
        "type": "RETURN_VALUE"
      }
    }
  }
]
}
```

Configure Instrumentation

In AppDynamics, instrumentation refers to how app agents interact with your application software to gather performance data and report it back to the AppDynamics Controller. The first step to instrumenting your application is [installing the app agents](#) on the servers where the code runs.

App agents ship with default instrumentation settings that cover the most common types of application frameworks and programming patterns. If your requirements are more complex, you can customize the instrumentation behavior to suit your environment.

See [Configure Instrumentation Overview](#) for information on how AppDynamics applies instrumentation settings across your business application.

Access Instrumentation Settings

Navigate to **Configuration > Instrumentation** to customize:

- [Transaction detection rules](#) that define entry points for [business transactions](#).
- [Backend detection rules](#) that define exit points for your [business transactions](#).
- [Error detection](#) settings that define which transactions qualify as [error transactions](#).
- [Service endpoints](#) to view metrics specific to services and transaction segments outside the context of a single business transaction.
- [Diagnostic data collectors](#) for an app agent to extract additional context about a specific transaction at transaction snapshot time. You can also configure data collectors for [Application Analytics](#).
- [Call Graph Settings](#) to tune the amount of data the app agent collects for call graphs.
- JMX metrics that the Java agent collects for specific products and frameworks. See "Configure JMX Metric Rules" on [Configure JMX Metrics from MBeans](#).
- Memory monitoring settings for agents that collect instance tracking data for specific classes or objects. See the following topics:
 - [Object Instance Tracking for Java](#)
 - [Object Instance Tracking for .NET](#)
 - [Object Instance Tracking for Node.js](#)
- [Asynchronous transaction demarcators](#) to set endpoints for asynchronous transactions.

Configuration Page Items

In addition to the instrumentation configuration options described on this page, there are many other ways to customize AppDynamics for your environment. For more information on the items on the **Configuration** page, review these pages:

- "Configure Thresholds" on [Transaction Thresholds](#).
- "View Baselines" on [Dynamic Baselines](#).
- [Information Points](#)
- [Development Level Monitoring](#)

If you have an End-User monitoring license, review these pages on **User Experience App Integration**:

- [Correlate Business Transactions for Browser RUM](#)
- [Automatic Injection of the JavaScript Agent](#)
- [Assisted Injection](#)

Configure Instrumentation Overview

The scope configuration model reduces the number of steps it takes to apply transaction detection rules to multiple tiers.

Under the [scope configuration model](#), you can apply settings to groups of tiers, in addition to individual tiers and nodes. Groups of tiers are called scopes. Only transaction detection settings for applications created in AppDynamics >= 4.3 adhere to the scope model.

Live Preview Mode

You can interactively experiment with transaction detection rule configurations using Live Preview. Live Preview streams data from an active node, providing real-time data for the following configurations:

- All transaction detection rules that apply to a node. See [Business Transaction Discovery Sessions](#).
- A single custom match rule applied to a node. See [Custom Match Rule Live Preview](#).

The following limits apply to Live Preview:

- 100 sessions on the Controller
- 20 sessions on an account
- 10 sessions on a business application

Programmatic Expressions

You can specify the following types of programmatic expressions when configuring detection rules:

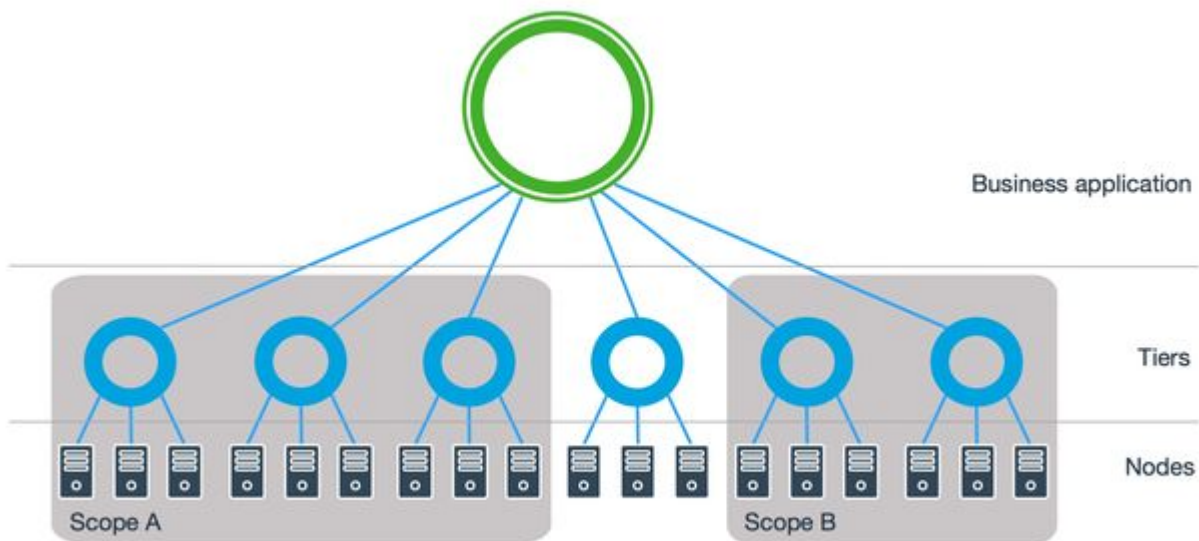

- Regular expression: A string or character search pattern
- Getter chains: Enable you to access data returned by methods in your application

Scope Configuration Model

The scope configuration model allows you to bundle multiple tiers into a scope, and apply transaction detection rules to that scope.

You can apply a rule to select tiers all at once. The Default Scope consists of all the tiers in the application.

In the diagram, you want to apply a rule to three of the six tiers in an application. Rather than manually applying the rule to each of the three tiers, you can bundle the tiers into a scope (Scope A) and apply the rule to the scope.

Creating a Custom Scope

You can create a custom scope by navigating to **Configuration > Instrumentation > Scopes**.

1. Click **Add**.
2. Enter a name for your scope.
3. In the **Include the following Tiers** dropdown, select one of these options:
 - a. **All Tiers in the Application**: creates a scope that includes all the tiers in the application, except tiers that you specify. You can select tiers to exclude from the scope in the **Available Tiers** box and clicking the left-pointing arrow.
 - b. **These Specific Tiers**: creates a scope that includes only tiers that you specify. You can select tiers to include in the scope in the **Available Tiers** box and clicking the left-pointing arrow.
4. Click **Save**.

To view the rules that are applied to a scope, select the scope in the Scopes tab. The rules applied to that scope display in the panel on the right.

Set the Scope for a Rule

When you create a new application, all rules for the application use the default scope. You can create additional scopes for that application, and choose which rules to apply to that scope. Each rule can only apply to one scope.

1. Click the Rules sub-tab.
2. Select the rule that you want to apply to a scope. The tiers that the rule is applied to are displayed in the panel on the right.
3. Click **Edit**.
4. Click **Change Scope**.
5. Select the scope that you want to apply this rule to.
6. Click **OK**.
7. Click **Save**.

To apply a rule to a scope, you need permissions to all the tiers in the scope. To apply a rule to the default scope, you need application-level permission.

Using Regular Expressions

Related pages:

- [Transaction Detection Rules](#)
- [Custom Match Rules](#)

Regular expressions display in various places in the AppDynamics configuration. These places include, for example, transaction detection rules, data collectors, EUM injection settings, health rules, and more. This page describes the use of regular expressions in AppDynamics.

Matching Guidelines

A match condition consists of a named property to match (such as a method name, Servlet name, URI, parameter, or hostname), a comparison operator, and a matching value. For complex match conditions, you can use a regular expression (often abbreviated to just regex).

Match rules are case sensitive. Also, matching is based on subsequence pattern matching. To match a complete string instead, you need to include "^" to match the start of the string and "\$" to match the end of the string in your regular expression.

In the context of business transaction matching, the pattern does not include the protocol (e.g., "http://"), host, port, or query parameters in the URL. So for example, a URI of `http://www.mysite.com:8000/account/settings.html?action=update` would be matched by a business transaction regular expression with only `/account/settings.html`.

Regular Expression Engines

The Java Agent uses Java libraries for regular expressions. See:

- Tutorial: <http://download.oracle.com/javase/tutorial/essential/regex/index.html>
- Javadoc: <http://download.oracle.com/javase/1.5.0/docs/api/java/util/regex/Pattern.html>

The .NET Agent uses the built in .NET regular expressions engine. See:

- MSDN: [.NET Framework Regular Expressions](#)

The Node.js Agent uses JavaScript regular expressions. See:

- https://developer.mozilla.org/en-US/docs/Web/JavaScript/Reference/Global_Objects/RegExp

The PHP Agent uses PHP's built-in PCRE regular expression engine and requires the same syntax, including delimiters (for example: `/^Foo/`). See:

- [PCRE Manual](#)

The Python Agent uses Python's regular expression syntax. See:

- <https://docs.python.org/2/library/re.html>

The Web Server Agent uses Perl regular expression syntax. See:

- http://www.boost.org/doc/libs/1_57_0/libs/regex/doc/html/boost_regex/syntax/perl_syntax.html

Regular Expression Examples

These examples show how to construct regular expressions to achieve different results.

Matching Non-Adjacent URL Segments

A typical use of regular expressions in the AppDynamics configuration is for business transaction custom match rules in which the expression is matched to a requested URI. In this context, it's common for an application's URI pattern to put information that would be useful for business transaction identification in different segments of the URI.

For example, given an example URL of `http://retailstore.example.com/store/jump/category/shoes/departments/view-all/cat630006p`, a business transaction might need to match on `/store/jump` and `all` to group user requests to view all of an available category.

A regular expression to match this case could be:

```
/store/jump.*\b?all\b
```

Matching Any Digit

Say you want to ignore numbers contained within a pattern. For example, consider the following URL examples:

- `/group/1/session/`
- `/group/1/session/`
- `/group/31/session/`
- `/group/2/session/`

Examples of matching regular expressions would be:

- `^/group/\d*/session/?$`
- `session`
- `/\d*/session/?$`

Requiring a Digit

To group URLs that contain letters then numbers into one business transaction, such as the following:

- `/aaa123.aspx`
- `/b1.aspx`

You could use an expression such as the following:

```
/[a-z]+?[0-9]+?
```

Not matched would be a URL that does not have digits after the letters, for example: `/z.aspx`

Handling Letter Casing

Regular expression matching is performed in a case-sensitive manner. To match any case letters, you can use something similar to the following:

```
/[a-zA-Z]+?[0-9]+?
```

Or match in a case-insensitive manner using the *i* modifier. For example:

```
(?i)\w*cart\w*
```

Would match `addToCart` as well as `addTocart` .

Backend Discovery Rules

For an example of a JDBC backend regular expression, see the section JDBC with complex URLs in [Example JDBC Backend Configuration](#).

 You can find resources for testing your own regular expressions at <http://www.regexplanet.com/advanced/java/index.html>. There you can find regular expression test pages for many language engines, including Java, JS, .NET, PHP and more.

Performance Considerations

Although regular expressions are a powerful way to set AppDynamics configurations, you should consider the following to avoid performance issues:

- Do not use wildcard expressions unless absolutely needed. You do *not* need to use wildcard expressions (.*) before or after a match, and each wildcard regular expression results in approximately an order of magnitude performance impact.
- The number of configurations, the frequency the configuration is applied, and the content length of the target string: For example, if the configuration using a regular expression is applied in many places at high frequency for longer target strings, you might consider reducing the usage of the configuration or decrease the frequency of its application.

Using Getter Chains

Related pages:

- [Transaction Detection Rules](#)

Getter chains let you access method data in various contexts of the AppDynamics configuration. For example, getter chains enable you to name business transactions based on return values. This page describes how to use getter chains.

Getter Chains

You can use getter chains to:

- Create a new JMX Metric Rule and define metrics from MBean attributes. See [Configure JMX Metrics from MBeans](#).
- Configure method invocation data collectors. See the Configuration Notes in [Data Collectors](#).
- Define a new business transaction custom match rule that uses a POJO object instance as the mechanism to name the transaction. See [POJO Entry Points](#).
- Configure a custom match rule for servlet entry points and name the transaction by defining methods in a getter chain. See "Split by POJO Method Call" on [Split Servlet Transaction by Payload Examples](#).

As a best practice, you should use getter chains with simple getter methods only. Getter chains on processing-intensive methods, such as one that make numerous SQL calls, can result in degraded performance for the application and agent.

For example, the following shows a simple get method that returns a property for a class, such as `MyUser.Name`:

```
public class MyUser
{
    private String Name {get; set;}
    private String Url;
    public String GetUrl() {
        return this.Url;
    }
}
```

Special Characters in Getter Chains

Use the following special characters as indicated:

- Parentheses `()` to enclose parameters
- Commas `,` to separate parameters
- Forward slashes `/` to separate type declarations from a value in a parameter
- Backslashes `\` to escape characters.
 - To search for a backslash `\`, escape the backslash with a backslash:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
GetString().Find(\\)
```

- To split a string by a backslash `\`, escape the backslash in Java and within the Getter Chain:

```
GetString.split(\\\\).[0]
```

- Dots `.` to separate methods and properties in the getter chain
- Dot `.` to represent "anything" must be escaped
- Curly braces `{ }` to delineate getter chains from static elements in custom expressions on HTTPRequest objects (including in the Java Servlet Transaction Naming Configuration window and in the Split Transactions Using Request Data tab of the servlet custom match and exclude rules)

Getter chains also treat spaces at the beginning or end of a string as special characters.

Escape Literal Characters

If the getter chain should treat a special character literally, escape it using a backslash. For parentheses, you only need to escape the closing parenthesis in a string.

- The following example shows the how to escape the dot in the string parameter.

```
GetAddress().GetParam(a\.b\.c\.)
```

The agent executes `GetParam("a.b.c.")` on the result of `GetAddress()` and returns the value of the parameter.

- In the following example, the first dot is part of the string method parameter, which requires an escape character. The second and third dots don't require an escape character because they are used as method separators.

```
GetUser(suze\.smith).GetGroup().GetId()
```

- The following example shows how to escape the opening and closing parenthesis in a search for "(" within a string.

```
GetString.Find(\\(\\))
```

.NET Notes and Examples

These sections apply to getter chains used in .NET Agent configurations.

-  Escape backslashes within a getter chain for .NET with the double backslash.

Declare Parameter Types

The .NET Agent identifies parameter types as follows:

- Dictionaries, anything with property accessors, use a normal parameter set, which defaults to string.

- Arrays use single integers as parameters.

Therefore `0` means `string/0` if you have a hash, or anything that translates to `get_Item` (any kind of property). `0` means `int/0` if you have an array.

When your getter chain uses a method with parameters other than the default type, you need to declare the parameter type.

- The following example demonstrates how to declare the parameter types to resolve the overloaded `Substring()` method. The forward slash serves as the type separator.

```
GetAddress(appdynamics, sf).Substring(int/0, int/10)
```

For instance, if `GetAddress(appdynamics, sf)` returns "303 2nd St, San Francisco, CA 94107", the full getter chain expression returns "303 2nd St".

- The following example shows how to declare the parameter types for a user-defined method that takes a float parameter, a boolean parameter, and an integer parameter. The forward slash serves as the type separator.

```
GetAddress(appdynamics, sf).MyMethod(float/0\\.2, boolean/true, boolean/false, int/5)
```

Access Indexed Properties and Dictionary Values

If your getter chain accesses a dictionary object, you can access the values using the following syntax:

- The following example returns the value for the key `suze.smith`.

```
UserDictionary.[string/suze\\.smith]
```

- The following example returns the value for the key `suze.smith` using the implied getter.

```
UserDictionary.get_Item(suze\\.smith)
```

Split by Character or Regular Expression Match in .NET Getter Chains

You can split values matched by character or as a string by matching a regular expression pattern. The result of a split operation is a string or character array that you can reference in your getter chain by an array index value.

The following examples illustrate how to use the character and string regular expression split operations in getter chains.

Split by Character

- The following chain splits a URL on the forward slash character. In this case, the first slash acts as a type separator. The getter chain returns the fourth item in the array.

```
GetUrl().Split(char[]//).[3]
```

The agent returns "Search" when it applies the getter chain to the following URL: `http://howdyworld.example.com/Search/Airfare`

- In the following example, the split occurs on the forward slash character, and the result is the length of the resulting array.

```
GetUrl().Split(char[]//).Length
```

- This example illustrates a transaction splitting rule for URIs that use a semicolon delimiter. The getter chain splits on the forward slash, then splits the fourth element on the semicolon.

```
GetUri().Split(char[]//).[3].Split(char[]/;).[0]
```

The agent returns `create-user` when it applies the getter chain to the following URL:

```
http://HowdyWorld.example.com/create-user;sessionId=BE7F31CC0235C796BF8C6DF3766A1D00?act=Add&uid=c42ab7ad-48a7-4353-bb11-0dfeabb798b5
```

Split by Regular Expression

For more control, you can split values by string-based pattern matching. Pattern matching is particularly useful for situations that require complex matching, such as matching content within a request body.

The following example shows a getter chain that splits the value returned by `GetAddress()` and selects the seventh element in the resultant array:

```
GetAddress().Split(string/\\W+).[6]
```

Given an address such as `303 2nd St, San Francisco, CA 94107`, the example splits the value by word and references the sixth word in the array, `CA` in this case.

Compose Getter Chains for HTTP Requests

The .NET Agent requires special syntax for getter chains for HTTP Requests:

- For ASP.NET WebForms, MVC, and MVC/WebAPI applications create getter chains based upon the `System.Web.HttpRequest` objects.
- For ASP.NET Core on the full framework, create getter chains based upon `Microsoft.AspNetCore.Http.Internal.DefaultHttpRequest` objects.

i If you have both ASP.NET and ASP.NET Core on the full framework apps in the same tier, you cannot use a getter chain to apply to both because the two frameworks use different objects to handle HTTP requests.

- Use the following syntax to delineate the boundaries of the getter chain:

```
`${myobject.myproperty}`
```

- The following example determines the user principal:

```
`${Context.User.Identity.Name}`
```

Places to use this syntax include:

- HTTP Request Data Collectors
- ASP.NET Transaction Detection custom expressions

Java Notes and Examples

The following sections apply to getter chains used in Java Agent configurations.

Values Passed in a Getter Chain

The value passed in a getter chain is always a string unless cast to another type.

The following cast types are supported:

- int
- float
- bool (the primitive Boolean value)
- boolean (a boxed boolean value; i.e. an object type that wraps a boolean)
- long
- object

The following section shows examples of how to refer to the types in parameters to getter chain methods. Notice that letter case is not important for the names of the types. Type casting is performed in a case-insensitive manner.

Java Getter Chain Examples

- Getter chain with integer parameters in the substring method using the forward slash as the type separator:

```
getAddress(appdynamics, sf).substring(int/0, int/10)
```

- Getter chain with various non-string parameter types:

```
getAddress(appdynamics, sf).myMethod(float/0.2, boolean/true, boolean/false, int/5)
```

- Getter chain with forward slash escaped; escape character needed here for the string parameter:

```
getUrl().split(\\) # node slash is escaped by a backward slash
```

- Getter chain with an array element:

```
getUrl().split(\\).[4]
```

- Getter chains that return Hashmap values:

```
get(object/myvalue).substring(int/0,int/10)  
get(object/ACTION)
```

- Getter chain with multiple array elements separated by commas:

```
getUrl().split(\\).[1,3]
```

- Getter chain retrieves property values, such as the length of an array:

```
getUrl().split(\\.).length
```

- Getter chain using backslash to escape the dot in the string parameter; the call is `getParam(a.b.c)`.

```
getAddress.getParam(a\\.b\\.c\\.)
```

- In the following getter chain, the first dot requires an escape character because it is in a string method parameter (inside the parentheses). The second dot does not require an escape character because it is not in a method parameter (it is outside the parentheses).

```
getName(suze\\.smith).getClass().getSimpleName()
```

The following getter chain is from a transaction splitting rule on URIs that use a semicolon as a delimiter.

```
getRequestURI().split(\\).[2].split(;).[0]
```

The call gets the URI using `getRequestURI()` and then splits it using the escaped forward slash. From the resulting array, it takes the third entry (as the split treats the first slash as a separator) and inserts what before the slash (in this case, nothing) into the first entry. Then it splits this result using the semicolon,

getting the first entry of the resulting array, which in this case contains the API name.
For example, given the following URI:

```
/my-webapp/xyz;jsessionid=BE7F31CC0235C796BF8C6DF3766A1D00?  
act=Add&uid=c42ab7ad-48a7-4353-bb11-0dfeabb798b5
```

The getter chain splits on the API name, so the resulting split transactions are "API.abc", "API.xyz" and so on.

Tip: When using `string.split()`, remember that it takes a regex and you have to escape any special regex characters.

For example, if you want to split on the left square bracket (`[]`):

```
Java syntax: split("\\[")  
Getter chain syntax: split(\\ \\ \\ \\ [)
```

A Vertical Bar or Pipe (`|`) is a reserved character in Getter strings. For methods with a regular expression parameter, use Unicode as an alternative.

For example:

```
split(string/\\u007C).[0] // return the first element of an string split by a Vertical Bar.
```

Blocklisted Classes or Packages and Methods of the Java Getter Chain

Certain packages and classes have been blocklisted from being accessed within getter chains.

The following methods and classes or packages have been blocklisted by the Java Agent for Getter Chains:

Methods:

- `getClassLoader`
- `loadClass`
- `invoke`

Classes or packages:

- `reflect`
- `nio.file`
- `ClassLoader`
- `io.File`
- `io.Socket`

- `net.Socket`
- `ProcessBuilder`
- `Runtime`

Transaction Detection Rules

Related pages:

- [.NET Business Transaction Detection](#)
- [PHP Business Transaction Detection](#)

AppDynamics uses different types of transaction detection rules to define entry points and name **business transactions**:

- [Automatic transaction discovery rules](#) include the default entry point types and naming configuration for each app agent type.
- [Custom match rules](#) offer finer control over transaction discovery and naming for a single entry point type.

In many cases, the built-in rules yield a useful set of business transactions. If not, you can create new rules or edit the existing rules to optimize the transaction detection for your environment.

Permissions

The *Configure Transaction Detection* permission is needed to customize transaction detection rules.

The *View Sensitive Data* permission, in combination with the *Configure Transaction Detection* permission, enables the use of [Live Preview](#) and [Business Transaction Discovery](#) features to stream live data from your application.

Live Preview

For Java and .NET environments, you can use interactive live preview tools to find business transaction entry points:

- [Business transaction discovery sessions](#) stream live data from the node to the Controller UI to help you make instrumentation decisions. These sessions display transactions based on all transaction detection rules active for the node.
- For certain types of entry points, [custom match rule live preview](#) enables you to preview transactions based on applying a single transaction detection rule on a node.

Business transactions within the context of the Live Preview, called transient transactions, do not persist after the Live Preview ends. Business transaction discovery sessions let you apply or discard rule changes when you end the session. Custom match live preview rules apply after you save the rule.

Some transient transactions may invoke exit calls to the same node where the Live Preview session is running. In certain cases, the agent may discover additional transient transactions and uninstrumented code on the downstream segment:

- The exit call and corresponding entry point are automatically discovered exit and entry points like HTTP or Web Service.
- Rare cases of custom activity in-process calls.

Manage Transaction Detection Rules

To customize transaction detection rules in the Controller UI, go to **Configuration > Instrumentation**. From the [Business Transactions](#) list, you can also click **Configure** to quickly access Transaction Detection settings.

You apply transaction detection rules to tiers using the flexible [scope configuration model](#). From the Transaction Detection tab, you can manage rules as follows:

- Manage rules for individual scopes on the Transaction Detection tab.

- Manage rules application-wide on the Rules sub-tab. The Rules sub-tab also shows you the tiers where rules are applied and according to which scope.
- View or modify the rules for specific tiers on the Tiers sub-tab.

To modify an existing rule, you can double-click it to display the **Rule Editor**. Click **+/Add** to define a new rule.

Use **Live Preview** button to start a **Business Transaction Discovery** session for nodes running the Java and .NET Agent.

Transaction Detection Rule Priorities

AppDynamics app agents apply transaction detection rules of the same type in the following order of precedence:

1. Rule priority from highest to lowest. A priority of 0 is the lowest priority possible.
2. Creation date from oldest to newest.

For example, consider an HTTP request that matches a priority 2 custom match rule and a priority 6 custom match rule. The agent applies the priority 6 rule.

When an incoming request matches more than one type of detection rule, AppDynamics applies the detection rules in the following order of precedence:

1. Custom match *include* rules according to the include rule priority. If the request matches an include rule, the agent names the business transaction based on the rule.
2. Custom match *exclude* rules according to the exclude rule priority. If the request matches an exclude rule, the app agent excludes the transaction from discovery.
3. Default automatic detection rules. If the request matches a default automatic detection rule, it names the transaction according to the auto-detection naming scheme.

To view the default order of transaction detection rules for a tier:

1. Navigate to **Configuration > Instrumentation > Transaction Detection > Tiers**.
2. Click a tier to see the rules ordered by precedence and priority.

For Java and .NET, you can set the `check-bt-excludes-early` node property to "true" to configure the app agent to evaluate custom match exclude rules before custom match include rules. This is a node-based configuration and does not affect the display order of rules in the Controller UI.

Export Detection Rules

You can migrate the rules between applications and tiers using the Controller API. See [Configuration Import and Export API](#).

Automatic Transaction Discovery Rules

Each AppDynamics app agent type has a default automatic transaction discovery rule that applies to all the [entry points](#) for that agent. When an agent identifies a business transaction that matches an automatic transaction discovery rule, it names the business transaction based on naming rules for the entry point type.

Automatic Transaction Naming

The naming logic varies depending on the application technology. For example:

- For web-oriented technologies that have URI entry points such as Java Servlets, detection rules name the transaction using the first two segments of the URI by default. See [URI Based Entry Points](#).
- For message-oriented technologies such as an asynchronous message listener or message-driven bean (JMS), the agent names the business transaction for the destination name (the queue name) or the listener class name (if the destination name is not available.)
- For Web services, the agent names the business transaction for the Web service name plus the operation name.

Customize Automatic Transaction Discovery Rules

You can customize automatic transaction discovery rules as follows:

- Add an automatic transaction discovery rule for an agent type.
- Enable or disable different types of automatically discovered entry points.
- Customize transaction naming for some entry points, such as most URI-based entry points.

To access the Rule Editor, double-click an Automatic Transaction Discovery rule for an app agent. Alternatively, you can create a new automatic transaction discovery rule for the agent type by clicking **Add**. Clicking the Rule Configuration tab displays the entry points for the automatic discovery rule.

When you edit, delete, or change the scope for an automatic transaction discovery rule, the Controller UI performs [validation](#) to ensure each tier has the correct automatic discovery rule available for its agent type.

If you are using the Java Agent you can preview the effects of your customizations before you apply them in production. See "Edit and Preview Transaction Discovery Rules" on [Business Transaction Discovery Sessions](#).

Disable Transaction Monitoring for Entry Points

Automatic transaction detection rules have a **Transaction Monitoring Enabled** checkbox for each entry point type to control automatic discovery. By default, all entry point types are enabled. When you disable discovery for an entry point type, the agent stops counting, measuring, and recording all activity for that entry point type for the scope where the rule is applied.

i The **Transaction Monitoring Enabled** configuration affects custom match rules in the same scope for the entry point type. For example, if you disable POJO monitoring in the Java Default Automatic Transaction Discovery Rule for a scope, the Java Agent will not discover any POJO transactions for the scope.

Following are the cases when you might want to disable monitoring:

- You know that you don't want to monitor any business transactions of a specific entry point type.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- You want to monitor transactions from a downstream call.

For example, consider an application where Servlets implement Spring Beans and you are interested in monitoring the transaction starting at the Spring Bean level. Disable Servlet monitoring and the auto-detection rule for Spring Beans will be the entry point for the transaction.

Disable Automatic Transaction Detection for an Entry Point Type

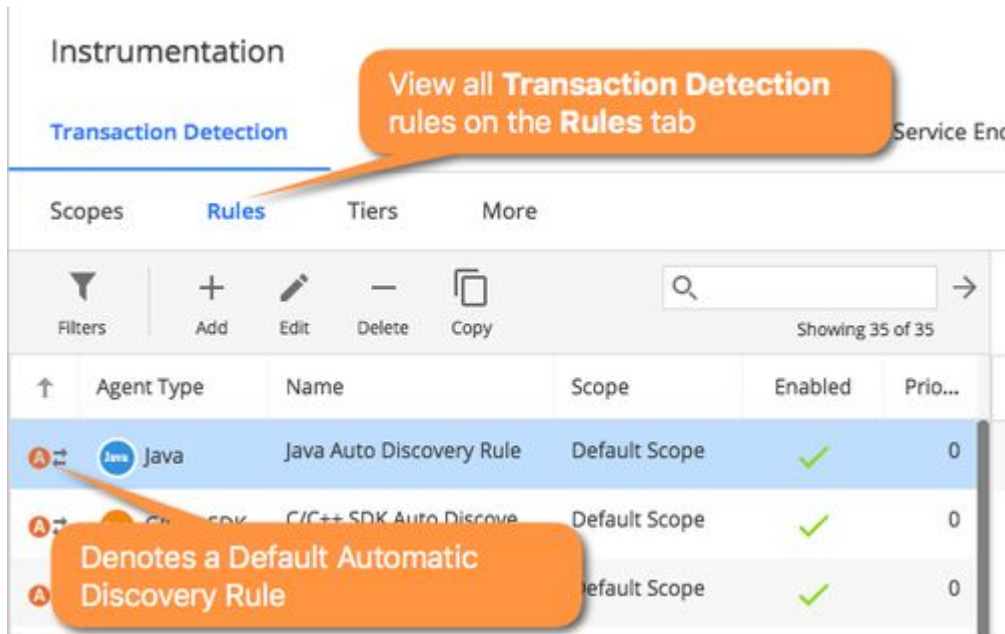

If you want to continue monitoring custom match rules, you can disable **Discover transactions automatically for <entry point type>**. When you disable automatic transaction discovery, the app agent stops reporting metrics for previously-detected transactions for the now disabled entry point type. The agent only detects transactions based on custom match rules. However, disabled transactions are not deleted or excluded. See [Organize Business Transactions](#) for information on deleting transactions.

- The agent does not discover any new transactions based on the Default Automatic Transaction Discovery Rule for the disabled type.
- The agent no longer auto-detects calls to methods and operations of the disabled entry point type.
- Custom match rules for the entry point type remain active and the agent reports metrics for transactions resulting from custom matches.
- Exit point detection remains enabled.

The *Discover Transactions automatically* configuration does not apply to [POJO entry points](#) or [POCO entry points](#).

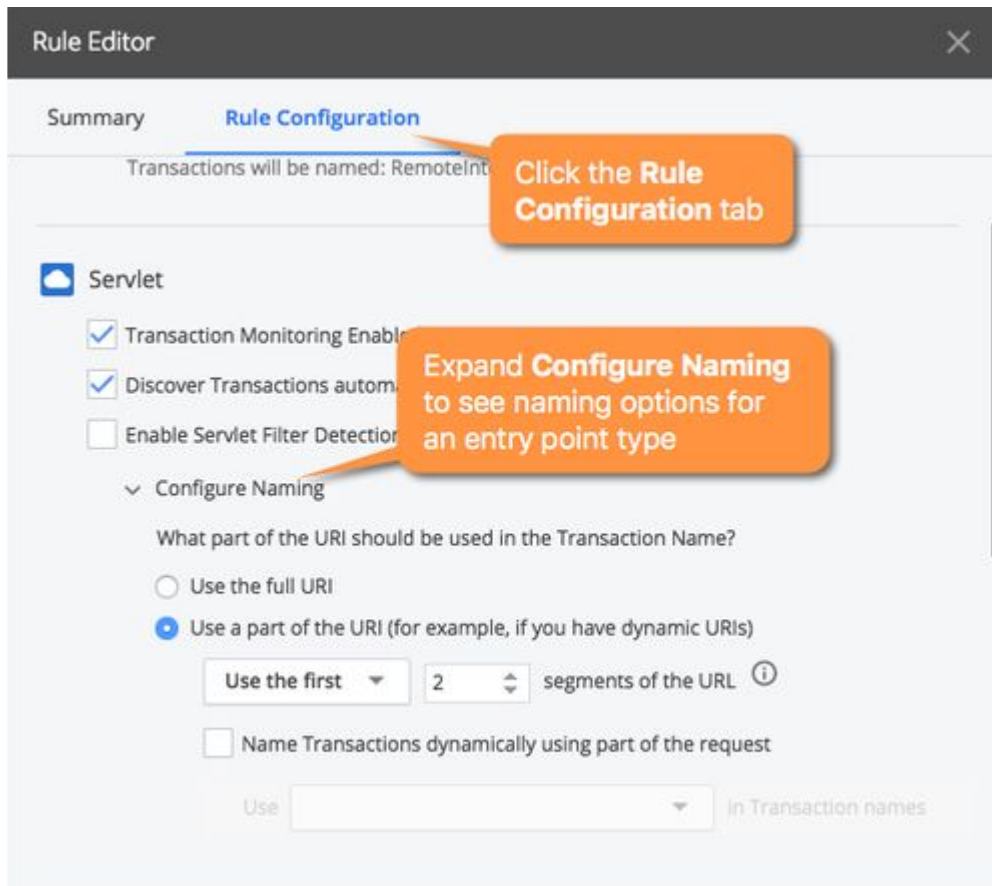

Customize Transaction Naming for an Entry Point

To view and edit the business transaction automatic discovery rules, go to **Configuration > Instrumentation > Transaction Detection**.

To customize transaction naming for an entry point type, double-click a Default Automatic Transaction Discovery rule for specific agent type. Click the Rule Configuration tab to see entry points for the rule. Entry point types that have customizable naming options have the **Configure Naming** expander, as shown below.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

For more information specific to customizing naming for URI-based transactions, see [URI Based Entry Points](#).

You can also customize transaction naming using a [Custom Match Rule](#).

Transaction Detection for Apache Web Servers

The AppDynamics Apache Agent monitors web server entry points and names business transactions originating on Apache web server tiers based on the request URI. You can modify the default business transaction naming scheme if needed.

Default Automatic Naming for Web Transactions

By default, the AppDynamics auto-detection naming scheme identifies all web server transactions using the full URI before the query string. For example, the following URI represents a funds transfer operation for an online bank:

```
http://bank.example.com/Account/Transferfunds/California
```

Based on the default scheme, the business transaction would be named `/Account/Transferfunds/California`.

You can customize the auto-detected naming scheme by configuring identification based on:

- URI segments
- Headers, cookies, and other parts of HTTP requests

To customize auto-detected naming:

1. On the **Transaction Detection** page, select the application or tier to configure and click the **Web Server** tab.
2. Verify that **Transaction Monitoring** is enabled and click **Discover Transactions automatically for http web requests**.
If you disable **Discover Transactions automatically for WEB requests**, the agent doesn't discover WEB transactions even if you configure custom naming.
3. Click **Configure Naming** for the **Web** type in the **Entry Points** panel.

Identify Transactions Using URI Segments

AppDynamics offers several options to automatically name web transactions based on the URI. Consider the following URL representing a checkout operation in an online store:

```
http://onlinestore.example.com/Web/Store/Checkout
```

You can configure AppDynamics to identify a more meaningful name using one of the following options:

- Click **Use the first** or **Use the last** to use the selected number of contiguous segments at the beginning or end of the URI. For example, to identify the checkout transaction using the last two segments of the URI: `/Store/Checkout`.
- If you need more flexibility, such as using non-contiguous segments in the name, click **Name Transactions dynamically using part of the requests** and specify the segments with the **Use URI segments in Transaction names** option.
- To name the transaction for specific URI segments, click **Use URI segment(s) in Transaction names**. This enables you to skip URI segments or use non-contiguous segments in the naming scheme.

Enter the segment numbers separated by commas: 1, 3. For example, the following URL represents the checkout transaction requested by a customer with ID 1234:

```
http://onlinestore.example.com/Store/cust1234/Checkout
```

The checkout transaction is the same regardless of the customer, so it makes sense to omit the customer ID and name the transaction based on the first and third segments of the URI: `/Store/Checkout`.

Identify Transactions Using Headers, Cookies, and Other Parts of HTTP Requests

To identify business transactions using particular parts of the HTTP request, click **Name Transactions dynamically using part of the request** and configure the option that makes sense for your application.

Carefully consider your naming configuration choices. If you use a value such as the request originating address and you have many clients accessing your application, it's likely that you would quickly reach the maximum number of registered business transactions. See "About the "All Other Traffic" Business Transaction" in [Business Transactions](#) for information about this event.

The following provides sample results based on the configuration options:

- To name transactions based upon the parameter name, click **Use a parameter value in Transaction names** and enter the **Parameter Name**.
For example, when you name the following transaction using the parameter name "category": `http://example.com/Store/Inventory?category=electronics`, AppDynamics names the transaction to include the category parameter value: `/Store/Inventory.electronics`.
- To use a header value in transaction names, click **Use header value in transaction names** and enter a **Header Name**.
For example, if you name the transaction using a header such as "Version", AppDynamics names transactions with the header value as follows: `/Store/Inventory.v2.5`.
- To use a cookie value in transaction names, click **Use a cookie value in Transaction names** and enter the **Cookie Name**.
For example, for a website that tracks a user's loyalty status in a cookie. Set the Cookie Name to "loyalty". AppDynamics names transactions for the loyalty cookie value: `/Store/Inventory.Status=Gold`.
- To Use a session attribute value in transaction names, Click **Use a session attribute in Transaction names** and enter the **Session Attribute Key**.
For example, a website stores a customer's region in the session property. Set the Session Attribute name to "region". AppDynamics names transactions for the region session attribute value: `/Store/Inventory.NorthAmerica`.
- To use the request method in Transaction names, click **Use the request method (GET/POST/PUT)** in Transaction names.
For example: `/Store/Inventory.GET`.
- To use the request host in Transaction names, click **Use the request host in Transaction names**. For example: `/Store/Inventory.192.0.2.0`
- To use the request originating address in Transaction names, click **Use the request originating address in Transaction names**. AppDynamics names transactions for the IP address of the request client. For example: `/Store/Inventory.192.0.2.10`.
- To use a regular expression on the URI to name the transaction, click **Apply a custom regular expression on the transaction name**. AppDynamics uses the following rules to name the transaction:
 - The Apache Agent uses [Perl style regular expressions](#).
 - AppDynamics tests the regular expression against the segments specified in the configuration.
 - AppDynamics names the business transaction for the substring match.
 - If the regular expression pattern isn't found, the business transaction name follows the URI rules.
 - If you use groups in the regular expression, AppDynamics names the business transaction for the first matching group. If no matching groups are found in the pattern match, AppDynamics names the transaction for the fully matched substring.
 For example consider the following URL: `http://mywebapp.example.com/abc/;jsessionid=12345008;mykey=mytransaction;anotherkey=foo`.
 Use the first two segments of the URI with the following regular expression to name the transaction for the value of `mykey`: `.*mykey.(\w+).*`.
 In this instance AppDynamics names the transaction `mytransaction`.

Custom Match Rules and Exclude Rules

You can create custom match rules and exclude rules for Web type entry points for Apache Agent. The configuration parameters work the same as those for custom naming in this page. If an excluded request on

the Web Server tier passes to another instrumented tier such as Java, PHP, or Python, the downstream agent will detect the transaction. See [Custom Match Rules](#).

Validation for Automatic Transaction Discovery Rules

When you first create a business application in AppDynamics, the Default Scope ensures that all tiers for the application have a default automatic discovery rule for every agent type. Because the scope configuration model is highly configurable, the Controller UI enforces validations in the following cases:

- When you change the automatic discovery rules for a scope.
- When you assign or reassign tiers to a scope.

When you attempt to make an invalid change, the Controller prevents the change and displays a message in the Controller UI.

These validations ensure that after configuration updates every tier in your business application has the default automatic discovery rule for its agent type. They also ensure that there is an automatic discovery rule for all agent types to handle any prospective tiers you add to your application.

Existing Tiers

Every existing tier must belong to a scope that includes an automatic transaction detection rule for the tier's agent type. For example, a Java tier must belong to a scope with a Java automatic transaction detection rule.

The following rules apply:

- You can remove a tier from scope only when the tier has an auto-discovery rule from another scope.
- You can remove an automatic transaction detection rule from a scope only when tiers have auto-discovery rule from another scope.

Prospective Tiers

To ensure that any new tier you add to your application has an automatic transaction detection rule available, there must be at least one automatic transaction detection rule for each agent type in a scope of the following types:

- A scope that contains all tiers.
OR
- A scope that contains all tiers excluding specific existing tiers.

Custom Match Rules

Related pages:

- [Using Regular Expressions](#)
- [Custom Exclude Rule Examples](#)
- [.NET Agent for Linux Business Transaction Configuration](#)

A custom match rule is a type of [transaction detection rule](#) that enables you to define criteria for business transaction discovery, and naming for an entry point type.

There are two types of custom match rules:

- A custom include rule defines an entry point to use in a new transaction.
- A custom exclude rule lets you prevent AppDynamics from detecting business transactions you are not interested in tracking. For example, application framework services, administrative console requests, or heartbeat pings, and so on.

Use [Live Preview](#) to experiment with certain custom match rule configurations and identify potential business transaction entry points:

- During a [Business Transaction Discovery Session](#), you can use the Classes/Methods browser or Uninstrumented Code to create [POJO](#) and [POCO](#) custom match rules.
- When you create or edit a [POJO](#) or [Servlet](#) entry point, you can use [Live Preview](#) for the individual rule you are creating.

Transaction Naming

When an app agent detects a request that matches a custom include rule, it names the business transaction based on the rule name. You can further refine the transaction name using transaction splitting for [URI based rules](#), for POJOs, or for POCOs.

If a request matches more than one custom include rule, it applies the rule with the highest number priority. See [Transaction Detection Rules](#).

Create a Custom Match Rule

1. Navigate to **Configuration > Instrumentation** and select the **Transaction Detection** subtab.
2. Select the **Rules** subtab.

 You can also add a rule within a specific scope on the Transaction Detection tab.

3. Select **Add** to open the Add Rule page with *Custom Match Rule* selected.
4. Select the **Agent Type** and the **Entry Point Type** and select **Next**.
5. On the Summary tab, make general rule configurations:
 - If you are creating a custom match exclude rule, click **Exclude Transactions discovered by this rule**.
 - Enter the rule *Name*. The app agent names requests that match the rule for the rule name.

 To avoid errors, do not include these special characters in the rule name: less than sign (<) and greater than sign (>).

- Optionally disable the rule, set the rule *Priority* and assign the rule to a *Scope*. For information on rule priorities, see [Transaction Detection Rules](#). For information on scopes, see [Scope Configuration Model](#).

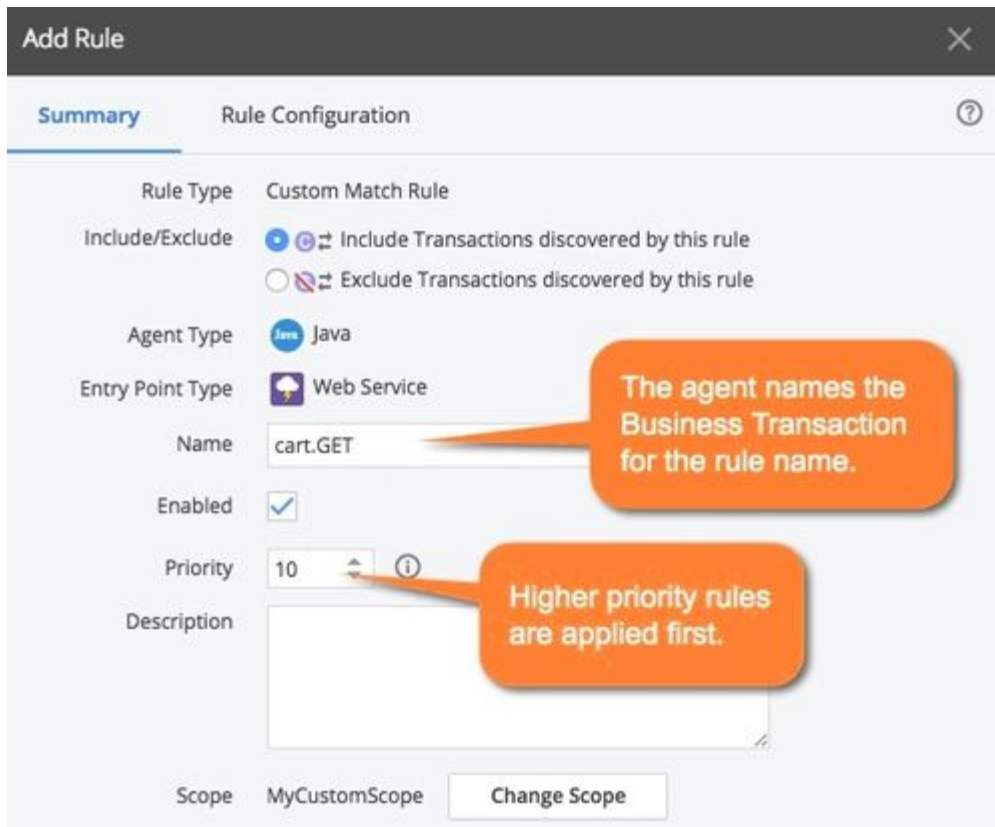

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- On the Rule Configuration tab, configure the match criteria based upon the entry point type. The PHP web choices, for example, let you specify HTTP-oriented match criteria, such as those for HTTP method, URI, and query parameters.

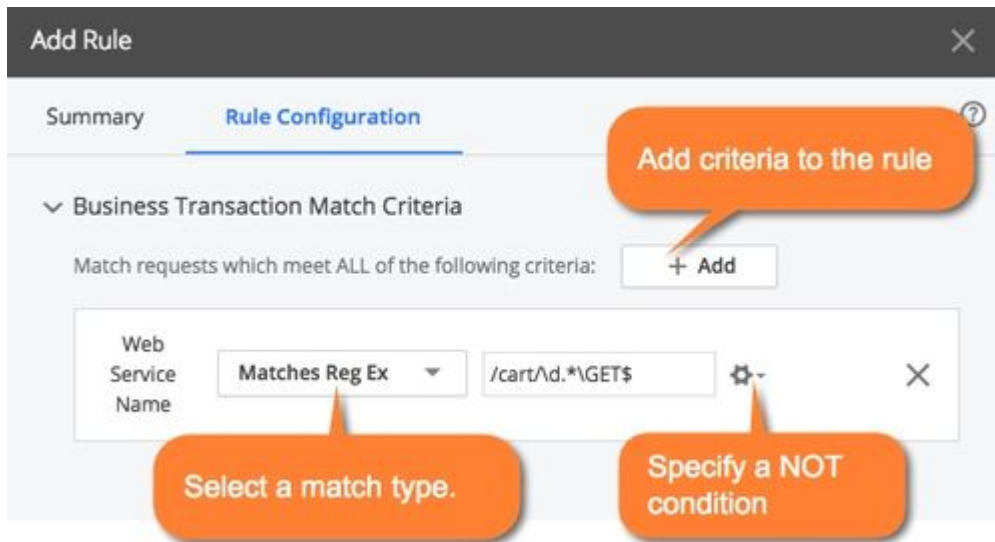

✔ Servlet and POJO entry point types feature a *Live Preview* button to launch [custom match rule live preview](#) session. A live preview streams data from an active node so you can interactively experiment with rule configuration in the Add Rule window.

Custom Match Include Rule Example

This example shows a custom match include rule named *cart.GET* in a scope named MyCustomScope.

The "cart.GET" rule generates business transactions for Web Service GET requests where the URI begins with `/cart/` followed by a number. AppDynamics names the resulting business transaction `cart.GET` :

You can add conditions to the rule to match based on specific HTTP parameters or hostnames.

For certain HTTP-based request types, such as Servlets or ASP.NET, a match rule can have more than one HTTP Parameter match condition. A request must match all HTTP Parameter conditions to match this rule. There is an implicit AND operator between the parameters rather than an OR operator.

You can use more complex regular expression matching. For example, the following request URLs:

- `example.com/aaa123.aspx`
- `example.com/b1.aspx`

To match any incoming request URL to this business transaction, use:

```
example\.com/[a-zA-Z]]+?[0-9]]+?
```

Any request to a URL that includes `example.com` followed by uppercase or lowercase letters and numbers would match this business transaction detection rule. A URL that has no digits after the letters, such as `example.com/z.aspx` does not match.

See [Using Regular Expressions](#) for more information on using regular expressions in the UI.

Transaction Splitting for URI Based Entry Points

You can configure business transaction splitting for these types of URI based entry points:

- Java Servlet
- ASP.NET
- PHP Web
- Node.js Web
- Python Web
- Web Server

When you enable transaction splitting, the agent resolves a subset of requests that match the custom include rule into a separate business transaction based on a dynamic part of a request. The app agent names the transaction:

```
<custom match rule name>.<name derived from the split configuration>.
```

Consider an application with incoming requests:

- `http://nwtrader.com/checkout?category=electronics`
- `http://nwtrader.com/checkout?category=clothing`

This example shows how to configure transaction splitting to resolve two requests into two different business transactions, named:

- Checkout.electronics
- Checkout.clothing

You can split servlet transactions based upon the payload. See [Split Servlet Transaction by Payload Examples](#).

Default Custom Exclude Rules

AppDynamics includes default exclude rules for the entry points for frameworks that are not usually of interest. Navigate to **Configuration > Instrumentation > Transaction Detection > Rules** and filter on **Rule Type: Custom Exclude** to view or modify the default custom match exclude rules. See [Custom Exclude Rule Examples](#).

To configure exclude rules for Service Endpoints, see [Service Endpoints](#).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Java Business Transaction Detection

This page lists different types of Java entry points for business transactions.

A tier can have multiple entry points. For example, a Java framework implementation may have a combination of pure Servlets or JSPs, Struts, Web services, and Servlet filters, all co-existing as monitored entry points on the same JVM.

The middle-tier components like EJBs and Spring beans are usually not considered entry points because they are normally accessed using either the front-end layers such as Servlets or from classes that invoke background processes.

For details on types of Java entry points and how to set up custom match rules, see:

- [Servlet Entry Points](#)
- [Struts Entry Points](#)
- [Spring Bean Entry Points](#)
- [EJB Entry Points](#)
- [POJO Entry Points](#)
- [Web Service Entry Points](#)
- [Binary Remoting Entry Points for Apache Thrift](#)
- [CometD Support](#)
- [JAX-RS Support](#)
- [Spring Integration Support](#)

Servlet Entry Points

AppDynamics automatically detects requests to servlet-based entry points and generates business transactions based on the requests. For general information on how to customize automatic transaction detection, see [URI Based Entry Points](#).

Frameworks Supported as Servlets or Servlets Filter

AppDynamics supports many web frameworks based on servlets or servlet filters. The servlet configuration settings in AppDynamics apply to these frameworks as well as to plain servlets. Frameworks include:

- Spring MVC
- Wicket
- Java Server Faces (JSF)
- JRuby
- Grails
- Groovy
- Tapestry
- ColdFusion

Custom Match Rules for Servlet Transactions

Custom match rule let you control how business transactions are generated for Servlet-based requests.

Match Conditions

Match conditions can be based upon the URI, HTTP method, hostname, servlet name, or other characteristics of the request.

For HTTP Parameter conditions, you can add more than one. If you configure more than one HTTP Parameter match criteria, they must all be met by a request to be subject to this business transaction identification and naming rule, as must all conditions you configure for the rule.

Some of the options have NOT conditions that you can choose to negate the configured condition. Choose this option in the gear icon next to the condition.

Splitting Transactions using Request Data or Payload

If you match by URI, you can have the transaction identified (or split) based on values from the request, such as URI patterns, request data, or payload. See [URI Based Entry Points](#) for information on naming or splitting transactions by the request elements.

When you create the rule, it appears in the Custom Match Rule list, where you can enable, disable, edit or remove the rule.

See [Split Servlet Transaction by Payload Examples](#) for use case examples.

POST Request Body Parameter Matching Considerations

You can configure Servlet-based custom match that match POST requests based on HTTP body parameter values. To avoid interfering with the operation of the application, the Java Agent applies some special processing measures and limits on how it accesses the body parameters. This behavior can affect whether

requests can be matched by POST body parameters for your particular application. If you are having trouble configuring matching by HTTP parameter in POST requests, you should understand this behavior.

Transaction Naming Match Criteria

For transaction match criteria, match conditions for HTTP parameters work under these conditions:

- If the parameter is a query string in the URL of the POST request, as opposed to the request body.
- If the Servlet Request body parameters have already been read and parsed by the application prior to the invocation of the servlet. A Servlet Filter, for example, may do this.

Otherwise, custom servlet match rules do not match HTTP parameter values in POST requests.

Transaction Splitting

For transaction split rules based on parameter matching in POST requests, the Java Agent defers transaction naming for incoming requests until the application servlet has accessed the request parameters.

The Java Agent considers the parameters "accessed" once the application invokes `getParameterMap()`, `getParameter()`, `getParameterNames()`, or `getParameterValues()` on the `ServletRequest` object. If the servlet does not call one of these methods, the agent will not apply the split rule and the transaction will not be named.

Exclude Rules for Servlets

To prevent specific Servlet methods from being monitored, add a custom [exclude rule](#). The controls for selecting Servlets to exclude are the same as those for custom match rules.

Split Servlet Transaction by Payload Examples

AppDynamics lets you split [servlet custom match rules](#) according to the request payload. For each of these examples, you must create a servlet custom match rule and enable the URI option on the Rule Configuration tab.

Split by POJO Method Call

Using a Java method to name a transaction is useful when:

- You might not have a clear URI pattern, or
- You are using an XML/JSON framework not otherwise supported

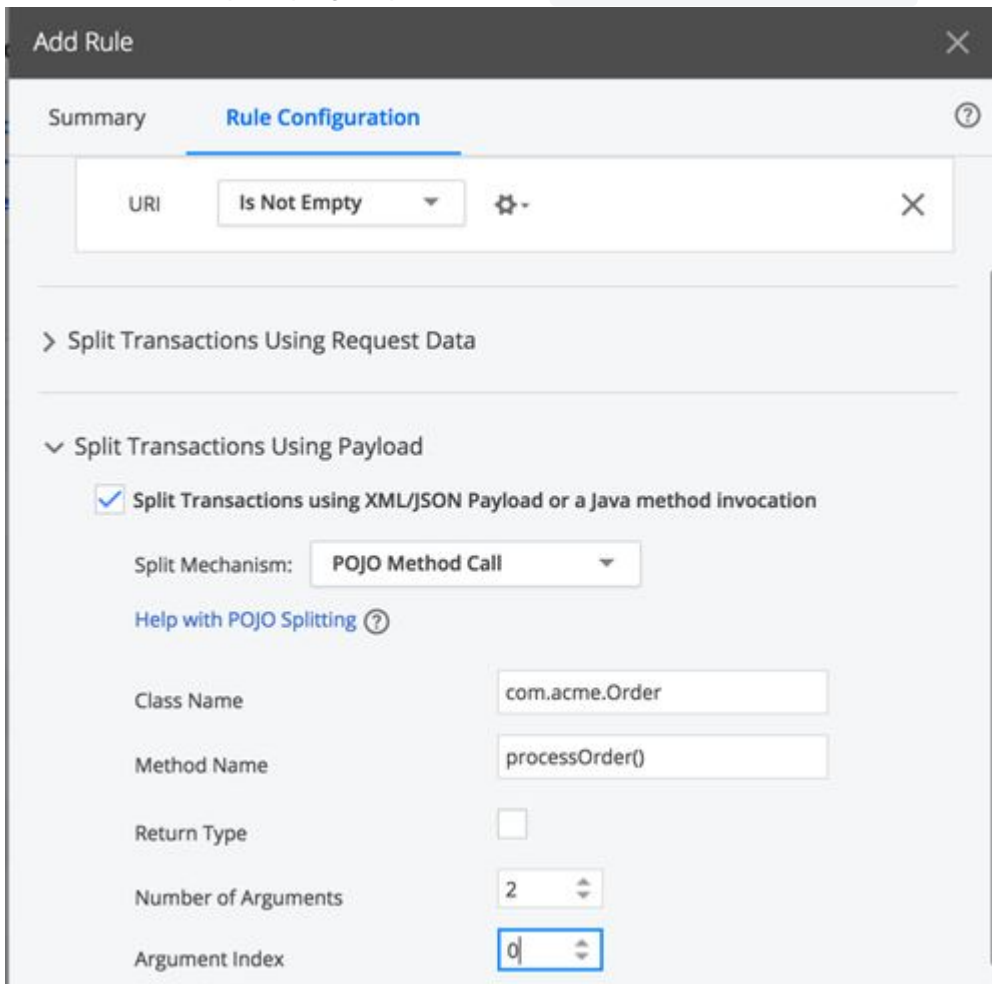

For example, consider the `processOrder()` method in the `doPost()` method of the servlet at the following URL: `http://acmeonline.com/store`.

```
public void doPost(HttpServletRequest req, HttpServletResponse resp) {
    //process the data from the sevlet request and get the orderType and the items
    processOrder(orderType,item)
    ...
}
public void processOrder(String orderType,String item) {
    //process order
}
```

You want to derive transaction naming from the first parameter to the `processOrder()` method, `orderType`.

1. On the Rule Configuration tab for the custom match rule, enable the **Split Transactions using the XML/JSON payload or Java method invocation**.
2. Select **POJO Method Call** as the splitting mechanism.
3. For the method, choose the `processOrder`, and specify the parameter to use by numeric position in the parameter (0 index). The following screenshot displays the configuration of a custom match rule which

will name all the qualifying requests into a `Store.order.creditcard` transaction:

In addition to the parameter, you can also specify either the return type or a recursive getter chain on the object to name the transaction. For example, if the method parameter points to a complex object like `PurchaseOrder`, you can use something like `getOrderDetails().getType()` to correctly name the transaction.

Split Transaction by JSP Name

You can identify transactions by JSP name, as follows:

1. On the Rule Configuration tab, enable the **Split Transactions using the XML/JSON payload or Java method invocation**.
2. Select **POJO Method Call** as the splitting mechanism.
3. Set the name of the class to `com.sun.faces.application.ViewHandlerImpl`.
4. Set the name of the method to `renderView()`.
5. Set the argument index to 1.

- Define the Method Call Chain or getter as `getViewId()`. The agent appends the value to the name of the transaction as follows: `<Name of the Custom Rule>.<path to jsp>`.

You can later rename these business transactions to a more user-friendly name if you like.

Split Transactions on XPath Expression

You can access values in an XML payload for business transaction naming or splitting using an XPath expression. Consider the following example from an Ecommerce order transaction where the XML represents an order for three items. The order uses credit card processing, which is the distinguishing element for this body:

```
<acme>
  <order>
    <type>creditcard</type>
    <item>Item1</item>
    <item>Item2</item>
    <item>Item3</item>
  </order>
</acme>
```

The URL is:

```
http://acmeonline.com/store
```

The `doPost()` method of the Servlet is:

```
public void doPost(HttpServletRequest req, HttpServletResponse resp) {
    DocumentBuilderFactory docFactory =
    DocumentBuilderFactory.newInstance();
    DocumentBuilder docBuilder = docFactory.newDocumentBuilder();
    Document doc = docBuilder.parse(req.getInputStream());
    Element element = doc.getDocumentElement();
    //read the type of order
    //read all the items
    processOrder(orderType, items)
    ...
}
```

Imagine you want to differentiate "Order" transactions based upon the type of order. You can use the XPath expression `//order/type` on this XML payload, which in this example evaluates to `creditcard`.

- On the Rule Configuration tab, click **Split transactions using XML/JSON Payload or a Java method invocation**.

2. Choose **XPath Expressions** for the Split Mechanism.
3. Enter the XPath expression that points to the value of the XML element to use for naming. In this example, `//order/type`

The agent appends the value of the XPath expression to the name of the business transaction, for example, `Store.order.creditcard`. Even though the agent doesn't name the transaction until after XML parsing, AppDynamics measures the duration of the business transaction to include the execution of the `doPost()` method.

You can use one or more XPath expressions to chain the names generated for the Business Transaction.

You can specify whether the request results in transaction splitting when the expression does not evaluate to a value.

Split Transactions on Java XML Binding

You can identify transactions for Java XML data binding frameworks for these types of frameworks:

- Castor
- JAXB
- JibX
- XMLBeans
- XStream

In the following example, the posted XML is unmarshalled to the `PurchaseOrderDocument` object, and the `getOrderType()` method should be used to identify the type of the order:

```
<acme>
  <order>
    <type>creditcard</type>
    <item>Item1</item>
    <item>Item2</item>
    <item>Item3</item>
  </order>
</acme>
```

The following snippet shows the `doPost()` method for the Servlet:

```

public void doPost(HttpServletRequest req, HttpServletResponse resp) {
    PurchaseOrderDocument poDoc = PurchaseOrderDocument.Factory.parse(po);
    PurchaseOrder po = poDoc.getPurchaseOrder();
    String orderType = po.getOrderType();

    //read all the items
    processOrder(orderType, items)
    ...
}

```

To split the transaction based upon the XML Binding:

1. On the Rule Configuration tab, check **Split transactions using XML/JSON Payload or a Java method invocation**.
2. Select **Java XML Binding** as the split mechanism.
3. Enter these values for the match criteria:
 - Unmarshaled Class Name: `PurchaseOrderDocument`
 - Method name: `getOrderType()`

The agent identifies the business transaction for this example as `Store.order.creditcard`:

This custom rule ensures that the Java agent intercepts the method in XMLBeans (which unmarshalls XML to Java objects). If the name of the transaction is not on a first level getter on the unmarshalled object, you can also use a recursive getter chain such as `getOrderType().getOrder()` to get the name.

Although the transaction name is not obtained until the XML is unmarshalled, the response time for the transaction is calculated from the `doGet()` method invocation.

Split Transactions on JSON Payload

You can access JSON payload for transaction identification purposes using the method where the Servlet unmarshalls the payload.

For example, the following JSON payload posts an `order` for an item `car` and uses `creditcard` for processing the order. The URL is `http://acmeonline.com/store`:

```

order :{
  type:creditcard,
  id:123,
  name:Car,
  price:23
}}

```

The following code snippet shows the `doPost` method of the Servlet:

```

public void doPost(HttpServletRequest req, HttpServletResponse resp) {

```

```

//create JSONObject from servlet input stream
String orderType = jsonObject.get("type");
//read the item for the order
processOrder(orderType,item)
...
}

```

After the application unmarshalls the posted JSON payload to the JSON object, the `type` key is available to identify the type of the order. In this case, this key uniquely identifies the business transaction.

To use the JSON payload for transaction identification you must set the `enable-json-bci-rules` node property to `true` on each node to enable this rule. To configure the rule:

1. On the Rule Configuration tab, check **Split transactions using XML/JSON Payload or a Java method invocation**.
2. For the JSON object key, enter the name of the JSON object. For example, `type`.

The agent automatically intercepts the `JSONObject.get("$JSON_Object_Key")` method to name the transaction. Although the agent doesn't obtain the transaction name until the JSON object is unmarshalled, the response time for the transaction will be calculated from the `doGet()` method.

Struts Entry Points

When your application uses Struts to service user requests, AppDynamics intercepts individual Struts Action invocations and names the user requests based on the Struts action names. A Struts entry point is a Struts Action that is being invoked.

AppDynamics supports the following versions of Struts:

- Struts 1.x
- Struts 2.x

Struts Action invocations are typically preceded by a dispatcher Servlet, but identification is deferred to the Struts Action. This ensures that the user requests are identified based on the Struts Action and not from the generic URL for Dispatcher Servlet.

The response time for the Struts-based transaction is measured when the Struts entry point is invoked.

Struts Request Names

When a Struts Action is invoked, by default AppDynamics identifies the request using the name of Struts Action and the name of the method. All automatically discovered Struts-based transactions are thus named using the convention `<Action Name>.<Method Name>`.

For example, if an action called ViewCart is invoked with the `SendItems()`, the transaction is named `ViewCart.SendItems`.

For Struts 1.x the method name is always `execute`.

You can rename or exclude auto-discovered transactions. See [Organize Business Transactions](#).

Custom Match Rules for Struts Transactions

For finer control over the naming of Struts-based transactions, use custom match rules.

A custom match rule lets you specify customized names for your Struts-based requests. You can also group multiple Struts invocations into a single business transaction using custom match rules. See [Custom Match Rules](#) for information about accessing the configuration screens.

The matching criteria for Struts transactions are: Struts Action class names, Struts Action names, and Struts Action method names.

Exclude Rules for Struts Actions or Methods

To prevent specific Struts Actions and methods from being monitored, add a [custom exclude rule](#). The criteria for Struts exclude rules are the same as those for custom match rules. In particular, you may need to exclude custom-built dispatch servlets, as described next.

Exclude Custom-built Dispatch Servlet

When a Struts action is called, it can demarcate a transaction as an entry point. AppDynamics instruments the Struts invocation handler to get the action name because the Struts action is not an interface. The invocation handler provides the Java Agent with the name of the action being invoked. If the dispatcher

Servlet is custom-built and has not been excluded from instrumentation, the wrong entry point could be instrumented and the business transaction could be misidentified.

To address this issue, add a custom exclude rule for the dispatcher servlet or add a BCI exclude for it.

Spring Bean Entry Points

This page describes how to configure transaction entry points for Spring Bean requests.

Spring Bean-based Transactions

AppDynamics allows you to configure a transaction entry point for a particular method for a particular bean in your environment. The response time is measured from when the Spring Bean entry point is invoked (after receipt at a dispatcher servlet).

Default Naming for Spring Bean Requests

When you enable automatic discovery for Spring Bean based requests, AppDynamics automatically identifies all the Spring Beans based transactions and names these transactions using the following format:

```
BeanName.MethodName
```

By default, the transaction discovery for Spring Bean-based requests is turned off. You can enable it in any Automatic Transaction Discovery rule for Java. Select **Discover Transactions automatically for all Spring Bean invocations** on the Rule Configuration tab.

When a class is mapped to multiple Spring bean names, by default only the name of the first Spring bean found is used. This may not be ideal for your application such as cases where a call graph for web service A that has Spring beans from web service B. To contend with this scenario, you can remove the Bean name from the transaction name using the `capture-spring-bean-names` node property, as described on [App Agent Node Properties \(B-C\)](#).

Custom Match Rules for Spring Bean Requests

If you are not getting the required visibility with the auto-discovered transactions, you can create a [custom match rule](#) for a Spring Bean based transaction. You can match based on one or more of the following criteria:

- Bean ID
- Method Name
- Class Name
- Extends
- Implements

The following example creates a custom match rule for the `placeOrder` method in the `orderManager` bean.

Summary
Rule Configuration
?

▼ Business Transaction Match Criteria

Match requests which meet ALL of the following criteria: +

Bean ID Equals orderManager ⚙️ ✕

Method Name Equals placeOrder ⚙️ ✕

Exclude Rules Spring Bean Transactions

To exclude specific Spring Bean transactions from detection, add a [custom exclude rule](#).

The criteria for Spring Bean exclude rules are the same as those for custom match rules.

EJB Entry Points

AppDynamics allows you to configure an EJB-based transaction entry point on either the bean name or method name. The response time for the EJB transaction is measured when the EJB entry point is invoked.

Default Naming for EJB Entry Points

AppDynamics automatically names all the EJB transactions `<EJBName>.<MethodName>`.

Enabling EJB Transaction Detection

By default, automatic transaction discovery for EJB transactions is turned off. To get visibility into these transactions, enable the auto-discovery for EJB based transactions explicitly.

Before you enable auto-discovery for EJB based transactions, note that:

- If the EJBs use Spring Beans on the front-end, the transaction is discovered at the Spring layer and the response time is measured from the Spring Bean entry point.
- AppDynamics groups all the participating EJB-based transactions (with remote calls) in the same business transaction. However, if your EJBs are invoked from a remote client where the App Server Agent is not deployed, these EJBs are discovered as new business transactions.

You can enable auto-discovery for EJB transactions in any Automatic Transaction Discovery rule for Java. Check **Discover Transactions automatically for all EJB invocations** on the **Rule Configuration** tab.

Custom Match Rules for EJB based Transactions

If you are not getting the required visibility with auto-discovered transactions, create a [custom match rule](#) for an EJB based transaction.

The following example creates a custom match rule for the receiveOrder method in the `TrackOrder` bean.

The screenshot shows the 'Rule Configuration' tab in the AppDynamics interface. Under the 'Business Transaction Match Criteria' section, there is a list of criteria. The criteria are: 'EJB Name' with the operator 'Equals' and the value 'TrackOrder', and 'Method Name' with the operator 'Equals' and the value 'recieveOrder'. Each criterion has a gear icon for settings and an 'X' icon for removal. A '+ Add' button is visible above the list.

In addition to the bean and method names, other match criteria that could be used to define the transaction are the EJB type, class name, superclass name, and interface name.

Exclude Rules for EJB Transactions

To exclude specific EJB transactions from detection add a [custom exclude rule](#). The criteria for EJB exclude rules are the same as those for custom match rules.

POJO Entry Points

This page describes how to create custom match rules for POJO (Plain Old Java Object) applications. See [Custom Match Rule Live Preview](#) for instructions about interactively working with live data to create a POJO.

About POJO Custom Match Rules

[Custom match rules](#) for POJOs let you configure business transaction detection in application environments that run pure Java applications or that use frameworks with entry points that are not automatically detected.

Unlike common frameworks, which are characterized by well-known entry points for applications, the logical entry point for a business transaction for a POJO entry point could be any method in the application.

To configure a custom POJO entry point, therefore, you need to identify the method that AppDynamics should consider the business transaction entry point. Keep in mind that the start and end of the execution of the method will correspond to the start and end of the business transaction, so the method should encapsulate the complete execution of the business transaction.

For example, consider the method execution sequence:

```
com.foo.threadpool.WorkerThread.run()
  calls com.foo.threadpool.WorkerThread.runInternal()
    calls com.foo.Job.run()
```

The first two calls to `run()` method are the blocking methods that accept a job and invoke it. The `Job.run()` method is the actual unit of work, because `Job` is executed every time the business transaction is invoked and finishes when the business transaction finishes.

Methods like these are the best candidates for POJO entry points. The response time for POJO transactions is measured from this entry point, and remote calls are tracked the same way as are remote calls for a Servlet's Service method.

Creating POJO Custom Match Rules

You can create a POJO entry point by adding a [custom match rule](#) with *POJO* as the Entry Point Type. The agent names business transactions for the custom match rule.

i In order for the agent to discover POJO transactions, your custom match rule must belong to a scope that also includes a Default Java Automatic Transaction Discovery rule with POJO transaction monitoring enabled.

You can classify matching transactions as background tasks by enabling the **Background Task** check box. When a request runs as a background task, AppDynamics reports only Business Transaction metrics for the request. It does not aggregate response time and calls metrics at the tier and application levels for

background tasks. This ensures that background tasks do not distort the baselines for the business application. Also, you can set a separate set of thresholds for background tasks. For more information, see [Monitor Background Tasks](#).

The custom match rule configuration offers several options for matching method invocations and splitting matched calls into separate business transactions, as described below.

i If you are running on IBM JVM v1.5 or v1.6, you must restart the JVM after defining the custom match rules.

Matching by Class and Method

You can specify matching criteria for the custom rule based on various forms of a method or class to which the method belongs.

When specifying the method name matching criteria, use parameter matching to match against a particular method signature. For example, say you want to instrument one of more methods in the following class:

```
class A
{
    public void m1();
    public void m1(String a);
    public void m1(String a, com.mycompany.MyObject b);
}
```

Configure instrumentation for each method based on its signature as follows:

- To instrument the first method signature (with no parameters), create a POJO-based business transaction match rule as follows:
 - Match Classes: with a Class Name that Equals A
 - Method Name: Equals m1()
- To instrument the second method, create a match rule as follows:
 - Match Classes: with a Class Name that Equals A
 - Method Name: Equals m1(java.lang.String)
- To instrument the third method, create a match rule as follows:
 - Match Classes: with a Class Name that Equals A
 - Method Name: Equals m1(java.lang.String, com.mycompany.MyObject)

You can also match methods that belong to classes with certain annotations. For example, say you want to match all classes that are annotated with `@com.acme.Processor`. The custom rule configuration can define the annotation as follows:

When calls to the process() method match, the result is a business transaction named for the custom match rule name.

Matching on Inner Classes and Inner Interfaces

You can match on inner classes and inner interfaces by adding a \$ sign after the class name. For example, you could specify the following for the class name:

```
com.my.package.OuterClass$InnerClass
```

Splitting Matches into Separate Business Transactions

With only transaction matching configured, all requests matched by the match rule belong to the custom business transaction. Alternatively, you can create a match rule that generates multiple named business transaction based on criteria in the request.

For example, the following configuration defines a custom match rule that matches by superclass. In the example, the entry point matches the process() method defined in classes that extend the com.acme.AbstractProcessor superclass. In our example, the superclass is extended by the subclasses SalesProcessor, InventoryProcessor, BacklogProcessor.

1. Create A custom rule that matches the superclass matches all of those subclasses:
2. Split the transaction on class name, you can have separate business transactions created for the respective subclasses. AppDynamics names the transactions with the class name, prepending the match rule name to the class name. For example, Process.SalesProcessor, Process.InventoryProcessor, and Process.BacklogProcessor.

▼ Transaction Splitting

Split POJO Transactions

Name Business Transactions using the following... + Add

Simple Class Name and Method Name
×

It's possible that parameter values carry what would be meaningful identifiers for business transactions in your application. For example, say the `jobType` parameter in the following method may have the values of `Sales`, `Inventory` or `Backlog`.

```
public void process(String jobType,String otherParameters...)
```

You can split the transaction based on parameter value by indicating the zero-based position of the parameter in the method signature, `0` in the example:

The `toString()` method indicates how the value of the parameter should be rendered. See [Using Getter Chains](#) for more information. As indicated in the dialog, you can use other transaction splitting criteria as well, including thread ID, method name, class name, and so on.

The name of the rule is prepended to the dynamically-generated name to form the business transaction name.

Exclude Matches from Transaction Splitting

An exclude rule defines criteria which, when matched by a transaction instance, prevents transaction splitting from occurring as otherwise configured. In effect, this nullifies the effects of transaction splitting for the subset of transactions matched by the exclude condition.

Monitor Java Interface Static and Default Methods

As of Java 8, Java interfaces can include static and default methods. This page describes how to monitor these types of interface methods.

i Note that another Java language feature introduced in Java 8, lambda method interfaces, are not supported by the AppDynamics Java Agent.

Interface Static Methods

The following code snippet shows an example static interface method:

```
package jdk8;

interface InterfaceForStaticMethod
{
    static int sum(int acc, int x)
    {
        return acc + x;
    }
}
```

The actual bytecode for the method would reside in the compiled class file, so a class match against the interface class in the AppDynamics configuration would result in the instrumentation of that class for a business transaction.

To instrument such methods, create a POJO business transaction match rule for the `interfaceForStaticMethod`, such as:

In this case, the rule would match classes with a Class Name of `jdk8.InterfaceForStaticMethod`.

Interface Default Methods

Interfaces can also define default methods. As with interface static methods, the bytecode for default methods resides in the compiled class files.

When configuring instrumentation for a default method:

- If the targets are classes that do *not* override the default method, target the interface via a class match
- If the targets are classes that do override the default method, target the interface via an interface match

Instrument an Interface Default Method Directly

Given the following interface:

```
package jdk8;

interface InterfaceForConcreteClassDefaultMethod
{
    default int sum(int acc, int x)
    {
        return acc + x;
    }
}
```

And its implementing class:

```
package jdk8;
```

```
class ClassForDefaultMethod implements InterfaceForConcreteClassDefaultMethod
{
}
```

In this example, the `ClassForDefaultMethod` does *not* override the default method. Therefore, you can use a class match against the interface such as:

Instrument an Overridden Default Method

Given the following interface:

```
package jdk8;

interface InterfaceForAnonymousClassDefaultMethod
{
    default int sum(int acc, int x)
    {
        return acc + x;
    }
}
```

And:

```
InterfaceForAnonymousClassDefaultMethod i = new InterfaceForAnonymousClassDefaultMethod()
{
    @Override
```

```
public int sum(int acc, int x)
{
    return acc + x;
}
};
```

Because the method is overridden, the target `bytecode` resides in the anonymous class, `InterfaceForAnonymousClassDefaultMethod`. So you need to create an interface match POJO business transaction match rule such as:

The screenshot shows the 'Rule Configuration' tab of a configuration interface. It features a 'Match Class & Method' section with the following settings:

- Match Classes:** A dropdown menu is set to 'with a Class Name that'. Below it, a dropdown menu is set to 'Equals' and a text input field contains 'jdk8.InterfaceForAnonymousClass'.
- Method Name:** A dropdown menu is set to 'Equals' and a text input field contains 'sum'. A gear icon is visible to the right of the input field.

At the bottom of the configuration area, there is a link labeled 'Browse classes and methods'.

Instrument Java Lambda Expressions

This page describes [Lambda](#) expressions, a Java language feature introduced in Java 8 that enables a functional style of programming in Java.

Java Lambda

Here's a short example:

```
LambdaMethodInterface i = (acc, x) -> acc + x;
```

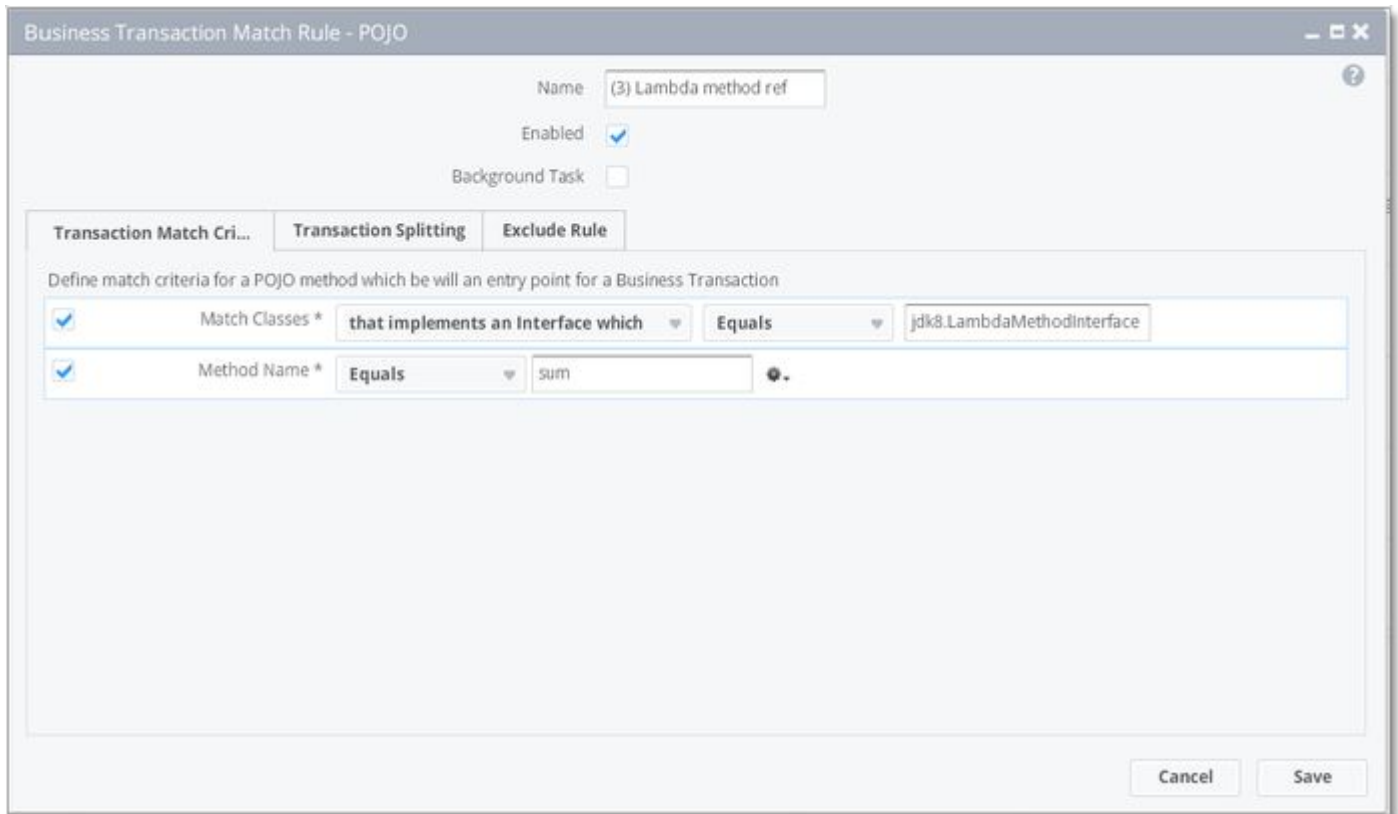

In the JVM, this creates an anonymous instance of the associated `FunctionalInterface`, as shown below:

```
package jdk8;

@java.lang.FunctionalInterface
interface LambdaMethodInterface
{
    int sum(int acc, int x);
}
```

Instrument Java Lambda Instances

To instrument lambda instances, create a POJO business transaction match rule for the `LambdaMethodInterface`, for example:

This sample rule matches classes that implement the interface name `jdk8.LambdaMethodInterface`.

Web Service Entry Points

When your application uses Web Services to service user requests, AppDynamics intercepts the Web Service invocations and names requests based on the Web Service action names and operation name. A Web Service entry point is a Web Service endpoint that is being invoked.

This is relevant only when the Web Service invocation is part of the entry point tier or in cases where the transaction should be continued in a downstream tier using a correlation header transported in the SOAP Envelope.

Web Service invocations are usually preceded by a dispatcher Servlet, but identification is deferred to the Web Service endpoints. This configuration ensures that the requests are identified or correlated based on the Web Service or its payload and not based on the generic URL for the dispatcher Servlet.

Default Naming

When the Web Service endpoint is invoked, the request is named after the Web Service name and the operation name.

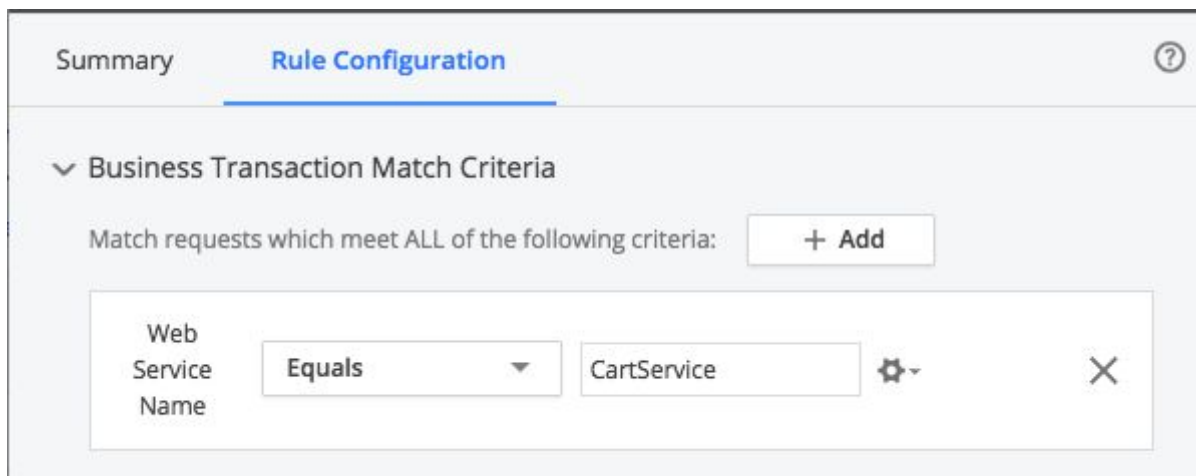

For example, if a service called `CartService` is invoked with the `Checkout` operation, the is named `CartService.Checkout`.

You can rename or exclude these automatically discovered transactions. See [Organize Business Transactions](#).

Custom Match Rules for Web Services

You can aggregate different Web Service requests into a single business transaction using the web service name or the operation name. You do this by creating custom match rules for Web Services. See [Custom Match Rules](#) for information about accessing the configuration screens.

This example names all operations for the Web Service named `CartService` :

Exclude Rules

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

To exclude specific Web Services or operation names from detection, add an exclude rule. See [Custom Match Rules](#). The criteria for Web Service exclude rules are the same as those for custom match rules.

Transaction Splitting for Web Services Based on Payload

1. Disable the Web Service automatic transaction discovery.
2. Disable the following default exclude rules:
 - Apache Axis Servlet
 - Apache Axis2 Servlet
 - Apache Axis2 Admin Servlet
3. Add the custom match rule for Axis or Axis2 Servlet (based on the version being used) and split the transaction using payload or request depending on the pattern in your scenario.

Exclude Rule for JBoss Correlation

To detect Web Service entry and to support correlation in JBoss SOAP Web Service, you must create a Servlet exclude rule by excluding the class name, `org.jboss.wsf.stack.cxf.CXFServletExt` as follows:

1. In **Add Rule**, select **Custom Match Rule**.
2. Select **Servlet** as the **Entry Point Type**.
3. Select **Exclude Transactions discovered by this rule**.

The screenshot shows the 'Add Rule' dialog box with the following configuration:

- Rule Type:** Custom Match Rule
- Include/Exclude:**
 - Include Transactions discovered by this rule
 - Exclude Transactions discovered by this rule
- Agent Type:** Java
- Entry Point Type:** Servlet
- Name:** (Empty text field)
- Enabled:**
- Priority:** 0
- Description:** (Empty text area)
- Scope:** Select Scope

4. Click **Save**.
5. In the Rule Configuration tab, specify the class name as `org.jboss.wsf.stack.cxf.CXFServletExt`.
6. Click **Save**.

Binary Remoting Entry Points for Apache Thrift

Apache Thrift is a binary remoting protocol. Cassandra uses the Thrift protocol to achieve portability across programming languages. Applications written in many different languages can make calls to the Cassandra database using the Thrift protocol.

AppDynamics is preconfigured to detect business transaction entry points for Cassandra with Thrift framework applications. Note that Binary Remoting entry points are not available as [Service Endpoints](#).

AppDynamics measures performance data for Thrift transactions as for any other transaction. Thrift entry points are POJO-based. The response time for the transaction is measured from the POJO entry point, and the remote calls are tracked the same way as remote calls for a Servlet's Service method.

Default Naming for Binary Remoting (Thrift) Entry Points

When the automatic discovery for a request using Binary Remoting (Thrift) protocol is enabled, AppDynamics automatically identifies all the transactions and names them using the following format:

```
RemoteInterfaceClassName:MethodName
```

Enabling Detection for Binary Remoting (Thrift) Entry Points

Binary Remoting (Thrift) entry points are enabled by default, but if you are not seeing them in the Tier Flow Map, verify that they have been enabled in the Java automatic transaction detection rule. For more information, see [Transaction Detection Rules](#).

When enabled, you can see Thrift calls from calling tiers to the Cassandra database in the List View of the Tier Dashboard. Since the transactions using the Thrift protocol are POJO-based, they appear as POJO in the Type column.

Creating Custom Match Rules for Binary Remoting (Thrift) Requests

If you are not getting the required visibility with the auto-discovered transactions, you can configure [custom match rules](#) and transaction splitting for specific classes and methods.

When creating the custom match rule, choose POJO as the rule type. The rule should be defined on the class and method you want to use as the entry point. Someone who is familiar with your application code may need to help you make this determination.

For information about and examples of the various POJO-based business transaction match rules you can create for Binary Remoting (Thrift), see [POJO Entry Points](#). The rules for Binary Remoting (Thrift) entry points are the same as those for POJO entry points.

CometD Support

Related pages:

- [Jetty Startup Settings](#)
- [Exclude Rules](#)

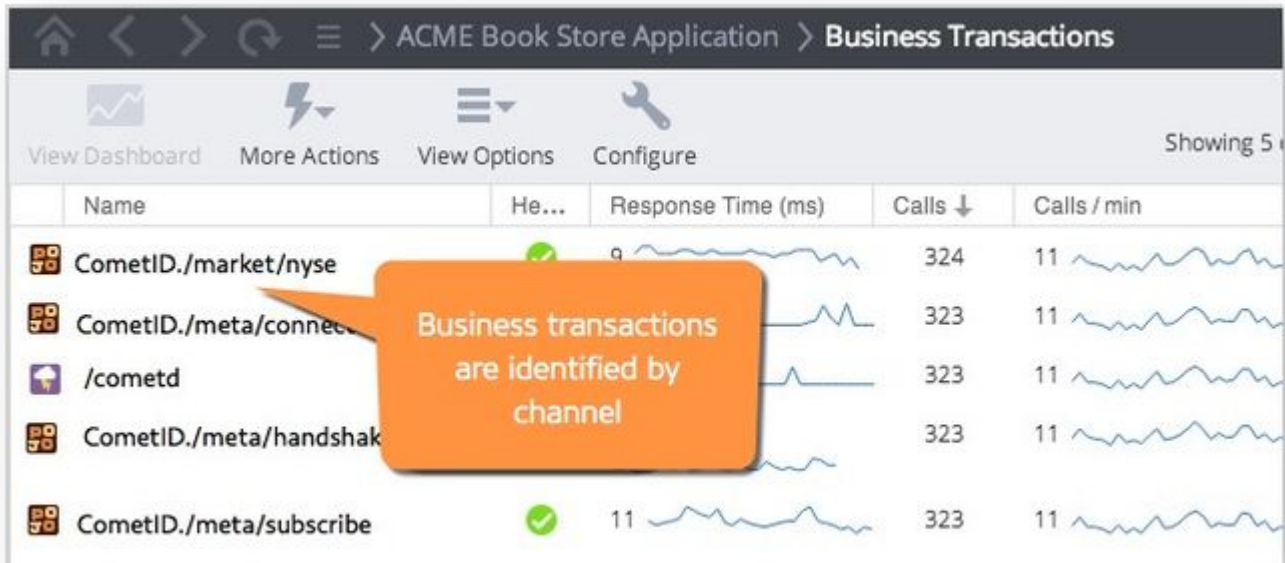

CometD is an HTTP-based event routing bus for transporting asynchronous messages over HTTP. CometD provides both a JavaScript API and a Java API and is often used for real-time interactive applications such as multi-player games and chat rooms.

CometD is distributed as a WAR file. When you instrument the CometD application container that runs the WAR (typically a Jetty server) with the Java agent, AppDynamics automatically detects and tracks CometD activity, as described in the following section.

About the Built-in Support

AppDynamics supports both the WebSocket and the HTTP long-polling client transports in CometD. It tracks CometD messages as they traverse channels using POJO rules that split business transactions based on channel name.

Accordingly, business transactions in AppDynamics correspond to CometD channels. The following screenshot shows a business transaction generated for the `/market/nyse` channel:

AppDynamics provides built-in exclude rules for the servlets that implement CometD transport functions, `org.cometd.annotation.AnnotationComet` and `org.cometd.server.CometdServlet`. For best results, you should exclude tracking for the container servlet as well, as described in the next section.

Create Container Transport Servlet Exclude Rules

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

CometD is implemented as a servlet. Since the servlet implements transport activity, you should create exclude rules for the servlets that perform the CometD transport function. This ensures that the results of business transaction discovery do not obscure the POJO-based BTs corresponding to CometD channels.

CometD is generally contained within a Jetty container, so the rules should exclude the Jetty container tracking in most cases. For Jetty, you should configure exclude rules for these Jetty servlets:

- EQUALS, `org.eclipse.jetty.server.handler.ContextHandler`
- EQUALS, `org.eclipse.jetty.servlet.ServletContextHandler`
- ENDSWITH, `jetty.plugin.JettyWebAppContext`

If using another type of container, you should create similar exclude rules for the equivalent supporting classes.

JAX-RS Support

The Java Agent supports Jersey 1.x and 2.x by default.

Business transaction entry points are named using the following app agent node properties:

- [rest-num-segments](#)
- [rest-transaction-naming](#)
- [rest-uri-segment-scheme](#)

Business Transaction Naming Scheme

By default, the Java Agent makes a best-effort basis to name JAX-RS-based transactions using the class annotation, method annotation, and HTTP method of the detected entry point, in the following form:

```
{class-annotation}/{method-annotation}.{http-method}
```

In some situations where the annotation values are not available, the agent may name the transaction as follows:

```
{fully qualified class name}.{method}
```

For example, when the JAX RS service endpoints don't have the class and method names in them explicitly, but the annotations are inferred in some other way.

For annotation inheritance cases, the agent attempts to fetch the annotations from the superclasses and interfaces as described by the [JAX RS specification](#). The specification makes the following recommendation:

For consistency with other Java EE specifications, it is recommended to always repeat annotations instead of relying on annotation inheritance.

Repeating annotations on the endpoint methods enables the Java Agent to name business transaction according to the default scheme.

rest-transaction-naming Variables

The `rest-transaction-naming` node agent property enables you to control naming for JAX-RS-based business transactions. You can use variables to have the transactions named with runtime values, for example, based on the method name, class name, parameter values, and more. For a full list of variables, see [App Agent Node Properties Reference](#).

You can add a getter chain after any of the parameters to operate on the parameter values. To do so, add ':' followed by the getter chain. Standard getter chain escape requirements and rules apply.

Naming Examples

The following example shows naming based on a part of the value of the sixth parameter:

```
rest-transaction-  
naming={param-5:toString().toLowerCase().substring(5,20)}
```

The characters '{' and '}' are reserved. If used in getter chains or as text in the name the characters must be escaped with '\'. E.g. {{ class-name }} would display as { com.singularity.RestObject }.

You can use characters in addition to parameters. For example, in the following example, the class name and method name are separated by a slash:

```
rest-transaction-naming={class-name}/{method-name}
```

Based on this example, when the Java Agent sees a REST resource with a class name of `com.company.rest.resources.Employees` with a `CreateNewEmployee` method, it names the business transaction `com.company.rest.resources.Employees/CreateNewEmployee`.

Spring Integration Support

In Spring-based applications, [Spring Integration](#) enables lightweight messaging and supports integration with external systems via declarative adapters.

The Java Agent automatically discovers entry points based on the `MessageHandler` interface. The Java Agent automatically discovers exit points for all Spring Integration Release 2.2.0 channels except `DirectChannel`.

The Java Agent supports tracking application flow through Spring Integration [messaging channels](#). For pollable channels:

- A continuing transaction is tracked if the Spring Integration framework is polling for messages.
- If the application code polls for messages in a loop, the span of each loop iteration is tracked as a transaction. Tracking begins when the loop begins and ends when the iteration ends.

Entry Points

Originating transactions begin with `MessageHandler.handleMessage()` implementations. If the incoming message is already recognized by the Java Agent then a continuing transaction is started.

Exit Points

Exit points are based on `MessageChannel.send()`.

Most message channels exist inside the JVM. To represent this arrangement in a flow map, the Controller UI shows a link from the tier to the message channel component name (bean name) and then back to the tier.

Spring Integration Support Customizations

The following sections describe typical scenarios for tuning the default Spring Integration monitoring.

Track Application Flow Before Message Handler is Executed

In cases where a lot of application flow happens before the first `MessageHandler` gets executed, you should enable tracking the application flow as follows:

- Find a suitable POJO entry point and [configure it](#).
- Set the `enable-spring-integration-entry-points` node property to `false`. This property is set to `true` by default.
- Restart the application server

Limit Tracking of Looping Pollable Channels

To safeguard against cases where `pollableChannel.receive()` is not called inside a loop, you can ensure that the Java Agent tracks a pollable channel loop only if it happens inside a class/method combination similar to that defined in the following example.

You can configure the `spring-integration-receive-marker-classes` node property for each class/method combination that polls messages in a loop, in which case only those class/methods identified in this node property are tracked.

```
class MessageProcessor {
    void process() {
        while(true) {
            Message message = pollableChannel.receive()
        }
    }
}
```

For example, for the loop above, set the `spring-integration-receive-marker-classes` node property as follows and restart the application server:

```
spring-integration-receive-marker-classes=MessageProcessor/process
```

i The `spring-integration-receive-marker-classes` node property must be configured before the method `process()` gets executed for any changes to take effect. Restart the application server after setting this property.

.NET Business Transaction Detection

Related pages:

- [Transaction Detection Rules](#)
- [Organize Business Transactions](#)
- [Configuration Import and Export API](#)
- [.NET Agent for Linux Business Transaction Configuration](#)

The page lists different types of ASP.NET entry points for business transactions:

- [POCO Entry Points](#)
- [ASP.NET Entry Points](#)
- [WCF Entry Points](#)
- [ASP.NET Web Service Entry Points](#)
- [ASP.NET Core Instrumentation Options](#)
- [Name MVC Transactions by Area, Controller, and Action](#)

POCO Entry Points

Certain types of applications, such as Windows Services or standalone applications, may not have entry points that are automatically detected by the .NET Agent.

For these cases, you can create custom match rules for Plain Old CLR Objects (POCOs).

POCO Custom Match Rules Overview

To create a POCO custom match rule, define the custom match rule on the .NET class/method that is the most appropriate entry point for the business transaction. Someone who is familiar with your application code can help make this determination. You can also refer to the [Custom Match Rules](#) page.

You can optionally enable the Background Task option to have the transaction monitored as a background task. AppDynamics reports only Business Transaction metrics for background task transactions. It does not aggregate response time and call metrics at the tier and application levels for background tasks.

See [Monitor Background Tasks](#) for more information.

After you create the rule, AppDynamics detects traffic on the matched entry point method and registers a business transaction for it, naming the transaction with the name of the custom match rule.

i By default, you have to wait one minute and then restart the application to apply instrumentation changes required for new POCO entry points. If you create an application-level POCO that applies to a tier that has not yet registered with the Controller, you may need to restart the application after the tier registers in order to see the business transaction. You can [enable Runtime Reinstrumentation](#) for the .NET Agent so that you don't need to restart your application after instrumentation changes.

As an alternative to defining POCO entry points as described here, you can use the transaction discovery tool to create match rules based on discovered transactions. See [Business Transaction Discovery Sessions](#).

i The .NET Agent for Linux supports the configuration of simple POCO business transactions through the Controller UI. See [.NET Agent for Linux Business Transaction Configuration](#)

Define a POCO Entry Point

On an originating tier, a POCO entry point is the method that starts the business transaction. If the POCO entry point is on a downstream tier, it may correlate to an upstream exit point. When defining a POCO entry point, it is important to choose a method that begins and ends every time the business transaction executes. See [Business Transactions](#).

Good candidates for POCO entry points include the following:

- A method in a socket application that executes every time a client connects.
- A loop in a standalone application that batch processes records via a web service call. For example, an expense reporting system that loops through approved expenses to submit them for reimbursement.
- A Windows service that regularly executes a database call to check for new jobs to process. In this example, the POCO entry point would be defined on the namespace JobProcessor, class JobProcessorCore and method ProcessJobs:

.NET

```

using System.Threading;
using System;
using System.Threading.Tasks;
using System.Configuration;
using System.Collections.Generic;

namespace JobProcessor {
    class JobProcessorCore {
        public void Process() {
            while(running) {
                ProcessJobs ();

                // run jobs again after 1 minute
                Thread.Sleep(60000);
            }
        }

        private void ProcessJobs() {
            var logic = new JobManagement ();
            var jobs = logic.GetJobs(); // Query Database for a list of jobs to process

            foreach (var job in jobs) {
                logic.ExecuteJob(job); // logic for executing a job
            }
        }
    }
}

```

Task-Based POCO Entry Point Methods

AppDynamics automatically tracks POCO transactions for asynchronous, Task-based method entry points as end-to-end transactions. End-to-end latency metrics reflect the time it takes to complete the asynchronous actions associated with such methods.

To be tracked as an end-to-end transaction, the method you define as the POCO entry point must return a `Task` object and use the `async` modifier. In other words, the method signature should look similar to the following:

```

public async Task<int> SearchBestPrice()
{

```

```
    ...  
}
```

AppDynamics records the response times for such methods as it does for other types of methods—the response time reflects the time from when the method is called to when it returns control to the calling thread. However, for asynchronous task-based methods, AppDynamics records the time it takes for the asynchronous task to be fulfilled as an end-to-end transaction latency metric.

 For .NET Agents $\geq 20.3.0$, time spent on asynchronous tasks is reported in average response time (ART) but not reported in the end-to-end latency metric.

See [End-to-End Latency Performance](#).

ASP.NET Entry Points

Related pages:

- [Transaction Detection Rules](#)
- [Business Transactions](#)

AppDynamics automatically detects entry points for client requests to ASP.NET applications. If the request occurs on an [originating tier](#), the method or operation marks the beginning of a business transaction and defines the transaction name. In most cases, this type of entry point maps to a user request or action such as "Cart/Checkout". AppDynamics allows you to configure transaction naming based upon the ASP.NET request.

For information on how to configure default ASP.NET transaction detection, see [URI Based Entry Points](#).

Custom Match Rules for ASP.NET Transactions

Custom match rules provide greater flexibility for transaction naming. When you define a match rule, AppDynamics uses the rule name for the business transaction name.

See [Custom Match Rules](#) for general information on how to create custom match rule.

 The .NET Agent for Linux supports the configuration of simple ASP.NET business transactions through the Controller UI. See [.NET Agent for Linux Business Transaction Configuration](#).

When AppDynamics detects a request matching your specified criteria, it identifies the request using your custom name. You can use the following criteria to match transactions:

Method: Match on the HTTP request method, GET, POST, PUT or DELETE.

-  With automatic discovery for ASP.NET transactions enabled, configuring the match on `GET` or `POST` causes the agent to discover both GET and POST requests. If you only want either `GET` or `POST` requests for the transaction, consider the following options:
- Disable automatic discovery for ASP.NET transactions.
 - Create an exclude rule for the method you don't want: `GET` or `POST`.

URI: Set the conditions to match for the URI.

- For rules on regular expressions for .NET, see [.NET Framework Regular Expressions](#).
- Optionally click the gear icon to set a NOT condition.
- You must set a URI match condition in order to use transaction splitting.

HTTP Parameter: Match on HTTP parameter existence or a specific HTTP parameter value.

Header: Match on a specific HTTP header's (parameter's) existence or a specific HTTP header value.

- Hostname: Match on the server hostname. Optionally click the gear icon to set a NOT condition.
- Port: Match on the server port number. Optionally click the gear icon to set a NOT condition.
- Class Name: Match on the ASP.NET class name. Optionally click the gear icon to set a NOT condition.
- Cookie: Match on cookie existence or specific cookie value.
- Hostname, Port, and Class Name options are non-functional in the .NET Agent 4.5.9 for Linux.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Split Custom ASP.NET Transactions

AppDynamics lets you further refine ASP.NET custom transaction names using transaction splitting.

- To use transaction splitting, you must specify URI match criteria for the custom match rule.
- The *Split Transactions Using Request Data* options work the like the automatic transaction detection configuration options described in [URI Based Entry Points](#).

For example, you have a custom match rule named `MyTransaction` that matches the following URL: `http://example.com/Store/Inventory?category=electronics`. You can split the transaction on the parameter value as follows:

The screenshot shows the configuration for a custom match rule. It is divided into two main sections:

- HTTP Request Match Criteria:** This section is expanded to show a list of criteria. The criteria is: URI **Contains** Inventory. There is a '+ Add' button to add more criteria and a gear icon for settings.
- Split Transactions Using Request Data:** This section is also expanded. It has a checked checkbox labeled 'Split Transactions Using Request Data'. Below it, there is a dropdown menu set to 'a parameter value' followed by the text 'in Transaction names'. At the bottom, there is a text input field for 'Parameter Name' containing the value 'category'.

The .NET Agent names the resulting transaction `MyTransaction.electronics`.

WCF Entry Points

Related pages:

- [Configure Business Transaction Detection for .NET](#)
- [Windows Communication Foundation](#) (Microsoft Windows Reference)

AppDynamics automatically detects entry points for client requests to Windows Communication Foundation (WCF) services. If the request occurs on an originating tier, the method or operation marks the beginning of a business transaction and defines the transaction name. For information on originating tiers, see [Business Transactions](#).

The .NET Agent detects async entry points for the following patterns:

- Task-based asynchronous operations
- IAsyncResult Begin-End Asynchronous pattern

Controlling Correlation Header Location

In 4.4 and earlier, when WCF calls execute on a downstream tier, AppDynamics includes them as part of the business transaction from the originating tier. If the downstream WCF service uses the NetTcpBinding in WCF, you must register the app agent node property `enable-soap-header-correlation` with a value of `true`. See 'enable-soap-header-correlation' on [App Agent Node Properties Reference](#). Otherwise, the .NET Agent will detect the WCF call as the entry point for a new business transaction.

In the following table, when the node property is set to the default (false), the correlation message with header will only successfully deliver when sent over HTTP, not over SOAP with an HTTP wrapper or other protocol. When the node property is set to true, the correlation message with header will succeed in all scenarios.

	<code>enable-soap-header-correlation</code>	HTTP	SOAP (HTTP)	SOAP (other)
4.4 default	false	X	-	-
4.4	true	X	X	X

In 4.4.1 and later, the `enable-soap-header-correlation` node property and the default behavior for SOAP calls over non-HTTP protocols in WCF have changed. In addition, a new property, `disable-soap-header-correlation-non-http`, has been added. See `disable-soap-header-correlation-non-http` on [App Agent Node Properties Reference](#). With the new default AppDynamics will, by default, include downstream WCF services using NetTcpBinding as part of business transactions.

The following table captures the changes and additions of the correlation data for the following use cases:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- When the node properties for both `enable-soap-header-correlation` and `disable-soap-header-correlation-non-http` are set to the default (`false`), the correlation message with header will only successfully deliver when sent over HTTP or SOAP wrapped in a protocol other than HTTP.
- When the node property for `enable-soap-header-correlation` is set to `true`, and the `disable-soap-header-correlation-non-http` node property is set to the default (`false`), the correlation message with header will succeed in all scenarios.
- When the node property for `enable-soap-header-correlation` is set to the default (`false`), and the `disable-soap-header-correlation-non-http` node property is set to `true`, the correlation message with header will only successfully deliver when sent over HTTP, not over SOAP with an HTTP wrapper or other protocol.
- When the node properties for both `enable-soap-header-correlation` and `disable-soap-header-correlation-non-http` are set to `true`, the correlation message with header will only successfully deliver when sent over HTTP or SOAP with an HTTP wrapper, not over SOAP with another protocol.

i When upgrading from 4.4.0 to 4.4.1 or later, the `enable-soap-header-correlation` property retains its previous value and `disable-soap-header-correlation-non-http` defaults to `false`.

	<code>enable-soap-header-correlation</code>	<code>disable-soap-header-correlation-non-http</code>	HTTP	SOAP (HTTP)	SOAP (other)
4.5 default	<code>false</code>	<code>false</code>	X	-	X
4.5	<code>true</code>	<code>false</code>	X	X	X
4.5	<code>false</code>	<code>true</code>	X	-	-
4.5	<code>true</code>	<code>true</code>	X	X	-

By default, the .NET Agent does not correlate EUM transactions for WCF entry points. You can enable EUM correlation for WCF using the `wcf-enable-eum` node property. This feature is useful when an instrumented mobile application calls directly into a WCF entry point. See 'wcf-enable-eum' on [App Agent Node Properties Reference](#).

Automatic Naming for WCF Transactions

By default, the AppDynamics auto-detection naming scheme identifies all WCF transactions using the service name and operation name:

```
ServiceName.OperationName
```

For example, a web service for a travel website books reservations from client front ends:

`TravelService.BookTravel`. You can rename or exclude automatically discovered transactions from the Business Transactions List.

Custom Match Rules for WCF Transactions

Custom match rules provide flexibility for WCF transaction naming. When you define a match rule, AppDynamics uses the rule name for the business transaction name. See [Custom Match Rules](#) for more information.

When AppDynamics detects a request matching your specified criteria, it identifies the request using your custom name. You can match based upon:

Web Service Name

- For rules on regular expressions for .NET, see [.NET Framework Regular Expressions](#).
- Optionally use the gear dropdown to set a NOT condition.

Operation Name

- For rules on regular expressions for .NET, see [.NET Framework Regular Expressions](#).
- Optionally use the gear dropdown to set a NOT condition.

For example, you could report all operations for a TravelService, such as `SearchTravel` and `BookTravel`, as one business transaction.

ASP.NET Web Service Entry Points

AppDynamics automatically detects entry points for client requests to ASP.NET web services. If the request occurs on an originating tier, the method or operation marks the beginning of a business transaction and defines the transaction name. For more information on originating tiers, see [Configure Business Transaction Detection for .NET](#).

When web service calls execute on a downstream tier, AppDynamics includes them as part of the business transaction from the originating tier.

Automatic Naming for Web Service Transactions

By default, the AppDynamics auto-detection naming scheme identifies all web service transactions using the service name and operation name:

```
ServiceName.OperationName
```

For example, a web service for a travel website books reservations from client front ends.

Name	Health	Response Time (ms)	Calls	Calls / min	Errors
TravelService.BookTravel	✔	44	1	< 1	0

You can rename or exclude automatically discovered transactions from the business transaction list.

Custom Match Rules for ASP.NET Web Service Transactions

Custom match rules provide flexibility for ASP.NET web service transaction naming. When you define a match rule, AppDynamics uses the rule name for the business transaction name.

To access the Custom Match Rules pane, see 'To create custom match rules for .NET entry points' on [.NET Business Transaction Detection](#).

To create an ASP.NET web service custom match rule

1. In the **Custom Match Rules** pane, click the plus symbol (+) to add an entry point.
2. Click **Web Service** in the dropdown. Click **Next**.
3. Name the **New Business Transaction Match Rule**.
 - AppDynamics uses the rule **Name** to name the BT.
 - The Controller enables the rule by default. Disable it later if needed.
 - Set the **Priority** for the match rule. AppDynamics applies higher priority rules first.
4. Set one or more of the following match criteria. When AppDynamics detects a request matching your specified criteria, it identifies the request using your custom name.

Web Service Name

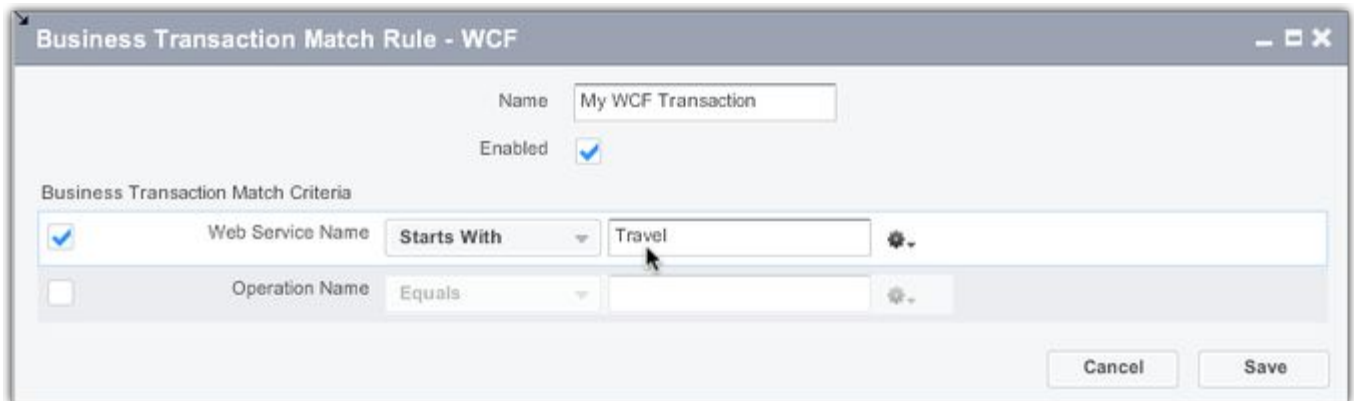

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- For rules on regular expressions for .NET, see [.NET Framework Regular Expressions](#).
- Optionally use the gear dropdown to set a NOT condition.

Operation Name

- For rules on regular expressions for .NET, see [.NET Framework Regular Expressions](#).
- Optionally use the gear dropdown to set a NOT condition.

For example, to report all operations for a TravelService, such as `SearchTravel` and `BookTravel`, as one business transaction:

5. Click **Create Custom Match Rule**.

The rule appears in the **Custom Match Rule** list. The business application or tier you customized displays a green check in the **Select Application or Tier** pane.

After the agent receives the updated configuration, it discovers the new business transaction and displays it in the Business Transactions list.

ASP.NET Core Instrumentation Options

When you develop an ASP.NET Core application, a pipeline is built by connecting the configured middleware components together.

By default (for example, when you re-use the standard template application startup code), you do not have to define how to build the pipeline or the sequence of middleware components in this pipeline. Everything works as defined. For applications with more complex processing demands, you would typically modify the middleware pipeline and consider how the .NET Agent instruments ASP.NET Core applications. [See middleware pipeline information from the Microsoft site.](#)

The .NET Agent can instrument this middleware pipeline at different points along the pipeline. Each instrumentation option provides advantages and disadvantages:

- Resource invoker instrumentation
- Endpoint instrumentation
- HTTP instrumentation
- MVC routing instrumentation

Resource Invoker Instrumentation

- Default setting for ASP.NET Core 2.x.
- For ASP.NET Core 3.x and 5.0, set the node property `aspdotnet-core-instrumentation (string) = "ResourceInvoker"` to enable it.

This instrumentation occurs at the end of the pipeline just before it calls the controller action or page handler. This applies to Razor Page handlers, and MVC and Web API controller actions.

The advantage is that only actual action code is instrumented, and the .NET Agent instrumentation does not execute for any other web requests such as: static files and not found paths (`Error Code 404`).

This is the most lightweight instrumentation option. It is the optimal choice for most ASP.NET Core applications, especially where minimal or no customization was applied to the middleware pipeline from the default application code.

Endpoint Instrumentation

- Default setting for ASP.NET Core 3.x and 5.0 (as of .NET Agent 21.3).
- Not available for ASP.NET Core 2.x.

With the improved endpoint routing introduced in ASP.NET Core 2.2, all routing for Web API, MVC, and Razor Pages was merged into a new architecture enabling the .NET Agent to perform instrumentation just after the `EndpointRoutingMiddleware`.

The advantage of using Endpoint instrumentation (instead of Resource Invoker instrumentation) is that the `Business Transaction` is tracked through the execution of all middleware after the `EndpointRoutingMiddleware`. This provides more visibility into operations performed before the controller action is executed. This includes only middleware that participates in the routing process such as authentication and authorization, but excludes middleware such as health checks, serving up static files, and so on.

Endpoint instrumentation balances full pipeline visibility (which may introduce too much noise and overhead) with no visibility (using Resource Invoker instrumentation).

HTTP Instrumentation

- This setting is available for ASP.NET Core 2.x, 3.x, and 5.0 (as of .NET Agent 21.3).
- Set the node property `aspdotnet-core-instrumentation (string) = "HTTP"` to enable it.

This instrumentation option instruments the full middleware pipeline by instrumenting every single web request. It provides the most visibility of all options. However, when enabling this option, you must consider:

- MVC naming is not possible because the request URL has not been decoded by the routing middleware. It may not be an MVC request; if it is, then controller and action names have not been resolved. All business transactions will use the URL path as its name.
- Because the .NET Agent instrumentation runs and inspects every web request (even requests that result with `404 Errors`, and so on), it has a greater performance impact on the application. To understand the performance impact, you should test this option either in a pre-production environment, or on a limited node count before you enable the option for the entire tier or application.

MVC Routing Instrumentation

- This is the original instrumentation option introduced for ASP.NET Core 1.x. It is the default setting for ASP.NET Core 1.x, and a configurable option for 2.x.
- Set the node property `aspdotnet-core-instrumentation (string) = "Legacy"` to enable this for ASP.NET Core 2.x.

The MVC Routing instrumentation functionality has been deprecated with ASP.NET Core 3.0. It provides full pipeline visibility by instrumenting from the first middleware in the pipeline. However, when attempting to do MVC naming of incoming web requests, it may cause issues. It assumes that you built the middleware pipeline in a specific way, and contains very specific middleware request delegates.

If you are using ASP.NET Core 2.x, and need full pipeline visibility with MVC naming, then this is the only available option for you.

Name MVC Transactions by Area, Controller, and Action

Related pages:

- [Business Transactions](#)
- [Transaction Detection Rules](#)

By default, the AppDynamics .NET Agent names ASP.NET transactions based upon the [URI](#). For ASP.NET Core on the full framework, the agent uses MVC area, Controller, and action naming by default, and can also be configured to use the URI. This page describes the MVC transaction naming configuration options for both ASP.NET and ASP.NET Core on the full framework.

i For transactions using the MVC naming conventions, the automatic transaction detection configuration settings apply to the MVC segments, not to the URI.

MVC Transaction Naming

For some MVC applications, URI-based naming may not produce meaningful business transaction names. Depending on the URI scheme, it might create many business transactions, pushing you quickly over your business transaction limit and causing most traffic to fall into the *All other traffic* business transaction.

For example, consider an MVC application that indicates store locations in the URL as the result of a city location search, such as the following sample URL:

`http://myapp.mycompany.com/Bellevue`

Based on this URL, AppDynamics registers a business transaction named `/Bellevue`. Each search result with a unique city would similarly generate a unique business transaction.

Name	Health	Server Time (ms)	Calls	Calls / min
/Bellevue	✓		4	4
/Mountain View	✓		14	14
/San Francisco	✓		9	9
/San Jose	✓	1	11	11
/Seattle	✓	1	21	21

Alternatively, you can configure the agent to identify transactions by the area, Controller, or action name. After you configure the agent to name transactions by Controller and action, the agent identifies the business transaction based on the Controller and action name, in this case, `Search/Results`.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

 View Dashboard  More Actions  View Options  Configure					
Name	Health	Server Time (ms)	Calls	Calls / min	
 /Search/Results		1	166	55	

In this example, the new business transaction combines search requests for all cities into one transaction, resulting in a more logical unit for measuring application performance.

Similarly, if your application uses areas to logically group Controllers, you can configure the use of area name in the business transaction.

For background information on ASP.NET Routing, see this Microsoft Developer Network article: msdn.microsoft.com/en-us/library/cc668201.aspx

Configure Node Properties for MVC Transactions

You can configure custom MVC transaction naming using node properties. This table describes how to configure node properties for MVC transactions based on the type of entry point.

 The node property supports: MVC 3, MVC 4, and WebAPI transactions.

Type of Entry Point	Name Business Transactions	Transaction Naming Configuration
ASP.NET hosted in IIS (<code>aspdotnet-mvc-</code>)	To name business transactions using the Controller and Action values	Register the <code>aspdotnet-mvc-naming-controlleraction</code> node property with a value = <code>true</code>
	To name business transactions using the Area and Controller values	Register the <code>aspdotnet-mvc-naming-controllerarea</code> node property with a value = <code>true</code>
	To include all three component values (Controller, Action, and Area) in business transaction names	<ol style="list-style-type: none"> 1. Register both node properties 2. Configure the ASP.NET transaction naming to use three URI segments instead of two (default) See Automatic Transaction Discovery Rules .

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Type of Entry Point	Name Business Transactions	Transaction Naming Configuration
ASP.NET Core on the Full Framework (<code>aspdotnet-core-</code>)	To name business transactions using the URI	Register both of these node properties with a value = <code>false</code> <ul style="list-style-type: none"> <code>aspdotnet-core-naming-controllerarea **</code> <code>aspdotnet-core-naming-controlleraction</code>
	To omit the Area value from your transaction names	Register the <code>aspdotnet-core-naming-controllerarea</code> node property with a value = <code>false</code>
.NET Agent for Linux	To use MVC Area, Controller, URI, and Action in business transactions name	Register the <code>aspdotnet-mvc-naming-controlleraction</code> node property with a value = <code>true</code>

To register a new node property, see [App Agent Node Properties](#).

After you modify any transaction naming configuration, and traffic to the previously registered business transactions terminates, you can delete the old business transactions.

Node.js Business Transaction Detection

Related pages:

- [Transaction Detection Rules](#)

This page provides instructions about transaction detection and configuration for the Node.js Agent.

GraphQL Business Transactions

GraphQL is a query and schema definition language that allows servers to expose an API over a HTTP endpoint. You specify the required data in the request payload and send all the requests from the client to a server endpoint.

AppDynamics supports GraphQL when used with the `express-graphql` module, view [GraphQL HTTP Server Middleware](#).

1. On the server side, you define a schema that describes the data and available operations on said data.
2. Then, you invoke operations defined by the schema to retrieve data (through URL requests that receive GraphQL queries) and mutate it.

In the current model, the Node.js Agent identifies an individual Business Transaction from the various requests coming to the server, but the agent does not capture the request payload.

GraphQL Business Transactions determines the business transaction through the incoming endpoint and incoming GraphQL payload, allowing further visibility into the GraphQL Node.js applications. Every GraphQL query that matches this URL is aggregated into one Business Transaction. With GraphQL Business Transactions, the Node.js Agent can be configured in the Controller to identify if an incoming business transaction matches a specific URI (for example, starting with `/QL`) and split that transaction with an operation into multiple transactions.

By default, GraphQL Business Transactions is disabled. To configure the Node.js Agent to enable GraphQL Business Transactions, set `enableGraphQL` to `true` in the call to `profile()`:

```
enableGraphQL: true,
```

Once GraphQL Business Transactions is enabled, you can configure a GraphQL custom match rule for a Node.js application:

1. In the Controller, select **Configuration > Instrumentation > Transaction Detection**.
2. Click **Add Rule > Summary > Custom Match Rule**.
3. Select Node.js in the **Agent Type** dropdown. Click **Next**.
4. Enter a name for the match rule and ensure that the enabled checkbox is checked.
5. Click **Select Scope** and select the desired scope for the rule. Click **OK**.
6. Next, navigate to **Rule Configuration > HTTP Request Match Criteria** and click **Add**.
7. Select URI as the criteria and choose the desired operation from the dropdown list. Then, enter the desired value for the GraphQL incantation (for example, the URL prefix).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

8. Navigate to **Split Transactions Using Request Data** and click the **Split Transactions Using Request Data** checkbox.
9. Select **the graphql operation name** from the dropdown and select **Save**.

PHP Business Transaction Detection

Related pages:

- [Configuration Import and Export API](#)
- [Configure PHP Custom Match and Exclude Rules](#)

This page describes transaction detection and configuration procedures that related specifically to the PHP Agent. See [Transaction Detection Rules](#).

PHP Entry Points

The entry point is where the business transaction begins, typically a URI or a page callback name, MVC controller action, page template name, or page template. The PHP Agent automatically detects and monitors the entry point types listed under PHP Frameworks and Protocols in [PHP Supported Environments](#).

If the agent cannot detect the framework, the entry point type defaults to PHP Web. PHP Web automatically detects all HTTP requests to the application.

Enable Monitoring by Entry Point

You can enable and disable transaction monitoring for each entry point type.

When monitoring is disabled, the agent stops counting, measuring, and recording all activity on servers of that type.

Enable or disable monitoring by checking or clearing the **Transaction Monitoring** checkbox in the **Transaction Detection** panel for the PHP entry point type.

Transaction Naming

By default, PHP Agent names transactions are named after the first two segments in the service request URL. You can modify the default naming scheme in the same manner as for any web-based business transaction entry point.

For PHP-based entry point tiers that use a multi-layered framework architecture, the last framework that processes the transaction determines the name of the PHP business transaction. For example, for an incoming request processing path of PHP Web > MVC > Drupal 8, a new business transaction would be named based on the Drupal 8 invocation rather than the preceding layers in the request processing flow.

Virtual Host Naming by Entry Point

If you have multiple virtual hosts configured on a single web server, you can differentiate among the business transactions by adding the virtual host name as a prefix to the default business transaction name. Enable use of the prefix by checking the **Use Virtual Host in Business Transaction names** checkbox in the **Transaction Detection** panel for the PHP entry point type. Transactions discovered and named subsequent to this configuration will use the virtual host name as a prefix to the default name.

For example, an application has two `exit.php` actions running on the same physical host. One action runs on a virtual host named `phpagent1` and the other runs on a virtual host named `phpagent2`. Transaction naming will occur as follows:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

-
- virtual host name is not used: agent identifies all requests to `exit.php` as a single business transaction named `exit.php`
 - virtual host name is used: agent identifies requests as two different business transactions named `phpagent1 : exit.php` and `phpagent2 : exit.php`

Customize Transaction Detection and Naming

If the default contentions do not produce transactions to fit your needs, you can change the transaction configuration as follows:

- Create exclude rules to eliminate entry points that you do not need to monitor.
- Create custom match rules that specify matching rules for identifying and naming transactions.
- For PHP Web entry points, you can also configure transaction naming.

To access the transaction detection panes, select **Configuration > Instrumentation > Transaction Detection > PHP-Transaction Detection**.

Configure PHP Custom Match and Exclude Rules

Related pages:

- [Transaction Detection Rules](#)
- [Using Regular Expressions](#)

This page summarizes the criteria that you can use for creating custom match and exclude rules for each entry point type.

The criteria are the same for custom match and exclude rules.

If you disable automatic detection for an entry point type and then apply custom match rules, the agent discovers only requests defined by those match rules. For example, if you have a PHP MVC custom match rule that matches on "Action contains search", and another rule that matches on "Action contains view", requests that contain "search" or "view" are the only MVC transactions that the agent detects.

On the other hand, if you do not disable automatic detection and you apply a custom match rule "Action contains search", all the requests that match that criterion are grouped together as a single "search" transaction and then any other requests (those that do not contain "search") are discovered using automatic detection.

Accessing Custom Rule Configuration

1. Click **Configuration Instrumentation > Transaction Detection > PHP-Transaction Detection**.
2. Scroll down to either the **Custom Match Rule** section or the **Exclude Rule** section.
3. Click **+** to create a new rule, then select from the dropdown the entry point type to which the rule applies.

PHP Web

Matching criteria can include one or more of the following:

- HTTP method
- URI segments
- HTTP parameter (value or existence)
- HTTP header (value or existence)
- Port
- Cookie (value or existence)

See [Set Priority When Multiple Rules Apply in Custom Match Rules](#).

Transaction Splitting

For PHP Web, if a transaction is configured to identify the entry point based on the URI, you can optionally split the transaction into multiple transactions. For example, a login request may be automatically detected as a single transaction, but you want to split it into two transactions based on whether the request branches to a new-user or existing-user operation.

You can split a PHP Web transaction using request data from the transaction names such as URI segments, parameter values, header values, and cookie values.

PHP Web Splitting Example

For example, to split a custom match rule transaction "mobile checkout" by the mobile carrier parameter, so the agent detects separate transactions as follows:

- products/mobile/checkout?carrier=verizon
- products/mobile/checkout?carrier=sprint
- products/mobile/checkout?carrier=att

To split transactions based upon the carrier parameter:

1. On the Rule Configuration tab, set a URI match option.
2. Check **Split Transactions Using RequestData**.
3. Select **Use a parameter value in Transaction names**.
4. Enter "carrier" for the **Parameter Name**.

The agent creates the following transactions: "mobile checkout.verizon", "mobile checkout.sprint", and "mobile checkout.att".

PHP Web Custom Match Rules vs Auto-Detection Rules of Other Types

If a custom match rule configured for PHP Web matches the same criteria as an auto-detection rule for a business transaction of a different transaction type in the same application, the PHP Web custom match rule takes precedence and the business transaction appears as a PHP Web transaction type.

However, if a custom match rule for PHP Web and a custom match rule for another transaction type match the same criteria, precedence depends on the values of the rules' priorities. See [Setting Match Rule Priority](#) for information on rule priorities.

PHP MVC

By default, for most MVC frameworks, the business transaction is named using the controller:action. For modular MVC frameworks, the business transaction is named using the module:controller:action.

You can modify detection to match only a portion of the module, controller or view name (such as "Begins with" or "Contains") or on a regular expression, rather than the default which matches the entire name using "Equals" for the match condition.

You cannot configure a single match rule that matches on both the controller and the action. You can create MVC custom match rules using any of the following:

- controller name only
- action name only
- module name and action
- module and controller name

PHP Web Service

By default, for Web Services frameworks, the business transaction is named for the entire web service name and the entire operation name using "Equals" for the match condition.

You can modify detection with a custom rule that matches on only the web service name or only the operation name. You can match on a portion of either name or use a regular expression.

PHP Drupal

By default, AppDynamics automatically names Drupal transactions based on the entire page callback name of the Drupal module using "Equals" for the match condition.

You can modify detection with a custom match rule that uses just a portion of the page callback name or use a regular expression.

PHP Wordpress

By default, AppDynamics automatically names Wordpress transactions based on the entire Wordpress template name using "Equals" for the match condition.

You can modify detection with a custom match rule that uses just a portion of the template name, or use a regular expression.

PHP CLI

By default, AppDynamics automatically names PHP CLI transactions based on the last two segments of the script's directory path plus the name of the script.

The agent creates a business transaction instance every time the script is run.

You can modify detection with a custom match rule that matches on a different portion of the script path and name or uses a regular expression.

Custom Exclude Rule Examples

Custom exclude rules prevent detection of business transactions that match certain criteria. You might want to use exclude rules in the following situations:

- AppDynamics detects business transactions that you do not want to monitor.
- To stay within agent and controller limits, you want to reduce the total number of business transactions.
- You need to suppress a default entry point to allow for the detection of a more precise entry point defined by a custom match rule.

You can customize existing rules or set up new rules. See [Custom Match Rules](#).

Change the Default Exclude Rule Settings

AppDynamics has a default set of custom exclude rules for various agent types. Sometimes you need to disable a default rule or add a new custom exclude rule. Different entry point types include different match criteria that you can use to exclude transactions.

You can view the default rules on the **Transaction Detection > Rules** tab:

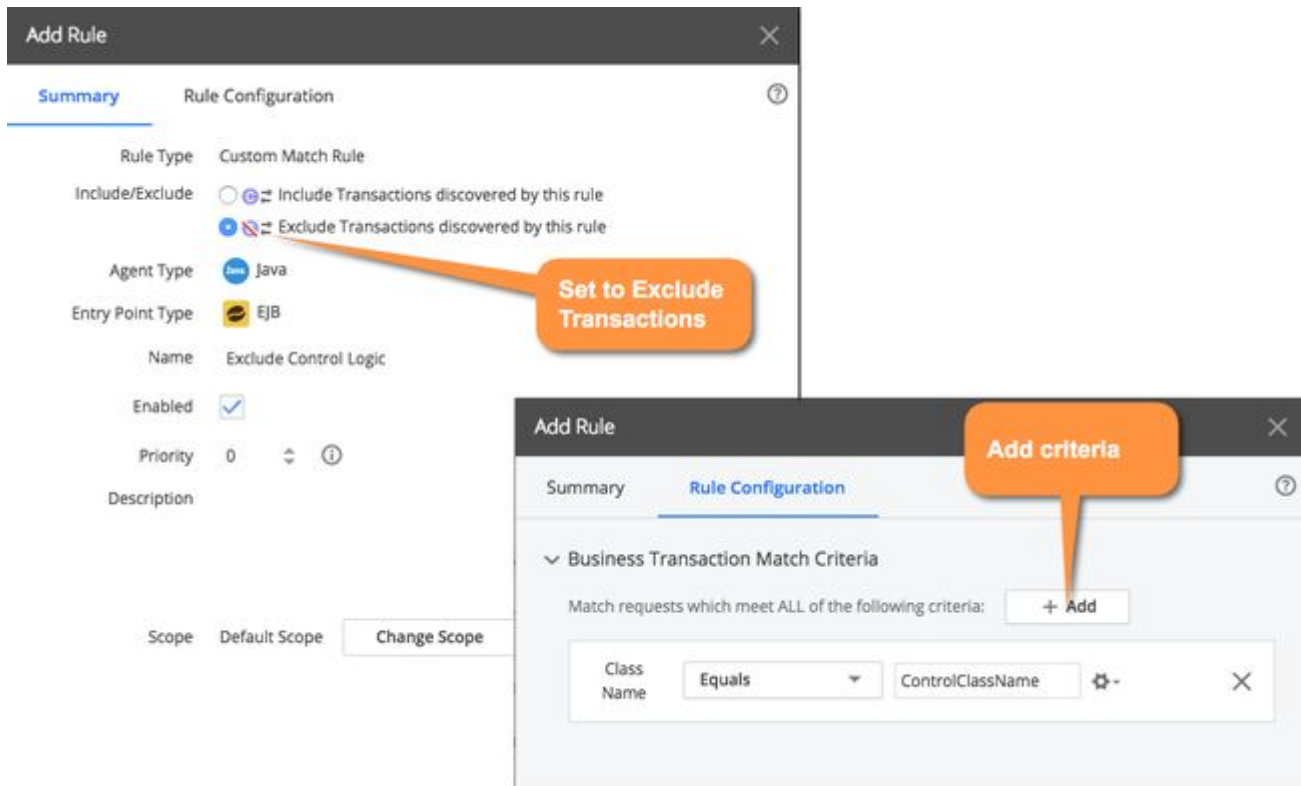

↓	Agent Type	Name	Scope	Enabled	Priori...
	Java	Spring WS - Base servlet for...	Default Scope	✓	0
	Java	Spring WS - dispatching of ...	Default Scope	✓	0

	Python	Python Static Content Filter	Default Scope	✓	0

Define Transaction Names Using Downstream Application Logic

Sometimes an incoming request invokes control logic in your code that uses payload data to execute different business logic. In such cases, it makes sense to name your business transactions for the business logic class and method. You can use a custom exclude rule to prevent AppDynamics from naming the business transaction for control logic. Then you can identify the transaction by the business logic instead.

Consider an example where you have implemented both the control logic and business logic as EJBs. With **EJB** discovery enabled, AppDynamics discovers and names business transactions based on the control class and method. You can create an EJB exclude rule for the control class name using the **Class Name Equals** match criteria. After you create the rule AppDynamics discovers and names the business transactions for your business logic APIs:

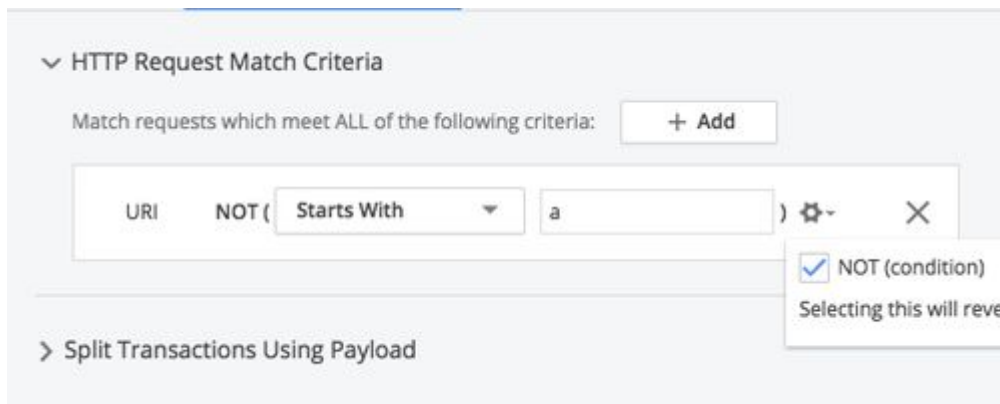

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Use an Exclude Rule as a Filter

Custom exclude rules filter out unwanted requests from transaction discovery. You can specify match criteria that allow eligible requests but ignore everything else.

For example, you want to use default discovery rules. Your application receives URI ranges that start with `/a`, `/b` ... `/z`. However, you only want to monitor URIs only when they start with `/a`. You can create a custom exclude rule that does a "Match : Doesn't Start With `/a`" as shown here:

In another example, imagine a specific an application that implements Spring Beans of the classes `java.lang.String` and `java.util.ArrayList`. This means that AppDynamics identifies all

instances of these classes as Spring Beans with the same IDs. To fix the problem, you can define a custom exclude rule specific Spring Bean IDs:

The screenshot displays the 'Add Rule' configuration window in AppDynamics. The 'Rule Configuration' tab is selected, showing the following settings:

- Rule Type:** Custom Match Rule
- Include/Exclude:** Exclude Transactions discovered by this rule (selected)
- Agent Type:** Java
- Entry Point Type:** Spring Bean
- Name:** (empty text field)
- Enabled:**
- Priority:** 0
- Description:** (empty text area)
- Scope:** Default Scope

The 'Business Transaction Match Criteria' section is expanded, showing a criteria entry: 'Bean ID Equals MyBean'.

Custom Match Rule Live Preview

This page provides instructions and information for the custom transaction detection rule Live Preview.

 You must have Configure Transaction Detection and View Sensitive Data permissions to use Live Preview. See [Manage Custom Roles](#).

When you create or edit servlet or POJO custom match rules in AppDynamics, you can click **Live Preview** to inspect pertinent transaction data from a node.

Custom transaction detection rule Live Preview session lets you interactively preview the effect of rule updates on your business transactions. Live Preview also provides tools for the different rule types to let you inspect the live data streaming from your application.

When you launch Live Preview, select the node where you want to preview transactions. Nodes are organized by tier. You can see which nodes have active agents and if there is a live preview session already running on a node.

Preview Business Transactions

When you initiate a custom match rule live preview session, the Controller shows the rule configuration in the left pane. Click **Preview Business Transactions** in the right pane to see resulting transactions. You can edit the rule and click **Apply** to update the changes within the session.

When the agent discovers an entry point for a rule but the transaction payload contains correlation data from an existing transaction, Live Preview displays a [masked transaction](#).

POJO Match Rule Tools

You can use these tools to inspect data and configure the entry point for a POJO custom match rule:

- **Classes/Methods browser**—lets you search for classes.
 - You can right-click a class or method in the result to set the class and method match criteria for the POJO.
 - You can view method invocations for a selected method.

In live preview mode, the number of methods and classes that can be returned by an agent is now limit-bounded. The limits are:

- Maximum number of classes: 1000
- Maximum number of methods: 300

You can change limits by modifying the node properties

```
classmethodservice.max.no.of.classes.reported and
classmethodservice.max.no.of.methods.reported , respectively
```

- **Method Invocations**—lets you inspect live data from the server for the specified method.
 - a. Expand a method invocation to see detailed information including invoked objects, parameters, and return values.

- b. Right-click on a data point to use it in transaction splitting.
AppDynamics automatically creates a splitting rule following the `get<field>()` syntax.
If your code follows another convention, you need to manually specify the getter method for the data point.
- c. You can also copy a [getter chain](#) to the clipboard.

The example below shows the data for a method, `Order.setQuantity()` :

The screenshot displays the AppDynamics interface during a live preview. At the top, there's a status bar with 'End Live Preview', 'Connected 00:22:09', and the environment 'ECommerce-E2E-Demo_WS_NODE'. Below this are navigation buttons: 'Preview Business Transactions', 'Tools', and 'Method Invocations'. A toolbar includes 'Filter', 'Refresh', 'Stop Streaming', and a search box. Filter criteria are set to 'Match Classes with a Class Name that Equals com.a...' and 'Method Name: Equals setQuantity'. The main area shows a tree view of a method invocation. The 'id' field is selected, and a context menu is open with the following options: 'Name Transaction using this Object (Splitting)', 'Copy Getter chain to Clipboard', 'Copy Name to Clipboard', and 'Copy Details to Clipboard'. Two callout boxes provide instructions: one points to the 'Method Invocation' node saying 'Expand a method invocation to preview live data.', and another points to the context menu saying 'Right-click to use an object in transaction naming or copy information to the clipboard.'

Servlet Match Rule Tools

When you use Live Preview to inspect data for a servlet custom match rule, AppDynamics shows live HTTP Requests that meet the rule criteria. You can click an individual Request URL to view detailed request data: headers, cookies, and parameters.

1. Right-click an individual data point, such as a header, to add the value to the match criteria or to set it as a transaction splitting option.
2. You can group the incoming HTTP requests by various parts of the request and its payload, such as the URI, an HTTP parameter, a header, etc. You can right-click a result from the **Values** column and add the value to the **HTTP Request Match** criteria.

Masked Transactions

Live Preview flags transactions that are downstream from another existing business transaction as masked transactions. To view the originating business transactions masking the current transaction, click the link indicating the number of transactions.

The screenshot shows the 'Preview Business Transactions' interface. A transaction named 'My Servlet' is highlighted, with a callout indicating it is masked by 8 business transactions. A modal window displays the following upstream transactions:

Business Transaction Name	Transaction State	Load
test rule	Originating	7
ViewCart.sendItems	Originating	2
Order.update	Originating	2

Click a business transaction name to view the business transaction dashboard for the masking transaction.

If you want to view metrics for the current entry point outside of a masking transaction or transactions, you can either:

- Deactivate the business transaction detection rules that created the upstream transactions, or
- Create a [service endpoint](#) for the entry point.

Otherwise, you can continue to track the performance of the masked entry point as a segment of the business transaction it currently belongs to.

URI Based Entry Points

For almost every web-based framework or platform, there is a URI based business transaction entry point for user requests. AppDynamics App Agents automatically discover the following URI-based entry points:

- Java Agent: Servlet entry points
- .NET Agent: ASP.NET entry points
- Node.js Agent: Node.js web entry points
- Python Agent: Python web entry points

The Web server Agent can detect Web request entry points, but automatic discovery is turned off by default so an agent on a downstream node can name the transaction.

URI based entry points all have similar configuration options for [Automatic Transaction Discovery](#) and [Custom Match](#) rules.

For additional functionality that applies to servlets, see [Servlet Entry Points](#).

Default Naming

By default, when an app agent detects a URI request, it names the business transactions using the first two segments of the URI. For example, consider the following URI for a checkout operation in an online store: `http://acmeonline.com/store/checkout`.

The agent names the business transaction `"/store/checkout"` and assigns all requests that match that URI to the `"store/checkout"` business transaction.

If the first two segments of the URI do not contain enough information to effectively identify the business transaction in your environment, you can edit the [automatic discovery rule](#) to name the transaction based upon the URI and its context. Alternatively, you can create a [custom match rule](#) to specify a name.

 For ASP.NET Core on the full framework, the default naming convention uses the Controller, action, and area. See [Name MVC Transactions by Area, Controller, and Action](#) for more information and configuration options.

Customize Automatic Naming Rules

When you edit or create a new Default Automatic Discovery Rule for URI based entry points, you can adjust naming to:

- Use the full URI to name transactions.
- Use part of the URI to dynamically name transactions.

Expand the **Configure Naming** option on the **Rule Configuration** tab to display the configuration options.

When you configure the rule to **Use the full URI**, the agent creates a business transaction name for the full request URI. There are no dynamic naming options. For example, for the URI `http://acmeonline.com/store/coats/men`, the agent names the transaction `"/store/coats/men"`.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- ✓ **Use the full URI** works well for Grails servlet transactions because the default naming scheme often doesn't differentiate between multiple transactions.

When you use parts of the URI to name transactions, you have several options to configure transaction naming:

- [Use a Part of the URI](#)
- [Use Headers, Cookies, and Other Parts of HTTP Requests](#)
- [Use a Custom Expression](#)

Use a Part of the URI

AppDynamics offers the following options to automatically name URI based transactions based upon the URI:

- Use the first or last URI segments
- Use specific URI segments

For the following URL the first two segments of the URI don't provide a significant name for the business transaction:

`http://example.com/Web/Store/Checkout` yields a default transaction name of "Web/Store".

You can use one of the following options to identify more meaningful transaction names:

- Click **Use the first** or **Use the last n** segments to use two contiguous segments at the beginning or end of the URI, where **n** is the number of segments. For example, if identify the checkout transaction using the last two segments of the URI, the agent names the transaction `"/Store/Checkout"`.
- If you need more flexibility, such as using non-contiguous segments in the name, click **Name Transactions dynamically using part of the request**. Select **Use URI segments in Transaction names** option. To specify multiple segments, enter a comma-separated list of segment numbers.

For example, the following URL represents the checkout transaction requested by a customer with ID 1234: `http://example.com/Store/cust1234/Checkout`

The checkout transaction is the same regardless of the customer, so it makes sense to name the transaction based upon the

first and third segments of the URI. AppDynamics names the transaction: "StoreCheckout".

▼ Configure Naming

What part of the URI should be used in the Transaction Name?

Use the full URI

Use a part of the URI (for example, if you have dynamic URIs)

ⓘ

Name Transactions dynamically using part of the request

Use in Transaction names

Segment Numbers

Enter a comma separated list of segment numbers (e.g. 1, 3, 4)

Use Headers, Cookies, and Other Parts of HTTP Requests

When you use the **Name Transactions dynamically using part of the request** option, you can choose to identify your URI based transactions using particular parts of the HTTP request. Note that not all agents offer all the naming options below.

i Carefully consider your naming configuration choices. If you use a value such as the request originating address and you have many clients accessing your application, you may see the all other traffic business transaction.

- To use HTTP parameter values in transaction names, select **Use a parameter value in Transaction names** and enter the **Parameter Name**.

For example, consider the following URL: `http://example.com/Store/Inventory?category=electronics`

What part of the URI should be used in the Transaction Name?

Use the full URI

Use a part of the URI (for example, if you have dynamic URIs)

Use the first segments of the URL ?

Name Transactions dynamically using part of the request

Use in Transaction names

Parameter Name

AppDynamics names the transaction to include the category parameter value "/Store/Inventory.electronics".

- To use a header value in transaction names, select **Use header value in Transaction names** and enter a **Header Name**. For example, consider a site that uses the custom header "Version", AppDynamics names transactions with the header value "/Store/Inventory.v2.5".
- To use a cookie value in transaction names, select **Use a cookie value in Transaction names** and enter the **Cookie Name**. For example, a website tracks a user's loyalty status in a cookie. Set the Cookie Name to "loyalty". AppDynamics names transactions for the loyalty cookie value "/Store/Inventory.Status=Gold"
- To Use a session attribute value in transaction names, Click **Use a session attribute in Transaction names** and enter the **Session Attribute Key**. For example, a website stores a customer's region in the session property. Set the Session Attribute name to "region". AppDynamics names transactions for the region session attribute value "/Store/Inventory.NorthAmerica".
- To use the request method in Transaction names, click **Use the request method (GET/POST/PUT) in Transaction names**. For example AppDynamics names the transaction "/Store/Inventory.GET".
- To use the request host in Transaction names, click **Use the request host in Transaction names**. For example AppDynamics includes the request host id in the transaction name "/Store/Inventory.192.0.2.0".
- To use the request originating address in Transaction names, click **Use the request originating address in Transaction names**. AppDynamics names transactions for the IP address of the request client "/Store/Inventory.192.0.2.10".

Use a Custom Expression

You can use a custom expression on the URI to name:

- Java servlet transactions
- .NET ASP.NET transactions

Select **Name Transactions dynamically using part of the request** and choose **Use a custom expression in Transaction names**. Enter your custom expression getter chain as follows:

For Java, you can use getter chains to access values from the `HttpServletRequest` object. For example, suppose you want to use a combination of the authenticated user and the value of an

`HttpServletRequest` :

```

    ${getParameter(myParam)}-${getUserPrincipal().getName()}
    
```

The equivalent code expression would evaluate to:

```
request.getParameter("myParam")+"-"+request.getUserPrincipal()
```

You can create a custom expression on the `HttpServletRequest` to identify all Servlet based requests (modify global discovery at the transaction naming level) or for a specific set of requests (custom rule).

A custom expression for a servlet transaction can have a combination of any of the following getter methods on request attributes:

Getters on Request Attributes	Transaction Identification
<code>getAuthType()</code>	Use this option to monitor secure (or insecure) communications.
<code>getContextPath()</code>	Identify the user requests based on the portion of the URI.
<code>getHeader()</code>	Identify the requests based on request headers.
<code>getMethod()</code>	Identify user requests invoked by a particular method.
<code>getPathInfo()</code>	Identify user requests based on the extra path information associated with the URL (sent by the client when the request was made).
<code>getQueryString()</code>	Identify the requests based on the query string contained in the request URL after the path.
<code>getRemoteUser()</code>	Identify the user requests based on the login of the user making this request.
<code>getRequestedSessionId()</code>	Identify user requests based on the session id specified by the client.
<code>getUserPrincipal()</code>	Identify user requests based on the current authenticated user.

For .NET, you can use [getter chains](#) to access properties and methods for the `HttpRequest` object for ASP.NET or `Microsoft.AspNetCore.Http.Internal.DefaultHttpRequest` for ASP.NET Core on the full framework.

- Enclose getter chains inside braces: `${ }`. The custom expression may contain multiple getter chains.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- Use [getter chain](#) syntax.
- Use any [HttpRequest](#) request attributes or methods.

For example, consider the URL `http://mystore.example.com/Store/Inventory-Furniture`. The following custom expression uses two getter chains to access properties of the `HttpRequest` object:

```
${Url.ToString().Split(Char[]/-).[2]}-${UserAgent}
```

- The first getter chain fetches the URL, splits it on the dash character ("-"), and uses the second string in the array.
- The second getter chain fetches the `HttpRequest.UserAgent` property.
- The literal dash character "-" separates the two getter chains.

The result is the following business transaction name:

Furniture-Mozilla/5.0 (Windows NT 6.3; Trident/7.0; rv:11.0) like Gecko

Message Queue Entry Points

Most frequently an instrumented application calls to a message queue as a [remote service](#) or backend. However, in cases when an application uses asynchronous message listeners or message-driven beans as the primary trigger for business processing on an originating tier, AppDynamics can intercept the message listener invocations and track them as business transactions.

AppDynamics discovers the following types of business transaction entry points:

- Java JMS entry points.
- .NET Message Queue entry points

Message queue entry points all have similar naming configuration options for [Automatic Transaction Discovery](#) and [Custom Match Rules](#).

Default Naming

By default, the AppDynamics auto-detection naming scheme identifies all message queue transactions using the destination name. Otherwise, if the destination name is not available, AppDynamics uses the listener class name.

Custom Match Rule Options

When you create a JMS or Message Queue custom match rule, the agent names matching transactions for the custom match rule name. See [Custom Match Rules](#).

You have the option to specify the following match criteria as a combination of the following entry point properties:

- The **Message Destination** as **Queue**, **Topic** or **Unknown**.
- **Message Property**. You can match against a property's existence or against a property's value.
- **Message Content**.

Business Transaction Discovery Sessions

Business Transaction Discovery Sessions provide interactive tools to help you create the optimal set of transaction detection rules and discover crucial business transactions.

During a discovery session, you can preview the effects of all the transaction detection rules on a node. This way you can create rules that capture the precise business transactions that impact your business and avoid rules that generate too many transactions.

Within the context of the discovery session, you can:

- Edit Java Agent transaction detection rules and Preview Business Transactions. (Java only)
- Identify entry points from Uninstrumented Code.
- Browse Classes/Methods to identify entry points.

During the business transaction discovery session, you can test out various transaction detection rule configurations without impacting your production environment.

Any business transactions discovered within the context of the discovery session, called transient transactions, do not persist after the session ends. When you end the session you have the opportunity to discard the rule changes or to apply them to your production configuration.

Permissions

You need the following permissions to launch a Business Transaction Discovery Session:

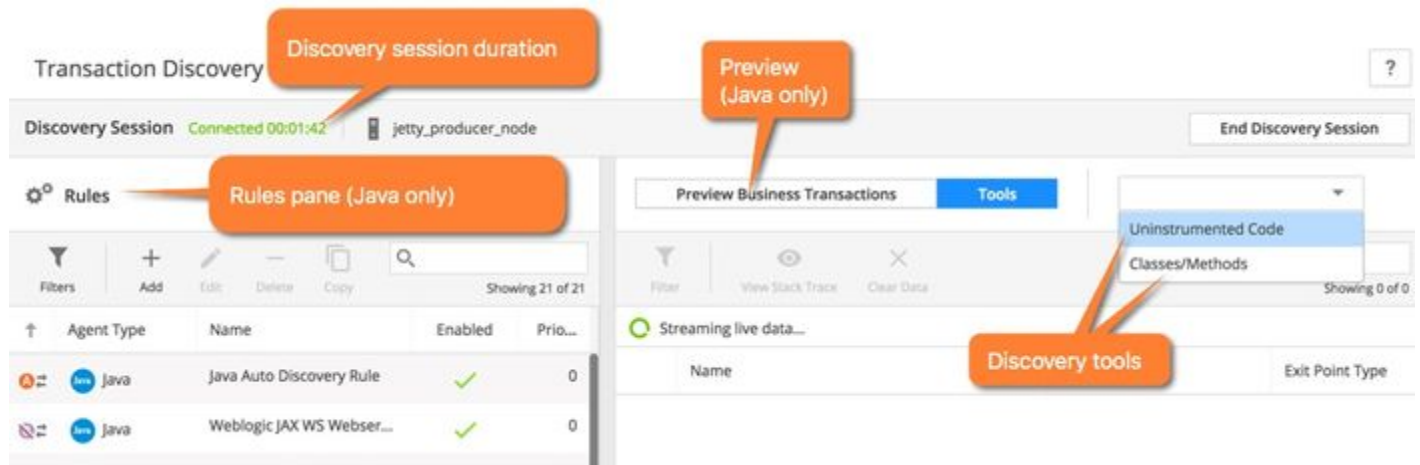

- Configure Transaction Detection
- View Sensitive Data

For information on AppDynamics Role Based Access Control, see [Manage Custom Roles](#).

Launch a Business Transaction Discovery Session

1. Navigate to **Configuration > Instrumentation** and click the Transaction Detection tab.
2. Click **Live Preview**.
3. Click **Start Discovery Session** to start a Business Transaction Discovery session.
4. Select the node to act as the source of the live data stream.
Nodes are organized by tier. You can see which nodes have active agents and if there is a discovery session already running on a node.

The Transaction Discovery page displays information about the discovery session lets you navigate among the available interactive transaction discovery tools:

i The transaction discovery tool works as it did in previous versions for upgraded business applications. See [Business Transaction Discovery Sessions](#).

When you initiate a transaction discovery session on a Java node, the Rules pane displays the active transaction discovery rules that apply to the node. The right-hand pane lets you **Preview Business Transactions** or use the available interactive **Tools**: Uninstrumented Code detection and the Classes/Methods Browser.

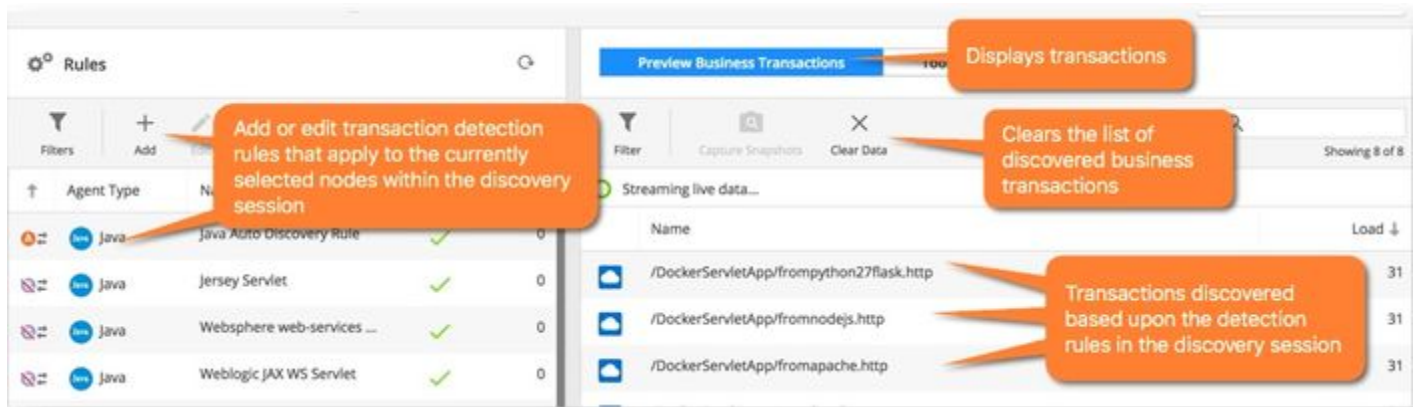

When you launch a discovery session on a .NET node, you see the available tools: Uninstrumented Code detection and the Classes/Methods Browser.

During a discovery session, you can use other features of AppDynamics while the discovery process continues in the background. This is useful for busy environments with many active transactions. You can give AppDynamics a few minutes to complete the discovery. When you are ready to return to the Transaction Discovery page click **Configuration > Instrumentation** and click the **Live Preview** button to resume your discovery session.

Edit and Preview Transaction Discovery Rules

You can add, edit, or delete any type of [transaction detection rule](#) for the Java Agent in the Rules pane. Click **Apply** to update the rule within the context of the discovery session.

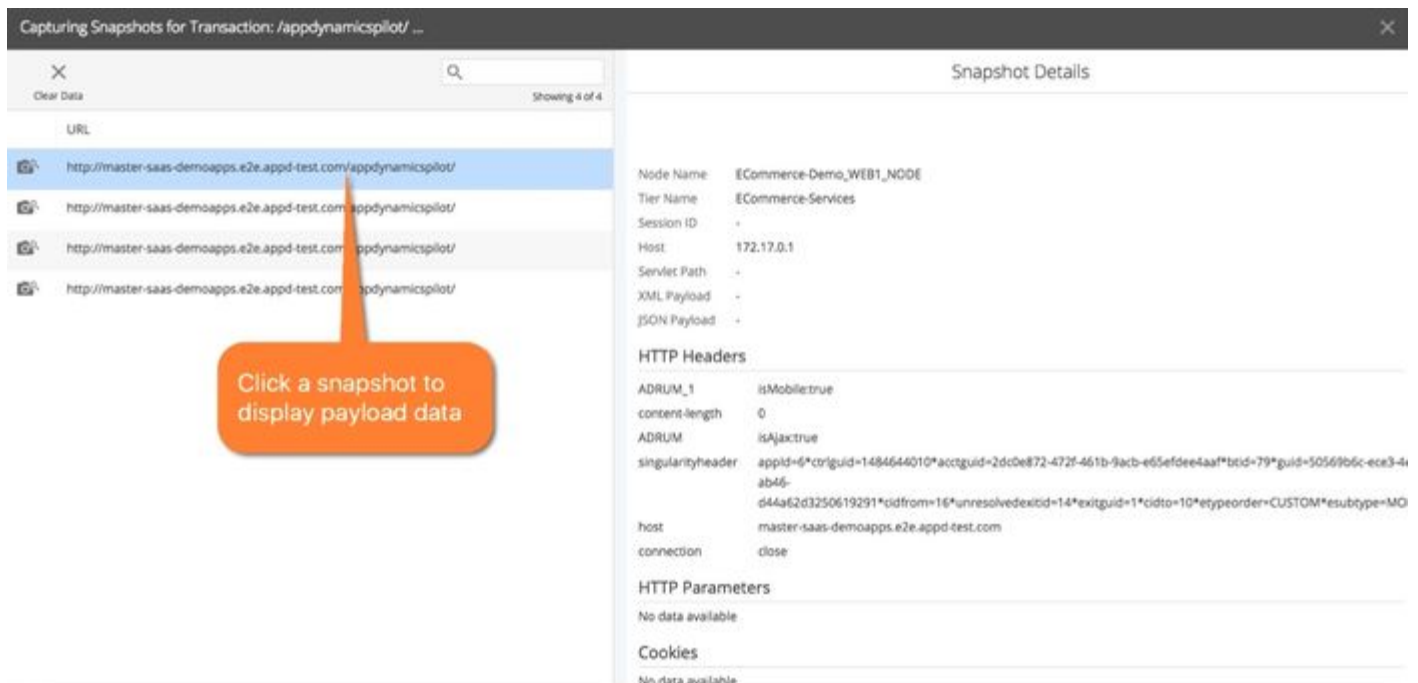

To see the effects of your changes, click **Preview Business Transactions**. As the app agent discovers business transactions based on the rule configuration, the transactions show up in a list in the right-hand pane:

You can select a transaction and click **Capture Snapshots** to collect transaction snapshots.

⚠ The Capture Snapshots feature is only available for Servlets.

Click a specific snapshot to display the payload data for the business transaction in the Snapshot Details:

When you create [custom match rules](#) for servlets or for [POJOs](#) you can start a [Live Preview](#) session limited to the specific rule.

Inspect Uninstrumented Code to Discover Entry Points

When the app agent doesn't automatically discover an entry point for a framework in your application, you can use Uninstrumented Code detection to find entry points for the framework. After you identify an entry point you want to track as a business transaction, you can create a [custom match rule](#).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Uninstrumented Code detection identifies the support exit calls for an app agent on the node when the entry point is undetected. In the following example the Java Agent discovers some uninstrumented JDBC exit points:

	Load	Timestamp	Exit Point Type
org.apache.tomcat.dbcp.dbcp2.PoolingDataSource:...	2	12/09/16 2:15:28 PM	JDBC
org.apache.tomcat.dbcp.dbcp2.PoolingDataSource:...	2	12/09/16 2:15:28 PM	JDBC
org.apache.tomcat.dbcp.dbcp2.BasicDataSource:ge...	2	12/09/16 2:15:28 PM	JDBC
org.apache.tomcat.dbcp.dbcp2.PoolingDataSource:...	2	12/09/16 2:15:28 PM	JDBC
com.mysql.jdbc.PreparedStatement:executeQuery	2	12/09/16 2:15:28 PM	JDBC

You can select an exit point and click **View Stack Trace** to display the call stack for the exit point. Select any call in the stack trace and click **Monitor** to show interactive data for that specific call. When the agent returns the monitoring result, you can inspect the values for a specific method invocation including the **Invoked Object**, **Return Value**, **Parameters**, and more.

The example below shows the upstream stack trace for the `com.mysql.jdbc.PreparedStatement:executeQuery` JDBC exit call:

Uninstrumented Code Stack Trace

Monitor + Add POJO Rule

com.mysql.jdbc.PreparedStatement:executeQuery

Name

- org.apache.coyote ajp.AbstractAjpProcessor:process:873
- org.apache.catalina.connector.CoyoteAdapter:service:528

When you identify the method you want to instrument, you can click to add a POJO or POCO. The Controller UI automatically populates the Rule Configuration in the Add Rule editor with the class and method you want to instrument. Complete the custom match rule for the [POJO](#) or [POCO](#) as normal.

Search for Classes and Methods to Instrument

If you are familiar with your application code, you can use the Classes/Methods browser to search the running code for specific classes and methods to instrument. The example below illustrates how a search for `jetty.server` in a sample application returns both instrumented and uninstrumented classes and methods:

When you identify a method you want to instrument, right-click the method to open the Add Rule editor. AppDynamics automatically populates the class and method configuration based upon your search criteria from the Class/Method browser. You can right-click a class to instrument it, but you must add the method before you can save the POJO or POCO. Complete the custom match rule for the [POJO](#) or [POCO](#) as normal.

Backend Detection Rules

Related pages:

- [Java Backend Detection](#)
- [.NET Backend Detection](#)

In AppDynamics, databases and remote services (and in fact, any detected out of process components that are involved in Business Transaction processing) are collectively known as backends.

AppDynamics discovers backends from exit point instrumentation placed in the application code. An exit point is the precise location in the code where an outbound call is made from an instrumented node. AppDynamics automatically discovers a wide range of backends.

Default Automatic Backend Discovery

A discoverable backend is identified by its type and associated properties. The precise set of properties used to identify any given backend is dependent on its type. The type itself is defined in the built-in backend discovery rules for backend types supported out of the box. For exit calls to backends that are not instrumented with APM agents, AppDynamics uses the backend properties to identify and name the backend. Where a backend call is actually processed by a downstream tier also instrumented with AppDynamics, ensure that any given backend that is identified will always result in calls that will be processed by just one downstream tier.

This means, for example, that if tier A makes an HTTP call to an HTTP router on localhost:4040 which will forward the call to tier B or tier C depending on the URL, custom backend naming rules will be required to include enough segments of the request URL - as well as the host and port - such that requests destined for tier B will be associated with a backend with a different set of backend properties than those associated with tier C.

The **Automatic Backend Discovery** list in the **Configuration > Instrumentation > Backend Detection** tab shows the configurable backend discovery rules.

The automatic discovery rules vary according to the type of backend being identified, but generally include settings for enabling automatic discovery of the backend type, enabling correlation, and properties used to identify and name the backend. AppDynamics uses transaction correlation to track request processing across distributed tiers. Certain types of backends are automatically discovered as *high volume* exit points (sometimes called turbo exit points). These backend types include cache servers, EhCache, Danga Memcache, Memcached, and Oracle Coherence. For more about high volume exit points, see [Exit Point Detection Rules](#).

When an exit point is identified for the first time, the exit call results in a backend discovery event.

Service Proxy

Sometimes an inaccurate identification of the backend destination causes each call that is sent (based on configuration) to a single backend, to arrive at one of several different downstream tiers.

For example, this situation may occur if the naming of the backend is based on the backend host and port where a particular backend's host:port combination actually identifies an Apache server. The Apache server then forwards requests to different downstream tiers based on the URL acting as a service proxy. When the

AppDynamics Controller detects this situation, it will automatically instruct the upstream agent to identify the backend as a service proxy. Once that occurs, a service proxy icon will display on the flow map between the upstream tier and all of the possible target tiers shown downstream. See [Service Proxy](#).

Permissions

To modify backend detection, you need the **Configure Backend Detection** permission.

Modify Automatic Discovery

If you know that the application flow map should be showing a specific backend and you are not seeing it, you can modify the configuration to detect backends. You can:

- Edit the default backend discovery rules.
- Create new custom backend discovery rules.
- Create new custom exit points to provide visibility for backend types that are not automatically discovered.
- Disable automatic discovery of backends that are not of interest.
- Disable correlation for the backend.

In many cases, you can achieve the level of customization that you need by editing the default rules rather than creating new rules.

To edit a rule, in the Backend Detection tab, select the application and click **Edit Automatic Discovery**.

Edit Backend Discovery Rule ✕

Summary
Rule Configuration

▼ **Backend Naming Configurations**

Configure how Backends will be named, what properties to use in the name, and how to use those properties. All of the properties used will be concatenated together in the Backend name.

Server Pool

Use it as is ▼

Vendor

Use it as is ▼

Cancel
Save

For certain backend types—particularly those named by URL—the name of the discovered backend instances include a port number. If the app agent is unable to discover the port number for some reason, the port number is displayed in the UI as "-1". This can happen, for example, when a port is not a public port

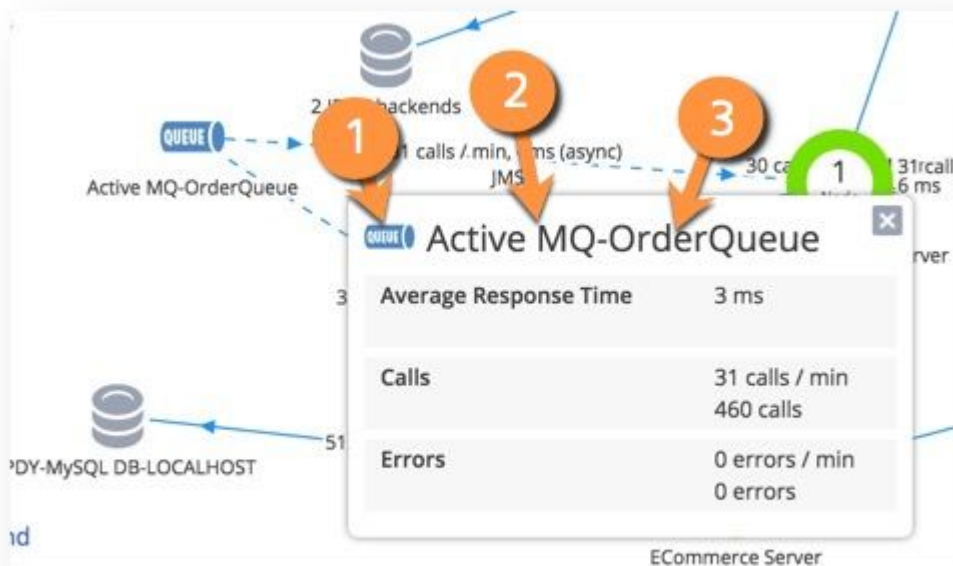

or the API for discovering the port is not available on the application environment (often the case for an RMI backend type). Despite having an unknown port number, the backends are nonetheless uniquely identified.

Configurable Properties and Naming

For many of the automatically discovered backend types, AppDynamics uses a set of configurable properties to identify and name the backend. For example, the properties for a JMS messaging queue are something like this:

- DestinationType (for example, QUEUE)
- Destination (for example, OrderQueue)
- Vendor (for example, Active MQ)

The following informational popup shows how the values are used to identify a discovered backend. In the following example, callout 1 shows the value that corresponds to the destination type, callout 2 to the vendor name, and callout 3 to the destination queue name:

Aggregate or Split Backends

You can change the default configuration for the backend types shown in the UI to aggregate or split the backends. For example, you could disable the Vendor property for JMS backend detection to aggregate (join) all JMS backends with the same destination and destination type. The metrics for all JMS backends with the same destination and destination type would be aggregated as one backend.

For properties that you want to use, you can also configure how AppDynamics uses the property. For example, if the URL property is used to identify a backend and your URLs include a file name, the default configuration results in a separate backend for every file.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

To reduce the number of backends identified using the URL property, configure which parts of the URL to use. For example, run a regular expression on the URL to discard the file name or any other parts of the URL that you do not want used for identification.

Add Custom Backend Discovery Rules

AppDynamics provides the additional flexibility to create new custom discovery rules for the automatically discovered backend types.

To create a custom discovery rule for an automatically discovered backend type, select the backend type in the **Automatic Backend Discovery** list. Click **Add** (the + icon) to create a new rule. Specify the following:

- **Name** for the custom rule.
- **Enabled** to enable or disable the rule.
- **Correlation Enabled** to specify whether or not to send business transaction correlation data to the backend.
- **Priority** for this custom rule compared to other custom rules for this backend type. The higher the number, the higher the priority. A value of 0 (zero) indicates that the default rule should be used.
- **Match Conditions** used to identify which backends are subject to the custom naming rules. AppDynamics applies the default rules to backends that do not meet all the defined match conditions.
- **Backend Naming Configuration** used to name the backends matching the match conditions. The naming configuration must include the property used by the match condition.

See specific exit points for examples.

All Other Traffic Backends

AppDynamics limits the number of backend systems that can be registered and tracked. Once the limit is reached (databases and remote services combined), additional backend are put in the "All other traffic for <type>" category.

The "type" is the backend type such as HTTP or Web Service. HTTP calls and JMS queues are the most common types that may reach the limit with the default configuration rules.

On a flow map, the category appears as follows:

Metrics for the backend calls grouped in the "All other traffic" category are aggregated. If the group includes backend instances that you want to be individually tracked, you can manage backend detection, as described in [Manage Backend Discovery](#).

Backend Registration Limits

The limits on the number of backends that can be registered:

- The Controller enforces a limit of 1000 backend registrations in the business application for each type of backend (that is, 1000 HTTP backends, 1000 JMS backends, and so on). This setting is controlled by the `backend.registration.limit` Controller Setting. This limit applies whether the backends are resolved to a tier or unresolved.

- Agents apply a limit of 300 unresolved backends per application.

When the backend count exceeds the limit, the "All Other Traffic" category is automatically created. The logs indicate that a limit has been reached by a log entry such as the following:

```
[pool-1-thread-2] 21 Mar 2013 11:28:01,702 DEBUG AFastBackendResolver - Not discovering backend call [Exit Point Type [WEB_SERVICE] Properties [{SERVICE_NAME=ZipCodeService002.wsdl}] Display Name [ZipCodeService002.wsdl]] because maximum limit of discovered backends [300] reached.
```

Manage Backend Discovery

After reaching the backend registration limit, you should make sure that the systems being tracked as first-class registered backends are the ones that are important to you relative to those in the "All Other Traffic" category.

Also make sure that application environmental conditions are not causing an excess number of backends to be registered. These conditions may include:

- JMS queues that use the session ID in the destination. This causes each session to be identified as a separate backend.
- Calls to message queues hosted on the same server. In this case, you might not be interested in seeing each queue separately, and instead, want to aggregate everything for the same host and port to the same backend.
- Dynamic generation of IP addresses, such as when you host a service on Amazon Elastic Compute Cloud (Amazon EC2).
- Different JDBC drivers connecting to the same database may cause many backends. This can happen when there are slight variations in the driver metadata that AppDynamics uses to identify the database. For example, if two different JDBC drivers are used to access the same database, something as simple as a different spelling or format of the database name (ORACLE, oracle, or ORACL) can generate multiple database names when they are the actually the same physical database.

To manage backend registrations, you can change the configuration of the backend detection rules. For example, if a property causes excessive unique identification, consider removing the property or modifying its use in the detection and naming rule. If you created custom exit points, consider refining or removing them.

Delete Unnecessary Backends

Some backends may no longer have traffic. You can delete unused backends from the Remote Services List, any Remote Service dashboard, the Databases List, and any Database dashboard. If the backend has new traffic in the future, the app agent rediscovers it and reregisters it with the Controller.

You can also configure the Controller to automatically remove stale backends. See [Stale Remote Service Removal](#).

Organize Backends in Flow Maps

Once you have configured detection for all the backends you require, you may need to organize the way they appear in the UI. See [Group Remote Services on Flow Maps](#).

Exit Point Detection Rules

Custom exit points enable you to identify backend types that are not automatically detected. For example, you can define a custom exit point to monitor code calls to a file system read method.

After you have defined a custom exit point, the backend appears on the flow map with the type-associated icon you selected when you configured the custom exit point. See [Custom Exit Points for Java](#).

Configuration Notes

You configure exit point detection in the **Configuration > Instrumentation** page. Select the Backend Detection tab and choose the application or tier on which to configure an exit point and the application type of the exit point, Java, .NET, and so on. From there you can add new exit points or modify existing ones.

The specific configuration options available differ based on the application type, but in general, you identify the exit point and specify the mechanism for it to be detected, such as a class and method name. These additional notes apply to exit point configuration:

- If the method you are using to identify the exit point is overloaded, you need to add the parameters that identify the signature for this form of the method.
- Match conditions let you restrict the method invocations for which you want AppDynamics to collect metrics based on runtime values tested by the condition. Match conditions can test parameter values or any value accessible by getter chain from the invoked object.
- Optionally, you can split an exit point based on a method parameter, the return value, or the invoked object.
- You can configure custom metrics and transaction snapshot data to collect for the backend.
- If you configure a custom backend for a method that encapsulates an automatically detected backend, such as an HTTP client call, you may lose correlation from the automatically detected exit call.
- Splitting a backend on return value may break correlation.

You are limited to 50 characters for the exit point value when adding a custom exit point or splitting/grouping exit points.

Adding a Custom Exit Point

When adding a custom exit point, you specify the class and method that identify an external call to the exit point. You can refine the call by specifying a return value, parameter, or getter chain match value.

The type you choose determines the icon that appears in the flow map for the custom exit point. If the type is not listed, select **Use Custom** and enter a string in the **Type** field to identify the exit point calls in the UI.

Note that you can also split the exit point based on these values. If you add a split condition for an exit point, it means that any exit point that matches the overall match condition for the custom exit point is further evaluated against the split condition. If its call matches the split condition, it is given the more specific name you configure in the split exit point configuration.

High Volume Exit Points

The **Is High Volume** option for custom exit points lets you create an optimized exit point configuration for backend systems with high-performance requirements, such as caching servers or in-memory databases.

A "high volume" exit point keeps the overhead associated with the exit point to a negligible amount by bypassing certain processing operations on calls to this exit point. As a result, transaction correlation and error detail reporting are not available for the exit point, nor are match conditions in the exit point configuration.

With a high volume exit point, you do get the number of calls, number of errors, and average response time for calls.

Split and Group Exit Points

By splitting an exit point, you can use dynamic application values to identify an exit point. Specifically, you can use the value of either a method parameter, the method return value, or a value returned by a specified getter chain on the invoked object of the identified method. The configuration settings you use to configure exit point splitting are the same as used for Data Collectors. See [Data Collectors](#) for information on how to use the configuration UI.

A simple example of how you would use exit point splitting is for a cache exit point. In this example, say you configure splitting for an exit point that identifies a method for writing to the cache. The object on which the method for writing to the cache offers a method to get the current cache name, the `getCacheName()` method. By configuring a split on this method (as a getter chain on the invoked object), you can have the exit point named with the name of the cache node, as dynamically determined:

Splitting also lets you group exit points. Given an exit point for `NamedCache.entrySet()`, as shown in the example above, suppose we created another exit point. This one uses the `getAll()` method on the same

class, `NamedCache` . It also has a split configuration that uses the `getCacheName()` method of the invoked object.

If the `getCacheName()` getter chain points to the same cache name when the `getAll()` and the `entrySet()` methods are invoked, they will be shown as calls to the same backend.

Java Backend Detection

Related pages:

- [Exit Point Detection Rules](#)
- [Monitor Databases](#)
- [Remote Services](#)

The AppDynamics Java Agent automatically discovers common types of remote services as backend systems based on the exit point associated with the backend. If AppDynamics does not automatically discover a backend system used in your environment, check whether it's an automatically discovered type (based on the list below) and compare the default exit points for the type to that used in your application environment.

Each automatically discovered backend type has a default discovery rule. Many backend types have a set of backend naming properties. Where individual properties are configurable, you can configure the property as follows:

- Use the property as is.
- Use segments of the property.
- Run a regular expression on the property. See [Using Regular Expressions](#).
- Execute methods on the property. See [Using Getter Chains](#).

For instructions to revise backend discovery rules, see [Backend Detection Rules](#).

Amazon Simple Notification Service Backends

AppDynamics detects exit calls to the Amazon SNS messaging service using the Amazon SNS Client:

```
AmazonSNSClient.publish .
```

Amazon SNS Naming Properties

You can enable or disable the use of the following properties for Amazon S3 backend identification:

Configurable Properties	Default Automatic Amazon SNS Backend Discovery/Naming
Vendor	Yes
Topic ARN	Yes

Amazon Simple Queue Service Backends

AppDynamics can detect the following types of Amazon Web Services SQS message queue actions:

- Basic send/receive
- Batched send/receive
- Asynchronous send/receive

Correlating SQS traffic requires you to configure the continuation entry point for the SQS message.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Amazon Simple Storage Service Backends

AppDynamics automatically detects the following exit points for Amazon Web Services S3 backends:

- `AmazonS3Client.deleteObject`
- `AmazonS3Client.getObject`
- `AmazonS3Client.getObjectMetadata`
- `AmazonS3Client.listObjects`
- `AmazonS3Client.putObject`

Amazon S3 Naming Properties

You can enable or disable the use of the following properties for Amazon S3 backend identification:

Configurable Properties	Default Automatic Amazon S3 Discovery/ Naming
Bucket Name	Yes
Vendor	Yes
Object Key	No

Amazon Web Services Backends

AppDynamics detects the following exit calls to the following Amazon Web Services:

- DynamoDB requests using the `AmazonDynamoDBClient` create, read, update, and delete (CRUD) methods using the Amazon low-level DynamoDB API. The agent discovers the Document API calls as the underlying low-level API call.

Amazon Web Service Naming Properties

For Amazon Web Services, you can enable or disable the use of the following naming properties for backend identification:

Configurable Properties	Default Automatic Amazon Web Service Backend Discovery/Naming
Vendor	Yes
Service	Yes
Endpoint	Yes

Apache Cassandra CQL Backends

By default, AppDynamics automatically detects and identifies exit calls to Apache Cassandra using Thrift and DataStax drivers.

i Exceptions returned from Cassandra backends show up as separate exit calls. For the DataStax 1.0 driver, the Java Agent detects an "unknown" Cassandra backend in order to capture the error details.

Cassandra Backend Naming Properties

You can enable or disable the use of the properties below for Cassandra backend identification:

i When you configure Cassandra backend naming, consider the following:

- For DataStax clients, AppDynamics does not recommend using the keyspace property. Due to driver limitations, the keyspace property is only available when `Statement.setKeyspace` is called explicitly in Cassandra. This can lead to the discovery of multiple backends.
- Thrift clients don't support Cluster Name, Rack or Data Center properties, so those properties return null for Thrift.

Configurable Properties	Default Automatic Cassandra CQL Backend Discovery/Naming
Cluster Name	Yes
Keyspace	No
Host	Yes
Port	Yes
Data Center	No
Rack	No

Apache Kafka Backends

By default, the Java Agent detects publish activity to Apache Kafka as an exit point from a Java node. You can configure the Java Agent to detect Kafka consumer activity as an entry point, see [Apache Kafka Consumer Backends](#).

Kafka Backend Naming Properties

You can enable or disable the use of the following properties for Kafka backend identification:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Configurable Properties	Default Automatic IBM MQ Backend Discovery/ Naming
Vendor	Yes
Topic Name	Yes
Broker URL	No

Default Kafka JMX Metrics

There are lots of JMX metrics that are exposed by Kafka Producer and Consumer. We have selected a few of the metrics that we think could be useful for customers and created OOTB rules for them. PFB the list of metrics supported by Producer and Consumer respectively. In case you are interested in any of the other metric for which OOTB rule is not available you can go to MBean browser, select the metric and create a rule out of it.

Couchbase Backends

By default, AppDynamics automatically detects and identifies exit calls made to the Couchbase cluster node.

Couchbase Backend Naming Properties

You can enable or disable the use of the following properties for Couchbase exit backend identification:

Configurable Properties	Default Automatic Couchbase Backend Discovery/Naming
Server Pool	Yes
Vendor	Yes
Bucket Name	Yes

HTTP Backends

HTTP exit point activity includes all HTTP calls done outside of a web service call. Web service calls are not considered an HTTP exit point. By default, the Java Agent names the HTTP backend for the Host and Port properties. For instance, "myHTTPHost:5000".

HTTP Backend Naming Properties

You can enable or disable the use of the following properties for HTTP backend identification:

Configurable Properties	Default Automatic HTTP Backend Discovery/ Naming
Host	Yes
Port	Yes
URL	No
Query String	No

For examples of common HTTP backend configurations, see [HTTP Backend Detection](#).

For sample JDBC backend configurations, see [Example JDBC Backend Configuration](#).

IBM Websphere Message Queue Backends

IBM MQ, also known as IBM WebSphere MQ and IBM MQSeries, is IBM's message-oriented middleware similar to JMS. Several additional properties are configurable, such as host and port. This is useful where you have lots of queues and you want to monitor them based on a subset of the properties.

IBM MQ Backend Naming Properties

You can enable or disable the use of the following properties for IBM MQ backend identification:

Configurable Properties	Default Automatic IBM MQ Backend Discovery/ Naming
Destination	Yes
Destination Type	Yes
Host	Yes
Port	Yes
Major Version	Yes
Vendor	Yes

For examples of common message queue configuration scenarios, see [Example Message Queue Backend Configuration](#).

Java Message Service Backends

JMS backend activity includes all JMS message send and publish activity. By default, AppDynamics identifies JMS back ends using the properties of the JMS server such as: vendor, destination name, and destination type. The default configuration uses all three properties of the JMS queue.

JMS Backend Naming Properties

You can enable or disable the use of the following properties for JMS backend identification:

Configurable Properties	Default Automatic JMS Backend Discovery/ Naming
Destination	Yes
Destination Type	Yes
Vendor	Yes

Transaction names are derived from the enabled properties, for example, "ActiveMQ-OrderQueue".

For examples of common message queue configuration scenarios, see [Example Message Queue Backend Configuration](#).

JDBC Backends

JDBC backend activity consists of all JDBC calls including inserts, queries, updates, getting connections from connection pools, and so on.

Expand to show exit calls the agent captures for the Oracle JDBC driver as an example...

Class	Method
<code>oracle.jdbc.driver.PhysicalConnection</code>	<ul style="list-style-type: none"> <code>prepareStatement</code> <code>prepareCall</code> <code>commit</code> <code>rollback</code>
<code>oracle.jdbc.driver.OracleStatement</code>	<ul style="list-style-type: none"> <code>executeQuery</code> <code>executeUpdate</code> <code>execute</code>
<code>oracle.jdbc.driver.OracleDataSource</code>	<ul style="list-style-type: none"> <code>getConnection</code>

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Class	Method
<code>oracle.jdbc.driver.OraclePreparedStatement</code>	<ul style="list-style-type: none"> <code>executeQuery</code> <code>addBatch</code> <code>execute</code> <code>executeUpdate</code>
<code>oracle.jdbc.driver.OraclePreparedStatementWrapper</code>	<ul style="list-style-type: none"> <code>execute</code> <code>executeQuery</code> <code>executeUpdate</code>

The Java Agent measures the response time for a database call as the round trip time it takes for a JDBC call to return. The response time for a database call includes network round trip time + database connection time + SQL query time or any other time spent in the database.

By default, the agent identifies JDBC backends using the following logical properties of the database:

- URL
- Host name
- Port number
- Database schema
- Version
- Vendor

If a database backend has the same hostname, port number, and database type as a database server already configured in a database Collector, the database backend is automatically matched with the Collector, and drill-downs from the Application Flow Map, Tier Flow Map or Node Flow Map to Database Monitoring are enabled.

JDBC Backend Naming Properties

You can enable or disable the use of the following properties for JDBC backend identification:

Configurable Properties	Default Automatic JDBC Backend Discovery/Naming	Description
URL	Yes	JDBC URL provided to the driver
Host	Yes	Database host
Port	Yes	Database port
Database	Yes	Database schema

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Configurable Properties	Default Automatic JDBC Backend Discovery/Naming	Description
Version	Yes	Database version as reported by JDBC driver
Vendor	Yes	Database vendor as reported by JDBC driver

Jolt Backends

AppDynamics detects exit calls to Tuxedo services from the JoltRemoteService class in the Jolt Class Library.

Jolt Naming Properties

You can enable or disable the use of the following naming properties for Jolt backend identification.

Configurable Properties	Default Automatic Jolt Backend Discovery/Naming
Host	Yes
Port	Yes
Service	Yes

MongoDB Backends

By default, the Java Agent detects exit calls to MongoDB using the Mongo Java Driver over the MongoDB Wire Protocol. The agent detects the exit point on the Wire Protocol methods and excludes the methods between the external API and the Wire Protocol.

MongoDB Backend Naming Properties

Configurable Properties	Default Automatic MongoDB Backend Discovery/Naming
Host	Yes
Port	Yes
Database	Yes

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

RabbitMQ Backends

RabbitMQ is open source, commercially supported, messaging middleware that runs on many different operating systems. The Java Agent discovers exit points using the RabbitMQ Java API, amqp-client.jar in most distributions. By default, RabbitMQ backends are identified by Host, Port, Routing Key, and Exchange. For instance: "amqp://guest@127.0.0.1:5672/exchange/task_queue".

RabbitMQ Backend Naming Properties

You can enable or disable the use of the following properties for RabbitMQ backend identification:

Configurable Properties	Default Automatic RabbitMQ Backend Discovery/Naming
Host	Yes
Port	Yes
Routing Key	Yes
Exchange	Yes

For examples of common message queue configuration scenarios, see [Example Message Queue Backend Configuration](#).

RMI Backends

The Java Agent automatically discovers backends called using the standard Java RMI API. For a list of supported RMI frameworks, see 'RPC/Web Services API/HTTP Client Support' on [Java Supported Environments](#).

RMI Backend Naming Property

The JAVA Agent names the RMI backend for the URL. You can configure how the agent uses the URL to name the RMI backend.

Thrift Backends

By default, AppDynamics automatically detects and identifies Apache Thrift exit points (backends). See [Apache Thrift](#) for details.

Thrift Backend Naming Properties

You can enable or disable the use of the following properties for Thrift exit backend identification:

Configurable Properties	Default Automatic Thrift Backend Discovery/ Naming
Host	Yes
Port	Yes
transport	Yes

Web Services Backends

Web service backend activity includes all web service invocations. Web service backends are identified using the web service name.

Web Services Backend Naming Properties

Configurable Properties	Default Automatic Web Service Backend Discovery/Naming
Service	Yes
URL	No
Operation	No
Soap Action	No
Vendor	No

i By default, the gRPC backend is identified as `ServiceName-gRPC`. This is also configurable under web services backend.

Custom Exit Points for Java

This page describes settings you can use to create custom exit point configurations for specific backends in Java environments.

In general, custom exit rules match calls to custom backends by class and method name. In some cases, you need to configure splitting as well. The following tables give you the class and method names to use for the various types.

Enter the configuration settings in the corresponding fields in the custom exit point UI. The following screenshot illustrates a sample configuration for an EhCache custom match rule:

For more about creating custom exit points, see [create a custom exit point](#).

i Oracle Coherence, EhCache, and Memcached backends are detected automatically as **high volume exit points**. You can create custom exit points for the backends as described here for particular backend splitting and naming results.

Coherence Exit Points

Name of the Exit Point	Type	Method Name	Class Match Criteria	Class/ Interface/ Superclass/ Annotation Name	Method Name	Splitting Configuration
Coherence.Put	Cache		that implements an interface which	com.tangosol.net.NamedCache	put	getCacheName()
Coherence.PutAll	Cache		that implements an interface which	com.tangosol.net.NamedCache	putAll	getCacheName()
Coherence.EntrySet	Cache		that implements an interface which	com.tangosol.net.NamedCache	entrySet	getCacheName()
Coherence.KeySet	Cache		that implements an interface which	com.tangosol.net.NamedCache	keySet	getCacheName()
Coherence.Get	Cache		that implements an interface which	com.tangosol.net.NamedCache	get	getCacheName()
Coherence.Remove	Cache		that implements an interface which	com.tangosol.net.NamedCache	remove	getCacheName()

EhCache Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/ Superclass/ Annotation Name	Method Name	Splitting Configuration
EhCache.Get	Cache	With a class name that	net.sf.ehcache.Cache	get	getName()
EhCache.Put	Cache	With a class name that	net.sf.ehcache.Cache	put	getName()
EhCache.PutIfAbsent	Cache	With a class name that	net.sf.ehcache.Cache	putIfAbsent	getName()
EhCache.PutQuiet	Cache	With a class name that	net.sf.ehcache.Cache	putQuiet	getName()
EhCache.Remove	Cache	With a class name that	net.sf.ehcache.Cache	remove	getName()
EhCache.RemoveAll	Cache	With a class name that	net.sf.ehcache.Cache	removeAll	getName()
EhCache.RemoveQuiet	Cache	With a class name that	net.sf.ehcache.Cache	removeQuiet	getName()
EhCache.Replace	Cache	With a class name that	net.sf.ehcache.Cache	replace	getName()

LDAP Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/ Superclass/ Annotation Name	Method Name
LDAPExitPoint.Bind	LDAP	With a class name that	javax.naming.directory.InitialDirContext	bind

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/ Superclass/ Annotation Name	Method Name
LDAPExitPoint.Rebind	LDAP	With a class name that	javax.naming.directory.InitialDirContext	rebind
LDAPExitPoint.Search	LDAP	With a class name that	javax.naming.directory.InitialDirContext	search
LDAPExitPoint.ModifyAttributes	LDAP	With a class name that	javax.naming.directory.InitialDirContext	modifyAttributes
LDAPExitPoint.GetNextBatch	LDAP	With a class name that	com.sun.jndi.ldap.LdapNamingEnumeration	getNextBatch
LDAPExitPoint.NextAux	LDAP	With a class name that	com.sun.jndi.ldap.LdapNamingEnumeration	nextAux
LDAPExitPoint.CreatePooledConnection	LDAP	With a class name that	com.sun.jndi.ldap.LdapClientFactory	createPooledConnection
LDAPExitPoint.Search	LDAP	With a class name that	com.sun.jndi.ldap.LdapClientFactory	search
LDAPExitPoint.Modify	LDAP	With a class name that	com.sun.jndi.ldap.LdapClientFactory	modify

Mail Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/ Superclass/ Annotation Name	Method Name
MailExitPoint.Send	Mail Server	With a class name that	javax.mail.Transport	send
MailExitPoint.SendMessage	Mail Server	With a class name that	javax.mail.Transport	sendMessage

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Memcached Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/ Superclass/ Annotation Name	Method Name
Memcached.Add	Cache	With a class name that	net.spy.memcached.MemcachedClient	add
Memcached.Set	Cache	With a class name that	net.spy.memcached.MemcachedClient	set
Memcached .Replace	Cache	With a class name that	net.spy.memcached.MemcachedClient	replace
Memcached .CompareAndSwap	Cache	With a class name that	net.spy.memcached.MemcachedClient	cas
Memcached.Get	Cache	With a class name that	net.spy.memcached.MemcachedClient	get
Memcached .Remove	Cache	With a class name that	net.spy.memcached.MemcachedClient	remove

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

MongoDB Exit Points

Name of Exit Point	Type	Class Match Criteria	Class/ Interface/ Superclass/ Annotation Name	Method Name	Splitting Config/ Custom Exit Point Identifier		Snapshot Data Operation on Invoked Object
					Collect Data From	Getter Chain Operation on Invoked Object	
MongoDB.Insert	JDBC	With a class name that	com.mongodb.DBCollection	insert	Invoked Object	getDB().getName()	Parameter_0.toString()
MongoDB.Find	JDBC	With a class name that	com.mongodb.DBCollection	find	Invoked Object	getDB().getName()	Parameter_0.toString()
MongoDB.Update	JDBC	With a class name that	com.mongodb.DBCollection	update	Invoked Object	getDB().getName()	Parameter_0.toString()
MongoDB.Remove	JDBC	With a class name that	com.mongodb.DBCollection	remove	Invoked Object	getDB().getName()	Parameter_0.toString()
MongoDB.Apply	JDBC	With a class name that	com.mongodb.DBCollection	apply	Invoked Object	getDB().getName()	Parameter_0.toString()

Avoiding high overhead

AppDynamics recommends that you avoid instrumenting highly-used methods, such as the find() method, because the activity around these methods can cause an undesired amount of overhead on the system.

Sample MongoDB Exit Point Configuration

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

SAP Exit Points

Name of the Exit Point	Type	Class Match Criteria	Class/Interface/ Superclass/Annotation Name	Method Name
SAP.Execute	SAP	With a class name that	com.sap.mw.jco.rfc.Middle wareRFC\$Client	execute
SAP.Connect	SAP	With a class name that	com.sap.mw.jco.rfc.Middle wareRFC\$Client	connect
SAP.Disconnect	SAP	With a class name that	com.sap.mw.jco.rfc.Middle wareRFC\$Client	disconnect
SAP.Reset	SAP	With a class name that	com.sap.mw.jco.rfc.Middle wareRFC\$Client	reset
SAP.CreateTID	SAP	With a class name that	com.sap.mw.jco.rfc.Middle wareRFC\$Client	createTID
SAP.ConfirmTID	SAP	With a class name that	com.sap.mw.jco.rfc.Middle wareRFC\$Client	confirmTID

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Example Message Queue Backend Configuration

Monitor the Server by Ignoring the Queue Name

In JMS example, the application is making calls to a message server that handles several queues. The sample destination names look like this:

- AccountQ
- AccountReplyQ
- AccountRecQ
- AccountDebitQ

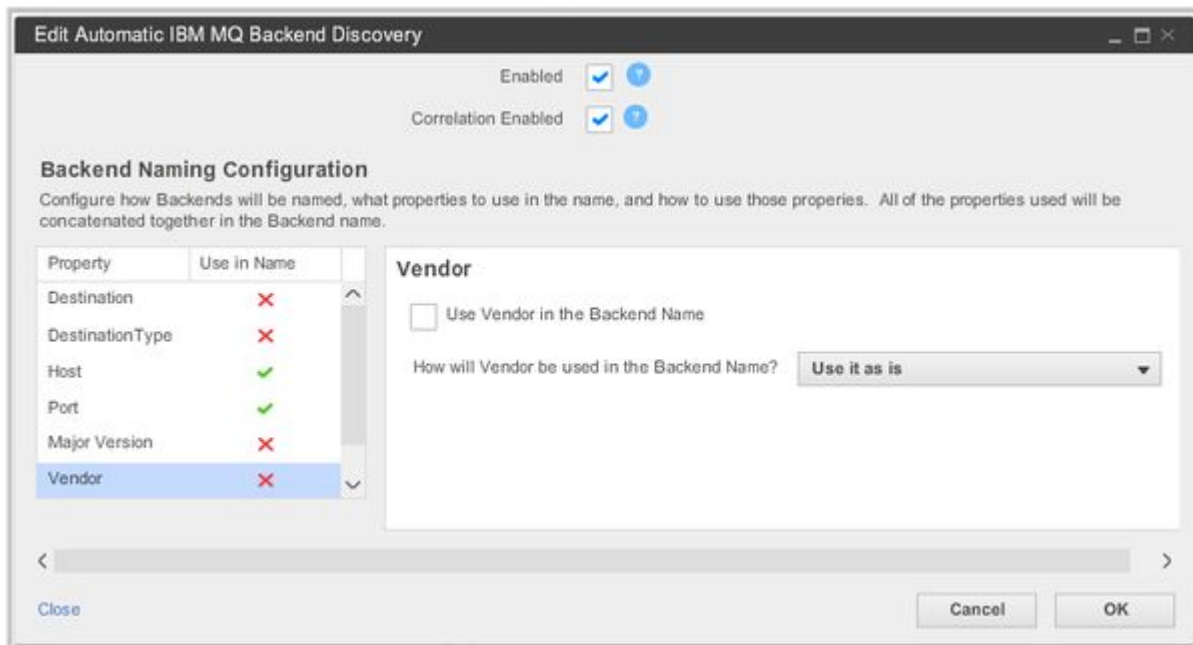

The default automatic discovery rule detects one backend for each unique destination and so the flow map shows one queue backend for each different queue name. In this example, each of the above would show as a separate backend on the application flow map. If you are interested in monitoring the performance of the server and not each queue name, you can modify the configuration to ignore the Destination property and use just the Type and Vendor.

To achieve this result, you create a new custom JMS Discovery Rule.

Taking IBM MQ for another example, the application is making calls to a message server that handles several queues. The sample destination names look like this:

- MQhostwest-US:1521
- MQhosteast-US:1521
- MQhostsouth-US:1521

The default automatic discovery rule detects one backend for each unique destination and so the flow map shows one queue backend for each different queue name. In this example, each of the above would show as a separate backend on the application flow map. If you are interested in monitoring the performance of the server and not each queue name, you can create a discovery rule that just uses the Host and Port, as follows:

Temporary Queues

In this example an application creates many temporary JMS response queues that are deleted after the message is received. By default, AppDynamics discovers these queues separately and lists each one as a unique remote service. This default behavior probably does not enable effective monitoring. Instead, you can create a custom JMS discovery rule stating that if the destination name contains "TemporaryQueue", list it as "WeblogicTempQueue", or whatever name makes sense in your monitoring environment. In this way, you can monitor the performance that matters. The configuration to accomplish this is shown in the following screen shot:

Create Custom JMS Backend Discovery Rule
✖

Name:

Enabled: ?

Correlation Enabled: ?

Priority: ?

Match Conditions

Backends that match ALL of the enabled match conditions below will be discovered and named according to the 'Backend Naming Configuration' below. You must configure at least one condition.

<input type="checkbox"/>		Destination	Equals	<input type="text"/>	⚙️
<input type="checkbox"/>		DestinationType	Equals	<input type="text"/>	⚙️
<input type="checkbox"/>		Vendor	Equals	<input type="text"/>	⚙️

Backend Naming Configuration

Configure how Backends will be named, what properties to use in the name, and how to use those properties. All of the properties used will be concatenated together in the Backend name.

Property	Use in Name
Destination	<input checked="" type="checkbox"/>
DestinationType	<input checked="" type="checkbox"/>
Vendor	<input checked="" type="checkbox"/>

Destination

Use Destination in the Backend Name

How will Destination be used in the Backend Name? Run a Regular Expression on it

Regular Expression:

Regular Expression Groups: (Comma Separated List of list)

Close
Cancel
OK

Session ID in the Queue Name

If your JMS queues use the session ID in the destination, this causes each session to be identified as a separate backend. In this case, you might not be interested in seeing each queue separately, and instead want to aggregate everything for the same host and port to the same backend. You can generate the right name and the correct number of backends to monitor by editing the automatic discovery rule. Doing this enables you to monitor the key performance indicators (KPIs) that are of most interest to you.

Example JDBC Backend Configuration

Related pages:

- [Java Backend Detection](#)
- [Using Regular Expressions](#)

Depending on exactly what you need to monitor, you may want to change the default JDBC configuration. When you see the same physical database represented as multiple JDBC databases, you may need to [revise the automatic discovery rule](#). Doing this enables you to more effectively monitor the key performance indicators (KPIs) that are of most value to you.

Multiple Databases from Same Vendor

JDBC connections to the same physical Oracle database (with the same URI) may appear as multiple backends. In some circumstances, the Vendor property captured for the database is different. This can happen when different drivers are used to access the database. For example, you might see JDBC backends with the following vendor names:

- Oracle DB
- Oracle

If the database driver package name matches the standard Oracle database driver, then the vendor name used is "Oracle DB". If it doesn't match, then the product name from the database metadata (using the `java.sql.DatabaseMetaData` class) is used as a vendor name. So database calls that use different drivers to reach the same physical database may be detected as separate databases. You can fix this by disabling the use of the Vendor property in the discovery rule.

JDBC with Complex URLs

In this example, the database URL is configured for high availability, so it is quite long and complex. Choosing the **Run a regular expression on it URL** option is the way to go. Disable the use of the Host and Port properties for JDBC automatic discovery. Instead enable the use of the URL that appears in the JDBC call, along with a regular expression to get the correct database naming and discovery.

For example, to extract all the hosts and all the ports from the following URL:

```
jdbc:oracle:thin:@(DESCRIPTION_LIST=(LOAD_BALANCE=OFF)(FAILOVER=ON)
(DESCRIPTION=(ADDRESS_LIST=(LOAD_BALANCE=ON)(ADDRESS=(PROTOCOL=TCP)(HOST=titanpfmcl01)
(PORT=1521)))(CONNECT_DATA=(SERVICE_NAME=trafrefpfm01.global.trafigura.com)))
(DESCRIPTION=(ADDRESS_LIST=(LOAD_BALANCE=ON)(ADDRESS=(PROTOCOL=TCP)(HOST=titanpfmcl02)(PORT =
1521)))(CONNECT_DATA=(SERVICE_NAME=trafrefpfm01.global.trafigura.com))))
```

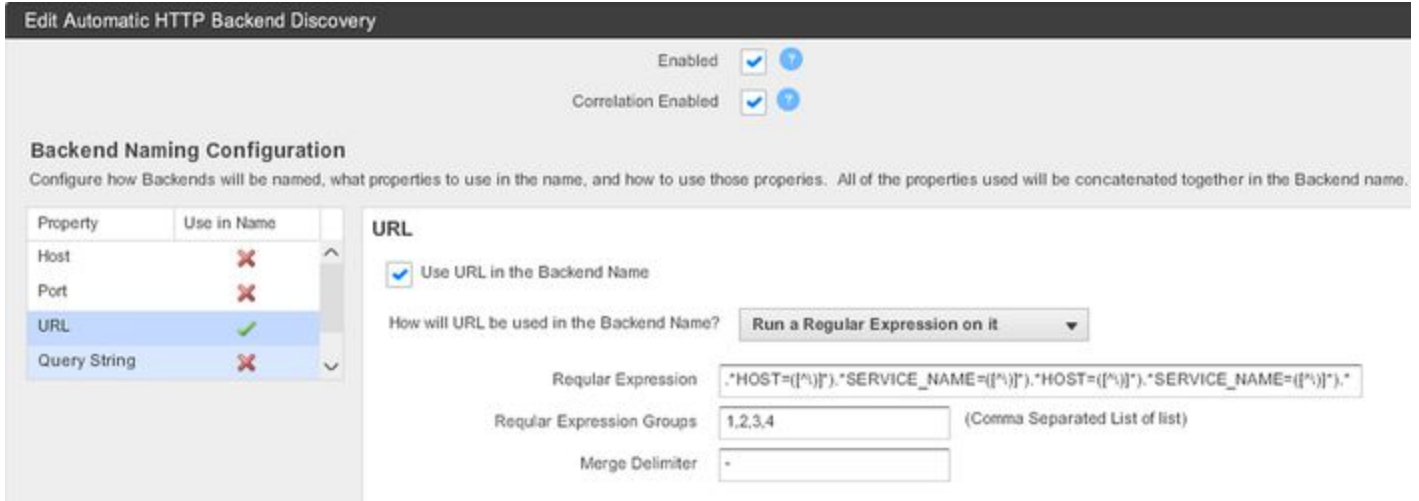

This sample is for a string that contains the host and service name twice. You can also use port in your regular expression if needed by your requirements.

The following regular expression applied to the previous high availability URL results in a backend name similar to this: `titanpfmcl01-trafrefpfm01.global.trafigura.com-titanpfmcl02-trafrefpfm01.global.trafigura.com`.

```
. *HOST=([\^\\]) * . *SERVICE_NAME=([\^\\]) * . *HOST=([\^\\]) * . *SERVICE_NAME=([\^\\]) * . *
```

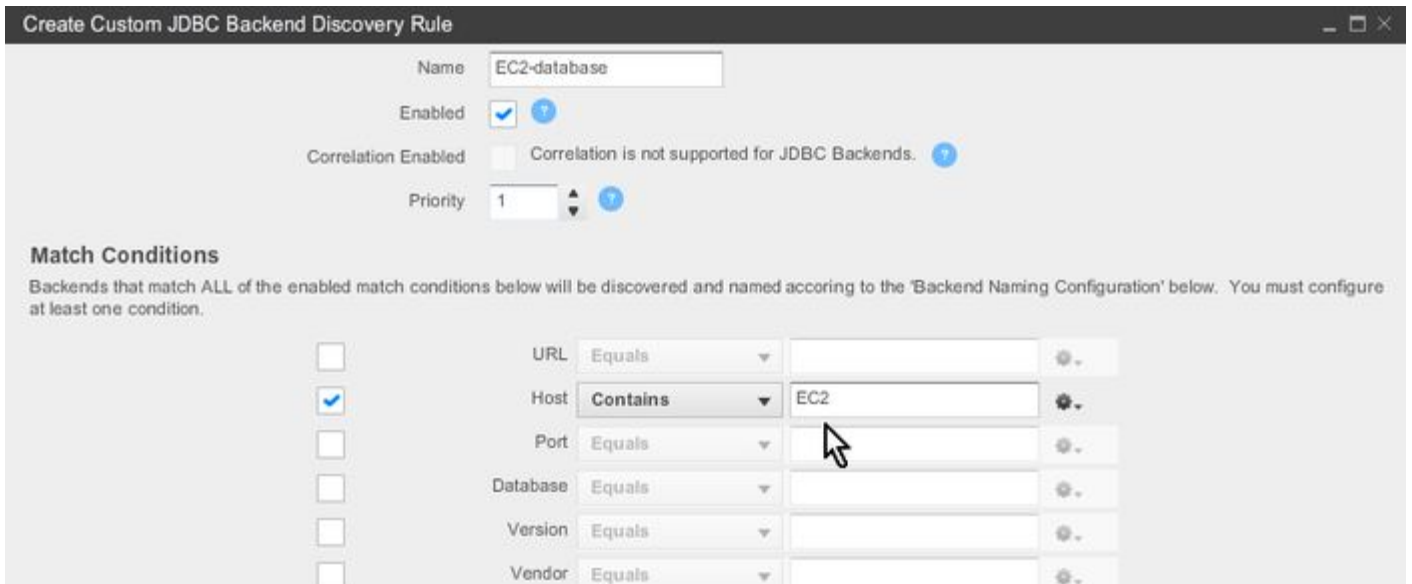

Note: the expression starts and end with "." Set **Regular Expression Groups** to **1,2,3,4**.
Set the **Merge Delimiter** to "-".

This configuration looks like this in the UI:

EC2 Hosted Databases

AppDynamics automatically discovers JDBC backends based on host, port, URL, database, version and vendor values. To monitor all JDBC databases that contain "EC2" in their host names as a single database, create a JDBC custom discovery rule and use the following match condition: Host Contains "EC2" as shown in the following screen shot.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Assuming host names of the format "EC2-segment2-segment3", use the following naming configuration:

Backend Naming Configuration
Configure how Backends will be named, what properties to use in the name, and how to use those properties. All of the properties used will be concatenated together in the Backend name.

Property	Use in Name
URL	✗
Host	✓
Port	✗
Database	✗
Version	✗
Vendor	✗

Host

Use Host in the Backend Name

How will Host be used in the Backend Name? Use a segment of it

Use the First N Segments: 1 (Number of Segments)

Split Delimiter -

Merge Delimiter

Close Cancel OK

This configuration results in a single database icon on the flow map named "EC2".

Apache Kafka Consumer Backends

You can configure the AppDynamics Java Agent to detect entry points for Apache Kafka consumer activity using `KafkaConsumer.poll()` (introduced in Kafka v0.10) and `Kafka SimpleConsumer.fetch()` (introduced in Kafka v0.9). Prior to version 0.11, the Kafka payload did not include a location to store correlation data, so end-to-end Business Transaction correlation is only possible with the Kafka client and broker ≥ 0.11 .

KafkaConsumer.poll

To instrument Kafka consumer entry points using `KafkaConsumer.poll()`, identify the method in which the consumer reads messages in a loop with a custom interceptor definition. We instrument the iterator's next method to start and end the Business Transaction for each message. There could be many iterators used for iterating messages but we only support iterators of the following types:

- `kafka.consumer.ConsumerIterator`
- `org.apache.kafka.clients.consumer.ConsumerRecords$ConcatenatedIterable$1`

1. Identify the class and method of the loop that processes messages from Kafka. Consider, for example, a class `MyConsumer` that employs the following loop to poll and process messages from Kafka:

```
ConsumerRecords<String, String> records = kafkaConsumer.poll(1000);
pollMessages(records);
private void pollMessages(ConsumerRecords<String, String>records) throws Exception {
    //AppDynamics instrumentation gets applied here
    for (ConsumerRecord<String, String> record : records) {
        //Processing of the records
        System.out.println(record.value());
    }
}
```

For this case, you want to intercept:

- Class: `MyConsumer`
- Method: `pollMessages`

The interceptor can also be applied to a method that processes individual records, not just a loop. For example:

```
ConsumerRecords<String, String> records = kafkaConsumer.poll(1000);
pollMessages(records);
private void pollMessages(ConsumerRecords<String, String>records) throws Exception {
    //AppDynamics instrumentation gets applied here
    for (ConsumerRecord<String, String> record : records) {
        processRecord(record)
    }
}
```

- Use your preferred text editor to create and edit a file named `custom-interceptors.xml` at the following path:

```
<agent_home>/<version_number>/conf
```

For example:

```
/usr/home/appdynamics/appagent/ver4.3.1.0/conf/custom-interceptors.xml
```

- Copy the following XML to `custom-interceptors.xml`:

```
<custom-interceptors>
  <custom-interceptor>
    <interceptor-class-name>com.singularity.KafkaMarkerMethodInterceptor</interceptor-
class-name>
    <match-class type="matches-class">
      <name filter-type="equals">my-fully-qualified-class-name</name>
    </match-class>
    <match-method>
      <name>my-method-name</name>
    </match-method>
  </custom-interceptor>
</custom-interceptors>
```

- Set the value of the class name to the name of your consumer class. For instance, to specify the `MyConsumer` class:

```
<match-class type="matches-class">
  <name filter-type="equals">com.mycompany.mypackage.MyConsumer</name>
</match-class>
```

- Set the value of the method name to the name of your message processing loop method. For instance, to specify the `pollMessages` method:

```
<match-method>
  <name>pollMessages</name>
</match-method>
```

After the Java Agent reads the updated configuration, it detects consumer activity and upstream Kafka queue. The application flow map shows the tier receiving data from the Kafka queue.

Kafka SimpleConsumer Entry Points

To enable consumer entry points for Kafka clients that retrieve messages using `SimpleConsumer.fetch()`, register the `enable-kafka-consumer` node property with a value of "true."

 Kafka consumer activity shows up as an exit call in this case.

.NET Backend Detection

The .NET Agent automatically detects many common backend types. Most backend types have a default discovery rule and a set of configurable properties. To revise backend discovery rules, see [Backend Detection Rules](#) and [Exit Point Detection Rules](#).

For all other traffic transactions, see [Business Transactions](#).

ADO.NET Backends

The .NET Agent automatically discovers ADO.NET data providers implementing standard Microsoft interfaces as database backends. See [.NET Supported Environments](#).

Because the ADO.NET API is interface-based, AppDynamics instruments all ADO.NET database providers that implement these interfaces by default.

AppDynamics uses database identification information from the ADO.NET connection string. The connection string specifies the server address and schema, or the local file name. Most connection strings are formatted based on common rules that you can parse and distill to a database name. However because no standards exist for the connection string, the ADO.NET provider implementer determines the format.

For some providers, AppDynamics may fail to parse the connection string. In these cases, the .NET Agent uses the complete connection string minus any user password. The property is labeled ADO.NET connection string, and the value shows the connection string minus any user password.

For example, the .NET Agent names this database backend using the connection string pattern `<datasource name>-<database name>`

```
.\SQLEXPRESS-HowdyWorldDB
```

ADO.NET Configurable Properties

You can enable or disable the use of these properties for ADO.NET exit points:

Configurable Properties	Default Detection and Naming Property?	Description
Host	Yes	Data source or database server
Database	Yes	Database name
Vendor	No	Type of client-side ADO.NET library
Connection String	No	Full connection string with password filtered out

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Configurable Properties	Default Detection and Naming Property?	Description
Port	No	Port number

Directory Service Backends

The .NET Agent automatically discovers exit calls to directory services that use the [System.DirectoryServices.Protocols \(S.DS.P\)](#) libraries.

The agent names the backend for the server name. If the agent cannot derive the server name from the request, it then constructs a name using Domain Component (DC) values.

For example: `activedirectory.example.com`

HTTP Backends

AppDynamics automatically detects HTTP exit points (backends). See [HTTP Backend Detection](#).

.NET Agent for Windows

For the .NET Agent for Windows, the default HTTP automatic discovery rule uses the URL property. From the enabled properties, AppDynamics derives a display name using the URL.

For example: `http://api.example.com:8989/searchfares`

.NET Agent for Linux

For the .NET Agent for Linux, the default HTTP automatic discovery rule for backends uses the host name and port number.

For example: `http://api.example.com:8989/`

HTTP Configurable Properties

For both Windows and Linux versions of the .NET Agent, you can enable or disable the use of these properties for HTTP exit points:

Configurable Properties	Default Detection and Naming Property?		Description
	.NET Agent for Windows	.NET Agent for Linux	
Host	No	Yes	HTTP host

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Configurable Properties	Default Detection and Naming Property?		Description
	.NET Agent for Windows	.NET Agent for Linux	
Port	No	Yes	HTTP port number
URL	Yes	No	Full URL
Query String	No	Yes	HTTP parameters/query string

i As of 4.5.13, you can customize HTTP backend detection and naming for the .NET Agent for Linux through the Controller UI. Customizing HTTP backend detection and naming is a feature preview that is recommended for pre-production systems. See [Enable Preview Features](#).

Message Queue Backends

By default, AppDynamics automatically detects and identifies many message queue exit points. For a list of the supported message-oriented middleware products, see [Supported Remote Service Detection for .NET](#).

The default queue automatic discovery rule uses the destination property to name the message queue backend.

For example: `HowdyWorldQueue$\HWT_MQ_Server1_MsgQ`

Message Queue Configurable Properties

This table lists the properties used for queue exit points. However, each message-oriented product is different and there may be variations in the properties, or their names.

Configurable Properties	Default Detection and Naming Property?	Description
Host	No	Queue server name
Destination	Yes	Name of topic or queue
Destination Type	No	Queue or topic

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Configurable Properties	Default Detection and Naming Property?	Description
Vendor	No	Vendor from the client library

For specific queue types, see:

- [MSMQ Backends for .NET](#)
- [NServiceBus Backends for .NET](#)
- [RabbitMQ Backends for .NET](#)

MongoDB Backends

By default, the .NET Agent detects MongoDB exit calls for create, read, update, and delete (CRUD) operations using the C# and .NET MongoDB Driver versions: 1.10, 2.0, 2.2, and 2.4.

The default MongoDB automatic discovery rule uses the host, port, and database name to name the MongoDB backend.

For example: `mymongohost.27017.mymongodb`

MongoDB Configurable Properties

You can configure the use of these properties for MongoDB exit points:

Configurable Properties	Default Detection and Naming Property?	Description
Host	Yes	MongoDB host
Port	Yes	MongoDB port
Database	Yes	MongoDB database name

.NET Remoting

When an application uses .NET remoting, AppDynamics automatically detects and identifies remoting exit points (backends). See [Enable Correlation for .NET Remoting](#) to configure downstream correlation.

The default remoting automatic discovery rule uses the URL property.

For example: `tcp://remoting.example.com:8648/MovieTicketBooking`

.NET Remoting Configurable Properties

You can configure the use of this property for .NET Remoting exit points:

Configurable Properties	Default Detection and Naming Property?	Description
URL	Yes	Full URL

WCF Backends

AppDynamics automatically detects and identifies WCF exit points (backends) when an application uses the WCF client library. The default WCF automatic discovery rule uses the remote address property. The agent uses the enabled properties to derive a display name using the remote address.

For example: `http://wcf.example.com:8205/Services/Service1.svc`

Agent Compatibility

This table describes the WCF backend detection support for each variant of the .NET Agent:

Agent and Version	WCF Backend Detection Support
.NET Agent for Windows (.NET Framework)	Fully supported
.NET Agent for Linux >= 20.7.0	Partially supported <ul style="list-style-type: none"> • Works with .NET Core >= 3.1 • Compatible with asynchronous calls over HTTP • Does not support the Operation Contract, Service Contract, and SOAP Action properties.
.NET Agent for Windows (.NET Core) >= 21.3.0	

WCF Configurable Properties

You can enable or disable the use of these properties for WCF exit points:

Configurable Properties	Default Detection and Naming Property?	Description
Remote Address	Yes	URL minus the query, fragment, and user information (name and password)
Operation Contract	No	WCF operation contract name
Service Contract	No	WCF service contract name
URL	No	Full URL

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Configurable Properties	Default Detection and Naming Property?	Description
Host	No	Host portion of URL
Port	No	Port number if present in the URL; otherwise, protocol default
SOAP Action	No	For web service calls, the SOAP action

.NET Web Services Backends

When an application uses the Microsoft Web Services client library, AppDynamics automatically detects and identifies web services exit points (backends) by default. The default web services automatic discovery rule uses the URL property. From the enabled properties, AppDynamics derives a display name using the URL.

For example: `http://webservice.example.com:8105/Services/Service1.asmx`

Web Services Configurable Properties

You can enable or disable the use of these properties for Web Services exit points:

Configurable Properties	Default Detection and Naming Property?	Description
Service	No	Web service name
URL	Yes	Full URL
Operation	No	Web service operation name
Soap Action	No	SOAP action

Custom Exit Points

To monitor a backend that is not included in [.NET Supported Environments](#), you can [configure a custom exit point](#).

i By default, you have to restart the instrumented application for instrumentation changes to take effect. You can [enable Runtime Reinstrumentation](#) for the .NET Agent to avoid having to restart your application and the `AppDynamics.Agent.Coordinator` after instrumentation changes.

Asynchronous Exit Points for .NET

Related pages:

- [.NET Backend Detection](#)
- [Using Asynchronous Methods in ASP.NET 4.5](#)

Asynchronous programming patterns can enhance the scalability and performance of applications. Microsoft .NET lets you designate methods as asynchronous tasks.

The .NET runtime releases resources for asynchronous methods while tasks complete. When task processing finishes, the runtime calls back to the originating asynchronous method so the method may continue processing.

The .NET Agent detects certain asynchronous programming patterns as exit points. Because tasks may execute in parallel, AppDynamics sometimes represents asynchronous activity differently from synchronous activity in the Controller.

AppDynamics differentiates .NET async backend tracking from thread correlation. To configure thread correlation, see [Thread Correlation for .NET](#).

Supported Asynchronous Exit Point Patterns

The agent discovers exit points for Microsoft .NET 4.5 *async* and *await* keywords. See [Asynchronous Programming with Async and Await](#).

The agent detects asynchronous exit points for the following backend types:

- ADO.NET
- Azure Blob Storage, Azure File Storage, and Azure Table Storage
- CosmosDB
- HTTP
- MongoDB
- WCF
- Web Service

i Backend types are different for the .NET Core microservices agent. See [.NET Core Microservices Agent Support](#).

Flow maps in the Controller UI represent asynchronous exit points as dotted lines labeled "async". Because calls in an asynchronous transaction may execute simultaneously, the Controller doesn't display end-to-end percentage times for individual asynchronous calls.

Troubleshoot Asynchronous Calls in Transaction Snapshots

Transaction snapshots include several features to help you discover problem areas in business transactions that use asynchronous methods. For an overview of transaction snapshots, see [Transaction Snapshots](#).

Transaction Snapshot Flow Map

The Transaction Snapshot Flow Map graphically represents the business transaction. It displays the user experience, execution time, and timestamp of the transaction. The flow map also provides details of the overall time that is spent in a particular tier and in database and remote service calls. The *async* label indicates asynchronous calls.

Snapshot Execution Waterfall View

The transaction Snapshot Execution Waterfall View shows a timeline representation of the end-to-end execution of the business transaction. Synchronous and asynchronous processes appear on a bar diagram illustrating their relative execution time arranged in chronological order. Synchronous calls are represented by solid line arrows, and asynchronous calls are represented by dotted line arrows.

The waterfall view enables you to visually identify which processes are running the longest. Double-click a bar to drill down to a call graph and investigate problematic code.

Analyze Asynchronous Activity in the Metric Browser

The Metric Browser displays asynchronous activity in the following places:

- **Business Transaction Performance > Business Transactions > tier > business transaction > Thread Tasks > Asynchronous Operation > External Calls**
- **Overall Application Performance > tier > Thread Tasks > Asynchronous Operation > External Calls**
- **Overall Application Performance > tier > Individual Nodes > node name > Thread Tasks > Asynchronous Operation > External Calls**

MSMQ Backends for .NET

Related pages:

- [.NET Backend Detection](#)
- [App Agent Node Properties](#)

The AppDynamics .NET Agent (agent) automatically detects MSMQ backends when an instrumented tier makes a call to MSMQ. MSMQ exit points are methods that publish or push messages to a queue. If you are using NServiceBus over the MSMQ transport, see [NServiceBus Backends for .NET](#).

MSMQ entry points are methods that listen or poll for new messages in the queue. Before the agent can detect entry points or perform downstream correlation for MSMQ you must define the correlation field and, for multithreaded architectures, specify threading architecture.

Exit Points and Backend Naming

The agent names the queue for the queue name returned from the system.

Entry Points

To enable downstream correlation for MSMQ, you must configure the agent.

Define the MSMQ Correlation Field

Register the *msmq-correlation-field* app agent node property on both the publishing tier and on the receiving tier. Specify the field where the agent will write and read correlation information.

The agent supports the following fields:

- Extension, the default field
- Label

By default, the .NET Agent writes to the Extension field. However, some frameworks built on MSMQ write data to the Extension field. In this case, the Extension field does not work because it is already in use, so you must configure the .NET Agent to write correlation data to the Label field.

Choose a field not in use by your queue implementation. If your implementation uses both the "Label" and "Extension" fields, downstream correlation is not currently possible.

See "msmq-correlation-field" on [App Agent Node Properties Reference](#). For instructions to register a node property, see [App Agent Node Properties](#).

Specify the threading architecture

If your queue implementation uses a multithreaded architecture, you must register the *msmq-single-threaded* app agent node property to specify the threading architecture. Set *msmq-single-threaded* to "False" for multithreaded implementations of MSMQ. See "msmq-single-threaded" on [App Agent Node Properties Reference](#). For instructions to register a node property, see [App Agent Node Properties](#).

The threading architecture dictates how the agent calculates the call timing for the message queue:

- For single-threaded queues, the agent calculates the call time between receive requests. The call time begins at the end of the first receive method and ends when the next receive method starts.

In the following example, the length of the `ProcessMessage()` method:

```
MessageQueue messageQueue;  
for(;;)  
{  
    var message = messageQueue.Receive();  
    ProcessMessage(message);  
}
```

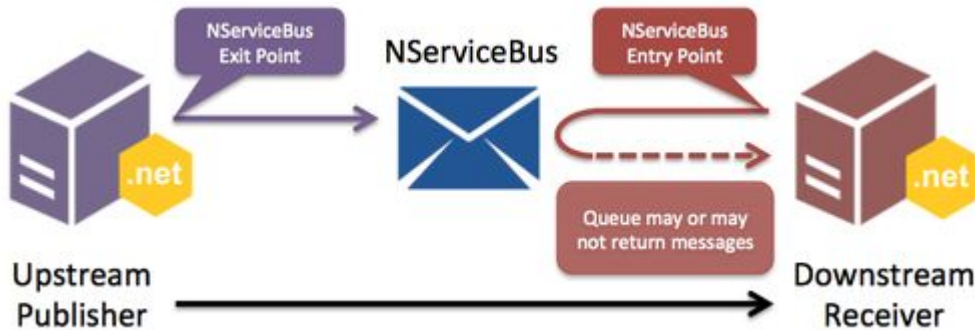

- For multithreaded queues, the agent does not capture timing.

NServiceBus Backends for .NET

Related pages:

- [.NET Backend Detection](#)

The AppDynamics .NET Agent automatically discovers exit points to NServiceBus backends when an instrumented tier makes a call to NServiceBus over MSMQ or RabbitMQ transports. The agent discovers NServiceBus entry points for downstream correlation from NServiceBus version 5.

Exit Points and Backend Naming

NServiceBus exit points are methods that publish or push messages to a queue from an upstream tier. The agent detects exit points regardless of the NServiceBus version or threading architecture. The agent names the queue for the queue name returned from the system.

Entry Points in a Single-threaded Architecture

NServiceBus entry points are methods that listen or poll for new messages in the queue. When the message receiver uses a single-threaded architecture, the .NET Agent automatically discovers entry points and correlates downstream activity without additional configuration.

The agent measures the call time from the end of the first receive method to the start of the subsequent receive method. In the following example loop, the length of the `ProcessMessage()` method:

```

MessageQueue messageQueue;
for(;;)
{
    // Call timing for previous iteration ends.
    var message = messageQueue.Receive();
    // Call timing begins.
    ProcessMessage(message);
}

```

Entry Points in a Multithreaded Architecture

For the .NET Agent to automatically detect NServiceBus entry points when the receiver is running a multithreaded architecture, set the `nservicebus-single-threaded` app agent node property to "false" on the receiver. See "nservicebus-single-threaded" on [App Agent Node Properties Reference](#). For instructions to register a node property, see [App Agent Node Properties](#).

For multi-threaded message receivers, the agent does not capture timing.

Resolve Issues with NServiceBus Backends

- If you have NServiceBus version 5 and are not seeing downstream correlation on the receiver, verify the threading architecture on the receiver. Set the `nservicebus-single-threaded` app agent node property to "false" on the multithreaded receivers.
- Only use the node properties for MSMQ, `msmq-single-threaded` and `msmq-correlation-field`, if you are using MSMQ independently of NServiceBus. The .NET Agent does not use MSMQ node properties when discovering and instrumenting NServiceBus over MSMQ transport.
- If you are using NServiceBus version 4, you can disable NServiceBus instrumentation on both the publisher and the receiver:
 - Copy the following Instrumentation element to a child of the Machine Agent element:

```
<!--Disable NServiceBus instrumentation-->
  <instrumentation>
    <instrumentor name="NServiceBusReceiveContextInstrumentor"
enabled="false" />
    <instrumentor name="NServiceBusPublishExitInstrumentor"
enabled="false" />
    <instrumentor name="NServiceBusEntryInstrumentor" enabled="false" /
  >
    <instrumentor name="NServiceBusExitInstrumentor" enabled="false" />
  </instrumentation>
```

For more information, see "Instrumentation Element" on [.NET Agent Configuration Properties](#).

- Configure the publisher and receiver as you would for [MSMQ](#) or [RabbitMQ](#).

RabbitMQ Backends for .NET

Related pages:

- [.NET Backend Detection](#)
- [RabbitMQ Monitoring Extension](#)

The AppDynamics .NET Agent automatically detects RabbitMQ backends based upon calls from instrumented tiers. RabbitMQ exit points are methods that publish or push messages to a queue. RabbitMQ entry points are methods that listen or poll for new messages in the queue.

If you are using NServiceBus over the RabbitMQ transport, see [NServiceBus Backends for .NET](#).

Exit Points and Backend Naming

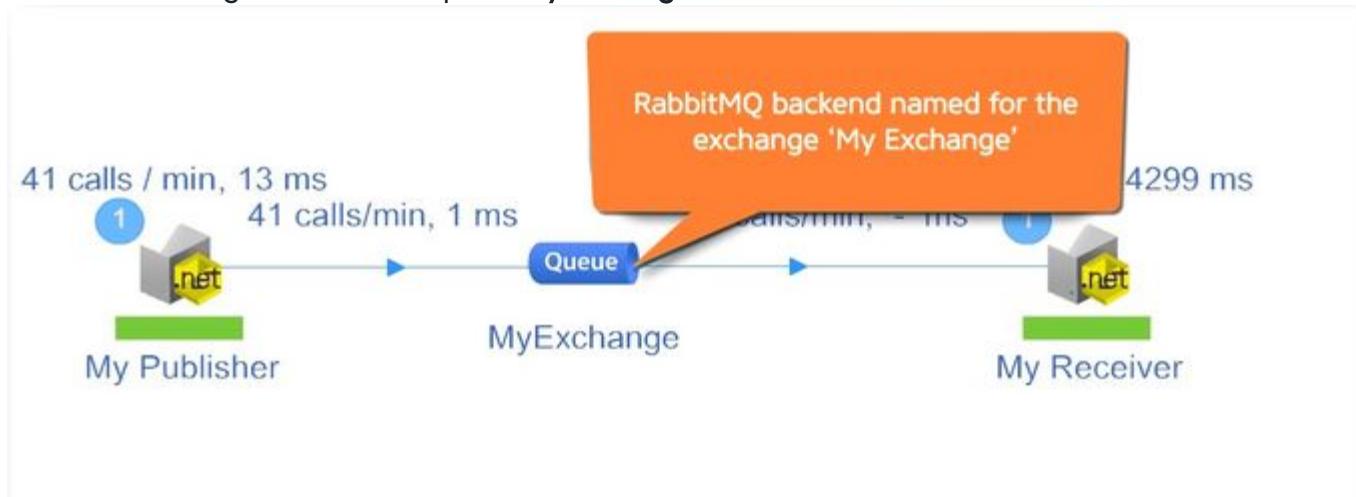

The agent discovers a RabbitMQ backend exit point when your application sends a message to the queue using the `BasicPublish()` method.

By default, the agent names the RabbitMQ backend for the exchange parameter of the `BasicPublish()` method.

For example:

```
model.BasicPublish("MyExchange", "", false, false,
    basicProperties, Encoding.UTF8.GetBytes(message));
```

In this case the agent names the queue **MyExchange**.

You can refine the backend name to include some or all segments of the routing key. To configure RabbitMQ naming you must be familiar with your implementation RabbitMQ exchanges and routing keys. See [RabbitMQ Exchanges and Exchange Types](#).

Refine backend naming

Register the *rmqsegments* node property. For instructions on how to set a node property, see [App Agent Node Properties](#).

Name: *rmqsegments*

Description: "Configure RabbitMQ naming to include routing key segments."

Type: Integer

Value: <integer>

The routing key is a string. The agent treats dot-separated (".") substrings of the routing key as segments. Set the value to an integer that represents the number of routing key segments to include in the name.

In the following example the routing key is "abc.def.ghi". Set the *rmqsegments* value to "2" to name the queue "MyExchange.abc.def".

```
model.BasicPublish("MyExchange", "abc.def.ghi", false, false,
    basicProperties, Encoding.UTF8.GetBytes(message));
```

After you save the node property, the Controller sends the configuration to the agent. After some time the RabbitMQ backend shows up with the new name.

Entry Points

The agent discovers RabbitMQ backend entry point when your application polls the queue. AppDynamics auto-detects RabbitMQ based upon the following patterns:

- [BasicGet](#)
- [HandleBasicDeliver](#)

BasicGet Method

The agent detects the pattern below where the application periodically polls the message queue using the `BasicGet()` method. The call timing is limited to the time spent inside the `while` loop. The timer only starts when the `BasicGet` result returns a value at line 4. The timer ends when the next `BasicGet` executes. In this example, the application polls every five seconds, so the execution time equals the time in the `if` loop plus five seconds.

RabbitMQ Client before version 6.x:

```

1  while (true)
2  {
3      var result = channel.BasicGet("MyExchange", true);
4      if (result != null)
5      {
6          var body = result.Body;
7          var message = Encoding.UTF8.GetString(body);
8          Console.WriteLine("Received: {0}.", message);
9      }
10
11     Thread.Sleep(5000);
12 }

```

RabbitMQ Client version 6.x:

```

1  while (true)
2  {
3      var result = channel.BasicGet("MyExchange", true);
4      if (result != null)
5      {
6          var body = result.Body.ToArray()
7          var message = Encoding.UTF8.GetString(body);
8          Console.WriteLine("Received: {0}.", message);
9      }
10
11     Thread.Sleep(5000);
12 }

```

HandleBasicDeliver Method

The agent detects the `HandleBasicDeliver()` method for custom implementations of the `IBasicConsumer` interface. In this case, the call timing reflects the execution time for the `HandleBasicDeliver` method.

Correlation Over Microsoft BizTalk

When you install the .NET Agent on a Microsoft BizTalk Server, the agent automatically discovers BizTalk entry points and exit points so you can monitor your BizTalk integration.

Requirements

- Microsoft BizTalk 2010, 2013
- BizTalk must be a downstream tier from an originating tier for a business transaction. The agent doesn't discover BizTalk as the originating tier of a transaction.

Entry Points

The .NET Agent detects incoming BizTalk requests using the WCF Send Adapter or the SOAP Send Adapter.

Instrument the BizTalk Service

1. Install the .NET Agent on the BizTalk server. See [Install the .NET Agent for Windows](#).
2. Register the "enable-soap-header-correlation" app agent node property with a value of "true" for the nodes upstream from the BizTalk tier. See [App Agent Node Properties](#).
3. Instrument the BizTalk service executables: BTSNTSvc.exe and BTSNTSvc64.exe. See [Configure the .NET Agent for Windows Services and Standalone Applications](#). For instance:

```
<standalone-applications>
  <standalone-application executable="BTSNTSvc">
    <tier name="BizTalk Service"/>
  </standalone-application>
</standalone-applications>
```

If you run multiple instances of BizTalk on the same Windows server, you can assign the different instances to unique nodes using command line options. For example, to differentiate nodes within the same tier, specify the BizTalk Service command "name" parameter in the standalone application `command-line` attribute:

```
<standalone-applications>
  <standalone-application executable="BTSNTSvc" command-
line="-name &quot;BizTalk1&quot;;">
    <tier name="BizTalk Service"/>
    <node name="BizTalk1"/>
  </standalone-application>
  <standalone-application executable="BTSNTSvc" command-
line="-name &quot;BizTalk2&quot;;">
    <tier name="BizTalk Service"/>
    <node name="BizTalk2"/>
  </standalone-application>
</standalone-applications>
```

```

</standalone-application>
</standalone-applications>

```

Notice the use of quotes to enclose the name command-line parameter.

4. Optionally enable BizTalk performance counters. For more information, see [Manage Windows Performance Metrics](#). Refer to the Microsoft BizTalk Server documentation for descriptions of individual performance counters.

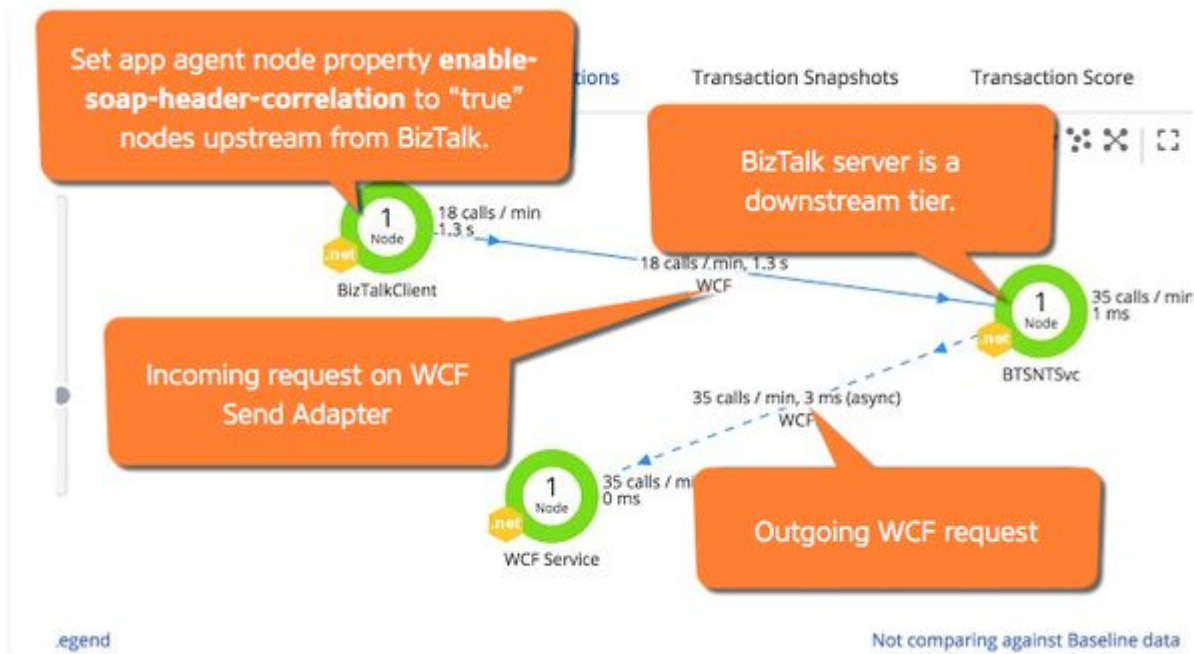

```

<machine-agent>
  <!-- BizTalk Performance Counters -->
  <perf-counters>
    <perf-counter cat="BizTalk:Message Agent" name="High
database session" instance="*" />
    <perf-counter cat="BizTalk:Message Agent" name="High
database size" instance="*" />
    <perf-counter cat="BizTalk:Message Agent" name="High in-

    <perf-counter cat="BizTalk:Message Agent" name="High
message delivery rate" instance="*" />
    <perf-counter cat="BizTalk:Message Agent" name="High
message publishing rate" instance="*" />
    <perf-counter cat="BizTalk:Message Agent" name="High
process memory" instance="*" />
    <perf-counter cat="BizTalk:Message Agent" name="High
system memory" instance="*" />
    <perf-counter cat="BizTalk:Message Agent" name="High
thread count" instance="*" />
    <perf-counter cat="BizTalk:Message Agent" name="Message
delivery delay (ms)" instance="*" />
    <perf-counter cat="BizTalk:Message Agent" name="Message
delivery throttling state" instance="*" />
    <perf-counter cat="BizTalk:Message Agent" name="Message
publishing delay (ms)" instance="*" />
    <perf-counter cat="BizTalk:Message Agent" name="Message
publishing throttling state" instance="*" />
    <perf-counter cat="BizTalk:Message Agent" name="Message
delivery incoming rate" instance="*" />
    <perf-counter cat="BizTalk:Message Agent" name="Message
delivery outgoing rate" instance="*" />
    <perf-counter cat="BizTalk:Message Agent" name="Message

```

```
publishing incoming rate" instance="*"/>
  <perf-counter cat="BizTalk:Message Agent" name="Message
publishing outgoing rate" instance="*"/>
  <perf-counter cat="BizTalk:Message Agent" name="Message
delivery throttling state duration" instance="*"/>
  <perf-counter cat="BizTalk:Message Agent" name="Message
delivery throttling user override" instance="*"/>
  <perf-counter cat="BizTalk:FILE Receive Adapter"
name="Bytes received/Sec" instance="*"/>
  <perf-counter cat="BizTalk:FILE Receive Adapter"
name="Lock failures/sec" instance="*"/>
  <perf-counter cat="BizTalk:FILE Receive Adapter"
name="Messages received/Sec" instance="*"/>
  <perf-counter cat="BizTalk:FILE Send Adapter" name="Bytes
sent/Sec" instance="*"/>
  <perf-counter cat="BizTalk:FILE Send Adapter"
name="Messages sent/Sec" instance="*"/>
  <perf-counter cat="BizTalk:SOAP Receive Adapter"
name="Messages received/Sec" instance="*"/>
  <perf-counter cat="BizTalk:SOAP Send Adapter"
name="Messages sent/Sec" instance="*"/>
</perf-counters>
</machine-agent>
```

Once you've completed instrumentation, the .NET Agent correlates traffic through your BizTalk server:

If you enabled Performance Counter metrics, they appear under the Custom Metrics tree in the Metric Browser.

Apache Web Server Backend Detection

The Apache Agent discovers Apache Modules as backends. To review general information about monitoring backends, see [Backend Detection Rules](#).

Apache Modules

The Apache Agent automatically detects loaded Apache modules as remote services:

- Modules must be in the handler stage.
- The agent excludes a list of common modules from discovery, see "Remote Service Detection" on [Supported Apache Web Servers](#).

By default, the Apache Agent includes metrics for module backends with the downstream backend or tier. The Controller doesn't display the module on flow maps. For example, if Apache calls `mod_jk.c`, the module backend doesn't show on flow maps and metrics are included with the downstream Tomcat backend or tier.

To view Apache modules on the flow map and to see separate metrics for Apache modules, set `AppDynamicsResolveBackends` to "OFF" in the `appdynamics_agent.conf` file. See [Install the Apache Agent](#).

The agent names the Apache modules backend for the module name and the server: `<module>-<host>:<port>` . For example, `mod_jk.c-myapache.example.com:80`.

Previously, the backend name for requests routed through the reverse proxy was `mod_proxy.c-<ip and port of server >` . It is now resolved to the actual URL where the request is transferred to.

To add end segments that are displayed in the backend naming, set `AppDynamicsBackendNameSegments` with the required end segments. See [Install the Apache Agent](#).

HTTP Backend Detection

Related pages:

- [Java Backend Detection](#)
- [.NET Backend Detection](#)

AppDynamics automatically detects HTTP backends when outbound calls are made through supported HTTP clients, and by default names them according to their host and port. If the default configuration results in names that are not meaningful for your application (such as EC2 host names, file paths, and ports in the name) you can change the default discovery rule.

Additionally, if an HTTP call is destined for an http router which could route the request to one of several instrumented downstream tiers then the default naming rules will need to be modified such that the name includes enough segments of the target URL such that each destination tier is associated with a differently named backend.

HTTP Backend Naming

To ensure that the HTTP backends detected in your application have meaningful names, and that Business Transaction correlation functions correctly, your custom configuration will need to take into account the specific format used in your environment.

The format can vary even within a single environment. For example, some backend systems may have hostnames prefixed with `ec2storage`, which may not be meaningful in naming, while others may use hostnames such as `salesforce.com`, which may be meaningful.

To account for different formats, you should create a custom rule rather than changing the automatic discovery rule. This lets you apply different rules for different URL formats.

You can then apply a specialized approach for each case, as in the following examples:

- For format "ec2storage/servicename", you would use the URL
- For format "[salesforce.com](#)", use the host name
- For the other backends, you may use a query string
- For calls that could hit one of several downstream tiers via an HTTP router, you should use sufficient segments of the target URL in the name such that each downstream tier that could process the request is associated with a differently named backend

In some cases, your HTTP backend discovery configuration might consist of a combination of the default rule and custom rules. The following section walks you through a specific example:

Use the URL Path in a Detection Rule

For example, when all the HTTP backends for a tier or application have a similar format, such as a prefix like "ec2storage", you can generate the right name and the correct number of backends to monitor by editing the automatic discovery rule. This enables you to monitor the KPIs that are interested in.

Consider an application with the following HTTP URLs:

```
http://ec2-17:5400/service1
http://ec2-17:5450/service2
http://ec2-18:5400/service1
```

`http://ec2-18:5450/service2`

In this case, measuring performance based on host name would not be useful, since the IP addresses are transient and all performance numbers would be irrelevant after the IP addresses recycle. Instead, you can monitor by service name by avoiding the use of Host and Port properties and using only the URL property, as follows:

1. Edit the **Automatic Backend Discovery** rule for HTTP for your agent type. See [Backend Detection Rules](#) for details on accessing this pane.
2. First, select and disable the use of **Host** and **Port**.
3. Then select and enable the property you want to use to uniquely identify the backend. In this case, select **URL** and check **Use URL in the Backend Name**.
4. For the field **How will URL be used in the Backend name?**, select **Use a segment of it**.
5. From the segment options dropdown, select **Use the first N Segments**.
The important URL segment is for the "create" service, so your configuration is the same as in the previous screenshot.
6. Enter "/" slash for the **Split Delimiter**.
Use a similar technique to strip out some segment of the URL, such as a user name as in the following URLs:
[`http://host:34/create/username1`]
[`http://host:34/create/username2`]
7. Once you change the configuration, delete all HTTP backends. When the agent rediscovers the backends with the new configuration, the flow map shows only the service backends.

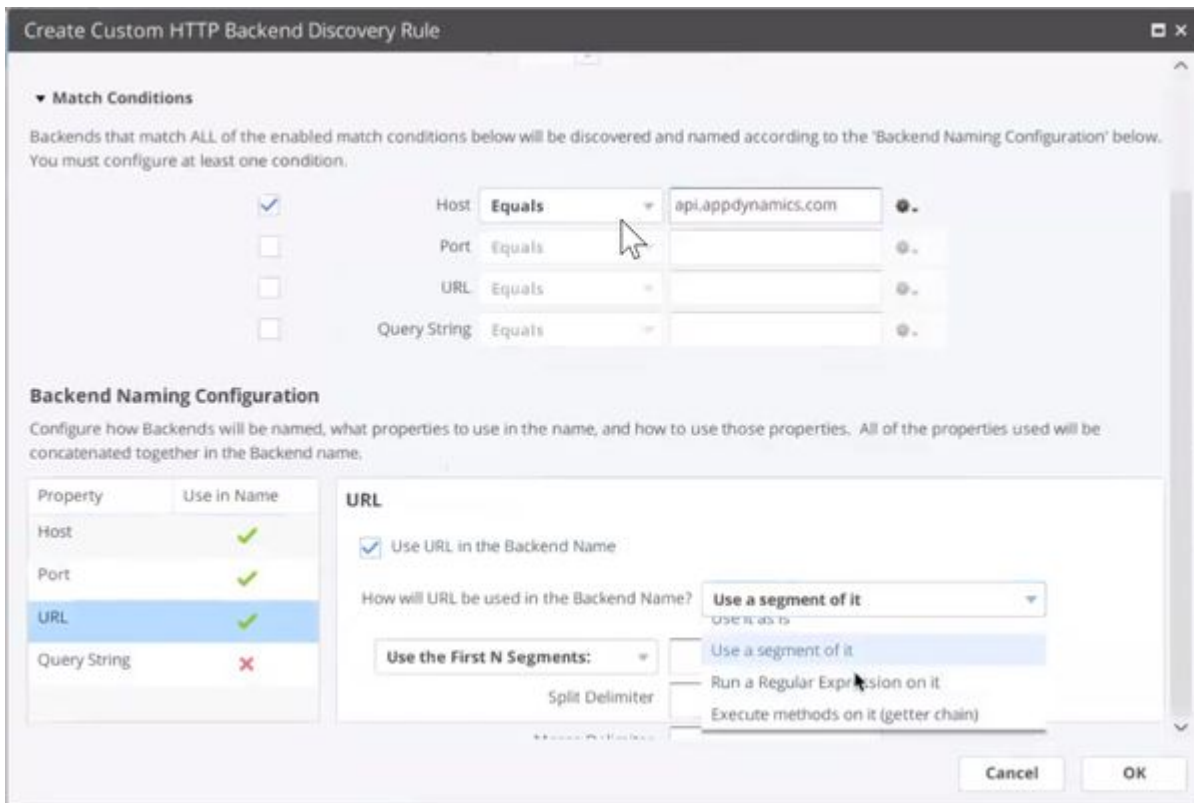

Custom HTTP Backend Detection and Naming Configuration

i You can now customize HTTP backend detection and naming for the .NET Agent for Linux through the Controller UI.
Customizing HTTP backend detection and naming is a feature preview in the .NET Agent for Linux 4.5.13, recommended for pre-production systems. See [Enable Preview Features](#).

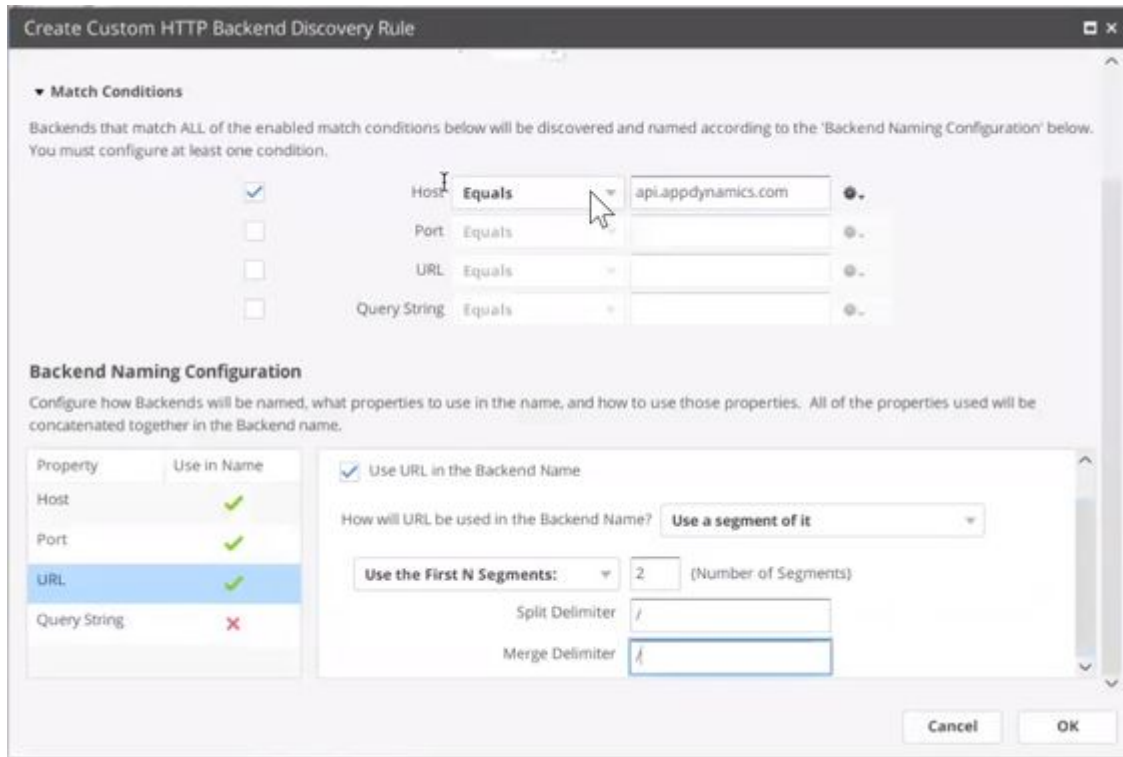

By default, AppDynamics uses the host name and port number to detect and name HTTP backends. This may be suitable in many cases, however, when your microservices, containers or serverlets are managed by an API gateway or portal, backend services communicating with a client or with each other cannot be correctly mapped to the proper tiers unless you edit automatic discovery to use a portion of the query string or use HTTP custom discovery rules to uniquely name them. AppDynamics recommends you create a custom HTTP backend discovery rule in this case.

The following screenshots provide an example configuration.

Here we choose Match Conditions to describe the API gateway host, in this case, api.appdynamics.com.

This screenshot shows where we choose to use the First 3 segments, using '/' as both the split and merge delimiters.

Configuring the HTTP Backend Discovery Rule as above detects backend metrics and reports them under a business transaction name that begins with api.appdynamics.com followed by the first three segments of the URL of the transaction, such as api.appdynamics.com/api/catalog or api.appdynamics.com/api/payment. Transactions matching the configured HTTP discovery rule are recognized as individual backends even when they share the same host name and port number. These transactions can be mapped to different tiers so you can analyze the metrics of the transactions that occur behind the API gateway.

There is a known issue in HTTP backend detection configuration in the current preview. When defining HTTP backend using URL segments, segment enumeration starts with number 2 instead of number 1, and segment 1 always returns empty. For example, to define unique backends using the first two segments of the URL, you would need to configure HTTP backend detection to use the first 3 segments or segment 2 and 3.

Service Proxy Overview

! AppDynamics has identified an issue where Business Transactions have started reporting to all other traffic. Please see [Support Advisory: Business Transactions Reporting to All Other Traffic](#) before enabling Service Proxy Detection.

In Application Performance Management (APM), the service that is called in an application environment is usually identified by specific properties, such as the host or port properties. However in an environment with a gateway or service proxy, the host and port actually identify a *device* instead of the ultimate downstream tier that handles the request.

This inaccurate identification of the backend destination causes the system to periodically change the association of the single backend with one of the potential target downstream tiers to which the gateway could route. This results in the joining of incomplete flow maps and inconsistencies between tiers that are included within Business Transaction snapshots, and the corresponding Business Transaction flow map.

The service proxy identification feature enables the system to resolve and identify the correct backend and displays the correct component structure in the flow map. The service proxy detects these changes in the backend association and instructs the upstream agent to identify the affected backend(s) as a service proxy.

As a result, the flow map will show a service proxy (represented by this icon ) between the upstream and downstream tiers, for example:

The service proxy is also visible in the **Remote Services** list:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Name ↑	Type	Response Time (ms)	Calls	Calls / min	Errors	Errors / min
backendresolution:7900	HTTP	2,004	100	20	0	0

If the upstream agent is an older version than what is currently supported, an event is generated with the following Agent Configuration Error message:

i The service proxy feature is supported on these agents:

- Java Agent $\geq 20.5.0$
- .NET Agent $\geq 21.3.0$
- Node.js Agent $\geq 21.4.0$

Summary Automatic Service Proxy Discovery functionality has minimum agent version requirements for agents upstream of discovered proxies. Please check the documentation for details.

No Actions Executed **i**

The service proxy icon is also available on these flow maps:

- Application Dashboard
- Tiers and Nodes
- Drill Down Backend Node
- Transaction Snapshot (Waterfall View)

Enable Service Proxy Detection

The backend is identified as a service proxy in the Controller.

i

- For *SaaS customers*: To request that your Controller has the service proxy feature enabled, you should work closely with your AppDynamics account representative.
- For *on-premises customers*: To enable the service proxy feature:
 - a. [Access the Controller Administration Console.](#)

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- b. Open the admin.jsp page in the Controller from the url:
`<controllerhost>:<controllerport>/admin.jsp`
- c. Access **Controller Settings**.
- d. Search for these two properties, and set each of them to `true` :
 - `backend.detect.loadbalancer.enabled = true`
 - `backend.detect.urimisconfig.enabled = true`
- e. Save your changes.

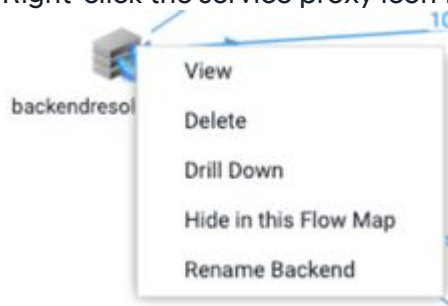

Once the Controller resolves the backend, it then sends the configuration information to the agent.

Delete a Service Proxy

If you remove the service proxy from the infrastructure but continue to use the same host and same port for the downstream nodes, then the service proxy will still show on the flow map. You must manually delete the service proxy to directly resolve the upstream and downstream tiers correctly.

To delete a service proxy for a backend node:

1. Right-click the service proxy icon from the flow map to open a popup menu.

2. Select **Delete**.

Error Detection

You can customize how AppDynamics associates code events with business transaction errors by adding or removing the methods, log messages, HTTP codes, or redirect pages that are configured to indicate business transaction errors.

Permissions

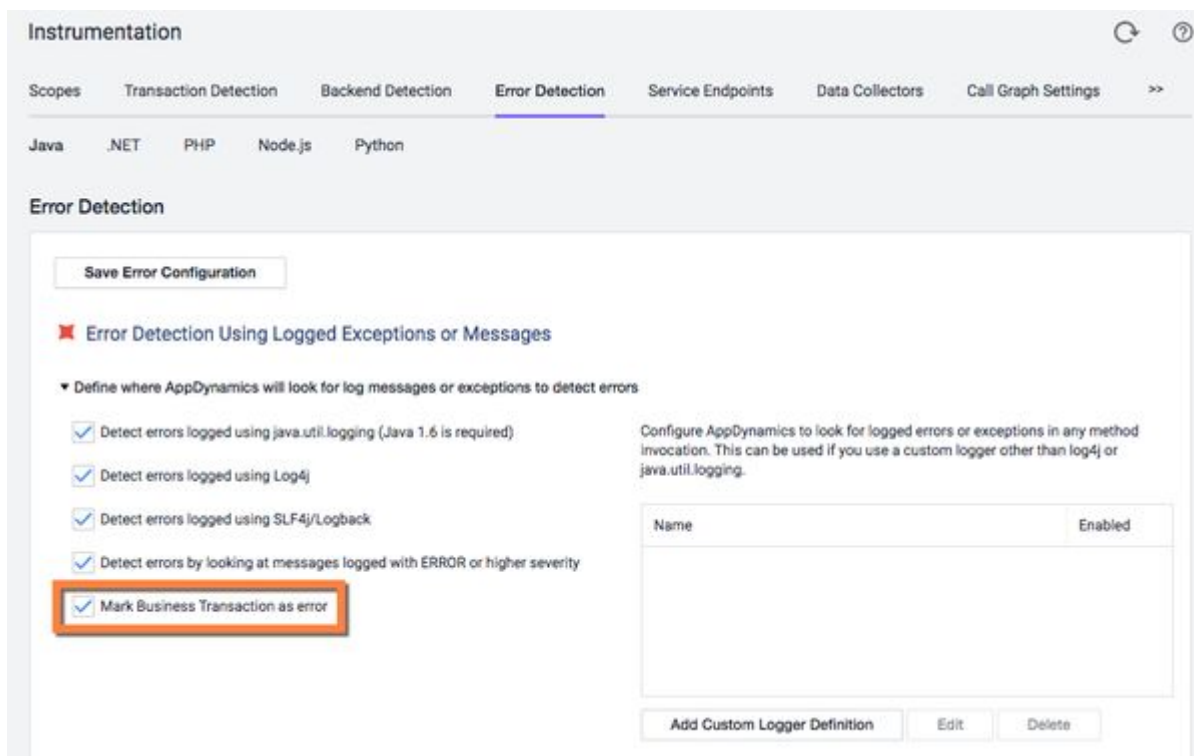

To configure error detection, you need the "Configure Error Detection" permission.

Error Detection Configuration

You can view or modify error detection configuration in the Error Detection tab. In the Controller UI, open an application and navigate to **Configuration > Instrumentation > Error Detection**.

The Error Detection tab takes you to the configurable options for each programming language or platform. You configure settings individually for each language or platform. Some settings are platform-specific. For example, custom loggers and error detection using redirect pages are available for Java and .NET only. Configuration changes made in the Error Detection tab apply to all business transactions for the selected application. You cannot make changes to individual transactions.

To prevent marking transactions as errors, uncheck the **Mark Business Transaction as error** for each applicable language or platform. If unchecked, the transactions are not added to the error count metric and are considered in other metrics, such as response time, despite the occurrence of the error.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Supplement Error Detection

For Java and .NET, you can supplement the methods that AppDynamics considers error methods from common error handling frameworks with your own, custom-defined error methods by defining a custom logger. When the application invokes the method in a business transaction, AppDynamics considers the transaction to be an error transaction for metric purposes.

In the custom logger configuration, you can specify the parameter that contains the exception or error information passed to the method. This information will appear as the error message in AppDynamics, which invokes `toString()` on the parameter to extract the message.

To configure a custom logger:

1. In the Controller UI, on the Error Detection configuration tab, click **Add Custom Logger Definition** in the error configuration panel.
2. Enter a descriptive name for the custom logger definition and use the settings to identify the class name and method for the custom logger. For more information on how to use the AppDynamics UI to identify classes and methods, see [Data Collectors](#).
3. For the **Method Parameter** field, add a parameter definition for each parameter in the signature of the method.
If the method is overloaded, create a logger definition for each form of the overloaded method where you want to detect errors. Your custom method must accept at least one parameter, which should be the parameter that conveys the logged error or exception information.
4. For the **Exception Parameter** field, identify the parameter in the method signature that contains the exception object by index number (0-based).
This parameter, identified by an index, can be any type of object, including Arrays. If the object is not null, AppDynamics converts the object to a string, the result of which constitutes the error details. A business transaction is considered to be an error only if a non-null exception object is passed to the logger method.

Consider the following custom logger class and methods in a .NET application:

- Namespace and class = `Logging.MyLogger`
- `logger.Error(string message, int param1)`
- `logger.Error(string message, int param1, int param2)`

Notice that the `Error` method is overloaded. To capture errors logged in the second form of the method using the first parameter as the error to log. This screenshot illustrates the configuration:

Custom Logger Definition ✕

A custom logger definition needs the method signature with the fully qualified class/interface/super-class/annotation name and the method name. If the method is overloaded, it is recommended that you also specify the fully qualified parameter types.

Name

Enabled

Define the Class and Method Signature

Class equals

Method Name

Method Parameters

:::	Param Index 0	<input type="text" value="System.String"/>	-	^	(i)
:::	Param Index 1	<input type="text" value="System.Int32"/>	-		
:::	Param Index 2	<input type="text" value="System.Int32"/>	-	v	

Specify the parameter index for the exception object

Exception Parameter

Notice that the exception parameter is set to 0, identifying the `string message` method parameter as the error message. When enabled, AppDynamics detects and reports the custom logger.

Detect HTTP Responses or Redirect Pages as Errors

In Java, .NET, Node.js, and Python you can configure errors based on HTTP response codes. If the error code is set as part of business transaction processing, the transaction is marked as an error. For PHP, it is possible to classify transactions as in error based on 4xx HTTP return codes using the [PHP Agent Configuration Settings](#).

By default, AppDynamics captures HTTP error codes from 400 to 505. HTTP response codes may convey errors that occur at the business level of an application. For example, in an e-commerce application, a 522 error might indicate that an item is out of stock. For this case, you may want to include the error as a default transaction error indicator.

To exclude a return code add them to the error detection list by creating a custom error code range and then disabling that error code by clearing its **Enabled** checkbox. This in effect excludes the error code as an error indicator.

Error Detection Using HTTP Return Codes

Detect Errors based on HTTP Return Codes ?

To identify certain HTTP error code(s) as errors and define them as custom error types, add a code or a range of codes against a custom error name. This name would be used in the application error list, and these codes will be used to identify errors in Business Transactions.

Description	Lower Bound (inclusive)	Upper Bound (inclusive)	Enabled
InventoryEmpty Error	522	522	<input checked="" type="checkbox"/>
Do Not Report Error Code	512	520	<input type="checkbox"/>

Add Code **Delete**

For Java and .NET agents, you can specify custom redirect target error pages as error indicators. To specify a redirect page, click **Add Error Redirect Page** and add a name for the configuration and a regular expression to match the URL of the page, such as `AcmeErrorPage.jsp`.

Ignore Exceptions and Log Messages as Error Indicators

Certain types of exceptions, loggers or log messages as transaction error indicators may not reflect events that should be counted as transaction errors in your environment. They may include exceptions raised by application framework code or by user login failures.

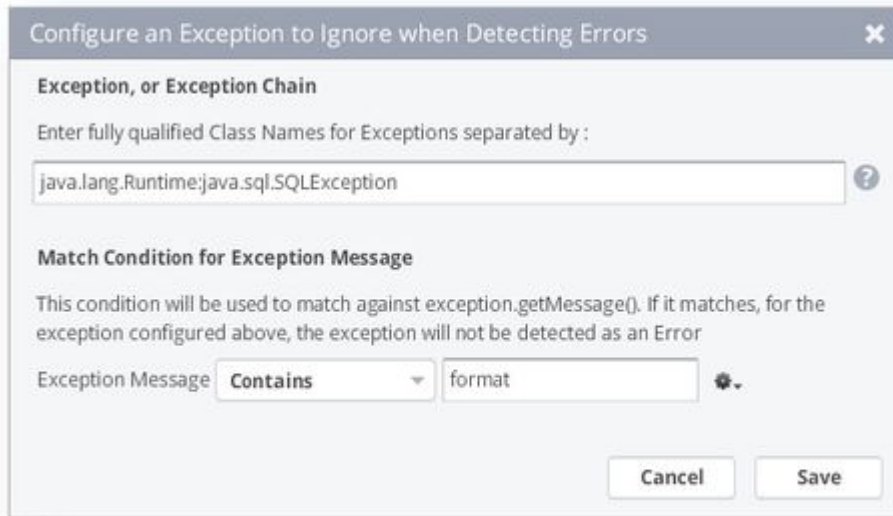

When you configure an exception to be ignored, the agent detects the exception, increments the exception count, and displays the exception in Exceptions lists in the UI, but the business transaction in which the error is thrown is not considered an "error transaction" for monitoring purposes. The transaction snapshot would not show the exception in the Summary or Error Details section and the user experience for the transaction instance would be unaffected by the exception.

To configure exceptions for the agent to ignore, click the **Add New Exception to Ignore** button in the error configuration window.

Enter the class name of the exception to be ignored and the match condition for the exception message. For the match condition, if you do not need to filter for specific messages in the exception, select "Is Not Empty". If you want to filter for Null, select "Is Not Empty" and use the gear icon to select NOT, which, in effect, tests for "is empty".

i The text field for **Match Condition for Exception Message** cannot contain the characters `"`, `<`, `>`, and `&`.

The following example directs the agent to ignore `java.lang.RuntimeExceptions` that wrap a `javax.sql.SQLException` only when the exception.getMessage() call in the root exception contains the string "format". (Other types of `java.lang.Runtime` exceptions will not be ignored.)

When you define the class of an exception to ignore by an exception chain, the exception message against which the match condition is applied must be in the root exception of the chain. The match is not applied to any nested exceptions.

In .NET and Java, you can specify that errors logged with certain loggers or logger categories be ignored. Click **Add New Category/Logger to Ignore**.

Error Detection Notes by Platform

The following sections list error detection configuration and error monitoring considerations, if any, by application platform.

Error Configuration for .NET

By default, the Windows .NET Agents can instrument calls using NLog and Log4Net. They can also gather information from System Trace and the Event Log. Beginning with Agents $\geq 4.5.19$ on Linux, and $\geq 21.2.0$ on Windows, Agents running on .NET Core can also instrument calls using loggers that implement the Microsoft.Extensions.Logging.ILogger API. To instrument calls using other loggers, add a custom logger definition. See [Configuring a Custom Logger](#).

Messages logged as higher than ERROR include severe levels such as CRITICAL or FATAL.

If you do *not* want system trace or event log errors to be monitored, disable them by checking the appropriate box. System trace errors are anything written as an error message to the Listeners collection via TraceError.

Event log errors are anything written to the EventLog when the type is set to error. For example:

```
myEventLog.WriteEntry(myMessage, EventLogEntryType.Error, myID);
```

Error Configuration for PHP

The PHP Agent instruments the PHP reporting facility. PHP applications can use `trigger_error` to report errors through that facility. PHP extensions and PHP itself can also use the PHP facility for reporting errors.

By default, the agent can check for PHP errors using multiple thresholds:

- If you select Error, the agent reports only messages and exceptions marked Error.
- If you select Warning, the agent reports only messages and exceptions marked Error and Warning.
- If you select Notice, the agent reports messages and exceptions marked Error, Warning and Notice.

Error Configuration for Node.js

The Node.js Agent reports exceptions thrown by the Node.js application or by Node.js itself.

You can configure certain exceptions or logged messages not to cause transactions to be reported as errors using the 'Ignored Exceptions' and 'Ignored Messages' lists. See [Ignoring Exceptions and Log Messages as Error Indicators](#).

Error Configuration for Python Notes

By default, the Python Agent reports error transactions for unhandled exceptions, HTTP status codes greater than or equal to 400, and messages logged at ERROR or higher by the Python logging module.

If you do not want any logged errors to cause transactions to be reported as errors, clear the "Mark Business Transaction as error" checkbox. If you do not want to capture logged messages at all, clear the "Detect Errors" checkbox.

You can configure certain exceptions or logged messages not to cause transactions to be reported as errors using the 'Ignored Exceptions' and 'Ignored Messages' lists. See [Ignoring Exceptions and Log Messages as Error Indicators](#).

Service Endpoint Detection

AppDynamics automatically detects [service endpoints](#) for Java applications. You can configure custom service endpoints for Java or .NET to monitor the performance of services.

You can also configure exclude rules for service endpoints, which prevent agents from registering service endpoints for methods that match the exclude rules. The order of precedence for match, exclude and automatic rules are:

1. Exclude rules
2. Custom service endpoint rules
3. Automatic discovery

Permissions

To configure service endpoints your user account must have the Configure Service Endpoints permission for the business application. For information on AppDynamics Role Based Access Control, see [Application Permissions](#).

Configure Custom Service Endpoints

You configure custom service endpoints like you configure custom match rules for business transactions:

1. From the **Service Endpoints** pane, click **Configure**.
2. Click the Custom Service Endpoint tab.
3. Choose the tier on which the service runs and click the plus icon to add a service endpoint configuration. The configuration settings are similar to business transaction entry point configuration settings. See [Custom Match Rules](#).

As you choose a method for a service endpoint, avoid methods that occur within the following programming patterns:

- High-frequency loops, such as a for or while loop.
- Recursive functions.

Service endpoints inside such structures may cause performance overhead. Instead, consider adding a service endpoint at a point in the code upstream from a high-frequency loop or recursive function.

Configure service endpoint exclude rules in the same pane as the custom service endpoints. Click **Is Exclude Rule** on the **New Service Endpoint Definition** pane.

Automatic Discovery for Java

The Java Agent automatically discovers service endpoints. To configure service endpoint automatic detection settings, click to **Configure** on the **Service Endpoints** pane. You can configure the following settings:

- For existing service endpoint detection rules, you can enable or disable the detection rule.
- For servlet service endpoints, you can modify automatic naming as you would with servlet business transactions.

POJO Service Endpoints

For the Java Agent to detect Plain Old Java Objects (POJO) service endpoints, you must do the following:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- Create at least one POJO custom service endpoint definition and enable it. The agent only detects POJO service endpoints for enabled custom service endpoint definitions.
- Verify automatic discovery for POJO service endpoints is enabled. It is enabled by default.

 When you disable automatic discovery for POJO service endpoints, the agent doesn't detect custom service endpoints.

Asynchronous Worker Thread Service Endpoints

The Java Agent automatically detects asynchronous worker threads spawned within a transaction as service endpoints. The agent names worker thread service endpoints for the class name, for example, "worker1". There is no end-to-end latency metric for worker thread service endpoints.

To disable worker thread service endpoints, register the `enable-async-service-endpoints` app agent node property with a value of "false". See [App Agent Node Properties](#).

Configure Service Endpoints for .NET

The .NET Agent doesn't automatically discover service endpoints. To define a custom service endpoint for .NET, navigate to **Configuration > Instrumentation > Service Endpoints > Custom Service Endpoints**. Define the service endpoint as you would a custom match rule for a business transaction. See [Service Endpoints](#) and [Transaction Detection Rules](#).

You can create service endpoints for the following entry point types:

- ASP.NET
- Message Queues
- POCO
- WCF
- Web Service

 The .NET Agent doesn't support service endpoints for MSMQ.

By default, you need to restart the instrumented application for instrumentation changes such as adding a POCO service endpoint to take effect. You can [enable Runtime Reinstrumentation](#) for the .NET Agent so that you don't need to restart your application and the `AppDynamics.Agent.Coordinator` after instrumentation changes.

After you configure a custom service endpoint, you can monitor it on the service endpoint dashboard that shows KPIs and transaction snapshots where the service endpoint executed. You can also use the metric browser to analyze service endpoint performance. See [Service Endpoints](#).

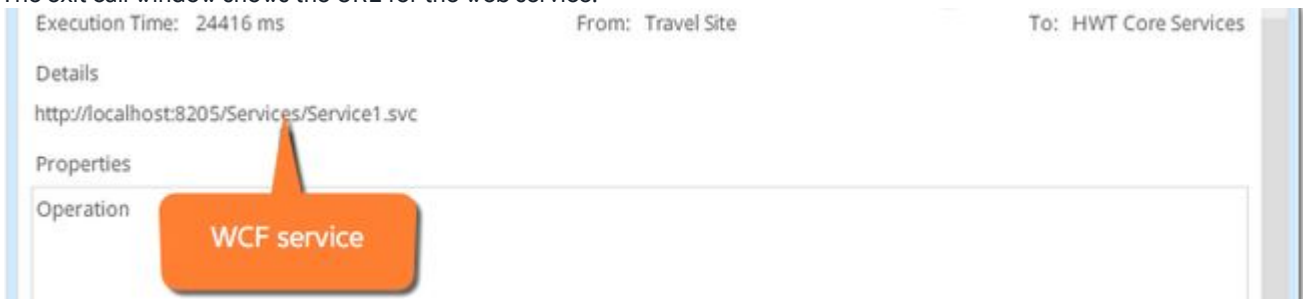

Tips for Defining .NET Service Endpoints

The methods that serve as the entry points for business transactions are often the same methods that you want to monitor as service endpoints as well. You can create service endpoints on the originating entry point for a business transaction.

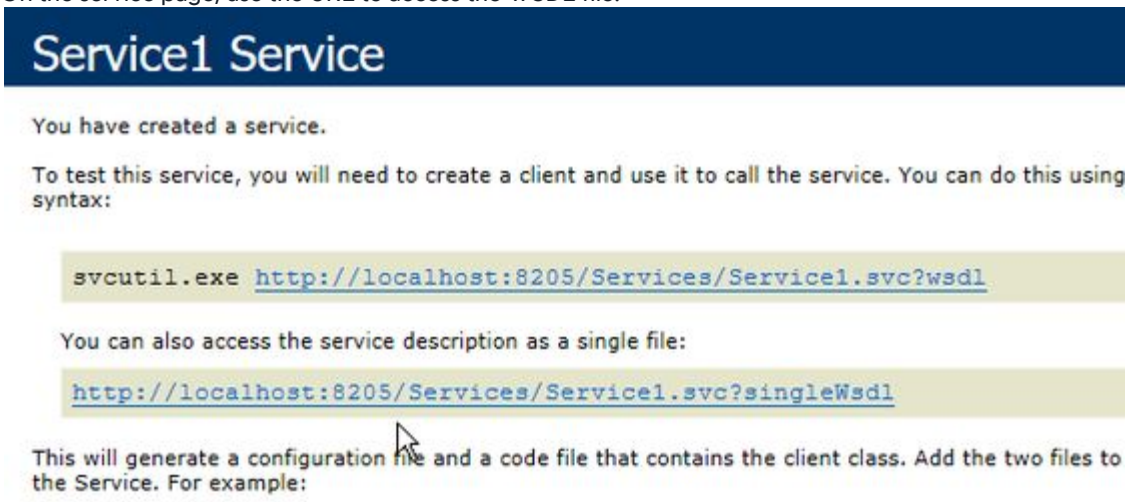

- For ASP.NET service endpoints, you can use the URL to define the service endpoint. For example, in the Travel Site tier above, set a URL match to `"/Travel/Search"`
- For WCF and ASP.NET web service entry points, you can use an existing transaction snapshot to find the URL for the service.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- a. Open a full transaction snapshot for the business transaction.
- b. From the upstream tier, click the exit call link, either **WCF** or **Web Service**.
The exit call window shows the URL for the web service.

- c. Open the service URL in a browser.
- d. On the service page, use the URL to access the WSDL file.

- e. The `<wsdl:service name="Service1">` element shows the service name.

```
<wsdl:service name="Service1">
```

- Define POCO service endpoints exactly as you would a POCO custom match rule for a business transaction.

Data Collectors

Works with:

You can use data collectors to supplement business transaction and transaction analytics data with application data. The application data adds context to business transaction performance issues. For example, they may show the values of particular parameters or return values for business transactions affected by poor performance.

This data shows the business context affected by performance issues, such as the specific user, order, or product.

Types of Data Collectors

There are two types of data collectors:

- Method invocation data collectors - Capture code data, such as method arguments, variables, and return values.
- HTTP data collectors - Capture the URLs, parameter values, headers, and cookies of HTTP messages exchanged in a business transaction.

See [Collect Transaction Analytics Data](#).

View Collected Data

When applied to business transactions, the data collectors supplement the information shown in transaction snapshots. The information captured by HTTP data collectors appears in the HTTP DATA and COOKIES sections, while method invocation data appears in the Business Data section.

To view collected data:

1. Navigate to the **Transaction Snapshots** pane.
2. Double-click the transaction for which you want to view data for.
3. Click **Data Collector** to view collected data.

Configure a Data Collector

To configure data collectors, you need the Configure Diagnostic Data Collectors permission. Follow these steps to configure a data collector:

1. Identify the method on which to capture data. To do this, define the method signature and (optionally) filters based on the value of a code point in the method (such as, return value or argument).
2. Specify the actual code point that serves as the source of the data.
3. If the data collector applies to business transactions, then select the applicable business transactions.

When creating a data collector, you typically need to know the code on which you are setting up the collector, and whether it is based on access to the source code for the application, or its documentation. For the JVM 1.5 and .NET application environments, you must restart the JVM or application server if your method invocation data collector results in modifications to instrumentation configuration (class name, method name, method parameters, and so on).

These platform-specific considerations apply to data collectors:

- For C/C++ SDK: Create a method data collector using the `appd_bt_add_user_data function()`, not the Controller UI as described here. See [C/C++ SDK Reference](#).
- For Node.js Agent: Create a method data collector using only the `addSnapshotData()` Node.js API, not the Controller UI as described here. See [Node.js Agent API Reference](#).
- For Python Agent: Create a method data collector using the `add_snapshot_data()` Python Agent API, not the Controller UI. See [Python Agent API Reference](#).
- For PHP method data collectors, only the **with a Class Name that** option is valid. You cannot add a method data collector to a standalone PHP function.

Configure a Data Collector Automatically

You can add a data collector directly from a transaction snapshot through the call graph. This automatically adds the class and method for you.

1. Double-click a call graph.
2. Drill down to the node you want.
3. Right-click the method you want.
4. Click **Configure Instrumentation for this Class/Method**.
5. Complete the wizard.

Configure a Data Collector Manually

Data collectors can be manually configured in at least two ways.

From the left pane:

1. Click **Configuration** in the left pane.
2. Click **Instrumentation**.
3. Click the Data Collectors tab, and click **Add** below the data collector box for the type of data collector you want to add. The data collector configuration panel displays.

From a call graph:

1. Double-click a call graph.
2. Click **Data Collectors** in the menu bar.
3. Click **Actions**.
4. Click **Configure Data Collectors**.
5. Click **Add** at the bottom of the data collector box for the type of data collector you want to add. The data collector configuration panel displays.

Note the following platform-specific considerations applicable to data collectors:

- C/C++ SDK - Create a method data collector using the `appd_bt_add_user_data function()`, not the Controller UI as described here. See [C/C++ SDK Reference](#).
- Node.js Agent - Create a method data collector only using the `addSnapshotData()` Node.js API, not the Controller UI as described here. See [Node.js Agent API Reference](#).
- Python Agent - Create a method data collector using the `add_snapshot_data()` Python Agent API, not the Controller UI. See [Python Agent API Reference](#).
- PHP method data collectors - Only the "with a Class Name that" option is valid. Also, you cannot add a method data collector to a standalone PHP function.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

The general steps for configuring a data collector are:

1. Identify the method on which to capture data. To do this, define the method signature and (optionally) filters based on the value of a code point in the method (such as return value or argument).
2. Specify the actual code point that serves as the source of the data.
3. If the data collector applies to business transactions, choose the applicable business transactions.

Typically, creating a data collector requires knowledge of the code on which you are setting up the collector, whether based on access to the source code for the application or its documentation. For some application environments, including JVM 1.5 and .NET, you will need to restart the JVM or application server if your method invocation data collector results in modifications to instrumentation configuration (class name, method name, method parameters, and so on).

Configuration Notes

- The **Apply to new Business Transactions** option applies the collector to business transactions created after you have configured the data collector. Otherwise, the data collector applies only to the business transactions you select in the subsequent data collector configuration pane.
- For **Class**, select the match condition that the data collector can use to identify the class, such as class name, implemented interface name, and so on. If matching by class name, then use the fully qualified name of the class, as appropriate for the application platform. For example, the form of the equals field value would be:
 - In Java: `com.appdynamics.model.Item`
 - In .NET: `Bookstore.Item`
 - In PHP: `book`
- **Is this Method Overloaded:** If this is an overloaded method, then add parameters that identify the signature. You must create a data collector definition for each form of the method for which you want to capture data. For example, given the overloaded method in this table, to capture data for only the second two forms, you would need to create two data collectors. The parameters to configure are shown:

Signature	Parameters to Configure
<code>getName()</code>	◦ None
<code>getName(int studentId)</code>	◦ Param Index 0: java.lang.int
<code>getName(int studentId, string name)</code>	◦ Param Index 0: java.lang.int ◦ Param Index 1: java.lang.String

- You can refine the method selection to meet specific conditions. If you configure more than one match condition, then all match conditions must be satisfied by the request for the data collector to be applied to the request.
- Once you identify the method, specify the code point from which you want to capture data, such as the method return value, argument, or a value captured by the getter chain on the invoked object. Configure this code point in the **Specify the Data to Collect from this Method Invocation** section of the configuration settings.
- HTTP data collector can capture data from HTTP parameters, request attributes, cookies, and other data. Notice that the Content-Length HTTP header is already captured in AppDynamics as the Average Request Size metric. However, you may choose to configure a data collector for this header to have the value appear in transaction snapshots, providing you insight into, for example, whether message size corresponds to slow performance.
- You can configure multiple data collectors. The effect of multiple data collectors is cumulative. For example, if you add a custom data collector that does not include the collection of the URL HTTP request attribute, but keep the Default HTTP Request Data Collector configuration in which the URL is configured to be collected, then the URL is collected.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Method Invocation Data Collector Example

Method invocation data collectors are applicable to Java and .NET.

In this example of a manual setup (not using the wizard), we'll set up a method invocation data collector on a Java application. We want to create a data collector on the method `getCartTotal()`, which is shown in this code snippet with the method `getUser()` and which we will use later as a data source.

```

package com.appdynamicspilot.model;
...
public class Cart implements java.io.Serializable {
    ...
    private Double fakeAmount = 0.0;
    ...
    private User user;
    ...
    public User getUser() {
        return user;
    }
    ...
    public Double getCartTotal() {
        if (fakeAmount == 0.0) {
            double total = 0;
            if (items != null) {
                for (Item item : items) {
                    total += item.getPrice();
                }
            }
            return total;
        }
        return fakeAmount;
    }
    ...
}

```

To configure a data collector for an application, add a data collector and then configure it:

1. When you add your data collector, make your selections as appropriate for your configuration.
2. Add a class and a method, if not already filled in. Class and Method Name are used to identify the method.
3. At the **Enable Data Collector** for checkboxes, select **Transactions Snapshots** to add metadata for troubleshooting purposes and for APM snapshots, or select **Transaction Analytics** to collect metadata about every execution of the transaction to use later in the analytics platform. It is recommended that you start with **ONLY Transactions Snapshots**. Enable Transactions Analytics after the targeted data collection is confirmed.
4. Click **Add Parameter** or **Add Match Condition** to select the correct parameter from the popup.

- a. Method Parameters are added if the method is overloaded. Clicking **Add Parameter** adds the Param Index 0. Add the fully qualified class name for the parameter.
- b. Match Conditions allow you to pick specific data when a method or line of code is called multiple times. Match Conditions engage method parameters or return values. Selecting **Add Match Condition** opens the Create Match Condition popup. Make your selections, and then click **Save**.
- c. When setting up your data collector, note the checkbox beside **Apply to new Business Transactions**.
 - i. Checking this box automatically applies the rule to new business transactions.
 - ii. Not checking this box requires you to manually apply the rule to business transactions by navigating to **Configuration > Instrumentation > Data Collectors**.
- d. To add multiple collection types, click **Add** beneath Specify the Data to Collect from this Method Invocation to configure the source of data. For this section of code, use an invoked object and a getter chain of `user.getCustomerName`. This code snippet is an example of how to capture the user name on the invoked object. The `Cart` class instantiates a `User` object based on the following class in the same package as `Cart`. Note that the `User` class includes a method for returning the name of the user, `getCustomerName()`.

```
package com.appdynamicspilot.model;
...
public class User implements java.io.Serializable {
    ...
    private String customerName = null;
    ...

    public String getCustomerName() {
        return customerName;
    }
    public void setCustomerName(String customerName) {
        this.customerName = customerName;
    }
    ...
}
```

Using a getter chain, you can identify this method as another data source in the same data collector. For example, you could select **Invoked Object** as the source of the data. The getter chain `getUser().getCustomerName()` is the operation on the invoked object.

For the PHP agent, if a method return value collected by MIDC is not stored in any variable, it is seen as null in both snapshot and Analytics data.

5. When finished, click **Save**.

After you configure the method invocation data collectors, you can click **Configure Transactions using this Data Collector** on the Instrumentation pane to drag and drop (or highlight and move) the transactions to a given data collector.

When complete, transaction snapshots for slow, very slow, and stalled transactions, the transaction snapshots will include the specified user data.

HTTP Data Collector Example

In the HTTP Data Collector configuration, specify the request data that you want to display in the snapshot.

To configure a data collector, add a data collector and then configure it:

1. Make your selections as appropriate for your configuration.
2. Determine if you are collecting parameters, cookies, session keys, or header data.
3. Click **+Add** beneath a data type to specify the request data that you want to display in the snapshot, and fill in as appropriate.

When setting up your data collector, note the checkbox beside **Apply to new Business Transactions**.

- a. Checking this box will automatically apply the rule to new business transactions.
 - b. Not checking this box requires you to manually apply the rule to business transactions by navigating to **Configuration > Instrumentation > Data Collectors**.
4. When finished, click **Save**.

Call Graph Settings

Related pages:

- [Transaction Thresholds](#)
- [Transaction Snapshot Collection](#)

Works with:

You can control the data captured in call graphs with the **Call Graph Settings** panel.

Permissions

To configure call graph settings, you need the **Configure Call Graph Settings** permission.

Call Graph Granularity

To control the granularity for call graphs, use the following settings:

- **Control granularity for Methods:** To ensure low-performance overhead, choose a threshold in milliseconds for method execution time. Methods taking less than the time specified here are filtered out of the call graphs.
- **Control granularity for SQL calls:** You can specify a threshold for SQL queries. SQL queries taking less than the specified time in milliseconds are filtered out of the call graphs. See [Tune Java Agent Performance](#).

i Only SQL Capture Settings apply to call graph configuration for the Node.js agent.

To access call graph configuration, click **Configuration > Instrumentation** and choose the Call Graph Settings tab. There are subtabs for each application type.

Exclude Packages or Namespaces from Call Graphs

A call graph can potentially contain hundreds of methods. You can exclude packages (Java) or namespaces (.NET) with classes that you do not want to monitor.

For Java, some packages are excluded by default. These are visible in the Excluded Packages list. The packages that are excluded by default cannot be removed. However, you can include a particular sub-package from an excluded package.

You can customize call graph instrumentation from the call graph instrumentation page. From there, choose from these configuration options:

- Use the **Add Custom Package Exclude** (Java) or **Add Custom Namespace Exclude** (.NET) configuration options to exclude specific packages or namespaces from call graphs.
- Use the **Add Always Show Package/Class** (Java) or **Add Always Show Namespace/Class** (.NET) configuration options to have a package or namespace always shown in call graphs.

When the Controller constructs a call graph it uses excluded packages and included sub packages to determine which calls to include. However, the Controller includes some calls even if they are listed among the excluded packages. For example, web service calls.

SQL Capture Settings

The SQL capture settings control whether SQL statements are captured and presented in the Controller UI with dynamic parameters bound to their runtime values. For example, consider Java code that constructs a SQL call as follows:

```
stmt = new PreparedStatement("select * from user where ssn = ?")
stmt.bind(1, "123-123-1234")
stmt.execute()
```

With the capture raw SQL option enabled, AppDynamics captures and presents the SQL call in the following form:

```
select * from user where ssn = '123-123-1234'
```

If capture raw SQL is disabled, the SQL call appears in its original form, with question mark parameters not bound to values. Disabling capture-raw-sql and using question mark parameters in SQL prepared statements gives you a mechanism for preventing sensitive data from appearing in the Controller UI.

It is important to note that the sensitive values must be parameterized in the original, prepared statement form of the SQL statement, as shown above. The following statement results in the potentially sensitive information (social security number) appearing in the Controller UI whether capture raw SQL is enabled or disabled since the sensitive data is not parameterized.

```
stmt = new PreparedStatement("select * from user where ssn = '123-123-1234'")
```

To configure SQL capture settings, in the Call Graph Settings tab, scroll down to the **SQL Capture Settings** section and choose one of the following options:

- **Capture Raw SQL:** Select this option to have SQL statements that are composed as prepared statements captured with dynamic parameters bound to runtime values. By default, private SQL data and queries that take less than 10 ms are not captured.

Important

You can select this option to capture raw query details for NoSQL databases such as MongoDB, DynamoDB, and CassandraDB and the relational queries will not be scrubbed.

When you enable Capture Raw SQL in .NET environments, the agent captures the parameters for ADO.NET stored procedure calls even though the parameters are not represented by question marks. It does not capture stored procedure local variables that are not available to the CLR.

- **Filter Parameter values:** Select this option to have SQL statements that are composed as prepared statements captured without dynamic parameters bound to runtime values.

Configure JMX Metrics from MBeans

Related pages:

- [Exclude JMX Metrics](#)

This page describes how to create persistent JMX metrics from MBean attributes. See [Monitor JMX](#).

There are many helpful [JMX topics](#) on the AppDynamics community to help you with platform-specific troubleshooting tips.

JMX Metric Rules and Metrics

You can add persistent JMX-based metrics to AppDynamics using metric rules. Once you create a persistent JMX metric, you can:

- View it in the Metric Browser.
- Add it to a Custom Dashboard.
- Create a health rule for it so that you can receive alerts.

You can use the MBean Browser or JMX Metrics Rules Panel to create new metrics. MBean query expressions are supported.

You must have Configure JMX permissions for the application to configure new JMX Metrics your user account. See [Manage Custom Roles](#).

Access the MBean Browser

If the MBean is already monitored and you want to create a metric from one of its attributes, you can do so from the MBean Browser.

To create a metric from an existing MBean attribute:

1. Open the Node Dashboard of the node that hosts the MBean, and navigate to **MBean Browser > JMX**.
2. Expand the domains listed in the left panel and select the MBean that contains the attribute of interest.
3. Expand the **Attributes** section, select the attribute, and click **Create Metric**.

Configure JMX Metric Rules

1. Navigate to **Configuration > Instrumentation > JMX** to add an MBean and attributes, possibly based on complex matching patterns.
2. From the JMX Metric Configurations panel, click the Java platform to add the metric to a platform group.
3. Alternatively, create a new group and add your metric to the group.
Groups allow you to organize metrics to meet your needs. For example, you may choose to keep custom metrics with their Java platform, or put all metrics you add into a Custom group to differentiate them from out-of-the-box metrics.

JMX Metric Settings

The general settings for adding instrumentation for an MBean are:

- The **Name** is the identifier you want to display in the UI for the MBean.
- An **Exclude Rule** excludes matched MBeans that would otherwise be included by other rules. See [Exclude MBean Attributes](#).
- **Enabled** means that you want this rule to be applied.
- The **Metric Path** determines where the metric appears in the metric browser. For example, in the screenshot below, the metric path is "Web Container Runtime" for JMX metric "Tomcat_HttpThreadPools".

In the MBeans subpanel, add matching criteria to identify the MBeans that you want to monitor.

- The **Domain name** is the Java domain. This property must be the exact name; no wildcard characters are supported.
- The **Object Name Match Pattern** is the full object name pattern. The property may contain wildcard characters, such as the asterisk for matching all the name/value pairs. For example, specifying `jmx:type=Hello,*` matches a JMX MBean `ObjectName, jmx:type=Hello,name=hello1,key1=value1`.
- The **Instance Identifier** is the MBean ID. Instance Identifier is a field in the JMX Object pattern that can be used to categorize the runtime context of MBean category that has the same set of attributes. For example, the user category has two HTTP ports: 8090 and 8181. But attributes such as `currentThreadsBusy` and `maxThreads` are the same. If a JMX pattern has both HTTP and AJP, but the user is interested in monitoring only HTTP and not AJP thread pool, then the user uses an identifier, a name that matches HTTP so that only HTTP ports related MBean data is collected.
- **Advanced MBean Matching Criteria** is an optional control for matching against attribute values. Identify the attribute name and value to test, along with matching criteria, such as a substring match.

Without any instance identifier specified, a tree of resources or attributes is shown on the JMX Metric browser that matches the Object Name Match Pattern.

For example:

```
JMX -->
  ConnectionPoolModules
    ConnectionPoolA
      PoolSize
    ConnectionPoolB
      PoolSize
```

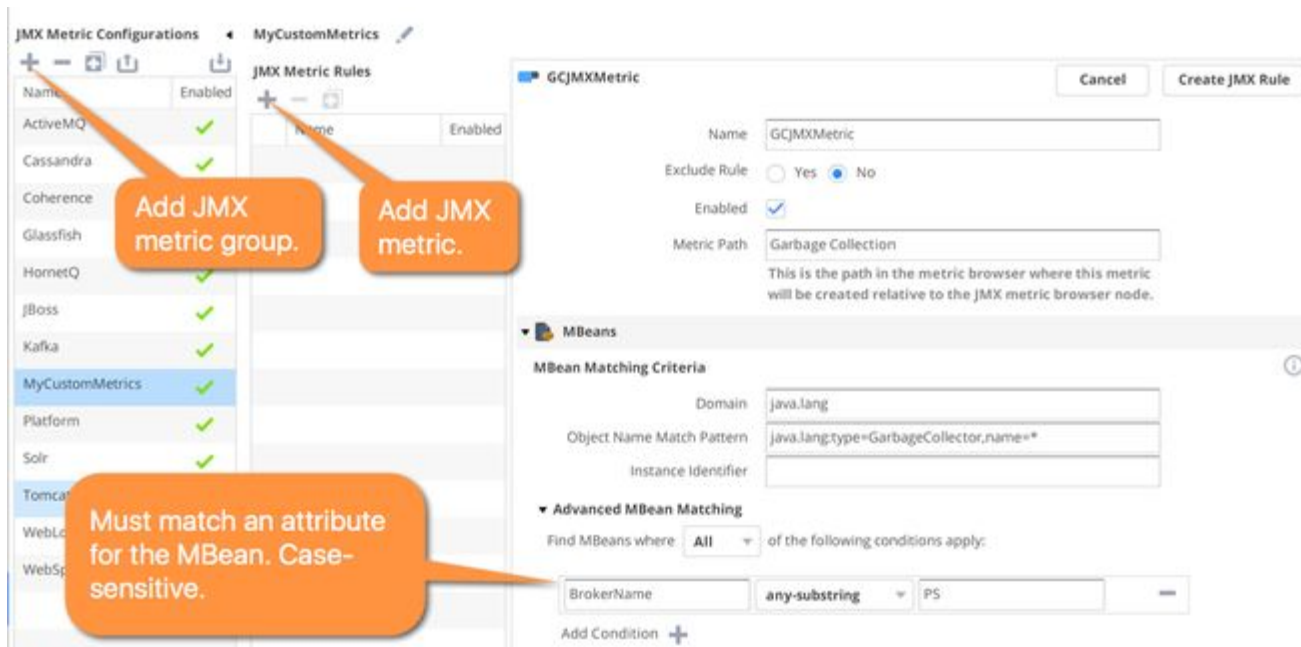

If you specify an `instanceIdentifier` like `instance identifier = path2`, it will show the second level attributes on the top level also.

The above tree will be shown as in the following example. The `PoolSize`, which is in the second level, also appears in the top level.

```
JMX -->
  ConnectionPoolModules
    PoolSize
  ConnectionPoolA
```

For example, this screenshot displays the MBean matching criteria for the GCJMXMetric rule.

For all matched MBeans, you can define one or more metrics for the attributes of those MBeans:

- **Metric Getter Chain**—Expressions can be executed against any value. In addition, getter chains for Strings and Booleans are supported using implicit conversion. See [MBean Getter Chains](#).
- **Metric Time Rollup**—Determines how the metric will be aggregated over a period of time. You can choose to either average or sum the data points, or use the latest data point in the time interval.
- **Metric Cluster Rollup**—Defines how the metric will be aggregated for a tier, using the performance data for all the nodes in that tier. You can either average or sum the data.
- **Metric Aggregator Rollup**—Defines how the Agent rolls up multiple individual measurements (observations) into the observation that it reports once a one minute. For performance reasons, Agents report data to the Controller at one-minute intervals. Some metrics, such as Average Response Time, are measured (observed) many times in a minute. The Metric Aggregator Rollup setting determines how the Agent aggregates these metrics. You can average or sum observations on the data points or use the current observation. Alternatively, you can use the delta between the current and previous observation.

For example, the maxThreads MBean attribute is mapped to the Maximum Threads metric in the JMX metrics browser as shown here:

MBean Attribute	<input type="text" value="maxThreads"/>
Metric Name	<input type="text" value="Maximum Threads"/>
▶ Advanced	
MBean Attribute	<input type="text" value="currentThreadCount"/>
Metric Name	<input type="text" value="Current Threads in Pool"/>
▶ Advanced	
Add Attribute +	

Export and Import JMX Configuration

After you modify the JMX configuration, you can backup or transfer the configuration using the JMX Configurations export and import icons at the top of the JMX Metric Configuration panel on the JMX instrumentation page. The configuration exports as an XML file.

Deactivate Transaction Monitoring for JMX Monitored Nodes

In some circumstances, such as for monitoring caches and message buses, you want to collect JMX metrics without the overhead of transaction monitoring.

You can do so by turning off transaction detection at the entry point. See [Transaction Detection Rules](#).

MBean Getter Chains

Getter chains in custom MBean configuration specify the method that retrieves the value of interest.

Expressions can be executed against any value. In addition to getter chain support for numeric boxed primitives (Short, Integer, Long, and so on), Strings and Booleans are supported using implicit conversion.

Boolean and String are implicitly converted to an Integer:

- Booleans are automatically converted to 0 (false) and 1 (true).
- Strings are converted to numeric values.

This example illustrates how to use a getter chain, given the class with a `getSomething()` method that returns the time:

```

1 package com.appdynamics.flexibleapp.mbean;
2
3 public class MyComplexObject
4 {
5     public long getSomething()
6     {
7         return System.currentTimeMillis();
8     }
9 }

```

In this example the metric getter chain configuration would be:

The screenshot shows the configuration interface for a custom metric. On the left, a list of application servers is shown with green checkmarks, and 'MyCustomMetrics' is selected. The main configuration area is divided into two sections:

- MBeans:**
 - MBean Matching Criteria:**

 - Define Metrics from MBean Attribute(s):**
 - MBean Attribute:
 - Metric Name:
 - Advanced:**
 - Metric Getter Chain: ⓘ
 - Metric Time Rollup: ⓘ

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Exclude JMX Metrics

This page describes how to exclude MBean attributes from being monitored as JMX metrics. For background information about JMX metrics, see [Monitor JMX](#).

Customize Metrics To Gather

AppDynamics provides a default configuration for certain JMX metrics. However, in situations where an environment has many resources, there may be too many metrics gathered. AppDynamics lets you exclude resources and particular operations on resources.

Exclude a Metric

For example, suppose you want to exclude monitoring for HTTP Thread Pools. Follow the procedure described in [Create a new JMX Metrics Rule](#), using the following criteria:

1. Set the **Exclude Rule** option to **Yes**.
2. Provide the **Object Name Match Pattern**:

`Catalina:type=ThreadPool, *`

3. Provide the **Advanced MBean Matching** value:

`http`

This configuration directs AppDynamics to stop monitoring metrics for HTTP Thread Pools. You can clear the **Enabled** checkbox to disable the rule.

Exclude MBean Attributes

Some MBean attributes contain sensitive information that you do not want the Java Agent to report. You can configure the Java Agent to exclude these attributes using the `<exclude object-name>` setting in the `app-agent-config.xml` file.

To exclude an MBean attribute:

1. Open the `AppServerAgent/conf/app-agent-config.xml` file.
2. The new configuration takes effect immediately if the `agent-overwrite` property is set to `true` in the `app-agent-config.xml`. If `agent-overwrite` is `false`, which is the default, then the new configuration will be ignored and you have to restart the agent. Set the property to `true`.

```
<property name="agent-overwrite" value="true"/>
```

3. Locate the `JMXService` section. It looks like this:

```
<agent-service name="JMXService" enabled="true">
```

4. In the `JMXService <configuration>` section add the `<jmx-mbean-browser-excludes>` section and the `<exclude object-name>` property as per the instructions in the comment.

```
<configuration>
  <!--
    Use the below configuration sample to create rules to
    exclude MBean attributes from MBean Browser.
    <exclude object-name=<MBean name pattern> attributes=<
  * |comma separated list of attribute names> >
    The example below will exclude all attributes of
    MBeans that match "Catalina:*".
    <jmx-mbean-browser-excludes>
      <exclude object-name="Catalina:*" attributes="*" />
    </jmx-mbean-browser-excludes>
  -->
</configuration>
```

5. Save the file.

JMX Logging

JMX logs contain information about JMX interactions between AppDynamics agents and the monitored server's JMX domains.

JMX log entries are useful for diagnosing problems associated with JMX metrics or with JVM metrics that rely on JMX. For example, they can help you determine why MBeans or metrics created from MBeans do not appear in the Controller UI.

The name of the log is `JMXYear_mon_day_hr_min.#.log`, where # is the log set. See [Agent Log Files](#) for information about the structure of the log files into sets.

The JMX log file can reach a maximum of 5MB within a set.

Collecting JMX log (sample):

```
<ADRRFAAppender name="JMXLogger" fileName="JMX.log">
  <PatternLayout pattern="[%t] %d{DATE} %5p - %m%n" />
  <SizeBasedTriggeringPolicy size="20 MB" />
  <ADRollerStrategy max="5" />
</ADRRFAAppender>
```

```
<AsyncLogger name="com.singularity.JMX" level="info"
additivity="false">
  <AppenderRef ref="JMXLogger" />
</AsyncLogger>
```

These configurations can be used in `log4j2.xml` file.

Asynchronous Transaction Demarcators

To monitor end-to-end transaction performance for an asynchronous transaction, you must identify the demarcator for the transaction's logical endpoint. There are two ways you can define a transaction demarcator:

- For Java applications, you can specify a tier on which the end to end transaction processing is completed. This lets you determine the logical transaction response time for transactions that perform asynchronous backend calls (such as JMS calls or web service calls). When the last of the threads spawned by the transaction terminates on that tier, the agent considers the transaction complete.

The Java Agent uses patent-pending heuristics to determine when the last thread associated with the Business Transaction has run. These heuristics are successful for many common cases. In complex environments with many thread handoffs unconstrained by frameworks, these heuristics may be inaccurate. For example Reactive Java, AKKA, or Scala environments.

You should validate that the last thread on tier mechanism returns an end to end time consistent with the end to end latency shown within full transaction snapshots.

- For Java or .NET applications, you can identify the method that acts as the logical endpoint for the transaction processing sequence. For a response handler, this could be a method that watches for spawned threads to complete and when done, assembles the response and sends it back to the client. The end to end transaction time includes the time it takes for this configured method to finish processing, not when the method is invoked.

You may specify more than one endpoint demarcator for a particular business transaction. In this case, the first match ends the transaction for purposes of end-to-end latency monitoring. Be careful not to configure multiple demarcators that could be satisfied on different tiers for a given transaction.

For the last thread on tier demarcator type, the transaction endpoint is considered to be the time when the thread that receives the traced transaction terminates or the latest points at which any descendant threads terminate.

For the method-based transaction demarcator option, you can configure the demarcator to consider runtime state, such as the values of parameters passed to the method. This allows you to account for an application design in which the completion of a logical business transaction is signaled by the value of a method parameter or return value.

For .NET POCO entry point on methods that return a `Task` class, AppDynamics tracks the return of the task object as an end to end latency transaction automatically. You can configure your own transactions as end to end transactions for Java and .NET applications as described here. See [POCO Entry Points](#) for information on `Task`-based POCO entry points.

To create the configuration:

1. Open the **Configuration > Instrumentation** page and choose **Asynchronous Transactions** from the top menu. You likely need to expand the menu list (>>) to view the **Asynchronous Transactions** item.
2. Click **Add** and choose the demarcator method:
 - Java only: **Transaction is complete when last thread on specified Tier is finished running.**
 - Java or .NET: **Transaction is complete when specified class/method is invoked.**
3. Follow the instructions that display for the option you choose. Note the following points:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

-
- You configure the class/method option using the standard method selector. See [Configure Instrumentation](#) for more information about identifying classes and methods in the AppDynamics configuration.
 - For the last thread on the tier approach, first, give a name for the transaction configuration and choose the tier.

4. Choose the business transaction where the configuration applies.

The threads in the logical transaction processing flow must be traceable by AppDynamics, including the thread that contains the end-point method. If needed, configure custom thread correlation to ensure that all threads are properly traced. For more information on thread correlation, see [Configure the Thread Correlation in Java Agent](#) and [Thread Correlation for .NET](#).

Automatic Instrumentation of Specialist Packages/Frameworks

Related pages:

- [Transaction Detection Rules](#)
- [Backend Detection Rules](#)

One of the goals of the AppDynamics Application Performance Management (APM) Platform is to provide maximum visibility into Enterprise IT systems for the minimum of set-up effort.

To achieve this, AppDynamics configures its agents to place instrumentation on entry points, exit points, and thread hand-offs right out of the box. The user interface facilitates configuring naming rules for transactions and backends.

Within this documentation, you can find pages about Supported Environments, Transaction Detection, and Backend Detection for many common frameworks (including servlet, JAX-RS, and JDBC) and many HTTP clients.

In addition, the following pages describe the specialized out-of-the-box configuration for instrumenting off-the-shelf products, packages, or frameworks whose entry and exit points are too complex for the more general documentation:

- [IBM-BPM Support](#)
- [Spring Batch Support](#)
- [OSB Support](#)
- [Open Tracing Support](#)

IBM-BPM Support

IBM® Business Process Manager (IBM BPM) is a comprehensive business process management platform. It provides tools to enable authoring, testing, and deployment of business processes, as well as management capabilities. See [IBM documentation](#).

IBM BPM 8.5.7 is used to define and execute Business Process Definitions (BPDs) which combine elements of human interaction Client-Side Human Services (CSHS) or 'user tasks' for example, manual loan approvals and so on with elements of system integration system tasks, for example, registering a loan approval in a CRM system and so on. These processes are critically important and it is, therefore, natural to use AppDynamics Business Transactions to monitor the system integration elements of the processes to ensure the performance and reliability of these technical integrations. You can also use the AppDynamics Business Journeys capability to monitor the end-to-end progress of the processes, including the elements of human interaction.

AppDynamics Instrumentation Use Cases

To facilitate these monitoring use cases, the AppDynamics agent provides out-of-the-box configuration necessary to:

- Appropriately start and name Business Transactions originated within IBM BPM to allow management of system tasks with App iQ APM
- Correlate the processing within IBM BPM to facilitate end-to-end tracing of these Business Transactions
- Collect sufficient process metadata to allow these Business Transactions to be used within Business Journeys to provide visibility into the progress of processes including the human interactions

Agent Installation and Setup

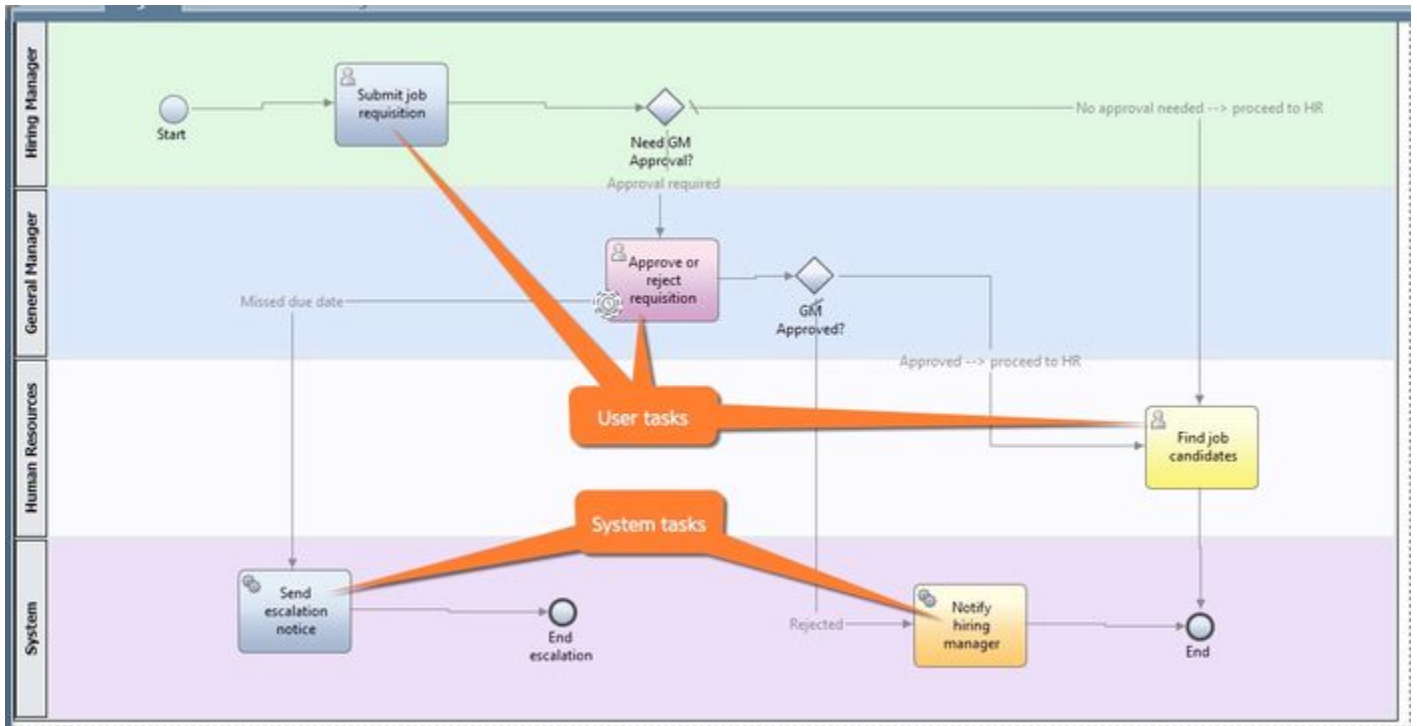

IBM BPM runs in WebSphere, see [IBM WebSphere and InfoSphere Startup Settings](#) for more details.

Business Process Definitions: System and User Tasks

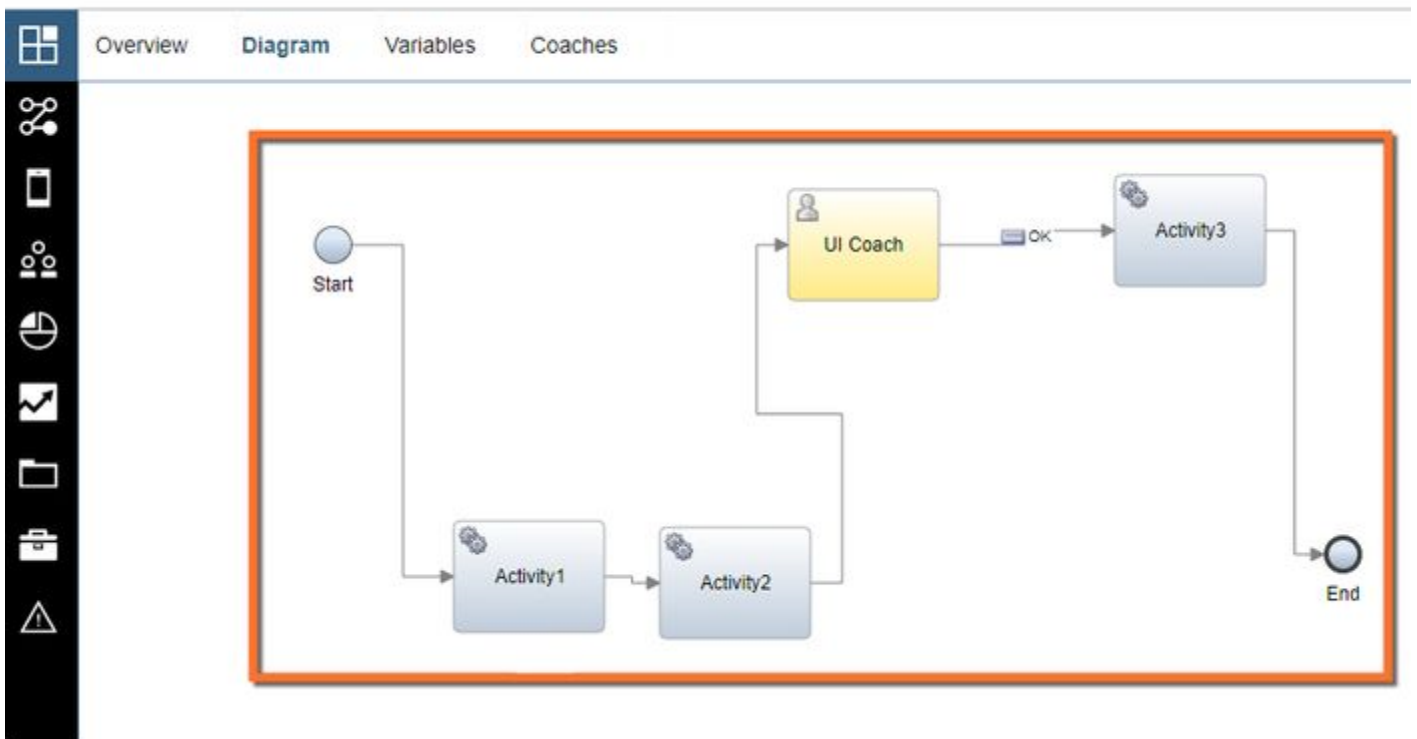

A BPD process consists of the flow of a business process which may involve user interactions. It consists of User Tasks, System Tasks, and other logic.

The screenshot displays a sample process within the BPD designer:

User tasks, in turn, break down into one or more user interactions, such as submit a form and approve a decision. They can be implemented as a CSHS, one of which is shown below:

Client-Side Http Service ▾ ⊗ ⓘ ⚠

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

A CSHS always starts with a start event and consists of one or more activities each of which uses a system service as the underlying implementation, and one or more Coaches, which define the user interactions.

Business Transaction Support

Business Transaction Support for Client Side Human Services

CSHS Transaction naming

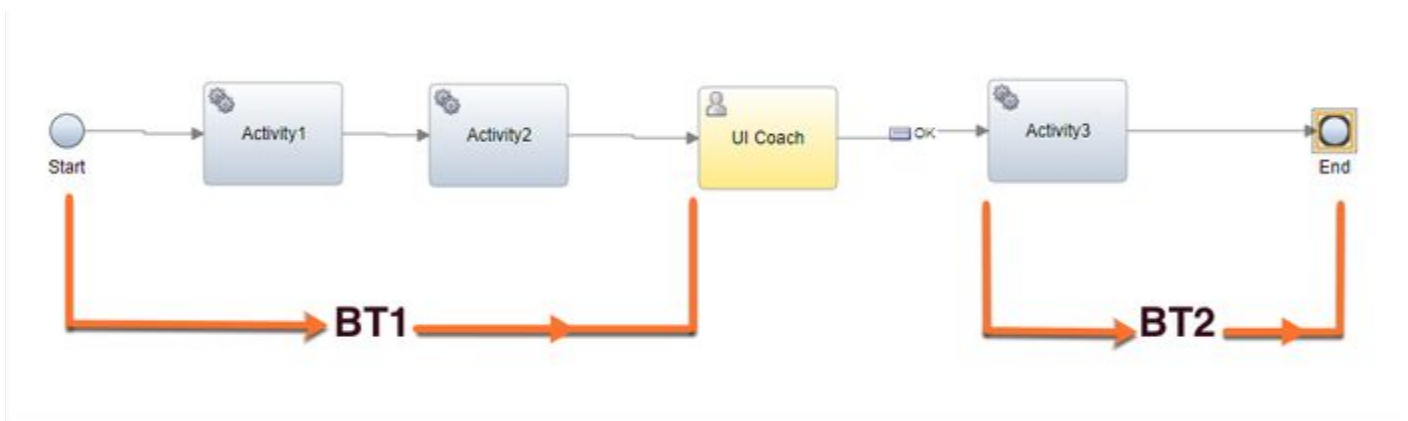

All Business Transactions detected within a CSHS are detected as servlet type transactions, and their naming can be configured using custom servlet naming rules. The default servlet naming rule uses only the first two segments of the URL for naming, hence, without custom naming configuration the Business Transactions will be detected as –

`/<Project Name> /<BPD Name>`

CSHS Transaction naming control

To disable the IBM BPM specific naming for CSHS Business Transactions use the `disable-ibmbpm-usertask-bt-naming` node property.

Since the Business Transaction is designed to monitor technical activity only, one CSHS may spawn multiple Business Transactions:

Any element inside a CSHS is associated with the following identifiers:

- Project Name
- BPD Process Name
- User Task Name
- CSHS Process Name
- Activity Name or Coach Name

Additionally, for Activity (Service), the activity has a service as its implementation which has its own identifier (Service Name).

These are annotated on screenshots of the IBM design tools:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

BPD Screen

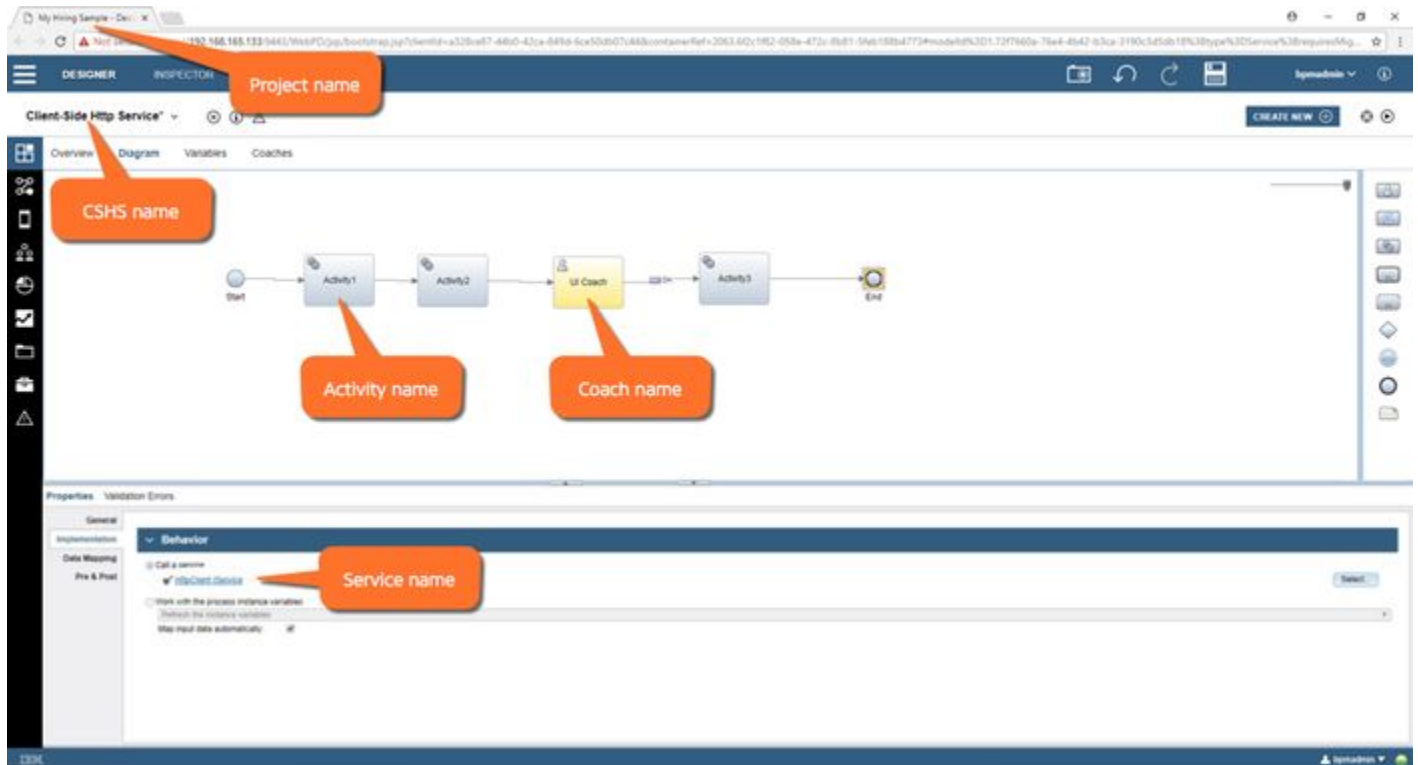

The screenshot displays the IBM Process Designer interface. The main workspace shows a Business Process Diagram (BPD) for the process 'Standard HR Open New Position'. The diagram is organized into swimlanes: Hiring Manager, General Manager, and System. Key tasks and events include 'Submit job requisition', 'Approve or reject requisition', 'Send escalation notice', and 'Notify hiring manager'. A decision diamond labeled 'GM Approved?' is present. A callout points to 'Client-Side Human Service (CSHS)' in the properties panel.

Annotations in the image identify the following elements:

- Project name:** Points to the top-left corner of the application window.
- BPD process:** Points to the title bar of the process diagram.
- User task name:** Points to the 'Submit job requisition' task in the Hiring Manager swimlane.
- Client-Side Human Service (CSHS):** Points to the 'Client-Side Http Service' in the properties panel.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

CSHS Screen

Business Transaction Detection and Naming at the Start and End Points within a CSHS

Within a CSHS, there can be one or more activity-services involved in the flow. Each of this hits a specific REST URL. Hence, an HTTP entry point is defined for each of these services.

- For example, the default URL for the **Start** BT –
`/teamworks/process.lsw`
- For example, the default URL for the **End** BT –
`/teamworks/cfecontroller`

Business Transactions originating from the start of a user task are detected as servlet Business Transactions and are named according to the following scheme:

```
<Project Name>/<BPD Name>/<Task Name>/<CSHS Name>/Start:Event
```

For example (corresponding to the images shown above, BPD image and CSHS image), the Business Transactions would be named –

```
/My Hiring Sample/Standard HR Open New Position/Step: Submit job requisition/Client-Side Http Service/Start:Event
```

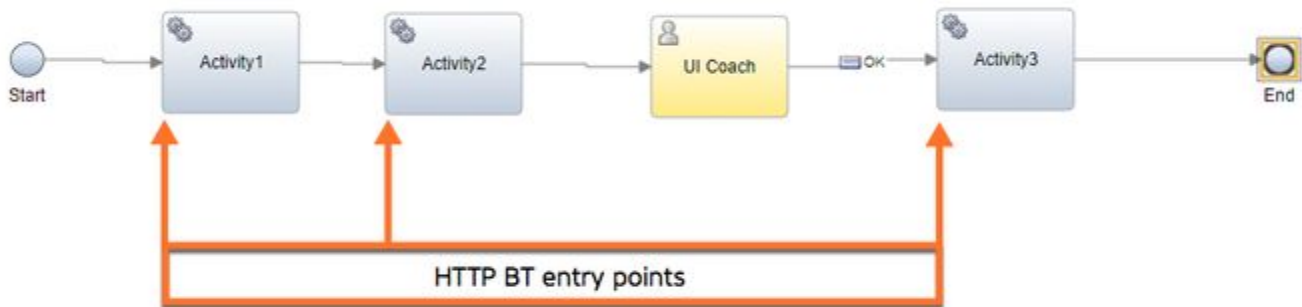

```
/My Hiring Sample/Standard HR Open New Position/Step: Submit job requisition/Client-Side Http Service/End:Event
```

Business Transaction Detection and Naming at an Activity (Service) Node Within a CSHS

Each user task in the BPD process has a CSHS as its implementation. Within a CSHS, there can be one or more activity-services involved in the flow. Each of them hits a specific REST URL. Hence, HTTP entry point is defined for each of these services.

For example, the default URL is –

```
/rest/bpm/wle/v1/coachflow/service/1.a22ce595-1573-4fdd-90f6-734884753610
```

Business Transactions originating within a CSHS activity service are detected as servlet Business Transactions and are named according to the following scheme:

`/<Project Name>/<BPD Name>/<Task Name>/ <CSHS Name>/ <Activity Name>/<Implementation Service Name>:Service`

For example (corresponding to the images BPD image and CSHS image), the Business Transactions would be named:

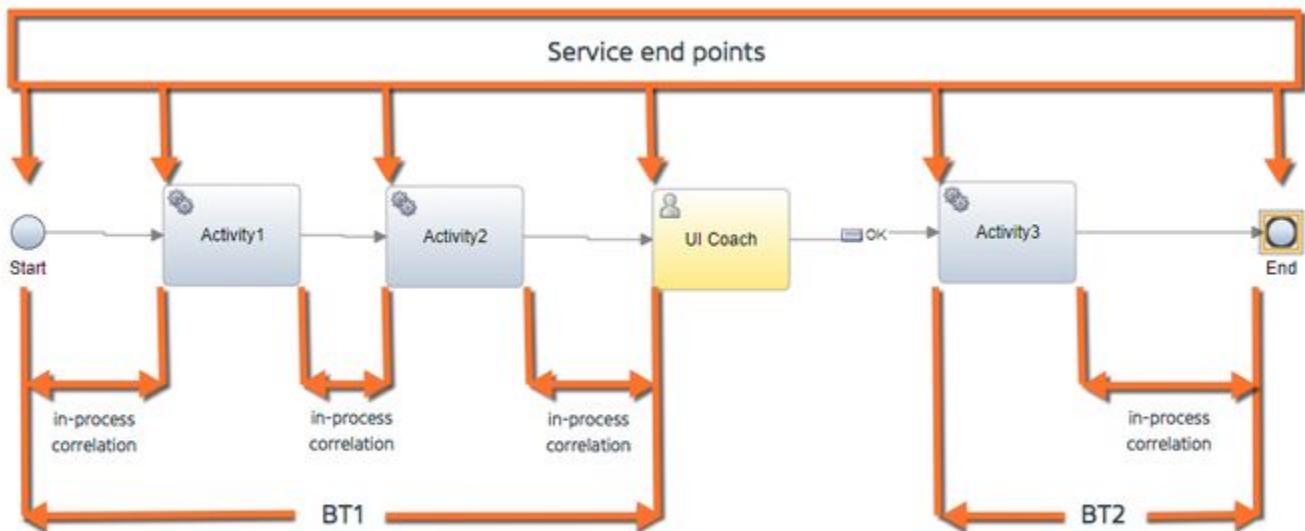

`/My Hiring Sample/Standard HR Open New Position/Step: Submit job requisition/Client-Side Http Service/Activity1/HttpClient IService:Service`

Business Transaction Detection at the CSHS Coach

A User Task in a BPD process has a CSHS as its implementation. Within a CSHS, there can be one or more UI Coach(es) involved in the flow. Each UI Coach represents the UI page(s) which opens up for the user to perform some actions (like completing a form, approving something, and so on). Each of these hits a specific REST-URL. Hence, the servlet entry point is used for the naming of the UI Coach.

For example, the default URL for this Business Transactions is –

`/teamworks/generatecoachng`

Business Transaction Naming Scheme at Coach of CSHS

The Business Transactions originating on entry to a UI coach are detected as Servlet Business Transactions

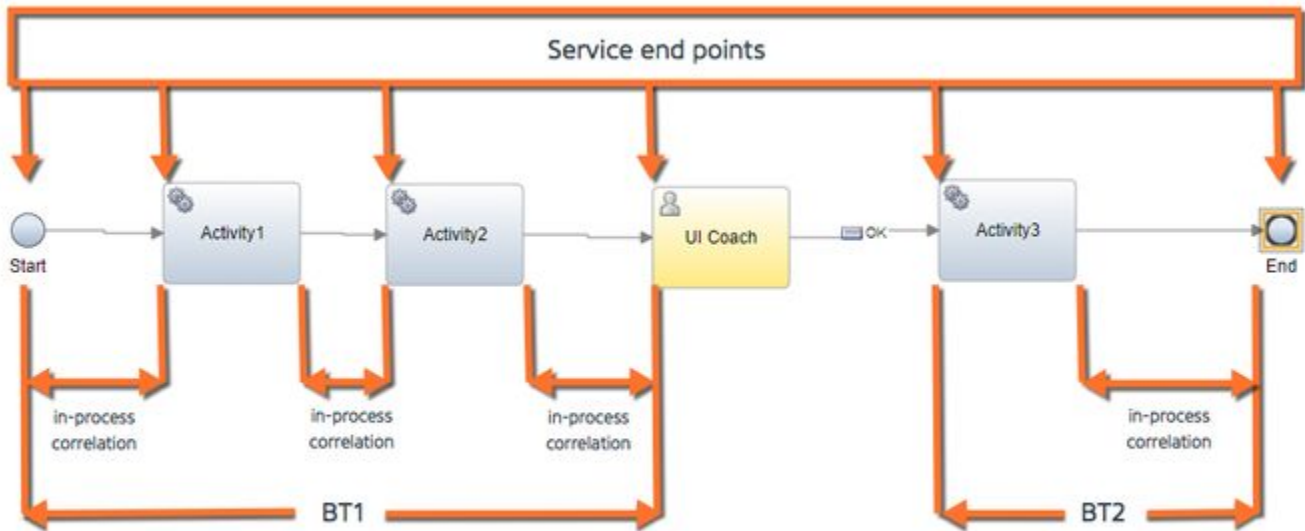

–
`/<Project Name>/<BPD Name>/<Task Name>/<CSHS Name>/<Coach Name>:Coach`

For example (corresponding to the images BPD image and CSHS image), the business transaction would be named:

`/My Hiring Sample/Standard HR Open New Position/Step:Submit job requisition/Client-Side Http Service/UI Coach:Coach`

In-Process Correlation Between Elements within a CSHS

There can be more than one element involved within a User Task (CSHS) with no user interaction in between them. These form a part of the same business transaction. Service Endpoints give visibility of the individual steps within the resulting business transaction as illustrated below:

Business Transaction Support for System Tasks within a BPD Process

POJO business transactions are generated for System Tasks within a BPD process.

The POJO business transactions are named using four identifiers:

1. Project Name (<project-name>)
2. BPD Process Name (<bpd-name>)
3. System Task Name (<task-name>)
4. Implementation Process Name (<implementation-name>)

If any identifier's value is not available, it is replaced with <UNKNOWN> in the resulting transaction name.

For example, a business transaction detected for default configuration (<project-name> / <bpd-name> / <task-name> / <implementation-name>) is:

Name ↓	Health	Response Time (ms)	Calls
My Hiring Sample / Standard HR Open New Position / Step: Send escalation notice / HttpClient (Service)	🟢	187	29
InterServerMessageListener:TWServerTopic	🟢	3	1,074
Internal Order Approval App / IDA_BPD / Step: IDA_Outbound_Integration Service / IDA_Outbound_Int...	🟢	135	5
DataDefLoaderBean:DataDefLoaderQueueDestinationSingleCluster	🟢	80	542
CacheRequestListenerBean:cacheTopic	🟢	6	250
/WebPO/jsp/registryReader.jsp	🟢	16	2
/teamworks/redirect-login.jsp	🟢	48	6

The default naming scheme can be customized using the `ibmbpm-systemtask-bt-naming` node property.

The property value is comma-separated identifiers chosen from project, bpd, task, implementation, and is order sensitive.

For example if,

value = "project, task" means POJO Business Transactions are named as: `<project-name>/<task-name>`

value = "task, project" means POJO Business Transactions are named as: `<task-name>/<project-name>`

value = "none" means POJO Business Transactions are not detected (disabled)

value = "default" means all the identifiers are used for Business Transactions naming in a default order, that is, they are named as `<project-name>/<bpd-name>/<task-name>/<implementation-name>`

Set `ibmbpm-systemtask-bt-naming` property to "none" to disable detection of Business Transactions for system tasks.

Built-in Data Collectors

i Controlling the Built in Data Collectors

To disable the out of the box data collectors use the `disable-ibmbpm-data-collectors` node property.

For a System Task or a User Task, the following data collectors are available:

- PROCESS NAME
- TASK ID
- TASK NAME
- BPD INSTANCE ID
- BPD NAME
- PROJECT NAME

In addition to these, for a CSHS implementation of a User Task, if the IBM BPM specific naming Business Transactions naming scheme is enabled, an additional data collector, **ACTUAL URL**, will also be present, populated with the actual URL hit when the business transaction is initiated.

Additional data collectors defined for a User Task depending upon the element of the CSHS being called can be:

- COACH NAME for Coach
- EVENT TYPE for Start and End (value is either **Start** or **End** depending upon on the event)
- ACTIVITY NAME for Activity (Service)
- SERVICE NAME for Activity (Service – denoting the implementation service of the activity)

Sample Data Collectors

You can view the snapshot data collectors as:

Configuration Notes

There are some other configuration settings that may be helpful when implementing AppDynamics for IBM BPM monitoring:

- Increase the value of the node-property `max-business-transactions` if necessary, to accommodate the number of tasks involved in the BPD process (the default = 50).
- Add a node property `framework-support` with a value of "none" to disable CometD and GWT POJO Business Transactions a large number of which otherwise get detected. These correspond to activity within the IBM tooling and are not valuable for BPM monitoring.
- Exclude Servlet Business Transactions like `/portal/login`, `/webasset/..`, which are not valuable for BPM monitoring.

Node Properties That Control IBM BPM Instrumentation

Node Properties available when using IBM-BPM support:

- `disable-ibmbpm-usertask-bt-naming`: Sets whether Business Transactions naming scheme for IBM-BPM UserTask Business Transactions should be disabled (value = true) or enabled (value = false).
When it is set to "true", the Business Transactions would be named as per the default URL and not the meaningful names.
- `disable-ibmbpm-usertask-bt-in-process-correlation`: Sets whether Business Transactions in-process correlation for IBM-BPM UserTask Business Transactions should be disabled (value = true) or enabled (value = false).
- `ibmbpm-systemtask-bt-naming`: Decides Business Transactions naming scheme for IBM-BPM System Task POJO Business Transactions.
- `disable-ibmbpm-data-collectors`: Sets whether data-collectors for IBM-BPM task Business Transactions should be disabled (value = true) or enabled (value = false).

Spring Batch Support

Spring Batch is an open-source project for batch processing (execution of a series of jobs).

A Batch Job is composed of one or more Steps. Each step consists of a Tasklet (explicitly or implicitly using ItemReader and ItemWriter). Each level (Job, Step and Tasklet) has an execute method.

Step execution can be parallelized using multiple threads. Remote Chunking (processing of part of Step, chunk on a remote JVM) can also be done with the help of JMS. Different steps in a job can be executed in separate threads use-case permitting.

From an APM perspective, tracking batch workloads at the Job level brings limited value, since batch Jobs are usually very long-running and an alert that the Job overran would come too late for remedial action to be taken. For this reason, the AppDynamics Business Transactions should be placed at the Tasklet level, meaning one batch Job will be composed of many Tasklet Business Transaction executions.

You can turn off spring batch instrumentation using the [spring-batch-enabled](#) node property.

Alerting on the response times of these Business transactions allows AppDynamics users to:

- Proactively detect that a Batch Job is progressing more slowly than usual, and thus predict if it will overrun any batch window
- Troubleshoot the root-cause of any unusual slow-downs in the progress of batch jobs in order that the issue can be remediated before the Job overruns

To achieve this, from Java Agent 4.5:

- Creates BTs at Tasklet.execute, named after the Job, Step, and Tasklet
- Correlates chunks across thread boundaries or process boundaries through JMS

OSB Support

Oracle Service Bus (OSB) is Oracle's Enterprise Service Bus (ESB) implementation. It is configuration-based and policy-driven and provides reliable service-oriented integration, service management, and traditional message brokering across heterogeneous IT environments.

This service-infrastructure software adheres to the SOA principles of building coarse-grained, loosely coupled, and standards-based services. Additionally, OSB acts as a message brokering, service monitoring, administration, dynamic routing, and message transformation layer to infrastructure.

OSB relies on Oracle WebLogic Server run-time facilities. OSB supports various service types and transports.

From agent release 4.5.8, AppDynamics supports Business Transaction entries and exits for the HTTP and JMS transports and correlates activity through the broker to give end-to-end transaction visibility. Outbound flows using other transports will be shown as uncorrelated custom backends on the flowmap.

If you want to use custom configuration to influence how the agent instruments non-http and jms outbound transportation, you can use the `ignore-exit-types` [node property](#) to disable the default behavior.

For Business Transactions originating in OSB itself, the transaction naming scheme that will be used is dependent on the OSB Proxy Service Type.

Service Type	Naming Scheme
REST, WSDL, SOAP	WebService Entry
Messaging, XML	Servlet Entry

For more details on proxy service types and transports in OSB, see [Oracle documentation](#).

Open Tracing Support

OpenTracing is an open standard for Tracing in-process and out-of-process distributed transactions. At a high level, it performs shallow stitching of method executions involved in a business flow, and hence enables measuring it end to end.

AppDynamics Tracer is an implementation based on OpenTracing 0.31.0 standards.

Prerequisite

For the OpenTracer to work correctly, use the [Executor strategy](#) in the Java agent. You can specify it in `app-agent-config.xml` or as node property:

```
<!--As part of app-agent.config.xml-->
<property name="async-instrumentation-strategy" value="executor"/>
```

Or, just specify the following node property in the Controller:

```
async-instrumentation-strategy = "executor"
```

Obtain the AppDynamics OpenTracer

Install the Dependency

The OpenTracer jar can be accessed directly, or downloaded from Maven Central, or it can be downloaded from the AppDynamics portal. The library version changes with each new OpenTracer release, and is not tightly coupled to the version of the underlying agent, which must be at least = 4.5.13.

[Gradle](#) [Maven](#) [SBT](#)

```
dependencies {
    compile group: 'com.appdynamics.agent', name: 'opentracer', version: '4.5.13.27526'
}
```

Gradle [Maven](#) [SBT](#)

```
<dependency>
  <groupId>com.appdynamics.agent</groupId>
  <artifactId>opentracer</artifactId>
  <version>4.5.13.27526</version>
</dependency>
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Gradle Maven SBT

```
libraryDependencies += "com.appdynamics.agent" % "opentracer" % "4.5.13.27526"
```

Enable or Disable the Tracer

By default when plugged in, OpenTracer is enabled. There are two ways to disable it:

- Programmatically you can enable and/or disable using:

```
AppdynamicsTracerConfiguration.appdTracingConfiguration().setTracingEnabled();
```

Optionally,

- At startup, you can specify the system property to enable and/or disable using:

```
-Dappdynamics.opentracing.enabled=false
```

Plug the Tracer into Lightbend Telemetry

The first OpenTracing use case validated by AppDynamics is its use with Lightbend telemetry (also known as the Cinnamon agent), which allows transaction tracing through applications built on the Lightbend reactive platform, for example those built on Akka HTTP. For more details, refer to the [Lightbend documentation](#), in particular as it relates to [OpenTracing integration](#).

Full instructions as to how to set up Lightbend Telemetry are beyond the scope of the AppDynamics documentation. At a high level, the necessary steps for configuration are:

1. Configure the Lightbend telemetry agent. For Lightbend instructions, see [Instructions](#).
2. Enable tracing for the Akka HTTP endpoints you want the AppDynamics agent to trace. For Lightbend instructions, see [OpenTracing Configuration](#).

i Ensure the active sampler is set to `const-sampler` in your `cinnamon.opentracing` file. (The low-overhead nature of the AppDynamics Java agent means that you can safely ignore the comment in the sample configuration file that states this should only be used for non-production).

3. Plug the AppDynamics OpenTracing implementation in to Lightbend Telemetry as a custom OpenTracing tracer using the `AppdynamicsTracerFactory` as described in the [Lightbend documentation](#). A sample AppDynamics tracer factory is provided below:

```
import com.appdynamics.opentracing.core.AppdynamicsTracerFactory;
import com.lightbend.cinnamon.opentracing.TracerFactory;
import io.opentracing.Tracer;
```

```
public class AppdynamicsTracerPlugin implements TracerFactory {
    @Override
    public Tracer create() {
        return AppdynamicsTracerFactory.getTracer();
    }
}
```

Development Level Monitoring

Works with:

Development Level Monitoring and AppDynamics

AppDynamics monitors your production applications in a way that is designed to provide maximum visibility with the least amount of overhead. Development level monitoring is a mode in which certain default limits on the data that AppDynamics collects are turned off, giving you additional visibility on application activities.

This default mode is production-level monitoring and applies limits to the retention of certain types of information. In a testing environment or other environments where overhead is not an issue, you can enable development level monitoring. Development mode is intended for temporary use while setting up AppDynamics or for occasional application troubleshooting.

You apply development monitoring to a specific business transaction and originating node combination. An *originating node* is one or more of the nodes that serve as the entry points for the transaction.

Transactions originating on an enabled node are subject to development level monitoring on downstream nodes that participate in processing that business transaction. Note that this applies for that business application only, however. Processing for a continuing transaction in another business application is not monitored at the development level unless you have enabled development level monitoring at the continuing business application as well.

While development monitoring increases the retention of call graphs and SQL statement capture, certain limits still apply. The limits specify maximum thresholds for calls per minute, Java heap utilization, and snapshot segments generated across the Controller. If the thresholds are exceeded, development level monitoring is turned off. See [Development Level Monitoring Limits](#).

Effects of Development Mode

Enabling development level monitoring affects the capture of the following information:

- **Exit Calls**—AppDynamics increases information collected for exit calls to backend systems. For database backends, the agent collects all SQL statements without per-transaction limits. The agent also collects all JDBC and ADO.NET calls attached to methods, even when the call duration is less than 10 ms.
- **Snapshots**—The agent attempts to take a snapshot for every transaction, ignoring the values for these agent node properties:
 - [max-concurrent-snapshots](#)
 - [on-demand-snapshots](#)

Development mode does not guarantee snapshots for every transaction since it was not designed to capture data on every request.

- **Call Graphs**—The agent captures full call graphs in development mode.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

 Users must belong to a role with the Configure Monitoring Level (Production/Development) permission for the application to set development level monitoring. See [Manage Custom Roles](#).

Enable Development Level Monitoring

You enable development level monitoring in the context of a particular business transaction/originating node combination. To avoid exceeding development mode limits described in [Development Level Monitoring Limits](#), it is recommended that you enable development monitoring at the smallest scope possible.

To enable development level monitoring:

1. In the business application for which you want to enable monitoring, click **Configuration > Development Level Monitoring**.
2. Enable the **Development Level Monitoring** switch at the top of the page.
For agents ≤ 4.3 , enabling development level monitoring applies globally, rather than for a particular business transaction. For agents > 4.3 , you need to configure the business transaction and node to which the configuration applies, as described in the following step.
3. Select the Business Transaction for which you want to enable development monitoring.
4. Click the **Enabled** checkbox next to the originating nodes on which you want to enable development level monitoring.

Turn Off Development Level Monitoring

Even in pre-production environments, enabling development level monitoring would normally be a temporary measure done in select cases. When finished, turn off development level monitoring for the business application, as described here.

To turn off development level monitoring:

1. In the business application for which you want to turn off development level monitoring, click **Configuration > Development Level Monitoring**.
2. Use the **Development Level Monitoring** switch at the top of the page to turn off development level monitoring. The switch turns off such monitoring for all business transactions in the business application.

Development mode may also be turned off automatically.

Development Level Monitoring Limits

The following agent-applied and Controller-applied limits prevent excessive resource consumption during development mode.

App Agent Limits

These limits apply for an App Agent:

- For each node, a maximum of 500 calls per minute. (See [dev-mode-suspend-cpm](#).)
- For each JVM, the maximum heap utilization percentage of 90%. (See [heap-storage-monitor-devmode-disable-trigger-pct](#).)

If a limit is exceeded, an agent log event is generated indicating that the development mode has been turned off because limits were exceeded

Controller Limits

The Controller monitors the number of snapshot segments collected during development monitoring across business transactions. A snapshot segment corresponds to the processing activities for a business transaction on a particular tier. A single business transaction that traverses many tiers can generate more data than several business transactions that only traverse a few tiers.

When the threshold of 5000 snapshot segments per minute is exceeded, the Controller turns off development mode for the top contributing business transactions. The Controller turns off development mode on as many business transactions as are needed to reduce the snapshot segment contribution by 20%.

For example, if a single business transaction is accountable for 25% of the snapshot segments when the threshold is exceeded, only it is turned off. As another example, given the following business transactions and the percentage of snapshot segments, they each contributed when the threshold was exceeded, the first two are turned off:

1. BT1: 17%
2. BT2: 16%
3. BT3: 15%
4. BT4: 15%
5. BT5: 13%
6. BT6: 12%
7. BT7: 12%

You cannot configure this Controller limit.

App Server Agents Supported Environments

This page provides an aggregated view of the supported environments for the App Server agents.

i App Server agents have been tested successfully on AWS Outposts using these instructions: [Install App Server Agents](#).

Java Agent

This page lists the application environments and versions supported by the AppDynamics Java Agent.

Java Agent Supported Platforms

In the following tables, note that:

- A dash ("-") in a table cell indicates that this column is not relevant or not supported for that particular environment.
- In cases where no version is provided, assume that all versions are supported. Contact AppDynamics Sales for confirmation.
- For environments that require additional configuration, a separate table describing or linking to configuration information follows the support matrix.
- For environments supported by AppDynamics End User Monitoring, see [Supported Environments and Versions - Web EUM](#).
- For environments supported by AppDynamics Server Visibility, [Machine Agent Requirements and Supported Environments](#).

JVM Support

The AppDynamics Java Agent uses the standard JVM Tool Interface (JVMTI) mechanism allowing it to instrument any software running on a JVM supporting this mechanism.

AppDynamics certifies the successful operation of the basic mechanisms of instrumentation used by the agent on the following Java runtimes. These capabilities are supported on both JRE or full JDK installations.

Where the agent supports the following advanced memory monitoring features, they are listed for the JVM: Object Instance Tracking (OIT), Automatic Leak Detection (ALD), Content Inspection (CI), and Access Tracking (AT).

JVM	OS	Memory Monitoring Features
AdoptOpenJDK 8, 9, 10, 11, 12, 13, 14, 15, 16 (supported for both Hotspot and OpenJ9 JVMs)	Linux, Windows, MacOS	ALD
Amazon Corretto 8, 11	Linux, Windows	OIT, ALD, CI, AT
Azul Zing 15.x.	Linux x64	OIT, ALD

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

JVM	OS	Memory Monitoring Features
Azul Zulu OpenJDK 1.6, 1.7, 1.8, 9, 10, 11, 13, 14, 15, 16 JDK11 is supported from 4.5.6 onwards JDK13 is supported from 4.5.15 onwards JDK14 is supported from 20.4.0 onwards JDK15 is supported from 20.10.0 onwards JDK16 is supported from 21.4.0 onwards	Linux, Windows	OIT, ALD, CI, AT
GraalVM 20.0.0, 20.2.0	Linux, Windows, MacOS	OIT, ALD, CI, AT
HP OpenVMS		
IBM JVM 1.6.x, 1.7.x, 1.8.x	AIX, HP-UX, Linux, Solaris, Windows, z/OS	ALD, CI Object instance tracking, automatic leak detection, and custom memory structure monitoring are not supported with the AppDynamics IBM Java Agent. IBM JVMs can be instrumented with the AppDynamics Sun Java Agent to work around this limitation; however, this only enables automatic leak detection and custom memory structure monitoring. Object instance tracking is not available. Working around this limitation can result in negative performance impact and is not recommended. In such cases, the IBM JVM needs to be restarted to enable custom memory structure monitoring.
Oracle Rokit JVM 28.1+	Linux Intel 64, Windows	
Oracle/BEA JRockit 1.6		

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

JVM	OS	Memory Monitoring Features
Oracle/Sun JVM 1.6, 1.7, 1.8, 9, 10, 11, 12, 13, 14, 15, 16 JDK11 is supported from 4.5.6 onwards JDK12 is supported from 4.5.11 onwards JDK13 is supported from 4.5.15 onwards JDK14 is supported from 20.4.0 onwards JDK15 is supported from 20.10.0 onwards JDK16 is supported from 21.4.0 onwards	Solaris Sparc 64, Windows, Linux	OIT, ALD, CI, AT Content Inspection and Access Tracking require a JVM restart.
Open Source OpenJDK 1.7, 1.8, 9, 10, 11, 12, 13, 14, 15, 16 OpenJDK11 is supported from 4.5.6 onwards OpenJDK12 is supported from 4.5.11 onwards JDK13 is supported from 4.5.15 onwards JDK14 is supported from 20.4.0 onwards JDK15 is supported from 20.10.0 onwards JDK16 is supported from 21.4.0 onwards	Solaris Sparc 64, Windows, Linux	OIT, ALD
SAP JDK 6+	Windows, Solaris, Linux, HP-UX, i5/OS, AIX	

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

JVM Application Server and Framework Support

AppDynamics supports the use of the Java Agent to instrument any application component running on a supported JVM, irrespective of how that component is built. The power of the AppDynamics platform is that it can automatically discover the topology and behavior of complex enterprise applications without requiring deep technical knowledge of the application's underlying code.

Frequently, Java-based systems employ standard framework code to implement business logic. Automatic instrumentation of framework code relies on knowledge of the business logic and programming patterns employed by the framework. AppDynamics instrumentation targets processing hand-offs between components, called [entry points and exit points](#), either within the JVM or between JVMs. This includes hand-offs between frameworks in cases where multiple frameworks are being used together. This section covers the capabilities for frameworks for which AppDynamics provides automatic detection rules.

Monitoring application components built using frameworks not listed here may require custom configuration. The custom configuration may involve, for example, custom [POJO entry or exit points](#). If you understand how the application behaves internally, you can easily configure this type of instrumentation. For more complex configuration tasks, contact your account representative to discuss how to engage the AppDynamics customer success organization.

JVM Language Frameworks Support

No additional configuration is required for these frameworks.

Vendor	JVM Language Framework	Version	Correlation/Entry Points	Exit Points	Transports	Notes
Open Source	Akka Actor	2.1 – 2.5.x	Yes	Yes	Netty	4.3.1 required for 2.4.x 2.5x support includes Persistence Remoting exit/entry supported

Vendor	JVM Language Framework	Version	Correlation/Entry Points	Exit Points	Transports	Notes
Open Source	Akka HTTP Name: akka-http-stream-entry-enabled Type: Boolean Default: False	Akka Actor 2.5.x Akka HTTP upto 10.2.4 Scala 2.11, 2.12	Yes	Yes	HTTP	EUM is supported Support for Non-Route DSL
Open Source	Http4s Blaze Client	Blaze versions: 0.21.1, 0.21.0, 0.20.23, 0.20.5 scala 2.11, 2.12	No	Yes	HTTP	
Open Source	Groovy	-	Yes	Yes		
Open Source	Ktor	1.0.x -1.5.x	Yes (Netty Engine)	-	HTTP	EUM is supported
Open Source	Play for Scala Play for Java	2.1 – 2.8 Scala 2.11, 2.12	Yes	-	HTTP over Netty server Akka HTTP server	Includes framework specific entry and exit points Play EUM-APM correlation supported
Open Source	Scala	2.11.6				

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Vendor	JVM Language Framework	Version	Correlation/Entry Points	Exit Points	Transports	Notes
Open Source	Spray toolkit (Spray.io)	1.1.x 1.1.3	Yes	Yes	HTTP	Entry points are detected and configurable as servlet entry point and exit points as HTTP exits
Pivotal	Grails	-	-	-	-	

Java Frameworks Support

The Java Agent supports these Java frameworks. Some require additional configuration as indicated in the Configuration Notes column.

Vendor	Framework	Version	SOA protocol (WebServices)	Auto Naming	Entry Points	Exit Points	Detection	Configuration Notes
Adobe	BlazeDS	-	HTTP and JMS adaptor	-	Yes		-	Example Message Queue Backend Configuration

Tibco	ActiveMatrix BusinessWorks Service Engine	5.x, 6.x	-	To enable correlation using a header transported in the <code>SOAP:Envelope</code> set node property <code>enable-soap-header-correlation=true</code>	-	Yes	Tibco ActiveMatrix BusinessWorks Service Engine Settings
	Application Server (OC4J)	-	-	Yes, detect and correlate for 10.x	-	Yes	

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Vendor	Application Server / OSGi Runtime	Version	SOA Protocol	RMI Supported	JMX	Entry Points	Configuration Notes
-	Grails, with Tomcat 7.x, Glassfish v3, Weblogic 12.1.1 (12c)	-	-	-	-		

Servlet 3.x detection is not supported.

PaaS Providers

PaaS Provider	Buildpack
Pivotal Cloud Foundry	Java Buildpack 3.4 and higher See Using AppDynamics with Java Applications on Pivotal Cloud for more information.
Red Hat Openshift 3	JBoss EAP 6.4 and 7.x WildFly 8.1 Docker images For documentation and download information, see the AppDynamics Java APM Agent page on the Red Hat Customer Portal.

Message Oriented Middleware Support

The Java Agent supports the following message oriented middleware environments. Some require additional configuration as indicated in the Configuration Notes column. Message oriented middleware servers are usually found by the Java Agent as an entry point.

Vendor	Messaging Server	Version	Protocol	Correlation/Entry Points	Exit Points	JMX	Configuration Notes
Amazon	Simple Queue Service (SQS)	-	-	Yes (correlation only)	Yes	-	See "Amazon Simple Queue Service Backends" on Java Backend Detection
Amazon	Simple Notification Service (SNS)	-	-	No	Yes	-	See "Amazon Simple Notification Service Backends" on Java Backend Detection
Apache	ActiveMQ	5.x+	JMS 1.x	Yes	Yes	Yes	
Apache	ActiveMQ	5.x+	STOMP	No	-	Yes	
Apache	ActiveMQ	5.8.x+	AMQP 1.0	No	-	Yes	Example Message Queue Backend Configuration
Apache	Axis	1.x, 2.x	JAX-WS	Yes	Yes	-	Default exclude rules exist for Apache Axis, Axis2, and Axis Admin Servlets. See also "Web Service Entry Points" on Java Backend Detection .
Apache	Apache CXF	2.1	JAX-WS	Yes	Yes	-	To enable correlation, set node property <code>enable-soap-header-correlation=true</code> .

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Vendor	Messaging Server	Version	Protocol	Correlation/Entry Points	Exit Points	JMX	Configuration Notes
Apache	Kafka	0.9.0.0 to 2.5.0	-	Yes	Yes	Yes	Kafka consumer entry points are disabled by default. Correlation is supported. See Apache Kafka Consumer Backends .
Apache	Synapse	2.1	HTTP	Yes	Yes	-	To enable correlation, set node property <code>enable-soap-header-correlation=true</code>
Fiorano	Fiorano MQ		-	-	-	-	
IBM	IBM Web Application Server (WAS)	6.1+, 7.x	Embedded JMS	-	Yes	-	Example Message Queue Backend Configuration
IBM	IBM MQ (formerly IBM WebSphere MQ)	6+	JMS	Yes	Yes	-	Example Message Queue Backend Configuration
Mulesoft	Mule ESB	3.4, 3.6, 3.7, 3.8, 3.9, 4.1.x, 4.2.0, 4.2.1	HTTP, JMS	Yes	Yes	-	Mule ESB Startup Settings
Open Source	Eclipse Vert.x verticles	3.3.x, 3.4.x, 3.5.0, 3.6.0	-	Yes (correlation only)	Yes	-	The Java Agent detects messaging exit calls between verticles.
Open Source	Open MQ	-	-	-	-	-	

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Vendor	Messaging Server	Version	Protocol	Correlation/Entry Points	Exit Points	JMX	Configuration Notes
Oracle	Java Message Service	2.0	JMS	Correlation of the listener is disabled by default	Yes		
Oracle	Oracle AQ	-	JMS	-	Yes	-	
Oracle	OSB deployed on WebLogic	12.2.1	HTTP JMS	Yes	Yes		OSB Support
Oracle / BEA	WebLogic	9.x+	JMS 1.1	Yes	Yes	Yes	Oracle WebLogic Startup Settings
Progress	SonicMQ	-	-	-	-	-	
Pivotal	RabbitMQ	-	HTTP	-	Yes	-	See "RabbitMQ Backends" on Java Backend Detection
Rabbit	RabbitMQ Spring Client	-	-	Yes	Yes	-	See "RabbitMQ Backends" on Java Backend Detection
Red Hat	HornetQ (formerly JBoss Messaging and JBoss MQ)	-				Yes	
Red Hat	JBoss A-MQ	4.x+	-	-	-	Yes	

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Vendor	Messaging Server	Version	Protocol	Correlation/Entry Points	Exit Points	JMX	Configuration Notes
Spring	Spring Integration	2.2.0+, 4.0+	JMS	Yes	Yes	Yes	Spring Integration Support See also "Java Message Service Backends" on Java Backend Detection
WSO2	ESB	4.7.0	-	Yes	Yes	-	EUM Correlation is not supported
WSO2	API Microgateway	3.1.x, 3.2.0, 3.2.1	HTTP	Yes	Yes	-	See WSO2 API Microgateway Startup Settings

JDBC Drivers and Database Servers Support

The Java Agent supports these JDBC driver and database server environments. AppDynamics can follow transactions using these drivers to the designated database.

JDBC Vendor	Driver Version	Driver Type	Database Server	Database Version
Apache	10.9.1.0	Embedded or client	Derby	-
Apache	-	-	Cassandra	-
Progress	DataDirect	data connectivity for ODBC and JDBC driver access, data integration, and SaaS and cloud computing solutions	-	-
IBM	JDBC 3.0 version 3.57.82 or JDBC 4.0 version 4.7.85	DB2 Universal JDBC driver	DB2	9.x

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

JDBC Vendor	Driver Version	Driver Type	Database Server	Database Version
IBM	JDBC 3.0 version 3.66.46 or JDBC 4.0 version 4.16.53	DB2 Universal JDBC driver	DB2	10.1
IBM	-	Type IV	Informix	-
Maria				1.4.x - 2.6.x
Microsoft	4	Type II	MS SQL Server	2012
Oracle MySQL, MySQL Community	5.x, 6.x, 8.x	Type II, Type IV	MySQL	5.x
Oracle	RAC			
Oracle	9i, 10g 11g, 12c, 18c, 19c	Type II, Type IV	Oracle Database	8i+
Open Source PostgreSQL	42.2.5	Type IV	Postgres	8.x, 9.x, 11x
Sybase	jConnect	Type IV	Sybase	-
Teradata			Teradata	-

Notes:

- Type II is a C or OCI driver
- Type IV is a thin database client and is a pure Java driver

NoSQL/Data Grids/Cache Servers Support

The Java Agent supports these NoSQL, data grids and cache server environments. Some require additional configuration. Click the link on the database, data grid or cache name in the following support matrix for information about additional configuration required or related configuration topics.

Vendor	Database/Data Grid/Cache	Version	Correlation/Entry Points	JM X	Configuration Notes
Amazon	DynamoDB	-	Exit Points	-	See "Amazon Web Services" on Java Backend Detection .
Amazon	Simple Storage Service (S3)	-	-	-	"Amazon Simple Storage Service Backends" on Java Backend Detection .
Apache	Casandra <ul style="list-style-type: none"> • DataStax drivers • Thrift drivers 	1.x, 2.x	Correlation for Thrift drivers only	Yes	<ul style="list-style-type: none"> • "Cassandra Backends" on Java Backend Detection. • For Cassandra server-side support, see Apache Cassandra Startup Settings
Apache	Lucene - Apache Solr	1.4.1	Entry Points	Yes	Apache Solr Startup Settings
Couchbase	Couchbase	3.x	Exit Points	-	See "Couchbase Backends" on Java Backend Detection

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Business Transaction Error Detection

The Java Agent supports the following logging frameworks for business transaction error detection:

- Apache Log4j and Log4j 2
- java.util.logging
- Simple Logging Facade for Java (SLF4J)
Support for the following method has been added: `public void error(String format, Object... argArray)`
- Logback

To instrument other types of loggers, see [Error Detection](#).

.NET Agent

Error rendering macro 'include'

com.atlassian.renderer.v2.macro.MacroException: No page title provided.

Node.js Agent

This page provides an overview of supported environments for the Node.js Agent.

Node.js Agent Versions

Agent Versions	Node.js Versions
>= 21.1.0	8.6+, 9, 10, 11, 12, 13, 14, 15
>= 20.5.0	8.6+, 9, 10, 11, 12, 13, 14
20.4.0	8.6+, 9, 10, 11, 12, 13
>= 4.5.21	8.6+, 9, 10, 11, 12
>= 4.5.12	6, 7, 8, 9, 10, 11
4.5.11	0.8, 0.10, 0.12, 4, 5, 6, 7, 8, 9, 10, 11

For agent >= 4.5.12, the `npm install` command will stop and print a message for the following scenarios.

- Node.js version less than 6.x:
 - This version of AppDynamics agent supports Node.js versions 6.0 and above.
 - For older versions of Node.js, use the AppDynamics agent 4.5.11 by installing with `npm install appdynamics@4.5.11`.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- Node.js version less than 8.x on Mac:
 - This version of AppDynamics agent on Mac OS supports Node.js >= 8.0.
 - For older versions of Node.js, use the AppDynamics agent 4.5.11 by installing with `npm install appdynamics@4.5.11`.

Operating Systems

- Alpine Linux Docker >= 3.7 on 64-bit platform
- Linux distribution based on glibc 2.5 and later and the x86/x86-64 architecture
- Mac OS X >= 10.8, x86/x86-64 architecture
- Windows Server 2012 R2 and later on 64-bit platform with Node.js >= 0.12.0

Transaction Naming

Entry Type	Default Transaction Naming
Node.js Web	URI

HTTP Exit Points

Supported HTTP Exit Points
Node.js HTTP client library

See [Node.js Documentation](#) for the Node.js HTTP client library.

Database Exit Points

Supported Database Exit Points
Cassandra
Couchbase
DynamoDB (using AWS SDK Driver)
Redis
Memcached
MongoDB
MSSQL
MySQL
PostgreSQL

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

PHP Agent

Related pages:

- [PHP Business Transaction Detection](#)

PHP Agent Support

PHP Versions

PHP Agent supports these versions of PHP:

- 5.6
- 7.0
- 7.1
- 7.2
- 7.3
- 7.4

PHP Web Servers

Apache 2.2 and 2.4 in these modes:

- `prefork` mode using `mod_php`
- worker MPM mode using `mod_fastcgi` with `php -fpm` or `mod_fcgid` with `php -cgi`

Any web server compatible with `php -fpm`.

Operating Systems

- Any Linux distribution based on `glibc 2.5+` and the x86 32-bit or x86 64-bit architecture
- Mac OS X 10.9+

i PHP Agent supports 32-bit operating system only on PHP 5.6.

PHP Frameworks and Protocols

Framework/Protocol	Version	Entry Point Type
Drupal	7	Drupal
Drupal	8	PHP MVC
WordPress	3.4+, 4.x, 5.x	Wordpress
Zend	1, 2, 3	PHP MVC
CodeIgniter	2.x, 3.x, 4.x	PHP MVC

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Framework/Protocol	Version	Entry Point Type
FuelPHP	1.5x, 1.6x, 1.8x	PHP MVC
Magento	1.5, 1.6, 1.7, 2.3	PHP MVC
Symfony	1, 2, 3, 4	PHP MVC
CakePHP	2.x, 3.x, 4.x	PHP MVC
Laravel	5.7, 6, 8, 9.x	PHP MVC
HTTP		PHP Web
CLI		PHP CLI

If your PHP framework is not listed here, the agent detects your entry points as PHP Web and names the business transactions based on the first two segments of the URI — the default naming convention for PHP Web transactions. So it is still possible to monitor applications on *unsupported* frameworks. Laravel BTs are detected as symfony, as laravel itself is built on top of symfony.

There are few limitations of the PHP Agent. The PHP Agent does not:

- Monitor PHP applications in Zend Thread Safety (ZTS) mode. If you are using ZTS, AppDynamics suggests that you review your dependencies on ZTS to confirm that you actually need it, and if you do not, to switch to the non-ZTS mode
- Support Zend Monitor
- Officially support plug-ins that encrypt and, or obfuscate PHP code such as Zend Guard or ionCUBE Loader
- Support compatibility with the Xdebug module

Transaction Naming

Framework/Environment	Default Transaction Naming
Drupal	page callback name
Wordpress	template name
PHP MVC Frameworks	controller:action
PHP Modular MVC Frameworks	module:controller:action

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Framework/Environment	Default Transaction Naming
PHP Web	URI
PHP Web Service	service name.operation name
PHP CLI	last two segments of the script's directory path plus the name of the script

Virtual host prefixing is available for all supported entry point types except PHP CLI.

PaaS Providers

PaaS Provider	Buildpack
Pivotal Cloud Foundry	https://github.com/Appdynamics/php-buildpack See http://docs.pivotal.io/appdynamics/index.html for information about integration with PCF.

Exit Points

Supported HTTP Exit Points
<code>curl/curl-multi*</code>
<code>drupal_http_request()</code>
<code>fopen()</code> , <code>file_get_contents()</code>
<code>Zend_HTTP_Client::request()</code>

*The total time reported for a `curl/multi_curl` request in the Controller is the same as reported by the function `curl_getinfo`. Also, we report the the following execution metrics in the exit call details for the `curl/multi_curl` request which are included in the total time:

- `namelookup_time`
- `connect_time`
- `pretransfer_time`
- `redirect_time`

Supported Database Exit Points

MySQL old native driver (removed for PHP 7)

MySQLi Extension*

OCI8

PDO

PostgreSQL accessed via PDO and pgsql extensions

* `mysqli_multi_query` is not supported.

Supported Cache Exit Points

Memcache

Memcached

Predis 0.8.5 and 1.1.1, on PHP versions 5.6 and higher

Phredis 4.1

Although Predis is a full PHP client library, the PHP Agent supports Predis as an exit point only, not as an entry point.

Supported Web Service Exit Points

PHP SOAPClient

NuSOAP 0.9.5

Supported Message Queue Exit Points

RabbitMQ

RabbitMQ support requires the [amqp extension](#).

Opcode Cache Compatibility

Alternative PHP Cache (APC)	
-----------------------------	--

Python Agent

Related pages:

- [Python Agent](#)

Python Agent Support

Python Versions

The Python agent supports Python 2.7, 3.4, 3.5, 3.6, 3.7, 3.8, and 3.9.

Operating Systems

The Python agent operates on any Linux distribution based on glibc 2.12+ and the x86 32-bit or x86 64-bit architecture.

- Support for Mac OS X will be deprecated from the 20.7.0 version of the Python Agent.
- Support for centos5 has been deprecated.

Python Frameworks and Protocols

Framework/Protocol	Version	Entry Point Type	Default Transaction Naming
WSGI	1.0	Python Web	First two segments of URI
Tornado	3.2 - 4.5 (all versions), Tornado 5.x without asyncio library, Tornado 6 (for Python 3.5.3+)	Python Web	First two segments of URI

AppDynamics has tested the Python Agent on Tornado, Django, Flask, CherryPy, Bottle, and Pyramid.

You can configure the agent to instrument any WSGI-based application or framework as Python Web, including but not limited to those listed below.

At present, the Python agent fully supports exception detection in Django, Flask, CherryPy, Bottle, Pyramid, and Tornado frameworks. Other WSGI frameworks and custom WSGI applications may install exception handlers that effectively hide some exceptions from the agent. In such cases, the agent will only detect

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

exceptions during exit calls, missed exceptions that are propagated to the WSGI server, and exceptions reported via the custom business transaction API.

WSGI-Based Frameworks	Notes
Bottle	0.12.19
CherryPy	18.6.0
Django	3.1.5
Flask	1.1.2
PasteDeploy	2.1.0
Pyramid	1.10.5
mod_wsgi	4.7.1

Database Exit Points

Supported Database Exit Points	Version
cx_Oracle	5.1.x
MongoDB	3.1+
MySQL-Python	
mysqlclient	
MySQL Connector/Python	
Psycopg 2	
PyMySQL	
TorMySQL	

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

HTTP Exit Points

Supported HTTP Exit Points
httplib*
httplib2
requests
urllib
urllib2
urllib3
tornado.httpclient

* The agent detects calls to any external library built on top of `httplib`. Therefore, backend calls to such services, such as, boto, dropbox, python-twitter are detected and displayed as HTTP exit calls.

Cache Exit Points

Supported Cache Exit Points
Memcache
Redis-py

Apache Web Server Agent

Related pages:

- [Browser RUM Supported Environments](#)

Apache Server Agent Support

Apache Web Servers

Supported Apache Web Server Version

- Apache HTTP Server 2.2.x
- Apache HTTP Server 2.4.x
- IBM HTTP Server >= 7.0
- Oracle HTTP Server >= 11g

Operating Systems

- Any Linux distribution based on glibc >= 2.12

Automatically Discovered Business Transactions

The Apache Agent automatically discovers the following business transactions:

Type	Custom Configuration Options	Downstream Correlation
Web (HTTP)	Yes	Yes

By default the agent excludes requests for the following static file types:

```

bm  jar  png
p   jpe  pps
ca  g    properties
b   jpg  swf
cla js    tif
ss  mo   txt
co  v    zip
nf  mp
css 3
do  mp
c   4
gif pdf
ico
    
```

Remote Service Detection

Apache Modules

The Apache Agent automatically detects loaded Apache modules as remote services. The agent excludes a list of common modules from detection.

Show the list of excluded modules...

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

 For End User Monitoring, the Apache Agent does not support automatic injection of the Javascript `adrum` header and footer to instrument web pages.

Third-Party Modules

The Apache Agent ≥ 20.5 requires the use of the latest version of SiteMinder 12.52 SP1 to eliminate a known bug in SiteMinder.

Site Minder

Product Name=CA SiteMinder Web Agent
FullVersion=12.52.110.2813
Version=12.52
Update=110
Build Number=2813

C++ Agent

C/C++ Supported Platforms

Operating Systems

- Any Linux distribution based on glibc \geq 2.5 and the x86 32-bit or x86 64-bit architecture
- Windows Server \geq 2012 R2
 - Visual Studio \geq 2015

 To develop with the C++ SDK, you need Visual Studio \geq 2015 . However, the SAP ABAP Agent on Windows leverages the same SDK and does not require development work. You must install the Visual Studio C++ Redistributable; the full development environment is not required.

Go Language Agent

Go Supported Platforms

Language Support

All Go language versions are currently supported.

Operating Systems

- Any Linux distribution based on `glibc` \geq 2.5, and the x86 32-bit or x86 64-bit architecture
- Mac OS X \geq 10.8 on x86/x86-64 architecture

 AppDynamics does not currently support Mac on Apple silicon (Apple M1 chip, ARM-based architecture).

IIB Agent

 **Error rendering macro 'include'**

com.atlassian.renderer.v2.macro.MacroException: No page title provided.

End User Monitoring

AppDynamics GovAPM End User Monitoring (EUM) provides end-to-end visibility on the performance of your web and mobile applications from the end user's perspective. EUM helps troubleshoot problems such as slow web or Ajax. EUM provides metrics on application performance and user activity, such as:

- How server performance impacts your web and device performance
- How third-party APIs impact your web and device performance
- Where your heaviest loads originate from
- How your users connect to and navigate your application

Installation

Overview of End User Monitoring

AppDynamics End User Monitoring (EUM) gives you visibility on the performance of your application from the viewpoint of the end user.

While Application Performance Monitoring (APM) measures user interaction starting at the web server or application server entry point, EUM extends that visibility all the way to the web or mobile application. As a result, EUM reveals the impact the network and browser rendering time have on the user experience of your application.

The diagram below provides an overview of the different components, deployment models (SaaS/on-premises), and the Controller UI as seen by AppDynamics end users. The SaaS deployment employs services (Controller Service, Events Service, EUM Service, EUM Synthetic Monitoring Service) to collect, store, and process data, whereas, the on-premises deployment requires customers to install discrete components such as the Controller and servers (Events Server, EUM Server) that run processes to collect, store, and process data.

Annotations are provided for each label below the diagram.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Step	Description	Component(s)								
1	The Browser and Mobile Agents run in web/mobile applications, collect metrics, and then transmit that data to either a SaaS or an on-premises deployment of AppDynamics.	<ul style="list-style-type: none"> • Browser/Mobile Apps • EUM Agents 								
2	The AppDynamics SaaS Cloud, consisting of the components listed to the right, stores, processes, and analyzes data, and then delivers RUM metrics to the Controller UI.	<table border="1"> <tr> <td data-bbox="974 508 1105 722">A</td> <td data-bbox="1105 508 1497 722">Controller Service - stores data and metadata, makes calls to the EUM Server for raw data and the Events Service for analytic data.</td> </tr> <tr> <td data-bbox="974 722 1105 936">B</td> <td data-bbox="1105 722 1497 936">Events Service - stores short-term RUM data (such as sessions, network requests, snapshots) for heavier analysis.</td> </tr> <tr> <td data-bbox="974 936 1105 1079">C</td> <td data-bbox="1105 936 1497 1079">EUM Service - verifies, aggregates, and packages raw browser app metrics.</td> </tr> <tr> <td data-bbox="974 1079 1105 1293">D</td> <td data-bbox="1105 1079 1497 1293">EUM Synthetic Monitoring Service - schedules and executes Browser Synthetic jobs and returns session data to the Controller.</td> </tr> </table>	A	Controller Service - stores data and metadata, makes calls to the EUM Server for raw data and the Events Service for analytic data.	B	Events Service - stores short-term RUM data (such as sessions, network requests, snapshots) for heavier analysis.	C	EUM Service - verifies, aggregates, and packages raw browser app metrics.	D	EUM Synthetic Monitoring Service - schedules and executes Browser Synthetic jobs and returns session data to the Controller.
A	Controller Service - stores data and metadata, makes calls to the EUM Server for raw data and the Events Service for analytic data.									
B	Events Service - stores short-term RUM data (such as sessions, network requests, snapshots) for heavier analysis.									
C	EUM Service - verifies, aggregates, and packages raw browser app metrics.									
D	EUM Synthetic Monitoring Service - schedules and executes Browser Synthetic jobs and returns session data to the Controller.									
3	The on-premises deployment of AppDynamics has most of the same components and data as the SaaS model. In this model, DevOps install and administer their own Controller, Events Service, and EUM Server. The EUM Synthetic Monitoring Service and sessions data, however, are not available in the on-premises deployment.	<ul style="list-style-type: none"> • Controller • Events Server • EUM Server <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p>i See the descriptions for each component above in step 2. The performs the same functions as the EUM Service.</p> </div>								

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Step	Description	Component(s)
4	AppDynamics users can go to the AppDynamics Controller UI to view and analyze RUM metrics as snapshots, pages, Ajax requests, sessions, network requests, or in the form of charts and graphs.	Controller UI  See the description for the Controller UI in step 2.

Understand End User Activity

Using EUM, you can determine:

- Where geographically your heaviest application load is originated.
- Where geographically your slowest End User response times occur.
- How performance varies by
 - location.
 - client type, device, browser and browser version, and network connection for web requests.
 - application and application version, operating system version, device, and carrier for mobile requests.
- What your slowest web/Ajax requests are, and where the problem may lie.
- What your slowest mobile network requests are, and where the problem may lie.
- How application server performance impacts the performance of your web and mobile traffic.
- Whether your mobile applications are experiencing errors or crashes and the root cause of the issues. For example, for mobile applications, EUM provides stack traces and event trails for the crash or error, helping you troubleshoot and optimize mobile applications.

View EUM Data

The performance information generated by EUM is distinct from the application monitoring data generated by app server agents.

EUM data appears in various locations in the Controller UI, including in the **User Experience** dashboard, **Metric Browser**, and AppDynamics **Analytics** pages.

When linked to application business transactions, EUM data gives you a complete view of your end users' experience from the client request, through the application environment, and back to the client as the user response.

You can view EUM performance data in the Controller UI in the **User Experience** tab. From there, you can access information specific to browser applications.

Access the SaaS EUM Server

The SaaS EUM Server consists of the components listed below. Each component may have different endpoints depending on the region of your Controller.

- EUM Services - The JavaScript Agent sends data to the EUM Services. The Controller fetches data from the EUM Server.
- Events Service - The EUM Server sends analytics data to the Events Service. The Controller also queries the Events Service.
- Synthetic Services - The Synthetic Private Agent and Synthetic Hosted Agent send data to the Synthetic Services.

If your SaaS deployment requires access to any of these components on the Internet, make sure the URLs given in [SaaS Domains and IP Ranges](#) are accessible from your network.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

How EUM Works with other AppDynamics Products

This section describes how other App iQ Platform products work with EUM to provide complete, full visibility on application health and user experience.

EUM and Application Performance Monitoring

Using APM with EUM provides you with greater insight into how the performance of your business application affects the end-user experience. To integrate APM with EUM, you correlate business transactions with browser snapshots. This enables you to trace bad user experiences to issues with your backends such as an unresponsive web service, bad database query or slow server response. To learn how to integrate APM with EUM, see [Correlate Business Transactions for Browser RUM](#).

You can also use the app server agents running on business applications that serve your browser applications to inject JavaScript agent into the code that runs on the browser. This obviates the need to manually inject the JavaScript agent. For more information, see [Automatic Injection](#) and [Assisted Injection](#).

You must assign unique names to EUM applications and business applications. For example, if you created the business application "E-Commerce", you cannot create a browser application with that same name or vice versa.

EUM and Application Analytics

[AppDynamics Application Analytics](#) enables you to use the powerful [AppDynamics Query Language \(ADQL\)](#) to analyze different types of EUM data through complex queries. The Analytics components are based on the Events Service, which is also the source of data for [Browser Analyze](#). Analytics requires a license separate from the EUM licenses.

Learn More

For more information on the type of user monitoring you interested in, see:

- [Browser Real User Monitoring](#)
- [Browser Synthetic Monitoring](#)
- [Mobile Real User Monitoring](#)

Correlate Business Transactions for EUM

Related pages:

- [Business Transactions](#)

This page describes how to correlate business transactions for End User Monitoring (EUM). You can correlate the network request events of EUM applications with the business transactions of [Business Applications](#). The EUM application can be a browser, mobile, or IoT application. The correlation is made between EUM application beacons containing network request event information and instances of business transactions (transaction snapshots).

For detailed information, including how and what is correlated for each type of EUM application, see these pages:

- [Correlate Business Transactions for Browser RUM](#)

Benefits of Correlating Business Transactions

By correlating business transactions with network request snapshots, you can identify potential issues with the backend application that are causing bad user experiences. For example, you might find that a server error or a database query is causing a slow user experience.

Before You Begin

To correlate business transactions:

1. Purchase [licenses](#) for Application Performance Monitoring (APM) and End User Monitoring (EUM).
2. Instrument a business application with a [supported app server agent](#).
3. Instrument an EUM application (browser, mobile, or IoT application).

i If [automatic business transaction correlation](#) is not supported for your app server agent, you can [manually enable business transaction correlation](#) in the Controller UI.

Business Transaction Correlation Support for App Server Agents

This table shows the app server agents that support business transaction correlation.

- [Automatic correlation](#) support means that business transactions are automatically correlated.
- For [manual correlation](#), you must [manually enable business transaction correlation](#).

App Server Agent	Type of Correlation Support
Java Agent	Automatic (Java Agent >= 20.3.0, and Controller >= 20.4.0)
.NET Agent	.NET Framework: Automatic (.NET Agent >= 20.9.0, and Controller >= 20.10.0)

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

App Server Agent	Type of Correlation Support
	.NET Core: Automatic (.NET Agent >= 21.1.0, and Controller >= 20.10.0), Windows only
	Linux: Automatic (.NET Agent >= 21.5)
Node.js Agent	Manual
PHP Agent	Manual
Python Agent	Manual

Access Business Transaction Correlation

To configure business transaction correlation:

1. In the **Application Dashboard**, click **Configuration > User Experience App Integration**.
2. Under the **Business Transaction Correlation** tab, there are two options depending on the [correlation support for your App Server Agents](#):
 - For agents with support for automatic correlation, see [Automatic Correlation of Business Transactions](#).
 - For agents without support for automatic correlation, see [Manually Enable Business Transaction Correlation](#).

Automatic Correlation of Business Transactions

By default, the correlation of business transactions of business applications instrumented with Java Agent >= 20.3.0 is enabled.

Under the **Business Transaction Correlation** tab, you can choose to opt out or filter requests with match or exclude rules.

User Experience App Integration

[Business Transaction Correlation](#) [JavaScript Agent Injection](#)

What is Business Transaction Correlation?

Business Transaction Correlation allows client-side requests in Browser & Mobile Apps to be correlated with server-side Business Transactions.

With a supported version, APM agents (Java, .NET, etc) may add cookies identifying the executing Business Transaction. A sample of Browser Snapshots & Mobile Network Requests will show correlated server-side Transaction Snapshots.

[Learn more about Correlating Business Transactions to RUM.](#)

Enable Automatic Correlation by Upgrading to Supported Agents

The following APM agents support automatic correlation, a process where agents add metadata allowing correlation of client and server-side measurements. For optimal results, ensure your agent fleet is running a supported version or above. Upgrading will enable correlation for all applications with no further action required. Check your deployed agent versions by navigating to Settings > AppDynamics Agents (requires Admin privileges).

Upgrade to latest agents

Java 20.3.0+
.NET Coming Soon

Opt Out of Correlation

If you do not want BT snapshots to be correlated to User Experience snapshots by default, you may [opt out of correlation](#). You can always opt in to correlation again.

Filtering Options

Customize when Business Transaction correlation headers will be attached to requests.

- > [Request Match Rules](#)
- > [Request Exclude Rules](#)

Opt In to Automatic Correlation

To opt in to have business transactions automatically correlated, you must use Java Agent $\geq 20.3.0$. If you are using an older version of the Java Agent, you must upgrade the agent.

For unsupported agents, you need to [manually enable business transaction correlation](#).

Opt Out of Automatic Correlation

If business transaction correlation is enabled by default, you can opt out by:

1. In the **Application Dashboard**, click **Configuration > User Experience App Integration**.
2. Under the **Business Transaction Correlation > Opt Out of Correlation**, click **opt out of correlation**.
3. From the **Opt Out of Correlation** dialog, click **Opt Out**.

Opt Out of Correlation
✕

By opting out, you will lose the ability to trace front-end requests to backend transaction snapshots.

Cancel
Opt Out

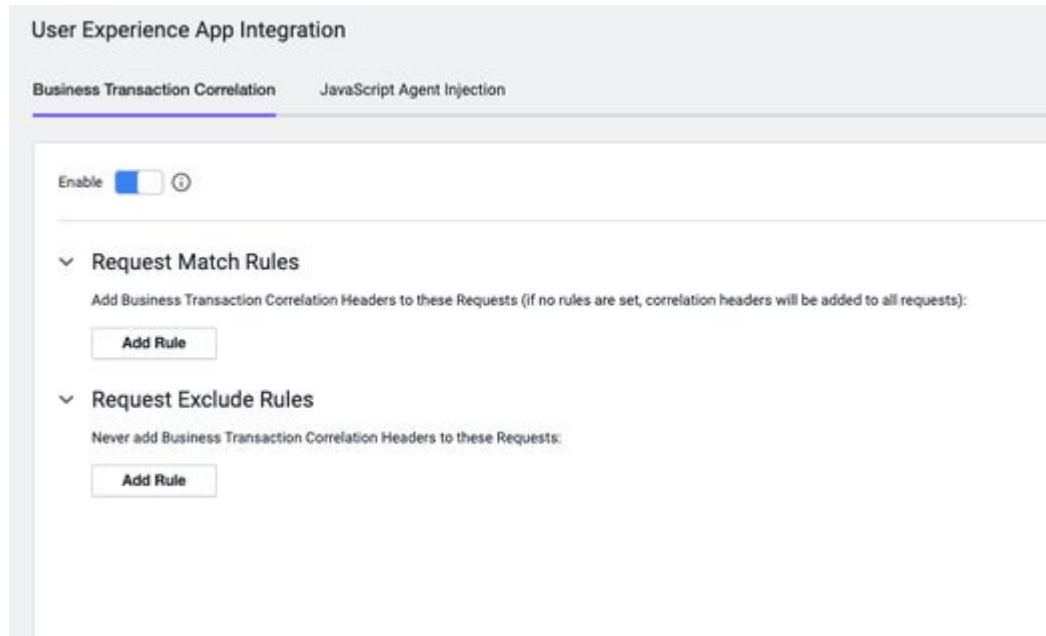

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Manually Enable Business Transaction Correlation

For app agents that do not have automatic correlation support, you need to manually enable business transaction correlation.

To manually enable business transaction correlation:

1. In the **Application Dashboard**, click **Configuration > User Experience App Integration**.
2. Under the **Business Transaction Correlation** tab, check the **Enable Business Transaction Correlation** checkbox.

Disable Business Transaction Correlation

To disable business transaction correlation:

1. In the **Application Dashboard**, click **Configuration > User Experience App Integration**.
2. Under the **Business Transaction Correlation** tab, toggle the **Enable** button.

Filter Business Transactions for Correlation

You can also specify which business transactions includes or excludes correlation headers. If you do not add request match rules or request exclude rules, all requests have correlation headers by default.

To add a request match or exclude rule:

1. From **Filtering Options**, expand **Request Match Rules** or **Request Exclude Rules**.
2. Click **Add Rule**.
3. Check the **Method** to use the default **HTTP** method **GET** or select a different **HTTP** method.
4. Check the **URI** checkbox and select one of the matching methods from the dropdown:
 - **Starts With**
 - **Ends With**

-
- **Contains**
 - **Equals**
 - **Matches RegEx**
 - **Is in List**
5. (Optional) Click  and check the **NOT** checkbox. This condition reverses the results by excluding the requests that match the specified parameters.
 6. Click **Add Rule**.

EUM Data

Related pages:

- [Using the Controller APIs](#)

With the iOS 14 release (supported by iOS Agent 20.10.0), Apple introduced a new data collection policy. See [iOS Data Collection Disclosure](#) for details.

This page describes the types of EUM data, how data is collected, where data is stored, and where data is displayed in the Controller. For data retention and license consumption details, see [License Entitlements and Restrictions](#).

Types of EUM Data

Metric Data

Metrics are data that reflect your application's performance. Browser RUM captures metrics from browser applications, such as timing and Ajax metrics. Mobile RUM captures metrics from mobile applications, such as crash metrics and network request metrics. You can view and analyze EUM metrics in the [Metric Browser](#).

To learn more about EUM metrics, see:

- [Browser RUM Metrics](#)
- [Browser Synthetic Metrics](#)
- [Extensions and Custom Metrics](#)

Custom Data

Browser RUM

You can add specific user information from a browser snapshot of your application. The information is expressed as key-value pairs, appears in the **User Data** section of the snapshot, and is available for page snapshots, Ajax requests, and virtual pages. To learn how to set custom user data, see [Add Custom User Data to a Page Browser Snapshot](#).

EUM Analytics Data

You can view EUM data in [Analytics](#) if you have a [Real User Monitoring Peak license](#). The EUM Analytics data consists of event data and is stored in the Events Service and [visualized in widgets](#). EUM Analytics provides data for these event types:

- [Browser Requests Event Data](#)
- [Browser Sessions Event Data](#)
- [Mobile Requests Event Data](#)
- [Mobile Sessions Event Data](#)
- [Mobile Crash Report Event Data](#)
- [Synthetic Sessions](#)
- [Connected Device Data](#)

Cookies for Browser Applications

Browser RUM uses two different kinds of short-lived cookies for the JavaScript Agent to collect data and correlate events. Both types of cookies do not contain any personally identifiable information (PII) and are immediately deleted after being read.

- **ADRUM** cookie: Written by the JavaScript Agent, this cookie contains the referral page URL and some timing information to assist in gathering First Byte Time for some browser types. When the agent loads on the subsequent page, it reads the information and then deletes the cookie. If there is no agent on that page, the cookie is deleted when the browser is closed. For privacy purposes, the URL of the referral page is hashed.
- **ADRUM_BT** cookies: Written by the server-side agent when the page is served from an instrumented server. These cookies help correlate browser data with related server-side performance data (Business Transactions).
 - **ADRUM_BTa** : Contains the backend transaction ID as well as timing info and is used to correlates end-user experience with the health of the backend app.
 - **ADRUM_BTg** : Contains the backend transaction ID and is used as an alternative method to correlate end-user experience with the health of the backend app.
 - **ADRUM_BT[1-5]** : Contains the business transaction numbers as well as timing and error info for the first five business transactions, such as **ADRUM_BT1** , **ADRUM_BT2** , etc.
 - **ADRUM_BTs** : Contains a link from a browser snapshot to a server snapshot.
 - **ADRUM_BTh** : Written only if there was a server-side error.

If Browser RUM detects that the page is HTTPS, the `Security` attribute is set for cookies. The `Security` attribute is a flag that forbids a cookie from being transmitted via an unencrypted HTTP connection.

- **SameSite** cookies: Provides the JavaScript Agent access to **ADRUM_BT** cookie to maintain Business Transaction correlation. When SameSite cookies are present, the agent has access to the **ADRUM_BT** cookie with Business Transaction data. Without SameSite cookies, the agent cannot parse Business Transaction data in the cookie sent from the application server. This is because the agent is loaded from a different domain than the browser website.

Web Storage

Browser RUM stores key-value pairs in web storage to associate page views with a particular session and browser. The value for each key is a randomly generated ID.

The following lists the keys and the expiration time for each key-value pair:

- **ADRUM_AGENT_INFO** (never)
- **ADRUM_CLIENTINFO** (never)
- **ADRUM_XD_AGENT_ID** (never)
- **ADRUM_XD_AGENT_INFO** (1 week)

Mobile Local Storage

Mobile agents use beacons to transmit metrics, app metadata, network requests, crashes, and custom data. When a beacon cannot be transmitted, the data is persisted in permanent storage within the container of the application and subject to the security configuration of the device and application. No encryption is currently being utilized. Once the network connection is restored, the beacons resume transmitting data.

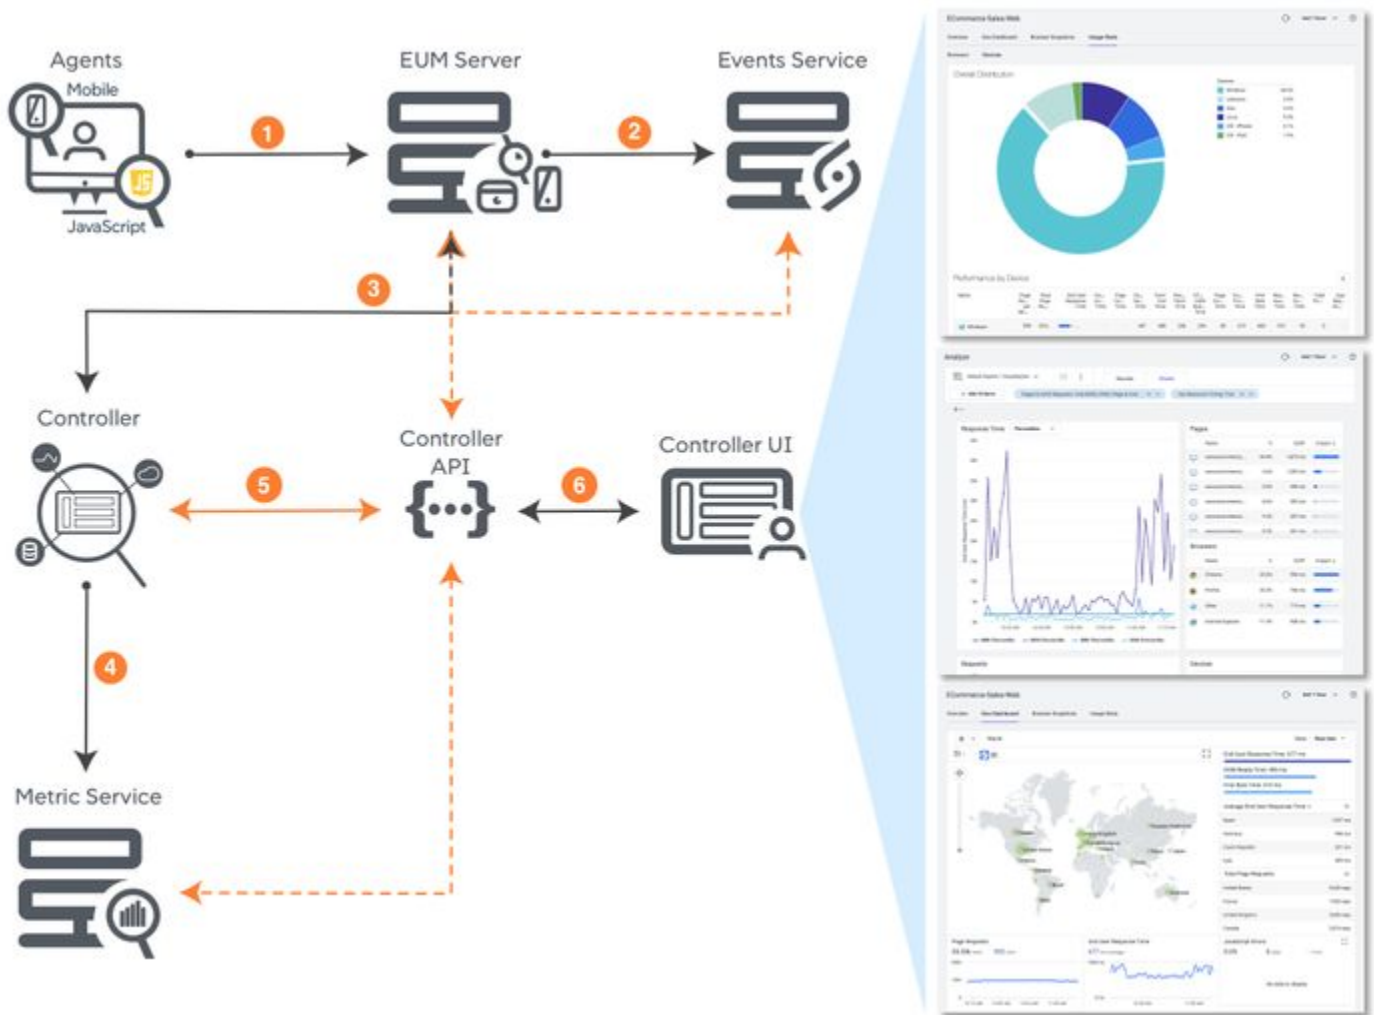

Because some of the data is provided by the developer's instrumentation of the app, such as breadcrumbs, user info, and the app (URLs, crash reports), some information is not explicitly collected by AppDynamics.

Mobile agents also locally store a randomly generated ID for tracking sessions and license usage. The ID is stored in the Events Service.

Data Storage and Retrieval

AppDynamics uses four data storage components to store Browser RUM and Mobile RUM data: the EUM Server, the Events Service, the Metric Service, and the Controller. The Controller UI has no visibility into which storage component holds the data because it only interacts with the Controller API.

- 1 Browser RUM utilizes a JavaScript Agent and Mobile RUM utilizes Mobile agents to send raw data to the EUM Server. The EUM Server verifies, aggregates, and packages the data once every minute.
- 2 The EUM Server sends the data to the Events Service and
- 3 to the Controller.
- 4 The Controller sends the data to the Metrics Service.
- 5 The Controller API fetches the data from one of the four data stores and
- 6 delivers it to the Controller UI when it receives data requests.

Data Storage Details

Browser RUM

This table shows where different Browser RUM data is stored. To see how long the data is retained, see [License Entitlements and Restrictions](#). Resource details are only available for those browser snapshots with resource timing.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Access EUM Data

In addition to accessing EUM data through the Controller UI, you can also access event data through [Analytics](#) and the [AppDynamics APIs](#). The AppDynamics APIs include the [Analytics Events API](#) and the [Metric and Snapshot API](#) that you can use to access EUM metric data.

If you have enabled Analytics and Browser RUM, you can use Browser Analytics to view data for these event types:

- [Browser Requests](#)
- [Browser Sessions](#)

If you have enabled Analytics and Browser Synthetic Monitoring, you can use Synthetic Analytics to view data for this event type:

- [Synthetic Sessions](#)

If you have enabled Analytics and Mobile RUM, you can use Mobile Analytics to view data for these event types:

- [Mobile Requests](#)
- [Mobile Sessions](#)
- [Mobile Crash Reports](#)

If you have enabled IoT Monitoring, you can use Connected Devices Analytics to view data for the event types below. You *do not* need to enable Analytics to use IoT Analytics.

- [Connected Device Data](#)

Data and Deployment Models

AppDynamics offers SaaS and on-premises deployment models. You can access most Browser and Mobile RUM data from either deployment model.

Browser Monitoring

i AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include the following products:

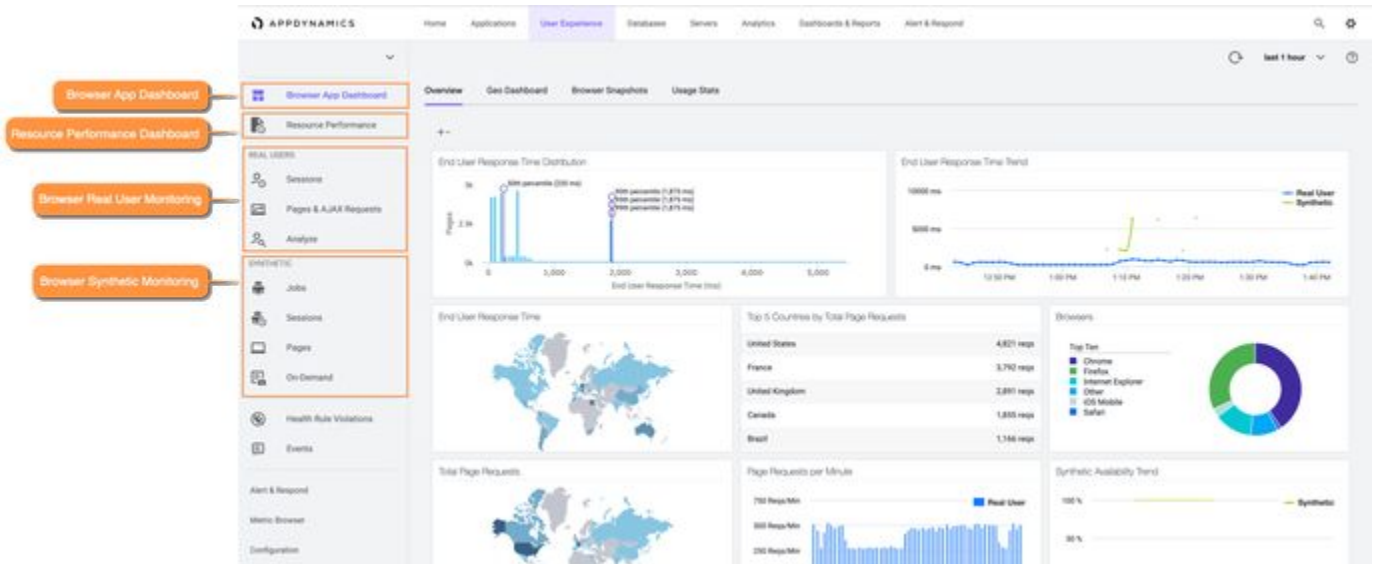

- APM (Pro/Peak)
- Browser Real User Monitoring (BRUM) (Pro/Peak)
- Mobile Real User Monitoring (Pro/Peak)
- Database Visibility
- Server Visibility, including Cluster Agent
- Transaction Analytics

AppDynamics offers two products to monitor browser applications:

- **Browser Real User Monitoring** (Browser RUM) - Monitors how your web application is performing, using real user data to analyze application performance and user experience.
- **Browser Synthetic Monitoring** - Analyzes application availability and performance, using scheduled testing to analyze website availability.

Overview of the Controller UI for Browser Monitoring

Browser RUM and Browser Synthetic Monitoring share two dashboards: Browser App Dashboard and Resource Performance Dashboard.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Browser App Dashboard

The [Browser App Dashboard](#) provides a high-level understanding of how your application's overall performance. When you first navigate to a browser application, you are defaulted to the **Browser App Dashboard > Overview** tab. The **Overview** tab contains widgets for both Browser and Synthetic data.

Resource Performance Dashboard

The [Resource Performance Dashboard](#) provides a high-level understanding of how your resources affect the performance of your browser application. You can use this dashboard to pinpoint resource-related performance issues affecting the user experience. You can toggle between viewing Browser and Synthetic data.

Real Users

Browser RUM contains these UI tabs for more detailed real-user data analysis:

- [Browser RUM Sessions](#)
- [Pages & AJAX Requests](#)
- [Browser RUM Analyze](#)

Synthetic

Browser Synthetic Monitoring contains these UI tabs for more detailed synthetic user data analysis:

- [Synthetic Jobs](#)
- [Synthetic Sessions](#)
- [Synthetic Pages](#)
- [Synthetic On-Demand](#)

Differences Between Browser RUM and Browser Synthetic Monitoring

Although Browser Synthetic Monitoring and Browser RUM report similar metrics, there are differences in:

- Hardware
- Network connections
- Different browsers
- Browser caching is not present in synthetic sessions

If you see a sudden change in any of those metrics, you should compare the results of Browser Synthetic Monitoring and Browser RUM to determine if there is an existing problem.

Performance Versus Workflows

Browser RUM excels at capturing the full breadth of performance and your real users' experience. Browser Synthetic Monitoring gives you confidence that your key workflows are always working and performing.

Synthetic Metrics and Screenshots

Browser Synthetic Monitoring can collect certain data that Browser RUM cannot. For example, Browser Synthetic Monitoring provides screenshots, which help you see per-page testing. You can also use the Visually Complete Time metric and other related metrics to understand how users experience page load time.

How to Use Browser RUM and Browser Synthetic Monitoring Together

Identify Issues

Although Browser RUM can detect certain kinds of problems (like JavaScript exceptions), it cannot comprehensively test for functional correctness. For example, you may want to verify that your online store has reasonable prices a list of items. If your site is down entirely, then the JavaScript Agent will never be loaded, so errors or verifications will not be reported. Fortunately, Browser Synthetic Monitoring will keep running, discover the error, alert you, and provide detailed information about the problem.

Control Environmental Factors

Hardware, browsers, operating systems, and networks complicate performance analysis in Browser RUM. Browser Synthetic Monitoring uses consistent hardware, software, and network configurations you set when you create a synthetic job, so if you see deviations in performance, you can be fairly certain a problem exists.

Browser App Dashboard

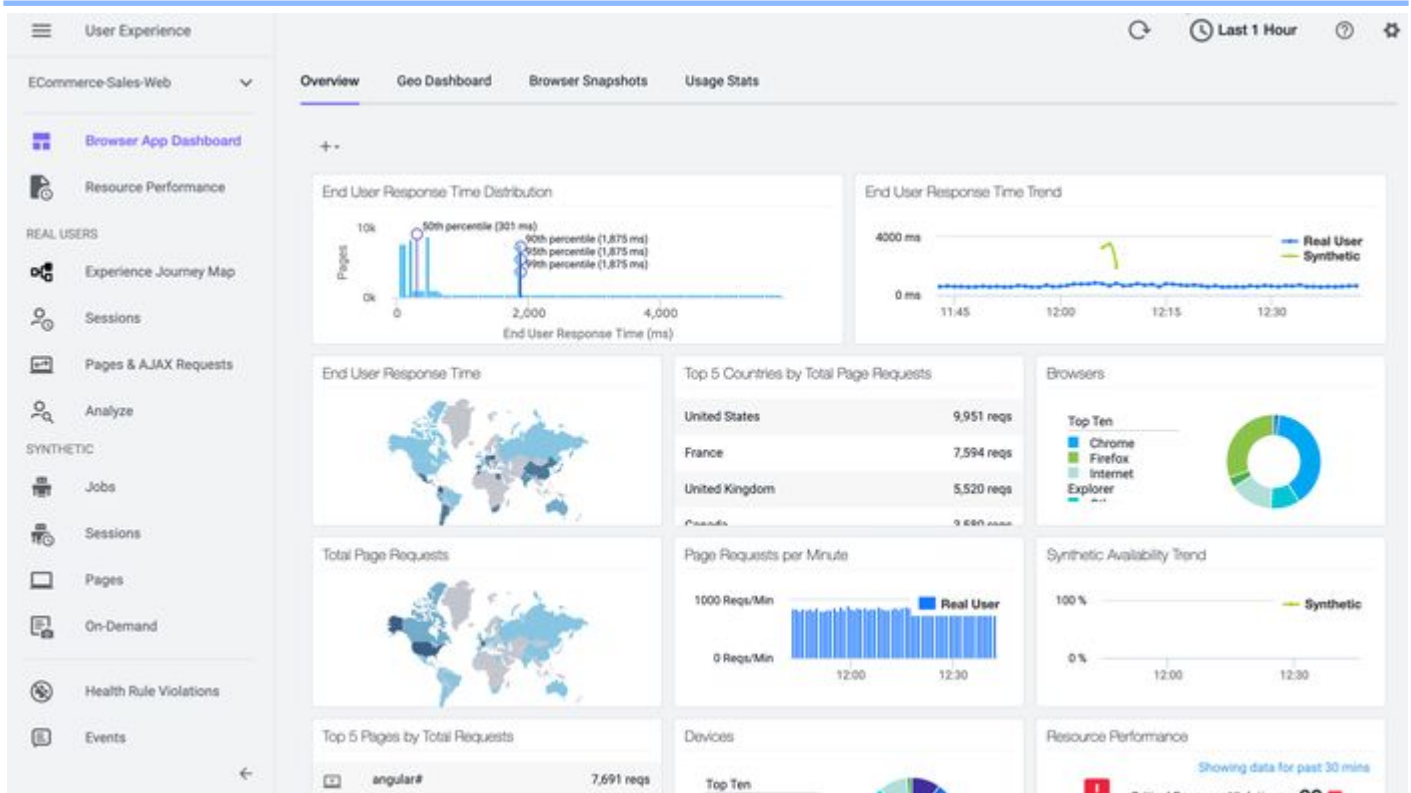

The **Browser App Dashboard** gives you a high-level overview of your browser application performance. To access the **Browser App Dashboard**:

1. In the Controller, go to **User Experience**.
2. Under **Browser Apps**, select an application.
3. In the left navigation bar, click **Browser App Dashboard**.

Overview

The **Overview** tab displays a set of configurable widgets. The default widgets contain multiple graphs and lists featuring common high-level indicators of application performance. You can remove a widget by clicking the **X** icon and add a widget using the **+** icon.

i For SPA2 applications, the **Overview** tab only displays data for base pages and virtual page events. Data from Iframe and Ajax requests is not included. If you have an application that only has Iframe and Ajax requests, then the **Overview** tab will not display any data.

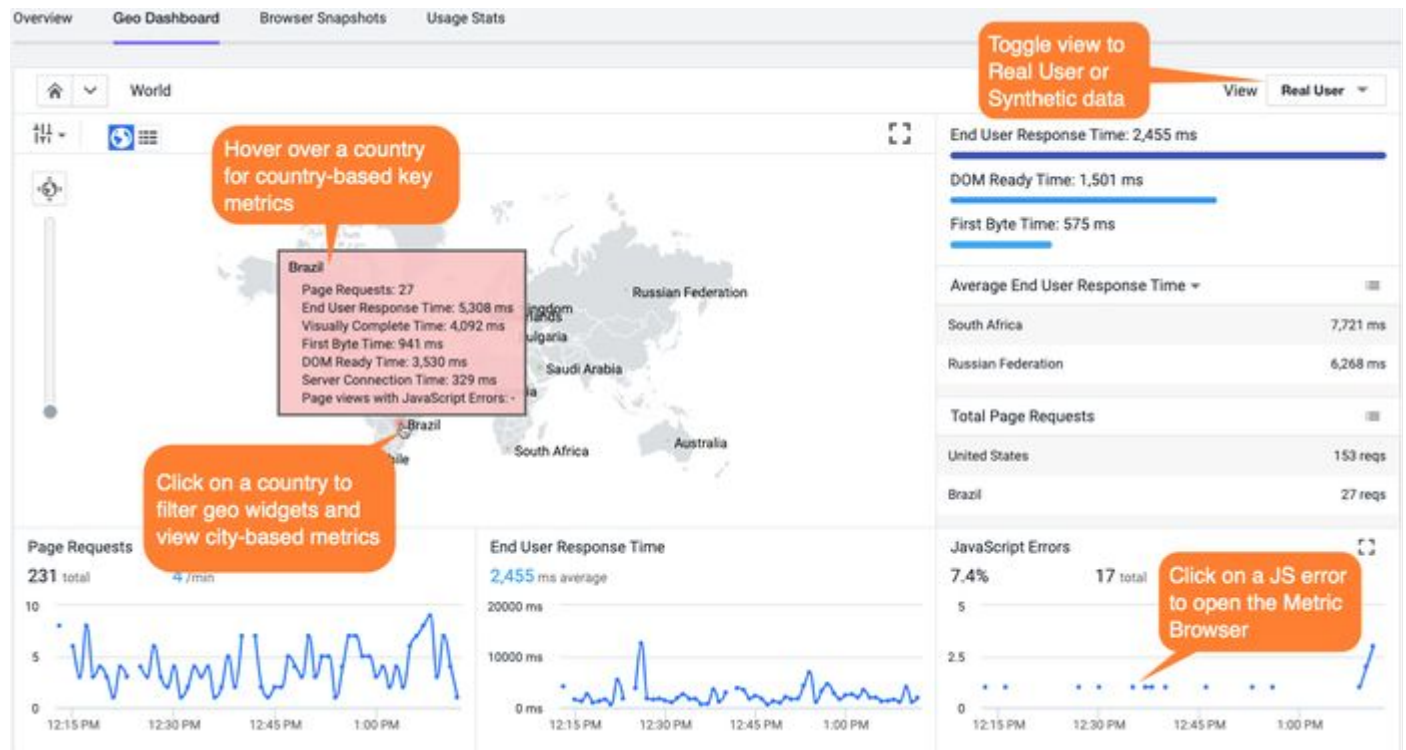

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Geo Tab

The **Geo** tab displays key performance metrics by geographic location based on page loads. If you are using Browser Synthetic Monitoring for an application, you can view either Real User or Synthetic data using the **View** dropdown. See [Browser Synthetic Monitoring versus Browser Real User Monitoring](#).

The metrics displayed throughout the dashboard are for the region currently selected on the Map or in the Grid. For example, on the map if click on France, the widgets and trend graphs update to display data for France.

See [Browser RUM Metrics](#) for definitions of the metrics.

Map View Labels

The Map view displays load circles with labels for countries that are in the key timing metrics given in the right panel. Some countries and regions, however, are only displayed in the Grid view.

Regions and Countries

Regions are subdivisions of a country, such as a state, province, or city. In the default Map view, key performance metrics are displayed by country. You can check the **Show regions in Global View** box to view the key performance metrics by region. The default Grid and Map views display key performance metrics by country, but you can view metrics based on region. Because the Map view displays fewer regions than the Grid view, if you do not see a region displayed in the Map view, switch to the Grid view.

See [Browser RUM Countries and Regions by Geo Dashboard](#) for a list of the countries and regions available in the Map and Grid views.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Unknown Locations

An unknown location means the agent cannot determine the country from which the request originated.

You may also see metrics reported for a location named "Anonymous Proxy". This means that the agent cannot identify one or more private IP addresses, and the "Anonymous Proxy" represents aggregated metrics from those IP addresses.

One of the effects of Unknown regions is that it possible for a country to display as slow (red circles) on the global map, but when you drill down to the country all its regions appear normal (green circles). Or a country may display as normal on the global map, but some sub-regions may display as slow when you drill down.

Browser Snapshots

The **Browser Snapshots** tab captures and displays a broad set of metrics associated with a single request. You can drill down into errors and view any server-side transaction snapshots associated with that request (if your app server is instrumented with server-side app agents). See [Browser Snapshots](#) for more information.

Usage Stats

The **Usage Stats** tab presents aggregated page load usage data based on your users' browser type, device, and platform.

Usage Stats data helps you discover:

- The slowest browsers in terms of total end-user response time.
- The slowest browsers to render the response page.
- The browsers that most of your end users use.
- The browsers that most of your end users use in a particular country or region.

Devices data shows mobile access only via browsers on the device. **Devices** helps you discover:

- The slowest devices in terms of total end-user response time
- The slowest devices to connect to the server
- The devices that most of your end users use
- The devices that most of your end users use in a particular country or region

Browser Snapshots

Related pages:

- [Transaction Snapshots](#)
- [Configure Browser Monitoring Snapshot Thresholds](#)
- [Add Custom User Data to a Page Browser Snapshot](#)

This page describes browser snapshots. When Browser RUM is enabled, the JavaScript Agent collects browser snapshots for:

- Every base page (including virtual pages), iframe, and Ajax request; these serve as a heartbeat snapshot
- The slowest page for every region, every device, and every browser
- Unique JavaScript errors; identified by script name and line number
- Unique Ajax errors; identified by the HTTP error code in the Ajax response

For more information about browser snapshot collection, see [Configure Browser Snapshot Collection](#).

Browser Snapshots Tab

A list of available browser snapshots appears. You can change the time frame of your search by changing the **Time Frame** dropdown.

List Key

Normal user experience

Slow user experience

Very slow user experience

JavaScript errors (Hover over the icon for a popup with summary information)

Correlated server-side transaction snapshot exists

Snapshot includes resource timing information

Browser Snapshot Types

There are three browser snapshot types, depending on whether the original object was a page, an iframe, or an Ajax request.

- [Page Snapshots](#)
- [Ajax Request Snapshots](#)
- [Iframe Snapshots](#)

Page Snapshots

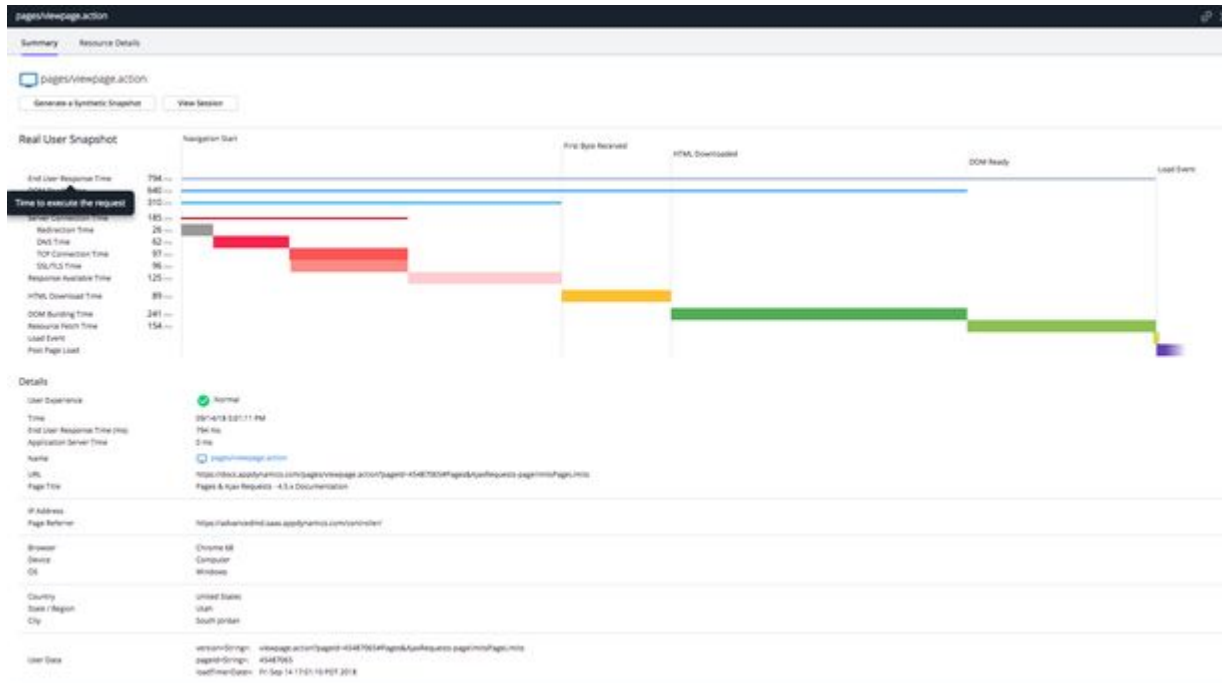

Related pages:

- [Ajax Request Snapshots](#)
- [Iframe Snapshots](#)

Page snapshots give you a detailed look at individual browser page requests. The **Summary** tab covers the general characteristics of the page.

Waterfall Graph

The top of the page snapshot **Summary** tab displays a waterfall graph of the overall transaction timing for the page. You can hover over each of the metrics to see a popup definition for that metric.

For more information about metrics, see [Browser RUM Metrics](#). Additional details associated with the snapshot, including any related snapshots and any custom user data, are displayed as a table below the graph.

Generate a Synthetic Snapshot - SaaS Only

Synthetic snapshots use geographically distributed agents to create snapshots of web page download performance without the idiosyncratic and potentially skewing effects of real-user, last-mile performance. Click **Generate a Synthetic Snapshot** to create an on-demand synthetic snapshot to compare with a problematic real user monitoring snapshot.

Correlated Transaction Snapshots and Business Transactions

If server-side correlation has been set up, a link to any related business transaction is shown:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Business Transactions

View Details

Name ↑	Time (ms)
Fetch Catalog	7,474

Click to view the business transaction flow map.

Clicking the link takes you to the flow map for that business transaction on the server side.

If the business transaction created a transaction snapshot, links to the business transaction, tier, and node flow maps are displayed, along with a direct link to the transaction snapshot flow map. Cross-app correlation is supported.

Transaction Snapshots

View Details

Time ↑	Exe Time (ms)	URL	Business Transaction	Tier	Node
09/14/18 5:30:10 PM	7474	/appdynamicspilot/ViewItems.action	Fetch Catalog	ECommerce-Ser...	ECommerce-Sal...

In this case, the transaction snapshot also has a link back to the browser snapshot.

Transaction: 54bdd5d8-0402-42bb-9383-d67e5bb1c19a

Overview | Slow Calls and Errors | Waterfall View | Segment List | Data Collectors

Summary

Server	Browser
	12177 ms
Page Name	www.ecommerce.com/store/ViewItems.action
Browser	Internet Explorer 9
Device Type	Computer
Device OS	Windows
Location	Bucharest, Bucharest, Romania

XE-Oracle DB-or...4bit Production

11.5 s (94.7%) HTTP

Internet Explorer 9
640 ms (5.3%)

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

JavaScript Errors

If there are JavaScript errors on the page, they are displayed below the waterfall graph.

Script Origin	Line #	Message
/bryan.js	521	TimeoutException
rookie.js	521	ArrayIndexOutOfBoundsException

Note: Callouts in the image indicate 'Script with errors' pointing to the script origin and 'The line and error message' pointing to the line number and message.

You can configure to ignore errors if you are seeing too many irrelevant or excessive errors. See [Configure JavaScript and Ajax Error Detection](#) for instructions.

i When an error occurs in a script that is hosted on a domain other than the domain of the current page, most browsers prevent the JavaScript Agent from recording any details of the error. In such cases, the string `CROSSDOMAIN` is displayed as the **Script Origin**.

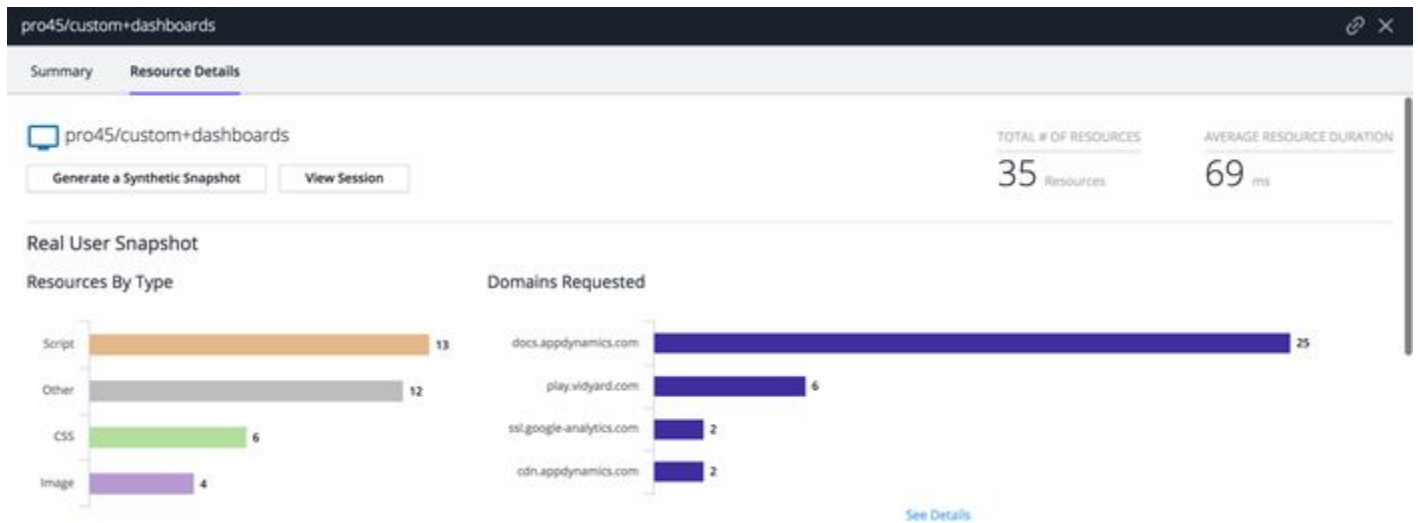

User Data

If you have [custom user data](#) set up, the data appears in the **Details** section:

User Data	Value
algo<String>	LOG(N)
Random Number<String>	1938299132
hotel<String>	AppDynamics Resort

Resource Details

If the [browser](#) supports the [Resource Timing API](#), the Resource Details tab gives you a detailed breakdown of the performance of resources—scripts, CSS files, fonts, SVGs, and images—as they are loaded into the page.

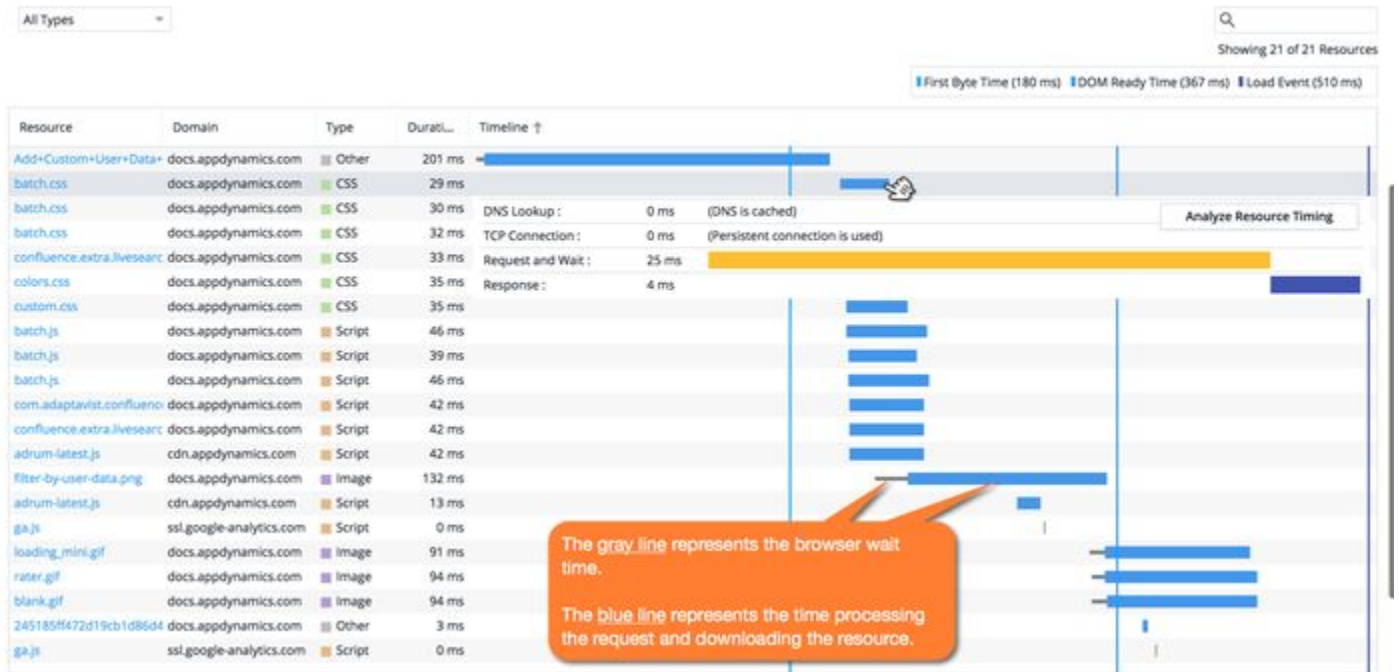

Resource Waterfall

The **Resource Waterfall** provides a snapshot of when each resource was loaded in the page load process (before First Byte Time, before DOM Ready Time, before Onload), including the name of the resource, the domain from which it was fetched, the type of resource, and how long it took. You can filter the items by type using the upper-right dropdown and search using the search box.

To see more details, click any of the blue timelines. These are from the primary domain or cross-domains that have set the `Timing-Allow-Origin` HTTP header. See [Resource Timing Metrics](#) for descriptions and explanations about how the metrics are calculated.

Resource Waterfall

Grey timelines indicate cross-domains that have not set the `Time-Allow-Origin` HTTP header. Working with your CDN provider to add this header can mean you get better information on shared and CDN-served content.

Unknown Metrics in Page Snapshots

Browser RUM captures metrics using your end-users' web browsers. Occasionally, you may see unknown data reported for one or metrics in a browser snapshot. This occurs on older or less sophisticated browsers that do not support the collection of a given metric.

See [Browser Monitoring Metrics](#) for details about which metrics may not be captured based on browser capabilities.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Ajax Request Snapshots

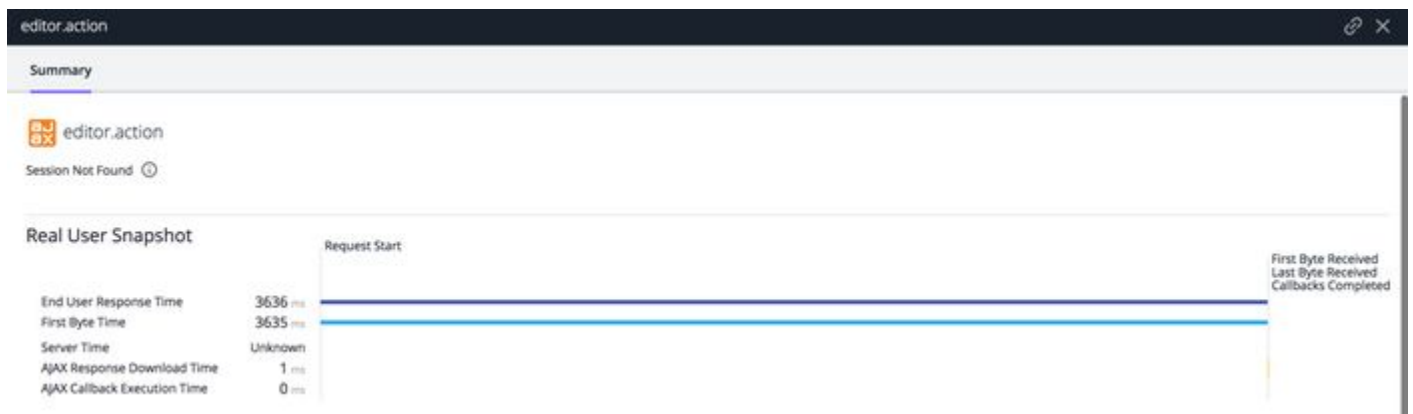

Related pages:

- [Page Snapshots](#)
- [Iframe Snapshots](#)

Ajax request snapshots give you a detailed look at an individual Ajax request. The **Summary** tab of the snapshot describes the general characteristics of the page.

Waterfall Graph

The top of the Ajax snapshot displays a waterfall graph of the overall transaction timing for the Ajax request. The snapshot is labeled either a **Real User Snapshot** or a **Synthetic Snapshot** based on the origin of the request. You can hover over each of the metrics to see a popup definition for that metric.

For a detailed description of what these metrics mean, see [Browser RUM Metrics](#).

Details

Much of the information is the same as you see for [page snapshots](#). The main differences are:

- If there is an Ajax error, the error code returned with it is listed.
- The parent page from which the Ajax call originates is listed.

You can configure errors to ignore if you are seeing too many errors that are not of interest. See [Configure JavaScript and Ajax Error Detection](#).

Iframe Snapshots

Related pages:

- [Page Snapshots](#)
- [Ajax Request Snapshots](#)

Iframe-based snapshots give you a detailed look at an individual iframe request. The UI display is identical to [Page Snapshots](#) except in the **Details** section, where the parent page may also be displayed.

Details	
User Experience	 Normal

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Resource Performance Dashboard

Deployment Support

Related pages:

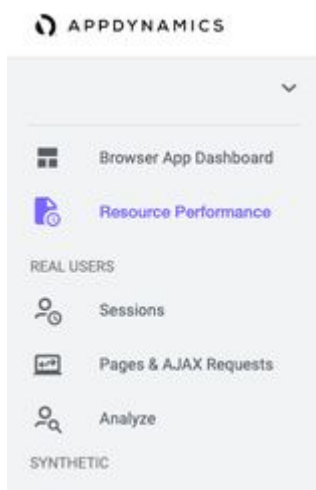

- [Use Cases for the Resource Performance Dashboard](#)
- [Browser RUM Metrics](#)
- [Configure Resource Violation Rules](#)

The **Resource Performance Dashboard** provides a high-level overview of how your resources affect the performance of your browser application. You can use this dashboard to pinpoint resource-related performance issues affecting the user experience, such as the following:

- A prioritized list of resource performance issues by comparing their performance against thresholds
- Changes in the number of resources
- Large resources (images, JavaScript, CSS, etc.)
- Size increase of resources impacting performance. For example, a page banner might be replaced with an uncompressed image, slowing down the page load.
- Slow CDNs
- Resources that haven't been compressed
- Comparison of real user and synthetic resource performance

Overview of the Resource Performance Dashboard UI

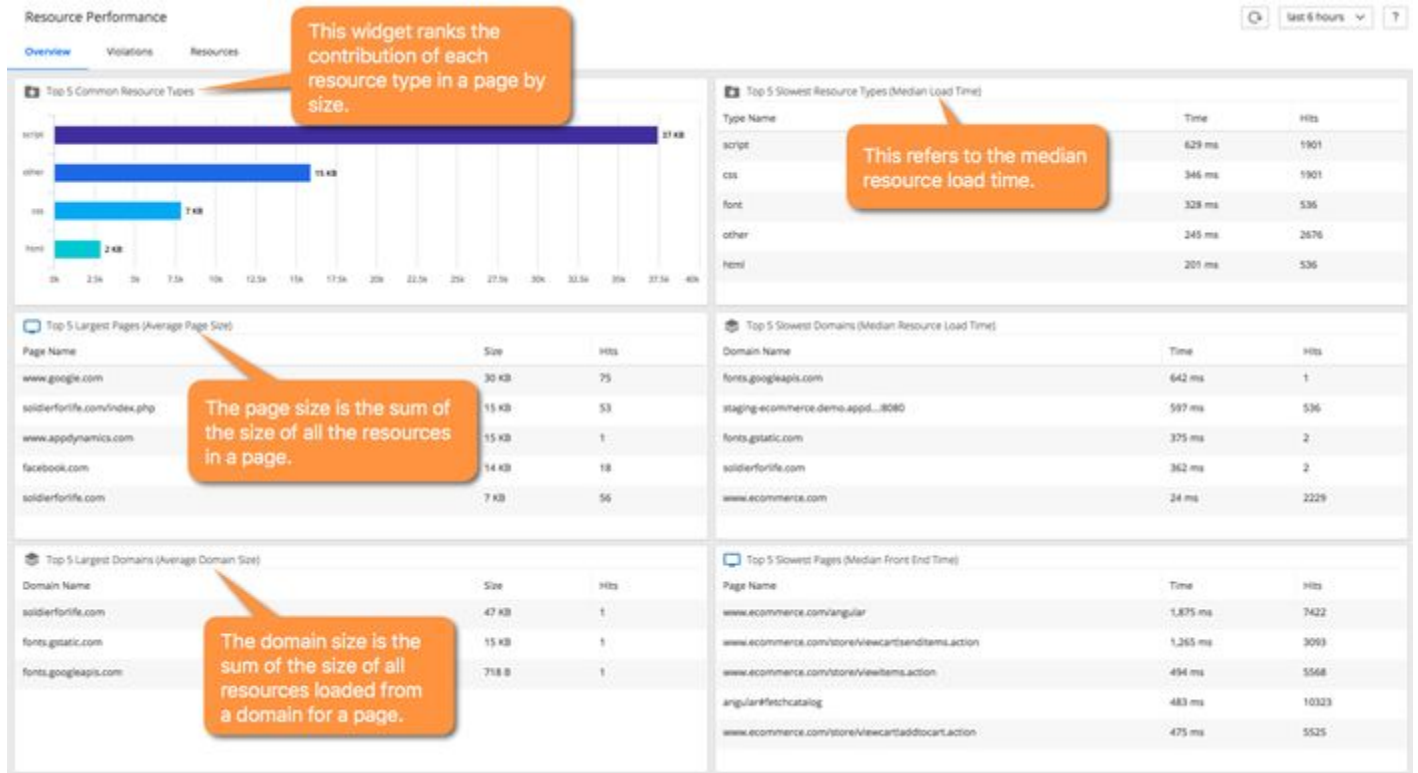

Once you navigate to a browser application, the **Resource Performance Dashboard** is located on the left-side panel.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

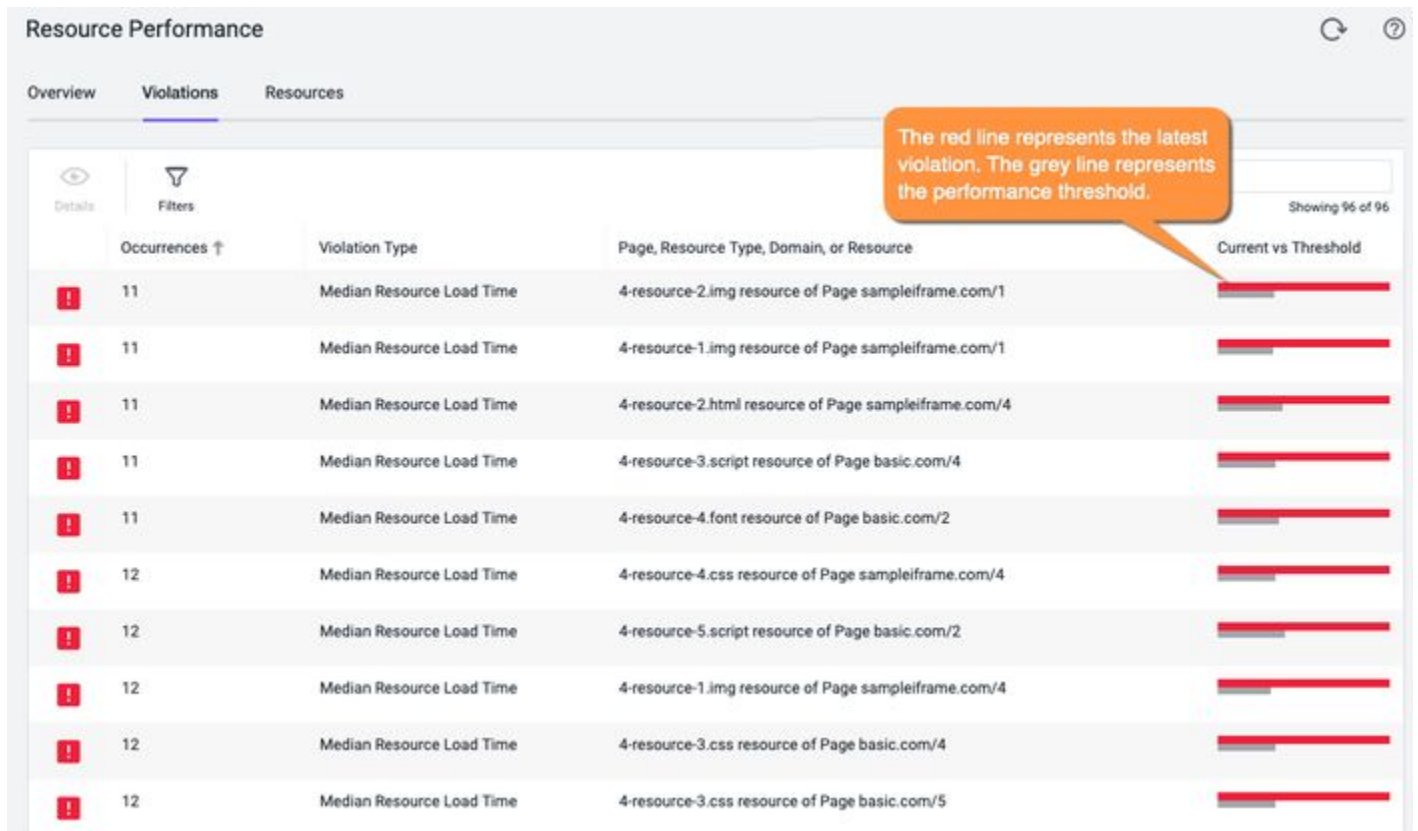

Overview Tab

The **Overview** tab displays widgets providing high-level indicators of resource performance over a specified time period. The dashboard can be filtered to real user or synthetic data. The widgets only show a small number of resources, but you can click **See More** to view up to 100 resources per widget.

Violations Tab

The **Violations** tab shows a list of pages, resource types, and domain or resource violations that have exceeded performance thresholds. You can use the **Violations** tab to not only find problematic resources, but also to become aware of sudden changes that negatively impacted the performance of a resource. Clicking a specific violation leads to the **Resources** tab, and the data is filtered with that violation for further diagnostics. The configured violation rules are evaluated every 10 minutes for the last 30 minutes.

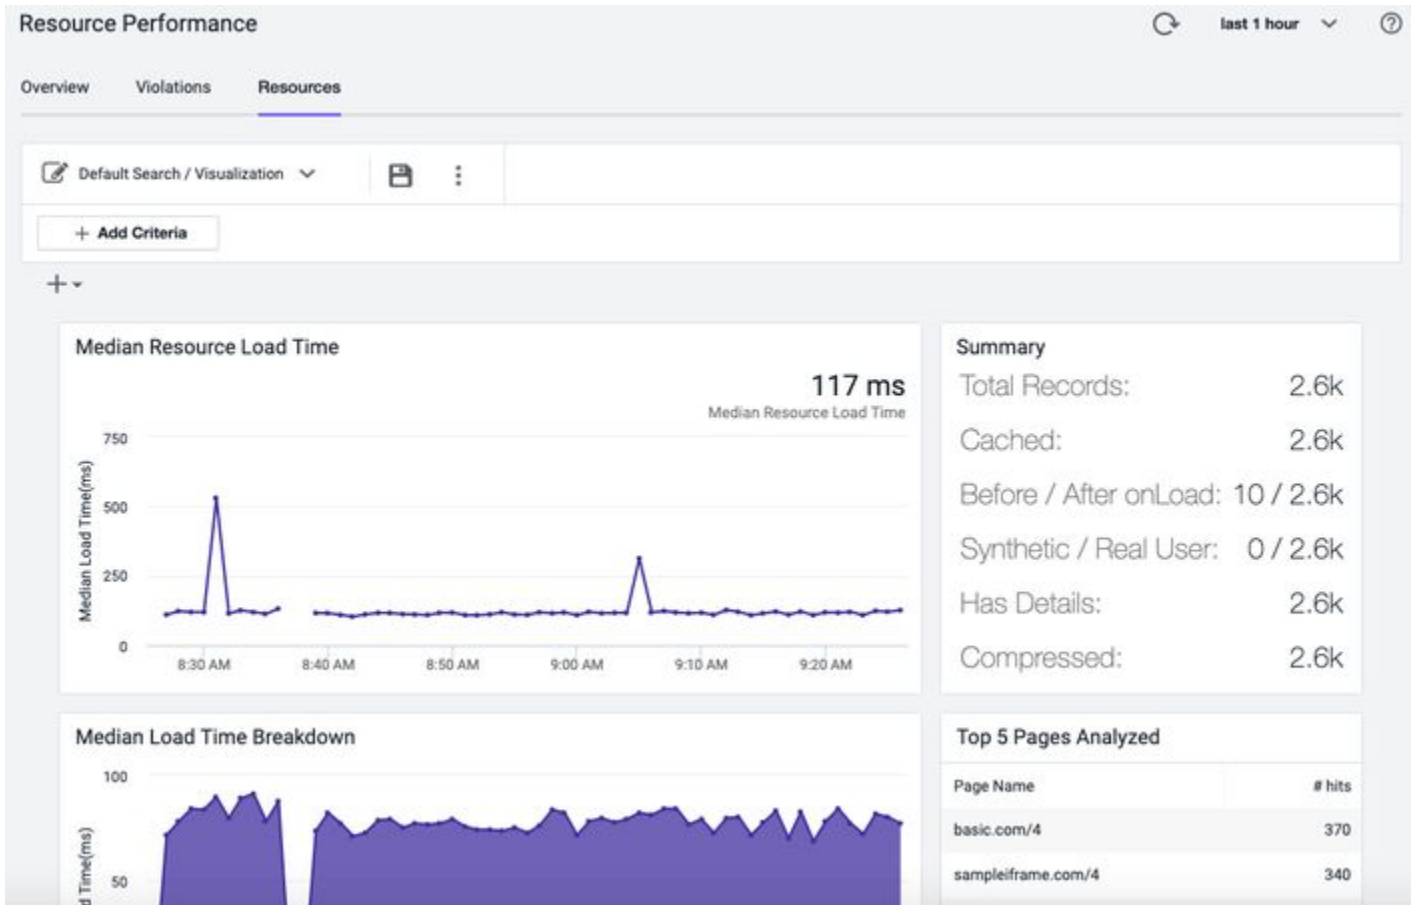

Violation Types

The supported violation types include:

- Median Domain Load Time
- Average Domain Size
- Average Page Size
- Median Resource Load Time
- Average Resource Size
- Median Resource Type Load Time
- Average Resource Type Size

Resources Tab

You can use the **Resources** tab to diagnose a problematic resource. You can also add criteria as a filter to the widgets. All use cases to troubleshoot a resource leads to the **Resources** tab where you can learn more about an individual resource's impact on an application. See [Use Cases for the Resource Performance Dashboard](#) for examples.

Additional Resource Performance Data Information

For the **Resource Performance Dashboard** to be effective, it is highly recommended that you set the `Timing-Allow-Origin` HTTP header in all of your CORS domains to enable access to resource timing information. Without this header, the JavaScript Agent cannot capture the resource size, and, of the supported [Resource Performance Dashboard](#), only the resource load time can be calculated.

For information about resource performance data retention, see [License Entitlements and Restrictions](#).

Use Cases for the Resource Performance Dashboard

The Resource Performance Dashboard provides a high-level overview of how your resources affect the performance of your browser application.

The table presents common troubleshooting and analysis use cases for resource performance.

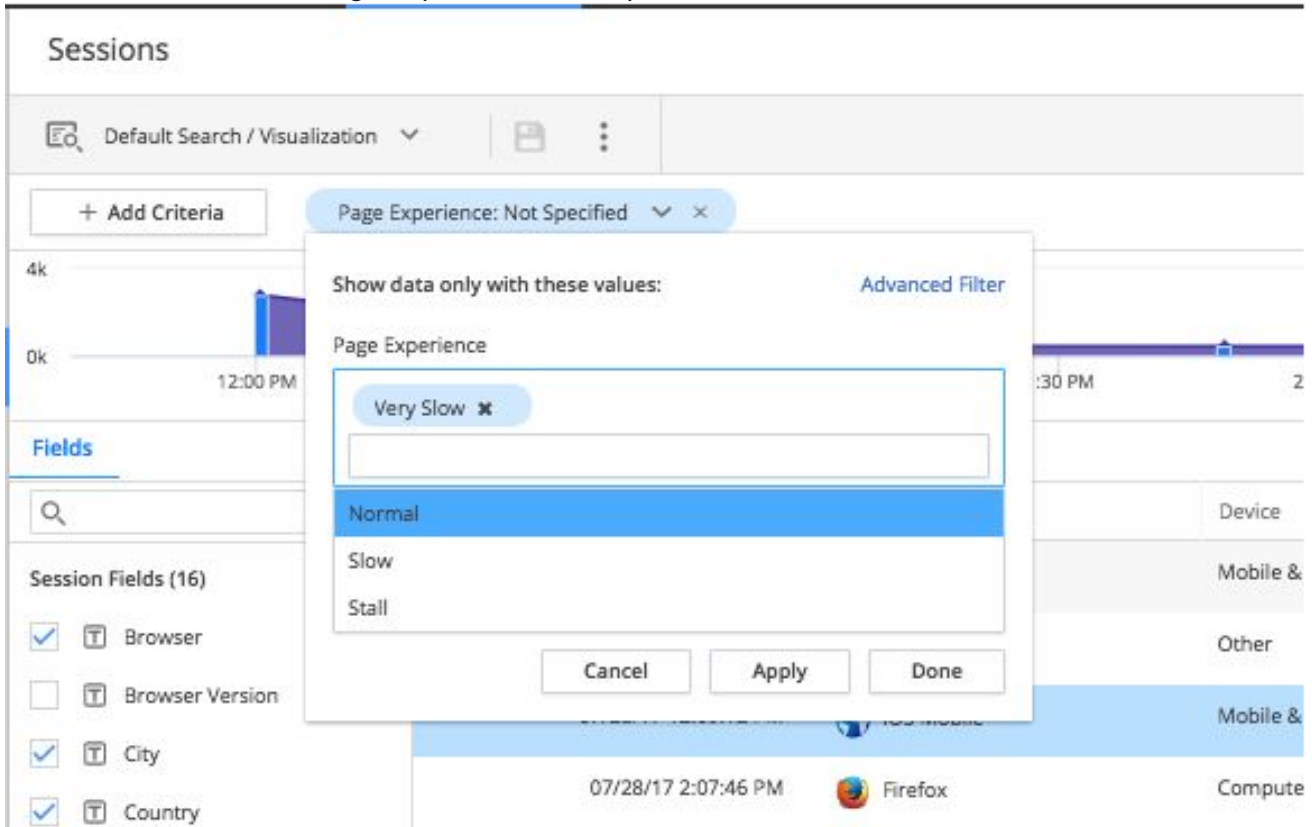

Goal	Use Case
Detect and resolve poor performance issues	Troubleshoot from Sessions
Track and monitor resource violations	Discover Top Resource Violations
View a resource's performance from a particular region	Analyze Resources by Region
Diagnose cause of lengthy load time for image resources	Diagnose Problematic Resources

Troubleshoot a Resource from Sessions

Follow these steps to troubleshoot a resource from **Sessions**:

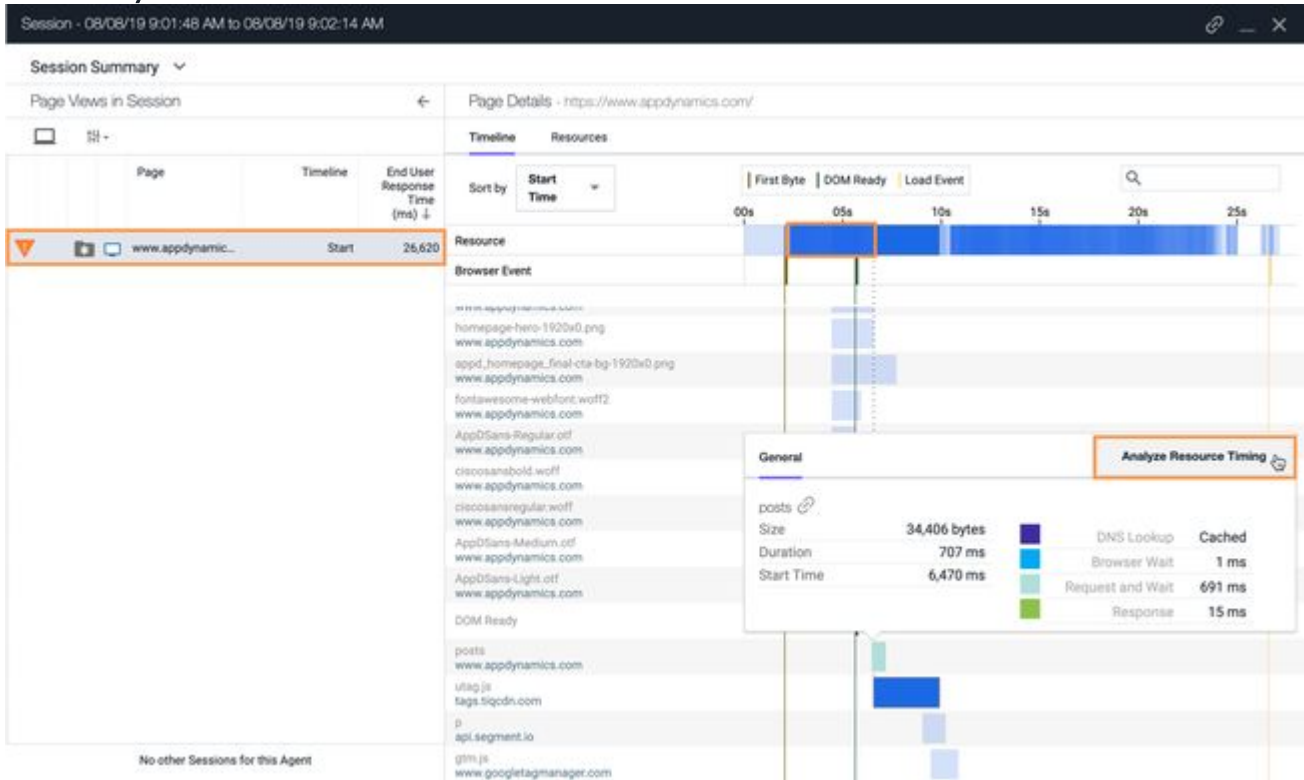

1. Go to **Sessions**.

2. Add criteria and set the Page Experience to Very Slow.

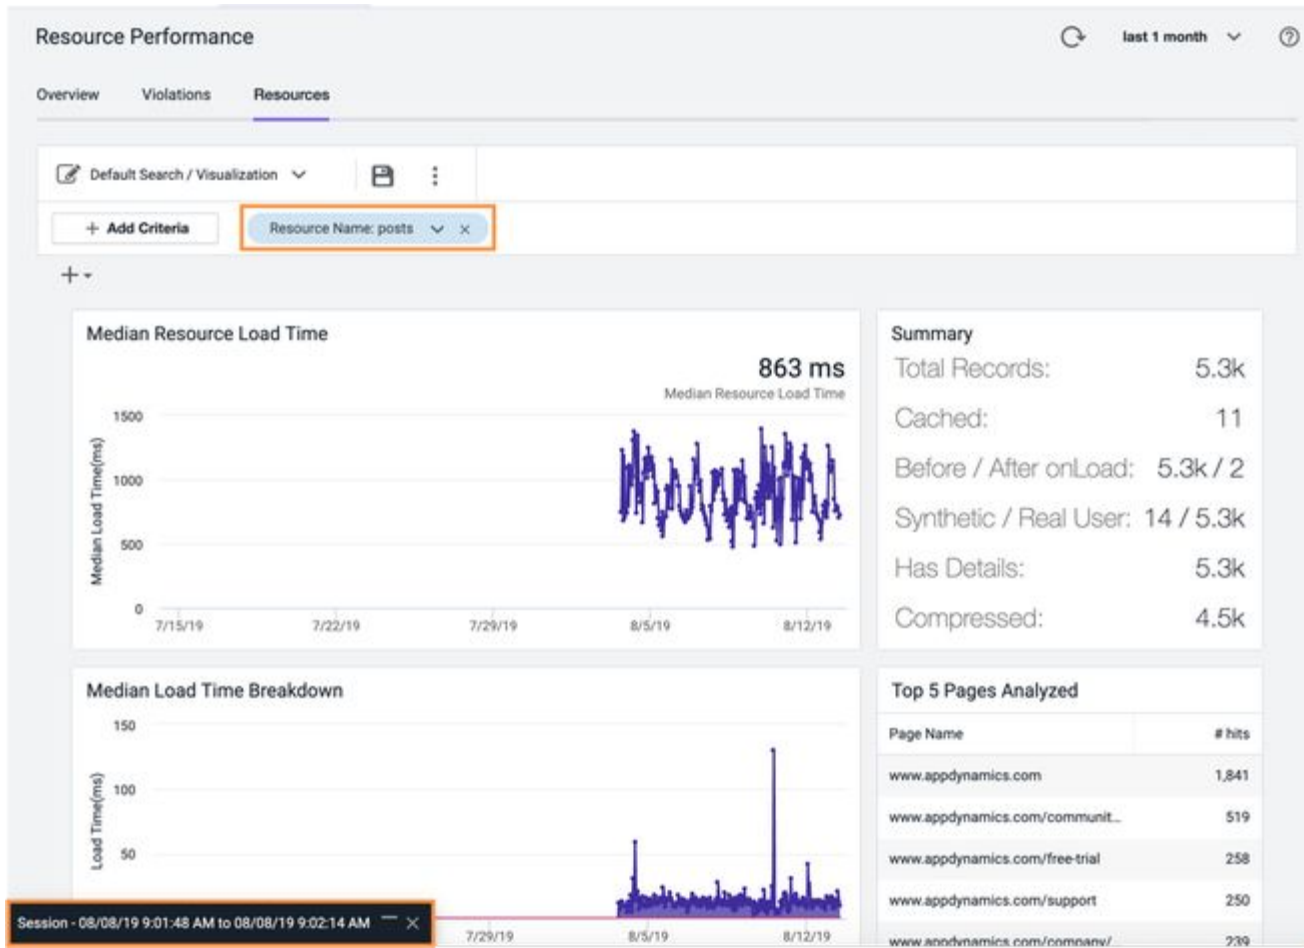

3. Double-click on a session record.
4. In the **Session Summary** select the page with the longest **End User Response Time**.
5. In the **Waterfall** tab, click a problematic resource to open the **Resource Details** dialog.

6. Click Analyze Resource.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

7. You are redirected to **Resource Performance > Resources**. The resource becomes the filter for the dashboard data.

8. In the widgets, look for patterns or possible factors such as geographic location, domains, and so on. See [Diagnose Problematic Resources](#) to learn some strategies for diagnosing resource issues.

i To rule out environmental factors such as network connections, browser, and so on, create a synthetic job that calls a page with the resource to confirm the resource is the problem.

Discover Top Resource Violations

Follow these steps to determine which resource is causing the most performance violations:

1. Go to the **Resource Performance > Violations**.
2. Select the **Occurrences** column so that number of occurrences is in descending order.

3. Double-click the top-occurring violation.

Resource Performance

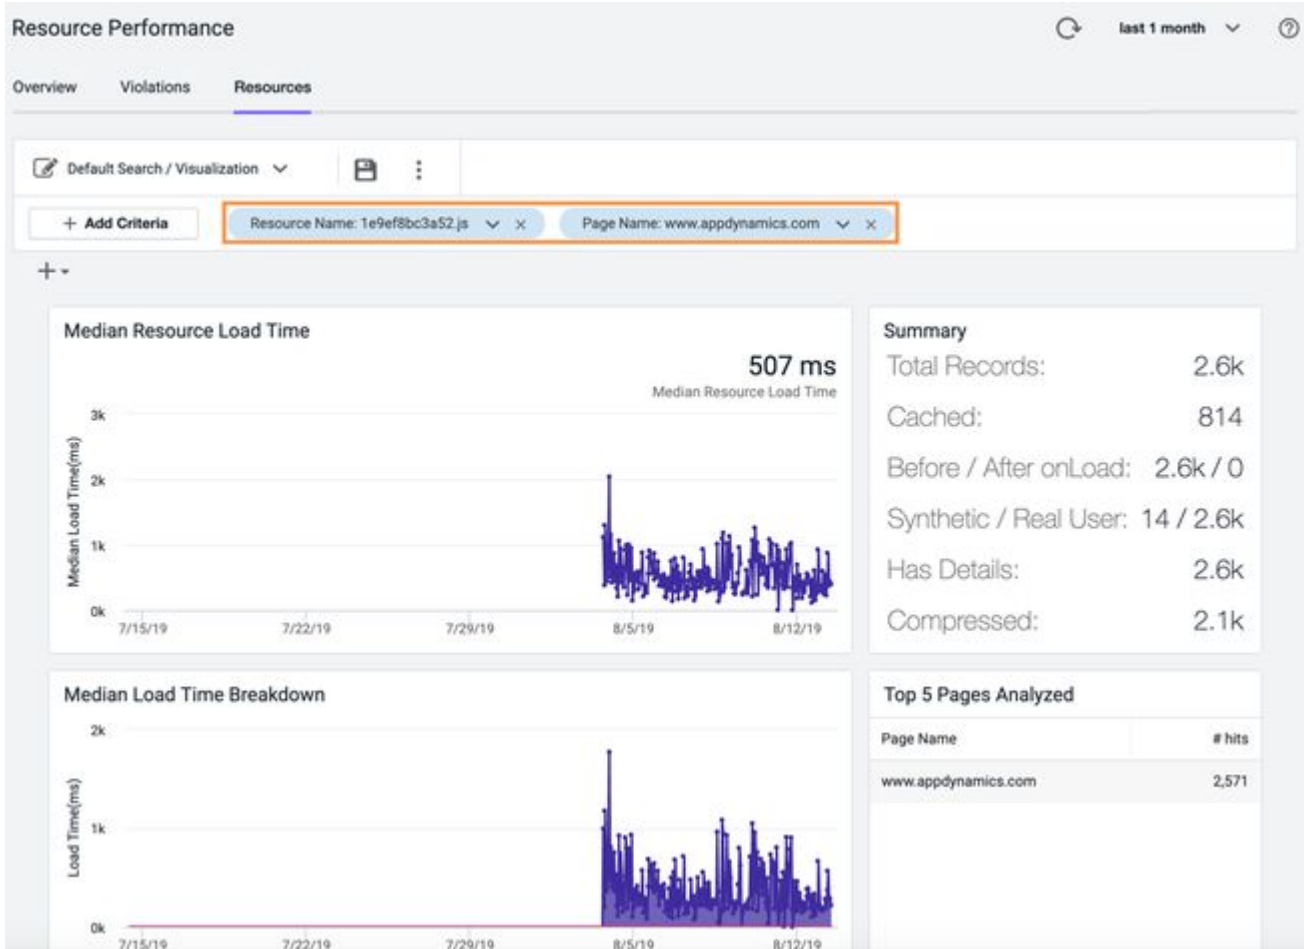

Overview **Violations** Resources

Details Filters Showing 106 of 106

	Occurrences ↓	Violation Type	Page, Resource Type, Domain, or Resource	Current vs Threshold
	62	Avg Resource Size	1e9ef8bc3a52.js resource of Page www.appdynamics.com	
	57	Avg Resource Type Size	img resources of Page www.appdynamics.com	
	57	Avg Resource Size	homepage-hero-1920x0.png resource of Page www.appdynamics.com	
	56	Median Resource Load Time	posts resource of Page www.appdynamics.com	
	55	Median Resource Type Load Time	other resources of Page www.appdynamics.com	
	53	Median Resource Type Load Time	script resources of Page www.appdynamics.com	
	53	Median Resource Load Time	homepage-hero-1920x0.png resource of Page www.appdynamics.com	
	50	Median Resource Load Time	1e9ef8bc3a52.js resource of Page www.appdynamics.com	
	45	Median Resource Type Load Time	img resources of Page www.appdynamics.com	
	41	Median Resource Load Time	nhanatan.nif resource of Page www.appdynamics.com	

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

4. You are redirected to the **Resources** tab with information for the resource in violation.

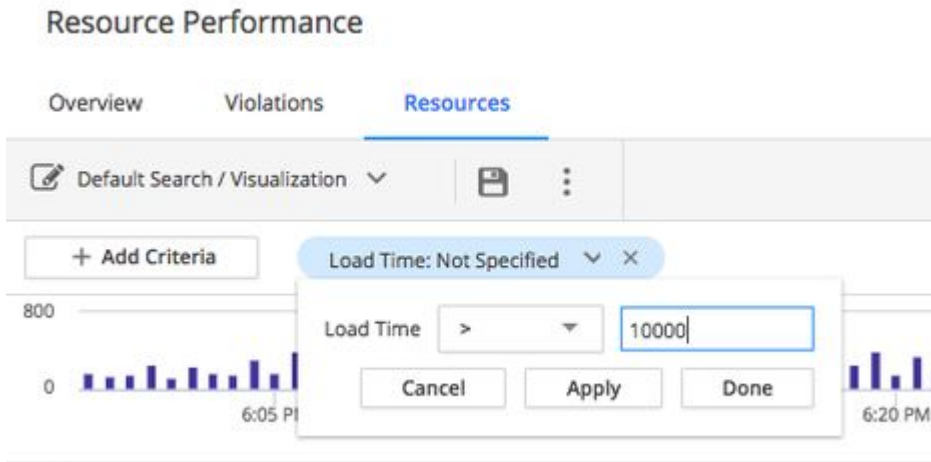

Analyze Resources by Region

Follow these steps to analyze and monitor a resource based on a region:

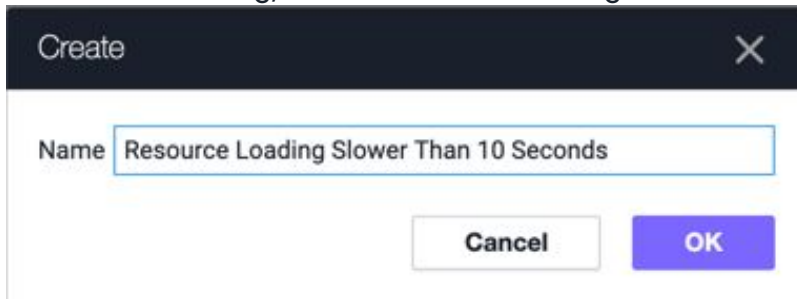

1. Go to the **Resources** tab.
2. From the **Add Criteria** drop-down, select **Load Time** and specify the value to be greater than 10000 (10 seconds).

3. Click **Apply**.

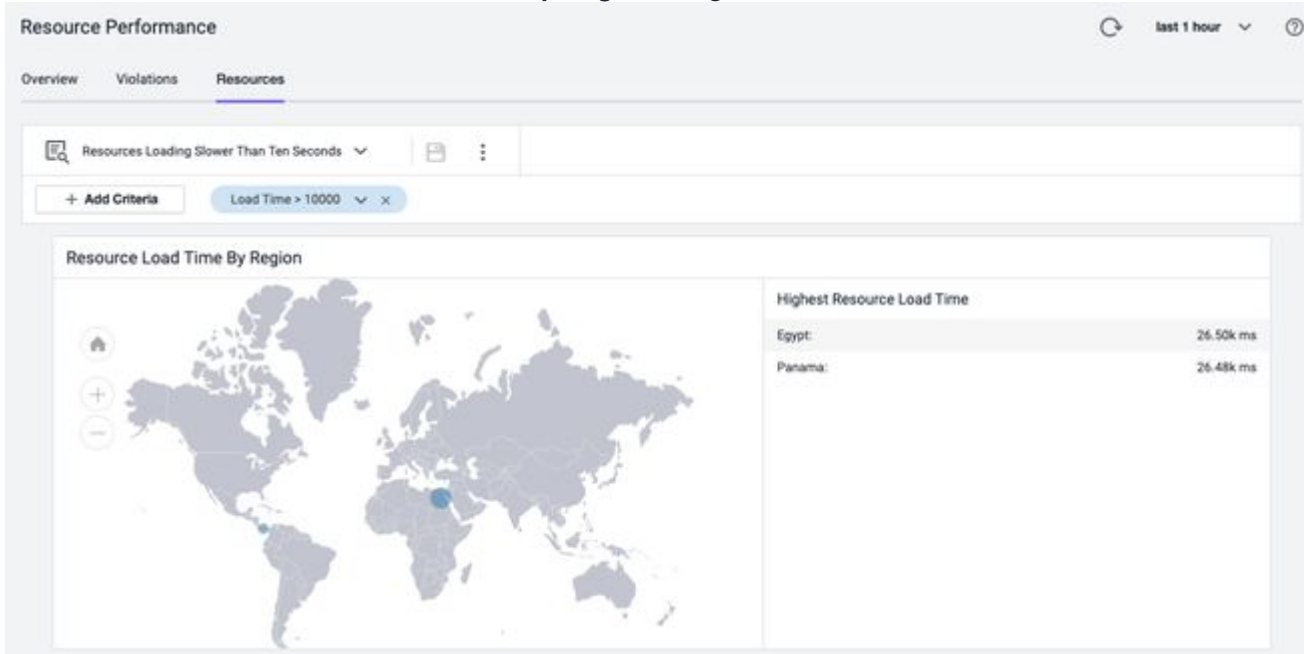

4. Click .

5. In the **Create** dialog, enter "Resources Loading Slower Than 10 Seconds," and click **OK**.

6. Scroll down to the **Resource Load Time by Region** widget.

Diagnose Problematic Resources

Follow these steps to diagnose why certain image resources are taking a long time to load:

1. From the **Violations** tab, double-click on a resource. You are redirected to the **Resources** tab with the resource applied as a data filter.

The screenshot shows the 'Resource Performance' dashboard with the 'Violations' tab selected. The table below lists various violations, with the row for 'Avg Resource Type Size' for 'img resources of Page www.appdynamics.com' highlighted in orange.

Occurrences ↓	Violation Type	Page, Resource Type, Domain, or Resource	Current vs Threshold
85	Avg Resource Size	1e9ef8bc3a52.js resource of Page www.appdynamics.com	
81	Avg Resource Type Size	img resources of Page www.appdynamics.com	
81	Avg Resource Size	homepage-hero-1920x0.png resource of Page www.appdynamics.com	
76	Median Resource Type Load Time	other resources of Page www.appdynamics.com	
74	Median Resource Load Time	posts resource of Page www.appdynamics.com	
62	Median Resource Type Load Time	script resources of Page www.appdynamics.com	
59	Median Resource Load Time	homepage-hero-1920x0.png resource of Page www.appdynamics.com	
58	Median Resource Load Time	1e9ef8bc3a52.js resource of Page www.appdynamics.com	
57	Median Resource Type Load Time	img resources of Page www.appdynamics.com	

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

2. Select criteria fields to determine possible causes, such as **Region, Cached, Compressed, Load Time, Domain**, and so on.

- Example: Confirm that resources are cached or compressed.
- Example: Add criteria that may indicate issues with the server based on the location of the resource, such as **DNS Lookup Time, Connection Time, Wait Time**, and **Request Time**.

The screenshot displays the 'Resource Performance' dashboard. At the top, there are tabs for 'Overview', 'Violations', and 'Resources'. Below the tabs is a search bar with a 'Default Search / Visualization' dropdown and an 'Add Criteria' button. Four criteria are applied and highlighted with an orange box: 'Resource Type: img', 'Page Name: www.appdynamics.com', 'URL: https://www.appdynamics.com/media/uploaded...', and 'Cached: False'. Below the criteria are three main sections: a line chart for 'Median Resource Load Time' showing a single data point at 1,899 ms; a bar chart for 'Median Load Time Breakdown'; and a table for 'Top 5 Pages Analyzed' showing 'www.appdynamics.com' with 2 hits. To the right of the charts is a 'Summary' table with the following data:

Summary	
Total Records:	2
Cached:	0
Before / After onLoad:	2 / 0
Synthetic / Real User:	0 / 2
Has Details:	2
Compressed:	0

3. Search for patterns that indicate the cause within the widgets, providing insights such as:

- Resource load time speed in certain regions
- Top pages using the resource
- Median load time breakdown showing that load time slows down at certain intervals
- Resource size increases

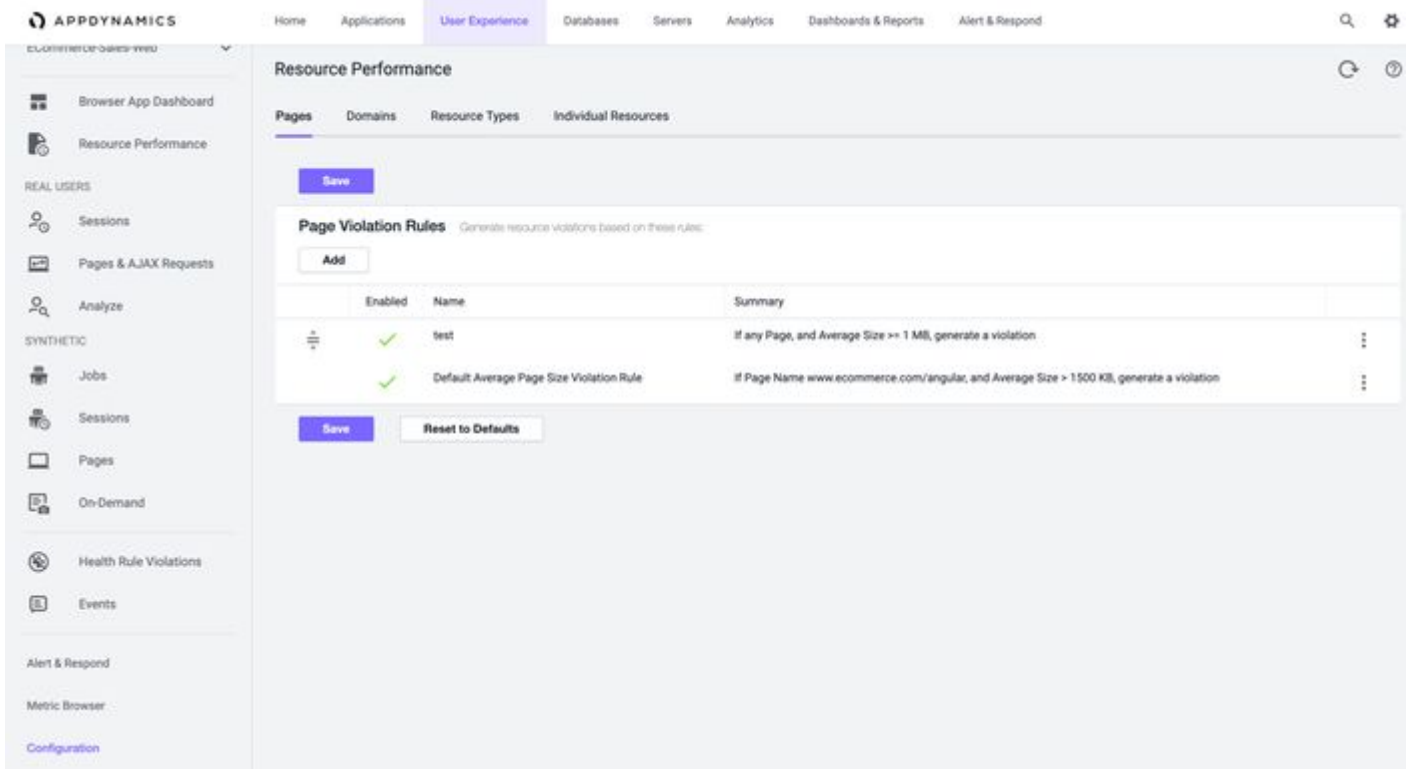

To rule out environmental factors such as network connections, browser, and so on, create a synthetic job that calls a page with the resource to confirm the resource is the problem.

Configure Resource Violation Rules

This page describes how to configure resource violation rules for the Resource Performance Dashboard. You can configure violation rules for pages, domains, resource types, and individual resources. You can use or edit the default rules per category or create your own rules. Resource Performance configuration is only available to admin-level users.

To configure resource violation rules, navigate to **Configuration > Resource Performance**.

Pages Violation Rules

Page violations help monitor your most important pages and ensure they are light and efficient for end users. You can set violation rules for all pages, individual pages, or by pages matching query criteria within an application. The average page size can be set to megabytes, kilobytes, or bytes. This helps you troubleshoot application performance based on pages.

Edit Page Violation Rule
✕

Enabled

Affected Page

All Pages in the Application

Pages Matching the Following Criteria

These specified Pages

Affected Pages > Specific Value

Use Case

In this scenario, your home page size average is 1500 KB, and you want to be notified when it surpasses that threshold. You can set your home page at a maximum size of 1500 KB. If the violation rule is triggered, you will see the violation in the Violations tab as well as in the "Resource Performance" widget in the Browser App Dashboard.

Domain Violation Rules

Domain violations help monitor the effects of domain performance on your application. You can set violation rules for all affected domains, individual domains, or by domains matching query criteria within an application. The median load time per page view can be set to milliseconds or seconds, and the average domain size can be set to megabytes, kilobytes, or bytes. This helps you troubleshoot poor application performance based on domains.

Edit Domain Violation Rule
✕

Enabled

Affected Domain

All Domains in the Application

Criteria

Generate a violation when > Specific Value for any of the Affected Domains for any of the Affected Pages

Use Case

In this scenario, you want to monitor the performance of your CDN. You can set your CDN domains to a maximum median load time of 1000 ms for all domains in the application. If the violation rule is triggered,

you will see the violation in the Violations tab as well as in the "Resource Performance" widget in the Browser App Dashboard.

Resource Type Violation Rules

Resource type violations help monitor the effects of resource types, such as images, html, css, and so on, within your application. You can set violation rules for all affected resource types or by individual resource type within an application. You can also set the rule to one page, pages matching query criteria, or all pages in the application. The median load time per page view can be set to milliseconds or seconds, and the average domain size can be set to megabytes, kilobytes, or bytes. This helps you troubleshoot poor application performance based on resource types.

✕
Edit Resource Type Violation Rule

Enabled

Affected Resource Type

Affected Pages

Criteria
 Generate a violation when for any of
 the Affected Resource Types for any of the Affected Pages

Use Case

In this scenario, you want to monitor all the images in all pages across your application. You can set all images to maximum average size of 500 KB for all pages in the application. If the violation rule is triggered, you will see the violation in the Violations tab as well as in the "Resource Performance" widget in the Browser App Dashboard.

Individual Resource Violation Rules

Individual resource violations help monitor the effects of one resource across your application. You can set violation rules for all affected resources or by resources matching query criteria within an application. The median load time per page view can be set to milliseconds or seconds, and the average domain size can be set to megabytes, kilobytes, or bytes. This helps you troubleshoot poor application performance based on individual resources.

Edit Resource Violation Rule ✕

Criteria
Generate a violation when for any of
the Affected Resources for any of the Affected Pages

Use Case

In this scenario, you want to monitor all resources on your home page. You can set all resources to a maximum load time per page view at 2 ms within the scope of the home page. If the violation rule is triggered, you will see the violation in the Violations tab as well as in the "Resource Performance" widget in the Browser App Dashboard.

Browser Real User Monitoring

Related pages:

- [End User Monitoring](#)

This page provides an overview of AppDynamics Browser Real User Monitoring (Browser RUM).

Browser Real-User Monitoring (Browser RUM) allows you to see how your web application is performing from the point of view of a real end user. You can drill into the data to explore how users experience your application in their web browsers and answer questions like:

- Which 1st or 3rd-party Ajax or iframe calls are slowing down page load time?
- How does server performance impact end-user experience in aggregate or in individual cases?

Monitor Your Application

Browser RUM offers multiple ways to look at your data in real time. You can:

- Understand and improve your web page's performance
 - Know how your pages, Ajax requests (XHR, Fetch API calls), and IFrames are performing over time. See [The Pages & Ajax Requests View](#).
 - Gain insight into individual requests, with detailed charts on how your pages, Ajax requests, and IFrames load and build in your end user's browsers, with links, if enabled, to reports on server-side performance. See [Browser Snapshots](#).
 - Find your worst performing pages by multiple common metrics. See [Top Pages](#).
- Reduce errors
 - Learn which pages are loading with JavaScript errors, including the script file and line number that are creating the problem. See [Browser Snapshots](#).
- Learn about your users
 - See how your web users are connecting to your application by device/platform and browser. See [Browser App Dashboard](#).
 - Find out where geographically your web users are and how your application is performing across countries and regions. See [Browser App Dashboard](#).
 - Understand how users are navigating through your website and what actions they are taking. See [Browser RUM Sessions](#).

For more information on using Browser RUM, see [Overview of the Controller UI for Browser RUM](#).

How Browser RUM Works

Browser RUM works in the following way:

1. An end user requests the first page from your web application.
2. Your web application executes whatever business logic that particular page requires.
3. Your web application creates the response page to return to the end user. The response page includes:
 - a. application-specific information.
 - b. a copy of a small JavaScript script that knows how to collect relevant performance information about that page. This script is called the JavaScript Agent.
4. The page, with the JavaScript Agent included, is returned to the end user.
5. As the page is being constructed in the browser, the script collects relevant information about the page's performance.
6. At approximately the same time as the `onload` event for the page fires, a copy of a somewhat larger JavaScript file, the JavaScript Agent extension, is downloaded asynchronously by the injected agent.

7. This second script packages the collected performance information and sends it via a web beacon to the EUM Server collector for processing.
8. The two scripts work together to collect and send performance information as the end user navigates through the instrumented pages of your application.

Set Up and Configure Browser RUM

Browser RUM is easy to set up. It is also highly configurable. You can:

- Set up and enable Browser RUM. See [Set Up and Access Browser RUM](#).
- Instrument your application to work with Browser RUM. For more information, see [Configure the JavaScript Agent](#).
- Set up how your information appears in the Controller UI. For more information, see [Configure the Controller UI for Browser RUM](#).

License and Enable Browser RUM

- Browser RUM requires a separate license and must be enabled before it is available for use. For information about licensing, including a description of the types of licenses, see [EUM Accounts, Licenses, and App Keys](#).
- For information on enabling or disabling Browser RUM, see [Enable and Disable Browser RUM](#).

Set Up and Access Browser RUM

Related pages:

- [EUM Accounts, Licenses, and App Keys](#)
- [Inject the JavaScript Agent](#)

This page explains how to set up Browser Real User Monitoring (Browser RUM). Browser RUM collects metrics on your end user's web browsers via the AppDynamics JavaScript Agent. Your web application must be configured to insert this agent into the web pages. This process is called injection. See [Inject the JavaScript Agent](#) on how to inject the JavaScript Agent into your web pages.

To access Browser RUM, you need an [EUM Account](#) and a Browser RUM license. EUM must be enabled through the Controller UI. You can [Enable and Disable EUM](#) if you decide not to use the feature.

EUM Account

A special EUM account is required. An EUM account is created when you have a license for Browser RUM, Browser Synthetic, or Mobile RUM. There is an account license key associated with this account.

For on-premises customers, the account license key is set up within the Controller license file. If you added EUM after your initial installation, you may need to upload and install the new Controller license file. If you are a SaaS customer, the EUM license is set up in the SaaS Controller for you.

Each Browser RUM license provides a certain number of page views per year. For information on how to examine your current page view usage, see [EUM Accounts, Licenses, and App Keys](#).

Access Browser Monitoring Configuration

Your data is displayed in the Controller UI in the context of an EUM application. You must assign unique names to EUM applications and business applications. For example, if you created the business application "E-Commerce", you cannot create a browser, mobile, or IoT application with that same name or vice versa. An EUM application name is associated with an EUM App Key, which identifies data coming into the Controller.

1. If you do not yet have an EUM application, click the **User Experience** tab, the **Browser Apps** tab, and the **+Add** button. You can create an application name either by using the **Getting Started Wizard** or by simply choosing an application name.
2. Open the EUM application you are interested in by double-clicking on the application name in the **Browser Apps** list.
3. In the left navigation bar of the application UI, click **Configuration**.

Browser RUM Prerequisites

To turn on Browser RUM, you need to:

- [Enable Browser RUM](#)
- [Inject the JavaScript Agent](#) into your application pages

If you are an on-prem customer, your JavaScript Agent version should be equal to or less than your EUM Server version.

Enable and Disable Browser RUM

At the top of the **Configuration > Instrumentation** page, toggle the **Browser Monitoring**:

Instrumentation

Browser Monitoring: ON App Key: [REDACTED]

Base Page and iFrames AJAX Virtual Pages Errors Settings

Save

Exclude Rules For Real User Monitoring, exclude the Page if any of the following are true:

Add

Name	Enabled	Summary
Click the Add button to add a new rule		

Include Rules For Real User Monitoring, evaluate these rules in this order to create and name the Page: ⓘ

Add

Name	Enabled	Summary
Default Naming Configuration	✓	Name the Page using: Full-Domain; first 2 segments of the URL.

Save

To disable Browser RUM, toggle the switch to **OFF**.

Inject the JavaScript Agent for Browser RUM into Your Application Pages

The JavaScript Agent for Browser RUM collects Browser RUM metrics. See [Browser RUM Metrics](#) for more detail.

The JavaScript Agent for Browser RUM must be inserted into the headers of the pages for which you want to see these metrics. This process is called *injection*. There are several ways to accomplish this. See [Inject the JavaScript Agent](#).

External Access Locations

Browser RUM is made up of several components, which, in various configurations, can either be located on the Internet or hosted inside your own data center/network. On-premises access points are configured at installation or through the UI. If your installation requires access to any of these components on the Internet, see [Access the SaaS EUM Server](#) for more information.

If you are using the AppDynamics CDN to fetch the JavaScript Agent (`adrum.js`) and JavaScript Agent extension (`adrum-ext.js`), you also need to make sure that `cdn.appdynamics.com` is accessible from your network.

Additional Browser RUM Configurations

You can also configure:

- [Page Identification and Naming](#)
- [JavaScript and Ajax Error Detection](#)
- [Browser Snapshot Thresholds](#)
- [Browser Snapshot Collection Rules](#)

Overview of the Controller UI for Browser RUM

Browser RUM presents information in these views:

- An **Overview** dashboard, with sections for:
 - [widgets](#) for graphic display of common metrics
 - [map-based performance](#) display
 - [snapshots](#) of individual requests
 - [usage statistics](#) by browser and device/platform
- [Unified data for entire sessions](#), following an individual user's path as they navigate through your site
- Detailed information on the performance of individual pages, as
 - [aggregated lists](#) of page, Ajax, iframe, and virtual page request types
 - [multi-faceted data](#) from a complete data store

Access a Browser RUM Application

To see the data for your app in the Controller UI, you must first open your application:

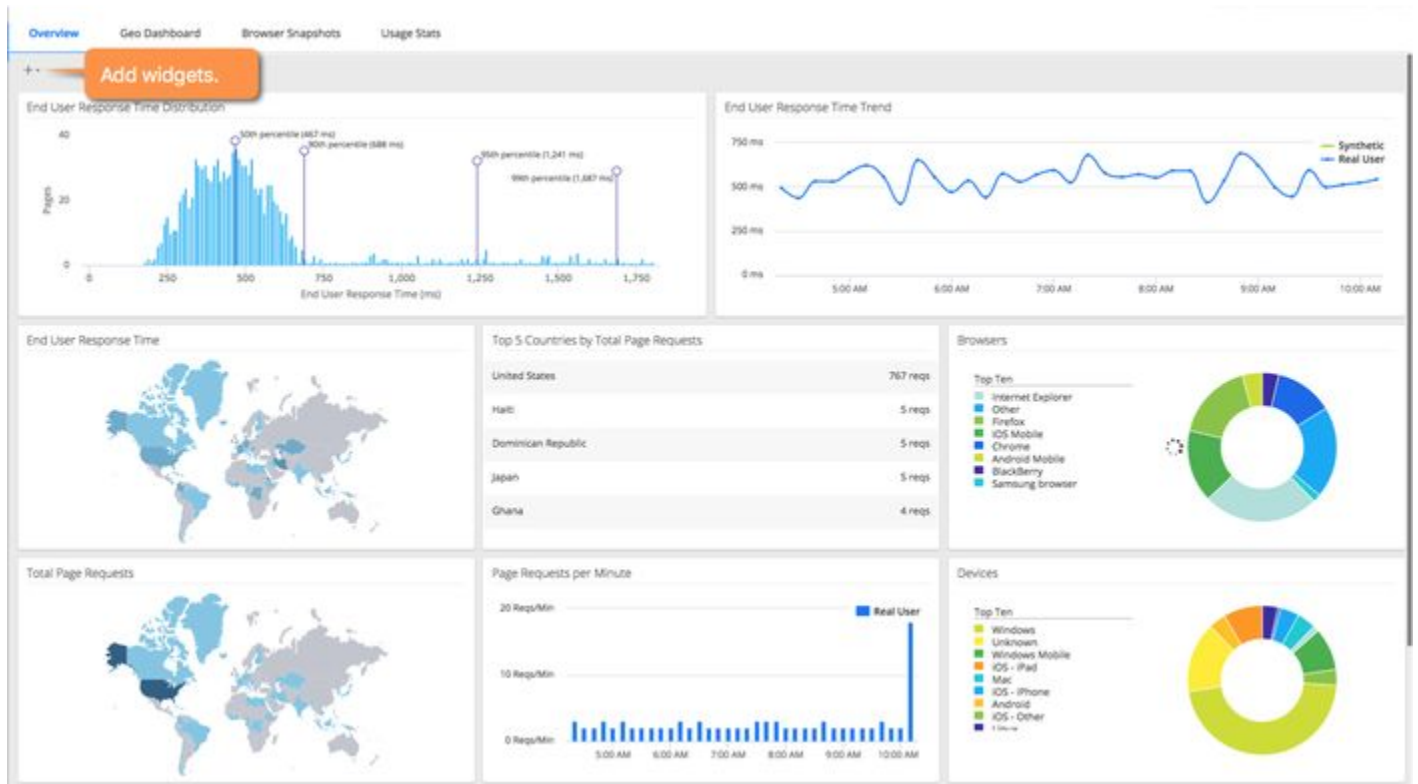

1. In the top tab bar, select **User Experience**. The list of instrumented Browser and Mobile Apps is displayed.
2. Make sure the **Browser App** tab is selected.
3. Double-click on the app you are interested in. The monitoring UI opens.

Browser App Dashboard

This view is good for getting a high-level understanding of how your app is performing overall.

Overview

The **Overview** tab is made up of a set of widgets showing common usage metrics. You can add, delete, move, and resize widgets as you wish. If you see a metric that interests you, click through to the main view. If you are using Synthetic, data from both RUM and Synthetic (separated by color) show up in some of the widgets.

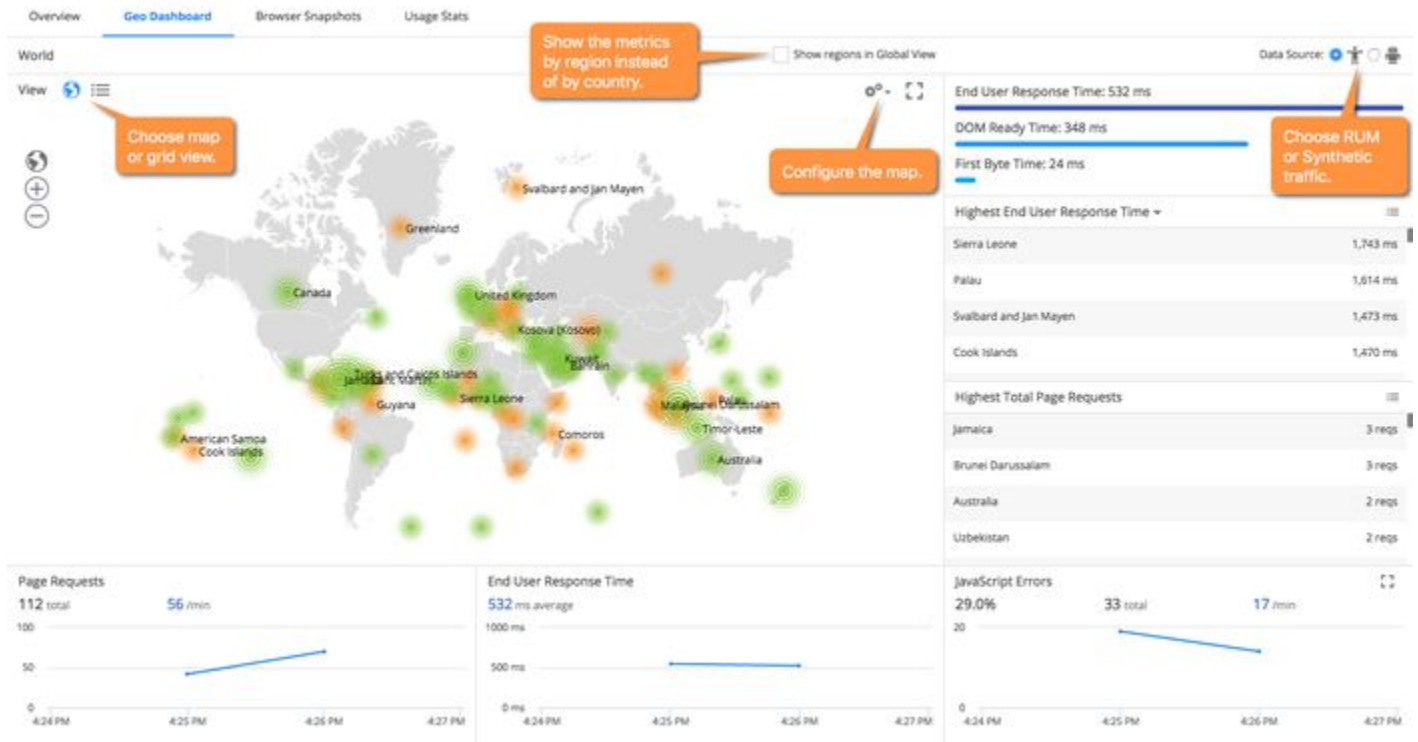

For more information, see [Browser App Dashboard](#).

Browser App Geo Dashboard

The **Geo Dashboard** view provides high-level insight into how your application is performing across the world for your users. The size of a dot indicates the number of page views from that region, and the color indicates the average page load End User Response time in that region (red is slow). You can click to drill down to areas of specific interest. You can also see the same information presented in tabular form by clicking the grid icon in the upper left of the panel.

If you are using Synthetic, you can also select to see either RUM or Synthetic data displayed here. By default, the **Geo Dashboard** displays key performance metrics by country, but you can view performance metrics by region by checking the **Show regions in Global View**.

For more information, see [Browser App Dashboard](#).

i The option **View Dark Mode** has been removed from the **Geo Dashboard**.

Browser Snapshots

The **Browser Snapshot** view provides access to detailed information for individual requests. The list includes both periodic snapshots of requests operating within normal boundaries and problem snapshots of requests that have exceeded one or more configurable performance criteria. Double-clicking a specific item takes you to a detailed graphical representation of the execution flow of that request and other data associated with it.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

For more information, see [Browser Snapshots](#).

Usage Stats

The **Usage Stats** view presents aggregated page load usage data based on the browser type and device/platform employed by your users. The view also breaks down performance by type and usage by country.

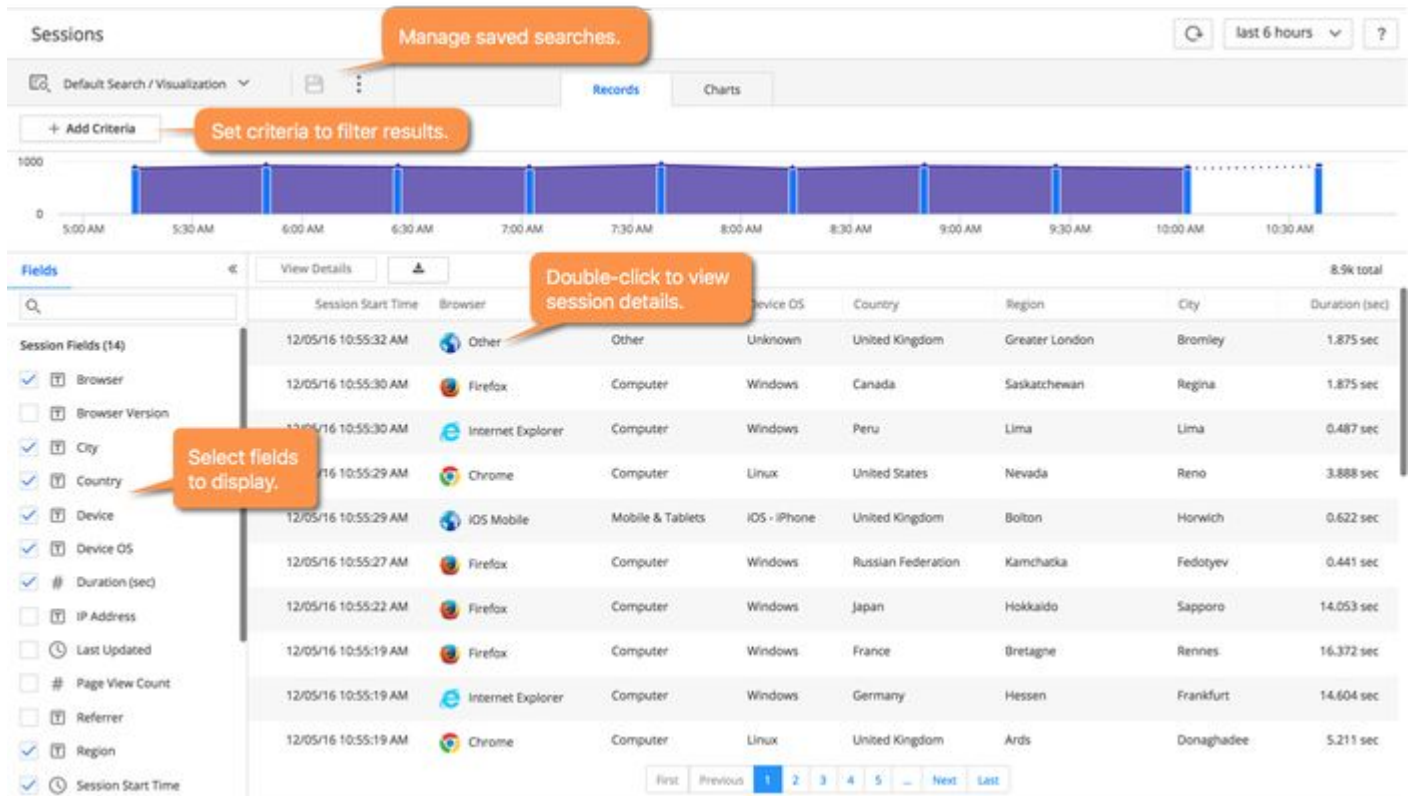

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

For more information, see [Browser App Dashboard](#).

Sessions

In most cases, users interact with your web application over a series of real (or virtual) pages. Sessions allow you to track your users' interactions across time, as they navigate through an entire engagement period with your app. Using Browser RUM Sessions, you can analyze session results from all requests, as stored in the AppDynamics Events Service. Use the **Records** tab to focus on pertinent data and the **Charts** tab to view a dashboard of useful graphics widgets. Or follow a session from page to page using the **Session Detail** dialog.

For more information, see [Browser RUM Sessions](#).

Pages & Ajax Requests

This view is good for tracking the performance of individual pages and components as well as understanding any issues that may be emerging. The **Pages & Ajax Requests** view shows you an aggregated view of how each of your page, Ajax request, iframe, and virtual page types are performing over time. You can look at **All Pages** for an overall sense or select a **Top Pages** view to see the worst performing pages sorted by common metrics like Page views with JavaScript Errors and First Byte Time. And you can drill down to a graphical dashboard showing a wide range of charted performances characteristics for any specific request type.

For more information, see [The Pages & Ajax Requests View](#).

Analyze

The **Analyze** view allows you to query a complete repository of all traffic data that Browser RUM has collected in the past two weeks and display that data in multiple ways.

For more information, see [Browser RUM Analyze](#)

Enable Browser RUM

Browser RUM requires a separate license and must be enabled before it is available for use.

For information about licensing, see [EUM Accounts, Licenses, and App Keys](#).

For information on enabling or disabling Web User Experience, see [Set Up and Access Browser RUM](#).

Browser RUM Sessions

This page describes Browser RUM sessions, and the **Session UI** you use to view session data.

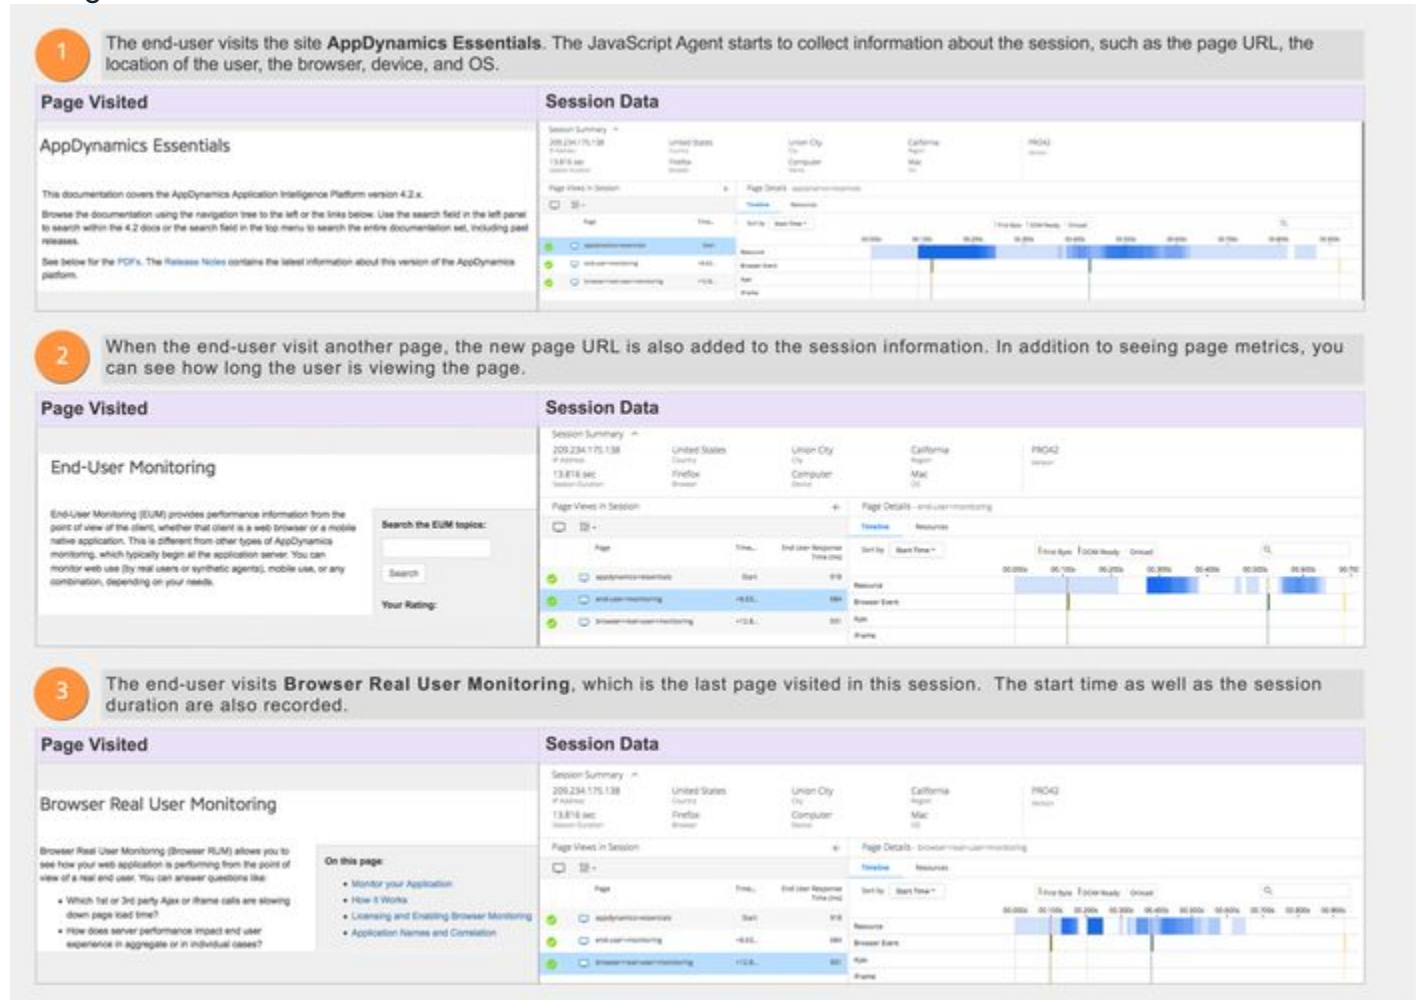

Browser RUM Session

A Browser RUM session is a collection of chronological events for a particular end user from the start of a session to a configurable period of inactivity. An event represents an activity occurring at the moment in time that can be recorded, aggregated, and correlated at certain levels. In Browser RUM, events are limited to page loads, virtual page loads, iFrames, and Ajax requests.

 Only Ajax requests [configured to be published to the Events Service](#) are included in sessions.

For example, when a user purchases product from an e-commerce site, the session might capture the page/virtual page loads, iFrames, or Ajax requests for the user logging in (start), selecting and paying for products, and logging out (end).

This figure describes how the user's actions cause events that are tracked in the session.

RUM Sessions Importance

You can think of sessions as a time-based context to analyze a user's experience interacting with an application. By examining RUM sessions, you can understand how your applications are performing and how users are interacting with them. This enables you to better manage and improve your application, whether that means modifying the UI or optimizing performance.

Use Cases

In some use cases, you can use RUM sessions to analyze a user's or a group's behavior. You analyze a user's behavior based on the user's unique ID across multiple sessions in what is called *sniping*. In addition, you can query for a segment of users with similar behavior, such as visiting a certain specific page or using a particular device. This technique of grouping users with similar behavior is called *bucketing*. Browser RUM sessions allow you to query users on a wide array of criteria such as the type of browser, device, location, landing page, IP address, and more.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

How EUM Captures RUM Sessions

The JavaScript Agent loads a temporary GUID into the browser local storage and then transmits beacons to the EUM Cloud or EUM Server that include this GUID. We can then use the GUID to track the user's device over the duration of one or more sessions. The EUM Cloud then publishes these events into a session record stored in the Events Service.

Session Persistence

Sessions persist until a period of user inactivity that you configure in the controller. Sessions can also end when the GUID is removed from local storage, which can happen for a number of reasons. For example, the user could clear local storage or the browser is configured to clear the local storage when the browser is closed.

Maximum Session Time

We don't technically limit the time of a session. Instead, we restrict the maximum number of events to 1000. You can, however, configure the maximum time for each event by [configuring session monitoring timeouts](#) and then derive the maximum time for a session by multiplying the configured session inactivity timeout by 1000. For example, if you configure the session inactivity timeout for each event to be five minutes, the maximum session time would be 5000 minutes. Of course, in this case, most sessions would not last 5000 minutes because end users would trigger events well before the maximum time of five minutes.

Single Page / Multiple Page Sessions

When the browser cannot write the GUID to local storage, Browser RUM cannot track the user's device over one or more sessions. Instead, Browser RUM uses the temporary GUID in memory to create one-page or multiple *virtual* page sessions. Virtual pages are simply those sections of the DOM that are dynamically created and loaded into the current page.

Privacy/Security of Session Data

We do not perform [browser or device fingerprinting](#). By default, we do not store user IP addresses. If you [configure the Controller to store IP addresses](#), then the IP addresses are stored for up to 14 days.

Browser RUM Support for Sessions

JavaScript Agent Version Requirement for Sessions

You are required to use the JavaScript Agent ≥ 4.2 . Older versions of the JavaScript Agent do not support sessions.

Browser Requirements for Sessions

To use Browser RUM sessions, your browser is required to support for the following:

- [cross-origin resource sharing \(CORS\)](#) for beacons
- [local storage](#) for multiple-page sessions (single-page / multiple virtual page sessions don't need local storage)

Browser RUM sessions do not support beacons implemented with GIFs.

Session Limits

The table below lists the limits for session operations per account.

Session Operations	Maximum Per Account
Stored session resource snapshots	10k per minute
Pending uploads of resource timing snapshots	100k
Published session beacons	10k per minute
Tracked sessions	5k per minute

 After the pending uploads of resource timing snapshots reach 100k, no further resource-timing snapshots are queued.

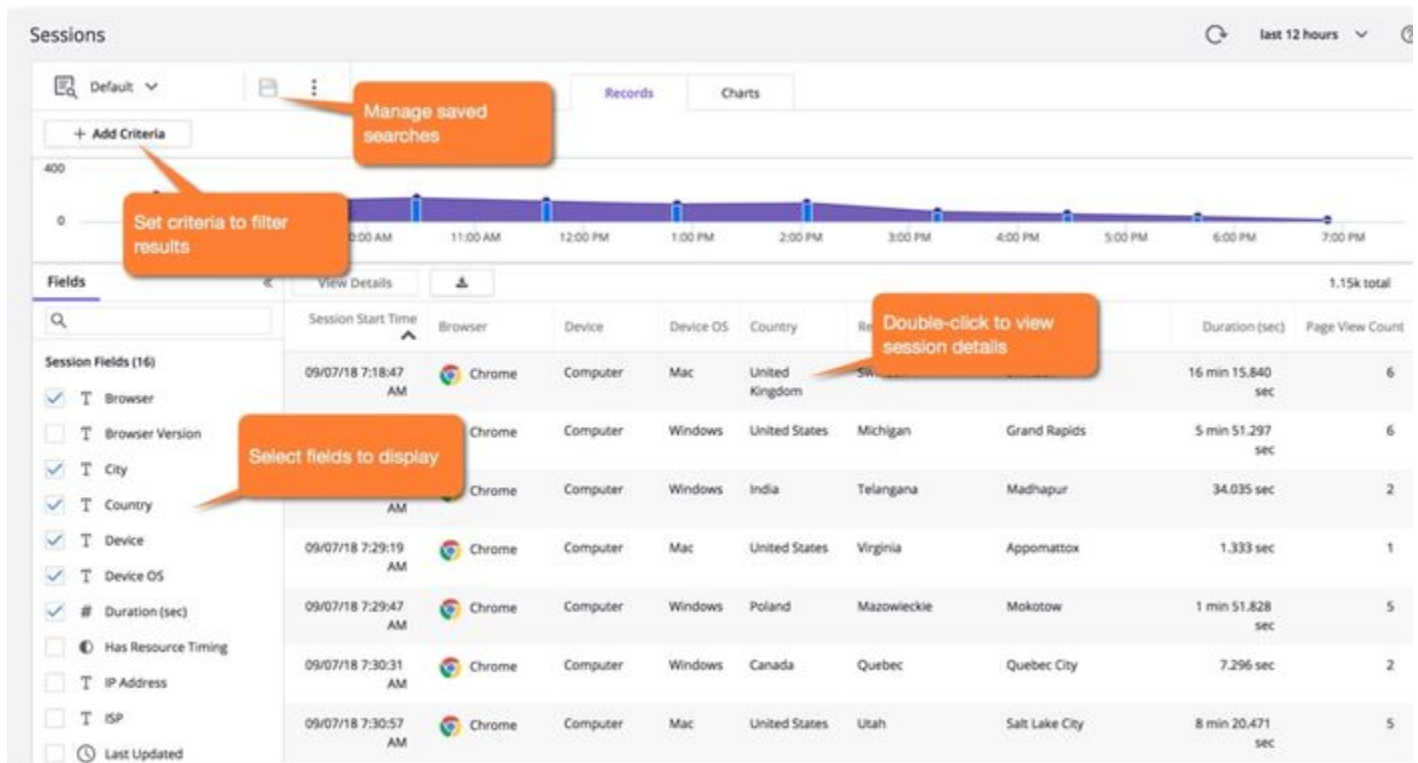

Sessions UI

As in [Browser RUM Analyze](#), the main **Sessions** page is made up of two tabs:

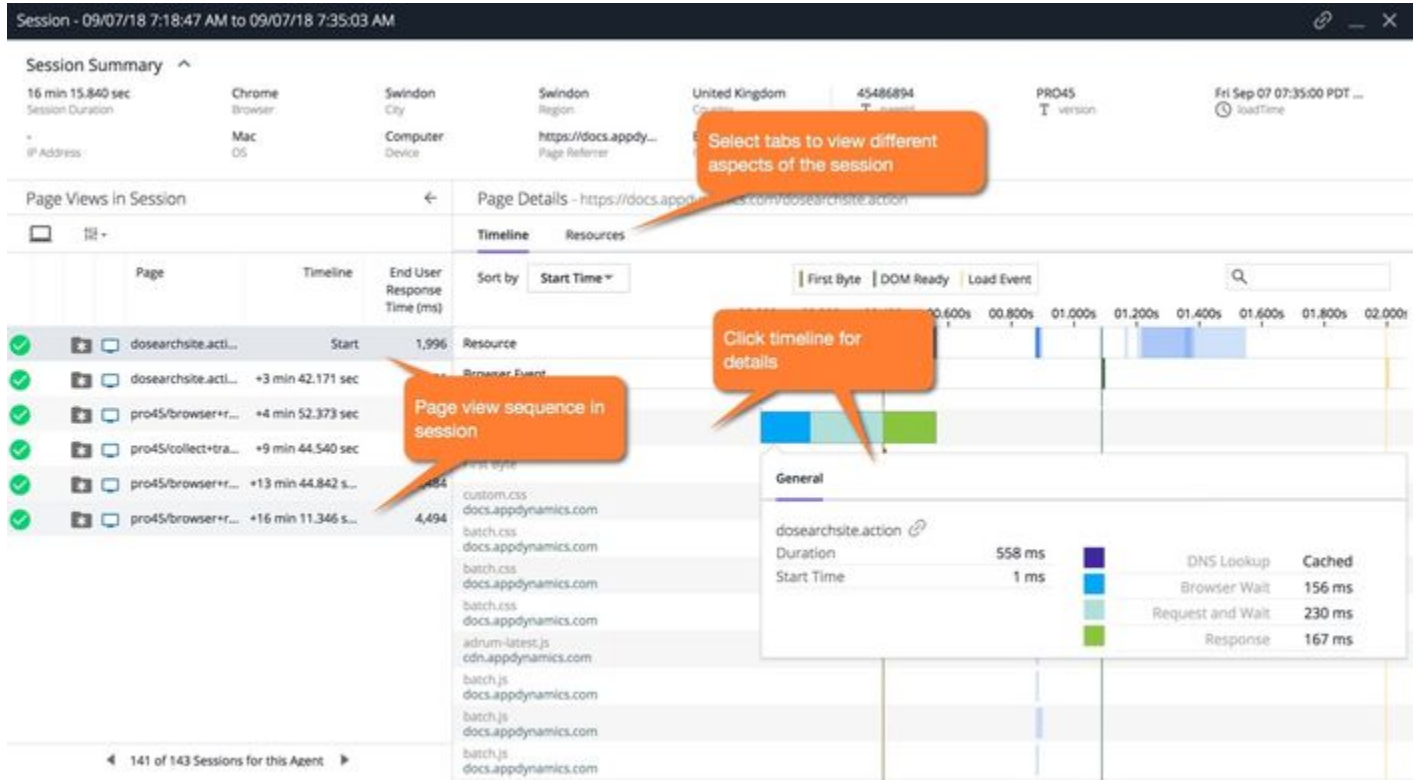

- [Records](#)
- [Charts](#)

Records

The Records tab lets you scan individual sessions and allows you to filter and sort to get exactly the data in which you are interested.

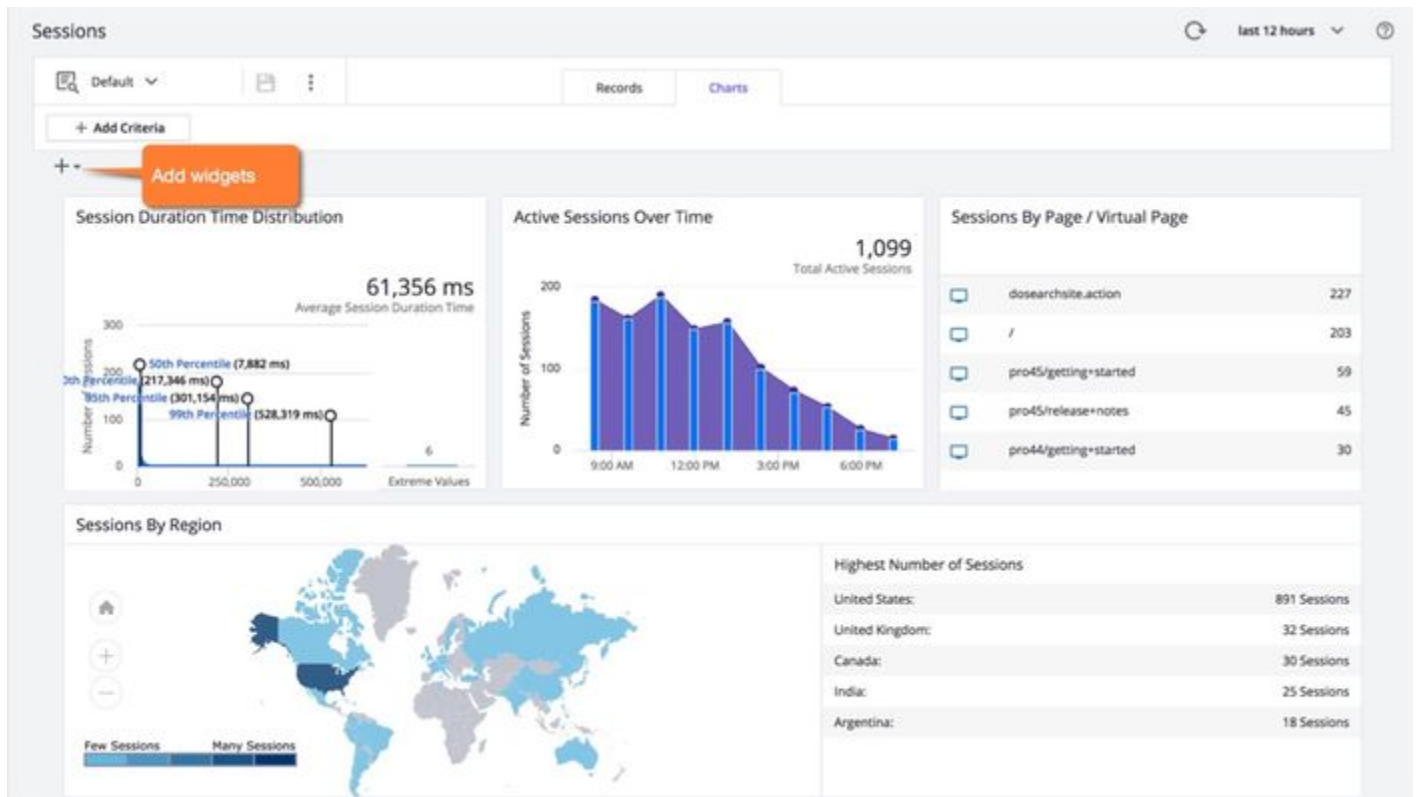

Click **View Details** or double-click an item to see the information for a specific session. The sequence of page views for the session is shown on the left side of the screen. Select a specific page view to see detailed information, including a page load waterfall, tabular details for resources, and, if your backend is instrumented with AppDynamics, correlated server-side business transactions.

Charts

The Charts tab provides you with a set of predefined widgets of the data set you have created plus a custom widget builder. As with the Charts tab of the **Analyze** UI, you can delete, re-add, resize, and drag-and-drop to move the widgets.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Pages & Ajax Requests

The **Pages & Ajax Requests** page provides detailed information on how your pages, Ajax requests, iframes, and virtual pages perform over time.

Access Pages & Ajax Requests

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Pages & Ajax Requests**.

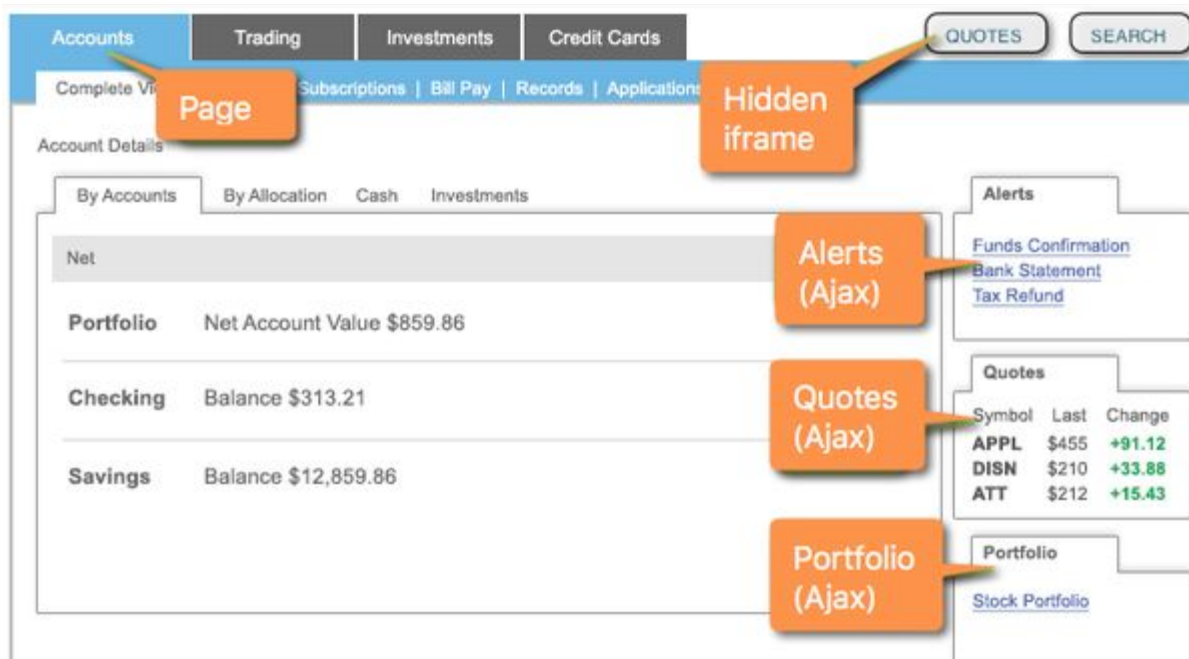

What is a Page?

In Browser RUM, a page represents an individual source for the information that an end-user sees in one browser window.

Types of Pages

A base page is the core HTML page, and may also include one or more iframes, which you can nest.

A base page or an iframe can also make one or more Ajax requests (using XMLHttpRequest or the Fetch API) to fetch data to display on the Web page.

You can collect Browser RUM metrics for base pages, iframes, Ajax requests, and virtual pages.

Each base page, iframe, Ajax request, and virtual page type is assigned a unique name, which you can configure. See [Configure Page Identification and Naming](#).

Pages & Ajax Requests

The **Pages & Ajax Requests** page has two options: **All Pages** and **Top Pages**, selected using the dropdown in the upper right. **All Pages** displays a list showing a high-level summary of all the monitored types, along with their key performance indicators. **Top Pages** displays the ten worst performing items grouped by common metrics: Requests per Minute, Page Render Time, and so forth. Use this option for a quick start to troubleshooting.

How the All Pages List is Organized

The **All Pages** list displays each monitored base page, iframe, Ajax request, and virtual page type.

Click a column header to sort the pages based on the column's metric.

To view a dashboard for a specific page item in the list, select it and click **View Dashboard** or just double-click the page. See [Page, Ajax, and Iframe Dashboards](#).

To filter the types of pages displayed in the list, select the type at the top of the list. Check **With Load** to see only pages currently reporting load.

More Actions Menu

Using the **More Actions** menu, you can select a page in the list and make changes to it, including directing the agent to ignore the page and stop reporting metrics for it.

Access Top Pages

Click the **View** dropdown on the upper-right side of the page and select **Top Pages** as a shortcut to troubleshooting the ten worst performing pages regarding various metrics.

Page Limits

There is a limit of 500 total base pages (including virtual pages) plus iframes and 500 Ajax calls that can be individually tracked per application. If your usage exceeds these limits, the Controller begins to drop metrics. If your installation is approaching these limits, you can modify how your metrics are collected by:

- Limiting the number of pages you instrument. If you are using manual injection, remove the JavaScript Agent from pages that are less important. See [Inject the JavaScript Agent](#) for more on injection types. If you are using automatic injection, create request match rules and request exclude rules to restrict injection to pages that meet certain criteria. See [To Create Match Rules for Automatic Injection](#).
- Using custom naming rules to group similar pages together. See [Configure Page Identification and Naming](#).

If you reached your page limit, you need to delete the affected old page names before any new page names can be added to the database. Doing so also deletes any accumulated metrics for those page names.

Page, Ajax, and Iframe Dashboards

Dashboards provide quick access to graphic representations of metrics for pages (including virtual pages), iframes, and Ajax request types. Each page, iframe, and Ajax request type has a dashboard. See [Page and IFrame Dashboards](#) and [Ajax Dashboard](#).

Access These Dashboards

To view a dashboard for a page, iframe or Ajax request type:

1. Open the browser application in which you are interested.
2. On the left navigation bar of your application, select **Pages & AJAX Requests**.
3. From the list, select the page, iframe or Ajax request type in which you are interested.
4. Either double-click the item, or select the item and then click **Details**.

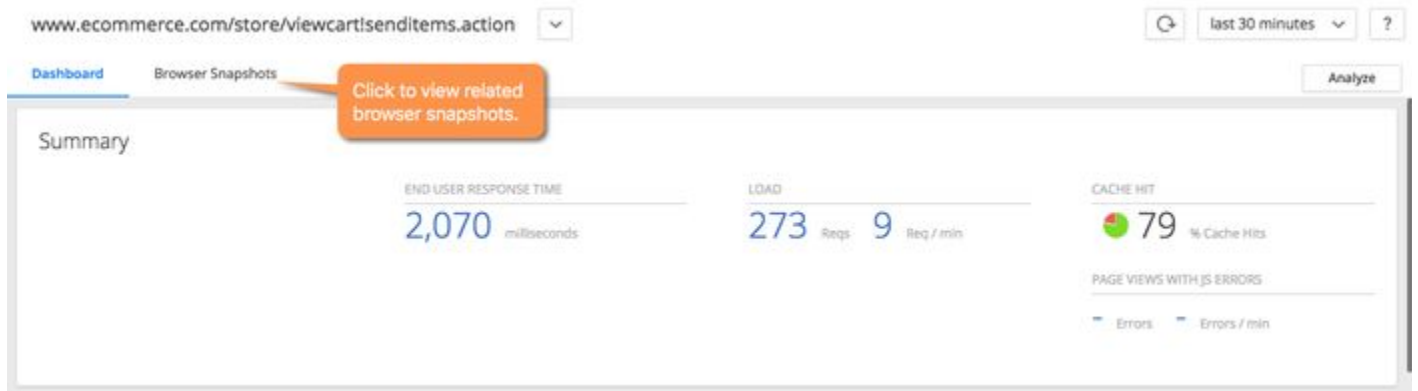

Page and IFrame Dashboards

Page and iframe dashboards are divided into six areas:

- A summary of key performance indicators. To see browser snapshots associated with these instances of this page type, open the Browser Snapshots tab. To move to the **Analyze** view, click **View Analyze**.
- A waterfall graph of the entire load sequence. To see details for each set of data, use the **Trends/Details** checkboxes.
- Four sections of **Trends/Details** across time for the main performance categories:
 - Overall performance
 - Time between the request and the first byte of the response
 - Time taken by the server to process the request through the completion of the HTML download for the item
 - Time taken to process and render the item, including any external resources, in the browser
- Detailed information on the performance of Ajax requests and iframes for this item.

Page Dashboard Summary Section

This section provides a quick overview of the item's performance over time.

Key performance indicators—End User Response Time, Load, Cache Hits, and Page Views with JS errors—across the period selected in the timeframe dropdown from the upper-right side of the Controller UI are displayed across the top of the summary area. Cache Hits indicates a resource fetched from a cache, such as a CDN, rather than from the source. This metric is only reported when there is a correlated AppDynamics agent on the server-side source.

Timing Breakdown

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

The waterfall graph shown below displays the average times needed for each aspect of the page load process. For more information on what each of the metrics measures, hover over its name on the left. A popup appears with a definition. See [Browser RUM Metrics](#).

To see detailed breakouts of the data behind the graph, check the **Trend/Detail** checkbox by the data group in which you are interested. To turn the details off, uncheck the checkbox.

i Some metrics—for example, TCP Connection Time—only appear if they have a non-zero value.

Overall Performance

This section displays detailed trend graphs of key performance metrics measured across the selected timeframe. To see detailed information for a particular moment, hover over the graph and a popup with that information appears. To see any of the listed total metrics in the context of the metric browser, click the desired value (shown in link blue) on the left side of the panel. The **Metric Browser** appears, with that metric displayed. You can then use the **Metric Browser** to compare other related values in one display.

Key Performance Times / Load

This section displays detailed trend graphs of key performance indicators and the request load across the selected timeframe. They measure:

- Time between the user's request and the completion of the page load of the response.
- Time between the user's request and the DOM being loaded.
- Time between the user's request and the browser receiving the first response byte.
- Number of requests per minute.

Server Connect Time Breakdown / Response Available Time

This section displays detailed trend graphs of initial server connection metrics measured across the selected timeframe. They measure:

- Time the user's request takes in negotiating its initial connection with the server, which may include the DNS, TCP Connect, and SSL/TLS time. The **Total Server Connect** value is always displayed.
- Time between that initial connection and the time the first byte of information begins to arrive at the browser.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Server Time / HTML Download Time / Related Business Transactions

This section displays detailed graphs for the time spent acquiring the page data:

- Time the request takes on the server.
- Time it takes to complete the download of the HTML to the page.
- If the request is correlated with a server-side app agent, related business transactions on the server are displayed. Cross-app correlation is supported.

DOM Building Time / Resource Fetch Time / Page Resources Requested

This section displays detailed graphs for the time spent creating the page and getting resources. They measure:

- Time required by the browser to create the DOM from the end of the HTML download.
- Time required to fetch any external resources. For example, the results of a third-party Ajax request.

The **Page Resources Requested** section displays detailed graphs of when in the page load cycle individual external—first and third-party—resources are fetched, and how much time is taken to fetch them, based on the selected timeframe. They measure:

- Average time and load associated with that resource
- If the request is blocking or non-blocking
- Request and response time per resource request
- Type—iframe or Ajax—of the resource

To see the dashboard for any of the listed resources, click the name.

Ajax Dashboard

The **Ajax Dashboard** is divided into three areas:

- A summary, with a waterfall graph of the entire load sequence. To see details for each set of data, use the **Trends/Details** checkboxes.
- Two sections of **Trends/Details** across time for the main performance categories:
 - Overall performance
 - Time used by the server to process the request through the browser's incorporation of the data into the HTML document

Ajax Dashboard Summary Section

This section provides a quick overview of the item's performance over time.

Key performance indicators—End User Response Time, Load, Cache Hits and Views with Errors—across the period selected in the timeframe dropdown from the upper-right side of the GUI—are displayed across the top of the summary area.

A waterfall graph displays the average times needed for each aspect of the Ajax request load process.

For more information on what each of the metrics measures, hover over its name on the left side of the graph. A popup appears with a definition. See the graphic above for an illustration. See [Browser RUM Metrics](#).

To see detailed breakouts of the data behind the graph, check the **Trend/Detail** checkbox by the data group in which you are interested.

Timing Breakdown

A waterfall graph shown below displays the average times needed for each aspect of the Ajax request. For more information on what each of the metrics measures, hover over its name on the left. A popup appears with a definition. See [Browser RUM Metrics](#).

To see detailed breakouts of the data behind the graph, check the **Trend/Detail** checkbox by the data group in which you are interested. To turn off details, uncheck the checkbox.

Overall Performance

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

This section displays detailed trend graphs of key performance metrics, load requests, and Ajax request errors measured across the selected timeframe. To see detailed information for a particular moment, hover over the graph and a popup with that information appears. To see any of the listed total metrics in the context of the metric browser, click the desired value (shown in link-blue) on the left side of the panel. The [metric browser](#) appears, with that metric displayed. You can then use the metric browser to compare other related values in one display.

Ajax Response Download and Ajax Callback Execution Time

This section displays detailed trend graphs of the Ajax response download time and the Ajax callback execution time. To see detailed information for a particular moment, hover over the graph to view a popup.

These metrics measure the total time for processing all server-side business transactions for this item.

- Total time for the browser to completely download all of the Ajax responses
- Time for the browser to complete any Ajax callbacks

Browser RUM Analyze

Related pages:

- [Analytics Browser Requests Data](#)
- [Analytics Browser Sessions Data](#)

Browser RUM collects data on every load event that you have instrumented, and it also takes detailed snapshots periodically and when performance issues are detected. Over time, the load event metrics are rolled up based on averages and percentiles. Sometimes you want to see results based on *all* of the data.

With **Browser Analyze**, every event is collected and stored for a [license specified period](#) in the AppDynamics Platform Events Service. Using the Analyze tab you can see results based on this cumulative data.

The **Analyze** view is comprised of two tabs:

- [Records](#)
- [Charts](#)

Access the Browser Analyze View

1. Open the application in which you are interested.
2. On the left navigation bar, select **Analyze**.

Records

The Records tab lets you scan individual events and filter and sort to get exactly the data set in which you are interested.

The screenshot shows the 'Analyze' interface with several callouts:

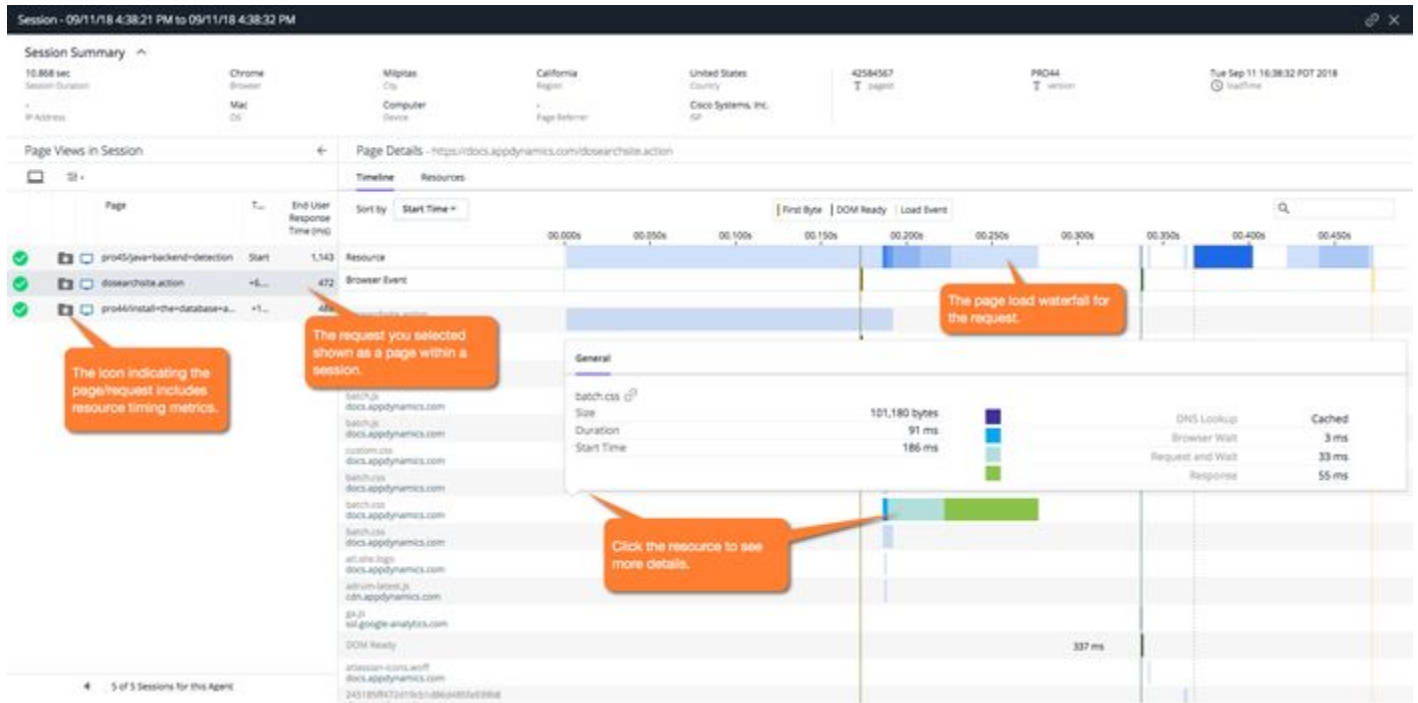

- Manage searches.**: Points to the search management icon at the top.
- Select and view saved searches.**: Points to the search criteria dropdown.
- Filter results.**: Points to the search filter dropdown.
- View details of selected item.**: Points to the 'View Details' button for a selected row in the table.
- Select fields to view.**: Points to the 'Fields' list on the left side.
- Filter pages by record type.**: Points to the 'Limit your search by record type' section in the 'View Details' dialog.

The 'View Details' dialog box is open, showing options to filter by page type or name, and by record type. The record type is currently set to 'Page & AJAX Loads'.

Resources Loaded per Pageview	Browser Version	Page Referrer
32	68	null
34	68	https://www.google.com/
17	68	https://docs.appdynamics.com/display/PRO45/java+Be...
31	68	https://docs.appdynamics.com/display/PRO45/standa...
31	68	https://docs.appdynamics.com/00search/site.action
16	68	https://docs.appdynamics.com/display/PRO45/installi...
54	68	https://www.google.com/
31	68	https://docs.appdynamics.com/
25	68	https://docs.appdynamics.com/display/PRO45/install-d...
53	68	https://www.google.com/

After you click **View Details**, you see the details of a particular request as a page with a [browser session](#) in the **Session Details** dialog.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

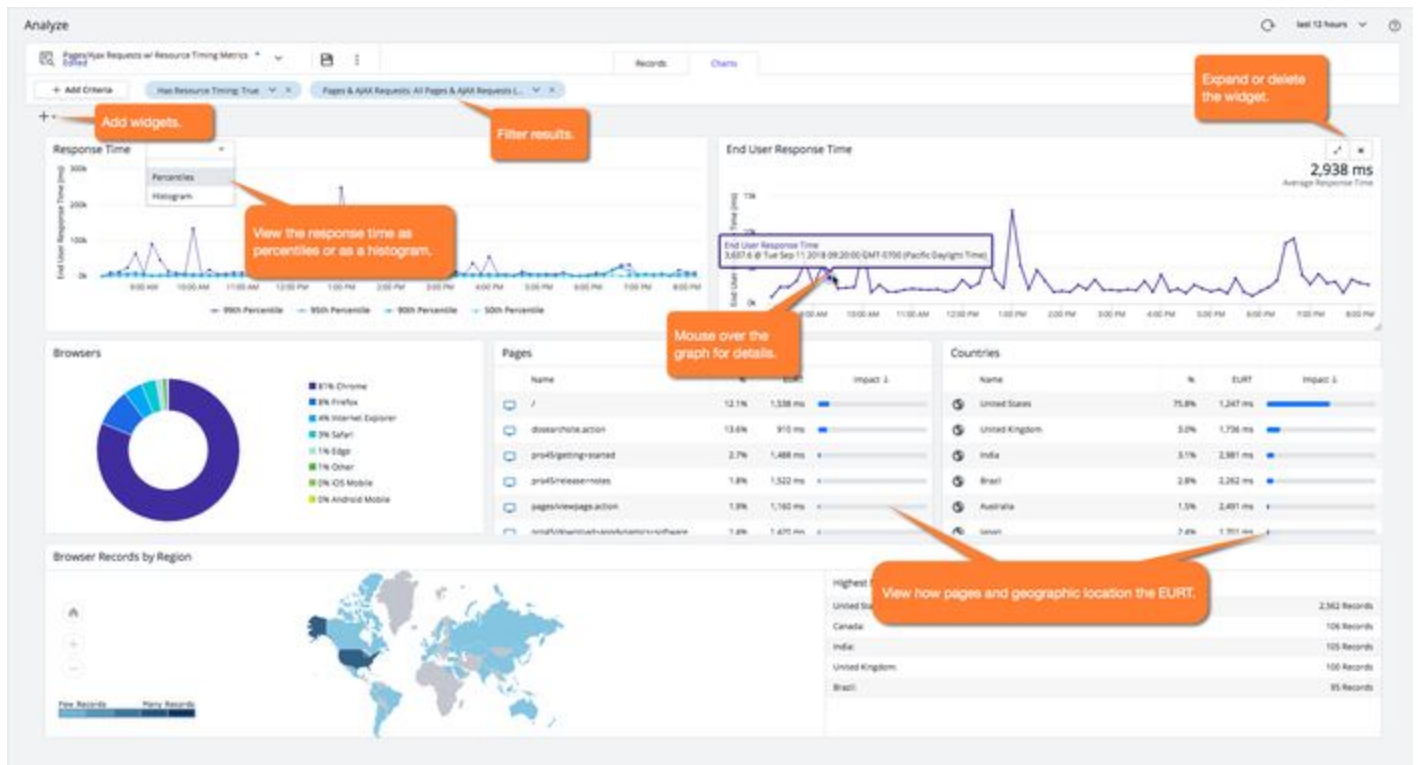

Charts

The Charts tab provides you with a set of predefined widgets that offer visualizations of the data set you have created.

You can quickly see how pages, browsers, and geographic location (such as, dimensions) affect the end user response time (EURT). You can also delete, re-add, resize, and drag-and-drop to move all of the widgets.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

i The time series widgets such as **Response Time** and **End User Response Time** use median values, not averages.

Request Number Differences in Browser Analyze and Pages & AJAX Requests

The number of requests for a page over a period of time should be the same in **Pages & AJAX Requests** and **Browser Analyze**, but they may vary for these reasons:

- If there are fewer requests given in **Browser Analyze**, the Events Service, which is responsible for the data in **Browser Analyze**, has probably not received all of the records yet. To verify this, compare the time of the last request for the page in **Browser Analyze** and **Pages & AJAX Requests**. The latter will most likely have a later timestamp.
- If there are more requests given in **Browser Analyze**, it's possible that the reason is because error records are included in the total number of requests in **Pages & AJAX Requests**, but listed separately in **Browser Analyze**. The errors are listed separately in **Browser Analyze** to enable you to investigate and understand the cause of the error.

Browser Analyze versus Browser Request Analytics

The data shown on the **Analyze** page is processed and stored by the AppDynamics Platform Events Service. The **Charts** tab displays a set number of widely used chart types to let you explore your application's performance. A separate product, **AppDynamics Application Analytics**, has a component called Browser Analytics. This component is based on the same Events Service and uses the same data, but it offers additional capabilities, including:

- Additional predefined widgets, such as the funnel widget
- ADQL for searching the data
- Creating custom widgets

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- Manipulating multiple dashboard types
- Longer retention time for data storage

Browser Analytics requires a license separate from the Browser RUM license.

To reduce noise in data stored in the Event Service, Ajax calls from the following tracker domains are no longer published to the Events Service:

- `.mixpanel.com`
- `.google-analytics.com`
- `.altocloud.com`
- `.optimizely.com`
- `inspectlet.com`

Configure the Controller UI for Browser RUM

You can [enable or disable Browser RUM](#) with the **Browser Monitoring** toggle.

You can manage how Browser RUM information is displayed in the Controller UI, including:

- [The display names for your pages, Ajax requests, and iframes](#)
- [The display names for your virtual pages](#)
- [The errors that should be shown in the UI, and the ones that should not be shown](#)

You can also configure:

- [The thresholds for slow, very slow, and stalled transactions](#)
- [When browser snapshots should be taken](#)
- [Percentile levels you would like to display, if any](#)
- [Which Ajax requests should be sent to the Event Service](#)
- [The session timeout period](#)
- [Whether to store request IP addresses or not](#)

In addition, you can do the following:

- [Choose a hosting option for the JavaScript Agent](#)

To configure Browser RUM from the Controller UI, your user account must belong to a role that has the **Configure EUM** permission. See [End User Monitoring Permissions](#) for more information.

Access the Browser RUM Instrumentation Configuration

To access the instrumentation configuration for a browser app:

1. Open the browser application in which you are interested.
2. From the left-hand navigation menu, click **Configuration**.
3. From the **Configuration** page, click **Instrumentation >**.

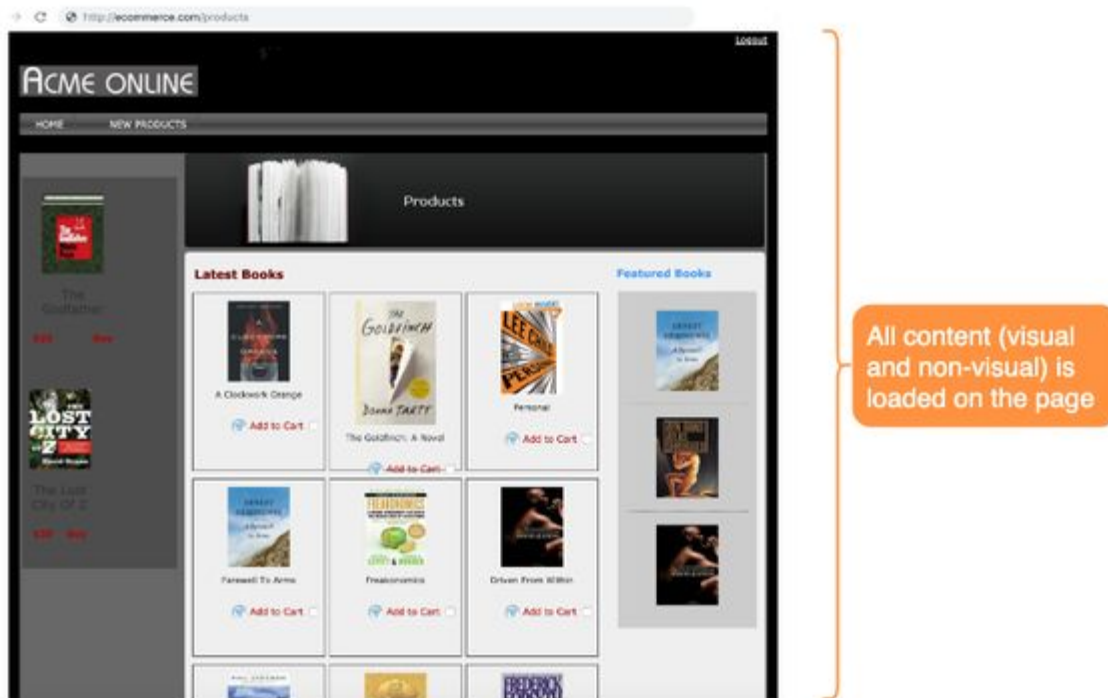

Configure the Primary Metric

The default primary metric is set to End User Response Time (EURT), but you can choose between EURT and Visually Complete Time (VCT). Once the primary metric is configured, the Controller UI dashboards, summaries, and charts will automatically update to show trending data for that configured metric. This allows you to view the EUM event timing that is most relevant to your business needs.

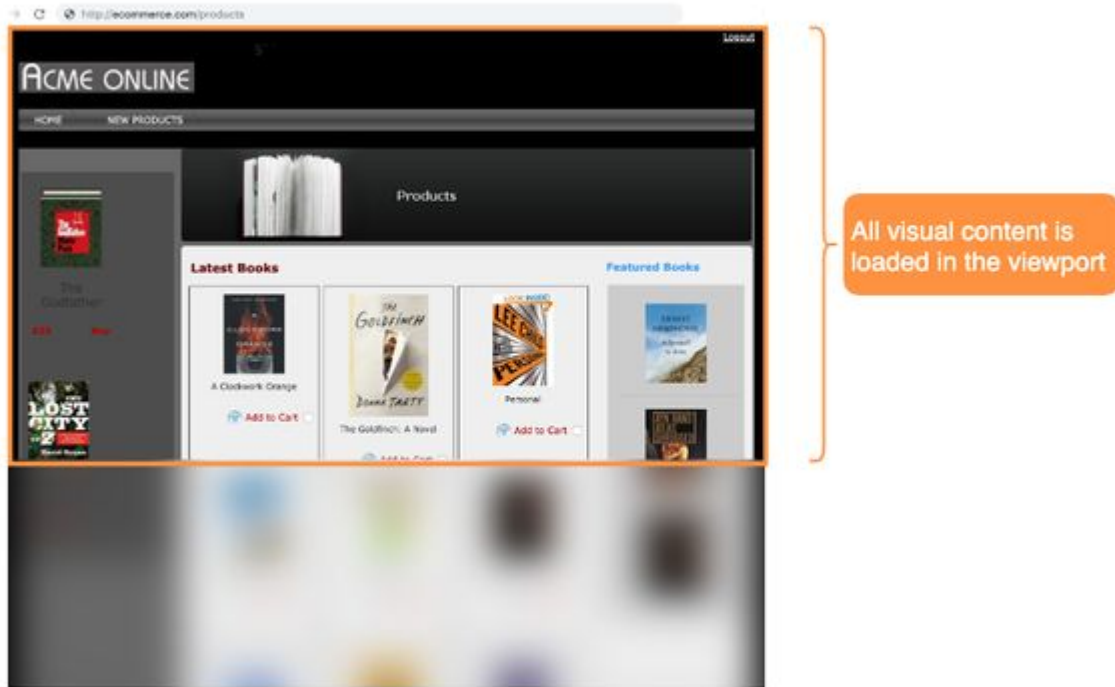

Available Metrics

You can set the primary metric to EURT or VCT. The default primary metric is EURT. EURT tracks the total amount of time for all content on a web page to be loaded. VCT tracks the total amount of time for all visual content to be loaded in the viewport. To see how EURT and VCT are calculated for SPA pages, see [SPA2 Metrics](#).

EURT VCT

EURT VCT

Primary Metric Visibility

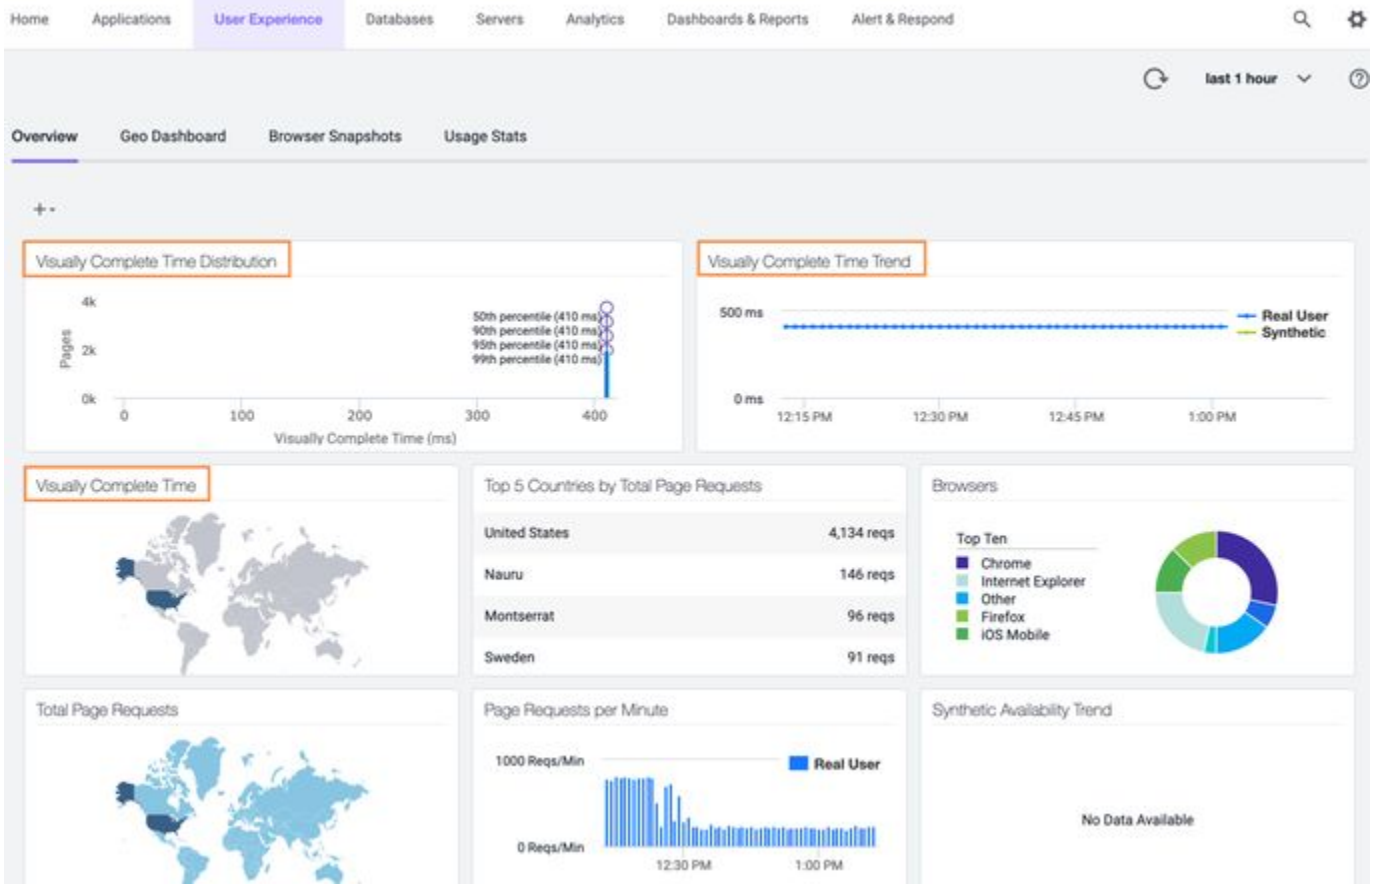

The primary metric is visible across several dashboards, charts, and summaries. The following screenshots are examples of primary metric visibility when configured to VCT.

[Browser App Overview](#)

[Geo Dashboard](#)

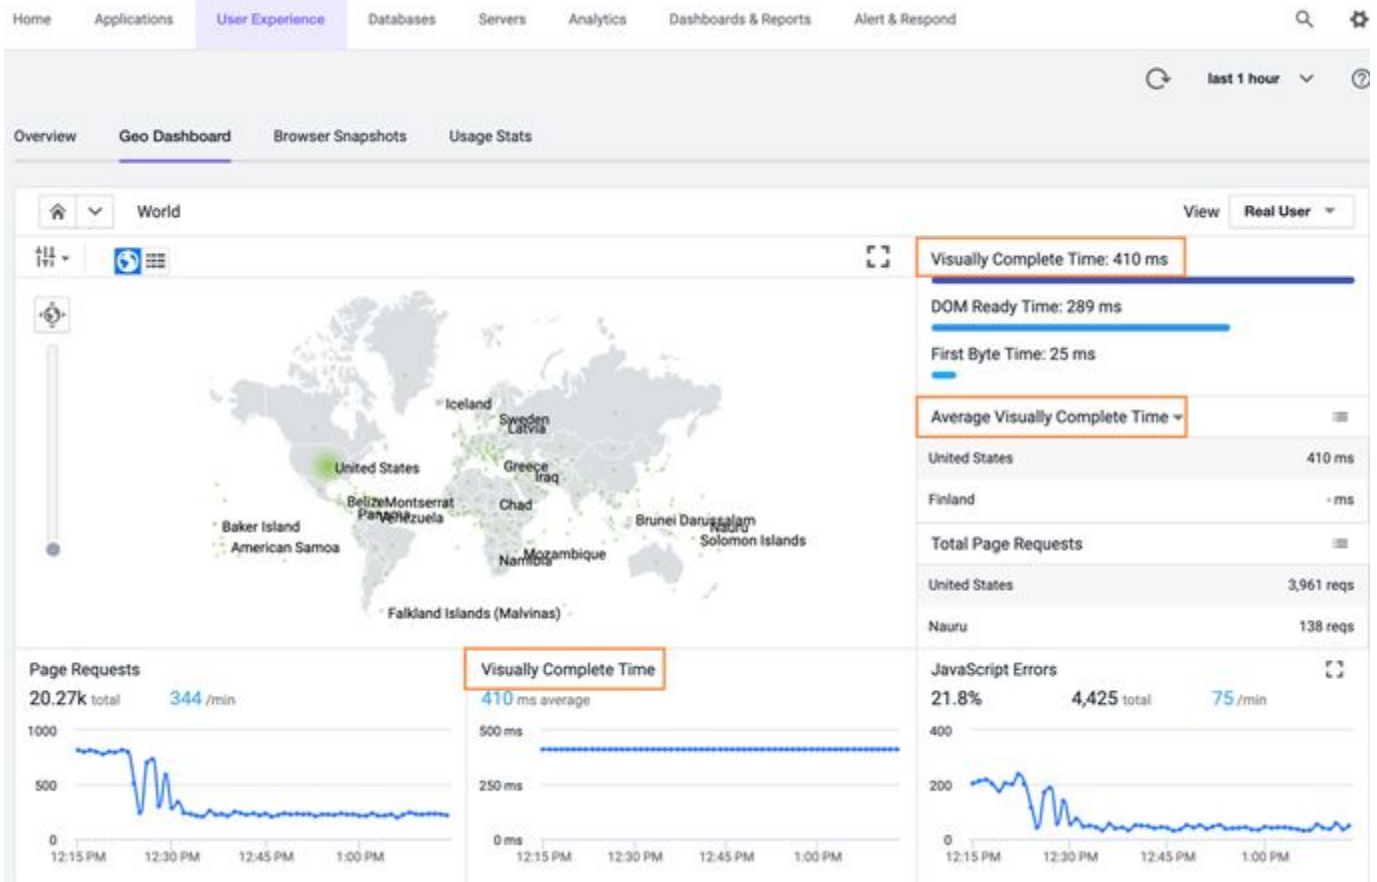

[Browser Snapshots](#)

[Pages & AJAX Requests](#)

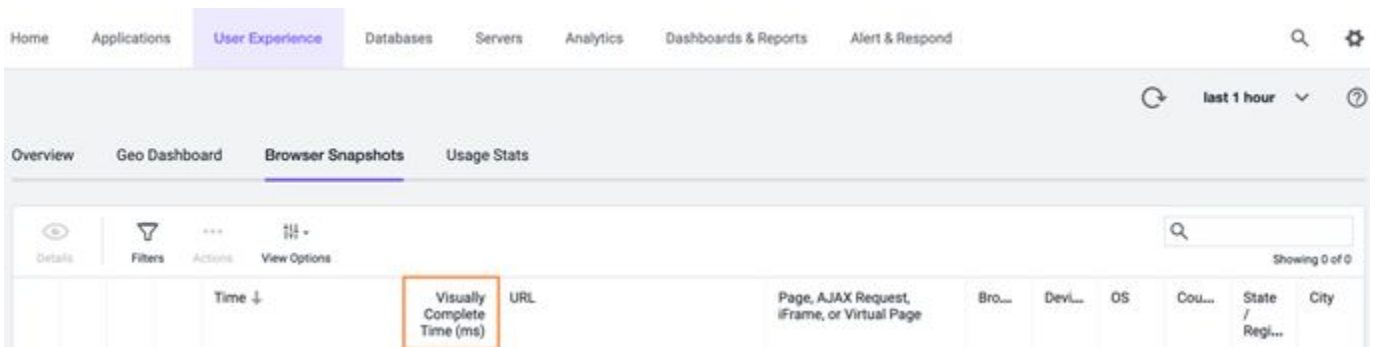

[Browser App Overview](#)

Browser App Overview Geo Dashboard Browser Snapshots Pages & AJAX Requests

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Configure the Primary Metric

Configure Primary Metric

To configure the primary metric, go to **Configuration > Instrumentation > Settings**.

Disable the Primary Metric

For SPA2 applications, configuring the primary metric causes base page events to be sent on navComplete; previously the base page events were sent upon page load. This may cause slow performance, and you may want to disable the primary metric.

To disable the primary metric, add the following flag in your JavaScript code:

```
config.enablePrimaryMetrics = false
```

Configure Page Identification and Naming

Related pages:

- [Configure Virtual Page Naming](#)
- [Page, Ajax, and Iframe Dashboards](#)
- [Set Custom Page Names](#)

You can configure the display names by which various pages and iframes are referred to and sorted in Controller lists and dashboards. On this page, the term "pages" includes iframes and base pages.

With rules, you can:

- Use the AppDynamics default naming rule, which you can leave as is or modify.
- Create custom include rules to override the default convention.
- Create custom exclude rules to exclude from monitoring pages that meet certain criteria.
- Disable the default naming configuration and use only your custom include rule(s).

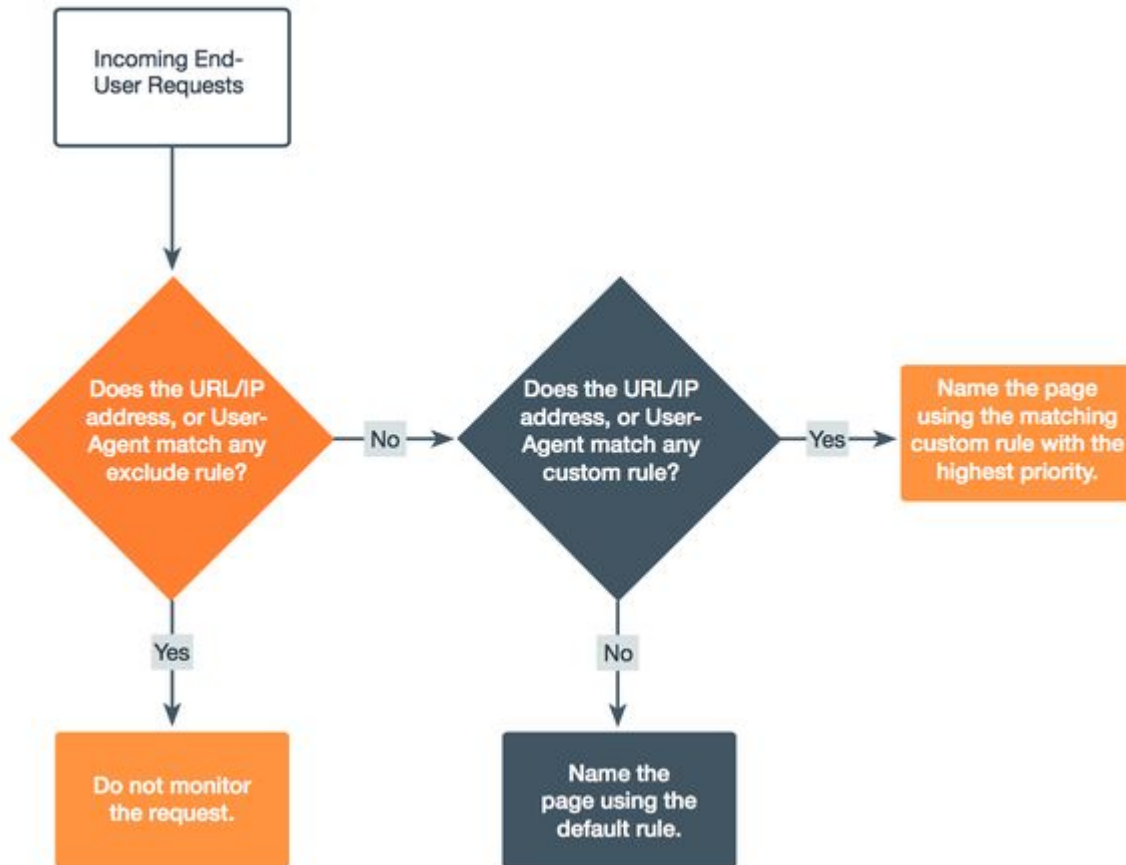

No matter how the page is named, AppDynamics always reports the page name in lowercase.

Access Exclude/Include Rules

1. In the Controller, click the **User Experience** tab.
2. Click a browser application.
3. On the left navigation bar, click **Configuration**.
4. Click **Instrumentation >**.
5. From the **Base Page and iFrames** tab, define include/exclude rules or modify the Default Naming Configuration.
6. To save any configuration changes, click **Save**.

Evaluation Logic for Exclude/Include Rules

This is the order in which AppDynamics evaluates the page naming rules.

Default Page Naming Rules

If you enable the default naming configuration and do not modify it, AppDynamics identifies and names your pages using the first two segments of the page URL.

You can modify the default configuration by double-clicking **Default Naming Configuration** in the **Include Rules** section. This opens the **Include Rule** popup, where you can select the dropdown list **using parts of the URL** to include the protocol or domain in the name, use different segments of the URL, or include query parameters or anchors in the name.

The 'Include Rule' dialog box is shown with the following configuration:

- Enabled
- Name Pages: (dropdown)
- Show Protocol (Ex: http, https, etc)
- Show Domain (Ex: mywebsite.com)
 - Show Full Domain
 - Show Sub-domain
- Path Segments:
 - Don't use path segments
 - Use first 0 segments
 - Use last 2 segments
 - Use segment numbers
- Query String Parameters to use in Page Name (Optional)
- What part of anchor should be used in Page Name:
 - Don't use the anchor
 - Use first 1 segments
 - Use last 1 segments
 - Use segment numbers

Buttons: Cancel, OK

You can also choose the dropdown **using a Regex match on the URL** to match page names by running a regular expression.

The 'Include Rule' dialog box is shown with the following configuration:

- Enabled
- Name Pages: (dropdown)
- Use regex on the URL and use groups

Buttons: Cancel, OK

If you do not want to use the default convention at all, disable it by clearing the **Enabled** checkbox. In this case, you must configure at least one custom page naming rule so that AppDynamics can identify and name pages.

Custom Include Rules

You can create custom include rules for identifying and naming pages.

To create a custom include naming rule, from the **Include Rules** section, click **Add**. Then you use the same **Include Rule** popup to configure the custom include rule to identify and name the page.

The order of the include rules in the list determines the priority of the rules: The rules at the top are evaluated first, and the rules at the bottom are evaluated last. You cannot change the priority of **Default Naming Configuration**, but you can modify or disable it.

Guidelines for Using Regular Expressions in Include Rules

When using regular expressions to match URLs in your include rules, note the following guidelines:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- URL strings are case-sensitive. So, although the page names displayed in [Pages & Ajax Requests](#) are converted to lowercase, your regular expressions still need to match the case used in URLs that your include rule are trying to capture.
- Your regular expression should match the entire URL, from beginning to end, not just a section; otherwise, the rule will not match. This differs from using regular expressions in [custom match rules for naming transactions](#), which only need to match sections of the URL.
- Beacons for older browsers (primarily Internet Explorer 6-8) are sent using image requests, and therefore, have an inherent length limitation. To manage this limitation, Browser RUM does not support URLs longer than 180 characters, page names longer than 50 characters, and user data longer than 128 characters for these browsers.

Limitations

- If you are using the regex expression "and use groups" to group pages by a custom page name (i.e. you want the page `/my-business/checkout` to display as `/checkout/my-business`), the regex logic defaults to ascending order of the groups. For example, the regex expression "and use groups = 3,2" will default to "use groups = 2,3".

Example Include Rule

Suppose you have multiple pages that include the string `search/r/region` in their URLs, such as `search/r/region01`, `search/r/region23`, etc., and you want to name all the pages from that set as a single-page named `search/r/region`. By selecting the dropdown **using a Regex match on the URL**, you can enter a regular expression to remove the domain name and the number at the end of the URL, grouping all your `/search/r/region` URLs into one set. Because all the URLs contain `search/r/region`, AppDynamics now collects information for them all under the single-page name `search/r/region`. Otherwise, AppDynamics uses the default page naming rule or a rule with higher priority.

Include Rule

Configure Naming for Ajax Requests

Related pages:

- [The Pages & Ajax Requests View](#)
- [Configure Page Identification and Naming](#)
- [Page, Ajax, and Iframe Dashboards](#)
- [Set Custom Page Names](#)

You can configure the display names by which Ajax requests are referred to and sorted in controller lists and dashboards.

Access Naming Rules for Ajax Requests

1. Open the browser application in which you are interested.
2. On the left navigation bar, go to **Configuration > Instrumentation > AJAX > Monitor**.

Naming Rules for Ajax Requests

The logic for naming Ajax requests is nearly identical to that for [naming virtual pages](#) in that they can use anchors (the part of the URL after the #) to distinguish among Ajax requests. In these cases, using the **What part of anchor should be used in page name** section allows you to specify which Ajax request is being accessed correctly. The difference in naming rules for Ajax requests is that you can also specify the HTTP method(s) to filter in the rule.

For example, the Ajax naming include rule below specifies the HTTP methods `POST` and `PUT` and is configured to show the HTTP method in the results displayed in the Controller UI:

Include Rule
✕

Enabled

Rule Name

Criteria
 This Include Rule applies to any URL that Contains

GET POST PUT DELETE

Name Pages

Show HTTP Method (GET, POST, PUT, or DELETE)
 Show Protocol (Ex: http, https, etc)
 Show Domain (Ex: mywebsite.com)
 Show Full Domain Show Sub-domain

Path Segments
 Don't use path segments
 Use first segments
 Use last segments
 Use segment numbers ⓘ

Query String Parameters to use in Page Name (Optional)

POST Parameters to use in Page Name (Optional)

What part of anchor should be used in Page Name
 Don't use the anchor
 Use first segments
 Use last segments
 Use segment numbers ⓘ

You can also create exclude rules that specify which Ajax requests to filter based on the specified HTTP method(s) as shown here:

Exclude Rule ✕

Enabled

Rule Name

Criteria
This Exclude Rule applies to any URL that

GET POST PUT DELETE

Configure Which Ajax Requests Are Sent to the Events Service

Modern web pages often include a large number of Ajax requests. Not all of these Ajax requests may be equally important to monitor, but they all equally affect [license entitlements and restrictions](#). Thus, you may want to configure which Ajax requests are sent to the Events Service to manage the impact on your overall Events Service usage.

To do this, you can create rules to specify the requests to be sent to the Events Service, either by excluding a request entirely, including a particular request or a sample of that request types by percentage or by just allowing the request to be sent. In general, the behavior follows this pattern:

- If no rules are specified, no data on Ajax requests is sent.
- If exclude rules are specified, and an Ajax request satisfies a rule, that data is *not* sent.
- If include rules are specified, any Ajax request that satisfies a rule is sent, based on sampling defined by the percentage indicated in the rule.
- If both include and exclude rules are specified, an Ajax request that satisfies an include rule but does *not* satisfy an exclude rule is sent.
- If you *only* configure exclude rules and the sample percentage, the non-excluded calls would be sampled at the specified rate.

See [Configure Page Identification and Naming](#) for more information about default naming rules and how rules are evaluated.

Access Ajax Requests Rules

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation >**.
4. Select the **Ajax > Events Service** tab.

Configure Exclude Rules

1. Click **Add** to create a new rule. The **Exclude Rule** popup appears.
2. Specify a display name for the rule.
3. Check **Enabled** to enable the rule.
4. Enter a string and select one of the options in the dropdown to match the URLs that you want to exclude from the Ajax requests.
5. Click **OK** to save the rule.

Configure Include Rules

1. From the **Events Service Include Rules** section, click **Add** to create a new rule. The **Include Rule** popup appears.
2. Give your rule a display name.
3. Check **Enabled** to enable the rule.
4. For **Criteria**, enter a string and select one of the options in the dropdown to match URLs for including Ajax requests.
5. Configure how to name pages:
 - Select one of the options from the dropdown to determine the part of the URL.
 - Select the path segment.
 - Enter the query string to use in the page name.
 - Select the part of the anchor (or none) to use in the page name.

6. Click **Save**.

Configure Virtual Page Naming

Related pages:

- [The Pages & Ajax Requests View](#)
- [Page, Ajax, and Iframe Dashboards](#)
- [Set Custom Page Names](#)

Web applications built using Single Page Application (SPA) principles minimize network traffic by transferring computing work for creating what the user sees to the browser. The initial page request downloads necessary data for constructing the application, with some possible exceptions. For example, HTML partials and fragments may be fetched dynamically from the backend in response to user interaction.

The individual views that the user sees are known as virtual pages. Browser RUM supports virtual pages created using the AngularJS framework, sometimes known simply as Angular.

In AngularJS, a virtual page is an individual view, comprised of the rendered template of the current route in the context of the main layout file. You can configure how AngularJS virtual pages are referred to and sorted in UI lists and dashboards. For more information on using Browser RUM with virtual pages, see [AngularJS Support](#).

Access Virtual Page Naming Rules

1. Open the browser application in which you are interested.
2. On the left navigation bar, click **Configuration**.
3. Click **Instrumentation >**.
4. Select the **Virtual Pages** tab.

Virtual Page Naming Rules

The logic for naming virtual pages is identical to that for [naming regular pages](#), with one exception. Because AngularJS pages can use anchors (the part of the URL after the #) to distinguish among virtual pages, in these cases, using the **What part of anchor should be used in page name** section allows you to specify which virtual page is being accessed correctly.

Include Rule ✕

Configure JavaScript and Ajax Error Detection

Related pages:

- [Set Up and Access Browser RUM](#)
- [Browser Snapshots](#)

You can enable and disable reporting of JavaScript and Ajax request errors. When enabled, the Browser Monitoring UI reports Ajax request errors in the following places:

- **Geo Dashboard**
- **User Stats** page and device dashboards
- Page list
- Browser snapshots

Also, you can configure which errors are included in the error count by specifying the errors to "ignore". You can specify errors to ignore by:

- The script and/or error message
- Page
- URL

"Ignored errors" are not actually ignored. They are still tracked, but the error count in the places where error totals are reported on the user interface is not incremented.

Access Error Detection Rules

1. From the browser application you are interested in, click **Configuration**.
2. Click **Instrumentation** >.
3. Select the Errors tab.

Enable and Disable Browser RUM Error Detection

In the Errors tab:

- Check/clear the **Enable JavaScript Error Capture** checkbox to enable/disable JavaScript error display.
- Check/clear the **Enable AJAX Request Error Capture** check box to enable/disable Ajax error display.

When both checkboxes are clear, no JavaScript or Ajax request errors are displayed.

Even if capture is enabled globally, you can configure certain errors to be ignored so that they are not counted in the error totals.

Configure Rules to Ignore Errors based on Script or Error Message

You can configure the agent to ignore specific JavaScript errors that are identified by:

- a matching string pattern in the name of the script that generated the error
- the line number in the script
- a matching string pattern in the error message

You can specify one, two, or all three of these criteria. Configure more criteria to increase the granularity of which errors you ignore.

Add Rules to Ignore Errors

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

From the **Ignore JavaScript Error Rules** section, click **Add** to open the **Ignore JavaScript Errors** popup. From there, you can enable the rule, specify the script name, line number, and optionally, the error message.

For example, the following configuration in the **Ignore JavaScript errors** section where all three fields are specified means "Ignore all errors generated by line 27 of a script whose name starts with "Nightly" and whose error message contains the string "WARNING::".

If the line number were not specified (e.g., set to 0), the configuration would mean "Ignore all errors generated any line of a script whose name starts with "Nightly" and whose error message contains the string "WARNING::".

If neither the line number nor the error message field was specified, the configuration would mean "Ignore all errors generated by any line of a script whose name starts with "Nightly".

If the error message were the only field specified, the configuration would mean "Ignore all errors generated by any script when the error message contains the string "WARNING::".

Modify Rules

To modify an existing ignore rule, you can either double-click the rule in the list or select the rule and then click **Edit** from the dropdown. To remove an ignore rule, select the rule in the list and then click **Delete** from the dropdown.

Configure Rules to Ignore Errors by Page

You can also ignore all errors generated by a specific page, iframe, or Ajax request.

From the **Ignore Errors from these Pages** section, click **Add** to open the **Ignore errors from specific Pages** popup, where you can create a rule for every page for which you want to ignore all errors.

To remove an ignore rule, select it in the list and click **Delete** from the dropdown.

Configure Rules to Ignore Errors by URL

You can ignore all errors generated by a specific URL.

From the **Ignore Errors from these URLs** section, click **Add** to open the **Ignore errors from specific URLs** popup, where you can create a rule for every URL for which you want to ignore all errors.

Ignore errors from specific URLs

URL

To remove an ignore rule, select it in the list and click **Delete** from the dropdown.

Configure Browser RUM Performance Thresholds

You can configure the thresholds that define slow, very slow, and stalled end-user requests. These thresholds are used to trigger browser snapshots. See [Transaction Thresholds](#) for a detailed discussion about static, dynamic, percentage, and standard deviation thresholds.

You can define Browser Monitoring thresholds as one of the following:

- a multiple of the standard deviation. The default standard deviation threshold duration is two hours. For example: "Experience is slow if end-user response time is slower than 3 X the standard deviation."
- a static value; For example: "Experience is stalled if end-user response time is slower than 30000 ms."

The default thresholds are:

- Slow = 3 x standard deviation
- Very Slow = 4 x standard deviation
- Stalled = 45000 ms

Access Browser RUM Threshold Rules

1. Open the browser application in which you are interested.
2. On the left navigation bar, click **Configuration**.
3. Click **Instrumentation >**.
4. From the Settings tab, find the **Thresholds for Slow End User Experience** section.

Configure Browser RUM Threshold Rules

1. Select the relevant radio button to indicate whether the threshold is based on standard deviations or static values.
2. Type the values in the fields or select them using the scrollbars for one or more of the following:
 - a. **Slow greater than**
 - b. **Very slow greater than**
 - c. **Stall greater than**
3. Click **Save**.

Configure Browser Snapshot Collection

Related pages:

- [Browser Snapshots](#)
- [Set Up and Access Browser RUM](#)

Every page view and AJAX request sends a beacon to the EUM server. Every minute, the EUM server evaluates the collection of beacon samples and sends what are called "snapshots" to the Controller.

With browser snapshots, you can enable or disable:

- Slow snapshot collection, that is snapshots of requests where the End User Response Time is higher than the configured threshold.
- Periodic snapshot collection.
- Error snapshots, that is snapshots of requests for which a JavaScript error is reported or an Ajax request receives an HTTP error response. An error response is any HTTP code equal to or greater than 400.

If all three kinds of browser snapshot types—periodic, error, and slow response time—are disabled, the agent does not collect any browser snapshots.

Access Snapshot Collection Rules

1. Open the browser application in which you are interested
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation >**.
4. Select the Settings tab.
5. Find the **Event Policy Configuration** section.

Configure Snapshot Collection Rules

1. Check or clear the checkbox for one or more of the following:
 - **Enable Slow Snapshot Collection** to enable/disable slow response time snapshot collection.
 - **Enable Periodic Snapshot Collection** to enable/disable periodic snapshot collection.
 - **Enable Error Snapshot Collection** to enable/disable error snapshot collection.
2. Click **Save**.

Configure Web Percentile Metrics

Related pages:

- [Browser App Dashboard](#)
- [EUM Data](#)

Parts of the Controller UI for Browser RUM rely on the processing done by the Events Service, including some of the widgets in the **Browser App Dashboard** and the **Analyze** page. For these metrics, you can choose to display either averages or percentiles.

A percentile is a measure that indicates a value below which a given percentage of values in a set falls: for example, the 99th percentile means that 99% of all values are below this level. Using percentiles can be a good way to reduce the impact of extreme outliers in performance metrics, which can be useful in the often noisy environments of end-user monitoring. The [Metric Browser](#) also displays the percentiles.

You can:

- Enable/disable percentile metric display
- Set up to four different percentile levels to be applied to metrics

Access Configure Percentile Metrics

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation >**.
4. Select the **Settings** tab.
5. Find the **Configure Percentile Metrics** section.

Configure Percentile Metrics

1. Check the **Enable Percentile Metrics** checkbox.
2. Enter up to four percentile levels to collect in the **Percentiles to Collect** fields. Each value must be a whole number between 1 and 99.

Configure Session Monitoring Timeouts

You can control the timeframe for browser sessions by setting an inactivity limit. No activity beyond this limit is connected to previous activity as part of an individual session. See [Session Persistence](#) to learn more about how the duration of a session is determined.

Access Session Monitoring

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation >**.
4. Select the Settings tab.
5. Find the **Configure Session Monitoring** section.

Set Inactivity Timeout

From **Configure Session Monitoring**, set the number of minutes for the **Session Inactivity Timeout** field.

Configure Request IP Address Storage - Browser

For security and privacy reasons, Browser RUM does *not* store source IP addresses associated with requests. To have Browser RUM store IP addresses associated with requests, follow the instructions below.

1. Open the browser application in which you are interested.
2. On the left navigation bar, select **Configuration**.
3. Click **Instrumentation >**.
4. Select the Settings tab.
5. At the bottom of the Settings tab, check the **Store IP Address** checkbox to enable IP address storage. (By default, the box is *not* checked.)
6. Click **Save**.

Inject the JavaScript Agent

Related pages:

- [Overview of Injection Types](#)
- [Undo Injection](#)

This page describes how JavaScript Agent injection works, including the different injection types.

To instrument your application for Browser RUM, you must configure your JavaScript Agent and insert it into the page that is returned to the end user as part of the normal process it follows. The act of inserting the agent is called *injection*. There are several ways to inject the JavaScript Agent for Browser RUM into your web pages. You also have several JavaScript hosting options to choose from that offer differing degrees of control, simplicity, and reliability.

To configure the JavaScript Agent, see [Configure the JavaScript Agent](#).

How the JavaScript Agent Works

The JavaScript Agent consists of two files: `adrum.js` and `adrum-ext.js`.

1. The file `adrum.js` is injected into each instrumented page, as close to the top as possible, as the page is served. The file loads synchronously at around 90 KB (30 KB with compression).
2. This first JavaScript file starts a timer and does some quick configuration and setup.
3. At the `onload` event, `adrum-ext.js` is fetched *asynchronously* to prevent blocking the page load. This is the code that does most of the heavy lifting. Once it has been fetched, it is cached for 24 hours on the browser.
4. When cross-domain session correlation is enabled, the first time a user visits a domain, the browser additionally loads the file `adrum-xd.html` to generate or load a piece of common information that enables cross-domain sessions. Future visits will not load `adrum-xd.html` again.
5. When the page has completed loading, the collected data is bundled into a beacon and sent to the EUM Server by `adrum-ext.js`.
6. The data is processed by the EUM Server and then made available for pickup by the Controller.

 Not all types of injection are supported on all frameworks and platforms. See the Script Injection columns in the [Supported Platform Matrix for Browser Monitoring](#) matrices to find out what types are supported for your application.

Injection Methods

There are three methods for injecting the JavaScript Agent. See the following for each injection method:

- [Manual Injection of the JavaScript Agent](#)
- [Automatic Injection of the JavaScript Agent](#)
- [Assisted Injection](#)

JavaScript Agent Hosting Options

The `adrum.js` file is inserted into the page when it is downloaded from your web application. The `adrum-ext.js` (and `adrum-xd.html` when cross-domain session correlation is enabled) file is loaded asynchronously by the `adrum.js` file. By default, `adrum-ext.js` and `adrum-xd.html` are fetched by the highly available Amazon CloudFront CDN infrastructure.

There are three hosting options for the JavaScript Agent:

- AppDynamics CDN - All the JavaScript Agent files are from the host `cdn.appdynamics.com`. This is the simplest hosting option and ideal for testing.
- Self-Hosting - You host all of the JavaScript Agent files. This option gives you the most control and is recommended for production.
- Shared Hosting - You host the main file `adrum.js`, but the other files that are loaded asynchronously are from the AppDynamics CDN. This choice offers control of the most important file of the JavaScript Agent and is ideal for small to medium-sized businesses that don't have the resources or prefer not to host the entire JavaScript Agent.

See [Manual Injection of the JavaScript Agent](#) for step-by-step instructions.

Cross-domain session correlation

By default, Browser RUM sessions are restricted to one domain. Thus, when an end user navigates to a page in another domain or even subdomain, the session for that user is ended. You can, however, configure Browser RUM to enable sessions to continue across subdomains. Thus, when an end user navigates from `http://example1.com/` to `http://example2.com/`, the session will continue as long as the configured session inactivity time has not expired.

How Sessions Are Correlated Across Multiple Domains

For sessions to be correlated across domains, each page is required to use HTTPS to load the file `adrum-xd.html` from the same URL. If your pages are fetching the files `adrum-ext.js` and `adrum-xd.html` files from the AppDynamics CDN (this includes the shared hosting use case), sessions will automatically be correlated across domains because the pages will be fetching the file `adrum-xd.html` from the AppDynamics CDN.

For those *self-hosting* the JavaScript Agent files, you will need to configure the JavaScript Agent to use HTTPS to load the `adrum-ext.js` file from the same URL. The `adrum-xd.html` file is served from the location of the `adrum-ext.js` file. See the sections below for configuration instructions for the two use cases.

Configuration for Session Correlation Across Multiple Domains

AppDynamics CDN / Shared Hosting

When using the AppDynamics CDN or shared hosting, your JavaScript Agent configurations must enable cross-domain session correlation and use HTTPS to call the `adrum-ext.js` file. Thus, in your JavaScript Agent configuration make sure you have the following lines:

```

...
config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
config.xd = {enable : true};
...

```

Self-Hosting

When using self-hosting, your JavaScript Agent configurations must enable cross-domain session correlation and use HTTPS to call the `adrum-ext.js` file from the same URL. Thus, in your JavaScript Agent configuration make sure you have the following lines and that the value for `adrumExtUrlHttps` is the same for all pages requiring cross-domain session correlation.

```

...
// HTTPS is needed to fetch adrum-xd.html.
config.adrumExtUrlHttps = 'https://<your-adrum.ext-host>';
// This config enables cross-domain session correlation.
config.xd = {enable : true};
...

```

Set the Geo Server URL

By default, end-users' locations are resolved using public geographic databases. You can host an alternate geo server for your countries, regions, and cities instead of using the default geo server hosted by AppDynamics. See [Install and Host a Custom Geo Server for Browser RUM](#).

Custom Configuration

You can add configuration for `adrum.js` to customize and extend the functionality of the JavaScript Agent. See [Configure the JavaScript Agent](#) for instructions and examples on adding custom configuration.

JavaScript Agent Limitations

The JavaScript Agent cannot monitor and report the activity of [service workers](#) or [web workers](#). For example, if you use a service worker to make an XHR request, the JavaScript Agent will not be able to report it.

Overview of Injection Types

You need to inject the JavaScript Agent into your web pages to use Browser RUM. There are several injection types that you can use depending on your use case. This page describes the different injection types, how they work, and when to use each type.

Choosing an Injection Method

If you are uncertain which procedure to use to inject the agent into your web pages, follow these guidelines in the given order:

- If you want to use Browser RUM and do not have any app agents on the server side, use manual injection. See [Manual Injection of the JavaScript Agent](#).
- If automatic injection is available and works for your framework, use automatic injection. Automatic injection requires the least amount of effort because you do not have to manually instrument every page. Check the matrices at [Browser RUM Supported Environments](#) to see if automatic injection has been tested in your environment. Also, see [Automatic Injection of the JavaScript Agent](#).
- If you cannot use automatic injection, and you can edit the source code of *your web pages*, use manual injection. See [Manual Injection of the JavaScript Agent](#).
- If you cannot use automatic injection, and you can edit the source code of *your web application*, use one of the kinds of assisted injection. See [Assisted Injection-Using Attribute Injection](#).

Manual Injection

Manual injection is supported on all platforms and frameworks. To set up a manually injected page:

- Choose a JavaScript Agent hosting option. See [JavaScript Agent Hosting Options](#) to learn what hosting option best suits your use case.
- Manually configure each page to find the location of the JavaScript Agent, so that it can be executed as the page is constructed by the browser.

For detailed instructions on using manual injection in your application, see [Manual Injection of the JavaScript Agent](#).

Automatic Injection

If you are using a Java or .NET app agent on the server-side, and your application is running in an environment that supports any of the following:

- Apache Jasper JSP compiler (for Java) or
- ASP.NET or ASPX (for .NET) or
- ASP.NET Core (for .NET; Windows support only)

You *may* be able to use automatic injection, where the server-side app agent completely manages injecting the code at runtime. For instructions on using automatic injection in your application, see [Automatic Injection of the JavaScript Agent](#).

Assisted Injection

Assisted injection is available in two variants. In both cases, some of the work is done manually by you and some of the work is done by the server-side Java or .NET app agent.

 Assisted injection is currently not supported for .NET Core.

Assisted Injection Using Injection Rules (Java Only)

In this type of assisted injection, you configure rules that define which app server Java classes and methods write to the output stream of your application and the writer object that is used to do that writing. AppDynamics intercepts the method and injects the JavaScript Agent into the output stream. You also specify which server-side business transactions you wish to have instrumented in this way.

For detailed information on using this form of assisted injection, see [Assisted Injection](#).

Assisted Injection Using Attribute Injection

In this type of assisted injection, you copy small code snippets appropriate to your framework into your page templates or other code that creates your pages. This snippet contains the two variables `JS_HEADER` and `JS_FOOTER`, which the app agent replaces with the appropriate information in the response object at runtime.

For detailed information on using this form of assisted injection, see [Using Attribute Injection](#).

Container-Based Injection

If you are using Nginx or Apache as a web container or as a reverse proxy in front of your web container, you can use directives to inject the agent into the response object. See [Injection Using Nginx](#) or [Injection Using Apache](#).

Manual Injection of the JavaScript Agent

This page describes how to instrument a browser application by manually injecting the JavaScript Agent. To configure the JavaScript Agent before injection, see [Configure the JavaScript Agent](#).

Manually Inject the JavaScript Agent

The Controller UI allows you to configure the JavaScript Agent, generate an HTML snippet, and add that snippet to the header of the web pages.

1. In the Controller UI, go to a browser application.
2. In the left navigation menu, select **Configuration > Configure JavaScript Agent**.
3. [Configure the JavaScript Agent](#).
4. Save and copy the HTML snippet.
5. Add the HTML snippet to the header of the web pages.

JavaScript Agent Placement

The recommended location for the JavaScript Agent is at the top of the `<head>` section.

The `adrum.js` file captures the time as the page begins to load and measures that amount of time against the time that other timings are calculated for all browsers. Many modern browsers, however, support the Navigation Timing API (see [this list](#)), and for these browsers, timings can be acquired via the API. In this case, it is possible to place the JavaScript Agent somewhere else on the page, but useful timing information is only available for those `NavTime`-capable browsers.

Synchronous Versus Asynchronous Script Load

AppDynamics recommends that the `adrum.js` file loads synchronously because once downloaded, the JavaScript Agent begins monitoring for page data such as Ajax events, resources, and errors.

If `adrum.js` loads asynchronously for the first time (through the `async` attribute), the JavaScript Agent might not report all page data.

Use Previous JavaScript Agent Versions

Previous versions of the agent can be found at the following location, where `VERSION` is the version number you want to access (for example, `4.5.0`).

```
http://cdn.appdynamics.com/adrum/adrum-VERSION.js
```

- If you are using a SaaS EUM Cloud and want a hosted version of `adrum.js`, AppDynamics recommends you use the `adrum-latest.js` version. However, you can use any version of the JavaScript Agent as it is compatible with any SaaS EUM Cloud version currently being deployed.
- If you are using an on-premises EUM Server and want to use a hosted version of `adrum.js`, you need to match the `adrum.js` version to your EUM Server version.
- For Controller versions, a JavaScript Agent version is compatible with Controller versions with the same or older versions. For example, JavaScript Agent `20.6.0` is compatible with Controller `<= 20.6.0`.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Verify Manual Injection

Once the agent is injected, it can take the AppDynamics Controller a few minutes to discover and recognize the page, which must happen before data will begin to appear. If, however, you have configured your page using manual injection and are not seeing Browser RUM metrics after running load for a while, check the web page to confirm that the JavaScript Agent for Browser RUM is present in the page. If not, try injecting the script again.

If, after two attempts, you still do not see Browser RUM metrics, try one of the other injection schemes if they are available for your platform. See [Troubleshoot Browser RUM](#).

Automatic Injection of the JavaScript Agent

This page describes how to instrument a browser application by automatically injecting the JavaScript Agent. Automatic injection uses AppDynamics server-side agents to automatically add the `adrum` header and footer to each of your web pages.

Automatic Injection Support for Server-side Agents

The [Java Agent](#) and [.NET Agent](#) support automatic injection. See [.NET Supported Environments](#) for version specifics.

Automatic injection is available only for server-side applications built on these environments:

- Jasper-supported JSP (Java)
- ASP.NET
- ASP.NET Core
- ASPX (.NET) Framework

- Although the [Apache Agent](#) does *not* support automatic injection, you can [configure Apache](#) or [Nginx](#) to inject the JavaScript Agent.
- If the server-side application does not return well-formed HTML, the JavaScript Agent may not be able to instrument the page. For example, the JavaScript Agent may not be able to instrument HTML pages that are missing elements or have unclosed tags.

JavaScript Agent and Controller Versions

The table below lists the Javascript Agent version deployed for auto-injection in each Controller version.

The JavaScript Agent version does not match the Controller version because the Controller and agents have different release cycles.

Controller Version	JavaScript Agent Version Supported for Auto-Injection
21.4.0	20.12.0

Access the User Experience App Integration Panel

1. From the **Applications** page, open the [business application](#) that you want to automatically inject the JavaScript Agent into your browser application.
2. From the left navigation bar, select **Configuration**.
3. Click **User Experience App Integration**.

Enable Business Transaction Correlation

From the **Business Transaction Correlation**, check the **Enable Business Transaction Correlation** check box to correlate Pages and Ajax requests with server-side business transactions.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Specify Business Transactions to Include Correlation Headers

You can also specify which business transactions will include or exclude correlation headers. If you do not add request match rules or request exclude rules, correlation headers will be added to all requests.

To add a request rule:

1. Click the **plus** icon. The **Create HTTP Request Match Rule** will display.
2. Check the **Method** checkbox and select an HTTP method that you want to match.
3. Check the **URI** checkbox and enter your criteria.
4. Click **Save**.

Enable Automatic Injection

1. Select the JavaScript Agent Injection tab.
2. From the **Inject the JavaScript Agent configured for this Browser App** dropdown, select the browser application you want to use automatic injection.
3. Check the **Enable Automatic Injection of JavaScript** check box to enable automatic injection.
4. If you enabled automatic injection, click **OK** in the **Confirm Enabling Automatic Injection** dialog.
5. Click **Save** in the outer configuration pane.

Configure Automatic Injection

After you have enabled automatic injection:

- You must specify the server-side business transactions for which automatic JavaScript injection is enabled.
- You can limit which pages to inject by creating custom match and exclude rules for automatic injection. If you do not configure these rules, by default AppDynamics injects all pages visited by the enabled business transactions.

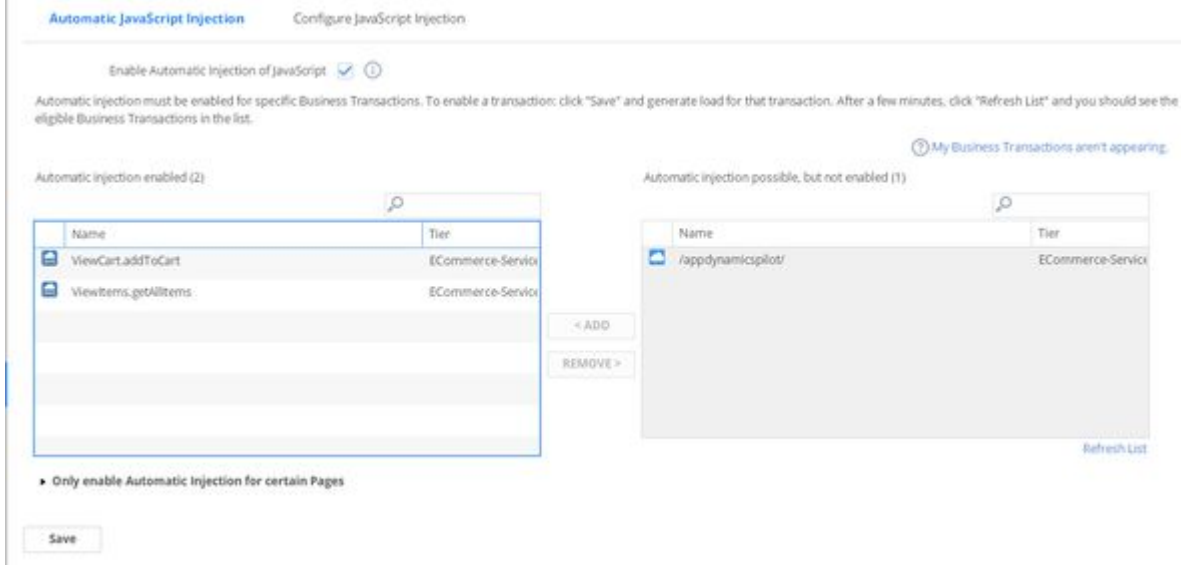

Use these rules to fine-tune which business transactions to include or exclude from injection based on match criteria. For example, you can exclude all business transactions that have a certain string in their URLs or set a certain cookie. The configurations for include rules and exclude rules are similar. It depends on your situation whether it is more convenient to restrict transactions based on inclusion or exclusion.

Specify Business Transactions for Automatic Injection

You must select at least one business transaction for automatic injection.

1. From the list on the right shown in the screenshot, select one or more business transactions. (If you don't see any business transactions, click **Refresh List**.) Not all your business transactions may appear here—the list includes only those transactions that AppDynamics can parse for automatic injection, those based on Jasper-compiled JSPs or ASP.NET, ASP.NET Core, or ASPX.NET pages.
2. Click **< Add** to move the business transaction to the list on the left.

- Repeat until all the transactions you wish to enable are on the left and those you do not wish to enable are on the right.

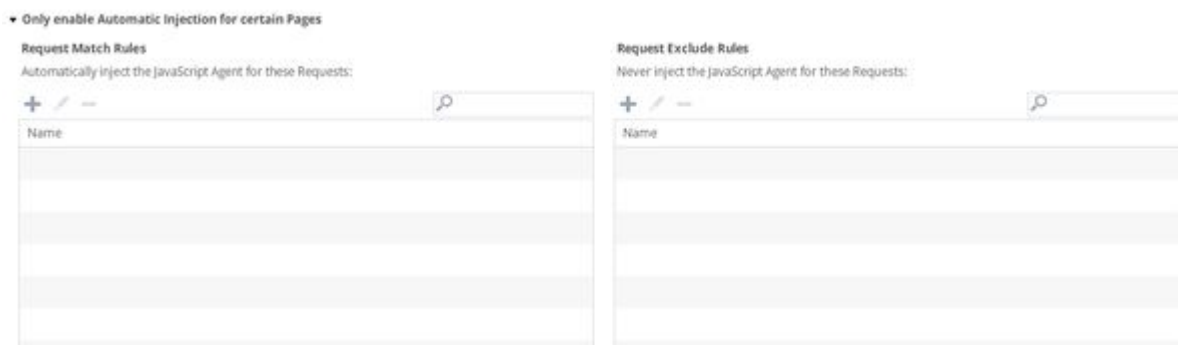

- Click **Save**.

Create Match Rules for Automatic Injection

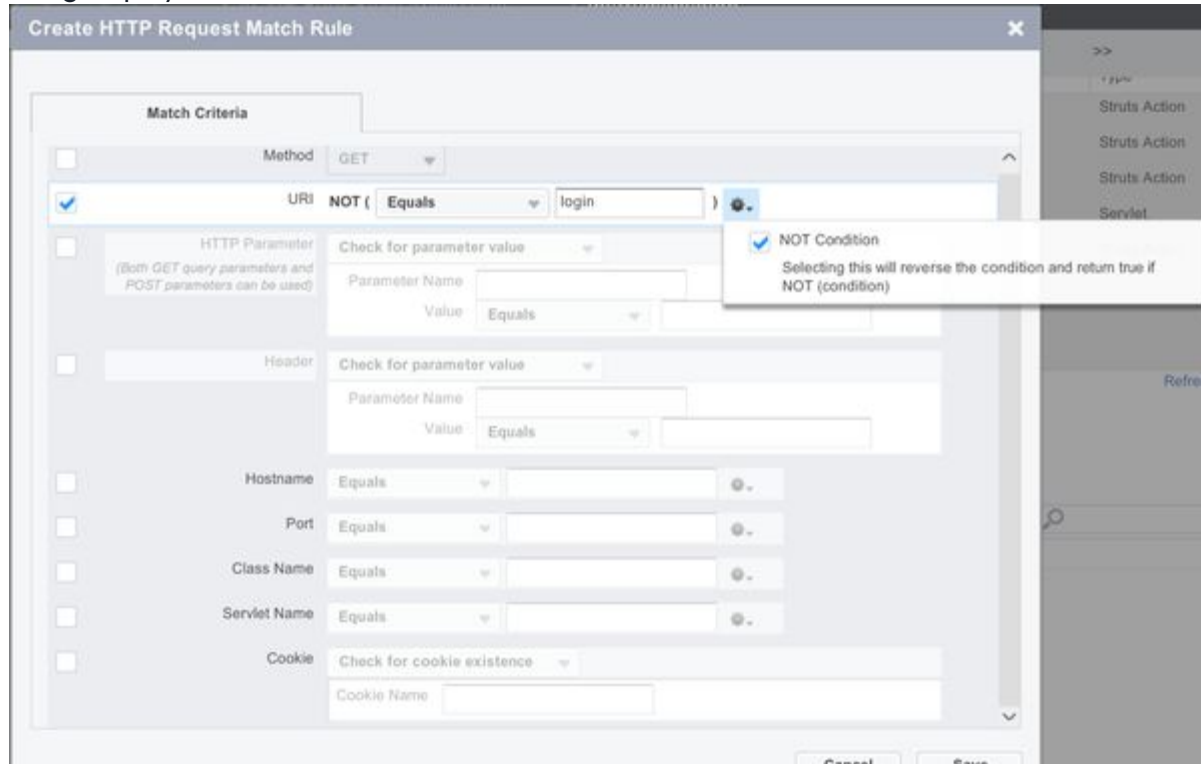

You may not wish to instrument every page in your application. For example, if your application has a very large number of pages, you might want to instrument only the key ones for your business, to avoid hitting licensing limits. Or, when you are in the setup and test phase, you might only want to instrument a few pages to keep your initial sample manageable.

Use match rules to include or exclude certain pages:

- Expand **Only enable Automatic Injection for certain Pages** if it is closed.

2. Click the **plus** icon to create a match rule or an exclude rule. The **Create HTTP Request Match Rule** dialog displays.

3. Select one or more criteria to match. If you select multiple criteria, **all** must match for the rule to come into effect. Use the **gear** icon to set a NOT condition. See [Using Regular Expressions](#) for general information about match rules.
4. Click **Save**.
5. Click **Save** in the outer configuration pane.

You can later edit or remove a match rule by selecting it in the list and clicking the edit or delete icon.

Injection Using Nginx

Related pages:

- [Manual Injection of the JavaScript Agent](#)
- [Automatic Injection of the JavaScript Agent](#)
- [Using Attribute Injection](#)

If you are using Nginx as your web container, or use Nginx as a reverse proxy, you can use a container substitution module to automatically inject the JavaScript Agent into your pages. The module intercepts the response object as it is being returned and makes a string substitution.

Download the Agent

You must first download the JavaScript Agent from the **Configuration** screen.

1. Open the browser application in which you are interested.
2. From the left navigation menu, select **Configuration**.
3. Click the **Configure and download JavaScript Agent**.
4. For the JavaScript hosting option, select **I will host all the JavaScript agent files**.
5. Click **Download** to download the JavaScript Agent.
6. Place the file somewhere accessible to the Nginx instance. The name of the saved file should be `adrum.js`.

Configure Nginx with `ngx_http_sub_module`

The `ngx_http_sub_module` module is a filter that modifies a response by replacing one specified string by another. You can use this feature to have the server automatically inject the header portion of the JavaScript Agent into a served page. For more information on the process, see the Nginx documentation, [Module ngx_http_sub_module](#).

For example, modify the location context to replace the `<head>` tag with the `<head>` tag and the JavaScript Agent scripts.

Sample Nginx Configuration

```
location / {
    sub_filter      <head>
        '<head><script>>window["adrum-app-key"]="<EUM_APP_KEY>";window["adrum-start-time"]=new
Date().getTime();</script><script type="text/javascript" src="//cdn.appdynamics.com/adrum/
adrum-latest.js"></script>';
    sub_filter_once on;
}
```

In the sample above, note that `/adrum-latest.js` is the path to a copy of the `adrum` file that is accessible to the server. Also, note the timer initialization `<script>>window['adrum-start-time'] = new`

`Date().getTime();</script>`. Keep these as close as possible to the top of the document, preferably right after the `<head>` tag, ensures the best possible timings.

i If you use `<meta>` tags, you should place them right after your `<head>` tag, and then place the JavaScript Agent directly after the last `<meta>` tag. This can avoid issues with some versions of IE.

You may need to escape some characters, depending on your platform. For example, on Mac OS:

```
location / {
    sub_filter      <head>
        '<head><script>>window[\'adrum-start-time\'] = new Date().getTime();</script><script
src="/adrum.js"></script>';
    sub_filter_once on;
}
```

i This Nginx module is often used for adding the Google Analytics script. Be careful not to overwrite any existing GA script when you do this.

Possible variations on the script string can be found in [Configure the JavaScript Agent](#).

Configure Nginx without `ngx_http_sub_module`

You can configure Nginx without the `ngx_http_sub_module` module if you prefer. Insert the required script into the `conf.d/default.conf` location.

Sample Nginx Configuration

```
location / {
    sub_filter      <head>
        '<head><script>>window["adrum-app-key"]="<EUM_APP_KEY>";window["adrum-start-time"]=new
Date().getTime();</script><script type="text/javascript" src="//cdn.appdynamics.com/adrum/
adrum-latest.js"></script>';
    sub_filter_once on;
}
```

Injection Using Apache

Related pages:

- [Manual Injection of the JavaScript Agent](#)
- [Automatic Injection of the JavaScript Agent](#)
- [Using Attribute Injection](#)
- [Using Injection Rules](#)

This page describes how to instrument a browser application using Apache to automatically inject the JavaScript Agent. If you are using Apache as your web container, or you are currently using, or willing to use, Apache as a reverse proxy, you can use a container substitution module to automatically inject the JavaScript Agent into your pages. The module intercepts the response object as it is being returned and makes a string substitution.

 This method uses the two Apache modules `mod_substitute` and `mod_filter`.

Download the Agent

You must first download the JavaScript Agent from the Browser Monitoring configuration pane.

1. Open the browser application in which you are interested.
2. From the left navigation menu, select **Configuration**.
3. Click the **Configure and download JavaScript Agent**.
4. For the JavaScript hosting option, select **I will host all the JavaScript agent files**.
5. Click **Download** to download the JavaScript Agent.
6. Place the file somewhere accessible to the Apache instance. The name of the saved file should be `adrum.js`.

Configure Apache

The basic configuration procedure includes:

1. [Make Sure the Modules are Loaded](#)
2. [Create an Adrum Configuration File](#)
3. [Add the Location of the Adrum Configuration File to httpd.conf](#)
4. [Restart the Web Server](#)

Make Sure the Modules are Loaded

Check your global Apache `httpd.conf` file and make sure that the following two `LoadModule` commands are in the file:

```
LoadModule substitute_module modules/mod_substitute.so
LoadModule filter_module modules/mod_filter.so
```

Create an Adrum Configuration File

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Create a file named `adrum.conf` with contents similar to the example below, based on your Apache version. (See this [Stack Overflow](#) post for details.) In this case, the substitution rule covers the location of the entire site (`Location /`) but you can also recursively select a specific directory and its subdirectories by using `/somedirectory`.

Sample adrum.conf Apache 2.2

Replace the sample code below with your own JavaScript Agent script.

```
<Location "/">
  SetOutputFilter INFLATE;SUBSTITUTE;DEFLATE
  AddOutputFilterByType SUBSTITUTE text/html
  Substitute "s#<head>#<head><script>>window['adrum-start-time'] = new Date().getTime();</
script><script>(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] ||
(window['adrum-config'] = {}));</script><script src='./adrum.js'></script>#inq"
</Location>
```

i If you use `<meta>` tags, you should place them right after your `<head>` tag, and then place the JavaScript Agent directly after the last `<meta>` tag and before other `<script>` tags. This can avoid issues with some versions of IE and improve the accuracy of the resource timing.

Sample adrum.conf Apache 2.4

Replace the sample code below with your own JavaScript Agent script.

```
<Location "/">
  AddOutputFilterByType SUBSTITUTE text/html
  Substitute "s#<head>#<head><script>>window['adrum-start-time'] = new Date().getTime();</
script><script>(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] ||
(window['adrum-config'] = {}));</script><script src='./adrum.js'></script>#inq"
</Location>
```

Where `./adrum.js` is the path to a copy of the `adrum` file that is accessible to the server. The flags after the `#` are:

- `i` - matching is case-insensitive
- `n` - pattern is treated as a fixed string (removing the `n` means the pattern is treated as a regular expression)
- `q` - module does not flatten the buckets after each substitution - this can speed performance.

For more information, see the Apache module docs [here](#).

If your `<head>` tag has an attribute like `<head lang="en">`, you can use a regex in the substitution string and omit the `n` flag. Replace the sample code below with your own JavaScript Agent script.

```
Substitute "s#(<head[^\>]*>)#$1<script>window['adrum-start-time'] = new Date().getTime();</script><script>(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] || (window['adrum-config'] = {}));</script><script src='./adrum.js'></script>#iq"
```

i Note the timer initialization: `<script>window['adrum-start-time'] = new Date().getTime();</script>`. Injecting these scripts as close as possible to the top of the document, preferably right after the `<head>` tag, ensures the best possible timings. Also, if you use `<meta>` tags, you should place them right after your `<head>` tag, and then place the JavaScript Agent directly after the last `<meta>` tag and before other `<script>` tags. This can avoid issues with some versions of IE and again improve the accuracy of the resource timing.

(Optional) Adjust for gzipped resources

If your page is compressed, the substitution won't work unless the content is INFLATEd, the substitution is made, and then the content is DEFLATEd. There are multiple ways to do this. For example, in the `FilterProvider` line:

```
FilterProvider AdrumFilter INFLATE;SUBSTITUTE;DEFLATE
resp=Content-Type $text/html
```

See this [Stack Overflow](#) post for more information. If you are using Apache as a proxy, you can also instruct it not to accept gzip-encoded content.

Add the Location of the Adrum Configuration File to `httpd.conf`

Add the following line to your global Apache `httpd.conf` file:

```
Include [absolutePathTo]/adrum.conf
```

Alternatively, you can add the directives to the `httpd.conf` file directly instead of creating a separate adrum file.

Restart the Web Server

To pick up the new configuration, restart:

```
sudo apcheectl -k restart
```

i If you get a warning "Useless use of AllowOverride in line 2 of [absolutePathTo]/adrum.conf", it can be ignored. It simply means `AllowOverride` is redundant. You can remove it if you wish.

Possible variations on the script string can be found in [Configure the JavaScript Agent](#).

Other Alternatives

If you are setting up your automatic injection using an Apache instance that is configured as a reverse proxy, you *must* use the `Location` directive method described above, with the `ProxyPass` and `ProxyPassReverse` directives also in the `Location` directive. If you are using an Apache instance that is your primary web container you have two additional options for describing the actual substitution step:

- [Using the Directory Directive](#)
- [Using .htaccess](#)

Use the Directory Directive

You can use the `Directory` directive instead of the `Location` directive.

Use .htaccess

Add lines similar to this to an `.htaccess` file in the base document directory for your site, replacing your filter name for `<MyFilter>`. If you don't have an `.htaccess` file, create one:

Apache 2.2

Replace the sample code below with your own JavaScript Agent script.

```
Substitute "s#<head>#<head><script>>window['adrum-start-time'] = new Date().getTime();</script><script>(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] || (window['adrum-config'] = {}));</script><script src='./adrum.js'></script>#inq"
```

```
AllowOverride Options
FilterDeclare <MyFilter>
FilterProvider <MyFilter> SUBSTITUTE resp=Content-Type $text/html
FilterChain <MyFilter>
Substitute "s#<head>#<head><script>>window['adrum-start-time'] = new Date().getTime();</script><script>(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] || (window['adrum-config'] = {}));</script><script src='./adrum.js'></script>#inq"
```

Apache 2.4

Replace the sample code below with your own JavaScript Agent script.

```
Substitute "s#<head>#<head><script>>window['adrum-start-time'] = new Date().getTime();</script><script>(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] || (window['adrum-config'] = {}));</script><script src='./adrum.js'></script>#inq"
```

AddOutputFilterByType SUBSTITUTE text/html

```
Substitute "s#<head>#<head><script>>window['adrum-start-time'] = new Date().getTime();</script><script>(function(config){config.appKey='<EUM_APP_KEY>';})(window['adrum-config'] || (window['adrum-config'] = {}));</script><script src='./adrum.js'></script>#inq"
```

Where `./adrum.js` is the path to a copy of the adrum file that is accessible to the server. Make sure `.htaccess` is world-readable.

Assisted Injection

Related pages:

- [Automatic Injection of the JavaScript Agent](#)
- [Injection Using Nginx](#)
- [Injection Using Apache](#)

This page describes how to instrument a browser application through assisted injection of the JavaScript Agent. Assisted injection is when your server-side application injects the JavaScript Agent into your browser application. You can configure your [business applications](#) to inject the JavaScript Agent into your browser applications.

Types of Assisted Injection

You can perform assisted injection with rules or through attributes. This table summarizes the platforms supported for each type of assisted injection and the process for performing the assisted injection.

Type of Assisted Injection	Supported Platforms	Description
Injection Rules	Java	<p>Type of assisted injection uses rules to configure which Java classes should be intercepted.</p> <p>You create the injection rules in the User Experience App Integration Panel of the Controller UI for the business application that will inject the JavaScript Agent.</p>
Attribute Injection	Java, ASP.NET	<p>Type of assisted injection relies on templates that tell the app agent where to inject information.</p> <p>You enable attribute injection in the User Experience App Integration Panel of the Controller UI for the business application that will inject the JavaScript Agent.</p> <p>Additionally, you add code snippets in the page templates that determine where the JavaScript Agent is injected.</p>

Injection Rules (Java Only)

To have your server-side application use assisted injection of the JavaScript Agent using injection rules, you define rules to configure:

- The Java classes and methods that should be intercepted

- The Java writer object and method to use to add the agent to the response object

 Assisted injection using rules is available for Java frameworks only.

Access the User Experience App Integration Panel

1. From the **Applications** page, open the **business application** that you want to automatically inject the JavaScript Agent into your browser application.
2. From the left navigation bar, select **Configuration**.
3. Click **User Experience App Integration**.

Create JavaScript Injection Rules

1. In the JavaScript Agent Injection tab, select a browser application from the **Inject the JavaScript Agent configured for this Browser App** dropdown.
2. From the Configure JavaScript Injection tab, expand **Create Injection Rules**.
3. Click the + icon to open the **Create Manual Injection Rule** dialog.
4. From the Where to Inject JavaScript tab:
 - a. In the **Name** field, enter a name for the rule.
 - b. Check **Enable**.
 - c. In the **Class and Method to intercept** section, define match conditions for the class and method that write to the output stream in your application. This is the class that server-side agent intercepts for injection.
 - d. If the write method is overloaded:
 - i. Check the **Is this Method Overloaded?** checkbox.
 - ii. Click **Add Parameter**.
 - iii. Add the parameters that define the method.
 - e. In the **Pointer to the writer** section:
 - i. Select how to obtain a reference to the writer object using either the selected method with a configured number of parameters, return value, or invoked object.
 - ii. Specify a getter chain.
 - f. In the **Injection options** section, specify:
 - the output stream write method the server-side agent should use to inject the JavaScript Agent
 - when the injection should occur: when the method begins or when the method ends
 - which part of the script should be injected: the header or the footer
 - optional prefix to output before writing the header or footer, such as `<DOCTYPE . . . >`
5. Click **Create Injection Rule**.

Attribute Injection

To have your server-side application use assisted injection of the JavaScript Agent using attribute injection, you:

- Enable attribute injection
- Copy code snippets into your page template

 Only [Servlet containers](#) supported assisted injection.

Access the User Experience App Integration Panel

1. From the **Applications** page, open the [business application](#) that you want to automatically inject the JavaScript Agent into your browser application.
2. From the left navigation bar, select **Configuration**.
3. Click **User Experience App Integration**.

Access the JavaScript Injection Configuration Panel

1. From the **User Experience App Integration** page, click the JavaScript Agent Injection tab.
2. In the JavaScript Agent Injection tab, select a browser application from the **Inject the JavaScript Agent configured for this Browser App** dropdown.

Copy Code Snippets into Your Page Template

These examples show code snippets that you can copy directly into your page templates or into other pages. These code snippets direct the app agent where to inject information. The header value must be injected at the very top of the `<head>` section and the footer value must be added at the very end of the code creating the page.

If you have already injected the header portion of the agent using manual injection, you can use these code snippets to automatically inject the footer data portion only. In this case, add only the `JS_FOOTER` values shown in the sections below.

JSF

```
<h:outputText rendered="#{AppDynamics_JS_HEADER != null}" value="#{request.getAttribute("AppDynamics_JS_HEADER")}" escape="false"/>
<h:outputText rendered="#{AppDynamics_JS_FOOTER != null}" value="#{request.getAttribute("AppDynamics_JS_FOOTER")}" escape="false"/>
```

JSP

```
<% if (request.getAttribute("AppDynamics_JS_HEADER") != null) { %> <%=request.getAttribute("AppDynamics_JS_HEADER")%> <% } %>
<% if (request.getAttribute("AppDynamics_JS_FOOTER") != null) { %> <%=request.getAttribute("AppDynamics_JS_FOOTER")%> <% } %>
```

Servlet

```
if (request.getAttribute("AppDynamics_JS_HEADER") != null)
{
    out.write(request.getAttribute("AppDynamics_JS_HEADER").toString());
}
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
}  
if (request.getAttribute("AppDynamics_JS_FOOTER") != null)  
{  
    out.write(request.getAttribute("AppDynamics_JS_FOOTER").toString());  
}
```

Groovy

```
<g:if test="{AppDynamics_JS_HEADER}">  
    ${AppDynamics_JS_HEADER}  
</g:if>  
  
<g:if test="{AppDynamics_JS_FOOTER}">  
    ${AppDynamics_JS_FOOTER}  
</g:if>
```

Velocity Template

```
#if ($AppDynamics_JS_HEADER)  
    $AppDynamics_JS_HEADER  
#end  
#if ($AppDynamics_JS_FOOTER)  
    $AppDynamics_JS_FOOTER  
#end
```

ASP.NET C#

```
<% if (Context.Items.Contains("AppDynamics_JS_HEADER"))  
    Response.Write(Context.Items["AppDynamics_JS_HEADER"]); %>  
<% if (Context.Items.Contains("AppDynamics_JS_FOOTER"))  
    Response.Write(Context.Items["AppDynamics_JS_FOOTER"]); %>
```

MVC Razor

```
@if(HttpContext.Current.Items.Contains("AppDynamics_JS_HEADER"))  
{ @Html.Raw((string)HttpContext.Current.Items["AppDynamics_JS_HEADER"]) }  
@if(HttpContext.Current.Items.Contains("AppDynamics_JS_FOOTER") )  
{ @Html.Raw(HttpContext.Current.Items["AppDynamics_JS_FOOTER"].ToString()) }
```

Undo Injection

Related pages:

- [Manual Injection of the JavaScript Agent](#)
- [Automatic Injection of the JavaScript Agent](#)
- [Assisted Injection](#)

If you try one way to inject and it does not work, AppDynamics recommends that you undo the current injection configuration before implementing another one.

Reverse Manual Injection

To undo manual injection, simply delete the JavaScript Agent from your web pages.

Undo Automatic Injection

To undo automatic injection:

1. Navigate to the **Application Dashboard** of the application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration**.
3. From the **Inject the JavaScript Agent configured for this Browser App** dropdown, select your browser application.
4. From the Automatic JavaScript Injection tab, clear the **Enable Automatic Injection of JavaScript** check box.

Undo Assisted Injection Using Attribute Injection

To undo assisted injection using attribute injection:

1. Navigate to the **Application Dashboard** of the application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration**.
3. From the **Inject the JavaScript Agent configured for this Browser App** dropdown, select your browser application.
4. From the Configure JavaScript Injection tab, clear the **Request Attribute Injection** check box.

Undo Assisted Injection Using Injection Rules

To undo assisted injection using injection rules:

1. Navigate to the **Application Dashboard** of the application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration**.
3. From the **Inject the JavaScript Agent configured for this Browser App** dropdown, select your browser application.
4. From the Configure JavaScript Injection tab, double-click the rule that you'd like to disable.
5. Clear the **Enabled** check box.

You can also simply delete rules by selecting the rule and then clicking the **Delete** icon.

Upgrade the JavaScript Agent

Related pages:

- [Manual Injection](#)
- [Automatic Injection](#)
- [Assisted Injection](#)
- [Undo Injection](#)

This page covers how to upgrade the JavaScript Agent version. Upgrading to the latest version of the JavaScript Agent will allow you to use the [latest features and get the latest bug fixes](#).

The following sections will discuss possible compatibility issues, show you a new way to include the JavaScript Agent, and provide you with manual injection code examples for the [different JavaScript Agent hosting options](#).

Compatibility Issues

For on-premises deployments, your JavaScript Agent version should be the same or older than your EUM Server version. For example, if you have deployed the EUM Server 20.3.0, the latest version of the JavaScript Agent you can use is 20.3.0. We recommend to upgrade your EUM Server to the latest version so you can take advantage of the latest JavaScript Agent features.

- If you are using a SaaS EUM Cloud and want a hosted version of `adrum.js`, AppDynamics recommends you use the `adrum-latest.js` version. However, you can use any version of the JavaScript Agent as it is compatible with any SaaS EUM Cloud version currently being deployed.
- If you are using an on-premises EUM Server and want to use a hosted version of `adrum.js`, you need to match the `adrum.js` version to your EUM Server version.
- For Controller versions, a JavaScript Agent version is compatible with Controller versions with the same or older versions. For example, JavaScript Agent 20.6.0 is compatible with Controller $\leq 20.6.0$.

Injection Code Changes

If the URL to the server hosting your JavaScript Agent is the same for both HTTP and HTTPS, you should no longer use `document.write` to inject the `<script>` tag. Instead, just hardcode the `<script>` tag with the following syntax:

```
<script src="//cdn.appdynamics.com/adrum/adrum.js"></script>
```

Injection Code for Different Hosting Options

The injection code will vary slightly depending on your deployment (SaaS/on-premises). The following provides you with code snippets for each type of deployment. Be sure to place the code snippets below right after the `<head>` tag.

[AppDynamics CDN](#) Self-Hosting Shared Hosting

In the string below:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- Replace the string `<EUM_APP_KEY>` in the code below with your own EUM app key.
- Replace `< eum-col.appdynamics.com >` in the code below with your corresponding collector URL.

```
<script charset='UTF-8'>
window['adrum-start-time'] = new Date().getTime();
(function(config){
  config.appKey = '<EUM_APP_KEY>';
  config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
  config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
  config.beaconUrlHttp = 'http://eum-col.appdynamics.com';
  config.beaconUrlHttps = 'https://eum-col.appdynamics.com';
  config.xd = {enable : false};
})(window['adrum-config'] || (window['adrum-config'] = {}));
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js'></script>
```

AppDynamics CDN [Self-Hosting](#) Shared Hosting

In the code snippet below:

- Replace the string `<EUM_APP_KEY>` with your own EUM app key.
- Replace the string `<your-cdn.com>` with the URL to your server hosting the JavaScript Agent.
- Replace `< eum-col.appdynamics.com >` in the code below with your corresponding collector URL.

```
<script charset='UTF-8'>
window['adrum-start-time'] = new Date().getTime();
(function(config){
  config.appKey = '<EUM_APP_KEY>';
  config.adrumExtUrlHttp = 'http://<your-cdn.com>';
  config.adrumExtUrlHttps = 'https://<your-cdn.com>';
  config.beaconUrlHttp = 'http://eum-col.appdynamics.com';
  config.beaconUrlHttps = 'http://eum-col.appdynamics.com';
  config.xd = {enable : false};
})(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//<your-cdn.com>/adrum/adrum.js'></script>
```

AppDynamics CDN Self-Hosting [Shared Hosting](#)

In the code snippet below:

- Replace the string `<EUM_APP_KEY>` with your own EUM app key.
- Replace the string `<your-cdn.com>` with the URL to where you're hosting the JavaScript Agent.
- Replace `< eum-col.appdynamics.com >` in the code below with your corresponding collector URL.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
<script charset='UTF-8'>
window['adrum-start-time'] = new Date().getTime();
(function(config){
  config.appKey = '<EUM_APP_KEY>';
  config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
  config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
  config.beaconUrlHttp = 'http://eum-col.appdynamics.com';
  config.beaconUrlHttps = 'https://eum-col.appdynamics.com';
  config.xd = {enable : false};
})(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//<your-cdn.com>/adrum/adrum.js'></script>
```

Configure the JavaScript Agent

Related pages:

- [Injection Problems](#)
- [Inject the JavaScript Agent](#)

This page describes configuration and hosting options for the JavaScript Agent.

Configure the JavaScript Agent

To configure the JavaScript Agent in the Controller:

1. Go to a browser application.
2. In the left-hand panel, go to **Configuration > Configure the JavaScript Agent**.
3. Select a [hosting option](#).
4. Customize the code snippet in **Step 2: Advanced settings (Optional)**.
5. Click **Save**.

Advanced Configurations

This table describes advanced configurations for the JavaScript Agent snippet. You can add these advanced configurations manually or using Controller $\geq 20.7.0$. When you check a box in the UI, such as **Use HTTPS by default**, the JavaScript snippet automatically updates to reflect the selection, such as `config.useHTTPSAlways = true` added to the UI snippet.

Available in SaaS Controller $\geq 20.7.0$	Manual Configuration Instructions	Summary
✓	Use HTTPS by default	Use HTTPS as the default transport protocol for the JavaScript Agent. If unchecked, the agent chooses the transport protocol used to load the base page.
✓	Set cookie to strict domain	Limit the cookie to the full strict domain name. If unchecked, the cookie is set to the broadest version of the originating domain (such as, <code>*.domain.com</code>).
✓	Set GeoServer URL	If your application uses internet IP addresses or users connect through a VPN, enter your custom GeoServer URL to map internal IP addresses to physical locations. If unchecked, end-user locations are resolved using the default GeoServer.
✓	Configure URL length	Set the maximum number of segments and characters in resource URLs to view more or less of a URL in the Controller UI.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Available in SaaS Controller >= 20.7.0	Manual Configuration Instructions	Summary
✓	Hide URL query string	By default, URL query strings may be long or contain sensitive information. Check this box to hide the full string from the Controller UI.
✓	Cross-domain session correlation	Enable sessions to continue across subdomains. If unchecked, sessions are restricted to one domain and navigating from one domain to another will end the session.
✓	Configure request origin location	Set a specific IP address or location as the origin of the request. You can specify only the IP address, or the complete location (IP, country, region, and city).
✓	Configure resource options	Configure which resources are monitored based on how they are ordered, the maximum number of resources that will be evaluated, and whether the resource timing buffer should be cleared when it's full.
✓	Modify resource sampling options	Modify how the resources are ordered (using the sampling algorithm) and the maximum number of resources to be evaluate.
✓	Capture page title	Capture the page title as part of the beacon, displayed in Browser Snapshots . Uncheck this setting to hide the page title for security or privacy reasons. Check this setting to set a custom page title with an arbitrary URL string.
✓	Enable SPA2 monitoring	Monitor single-page applications (SPAs) to detect virtual pages and correlate resources, JavaScript errors, and AJAX requests.
✓	Enable resource timing buffer clearing for SPAs	For SPAs, the JavaScript Agent by default clears the resource timing buffer after it is full and saves the data in a local buffer. You can configure the JavaScript Agent so that the resource timing buffer is not cleared to capture resource timing data.
✓	Set the custom page name	The page name is used to identify and group pages in Pages & AJAX Requests . If unchecked, the default page name consists of the hostname, port, and path.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Available in SaaS Controller >= 20.7.0	Manual Configuration Instructions	Summary
✓	Filter virtual pages	Configure rules to exclude specific virtual pages from being monitored.
✓	Monitor Fetch API calls	By default, the JavaScript Agent monitors Fetch API calls for all SPAs except applications using Zone libraries, including Angular applications. Only consider disabling this setting for specific use cases.
✓	Set AJAX request limit	To prevent an overload of AJAX requests, you can limit the number of requests sent per base and virtual pageview. The limit is 250 requests for single-page applications (SPAs) and 50 requests for non-SPAs.
✓	Filter XHR calls by URL	Include or exclude specific XHR calls to be monitored.
	Report events with the JavaScript API	The JavaScript API enables you to manually report events to the agent so that it can time the various parts of your virtual page loads and correlate Ajax calls to those page loads. You can also capture and report errors with this API.
	Limit beacon types	By default, sending image beacons is disabled and beacons are only sent with Cross-Origin Resource Sharing (CORS). If you have an older browser that does not support CORS beacons, you can enable sending image beacons.
	Disable browser monitoring programmatically	For pages in which the JavaScript Agent was injected manually, you can disable the agent programmatically by adding a script to the header.
	Handle the window.onerror event	If any script on your monitored web pages or library code sets the JavaScript <code>window.onerror</code> event, add the method <code>ADRUM.listenForErrors()</code> to the page immediately after setting <code>window.onerror</code> .

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Available in SaaS Controller >= 20.7.0	Manual Configuration Instructions	Summary
	Set Ajax request names based on captured POST parameters	You can configure the JavaScript Agent to capture <code>POST</code> parameters and then use the parameter(s) to name the Ajax request in Pages & Ajax Requests. This configuration enables you to identify and sort Ajax requests from the same page based on <code>POST</code> parameter(s).
	Set custom virtual page names	You can configure the JavaScript Agent to use any arbitrary string (that is not necessarily a part of the URL) to name a virtual page.
	Add custom user data to a page browser snapshot	You can add user information that is specific to your application to a browser snapshot. The information is expressed as key-value pairs that are attached the JavaScript Agent configuration and later included in the beacons sent to the EUM Server.
	Disable the primary metric	You can disable the primary metric to help improve application performance.

Configure Shared-Hosting

If you are using shared-hosting and do not want to use the default CDN, follow these instructions to provide your own CDN for only hosting the main JavaScript Agent file (`adrum-[version].js`):

1. From **Controller Admin**, go to **Controller Settings**.
2. For the values of settings `eum.jsagent.cdn.host.http` and `eum.jsagent.cdn.host.https`, enter the URLs where the JavaScript Agent files are being hosted.
3. Confirm these URLs match the URLs in the JavaScript snippet you want to inject.

Configure Self-Hosting

If you are self-hosting and do not want to use the default CDN, follow these instructions to provide your own CDN for hosting all of the JavaScript Agent files:

1. From the **Controller Admin**, go to **Controller Settings**.
2. For the values of settings `eum.jsagent.cdn.host.http` and `eum.jsagent.cdn.host.https`, enter the URLs where the JavaScript Agent files are being hosted.
3. Confirm these URLs match the URLs in the JavaScript snippet you want to inject.

Next Steps

After you configure the JavaScript Agent, inject the JavaScript snippet in your page HTML with one of these methods:

- [Manual Injection of the JavaScript Agent](#)
- [Automatic Injection of the JavaScript Agent](#)
- [Assisted Injection](#)

See [Overview of Injection Types](#) for differences between the injection methods.

Add Custom User Data to a Page Browser Snapshot

Related pages:

- [Page Snapshots](#)

You can add user information that is specific to your application to a browser snapshot. The information is expressed as key-value pairs that are attached the JavaScript Agent configuration and later included in the beacons sent to the EUM Server.

The JavaScript Agent initializes user data differently depending on the page type (base, Ajax, virtual) and the method used (immediately invoked function expressions, function pointers, and literals). See [Methods for Setting Custom User Data](#) to learn when the JavaScript Agent initializes the user data for each page type and method.

The maximum size allowed for user data in a page is 2048 characters (CORS beacon) or 100 bytes (image beacon). The maximum size includes the keys-value pairs, syntax characters such as braces, and quotation marks.

View Custom User Data

Custom user data appears in **Browser Analyze**, **Browser Snapshots**, and **Sessions**. View the following tabs to learn more about how user data is viewed and used in the Controller UI.

[Browser Analyze](#) Browser Snapshots Sessions

In this **Browser Analyze** screenshot, the user data vehicleYear is used to sort the records. You can also select fields to view user data.

Browser Analyze [Browser Snapshots](#) [Sessions](#)

You view user data in the **Session Summary** of the **Session Details** dialog as shown in this screenshot. In sessions, the custom user data is only included when the base page with the custom user data is the first page of the session.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Methods for Setting Custom User Data

You can use several methods to set custom data for each page type (base, Ajax, virtual). Each method has its own syntax, execution time, and use case. This table outlines the execution time and potential use case for each method and page type.

Method Type	Page Type	Execution Time	Potential Use Cases
Immediately Invoked Function Expressions (IIFE)	Base	These are JavaScript functions that run as soon as they are defined. They're also known as self-executing anonymous functions.	<p>If your base/virtual page or Ajax request depends on information from different resources, you can set static information for custom user data with IIFE.</p> <p>For example, if two different server scripts generate content for the base page, you could use the IIFE on the client to set the static user data.</p>
	Ajax		
	Virtual		

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Method Type	Page Type	Execution Time	Potential Use Cases
Function pointers	Base	The JavaScript Agent executes function pointers when the <code>onload</code> event is triggered.	Data extracted from cookies, the page, and meta data.
	Ajax	This event is triggered when an Ajax call is made. Custom user data for the Ajax events are attached to AJAX requests.	Meta data regarding the Ajax request such as the URL, HTTP method, or the request payload.
	Virtual	This event is triggered when the virtual page is created. The virtual page is a dynamically recreated version of the base page, and custom user data set for <code>VPageView</code> events are attached to the virtual page records.	Use if the information is derived or found somewhere on the page because of the creation of the virtual page. User-specific fields or user data set based on the URL and DOM changes.
Literals	Base	You can simply use literal values to set custom data. The values, as with IIFE, are set as soon as the values are defined.	Constants, static data extracted and set on the server.
	Ajax		
	Virtual		

User Data Types

For each event callback that is triggered, you can add user data by returning objects containing key-value pairs of different data types. Each user data type is an object containing properties of a specific data type.

Make sure the data type correctly matches the key-value pair. If you send the wrong key-value inside the `userData` object, such as adding a date key-value pair in a string data type, you will receive a generic error.

Data Type	Description	Example
<code>userData</code>	This data type is for setting one or more properties of type <code>string</code> . The value must be in a string, even if the value is set to a numeric value.	<pre>{ user: "john_thompson", cart: "100.00" };</pre>
<code>userDataLong</code>	This data type is for setting one or more properties of type <code>long</code> and must be a numeric value without decimals.	<pre>{ numberOfProducts: 17, numberOfSales: 1213 };</pre>
<code>userDataDouble</code>	This data type is for setting one or more properties of type <code>double</code> and must be a numeric value with decimals.	<pre>{ monthlyVisitFrequency: 0.13333333, avgCustomerConversion: 0.0361922 };</pre>
<code>userDataBoolean</code>	This data type is for setting one or more properties of type <code>boolean</code> .	<pre>{ returnCustomer: true, subscriber: false };</pre>
<code>userDataDate</code>	This data type is for setting one or more properties of type <code>date</code> . The value must be the converted Epoch value of the date.	<pre>{ epoch1: 1448675019877, epoch2: 1418475982737 };</pre>

Syntax of User Data Objects

You add user data as objects for each page event to the JavaScript Agent configuration. The base page, Ajax, and virtual pages have the following corresponding user data objects:

- `PageView`
- `Ajax`

- `VPageView`

The `PageView`, `Ajax`, and `VPageView` objects have slightly different syntaxes. `UserPageName` is only available for `PageView` and `VPageView`, and not for `Ajax` and `Error`.

    }
}
};

```

Capture Ajax Data for Setting User Data

When setting user data for the Ajax event, the JavaScript Agent configuration provides a `context` object that has properties for the HTTP method, the request URL, and the request payload of the Ajax request. You can use this information to set values for the user data configuration object.

i The JavaScript Agent does not intercept or expose the response from the Ajax request. Thus, you can only include the request information (HTTP method, request URL, and request payload) in the user data that you report.

Ajax Context Object

To access the URL and HTTP method of the Ajax request, you can simply access the `method` and `url` properties of the `context` object. For the request payload of the Ajax request, you need to first match the payload parameters (HTTP method or Ajax URL) to access the `data` property. See [Match the Ajax Payload Parameters](#) to learn how to define the filters to match the payload parameters.

The `context` object has the following properties:

Property	Description	Data Type	Requirement to Access Property
<code>method</code>	The HTTP method used to make the Ajax request.	string	XHR call
<code>url</code>	The URL used to make the Ajax request.	string	XHR call
<code>data</code>	The request payload attached to the Ajax request.	Any data type that can be passed as the body to <code>xhr.send</code> .	<ul style="list-style-type: none"> XHR call XHR filter for the payload parameter

Match the Ajax Payload Parameters

To access the request payload, you need to use `xhr.payloadParams` array to match the HTTP method and/or the Ajax URL. To match the Ajax URL, you can specify one or more patterns. To match the HTTP method, you include one or more objects specifying HTTP methods.

In the "Match HTTP Methods" example, the `payloadParams` array is used to match the HTTP methods "POST" and "GET". In the "Matching URLs" example, the `payloadParams` array is used to match URLs with the following string: `'.**/xhr/uptime'`.

[Match HTTP Methods](#) [Match URLs](#)

```
<script type = 'text/javascript' charset = 'UTF-8' >
  window['adrum-config'] = {
    xhr: {
      payloadParams: [{
        method: 'POST'
      }, {
        method: 'GET'
      }]
    },
    ...
  }
```

[Match HTTP Methods](#) [Match URLs](#)

```
window['adrum-config'] = {
  xhr: {
    payloadParams: [{urls: [{pattern: '.*xhr/uptime'}]}]
  },
  ...
}
```

Ajax Payload Filter Examples

Conventional Ajax Requests

In the following examples, the data from a conventional Ajax request payload is used to set custom user data. For capturing the request payload for Fetch API calls, see [Ajax Requests Using the Fetch API](#).

[Match HTTP Methods Example](#) [Match URLs Example](#)

This example only sets the user data configuration objects with data from the Ajax request payload if the HTTP method is `POST`.

```
<script type='text/javascript' charset='UTF-8'>
  window['adrum-config'] = {
    xhr: {
      payloadParams: [{method: 'POST'}]
    },
    userEventInfo: {
      "Ajax" : function(context) {
```

```

    if (context.data && context.data.indexOf("purchase") > -1) {
      // The URLSearchParams API does not work on IE/Edge
      var payload = new URLSearchParams(context.data);
      return {
        userData: {
          username: payload.get("username"),
          email: payload.get("email"),
          phone: payload.get("phone")
        },
        userDataLong: {
          customerId: Number(payload.get("customer_id"),
          totalPurchases: Number(payload.get("total_purchases"))
        },
        userDataDouble: {
          purchaseTotal: Double(payload.get("total"))
        },
        userDataBoolean: {
          discounted: Boolean(payload.get("discounted"),
          vipMember: Boolean(payload.get("member"))
        },
        userDataDate: {
          purchaseTime: Date.now()
        }
      }
    }
  };
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>

```

[Match HTTP Methods Example](#)
[Match URLs Example](#)

This example only sets the user data configuration objects with data from the Ajax request payload if the Ajax URL matches the pattern `".*/transaction"`. For example, the URL `http://example.com/transaction` would match the pattern and cause the user data configuration to be set with data from the Ajax request payload.

```

<script type='text/javascript' charset='UTF-8'>
  window['adrum-config'] = {
    xhr: {
      payloadParams: [{urls: [{pattern: '.*\/transaction'}]}]
    },
    userEventInfo: {
      "Ajax" : function(context) {

```

```

    if (context.data && (context.data.indexOf("username") > -1) &&
(context.data.indexOf("customer_id") > -1) && (customer.data.indexOf("phone") > -1)) {
    // The URLSearchParams API does not work on IE/Edge
    var payload = new URLSearchParams(context.data);
    return {
      userData: {
        username: payload.get("username"),
        email: payload.get("email"),
        phone: payload.get("phone")
      },
      userDataLong: {
        customerId: Number(payload.get("customer_id"))
        totalPurchases: Number(payload.get("total_purchases")) || 0
      },
      userDataDouble: {
        purchaseTotal: Number(payload.get("total")) || 0
      },
      userDataBoolean: {
        discounted: Boolean(payload.get("discounted")) || false,
        vipMember: Boolean(payload.get("member")) || false
      },
      userDataDate: {
        purchaseTime: Date.now()
      }
    }
  }
};
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>

```

Ajax Requests Using the Fetch API

The example below demonstrates how to use the JavaScript Agent configuration to match the HTTP method, the request URL, and the request body for Ajax calls using the Fetch API. The Fetch API call is also provided to add context. The JavaScript Agent **cannot access** the request body, however, if [you supply your own Request object](#) to the `fetch` method.

[Fetch API Call](#) Match HTTP Method and URL Example

This Fetch API example sets the from the Ajax request payload if the HTTP method is `POST`.

```

<script type='text/javascript' charset='UTF-8'>
  // Note: URLSearchParams() is not supported in IE/Edge
  let queryParams = new URLSearchParams(window.location.search.substr(1));

```

```

fetch('https://my-json-server.typicode.com/typicode/demo/posts', {
  method: 'post',
  body: queryParams.toString()
}).then(function(response) {
  return response.json();
}).then(function(data) {
  console.log('Posted content:', data.request_url);
});
</script>

```

Fetch API Call [Match HTTP Method and URL Example](#)

This example only sets the user data configuration objects with data from the Ajax request payload if the HTTP method is `POST` and the Ajax URL matches the pattern `"/posts"`.

```

<script type='text/javascript' charset='UTF-8'>
window['adrum-config'] = {
  xhr: {
    payloadParams: [{method: 'POST'}, {urls: [{pattern: '/posts'}]}]
  },
  userEventInfo: {
    "Ajax": function (context) {
      var payload = null;
      if (context.data && (context.data.indexOf("id") > -1) && (context.data.indexOf("
title") > -1)) {
        // The URLSearchParams API does not work on IE/Edge
        payload = new URLSearchParams(context.data).toString();
      } else if (context.data && context.data.indexOf("id") > -1) {
        // The URLSearchParams API does not work on IE/Edge
        var params = new URLSearchParams(context.data);
        params.set("title", "Post for " + params.get("id"));
        payload = params.toString();
      } else {
        payload = "Payload is not available";
      }
      return {
        userData: {
          username: "xhr_user",
          cart: "218.50",
          payload: payload
        }
      }
    }
  }
};
</script>

```

```
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
```

Custom User Data Examples

The following examples show you how to set custom data for different page types and using the different methods:

- [Setting User Data with Function Pointers](#)
- [Setting User Data with an Anonymous Function](#)
- [Setting User Data with Multiple Methods](#)

Setting User Data with Function Pointers

The example below assigns a value to the `userPageName` property of the `PageView` object by executing the function `extractUserData`, which extracts data from the cookies.

```
< script type = 'text/javascript'
charset = 'UTF-8' >
  (function (config) {
    (function (info) {
      info.PageView = extractUserData;
    })(config.userEventInfo || (config.userEventInfo = {}))
  })(window['adrum-config'] || (window['adrum-config'] = {}));

function extractUserData() {
  var cookies = document.cookie.split(';');
  for (var i = 0; i < cookies.length; i++) {
    var cookie = cookies[i].trim();
    if (cookie.indexOf("role=") === 0) {
      var role = cookie.substring(5);
    }
  }
  return {
    userPageName: role
  };
} <
/script> <
script src = '//cdn.appdynamics.com/adrum/adrum-latest.js'
type = 'text/javascript'
charset = 'UTF-8' > < /script>
```

Setting User Data with an Anonymous Function

You can also use anonymous functions that return an object as shown in this example for setting user data for virtual pages.

```

< script type = 'text/javascript'
charset = 'UTF-8' >
  (function (config) {
    (function (info) {
      info.VPageView = function () {
        return {
          userData: {
            version: window.location.href.split("/")[4],
            space: space(),
            email: getEmail()
          },
          userPageName: $('title').get(0).text,
          userDataDate: {
            currentTime: ((new Date()).getTime())
          },
          userDataBoolean: {
            watchingPage: watchingPage()
          }
        }
      }
    })
  })(config.userEventInfo || (config.userEventInfo = {}))
})(window['adrum-config'] || (window['adrum-config'] = {})); <
/script> <
script src = '//cdn.appdynamics.com/adrum/adrum-latest.js'
type = 'text/javascript'
charset = 'UTF-8' > </script>

```

Setting User Data with Multiple Methods

You might also want to use a combination of literal values, named and anonymous functions as this example does for setting user data for the `Ajax` event. Note, the `context` object is only available for `Ajax` events, and this object has the properties `data` (stores the request payload), `method` (HTTP method used to make Ajax request), and `url` (the Ajax request URL).

```

<script type='text/javascript' charset='UTF-8'>
  (function(config){
    (function(info) {
      info.Ajax = function(context) {
        return {
          userPageName: $('title').get(0).text,
          userData: extractUserData(context)
          userDataBoolean: {
            "visited": true
          }
        }
      }
    })
  });

```

```
})(config.userEventInfo || (config.userEventInfo = {}))
})(window['adrum-config'] || (window['adrum-config'] = {}));

function extractUserData(context) {
  var cookies = document.cookie.split(';');
  for (var i = 0; i < cookies.length; i++) {
    var cookie = cookies[i].trim();
    if (cookie.indexOf("email=") === 0) {
      var role = cookie.substring(5);
    }
  }
  return {
    role: role,
    url: context.url,
    method: context.method
  };
}
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
```

Set Custom Page Names

Related pages:

- [Configure Naming for Ajax Requests](#)
- [Configure Virtual Page Naming](#)

This page describes how to set custom page names. In the **Configuration > Instrumentation** page, you can configure rules that name pages, iframes and Ajax requests based on various parts of the page URL. See [Configure Page Identification and Naming](#).

You can also configure the JavaScript Agent to use any arbitrary string, not necessarily a part of the URL, to name a page or an iframe, but not an Ajax request. To do so, you assign a string of 760 characters or less to the `userPageName` property of the `PageView` object. If the string length exceeds 760 characters, the page name will not be set.

For example, this configuration shown below would set the page name to "My Custom Page". That page name would then be used to identify and group pages in the **Pages & AJAX Requests** page in the Controller UI.

```

<head>
  <script type='text/javascript' charset='UTF-8'>
    (function (config) {
      (function (info) {
        info.PageView = {
          userPageName: "My Custom Page"
        }
      })(config.userEventInfo || (config.userEventInfo = {}));
    })(window['adrum-config'] || (window['adrum-config'] = {}));
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
  UTF-8'></script>
  ....
</head>
  
```

The default page name consists of the hostname, port, and path. For example, if the page URL is `http://example.com:8080/yourpath`, the default page name would be `example.com:8080/yourpath`.

Set Custom Virtual Page Names

Related pages:

- [Configure Page Identification and Naming](#)
- [Configure Naming for Ajax Requests](#)
- [Configure Virtual Page Naming](#)

This page explains how to create custom virtual page names.

To name virtual pages with the JavaScript Agent, you need to [enable SPA2 monitoring](#). You can configure the JavaScript Agent to use any arbitrary string, not necessarily a part of the URL, to name a virtual page. The virtual page name must consist of a string of 760 or fewer alphanumeric characters. If the string length exceeds 760 characters, the page name will not be set.

i If you are using [SPA1 monitoring](#), the method called to set the name the virtual page will be ignored.

To name a virtual page, you execute the method `setVirtualPageName` with `ADRUM.command` as shown below. The `ADRUM` object is globally accessible after you load the JavaScript Agent (`adrum-latest.js`).

```
<head>
  <script charset='UTF-8' type='text/javascript'>
    window['adrum-start-time'] = new Date().getTime();
    (function(config){
      config.appKey = '<EUM_APP_KEY>';
      ...
    })(window['adrum-config'] || (window['adrum-config'] = {}));
  </script>
  <script charset='UTF-8' src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/
  javascript' ></script>
  <script type='text/javascript' charset='UTF-8'>
    ...
    ADRUM.command("setVirtualPageName", "myCustomVPName");
  </script>
</head>
```

When you name a virtual page with `setVirtualPageName`, the custom name will be applied to the next virtual page you manually mark with `markVirtualPageBegin`. Thus, the virtual page currently being monitored will not get the custom name.

The code example below shows how to call the methods to manually mark the beginning and end of the virtual page as well as execute `setVirtualPageName` to name the next virtual page that is monitored. See [Report Virtual Pages](#) to learn how to manually mark the beginning and end of virtual pages with the JavaScript API.

```

.controller('VPNaming', ['$scope', '$http', function ($scope, $http) {
    $scope.startVirtualPageWithCustomUrl = function () {
        console.log("Marking the beginning of the virtual page and waiting for the
end to be manually marked.");
        ADRUM.markVirtualPageBegin("homepage", true);
    }
    $scope.startVirtualPageNotWaitingForMarkVirtualPageEnd = function () {
        console.log("Marking the beginning of the virtual page and allowing the JS
Agent to mark the end of the virtual page.");
        ADRUM.markVirtualPageBegin("homepage", false);
    }
    $scope.endVirtualPage = function () {
        console.log("Manually marking the end of the virtual page.");
        ADRUM.markVirtualPageEnd();
    }
    $scope.setVirtualPageName = function () {
        console.log("Setting a custom name for the next virtual page to be monitored:
have it's beginning and end marked.");
        ADRUM.command("setVirtualPageName", "myCustomVPName");
    }
}
]);

```

Set Ajax Request Names Based on Captured POST Parameters

Related pages:

- [Configure Virtual Page Naming](#)
- [Page, Ajax, and Iframe Dashboards](#)
- [Set Custom Page Names](#)

You can configure the JavaScript Agent to capture POST parameters and then use the parameter(s) to name the Ajax request in the **Pages & Ajax Requests** page. This enables you to identify and sort Ajax requests from the same page based on POST parameter(s).

For example, customers on your home page of your website can either register an account or log in. The Ajax request may pass the parameter `action` to reflect one of these user actions. By capturing the `action` parameter, you can differentiate the Ajax requests to monitor performance and debug issues.

Configure the JavaScript Agent to Capture Parameters

You use the `xhr` object to configure the JavaScript Agent to capture POST parameters. The `xhr` object has the property `parameter` that is used to match resource URLs and define a callback for parsing the request body and return the desired results.

In the example below, the configuration sets a pattern to match the URL `http://www.mystore.com`, parses the request body, and returns an object containing the parameter `action`. As mentioned earlier, you could use a configuration like this to differentiate Ajax requests that are sending requests to register or log in users.

```
<script type='text/javascript' charset='UTF-8'>
  window['adrum-start-time'] = new Date().getTime();
  window['adrum-config'] = {
    xhr: {
      parameter : {
        urls : [{pattern : '^https?:\\/\\/www\\.mystore\\.com'}]},
        getFromBody: function(data) {
          if (typeof data === 'string') {
            var fields = data.split("&");
            for (var i = 0; i < fields.length; i++) {
              var keyAndValue = fields[i].split('=');
              if (keyAndValue.length > 1) {
                var key = keyAndValue[0],
                    value = keyAndValue[1];
                if (key === 'action')
                  return {action: value};
              }
            }
          }
        }
      }
    }
  }
}
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

    }
  }
</script>
<script charset='UTF-8'>
  (function(config){
    config.appKey = '<EUM_APP_KEY>';
    config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
    config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
    config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
    config.beaconUrlHttps = 'https://col.eum-appdynamics.com';
    config.xd = {enable : true};
  })(window['adrum-config'] || (window['adrum-config'] = {}));

  (function (cfg) {
    if (cfg.beacon) cfg.beacon.neverSendImageBeacon = true;
    else cfg.beacon = { neverSendImageBeacon: true };
  })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>

```

Create an Ajax Include Rule

To name an Ajax request based on a captured request parameter, you need to define an include rule that specifies the captured POST parameter. See [Configure Naming for Ajax Requests](#) to learn how to create include rules for Ajax requests.

The example include rule below uses the full domain and the captured POST parameter to name the Ajax request in the **Pages & Ajax Requests** page. For example, if an Ajax request is made to `www.mystore.com` and the value of the `action` parameter is `register`, the Ajax request will be named `www.mystore.com/register`.

Include Rule
✕

Enabled

Rule Name

Criteria
 This Include Rule applies to any URL that

GET POST PUT DELETE

Name Pages

Show HTTP Method (GET, POST, PUT, or DELETE)
 Show Protocol (Ex: http, https, etc)
 Show Domain (Ex: mywebsite.com)
 Show Full Domain Show Sub-domain

Path Segments
 Don't use path segments
 Use first segments
 Use last segments
 Use segment numbers ⓘ

Query String Parameters to use in Page Name (Optional)

POST Parameters to use in Page Name (Optional)

What part of anchor should be used in Page Name
 Don't use the anchor
 Use first segments
 Use last segments
 Use segment numbers ⓘ

View Results in Pages & Ajax Requests

From the **Pages & Ajax Requests** page, you can view the Ajax requests that are named based on your include rule.

Using the configuration and include rule shown above, you might see the following Ajax request with the name **mystore.com/register**.

Pages & AJAX Requests

Details | Filters | Actions | View Options | All Pages ▾

Type	Name	Requests ↓	Requests per Minute	End User Response Time (ms)
	mystore.com/register	983,613	57  70	

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Handle the `window.onerror` Event

Related pages:

- [JavaScript Errors](#)
- [Configure JavaScript and Ajax Error Detection](#)
- [Visualize JavaScript Errors](#)

If any script on your monitored web pages, including library code, sets the JavaScript `window.onerror` event, add the following method to the page immediately after setting `window.onerror`:

```
<script>
ADRUM.listenForErrors()
</script>
```

The JavaScript Agent (`adrum.js`) sets `window.onerror` to listen for uncaught JavaScript errors. If this listener is overwritten, errors are not reported.

The agent invokes your original `onerror` handler.

Disable Browser Monitoring Programmatically

Related pages:

- [Enable and Disable Browser RUM](#)

For pages in which the JavaScript Agent was injected manually, you can disable the agent programmatically by adding a script to the header.

To disable Browser Monitoring add the snippet below before `adrum.js` agent is injected.

```
window["adrum-disable"] = true
```

For example:

```
<head>
  <script type='text/javascript' charset='UTF-8'>
    // before adrum.js
    window["adrum-disable"] = true
  </script>

  <script>
    window["adrum-start-time"] = new Date().getTime();
  </script>
  <!-- adrum.js injection -->
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>
  ...
</head>
```

Old Browser Monitoring data is preserved, but no new monitoring data is collected while the agent is disabled.

You can re-enable monitoring by removing the disable script statement.

Set the Exact Current Domain in the JavaScript Agent Cookie

This page describes how to set the current domain in the JavaScript Agent cookie.

The JavaScript Agent itself writes a session cookie to the page, for timing purposes. This cookie is set when the user clicks a link and the `unload` event is fired. By default, the cookie is set to the broadest possible version of the originating domain (such as, `*.domain.com`) to increase the likelihood that the next page opened in the same domain can access that cookie. See [Cookies and Browser Monitoring Data](#).

In some cases, however, it may be necessary to limit the cookie to the full exact domain name. To do this, add a flag in the `"adrum-start-time"` script to the header of each page right *after* the `<head>` tag and *before* the entry that includes the location of the agent (`adrum.js`). The flag should read:

```
window["adrum-use-strict-domain-cookies"] = true.
```

After you include the start-time line, the strict domain flag, and the agent, the `<head>` section in your monitored web pages should look something like this:

```
<head>
  <script type='text/javascript' charset='UTF-8'>>
    window["adrum-start-time"] = new Date().getTime();
    window["adrum-use-strict-domain-cookies"] = true;
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
  UTF-8'></script>
  ...
</head>
```

Limit Beacon Types

Related pages:

- [Alter or Eliminate the Page Title Captured in the Beacon](#)

The JavaScript Agent collects and sends information to the EUM Server via a beacon, either through Cross-Origin Resource Sharing (CORS) or an image beacon which returns a small, transparent `.gif` file.

If you want the agent to only use CORS to transport the beacon, you can turn off the image beacon request mechanism. To turn off the image beacon request, add the following snippet to your HTML preceding the injected `adrum.js` script:

```
<head>
  <script type='text/javascript' charset='UTF-8'>
    (function (cfg) {
      if (cfg.beacon) cfg.beacon.neverSendImageBeacon = true;
      else cfg.beacon = { neverSendImageBeacon: true };
    })(window['adrum-config'] || (window['adrum-config'] = {}));
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>
  ...
</head>
```

Alter or Eliminate the Page Title Captured in the Beacon

Related pages:

- [Limit Beacon Types](#)
- [Set Custom Page Names](#)

In a standard Browser RUM beacon, the value for `document.title` is collected as part of the data to be sent in the beacon. You may want to alter or eliminate the page title for security or privacy reasons.

You can choose to:

- Not collect a page title at all
- Use a title that is created by a function with 0 arguments
- Use a title that is an arbitrary string

i The page title is different than the page name. The page title is just additional information included in browser snapshots, whereas, the page name is used to identify and group records in the **Pages & AJAX Requests** page.

Remove a Page Title

To remove the page title entirely, add the following snippet to your page before you inject the `adrum.js` script:

```
<head>
  <script type='text/javascript' charset='UTF-8'>
    (function (config) {
      (function (page) {
        page.captureTitle = false;
      })(config.page || (config.page = {}));
    })(window['adrum-config'] || (window['adrum-config'] = {}));
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
  ...
</head>
```

Use a Page Title Created by a Function

To use a function with no arguments to create a page title, before you inject the `adrum.js` script, define your function and call it, as in this example:

```
<head>
  <script type='text/javascript' charset='UTF-8'>
    function title() { return document.title.split('-').slice(1,3).join('-'); } // define
  a function
    (function (config) {
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

    (function (page) {
      page.title = title; // call your function
    })(config.page || (config.page = {}));
  })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8' />
  ...
</head>

```

Something like this could be used, for example, to remove sensitive data from the page title.

Use an Arbitrary String as a Page Title

To use any arbitrary string as the page title, before you inject the `adrum.js` script, set `page.title`.

```

<head>
  <script type='text/javascript' charset='UTF-8'>
    (function (config) {
      (function (page) {
        page.title = "My Special Page Title";
      })(config.page || (config.page = {}));
    })(window['adrum-config'] || (window['adrum-config'] = {}));
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>
  ...
</head>

```

This would set the page title in the beacon to "My Special Page Title".

Modify Resource Sampling Options

Related pages:

- [Page Browser Snapshots](#)
- [Capture Resource Timing Data Without Loss](#)

Some pages use a very large number of resource files, more than can usefully be monitored. By default, the JavaScript Agent decides which resource files to monitor based on two factors:

- How the resources are ordered (the sampling algorithm used)
- The maximum number of resources to be evaluated

Both of these factors can be modified.

To modify the sampling algorithm, use `resTiming.sampler`. Possible values are:

- Top N: the resources that take the most time to load, up to the maximum number
- First N: the resources that load first, up to the maximum number
- Relevant N: the resources that are deemed "most relevant" by an algorithm that takes into account both overall load time and when in the sequence the resource loads. So, for example, something that takes a long time to load and is early in the load sequence is "more relevant" than something that takes exactly the same time to load, but does so later in the sequence, on the assumption that the former would have more impact on the overall user experience. This is the default.

To modify the maximum number of resources to be evaluated, use `resTiming.maxNum`.

For example, to sample based on Top N and to set the max number at 100, you could add the following snippet to your page, *before* you inject the `adrum.js` script.

```
<head>
  <script type='text/javascript' charset='UTF-8'>
    (function (config) {
      config.resTiming = {
        sampler: "TopN",
        maxNum: 100
      };
    })(window['adrum-config'] || (window['adrum-config'] = {}));
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
  UTF-8'></script>
  ...
</head>
```

Set the Origin Location of the Request

Related pages:

- [Geo Dashboard](#)

There are some cases where it would be useful to be able to set a specific IP address/location as the origin of the request by modifying the JavaScript Agent itself. Add the following snippet to your page, before you inject the `adrum.js` script:

```
<head>
  <script type='text/javascript' charset='UTF-8'>
    window['adrum-config'] = (function(config) {
      config.geo = {
        localIP: "192.168.200.255",
        city: "San Francisco",
        region: "California",
        country: "USA"
      };
      return config;
    })(window['adrum-config'] || {});
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
</head>
```

You can use this snippet in two ways:

- Specify only the IP address, in which case this IP address has the highest precedence for use by the geo server, local or cloud-based, in resolving the request location.
- Specify all of IP, `country`, `region`, and `city`, in which case the request location is set by the script, and is not resolved by the Geo Server.

If you specify only some of the location parameters, the entire configuration is ignored. For example, if you only specified country, but not region, the entire configuration is ignored.

The value for `city` is only displayed in snapshots and can be any string. Using this value it is possible to specify location more precisely, as desired, for example, San Francisco, Sutter Street.

Hide All or Parts of the URL Query String

Related pages:

- [Configure Resource URL Segments](#)

By default, we capture URLs with their query strings. Because query strings may result in very long URLs or contain information that you don't want to expose, you may want to prevent all or parts of the query string from being displayed in the Controller UI.

You can do this by configuring the JavaScript Agent to remove query strings from URLs for the following:

- pages
- virtual pages
- XHR calls
- referrers
- scripts
- resources

Filter for URL Query Strings

The filter `filterURLQuery` is used to remove query strings from URLs. You can use it to remove all query strings or specific key-value pairs from query strings. The table below specifies the supported values and describes the result of the filter.

Filter	Value	Default	Description
<code>filterURLQuery</code>	<code>true</code>	No	Removes query strings from all URLs.
<code>filterURLQuery</code>	<code>false</code>	Yes	Retains the query strings for all URLs.
<code>filterURLQuery</code>	array of strings	No	Each string represents a key in the query string. The given keys are removed from the query string. Strings that do not match keys in the query string will have no effect on the filtering.

Unsupported values will result in the default behavior of retaining the entire query string for all URLs.

Remove All Query Strings

The configuration below will remove all URL query strings, so you'll only see the domain name and the URL path in the Controller UI.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

<head>
  <script type='text/javascript' charset='UTF-8'>
    (function (config) {
      config.urlCapture = {
        filterURLQuery: true
      }
    })(window['adrum-config'] || (window['adrum-config'] = {}));
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
  UTF-8'></script>
  ....
</head>

```

Remove Specific Keys From Query Strings

This configuration will remove the key-value pairs from the query string where the keys match the strings "name", "page", and "id" given in the array.

```

<head>
  <script type='text/javascript' charset='UTF-8'>
    (function (config) {
      config.urlCapture = {
        filterURLQuery: ["name", "page", "id"]
      }
    })(window['adrum-config'] || (window['adrum-config'] = {}));
  </script>
</head>

```

Configure the JavaScript Agent to Use HTTPS

Related pages:

- [Limit Beacon Types](#)
- [Enable the Content Security Policy \(CSP\)](#)

By default, the JavaScript Agent chooses the same transport (protocol) used to load the base page, but you can configure the JavaScript Agent to use HTTPS for a more secure network connection.

When configured to use HTTPS, the JavaScript Agent will use HTTPS to do the following:

- fetch `adrum-ext.js`
- fetch geolocation data
- send CORS beacons
- send image beacons

Set the `useHTTPSAlways` Flag

Following the code example below, you can set the boolean `useHTTPSAlways` to `true` to configure the JavaScript Agent to always use HTTPS.

```
<head>
  <script type='text/javascript' charset='UTF-8'>
    (function(cfg) {
      cfg.useHTTPSAlways = true;
    })(window['adrum-config'] || (window['adrum-config'] = {}));
  </script>
  <script src='https://cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript'
  charset='UTF-8'></script>
  ...
</head>
```

Configure Resource URL Segments

Related pages:

- [Hide All or Parts of the URL Query String](#)

This page covers how to configure URL segments for resources. To configure page URLs, see [Set Custom Page Names](#).

When the number of segments or the length of a segment exceeds the default maximum, the URL will appear truncated in the Controller UI. For example, the resources shown in the Resource Details tab or the **Session Details** dialog may display truncated because of the number of URL segments or the length of the segments in the URL.

You can set configurations for the JavaScript Agent that set the maximum number of segments and the maximum number of characters for each segment. This allows you to view more or even less of the resource URLs in the Controller UI.

Segment Definition

A segment is a fragment of a URL. The following constitute one segment:

- `<protocol>://<domain-name>:<port>`
- `?key=value&key=value` (query string)
- `#someAnchor` (anchor)
- `/file-path/` (file path specified between two forward slashes)

For example, this URL consists of five segments: `http://example.com:8090/a/b.html#someAnchor?test=true&segments=5`

Truncation Rules and Examples

The maximum number of segments determines how many segments will be displayed in the Controller UI. The last segment will always be shown, and then the first n number of segments until the maximum number is reached.

For example, if the original URL is `http://example.com:8090/a/b.html#someAnchor?test=true&segment=5` and the configured maximum number of segments is 3, then the Controller UI would display the following: `http://example.com:8090/a/...?test=true&segment=5`

The maximum length of segments determines how many characters of a segment will be displayed in the Controller UI. The truncation rules are slightly more complicated as they depend on the type of segment:

- For the segment `<protocol>://<domain-name>:<port>`, the `<protocol>` and `<port>` are displayed, and if the remaining amount of the maximum length is greater than the length of `<domain-name>`, then the entire domain name is displayed. If the remaining amount of the maximum length is less than the length of `<domain-name>`, then the Controller UI would only display `http...8090`.

- For query strings, anchors, and file paths, the first character (? , #, /) is displayed as well as the last *n* number of characters until the maximum length is reached. For example, for the segment `?test=true&segment=5` , if the maximum length is 10, then the segment will be displayed as the following: `?...segment=5`

Default Values for Segments

The variable for setting the maximum number of segments to display is `maxResUrlSegmentNumber` . The variable for setting the maximum length of segments is `maxResUrlSegmentLength` .

The following are the default values for the two variables:

- `maxResUrlSegmentNumber=10`
- `maxResUrlSegmentLength=64`

Set the Maximum Number of Segments

The code snippet below sets the maximum number of segments to display at 15.

```
<head>
  <script type='text/javascript' charset='UTF-8'>
    (function(config){
      config.maxResUrlSegmentNumber = 15;
    })(window['adrum-config'] || (window['adrum-config'] = {}));
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
  UTF-8'></script>
  ...
</head>
```

Set the Maximum Length of Segments

The code snippet below sets the maximum number of characters of segments to display at 100.

```
<head>
  <script type='text/javascript' charset='UTF-8'>
    (function(config){
      config.maxResUrlSegmentLength = 100;
    })(window['adrum-config'] || (window['adrum-config'] = {}));
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
  UTF-8'></script>
  ...
</head>
```

Exclude Virtual Pages from Being Monitored

You can exclude virtual pages from being monitored based on the virtual pages' URLs.

You define `exclude` filters to match URLs of virtual pages that you don't want to be monitored. You cannot, however, exclude virtual pages that you are [manually reporting with the SPA2 JavaScript API](#).

Virtual Page Object

The `vp` object contains the `exclude` filter that specifies an array of patterns to match the URLs of virtual pages to exclude. By defining an `exclude` filter, you automatically [enable SPA2 monitoring](#).

```
"spa": {
  "spa2": {
    "vp": {
      "exclude": {
        "urls": [{"pattern": 'api'}, {"pattern": "resources"}]
      }
    }
  }
}
```

Virtual Page Filter Example

To use the virtual page filter, you set the JavaScript Agent with the `exclude` filter before you inject the `adrum.js` script.

For example, in the code snippet below, the pattern would match and exclude all virtual pages with URLs that have the strings "contact", "api", or "api" followed by one or more characters.

```
<head>
  <script type='text/javascript' charset='UTF-8'>
    (function(config){
      config.spa = {
        spa2: {
          vp: {
            exclude: {
              "urls": [{"pattern": "contact"}, {"pattern": "api*"}]
            }
          }
        }
      }
    });
  })(window["adrum-config"] || (window["adrum-config"] = {}));
</script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
  UTF-8'></script>
  ...
</head>
```

Set the Number of Ajax Requests

Related pages:

- [Ajax Dashboard](#)
- [Ajax Request Snapshots](#)
- [Configure Naming for Ajax Requests](#)
- [Configure JavaScript and Ajax Error Detection](#)

This page covers how to set the number of Ajax Requests.

By default, the JavaScript Agent limits the Ajax requests (using XHR or the Fetch API) sent for base or virtual pages. The limit is 250 requests for single-page applications (SPAs) and 50 for non-SPAs. Although base or virtual pages normally do not send large amounts of Ajax requests, in some cases, a page may send redundant Ajax requests, especially those containing error reports.

For example, a series of redundant Ajax requests containing a dead loop of errors and exceptions with no new information could overload the EUM Server. To prevent an overload of Ajax requests, you can configure the JavaScript Agent to limit the number of Ajax requests sent for base and virtual pages.

Set the Number of Ajax Requests

The code example below limits the number of Ajax request per base or virtual page to 7.

```
<head>
  <script type='text/javascript' charset='UTF-8'>
    window["adrum-start-time"] = new Date().getTime();
    window['adrum-config'] = {
      xhr: {
        maxPerPageView: 7
      }
    };
    ...
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>
  ...
</head>
```

Set an Unlimited Number of Ajax Requests

For use cases where all Ajax requests for a page need to be captured, you can configure the JavaScript Agent to report an unlimited number of Ajax requests per page with the configuration `xhr.maxPerPageView`.

i To prevent an overload of Ajax requests, it is highly recommended to only use this configuration for use cases when you absolutely need to capture all Ajax requests.

The following code example configures the JavaScript Agent to report an unlimited number of Ajax requests per page:

```
<head>
  <script type='text/javascript' charset='UTF-8'>
    window["adrum-start-time"] = new Date().getTime();
    window['adrum-config'] = {
      xhr: {
        maxPerPageView: "UNLIMITED"
      }
    };
    ...
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>
  ...
</head>
```

Capture Resource Timing Data Without Loss

Most browsers stop capturing resource timing data in a page when the number of resources reaches 150 because of the limit set by the [Resource Timing API](#). You can configure the JavaScript Agent for conventional web pages (non-single page applications) and single-page applications (SPAs), however, to overcome this limitation.

i For Internet Explorer, you currently *cannot* use the JavaScript Agent configuration above to override the Resource Timing API's default limit of resources returned by the browser.

Because the JavaScript Agent configuration is different for non-SPA and SPA, see these sections for details and instructions:

- [Set and Clear the Resource Timing Buffer for Non-SPAs](#)
- [Disable the Clearing of the Resource Timing Buffer for SPAs](#)

Set and Clear the Resource Timing Buffer for Non-SPAs

For non-SPAs, you can configure the JavaScript Agent to use a buffer to capture resource timing data and then set a flag to clear the buffer once the beacon has transmitted the resource timing data to the EUM Server. Clearing the buffer clears the browser's resource buffer array and ensures that new resources will be sent in the next beacon.

i Overriding the Resource Timing API and clearing the buffer may affect JavaScript code on your page that is using the Resource Timing API. Thus, the JavaScript Agent uses the default set by the Resource Timing API unless you override the default by configuring the JavaScript Agent to set and clear the resource timing buffer.

JavaScript Configuration Example

The `resTiming` object is used for configuring the buffer size (maximum number of resources to return) and whether the buffer is reset once the beacon is transmitted to the EUM Server. The code snippet below shows you how to specify the buffer size and set the flag for clearing the buffer with the properties `bufSize` and `clearResTimingOnBeaconSend`.

```
<head>
  <script type='text/javascript' charset='UTF-8'>
    window['adrum-config'] = {
      resTiming: {
        bufSize: 200,
        clearResTimingOnBeaconSend: true
      }
    };
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
  UTF-8'></script>
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
</head>
```

Disable the Clearing of the Resource Timing Buffer for SPAs

For SPAs, the JavaScript Agent by default clears the resource timing buffer after it's full and saves the data in a local buffer. You can configure the JavaScript Agent so that the resource timing buffer is not cleared to capture resource timing data.

i If the resource timing buffer is not cleared, the resource timing correlation may miss some resources due to the buffer limit of the browser.

JavaScript Configuration Example

The default for `clearResTiming` is `true`. Setting `clearResTiming` to `false`, as shown below, disables the automatic clearing of the resource timing buffer. The resource timing buffer for virtual pages will also not be cleared.

```
window['adrum-config'] = {
  ...
  "spa": {
    "spa2": {"clearResTiming": false}
  }
}
```

Filter XHR Calls by URLs

Related pages:

- [Set the Number of Ajax Requests](#)
- [Configure Naming for Ajax Requests](#)
- [Configure Which Ajax Requests Are Sent to the Events Service](#)

If you have many XHR calls (using XMLHttpRequest or the Fetch API) from your page that you do not need to monitor, you can use XHR filters so that the Agent only monitors a regex-defined list of specified calls.

When XHR calls are monitored, the absolute path of the XHR calls is provided to the JavaScript Agent. In the Controller UI, those monitored XHR calls will be displayed as configured by naming rules. If there are no naming rules, the absolute path of the XHR call is displayed.

XHR Filters

You can use the XHR filters below to include or exclude XHR calls. The filters can be in the form of an XHR filter object or an array of XHR filter objects.

- `xhr.include`
- `xhr.exclude`

Filter Object Structure

The XHR filter object has two properties: `urls` and `method`. The `urls` property is an array of objects containing a `pattern` property that specifies a regular expression for matching URLs.

The `method` property is a string that specifies an HTTP method. You can use one or both of the properties. If you only use the `urls` array, the matched URLs will be either included or excluded for all HTTP methods. If you only specify `method`, all calls using the specified HTTP method will be either included or excluded.

The following is the general structure for the filter object:

```
{
  urls:
    [
      {
        pattern: ".*foo.*"
      },
      {
        pattern: ".*bar.*"
      }
    ],
  method: 'GET'
}
```

XHR Filter Example

To use XHR filters, you must assign XHR filters to `xhr.include` and `xhr.exclude` before you inject the `adrum.js` script. It's important to note that the exclude patterns override the include patterns, so those URLs that are matched by both the include and exclude patterns will ultimately be excluded.

For example, in the code snippet below, the include pattern would match all HTTP requests to `http://somedomain/app_status/user-profile.jsp`, but the exclude pattern would exclude POST calls to that URL.

```
<head>
  <script type='text/javascript' charset='UTF-8'>
    (function(config){
      (function(xhr) {
        xhr.include = {
          urls: [
            {
              pattern: ".*ajax_info.txt"
            },
            {
              pattern: ".*app_status.*"
            }
          ]
        };
        xhr.exclude = {
          urls = [
            {
              pattern: ".*user-profile.*"
            }
          ],
          method: "POST"
        };
      })(config.xhr || (config.xhr = {}));
    })(window["adrum-config"] || (window["adrum-config"] = {}));
  </script>
  <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
  ...
</head>
```

Report Events with the JavaScript API

The JavaScript API enables you to manually report events to the agent so that that it can time the various parts of your virtual page loads and correlate Ajax calls to those page loads. You can also capture and report errors using this API.

Notify the Agent of Events

Events are reported to the JavaScript Agent (ADRUM) by calling the `ADRUM.report` method and passing in an event tracker object.

API	Description
<code>ADRUM.report(tracker: eventTracker);</code>	Notifies the agent of an event.

Report Virtual Pages

SPA1 Monitoring

For [SPA1 monitoring](#), use the event tracker [VPageView](#) to manually report virtual pages.

SPA2 Monitoring

You are required to [enable SPA2 monitoring](#) to use the API below to manually report virtual pages for SPAs. These APIs will also work in non-SPAs if you enable SPA2 monitoring.

To report virtual pages, you mark the beginning and end of virtual pages with the methods below. Both methods are called from the `ADRUM` object. See also [Set Custom Virtual Page Names](#).

API	Parameter(s)	Default Value	Descriptions
<code>markVirtualPageBegin(VPName : string, manuallyMarkVPEnd?: boolean)</code>	<code>VPName</code>	N/A	<p>Used to set the label for the virtual page. This label will be displayed in the Controller UI.</p> <p>The virtual page name must consist of a string of 760 or fewer alphanumeric characters.</p> <p>If the string length exceeds 760 characters, the page name will not be set.</p>

API	Parameter(s)	Default Value	Descriptions
	<code>manuallyMarkVPEnd</code>	<code>true</code>	<p>A flag that indicates whether you or the JavaScript Agent mark the end of the virtual page.</p> <p>When set to <code>true</code>, you need to call <code>markVirtualPageEnd</code> to report the virtual page.</p> <p>When set to <code>false</code>, the JavaScript Agent will automatically mark the end of the virtual page.</p>
<code>markVirtualPageEnd()</code>	N/A	N/A	Calling this method marks the end of the virtual page and triggers the JavaScript Agent to send a beacon with the virtual page information.

How the API Works

The steps below describe the process of manually reporting virtual pages with the API:

1. Start monitoring a virtual page by manually marking the beginning of the virtual page with `ADRUM.markVirtualPageBegin(VPName, manuallyMarkVPEnd)`.
2. A beacon with the set virtual page name is sent to the EUM Server. If `manuallyMarkVPEnd` is set to `true`, the JavaScript Agent will wait for you to call `ADRUM.markVirtualPageEnd` to report the virtual page. If `manuallyMarkVPEnd` is set to `false`, the JavaScript Agent will automatically mark the end of the virtual page.
3. You either call `ADRUM.markVirtualPageEnd()` to mark the end of the virtual page or the JavaScript Agent automatically marks the end of the virtual page.
4. The JavaScript Agent reports the virtual page metrics to the EUM Server.

Example of Reporting Virtual Pages

The Angular example below shows both ways to mark the beginning of a virtual page. The function `manualMarkVPEnd` calls `ADRUM.markVirtualPageBegin` that uses the default requiring you to manually mark the end of the virtual page. The function `allowJSAgentMarkVPEnd` passes the value `false` as the second parameter, so that the JavaScript Agent will automatically mark the end of the virtual page for you.

```

angular.module('myApp.controllers', [])
  .controller('VPCtrl', ['$scope', '$http', function ($scope, $http) {
    $scope.manualMarkVPEnd = function () {
      console.log("Mark the beginning of the virtual page and wait for
markVirtualPageEnd() to be called.");
      ADRUM.markVirtualPageBegin("VPEXample-ManuallyMarkEnd");
    }
    $scope.allowJSAgentMarkVPEnd = function () {
      console.log("Mark the beginning of the virtual page and allow the JS Agent to
mark the virtual page end.");
      ADRUM.markVirtualPageBegin("virtualPageExample-JSAgentMarksEnd", false);
    }
    $scope.endVirtualPage = function () {
      console.log("Mark the end of the virtual page.");
      ADRUM.markVirtualPageEnd();
    }
    ...
  }
]);

```

Report Events

Events are reported to the agent using event trackers. There are three different kinds of event trackers:

Event Tracker	Enabled for SPA2 Monitoring?	Description
VPageView	No	Used to track the stages of a virtual page view.
Ajax	Yes	Used to track Ajax requests.
Error	Yes	Used to track errors.

Common Properties

There are also two properties that are common to all tracker types:

- Gets or sets a URL

API	Description
<code>url(url?: string)</code>	Gets or sets a URL.

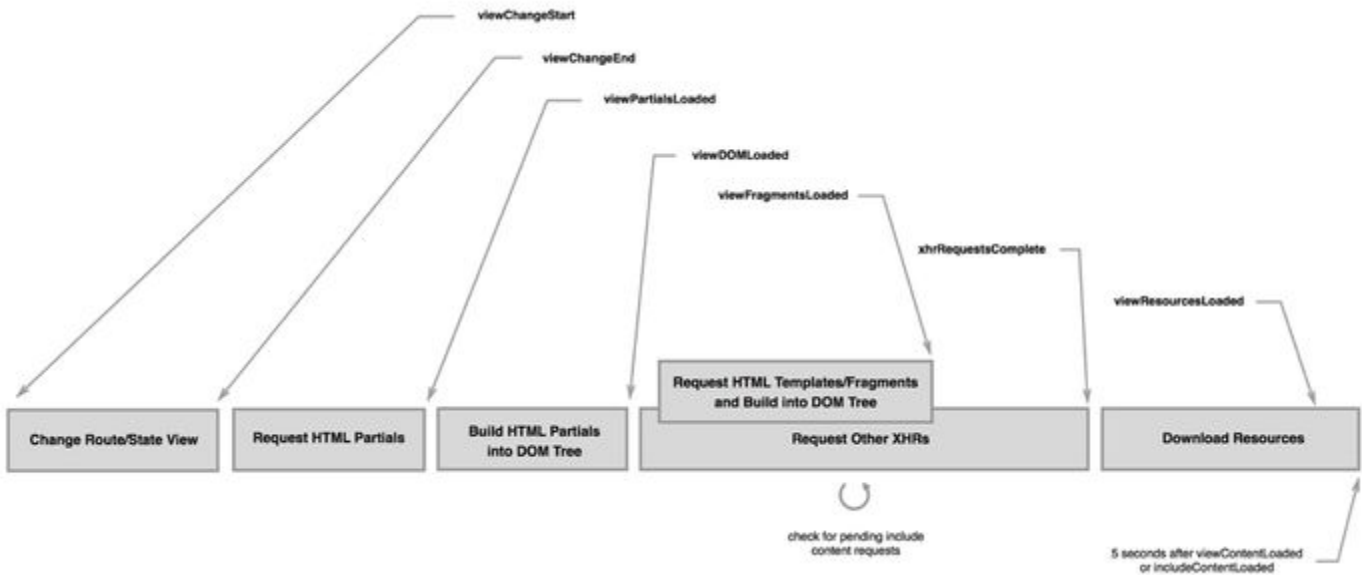

- Gets or sets the parent event identifier

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

API	Description
parent(parent?: object)	Gets or sets the parent event identifier.

VPageView

The following is the page view load flow in SPA1 monitoring. You'll use the SPA1 monitoring API below to set timing marks to match the below workflow as closely as possible in your own single page app framework. For SPA2 monitoring, see [Report Virtual Pages: SPA2 Monitoring](#) to learn about the SPA2 APIs for manually reporting virtual pages.

Based on the marks you set, AppDynamics derives the following key timing metrics. Marks should be called in the order in which they occur in the flow. The following table describes which marks used to calculate each metric.

Full Metric Name	Short Metric Name	How Calculated
End User Response Time (not used for waterfall UI)	PLT	virtualPageStart to virtualPageEnd
HTML Download Time	DDT	viewChangeStart to viewChangeEnd
HTML Download and DOM Building Time	DRT	viewChangeStart to viewDOMLoaded

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Full Metric Name	Short Metric Name	How Calculated
DOM Building Time	DPT	viewChangeEnd to viewDOMLoaded
DOM Ready Time (used instead of PLT for waterfall UI)	DOM	viewChangeStart to viewDOMLoaded

Instantiate using `ADRUM.events.VPageView()`.

API	Description
<code>start()</code>	Indicates when a virtual page starts. It automatically calls: <ul style="list-style-type: none"> <code>startCorrelatingXhrs()</code> <code>markVirtualPageStart()</code>
<code>end()</code>	Indicates when a virtual page ends. It automatically calls: <ul style="list-style-type: none"> <code>stopCorrelatingXhrs()</code> <code>markVirtualPageEnd()</code>
<code>startCorrelatingXhrs()</code>	Correlates the Ajax requests sent after this call with the virtual page view event. The last tracker calling this method wins. <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p>i This method is called automatically in the VPageView constructor. When a VPageView is created, the AJAX requests made after that call are automatically correlated to that VPageView. Use this separate call only when you want to set up manual correlation.</p> </div>
<code>stopCorrelatingXhrs()</code>	Stops correlating Ajax requests to the virtual page view event. <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p>i Use this separate call only when you wish to set up manual correlation.</p> </div>
Setters	The default value for these is the time when the API is called.
<code>markViewChangeStart()</code>	Sets the view change start time.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

API	Description
<code>markViewChangeEnd()</code>	Sets the view change end time.
<code>markViewDOMLoaded()</code>	Sets the view DOM loaded time.
<code>markXHRRequestsCompleted()</code>	Sets the XHR requests completed time.
<code>markViewResourcesLoaded()</code>	Sets the view resources loaded time. This includes images, CSS files, and scripts.
<code>markVirtualPageStart()</code>	Sets the virtual page start time.
<code>markVirtualPageEnd()</code>	Sets the virtual page end time.
Getters	
<code>getViewChangeStart()</code>	Gets the view change start time.
<code>getViewChangeEnd()</code>	Gets the view change end time.
<code>getViewDOMLoaded()</code>	Gets the view DOM loaded time.
<code>getXhrRequestsCompleted()</code>	Gets the XHR requests completed time.
<code>getViewResourcesLoaded()</code>	Gets the view resources loaded time.
<code>getVirtualPageStart()</code>	Gets the virtual page start time.
<code>getVirtualPageEnd()</code>	Gets the virtual page end time.

Ajax

Instantiate using `ADRUM.events.Ajax()`.

API	Description
Property Setters/Getters	Call this without a parameter to get the value and with a parameter to set the value.
<code>method(method?: string)</code>	Gets or sets the method ("GET" or "POST") of the Ajax.
Timing Setters	The default value for these is the time when the API is called.
<code>markSendTime(sendTime?: number)</code>	Sets the time the request is sent.
<code>markFirstByteTime(firstByteTime?: number)</code>	Sets First Byte Time.
<code>markRespAvailTime(respAvailTime?: number)</code>	Sets Response Available Time.
<code>markRespProcTime(RespProcTime?: number)</code>	Sets the time the response is completely processed.
Timing Getters	
<code>getSendTime()</code>	Gets the time the request was sent.
<code>getFirstByteTime()</code>	Gets First Byte Time.
<code>getRespAvailTime()</code>	Gets Response Available Time
<code>getRespProcTime()</code>	Gets the time the response was completely processed.

Errors

Instantiate using `ADRUM.events.Error()`.

API	Description
Property Setters/Getters	Call these without a parameter to get the value and with a parameter to set the value.
<code>msg(msg?: string)</code>	Gets or sets the error message.
<code>line(line?: number)</code>	Gets or sets the line number of source code where the error happened.

Correlate Ajax Requests

Ajax requests can be correlated to virtual page views automatically or manually. When you create a `vPageView` tracker, `startCorrelatingXhrs()` is called automatically in the constructor, correlating any subsequent Ajax calls with that `VPageView` event. To set up manual correlation, call `stopCorrelatingXhrs()` to stop the automatic process and then call `startCorrelatingXhrs()` where you wish correlation to re-commence.

Sample Code

Report a custom Error event by passing properties via setters

```
var errorT = new ADRUM.events.Error();
errorT.msg('I am a custom error at line 100');
errorT.line(100);
ADRUM.report(errorT);
```

Report a custom Error event by passing properties via the constructor

```
var errorT = new ADRUM.events.Error({
  msg: 'I am a custom error at line 100',
  line: 100
});
ADRUM.report(errorT);
```

Report a custom Ajax event passing properties via setters

```
var ajaxT = new ADRUM.events.Ajax();
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

// set url
ajaxT.url('your xhr Url');

// mark timings
ajaxT.markSendTime(100);
ajaxT.markFirstByteTime(200);
ajaxT.markRespAvailTime(300);
ajaxT.markRespProcTime(400);
ADRUM.report(ajaxT);

```

Set up backbone SPA monitoring

```

var AppRouter = Backbone.Router.extend({
  routes: {
    "wines/:id": "wineDetails"
  },
  wineDetails: function (id) {
    var vpView = new ADRUM.events.VPageView();
    vpView.markVirtualPageStart();
    // vpView.markViewChangeStart();
    var wine = new Wine({id: id});
    wine.fetch({success: function(){
      vpView.markXhrRequestsCompleted();
      $("#content").html(new WineView({model: wine}).el);
      vpView.markViewDOMLoaded();
      vpView.markVirtualPageEnd();
      ADRUM.report(vpView);
    }});
    this.headerView.selectMenuItem();
  }
});

```

Correlate Ajax requests with VPageView Events

```

var vPageView = new ADRUM.events.VPageView({
  url: 'http://localhost/#virtualpage1',
});

vPageView.start();

// SPA view routing and HTML partials fetching
vPageView.markViewChangeStart()

```

```

// AJAX requests for the HTML partials are automatically correlated with the VPageView
...
vPageView.markViewChangeEnd();

// HTML partials inserted into Browser DOM tree
...
vPageView.markViewDOMLoaded();

// SPA HTML AJAX data fetching
// Data AJAX requests are automatically correlated with the VPageView
...

vPageView.markXHRRequestsCompleted();

// call this when ending a new virtual page
vPageView.end();

ADRUM.report(vPageView);

```

You can exclude certain Ajax calls from being monitored by configuring ADRUM itself. Before you invoke the `adrum.js` script at the top of your page, add lines similar to the following:

Exclude Ajax from VPageView using ADRUM configuration

```

window['adrum-config'] = {
  "spa": {
    "angular": {
      "vp": {
        "xhr": {
          "exclude": {
            "urls": [{
              "pattern": 'heartBeatAjax'
            }]
          }
        }
      }
    }
  }
}

```

Or you can exclude certain Ajax calls using the `vPageView.stopCorrelatingXhrs()` call, and then turn correlation back on with `vPageView.startCorrelatingXhrs()`, as in the following:

Exclude Ajax from VPageView event manually

```
var vPageView = new ADRUM.events.VPageView();
vPageView.stopCorrelatingXhrs();

var xhr = new XMLHttpRequest();
xhr.open('GET', '/heartBeatAjax');
xhr.send();

vPageView.startCorrelatingXhrs();
```

Disable Monitoring of Fetch API Calls

By default, the JavaScript Agent reports Ajax requests made with XMLHttpRequest object (XHR) and the Fetch API.

You should only consider disabling monitoring support for the Fetch API for these use cases:

- You just started using the JavaScript Agent 4.5.6 and start to see JavaScript errors caused by asynchronous Ajax requests.
- Your browser app uses one of the libraries which modifies Javascript Promise:
 - [Bluebird](#)
 - [shim.js](#)
 - [Zone.js](#)

i If you use the zone.js library, you can still enable monitoring for the Fetch API by adding `isZonePromise = true` and `config.fetch = true` to your JavaScript snippet:

SPA Non-SPA

```
<script type='text/javascript' charset='UTF-8'>
  (function(config){
    config.fetch = true; // This is the default setting.
    config.isZonePromise = true;
    config.spa = {
      "spa2": true
    };
  })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/
javascript' charset='UTF-8'></script>
```

SPA Non-SPA

```
<script type='text/javascript' charset='UTF-8'>
  (function(config){
    config.fetch = true;
    config.isZonePromise = true;
  })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/
javascript' charset='UTF-8'></script>
```

Disable Monitoring of Fetch API Calls

To disable monitoring for the Fetch API, add `config.fetch = false` to your JavaScript snippet:

[SPA](#) [Non-SPA](#)

```
<script type='text/javascript' charset='UTF-8'>
  (function(config){
    config.fetch = false;
    config.spa = {
      "spa2": true
    };
  })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>
```

[SPA](#) [Non-SPA](#)

```
<script type='text/javascript' charset='UTF-8'>
  (function(config){
    config.fetch = false;
  })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='
UTF-8'></script>
```

Disable the Primary Metric

For SPA2 applications, configuring the primary metric causes base page events to be sent on navComplete; previously the base page events were sent upon page load. This may cause slow performance, and you may want to disable the primary metric.

To disable the primary metric, add the following flag in your JavaScript code:

```
config.enablePrimaryMetrics = false
```

Correlate Business Transactions for Browser RUM

Related pages:

- [Correlate Business Transactions for EUM](#)
- [Business Transactions](#)

You can correlate page and Ajax requests with business transactions. The correlation is made between instances of page/Ajax requests (browser snapshots) and instances of business transactions (transaction snapshots).

How Browser Application Network Requests Are Correlated

When an end user requests a page from your browser app:

1. The App Agent:
 - Sends HTTP headers identifying the business transaction and the HTML with the injected JavaScript Agent to the end user's browser.
 - Aggregates backend metrics and sends them along with the business transaction identifiers to the Controller. This serves as the content for the transaction snapshot.
2. The JavaScript Agent sends browser metrics and the business transaction identifiers (from the HTTP header) to the EUM Server. This serves as the content for the browser snapshot.
3. The Controller fetches the metrics and business transaction identifiers from the EUM Server. These business transaction identifiers are then used to correlate the browser snapshot with the transaction snapshots.

View Business Transactions Correlated with Browser Applications

There are several ways to navigate from a browser snapshot to its correlated business transaction. The following steps show you one possible way.

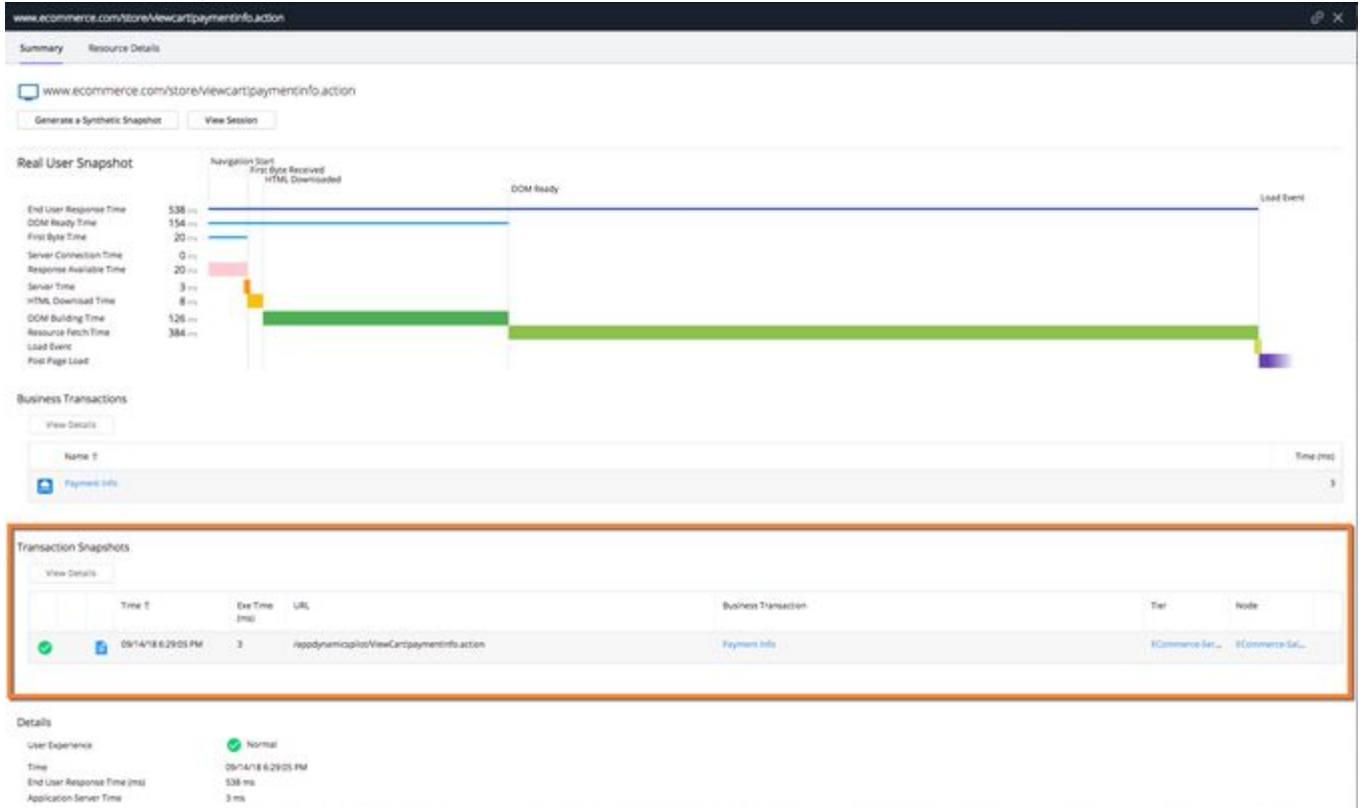

1. From the **Browser App Dashboard**, click **Browser Snapshots**.
2. Click **Filters** and check the **Server Snapshot Exists** checkbox.

3. You should now only see browser snapshots that have transaction snapshots:

Time	End User	URL	Browser	Device	OS	Country	State / Region

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

4. Double-click one of the browser snapshots to open the **Browser Snapshot Details** dialog containing a transaction snapshot.

5. You can then click links in the transaction snapshot or transaction snapshot itself to view corresponding pages in APM.

Get Complete Timing Data for Correlated Business Transactions

i This functionality is currently not supported for .NET Core.

To get the full real execution time for correlated business transactions, your injection method may need to write the `JS_FOOTER` variable to your page. Manual injection gives the server-side agent the ability to write data only to the header of the page as it is being constructed by your web application.

It is possible that complete business-transaction timing information is not available at the moment that the header data is written. Using the footer allows the server-side agent to write timing data at the footer of the page, by which time a fuller picture of business transaction timing may be available.

You can write the `JS_FOOTER` data variable into the footer of a web page using the following techniques:

- If you use automatic injection for the injecting into the `head` element, you automatically get an injection into the footer as well.

- If you use manual injection for the `head` element, for applications built on Java platforms you can use assisted injection to inject into the footer. Or for applications built on Java servlet or ASP.NET platforms, you can use assisted injection using attribute injection.

If you cannot add the `JS_FOOTER` variable to your page, the timing shown for correlated business transactions may be the average response time for that transaction rather than the real execution time for that specific page.

Avoid Tagging Cookies with the `HttpOnly` Flag

Servers set the `HttpOnly` flag on cookies to prevent their contents from being accessed by JavaScript. This is often done for session cookies to hide the session identifier as a security measure. The JavaScript Agent, however, needs to be able to read special cookies set by the AppDynamics server-side agent (all prefixed with `ADRUM`) to collect correlation information. If `HttpOnly` is set on these cookies, no server-side correlation information can be transmitted. Thus, make sure that your server does *not* set the `HttpOnly` flag on any cookies prefixed with `ADRUM`.

If you want to securely transmit cookies, use HTTPS. The app agent sets the `secure` flag if the originating base page is loaded over HTTPS.

These can be turned off, but that would prevent correlation from working for base pages unless the customer changes the page source code to use footer injection.

Monitor Single-Page Applications

Browser RUM's single-page application (SPA) monitoring enables you to:

- Monitor the performance/throughput of user experiences of SPAs.
- Troubleshoot and resolve SPA problems within the context of the page load.
- Assist with business decisions by analyzing SPA data through analytics.
- Enable developers to quickly ship better web applications to the marketplace.

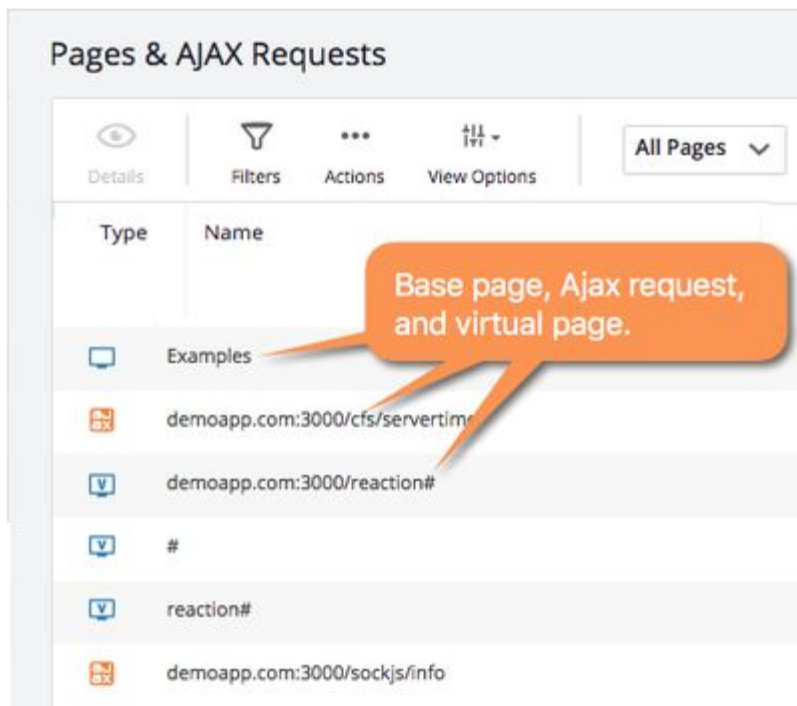

What Is SPA?

A single-page application (SPA) is a web technology and design paradigm that reduces browser-level page loads by using JavaScript to fetch resources and build pages. This creates a smoother, faster user experience more similar to a desktop or mobile application than a traditional web page. [React](#) and [Angular](#) are two popular JavaScript frameworks used to create SPAs.

Base Pages vs. Virtual Pages

When a user navigates to a SPA, the initial page download is considered the "base page." The base page includes the HTML skeleton, the core CSS, and the JavaScript framework for fetching and constructing new content. The ensuing pages are constructed from resources downloaded with the base page or fetched dynamically from the backend in response to user interaction. This new content (or views) constructed from different sources by the SPA are called "virtual pages."

For SPAs, you will have base pages, virtual pages, and Ajax requests. From **Pages & AJAX Requests**, you are able to view all three types and details for each as shown below.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

SPA1 and SPA2 Monitoring

Until 4.4.3, Browser RUM only provided auto-instrumentation for AngularJS 1 SPA applications. For other frameworks, you had to manually report events with the JavaScript Agent API. This limited auto-instrumentation for SPA is known as *SPA1 monitoring*.

From JavaScript Agent \geq 4.5.16, Browser RUM has been certified for Angular 1-9. This support for the auto-instrumentation for all SPA frameworks is known as *SPA2 monitoring*.

This table describes the support for SPA1 and SPA2 monitoring:

SPA Monitoring Version	Auto-Instrumentation	Metrics	JavaScript API
SPA1	AngularJS 1 only	<ul style="list-style-type: none"> • Base / Virtual Pages: Browser RUM page timing metrics • Ajax Requests: All available Ajax metrics 	Yes
SPA2	All SPA frameworks. Auto-instrumentation is certified for React and Angular 1-9 (JavaScript Agent \geq 4.5.16).	<ul style="list-style-type: none"> • Base pages: Browser RUM page timing metrics, including End User Response Time (EURT), Visually Complete Time (VCT), and Page Complete Time (PCT) • Virtual Pages: End User Response Time (EURT), Visually Complete Time (VCT) • Ajax Requests: All available Ajax metrics 	Yes

Which SPA Monitoring to Use?

In general, you are highly recommended to use SPA2 monitoring. For most applications, the JavaScript Agent using SPA2 monitoring identifies the SPA transitions deterministically and captures the metrics and resources correctly without you having to write any special configuration or call methods from the JavaScript Agent API. If your SPA applications are built with AngularJS 1, you can simply add some configuration to enable auto-instrumentation.

View SPA2 Monitoring Data

Throughout the Controller, you can view [SPA2 Metrics](#) in various EUM dashboards in the Controller. You can also [Configure the Primary Metric](#) to choose a default displayed SPA2 metric for Browser RUM dashboards and widgets.

Browser Snapshots

The Browser Snapshots tab displays a list of different types of pages as shown below. You can view relevant metrics for all the pages and other metrics for base pages and Ajax requests.

The screenshot shows the 'Browser Snapshots' page in AppDynamics. The table lists various browser snapshots with columns for Time, End User Response Time (ms), First Byte Average Time (ms), Front End Average Time (ms), Resource Fetch Average Time (ms), URL, Page, Ajax Request, IFrame, or Virtual Page, and Page Type. Two callouts are present: one pointing to the 'End User Response Time' column stating 'The EURT is available for all pages, but other metrics are only available for base pages and Ajax requests.', and another pointing to the 'Page, Ajax Request, IFrame, or Virtual Page' column stating 'Provides the URL, and the type of page'.

GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

SPA1 Monitoring

i We recommend you use SPA2 Monitoring for all SPA frameworks, especially Angular 1–5 and React.

This page describes how to use SPA1 monitoring for AngularJS 1 applications and manually report events for Ember.js applications. This page also provides information about the AngularJS 1 support for SPA1 monitoring.

SPA Requirements

- IE 10 and Edge is supported. IE ≥ 10 and Edge *cannot* be in compatibility mode with \leq IE 9 browsers.
- For non-AngularJS frameworks, the JavaScript Agent ≥ 4.2 is required.

Manual Injection for Angular 1.x Applications

For non-Angular applications, `adrum.js` needs to be loaded before any other JavaScript on the page. When you are using AngularJS 1, however, you need to inject `adrum.js` after `angular.js`, but before `angular.js` is bootstrapped.

To learn which Angular versions have monitoring support, see [Monitoring Support for AngularJS](#).

Manual Injection for Ember.js Applications

For [Ember.js](#) applications, you manually inject the JavaScript Agent much in the same way you would do for web pages loaded from an HTTP request. To monitor virtual pages, you manually start and end Virtual Page events based on events triggered when pages are dynamically created. You can also monitor virtual pages to report errors for pages.

The following sections will show you how to inject the JavaScript Agent and monitor virtual pages.

Manual Injection of the JavaScript Agent

The file `app/index.html` is the HTML skeleton for all dynamics pages in Ember.js. Thus, you can inject the JavaScript Agent in this file so it is included in every page.

Monitor Virtual Pages

When a user requests a new page, the route handler renders the associated template to form the new content of the virtual page. You can listen for events in the route handler indicating when the handler is started and completed, which in effect mark the lifetime of the virtual page. To monitor the virtual page, you start a Virtual Page Event when the `activate` event is triggered, close the Virtual Page when the `deactivate` event is triggered, and then report the completed virtual page.

The code snippet below listens to the `activate` and `deactivate` events and reports the created virtual page event.

```

import Ember from 'ember';
import config from '../config/environment';

export default Ember.Route.extend({
  beforeEnterAbout: Ember.on('activate', function(){
    console.log('hello about');
    config.aboutVpView = new ADRUM.events.VPageView();
    config.aboutVpView.start();
  }),
  afterEnterRental: Ember.on('deactivate', function(){
    console.log('goodbye about');
    config.aboutVpView.end();
    ADRUM.report(config.aboutVpView);
  })
});

```

Use Virtual Pages to Capture Errors

You can also create actions in the routing handlers that can be monitored through virtual pages. For example, you might want to monitor Ajax calls. You can create an action that performs the Ajax call and then use a Virtual Page event to capture the results and errors as shown in the code snippet below.

```

actions: {
  makeXHRCall() {
    config.xhrVpView = new ADRUM.events.VPageView();
    config.xhrVpView.start();
    var xmlhttp = new XMLHttpRequest();
    xmlhttp.onreadystatechange = function () {
      if (xmlhttp.readyState === 4) {
        console.log(xmlhttp.responseText);
        config.xhrVpView.end();
        ADRUM.report(config.xhrVpView);
      }
    };
    xmlhttp.open("GET", "http://localhost:3000", true);
    xmlhttp.send(null);
  }
}

```

Monitoring Support for AngularJS 1

The JavaScript Agent supports monitoring by default for [AngularJS versions 1.x](#).

Routing Engines

AngularJS 1 applications that have multiple Views use a *route* to move from one virtual page to another. You can use Browser RUM to instrument any virtual page that uses either of two routing engines, `ngRoute` or `ui-router`.

Metrics

Because virtual pages are constructed in the browser, normal page view metrics must be adjusted. In essence, what a metric for AngularJS 1 must do is correlate the time between various routing events, using their timestamps. Metrics are calculated as follows:

Full Metric Name	Short Metric Name	Calculation
End User Response Time (not used for waterfall UI)	PLT	virtualPageStart to virtualPageEnd
HTML Download Time	DDT	viewChangeStart to viewChangeEnd

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Full Metric Name	Short Metric Name	Calculation
HTML Download and DOM Building Time	DRT	viewChangeStart to viewDOMLoaded
DOM Building Time	DPT	viewChangeEnd to viewDOMLoaded
DOM Ready Time (used instead of PLT for waterfall UI)	DOM	viewChangeStart to viewDOMLoaded

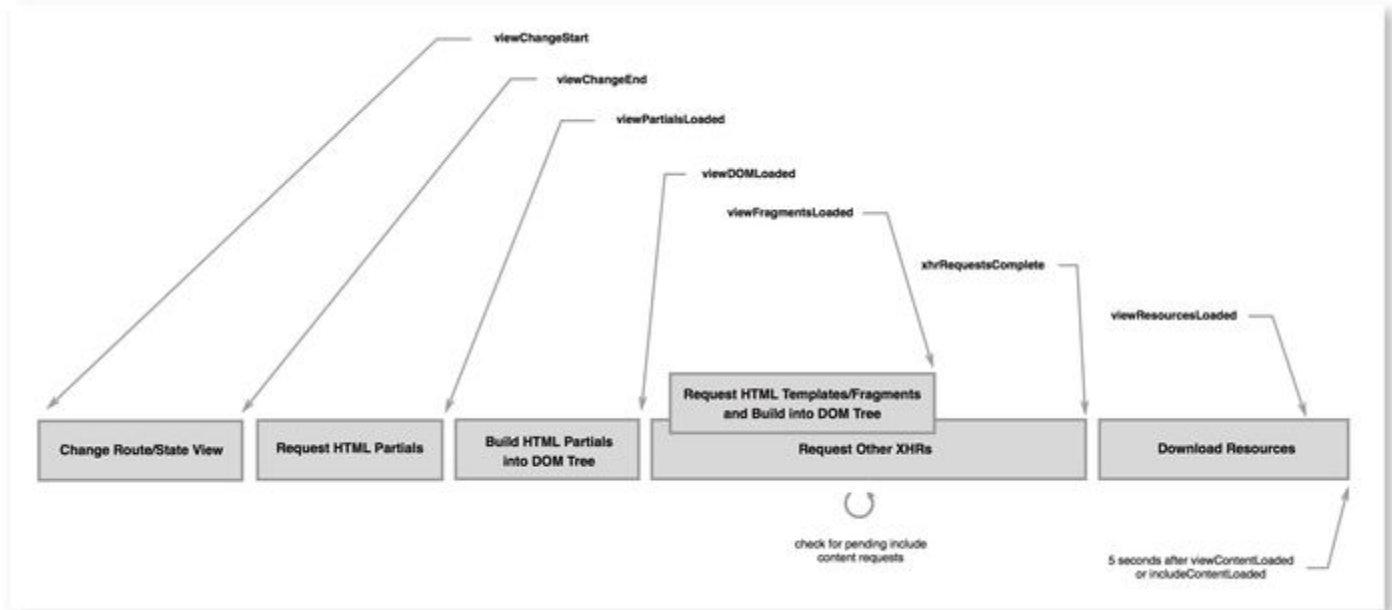

Because the two routing engines function in slightly different ways, what the AppDynamics event consists of differs slightly, based on the engine.

AppDynamic Event Name	ngRoute Equivalent	ui-router Equivalent
virtualPageStart	locationChangeStart	stateChangeStart
viewChangeStart	routeChangeStart	stateChangeStart
viewChangeEnd	routeChangeSuccess	stateChangeSuccess
viewDOMLoaded	viewContentLoaded	viewContentLoaded (may happen multiple times - timestamp overwritten each time)
viewFragmentsLoaded	load time of the last HTML fragment	
xhrRequestsCompleted	response time of the last XHR requests	
viewResourcesLoaded	load time of the last resources	
virtualPageEnd	the latest one among viewContentLoaded, xhrRequestsCompleted, and viewResourcesLoaded	

Page Load Process Visualized

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Visualized the page load process looks something like this:

Compare these to the standard page metrics, which are shown in [Browser RUM Metrics](#).

Exclude Heartbeats or Background Requests from Timings

You may wish to exclude certain events from your virtual page timings. To do this, you can customize the JavaScript Agent when you [inject](#) it.

Add the following snippet *before* you add the JavaScript Agent file, `adrum.js`, to the page:

Option for excluding XHRs

```
<script type="text/javascript">
(function(config) {
  (function(spa) {
    (function(angular) {
      (function(vp) {
        vp.xhr = {
          "exclude": {
            "urls": {
              pattern: '.*\/dealActiveUsers'
            }
          }
        };
      })(angular.vp || (angular.vp = {}));
    })(spa.angular || (spa.angular = {}));
  });
})(config);

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

    })(config.spa || (config.spa = {}));
  })(window["adrum-config"] || (window["adrum-config"] = {}));
</script>

```

Enable Resource Timing Collection for Virtual Pages

By default, Virtual Pages for AngularJS 1 do not include resource timing metrics. You need to set the Angular virtual page property `includeResTimingInEndUserResponseTiming` to `true`.

The JavaScript configuration below shows you how to enable resource timing collection for AngularJS 1 virtual pages. The configuration also sets limits for XHR calls per page, the buffer size for resource timings, and sets the flag for clearing resource timing metrics when a beacon is sent.

```

window['adrum-config'] = {
  "xhr": {
    "maxPerPageView": 10000
  },
  "resTiming": {
    bufSize: 300,
    "clearResTimingOnBeaconSend": true
  },
  "spa": {
    "angular": {
      "vp": {
        "metrics": {
          "includeResTimingInEndUserResponseTiming": true
        }
      }
    }
  }
}

```

View Correlated Server Times

Since there isn't a regular HTML page timing to which correlated server timings can be linked, to view server times you must drill down from the Dashboard or Snapshot virtual page view to the component XHR requests. The server times can be seen there.

SPA2 Monitoring

For SPA2, you only need to set a flag to enable the JavaScript Agent to auto-instrument SPAs. When SPA2 auto-instrumentation is enabled, the JavaScript Agent:

- Detects virtual pages
- Measures the end-to-end time for virtual pages
- Correlates resources, JavaScript errors, and Ajax requests
- Names virtual pages

To enable SPA2 monitoring, see [Configure SPA2 Monitoring](#).

How SPA2 Monitoring Works

The diagram below demonstrates how the JavaScript Agent defines the start and end points for the End User Response Time (EURT) metric and correlates with Ajax requests, resources, and JavaScript errors.

Step	Browser Activity	JavaScript Agent Actions
1	The user navigates to the base page of a SPA. The HTML skeleton, core CSS, and JavaScript are loaded into the browser.	The JavaScript Agent sends a beacon for the base page.

Step	Browser Activity	JavaScript Agent Actions
2	From the base page, the user clicks a button to view products. The URL changes as the virtual page is loaded through a combination of previously downloaded content and from new content fetched through Ajax requests.	The JavaScript marks the user action as the start time of the virtual page.
3	User actions and the browser activity cease for five seconds. The browser activity includes requesting resources, making Ajax calls, and so on.	<p>The JavaScript Agent or your code using the JavaScript API marks the end time of the virtual page as the last time browser activity was seen after the URL changed. The JavaScript Agent then sends a beacon for the virtual page; however, if the virtual-page load stalls on one slow activity, the JavaScript Agent waits eight seconds before marking the end of the virtual page.</p> <p>Any activities such as Ajax requests, resource loads, and JavaScript errors that happened during the virtual page load will be correlated to that virtual page.</p> <p>There are some kinds of browser activities that aren't accessible to JavaScript. For example, the time that the browser takes render the DOM to the screen after the DOM has been updated. Therefore, if your virtual pages don't request any resources, you will likely see a very fast EURT (<10ms).</p>

SPA2 Metrics

Browser RUM calculates metrics differently for base pages, Ajax requests, and virtual pages. The diagrams below demonstrate the differences between base page and virtual page metrics from the end-user perspective. See [Browser RUM Metrics](#) for metric definitions.

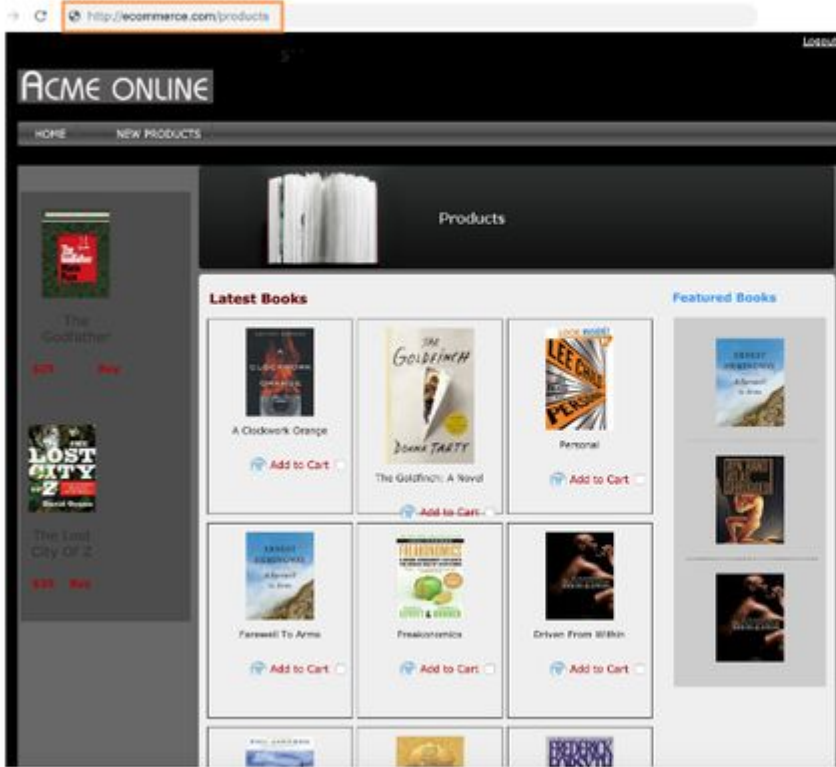

For base pages, Browser RUM calculates End User Response Time (EURT), Visually Complete Time (VCT), and Page Complete Time (PCT). For virtual pages, Browser RUM calculates EURT and VCT.

End User Response Time

End User Response Time (EURT) calculates the total time for all content (visual and non-visual) to be loaded on a page.

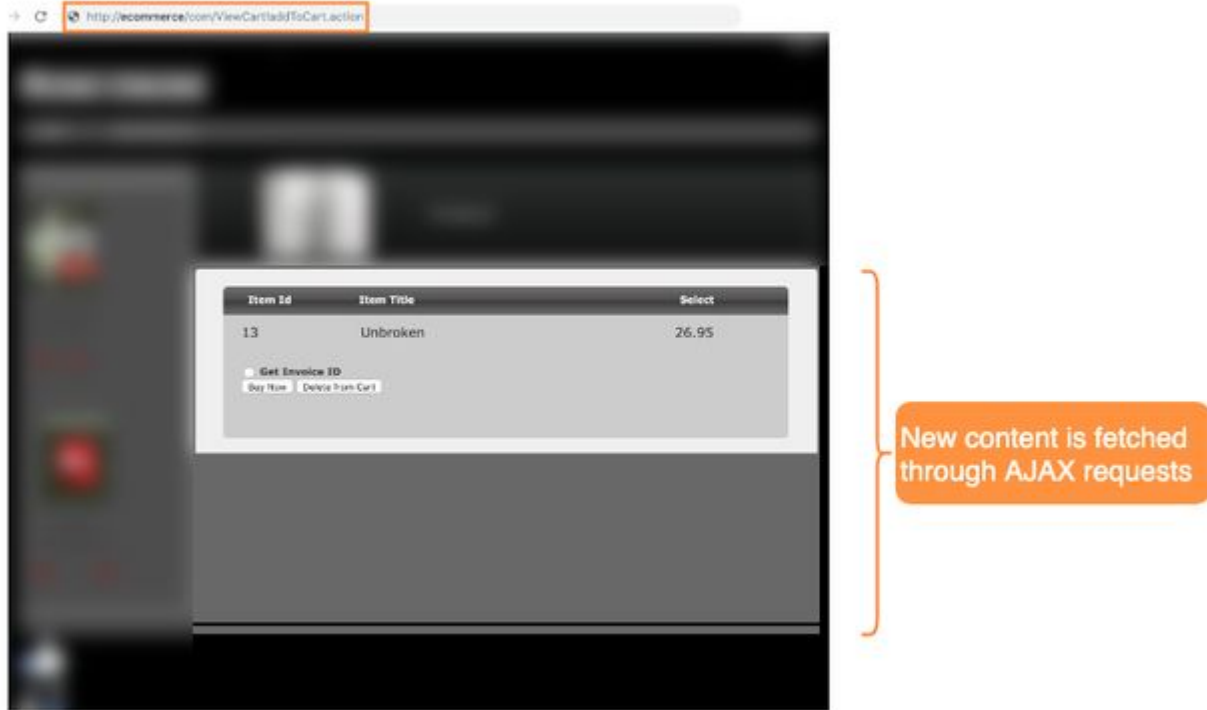

[Base Page](#) Virtual Page

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

All content (visual and non-visual) is loaded on the page

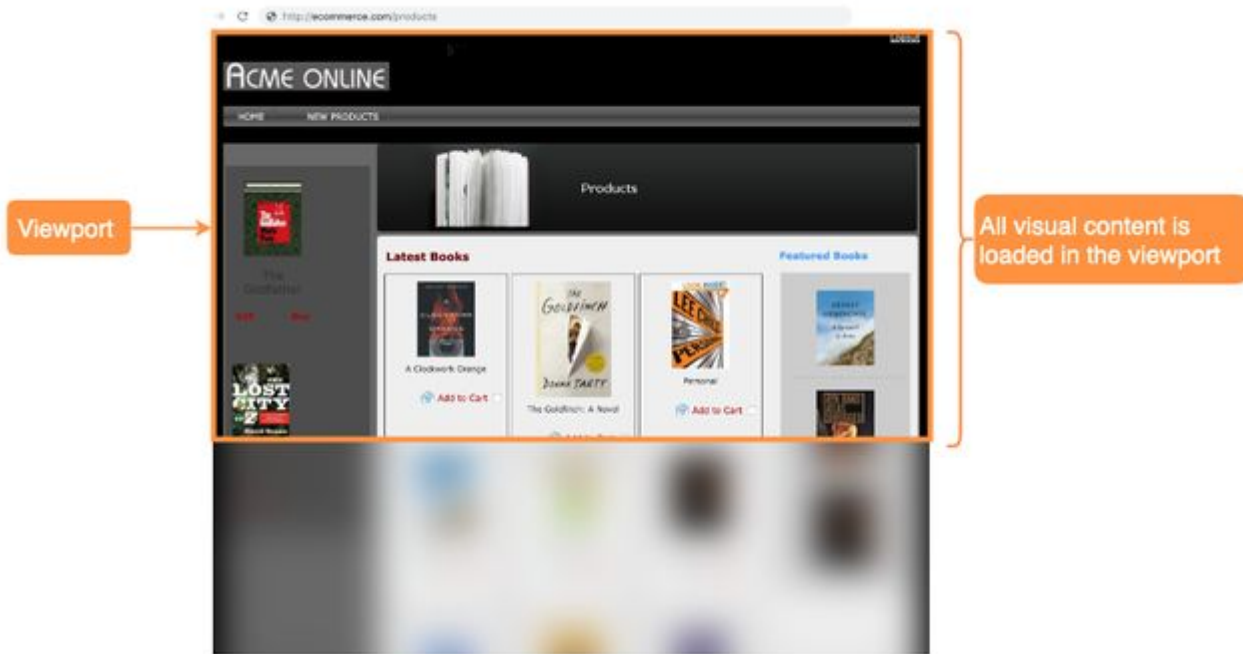

Base Page [Virtual Page](#)

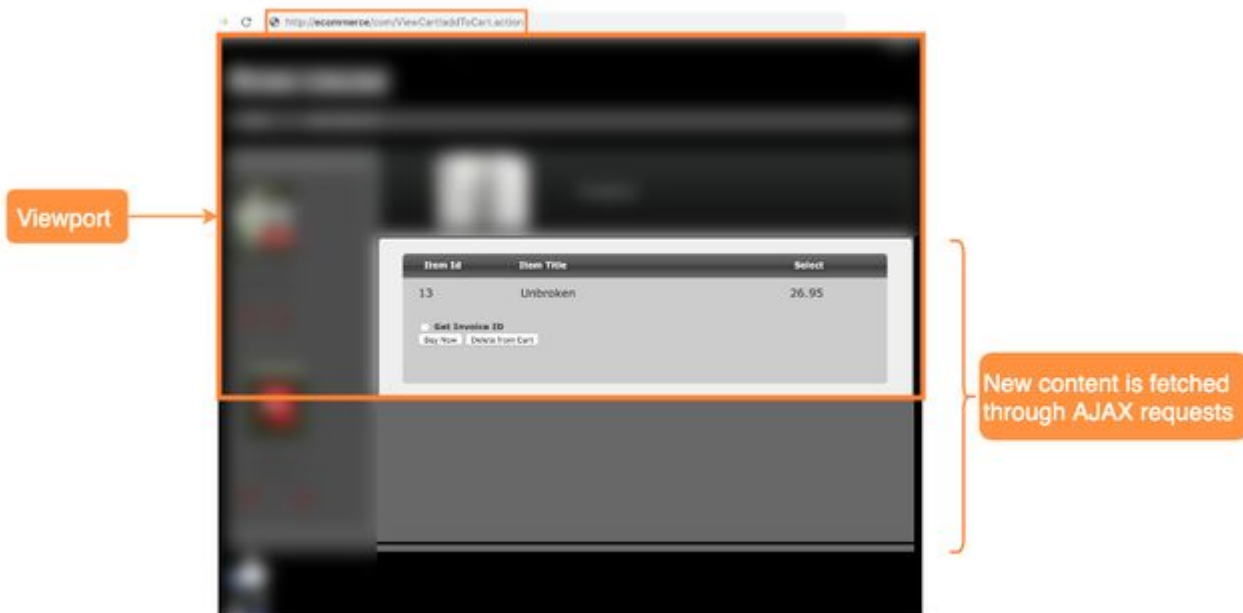

Visually Complete Time

Visually Complete Time (VCT) calculates the point in time when the browser has finished loading all visual content in the viewport.

[Base Page](#) Virtual Page

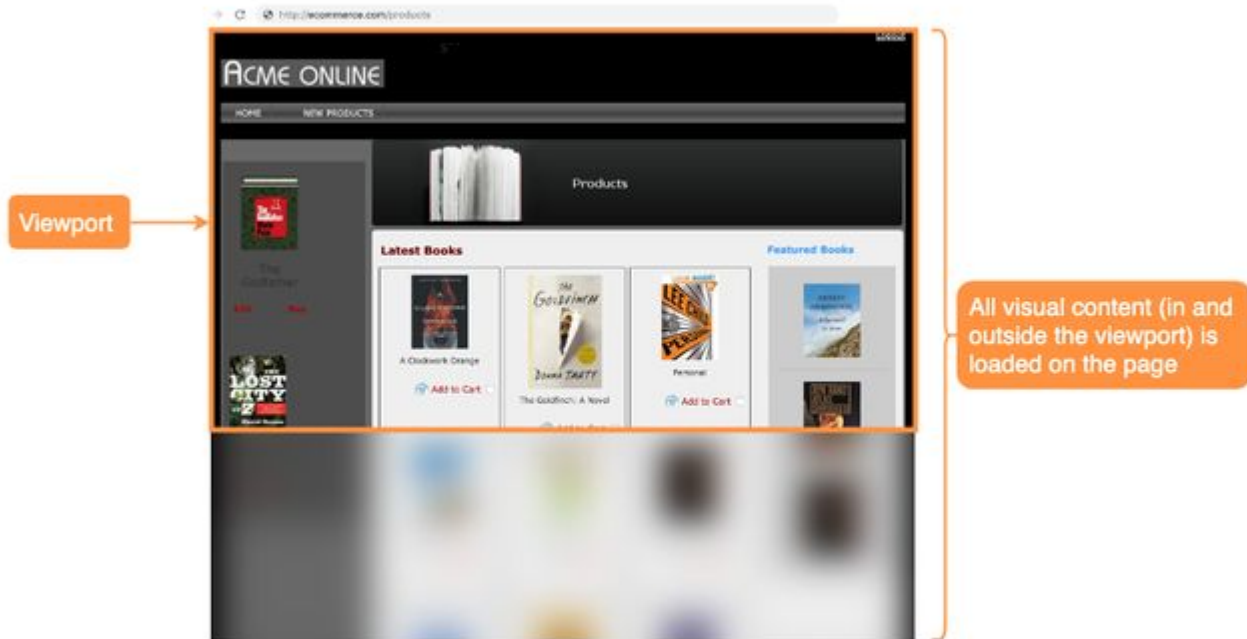

Base Page [Virtual Page](#)

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Page Complete Time

Page Complete Time (PCT) is a SPA2 metric for base pages only. PCT calculates the point in time when the browser has finished loading all visual content on the page, regardless of whether the content is in or outside the viewport.

Configure SPA2 Monitoring

SPA2 Requirements

- JavaScript Agent ≥ 20.2
- Controller / EUM Server ≥ 20.2 (for on-premises deployments)
- [Enable SPA2 monitoring](#)
- IE 10 and Edge are supported. IE ≥ 10 and Edge *cannot* be in compatibility mode with IE ≤ 9 browsers.
- For non-AngularJS frameworks, the JavaScript Agent ≥ 20.2 is required.

i Angular 6-9 SPAs are supported by JavaScript Agent version ≥ 20.2 . To manually report and name virtual pages with the JavaScript Agent API, you will need to use the JavaScript Agent ≥ 20.2 . The JavaScript Agent ≥ 20.2 does not support the use of the JavaScript Agent API to manually report events.

Enable/Disable SPA2 Monitoring

In the JavaScript Agent configuration, set `spa2` to `true` and then inject the JavaScript Agent as shown below. You can use either [manual](#) or [automatic](#) injection. The default value for `spa2` is `false`, so to enable SPA2 monitoring, you must set `spa2` to `true`.

i Make sure you set the configuration, including enabling SPA2 monitoring, *before* you load the JavaScript Agent.

```
<script charset='UTF-8'>
  window['adrum-start-time'] = new Date().getTime();
  (function(config){
    config.appKey = '<EUM_APP_KEY>';
    config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
    config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
    config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
    config.beaconUrlHttps = 'https://col.eum-appdynamics.com';
    config.xd = {enable : false};
    config.spa = {
      "spa2": true
    };
  })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8'></script>
```

Disable SPA2 Monitoring

To disable SPA2 auto-instrumentation, just set `spa2` to `false`. Although the default value for `spa2` is `false`, you are recommended to set the configuration to `false` and *not* just remove it.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Migrate from SPA1 to SPA2 Monitoring

To migration from SPA1 to SPA2 monitoring:

1. Read [SPA1 Monitoring](#) and [SPA2 Monitoring](#) to confirm that your use case is suitable for SPA2.
2. Meet the [SPA2 requirements](#).
3. [Enable SPA2 monitoring](#).

Fetch API Support for SPA2 Monitoring

The JavaScript Agent monitors Fetch API calls by default for all SPAs except for Angular applications.

For Angular.js and Angular 2-9 applications, follow these steps to ensure Fetch API calls are monitored.

1. The JavaScript Agent is configured to monitor Fetch API calls by default. Make sure that your JavaScript Agent configuration *doesn't* have the following:

```
config.fetch = false
```

2. Load the JavaScript Agent before Angular (recommended, but not required).

```
<script src="adrum.js"></script>
<script src="angular.js"></script>
```

3. Add the following configuration to ensure the JavaScript Agent monitors the Angular application correctly.

[>= 20.2](#)

```
function(config) {
  ...
  config.isZonePromise = true;
  ...
})(window['adrum-config'] || (window['adrum-config'] = {}));
```

Troubleshoot SPA Monitoring

This page describes how to troubleshoot issues with monitoring SPAs.

Problems With Dynamically Loading the JavaScript Agent

Because Angular allows you to dynamically load modules with `AppdInitServlet`, you may be tempted to dynamically load `adrum.js`. The problem with dynamically loading `adrum.js`, however, is that this could cause a race condition between the time `adrum.js` is evaluated and the time `angular.js` is bootstrapped. This race condition can result in JavaScript Agent missing virtual pages or XHR events.

You can avoid this race condition by doing the following:

- Loading Angular first and then immediately loading the JavaScript Agent. See [Load Angular and the JavaScript Agent](#).
- [Bootstrap Angular](#) after you have loaded the JavaScript Agent.

Load Angular and the JavaScript Agent

The key here is simply to make sure that you load `angular.js` first and then immediately load `adrum.js` as shown below.

```
<script src="angular.js"></script>
<script src="adrum.js"></script>
```

Bootstrap Angular

Manual (Recommended)

After you have loaded `adrum.js`, you can then bootstrap Angular through [manual initialization](#). You should load both `angular.js` and `adrum.js` as soon as possible, so that the JavaScript Agent can get more accurate metrics about the page load and the HTML DOM Ready /Build time. The examples below follow the recommended procedure of first loading `angular.js`, then `adrum.js`, and then bootstrapping `angular.js`

[AppDynamics CDN](#) Self-Hosting Shared Hosting

```
<!doctype html>
<html>
  <head>
    <script src="http://code.angularjs.org/snapshot/angular.js"></script>
    <script charset='UTF-8'>
      window['adrum-start-time'] = new Date().getTime();
      (function(config){
        config.appKey = '<EUM_APP_KEY>';
        config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

        config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
        config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
        config.beaconUrlHttps = 'https://col.eum-appdynamics.com';
        config.xd = {enable : false};
    })(window['adrum-config'] || (window['adrum-config'] = {}));

[Self-Hosting](#)
[Shared Hosting](#)

```

<!doctype html>
<html>
  <head>
    <script src="http://code.angularjs.org/snapshot/angular.js"></script>
    <script>
      // Assumes that you downloaded the JS Agent and copied it to the 'js'
      directory of your app root.
      (function(config){
        config.appKey = '<EUM_APP_KEY>';
        config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
        config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
        config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
        config.beaconUrlHttps = 'https://col.eum-appdynamics.com';
        config.xd = {enable : false};
      })(window['adrum-config'] || (window['adrum-config'] = {}));
    </script>
    <script src="//<your-cdn.com>/adrum/adrum.js" type="text/javascript"
    charset="UTF-8"/>
  </head>
  <body>
    <div ng-controller="TestController">
      It's {{currentTime}}!
    </div>
    <script>
      angular.module('angularApp', [])
        .controller('TestController', ['$scope', function ($scope) {
          $scope.currentTime = new Date().toLocaleString();
        }]);
    </script>
  </body>
</html>

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

    angular.element(document).ready(function() {
      angular.bootstrap(document, ['angularApp']);
    });
  </script>
  <script src="js/adrum.js"></script>
</body>
</html>

```

Deferred (Optional)

If manual bootstrap is not possible, you can use [deferred bootstrap](#). What this means is that you pause the bootstrap until `adrum.js` is successfully loaded, at which point, you resume the bootstrapping with `angular.resumeBootstrap()` as shown in the example below.

```

<!doctype html>
<html>
  <head>
    <script src="http://code.angularjs.org/snapshot/angular.js"></script>
    <script>
      // This defers the bootstrap.
      window.name = 'NG_DEFER_BOOTSTRAP!';
      angular.module('angularApp', [])
        .controller('TestController', ['$scope', function ($scope) {
          $scope.currentTime = new Date().toLocaleString();
        }]);
      angular.element(document).ready(function() {
        angular.bootstrap(document, ['angularApp']);
      });
    </script>
    // For simplicity, we're just showing the injection snippet using the AppDynamics
    CDN.
    <script charset='UTF-8'>
      window['adrum-start-time'] = new Date().getTime();
      (function(config){
        config.appKey = '<EUM_APP_KEY>';
        config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
        config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
        config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
        config.beaconUrlHttps = 'https://col.eum-appdynamics.com';
        config.xd = {enable : false};
      })(window['adrum-config'] || (window['adrum-config'] = {}));
    </script>
    <script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript'
    charset='UTF-8'></script>
  </head>
  <body>
    <div ng-controller="TestController">

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

    It's {{currentTime}}!
  </div>
  <script>
    // Resume the bootstrapping.
    angular.resumeBootstrap()
  </script>
</body>
</html>

```

Manually Initializing the JavaScript Agent (Optional)

If `adrum.js` loads successfully, but does not initialize, you can manually initialize it by calling `ADRUM.ng.ngMonitor.init()` as shown below. This will force the JavaScript Agent to initialize even after the Angular bootstrap.

```

<html>
  <head>
    <script src="http://code.angularjs.org/snapshot/angular.js"></script>
    <script>
      // This defers the bootstrap.
      window.name = 'NG_DEFER_BOOTSTRAP!';
      angular.module('angularApp', [])
        .controller('TestController', ['$scope', function ($scope) {
          $scope.currentTime = new Date().toLocaleString();
        }]);
      angular.element(document).ready(function() {
        angular.bootstrap(document, ['angularApp']);
      });
    </script>
  </head>
<!doctype html>
<html>
  <head>
    <script src="http://code.angularjs.org/snapshot/angular.js"></script>
    <script>
      // This defers the bootstrap.
      window.name = 'NG_DEFER_BOOTSTRAP!';
      angular.module('angularApp', [])
        .controller('TestController', ['$scope', function ($scope) {
          $scope.currentTime = new Date().toLocaleString();
        }]);
      angular.element(document).ready(function() {
        angular.bootstrap(document, ['angularApp']);
      });
    </script>
    // For simplicity, we're just showing the injection snippet using the AppDynamics
    CDN.
    <script charset='UTF-8'>
      window['adrum-start-time'] = new Date().getTime();
    </script>
  </head>
</html>

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

(function(config){
  config.appKey = '<EUM_APP_KEY>';
  config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
  config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
  config.beaconUrlHttp = 'http://col.eum-appdynamics.com';
  config.beaconUrlHttps = 'https://col.eum-appdynamics.com ';
  config.xd = {enable : false};
})(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript'
charset='UTF-8'></script>
</head>
<body>
  <div ng-controller="TestController">
    It's {{currentTime}}!
  </div>
  <script>
    // Resume the bootstrapping.
    angular.resumeBootstrap();
    ADRUM.ng.ngMonitor.init();
  </script>
</body>
</html>

```

i In some cases, you may be able to place `ADRUM.ng.ngMonitor.init()` **before** `angular.resumeBootstrap()`.

Enable the Content Security Policy (CSP)

This page describes how to enable Content Security Police (CSP) so your application is compatible with Browser RUM.

Directives Required for CSP

To enable CSP for instrumented applications, you add the following required directives in the `Content-Security-Policy` header:

- `script-src`
- `connect-src`

In certain cases, you are also required to use the following directives:

- `child-src`
- `frame-ancestors`
- `img-src`

`script-src`

The `script-src` directive specifies the location of `adrum-ext.js`. By default, `adrum-ext.js` is loaded from our content delivery network (CDN) at `cdn.appdynamics.com`. The example below shows how you might use the `script-src` directive.

```
script-src cdn.appdynamics.com;
```

To measure first-byte time accurately, include the following line at the top of pages:

```
window["adrum-start-time"] = new Date().getTime();
```

For this line to be read, you also need to set the `script-src` directive to `'unsafe-inline'` as shown here:

```
script-src 'unsafe-inline';
```

`connect-src`

The `connect-src` directive specifies the location where beacons are sent. If you are using the SaaS-based EUM, you might use something like the following:

```
connect-src col.eum-appdynamics.com;
```

If you are using on-prem EUM, you would have `connect-src` point to your EUM Server.

child-src

For cross-domain sessions, we load `adrum-xd.html` into an iframe. By default, this is loaded from our CDN, so you need to have `child-src` specify a CDN as shown below.

```
child-src cdn.appdynamics.com;
```

frame-ancestors

If `adrum-xd.html` is hosted locally, you would use the `frame-ancestors` directives in the following way:

```
frame-ancestors /path/to/adrum-xd.html;
```

img-src

In older browsers, we send our beacons as image beacons. Although older browsers don't support CSP, you can configure the JavaScript Agent to always send image beacons. You do this using `img-src` directive to specify the beacon location as shown in the example below.

```
img-src col.eum-appdynamics.com;
```

Example Content-Security-Policy Header

The following `Content-Security-Policy` header loads the `adrum` files from our CDN and then sends beacons to our SaaS-based EUM.

```
Content-Security-Policy: connect-src 'self' col.eum-appdynamics.com; script-src 'unsafe-inline' cdn.appdynamics.com; img-src cdn.appdynamics.com; child-src cdn.appdynamics.com
```

Host a Geo Server

- [Browser RUM Countries and Regions by Geo Dashboard](#)

AppDynamics hosts a Geo Server that resolves the user's geographic location based on the request's reported IP address. You may prefer to host your own Geo Server if:

- You have intranet applications where the public IP address does not provide meaningful location information but the user's private IP does.
- You have a hybrid application where some users access the application from a private location and some access it from a public one. If a user doesn't come from a specific private IP range mapped by the custom geo server, the system can be set to default to the public Geo Server.

The custom Geo Server supports an HTTP header, `AD-X-Forwarded-For`. You can use this to declare an IP address specifically for the purpose of geo resolution. Custom Geo Server also supports the HTTP header `X-Real-IP`.

To host a custom geo server:

1. [Download the Geo Server File](#)
2. [Set the Location of the Geo Server](#)
3. [Create the IP Mapping File](#)

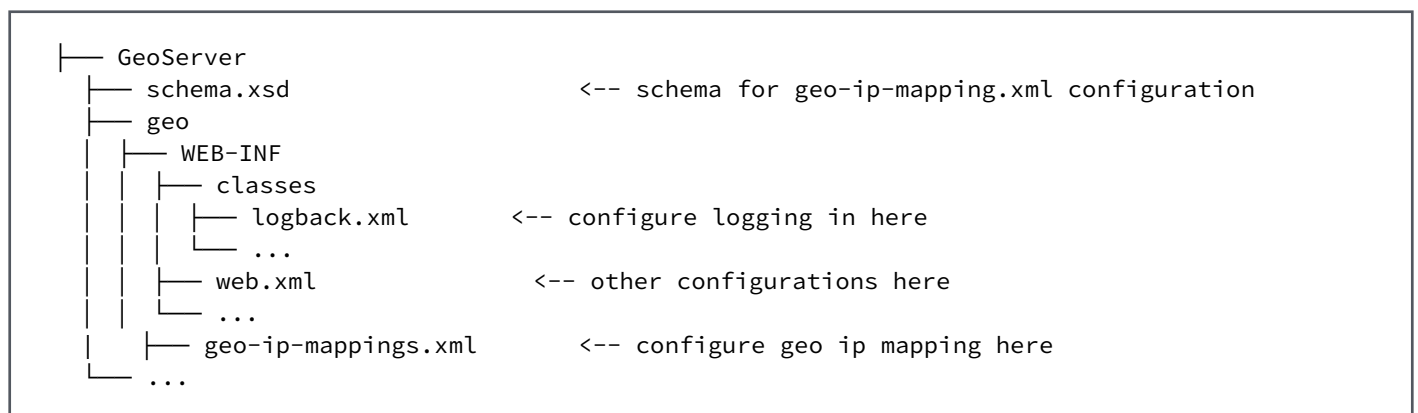

Requirements for Geo Server Host

- 2 GB of memory
- Java 8.x

Download and Install the Geo Server File

Download the `GeoServer.zip` file from AppDynamics at <https://download.appdynamics.com/download>.

Uncompress the zip to a `GeoServer` folder with the following structure:

To install the geo server, copy the `geo` folder to the `TOMCAT_HOME/webapps` of your Tomcat server. Do not deploy the server in the same container as the Controller.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Set the Location of the Geo Server

Enter the URL, including the context root, of your hosted geo server in the **Geo Server URL** field in the **Browser RUM** configuration screen in the Controller UI as shown below.

Configure and download JavaScript Agent

Set the Geo Server URL

optional

http://

https://

! If you are using manual injection for your JavaScript agent, you must make sure that the copy of the script that you use is one that you have downloaded *after* this URL is set.

Create the IP Mapping File

The `geo-ip-mappings.xml` IP mapping file specifies the locations for which Browser RUM provides geographic data. It maps IP addresses to geographic locations.

Use the sample file in the `geo` subdirectory as a template. Any modifications at runtime are reloaded without a restart.

This file contains a `<mapping>` element for every location to be monitored. The file has the following format.

```
<mappings>
  <mapping>
    <subnet from="192.168.1.1" mask="255.255.255.0"/>
    <location country="United States" region="California"
city="San Francisco"/>
  </mapping>

  <default country="United States" region="California"
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
city="San Francisco"/>
</mappings>
```

You can also use IP-range-based mapping instead of subnet-based:

```
<mapping>
  <ip-range from="10.240.1.1" to="10.240.1.254" />
  <location country="France" region="Nord-Pas-de-Calais"
city="ENGLOS" />
</mapping>
```

This data is visible in browser snapshots and can be used to filter browser snapshots for specific locations: The `<country>`, `<region>`, and `<city>` elements are required. If the values of `<country>` and `<region>` do not correspond to an actual geographic location already defined in the geographic database, map support is not available for the location in the map panel, but Browser RUM metrics are displayed for the location in the grid view of the geographic distribution, end user response time panel, trend graphs, browser distribution panel, and in the Metric Browser. The `<city>` element can be a string that represents the static location of the end-user. You will notice a `<default>` element. If there is an IP address that is not covered by your IP mapping file, this is the value that is used. To use a public geo server for non-covered IP addresses, see [Using a Hybrid Custom-Public Geo Server Setup](#).

The screenshot shows the AppDynamics interface with the 'Browser Snapshots' tab selected. An orange callout bubble points to the 'Filter by location' button. The 'Geography' filter section is expanded, showing 'Country' set to 'Japan', 'State / Region' set to 'Miyagi', and 'City' set to 'Natori'. A table of browser snapshots is visible, with columns for 'Server Side', 'Geography', 'End User Response Time (ms)', and 'URL'. The table contains five rows of data, each with a green checkmark in the 'Geography' column.

Server Side	Geography	End User Response Time (ms)	URL
<input type="checkbox"/> Server Snapshot Exists <input type="checkbox"/> Server Error Occurred	✓	1,018	https://docs
	✓	626	https://docs
	✓	132	https://docs
	✓	56	https://docs
	✓	54	https://docs

The valid names for country and region are those used in the map in the geo dashboard. You can hover over a region in the dashboard to see the exact name (including spelling and case) of the region. See [The Browser Geo Dashboard View](#).

Using a Hybrid Custom-Public Geo Server Setup

If you want Browser RUM to evaluate any non-mapped IP address using the public geo server, remove the `<default>` element. In this case, locating any non-mapped IP address is done in the EUM cloud, not locally.

Customize File Locations

You can customize where certain files are stored in the GeoServer directory.

Change Log Location

By default, logs are written to `TOMCAT_HOME/logs`, but you can configure this using `TOMCAT_HOME/webapps/geo/WEB-INF/classes/logback.xml`. Open the file with a text editor and edit the `LOG_HOME` property.

```
<property name="LOG_HOME" value="{path-to-file}/logs"/>
```

Change Mapping File Location

By default, the geo server looks for `geo-ip-mappings.xml` in `TOMCAT_HOME/webapps/geo/`. To change the location, open `TOMCAT_HOME/webapps/geo/WEB-INF/web.xml` with a text editor and change value for `AD_GEO_CONFIG_FILE`.

```
<web-app ...>
  <!-- ... -->
  <servlet>
    <servlet-name>FrontControllerServlet</servlet-name>
    <servlet-class>com.appdynamics.eum.geo.web.FrontControllerServlet</servlet-class>
    <context-param>
      <param-name>AD_GEO_CONFIG_FILE</param-name>
      <param-value>{path-to-file}/geo-ip-mappings.xml</param-value>
    </context-param>
    <!-- ... -->
  </servlet>
  <!-- ... -->
</web-app>
```

i In previous versions of the geo server, the enclosing tag was a `<context-param>`. This has now been changed to an `<init-param>`.

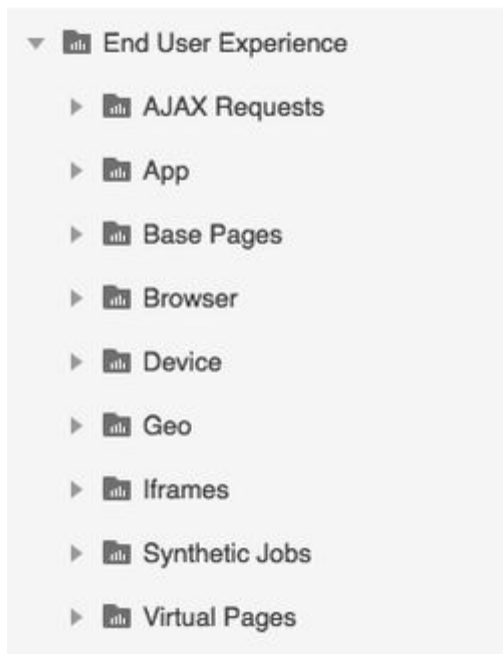

Browser RUM Metrics

Key Browser RUM metrics display on the **Geo, Pages & AJAX Requests**, and **Usage Stats** dashboards. They are also visible on the **All Pages** and **Top Pages** lists and in the [Metric Browser](#).

In addition, the **Metric Browser** enables you to view these metrics in the context of Ajax requests, Iframes, applications, base pages, browsers, devices, and geographic locations.

You can build custom health rules based on Browser RUM Page, Ajax, and Iframe metrics in the health rule builder. Use these rules to automatically monitor key metrics in your installation. See [Health Rules](#).

Browser RUM Timing Metrics Overview

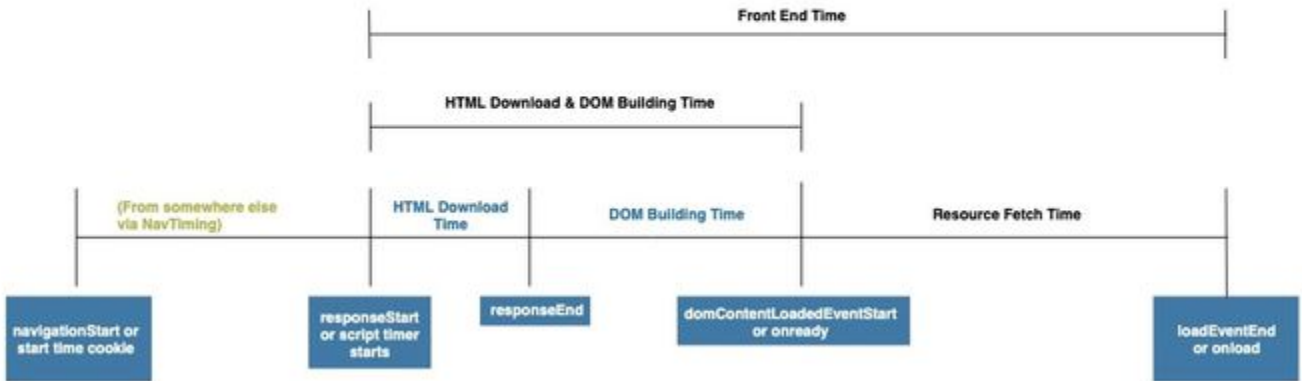

The following provides an overview of the first Browser RUM page and Iframe timing metrics. For key Ajax metrics, see [Ajax Metrics Availability](#). Metrics in blue are available only from NavTime browsers. You may see a value of `unknown` for some metrics taken using older browsers.

When users begin to load the first instrumented page, the JavaScript Agent starts a timer. The timer or the NavTime `responseStart` starts the first-page timing.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

[First Page](#) [Subsequent Pages](#) [Connection Details](#)

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Subsequent Pages

Connection Details

i Because a NavTime browser always sets `navigationStart`, you can retrieve this information even on the first page a user loads from your site.

NavTiming-capable browsers also provide highly granular information on connection details.

Browser RUM Metrics Defined

Timing metrics are the average times, in milliseconds, over the time range selected in the Controller UI or REST API call. The three-letter abbreviation is the short name as it is recorded in the web beacon.

Name (Short Name)	NavTiming Capable Browsers ¹	Browsers without NavTiming Support	Available For . . .	Definition
Ajax Callback Execution Time (DPT)	responseEnd to domContentLoadedEventStart (context of the Ajax object)	responseEnd to domContentLoadedEventStart (context of the Ajax object)	Ajax Requests (XHR, Fetch API)	Time for the browser to process the Ajax response. This typically includes the time to apply the response data to the DOM.
Ajax Response Download Time (DPT)	responseStart to responseEnd (context of the Ajax object)	responseStart to responseEnd (context of the Ajax object)	Ajax Requests (XHR, Fetch API)	Time for the browser to download the complete Ajax response.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Name (Short Name)	NavTiming Capable Browsers ¹	Browsers without NavTiming Support	Available For . ..	Definition
Ajax Request Errors per Minute (Short name based on AR Entries)			<ul style="list-style-type: none"> • Ajax Requests (XHR, Fetch API) • App • Browser • Device • Geo 	Total number of Ajax requests that generate an error per minute.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Name (Short Name)	NavTiming Capable Browsers ¹	Browsers without NavTiming Support	Available For . ..	Definition
Ajax Requests per Minute (Short name based on PL C entries)			<ul style="list-style-type: none"> • App • Browser • Device • Geo 	Total number of Ajax requests per minute.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. Name (Short Name)	NavTiming Capable Browsers ¹	Browsers without NavTiming Support	Available For . . .	Definition
Visually Complete Time (VCT)	N/A	N/A	<ul style="list-style-type: none"> • App • Base Pages • Browser • Device • Geo • Frames 	<p>Total time for all visual elements within the first screen (above-the-fold content) to load in an end user's browser.</p> <p>Calculated using the last visual change to the page in a browser window.</p> <p>For information about Visually Complete Time for SPA2 pages, see SPA2 Metrics.</p>

Ajax Metrics Availability

Because Ajax requests occur in the context of the larger page, these four core metrics are always available, regardless of the browser type.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Ajax Core Metrics

For more information on which browsers support the Navigation Timing API, see the [Can I Use](#) website.

Resource Timing Metrics

Resource timing metrics are the median times in milliseconds. The resource timing metrics shown in the Resource Performance Dashboard are raw data.

Metric Name	How It's Calculated	Description
Browser Wait	<code>startTime</code> or <code>redirectEnd</code> to <code>fetchStart</code>	Time from the redirection or request start until the browser begins to fetch the resource.
Redirect Time	<code>redirectStart</code> to <code>redirectEnd</code>	Time for all redirects associated with fetching resources.
DNS Wait Time	<code>fetchStart</code> to <code>domainLookupStart</code>	Time from when the browser starts to fetch the resource until the browser starts the domain name lookup for the resource.
DNS Time	<code>domainLookupStart</code> to <code>domainLookupEnd</code>	Time to complete the domain lookup portion of the server connection time.
TCP Wait Time	<code>domainLookupEnd</code> to <code>connectStart</code>	Time for the browser to find the domain name for the resource before a connection is made.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metric Name	How It's Calculated	Description
Connection Time	<code>connectStart</code> to <code>connectEnd</code>	Time to complete the establish the TCP connection for a resource: the equivalent of one network roundtrip of latency.
SSL Time	<code>secureConnectionStart</code> to <code>connectEnd</code> (if <code>secureConnectionStart</code> exists)	Time to establish a secure connection to the server.
Request Wait Time	<code>connectEnd</code> to <code>requestStart</code>	Time for the request is made for a resource from the server, cache, or local resource before the connection is closed.
Request Time	<code>requestStart</code> to <code>responseStart</code>	Time for the browser to complete the request for a resource from the server, cache, or local resource.
Response Time	<code>responseStart</code> to <code>responseEnd</code>	Time for the browser to download the complete HTML document content. In the context of an Ajax request, the time for the browser to download the complete Ajax response.
First Byte Time	<code>startTime</code> to <code>responseStart</code>	Time from when the request is made until the first byte of the resource is received by the browser.
Resource Load Time	<code>startTime</code> to <code>responseEnd</code>	Time for the browser to start a request and receive a response for a resource.
Browser Queue Time	Browser Wait + DNS Wait Time + Request Wait Time	Total wait time of the resource.
TCP Time	<code>secureConnectionStart</code> to <code>connectStart</code>	Time spent to establish a secure connection to the server (same as SSL Time).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Configure Timing Metrics

If your application continuously sends Ajax requests or resources, you may want to configure the default JavaScript timing metrics below.

For example, if in your SPA2 app the Ajax requests are sent at a faster rate (i.e 2 seconds) than the default `maxInactive` time (3 seconds), the Page Load Time metric could be incorrectly inflated. To fix this, you could configure `maxInactiveTime` to 2 seconds so Page Load Time matches the rate of the Ajax requests.

`maxResourceQuietTime`

If all registered resources are loaded and the time elapsed between `currentTime` and last resource load time is \geq `maxQuietTime`, the resource observer stops.

```
(function(config){
  config.navComplete = {
    maxResourceQuietTime: 5000 // For SPA2 applications, the default value is
    5000 (5 seconds). For non-SPA applications, the default value is 1000 (1
    second).
  };
})(window['adrum-config'] || (window['adrum-config'] = {}));
```

`maxXhrQuietTime`

If all XHRs are successful and the time elapsed between `currentTime` and last XHR load time is \geq `maxQuietTime`, the XHR observer stops.

```
(function(config){
  config.navComplete = {
    maxXhrQuietTime: 3000 // For SPA2 applications, the default value is 3000 (3
    seconds). For non-SPA applications, the default value is 1000 (1 second).
  };
})(window['adrum-config'] || (window['adrum-config'] = {}));
```

About timing metrics and `NavComplete`

`maxResourceQuietTime` and `maxXhrQuietTime` contribute toward the page observation period to be marked complete (`navComplete`). There are two ways for `navComplete` to occur:

1. Both the XHR observer (`maxXhrQuietTime`) and the resource observer (`maxResourceQuietTime`) have stopped running.
2. The time elapsed since the last download activity has exceeded the `maxQuietTime`. This means enough time has passed since the latest resource or XHR load.

Once either of these scenarios is reached, the JavaScript Agent will consider the page to be complete, mark the timing as Visually Complete Time, and report the page to AppDynamics.

maxInactiveTime

`maxInactiveTime` is the current time minus when the last resource (i.e. Ajax call) happened. If this value is greater than `maxInactiveTime`, the navigation observer is assumed complete and the Visually Complete Time value is sent.

```
(function(config){
  config.navComplete = {
    maxInactiveTime: 3000 // For SPA2 applications, the default value is 3000 (3
seconds). For non-SPA applications, the default value is 1000 (1 second).
  };
})(window['adrum-config'] || (window['adrum-config'] = {}));
```

Browser RUM Supported Environments

This page describes the supported environments and versions for Browser RUM.

Browser RUM Support

Browser Compatibility

- IE 10, 11, Edge
- Chrome $\geq 1.0.154.60$, including Mobile
- Headless Chrome ≥ 59
- Firefox, including Mobile
- Safari ≥ 4 , including Mobile
- Opera ≥ 12

i Browsers are rapidly evolving, and not all versions have been individually tested with Browser RUM. You can view the [browser versions likely to support the Resource Timing API](#).

Browser Requirements for Sessions

To use Browser RUM sessions, your browser is required to support for the following:

- [cross-origin resource sharing \(CORS\)](#) for beacons
- [local storage](#) for multiple-page sessions (single-page / multiple virtual page sessions don't need local storage)

i Browser RUM sessions do not support beacons implemented with GIFs.

JavaScript Agent Version Requirement for Sessions

You are required to use the JavaScript Agent ≥ 4.2 . Older versions of the JavaScript Agent do not support sessions.

Injection Types for Browser RUM in Java Environments

Listed below are the injection types with their supported frameworks/technologies:

- **Automatic Injection:** JavaServer Pages (JSP) compiled using the [Jasper compiler](#). Jasper is the default JSP compiler in [Tomcat](#), [Glassfish](#), and [JBoss](#).
- **Assisted Injection:** All [Servlet](#) frameworks.
- **Manual Injection:** All technologies that generate HTML pages.

See [Inject the JavaScript Agent](#) for details.

Injection Types for Browser RUM in .NET Environments

AppDynamics certifies Browser RUM instrumentation for the following .NET environments:

- .NET Framework
- .NET Core

Browser RUM Instrumentation for .NET Framework

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Supported Runtime Environments for Browser RUM .NET Framework include:
 Microsoft IIS versions 6.0, 7.0, 7.5, 8.0, 8.5

- All listed frameworks support [manual injection of the JavaScript Agent for Browser RUM](#).
- The Script Injection column lists additionally supported script injection strategies. See [Inject the JavaScript Agent](#) for details.

Web Application/AJAX Frameworks	Versions	Additional Supported Script Injection Methods
ASP.NET Web Forms (.aspx)	3, 4	Automatic , Using Attribute Injection
ASP.NET MVC Web Forms (.aspx)	3 - 5	Automatic , Using Attribute Injection
ASP.NET MVC Razor	3 - 5	Automatic , Using Attribute Injection
Microsoft SharePoint	2007, 2010	Automatic

 AppDynamics does not support Browser RUM instrumentation of legacy ASP (.asp) pages.

Browser RUM Instrumentation for .NET Core

AppDynamics currently supports Windows only.

Web Application/AJAX Frameworks	Versions	Supported Script Injection Methods
ASP.NET Core MVC	3.1, 5	Automatic
ASP.NET Core Razor Pages	3.1, 5	Automatic

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Browser RUM Countries and Regions by Geo Dashboard

The countries and regions in the sections below can be displayed in the **Geo Dashboard**. Each of these countries and regions also displays their own aggregate Browser RUM data. Data can be collected from areas not in the following list, but it will not be displayed in these parts of the interface. Some countries and regions are only displayed in the grid view.

Countries

Grid View

The following countries are displayed in the grid view of the **Geo Dashboard**.

A – D	E – K	L – Q	R – Z
Afghanistan	Ecuador	Lao People's	Reunion
Aland Islands	Egypt	Democratic	Romania
Albania	El Salvador	Republic	Russian
Algeria	Equatorial	Latvia	Federation
American	Guinea	Lebanon	Rwanda
Samoa	Eritrea	Lesotho	Saint
Andorra	Estonia	Liberia	Barthelemy

Troubleshoot Browser RUM

These pages provide methods to solve common problems:

- [Browser RUM License Troubleshooting](#)
- [Browser RUM Metrics Not Reported](#)
- [Pages Not Monitored](#)
- [Injection Problems](#)
- [Browser Snapshot Problems](#)
- [Connection Problems](#)
- [Create a HAR File to Troubleshoot Web Download Issues](#)

Browser RUM License Troubleshooting

Related pages:

- [EUM Accounts, Licenses, and App Keys](#)

The following sections discuss how to solve common license problems.

No EUM Account License Key

The EUM account license is separate from the Controller license. Although the license file includes the EUM license key, the EUM account license is provisioned separately.

Controllers cannot share an EUM license key, but applications can.

If you need an EUM license, call your AppDynamics sales representative or email salesops@appdynamics.com.

Browser RUM Not Working in Production

If you are running more than one Controller, each instance requires a unique license. Make sure you are not trying to use the same license on more than one Controller.

Browser RUM Metrics Not Reported

This page provides a high-level overview to check your Browser RUM setup.

Check for Load

Make sure there is load running on your app for the pages that you want to monitor for the selected period.

When Browser RUM discovers a new page, iframe, or Ajax call for the first time, there will be a several minute delay before data for it appears in the Controller UI.

- It takes up to two or three minutes for the agent to register with the Controller. No metrics are captured during this time.
- After the page is registered and traffic starts flowing, it can take an additional two or three minutes for the metrics to appear in the AppDynamics console.
- After that, the delay between an end-user click and the appearance of Browser RUM data is two to three minutes.

Confirm Browser RUM Is Enabled

Make sure you enable Browser RUM for the app. Enable it if it is disabled. See [Enable and Disable Browser Monitoring](#).

Ensure Pages Are Instrumented

Examine the source of your web page to ensure that you have instrumented the pages that you want to monitor.

Check Connectivity

Make sure there is connectivity from the browser to the EUM Cloud.

Examine Beacons for Issues

If beacons are not present or their status is not valid, verify your Browser RUM configuration. See [Set Up and Access Browser RUM](#).

To examine your instrumented application for issues, verify the following:

- The JavaScript Agent extension (`adrum.ext`) is loaded and its status is OK (200).
- The EUM beacon is sent:
 - As a `.gif` request—older browsers
 - A GET request for `adrum.gif` is loaded, and its status is OK (200).
 - The `ky` parameter in the beacon is set to your application key.
 - As a CORS-based request—deprecated
 - A POST request has been sent with a status of OK (200).
 - The app key is sent in the body of the beacon.
 - As a CORS-based request
 - A POST request has been sent with a status of OK (200).
 - The app key is sent in the URL.

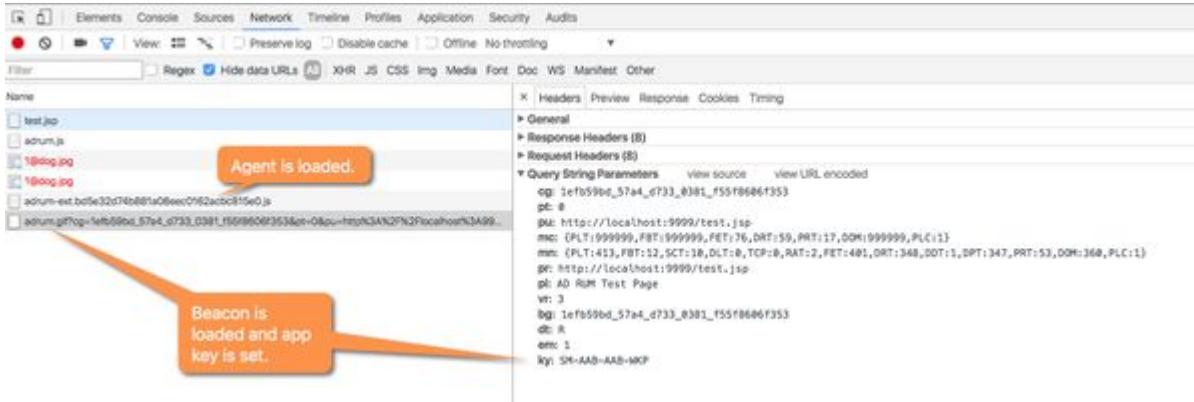

Beacons for using image requests have an inherent length limitation. Because of this, URLs longer than 180 characters, page names longer than 50 characters, and user data (key and value combined) longer than 113 characters are not supported in these browsers.

Use Developer Tools to Examine Your Application

You can use the developer tools in your web browser to examine your application.

This screenshot shows a `.gif`-based beacon in Chrome.

This screenshot shows a CORS-based beacon with a key in the URL path.

Create a [HAR file](#) to confirm that the browser is downloading the expected resources for your web page.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Pages Not Monitored

You may find that some pages have not been monitored as expected. This page may help you determine the reason why these pages have not been monitored.

Verify Pages Have Been Injected

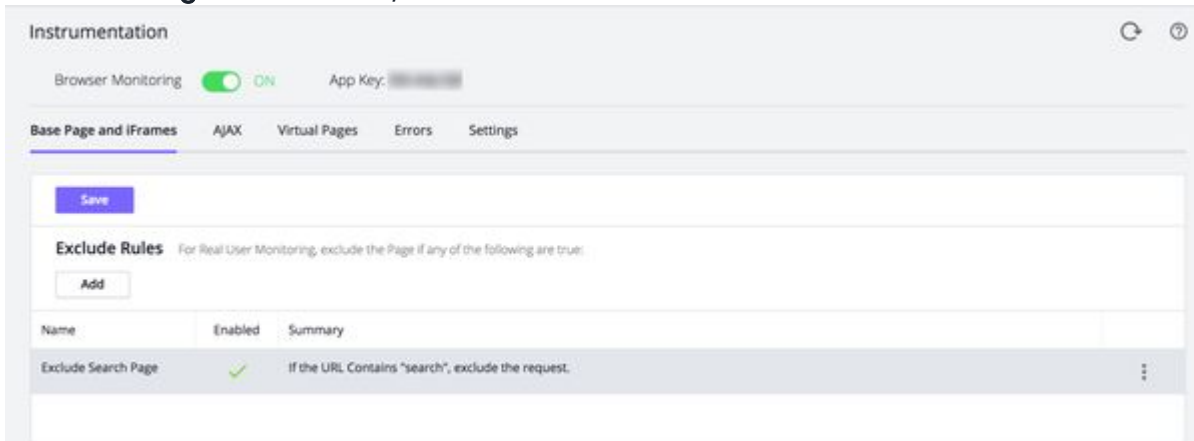

If only some web pages are not reporting data, first verify that those pages have been injected with the JavaScript Agent. See [Verifying that the JavaScript Agent for Browser RUM was injected](#).

Check Exclude Rules

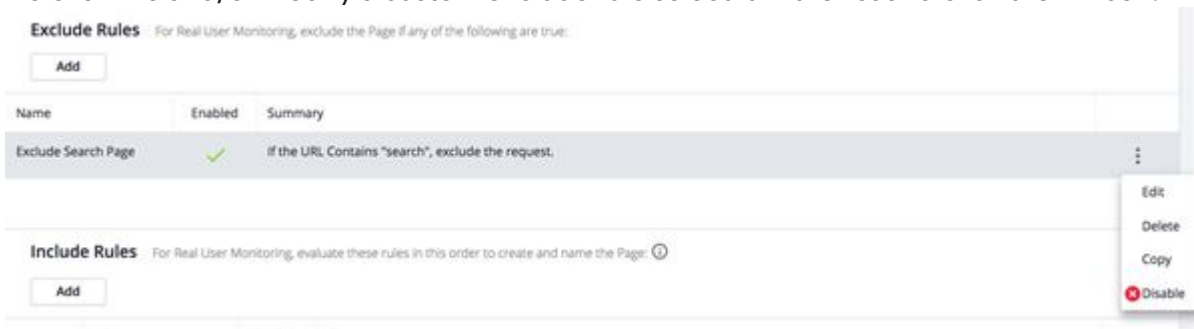

If the agent has been injected, the page may have been excluded from monitoring by custom exclude rules. You can check and modify these rules.

To access custom exclude rules for pages:

1. Click **Configuration > Instrumentation**.
2. Click the **Base Pages and iFrames** tab.
3. From **Base Pages and iFrames**, check the custom rules under the **Exclude Rules** section.

4. To examine and/or modify a custom exclude rule select it in the list and click the  icon:

5. If you want to remove a custom exclude rule, select and click **Delete**.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Check Automatic Injection Configuration

In addition, certain pages could have been excluded by the injection configuration. This can happen when automatic injection is used with a limited set of pages enabled for injection. If you used automatic injection, check your automatic injection configuration to see if the missing pages are enabled for injection.

Examine the **Request Match Rules** and **Request Exclude Rules** lists under **Only enable Automatic Injection for certain Pages** in the **Automatic JavaScript Injection** tab. See [Automatic Injection of the JavaScript Agent](#). Pages can also be bypassed by assisted injection using injection rules when an injection rule specifies only classes and methods to be injected. If you used assisted injection with injection rules, check your injection rules. See [Assisted Injection](#).

Configure the JavaScript Agent to Monitor Older Browsers

The JavaScript Agent by default supports modern browser and no longer tests or certifies the collection and reporting of data from older browsers. If you find that older browsers are accessing your web pages and that they are not being monitored, you can configure the JavaScript Agent to monitor older browser with the following configuration.

```
(function(config){
  ...
  "beacon": { "neverSendImageBeacon": false },
  ...
})(window['adrum-config'] || (window['adrum-config'] = {}));
```

Ajax Requests Not Monitored

You may find that some Ajax requests have not been monitored as expected. The page may help you determine why these pages have not been monitored.

Check Exclude Rules

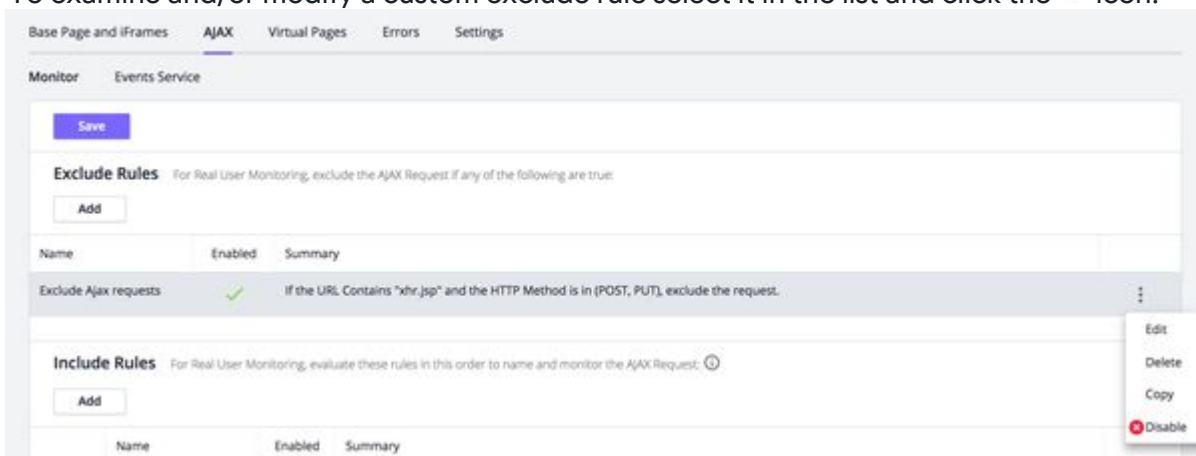

If the agent has been injected, the Ajax event may have been excluded from monitoring by custom exclude rules. You can check and modify these rules.

To access custom exclude rules for pages:

1. Click **Configuration > Instrumentation**.
2. From the AJAX tab, check the custom rules under the **Exclude Rules** section.

3. To examine and/or modify a custom exclude rule select it in the list and click the  icon:

4. If you want to remove a custom exclude rule, select and click **Delete**.

Verify That XHR Objects Were Reused Correctly

Browser RUM can monitor multiple Ajax calls made from a reused `XMLHttpRequest` object, but if the `XMLHttpRequest` object is reused (opened) before the last request is completed, the JavaScript agent cannot collect all the metrics for all the Ajax requests.

Incorrect Method to Reuse XMLHttpRequest Object

In the example below, the `xhr` object is making a request to `/multi-bt` before the request to `/xhr/uptime` has completed, so the JavaScript Agent only reports the second Ajax request to `/multi-bt`.

```
function reuseXHRBeforeReady() {
  var xhr = newXhr();
  xhr.open("GET", "/xhr/uptime");
  xhr.onreadystatechange = safe(function() {
    if (xhr.readyState == 4) {
      if (typeof(console) !== "undefined" && console !== null && console.log)
        console.log("onreadystatechange for xhr1: " + xhr.responseText);
      document.getElementById("result").innerHTML = xhr.responseText;
    }
  });
  xhr.send(null);
  xhr.open("GET", "/multi-bt");
  xhr.onreadystatechange = safe(function() {
    if (xhr.readyState == 4) {
      if (typeof(console) !== "undefined" && console !== null && console.log)
        console.log("onreadystatechange for xhr2: " + xhr.responseText);
      document.getElementById("result").innerHTML = xhr.responseText;
    }
  });
  xhr.send(null);
}
```

When an Ajax request cannot be reported because the `XMLHttpRequest` object is reused (opened) before the last request is completed, the JavaScript Agent logs that an Ajax request was *not* reported in a message similar to the one below. You will most likely have to modify your JavaScript so that new Ajax requests are only made after previous requests are completed.

```
EXT~ The reused XHR object calls open() before finishes last job. No event of XHR to '" +
this._adrumAjaxT.url() + "' is reported.
```

Correct Method to Reuse XMLHttpRequest Object

The correct method to reuse the `XMLHttpRequest` object to make more than one request is to nest the calls so that new calls are only made when previous calls have been completed. In the example below, the

call to `/xhr/multi-bt2` is only made when the call to `/multi-bt` has completed, so both calls are reported as Ajax requests.

```
function reuseXHR() {
  var xhr = newXhr();
  xhr.open("GET", "/xhr/uptime");
  xhr.onreadystatechange = safe(function() {
    if (xhr.readyState == 4) {
      document.getElementById("result").innerHTML = xhr.responseText;
      xhr.open("GET", "/multi-bt");
      xhr.onreadystatechange = safe(function() {
        if (xhr.readyState == 4) {
          if (typeof(console) !== "undefined" && console !== null && console.log)
            console.log("onreadystatechange for xhr2: " + xhr.responseText);
          document.getElementById("result").innerHTML = xhr.responseText;

          // Reuse xhr again
          xhr.open("GET", "/xhr/multi-bt2");
          xhr.onreadystatechange = safe(function() {
            console.log("/xhr/multi-bt2 responded.");
          });
          xhr.send(null);
        }
      });
      xhr.send(null);
    }
  });
  xhr.send(null);
}
```

Check Injection Configuration

In addition, certain Ajax requests could have been filtered out by the injection configuration. This can happen when the injection uses [XHR filters to limit which Ajax requests are monitored](#). Check your injection configuration to verify that the filtering did not prevent the calls from being monitored.

Injection Problems

You must inject the JavaScript Agent for Browser RUM into every page that you want to monitor.

Verify Injection

View the source of your web page. When automatic or assisted injection is used, you should see the script for the JavaScript Agent inline in the web page. When manual injection is used, you will see:

```
<script src="/path_to_adrum.js"/>
```

If you used manual injection, use the normal procedures that you use to verify other types of code changes in your web pages. Keep in mind that various caches, such as the server page, CDN or browser caches, can prevent the page from actually being reloaded. If you cannot get manual injection to work, try one of the other injection schemes if they are available for your platform. See [Inject the JavaScript Agent](#) for information about the various injection strategies.

Verify Automatic Injection is Enabled

To verify that automatic injection is enabled:

1. Open the business application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration > JavaScript Agent Injection**.
3. From **Inject the JavaScript Agent configured for this Browser App**, confirm that your browser app receiving the automatic injection is selected.
4. Select the Automatic Injection tab.
5. Confirm that the **Enable Automatic Injection of JavaScript** checkbox is checked.
6. Verify that automatic injection is enabled for all of the business transactions that you want to monitor. If some of those business transactions are in the **Automatic injection possible, but not enabled list**, move them to the **Automatic injection enabled list**. If the business transaction that you want to monitor does not appear in either list, automatic injection is not possible for that business transaction.
7. Click **Save** if you made any changes.

See [Automatic Injection of the JavaScript Agent](#) for information about creating and enabling injection rules.

Verify Assisted Injection is Enabled

To verify that assisted attribute injection is enabled:

1. Open the business application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration > JavaScript Agent Injection**.
3. From **Inject the JavaScript Agent configured for this Browser App**, confirm that your browser app receiving the automatic injection is selected.
4. Select the Configure JavaScript Injection tab.
5. Confirm that the **Request Attribute Injection** is checked.
6. Click **Save** if you made any changes.

To verify that assisted injection using injection rules is enabled:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

1. Open the business application that is injecting the JavaScript Agent.
2. Click **Configuration > User Experience App Integration > JavaScript Agent Injection**.
3. From **Inject the JavaScript Agent configured for this Browser App**, confirm that your browser app receiving the automatic injection is selected.
4. Select the Configure JavaScript Injection tab.
5. Confirm that there are enabled injection rules in the table under **Create Injection Rules**.
6. From the Where to Inject JavaScript tab, confirm that the rules are correct.
7. From the Inject for these Business Transactions tab, confirm that the rules are applied for the desired business transactions.
8. Click **Save** if you made any changes.

See [Assisted Injection](#) for information about creating and enabling injection rules.

Change Your Injection Strategy

If you try one way to inject the JavaScript Agent and it does not work, it is best to undo the current injection configuration before implementing another one.

- To undo automatic injection, clear the **Enable Automatic Injection of JavaScript** check box.
- To undo assisted injection using attribute injection, clear the **Request Attribute Injection** check box, and manually delete the code snippets.
- To undo manual injection, manually delete the JavaScript Agent code from your web pages.
- To undo assisted injection using injection rules, clear the **Enable** check box for each injection rule in the injection rules list.

If multiple copies of the agent exist on a page, the second copy does not execute.

Fix Page Rendering Issues

The rendering of pages in some browsers, in particular, Internet Explorer (IE), may be adversely affected by the JavaScript Agent injection.

After you have confirmed that the JavaScript Agent injection is causing the issue, try the following:

1. [Inject the JavaScript Agent after the last `<meta>` element](#).
2. [Inject the JavaScript Agent just before the closing `<head>` element](#).

If you are using automatic injection, see [Troubleshoot Automatic Injection](#).

Injecting the JavaScript Agent just before the closing `<head>` tag is *not* the recommended practice because the JavaScript Agent will not capture the resource timing metrics for resources loaded before it. Thus, only do this as a last resort.

Inject After Last Meta Element

To avoid rendering issues and capture resource timing metrics, you are recommended to inject the JavaScript injection right after the last `<meta>` element in the `<head>` as shown below.

```
<head>
  <meta charset="UTF-8">
  <meta name="description" content="Fancy Web Page">
```

```

<meta name="keywords" content="HTML,CSS,XML,JavaScript">
<meta name="author" content="John Doe">
<meta name="viewport" content="width=device-width, initial-scale=1.0">

// Injection of the JavaScript Agent after the last <meta> tag
<script charset='UTF-8'>
  window['adrum-start-time'] = new Date().getTime();
  (function(config){
    config.appKey = 'SH-AAB-AAC-XAR';
    config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';
    config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
    config.beaconUrlHttp = 'http://eum-col.appdynamics.com';
    config.beaconUrlHttps = 'https://eum-col.appdynamics.com';
    config.xd = {enable : false};
  })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8' />
// The rest of the JS and CSS files
<script src="https://code.jquery.com/jquery-<version>.js" integrity="sha256-DZAnKJ/6XZ9si04Hgrsxu/8s717jciZLy3oi35EouyE=" crossorigin="anonymous"></script>
<script src="js/custom-script.js"></script>
<link type="text/css" rel="stylesheet" href="css/custom-style.css" />
...
</head>

```

Inject Before the Closing Head Element

On rare occasions, some browsers, in particular, Internet Explorer (IE), will still render the page incorrectly because of where the JavaScript Agent is injected. In such cases, as a last resort, try injecting the JavaScript Agent right before the closing `<head>` element:

```

<head>
  <meta charset="UTF-8">
  <meta name="description" content="Fancy Web Page">
  <meta name="keywords" content="HTML,CSS,XML,JavaScript">
  <meta name="author" content="John Doe">
  <meta name="viewport" content="width=device-width, initial-scale=1.0">
  <script src="https://code.jquery.com/jquery-<version>.js" integrity="sha256-DZAnKJ/6XZ9si04Hgrsxu/8s717jciZLy3oi35EouyE=" crossorigin="anonymous"></script>
  <script src="js/custom-script.js"></script>
  <link type="text/css" rel="stylesheet" href="css/custom-style.css" />
  ...
  // Injection of the JavaScript Agent before the closing <head> tag
  <script charset='UTF-8'>
    window['adrum-start-time'] = new Date().getTime();
    (function(config){
      config.appKey = 'SH-AAB-AAC-XAR';
      config.adrumExtUrlHttp = 'http://cdn.appdynamics.com';

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
    config.adrumExtUrlHttps = 'https://cdn.appdynamics.com';
    config.beaconUrlHttp = 'http://eum-col.appdynamics.com';
    config.beaconUrlHttps = 'https://eum-col.appdynamics.com';
    config.xd = {enable : false};
  })(window['adrum-config'] || (window['adrum-config'] = {}));
</script>
<script src='//cdn.appdynamics.com/adrum/adrum-latest.js' type='text/javascript' charset='UTF-8' />
</head>
```

Troubleshoot Automatic Injection Issues

If you are using the .NET Agent to automatically inject the JavaScript Agent into pages and the pages are not rendering correctly:

1. Use manual injection and make sure that the JavaScript Agent is injected after the last <meta> element.
2. If you cannot use manual injection, [add the registered node property](#) `eum-header-beforeendofheadtag` to a Web tier or particular nodes. This node property configures the .NET Agent in the specified tier or nodes to inject the JavaScript Agent right before the closing <head> tag.

Browser Snapshot Problems

This page provides help with troubleshooting problems with browser snapshots.

No Browser Snapshots

If you do not see any browser snapshots, it is possible that browser snapshot collection has been disabled. If periodic collection and error collection and slow collection are all disabled, the agent does not collect any browser snapshots. See [Configure Browser Snapshot Collection](#).

Also, check the thresholds that define slow end-user experience. AppDynamics collects browser snapshots only for slow-performing requests, so if the thresholds are set too high, no requests are flagged as slow. See [Configure Browser RUM Performance Thresholds](#).

No Correlation between Browser Snapshots and Business Transactions

You get server-side correlation with browser snapshots only if the business transactions associated with the browser snapshot are running on application servers instrumented with AppDynamics app agents. This could explain why you do not see any or do not see all of the business transactions that you expect to see. Check which of your servers are instrumented by app agents and which are not. You may need to get more AppDynamics app agent licenses to get correlation.

If the app servers are all instrumented with AppDynamics app agents, it is possible that the business transactions that you expect to see were not injected with the JavaScript Agent for Browser Monitoring. This can happen when automatic injection is used with a limited set of business transactions enabled for injection. If you used automatic injection, check your automatic injection configuration to see if the missing business transactions are enabled for injection. See [Verifying that the JavaScript Agent for Browser RUM was injected](#) and [Automatic Injection of the JavaScript Agent](#). Business transactions can also be excluded with assisted injection using injection rules when an injection rule specifies only certain business transactions to be injected. If you used assisted injection with injection rules, check your injection rules. See [Assisted Injection](#).

No Transaction Snapshots Associated with Browser Snapshots

Even if all your app servers are instrumented with AppDynamics app agents, it is possible that no associated transaction snapshots were captured at the time of the browser snapshot. For example, if no transactions were slow at the time of the browser snapshot, you probably will not see any transaction snapshots. See [Transaction Snapshots](#) for information about when transaction snapshots are captured. You can modify transaction snapshot capture.

On the browser side, if a browser snapshot is associated with a transaction snapshot, you will see it in the **Transaction Snapshots** section of the browser snapshots. See [Business Transactions in Browser Snapshots](#). On the server side, if a transaction snapshot is associated with a browser snapshot, you will see an EUEM GUID in the **ADDITIONAL DATA** tab in the transaction snapshot. See [Transaction Snapshots](#).

Not Getting Full Timing Data for Business Transactions Associated with Browser Snapshots

To ensure full business transaction timing information using older agents and controllers (3.8 and before), you need to inject the JavaScript footer for Browser RUM into the footer of your web pages. Manual

injection of the agent does not inject into the footer, so you need to use another injection method to get this functionality.

See [Getting Full Timing Data for Associated Business Transactions](#) and [Choosing Your Injection Method](#).

No Correlation between Cross Domain AJAX Requests and Business Transactions

Your JavaScript Agent may not be able to correlate Ajax requests with business transactions because browsers restrict access to certain HTTP response headers. Your application, however, can explicitly give browsers access to HTTP headers by sending the HTTP response header `Access-Control-Expose-Headers` with a list of the headers that you want the JavaScript Agent to access.

The process of correlating cross-domain Ajax requests and business transactions consists of the following two steps:

1. Set the agent, tier, or application node property `always-add-eum-metadata-in-http-headers` to `true`. If this property doesn't exist, you need to add and register it as described in [Add a Registered Node Property](#).
2. Modify the application code, so that the returned response header includes the field `Access-Control-Expose-Headers` as shown below:

```
Access-Control-Expose-Headers:
ADNUM_0,ADNUM_1,ADNUM_2,ADNUM_3,ADNUM_4,ADNUM_5,ADNUM_6,ADNUM_7,ADNUM_8,ADNUM_9,ADNUM_10,
ADNUM_11,ADNUM_12,ADNUM_13,ADNUM_14,ADNUM_15,ADNUM_16,ADNUM_17,ADNUM_18
```

Connection Problems

If your browser cannot connect to the AppDynamics EUM cloud and you use an on-premises Controller, but not an on-premises EUM Server, it is possible that:

- You have no Internet connectivity
- A firewall is blocking the port

Verify Connectivity

Navigate to [SaaS Domains](#) and select your geolocation. Find the EUM API Domain and add the following endpoint: `eumaggregator/ping`

If you receive a "ping" in the panel, you should be able to connect to the EUM Cloud.

- i** If you are using IE on a Windows system, make sure the browser itself does not have a proxy (with authentication) set up. If it does, the test link may work but not the actual connection.

Make sure you have also unblocked any firewalls and verified the keystore entries.

Unblock Your Firewall

The Controller needs to be able to use HTTP over SSL (HTTPS) on port 443 to reach the EUM Cloud Aggregator in your region.

Navigate to [SaaS Domains](#) and select your geolocation. Find the EUM API Domain and add the following endpoint: `eumaggregator/ping`

If your Controller is behind a firewall, you can either open your Controller's firewall or use a forward proxy. To open the firewall, see the instructions unique to your firewall.

- i** You only need to open the firewall for the specific host and port, not for the entire `*.eum-appdynamics.com` domain.

Use a Forward Proxy:

1. Set up an HTTP proxy to your SaaS EUM API Server. Navigate to [SaaS Domains](#) and select your geolocation. Find the EUM API Domain and add the following endpoint: `eumaggregator/ping`

- i** This is a cleartext/pass-through proxy. Authentication is not supported on the first level. If the client network itself requires authentication, you must set up an intermediate proxy between your Controller and this proxy to pass on the credentials you need to get out of your network.

2. Configure the HTTP proxy host and port in the `<Controller-Installation-Directory>/appserver/glassfish/domains/domain1/config/domain.xml` file by adding the following JVM options to the existing `java-config` element:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
<jvm-options>  
  -Dappdynamics.controller.http.proxyHost=myhost  
</jvm-options>  
<jvm-options>  
  -Dappdynamics.controller.http.proxyPort=8888  
</jvm-options>
```

3. Restart the Controller's app server.

JavaScript Errors

This page provides helpful tips for finding and solving common JavaScript errors.

Enable Error Reporting

It is possible that reporting is disabled or that certain JavaScript or Ajax errors that you would like to be reported have been configured to be ignored. See [Configure JavaScript and Ajax Error Detection](#).

If another script on your monitored pages sets the JavaScript `window.onerror` event, this setting can interfere with Browser RUM error capture. See [Handle the window.onerror Event](#).

Visualize JavaScript Errors

You can use Analytics to query your Browser Request event data and create a JavaScript exception and error summary dashboard.

See [Visualize JavaScript Errors](#).

View Error Information for Cross-Domain JavaScript

By default and for security reasons, most modern browsers do not provide access to the error information in `window.onerror` for scripts that are loaded from other domains. To access this error information, you need to enable [cross-origin resource sharing \(CORS\)](#). Firefox and Chrome both allow you to enable CORS by making small changes to your server and `script` element in your HTML.

If you have **not** enabled CORS, the error message "CROSSORIGIN" displays:

JavaScript Errors

Script Origin	Line #	Message
CROSSORIGIN	0	Script error

Once CORS is enabled, you will be able to see error details like those shown here.

Also, when you can navigate to your page from Chrome and then open **JavaScript Console > Network > Headers**, you'll see the HTTP response header `access-control-allow-origin: *`.

In the following sections, we're going to show you how to make changes to access the error information in `window.onerror` cross-domain scripts.

Server Change

To [enable CORS](#), you need to add this header to responses that are not from the same domain as the caller:

```
Access-Control-Allow-Origin: *
```

Script Tag Change

The `script` element has a new non-standard attribute called `crossorigin`. The most secure value for `crossorigin` would be `anonymous`. So, you'll have to modify your script tags to look like the following.

```
<script src="http://sub.domain.com/adrum.js" crossorigin="anonymous"></script>
```

Browser Support for CORS

In the future, we expect most browsers to enable CORS. Internet Explorer 10+ already has native support for CORS and reports errors to `window.onerror` for both local and cross-domain scripts. See [CORS: Browser support](#) to see a list of browsers/layout engines that support CORS.

Mobile Real User Monitoring

Related pages:

- [Set Up and Access Mobile RUM](#)

Mobile Real User Monitoring (Mobile RUM) allows you to understand your native iOS, Android, Xamarin, Cordova-based, or React Native mobile application as your end users actually use it.

It provides you with visibility into the functioning of the application itself and the application's interactions with the network it uses and any server-side applications it may talk to. This page introduces Mobile RUM.

Benefits of Mobile RUM

With Mobile RUM, you can:

- Understand and improve your mobile application's performance
 - Know when your application is slow because of networking problems. See [Network Requests List](#).
 - Determine whether a request is slow because of your servers or because of the network connection. See [Network Request Dashboard](#).
 - Trace an individual request from the initial user action in the mobile application through the associated business transaction(s) on the application server(s). See [Network Request Snapshots](#).
 - Estimate the network performance you can expect for different requests, carriers, devices, and geographies by viewing current metrics. See **Usage Stats** in [Mobile App Dashboard](#).
 - Detect slow UI issues known as "application not responding" (ANR). You can track ANRs in the [Code Issues Dashboard](#), identify [sessions where ANRs occurred](#), and [configure ANR thresholds](#) to define severity levels.
- Reduce crashes
 - Observe when your application crashes and what caused each crash. See [Crash Analyze](#) and [Crash Snapshots](#).
 - Learn which environments experience the most crashes. See [Crash Dashboard](#).
- Reduce errors
 - Observe how many network errors occur and which requests caused them. See [Network Requests List](#) and [Network Request Dashboard](#).
 - Capture errors and exceptions from your mobile applications, so that they are displayed in the [Code Issues Dashboard](#) and the [session records and details](#). To learn how to use the SDKs to report errors, see [Report and Exceptions \(iOS/Android\)](#).
- Learn about your users
 - Learn which devices and technologies most of your users are running. See **Usage Stats** in [Mobile App Dashboard](#) and [Crash Dashboard](#).
 - View where your users are located in the world. See **Geo Dashboard** in [Mobile App Dashboard](#).
 - Understand how users are navigating through your application and what actions they are taking. See [Mobile Sessions](#).
 - Capture user interactions with your mobile application such as button clicks and when text is edited. See "Enable User Interaction Capture Mode" ([iOS/Android](#)) to learn how.
- Customize the data that Mobile RUM returns
 - Create new metrics and timers. See [Customize the iOS Instrumentation](#), [Customize the Android Instrumentation](#), [Customize the Xamarin Instrumentation](#), and [Customize the Cordova Instrumentation](#).
 - Collect diagnostic data from your executing code via information points. See [Customize the iOS Instrumentation](#), [Customize the Android Instrumentation](#), [Customize the Xamarin Instrumentation](#), and [Customize the Cordova Instrumentation](#).

How It Works

To use Mobile RUM, you add a small piece of highly performant code, the Mobile Agent, to the source of your mobile application. This process is called *instrumenting* and is described in [Instrument iOS](#)

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

[Applications](#), [Instrument Android Applications](#), [Instrument Xamarin Applications](#), [Instrument Cordova Applications](#), and [Instrument React Native Applications](#).

As your end users interact with your application, the agent collects [metrics and any error information](#) on the application's performance and sends that information to the EUM Server, where it is processed. The EUM Server then makes the data available to the AppDynamics controller UI, where it is displayed in a series of dashboards and charts.

If your application crashes, the agent also creates a *crash snapshot* with information to help you analyze what happened, including the crashed function, the source file containing the crashed function, the line number, if available, and a stack trace of the application at the time of the crash, along with various other identifying data. And if the server-side application with which your mobile app interacts is also instrumented, you can get correlated metric information for the entire round-trip request life cycle.

Data Collection

When the agent detects that something of interest has occurred in the application, it collects data describing that event and stores it in a local buffer. Typically, this data consists of approximately 200-400 bytes per event. The agent periodically flushes this local buffer by sending the events in the buffer to the EUM Server in a request called a beacon. To minimize power consumption, the agent schedules these flushes, if possible, when the application is using the network.

If a network connection to the EUM Server is not available, the agent deletes older events to prevent unbounded growth in the buffer. The maximum size of the buffer is 200 events.

If the EUM Server is unavailable for extended periods of time, the agent may delete older data to prevent unbounded growth in the buffer.

License and Enable Mobile RUM

- Mobile RUM requires a separate license from that of your application server. For information about licensing, see [License Entitlements and Restrictions](#).
- For information on enabling or disabling Mobile RUM monitoring, see [Enable Mobile RUM on Your Controller](#).

AppDynamics Mobile RUM allows you to investigate the performance of your mobile application. [AppDynamics Mobile App](#) allows you to monitor your Controller from your mobile device.

Configure the Controller UI for Mobile RUM

Using the Controller UI, you can configure:

- [How to rename mobile requests](#)
- [Thresholds that cause network request snapshots to be considered slow, very slow or stalled](#)
- [Percentile levels to display, if any](#)
- [Which network requests are sent to the Event Service](#)
- [If the IP address from which the request comes should be stored](#)

To configure Mobile RUM from the Controller UI, your user account must belong to a role that has the **Configure EUM** permission. See [End User Monitoring Permissions](#).

Access the Mobile Container Configuration

To access mobile request configuration:

1. Open the mobile application in which you are interested.
2. From the left-hand navigation menu, click **Configuration**.
3. From the **Configuration** page, click **Mobile App Group Configuration >**.

Configure Application Not Responding Thresholds

The Mobile Agent uses configurable thresholds to set the severity level for application-not-responding (ANR) errors. The severity levels for ANRs are **warning** and **critical**, and these levels can be used to set health rules and receive alerts for health rule violations.

You can use Controller UI to configure thresholds for warning and critical severity levels. These thresholds will be propagated to the Mobile Agents without the need to redeploy the application.

Default Network Request Thresholds

The Mobile Agent uses the following default values to determine the severity level:

- **Warning:** greater than 3000 ms
- **Critical:** greater than 5000 ms

You should set custom thresholds best suited for your mobile applications.

Configure Application Not Responding Thresholds

1. From the **Mobile App Group Configuration** page, click the Settings tab.
2. In the **Configure Application Not Responding Thresholds** section, set the thresholds for **Warning Threshold** and **Critical Threshold** in milliseconds.
3. Click **Save**.

Configure Mobile Crash Alerts

New [crashes](#) are shown in the **Events** widget, and you can configure Mobile RUM to send you alerts when new crashes occur. See [Crash Alerts](#).

To restrict the number of alerts for new crashes, follow these instructions configure the number of crashes that must occur before you are alerted.

Access Configure Mobile Crash Alerts

1. Open the mobile application in which you are interested.
2. On the left navigation bar, select **Configuration**.
3. Click **Mobile App Group Configuration >**.
4. Select the Settings tab.
5. Navigate to the **Configure Mobile Crash Alerts** section.

Set Threshold for New Crash Alerts

From **Configure Mobile Crash Alerts**:

1. Set the threshold for new crash alerts. The default value is 1.
2. Click **Save**.

Configure Mobile Network Request Naming

This page describes how to modify the default naming configuration for [network requests](#) and create include/exclude naming rules for network requests.

i If you create a rule for capturing mobile network requests and later disable the rule, the URLs that were formerly captured by the rule will be displayed with the network request name "/" unless you have another rule that captures the URL. To avoid this from occurring, you can create a custom rule that serves as a catch-all for URLs that are not captured by custom rules. See [Network Request Limits](#).

Default Network Request Naming Configuration

By default, AppDynamics names network requests using:

- Hostname
- First two segments of the URL

For example, if an application makes this HTTP request:

```
http://myapp.com/friends/profiles/12345
```

The default name that is displayed in the Controller UI for that request is:

```
myapp.com/friends/profiles
```

If this is adequate for your needs, you can leave the default setting.

i The naming rules you configure here apply to all the mobile applications that are in the same Mobile App Group.

Modify the Default Naming Configuration Rule

You may want to configure a different default rule for naming your network requests to help you visualize the parts of your application more clearly. The task is similar to configuring naming rules for business transactions on the server side. Try to group logically related requests together while keeping unrelated requests in separate groups.

- If the default hostname and first two segments of the URL for all your requests are identical, you might want to name the requests based on the last segments or a selection of non-contiguous segments of the URL to distinguish among requests in the network requests list.
- You can also name the requests based on query parameters. For example, if the request passes an order number, you could specify that the value of the `order-number` query parameter is used in the network request name.
- You can also base the name on a regular expression run on the URL. AppDynamics uses the Java libraries for regular expressions. See:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- Tutorial: <http://download.oracle.com/javase/tutorial/essential/regex/index.html>
- Javadoc: <http://download.oracle.com/javase/1.5.0/docs/api/java/util/regex/Pattern.html>

Modify the Default Network Request Naming Rule

The default configuration covers how all your requests are named if you do not customize them further.

1. From the **Network Request** tab, scroll down to the **Include Rules** section.
2. Double-click **Default Naming Configuration**.
3. In the **Include Rule** dialog, select the elements you want to use for your default network request naming.
4. Click **OK**.
5. Click **Save**.

Create Mobile Include Rules

By default, the same request naming rule is applied to every URL that your application requests. If you want to apply different naming rules to different URLs, create include rules.

For example, if some requests call your own in-house server and others call out to a third-party API, you may want to see all the third-party API calls as one network request and use the default naming rules for the calls to your own server. You would create a custom naming rule that matches the third party calls and uses only the host in the default rule name or perhaps also include certain query parameters.

Create an Include Rule

1. From the **Network Request** tab, scroll down to the **Include Rules** section.
2. Click **Add**.
3. In the **Include Rule** dialog, enter a name for the custom rule that you are creating.
4. Check the **Enabled** check box to enable the rule.
5. Select the check boxes and radio buttons and enter the match criteria for AppDynamics to use to name network requests.
6. Click **OK**.

Guidelines for Using Regular Expressions in Mobile Include Rules

When using regular expressions to match URLs in your include rules, you should note the following:

- URL strings are case-sensitive. So, although the page names displayed in the [Network Request Dashboard](#) are converted to lowercase, your regular expressions still need to match the case used in URLs that your include rule are trying to capture.
- Your regular expression should match the entire URL, from beginning to end, not just a section; otherwise, the rule will not match. This differs from using regular expressions in [custom match rules for naming transactions](#), which only need to match sections of the URL.

Sample Include Rule

The following rule creates a custom match rule for requests in which the URL contains "ourpartner.com". This rule uses the protocol, the subdomain and the third and fourth segments of the URL in the network request name.

Include Rule
✕

Enabled

Rule Name

Criteria
 This Include Rule applies to any URL that Contains

Name Network Requests
using parts of the URL

Show Protocol (Ex: http, https, etc)
 Show Domain (Ex: mywebsite.com)
 Show Full Domain Show Sub-domain

Path Segments
 Don't use path segments
 Use first segments
 Use last segments
 Use segment numbers

Query String Parameters to use in Network Request Name (Optional)

What part of anchor should be used in Network Request Name
 Don't use the anchor
 Use first segments
 Use last segments
 Use segment numbers

Cancel
OK

You can temporarily cancel the application of a custom naming rule by clearing the **Enabled** checkbox in the custom rule configuration. In this case, the default naming rule is applied to requests that would have been named by the disabled custom rule. To remove the rule permanently, select the custom rule in the **Custom Naming Rules** list and click the **Delete** icon.

Create Mobile Exclude Rules

If there are certain types of requests that you do not want to monitor, create custom exclude rules for them based on the URL and/or the application name. Excluded network requests are not reported or counted toward the network request limit of 500 requests per controller application.

Create an Exclude Rule

1. From the Network Request tab, scroll down to the **Exclude Rules** section.
2. Click **Add**.
3. In the **Exclude Rule** dialog, enter a name for the exclude rule that you are creating.
4. Check the **Enabled** check box to enable the rule.
5. Select the check boxes and radio buttons and enter the match criteria for AppDynamics to use to name network requests.
6. Click **OK**.

You can temporarily cancel the application of an exclude rule by clearing the **Enabled** checkbox in the exclude rule configuration. To remove the rule permanently, select the exclude rule in the **Exclude Rules** list and click the **Delete** icon.

Change Priority of Rules

Rules are evaluated in the order that they appear in the include or exclude list. You can change the priority of the rules by dragging and dropping rules towards the top (higher priority) or towards the bottom of the list (lower priority). Custom rules are always evaluated before the default naming rule, beginning with the custom rule that has the highest priority.

Configure Mobile Network Request Thresholds

Related pages:

- [Network Request Limits](#)
- [Network Requests](#)

The Mobile Agent uses configurable thresholds to determine whether network request time is normal, slow, very slow or stalled. It uses these thresholds:

- To decide whether to create a mobile request snapshot
- For labeling network request experience in a network request snapshot

Default Network Request Thresholds

By default, the Mobile Agent uses these default values to determine whether a request is slow or stalled:

- **Slow:** Greater than 3 standard deviations
- **Very slow:** Greater than 4 standard deviations
- **Stall:** Greater than 45000 ms

You should configure these defaults to conform to your own criteria for your mobile applications. An absolute threshold rather than one based on the standard deviation is often more appropriate for mobile applications.

Configure Network Request Thresholds

1. From the **Mobile App Group Configuration** page, click the Settings tab.
2. In the **Thresholds for Slow End User Experience** section, set the thresholds for slow, very slow, and stalled in milliseconds or by standard deviations.
3. Click **Save**.

Configure Mobile Percentile Metrics

Parts of the Controller UI for Mobile RUM rely on the processing done by the Events Service, including some of the widgets in the **Mobile App Dashboard Overview**, **Network Requests Analyze**, and **Crash Analyze**.

For the **Mobile App Dashboard**, **Network Requests Analyze**, and **Crash Analyze**, you can choose widgets to display the metrics collected using either averages or percentiles.

A *percentile* is a measure that indicates a value below which a given percentage of values in a set falls: for example, the 99th percentile means that 99% of all values are below this level.

Using percentiles can be a good way to reduce the impact of extreme outliers in performance metrics, which can be useful in the often noisy environments of end-user experience monitoring. Percentiles also display in the **Metric Browser**.

You can:

- Enable or disable percentile display of metrics.
- Set up to four different percentile levels to be applied to metrics.

Access Configure Percentile Metrics

From the **Configuration > Mobile App Group Configuration**, click the Settings tab and navigate to the **Configure Percentile Metrics** section.

Configure Percentile Metrics

You can change the percentiles which are used to evaluate data via the Events Service.

1. Check the box to enable percentile metric display.
2. Add up to four percentile levels to collect. Each value must be a whole number between 1 and 99.

i If you change the percentiles to collect new values, it takes time for the recalculation to occur. If you review the **Metric Browser**, you will see metrics based on the old percentiles until the moment that you update the values, when they change to reflect the change.

Configure Request IP Address Storage - Mobile

Related pages:

- [Network Request Limits](#)
- [Network Requests](#)

For security and privacy reasons, Mobile RUM does not store source IP addresses associated with network requests.

To have Mobile RUM store source IP addresses associated with network requests, following the instructions below.

1. From the **Mobile App Group Configuration** page, select the Settings tab.
2. Click the **Mobile Network Request Naming, Thresholds & Percentiles** tab.
3. Check the **Store IP Address** checkbox to enable IP address storage. (By default, the box is not checked.)

Store IP Address ⓘ

Save

4. Click **Save**.

Configure Session Monitoring

Sessions begin when a user starts using your application and ends after a configurable period of user inactivity. Increasing the period of user inactivity enables sessions to capture more user events, but this could impact the [session limits](#) of your account. See [Mobile Sessions](#).

Access Session Monitoring

1. Open the mobile application in which you are interested.
2. From the left-hand navigation menu, select **Configuration**.
3. Click **Mobile App Group Configuration >**.
4. Select the Settings tab.
5. Find the **Configure Session Monitoring** section.

Set Inactivity Timeout

From **Configure Session Monitoring**:

1. Set the number of minutes for the **Session Inactivity Timeout** field.
2. Click **Save**.

Configure Which Network Requests Are Sent to the Event Service

Related pages:

- [Network Request Limits](#)

Your mobile app may make various kinds of [network requests](#), and not all of them may be equally important to monitor in detail. For example, any requests to [Google Analytics](#) that your app may make are useful but probably aren't as important to analyze as the requests it makes to your backend.

To manage the impact on your overall Event Service usage, you can create rules which specify which of these network requests should be sent on to the Event Service, either by excluding a request entirely, including a particular request or a sample of that request types by percentage, or by simply allowing the request to be sent on.

The behavior follows this pattern:

- If no rules are specified, data on all network requests are sent on.
- If exclude rules are specified, and a network request satisfies a rule, that data is *not* sent on.
- If include rules are specified, any network request that satisfies a rule is sent on, based on sampling defined by the percentage indicated in the rule.
- If both include and exclude rules are specified, a network request that satisfies an include rule but does *not* satisfy an exclude rule is sent on.

Access Network Requests Rules

From the **Mobile App Group Configuration** page, select the Event Service tab.

Configure Include Rules

1. Click **Add** to create a new rule. The **Include Rule** popup displays.

2. Give your rule a display name.
3. Check **Enabled** to place the rule in force.
4. Specify the Network Request **URL** using any of the options in the dropdown.
5. If you want to sample this request type, select a percentage for sampling.
6. Click **OK**.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Configure Exclude Rules

1. Click **Add** to create a new rule. The **Exclude Rule** popup displays.

2. Specify a display name for the rule.
3. Check **Enabled** to place the rule in force.
4. Specify the Network Request **URL** using any of the options in the dropdown.
5. Specify the percentage of URLs to sample.
6. Click **OK**.

Change Priority of Rules

Rules are evaluated in the order that they appear in the include or exclude list. You can change the priority of the rules by dragging and dropping rules towards the top (higher priority) or towards the bottom of the list (lower priority). Custom rules are always evaluated before the default naming rule, beginning with the custom rule that has the highest priority.

Correlate Business Transactions for Mobile RUM

Related pages:

- [Correlate Business Transactions for EUM](#)
- [Business Transactions](#)

You can correlate mobile network requests with business transactions. In actuality, the correlation is made between instances of network requests (network request snapshots) and instances of business transactions (transaction snapshots).

Mobile Network Requests Correlation

When an end user takes an action with your mobile application that requires a network request:

1. The App Agent:
 - Sends HTTP headers identifying the business transaction to the end user's mobile device.
 - Aggregates backend metrics and sends them along with the business transaction identifiers to the Controller. This serves as the content for the transaction snapshot.
2. The Mobile Agent sends metrics and the business transaction identifiers (from the HTTP header) to the EUM Server. This serves as the content for the network request snapshot.
3. The Controller fetches the metrics and business transaction identifiers from the EUM Server. Using the business transaction identifiers, the Controller correlates the network request snapshot with the transaction snapshots.

View Business Transactions Correlated with Mobile Applications

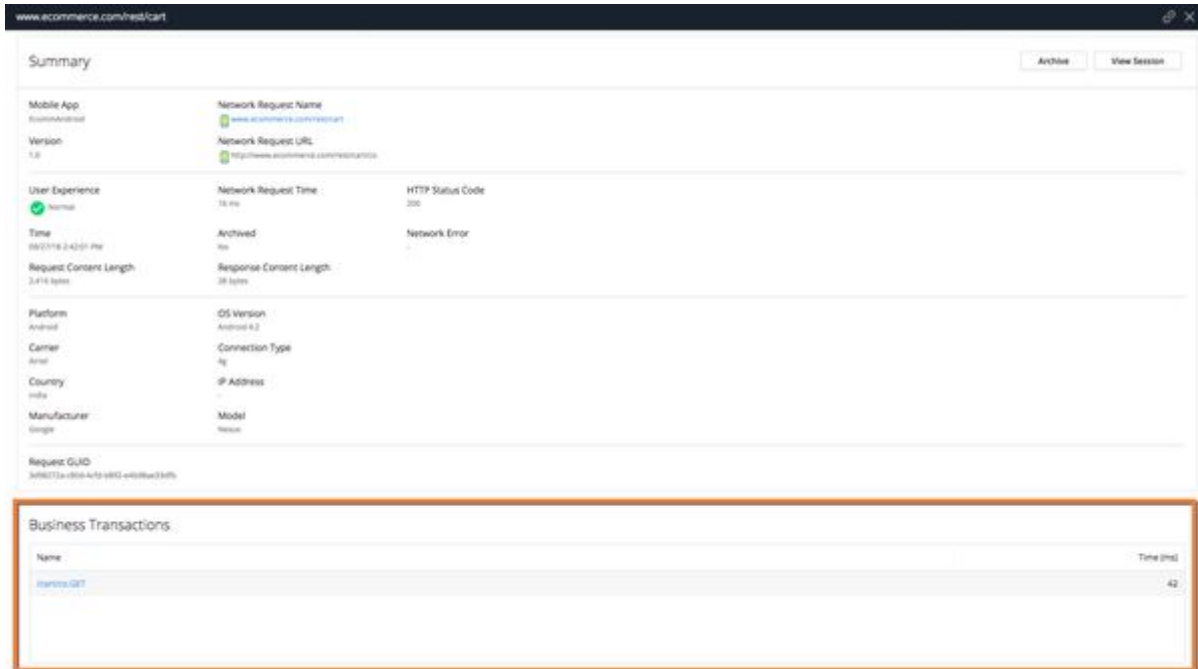

There are several ways to navigate from a mobile network request snapshot to its correlated business transaction. This procedure provides a sample navigation:

1. From the **Mobile App Dashboard**, click **Network Requests**.
2. Click **Snapshots**.
3. You should now see network transaction snapshots:

	Timestamp	Mobile App Version	Network Request Name	Network Request Time (ms)	Device / Manufacturer	Model	OS Version	HTTP Status Code	Network Error
✓	09/27/18 2:42:01 ...	1.0	www.ecommerce.com/hesst/cart	16	Google	Nexus	Android 4.2	200	
✓	09/27/18 2:30:01 ...	2.1	www.ecommerce.com/hesst/cart	1,008	Amazon	Kindle Fire	Android 2.3	200	
✓	09/27/18 2:29:02 ...	2.1	www.ecommerce.com/hesst/cart	14	Google	Nexus	Android 4.1	200	
✓	09/27/18 1:22:11 ...	2.0	www.ecommerce.com/hesst/ta...	3,169	Samsung	Galaxy Nexus	Android 2.3	200	
⚠	09/27/18 1:12:24 ...	2.1	www.ecommerce.com/hesst/user	24	Samsung	Galaxy Nexus	Android 2.3	200	
✓	09/27/18 12:52:09...	1.0	www.ecommerce.com/hesst/user	17	Amazon	Kindle Fire	Android 4.1	200	
✓	09/27/18 12:14:07...	1.0	www.ecommerce.com/hesst/ta...	3,219	Amazon	Kindle Fire	Android 4.1	200	

4. Double-click one of the browser snapshots to open the **Network Request Snapshot Details** dialog. If a correlated transaction snapshot exists, a link displays in the **Business Transactions** section:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

5. You can then click links in the transaction snapshot or transaction snapshot itself to view corresponding pages in APM.

Instrument iOS Applications

 With the iOS 14 release (supported by iOS Agent 20.10.0), Apple introduced a new data collection policy. See [iOS Data Collection Disclosure](#).

Before you can monitor your iOS application, you will need to instrument your application to enable the iOS Agent to collect mobile metrics.

After you have [set up and accessed Mobile RUM](#), follow these instructions:

1. [Install the iOS SDK](#)
2. [Instrument an iOS Application](#)
3. [Customize the iOS Instrumentation \(Optional\)](#)
4. [Troubleshoot the iOS Instrumentation \(Optional\)](#)

Install the iOS SDK

Related pages:

- [Instrument an iOS Application](#)
- [Customize the iOS Instrumentation](#)
- [Troubleshoot the iOS Instrumentation](#)

i With the iOS 14 release (supported by iOS Agent 20.10.0), Apple introduced a new data collection policy. See [iOS Data Collection Disclosure](#) for details.

You can install the iOS SDK using CocoaPods or by manually downloading and installing it. We recommend that you use CocoaPods to install the iOS SDK because it handles the dependencies, the build settings, and simplifies [upgrading](#).

Follow the instructions for your preferred installation method:

- [CocoaPods Install](#)
- [Manual Install](#)

iOS SDK Install Requirements

To install the iOS SDK, you must be running Xcode ≥ 7 .

CocoaPods Install

1. Add the line below to a `target` block in your Podfile:

```
pod 'AppDynamicsAgent'
```

For example:

```
platform :ios, '8.0'
use_frameworks!

target 'YourApp' do
  pod 'AppDynamicsAgent'
end
```

2. In your project directory, run this command:

```
pod install
```

Manual Install

To manually install the iOS SDK, follow these steps:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- [Download the iOS SDK](#)
- [Add the Framework to the App](#)
- [Add Required Libraries](#)
- [Set the -ObjC Flag](#)

Download the iOS SDK

1. Navigate to the [AppDynamics Download page](#).
2. From the **APP AGENT** list, check the **Mobile RUM Agent - iOS** checkbox.
3. Click **Download** for the latest iOS Agent that will appear in the **Releases** results. This downloads a file named `iOSAgent-<version>.zip`.

Add the Framework to the App

 You can only use a Swift framework if that framework was built with the exact same version of Swift as the Xcode compiling your app.

1. Unzip `iOSAgent-<version>.zip`.
2. Import the `ADEUMInstrumentation.framework` (or `ADEUMInstrumentation.xcframework`) folder into your project Xcode.

 If you don't see that Xcode has automatically added the correct path(s), add a project-relative path to your frameworks.

Add Required Libraries

The AppDynamics iOS Agent requires these libraries:

- `SystemConfiguration.framework`
- `CoreTelephony.framework`
- `libz.dylib` or `.tbd`

To add the libraries:

1. Select the target that builds your app in Xcode.
2. Select the Build Phases tab.
3. Expand the **Link Binary With Libraries** section.
4. If any of the above libraries are not listed:
 - Click the **+** button.
 - Locate the missing library in the list.
 - Click **Add**.

Repeat this step for each missing library.

Set the -ObjC Flag

You also need to add the `-ObjC` flag to Other Linker Flags.

1. Select your project in the **Project Navigator**.
2. In the target list, select the target that builds your application.
3. Select the **Build Settings** tab.
4. Scroll to **Linking** and open.
5. Go to **Other Linker Flags** and double-click to open the popup.
6. If the `-ObjC` flag is not in your list, click **+** and add it.

The `-ObjC` flag is necessary because the iOS Agent defines categories with methods that can be called at runtime, and by default, these methods are not loaded by the linker. As a result, you'll get an "unrecognized selector" runtime exception. The use of `-ObjC` ensures the methods will be loaded.

Upgrade the iOS SDK

Upgrade with CocoaPods

1. In your project directory, run this command: `$ pod update`
2. Rebuild.

Upgrade Manually

To pick up new features or to get crucial bug fixes you want to upgrade the iOS SDK in your app.

1. [Download the updated SDK.](#)
2. [Replace the `.framework` file using the updated SDK.](#)
3. Rebuild your app.

Instrument an iOS Application

Follow these steps to get your EUM App Key and instrument your iOS apps.

- [Get Your Application Key](#)
- [Initialize the Agent](#)
- [Generate a dSYM File](#)
- [Monitor Crashes with the dSYM File](#)
- [Customize the Instrumentation \(Optional\)](#)
- [Configure the iOS Agent for On-Premises Deployments \(Optional\)](#)

Get Your Application Key

After you completed the **Getting Started Wizard**, you were given an EUM App Key. You will need this key when you modify the source code. In some cases, multiple mobile applications can share the same key.

If you have completed the **Getting Started Wizard**, but don't have your EUM App Key, see [Get Your Application Key](#).

Initialize the Agent

[Objective-C](#) [Swift](#) [Apple Watch Extensions](#)

Edit your app's `AppDelegate.m` file to initialize the Mobile Agent as soon as the app launches. This registers your application and only needs to be done once in your code.

1. In the `AppDelegate.m` file, add this `import` statement:

```
#import <ADEumInstrumentation/ADEumInstrumentation.h>
```

2. In the method `didFinishLaunchingWithOptions`, create an `ADEumAgentConfiguration` object with the EUM App Key that you received when completing the **Getting Started Wizard** to initialize the iOS Agent:

```
// Example EUM App Key: "AAA-AAB-AUM"
ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc]
initWithAppKey:<#EUM_APP_KEY#>];
```

Your code should look something like the following:

```
#import <ADEumInstrumentation/ADEumInstrumentation.h>
#import "AppDelegate.h"

// ...
-(BOOL)application:(UIApplication *)application didFinishLaunchingWithOptions:
(NSDictionary *)launchOptions
```

```

{
    // Example EUM App Key: "AAA-AAB-AUM"
    ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc]
initWithAppKey:<#EUM_APP_KEY#>];
    // other tasks
    return YES;
}

```

- Configure the iOS Agent to report metrics and screenshots to the [SaaS EUM Server in your region](#) and initialize the agent by passing the `ADEumAgentConfiguration` object to the method `initWithConfiguration`. (If you are using an on-premises EUM Server, see [Configure the iOS Agent for On-Prem Deployments \(Optional\)](#).)

```

#import <ADEumInstrumentation/ADEumInstrumentation.h>
#import "AppDelegate.h"

// ...
-(BOOL)application:(UIApplication *)application didFinishLaunchingWithOptions:
(NSDictionary *)launchOptions
{
    ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc]
initWithAppKey:<#EUM_APP_KEY#>];
    //The default SaaS EUM Server and Screenshot Service are in the Americas,
    // so you can omit the following settings if you are in the Americas.
    config.collectorURL = "https://<your_region>.eum-appdynamics.com";
    config.screenshotURL = "https://<you_region>-image.eum-appdynamics.com/";
    [ADEumInstrumentation initWithConfiguration: config];
    // other tasks
    return YES;
}

```

- (Optional) If your application is using another tool to report crashes, the iOS Agent may warn you with the following message:

```

Agent has detected a third party crash reporting tool. You may wish to disable
AppDynamics Crash Reporting by setting the crashReportingEnabled configuration flag to
NO

```

You are recommended to use only one crash reporting tool for better results. See [Disable Crash Reporting](#) for instructions on how to disable the iOS Agent's crash reporting.

- Save the file.

Objective-C [Swift](#) Apple Watch Extensions

The iOS Agent is compatible with applications created using the Swift programming language.

1. In your application's `AppDelegate` class, add this `import` statement:

```
import ADEumInstrumentation
```

2. In the `AppDelegate` class `didFinishLaunchingWithOptions`, create an `ADEumAgentConfiguration` object with the EUM App Key that you received when completing the **Getting Started Wizard** to initialize the iOS Agent:

```
#import <ADEumInstrumentation/ADEumInstrumentation.h>
#import "AppDelegate.h"

// ...
func application(_ application: UIApplication, didFinishLaunchingWithOptions
launchOptions: [UIApplication.LaunchOptionsKey: Any]?) -> Bool {
    let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>)
}

```

3. Configure the iOS Agent to report metrics and screenshots to the [SaaS EUM Server in your region](#), and initialize the agent by passing the `initWith()` method that takes the `ADEumAgentConfiguration` object as a parameter.

i If you are using an on-premises EUM Server, see [Configure the iOS Agent for On-Prem Deployments \(Optional\)](#).

```
#import <ADEumInstrumentation/ADEumInstrumentation.h>
#import "AppDelegate.h"

// ...
func application(_ application: UIApplication, didFinishLaunchingWithOptions
launchOptions: [UIApplication.LaunchOptionsKey: Any]?) -> Bool {
    let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>)
    config.collectorURL = "https://<your_region>.eum-appdynamics.com"
    config.screenshotURL = "https://<your_region>-image.eum-appdynamics.com"
    ADEumInstrumentation.initWith(config)
    // other tasks
    return true
}
// ...

```

4. (Optional) If your application is using another tool to report crashes, the iOS Agent will warn you with the following message:

Agent has detected a third party crash reporting tool. You may wish to disable AppDynamics Crash Reporting by setting the `crashReportingEnabled` configuration flag to NO

We recommend you use only one crash reporting tool for better results. See [Disable Crash Reporting](#) for instructions on how to disable the iOS Agent's crash reporting.

5. Save the file.

Objective-C Swift [Apple Watch Extensions](#)

Apps written for watchOS 1 contain a WatchKit extension that runs on the user's iPhone, but watchOS 2 also supports a new architecture, where the [WatchKit](#) extension runs on the Apple Watch itself. AppDynamics supports the watchOS 1 architecture, but not the new watchOS 2 architecture. Note that apps using the watchOS 1 architecture can run on both watchOS 1 and 2, so if your application is designed for watchOS 1, you can use AppDynamics on both versions of watchOS.

Because watchOS 1 apps are functionally launched in response to an interaction with the Watch UI, the SDK initialization code should be called at the point of that interaction in the iPhone app, which is usually not at the extension's `AppDelegate.m` call. The syntax remains the same.

Generate a dSYM File

To enable the agent to provide human-readable information in the crash snapshots that are produced if the application crashes, compile with the `DWARF with dSYM` file option to generate a debug symbols (dSYM) file for the application. For more details about why you would want to do this, see [Get Human-Readable Crash Snapshots](#).

1. In Xcode, select your project in the **Project Navigator**.
2. In the target list, select the target that builds your application.
3. Select the **Build Settings** tab.
4. In the **Build Options** section, make sure that the **Debug Information Format** is set to `DWARF with dSYM File`.
5. Rebuild the Xcode project.

Monitor Crashes with the dSYM File

This step is optional but highly recommended if you plan to monitor crashes. AppDynamics needs the dSYM file for the application to produce human-readable stack traces for crash snapshots.

For instructions, see [Upload the dSYM File](#).

Customize the Instrumentation (Optional)

The `ADEumInstrumentation` class has additional methods to allow you to extend the kinds of data you can collect and aggregate using AppDynamics. There are five basic kinds of extensions that you can create:

- Custom timers: any arbitrary sequence of events within your code timed, even spanning multiple methods
- Custom metrics: any integer-based data you wish to collect
- User data: any string key/value pair you think might be useful
- Information points: how often a single method is invoked, and how long it takes to run
- Breadcrumbs: context for a crash

See [Customize the iOS Instrumentation](#).

Configure the iOS Agent for On-Premises Deployments (Optional)

By default, the agent is configured to send its beacons to the EUM Cloud, which is an instance of the EUM Server running on AWS. If you wish to instrument your app in an environment that is using an on-premises version of the EUM Server, you need to modify the URL to which the agent sends its beacons. You do this using the `ADEumAgentConfiguration` object to set the Collector URL and the Screenshot Service URL to your on-premises EUM Server URL.

i The iOS Agent knows which path to use to make calls to different services (Collector/Screenshot Service). For example, if the EUM Server URL is `https://myEUMServerURL.com:7001`, the iOS Agent will know to use `https://myEUMServerURL.com:7001/eumcollector` to make requests to the EUM Collector. By specifying the Collector URL, you will *not* be able to use the SaaS deployment of the EUM Cloud for the Screenshot Service.

To get the EUM Server URL:

1. Open the [Administration Console](#).
2. From the left navigation bar, click **Controller Settings**.
3. In the search field, enter `eum.beacon.host` or `eum.beacon.https.host` if you're using HTTPS.
4. Copy the value for the configuration. This is your EUM Server URL.

The code examples below show how to set the Collector URL and Screenshot Service URL using Objective-C and Swift.

[Objective-C](#) [Swift](#)

```
ADEumAgentConfiguration *adeumAgentConfig = [[ADEumAgentConfiguration alloc]
initWithAppKey:<#EUM_APP_KEY#>];
// Set the Collector URL and Screenshot Service URL to the EUM Server URL.
adeumAgentConfig.collectorURL = <#COLLECTOR_URL:PORT#>;
adeumAgentConfig.screenshotURL = adeumAgentConfig.collectorURL;
[ADEumInstrumentation initWithConfiguration:adeumAgentConfig];
```

[Objective-C](#) [Swift](#)

```
let configuration = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>)
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
// Set the Collector URL and Screenshot Service URL to the EUM Server URL.  
config.collectorURL = <#COLLECTOR_URL:PORT#>  
config.screenshotURL = config.collectorURL  
ADEumInstrumentation.initWith(configuration)
```

Enable HTTP to Send Beacons to On-Premises EUM Servers

If you use an on-premises EUM Server and you wish to use HTTP to dispatch your beacons to the EUM Server, starting with iOS 9 you need to set a flag in your app's `info.plist` file to allow it to use the unsecured connection. By default, HTTPS is enforced in all iOS 9 applications by App Transport Security (ATS), and the iOS Agent complies with ATS when used with the EUM Cloud.

Customize the iOS Instrumentation

Related pages:

- [Install the iOS SDK](#)
- [Instrument an iOS Application](#)
- [iOS SDK Documentation](#)

Once you have [instrumented your iOS application](#) with the Mobile iOS SDK, you can also use the APIs exposed by the SDK to customize the data for your app that appears in the Controller UI.

The following sections show you how to use the iOS SDK to customize your instrumentation.

- [Collect Additional Types of Data](#)
- [Capture User Interactions](#)
- [Programmatically Take Screenshots](#)
- [Block and Unblock Screenshots](#)
- [Disable the Agent to Stop Sending User Data to the Collector](#)
- [Add a Crash Reporting Callback](#)
- [Disable Crash Reporting](#)
- [Report Errors and Exceptions](#)
- [Configure Application-Not-Responding \(ANR\) Detection](#)
- [Configure Hybrid Application Support](#)
- [Programmatically Control Sessions](#)
- [Start and End Session Frames](#)
- [Configure the Agent for Custom App Names](#)
- [Configure the Agent for Ignoring Some HTTP Requests](#)
- [Use the Agent with a Custom HTTP Library](#)
- [Transform URLs for Network Requests](#)
- [Enable Logging and Set Logging Level](#)
- [iOS SDK Documentation](#)

Because the agent [stores data about events in a local buffer](#) before reporting the information, you are recommended to use the APIs with discretion.

Collect Additional Types of Data

You can use methods available in the ADEUMInstrumentation class to collect six additional types of data:

Type of Data	Description	Specifications	Where Data is Displayed
Info points	How often a method is invoked, and how long it takes to run.	<ul style="list-style-type: none"> • Data is numeric • Names must consist of alphanumeric characters and/or spaces 	<ul style="list-style-type: none"> • Metric Browser • Custom Data • Network Request Snapshots • Mobile Sessions • Network Request Analyze

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Type of Data	Description	Specifications	Where Data is Displayed
Custom timers	Any arbitrary sequence of events within your code timed, even spanning multiple methods.	<ul style="list-style-type: none"> Data is numeric Metric names must consist of alphanumeric characters and/or spaces 	<ul style="list-style-type: none"> Metric Browser Custom Data
Custom metrics	Any integer-based data you wish to collect.	<ul style="list-style-type: none"> Data is numeric Metric names must consist of alphanumeric characters and/or spaces 	<ul style="list-style-type: none"> Metric Browser Custom Data
User data	Any string key/value pair you think might be useful.	<ul style="list-style-type: none"> Data can be any type Metric names have no restrictions 	<ul style="list-style-type: none"> Network Request Snapshots Mobile Sessions Network Request Analyze Crash Snapshots
Breadcrumbs	The context for a crash.	<ul style="list-style-type: none"> Data can be any data type Metric names have no restrictions 	<ul style="list-style-type: none"> Network Request Snapshots Mobile Sessions Network Request Analyze Crash Snapshots
User interaction	Capture when users press buttons, click on lists, and select text.	<ul style="list-style-type: none"> Data can be any data type Metric names have no restrictions 	<ul style="list-style-type: none"> Network Request Snapshots Mobile Sessions Network Request Analyze

i When you have set up additional data types, the Mobile Agent packages that data in a mobile beacon. Normally, the beacon is transmitted when the instrumented app sends an HTTP request or when the app is restarted following a crash, but if custom data has been collected and neither of those events has occurred for at least five minutes, the custom data is sent at that time.

Info Points

Information points allow you to track how your own code is running. You can see how often a method is invoked, and how long it takes to run, by using `beginCall` and `endCall`, something like the following:

[Objective-C](#) `Swift`

```

- (void)myMethod
{
    id tracker = [ADEumInstrumentation beginCall:self selector:_cmd];
    // Implementation of method here ...
    [ADEumInstrumentation endCall:tracker];
}

```

Objective-C [Swift](#)

```

func myMethod() {
    let tracker = ADEumInstrumentation.beginCall(self, selector: #function)
    // Implementation of method here ...
    ADEumInstrumentation.endCall(tracker)
}

```

If an exception is thrown, it is also reported. This information appears in the **Custom Data** view in the Controller UI.

Custom Timers

Custom timers allow you to time any arbitrary sequence of events within your code, even spanning multiple methods, by using `startTimer` and `stopTimer`. For example, to track the time a user spends viewing a screen, the instrumentation could look like this:

[Objective-C](#) [Swift](#)

```

- (void)viewDidAppear:(BOOL)animated {
    [super viewDidAppear:animated];
    [ADEumInstrumentation startTimerWithName:@"View Lifetime"];
}
- (void)viewDidDisappear:(BOOL)animated {
    [super viewDidDisappear:animated];
    [ADEumInstrumentation stopTimerWithName:@"View Lifetime"];
}

```

Objective-C [Swift](#)

```

func viewDidAppear(_ animated: Bool) {

```

```

    super.viewDidAppear(animated)
    ADEumInstrumentation.startTimer(withName: "View Lifetime")
}
func viewDidDisappear(_ animated: Bool) {
    super.viewDidDisappear(animated)
    ADEumInstrumentation.stopTimer(withName: "View Lifetime")
}

```

This information appears in the **Custom Data** view of the Controller UI.

i Calling `startTimerWithName` again with the same name value resets a named timer.

Custom Metrics

Any integer-based data can be passed to the agent. The first parameter to the `report.MetricWithName` call is the name you want the metric to appear under in the Controller UI. The metric name should only contain alphanumeric characters and spaces. Illegal characters are replaced by their ASCII hex value.

Reporting a metric called "My custom metric", for example, would look something like this:

```
[ADEumInstrumentation reportMetricWithName:@"My custom metric" value:<#VALUE HERE#>];
```

This information appears in the **Custom Data** view of the Controller UI.

Custom User Data

You can set and later remove any string key/value pair you think might be useful with the following methods:

- `setUserData(key, value, success, error)`
- `removeUserData(key)`

Parameters

The following table describes the parameters:

Name	Type	Description
key	string	The key identifying the key-value pair.
value	string	The value associated with the key.
success	function	The user-defined callback for successful cases.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Name	Type	Description
error	function	The user-defined callback for failed cases.

Example

The code example below shows how to set user data with the SDK API:

[Objective-C](#) [Swift](#)

```
- (void) onUserLoggedIn:(NSString *)userid {
    [ADEumInstrumentation setData:@"User ID" value:userid];
    ...
}
```

[Objective-C](#) [Swift](#)

```
func onUserLoggedIn(in userid: String?) {
    ADEumInstrumentation.setData("User ID", value: userid)
}
```

The code example below shows how to remove user data with the SDK API:

[Objective-C](#) [Swift](#)

```
- (void) onUserLoggedIn:(NSString *)userid {
    [ADEumInstrumentation removeUserData:@"User ID"];
    ...
}
```

[Objective-C](#) [Swift](#)

```
func onUserLoggedIn(in userid: String?) {
    ADEumInstrumentation.removeUserData("User ID")
}
```

This information is available in **Network Request Analyze** and is added to any crash snapshots that may be taken. Keys and values are limited to 2048 characters each.

You can also set user data with values of other types (Long, Boolean, Double, Date) using the following methods:

- `setUserDataLong:value`
- `setUserDataBoolean:value:`
- `setUserDataDouble:value:`
- `setUserDataDate:value:`

Breadcrumbs

Breadcrumbs allow you to situate a crash in the context of your user's experience. Set a breadcrumb when something interesting happens. If your application crashes at some point in the future, the breadcrumb will be displayed along with the crash report.

There are two ways of leaving breadcrumbs:

- [Crash Reports Only](#)
- [Modal](#)

Using this method means that breadcrumbs are reported in crash reports only.

```
+ (void)leaveBreadcrumb:(NSString *)breadcrumb
```

Using this method lets you fine tune where the breadcrumbs are reported, either only in crash reports or in crash reports *and* sessions.

```
+ (void)leaveBreadcrumb:(NSString *)breadcrumb mode:(ADEumBreadcrumbVisibility)mode
```

Where `mode` is either:

- `ADEumBreadcrumbVisibilityCrashesOnly`
- `ADEumBreadcrumbVisibilityCrashesAndSessions`

i If the `breadcrumb` is over 2048 characters, it is truncated. If it is empty or `nil`, no breadcrumb is recorded. Each crash report displays the *most recent* 99 breadcrumbs.

Capture User Interactions

You can enable the iOS Agent to track certain UI events triggered by user interactions. Once user interactions have been captured, you can sort sessions by UI event and view UI events in the timeline of the session waterfall.

You can capture when users do one or all of the following:

- press buttons
- select table cells
- select text fields
- select text views

i Security and Privacy Concerns

The interaction capture mode is disabled by default for security and privacy reasons as user interactions may contain sensitive information. Moreover, this potential security and privacy issue may be compounded if you enable both the capturing of UI interactions and screenshots.

Enable User Interaction Capture Mode

To enable user interaction capture mode, you assign the capture mode to the property `interactionCaptureMode` of the `ADEumAgentConfiguration` object. The instrumentation code example below configures the iOS Agent to capture all the supported types of user interactions.

```
ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc] initWithAppKey:
<#EUM_APP_KEY#>];
config.interactionCaptureMode = ADEumInteractionCaptureModeAll;
[ADEumInstrumentation initWithConfiguration:config];
```

You can also configure the iOS Agent to only capture one type of user interaction:

```
ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc] initWithAppKey:
<#EUM_APP_KEY#>];
config.interactionCaptureMode = ADEumInteractionCaptureModeButtonPressed;
[ADEumInstrumentation initWithConfiguration:config];
```

Programmatically Take Screenshots

By default, mobile screenshots are enabled on the agent-side but disabled on the Controller-side. To programmatically take manual screenshots, you must [enable screenshots in the Controller UI](#) and add the following API:

Objective-C Swift

```
[ADEumInstrumentation takeScreenshot];
```

Objective-C Swift

```
ADEumInstrumentation.takeScreenshot()
```

Disable Screenshots

You can disable screenshots from the Controller UI or with the iOS SDK. To disable screenshots with the iOS SDK, set the property `screenshotsEnabled` of the `ADEumAgentConfiguration` object to `NO` for Objective-C and `false` for Swift as shown below.

[Objective-C](#) [Swift](#)

```
ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc] initWithAppKey:
<#EUM_APP_KEY#>];
config.screenshotsEnabled = NO;
[ADEumInstrumentation initWithConfiguration:config];
```

[Objective-C](#) [Swift](#)

```
let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>);
config.screenshotsEnabled = false;
ADEumInstrumentation.initWith(config);
```

Block and Unblock Screenshots

You can also use the iOS SDK to block screenshots from being taken during the execution of a code block. This just temporarily blocks screenshots from being taken until you unblock screenshots. This enables you to stop taking screenshots in situations where users are entering personal data, such as on login and account screens.

The `ADEumInstrumentation` class provides the methods `blockScreenshots` and `unblockScreenshots` to block and unblock screenshots. If screenshots are disabled through the property `screenshotsEnabled` of the `ADEumAgentConfiguration` object or through the Controller UI, these methods have no effect. You can also call `screenshotsBlocked` to check if screenshots are being blocked.

The following example demonstrates how you could use the API to block and unblock screenshots for a user login.

[Objective-C](#) [Swift](#)

```

#import "ADEumInstrumentation.h"
...

- (IBAction)loginUser:(id)sender {
    if(![ADEumInstrumentation screenshotsBlocked]) {
        [ADEumInstrumentation blockScreenshots];
    }
    LoginCredentials creds = [UserLogin getUserCreds];
    if(creds.authorized) {
        [LoginUser redirectToProfile:creds.user]
        [ADEumInstrumentation unblockScreenshots];
    }
}
...

```

Objective-C [Swift](#)

```

import ADEumInstrumentation
...

@IBAction func loginUser(_ sender: UIButton) {
    if(!ADEumInstrumentation.screenshotsBlocked()) {
        ADEumInstrumentation.blockScreenshots()
    }
    let creds = UserLogin.getUserCreds()
    if(creds.authorized) {
        LoginUser.redirectToProfile(credits.user)
        ADEumInstrumentation.unblockScreenshots()
    }
}
...

```

Disable the Agent to Stop Sending User Data to the Collector

You can disable the agent to stop sending all data to the collector while the agent is initialized and running. For example, you can disable the agent if your app has an option for users to opt-out of monitoring for privacy reasons.

`shutdownAgent`

The `shutdownAgent` call stops outgoing data to the collector, and does not persist data on the device.

Objective-C [Swift](#)

```
[ADEumInstrumentation shutdownAgent];
```

Objective-C [Swift](#)

```
ADEumInstrumentation.shutdownAgent()
```

- The call only stops the traffic out of the agent.
- Once the agent has been initialized, the call cannot be removed, and a license will have been consumed.
- If you want to make this state permanent for a device, add code in UserDefaults to save the state and use that flag to conditionally initialize the agent in your code.

restartAgent

To re-enable the agent and reverse `shutdownAgent`, use `restartAgent`.

Objective-C [Swift](#)

```
[ADEumInstrumentation restartAgent];
```

Objective-C [Swift](#)

```
ADEumInstrumentation.restartAgent();
```

- This call will respect the server side calls that can remotely shutdown the agent in a similar way.
- The call is only in effect while the app is running.
- The call will be ignored if the agent has been remotely disabled.
- If the call is removed from memory and the app restarts, or the device is rebooted, the agent will be initialized as normal.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Add a Crash Reporting Callback

You may want to make crash report information that Mobile RUM collects available to other parts of your code, for example, to Google Analytics, if you are using it. To enable you to pass on summary crash information, you can set up a crash report runtime callback. To get a callback when the iOS Agent detects and then reports a crash, you need to implement the following protocol in your code:

```
@protocol ADEumCrashReportCallback <NSObject>

- (void)onCrashesReported:(NSArray<ADEumCrashReportSummary *> *)crashReportSummaries;

@end
```

 This callback is invoked on your app's UI thread, so any significant work should be done on a separate work thread.

Each `ADEumCrashReportSummary` passed in has the following properties:

```
@interface ADEumCrashReportSummary : NSObject

/** Uniquely defines the crash, can be used as key to find full crash report. */
@property (nonatomic, readonly) NSString *crashId;

/** The exception name, may be `nil` if no `NSException` occurred. */
@property (nonatomic, readonly) NSString * ADEUM_NULLABLE exceptionName;

/** The exception reason, may be `nil` if no `NSException` occurred. */
@property (nonatomic, readonly) NSString * ADEUM_NULLABLE exceptionReason;

/** The Mach exception signal name */
@property (nonatomic, readonly) NSString *signalName;

/** The Mach exception signal code */
@property (nonatomic, readonly) NSString *signalCode;

@end
```

If you are sending the information to another analytics tool, such as Google Analytics, it is best to include all five properties:

- `exceptionName` and `exceptionReason` are optional and useful for a quick identification of what the crash is. These are only present if the crash cause occurred within an exception reporting runtime, such as Objective-C.
- `signalName` and `signalCode` are useful for quick identification of the crash. These are from the system and are independent of the runtime.
- For additional information, `crashId` can be used to look up the crash in the AppDynamics Controller UI.

For example, to print the crash information to iOS's logger, you could implement an `ADEumCrashReportCallback` class like this:

```
// assumes the containing object has "adopted" the protocol
- (void)onCrashesReported:(NSArray<ADEumCrashReportSummary *> *)summaries {
    for (ADEumCrashReportSummary *summary in summaries) {
        NSLog(@"Crash ID: %@", summary.crashId);
        NSLog(@"Signal: %@ (%@)", summary.signalName, summary.signalCode);
        NSLog(@"Exception Name:\n%@", summary.exceptionName);
        NSLog(@"Exception Reason:\n%@", summary.exceptionReason);
    }
}
```

You set the object that implements the `ADEumCrashReportCallback` protocol during agent configuration:

```
ADEumAgentConfiguration *config = [ADEumAgentConfiguration new];
config.crashReportCallback = myCrashReportCallback;
```

Your callback is invoked, on the main/UI thread, if a crash from a previous run is detected and collected. See the [latest iOS SDK documentation](#) for more information.

Disable Crash Reporting

Crash reporting is enabled by default, but you can manually disable crash reporting through the instrumentation configuration. If you are using other crash reporting tools, you might disable crash reporting to minimize conflicts and optimize the crash report results.

You can disable crash reporting by configuring the instrumentation with the `crashReportingEnabled` property as shown in the following code example.

[Objective-C](#) [Swift](#)

```
ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc] initWithAppKey:appKey];
config.crashReportingEnabled = No;
[ADEumInstrumentation initWithConfiguration:config];
```

[Objective-C](#) [Swift](#)

```
let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>);
config.crashReportingEnabled = false;
ADEumInstrumentation.initWith(config);
```

Report Errors and Exceptions

 The `domain: String` used to initialize the standard `NSError` object used for `reportError` should not use unique string such as Hashes, `StackTraceID` or `ThreadID`. Including those will create an infinite number of `Error Group` which will impact performance.

To add unique error strings and values, you have two data collection options:

- Add a string value as a breadcrumb. If the event/error, you are reporting has a single value attached, add the value to `leaveBreadcrumb`. See [Breadcrumbs](#).
- Add string name and integer values. If the event/error, you are reporting has both name and integer values attached, add the values to `reportMetricWithName`. See [Custom Metrics](#).

You can report exceptions using the method `reportError` from the `ADEumInstrumentation` class. Reported exceptions will appear in session details.

The method can have the following two signatures:

Objective-C Function Signature	Description
<pre>(void)reportError:(NSError *)error withSeverity (ADEumErrorSeverityLevel)severity;</pre>	<p>Use this signature to report errors, set the severity level of the issue, and send the stack trace.</p> <p>This function signature sends the stack trace by default. If you don't want to send the stack trace, use the function signature below with the additional argument <code>andStackTrace</code> and set its value to <code>NO</code>.</p> <div style="border: 1px solid #ccc; background-color: #fff9c4; padding: 10px; margin-top: 10px;"> <p> The <code>domain: String</code> used to initialize the standard <code>NSError</code> object used for <code>reportError</code> should not use unique string such as <code>Hashes</code>, <code>StackTraceID</code> or <code>ThreadID</code>. Including those will create an infinite number of <code>Error Group</code> which will impact performance.</p> <p>To add unique error strings and values, you have two data collection options:</p> <ul style="list-style-type: none"> • Add a string value as a breadcrumb. If the event/error, you are reporting has a single value attached, add the value to <code>leaveBreadcrumb</code>. See Breadcrumbs. • Add string name and integer values. If the event/error, you are reporting has both name and integer values attached, add the values to <code>reportMetricWithName</code>. See Custom Metrics. </div>

Objective-C Function Signature	Description
<pre>(void)reportError:(NSError *)error withSeverity: (ADEumErrorSeverityLevel)severity andStackTrace:(BOOL)stacktrace;</pre>	<p>Use this signature to report errors, set the severity level of the issue, and explicitly specify whether the stack trace should be included.</p> <p>If you include the stack trace with the reported error by setting <code>stacktrace</code> to <code>YES</code>, you can view the stack trace in the Code Issues Details dialog.</p> <p>To report the error without the stack trace, set <code>stacktrace</code> to <code>NO</code>.</p> <div style="background-color: #fff9c4; padding: 10px; border: 1px solid #ccc;"> <p> The string message used to construct a new throwable used for <code>reportError</code> should not use unique string such as hashes, <code>StackTraceID</code> or <code>ThreadID</code>. Including those will create an infinite number of <code>Error Group</code> which will impact performance. To add unique error strings and values, you have two data collection options:</p> <ul style="list-style-type: none"> • Add a string value as a breadcrumb. If the event/error, you are reporting has a single value attached, add the value to <code>leaveBreadcrumb</code>. See Breadcrumbs. • Add string name and integer values. If the event/error, you are reporting has both name and integer values attached, add the values to <code>reportMetricWithName</code>. See Custom Metrics. </div>

Severity Levels

You can also set one of the following severity levels for an issue. With the severity level, you can filter errors in the **Code Issues Dashboard** or **Code Issues Analyze**.

- `ADEumErrorSeverityLevelInfo`
- `ADEumErrorSeverityLevelWarning`
- `ADEumErrorSeverityLevelCritical`

Examples of Reporting Errors

The example below uses the API to report possible exceptions and set the severity level to `ADEumErrorSeverityLevelCritical` for a failed attempt to perform a file operation.

Objective-C [Swift](#)

```

NSError *err = nil;
[[NSFileManager defaultManager] contentsOfDirectoryAtPath:@"pathToFile" error:&err];
if (err) {
    [ADEumInstrumentation reportError:err withSeverity:ADEumErrorSeverityLevelCritical,
andStackTrace: NO];
} else {
    ...
}
  
```

 Objective-C [Swift](#)

```

var err: Error? = nil
try? FileManager.default.contentsOfDirectory(atPath: "pathToFile")
if err != nil {
    ADEumInstrumentation.reportError(err, withSeverity: ADEumErrorSeverityLevelCritical,
andStackTrace: false)
} else {
    ...
}
  
```

You can also create and report custom errors with the following. Note that because `reportError` is not passed the argument `andStackTrace`, by default, the stack trace is automatically included with the error.

 The `domain: String` used to initialize the standard `NSError` object used for `reportError` should not use unique string such as Hashes, `StackTraceID` or `ThreadID`. Including those will create an infinite number of `Error Group` which will impact performance.

To add unique error strings and values, you have two data collection options:

- Add a string value as a breadcrumb. If the event/error, you are reporting has a single value attached, add the value to `leaveBreadcrumb`. See [Breadcrumbs](#).
- Add string name and integer values. If the event/error, you are reporting has both name and integer values attached, add the values to `reportMetricWithName`. See [Custom Metrics](#).

 Objective-C [Swift](#)

```

NSString *domain = @"com.YourCompany.AddUsers.ErrorDomain";
NSString *desc = NSLocalizedString(@"Unable to add user.", @"");
  
```

```

NSDictionary *userInfo = @{ NSLocalizedDescriptionKey : desc };
NSError *error = [NSError errorWithDomain:domain
                        code:-101
                        userInfo:userInfo];
[ADEumInstrumentation reportError:error withSeverity: ADEumErrorSeverityLevelWarning];
  
```

Objective-C [Swift](#)

```

var domain = "com.YourCompany.AddUsers.ErrorDomain"
var desc = NSLocalizedString("Unable to add user.", comment: "")
var userInfo = [NSLocalizedDescriptionKey: desc]
var error = NSError(domain: domain, code: -101, userInfo: userInfo)
ADEumInstrumentation.reportError(error, withSeverity: ADEumErrorSeverityLevelWarning)
  
```

Configure Application-Not-Responding (ANR) Detection

By default, the iOS Agent does not detect ANR issues, and when ANR detection is enabled, the ANR issues are reported without stack traces. You must manually enable ANR detection and set a flag to include stack traces through the iOS Agent configuration. For more information about ANR monitoring, see [Code Issues](#). To specify thresholds for ANR issues, see [Configure Application Not Responding Thresholds](#).

Enable ANR Detection

You enable the detection of ANR issues by configuring the instrumentation with the `anrDetectionEnabled` property as shown below.

[Objective-C](#) [Swift](#)

```

ADEumAgentConfiguration *adeumAgentConfig = [[ADEumAgentConfiguration alloc]
initWithAppKey: <#EUM_APP_KEY#>];
// Enable ANR detection
adeumAgentConfig.anrDetectionEnabled = YES;
[ADEumInstrumentation initWithConfiguration:adeumAgentConfig];
  
```

Objective-C [Swift](#)

```
let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>);
// Enable ANR detection
config.anrDetectionEnabled = true;
ADEumInstrumentation.initWith(config);
```

Report Stack Traces with ANRs

In addition to enabling ANR detection, you set the property `anrStackTraceEnabled` to `YES` (Objective-C) or `true` (Swift) to report stack traces with the ANRs.

Objective-C Swift

```
ADEumAgentConfiguration *adeumAgentConfig = [[ADEumAgentConfiguration alloc]
initWithAppKey: <#EUM_APP_KEY#>];
// Enable ANR detection
adeumAgentConfig.anrDetectionEnabled = YES;
// Set the flag to include stack traces with ANRs
adeumAgentConfig.anrStackTraceEnabled = YES;
[ADEumInstrumentation initWithConfiguration:adeumAgentConfig];
```

Objective-C Swift

```
let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>)
// Enable ANR detection
config.anrDetectionEnabled = true
// Set the flag to include stack traces with ANRs
config.anrStackTraceEnabled = true
ADEumInstrumentation.initWith(config)
```

Configure Hybrid Application Support

By default, the iOS Agent instruments [iOS WKWebViews](#), but does not collect and report Ajax calls. See [Hybrid Application Support](#) for an overview and an explanation of how it works.

You can configure the static or runtime configuration to disable hybrid application support or modify its behavior. The sections below show you how to change the defaults for hybrid support through either runtime or static configuration.

Runtime Configuration for Hybrid Application Support

The code example below disables the injection of the JavaScript Agent. By disabling the injection, the WKWebViews in your application will not be instrumented and Ajax calls will not be reported.

```
ADEumAgentConfiguration *adeumAgentConfig = [[ADEumAgentConfiguration alloc] initWithAppKey:
<#EUM_APP_KEY#>];
// Disable the JavaScript Agent Injection
adeumAgentConfig.jsAgentEnabled = NO;
[ADEumInstrumentation initWithConfiguration:adeumAgentConfig];
```

The JavaScript Agent injection is enabled by default. To also enable the collection and reporting of Ajax calls:

```
ADEumAgentConfiguration *adeumAgentConfig = [[ADEumAgentConfiguration alloc] initWithAppKey:
<#EUM_APP_KEY#>];
// Enable the collection and reporting of Ajax calls
adeumAgentConfig.jsAgentAjaxEnabled = YES;
[ADEumInstrumentation initWithConfiguration:adeumAgentConfig];
```

Static Configuration for Hybrid Application Support

You should use static configuration for the following reasons:

- force the instrumentation of WKWebViews and/or Ajax calls (override the runtime configuration)
- disable hybrid support and override the runtime configuration
- set the URL to your self-hosted JavaScript Extension file

The table below describes the supported properties and provides the default value for the `info.plist` file.

Property	Default Value	Description
<code>serverJsAgentEnabled</code>	<code>true</code>	<p>If the client receives a <code>false</code> for this flag, then the JavaScript Agent will be disabled. Thus, the WKWebViews and Ajax requests will not be monitored.</p> <p>The injection occurs during the creation of a new WKWebView. So, if a WKWebView is created when this flag is set to <code>false</code>, that particular WKWebView won't be instrumented even if the flag is subsequently set to <code>true</code>.</p>

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Property	Default Value	Description
ForceWebviewInstrumentation	false	When set to <code>true</code> , the iOS Agent will inject the JavaScript Agent into the WKWebViews regardless of the runtime configuration.
ForceAjaxInstrumentation	true	When set to <code>true</code> , Ajax operations will always be collected and reported regardless of the runtime configuration.
ADRUMExtUrlHttp	http:// cdn.appdynamics.com	The JavaScript Agent consists of two components: the base JavaScript Agent and the JavaScript Agent extension. The base JavaScript Agent is built into the Mobile Agent binary and injected according to the rules above. After initialization, the JavaScript Agent fetches the JavaScript Agent extension from the URLs specified by these properties.
ADRUMExtUrlHttps	https:// cdn.appdynamics.com/	

Example Configuration

The example `info.plist` below forces the instrumentation of WKWebViews (overriding the runtime configuration), but does not force the collection and reporting of Ajax requests. The configuration also sets the URL where the JavaScript Extension file is obtained.

```

<plist>
  <dict>
    ...
    <key>ADEUM_Settings</key>
    <dict>
      <key>ForceWebviewInstrumentation</key>
      <true/>
      <key>ForceAjaxInstrumentation</key>
      <false/>
      <key>ADRUMExtUrlHttp</key>
      <string>http://<your-domain>/adrum.cdn</string>
      <key>ADRUMExtUrlHttps</key>
      <string>https://<your-domain>/adrum.cdn</string>
    </dict>
    ...
  </dict>

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
</plist>
```

Programmatically Control Sessions

By default, a mobile session ends after a period of user inactivity. For example, when a user opens your application, the session begins and only ends after the user stops using the app for a set period of time. When the user begins to use the application again, a new session begins.

Instead of having a period of inactivity to define the duration of a session, however, you can use the following API to programmatically control when sessions begin and end:

```
- (void)startNextSession
```

When you call the method `startNextSession` from the `ADEumInstrumentation` class, the current session ends and a new session begins. The API enables you to define and frame your sessions so that they align more closely with business goals and expected user flows. For example, you could use the API to define a session that tracks a purchase of a product or registers a new user.

Excessive use of this API will cause sessions to be throttled (excessive use is >10 calls per minute per iOS Agent, but is subject to change). When not using the API, sessions will fall back to the default of ending after a period of user inactivity.

Example of a Programmatically Controlled Session

In the example below, the current session ends and a new one begins when the check out is made.

[Objective-C](#) [Swift](#)

```
-(void) checkout {
    AppDelegate *appDelegate = (AppDelegate *) [[UIApplication sharedApplication]
delegate];
    NSString *checkoutUrl = [appDelegate.url stringByAppendingString:@"rest/cart/co/"];
    NSURL *url = [NSURL URLWithString:checkoutUrl];
    NSMutableURLRequest *request = [[NSMutableURLRequest alloc] initWithURL:url
cachePolicy:NSURLRequestUseProtocolCachePolicy timeoutInterval:60.0];
    NSURLResponse *response = nil;
    NSError *error = nil;

    NSData *body = [NSURLConnection sendSynchronousRequest:request
returningResponse:&response error:&error];
    const char *responseBytes = [body bytes];
    if (responseBytes == nil)
        checkoutResponse = [NSString stringWithUTF8String:"Could not connect to the
server"];
    else {
        checkoutResponse = [NSString stringWithUTF8String:responseBytes];
        [ADEumInstrumentation startNextSession];
    }
}
```

```

}
}

```

Objective-C [Swift](#)

```

func checkout() {
    let appDelegate = UIApplication.shared.delegate as? AppDelegate
    let checkoutUrl = appDelegate?.url ?? "" + ("rest/cart/co/")
    let url = URL(string: checkoutUrl)
    var request: NSMutableURLRequest? = nil
    if let url = url {
        request = NSMutableURLRequest(url: url, cachePolicy: .useProtocolCachePolicy,
        timeoutInterval: 60.0)
    }
    var response: URLResponse? = nil
    var error: Error? = nil
    var body: Data? = nil
    if let request = request {
        body = try? NSURLConnection.sendSynchronousRequest(request, returning: &response)
    }
    let responseBytes = Int8(body?.bytes ?? 0)
    if responseBytes == nil {
        checkoutResponse = String(utf8String: "Could not connect to the server")
    } else {
        checkoutResponse = String(utf8String: &responseBytes)
        ADEumInstrumentation.startNextSession()
    }
}
}

```

Start and End Session Frames

You can use the `SessionFrame` API to create session frames that will appear in the session activity. Session frames provide context for what the user is doing during a session. With the API, you can improve the names of user screens and chronicle user flows within a business context.

Use Cases

The following are common use cases for the `SessionFrame` API:

- One `ViewController` performs multiple functions and you want more granular tracking of the individual functions.
- A user flow spans multiple `ViewController` or user interactions. For example, you could use the API to create the session frames "Login", "Product Selection", and "Purchase" to chronicle the user flow for purchases.
- You want to capture dynamic information based on user interactions to name session frames, such as an order ID.

SessionFrame API

The table below lists the three methods you can use with session frames. In short, you start a session frame with `startSessionFrame` and then use the returned `ADEumSessionFrame` object to rename and end the session frame.

[Objective-C](#) [Swift](#)

Class	Method	Description
<code>ADEumInstrumentation</code>	+ (ADEumSessionFrame *)startSessionFrame:(NSString *)name	Use this to start and name your session frame. Naming session frames enable you to easily identify and track the frames in the Sessions Dialog .
<code>ADEumSessionFrame</code>	- (void)updateName:(NSString *)name	Rename the session frame name. You call this method from the <code>ADEumSessionFrame</code> object returned from <code>startSessionFrame</code> .
<code>ADEumSessionFrame</code>	- (void)end	End the session frame. You call this method from the <code>ADEumSessionFrame</code> object returned from <code>startSessionFrame</code> .

[Objective-C](#) [Swift](#)

Class	Method	Description
<code>ADEumInstrumentation</code>	<code>startSessionFrame(_ name: String?) -> ADEumSessionFrame</code>	Use this to start and name your session frame. Naming session frames enable you to easily identify and track the frames in the Sessions Dialog .

Class	Method	Description
ADEumSessionFrame	updateName(_ name: String?)	Rename the session frame name. You call this method from the ADEumSessionFrame object returned from startSessionFrame .
ADEumSessionFrame	end()	End the session frame. You call this method from the ADEumSessionFrame object returned from startSessionFrame .

Session Frame Example

In the following example, the `SessionFrame` API is used to track user activity during the checkout process.

[Objective-C](#) [Swift](#)

```
#import "ADEumSessionFrame.h"
...
@property (nonatomic, strong) ADEumSessionFrame *checkoutSessionFrame;

- (IBAction)checkoutCartButtonClicked:(id)sender {
    // The user starting to check out starts when the user clicks the checkout button
    // this may be after they have updated quantities of items in their cart, etc.
    checkoutSessionFrame = [ADEumInstrumentation startSessionFrame:@"Checkout"];
}

- (IBAction)confirmOrderButtonClicked:(id)sender {
    // Once they have confirmed payment info and shipping information, and they
    // are clicking the "Confirm" button to start the backend process of checking out
    // we may know more information about the order itself, such as an Order ID.
    NSString *newSessionName = [NSString stringWithFormat:@"Checkout: Order ID %@",orderId];
    [checkoutSessionFrame updateName:newSessionName];
}

- (void)processOrderCompleted {
    // Once the order is processed, the user is done "checking out" so we end
    // the session frame
    [checkoutSessionFrame end];
}
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

    checkoutSessionFrame = nil;
  }

  - (void)checkoutCancelled {
    // If they cancel or go back, you'll want to end the session frame also, or else
    // it will be left open and appear to have never ended.
    [checkoutSessionFrame end];
    checkoutSessionFrame = nil;
  }

```

Objective-C [Swift](#)

```

import ADEumSessionFrame
...

var checkoutSessionFrame: ADEumSessionFrame?
@IBAction func checkoutCartButtonClicked(_ sender: UIButton) {
    // The check out starts when the user clicks the checkout button.
    // This may be after they have updated quantities of items in their cart, etc.
    checkoutSessionFrame = ADEumInstrumentation.startSessionFrame("Checkout")
}

@IBAction func confirmOrderButtonClicked(_ sender: UIButton) {
    // Once users have confirmed payment info and shipping information, and they
    // are clicking the "Confirm" button to start the backend process of checking out,
    // we may know more information about the order itself, such as an order ID.
    let newSessionName = "Checkout: Order ID \(orderId)"
    checkoutSessionFrame.updateName(newSessionName)
}

func processOrderCompleted() {
    // Once the order is processed, the user is done "checking out", so we end the session
    // frame.
    checkoutSessionFrame.end()
    checkoutSessionFrame = nil
}

func checkoutCancelled() {
    // If they cancel or go back, you'll want to end the session frame also, or else it
    // will be
    // left open and appear to have never ended.
    checkoutSessionFrame.end()
    checkoutSessionFrame = nil
}

```

Configure the Agent for Custom App Names

By default, AppDynamics detects the application name by extracting the last segment from the [bundle ID](#). There may be cases, however, where you deploy the same app binary with different bundle IDs to various regional app stores. To make sure all the data belonging to one app is collected and displayed together, despite varying bundle IDs, you can set a common name by giving the apps a custom name. To do this, set the application name property in the `ADEumAgentConfiguration` instance that you use to set up `ADEumInstrumentation`. See the [latest iOS SDK documentation](#) for more information.

By default, AppDynamics stores the application name from the bundle ID string. However, the Controller UI only displays the last segment of the bundle ID string, which is after the last dot (if present). For example, if the bundle ID is `com.example.appdynamics.HelloWorld`, the application name in the UI will display "HelloWorld." This applies to both default and custom app names.

```
@property (nonatomic, strong) NSString *applicationName;
```

Configure the Agent for Ignoring Some HTTP Requests

In some cases, HTTP requests using NSURL are used for internal purposes in an application and do not represent actual network requests. Metrics created based on these requests are not normally useful in tracking down issues, so preventing data on them from being collected can be useful. To ignore specific NSURL requests, set the excluded URL patterns property in the `ADEumAgentConfiguration` instance that you use to set up `ADEumInstrumentation`. Use the simplest regex possible. See the [latest iOS SDK documentation](#) for more information.

```
@property (nonatomic, strong) NSSet * excludedUrlPatterns;
```

Use the Agent with a Custom HTTP Library

The iOS Agent automatically detects network requests when the underlying implementation is handled by either by the `NSURLConnection` or the `NSURLSession` classes. This covers the great majority of iOS network requests. In some cases, however, mobile applications use custom HTTP libraries.

- To have the iOS Agent detect requests from a custom library, [add request tracking code](#) to your application manually, using the `ADEumHTTPRequestTracker` class.
- To [set headers to allow correlation](#) with server-side processing, use the `ADEumServerCorrelationHeaders` class.
- To [configure the agent to use your custom library](#) to deliver its beacons over HTTP, use the `ADEumCollectorChannel` protocol and the `ADEumAgentConfiguration` class.

Add Request Tracking

To add request tracking manually, you tell the agent when the request begins and when it ends. You also set properties to tell the agent the status of the response.

Start and complete tracking a request

To begin tracking an HTTP request, call the following method immediately before sending the request.

⚠ You must initialize the agent using one of the `ADEumInstrumentation`'s `initWithKey` methods before using this method.

```
@interface ADEumHTTPRequestTracker : NSObject
...
+ (ADEumHTTPRequestTracker *)requestTrackerWithURL:(NSURL *)url;
```

Where `url` is the URL being requested. This parameter must not be `nil`.

To complete tracking an HTTP request, immediately after receiving a response or an error, set the appropriate `properties` on the tracker object and call the following method to report the outcome of the request back to the agent. You should not continue to use this object after calling this method. To track another request, call `requestTrackerWithURL` again.

```
- (void)reportDone;
```

Properties to be set

The following properties should be set on the `requestTrackerWithURL` object to describe to the agent the results of the call.

```
@property (copy, nonatomic) NSError *error;
```

Indicates the failure to receive a response, if this occurred. If the request was successful, this should be `nil`.

```
@property (copy, nonatomic) NSNumber *statusCode;
```

Reports the HTTP status code of the response, if one was received.

- If a response was received, this should be an integer.
- If an error occurred and a response was not received, this should be `nil`.

```
@property (copy, nonatomic) NSDictionary *allHeaderFields;
```

Provides a dictionary representing the keys and values from the server's response header. The format of this dictionary should be identical to the `allHTTPHeaderFields` property of `NSURLRequest`. The dictionary elements consist of key/value pairs, where the key is the header key name and the value is the header value.

If an error occurred and a response was not received, this should be `nil`.

Example

Given a request snippet like this:

```
- (NSData *)sendRequest:(NSURL *) url error:(NSError **)error {
    // implementation omitted
    NSData *result = nil;
    if (errorOccurred) {
        *error = theError;
    } else {
        result = responseBody;
    }
    return result;
}
```

Adding the tracker could look something like this:

```
- (NSData *)sendRequest:(NSURL *)url error:(NSError **)error {
    ADEumHTTPRequestTracker *tracker = [ADEumHTTPRequestTracker requestTrackerWithURL:url];
    // implementation omitted
    NSData *result = nil;
    if (errorOccurred) {
        *error = theError;
        tracker.error = theError;
    } else {
        tracker.statusCode = theStatusCode;
        tracker.allHeaderFields = theResponseHeaders;
        result = responseBody;
    }
    [tracker reportDone];
    return result;
}
```

Enable Server-Side Correlation

To enable correlation between your request and server-side processing, add specific headers to outgoing requests that the server-side agent can detect and return the headers obtained from the server-side agent in the response to make them available to the iOS Agent.

i This is done automatically for standard HTTP libraries.

```
@interface ADEumServerCorrelationHeaders : NSObject
+ (NSDictionary *)generate;
@end
```

You must:

1. Call the `generate` method and set the generated headers *before* sending a request to the backend.
2. Report back the response headers, using the `allHeaderFields` property shown above.

Configure Agent to Use Custom HTTP Library

The iOS Agent uses HTTP to deliver its beacons. To have the agent use your custom HTTP library for this purpose, do the following.

1. Implement a class that conforms to this protocol:

```
/**
 * Protocol for customizing the connection between the agent SDK and the collector.
 */
@protocol ADEumCollectorChannel <NSObject>

/**
 * Sends a request synchronously and returns the response received, or an error.
 *
 * The semantics of this method are exactly equivalent to NSURLConnection's
 * sendSynchronousRequest:returningResponse:error: method.
 *
 * @param request The URL request to load.
 * @param response Out parameter for the URL response returned by the server.
 * @param error Out parameter used if an error occurs while processing the request. May be
 * NULL.
 */
- (NSData *)sendSynchronousRequest:(NSURLRequest *)request returningResponse:
(NSURLResponse **)response error:(NSError **)error;
@end
```

2. Set the `collectorChannel` property in `ADEumAgentConfiguration` before initializing `ADEumInstrumentation`, passing in an instance of your class that implements `ADEumCollectorChannel`. See the [latest iOS SDK documentation](#) for more information.

```
@property (nonatomic, strong) id<ADEumCollectorChannel> collectorChannel;
```

Attach Custom Data to a Network Request

You can attach custom data to a network request by calling one (or multiple) of the following methods to add attributes to `ADEumHTTPRequestTracker` :

- `setUserDataLong:value:`
- `setUserDataBoolean:value:`
- `setUserDataDouble:value:`
- `setUserDataDate:value:`

Sample

```
- (NSData *)sendRequest:(NSURL *)url error:(NSError **)error {
    ADEumHTTPRequestTracker *tracker = [ADEumHTTPRequestTracker requestTrackerWithURL:url];
    // implementation omitted
    NSData *result = nil;
    if (errorOccurred) {
        *error = theError;
        tracker.error = theError;
    } else {
        tracker.statusCode = theStatusCode;
        tracker.allHeaderFields = theResponseHeaders;
        result = responseBody;
    }

    // Custom data can be added to this one request.
    // Different types can be used.
    // The data added will only appear for this network request and will not persist.
    [tracker setUserData:@"trackerStringKey" value:@"Test String Value"];
    [tracker setUserDataLong:@"trackerLongKey" value:66004024];
    [tracker setUserDataBoolean:@"trackerBooleanKey" value:1];
    [tracker setUserDataDouble:@"trackerDoubleKey" value:5905400.6];
    [tracker setUserDataDate:@"trackerDateKey" value:[NSDate date]];

    [tracker reportDone];
    return result;
}
```

Transform URLs for Network Requests

When your application makes network requests, you may not want to report URLs containing sensitive information to the EUM Server. You can instead transform the network request URL before reporting it or ignore it altogether.

To do so:

1. [Implement a network request callback](#) that modifies or ignores specific URLs.

2. [Register the network request callback](#) in the initialization code.

Implement the Network Request Callback

The callback that modifies or ignore specific URLs is an implementation of the protocol below. The callback method `networkRequestCallback` is synchronous, so it is recommended that you return from the function quickly.

```
- (BOOL)networkRequestCallback:(ADEumHTTPRequestTracker *)networkRequest
```

Transforming URLs

The `networkRequestCallback` method, in general, should follow the steps below to transform URLs:

1. Identify specific URLs using techniques such as regex or pattern matching.
2. Modify the `url` property of the `ADEumHTTPRequestTracker` object. (Modifying other properties of the `ADEumHTTPRequestTracker` object will be ignored.)
3. Assign a valid URL to the `url` property.
4. Return `YES` (Objective-C) or `true` (Swift).

The first step is optional as you could choose to transform the URLs of all network requests.

[Objective-C](#) [Swift](#)

```
- (BOOL)networkRequestCallback:(ADEumHTTPRequestTracker *)networkRequest
{
    NSString *maskURL = @"http://networkrequest-mask.com";
    NSURL *url = [NSURL URLWithString:maskURL];
    networkRequest.url = url;
    return YES;
}
```

[Objective-C](#) [Swift](#)

```
func networkRequestCallback(_ networkRequest: ADEumHTTPRequestTracker?) -> Bool {
    let maskURL = "http://networkrequest-mask.com"
    let url = URL(string: maskURL)
    networkRequest?.url = url
    return true
}
```

In general, however, you would want to identify and transform URLs that contain sensitive information as implied in the example below.

[Objective-C](#) [Swift](#)

```

- (BOOL)networkRequestCallback:(ADEumHTTPRequestTracker *)networkRequest
{
    NSString *urlString = networkRequest.url.absoluteString;
    BOOL returnBeacon = YES;
    NSString *maskURL = @"http://customer-account.com";
    if (![urlString rangeOfString:@"accountInfo"].location == NSNotFound) {
        networkRequest.url = [NSURL URLWithString:maskURL];
    }
    return returnBeacon;
}
  
```

[Objective-C](#) [Swift](#)

```

func networkRequestCallback(_ networkRequest: ADEumHTTPRequestTracker?) -> Bool {
    let urlString = networkRequest?.url.absoluteString
    returnBeacon = true
    let maskURL = "http://customer-account.com"
    if !(Int((urlString as NSString)?.range(of: "accountInfo").location ?? 0) ==
    NSNotFound) {
        networkRequest?.url = URL(string: maskURL)
    }
    return returnBeacon
}
  
```

Ignoring URLs

If the `networkRequestCallback` method returns false, the beacon is dropped. The general process for ignoring beacons is as follows:

1. Identify specific URLs using techniques such as regex or pattern matching.
2. Return `false`.

You could theoretically ignore all network requests by having the callback `networkRequestCallback` always return `NO` (Objective-C) or `false` (Swift):

[Objective-C](#) [Swift](#)

```

- (BOOL)networkRequestCallback:(ADEumHTTPRequestTracker *)networkRequest
{
    return NO;
}

```

Objective-C [Swift](#)

```

func networkRequestCallback(_ networkRequest: ADEumHTTPRequestTracker?) -> Bool {
    return false
}

```

In general, though, you would identify network requests that you didn't want to monitor and return `NO` (Objective-C) or `false` (Swift) to ignore the network request as implied by this example.

[Objective-C](#) Swift

```

- (BOOL)networkRequestCallback:(ADEumHTTPRequestTracker *)networkRequest
{
    NSString *urlString = networkRequest.url.absoluteString;
    BOOL returnBeacon = YES;
    if (![urlString rangeOfString:@"avatar"].location == NSNotFound) {
        returnBeacon = NO;
    }
    return returnBeacon;
}

```

Objective-C [Swift](#)

```

func networkRequestCallback(_ networkRequest: ADEumHTTPRequestTracker?) -> Bool {
    let urlString = networkRequest?.url.absoluteString
    var returnBeacon = true
    if !(Int((urlString as NSString)?.range(of: "avatar").location ?? 0) == NSNotFound) {
        returnBeacon = false
    }
    return returnBeacon
}

```

Register the Callback

After implementing the callback, you register the object implementing the protocol method in the initialization code as shown below. When the iOS Agent is ready to create a network request beacon, it will first call the callback with an `ADEumHTTPRequestTracker` object.

[Objective-C](#) [Swift](#)

```
ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc] initWithAppKey:
<#EUM_APP_KEY#>];
config.networkRequestCallback = self;
[ADEumInstrumentation initWithConfiguration:config];
```

[Objective-C](#) [Swift](#)

```
let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>)
config.networkRequestCallback = self
ADEumInstrumentation.initWith(config)
```

Enable Logging and Set Logging Level

You use the method `loggingLevel` to enable and set the logging level. You can set logging to one of the following levels:

- `ADEumLoggingLevelOff`
- `ADEumLoggingLevelAll`
- `ADEumLoggingLevelVerbose`
- `ADEumLoggingLevelDebug`
- `ADEumLoggingLevelInfo`
- `ADEumLoggingLevelWarn`
- `ADEumLoggingLevelError`

Use verbose, all, and debug levels of logging only for troubleshooting and be sure to turn off for production.

Examples:

[Objective-C](#) [Swift](#)

```

-(BOOL)application:(UIApplication *)application didFinishLaunchingWithOptions:
(NSDictionary *)launchOptions
{
    // appKey should be assigned your EUM app key
    ADEumAgentConfiguration *config = [[ADEumAgentConfiguration alloc] initWithAppKey:
<#EUM_APP_KEY#>];
    config.loggingLevel = ADEumLoggingLevelAll;
    [ADEumInstrumentation initWithConfiguration:config];
    ...
}

```

Objective-C [Swift](#)

```

func application(_ application: UIApplication, didFinishLaunchingWithOptions
launchOptions: [UIApplicationLaunchOptionsKey: Any]?) -> Bool {
{
    // appKey should be assigned your EUM app key
    let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>)
    config.loggingLevel = .all
    ADEumInstrumentation.initWithConfiguration(config)
    ...
    return true
}
}

```

iOS SDK Documentation

See the [latest iOS SDK documentation](#) or the previous versions listed below:

- <https://sdkdocs.appdynamics.com/ios-sdk/21.8/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/21.6/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/21.5/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/21.2/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/20.12/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/20.10/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/20.8/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/20.7/html/>
- <https://sdkdocs.appdynamics.com/ios-sdk/2020.3/html/>

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

 The `domain: String` used to initialize the standard `NSError` object used for `reportError` should not use unique string such as `Hashes`, `StackTraceID` or `ThreadID`. Including those will create an infinite number of `Error Group` which will impact performance.

To add unique error strings and values, you have two data collection options:

- Add a string value as a breadcrumb. If the event/error, you are reporting has a single value attached, add the value to `leaveBreadcrumb`. See [Breadcrumbs](#).
- Add string name and integer values. If the event/error, you are reporting has both name and integer values attached, add the values to `reportMetricWithName`. See [Custom Metrics](#).

Upload the dSYM File

Related pages:

- [Manage the dSYM Files with Bitcode Enabled](#)
- [Troubleshoot the iOS Instrumentation](#)

AppDynamics needs the dSYM file for the application to produce human-readable stack traces for crash snapshots. For details about why you should do this, see [Get Human-Readable Crash Snapshots](#).

If you update the application, you need to provide the new dSYM file for the new application version. The dSYM file contains a UUID that links it to a specific Xcode build, so AppDynamics can unambiguously match the correct dSYM file with an incoming crash report with no additional information.

To upload the dSYM file:

- [Enable the dSYM file](#)
- [Set up your environment to upload the file automatically each time you build](#) or [upload the file manually](#)

Enable the dSYM File

To enable the agent to provide human-readable information in the crash snapshots that are produced if the application crashes, compile with the `DWARF with dSYM` file option to create a debug symbols file for the application.

To enable dSYM:

1. In Xcode, select your project in the **Project Navigator**.
2. In the target list, select the target that builds your application.
3. Select the **Build Settings** tab.
4. In the **Build Options** section, make sure that the **Debugging Information Format** is set to `DWARF with dSYM File`.

Upload the dSYM File to AppDynamics Automatically with Each Build

Automating the upload of your dSYM file reduces the number of manual steps required for each build and ensures that all builds have appropriate dSYM files available for AppDynamics to use.

1. In Xcode, select your project from the **Project Navigator**.
2. Click on the application target.
3. Select the **Build Phase** tab in the **Settings** editor.
4. Click the + icon in the upper left corner of the main panel.
5. Select **New Run Script Phase** from the dropdown.
6. In the script box, add these lines:

```
export ADRUM_ACCOUNT_NAME="<Account_Name_HERE>" // From the View License - End User
Monitoring section of the License Page
export ADRUM_LICENSE_KEY="<License_Key_HERE>" // From the View License - End User
Monitoring section of the License Page
```

```
SCRIPT=$(/usr/bin/find "${SRCROOT}" -name xcode_build_dsym_upload.sh | head -n 1)
/bin/sh "${SCRIPT}"
```

7. There are also some optional parameters you can set if desired. To set them, add the following line(s) after the second `export` statement above. Set to `1` to enable.

```
export ADRUM_UPLOAD_WHEN_BUILT_FOR_SIMULATOR=0
export ADRUM_TREAT_UPLOAD_FAILURES_AS_ERRORS=0
export ADRUM_EUM_PROCESSOR="<EUM\_SERVER\_URL>"
```

The last statement should be used to set the URL for [regional cloud location for SaaS-based EUM accounts](#), or for on-premise server.

Upload the dSYM File to AppDynamics Manually

To upload the file manually:

1. [Get the dSYM file from Xcode](#)
2. [Upload the dSYM file to AppDynamics using the UI](#)
or
[Upload the dSYM File to AppDynamics Using the API](#)
3. [Check Uploaded dSYMs Using the REST API](#)

Get the dSYM file from Xcode

1. In Xcode, run the Xcode build: **Product > Build**.
2. View the log navigator: **View > Navigators > Show Report Navigator**.

 Older versions of Xcode used **Show Log Navigator**.

3. Click the log entry for the most recent build.
4. Near the end of the log, find and mouse over the log entry named `Generate <Your_App_Name>.app.dSYM`.
5. Click the button on the right side of the entry to expand it.
The end of the displayed command is the path to the dSYM file.
6. Navigate to this dSYM file in the Finder.
7. Right-click on the dSYM file and choose **Compress**.
8. Upload to AppDynamics the `.zip` file that **Finder** generates.

Upload the dSYM File to AppDynamics Using the UI

1. From the Mobile App menu, click **Configuration**.
2. Click **Mobile App Configuration >**.
3. From **dSYM Mappings**, click **Upload dSYM package file for iOS crashes**.
4. From the **XCode dSYM package upload** dialog, click **Choose File**.
The uploader expects a file with a `.zip` extension.

5. In the file browser locate the zipped dSYM file for the application that you are instrumenting and click **Open**.
6. Click **Upload**.

Upload the dSYM File to AppDynamics Using the REST API

The API uses HTTP basic authentication. The username is your EUM account name and the password is your EUM license key.

Set up your HTTP basic authentication credentials

1. In the upper-right corner of the Controller UI, click **Settings > License**.
2. From the Account Usage tab, scroll down to the **User Experience** section.
3. Click **Show** next to License Key to display the EUM license key. This is your password for authentication.

User Experience

Account Name e2e
License Key 4996dd76-6ac0-4cf0-80cb-XXXXXXXXXX [Hide](#)

4. [URL-encode](#) the EUM account name and the EUM license key.

Send the dSYM File

Send the dSYM as a zip archive in the body of a `PUT` request to following [URI](#):

[Americas](#) [EMEA](#) [APAC](#)

`https://api.eum-appdynamics.com/v2/account/<EUM_Account_Name>/ios-dsym`

[Americas](#) [EMEA](#) [APAC](#)

`https://fra-api.eum-appdynamics.com/v2/account/<EUM_Account_Name>/ios-dsym`

[Americas](#) [EMEA](#) [APAC](#)

`https://syd-api.eum-appdynamics.com/v2/account/<EUM_Account_Name>/ios-dsym`

You must set a Content-Type header, `-H Content-Type:application/octet-stream`, and your URL-encoded account name (the username) and license key (the password) to the call.

Sample Request and Response

This is a sample request and response using the REST API.

Upload Request

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

The following example uses `curl` to send a dSYM file named `UISampleApp.app.dSYM.zip`. The EUM account name is "Example account" and the password is "Example-License-Key-4e8ec2ae6cfe", the EUM License Key. The plus signs replace spaces in the account name when the account name is URL-encoded.

[Americas](#) [EMEA](#) [APAC](#)

```
curl -v -H Content-Type:application/octet-stream --upload-file UISampleApp.app.dSYM.zip --
user Example account:Example-License-Key-4e8ec2ae6cfe https://api.eum-appdynamics.com/v2/
account/Example+account/ios-dsym
```

[Americas](#) [EMEA](#) [APAC](#)

```
curl -v -H Content-Type:application/octet-stream --upload-file UISampleApp.app.dSYM.zip --
user Example account:Example-License-Key-4e8ec2ae6cfe https://fra-api.eum-appdynamics.com/
v2/account/Example+account/ios-dsym
```

[Americas](#) [EMEA](#) [APAC](#)

```
curl -v -H Content-Type:application/octet-stream --upload-file UISampleApp.app.dSYM.zip --
user Example account:Example-License-Key-4e8ec2ae6cfe https://syd-api.eum-appdynamics.com/
v2/account/Example+account/ios-dsym
```

Upload Response

The successful output of the sample request looks like this:

Check Uploaded dSYMs Using the REST API

You can check to make sure that your dSYMs have successfully uploaded using two REST APIs.

1. [Get a list of the UUIDs for the last 50 dSYMs you have uploaded](#)
2. [Check if a specific dSYM has been uploaded](#)

List of the Last 50 dSYMs Uploaded

The `dsymQuery` method allows you to retrieve a list of UUIDs for up to the last 50 dSYM files that have been uploaded to your account, along with the time they were uploaded. The response is displayed as JSON, by upload time, with the most recent first.

1. Set up your authentication as described in [Upload the dSYM File to AppDynamics Using the REST API](#).
2. Create a GET request of the form:

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://<EUM_Cloud/
Server_Host:Port>/v2/account/Example+account/crash-symbol-file-query/dsym
```

- `EUM_Cloud` refers to SaaS-based EUM Cloud URLs. For a complete list, see [SaaS Domains and IP Ranges](#).
- `EUM_Server_Host` refers to the URL pointing to your on-premises EUM Server.
- `EUM_Account_Name` is your EUM account name.
- `GUID_To_Check` is the GUID of the ProGuard file in which you are interested.

Sample Request

[Americas](#) [EMEA](#) [APAC](#)

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://api.eum-appdynamics.com:443/v2/account/Example+account/crash-symbol-file-query/dsym
```

Americas EMEA APAC

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://fra-api.eum-appdynamics.com:443/v2/account/Example+account/crash-symbol-file-query/dsym
```

Americas EMEA APAC

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://syd-api.eum-appdynamics.com:443/v2/account/Example+account/crash-symbol-file-query/dsym
```

Sample Response

```
{"dSymFiles":[
{"uploadTime":"mm/dd/yyyy 14:15:32","UUID2":"my_uuid2"},
{"uploadTime":"mm/dd/yyyy 14:15:32","UUID":"my_uuid"}
]}
```

Check for Specific dSYM by UUID

The `checkForDSymFile` method allows you to check if a specific dSYM by UUID has been uploaded. The upload time is returned in the response.

1. Set up your authentication as described in [Upload the dSYM File to AppDynamics Using the REST API](#).
2. Create a GET request of the form:

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://<EUM_Cloud/Server_Host:Port>/v2/account/Example+account/crash-symbol-file-query/dsym/uuid/<UUID_to_Check>
```

- `EUM_Cloud` refers to SaaS-based EUM Cloud URLs. For a complete list, see [SaaS Domains and IP Ranges](#).
- `EUM_Server_Host` refers to the URL pointing to your on-premises EUM Server.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- `EUM_Account_Name` is your EUM account name.
- `GUID_To_Check` is the GUID of the ProGuard file in which you are interested.

Sample Request

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://<EUM_Cloud/Server_Host:Port>/v2/account/Example+account/crash-symbol-file-query/dsym/uuid/<UUID_to_Check>
```

Sample Response

```
{"uploadTime":"mm/dd/yyyy 14:15:32","UUID":"my_uuid"}
```

Manage the dSYM Files with Bitcode Enabled

Related pages:

- [Upload the dSYM File](#)

With iOS 9, Apple introduced a new mode of building and distributing iOS apps called [App Thinning](#). As part of this initiative, apps containing bitcode are delivered.

If you choose to create your app containing bitcode, the process of acquiring your dSYM files for upload while you are in local development, debugging, and testing mode (Xcode on simulators or [Devices](#)) is exactly the same as in earlier versions.

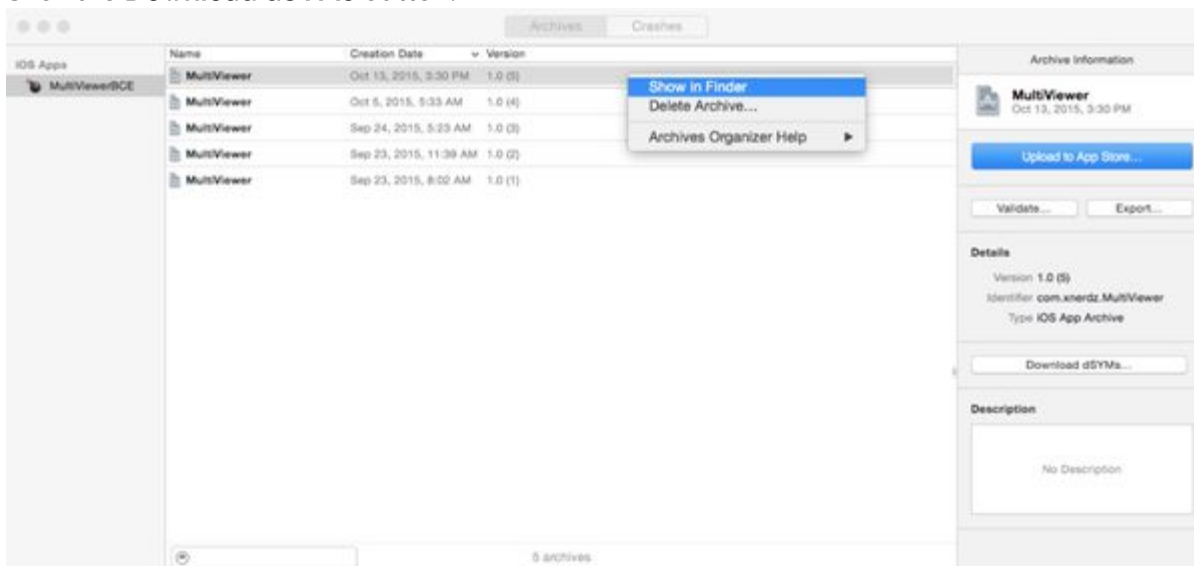

It also works if you are using [Ad Hoc Provisioning](#). But once you have used [iTunes Connect](#) to upload your application to Apple, for either TestFlight beta testing or application release, you have to take a few additional steps to get your dSYM files for use with AppDynamics.

Get and Upload the Correct dSYM File

As part of the process of preparing to upload your application using iTunes Connect, you [create an archive](#). After the app is uploaded to iTunes Connect, it is processed by Apple. To have the correct version of the dSYM for AppDynamics, you must download this processed version to your local archive.

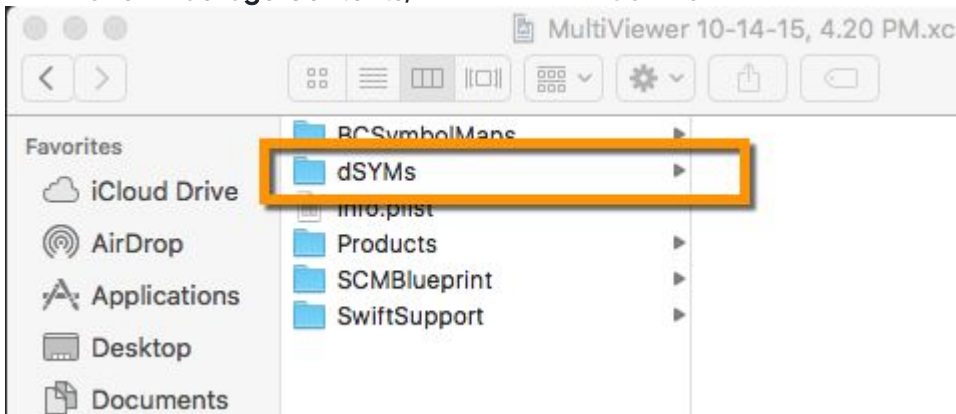

To download the processed dSYM file, in the Xcode **Archives Organizer**:

1. Make sure this version of the application is available for download (either TestFlight or the iTunes store).
2. In the **Archives** organizer, select the archive for this version.
3. Click the **Download dSYMs** button.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- Right-click the `.xcarchive` file you receive and select **Show in Finder**. Right-click again and select **Show Package Contents**, and select the **dSYMs** folder.

- Zip this directory and upload.

See the [Apple Developer docs](#).

Upload Missing dSYM Files

If you have crashes that AppDynamics could not symbolicate because it did not have a correct dSYM file, you get an error message in the **Crashes Details** dialog.

The screenshot displays the 'Crashes Details' dialog for a SIGSEGV in 'promoview : 327'. It includes a 'Crash Summary' with 8299 total crashes and 1001 impacted users. A 'Crash Trend' graph shows a steady increase in crashes over time. The 'Stack Trace at 05/24/19 7:00:55 PM' shows the following frames:

Frame	Address	Symbol	Function
0-2	libsystem_platform.dylib - libsystem_c.dylib	0x35b09978 - 0x35a18a0	__platform_memmove - __strcpy_chk
3	ECommerce-iOS	0x000ec9fe	promoview(Promoview : 327)
4-18	UIKit - UIKit	0x27951cd6 - 0x2798218a	-[UIApplication sendAction:to:from:for:with:] - UIApplicationMain
19	ECommerce-iOS	0x000e005a	
20	libdyld.dylib	0x359a1870	start

The 'Events Prior to Crash' section shows the following sequence:

Time	Event
7:00:47 PM	ChangeAddressView
7:00:42 PM	SettingsView
7:00:37 PM	CartView
7:00:31 PM	ListView
7:00:25 PM	LoginView

A warning message at the top right states: 'Some dSYM files need to be uploaded. Upload'.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

If you click **Upload missing dSYM files in Instrumentation**, a list of dSYM hashes appears. Match the missing files with the dSYMs in your archives, as shown above. If necessary, click **Download dSYMs** to update the archive. Upload the necessary files to AppDynamics.

Some of the missing dSYM files that AppDynamics reports may belong to simulation/debug builds that have crashed. In this case, the dSYMs may no longer be available.

Troubleshoot the iOS Instrumentation

Related pages:

- [Install the iOS SDK](#)
- [Instrument an iOS Application](#)
- [Customize Your Instrumentation With the iOS SDK](#)

This page provides instructions and tips for solving some common iOS instrumentation issues.

Agent Not Detecting Requests

First, confirm that you are using either the `NSURLConnection` or the `NSURLSession` class. By default, you are required to make network requests. If you are using a custom HTTP library, make sure you follow the instructions given in [Use the Agent with a Custom HTTP Library](#).

If you are using `NSURLSession`, be sure to create an instance of `NSURLSession` *after* initializing the iOS agent. This is because the agent may not be aware of objects created before the instrumentation is initialized.

Unrecognized Selector Error

If you are instrumenting your app using the manual method and you see this error message:

```
+[NSURLConnection ADEumInsertHooks]: unrecognized selector sent to class <hex value>
```

Then, you did not add `-ObjC` to your link flags. See [Set the -ObjC Flag](#) for instructions.

Overview of the Controller UI for Mobile RUM

This page provides an overview of the Controller UI for Mobile RUM applications. Mobile RUM presents your application information in the following ways:

- **Mobile App Dashboard:** An overview dashboard, with tabs for
 - Widgets for visually displaying common metrics
 - Map-based performance display
 - Usage statistics
- **Experience Journey Map:** A map of top user journeys navigating your mobile application
- **Mobile Sessions:** A detailed list of mobile sessions, following users as they interact with your application
- **Network Requests Lists:** A detailed list of network requests with dashboards
- **Crashes:** A dashboard displaying of application crash trends and detailed snapshots of individual crashes with stack traces
- **Custom Data:** A dashboard specific data you want the agent to collect for you

Access a Browser RUM Application

To see application data in the Controller UI:

1. In the top tab bar, select **User Experience**. The list of instrumented Browser and Mobile Apps displays.
2. Select the **Mobile App** tab.
3. Double-click a mobile application.

Mobile App Dashboard

The **Mobile App Dashboard** provides a high-level overview of how your application is performing, including the following:

- [Widget-based overview](#)
- [Geo dashboard](#), displaying where your requests originate, including a variety of key performance metrics
- [Set of aggregated usage statistics](#), by device, carrier, connection type, OS version, and app version

Access the Mobile App Dashboard View

1. Open the application you want.
2. From the left navigation bar of your application, select **Mobile App Dashboard**.
3. Click the tab for the view you want to access.

Overview Dashboard

The **Overview Dashboard** displays a set of configurable widgets, showing multiple graphs and lists featuring common high-level indicators of application performance. You can delete widgets, re-add them, resize them, and drag them to different locations.

Geo Dashboard

The Mobile App **Geo Dashboard** displays key performance metrics by geographic location.

The dashboard is divided into three panels:

- A main panel in the upper left that displays geographic distribution of mobile users on a map, if you clicked the map view icon, or on a grid, if you clicked the grid view icon.
- A panel on the right displaying key timings.
- A lower panel with dynamic trend graphs of KPIs.

The metrics displayed throughout the geo dashboard are for the country currently selected on the map or in the grid. For example, if you zoom down from the world view to France on the map, the panel on the right disappears and the trend graphs display data for France.

See [Mobile RUM Metrics](#) for definitions of the metrics.

Map View Labels

The map view displays load circles with labels for countries that are in the key timing metrics given in the right panel. Some countries and regions, however, are only displayed in the grid view.

Regions and Countries

Regions are subdivisions of a country, such as a state, province, or city. In the default map view, key performance metrics are displayed by country. The grid view, like the map view, by default displays key performance metrics by country, but can also be configured to show the metrics by region. Because the map view displays fewer regions than the grid view, if you do not see a region displayed in the map view, switch to the grid view.

See [Browser RUM Countries and Regions by Geo Dashboard](#) for a list of the countries and regions available in the map and grid views.

Unknown Locations in Map and Grid Views

An unknown location is one for which the agent cannot determine the country from which the request originated.

You may also see metrics reported for a location named **Anonymous Proxy**. The data for **Anonymous Proxy** represents the aggregated metrics from one or more private IP addresses that the agent cannot identify.

One of the effects of Unknown regions is that it possible for a country to display as slow (red circles) on the global map, but when you drill down to the country all its regions appear normal (green circles). Or a country may display as normal on the global map, but some sub-regions may display as slow when you drill down.

Usage Stats

This tab shows graphical and tabular breakdowns of usage by device, carrier, connection type, OS version, and app version. The breakdowns for the connection type are based on network requests. The other usage breakdowns are based on "app opens", *not* network requests. App opens are counted when a mobile application is booted or brought to the foreground. In the case of Android, the app opens occur when the method `onResume` is called for an activity. For iOS, the app opens occur when the method `applicationDidBecomeActive` is called.

i The Android Agent obtains the carrier name by calling the Android SDK method `android.telephony.TelephonyManager.getSimOperatorName` and obtains the device name with the Android SDK property `android.os.Build.MANUFACTURER`. If the value for either the carrier or device name is "unknown", this indicates that the method `getSimOperatorName` or the property `MANUFACTURER` did not return a value.

Mobile Screenshots

Mobile screenshots provide context to the data collected in the Controller UI. They also allow you to better understand the user experience.

Screenshots enable you to:

- **Verify Presentation:** Determine if an app is displaying correctly on different devices.
- **Understand User Behavior:** Determine where users are clicking on the screen.
- **Troubleshoot Bugs:** Analyze bugs and errors by correlating code issues with screenshots. You'll be able to see what the user is doing when issues happen.

AppDynamics Version Requirements

You must use these AppDynamics software versions:

- Controller \geq 4.3.2
- iOS/Android Agents \geq 4.3.2
- AppDynamics Cordova Plugin \geq 1

Screenshot Limitations

Mobile screenshots have the following limitations:

- Only iOS/Android/Cordova platforms are supported.
- You can enable or disable screenshots or explicitly exclude screenshots for specific screens/activities.
- You cannot set a minimum/maximum number of screenshots per session.
- Touch points are not collected unless screenshots are in automatic mode.
- The touch points will not be included in screenshots from past sessions.
- The UI Event feature is not related to screenshots or touch points in any way. Thus, the screenshot will not be directly correlated with a UI event in the **Waterfall**.

Types of Screenshots

Mobile RUM captures conventional screenshots and touch-point screenshots that capture user touch events. Both types of screenshots have timestamps, but the latter will also plot "user touches" on the panel.

Conventional Screenshots	Touch Point Screenshots
 <p>The conventional screenshot will simply show what your users viewing. These screenshots can be taken programmatically or by enabling automatic screenshots in the Controller UI.</p>	 <p>The touch point screenshot shows where users touched the screen when using your app. Touch points are only collected when automatic capture mode is enabled.</p>

When Screenshots Are Taken

Screenshots can only be captured if the Mobile Agent and the Controller UI have enabled screenshots.

Once screenshots have been enabled, screenshots will be only taken if one or more of the following are true:

- The Mobile Agent uses the SDK API to manually take a screenshot.
- You have enabled automatic capture in the Controller UI.

Configure Mobile Screenshots

You have several methods for controlling when screenshots are taken. This page lists the settings for disabling/enabling and taking screenshots.

Screenshot Control Settings

This table lists the different settings for screenshots, the user tasks required for the settings, and a description of what the settings accomplish. Screenshots are enabled by default in the iOS and Android Agents, but disabled in the Controller UI. To use screenshots, you need to enable screenshots in the Controller UI.

Screenshot Setting	User Tasks	Result
Disable Screenshots From Being Taken	Perform one of the following: <ul style="list-style-type: none"> <input type="checkbox"/> Disable screenshots with the iOS/Android SDK. <input checked="" type="checkbox"/> Disable screenshots in the Controller UI. 	<p>Only Disable Screenshots with the iOS/Android SDK</p> <p>Screenshots are globally disabled. The Controller UI cannot override the Mobile Agent setting.</p> <p>Only Disable Screenshots with the Controller UI</p> <p>The Controller will disable screenshot capture in the Mobile Agent. Because the Controller setting is propagated to the Mobile Agents through the EUM Server, the Mobile Agent may take screenshots before its screenshot setting has been updated. Once the Controller setting has been applied, however, the Mobile Agent will no longer take screenshots.</p>
Enable Screenshots	<ul style="list-style-type: none"> <input checked="" type="checkbox"/> Enable screenshots in the Controller UI. 	<p>The Mobile Agent can take screenshots, and the Controller UI will display them in the session results.</p>
Enable Screenshots - Manual Screenshots (Wi-Fi)	<ul style="list-style-type: none"> <input checked="" type="checkbox"/> Enable screenshots in the Controller UI. <input checked="" type="checkbox"/> Manually take screenshots using the iOS/Android SDKs. 	<p>You call the Mobile SDK to take screenshots. The screenshots are only uploaded to the Controller when the device is using Wi-Fi.</p>

Screenshot Setting	User Tasks	Result
Enable Screenshots - Automatic Screenshots (Wi-Fi)	<ul style="list-style-type: none"> ✓ Enable screenshots in the Controller UI. ✓ Configure the Controller UI to automatically take screenshots. 	Screenshots are automatically taken periodically. The screenshots are only transmitted when the device is using Wi-Fi.
Enable Screenshots - Manual Screenshots (Wi-Fi / Cellular Data)	<ul style="list-style-type: none"> ✓ Enable screenshots in the Controller UI. ✓ Configure the Controller UI to allow the use of cellular data. ✓ Manually take screenshots using the iOS/Android SDKs. 	You call the Mobile SDK to take screenshots.
Enable Screenshots - Automatic Screenshots (Wi-Fi / Cellular Data)	<ul style="list-style-type: none"> ✓ Enable screenshots in the Controller UI. ✓ Configure the Controller UI to automatically take screenshots. ✓ Configure the Controller UI to allow the use of cellular data. 	Screenshots are automatically taken periodically.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Take Mobile Screenshots

Related pages:

- [Customize the iOS Instrumentation](#)
- [Customize the Android Instrumentation](#)

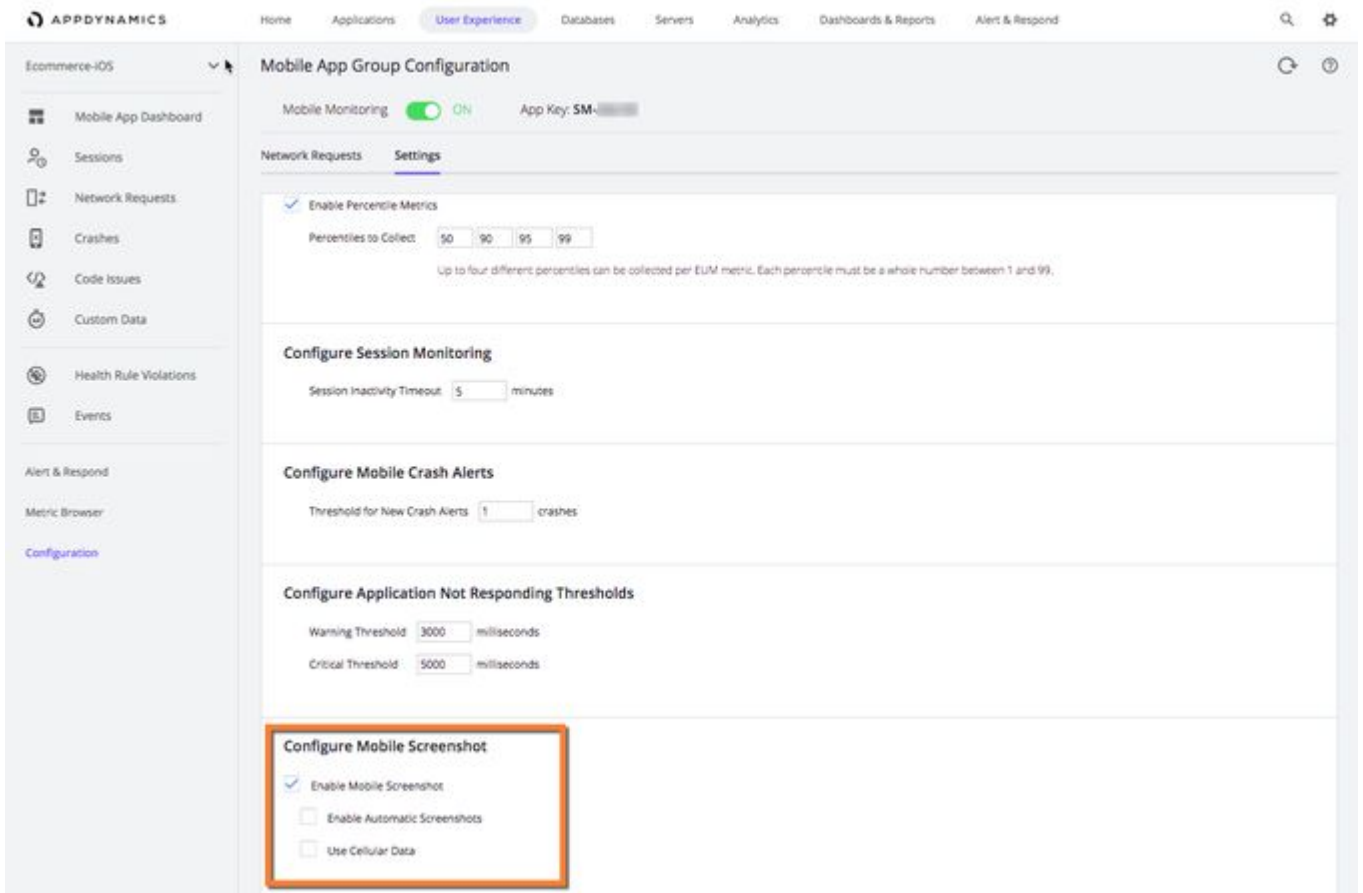

This page describes how to enable and disable screenshots and manual and automatic screenshots.

Enable Mobile Screenshots

Mobile screenshots are disabled by default (in the Controller) for security and privacy reasons as screenshots may contain sensitive information.

To enable mobile screenshots:

1. Navigate to one of your mobile apps.
2. Open the **Configuration** page.
3. Click **Mobile App Group Configuration**.
4. Check the **Enable Mobile Screenshot** checkbox.

5. (Optional) If you want to allow the application to take screenshots when using cellular data, check the **User Cellular Data** check box.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Enable Automatic Screenshots

Mobile screenshots are disabled by default (in the Controller) for security and privacy reasons as screenshots may contain sensitive information. If automatic screenshots are enabled, screenshots are taken every 10 seconds.

To enable automatic screenshots:

1. Navigate to one of your mobile apps in the Controller UI.
2. Open the **Configuration** page.
3. Click **Mobile App Group Configuration**.
4. Scroll down to **Configure Mobile Screenshot** and confirm that the **Enable Mobile Screenshot** checkbox is checked.
5. Check the **Enable Automatic Screenshots** check box.

Configure Mobile Screenshot

Enable Mobile Screenshot

Enable Automatic Screenshots

Use Cellular Data

-
6. (Optional) If you want to allow the application to take screenshots when using cellular data, check the **User Cellular Data** check box.

Programmatically Take Screenshots

You can use the Android or iOS SDK to programmatically take screenshots. See:

- [Android: Configure and Take Screenshots](#)
- [iOS: Configure and Take Screenshots](#)

View Mobile Screenshots

Mobile screenshots are included in the **Session Details**. You can view a timeline of the screenshots and touchpoints that were taken during the user's activity.

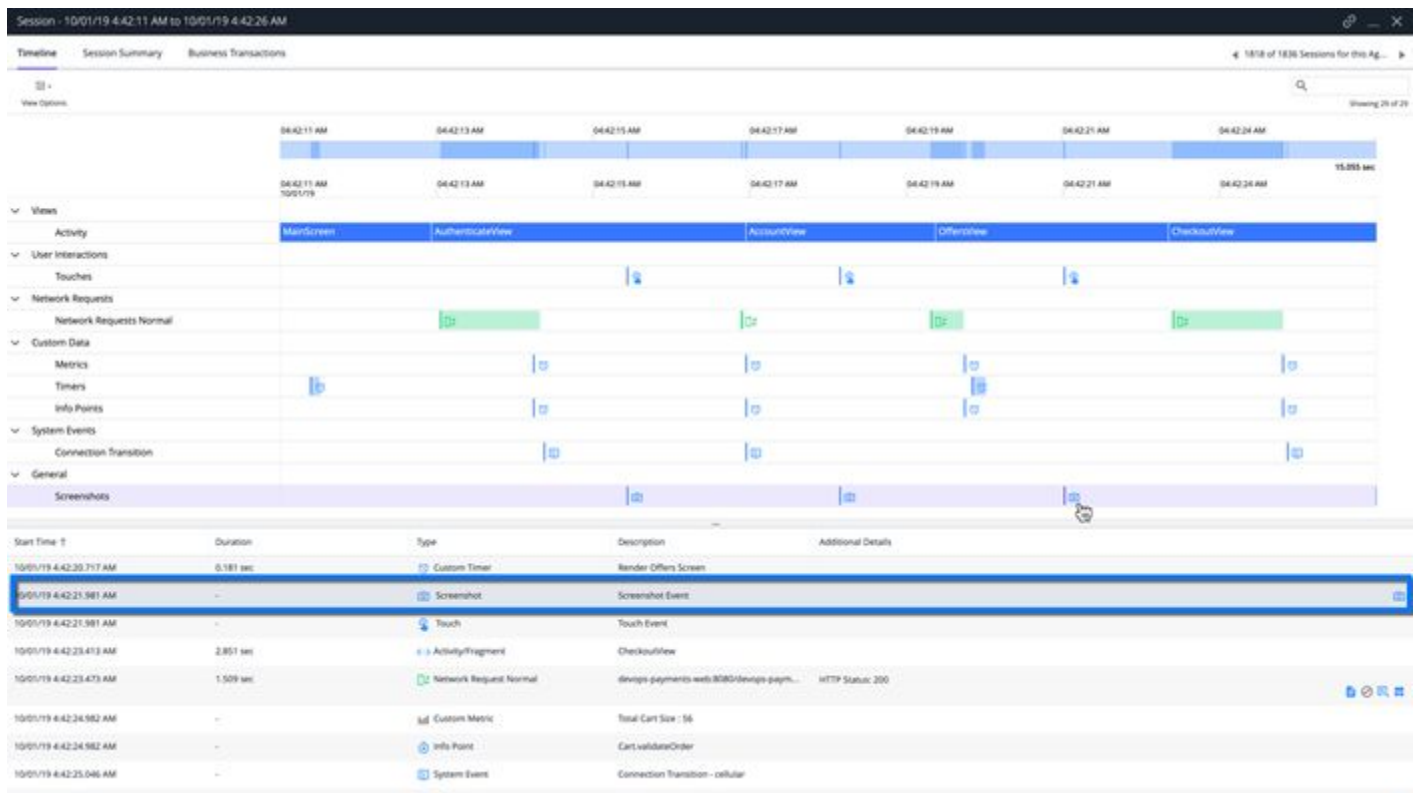

This page describes how to view screenshot and touch events in the timeline of the Timeline tab, and view thumbnails and full-size images of the screenshots and touches in the chronological event list.

Screenshot Events in the Timeline

Both conventional and touch-point screenshot events appear in the Timeline tab at the time that it was taken.

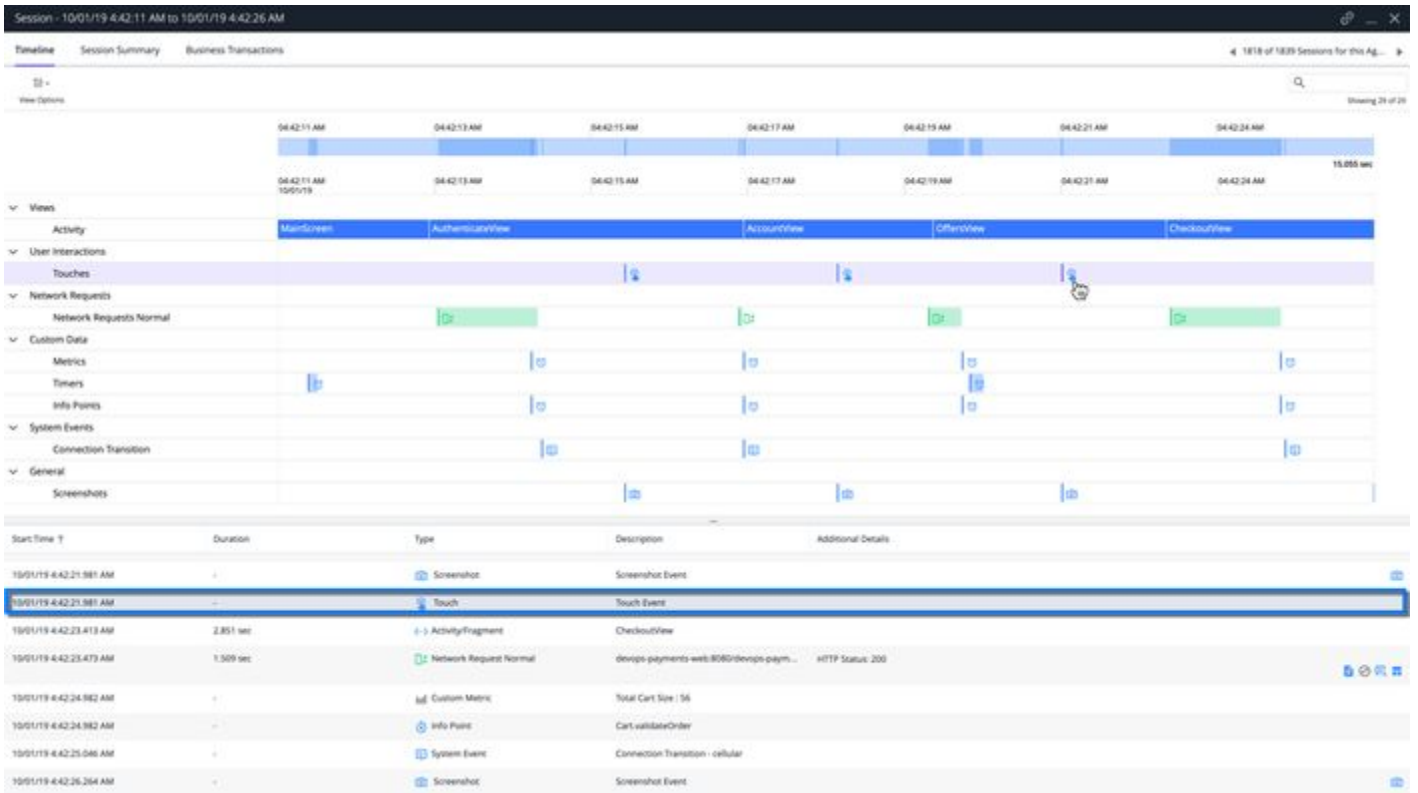

Conventional Screenshots

Conventional screenshots appear in **General > Screenshots**. Click the **camera** icon to view details of the screenshot event in the chronological event list at the bottom.

Screenshots of Touches

Screenshots of touches appear in **User Interactions > Touches**. Click the **screen touch** icon to view details of the touch event in the chronological event list at the bottom.

Screenshot Thumbnails

From the chronological list of events at the bottom of the page, you can hover over a screenshot or touch event to view a thumbnail. The screenshot of the touches displays the touch locations in pink.

Conventional Screenshot Thumbnail						Screenshot Thumbnail of Touches					
Start Time	Duration	Type	Description	Additional Details	Thumbnail	Start Time	Duration	Type	Description	Additional Details	Thumbnail

Mobile Health Rules

Related pages:

- [Policies](#)
- [Troubleshoot Health Rule Violations](#)

You can set [mobile health rules](#) to trigger [actions](#) when certain conditions are met or exceeded based on configured thresholds for mobile application metrics.

To [configure alerts and responses](#), you can use the **Getting Started Wizard** or manually create alerting policies based on mobile health rules. Alerts and responses help you to anticipate and take action for problems with your mobile applications.

This page describes the two types of mobile health rules, how to select mobile health rule types, create new mobile health rules, and how to view the health results of your mobile applications.

Mobile Health Rule Types

When you select the [health rule scope](#) for mobile applications, you are given a set of health rules based on the two [health rule types](#): **Mobile Apps** and **Network Requests**. You can create new health rules using the mobile health rule types or use a custom health rule type.

Mobile Apps Health Rule Type

The **Mobile Apps** health rule type can be used to add conditions based on a wide range of mobile application metrics such as application starts, crashes, or network requests for the application. The network request metrics for the **Mobile Apps** health rule type refer to all the network requests of the application. For example, when you configure a threshold for the metric **Slow Network Requests**, the **Mobile App** type health rule will evaluate all the network requests of the mobile application in determining which network requests are slow.

Network Requests Health Rule Type

The **Network Requests** health rule can only be used to add conditions based on network-related metrics such as HTTP errors, network errors, network request time, and network requests per minute. The network request metrics for the **Network Requests** health rule type refers to specific network requests. For example, when you configure a threshold for the metric **Slow Network Requests**, the **Network Requests** type health rule will evaluate one network requests, such as calls to `http://google.com` in determining which network requests are slow.

Custom Health Rule Type

The **Custom** health rule type allows you to use any metric. This enables you to set health rules that have metrics from different health rule types. For example, you could have a custom health rule that is based on configured thresholds for mobile metrics and business transaction metrics.

Create Health Rules

The process and user flow for creating health rules for mobile applications are similar to creating health rules for other applications. Thus, if you haven't created policies or health rules before, see [Configure Policies](#) and [Configure Health Rules](#) for general instructions. The sections below are not going to cover

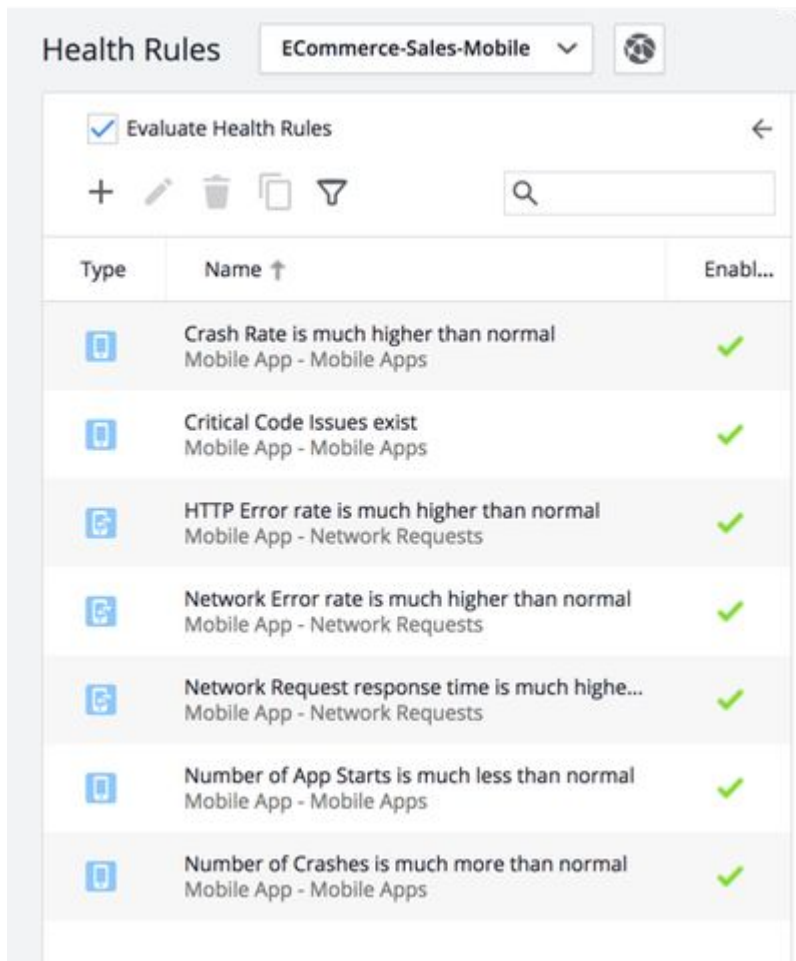

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

creating policies, but instead focus strictly on the important differences when creating health rules for mobile applications.

The first example will show you how to use the default set of mobile health rules, modify one of the default mobile health rules, and finally, how to create a new health rule using one of the mobile health rule types.

Using Default Health Rules

When you use the [health rule scope](#) for mobile applications, you are given a set of default health rules based on mobile health rule types. To enable these default health rules, click **Alert & Respond > Health Rules** to see the list of default health rules for mobile applications. You can use these default health rule types for your mobile applications by checking the **Evaluate Health Rules** checkbox:

Modify Default Health Rules

The default health rules for mobile applications are based on mobile health rule types and have default conditions based on preset values for mobile metrics. You may want to retain the default health rules, but want to customize the conditions for your mobile application. To do this, click the default health rule you

want to modify and navigate to either the **Critical Warning** or **Warning Condition** panel. You can then change the parameters of the existing conditions or add new conditions.

Select Mobile Applications for the Health Rules

You can choose whether to apply the health rules for mobile applications. Depending on the mobile health rule type, you have different criteria to choose when to apply the health rules.

For health rules based on the health rule type **Network Requests**, you can apply the health rules for:

- All network requests in the mobile app group
- Specified network requests
- Network requests matching criteria
- Network requests for specific mobile applications

For health rules based on the health rule type **Mobile Apps**, you can apply the health rules for:

- All mobile applications in a mobile app group
- Specified mobile applications
- Mobile applications matching criteria

Create New Health Rules

You may want to create additional health rules based on one of the mobile health rules or a custom health rule. You do this in the same way you would create any health rule, except from the **Create Health Rule** dialog, you would select either the mobile health rule type **Mobile Apps** or **Network Requests**:

Create Health Rule

Save

You can choose to apply the new health rule to mobile applications that you select, or those that match given criteria.

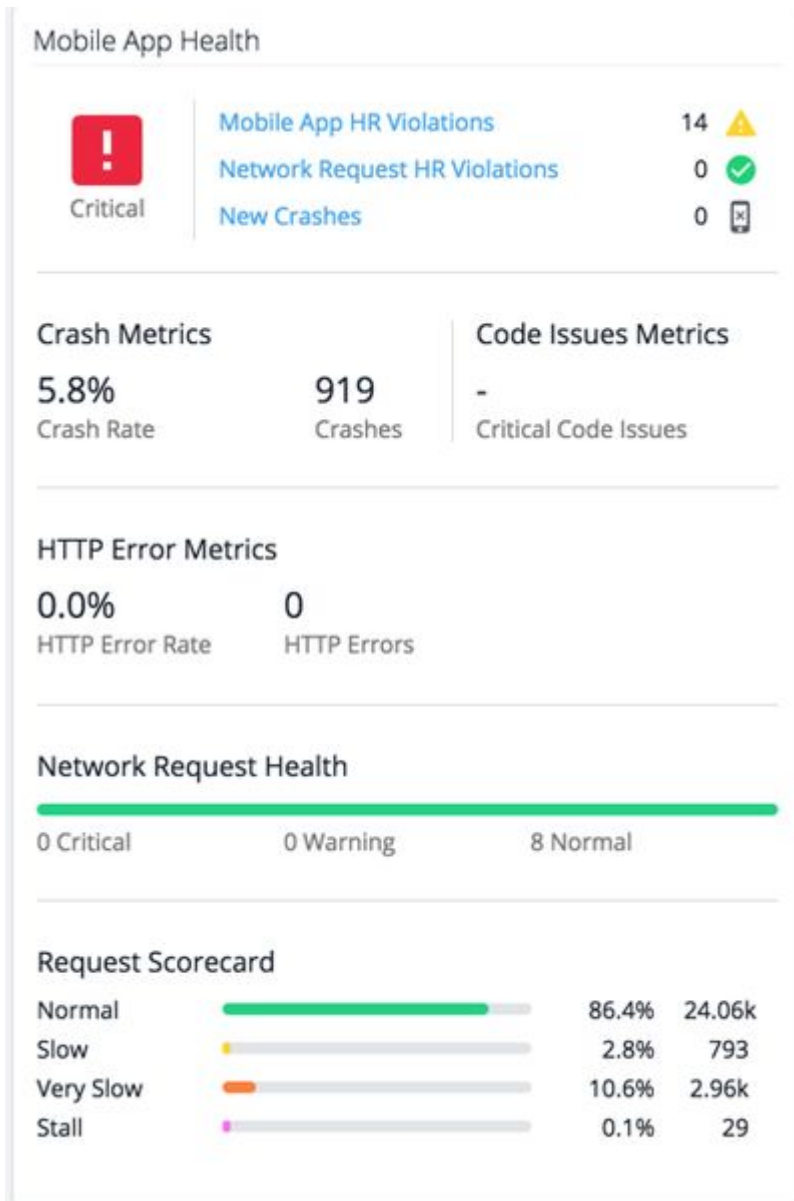

From the **Critical Criteria** and/or **Warning Criteria** panels, you can add conditions and define parameters with mobile metrics.

View Health Results

In addition to getting alerts when mobile applications are unhealthy, you can also view the health of your mobile application from certain widgets the **Mobile App Dashboard** and in the Events and Health Rule Violations tabs.

Overview Widgets

From the **Mobile Dashboard**, you should see the **Mobile App Health** widget. The widget displays health rule violations, crash metrics, and the network request health.

Events

The Events tab displays the health rule violations for your mobile application. See [Monitor Events](#).

Type ↑	Summary	Time	Business Transaction
Health Rule Violation Sta...	Health Rule Crash Rate has violated	12/16/18 3:58:55 PM	-
Health Rule Violation Sta...	Health Rule Crash Rate has violated	12/18/18 2:06:55 PM	-
Health Rule Violation Sta...	Health Rule Crash Rate has violated	12/18/18 11:30:55 AM	-
Health Rule Violation Sta...	Health Rule Crash Rate has violated	12/18/18 11:27:55 AM	-
Health Rule Violation Sta...	Health Rule Crash Rate has violated	12/18/18 5:10:55 AM	-
Health Rule Violation Sta...	Health Rule Crash Rate has violated	12/18/18 2:25:55 AM	-
Health Rule Violation Sta...	Health Rule Crash Rate has violated	12/18/18 1:10:55 AM	-

You can sort the health rule violations for your mobile application by event types, health rules, or custom events you created.

Health Rule Violations

The Health Rule Violations tab lists the health rule violations that have happened over the specified time or that are still open.

Health Rule	Affects	Sta...	Description ↑	Start Time	End Time	Duration
Crash Rate	EcommAndroid	Open	Crash Rate	12/18/18 2:06:55 PM	-	7 hours, 49 minutes Ongoing
Crash Rate	EcommAndroid	Res...	Crash Rate	12/09/18 5:31:55 AM	12/09/18 3:20:55 PM	9 hours, 49 minutes
Crash Rate	EcommAndroid	Res...	Crash Rate	12/17/18 10:57:55 AM	12/17/18 12:19:55 PM	1 hour, 22 minutes

Double-clicking one of the health rule violations in the list opens the **Health Rule Violation Details** dialog showing the type of health rule violation, the timeline, the events, and a description of the violation.

Mobile Sessions

Related pages:

- [EUM Data](#)
- [Mobile RUM Metrics](#)

In most cases, a user's interaction with your app is not limited to one action in one panel view. Sessions allow you to track your users' interactions across time, as they navigate an entire session with your app. By default, sessions begin when a user starts using your application and ends after a configurable period of user inactivity. You can also programmatically control sessions through the Mobile Agents SDKs ([Android](#), [iOS](#), [Xamarin](#), [Cordova](#)). Using Mobile Sessions, you can analyze *sessionized* results from all requests, as stored in the AppDynamics Events Service.

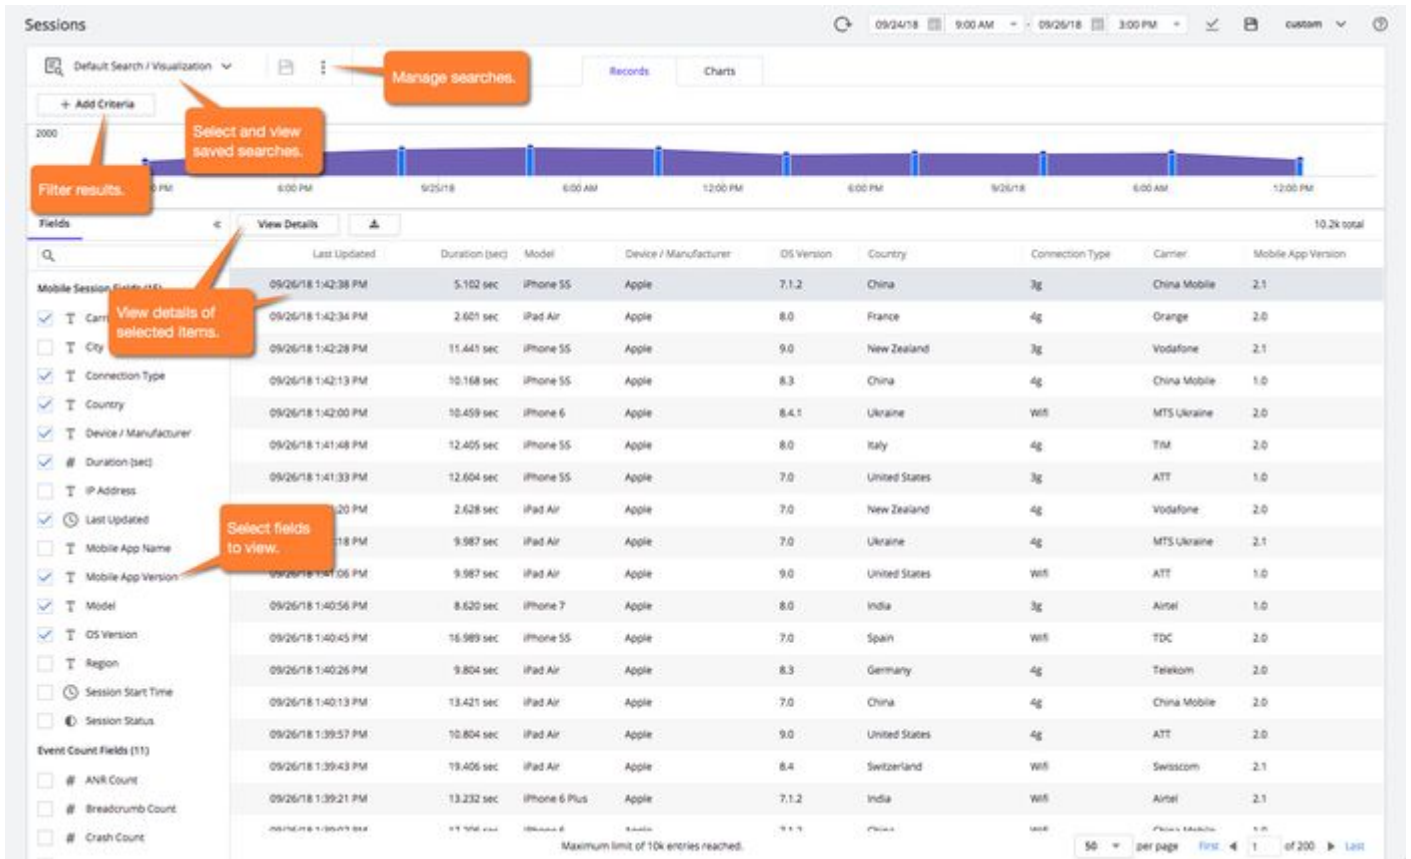

As in [Network Request Analyze](#), the main Sessions panel is comprised of these tabs:

- [Records](#)
- [Charts](#)

You can also view detailed information about each session in the [Session Details](#) dialog.

Records

The Records tab lets you scan individual sessions and allows you to filter and sort to get exactly the data in which you are interested.

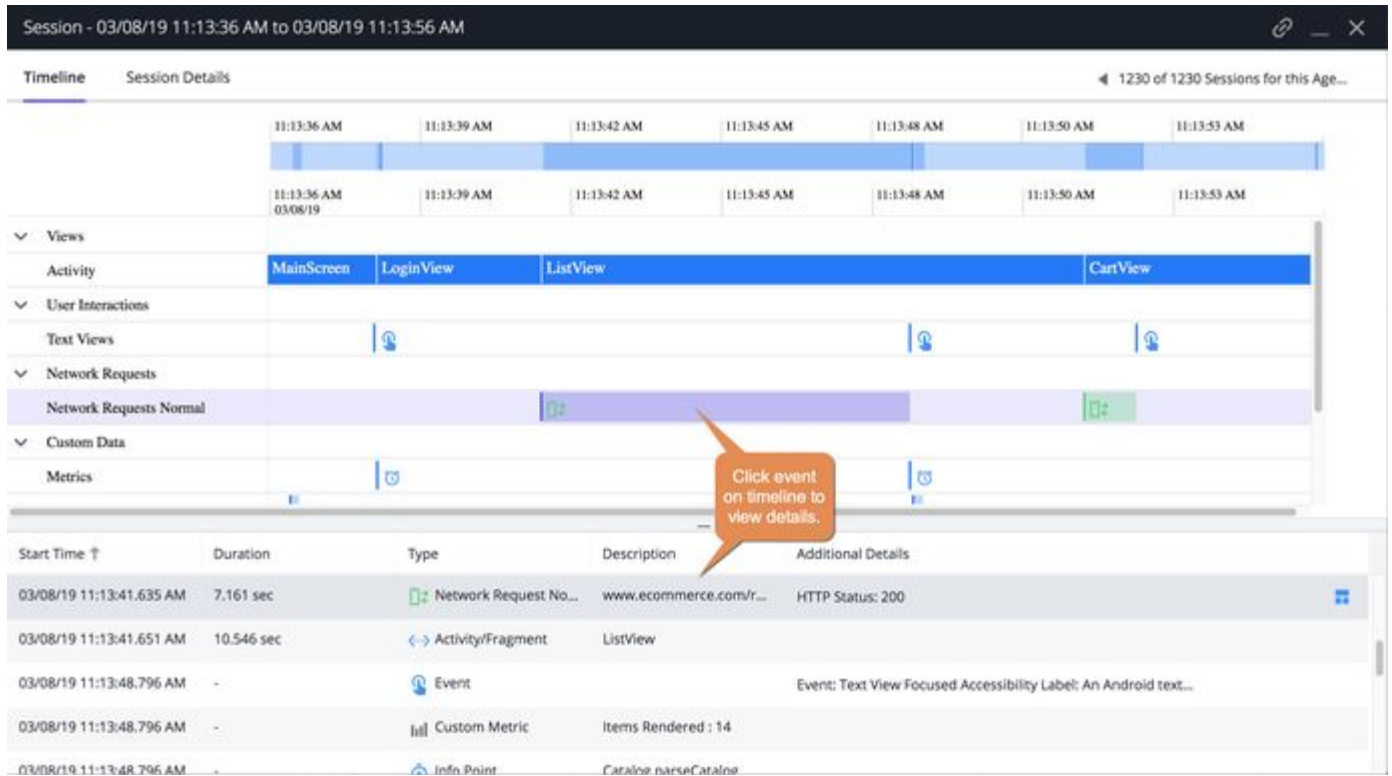

Session Details

Click **View Details** or double-click an item to see the information for a specific session.

Session Timeline

The sequence of session frames for the session is shown on the session timeline and on the bottom of the panel. Select a specific frame by clicking on an icon on the timeline to see details highlighted at the bottom of the panel. You can also select a frame row at the bottom to see it highlighted on the timeline.

Session Details Categories and Types

Categories	Subcategories	Type	About
Views	Activity	Activity/Fragment	The current Activity in the foreground of an Android app. If the current Activity is not sufficient to understand what the user is doing, consider using the Session Frame APIs.
	RootViews	RootView	The current RootView in the foreground of the iOS App. If the current RootView is not sufficient to understand what the user is doing, consider using the Session Frame APIs.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Categories	Subcategories	Type	About
	Session Frames	 Session Frame	A manual API to label large user activities that are not captured out of the box by Activity or RootView tracking.
Screenshots	-	 Screenshot	If you have configured mobile screenshots, they will appear in the timeline. They capture user events, and they can also be collected when in automatic mode.
User Interactions	Touches	 Event	If you have enabled the Mobile Agent to capture UI events, you can view the UI events triggered by user interactions in the Timeline . See "Enable User Interaction Capture Mode" (iOS / Android) to learn how to capture UI events.
	Buttons		
	Table Cells		
	Text Views		
	Text Fields		
Network Requests	Network Requests Normal	 Network Request Normal	Network requests include the requested URL, duration, and status details of the HTTP request. To jump to more Network Requests details, click  .
	Network Requests Slow	 Network Requests Slow	
	Network Requests Very Slow	 Network Requests Very Slow	
	Network Requests Stall	 Network Requests Stall	

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Categories	Subcategories	Type	About
Errors And Warnings	Application Not Responding Issues (ANRs)	 ANR	<p>You can view when the application was non-responsive in the timeline. ANRs are reported when the UI thread does not respond to an event for two seconds or more.</p> <p>To download or view the ANR Summary, click  or , respectively.</p>
	Crashes	 Crash	<p>When an app crashes the subsequent activity will appear in the timeline.</p> <p>To download or view the Crash Summary, click  or , respectively.</p>
	Errors	 Error	<p>If you have reported errors with the Mobile Agent SDKs, the errors will also appear in the timeline. See "Report Errors and Exceptions" (iOS/Android) to learn how to instrument your mobile apps to report errors and exceptions.</p> <p>To download or view the Error Summary, click  or , respectively.</p>
Custom Data	Metrics	 Custom Metric	<p>Custom metrics display integer-based data on any metric you define in your application.</p>
	Timers	 Custom Timer	<p>Custom timers display how long something takes between any arbitrary start point and end point, even if they span multiple methods.</p>

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Categories	Subcategories	Type	About
	Info Points	 Info Point	Information points display information on how a specific method in your code is performing.
	Breadcrumbs	 Breadcrumb	Breadcrumbs are short messages to mark interesting events in a session, controlled by the Breadcrumb APIs in the agent.
System Events	Connection Transition	 System Event	Connection transition indicates when a broadband transition has taken place, such as from Wifi to cellular.
	Agent Init	 System Event	Agent Init indicates when the Mobile Agent was first initialized. It can help with debugging the application lifecycle.

View Options

You can filter the categories in your timeline view by clicking **View Options**. Check all relevant categories for your search. All view options are checked by default.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Session Summary

You can see a summary of the session by clicking **Session Summary**.

Timeline	Session Summary	37 of 37 Sessions for this Agent						
2.001 sec Session Duration ⓘ	iOS Platform	8.0 OS Version	1.0 Mobile App Version	Wifi Connection Type	UserdataAllTypes Wizardry Level	Jenkins Name	342 # Length	
- IP Address	Telekom Carrier	Apple iPhone 5S Device	Hessen Region	Germany Country	true BooleanTrue ⓘ	-3.14 ## NumberPi	Wed Sep 14 18:26... 🕒 CurrentTime	

Business Transactions

You can see a list of business transactions in the session if applicable. This tab only appears if you have business transactions in the selected session.

Click the business transaction name to redirect to the transaction flow map.

Timeline	Session Summary	Business Transactions
Type	Name ↑	
	/cart/co.GET	
	/cart/{id}.GET	

Charts

The **Charts** page provides you with a set of predefined widgets that offer visualizations of the data set you have created. As with the **Charts** pages of the other Analyze/Session features of the UI, you can delete, re-add, resize, and drag-and-drop to move all of the widgets.

-  **Active Sessions Over Time**
Add a graph showing active sessions within the selected time range.
-  **Session Duration Time Distribution**
Add a graph showing session duration times within the selected time range.
-  **Sessions By Region**
Add a geographical map showing sessions counts as well as the top five locations.
-  **Device Name**
Add a bar chart showing sessions by device names.
-  **Device Manufacturer**
Add a bar chart showing sessions by device manufacturers.
-  **Application Version**
Add a bar chart showing sessions by Application Versions.
-  **Carriers**
Add a bar chart showing sessions by Carrier.
-  **OS Versions**
Add a bar chart showing sessions by OS Versions.
-  **Connection Types**
Add a bar chart showing sessions by connection types.
-  **Crashes By App Version - Top 5**
Add a table showing top 5 crashed sessions by app versions.
-  **Crashes By Device Name - Top 5**
Add a table showing top crashed sessions by device name.
-  **Crashes By Device Manufacturer - Top 5**
Add a table showing top 5 crashed sessions by device manufacturer.
-  **Crashes By Carrier - Top 5**
Add a table showing top 5 crashed sessions by carrier.
-  **Crashes By Connection Type - Top 5**
Add a table showing top 5 crashed sessions by connection type.
-  **Crashes By OS Version - Top 5**
Add a table showing top 5 crashed sessions by OS versions.
-  **Active Users By Region**
Add a geographical map showing active users in session counts as well as the top five locations.
-  **Countries By Session Count - Top 5**
Add a table showing top 5 countries by session count.
-  **Countries By Active Users - Top 5**
Add a table showing top countries by active users.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Network Requests

A network request is an HTTP request from your mobile app to a server-side application.

The iOS Agent detects network requests when the underlying implementation is handled by the `NSURLConnection` or `NSURLSession` classes.

The Android Agent detects network requests when the underlying implementation is handled by the `URLConnection`, `HttpsURLConnection`, `HttpClient`, `OkHttp`, or `ch.boye.httpclientandroidlib` classes.

 You can use the agent SDK to set up other HTTP classes.

View Network Requests

There are different ways of viewing network request data in the **Network Requests View**:

- [The Network Requests list](#) displays current network request types to your applications. You can sort the list according to key metrics such as the slowest response time, highest error rate, highest load, etc. You can view a [network request dashboard](#) that summarizes aggregate performance for a specific network request type.
- [Network Request Analyze](#) allows you to sort and filter a store of *all* the network request data your agents have collected and to see visualizations based on that data.
- A [Network Request Snapshot](#) reports information on an individual instance of a network request. Snapshots are useful for examining the details of the worst-performing requests. Access these snapshots from the [network request snapshots list](#).

Network request data is also displayed in the [Mobile App Dashboard](#).

- The Overview tab has the following widgets showing information about network requests:
 - **Network Request Scorecard:** Displays the number and percentage of normal, slow, very slow, and stalled network requests. Clicking on the widget opens the [Network Requests list](#).
 - **Network Request Health:** Displays the number of network requests evaluated as normal, critical, or warning based on default or configured health rules. Clicking on the widget opens the [Network Requests list](#).
 - **Network Request Time By Country:** Displays a heat map of the world based on the number of network requests. Clicking on the widget opens the [geographic view](#).
 - **Requests Per Minute:** Displays a bar graph showing the number of requests per minute over the specified time period. Clicking on the widget opens the geographic view.
 - **Network Requests Time Distribution:** Displays a bar graph showing the number of requests made at different network request times. In addition, the graph gives the percentage rank of the number of network requests in its frequency distribution of network request time. For example, the **95th percentile (5,419 ms)** indicates that 95% of the network requests had a network request time of 5,419 ms or less. Clicking on the widget opens the [Charts](#) tab of [Network Request Analyze](#).
 - **Network Request Time Trend:** Displays a line graph showing the average network response time over a specified time period. Clicking on the widget opens the geographic view.
 - **HTTP Errors:** Displays the number and rate of HTTP errors. Clicking on the widget opens the [Network Requests list](#).
 - **HTTP and Network Errors Trend:** Displays a line graph comparing the number of HTTP and network errors over a specified time period. Clicking on the widget opens the geographic view.
- The [geographic view](#) reports aggregated mobile data by geographic location. Monitor the geographic view to learn which countries have the highest number of requests, the longest request times, and the most errors.
- [Usage stats](#) display key network request metrics by various criteria: device, carrier, operating system version, connection type, and application. For example, you can see which carriers are the slowest or which devices are producing the most errors.

 The Controller processes a maximum of 2000 network requests per mobile app group and 500 network requests per mobile application. See [Network Request Limits](#) for suggestions on how to configure network request detection to stay under this limit.

Access the Network Requests View

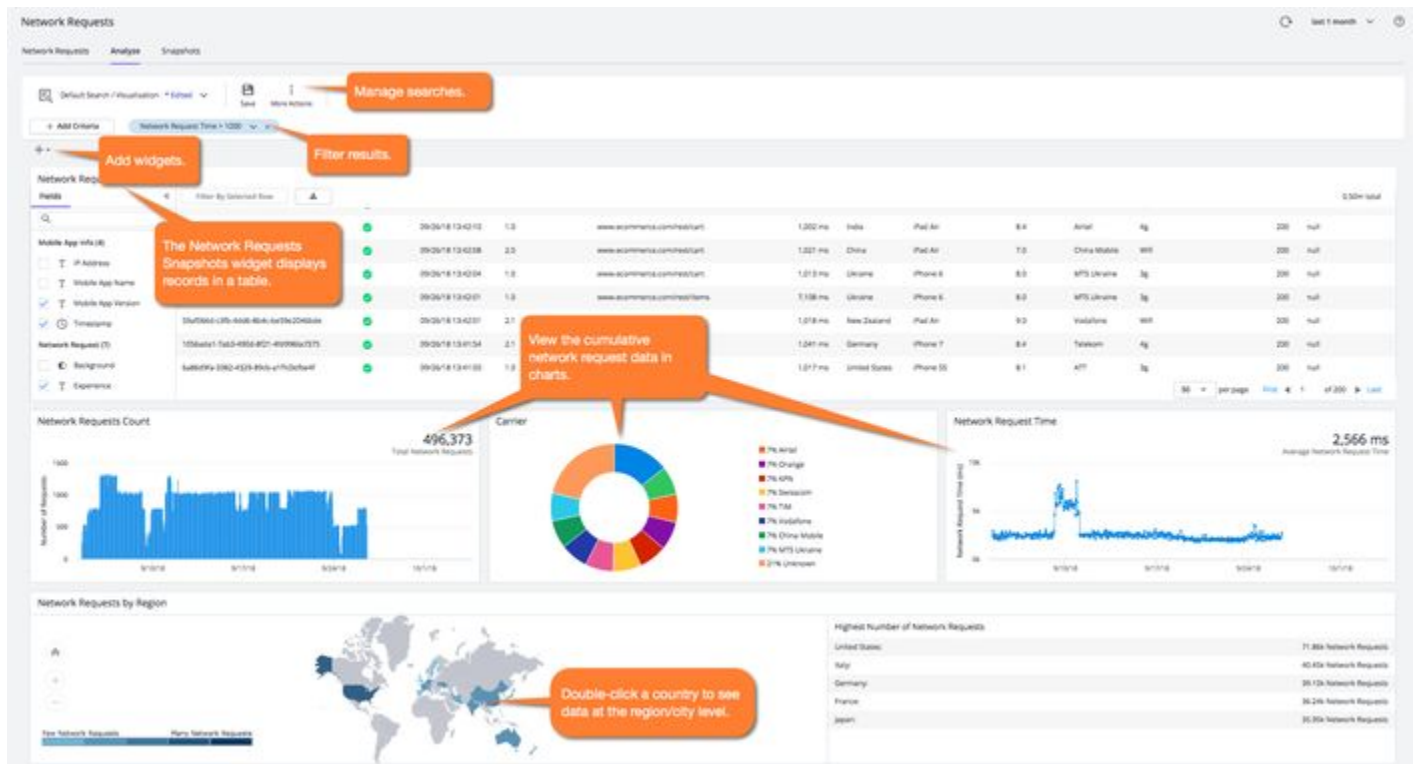

1. Open the application you want.
2. In the left navigation bar, select **Network Requests**.
3. Click the tab for the view you want to access.

Network Request Analyze

Mobile RUM collects data on every network request that you have instrumented, and it also takes detailed snapshots periodically in case performance issues have been detected.

Based on network request performance data, Mobile RUM calculates metrics which are associated with each network request and with predefined aggregations across network requests. You can focus on certain aspects of the performance data using more specific or flexible criteria, such as all network requests from a specific country *and* originating from a specific carrier.

With **Analyze**, every single network request event is collected and stored by the AppDynamics Events Service. Using **Analyze**, you can see results based on this cumulative data in tabular form or as charts.

Double-click a network request snapshot in the **Network Request Snapshots** widget to see the information for a specific request.

Network Request Details

Summary		
Mobile App Name com.appdynamics.Ecommerce-iOS	Network Request Name  www.ecommerce.com/rest/cart	
Mobile App Version 2.0		
User Experience  Normal	Network Request Time 1,048 ms	HTTP Status Code 200
Timestamp 09/26/18 13:42:37		
Platform iOS	OS Version 9.0	
Carrier Orange	Connection Type WiFi	
Country France	Region Drome	
Device iPhone 7		
Request GUID *		
User Data		

Mobile RUM Network Request Analyze Versus Mobile Requests Analytics

The data shown in the **Analyze** page is processed and stored by the AppDynamics Platform Events Service. **Network Request Analyze** provides a number of widely used visualization types to let you explore your application's performance. A separate product, AppDynamics Mobile Analytics, has components called Mobile Requests and Mobile Crash Reports. These components are based on the same Events Service and use the same data, but offer additional capabilities, including:

- Additional predefined widgets, such as the funnel widget
- ADQL for searching the data
- Creating custom widgets
- Manipulating multiple dashboard types
- Longer retention time for storing data

AppDynamics Mobile Requests Analytics requires a license separate from the Mobile RUM license. See [Analytics Mobile Requests Data](#).

Network Requests List

Related pages:

- [Network Request Dashboard](#)
- [Network Request Limits](#)

The **Network Requests** list shows all the network requests types from your instrumented mobile application, along with their key performance indicators.

Network Requests List Organization

The **Network Requests** list is a table that displays aggregated metrics for current requests, with one row for each request type. The columns display the name of the network request and the aggregated metrics associated with it. See [Mobile RUM Metrics](#) for descriptions of these metrics.

Click a column header to sort the list based on the column's metric. For example, if you want to sort by the slowest requests, click the **Network Request Time (ms)** column header. You can toggle the column to switch between ascending and descending order. Use **View Options** to configure the table. Check **With Load** if you want to show only network request types that have experienced active load, that is, those for which there were one or more measured network requests over the selected time period.

To view a network request dashboard:

1. Select the network request type in the list.
2. Click **Details** or double-click the network request.

More Actions Menu

Use the **More Actions** menu to select one or more requests in the list and perform these actions:

- **Exclude Request(s)**: Use this option to direct AppDynamics to ignore the selected request(s) and stop reporting metrics for them.
You can use the **View Excluded Requests** option to see requests that have been excluded and then you can "un-exclude" them.
- **Rename Request**: Use this option to rename one selected request in the AppDynamics console.
- **Delete Request(s)**: Use this option to remove the request(s) from the list. If AppDynamics discovers a deleted request again it will reappear in the list. To prevent it from re-appearing, use **Exclude Request(s)**.

Network Request Dashboard

Related pages:

- [Network Requests](#)
- [Network Requests List](#)
- [Network Request Analyze](#)
- [Mobile RUM Metrics](#)

Each network request type has its own dashboard that graphically displays key performance indicators for that type over the selected time range. To select the time range, use the general time range dropdown at the top right of the UI.

Network Request Dashboard Organization

The **Network Request Dashboard** displays summary key network request metrics for the time selected. To see any particular metric in the metric browser, click the metric value (in link blue).

The trend graphs for the key performance indicators are:

- **Network Request Time:** Average times in milliseconds.
- **Total Server Time:** Displayed only if the mobile request is correlated with a server-side application. The total server time is the interval between the time that the server-side application receives the network request to the time that it finishes processing the request. Use this graph to determine, on average, how much time is spent on the network versus how much time is spent on the server to process the user's request.
- **Load:** Total Requests and Requests per Minute.
- **Errors:** Network Errors and HTTP Errors in total and per minute.
- **Related Business Transactions:** If the request is correlated with a server-side application, the dashboard lists business transactions associated with the request below the performance metrics. You can click the link to a related business transaction to see its business transaction dashboard. If transaction snapshots were taken at the same time as the network request, the dashboard lists the transaction snapshots below the business transactions. See [Transaction Snapshots](#).

You can hover over any data point on any of the trend graphs to see the metric for a precise point:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Network Request Snapshots List

A network request snapshot captures the details of one instance of a network request. Examine these details to troubleshoot the causes of slow network request performance. See [Network Request Snapshots](#).

You access the list using the Network Request Snapshots tab. The network request snapshots list is a table that displays a row for each network request snapshot. The columns describe the properties of each snapshot.

To view a network request snapshot:

1. Select the network request snapshot in the list.
2. Click **Details** or double-click the request.

Network Request Snapshots

Related pages:

- [Network Request Snapshots List](#)
- [Transaction Snapshots](#)

Network request snapshots capture detailed information about individual network request instances by your application. They can help you troubleshoot the causes of poorly performing mobile applications.

When Network Request Snapshots are Captured

Mobile RUM starts capturing snapshots when user experience becomes slow, based on how you have configured the thresholds for slow, very slow, and stalled. See [Configure Mobile Network Request Thresholds](#).

Periodic snapshots of normal user experience are also captured at least once per minute.

Network Request Snapshot Content

A network request snapshot contains summary data about the individual request as well as any business transactions associated with the request if correlation with an instrumented server-side application is available.

The snapshot contains extensive metrics for the request in the Summary data, including:

- **User Experience:** Normal, Slow, Very Slow, or Stalled.
- **Time:** When the request was received by the EUM Cloud or EUM Server collector, in UNIX epoch time.
- **Mobile Network Request:** Link to the network request dashboard for the network request of which this snapshot is an instance. See [Network Request Dashboard](#).

Business Transactions in Network Request Snapshots

When a network request snapshot is associated with one or more business transactions on an instrumented server-side application, the business transactions are listed in the **Business Transactions** panel in the network request snapshot. You can click the link to see the business transaction dashboard for the associated business transaction.

If transaction snapshots for an associated business transaction were captured at the same time as the network request snapshot, they are linked in the **Transaction Snapshots** panel of the network request snapshot. If a call graph icon is displayed for a snapshot in the transaction snapshot list, a full or partial call graph is available for that transaction snapshot. This allows you to examine the cause of performance problems on the server side. Click the link to see the associated transaction snapshot.

Transaction snapshots are triggered on the server when slow or stalled business transactions are identified when a diagnostic session is started or periodically based on a configured interval. In general, slow, very slow, and stalled transactions are more likely to trigger a transaction snapshot on the server than transactions operating within the normal range. For more information about when server-side transaction snapshots are captured, see [Transaction Snapshots](#).

Access Network Request Snapshots from Transaction Snapshots

If a transaction snapshot seen from the server side also has generated a correlated network request snapshot, a mobile snapshot link appears in the top right of the transaction snapshot flow map. Click the link to open the network request snapshot.

Archive Network Request Snapshots

Normally network request snapshots are purged after two weeks. You can archive a snapshot beyond the normal snapshot lifespan to retain it for future analysis.

To archive a snapshot, click the **Archive** button in the upper right corner of the snapshot panel.

You can view archived snapshots by checking **Archived** as a view option in the network request snapshots list.

Customers with on-premises Controllers can modify the default two-week period by configuring the `event.retention.period` property in the **Controller Settings** section of the Administration console.

Crashes

Related pages:

- [Crash Analyze](#)
- [Crash Snapshots](#)
- [Crash Snapshot Properties](#)

Use crashes to get trend and detailed information on mobile application crashes.

A crash snapshot is a detailed report on a particular crash including the code that was executing when the application crashed. Crash snapshots help you understand the causes of crashes.

View Crash Information in Widgets

The **Crash Metrics** and **Events** widgets are on the **Mobile App Dashboard**. The **Crash Metrics** widget displays the crash rate and the number of crashes for your mobile application. The **Events** widget displays new crash events.

1. Open the application you want.
2. From the **Mobile App Dashboard**, both **Events** and **Crash Metrics Scorecard** widgets display.
3. Click **Crash Metrics** or click one of the new crash events in the **Events** widget to access the **Crash Dashboard**.

Access the Crash Dashboard

The [Crash Dashboard](#) is where you can view both summary and detailed information about crashes.

1. Open the application you want.
2. On the left navigation bar of your application, select **Crashes**.

Crash Alerts

You can configure AppDynamics to send you alerts when your mobile application crashes. You can configure email alerts for health rule violates based on some default health rules or by manually creating a policy with a notification action or creating an email digest.

 Crashes that have the status "Closed" do not trigger alerts.

Set Up Alerts for Crashes

Setting up alerts for crashes is similar to setting up alerts for other health rule violations:

1. [Configure Mobile Crash Alerts](#). This will configure the default number of crashes.
2. If desired, update the **Critical Criteria** and **Warning Criteria** for the health rule **Crash Rate is much higher than normal**. See [Configure Health Rules](#).
3. Create a policy that will be triggered when the health rule for crashes is violated. You'll need to configure an [action](#) to be taken when the policy is triggered.
4. After you set up the email alerts, when a health rule is violated, an email will be sent indicating whether there was a warning or critical alert and providing links to view crash and session details.

Create Email Digest for Crashes

You can create the same type of notification for crashes by creating an [email digest](#).

From the **Create Email Digest** dialog, check the **Mobile Crash** checkbox:

Create Email Digest ✕

Contents Health Rule Scope Object Scope Recipients

Name

Enabled

Frequency Hours

This Email Digest will contain these Events

- > Health Rule Violation Events
- Other Events
 - > Slow Transactions
 - > Code Problems
 - > Application Changes
 - > Server Crashes
 - > AppDynamics Config Warnings
 - > Discovery
 - > Synthetic Availability
 - > Synthetic Performance
 - > Mobile Crash
 - Errors
- Custom Events ?
 - + ✎ 🗑

Type	Properties
No Custom Events Selected	

You can then use the **Email Digest** wizard to add recipients, a custom message, and schedule the frequency to send emails.

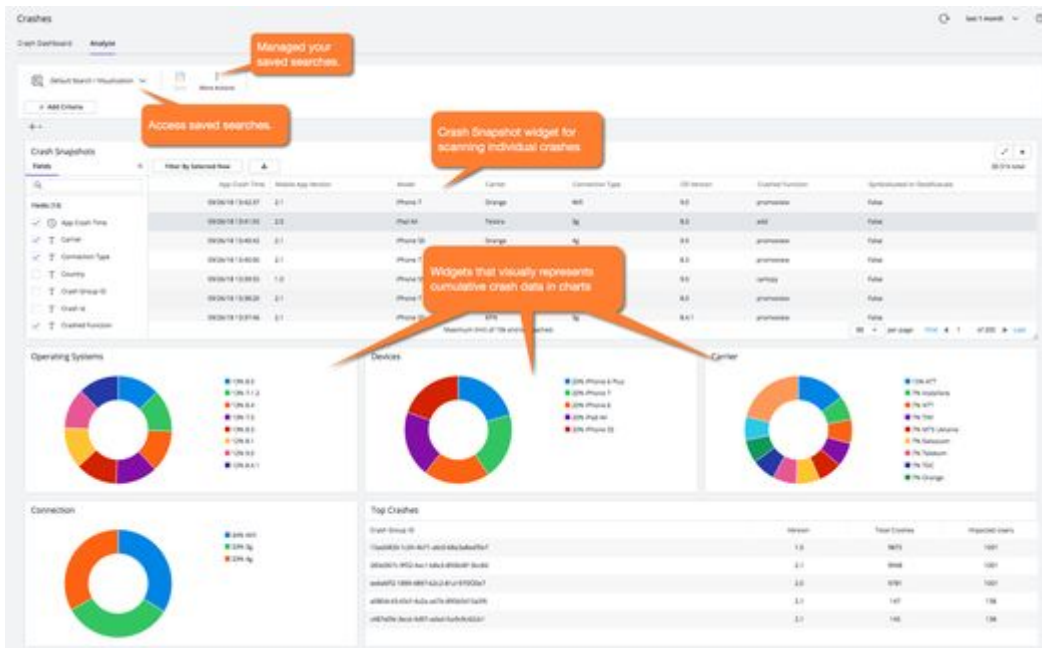

Crash Analyze

Related pages:

- [Instrument an iOS Application](#)

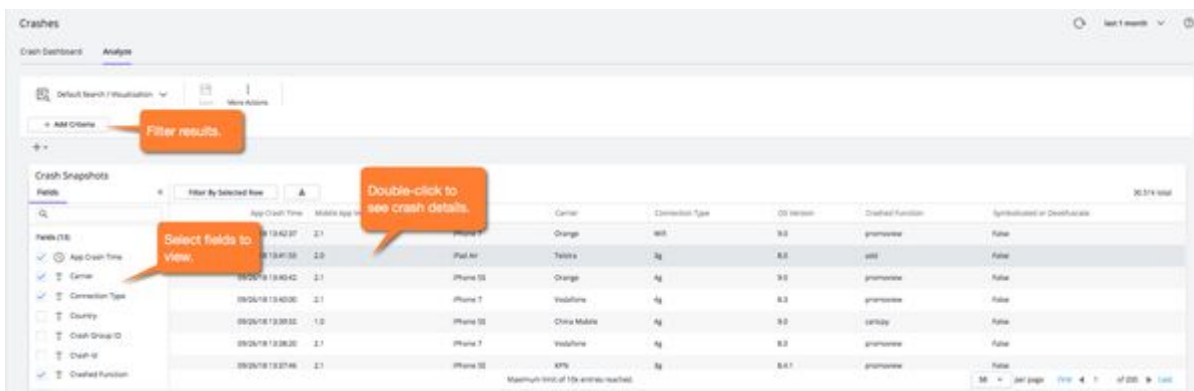

Crash Analyze lets you view and analyze the results based on the cumulative data. With **Crash Analyze**, every crash event is collected and stored by the AppDynamics Events Service.

The **Crash Analyze** page has the **Crash Snapshots** widget for viewing a list of current crash snapshots, with one row for each snapshot, and a selection of different widgets for visualizing the cumulative data in charts.

Crash Snapshots Widget

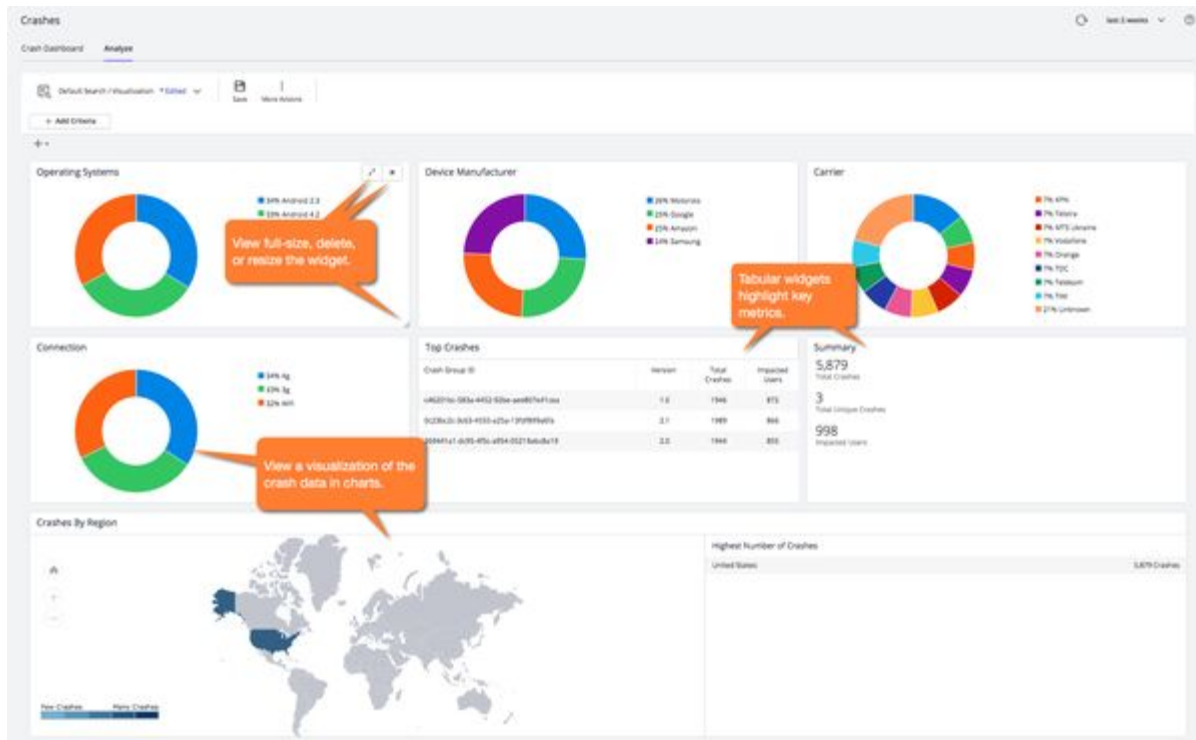

The Crash Snapshots tab lets you scan individual crashes and allows you to filter and sort to get exactly the crash set in which you are interested. The columns of the table are fields representing the crash snapshot properties. See [Crash Snapshot Properties](#). Click **View Details** to see information for a specific crash.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Chart and Tabular Widgets

The chart widgets provide you with a set of predefined widgets that offer visualizations of the data set you have created. The tabular widgets highlight key metric points such as top crashes. You can delete, re-add, re-size, and drag-and-drop to move all of the widgets. You can also set criteria to visualize a subset of the data.

i You can also view crash snapshots in the context of a separate product, AppDynamics Mobile Analytics. It offers additional mechanisms to analyze and visualize crash patterns, including:

- Additional predefined widgets, such as the funnel widget
- ADQL for searching the data
- Custom widgets
- Manipulating multiple dashboard types
- Longer retention time for storing data

AppDynamics Mobile Crash Report Analytics requires a license separate from the Mobile RUM license.

Crash Dashboard

Related pages:

- [Crash Snapshots](#)
- [Crash Snapshot Properties](#)

The **Crash Dashboard** aggregates mobile application crash data over time, using the Events Service. This service collects and stores *all* the data collected by the mobile agent.

The **Crash Dashboard** is divided into two panels and has the **App Version** dropdown that enables you to view crash data for different versions of your application.

Summary Crash Trend

This panel displays a running total of crashes, unique crashes, impacted users, crash rate, and crash trends. The crash trends is a timeline of crash rates. It also reports any iOS crash reports that were uploaded without the accompanying dSYM file. For more information on how to use dSYM files with crashing reports, see [Get Human-Readable Crash Snapshots](#).

Unique Crashes

Multiple crashes can be caused by the same underlying code issue. The **Unique Crashes** panel displays a list of crashes grouped by common characteristics and displays basic information about the crash. You can view open, closed, or all crashes.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Unique Crash Details

To see more detail per crash, click the crash that interests you, in blue. The dashboard for that crash appears, with a header, trend bar graph, crash distribution charts, and a snapshot of the crucial details common to all the crash snapshots. See the [Crash Summary](#) section on the [Crash Analyze](#) page.

Crash Status

In addition to viewing crash details, from the **Unique Crashes** panel, you can select a unique crash, click **Actions**, and set the status to either open or closed. You can set the status to mark those unique crashes that you want to ignore or have fixed the root cause of.

The screenshot shows the 'Unique Crashes' interface. At the top, there are tabs for 'Details' and 'Actions', and a 'Show All Crashes' dropdown. Below is a table with the following data:

Unique ID	Mobile App Version	Total Crashes	Impacted Users	Status	Runtime
NullPointerException in Utilities.crashMe	hMe	394	334	open	SDK
NullPointerException in Utilities.crashMe		360	301	open	SDK
NullPointerException in CarFragment.crashMe		353	298	open	SDK

An orange callout box with a speech bubble icon points to the 'Actions' menu for the first row, containing the text: "To hide crashes, change the status of the selected crash to closed."

When a crash is marked as closed, the crash will no longer trigger a new crash event, so you will not see the crash in the **Events** widget of the **Mobile App Dashboard**, the **Events** page, and it will not be included in alerts for new crashes.

Crash Snapshot Properties

Related pages:

- [Network Requests List](#)
- [Network Request Analyze](#)
- [Network Request Snapshots List](#)
- [Network Request Snapshots](#)
- [Analytics Mobile Crash Reports Data](#)

This page describes the list of crash snapshot properties. They display in the **Crash Snapshot Details** panel when you open a crash snapshot from **Crash Analyze**.

- **Carrier:** Name of the mobile carrier.
- **Connection Type:** Active connection type at the time of the crash, if known.
- **Crashed File/Line/Function:** Name of the source file containing the crashed function, with the line number, if available. The name of the topmost function on the crashed thread's call stack. If this function is an Objective-C method, this name includes the class name. For Android, this name is the fully qualified name of the topmost method on the uncaught exception's stack trace.
- **Crash Time:** Timestamp when the crash occurred, based on the mobile device's clock.
- **Device/Manufacturer:** Model or manufacturer name of the mobile device on which the crash occurred.
- **Events Prior to Crash:** Any breadcrumbs you might have set up.
- **Exception Name:** Name of the fatal signal (iOS) or uncaught exception (Android) associated with the crash.
- **Memory Usage:** Memory used by the app when the crash occurred.
- **Mobile App:** Name of the app that crashed.
- **OS Version:** Operating system version of the mobile device on which the crash occurred.
- **Platform:** iOS or Android.
- **Request Timestamp:** Time when the beacon arrived at the Collector. Snapshot only.
- **User Data:** Any user data you might have added.
- **Version:** Version string of the crashed application.

Crash Snapshot list only

- **Country:** Originating country.
- **Crash id:** Unique identifier for the crash.
- **Deobfuscated:** For Android: **true**, if this crash report has been matched with a ProGuard mapping file and deobfuscated; otherwise, **false**.
See Upload the Proguard Mapping File in [Get Human-Readable Crash Snapshots](#). A **false** value for this property does not necessarily indicate that the crash report will not be human-readable since it is possible that the application in question was not obfuscated.
- **Symbolicated:** For iOS: **true**, if this crash report has been matched with a dSYM file and symbolicated; otherwise, **false**.
The application must have been compiled with the **Debugging Information Format** set to **DWARF with dSYM File** for a crash report to exist. See [Upload the dSYM File](#) and [Get Human-Readable Crash Snapshots](#).

Crash Snapshots

Related pages:

- [Crash Analyze](#)
- [Crash Snapshot Properties](#)

Crash snapshots provide detailed information for one application crash. When an instance of an instrumented application crashes, a crash snapshot is created.

The snapshot provides information to help you analyze the cause of the crash, including:

- Crashed function
- Source file containing the crashed function
- Line number in the source file, if available
- Stack trace of the application at the time of the crash

For iOS applications, crash snapshots are based on:

- Fatal signals (SIGSEGV, and so on)
- Unhandled Objective-C exceptions

For Android applications, crash snapshots are based on unhandled Java exceptions.

Crash Snapshot Details

The **Crash Snapshot Details** dialog has the two panels **Crash Summary** and **Crash Distribution**. The **Crash Summary** panel displays basic crash information and the stack trace. The **Crash Distribution** panel displays widgets with distributed crash metrics by the crash group and the stack trace.

To view crash snapshot details:

1. From the Records tab, select a crash snapshot in the list.
2. Click **View Details**.

Crash Summary

The **Crash Summary** panel of the snapshot displays the key properties of the snapshot. If you have customized your instrumentation ([Android/iOS](#)) to include breadcrumbs, they are displayed in the **Events Prior to Crash** panel. Up to 99 breadcrumbs display, beginning with the most recent. Not all of this information may be available. If you added user data ([Android/iOS](#)), it also displays here.

The **Stack Trace** panel displays the call stack of the crashed application, showing the thread in which the crash occurred. This is the full stack trace for this specific crash, not the aggregated stack trace shown in the **Unique Crash Dashboard**. You can view the formatted stack trace that groups threads and parses the output or the raw log output for the stack trace.

Click **Download** to access the stack trace in a file that you can forward to developers or port to logging platforms. To see the crash in the context of the mobile session, click **View Session**.

User Data
No data available

If the information in the stack trace is cryptic, it is possible that source code for your iOS app was not symbolicated or the source code for your Android app was obfuscated. See [Get Human-Readable Crash Snapshots](#) for information about why this happens and what you can do about it.

Crash Distribution

The **Crash Distribution** panel displays smaller-sized widgets from the Charts tab with distributed metrics for the crash group and the stack trace.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Get Human-Readable Crash Snapshots

Related pages:

- [Crash Snapshots](#)

The information in most raw crash stack traces is not fully human-readable. To make your crash stack traces more easily understood, you need to provide a platform-specific mapping file that can translate the raw data into human-readable output. Normally, you upload the file at the time that you instrument your mobile application.

- For iOS, see [Upload the dSYM File](#).
- For Android, see [Manually Upload Mapping Files](#).

This page explains the advantages of providing these files.

iOS dSYM File

For iOS applications, the raw data in the stack traces in crash snapshots consists of memory addresses of stack frames that point to executable application code. It also includes symbols and memory offsets for the system library code used by the application. Such a partially symbolicated stack trace looks something like this:

```
Thread 11 Crashed:
0  libobjc.A.dylib                0x38cb50fc objc_retain + 12
1  SomeApp                        0x003a2204 0xc6000 + 2998788
2  SomeApp                        0x003a0854 0xc6000 + 2992212
3  SomeApp                        0x003a09d4 0xc6000 + 2992596
4  SomeApp                        0x003948e4 0xc6000 + 2943204
5  Foundation                     0x2f3a2dc2 __NSThread__main__ +
1058
6  libsystem_pthread.dylib        0x392cec5a _pthread_body + 138
7  libsystem_pthread.dylib        0x392cebca _pthread_start + 98
8  libsystem_pthread.dylib        0x392cccc thread_start + 4
```

AppDynamics attempts to display stack traces with the names of functions with offsets into those functions to help you identify the line of code that was executing when the application crashed. To get the symbols that map to the executable code, it needs the dSYM (desymbolication) file for the crashed application.

If the dSYM file for the crashed application has been uploaded, the symbolicated stack trace shows the function name and the offset into the function where the app crashed. It looks something like this:

```
Thread 0 Crashed:
0  libobjc.dylib                 objc_release + 0x14
1  CoreFoundation                CFStringCreateWithFormat + 0x4
2  UIKit                          -[UIButton init] + 0x96
3  MyApp                          createUI (MyAppDelegate.m:42)
```

The dSYM file is created when the application source code is compiled with the **Debugging Information Format** set to `DWARF with dSYM file`. AppDynamics recommends that you build all the iOS apps that you want to monitor using this option and then upload the dSYM file to AppDynamics. The best time to do this is when you instrument the app.

If a dSYM has been uploaded for a crashed application, in the crash list the **Symbolicated** column for the associated crash snapshot is true.

If the `symbolicated` property is `false` and you want to see user-friendly stack traces in your crash snapshots for this application, you need to locate and upload the dSYM file for the crashed application.

ProGuard Mapping File for Android

If an Android app was not obfuscated to prevent reverse engineering, you should see human-readable stack traces in your crash snapshots by default.

If the code was obfuscated, however, AppDynamics needs the ProGuard mapping file to be able to deobfuscate the app. The best procedure is to upload this file at the time you build the app.

If a ProGuard mapping file has been uploaded for a crashed application, in the crash list the **Deobfuscated** column for the crash snapshot is `true`.

If the `deobfuscated` property is `false` and the stack traces you see in the crash snapshots are obfuscated, you need to locate and upload the mapping file for the application.

Code Issues

Code issues consist of caught non-fatal exceptions or application not responding (ANR) issues. A code issue snapshot is a detailed report on a particular event including the code that was executing when the exception or ANR occurred.

Code issue snapshots help you understand the causes of these issues. Use **Code Issues** to get trend and detailed information on application non-responsive issues (ANRs) and caught errors and exceptions.

Catch and Report Code Issues

All the Mobile Agents except the iOS Agent will automatically detect and report ANRs. For iOS, you have to [enable ANR detection](#). To catch and report errors and exceptions, you instrument your mobile applications with iOS, Android, and Xamarin SDKs.

See the section "Report Errors and Exceptions" ([iOS](#), [Android](#), [Xamarin](#)) to learn how to use the SDKs to manually catch and report errors and exceptions.

Access the Code Issues Dashboard

The [Code Issues Dashboard](#) is where you can view both summary and detailed information about code issues.

1. Open the application you want.
2. On the left navigation bar of your application, select **Code Issues**.

View Code Issue Widgets

The **Summary Code Issue Trend** and **Unique Code Issues** widgets are on the **Code Issues Dashboard**. The **Summary Code Issue Trend** widget displays the number of code issues, impacted users, and unique code issues as well as graph the code issues on a timeline. The **Unique Code Issues** widget displays details about the unique code issues such as the severity, the issue type, runtime, impacted users, and mobile app version.

To view code issue information:

1. Open the application you want.
2. From the **Code Issues Dashboard**, both **Summary Code Issue Trend** and **Unique Code Issues** widgets display.
3. You can click one of the unique code issues in the **Unique Code Issues** widget to view the **Code Issues Details** dialog.

Code Issues Analyze

The **Code Issues Analyze** page has the **Code Issue Events** widget for viewing a list of current code issue snapshots, with one row for each snapshot, widgets for visualizing code issues data, and widgets for highlighting key data points.

Code Issues Analyze enables you to view and analyze the results based on cumulative data based on configured criteria. You can delete, re-add, re-size, and drag-and-drop to move all of the widgets. You can set criteria to visualize a subset of the data. Every code issue event in **Code Issues Analyze** is collected and stored by the AppDynamics Events Service.

The screenshot shows the 'Code Issues Analyze' dashboard. At the top, there's a search bar and a 'Default Search / Visualization' dropdown. Below that is a table of 'Code Issue Events' with columns for ID, timestamp, version, severity, error message, device, and status. Callouts point to the search bar ('Access saved searches.'), a table row ('Double-click to view code issue details.'), and the 'Fields' list on the left ('Select fields to view.').

Below the table are several summary and visualization widgets:

- Top Code Issues:** A table listing top groups with columns for Group ID, version, total code issues, and impacted users.
- Summary:** A box showing 276 Total Code Issues, 122 Total Unique Code Issues, and 21 Impacted Users.
- Code Issue Trend:** A bar chart showing the number of code issues over time from 4:42 PM to 5:30 PM.
- Code Issue Type:** A donut chart showing 51% ANR and 49% Error.
- Code Issue Severity:** A donut chart showing 61% Info, 23% warning, and 16% critical.
- Operating Systems:** A donut chart showing 89% 9.0, 6% 7.0, and 5% 8.0.
- Code Issues By Region:** A world map with a legend for 'New Code Issues' and 'More Code Issues'.
- Highest Number of Code Issues:** A table listing countries: United States (108), Turkey (46), China (35), Singapore (23), and Germany (17).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Code Issue Events Widget

The **Code Issue Events** widget enables you to scan individual code issues, filter, and sort to get exactly the code issue in which you are interested. The columns of the table are fields representing the code issue properties. See [Code Issue Snapshot Properties](#).

The screenshot displays the 'Code Issue Events' widget interface. At the top, there's a 'Code Issues' header with a refresh icon and a 'last 6 months' filter. Below this is a 'Code Issue Dashboard' section with 'Analyze' selected. A search bar and 'Save' button are present. A '+ Add Criteria' button is also visible. The main area is a table titled 'Code Issue Events' with 45 total entries. The table has columns: eventid, Timestamp, Mobile App Version, severity, eventtype, description, Device Model, Carrier, Connection Type, OS Version, and symbolicname/affected. On the left, a 'Fields' list includes: Agents ID, Agent Version, App Key, Carrier, City, Connection Type, Country, description, Device Manufacturer, Device Model, Device Name, eventid, eventindex, eventtype, filename, groupid, jellbroken, Line Number, Mobile App Name, Mobile App Version, OS Version, pickupTimestamp, Platform, Region, severity, symbolicname/affected, symbolicname, Timestamp, and timestamp. The table rows show various error events like 'NSCocoaErrorDomain: 52 in foo', 'App Not Responding in foo', and 'NSMachOErrorDomain: 16 in bar'.

Other Code Issue Widgets

The other widgets fall into the following three categories: tables, charts, a summary, and a hybrid.

Table Widgets

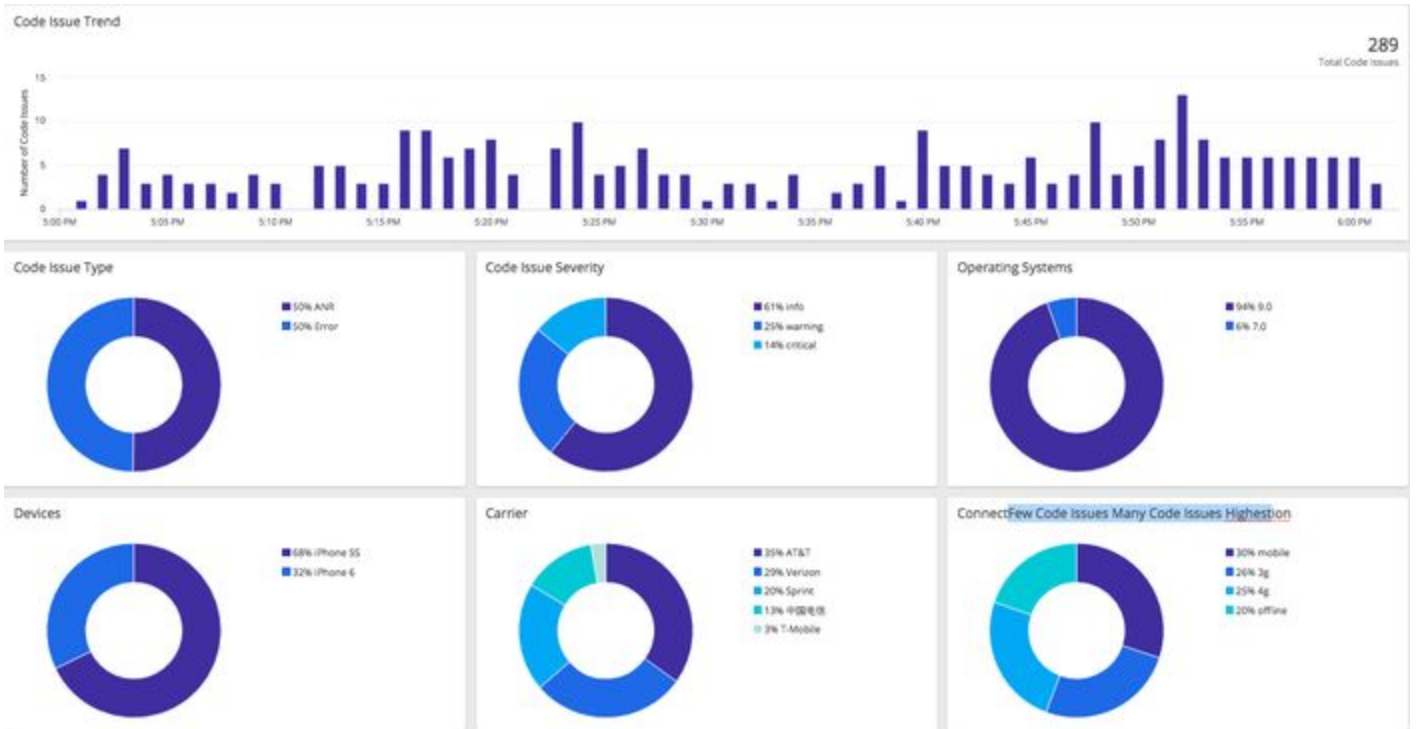

The table widgets display rows of code issues in tabular form. The **Code Issue Events** widget lists the code issue snapshots.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Code Issue Events							Top Code Issues			
Fields	Filter By Selected Row						Group ID	Version	Total Code Issues	Impacted Users
<input checked="" type="checkbox"/> Connection Type <input type="checkbox"/> Country <input checked="" type="checkbox"/> description <input type="checkbox"/> Device Manufacturer <input type="checkbox"/> Device Model <input type="checkbox"/> Device Name <input type="checkbox"/> eventCompletionTimeSta... <input checked="" type="checkbox"/> eventid	eventid	Timestamp	Mobile App Version	severity	eventtype	description

							315d5294-0884-4591-aec6-47f698d3c714	1.0	1	1

Chart Widgets

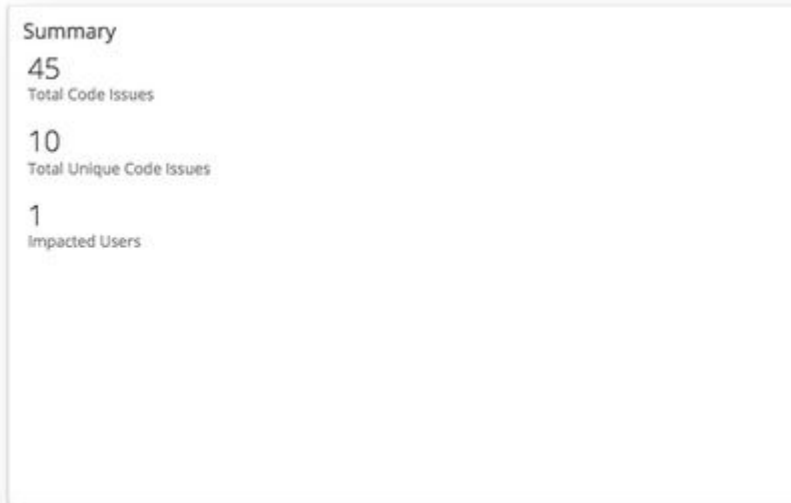

The chart widgets visualize the code issue data. For example, you can view the code issues data in pie charts showing the ratio of ANRs to caught errors/exceptions, severity levels, operating systems, and so on.

Summary Widget

The **Summary** widget lists totals for key statistics.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Hybrid Widget

The **Code Issues By Region** widget is a hybrid, displaying geographic data in a map and listing the data points in a table.

Code Issues in Mobile Analytics

Code issue snapshots can also be viewed in the context of a separate product, AppDynamics Mobile Analytics. It offers additional mechanisms to analyze and visualize code issue patterns, including:

- Additional predefined widgets, such as the funnel widget
- ADQL for searching the data
- Custom widgets

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

-
- Manipulating multiple dashboard types
 - Longer retention time for storing data

AppDynamics [Analytics Mobile Non-Fatal Issues Data](#) requires a license separate from the Mobile RUM license.

Code Issue Snapshots

Code issue snapshots provide the detailed information for one code issue. A code issue snapshot is created when an instance of an instrumented application experiences an ANR, slow UI, or manually reports a caught exception. To manually report caught exceptions, you use either the [iOS SDK](#) or the [Android SDK](#).

- Thread that contains a function that is not responding or has a caught exception
- Source file containing the function that is not responding or has the caught exception
- Line number in the source file, if available
- Stack trace of the application at the time of the code issue

For iOS applications, code issue snapshots are based on:

- ANRs
- Handled Objective-C exceptions
- Slow UI

For Android applications, crash snapshots are based on:

- ANRs
- Handled Java exceptions
- Slow UI

Code Issue Snapshot Details

The **Issue Snapshot Details** dialog has the two panels **Issue Summary** and **Issue Distribution**. The **Issue Summary** panel displays basic information about the code issue and the stack trace. The **Issue Distribution** panel displays widgets with distributed issue metrics by code issue group as well as the stack trace.

View Code Issue Snapshot Details

1. Navigate to **Code Issues > Analyze**.
2. From the **Code Issue Events** widget, double-click one of the code issue snapshots.

Issue Summary

The **Issues Summary** panel of the snapshot displays the key properties of the snapshot. Unlike with crashes, code issues do not include breadcrumbs.

The **Stack Trace** panel displays the call stack of the code issue, showing the thread in which the caught exception or ANR occurred. This is the full stack trace for this specific code issue, not the aggregated stack trace shown in the **Unique Issue Dashboard**. You can view the formatted stack trace that groups threads and parses the output or the raw log output for the stack trace.

userIsAGoat+Boolea: true

Click **Download** to grab the stack trace in a file that you can forward to developers or port to logging platforms. To see the code issue in the context of the mobile session, click **View Session**.

Issue Distribution

The **Issue Distribution** panel displays smaller-sized widgets from the **Analyze** tab with distributed metrics for the code issue group.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Code Issue Snapshot Properties

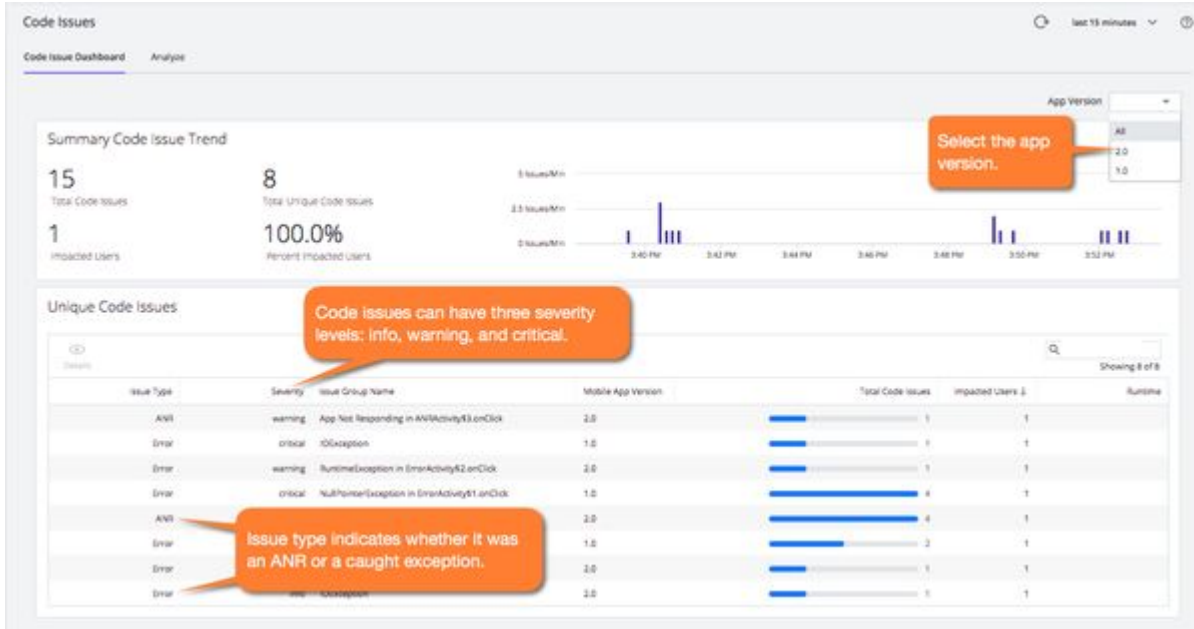

This page lists the code issue snapshot properties. They appear in the **Code Issue Snapshot Details** panel when you open a code issue snapshot from **Code Issue Analyze**.

- **Agent ID:** The ID of the Mobile Agent reporting the code issue.
- **Agent Version:** The version of the Mobile Agent reporting the code issue.
- **Application Key:** The application key.
- **Carrier:** The name of the mobile carrier.
- **City:** The originating city.
- **Client Time:** The timestamp of a device when the beacon was made.
- **Connection Type:** The active connection type at the time of the code issue, if known.
- **Country:** The originating country.
- **Description:** The type of code issue, such as an application not responding (ANR) or a caught non-fatal exception.
- **Device/Manufacturer/Model:** The model or manufacturer name of the mobile device on which the code issue occurred.
- **Event Type:** Type of code issue (for example, ANR, Caught Exception)
- **Jailbroken:** Flag indicating whether the mobile device has been jailbroken.
- **Group ID:** The event group id after grouping.
- **Mobile App:** The name of the app that had the code issue.
- **OS Version:** The operating system version of the mobile device on which the code issue occurred.
- **Platform:** iOS or Android.
- **Region:** The originating region, such as the province or state.
- **Request Timestamp:** When the beacon arrived at the Collector. Snapshot only.
- **Severity:** The severity level set for the code issue.
- **Symbolication/Obfuscation:** Flag indicating whether the application code has been symbolicated/obfuscated.
- **User Data:** Any user data you might have added.
- **Version:** The version string of the application that had the code issue.

Code Issues Dashboard

The **Code Issues Dashboard** aggregates mobile application caught exceptions and ANRs over time, using the Events Service. This service collects and stores *all* the data collected by the mobile agent.

The **Code Issues Dashboard** is divided into two panels and has the dropdown **App Version** to view code issues for different versions of your application.

Summary Code Issue Trend

This panel displays a running total of code issues, unique code issues, impacted users, the percent of impacted users, and code issue trends. The code issues trends is a timeline of code issues.

Unique Code Issues

Multiple code issues can be caused by the same underlying issue. The **Unique Code Issues** panel displays a list of code issues grouped by common characteristics and displays basic information about the issue.

Unique Code Issues

Issue Type	Severity	Issue Group Name	Mobile App Version	Total Code Issues	Impacted Users	Runtime ↑
ANR	info	App Not Responding	2.0.0	1	1	
ANR	info	App Not Responding in baz	1.9.3	2	2	
ANR	info	App Not Responding in foo	2.1.1	1	1	
ANR	warning	App Not Responding in baz	2.0.0	2	2	
Error	critical	NSCocoaErrorDomain: 16 in baz	2.0.0	1	1	
ANR	info	App Not Responding in someUIFrame	2.1.1	1	1	
Error	info	NSMachErrorDomain: 16 in someUIFrame	2.0.0	1	1	
Error	critical	NSPOSIXErrorDomain: 16 in foo	2.0.0	1	1	
ANR	info	App Not Responding in baz	1.9.3	2	2	
Error	info	NSMachErrorDomain: 52 in baz	2.1.1	1	1	
ANR	warning	App Not Responding	2.1.1	1	1	
Error	warning	NSMachErrorDomain: 16 in bar	2.0.0	2	2	
ANR	info	App Not Responding in bar	2.1.1	1	1	
ANR	info	App Not Responding in foo	2.0.0	1	1	
ANR	info	App Not Responding in bar	1.9.3	1	1	

Unique Issue Details

To see more detail per code issue, select the unique code issue that interests you and click **Details**. The **Unique Issue** dialog has the two tabs Issue Summary and Issue Distribution.

Issue Summary

The Issue Summary tab has two main panels. The top panel shows summary information such as the total code issues, the issue type, impacted users, the runtime, and a code issue trend bar graph.

The bottom panel shows a sequence of threads in the stack trace that you can expand for more information, a **Properties** section with general information about the device, and a **User Data** section with any set user data.

[iOS](#) [Android](#)

The stack trace for iOS applications shows the concatenated image and symbol names. For example, the concatenated "UIKit" (an image name) and "bar" (the symbol name) forms "UIKitbar".

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Issue Distribution

The Issue Distribution tab displays the same stack trace panel, but the top panel dashboard instead displays the distribution charts for the code issue.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Code Issue Alerts

You can configure AppDynamics to send you alerts when your mobile application has code issues. You can configure email alerts for health rule violates based on the default health rule or by manually creating a policy with a notification action.

Set Up Alerts for Code Issues

This basic workflow describes how to set up alerts for code issues:

1. **Report Errors:** In your application code, use the iOS, Android, or Xamarin SDK to report errors. Set the severity to either `INFO`, `WARNING`, or `CRITICAL`. Only errors with the severity of `CRITICAL` trigger alerts with the default health rule.
2. **Configure Thresholds:** Set the warning and critical thresholds for application not responding issues:
 - a. Navigate to **Configuration > Mobile App Group Configuration > Settings**.
 - b. From **Configure Application Not Responding Thresholds**, set the values for **Warning Threshold** and **Critical Threshold**. Any value that is less than the warning threshold will be labeled as **Info**.
3. **View alerts for code issues.**

Report Errors with the Mobile SDKs

See "Report Errors and Exceptions" ([iOS/Android/Xamarin](#)) to report errors and set the severity for iOS, Android, or Xamarin applications.

Configure Threshold for Code Issue Alerts

You can configure the thresholds for ANRs that must be reached before you are alerted. See [Configure Application Not Responding Thresholds](#).

View Code Issue Alerts

The health rule **Critical Code Issues exist** is used to send alerts when one if the following occurs:

- You have used the Android or iOS SDK to report an error with the severity of `CRITICAL`.
- The time that your application has not responded exceeded the critical threshold.

After you set up the email alerts, when a health rule is violated, an email will be sent indicating whether there was a warning or critical alert and providing links to view code issue and session details.

Custom Data

Mobile RUM provides substantial information on crashes and network and server-related performance. You may want, however, to customize the Mobile Agent to collect other metrics and data to understand how your application is performing for your users.

For information on customizing the agent, including sample code, see:

- [Customize the iOS Instrumentation](#)
- [Customize the Android Instrumentation](#)

To see the results of your data collection, you use the **Custom Data** view.

Custom Data Types

There are three kinds of custom data that you can collect:

- [Info Points](#)
- [Custom Timers](#)
- [Custom Metrics](#)

 There are two other types of custom data: the breadcrumb and user data. Breadcrumbs display only in Crash Snapshots. User data is available in **Crash Analyze** and **Network Request Analyze**. See the agent SDK docs for more information.

Info Points

An information point allows you to collect information on how a specific method in your code is performing. How many times was a particular method executed? Was an exception thrown? If you need to monitor multiple methods, you can create multiple info points.

If you know there are important methods you always want to monitor, create static info points as described in [Customize the iOS Instrumentation](#) and [Customize the Android Instrumentation](#).

Custom Timers

Custom timers allow you to time how long something takes between any arbitrary start point and end point, even if they span multiple methods. For example, how long did it take to repaint a frame buffer? How long did the app take to start up?

Custom Metrics

Custom metrics allow you to collect data on any metric you define in your application. Metrics can be any integer-based data. Over the specified time frame, Mobile RUM calculates the minimum, maximum, average, sum, and count of these values.

View Custom Data

Your data is shown in tabular format in two tabs.

Custom Timers & Metrics

Click on any value (in blue) to display the same metric in the Metric Browser.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Set Up and Access Mobile RUM

You set up and configure Mobile RUM in two areas:

- Your AppDynamics Controller
- Your iOS, Android, Xamarin, or Cordova application

To prepare Mobile RUM you need to make changes in both these areas in a particular order.

You need to do the following:

1. [Check your prerequisites](#)
2. [Review Controller capacity](#)
3. [Evaluate your mobile application](#)
4. [Complete the Getting Started Wizard](#)
5. [Instrument and verify your app](#)
6. [Configure network request naming and thresholds](#)

Check Your Prerequisites

Before you can use AppDynamics to monitor your mobile application, you need to make sure you have the following prerequisites:

- An AppDynamics account, with access to an AppDynamics Controller
- A Mobile RUM License. See [Set Up and Access Mobile RUM](#).
- Access to your mobile application source code

Review Your Controller Capacity

If you use an on-premises Controller and plan to monitor mobile applications, assess your Controller's capacity to accommodate the increase in the number of metrics that Mobile RUM will generate. The number of individual metric data points generated depends on the level of activity of your mobile applications. As a rough guide, the use of Mobile RUM can increase the number of metric data points by as much as 15 to 25K per instrumented application, if your applications are heavily accessed by mobile users. The actual number depends on how many network requests your applications receive.

 The number of separate RUM metric *names* saved in the Controller database can be larger than the kinds of individual data points saved. For example, a metric name for a metric for iOS 5 might still be in the database even if all your users have migrated away from iOS 5. So, the metric name would no longer have an impact on resource utilization, but it would count against the default limit in the Controller for metric names per application. The default limit for *names* is 200,000 for Browser RUM and 100,000 for Mobile RUM.

For more information about Controller sizing, see [Controller System Requirements](#).

Evaluate Your Mobile Application

By default, Mobile RUM can monitor your application in two ways: network requests and crash reporting.

If you want to collect information on network requests, your application must make HTTP calls using specific classes:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- An iOS application must use `NSURLConnection` or `NSURLSession` to generate network requests.
- An Android application must itself (i.e., not via an external framework) use `URLConnection`, `HttpsURLConnection`, `HttpClient`, `OkHttp`, or `ch.boye.httpclientandroidlib` to generate network requests.
- Using the SDK, custom HTTP libraries can also be monitored and used by the agent itself. See [Customize the iOS Instrumentation](#) and [Customize the Android Instrumentation](#) for more information.

Even if your application does not generate network requests, or if you do not want to monitor that activity, you can use AppDynamics purely to monitor crashes. You can also extend the Mobile Agents using the SDK to collect other data, like how your application is functioning internally.

Complete the Getting Started Wizard

Use the **Getting Started Wizard** to create a mobile app group, get an EUM App Key, and guide you through the instrumentation process. Once you have successfully completed the steps in the wizard, Mobile RUM will automatically be enabled for the created mobile app group.

i Your Controller must have a Mobile RUM license before you can enable the Mobile RUM functionality.

Enable Mobile RUM

To enable Mobile RUM:

1. Open your mobile application.
2. From the left-hand navigation bar, click **Configuration**.
3. Toggle the **Mobile Monitoring** switch to **ON**.

The screenshot displays the 'Mobile App Group Configuration' interface. At the top, 'Mobile Monitoring' is set to 'ON' with a green toggle switch. Below this, there are tabs for 'Network Requests' and 'Settings'. Under 'Network Requests', there are sub-tabs for 'Monitor' and 'Events Service'. The 'Monitor' tab is active, showing a 'Save' button at the top. Below the 'Save' button, there are sections for 'Exclude Rules' and 'Include Rules'. The 'Exclude Rules' section has an 'Add' button and a note: 'First, exclude the Network Request if any of the following are true:'. The 'Include Rules' section has an 'Add' button and a note: 'Then, evaluate these rules in this order to name and monitor the Network Request:'. Below the 'Include Rules' section, there is a table with the following content:

Name	Enabled	Summary
Default Naming Configuration	✓	Name the Network Request using: Full-Domain; first 2 segments of the URL.

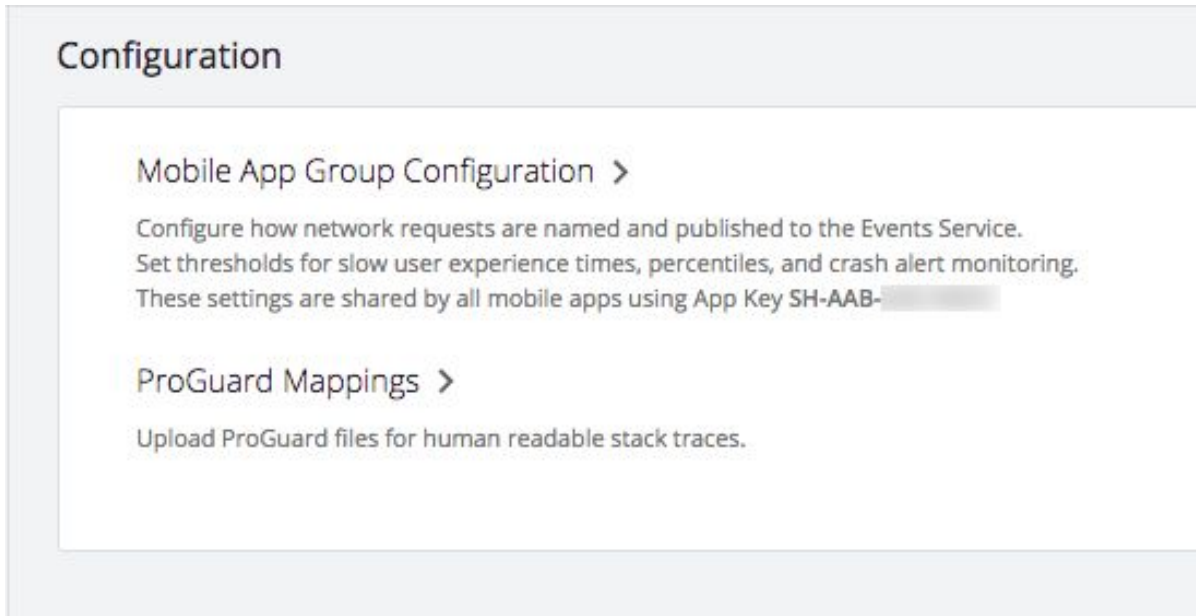

At the bottom of the 'Include Rules' section, there is another 'Save' button.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Get Your Application Key

To find your App Key after you've completed the **Getting Started Wizard**:

1. Open your mobile application.
2. From the left-hand navigation bar, click **Configuration**.
3. From the **Configuration** page, you can view the EUM App Key in the **Mobile App Group Configuration** section as shown below.

Instrument and Verify Your App

The method you follow to instrument your app depends on your platform:

- [Instrument iOS Applications](#)
- [Instrument Android Applications](#)
- [Instrument Xamarin Applications](#)
- [Instrument Cordova Applications](#)

Configure Network Request Naming and Thresholds

You can customize how you want the Controller to name your application's requests and what performance thresholds you want to be in effect. See [Configure the Controller UI for Mobile RUM](#).

External Access

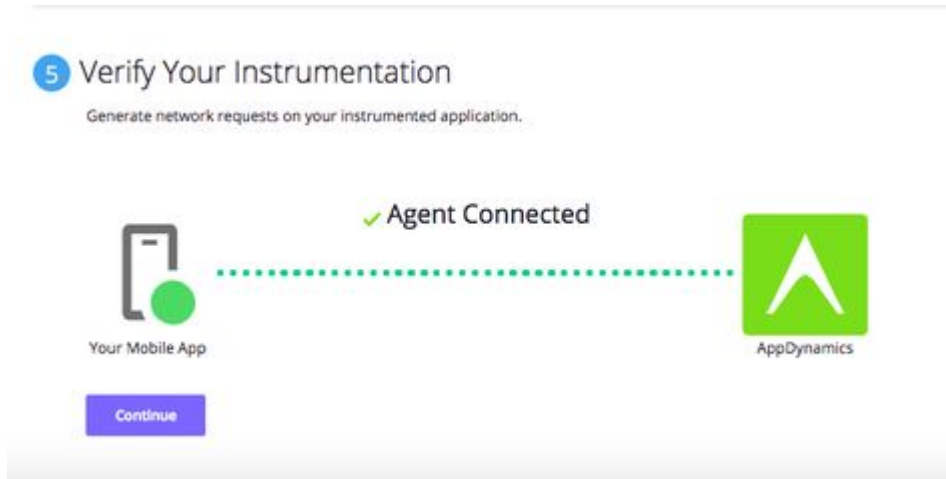

Mobile RUM is made up of several components, any or all of which can either be located on the Internet or hosted inside your own data center/network. On-premises access points are configured at installation or through the UI. If your installation requires access to any of these components on the Internet, see [Access the SaaS EUM Server](#) for more information.

Confirm the Mobile Agent Connection to the Controller

Related pages:

- [Instrument iOS Applications](#)
- [Instrument Android Applications](#)

After you have instrumented your application, the **Getting Started Wizard** will show you a verification that the Mobile Agent has connected to the Controller.

If you left the **Getting Started Wizard**, you can always verify the instrumentation by doing the following:

1. In the Controller, open **User Experience > Mobile Apps**.
2. Check the list of registered mobile applications to verify that the application is registered with the Controller. You can also view some basic information about the app such as the health, sessions, crashes, network request information, and whether the monitoring is enabled.

The screenshot shows the 'User Experience' dashboard with a table of mobile applications. The table has columns for Name, Health, Sessions, Crashes, Crash Rate, Network Requests, and Monitoring Status. The data is as follows:

Name	Health	Sessions	Crashes	Crash Rate	Network Requests	Monitoring Status
ECommerce - Android	Green	1,059	33	3.1%	6,487	Enabled
ECommerce - iOS	Green	1,094	70	6.2%	6,470	Enabled
ECommerce iOS (M)	Green	4,814	308	6.2%	23,319	Enabled
ECommerce Android	Green	4,887	313	6.2%	23,270	Enabled

3. Start monitoring your application. See [Overview of the Controller UI for Mobile RUM](#).

Instrument Android Applications

Related pages:

- [Customize the Android Build](#)
- [Customize the Android Instrumentation](#)
- [Upgrade the Android Agent](#)

To instrument Android Applications, you need to first build the application for the platform you are using and then add the instrumentation code.

To get started, follow the instructions below:

1. [Build the Android Application](#)
2. [Instrument the Android Application](#)

Build the Android Application

To build your application, follow the instructions for your platform:

- [Gradle/Android Studio](#)
- [Maven](#)
- [Ant](#)

If you are fetching the AppDynamics Android SDK from the [AppDynamics Download](#) page, see [Download Manually](#).

Gradle/Android Studio

Complete the following steps to configure the build for your Android application:

1. [Confirm the compatibility of your Gradle, Android Tools with the AppDynamics plugin versions.](#)
2. [Install the Android Agent.](#)
3. [Activate the plugin.](#)

Install the Android Agent

Use the native package system to install the Android Agent. In the app module `build.gradle`, add the class path of the AppDynamics Gradle Plugin to the build path dependencies clause. For `classpath` `'com.appdynamics:appdynamics-gradle-plugin:'` use the latest Android Agent version from the AppDynamics Downloads Portal. However, you can use an older version of the AppDynamics plugin for [compatibility between your Gradle and Android Tools](#) or for other reasons.

If you are unable to use the Android Gradle plugin 3.4.1 or higher, you will have to use the Android Agent 20.4.0 or an earlier version.

```
buildscript {
    repositories {
        jcenter()
    }
}
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

dependencies {
    classpath 'com.android.tools.build:gradle:1.1.0'
    classpath 'com.android.tools.build:gradle:3.4.1' // 3.4.1 or higher
    classpath 'com.appdynamics:appdynamics-gradle-plugin:<android-agent-version>' // Set
to your Android Agent version.
}
}
allprojects {
    repositories {
        jcenter()
    }
}
}

```

Activate the Plugin

In your module-level `build.gradle`, add the `adeum` plugin immediately after the `com.android.application` plugin, so that it looks similar to the example below:

```

apply plugin: 'com.android.application'
apply plugin: 'adeum' // this line added for AppDynamics

```

Apache Maven Project

If your application is a [Maven Project](#):

1. Add the following code to the `<dependencies>` section:

```

<dependency>
  <groupId>com.appdynamics</groupId>
  <artifactId>appdynamics-runtime</artifactId>
  <version>1.0</version>
</dependency>

```

2. Add the following code to the `<plugins>` section:

```

<plugin>
  <groupId>com.appdynamics</groupId>
  <artifactId>appdynamics-maven-plugin</artifactId>
  <version>1.0</version>
  <executions>
    <execution>
      <phase>compile</phase>
      <goals>

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

        <goal>adinject</goal>
      </goals>
    </execution>
  </executions>
</plugin>

```

Ant/Eclipse

See the Knowledge Base article [Use Ant to Build Android Apps with the AppDynamics Android SDK](#) for instructions.

Instrument the Android Application

After you have completed [building your application](#), follow the steps below:

1. [Add the Required Permissions](#)
2. [Get the Application Key](#)
3. [Modify the Source](#)
4. [Run the Build](#)
5. [Verify Instrumentation](#)

Add the Required Permissions

Open your application's `AndroidManifest.xml` file and verify that it has these permissions:

```

<uses-permission android:name="android.permission.INTERNET"></uses-permission>
<uses-permission android:name="android.permission.ACCESS_NETWORK_STATE"></uses-permission>

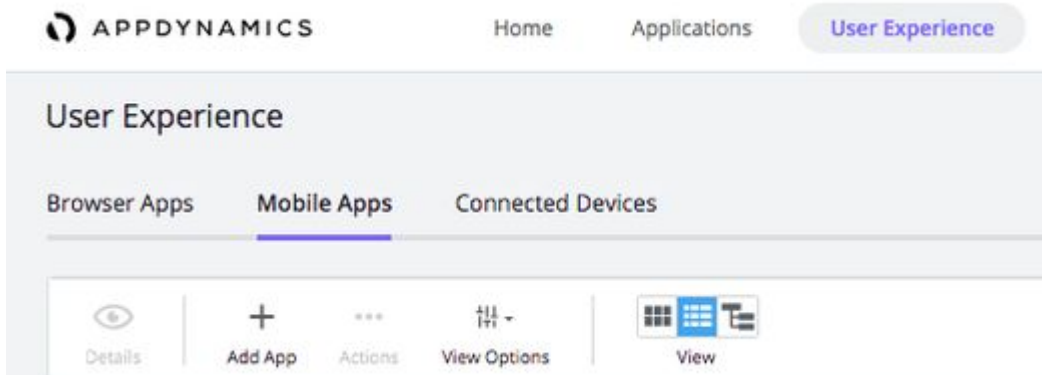

```

If both of these permissions are not present, add them.

Get Your EUM App Key

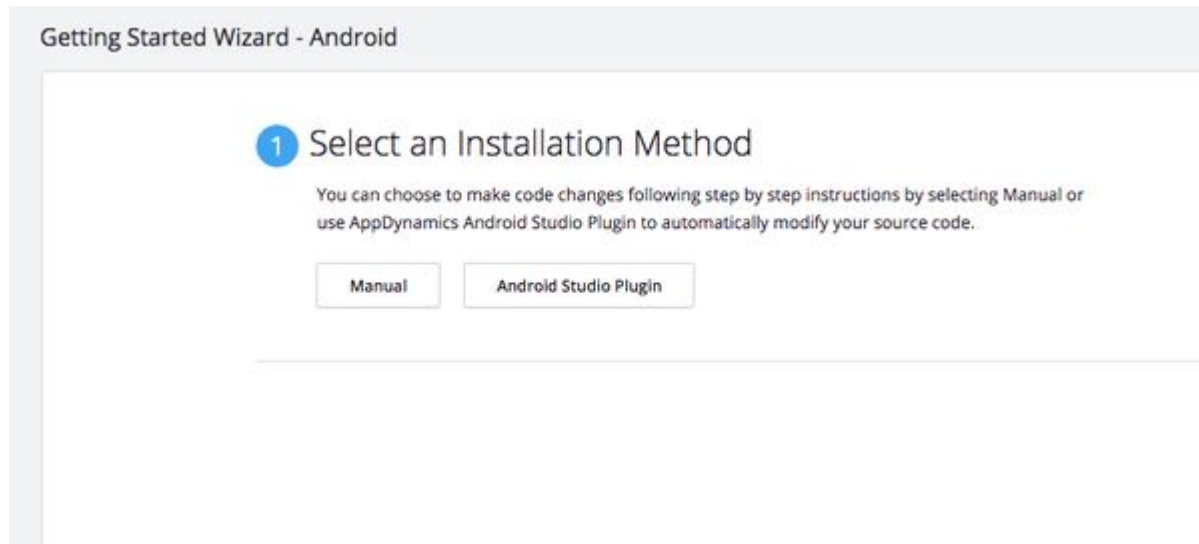

To get your EUM App Key in the Controller UI:

1. From the top navigation bar of your Controller UI, go to **User Experience > Mobile Apps**.

2. Click **Add App > Android** to open the Getting Started Wizard - Android page.

i Due to AppDynamics' discontinued support of Android Studio >= 4.0, we no longer recommend using the Android Studio Plugin installation method as of May 2020 (when Android Studio 4.0 released).

3. Click **Manual**.
4. Select the **Create a new Mobile App Group** radio button, enter an application name, and click **Continue**.
5. Copy the displayed App Key and the Collector URL.

Create a new Mobile App Group (you can always change this name later):

My Test App

Continue

Your App Key is: SH-
Your Collector URL is: <https://eum-col.appdynamics.com>

If you cannot get the EUM App Key from the **Getting Started Wizard**, see [Access Browser Monitoring Configuration](#).

Modify the Source

1. In the source file that defines your application's primary Activity, add the following import:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
import com.appdynamics.eumagent.runtime.Instrumentation;
```

- In your primary Activity's `onCreate()` method, add the following lines, passing in the EUM App Key from [Step 2](#) above:

```
Instrumentation.start(<EUM_APP_KEY>, getApplicationContext());
```

- Save the file.
Your code should look something like this.

```
import com.appdynamics.eumagent.runtime.Instrumentation;
...
@Override public void onCreate(Bundle savedInstanceState) {
    Instrumentation.start(<EUM_APP_KEY>, getApplicationContext());
    ...
}
```

- Configure the Android Agent to report metrics and screenshots to the [SaaS EUM Server and Screenshot Service in your region](#) when initializing the agent with the methods `withCollectorURL` and `withScreenshotURL`. (If you are using an on-premises EUM Server, see [Customize the Agent Configuration](#) for implementation details.)

```
import com.appdynamics.eumagent.runtime.Instrumentation;
...
@Override public void onCreate(Bundle savedInstanceState) {
    Instrumentation.start(AgentConfiguration.builder()
        .withAppKey("<EUM_APP_KEY>")
        .withContext(getApplicationContext())
        // The default SaaS EUM Server and Screenshot Service are in the Americas,
        // so you can omit the following settings if you are in the Americas.
        .withCollectorURL("https://<your_region>.eum-appdynamics.com")
        .withScreenshotURL("https://<your_region>-image.eum-appdynamics.com/")
        .build());
    ...
}
```

- In your module-level `build.gradle` file, add your AppDynamics account information as configurations in the `adeum` snippet. If you complete this step in the Getting Started Wizard, the configurations will populate in the UI code snippet. If you cannot get the EUM App Key from the **Getting Started Wizard**, see [Access Browser Monitoring Configuration](#).

```
dependencies {
```

```

compile 'com.appdynamics:appdynamics-runtime:<latest version>'
// This line is added for AppDynamics.
}

adeum { // This section is added for AppDynamics.
account {
  name '<account name>'
  licenseKey '<key>'
}

```

- a. If you are using Android Studio, you need to add a build script block to the top of your project's `build.gradle` file and define the gradle plugin dependency:

```

// project build.gradle
buildscript {
  dependencies {
    classpath("com.appdynamics:appdynamics-gradle-plugin:<latest-version>")
  }
}

plugins {
  id 'com.android.application' version '7.2.1' apply false
  id 'org.jetbrains.kotlin.android' version '1.7.0' apply false
  id 'org.jetbrains.kotlin.plugin.serialization' version '1.7.0'
}

```

If the option above is unavailable, you can also add a dependency resolution strategy block to the plugin management block of your `settings.gradle` file:

```

// project settings.gradle

pluginManagement {
  repositories {
    gradlePluginPortal()
    google()
    mavenCentral()
  }
}

resolutionStrategy {
  eachPlugin { plugin ->
    if (plugin.requested.id.id == "com.appdynamics.appdynamics-gradle-
plugin") {
      useModule("com.appdynamics:appdynamics-gradle-plugin:<latest-
version>")
    }
  }
}

```

```

    }
  }
}

```

Run the Build

Build your Android app following the instructions for your build system:

- [Android Studio](#)
- [Gradle](#)
- [Maven](#)

In the console, you should see something like this:

```

[injector] /
=====
[injector] | AppDynamics BCI Instrumentation
summary |
[injector]
\=====
[injector]
[injector]
[injector] - Total number of classes visited (#720
classes)
[injector] - Total number of classes instrumented (#1
classes)
[injector] - Total number of classes failed to
instrument (#2 classes)
[injector] - Total number of features discovered (#3)
[injector]

```

Verify the Instrumentation

Based on the build system you used, verify that the instrumentation was successful:

- [Gradle/Android Agent Installer Plugin](#)
- [Maven](#)
- [Ant](#)

Gradle/Android Agent Installer Plugin

If you didn't use the `-i` flag, check to make sure there is a line in your console output that contains "inject". If you don't see this information printed in your console, either your project is incorrectly configured or the injector failed to run completely. There is a very detailed log of this

process either at `<project>/target/appdynamics_eum_android_bci.log` or `<module>/target/appdynamics_eum_android_bci.log`.

Maven

If you don't see this information printed in your console, either your project is incorrectly configured or the injector failed to run completely. There is a very detailed log of this process either at `<project>/target/appdynamics_eum_android_bci.log` or `<module>/target/appdynamics_eum_android_bci.log`.

Ant

If you don't see this information printed in your console, either your project is incorrectly configured or the injector failed to run completely. There is a very detailed log of this process either at `<project>/target/appdynamics_eum_android_bci.log` or `<module>/target/appdynamics_eum_android_bci.log`.

Customize the Android Build

Related pages:

- [Customize the Android Instrumentation](#)

[Build the Android Application](#) showed you how to use the bare minimum configuration to build your application.

The following pages show you how to add additional configuration to customize your build:

- [Automatically Upload Mapping Files](#)
- [Configure ProGuard to Prevent Obfuscation and Class Removal](#)
- [Exclude Classes from Being Instrumented](#)

Automatically Upload Mapping Files

You can configure the build to add your EUM account information so that you can automatically upload your ProGuard or DexGuard mapping files for crash reports with each build.

This is the recommended way of managing these types of mapping files, although manual modes are available for uploading mapping files. If you do not use ProGuard or DexGuard to obfuscate your files you can ignore this section. See [Configure ProGuard to Prevent Obfuscation and Class Removal](#).

DexGuard Limitation

DexGuard mapping files must be in the default location. This means that your DexGuard configurations should not specify `--printMapping`, which changes where to print the mapping file.

Upload to the SaaS EUM Server

If you are using the SaaS EUM Server, you just need to provide your account name and license key to automate uploading as shown below.

```

adeum {
    url COLLECTOR_URL // For SaaS it's optional to set your region's endpoint. Default is
    https://api.eum-appdynamics.com. See https://docs.appdynamics.com/display/PAA/
    SaaS+Domains+and+IP+Ranges for a list of regions. For on-prem it is the public collector URL.
    account {
        licenseKey EUM_LICENSE_KEY name EUM_ACCOUNT_NAME
    }
    proguardMappingFileUpload {
        failBuildOnUploadFailure false enabled true // This specifies whether the entire
        build should fail if mapping file upload fails. Enabled refers to whether auto-uploading of
        mapping file is enabled.
    }
    excludeClasses = ['android.support.multidex.*', 'okio.**'] // This specifies any classes
    customers would like to exclude from auto-instrumentation. The notation is standard java
    package/class specification used in Gradle.
    enabledForDebugBuilds = true // Whether auto-instrumentation is enabled for debug builds,
    true by default.
    enabledForReleaseBuilds = true // Whether auto-instrumentation is enabled for release
    builds, true by default.
    webViewCallbackCrashReportingEnabled = false // Auto-instrumentation is enabled for
    WebViewClient and WebViewClient
    ...

    // This block specifies how to handle native crashes. By default, this is not enabled.
    nativeCrashHandling {
        if (BUILD_NDKLIB) {

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

    enabled = true
    symbolUpload {
      variantLibraryPaths = ["appRelease": "ndkLib/obj/local"]
    }
  }
}

```

Upload to the On-Premises EUM Server

If you are using an on-premises deployment, in addition to supplying your account name and license, you must also assign the URL to your on-premises EUM Server to the `url` property as shown:

```

adeum{
  // The account information is also needed for on-prem deployments.
  account {
    name "The EUM Account Name from the License screen"
    licenseKey "The EUM License Key from the License screen"
  }
  ...
  // Add this information to point to the on-prem EUM Server.
  url "https://<your-on-prem-eum-server>:7001"
}

```

Modify the Default Upload Behavior

You can also modify the default upload behavior for both on-premises and SaaS deployments. For on-premises deployments, you will need to provide the URL to your on-premises EUM Server with the `url` property.

The configuration example below sets `failBuildOnUploadFailure` to `true`, so that the build will fail if the upload to the URL specified by `url` is unreachable. The object `proguardMappingFileUpload` is used for both ProGuard and DexGuard mapping files. If you don't want your build to fail because the ProGuard or DexGuard mapping file couldn't be uploaded, do *not* modify the default setting.

```
adeum{
    ...
    // Add this information to point to the on-prem EUM Server.
    url "https://<your-on-prem-eum-server>:7001"

    // Add this information if you want to modify upload behavior.
    proguardMappingFileUpload {
        failBuildOnUploadFailure true // If true, will fail build. Defaults to false.
        enabled true //enables automatic uploads. Defaults to true
    }
}
```

Configure ProGuard to Prevent Obfuscation and Class Removal

If you use ProGuard to verify or optimize your code, add the following lines to the ProGuard configuration file `proguard-rules.pro` under Gradle Scripts to prevent ProGuard from obfuscating or removing classes needed for proper instrumentation.

```
-keep class com.appdynamics.eumagent.runtime.DontObfuscate
-keep @com.appdynamics.eumagent.runtime.DontObfuscate class *
{ *; }
```

Configure ProGuard to Prevent Obfuscation and Class Removal

Related pages:

- [Automatically Upload Mapping Files](#)

If you use ProGuard to verify or optimize your code, add the following lines to the ProGuard configuration file `proguard-rules.pro` under Gradle Scripts to prevent ProGuard from obfuscating or removing classes needed for proper instrumentation.

```
-keep class com.appdynamics.eumagent.runtime.DontObfuscate
-keep @com.appdynamics.eumagent.runtime.DontObfuscate class * { *; }
```

Exclude Classes from Being Instrumented

You can exclude one or more class names from being instrumented, using the "adeum" `excludeClasses` snippet.

Class names can contain wildcards:

- '?' for a single character
- '*' for any number of characters, but *not* the package separator
- '**' for any number of (any) characters
- '\$' prefix for an inner class name

To exclude named classes from instrumentation, add the class names to the `excludeClasses` array, using matching patterns where needed:

```
...
adeum {
    // Excludes all the classes in the android.support.multidex and okio packages.
    excludeClasses = ['android.support.multidex.*', 'okio.**']
}
...
```

Customize the Android Instrumentation

Related pages:

- [Instrument Android Applications](#)
- [Android SDK Documentation](#)

Once you have instrumented your Android application with the Android SDK, you can also use the APIs exposed by the SDK to customize the data for your application that appears in the Controller UI. The following sections show you how to use the Android API to customize your instrumentation:

- [Collect Additional Types of Data](#)
- [Add a Crash Reporting Callback](#)
- [Disable Crash Reporting](#)
- [Report Errors and Exceptions](#)
- [Disable the Agent to Stop Sending User Data to the Collector](#)
- [Configure Hybrid Support](#)
- [Programmatically Control Sessions](#)
- [Start and End Session Frames](#)
- [Use a Custom HTTP Library](#)
- [Customize the Agent Configuration](#)
- [Capture User Interactions](#)
- [Programmatically Take Screenshots](#)
- [Block/Unblock Screenshots](#)
- [Transform URLs for Network Requests](#)
- [Enable Logging and Set Logging Level](#)
- [Android SDK Documentation](#)

i Because the Android Agent [stores data about events in a local buffer](#) before reporting the information, we recommend you use the APIs with discretion.

Collect Additional Types of Data

The `Instrumentation` class has additional methods to allow you to extend the kinds of application data you can collect and aggregate using Mobile RUM. There are six basic kinds of extensions that you can create:

Extension	Description	Specification	Where Data is Displayed in the Controller UI
Info points	How often a method is invoked, and how long it takes to run	<ul style="list-style-type: none"> • Data is numeric • Names must consist of alphanumeric characters and/or spaces 	<ul style="list-style-type: none"> • Metric Browser • Custom Data • Network Request Snapshots • Mobile Sessions • Network Request Analyze

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Extension	Description	Specification	Where Data is Displayed in the Controller UI
Custom timers	Any arbitrary sequence of events within your code timed, even spanning multiple methods	<ul style="list-style-type: none"> Data is numeric Metric names must consist of alphanumeric characters and/or spaces 	<ul style="list-style-type: none"> Metric Browser Custom Data
Custom metrics	Any integer-based data you wish to collect	<ul style="list-style-type: none"> Data is numeric Metric names must consist of alphanumeric characters and/or spaces 	<ul style="list-style-type: none"> Metric Browser Custom Data
User data	Any string key/value pair you might find useful	<ul style="list-style-type: none"> Any data type Metric names have no restrictions 	<ul style="list-style-type: none"> Network Request Snapshots Mobile Sessions Network Request Analyze Crash Snapshots
Breadcrumbs	The context of a crash	<ul style="list-style-type: none"> Any data type Metric names have no restrictions 	<ul style="list-style-type: none"> Network Request Snapshots Mobile Sessions Network Request Analyze Crash Snapshots
User interactions	Captured when users press buttons, click on lists, and select text	<ul style="list-style-type: none"> Any data type Metric names have no restrictions 	<ul style="list-style-type: none"> Network Request Snapshots Mobile Sessions Network Request Analyze

When you have set up info points, custom timers, custom metrics, and/or user data, the Mobile Agent packages that data in a mobile beacon. Normally, the beacon is transmitted when the instrumented application sends an HTTP request or when the application starts after a crash, but if custom data has been collected and neither of those events has occurred for at least 5 minutes, the custom data is sent at that time.

Info Points

Information points allow you to track how your own code is running. You can see how often a method is invoked, how long it takes to run, and if an exception is thrown. The simplest way to set up an information point is to use the `@InfoPoint` annotation. For example:

```
@InfoPoint
public void infoPointMethod(String arg1, int arg2, long value) {
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

System.out.println("Executing infoPointMethod!");
}

```

You can also do this manually, using the `CallTracker` interface. For example, to collect information on the `downloadImage` method, you could use code similar to this:

```

private void downloadImage(URL url) {
    CallTracker tracker =
        Instrumentation.beginCall("com.example.android.awesomeapp.ImageDownloader",
"downloadImage")
            .withArguments(url);
    try {
        //download image.
        tracker.reportCallEnded()
    } catch(Exception e) {
        //handle exception thrown
        tracker.reportCallEndedWithException(e);
    }
}

```

This information appears in the **Custom Data** view of the Controller UI.

Custom Timers

Custom timers allow you to time any arbitrary sequence of events within your code, even spanning multiple methods, by using `startTimer` and `stopTimer`.

```

public class MyActivity extends Activity {
    @Override
    protected void onStart(){
        Instrumentation.startTimer("Time Spent on MyActivity");
        //your code here.
    }

    @Override
    protected void onStop(){
        Instrumentation.stopTimer("Time Spent on MyActivity");
        //your code here.
    }
}

```

The methods `startTimer(String)` and `stopTime(String)` can be called from different threads.

Calling `startTimer` again with the same name value resets a named timer.

This information appears in the **Custom Data** view of the Controller UI.

Custom Metrics

Any integer-based data can be passed to the Android Agent. The first parameter to the `reportMetric` call is the name you want the metric to appear under in the Controller UI. The metric name should only contain alphanumeric characters and spaces. Illegal characters are replaced by their ASCII hex value.

For example, to track the number of times your users click the checkout button in your UI, you could use code similar to this.

```
findViewById(R.id.checkout_button).setOnClickListener(new View.OnClickListener(){
    @Override
    public void onClick(View view){
        //run your checkout routine.
        Instrumentation.reportMetric("Checkout Count", 1);
    }
});
```

This information appears in the **Custom Data** view of the Controller UI.

Custom User Data

You can set and later remove any string key/value pair you think might be useful with the following methods:

- `setUserData(key, value, success, error)`

Parameters

The following table describes the parameters:

Name	Type	Description
key	string	The key identifying the key-value pair.
value	string	The value associated with the key.
success	function	The user-defined callback for successful cases.
error	function	The user-defined callback for failed cases.

Example

The code example below shows how to set user data with the SDK API:

```
void onUserLoggedIn(String userid) {
    Instrumentation.setUserData("User ID", userid);
}
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

    ...
  }

```

The code example below shows how to remove user data with the SDK API:

```

void onUserLoggedIn(String userid) {
    Instrumentation.removeUserData("User ID", userid);
    ...
}

```

This information is available in **Network Request Analyze** and is added to any crash snapshot. Keys and values are limited to 2048 characters each.

You can also set user data with values of other types (Long, Boolean, Double, Date) using the following methods:

- [setUserDataLong](#)
- [setUserDataBoolean](#)
- [setUserDataDouble](#)
- [setUserDataDate](#)

Breadcrumbs

Breadcrumbs allow you to situate a crash in the context of your user's experience. Set a breadcrumb when you want to capture a series of events. If your application crashes at some point in the future, the breadcrumb will be displayed along with the crash report.

There are two ways of leaving breadcrumbs:

- Crash Reports Only
- Modal

Crash Reports Only

Using this method means that breadcrumbs are reported in crash reports only.

```

public static void leaveBreadcrumb(java.lang.String breadcrumb)

```

Modal

Using this method lets you fine tune where the breadcrumbs are reported, either only in crash reports or in crash reports *and* sessions.

```

public static void leaveBreadcrumb(java.lang.String breadcrumb, int mode)

```

Where `mode` is either:

- `CRASHES_ONLY`
- `CRASHES_AND_SESSIONS`

If the `breadcrumb` is over 2048 characters, it is truncated. If it is empty, no breadcrumb is recorded. Each crash report displays the most recent 99 breadcrumbs.

Add a Crash Reporting Callback

You may want to make crash report information (that the Android Agent collects) available to other parts of your code, for example, to Google Analytics. To enable passing on summary crash information, you can set up a crash report runtime callback. To get a callback when the Android Agent detects and then reports a crash, implement the following interface in your code:

```
public interface CrashReportCallback {
    void onCrashesReported(Collection<CrashReportSummary> summaries);
}
```

The Android Agent sends a collection of crash report summaries instead of an individual callback in the event that there is more than one crash, producing multiple crash report summaries.

The method `onCrashesReported` is invoked during the next initialization of the Android Agent after a crash has occurred.

This callback is invoked on your app's UI thread, so any work should be done on a separate work thread.

Each `CrashReportSummary` has the following properties:

```
public class CrashReportSummary {
    public final String crashId;
    public final String exceptionClass;
    public final String exceptionMessage;
}
```

If you are sending the information to another analytics tool, such as Google Analytics, we recommend to include all three properties: `exceptionClass` and `exceptionMessage` are useful for quick identification of the crash, and `crashId` is useful to look up the crash in the Controller UI.

For example, to print the crash information to Android's logger, you could implement a `CrashReportCallback` class like this:

```
public static class MyCrashReportCallback implements CrashReportCallback {
    @Override
    public void onCrashesReported(Collection<CrashReportSummary> summaries) {
        for (CrashReportSummary crash : summaries) {
```

```

        Log.e("MyApp", "Crash Detected: " + crash.exceptionClass + " : " +
        crash.exceptionMessage + " (" + crash.crashId + ")");
    }
}
}

```

You set your callback as using the `AgentConfiguration` object:

```

final AgentConfiguration config = AgentConfiguration.builder()
    .withAppKey(appKey)
    .withContext(context)
    .withCrashCallback(new MyCrashReportCallback())
    .build();

```

Your callback is invoked after a crash, during the next initialization, on the main thread. For more information, see the [latest JavaDocs](#) for the complete Android SDK API.

Disable Crash Reporting

Crash reporting is enabled by default, but you can manually disable crash reporting through the instrumentation configuration. If you are using other crash reporting tools, you might disable crash reporting to minimize conflicts and optimize the crash report results.

You can disable crash reporting by configuring the instrumentation with the `crashReportingEnabled` property as shown in the following:

```

let config = ADEumAgentConfiguration(appKey: <#EUM_APP_KEY#>);
config.crashReportingEnabled = false;
ADEumInstrumentation.initWith(config);

```

Report Errors and Exceptions

The string message used to construct a new throwable used for `reportError` should not use unique string such as hashes, `StackTraceID` or `ThreadID`. Including those will create an infinite number of `Error Group` which will impact performance.

To add unique error strings and values, you have two data collection options:

- Add a string value as a breadcrumb. If the event/error, you are reporting has a single value attached, add the value to `leaveBreadcrumb`. See [Breadcrumbs](#)
- Add string name and integer values. If the event/error, you are reporting has both name and integer values attached, add the values to `reportMetric`. See [Custom Metrics](#).

You can report exceptions using the method `reportError` from the `Instrumentation` class. Reported exceptions will appear in session details.

You can also set one of the severity levels below for an issue. With the severity level, you can filter errors in the **Code Issues Dashboard** or **Code Issues Analyze**.

- `ErrorSeverityLevel.INFO`
- `ErrorSeverityLevel.WARNING`
- `ErrorSeverityLevel.CRITICAL`

The example below uses the API to report possible exceptions and sets the severity level to `ErrorSeverityLevel.CRITICAL` (critical) when writing to a file.

```
private void writeToFile(String filePath, String data) {
    try {
        OutputStream outputStream = new FileOutputStream(filePath);
        Writer outputStreamWriter = new OutputStreamWriter(outputStream);
        outputStreamWriter.write(data);
        outputStreamWriter.close();
    } catch (IOException e) {
        Log.e("Exception", "File write failed: " + e.toString());
        Instrumentation.reportError(e, ErrorSeverityLevel.CRITICAL);
    }
}
```

Disable the Agent to Stop Sending User Data to the Collector

You can disable the agent to stop sending all data to the collector while the agent is initialized and running. For example, you can disable the agent if your app has an option for users to opt-out of monitoring for privacy reasons.

`shutdownAgent`

The `shutdownAgent` call stops outgoing data to the collector, and does not persist data on the device.

```
Instrumentation.shutdownAgent();
```

- The call only stops the traffic out of the agent.
- Once the agent has been initialized, the call cannot be removed, and a license will have been consumed.
- If you want to make this state permanent for a device, add code in `UserDefaults` to save the state and use that flag to conditionally initialize the agent in your code.

`restartAgent`

To re-enable the agent and reverse `shutdownAgent`, use `restartAgent`.

```
Instrumentation.restartAgent();
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- The call will respect the server side calls that can remotely shutdown the agent in a similar way.
- The call is only in effect while the app is running.
- The call will be ignored if the agent has been remotely disabled.
- If the call is removed from memory and the app restarts, or the device is rebooted, the agent will be initialized as normal.

Configure Hybrid Support

By default, the Android Agent instruments [Android WebViews](#) by injecting the JavaScript Agent into WebViews. See [Hybrid Application Support](#) for an overview and an explanation of how it works.

Runtime Configuration for Hybrid Support

The code example below disables the injection of the JavaScript Agent. If the client receives a `false` for this flag, then the JavaScript Agent will be disabled. Thus, WebViews will not be instrumented, and Ajax requests will not be monitored.

```
Instrumentation.start(
    AgentConfiguration.builder()
        .withAppKey(getString(R.string.app_key))
        .withContext(applicationContext)
        .withJSAgentInjectionEnabled(false)
        .build())
```

The injection occurs during the creation of a new `WKWebView`. So, if a `WKWebView` is created when this flag is set to `false`, that particular `WKWebView` won't be instrumented even if the flag is subsequently set to `true`.

The collection and reporting of Ajax calls are disabled by default. To enable the injection and the collection and reporting of Ajax calls, pass `true` to the method `jsAgentEnabled` in the instrumentation configuration as shown below.

```
Instrumentation.start(
    AgentConfiguration.builder()
        .withAppKey(getString(R.string.app_key))
        .withContext(applicationContext)
        .withJSAgentAjaxEnabled(true)
        .build())
```

Programmatically Control Sessions

By default, a mobile session ends after a period of user inactivity. For example, when a user opens your application, the session begins and only ends after the user stops using the application for a set period of time. When the user begins to use the application again, a new session begins.

Instead of having a period of inactivity to define the duration of a session, however, you can use the following API to programmatically control when sessions begin and end:

```
void startNextSession()
```

When you call the method `startNextSession` from the Instrumentation class, the current session ends and a new session begins. The API enables you to define and frame your sessions so that they align more closely with business goals and expected user flows. For example, you could use the API to define a session that tracks a purchase of a product or registers a new user.

Excessive use of this API will cause sessions to be throttled (excessive use is >10 calls per minute per Android Agent, but is subject to change). When not using the API, sessions will fall back to the default of ending after a period of user inactivity.

Example of a Programmatically Controlled Session

In the code example below, the current session ends and a new one begins when the check out is made.

```
public void checkoutCart(){
    if (currentCartItems!=null && currentCartItems.size()>0){
        CheckoutTask checkoutReq = new CheckoutTask();
        checkoutReq.execute(getEndpoint() + "cart/co");
        currentCartItemsMap.clear();
        convertItemsMaptoList();
        Instrumentation.startNextSession();
    } else {
        displayToast("There are no items in the cart");
    }
}
```

Start and End Session Frames

You can use the `SessionFrame` API to create session frames that will appear in the session activity.

Session frames provide context for what the user is doing during a session. With the API, you can improve the names of user screens and chronicle user flows within a business context.

Use Cases

The following are common use cases for using the `SessionFrame` API:

- One Activity performs multiple functions and you want more granular tracking of the individual functions.
- A user flow spans multiple activities or user interactions. For example, you could use the API to create the session frames "Login", "Product Selection", and "Purchase" to chronicle the user flow for purchases.
- You want to capture dynamic information based on user interactions to name session frames, such as an order ID.

SessionFrame API

The table below lists the three methods you can use with session frames.

Class	Method	Description
Instrumentation	<pre> static SessionFrame startSessionFrame(String sessionFrameName) </pre>	<p>Use this to start and name your session frame.</p> <p>Naming session frames enable you to easily identify and track the frames in the Sessions Dialog.</p>
SessionFrame	<pre> static void updateName(String updatedSessionFrameName) </pre>	<p>Use this to start and name your session frame.</p> <p>Naming session frames enable you to easily identify and track the frames in the Sessions Dialog.</p>
SessionFrame	<pre> static void end() </pre>	<p>End the session frame. You call this method from the <code>SessionFrame</code> object returned from <code>startSessionFrame</code>.</p>

Session Frame Example

In the following example, the `ShoppingCartActivity` class uses the `SessionFrame` API to track user activity during the checkout process.

```

public class ShoppingCartActivity extends Activity {

    SessionFrame checkoutSessionFrame;

    public void onCheckoutCartButtonClicked() {
        // The user starts the checkout by clicking the checkout button.
        // This may be after they have updated the quantities of items in the cart, etc.
        checkoutSessionFrame = Instrumentation.startSessionFrame("Checkout");
    }

    public void onConfirmOrderButtonClicked() {
        // Once they have confirmed payment info and shipping information, and they
        // are clicking the "Confirm" button to start the backend process of checking out,
        // we may know more information about the order itself, such as an order ID.
        checkoutSessionFrame.updateName("Checkout: Order ID " + orderId);
    }

    public void onProcessOrderCompleted() {
        // Once the order is processed, the user is done "checking out", so we end the session
        // frame.
        checkoutSessionFrame.end();
    }
}

```

```

    checkoutSessionFrame = null;
  }

  public void onCheckoutCanceled() {
    // If the user cancels or returns to the cart, you'll want to end the session frame also,
    // or else it will be
    // left open and appear to have never ended.
    checkoutSessionFrame.end();
    checkoutSessionFrame = null;
  }
}

```

Use a Custom HTTP Library

The Android Agent automatically detects network requests when the underlying implementation is handled by any one of the supported network libraries. To have the Android Agent detect requests from a custom library, [add request tracking code](#) to your application manually, using the `HttpRequestTracker` interface.

Supported Network Libraries

The libraries below cover the great majority of Android network requests. In some cases, however, mobile applications use custom HTTP libraries.

- `URLConnection`
- `HttpsURLConnection`
- `HttpClient` classes
- `OkHttp`
- `OkHttp3`
- `ch.boye.httpclientandroidlib`

To [set headers to allow correlation](#) with server-side processing, use the `ServerCorrelationHeaders` class.

Add Request Tracking

To add request tracking manually, you use an `HttpRequestTracker` object to tell the agent when the request begins and when it ends and to report fields of the response to the agent.

Tracking a request

To begin tracking an HTTP request, use an instance of the following interface.

You must initialize the agent using the `Instrumentation.start` method before using this interface.

```

public interface HttpRequestTracker {
    public Exception getException();
    public HttpRequestTracker withException(Exception e);
}

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

public String getError();
public HttpRequestTracker withError(String error);

public int getResponseCode();
public HttpRequestTracker withResponseCode(int responseCode);

public Map<String, List<String>> getResponseHeaderFields();
public HttpRequestTracker withResponseHeaderFields(Map<String, List<String>>
responseHeaderFields);

/**
 * Stops tracking an HTTP request.
 *
 * Immediately after receiving a response or an error, set the appropriate fields and call
 this method to
 * report the outcome of the HTTP request. You should not continue to use this object
 after calling this
 * method -- if you need to track another request, obtain a new instance.
 */
public void reportDone();
}

```

Example

Given a request snippet like this:

```

public byte[] sendRequest(URL url) throws HttpException {
    try {
        // implementation omitted
        return responseBody;
    } catch (UnderlyingException e) {
        throw new HttpException(e);
    }
}

```

Adding the tracker could look like this:

```

public byte[] sendRequest(URL url) throws HttpException {
    HttpRequestTracker tracker = Instrumentation.beginHttpRequest(url);
    try {
        // implementation omitted
        tracker.withResponseCode(theResponseCode)
                .withResponseHeaderFields(theResponseHeaderFields)
                .reportDone();
        return responseBody;
    } catch (UnderlyingException e) {
        tracker.withException(e)
    }
}

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

        .reportDone();
    }
    throw new HttpException(e);
}
}

```

Attach a Custom User Data Property to a Network Request

You can attach a [custom user data](#) property to a specific network request by adding user data to `HttpRequestTracker`.

```

public HttpRequestTracker withUserData(String key, String value)
public HttpRequestTracker withUserLong(String key, Long value)
public HttpRequestTracker withUserBoolean(String key, Boolean value)
public HttpRequestTracker withUserDouble(String key, Double value)
public HttpRequestTracker withUserDate(String key, Date value)

```

Example

```

public byte[] sendRequest(URL url) throws HttpException {
    HttpRequestTracker tracker = Instrumentation.beginHttpRequest(url);
    try {
        // implementation omitted
        tracker.withResponseCode(theResponseCode)
            .withResponseHeaderFields(theResponseHeaderFields)
            .withUserData("key", "value")
            .withUserLong("number", 100)
            .withUserBoolean("boolean", true)
            .withUserDouble("double", 1.1234)
            .withUserDate("date", 1609488000)
            .reportDone();
        return responseBody;
    } catch (UnderlyingException e) {
        tracker.withException(e)
            .reportDone();
        throw new HttpException(e);
    }
}

```

Enable Server-Side Correlation

To enable correlation between your request and server-side processing, add specific headers to outgoing requests that the server-side agent can detect.

This is done automatically for standard HTTP libraries.

```

public class ServerCorrelationHeaders {

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

    public static Map<String, List<String>> generate();
  }

```

You must:

1. Call the `generate` method and set the generated headers *before* sending a request to the backend.
2. Report back the response headers, using data from the `withResponseHeaderFields` field.

Override the Request/Response Content-Length

- You can generally obtain the content lengths of the network request and response by passing the headers with `HttpRequestTracker.withRequestHeaderFields()` and `HttpRequestTracker.withResponseHeaderFields()`.
- If for some reason this does not work for your custom HTTP tracking (i.e. the network library doesn't populate those fields until its being transmitted), then you can still report the request and response content lengths using `HttpRequestTracker.withRequestContentLength(Long length)` and `HttpRequestTracker.withResponseContentLength(Long length)`.
- For example, you want to track a request that has a `byte` array of content. You can report the request content length by passing the size of the byte array:

```

byte[] requestContent;
HttpRequestTracker tracker;
tracker.withRequestContentLength(requestContent.size());

```

Customize the Agent Configuration

To customize the behavior of the agent itself, you pass the `AgentConfiguration` object to the `Instrumentation.start` method. The `AgentConfiguration` object allows you to:

- Point to an on-premises EUM Server
- Enable logging
- Custom-set the application name, which is useful if you deploy the same application binary with different package names to different geographic areas. This ensures that all the data ends up being processed under the same name.
- Ignore HTTP requests internal to your application that are not used for network requests
- [Configure the agent to use your custom HTTP library to send its beacons](#)

Syntax

See the [latest JavaDocs](#) for more information.

```

Instrumentation.start(AgentConfiguration.builder()
    .withAppKey("<EUM_APP_KEY>")
    .withContext(getApplicationContext())
    .withCollectorURL(collectorURL*) // The URL of the EUM Server(on-prem)
    .withCompileTimeInstrumentationCheck(true) // Set to false if you are using features of
the SDK only, like custom HTTP support, but not to instrument your app.
    .withLoggingEnabled(true)//set default INFO logging. Tagged "AppDynamics".

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

    .withApplicationName(applicationName)//set a custom app name
    .withExcludedUrlPatterns(excludedUrlPatterns) // Set excluded url regex patterns for
http tracking
    .withCollectorChannelFactory(collectorChannelFactory()) // The custom HTTP
implementation to use
    .build();
  
```

*For a list of URLs of EUM servers, see [SaaS Domains and IP Ranges](#).

Configure the Agent to Use Custom HTTP Library

The Android Agent uses HTTP to deliver beacons. If you want the agent use your custom HTTP library to deliver beacons:

1. Implement a class that extends the following abstract class:

```

public abstract class CollectorChannel {
    private URL url;
    private int connectTimeout;
    private int readTimeout;
    private Map<String, List<String>> requestProperties = new HashMap<String,
List<String>>();
    private String requestMethod;

    public void setURL(URL url) {
        this.url = url;
    }

    public URL getURL() {
        return url;
    }

    public void setConnectTimeout(int connectTimeout) {
        this.connectTimeout = connectTimeout;
    }

    public int getConnectTimeout() {
        return connectTimeout;
    }

    public void setReadTimeout(int readTimeout) {
        this.readTimeout = readTimeout;
    }

    public int getReadTimeout() {
        return readTimeout;
    }

    public void addRequestProperty(String property, String value) {
  
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

    if (!requestProperties.containsKey(property)) {
        requestProperties.put(property, new ArrayList<String>());
    }
    requestProperties.get(property).add(value);
}

public Map<String, List<String>> getRequestProperties() {
    return Collections.unmodifiableMap(requestProperties);
}

public void setRequestMethod(String requestMethod) {
    this.requestMethod = requestMethod;
}

public String getRequestMethod() {
    return requestMethod;
}

public abstract OutputStream getOutputStream() throws IOException;

public abstract InputStream getInputStream() throws IOException;

public abstract int getResponseCode() throws IOException;

public abstract Map<String, List<String>> getHeaderFields() throws IOException;
}

```

This interface is loosely based on `URLConnection`.

2. Implement a version of the `CollectorChannelFactory` interface:

```

public interface CollectorChannelFactory {

    /**
     * Returns a new instance of CollectorChannel.
     *
     * If you want to supply a custom CollectorChannel, implement this interface, and
     return
     * an instance of your concrete implementation of CollectorChannel from this method.
     */
    public CollectorChannel newCollectorChannel();
}

```

The implementation of `newCollectorChannel` should return a new instance of your implementation of `CollectorChannel`.

3. Pass the `CollectorChannelFactory` to the `AgentConfiguration` object.

Capture User Interactions

You can enable the agent to track certain user interactions. Once user interactions have been captured, you can sort sessions by UI event and view the UI event in the timeline of the session waterfall.

You can capture when users do one or all of the following:

- Press buttons
- Select a text field
- Click a list item

Security and Privacy Concerns

The interaction capture mode is disabled by default for security and privacy reasons as user interactions may contain sensitive information. This potential security and privacy issue may be compounded if you enable both the capturing of UI interactions and screenshots.

Enable User Interaction Capture Mode

To enable user interaction capture mode, pass the capture mode to the method `withInteractionCaptureMode()` from an `AgentConfiguration` object. The instrumentation code example below configures the Android Agent to capture all the supported types of user interactions.

```
Instrumentation.start(AgentConfiguration.builder()
    .withAppKey("<EUM_APP_KEY>")
    .withContext(getApplicationContext())
    .withInteractionCaptureMode(InteractionCaptureMode.All)
    .build());
```

You can also configure the Android Agent to only capture one type of user interaction:

```
Instrumentation.start(AgentConfiguration.builder()
    .withAppKey("<EUM_APP_KEY>")
    .withContext(getApplicationContext())
    .withInteractionCaptureMode(InteractionCaptureMode.ButtonPressed)
    .build());
```

Programmatically Take Screenshots

By default, mobile screenshots are enabled on the agent-side but disabled on the Controller-side. To programmatically take manual screenshots, you must [enable screenshots in the Controller UI](#) and add the following API:

```
Instrumentation.takeScreenshot();
```

For example, you can take a screenshot after loading a UI element to view how the element is displayed to your users:

```
@Override
protected void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    setContentView(R.layout.activity_spinner_with_toast);
    spinner = (Spinner) findViewById(R.id.spnOptions);
    btnSpinnerVal = (Button) findViewById(R.id.btnSpinnerValue);
    loadSpinner();
    Instrumentation.takeScreenshot();
}
```

Disable Screenshots

You can [disable screenshots from the Controller UI](#) or with the Android SDK. To disable screenshots with the Android SDK, use the method `withScreenshotsEnabled(false)` from the `AgentConfiguration` class:

```
Instrumentation.start(AgentConfiguration.builder()
    .withAppKey("<EUM_APP_KEY>")
    .withContext(getApplicationContext())
    .withScreenshotsEnabled(false)
    .build());
}
```

Block/Unblock Screenshots

You can also use the Android SDK to block screenshots from being taken during the execution of a code block. This just temporarily blocks screenshots from being taken until you unblock screenshots. This enables you to stop taking screenshots in situations where users are entering personal data, such as on login and account screens.

You use the methods `Instrumentation.blockScreenshots()` and `Instrumentation.unblockScreenshots()` to block and unblock screenshots. If screenshots are disabled through `AgentConfiguration.Builder.withScreenshotsEnabled(true)` or through the Controller UI, these methods have no effect. You can call `Instrumentation.screenshotsBlocked()` to check if screenshots are being blocked.

The following example demonstrates how you could use the API to block and unblock screenshots when displaying user information.

```

public class UserAccountActivity extends Activity {
    ...
    public void displayCustomerAccount() {
        // Check to see if screenshots are blocked
        if (! Instrumentation.screenshotsBlocked()) {
            // If screenshots aren't blocked, block them before showing customer details
            Instrumentation.blockScreenshots();
        }
        // Code to display customer details
        displayAccount(this.user);
        // After you're done, unblock screenshots
        Instrumentation.unblockScreenshots();
    }
    ...
}

```

Transform URLs for Network Requests

When your application makes network requests, you may not want to report URLs containing sensitive information to the EUM Server. You can instead transform the network request URL before reporting it or ignore it altogether:

1. Implement a network request callback that modifies or ignores specific URLs.
2. Register the network request callback in the initialization code.

Implement the Network Request Callback

The callback that modifies or ignores specific URLs is an implementation of the interface below. The method `onNetworkRequest` is synchronous, we recommend that you return from the function quickly.

```

public interface com.appdynamics.eumagent.runtime.NetworkRequestCallback {
    boolean onNetworkRequest(HttpRequestTracker httpRequestTracker);
}

```

Transforming URLs

The `onNetworkRequest` method, in general, should follow the steps below to transform URLs:

1. Identify specific URLs using techniques such as regex or pattern matching.
2. Modify the `url` property of the `HttpRequestTracker` object.
3. Assign a valid URL to the `url` property. Modifying other properties of the `HttpRequestTracker` object will be ignored.
4. Return `true`.

The first step is optional as you could choose to transform the URLs of all network requests.

```

private static class myNetworkRequestCallback implements
com.appdynamics.eumagent.runtime.NetworkRequestCallback {
    @Override
    public boolean onNetworkRequest(HttpRequestTracker httpRequestTracker) {
        URL urlMask = new URL("http://networkrequest-mask.com/");
        httpRequestTracker.withURL(urlMask);
        return true;
    }
}

```

In general, however, you would want to identify and transform URLs that contain sensitive information. For example:

```

private static class myNetworkRequestCallback implements
com.appdynamics.eumagent.runtime.NetworkRequestCallback {
    @Override
    public boolean onNetworkRequest(HttpRequestTracker httpRequestTracker) {
        String urlString = httpRequestTracker.getURL().toString();
        try {
            URL url = new URL("http://customer-account.com/");
            if (urlString.contains("accountInfo")) {
                // Change the URL for calls to Facebook
                httpRequestTracker.withURL(url);
                return true;
            }
        } catch (MalformedURLException e) {
            return false;
        }
        return true;
    }
}

```

Ignoring URLs

If the `onNetworkRequest` method returns `false`, the beacon is dropped. The general process for ignoring beacons is:

1. Identify specific URLs using techniques such as regex or pattern matching.
2. Return `false`.

You could also ignore all network requests with the following implementation of `onNetworkRequest`:

```

private static class myNetworkRequestCallback implements
com.appdynamics.eumagent.runtime.NetworkRequestCallback {

```

```

@Override
public boolean onNetworkRequest(HttpRequestTracker httpRequestTracker) {
    return false;
}
}

```

In general, you would identify network requests that you didn't want to monitor and return `false` to ignore the network request. For example:

```

private static class myNetworkRequestCallback implements
com.appdynamics.eumagent.runtime.NetworkRequestCallback {
    @Override
    public boolean onNetworkRequest(HttpRequestTracker httpRequestTracker) {
        String urlString = httpRequestTracker.getURL().toString();
        try {
            URL url = new URL("http://socialnetworksite.com/");
            if (urlString.contains("avatar")) {
                // Ignore calls for avatars
                return false;
            }
        } catch (MalformedURLException e) {
            return false;
        }
        return true;
    }
}

```

Register the Network Request Callback

After implementing the callback, you register it in the initialization code. When the Android Agent is ready to create a network request beacon, it will first call the callback with an `HttpRequestTracker` object.

To register the callback in the initialization code:

```

Instrumentation.start(AgentConfiguration.builder()
    .withContext(getApplicationContext())
    .withAppKey("<EUM_APP_KEY>")
    .withNetworkRequestCallback(new myNetworkRequestCallback())
    .build());

```

Enable Logging and Set Logging Level

You use the method `withLogLevel` of the class `AgentConfiguration` to enable logging and set the logging level. You can set logging to one of the following levels:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- LOGGING_LEVEL_NONE
- LOGGING_LEVEL_INFO
- LOGGING_LEVEL_VERBOSE

Use verbose logging only for troubleshooting. Make sure to disable for production.

Example:

```
AgentConfiguration config = AgentConfiguration.builder()
config.withAppKey(appKey)
config.withContext(context)
    .withLogLevel(Instrumentation.LOGGING_LEVEL_VERBOSE)
    .build();
Instrumentation.start(config);
```

Android SDK Documentation

For the complete SDK API documentation, see the [latest JavaDocs](#) or the previous versions listed below:

- <https://sdkdocs.appdynamics.com/android-sdk/21.11/>
- <https://sdkdocs.appdynamics.com/android-sdk/21.6/>
- <https://sdkdocs.appdynamics.com/android-sdk/21.5/>
- <https://sdkdocs.appdynamics.com/android-sdk/21.2/>
- <https://sdkdocs.appdynamics.com/android-sdk/20.11/>
- <https://sdkdocs.appdynamics.com/android-sdk/20.10/>
- <https://sdkdocs.appdynamics.com/android-sdk/20.7/>
- <https://sdkdocs.appdynamics.com/android-sdk/20.5/>
- <https://sdkdocs.appdynamics.com/android-sdk/20.3/>

Manually Upload Mapping Files

Related pages:

- [Automatically Upload Mapping Files](#)

If you have obfuscated your code and want to monitor crashes, you will need to upload the ProGuard or DexGuard mapping files. AppDynamics needs the mapping file for the application to produce human-readable stack traces for crash snapshots. For details about why you should do this, see [Get Human-Readable Crash Snapshots](#).

DexGuard is built on ProGuard, so the Controller UI and some of the REST API for uploading mapping files will refer to ProGuard for both ProGuard and DexGuard files.

This page describes the requirements, the available methods, and instructions to manually upload the mapping files.

 We recommend you set up [automatic uploading](#) of the ProGuard or DexGuard mapping files using Gradle and your `build.gradle` file.

Requirements

To manually upload the mapping files, you need to associate the mapping file with the correct version of the application by providing the following:

- Android package name for the application
- Version code for that application (specified in either the `AndroidManifest.xml` file or the `build.gradle` file)

Upload Methods

You can then either upload the mapping file using the **Upload Missing ProGuard Mappings** dialog in the Controller UI or use a special REST API. Perform the upload separately for each ProGuard mapping file that you are providing. You can also check your uploads with a separate REST API.

 If you update your application, you need to upload the new version of the mapping file.

Upload with the Controller UI

1. From the Mobile App menu, click **Configuration**.
2. Click **ProGuard Mappings** >.
3. From the **Upload missing ProGuard Mapping** dialog:
 - a. Enter the version code (a number) for the package. This is the `versionCode` property specified in either the `AndroidManifest.xml` file or the `build.gradle` file of the application for which this mapping file was generated.
 - b. Click **Choose File**.
The uploader expects a file with the `.txt` extension. The file is named `mapping.txt`.
 - c. In the file browser, locate and select the mapping file and click **Open**.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

d. Click **Upload**.

Upload with the REST API

The API uses HTTP basic authentication. The username is your AppDynamics EUM account name and the password is your EUM license key.

Send the mapping file

Send the mapping file as a text file in the body of the PUT request to the following URL:

[Americas](#) [EMEA](#) [APAC](#)

```
https://api.eum-appdynamics.com/v2/account/<MyAccountName>/<androidPackageName>/<versionCode>/proguard-mapping
```

[Americas](#) [EMEA](#) [APAC](#)

```
https://fra-api.eum-appdynamics.com/v2/account/<MyAccountName>/<androidPackageName>/<versionCode>/proguard-mapping
```

[Americas](#) [EMEA](#) [APAC](#)

```
https://syd-api.eum-appdynamics.com/v2/account/<MyAccountName>/<androidPackageName>/<versionCode>/proguard-mapping
```

These parameters are required:

- `MyAccountName` : the URL-encoded version of your account name.
- `androidPackagename` : the name of the Android package for which this mapping file was generated.
- `versionCode` : the string representation of the "versionCode" property specified in either the `AndroidManifest.xml` file or the `build.gradle` file of the application for which this mapping file was generated.

The request body contains the mapping file. You need to add a `Content-Type` header, `-H Content-Type:text/plain`, and your account name and license key/password to the call.

Sample Request and Response Using the REST API

This is a sample request and response using the REST API.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Upload Request

The following example uses curl to send a ProGuard mapping file. You would use a similar command to send a DexGuard mapping file. The account name is "Example account" and the license key/password is "Example-License-Key-4e8ec2ae6cfe". The plus signs replace spaces in the account name when the account name is URL-encoded. The package name of the Android application is "com.example.networklogger". The mapping file corresponds to the version with `versionCode`.

[Americas](#) [EMEA](#) [APAC](#)

```
curl -v -H Content-Type:text/plain --upload-file mapping.txt --user
Example+account:Example-License-Key-4e8ec2ae6cfe https://api.eum-appdynamics.com/v2/
account/Example+account/com.example.networklogger/1/proguard-mapping
```

[Americas](#) [EMEA](#) [APAC](#)

```
curl -v -H Content-Type:text/plain --upload-file mapping.txt --user
Example+account:Example-License-Key-4e8ec2ae6cfe https://fra-api.eum-appdynamics.com/v2/
account/Example+account/com.example.networklogger/1/proguard-mapping
```

[Americas](#) [EMEA](#) [APAC](#)

```
curl -v -H Content-Type:text/plain --upload-file mapping.txt --user
Example+account:Example-License-Key-4e8ec2ae6cfe https://syd-api.eum-appdynamics.com/v2/
account/Example+account/com.example.networklogger/1/proguard-mapping
```

Upload Response

The successful output of the example request looks like this:

[Americas](#) [EMEA](#) [APAC](#)

```
curl -v -H Content-Type:text/plain --upload-file mapping.txt --user
Example+account:Example-License-Key-4e8ec2ae6cfe https://api.eum-appdynamics.com/v2/
account/Example+account/com.example.networklogger/1/proguard-mapping
```

[Americas](#) [EMEA](#) [APAC](#)

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
curl -v -H Content-Type:text/plain --upload-file mapping.txt --user
Example+account:Example-License-Key-4e8ec2ae6cfe https://fra-api.eum-appdynamics.com/v2/
account/Example+account/com.example.networklogger/1/proguard-mapping
```

Americas EMEA APAC

```
curl -v -H Content-Type:text/plain --upload-file mapping.txt --user
Example+account:Example-License-Key-4e8ec2ae6cfe https://syd-api.eum-appdynamics.com/v2/
account/Example+account/com.example.networklogger/1/proguard-mapping
```

Check Uploaded Mapping Files Using the REST API

You can check to make sure that your mapping files have successfully uploaded using two REST APIs.

1. [Get a list of the GUIDs for the last 50 mapping files you have uploaded.](#)
2. [Check if a specific mapping file has been uploaded.](#)

List of the Last 50 Mapping Files Uploaded

The `proguardQuery` method allows you to retrieve a list of GUIDs for up to the last 50 mapping files (ProGuard or DexGuard) that have been uploaded to your account, along with the time they were uploaded. The response is displayed as JSON, by upload time, with the most recent first.

1. Set up your authentication as described in [Upload with the API](#).

- Create a GET request of the form:

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://
<EUM_Cloud/EUM_Server_Host:port>/v2/account/<EUM_Account_Name>/crash-
symbol-file-query/proguard
```

- `EUM_Cloud` refers to SaaS-based EUM Cloud URLs. For a complete list, see [SaaS Domains and IP Ranges](#).
- `EUM_Server_Host` refers to the URL pointing to your on-premises EUM Server.
- `EUM_Account_Name` is your EUM account name.
- `GUID_To_Check` is the GUID of the ProGuard file in which you are interested.

Sample Request

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Sample Response

```
{"proguardFiles": [
{"packageName":"my_package_name1", "version":"1", "uploadTime":"mm/dd/yyyy 16:09:23","GUID":"
my_build_id1"},
{"packageName":"my_package_name2", "version":"1", "uploadTime":"mm/dd/yyyy 16:09:23","GUID":"
my_build_id2"}
]}
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Check for Specific Mapping File by GUID

The `checkForProguardFile` method allows you to check if a specific ProGuard or DexGuard file by GUID has been uploaded. The upload time is returned in the response.

- a. Set up your authentication as described in [Upload with the REST API](#).
- b. Create a GET request of the form:

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://<EUM_Cloud/
EUM_Server_Host:port>/v2/account/<EUM_Account_Name>/crash-symbol-file-query/proguard/
guid/<GUID_To_Check>
```

- `EUM_Cloud` refers to SaaS-based EUM Cloud URLs. For a complete list, see [SaaS Domains and IP Ranges](#).
- `EUM_Server_Host` refers to the URL pointing to your on-premises EUM Server.
- `EUM_Account_Name` is your EUM account name.
- `GUID_To_Check` is the GUID of the ProGuard file in which you are interested.

Sample Request

[Americas](#) [EMEA](#) [APAC](#)

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://api.eum-
appdynamics.com:443/v2/account/<EUM_Account_Name>/crash-symbol-file-query/proguard/
guid/my_build_id1
```

[Americas](#) [EMEA](#) [APAC](#)

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://fra-api.eum-
appdynamics.com:443/v2/account/<EUM_Account_Name>/crash-symbol-file-query/proguard/
guid/my_build_id1
```

[Americas](#) [EMEA](#) [APAC](#)

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
curl --user Example+account:Example-License-Key-4e8ec2ae6cfe https://syd-api.eum-appdynamics.com:443/v2/account/<EUM_Account_Name>/crash-symbol-file-query/proguard/guid/my_build_id1
```

Sample Response

```
{"packageName":"mypackagename","version":"1","uploadTime":"mm/dd/yyyy 16:09:23","GUID":"my_build_id1"}
```

Troubleshoot the Android Instrumentation

Related pages:

- [Instrument Android Applications](#)
- [Customize the Android Build](#)
- [Customize the Android Instrumentation](#)

This page provide instructions and tips for solving some common Android instrumentation issues.

Dex Failure After Upgrading Agent

If you build your application with Gradle and you get a dex failure after upgrading the Mobile Agent, you likely need to clear the Gradle cache.

Use Android Studio

To clear the cache using Android Studio:

1. Select **Build > Clean Project**.
2. Select **File > Invalidate Caches**.

 Sometimes a restart is also necessary.

Using the Command Line

To clear the cache using the command line:

1. Stop Gradle.

```
$ gradlew --stop
```

2. You may also need to refresh dependencies.

```
$ gradlew --refresh-dependencies
```

You can also try removing the AppDynamics cached images.

1. Find the images.

```
$ find ~/.gradle/caches -name com.appdynamics
```

2. Delete them.

```
$ find ~/.gradle/caches -name com.appdynamics -print0 | xargs -0 rm -r
```

Instrumentation Appears to Be Running After Being Disabled

If you disabled the instrumentation in Android using the Gradle flag `enabledForDebugBuilds`, but the instrumentation task still runs, this is because of the Transform API.

Android Gradle Plugin 1.5.0 introduced the Transform API that the Android Agent uses to do the bytecode injection. Due to the limitations of the Transform API, even when instrumentation is disabled, the `transformClassesWithAppDynamicsForDebug` task will still appear in the Gradle task log. To ensure that it is not actually instrumenting, run `gradle` with `--info` flag to show the info logs.

You should see the following log:

```
Instrumentation is disabled for this build variant. Just copying
the input files to fulfill Transform contract.
```

Crashes Are Not Reported After Using Custom Default Uncaught Exception Handler

Install your exception handler before you start the Android Agent. When an uncaught exception is handled by the agent, it will first store the crash report, and then call your exception handler.

Network Requests Are Not Being Reported

Please see the [list of supported networking libraries](#). If your library is not on the list, you can always [report these network requests manually](#).

For builds with the `debuggable` attribute, auto-instrumentation (the `enableInstrumentation` build attribute) is disabled to improve build speeds, and you cannot enable auto-instrumentation for those builds. Debuggable builds using Android Agent 20.5.0-20.7.0 do not auto-instrument network requests.

Exclude Classes from Being Instrumented

- `excludeClasses`

Enforce a Different Runtime Version from the Plugin Version

- `dependencies.compile 'com.appdynamics:appdynamics-runtime:4.5.+'`
`adeum.dependencyInjection.enabled = false`

Upgrade the Android Agent

As new features are added to the agent, you will need to upgrade the Android SDK in your app. The process of installing and updating the latest Android SDK is the same.

To upgrade, you simply update the build file for your platform:

- [Gradle/Android Studio](#)
- [Maven](#)

Instrument Xamarin Applications

Before you can monitor your Xamarin application, you will need to instrument your application to enable the Xamarin Agent to collect mobile metrics.

After you have [set up and accessed Mobile RUM](#), follow these instructions:

1. [Confirm that the Xamarin Agent supports your platform](#)
2. [Understand the limitations of the Xamarin Agent](#)
3. [Instrument a Xamarin Application](#)
4. [Customize the Xamarin Instrumentation \(Optional\)](#)

Xamarin Agent Support

Supported Platforms

The Xamarin Agent can only be used with iOS and Android platforms. All other platforms will build and run without errors, but no monitoring will occur.

Supported Libraries

- .NET Standard 2.0 (with Xamarin Agent \geq 20.10.0)

Recommendations

The Xamarin \leq 50.2 only supported the instrumentation of applications that reference the Portable Class Libraries (PCL). From Xamarin \geq 50.3, the Xamarin Agent only supports the .NET Standard library and the instrumentation of applications that reference the .NET Standard library. If you still need PCL support, you are recommended to use Xamarin \leq 50.2.

Limitations

The Xamarin Agent has these limitations:

- Automatic instrumentation is not supported, so you will need to manually report events and metrics.
- Symbolication is not supported, although the Xamarin Agent *does* report uncaught exceptions and native application crashes.

Instrument Xamarin Applications

Follow the steps below to manually instrument your Xamarin iOS, Android, and Forms apps.

- [Xamarin Agent Support](#)
- [Instrument Xamarin Applications](#)
- [Customize Your Instrumentation \(Optional\)](#)
- [Point to an On-Premises EUM Server \(Optional\)](#)

Add the Xamarin Agent Package

You obtain the Xamarin Agent from the [NuGet Gallery](#). Follow the instructions given in [Adding a Package](#) to add the package `AppDynamics.Xamarin.Agent` from [nuget.org](#).

Get Your Application Key

Complete the **Getting Started Wizard** to get an EUM App Key. You will need this key when you modify the source code. In some cases, multiple mobile applications can share the same key.

Because there is no Xamarin platform option, you will need to choose either Android or iOS. For Android, you will need to select **Manual**.

If you have completed the **Getting Started Wizard**, but don't have your EUM App Key, see [Get Your Application Key](#).

Add the Required Permissions (Android Deployments Only)

Open the file `Properties/AndroidManifest.xml` and verify that it has these permissions:

```
<uses-permission android:name="android.permission.INTERNET"></uses-permission>
<uses-permission android:name="android.permission.ACCESS_NETWORK_STATE"></uses-permission>
```

If these permissions are not present, add them.

Link the AppDynamics Agent Assembly

Forms Solution

Xamarin Forms is the unified development environment for running all platforms. If you try to run something on an **unsupported platform**, linking our agent won't allow you to monitor the application, but it also will not cause any errors.

To use the Xamarin Agent for your iOS/Android apps, add the `using` directive at the top of the `App.xaml.cs` file:

```
using Xamarin.Forms;
using AppDynamics.Agent;

namespace <AppName>
{
    public partial class App : Application
    {
        ...
    }
}
```

iOS Solution

To use the Xamarin Agent in iOS apps, add the `using` directive at the top of the `AppDelegate.cs` file:

```
using Foundation;
using UIKit;
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

using AppDynamics.Agent;

public class AppDelegate : UIApplicationDelegate
{
    ...
}

```

Android Solution

To use the Xamarin Agent in Android apps, add the using directive at the top of the `MainActivity.cs` file:

```

using Android.App;
using Android.Widget;
using Android.OS;
using System;
using Android.Content;
using AppDynamics.Agent;

namespace <AppName>
{
    [Activity(Label = "Phoneword", MainLauncher = true, Icon = "@mipmap/icon")]
    public class MainActivity : Activity
    {
        ...
    }
    ...
}

```

Initialize the Agent

To initialize the Xamarin Agent, you use the code below for iOS and Android. Use the EUM app key (enter as a string) that you received after completing [step 2](#).

```

var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);

```

i If you are running an on-premises EUM Server, you need to specify the URL to the EUM Server. See [Point to an On-Premises EUM Server \(Optional\)](#) to learn how.

Forms Solution

For Forms Solutions, you only need to place the initialize code in the constructor of the `App.xaml.cs` file for the Xamarin Agent to instrument both Android and iOS applications.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

public App()
{
    InitializeComponent();
    // This initialization code is used by both iOS and Android apps.
    var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
    AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
    MainPage = new FormsExamplePage();
}

```

If you have application code in the `MainActivity.cs` file for Android or `AppDelegate.cs` for iOS that you want to instrument, however, you should initialize the Xamarin Agent in those files as you would do for [iOS Solutions](#) and [Android Solutions](#).

iOS Solution

For iOS apps, you place the initialize code in the `AppDelegate.cs` file in the method `FinishedLaunching` of the class `AppDelegate` as shown below.

```

public class AppDelegate : UIApplicationDelegate
{
    // class-level declarations
    public override UIWindow Window
    {
        get;
        set;
    }
    public override bool FinishedLaunching(UIApplication application, NSDictionary launchOptions)
    {
        // The two lines below initialize the AppDynamics instrumentation.
        var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
        AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
        ...
        return true;
    }
    ...
}

```

You may also consider placing it in the `Main.cs` in the method `Main`.

Android Solution

In the `MainActivity.cs` file, place the initialization code in the method `OnCreate`:

```

class MainActivity {

```

```

protected override void OnCreate(Bundle savedInstanceState) {
  // The two lines below initialize the AppDynamics instrumentation.
  var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
  AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
  ...
}

```

Build the Application

Run and build your application from Visual Studio. From the **Getting Started Wizard**, you should see that the application has **connected and the instrumentation has been verified**.

For iOS projects with the Xamarin Agent `>=20.10.0`, you must add the additional `MtouchExtraArgs` argument `--gcc_flags "-ObjC -lz"` for each build configuration, such as the `debug` and `release` builds. If the iOS project file is edited directly, the build configuration should contain the `MtouchExtraArgs` element:

```

<PropertyGroup Condition=" '$(Configuration)|$(Platform)' == 'Debug|iPhoneSimulator' ">
  <DebugSymbols>true</DebugSymbols>
  <DebugType>full</DebugType>
  <Optimize>false</Optimize>
  <OutputPath>bin\iPhoneSimulator\Debug</OutputPath>
  <DefineConstants>DEBUG;ENABLE_TEST_CLOUD;</DefineConstants>
  <ErrorReport>prompt</ErrorReport>
  <WarningLevel>4</WarningLevel>
  <CodesignKey>iPhone Developer</CodesignKey>
  <MtouchDebug>true</MtouchDebug>
  <MtouchFastDev>true</MtouchFastDev>
  <MtouchLink>SdkOnly</MtouchLink>
  <MtouchArch>x86_64</MtouchArch>
  <MtouchHttpClientHandler>HttpClientHandler</MtouchHttpClientHandler>
  <MtouchTlsProvider>Default</MtouchTlsProvider>
  <DeviceSpecificBuild>false</DeviceSpecificBuild>
  <MtouchExtraArgs>--gcc_flags "-ObjC -lz"</MtouchExtraArgs>
</PropertyGroup>

```

Customize Your Instrumentation (Optional)

The Xamarin SDK has additional classes to allow you to extend the kinds of application data you can collect and aggregate using Mobile RUM. See [Customize the Xamarin Instrumentation](#).

Point to an On-Premises EUM Server (Optional)

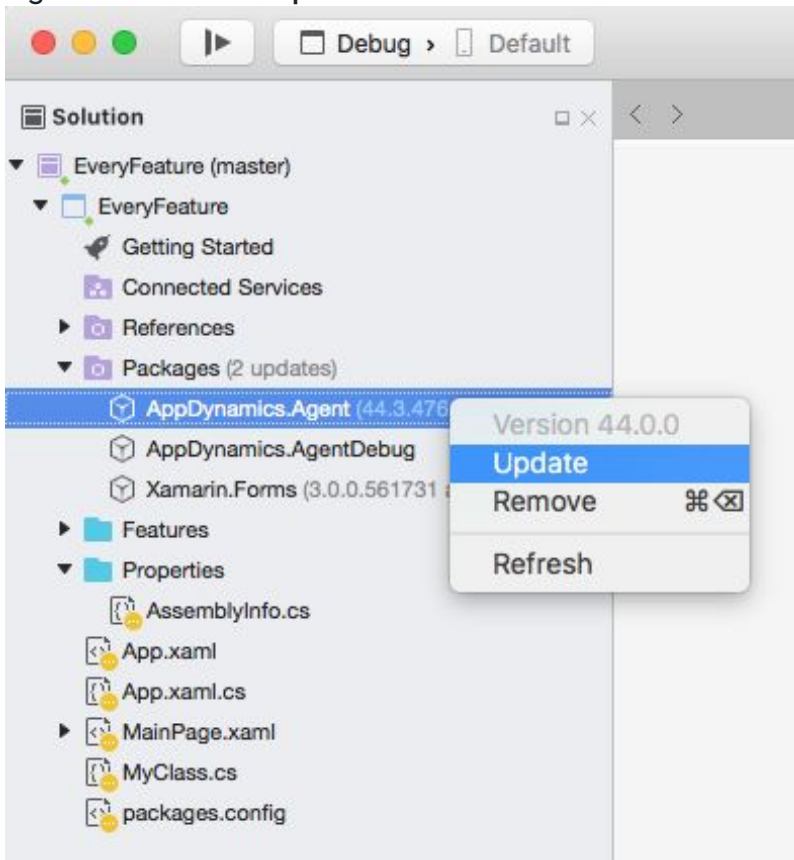

To use an on-premises EUM Server, you pass the URL to the on-premises EUM Server when you initialize the instrumentation with the EUM App Key from [Get Your Application Key](#):

```
var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
config.CollectorURL = <COLLECTOR_URL:PORT>;
AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
```

Upgrade the Xamarin Agent

As new features are added to the agent, you will need to upgrade the Xamarin Agent package in your app.

1. From Visual Studio, open the Xamarin application that has the AppDynamics Agent package.
2. From the **Packages** folder, select the AppDynamics Agent.
3. Right-click and click **Update**.

Customize the Xamarin Instrumentation

Related pages:

- [Instrument Xamarin Applications](#)
- [Xamarin SDK Documentation](#)

The following sections show you how to use the Xamarin SDK to customize your instrumentation.

- [Track Calls](#)
- [Timing Events](#)
- [Report Metrics](#)
- [HTTP Requests](#)
- [Leave Breadcrumbs](#)
- [Disable the Agent to Stop Sending User Data to the Collector](#)
- [Report Errors and Exceptions](#)
- [Report Aggregate Exceptions as Crashes](#)
- [Disable Crash Reporting](#)
- [Programmatically Control Sessions](#)
- [Start and End Session Frames](#)
- [Add User Data](#)
- [Set the Logging Level \(Optional\)](#)
- [Xamarin SDK Documentation](#)

i Because the agent [stores data about events in a local buffer](#) before reporting the information, you are recommended to use the APIs with discretion.

Track Calls

You can instrument methods to see how often the instrumented a method is invoked and how long it takes to run. To do this, add a call at the beginning and end of the method you'd like to instrument.

In the example below, the code executed in the constructor for the class `ShoppingCart` will be tracked and reported. In your own code, start tracking calls by specifying the class and method in `BeginCall` and then complete the tracking and report the data by calling `ReportCallEnded`.

```

using AppDynamics.Agent;
...
public class ShoppingCart {
    public ShoppingCart() {

        // Code to create the shopping cart
    }
    void CheckOut(int custId, int transactionId) {
        var tracker = Instrumentation.BeginCall("ShoppingCart", "CheckOut", custId,
transactionId);
        // The code placed here will be tracked and reported.
        tracker.ReportCallEnded();
    }
}

```

Timing Events

Sometimes you want to time an event in your application that spans multiple methods. You can do this by calling `StartTimerWithName` when the event starts, and then `StopTimerWithName` when it ends. For example, to track the time a user spends viewing a screen, the instrumentation might look something like the following:

```

using AppDynamics.Agent;
...
async private void StartCapturePreview_Click(object sender, RoutedEventArgs e) {
    capturePreview.Source = captureManager;
    Instrumentation.StartTimerWithName("CapturePreview");
    await captureManager.StartPreviewAsync();
}
async private void StopCapturePreview_Click(object sender, RoutedEventArgs e) {
    await captureManager.StopPreviewAsync();
    Instrumentation.StopTimerWithName("CapturePreview");
}

```

Report Metrics

To report other types of data, you can use a metric. The metric name should only contain alphanumeric characters and spaces. Illegal characters are replaced by their ASCII hex value. The metric value must be a long integer.

The snippet below shows how you might report a metric.

```

using AppDynamics.Agent;
...
Instrumentation.ReportMetricWithName("Database Rows", 5123);

```

HTTP Requests

You can report a Network Request using the `AppDynamics.Agent.HTTPRequestTracker` class.

The following is an example of using `HTTPRequestTracker` with the `System.Net.Http.HttpClient` class. The `tracker` object synchronously captures and reports the network request as well as any network errors.

```
using AppDynamics.Agent;
...
public async Task<string> Fetch(Uri uri) {
    var client = new HttpClient();
    // Create AppDynamics Tracker
    var tracker = HTTPRequestTracker.Create(uri);
    // Add AppDynamics Server Correlation Headers
    foreach (var header in ServerCorrelationHeaders.Generate) {
        // Each header could have multiple values
        foreach (var value in header.Value) {
            client.DefaultRequestHeaders.Add(header.Key, value);
        }
    }
    HttpResponseMessage response = null;
    try {
        response = await client.GetAsync(uri);
    } catch (Exception ex) {
        // Capture any network errors.
        tracker.Exception = ex;
        tracker.ReportDone();
        throw ex; //you decide to throw it or not
    }
    if (!response.Equals(null)) {
        // Capture request information such as the
        // status code, status message, and headers.
        tracker.ResponseCode = (int)response.StatusCode;
        tracker.StatusLine = response.ReasonPhrase;
        tracker.ResponseHeaderFields = response.Headers;
        tracker.ReportDone();
        return await response.Content.ReadAsStringAsync();
    }
    return null;
}
```

Leave Breadcrumbs

You can leave breadcrumbs to mark interesting events. For example, if your application crashes, the breadcrumbs you left with be displayed in the crash report and could provide context. You can also configure the breadcrumb to appear in sessions.

The following is the method signature for leaving breadcrumbs:

```
static void AppDynamics.Agent.Instrumentation.LeaveBreadcrumb(string breadcrumb,
BreadcrumbVisibility mode)
```

You use the mode to set the visibility of the breadcrumb. The visibility defines where you will see the breadcrumb in the Controller UI. The value of `mode` can be one of the following:

- `BreadcrumbVisibility.CrashesOnly` – The breadcrumb will only appear in crash snapshots.
- `BreadcrumbVisibility.CrashesAndSessions` – The breadcrumb will appear in crash snapshots and sessions.

Thus, you would use the method below to set breadcrumbs that are only reported in crash reports:

```
using AppDynamics.Agent;
...
Instrumentation.LeaveBreadcrumb("GetUserInfo", BreadcrumbVisibility.CrashesOnly);
```

If you would like to see the breadcrumb in crash reports and sessions:

```
using AppDynamics.Agent;
...
Instrumentation.LeaveBreadcrumb("GetUserInfo", BreadcrumbVisibility.CrashesAndSessions);
```

Disable the Agent to Stop Sending User Data to the Collector

You can disable the agent to stop sending all data to the collector while the agent is initialized and running. For example, you can disable the agent if your app has an option for users to opt-out of monitoring for privacy reasons.

`shutdownAgent`

The `shutdownAgent` call stops outgoing data to the collector, and does not persist data on the device.

```
using AppDynamics.Agent;
...
Instrumentation.shutdownAgent();
```

- The call only stops the traffic out of the agent.
- Once the agent has been initialized, the call cannot be removed, and a license will have been consumed.
- If you want to make this state permanent for a device, add code in `UserDefaults` to save the state and use that flag to conditionally initialize the agent in your code.

`restartAgent`

To re-enable the agent and reverse `shutdownAgent`, use `restartAgent`.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
using AppDynamics.Agent;
...
Instrumentation.restartAgent();
```

- This call will respect the server side calls that can remotely shutdown the agent in a similar way.
- The call is only in effect while the app is running.
- The call will be ignored if the agent has been remotely disabled.
- If the call is removed from memory and the app restarts, or the device is rebooted, the agent will be initialized as

Report Errors and Exceptions

You can report exceptions using the method `reportError` from the `Instrumentation` class. Reported exceptions will appear in session details.

You can also set one of the severity levels below for an issue. With the severity level, you can filter errors in the **Code Issues Dashboard** or **Code Issues Analyze**.

- `ErrorSeverityLevel.INFO`
- `ErrorSeverityLevel.WARNING`
- `ErrorSeverityLevel.CRITICAL`

The example below uses the API to report possible exceptions and sets the severity level to `ErrorSeverityLevel.CRITICAL` (critical) when writing to a file

```
using AppDynamics.Agent;
...
try {
    // possible exception //
}
catch (Exception e){
    Instrumentation.ReportError(exception, ErrorSeverityLevel.CRITICAL);
}
```

Report Aggregate Exceptions as Crashes

You can configure the Xamarin Agent to report aggregate exceptions (handled and unhandled) as crashes by setting the boolean property `EnableAggregateExceptionHandler` to `true`. When the property is set to `false`, only unhandled exceptions are reported. The default value is `false`.

The following code example configures the Xamarin Agent to report aggregate exceptions (handled and unhandled) as crashes.

```
using AppDynamics.Agent;
...
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
var config = AppDynamics.Agent.AgentConfiguration.Create(<EUM_APP_KEY>);
AppDynamics.Agent.Instrumentation.EnableAggregateExceptionHandling = true;
AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
...
```

Disable Crash Reporting

Crash reporting is enabled by default, but you can manually disable crash reporting through the instrumentation configuration. If you are using other crash reporting tools, you might disable crash reporting to minimize conflicts and optimize the crash report results.

You can disable crash reporting by configuring the instrumentation with the `crashReportingEnabled` property as shown in the following:

```
import { Instrumentation } from '@appdynamics/xamarin-agent';

Instrumentation.start({
    appKey: <#EUM_APP_KEY#>,
    crashReportingEnabled: false
})
```

Programmatically Control Sessions

By default, a mobile session ends after a period of user inactivity. For example, when a user opens your application, the session begins and only ends after the user stops using the app for a set period of time. When the user begins to use the application again, a new session begins.

Instead of having a period of inactivity to define the duration of a session, however, you can use the following API to programmatically control when sessions begin and end:

```
static void AppDynamics.Agent.Instrumentation.StartNextSession()
```

When you call the method `StartNextSession`, the current session ends and a new session begins. The API enables you to define and frame your sessions so that they align more closely with business goals and expected user flows. For example, you could use the API to define a session that tracks a purchase of a product or registers a new user.

Excessive use of this API will cause sessions to be throttled (excessive use is > 10 calls per minute per Xamarin Agent, but is subject to change). When not using the API, sessions will fall back to the default of ending after a period of user inactivity.

Example of a Programmatically Controlled Session

In the example below, the current session ends and a new one begins when an item is bought.

```
using AppDynamics.Agent;
...
public async Task BuySaleItemAsync(SaleItem item)
{
    try
    {
        bool buySucceeded = await this.MobileService.InvokeApiAsync<SaleItem, bool>("buy",
item);
        if (buySucceeded)
        {
            await UserDialogs.Instance.AlertAsync("Thanks for buying this item");
            Instrumentation.StartNextSession();
        }
    }
    catch (Exception e)
    {
        Debug.WriteLine(@"Unexpected error {0}", e.Message);
    }
}
```

Start and End Session Frames

You can use the `ISessionFrame` API to create session frames that will appear in the session activity. Session frames provide context for what the user is doing during a session. With the API, you can improve the names of user screens and chronicle user flows within a business context.

Use Cases

The following are common use cases for the `ISessionFrame` API:

- One screen performs multiple functions and you want more granular tracking of the individual functions.
- A user flow spans multiple screens or user interactions. For example, you could use the API to create the session frames "Login", "Product Selection", and "Purchase" to chronicle the user flow for purchases.
- You want to capture dynamic information based on user interactions to name session frames, such as an order ID.

ISessionFrame API

The table below lists the two methods and one property you can use with session frames. In short, you start a session frame with `StartSessionFrame` and then use the returned `ISessionFrame` object to rename and end the session frame.

Class	Method/Property	Description
Instrument	Method: <pre>static ISessionFrame StartSessionFrame(string sessionFrameName)</pre>	Use this to start and name session frames. Naming session frames allows you to track the frames in the session.
ISessionFrame	Property: <pre>string Name</pre>	Rename the session frame. You assign the updated Name property from the ISessionFrame.StartSessionFrame() method.
ISessionFrame	Method: <pre>static void End()</pre>	End the session frame. You call this method from the ISessionFrame object returned from StartSessionFrame().

Session Frame Example

In the following example, the `ISessionFrame` API is used to track user activity during the checkout process.

```
using AppDynamics.Agent;
...

namespace ShoppingApp {
    public partial class ShoppingCart : ContentPage {
        private ISessionFrame sessionFrame;
        private string orderId;
        ...
        void checkoutCartButtonClicked(object sender, EventArgs e) {
            // The checkout starts when the user clicks the checkout button.
            // This may be after they have updated quantities of items in their cart, etc.
            sessionFrame = Instrumentation.StartSessionFrame("Checkout");
        }
        void confirmOrderButtonClicked(object sender, EventArgs e) {
            // Once they have confirmed payment info and shipping information, and they
            // are clicking the "Confirm" button to start the backend process of checking out,
            // we may know more information about the order itself, such as an order ID.
            sessionFrame.Name = $"Checkout: Order ID {this.orderId}";
        }
        void processOrderCompleted(object sender, EventArgs e) {
            // Once the order is processed, the user is done "checking out" so we end
            // the session frame.
        }
    }
}
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

        sessionFrame.End();
    }
    void checkoutCancelled(object sender, EventArgs e) {
        // If they cancel or go back, you'll want to end the session frame also, or else
        // it will be left open and appear to have never ended.
        sessionFrame.End();
    }
}
}

```

Add User Data

You can set a key/value pair of strings to record important events or information. Below is the method signature for setting user data:

```

static void AppDynamics.Agent.Instrumentation.SetUserData(string key, string value)

```

For example, you might want to log the user ID when the method for logging in the user is called:

```

using AppDynamics.Agent;
...
void LogInUser(UserCredentials) {
    // Log in user
    ...
    // Set user data with the user name.
    Instrumentation.SetUserData("user_id", UserCredentials.ID);
}

```

This information is available in **Network Request Analyze** and is added to any crash snapshots that may be taken. Keys and values are limited to 2048 characters each.

You can also set user data with values of other types (long, boolean, double, DateTime) using the following methods:

- [SetUserDataBoolean](#)
- [SetUserDataDate](#)
- [SetUserDataDouble](#)
- [SetUserDataLong](#)

To remove user data, use the following methods:

- [RemoveUserData](#)
- [RemoveUserDataBoolean](#)
- [RemoveUserDataDate](#)
- [RemoveUserDataDouble](#)
- [RemoveUserDataLong](#)

Set the Logging Level (Optional)

You can set the logging level with the configuration `LoggingLevel` as part of the class `AgentConfiguration`.

You can set `LoggingLevel` to one of the levels listed in the table below.

Level	Description
Off	Agent will emit no messages at all.
Error	Only show errors and initial banner. This is the default.
Warn	Warning level messages and above.
Info	Information level messages and above May be useful to the developer.
Debug	Debug level messages and above. Useful for support personnel and developers.
Verbose	Verbose level messages and above. Use verbose logging only for troubleshooting. Be sure to disable for production.
All	All messages.

For example:

```
var config = AppDynamics.Agent.AgentConfiguration.Create("<#Your App Key#>");
config.LoggingLevel = AppDynamics.Agent.LoggingLevel.All;
AppDynamics.Agent.Instrumentation.InitWithConfiguration(config);
```

Xamarin SDK Documentation

For the complete SDK API documentation, see the [latest Xamarin SDK documentation](#) or the previous versions listed below:

- <https://sdkdocs.appdynamics.com/xamarin-sdk/21.2/html/>
- <https://sdkdocs.appdynamics.com/xamarin-sdk/20.11/html/>
- <https://sdkdocs.appdynamics.com/xamarin-sdk/2020.10/html/>
- <https://sdkdocs.appdynamics.com/xamarin-sdk/2020.4/html/>
- <https://sdkdocs.appdynamics.com/xamarin-sdk/2020.3/html/>

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Instrument Cordova Applications

Related pages:

- [Hybrid Application Support](#)
- [Customize the Cordova Instrumentation](#)
- [Update Cordova Agent Configurations](#)

Follow the steps below to get your EUM App Key and instrument your Cordova-based apps.

- [Check Requirements](#)
- [Get Your Application Key](#)
- [Install and Initialize the Cordova Plugin](#)
- [Customize the Cordova Application Instrumentation](#)

 For native mobile applications, follow either the iOS Instrumentation or Android Instrumentation instructions. The mobile agents will inject the JavaScript Agent and auto-instrument your mobile application including the auto-instrumentation of the WKWebView.

Check Requirements

To use the AppDynamics Cordova plugin, your hybrid application must be using the following:

- Cordova $\geq 8.0.0$
- npm $\geq 3.10.10$
- Node.js $\geq 6.11.3$
- WKWebView for iOS applications

WKWebView Requirements

By default, the Cordova iOS platform command adds a version of `cordova-ios` that supports UIWebView. AppDynamics does not support UIWebView, so you must manually change this to WKWebView.

1. Run the following command:

```
(ionic) cordova platform add ios
```

2. Verify the log output returns:

```
Using WKWebView
```

3. If the log output returns `Using UIWebView`, you must manually change it to `Using WKWebView`.

Get Your Application Key

After you completed the **Getting Started Wizard**, you were given an EUM App Key. You will need this key when you modify the source code. In some cases, multiple mobile applications can share the same key.

If you have completed the **Getting Started Wizard**, but don't have your EUM App Key, see [Get Your Application Key](#).

Install and Initialize the Cordova Plugin

The AppDynamics Cordova plugin is certified to work with the Ionic and PhoneGap frameworks. Thus, the installation instructions below are for Ionic and PhoneGap applications. See the plugin installation instructions for your Cordova-based framework.

[Ionic](#) [PhoneGap](#)

From the root directory of your Ionic application, run the following commands to install the plugin and build the mobile app. See the [Ionic Cordova plugin documentation](#) for more information.

1. Replace the values in brackets with the configurations for your app and run the command to add the configured plugin.

For SaaS deployments:

```
ionic cordova plugin add appd-plugin-eum-mobile --variable APP_KEY="<#EUM_APP_KEY#>" --variable SCREENSHOTS_ENABLED=<true|false> --variable LOGGING_LEVEL=[0-6] --save
```

For on-prem deployments, replace the value for the variable `COLLECTOR_URL` with the URL to your EUM Server and the value for `SCREENSHOT_URL` with the URL to your on-prem Screenshot Service.

```
ionic cordova plugin add appd-plugin-eum-mobile --variable APP_KEY="<#EUM_APP_KEY#>" --variable SCREENSHOTS_ENABLED=<true|false> --variable LOGGING_LEVEL=[0-6] --variable COLLECTOR_URL="http(s)://<on-prem_eum_server_url>:<PORT>" --variable SCREENSHOT_URL="http(s)://<on-prem_screenshot_service_url>" --save
```

2. (Optional) You can also disable or set the interaction capture mode ([iOS/Android](#)) and set the URL to test the network connectivity of Cordova iOS applications.

- a. The interaction capture mode is on by default, but you can disable it by setting the variable `INTERACTION_CAPTURE_MODE` to `0` or specify the desired capture mode for the platform (see the interaction mode values for iOS and Android in the table below). Setting `INTERACTION_CAPTURE_MODE` only controls capturing of webview interactions. If you set `INTERACTION_CAPTURE_MODE` to `0`, interactions with webviews will no longer be captured. However, interactions with native UI elements, such as UI Buttons under iOS, will still be captured, as they always are captured by the underlying native agent for each platform.

```
ionic cordova plugin add appd-plugin-eum-mobile --variable APP_KEY="<#EUM_APP_KEY#>" --variable INTERACTION_CAPTURE_MODE=<see modes in table below> --variable SCREENSHOTS_ENABLED=<true|false> --variable LOGGING_LEVEL=[0-6]
```

```
--variable COLLECTOR_URL="http(s)://<on-prem_eum-server_url>:<PORT>" --variable
SCREENSHOT_URL="http(s)://<on-prem_screenshot_service-url>" --save
```

[iOS](#) [Android](#)

Capture Mode	Value	Description
Capture None	0	No user interactions are captured.
Button Pressed	1	Button presses are captured.
Table Cell Selected	2	Table cell selections are captured.
Text Field Selected	4	Text field selections are captured.
Text View Selected	8	Text view selections are captured.
All	-1	All user interactions are captured.

[iOS](#) [Android](#)

Capture Mode	Value	Description
Capture None	0	No user interactions are captured.
Button Pressed	1	Button presses are captured.
Edit Text Selected	2	Selection of edited text is captured.
List Item Selected	4	Selection of list item is captured.
All	-1	All user interactions are captured.

- b. By default, the Cordova Plugin will use `http://google.com/` to test the connectivity of Cordova iOS applications. You can, however, use a different URL to test the connectivity by setting the variable `REACHABILITY_HOST` to the URL. In the example below, the Cordova Plugin is configured to use `http://example.com` to test the connectivity of the Cordova iOS application.

```
ionic cordova plugin add appd-plugin-eum-mobile --variable
APP_KEY="<#EUM_APP_KEY#>" --variable REACHABILITY_HOST="http://example.com" --
variable SCREENSHOTS_ENABLED=<true|false> --variable LOGGING_LEVEL=[0-6] --save
```

3. Build the mobile app:

```
ionic cordova build [android, ios]
```

Ionic [PhoneGap](#)

From the root directory of your PhoneGap application, run the commands below to install the plugin. See the [PhoneGap plugin documentation](#) for more information.

1. Replace the values in brackets with the configurations for your app and run the command to add the configured plugin.

For SaaS deployments:

```
phonegap cordova plugin add appd-plugin-eum-mobile --variable APP_KEY="<#EUM_APP_KEY#>"
--variable SCREENSHOTS_ENABLED=<true|false> --variable LOGGING_LEVEL=[0-6] --save
```

For on-prem deployments, replace the value for the variable `COLLECTOR_URL` with the URL to your EUM Server and the value for `SCREENSHOT_URL` with the URL to your on-prem Screenshot Service.

```
phonegap cordova plugin add appd-plugin-eum-mobile --variable APP_KEY="<#EUM_APP_KEY#>"
--variable SCREENSHOTS_ENABLED=<true|false> --variable LOGGING_LEVEL=[0-6] --variable
COLLECTOR_URL="http(s)://<on-prem-eum-server-url>:<PORT>" --variable SCREENSHOT_URL="ht
tp(s)://<on-prem-screenshot-service-url>" --save
```

2. (Optional) You can also set variables to enable user interaction capture mode ([iOS/Android](#)) and troubleshoot the network connectivity of Cordova iOS applications.

- a. The interaction capture mode is on by default, but you can disable it by setting the variable `INTERACTION_CAPTURE_MODE` to `0` or specify the desired capture mode for the platform (see the interaction mode values for iOS and Android in the table below). Setting `INTERACTION_CAPTURE_MODE` only controls capturing of webview interactions. If you set `INTERACTION_CAPTURE_MODE` to `0`, interactions with webviews will no longer be captured. However, interactions with native UI elements, such as UI Buttons under iOS, will still be captured, as they always are captured by the underlying native agent for each platform.

```
phonegap cordova plugin add appd-plugin-eum-mobile --variable
APP_KEY="<#EUM_APP_KEY#>" --variable INTERACTION_CAPTURE_MODE=<see modes in table
below> --variable SCREENSHOTS_ENABLED=<true|false> --variable LOGGING_LEVEL=[0-6]
--save
```

[iOS](#) [Android](#)

Capture Mode	Value	Description
Capture None	0	No user interactions are captured.
Button Pressed	1	Button presses are captured.
Table Cell Selected	2	Table cell selections are captured.
Text Field Selected	4	Text field selections are captured.
Text View Selected	8	Text view selections are captured.
All	-1	All user interactions are captured.

 iOS [Android](#)

Capture Mode	Value	Description
Capture None	0	No user interactions are captured.
Button Pressed	1	Button presses are captured.
Edit Text Selected	2	Selection of edited text is captured.
List Item Selected	4	Selection of list item is captured.
All	-1	All user interactions are captured.

- b. By default, the Cordova Plugin will use `http://google.com` to test the connectivity of Cordova iOS applications. You can, however, use a different URL to test the connectivity by setting the variable `REACHABILITY_HOST` to the URL. In the example below, the Cordova Plugin is configured to use `http://example.com` to test the connectivity of the Cordova iOS application.

```
phonegap cordova plugin add appd-plugin-eum-mobile --variable
APP_KEY="#EUM_APP_KEY#" --variable REACHABILITY_HOST=http://example.com --
variable SCREENSHOTS_ENABLED=true|false --variable LOGGING_LEVEL=[0-6] --save
```

3. Build the mobile app:

```
phonegap cordova build [android, ios]
```

Customize the Cordova Application Instrumentation

See [Customize the Cordova Application](#) showing how to use the Cordova SDK through examples and brief explanations.

Update Cordova Agent Configurations

To update the configurations set when you first added the Cordova plugin to your application, the suggested practice is to remove the values for configuration values and then add new configuration values.

See the following examples:

- [WkWebView Requirements](#)
- [Change the App Key](#)
- [Change the App Name](#)

Change the App Key

To change the app key for your Ionic or PhoneGap applications:

1. Remove the old value for the variable `APP_KEY` with the `remove` command:

```
cordova plugin remove --variable APP_KEY="old-app-key" appd-plugin-eum-mobile
```

2. Add new value for the variable `APP_KEY` with the `add` command. Be sure to include the variables that you set when you first added the plugin (represented by `<variable_list>` below). For example, if you set `REACHABILITY_HOST=http://example.com` when you first added the plugin, you will need to reset the variable when running the `add` command again.

```
cordova plugin add --variable APP_KEY="new-app-key" <variable_list> appd-plugin-eum-mobile
```

Change the App Name

To change the name of your Ionic or PhoneGap applications:

1. Remove the old value for the variable `APP_NAME` with the `remove` command:

```
cordova plugin remove --variable APP_NAME="old-app-name" appd-plugin-eum-mobile
```

2. Add new value for the variable `APP_NAME` with the `add` command. Be sure to include the variables that you set when you first added the plugin (represented by `<variable_list>` below). For example, if you set `REACHABILITY_HOST=http://example.com/` when you first added the plugin, you will need to reset the variable when running the `add` command again.

```
cordova plugin add --variable APP_NAME="new-app-name" <variable_list> appd-plugin-eum-  
mobile
```

Customize the Cordova Instrumentation

Related pages:

- [Instrument Cordova Applications](#)
- [Cordova SDK Documentation](#)

Once you have [instrumented your Cordova-based application](#) with the Cordova Plugin, you can also use the APIs to customize the data for your app that appears in the Controller UI. The following sections show you how to use the Cordova Plugin SDK API to customize your instrumentation:

- [Using the Cordova Plugin SDK API](#)
- [Change the App Key](#)
- [Collect Additional Types of Data](#)
- [Programmatically Control Sessions](#)
- [Start and End Session Frames](#)
- [Configure and Take Screenshots](#)
- [Block and Unblock Screenshots](#)
- [Enable Logging and Set Logging Level](#)
- [Cordova SDK Documentation](#)

Using the Cordova Plugin SDK API

Syntax

To call SDK API methods, use the following syntax: `window.plugins.ADEUMMobilePlugin.<method>`

Arguments

The last two arguments for all of the SDK API methods should always be two functions. The first function should handle successful cases and the last method should handle failures.

For example:

```

window.plugins.ADEUMMobilePlugin.changeAppKey("<EUM_APP_KEY>",
  (success) => {
    this.showAlert("changeAppKey return: success");
  },
  (error) => {
    this.showAlert("changeAppKey error:" + error);
  }
);
  
```

Add Methods to Call SDK APIs

To use the SDK APIs, you are recommended to create class methods that call the SDK APIs as shown below.

```

export class HomePage {
  ...
  someMethod(event) {
  
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

    window.plugins.ADEUMMobilePlugin.<method>(<arg1>, <success_function>,
    <failure_function>);
  }
  ...
}

```

Example

Thus, for the `HomePage.js` file, your `HomePage` class could have the method `takeScreenshot` that calls the SDK API method `screenshot` as shown here.

```

export class HomePage {
  ...
  takeScreenshot(event) {
    // Call the Cordova plugin SDK methods
    window.plugins.ADEUMMobilePlugin.screenshot(
      (success) => {
        this.showAlert("crash return: success");
      },
      (error) => {
        this.showAlert("crash error:" + error);
      });
  }
  ...
}

```

Change the App Key

To change the EUM application key, you use the method `changeAppKey` with the parameters below.

Parameter Name	Data Type	Description
<code>appKey</code>	string	The EUM application key.
<code>success</code>	function	A user-defined function that is called when <code>changeAppKey</code> is successful.
<code>error</code>	function	A user-defined function that is called when <code>changeAppKey</code> fails.

For example, you could create a new method that takes a new app key and passed it to the SDK API method `changeAppKey`.

```

changeAppKey(event, newAppKey) {
  window.plugins.ADEUMMobilePlugin.changeAppKey(newAppKey,
    (success) => {
      this.showAlert("changeAppKey return: success");
    },
    (error) => {
      this.showAlert("changeAppKey error:" + error);
    }
  );
}

```

Collect Additional Types of Data

You can use methods available in the `ADEUMMobilePlugin` class to collect five additional types of data:

- [Info points](#)
- [Custom timers](#)
- [Custom metrics](#)
- [User data](#)
- [Breadcrumbs](#)

Info Points

Information points allow you to track how your own code is running. You can see how often a method is invoked, and how long it takes to run by calling `beginCall`. When the callbacks `success` or `error` are called, the call to track the info point ends.

- `beginCall(name, functionName, args, success, error)`

Parameters

The table below describes the parameters for the two methods:

Name	Type	Description
<code>name</code>	string	The name of the file or module where the info point is being recorded.
<code>functionName</code>	string	The function that is invoking <code>beginCall</code> to track an info point.
<code>success</code>	function	The user-defined callback for successful cases.
<code>error</code>	function	The user-defined callback for failed cases.

Example

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

For example, you can use create info points with something like the code below to determine how a method is invoked, and how long it takes to run:

```
beginCall(event) {
  window.plugins.ADEUMMobilePlugin.beginCall("home.ts", "callTrackerFunction", "event",
    (tracker) => {
      tracker.reportCallEndedWithReturnValue("Return from home.ts",
        (success) => { console.log("End call with return value success:" +
success);});
      (error) => { console.log("End call with return value error:" + error); });
    },
    (error) => {
      console.log("Begin call error:" + error);
    }
  );
}
```

Custom Timers

You can create custom timers to time any arbitrary sequence of events within your code, even spanning multiple methods. You create the custom timers using the SDK API methods `startTimer` and `stopTimer`.

- `startTimerWithName(name, success, error)`
- `stopTimerWithName(name, success, error)`

Parameters

The two methods take the following parameters:

Name	Type	Description
<code>name</code>	string	The name of the custom timer. Allowed characters are [A-Za-z\s0-9]. Illegal characters are replaced by their ASCII hex value.
<code>success</code>	function	The user-defined callback for successful cases.
<code>error</code>	function	The user-defined callback for failed cases.

Example

For example, to track the time a user spends viewing a screen, the instrumentation could look like this:

```
startTimer(event) {
  window.plugins.ADEUMMobilePlugin.startTimerWithName(data.name,
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

    (success) => {
      this.showAlert("startTimerWithName return: success");
    },
    (error) => {
      this.showAlert("startTimerWithName error:" + error);
    }
  );
}
stopTimer(event) {
  window.plugins.ADEUMMobilePlugin.stopTimerWithName(data.name,
    (success) => {
      this.showAlert("stopTimerWithName return: success");
    },
    (error) => {
      this.showAlert("stopTimerWithName error:" + error);
    }
  );
}
}

```

Custom Metrics

You can also report custom metrics.

You create custom metrics with the `reportMetricWithName` :

- `reportMetricWithName(name, value, success, error)`

Parameters

The `reportMetricWithName` method takes the following parameters:

Name	Type	Description
<code>name</code>	string	The name of the custom metric. The metric names must consist of alphanumeric characters. Illegal characters are replaced by their ASCII hex value.
<code>value</code>	number	if value is not a whole number an error will be returned.
<code>success</code>	function	User-defined success callback.
<code>error</code>	function	User-defined error callback.

Example

For example, the following method could be used to report custom metrics:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

reportMetric(event, data) {
  window.plugins.ADEUMMobilePlugin.reportMetricWithName(data.name, parseInt(data.value),
    (success) => {
      this.showAlert("reportMetricWithName : success");
    },
    (error) => {
      this.showAlert("reportMetricWithName error:" + error);
    }
  );
};

```

Breadcrumbs

Breadcrumbs allow you to situate a crash in the context of your user's experience. Set a breadcrumb when something interesting happens. If your application crashes at some point in the future, the breadcrumb will be displayed along with the crash report. Each crash report displays the most recent 99 breadcrumbs.

You create and leave breadcrumbs with the following SDK API method:

- `leaveBreadcrumb(breadcrumb, mode, success, error)`

Parameters

The method `leaveBreadcrumb` takes the following parameters:

Name	Type	Description
<code>breadcrumb</code>	string	The string to include in the crash report and sessions. Truncated at 2048 characters; empty values are ignored.
<code>mode</code>	number	The mode determining where the breadcrumb will be displayed: <ul style="list-style-type: none"> • 0 - for crashes only • 1 - for crashes and sessions. The mode defaults to crashes if the value is not parseable.
<code>success</code>	function	The user-defined callback for successful cases.
<code>error</code>	function	The user-defined callback for failed cases.

Example

This code example shows how to use the SDK API to leave a breadcrumb:

```

breadcrumb(mode) {
  window.plugins.ADEUMMobilePlugin.leaveBreadcrumb( "breadcrumb1", mode,
  (success) => {
    this.showAlert("leaveBreadcrumb return: success");
  },
  (error) => {
    this.showAlert("leaveBreadcrumb error:" + error);
  }
)

```

Add Custom User Data

You can set and later remove any string key/value pair you think might be useful with the following methods:

- `setUserData(key, value, success, error)`
- `removeUserData(key, success, error)`

Parameters

The following table describes the parameters:

Name	Type	Description
<code>key</code>	string	The key identifying the key-value pair.
<code>value</code>	string	The value associated with the key.
<code>success</code>	function	The user-defined callback for successful cases.
<code>error</code>	function	The user-defined callback for failed cases.

Example

The code example below shows how to set and remove user data with the SDK API:

```

setCustomData(event, data) {
  window.plugins.ADEUMMobilePlugin.setUserData(data.name, data.value,
  (success) => {
    this.showAlert("setUserData return: success");
  },
  (error) => {
    this.showAlert("setUserData error:" + error);
  }
);

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

};
removeUserData(event, key) {
  window.plugins.ADEUMMobilePlugin.removeUserData(key,
    (success) => {
      this.showAlert("removeUserData return: success");
    },
    (error) => {
      this.showAlert("removeUserData error:" + error);
    }
  );
}

```

Programmatically Control Sessions

By default, a mobile session ends after a period of user inactivity. For example, when a user opens your application, the session begins and only ends after the user stops using the app for a set period of time. When the user begins to use the application again, a new session begins.

Instead of having a period of inactivity to define the duration of a session, however, you can use the following API to programmatically control when sessions begin and end.

```
startNextSession(success, error)
```

When you call the method `startNextSession` from `ADEUMMobilePlugin`, the current session ends and a new session begins. The API enables you to define and frame your sessions so that they align more closely with business goals and expected user flows. For example, you could use the API to define a session that tracks a purchase of a product or registers a new user.

Excessive use of this API will cause sessions to be throttled (excessive use is >10 calls per minute, but is subject to change). When not using the API, sessions will fall back to the default of ending after a period of user inactivity.

Example of a Programmatically Controlled Session

In the example below, the current session ends and a new one begins when the checkout is made.

```

completeCheckout() {
  if (this.validateAddress() && this.validatePayment()){
    let loader = this.loader.create({
      content: "Completing the checkout..."
    });
    loader.present();
    return this.order.create({
      shipping_address: this.address,
      billing_address: this.address,
      cart_id: Number(this.configuration.get('cart_id'))
    })
  }
  ...
}

```

```

window.plugins.ADEUMMobilePlugin.startNextSession(
  (success) => {
    console.log("startNextSession return: success");
  },
  (error) => {
    console.log("startNextSession error:" + error);
  }
);
}

```

Start and End Session Frames

You can use Cordova Plugin to create session frames that will appear in the session activity. Session frames provide context for what the user is doing during a session. With the API, you can improve the names of user screens and chronicle user flows within a business context.

Use Cases

The following are common using session frames:

- One page performs multiple functions and you want more granular tracking of the individual functions.
- A user flow spans multiple pages or user interactions. For example, you could use the API to create the session frames "Login", "Product Selection", and "Purchase" to chronicle the user flow for purchases.
- You want to capture dynamic information based on user interactions to name session frames, such as an order ID.

SessionFrame API

The table below lists the three methods you can use with session frames. In short, you start a session frame with `startSessionFrame` and then use `updateName` and `end` to rename and end the session frame.

Method	Parameters	Description
<code>startSessionFrame(name, success, error)</code>	<ul style="list-style-type: none"> • <code>name</code> (string) - The name of the session frame. • <code>success</code> (function) - The user-defined success callback. • <code>error</code> (function) - The user-defined error callback. 	<p>Use this to start and name your session frame.</p> <p>You call this method from <code>window.plugins.ADEUMMobilePlugin</code>.</p>
<code>updateName(name, success, error)</code>	<ul style="list-style-type: none"> • <code>name</code> (string) - The name of the session frame. • <code>success</code> (function) - The user-defined success callback. • <code>error</code> (function) - The user-defined error callback. 	<p>Rename the session frame name.</p> <p>You call this method from the <code>ADEUMMobilePlugin</code> object.</p>

Method	Parameters	Description
<pre>end(success, error)</pre>	<ul style="list-style-type: none"> <code>success</code> (function) - The user-defined success callback. <code>error</code> (function) - The user-defined error callback. 	<p>End the session frame.</p> <p>You call this method from the <code>ADEUMMobilePlugin</code> object.</p>

Session Frame Example

In the following example, session frames are used to track user activity during the checkout process.

```
declare var window: any;
@Component({
  ...
})
export class OrderPage {
  sessionFrame: any;
  ...

  checkoutCartButtonClicked() {
    // The user starting to check out starts when the user clicks the checkout button
    // this may be after they have updated quantities of items in their cart, etc.
    window.plugins.ADEUMMobilePlugin.startSessionFrame("Checkout",
      (sessionFrame) => {
        // The returned object is saved to the class property 'sessionFrame' so
        // the SessionFrame API methods 'updateName' and 'end' can be called from it
        later.
        this.sessionFrame = sessionFrame;
      },
      (error) => {
        console.log("startSessionFrame call error:" + error);
      }
    );
  }
  confirmOrderButtonClicked() {
    // Once they have confirmed payment info and shipping information, and they
    // are clicking the "Confirm" button to start the backend process of checking out
    // we may know more information about the order itself, such as an Order ID.
    this.sessionFrame.updateName("Checkout: Order ID " + this.orderId,
      (success) => {
        console.log("Order has been placed and sessionFrame updated:" + this.orderId)
      },
      (error) => {
        console.log("Order has been placed but sessionFrame couldn't be updated
        because of the error " + error);
      }
    );
  }
}
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```

    );
  }
  processOrderCompleted() {
    // Once the order is processed, the user is done "checking out" so we end
    // the session frame.
    this.sessionFrame.end(
      (success) => {
        console.log("Order was completed and sessionFrame ended: " + success);
      },
      (error) => {
        console.log("Order was completed but sessionFrame couldn't be ended because
of: " + error);
      }
    );
  }
  checkoutCancelled() {
    // If they cancel or go back, you'll want to end the session frame also, or else
    // it will be left open and appear to have never ended.
    this.sessionFrame.end(
      (success) => {
        console.log("Order was cancelled and sessionFrame ended: " + success);
      },
      (error) => {
        console.log("Order was cancelled but sessionFrame couldn't be ended because
of: " + error);
      }
    );
  }
} // end of export class OrderPage

```

Configure and Take Screenshots

By default, mobile screenshots are enabled on the agent-side but disabled on the Controller-side. These screenshots appear in the Controller in the [Sessions Details](#) dialog. To programmatically take manual screenshots, you must [enable screenshots in the Controller UI](#) and add the Screenshot API below.

```

screenshot(event) {
  // make a call to plugin
  console.log("screenshot click handler");
  window.plugins.ADEUMMobilePlugin.takeScreenshot(

  (success) => {
    this.showAlert("screenshot return: success");
  },
  (error) => {
    this.showAlert("screenshot error:" + error);
  });
}

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
}

```

This will capture everything, including personal information, so you must be cautious of when to take the screenshot.

Block and Unblock Screenshots

You can also block screenshots from being taken during the execution of a code block. This just temporarily blocks screenshots from being taken until you unblock screenshots. This enables you to stop taking screenshots in situations where users are entering personal data, such as on login and account screens.

```
logInScreen(event) {
  // Block Screen while getting user input
  window.plugins.ADEUMMobilePlugin.blockScreenshots(
    (success) => {
      console.log("blockScreenshots return: success");
      this.getUserInput();
      this.submitUserInput();
    },
    (error) => {
      console.log("blockScreenshots error:" + error);
    }
  );
  // Unblock screen and return to home page
  window.plugins.ADEUMMobilePlugin.unblockScreenshots(
    (success) => {
      console.log("unblockScreenshots return: success");
      this.homePage()
    },
    (error) => {
      console.log("unblockScreenshots error:" + error);
    }
  );
}
```

Enable Logging and Set Logging Level

You use the method `loggingLevel` to enable and set the logging level. You can set logging to one of the following levels:

Value	Logging Level	Description
0	None	No logs are displayed. This level disables logging.
1	Error	Only error messages are displayed. This is the default logging level.
2	Warn	Warning and error messages are displayed.
3	Info	Warning, errors, and developer-focused messages are displayed.
4	Debug	Errors, warnings, developer information, and debugging messages are displayed.
5	Verbose	Errors, warnings, developer information, debugging, and troubleshooting messages are displayed.
6	All	All the supported log messages are displayed.

You enable logging by setting the logging level in the instrumentation configuration. For example, in this example, you are enabling logging and setting the logging level to `Info` :

```

window.plugins.ADEUMMobilePlugin.initWithConfiguration(
  {
    "appKey": "<EUM_APP_KEY>",
    "loggingLevel": 3
  },
  (success) => {
    this.showAlert("initWithConfiguration return: success");
  },
  (error) => {
    this.showAlert("initWithConfiguration error:" + error);
  }
);

```

Cordova SDK Documentation

For the Cordova SDK API reference documentation, see the [latest JSDoc documentation](#) or the previous versions listed below:

- <https://sdkdocs.appdynamics.com/cordova-plugin/21.2/>
- <https://sdkdocs.appdynamics.com/cordova-plugin/20.11/>
- <https://sdkdocs.appdynamics.com/cordova-plugin/20.10/>
- <https://sdkdocs.appdynamics.com/cordova-plugin/20.7/>

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Requirements

- React Native ≥ 0.60

The React Native Agent has been tested and certified to work with React Native ≥ 0.60 . React Native is in rapid development; thereby any minor update to React Native could potentially affect the functionality of the React Native Agent.

- (iOS only): Pod target and Xcode deployment target must both be ≥ 11 . Find the pod target version in the `podfile` located in `<your_react_native_app>/ios/`.

Get Your Application Key

From the Controller's **Getting Started Wizard**, create either an iOS or an Android application. You will be given an EUM App Key that you will use to instrument your application. In some cases, multiple mobile applications can share the same key.

If you have completed the **Getting Started Wizard**, but don't have your EUM App Key, see [Get Your Application Key](#).

Eject Your React Native Application

If you created your React Native application with one of the commands in the following table, you will need to eject the application:

Command	Why Ejection Is Needed
<code>create-react-native-app</code>	This command enables you to quickly set up and run a Native React application with no configuration but does <i>not</i> provide the full development environment required by the React Native Agent.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Command	Why Ejection Is Needed
<code>expo init</code>	Expo projects do not currently support the React Native Agent module.

If you created your app with `create-react-native-app`, use `npm` to eject the app. If you used `expo`, run the `expo` command below to eject the app.

From your project directory, run the command appropriate for your use case:

`npm expo`

```
npm run eject
```

`npm expo`

```
expo eject
```

Install the React Native Agent

This module injects the native AppDynamics agents into your application and offers a JavaScript bridge to the `Instrumentation` management interface.

1. Install the React Native Agent:

```
npm install --save @appdynamics/react-native-agent
```

2. Build the configuration to enable the build-time instrumentation of your application:

```
node node_modules/@appdynamics/react-native-agent/bin/cli.js install
```

 The React Native Agent CLI assumes you've kept the default project structure created with the `react-native` CLI tools.

If the above commands failed, see [Manually Install the React Native Package](#). Otherwise, process to [\(Android only\) Add Permissions](#)

(Only If Required) Manually Install the React Native Package

Most users do not have to manually install the package, but the command above may fail if you heavily modified your iOS and Android projects.

Follow these steps to manually install the React Native package:

[Android](#) [iOS](#)

1. Add the following line to your `android/build.gradle` :

```
apply from: '../node_modules/@appdynamics/react-native-agent/android/adeum.gradle'
```

2. Make sure the file `settings.gradle` contains a reference to the Appdynamics agent module as shown below.

```
include ':@appdynamics_react-native-agent'
project(':@appdynamics_react-native-agent').projectDir = new
File(rootProject.projectDir, '../node_modules/@appdynamics/react-native-agent/android')
```

3. Also, `android/app/build.gradle` should contain a reference to the Appdynamics agent module.

```
dependencies {
    implementation project(':@appdynamics_react-native-agent')
    // ...
}
```

[Android](#) [iOS](#)

For iOS, confirm that the following files exist:

File	File Location	Example
<code>ADEUMReactNative.xcodeproj</code>	<code>Libraries</code> or <code>node_modules</code> directory	<code><your_react_native_app>/node_modules/@appdynamics/react-native-agent/ios/ADEUMReactNative.xcodeproj</code>

File	File Location	Example
libADEUMReactNative.a	From Xcode , the file should be listed on the Build Phases > Link Binary With Libraries tab or in the following directory: <pre><your_react_native_app>/ ios/build/ <your_react_native_app>/ Build/Products/Debug- iphonesimulator/</pre>	<pre><your_react_native_app>/ ios/build/ <your_react_native_app>/ Build/Products/Debug- iphonesimulator/ libADEUMReactNative.a</pre>

(Android only) Add Permissions

Add the following permissions to your app's `AndroidManifest.xml` (which should be located under `android/app/src/main/`).

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.your.application">

  // Add the following:
  <uses-permission android:name="android.permission.ACCESS_NETWORK_STATE"/>

  // ...
</manifest>
```

The React Native Agent tries to minimize its network footprint. Without this permission, the agent always assumes poor network conditions and some metrics may not get reported.

Instrument Your Application Code

In the `index.js` file of your React application:

1. At the top of the file near the other `import` statements, add the following line of code to import the Native React Agent:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

2. In the same file and in the global scope, initialize the instrumentation with the following, making sure to replace `<EUM_APP_KEY>` with a string containing your [EUM App Key](#).

```
Instrumentation.start({
  appKey: <EUM_APP_KEY>,
});
```

3. Verify that your `index.js` file looks similar to the following:

```
import {AppRegistry} from 'react-native';
import App from './App';
// === Add the following to import the React Native Agent
import { Instrumentation } from '@appdynamics/react-native-agent';

// Initialize the instrumentation
Instrumentation.start({
  appKey: 'YOUR-APP-KEY',
});

// Create a component
const App = () => (
  // Other components
);

// Register the App component
AppRegistry.registerComponent('my-application', () => App);
```

Build and Run Your React Native Applications (Optional)

1. Run the command to build and run the app for your platform.

[Android](#) [iOS](#)

```
react-native run-android
```

Android [iOS](#)

```
react-native run-ios
```

2. From the Controller UI, [verify that the instrumentation was successful](#).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Point to an On-Premises EUM Server (Optional)

To use an on-premises EUM Server, pass the URL to the on-premises EUM Server when you initialize the instrumentation with the EUM App Key from [Get Your Application Key](#).

```
Instrumentation.start({
  appKey: <EUM_APP_KEY>,
  collectorURL: <COLLECTOR_URL>
});
```

Customize the React Native Instrumentation

The sections below describe how to use the React Native APIs to customize your instrumentation.

- [Using the React Native Agent APIs](#)
- [Change the App Key](#)
- [Collect Additional Types of Data](#)
- [Report Info Points](#)
- [Set Custom Timers](#)
- [Create Custom Metrics](#)
- [Add Custom User Data](#)
- [Leave Breadcrumbs](#)

- [Disable Crash Reporting](#)
- [Report Errors and Exceptions](#)
- [Log Silenced Errors](#)
- [Use the Agent with a Custom HTTP Library](#)
- [React Native API Documentation](#)

Using the React Native Agent APIs

After you have installed and initialized the React Native Agent, you instrument your application code by importing the class, interface, or enumeration and then calling API methods.

Import Syntax

To access the React Native Agent APIs, use an import statement at the top of the file. The following line imports the class `Instrumentation` :

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

API Method Syntax

Once the class, interface, or enumeration has been imported, call the API methods from the imported component. In this example, you set custom user data with `setUserDataBoolean` from the `Instrumentation` class.

```
Instrumentation.setUserDataBoolean("Boolean Key", true);
```

Change the App Key

You can use the React Native API to dynamically change the EUM App Key. You receive the app key when creating a mobile app in the Controller UI. See [Set Up and Access Mobile RUM](#) for more information about app keys.

Class

The API to change app keys is available through the `Instrumentation` class.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

Methods

The API consists of the following method:

- `changeAppKey(appKey)`

Method Parameters

The `changeAppKey` method takes the following parameter:

Parameter Name	Data Type	Description
<code>appKey</code>	string	The EUM App Key.

Examples

In this example, you create a method that takes a new app key and passes it to the API method `changeAppKey`.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
private updateAppKey(newAppKey) {
  Instrumentation.changeAppKey(newAppKey);
}
```

Collect Additional Types of Data

The React Native APIs have methods that extend the application data types you can collect and aggregate with Mobile RUM. There are six basic kinds of extensions that you can create:

Type of Data	Description	Specifications	Where Data is Displayed
Info points	How often a method is invoked, and how long it takes to run.	<ul style="list-style-type: none"> Data is numeric Names must consist of alphanumeric characters and/or spaces 	<ul style="list-style-type: none"> Metric Browser Custom Data Network Request Snapshots Mobile Sessions Network Request Analyze
Custom timers	Any arbitrary sequence of events within your code timed, even spanning multiple methods.	<ul style="list-style-type: none"> Data is numeric Metric names must consist of alphanumeric characters and/or spaces 	<ul style="list-style-type: none"> Metric Browser Custom Data
Custom metrics	Any integer-based data you wish to collect.	<ul style="list-style-type: none"> Data is numeric Metric names must consist of alphanumeric characters and/or spaces 	<ul style="list-style-type: none"> Metric Browser Custom Data
User data	Any string key/value pair you think might be useful.	<ul style="list-style-type: none"> Data can be any type Metric names have no restrictions 	<ul style="list-style-type: none"> Network Request Snapshots Mobile Sessions Network Request Analyze Crash Snapshots
Breadcrumbs	The context for a crash.	<ul style="list-style-type: none"> Data can be any data type Metric names have no restrictions 	<ul style="list-style-type: none"> Network Request Snapshots Mobile Sessions Network Request Analyze Crash Snapshots
User interactions	Capture when users press buttons, click on lists, and select text.	<ul style="list-style-type: none"> Data can be any data type Metric names have no restrictions 	<ul style="list-style-type: none"> Network Request Snapshots Mobile Sessions Network Request Analyze

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Report Info Points

Information points allow you to track how your own code is running. Unlike the other React Native APIs that require importing a module and using a method from that module, you add annotations to your code to report info points.

Class/Interface

The API is available through the `InfoPoint` function.

```
import { InfoPoint } from '@appdynamics/react-native-agent';
```

Methods

With the `@InfoPoint` annotation, you only need to provide a function to report info points.

The `@InfoPoint` annotation has two signatures:

- `@InfoPoint`
- `@InfoPoint({className: string, fnName: string})`

Method Signatures

Methods	Parameters	Description
<code>@InfoPoint</code>	None	Automatically reports the info points of the method that is being annotated.
<code>@InfoPoint({className: string, fnName: string})</code>	Object <ul style="list-style-type: none"> • <code>className</code> - The name of the file or module where the info point is recorded. • <code>fnName</code> - The function that invokes <code>beginCall</code> to track an info point. 	Manually specify the class and function names to annotate. For example: <pre>@InfoPoint({ className: 'Automobiles', fnName: 'checkInventory' })</pre>

Examples

The following examples show you how to use automatic and manual reporting of info points.

We recommended you use automatic reporting if your code will not be minified: it's simpler and reports the same information. If your code will be minified, however, you should manually report the class and function names to avoid reporting the useless class and function names created by minification.

Automatic Reporting

Add the annotation `@InfoPoint` to automatically create an info point for the method below it. Info point reports how the method is invoked and how long it takes to run.

```
import { InfoPoint } from '@appdynamics/react-native-agent';

class InfoPointsScreen extends Component {

  @InfoPoint
  public infoPointMethod(arg1, arg2, value) {
    console.log("Executing infoPointMethod!");
  }
}
```

Manually Reporting

To create an info point for a specific method in a class (the symbol names), pass an object to the `@InfoPoint` annotation that specifies the class and method name as shown below.

```
import { InfoPoint } from '@appdynamics/react-native-agent';

class InfoPointsScreen extends Component {

  @InfoPoint({ className: 'MyClass', fnName: 'infoPointMethod' })
  public infoPointMethod(arg1, arg2, value) {
    console.log("Executing infoPointMethod!");
  }
}
```

Set Custom Timers

You create custom timers to time any arbitrary sequence of events within your code, even spanning multiple methods.

Class/Interface

The Custom Timers API is accessible through the `Instrumentation` class:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

Methods

You create the custom timers using the following React Native Agent API methods:

- `startTimerWithName(name)`
- `stopTimerWithName(name)`

Method Parameters

Both methods take the following parameter:

Name	Type	Description
<code>name</code>	string	The name of the custom timer. Allowed characters are [A-Za-z\s0-9]. Illegal characters are replaced by their ASCII hex value.

Examples

For example, to track the time a user spends viewing a screen, the instrumentation could look like this:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
private startCustomTimer() {
  Instrumentation.startTimer("My timer");
}
private stopCustomTimer() {
  Instrumentation.stopTimer("My timer");
}
```

Create Custom Metrics

The React Native API enables you to report custom metrics. You specify the name of the custom metric that will appear in the Controller UI.

Class

The Custom Metrics API is accessible through the `Instrumentation` class:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

Methods

You create custom metrics with the `reportMetric`:

- `reportMetric(name, value)`

Method Parameters

The `reportMetric` method takes the following parameters:

Name	Type	Requirements	Description
<code>name</code>	string	The metric names must consist of alphanumeric characters. Illegal characters are replaced by their ASCII hex value.	The name of the custom metric.
<code>value</code>	number	The value must be a whole number, otherwise, an error will be returned.	The numeric value associated with the custom metric.

Examples

For example, the following method could be used to report custom metrics:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
private reportMetrics() {
  Instrumentation.reportMetric("Normal metric", 23);
  Instrumentation.reportMetric("Large metric", Number.MAX_SAFE_INTEGER + 1);
  Instrumentation.reportMetric("Small metric", Number.MIN_SAFE_INTEGER - 1);
}
```

Add Custom User Data

Use the Custom User Data API to set and remove key/value pairs of different data types. The key must be unique across your application.

Class

The Custom User Data API is accessible through the `Instrumentation` class:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

Methods

The API provides the following methods for setting and removing custom user data:

Methods for Setting Custom User Data

- `setUserData(key, value)`

Methods for Removing Custom User Data

- `removeUserData(key)`

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- | | |
|---|--|
| <ul style="list-style-type: none"> • <code>setUserDataDate(key, value)</code> • <code>setUserDataDouble(key, value)</code> • <code>setUserDataInteger(key, value)</code> | <ul style="list-style-type: none"> • <code>setUserDataDate(key)</code> • <code>setUserDataDouble(key)</code> • <code>setUserDataInteger(key)</code> |
|---|--|

Method Parameters

The following table lists the parameters for the methods for setting custom user data.

Methods for Setting Custom User Data	Parameters	Data Type
<code>setUserData</code>	key	string
	value	string null
<code>setUserDataBoolean</code>	key	string
	value	boolean
<code>setUserDataDate</code>	key	string
	value	Date object
<code>setUserDataDouble</code>	key	string
	value	number
<code>setUserDataInteger</code>	key	string
	value	number

The following table lists the parameters for the methods for removing custom user data.

Methods for Removing Custom User Data	Parameters	Data Type
<code>removeUserData</code>	key	string
<code>removeUserDataBoolean</code>		

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Methods for Removing Custom User Data	Parameters	Data Type
<code>removeUserDataDate</code>		
<code>removeUserDataDouble</code>		
<code>removeUserDataInteger</code>		

i The method `removeUserData` is called when setting custom data to the value `null`. For example, the method `Instrumentation.setUserData("name", null)` will call `Instrumentation.removeUserData("name")`.

Examples

The following code example shows how to set and remove user data with the Custom User Data API:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
private setUserData() {
  Instrumentation.setUserData("userId", "AISJ1723871");
  Instrumentation.setUserDataBoolean("isVip", true);
  Instrumentation.setUserDataDate("purchaseDate", new Date(1234567890));
  Instrumentation.setUserDataDouble("monthlyVisits", 1.2345);
  Instrumentation.setUserDataInteger("totalPurchasedItems", 42);
}
private clearUserData() {
  Instrumentation.removeUserData("userId", null);
  Instrumentation.removeUserDataBoolean("isVip", null);
  Instrumentation.removeUserDataDate("purchaseDate", null);
  Instrumentation.removeUserDataDouble("monthlyVisits", null);
  Instrumentation.removeUserDataInteger("totalPurchasedItems", null);
}
```

Leave Breadcrumbs

Breadcrumbs enable you to situate a crash in the context of your user's experience. Set a breadcrumb when something interesting happens. If your application crashes at some point in the future, the breadcrumb will be displayed along with the crash report. Each crash report displays the most recent 99 breadcrumbs.

Class

The Breadcrumb API is accessible through the `Instrumentation` class:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

Methods

You create and leave breadcrumbs with the following API method:

- `leaveBreadcrumb(breadcrumb, mode)`

Method Parameters

The method `leaveBreadcrumb` takes the following parameters:

Name	Type	Description
<code>breadcrumb</code>	string	The string to include in the crash report and sessions. Truncated at 2048 characters; empty values are ignored.
<code>mode</code>	Enumeration	<p>The mode determining where the <code>breadcrumb</code> will be displayed. You can report crashes only or crashes and sessions with the following modes:</p> <ul style="list-style-type: none"> • <code>BreadcrumbVisibility.CRASHES_ONLY</code> • <code>BreadcrumbVisibility.CRASHES_AND_SESSIONS</code> <p>The default mode is <code>BreadcrumbVisibility.CRASHES_ONLY</code>. If the value is invalid, the default mode will be applied.</p>

Examples

Basic Usage

The following example shows the syntax and usage of the Breadcrumb API.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
private leaveBreadcrumb() {
  Instrumentation.leaveBreadcrumb("Drop a breadcrumb button implementation",
  BreadcrumbVisibility.CRASHES_AND_SESSIONS);
}
```

Extended Use Case

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Supposed your React Native app has a wizard that shows different steps of a process sequentially on the same screen. In the case of a crash or an "Application Not Responding" (ANR) error, you would want to know what step of the wizard caused the crash or ANR.

If your app had a wizard engine similar to the one below, you could leave a breadcrumb for each screen to track events and issues.

```

async function wizard(...screens) {
  let currentScreen = 0;
  while (true) {
    const screen = screens[currentScreen];
    if (screen == null) return;
    // Report the current screen with AppDynamics instrumentation
    Instrumentation.leaveBreadcrumb('wizard screen ' + screen.name);
    currentScreen += await screen.action();
  }
}

```

The wizard engine could be used for a checkout:

```

wizard(
  { name: 'review cart', action:reviewCartAction },
  { name: 'chose payment', action:chosePaymentAction },
  { name: 'chose address', action:choseAddressAction },
  { name: 'review order', action:reviewOrderAction },
  { name: 'checkout', action:checkoutAction }
)

```

If you receive an alert that your app is triggering a lot of ANRs, you can diagnose the problem through the mobile sessions where the ANRs occur. In the session, you will see the breadcrumbs associated with the ANRs. For example, you may discover that the breadcrumbs "review cart" and "chose payment" are associated with ANRs, but "chose address" is not. Further investigation of the payment screen could lead to the discovery that the process that is encrypting credit card numbers is running on the main thread and freezing the app.

Capture User Interaction

The React Native Agent can track certain UI events triggered by user interactions. Once user interactions have been captured, you can sort sessions by UI event and view UI events in the timeline of the session waterfall.

Supported User Interactions

You can capture when users do one or all of the following:

- press buttons
- select table cells
- select text fields

- select text views

Security and Privacy Concerns

The interaction capture mode is disabled by default for security and privacy reasons, as user interactions may contain sensitive information. Moreover, this potential security and privacy issue may be compounded if you enable both the capturing of UI interactions and screenshots.

Class

The Interaction Capture Mode API is accessible through the `InteractionCaptureMode` class, but you also need the `Instrumentation` class to start instrumentation with the configured user capture mode.

```
import { Instrumentation, InteractionCaptureMode } from '@appdynamics/react-native-agent';
```

Properties

The following properties are accessed through the `InteractionCaptureMode` class and used to configure the user interaction capture. For example: `InteractionCaptureMode.All`

Property	Description	Platform Support
<code>All</code>	Track all the user interactions.	iOS, Android
<code>ButtonPressed</code>	Track button presses.	iOS, Android
<code>ListViewItemsSelected</code>	Track "List Item" clicks and focus changes for <code>android.widget.AbsListView</code> and its subclasses.	Android
<code>None</code>	Disables the tracking of any user interactions.	iOS, Android
<code>TableCellSelected</code>	Track table cell selection.	iOS
<code>TextFieldSelected</code>	Track text field selection.	iOS, Android
<code>TextViewSelected</code>	Track text view selection.	iOS

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Methods

The API methods take an array of user interaction capture modes and return an `InteractionCaptureMode` object that determines which user interactions will be captured. The methods do not mutate the object.

Method	Description
<code>with</code>	Combines the multiple user interaction capture modes.
<code>without</code>	Excludes the specified user interaction modes from being captured.

Examples

Set User Interaction Mode with API Properties

The following example configures the React Native Agent to capture all user interactions.

```
import { Instrumentation, InteractionCaptureMode } from '@appdynamics/react-native-agent';
...
Instrumentation.start({
  appKey: <EUM_APP_KEY>,
  // ...your other configurations

  // Capture all user interactions
  interactionCaptureMode: InteractionCaptureMode.All
})
```

Combine User Interaction Modes

In the following example, the `with` method combines the `ButtonPressed` (button presses) and `TextFieldSelected` (text field selected) modes with the `None` mode, effectively just enabling those two user interaction modes.

```
import { Instrumentation, InteractionCaptureMode } from '@appdynamics/react-native-agent';
...
Instrumentation.start({
  appKey: <EUM_APP_KEY>,
  // ...your other configurations

  // Only enable "ButtonPressed" and "TextFieldSelected" interaction modes, and disable the
  rest.
  interactionCaptureMode: InteractionCaptureMode.None.with(
    InteractionCaptureMode.ButtonPressed,
    InteractionCaptureMode.TextFieldSelected
  )
})
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
)
})
```

Exclude User Interaction Modes

The following example excludes the user interaction modes `ButtonPressed` (button presses) and `TextFieldSelected` (text field selected) from the mode `InteractionCaptureMode.All` (all user interactions). Effectively, the React Native Agent would be configured to only capture `ListItemSelected` ("List Item" clicks), `TableCellSelected` (table cell selection), and `TextViewSelected` (text view selected) modes.

```
import { Instrumentation, InteractionCaptureMode } from '@appdynamics/react-native-agent';
...
Instrumentation.start({
  appKey: <EUM_APP_KEY>,
  // ...your other configurations

  // Include all capture modes except "ButtonPressed" and "TextFieldSelected".
  interactionCaptureMode: InteractionCaptureMode.All.without(
    InteractionCaptureMode.ButtonPressed,
    InteractionCaptureMode.TextFieldSelected
  )
})
```

Disable the Agent to Stop Sending User Data to the Collector

You can disable the agent to stop sending all data to the collector while the agent is initialized and running. For example, you can disable the agent if your app has an option for users to opt-out of monitoring for privacy reasons.

`shutdownAgent`

The `shutdownAgent` call stops outgoing data to the collector, and does not persist data on the device.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
Instrumentation.shutdownAgent();
```

- The call only stops the traffic out of the agent.
- Once the agent has been initialized, the call cannot be removed, and a license will have been consumed.

`restartAgent`

To re-enable the agent and reverse `shutdownAgent`, use `restartAgent`.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
Instrumentation.restartAgent();
```

- This call will respect the server side calls that can remotely shutdown the agent in a similar way.
- The call is only in effect while the app is running.
- The call will be ignored if the agent has been remotely disabled.
- If the call is removed from memory and the app restarts, or the device is rebooted, the agent will be initialized as normal.

Programmatically Control Sessions

By default, a mobile session ends after a period of user inactivity. For example, when a user opens your application, the session begins and only ends after the user stops using the app for a set period of time. When the user begins to use the application again, a new session begins. Instead of having a period of inactivity to define the duration of a session, however, you can use this API to programmatically control when sessions begin and end.

Class

The API is accessible through the `Instrumentation` class:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

Methods

The API provides the following method for ending the current session and starting a new session:

Method	Description
<code>startNextSession()</code>	When you call the method <code>startNextSession</code> from <code>Instrumentation</code> , the current session ends and a new session begins. The API enables you to define and frame your sessions so that they align more closely with business goals and expected user flows. For example, you could use the API to define a session that tracks a purchase of a product or registers a new user.

i Excessive use of this API will cause sessions to be throttled (excessive use is >10 calls per minute, but is subject to change). When not using the API, sessions will fall back to the default of ending after a period of user inactivity.

Examples

In the following example, the current session ends and a new one begins when the check out is made.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
private checkoutCart(){
  if (currentCartItems!=null && currentCartItems.size()>0){
    CheckoutTask checkoutReq = new CheckoutTask();
    checkoutReq.execute(getEndpoint() + "cart/co");
    currentCartItemsMap.clear();
    convertItemsMaptoList();
    Instrumentation.startNextSession();
  } else {
    displayToast("There are no items in the cart");
  }
}
```

Start and End Session Frames

You can use the React Native Agent API to create session frames that appear in the session activity. Session frames provide context for what the user is doing during a session. With the API, you can improve the names of user screens and chronicle user flows within a business context.

Use Cases

The following are common use cases for session frames:

- One page performs multiple functions and you want more granular tracking of the individual functions.
- A user flow spans multiple pages or user interactions. For example, you could use the API to create the session frames "Login", "Product Selection", and "Purchase" to chronicle the user flow for purchases.
- You want to capture dynamic information based on user interactions to name session frames, such as an order ID.

Class/Interface

The `SessionFrame` API is accessible through the `Instrumentation` class.

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

To update the name and end a session frame, you would use the `SessionFrame` interface.

Methods

The following table lists the three methods you can use with session frames. In short, you start a session frame with `startSessionFrame` and then use `updateName` and `end` to rename and end the session frame.

Method	Description
<code>startSessionFrame(name)</code>	Starts the session frame. You call this method from <code>Instrumentation</code> , and it returns <code>SessionFrame</code> object.
<code>updateName(name)</code>	Updates the name of the session frame. You call this method from the <code>SessionFrame</code> object.

Method Parameters

The methods `startSessionFrame` and `updateName` takes the following parameter:

Parameters	Data Type	Description
<code>name</code>	string	The name of the session frame.

Session Frame Example

In the following example, session frames are used to track user activity during the checkout process.

```

let sessionFrame: SessionFrame | undefined;

private onCheckoutCartButtonClicked() {
  // The user starts the checkout by clicking the checkout button.
  // This may be after they have updated the quantities of items in the cart, etc.
  sessionFrame = Instrumentation.startSessionFrame("Checkout");
}
private onConfirmOrderButtonClicked() {
  // Once they have confirmed payment info and shipping information, and they
  // are clicking the "Confirm" button to start the backend process of checking out,
  // we may know more information about the order itself, such as an order ID.
  if (sessionFrame) {
    sessionFrame.updateName("Checkout: Order ID " + orderId);
  }
}
private onProcessOrderCompleted() {
  // Once the order is processed, the user is done "checking out", so we end the session
  // frame.
  if (sessionFrame) {
    sessionFrame.end();
    sessionFrame = null;
  }
}

```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
private onCheckoutCancelled() {
  // If the user cancels or returns to the cart, you'll want to end the session frame also,
  // or else it will be
  // left open and appear to have never ended.
  sessionFrame.end();
  sessionFrame = null;
}
}
```

Configure and Take Screenshots

By default, mobile screenshots are enabled on the agent-side but disabled on the Controller-side. These screenshots appear in the Controller in the [Sessions Details](#) dialog. To programmatically take manual screenshots, you must [enable screenshots in the Controller UI](#) and add the Screenshot API below.

Class

The Screenshot API is accessible through the `Instrumentation` class:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

Methods

The Screenshot API provides the following methods:

Method	Return Value	Description
<code>takeScreenshot()</code>	None	<p>Asynchronously takes a screenshot of the current screen.</p> <p>This will capture everything, including personal information, so you must be cautious of when to take the screenshot.</p> <p>These screenshots will show up in the Sessions screen for this user.</p> <p>The screenshots are taken on a background thread, compressed, and only non-redundant parts are uploaded, so it is safe to take many of these without impacting the performance of your application.</p>
<code>screenshotsBlocked()</code>	Promise<boolean>	Returns a Boolean indicating whether screenshot capture is blocked.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Method	Return Value	Description
<code>blockScreenshots()</code>	Promise<void>	Blocks screenshot capture and returns a Promise that resolves when screenshots are effectively blocked.
<code>unlockScreenshots()</code>	Promise<void>	<p>Unblocks screenshot capture if it is currently blocked. Otherwise, this has no effect.</p> <p>If screenshots are disabled through <code>AgentConfiguration.screenshotsEnabled</code> or through the Controller UI, this method has no effect.</p> <p>If screenshots are set to manual mode in the Controller UI, this method unblocks for manual mode only.</p>

Configure Screenshots

Disable Screenshots

You can [disable screenshots from the Controller UI](#) or with the React Native API. To disable screenshots, set the property `screenshotsEnabled` to `false` when initializing the Native React Agent.

```
Instrumentation.start({
  appKey: <EUM_APP_KEY>,
  screenshotsEnabled: false,
  ...
});
```

Set On-Prem Screenshot Service

If you have deployed an on-prem EUM Server, you will need to specify the URL to the EUM Server with the property `screenshotURL`.

```
Instrumentation.start({
  appKey: <EUM_APP_KEY>,
  screenshotURL: "https://<COLLECTOR_URL>:<PORT>",
  ...
});
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Examples

Take Screenshots

You can configure the Controller UI to automatically take screenshots or use the React Native API to manually take a screenshot as shown below:

```
private loadShoppingCart() {
  // Load shopping cart
  this.setState({
    shoppingCart: this.state.cart
  });
  // Manually take screenshot
  Instrumentation.takeScreenshot();
}
```

i This will capture everything, including personal information, so precaution is necessary when taking screenshots

Block and Unblock Screenshots

You can also block screenshots from being taken during the execution of a code block. This just temporarily blocks screenshots from being taken until you unblock screenshots. This enables you to stop taking screenshots in situations where users are entering personal data, such as on login and account screens.

```
private displayCustomerAccount() {
  // Check to see if screenshots are blocked
  if (!Instrumentation.screenshotsBlocked()) {
    // If screenshots aren't blocked, block them before showing customer details
    Instrumentation.blockScreenshots();
  }
  // Code to display customer details

  // After you're done, unblock screenshots
  Instrumentation.unblockScreenshots();
}
```

Enable Logging and Set Logging Level

You enable logging by setting the logging level in the instrumentation configuration. You are recommended to disable logging for production.

Class

The Logging Level API is accessible through the `LogLevel` class:

```
import { LoggingLevel } from '@appdynamics/react-native-agent';
```

Configuration Properties

You enable and set the logging level with the following configuration property:

- `loggingLevel`

Logging Levels

You can set logging to one of the following levels:

Enumeration	Logging Level	Description
<code>LoggingLevel.NONE</code>	None	No logs are displayed. This level disables logging.
<code>LoggingLevel.INFO</code>	Info	Warning, errors, and developer-focused messages are displayed.
<code>LoggingLevel.VERBOSE</code>	Verbose	Errors, warnings, developer information, debugging, and troubleshooting messages are displayed.

Examples

In the following example, logging is enabled and the logging level is set to `VERBOSE` :

```
private async start() {
  try {
    await Instrumentation.start({
      appKey: this.state.appKey,
      loggingLevel: LoggingLevel.VERBOSE,
      anrDetectionEnabled: true,
      interactionCaptureMode: InteractionCaptureMode.None.with(
        InteractionCaptureMode.ButtonPressed,
        InteractionCaptureMode.ListViewItemSelected,
        InteractionCaptureMode.TableCellSelected,
        InteractionCaptureMode.TextFieldSelected,
        InteractionCaptureMode.TextViewSelected
      )
    })
  }
}
```

Receive a Crash Report Summary for Native Crashes

You can use `CrashReportCallback` to receive a report for native crashes.

Class

The `CrashReportCallback` API is accessible through the `Instrumentation` class:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
```

How to Use

1. Submit the `CrashReportCallback` object as the `crashReportCallback` native agent configuration option.

```
Instrumentation.start({
  crashReportCallback: (summaries: CrashReportSummary[]) => {
    console.log(summaries);
  },
});
```

2. On application restart, you will receive a `CrashReportSummary` for each crash.

```
export type CrashReportSummary = {
  crashId: string;
  exceptionName: string;
  exceptionReason: string;
  signalName: string;
  signalCode: string;
};
```

`CrashReportSummary` Properties

`CrashReportSummary` has the following properties:

Name	Type	Description
<code>crashId</code>	string	Uniquely defines the crash. Can be used as key to find the full crash report or look up the crash in the Controller UI.
<code>exceptionName</code>	string	The exception name, may be <code>null</code> if no exception occurred.
<code>exceptionReason</code>	string	The exception reason, may be <code>null</code> if no exception occurred.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Name	Type	Description
signalName	string	The exception signal name.
signalCode	string	The exception signal code.

Disable Crash Reporting

Crash reporting is enabled by default, but you can manually disable crash reporting through the instrumentation configuration. If you are using other crash reporting tools, you might disable crash reporting to minimize conflicts and optimize the crash report results.

You can disable crash reporting by configuring the instrumentation with the `crashReportingEnabled` property as shown in the following:

```
import { Instrumentation } from '@appdynamics/react-native-agent';

Instrumentation.start({
  appKey: <#EUM_APP_KEY#>,
  crashReportingEnabled: false
})
```

Report Errors and Exceptions

You can report exceptions using the method `reportError` from the `Instrumentation` class. Reported exceptions will appear in session details.

You can also set one of the severity levels below for an issue. With the severity level, you can filter errors in the **Code Issues Dashboard** or **Code Issues Analyze**.

- `ErrorSeverityLevel.INFO`
- `ErrorSeverityLevel.WARNING`
- `ErrorSeverityLevel.CRITICAL`

The example below uses the API to report possible exceptions and sets the severity level to `ErrorSeverityLevel.CRITICAL` (critical) when writing to a file

```
import { Instrumentation, ErrorSeverityLevel } from '@appdynamics/react-native-agent';
...
try {
  await asyncTask();
} catch (error) {
  Instrumentation.reportError(error, ErrorSeverityLevel.CRITICAL);
}
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
}
...

```

Log Silenced Errors

If you use React Native's `ErrorBoundary`, the errors are silently caught, but the agent will not receive and log them. If you want silenced crashes to be logged, we recommend you use `ErrorBoundary` provided in the AppDynamics React Native package:

```
import { ErrorBoundary } from '@appdynamics/react-native-agent'
```

Use the Agent with a Custom HTTP Library

The agent automatically detects network requests when the underlying implementation is handled by `NSURLConnection` / `NSURLSession` classes (iOS) or `URLConnection` / `OkHttp` (Android). This covers most network requests, but in some cases, mobile applications use custom HTTP libraries.

To enable the agent to detect requests from a custom library, add request tracking code to your application manually with the `RequestTracker` class.

 You must initialize the agent with a valid key using the `Instrumentation.start()` interface before using this method.

Request Tracker Properties

The following properties should be set on the `RequestTracker` object to describe the parameters of the custom call.

Property	Description	Code
<code>error</code>	<p>Javascript error or <code>null</code></p> <p>An error describing the failure to receive a response, if one occurred. If the request was successful, this should be left <code>null</code>.</p>	<pre>tracker.setError(e);</pre>

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Property	Description	Code
<code>statusCode</code>	Number or <code>null</code> The status code of response, if one was received. If a response was received, this should be an integer. If an error occurred and a response was not received, this should remain <code>null</code> .	<pre>tracker.setResponseStatusCode(response.statusCode);</pre>
<code>requestHeaders</code>	Dictionary or <code>null</code> A dictionary representing the keys and values from the client's request header.	<pre>tracker.setRequestHeaders(headers);</pre>
<code>responseHeaders</code>	Dictionary or <code>null</code> A dictionary representing the keys and values from the server's response header. If an error occurred and a response was not received, this should be <code>'null'</code> .	<pre>tracker.setResponseHeaders(headers);</pre>

Track a Custom HTTP Request

To add manual request tracking, you must specify when the request begins, when it ends and what the status of the response is.

1. Create a `RequestTracker` object immediately before sending the request:

```
import { Instrumentation } from '@appdynamics/react-native-agent';
...
const tracker = new RequestTracker({ "My_URL" });
```

i "MY_URL" is the URL being called. This parameter must not be `null`.

2. (Optional) Add your custom headers to the tracker before sending the request:

```
const headers = {
  'Content-Length': '5000',
};
tracker.setRequestHeaders(headers);
```

i `requestHeaders`: A dictionary (or `null`) representing the keys and values from the request headers.

3. (Optional) Enable correlation between your request and server-side processing. Add specific headers to outgoing requests that the server-side agent can detect and return the headers obtained from the server-side agent in the response to make them available to the agent:

```
tracker.addServerCorrelationHeaders()
```

4. Immediately after receiving a response or an error, set properties on the tracker object based on whether the request finished successfully or ended in error:

```
try {
  const response = await customRequest(url);
  tracker.setResponseStatusCode(response.statusCode);
  tracker.setResponseHeaders(response.headers);
} catch (e) {
  tracker.setError(e);
}
```

6. Call `reportDone()`:

```
tracker.reportDone();
```

⚠ To track another request, instantiate a new tracker object again.

Complete example

```
const tracker = new requestTracker({
  url: <MY_URL>
});
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
const headers = {
  'Content-Length': '5000',
};
tracker.setRequestHeaders(headers);
tracker.addServerCorrelationHeaders();

try {
  const response = await customRequest(url);
  tracker.setResponseStatusCode(response.statusCode);
  tracker.setResponseHeaders(response.headers);
} catch (e) {
  tracker.setError(e);
} finally {
  tracker.reportDone();
}
```

Get More Information about Mobile RUM

Use the following to find out more about Mobile RUM.

- [Mobile RUM Metrics](#)
- [Mobile RUM Supported Environments](#)
- [Real User Monitoring Licenses](#)
- [Network Request Limits](#)

Hybrid Application Support

AppDynamics supports monitoring for hybrid applications based on the iOS/Android native SDK or any Cordova-based framework.

Hybrid Applications

Hybrid applications are web applications running inside an Android or iOS native shell. The web application can be in the form of an [Android WebView](#), an [iOS WKWebViews](#), or a Cordova web application that consists of HTML, CSS, JavaScript, and other resources just like a conventional web application.

Hybrid Use Cases

Mobile RUM supports these two use cases.

- Native Mobile applications that run web applications or web views. Examples of this are Android WebViews and iOS WKWebView.
- Applications written in Cordova-based frameworks, such as Ionic, that provide a native shell for running a web application and an interface for native mobile APIs.

Hybrid Application Instrumentation Requirements

For instrumenting hybrid apps, you are required to:

- Manually instrument the iFrames with the JavaScript Agent. For mobile native applications, the JavaScript Agent is injected into the top-level WebView or WKWebView instance, not in embedded web pages (iFrames).
- Manually report events for Cordova-based applications using the [plugin JavaScript API](#).
- Use Android WebViews or iOS WKWebView for hybrid applications with embedded web views. See [Instrument Cordova Applications](#).

Instrumentation Steps

To monitor your hybrid applications, you will need to [set up and access Mobile RUM](#) and follow the steps below based on your hybrid use case:

Native iOS Application	Native Android Application	Cordova-Based Applications
<ol style="list-style-type: none"> 1. Instrument an iOS Application 2. Configure Hybrid Support for the iOS Application 	<ol style="list-style-type: none"> 1. Customize the Android Build 2. Instrument an Android Application 3. Configure Hybrid Support for Android Applications 	<ol style="list-style-type: none"> 1. Instrument a Cordova Application 2. Customize the Cordova Instrumentation

How it Works

For native Android/iOS applications, the Android Agent or iOS Agent will inject the JavaScript Agent into an [Android WebView](#) or [iOS WKWebView](#). For Cordova-based applications, the AppDynamics plugin will inject the JavaScript Agent into the web application.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

The diagrams below provide an overview of how Mobile RUM is used to monitor mobile native applications and Cordova-based applications.

Mobile Native Application Architecture

- 1 You instrument your mobile application with either the Android/iOS Agent.
- 2 When your mobile application instantiates a WebView or WKWebView instance, the Mobile Agent injects the JavaScript Agent into it.
- 3 The JavaScript Agent monitors the performance and WebView usage.
- 4 The JavaScript Agent reports the application activity by sending beacons to the Mobile Agent.
- 5 The Mobile Agent repackages the browser beacons into mobile beacons and sends the beacons to the EUM Server.

Cordova-Based Application Architecture

- 1 The AppDynamics Cordova plugin injects the JavaScript Agent into the Cordova WebView.
- 2 The Cordova-based application uses the plugin's JavaScript binding to configure the Mobile Agent.
- 3 The JavaScript Agent injected into the WebView monitors the application activity and performance.
- 4 The JavaScript Agent sends browser beacons to the Mobile Agent.
- 5 The Mobile Agent parses and converts the browser beacons into mobile beacons.
- 6 The Mobile Agent sends the mobile beacons to the EUM Server.

Mobile Agent and JavaScript Agent Compatibility

When hybrid app support is enabled, the Mobile Agents use an embedded JavaScript Agent to monitor mobile web pages. If you are already monitoring the same mobile web pages with a browser application, the JavaScript Agent version used to instrument the browser application may be different than the JavaScript Agent version used by the Mobile Agent. If the two versions of the JavaScript Agent are incompatible, the Mobile Agent will not be able to instrument web views or access event notifications from web views.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

How to Ensure Compatibility

To ensure compatibility, browser applications should use JavaScript Agent version $\geq 4.5.4$ and mobile applications should use Mobile Agent versions $\geq 4.5.5$. When using compatible versions of the JavaScript Agents, the JavaScript Agent of the browser app will report beacons for a web page, and the embedded JavaScript Agent of the mobile app will be ignored and not report beacons because a web page cannot be instrumented with the JavaScript Agent multiple times.

 If you have disabled the Mobile Agent's hybrid app support, there will be no compatibility issues regardless of the JavaScript Agent version used by the browser application.

Troubleshooting Incompatible JavaScript Agent Versions

If you are using incompatible versions of the JavaScript Agents, do one of the following to correct the problem:

- Upgrade the JavaScript Agent that you are using to instrument the browser application.
- In the mobile instrumentation, disable the hybrid support ([iOS/Android](#)), so that the mobile web pages are only instrumented by the browser application instrumented with the older version of the JavaScript Agent.

Hybrid Application Network Requests

Network calls made in the context of the WebView for Cordova-based applications show up as Ajax calls from the JavaScript Agent.

iOS Data Collection Disclosure

With the iOS 14 release, [Apple introduced a new data collection policy](#). This page describes how Apple's iOS 14 data use policy applies to AppDynamics.

Data Collection with Screenshots

When you use the Mobile Screenshots feature, the iOS Agent captures an image of the your user's screen and may send a copy of the image to the AppDynamics server for the Controller to visualize app usage. These screenshots may capture anything your application displays, including any user data your user submits. It is your responsibility to review the data captured in the screenshots and determine where such captured data falls in Apple's categorization of types of disclosable data. See [Data Collection Details](#).

Disable Mobile Screenshots

You can use `blockScreenshots()` to temporarily disable screenshots for any screen which may display such data. See [Customize the iOS Instrumentation](#).

Data Collection Details

AppDynamics does not enable any targeted advertisements, data broker, or data combination as described in the Apple iOS 14 User Privacy and Data Use Policy. In addition, ID for Vendors (IDFV) as defined under such guidelines is not currently used in any AppDynamics Mobile features.

This table references <https://developer.apple.com/app-store/app-privacy-details/> and describes how AppDynamics does or does not collect data.

A p p l e D a t a C a t e g o r y	Apple Data Description	AppDynamics Data Collection
C o n t a c t I n f o	<p>Name Such as first or last name</p> <hr/> <p>Email Address Including but not limited to a hashed email address</p> <hr/> <p>Phone Number Including but not limited to a hashed phone number</p> <hr/> <p>Physical Address Such as home address, physical address, or mailing address</p> <hr/> <p>Other User Contact Info Any other information that can be used to contact the user outside the app</p>	Subject to screen capture functionality

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

A p p l e D a t a C a t e g o r y	Apple Data Description	AppDynamics Data Collection
H e a l t h a n d F i t n e s s	<p>Health Health and medical data, including but not limited to from the Clinical Health Records API, HealthKit API, MovementDisorderAPIs, or health-related human subject research or any other user provided health or medical data</p> <p>Fitness Fitness and exercise data, including but not limited to the Motion and Fitness API</p>	Does not collect data
F i n a n c i a l I n f o	<p>Payment Info Such as form of payment, payment card number, or bank account number. If your app uses a payment service, the payment information is entered outside your app, and you as the developer never have access to the payment information, it is not collected and does not need to be disclosed.</p>	Does not collect data

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

A p p l e D a t a C a t e g o r y	Apple Data Description	AppDynamics Data Collection
	Credit Info Such as credit score	
Other Financial Info Such as salary, income, assets, debts, or any other financial information		
L o c a t i o n	Precise Location Information that describes the location of a user or device with the same or greater resolution as a latitude and longitude with three or more decimal places	Does not collect data
	Coarse Location Information that describes the location of a user or device with lower resolution than a latitude and longitude with three or more decimal places, such as approximate location services	

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

A p p l e D a t a C a t e g o r y	Apple Data Description	AppDynamics Data Collection

Mobile Agent Version and Deployment Support Matrix

Related pages:

- [Mobile RUM Supported Environments](#)

Using the AppDynamics Mobile Agents with the following recommended minimum Controller/EUM Server versions will ensure that all features for the specified releases will function correctly and that there will be no unexpected side effects.

 Although mobile agents may be compatible with future releases of the Controller and EUM Server, AppDynamics only provides support for mobile agent versions with the Controller and EUM Server for one year after the release of the mobile agent. Starting June 1 2022, all mobile agents older than 21.2 will not be supported.

Mobile Agent	Minimum Agent Version(s)	Download Site
Android Agent	20.3.x	https://mvnrepository.com/artifact/com.appdynamics/appdynamics-injector
Cordova Plugin	20.3.x	https://www.npmjs.com/package/appd-plugin-eum-mobile
iOS Agent	20.3.x	https://cocoapods.org/pods/AppDynamicsAgent
React Native Agent	20.3.1	https://www.npmjs.com/package/@appdynamics/react-native-agent
Xamarin Agent	20.3.x	https://www.nuget.org/packages/AppDynamics.Agent/

Deployment Support for Mobile Agent Features

For deployment support for individual mobile features, see:

- [iOS SDK Documentation](#)
- [Android SDK Documentation](#)
- [Xamarin SDK Documentation](#)
- [Cordova SDK Documentation](#)
- [React Native Agent Documentation](#)

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Mobile Device Metric Collection

This page explains what mobile device metrics are collected, and how to enable collection and view device metrics in the Controller UI. To learn how Apple's iOS 14 data use policy applies to AppDynamics mobile device metric collection, see [iOS Data Collection Disclosure](#).

Mobile agents can capture the following mobile device metrics:

- **Memory (RAM):** total memory of the device (i.e. 8GB total memory) and the resource consumption (i.e. 34% of device memory has been consumed)
- **Disk Space:** total storage capacity of the device (i.e. 64GB total storage capacity) and storage usage (i.e. 65% of device storage has been consumed)
- **Battery:** battery level of the device (i.e. include charging and lower power mode statuses)

 For Android devices, the metrics reported in the UI might not exactly match the Android device metrics. Due to API limitations, the memory value that the Android Agent returns might not include segments on the device's reserved memory. For example, an Android device might have 64GB storage and 8GB memory, but the Android Agent might report only 53GB storage and 6.5GB memory. This discrepancy varies based on device type and manufacturer.

Support

- Available for both SaaS and on-prem deployments
- Controller $\geq 20.11.0$
- Android Agent $\geq 20.10.0$
- iOS Agent $\geq 20.10.0$

Enable and Configure Device Metric Collection

To configure device metric data collection in the Controller UI:

1. Go to a browser application.
2. In the left-hand panel, go to **Configuration > Mobile App Group Configuration > Settings**.
3. Under **Configure Mobile Device Metrics**, enable each option. It may take a few minutes for data to appear on the **Mobile App Dashboard**.
4. Set **Frequency of data collection** to how often device data is collected for the options you enabled. For example, if the frequency is set to 2, every 2 minutes the enabled device data is collected and [shown in the dashboard widgets](#).

Warning

The maximum frequency is 2 minutes and collects the most data. However, sessions under 2 minutes or temporary metric spikes will not be captured.

Add Device Metric Widgets to the Mobile App Dashboard

You can view device metric widgets on the **Mobile App Dashboard**. To add device metric widgets:

1. Go to the **Mobile App Dashboard**.
2. In the top-left corner, click **+**.

3. Add the widgets **Device Memory Capacity**, **Device Storage Capacity**, and **Device Battery Capacity**.
4. Click on a widget and view performance and sessions by battery, memory, and storage.

View Sessions with Device Metrics

On the **Sessions** dashboard, you can add columns to sort sessions for each device metric. To add device metric columns:

1. Go to **Mobile Session Fields**.
2. Check the fields **Critical Battery Usage**, **Critical Memory Usage**, and **Critical Storage Usage**.

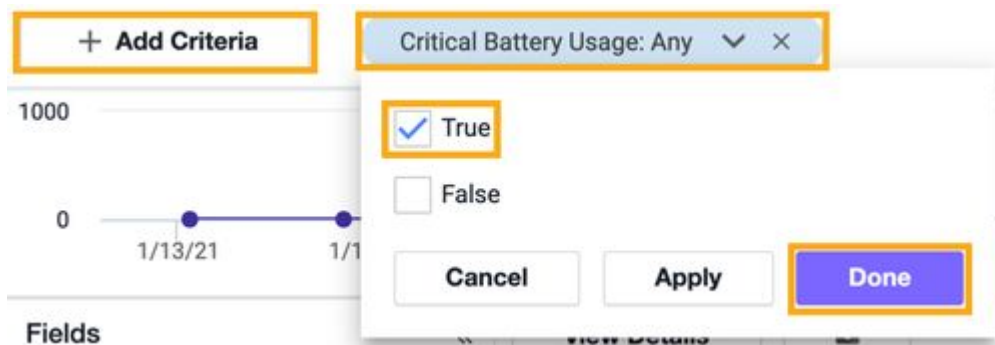

Mobile Session Fields (14)

- T Agent Version
- T Country
- Critical Battery Usage
- Critical Memory Usage
- Critical Storage Usage

Filter Sessions by Device Metric Values

You can filter sessions by [critical device states you configured](#). For example, if you want to look at sessions with over 90% device storage used:

1. Go to **Sessions**.
2. Click **+ Add Criteria**.
3. Select "Critical Battery Usage: Any".
4. Check "True."

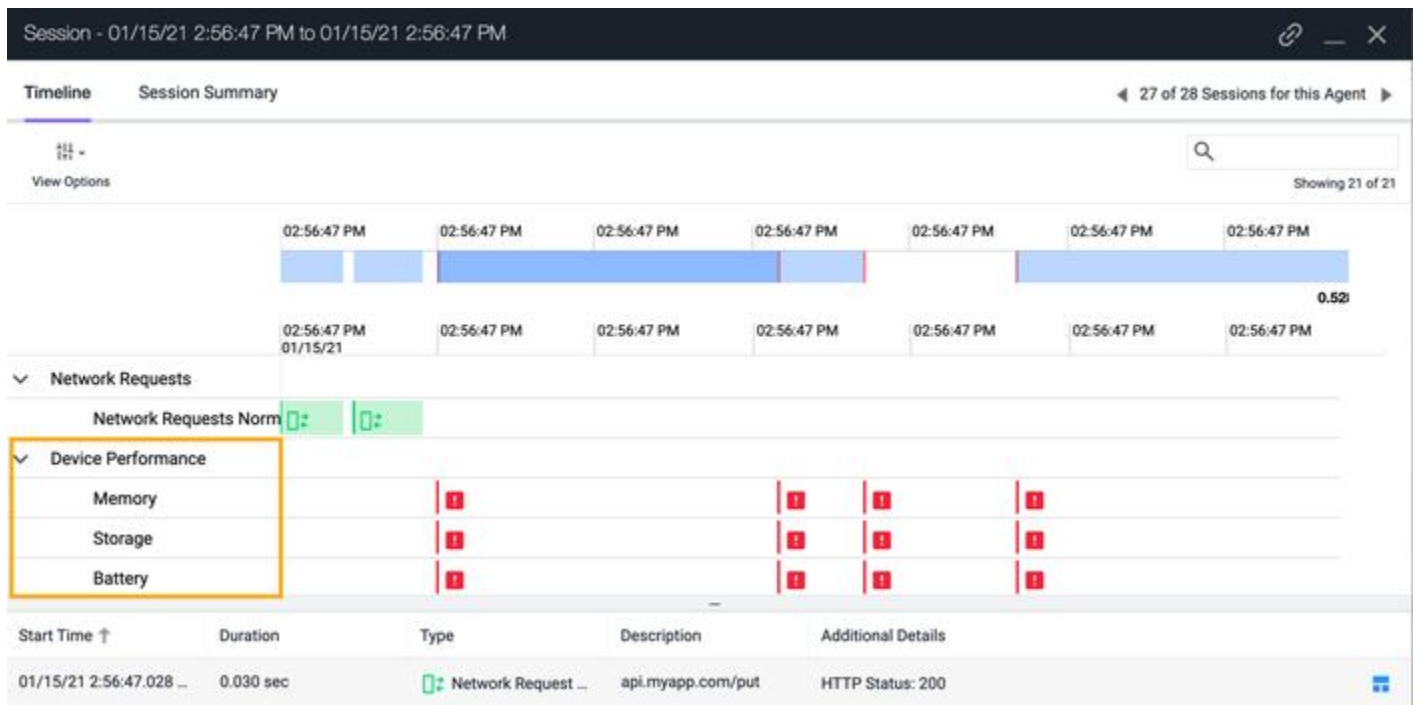

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Set Critical Usage Thresholds

You can set the usage threshold to trigger a critical event. To configure what usage percentage triggers a critical event:

1. Go to **Configuration > Mobile App Group Configuration > Settings**.
2. Under **Configure Mobile Device Metrics**, enter a value for each device metric threshold. For example, if you want to capture battery usage below 50%, set **Enable Battery Usage and Capacity Metrics** to 50%. When that configured threshold is reached, the resource consumption (percentage value) is captured by the agent and shown in session data.

When you look at a mobile session, you can see the critical events you configured.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Mobile RUM Metrics

AppDynamics displays key metrics for Mobile RUM on the various dashboards in the Mobile UI and in the **Metric Browser**.

i With the exception of App Crashes per Minute, the crash information displayed in the Controller UI is based on data stored in the Events Store and does not display in the **Metric Browser**.

Crashes

Crash measurements are created using the Analyze event store, and display in the **Crash Dashboard**.

- **Total Crashes:** total number of crashes over the selected time range
- **Total Unique Crashes:** total number of unique crash types over the selected time range
- **Impacted Users:** total number of unique users affected by a crash
- **Crashes by Usage Stats:** percentage of crashes based on device, OS version, carrier, and connection type
- **Crashes by Geo Location:** total number of crashes by origin over the selected time range

Crash Metrics

- **App Crashes per Minute:** arithmetic average number of crashes

HTTP Errors

An HTTP error occurs when an HTTP request is sent and a response is received, but the response status code indicates that an error occurred. These errors suggest that the network is working correctly, but a problem exists on the client side (4xx status codes) or the server side (5xx status codes) that prevented normal handling of the request.

- **HTTP Errors Per Minute:** arithmetic average of errors per minute for errors that return an HTTP response code between 400 and 599
- **HTTP Errors (total):** total number of HTTP errors over the selected time range (shown in the **Geo Dashboard**)

Mobile Device Metrics

See [Mobile Device Metric Collection](#) for more information.

Network Errors

A network error is any occurrence that prevents the HTTP request from being sent or the HTTP response from being received successfully.

- **Network Errors per Minute:** arithmetic average of network errors per minute
- **Network Errors (total):** total number of network errors over the selected time range (shown in the **Geo Dashboard**)

Typical causes of network errors include:

- Host cannot be resolved
- Host refused connection
- Connection timed out
- Device is offline
- General connectivity problems

Network Requests

Network request metrics are reported for each platform and instrumented mobile application.

- **Network Request Time:** arithmetic average interval in milliseconds between the time that a mobile application initiates a request by calling the system API and the time that the system returns the response to the application
- **Requests per Minute:** arithmetic average number of HTTP requests per minute
- **Total Requests:** total of HTTP requests per minute over the selected time range (shown in the **Geo Dashboard**)
- **Request Content Length:** total number of bytes of data in the body of the request. The body is the part that comes after the blank line below the headers
- **Response Content Length:** total number of bytes of data in the body of the response

Mobile RUM Supported Environments

See the following for the list the supported environments forth following mobile agents:

- [Android Agent](#)
- [iOS Agent](#)
- [Xamarin Agent](#)
- [Cordova Plugin](#)
- [React Native Agent](#)

Android Agent

Supported Environments	Name	Supported Version(s)
Operating System	Android	>= 2.3.3
Architecture	arm64-v8a, armeabi, armeabi-v7a, mips, mips64, x86, and x86_64	-
Frameworks	Ant	-
	Gradle	>= 0.6.3
	Maven	>= 3.1.1
Crash Reporters	Mobile RUM does not officially support 3rd-party crash reporters.	N/A
HTTP Libraries	URLConnection / HTTPSURLConnection	-
	HttpClient	-
	OkHttp	2.2.0 - 3.9.0
	ch.boye.httpclientandroidlib	-
	retrofit	-
	retrofit2	-

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Supported Environments	Name	Supported Version(s)
	Other HTTP libraries can be added by using the agent SDK. See Customize the Android Instrumentation for more information.	-

Android Gradle Plugin Version	Minimum Android Agent Version
0.6.3	3.8.2.0
0.7.3 - 0.9.2	3.8.3.0
0.10.0 - 0.12.0	3.9.0.0
1.1.2 - 1.1.3	4.0.3.3
1.3.0 - 1.4.0	4.0.7
1.5.0 - 2.2.0	4.2.0*
2.3.0 - 3.4.0 (forces Build Tools 25.0.0 or higher)	4.2.9
>= 3.4.1	>= 20.7.1

Recommendations for Android Agent Versions

- If your project uses Android Gradle Plugin version < 3.4.1, use Android Agent 20.4.0.
- If your project uses Android Gradle Plugin version >= 3.4.1, use Android Agent >= 20.7.1.

* Android Agent Plugin versions before 4.2.9 are not compatible with Android Build Tools versions >=24 because of the Java 8 bytecode generated in class files.

iOS Agent

Supported Environments	Name	Supported Version(s)
Operating System	iOS	>= 9
Architecture	Apple 32-bit ARM, Apple 64-bit A7	-

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Supported Environments	Name	Supported Version(s)
Framework	XCode	>= 8
Crash Reporters	Mobile RUM does not officially support 3rd-party crash reporters.	N/A
Apple WatchKit Extension Environments	watchOS	1
HTTP Libraries	<code>NSURLConnection</code>	-
	<code>NSURLSession</code>	-
	Alamofire - Initialize the iOS Agent before initializing Alamofire to ensure that network requests are monitored. If you need to make a network request(s) prior to iOS Agent initialization, see Alamofire Guidelines .	-
	Other HTTP libraries can be added by using the agent SDK. See Customize the iOS Instrumentation for more information.	-

Alamofire Guidelines

If you need to use Alamofire to make a network request(s) prior to initializing the iOS Agent, you can use the following sample code as a guideline for making the necessary changes.

To ensure that Alamofire network requests made after iOS agent initialization will be instrumented, you can initialize a custom instance of `Session` (the principle class defined in Alamofire 5, renamed from previous Alamofire versions). This will create a new instance of `URLSession`, which can be instrumented by the iOS Agent. Any Alamofire network requests made prior to the agent initialization and creation of the `Session` instance cannot be instrumented by the agent.

- The order of operations in this code is very important. See the inline comments.
- This code assumes you are initially creating a customized instance of `Session` (which is common practice). If not, you can eliminate the first usage of customized `Session` and defer its creation until after the iOS agent initialization.

- You can test this code by going to <https://www.google.com/?q=request%202>, which is instrumented because it occurs after the replacement of `mySession` with `instrumentedSession`. The other two requests are not instrumented.

```

import UIKit
import Alamofire
import ADEUMInstrumentation

var mySession:Session? // customized Session singleton

@UIApplicationMain
class AppDelegate: UIResponder, UIApplicationDelegate {

    func application(_ application: UIApplication, didFinishLaunchingWithOptions
launchOptions: [UIApplication.LaunchOptionsKey: Any]?) -> Bool {
    // Override point for customization after application launch.

    // create customized instance of AF Session
    let myConfiguration = URLSessionConfiguration.af.default
    mySession = Session(configuration: myConfiguration)

    let myUrl1 = URL(string: "https://www.google.com/?q=request%201")!
    let urlRequest1 = URLRequest(url: myUrl1)

    // the first network request prior to ADEUMInstrumentation.initWith will not be
instrumented
    mySession?.request(urlRequest1 as URLRequestConvertible).response {
        response in debugPrint(response)

        // initialize iOS agent
        let config = ADEUMAgentConfiguration(appKey: "XX-XXX-XXX-XXX")
        config.loggingLevel = .all
        ADEUMInstrumentation.initWith(config)

        // update our Session instance singleton, instrumentedSession, so that URLSession
will be instrumented
        let myConfiguration = URLSessionConfiguration.af.default
        let instrumentedSession = Session(configuration: myConfiguration)
        // replace mySession with instrumentedSession
        mySession = instrumentedSession

        // subsequent requests use updated mySession from instrumentedSession, so should
be instrumented
        let myUrl2 = URL(string: "https://www.google.com/?q=request%202")!
        let urlRequest2 = URLRequest(url: myUrl2)
        mySession?.request(urlRequest2 as URLRequestConvertible).response {
            response in debugPrint(response)

```

```

    }
  }
  // has instrumentedSession been created yet? Indeterminate. If not, this request
  won't be instrumented
  let myUrl3 = URL(string: "https://www.google.com/?q=request%203");
  let urlRequest3 = URLRequest(url: myUrl3)
  mySession?.request(urlRequest3 as URLRequestConvertible).response {
    response in debugPrint(response)
  }
  return true
}
}
}

```

Xamarin Agent

Supported Environments	Name	Supported Version(s)
Operating System	Android	>= 2.3.3
	iOS	>= 9
Architecture	Xamarin.Android Supported CPU Architectures	-
	Apple 32-bit ARM, Apple 64-bit A7 - See 32/64-bit platform considerations for information regarding the correct architecture for your iOS version.	-
Framework	.NET - Mono	>= 4.8
Crash Reporters	Mobile RUM does not officially support 3rd-party crash reporters.	N/A
Apple WatchKit Extension Environments	Not supported	-

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Supported Environments	Name	Supported Version(s)
HTTP Libraries	N/A - The Xamarin Agent does not support automatic instrumentation for network requests made with any library. You will need to manually instrument HTTP network requests regardless of what library is used.	-

Cordova Plugin

Supported Environments	Name	Supported Version(s)
Operating System	Android	4.4 - 8.1
	iOS	>= 9
Architecture	Android: arm64-v8a, armeabi, armeabi-v7a, mips, mips64, x86, and x86_64	-
	iOS: Apple 32-bit ARM, Apple 64-bit A7	-
Framework	Apache Cordova	>= 7
Crash Reporters	Mobile RUM does not officially support 3rd-party crash reporters.	N/A
Apple WatchKit Extension Environments	Not supported	-
HTTP Libraries	Android: <ul style="list-style-type: none"> • <code>URLConnection /</code> <code>HttpsURLConnection</code> • <code>HttpClient</code> • <code>OkHttp</code> • <code>ch.boye.httpclientandroidlib</code> 	-

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Supported Environments	Name	Supported Version(s)
	iOS: <ul style="list-style-type: none"> NSURLConnection NSURLSession 	-

React Native Agent

Supported Environments	Name	Supported Version(s)
Operating System	Android	>= 4.1 (with React Native Agent >= 20.10.1)
	iOS	>= 11 (with React Native Agent >= 20.10.1)
Architecture	Android: arm64-v8a, armeabi, armeabi-v7a, mips, mips64, x86, and x86_64	-
	iOS: Apple 64-bit A7 (with React Native Agent >= 20.10.1)	-
Framework	React Native	>= 0.60 (with React Native Agent >= 20.10.1) < 0.60 (with React Native Agent 20.7.0)
Crash Reporters	Mobile RUM does not officially support 3rd-party crash reporters.	N/A
Apple WatchKit Extension Environments	Not supported	-

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Supported Environments	Name	Supported Version(s)
HTTP Libraries	Android: <ul style="list-style-type: none"> • HttpURLConnection / HttpsURLConnection • HttpClient • OkHttp • ch.boye.httpclientandroidlib 	-
	iOS: <ul style="list-style-type: none"> • NSURLConnection • NSURLSession 	-

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Network Request Limits

The EUM Server (on-premises/SaaS) can process a maximum of 2000 network request types per mobile app group and 500 network requests per mobile application.

If the number of network requests for an application exceeds one of these limits, AppDynamics continues to monitor network requests that have already been discovered, but new network requests will not be discovered. Should a limit be exceeded, a warning appears on the network request list.

You can use these techniques to keep your usage under the two network request limits.

Remove Network Requests Without Load

Removing network request types that have been discovered but are not receiving any load is a good place to start to reduce the number of your registered requests.

i Deleting network requests does not prevent them from being re-discovered in the future if the request once again comes under load. To prevent specific network requests from ever being discovered, you must create exclude rules. See the section "Creating Mobile Exclude Rules" in [Configure Mobile Network Request Naming](#).

Delete network requests with no load

1. In the **Network Requests** list, uncheck the **With Load** checkbox.
2. Refresh the list.
3. Find the requests that have no load. They are candidates for removal.
4. Select the requests that you want to delete.
5. In the **More Actions** dropdown, click **Delete Request(s)**.

Exclude Requests That Do Not Need to Be Monitored

The Mobile Agent may be detecting network requests types that are not interesting for you to monitor. You have two methods to exclude these types of network requests.

The first method is to add custom exclude rules from **Configuration > Mobile Request Naming, Thresholds, & Percentiles**. See [Creating Mobile Exclude in Rules](#) for explicit instructions.

Using custom exclude rules, network requests for new data that match the exclude rules will not be registered. The load on the existing network requests that match the exclude rule will drop to zero. To delete any network requests of the excluded type that have already been registered from the network request list, follow the procedure described in [Delete network requests with no load](#).

The second method is to select an existing network request from the **Network Requests** list and then exclude it. This will change the app's exclude rules so that incoming data matching that request will not be tracked. In addition, the historical data for that request will be deleted.

To use the second method for the exclude rules that prevent a network request from being tracked and remove historical data for that network request:

1. From **Network Requests**, select the network request you want to exclude.

-
2. Click **Actions > Exclude Requests** to open the **Exclude Requests** dialog.
 3. Click **Exclude**.

Group Network Requests of Similar Type

Review the default network request naming rule described in [Configure Mobile Network Request Naming](#). It is possible that the default rule is generating many more network requests types than are desirable.

For example, perhaps your application loads images dynamically and stores them on your server with URLs like `http://myapp.com/image/image1234.jpg`. This would cause a separate network request to be generated for each image, which is probably not what you want. You could create a custom naming rule to group all the image URLs as a single network request. See [Configure Mobile Network Request Naming](#).

After you have created custom rules to reduce the number of network requests detected, unregister the network requests for those are now covered by the custom rule, following the procedure described in [Delete network requests with no load](#).

Troubleshoot Mobile Applications

You can use Mobile RUM to investigate two different kinds of problems that can arise with your mobile applications:

- Slow network requests
- Mobile application crashes

Identify Your Slowest Network Request Types

To identify slow network requests:

1. Open the application in which you are interested.
2. In the left navigation bar, click **Network Requests**.
3. Select the Network Requests tab.
4. Click the top of the **Network Request Time (ms)** column, then toggle it to sort the network requests with the slowest ones at the top.
5. Skip over network requests that you expect to run for a long time or that have very little load (low Requests per Minute).
6. Select and double-click one of the slow network requests that you want to investigate.
7. In the network request dashboard, view the **Key Performance Indicators** at the top of the **Network Request Dashboard**. For example:
 - If the value for Network Request Time is large, the request or response body may be too large and is taking a while to transmit, or the data connection might be slow.
 - If the backend server is instrumented and the value for Total Server Time makes up a significant amount of the delay, scroll down to the **Related Business Transactions** section to investigate related business transactions on the server side.

Access Details of Individual Instances of Slow Requests

To investigate the cause of slow requests:

1. Select the Snapshots tab. The **Snapshots List** opens.
2. Click **Filters**.
3. In the **Network Request Names** dropdown under **Network in the Filters** panel, check the check box for the network request that you identified in [Identify your slow network requests](#), then click **Search**. This restricts the list to snapshots for that network request only.
4. Click **Filters** again to close the filters panel.
5. In the list, click the top of the **Network Request Time (ms)** column, then toggle it to sort the network request snapshots with the slowest requests at the top.
6. Select and double-click one of the slow network requests. The network request snapshot displays the details of the slow request.
7. If this request is associated with a server-side application that is also instrumented, scroll down to see if transaction snapshots for this request are available on the server side. If transaction snapshots are available and if most of the time for this network request is spent on the server, click through to the related transaction snapshots to understand what is causing the slow performance on the server. See [Transaction Snapshots](#).

Identify Applications that Crash the Most or Affect the Most Users

To troubleshoot mobile application crashes with crash dashboards and crash snapshots:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

1. Open the application in which you are interested.
2. On the left navigation bar, click **Crashes**.
3. Select the Crash Dashboard tab.
4. Check the **Unique Crashes** list.
5. Sort either by **Total Crashes** or **Impacted Users**, depending on what you want to know. In the screenshot below, the list is sorted by impacted users.

Unique Crashes

Unique Crash Location	Mobile App Version	Total Crashes	Impacted Users	Status	Runtime
S1000V in promo/issue	2.1	15,135	1001	open	SDK
S1000V in add	2.0	6,343	1001	open	SDK
S1000V in cartage	1.0	10,046	1001	open	SDK
S1000V in promo/issue	2.1	147	138	open	SDK
S1000V in promo/issue	2.1	145	138	open	SDK
S1000V in add	2.0	144	134	open	SDK
S1000V in cartage	1.0	127	129	open	SDK
S1000V in cartage	1.0	136	126	open	SDK
S1000V in add	2.0	138	126	open	SDK
S1000V in cartage	1.0	15	15	open	SDK
S1000V in cartage	1.0	13	13	open	SDK
S1000V in add	2.0	11	11	open	SDK
S1000V in promo/issue	2.1	10	10	open	SDK
S1000V in promo/issue	2.1	7	7	open	SDK
S1000V in add	2.0	6	6	open	SDK

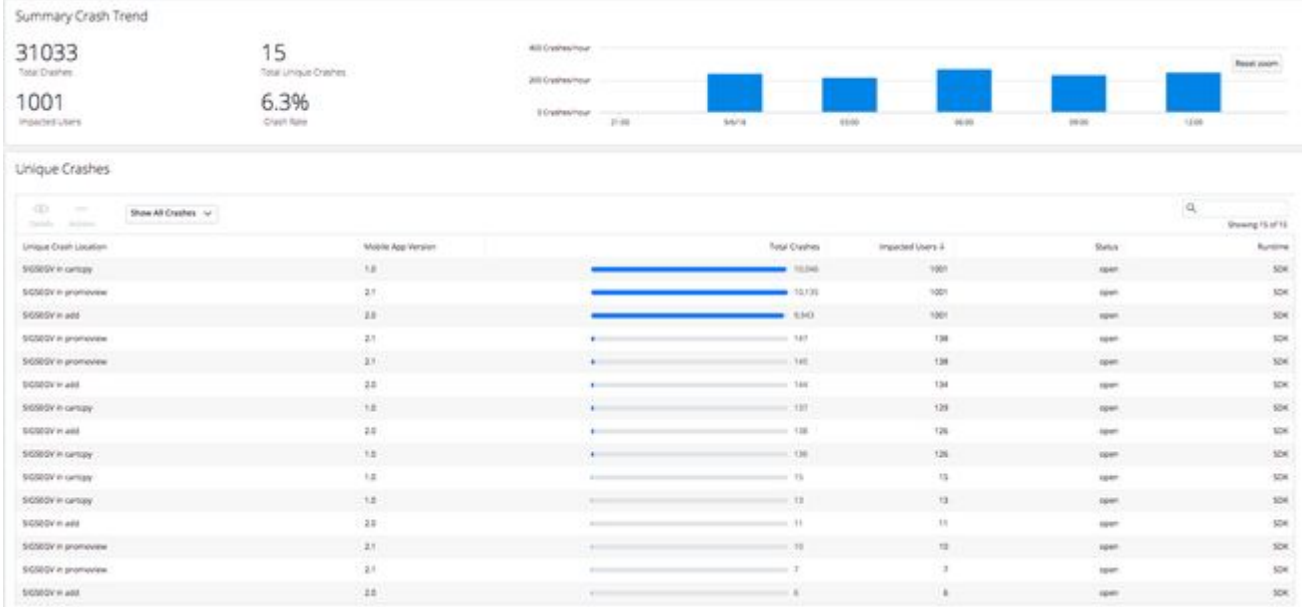

6. View the **Summary Crash Trend** graph to discover particularly problematic time periods.

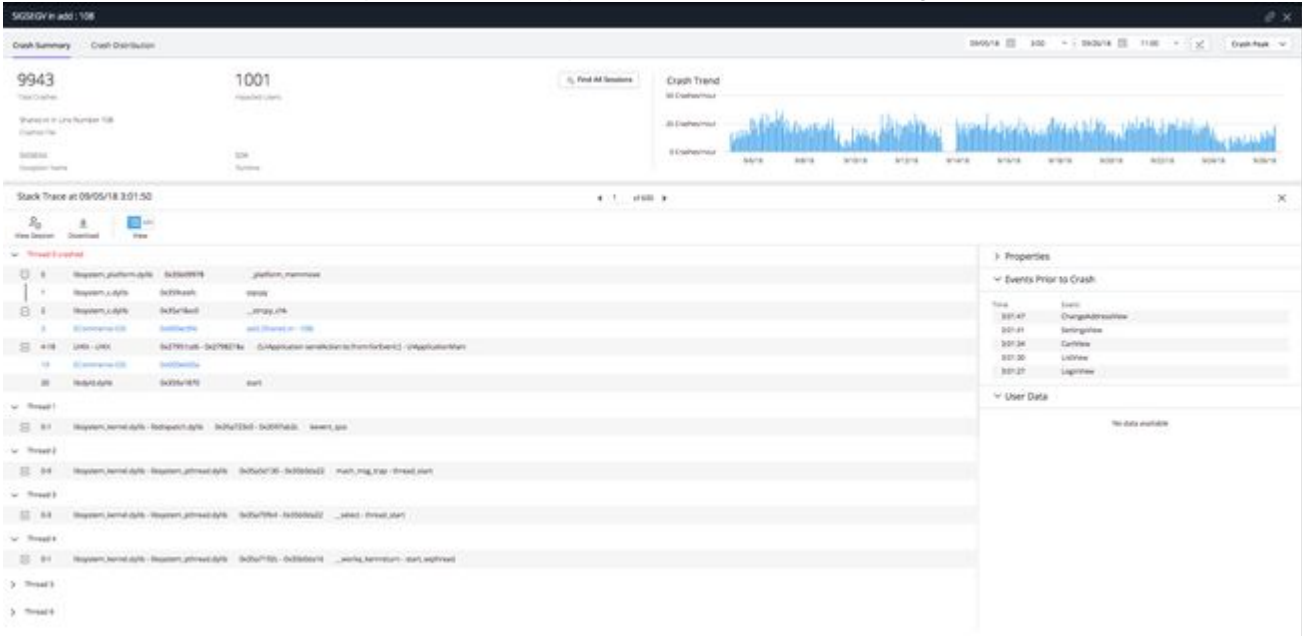

7. To find crashes in the problematic timeframe, click **Analyze** and drag up on the timeline where the most crashes occurred.

8. You should see the crash list reduced to those that occurred during the custom time period.

9. Double-click one of the unique crashes to open the **Crash Details** dialog.

- From here, you can view the stack trace of the crash snapshot, note the thread and function in which the crash occurred. For some crashes, the crashed line number is also available. Optional: Click **Download** to get a text version of the stack trace to send to your application development team.
- To access a complete data set for crashes that belong to this crash group, click **Find Sessions**. This opens the **Mobile Sessions** view with a filter for this **Crash Group** already selected.

Database Visibility

Database Visibility in AppDynamics provides end-to-end visibility on the performance of your database, helps you troubleshoot problems such as slow response times and excessive load, and provides metrics on database activities, such as:

- SQL statements or stored procedures that are consuming most of the system resources
- Statistics on procedures, SQL statements, and SQL query plans
- Time spent on fetching, sorting, or waiting on a lock
- Activity from the previous day, week, or month

Installation And Administration

Overview of Database Visibility

Related pages:

- [Add Database Collectors](#)
- [Database Visibility](#)

Database Visibility provides metrics on the performance of your database and helps troubleshoot performance-related issues.

Components of Database Visibility

AppDynamics Database Visibility consists of four main components:

- Database Agent
- Collector
- Controller
- Events Service

Database Agent

The AppDynamics Database Agent is a standalone Java program that collects performance metrics about your database instances and database servers. You can deploy the Database Agent on any machine running Java 1.8 or higher. The machine must have network access to the AppDynamics Controller and the database instance that you want to be monitored.

A database agent running on a typical machine with 16 GB of memory can monitor about 25 databases. On larger machines, a database agent can monitor up to 200 databases. To monitor more than 100 databases, increase the initially allocated heap size for the Database Agent JVM. See [Database Visibility Supported Environments](#).

Collector

The Database Agent Collector is the process that runs within the Database Agent to collect performance metrics about your database instances and database servers. One collector collects metrics for one database instance. Multiple collectors can run in one Database Agent.

AppDynamics Database Visibility detects when a database back end has matching credentials with a database server being monitored by a collector. Database Visibility automatically associates the back end with the collector, so you can view its performance with the Application Flow Map, Tier Flow Map, or Node Flow Map.

Controller

The [Controller](#) is the central interface where you can see all your database instances and database server performance metrics.

The following types of information are sent to the Controller:

- Database-level metrics, such as the number of queries processed and other database statistics.
- Names and attributes of all sessions, clients, queries, and other objects on the monitored system.

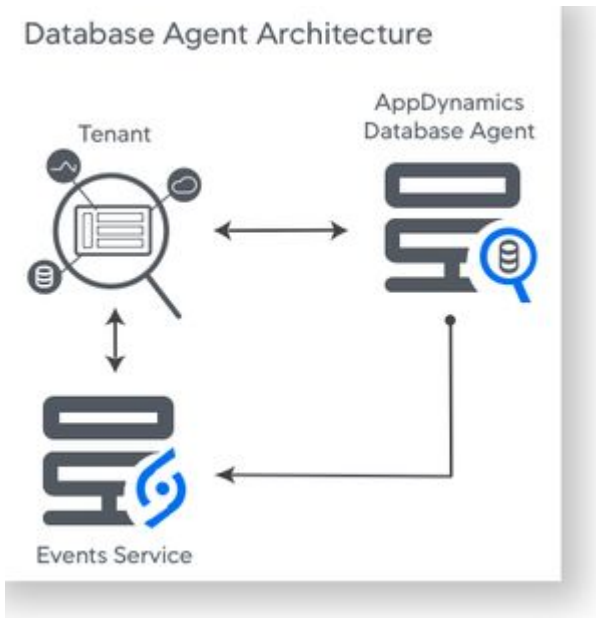

Events Service

Event service stores high volumes of metric data.

The following types of information are sent to the Events Service:

- The time that each query spends at each wait state.
- Individual query statistics for databases that support it.
- Information about individual execution plans in databases that support it.

Database Agent Architecture

Database Visibility Supported Environments

Related pages:

- [Add Database Collectors](#)
- [Database Visibility](#)

This page describes the application environments and versions supported by the Database Visibility Agent.

Database Visibility Support

Once Database Visibility is available, you can create collectors that run on the Database Agent to monitor any of these systems:

Database	Supported through Amazon RDS	Version
Apache Cassandra		>= 3.11.4
Datastax Enterprise (DSE) Cassandra		>= 6.7.3
Couchbase		>= 4.5
IBM DB2 LUW		9.x, 10.x, 11.x
MongoDB, MongoDB cluster		>= 2.6
MySQL	Yes	All versions including MySQL Version 8.0, Percona, MariaDB, and Aurora
Microsoft SQL Server	Yes	2005, 2008, 2012, 2014, 2016, 2017, 2019, and SQL Azure
Microsoft SQL Server on Linux		<p>SQL Server on Linux is currently available as a public preview and is not recommended for production use.</p> <p>Database Visibility works well with this preview release, but monitoring results may vary until a stable version of SQL Server on Linux is available.</p>
Oracle, Oracle RAC	Yes	10g (>= 10.2), 11g, 12c, 18c, and 19c

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Database	Supported through Amazon RDS	Version
PostgreSQL	Yes	All the versions including Azure Database for PostgreSQL and Aurora
Sybase ASE		>= 15
Sybase IQ		All versions

Operating System	Version
Windows	64-bit  From 20.5 release, 32-bit is unsupported.
Linux	32-bit and 64-bit
Solaris	All versions
AIX	>= 6.1
Amazon RDS	All versions

To avoid metric value errors, use a 64-bit JRE with the 64-bit operating system.

 **Recommended**

If you use a third-party application along with Database Visibility to monitor Sybase, the data displayed in the controller may not display correctly. For accurate metrics, do not use both a third-party application and Database Visibility to monitor Sybase.

Database Visibility System Requirements

This page describes the hardware and software requirements using Database Visibility.

Hardware Requirements

Hardware requirements vary depending on database activity. If your database activity increases, you may need to adjust your hardware configuration.

The machine running the Database Agent should meet the following hardware requirements:

- 1 GB of heap space and an additional 512 MB of heap space for each monitored database instance. For less busy databases, you may reduce the heap space to 256 MB per monitored database instance.
- 2 GHz or higher CPU.

Database Instance

A Database instance can be a node in the Oracle RAC, MongoDB, Couchbase cluster, standalone-collector, or a sub-collector.

This table shows sample calculations for heap space allocation:

Number of Database Instances Monitored	Heap Space Allocation
5	$(5 \times 512 \text{ MB}) + 1024 \text{ MB} = 3,584 \text{ MB}$
20	$(20 \times 512 \text{ MB}) + 1024 \text{ MB} = 11,264 \text{ MB}$
100	$(100 \times 512 \text{ MB}) + 1024 \text{ MB} = 52,224 \text{ MB}$

AppDynamics Controller Sizing Requirements

The Controller database should meet the following hardware requirements:

- 500 MB of disk space per collector per day
- 500 MB of disk space for the Events Service per day. By default, the Events Service retains data for 10 days.

See [Controller System Requirements](#).

Note

The Database Agent requires the [Events Service](#). Start Event Service before you start the Database Agent.

Software Requirements

- The Database Agent runs on a Java Virtual Machine. You must have Java \geq 1.8.
- The operating systems Linux and Windows are supported.

Network Requirements

- The machine on which the database is running or the machine you want to monitor must be accessible from the machine where the Database Agent is installed and running. This machine must have a network connection, internet, or intranet.
- If your databases are behind a firewall, you must configure the firewall to permit the machine running the Database Agent program access to the databases. The database listener port (and optionally the SSH or WMI port) must be open.
- The network bandwidth used between the agent and the controller is approximately 300 KB per minute per collector for a large database with 200 clients using 50 schemas, processing about 10,000 queries a minute. The actual numbers depend on the type of database server, the number of individual schemas on the server, and the number of unique queries executed daily, and therefore varies.

Administer the Database Agent

Related pages:

- [Database Visibility](#)
- [Database Agent Configuration Properties](#)
- [Add Database Collectors](#)
- [Start the Database Agent Automatically on Linux](#)
- [Start the Database Agent Automatically on Windows](#)

The Database Agent is a standalone Java program that collects performance metrics about your database instances and database servers. You can view these performance metrics in the Metric Browser of the AppDynamics Controller UI.

To start monitoring your database, you must first install the Database Agent. You may want to install multiple agents for the following reasons:

- You have databases on multiple networks that are not accessible by one machine.
- You have multiple SQL Server instances that each require different credentials, and you want to connect to them through Windows Authentication.
- You want one or more agents to back up a primary agent. Backup agents ensure that your database instances are continually monitored during agent failure or machine downtime.

Prepare to Install the Database Agent

Related pages:

- [Database Visibility](#)
- [Database Agent Configuration Properties](#)
- [Add Database Collectors](#)
- [Start the Database Agent Automatically on Linux](#)
- [Start the Database Agent Automatically on Windows](#)

Database Agent Installation Requirements

Ensure that your environment meets these requirements:

- Java \geq 1.8
- The machine that you install the agent on has network access to the databases that you want to monitor.

Controller Communication Information

If you are installing using the Database Agent downloaded from the **Getting Started Wizard**, the Controller communications information is already configured for you in the agent `controller-info.xml` file.

To complete the **Getting Started Wizard - Databases**, you need:

- Controller Host Name
- Controller Port Number

If you are installing using the agent installation zip file downloaded from the AppDynamics portal, you need:

- Controller Host Name
- Controller Port Number
- Account Access Key

See [Agent-to-Controller Connections](#).

Install the Database Agent

Related pages:

- [Database Visibility](#)
- [Database Agent Configuration Properties](#)
- [Add Database Collectors](#)
- [Enable SSL and SSH for Database Agent Communications](#)
- [Start the Database Agent Automatically on Linux](#)
- [Start the Database Agent Automatically on Windows](#)

This page describes how to manually install the Database Agent. You can alternatively follow the steps in the **Download & Install Wizard**, which you can access from the Home page in the Controller UI. The wizard simplifies the install process.

To avoid permission issues, you should install the Database Agent as the same user who will run the agent, or as an administrator on the host machine. To run the Database Agent, you must have write privileges to the logging output directory and to the `conf` directory, which are located in the agent installation directory.

Install the Agent Software

1. Download the version of the installation package that is appropriate for your OS environment from the AppDynamics Download Center (<http://download.appdynamics.com>).
2. Extract the zip file to the destination directory. Do not use spaces in the agent installation destination directory.
3. Log on as an administrator to the machine where you will be installing the Database Agent.

Windows

Double-click the `dbagent-x.x.x.zip` file and extract the files to `<db_agent_home>`. If necessary, you can unblock the zip file before you extract it as follows: Right-click on the zip file, select **Properties** and choose **unblock**.

 There are two versions of the database agent: one that is 32-bit and one that is 64-bit (*as of 4.5.2*). Choose a version based on your OS requirements.

Linux

Enter the following on the command line:

```
unzip dbagent-x.x.x.zip -d <db_agent_home>
```

 **Running Multiple Database Agents**

You can have multiple Database Agents concurrently running the agent jar in the `<db_agent_home>` directory on the same machine. Some system properties may be required depending on how you'll be using the agents.

Database Agent Licensing (On-premises Only)

Obtain a `license.lic` file with Database Monitoring licensing from your sales or support representative and put the license file in the directory where you installed the Controller. After placing the license in the directory, the Controller may take a minute or two to detect the new license. [Restarting the Controller](#) forces it to detect new licenses.

Configure the Agent

You can [configure properties](#) for the Controller host name, port number, and account access key using either the `<db_agent_home>/conf/controller-info.xml` file or by adding system properties to the Database Agent startup script.

Controller Host Name

Configure using controller-info.xml: `<controller_host>`

Configure using System Properties: `-Dappdynamics.controller.hostName`

Required: Yes

Default: None

Controller Port

Configure using controller-info.xml: `<controller_port>`

Configure using System Properties: `-Dappdynamics.controller.port`

Required: Yes

Default: For On-premises Controller installations: Port 8090 for HTTP and 8181 for HTTPS communication.
 For SaaS Controller service: Port 80 for HTTP and port 443 for HTTPS communication.

Account Access Key

Configure using controller-info.xml: `<account_access_key>`

Configure using System Properties: `-Dappdynamics.agent.accountAccessKey`

Required: Yes

Default: None

Optional Configurations:

- Configure the agent to use SSL, see [Enable SSL for Communicating with the Controller](#).
- Configure the agent to use Proxy Settings, see [Proxy Settings for the Controller](#).
- Configure the agent to run automatically when the Machine starts on [Linux](#) or [Windows](#).
- Configure the agent to uniquely identify itself to the Controller, such as when you require multiple agents. See [Multiple Agent Environment Properties](#).
- Configure the agent to act as a backup to another Database Agent. See [Multiple Agent Environment Properties](#).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- Configure the logging level of the Database Agent running on the agent JVM. The [attached log file](#) shows an example of the agent log file when the agent logging is set to INFO level. This is the default. The log files are in `<db_agent_home>\logs`.

Start the Controller Events Service (On-premises Only)

In an on-premises environment, for monitoring the database you must start the controller events service before starting Database Agent.

Linux

```
bin/platform-admin.sh start-events-service
```

Windows

```
bin\platform-admin.exe start-events-service
```

Launch the Database Agent using System Properties

The following assumes that all the necessary parameters have been specified in the `controller-info.xml`.

Method 1: Launch Agent with Start Script

You can use a script to start the agent. This is the recommended method.

Linux

```
./start-dbagent -Xms<min_heap_size> -Xmx<max_heap_size> &
```

Windows

```
start-dbagent.bat -Xms<min_heap_size> -Xmx<max_heap_size>
```

Alternatively, you can launch the agent as a Windows Service (*as of 4.5.4*). See [Install the Database Agent as a Windows Service](#).

Method 2: Launch Agent with Java Command

Alternatively, you can launch the agent with these Java commands:

Linux

```
java -XX:+HeapDumpOnOutOfMemoryError -XX:OnOutOfMemoryError="kill -9 %p" -jar db-agent.jar
```

Windows

```
C:\java -Djava.library.path="<db_agent_home>\auth\x64" -Ddbagent.name="Scarborough Network Database Agent" -jar <db_agent_home>\db-agent.jar
```

System Properties

Database Agent Name

Configure using System Properties: `-Ddbagent.name=<db_agent_name>`

Type: ASCII string, including spaces. If `<db_agent_name>` contains spaces, you must enclose the entire name in double quotes (" ").

Required: Yes, when you have multiple agents reporting to the same Controller.

Default: Default Database Agent

Java Library Path

Configure using System Properties: `-Djava.library.path=<db_agent_home>\auth\x64`

Type: ASCII string, including spaces. If `<db_agent_home>` contains spaces, you must enclose the entire name in double quotes (" ").

Required: Yes, for Windows only

Specify:

For 64-bit systems: `<db_agent_home>\auth\x64`

For 32-bit systems: `<db_agent_home>\auth\x86`

Increase the JVM Memory

To monitor multiple databases, you may need to increase the JVM memory allocation size. Increased activity on the databases you are monitoring results in increased memory usage.

Use one of the following commands to start the agent, and to initially allocate 1536 MB to the agent instead of the default of 64 MB.

For Windows 64-bit

```
C:\>java -Xmx1536m -Djava.library.path="<db_agent_home>\auth\x64" -jar <db_agent_home>\db-agent.jar
```

For Linux

```
% java -Xmx1536m -jar <db_agent_home>/db-agent.jar
```

Verify the Database Agent Installation

Related pages:

- [Database Agent Configuration Properties](#)
- [Agent and Controller Compatibility](#)

Review the Agent Logs

After a successful install, your agent logs, located at `<db_agent_home>/logs`, should contain this message:

```
Started AppDynamics Database Agent Successfully
```

If the agent log file is not present, the Database Agent may not be accessing the Database Agent command properties. To troubleshoot, check the application server log file where STDOUT is logged. It will have the fallback log messages, useful for troubleshooting the agent.

Verify that the Agent is Reporting to the Controller

1. Click **Settings > AppDynamics Agents**.
2. Click the Database Agents tab.

A list for each Database Agent reporting to the Controller should display. An agent can have one of the following statuses:

- Active: The agent is running
- Passive: The agent is used as a backup for active agents

If you don't see the Database Agent, check your `controller-info.xml` properties to ensure they have specified the correct host properties.

Verify that the Agent is Running

Use the following command to verify that the agent process is running:

Linux:

```
ps -ef | grep db-agent
```

Windows:

1. Open a command-line console.
2. Start the **Task Manager** and click the Processes tab.
3. The agent process should be running. If it is not running, then stop and restart the agent.

Upgrade the Database Agent

Related pages:

- [Database Agent Configuration Properties](#)
- [Agent and Controller Compatibility](#)

Important Upgrade Notes

- Before upgrading, ensure that you have all the required user permissions as mentioned in each database collector configuration.
- If you are upgrading the Controller and agents, first upgrade the Controller and then upgrade the Database Agents.
- **Shut down** the Database Agent process before you install the new agent. All Database Agents that are running from the same install location need to be shut down when updating that install location.
- Download the installation package that is appropriate for your OS environment from the [AppDynamics Download Center \(https://download.appdynamics.com/download/\)](https://download.appdynamics.com/download/).
- Back up the `<db_agent_home>` directory so you can revert to the previous installation if required. To maintain the same configuration information, you will also need the `<db_agent_home>\conf\controller-info.xml` file.
- If both the old and new agents are ≥ 4.2 , you can keep the old agent running while installing the new agent, allowing you to upgrade the agent with no downtime. Once you see the new agent showing up as "ACTIVE" in the agents page in the Controller, stop the old agent.

Stop the Agent

Stop the agent as described [for your specific installation in Start and Stop the Database Agent.](#)

Back up the Existing Agent Directory

Make a copy of the existing agent directory, `<db_agent_home>`. Backing up allows you to revert to the previous agent installation if you need to. You can also copy over the `controller-info.xml` configuration file to the new installation to ensure the agent configuration is maintained.

Install the Agent

Install the Database Agent as described for your specific installation in [Administer the Database Agent.](#)

Copy the controller-info.xml File

To ensure the agent configuration is maintained, copy the `<backup_db_agent_home>\conf\controller-info.xml` file to the new installation directory, `<db_agent_home>\conf`.

Start the New Agent

See [Start and Stop the Database Agent.](#)

Verify the Database Agent Installation

See [Verify the Database Agent Installation.](#)

Uninstall the Database Agent

Related pages:

- [Administer the Database Agent](#)
- [Database Agent Configuration Properties](#)
- [Manage App Agents](#)

To uninstall the database agent:

1. Shut down the JVM that the database agent runs on.
2. Delete the installation directory.

If you have the agent installed the agent as a service, you must also [stop the Database Agent](#) service.

To prevent a Database Agent from connecting to the Controller, ensure that it doesn't start up. This frees the license associated with the agent in the Controller and makes it available for use by another Database Agent.

Configure the Database Agent

Once you have installed and launched the Database Agent, you can further customize the agent.

- [Database Agent Configuration Properties](#)
- [Enable SSL and SSH for Database Agent Communications](#)
- [Enable Snapshot Correlation for Oracle](#)
- [Increasing JVM Memory](#)
- [Database Agent Logging](#)

Database Agent Configuration Properties

This page describes how configure a Database Agent.

Related pages:

- [Administer the Database Agent](#)

Where to Configure Database Agent Properties

You can configure agent properties in the following locations:

- The `controller-info.xml` file located in the `<db_agent_home>/conf` directory
- The system properties (`-D options`) section in the JVM start-up command. The system properties override the settings in the `controller-info.xml` file. System properties are case-sensitive.

```
java -XX:+HeapDumpOnOutOfMemoryError -XX:OnOutOfMemoryError="kill -9 %p" -jar db-agent.jar
```

Alternatively, you can use a script to start the agent.

Windows	<code>start-dbagent.bat -Xms<min_heap_size> -Xmx<max_heap_size></code>
Linux	<code>./start-dbagent -Xms<min_heap_size> -Xmx<max_heap_size> &</code>

Example Database Agent controller-info.xml File

```
<?xml version="1.0" encoding="UTF-8"?>
<controller-info>

  <controller-host>192.10.10.10</controller-host>
  <controller-port>8090</controller-port>
  <account-access-key>165e65645-95c1-40e3-9576-6a1424de9625</
account-access-key>
  <!-- The following attribute enables or disables SSL
communications between the agent and the Controller.-->
  <controller-ssl-enabled>>false</controller-ssl-enabled>

  <!-- The following account-related parameters are necessary
only for SaaS installations-->
  <!--account-name></account-name-->

</controller-info>
```

Example Startup Configuration Using System Properties

A bash example. Note that the system properties are case-sensitive.

```
-Dappdynamics.controller.hostName=192.168.1.20  
-Dappdynamics.controller.port=8090
```

Database Agent Properties

This section describes the Database Agent configuration properties, including their `controller-info.xml` elements and their system property options.

Required System Properties

Path to the Agent jar File

Description: Provides the absolute path to the jar file.

System Property: `-jar`

Value: `<db_agent_home>db-agent-jar`

Type: ASCII string, including spaces. If `<db_agent_home>` contains spaces, you must enclose the entire name in double quotes (" ").

Required: Yes

Example: `-jar="D:\AppDynamics\Database Agent\db-agent.jar"`

Path to the Java Library

Description: Provides the absolute path to `sqljdbc_auth.dll`.

System Property: `-Djava.library.path`

Value:

- For 64-bit systems: `<db_agent_home>\auth\x64`
- For 32-bit systems: `<db_agent_home>\auth\x32`

Type: ASCII string, including spaces. If `<db_agent_home>` contains spaces, you must enclose the entire name in double quotes (" ").

Required: Recommended. Required for SQL Server Windows Authentication on Windows 64-bit systems.

Example: `-Djava.library.path="D:\AppDynamics\Database Agent\auth\x64"`

Optional System Properties

Disable Retry on Auth Failure

Description: Stops retrying to establish JDBC connection when JDBC authentication fails.

System Property: `-Dretry.on.auth.failure=false`

Default: The system property is set to true.

Type: String

Supported Locales for Parsing Numbers

Description: Specifies which locale to use for parsing numbers. See [Java 7 Supported Locales](#) or [Java 8 Supported Locales](#) for valid values. Use the values for the Java version that you are running in your environment.

System Property: `-Ddbagent.language`

Default: The system property is set to `en-US` or `en_US`.

Type: String

Agent-Controller Communication Properties

Controller Host Property

Description: This is the host name or the IP address of the AppDynamics Controller, for example, 192.168.1.22 or myhost or myhost.abc.com. This is the same host that you use to access the AppDynamics Controller UI.

Element in controller-info.xml: `<controller-host>`

System Property: `-Dappdynamics.controller.hostName`

Environment Variable: `APPDYNAMICS_CONTROLLER_HOST_NAME`

Type: String

Default: None

Required: Yes

Controller Port Property

Description: This is the HTTP(S) port of the AppDynamics Controller. This is the same port that you use to access the AppDynamics browser-based user interface. If the Controller SSL Enabled property is set to true, specify the HTTPS port of the Controller; otherwise, specify the HTTP port. See **Controller SSL Enabled Property**.

Element in controller-info.xml: `<controller-port>`

System Property: `-Dappdynamics.controller.port`

Environment Variable: `APPDYNAMICS_CONTROLLER_PORT`

Type: Positive Integer

Default: For on premises installations, port 8090 for HTTP and port 8181 for HTTPS are the default ports the Controller listens to.

For the SaaS Controller Service, port 80 for HTTP and port 443 for HTTPS are the default ports the Controller listens to.

Required: Yes

Account Access Key Property

Description: This is the account access key used to authenticate with the Controller.

Element in controller-info.xml: `<account-access-key>`

System Property: `-Dappdynamics.agent.accountAccessKey`

Environment Variable: `APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY`

Type: String

Default: None

Required: Yes. Earlier than 4.1, this property was required only for SaaS and multi-tenant Controllers. The account access key property is now required to authenticate all agent to Controller communications.

Example: `-Dappdynamics.agent.accountAccessKey=165e65645-95c1-40e3-9576-6a1424de9625`

Multiple Agent Environment Properties

The following properties are useful when you are configuring your system to include more than one Database Agent.

Database Agent Name Property

Description: This property uniquely identifies the Database Agent to the Controller.

System Property: `- Ddbagent.name=<db_agent_name>`

Type: ASCII string, including spaces. If `<agent_name>` contains spaces, you must enclose the entire name in double quotes (" ").

Default: Default Database Agent

Required: Required when you have more than one Database Agent reporting to the Controller.

You may want to run multiple **Database Agents** under the following conditions:

- When you have databases spread across multiple networks, and one machine cannot access all the databases on all the networks. In this case, you can have a uniquely named Database Agent in each network that monitors the databases only visible on that network.
- If you have multiple SQL Server instances that each require different credentials, and you want to connect to them via Windows Authentication. When using Windows Authentication, the Database Agent will use the credentials of the currently logged in user.
- When you want one or more agents to back up a primary agent. The database agent names for your backup agents must match the database agent name of your primary agent. The last agent you launch will be the primary agent.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Example: `-Ddbagent.name="Scarborough Network Database Agent"`

Unique Host ID

Description: The Unique Host ID logically partitions a single physical host or virtual machine such that it appears to the Controller that the application is running on different machines. Set the value to a string that is unique across the entire managed infrastructure. The string must not contain any spaces. If you have a machine agent that is running on the same host as that of the database agent, then this property value must be different than that of the machine agent. If you are running multiple database agents from the same host with the same name, then this property value must be different for those agents.

System Property: `-Dappdynamics.agent.uniqueHostId`

Type: String

Default: None

Environment Variable: `APPDYNAMICS_AGENT_UNIQUE_HOST_ID`

Multi-Tenant Mode Properties

If the AppDynamics Controller is running in multi-tenant mode or if you are using the AppDynamics SaaS Controller, specify the account name and account access key for this agent to authenticate with the Controller.

If the Controller is running in single-tenant mode (the default) there is no need to configure these values.

Account Name Property

Description: This is the account name used to authenticate with the Controller. If you are using the AppDynamics SaaS Controller, the Account Name is in the Welcome email AppDynamics sent to you.

Element in controller-info.xml: `<account-name>`

System Property: `-Dappdynamics.agent.accountName`

Environment Variable: `APPDYNAMICS_AGENT_ACCOUNT_NAME`

Type: String

Default: None

Required:

Yes for AppDynamics SaaS Controller and other multi-tenant users

No for single-tenant users

Proxy Properties for the Controller

These properties route data to the Controller through a proxy.

Proxy Host Property

Description: This is the proxy host name or IP address.

Element in controller-info.xml: Not applicable

System Property: `-Dappdynamics.http.proxyHost`

Type: String

Default: None

Required: No

Proxy Port Property

Description: This is the proxy HTTP(S) port.

Element in controller-info.xml: Not applicable

System Property: `-Dappdynamics.http.proxyPort`

Type: Positive Integer

Default: None

Required: No

Proxy User Name

Description: The name of the user that is authenticated by the proxy host.

Element in controller-info.xml: Not applicable

System Property: `-Dappdynamics.http.proxyUser`

Type: String

Default: None

Required: No

Proxy Password

Description: The absolute path to the file containing the password of the user that is authenticated by the proxy host. The password must be the first line of the file.

If [Use Encrypted Credentials](#) is false, enter the password in plain text. If [Use Encrypted Credentials](#) is true, encrypt the password. See [Encrypt Agent Credentials](#).

Element in controller-info.xml: Not applicable

System Property: `-Dappdynamics.http.proxyPasswordField`

Type: String

Default: None

Required: No

Other Properties

Controller SSL Enabled Property

Description: This property specifies whether the agent should use SSL (HTTPS) to connect to the Controller. If SSL Enabled is true, set the Controller Port property to the HTTPS port of the Controller. See **Controller Port Property**.

Element in controller-info.xml: `<controller-ssl-enabled>`

System Property: `-Dappdynamics.controller.ssl.enabled`

Environment Variable: `APPDYNAMICS_CONTROLLER_SSL_ENABLED`

Type: Boolean

Default: False

Required: No

Enable SSL and SSH for Database Agent Communications

Enable SSL for the Database Agent

This page describes how to configure the Database Agent to connect to the Controller using SSL. It assumes that you use a SaaS Controller or have configured the on-premises Controller to use SSL.

The Database Agent supports extending and enforcing the SSL trust chain when in SSL mode.

Requirements

Gather this information:

- The Controller SSL port.
 - For SaaS Controllers the SSL port is 443.
 - For on-premises Controllers the default SSL port is 8181, but you may configure the Controller to listen for SSL on another port.
- The signature method for the Controller's SSL certificate:
 - A publicly known certificate authority (CA) signed the certificate. This applies for DigiCert, Verisign, Thawte, and other commercial CAs.
 - A CA internal to your organization signed the certificate. Some companies maintain internal certificate authorities to manage trust and encryption within their domain.
 - The Controller uses a self-signed certificate.

Establish Trust for the Controller's SSL Certificate

To establish trust between the Database Agent and the AppDynamics Controller, you must create an agent truststore that contains the root certificate for the authority that signed the Controller's certificate.

i If you secured your on-premises Controller with a self-signed certificate, see [Keystore Certificate Extractor Utility](#) for instructions to create the agent keystore.

1. Obtain one of the following root certificates:
 - DigiCert Global Root CA for the AppDynamics SaaS Controller
 - Root certificate for the publicly known certificate authority (CA) that signed the certificate for your on-premises Controller
 - Root certificate for the internal CA that signed the Controller certificate for your on-premises Controller
2. Run the Java keytool command to create the Database Agent truststore:

```
keytool -import -alias rootCA -file  
<root_certificate_file_name> -keystore cacerts.jks -storepass  
<truststore_password>
```

For example:

```
keytool -import -alias rootCA -file /usr/home/appdynamics/
DigicertGlobalRootCA.pem -keystore cacerts.jks -storepass
MySecurePassword
```

i Make note of the truststore password, you need it to configure the Database Agent.

3. Install the agent truststore to the Database Agent configuration directory:

```
<db_agent_home>/conf/
```

Secure the Database Agent Truststore

AppDynamics recommends you take the following security measures to prevent tampering with the Database Agent truststore:

- Secure the truststore file through file system permissions:
 - Make the Database Agent truststore readable by any user.
 - Make the truststore owned by a privileged user.
 - Make the truststore writable only by the specified privileged user.
- Secure the Database Agent configuration files so that they are only readable by the agent runtime user and only writable by a privileged user:
 - Global configuration file: `<db_agent_home>/conf/controller-info.xml`.

Configure SSL System Properties for the Database Agent

1. Configure the following system properties in the versioned `controller-`

`info.xml`: `<db_agent_home>/<version_number>/conf/controller-info.xml`. See "SSL

Configuration Properties" on [Database Agent Configuration Properties](#) for full details on each property.

- **Controller Port:** the SSL port for the Controller. 443 for AppDynamics SaaS.
`<controller-port>443</controller-port>`
- **Controller SSL Enabled:** true.
`<controller-ssl-enabled>>true</controller-ssl-enabled>`
- **Controller Keystore Password:** the plain text password for the Database Agent truststore.
`<controller-keystore-password>MySecurePassword</controller-keystore-password>`
- **Controller Keystore Filename:** path of the Database Agent truststore relative to `<db_agent_home>/<version>/conf`. Required if you use a truststore other than the default `<db_agent_home>/<version_number>/conf/cacerts.jks`.
`<controller-keystore-filename>../../conf/cacerts.jks</controller-keystore-filename>`

i You can specify the Controller port and enable SSL for the Controller in the JVM startup script, but you must specify the truststore password and filename in the `controller-info.xml` file.

2. Save your change to the `controller-info.xml` file and restart the Database Agent.

Sample SSL `controller-info.xml` Configuration

```
<?xml version="1.0" encoding="UTF-8"?>
<controller-info>
  <controller-host>mycompany.saas.appdynamics.com</controller-host>
  <controller-port>443</controller-port>
  <controller-ssl-enabled>true</controller-ssl-enabled>
  <controller-keystore-password>MySecurePassword</controller-keystore-password>
  <controller-keystore-filename>../../conf/cacerts.jks</controller-keystore-filename>
  ...
</controller-info>
```

Keystore Certificate Extractor Utility

The Keystore Certificate Extractor Utility exports certificates from the Controller's Java keystore for the Database Agent truststore. It installs to the following location:

```
<agent_home>/utils/keystorereader/kr.jar
```

To avoid copying the Controller keystore to a Database Agent machine, you can run this utility from the Controller server. Access the agent distribution on the Controller at the following location:

1. Run the Keystore Certificate Extractor Utility from the Controller:

```
% /<full path to application JRE>/bin/java -jar <controller_home>/appserver/glassfish/
domains/domain1/appagent/<controller_version>/utils/keystorereader/kr.jar
```

2. Enter the following when prompted:

- The full path to the Controller's keystore:

```
Enter input keystore: <controller_home>/appserver/glassfish/domains/domain1/config/
keystore.jks
```

- The truststore output file name. By default the Database Agent looks for `cacerts.jks`.

```
Enter output agent truststore file name: <controller_home>/appserver/glassfish/
domains/domain1/config/keystore.jks
```

The password for the Controller's certificate, which defaults to "changeit". If you don't include a password, the extractor applies the password "changeit" to the output truststore.

◦ **Example command to execute kr.jar**

```
<full path to application JRE>/bin/java -jar kr.jar <controller_home>/appserver/  
glassfish/domains/domain1/config/keystore.jks cacerts.jks  
<controller_certificate_password>
```

3. Install the agent trust store to the agent configuration directory:

```
<db_agent_home>/conf/
```

Enable SSH for the Database Agent

i For Linux hosts only

Applies only when Database Agent is running on a Linux host.

When the Database Agent is running on Linux and you want to monitor hardware, except to monitor the local host, authentication is required and a password is passed between the Database Agent and the database server.

i SSH port option

The SSH port option does not appear unless the Database Agent is running on Linux.

1. On the agent machine, generate the rsa or dsa key as follows:

Generate rsa key

```
% ssh-keygen -b 1024 -f id_rsa -t rsa
```

or

Generate dsa key

```
% ssh-keygen -b 1024 -f id_dsa -t dsa
```

This will create a rsa or dsa 1024-bit key and put the keys into `/home/<user_name>/.ssh/id_rsa` and `/home/<user_name>/.ssh/id_rsa.pub` or `/home/<user_name>/.ssh/id_dsa` and `/home/<user_name>/.ssh/id_dsa.pub` files. Do not change the names of these files.

2. Copy the private key, `/home/<user_name>/.ssh/id_rsa` or `/home/<user_name>/.ssh/id_id_dsa` into the `<db-agent_home>/keys` directory.
3. On both the monitored machine and the agent machine, verify that you have the correct permissions on the `.ssh` directory, or set them as follows:

.ssh directory permissions

```
% cd /home/<user_name>
% chmod 755 .ssh
```

4. On the monitored machine, verify that you have a `/home/<user_name>/.ssh/authorized_keys` file. If you do not have this file, create the `authorized_keys` file on the monitored machine as follows:

Create authorized_keys file

```
% cd /home/<user_name>/.ssh
% touch .ssh/authorized_keys
```

5. Verify that you have the correct permissions to the `/home/<user_name>/.ssh/authorized_keys` file, or change the permissions as follows:

authorized_keys file permissions

```
% cd /home/<user_name>/.ssh
% chmod 644 authorized_keys
```

6. Append (do not copy) the file `'id_rsa.pub'` or the file `'id_dsa.pub'` to the file, `/home/<user_name>/.ssh/authorized_keys`, such as follows:

Append rsa public key to authorized key

```
% echo /home/<user_name>/.ssh/id_rsa.pub >> /home/<user_name>/.ssh/authorized_keys
```

or

Append dsa public key to authorized key

```
% echo /home/<user_name>/.ssh/id_dsa.pub >> /home/<user_name>/.ssh/authorized_keys
```

7. The SSH port of the database Collector is set to 22 by default. You can change it by navigating to the Monitoring Hardware section of the Collector configuration dialog. In the dialog, set the SSH port to the port you require.
8. Save your change to the Collector configuration and restart the Database Agent.

Enable SSH via PEM certificate

For Linux, AppDynamics also supports certificate-based authentication via Privacy Enhanced Mail (PEM). To implement certificate-based authentication:

1. Enable the **Use certificate** option in the Monitoring hardware section of the Collector configuration dialog.
2. Copy the PEM file to the `<db_agent_home>/keys` directory. Note, if the `home/<user_home>/.ssh` directory exists, the agent will use the certificate found there.
3. Restart the agent.

Monitor SSL-enabled PostgreSQL on Amazon RDS

To monitor a PostgreSQL instance that uses SSL connections, complete the following steps.

1. Create the `.postgresql` directory under the system home folder, then create a file, `root.crt` in the directory.
2. Download PEM file from Amazon and copy to a local directory.
3. Convert the PEM file to a DER file using the following `openssl` command:

```
openssl x509 -outform der -in rds-combined-ca-bundle.pem -out rds-combined-ca-bundle.der
```

4. Add the certificate to the Java keystore using the following command:

```
sudo keytool -import -noprompt -trustcacerts -alias AmazonRDS -file rds-combined-ca-bundle.der -keystore $JAVA_HOME/jre/lib/security/cacerts -storepass changeit
```

You can verify that the certificate was added by running the following command:

```
keytool -list -keystore $JAVA_HOME/jre/lib/security/cacerts -storepass changeit
```

5. Re-start the dbagent process to register the certificate you added.
6. In the Controller, create a new collector for PostgreSQL.
 - a. In the **Custom JDBC Connection String** field, enter the following JDBC string:

```
jdbc:postgresql://<RDS-Hostname>:<RDS-Port>/postgres?ssl=true
```
 - b. In the **ADVANCED OPTIONS** section, select **Connection Properties** and then specify these property details:

Property Name	Property Value
<code>sslrootcert</code>	The location of the downloaded PEM file
<code>sslmode</code>	<code>verify-full</code>

Monitor SSL-enabled MySQL on Amazon RDS

To monitor a MySQL instance that uses SSL connections, enable MySQL in SSL mode, consulting the online documentation appropriate to your deployment.

Download the files shown below as they are required to complete this procedure:

- ca.pem
- server-cert.pem
- server-key.pem
- client-cert.pem
- client-cert.key

Run the following commands at the command line. Substitute URLs and other information from your deployment for the placeholders in the examples.

1. Test your local SSL connection:

```
mysql -h ec2-11-111-111-11.us-west-2.compute.amazonaws.com -u Testssl --ssl-ca=/etc/certs/ca.pem --ssl-cert=/etc/certs/server-cert.pem --ssl-key=/etc/certs/server-key.pem -p
```

2. Verify the remote connection:

```
mysql -h ec2-11-111-111-11.us-west-2.compute.amazonaws.com -u Testssl --ssl-ca=/home/appdynamics/cert/ca.pem --ssl-cert=/home/appdynamics/cert/client-cert.pem --ssl-key=/home/appdynamics/cert/client-key.pem -p
```

3. Import the ca.pem file to the default truststore:

```
sudo keytool -importcert -alias MySQLCACert -file ca.pem -keystore $JAVA_HOME/jre/lib/security/cacerts -storepass changeit
```

- Do not forget the password, as you need it in step 7

4. Convert the client key and certificate files to a PKCS #12 archive:

```
openssl pkcs12 -export -in client-cert.pem -inkey client-key.pem -name "mysqlclient" -passout pass:changeit -out client-keystore.p12
```

5. Import the client key and certificate into a Java keystore:

```
sudo keytool -importkeystore -srckeystore client-keystore.p12 -srcstoretype pkcs12 -srcstorepass changeit -destkeystore $JAVA_HOME/jre/lib/security/cacerts -deststoretype JKS -deststorepass changeit
```

6. Verify that the certificate was added:

```
keytool -list -keystore $JAVA_HOME/jre/lib/security/cacerts -storepass mypassword
```

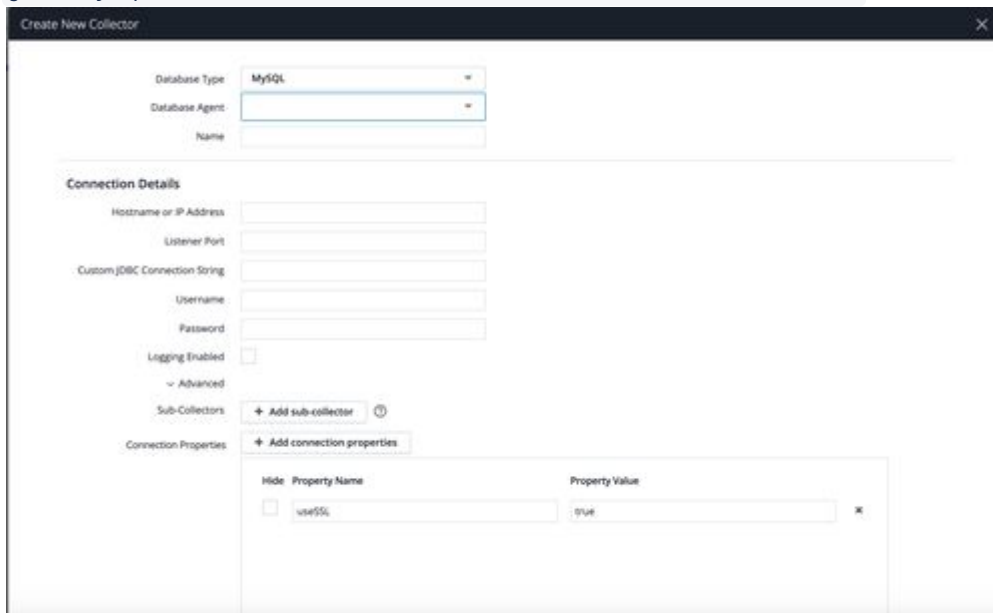

7. Start the db-agent after ensuring that the following properties are added:

```
/<full path to application JRE>/bin/java -jar -Djavax.net.ssl.trustStore=$JAVA_HOME/jre/lib/security/cacerts -Djavax.net.ssl.trustStorePassword=changeit -Djavax.net.ssl.keyStore=$JAVA_HOME/jre/lib/security/cacerts -Djavax.net.ssl.keyStorePassword=changeit db-agent.jar
```

8. In the Controller, create a new collector for MySQL

- In the Configuration panel, add the connection property with Property Name "useSSL" and Property Value "true"
- Alternatively, you can also use the following custom connection string:

```
jdbc:mysql://<RDS-Hostname>:<RDS-Port>/database?useSSL=true
```

Monitor SSL-enabled MongoDB

You can configure your MongoDB instance to use SSL connections.

1. Create a keystore on the database agent host.
2. Import the SSL certificates to this keystore using the following command:

```
keytool -importcert -trustcacerts -file <mongodb certificate location> -keystore  
<keystore e.g. path/mongo.jks> -storepass <keystore password> -alias <alias>
```

3. Start the database agent with the following flags:

```
java -Ddbagent.name=<DBAgent Name> -Djavax.net.ssl.trustStore=<keystore e.g. path/  
mongo.jks> -Djavax.net.ssl.trustStorePassword=<keystore password> -jar db-agent.jar
```

4. Create the mongodb collector with custom URL:

```
mongodb://<mongodb-host>:27017/?ssl=true
```

Enable Snapshot Correlation for Oracle

For the Oracle Collector AppDynamics Database Visibility to collect database queries, sessions, clients, and schemas information that occurred during snapshots captured by the Java Agent, you need to set the `jdbc-dbcam-integration-enabled` App Agent property for the Java Agent.

For information on the `jdbc-dbcam-integration-enabled` property, see [App Agent Node Properties](#).

For information on snapshot correlation between the Oracle database Collector and a Java business transaction, see [Access Database Visibility from Application Monitoring Views](#)

Increasing JVM Memory

To monitor multiple databases, you may need to increase the JVM memory allocation size. Increased activity on the databases you are monitoring results in increased memory usage.

Use one of the following commands to start the agent, and to initially allocate 1536 MB to the agent instead of the default of 64 MB.

For Windows 64-bit

```
C:\>java -Xmx1536m -Djava.library.path="<db_agent_home>\auth\x64" -jar <db_agent_home>\db-agent.jar
```

For Linux

```
% java -Xmx1536m -jar <db_agent_home>/db-agent.jar
```

Database Agent Logging

By default, the Database Agent writes log files to the `log` directory.

Configure Agent Logging

You can configure the agent to generate log files.

1. From the agent home directory, navigate to log directory.
2. Open `log4j.xml`.
3. Find `logger name="com "`. Inside this tag, set `level value` to `debug`, as shown below:

```
<logger name="com">
  <level value="debug"/>
</logger>
```

4. Let the agent run for 10 minutes to generate some logs.
5. From the agent home directory, navigate to the `log` directory to view your logs.

Start and Stop the Database Agent

Start the Agent

If you are using an on-premises version of Database Visibility, you must [start the Events Service](#) before you start the Database Agent. Before starting the agent, you must [configure the properties in this file](#). You must specify these properties:

- Controller Host Property
- Controller Port Property
- Account Access Key Property

Start the Agent in a Command Shell

The following assumes that all the necessary parameters have been specified in the `controller-info.xml`. The `controller-info.xml` file describes the properties of agent to Controller communications. Note that `<db_agent_home>` is the absolute path to the location where the Database Agent is installed. Setting the heap size is recommended as shown below. See [Database Visibility System Requirements](#).

Windows

```
cd <db_agent_home>
start-dbagent.bat -Xms<min_heap_size> -Xmx<max_heap_size>
```

Linux

```
cd <db_agent_home>
./start-dbagent -Xms<min_heap_size> -Xmx<max_heap_size> &
```

Start the Agent as a Service

See [Install the Database Agent as a Windows Service](#), [Start the Database Agent Automatically on Windows](#), and [Start the Database Agent Automatically on Linux](#).

Stop the Agent

Stop the Agent in a Command Shell

If the Database Agent process is running in the background, you can stop it by simply entering the kill command with the process ID as the argument. If it is running in the foreground in a console, you can press Ctrl+C to shut down the agent.

Stop the Agent Service in Windows

In the Windows Services application, select **AppDynamics Database Agent** and click **Stop**.

Start the Database Agent Automatically on Linux

Related pages:

- [Install the Database Agent](#)
- [Database Agent Configuration Properties](#)

To enable the Database Agent to start automatically whenever the machine starts up:

1. Create an initialization script that starts the agent, as in the sample [initialization script](#) that is an attachment to this page.
In your script, set the `JAVA` and `AGENT_HOME` values to the paths for your system. Also, configure agent options and heap size, as needed.

2. Enable execution permissions for the script. For example, given an initialization script named `db-agent`, enter:

```
sudo chmod 775 db-agent
```

3. Place the script in the initialization directory on your system, typically `/etc/init.d`. Alternatively, create a symbolic link to the script from the `init.d` directory to the script if you want to keep it in another location.
4. Add the script as a service as follows:

- For Red Hat and most Linux Operating Systems, run these commands, replacing `db-agent` with the name of your file or symbolic link:

```
chkconfig --add db-agent
chkconfig --level 2345 db-agent on
```

- For Ubuntu and Debian Operating Systems, run this command, replacing `db-agent` with the name of your file or symbolic link:

```
update-rc.d -f db-agent start 99 2 3 4 5 .
```

In the command:

- `start` is the argument given to the script (start, stop).
- `99` is the start order of the script (1 = first one, 99 = last one)
- `2 3 4 5` are the runlevels to start
- Be sure to include the dot (.) at the end of the command.

The Database Agent now starts automatically upon machine startup. When setting the agent to automatically start up using Task Scheduler when the machine starts or restarts, ensure the agent runs with the highest privileges available.

Start the Database Agent Automatically on Windows

Related pages:

- [Administer the Database Agent](#)
- [Database Agent Configuration Properties](#)
- [Database Visibility](#)

Most Windows server software runs as a service when the machine boots up. You can create a Windows service to run the Database Agent by executing a script bundled with the product.

Install the Database Agent as a Windows Service

To create the Database Agent as a Windows service, run the following command as an administrator:

```
cscript <db_agent_home>\InstallService.vbs <jvm_options>
```

`<db_agent_home>` is the path to the install directory.

A Windows service named `Appdynamics Database Agent` is created.

`SilentInstall` and `serviceName` are optional parameters, which can be used along with the preceding command. The following syntax shows how to add these parameters:

```
cscript <db_agent_home>\InstallService.vbs SilentInstall serviceName=<name_of_the_service>  
<jvm_options>
```

`<db_agent_home>` is the path to install directory, and `<name_of_service>` is the name that you want to use for renaming the service.

You can use `SilentInstall` to create the Database Agent as a Windows service in the silent mode where the script skips user input for installation.

For database Agent ≥ 20.5 , you can add a service with a different name or change the name of the service by using the `serviceName` parameter. If you do not specify any value for this parameter, the service name is set to `Appdynamics Database Agent` by default.

To use different Windows service name for different Database Agents, ensure that you run each Database Agent as a service from different install directories.

```
Administrator: Command Prompt

The screenshot below shows the Windows Service Control Manager.

If you choose to use Windows authentication for Microsoft SQL Server, you must change your login credentials and restart the database agent service.

Uninstall the Database Agent as a Service

To uninstall the database agent service, run the following command as an administrator:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
cscript <db_agent_home>\UninstallService.vbs
```

Uninstalled service 'Appdynamics Database Agent'.

Done.
Removing Database Agent VM options

Done.

C:\WINDOWS\system32>
```

Running the Agent on Windows Using the Task Scheduler

It is recommended to run the Database Agent as a Windows service. However, if you choose to run the agent using Task Scheduler, ensure the agent runs with the highest privileges available. When using Task Scheduler, if the host is restarted, the agent will not start automatically.

Add Database Licenses

Related pages:

- [Add Database Collectors](#)
- [License Management in the Controller](#)

The Controller requires a license for the total number of databases to monitor concurrently. For Database Agent license details, see [License Entitlements and Restrictions](#).

Manage Licenses in the Controller

To view and manage license consumption in the Controller, see [License Management in the Controller](#).

Transfer a License Between Databases

A database license is allocated to the first agents that register with the Controller up to the licensed limit.

To transfer a license for the Database Agent to another database, you simply remove the Collector for the old database and then add a new Collector for the database you want to monitor instead. See [Add Database Collectors](#).

If you disable a collector, it still consumes a license.

Configure Controller Settings for Monitoring Database

i GovAPM users do not have access to configuring controller settings for monitoring databases. To modify controller settings, contact support and specify that you are a FedRAMP or GovAPM user.

You can configure parameters for the controller, such as the number of events sent to the Events Service at a given time.

To change the Controller settings for Database Agents:

1. Log in to the Administration Console.
2. Click **Controller Settings**.
3. Change the settings as needed and **Save**.

Controller Settings

Property Name	Property Overview	Default	Minimum Value
<code>dbmon.event.publisher.esclient.batch.size</code>	Batch size for each Event Service client used by Database Monitoring.	1500	200
<code>dbmon.event.publisher.queue.size</code>	Maximum measurement queue size maintained by Database Monitoring.	10000	10000
<code>dbmon.config.data.retentionperiod</code>	Number of days to retain database monitoring data (queries, clients, users, sessions, schemas) excluding the current day. Data reported before the retention period might be unrecoverable, even for a momentary update of this property.	10	1
<code>dbmon.config.max.custommetric</code>	Number of custom metrics that can be created per collector.	40	0

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Configure the Agent Settings for Monitoring Database

This page provides information about the different agent properties that are used for database monitoring. For configuring the basic agent properties, see [Database Agent Configuration Properties](#).

You can update the following properties using the `controller-info.xml` file located in the `<db_agent_home>/conf` directory.

The following table includes the property names that can be used for any specific database or for all the databases along with the purpose of the properties.

Agent Properties for Monitoring Relational Databases

Property Name	Database	Purpose
<code>-Ddbagent.disable.sybase.ase.system.monitoring</code>	Sybase	<p>This property specifies whether the agent should monitor Sybase. You may want to disable Sybase monitoring if you are already using other database monitoring tools. Database Visibility will stop executing SQL queries for Sybase databases. As a result, the following metrics might not show reliable data:</p> <ul style="list-style-type: none"> • Calls per Minute (KPI) • All metrics under Server Statistic in the Metric Browser • The Load value on the Sybase dashboard

Property Name	Database	Purpose
-Ddbagent.sampling.interval	All relational database	This is the interval at which queries are sampled. The interval can be 1s, 2s, 5s, 10s, 20s, or 30s. For example, if you have configured the property value as 2s, the Time is displayed for 2s, 4s, 6s, and so on (in increments of 2).

Property Name	Database	Purpose
---------------	----------	---------

 This property can be used for MongoDB Bandwidth

Agent properties for monitoring Cassandra

Property Name	Purpose	Default Value
<code>dbagent.cassandra.sampling.interval.seconds</code>	The interval at which queries are sampled. According to the sampling interval (between 1 and 60), the sampling threshold is set (between 300 ms and 1000 ms).	10
<code>dbagent.cassandra.max.query.execution.time.seconds</code>	Maximum query execution time. Queries executing for more than this duration are not be sampled.	300
<code>dbagent.cassandra.query.sampling.limit</code>	The maximum number of queries to sample in a single sampling period. If this value is 0, query sampling is disabled.	100,000
<code>dbagent.cassandra.dse.skip.slow.query.table.for.sampling</code>	Whether to use sampling from query traces instead of the node_slow_log table for DSE Cassandra.	false

Property Name	Purpose	Default Value
<code>dbagent.cassandra.apache.sampling.threshold.in.milliseconds</code>	<p>Defines the sampling threshold for Apache Cassandra. In other words, queries taking more than this threshold to execute, are sampled by the database agent.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p> This property sets a fixed sampling threshold. To use a dynamic sampling threshold based on the sampling interval set a negative value to this property.</p> </div>	-1

Add Database Collectors

To enable the Database Agent to collect data, you must add and configure a Database Collector for each database that you want to monitor. The Database Collector is the process that runs within the Database Agent to collect performance metrics about your database instances and database servers.

Required Database Permissions

You must have the required permissions to monitor your databases. See [Database Visibility Supported Environments](#).

AppDynamics Permissions

To add, edit, and create collectors, users need a role with the proper permissions:

- Can Create Collectors
- Can Edit All Collectors
- Can Delete All Collectors

See [Database Permissions](#).

Add a Database Collector

1. Click the Configuration tab in the left panel menu.
2. Click the **Collectors** option.
3. In the Collectors panel, click **Add (+)**.
4. Complete each field of the **Create New Collector** dialog
5. If you want to add a sub-collector to be monitored, click **Advanced >> +Add sub-collector** to enter host and port details.

 Sub-collectors are applicable only to relational database types.

6. Click **OK**. Your database administrator can provide you with the necessary details.

After you have added a collector, you can configure the collector for your database. You can also [link a database](#) on the application flow maps to a database instance monitored by Database Visibility.

Hardware Monitoring

For information on the fields to complete in order for the Database Agent to monitor the server hardware in addition to the database, see [Configure the Database Agent to Monitor Server Hardware](#).

Verify Collector Setup

Once the Collector is up and running, in just a short time you can start viewing the historical activity data.

The Collector configuration window now has a collector icon you can click to edit the details of the collector if required. The Collector will also appear in the list of Databases shown in the left navigation menu. It might take a few minutes before the Collector and its metrics are reported.

From the left navigation menu, click **Databases** to see a high-level view of the activity of all the configured Collectors.

Click the name of the database to see more details of the metrics AppDynamics Database Monitoring has captured.

For information on using and interpreting the Collector windows, see [Monitor Databases and Database Servers](#).

Edit a Database Collector

From the Collectors panel, you can edit any of the details of the collector except the type of database platform to monitor.

For more information on collector fields, see the collector configuration page for your database.

- [Configure IBM DB2 Collectors](#)
- [Configure Microsoft SQL Server Collectors](#)
- [Configure Microsoft Azure Collectors](#)
- [Configure MongoDB Collectors](#)
- [Configure MySQL Collectors](#)
- [Configure Oracle Collectors](#)
- [Configure PostgreSQL Collectors](#)
- [Configure Sybase Collectors](#)
- [Configure Sybase IQ Collectors](#)

Delete a Database Collector

From the Collectors panel, you can delete a database Collector.

Export Database Collector Data

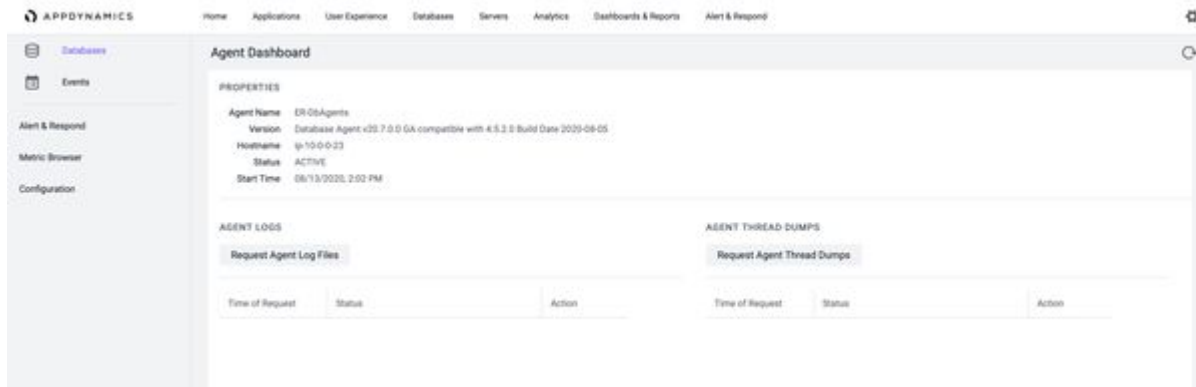

From the Collectors panel, you can click on **Actions > Export Data** to generate a CSV file containing the following data for each collector:

- Collector name
- Host name
- Port number
- Username
- Database type
- Agent name

View Database Agent Properties and Logs

You can view the database agent properties along with the agent logs and thread dumps by accessing **Agent Dashboard**. These logs are required for debugging and troubleshooting the issues.

To access **Agent Dashboard**, click the agent name under **Agent Name** on the **Collectors** page.

You can click **Request Agent Log files** to either download logs from a specific logger by setting a specific log level for a specific duration or download all logs.

You can click **Request Agent Thread Dumps** to download the required number of thread dumps.

See [Agent Log Files](#) and [Request Agent Log Files](#).

Troubleshooting Collector Problems

Collectors that have not been configured correctly, or that cannot connect to the database for any reason, will show an error on the **Databases** overview page and individual database dashboards. Hovering over the error icon displays the potential reason for the error.

If your Collector isn't reporting any metrics after a few minutes, and you know the database is up and running with activity, check the **Events** panel. [Agent Diagnostic Events](#) can appear if the password is incorrect or communication errors have occurred. The message summaries on the **Events** panel can help you diagnose and troubleshoot Collector problems.

Check the collector configuration to ensure all the values you entered are correct.

Ensure that your Database Agent has network connection to the databases you want to monitor along with the required permissions. See [Database Monitoring Requirements and Supported Environments](#).

Configure Cassandra Collectors

This page provides configuration details for Cassandra collectors.

Prerequisites

To monitor Cassandra with Database Visibility, you must be running version:

- Apache Cassandra >= 3.11.4
- Datastax Enterprise (DSE) Cassandra >= 6.7.3

Connection Details

	Field	Description
Create New Collector	Database Type	The Database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent.
	JMX Port	The port to remotely connect through JMX (optional for DSE Cassandra). See JMX Configurations .
	JMX Username	The name of the JMX user who is connecting to and monitoring the database using the Database Agent. See JMX configurations .
	JMX Password	The password of the JMX user who is connecting to and monitoring the database through the Database Agent.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

	Field	Description
Username and Password	Username	The name of the user who is connecting to and monitoring the database using the Database Agent. The user must have the permissions described in: <ul style="list-style-type: none"> • User Permissions for Apache Cassandra • User Permissions for DSE Cassandra
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
Advanced Options	SSL Connection	Click to enable SSL Connection: <ul style="list-style-type: none"> • Truststore Location: Location of the certificate on the DB Agent host. • Truststore Type: Type of SSL Connection. There are two truststore types: <ul style="list-style-type: none"> PKCS12 (default) SSO: Enables auto-login. If you use SSO, you only need to provide the truststore location and truststore type • Truststore Password: Password for SSL Connection. <p>If you also use client certificate authentication, then click the Enable SSL Client Authentication box.</p> <ul style="list-style-type: none"> • Keystore Location: location of the certificate on the DB Agent host • Keystore Type: type of SSL Connection • Keystore Password: password for SSL Connection
	Monitor Operating Systems	See Configure the Database Agent to Monitor Server Hardware .

Cassandra Configurations

These are the required configurations:

- **Query Capture Configurations**
 - [Apache Cassandra](#)
 - [DSE Cassandra](#)
- **JMX Configurations for Apache/DSE Cassandra**
 - a. Open `cassandra-env.sh` file.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

b. To enable JMX for:

- i. local connection, under the if [`"$LOCAL_JMX" = "yes"`]; then statement, set:

```
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.authenticate=true"
```

- ii. for remote connection, under the corresponding else statement, set:

```
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.authenticate=true"
```

c. Set the path to the credentials file, `jmxremote.password` :

```
JVM_OPTS="$JVM_OPTS -Dcom.sun.management.jmxremote.password.file=PATH TO FILE"
```

- d. In the `jmxremote.password` file, set JMX credentials to be the same as that of the database user credentials to be specified in the collector configuration:

```
username password
```

i You may choose to give ReadOnly JMX access to the database monitoring user by defining in the `jmxremote.access` file as mentioned in [Enabling JMX authentication and authorization](#).

Database Column Families Panel

To see the Top N Queries run on a column family, double-click or single-click the column family, and then click **View Top Queries**. For more details about a query, double-click a query to open the Query Details panel.

Access the Column Lists Panel

To access the **Column Lists** panel:

1. Click the name of the database from the list.
2. Click the Column Families tab. You may have to click the expand button (>>) to see the tab. Use the **Top column families** dropdown to view information for the top 10, 50, 100 or 200 column families sorted by total time spent in the database.

Features of the Column Families Panel

On the **Database Column Families** panel, you can see this information:

- **Column Family:** The names of the column families on which queries have been executed in this database.
- **Keyspace:** The names of the keyspace on which queries have been executed in this database.
- **Elapsed Time:** Duration of time queries executed in the column family.
- **Weight (%):** Time spent on executing queries on column families as a percentage of the total time spent by all column families.

Column Family	Keyspace	Elapsed Time	Weight (%)
load_test	loadkeyspace	0h 45m 53s	99
N/A	N/A	0h 0m 15s	1

Click **Actions** to export the data on this panel in a `.csv` formatted file that is automatically downloaded to your specified downloads directory.

Enable Cassandra Monitoring

Before you can enable Cassandra monitoring, you must meet these requirements:

- Controller \geq 4.5.17
- Database Agent \geq 4.5.16
- Set the account level property to " `dbmon.cassandra.monitoring.enabled` ":

To enable Cassandra monitoring :

1. Go to `<controller_url>/admin.jsp` , then click **Account Settings**. A list of accounts display.
2. Select an account from the list of options to enable Cassandra monitoring, then click **Edit**.
3. Click **+ Add Property**. Two blank fields display.
4. Enter `dbmon.cassandra.monitoring.enabled` and `true` in the first and second blank fields, respectively.

5. Select **Save**.

Query Capture Configurations for Apache Cassandra

The Database Agent captures only traced queries. To enable query tracing:

1. [Turn on tracing in the CQLSH prompt](#)
2. [Enable tracing for the statement/prepared statement in the client application](#)
3. [Enable probabilistic tracing](#)

Add this configuration to the `cassandra.yaml` file:

```
# TTL for different trace types used during logging of the repair process.  
tracetype_query_ttl: 300
```

This reduces the persistence of entries in `system_traces` keyspace (sessions and events) from 24 hours to 30 minutes. You may allow longer retention based on the number of queries being traced.

User Permissions for Cassandra

These are the user permissions to configure Cassandra:

```
CREATE ROLE appdynamics_role;  
GRANT SELECT ON KEYSPACE system_traces TO appdynamics_role;  
GRANT appdynamics_role TO appdynamics;
```

Query Capture Configurations for DSE Cassandra

In the `dse.yaml` file, configure (or uncomment and edit) these parameters:

```

cql_slow_log_options:
  enabled: true
  # When t > 1, log queries taking longer than t milliseconds.
  #   0 <= t <= 1, log queries above t percentile
  threshold: 2000
  # Initial number of queries before percentile filter becomes active
  minimum_samples: 100
  ttl_seconds: 259200
  # Keeps slow queries in-memory only and doesn't write data to the database.
  # WARNING - if this is set to 'false' then set threshold >= 2000, otherwise there will be
  a
  # high load on the database.
  skip_writing_to_db: false
  # The number of slow queries to keep in-memory
  num_slowest_queries: 5
  
```

You can adjust all of these parameters, except "enabled" and "skip_writing_to_db", per the monitoring requirements.

User Permissions for DSE Cassandra

```

CREATE ROLE appdynamics_role;
GRANT SELECT ON KEYSPACE system_traces TO appdynamics_role;
GRANT SELECT ON TABLE dse_perf.node_slow_log TO appdynamics_role;
GRANT appdynamics_role TO appdynamics;
  
```

Configure Couchbase Collectors

To monitor Couchbase with Database Visibility, you must have:

- Couchbase >= 4.5
- Database Agent >= 20.x

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for Couchbase .
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
Advanced Options	Exclude Databases	The databases that you want to exclude, separated by commas.
	Monitor Operating Systems	See this page for more details, Configure the Database Agent to Monitor Server Hardware .

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

User Permissions for Couchbase

The monitoring user must have Full Administrator or Read-only Administrator privileges. Alternatively, if you do not want the monitoring user to have Administrator privileges, you can assign a combination of Data Monitoring and Query System Catalog privileges (available for Couchbase >= 5).

Configure IBM DB2 Collectors

This page describes configuration details for IBM DB2 collectors.

Prerequisites

To monitor IBM DB2 with Database Visibility, you must be running DB2 >= 9.x.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Database	The name of the database instance that you want to monitor. <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> If the database instance hosts multiple databases, ensure to create separate collector for each database. </div>
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent.
	Custom JDBC Connection String	The JDBC connection string generated by the database agent, for example, <code>jdbc:db2://</code> . You can also specify a custom connection string, which is useful for setting custom authentication options. If you are using the connection string for Kerberos authentication, ensure to select the Kerberos option under Advanced Options .

Section	Field	Description
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for IBM DB2 LUW .
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
	Cyberark	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the <code>JavaPasswordSDK.jar</code> file from the CyberArk web site and rename the file to <code>cyberark-sdk-9.5.jar</code> . Then, you must copy the JAR file to the lib directory of the database agent zip file.

Section	Field	Description
Advanced Options	Sub-Collectors	<p>Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. To monitor a custom cluster, you can add additional hostname or IP address, and port details for each sub-collector. You can add up to a total of 29 sub-collectors. Thereby, 30 databases can be monitored in a custom cluster. In addition to the licenses consumed by the main collector, each sub-collector consumes one or more licenses, depending on the database type.</p> <div style="border: 1px solid #0070C0; background-color: #D9E1F2; padding: 10px; margin-top: 10px;"> <p>Note</p> <ul style="list-style-type: none"> All connection parameters other than the hostname or IP address, and port details of the sub-collector are the same as the main collector. If you want to specify different parameters for the sub-collectors, while creating or editing the collector configuration, you can do that only through the Create Collector API. You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data. </div>
	Connection Properties	<p>Click to add a new JDBC connection property or edit an existing property for relational databases.</p> <p>For monitoring the database using Kerberos authentication, follow the instructions mentioned at Monitor IBM DB2 Databases Using Kerberos Authentication.</p>
	Kerberos	Click to use Kerberos authentication to manage the database user and host user passwords.
	Monitor Operating System	See Configure the Database Agent to Monitor Server Hardware .

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

User Permissions for IBM DB2 LUW

The monitoring user needs SYSMON authority and connection privileges to monitor. This user must be a part of the sysmon_group.

To generate an execution plan, you must create the associated EXPLAIN tables in the schema.

DB2 >= 9.7

For complete Database Visibility functionality, the following monitoring switches of the DB2 server need to be enabled: "TIMESTAMP".

To enable the "TIMESTAMP" monitoring switch, enter:

```
update dbm cfg using dft_mon_timestamp on;
update db cfg using mon_act_metrics BASE
```

Privileges

```
grant select on SYSIBMADM.MON_CURRENT_SQL to user DBMon_Agent_User
grant select on SYSIBMADM.MON_LOCKWAITS to user DBMon_Agent_User
grant execute on function SYSPROC.MON_GET_CONNECTION to user DBMon_Agent_User
grant execute on function SYSPROC.MON_GET_PKG_CACHE_STMT to user DBMon_Agent_User
(version 10.5 and above) grant execute on function SYSPROC.MON_GET_TRANSACTION_LOG to
DBAgent_User
(version 10.5 and above) grant execute on function SYSPROC.MON_GET_DATABASE to DBAgent_User
```

Replace `DBMon_Agent_User` with the user name under which you run the Database Visibility Agent.

DB2 9.5

For complete Database Visibility functionality, the following monitoring switches of the DB2 server need to be enabled: "STATEMENT", and "TIMESTAMP".

To enable these monitoring switches, enter:

```
update dbm cfg using dft_mon_stmt on;
update dbm cfg using dft_mon_timestamp on;
```

Privileges

```
grant select on SYSIBMADM.SNAPSTMT to user DBMon_Agent_User
grant select on SYSIBMADM.SNAPAPPL_INFO to user DBMon_Agent_User
grant select on table SYSIBMADM.ENV_PROD_INFO to user DBMon_Agent_User
```

where `DBMon_Agent_User` is the user name under which you run the Database Visibility Agent.

User Permissions When restrict_access is Set to YES

If your database has the `restrict_access` parameter set to YES, you must grant these privileges:

```
grant select on SYSIBMADM.MON_CURRENT_SQL to user DBMon_Agent_User;
grant select on SYSIBMADM.MON_LOCKWAITS to user DBMon_Agent_User;
grant execute on function SYSPROC.MON_GET_CONNECTION to user DBMon_Agent_User;
grant select on SYSIBMADM.SNAPAPPL_INFO to user DBMon_Agent_User;
grant EXECUTE on function SYSPROC.MON_GET_PKG_CACHE_STMT to user DBMon_Agent_User;
grant execute on function SYSPROC.MON_GET_TRANSACTION_LOG to user DBMon_Agent_User;
grant EXECUTE on package NULLID.SQLC2K26 to user DBMon_Agent_User;
grant select on SYSIBM.SYSDUMMY1 to user DBMon_Agent_User;
grant select on SYSIBMADM.ENV_PROD_INFO to user DBMon_Agent_User;
grant select on SYSIBMADM.ENV_SYS_RESOURCES to user DBMon_Agent_User;
grant execute on function SYSPROC.SNAP_GET_STMT(varchar(),Integer) to user DBMon_Agent_User;
grant select on SYSCAT.STATEMENTS to user DBMon_Agent_User;
grant select on SYSIBMADM.DBCFG to user DBMon_Agent_User;
grant execute on function SYSPROC.SNAP_GET_DB(varchar(),Integer) to user DBMon_Agent_User;
grant EXECUTE on package NULLID.SYSSH200 to user DBMon_Agent_User;
grant select on SYSIBMADM.ENV_SYS_RESOURCESto user DBMon_Agent_User;
grant select on SYSCAT.DBAUTH to user DBMon_Agent_User;
grant execute on function SYSPROC.SNAP_GET_DBM(Integer) to user DBMon_Agent_User;
grant select on syscat.schemata to user DBMon_Agent_User;
```

Replace `DBMon_Agent_User` with the user name under which you run the Database Visibility Agent.

Generate Execution Plans

To generate an execution plan in DB2, the monitoring user ID must have access to the `explain_*` tables.

1. Create the explain tables one of these methods:

- Call the `SYSPROC.SYSINSTALLOBJECTS` procedure: `{{}}`

```
{{db2 CONNECT TO database-name
db2 }}
```

```
{{CALL SYSPROC.SYSINSTALLOBJECTS('EXPLAIN', 'C',
CAST (NULL AS VARCHAR(128)), CAST (NULL AS VARCHAR(128)))}}
```

This call creates the explain tables under SYSTOOLS schema. To create them under a different schema, specify a schema name as the last parameter in the call.

- Run the `EXPLAIN.DDL` command file: `{{}}`

```
{{db2 CONNECT TO database-name
db2 -tf EXPLAIN.DDL}}
```

```
{{}}
```

 Explain plans will not function properly unless the monitoring user ID is granted SELECT privilege on every table being accessed in the SQL as well as the necessary explain_* tables.

Monitor IBM DB2 Databases Using Kerberos Authentication

For the Database Agent to connect to and monitor the DB2 databases using Kerberos authentication, these settings are required:

- Start the Database Agent using the `Djava.security.krb5.conf="<path of the Kerberos configuration file>"`:

```
nohup java -Djava.security.krb5.conf="<path to Kerberos configuration file>"
```

- In the **CONNECTION DETAILS** section of the Collector configuration dialog, specify **Hostname or IP Address, Database, Listener Port**, and **Custom JDBC Connection String** with Kerberos details:

```
jdbc:DB2:Tds:<hostname>:<portnum>?<Kerberos connection details>
```

- In the **ADVANCED OPTIONS** section of the Collector configuration dialog, ensure to provide these details:
 - Select **Kerberos**.
 - Select **Connection Properties**, then specify these JDBC connection properties:

Property Name	Property Value
securityMechanism	11
kerberosServerPrincipal	<Specify the name of the Kerberos Principal>

Configure Microsoft SQL Server Collectors

This page provides configuration details for Microsoft SQL Server collectors.

Prerequisites

To monitor Microsoft SQL Server with Database Visibility, you must be running the 2005 version or newer.

 To configure an Azure SQL Managed instance, follow the configuration procedures of a Microsoft SQL Server Collector described in this topic.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on. To monitor a cluster, specify the hostname or IP address of the listener of the cluster. See Monitor the Microsoft SQL Server Cluster to enable monitoring the MSSQL cluster.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent. If you are using a Microsoft SQL Server cluster, specify the listener port of the cluster. To enable monitoring of all the nodes in a cluster, you must enable the monitoring of the cluster. This allows the agent to automatically discover all the nodes present in a cluster. See Monitor the Microsoft SQL Server Cluster

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Section	Field	Description
	Windows Authentication	Click to enable Windows authentication when connecting to the database.
	Custom JDBC Connection String	The JDBC connection string generated by the database agent, for example, <code>jdbc:sqlserver://</code> . You can also specify a custom connection string, which is useful for setting custom authentication options.
User name and Password	User name	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for Microsoft SQL Server.
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
	CyberArk	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the <code>JavaPasswordSDK.jar</code> file from the CyberArk web site and rename the file to <code>cyberark-sdk-9.5.jar</code> . Then, you must copy the JAR file to the <code>lib</code> directory of the database agent zip file.

Section	Field	Description
Advanced Options	Sub-Collectors	<p>Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. To monitor a custom cluster, you can add additional hostname or IP address, and port details for each sub-collector. You can add up to a total of 29 sub-collectors. Thereby, 30 databases can be monitored in a custom cluster. In addition to the licenses consumed by the main collector, each sub-collector consumes one or more licenses, depending on the database type.</p> <div style="border: 1px solid #0070C0; padding: 10px; margin-top: 10px;"> <p>Note</p> <ul style="list-style-type: none"> All connection parameters other than the hostname or IP address, and port details of the sub-collector are the same as the main collector. If you want to specify different parameters for the sub-collectors, while creating or editing the collector configuration, you can do that only via the Create Collector API. You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data. </div>
	Connection Properties	Click to add a new JDBC connection property or edit an existing property for relational databases.
	Exclude Databases	The databases that you want to exclude, separated by commas.
	Monitor Operating System	See this page for more details, Configure the Database Agent to Monitor Server Hardware .

Note

To handle High Availability (Multi-AZ) for Amazon RDS, set the databaseName JDBC connection string property to a user database.

Monitor Microsoft SQL Server

You can monitor the SQL Server either using an existing user account or by creating a new user account, with relevant privileges.

Monitor the Microsoft SQL Server Cluster

You can monitor all the nodes in the availability group of an MSSQL database server 2012 or later.

To enable monitoring of all the nodes, you must enable the `dbagent.mssql.cluster.discovery.enabled` property either at the Controller level or at the agent level.

This property is disabled by default.

Authentication Methods

You can monitor the SQL server using either of the following authentication methods:

- Windows authenticated account (if the Database Agent is running on Windows)
- SQL Server authenticated account (if the Database Agent is running on Windows or Linux)

Before you Begin

To connect to the SQL Server database using a Windows authenticated account, perform the following:

- Select **Windows Authentication** checkbox when creating the collector using "Create New Collector" dialog.

Note

Do not specify the username and password when updating database connection details.

- Specify the path to the Database Agent authentication library as follows:

Version Details	Path
Windows 64-bit	<pre>java -Djava.library.path="C:\dbagent_install_dir\auth\x64" -jar db-agent.jar</pre>
Windows 32-bit	<pre>java -Djava.library.path="C:\dbagent_install_dir\auth\x86" -jar db-agent.jar</pre>

- Ensure that the Windows account user has appropriate privileges to authenticate the database server and can start the database agent.

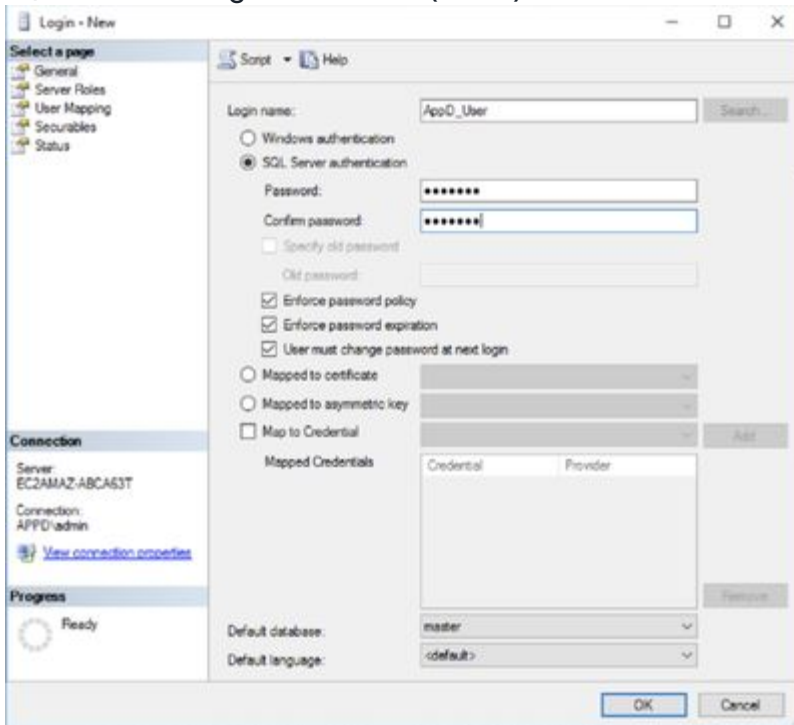

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- Change the logon credentials of the service to the Windows account with SQL Server access, if using a Windows service to run the Database Agent.

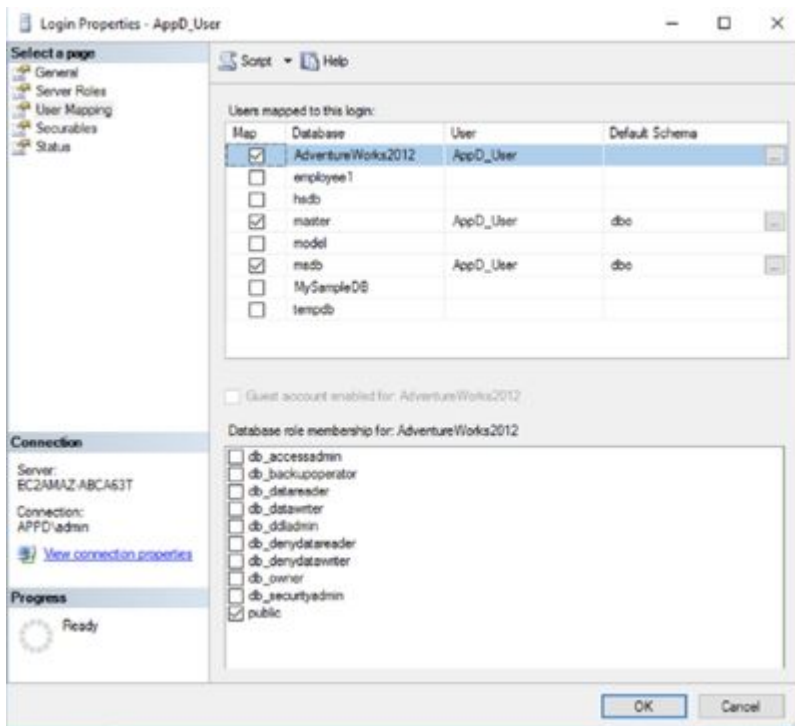

Server Level Permissions for SQL Server Logon

To create a new SQL Server user (with minimum permissions required to monitor), perform the following steps:

1. Create a new login for the AppDynamics SQL Server Database Collector, such as `AppD_User`, using SQL Server Management Studio (SSMS).

2. To map the new user to "master" and "msdb" databases, click "master" and "msdb" under **Users mapped to this login**.

i User mapping to "master" and "msdb" are mandatory for monitoring. To view object information in the Object Browser screens, additional mapping to other databases is required.

- After creating the login, grant the following privileges to the user by substituting `AppD_User` with the name you specified on the Login - New window:

```
use master
GRANT VIEW ANY DATABASE TO AppD_User;
GRANT VIEW ANY definition to AppD_User;
GRANT VIEW server state to AppD_User;
GRANT SELECT ON [sys].[master_files] TO AppD_User;
```

Optional Object Permissions for SQL Server

The following object permissions are required for optional screens within the Database (DB) Visibility user interface:

Screen	Object Permissions
Object Browser > Users	<div data-bbox="894 359 1495 478" style="border: 1px solid black; padding: 5px;"> <pre>GRANT execute on sp_helplogins to AppD_User;</pre> </div> <div data-bbox="894 485 1495 625" style="border: 1px solid black; padding: 5px; background-color: #e6f2ff;"> <p>Note securityAdmin role is required</p> </div>
Object Browser > Storage	<p>To view object storage metadata, user mapping to other databases of interest is required.</p> <div data-bbox="894 779 1495 919" style="border: 1px solid black; padding: 5px; background-color: #e6f2ff;"> <p>Note public role is required</p> </div>
Object Browser > Job Status	<div data-bbox="894 978 1495 1255" style="border: 1px solid black; padding: 5px;"> <pre>use msdb GRANT SELECT on dbo.sysjobsteps TO AppD_User; GRANT SELECT on dbo.sysjobs TO AppD_User; GRANT SELECT on dbo.sysjobhistory TO AppD_User;</pre> </div>
Object Browser > Error Log	<p>For versions <= 2005:</p> <div data-bbox="894 1346 1495 1465" style="border: 1px solid black; padding: 5px;"> <pre>GRANT execute on sp_readErrorLog to AppD_User;</pre> </div> <p>For versions > 2005:</p> <div data-bbox="894 1528 1495 1619" style="border: 1px solid black; padding: 5px;"> <pre>GRANT EXECUTE ON xp_readerrorlog</pre> </div> <div data-bbox="894 1640 1495 1766" style="border: 1px solid black; padding: 5px; background-color: #e6f2ff;"> <p>Note securityAdmin role required</p> </div>

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Microsoft SQL Server on AWS RDS Permissions

The user account used for monitoring can be a Windows authenticated account (if the Database Agent is running on Windows) or SQL Server authenticated (if AppDynamics Database Visibility is running on Windows or Linux).

Minimum Permissions Required for SQL Server Logon

You can use the procedure to create a SQL Server user with the minimum permissions required.

Use the following to create a SQL Server logon user that provides the minimal level of permissions required in order to gain full AppDynamics Database Visibility/SQL Server functionality.

i Master users created in the AWS RDS instance are the instance masters. If you want to provide access to a local user for monitoring, use the same master user and create a custom monitoring role and assign the same to the user.

1. Using SQL Server Management Studio, create a new login for the AppDynamics SQL Server Database Collector, such as `DBMon_Agent_User`.
2. (For users other than master user) Execute these commands as a batch from a query window in Management Studio. This example shows grants to the role assigned to `DBMon_Agent_User` to monitor the database:

```
USE master
GO
CREATE SERVER ROLE monitoring_role
USE master
GO
ALTER SERVER ROLE DBMon_Agent_User ADD MEMBER Monitoring_User
GRANT CONNECT SQL TO Monitoring_User
GRANT VIEW ANY DATABASE TO Monitoring_User
GRANT VIEW ANY DEFINITION TO Monitoring_User
GRANT VIEW SERVER STATE TO Monitoring_User
```

3. From the User Mapping tab, map the new user to the master and msdb databases.

i Viewing Object Information

To view object information on the **Database > Objects Browser**, map the monitoring user to the databases of interest.

4. Once you have created the login, give the following privileges to the user, substituting `DBMon_Agent_User` with the name you specified on the **Login - New** panel:

i You can execute the following as a batch from a query window in Management Studio. The example shows grants to `DBMon_Agent_User`; remember to change this if you have set up a different login.

```
use master
ALTER SERVER ROLE processadmin ADD MEMBER DBMon_Agent_User;
GRANT VIEW ANY DATABASE TO DBMon_Agent_User;
GRANT VIEW ANY definition to DBMon_Agent_User;
GRANT VIEW server state to DBMon_Agent_User;
```

where `DBMon_Agent_User` is the name of the SQL Server user account specified in **Create New Collector, Connection Details, Username** field.

To generate an execution plan on AWS RDS, you need additional permissions. The `SHOWPLAN` permission must be provided explicitly for each database:

```
USE <DB NAME>
go
GRANT SHOWPLAN to DBMon_Agent_User;
go
```

Configure Microsoft Azure Collectors

To monitor Microsoft Azure with Database Visibility, you must run Microsoft Azure >= 2008.

 To configure an Azure SQL Managed Instance, follow the configuration procedures of a Microsoft SQL Server Collector. See [Configure Microsoft SQL Server Collectors](#). Procedures in this page are specific to an Azure SQL Database collector and **not** applicable for an Azure SQL Managed Instance.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Section	Field	Description
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Database	The name of the database instance that you want to monitor.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent
	Custom JDBC Connection String	The JDBC connection string generated by the database agent. You can also specify a custom connection string, which is useful for setting custom authentication options.

Section	Field	Description
User name and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for Microsoft Azure .
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
	CyberArk	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the <code>JavaPasswordSDK.jar</code> file from the CyberArk web site and rename the file to <code>cyberark-sdk-9.5.jar</code> . Then, you must copy the JAR file to the <code>lib</code> directory of the database agent zip file.
Advanced Options	Sub-Collectors	<p>Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. To monitor a custom cluster, you can add additional hostname or IP address, and port details for each sub-collector. You can add up to a total of 29 sub-collectors. Thereby, 30 databases can be monitored in a custom cluster. In addition to the licenses consumed by the main collector, each sub-collector consumes one or more licenses, depending on the database type.</p> <div style="border: 1px solid #0070C0; padding: 10px; margin-top: 10px;"> <p>Note</p> <ul style="list-style-type: none"> All connection parameters other than the hostname or IP address, and port details of the sub-collector are the same as the main collector. If you want to specify different parameters for the sub-collectors, while creating or editing the collector configuration, you can do that only via the Create Collector API. You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data. </div>

Section	Field	Description
	Connection Properties	Click to add a new JDBC connection property or edit an existing property for relational databases.
	Monitor or Operating System	See this page for more details, Configure the Database Agent to Monitor Server Hardware .

User Permissions for Microsoft Azure

The user account used for monitoring can be an SQL Server authenticated account (if AppDynamics Database Visibility is running on Windows or Linux).

Minimum Permissions Required for SQL Server Logon

You can create an SQL Server authenticated login or user with minimal level of permissions. To create an SQL Server login, you must be connected to the primary database from an admin account via SQL Server Management Studio (SSMS) or SQL Editor.

 The read-only access to the master database is required for the user account to monitor the database.

1. Run the command given below to create a login. Specify a secure password in the command.

```
CREATE LOGIN DBMon_Agent_User WITH PASSWORD = 'Password123'
```

2. Run the following command in your Azure SQL database to create a user account for the newly created login:

```
CREATE USER DBMon_Agent_User FOR LOGIN DBMon_Agent_User WITH DEFAULT_SCHEMA = dbo
```

-
3. While connected to your Azure SQL database, run the command given below to grant the pre-requisite roles and privileges:

```
grant VIEW DATABASE STATE to DBMon_Agent_User
```

Configure MongoDB Collectors

To monitor MongoDB with Database Visibility, you must run MongoDB ≥ 2.2 .

If you are configuring a collector for a MongoDB cluster, you only need to configure one collector for the entire cluster. You can choose any node in the cluster to connect to, and the entire cluster will automatically be detected.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Section	Field	Description
	Custom Connection String	<p>The connection string generated by the database agent. You can also specify a custom connection string, which is useful for setting custom authentication options.</p> <div style="border: 1px solid #0070C0; padding: 5px; background-color: #E6F2FF;"> <p> Ensure that you do not specify the username and password in the custom connection string because it can cause a security risk.</p> </div>
	SRV Record	<p>Enable this field to use the SRV record, where the connection string includes <code>mongodb+srv</code>.</p>
User name and password	User name	<p>The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for MongoDB.</p>
	Password	<p>The password of the user who is connecting to and monitoring the database through the Database Agent.</p>
	CyberArk	<p>Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the <code>JavaPasswordSDK.jar</code> file from the CyberArk web site and rename the file to <code>cyberark-sdk-9.5.jar</code>. Then, you must copy the JAR file to the <code>lib</code> directory of the database agent zip file.</p>

Section	Field	Description
Advanced	Exclude Database	The databases that you want to exclude, separated by commas.
Collector	Monitor Operating System	See Configure the Database Agent to Monitor Server Hardware .

i When configuring the collector, ensure that you encode the username and password that uses special characters.

User Permissions for MongoDB

For MongoDB < 2.6.x, the readAnyDatabase and ClusterMonitor built-in roles are required to monitor using AppDynamics Database Visibility. For MongoDB shared clusters, the monitoring user must have access to all shards.

For MongoDB >= 2.6, the `clusterMonitor` built-in role in addition to read is required.

If you choose to create a new user to monitor MongoDB, the user must be created in the admin database.

You can configure user roles as shown in the sample query below:

```
use admin
db.createUser({ user: "tanujaAdmin",
pwd: "tanuja123",
  roles: [
    { role: "clusterMonitor", db: "admin" },
    { role: "read", db: "admin" },
  ]
})
```

Configure MySQL Collectors

To monitor MySQL with Database Visibility, you must run MySQL \geq 2.2.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent
	Custom JDBC Connection String	The JDBC connection string generated by the database agent, for example, <code>jdbc:mysql://</code> . You can also specify a custom connection string, which is useful for setting custom authentication options.
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for MySQL .
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.

Section	Field	Description
	CyberArk	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the JavaPasswordSDK.jar file from the CyberArk web site and rename the file to <code>cyberark-sdk-9.5.jar</code> . Then, you must copy the JAR file to the lib directory of the database agent zip file.
Advanced Options	Sub-Collectors	<p>Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data. </div>
	Connection Properties	Click to add a new JDBC connection property or edit an existing property for relational databases.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Section	Field	Description
	Exclude Databases	The databases that you want to exclude, separated by commas.
	Monitor Operating System	See Configure the Database Agent to Monitor Server Hardware .

User Permissions for MySQL

The MySQL user the Database Agent uses to monitor the MySQL database must have "SELECT", "PROCESS", and "SHOW DATABASES" privileges on all databases.

The user must also have the "REPLICATION CLIENT" privilege to collect these metrics:

- Slave_io_running
- Slave_sql_running
- Seconds_behind_master
- SQL_Delay

If you do not have a suitable existing user, you can use the command below to create a new user.

```
GRANT SELECT,PROCESS,SHOW DATABASES on *.* to 'DBMon_Agent_User'@'host' identified by 'password';
GRANT REPLICATION CLIENT ON *.* to 'DBMon_Agent_User'@'host';
FLUSH privileges;
```

Substitute `DBMon_Agent_User` with the username under which you run the Database Visibility Agent. Substitute `host` with the hostname or IP address of the machine running the AppDynamics Database Agent, and substitute `password` with a secure password.

Set the `max_allowed_packet` parameter to `1073741824` on the server.

Troubleshooting MySQL Permissions

View MySQL Error Logs

To view the error log file, these conditions must be met:

- `secure_file_priv` is either empty or the name of the folder containing the error log file. You must restart MySQL for changes in the `secure_file_priv` variable to take effect.
- The error log file is readable to all users.
- `max_allowed_packet` is larger than the error log file size.
- The user has FILE privileges.

Configure Oracle Collectors

To monitor Oracle with Database Visibility, you must be running Oracle 10g or newer.

If you are configuring a collector for Oracle RAC, you only need to configure one collector for the entire cluster. You can choose any node in the cluster to connect to, and the entire cluster will automatically be detected.

i If you are using Oracle 12c as PDB, the query for system metrics is available from Oracle Database 12c Release 2 (12.2.0.1) onwards. See the Oracle documentation for more information.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent
	SID or Service Name	<p>The SID or service name of the Oracle instance you want to monitor.</p> <p>For CDB (container database) monitoring, provide the CDB service name and for PDB (pluggable database) monitoring, provide the PDB service name.</p> <p>For PDB (pluggable database) monitoring, the service name must be present in all the nodes that have PDB so that all the nodes get monitored.</p>

Section	Field	Description
	Custom JDBC Connection String	<p>The JDBC connection string generated by the database agent, for example,</p> <pre>jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=</pre> <p>. You can also specify a custom connection string, which is useful for setting custom authentication options.</p> <p>When using connection string for Kerberos, ensure that you select the LDAP/Kerberos option under Advanced Options.</p>
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for Oracle .
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.
	Cyberark	<p>Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the <code>JavaPasswordSDK.jar</code> file from the CyberArk web site and rename the file to <code>cyberark-sdk-9.5.jar</code>. Then, you must copy the JAR file to the lib directory of the database agent zip file.</p>

Section	Field	Description
	SSL Connection	<p>Click to enable the SSL connection. You can use SSL Connection for authentication and signing credentials.</p> <ul style="list-style-type: none"> Truststore Location: location of the SSL certificate that is stored on the DB Agent host Truststore Type: type of truststore used for SSL certificate. There are two truststore types: PKCS12 (default) SSO: enables auto-login. If you use SSO, you only need to provide the truststore location and truststore type. Truststore Password: password for SSL certificate. <p>If the <code>SSL_CLIENT_AUTHENTICATION</code> parameter is set to true in <code>listener.ora</code> and <code>sqlnet.ora</code>, then click the Enable SSL Client Authentication box.</p> <ul style="list-style-type: none"> Keystore Location: location of the SSL certificate on the DB Agent host Keystore Type: type of SSL certificate Keystore Password: password of SSL certificate
	LDAP/Kerberos	Use LDAP/Kerberos authentication to manage the database user and the host user passwords.
	Monitor Operating System	See this page for more details, Configure the Database Agent to Monitor Server Hardware .

User Permissions for Oracle

For versions of Oracle 10g and later

The following permissions are required for the Oracle user:

- CREATE SESSION
- SELECT_CATALOG_ROLE

To create a user with these permissions, you can run the following SQL. In this SQL, change " password " to a safe and secure password, and change the `tablespace` names, " users " and " temp " to those available in your Oracle instance.

```
CREATE USER DBMon_Agent_User IDENTIFIED BY password
default tablespace users
temporary tablespace temp;

GRANT CREATE SESSION, SELECT_CATALOG_ROLE TO DBMon_Agent_User;
```

where `DBMon_Agent_User` is the user name under which you run the Database Visibility Agent.

For versions of Oracle 12c and later with Multitenant Container Database Option enabled

The following permissions are required for the Oracle user:

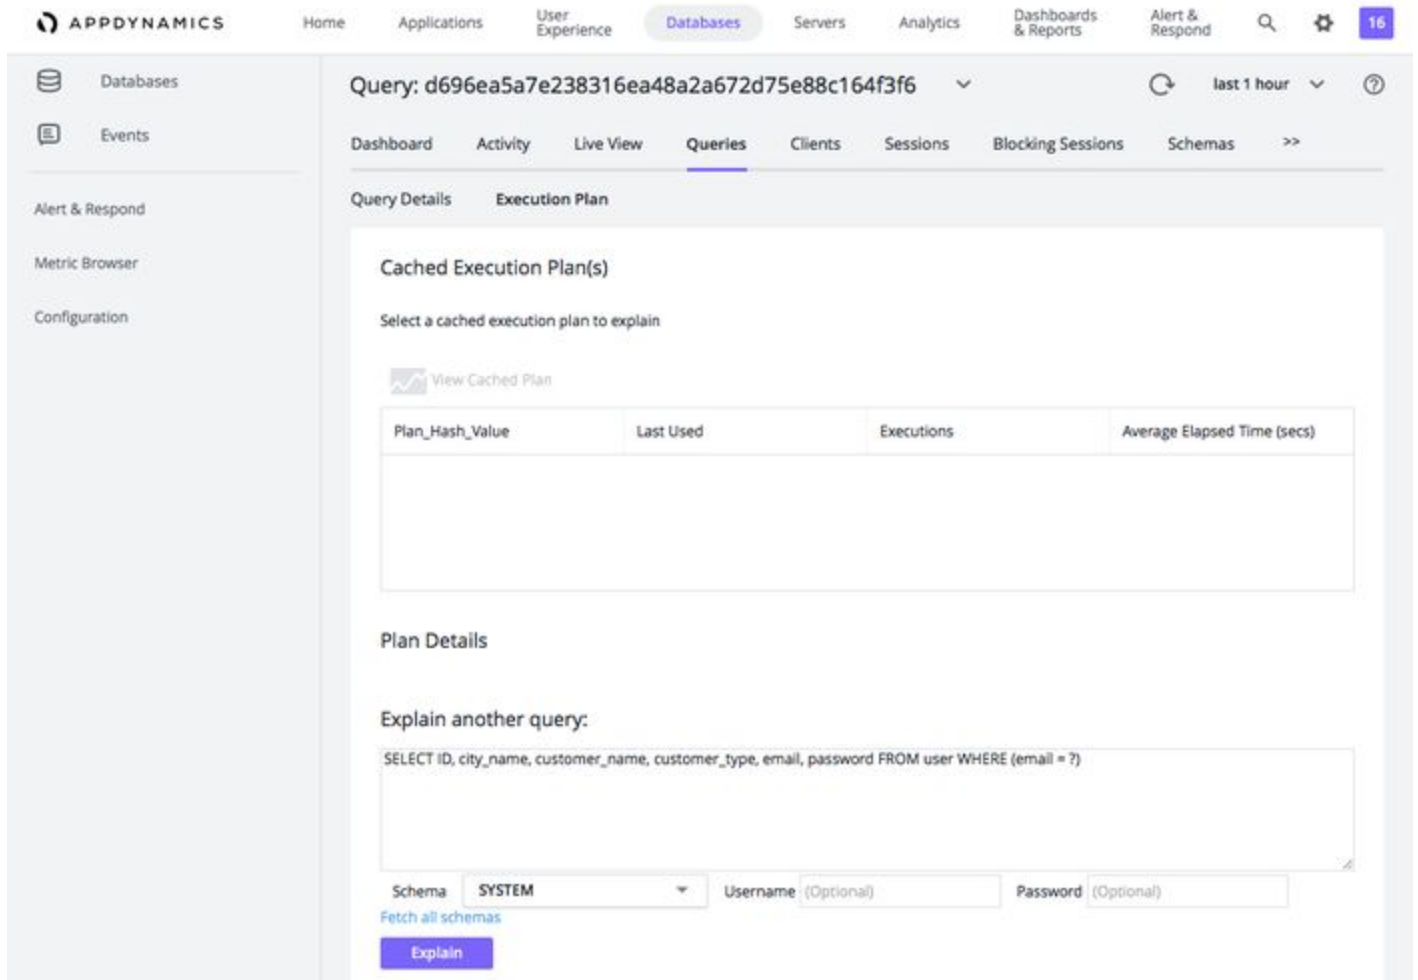

- CREATE SESSION
- SELECT_CATALOG_ROLE

To create a user with these permissions, you can run the following SQL. In this SQL, change "password" to a safe and secure password, and change the tablespace names, "users" and "temp" to those available in your Oracle instance.

```
CREATE USER C##DBMon_Agent_User IDENTIFIED BY password default tablespace users temporary
tablespace temp CONTAINER=ALL;
GRANT CREATE SESSION, SELECT_CATALOG_ROLE TO C##DBMon_Agent_User CONTAINER=ALL;
ALTER USER C##DBMon_Agent_User QUOTA 100M ON USERS;
alter user C##DBMON_AGENT_USER set container_data=all container=current;
```

Permissions Required for Oracle Explain Plans

To generate an execution plan for a specified query, paste the query text into the **Explain another query** box. You must provide a plan table in the AppDynamics monitoring user's schema. You can find a sample output table named `PLAN_TABLE` in the `UTLXPLAN.SQL` script. To update or view the plan table, you need INSERT and SELECT privileges. To explain a query, you need access privileges for the tables and views included in that query.

AppDynamics Database Visibility can generate explain plans within its SQL drill-down window. To enable this functionality, you must have a plan table accessible to the AppDynamics Database Visibility schema user. You can create this plan table with the following command from `sqlplus` when logged on as the AppDynamics Database Visibility user:

Windows:

```
@?\rdbms\admin\utlxplan.sql
```

Linux:

```
@?/rdbms/admin/utlxplan.sql
```

Permissions for individual views and tables

You can grant permission to individual views and tables even if the `SELECT_CATALOG_ROLE` permission is not available to your organization.

1. Execute permissions on `dbms_application_info.set_module`.
2. Select permissions on the following privileges:

`dba_data_files`

`dba_ind_columns`

`dba_indexes`

`dba_objects`

`dba_procedures`

`dba_segments`

`dba_sequences`

`dba_synonyms`

`dba_tab_columns`

`dba_tables`

`dba_users`

`dba_views`

`gv$instance`

`gv$containers`

`gv$parameter`

`v$archive_dest`

`v$archive_dest_status`

`v$database`

`v$datafile`

`v$event_name`

`v$instance`

`v$license`

`v$log`

`v$osstat`

`v$parameter`

`v$process`

`v$session`

`v$sesstat`

`v$session_wait`

`v$sga`

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
v$sql  
v$sql_plan  
v$sqlstats  
v$sqltext  
v$statname  
v$sysmetric  
v$sysstat  
v$system_event
```

 When you are granting access to `v$` views, you must grant `SELECT` on the underlying objects, which are named using the `v_` format, e.g. `GRANT SELECT on v_$archive_dest`.

Configure Oracle RAC

Related pages:

- [Database Topology Window](#)

If you are configuring a collector for Oracle RAC, you only need to configure one collector for the entire cluster. You can choose any node in the cluster to connect to, and the entire cluster is automatically detected.

If you have sub-collectors, it will disable automatic cluster discovery.

When the Database Visibility collector connects to the hostname or IP address defined in the collector configuration, it auto-discovers the RAC instance. Once a successful connection is made to a node within the RAC, then a query on `GV$INSTANCE` will be used to return the details of the other member nodes and to populate the [Topology Window](#).

When monitoring Oracle RAC, the Controller displays the aggregate data for the entire cluster.

User Permissions for Oracle RAC

When you upgrade to 4.3, you may encounter the following error: Network access denied by access control list (ACL). You can resolve the error by enabling ACLs for the monitoring user.

```

begin
dbms_network_acl_admin.create_acl (
acl          => 'Resolve_Access.xml',
description  => 'Resolve Network Access using UTL_INADDR',
principal   => '<DBMON USER>',
is_grant     => TRUE,
privilege    => 'resolve',
start_date  => null,
end_date     => null
);
commit;
end;
/

begin
dbms_network_acl_admin.assign_acl (
acl          => 'Resolve_Access.xml',
host         => '*',
lower_port   => null,
upper_port   => null);
commit;
end;
/

```

Monitor Oracle Databases Using Kerberos Authentication

For the Database Agent to connect to and monitor the Oracle databases using Kerberos authentication, these settings are required:

- Start the Database Agent using the property, `java.security.krb5.conf` :

```
nohup java -Djava.security.krb5.conf="<path to Kerberos configuration file>"
```

- In the **CONNECTION DETAILS** section of the Collector configuration dialog, specify the JDBC connection string:

```
jdbc:Oracle:Tds:<hostname>:<portnum>?<Kerberos connection details>
```

- In the **ADVANCED OPTIONS** section of the Collector configuration dialog, ensure to provide these details:
 - Select **LDAP/Kerberos**.
 - Select **Connection Properties**, then specify these JDBC connection properties:

Property Name	Property Value
oracle.net.authentication_services	(KERBEROS5)
oracle.net.kerberos5_mutual_authentication	true
oracle.net.kerberos5_cc_name	"<cache_file_path>" For example: "I:\\Kerberos\\krb5ccFile"

Configure PostgreSQL Collectors

You can monitor any version of PostgreSQL with Database Visibility.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent.
	Custom JDBC Connection String	The JDBC connection string generated by the database agent, for example, <code>dbc:postgresql://</code> . You can also specify a custom connection string, which is useful for setting custom authentication options.
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for PostgreSQL .
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.

Section	Field	Description
	CyberArk	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the <code>JavaPasswordSDK.jar</code> file from the CyberArk web site and rename the file to <code>cyberark-sdk-9.5.jar</code> . Then, you must copy the JAR file to the lib directory of the database agent zip file.
Advanced Options	Sub-Collectors	<p>Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. To monitor a custom cluster, you can add additional hostname or IP address, and port details for each sub-collector. You can add up to a total of 29 sub-collectors. Thereby, 30 databases can be monitored in a custom cluster. In addition to the licenses consumed by the main collector, each sub-collector consumes one or more licenses, depending on the database type.</p> <div style="border: 1px solid #0070C0; padding: 5px;"> <p> • All connection parameters other than the hostname or IP address, and port details of the sub-collector are the same as the main collector. If you want to specify different parameters for the sub-collectors, while creating or editing the collector configuration, you can do that only via the Create Collector API.</p> <p>• You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data.</p> </div>
	Connection Properties	Click to add a new JDBC connection property or edit an existing property for relational databases.
	EnterpriseDB	Click if your PostgreSQL database installation is an EnterpriseDB distribution.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Section	Field	Description
	Exclude Databases	The databases that you want to exclude, separated by commas.
	Monitor Operating System	See Configure the Database Agent to Monitor Server Hardware .

User Permissions for PostgreSQL

The monitoring user must either have a role of superuser or be granted access to the `pg_stat_activity` table using the technique described below.

The following script allows you to create a SECURITY DEFINER function that is owned by the superuser, and runs the query you want, thus allowing non-superusers to see the contents of `pg_stat_activity` by calling the `get_sa()` function and `pg_stat_statements` by calling the `get_querystats()` function respectively. The script must be executed by the superuser.

i Ensure that you create the `pg_stat_statements` extension by using the command, `create extension pg_stat_statements`.

```
CREATE FUNCTION get_sa()
RETURNS SETOF pg_stat_activity LANGUAGE sql AS
$$ SELECT * FROM pg_catalog.pg_stat_activity; $$
VOLATILE
SECURITY DEFINER;

CREATE VIEW pg_stat_activity_allusers AS SELECT * FROM get_sa();
GRANT SELECT ON pg_stat_activity_allusers TO public;
```

```
CREATE FUNCTION get_querystats()
RETURNS SETOF pg_stat_statements LANGUAGE sql AS
$$ SELECT * FROM pg_stat_statements; $$
VOLATILE
SECURITY DEFINER;
CREATE VIEW pg_stat_statements_allusers AS SELECT * FROM get_querystats();
GRANT SELECT ON pg_stat_statements_allusers TO public;
```

The monitoring user must also be able to connect remotely to the PostgreSQL instance from the AppDynamics for Databases machine.

Configure Sybase Collectors

To monitor Sybase with Database Visibility, you must run Sybase ≥ 15 .

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent.
	Custom JDBC Connection String	The JDBC connection string generated by the database agent, for example, <code>jdbc:sybase:</code> . You can also specify a custom connection string, which is useful for setting custom authentication options.
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for Sybase .
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.

Section	Field	Description
	CyberArk	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the JavaPasswordSDK.jar file from the CyberArk web site and rename the file to <code>cyberark-sdk-9.5.jar</code> . Then, you must copy the JAR file to the lib directory of the database agent zip file.
Advanced Options	Sub-Collectors	<p>Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. To monitor a custom cluster, you can add additional hostname or IP address, and port details for each sub-collector. You can add up to a total of 29 sub-collectors. Thereby, 30 databases can be monitored in a custom cluster. In addition to the licenses consumed by the main collector, each sub-collector consumes one or more licenses, depending on the database type.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p> • All connection parameters other than the hostname or IP address, and port details of the sub-collector are the same as the main collector. If you want to specify different parameters for the sub-collectors, while creating or editing the collector configuration, you can do that only via the Create Collector API.</p> <p>• You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data.</p> </div>
	Connection Properties	Click to add a new JDBC connection property or edit an existing property for relational databases.
	Exclude Databases	The databases that you want to exclude, separated by commas.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Section	Field	Description
	Monitor Operating System	See Configure the Database Agent to Monitor Server Hardware .

User Permissions for Sybase

For complete AppDynamics Database Visibility functionality, the monitoring user requires the permissions listed in the table below.

Permission type	Permission
Role permission	<ul style="list-style-type: none"> sa_role mon_role
Select permission	<ul style="list-style-type: none"> master.dbo.monWaitEventInfo master.dbo.sysconfigures master.dbo.sysmonitors master.dbo.monProcess master.dbo.monProcessLookup master.dbo.monProcessSQLText master.dbo.monProcessProcedures
Execute permission	<ul style="list-style-type: none"> sp_sysmon

If you require to browse the objects of a custom database, use the following command:

```
use [custom-db-name]
sp_adduser <user-name>
```

To create a new dedicated user for AppDynamics Database Visibility, you can use following sample user creation script. Before running the script, change "password" to a more secure value.

```
exec sp_addlogin 'DBMon_Agent_User', 'password', @defdb='master', @deflanguage='us_english',
@fullname='DBMon_Agent_User monitoring account', @auth_mech = 'ANY'
go
exec sp_locklogin 'DBMon_Agent_User', 'unlock'
go
exec sp_role 'grant', 'mon_role', 'DBMon_Agent_User'
go
```

where DBMon_Agent_User is the user name under which you run the Database Visibility Agent.

Also, the following configuration parameters must be set to 1 (true) to monitor the Sybase ASE database with AppDynamics Database Visibility: "enable monitoring", "wait event timing", "SQL batch

capture ", and "object lockwait timing ". You should also set "max SQL text monitored " to at least 8192 (8kB).

Here is an example of the commands required to configure these settings:

```
sp_configure "enable monitoring", 1
go
sp_configure "wait event timing", 1
go
sp_configure "SQL batch capture", 1
go
sp_configure "object lockwait timing", 1
go
sp_configure "max SQL text monitored", 8192
go
```

If the value for "max SQL text monitored " was previously less than 4096, then increasing this setting will require that you restart the Sybase ASE instance.

To monitor Sybase >= 15.7 without the sa_role permission, run these commands:

```
use sybssystemprocs
grant execute on sp_sysmon to mon_role
```

If you choose to monitor Sybase using sp_sysmon , you may encounter the following errors:

- Thread utilization is incorrectly reported. View the official report [here](#).
- Timeslice error in mmap64 or mda_flush_iostats. View the official report [here](#).

Configure Sybase IQ Collectors

You can monitor any version of Sybase IQ with Database Visibility.

Connection Details

Section	Field	Description
Create New Collector	Database Type	The database type that you want to monitor.
	Agent	The Database Agent that manages the collector.
	Collector Name	The name you want to identify the collector by.
Connection Details	Hostname or IP Address	The hostname or IP address of the machine that your database is running on.
	Listener Port	The TCP/IP address of the port on which your database communicates with the Database Agent.
	Custom JDBC Connection String	The JDBC connection string generated by the database agent, for example, <code>jdbc/sybase:iq:</code> . You can also specify a custom connection string, which is useful for setting custom authentication options.
Username and Password	Username	The name of the user who is connecting to and monitoring the database through the Database Agent. The user should have the permissions described in User Permissions for Sybase IQ .
	Password	The password of the user who is connecting to and monitoring the database through the Database Agent.

Section	Field	Description
	CyberArk	Click to enable CyberArk for database username and password. When CyberArk is enabled, information about Application, Safe, Folder, and Object is required to fetch the username and password for your database. To use CyberArk with Database Visibility, you must download the <code>JavaPasswordSDK.jar</code> file from the CyberArk web site and rename the file to <code>cyberark-sdk-9.5.jar</code> . Then, you must copy the JAR file to the <code>lib</code> directory of the database agent zip file.
Advanced Options	Sub-Collectors	<p>Click to monitor multiple database instances in a consolidated view, and aggregate metrics of multiple databases. To monitor a custom cluster, you can add additional hostname or IP address, and port details for each sub-collector. You can add up to a total of 29 sub-collectors. Thereby, 30 databases can be monitored in a custom cluster. In addition to the licenses consumed by the main collector, each sub-collector consumes one or more licenses, depending on the database type.</p> <div style="border: 1px solid #0070C0; padding: 10px; background-color: #E6F2FF;"> <p> • All connection parameters other than the hostname or IP address, and port details of the sub-collector are the same as the main collector. If you want to specify different parameters for the sub-collectors, while creating or editing the collector configuration, you can do that only via the Create Collector API.</p> <p>• You cannot convert a custom cluster collector to a standalone collector. If you want to monitor a standalone database, delete the entire custom cluster collector and create a fresh standalone collector. However, note that deleting the custom cluster collector will delete all its historical data.</p> </div>
	Connection Properties	Click to add a new JDBC connection property or edit an existing property for relational databases.
	Exclude Databases	The databases that you want to exclude, separated by commas.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Section	Field	Description
	Monitor Operating System	See Configure the Database Agent to Monitor Server Hardware .

User Permissions for Sybase IQ

To monitor with a non-DBA account, you need:

- User account with SERVER OPERATOR system privilege.
- Execution privileges on several procedures which can be granted as follows:

```
grant execute on sp_iqconnection to DBMon_Agent_User
grant execute on sp_iqtransaction to DBMon_Agent_User
grant execute on sp_iqcontext to DBMon_Agent_User
grant execute on sp_iqstatus to DBMon_Agent_User
grant execute on sp_iqcolumn to DBMon_Agent_User
grant execute on sp_iqindex to DBMon_Agent_User
```

where `DBMon_Agent_User` is the user name under which you run the Database Visibility Agent.

- Grant DBA authority to `DBMon_Agent_User` :

```
grant DBA to DBMon_Agent_User
```

Monitor Sybase Databases Using Kerberos Authentication

For the Database Agent to connect to and monitor Sybase databases using Kerberos authentication, these settings are required:

- In the Connection Details section of the **Collector** configuration dialog, specify the JDBC connection string:

```
jdbc:sybase:Tds:<hostname>:<portnum>?REQUEST_KERBEROS_SESSION=true&SERVICE_PRINCIPAL_NAME=<my server>
```

- Start the Database Agent using the `-Djavax.security.auth.useSubjectCredsOnly=false` option:

```
nohup java -Djavax.security.auth.useSubjectCredsOnly=false /<db_agent_home>/db-agent.jar &
```

Configure the Database Agent to Monitor Server Hardware

Related pages:

- [Monitor Database Server Hardware](#)

In addition to monitoring the database server, the Database Agent can also monitor the hardware that hosts the database server. To configure the Database Agent to monitor the database server hardware, complete the **Hardware Monitoring** section of the [Collector configuration](#) dialog.

Click **Databases > Configuration > Collectors** and then choose an existing collector to monitor the hardware for that database server and click **Edit**, or click **Add** to set up a new collector to monitor a different database server and the hardware hosting that server.

Complete the Hardware Monitoring Section

The following describes the fields in the **Collector Configuration** dialog that you must complete if you want to monitor the database server host hardware, in addition to the database server.

i For Oracle database, the **CPU** and the **Memory** metrics are monitored even when hardware monitoring is disabled.

Monitor Operating System: Select if you want CPU consumption metrics collected from the monitored host.

Operating System: Specify the operating system of the monitored host: Windows, Linux, Solaris, AIX, or RDS.

Use Local WMI: Check this box if you want to monitor the machine the Database agent is running on, i.e. localhost. When selected, the authorization fields are not used because no authorization is required.

Domain: For Windows only, specify the name of the domain in which the hardware resides.

SSH Port: For Linux, AIX, and Solaris only, specify the Secure Shell (SSH) port number the Controller should use for encrypted communications with the monitored host. The default port number of 22 will be used if you do not specify a different port number here.

Use certificate: For Linux, AIX, and Solaris only, AppDynamics also supports certificate-based authentication through Privacy Enhanced Mail (PEM). To implement certificate-based authentication, enable the **Use certificate** option and copy the PEM file to the `<db_agent_home>\keys` directory. Note, if the `$HOME/.ssh` directory exists, the agent will use the certificate found there. This option appears only if the agent is running on a machine running Linux, AIX or Solaris.

Username: Specify the name of the user the Database Agent uses to log on to the monitored host. To collect OS metrics from a Windows host, the configured user (or Collector Service user if using Windows Authentication) must be able to establish a WMI connection to the target host and collect Windows Performance Counters.

Password: Specify the password of the user the Database Agent uses to log on to the monitored host. The number of echo characters shown in the password text field should not be interpreted to imply the number of characters stored for the (encrypted) user password.

- Windows hardware monitoring is not supported by Database Agent installed on a Linux system. However, Database Visibility can support hardware metrics for SQL server through SQL query collection.
 - Database Visibility does not collect hardware metrics for the following database servers because these database servers require SSH connection to collect hardware metrics:
 - Apache Cassandra
 - Datastax Enterprise (DSE) Cassandra
 - Couchbase
 - IBM DB2
 - MongoDB
 - MySQL
 - Sybase
- You must enable **Monitor Operating System** to collect the hardware metrics for these database servers.
- For Oracle and MSSQL database, hardware metrics can be collected through either SQL query collection or SSH connection. However, Database Visibility does not support collecting hardware metrics using SQL query for the preceding list of database servers.

Resolve Metric Reporter Type Mismatch Problem

Switch from the Java Hardware Monitor to the [Hardware Monitor](#) if you see messages similar to the following in the logs:

```
[Worker-7] 12 Sep 2014 07:27:49,449 WARN MonitorOutputHandler - Metric Reporter type mismatch
for metric [Hardware Resources|Network|Incoming packets/sec]
com.singularity.ee.agent.commonservices.metricgeneration.metrics.MetricReporterTypeMismatchEx
ception: Aggregator of OBSERVATION already exists for metric Metric Identifier[Hardware
Resources|Network|Incoming packets/sec] ID[0]
```

Required Monitored Host Permissions

Database Agent User Permissions

Database Visibility collects the stats from common commands like `vmstat/iostat` or gathering metrics from the file system such as `/proc` and as such the user that runs the Database Agent requires no special permissions, just the ability to run those common commands and write to files in the Database Agent directory.

Database Agent Collector Authentication

When monitoring the database host, Database Visibility must log in to the host system to gather system information. There are three ways to authenticate the Database Collector to access the monitored host:

- Specify a username and password in the Collector configuration dialog
- Place a PEM file or an `id_rsa` file in the `<agent home>/keys` directory
- If the Database Agent is running on LINUX, Solaris or AIX, place SSH keys in the `<home>.ssh` directory of the user running the agent. You can create an SSH key using the same procedure as described for the Controller. See [Configure a Controller SSH Key](#).

Required SSH Permissions

When monitoring the database host, Database Visibility uses SSH on Linux and Windows systems to gather system information. SSH access can be through either an authenticated username/password or a private key.

You can create an SSH key using the same procedure as described for the Controller. See [Configure a Controller SSH Key](#).

Configure WMI Permissions and Security

Related pages:

- [WMI and the Database Agent on the AppDynamics Community](#)

To monitor Windows-based machine hardware with AppDynamics Database Visibility, AppDynamics uses Windows Management Instrumentation (WMI) to remotely gather the metrics. WMI is often complicated to troubleshoot when the Database Agent is running on a Linux or Unix-like machine.

This page describes requirements for the target machine configuration that can help you avoid some problems and pitfalls. It also provides some additional considerations regarding using WMI to monitor a SQL Server database agent and preventing unauthorized remote access to WMI.

Named Windows Account:

The user specified in the collector configuration that the AppDynamics Database Agent uses to connect to the target machine is referred to as <named Windows account>.

The following are required when the Database Agent is hosted on AIX, Linux or Solaris platforms to monitor Windows ≥ 7 systems.

- Ensure that the named Windows account is a member of the local Administrators group.
- [Ensure User Account Meets Minimum Security Requirements When Using WMI](#)
- [Enable Remote Registry Access](#)
- [Grant access to WBEM scripting locator](#)

The following are required when the Database Agent is hosted on AIX, Linux, or Solaris platforms to monitor Windows ≥ 2012 systems.

- [Grant full control permissions to select registry keys](#)

The following is required when the Database Agent is hosted on Windows.

- Ensure that the named Windows account is a member of the local Administrators group.

Requirements to Monitor Windows ≥ 7 Systems (Agent Running on Unix-like Platform)

The following are required when the Database Agent is hosted on AIX, Linux, or Solaris platforms to monitor Windows ≥ 7 systems.

Ensure User Account Meets Minimum Security Requirements When Using WMI

Enable Security Options for Windows Systems are Part of a Domain

Ensure the named Windows account has the correct permissions for WMI Control.

1. Run the `wmicmgmt.msc` program.
2. Right-click the **WMI Control** icon on the left and click **Properties**.
3. Click **Security**.
4. Click the root node of the tree, and click **Security**.
5. Ensure that the named user account running the Database Agent has the relevant permissions.

The minimum permissions that your remote Windows account needs for the Database Agent are:

- Execute Methods
- Enable Account
- Remote Enable

If the named Windows account does not have all of these permissions, you may receive an access denied error or the following errors:

Error=800706BA The RPC server is unavailable. SWbemLocator

or

Error=80070005 Access is denied SWbemLocator

Enable Classic Security Options for Local (Non-Domain) Windows Systems

Applies to Windows computers that are not part of a domain.

1. Open the **Control** panel, and go to **Administrative Tools > Local Security Policy**. The **Local Security Settings** panel appears.
2. Go to **Local Policies > Security Options**.
3. Change the value of **Network access: Sharing and security model for local accounts** to **Classic**.

Enable Remote Registry Access

The Remote Registry service must be running on the target machine. If the Remote register service is off, you will receive the following error:

Message not found for errorCode: 0xC0000034

or

Access is denied

By default Windows >= 7 systems will still deny remote access to the registry, even if the Remote Registry service is started.

To test this:

1. Attempt to access the replica registry using Regedit on another machine.
2. If you get an error similar to **Access is denied**, run PowerShell as an administrator on the replica, and execute `Enable-PSRemoting`.
3. Restart the machine and try launching the replica again.

Grant Access to WBEM Scripting Locator

The Database Agent requires full access to the WBEM Scripting Locator. On the target system, allow full access to the WBEM Scripting Locator as follows:

1. As an Administrator on the target machine, launch Regedit.
2. Locate the registry key:

76A64158-CB41-11D1-8B02-00600806D9B6 in HKEY_CLASSES_ROOT\CLSID

3. Right-click the key and click **Permissions**.
4. Click **Advanced**.
5. Click **Owner** and change the owner to the Administrators group. Click **Apply**.
6. Click **Permissions** and change the permissions for the Administrators group to **Full Control**. Click **Apply**.
7. Close Regedit.
8. Restart the Remote Registry Service, using **Administrative Tools > Services**.

Configure the Firewall

WMI uses RPC which listens on port 135 but then allocates a dynamic port for subsequent communication. Configure your Firewall to always allow the TCP port 135 exception and follow the dynamic RPC ports. If there is a problem with the firewall, port 135 then you will probably see this error:

```
ERROR: Message not found for errorCode: 0xC0000001
```

See [How to configure RPC dynamic port allocation to work with firewalls](#).

Additional Requirements to Monitor Windows >= 2012 Systems (Agent Running on Unix-like Platform)

In addition to the requirements described in [Requirements to Monitor Windows >=7 Systems](#), the following are also required when the Database Agent is hosted on AIX, Linux, or Solaris platforms to monitor Windows >= 2012 systems.

Grant Full Control Permissions to Select Registry Keys

For the Database Agent running on AIX, Linux, or Solaris to monitor Windows >= 2012 (64-bit) systems, complete the following changes on the target system.

1. As an Administrator on the target machine, launch Regedit.
2. Change the permissions for both of these registry keys to **Full Control**:
`72C24DD5-D70A-438B-8A42-98424B88AFB8`
 in `HKEY_LOCAL_MACHINE\SOFTWARE\Classes\Wow6432Node\CLSID`
`76A64158-CB41-11D1-8B02-00600806D9B6` in `HKEY_CLASSES_ROOT\CLSID`
3. Find this registry key:
`72C24DD5-D70A-438B-8A42-98424B88AFB8` in
`HKEY_LOCAL_MACHINE\SOFTWARE\Classes\Wow6432Node\CLSID`
4. Right-click and click **Permissions**.
5. Change the owner to the Administrators group.
6. Change the permissions for the Administrators group to **Full Control**.
7. Change owner back to **TrustedInstaller**. User is <NT Service\Trusted Installer> on the local machine.
8. Repeat steps 4 to 6 above for this registry key:
`76A64158-CB41-11D1-8B02-00600806D9B6` in `HKEY_CLASSES_ROOT\CLSID`.
9. Close Regedit.
10. Restart the Remote Registry service, using **Administrative Tools > Services**.

General Considerations for all Platforms

This information applies to the Database Agent running on Windows systems.

Use Windows Authentication for Microsoft SQL Server

To use Windows Authentication for the Database Agent to connect to a Microsoft SQL Server database instance, you must use a command similar to the following to start the Database Agent; specifying the path to the Database Agent authentication library.

Windows 64-bit

```
java -Djava.library.path="C:\dbagent404\auth\x64" -jar db-agent.jar
```

Windows 32-bit

```
java -Djava.library.path="C:\dbagent404\auth\x86" -jar db-agent.jar
```

The Windows account used to start the Database Agent must be a Windows user who can authenticate with the database server.

Monitor Databases and Database Servers

For roles and permissions required to view Database Monitoring windows, see [Manage Custom Roles](#).

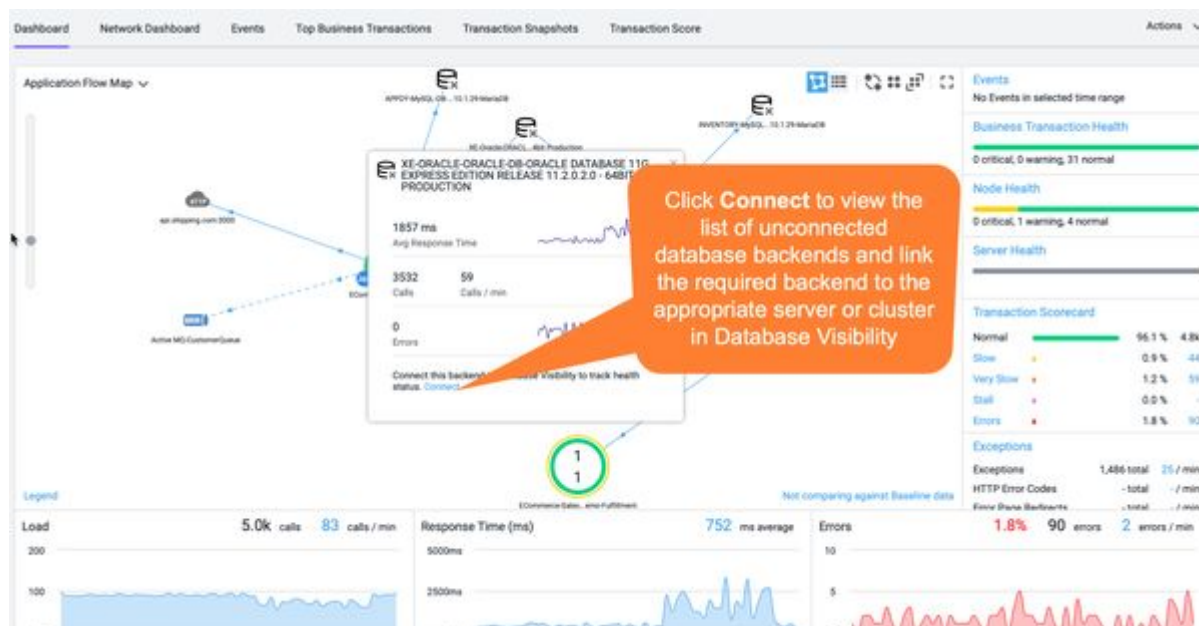

Access Database Visibility from Application Monitoring Views

Related pages:

- [Monitor Database Performance](#)
- [App Agent Node Properties](#)

To view the application dashboard of a specific application, click the application on the **Home** page. On the application dashboard, you can view the following:

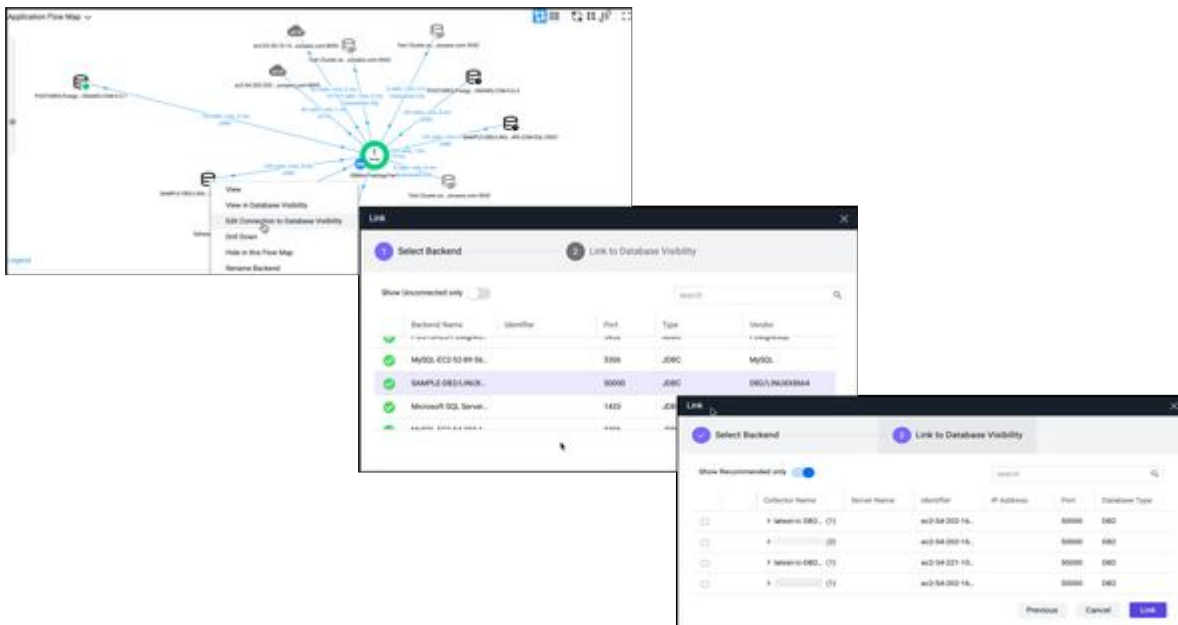

- **Unconnected Backends:** If there are any unconnected backend database servers, the flowmap displays the unconnected database server icon. You can click the icon, then click **Connect** to connect the backend database to the appropriate server or cluster in **Database Visibility**.
- **Status of the Database:** There are different icons to display different states of the database based on the health rule violation. For information about the different icons, see [Database Icons](#).
- **Quick View of Database Visibility:** If you require to view some of the main metrics without going to the **Database Visibility** UI, you can click the database icon and the quick view of the metrics is displayed. For detailed information, click **View in Database Visibility**.

View Database Activity in Database Visibility

Once you have [configured a database Collector](#) in AppDynamics Monitoring, you can access Database Visibility either from the AppDynamics Home page or you can link to the Database Visibility database instance Dashboard by right-clicking the database and selecting **View in Database Visibility** on the Application Flow Map, Tier Flow Map or Node Flow Map.

Database backends with the same hostname, port number, and database type as a database server already configured in a database Collector are automatically matched with the Collector, and drilldowns from the Application Flow Map, Tier Flow Map or Node Flow Map to Database Visibility are enabled.

✓ The AppDynamics Database Visibility section in the Application Database Dashboard displays which database Collector is associated with the database. If you require to change this association, right-click the database and then click **Edit Connection to Database Visibility** and choose the appropriate server or cluster that is configured in **Database Visibility**.

View Business Transaction Snapshot Correlated Database Details

Available for Java, .NET, and PHP applications and their relational database backends, snapshot correlation shows the details of queries executed by the business transaction. It also shows the clients, sessions, and schemas in which those queries were executed.

View Database Details

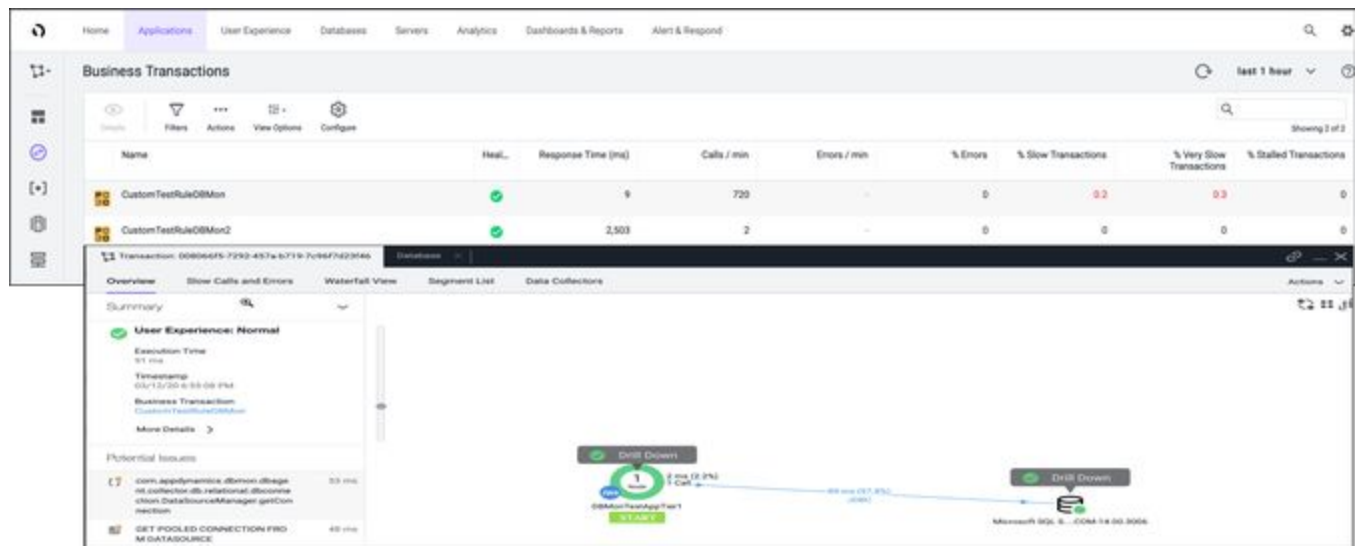

1. On the [Business Transactions](#) page, double click any business transaction to view the queries that are executed in that transaction.
2. Click the DB Queries tab. On this tab, you can view the queries that were issued by this business transaction.

View Correlated Database Details

1. From a list of business transactions with snapshots, choose a long-running business transaction that accesses the database, one that takes a few seconds or more. These are more likely to have captured database details.
2. Double-click **Drill Down** above the database icon. The correlated database details window appears.
3. Click the Queries, Clients, Sessions, and Schema tabs to view details of database activity that occurred around the time when the snapshot was captured. For relational databases, these details reflect the

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

database activity from the transaction snapshot. For non-relational databases, these details reflect the database activity that occurred around the time of the transaction snapshot.

i For Oracle backends only: If you want to list only the queries executed by the Transaction Snapshot in the Transaction Snapshot window, you can enable the `jdbc-dbcam-integration-enabled` node property for the Java Agent.

Discover Normal Database and Server Activity

Related pages:

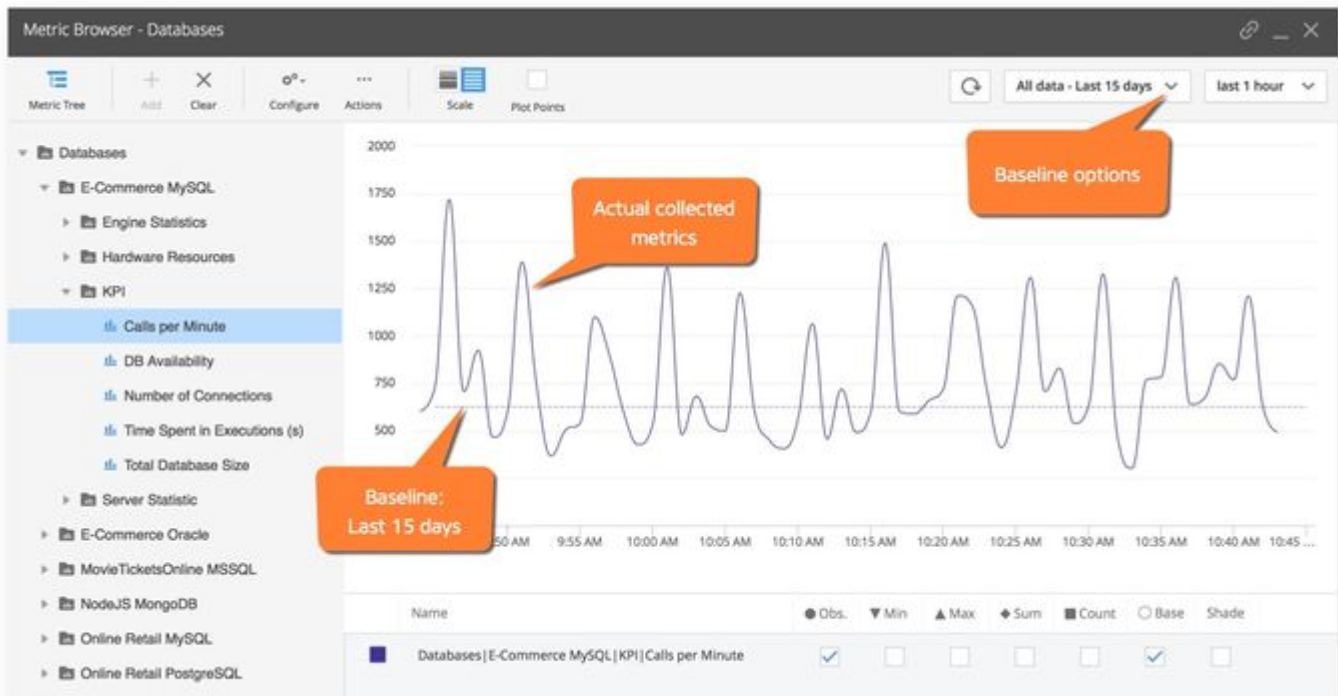

- [Dynamic Baselines](#)
- [Health Rules](#)

AppDynamics Database Visibility automatically learns to detect performance anomalies using baselines that are specific to your database and database server environments.

AppDynamics creates baselines by collecting metrics from your monitored databases and servers over defined periods of time. This establishes what is normal for your environment. You can also create your own baselines.

View Performance Metrics on the Metric Browser

On the Metric Browser for Database Visibility, you can visualize performance metrics and see how they deviate from expected behaviors established by the baseline.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Important information

Garbage collection affects all monitored entities, including database queries, sessions, clients, and schemas. Entities that are garbage collected will be displayed as unavailable.

View Overall Database and Server Performance

Related pages:

- [Access Database Visibility from Application Monitoring Views](#)

Database Visibility provides overall views of your databases that show key performance indicators.

Access the Databases Window

From AppDynamics Home, click **Databases**.

Features of the Databases Window

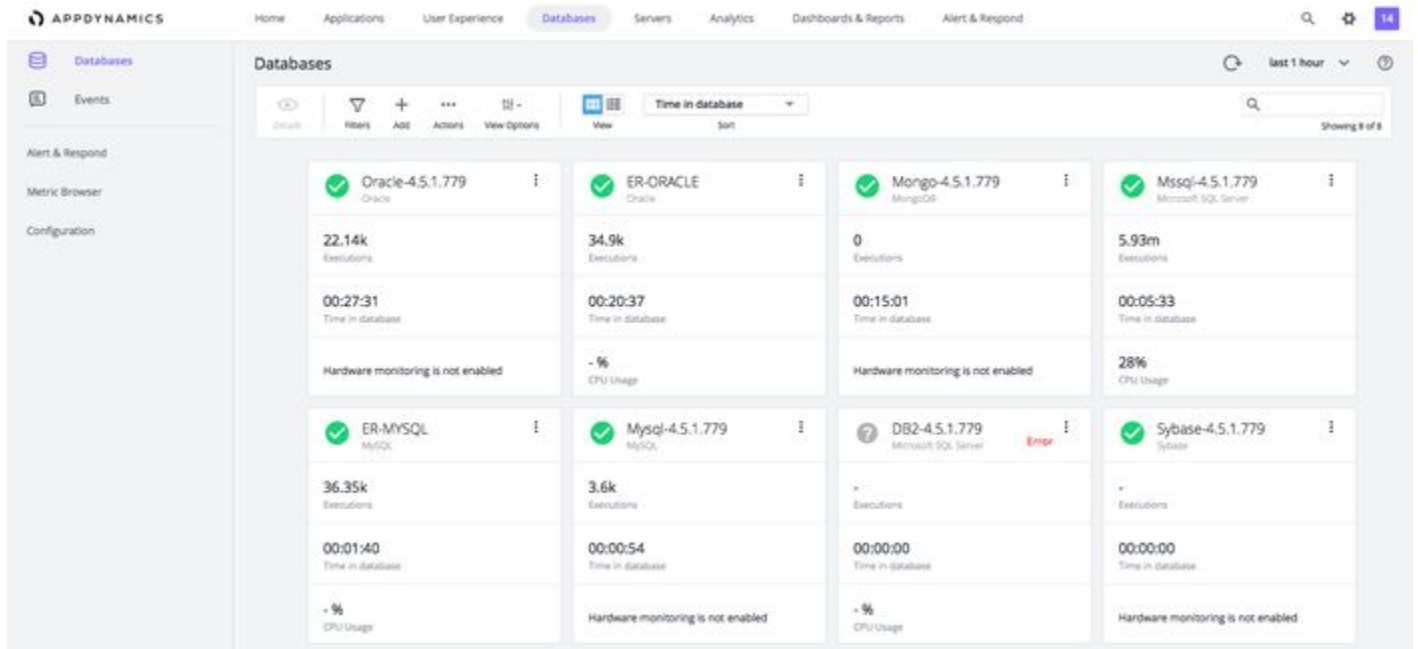

On the views of the Databases window you can:

- Show only databases meeting certain criteria by entering search criteria in the search box on the top right of the page.
- Click **Filters** to show only databases meeting certain search criteria, such as criteria that describes Health, Load, Time in database or Type.
- Click **+** to add a new database Collector.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.
- Click **View** to switch between card and list view.
- See the overall performance of your databases and if there are any critical issues with them. The server health or status indicates whether criteria has been met for normal, warning or critical health rules. The green checkmark indicates that the database is operating within normal conditions, the red exclamation mark indicates that at least one critical health rule has been violated.
- Click the name of the database to switch to the Database Dashboard for that specific database.

Databases Card View

From the Databases card view, you can view:

- The **Total Executions** graph that provides insight into the total number of calls (transactions for PostgreSQL databases) monitored for the database over the selected time period.
- The **Time in Database** graph that indicates the total time spent executing those calls during the selected time period. This metric is expressed in hours, minutes, and seconds.
- **CPU Usage** metrics that when enabled shows the percentage of CPU capacity consumed by the database.

Databases List View

From the Databases list view, you can:

- Click **View Options** to turn the spark charts on and off.
- Get to the databases you want to see quickly if you are monitoring many databases.
- Click on any point in the spark charts to see a metric for that point in time. For example, clicking on a point in the calls Trend shows how many calls were monitored at that time.
- Click on a column name to sort the list on that key.

Database Dashboard

Related pages:

- [Access Database Visibility from Application Monitoring Views](#)
- [View Overall Database and Server Performance](#)
- [Discover Normal Database and Server Activity](#)
- [Database Health Rules and Alerts](#)
- [Monitor Database Performance](#)

The dashboard for each individual database provides detailed information about your database.

Permissions

To view database collectors, users need a role with the **Can View All Collectors** permission.

Access the Database Dashboard

You can access the Database Dashboard in one of these ways:

- In AppDynamics Home, on the **Databases** card, click the name of the database for which you want to see the Database Dashboard.
- In the Databases overview panel, click the name of the database for which you want to see the Database Dashboard.

Features of the Database Dashboard

On the Database Dashboard you can:

- Click the dropdown arrow next to the database Collector name at the top of the page to choose a database that you want to see the dashboard for.
- Click the down-arrow next to the clustered database Collector name to navigate between different nodes of the cluster.
- Click the status icon below **SERVERS** in the top section of the dashboard to go directly to **Events** where you can see any recent events.

On the Database Dashboard, you can view:

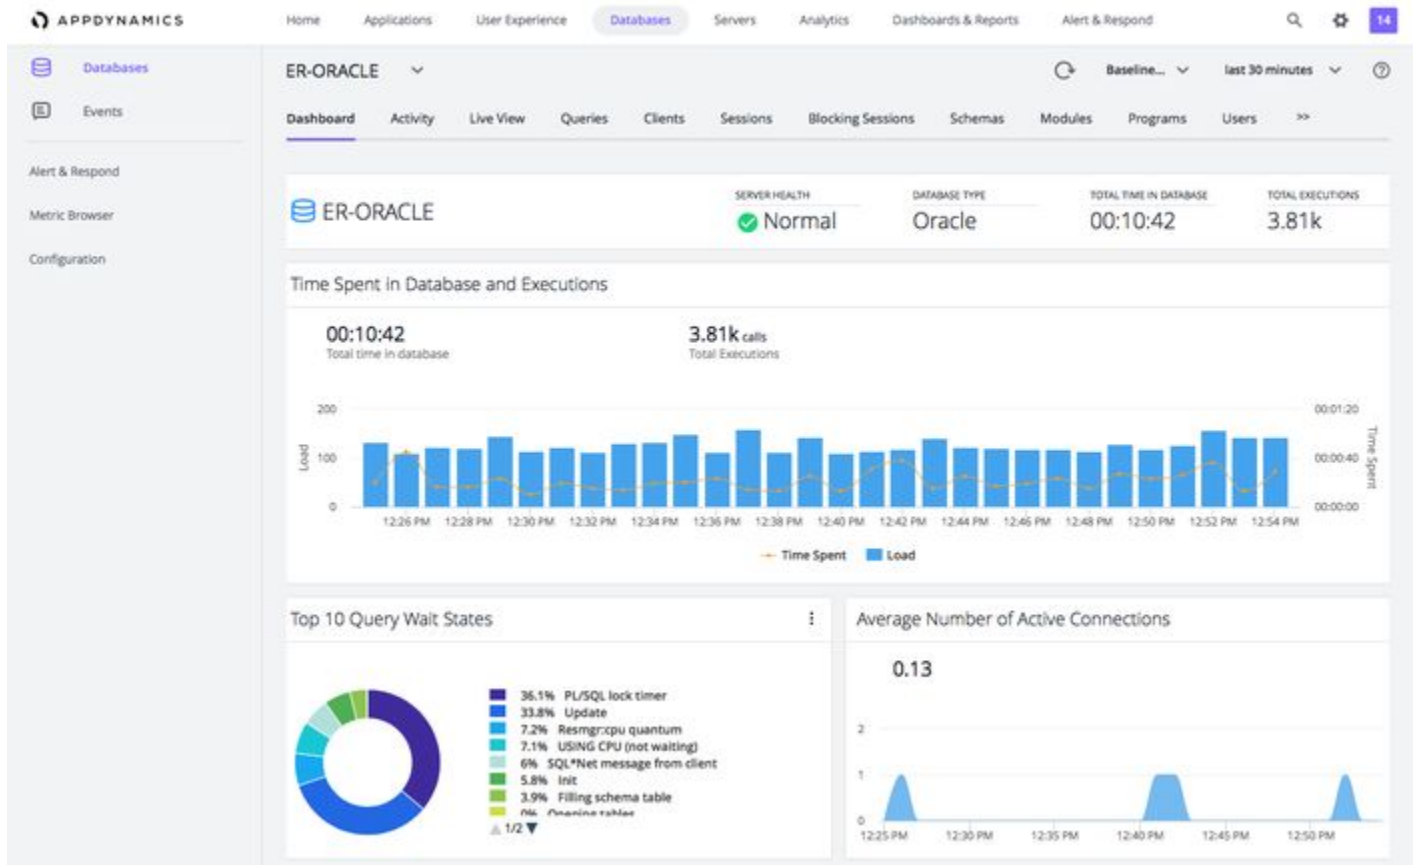

- **Server Health:** Server Health at the top of this panel indicates the extent to which health rules are being violated:
 - Green - Healthy server
 - Yellow/orange - server with warning-level violations
 - Red - server with critical-level violations
- **Type:** The database type.
- **Time Spent in Database and Executions:**
 - Load - At a glance, you can see the total number of calls (transactions for PostgreSQL databases) during the specified time period and the number of calls for any point in time.
 - Time spent in Database - The total time spent executing SQL statements during the specified time period.
 - Changes - Changes made to the database configuration parameters.
 - Max CPU - It displays the CPU cores present in the database server and is disabled by default. The CPU core count is collected using SQL (for Oracle, DB2, and MSSQL) and Hardware monitoring (if enabled for MySQL, PostgreSQL and Sybase).
- **Top 10 SQL Wait States (not available for Couchbase):** Activities that contribute to the time it takes the database to service the request. The wait states consuming the most time may point to performance bottlenecks. For example, a db file sequential read wait state may be caused by segment header contention on indexes or by disk contention. See your database platform documentation for descriptions of the SQL wait states. For example:
 - Wait State - CHECKPOINT_QUEUE
 - Description - Used by background worker that waits on events on queue to process checkpoint requests.
 - Recommended Action - You should be able to safely ignore this action because it indicates that the checkpoint background worker is waiting for work to do. If you thought you had issues with checkpoints not working or log

truncation, you might see if this worker ever "wakes up". Expect higher wait times as this will only wake up when there is work to do.

- **Top 10 Phases (Couchbase only):** The phases that have processed the most documents.
- **Average number of active connections:** The average number of sessions that are actively running a query during the selected time period.

i Accessing the Comparison Report

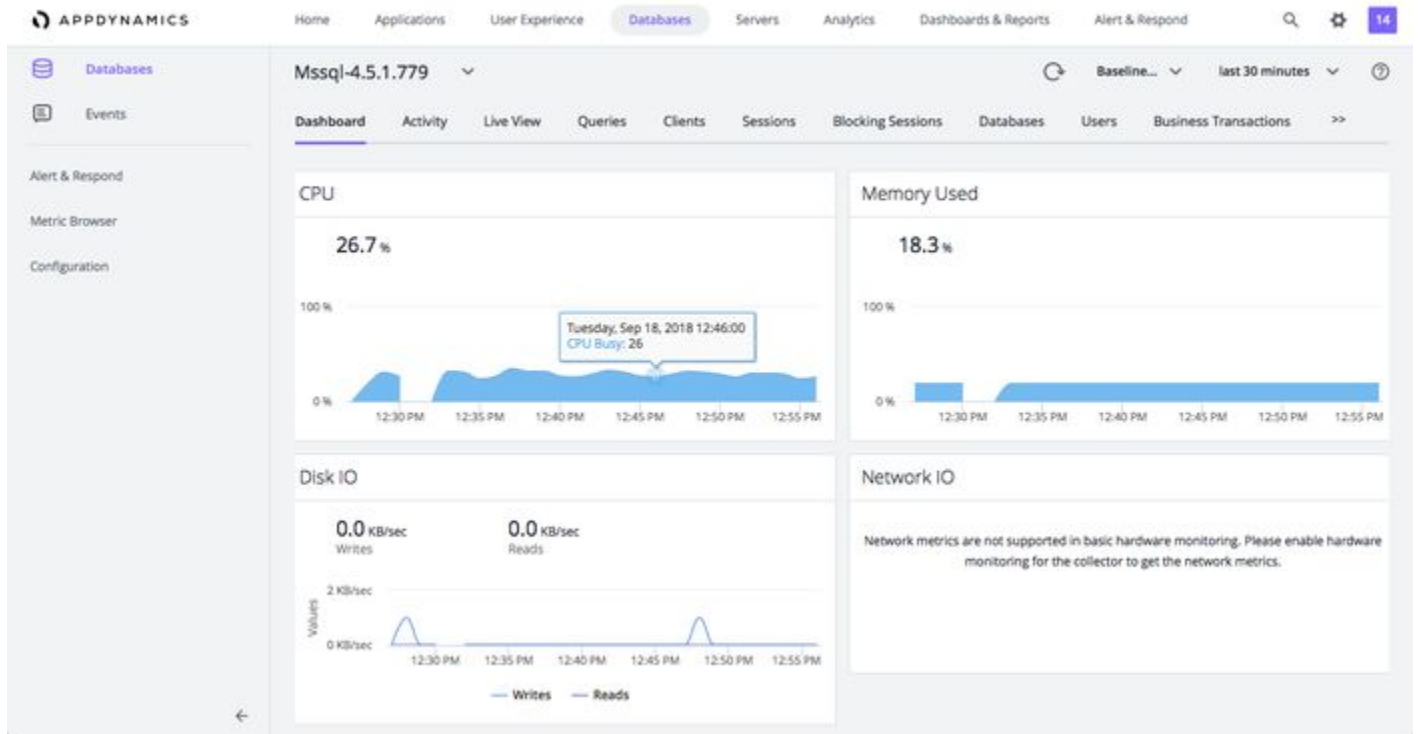

Click on any data point to view the time comparison report, which shows query run times and wait states 15 minutes before, and 15 minutes after the selected time.

The **CPU, Memory, Disk I/O, and Network I/O** graphs display when the Database Agent has been configured to also monitor the database host hardware. See, "Configure the Database Agent to Monitor Server Hardware" on [Add Database Collectors](#).

- **CPU:** The CPU graph shows the relative percentages of CPU processing time used for handling system and users processes.
- **Memory:** The Memory graph shows the percentage of total memory in use at any point in time.
- **Disk I/O:** The Disk I/O graph shows disk usage, the volume of data read and written.
- **Network I/O:** The Network I/O graph shows network activity, the volume of data sent and received.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

✓ Accessing the Metric Browser

To see more information about a specific metric, double click any point on the graph and the Metric Browser opens displaying that metric. You can then hover over a point on the graph in the Metric Browser for more information about the metric. This feature is available for all the graphs except the SQL wait states graph.

Database Activity Window

Related pages:

- [Access Database Visibility from Application Monitoring Views](#)
- [Database Visibility](#)
- [Monitor Databases and Database Servers](#)
- [Monitor Database Performance](#)

The following describes the reports available in Database Visibility on the Database Activity Window. The reports available depend on the database platform being monitored. The reports are listed in alphabetical order and indicate which database platform supports them.

Access the Database Activity Window

To access the Database Activity window

1. To view a database's activity, click the name of the database.
2. Click the **Activity** tab.

Features of the Database Activity Windows

To view the database reports of different databases, click the down arrow next to the database name at the top of the page. From the list, select the database you want to view or search for the database in the search bar. Click the refresh icon to show only databases that meet that search criterion.

The activity reports available are described below. The reports available are database-dependent. The reports are listed in alphabetical order and indicate which database platform supports them. The reports will only show 10 days of data, which is the Events Service limit.

Wait State

Description: This report displays time-series data on Wait Events (states) within the database. Each distinct wait is color-coded, and the Y-axis displays time in seconds. This report also displays data in a table and highlights the time spent in each wait state for each SQL statement.

Relevance: The wait states consuming the most time may point to performance bottlenecks. For example, db file sequential reads may be caused by segment header contention on indexes or by disk contention.

Platform: IBM DB2, Microsoft SQL Server, MySQL, Oracle, PostgreSQL, Sybase, and Sybase IQ

Max CPU - It displays the CPU cores present in the database server and is disabled by default. The CPU core count is collected using SQL (for Oracle, DB2, and MSSQL) and Hardware monitoring (if enabled for MySQL, PostgreSQL and Sybase).

Phase

Description: This report displays the number of documents processed during a phase of query execution.

Relevance: The phase processing the most documents may point to performance bottlenecks.

Platform: Couchbase

Top Activity

Description: Display the top time in database SQL statements in a time-series view. This report also displays data in a table and highlights the time spent in the database for each of 10 top SQL statements. Only queries reported by newer agents are grouped; the queries reported by older agents may not appear upon grouping.

Relevance: Use this report to see which SQL statements are using the most database time. This helps to determine the impact of specific SQL statements on overall system performance allowing you to focus your tuning efforts on the statements that have the most impact on database performance.

Platform: IBM DB2, Microsoft SQL Server, MySQL, Oracle, PostgreSQL, Sybase, Sybase IQ, and Couchbase

Time Comparison

Description: This report allows compares the performance of two databases during the same time period based on a specific statistic type. You can click Group Similar to group together queries with the same number of parameters. Only queries reported by newer agents are grouped; the queries reported by older agents may not appear upon grouping.

Relevance: You may want to compare the performance of your development and production databases before and after you tune the SQL queries or add an index or join. This report can help you determine the effectiveness of any performance tuning procedures you have implemented.

Platform: IBM DB2, Microsoft SQL Server, MySQL, Oracle, PostgreSQL, Sybase, and Sybase IQ

I/O

Description: This report gives information on physical I/O performed by the database instance.

The SQL Server and PostgreSQL I/O reports include the following metrics:

- Time spent in the database
- Query throughput
- CPU usage (if hardware monitoring is enabled)
- Read and Write I/O. This metric is only available for SQL Server.
- Per file statistics (if the agent is run with the `dbagent.mssql.datafile.statistics` property). This metric is only available for SQL Server.
- Per database statistics. This metric is only available for PostgreSQL.

Relevance: Your physical disk I/O may be affecting database performance.

Poor response times may mean one of the following:

- You're doing too much physical I/O and need to adjust your I/O capacity
- You're scanning tables or indexes when you should be doing seeks
- Your database tables are missing indexes
- Your SQL needs to be tuned

Platform: Microsoft SQL Server, Oracle, PostgreSQL

Top Query

Description: This report displays the top 10 SQL statements for the specified statistic in a time-series view.

You can filter queries by command type using the **Command Type** dropdown menu and by statistic type using the **Statistic Type** dropdown menu.

With the Controller version 21.2.0 and later, some of the unused statistic types under the **Statistic Type** dropdown menu are removed from the list. You can filter queries using the most common statistic types.

Relevance: Use this report to see which SQL statements are using the most database resources. This helps to determine the impact of specific SQL statements on overall system performance allowing you to focus your tuning efforts on the statements that have the most impact on database performance. You can choose one of many statistics to base the report on.

Platform: IBM DB2, Microsoft SQL Server, Oracle

Query Wait State

Description: This report displays the wait times for all queries.

Relevance: Use this report to see how much time queries are spending in different wait states.

Platform: IBM DB2, Microsoft SQL Server, MongoDB, MySQL, Oracle, PostgreSQL, Sybase, and Sybase IQ

Parameter Changes

Description: This report displays changes to the database configuration parameters. You can select a parameter change and click one of the following options:

- **View Event Details:** Displays the parameter change event details, such as comments associated with the parameter change.
- **View Comparison Report:** Compares the query run times and wait states 15 minutes before and 15 minutes after the database parameter was changed. The comparison report is not available for clusters.

Relevance: Use this report to keep track of the changes you make to the database configuration parameters.

Platform: IBM DB2, Microsoft SQL Server, Microsoft Azure, MySQL, Oracle, PostgreSQL, Sybase ASE, and Sybase IQ

BT Activity

Description: This report displays the top (Java or PHP) business transactions that make calls to the database.

Relevance: Use this report to see which business transactions are affected by the database.

Platform: IBM DB2, Microsoft SQL Server, Microsoft Azure, MySQL, Oracle, PostgreSQL, Sybase ASE, and Sybase IQ

Database Topology Window

The Topology view displays current activity for the routing service and shards of a MongoDB database, Oracle RAC server or a custom cluster. The Topology view shows key performance metrics for the routing service and shards or nodes of the database.

Access the Database Topology Window

To access the Database Topology window:

1. To view a database's topology, click the name of the database.
2. Click the Topology tab.

Database Topology Window Features

From the Database Topology window, you can:

- Select the **Auto Refresh** box. From the **Every** list, you can choose how often the system updates the live view.
- Click the dropdown arrow next to the database Collector name at the top of the page to choose a node or cluster that you want to see the metric views for. You can either select the database Collector name from the list or search for the database Collector by entering text in the search bar and then clicking the refresh icon to show only database Collectors that meet those search criteria.
- Hover over the sections of the trends to see their details.
- Click a column title on the **Topology** name list to sort the topologies using that column as the sort key.

From the Topology window, you can view:

- **Health:** Indicates whether any health rules for the routing service or shards of the replica set or nodes have been violated.
- **Role:** The role performed by the shard. The routing service routes the queries to the shards to balance the load. The members or shards of the replica sets can have either primary or secondary shard role.
- **Num Queries:** The number of queries handled.
- **Queries Trend:** The trend of queries handled over time.
- **Time in Database:** The time required for the database to respond to the queries.
- **Time Spent in Database Trend:** The trend of time spent in the database over time.

 If you change the port number for a monitored database node, the Topology window shows a new node with the new port number, as well as the original node with the old port number. The original node remains in the Topology window for the duration of the retention period that you specify in [Controller Settings](#).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Database Live View Window

Related pages:

- [Access Database Visibility from Application Monitoring Views](#)
- [Database Visibility](#)
- [Monitor Databases and Database Servers](#)
- [Monitor Database Performance](#)

The Live View displays current activity for the database server. The live view shows key performance metrics for the last time period, which can be refreshed in a specified time interval between 10 seconds and 5 minutes.

Access the Database Live Window

To access the Database Live window:

1. To view a database's current performance, click the name of the database.
2. Click the **Live View** tab.
3. For clustered databases, select the node to view its details.

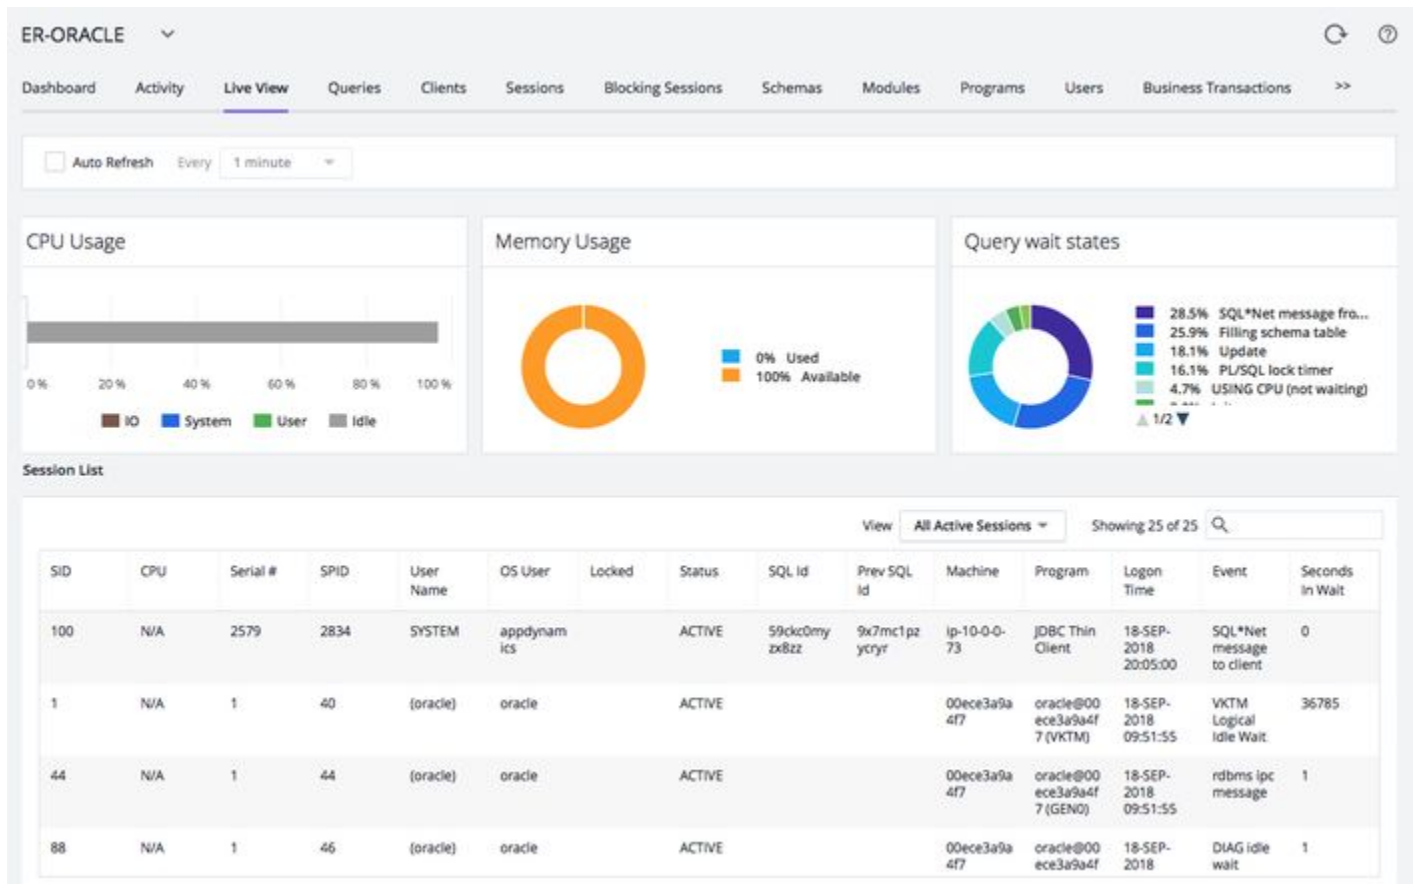

Database Live Window Features

From the Database Live window, you can:

- Select the **Auto Refresh** box and then from the **Every** list, choose how often you want the system to update the live view.
- Click the down arrow next to the database collector name at the top of the page to choose to view the live view of a different database Collector by either selecting the database Collector name from the list or by searching for the database collector by entering text in the search bar and then clicking the refresh icon to show only database collectors that meet that search criteria.
- Hover over the sections of the charts to see their details.
- Click the **View** list to view **All Active Sessions** or **All Sessions**.
- Click a column title on the **Session List** to sort the Session List using the clicked column as the sort key.

From the Database Live window, you can view:

- **CPU Usage:** If you have enabled Hardware Monitoring for the server the chart shows the percentage of available CPU resources consumed by users and the system and a break down of how the CPU is being used.
 - IO - Disk input and output.
 - System - Database operating system activities.
 - User - User interaction with the database.
- **Memory Usage:** Displays how much memory is in use and how much is available.
- **Query wait states:** Activities that contribute to the time it takes the database to service the request. The wait states consuming the most time may point to performance bottlenecks. For example, database file sequential reads may be caused by segment header contention on indexes or by disk contention.
- **Session List:** A table describing database usage instances and their properties. The database session is the application interaction with the database, a new session is started for each request. The columns displayed are database dependent.
- **Blocking Tree:** A tree showing all the sessions causing blocks. Nested under each blocking session are the sessions being blocked and the corresponding queries and blocked objects.

For SQL Server, the **CPU Usage** and **Memory Usage** statistics are displayed in Live View even when hardware monitoring is disabled.

In the Live View for database clusters, you must select a node from the dropdown menu to view that node's activity.

Database Queries Window

Related pages:

- [Access Database Visibility from Application Monitoring Views](#)
- [Add Database Collectors](#)
- [Database Visibility](#)
- [Monitor Databases and Database Servers](#)
- [Monitor Database Performance](#)

The Queries window displays the SQL statements and stored procedures that consume the most time in the database. You can compare the query weights to other metrics such as SQL wait times to determine SQL that requires tuning.

Access the Database Queries Window

To access the Database Queries window:

1. To view database queries, click the name of the database.
2. Click the Queries tab.

Database Queries Window Features

From the Database Queries window, you can:

- View the top N queries. These are the queries that consumed the greatest amount of database time to complete.
- Choose to display the top 5, 10, 100 or 200 queries.
- Click the name of a column to sort the **Query** list using that key.
- Click **Filter by Wait States** to choose wait states to filter the **Query** list by. The filtered list only displays queries that caused the selected wait states.
- Check the **Group Similar** box to group together queries with the same syntax. Queries that share the same syntax but different 'IN' clause parameters are still grouped together. Query grouping is case-insensitive. Double-click a query group to dive into the Group Details for more information about that query group. Only queries reported by newer agents are grouped; the queries reported by older agents may not appear upon grouping.
- Search for a specific query, by entering text in the search bar that may appear in the Query. This is useful if you found a slow query in the Slow Database calls window of AppDynamics Application monitoring.
- Double-click a query or select a query and click **View Query Details** to dive into the **Query Details** for more detailed information about that specific query. If you see a message saying that query details are unavailable, you may need to update your permissions or extend your query retention period.
- Click the down arrow next to the database Collector name at the top of the page to choose to view the database queries of a different database Collector by either selecting the database Collector from the list or by searching for the database Collector by entering text in the search bar and then clicking the refresh icon to show only database Collectors that meet that search criteria.
- Click **Actions** to:
 - Export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.
 - Rename the selected query so that it is easier to identify. Note that the query name is associated with the query itself. Thus, when a query's retention period expires, both the query and the query name disappear.

From the Database Queries window, you can view:

- **Query Id:** This is the unique ID assigned to the query internally by the database.
- **Query:** The text of the query, custom query name, or, in the case of a stored procedure invocation, the name of the stored procedure. If the user does not have the ANY permission to view the stored procedure name, the definition of the stored procedure is shown instead of the stored procedure name.

For SQL Server, Azure, Oracle, PostgreSQL and DB2 the metrics Number of Executions, Average Response Time and Elapsed Time are inferred from the query index. When you are viewing the queries with Group Similar checked, the statistics reflect only the queries that have captured query statistics. Queries that do not have query statistics are excluded from the statistic values.

For databases such as MySQL and MongoDB which do not have a query index, no data will appear in the Number of Executions and Average Response Time columns. However, Elapsed Time can be inferred for MySQL and MongoDB databases using the wait state index. Elapsed Time can also be inferred using the wait state index when query statistics for a query run on an SQL Server, Azure, Oracle, PostgreSQL or DB2 database are otherwise not available. When query statistics are not available for a query run on an SQL Server, Azure, Oracle, PostgreSQL or DB2 database, the Number of Executions and Average Response Time statistics cannot be reported and are marked with a hyphen (-). This means that the database did not provide statistics for this query in the selected time range.

- **Elapsed Time:** The total time consumed by all executions of this query. Query statistics such as Number of Executions, Average Response Time and Elapsed time are available for databases supporting the query index, such as SQL Server, Azure, Oracle, PostgreSQL and DB2. For databases where the query index is not available, the elapsed time is inferred from the wait state index.

By default, the query sampling frequency is once every second. If a query takes less than one second and happens to occur in the time between sampling instances, its elapsed time is reported as 0 seconds.

You can configure the sampling frequency by adding the `-Ddbagent.sampling.interval= <value>` property for Database Agent. For information about adding the system properties, see [Database Agent Configuration Properties](#).

- **Number of Executions:** (supported for SQL Server, Azure, Oracle, DB2, PostgreSQL) The number of times the query ran during the specified time period. If you are monitoring Greenplum, the number of executions appears as 0.
- **Average Response Time (hh:mm:ss):** (supported for SQL Server, Azure, Oracle, DB2, PostgreSQL) The average time required during the specified time period to respond to the query.
- **Weight (%):** The percentage of the total time consumed by the query.

Query Id	Query	Elapsed Time	Number of Execut...	Average Response Time (hh:mm:ss)	Weight (%) ↓
47de1ca0600a1...	/* mysql-connector-java-5.1.33 (Revision: alexander.soklakov@oracle.com-20140908134200-8ukofe1iz0r2b63) */SHOW VARIABLES WHERE Variable_name = ? OR Variable_name = ? OR Variable_name = ? OR Variable_name = ? OR Variable_name = ? OR	6814:37:07	6037206	00:00:04.06	42.4

Once you have identified the statements that are consuming the most resources, you can dig down deeper for details that can help you tune the SQL statement. For in-depth query details, click a SQL statement and then click **View Query Details**. See [Database Query Details Window](#).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Database Query Details Window

Related pages:

- [Access Database Visibility from Application Monitoring Views](#)
- [Add Database Collectors](#)
- [Database Visibility](#)
- [Monitor Databases and Database Servers](#)
- [Monitor Database Performance](#)

Once you have identified the statements on the [Database Queries window](#) that are spending the most amount of time in the database, you can dig down deeper for details that can help you tune those SQL statements. The database instance Query Details window displays details about the query selected on the [Database Queries window](#).

Access the Database Query Details Window

To access the Database Query Details window:

1. To view a database's query details, click the name of the database.
2. Click the Queries tab.
3. Select a query and click **View Query Details**.

Database Query Details Window Features

From the Database Query Details window, you can:

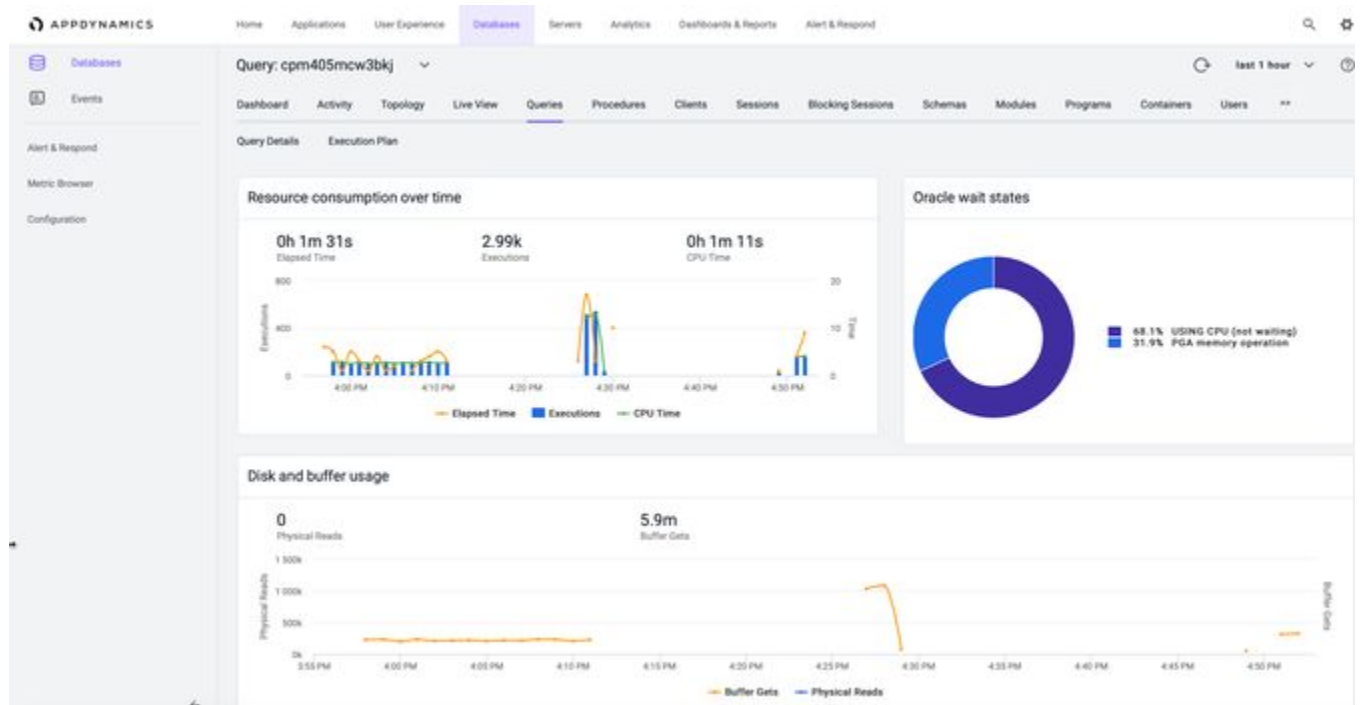

- Click **Execution Plan** to view an explanation plan for the query you selected on the Queries window if it was a SELECT query.
- Click on the graphs to see metrics for that specific point in time.
- Click the down arrow next to the database Collector name at the top of the page to choose to view the query details of a different database Collector.

From the Database Query Details window, you can view:

- **Resource consumption over time:** For SQL Server, Azure, Oracle, and DB2, shows the amount of time the query spent in the database using resources, the number of executions, and the amount of CPU time consumed. Query statistics are only available for the aforementioned database platforms.
The resource consumption card is also available for query groups. If all queries in the group have query metrics (for example, elapsed time and number of executions), then the aggregate of the group's metrics are shown. If none of the queries in the group have query metrics, then the aggregate elapsed time of the queries in the group, taken from the wait state index, is shown. If some queries in the group have query metrics and others do not, then the aggregate value of the available query metrics is shown.
- **Business Transactions Executing Similar Queries:** Displays the Java or PHP business transactions that execute queries similar to this query.
- **Disk and buffer usage:** Displays data when hardware monitoring is enabled for this database collector. This graph shows at a glance how effectively the database buffer is used. SQL that runs frequently is best kept in the buffer as physical disk reads are much more time-consuming. You may need to optimize your buffer manager if you see that the ratio of physical reads to buffer gets is too high.
- **Clients:** Shows the machines that executed the selected SQL statement and the percentage of the total time required to execute the statement performed by each machine. The table also shows the applications, nodes, and tiers of the machines.
- **<database_type> wait states:** Activities that contribute to the time it takes the database to service the selected SQL statement. The wait states consuming the most time may point to performance bottlenecks. For example, a db file sequential read wait state may be caused by segment header contention on indexes or by disk contention. See your database platform documentation for descriptions of the SQL wait states and recommended actions.
- **Query Active in Database/Schema:** Shows the schemas that have been accessed by this SQL.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- **Query ID (Oracle) SQL Handle (SQL Server):** A unique ID that allows the database server to more quickly locate this SQL statement in the cache.
- **Query:** The entire syntax of the selected SQL statement. You can click the pencil icon in the top right corner of the Query card to edit the query name so that it is easy to identify.
- **Queries in Group (only in Group Details view):** The top 100 queries in the query group
- **Users:** The users that executed this query.
- **Programs/Applications:** The program/application from which this query was executed.
- **Procedures:** The list of procedures for the queries that you monitor.
- **Containers:** The containers on which the query runs.

To see how the SQL was executed internally within the database, click the Execution Plan tab. The statement execution plan is the sequence of operations the database performs to run the statement.

i Oracle Explain Plan Limitations

For Oracle, AppDynamics Database Visibility displays execution plans for only SELECT, UPDATE, INSERT, and DELETE statements because Database Visibility relies on the [Oracle EXPLAIN PLAN](#) statement to obtain the execution plans and the Oracle EXPLAIN PLAN statement only provides the Oracle optimizer's execution plans for SELECT, UPDATE, INSERT, and DELETE statements. See also, [User Permissions for Oracle](#).

If you have a poorly performing piece of SQL that you are trying to tune, the obvious place to start is to look at the most costly step of the execution plan.

Tuning SQL is a vast topic, but a couple of things to look out for include:

- Index or table scans: May indicate a need for better or additional indexes.

-
- **Bookmark Lookups:** Consider changing the current clustered index, using a covering index and limiting the number of columns in the SELECT statement.
 - **Filter:** Remove any functions in the WHERE clause, don't include views in your Transact-SQL code, may need additional indexes.
 - **Sort:** Does the data really need to be sorted? Can an index be used to avoid sorting? Can sorting be done at the client more efficiently?

Database Query Execution Plan Window

Related pages:

- [Access Database Visibility from Application Monitoring Views](#)
- [Add Database Collectors](#)
- [Database Visibility](#)
- [Monitor Databases and Database Servers](#)
- [Monitor Database Performance](#)

The Database Query Execution Plan window can help you to determine the most efficient execution plan for your queries. Once you've discovered a potentially problematic query, you can run the EXPLAIN PLAN statement to check the execution plan that the database created. A query's execution plan reveals whether the query is optimizing its use of indexes and executing efficiently. This information is useful for troubleshooting queries that are executing slowly.

Access the Database Query Execution Plan Window

To access the Database Query Execution Plan window:

1. To view a query execution plan, click the name of the database.
2. Click the Queries tab.
3. Click a **SELECT** statement to examine and click **View Query Details**.
4. Click the Execution Plan tab.

Database Query Execution Plan Window Features

From the Database Query Execution Plan window, you can:

- Click **Explain** to view the execution plan for a query.
- Click **Schema** to choose a different schema and then explain the execution plan based on that schema. If you want to view the execution plan for a query that belongs to a schema outside the scope of your database account permissions, you can enter a username and password for a different database account that has access to the schema.
- If you want to improve a suboptimal query, you can modify the query and paste it into the **Explain another query** box. Click the **Explain** button to generate the execution plan for your modified query and determine whether the modified query is more efficient.
- Click the down arrow next to the query name at the top of the page to choose to view queries and query execution plans of a different database Collector. You can either select the database Collector name from the list or search for the database Collector in the search bar. Click the refresh icon to show only database Collectors that meet your search criteria.

If you are using MSSQL, you can perform these steps to view the costly operations (the amount of work such as CPU usage, I/O, and memory required to complete the operation) in the execution plan along with the warnings (if any) in the plan:

1. Under **Query Plan Handle(s)**, select a cached execution plan.
2. Click **View Cached Plan**.

You can view the following details:

Top Plan Operations:

Field Name	Description
Operation	The object scan (table or index) operation in the execution plan
Database	The database name of the object
Schema	The schema of the object in the database
Object Name	The name of the object (table or index) that is scanned in the operation
Estimated I/O Cost	The estimated cost of the input/output (I/O) to perform the operation
Estimated CPU Cost	The estimated CPU cost to perform the operation
Estimated number of rows	The estimated number of rows in the object

Warnings: This table includes the warnings in the execution plan related to any issue such as Typecast. This table helps you in understanding the potential performance-degrading activities that happen during the query execution. This table includes these fields:

Issue: The issue description for the warning.

Expression: The query expression used in the execution plan that correlates to the issue.

If you are using Oracle, SQL Server or Azure you can view the execution plan in one of the following ways:

- Select a cached execution plan and click **View Cached Plan** to view the plan details.
- Double-click a cached execution plan.

If you are using MySQL, you can also:

- Choose to explain the query on another schema. In **Plan Details**, from the list on the right, choose the schema name and then click **Explain**.
- Copy the text in the Parsed SQL output box and paste it into the **Explain another query** box where you can edit it and then explain the edited version of the query.

From the Database Query Execution Plan window, you can view:

- **Cached Execution Plan(s):** identifying details of the cached execution plan, which vary from one database to another. For SQL Server, the execution plan is rendered as a diagram.
- **Plan Details:** execution plan details, showing the step by step procedure the database followed to process the selected query.
- **Referenced Objects:** the database objects accessed by the execution plan.

Database Procedures Window

The Database **Procedures** window is available for Oracle Server.

The Database **Procedures** window shows you the names of the Top N procedures on the database instance based on time. To see the Top N Queries that are executed in a procedure, click a procedure name and then click **View Top Queries**. From the **Procedures** top queries page, to see more details about a query you can double-click a query to open the [Query Details](#) window.

Access the Database Procedures Window

To access the Database Procedures window:

1. To view a database's procedure, click the name of the database.
2. Click the Procedures tab.

Database Procedures Window Features

From the Database Procedures window, you can:

- Choose to view information for the top 10, 50, 100 or 200 procedures that most frequently access the database server.
- Double click the name of a procedure to view the top queries for one procedure in particular, or select the procedure and then click **View Top Queries**.
- Click the down arrow next to the database collector name at the top of the page to choose to view the procedures of a different Oracle database collector by either selecting the database collector from the list or by searching for the database collector by entering text in the search bar and then clicking the refresh icon to show only database collectors that meet that search criteria.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database **Procedures** window, you can view:

- **Procedure:** The name of the procedure run by an active session in the database.
- **Elapsed Time:** The time taken by the procedure.
- **Weight (%):** The percentage of time the procedure was consuming the database resources in comparison with the usage percentage of other procedures.

The screenshot shows the AppDynamics interface for a database cluster. The 'Procedures' tab is active, displaying a table of database procedures. The table has three columns: Procedure, Elapsed Time, and Weight (N). The 'N/A' row has the highest weight of 98.

Procedure	Elapsed Time	Weight (N)
N/A	167h 4m 31s	98
SHERLOCK	2h 11m 6s	1
DBMS_STATS.GATHER_DATABASE_STATS_JOB_PROC	0h 43m 26s	0

The Database Clients window shows you the hostname or IP addresses of the Top N clients using the database. A database client is any host that accesses the database instance. To see the Top N Queries run by the client, click a client name and then click **View Top Queries**. From the client top queries page, to see more details about a query you can double-click a query to open the [Query Details](#) window.

Access the Database Clients Window

To access the Database Clients window:

1. To view a database's clients, click the name of the database.
2. Click the Clients tab.

Database Clients Window Features

From the Database Clients window, you can:

- Choose to view information for the top 10, 50, 100 or 200 clients sorted by total time spent in the database.
- Choose to view information for one client in particular.
- Click the down arrow next to the database name at the top of the page to choose to view the database clients of a different database by either selecting the database from the list or by searching for the database by entering text in the search bar and then clicking the refresh icon to show only databases that meet that search criteria.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database Clients window, you can view:

- **Client:** The names of the machines that have connected to the database.
- **Elapsed Time:** The total time spent by the client executing queries.
- **Weight (%):** The percentage of time the client was connected to the database in comparison with connection times of other clients.

Database Sessions Window

Related pages:

- [Access Database Visibility from Application Monitoring Views](#)

The **Sessions** window shows you the Session ID of the Top N sessions using the database sorted by time spent. To see the Top N SQL run by a session, click the **Session ID** and then click **View Top Queries**. From the Client top queries page, to see more details about a query, double-click a query to open the Query Details window and from there see the Execution Plan of the query.

Access the Database Sessions Window

To access the Database Sessions window:

1. To view a database's sessions, click the name of the database.
2. Click the Sessions tab.

Database Sessions Window Features

From the Database Sessions window, you can:

- Choose to view information for the top 10, 50, 100 or 200 sessions consuming database resources.
- Double click a **Session ID** to view the queries run in that particular session.
- Click the down arrow next to the database name at the top of the page to choose to view the database sessions of a different database by either selecting the database from the list or by searching for the database by entering text in the search bar and then clicking the refresh icon to show only databases that meet that search criteria.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database Sessions window, you can view:

- **Session ID**: the Session ID of each database instance usage.
- **Weight (%)**: the percentage of time that instance was using the database in comparison with the database usage of other sessions.

Database Blocking Sessions Window

The blocking tree displays a tree view of sessions that are blocking other sessions for Oracle, SQL Server, Sybase ASE, and DB2. You can use the blocking tree to determine the cause of deadlocks.

Access the Database Blocking Sessions Window

To access the Database Topology window:

1. To view a database's blocking sessions, click the name of the database.
2. Click the Blocking Sessions tab.

Database Blocking Tree Window Features

From the Database Blocking Tree window you can expand the tree of a blocking session to see the sessions it is blocking.

From the Database Sessions window, you can view:

- **Session ID:** the Session ID of the sessions causing the block, and the sessions being blocked
- **Client:** the names of the machines where the session is blocked
- **User:** the user of the blocked session
- **Query:** the query that is blocked or causing the block
- **Blocked Object:** the object that is blocked
- **First occurrence of block:** the time that the block first occurred in the specified time range
- **Block Duration:** the amount of time that the session was blocked or causing the block

Database Schemas and Databases Windows

The Database Schemas window is available only for Oracle database servers.

The Database Databases window is available for other database servers.

The database Schemas or Databases window shows you the names of the Top N busiest schemas or databases on the database server. To see the Top N Queries run on a specific Database or Schema, click a name and then click **View Top Queries**. From the Schema or Database top queries page, to see more details about a query you can double-click a query to open the [Query Details](#) window.

Access the Database Schemas or Databases Window

To access the Database Schemas or Database window:

1. From the AppDynamics Home page, on the **Databases** card, click the name of the database that you want to view the schemas or databases for.
2. Depending on the platform, click either the Schemas or Databases tab.

Database Schemas or Databases Window Features

From the Database Schemas and Databases window you can:

- Choose to view information for the top 10, 50, 100 or 200 schemas or databases containing the most time spent executing queries by the database server.
- Double click the name of a schema or database to view the top queries for one schema database in particular, or select the schema or database and click **View Top Queries**.
- Click the down arrow next to the Database Collector name at the top of the page to choose to view the database schemas or databases of a different database Collector by either selecting the database Collector from the list or by searching for the database Collector by entering text in the search bar and then clicking the refresh icon to show only database Collectors that meet that search criteria.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database Schemas or Databases window, you can view:

- **Schema or database:** The names of the schemas or database on the database server.
- **Weight (%):** The percentage of time the schema or database was used by the database server in comparison with the usage percentage of other schemas or databases.

Database Modules Window

The Database Modules window is available only for Oracle database servers. The **Module** field is often identical to the **Program** field unless it has been programmatically set with a call to `DBMS_APPLICATION_INFO`. Some packaged applications, such as Oracle E-Business Suite, automatically set the **Module** field with relevant identifiers.

The Database Modules window shows you the names of the Top N busiest modules on the Oracle database server. To see the Top N Queries run on the database by a module, click a module name and then click **View Top Queries**. From the Modules top queries page, to see more details about a query you can double-click a query to open the [Query Details](#) window.

Access the Database Modules Window

To access the Database Modules window:

1. To view a database's modules, click the name of the database.
2. Click the Modules tab.

Database Modules Window Features

From the Database Modules window, you can:

- Choose to view information for the top 10, 50, 100 or 200 modules most frequently accessing the database server.
- Double click the name of a module to view the top queries for one module in particular, or select the module and click **View Top Queries**.
- Click the down arrow next to the database collector name at the top of the page to choose to view the modules of a different Oracle database collector by either selecting the database collector from the list or by searching for the database collector by entering text in the search bar and then clicking the refresh icon to show only database collectors that meet that search criteria.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database Modules window, you can view:

- **Module:** The name of the module run by the active sessions in the database.
- **Weight (%):** The percentage of time the module was consuming the database resources in comparison with the usage percentage of other modules.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Database Containers Window

The Database **Containers** window is available for Oracle Server.

The **Containers** window displays the names of the Top N containers on the database instance based on time. To see the top N queries run on the container, click a container name and then click **View Top Queries**. From the **Containers** top queries page, to see more details about a query you can double-click a query to open the [Query Details](#) window.

Access the Database Containers Window

To access the Database Containers window:

1. To view a database's containers, click the name of the database.
2. Click the Containers tab.

Database Containers Window Features

From the Database Containers window, you can:

- Choose to view information for the top 10, 50, 100 or 200 containers most frequently accessing the database server.
- Double click the name of a container to view the top queries for one container in particular, or select the container and click **View Top Queries**.
- Click the down arrow next to the database collector name at the top of the page to choose to view the containers of a different Oracle database collector by either selecting the database collector from the list or by searching for the database collector by entering text in the search bar and then clicking the refresh icon to show only database collectors that meet that search criteria.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database Containers window, you can view:

- **Container:** The name of the container where queries run in the database.
- **Elapsed Time:** The time taken by the queries to run on the container.
- **Weight (%):** The percentage of time the Container was consuming the database resources in comparison with the usage percentage of other Containers.

Container	Elapsed Time	Weight (%) ↓
CDB\$ROOT	0h 7m 37s	79
CDB	0h 2m 0s	21

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Database Users Window

The Database **Users** window shows you the users using the database. To see the Top N Queries run by a user, double-click the User name, or single-click the User name and then click **View Top Queries**. From the User top queries page, to see more details about a query you can double-click a query to open the Query Details window.

Access the Database Users Window

To access the Database Users window:

1. To view a database's users, click the name of the database.
2. Click the Users tab. You may need to click the expand button (>>) to see the Users tab.

Database Users Window Features

From the Database Users window, you can:

- Use the **Top users** dropdown menu to view information for the top 10, 50, 100 or 200 users sorted by total time spent in the database.
- Click a user to view information for about that user.
- Click the down arrow next to the database name at the top of the page to choose to view the database users of a different database. You can either select the database from the list or search for the database by entering text in the search bar and clicking the refresh icon to show only databases that meet that search criterion.
- Search for the database by entering text in the search bar and then clicking the refresh icon to show only databases that meet that search criterion.
- Click **Actions** to export the data on this window in a .csv formatted file that is automatically downloaded to your specified downloads directory.

From the Database Users window, you can view:

- **User:** The names of the user accounts that have connected to the database.
- **Elapsed Time:** Duration of time that the user spent executing queries.
- **Weight (%):** Time the user spent executing queries as a percentage of the total time spent by all users.

The screenshot shows the 'Database Users' window for 'ECommerce-Oracle'. The 'Users' tab is selected. A dropdown menu shows '100' top users. The table below lists the top users with their names, elapsed times, and weights.

User	Elapsed Time	Weight
APPDY	01:07:51	
WORLD	00:32:58	
SYSTEM	00:00:01	
APEX_040000	00:00:01	

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Database Buckets Window

The **Buckets** window is available only for Couchbase collector.

The **Buckets** window shows you the names of the top 200 buckets sorted in descending order based on operations. To see the details of a specific bucket, click a bucket name, and then click **View Bucket Details**.

Access the Buckets Window

1. From the AppDynamics Home page, on the **Databases** card, click the name of the Couchbase collector that you want to view the buckets for.
2. Click the Buckets tab.

Buckets Window Features

From the Buckets window, you can:

- Double click the name of the bucket to view the bucket statistics for the selected time range.
- Click the down arrow next to the Couchbase collector name at the top of the page to choose to view the buckets of a different Couchbase collector by either selecting the Couchbase collector from the list or by searching for the Couchbase collector by entering text in the search bar and then clicking the refresh icon to show only database collectors that meet that search criteria.
- Click **Actions** to export the data on this window in a `.csv` formatted file that is automatically downloaded to your specified downloads directory.

From the Buckets window, you can view statistics for a bucket:

Operations (`ops`), Bytes Read (`bytes_read`), Bytes Written (`bytes_written`), Total Disk Size, in MB (`couch_total_disk_size`), Hit Ratio (`hit_ratio`)

Bucket Name	Operations/min	Bytes Read	Bytes Written	Total Disk Size (MB)	Hit Ratio
travel-sample	31291.36	1659180.73	38013243.66	164.00	99.93
beer-sample	0.00	334.34	48899.80	51.00	0.00
gamesim-sample	0.00	363.66	52427.07	41.00	0.00
loadBucket	0.00	345.25	56813.57	10.00	0.00

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Database Business Transactions Window

The Database **Business Transactions** window shows you the top Java or PHP business transactions, ranked by their cumulative execution time on the database. To see the Top N SQL run by a business transaction, click the business transaction and then click **View Top Queries**. From the Business Transaction top queries page, you can double-click a query to open the Query Details window.

Supported Platforms

AppDynamics supports Java as an application framework. Relational databases are supported as backends that need to be mapped on the Java APM to a monitored instance in database visibility. For more information, see [Linking Database with application backend](#).

Access the Database Business Transactions Window

To access the Top Business Transactions window:

1. To view a database's business transactions, click the name of the database.
2. Click the Business Transactions tab.

Database Business Transactions Window Features

From the Database Business Transactions window, you can:

- Choose to view information for the top 10, 50, 100 or 200 business transactions executing queries on the database.
- Double-click a business transaction to view the queries run in that particular transaction.
- Click the down arrow next to the database name at the top of the page to choose to view the business transactions that access a different database by either selecting the database from the list or by searching for the database by entering text in the search bar and then clicking the refresh icon to show only databases that meet that search criteria.
- Click **Actions** to export the data on this window in a `.csv` formatted file that is automatically downloaded to your specified downloads directory.

From the Database Business Transactions window, you can view:

- **Business Transaction:** the business transactions that run the most number of queries on the database.
- **Application:** the application that each business transaction is executing in.
- **Weight (%):** the percentage of time that business transaction took to execute compared to other business transactions.

Business Transaction	Application	Weight (%) ↓
Checkout	ECommerce-Sales-Demo	57.2
Checkout - Mobile	ECommerce-Sales-Demo	42.8

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Database Applications Window

The Database **Applications** window is available for Postgres, Sybase ASE, Sybase IQ, and DB2.

The **Applications** window shows you the names of the Top N Applications on the database instance based on time. To see the Top N Queries run on the database by an application, click the name of an application and then click **View Top Queries**. From the Applications top queries page, to see more details about a query you can double-click a query to open the Query Details window.

Access the Database Applications Window

To access the Database Applications window:

1. To view a database's applications, click the name of the database.
2. Click the Applications tab.

Database Applications Window Features

From the Database Applications window, you can:

- Choose to view information for the top 10, 50, 100 or 200 applications most frequently accessing the database server.
- Double click the name of an application to view the top queries for one application in particular, or select the application and click **View Top Queries**.
- Click the down arrow next to the database collector name at the top of the page to choose to view the applications of a different MongoDB database collector by either selecting the database collector from the list or by searching for the database collector by entering text in the search bar and then clicking the refresh icon to show only database collectors that meet that search criteria.
- Click **Actions** to export the data on this window in a `.csv` formatted file that is automatically downloaded to your specified downloads directory.

From the Database Applications window, you can view:

- **Applications:** The name of the application run by an active session in the database.
- **Weight (%):** The percentage of time the application was consuming the database resources in comparison with the usage percentage of other applications.

Database Object Browser Window

Related pages:

- [Access Database Visibility from Application Monitoring Views](#)
- [Database Visibility](#)
- [Monitor Databases and Database Servers](#)
- [Monitor Database Performance](#)

When you detect a problem with database performance, you may be able to correct the problem by adding an index, refusing access to certain users, or creating a new index on a table. You can browse through the database objects to find ways to tune the database, including the indexes that are currently available on the various tables. The contents of the **Database Object Browser** are updated when you access them or click **Refresh**.

The objects available for browsing are database dependent. For clustered databases, select the node to browse its objects.

Access the Database Objects Window

To access the Database Objects window:

1. To view a database's objects, click the name of the database.
2. Click the Objects tab.

Database Objects Window Features

From the **Database Objects** window you can:

- Click an object type in the tree to see more information about it.
- For Oracle, search for a specific database item.
- Click the down arrow next to the database name at the top of the page to choose to view the database objects of a different database by either selecting the database from the list or by searching for the database by entering text in the search bar and then clicking the refresh icon to show only databases that meet that search criteria.

The screenshot displays the AppDynamics interface for an Oracle database instance. The top navigation bar includes 'Dashboard', 'Activity', 'Live View', 'Queries', 'Clients', 'Sessions', 'Blocking Sessions', 'Schemas', 'Modules', 'Programs', 'Users', and 'Business Transactions'. The main content area is titled 'Oracle-4.5.1.779' and shows a list of instance properties:

Property	Value
Instance Number	1
Instance Name	orcl12c
Host Name	ip-10-0-0-33.us-west-2.compute.internal
Version	12.2.0.1.0
Startup Time	2018-03-26 18:23:03.0
Status	OPEN
Parallel	NO
Thread#	1
Archiver	STOPPED
Log Switch Wait	
Logins	ALLOWED
Shutdown Pending	NO
Database Status	ACTIVE
Instance Role	PRIMARY_INSTANCE
Active State	NORMAL
Blocked	NO
Con Id	0
Instance Mode	REGULAR
Edition	EE
Family	
Database Type	SINGLE

The following are some examples of browsable content.

- Database uptime and version for all platforms
- **Users:** who has access to the database for all platforms (supported for Oracle, MySQL)
- **Job Status:** status of SQL agent job (supported for SQL Server)
- **Parameters:** database initialization parameters (supported for Oracle)
- **Variables:** system variables indicating how the database was configured.
- **Current Statistics:** the current value of statistics collected. The various statistics available are database dependent and are a superset of those shown in the **Database Monitoring - Metric Browser** page.
- **System Waits:** SQL waits experienced by the database
- **Database Objects:** search for specific objects, and browse through database schemas, tables, columns, and indices.

Database Custom Metrics Window

The **Custom Metrics** window displays metrics for the custom queries that you specified for Database Visibility to monitor. See [Configure Custom Metrics](#).

Access the Database Custom Metrics Window

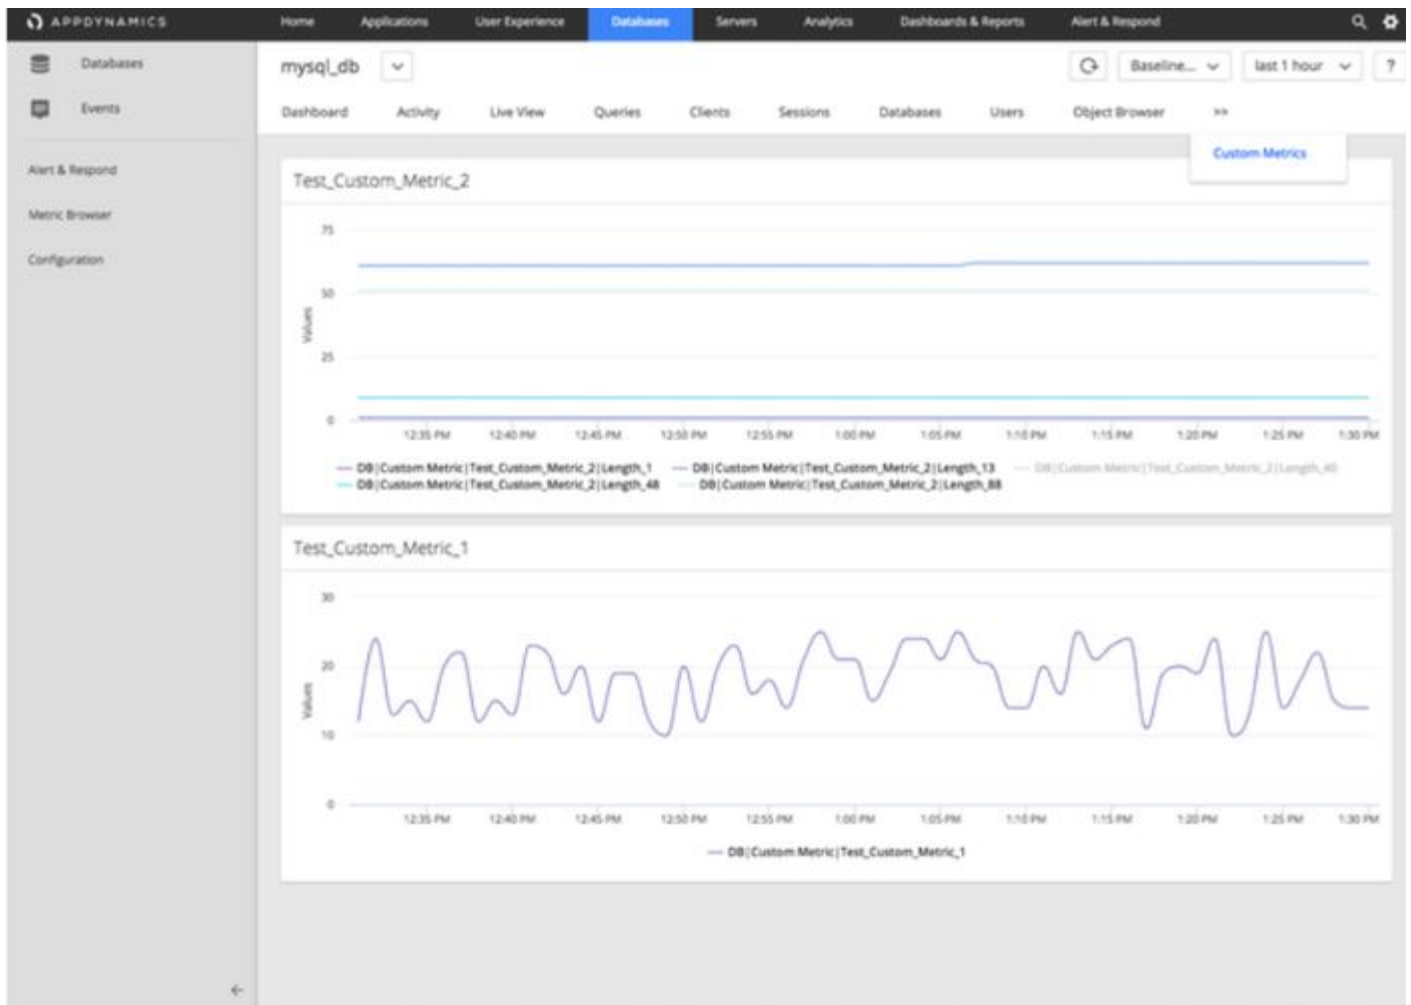

To access the Database **Custom Metrics** window:

1. To view a database's objects, click the name of the database.
2. Click the Custom Metrics tab.

Database Custom Metrics Window Features

From the Database Custom Metrics window, you can:

- View the values for each row of the custom query output. For example, if the query returns four rows, then the graph displays four lines.
- Double-click the graph to view the custom metric in the **Metric Browser**.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Monitor Database Server Hardware

Access the Database Server Hardware Metrics Window

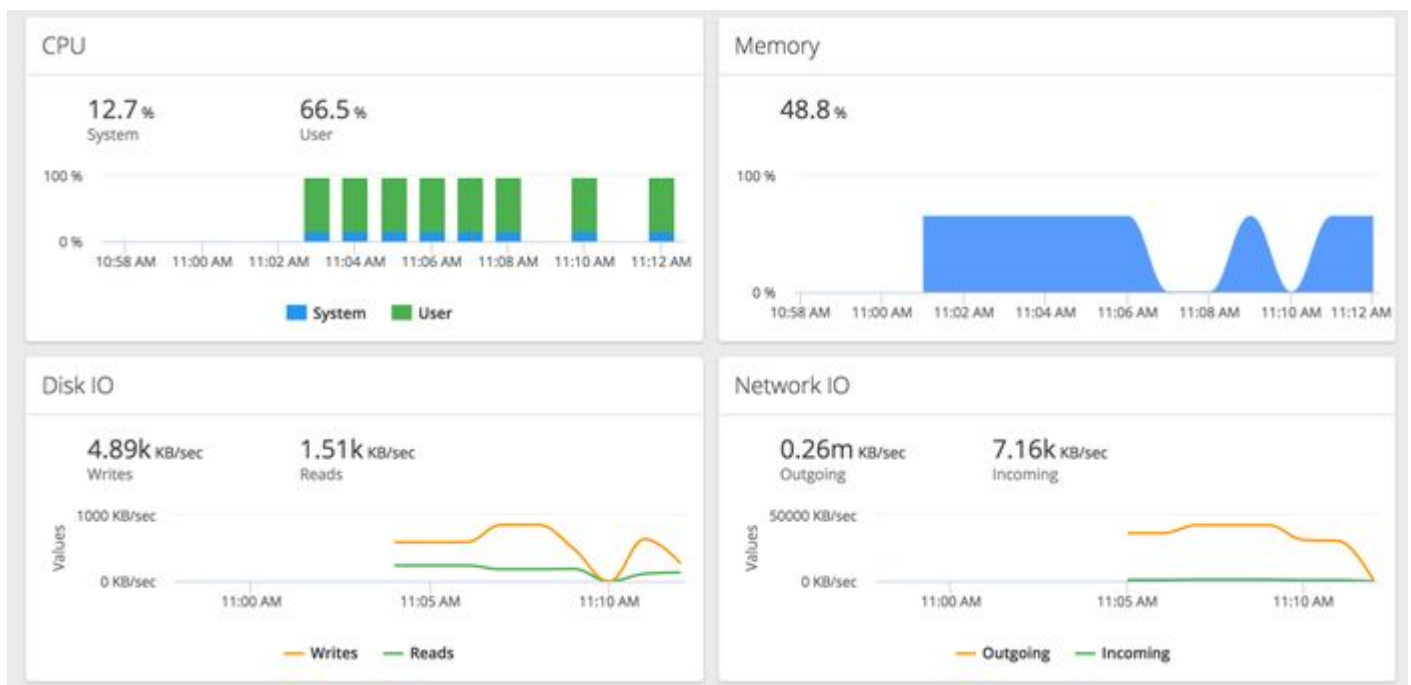

Hardware metrics are reported on:

- [Database Dashboard](#) window
- [Database Live](#) window
- [Metric Browser](#)

Hardware Metrics Graphs Features

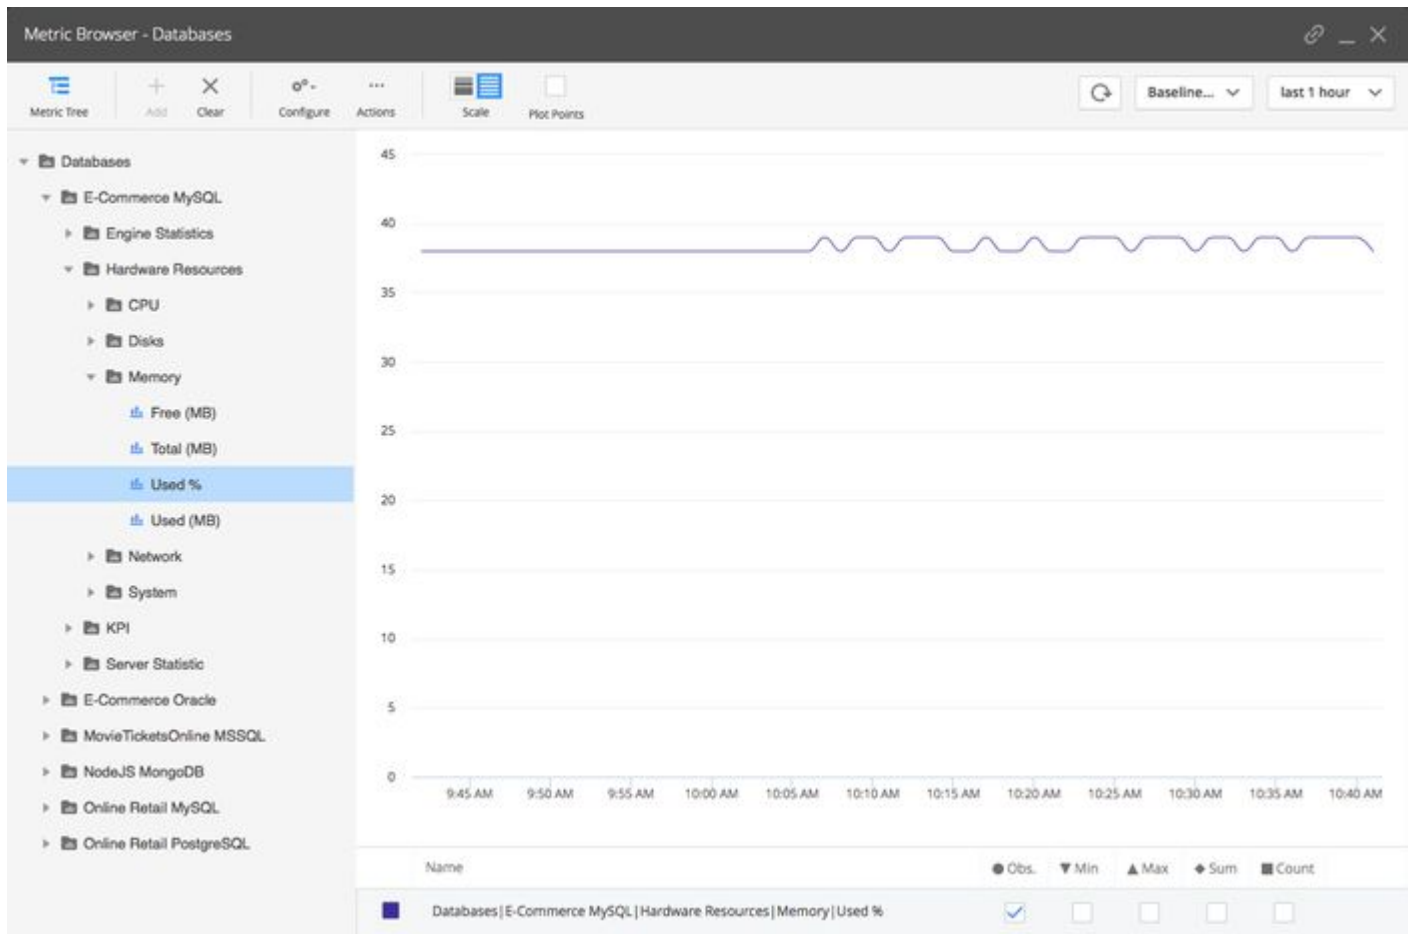

On the hardware metrics graphs, you can:

- Click anywhere on the graphs to get details about activity at that point in time.
- Double-click KPI points in the graph to display the Metric Browser showing the selected metric. Metrics are collected by the agent and reported once a minute.

Compare Server and Database Metrics

You can view and compare hardware and database metrics in the [Metric Browser](#). This can help you visualize the effect of server performance on database performance.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Database Health Rules and Alerts

You can configure AppDynamics Database Visibility to alert you when certain conditions are met or exceeded for monitored databases, operating systems, and server hardware. Use the **Getting Started Wizard** to guide you through the process if you are a new AppDynamics Pro user.

You configure [Health Rules](#), [Actions](#), [Policies](#), and Email Digests for monitoring databases almost exactly as you would configure these for monitored applications.

To view the health rules for your databases, click **Alert & Respond > Health Rules** and select **Databases** from the dropdown at the top. Use the Affected Entities tab of the **Create Health Rule** dialog to specify the **Database Health** rules. See [Alert and Respond](#).

In the Affected Entities tab, you can apply a database health rule to all databases, all databases of a specific database type, or to select instances of a specific database type being monitored. You can select the metrics on which to base the health rule. The health rule is violated when specified critical or warning conditions are met.

The screenshot shows the 'Create Health Rule' dialog box with the 'Affected Entities' tab selected. The dialog has four tabs: Overview, Affected Entities, Critical Criteria, and Warning Criteria. Under 'Affected Entities', there are three dropdown menus: 'Select Health Rule Type' (Database Health), 'Select what Database Type this Health Rule affects' (All Database Types), and 'Select Databases' (All Databases). At the bottom right, there are 'Cancel' and 'Save' buttons.

Similarly, you can create the health rule for Database Agent (**DB Agent Health**) and the Affected Entities tab of the **Create Health Rule** dialog allows specifying the **DB Agent Health** rule. You can apply a Database Agent (**DB Agent Health**) rule to all the Database Agents or specific Database Agents. You can select the required metrics on which to base the health rule. The health rule is violated when specified critical or warning conditions are met.

Create Health Rule ✕

i Each Health Rule is only evaluated for the subset of databases or database that you currently have permissions for. If your permissions have changed since you created the Health Rule, then your current permissions are applied to the Health Rule evaluation.

Database Policy Actions are limited to email or SMS message notifications, and custom actions that have been uploaded to the Controller.

Once you have defined Health Rules and Actions, you can create a Policy based on a Health Rule to send you an email or an SMS message when a Health Rule is violated.

Database Monitoring Metrics

Related page:

[Metric Browser](#)

This document describes metrics collected by the Database Agent. It shows the path to the metric from the main AppDynamics menu down to the relevant branch of the Metric Browser tree. Some of these metrics are displayed in the Database Visibility user interface and so are also documented with the name of the window, column, section, and metric name.

The Metric Browser window name uses the following format:

- Metric Browser - *application_name*: When you access the Metric Browser from Applications.
- Metric Browser - Database Monitoring: When you access the Metric Browser from Infrastructure.

For most types of metrics in the browser, you can click any of the points in the graph to view more information about the metric observed at that point in time. The information shown includes the metric identifier, date and time of the observation, along with any of the following values relevant to the metric:

- **Obs** (observed value): the average of all data points seen for that interval. For a cluster or a time rollup, this represents the weighted average across nodes or over time.
- **Min**: the minimum data point value seen for that interval
- **Max**: the maximum data point value seen for that interval
- **Sum**: the sum of all data point values seen for that interval.
- **Count**: number of observations aggregated in that one point. For example, a count of 5 indicates that there were 5 1-minute data points aggregated into one point.

Key Performance Indicators (KPI)

These metrics are available for all database platforms supported.

Calls per Minute: The number of SQL calls to the database per minute.

DB Availability: The times when the database is available (has an active connection). If the database is not available, nothing is reported.

Number of Connections: The number of connections established with the database at any point during the selected time period. A connection is a session established between a database client and a server. Since the value displayed is the average number of connections over a time range, it is common to see a very low number or 0 for this metric.

Time Spent in Execution (s): The current amount of time the database spent executing SQL statements.

Total Database Size (PostgreSQL only): The amount of disk space (in MB) that the database is using.

Total Lock Time: Total time the database was in lock state in seconds.

Hardware Memory Metrics

These are the memory metrics that are available when you use hardware monitoring:

Total (MB): The total available memory.

Free (MB): The difference between the total and the used memory.

Used (MB): The amount of the memory used in MB.

i The buffered memory and swap cache memory is a part of the used memory. However for Database Agent <21.2, the buffered memory and swap cache memory is not a part of the used memory

Cassandra Metrics

Metrics	Description
Average Read Write latency (microseconds)	Total Read Write divided Number of Reads Writes
Commands Completed(Only For DSE Cassandra)	Total read repair commands completed since startup.
Commands Pending(Only For DSE Cassandra)	A current number of the read repair commands pending.
Compaction Tasks Completed	The number of completed compactions since server start or restart.
Compaction Tasks Pending	The estimated number of compactions remaining to perform.
Disk Load (bytes)	The size (in bytes) of the on-disk data size the node manages.
Dropped Mutations	A dropped Write attempt on a node
Exceptions	The number of internal exceptions caught. Under normal exceptions, this should be zero.
GC Collection Count	The total number of collections that have occurred.
GC Collection Time (ms)	The time (in milliseconds) that Cassandra JVM takes to perform the garbage collection.
Heap Memory Used (bytes)	The heap Memory Used by JVM in bytes.
Key Cache Hit Percentage	The percentage of Key cache(Cache for partition to sstable offsets) hit rate.
Max Partition Size	The size of the largest compacted partition (in bytes).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metrics	Description
Memtable Live Data Size (bytes)	The disk space used by SSTables that belongs to this table (in bytes).
Messaging Latency	The latency for inter-node communication.
Non Heap Memory Used (bytes)	The memory used by JVM other than heap memory (in bytes).
Number of Reads Writes	The number of the <code>Reads Write</code> requests.
Prepared Statements Executed	A number of Prepared Statements executed.
Process CPU Load Percentage	The Percentage of the <code>recent cpu usage</code> for the Java Virtual Machine process.
Read Failures	The number of failed <code>Read</code> operations
Read Repair Attempted(Only For DSE Cassandra)	The read repairs attempted since startup.
Read Repaired Background(Only For DSE Cassandra)	A number of the read repairs performed asynchronously since startup.
Read Repaired Blocking(Only For DSE Cassandra)	A number of the read repairs performed synchronously since startup.
Read Timeout Exceptions	The number of timeouts encountered for the read request.
Read Unavailability Exceptions	The number of unavailable exceptions encountered for the read request.
Read Write Throughput	Derived from Number of Reads Writes metrics over 1 minute.
Regular Statements Executed	A number of nonprepared statements executed.
Repair Age Percentage	The percentage of the table data that is repaired on disk.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metrics	Description
Responses Completed(Only For DSE Cassandra)	The current read repairs completed count.
Responses Pending(Only For DSE Cassandra)	The current read repair responses pending count.
System CPU Load Percentage	The Percentage of the <code>recent cpu usage</code> for the whole system.
ThreadPools Request Active Tasks Authz Stage	The number of tasks being actively worked on by AuthzStage thread pool.
ThreadPools Request Active Tasks Read Repair Stage	The number of tasks being actively worked on by Read Repair Stage thread pool.
ThreadPools Request Active Tasks Request Response Stage	The number of tasks being actively worked on by Request Response Stage thread pool.
ThreadPools Internal Active Tasks Anti Entropy Stage	The number of tasks being actively worked on by Anti Entropy Stage thread pool.
ThreadPools Internal Active Tasks Background IO Stage	The number of tasks being actively worked on by Background IO Stage thread pool.
ThreadPools Internal Active Tasks Gossip Stage	The number of tasks being actively worked on by Gossip Stage thread pool.
ThreadPools Internal Active Tasks Internal Response Stage	The number of tasks being actively worked on by Internal Response Stage thread pool.
ThreadPools Internal Active Tasks Migration Stage	The number of tasks being actively worked on by Migration Stage thread pool.
ThreadPools Internal Active Tasks Misc Stage	The number of tasks being actively worked on by Misc Stage thread pool.
ThreadPools Request Pending Tasks Authz Stage	The number of queued tasks queued up by AuthzStage thread pool.
ThreadPools Request Pending Tasks Read Repair Stage	The number of queued tasks queued up by the Read Repair Stage thread pool.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metrics	Description
ThreadPools Request Pending Tasks Request Response Stage	The number of queued tasks queued up by Request Response Stage thread pool.
ThreadPools Internal Pending Tasks Anti Entropy Stage	The number of queued tasks queued up by Anti Entropy Stage thread pool.
ThreadPools Internal Pending Tasks Background IO Stage	The number of queued tasks queued up by Background IO Stage thread pool.
ThreadPools Internal Pending Tasks Gossip Stage	The number of queued tasks queued up by Gossip Stage thread pool.
ThreadPools Internal Pending Tasks Internal Response Stage	The number of queued tasks queued up by Internal Response Stage thread pool.
ThreadPools Internal Pending Tasks Migration Stage	The number of queued tasks queued up by Migration Stage thread pool.
ThreadPools Internal Pending Tasks Misc Stage	The number of queued tasks queued up by Misc Stage thread pool.
ThreadPools Request Currently Blocked Tasks Authz Stage	The number of tasks that were blocked due to queue saturation on AuthzStage thread pool.
ThreadPools Request Currently Blocked Tasks Read Repair Stage	The number of tasks that were blocked due to queue saturation on Read Repair Stage thread pool.
ThreadPools Request Currently Blocked Tasks Request Response Stage	The number of tasks that were blocked due to queue saturation on Request Response Stage thread pool.
ThreadPools Internal Currently Blocked Tasks Anti Entropy Stage	The number of tasks that were blocked due to queue saturation on Anti Entropy Stage thread pool.
ThreadPools Internal Currently Blocked Tasks Background IO Stage	The number of tasks that were blocked due to queue saturation on Background IO Stage thread pool.
ThreadPools Internal Currently Blocked Tasks Gossip Stage	The number of tasks that were blocked due to queue saturation on Gossip Stage thread pool.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metrics	Description
ThreadPools Internal Currently Blocked Tasks Internal Response Stage	The number of tasks that were blocked due to queue saturation on Internal Response Stage thread pool.
ThreadPools Internal Currently Blocked Tasks Migration Stage";	The number of tasks that were blocked due to queue saturation on Migration Stage thread pool.
ThreadPools Internal Currently Blocked Tasks Misc Stage";	The number of tasks that were blocked due to queue saturation on Misc Stage thread pool.
Total Read Write latency (microseconds)	Total Read Write Latency
Write Failures	The number of failed <code>Write</code> operations
Write Timeout Exceptions	Number of timeouts encountered for write request.
Write Unavailability Exceptions	Number of unavailable exceptions encountered for write request.

Couchbase Metrics

Gc_num: Number of objects garbage collected

Gc_pause_time: Garbage collection pause time

Gc_pause_percent: Garbage collection pause percentage

Memory_usage: Memory (in GB) currently used by Couchbase

Memory_total: Memory (in GB) used by Couchbase over the total period of time

Memory_system: Memory (in GB) used by the system.

Cpu_user_percent: Percentage of CPU used by the user

Cpu_sys_percent: Percentage of CPU used by the system

Request_completed_count: Number of requests completed

Request_active_count: Number of active requests

Request_per_sec_1min: Requests per second in the last minute

Request_per_sec_5min: Requests per second in the last 5 minutes

Request_per_sec_15min: Requests per second in the last 15 minutes

Request_time_mean: Average request time

Request_time_median: Median request time

Request_time_80: 80th percentile request time

Request_time_95: 95th percentile request time

Request_time_99: 99th percentile request time

Request_prepared: Number of requests prepared

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

cpu_utilization_rate: Rate of CPU utilization
swap_total: Total amount of swap available
swap_used: Amount of swap used
mem_total: Total available memory
mem_free: Total amount of free memory

cmd_get: Compare and Swap gets
couch_docs_actual_disk_size: The physical memory used in the node
couch_docs_data_size: Data size of couch documents associated with a node
couch_spatial_data_size: Size of object data for spatial views
couch_spatial_disk_size: Amount of disk space occupied by spatial views
couch_views_actual_disk_size: Amount of disk space occupied by Couch views
couch_views_data_size: Size of object data for Couch views
curr_items: Number of active items in memory
curr_items_tot: Total number of items
ep_bg_fetched: Disk reads per second
get_hits: Number of get hits
mem_used: Engine's total memory usage
ops: Spatial operations
vb_replica_curr_items: Number of in memory items
operations per second: The total amount of operations per second (including XDCR) to this bucket (measured from `cmd_lookup + cmd_set + incr_misses + incr_hits + decr_misses + decr_hits + delete_misses + delete_hits + ep_num_ops_del_meta + ep_num_ops_get_meta + ep_num_ops_set_meta`).
active docs resident %: The percentage of active items cached in RAM in this bucket (measured from `vb_active_resident_items_ratio`).
gets per sec: The number of reads (get operations) per second from this bucket (measured from `cmd_get`).
sets per sec: The number of writes (set operations) per second to this bucket (measured from `cmd_set`).
deletes per sec: The number of delete operations per second for this bucket (measured from `delete_hits`).
disk creates per sec: The number of new items created on disk per second for this bucket (measured from `vb_active_ops_create + vb_replica_ops_create + vb_pending_ops_create`).
disk updates per sec: The number of items updated on disk per second for this bucket (measured from `vb_active_ops_update + vb_replica_ops_update + vb_pending_ops_update`).
disk reads per sec: The number of reads per second from disk for this bucket (measured from `ep_bg_fetched`).
disk read failures: The number of disk read failures (measured from `ep_data_read_failed`).
disk write failures: The number of disk write failures (measured from `ep_data_write_failed`).
temp OOM per sec: The number of back-offs sent per second to client SDKs due to the out-of-memory situations from this bucket (measured from `ep_tmp_oom_errors`).
cache miss ratio: The percentage of reads per second to this bucket from disk as opposed to RAM

(measured from `ep_bg_fetches / cmd_lookup * 100`).

disk queue fill rate: The total number of items per second being put on the disk queue in this bucket (measured from `ep_diskqueue_fill`).

disk queue drain rate: The total number of items per second being written to disk in this bucket (measured from `ep_diskqueue_drain`).

disk write queue: The number of items waiting to be written to disk in this bucket (measured from `ep_queue_size+ep_flusher_todo`).

DB2 Server Metrics

ACTIVE_SORTS: The number of sorts in the database that currently have a sort heap allocated.

AGENTS_TOP: At the database level, it is the maximum number of agents for all applications.

APPLS_CUR_CONS: The number of applications that are currently connected to the database.

APPLS_IN_DB2: The number of applications that are currently connected to the database, and for which the database manager is currently processing a request.

BINDS_PRECOMPILES: The number of binds and pre-compiles attempted. You can use this element to gain insight into the current level of activity within the database manager. This value does not include the count of `int_auto_rebinds`, but it does include binds that occur as a result of the `REBIND PACKAGE` command.

CONNECTIONS_TOP: The highest number of simultaneous connections to the database since the database was activated.

COORD_AGENTS_TOP: The highest number of coordinating agents. If the peak number of coordinating agents represents too high a workload for this node, you can reduce this upper boundary by changing the `max_coordagents` configuration parameter.

DDL_SQL_STMTS: The number of SQL Data Definition Language (DDL) statements that were executed.

DEADLOCKS: The number of deadlocks that have occurred.

DIRECT_READ_REQS: Use the following formula to calculate the average number of sectors that are read by a direct read: `direct_reads / direct_read_reqs`.

DIRECT_READ_TIME: Time spent doing direct read operations.

DIRECT_READS: Direct reads are performed in units, the smallest being a 512-byte sector. They are used when: Reading LONG VARCHAR columns, Reading LOB (large object) columns, Performing a backup.

DIRECT_WRITE_REQS: Use the following formula to calculate the average number of sectors that are written by a direct write: `direct_writes / direct_write_reqs`.

DIRECT_WRITE_TIME: Time spent doing direct write operations.

DIRECT_WRITES: Direct writes are performed in units, the smallest being a 512-byte sector. They are used when: Writing LONG VARCHAR columns, Writing LOB (large object) columns, Performing a restore, Performing a load, Allocating new extents for SMS table space if MPFA is enabled (which is the default).

DYNAMIC_SQL_STMTS: The number of dynamic SQL statements that were attempted.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

ELAPSED_EXEC_TIME_MS: The total time (in milliseconds) required to execute all the statements for a particular application during the specified time period.

ELAPSED_EXEC_TIME_S: The total time (in seconds) required to execute all the statements for a particular application during the specified time period.

FAILED_SQL_STMTS: The number of SQL statements that were attempted, but failed.

INT_AUTO_REBINDS: The number of commits initiated internally by the database manager.

INT_COMMITS: The number of commits initiated internally by the database manager.

INT_DEADLOCK_ROLLBACKS: The number of forced rollbacks initiated by the database manager due to a deadlock. A rollback is performed on the current unit of work in an application selected by the database manager to resolve the deadlock.

INT_ROLLBACKS: The number of rollbacks initiated internally by the database manager.

INT_ROWS_DELETED: The number of rows deleted from the database as a result of internal activity.

INT_ROWS_INSERTED: The number of rows inserted into the database as a result of internal activity caused by triggers.

INT_ROWS_UPDATED: The number of rows updated from the database as a result of internal activity.

LOCK_ESCALAS: The number of times that locks have been escalated from several row locks to a table lock.

LOCK_LIST_IN_USE: The total number of bytes of lock list memory in use.

LOCK_TIMEOUTS: The number of times that a request to lock an object timed-out instead of being granted.

LOCK_WAIT_TIME: The total elapsed time (in milliseconds) spent waiting for locks.

LOCK_WAITS: The number of times that applications or connections waited for locks.

LOCKS_HELD: The number of locks currently held.

LOCKS_WAITING: The number of agents waiting on a lock.

LOG_HELD_BY_DIRTY_PAGES: The amount of log (in bytes) corresponding to the difference between the oldest dirty page in the database and the top of the active log.

LOG_READ_TIME_NS: The total elapsed time spent by the logger reading log data from the disk. For event monitors that write to tables, the value of this element is given in microseconds by using the BIGINT data type.

LOG_READ_TIME_S: At the database level, this is the number of subagents for all applications.

LOG_READS: The number of log pages read from disk by the logger.

LOG_TO_REDO_FOR_RECOVERY: The size of the log (in bytes) that will have to be redone for crash recovery.

LOG_WRITE_TIME_NS: The total elapsed time spent by the logger writing log data to the disk. For event monitors that write to tables, the value of this element is given in microseconds by using the BIGINT data type.

LOG_WRITE_TIME_S: At the database level, this is the number of subagents for all applications.

LOG_WRITES: The number of log pages written to disk by the logger.

NUM_ASSOC_AGENTS: At the database level, this is the number of subagents for all applications.

NUM_INDOUBT_TRANS: The number of outstanding indoubt transactions in the database. Indoubt transactions hold log space for uncommitted transactions, which can cause the logs to become full. When the logs are full, further transactions cannot be completed. The resolution of this problem involves a manual process of heuristically resolving the indoubt transactions. This monitor element provides a count of the number of currently outstanding indoubt transactions that must be heuristically resolved.

NUM_LOG_BUFFER_FULL: The number of times agents had to wait for log data to write to disk while copying log records into the log buffer.

NUM_LOG_DATA_FOUND_IN_BUFFER: The number of times log data was read from buffer instead of from disk, which is slower.

NUM_LOG_PART_PAGE_IO: Number of I/O requests issued by the logger for writing partial log data to disk. To determine if the current disk is adequate for logging, use this metric in conjunction with log_writes, log_write_time, and num_log_write_io.

NUM_LOG_READ_IO: Number of I/O requests issued by the logger to read log data from disk. To determine if the current disk is adequate for logging, use this metric in conjunction with log_reads and log_read_time.

NUM_LOG_WRITE_IO: Number of I/O requests issued by the logger to write log data to disk. To determine if the current disk is adequate for logging, use this metric in conjunction with log_writes and log_write_time.

POOL_ASYNC_DATA_READ_REQS: Number of asynchronous read requests by the prefetcher to the operating system. These requests are usually large block I/Os of multiple pages.

POOL_ASYNC_DATA_READS: Number of data pages read in from the table space physical containers by asynchronous engine dispatchable units for all types of table spaces. To determine the number of physical read that were performed synchronously, use this metric along with the pool_data_p_reads metrics.

POOL_ASYNC_DATA_WRITES: Number of times a buffer pool data page was physically written to disk by either an asynchronous page cleaner or prefetcher. To determine how well the buffer page cleaners are performing, use this metric in conjunction with pool_data_writes and pool_async_data_writes.

POOL_ASYNC_INDEX_READS: Number of index pages read in from the physical table space containers by asynchronous engine dispatchable units for all types of table spaces. To determine how well the prefetchers are working, compare the ratio of asynchronous reads to total physical reads. Use this information to tune the num_ioservers configuration parameter.

POOL_ASYNC_INDEX_WRITES: Number of times a buffer pool index page was physically written to disk by either an asynchronous page cleaner or prefetcher.

POOL_ASYNC_READ_TIME: Total number of milliseconds spent reading in data and index pages from physical table space containers by asynchronous engine dispatchable units for all types of table spaces. Use this metric to analyze the I/O work being performed.

POOL_ASYNC_WRITE_TIME: Total number of milliseconds spent writing data or index pages from the buffer pool to disk by database manager page cleaners. Use this metric to analyze the I/O work being performed.

POOL_DATA_FROM_ESTORE: Number of buffer pool data pages read from the extended storage monitor.

POOL_DATA_L_READS: Number of data pages which have been requested from the buffer pool (logical) for regular and large table spaces. The functionality to record buffer pool information at the statement level is supported for API and CLP snapshot requests.

POOL_DATA_P_READS: Number of data pages read in from the table space containers (physical) for regular and large table spaces. The functionality to record buffer pool information at the statement 7 level is supported for API and CLP snapshot requests.

POOL_DATA_WRITES: Number of times a buffer pool data page was physically written to disk.

POOL_DRTY_PG_STEAL_CLNS: Number of times a page cleaner was invoked because a synchronous write was needed during the victim buffer replacement for the database.

POOL_DRTY_PG_THRSH_CLNS: Number of times a page cleaner was invoked because a buffer pool had reached the dirty page threshold criterion for the database.

POOL_INDEX_L_READS: Number of index pages which have been requested from the buffer pool (logical) for 9 regular and large table spaces. The functionality to record buffer pool information at the statement level is supported for API and CLP snapshot requests.

POOL_INDEX_P_READS: Number of index pages read in from the table space containers (physical) for regular and large table spaces. The functionality to record buffer pool information at the statement level is supported for API and CLP snapshot requests.

POOL_INDEX_WRITES: Number of times a buffer pool index page was physically written to disk.

POOL_LSN_GAP_CLNS: Number of times a page cleaner was invoked because the logging space used had reached a predefined criterion for the database.

POOL_NO_VICTIM_BUFFER: Number of times an agent did not have a preselected victim buffer available.

POOL_READ_TIME: Number of milliseconds spent reading in data and index pages from the physical table space for all types of table spaces.

POOL_TEMP_DATA_L_READS: Number of data pages which have been requested from the logical buffer pool for temporary table spaces.

POOL_TEMP_DATA_P_READS: Number of data pages read in from the physical table space containers for temporary table spaces.

POOL_TEMP_INDEX_L_READS: Number of index pages which were requested from the logical buffer pool for temporary table spaces.

POOL_TEMP_INDEX_P_READS: Number of index pages read in from the physical table space containers for temporary table spaces.

POOL_WRITE_TIME: Number of milliseconds spent physically writing data or index pages from the buffer pool to disk.

PREFETCH_WAIT_TIME: Number of milliseconds spent waiting for an I/O prefetcher server to finish loading pages into the buffer pool.

ROWS_DELETED: Number of row deletions attempted.

ROWS_INSERTED: Number of row insertions attempted.

ROWS_READ: Number of rows read from tables.

ROWS_SELECTED: Number of rows that have been selected and returned to the application.

ROWS_UPDATED: Number of row updates attempted.

SEC_LOG_USED_TOP: The maximum number of bytes of secondary log space used.

SEC_LOGS_ALLOCATED: Number of secondary log files currently being used for the database.

SELECT_SQL_STMTS: The number of SQL SELECT statements that were executed.

SORT_HEAP_ALLOCATED: The number of allocated pages of sort heap space for all sorts at the level chosen and at the current time.

SORT_OVERFLOWS: The number of sorts that ran out of sort heap and may have required disk space for temporary storage.

SORT_SHRHEAP_ALLOCATED: The total amount of shared sort memory allocated in the database.

SORT_SHRHEAP_TOP: Database-wide shared sort memory high-water mark in 4k pages.

STATIC_SQL_STMTS: The number of static SQL statements that were attempted.

TOT_LOG_USED_TOP: The maximum number of bytes used for log space.

TOTAL_APP_COMMITS: Total number of commit statements issued by the client application.

TOTAL_APP_ROLLBACKS: Total number of rollback statements issued by the client application.

TOTAL_CONS: Number of newly opened connections to the database.

TOTAL_LOG_AVAILABLE: Number of bytes of active log space in the database that is not being used by uncommitted transactions.

TOTAL_LOG_USED: Number of bytes of active log space currently used in the database.

TOTAL_SEC_CONS: The number of connections made by a subagent to the database at the node.

TOTAL_SORT_TIME: The total elapsed time (in milliseconds) for all sorts that have been executed.

TOTAL_LOCK_TIME: The total time for which database is in locked state.

TOTAL_SORTS: The number of sorts that have been executed.

TOT_LOG_USED_TOP: The maximum amount of total log space used (in bytes).

UID_SQL_STMTS: Number of SQL UPDATE, INSERT, and DELETE statements that were executed.

UNREAD_PREFETCH_PAGES: Number of pages that the prefetcher read in that were never used.

MongoDB Server Metrics

asserts_msg: The number of message asserts. These are internal server errors that have a well defined text string. Stack traces are logged for these.

asserts_regular: The number of regular asserts raised since this process started.

asserts_user: The number of user asserts. These are errors that can be generated by a user such as out of disk space or duplicate key.

asserts_warning: The number of warnings raised since this process started.

BackgroundFlushing_flushes: The number of times the database has flushed all writes to disk.

BackgroundFlushing_total_ms: The number of milliseconds (ms) that the mongod processes have spent writing (i.e. flushing) data to disk.

Connections_available: The number of unused available connections that the database can provide. Consider this value in combination with the value of current to understand the connection load on the database, and the UNIX ulimit Settings document for more information about system thresholds on available connections.

Connections_current: The number of connections to the database server from clients. This number includes the current shell session. Consider the value of available to add more context to this datum. This figure will include the current shell connection as well as any inter-node connections to support a replica set or sharded cluster.

Cursor_timedOut: The number of cursors that have timed out since the server process started. If this number is large or growing at a regular rate, this may indicate an application error.

Cursor_totalOpen: The number of cursors that MongoDB is maintaining for clients. Because MongoDB exhausts unused cursors, typically this value small or zero. However, if there is a queue, stale tailable cursors, or a large number of operations this value may rise.

globalLock_ActiveClients: The number of connected clients.

globalLock_CurrentQueue: The number of operations queued waiting for the lock. A consistently small queue, particularly of shorter operations should cause no concern. Also, consider this value in light of the size of queue waiting for the read lock (e.g. readers) and write lock (e.g. writers) individually.

Mem_mapped: The number of megabytes of memory mapped by the database. Because MongoDB uses memory-mapped files, this value will be roughly equivalent to the total size of your databases.

Mem_resident: The amount of RAM, in megabytes (MB), currently used by the database process. In normal use this value tends to grow. In dedicated database servers this number tends to approach the total amount of system memory.

Mem_virtual: The quantity, in megabytes (MB), of virtual memory used by the mongod process. With journaling enabled, the value of virtual is at least twice the value of mapped. If virtual value is significantly larger than mapped (e.g. 3 or more times), this may indicate a memory leak.

Network_bytesIn: The amount of network traffic, in bytes, received by this database. Use this value to ensure that network traffic sent to the mongod process is consistent with expectations and overall inter-application traffic.

Network_bytesOut: The amount of network traffic, in bytes, sent from this database. Use this value to ensure that network traffic sent by the mongod process is consistent with expectations and overall inter-application traffic.

Network_numRequests: The number of distinct requests that the server has received. Use this value to provide context for the bytesIn and bytesOut values to ensure that MongoDB network utilization is consistent with expectations and application use.

OpCounters_command: The number of commands sent to MongoDB.

OpCounters_delete: The number of Delete operations.

OpCounters_getmore: The number of GetMore operations.

OpCounters_insert: The number of Insert operations.

OpCounters_query: The number of Query operations.

OpCounters_update: The number of Update operations.

Oplog_Max_Size (*new in 4.5.4*): The maximum size of the operation log

Oplog_Size (*new in 4.5.4*): The size of the operation log

OplogTimeDiff_in_sec (*new in 4.5.4*): The difference (in seconds) between the first entry in the log and the last entry in the log

Repl_command: The number of Replicated Commands issued to the database.

Repl_delete: The number of Replicated Delete operations.

Repl_getmore: The number of GetMore operations. This counter can be high even if the query count is low. Secondary nodes send getMore operations as part of the replication process.

Repl_insert: The number of replicated insert operations.

Repl_query: The number of Replicated Queries.

Repl_update: The number of Replicated Update Operations.

Replication_MyState (*new in 4.5.4*): An integer between 0 and 10 that represents the replica state of the current member.

Index_missRatio: Ratio of index hits to misses. If there are a lot of index misses then you should look at your queries to see if they are optimally using your indexes. You may need to add new indexes to make the queries run faster. You can explain the query to see which index queries are hitting and the total execution time so you can compare query performance before and after adding the new indexes.

Microsoft SQL Server Metrics

Active cursors: The number of active cursors.

Active Temp Tables: The number of temporary tables/table variables in use.

Active Transactions: The number of active transactions for the database.

AU cleanup batches/sec: The number of batches per second that were completed successfully by the background task that cleans up deferred dropped allocation units.

AU cleanups/sec: The number of allocation units per second that were successfully dropped the background task that cleans up deferred dropped allocation units. Each allocation unit drop requires multiple batches.

Auto-Param Attempts/sec: The number of auto-parameterization attempts per second. Total should be the sum of the failed, safe, and unsafe auto-parameterizations. Auto-parameterization occurs when an instance of SQL Server tries to parameterize a Transact-SQL request by replacing some literals with parameters so that reuse of the resulting cached execution plan across multiple similar-looking requests is possible. Note that auto-parameterizations are also known as simple parameterizations in newer versions of SQL Server. This counter does not include forced parameterizations.

Average Latch Wait Time (ms): Average latch wait time (in milliseconds) for latch requests that had to wait.

Average Wait Time (ms): Average amount of wait time (in milliseconds) for each lock request that resulted in a wait.

Backup/Restore Throughput/sec: Read/write throughput for backup and restore operations of a database per second. For example, you can measure how the performance of the database backup operation changes when more backup devices are used in parallel or when faster devices are used. Throughput of a database backup or restore operation allows you to determine the progress and performance of your backup and restore operations.

Batch Requests/sec: The number of Transact-SQL command batches received per second. This statistic is affected by all constraints (such as I/O, number of users, cache size, complexity of requests, and so on). High batch requests mean good throughput.

Buffer cache hit ratio: Percentage of pages found in the buffer cache without having to read from disk. The ratio is the total number of cache hits divided by the total number of cache lookups over the last few thousand page accesses. The ratio is displayed as a percentage. After a long period of time, the ratio moves very little. Because reading from the cache is much less expensive than reading from disk, you want this ratio to be high. Generally, you can increase the buffer cache hit ratio by increasing the amount of memory available to SQL Server.

Bulk Copy Rows/sec: The number of rows bulk copied per second.

Bulk Copy Throughput/sec: Amount of data bulk copied (in kilobytes) per second.

By-reference Lob Create Count: Count of large object (lob) values that were passed by reference. By-reference lobs are used in certain bulk operations to avoid the cost of passing them by value.

By-reference Lob Use Count: Count of by-reference lob values that were used. By-reference lobs are used in certain bulk operations to avoid the cost of passing them by-value.

Cache Hit Ratio: Ratio between cache hits and lookups. The ratio is displayed as a percentage.

Cache Object Counts: The number of cache objects in the cache.

Cache Objects in use: The number of cache objects in use.

Cache Pages: The number of 8-kilobyte (KB) pages used by cache objects.

Cached Cursor Counts: The number of cursors of a given type in the cache.

Checkpoint pages/sec: The number of pages flushed to disk per second by a checkpoint or other operation that require all dirty pages to be flushed.

CLR Execution: Total execution time in CLR (microseconds)

Connection Memory (KB): Total amount of dynamic memory the server is using for maintaining connections.

Count Lob Readahead: Count of lob pages on which readahead was issued.

Count Pull In Row: Count of column values that were pulled in-row from off-row.

Count Push Off Row: Count of column values that were pushed from in-row to off-row.

Cursor memory usage: Amount of memory consumed by cursors in kilobytes (KB).

Count/sec: Times each type of cached cursor has been used. Cursor memory usage Amount of memory consumed by cursors in kilobytes (KB).

Cursor Requests/sec: The number of SQL cursor requests received by the server. Cursor worktable usage Number of worktables used by cursors. Data File(s) Size (KB) Cumulative size (in kilobytes) of all the data files in the database including any automatic growth. Monitoring this counter is useful, for example, for determining the correct size of Database pages Number of pages in the buffer pool with database content.

Cursor worktable usage: Number of worktables in use by cursors.

Data File(s) Size(KB): Cumulative size (Kb) of all data files in the database including any automatic growth. Monitoring this counter to determine the correct size of tempdb.

Database pages: Number of database pages in use.

DBCC Logical Scan Bytes/sec: The number of logical read scan bytes per second for database console commands (DBCC).

Deferred Dropped rowsets: The number of rowsets created as a result of aborted online index build operations that are waiting to be dropped by the background task that cleans up deferred dropped rowsets.

Dropped rowset cleanups/sec: The number of rowsets per second created as a result of aborted online index build operations that were successfully dropped by the background task that cleans up deferred dropped rowsets.

Dropped rowsets skipped/sec: The number of rowsets per second created as a result of aborted online index build operations that were skipped by the background task that cleans up deferred dropped rowsets created.

Errors/sec: The number of errors/sec.

Event Notifications Delayed Drop: The number of event notifications waiting to be dropped by a system thread.

Extent Deallocations/sec: The number of extents deallocated per second in all databases in this instance of SQL Server.

Extents Allocated/sec: The number of extents allocated per second in all databases in this instance of SQL Server.

Failed AU cleanup batches/sec: The number of batches per second that failed and required retry, by the background task that cleans up deferred dropped allocation units. Failure could be due to lack of memory or disk space, hardware failure, and other reasons.

Failed Auto-Params/sec: The number of failed auto-parameterization attempts per second. This should be small. Note that auto-parameterizations are also known as simple parameterizations in later versions of SQL Server.

Failed leaf page cookie: The number of times that a leaf page cookie could not be used during an index search since changes happened on the leaf page. The cookie is used to speed up the index search.

Failed tree page cookie: The number of times that a tree page cookie could not be used during an index search since changes happened on the parent pages of those tree pages. The cookie is used to speed up the index search.

Forced Parameterizations/sec: The number of successful forced parameterizations per second.

Forwarded Records/sec: The number of records per second fetched through forwarded record pointers.

Free list stalls/sec: The number of requests per second that had to wait for a free page.

Free Space in tempdb (KB): The amount of space (in kilobytes) available in FreeSpace Page.

FreeSpace Page Fetches/sec: Number of pages fetched/second by free space scans. These scans search for free space within pages already allocated to an allocation unit, to address requests to insert or modify record fragments.

FreeSpace Scans/sec: The number of scans per second that were initiated to search for free space within pages already allocated to an allocation unit to insert or modify record fragment. Each scan may find multiple pages.

Full Scans/sec: The number of unrestricted full scans per second. These can be either base-table or full-index scans.

Granted Workspace Memory (KB): Total amount of memory currently granted to executing processes such as hash, sort, bulk copy, and index creation operations.

Guided Plan Executions/sec: The number of plan executions per second in which the query plan has been generated by using a plan guide.

HTTP Authenticated Requests: The number of authenticated HTTP requests started per second. Index Searches/sec Number of index searches per second. These are used to start a range scan, reposition a range scan, revalidate a scan point, fetch a single index record, and search down the index to locate where to insert a new row.

Index Searches/sec: Number of index searches per second. These are used to start a range scan, reposition a range scan, revalidate a scan point, fetch a single index record, and search down the index to locate where to insert a new row.

Latch Waits/sec: The number of latch requests that could not be granted immediately.

Lazy writes/sec: The number of buffers written per second by the buffer manager's lazy writer. The lazy writer is a system process that flushes out batches of dirty, aged buffers (buffers that contain changes that must be written back to disk before the buffer can be reused for a different page) and makes them available to user processes. The lazy writer eliminates the need to perform frequent checkpoints in order to create available buffers.

LobHandle Create Count: Count of temporary lobs created.

LobHandle Destroy Count: Count of temporary lobs destroyed.

LobSS Provider Create Count: Count of LOB Storage Service Providers (LobSSP) created. One worktable created per LobSSP.

LobSS Provider Destroy Count: Count of LobSSP destroyed.

LobSS Provider Truncation Count: Count of LobSSP truncated.

Lock Blocks: Current number of lock blocks in use on the server (refreshed periodically). A lock block represents an individual locked resource, such as a table, page, or row.

Lock Blocks Allocated: Current number of allocated lock blocks. At server startup, the number of allocated lock blocks plus the number of allocated lock owner blocks depends on the SQL Server

Lock Memory (KB): Total amount of dynamic memory the server is using for locks.

Lock Owner Blocks: The number of lock owner blocks currently in use on the server (refreshed periodically). A lock owner block represents the ownership of a lock on an object by an individual thread. Therefore, if three threads each have a shared (S) lock on a page, there will be three lock owner blocks.

Lock Owner Blocks Allocated: Current number of allocated lock owner blocks. At server startup, the number of allocated lock owner blocks and the number of allocated lock blocks depend on the SQL

Lock Requests/sec: The number of new locks and lock conversions per second requested from the lock manager.

Lock Timeouts (timeout > 0)/sec: The number of lock requests per second that timed out, but excluding requests for NOWAIT locks.

Lock Timeouts/sec: The number of lock requests per second that timed out, including requests for NOWAIT locks.

Lock Wait Time (ms): Total wait time (in milliseconds) for locks in the last second.

Lock Waits/sec: The number of lock requests per second that required the caller to wait.

Log Bytes Flushed/sec: Total number of log bytes flushed.

Log Cache Hit Ratio: Percentage of log cache reads satisfied from the log cache.

Log Cache Reads/sec: Reads performed per second through the log manager cache.

Log File(s) Size (KB): Cumulative size (in kilobytes) of all the transaction log files in the database.

Log File(s) Used Size (KB): The cumulative used size of all the log files in the database.

Log Flush Wait Time Total wait time (in milliseconds) to flush the log.

Log Flush Waits/sec: The number of commits per second waiting for the log flush.

Log Flushes/sec: The number of log flushes per second.

Log Growths: Total number of times the transaction log for the database has been expanded.

Log Shrinks: Total number of times the transaction log for the database has been shrunk.

Log Truncations: Total number of times the transaction log for the database has been truncated.

Logical Connections: The number of logical connections to the system.

Logins/sec: Total number of logins started per second. This does not include pooled connections.

Logouts/sec: Total number of logout operations started per second.

Longest Transaction Running Time: The length of time (in seconds) since the start of the transaction that has been active longer than any other current transaction.

Mars Deadlocks: The number of Mars Deadlocks detected.

Maximum Workspace Memory (KB): Maximum amount of memory available for executing processes such as hash, sort, bulk copy, and index creation operations.

Memory Grants Outstanding: Total number of processes that have successfully acquired a workspace memory grant.

Memory Grants Pending: Total number of processes waiting for a workspace memory grant.

Mixed page allocations/sec: The number of pages allocated per second from mixed extents. These could be used for storing the IAM pages and the first eight pages that are allocated to an allocation unit.

Non-atomic yield rate: The number of non-atomic yields per second.

NonSnapshot Version Transactions: The number of currently active transactions that are not using snapshot isolation level and have made data modifications that have generated row versions in the Number of active cursor plans.

Number of active cursor plans: Number of cursor plans.

Number of Deadlocks/sec: The number of lock requests per second that resulted in a deadlock.

Number of SuperLatches: The number of latches that are currently SuperLatches.

Optimizer Memory (KB): Total amount of dynamic memory the server is using for query optimization.

Page compression attempts/sec: The number of pages evaluated for page-level compression. Includes pages that were not compressed because significant savings could be achieved. Includes all objects in the instance of SQL Server. For information about specific objects, see sys.dm_db_index_operational_stats (Transact-SQL).

Page Deallocations/sec: The number of pages deallocated per second in all databases in this instance of SQL Server. These include pages from mixed extents and uniform extents.

Page life expectancy: The number of seconds a page will stay in the buffer pool without references.

Page lookups/sec: The number of requests per second to find a page in the buffer pool.

Page reads/sec: The number of physical database page reads that are issued per second. This statistic displays the total number of physical page reads across all databases. Because physical I/O is expensive, you may be able to minimize the cost, either by using a larger data cache, intelligent indexes, and more efficient queries or by changing the database design.

Page Splits/sec: The number of page splits per second that occur as the result of overflowing index pages.

Page writes/sec: The number of physical database page writes issued per second.

Pages Allocated/sec: The number of pages allocated per second in all databases in this instance of SQL Server. These include pages allocations from both mixed extents and uniform extents.

Pages compressed/sec: The number of data pages that are compressed by using PAGE compression. Includes all objects in the instance of SQL Server. For information about specific objects, see `sys.dm_db_index_operational_stats` (Transact-SQL).

Percent Log Used: Percentage of space in the log that is in use.

Probe Scans/sec: The number of probe scans per second that are used to find at most one single qualified row in an index or base table directly.

Processes blocked: The number of currently blocked processes.

Range Scans/sec: The number of qualified range scans through indexes per second.

Readahead pages/sec: The number of pages read per second in anticipation of use.

Repl. Trans. Rate: The number of transactions per second read out of the transaction log of the publication database and delivered to the distribution database.

Safe Auto-Params/sec: The number of safe auto-parameterization attempts per second. Safe refers to a determination that a cached execution plan can be shared between different similar-looking Transact-SQL statements. SQL Server makes many auto-parameterization attempts some of which turn out to be safe and others fail. Note that auto-parameterizations are also known as simple parameterizations in later versions of SQL Server. This does not include forced parameterizations.

Scan Point Revalidations/sec: The number of times per second that the scan point had to be revalidated to continue the scan.

Skipped Ghosted Records/sec: The number of ghosted records per second skipped during scans.

Snapshot Transactions: The number of currently active transactions using the snapshot isolation level. N.B. The SOAP Empty Requests Number of empty SOAP requests started per second.

SOAP Empty Requests: The number of SOAP method invocations passed to the stored procedure (or template) with an empty string as its value (not a NULL value) in order to provide an included input parameter with no value assigned to it.

SOAP Method Invocations: The number of SOAP method invocations started per second.

SOAP Session Initiate Requests: The number of SOAP Session initiate requests started per second.

SOAP Session Terminate Requests: The number of SOAP Session terminate requests started per second.

SOAP SQL Requests: The number of SOAP SQL requests started per second.

SOAP WSDL Requests: The number of SOAP Web Service Description Language requests started per second.

SQL Attention rate: The number of attentions per second. An attention is a request by the client to end the currently running request.

SQL Cache Memory (KB): Total amount of dynamic memory the server is using for the dynamic SQL cache.

SQL Compilations/sec: The number of SQL compilations per second. Indicates the number of times the compile code path is entered. Includes compiles caused by statement-level recompilations in SQL Server. After SQL Server user activity is stable, this value reaches a steady state.

SQL Re-Compilations/sec: The number of statement recompiles per second. Counts the number of times statement recompiles are triggered. Generally, you want the recompiles to be low. In later versions of SQL Server, recompilations are statement-scoped instead of batch-scoped recompilations in Microsoft SQL Server 2000. Therefore, direct comparison of values of this counter between SQL Server and earlier versions is not possible.

Stored Procedures Invoked/sec: This counter reports the total number of activation stored procedures invoked by all queue monitors in the instance per second.

SuperLatch Demotions/sec: The number of SuperLatches that have been demoted to regular latches in the last second.

SuperLatch Promotions/sec: The number of latches that have been promoted to SuperLatches in the last second.

Table Lock Escalations/sec: The number of times locks on a table were escalated to the TABLE or HoBT granularity. Target pages Ideal number of pages in the buffer pool.

Target pages: Ideal number of pages in the buffer pool.

Target Server Memory (KB): Total amount of dynamic memory the server can consume.

Task Limit Reached: The number of times that a queue monitor would have started a new task, but did not because the maximum number of tasks for the queue is already running.

Task Limit Reached/sec: The number of times per second that a queue monitor would have started a new task, but did not because the maximum number of tasks for the queue is already running.

Tasks Aborted/sec: The number of activation stored procedure tasks that end with an error or are aborted by a queue monitor for failing to receive messages.

Tasks Running: The number of activation stored procedures that are currently running.

Tasks Started/sec: The number of activation stored procedures started per second by all queue monitors in the instance.

Temp Tables Creation Rate: The number of temporary tables/table variables created per second.

Temp Tables For Destruction: The number of temporary tables/table variables waiting to be destroyed by the cleanup system thread.

Total Latch Wait Time (ms): Total latch wait time (in milliseconds) for latch requests in the last second.

TOTAL_LOCK_TIME: The total time for which database is in locked state.

Total Server Memory (KB): The committed memory from the buffer pool (in kilobytes).

Transactions/sec: The number of transactions started for the database per second.

Unsafe Auto-Params/sec: The number of unsafe auto-parameterization attempts per second. For example, the query has some characteristics that prevent the cached plan from being shared. These are designated as unsafe. This does not count the number of forced parameterizations.

Update conflict ratio: The percentage of those transactions using the snapshot isolation level that have encountered update conflicts within the last second. An update conflict occurs when a snapshot isolation level transaction attempts to modify a row that last was modified by another transaction that was not committed when the snapshot isolation level transaction started.

Update Snapshot Transactions: The number of currently active transactions using the snapshot isolation level and have modified data.

Used leaf page cookie: The number of times a leaf page cookie is used successfully during an index search since no change happened on the leaf page. The cookie is used to speed up the index search.

Used tree page cookie: The number of times a tree page cookie is used successfully during an index search since no change happened on the parent page of the tree page. The cookie is used to speed up the index search.

User Connections: The number of users currently connected to SQL Server.

Version Cleanup rate (KB/s): The rate (in kilobytes per second) at which row versions are removed from the snapshot isolation version store.

Version Generation rate (KB/s): The rate (in kilobytes per second) at which new row versions are added to the snapshot isolation version store.

Version Store Size (KB): The amount of space (in kilobytes) in Version Store unit count The number of active allocation units in the snapshot isolation version store.

Version Store unit creation: The number of allocation units that have been created in the snapshot isolation store since the instance of the Database Engine was started.

Version Store unit truncation: The number of allocation units that have been removed from the snapshot isolation store since the instance of the Database Engine was started.

Workfiles Created/sec: The number of work files created per second. For example, work files could be used to store temporary results for hash joins and hash aggregates.

Worktables Created/sec: The number of work tables created per second. For example, work tables could be used to store temporary results for query spool, lob variables, XML variables, and cursors.

Worktables From Cache Ratio: Percentage of work tables created where the initial two pages of the work table were not allocated but were immediately available from the work table cache. (When a work table is dropped, two pages may remain allocated and they are returned to the work table cache. This increases performance.)

Write Transactions/sec: The number of transactions that wrote to the database and committed, in the last second.

Microsoft SQL Azure Metrics

avg_cpu_percent: Average compute utilization in the percentage of the limit of the service tier.

avg_data_io_percent: Average data I/O utilization in percentage based on the limit of the service tier.

avg_log_write_percent: Average write resource utilization in the percentage of the limit of the service tier.

avg_memory_percent: Average memory utilization in the percentage of the limit of the service tier.

MySQL Server Metrics

Aborted_clients: The number of clients that were aborted (because they did not properly close the connection to the MySQL server). For some applications, this can be OK, but for some other applications you might want to track the value, as aborted connects may indicate some sort of application failure.

Aborted_connects: The number of failed attempts to connect to the MySQL server.

Bytes_received: The number of bytes received from all clients.

Bytes_sent: The number of bytes sent to all clients.

Com_alter_table: The number of times each ALTER TABLE statement has been executed.

Com_create_index: The number of times each CREATE INDEX statement has been executed.

Com_create_table: The number of times each CREATE TABLE statement has been executed.

Com_delete: The number of times each DELETE statement has been executed.

Com_insert: The number of times each INSERT statement has been executed.

Com_optimize: The number of times each OPTIMIZE statement has been executed.

Com_select: The number of times each SELECT statement has been executed.

Com_update: The number of times each UPDATE statement has been executed.

Connections: The number of connection attempts (successful or not) to the MySQL server.

Created_tmp_disk_tables: The number of temporary tables on disk created automatically by the server while executing statements.

Created_tmp_files: How many temporary files mysqld has created.

Created_tmp_tables: The number of in-memory temporary tables created automatically by the server while executing statements. If `Created_tmp_disk_tables` is large, you may want to increase the `tmp_table_size` value to cause temporary tables to be memory-based instead of disk-based.

Handler_delete: The number of times that rows have been deleted from tables.

Innodb_buffer_pool_pages_data: The number of pages containing data (dirty or clean).

Innodb_buffer_pool_pages_dirty: The number of pages currently dirty.

Innodb_buffer_pool_pages_flushed: The number of buffer pool page-flush requests.

Innodb_buffer_pool_pages_free: The number of free pages.

Innodb_buffer_pool_pages_misc: The number of pages that are busy because they have been allocated for administrative overhead such as row locks or the adaptive hash index. This value can also be calculated as `Innodb_buffer_pool_pages_total`.

Innodb_buffer_pool_pages_total: The total size of the buffer pool, in pages.

Innodb_buffer_pool_read_ahead_rnd: The number of random read-aheads initiated by InnoDB. This happens when a query scans a large portion of a table but in random order.

Innodb_buffer_pool_read_requests: The number of logical read requests InnoDB has done.

Innodb_buffer_pool_reads: The number of logical reads that InnoDB could not satisfy from the buffer pool and had to do a single-page read.

Innodb_buffer_pool_wait_free: Normally, writes to the InnoDB buffer pool happen in the background. However, if it is necessary to read or create a page and no clean pages are available, it is also necessary to wait for pages to be flushed first. This counter counts instances of these waits. If the buffer pool size has been set properly, this value should be small.

Innodb_buffer_pool_write_requests: The number writes done to the InnoDB buffer pool.

Innodb_data_fsyncs: The number of `fsync()` operations so far.

Innodb_data_pending_fsyncs: The current number of pending `fsync()` operations.

Innodb_data_pending_reads: The current number of pending reads.

Innodb_data_pending_writes: The current number of pending writes.

Innodb_data_read: The amount of data read so far, in bytes.

Innodb_data_reads: The total number of data reads.

Innodb_data_writes: The total number of data writes.

Innodb_data_written: The amount of data written so far, in bytes.

Innodb_dblwr_pages_written: The number of doublewrite operations that have been performed.

Innodb_dblwr_writes: The number of pages that have been written for doublewrite operations.

Innodb_log_waits: The number of times that the log buffer was too small and a wait was required for it to be flushed before continuing.

Innodb_log_write_requests: The number of log write requests.

Innodb_log_writes: The number of physical writes to the log file.

Innodb_pages_created: The number of pages created.

Innodb_pages_read: The number of pages read.

Innodb_pages_written: The number of pages written.

Innodb_row_lock_current_waits: The number of row locks currently being waited for.

Innodb_row_lock_time: The total time spent in acquiring row locks, in milliseconds.

Innodb_row_lock_time_avg: The average time to acquire a row lock, in milliseconds.

Innodb_row_lock_time_max: The maximum time to acquire a row lock, in milliseconds.

Innodb_row_lock_waits: The number of times a row lock had to be waited for.

Innodb_rows_deleted: The number of rows deleted from InnoDB tables.

Innodb_rows_inserted: The number of rows inserted into InnoDB tables.

Innodb_rows_read: The number of rows read from InnoDB tables.

Innodb_rows_updated: The number of rows updated in InnoDB tables.

Key_blocks_used: The number of used blocks in the key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

Key_read_requests: The number of requests to read a key block from the cache. **Key_writes** The number of physical writes of a key block to disk.

Key_reads: The number of physical reads of a key block from disk. If **Key_reads** is large, then your **key_buffer_size** value is probably too small. The cache miss rate can be calculated as $\text{Key_reads} / \text{Key_read_requests}$.

Key_write_requests: The number of requests to write a key block to the cache.

Key_writes: The number of physical writes of a key block from the MyISAM key cache to the physical disk.

Open_files: The number of files that are open. **Open_streams** The number of streams that are open (used mainly for logging).

Open_tables: The number of table cache misses. If the value is large, you probably need to increase **table_cache**. Typically you would want this to be less than 1 or 2 opened tables per second.

Opened_tables: The number of tables that have been opened. The number of tables that have been opened. If **Opened_tables** is big, your **table_cache** value is probably too small.

Qcache_free_blocks: The number of free memory blocks in the query cache.

Qcache_free_memory: The amount of free memory for the query cache.

Qcache_hits: The number of query cache hits.

Qcache_inserts: The number of queries added to the query cache.

Qcache_lowmem_prunes: The number of queries that were deleted from the query cache because of low memory.

Qcache_not_cached: The number of non-cached queries (not cacheable, or not cached due to the query_cache_type setting).

Qcache_queries_in_cache: The number of queries registered in the query cache.

Qcache_total_blocks: The total number of blocks in the query cache.

Questions: The number of statements that clients have sent to the server.

Seconds_Behind_Master: The number of seconds that the replica SQL thread is behind processing the primary binary log. This field directly drives MTTR. A high or increased number of Seconds_Behind_Master indicates a slow disk or poorly tuned machine running the database. If this value reaches 45 minutes or more, the ability to recover from a crash, or after a manual failover, is delayed. If this value is tracked by the Machine Agent through the MySQL extension and shows a generally positive slope, it indicates a death spiral.

Select_full_join: Joins performed without keys. This should be zero. This is a good way to catch development errors, as just a few such queries can decrease the system's performance.

Select_full_range_join: The number of joins that used a range search on a reference table.

Select_range: The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

Select_range_check: The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.

Select_scan: Number of queries that performed a full table scan. In some cases these are OK but their ratio to all queries should be constant. If you have the value growing it can be a problem with the optimizer, lack of indexes or some other problem.

Slave_IO_Running: Whether the I/O thread for reading the primary's binary log is running.

Slave_open_temp_tables: The number of temporary tables that the replica SQL thread currently has open.

Slave_SQL_Running: Whether the SQL thread for executing events in the relay log is running.

Slow_launch_threads: The number of threads that have taken more than slow_launch_time seconds to create.

Slow_queries: The number of queries longer than --long-query-time or that are not using indexes. These should be a small fraction of all queries. If it grows, the system will have performance problems.

Sort_merge_passes: The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the sort_buffer_size system variable.

Sort_range: The number of sorts that were done using ranges.

SQL_Delay: The number of seconds that the replica lags behind the primary

Threads_cached: The number of threads in the thread cache.

Threads_connected: The number of currently open connections.

Threads_created: This should be low. Higher values may mean that you need to increase the value of thread_cache or you have the number of connections increasing, which also indicates a potential problem.

Threads_running: The number of threads that are not sleeping.

Oracle Server Metrics

bytes received via SQL*Net from client: Total number of bytes received from the client over Oracle Net Services

bytes received via SQL*Net from dblink: Total number of bytes received from a database link over Oracle Net Services

bytes sent via SQL*Net to client: Total number of bytes sent to the client from the foreground processes

bytes sent via SQL*Net to dblink: Total number of bytes sent over a database link

CPU used by this session: Amount of CPU time (in 10s of milliseconds) used by a session from the time a user call starts until it ends. If a user call completes within 10 milliseconds, the start and end user-call time are the same for purposes of this statistics, and 0 milliseconds are added.

db block changes: Closely related to consistent changes, this statistic counts the total number of changes that were part of an update or delete operation that were made to all blocks in the SGA. Such changes generate redo log entries and hence become permanent changes to the database if the transaction is committed. This approximates total database work. It statistic indicates the rate at which buffers are being dirtied (on a per-transaction or per-second basis, for example).

db block gets: The number of times a CURRENT block was requested. See Also: consistent gets

db block gets from cache: The number of times a CURRENT block was requested from the buffer cache. This is a subset of db block gets statistics value.

DBWR checkpoint buffers written: The number of buffers that were written for checkpoints

DBWR checkpoints: The number of times the DBWR was asked to scan the cache and write all blocks marked for a checkpoint or the end of recovery. This statistic is always larger than background checkpoints completed.

DML statements parallelized: The number of DML statements that were executed in parallel.

enqueue conversions: Total number of conversions of the state of table or row lock.

enqueue deadlocks: Total number of deadlocks between table or row locks in different sessions.

enqueue releases: Total number of table or row locks released.

enqueue requests: Total number of table or row locks acquired.

enqueue timeouts: Total number of table and row locks (acquired and converted) that timed out before they could complete.

enqueue waits: Total number of waits that occurred during an enqueue convert or get because the enqueue get was deferred

exchange deadlocks: The number of times that a process detected a potential deadlock when exchanging two buffers and raised an internal, restartable error. Index scans are the only operations that perform exchanges.

execute count: Total number of calls (user and recursive) that executed SQL statements.

gc current block receive time: The total time required for consistent read requests to complete. It records the round-trip time for all requests for consistent read blocks.

index fast full scans (direct read): The number of fast full scans initiated using direct read.

index fast full scans (full): The number of fast full scans initiated for full segments.

index fast full scans (rowid ranges): The number of fast full scans initiated with rowid endpoints specified.

lob reads: The number of LOB API read operations performed in the session/system. A single LOB API read may correspond to multiple physical/logical disk block reads.

lob writes: The number of LOB API write operations performed in the session/system. A single LOB API write may correspond to multiple physical/logical disk block writes.

logons current: Total number of current logons. Useful only in V\$SYSSTAT.

Number of Small Reads: The total number of **physical reads** less the number of **physical read total multi block requests**.

Number of Small Writes: The total number of **physical writes** less the number of **physical write total multi block requests**.

opened cursors current: Total number of current open cursors.

Parallel operations not downgraded: The number of times parallel execution was executed at the requested degree of parallelism.

parse count (hard): Total number of parse calls (real parses). A hard parse is a very expensive operation in terms of memory use, because it requires Oracle to allocate a workheap and other memory structures and then build a parse tree.

parse count (total): Total number of parse calls (hard and soft). A soft parse is a check on an object already in the shared pool, to verify that the permissions on the underlying object have not changed.

parse time cpu: Total CPU time used for parsing (hard and soft) in 10s of milliseconds.

parse time elapsed: Total elapsed time for parsing, in 10s of milliseconds. Subtract parse time cpu from this statistic to determine the total waiting time for parse resources.

physical read bytes: Total size in bytes of all disk reads by application activity (and not other instance activity) only.

physical read IO requests: The number of read requests for application activity (mainly buffer cache and direct load operation) which read one or more database blocks per request. This is a subset of physical read total IO requests statistic.

physical read total bytes: Total size in bytes of disk reads by all database instance activity including application reads, backup and recovery, and other utilities. The difference between this value and physical read bytes gives the total read size in bytes by non-application workload.

physical read total IO requests: The number of read requests which read one or more database blocks for all instance activity including application, backup and recovery, and other utilities. The difference between this value and physical read total multi block requests gives the total number of single block read requests.

physical reads: Total number of data blocks read from disk. This value can be greater than the value of physical reads direct plus physical reads cache as reads into process private buffers also included in this statistic.

physical write bytes: Total size in bytes of all disk writes from the database application activity (and not other kinds of instance activity).

physical write IO requests: The number of write requests for application activity (mainly buffer cache and direct load operation) which wrote one or more database blocks per request.

physical write total bytes: Total size in bytes of all disk writes for the database instance including application activity, backup and recovery, and other utilities. The difference between this value and physical write bytes gives the total write size in bytes by non-application workload.

physical write total IO requests: The number of write requests which wrote one or more database blocks from all instance activity including application activity, backup and recovery, and other utilities. The difference between this stat and physical write total multi block requests gives the number of single block write requests.

physical writes: Total number of data blocks written to disk. This statistics value equals the sum of physical writes direct and physical writes from cache values.

physical writes direct: The number of writes directly to disk, bypassing the buffer cache (as in a direct load operation).

physical writes from cache: Total number of data blocks written to disk from the buffer cache. This is a subset of physical writes statistic.

process last non-idle time: The last time this process executed.

queries parallelized: The number of SELECT statements executed in parallel.

Read Percent:

recovery blocks read: The number of blocks read during recovery.

recursive calls: The number of recursive calls generated at both the user and system level. Oracle maintains tables used for internal processing. When Oracle needs to make a change to these tables, it internally generates an internal SQL statement, which in turn generates a recursive call.

recursive cpu usage: Total CPU time used by non-user calls (recursive calls). Subtract this value from CPU used by this session to determine how much CPU time was used by the user calls.

redo blocks written: This is the total number of redo blocks written. This statistic divided by "redo writes" equals the number of blocks per write.

redo buffer allocation retries: Total number of retries necessary to allocate space in the redo buffer. Retries are needed either because the redo writer has fallen behind or because an event such as a log switch is occurring.

redo log space requests: The number of times the active log file is full and Oracle must wait for disk space to be allocated for the redo log entries. Such space is created by performing a log switch.

redo log space wait time: Total elapsed waiting time for redo log space requests in 10s of milliseconds.

redo size: Total amount of redo generated in bytes.

redo synch time: Elapsed time of all redo synch writes calls in 10s of milliseconds

redo write time: Total elapsed time of the write from the redo log buffer to the current redo log file in microseconds.

redo writes: Total number of writes by LGWR to the redo log files. redo blocks written divided by this statistic equals the number of blocks per write.

session cursor cache count: Total number of cursors cached. This statistic is incremented only if `SESSION_CACHED_CURSORS > 0`. This statistic is the most useful in `V$SESSTAT`. If the value for this statistic in `V$SESSTAT` is close to the setting of the `SESSION_CACHED_CURSORS` parameter, the value of the parameter should be increased.

session cursor cache hits: The number of hits in the session cursor cache. A hit means that the SQL statement did not have to be reparsed. Subtract this statistic from parse count (total) to determine the real number of parses that occurred.

session logical reads: The sum of db block gets plus consistent gets. This includes logical reads of database blocks from either the buffer cache or process private memory.

session stored procedure space: Amount of memory this session is using for stored procedures.

Small IO Percent:

sorts (disk): The number of sort operations that required at least one disk write.

sorts (memory): The number of sort operations that were performed completely in memory and did not require any disk writes.

sorts (rows): Total number of rows sorted.

table scan rows gotten: The number of rows that are processed during scanning operations.

table scans (direct read): The number of table scans performed with direct read (bypassing the buffer cache).

table scans (long tables): Long (or conversely short) tables can be defined as tables that do not meet the short table criteria as described in table scans (short tables).

table scans (rowid ranges): During a parallel query, the number of table scans conducted with specified ROWID ranges.

transaction lock background get time: Useful only for internal debugging purposes.

transaction lock foreground wait time: Useful only for internal debugging purposes.

transaction rollbacks: The number of transactions being successfully rolled back.

TOTAL_LOCK_TIME: The total time for which database is in locked state.

user calls: The number of user calls such as login, parse, fetch, or execute

user commits: The number of user commits. When a user commits a transaction, the redo generated that reflects the changes made to database blocks must be written to disk. Commits often represent the closest thing to a user transaction rate.

user rollbacks: The number of times users manually issue the ROLLBACK statement or an error occurs during a user's transactions.

 Some of the obsolete metrics were removed and the following metrics are included with 20.11 and later versions of Controller.

DB|Server Statistic|DB time: The sum of CPU consumption of all the Oracle process and the sum of non-idle wait time

DB|Server Statistic|OS System time used: The total CPU time used for system calls

DB|Server Statistic|OS User time used: The total CPU time used for user calls

DB|Server Statistic|SMON posted for instance recovery: The total count or number of times SMON posted for instance recovery

DB|Server Statistic|SMON posted for txn recovery for other instances: The total count or number of times SMON posted for other transactions recovery in an Oracle RAC or a cluster

DB|Server Statistic|java call heap live size: The Java call heap live size

DB|Server Statistic|java call heap total size: The total Java call heap size

DB|Server Statistic|java call heap used size: The Java call heap used size

DB|Server Statistic|non-idle wait count: The total count of non-idle wait events

DB|Server Statistic|non-idle wait time: The total elapsed time for non-idle events

PostgreSQL Server Metrics

blks_hit: Number of times disk blocks were found already in the buffer cache, so that a physical disk read was not necessary. This only includes hits in the PostgreSQL buffer cache, does not include the operating system's file system .cache).

blks_read: Number of disk blocks read from the database.

confl_bufferpin: Number of queries in the database that were canceled because of pinned buffers.

confl_deadlock: Number of queries in the database that were canceled because of deadlocks

confl_lock: Number of queries in the database that were canceled due because of timeouts.

confl_snapshot: Number of queries in the database that were canceled because of old snapshots.

confl_tablespace: Number of queries in the database that were canceled because of dropped tablespaces.

numbackends: Number of backends currently connected to the database.

size_mb:

tup_deleted: Number of rows deleted by queries in the database.

tup_fetched: Number of rows fetched by queries in the database.

tup_inserted: Number of rows inserted by queries in the database.

tup_returned: Number of rows returned by queries in the database.

tup_updated: Number of rows updated by queries in the database.

xact_commit: Number of transactions in the database that have been committed.

xact_rollback: Number of transactions in the database that have been rolled back.

Sybase ASE and IQ Server Metrics

Sybase ASE

Metrics	Description
BytesReceived	The number of bytes received during client/server communications. This value is updated for HTTP and HTTPS connections.
BytesSent	The number of bytes sent during client/server communications. This value is updated for HTTP and HTTPS connections.
Connections	The number of connections to the database.
Deletes	The number of deferred and direct row deletes from the allpages-locked tables.
DiskIOChecks	The number of times the engine checked for asynchronous disk I/O. Modify the frequency of these checks with the i/o polling process count.
DiskIOCompleted	The number of asynchronous disk I/Os completed when the engine polled for outstanding asynchronous disk I/O.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metrics	Description
DiskIOPolled	The number of times the engine polled for completion of outstanding asynchronous disk I/O. The polling occurs whenever disk I/O checks indicate that asynchronous I/O is posted but still not complete.
IndexAccesses	The number of pages read that Adaptive Server retrieves using an index.
Inserts	The total number of insert operations executed.
LogicalReads	The number of buffers read from the cache.
MaxOutstandingIOs	The current number of I/O requests initiated by the engine that are not completed.
Merges	The total number of merge operations executed.
PacketsReceived	The number of packets received.
PacketsSent	The number of packets sent.
PhysicalReads	The number of buffers read from disk.
PhysicalWrites	The numbers of buffers written to disk from the cache.
Rollbacks	The number of transactions rolled back by the process.
Selects	The total number of select operations executed.
TableAccesses	The number of pages read that Adaptive Server retrieves without using an index.
TempDbObjects	The total number of temporary tables created using the process.
Total Lock Time	The number of times a task waits for a lock and the transaction is rolled back during a session-level or server-level lock timeout.
Transactions	The currently running transaction.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metrics	Description
ULCFlushes	The total number of times the user log cache is flushed.
ULCFlushFull	The number of times the user log cache is flushed because it was full.
Updates	The total number of <code>Update</code> operations executed.
WorkTables	The number of <code>Worktables</code> that are automatically created in <code>tempdb</code> by Adaptive Server.
Yields	The number of times a task is completed or yielded after running for the configured amount of time.

Sybase IQ

Metrics	Description
ActiveReq	Returns the number of server threads that are currently handling a request.
ActiveVersionsCount	Count of Active Transaction Versions.
ActiveVersionsCreateMB	Size in Mb of versions for the active transaction.
ActiveVersionsDeleteMB	Size in Mb of versions for active transactions.
BytesReceived	Returns the number of bytes received during client/server communications. This value is updated for HTTP and HTTPS connections.
BytesReceivedUncomp	Returns the number of bytes that would have been received during client/server communications if compression was disabled. (This value is the same as the value for BytesReceived if compression is disabled.)
BytesSent	Returns the number of bytes sent during client/server communications. This value is updated for HTTP and HTTPS connections.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metrics	Description
BytesSentUncomp	Returns the number of bytes that would have been sent during client/server communications if compression was disabled. (This value is the same as the value for BytesSent if compression is disabled.)
CacheFileDirty	Returns the number of cache pages that are dirty (needing a write).
CacheFree	Returns the number of cache pages not being used.
CacheHits	Returns the number of database page lookups.
CachePanics	Returns the number of times the cache manager has failed to find a page to allocate.
CachePinned	Returns the number of pinned cache pages.
CacheRead	Returns the number of cache reads.
CacheReplacements	Returns the number of pages in the cache that have been replaced.
CacheScavenges	Returns the number of times the cache manager has scavenged for a page to allocate.
Connections	The number of connections to the database.
DiskRead	Returns the number of disk reads.
OtherVersionsCount	Shows count of other db versions. These versions will eventually be dropped when they are no longer referenced or referencable by active transactions.
OtherVersionsMB	Shows space usage in MB of other db versions. These versions will eventually be dropped when they are no longer referenced or referencable by active transactions.
ProcessCPU	Returns CPU usage for the database server process. Values are in seconds. This property is supported on Windows and Unix. This property is not supported on Windows Mobile.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metrics	Description
ProcessCPUSystem	Returns system CPU usage for the database server process CPU. This is the amount of CPU time that the database server spent inside the operating system kernel. Values are in seconds. This property is supported on Windows and Unix. This property is not supported on Windows Mobile.
ProcessCPUUser	Returns user CPU usage for the database server process. Values are in seconds. This excludes the amount of CPU time that the database server spent inside the operating system kernel. This property is supported on Windows and Unix. This property is not supported on Windows Mobile.
RequestsReceived	Requests received by the server.
TempBufferCapacityCount	Capacity count of Temporary Buffers.
TempBufferCapacityMB	Capacity in Mb of Temporary Buffers.
TempBufferLockedCount	The number of Temporary Buffers that are locked.
TempBufferUsedCount	The number of Temporary Buffers in use.
Total Lock Time	The total time for which database is in locked state.
Transactions	The number of transactions.

Database Agent Events Reference

You can view Database Agent events on the **Database Monitoring > Events** window and in the `<agent_home>/logs/db-agent#.log` files. Database Agent events are of type Agent Diagnostic Event, with case-specific messages attached. See [Monitor Events](#).

Agent Diagnostic Events

Initialize/re-initialize the DB Collector

Summary: Initialize/re-initialize the DB collector

Description: Sent when database collector has successfully started. This happens when you configure a new collector, start/restart the agent process (in which case you'll see this event once for each collector), or when the collector recovers from a failure to communicate with the monitored database (for example, when the database goes down for a while, then comes back).

Severity: Info

Initialize/re-initialize the Hardware Metric Collector

Summary: Initialize/re-initialize the hardware metric collector

Description: Same as the above, but refers to a hardware collector, not a database collector.

This is sent when hardware collector has successfully started. This happens when you configure a new collector, start/restart the agent process (in which case you'll see this event once for each collector), or when the collector recovers from a failure to communicate with the monitored hardware (for example, when the system goes down for a while, then comes back).

Severity: Info

Server Parameter [?] has been Changed from [?] to [?]

Summary: Server parameter [?] has been changed from [?] to [?]

Description: The Database Agent constantly monitors database configuration parameters. When a parameter changes, which generally means a database administrator made a deliberate change, the agent sends this event. AppDynamics Database Visibility users can use these events to track configuration changes in their databases.

Severity: Info

JDBC Driver-related Agent Diagnostic Events

Summary: The text of the message is the error from the vendor's JDBC driver.

Description: When the agent fails to collect data from a monitored database, it sends this event, and goes into sleep mode for one minute. It will then retry contacting the database every minute until it succeeds. Once it succeeds, it will send an Agent Event "initialize/re-initialize" message, as described above. This

happens when the database goes down, or when you add a collector with a wrong password, or wrong hostname, etc.

When the Collector is in sleep mode because of an error, you'll see an indicator next to the database on the **Infrastructure** and **Infrastructure > Databases**, on **Configure > Collectors** panel. You will also see the full text of the error in the **Infrastructure > Events** panel.

Severity: Error

Wait State Filtering

Database wait states are pauses or delays in database activity. While Database Visibility collects data on all wait states, you may be more interested in some wait states than others. You can specify which wait states that you want to exclude from being reported by the agent so that you can focus on the critical wait states.

To specify wait states to exclude, navigate to **Configuration > Wait State Filtering**. Check the boxes of the wait states that you want to exclude. The wait states you exclude are no longer displayed in the Top 10 Query Wait States metric. In addition, any future queries that experience the wait states you exclude are not reported by the agent.

Configure Custom Metrics

Database Visibility extends monitoring by specifying SQL queries to run on the monitored database and the queries run during normal database activity. You can schedule these custom queries to run on regular intervals and collect the results in a custom metric. See [Database Custom Metrics Window](#).

To specify custom queries to run:

1. Navigate to **Configuration > Custom Metrics > New**.
2. Complete the following fields:
 - a. **Name:** The name you want to name your custom metric. Once you create a custom metric/event, you cannot change its name.
 - b. **Custom Query Metric Type:** The type of result that you want from the query.
 - i. Select the **Metric** type to generate metrics for which health rules can be defined. Metrics of this type are displayed in the **Metric Browser** or in the Custom Metrics tab of each collector.
 - ii. Select the **Event Data** type to generate custom events whenever the custom query output is non-empty. If you want to be notified when a custom event occurs, you can create a policy that is triggered by that custom event. Custom events are displayed in the Events tab. If the custom query outputs multiple rows, the first 40 rows will be included in the event details. Each row displays a maximum of 5000 characters, including the column separators (|).
 - c. **Database Type:** The database platform that you want to run the metric on.
 - d. **Databases:** The database instances that you want to run the metric on. You can run the metric on all database instances of the specified database type, or on specific database instances that you specify.
 - e. **Schedule:** The time interval at which you want to run the query. For metric type custom queries, the metric value reported in between the specified intervals is the value observed in the previous query execution.

The timeout for configured custom metric depends on the frequency of running the query. This table provides the timeout details based on the time interval:

Interval (minutes)	Timeout (seconds)
1	10
5	15
10	30
30	60
60	120
360	180
720	300
1440	300

- f. **Query Text:** The query that you want to execute. If you are creating a custom metric of Metric type, its query must have one of the following return types:
- i. Positive integer. For example, the query below returns a positive integer.

```
SELECT COUNT(*) FROM employees
```

- ii. String and positive integer. For example, the query below returns a string and a positive integer.

```
SELECT name, salary FROM employees
```

Custom queries appear for all collectors, but the data only reflects the collector that you created it for. You can test the semantics of the query and also validate the results by clicking the **Test Query** button.

i Custom query results are validated if the Database Agent \geq 4.5.5.

The following points provide information about using limits when configuring custom metrics:

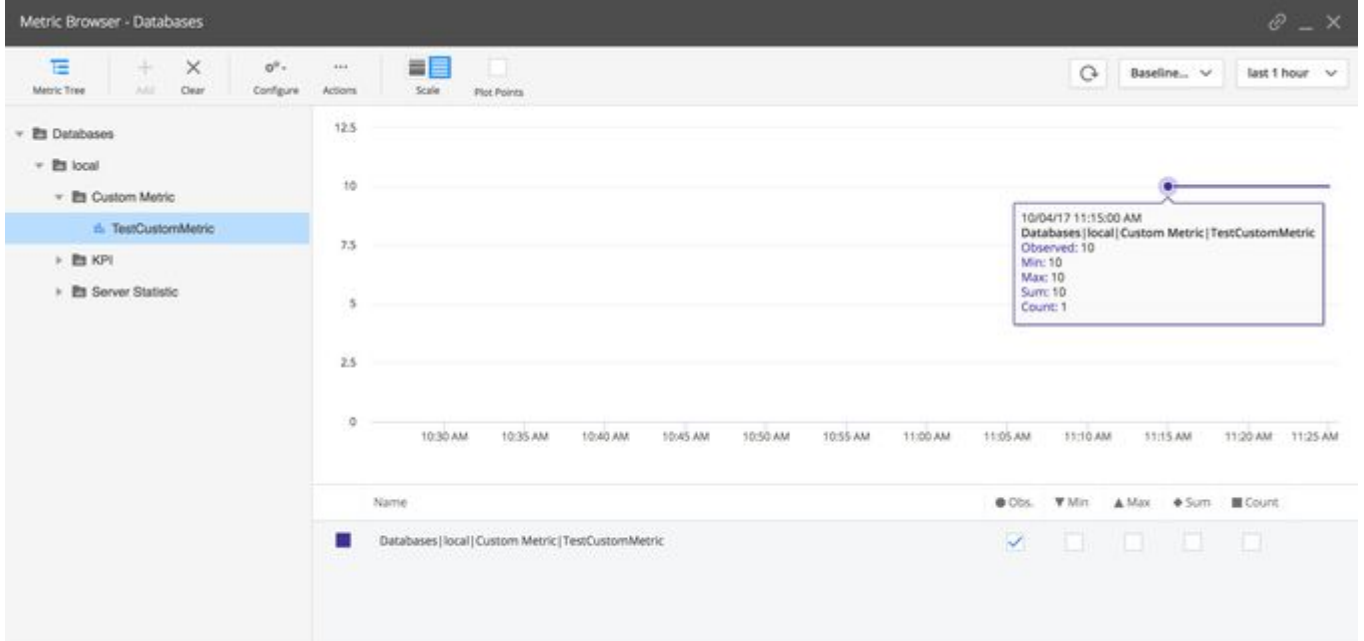

- The total number of custom metrics or events that you can create per account is the product of `total number of Collectors` and `dbmon.config.max.custommetric`.
By default, the value of `dbmon.config.max.custommetric` is 40. You can adjust the limit up to 150 using the `dbmon.config.max.custommetric` property in the [Controller Settings](#).
- Up to 150 custom metrics can be reported per collector per minute.
- You can increase the custom metrics limit from the agent configuration properties by using the key, `dbagent.custom.metric.reportable.per.server` and the `Max` value 150. See [Database Agent Configuration Properties](#) for information about the key value.
- The maximum limit configured in the agent takes precedence and overrides the maximum limit configured at the account level and Controller level. Therefore, the priority order is as following:
 - Agent-level configuration
 - Account-level configuration
 - Controller-level configuration

Custom metrics are supported for all relational databases: MySQL, Microsoft SQL Server, Oracle, PostgreSQL, DB2, and Sybase.

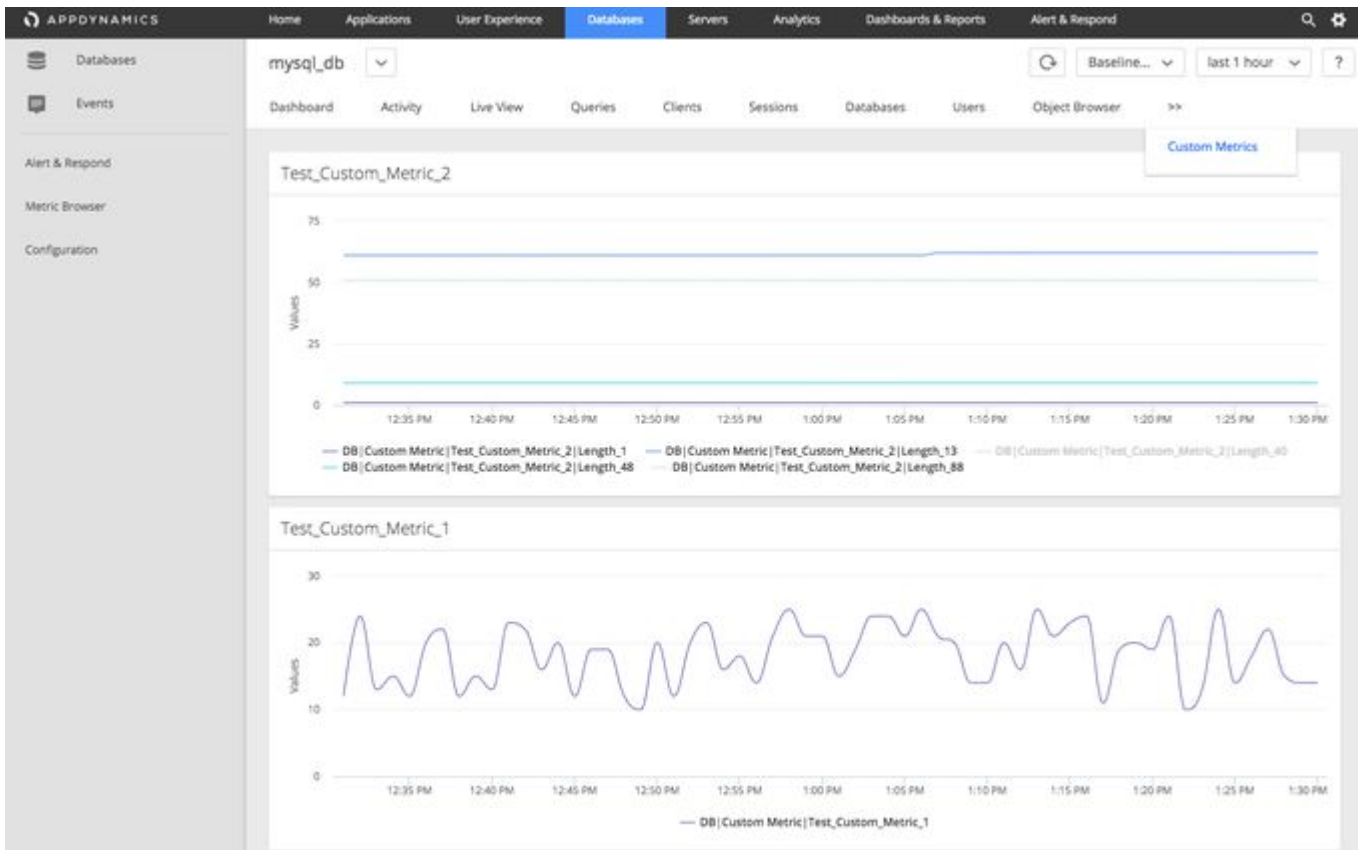

View Custom Metrics

You can view your custom metrics in the following locations:

- In **Databases > Metric Browser**, expand the database that you want to view custom metrics for.

- In **Databases**, open a database instance and click the Custom Metrics tab.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Configure Query Literals Security

In SQL, literals are the string or integer values representing data retrieved from the database. By default, literals are removed from SQL queries, as they can contain sensitive user data such as social security numbers, CC numbers, and so on.

To show literals in the queries, you can disable the **Remove literals from the queries** option.

1. Click **Databases**.
2. Click **Configuration**.
3. In the Security section, uncheck **Remove literals from the queries**.

Once you uncheck the option, literals will always be displayed in the queries. You can revert to hiding the literals by checking the option.

The Database Agent does not mask the literals that occur after an inline or single line comment. This limitation applies only to Oracle database. However, you can mask literals if you use block comments.

Infrastructure Visibility

AppDynamics Infrastructure Visibility provides end-to-end visibility on the performance of the hardware running your applications. You can use Infrastructure Visibility to identify and troubleshoot problems that can affect application performance such as server failures, JVM crashes, and network packet loss.

Infrastructure Visibility provides these metrics:

- CPU busy/idle times, disk and partition reads/writes, and network interface utilization (Machine Agents)
- Packet loss, round trip times, connection setup/tear down errors, TCP window size issues, and re-transmission timeouts (Network Visibility, additional license required)
- Disk/CPU/memory utilization, process, and machine availability (Server Visibility, additional license required)

Machine Agent

- [Administer the Cluster Agent](#)

Monitor Containers With Docker Visibility

- [Configure Docker Visibility](#)
- [Use Docker Visibility with Kubernetes](#)
- [Use Docker Visibility with Red Hat OpenShift](#)
- [Container Metrics](#)

Overview of Infrastructure Visibility

You can determine the root cause of application issues by looking at application, network, server, and machine metrics that measure infrastructure utilization.

For example, the following infrastructure issues may slow down your application:

- Too much time spent in garbage collection of temporary objects (application metric)
- Packet loss between two nodes that results in re-transmissions and slow calls (network metric)
- Inefficient processes that result in high CPU utilization (server metric)
- Excessively high rates of reads/writes on a specific disk or partition (hardware metric)

Infrastructure Visibility enables you to isolate, identify, and troubleshoot these types of issues.

Infrastructure Visibility is based on a Machine Agent that runs with an App Server Agent on the same machine. These two agents provide multi-layer monitoring:

1. The App Server Agent collects metrics about applications and identifies applications, tiers, and nodes with slow transactions, stalled transactions, and other application-performance issues.
2. The Network Agent monitors the network packets sent and received on each node and identifies lost/re-transmitted packets, TCP bottlenecks, high round trip times, and other network issues.
3. The Machine Agent collects metrics at two levels:
 - Server Visibility metrics for local processes, services, and resource utilization.
 - Basic machine metrics for disks, memory, CPU, and network interfaces.

This multi-layer monitoring enables you to determine possible correlations between application issues and service, process, hardware, network, or other issues on the machine.

	This Agent Monitors...	Example Metrics
1 App Agent 	apps app servers JVMs CLRs	Slow Transactions Stalled Transactions Response Times Wait Times Block Times Error %
2 Network Agent 	network packets TCP connections TCP sockets	Performance Impacting Events Packet loss and retransmissions Round Trip Times for data transfers TCP Window Size (Limited or Zero) Connection setup/teardown errors
3 Machine Agent  Server Visibility Hardware/OS	processes services caching swapping paging queueing	Hardware/Software Interrupts Virtual memory/swapping Process faults CPU/disk/memory utilization by process
	disks volumes partitions memory CPU network interfaces	CPU busy times Memory utilization Disk reads/writes JVM crashes

Network Visibility

Network Visibility monitors traffic flows, network packets, TCP connections, and TCP ports. Network Agents leverage the APM intelligence of App Server Agents to identify the TCP connections used by each application. Network Visibility includes:

- Detailed metrics about dropped/re-transmitted packets, TCP window sizes (Limited/Zero), connection setup/tear down issues, high round trip times, and other performance-impacting issues
- Network Dashboard that highlights network KPIs (Key Performance Indicators) for tiers, nodes, and network links
- Right-click dashboards for tiers, nodes, and network links that enable quick drill-downs from transaction outliers to network root causes
- Automatic mapping of TCP connections with application flows
- Automatic detection of intermediate load balancers that split TCP connections
- Diagnostic mode for collecting advanced diagnostic information for individual connections

Server Visibility

Server Visibility monitors local processes, services, and resource utilization. You can use these metrics to identify time windows when problematic application performance correlates with problematic server performance on one or more nodes.

Server Visibility is an add-on module to the **Machine Agent**. With Server Visibility enabled, the Machine Agent provides the following functionality:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- Extended hardware metrics such as machine availability, disk/CPU/virtual-memory utilization, and process page faults
- Monitor application nodes that run inside Docker containers and identify container issues that impact application performance
- The Tier Metric Correlator which enables you to identify load and performance anomalies across all nodes in a tier
- Import and define server tags used to query, filter, and compare related servers using custom metadata
- Monitor internal or external HTTP and HTTPS services
- Support for grouping servers so you can apply health rules to specific server groups
- Support for defining alerts that trigger when certain conditions are met or exceeded based on monitored server hardware metrics

Basic Machine Metrics

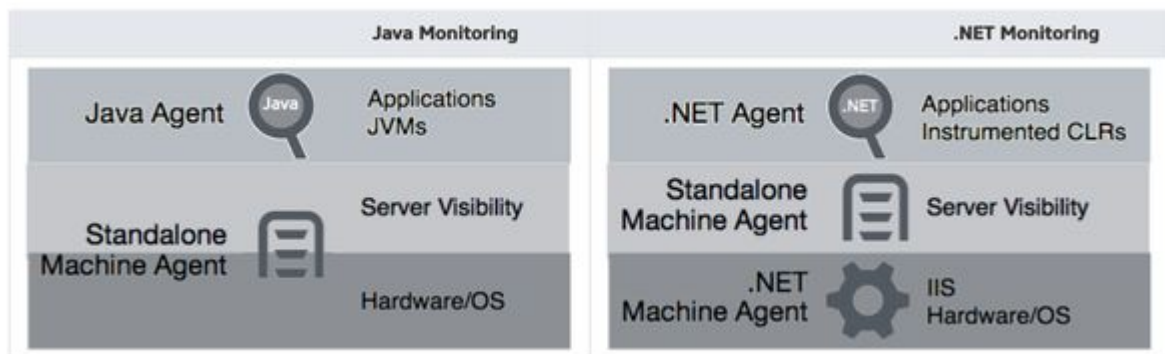

The Machine Agent collects basic hardware metrics from the server's OS and provides the following functionality:

- Basic hardware metrics from the server's OS such as CPU and memory utilization, throughput on network interfaces, and disk and network I/O
- Support for creating extensions to generate custom metrics
- Support for running remediation scripts to automate your runbook procedures. You can optionally configure the remediation action to require human approval before starting the script.
- JVM Crash Guard for monitoring JVM crashes and optionally running remediation scripts

Java and .NET Infrastructure Monitoring

Infrastructure Visibility uses different agents to monitor Java and .NET environments:

- The Java Agent collects metrics for business applications and JVMs. The Machine Agent collects Server Visibility and hardware/OS metrics.
- The [.NET Agent](#) collects metrics for business applications and instrumented CLR's. The .NET Agent includes a .NET Machine Agent that collects IIS and hardware/OS metrics (see [Monitor Windows Hardware Resources](#)). The Machine Agent collects Server Visibility metrics.

Infrastructure Visibility Strategies

You can use these strategies to locate infrastructure issues that affect application performance:

- Transaction snapshots for slow or stalled transactions – Use snapshots to correlate infrastructure metrics for the specific node so that you can identify the root cause of slow or stalled transactions.
- Metric correlation –
 - One example workflow is to open the Node Dashboard for a mission-critical server with a machine agent installed and then cross-compare data in the following tabs:
 - JVM (application performance)

-
- JMX (server performance)
 - Server (hardware resource consumption)
 - The [Network Dashboard](#) includes right-click dashboards for tiers, nodes, and network links. Use these dashboards to find correlations between application issues and network root causes.
 - The [Tier Metric Correlator](#) enables you to identify load and performance anomalies in a tier composed of a cluster of nodes running on containers or servers.
 - Health rules – Configure health rules on metrics such as garbage collection time, connection pool contention, or CPU usage to catch issues early in the cycle before any impact on your business transactions.
 - Infrastructure rules, policies, and alerts –
 - Create health rules on metrics such as garbage collection time, connection pool contention, or CPU usage to catch issues early in the cycle before any impact on your business transactions.
 - Define [policies](#) that trigger [actions](#) (such send an email, start diagnostics, or perform a thread dump) when Infrastructure metrics report a critical level.
 - You can configure alerts for JVM and CLR crashes respectively using [JVM Crash Guard](#) and the [.NET Machine Agent](#).
 - Configure the agent to [run scripts](#) in response to critical events (for example, restart an application or JVM in response to a crash).

With the right monitoring strategy in place, you can be alerted to problems and fix them before user transactions are affected.

Hardware Resources Metrics

This page describes the basic hardware metrics collected by the Machine Agent and the additional metrics collected by the Machine Agent for Server Visibility. Not all of the metrics that appear in the Hardware Resources branch of the Metric Browser tree are provided by the Machine Agent; some are collected by the Database Agent and are used in the Database Monitoring UI, while others might be custom metrics added by another extension run by your Machine Agent.

For most metrics in the Metric Browser, you can select any point in the graph to view more information about the metric observed at that point in time. The information includes the metric identifier, date and time of the observation, along with any of the following values relevant to the metric:

- **Obs** (observed value): Average of all data points seen for that interval. For a cluster or a time rollup, this represents the weighted average across nodes or over time.
- **Min**: Minimum data point value seen for that interval
- **Max**: Maximum data point value seen for that interval
- **Sum**: Sum of all data point values seen for that interval. For the Percentile Metric for the App Agent for Java, this is the result of the percentile value multiplied by the Count.
- **Count**: Number of data points generated for the metric in that interval. The collection interval for infrastructure metrics varies by environment.

CPU Metrics

Metric Name	Description	Basic or Server Visibility	Windows	Linux ¹	Solaris	AI X	Default Monitoring Mode ³
%Idle	Percentage of time the CPU was idle; the CPU had completed its tasks and has nothing to do.	Basic	✓	✓	✓	✓	KPI
%Busy	Percentage of time the CPU was busy processing system or user requests; this metric includes CPU Stolen time.	Basic	✓	✓	✓	✓	KPI

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metric Name	Description	Basic or Server Visibility	Windows	Linux ¹	Solaris	AIX	Default Monitoring Mode ³
%Stolen ⁴	Usually, stolen time is the percentage of time a virtual CPU waits for a real CPU while the hypervisor is servicing another virtual processor.	Basic	✓	✓	✓	✓	KPI
%Nice	Percentage of CPU time spent on low priority processes.	Server Visibility	✗	✓	✗	✗	Advanced
System	Percentage of time the CPU was busy processing kernel code.	Server Visibility	✓	✓	✓	✓	KPI
User	Percentage of time the CPU was busy processing non-kernel code.	Server Visibility	✓	✓	✓	✓	KPI
IOWait	Percentage of CPU time spent waiting for an I/O request.	Server Visibility	✗	✓	✓	✗	KPI
%Irq	Percentage of CPU time spent servicing hardware interrupts.	Server Visibility	✗	✓	✗	✗	Diagnostic
%SoftIrq	Percentage of CPU time spent servicing software interrupts.	Server Visibility	✗	✓	✗	✗	Advanced
%Busy 95th Percentile ²	The CPU %Busy percentage was at this level or lower 95% of the time.	Server Visibility	✗	✓	✗	✓	KPI

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metric Name	Description	Basic or Server Visibility	Windows	Linux ¹	Solaris	AIX	Default Monitoring Mode ³
IOWait 95th Percentile ²	The CPU %Busy percentage was at this level or lower 95% of the time.	Server Visibility	✗	✓	✗	✓	KPI

1 See [Linux Kernel Processes](#).

2 See [Percentile Metric Reporting must be Enabled](#).

3 See [Default Monitoring Mode](#).

4 See [Stolen Times are Reported Differently](#).

Memory Metrics

Metric Name	Description	Basic or Server Visibility	Windows	Linux ¹	Solaris	AIX	Default Monitoring Mode ³
Total (MB)	The total amount of memory.	Basic	✓	✓	✓	✓	KPI
Used %	The percentage of memory used.	Basic	✓	✓ ⁴	✓	✓	KPI
Used (MB)	The amount of memory used.	Basic	✓	✓ ⁴	✓	✓	Advanced
Free %	Percentage of free or unused memory available for processes.	Basic	✓	✓ ⁴	✓	✓	Advanced

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metric Name	Description	Basic or Server Visibility	Windows	Linux ¹	Solaris	AI X	Default Monitoring Mode ³
Free (MB)	The total amount of free or unused memory available for processes.	Basic	✓	✓ ⁴	✓	✓	Advanced
Swap Free (MB)	The total amount of free swap space. Reported for each hierarchical group.	Server Visibility	✓	✓	✓	✓	Advanced
Swap Total (MB)	The total amount of allocated swap space. Reported for each hierarchical group.	Server Visibility	✓	✓	✓	✓	KPI
Swap Used (MB)	The amount of swap space used. Reported for each hierarchical group.	Server Visibility	✓	✓	✓	✓	Advanced
Swap Used %	The percentage of available swap space used. Reported for each hierarchical group.	Server Visibility	✓	✓	✓	✓	KPI
Swap Free %	Percentage of free swap space. Reported for each hierarchical group.	Server Visibility	✓	✓	✓	✓	Advanced
Pages Paged In 95th Percentile ²	The paging-in rate to memory was at this level or lower 95% of the time.	Server Visibility	✗	✓	✗	✓	KPI

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metric Name	Description	Basic or Server Visibility	Windows	Linux ¹	Solaris	AI X	Default Monitoring Mode ³
Pages Paged Out 95th Percentile ²	The paging-out rate from memory was at this level or lower 95% of the time.	Server Visibility	✗	✓	✗	✓	KPI
Pages Swapped In 95th Percentile ²	The swapping rate of pages from disks was at this level or lower 95% of the time.	Server Visibility	✗	✓	✗	✓	KPI
Pages Swapped Out 95th Percentile ²	The swapping rate of pages to disks was at this level or lower 95% of the time.	Server Visibility	✗	✓	✗	✓	KPI

⁴ See [Configure Free/Used Memory Metric Calculation on Linux](#).

Disk and Partition Metrics

The agent reports metrics for each disk partition and for disks in aggregate. Only mounted partitions and local partitions are reported.

 SIGAR is not supported on Machine Agent.

Metric Name	Description	Basic or Server Visibility	Windows	Linux	Solaris	AIX	Default Monitoring Mode ¹
KB read/sec	The number of KB per second read from all disks and partitions.	Basic	✓	✓	✓	✓	Advanced
KB written/sec	The average amount of data per second written to all disks and partitions.	Basic	✓	✓	✓	✓	Advanced
Reads/sec	Number of read operations per second performed on all disks and partitions.	Basic	✓	✓	✓	✓	KPI
Writes/sec	Number of write operations per second performed on all disk and partitions.	Basic	✓	✓	✓	✓ 5	KPI
Avg IO Utilization (%)	The average time spent processing read/write requests on all disks and partitions as a percentage of the total reported time window. Databases often report high disk I/O utilization due to frequent read/write requests. For example, if the agent detects read/write processing in 55 out of 60 seconds, the Avg IO Utilization for that minute is 92%. This metric does not measure the amount of available disk space or read/write request sizes.	Server Visibility	✓	✓	✓	✓	KPI

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metric Name	Description	Basic or Server Visibility	Windows	Linux	Solaris	AI X	Default Monitoring Mode ¹
<partition> %CPU Time	The percentage of CPU processing consumed by a partition during read and write operations.	Basic	✗	✓	✗	✓	Diagnostic
<partition> Avg Service Time (ms)	Time in milliseconds spent performing read and write operations across one partition.	Basic	✗	✓	✓	✓	Diagnostic
<partition> Avg Queue Time (ms)	Time in milliseconds that a read or write request is in the queue before it gets processed across one partition.	Basic	✗	✓	✗	✓	KPI
<partition> KB read/sec	The average amount of data per second read from one specific partition.	Basic	✓	✓	✓	✓	Diagnostic
<partition> KB written/sec	The average amount of data per second written to one specific partition.	Basic	✓	✓	✓	✓	Diagnostic
<partition> Reads/sec	Number of read operations per second performed on one specific partition.	Basic	✓	✓	✓	✓	KPI
<partition> Writes/sec	Number of write operations per second performed on one specific partition.	Basic	✓	✓	✓	✓ 5	KPI
<partition> Space Available	The amount of unused or free disk space on a specific partition in KB.	Basic	✓	✓ ⁴	✓	✓	KPI

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metric Name	Description	Basic or Server Visibility	Windows	Linux	Solaris	AIX	Default Monitoring Mode ¹
<partition> Space Used	The amount of used or unavailable disk space on a specific partition in KB.	Basic	✓	✓ ⁴	✓	✓	Advanced
<partition> Avg IO Utilization (%)	The average time spent processing read/write requests as a percentage of the total reported time window. Databases often report high disk I/O utilization due to frequent read/write requests. For example, if the agent detects read/write processing in 55 out of 60 seconds, the Avg IO Utilization for that minute is 92%. This metric does not measure the amount of available disk space or read/write request sizes.	Server Visibility	✓	✓	✓	✓	KPI
<partition> Avg read time (ms)	The average time in milliseconds required to service a read request by all disks or by one specific disk or across one partition.	Server Visibility	✓ ²	✓	✓	✗	KPI
<partition> Avg write time (ms)	The average time in milliseconds required to service a write request across one partition.	Server Visibility	✓ ²	✓	✓	✗	KPI
<partition> Queue Time 95th Percentile ³	The queue time for read/write requests was this long or shorter 95% of the time for the reported time window.	Server Visibility	✗	✓	✗	✓	KPI

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

1 See [Default Monitoring Mode](#).

2 For some versions of Windows Server 2008 and Windows Vista, the Hardware Resources|Disks|<partition>|Avg Read Time (ms) and Hardware Resources|Disks|<partition>|Avg Write Time (ms) metrics will be reported as 0. This is due to a known bug with Windows. To resolve this issue, download the hotfix: <https://support.microsoft.com/en-us/kb/961435>.

3 See [Percentile Metric Reporting must be Enabled](#).

4 See [Configure Disk Usage Metric Collection on Linux](#).

5 See [HardwareMonitor and JavaHardwareMonitor Calculate "Writes/Sec" Differently on AIX Machines](#)

Volume Metrics

AppDynamics Server Visibility retrieves the volume space metrics on POSIX systems using the `df` command. The volume metrics are reported across all listed volumes and for each volume at a specified mount point, such as `"/boot"`. Only local volumes are reported.

Metric Name	Description	Basic or Server Visibility	Windows	Linux ¹	Solaris ²	AIX	Default Monitoring Mode ³
Total (MB)	The amount of storage space available (used and free) across all listed volumes or at the specified mount point. On Linux, the space reserved for root is not counted in the available space.	Server Visibility	✓	✓	✓	✓	KPI
Free (MB)	The amount of unused or free space across all listed volumes or on the selected volume at the specified mount point. On Linux, the space reserved for root is not counted in the available space.	Server Visibility	✓	✓	✓	✓	Advanced (volume)

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metric Name	Description	Basic or Server Visibility	Windows	Linux ¹	Solaris ²	AI X	Default Monitoring Mode ³
Used (MB)	The amount of storage space in use across all listed volumes or on the selected volume at the specified mount point.	Server Visibility	✓	✓	✓	✓	Advanced (<i>volume</i>)
Used (%)	The percentage of storage space in use across all listed volumes or on the selected volume at the specified mount point.	Server Visibility	✓	✓	✓	✓	KPI
Count	The number of partitions for which storage space metrics are collected.	Server Visibility				✓	KPI
<partition> Free (MB)	The amount of unused or free space for <partition>.	Server Visibility				✓	KPI
<partition> Total (MB)	The amount of storage space available (used and free) for <partition>.	Server Visibility				✓	KPI
<partition> Used (%)	The percentage of storage space in use for <partition>.	Server Visibility				✓	KPI
<partition> Used (MB)	The amount of storage space in use for <partition>.	Server Visibility				✓	Advanced

¹ Only **/dev** volumes are monitored on Linux.

² Only **/dev/dsk** and **/rpool** volumes are monitored on Solaris.

³ See [Default Monitoring Mode](#).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Load Metrics

The load metrics are reported for each machine. The CPU % (reported as part of the basic Machine Agent metrics) is the percentage of the CPU consumed by processes that are currently running. Load takes into account processes that are waiting to run. These metrics are shown as percentages in the Server Dashboard and are [scaled by 100 in the Metric Browser](#).

Metric Name	Description	Basic or Server Visibility	Windows	Linux	Solaris	AI X	Default Monitoring Mode ¹
Last 1 minute	CPU Load, presented as an average over the last 1 minute.	Server Visibility	✓	✓	✓	✓	KPI
Last 5 minutes	CPU Load, presented as an average over the last 5 minutes.	Server Visibility	✓	✓	✓	✓	KPI
Last 15 minutes	CPU Load, presented as an average over the last 15 minutes.	Server Visibility	✓	✓	✓	✓	KPI

¹ See [Default Monitoring Mode](#).

Machine Metrics

Metric Name	Description	Basic or Server Visibility	Windows	Linux	Solaris	AIX	Default Monitoring Mode ¹
Availability	The percentage of time the Machine Agent was reporting to the Controller. In the Server Visibility UI, this provides a percentage with 6 digits of precision (for example, 100.00000) to measure availability. The Machine Agent sends a heartbeat to the AppDynamics Controller once per minute to indicate the agent is reporting. Reported for each machine.	Server Visibility	✓	✓	✓	✓	KPI

¹ See [Default Monitoring Mode](#).

Network Metrics

The Machine Agent is configured to ignore virtual networks by default. See [Machine Agent Settings for Server Visibility](#).

Metric Name	Description	Basic or Server Visibility	Windows	Linux	Solaris	AIX	Default Monitoring Mode ¹
Incoming KB ²	The volume of data received by all monitored network devices.	Basic	✓	✓	✓	✓	Advanced
Incoming KB/sec	The amount of data per second received by all monitored network devices.	Basic	✓	✓	✓	✓	KPI

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metric Name	Description	Basic or Server Visibility	Windows	Linux	Solaris	AIX	Default Monitoring Mode ¹
Incoming packets ²	The number of packets received by all monitored network devices.	Basic	✓	✓	✓	✓	Advanced
Incoming packets/sec	The number of data packets per second received by all monitored network devices.	Basic	✓	✓	✓	✓	Advanced
Outgoing KB ²	The volume of data sent by all monitored network devices.	Basic	✓	✓	✓	✓	Advanced
Outgoing KB/sec	The volume of data sent per second by all monitored network devices.	Basic	✓	✓	✓	✓	KPI
Outgoing packets ²	The number of packets sent by all monitored network devices.	Basic	✓	✓	✓	✓	Advanced
Outgoing packets/sec	The number of data packets sent per second by all monitored network devices.	Basic	✓	✓	✓	✓	Advanced
Incoming Errors/min	The number of incoming packet errors the network incurs every minute.	Server Visibility	✓	✓	✓	✓	KPI
Outgoing Errors/min	The number of outgoing packet errors the network incurs every minute.	Server Visibility	✓	✓	✓	✓	KPI

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metric Name	Description	Basic or Server Visibility	Windows	Linux	Solaris	AI X	Default Monitoring Mode ¹
Avg Utilization (%)	The average network utilization as a percentage of the maximum possible throughput. This metric is not reported if the agent cannot determine the throughput (not supported for some devices and Linux versions). The percentage is rounded to the nearest integer. Therefore, very low utilization may be reported as 0%. Reported for: <ul style="list-style-type: none"> • Servers • <group> • <network interface> 	Server Visibility	✓	✓	✓	✓	KPI
<network interface> Incoming KB	The volume of data received by the selected network interface.	Basic	✓	✓	✓	✓	Advanced
<network interface> Incoming KB/sec	The volume of data received per second by the selected network interface.	Basic	✓	✓	✓	✓	KPI
<network interface> Incoming packets	The number of data packets received by the selected network interface.	Basic	✓	✓	✓	✓	Advanced

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metric Name	Description	Basic or Server Visibility	Windows	Linux	Solaris	AIX	Default Monitoring Mode ¹
<network interface> Incoming packets/sec	The number of data packets received per second by the selected network interface.	Basic	✓	✓	✓	✓	Advanced
<network interface> Outgoing KB	The volume of data sent by the selected network interface.	Basic	✓	✓	✓	✓	Advanced
<network interface> Outgoing KB/sec	The volume of data sent per second by all monitored network interface.	Basic	✓	✓	✓	✓	KPI
<network interface> Outgoing packets	The number of data packets sent per second by the selected network interface.	Basic	✓	✓	✓	✓	Advanced
<network interface> Outgoing packets/sec	The number of data packets sent per second by the selected network interface.	Basic	✓	✓	✓	✓	Advanced
<network interface> Incoming Errors/min	The number of incoming packet errors the network incurs every minute.	Server Visibility	✓	✓	✓	✓	KPI
<network interface> Outgoing Errors/min	The number of outgoing packet errors the network incurs every minute.	Server Visibility	✓	✓	✓	✓	KPI

¹ See [Default Monitoring Mode](#).

² The ServerMonitoring and JavaHardwareMonitor extensions calculate unidirectional throughput (packet/KB) metrics differently. ServerMonitoring reports the total number of packets/bytes in the last minute. JavaHardwareMonitor reports the total number of packets/bytes from the time the Machine Agent started.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Process Metrics

The following metrics are aggregated and reported for each process or process class (except Total Process Count, which measures all processes observed by the agent). See [Machine Agent Settings for Server Visibility](#) to modify the default process monitoring.

Metric Name	Description	Basic or Server Visibility	Windows	Linux ¹	Solaris ²	AIX	Default Monitoring Mode ³
Count	The number of processes in this class consuming CPU or memory resources or the total number of processes in this class.	Server Visibility	✓	✓	✓	✓	Diagnostic
CPU Used (%)	Percentage of the CPU bandwidth used by all processes in a process class. A process using 100% CPU is executing on all processors on the system. If there are four cores on the machine and the process is executing four threads, each executing on one core, then the process can use up to 400% CPU. If there are four cores on the machine and the process is executing one thread on one core, then the process can use up to 25% CPU.	Server Visibility	✓	✓	✓	✓	KPI
Major Faults/sec	Number of major page faults caused by all processes in this class.	Server Visibility	✗	✓	✗	✓	Diagnostic
Minor Faults/sec	Number of minor page faults caused by all processes in this class.	Server Visibility	✗	✓	✗	✓	Diagnostic

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metric Name	Description	Basic or Server Visibility	Windows	Linux ¹	Solaris ²	AI X	Default Monitoring Mode ³
Memory Used (%)	Percentage of memory consumed by the top 10 consuming processes or the percentage of memory used by all processes in this class.	Server Visibility	✓	✓	✓	✓	KPI
Memory Used (KB)	Amount of memory used by all processes in this class.	Server Visibility	✓	✓	✓	✓	Advanced
Memory Virtual (KB)	Current size of the virtual address space that the process is using. Use of virtual address space does not necessarily imply a corresponding use of either disk or main memory pages. Virtual space is finite and, by using too much, the process can limit its ability to load libraries.	Server Visibility	✓	✓	✓	✓	Advanced
Thread Count	The number of kernel threads used by all processes in this class.	Server Visibility	✓	✓	✓	✓	Diagnostic

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Metric Name	Description	Basic or Server Visibility	Windows	Linux ¹	Solaris ²	AI X	Default Monitoring Mode ³
Total Process Count	<p>All individual processes observed by the Machine Agent, <i>before</i> it filters out unreported processes and groups the remaining processes into classes. You can use this metric to identify anomalies in the number of processes running on a specific machine. For example, if the average Total Process Count on a machine is usually 200 to 300, and then suddenly rises to 2000 or more, this could indicate a problem on that machine.</p> <p>To collect this metric, the Machine Agent captures the number of processes every 30 seconds and calculates the average number of processes per minute.</p> <ul style="list-style-type: none"> • Observed is the average number of processes per minute. • Min and Max are the 30-second buckets with the least and most processes. • Count and Sum are the number of process captures each minute and the sum of the processes in each capture for that minute (capture1 + capture2). 	Server Visibility	✓	✓	✓	✓	Diagnostic

¹ See [Linux Kernel Processes](#).

2 When collecting Process metrics on Solaris, the Machine Agent observes and captures only the first 80 characters of each process name and argument list. The agent considers only the first 80 characters of each process string when it applies allowlists ("always monitor this process") and blocklists ("never monitor this process") defined in [ServerMonitoring.yml](#).

3 See [Default Monitoring Mode](#).

Service Availability Metrics

Reported for each service that is configured.

Metric Name	Description	Basic or Server Visibility	Windows	Linux	Solaris	AI X	Default Monitoring Mode ¹
Response Time (ms)	The elapsed time between sending a request and receiving a response from the monitored service.	Server Visibility	✓	✓	✓	✓	KPI
Response Size (bytes)	The size of the response received from the monitored service.	Server Visibility	✓	✓	✓	✓	KPI
Success Rate (%)	The percentage of successful requests over all requests made to the service.	Server Visibility	✓	✓	✓	✓	KPI

¹ See [Default Monitoring Mode](#).

Enable Percentile Metric Reporting

You must enable percentile metric reporting on both the Controller and the Machine Agent. By default, reporting is *disabled* on the Controller and *enabled* on the Machine Agent.

- To enable/disable reporting on the Controller, log in to the Controller Administration Console and set the `sim.machines.percentile.percentileMonitoringAllowed` property. See [Controller Settings for Machine Agents](#).
- To enable/disable reporting on the agent, open the `<machine_agent_home>/extensions/ServerMonitoring/conf/ServerMonitoring.yml` file and set the `percentileEnabled` property. See [Machine Agent Settings for Server Visibility](#).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Configure Disk Usage Metric Collection on Linux

You can configure the Linux Machine Agent to calculate the following metrics similar to using the Linux `df` command:

- Servers > Volumes > /opt > Disk Usage
- Metric Browser > Disks and Partitions > <partition> > Space Available
- Metric Browser > Disks and Partitions > <partition> > Space Used

Linux includes a mechanism for reserving some disk space to ensure that the system remains functioning even if non-privileged users consume all other disk space. By default, these metrics do not include this reserved space. The total disk space reported by the agent might differ from the total disk space reported by the Linux `df` command or other sources.

To override this default, and to ensure that these metrics include this reserved space, run the agent with the following command-line argument:

```
-Dappdynamics.machine.agent.extensions.calcVolumeFreeAndUsedWithDfCommand=true
```

This feature is supported for Linux versions of the Machine Agent only.

Configure Free/Used Memory Metric Collection on Linux

You can configure how the Machine Agent calculates the amount of free and used memory on Linux machines. By default, the agent calculates any slab-reclaimable memory as used (not free) memory. To configure the agent to calculate slab-reclaimable memory as free (not used) memory, run Machine Agent with the following command-line argument:

```
-Dappdynamics.machine.agent.extensions.countSlabReclaimableAsFreeMem=true
```

This setting affects the following metrics:

- Memory Usage (in Server Dashboard)
- Memory Used %, Memory Used MB, Memory Free %, and Memory Free MB (in Metric Browser)

Viewing Server Visibility Metrics

You can only view Server Visibility metrics in the Server Visibility version of the Metric Browser. You see this when you access the Metric Browser from the Servers tab in the top navigation bar of the Controller UI.

Machine Agent Versus .NET Machine Agent

If a server has both Machine and .NET Agents installed, there may be differences in metric values reported by the Machine Agent and the .NET Agent due to different averaging rates and measurement methods. See [.NET Compatibility Mode](#).

Streamlined Browsing Mode

The Server Metric Browser includes a Streamlined Browsing option for node metrics. Use this option to browse metrics for tiers that contain multiple nodes.

- With Streamlined Browsing enabled, each node in the browser tree view shows only metrics reported by the Machine Agent on the corresponding node.
- With Streamlined Browsing enabled, the **Hardware Resources** and **Custom Metrics** folders do not display.
- With Streamlined Browsing disabled, each node in the browser tree view also shows metrics for other nodes in the same tier (with no indication of the node that corresponds to which tier group).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

This streamlining option is not enabled by default. AppDynamics recommends that you enable this option. To enable this option, go to:

`http://<controller host>:<port>/controller/`

`admin.jsp` and set `sim.metrics.metricBrowser.machineMetricMappings.enabled` to `true`.

Streamlined Browsing Enabled	Streamlined Browsing Disabled
	

Linux Kernel Processes

The Machine Agent has a `processSelectorRegex` setting that specifies the set of processes monitored by the agent. The default `regex` filters out most kernel processes on Linux machines. The agent considers monitored processes only when it calculates CPU, Memory, and Process metrics. These metrics may differ from metrics reported by other sources such as Linux commands.

Default Monitoring Mode

The **Default Monitoring Mode** column indicates the default category of each metric when **Dynamic Monitoring Mode (DMM)** is enabled. When this mode is enabled, a Machine Agent reports metrics based on the DMM setting on that server:

- **KPI** – Report Key Performance Indicator metrics only
- **Diagnostic** – Report KPI and Diagnostic metrics
- **Advanced** – Report all unfiltered metrics on the Machine Agent.

Load Average Percentages are Scaled by 100 in the Metric Browser

Load Average metrics are shown as float values (such as 0.70 or 1.05) in the [Server Dashboard](#). In the Metric Browser, these metrics are multiplied by 100 to provide two decimal points of precision. If a server has an average load of 7.67, for example, the Server Dashboard shows the Load Average as 7.67 and the Metric Browser shows the Load as 767. To use one of the metrics in a health rule or custom dashboard, divide the metric by 100.

Stolen Times are Reported Differently

On Windows Machine Agents, if CPU %Stolen is not matching values reported by AppDynamics, it may be because Windows Performance Monitor's (Perfmon) counters operate at a granularity of 100ns for CPU metrics. For CPU %Stolen, the counters are provided by the Hypervisor, which operates on a granularity of 1ms. Windows Perfmon divides the CPU %Stolen counter (operating on 1ms) directly by time (in units of 100ns), which results in the CPU %Stolen values being reported at a very low percentage (~0.01%).

AppDynamics makes the correction between different units of time, which is why values reported by AppDynamics are greater than Perfmon's values by a factor of 10,000 (time in 1ms * 10,000 = time in 100ns). CPU %Stolen values reported by AppDynamics sometimes exceed 100% under high load. These CPU %Stolen values are a result of multiple cores being used by the guest machine, where %Stolen time is added across multiple cores.

To compute the %Stolen time:

1. On a PowerShell terminal in the monitored guest machine, run `Get-WmiObject Win32_PerfRawData_vmGuestLib_VCPU`.
2. Note the CpuStolenMs counter (in ms).
3. Note the Timestamp_PerfTime counter (in ms, take a look at Frequency_Perftime, this value should be 1000 (in hz)).
4. After a minute, run `Get-WmiObject Win32_PerfRawData_vmGuestLib_VCPU` again and take note of both the counters once more.
5. $\text{CPU \%Stolen} = 100\% * (\text{CpuStolenMS (at T2)} - \text{CpuStolenMs (at T1)}) / (\text{Timestamp_PerfTime (T2)} - \text{Timestamp_PerfTime (T1)})$.

HardwareMonitor and JavaHardwareMonitor Calculate "Writes/Sec" Differently on AIX Machines

The Machine Agent calculates the Disk metric writes/sec on AIX machines differently, depending on whether the HardwareMonitor or the JavaHardwareMonitor extension is used. These extensions assume different block sizes when calculating these metrics. For HardwareMonitor, the block size is 4096 bytes. For JavaHardwareMonitor (based on SIGAR), the block size is 512 bytes. Because the number of writes/sec is calculated as $\text{<kb_written>/<block_size>}$, the HardwareMonitor results are lower than those calculated by JavaHardwareMonitor.

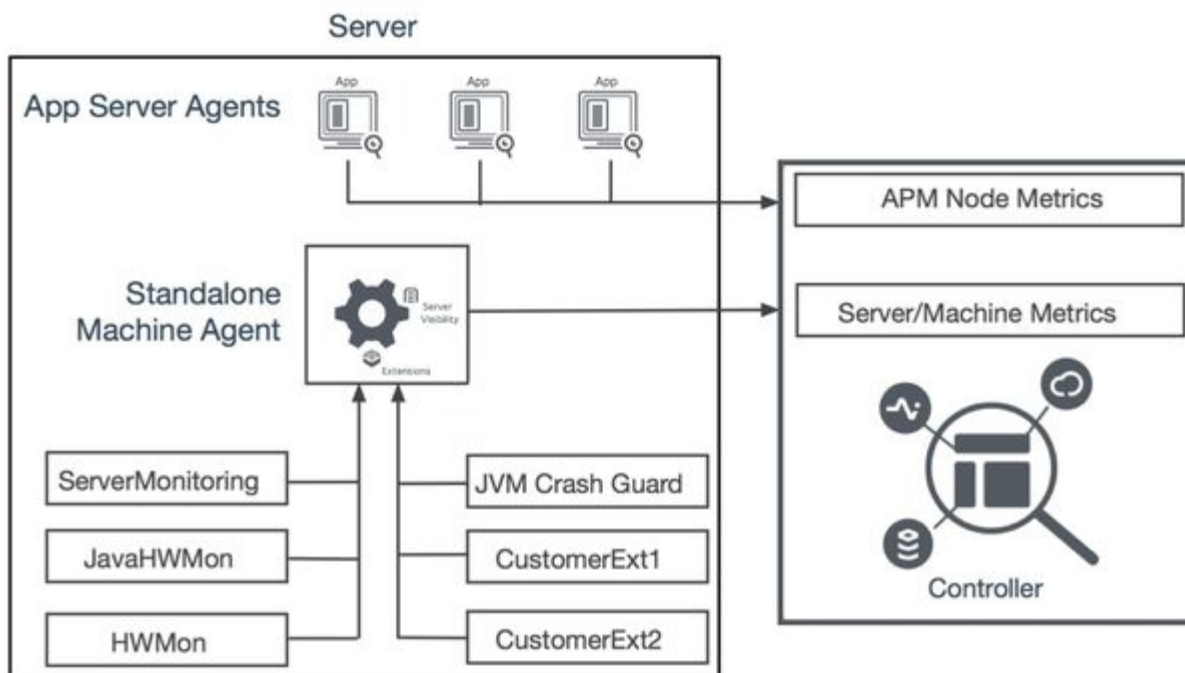

Machine Agent

You use the Machine Agent to collect basic hardware metrics. The Machine Agent is a Java program that has an extensible architecture enabling you to supplement the basic metrics reported in the AppDynamics Controller UI with your own custom metrics. The Machine Agent is also the delivery vehicle for AppDynamics [Server Visibility](#), which provides an expanded set of hardware metrics and additional monitoring capability. See [License Entitlements and Restrictions](#) for a complete list of licenses for Server Visibility and the Machine Agent.

Functionality provided by the Machine Agent includes:

- Reporting basic [hardware metrics](#) from the server's OS, for example, %CPU and memory utilization, disk and network I/O
- Reporting metrics passed to the Controller by [extensions](#)
- Running [remediation scripts](#) for policy actions
- Running [JVM Crash Guard](#)

The Machine Agent collects infrastructure metrics from multiple extensions and forwards them to the Controller. You can also use these metrics to find correlations between infrastructure issues on one or more servers and application-performance issues reported by the App Agents.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Machine Agent Requirements and Supported Environments

This page lists the application environments and versions supported by the Machine Agent. Any environments or versions that are not listed are not supported.

Machine Agent Supported Platforms

Supported platforms and environments for the Machine Agent depend on the metric data collection extension and the machine's OS. See [Machine Agent Metric Collection](#). Machine Agent $\geq 21.4.0$ collects `diskstats` from Linux kernels versions ≥ 4.18 .

The Azul JRE is included as a component in the AppDynamics products and modules. In response to how often Oracle produces and distributes JRE/JDK 8, AppDynamics replaced Oracle JRE with Azul JRE in the 20.5.0 Machine Agent.

JRE Requirements

The Machine Agent requires a Java Virtual Machine (JVM). Downloads for many of the supported operating systems include Azul JRE 1.8.0_262. The Machine Agent should work with most of the [JVMs supported by the Java Agent](#) JRE 1.8. However, it is extensively tested only for the Azul JRE.

- For tested platforms listed in the table, AppDynamics recommends using the latest available Machine Agent release from the [AppDynamics Downloads page](#).
- For Linux Flavors, the Machine Agent is bundled with Azul JRE 11. For Windows and Solaris, the Machine Agent is bundled with Azul JRE 1.8

If you upgrade the Linux Machine Agent to 21.1.0, then you must also upgrade all [extensions](#) to their latest versions to support Machine Agent 21.1.0.

- To run the Machine Agent on other platforms (such as AIX or HP-UX), use the unbundled Machine Agent ZIP without the JRE. For these platforms, you must install JRE 1.8 on the Machine Agent host.
- If you are using a 64-bit Operating System, use only a 64-bit JRE.

A 64-bit long has a maximum and minimum value of 9223372036854775807 and -9223372036854775808, respectively. To handle large values for metrics, run the Machine Agent using a 64-bit JDK.

JDK/JRE that is bundled with Machine Agent will work only if it meets the compatibility matrix requirements (JDK/JRE version, OS, architecture) listed here: [https://www.azul.com/downloads/?version=java-8-lts&os=rhel&architecture=x86-64-bit&package=jre](https://www Azul.com/downloads/?version=java-8-lts&os=rhel&architecture=x86-64-bit&package=jre)

If bundled JDK/JRE is not compatible with OS and architecture, then we suggest that you install the machine agent supported OS and architecture compatible JDK/JRE to run Machine Agent.

Bash Requirements

Linux and Solaris Machine Agents require Bash ≥ 3.1 .

Required Libraries

Linux systems must include the `procps` library.

This table provides instructions on how to install the library on some common flavors of Linux operating systems.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Linux Flavor	Command
Red Hat and CentOS	Use <code>yum</code> to install the library, such as: <code>yum install procps</code>
Fedora	Install the library <code>RPM</code> from the Fedora website: <code>yum install procps</code>
Ubuntu	Use <code>apt-get</code> , such as: <code>sudo apt-get install procps</code>
Debian	Use a package manager such as <code>APT</code> to install the library (as described in the previous Ubuntu instructions).
SUSE 12	Use <code>zypper</code> to install the library, such as: <code>zypper install procps</code>

Supported Environments

Tested Platforms

OS/Architecture	Architecture x64 (64-bit)	SPARC (64-bit)	POWER (64-bit)	Versions
AIX	No	No	Yes	7.1, 7.2
Linux / CentOS	Yes	No	No	6, 7
Linux / Debian	Yes	No	No	8, 9
Linux / Fedora	Yes	No	No	28, 29
Linux / openSUSE Leap	Yes	No	No	42.3, 15.0
Linux / Red Hat Enterprise Linux	Yes	No	No	6, 7, 8
Linux / SUSE Linux Enterprise	Yes	No	No	12, 15

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

OS/Architecture	Architecture x64 (64-bit)	SPARC (64-bit)	POWER (64-bit)	Versions
Linux / Ubuntu	Yes	No	No	14.04, 16.04, 18.04
Solaris	Yes	Yes	No	10, 11
Windows	Yes	No	No	2012 R2, 2016, 2019

Other Platforms

These other platforms (supported by JRE 1.8), should also be compatible with the Machine Agent. However, AppDynamics has not fully tested them.

- Oracle JRE 1.8
- IBM SDK, Java Technology Edition, Version 8
- HP JDK/JRE 8

The bundled version of the Machine Agent has been tested successfully on machines based on Power Architecture processors, including PowerPC processors. Server Visibility is only supported on AIX when using the unbundled Machine Agent ZIP without the JRE. When Server Visibility is required, AppDynamics recommends to use the unbundled Machine Agent version.

Hardware and Sizing Requirements

- Agent: One additional GB of RAM.
- Controller: Although we recommend that you install the AppDynamics Controller on a dedicated server, in some cases the Machine Agent can co-exist with the Controller on the same system. The exact number of Machine Agents that can be supported depends on whether other agents are reporting to the same Controller and whether the Machine Agents have Server Visibility enabled (more metrics are generated under Server Visibility). See [Controller System Requirements](#).

JVM Memory Requirements

The lightweight Machine Agent consumes minimal resources of your computer.

To accommodate the Machine Agent, AppDynamics recommends the following additional heap and PermGen space sizes:

- Maximum heap size (-Xmx): 256 MB
- Maximum PermGen heap size (-XX:MaxPermSize): 20 MB

By default, the JVM maximum heap size is set to 256 MB. To override this setting, you can set this flag through the `JAVA_OPTS` environment variable on your system. For example, if you enter: `export JAVA_OPTS="-Xms20m -Xmx128m "` on Linux, this sets the initial heap size to 20 MB and the max heap size to 128 MB.

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Extension Considerations

The exact CPU or memory overhead added by the agent can vary based on the extensions used and whether the extensions are Java. Java extensions require more heap space; the amount required depends on how you code the extension. If you start adding extensions, you should increase the maximum heap space to 256 MB or 512 MB. Additionally, you may need to increase the size of the initial memory allocation. Monitor the memory consumption of the agent to ensure that there are sufficient resources allocated to it. You can also enable Garbage Collection logging on the JVM to fine tune the heap size for the extensions.

These are example settings to increase the initial heap size:

- Linux and Unix systems: `<machine_agent_home>/bin/machine-agent -Xms64m`
- Windows: `cscript <machine_agent_home>\machine-agent.vbs -Xms64m`

Machine Agent Metric Collection

The Machine Agent collects hardware metrics using default extensions appropriate to specific operating systems. The following table lists the metric collection extension and its supported OS information. In some limited cases, you may want to change the default collection extension. The table also lists the most common reasons for changing the default extension.

Supported environments, observation rates, configurability, some metric names, and definitions depend on the extension.

OS	Default Metric Collection Extension	Metrics Collected	Reason to Change the Default Extension	Supported Environments
Microsoft Windows	JavaHardwareMonitor (if Server Visibility is disabled) ServerMonitoring (if Server Visibility is enabled)	Basic Metrics Server Visibility Metrics	To Customize Metrics for Virtual Disks and External Network Traffic The HardwareMonitoring extension is not recommended on Windows. See Monitoring Windows Guidelines	Machine Agent Requirements and Supported Environments
Linux	ServerMonitoring	Basic Metrics Server Visibility Metrics	To Machine Agent Metric Collection	Machine Agent Requirements and Supported Environments
Solaris / SunOS	HardwareMonitor (if Server Visibility is disabled) ServerMonitoring (if Server Visibility is enabled)	Basic Metrics Server Visibility Metrics	To Machine Agent Metric Collection	Machine Agent Requirements and Supported Environments

OS	Default Metric Collection Extension	Metrics Collected	Reason to Change the Default Extension	Supported Environments
AIX	JavaHardwareMonitor or	Basic Metrics	SIGAR (System Information Gatherer And Reporter) is not supported for your OS or Linux Distribution	SIGAR
HP-UX	Machine Agent Metric Collection	Basic Metrics	SIGAR is not supported for your OS or Linux Distribution	SIGAR
Mac OS X	Machine Agent Metric Collection	Basic Metrics	SIGAR is not supported for your OS or Linux Distribution	SIGAR
Solaris	HardwareMonitor (if Server Visibility is disabled) ServerMonitoring (if Server Visibility is enabled)	Basic Metrics Server Visibility Metrics	To Machine Agent Metric Collection	Machine Agent Requirements and Supported Environments

i In case of a time discrepancy issue on a server (not related to daylight savings time), where time is reset manually, the Machine Agent stops reporting. During this interruption, application and server data are not reported. To continue monitoring, you must restart the Machine Agent.

Java Hardware Monitor

The JavaHardwareMonitor is based on SIGAR (System Information Gatherer And Reporter). SIGAR is a legacy method of collecting basic hardware metrics and is used in pre-4.1 versions and for machines running operating systems that are not supported by the ServerMonitoring extension. The following sections list scenarios where you might want to change the extension used to collect the machine metrics.

Customize Metrics for Virtual Disks and External Network Traffic

By default, the Machine Agent reports metrics for network-mounted and local disks only. Additionally, only the external network traffic is aggregated (to ensure backward compatibility with previous versions of AppDynamics). For operating systems using the ServerMonitoring extension, you can change to the JavaHardwareMonitor to configure specific disks and network interfaces to be monitored. See [Configure](#)

[Metrics for Virtual Disks and External Network Traffic - JavaHardwareMonitor Extension Only](#) to customize the behavior of the JavaHardwareMonitor metrics

Metric Observation Rate

The JavaHardwareMonitor takes observations of metrics in two distinct ways:

- For disk and network metrics: One observation per minute. When you view the count for these metrics in the Metric Browser, you see the count of 1 per minute. If you select a 15-minute interval, the count would be 15 times 1 = 15 and so on.
- For CPU and memory metrics: One observation every two seconds. When you view the count for these metrics, you see the count of 30 per minute. If you select a 15-minute interval, the count would be 15 times 30 = 450 and so on.

Collect Basic Metrics Using JavaHardwareMonitor

Linux and Windows machines use the ServerMonitoring extension by default to report basic metrics. However if you have Server Visibility enabled, falling back to the JavaHardwareMonitor only affects the collection of the basic hardware metrics. The extended Server Visibility metrics are still collected correctly by the ServerMonitoring extension.

How to Change from ServerMonitoring to JavaHardwareMonitor

1. Stop the Machine Agent.
2. Disable basic ServerMonitoring:
 - a. Edit the `ServerMonitoring.yml` file from `<machine_agent_home>/extensions/ServerMonitoring/conf/`.
 - b. Change the value of `basicEnabled` to "false".

The `basicEnabled` setting controls whether the Machine Agent reports basic hardware metrics through the ServerMonitoring extension. Setting this to `false` enables the JavaHardwareMonitor to report the basic hardware metrics using the legacy SIGAR-based reporting.
 - c. Save the file.
3. Enable JavaHardwareMonitor:
 - a. Edit `monitor.xml` from `<machine_agent_home>/monitors/JavaHardwareMonitor/`.
 - For Linux, remove this line: `<enable-override os-type="linux">>false</enable-override>`.
 - For Windows, remove this line: `<enable-override os-type="windows">>false</enable-override>`.
 - b. Save the file.
4. Restart the Machine Agent.

Hardware Monitor

The HardwareMonitor extension is a collection of OS-specific scripts. SunOS and Solaris machines use this extension by default. For the operating systems that use the JavaHardwareMonitor by default, you may want to switch to an OS-specific monitor. You can switch to the OS-specific monitors when the JavaHardwareMonitor fails to report statistics and you see error logs similar to the following:

```
[Agent-Scheduler-1] 28 Nov 2013 13:13:55,435 ERROR
SigarMinuteTask - Error fetching network statistics for
interface [eth0:17]. Blacklisting it.
[Agent-Scheduler-1] 28 Nov 2013 13:13:55,435 ERROR
SigarMinuteTask - Error fetching disk i/o statistics for
interface [eth0:17]. Blacklisting it.
```

Collect Basic Hardware Metrics using HardwareMonitor

How to Change from JavaHardwareMonitor to an OS-Specific Monitor

1. Stop the Machine Agent.
2. Disable the JavaHardwareMonitor:
 - a. Locate and edit `monitor.xml` from `<machine_agent_home>/monitors/JavaHardwareMonitor/`.
 - b. Change the value `<enabled>true</enabled>` to `<enabled>>false</enabled>`.
 - c. Save the file.
3. Enable the HardwareMonitor for the OS you want to monitor:
 - a. Edit `monitor.xml` from `<machine_agent_home>/monitors/HardwareMonitor/`.
 - b. Change `<enabled>>false</enabled>` to `<enabled>>true</enabled>`.
 - c. Save the file.
4. Restart the machine agent.

Modify Free Memory Metric Configuration

If your Machine Agent installation is using an OS-specific HardwareMonitor for metric collection, then by default the agent reports free memory as the memory that is not used by any process nor in an I/O buffer or cache. It is more useful for the free memory metric to include memory that is in an I/O buffer or cache but can be available for new processes.

To include the memory in I/O buffers or cache that can be made available to new processes, modify the HardwareMonitor configuration:

1. Open `<machine_agent_home>/monitors/HardwareMonitor/config.sh`.
2. Set `REPORT_MEMORY_FREE_AS_MEMORY_AVAILABLE` to 1.
3. Restart the agent.

Monitoring Windows Guidelines

When using the Machine Agent on Windows:

- Check the server frequently to ensure that it has the latest Windows updates installed.
- If you have a Server Visibility license, use the ServerMonitoring extension.
- If you do not have a Server Visibility license, or if you want to collect Basic metrics only, use the JavaHardwareMonitor extension.
 - There is a known Windows issue when using the HardwareMonitor extension to collect metrics on Windows 8. As a result, AppDynamics does not recommend using the HardwareMonitor extension on Windows. You should use JavaHardwareMonitor instead.

Server Visibility on Windows

See [Server Visibility Requirements and Supported Environments](#).

Running the Machine Agent and .NET Agent on the Same Machine

To collect Machine or Server metrics on a machine with Machine and .NET Agents installed, you must enable .NET Compatibility Mode on both the Controller and the Machine Agent. See [.NET Compatibility Mode](#).

Configure Metrics for Virtual Disks and External Network Traffic - JavaHardwareMonitor Extension Only

By default, the Machine Agent reports metrics for network-mounted and local disks only. Additionally to ensure backward compatibility with previous versions of AppDynamics, only the external network traffic is aggregated.

You can customize the default behavior by modifying the auto-generated configuration file, `task-template.xml`. The `task-template.xml` file provides information about the current configuration of the Machine Agent and is created when you first start up the agent. It discovers the disks and network hardware on the machine where it is installed that the agent can monitor.

i This configuration applies to the JavaHardwareMonitor extension only. The ServerMonitoring extension is recommended if you have a Server Visibility license and the monitored system meets the system requirements. See [Server Visibility Requirements and Supported Environments](#)

Customize the Default Machine Agent Metric Collection

1. Locate the `task-template.xml` file.

This file is located in the `<machine_agent_home>/monitors/JavaHardwareMonitor/` directory when the Machine Agent starts the first time.

2. Edit the `task-template.xml` file:

- To enable aggregation operation for localhost (lo) network metrics, change the value of the aggregate attribute (for the network element "lo") to "true".
- To enable monitoring for a virtual disk, set the value of the enabled attribute to "true" for that disk.

The following is a sample `task-template.xml` file:

```
<config>
  <disk aggregate="false" enabled="false">sunrpc</disk>
  <disk aggregate="true" enabled="true">/dev/sdb1</disk>
  <disk aggregate="false" enabled="false">proc</disk>
  <disk aggregate="false" enabled="false">none</disk>
  <disk aggregate="false" enabled="false">devpts</disk>
  <disk aggregate="true" enabled="true">/dev/sda1</disk>
  <disk aggregate="false" enabled="false">nfsd</disk>
  <disk aggregate="true" enabled="true">/dev/mapper/saas4-binlog</disk>
  <disk aggregate="false" enabled="false">sysfs</disk>
  <disk aggregate="false" enabled="false">tmpfs</disk>

  <network aggregate="true" enabled="true">lo</network>
  <network aggregate="true" enabled="false">sit0</network>
  <network aggregate="true" enabled="true">eth0:1</network>
  <network aggregate="true" enabled="true">eth0</network>
  <network aggregate="true" enabled="false">eth1</network>
</config>
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

3. To prevent the Machine Agent from overwriting the file, rename the `task-template.xml` file to `task.xml` .

4. To monitor a special device that is not enabled, add a file named `task.xml` in the `<machine_agent_home>/monitors/JavaHardwareMonitor/` directory.

The format of the `task.xml` file must be exactly the same format as the `task-template.xml` file.

Not all disks and networks must be included in the `task.xml` file. If the Machine Agent finds a disk or a network that is not in the `task.xml` file, then it applies the default properties.

5. Restart the Machine Agent.

View Hardware Metrics

Without having to enable Server Visibility, you can view basic machine metrics in these locations:

- **Metric Browser** – Go to **Application Infrastructure Performance > Hardware Resources**.
- **Node** page > Server tab – Go to **Tiers & Nodes**, select the node of interest, and go to the Server tab.
- **Custom Dashboards** – To add CPU metrics to your Custom Dashboard, add the metrics for any node on your target machine. Metrics collected for a node associated with the machine agent are for the server hosting that node. Any machine metrics collected will be the same for nodes that are on the same machine.

Server Visibility provides additional metrics and pages to view basic and server metrics. See [Monitor Your Servers Using Server Visibility](#).

[Hardware Resources Metrics](#) describes metrics collected by the Machine Agent.

Customize Default Metrics

You can enable collection of metrics for [virtual disks and external network](#) traffic.

Add Custom Metrics

You can add [script-based](#) and [Java-based](#) custom monitoring extensions to collect additional metrics. For example, the [ehCache monitoring extension](#) available from [AppDynamics Exchange](#) can collect metrics to monitor Ehcache performance. The metrics appear in **Application Infrastructure Performance | Custom Metrics** section of the Metric Browser and which you can use on custom dashboards.

You can also send metrics to the Machine Agent using the [HTTP listener](#). See [Extensions and Custom Metrics](#).

Install the Machine Agent

This page provides requirements, permissions, and a procedure to install the Machine Agent.

To install Machine Agents in Kubernetes, see [Install Infrastructure Visibility with the Kubernetes CLI](#).

 Make sure to thoroughly test your deployment in a staging or test environment before deploying it to production.

JRE Requirements

- JRE 1.8 is required.
- The Machine Agent starts within its own JVM.
- You can use an existing JRE previously installed in your environment.

Permissions

- To avoid permission issues, install the agent as the same user who owns the Machine Agent files or as an administrator on the host machine.
- All files in the `<machine-agent-home>` installation directory should be readable by the Machine Agent.
- The user that runs the Machine Agent must have write privileges to the logging output directory and to the `/conf` directory in the agent installation directory.
- If you plan to enable the JVM Crash Guard, review the required permissions for [JVM Crash Guard](#).
- To create a non-root user to run the Machine Agent, see [Permissions Required to Run the Machine Agent](#).
- Windows permissions for files and subfolders are inherited by default from the parent folder (`<machine_agent_home>`). Appdynamics recommends that you restrict permissions to users authorized to start, stop, and configure the Machine Agent:
 - Read and Write permissions to all files and subfolders under `<machine-agent-home>` .
 - If running as a:
 - Terminal application, then restrict Read, Write, and Execute permissions for the file `<machine-agent-home>\bin\machine-agent.vbs` .
 - Service, then restrict Start, Stop, and Restart permissions for the Machine Agent service. You only need admin privileges to install the service. The Machine Agent runs under the local system account which has extensive privileges on the local system. However, if WMI access is revoked, then you must run the Machine Agent as Administrator. Typically, users do have WMI access. See [User Account Control and WMI](#).
- Enable Windows Script Host for the Windows Machine Agent.

Installation Directory and Path Name Requirements

The following table lists characters that are not supported for the `<machine-agent-home>` directory name or in any directory in the path:

Not Supported on any OS	Not Supported on Linux	Not Supported on Windows
Whitespace characters	% #	% # \ / : * ? " < >

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Not Supported on any OS	Not Supported on Linux	Not Supported on Windows
An exclamation point at the end of the directory name		Control characters such as ASCII EOL, CR, etc.

Configuration

The `controller-info.xml` file contains the properties used to specify agent to Controller communications. To specify the Controller host, port, and account access key properties, see [Plan the Machine Agent Configuration](#). Based on your installation requirements, you may need to configure additional properties.

Installation for New Machine Agent

The following steps are for *new* installations. To upgrade Machine Agent <= 4.3, see [Upgrade the Machine Agent](#).

1. [Plan the Machine Agent Configuration](#).
2. From [AppDynamics Downloads](#), download the Machine Agent installation package for your OS environment onto the machine you want to monitor.

i If there is no download bundle for your OS, use the Machine Agent zip file without the JRE, and use a separately downloaded JRE to run it. You need to download a separate JRE if the one already installed on the machine is a version earlier than JRE 1.8.

- [Install Using the Non-JRE Zip File](#) - Use this for OS environments other than Linux, Solaris, Windows, and Mac OS X.
- [Linux Install Using the RPM Package](#)
- [Linux Install Using ZIP with Bundled JRE](#)
- [Solaris Install Using ZIP with Bundled JRE](#)
- [Windows Install Using ZIP with Bundled JRE](#)

3. [Verify the Machine Agent Installation](#).
4. Start the Machine Agent by executing `<machine_agent_home>/bin/machine-agent`. If you have `java` or `system` properties, you can add them to the end of the command. To review machine usage, enter `machine-agent -h`.

Machine Agent Installation Scenarios

Related pages:

- [Plan the Machine Agent Configuration](#)
- [Where to Specify Machine Agent Configuration](#)
- [Machine Agent Configuration Properties](#)

This page describes scenarios for new Machine Agent installations.

APM Machine Agent Installation Scenario

This scenario contains a host server running one or more instrumented applications and one Machine Agent. When you install the Machine Agent on the same server with any app agent, do not specify the application name and tier name. The one Machine Agent reports the hardware metrics to each node where the app agent and the Machine Agent have matching host IDs.

If you plan to enable Server Visibility on a Windows server where a .NET APM agent is installed, you must enable .NET Compatibility Mode on both the Controller and the Machine Agent. See [.NET Compatibility Mode](#).

Licensing Note

>= 4.3 includes one Machine Agent license with each APM app agent. You can install this Machine Agent only on the same server with the app agent.

Independent Machine Agent Installation

This scenario contains a host server running only the Machine Agent without app agents. You do not need to specify an application or tier. You can view the Machine Agent metrics from the Servers list or the metric browser. This scenario requires a Server Visibility license.

Licensing Note

>= 4.3 requires a Server Visibility license for a Machine Agent installation.

If you are doing an Independent Machine Agent installation and you want the hardware metrics reported to nodes in an application, then you must configure the application name, tier name, and node name where you want the metrics to appear.

Using the values for the application name, tier name, and node where you want to see the metrics reported, configure these properties:

- Application name
- Tier name
- Node name
- `uniqueHostId` for both the Machine Agent and app agent (use the same value)

Unique Host ID Property

The `uniqueHostId` property is not required. However, if you do not define `uniqueHostId`, then the Machine Agent uses the Java API to retrieve the host ID. The results from the API can be inconsistent. The same JVM may return a different value for the same machine each time you restart the Machine Agent. As a workaround, AppDynamics recommends that you set the value of `uniqueHostId` to the host ID that you want to see in the UI. Use the same value for `uniqueHostId` for the App Agent.

Plan the Machine Agent Configuration

AppDynamics provides multiple ways to configure the Machine Agent. As part of planning your installation, determine which options work best in your environment:

- Controller-info.xml
- System properties
- Environment variables

See [Configure the Machine Agent](#).

Collect Configuration Information

Determine your configuration requirements and collect the necessary information. See [Machine Agent Configuration Properties](#).

Planning Item	Description
Determine your installation scenario	<p>For new installations, see Machine Agent Installation Scenarios.</p> <p>For upgrades, see Upgrade the Machine Agent.</p>
Location of the startup script	<p>You add startup arguments and system properties in the startup script.</p> <p>If you are using a Java service wrapper, you need to know the location of the wrapper configuration. See Where to Specify Machine Agent Configuration.</p>
Memory and CPU	<p>See Machine Agent Requirements and Supported Environments.</p>
Connecting the agent to the Controller	<p>You need to know the Controller host, Controller port, and account access key where you want your metrics to be reported. The account access key is generated at the Controller installation time and is located on the AppDynamics Administration Console.</p>
(Optional) SSL Communications	<p>If you plan to use SSL to communicate with the Controller, see Enable SSL for Machine Agent. SSL-related properties include:</p> <ul style="list-style-type: none"> • Controller SSL Enabled Property • Controller Keystore Password • Controller Keystore Filename • Force Default SSL Certificate Validation

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Planning Item	Description
Proxy Settings	If you plan to connect to the Controller using a proxy server, you need to know the Proxy host, Proxy port, and the path to the Proxy Password file.
Multi-tenant mode or SaaS Installations	In addition to the Account Access property, use the Account Name property to configure multi-tenant mode or SaaS account Information. This information is provided in the Welcome email from the AppDynamics Support Team. You can also locate this information in the <code><controller_home>/initial_account_access_info.txt</code> file.
Deploying from a common directory	See Deploy Multiple Machine Agents From a Common Directory .
Extension considerations	If you plan to use a number of extensions in your environment, see the "Extension Considerations" section in Machine Agent Requirements and Supported Environments .
Enabling Server Availability and Service Availability Monitoring	Server Availability requires a separate license. See Enable Server Visibility .

Install Using the Non-JRE Zip File

This page describes how to install the Machine Agent using the zip file that does not include the JRE. You can use this zip file if your environment already has Java ≥ 1.8 , or when installing on an OS environment that does not have an OS-specific installation package on the AppDynamics download site. The agent uses the JRE specified in the `$JAVA_HOME` environment variable or the default JRE for the server (enter `which java` in a terminal window).

i The following steps are for the Machine Agent with a bundled JRE. The standalone Machine Agent does not require these steps.

Install the Machine Agent

1. Before installing, review [Install the Machine Agent](#).
2. Download and unzip the ZIP file. Extract the contents to the agent installation directory, `<machine_agent_home>`.
3. Gather your configuration details and configure the agent by editing the `<machine_agent_home>/conf/controller-info.xml` file or by adding system properties to the JVM startup script file. See [Plan the Machine Agent Configuration](#).
 - a. *(Required)* Configure the Controller host name, port number, and account access key.
 - b. *(Required for Multi-Tenant Mode or SaaS installations)* Configure the Agent Account Information. See [Multi-Tenant Controller Accounts](#).
 - c. *(Optional)* Review memory requirements. See [Machine Agent Requirements and Supported Environments](#).
 - d. *(Optional)* Configure the agent to use SSL. See [Enable SSL for Machine Agent](#).
 - e. *(Optional)* Configure the agent to use proxy settings. See [Machine Agent Configuration Properties](#).
 - f. *(Optional)* For application and tier name, see [Machine Agent Installation Scenarios](#) to determine if you need to specify an application name and tier name. If you are installing the Machine Agent on the same server with any APM app agent, do not specify the application name and tier name.
4. Start the Agent:
 - Windows in a terminal window: `<machine_agent_home> \bin\machine-agent.vbs`
 - Linux or Unix-like: `<machine_agent_home> /bin/machine-agent`

Linux Install Using the RPM Package

Related pages:

- [Where to Specify Machine Agent Configuration](#)
- [Start and Stop the Machine Agent](#)

This page describes how to install the Machine Agent on Linux systems that support the [RPM Package Manager](#):

- CentOS
- RHEL
- Fedora
- openSUSE
- SUSE Linux Enterprise Server

For Linux systems that do not support RPM, use the [JRE Bundled Zip Archive](#).

The RPM installer makes these changes to the host machine:

- Creates an appdynamics-machine-agent group and an appdynamics-machine-agent user
- Assigns ownership of certain files in the machine-agent directory to the appdynamics-machine-agent user

These changes are necessary to enable non-root users to configure and run an RPM-installed agent. To use a different user or group for the machine agent service, set the MACHINE_AGENT_USER and MACHINE_AGENT_GROUP environment variables in a shell for RPM installation.

```
sudo MACHINE_AGENT_USER=myuser MACHINE_AGENT_GROUP=mygroup rpm -ivh appdynamics-machine-agent.rpm
```

If the specified user or group does not exist, an error message appears and the RPM installation stops. To continue, you must define users and groups.

If this is an issue in your environment, then you install the agent using the ZIP archive (see [Linux Install Using ZIP with Bundled JRE](#)).

Install the Machine Agent

1. Before installing, review [Install the Machine Agent](#).
2. Download and install the RPM Package. With administrative privileges, enter the following CLI code where <pkg-name.rpm> is the name of the package for your environment, such as `appdynamics-machine-agent-<version>.x86_64.rpm`.

```
sudo rpm -ivh <pkg-name.rpm>
```

The agent files are installed in `opt/appdynamics/machine-agent` and the agent is added as a service.

3. Gather your configuration details and configure the agent by editing <machine_agent_home>/conf/controller-info.xml file or by adding system properties to the JVM startup script file.
 - a. *(Required)* Configure the Controller host name, port number, and account access key.
 - b. *(Optional)* Review memory requirements. See [Machine Agent Requirements and Supported Environments](#).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

- c. (Optional) Configure the agent to use SSL. See [Enable SSL for Machine Agent](#).
- d. (Optional) Configure the agent to use proxy settings. See [Machine Agent Configuration Properties](#).
- e. (Required for Multi-Tenant Mode or SaaS installations) Configure the Agent Account Information. See [Multi-Tenant Controller Accounts](#).
- f. (Optional) Determine if you need to specify an application name and tier name. See [Machine Agent Installation Scenarios](#).

If you are installing the Machine Agent on the same server with any APM app agent, do not specify application name and tier name.

4. Start the Agent. You can start the agent as a service (requires sudo or root user) or from the command line. If `systemd` was detected during installation, you can use the `systemctl` command to start the agent service.
 - Using SysV – `service appdynamics-machine-agent start`
 - Using systemd – `systemctl start appdynamics-machine-agent`
 - From the Command Line – `<machine_agent_home> /bin/machine-agent`
 - From the Launcher – `<machine_agent_home> /etc/init.d/appdynamics-machine-agent start`

RPM Package Function

The RPM package manager installs the agent files to `opt/appdynamics/machine-agent`, creates symbolic links, sets environment variables, and adds the agent as a service.

Symbolic Links

The RPM package manager creates the symbolic links to agent scripts and configuration files in the `/etc` directory. You can edit these links to accommodate a different installation directory, JRE, or system user account running the agent.

Link for SysV Service Script

```
/etc/init.d/appdynamics-machine-agent >> /opt/appdynamics/machine-agent/etc/init.d/appdynamics-machine-agent
```

This script provides these service commands:

- `Start` – Starts the service, runs a script that starts the agent
- `Stop` – Stops the service
- `Restart` – Restarts the service
- `Status` – Returns the status of the service.

For example: `service appdynamics-machine-agent start`

Link for Environment Variables

SysV –

```
/etc/sysconfig/appdynamics-machine-agent >> /opt/appdynamics/machine-agent/etc/sysconfig/  
appdynamics-machine-agent
```

This script sets up the environment variables:

- `MACHINE_AGENT_HOME=/opt/appdynamics/machine-agent` – Specifies where the agent files are located.
- `JAVA_HOME=/opt/appdynamics/machine-agent/jre` – Specifies the JRE the agent uses. AppDynamics recommends that you use the RPM package installer that contains its own JRE. However, you can use a different JRE as long as it meets the [JRE requirements](#).
- `MACHINE_AGENT_USER=root` – Specifies the system user for starting the agent (default is root). AppDynamics recommends that you create a non-root user to run the machine agent. The new user needs to have read-access to `controller-info.xml` and write access to the log file. See [Permissions Required to Run the Machine Agent](#).

`systemd` – The environment variables are in the service file:

```
/etc/systemd/system/appdynamics-machine-agent.service >> /opt/appdynamics/machine-agent/etc/  
systemd/system/appdynamics-machine-agent.service
```

"MACHINE_AGENT_USER" variable doesn't exist in the `systemd` service file. The variable is just `User`.

Link for Agent to Controller Communication

Sets up a link to the `controller-info.xml` file containing the properties for agent-to-controller communication.

```
/etc/appdynamics/machine-agent/controller-info.xml >> /opt/appdynamics/machine-agent/conf/  
controller-info.xml
```

Logging Configuration

The `log4j.xml` file controls the detail of information logged by the agent. By default, the logging level is set to `info`.

```
/etc/appdynamics/machine-agent/logging/log4j.xml >> /opt/appdynamics/machine-agent/conf/  
logging/log4j.xml
```

Adds the Agent as a Service

After the package is installed, the `appdynamics-machine-agent` runs `opt/appdynamics/machine-agent/bin/postInstall.sh` to add the agent to the services. The installer either copies the `SysV` script to add

the service or, if `systemd` is detected, the installer copies the agent unit file `/etc/systemd/system/appdynamics-machine-agent.service` and adds the agent to the services using this unit file.

Installs a systemd Unit File for the Agent Service

If `systemcd` is detected on the system when you install the RPM package or run the `postinstall.sh` script, the `systemd` unit file for the agent service is copied to the following location: `/etc/systemd/system/appdynamics-machine-agent.service`

ExecStart: This option in the `systemd` service file points to a script that starts the agent as a daemon. If you did not install the Machine Agent in `/opt/appdynamics/machine-agent`, then change the path to `<machine-agent-home>/scripts/machine-agent-daemon`. If you did not edit the path, then it points to the correct place by default.

You can start and stop the agent service using the relevant `systemctl` commands. For information on all `systemctl` commands, see the [systemctl](#) man pages.

Command	Format
<code>start</code> <code>stop</code> <code>status</code> <code>restart</code>	<code>systemctl <command> appdynamics-machine-agent.service</code>
<code>disable</code> <code>enable</code> (Use the full path)	<code>systemctl <command> /etc/systemd/system/appdynamics-machine-agent.service</code>

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Linux Install Using ZIP with Bundled JRE

This page describes how to install the Machine Agent using the Linux ZIP archive that includes JRE 1.8. It is easier to download and use the RPM package if your Linux distribution supports the [RPM Package Manager](#).

Install the Agent

1. Before installing, see [Install the Machine Agent](#).

 Read/write privileges to the <machine-agent-home> installation directory are required.

2. Download and unzip the Agent zip bundle. From the command line, enter:

```
unzip <zip-bundle.zip> -d <machine_agent_home>
```

where <zip-bundle.zip> is the name of the zip archive for your environment and <agent_home> is the name of the directory where you want to install the agent.

3. Gather your configuration details and configure the agent by editing <machine_agent_home>/conf/controller-info.xml file or by adding system properties to the JVM startup script file. See [Linux Install Using ZIP with Bundled JRE](#).
 - a. *(Required)* Configure the Controller host name, port number, and account access key.
 - b. *(Optional)* Review memory requirements. See [Machine Agent Requirements and Supported Environments](#).
 - c. *(Optional)* Configure the agent to use SSL. See [Enable SSL for Machine Agent](#).
 - d. *(Optional)* Configure the agent to use proxy settings. See [Machine Agent Configuration Properties](#).
 - e. *(Required for Multi-Tenant Mode or SaaS installations)* Configure the Agent Account Information. See [Multi-Tenant Controller Accounts](#).
 - f. *(Optional)* Determine if you need to specify an application name and tier name. See [Linux Install Using ZIP with Bundled JRE](#).

If you are installing the Machine Agent on the same server with any APM app agent, do not specify application name and tier name.

4. To add the Machine Agent as a service, see [Add the Agent as a Service](#).
5. Start the Machine Agent by entering: `<machine_agent_home>/bin/machine-agent` . For example, from the <machine_agent_home> directory:

```
./bin/machine-agent
```

To review Machine Agent usage, enter: `machine-agent -h`

```
Usage: machine-agent [-dh] [-j JAVA_HOME] [-p pidfile] [-D prop] [-X prop]
Start the machine agent.
```

```
-d          daemonize (run in background)
-p pidfile  write PID to <pidfile>
-h
--help      print command line options
-D prop     set JAVA system property
-X prop     set non-standard JAVA system property
```

6. (Optional) Verify the installation. See [Verify the Machine Agent Installation](#).

Add the Agent as a Service Using SysV

1. Install the [Machine Agent](#).
2. Create a link to `/etc/sysconfig`:

```
ln -s <machine-agent-home>/etc/sysconfig/appdynamics-machine-agent /etc/sysconfig/
appdynamics-machine-agent
```

3. Copy the machine agent to `/etc/init.d`. For example:

```
cp <machine-agent-home>/etc/init.d/appdynamics-machine-agent /etc/init.d/appdynamics-machine-agent
```

4. Edit the environment variables in `/etc/sysconfig/appdynamics-machine-agent` configuration file:
 - `MACHINE_AGENT_HOME` – Specifies where the Machine Agent files are located.
 - `JAVA_HOME` – Specifies the JRE the agent uses. AppDynamics recommends that you use the Machine Agent bundled with the JRE. However, you can use an existing JRE. (1.8 or later).
 - `MACHINE_AGENT_USER` – Specifies the system user used to start the Machine Agent. By default this is root. AppDynamics recommends that you create a non-root user to run the Machine Agent. The new user needs to have read-access to `controller-info.xml` and write access to the log file. See [Permissions Required to Run the Machine Agent](#).
5. Add the agent as a service. For example, enter:

```
chkconfig --add appdynamics-machine-agent
```

For Ubuntu, you can use `update-rc.d` or `sysv-rc-conf`. See the [Ubuntu documentation](#) for details.

6. Start the agent service: `service appdynamics-machine-agent start`.
7. Verify that the Agent is reporting to the Controller. See [Linux Install Using ZIP with Bundled JRE](#).

Add the Agent as a Service Using systemd

1. Install the [Machine Agent](#).

2. Edit the environment variables and options in the service file as needed: `<machine-agent-home>/etc/systemd/system/appdynamics-machine-agent.service`
 - a. `MACHINE_AGENT_HOME` – Specifies where the Machine Agent files are located.
 - b. `JAVA_HOME` – Specifies the JRE the agent uses. AppDynamics recommends that you use the Machine Agent bundled with the JRE. However, you can use an existing JRE.
 - JRE `>= 1.7` for `= 4.3`
 - JRE `>= 1.8` for `>= 4.4`
 - c. `User` – This option in the service file specifies the system user to use to start the Machine Agent. By default this is root. AppDynamics recommends that you create a non-root user to run the Machine Agent. The new user needs to have read access to `controller-info.xml` and write access to the log files. See [Permissions for Non-Root User to Run the Machine Agent](#) .
The `systemd` service file does not include the "MACHINE_AGENT_USER" variable.

3. Copy the file:

```
cp <machine-agent-home>/etc/systemd/system/appdynamics-  
machine-agent.service \  
/etc/systemd/system/appdynamics-machine-agent.service
```

4. Enable the Machine Agent to start at system startup:

```
systemctl enable appdynamics-machine-agent
```

5. Start the agent service:

```
systemctl start appdynamics-machine-agent
```

6. Check the service status:

```
systemctl status appdynamics-machine-agent
```

7. Verify that the Agent is reporting to the Controller. See [Linux Install Using ZIP with Bundled JRE](#).

Solaris Install Using ZIP with Bundled JRE

This page describes how to install the Machine Agent on 64-bit Solaris using the ZIP archive that includes JRE 1.8.

i Adding the Machine Agent as a service is not supported on Solaris.

Install the Agent

1. Before installing, see [Install the Machine Agent](#).
2. The Machine Agent on Solaris is supported only when you install it in Global zones.
3. The Solaris agent requires that the `nawk` (new awk) utility is installed. Verify that the Solaris host has the `nawk` utility installed.
4. Download one of the two installation Machine Agent Bundles for Solaris from the AppDynamics Download Site:
 - For Sparc machines: Machine - Agent Bundle - 64-bit `solaris-sparcv9.zip`
 - For x86 machine: Machine Agent Bundle - 64-bit `Solaris.zip`
5. Unzip the agent Zip bundle:

```
unzip <zip-bundle.zip> -d <machine_agent_home>
```

where `<machine_agent_home>` is the install directory.

6. Gather your configuration details and configure the agent by editing `<machine_agent_home>/conf/controller-info.xml` file or by adding system properties to the JVM startup script file. See [Plan the Machine Agent Configuration](#).
 - a. *(Required)* Configure the Controller host name, port number, and account access key.
 - b. *(Required for Multi-Tenant Mode or SaaS installations)* Configure the Agent Account Information. See [Multi-Tenant Controller Accounts](#).
 - c. *(Optional)* Review memory requirements. See [Machine Agent Requirements and Supported Environments](#).
 - d. *(Optional)* Configure the agent to use SSL. See [Enable SSL for Machine Agent](#).
 - e. *(Optional)* Configure the agent to use proxy settings. See [Machine Agent Configuration Properties](#).
 - f. *(Optional)* Determine if you need to specify an application name and tier name.
However, if you are installing the Machine Agent on the same server with any APM app agent, do not specify the application name and tier name.
7. Start the agent from the command line:

```
% <machine_agent_home>/bin/machine-agent
```

8. Verify that the Agent is reporting to the Controller.

Windows Install Using ZIP with Bundled JRE

This page describes how to install Windows using ZIP with bundled JRE.

For some versions of Windows Server 2008 and Windows Vista, the Avg Read and Write Time disk metrics are reported as 0. This is due to a known Microsoft Windows bug. See [Microsoft Knowledge Base](#). If this affects you, download the available hotfix. This refers to the following metrics:

- Hardware Resources|Disks|<mount_point>|Avg Read Time (ms)
- Hardware Resources|Disks|<mount_point>|Avg Write Time (ms)

Install the Agent

1. Before installing, see [Install the Machine Agent](#).
2. Install all available Windows updates.
3. If you have not restarted your machine recently, you must restart it. Failure to do so may cause your machine to experience a CPU spike when you start the Machine Agent.
4. Download and unzip the Windows ZIP bundle. Extract the contents to the agent installation directory <machine_agent_home> .
5. Gather your configuration details and configure the agent by editing the <machine_agent_home>/conf/controller-info.xml file or by adding system properties to the JVM startup script file. See [Plan the Machine Agent Configuration](#).
 - a. *(Required)* Configure the Controller host name, port number, and account access key.
 - b. *(Required for Multi-Tenant Mode or SaaS installations)* Configure the Agent Account Information. See [Multi-Tenant Controller Accounts](#).
 - c. *(Optional)* Review memory requirements. See [Machine Agent Requirements and Supported Environments](#).
 - d. *(Optional)* Configure the agent to use SSL. See [Enable SSL for Machine Agent](#).
 - e. *(Optional)* Configure the agent to use proxy settings. See [Machine Agent Configuration Properties](#).
 - f. *(Optional)* Determine if you need to specify an application name and tier name. See [Windows Install Using ZIP with Bundled JRE](#).

However, if you are installing the Machine Agent on the same server with any APM app agent, do not specify the application name and tier name.

6. Start the agent. If no `-D` options are required on the command line, you can run the following `.vbs` scripts by selecting them from Windows Explorer.
 - a. As a Windows Service - Administrative privileges are required. You can specify AppDynamics-specific `-D` options from the command line or edit the controller-info.xml. You can also add other JVM properties as needed.
Open a terminal window and enter:

```
cscript <machine_agent_home>\InstallService.vbs <jvm_options>
```

You can now start or stop the AppDynamics Machine Agent service from Windows Services.

- b. From an application in the terminal window, enter:

```
cscript <machine_agent_home>\bin\machine-agent.vbs.
```

The usage parameters for `machine-agent.vbs` are:

Using machine-agent.vbs

```
> machine-agent.vbs -h
Usage: machine-agent.vbs[-h] [-j JAVA_HOME] [-Dprop1 ...] [-Xprop2 ...]
Start the machine agent.
    -h                print command line options
    -j JAVA_HOME      set java home for the agent
    -Dprop1           set standard system properties for the agent
    -Xprop2           set non-standard system properties for the agent
```

The following is an example of `machine-agent.vbs`:

```
> cscript machine-agent.vbs -Dappdynamics.controller.hostName=192.168.1.20
-Dappdynamics.controller.port=8090
```

Unquoted Service Path Enumeration Vulnerability

If you have installed Machine Agent primarily as a Windows service, you may encounter a security vulnerability known as Unquoted Service Path Enumeration Vulnerability.

Unquoted Service Path Enumeration Vulnerability occurs when the remote Windows host has at least one service installed that uses an unquoted service path, which contains at least one whitespace. A local attacker can gain elevated privileges by inserting an executable file in the path of the affected service.

To address this vulnerability, perform either of the following methods.

Method 1

1. Navigate to `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Services\Appdynamics Machine Agent`.
2. Change the `ImagePath` data value to enclose `C:\Program Files\AppDynamics\AppD_Infra_Monitoring\bin\MachineAgentService.exe` in double quotation marks.

Example:

```
"C:\Program Files\AppDynamics\AppD_Infra_Monitoring\bin\MachineAgentService.exe"
```

Method 2

1. Download the [Windows_Path_Enumerate.ps1](#) script and save it to a folder.
2. To list all vulnerabilities on the machine, open the powershell prompt and execute the following command:

```
<path containing downloaded Windows_Path_Enumerate.ps1>\Windows_Path_Enumerate.ps1  
-FixUninstall -FixEnv -WhatIf
```

3. Fix all vulnerabilities on the machine by executing the following command:

```
<path containing downloaded Windows_Path_Enumerate.ps1>\Windows_Path_Enumerate.ps1  
-FixUninstall -FixEnv
```

Deploy Multiple Machine Agents From a Common Directory

You can deploy the Machine Agent on multiple hosts from one central directory. This setup provides an easier method to update the agent because each agent instance starts from one set of executables in one central location.

Workflow Description

1. Set up the central agent directory:
 - a. Install the Machine Agent executables and config files in a central directory, such as an NFS-mounted shared directory.
 - b. Specify properties common to all remote agents in this central directory.
2. Configure each remote host to start an instance of the agent from this central directory:
 - a. Specify properties that are unique to the agent on that host, either in a startup script or on the command line.
 - b. Configure a startup script to start an instance of the Machine Agent from the central agent directory.

Set Up the Central Agent Directory

1. Download the latest Machine Agent ZIP file. See [Download AppDynamics Software](#).
2. Unzip the downloaded file to the desired root directory (`<central-agent-root-directory >`) on the central host.
3. Specify the properties common to all Machine Agent instances running on all remote hosts. Examples of common properties include the account name, and the Controller host and port. You specify these properties in `<central-agent-root-directory>/conf/controller-info.xml`.

Configure Each Remote Host to Start an Agent Instance

On each Machine Agent host, specify the properties unique to that agent such as: runtime directory, application name, tier name, and node name. To specify these properties, configure `-D` parameters in the startup script or on the command line. For example, the startup script on a remote host might include the following command:

```

<central_agent_root_directory>/bin/machine-agent
-Dappdynamics.agent.runtime.dir=<agent_runtime_dir>
-Dappdynamics.agent.applicationName=<application_name>
```

You should specify a unique runtime directory for each remote host to ensure that log files for each agent instance are saved to a separate directory. The agent log directory is located under the agent runtime directory, which you specify in the `-Dappdynamics.agent.runtime.dir` system property. The log directory is directly under the runtime directory (`<agent-runtime-dir>/logs`).

- Specify the runtime directory as an absolute path in the startup script on the remote host:

```
-Dappdynamics.agent.runtime.dir=<absolute_path_to_local_agent_runtime_directory>
```

- To change the log directory and file name from the default value, edit the file `<machine-agent-home>/confs/logging/log4.xml`. Change the value of the `"FileAppender" > "fileName"` and `"FileAppender" > "filePattern"` parameters to the desired directory and file name.
- The file-system permissions must allow creation of the log directory and file.

Verify the Machine Agent Installation

Related pages:

- [FAQs and Troubleshooting for the Machine Agent](#)
- [Machine Agent Configuration Properties](#)

Check Agent Logs

After a successful install, the agent log at `<machine_agent_home>/logs` , should contain the following message:

```
Started AppDynamics Machine Agent Successfully
```

If the agent log file is not present, the Machine Agent may not be accessing the command properties. To troubleshoot, check the application server log file where STDOUT is logged. It has the fallback log messages, which are useful for troubleshooting the agent.

Verify that the Agent is Reporting to the Controller

1. From the Controller Top Navigation Bar, select **Settings > AppDynamics Agents**.
2. Click the Machine Agents tab.
The listing for the Machine Agent displays. If you do not see the Machine Agent listed, check your property settings in `<machine_agent_home>/conf/controller-info.xml` . See [Resolve Machine Agent Installation Problems](#).

Machine Agent Not Reporting

If it seems that the Machine Agent is not reporting to the Controller, see [Machine Agent Not Reporting](#) article in the Community Knowledge Base.

Resolve Machine Agent Installation Problems

Related pages:

- [FAQs and Troubleshooting for the Machine Agent](#)
- [Machine Agent Configuration Properties](#)

Verify That the Agent Process is Running

Use the following command to verify that the agent process is running:

Linux:

```
ps -ef | grep machine
```

Windows:

1. Open a command line console.
2. Start the Task Manager and click the Processes tab.
3. The [agent process](#) should be running. If it is not running, stop and then restart the agent.

Resolve Agent Connectivity Problems

Make sure you have [configured](#) the Controller IP address, Controller port number, and Account Access Key in the agent startup command, script or plist, or in the controller-info.xml file.

After configuring, restart the agent and check the behavior. Machine Agent log files may also provide troubleshooting information.

If you start the Machine Agent, and it cannot register with the Controller or associate with the same node in the Controller, then the stack trace may indicate the reason.

For example, the following message in the stack trace may indicate that the application, tier, and node information was not provided during the Machine Agent startup command or in the controller-info.xml file.

```
<execution-output>System agent 239590 not associated with application, metric registration request refused.</execution-output>
```

Start and Stop the Machine Agent

This page contains a summary of the `start` and `stop` commands for the Machine Agent. See [Permissions Required to Run the Machine Agent](#).

i Running the Machine Agent with a Non-Bundled JRE

To run the Machine Agent with the default JRE on the machine (rather than the JRE bundled with the agent), you should first install a non-JRE version of the Machine Agent, and then run the non-JRE agent instead. See [Install Using the Non-JRE Zip File](#).

Start the Machine Agent

To start the Machine Agent with the bundled JRE, see [Install the Machine Agent](#).

To start the Machine Agent without the bundled JRE, specify the Java version and customize the `<path/to/java_location>` using the `-j` parameter and version JRE \geq 1.8. See [Machine Agent Requirements and Supported Environments](#) and [Install Using the Non-JRE Zip File](#). Make certain the path is valid and accessible for all users who start the Machine Agent.

```
<machine_agent_home>/bin/machine-agent -j <path/to/java_location>
```

For information on additional Java arguments, see:

- [Machine Agent Configuration Properties](#)
- [Metrics Limits](#)
- [Machine Agent HTTP Listener](#)

RPM-based Linux Systems

If you installed using the Linux RPM, start the Machine Agent:

- SysV systems: `service appdynamics-machine-agent start`
- systemd systems: Use the Machine Agent service launcher and enter: `systemctl start appdynamics-machine-agent`

Linux and Solaris Systems

If you installed using the JRE bundled zip archive for Linux and Solaris, run the launcher:

- Linux: `<machine_agent_home>/bin/machine-agent -d -p <machine_agent_home>/pidfile`
- Solaris: `<machine_agent_home>/bin/machine-agent -d -p <machine_agent_home>/pidfile`

Windows Systems

See [Windows Install Using ZIP with Bundled JRE](#).

Stop the Machine Agent

Non-JRE Bundled Zip Archive

If the Machine Agent process is running in the background, you can stop it by entering the `kill` command with the [process ID](#) as the argument. If it is running in the foreground in a console, press Ctrl+C to shut down the agent.

RPM-based Linux Systems

SysV: Use the service launcher:

```
% service /etc/init.d/appdynamics-machine-agent stop
```

systemd: Use the systemd unit file:

```
% systemctl stop appdynamics-machine-agent
```

Linux and Solaris Systems

Running in the Foreground: Press Ctrl+C to stop the agent process.

Running in the Background: Identify the process ID (PID) and use the `kill` command.

1. Identify the agent process: `ps -ef | grep machineagent`.
The output provides the process ID (PID) of the Machine Agent process.
2. Stop the agent process: `kill <machine_agent_PID>`.

Windows

In the foreground in a console window: Use Ctrl+C to shut down the agent.

As a Windows Service: Stop the service using either of these methods:

- In the Windows Services application, select **AppDynamics Machine Agent** and click **Stop**.
- Use the `MachineAgentService` command:

```
C:\> <machine_agent_home>\bin\MachineAgentService.exe /stop
```

Mac OS X

As a background process: Enter the `kill` command with the [process ID](#) as the argument.

As a service: From the bash command line:

```
> sudo launchctl unload -w <machine_agent_home>/com.appdynamics.machineagent.plist
```

Permissions Required to Run the Machine Agent

This page describes the permissions needed to run the Machine Agent. During installation, the default user for running the Machine Agent is set to root. This is because the only user that is standard on a UNIX or Linux system is root and we do not want to create users on your system. We recommend that you create a non-root user, for example `<machine_agent_user>`, and assign the appropriate permissions to that user. See [Install the Machine Agent](#).

For all environments, create a specific user with the necessary read/write/execute permissions.

- All files in the `<machine-agent-home>` installation directory should be readable by the Machine Agent.
- The user that runs the Machine Agent must have write privileges to the logging output directory and to the `/conf` directory in the agent installation directory.
- Additionally, the user that runs the Machine Agent needs execute access.

Important Notes

- You do not need to run the Machine Agent from a root or administrator account. However, if you enable the [JVM Crash Guard](#) on a monitored application running from a root or administrator account, then the Machine Agent requires root or administrator privileges to access the monitored application's JVM process and directory listings for crash files.
- You need to run with administrator or root privileges if you want to monitor networks or disks that are only available to the administrator or root user.
- The user that runs the Machine Agent must have write privileges to the `conf` and `logs` directories in the `<machine_agent_home>` directory.
- The Machine Agent implements a shutdown hook, so issuing the `kill` command (or Ctrl+C) from the operating system will cause the agent to perform a graceful shutdown.
- If the Machine Agent is not run by the root user or administrator user, the user that runs the Machine Agent should have permissions to execute the listed commands for the following environments. These commands are the source of metric collection.

AIX

- `awk`
- `cat`
- `cut`
- `date`
- `grep`
- `head`
- `ifconfig`
- `lparstat`
- `lsattr`
- `lsdev`
- `netstat`
- `ps`
- `svmon`
- `tail`
- `tr`

- `oslevel`
- `prtconf`
- `uname`
- `df`
- `iostat`
- `sed`
- `uptime`

Linux

- `awk`
- `basename`
- `cat`
- `df`
- `chroot`
- `date`
- `free`
- `getconf`
- `ip`
- `lsblk`
- `ps`
- `readlink`
- `sed`
- `tail`
- `tr`
- `uname`
- `uptime`
- `vmstat`

Windows

Windows permissions for files and subfolders are inherited by default from the parent folder (<machine_agent_home>). You should restrict permissions to users authorized to start, stop, and configure the Machine Agent:

- Read and Write permissions to all files and subfolders under <machine-agent-home>
- (If running as a terminal application) Read, Write, and Execute permissions for the file <machine-agent-home>\bin\machine-agent.vbs
- (If running as a service) Start, Stop, and Restart permissions for the Machine Agent service. You only need admin privileges to install the service. The Machine Agent runs under the local system account which has extensive privileges on the local system, so you do not need to run the Machine Agent as Administrator, unless WMI access is revoked. Normal users typically have WMI access. See <https://technet.microsoft.com/en-us/library/cc771551.aspx>.

Mac OS X, AIX, HP-UX, and Z/OS

There are no particular execute privileges required.

Solaris System Utilities

- `awk`
- `cat`
- `cut`
- `df`
- `dladm`
- `grep`
- `head`
- `ifconfig`
- `iostat`
- `isainfo`
- `kstat`
- `mpstat`
- `nawk`
- `netstat`
- `pagesize`
- `ps`
- `psrinfo`
- `sed`
- `swap`
- `tail`
- `tr`
- `uname`
- `uniq`
- `uptime`
- `vmstat`
- `wc`
- `zpool`

JVM Crash Guard

If you plan to enable JVM Crash Guard, see [JVM Crash Guard](#) for additional required permissions.

Configure the Machine Agent

Related pages:

- [Plan the Machine Agent Configuration](#)
- [.NET Compatibility Mode](#)

AppDynamics provides flexibility for configuring the Machine Agent so that you can choose the best fit for your deployment environment.

Not all options are available for all properties. See [Machine Agent Configuration Properties](#).

Configure the Machine Agent Properties

You can configure the Machine Agent by:

- Editing the `controller-info.xml` file located in the `<machine_agent_home>/conf` directory.
- Adding Agent system properties (`-D<system_property>`) to the Machine Agent start-up script or on the command line.
- Using environment variables. To configure the Agent with environment variables, set the value of the environment variable in the environment where the monitored application runs and restart the Agent. Environment variables exist for most of the Agent settings in the `controller-info.xml` file , but not all settings are configurable through environment variables. For those settings, you need to use system properties or `controller-info.xml` . See [Machine Agent Configuration Properties](#).

 Empty spaces and special characters are not allowed in either the full path to the Machine Agent home directory, or in the directory name itself. If the Machine Agent does not start up, review the path to determine if it contains empty spaces or special characters. For example, the path `/opt/appdynamics/ machine agent` is problematic, however, the path `/opt/appdynamics/ machine-agent` works correctly.

The JVM system properties and environment variables override the settings in the `controller-info.xml` file. The Agent applies the first non-empty value for a configuration property. The Machine Agent applies configurations using the following sources (in order).

1. Environment variables
2. System properties passed in the `start` command for the JVM
3. Global configuration file: `<machine-agent-home>/conf/controller-info.xml`

See [Where to Specify Machine Agent Configuration](#) for OS environment and install package details

Example Configuration

Machine Agent controller-info.xml File

```
<?xml version="1.0" encoding="UTF-8"?>
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

```
<controller-info>    <controller-host>your-controller-host</controller-host>
  <controller-port>your-controller-port</controller-port>
  <account-access-key>your-access-key<account-access-key>
  <controller-ssl-enabled>>true</controller-ssl-enabled>
  <enable-orchestration>>false</enable-orchestration>
  <sim-enabled>>false</sim-enabled>
  <unique-host-id>your-host-id</unique-host-id>
  <account-name>your-account-name</account-name>
</controller-info>
```

bash command-line Example

```
<machine_agent_home>/bin/machine-agent -Dappdynamics.controller.hostName=your-controller-host
-Dappdynamics.controller.port=your-controller-port -Dappdynamics.agent.accountAccessKey=your-
access-key -Dappdynamics.agent.uniqueHostId=your-host-id
-Dappdynamics.agent.accountName=your-account-name
```

Where to Specify Machine Agent Configuration

Related pages:

- [Install the Machine Agent](#)
- [Plan the Machine Agent Configuration](#)
- [Machine Agent Configuration Properties](#)

You configure Agent system properties in different ways based on your operating system and whether you are starting the Agent from the command line or as a service.

Linux As a Service

- SysV service launcher:
Specify the Agent system properties in the `<machine_agent_home>/etc/sysconfig/appdynamics-machine-agent` configuration file, and edit the `JAVA_OPTS` environment variable.
- systemd:
Specify the Agent system properties in the `<machine_agent_home>/etc/systemd/system/appdynamics-machine-agent.service` file, and edit the `JAVA_OPTS` environment variable.

Any UNIX-like System

When starting the Agent application on the command line for an UNIX-like system ((Linux, Solaris, Mac, AIX, and so on) using the `machine-agent` command, specify the agent system properties on the command line:

- Run agent in the background:

```
% nohup <machine_agent_home>/bin/machine-agent -D<system_property1>=<value1>  
-D<system_property2>=<value2> ... &
```
- Run agent in the foreground:

```
% <machine_agent_home>/bin/machine-agent -D<system_property1>=<value1>  
-D<system_property2>=<value2> ...
```

Windows

When installing and starting a Windows service (you need admin privileges), specify AppDynamics-specific `-D` options on the command line or in `controller-info.xml`.

Add other JVM properties on the command line:

```
<machine_agent_home> \cscript InstallService.vbs InstallService.cmd <jvm_options>
```

Mac OS X

Start the Agent service using the `<machine_agent_home>/osx-install.sh` script and specify the Agent system properties on the command line:

```
> sh <machine_agent_home>/osx-install.sh -D<system_property1>=<value1>  
-D<system_property2>=<value2> ...
```

When you run the `<machine_agent_home>/osx-install.sh` script, the `<machine_agent_home>/com.appdynamics.machineagent.plist.template` is updated with the installation directory and the java properties set for the Machine Agent.

Machine Agent Configuration Properties

This page describes the Agent configuration properties, including `controller-info.xml` elements, system property options (on the command line or in the startup script), and environment variables (where applicable). You configure Agent system properties based on your operating system and installation package.

The Agent updates dynamically in response to Agent configuration property changes, so you do not need to restart the Agent.

System Property Syntax

- System properties are case-sensitive
- Values that contain spaces must be enclosed with double-quotes

Reference

.NET Compatibility Mode

You must enable this mode if you want to collect and view Machine or Server metrics on a server with Machine and .NET Agents installed. See [.NET Compatibility Mode](#).

Element in controller-info.xml: `<dotnet-compatibility-mode>`

System Property:

`- Dappdynamics.machine.agent.dotnetCompatibilityMode`

Environment Variable: N/A

Type: boolean

Default: false

Required: This mode is required if you want to collect and view Machine or Server metrics on a server with Machine and .NET Agents installed.

Account Access Key

The account access key used to authenticate with the Controller. This key is generated during installation, and you can locate the key by reviewing the license information in the Controller Settings. See [Observe License Usage](#).

Element in controller-info.xml: `<account-access-key>`

System Property: `- Dappdynamics.agent.accountAccessKey`

Environment Variable: `APPDYNAMICS_AGENT_ACCOUNT_ACCESS_KEY`

Type: String

Default: None

Required: Prior to version 4.1, this property was required only for SaaS and multi-tenant Controllers. For versions 4.1 and later, the account access key property is required to authenticate all agent to Controller communications.

Example: - `Dappdynamics.agent.accountAccessKey=165e65645-95c1-40e3-9576-6a1424de9625`

Account Name

The account name used to authenticate with the Controller. If you are using the AppDynamics SaaS Controller, the Account Name is provided in the Welcome email sent by AppDynamics.

Element in controller-info.xml: `<account-name>`

System Property: - `Dappdynamics.agent.accountName`

Environment Variable: `APPDYNAMICS_AGENT_ACCOUNT_NAME`

Type: String

Default: None

Required: For AppDynamics SaaS Controller and multi-tenant users, but not for single-tenant mode (the default). When the Agent is registered with an AppDynamics SaaS Controller, features used to run [Remediation Scripts](#) are disabled. If you reconfigure the Agent `controller-info.xml` to register with a non-SaaS or on-premises Controller, the Agent can run local scripts as usual.

Agent Logging Directory

Deprecated. `appdynamics.agent.logs.dir` should be used instead. Behavior identical to Agent Logs Directory: `<appdynamics.agent.logs.dir>/logs/`.

System Property: - `Dappdynamics.agent.logging.dir`

Environment Variable: N/A

Type: String

Default: None

Required: No

Agent Logs Directory

Sets the logs directory for log files for nodes that use this agent installation. If this property is specified, all agent logs are written to `<appdynamics.agent.logs.dir>/logs`. See [Deploy Multiple Machine Agents From a Common Directory](#) when deploying multiple Machine Agents from a common directory. This property overrides the directory specified through the `appdynamics.agent.runtime.dir`. If `appdynamics.agent.logs.dir` property is not provided, the logs directory will be created on the same level as the Machine Agent installation folder. No changes are

expected in `log4j.xml` file.

System Property: - `Dappdynamics.agent.logs.dir`

Environment Variable: N/A

Type: String

Default: None

Required: No

Agent Runtime Directory

Sets the runtime directory for all runtime files (such as logs) for nodes that use this Agent installation. If you specify this property, then all Agent logs are written to `<agent-runtime-dir>/logs/node-name`. Use when deploying multiple Machine Agents from a common directory. See [Deploy Multiple Machine Agents From a Common Directory](#).

System Property: - `Dappdynamics.agent.runtime.dir`

Environment Variable: N/A

Type: String

Default: None

Required: No

Container Process Selector Blacklist Regex

Any container with a process matching this regex is ignored and is not registered in the Controller.

System Property: - `Dappdynamics.docker.container.process.selector.blacklist.regex`

Environment Variable: `APPDYNAMICS_DOCKER_CONTAINER_PROCESS_SELECTOR_BLACKLIST_REGEX`

Type: String

Default: None

Required: No

Controller Host

This is the host name or IP address of the AppDynamics Controller, for example: `192.168.1.22` or `myhost` or `myhost.abc.com`. This is the same host used to access the AppDynamics browser-based user interface.

Element in controller-info.xml: `<controller-host>`

System Property: - `Dappdynamics.controller.hostName`

Environment Variable: `APPDYNAMICS_CONTROLLER_HOST_NAME`

Type: String

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Default: None

Required: If the Enable Orchestration property is false.

If Enable Orchestration is true, and if the Agent is deployed in a compute cloud instance created by an AppDynamics workflow, do not set the Controller host unless you want to override the auto-detected value. See [Enable Orchestration Property](#).

Controller Keystore Filename

By default, the Agent looks for a Java truststore file named `cacerts.jks` in the `conf` directory in the Agent home. Use this property to enable full validation of Controller SSL certificates with a different Java truststore file. See [Machine Agent Configuration Properties](#).

Element in controller-info.xml: `<controller-keystore-filename>`

System Property: N/A

Environment Variable: N/A

Type: String

Default: None

Required: No

Controller Keystore Password

The plain text or encrypted value of the Controller certificate password. To encrypt or obfuscate passwords, see [Encrypt Agent Credentials](#).

Element in controller-info.xml: `<controller-keystore-password>`

System Property: N/A

Environment Variable: N/A

Type: String

Default: None

Required: No

Controller Port

The HTTP(S) port of the AppDynamics Controller. This is the same port that you use to access the AppDynamics browser-based user interface. If the Controller SSL Enabled property is set to true, specify the HTTPS port of the Controller; otherwise, specify the HTTP port. See [Controller SSL Enabled Property](#).

Element in controller-info.xml: `<controller-port>`

System Property: - `Dappdynamics.controller.port`

Environment Variable: `APPDYNAMICS_CONTROLLER_PORT`

Type: Positive Integer

On-premises Default: port 8090 for HTTP and port 8181 for HTTPS

SaaS Default: For the SaaS Controller Service, use port 443 for HTTPS connections.

Required: If the Enable Orchestration property is false.

If Enable Orchestration is true, and if the Agent is deployed in a compute cloud instance created by an AppDynamics workflow, do not set the Controller port unless you want to override the auto-detected value. See [Enable Orchestration Property](#).

Controller SSL Enabled

Specifies whether the Agent should use SSL (HTTPS) to connect to the Controller. If SSL Enabled is true, set the Controller Port property to the HTTPS port of the Controller. See [Controller Port Property](#).

Element in controller-info.xml: <controller-ssl-enabled>

System Property: - `Dappdynamics.controller.ssl.enabled`

Environment Variable: `APPDYNAMICS_CONTROLLER_SSL_ENABLED`

Type: Boolean

Default: false

Required: No

Create Node if Absent

Force the Machine Agent to create an APM node when the Agent registers with the Controller.

Element in controller-info.xml: <create-node-if-absent>

System Property: - `Dappdynamics.machine.agent.registration.createNodeIfAbsent`

Environment Variable: N/A

Type: Boolean

Default: true

Required: No. If you set the app/tier/node in your `controller-info.xml` file (existing upgrades or by accident), you can prevent the Machine Agent from creating APM nodes by setting this flag to false. See [Machine Agent Installation Scenarios](#).

Enable Docker Visibility

To enable [Docker Visibility](#) on the Agent, manually add the docker-enabled element in `controller-info.xml` setting, and set the flag to `true`.

Element in controller-info.xml: <docker-enabled>true</docker-enabled>

System Property: -`Dappdynamics.docker.enabled`

Environment Variable: `APPDYNAMICS_DOCKER_ENABLED`

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Type: Boolean

Default: false

Required: Yes

Enable HTTP Listener

When set to `true`, this property enables the Machine Agent HTTP listener. You can send metrics to the Machine Agent using its HTTP listener. You can report metrics through the Machine Agent by making HTTP calls to the Agent instead of piping to the Agent through `sysout`.

Element in controller-info.xml: N/A

System Property: - `Dmetric.http.listener`

Environment Variable: N/A

Type: Boolean

Default: false

Required: No

Enable Orchestration

Enables the Machine Agent workflow task execution when set to `true`. It also enables auto-detection of the Controller host and port when the app server is a compute cloud instance created by an AppDynamics orchestration workflow. In a cloud computing environment, auto-detection is necessary for the Create Machine tasks in the workflow to run correctly. The Machine Agent polls for task executions only when orchestration is enabled. If the host machine on which this Agent resides is not created through AppDynamics workflow orchestration, this property should be set to `false`. See [Controller Host Property](#) and [Controller Port Property](#).

Element in controller-info.xml: `<enable-orchestration>`

System Property: N/A

Environment Variable: N/A

Type: Boolean

Default: false

Required: No

Force Default SSL Certificate Validation

Used to override the default behavior for SSL validation.

This property has three states:

true: Forces the Agent to perform full validation of the certificate sent by the Controller, enabling the Agent to enforce the SSL trust chain. Use this setting when a public certificate authority(CA) signs your Controller SSL certificate.

false: Forces the Agent to perform minimal validation of the certificate. This property disables full validation of the Controller's SSL certificate. Use this setting when full validation of a SaaS certificate fails.

unspecified: The validation performed by the Agent depends on the context:

- If the Agent is connecting to a SaaS Controller, full validation is performed.
- If the Agent is connecting to an on-premises Controller and the `cacerts.jks` file is present, then full validation is performed using the `cacerts.jks` file.
- If the Agent is connecting to an on-premises Controller, and there is no `cacerts.jks` file, then minimal validation is performed

Element in controller-info.xml: N/A

System Property: - `Dappdynamics.force.default.ssl.certificate.validation`

Environment Variable: N/A

Type: Boolean

Default: None

Required: No

Enable Dynamic Monitoring Mode (DMM)

When this option is enabled, the Agent reports metrics based on the Dynamic Monitoring Mode specified for that Agent in the Controller. When this option is disabled, the Agent reports all metrics based on its local configuration; DMM settings on the Controller have no effect. Disabling DMM on an Agent is recommended only for mission-critical servers and other machines for which you are sure you want to collect all available metrics at all times. See [Dynamic Monitoring Mode and Server Visibility](#).

Element in controller-info.xml: `<dynamic-monitoring-enabled>`

System Property: `appdynamics.machine.agent.dynamicMonitoring.enabled`

Environment Variable: `APPDYNAMICS_DYNAMIC_MONITORING_ENABLED`

Type: Boolean

On-premises Default: True

SaaS Default: True

Required: No

HTTP Listener Port

To enable the Machine Agent HTTP listener, you must also specify the HTTP listener port.

Element in controller-info.xml: N/A

System Property: - `Dmetric.http.listener.port`

Environment Variable: N/A

Type: Numeric

Default: 8293

Required: Only if the HTTP listener is enabled.

Log4j

Logging functionality is done via Apache Log4j2. Use this property to provide a custom location for log4j configuration. In this case, you need to ensure that all file destinations are valid and contain absolute paths.

Element in controller-info.xml: N/A

System Property: - `Dlog4j.configurationFile`

Environment Variable: N/A

Type: Numeric

Default: None

Required: No

Machine Hierarchy

You need a Server Visibility license to use this feature.

This setting enables you to group servers together into arbitrary hierarchies by specifying a hierarchical path to the server. The server hierarchy displays in the Metric Browser and on the Server Dashboard. The server hierarchy is also used to select subgroups of machines for health rules. The last element of the path indicates the server name (a name of your choice). This name appears as the Name on the Servers list. If the path contains spaces, then you must it enclose it in double-quotes. See [Machine Agent Hierarchy](#).

Element in controller-info.xml: `<machine-path>`

System Property: - `Dappdynamics.machine.agent.hierarchyPath`

Environment Variable: `APPDYNAMICS_MACHINE_HIERARCHY_PATH`

Type: ASCII string with path elements that are separated by a "|" (bar).

Default: The value specified by [Unique Host ID](#). If the last part of the machine hierarchy is empty, the Unique Host ID is the machine name. For example, if machine hierarchy is "Data Center 1|Rack 2|" and Unique host ID is "Host ID 3", then the machine hierarchy will become "Data Center 1|Rack 2|Host ID 3".

Required: No

Limitation: The length of the characters composing the machine-path up to, but not including, the last pipe cannot exceed 95 characters.

Examples:

- *System Properties:* - `Dappdynamics.machine.agent.hierarchyPath= "Data Center 1|Rack 2|Machine3"`
- *controller-info.xml:*

```

<machine-path>
  "Data Center 1|Rack 2|Machine3"
</machine-path>
```

- *Environment Variable:* `APPDYNAMICS_MACHINE_HIERARCHY_PATH="Data Center 1|Rack 2|Machine3"`

Proxy Host

The proxy host name or IP address. The HTTP property works for both http and https proxy configuration. Proxy authentication cannot be used with SSL.

Element in controller-info.xml: N/A

System Property:

- `Dappdynamics .http.proxyHost`

Environment Variable: N/A

Type: String

Default: None

Required: If using a proxy to connect to the Controller; otherwise this is not required.

Proxy Password File

The absolute path to the file containing the password of the user that is authenticated by the proxy host. The password must be the first line of the file.

If `<use-encrypted-credentials>` is set to false, enter the password in plain text. If `<use-encrypted-credentials>` is set to true, encrypt the password. See [Encrypt Agent Credentials](#).

Element in controller-info.xml: N/A

System Property: - `Dappdynamics.http.proxyPasswordField`

Environment Variable: N/A

Type: String

Default: None

Required: No

Example: `-Dappdynamics.http.proxyPasswordField=/path/to/file-with-password`

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Proxy Port

The proxy HTTP(S) port. The proxy host name or IP address. The HTTP property works for both http and https proxy configuration. The default ports are 8090 (HTTP) and 443 (HTTPS).

Element in controller-info.xml: N/A

System Property:

- `Dappdynamics.http.proxyPort`

Environment Variable: N/A

Type: Positive Integer

Default: None

Required: Yes, if using a proxy to connect to the Controller. Otherwise, no.

Proxy User Name

The name of the user that is authenticated by the proxy host.

Element in controller-info.xml: N/A

System Property: - `Dappdynamics.http.proxyUser`

Environment Variable: N/A

Type: String

Default: None

Required: No

Server Visibility Enabled

Enable [Server Visibility](#) on the Agent. This requires a Server Visibility license.

Element in controller-info.xml: `<sim-enabled>`

System Property: - `Dappdynamics.sim.enabled`

Environment Variable: `APPDYNAMICS_SIM_ENABLED`

Type: Boolean

Default: false

Required: Required to enable Server Visibility. See [Enable Server Visibility](#).

Service Availability Update Interval

This setting controls the time, in milliseconds, to wait between sending Service Availability periodic events to the Controller. See [Service Availability](#).

Element in controller-info.xml: `<sam-event-update-interval-millis>`

System Property: - `Dappdynamics.machine.agent.sam.event.updateIntervalMillis`

Environment Variable: N/A

Type: Positive integer

Default: 300000 ms (5 minutes)

Required: No

Unique Host ID

This property logically partitions a single physical host or virtual machine. In the context of installing the Machine Agent, the unique Host ID property is not required. However, if you do not define a unique Host ID, then the Machine Agent uses the Java API to retrieve the host ID. The results from the API can be inconsistent, and may cause the same JVM to return a different value for the same machine, each time the Machine Agent is restarted. To avoid these issues, AppDynamics recommends that you set the value of unique Host ID to the host ID that you want to see in the UI.

Element in controller-info.xml: `<unique-host-id>`

System Property: - `Dappdynamics.agent.uniqueHostId`

Environment Variable: `APPDYNAMICS_AGENT_UNIQUE_HOST_ID`

Type: ASCII string without spaces and must be unique across the entire managed infrastructure.

Default: None

Required: Optional, but recommended.

Use Simple Hostname

By default (unless overridden with the `uniqueHostId` system property), the Agent determines the host name of the OS it is running in using reverse DNS lookup. In some circumstances, this host name may be set as the fully qualified domain name of the host name. If this property is set to `true`, the Agent removes any domain name and uses the simple hostname to identify the host. In cases where the host name is an IP address (which happens if the DNS lookup fails) then the full IP address in string form is used. The host name is used in mapping metrics gathered by the Machine Agent to application nodes. See [Unique Host ID Property](#).

Element in controller-info.xml: `<use-simple-hostname>`

Type: Boolean

Default: False

Required: No

For example: If this property is set to true ' `server.mydomain.com` ' becomes 'server'.

Independent Machine Agent Install Scenario

Typically, you only use the following properties if you are installing the Machine Agent on a server that does not have any AppDynamics App Agents installed.

Application Name

The name of the logical business application that this JVM node belongs to. This is not the deployment name (ear/war/jar) on the application server. If a business application of the configured name does not exist, it is created automatically.

Element in controller-info.xml: `<application-name>`

System Property: - `Dappdynamics.agent.applicationName`

Environment Variable: `APPDYNAMICS_AGENT_APPLICATION_NAME`

Type: String

Defaults: None

Required: No. See [Machine Agent Installation Scenarios](#).

Node Name

The name of the JVM node. When not specified, this defaults to `Node1` for the Machine Agent.

Element in controller-info.xml: `<node-name>`

System Property: - `Dappdynamics.agent.nodeName`

Environment Variable: `APPDYNAMICS_AGENT_NODE_NAME`

Type: String

Defaults: None

Required: No. See [Machine Agent Installation Scenarios](#).

Tier Name

The name of the logical tier that this JVM node belongs to. This is not the deployment name (ear/war/jar) on the application server. If a tier of the configured name does not exist, it is created automatically.

Element in controller-info.xml: `<tier-name>`

System Property: - `Dappdynamics.agent.tierName`

Environment Variable: `APPDYNAMICS_AGENT_TIER_NAME`

Type: String

Defaults: None

Required: No. See [Machine Agent Installation Scenarios](#).

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Controller Settings for Machine Agents

Related pages:

- [Database Size and Data Retention](#)
- [Controller Settings for Server Visibility](#)

This page describes Controller Admin settings that are specific to the Machine Agent. You need the root user password to change these settings.

You can change the amount of Machine Agent data you retain in the Controller database by changing the retention period for Machine Agent snapshots. Lowering the retention settings purges data that is aged out by the new retention setting and reduces the amount of data stored by the Controller on an ongoing basis. Consider the amount of Machine Agent data to retain when tuning the size of the Controller database.

Change the Controller Settings for Machine Agents

1. Log in to the Controller administration console using the root user password. See [Access the Administration Console](#).

```
http://<controller host>:<port>/controller/admin.jsp
```

Use the root user password to access the Admin console when the Controller is installed in single- or multi-tenant mode. See [Update the Root User and Glassfish Admin Passwords](#).

2. Select **Controller Settings**.
3. Change the settings as needed, and then select **Save**. Changes to the settings occur the next time you restart the Agent and it connects to the Controller.

Controller Settings Reference for Machine Agent

Property Name	Property Description	Default	Allowed Values
machine.agent.in-progress.actions.timeout	This property determines the length of time the Controller waits for the Agent to perform an IN-PROGRESS action before it stops the action.	864000ms (1 day)	1 to 840 hours (5 weeks)

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Property Name	Property Description	Default	Allowed Values
<code>machine.agent.max.new.actions.per.min</code>	Maximum number of new actions dispatched per minute for each Machine Agent. This is the maximum number of "runbook" actions sent to the Machine Agent. For example, you may request the Machine Agent to run a script because of a health rule violation, if the number of requests in a one minute period is greater than the preset value, then the action is executed the next minute.	15 per minute	1 to 289999
<code>machine.agent.pending.actions.timeout</code>	Determines how long the Controller waits for the Agent to perform a PENDING action before it stops the action.	180000 ms (12 hrs)	
<code>machine.agent.snapshots.buffer.size</code>	Size in Megabytes of the in-memory buffer storing machine snapshots uploaded from Agents prior to database flush.	50 MB	
<code>machine.snapshots.retention.period</code>	Time in hours to retain server snapshot data.	336 hours (2 weeks)	1 to 840 hours (5 weeks)

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Enable SSL for Machine Agent

Related pages:

- [Secure the Platform](#)
- [Controller SSL and Certificates](#)
- [Install the Machine Agent](#)

This page describes how to configure the AppDynamics Machine Agent to connect to the Controller using SSL. It assumes that you use a SaaS Controller or have configured the on-premises Controller to use SSL.

The Machine Agent supports extending and enforcing the SSL trust chain when in SSL mode.

Plan SSL Configuration

Gather this information:

- The Controller SSL port:
 - For SaaS Controllers: SSL port is 443
 - For on-premises Controllers: Default SSL port is 8181, but you may configure the Controller to listen for SSL on another port
- The signature method for the Controller's SSL certificate:
 - A publicly known certificate authority (CA) signed the certificate. This applies for DigiCert, Verisign, Thawte, and other commercial CAs.
 - A CA internal to your organization signed the certificate. Some companies maintain internal certificate authorities to manage trust and encryption within their domain.
 - The Controller uses a self-signed certificate.

Establish Trust for the Controller's SSL Certificate

To establish trust between the Machine Agent and the AppDynamics Controller, you must create an agent truststore that contains the root certificate for the authority that signed the Controller's certificate.

1. Obtain one of the following root certificates:
 - DigiCert Global Root CA for the AppDynamics SaaS Controller
 - The root certificate for the publicly known certificate authority (CA) that signed the certificate for your on-premises Controller
 - The root certificate for the internal CA that signed the Controller certificate for your on-premises Controller
2. Run the Java `keytool` command to create the Agent truststore:

```
keytool -import -alias rootCA -file  
<root_certificate_file_name> -keystore cacerts.jks -storepass  
<truststore_password>
```

For example:

```
keytool -import -alias rootCA -file /usr/home/appdynamics/  
DigicertGlobalRootCA.pem -keystore cacerts.jks -storepass  
MySecurePassword
```

 Note the truststore password; you will need this later to configure the Machine Agent.

3. Install the Agent truststore to the Agent configuration directory:

```
<machine_agent_home>/conf/
```

Secure the Machine Agent Truststore

AppDynamics recommends you take the following security measures to prevent tampering with the Machine Agent truststore:

- Secure the truststore file through filesystem permissions:
 - Make the Agent truststore readable by any user
 - Make the truststore owned by a privileged user
 - Make the truststore writable only by the specified privileged user
- Secure the `controller-info` configuration file so that it is only readable by the Agent runtime user and only writable by a privileged user:

```
<machine_agent_home>/conf/controller-info.xml
```

Enable SSL for the Machine Agent

1. Configure the following system properties in the `controller-info.xml`: `<machine_agent_home>/conf/controller-info.xml`. See [Machine Agent Configuration Properties](#) for full details on each property.

- **Controller Host:** Should be the same as either the Common Name or the Subject Alternative Name (SAN) in the certificate configured for the Controller.

```
<controller-host>common_name_in_certificate.com</controller-host>
```
- **Controller Port:** The SSL port for the Controller. It is 443 for AppDynamics SaaS.

```
<controller-port>443</controller-port>
```
- **Controller SSL Enabled:** true

```
<controller-ssl-enabled>>true</controller-ssl-enabled>
```
- **Controller SSL Password:** The plain text password for the Agent truststore.

```
<controller-keystore-password>MySecurePassword</controller-keystore-password>
```

 If you have enabled the Secure Credential Store, encrypt the password you enter here. See [Encrypt Agent Credentials](#).
- **Controller Keystore Filename:** The path of the Agent truststore relative to `<machine_agent_home>/conf`. This is required if you use a truststore other than the default `<machine_agent_home>/conf/cacerts.jks`.

```
<controller-keystore-filename>../conf/cacerts.jks</controller-keystore-filename>
```

 You can specify the Controller port and enable SSL for the Controller in the Machine Agent startup script, but you must specify the truststore password and filename in the `controller-info.xml` file.

 In JDK >= 9 (either JRE bundled with Machine Agent or a standalone JDK/JRE), the default keystore type in the `java.security` file has been changed from JKS to PKCS12.

If a JKS truststore is used and the `<controller-keystore-password>` is not provided, the agent will use the JKS truststore. If a PKCS12 truststore is used and the `<controller-keystore-password>` is not provided, the agent will not use the PKCS12 truststore.

If you are using a PKCS12 truststore, AppDynamics recommends that that you provide the `<controller-keystore-password>` . If you still want to work with a JKS-based truststore, you can convert a PKCS12 truststore to JKS format.

2. Restart the Machine Agent.

Sample controller-info.xml with SSL and Secure Credential Store Encryption Enabled

```
<?xml version="1.0" encoding="UTF-8"?>
<controller-info>
  <controller-host>mycompany.saas.appdynamics.com</controller-host>
  <controller-port>443</controller-port>
  <controller-ssl-enabled>true</controller-ssl-enabled>
  <!-- Encrypted Controller keystore / agent trust store password -->
  <controller-keystore-password>Tw49bd0hdCMB0Q5pfMMuYA/cA5B4pouVPkv48ovRm6c=</controller-keystore-password>
  <controller-keystore-filename>../../conf/cacerts.jks</controller-keystore-filename>
  ...
  <!-- Secure Credential Store configuration -->
  <!-- Enable the Secure Credential Store -->
  <use-encrypted-credentials>true</use-encrypted-credentials>
  <!-- Path to they secure credential keystore -->
  <credential-store-filename>/opt/appdynamics/secretKeyStore</credential-store-filename>
  <!-- Obfuscated secure credential keystore password -->
  <credential-store-password>n/8GvAZsKk4gM3Z6g+XQ1w==</credential-store-password>
</controller-info>
```

Keystore Certificate Extractor Utility

The Keystore Certificate Extractor Utility exports certificates from the Controller's Java keystore and writes them to an Agent truststore. You can run this utility with the Agent distribution on the Controller:

```
<controller_home>/appserver/glassfish/domains/domain1/appagent
```

1. Execute `kr.jar` and include the following parameters:

- The full path to the Controller's keystore:

```
<controller_home>/appserver/glassfish/domains/domain1/config/keystore.jks
```

- The truststore output file name. By default, the Machine Agent looks for `cacerts.jks` .
- The password for the Controller's certificate, which defaults to "changeit". If you do not include a password, the extractor applies the password "changeit" to the output truststore.

```
java -jar kr.jar <controller_home>/appserver/glassfish/domains/domain1/config/  
keystore.jks cacerts.jks <controller_certificate_password>
```

2. Install the Agent trust store to the Agent configuration directory:

```
<machine_agent_home>/conf/
```

.NET Compatibility Mode

This page explains how to set compatibility mode for the .NET Agent. Compatibility mode allows you to collect and view machine or server metrics on a server with Machine and .NET Agents installed.

Before You Begin

Review the list of requirements and general information about compatibility mode:

- .NET Compatibility Mode is required for metrics from a Machine Agent and a .NET Agent on the same server to be visibly associated with the same node in the Controller UI.
- Differences may exist between metric values reported by the Machine Agent and the .NET Agent due to different averaging rates and measurement methods.
- You must enable .NET Compatibility Mode on the Machine Agent.
- When .NET Compatibility Mode is enabled:
 - Events from Service Availability and Custom Extensions appear in the Servers tab, but are not associated with .NET applications in the Controller UI.
 - The Controller UI may show the server name with " -java-MA " appended to the host ID. Thus, a Machine Agent with a `<unique-host-id>` set to " ABC " might appear as " ABC-java-MA " in the Controller UI. This is expected behavior; the " -java-MA " suffix indicates that the host has a Machine Agent running in .NET Compatibility Mode.
- Do not specify the `<application-name>`, `<tier-name>`, or `<node-name>` properties on the Machine Agent. These properties are used with a Machine Agent on a host that has no other AppDynamics Agents installed.

Enable Compatibility Mode

To enable .NET Compatibility Mode:

1. Enable .NET Compatibility Mode on the Agent using one of two methods:
 - Set these options in `<machine_agent_home>/conf/controller-info.xml` :
 - i. `<dotnet-compatibility-mode> true </dotnet-compatibility-mode>`
 You may need to add this line to the `controller-info.xml` file.
 - ii. `<unique-host-id> <unique-host-id-of-dot-net-agent> </unique-host-id>`
 For both Agents to report metrics to the same node, the Machine Agent must use the same case-sensitive Unique Host ID used by the .NET Agent. See [FAQs and Troubleshooting](#).
 - Set the `./bin/machine-agent` system property to: `./bin/machine-agent -Dappdynamics.machine.agent.dotnetCompatibilityMode=true`
2. Save the `controller-info.xml` file.
3. Start or restart the Machine Agent to apply the changes.

Extensions and Custom Metrics

Using the Machine Agent, you can supplement the existing metrics in the AppDynamics Controller UI with your own custom metrics. There are many extensions currently available on the [AppSphere Community](#) site. Some are created by AppDynamics and some have been created by users.

Similar to built-in metrics, your custom metrics are subject to the following AppDynamics features:

- Automatic baselines and anomaly detection
- Availability to display on custom dashboards
- Availability to use in policies
- Visibility of all metrics in the Metric Browser and on the Infrastructure tab (where you can display external metrics and AppDynamics metrics on the same graph)

i The first reported metric value is visible in the **Server Visibility** metric browser, but not in the **Application Performance Monitoring** metric browser. This is an expected behavior designed to optimize metric reporting and prevent memory overhead.

Add New Custom Metrics

To create custom metrics, you create a monitoring extension. In your extension, you define the name and path of your metric (where it appears in the metric browser tree), what type of metric it is (sum, average, and so on), and how the data for the metric should be rolled up as it ages. Any custom metric reported to the Controller through any mode must be reported at least once every 300 seconds (five minutes). One Agent can run many extensions, although you may need to increase the amount of [memory for the JVM](#) Agent. You can have multiple copies of the same extension if they are in different directories.

A custom metric can be common across nodes or associated with a specific tier. When you create a metric, you specify the path in which it will appear in the metric tree. To create a common custom metric, use the root tree path Custom Metrics in your metric declaration. To create a tier-specific metric, specify the metric path associated with that component.

If your application uses a large number of AppDynamics extensions with the Machine Agent, you may need to increase the size of the memory allocation:

For Linux and Unix-like Systems

```
% <machine_agent_home>/bin/machine-agent -Xms64m
```

For Windows

```
> <machine_agent_home>\bin\machine-agent.cmd -Xms64m
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

 The wildcard feature is not supported for custom metrics.

Monitoring Extension Types

You can implement custom metrics using these mechanisms:

- Using a script:
You can write a shell script (Linux and Unix-like systems) or batch file (Windows) to report custom metrics every minute to the Machine Agent. The Machine Agent passes these metrics on to the Controller. See [Build a Monitoring Extension Using Scripts](#).
- Using Java:
Your custom metrics may be too complicated to collect using a script. For example, you may need to perform complex calculations or call a third-party API to retrieve the metrics. In this case, you can extend the `JavaServersMonitor` class to collect the metrics and report them to the Machine Agent. Your Java program extends the `JavaServersMonitor` class to provide your custom functionality. See [Build a Monitoring Extension Using Java](#).
- Using HTTP:
If you enable the Agent HTTP listener, you can post HTTP requests to the Machine Agent to send it custom metrics every minute. To do this, start the Machine Agent with a Jetty HTTP listener. See [Machine Agent HTTP Listener](#).

Build a Monitoring Extension Using Scripts

Related pages:

- [Extensions and Custom Metrics](#)
- [Build a Monitoring Extension Using Java](#)
- [Machine Agent HTTP Listener](#)

You can write a monitoring extension script (also known as a custom monitor or hardware monitor) to add custom metrics to the metric set that AppDynamics already collects and reports to the Controller. Your script reports the custom metrics every minute to the Machine Agent. The Machine Agent passes these metrics to the Controller.

This page describes the steps for adding custom metrics using a shell script and includes an example.

Review Existing Extensions

Before creating your own extension, review the extensions that have been created and shared among members of the AppDynamics community. New extensions are added continuously. It is possible that someone has already created what you need or something close enough that you can download and use it after making a few modifications.

See the [AppDynamics Exchange](#) for free downloads.

Agent Configuration Requirements

Confirm that you have correctly configured the Machine Agent in the `controller-info.xml` file and on the Agent `start` command on the command line. See [Machine Agent Configuration Properties](#).

Create a Monitoring Extension

To create a monitoring extension using a script:

1. Create your script. See [Create the Script File](#).
2. Create a `monitor.xml` configuration file. See [Create the monitor.xml File](#).
3. Create a subdirectory, `<your_extension_dir>`, in `<machine_agent_home>/monitors`. See [Create a directory under the Machine Agent monitors directory](#).
4. Copy your script file and the `monitor.xml` file into the new subdirectory.
5. Restart the Machine Agent.

Define Your Metrics

Metric names must be unique within the same metric path but need not be unique for the entire metric hierarchy. AppDynamics recommends using short metric names so that the whole name is visible when displayed in the Metric Browser. Prepend the metric path to the metric name when you upload the metrics to the Controller.

Metric Processing Qualifiers

The Controller has various qualifiers for how it processes a metric regarding aggregation, time rollup, and tier rollup. There are three types of metric qualifiers:

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

1. Aggregator qualifier
2. Time roll-up qualifier
3. Cluster roll-up qualifier

In the script, specify the metric qualifiers after the name-value pair for the metric. A typical metric entry in the script file has the following structure:

```
name=<metric name>,value=<long value>,aggregator=<aggregator
type>, time-rollup=<time-rollup strategy>, cluster-
rollup=<cluster-rollup strategy>
```

Aggregator Qualifier

The *aggregator* qualifier specifies how the Machine Agent aggregates the values reported during a one-minute period. Specify the aggregator qualifier as `aggregator="aggregator type"`. This value is an enumerated type. If no value is reported during that minute, no data is reported to the Controller, and an UNCHANGED notice appears in the Machine Agent log for that metric. Valid values are:

Aggregator Type	Description
AVERAGE	(Default) Average of all reported values in that minute
SUM	Sum of all reported values in the minute, causes the metric to behave like a counter
OBSERVATION	Last reported value in the minute

Time Roll-Up Qualifier

The *time-rollup* qualifier specifies how the Controller rolls up the values when it converts from one-minute granularity tables to 10-minute granularity tables, and 60-minute granularity tables over time. The value is an enumerated type. Valid values are:

Roll Up Strategy	Description
AVERAGE	Average of all one-minute values when adding it to the 10-minute granularity table; the average of all 10-minute values when adding it to the 60-minute granularity table
SUM	Sum of all one-minute values when adding it to the 10-minute granularity table; the sum of all 10-minute values when adding it to the 60-minute granularity table

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

Roll Up Strategy	Description
CURRENT	Last reported one-minute value in that 10-minute interval; the last reported 10-minute value in that 60-minute interval

Cluster Roll-Up Qualifier

The *cluster-rollup* qualifier specifies how the Controller aggregates metric values in a tier (a cluster of nodes). The value is an enumerated type. Valid values are:

Roll up Strategy	Description
INDIVIDUAL	Aggregates the metric value by averaging the metric values across each node in the tier
COLLECTIVE	Aggregates the metric value by adding up the metric values for all the nodes in the tier

For example, if a tier has two nodes, Node A and Node B, and Node A has three errors per minute and Node B has seven errors per minute, then the INDIVIDUAL qualifier reports a value of five errors per minute, and COLLECTIVE qualifier reports ten errors per minute. INDIVIDUAL is appropriate for metrics such as % CPU Busy, where you want the value for each node. COLLECTIVE is appropriate for metrics, such as Number of Calls, where you want a value for the entire tier.

Add a Monitoring Extension Script

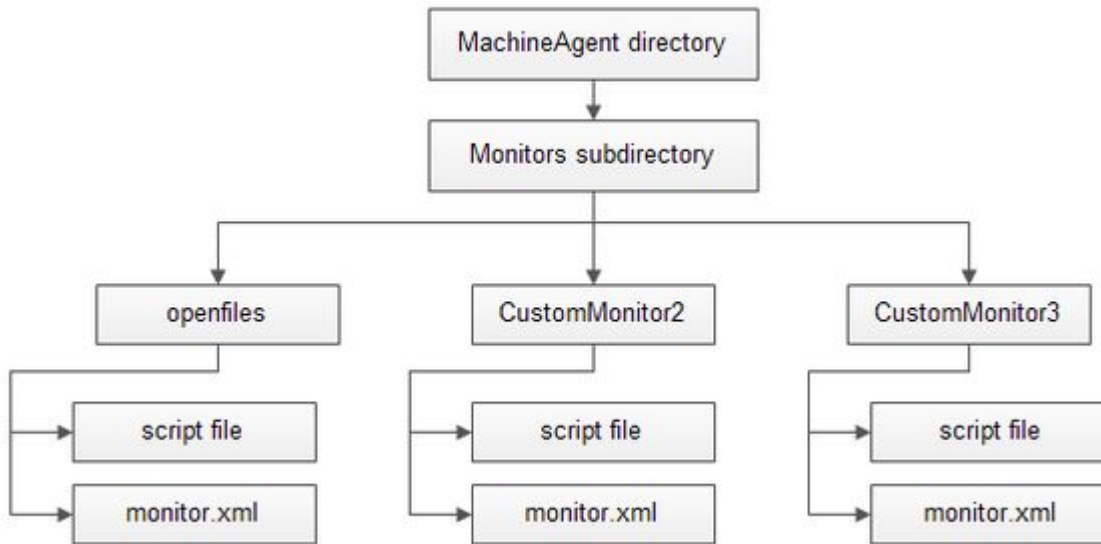

To add a monitoring extension script:

- [Create a Subdirectory Under the Machine Agent Monitors Directory](#)
- [Create the Script File](#)
- [Copy the Script File to the Subdirectory Created in Step 1](#)
- [Create the monitor.xml File](#)
- [Copy the monitor.xml file to the Subdirectory Created in Step 1](#)
- [Restart the Machine Agent](#)
- [Verify Execution of the Monitoring Extension Script](#)

Create a Subdirectory Under the Machine Agent Monitors Directory

The `<machine_agent_home>/monitors` directory is the repository for the Machine Agent extensions. For each new extension, create a subdirectory under the `/monitors` directory. The user running the Agent requires read, write, and execute permissions to this subdirectory.

For example to create an extension that monitors open files in the JVM, create a subdirectory named "openfiles" under `<machine_agent_home>/monitors`. The structure looks like:

Create the Script File

A script writes data to STDOUT. The Machine Agent parses STDOUT and sends information to the Controller every minute. Use these instructions to create the script file:

i For Windows custom metrics, PowerShell and VBScript are recommended over .bat files

To generate custom metrics on Windows, AppDynamics recommends that you use PowerShell and VBasic scripts instead of .bat files.

When a standard Windows batch (.bat) script echoes metric names, it surrounds the names with quotes. The quotes will cause the Machine Agent to ignore these metrics. PowerShell and VBasic scripts do not have this issue.

1. Specify a `name-value` pair for the metrics.

Each metric has a `name-value` pair that is converted to a java `'long'` value. A typical metric entry in the script file has this structure:

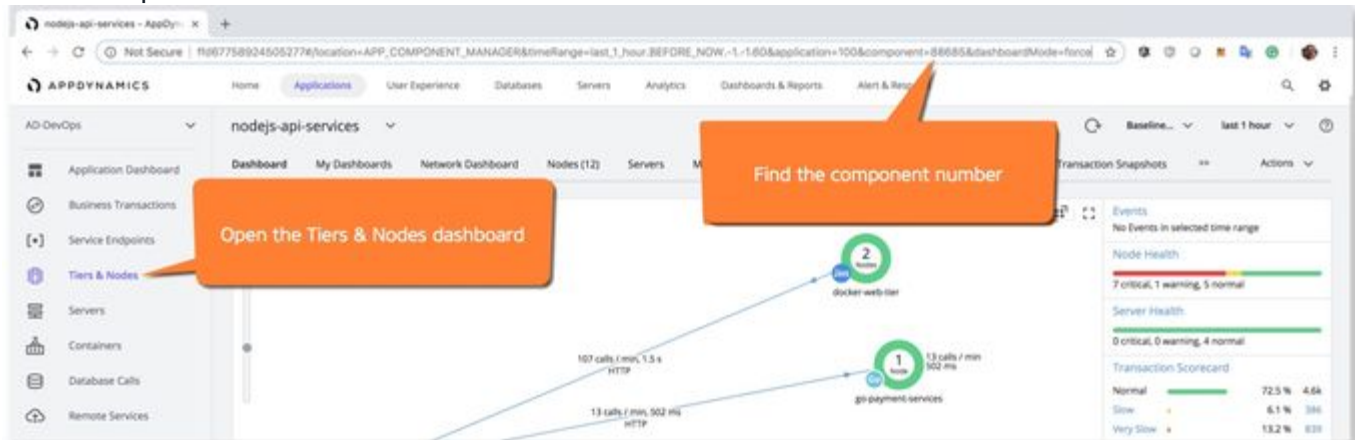

```

name=<metric name>,value=<long value>,aggregator=<aggregator
type>, time-rollup=<time-rollup strategy>, cluster-
rollup=<cluster-rollup strategy>
  
```

Use the following format:

Form	Format
Standard Form	Hardware Resources Instrument Name=Instrument Value
Fully Qualified Form	Hardware Resources <metric name>,value=<long value>

2. Define the category of the metric, for example:
 - a. Infrastructure (for the default hardware metrics, see [Machine Agent](#))
 - b. JVM
 - c. Custom Metrics, where Custom Metrics must have the path prefixes:
 - Custom Metrics
 - Server|Component:<tier-name-or-tier-id>
3. Metrics with the Custom Metrics prefix are common across all tiers in your application. Metrics with the Server|Component:<tier-name-or-tier-id> prefix appear only under the specified tier. To find the component ID of a tier, open the dashboard for the tier and review the URL. The ID appears as the component value in the URL:

! The Machine Agent has to be associated with the target or destination for the metrics. If you attempt to publish metrics to a tier that is not associated with the Machine Agent, the metrics are not reported.

The " | " character separates the branches in the metric hierarchy notifying the Controller where the metric should appear in the metric tree:

```
Custom Metrics|Hardware Resources|Disks|Total Disk Usage %
Custom Metrics|Hardware Resources|Disks|Disk 1|Current Disk Usage %
```

AppDynamics GovAPM functionality may vary depending on your license. Consult your ordering documentation and account representative for questions regarding included features. GovAPM deployments include APM (Pro/Peak), Browser Real User Monitoring (BRUM) (Pro/Peak), Mobile Real User Monitoring (Pro/Peak), Database Visibility, Server Visibility, including Cluster Agent, and Transaction Analytics.

You can insert a custom metric next to an existing type of metric. For example, the following declaration causes the custom metric named `pool usage` to appear next to the `JMX` metrics:
`Server|Component:18|JMX|Pool|First|pool usage`

4. You can then use the metric in health rules as would other types of JMX metrics. To monitor multiple metrics with the same script file, edit the script to write a different line for each one to STDOUT. For example:

```
name=Custom Metrics|Hardware Resources|Disks|Total Disk Usage
%, value=23
name=Custom Metrics|Hardware Resources|Disks|Disk 1|Current
Disk Usage %, value=56
```

Copy the Script File to the Subdirectory Created in Step 1

Ensure that the Agent process has execute permissions for the script file and for the contents of the file.

Create the monitor.xml File

For each custom monitoring extension script, create a `monitor.xml` file. The `monitor.xml` file executes the script file created in Step 2. You can edit the following sample file to create your own file:

```
<monitor>
  <name>HardwareMonitor</name>
  <type>managed</type>
  <description>Monitors system resources - CPU, Memory,
Network I/O, and Disk I/O.</description>
  <monitor-configuration>      </monitor-configuration>
  <monitor-run-task>
    <!-- Edit execution-style as needed. -->
    <execution-style>continuous</execution-style>
    <name>Run</name>
    <type>executable</type>
    <task-arguments></task-arguments>
    <executable-task>
      <type>file</type>
      <!-- Use only one file element per os-type. -->
      <file os-type="linux">linux-stat.sh</file>
      <file os-type="mac">macos-stat.sh</file>
      <file os-type="windows">windows-stat.bat</file>
      <file os-type="solaris">solaris-stat.sh</file>
```

```

        <file os-type="sunos">solaris-stat.sh</file>
        <file os-type="aix">aix-stat.sh</file>
    </executable-task>
</monitor-run-task>
</monitor>

```

The `os-type` attribute is optional for the `executable-task` file element when only one `os-type` is specified. One `monitor.xml` file executes one script per `os-type`.

1. Select the execution style: `continuous` or `periodic`.

Execution Style	Description	Example
